
575 Doppler Reference Charts in the Management of Impaired Fetal Growth Fetuses — Need for Standardization

Misgav Rottenstreich[1], Dahlia Klein[2], Moreyell Kahlon[1], Swati Agrawal[3], Homero Flores Mendoza[1], Howard Berger[4], Bryon DeFrance[1], Jon F. Barrett[5], Eran Ashwal[6]

[1]McMaster University, Hamilton, ON, [2]Université de Montréal, Montreal, QC, [3]Hamilton Health Sciences, Toronto, ON, [4]University of Toronto, Thornhill, ON, [5]Sunnybrook Health Science, University of Toronto, Toronto, ON, [6]McMaster University, North York, Tel Aviv

OBJECTIVE: Doppler studies play a crucial role in evaluating fetuses with impaired fetal growth. We aimed to assess the clinical variability of various published Doppler reference ranges for umbilical artery (UA), middle cerebral artery (MCA) pulsatility index (PI), and cerebroplacental ratio (CPR) in pregnancies complicated by impaired fetal growth, and their association with adverse perinatal outcomes.

STUDY DESIGN: This case control study included all singleton pregnancies without known genetic/structural anomalies and EFW and/or AC < 10th centile (Hadlock(for gestational age (2017-2022). Only cases with concurrent sampling of UA-PI, MCA-PI and CPR within 14 days of birth were considered. Abnormal fetal doppler was defined using clinically relevant cut-offs for gestational age: UA-PI > 95th centile, MCA-PI < 5th centile, and CPR < 5th centile. The primary outcome was a composite of adverse neonatal outcomes,

including any one of the following: antenatal fetal death, cesarean section for suspected fetal distress, 5-minute Apgar score < 7, arterial cord pH < 7.1, need for intubation, sepsis, necrotizing enterocolitis, and prolonged NICU admission (> 7 days). Multivariable logistic regression analysis was performed.

RESULTS: The cohort included 947 patients, of whom 438 (46.3%) experienced adverse perinatal outcomes, while 509 (53.7%) had normal outcomes. The predictive performance for adverse perinatal outcomes of various published Doppler reference values showed variability. Sensitivity ranged from 58.5% to 67.4% for UA, 55.4% to 61.4% for MCA, and 52.1% to 58.8% for CPR. Corresponding specificities ranged from 56.0% to 60.0%, 58.0% to 60.7%, and 61.4% to 61.9%, respectively (Table). After multivariate analysis, which controlled for relevant covariates, a range of association between clinically relevant cut-offs and adverse perinatal outcomes was demonstrated, with MCA-PI and CPR showing stronger associations with adverse outcomes.

CONCLUSION: Choosing a Doppler reference chart may result in significant variation in the clinical management of pregnancies complicated by impaired fetal growth.

Predictive values of Doppler studies for adverse perinatal outcome

576 Exploring the Possible Link between Gestational Diabetes and Offspring Autism: A Comprehensive Study

David Rubinshtein[1], Omri Zamstein[2], Tamar Wainstock[3], Eyal Sheiner[2]

[1]Soroka Medical Center, Beer-Sheva, HaDarom, [2]Soroka University Medical Center, Beer-Sheva, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom

OBJECTIVE: While several environmental and perinatal factors have been associated with the development of autism spectrum disorder (ASD), there is still much to uncover. In this study, we investigated the association between GDM (gestational diabetes mellitus), a condition that is becoming more widespread worldwide, and ASD in childhood.

STUDY DESIGN: A population-based cohort analysis using data from community clinics and a tertiary referral hospital was conducted. The analysis focused on deliveries that occurred between the years 2015 and 2017. We chose this specific year limit based as individuals born after that year may be too young to have received a diagnosis of ASD. The incidence of offspring ASD was compared between mothers with and without gestational diabetes mellitus diagnosis. To assess the cumulative ASD incidence, a Kaplan-Meier survival curve was utilized. Additionally, a Cox proportional hazards model was employed to account for potential confounding factors.

RESULTS: Out of 165,689 deliveries included in our study, 4,971 (3.0%) were complicated with diet-controlled gestational diabetes and 1,829 (1.1%) with gestational diabetes requiring medication. Parturients who had GDMA1 or GDMA2 were compared to those without gestational diabetes. Within this cohort, 862 offspring were diagnosed with ASD during childhood. Univariate analysis showed a significant association between GDM and its severity and the risk of ASD diagnosis (1.2% vs. 0.8% vs. 0.5% for GDMA2, GDMA1, and no GDM, respectively; p< 0.001; table). However, the cumulative morbidity observed in the Kaplan-Meier survival curve was comparable between the groups (Log-rank p-value = 0.111; figure). Moreover, when controlling for factors such as gestational age, maternal age, and cesarean section, using a Cox proportional hazards model, no association was found between any type of GDM and the risk of ASD (as seen in the table).

CONCLUSION: Although the long-term effects of gestational diabetes mellitus on offspring are a matter of concern, our study indicates that there is no significant link between this condition and ASD in children.

	No GDM (n= 158087)	GDMA1 (n= 4933)	GDMA2 (n= 1807)	P-value

577 Caffeine Intake and Adverse Pregnancy Outcomes Among Live Births: Results from the nuMoM2b Cohort

Rachel S. Ruderman[1], Alexa A. Freedman[2], Sunitha C. Suresh[3]

[1]University of Chicago, Chicago, IL, [2]NorthShore University HealthSystem, Evanston, IL, [3]NorthShore University Health System, Evanston, IL

OBJECTIVE: Studies of caffeine intake and adverse pregnancy outcomes (APO) have had mixed results and there is insufficient data to guide patients. We sought to determine the association between caffeine consumption and APO in a large prospective cohort.

STUDY DESIGN: This was a secondary analysis of live births in the Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-to-be (nuMoM2b). Caffeine intake was assessed by the self-reported Food Frequency Questionnaire in the first trimester. High caffeine was defined as ≥200 mg/day per existing literature. APO was defined as a composite of hypertensive disorders of pregnancy, preterm birth, and small for gestational age infant. Logistic models assessed associations between high caffeine intake, APO, and individual APOs, adjusted for confounders. As a secondary analysis, we grouped caffeine intake in 50 mg increments and tested whether consumption was associated with increased odds of APO.

RESULTS: The analysis included 7,320 pregnant people, for whom the average daily caffeine intake was 87.69mg(SD 89.39). 837(11.4%) of patients had high caffeine intake and 2,506(34.2%) had APO. When adjusted for confounders, high caffeine intake was not associated with a composite of APO (aOR 1.00, 95% CI 0.85-1.17), nor was it associated with any individual APO (Table 1). This finding persisted in a secondary analysis which found no statistically significant increased odds of APO (aOR 1.01, 95% CI .98-1.04, p=0.58) per 50 mg increase in caffeine intake.

CONCLUSION: Our study found no association between early pregnancy high caffeine intake and APO among livebirths in a large cohort of nulliparous low risk pregnant patients.

Association between Caffeine Intake and Adverse Pregnancy Outcomes

578 Dilapan-S versus Standard Methods for Cervical Ripening in Term Pregnancies: An Individual Patient Data Meta-Analysis

Antonio F. Saad[1], Claudia Pedroza[2], Rachana Gavara[3], Gupta Janesh[4], Ronald J. Wapner[5], George R. Saade[6]
[1]University of Texas Medical Branch, Galveston, TX, [2]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [3]Columbia University Medical Center, New York, NY, [4]Birmingham Women's and Children's NHS Foundation Trust, England, [5]Columbia University Irving Medical Center, New York, NY, [6]Eastern Virginia Medical School, Norfolk, VA

OBJECTIVE: Dilapan-S is a cervical ripening agent approved by the FDA that has been found to be just as effective as other agents. It can be utilized for outpatient ripening, but there have not been any large-scale studies conducted to compare its cesarean delivery rate. Our objective was to combine these trials to compare cesarean delivery rates for Dilapan-S compared with other cervical ripening methods, overall and in sub-groups.

STUDY DESIGN: This was a systematic review and meta-analysis of individual patient data (IPD) from randomized controlled trials comparing Dilapan-S to mechanical or pharmacologic cervical ripening methods for labor induction in singleton gestations. Ovid MEDLINE, Embase via Ovid, Ovid Emcare, CINAHL Plus, ClinicalTrials.gov, euclinicaltrialsregister.eu, and Scopus were searched. The primary outcome measure was cesarean delivery (CD) rates. Two reviewers independently selected studies, assessed the risk of bias, and extracted the data. Pre-specified subgroup analyses were performed for parity. Pooled odds ratios (ORs) adjusted for maternal age and parity with 95% confidence intervals (CI) were calculated using the frequentist and Bayesian approaches.

RESULTS: Four randomized controlled trials were identified, with 1731 women included (1036 allocated to Dilapan-S; 695 to alternative cervical ripening methods). CD rates were 28% and 30% with Dilapan-S and other methods, respectively. There was no difference in age and parity-adjusted analyses of CD rates between Dilapan-S and other methods (OR 1.03, 95% CI 0.8-1.3). Bayesian inference indicated a 95% probability of being non-inferior (5% margin) and a 4.5% probability of being inferior to other methods (Figure). Subgroup analysis demonstrated significant interaction with parity with a 99% probability of lowering cesarean rates among multiparous women treated with Dilapan-S (RR 0.63, 95% CI 0.4-0.9; Table).

CONCLUSION: Dilapan-S was at least non-inferior and marginally superior in lowering cesarean rates compared to other pre-induction cervical ripening agents. Parity impacted efficacy, with multiparous women benefiting the most.

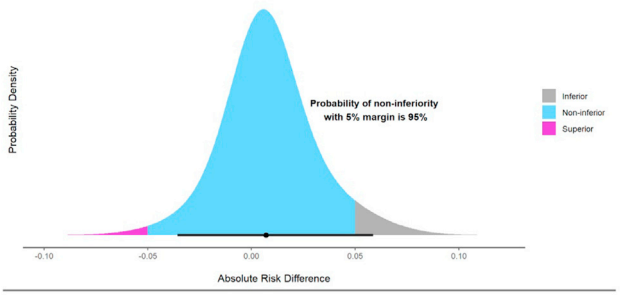

Table. Bayesian subgroup analysis of cesarean delivery by nulliparity comparing Dilapan-S to other methods.

Outcome	Dilapan-S (N=1030) n/N (%)	Other methods (N=692) n/N (%)	Bayesian adjusted RR (95% CrI)	Bayesian Posterior Probability (%) of RR <1 with Dilapan-S
Cesarean delivery				
Multiparous	43/435 (9.9)	41/246 (17)	0.63 (0.43, 0.91)	99
Nulliparous	248/595 (42)	166/446 (37)	1.15 (0.99, 1.35)	4

579 Effect of metformin on basal insulin dose change in pregnant patients with type 1 diabetes

Ajleeta Sangtani[1], LeAnn A. Louis[2], Mark Chames[3]
[1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Hospital System, Ann Arbor, MI, [3]University of Michigan Health System, Ann Arbor, MI

OBJECTIVE: Type 1 diabetes mellitus (T1D) is primarily an insulin deficient state, but superimposed insulin resistance is increasingly seen. In the setting of pregnancy some patients can require high doses of insulin, and achieving euglycemia can be difficult. We have historically used metformin in such patients. The purpose of this study is to determine if the use of metformin in pregnant patients with T1D alters the rate of basal dose increase.

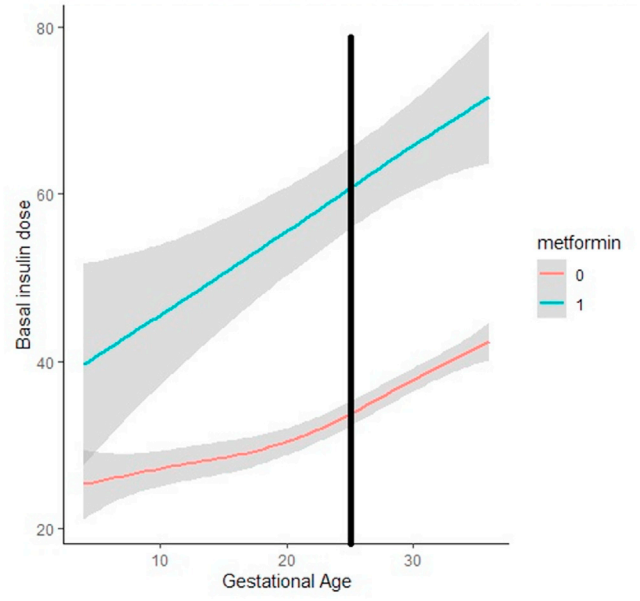
STUDY DESIGN: A retrospective cohort study was conducted. Patients were included if they had T1D diagnosed prior to pregnancy, more than one documented prenatal visit with recorded basal insulin dose, and available delivery records. Demographic data included age, parity, hypertensive disorders, gestational age (GA) at delivery, mode and indication for delivery, birthweight, and NICU admission. T-test and chi square were used for demographic analysis. Basal insulin doses at initial prenatal visit, as well as 20, 24, 28, 32, and 36 weeks were collected. A difference-in-difference analysis was conducted in R to determine if basal insulin dose trend changed in patients prescribed metformin compared to those not prescribed metformin.

RESULTS: 284 patients were eligible, of whom 29 were prescribed metformin. No difference was found between groups in age, parity, GA at delivery, mode or indication for delivery, hypertensive disorders, birthweight, or NICU admission. Starting basal insulin was 44u/d in metformin treated patients and 28u/d in non-treated patients ($p< 0.01$). Mean GA for starting metformin was 25 weeks. A difference-in-difference analysis using 25 weeks as the inflection point showed that metformin statistically significantly altered the trend of basal insulin dose compared to no medication (Figure 1, $p=0.03$).

CONCLUSION: T1D patients prescribed metformin had higher baseline insulin requirements. Treatment was initiated at a mean GA of 25

weeks, significantly altering the trajectory for basal insulin dose. No differences in pregnancy outcomes were seen between patients who were treated with metformin and those who were not, suggesting safety of this intervention.

Figure 1: Basal insulin dose by gestational age in pregnant patients with type 1 diabetes



580 Evaluating the Benefit of Obstetrical Interventions on Neonatal Survival in Periviable Twin Pregnancies

Antonio Jose Santos Roca[1], Patrick Soo Kim[1], Surya Sruthi Bhamidipalli[2], Bradley H. Sipe[3], Dalia Feltman[4], Brownsyne Tucker Edmonds[5], Tiffany Tonismae[6]

[1]Bayfront Health Hospital, St. Petersburg, FL, [2]Indiana University School of Medicine, Indianapolis, IN, [3]Maternal, Fetal, Neonatal Institute, John Hopkins All Children's Hospital, Atlanta, GA, [4]NorthShore University Health System Evanston Hospital, Evanston, IL, [5]Indiana University School of Medicine, Indianapolis, IN, [6]University of Louisville, School of Medicine, Crestwood, KY

OBJECTIVE: Evaluate the benefit of obstetrical interventions on neonatal survival in twin pregnancies at the threshold of viability.

STUDY DESIGN: This is a retrospective multi-center study of twin gestations delivered between 22 0/7 and 24 6/7 weeks gestation from January 2010 to July 2020 across 16 geographically distinct and diverse institutions. The primary objective was to assess the impact of obstetrical interventions on neonatal survival from delivery room. Secondary outcomes included assessing maternal demographic characteristics and mode of delivery on survival. Statistical analysis employed independent t-tests for continuous variables, chi square for categorical variables and generalized linear models to explore intervention differences.

RESULTS: **377** mothers met the inclusion criteria. Overall survival was 91.7% and was not impacted by maternal characteristics (age, parity, race/ethnicity, or insurance). Neonates who survived had a higher birth weight than those that died (595g ± 120 vs. 466g ± 113, p< 0.01). Obstetrics inventions including: antenatal corticosteroids (96% vs 83.2%, p< 0.01), magnesium sulfate (97.7% vs 83.6%, p< 0.01), tocolytic therapy (97.4% vs 88.8%, p< 0.01) and GBS prophylaxis (97.3% vs 88.2%, p< 0.01) demonstrated a significant increase in overall survival. Vaginal delivery was associated with increased survival compared to cesarean delivery (95.4% vs 88.7%, p=0.02). A stratified analysis of survival and obstetrical intervention by weeks of gestation is shown in Table 1. There was no difference in survival based on obstetrical intervention at 24wk. Antenatal corticosteroids were associated with increased survival at 22wk. Magnesium sulfate and tocolytic therapy were associated with increased survival at 23wk.

CONCLUSION: Receipt of obstetrical interventions and vaginal delivery increased overall survival from delivery room for twin neonates born in the periviable period.

581 Earlier diagnosis of cholestasis is associated with adverse pregnancy outcomes

Minhazur R. Sarker[1], Alexandra N. Mills[2], Lauren Ferrara[3], Chelsea A. DeBolt[4]

[1]University of California San Diego, San Diego, CA, [2]Icahn School of Medicine at Mount Sinai, New York, NY, [3]Mount Sinai School of Medicine, New York, NY, [4]Mount Sinai Hospital, New York, NY

OBJECTIVE: Intrahepatic cholestasis of pregnancy (IHCP) is associated with adverse pregnancy outcomes including fetal demise, spontaneous preterm labor, and meconium stained amniotic fluid. Studies have yet to determine if IHCP diagnosis earlier in pregnancy is associated with higher rates of adverse outcomes.

STUDY DESIGN: Retrospective cohort study of singleton, non-anomalous live gestations complicated by IHCP at Elmhurst Hospital Center from 2005-2019. We compared rates of adverse outcomes in pregnancies complicated by early (< 32 week gestational age) versus late (≥ 32 week gestational age) diagnosis of IHCP. Primary outcome of interest was rates of spontaneous preterm labor resulting in preterm delivery. Our secondary outcomes included rates of iatrogenic preterm birth, meconium stained amniotic fluid, cesarean delivery (CD) for non-reassuring fetal heart tracing (NRFHT), umbilical artery pH < 7.20, and neonatal intensive care unit (NICU) admission. Chi-square and multivariate regression tests determined the strength of association. In all analyses, a p-value < 0.05 and 95% CI not crossing 1.00 indicated statistical significance.

RESULTS: Of the 1247 pregnancies complicated by IHCP, 241 (19.3%) had early diagnosis and 1006 (80.7%) had late diagnosis of IHCP. Pregnancies with early diagnosis of IHCP had higher peak total bile acid levels, higher rates of prior preterm birth, higher incidence of ursodeoxycholic acid treatment, and were delivered at

an earlier gestational age. Earlier diagnosis of IHCP was associated with spontaneous preterm labor, iatrogenic preterm birth, and NICU admission. After adjusting for confounders and baseline differences including peak total bile acid levels, earlier diagnosis of IHCP remained associated with spontaneous preterm labor (OR 1.81; 95% CI 1.11-2.95), iatrogenic preterm birth, (OR 1.59; 95% CI 1.12-2.67), and NICU admission (OR 1.43; 95% CI 1.04-1.95).

CONCLUSION: Findings suggests that earlier diagnosis of IHCP is associated with adverse outcomes and that this is not entirely driven by peak total bile acid levels.

Univariate Analysis of Early vs Late IHCP diagnosis and adverse neonatal outcomes

	Early IHCP (n=241)	Late IHCP (n=1006)	p-value
Spontaneous Preterm Labor, n (%)	35 (14.52)	60 (5.96)	<0.01
Umbilical Arterial pH <7.20, n(%)	14 (5.81)	82 (8.15)	0.22
Iatrogenic Preterm Birth, n (%)	77 (31.95)	149 (14.81)	<0.01
Cesarean Delivery for NRFHT, n (%)	23 (9.54)	68 (6.76)	0.14
Meconium-stained fluid, n (%)	27 (11.20)	116 (11.53)	0.89
NICU admission, n (%)	116 (50.66)	358 (37.02)	<0.01

Multivariate logistic regression adjusted for peak total bile acid level, history of preterm birth, and ursodeoxycholic treatment

	Unadjusted Odds Ratio OR (95% CI)	Adjusted Odds Ratio OR (95% CI)
Spontaneous Preterm labor	2.68 (1.72-4.17)	1.81 (1.11-2.95)
Umbilical Arterial pH <7.20	0.69 (0.39-1.25)	0.68 (0.36-1.26)
Iatrogenic Preterm Birth	2.70 (1.96-3.73)	1.59 (1.12-2.67)
Cesarean Delivery for NRFHT	1.46 (0.89-2.39)	1.47 (0.85-2.54)
Meconium-stained fluid	0..97 (0.63-1.51)	0.74 (0.46-1.21)
NICU admission	1.75 (1.31-2.33)	1.43 (1.04-1.95)

582 Earlier diagnosis of severe cholestasis is associated with adverse pregnancy outcomes

Minhazur R. Sarker[1], Alexandra N. Mills[2], Lauren Ferrara[3], Chelsea A. DeBolt[4]

[1]University of California San Diego, San Diego, CA, [2]Icahn School of Medicine at Mount Sinai, New York, NY, [3]Mount Sinai School of Medicine, New York, NY, [4]Mount Sinai Hospital, New York, NY

OBJECTIVE: Intrahepatic cholestasis of pregnancy (IHCP) has a severity associated relationship with adverse pregnancy outcomes including intrauterine fetal demise, spontaneous preterm labor, and meconium stained amniotic fluid. Studies have yet to determine if severe IHCP diagnosis earlier in pregnancy is associated with more adverse outcomes.

STUDY DESIGN: Retrospective cohort study of singleton, non-anomalous live gestations complicated by severe IHCP (peak total bile acids $\geq$ 40 μmol/L) from 2005-2019. We compared rates of adverse outcomes in pregnancies complicated by early severe ($<$ 32 week gestational age) versus late severe ($\geq$ 32 week gestational age) IHCP diagnosis. Primary outcome of interest was rates of spontaneous preterm labor resulting in preterm delivery. Secondary outcomes included rates of iatrogenic preterm birth, meconium stained amniotic fluid, cesarean delivery (CD) for non-reassuring fetal heart tracing (NRFHT), umbilical artery pH $<$ 7.20, and neonatal intensive care unit (NICU) admission. Chi-square and multivariate regression tests determined the strength of association. In all analyses, a p-value $<$ 0.05 and 95% CI not crossing 1.00 indicated statistical significance.

RESULTS: Of the 1247 pregnancies complicated by IHCP during the study period, 455 (36.5%) were complicated by severe IHCP. Among severe IHCP cases, 108 (23.7%) had early diagnosis and 347 (76.3%) had late diagnosis. Pregnancies with early severe IHCP had higher rates of prior preterm birth, higher incidence of ursodeoxycholic acid treatment, and were delivered at an earlier gestational age. Early severe IHCP was associated with spontaneous preterm labor, iatrogenic preterm birth, and NICU admission. After adjusting for confounders and baseline differences, early severe IHCP remained associated with spontaneous preterm labor (OR 2.41; 95% CI 1.34-4.34), iatrogenic preterm birth, (OR 1.67; 95% CI 1.05-2.67), and NICU admission (OR 1.66; 95% CI 1.06-2.61).

CONCLUSION: Early severe IHCP is associated with adverse outcomes. Findings suggest increased duration of exposure to bile acids may contribute to adverse outcomes.

Univariate Analysis of Early vs Late Severe IHCP diagnosis and adverse neonatal outcomes

	Early Severe IHCP (n=108)	Late Severe IHCP (n=347)	p-value
Spontaneous Preterm Labor, n (%)	24 (22.22)	35 (10.09)	<0.01
Umbilical Arterial pH <7.20, n(%)	7 (6.48)	28 (8.07)	0.59
Iatrogenic Preterm Birth, n (%)	41 (37.96)	87 (25.07)	<0.01
Cesarean Delivery for NRFHT, n (%)	9 (8.33)	22 (6.34)	0.47
Meconium-stained fluid, n (%)	16 (14.81)	64 (18.44)	0.39
NICU admission, n (%)	61 (57.55)	148 (43.92)	0.01

Multivariate logistic regression adjusted for peak total bile acid level and history of preterm birth

	Unadjusted Odds Ratio OR (95% CI)	Adjusted Odds Ratio OR (95% CI)
Spontaneous Preterm labor	2.55 (1.44-4.52)	2.41 (1.34-4.34)
Umbilical Arterial pH <7.20	0.79 (0.33-1.86)	0.72 (0.30-1.71)
Iatrogenic Preterm Birth	1.83 (1.16-2.89)	1.67 (1.05-2.67)
Cesarean Delivery for NRFHT	1.34 (0.60-3.01)	1.22 (0.54-2.76)
Meconium-stained fluid	0.77 (0.42-1.40)	0.70 (0.38-1.29)
NICU admission	1.73 (1.11-2.69)	1.66 (1.06-2.61)

583 Earlier intervention for acute post-neuraxial hypotension in pregnancies with obesity may improve fetal acidemia

Minhazur R. Sarker[1], Dana R. Canfield[2], Lauren Ferrara[3], Angela Bianco[4], Chelsea A. DeBolt[5]

[1]University of California San Diego, San Diego, CA, [2]University of California, San Diego, La Jolla, CA, [3]Mount Sinai School of Medicine, New York, NY, [4]Mount Sinai Medical Center, New York, NY, [5]Mount Sinai Hospital, New York, NY

OBJECTIVE: Prior studies have demonstrated an association between obesity and fetal acidemia. We aimed to determine if pregnancies with obesity that experienced acute post-neuraxial hypotension were associated with fetal acidemia and if earlier intervention may be indicated.

STUDY DESIGN: Retrospective cohort study of non-labor, non-anomalous, term, singleton births via cesarean delivery under neuraxial from 2013-2019 that experienced acute post-neuraxial hypotension (systolic blood pressure (BP) $<$ 100 mmHg recorded prior to delivery). We compared rates of adverse outcomes in pregnancies with obesity (BMI $>$ 30 kg/m^2) or without (BMI $<$ 30 kg/m^2). Primary outcome was umbilical artery (UA) pH $<$ 7.1. Chi-square and multivariate regression tests determined the strength of association.

RESULTS: Of 2851 patients with acute post-neuraxial hypotension, 1432 (50.23%) had obesity while 1432 (49.77%) did not. Pregnancies with obesity were more likely to have diabetes and hypertensive disorders, and more often received combined spinal-epidural analgesia. After adjusting for confounders including maternal BMI, type of neuraxial anesthesia, and hypertensive disorders, an acute post-neuraxial hypotension in pregnancies complicated by obesity was associated with UA pH $<$ 7.1 (aOR 2.07 [1.25-3.42]) and umbilical cord base deficit $>$ 12 (aOR 2.52 [1.18-5.35]). When assessing the relationship between post-neuraxial systolic BP nadir and UA pH, pregnancies without obesity have decreased probability of UA pH $>$ 7.1 at a systolic BP of 100 mg Hg whereas pregnancies with obesity have a decreased probability of UA pH $>$ 7.1 at a systolic BP of 120 mm Hg. (Figure 1, p $<$ 0.01)

CONCLUSION: Findings suggest that in the setting of maternal obesity, acute post-neuraxial hypotension is associated with a greater odds of UA pH < 7.1. Earlier intervention for acute post-neuraxial hypotension in pregnancies with obesity may be warranted.

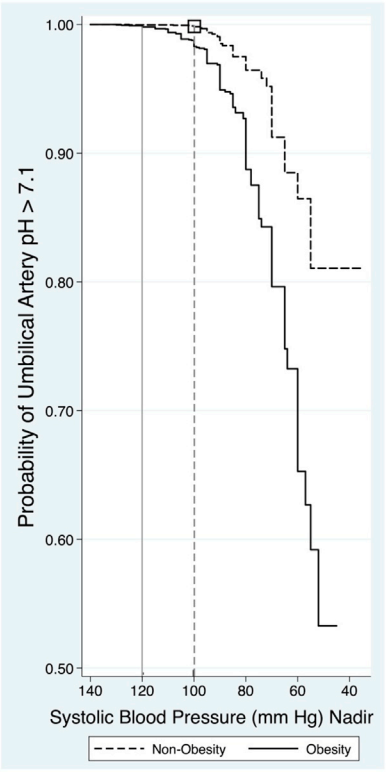

Figure 1. Relationship of post-neuraxial systolic BP nadir and probability of UA pH > 7.1 at time of delivery among pregnancies with and without obesity (BMI > 30 kg/m^2). Pregnancies without obesity begin to have a decrease in probability of UA pH > 7.1 starting at post-neuraxial systolic BP nadir of 100 mm Hg (label A) while pregnancies with obesity begin to have a decrease in probability of UA pH > 7.1 at a BP of 120 mm Hg (label B) (p < 0.01).

584 External validation and comparison of three prediction scores for severe maternal morbidity

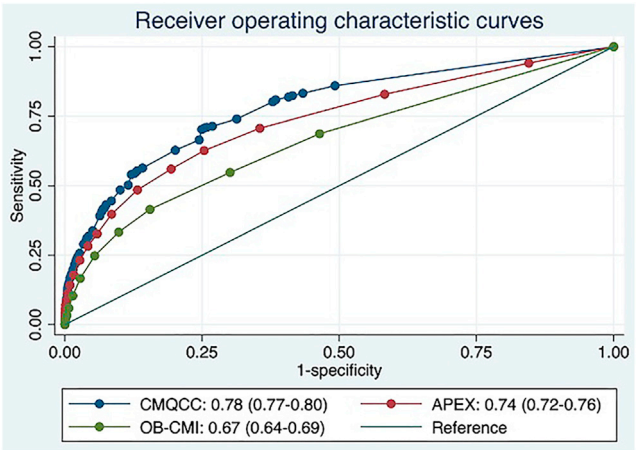
Alyssa Savelli Binsted, George R. Saade, Tetsuya Kawakita
Eastern Virginia Medical School, Norfolk, VA

OBJECTIVE: A number of tools and scores have been proposed to assess individual risk of severe maternal morbidity. We sought to examine and compare the validity of three scoring systems.

STUDY DESIGN: This was a retrospective cohort study of all individuals in the Consortium on Safe Labor dataset, which was conducted from 2002 to 2008. Individuals were excluded if they had missing information on risk factors. Severe maternal morbidity was defined based on the Centers for Disease Control and Prevention excluding blood transfusion. Risk scores were calculated for each participant using the California Maternal Quality Care Collaborative (CMQCC) scoring system, the Assessment of Perinatal Excellence (APEX) scoring system and the obstetric comorbidity index (OB-CMI). We calculated the probability of severe maternal morbidity according to the risk scores. The discriminative performance of the prediction score was examined by the receiver operating characteristic area under the curves (ROCAUCs) and their 95% confidence intervals (95% CI). ROCAUC for each score were compared using the DeLong test. Calibration plots were developed for each score to examine the goodness-of-fit.

RESULTS: Of 117, 332 individuals, 811 (0.7%) had severe maternal morbidity. The CMQCC scoring system had a significantly higher ROCAUC compared to the APEX and OB-CMI scoring systems (0.78 [95%CI 0.77-0.80] vs. 0.74 [95%CI 0.72-0.76] vs. 0.67 [95%CI 0.64-0.69]; P < 0.001). Calibration plots showed excellent concordance between the predicted and actual SMM for the APEX scoring system and OB-CMI (both Hosmer–Lemeshow test P-values = 1.00, suggesting goodness-of-fit). However, CMQCC scoring system underestimated the probability of severe maternal morbidity if the predicted probability was more than 25%.

CONCLUSION: Both CMQCC and APEX scoring systems had good discrimination to predict severe maternal morbidity. APEX scoring systems and OB-CMI had goodness-of-fit.



585 Association of Hospital Volume with Mode of Delivery and Neonatal Outcome Among Periviable Births

Peeraya S. Sawangkum[1], Jason L. Salemi[1], Jean Paul P. Tanner[2], Anjali J. Kaimal[3]
[1]University of South Florida, Tampa, FL, [2]College of Public Health, University of South Florida Morsani College of Medicine, Tampa, FL, [3]University of South Florida Morsani College of Medicine, Tampa, FL

OBJECTIVE: Delivery of a pregnancy in the periviable period should ideally occur at a center with a level III-IV neonatal intensive care unit, level III-IV maternal care designation, or both. Transfer before delivery has been associated with improved neonatal outcomes compared to postnatal transport[1]; however, antenatal transport is not always feasible depending on the clinical scenario. The purpose of this study is to determine the association between hospital delivery volume and neonatal outcomes with periviable deliveries.

STUDY DESIGN: Retrospective cohort study using a maternal-infant linked database of live births in the state of Florida from 2006 to 2019. Singleton deliveries of infants born at 22w0d to 25w6d in which neonatal resuscitation was attempted were included. We compared neonatal mortality and morbidity between deliveries occurring at lower-volume hospitals (defined as less than 2,000 deliveries per year) and higher-volume hospitals (greater than or equal to 2,000 deliveries per year).

RESULTS: We identified a total of 6,958 periviable live births who had resuscitation during the study period. As expected, the majority of periviable deliveries occured at higher-volume delivery hospitals (n=5,585, 84.2%). Infants born during the periviable period at lower-volume hospitals had higher mortality rates, with 13.5%, 26.9%, 35.7%, and 42.2% mortality at 24-hour, 7-day, 28-day, and 1-year of life respectively. Higher-volume hospitals exhibited mortality of 8.6%, 19.6%, 29.3%, and 36.7% at the same time intervals.

Overall, neonatal morbidity outcomes were clinically similar between the two groups (Table 1).

CONCLUSION: The majority of periviable deliveries occur at higher-volume hospitals, with lower rates of neonatal mortality across multiple time points when compared to lower-volume hospitals. Further research is needed to optimize support for neonates born in the periviable period at lower-volume centers when antenatal transfer is logistically challenging.

Table 1: Neonatal Outcomes by Hospital Volume

	Lower-Volume Hospital n (%) 1,100 (15.8)	Higher-Volume Hospital n (%) 5,858 (84.2)	p-value
Death

586 Association of Mode of Delivery for Periviable Birth with Neonatal Outcomes

Peeraya S. Sawangkum[1], Jason L. Salemi[1], Jean Paul P. Tanner[2], Anjali J. Kaimal[3]

[1]University of South Florida, Tampa, FL, [2]College of Public Health, University of South Florida Morsani College of Medicine, Tampa, FL, [3]University of South Florida Morsani College of Medicine, Tampa, FL

OBJECTIVE: To determine the association between mode of delivery for periviable infants with neonatal survival and morbidity.

STUDY DESIGN: Retrospective cohort study using a maternal-infant linked database of live births in the state of Florida from 2006 to 2019. Singleton deliveries of infants born at 22w0d to 25w6d in which neonatal resuscitation was attempted were included.

RESULTS: A total of 6,948 periviable deliveries were identified during the study period. Of those, 2,680 (38.6%) were vaginal births and 4,268 (61.4%) were cesarean births. Those delivering by cesarean were more likely to have medical complications such as hypertension, diabetes, autoimmune disease, preeclampsia, and fetal growth restriction; they were less likely to be in spontaneous labor. Rates of chorioamnionitis were similar between the two groups, as was mean birthweight. Among vaginal deliveries, 14.1% (n=377) of neonates died by 24 hours of life, as compared to 6.3% (n=271) of neonates delivered by cesarean. At one year, 42.5% (n=1,138) of neonates born vaginally had died, as compared to 34.5% (n=1,472) of those born via cesarean. Survival increased with each advancing gestational age week regardless of mode of delivery; however, survival among neonates delivered by cesarean remained higher in each gestational week category. Rates of sepsis, intraventricular hemorrhage, necrotizing enterocolitis, respiratory distress syndrome, retinopathy of prematurity, bronchopulmonary dysplasia, seizures, hypoxic ischemic encephalopathy, asphyxia, hypoxia, acidemia, chest tube placement, and gastric tube placements were similar among the two groups.

CONCLUSION: Our study indicates improved short- and long-term survival among periviable neonates delivered via cesarean section with similar rates of neonatal morbidity compared to those delivered vaginally. Further study is needed to understand the clinical situations in which cesarean is most likely to improve neonatal outcome in order to balance this against the maternal complications associated with cesarean during the periviable period.

Neonatal Outcomes Among Periviable Deliveries

	Vaginal Delivery n (%) 2,680 (38.6)	Cesarean Delivery n (%) 4,268 (61.4%)	p-value

587 Does sFlt1/PlGF predict superimposed preeclampsia in women with chronic hypertension during pregnancy? A meta-analysis

Audrey Scalia[1], Jessica Hao-Chen Wu[2], Giovanni Sisti[3]

[1]University of Arizona College of Medicine, Tucson, AZ, [2]Mount Sinai Hospital Chicago, Chicago, IL, [3]College of Medicine, University of Arizona, Tucson, AZ

OBJECTIVE: To identify the accuracy of the sFlt-1/PlGF ratio in predicting the occurrence of superimposed preeclampsia over chronic hypertension (CHTN).

STUDY DESIGN: We identified clinical studies in Embase, PubMed, ClinicalTrials.gov, and Cochrane library assessing the efficacy of the sFlt-1/PlGF ratio in the maternal sera to predict the occurrence of superimposed preeclampsia over CHTN. Using the meta-analytic method, we generated a forest plot for standardized mean differences (SMDs) with their respective 95% confidence intervals (CIs). We performed a subgroup analysis according to the gestational age at blood collection: before 27 weeks of gestation, and after 27 weeks of gestation. If the patients had more than one blood collection during gestation, we considered them as different patients for the purpose of the analysis. A p value < 0.05 was considered statistically significant.

RESULTS: Four articles were included in our final analysis. In two studies, the same patients had repeated blood collection during gestation. The total number of patients with CHTN was 775, of which 251 had superimposed preeclampsia and 524 did not. The gestational ages at blood collection in the four studies ranged from 12 to 30 weeks. Two studies had blood collected before 27 weeks of gestation, while four studies (the first two studies plus two others) had blood collected after 27 weeks of gestation. We found a statistically significant difference regarding the sFlt-1/PlGF ratio in CHTN

patients at ≥ 27 weeks of gestation who later developed superimposed preeclampsia vs. those who did not (SMD of 0.43; CI of 0.17 - 0.69) (Figure 1). The quality in prognostic studies tool (QUIPS) and the funnel plot symmetry revealed an overall low risk of bias. The heterogeneity of the studies was high (I2 = 61%).

CONCLUSION: The sFlt-1/PlGF ratio was significantly associated with the development of superimposed preeclampsia in patients with CHTN when measured after 27 weeks of gestation, but not before. Our findings are limited by the high heterogeneity and the small number of included studies.

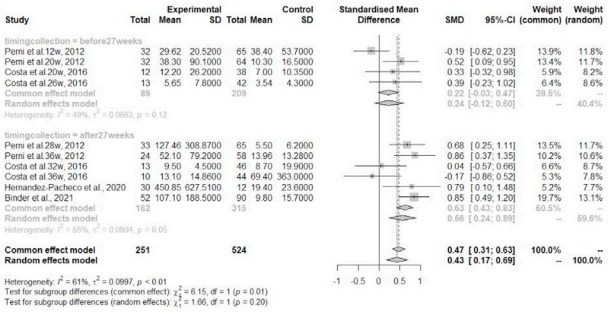

Figure 1. Forest plot of included studies. SD: standard deviation. SMD: standardized mean difference. CI: confidence interval.

588 Characterizing migraine headaches in pregnancy

Rachel C. Schell[1], Sofia Shirley[1], Yasmeen Alayli[1], Devin A. Macias[2], April R. Gorman[1], David B. Nelson[1], Catherine Y. Spong[1], Elaine L. Duryea[1]

[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Maternal Fetal Medicine Associates of Sacramento, Sacramento, CA

OBJECTIVE: To evaluate the frequency and characteristics of headaches in pregnancy.

STUDY DESIGN: This is a single-site, prospective observational study of pregnant patients evaluated for recurrent headaches during prenatal visits between 12/2020 and 9/2022. Patients were evaluated using standardized questions regarding their specific headache symptoms and medications used. Headaches were treated using a sequential medication algorithm, escalating therapy prior to referral to neurology. The frequency and characteristics of headaches across pregnancy as well as obstetric and neonatal outcomes were recorded. Statistical analyses included logistical regression and repeated-measures ANOVA tests.

RESULTS: During the study period, 963 pregnant patients were evaluated for recurrent headaches through 2956 clinic encounters. Of these, 342 (36.54%) patients were diagnosed with only tension-type headaches versus 594 (63.46%) with at least one migraine headache. Patients with tension headaches experienced consistent headache frequency across gestation whereas patients with migraine headaches experienced peak headache frequency in the second trimester (Table 1). Nausea, vomiting and photophobia were the most common symptoms associated with migraine headaches and all 3 decreased in frequency with advancing gestation. Eighty four percent of patients achieved adequate symptom control without escalation of the treatment algorithm beyond treatment using Tylenol with caffeine (Table 1). Only 41 (6.9%) patients required referral to neurology for management of their headaches.

CONCLUSION: Migraine headaches are more common in pregnancy when compared to recurrent tension-type headaches. The majority of migraine headaches can be adequately controlled with a sequential medication algorithm, with only 6.9% requiring referral to neurology.

Table 1: Characteristics of migraine headaches in pregnancy

	Trimester				
	1st	2nd	3rd	Total	p-value
Frequency of tension headache (#Ha/trimester)	4.6 ± 4.1	4.4 ± 4.6	4.1 ± 4.6	4.3 ± 4.5	<0.0001
Frequency of migraine headache (#Ha/trimester)	6.2 ± 5.2	8.4 ± 8.5	7.8 ± 7.8	7.8 ± 7.8

Ha, headache
*Treatment was escalated sequentially according to the following algorithm: Tylenol > Tylenol with caffeine > T/c/R/B > T/c/R/B with sumatriptan > neurology referral

589 Cost-Effectiveness Analysis of a Novel Fetal Vesicoamniotic Shunt - The Vortex Shunt

Jamie Schlacter[1], Enrico Danzer[2], Claire H. Packer[3], Eric Johnson[4], Aaron B. Caughey[5], Yair J. Blumenfeld[4], Kunj Sheth[4]

[1]New York University Grossman School of Medicine, New York, NY, [2]Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY, [3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [4]Stanford University, Stanford, CA, [5]Oregon Health & Science University, Portland, OR

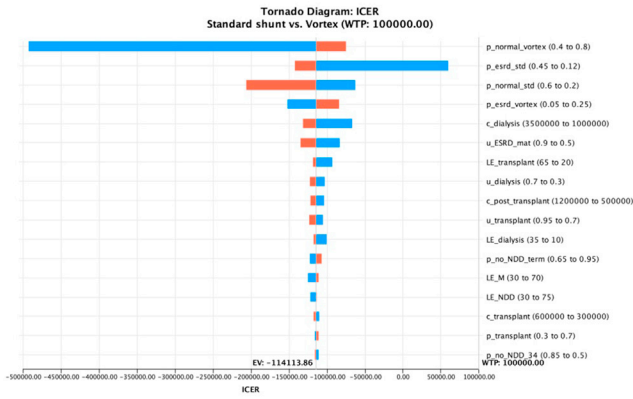
OBJECTIVE: The Vortex shunt, a novel fetal vesico-amniotic shunt (VAS), has shown improved dislodgement characteristics compared to current shunts in in-vitro and pre-clinical studies. We aimed to evaluate the Vortex shunt's potential cost-effectiveness compared to standard shunts.

STUDY DESIGN: We designed a decision-analytic model using TreeAge to compare outcomes and costs in fetuses undergoing VAS for fetal LUTO using the Vortex shunt compared to current shunts. We assumed a 50% dislodgement risk and 36% probability of end-stage renal disease (ESRD) for current shunts per published literature, and compared that to the Vortex shunt's expected 10% dislodgement risk and 18% ESRD rate. We used a theoretical cohort of 1,000 neonates, the number of annual U.S. LUTO cases. Outcomes included ESRD, neurodevelopmental disability (NDD), neonatal death, direct/indirect costs, and quality-adjusted life years (QALYs). A societal perspective with a lifetime horizon was used to determine cost in 2022 U.S. dollars. Maternal and neonatal QALYs were considered and took into account a standard 3% discount rate. The incremental cost-effectiveness ratio (ICER) was determined with a $100,000/QALY willingness to pay threshold. Model inputs were derived from literature, and sensitivity analyses were conducted to assess robustness and account for data uncertainty.

RESULTS: Of 1,000 LUTO pregnancies, the Vortex shunt resulted in 60 fewer cases of ESRD and 10 fewer children with NDD. The Vortex shunt was the dominant strategy indicating lower costs and higher QALYs compared to available shunts. Estimated lifetime savings totaled $132,976 for each fetus undergoing VAS. There were no differences in neonatal death. Sensitivity analyses suggest the Vortex

shunt is more cost effective across a wide range of model inputs and remains the dominant strategy when varying Vortex theoretical shunt dislodgement rate from 10% to 40%.

CONCLUSION: Our model suggests the Vortex shunt may be significantly more cost effective compared to current shunts. The Vortex shunt's actual dislodgement rate and renal outcomes must be validated in future studies.



590 Does Documentation of Postpartum Hemorrhage Risk Stratification Affect Maternal Outcomes?

Candice Schwartzenburg[1], Rachel L. Wiley[1], Ipsita Ghose[2], Hector Mendez Figueroa[3], Suneet P. Chauhan[4]

[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]University of Texas Medical School at Houston, Houston, TX, [3]University of Texas Health Science Center at Houston, Houston, TX, [4]University of Texas-Houston Medical School, Houston, TX

OBJECTIVE: Postpartum hemorrhage risk stratification (RS) at admission to labor and delivery is increasingly used as a quality metric. However, a reduction in adverse outcomes with risk stratification has not yet been established. We hypothesized that documented RS by RN or MD as compared to no RS is associated with a significant reduction in composite adverse maternal hemorrhagic outcomes (CAMHO).

STUDY DESIGN: This was a retrospective cohort study of all singleton gestations who delivered at a single-level IV center within a year. Cases were categorized into one of 3 groups: i) no RS (control); ii) RS by RN only, or; iii) RS by MD / RN. The CAMHO included the following: blood loss $\geq$ 1,000 mL, use of uterotonics, mechanical tamponade, surgical management of atony, blood transfusion, hysterectomy, thromboembolism, admission to intensive care unit, and maternal death. Multivariable Poisson regression models were used to calculate relative risks (aRR) adjusted for possible confounders along with 95% confidence intervals (CI).

RESULTS: Of the 4,544 total deliveries, 4,404 (96.9%) were included and among them 783 (18%) had no RS documented, 2,141 (49%) had RS by RN only, and 1,480 (33%) had RS by MD/RN. Overall, 941 (21.5%) of participants had CAMHO with the rate being similar among the groups: 21.5% in no RS group, 20.7% in RN only group, and 22.4% in MD/RN group. Compared to controls, the aRR for CAMHO was 1.01 (95% CI 0.84-1.12 when RS was done by RN and 1.06 (95% CI 0.97-1.18), when RS was done by MD/RN). None of the components of CAMHO, including the administration of uterotonics, differed between the 3 groups.

CONCLUSION: Compared to those who did not have risk stratification prior to delivery, patients who had RS performed in labor by RN alone or by MD/RN had no reduction in adverse maternal hemorrhagic outcomes. Further trials are needed to determine if risk stratification affects behavior and outcomes in labor and delivery.

Table 4: Composite Adverse Maternal Hemorrhagic Outcome (CAMHO)

	No RS (reference) N=783	RS by RN only N=2,141	No RS vs. RN only Adjusted RR	RS by MD N=1,480	No RS vs. MD Adjusted RR

591 Association of SARS-CoV-2 variant type and placental pathology changes

Angela R. Seasely[1], Christina T. Blanchard[1], Juliann Wang[2], Derek B. Moates[3], Sixto M. Leal Jr.[3], Virginia E. Duncan[3], Jodie Dionne Odom[3], Akila Subramaniam[1], Nitin Arora[3]

[1]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham School of Medicine, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: Pregnant people infected with SARS CoV-2 are at risk for increased disease severity and complications with level of risk varying across genotypic viral variants (pre-delta, delta, omicron). We sought to investigate the association between viral variant and placental pathology changes in pregnant patients with SARS CoV-2.

STUDY DESIGN: This was a retrospective cohort study of pregnant patients diagnosed with PCR-confirmed SARS CoV-2 (3/2020-4/2022) who delivered at a single institution. Variant type was based on genotypic sequencing data at our institution: pre-delta 3/2020-6/2021, delta 7/2021-12/15/2021, and omicron 12/16/21-4/2022. Primary outcomes were placental pathology findings characteristic of SARS CoV-2 placentitis: chronic histiocytic intervillositis, massive perivillous fibrinoid deposition, and trophoblast necrosis. Secondary outcomes included additional descriptors of placental pathology and infant variables.

RESULTS: A total of 530 women were included in the study and 406 (76%) had placental pathology available. Among these 406, 37% were admitted with a PCR-confirmed SARS CoV-2 test during the pre-delta period, 26% during delta, and 37% during omicron variant waves. Pregnant women admitted during the omicron wave were more likely to be vaccinated, and had milder disease severity (all $p<0.01$). We found no difference in placental pathology by variant wave. Chorionic villous ischemic changes were the only findings that were significantly different across variant waves, with higher rates seen in pre-delta and delta compared to omicron ($p<0.01$). Infant birthweight $< 10^{th}$ percentile ($p=0.04$) and infant head circumferences $< 10^{th}$ percentile ($p=0.01$) were also significantly different with the highest rates seen in the pre-delta wave.

CONCLUSION: The majority of placental pathology features were similar across SARS CoV-2 variant types. SARS CoV-2 placentitis

overall is a rare occurrence, and in our cohort appeared confined to the pre-delta and delta waves.

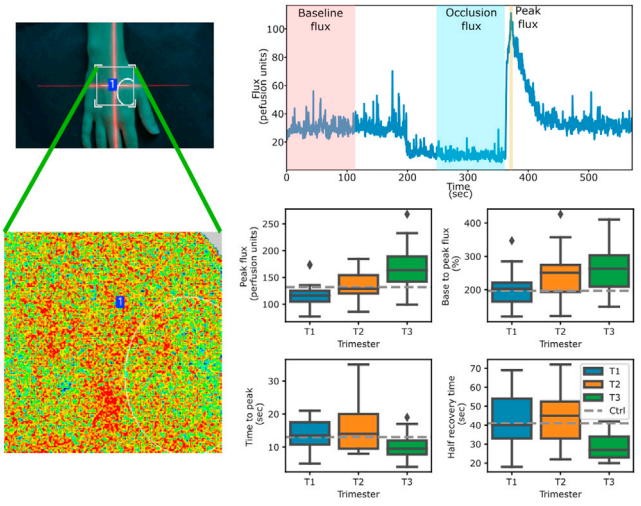
CONCLUSION: Microvascular reactivity improves from the first to the third trimester of pregnancy, and in pregnant compared to non-pregnant women. Using LSCI, we have, for the first time, presented objective measures of microvascular function in each trimester of pregnancy. These measures can be used to investigate deviations from normal microvascular response in pathologic conditions, such as preeclampsia, a disorder involving widespread endothelial dysfunction.



592 Assessment of skin microvascular response changes throughout pregnancy using laser speckle contrast imaging

Viola Seravalli[1], Mor Huri[1], Michela Santalucia[1], Gaia Impastato[1], Lorenzo Tofani[1], Mariarosaria Di Tommaso[2], Felice Petraglia[1]
[1]University of Florence, Florence, Toscana, [2]Azienda Ospedaliero-Universitaria Careggi, Firenze, Toscana

OBJECTIVE: To evaluate changes in skin microvascular response throughout pregnancy using laser speckle contrast imaging (LSCI), a novel non-invasive tool for the *in vivo* assessment of endothelial function, combined with post-occlusive reactive hyperemia (PORH), and to compare measurements with those of non-pregnant healthy subjects.

STUDY DESIGN: Twenty women with a singleton gestation were prospectively enrolled in the first trimester of pregnancy. Microvascular skin blood flow at the dorsal face of the hand was recorded using LSCI coupled with PORH at each trimester of pregnancy (T1, T2 and T3). Skin perfusion was recorded before (baseline flux), during (occlusion flux) and after (peak flux) a 3-min occlusion obtained with an inflated pneumatic cuff. Variations in the parameters of microvascular reactivity across gestation were assessed. Recordings from the third trimester were then compared with parameters obtained in 20 age-matched non-pregnant female controls.

RESULTS: The peak flux after occlusion release and the percentage increase of flux from baseline to the peak significantly increased from T1 to T3 (median change 40.9 Perfusion Units, 95% CI 19.3 - 59.5, p< 0.0001 and mean change 58.2%, 95%CI 24.57-91.84, p=0.005, respectively), and both parameters were higher in T3 compared to controls (p=0.03 and < 0.0001, respectively). The time to reach peak perfusion since cuff release and the half recovery time decreased from T1 to T3 (mean change -3.75 s, 95%CI -6.74 - -0.76, p=0.03, and mean change -12.65 s, 95%CI -19.19 - -6.11, p=0.001) and were lower in pregnant women at T3 compared to controls (p=0.006 and p< 0.0001, respectively).

593 Differences in Neonatal Outcomes Among Isolated and Non-isolated Prenatally Detected Omphaloceles

Matthew A. Shanahan, Christian M. Parobek, Simon Dadoun, Brian Burnett, April Adams
Baylor College of Medicine, Houston, TX

OBJECTIVE: An estimated 35-80% of pregnancies with prenatally detected omphaloceles (PDO) have additional anatomic anomalies, referred to as non-isolated omphaloceles. The true prevalence of isolated vs non-isolated omphaloceles remains unclear, as does the risk of perinatal and neonatal death in pregnancies with PDO. This study aimed to evaluate the rate of additional prenatally detected anomalies in pregnancies with PDO and compare neonatal outcomes among isolated and non-isolated PDO, in a modern cohort from a large academic center.

STUDY DESIGN: This was a retrospective cohort study at a large academic referral center from 2007-2023. All pregnancies with confirmed PDO were included. Maternal demographics & comorbidities, and fetal, perinatal, neonatal, & childhood outcomes were obtained. Pregnancies with isolated omphaloceles were compared to those with non-isolated omphaloceles with isolated defined as having no other major fetal structural abnormalities. The primary outcome was survival at 1 year of age. Bivariate analyses were performed, and logistic regression was used to assess the association of isolated omphalocele with the primary outcome.

RESULTS: 102 pregnancies were included, with n=42 (41.1%) isolated omphaloceles and n=60(58.9%) non-isolated. Baseline demographics and medical histories were similar between the groups. Isolated and non-isolated defect sizes were similar (2.9 ± 1.9 cm vs. 3.8 ± 3.3 cm, p=0.17) (Table). Birthweights and mode of delivery were similar between the groups. Isolated omphaloceles were associated with a significantly lower rate of neonatal death within one year (4.8% vs. 26.7%, aOR (95%CI) 0.17 (0.03-0.88)). Neonates

with an isolated omphalocele were also less likely to require intubation (38.1% vs 61.4%, aOR 0.37 (0.15-0.91)).

CONCLUSION: In a cohort of prenatally diagnosed omphaloceles, isolated omphaloceles had 5-fold reduced odds of death by 1 year compared to non-isolated omphaloceles. Isolated omphaloceles were also associated with decreased rate of intubation. These data can aid in counseling families with prenatally detected omphaloceles.

Table - Antenatal, perinatal, and neonatal outcomes compared between pregnancies with isolated and non-isolated omphaloceles. Statistical significance denoted by **bold** type. Data reported as n (%) unless otherwise noted. SD: Standard deviation. GA: gestational age. NICU: Neonatal intensive care unit. IQR: Interquartile range. OR: Odds ratio. CI: Confidence interval. aOR: Adjusted Odds ratio. #Adjusted for gestational age at delivery, aneuploidy, and omphalocele rupture.

594 Does Adding Abdominal Circumference to Estimated Fetal Weight Predict Neonatal Morbidity in Growth Restriction?

Ashley E. Shea[1], John Owen[2], Ashley N. Battarbee[1], Dian He[3], Katherine Grantz[4]

[1]University of Alabama at Birmingham, Birmingham, AL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [3]The Prospective Group, Inc; NICHD, NIH, Bethesda, MD, [4]National Institute of Child Health and Development, National Institutes of Health, Bethesda, MD

OBJECTIVE: SMFM and ACOG diagnostic criteria for fetal growth restriction (FGR) recently added abdominal circumference (AC) < 10th %ile as an additional criterion to traditional estimated fetal weight (EFW) < 10th %ile; however, how well this addition predicts neonatal morbidity (NNM) is unknown. We compared AC or EFW (EFW+AC) to EFW alone in the prediction of composite NNM (CNNM) and small-for-gestational-age (SGA) at birth.

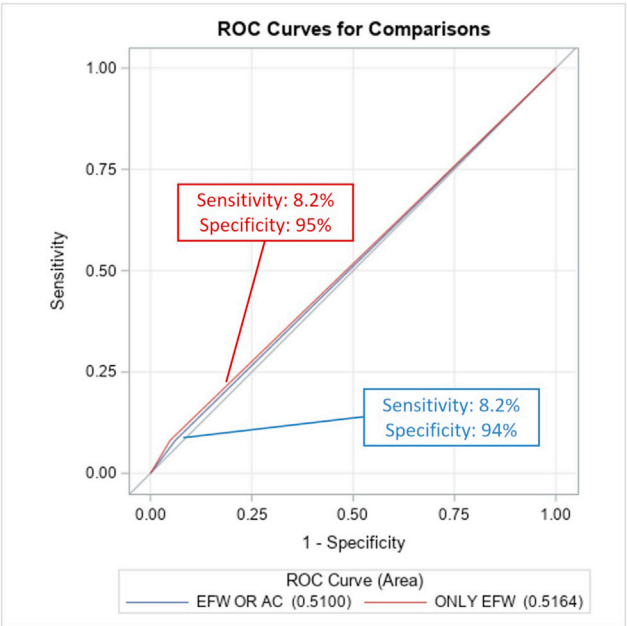
STUDY DESIGN: Secondary analysis of the NICHD Fetal Growth Study-Singletons with research quality ultrasounds from 2,802 low-risk patients at 12 US sites, 2009-2013. The last 3rd trimester ultrasound scan (mean gestational age 36.6 +/- 2.3 wks) was included from non-anomalous fetuses with known neonatal outcomes. Both EFW & AC were evaluated using NICHD charts. Outcomes were: 1) CNNM (see Figure footnote), and 2) SGA, defined as birthweight < 10th %ile by Fenton charts. Logistic regression assessed association of each FGR definition with outcomes and receiver operator characteristic area under the curve (AUC) assessed comparative predictive ability.

RESULTS: Of the 2,397 patients included, 7.4% were SGA at birth and 5.6% of neonates had CNNM; 6.3% of patients met criteria for FGR by EFW+AC vs 5.1% by EFW alone (p< 0.0001). Although both FGR definitions had acceptable discrimination of SGA- EFW+AC: AUC 0.72 [95% CI, 0.68-0.75], EFW alone: AUC 0.69 [95% CI, 0.66-0.73], risk of CNNM was not associated with either definition- EFW+AC: RR 0.75 [95% CI, 0.42-1.4], EFW alone: RR 0.60 [95%CI 0.33-1.1], and both were poor predictors of CNNM- EFW+AC: AUC 0.51 [95% CI, 0.49-0.53], EFW alone: AUC 0.52 [95% CI, 0.49-0.54] (Figure).

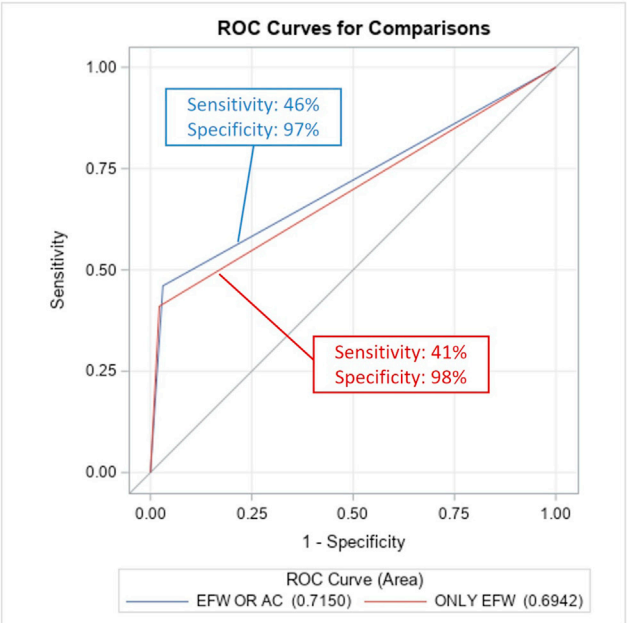
CONCLUSION: The addition of AC < 10th %ile to the traditional definition of FGR significantly increased the incidence of FGR, but it did not improve the prediction of CNNM compared to EFW alone in a low-risk population. Given the use of prenatal resources and risks associated with the diagnosis of FGR, future studies should evaluate whether the new definition is superior in prediction of NNM and so confirm its clinical utility.

Figure. Receiver operator characteristic area under the curves

Composite Neonatal Morbidity*



Small-for-Gestational-Age at Birth



*Composite neonatal morbidity includes any one of the following: acidemia, NICU >3 days, seizures, serious respiratory complications, exchange transfusion, intrapartum aspiration, necrotizing enterocolitis, hypoglycemia, sepsis, retinopathy, encephalopathy, or death.

595 Examining the Relationship between Maternal Preeclampsia and Autism Spectrum Disorder in Childhood: A Cohort Analysis

Noam Shema[1], **Omri Zamstein**[2], **Tamar Wainstock**[3], **Eyal Sheiner**[2]
[1]Soroka Medical Center, Beer Sheva, HaDarom, [2]Soroka University Medical Center, Beer-Sheva, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom

OBJECTIVE: Autism spectrum disorder (ASD) is of multifactorial origin, with some factors thought to be related to the prenatal period. Preeclampsia (PET) is a prevalent and serious pregnancy complication that is considered a disease with multiple contributing factors. This study was aimed to investigate the potential association between these two morbidities within our diverse population.

STUDY DESIGN: A population-based cohort analysis using data from community clinics and a tertiary referral hospital was conducted. The analysis specifically focused on deliveries that took place between 2005 and 2017, considering that individuals born after this period might be too young to receive an ASD diagnosis. The aim was to compare the incidence of ASD in offspring based on whether their mothers had been diagnosed with PET of varying severities, or not. To evaluate the cumulative incidence of ASD, we employed a Kaplan-Meier survival curve. Additionally, a Cox proportional hazards model was utilized to account for potential confounding factors.

RESULTS: Out of 165,689 parturient in the study, 4,268 (2.6%) were diagnosed with PET and 1,351 (0.8%) with PET with severe features (severe PET). PET, especially the severe form, was associated with adverse obstetrical outcomes, including intrauterine growth restriction, non-reassuring fetal heart rate tracing, earlier delivery, cesarean delivery, and lower birth weight ($p< 0.001$ for all;table). Out of 862 offspring diagnosed with ASD during childhood, the prevalence was higher in the PET group (0.5% for no PET, 0.8% for PET, and 0.7% for severe PET; $p=0.009$;table). However, the cumulative ASD morbidity derived from the Kaplan-Meier survival curve showed no significant difference among the groups (p-value=0.901; figure). Following adjustment for factors such as gestational age, maternal age, mode of delivery, and gender, the association between PET and ASD was no longer statistically significant.

CONCLUSION: In the endeavour to gain a deeper understanding of the obstetrical aspects related to the development of ASD, our findings indicate that PET does not play a contributory role.

Table. Preeclampsia severity, obstetrical characteristics, and childhood autism spectrum disorder prevalence.

	No preeclampsia (n= 160,070)	Preeclampsia (n= 4,268)	Severe preeclampsia (n= 1,351)	P-value
	Obstetrical outcomes

596 Delivery Outcomes in Triplet and Twin versus Singleton Pregnancies with Short Cervix

Kavya Shivashankar[1], Yara El Helou[2], Calla Holmgren[3], Rachel Harrison[4]

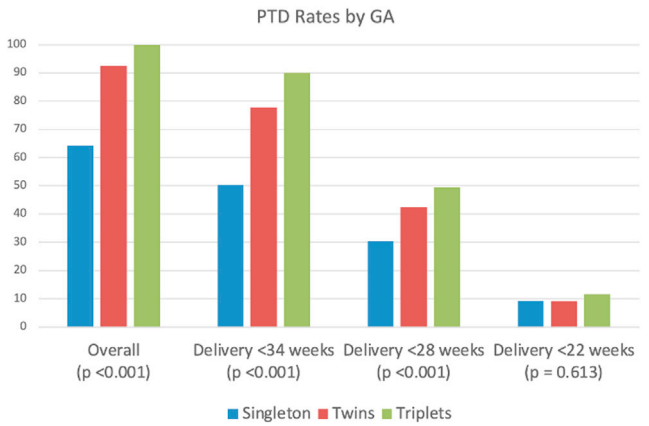
[1]University of Illinois Hospital, Chicago, IL, [2]University of Illinois at Chicago, Chicago, IL, [3]AAH Lutheran General Hospital, Park Ridge, IL, [4]Advocate Christ Hospital, Oak Lawn, IL

OBJECTIVE: Short cervix and multi-fetal gestation are independent risk factors for spontaneous preterm delivery (PTD). Our study aims to identify the impact of short cervix on delivery timing in triplet and twin pregnancies vs singleton pregnancies.

STUDY DESIGN: This is a retrospective cohort study of pregnant subjects from the National Inpatient Sample Database from 2017-2019 with a delivery encounter diagnosis of short cervix or cervical incompetence. Exclusion criteria were quadruplet or higher order multiple pregnancies and delivery at < 14 weeks. Subjects with singleton, twin, and triplet pregnancies were separated into three groups for comparison. Primary outcome was delivery gestational age (GA)< 22 weeks, < 28 weeks, and < 34 weeks. ANOVA, chi-squared, and logistic and linear regression were used for statistical analysis; p-value < 0.05 was considered statistically significant.

RESULTS: 18,232 singleton, 2,160 twin, and 125 triplet pregnancies with short cervix were identified for analysis. Average GA at delivery for pregnancies with short cervix was lower in triplets (27.3 +/- 4.6 weeks) and twins (28.7 +/- 5.3 weeks) vs singletons (31.7 +/- 6.7 weeks). Rates of PTD < 22 weeks were similar across groups — 11.6% in triplets vs 9.0% in twins vs 9.2% in singleton (p=0.613). At GA < 28 weeks, PTD was higher with triplets (49.6%) and twins (42.5%) vs singleton (30.5%) (p< 0.001). PTD rates at GA < 34 weeks were 89.9% for triplets, 77.7% for twins, and 50.3% for singleton (p< 0.001). These findings persisted when controlling for confounders. PTD was higher in triplets at GA < 28 weeks (aOR 2.16, 95%CI 1.50-3.10) and < 34 weeks (aOR 8.74, 95%CI 4.80-15.93). There remained no association with triplet pregnancy and delivery < 22 weeks in those with short cervix (aOR 1.30, 95%CI 0.76-2.23).

CONCLUSION: Triplet and twin pregnancies with short cervix are associated with increased rates of PTD compared to singleton pregnancies. The difference in PTD rates between triplet, twin, and singleton pregnancies with short cervix is insignificant at GA < 22 weeks, however becomes more salient with advancing gestational age.



597 De novo hypertension in the late postpartum period: a case for extending postpartum care

Colleen Sinnott[1], Suzanne Stammler[1], Lisbet S. Lundsberg[2], Caitlin Partridge[3], Jennifer F. Culhane[3], Anna Denoble[1]

[1]Yale University School of Medicine, New Haven, CT, [2]Yale, New Haven, CT, [3]Yale University, New Haven, CT

OBJECTIVE: To better inform efforts to improve and extend postpartum (PP) care, we sought to determine the incidence of de novo hypertension (HTN) up to 6 months PP in patients without evidence of HTN during pregnancy or immediately PP.

STUDY DESIGN: This retrospective cohort study included all patients delivering within an academic healthcare system. All blood pressures (BPs) from conception to 6 months PP were obtained from the electronic medical record (EMR) and used to construct a variable identifying patients with ≥ 2 systolic BPs ≥ 140 mm Hg or ≥ 2 diastolic BPs ≥ 90 mm Hg from conception to delivery encounter discharge. We excluded patients with an ICD code for chronic HTN or HDP hypertensive disorders of pregnancy in the EMR *or* evidence of HTN by our constructed variable. All BPs from the early PP period (delivery discharge to 6 weeks; EPP) and the late PP period (6 weeks to 6 months; LPP) were used to classify patients into one of four HTN stages per American College of Cardiology definitions (normotensive, elevated, stage 1 and stage 2). HTN stages in the LPP for the subset of patients who were also normotensive in the EPP were then examined to assess the risk of late-onset de novo HTN that would not otherwise be captured during standard postpartum care. We evaluated patient attributes associated with a new diagnosis of HTN in the LPP using X^2 tests.

RESULTS: In total, 18,270 patients were included. Despite normotensive pregnancies, 12.6% were elevated, 11.7% were stage 1, and 1.3% were stage 2 in the LPP (Table). Traditional risk factors for HTN (smoking, diabetes, age ≥ 35, and obesity) were observed more frequently in those who developed de novo HTN. Of the 7,872 patients who were normotensive in the EPP, 9.6% were subsequently classified as elevated, 7.7% as stage 1, and 0.5% as stage 2 HTN.

CONCLUSION: Even in the absence of evidence of HTN during pregnancy and early PP, many patients remain at risk for development of de novo HTN up to 6 months PP. Expansion of postpartum care may provide an opportunity to identify these patients and triage appropriate clinical care.

598 Disrupted SERPINA1 Expression in Trophoblast of Patients with Adherent Placentation

Erica L. Smith[1], Zehra Ordulu[1], Mehmet Genc[1], Marcella Rodriguez[2], Rebecca Wilson[1], Alyssa Williams[1], Alyssa Tipler[1], MacKenzie Dyrda[1], Vernoia Sadek[1], Helen Jones[1]
[1]University of Florida, Gainesville, FL, [2]INOVA Fairfax Hospital, Gainesville, FL

OBJECTIVE: Alpha 1 Antitrypsin (A1AT) is a protease inhibitor encoded by SERPINA1 gene and may contribute to abnormal placentation as demonstrated by increased syncytialization following knockout in cytotrophoblast as previously published from primary trophoblast research. This study aims to assess SERPINA1 expression by immunohistochemistry (IHC) on placental samples from histologically confirmed cases of placenta accreta spectrum (PAS).

STUDY DESIGN: Archived placental specimens in paraffin-embedded blocks were studied. The specimens were from patients without PAS, adherent (Stage 2 basal plate myometrial fibers [BPMF] and Grade 1) placentation and severely adherent (Grade 2 and 3) placentation. Specimens were studied with IHC to assess SERPINA1 expression and localization. Immunostained slides were scanned using a Zeiss Axioscan and semiquantitative scoring (−, +, ++, +++) was performed in the following cell types: extravillous trophoblast, syncytiotrophoblast, cytotrophoblast, villous fibroblast, and endothelium. ANOVA and Fischer's exact test were used to compare patient characteristics. Linear regressions were used to model the relation between placentation (no PAS, adherent or severely adherent), cell count and SERPINA1 expression.

RESULTS: SERPINA1 expression in cytotrophoblast cytoplasm correlated negatively with adherent placenta (coefficient=-0.31 (0.15); 95% confidence interval=0.62, -0.01; p= .001). There was no such relationship for syncytiotrophoblast, extravillous trophoblast, villous fibroblast or endothelium.

CONCLUSION: Current theories for PAS etiology differ, one implies an invasive trophoblast etiology while the other implies maternal disease typically attributed to prior uterine scarring. Our findings suggest A1AT downregulation in the cytoplasm of cytotrophoblasts is associated with adherent placentation. This is consistent with previous observation that A1AT dysfunction is linked with abnormal placental formation and may result in increased syncytialization of the cytotrophoblast, increase in placental mass, and expression of inflammatory cytokines.

599 Differing clinical management for postpartum hemorrhage and associated risk for intensive care unit admission

Moeun Son[1], Lisbet S. Lundsberg[2], Kevin Dysart[3], Caitlin Partridge[4], Heather Burris[5], Sara Handley[5], Rachel Ledyard[5], Kristie Baisden[6], Leah Berhane[6], Lauren Doamekpor[6], Susan Bersoff-Matcha[6], Jennifer F. Culhane[4]
[1]Weill Cornell Medical College, New York, NY, [2]Yale, New Haven, CT, [3]Nemours Children's Hospital, Wilmington, DE, [4]Yale University, New Haven, CT, [5]University of Pennsylvania, Philadelphia, PA, [6]U.S. Food and Drug Administration, Bethesda, MD

OBJECTIVE: Examine the risk of intensive care unit (ICU) admission associated with differing levels of care for postpartum hemorrhage (PPH) at 4 hospitals within 1 healthcare system.

STUDY DESIGN: Retrospective study of patients with PPH from 2013-2023 without placenta accreta spectrum disorders. A unified EHR database was used with standardized definitions and diagnosis codes. PPH was defined by ≥1 of 3 criteria: ICD codes, estimated blood loss ≥1L, or postpartum blood transfusion. PPH treatment was examined in 2 ways as the exposure: (1) dichotomous variable comparing usual care (including oxytocin infusion and uterine massage) vs. additional treatment (carboprost, methylergonovine, misoprostol, tranexamic acid ± procedures) and (2) 4-way comparison between usual care vs. additional treatment further categorized into 3 groups: less aggressive medication (2 types with < 2 doses of either or 1 type with < 3 doses), more aggressive medication (≥3 types, 2 type with ≥2 doses of either, or 1 type with ≥3 doses), and procedures (intrauterine balloon, curettage, O'Leary or B-lynch sutures, uterine artery embolization, and/or hysterectomy ± medications). The outcome was ICU admission. Bivariable and multivariable logistic regression analyses were performed.

RESULTS: Of 10,394 patients with PPH, 5047 (48.6%) had usual care and 5347 (51.4%) had additional treatment (3073 less aggressive medication use, 1347 more aggressive medication use, and 927 with procedures) (Table). In the dichotomous comparison, ICU admission risk was increased >2-fold with additional treatment vs. usual care. In the 4-way comparison, ICU admission risk increased with more aggressive treatment, with >7-fold increased risk with procedures vs. usual care. These increased odds persisted after adjusting for potential confounders. There was significant hospital-level variation in treatment patterns and risk for ICU admission.

CONCLUSION: Increasingly aggressive PPH treatment was associated with higher risks for ICU admission. Whether treatment differences indicate variability in quality of care or associate with other morbidities should be explored.

Table: Risk of ICU admission associated with type of postpartum hemorrhage (PPH) management

	Total	ICU Admission		
PPH Management	n (%)	n (%)	OR (95% CI)	aOR (95% CI)
Usual care	5047 (48.6)	64 (1.3)	Referent	Referent
Additional medications and/or procedures	5347 (51.4)	162 (3.0)	2.43 (1.82-3.26)	3.21 (2.30-4.50)
Less aggressive medication treatment	3073 (29.6)	48 (1.6)	1.23 (0.85-1.80)	1.44 (0.94-2.21)
More aggressive medication treatment	1347 (13.0)	36 (2.7)	2.14 (1.41-3.23)	3.45 (2.12-5.63)
Procedural intervention +/- medications	927 (8.9)	78 (8.4)	7.15 (5.10-10.03)	9.87 (6.48-15.03)

600 Does Mild Gestational Diabetes Increase Risk for Adverse Maternal Pregnancy Outcome?

Daniella Spielman[1], Traci Carson[2], Sein Lee[2], Amy M. Valent[3], Suchitra Chandrasekaran[4]

[1]Emory University School of Medicine, Atlanta, GA, [2]Emory University School of Public Health, Atlanta, GA, [3]Oregon Health & Science University, Portland, OR, [4]Emory University School of Medicine, Decatur, GA

OBJECTIVE: Pregnancies complicated by gestational diabetes (GDM) are at a higher risk for adverse maternal pregnancy outcomes (APO). If mild GDM (MGDM), the diagnosis of having an abnormal screening but normal diagnostic oral glucose tolerance test (OGTT), is associated with increased risks of APO is less clear. Using the large multi-site prospective cohort Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-to-be (nuMoM2b), we investigated if MGDM associates with APO (composite including one or more of the following: hypertensive disorders of pregnancy, cesarean section, preterm premature rupture of membranes, or preterm birth).

STUDY DESIGN: This is a secondary analysis of nuMoM2b. MGDM included 1-hour (hr) screening OGTT >135 mg/dL & < 2 elevated values on the 3-hr diagnostic OGTT (Carpenter-Coustan cutoffs). MGDM was subclassified into 3 groups: no abnormal values on 3-hr (GDM1), only abnormal fasting value on 3-hr (GDM2), & only abnormal post-glucose load value on 3-hr (GDM3). No GDM (NGDM) included normal 1-hr screening test. Wilcoxon Rank-Sum & Chi-square tests compared continuous and categorical variables respectively. Multivariable logistic regression calculating adjusted odds ratio (AOR) controlling for maternal age, race & body mass index were performed.

RESULTS: Of N=9289 subjects, 68.4% (n=6352) had NGDM, 7% (n=651) MGDM, 3% (n=280) GDM1, 0.4% (n=37) GDM2, & 3.6% (n=334) had GDM3 respectively (Table 1a). 39.8% of NGDM, 43.2% MGDM, 40.4% of GDM1, 54% of GDM2, & 44.3% GDM3 had an APO. When controlling for confounders, those with MGDM (AOR 1.4, 95% CI 1.1-1.9, p=0.02) & GDM1 (AOR 1.6, 95% CI 1.1-2.2, p< 0.02) had significantly higher odds of experiencing an APO.

CONCLUSION: It is unequivocal that GDM is associated with APOs. Innovatively, our data demonstrate that those with *no elevated values* on a 3-hr OGTT (theoretically the lowest risk group) had the highest odds of developing an APO. Further studies investigating the mechanistic underpinnings connecting the phenotypes of MGDM and APO development are imperative.

A value >135 mg/dL is defined as an abnormal 1-hour oral glucose tolerance test (OGTT).
Abnormal values on confirmatory 3-hour oral glucose tolerance test are defined by Carpenter-Coustan cutoffs.
[a] No GDM is defined as a 1-hour glucose tolerance test result <135 mg/dL.
[b] GDM1 is defined as an abnormal 1-hour OGTT and no abnormal values on 3-hour OGTT.
[c] GDM2 is defined as an abnormal 1-hour OGTT and an abnormal fasting value n 3-hour OGTT.
[d] GDM3 is defined as an abnormal 1-hour OGTT and an abnormal post-glucose load value on 3-hour OGTT.
[e] GDM is defined as a 1-hour OGTT > 200 mg/dL or an abnormal 1-hour OGTT and >2 abnormal values on confirmatory 3-hour OGTT.
[f] BMI, body mass index.
[g] Maternal mortality defined as maternal death during pregnancy or the first year postpartum.

601 Evolution of hypertension stages in pregnancy and postpartum from 2013-2022

Suzanne Stammler[1], Anna Denoble[1], Jennifer F. Culhane[2], Lisbet S. Lundsberg[3], Caitlin Partridge[2]

[1]Yale University School of Medicine, New Haven, CT, [2]Yale University, New Haven, CT, [3]Yale, New Haven, CT

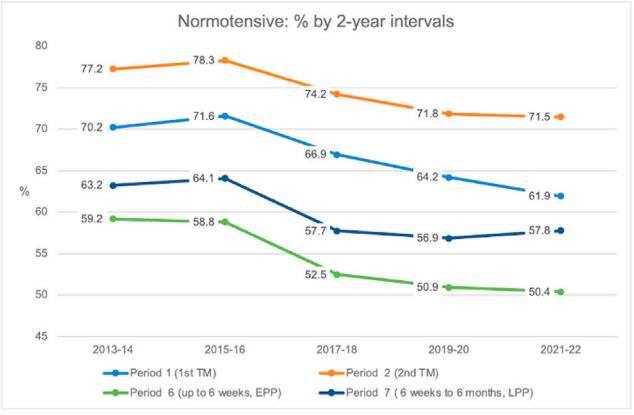
OBJECTIVE: We aimed to assess changes over time in the distribution of ACC/AHA hypertension (HTN) stages during pregnancy and postpartum (PP) from 2013-2022.

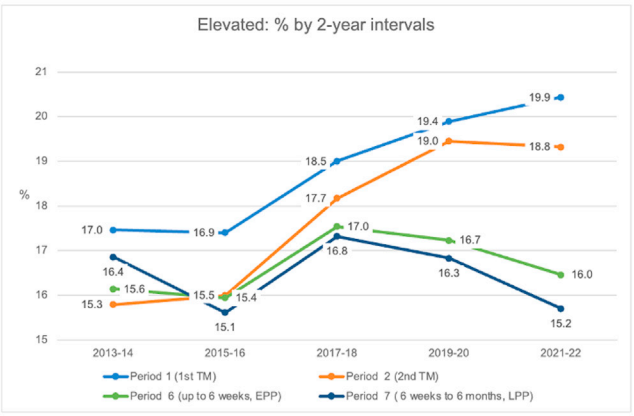
STUDY DESIGN: This was a retrospective cohort study of pregnancies within one healthcare system. Deliveries from 2013-2022 were analyzed in 2-year intervals. Every blood pressure (BP) was obtained from electronic medical records. Mean systolic (SBP) and diastolic (DBP) BPs were used to classify patients as normotensive (SBP < 120 mm Hg and DBP < 80mm Hg), elevated (SBP 120-129 mm Hg and DBP < 80 mm Hg), stage 1 (SBP 130-139 mm Hg or DBP 80-89 mm Hg), or stage 2 (SBP ≥ 140 mm Hg or DBP ≥90 mm Hg) per the ACC/AHA 2017 HTN guidelines for each of 7 discrete pregnancy periods: 1 = 1st trimester (TM), 2 = 2nd TM, 3 = 3rd TM, 4 = delivery admission to delivery, 5 = delivery to delivery discharge, 6 = up to 6 weeks (early) PP (EPP) and 7 = 6 weeks to 6 months (late) PP (LPP). HTN stages were reported by pregnancy periods and 2-year delivery intervals. Changes in HTN over time were computed.

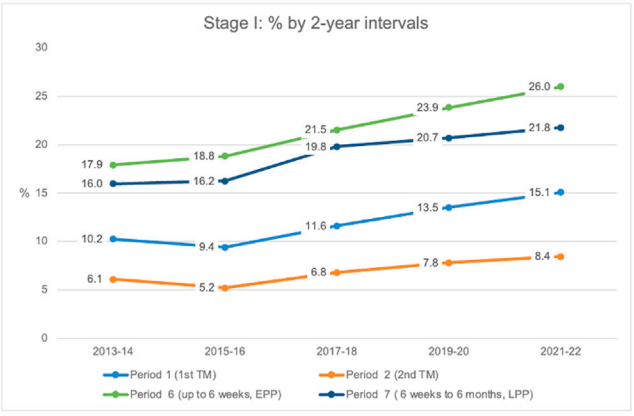
RESULTS: A total of 108,924 deliveries from 2013-2022 were included. The percentage of patients with BPs available for the 7 pregnancy periods ranged from 41.2% in the LPP to 99.5% for

period 5, but the proportion of patients contributing data did not change across the study. Over the 10-year interval, a decrease in normotensive BP was observed for all periods with largest decreases found in the EPP period from 59.2% in 2013-2014 to 50.4% in 2021-2022 (Δ-8.8%) and the 1st TM from 70.2% in 2013-2014 to 61.9% in 2021-2022 (Δ-8.3%). Elevated BPs and stage 1 HTN increased for every pregnancy period, most notably for elevated BPs in the 2nd TM (15.3% in 2013-2014 to 18.8% in 2021-2022: Δ+2.9%) and for stage 1 HTN in the EPP (17.9% in 2013-2014 to 26.0% in 2021-2022: Δ+8.2%).

CONCLUSION: The proportion of patients with elevated BPs or stage 1 HTN increased over the study period, with the most profound changes occurring in early pregnancy and early postpartum. Further exploration is needed to assess how maternal attributes may contribute to these observed changes in BP.







602 Fetal 'late bloomers' — factors and outcomes associated with apparent resolution of fetal growth restriction

Zachary D. Stanley[1], Jennifer E. Powel[2], Niraj R. Chavan[3], Lauren G. Farley[4], Tracy M. Tomlinson[3]
[1]St. Louis University, SSM Health, St. Louis, MO, [2]Hackensack Meridian Health - Jersey Shore University Medical Center, Neptune, NJ, [3]St. Louis University, St. Louis, MO, [4]University of Missouri, Kansas City, MO

OBJECTIVE: To evaluate characteristics associated with apparent resolution of fetal growth restriction (FGR) and assess risk of adverse pregnancy outcomes (APO) among those with resolution.

STUDY DESIGN: Passive prospective cohort analysis of singleton non-anomalous pregnancies meeting Delphi consensus-based FGR criteria at a single academic tertiary care institution 2011-2020. FGR resolution was defined as a birthweight $^{3}3^{rd}$ centile in combination with a lapse of ≥3 weeks between the last ultrasound meeting consensus criteria for FGR and delivery. The primary composite APO includes perinatal demise and/or poor condition at birth: 5-min Apgar< 7, cord pH ≤7.10, or base excess ≥12. Regression analyses were undertaken to identify factors associated with FGR resolution and those associated with the primary outcome.

RESULTS: Of 901 pregnancies meeting Delphi consensus criteria for FGR, ongoing sonographic surveillance revealed apparent resolution of FGR in 74 (8%) pregnancies. The median time since FGR criteria was last met and delivery was 5.9 (IQR 4.2, 8.0) weeks. Resolution was more likely among those with isolated abdominal circumference < 3rd centile at diagnosis (RR 2.90, 95%CI 1.87-4.49). Those with hypertensive disorders of pregnancy (RR 0.21, 95%CI 0.10-0.41), male fetal sex (RR 0.37, 95%CI 0.22-0.63), and absent/reversed umbilical artery end-diastolic flow at the time of FGR diagnosis (RR 0.09, 95%CI 0.01-0.61) were less likely to have resolution. 173/901 pregnancies (19%) had APO: 5/74 (7%) with apparent resolution of FGR vs 168/827 (20%) without (RR 0.33, 95%CI 0.14-0.78). We failed to find an independent association between resolution of FGR and APO (Figure).

CONCLUSION: We identified four characteristics associated with apparent resolution of FGR and found no evidence its resolution is associated with APO. Further investigation in cohorts with more cases of FGR resolution is warranted. Confirmation of our findings would provide evidence that rigorous antenatal testing for these pregnancies may be safely discontinued and indicate risks associated with their iatrogenic early delivery safely avoided.

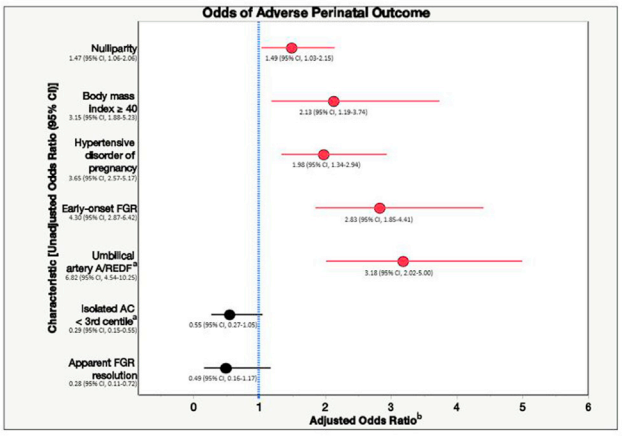


Figure. Odds of composite adverse perinatal outcome defined as perinatal demise and/or poor condition at birth: cord arterial pH ≤ 7.1, cord arterial base excess ≥ 12, 5-minute Apgar < 7. The bias-corrected bootstrapped (1000 replicates) area under the curve for the 7-factor model is 0.78 (95% CI 0.73-0.81). FGR, fetal growth restriction; A/REDF, absent/reversed end diastolic flow; AC, abdominal circumference; OR, odds ratio; [a]At the time of FGR diagnosis; [b]Adjusted for the other 6 covariates in the model

603 Differences in dosing strategies and perinatal outcomes for pregnant persons on buprenorphine compared with buprenorphine-naloxone

Emily H. Stetler[1], Tiffany Yang[2], Oladunni Ogundipe[1], Lauren Stewart[1], Chaitali Korgaonkar-Cherala[3], Julia Kim[1], Rakasa Pattanaik[1], Erika Zambrano Alvarez[4], Kimberly Herrera[1], Diana Garretto[5], David Garry[4], Cassandra Heiselman[4]

[1]Stony Brook University Hospital, Stony Brook, NY, [2]Stony Brook University, Stony Brook, NY, [3]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel, [4]Stony Brook Medicine, Stony Brook, NY, [5]Stony Brook University Hospital, E Northport, NY

OBJECTIVE: There is insufficient data on buprenorphine-naloxone (BUP-NA) in pregnancy, furthermore there is limited data to guide dosing strategies for medications for opioid use disorder (MOUD) beyond withdrawal symptoms. This study sought to compare perinatal outcomes between buprenorphine (BUP) and BUP-NA along with evaluating dosing alterations in pregnancy.

STUDY DESIGN: Retrospective single institution cohort study of pregnant persons with OUD who delivered between 2017 and 2023. Patients were divided based on MOUD: BUP vs BUP-NA. Exclusion criteria were no MOUD or methadone use for MOUD. Patient characteristics, obstetric and neonatal outcomes were collected, along with dosing requirements at the start of MOUD in pregnancy and at delivery. Groups were compared groups using Chi-square, McNemar test, and t-tests with statistical significance defined as $p < 0.05$.

RESULTS: 255 patients were identified. No differences were found comparing perinatal outcomes except for active drug use during pregnancy (p=0.04) (Table 1). Obesity (p=0.25), AMA (p=0.59), government assisted insurance (p=0.13), race/ethnicity (p=0.82), and rate of neonatal opioid withdrawal syndrome (NOWS) (p=.97) were similar. Changes in MOUD dosing occurred in 50.6% of patients. Initially, 50.5% of patients were on a split dosing strategy, and the rate increased by 17.5% by delivery, with 68% of patients requiring split dosing ($p< 0.01$). There was no difference in dosing frequencies between groups in the beginning of pregnancy versus delivery. More patients taking BUP-NA (69%) required an increase in dosage during pregnancy vs BUP (46.1%, $p < 0.01$). The frequency of weaning between the two groups (p=0.523) was similar with the majority (73.5%) not weaning.

CONCLUSION: Perinatal outcomes including NOWS were similar between BUP and BUP-NA in our cohort, supporting the growing literature of safety of BUP-NA in pregnancy. Split dosing strategies were required more frequently throughout pregnancy for all patients, however patients taking BUP-NA may need increased dosages during pregnancy compared to patients taking BUP.

	Buprenorphine (n=63)	Buprenorphine/naloxone (n=192)	p-value

604 Frequency of preterm birth after regional maternal transport for threatened preterm birth

Aneesa T. Stewart[1], Kelley Mclean[2], Gabriela Bosmenier Cruz[3]

[1]University of Vermont, Shelburne, VT, [2]University of Vermont Medical Center, Burlington, VT, [3]University of Vermont, Burlington, VT

OBJECTIVE: Perinatal regionalization, which allows for inpatient maternal transport in the context of predicted need for a higher level of neonatal care, has been demonstrated to reduce infant morbidity and mortality. However, some maternal transports will ultimately prove unnecessary in the context of threatened preterm birth (PTB). Here, we investigate maternal characteristics of those transported for threatened PTB from community-based hospitals to our tertiary academic center.

STUDY DESIGN: This was a retrospective cohort study of maternal transports for threatened PTB without PPROM between 21+0 and 35+6 weeks from 2019-2022. Chart review was used to collect gestational age (GA) at transport, prior obstetric history, and current pregnancy course and outcome. Fisher's exact and t-test were used for statistical analyses, with significance set at a p- value of < 0.05.

RESULTS: There were 502 maternal transports to our institution from 17 different community hospitals. Of these, 215 transports were for threatened PTB and/or PPROM, of which 151 were for threatened PTB alone. The average GA of transport was 31+3 weeks, and in 83% of cases, betamethasone was initiated before transport. Table 1 demonstrates the obstetric parity of the cohort overall and stratified by whether or not delivery occurred during transport hospitalization. As shown, there were no differences in obstetric history between the two groups. Most patients did not deliver during the transport hospitalization (96/151, 65%), though 65% ultimately delivered < 37 weeks. Only 5 patients delivered within 1 week of

discharge from the transport hospitalization. The cervical exam prior to transport was documented in 114 cases and was greater in those who delivered during the transport hospitalization (3.1 cm vs. 1.8 cm, p= < .001).

CONCLUSION: Prediction of need for acute transport for threatened PTB remains challenging regardless of prior obstetric history. While the majority of transports did not deliver during transport hospitalization, risk assessment for PTB was reasonably accurate, as 65% of the cohort ultimately delivered < 37 weeks.

Table 1: Obstetrical parity with respect to outcome during transport hospitalization

	Delivered, transport hospitalization %, (n)	Undelivered, transport hospitalization %, (n)	
Total (n= 151)	35.1(53)	64.9 (98)

605 Fetal extraction time during intrapartum cesarean deliveries and the risk of neonatal acidemia

Kali Stewart[1], Shannon E. Beermann[2], Katherine Carbonell[2], Lucy Simpson[3], Ebony B. Carter[4], Amanda C. Zofkie[4], Jeannie C. Kelly[4], Antonina I. Frolova[5], Anthony O. Odibo[5], Nandini Raghuraman[5], Bree A. Goodman[2]

[1]Washington University in St.Louis, St. Louis, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]Mercy Hospital, St. Louis, MO, [4]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO, [5]Washington University School of Medicine in St. Louis, St. Louis, MO

OBJECTIVE: Prolonged fetal extraction time, particularly during intrapartum cesarean delivery (CD), can be anxiety-provoking for providers, yet there is little known about neonatal risks with prolonged extraction times. We sought to evaluate the relationship between fetal extraction time and neonatal acidemia.

STUDY DESIGN: This is a case-control study of all intrapartum CD from June 2018-2021 at a single tertiary academic hospital with universal cord gas collection. Cases were patients with neonatal acidemia defined as umbilical artery (UA) pH < 7.1. Controls were patients with neonatal UA pH ≥7.1. We compared rates of neonatal acidemia between cases and controls at different fetal extraction times (defined as the duration of time from hysterotomy to delivery in minutes) using < 1 minute as a reference. Backwards stepwise multivariable logistic regression was used to adjust for potential confounders.

RESULTS: Of 1057 intrapartum CD, 107 (10.1%) were complicated by neonatal acidemia. The median (IQR) fetal extraction time was 1 minute (1-2) for both cases and controls (p=0.79). Cases and controls differed with respect to rates of pregestational diabetes, emergent cesarean delivery, general anesthesia, non-reassuring fetal status at time of delivery, and time from skin incision to hysterotomy. After adjusting for skin to uterine time and non-reassuring fetal status, the risk of neonatal acidemia did not increase until fetal extraction times were ≥ 5 minutes (aOR 2.86, 95% CI 1.02-8.01).

CONCLUSION: The risk for neonatal acidemia at the time of unscheduled intrapartum cesarean delivery is increased when fetal extraction is prolonged ≥ 5 minutes. These findings provide a reasonable period during which the primary surgeon can troubleshoot the extraction without impact on neonatal acidemia as well as a timeframe for surgeons to start enlisting additional assistance and employing aggressive tactics, such as hysterotomy extension, to expedite delivery.

Table 1. Fetal extraction times and risk of neonatal acidemia

Fetal extraction time	Neonatal Acidemia n=107	No Neonatal Acidemia n=950	OR (95%CI)	aOR[1] (95%CI)

606 Do social determinants of health influence prescribing practices of low dose aspirin prophylaxis?

Lauren Stewart[1], Bijal Parikh[2], Lena Woo[3], Cassandra Heiselman[2], David Garry[2], Kimberly Herrera[1]

[1]Stony Brook University Hospital, Stony Brook, NY, [2]Stony Brook Medicine, Stony Brook, NY, [3]Renaissance School of Medicine at Stony Brook University, Stony Brook, NY

OBJECTIVE: To evaluate social determinants of heath (SDH) and their effect on provider practices in prescribing low dose aspirin (LDA) for preeclampsia prophylaxis.

STUDY DESIGN: Retrospective cohort of patients who met SMFM criteria to recommend LDA prophylaxis that had live births at a single academic center between January - May 2021. Exclusion criteria: maternal age < 18 years and initiation of prenatal care in 3rd trimester. Patient characteristics, including SDH, criteria for LDA prophylaxis, timing of first prenatal visit and LDA initiation were collected. Statistical analysis was performed using Chi square, Fisher's exact, and student t-tests (significance defined as p < 0.05) to compare different SDH and LDA prescribing practices.

RESULTS: During the study period, 55% (N=375/622) patients met inclusion criteria. Race and primary language did not affect appropriate prescribing practices of LDA (Table 1). When LDA prescribing rates were compared between different race categories (e.g., African American race or Non-white race), there was no difference. Most patients initiated prenatal care prior to 16 weeks (86.1%); 77.8% of those prescribed LDA were optimally initiated prior to 16 weeks. LDA prescription did not differ between those that initiated care before or after 16 weeks (31.9% vs. 26.9%, p = 0.473). The relationship between prenatal care initiation and LDA prescription did not differ across any SDH category. Government assisted insurance decreased the likelihood of correct LDA prescription by providers (p = 0.041). There was a 37% lower chance of being appropriately prescribed LDA prophylaxis for patients with government assisted insurance (OR 0.63, 95% CI 0.41-0.98).

CONCLUSION: Only one social determinant of heath (SDH), government assisted insurance, was associated with lower prescription rate of LDA in patients at high risk of developing preeclampsia.

Do social determinants of health influence prescribing practices of low dose aspirin prophylaxis?

Table 1. Low dose aspirin prescribing practices by social determinants of health.

Factor	Prescribed Aspirin (n=117)	Not Prescribed Aspirin (n=258)	p-value
African American Race	19 (17.4%)	45 (16.2%)	0.774
Non-White Race	51 (43.6%)	118 (45.7%)	0.699
English Speaking	109 (93.2%)	233 (90.3%)	0.366
Government assisted insurance	52 (44.4%)	144 (55.8%)	0.041
AMA (≥35 years)	50 (42.7%)	87 (33.7%)	0.093
Gestational Age (wks) at first prenatal visit	10.8 (± 4.5)	10.9 (±5.2)	0.815
Initiation of prenatal care <16 weeks GA	103 (88.0%)	220 (85.3%)	0.473

607 Differences in provider practices in recommending low dose aspirin for preeclampsia prophylaxis

Lauren Stewart[1], Bijal Parikh[2], Lena Woo[3], Cassandra Heiselman[2], David Garry[2], Kimberly Herrera[1]

[1]Stony Brook University Hospital, Stony Brook, NY, [2]Stony Brook Medicine, Stony Brook, NY, [3]Renaissance School of Medicine at Stony Brook University, Stony Brook, NY

OBJECTIVE: We sought to evaluate differences of recommending low dose aspirin (LDA) prophylaxis (ppx) for preeclampsia prevention among providers.

STUDY DESIGN: Retrospective study of patients who received prenatal care and delivered at a single academic center between Jan - May 2021. Exclusion criteria: age < 18 years, transfer of care >28 weeks, and delivery < 20 wks gestation. Patient characteristics, ppx risk factor (RF) criteria based on SMFM guidance, OB provider type and prescribing practices were collected. Statistical analysis was performed using Chi square, Fisher's exact and multivariate logistic regression (significance, $p < 0.05$).

RESULTS: Of the 622 patients in the study period, 375 patients met criteria to initiate LDA ppx (i.e., ≥1 high RF or ≥2 moderate RFs) and were included in the analysis. All providers were more likely to prescribe LDA in patients with ≥1 high RF compared to ≥2 moderate RFs (< 0.01). There was no difference in rates of LDA ppx based on race, insurance type, obesity (BMI ≥30), class III obesity (BMI ≥40), and AMA. Providers who were more likely to recommend LDA were MFM (58.4%), any high risk practice (MFM/high risk resident clinic) (58.6%), and all resident clinics (44.7%), whereas general OB/GYN (12.0%), any general OB practice (19.7%) and midwives (6.8%) recommended LDA at lower rates (p< 0.01). The difference in provider type recommendation for those with ≥1 high RF (p< 0.01) and with ≥2 moderate RFs (p< 0.01) remained significant across provider type. (Table 1) In multivariate regression analysis (p< 0.01), the predictors of LDA recommendation were general OB/GYN provider (OR 0.16 (95%CI 0.06-0.46),p< 0.01), midwife provider (OR 0.11 (95%CI 0.04-0.32),p< 0.01), gravidity (OR 0.85 (95%CI 0.73-0.98)p=0.04), and moderate risk factors only (OR 0.10 (95%CI 0.05-0.18)p< 0.01).

CONCLUSION: MFM specialists and resident clinics appropriately recommended LDA more often than general OB/GYN and midwife practitioners, regardless of whether patients met criteria with ≥1 high RF or ≥2 moderate RFs.

Table 1. Provider practices in recommendation of low dose aspirin prophylaxis for preeclampsia prevention during pregnancy divided by criteria met for prophylaxis.

Low Dose Aspirin	Provider					P
	Resident	HROB	General OB/GYN	MFM	CNM	
Prescribed						
≥1 High Risk Factor	6 (85.7%)	13 (81.2%)	10 (52.6%)	49 (75.4%)	4 (28.6%)	0.003
≥2 Moderate Risk Factors	9 (24.3%)	6 (37.5%)	0 (0.0%)	17 (35.4%)	3 (3.4%)	<0.001
Not Prescribed						
≥1 High Risk Factor	1 (14.3%)	3 (18.8%)	9 (47.4%)	16 (24.6%)	10 (71.4%)	0.003
≥2 Moderate Risk Factors	28 (75.7%)	10 (62.5%)	64 (100%)	31 (64.6%)	86 (96.6%)	<0.001

608 Fully quantitative numeric cervical softening device at 37 weeks: Information for labor management decision making?

Molly J. Stout[1], Methodius G. Tuuli[2], Adam K. Lewkowitz[3], Julie Tumbarello[1], Emily Diveley, BSN[4], Wendy Sparks[1], Maya Diab[1], Michelle Moniz[1], AnneMarie E. Opipari[1], Jourdan E. Triebwasser[5], peinan Zhao[4]

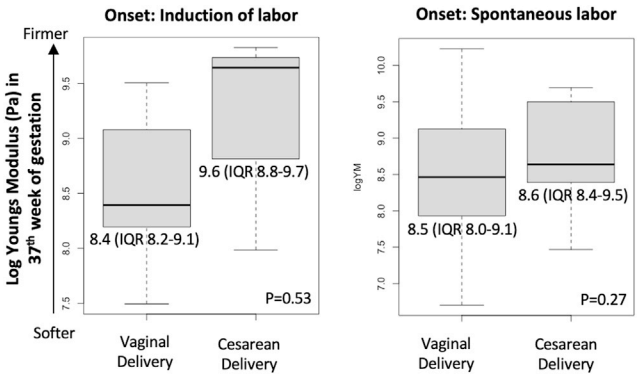
[1]University of Michigan, Ann Arbor, MI, [2]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [3]Warren Alpert Medical School of Brown University, Women & Infants Hospital Rhode Island, Providence, RI, [4]Washington University in St. Louis, St. Louis, MO, [5]University of Michigan, Ann Arbor, MI

OBJECTIVE: To utilize a novel, fully quantitative cervical elastography system (FQ-CES) which numerically quantifies cervical stiffness to examine association with onset of labor and mode of delivery.

STUDY DESIGN: This is a prospective cohort study of pregnant patients who underwent FQ-CES in the 37th week of pregnancy at a routine prenatal visit. We invented FQ-CES, which modifies a transvaginal ultrasound probe to quantify both pressure applied and tissue deformation, thereby yielding a fully quantified strain-based elastography system that provides a numeric quantification (Young's modulus) of cervical tissue stiffness. This system is operator independent and can be compared across patients and within patients over time. Singleton pregnancies without indication for delivery at 37 weeks were enrolled and FQ-CES were obtained. Patients remained enrolled regardless of their eventual timing or indications for delivery. The primary outcomes were onset of labor (spontaneous-SOL or induced IOL) and mode of delivery. Young's modulus was log transformed to achieve normality of distribution (logYM). The Wilcoxon rank sum test was performed to assess the tissue FQ-CES with type of labor and mode of delivery.

RESULTS: Of 149 patients included, 56 (37.5%) had IOL and 94 (63.1%) had SOL. 132 (88.5%) had vaginal birth and 17(11.4%) had cesarean birth. Cervical elastography at 37 weeks was not significantly different between groups but was nominally higher (indicating a firmer cervix) in those who underwent induction of labor that ended in cesarean delivery.

CONCLUSION: An operator-independent fully quantitative cervical elastography measurement at 37 weeks could be used to identify individuals at higher risk for cesarean birth and allow time to modify clinical care to optimize opportunity for vaginal delivery. Future intervention studies such as outpatient cervical ripening or modified inpatient ripening protocols based on cervical elastography measurement are warranted.



609 Does integrating diabetic educators in pregnancy management program improve glycemic control?

Heather Straub[1], Virginia Lijewski[2], Wehbe Amy[3], Kruse Jenifer[3], David Duarte-Corado[3]

[1]University of Colorado, Aurora, CO, [2]University of Colorado Anschutz, Denver, CO, [3]University of Colorado Anschutz, Aurora, CO

OBJECTIVE: To determine if integrating diabetic educators into pregnancy care improves glycemic control.

STUDY DESIGN: A formalized diabetes in pregnancy program was developed in 2019 involving 2 diabetic educators supervised by MFM provider & secure electronic messaging. We hypothesize that integration of diabetes educators improves glycemic control, & tested this using a pre-post study design. Prior to establishment of the program (10/1/2018-9/30/2019; PRE), communication was via telephone messaging with the MFM provider. The POST period was a year after the program began (10/1/2021-9/30/2022). Variables of interest were volume of patients seen, # of ultrasounds per patient, demographics, medication initiation, percentage of time of logs in goal, delivery medication advice & documentation of compliance. This study was IRB exempt.

RESULTS: In the PRE period, 87 women were seen for diabetes vs. 271 in the POST. There were no significant differences in age (32 vs 33, P=0.88), race/ethnicity (58.6% vs 59.8%, Non-Hispanic white), gestational age (weeks) of diagnosis (28 vs 29, P-0.09) or public insurance status (17.2% vs 17.7 %, P=0.85). (Table) In the POST group, there were significantly more women who were pre-gestational diabetic (14.8% vs 4.6%, P=0.01) & on continuous glucose monitoring (0% vs 6.3%, P=0.017). There was no difference in medication initiation (50.6% vs 56.8%), but a significant shift from Glyburide to Insulin (Table). Average number of scans per patient was not different (2.5 vs 2.1, P=0.37), but more patients only had 1 scan POST (52% vs 34%, P< 0.01). There was better compliance in the POST group with more uploads of glucose logs (average 5 vs 7, P< 0.01), more glucose values in range (81.8% vs 90.9%, P< 0.01) & documented delivery recommendations (29.9% vs 95.3%, P< 0.01). Documented reasons for non-compliance were stopping uploading logs, declining insulin & cancelling appointments.

CONCLUSION: A formalized diabetes in pregnancy program improved glycemic control parameters & resulted in a 3-fold increase in number of patients seen without increasing number of scans per patient.

Table: Comparison of selected maternal demographics & outcomes pre/post program initiation

	Pre-Program (n=87)	Post-Program (n=271)	P-value
Maternal age at first visit	32 (29-37)	33 (30-36)	0.88
Gravidity	2.0 (1.0-3.0)	2.0 (1.0-3.0)	0.71

610 Environmental exposures and disparities in infant mortality: a positive deviance analysis

Alison M. Stuebe[1], Brooke Jones[2], David Oh[3], Dorothy Cilenti[2], Amy Mullenix[4], Sarah Verbiest[5], Arrianna Marie Planey[6]

[1]University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, NC, [2]Gillings School of Global Public Health, Chapel Hill, NC, [3]NC State University College of Design, Raleigh, NC, [4]Maternal Health Learning and Innovation Center, Chapel Hill, NC, [5]Collaborative for Maternal and Infant Health, Chapel Hill, NC, [6]Health Policy and Management, Gillings School of Global Public Health, Chapel Hill, NC

OBJECTIVE: To identify factors that buffer adverse associations between county-level vulnerability and infant mortality disparities.

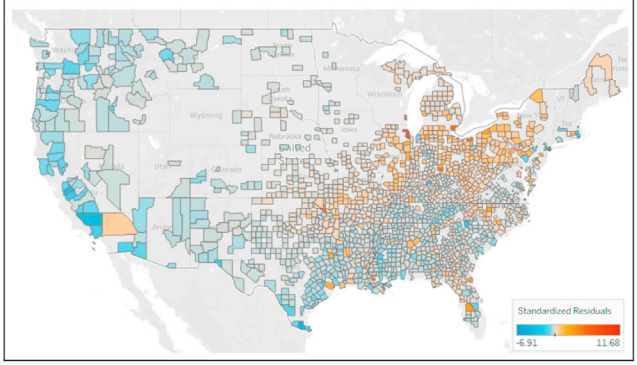
STUDY DESIGN: We conducted a positive deviance analysis of United States vital statistics data from 2017 to 2019, evaluating variation in county Black-white infant mortality difference (BW-IMD) per 1000 live births with Environmental Justice Index (EJI), a CDC index of social vulnerability, health vulnerability, and environmental burden. Using linear regression, we modeled the association between county BW-IMD and EJI. Among counties with above median EJI scores, we identified positive deviant counties (PDC) as those with observed BW-IMD >1.96 standard deviations below predicted. We used Wilcoxon tests to compare median EJI component measures between PDC and typical counties (TC), with p values < 0.001 considered to be statistically significant.

RESULTS: BW-IMD data was available for 2922 US counties, with a median BW-IMD of 6 per 1000 (range 2.6 to 11.6). Higher EJI scores were associated with higher BW-IMD (p< .0001). Among 1794 counties with EJI >50% (Figure), 24 (1.3%) were PDC. Compared with TC, PDC had higher proportions of residents who were not non-Hispanic white, spoke English "less than well," rented their homes, and had household income < $75,000. PDC had fewer residents without internet access, who were 65 or older, had a

disability, or lived in a mobile home. Chronic conditions were also less prevalent, including cancer, high blood pressure, and poor mental health. Overall environmental burden percentile was higher in PDC, with higher percentile scores for air pollution and proximity to transportation infrastructure, but better scores for built environment, including walkability and proximity to green space.

CONCLUSION: Positive deviance analysis identified protective factors for BW-IMD in high EJI counties, including non-White and non-English speaking communities, internet access, population health, walkability, and green space. Policies to strengthen community, wellbeing, and infrastructure have the potential to impact perinatal health disparities.

Figure: We analyzed standardized residuals for the association between Environmental Justice Index and Black-White infant mortality difference to identify positive outliers, counties with lower-than-predicted disparities in infant mortality. For counties with greater-than-median EJI scores, we present standardized residuals, with darker blue indicating lower-than-predicted disparities, and darker orange indicating higher-than-expected disparities.



611 Comparative Effectiveness of Alternate Antibiotic Therapies for Pregnant Patients with Group B Streptococcus Infections

Emma J. Swayze, Lydia M. Henry, Emily Liske, Erin Dolvin, Alexa Swailes

University of Tennessee Health Science Center, Memphis, TN

OBJECTIVE: Group B streptococcus infection is the most common cause of early-onset neonatal sepsis. Intrapartum antibiotic therapy is imperative to minimize maternal-to-fetal transmission of Group B Streptococcus (GBS). Penicillin is the agent of choice, with ampicillin or cefazolin as acceptable alternatives, but there is a paucity of data on the efficacy of alternate antibiotic therapies for penicillin-allergic patients. This study evaluates the effectiveness of alternate antibiotic therapies among pregnant patients at an urban safety net hospital.

STUDY DESIGN: This was a retrospective analysis of GBS+ pregnant patients from 2019 through 2022. Penicillin-allergic patients were matched 1:2 with non-allergic controls. Primary outcomes were GBS positive neonates, neonatal length of stay, GBS septicemia, Apgar scores, neonatal demise, and 30-day neonatal infectious complications (sepsis, deafness, pneumonia, or meningitis). Chi-square and Fischer exact analyses were performed on Stata version 16.1 (StataCorp, College Station, Texas).

RESULTS: 229 GBS+ pregnant patients were analyzed, including 84 penicillin-allergic (36.7%) and 145 non-allergic (63.3%). Patients were treated with vancomycin (n=66, 28.8%), clindamycin if susceptibilities were performed on maternal GBS culture (n=10, 4.4 %), cephalosporins (n=6, 2.6%), or penicillin/ampicillin (n=147, 64.2%). Rates of GBS positive infants were low but varied by antibiotic treatment (p< 0.01): penicillin (0%); vancomycin (0%); clindamycin (20%); and cephalosporins(16.7%). There was a significant difference in 30-day neonatal complications (p=0.03): penicillin (2.0%); vancomycin(0%); clindamycin (10%); and cephalosporins(16.7%) but no difference in length of stay, 1 or 5-minute Apgar scores, or neonatal demise.

CONCLUSION: Antibiotic effectiveness for GBS+ pregnant patients varied slightly by medication, but risk was low in all cohorts. Vancomycin appears to be most effective in reducing neonatal morbidity among penicillin-allergic patients, but alternative antibiotic therapies may also provide adequate coverage with a lower risk of promoting antibiotic resistance.

Table 1: Neonatal Outcomes in GBS positive mothers treated with alternative antibiotic therapies

	Antibiotic, N(%), n=229

612 Disparities in Mortality and Non-Transfusion Severe Maternal Morbidity Trends During Delivery Hospitalizations by Payer Status

Sbaa Syeda[1], Uma M. Reddy[2], Alexander M. Friedman[2], Timothy Wen[3]

[1]Columbia University Medical Center, New York, NY, [2]Columbia University, New York, NY, [3]University of California, San Francisco (UCSF), San Francisco, CA

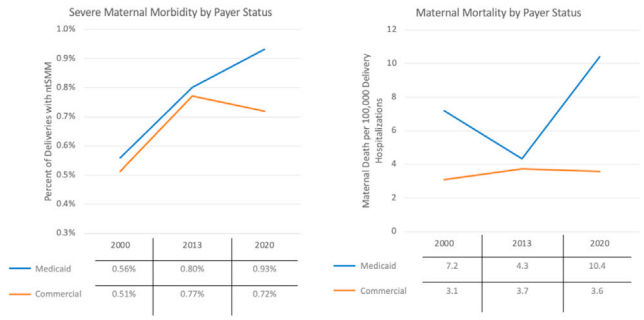
OBJECTIVE: Non-transfusion severe maternal morbidity (ntSMM) and maternal mortality are key indicators of population health with a disparate burden on certain socioeconomic groups. We sought to compare temporal trends in ntSMM and mortality among births by payer status.

STUDY DESIGN: This cross-sectional study analyzed data from the 2000-2020 Nationwide Inpatient Sample. Mortality and ntSMM (per Centers for Disease Control and Prevention criteria) trends were stratified by payer status (Medicaid versus commercial) and analyzed using joinpoint regression estimating the average annual percent change (AAPC) with 95% confidence intervals (CI). Logistic regression models were performed to estimate adjusted odds ratios (aORs) for maternal mortality and ntSMM accounting for demographic, hospital, and clinical factors.

RESULTS: Of 80.2 million births, 41.3% and 52.1% were Medicaid and commercially insured births, respectively. The rate of ntSMM increased steadily from 56 to 93 per 100,000 Medicaid births (AAPC

2.6%, 95% CI 1.9%, 3.4%). Among the commercially insured, ntSMM rates significantly increased from 51 to 77 per 100,000 births in 2000-2013 (AAPC 3.3%, 95% CI 2.4%, 5.0%), but later significantly decreased from 77 to 72 per 100,000 births in 2013-2020 (AAPC -2.3%, 95% CI -6.7%, -0.1%). Mortality did not significantly change over this time (Figure). Specifically, maternal deaths among individuals with Medicaid did not increase between 2000-2020 (AAPC 2.7%, 95% CI -0.5%, 6.2%) or between 2014-2020 (AAPC 12.1%, 95% CI -0.2%, 48.8%). In adjusted analysis, Medicaid births had 14% (aOR 1.14, 95% CI 1.12, 1.16) and 75% (aOR 1.75, 95% CI 1.48, 2.08) higher odds of ntSMM and mortality, respectively, compared to commercially insured births.

CONCLUSION: Disparities in ntSMM and maternal mortality persist based on socioeconomic status. While ntSMM rates have decreased among commercially insured births, it has continued to rise in those with Medicaid. Medicaid insured individuals are significantly more likely to incur ntSMM and die during delivery hospitalization compared to those with commercial insurance.



613 Association of maternal serum leptin levels in mid gestation with fetal adiposity

Junko Tamai[1], Satoru Ikenoue[2], Keita Hasegawa[1], Keisuke Akita[3], Kaoru Kajikawa[2], Marina Takahashi[2], Kunio Tanaka[1], Yuka Fukuma[1], Yuya Tanaka[1], Toshimitsu Otani[1], Yoshifumi Kasuga[1], Mamoru Tanaka[1]

[1]Keio University School of Medicine, Shinanomachi, Tokyo, [2]Keio University School of Medicine, Tokyo, Tokyo, [3]Keio University School of Medicine, Shinjuku-ku, Tokyo

OBJECTIVE: Leptin is one of the adipokines that has been associated with birth weight and infant adiposity. Recent improvements in ultrasound imaging have enabled better tissue characterization and more reliable quantification of fetal fat deposition at specific anatomical sites (arm, thigh and abdomen). However, the association between maternal serum leptin levels and change in fetal fat deposition remains unclear. This study aimed to investigate the association of maternal serum leptin in mid gestation with longitudinal change of fetal fat deposition in the arm, thigh and abdomen.

STUDY DESIGN: A prospective study was conducted in a cohort of 24 singleton pregnancies. Maternal blood sample was obtained at 24 weeks' gestation, and fetal ultrasonography was performed at 24, 30, and 36 weeks' gestation. 3D ultrasonography was used to acquire total contours of arm and thigh, then analyzed offline using appropriate software to determine subcutaneous fat area with standardized cross-sectional images. The fat area was calculated as difference between the total cross-sectional area and the lean mass area. Subcutaneous fat thickness in the abdomen was measured as the high-echoic region anterior to the margins of the ribs, proximal to the cord insertion. The association between maternal serum leptin level and fetal fat deposition was examined using Pearson product moment correlations.

RESULTS: Maternal serum leptin at 24 weeks was 23.6±3.1 ng/ml (mean±S.E.). Maternal leptin level was not associated with fetal fat deposition at 24 weeks and 30 weeks. Maternal leptin level significantly correlated with fetal arm fat area ($r = 0.407$, $p < 0.05$), and not with thigh fat area ($r = 0.245$, $p = 0.249$) or subcutaneous fat thickness in the abdomen ($r = 0.361$, $p = 0.084$) at 36 weeks.

CONCLUSION: Maternal serum leptin level at 24 weeks significantly correlated with fetal arm fat mass in late gestation. Maternal serum leptin level in mid-gestation could be a marker for identifying increased fetal adiposity in late gestation.

614 Childhood Opportunity Index and Severe Morbidity in a cohort complicated by Placenta Accreta Spectrum Disorder

Nicola F. Tavella[1], Henri M. Rosenberg[2], Alexandra N. Mills[3], Alexa Cohen[4], Myah Griffin[5], Itamar Futterman[6], Thomas Owens[7], Lois Brustman[8], Teresa Janevic[9], Meghana Limaye[10], Georgios Doulaveris[4], Pe'er Dar[11], Shoshana Haberman[6], Angela Bianco[2], Rebecca H. Jessel[1]

[1]Icahn School of Medicine at Mount Sinai Hospital, New York, NY, [2]Mount Sinai Medical Center, New York, NY, [3]Icahn School of Medicine at Mount Sinai, New York, NY, [4]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [5]NYU Langone Health, Atlanta, GA, [6]Maimonides Medical Center, Brooklyn, NY, [7]Mount Sinai West, New York, NY, [8]St. Luke's Roosevelt Hospital Center, New York, NY, [9]Mt. Sinai, New York, NY, [10]NYU Langone Health, New York, NY, [11]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY; on behalf of the New York City Maternal Fetal Medicine Research Consortium

OBJECTIVE: The objective of this study was to evaluate the association of the Childhood Opportunity Index (COI) with severe maternal and neonatal morbidity in a sample of cases complicated by Placenta Accreta Spectrum (PAS) in New York City (NYC). COI is a complex measure evaluating social and built environment regarding individual capacity for development.

STUDY DESIGN: This was a multicenter retrospective cohort study of histopathologically confirmed PAS cases between 1/1/2013 - 6/30/2022 at three NYC institutions. Subjects were assigned a COI value ranging from 0 to 1 based on their home zip code. Primary outcomes were composite maternal and neonatal morbidity. Outcomes were analyzed using logistic regression. Multivariate models adjusted for age, body mass index (BMI), race, ethnicity, insurance type, use of assisted reproductive technology, history of prior cesarean section, prior myomectomy, prior dilation & curettage, smoking, placental location, grade of placental invasion, presence of inter-disciplinary meeting, and delivering institution. Covariates were retained if $p < 0.10$.

RESULTS: 291 cases were included in these analyses. Logistic regressions were used to examine correlations between COI and severe morbidity. In univariate models, several maternal morbidity outcomes were significantly associated with COI. In the multivariate regression, mechanical ventilation's association with COI was still significant ($p < 0.01$). Regarding neonatal morbidity, only intraventricular hemorrhage had statistical significance in its association with COI (OR=0.98, CI 95%=0.96, 1.00).

CONCLUSION: These results suggest that socioenvironmental factors influence health outcomes through complex pathways in cases of severe morbidity. Different components of the composite outcomes correlated differently with COI values, suggesting that COI alone is insufficient to predict impact of social determinants of health on in

morbidity. Further research exploring the intersections of socio-environmental and clinical factors must be conducted.

615 Expectant management of preeclampsia with severe features: clinical outcomes based on severe features at diagnosis

Mary C. Tolcher, Alison N. Goulding, Josef Jackson, Felixnando Rubio, Jeevitha Patil, Steven Clark
Baylor College of Medicine, Houston, TX

OBJECTIVE: To evaluate latency and clinical outcomes based on severe features present at diagnosis among patients with preeclampsia with severe features (SPEC) who were expectantly managed.

STUDY DESIGN: Retrospective cohort study from two hospitals within our academic institution including patients diagnosed with SPEC between 24 0/7-33 6/7 weeks from 2015-2019. Patients were included if expectantly managed and excluded if delivery was planned immediately or following steroid administration. We compared outcomes based on severe features present at diagnosis.

RESULTS: 220 of 407 deliveries (54%) complicated by SPEC were expectantly managed. Three groups were established based on severe features at diagnosis: Group 1: severe blood pressure (BP) alone n=145; Group 2: symptomatic (headache, visual disturbances, or right upper quadrant/epigastric pain; +/- severe BP, n=52); Group 3: lab abnormalities (elevated liver function tests 2x normal, low platelets < 100,000, or creatinine >1.1 mg/dL; +/- severe BP, n=23). Fetal growth restriction was least likely in the lab abnormalities group (50% vs 61% vs 29%, p=0.01). The severe BP alone and lab abnormalities groups both had a median diagnosis-to-delivery interval of 3 days compared to 2 days among the symptomatic group (p=0.02). 43 (20%) had a latency of ≥7 days. Only 13 (6%) achieved 34 weeks. Indications for delivery differed by group (p< 0.001). Maternal ICU admission was more common in the lab abnormality group (3% vs 4% vs 17%, p=0.007), and maternal length of stay was longer in the severe BP alone group (8 vs 7 vs 6 days, p=0.004). Neonatal outcomes evaluated did not differ significantly.

CONCLUSION: In our cohort, the time from diagnosis of SPEC to delivery was 2-3 days depending on the severe features present at diagnosis, and only 6% reached 34 weeks. Indications for delivery differed by severe features present at diagnosis. Maternal ICU admission was more common among patients with lab abnormalities, and maternal length of stay was slightly longer for women with severe BP alone. Other clinical outcomes studied did not differ substantially.

616 Association between Cotinine Exposure and Outcomes in Patients with Prenatal Cannabis Use: A Secondary Analysis

Cassandra Trammel[1], Arpana Agrawal[2], Ryan Bogdan[2], Megan L. Lawlor[3], Nandini Raghuraman[3], Jeannie C. Kelly[4], Christopher D. Smyser[2], Cynthia Rogers[2], Ebony B. Carter[4]
[1]Washington University in St.Louis, St. Louis, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, St. Louis, MO, [4]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

OBJECTIVE: Existing data regarding prenatal cannabis use (PCU) and adverse outcomes are often confounded by tobacco use. We initially sought to assess maternal and neonatal outcomes in patients with isolated PCU, and performed a prospective cohort study with negative verbal tobacco use screening as criteria for enrollment. Interestingly, a large percent of enrolled patients were excluded from primary analysis due to urine drug screening (UDS) demonstrating exposure to cotinine, a tobacco metabolite. We sought to evaluate differences in outcomes between this excluded group and the larger PCU positive cohort.

STUDY DESIGN: We performed a secondary analysis of a prospective cohort study of patients with pre-pregnancy cannabis use who were enrolled in the first trimester. The primary outcomes were a pre-eclampsia and small for gestational age (SGA). Secondary outcomes included gestational hypertension, gestational diabetes, fetal growth restriction, preterm birth, mode of delivery, large for gestational age

(LGA)and APGARs. Descriptive statistics were used to compare baseline characteristics. Backwards stepwise logistic regression was used to control for potential confounders.

RESULTS: 235 patients were enrolled in the PCU arm of the initial study. After crossover between PCU arms and cotinine testing, 96 PCU patients were positive for cotinine (Cpos) and 131 were negative (Cneg). Baseline characteristics were similar in between groups, though the categorical distribution of income in the Cpos group was lower (p=0.006) and more Cpos patients had hypertensive disorders in prior pregnancies (23% Cpos vs 17% Cneg, p=0.03). Cpos patients had greater risk of SGA $< 5^{th}$ and 10^{th} percentiles in unadjusted analysis, but after controlling for confounds this finding only persisted for SGA$< 10^{th}$% (32% Cpos vs. 15% Cneg; aRR 2.16; 95% CI 1.21-3.42).

CONCLUSION: In patients with PCU, cotinine exposure was associated with a 2-fold increased risk of SGA $< 10^{th}$ percentile, underscoring the differing contributions of PCU and tobacco to the risk of adverse pregnancy outcomes.

Table 1: Maternal and neonatal outcomes in patients with cannabis use in pregnancy, stratified by urine-confirmed cotinine exposure.

617 Associations between Isolated Prenatal Cannabis Use and Outcomes: A Prospective Cohort Study

Cassandra Trammel[1], Arpana Agrawal[2], Ryan Bogdan[2], Megan L. Lawlor[3], Nandini Raghuraman[3], Christopher D. Smyser[2], Cynthia Rogers[2], Ebony B. Carter[4]
[1]Washington University in St.Louis, St. Louis, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, St. Louis, MO, [4]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

OBJECTIVE: Despite data linking prenatal cannabis use (PCU) to adverse childhood outcomes, use in pregnancy is rising. Studies are often confounded by tobacco use, a known risk factor for maternal antenatal morbidity and small for gestational age (SGA). We sought to assess antenatal and birthweight outcomes of patients with isolated PCU.

STUDY DESIGN: We performed a prospective cohort study of patients with pre-pregnancy cannabis use who were enrolled in the first trimester. Patients were not eligible if they self-reported tobacco use; patients were then followed with serial urine cotinine testing and excluded from final analysis if positive. Primary outcomes were SGA $< 10^{th}$ percentile and preeclampsia. Secondary outcomes included gestational hypertension, gestational diabetes, fetal growth restriction, preterm birth, mode of delivery, SGA $< 5^{th}$ percentile, large for gestational age (LGA), and 5-minute APGAR < 7. Descriptive statistics were used to compare baseline characteristics and backwards stepwise logistic regression was used to control for potential confounding.

RESULTS: 366 patients were enrolled: 235 PCU and 131 controls. After serial urine drug screening with exclusion for cotinine positivity (42% of PCU and 10% of controls), and crossover between groups, a total of 131 PCU and 125 controls remained. Patients with PCU were younger (25 vs 27 yrs, p=0.03), had lower BMI (27 vs 31 kg/m2, p=0.00), and were less likely to identify as Hispanic (1.5% vs 7.26%, p=0.02). Isolated PCU was not associated with preeclampsia (17% PCU vs. 14% control; aRR 1.36; 95% CI 0.62-2.63), SGA (15% vs. 11%; aRR 0.79; 95% CI 0.36-1.59), or any of the secondary maternal outcomes (Table 1). PCU was associated with a decreased risk of LGA in unadjusted analysis (5% vs. 14%; RR 0.33; 95% CI 0.13-0.83); this result was attenuated after adjustment (aRR 0.94; 95% CI 0.23-3.33).

CONCLUSION: Isolated PCU was not associated with differences in maternal or neonatal adverse pregnancy outcomes, consistent with prior literature. Additional study is ongoing to assess cannabis-specific outcomes in the newborn and early childhood periods.

618 Does a best practice implementation prompting providers on syphilis screening guidelines impact physician adherence?

Rylee Trotter[1], Ana Davie[2], juan Padilla-Ruiz[2], Sabrina DaCosta[2], Melania Ortega[2], Irene A. Stafford[3]
[1]University of Texas-Houston Medical School, Houston, TX, [2]The University of Texas Health Science Center at Houston, Houston, TX, [3]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX

OBJECTIVE: According to the 2021 Centers for Disease Control and Prevention Sexually Transmitted Disease Surveillance report, the number of congenital syphilis (CS) cases increased 754.8% from 2012 to 2021. Missed opportunities for CS prevention in Texas include a lack of provider adherence to screening mandates. A best practice advisory (BPA) was implemented in the electronic medical record system (EMR) in an academic obstetrical center in Texas in April 2023 to prompt providers to screen pregnant patients at initiation of prenatal care, 28 weeks gestation, and admission for delivery. This quality initiative aimed to determine if provider adherence to the screening mandate improved with the BPA.

STUDY DESIGN: This was a prospective cohort study of obstetric patients from a large public healthcare system in Southeastern Texas

between 12/01/22 and 05/31/23. Individuals who initiated care after 26 weeks gestation were excluded. Data regarding gestational age at each screen and corresponding results were collected prior to and after implementation of the BPA. The number of appropriately ordered syphilis screening tests pre- and post-BPA were compared using chi-square analysis with a p-value < 0.05 considered statistically significant.

RESULTS: Screening for syphilis at initiation of care did not increase with the BPA, however screening rates at admission for delivery increased significantly from 6% to 99% post-BPA ($p < 0.05$). Screening at both 28 weeks and delivery also increased significantly from 3% to 89% ($p < 0.05$), and screening at all three timepoints (initiation, 28 weeks, delivery) significantly increased from 2% to 47% ($p < 0.05$) [Table 1, Figure 1]. Notably, there was a 50% reduction in CS cases (8 to 4) following the BPA.

CONCLUSION: The use of a BPA within the EMR increased provider adherence to syphilis screening mandates for pregnant women in a high CS morbidity region. Given the differing screening mandates across the US, utilization of a BPA to inform providers about state-specific mandates can lead to improved compliance with perinatal syphilis screening and help prevent congenital syphilis.

Table 1. Screening rates before and after BPA implementation

Timepoints	BPA Implementation		
	Pre	Post	p value
Intake (n, %)	152 (49)	113 (51)	0.65

619 Effectiveness of cerclage in twin pregnancies with short cervix: systematic review and meta-analysis

Lissa van Gils[1], Renske dutilh[2], Marjon A. de Boer[2], Eva Pajkrt[2], Martijn A. Oudijk[2]
[1]Amsterdam UMC, location AMC, Amsterdam, Utrecht, [2]Amsterdam UMC, location AMC, Amsterdam, Noord-Holland

OBJECTIVE: Evaluate the effectiveness of cervical cerclage in preventing preterm birth (PTB) and improving neonatal outcomes in women with a twin pregnancy and an asymptomatic short cervix ($\leq$ 25mm).

STUDY DESIGN: On 17 April 2023, we systematically searched PubMed, MEDLINE, EMBASE, Web of Science, and Cochrane Library databases. Included were randomized controlled trials (RCTs), cohort, and case-control studies comparing cerclage vs. expectant management in women with twin pregnancies and an asymptomatic short cervix ($\leq$ 25mm) before 24 weeks.

RESULTS: We included 10 retrospective cohort studies and 1 prospective cohort, involving 563 patients with cerclage and 489 controls. Information regarding women involved in the RCTs could not be obtained because this data has not been made publicly available. In women with a cervical length of $\leq$ 25mm significantly less preterm births were reported in women with a cerclage as compared to expectant management (PTB before 37 weeks (RR 0.87, 95% CI 0.77-0.98), 34 weeks (RR 0.75, 0.62-0.91), 32 weeks (RR 0.61, 0.41-0.91), and 28 weeks (RR 0.62, 0.42-0.91) of gestation). Upon further analysis of studies explicitly describing spontaneous PTB (sPTB), in the cerclage group were less sPTB before 34 weeks (RR 0.72, 0.54-0.95) and 32 weeks (RR 0.70, 0.51-0.97). Cerclage was related to lower risk ratios for infants $<$ 1500g and respiratory distress syndrome.

In a subgroup of women with cervical length $<$ 15mm, cerclage reduced PTB before 34 weeks (RR 0.62, 0.44-0.87), 32 weeks (RR 0.62, 0.44-0.86), and 28 weeks (RR 0.53, 0.34-0.84), while the gestational age at birth was more advanced (MD 3.87 weeks, 2.97-4.77). In addition, sPTB was less frequent in women with a cerclage (before 34 weeks (RR 0.61, 0.41-0.91) and 32 weeks (RR 0.50, 0.33-0.77)).

CONCLUSION: Based on our meta-analysis, of observational studies, cerclage may benefit women with a twin pregnancy with cervical length $<$ 25mm and $<$ 15mm by reducing PTB and prolonging pregnancy. However, a large RCT is needed to validate these findings.

Outcomes	Studies	Cerclage n/N	No cerclage n/N	Risk ratio (95% CI)	I^2
Cervical length (< 25mm)

620 Childhood outcomes of multiples prenatally exposed to progesterone for the prevention of preterm birth

Emilie van Limburg Stirum, Marjon A. de Boer, Eva Pajkrt, Martijn A. Oudijk, Janneke van 't Hooft
Amsterdam UMC, location AMC, Amsterdam, Noord-Holland

OBJECTIVE: Progesterone is extensively used in pregnancy for the prevention of preterm birth in high risk women. We assessed the long-term effect of prenatal progesterone exposure versus placebo on child development and behaviour until early adolescence.

STUDY DESIGN: This study is a follow-up of the AMPHIA randomized controlled trial which assessed weekly intramuscular injections starting at 16 weeks of gestation of 250 mg 17-alpha-hydroxyprogesterone caproate (17-OHPC, n=336 women; 681 children) compared to placebo (n=335 women; 674 children) to prevent adverse neonatal outcome in multiple pregnancies. In this follow-up study children were assessed through parental, self-reported and teacher questionnaires at 11-14 years of age. Main outcome of interest were cognition, behaviour, mortality, gender identity, general health and a composite of mortality or survival with abnormal development.

RESULTS: In total 60 children deceased, 24 (3.7%) in 17-OHPC group versus 36 (5.6%) in the placebo group (OR 0.66, 95%CI 0.39-1.11). Developmental outcomes were collected for 303 of 1296

(23%) surviving children. No differences between 17-OHPC and placebo group were measured regarding child's cognition, behaviour, mortality, gender identity and general health up to 14 years of age. A composite of abnormal development or mortality did not differ between progesterone (9.5%) and placebo (10.1%) groups (OR 0.93, 95% CI 0.65-1.35).

CONCLUSION: Mortality or neurodevelopmental disability of children exposed in utero to 17-OHPC compared to placebo during the second and third trimester of pregnancy does not differ between groups at 11-14 years of age.

621 CD4+T-Cells cause increased glucose, hypertension, and organ dysfunction in a rat model of gestational diabetes

Jean Vel[1], Jan Williams[2], Danielle Frieson[2], Baoying Zheng[2], Mariah Wilson[2], Nathan Campbell[2], Babbette LaMarca[2], Evangeline Deer[2]

[1]University of Mississippi Medical Center, Madison, MS, [2]University of Mississippi Medical Center, Jackson, MS

OBJECTIVE: Gestational diabetes mellitus (GDM), impacts 10% of all pregnancies and refers to glucose intolerance, insulin sensitivity and beta islet cell dysfunction during pregnancy which is a risk factor for hypertensive disorders of pregnancy. The mechanisms of GDM are unknown and the management strategies are limited. The lack of an appropriate animal model of GDM further limits our understanding of this disease. Many studies show CD4+ T cells play a role in diabetes, therefore we hypothesize that CD4+ T cells play a role in the pathogenesis of GDM.

STUDY DESIGN: Splenic CD4+Tcells from female streptozotocin (STZ)-induced diabetic Dahl Salt Sensitive (DM-SS) rats and control nondiabetic female Dahl SS rats were injected on gestational day (GD) 12 into pregnant Sprague Dawley (SD) rats to create the DM-CD4+ T cells and nondiabetic control SS-CD4+ T cell pregnant rats. Glucose, blood pressure, renal, pancreatic and placental function were assessed on gestation day 19. Renal and pancreatic tissues were stained for Periodic acid Schiff (PAS) and hematoxylin and eosin (H&E). A one-way ANOVA was used for statistical analysis.

RESULTS: MAP increased in DM-CD4+ T cell rats (106±2, n=11, $p< 0.05$) and SS-CD4+ T cell rats (109±2, n=9, $p< 0.05$) compared to pregnant SD controls (92±2 mmHg, n=7). Proteinuria occurred with DM CD4+ T cells (9±1 $p< 0.05$) and SS-CD4+ T cells (10±1 $p< 0.05$) compared to pregnant SD controls (4±1 ml/day). Glucose tolerance was impaired and blood glucose was elevated only in recipients of DM-CD4+ T cells (136 ± 9 mg/dl, $p< 0.05$). Glomerular and pancreatic damage occurred in DM-CD4+T cell recipient rats ($p< 0.05$). Markers of renal dysfunction KIM-1 and NGAL were increased in DM-CD4+ T cell rats (42±8; 449 ±3, $p< 0.05$) compared to SS-CD4+ T cell rats(36±5; 47±4 pg/mg, $p< 0.05$) and pregnant SD rats (11±2;19±3 pg/mg). Placental mitochondrial dysfunction was impaired with DM-CD4T cells.

CONCLUSION: Collectively, these data indicate that CD4+ T cells induce a GDM phenotype identifying a new animal model for studying mechanisms of the pathophysiology of GDM.

622 Deep learning to assess twin gestation from blindly obtained ultrasound sweeps

Ambika V. Viswanathan[1], Teeranan Pokaprakarn[1], Elizabeth M. Stringer[1], Molly Foster[1], Juan Prieto[1], William Goodnight[2], Jeffrey Stringer[1]

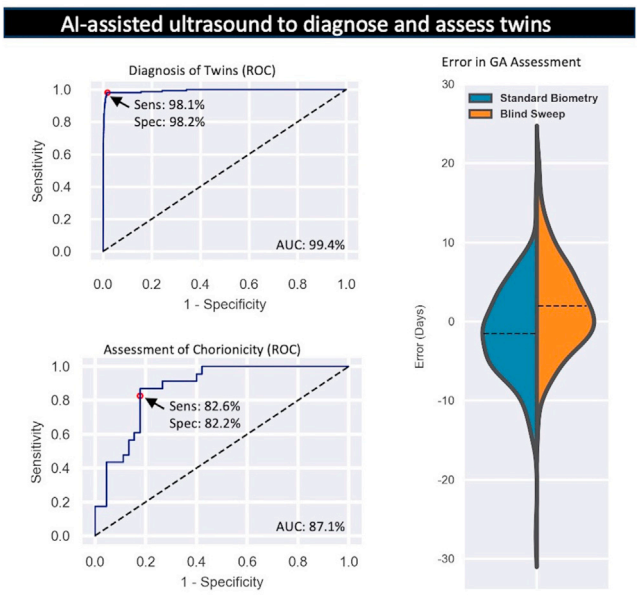
[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]UNC Hospitals, Chapel Hill, NC

OBJECTIVE: In low resource settings, twins often go undiagnosed until delivery. We sought to create a low-cost ultrasound tool for diagnosis and assessment of twins in settings where trained sonographers are scarce.

STUDY DESIGN: We collected blind ultrasound sweeps (~10 second cines in cranio-caudal and lateral directions) from pregnant people in North Carolina. The cohort was randomly divided at the patient level into discreet training/tuning (80%) and testing (20%) datasets. We built deep learning AI models to diagnose twins and estimate their gestational age (GA). We also explored assessment of chorionicity.

RESULTS: From Feb 2020 thru March 2023, 16,557 pregnancies contributed 30,106 studies containing blind sweeps. Of these, 490 pregnancies (1,215 studies) were twins. To evaluate twin diagnosis, we restricted the test set to studies ≥14 weeks GA (3,163 pregnancies; 5,424 studies). Among the 87% of studies in which the model could make a prediction, the area under the receiver operating curve (AUC-ROC) was 99.4% (sens: 98.1%; spec: 98.2%). To evaluate twin GA estimation, we restricted the test set to twin pregnancies whose GA had previously been established by early CRL or IVF (92 pregnancies; 185 scans). The model made a prediction in all studies with a mean absolute error of 4.6 ±0.3 days vs 4.5 ±0.3 days for biometry (difference, 0.1 days; 95% CI: -0.6, 0.8). To evaluate chorionicity assessment, we limited the test set to twins with scans performed < 24 weeks (67 pregnancies, 93 scans). Among the 73% of studies in which the model could make a prediction, AUC-ROC was 87.1% (sens: 82.6%; spec: 82.2%).

CONCLUSION: AI-assisted ultrasound, which can be deployed on low-cost point-of-care devices, can diagnose twins and assess their gestational age with high performance. Preliminary results for chorionicity assessment are encouraging but more training data from earlier GA are needed. These results presage a future where all patients carrying twins — not just those in rich countries — can access the diagnostic benefits of sonography.



623 Dimensions of COVID-19 Vaccine Uptake in Pregnant People: A Mixed Methods Approach

Meesha Vullikanti, Meghan Gerety, Robert Fuller
University of Virginia, Charlottesville, VA

OBJECTIVE: Population-based COVID-19 vaccines have been a highly debated medical innovation. Rationale for vaccine uptake is well-researched in the general population but poorly studied in pregnant people who have historically incorporated different dimensions of risk analysis in their medical decision-making due to their pregnancy status. While provider recommendation is the single most important driver of Tdap and influenza vaccination during pregnancy, the role of the healthcare provider has been less clear regarding COVID-19 vaccinations. This study addresses this gap in knowledge through a mixed-methods approach that analyzes COVID-19 vaccine uptake through EMR review and in-depth, semi-structured interviews.

STUDY DESIGN: A systematic retrospective medical chart review was performed for 915 patients who received prenatal care and delivered at an academic health care center between August 2021 and August 2022 alongside five semi-structured interviews with people who received prenatal care and delivered in Central Virginia that explored their experience of pregnancy during COVID-19 and their decision-making process around the COVID-19 vaccine.

RESULTS: Concurrent analysis of medical records and interviews revealed that discussion of the COVID-19 vaccine with the healthcare team was not associated with changes in vaccination uptake ($p=0.604$, logistic regression). Instead, pregnant people discussed how they incorporated anecdotal, informal discussions with trusted others into their decision-making process. Age, total number of prenatal visits, and influenza vaccine uptake were positively correlated with COVID-19 vaccine uptake, while prior COVID-19 infections during pregnancy were negatively correlated with COVID-19 vaccine uptake. Lastly, risk tolerance during pregnancy was seen as a finite resource, and its allocation was altruistic

CONCLUSION: The findings of this study, one of the first to characterize risk analysis and COVID-19 vaccine hesitancy in pregnant people, indicate that not only vaccine hesitancy but also medical decision-making in pregnant people is more complex than previously thought.

624 Contingency management for methamphetamine cessation during pregnancy: a cost-effectiveness analysis

Jessica D. Wallace[1], Sydney McCarthy[2], Uma Doshi[2], Jamie Lo[2], Aaron B. Caughey[2]
[1]University of Colorado, Aurora, CO, [2]Oregon Health & Science University, Portland, OR

OBJECTIVE: Methamphetamine use in pregnancy is rising and is associated with increased perinatal morbidity and mortality. Contingency management (CM) programs provide financial incentives for decreased use and are one of the most effective interventions for methamphetamine cessation in the general population. However, the use of CM during pregnancy to encourage methamphetamine cessation has not yet been studied. The objective of this study is to examine the cost-effectiveness of CM programs for pregnant individuals who use methamphetamines.

STUDY DESIGN: A decision-analytic model was built to compare CM programs with psychosocial support to standard of care for pregnant individuals who use methamphetamines. We estimated a theoretical cohort of 26,000 pregnant patients who use meth annually in the United States. We assumed CM patients received $725 in incentives. Probabilities associated with methamphetamine use were adjusted for race/ethnicity, insurance status, and tobacco use. Primary outcomes included costs, quality-adjusted life years (QALYs), methamphetamine cessation in pregnancy, preeclampsia, stillbirth, preterm birth, small for gestational age (SGA) neonates, infant death, and neurodevelopmental delay. The cost-effectiveness threshold was $100,000/QALY.

RESULTS: Contingency management was associated with methamphetamine cessation in 8,086 more individuals and a reduction of 135 stillbirths, 1,469 preterm births, 588 SGA neonates, 12 infant deaths, and 10 cases of neurodevelopmental delay. Overall, CM was the dominant strategy with decreased costs of $7 million and better outcomes with an increase of 107,290 QALYs.

CONCLUSION: Contingency management for methamphetamine cessation during pregnancy is a cost-effective intervention to promote abstinence from use and reduce rates of adverse pregnancy outcomes such as preterm birth and stillbirth. Implementing these programs should be considered when caring for these patients, but will need to be proactively funded.

Table 1. Outcomes associated with contingency management (CM) plus standard of care (SOC) versus SOC alone in a theoretical cohort of 26,000 pregnant people who use methamphetamines.

Outcome	CM +SOC	SOC	Difference
Preeclampsia	1593	1991	-398
Stillbirth	367	502	-135
Preterm birth	5,238	6,707	-1,469
Small for gestational age	3,986	4,574	-588
Infant death	57	69	-12
Neurodevelopmental disability	122	132	-10
Meth cessation in pregnancy	8970	884	+8086
Cost (USD)	$560,284,630	$568,050,577	-$7,765,947
Effectiveness (QALYs)	1,225,862	1,118,572	+107,290

625 Comparison of a New Tool for Obstetric Early Sepsis Versus Systemic Inflammatory Response Syndrome (SIRS)

Loren Walwyn-Tross, Kristy Palomares, Gregg Giannina
St. Peter's University Hospital, New Brunswick, NJ

OBJECTIVE: To compare a new clinical screening tool for obstetric early sepsis (TOES) against established SIRS criteria.

STUDY DESIGN: Retrospective case-control study of sixty-five patients diagnosed with sepsis either antepartum or within three days of

delivery. Sepsis was diagnosed utilizing the SIRS criteria. Sixty-five random controls with similar demographics without sepsis were used. The TOES tool (Table 1) was developed utilizing pregnancy-specific clinical parameters only excluding laboratory evaluations. The sensitivity, specificity, positive predictive and negative predictive values for TOES were determined. Group comparisons were performed with the Mann-Whitney Rand Sum test. Significance was set at a P value < 0.05.

RESULTS: There were no differences in the demographics (age, race, BMI, gravidity, parity, and gestational age) between the two groups. The temperature, respiratory rate, heart rate and TOES score were all higher in the sepsis group ($P < 0.001$). There was no difference between the systolic, diastolic and the mean arterial pressures (MAP) between the two groups. The sensitivity, specificity, positive predictive and negative predictive values for TOES were 95.4%, 96.9%, 96.9 % and 95.5% respectively.

CONCLUSION: TOES performed comparably to SIRS in screening for obstetric sepsis. We speculate that TOES, which only requires clinical parameters without laboratory testing may facilitate earlier identification of obstetric sepsis over traditional screening tools. We suggest that TOES may demonstrate improved clinical utility which may decrease adverse outcomes. Further validation of TOES with a prospective cohort is suggested.

Table 1. TOES Score ≥ 2 is a positive screen

626 Extracellular Vesicles Carrying Efflux Protein P-glycoprotein Alter Drug Transport Functions in Decidua

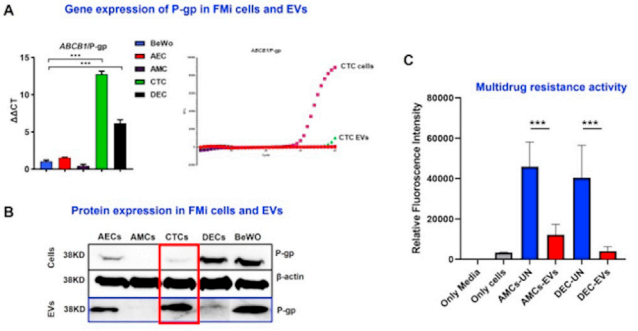
Amanda M. Wang[1], Ananth Kumar Kammala[2], Mohamed Bettayeb[3], Enkhtuya Radnaa[4], RamKumar Menon[1]
[1]University of Texas Medical Branch, League City, TX, [2]University of Texas Medical Branch, Galveston, TX, [3]University of Texas - Medical Branch, Galveston, TX, [4]University of Texas Medical Branch at Galveston, Galveston, TX

OBJECTIVE: P-glycoprotein (P-gp) is primarily reported in chorion trophoblast cells (CTC) for efflux drug transport. Its presence is reported in the neighboring amnion mesenchymal cells (AMC) and decidual cells (DEC), suggesting limited efflux capabilities of these cells. To test the hypothesis that CTC-derived extracellular vesicles (EVs) containing P-gp as cargo could induce P-gp expression in AMC and DEC, we examined CTC-EVs' impact on transitioning cells to perform efflux functions.

STUDY DESIGN: Gene expression levels of P-gp were analyzed in fetal membrane cells through quantitative real-time polymerase chain reaction (qRT-PCR), and protein levels were assessed using western blot analysis. CTC-derived EVs were isolated and characterized for size, shape, and quantity using nanoparticle tracking analysis, and the presence of P-gp was confirmed. Flow cytometry was utilized to evaluate CTC-EVs' effect on inducing P-gp expression in cells lacking it. The functional activity of P-gp in AMC and DEC was assessed through a multidrug resistance assay after exposure to CTC-derived P-gp-containing EVs. To validate our findings, decidual cells with P-gp knockdown (KD) using the CRISPR/Cas9 approach were treated with CTC-derived EVs containing P-gp and tested for restoration.

RESULTS: The gene and protein expression levels of P-gp in the amniochorion layers and their derived EVs were determined (Fig. 1A and 1B). Although the expression levels of EVs within the cells were low, both amniotic epithelial cells (AEC) and CTC-derived EVs carried P-gp. Treatment with CTC-derived EVs containing P-gp led to increased P-gp expression in AMC and DEC, resulting in enhanced drug efflux and a decrease in drug resistance (Fig. 1C). Furthermore, P-gp expression was reduced in trophoblast cells with P-gp KD but was restored upon treatment with chorion-derived EVs.

CONCLUSION: This study demonstrates that EV-mediated delivery of P-gp can induce drug efflux functions in cells in a paracrine fashion. The modulation of P-gp by EVs highlights the interplay between EVs and the cells of the feto-maternal interface drug transport mechanisms.



627 Does the dosing of low-dose aspirin for preeclampsia prevention alter serum extracellular vesicle characteristics?

Amanda M. Wang[1], Enkhtuya Radnaa[2], Rheanna Urrabaz-Garza[3], Kara M. Rood[4], Maged M. Costantine[4], Ananth Kumar Kammala[3], RamKumar Menon[1]
[1]University of Texas Medical Branch, League City, TX, [2]University of Texas Medical Branch at Galveston, Galveston, TX, [3]University of Texas Medical Branch, Galveston, TX, [4]The Ohio State University, Columbus, OH

OBJECTIVE: Extracellular vesicles (EVs) are essential for communication at the fetal-maternal interface. EVs represent the physiologic state of the cell at the time of its release. This study evaluated the

changes in the serum EV characteristics and their protein cargo in women with preeclampsia (PE) treated with aspirin (ASA).

STUDY DESIGN: Previously collected maternal samples from at-risk people receiving 81 mg vs. 162 mg aspirin, based on the development of PE or not. Samples were collected between 28-32 weeks (12-20 weeks after aspirin initiation). The optimal method of ultracentrifugation (UC) followed by size exclusion chromatography was chosen for EV isolation and characterization. EVs from women not on ASA (control), on 81 mg, or 162 mg ASA were isolated and characterized (size and quantity [ZetaView], shape [transmission electron microscopy], markers [Exoview]). Mass spectrometry-based proteomics experiments are performed using a stochastic sampling approach (data-dependent acquisition) for EV proteome cargo analysis.

RESULTS: Ultracentrifugation and size exclusion chromatography yielded EVs' highest number and quality. EV size and concentrations among groups were similar (Fig. 1A-B). TEM images validated intact and expected EVs' size and shape (Fig. 1C). Average gestational age at collection was 35 weeks for the control group (n=7), 29 weeks for 81 mg group (n=32), and 28 weeks for 162 mg group (n=13). ExoView analysis confirmed known EV markers of CD9, CD81, and CD63 (Fig. 1D) that were not different between groups. The proteomic analysis did not show any differences in total maternal serum EV proteins regardless of the dose of treatment or untreated groups.

CONCLUSION: Total serum EVs were not different between different doses of ASA-treated and untreated PE groups, as our current approach did not distinguish between fetal vs. maternal EVs. PE is a disease of the placenta and vasculature and therefore, we postulate that placental-specific (fetal) EV characterization is required to identify prognostic markers of ASA treatment.

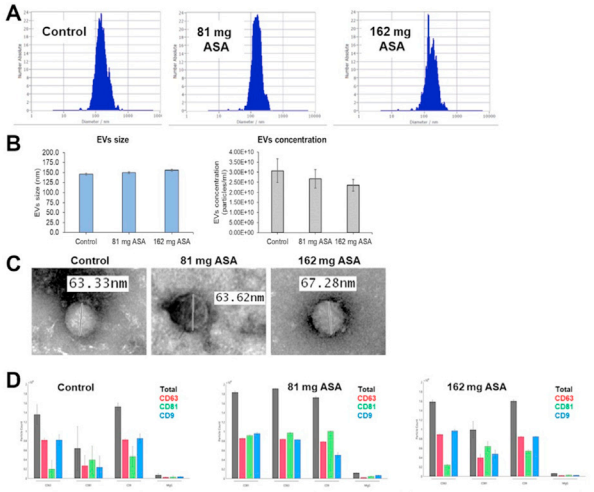


Figure 1. Characteristics of isolated human serum extracellular vesicles. **(a)** EV size and concentration. **(b)** EV size and concentration averages per study group. **(c)** Representative EV TEM images. **(d)** Reference EV markers.

628 Association of disease severity and placental pathology changes in pregnant patients with SARS-CoV-2

Juliann Wang[1], Christina T. Blanchard[2], Angela R. Seasely[2], Virginia E. Duncan[3], Jodie Dionne Odom[3], Akila Subramaniam[2], Nitin Arora[3]

[1]University of Alabama at Birmingham School of Medicine, Birmingham, AL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: Pregnant people infected with SARS CoV-2 are at increased risk for greater disease severity and complications. Prior studies have shown an unusual pathologic group of COVID placentitis in some patients diagnosed with SARS CoV-2 in pregnancy. We sought to investigate the association between disease severity and placental pathology in pregnant patients with confirmed SARS CoV-2.

STUDY DESIGN: This was a retrospective cohort study of all pregnant patients with PCR confirmed SARS CoV-2 (3/2020-4/2022) at a single institution. Disease severity was based on the NIH standard definitions and grouped into asymptomatic, mild/moderate, and severe/critical disease. Primary outcome evaluated by a trained placental pathologist were findings characteristic for SARS CoV-2 placentitis: chronic histiocytic intervillositis, massive perivillous fibrinoid deposition, and trophoblast necrosis. Secondary outcomes included additional descriptors of placental pathology and infant variables.

RESULTS: A total of 530 women delivered at our institution and were included in the study: 406 (77%) had placental pathology available. Among patients with placental pathology available, 46% were asymptomatic, 42% had mild/moderate disease, and 12% had severe/critical disease. Pregnant women with severe disease had an older age, higher BMI, and lower gestational age at delivery (all $p< 0.05$). SARS CoV-2 placentitis was observed in four patients (0.01%) with no association with disease severity. Higher disease severity was associated with chronic villous ischemic changes ($p< 0.01$), infant head circumferences $< 10^{th}$ percentile ($p< 0.01$), and decreased acute chorionic vasculitis ($p< 0.01$). All other placental pathology descriptors and infant variables were similar across groups.

CONCLUSION: Overall, we found no association between disease severity and risk of SARS CoV-2 placentitis.

	All (n=406)	Asymptomatic (n=186)	Mild/Moderate (n=173)	Severe/Critical (n=47)	P-value

629 Factors associated with SUD in pregnant individuals with reactive syphilis screening at a safety-net hospital

Kristen Warncke, Alesha M. White, Jessica E. Pruszynski, Emily H. Adhikari
University of Texas Southwestern Medical Center, Dallas, TX

OBJECTIVE: Substance use disorder (SUD) has been defined as a barrier to adequate maternal syphilis treatment. The objective of this study was to evaluate characteristics associated with SUD among those with reactive syphilis screening at a large safety-net healthcare system to identify opportunities for intervention.

STUDY DESIGN: Pregnant patients with syphilis before or during pregnancy from January 1, 2021 through December 31, 2022 were identified using reverse sequence screening in a large public healthcare system. Of these patients, those with SUD were identified via chart review. We compared maternal demographics, syphilis stage and initial nontreponemal titer, distance to prenatal clinic and preterm birth among those with and without SUD in pregnancy.

RESULTS: Of 499 patients with syphilis before or during pregnancy identified with reverse sequence screening, 98 (19.6%) had documented SUD. Compared to those without SUD, those diagnosed with SUD and syphilis were more likely to be non-Hispanic white, multiparous, and with late and limited prenatal care (Table). The distance to prenatal clinic (miles [IQR]) was greater for individuals with SUD (11.6 [6.8-17.9] vs 8.5 [4.1-14.8] miles, p=0.01). There was no difference in initial RPR titers or syphilis stage, with the majority having latent syphilis (unknown duration or late). Preterm delivery was significantly more frequent among those with SUD (30% vs 9%, p 0.002).

CONCLUSION: In a high-risk prenatal cohort referred for reactive syphilis testing in a safety-net healthcare system, increased distance to the prenatal clinic, late prenatal care and increased preterm birth characterized those with SUD during pregnancy. Early identification of SUD and syphilis through targeted linkage-to-care for syphilotherapy and SUD recovery may decrease barriers to adequate maternal syphilis treatment.

Table. Characteristics of patients with reactive reverse sequence syphilis screening with and without substance use disorders, January 1, 2021 through December 31, 2022

	SUD (n = 98)	No SUD (n = 401)	P value
Age, years	28.6 (5.4)	27.3 (6.0)	**0.03**

Stillbirth*	1 (3)	1 (1)	0.29

Data shown as n (%) or median (Q1-Q3) as appropriate. EGA, estimated gestational age.
*Denominator includes n=33 among those with and n=181 without SUD who delivered at our institution.

630 Development and validation of a clinical risk prediction model for small-for-gestational age infants

Timothy Wen[1], Audrey Kim[2], Lisa Bain[3], Kartik Venkatesh[4], Mark A. Clapp[5], Isabel Fulcher[6]
[1]University of California, San Francisco (UCSF), San Francisco, CA, [2]Delfina Care Inc., San Francisco, CA, [3]Stanford Medicine Children's Health, San Francisco, CA, [4]Ohio State University, Columbus, OH, [5]Massachusetts General Hospital, Boston, MA, [6]Delfina Care, Sunnyville, CA

OBJECTIVE: Small for gestational age (SGA) is defined as a birth weight of < 10th percentile for gestational age and is associated with adverse neonatal risks and increased resource utilization. Prenatal prediction of SGA as late as birth hospitalization admission could assist with risk stratification and improved allocation of resources on labor units.

STUDY DESIGN: Data from the National Vital Statistics System (NVSS) Birth Certificate and clinical data from an academic medical center (AMC) were utilized for the development, internal, and external validations. Non-anomalous, singleton births at >= 35 weeks were included for this analysis with the outcome of SGA based on neonatal weight using Fenton growth charts. A predictive model was developed using a stochastic gradient boosting algorithm adjusting for demographic (age, race/ethnicity, payer), obstetrical (delivery gestational age (GA), parity), clinical (body mass index, gestational weight gain (GWG), pregestational weight, chronic hypertension, pregestational/gestational diabetes, hypertensive disorders of pregnancy), and neonatal sex. Data from the 2019 NVSS was used to train and internally validate two models predicting SGA at birth. External validation was conducted on AMC and 2021 NVSS birth data. Measures of model performance are expressed as areas under the receiver operator curve (AUC) and with 95% confidence intervals (CI).

RESULTS: Model development was performed using 3.3 million NVSS births from 2019 and externally validated on 8,557 AMC births and 3.3 million NVSS births from 2021 with an SGA prevalence of 7.9%, 4.2%, and 8.8%, respectively. Internal validation yielded an AUC of 0.80 (95% CI: 0.80, 0.81) with delivery GA, prepregnancy weight, and GWG as the most important predictors. External validation yielded AUCs of 0.71 (95% CI: 0.68, 0.73) and 0.81 (95% CI: 0.80-0.81) on AMC and 2021 NVSS data, respectively.

CONCLUSION: SGA can be satisfactorily predicted using this clinically deployable machine learning model which can be implemented up until birth admission to improve resource utilization and team preparation in anticipation of birth.

631 Clinical utility of antenatal cfDNA screening for autosomal dominant disorders in the general population

Thomas Westover[1], Nicole Rook[2], Sandra James[2], Dineli Lewke[2], Jess Murawsky[2]
[1]Capital Health, Pennington, NJ, [2]Capital Health, Trenton, NJ

OBJECTIVE: We sought to evaluate the clinical utility and PPV of commercially available single gene cell free dna (sgNIPT) screening for autosomal dominant conditions in the general OB population.

STUDY DESIGN: MFM performs primary genetic screening/US in our USA regional perinatal ctr. From 2021-2023, we offered sgNIPT Natera Vistara to all singleton preg. Fetal/newborn DNA was assessed pre/postnatally after abnl US or abnl sgNIPT. Preg were classified as high or low risk for the mother or fetus to have a pathogenic dna variant in 30 prespecified genes. Small sample size precluded exact estimation of sgNIPT accuracy, statistical estimation yielded wide confidence intervals.

RESULTS: 4571 preg pts desired sgNIPT after prenatal counseling at median gest age 18 weeks (range 12-36). 12 preg pts had abnl sgNIPT (screen pos rate of 2.6/1000). 6 fetuses were high risk and 6 preg mothers were carriers (4 mosaic and 2 nonmosaic). No high risk pts had relevant personal/family history. 65/4571 assays were uninformative (1.4%). US, newborn physical exam and DNA data was available for all high risk preg whereas only US/newborn physical exam data was available for low risk preg precluding calculation of analytical sensitivity. PPV was 6/6 (100%) for an affected fetus (apert, thanatophoric, sotos, noonan, tuberous, OI). sgNIPT dxed 6/7 clinically affected fetuses (1 cornelia fetus had uninformative sgNIPT). 5/7 affected fetuses had abnl US. Two maternal full mutation carriers had normal fetal US with confirmed abnl fetal dna (OI). Four maternal "low mosaic" carriers (noonan tuberous cornelia) had normal fetal US/DNA; maternal leukocyte dna mutation analysis was normal suggesting presence of somatic tissue mosaicism.

CONCLUSION: sgNIPT screening in the general OB population allows for fetal risk assessment of dominant conditions but "false positive" results can occur due to the presence of maternal dna variants with variable expressivity, incomplete penetrance and somatic tissue mosaicism. Clinicians and families need to be aware of these issues. Ongoing research is needed to assess the sens/spec of sgNIPT for dominant disorders.

632 Barriers to providing training in opioid use disorder: a survey of OB/GYN residency program directors

Julia Whitley[1], Jeannie C. Kelly[2], Megan L. Lawlor[3], Karen George[4], Erika Banks[5], Phillip Ma[6], Jillian Catalanotti[6]
[1]Washington University in St. Louis, St. Louis, MO, [2]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, St. Louis, MO, [4]Larner College of Medicine at The University of Vermont, Burlington, VT, [5]New York University Grossman Long Island School of Medicine, Mineola, NY, [6]George Washington University School of Medicine and Health Sciences, Washington, DC

OBJECTIVE: Medication-assisted therapy (MAT) is recommended for pregnant patients with OUD. Few OB/GYN residency programs offer MAT training. We aimed to characterize training offered and identify perceived barriers to MAT training among OB/GYN program directors (PDs).

STUDY DESIGN: We administered a survey through email to all OB/GYN residency PDs asking whether they believe MAT is in-scope for OB/GYNs and perceived barriers in providing MAT training to residents. We collected PD demographic information including gender identity, race/ethnicity, age, and years as PD. We calculated number/percent for each response, and Fisher's exact test was used to determine associations between demographic, personal, or program information and MAT-related responses.

RESULTS: The overall response rate was 91.3%. The majority of PDs identified as female (73.9%) and white (74.3%), and 44.3% directed a university-based residency program. 62% of PDs agreed with the statement "Treating opioid use disorder with medication-assisted therapy is within the scope of practice of an OB/GYN." 40.1% of PDs reported no faculty in their department prescribe MAT, 36.4% have a colleague who does, and 15.1% of PDs themselves prescribe MAT. The leading reported barrier to providing training was lack of trained faculty (81.6%), followed by lack of faculty interest (42.7%). A greater proportion of PDs from programs with ≤ 4 residents per year (42.2%, p=0.001) reported provision of MAT training, compared to PDs from programs with more than 10 residents per year (6.21%, p=0.02). A greater percentage of PDs from programs having between 5 and 7 residents per year (50.7%, p=0.02) identified a lack of trained faculty as a barrier to providing MAT training, compared with PDs from programs with ≤ 4 residents per year (30.4%, p=0.03).

CONCLUSION: Although most PDs agree that MAT is in-scope for an OB/GYN, a minority prescribe MAT or have a colleague who prescribes MAT. Lack of trained faculty is a major barrier to providing MAT training, and focused efforts in faculty education may help address this barrier.

Table 1: Program director responses to questions about barriers to offering medication-assisted therapy training

What barriers prevent you from providing training in medication-assisted treatment of opioid use disorder using buprenorphine as part of your OB/GYN residency program? (select all that apply)*	Number of Program Directors selecting this response (%)
None – we currently provide this training	63 (61.2)
Low patient demand	38 (36.9)
Lack of resident interest	10 (9.7)
Lack of faculty interest	44 (42.7)
Lack of trained faculty	84 (81.6)
Lack of time in curriculum	36 (35.0)
Lack of training site for relevant clinical experience	38 (36.9)
Would like to do it, but just haven't prioritized it	36 (35.0)
Other barrier not listed	10 (9.7)

633 Comparisons of three-tiered risk assessment tools for postpartum hemorrhage related morbidity

Rachel L. Wiley[1], Ipsita Ghose[2], Hector Mendez Figueroa[3], Suneet P. Chauhan[4]
[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]University of Texas Medical School at Houston, Houston, TX, [3]University of Texas Health Science Center at Houston, Houston, TX, [4]University of Texas-Houston Medical School, Houston, TX

OBJECTIVE: In 2022, the California Maternal Quality Care Collaborative published Version 3 of the Hemorrhage Toolkit (CMQCC V3). We compared the likelihood of postpartum hemorrhagic morbidity (PPH-M) with CMQCC V3 risk assessment screen compared to the

classification schema promulgated by ACOG's Practice Bulletin (#183; published in 2017).

STUDY DESIGN: This was a retrospective cohort of all singletons delivered at ≥ 14 weeks at a Level IV center during 24 months. Chart abstraction was done by qualified medical staff, and the risk stratification was calculated at delivery. A composite PPH-M was defined as in Figure 1, and we assessed the predictive accuracies of the models by calculating AUC (area under the curve) for receiver-operating curves (ROC). A secondary analysis to examine risk of PPH-M with stratification by CMQCC V3 was compared, and adjusted risk ratios calculated using multivariable Poisson regression models.

RESULTS: Of 8,623 consecutive deliveries in the study period, 8,357 (97%) were singletons. For the CMQCC V3, 2,562 (31%) were low-, 3,084 (37%) were medium- and 2,711 (32%) were classified as high-risk. ACOG classified 3,475 (42%) as low-, 2,430 (29%) as medium- and 2,452 (29%) as high-risk. The models agreed approximately 55% of the time (kappa 0.33, "fair" agreement). Figure 1 shows the ROC curves in predicting PPH-M, with an AUC of 0.61 (95% CI 0.60 − 0.63) for CMQCC V3 and 0.57 (95% CI 0.56-0.59) for ACOG, which is significantly in favor of CMQCC (p< 0.001). The sensitivity of CMQCC was increased compared to ACOG (58% to 50%), but the specificity decreased (46% to 61%). A secondary analysis examined risk of PPH-M in CMQCC V3, and found that PPH-M was increased for high risk group when compared to low (aRR 1.88, 95% CI 1.65-2.14) or medium (aRR 1.78, 95% CI 1.59-1.99), but medium was not increased compared to low.

CONCLUSION: In our population, the CMQCC V3 is more likely to label patients at jeopardy for PPH-M as high-risk as compared to current ACOG risk stratification, however its utilization in clinical practice to improve outcomes remains uncertain.

	AUC	Sensitivity	Specificity	NPV	PPV
CMQCC	0.61	58.0%	46.0%	85.0%	17.3%
	0.60 - 0.63	56.7% - 59.3%	44.7% - 47.3%	84.0% - 85.9%	16.3%-18.2%
ACOG	0.57	50.4%	61.1%	83.8%	23.6%
	0.56 - 0.59	49.1% - 51.7%	59.8% - 62.3%	82.8% - 84.7%	22.5% - 24.7%

Figure 1. ROC Analysis of CMQCC V3 † Risk stratification tool compared to ACOG‡ Risk stratification tool using PPH-M*

*PPH-M composite: blood loss ≥ 1000 mL, use of uterotonics (excluding prophylactic oxytocin), mechanical tamponade, surgical intervention for atony (uterine artery ligation, uterine artery embolization, B-Lynch), transfusion, maternal venous thromboembolism, ICU admission, hysterectomy or maternal death

634 Echocardiography Parameters and Cardiac Geometry in Pregnancy by Race and Ethnicity

Gianna L. Wilkie, Lara Kovell

University of Massachusetts, Chan Medical School, Worcester, MA

OBJECTIVE: The study's objective was to assess normal transthoracic echocardiography (TTE) parameters and cardiac geometry among pregnant individuals by race and ethnicity.

STUDY DESIGN: We performed a retrospective cohort study of all pregnant individuals without cardiovascular disease who underwent a perinatal TTE considered normal at a single academic center between October 1, 2017 and May 1, 2022. Demographics and echocardiographic parameters were compared by self-reported race/ethnicity by Chi square, Fisher's exact, and analysis of variance test.

RESULTS: During the study period, 369 women had normal TTE in the perinatal period with a mean age of 31.8 ± 6.0 years old with a pre-gravid body mass index of 29.0 ± 7.0 kg/m^2. Subjects identified as 55.3% White, 24.7% as Hispanic, 14.1% as Black/African American, and 6.0% as Asian. Patients identifying as Black had higher rates of chronic hypertension (21.2%) compared to other races/ethnicities (p=0.02). TTE parameters of left ventricular (LV) ejection fraction, LV diastolic volume index, LV mass/mass index, LA volume index, tricuspid regurgitation peak gradient, septal and lateral e' differed by race/ethnicity (Table 1). There was a statistically significant difference in cardiac geometry by race and ethnicity (p=0.04).

CONCLUSION: While there were differences in TTE parameters by race and ethnicity, these differences may not be clinically significant as most mean values fall within the normal clinical ranges. There was an increase in concentric remodeling seen in Black/African American patients likely due to the increased rate of chronic hypertension seen in this population. Further larger, prospective studies are needed to better evaluate cardiac and perinatal outcomes associated with differences in cardiac geometry in pregnancy.

Table 1. Echocardiography Parameters in Pregnancy by Race and Ethnicity

	Reference Mean	Asian (n=22)	Black/African American (n=52)	Hispanic (n=91)	White (n=204)	P-Value

635 Effect of Medications on Postpartum Cerebral Autoregulation in Preeclampsia with Severe Features

Helen Woolcock[1], Maria Katsidoniotaki[2], Noora Haghighi[1], Casandra Almonte[1], Anne-Sophie van Wingerden[1], Eduard Valdes[1], Aymen S. Alian[3], Whitney A. Booker[1], Natalie Bello[4], Randolph Marshall[1], Ioannis Kougioumtzoglou[2], Nils Petersen[3], Eliza C. Miller[1]

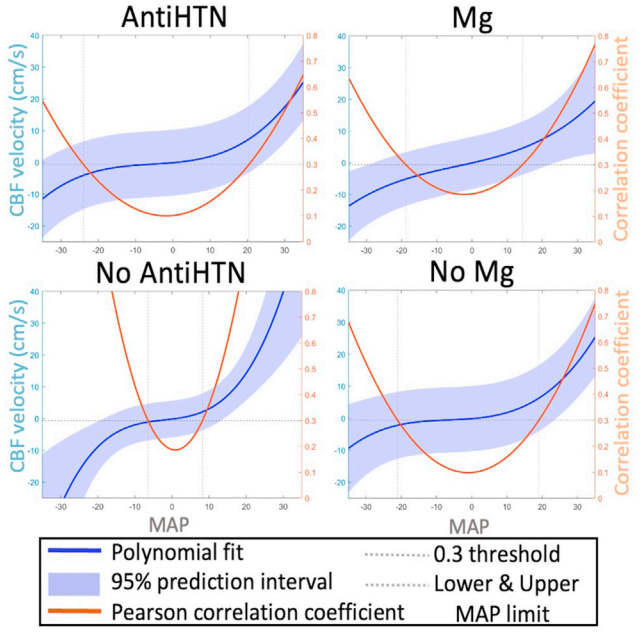
[1]Columbia University Irving Medical Center, New York, NY, [2]Columbia University, New York, NY, [3]Yale University School of Medicine, New Haven, CT, [4]Cedars-Sinai Medical Center, Los Angeles, CA

OBJECTIVE: Effective cerebral autoregulation (CA) typically maintains constant cerebral blood flow (CBF) within a mean arterial pressure (MAP) range of 50 − 150 mmHg in healthy adults. Impaired CA may contribute to increased risk of cerebrovascular complications in individuals with preeclampsia, due to preeclampsia-associated endothelial and autonomic dysfunction. We characterized CA curves in postpartum individuals treated for preeclampsia with severe features (PSF) and investigated the effects of recent treatment with intravenous magnesium (Mg) and antihypertensives (antiHTN).

STUDY DESIGN: We prospectively recruited individuals with PSF and measured CA using transcranial doppler (TCD) and finger plethysmography within 1 week of delivery. We constructed polynomial S-curves and calculated Pearson correlation coefficients to describe CA in patients who did and did not receive Mg or antiHTN within 24 hours prior to TCD. A correlation coefficient of > 0.3 indicates high correlation between MAP and CBF velocity, suggesting impaired CA.

RESULTS: We included 51 individuals with PSF, of whom 38 (75%) were treated with antiHTN, 3 (6%) were treated with Mg and 7 (14%) were treated with both antiHTN and Mg within the 24 hours prior to CA measurements. The CA S-curve in those recently treated with Mg appeared more linear with a less well-defined plateau, suggesting impaired CA. In the antiHTN group, the S-curve plateau was wider, compared with the non-antiHTN group (**Figure**).

CONCLUSION: Our results suggest that commonly used treatments for preeclampsia affect CA. Specifically, CA may function more effectively in PSF patients receiving antiHTN in the first week postpartum, compared to those not receiving antiHTN. In contrast, we observed impaired CA in those recently treated with Mg. These findings may have implications for clinical blood pressure management in the postpartum period in patients with PSF. Future studies should explore specific antiHTN medications and their interactions with Mg to better characterize their effects on CA.



636 Association between histological and clinical chorioamnionitis in patients with PPROM

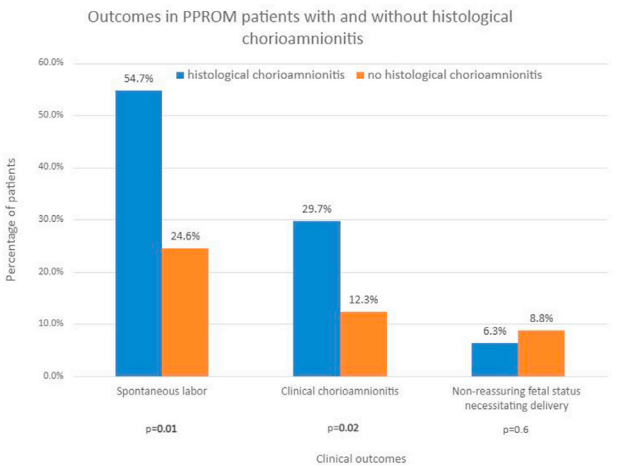
Evaline Xie[1], Julia Burd[2], Bridget C. Huysman[2], Roxane M. Rampersad[3], Jeannie C. Kelly[3], Ebony B. Carter[3], Antonina I. Frolova[2], Anthony O. Odibo[2], Nandini Raghuraman[2]
[1]Washington University in St. Louis, St. Louis, MO, [2]Washington University School of Medicine in St. Louis, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

OBJECTIVE: Chorioamnionitis is a morbid complication and indication for early delivery in patients with preterm prelabor rupture of membranes (PPROM). Prior studies have shown wide variation and discordance in rates of histological versus clinical chorioamnionitis, and the clinical outcomes associated with histological chorioamnionitis (HCA) are unclear. We investigated outcomes in patients with HCA after PPROM.

STUDY DESIGN: This single-center retrospective cohort study included singleton gestations with PPROM between 24^{+0} and 33^{+6} weeks with at least 24 hours of latency after PPROM diagnosis from 2019-2021. We included all patients who had placental pathology evaluations performed. The primary outcome was clinical chorioamnionitis. Secondary outcomes were spontaneous labor and non-reassuring fetal status (NRFS). Outcomes were compared between patients with and without HCA, defined by chorioamnionitis, chorionitis, or funisitis of the amniotic membranes, chorionic plate, and/or umbilical cord as reported on placental pathology. Descriptive and bivariate analyses were used to compare outcomes.

RESULTS: Of the 125 patients meeting inclusion criteria, 121 (96.8%) had placental pathology performed and 64 (52.9%) had HCA. Patients with HCA were more likely to be diagnosed with clinical chorioamnionitis (29.7% vs. 12.3%, p=0.02) and spontaneous labor (54.7% vs. 24.6%, p=0.01) compared to patients without HCA. There was no difference in rates of delivery for NRFS between patients with and without HCA. Among patients delivered for clinical chorioamnionitis, 33.3% did not have HCA. Composite neonatal infectious morbidity did not differ with HCA (4.7% vs. 1.8%, p=0.37).

CONCLUSION: More than half of patients with PPROM have HCA. Although HCA was associated with a higher incidence of clinical chorioamnionitis, it appears to be a common pathologic diagnosis with < 30% that have clinical chorioamnionitis. The utility of routine placental evaluation after PPROM should be studied further.



637 Effects of universal intrauterine pressure monitoring on labor outcomes among patients with obesity

Eileen Xu[1], Nandini Raghuraman[2], Katherine H. Bligard[2], Jeannie C. Kelly[3], Ebony B. Carter[3], Alison G. Cahill[4], Antonina I. Frolova[2]

[1]Washington University in St. Louis, School of Medicine, St. Louis, MO, [2]Washington University School of Medicine in St. Louis, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO, [4]University of Texas at Austin, Dell Medical School, Austin, TX

OBJECTIVE: Labor in patients with obesity is associated with increased cesarean rates due to labor dystocia. Active labor management in this population is often complicated by suboptimal monitoring of uterine contractions using external tocodynamometry, contributing to over-diagnosis of labor dystocia. We hypothesized that universal intrauterine pressure catheter (IUPC) use in patients with obesity would result in decreased cesarean rates compared to provider-initiated IUPC use.

STUDY DESIGN: This was a secondary analysis of a prospective study which included nulliparous patients with a BMI≥30kg/m^2 delivering at ≥37 weeks gestation at a single tertiary care center. Patients in this study had universal IUPC insertion at time of amniotomy (Universal-IUPC cohort) and were enrolled between 2020 and 2021. Historic controls were selected from nulliparous patients with IUPC use only at discretion of provider (PRN-IUPC) delivering between 2010 and 2014 at the same institution. Matching was performed on BMI and gestational age week at delivery in a 1:4 ratio. The primary outcome was cesarean delivery rate. Secondary outcomes were oxytocin use and maximum oxytocin dose. Multivariable logistic regression was used to compare outcomes between the Universal-IUPC and PRN-IUPC cohorts.

RESULTS: The Universal-IUPC cohort had 100% IUPC use while 76.2% of the PRN-IUPC cohort had an IUPC placed during labor. BMI and gestational age at delivery were similar between groups. Universal-IUPC cohort was older (27.3 vs 23.8 years, p< 0.01) and had more patients undergoing induction of labor (100 vs 57.4%, p< 0.01). Cesarean delivery rates for Universal-IUPC cohort were significantly lower than that of the PRN-IUPC cohort after adjusting for labor induction (27.9% vs 37.7%; aOR 0.39, 95%CI 0.30-0.74). Oxytocin use and maximum dose were not significantly different between the two cohorts.

CONCLUSION: Among patients with obesity, universal IUPC use may decrease cesarean rates. Further studies evaluating methods of uterine contraction monitoring in patients with obesity may decrease obstetric morbidity for this patient population.

638 Assessment of Maternal and Neonatal Outcomes in Newly Diagnosed Intrapartum Gestational Hypertension

Kevin Yeagle[1], Jaimey M. Pauli[2], Christina Stetter[3], Allen Kunselman[4]

[1]Penn State Health, Hershey, PA, [2]Penn State Milton S. Hershey Medical Center, Hershey, PA, [3]Penn State Hershey Medical Center, Hershey, PA, [4]Penn State College of Medicine, Hershey, PA

OBJECTIVE: Hypertensive disorders, including gestational hypertension (HTN) are a leading cause of adverse perinatal outcomes. There are currently limited data assessing these same outcomes in individuals who are diagnosed with intrapartum HTN only. The objective of this study was to compare the rate of progression to preeclampsia (PET) in intrapartum HTN versus gestational HTN. Our hypothesis was that intrapartum HTN was associated with a lower rate of progression to PET.

STUDY DESIGN: A retrospective cohort study was performed comparing the rate of progression to PET between gestational HTN and intrapartum HTN (defined as at least two elevated BPs (140 mmHg systolic or 90 mmHg diastolic) at least 4 hours apart, occurring only during the intrapartum period and not in the current or prior pregnancies). 142 individuals were included in the gestational HTN group, and 25 in the intrapartum group. The primary outcome was defined as the rate of PET in each group. Secondary outcomes included mode of delivery, severe features and neonatal outcomes (NICU admission, hypoglycemia, respiratory support, mortality). Statistical analysis was performed using Fisher's Exact Test.

RESULTS: The two groups were similar in age, BMI, and demographics. The intrapartum HTN group was more likely to be nulliparous (80% vs 67.6%) and later in gestation (39.3 vs 37.0 weeks) compared with the gestational HTN group. The development of PET was higher with gestational HTN compared to intrapartum HTN (85.9% vs 64.0%, p=0.018). In the secondary outcomes NICU admissions were increased in gestational HTN compared with the intrapartum HTN (31.9% vs 8%, p=0.015).

CONCLUSION: Individuals with intrapartum HTN are less likely to progress to PET than those with gestational HTN. However, the rates of PET in both groups are quite high and limited outcomes for the patient and newborn were examined. As intrapartum HTN has not been extensively evaluated previously, more research is needed to further characterize the impact of this diagnosis and potential management strategies to improve outcomes.

Table 1	Gestational HTN (n=142)	Intrapartum HTN (n=25)	*P*
Preeclampsia	122 (85.9)	16 (64.0)	0.018
Severe features	87 (71.3)	14 (87.5)	0.235
Mg administration	98 (69.0)	12 (48.0)	0.065
Readmission for HTN	4 (2.8)	3 (12.0)	0.069
Neonatal			
NICU admission	43 (31.9)	2 (8.0)	0.015
Hypoglycemia	11 (8.2)	0 (0.0)	0.215
Respiratory support	28 (20.9)	5 (20.0)	1.0
Mortality	0 (0.0)	0 (0.0)	N/A

Table 1: Primary outcomes (preeclampsia) and secondary outcomes (severe features, readmission, neonatal) of groups: Gestational Hypertension (HTN) and Intrapartum Hypertension (HTN); Data are n (%). *P* was determined by Fisher's Exact Test.

639 Eclampsia and adverse effects: comparison between 1 versus 2 grams per hour intravenous magnesium sulfate

Enav Yefet[1], Tamar Negri Choshen[2], Yaara Braester[3], Manal Massalha[2], Evgeniya Marchenko[2], Zohar Nachum[4]

[1]Tzafon Medical Center, Afula, HaZafon, [2]Emek medical center, Afula, HaZafon, [3]Ochsner Clinic Foundation, LA, [4]Emek medical center, Timrat, HaZafon

OBJECTIVE: While magnesium sulfate (MgS) is recognized as effective treatment for prevention of eclampsia, there is no consensus regarding the appropriate maintenance dosage.

Our research compared the efficacy, serum Mg concentrations and adverse effects rate of a maintenance dose of 1 g/h and 2 g/h of MgS in the prevention of eclampsia.

STUDY DESIGN: A retrospective cohort study of all women with severe pre-eclampsia/eclampsia, who were treated with MgS between August 2005 and September 2019. Women received a loading dose of 4 g MgS sulfate for 20 minutes, after which MgS was administered at 2 g/h until July 2013 (N=375) and afterwards was given at 1 g/h (N=306). MgS was administered up to 48h before delivery and 24h after delivery. Serum Mg concentrations were measured every 8 hours. The primary outcomes were (1) the rate of eclampsia and (2) the rate of the total adverse effects. Assuming that the rate of eclampsia will be 0.5% and 3% in the 2g/h versus 1 g/h groups, 680 women were required (5% one sided alpha, 80% power). This sample size was sufficient to detect 10% difference in the rate of adverse effects between 2 g/h and 1 g/h (40% versus 30%, respectively, 5% one sided alpha, 86% power).

RESULTS: Groups' outcomes are presented in the table. While there was no difference between the 1 g/h versus 2 g/h groups regarding the rate of eclampsia (2 (0.7%) versus 1 (0.3%), respectively; P=0.45), patients treated with a maintenance dose of 1 g/h suffered from fewer adverse effects compared with 2 g/h (40 (13%) versus 162 (43%), respectively; P< 0.0001). Additionally, both maximal and mean serum magnesium levels were significantly lower in patients treated with 1 g/h, and more patients from this group did not reach a serum level of 4.8 mg/dL which is the accepted therapeutic level (48 (16%) versus 305 (81%) in the 1 g/h versus 2 g/h, respectively; P< 0.0001).

CONCLUSION: We conclude that 1 g/h is the preferred maintenance dose due to the lower rate of adverse effects and the same efficacy of treatment. Additionally, we concluded that the accepted therapeutic window for MgS needs to be re-evaluated.

Table: Study outcomes

Outcome	1 g/h (n=306)	2 g/h (n=375)	p value
Eclampsia during MgSO4 treatment	2 (0.7%)	1 (0.3%)	0.45
[a]Mean Serum MgSO4 levels (mg/dL)	3.7 (0.8)	5.1 (1.2)	<0.0001
[a]Maximal serum MgSO4 levels	4.2 (1.7)	6.0 (4.8)	<0.0001
[a]Serum MgSO4 level reached toxic level (≥8.4 mg/dL)	4 (1.3%)	7 (1.9%)	0.76
[a]Serum MgSO4 reached lower therapeutic level (≥4.8 mg/dL)	48 (16%)	305 (81%)	<0.0001
Lowered dose or early treatment termination	1 (0.3%)	44 (12%)	<0.0001
Adverse effects overall	40 (13%)	162 (43%)	<0.0001
Nausea and Vomiting	16 (5%)	30 (8%)	0.15
Dyspnea	7 (2%)	17 (5%)	0.11
Headache	23 (8%)	93 (25%)	<0.0001
Weak reflexes	0 (0%)	30 (8%)	<0.0001
Flushing	2 (0.6%)	17 (5%)	0.002
Fatigue	0 (0%)	18 (5%)	0.0001
Tremor	3 (1%)	5 (1.3%)	0.74
Dizziness	6 (2%)	13 (3%)	0.24
Confusion	0 (0%)	1 (0.2%)	1
Dry Mouth	0 (0%)	3 (0.8%)	0.26
Malaise	1 (0.3%)	9 (2%)	0.03

[a]Serum MgSO4 levels were missing for 2 patients in the 1 g/h group, therefore n=304 for these variables

640 Do women with one abnormal value of oral-glucose-tolerance-test according to Carpenter and Coustan have gestational-diabetes-mellitus?

Enav Yefet[1], Yuri Perlitz[2], Zohar Nachum[3]
[1]Tzafon Medical Center, Afula, HaZafon, [2]Tzafon Medical Center, Poriya, HaZafon, [3]Emek medical center, Timrat, HaZafon

OBJECTIVE: Gestational diabetes mellitus (GDM) is diagnosed by the two step strategy of performing 50g glucose challenge test (GCT) followed by 100g oral glucose tolerance test (OGTT). The accepted cutoffs for GDM diagnosis using the 100g OGTT are two elevated values according to the criteria of either Carpenter and Coustan (C&C) or the 1979 National Diabetes Data Group. In the present study we examined the effect of one OGTT abnormal value only according to C&C criteria on pregnancy outcomes.

STUDY DESIGN: A population based retrospective cohort study of women who delivered at Emek medical center in Israel between July 2013 and September 2021 was conducted. Women were divided to the following groups: (1) Women without GDM (either normal GCT or OGTT; N=14,450), (2) women with one abnormal OGTT value only according to C&C (fasting glucose 95-104, one hour 180-189, 2 hours 155-164 and 3 hours 140-144 mg/dL; N=661), and (3) women with GDM defined as at least two abnormal OGTT values according to C&C (N=904). Only the last group was treated for GDM. The primary outcome was the rate of large for gestational age (LGA) neonates.

RESULTS: Univariable and multivariable analyses are presented in the table. After controlling for background characteristics, one abnormal glucose value increased the risk, compared to the control group, for LGA (OR_{adj}1.9 95%CI[1.6-2.4]), macrosomia (2.4 [1.9-3.2]), hypertensive diseases of pregnancy (1.4 [1.07-1.9]) and shoulder dystocia (3 [1.2-7.8]). The risk for LGA and macrosomia was also higher in the one abnormal glucose value group compared to the two abnormal glucose values group (1.4 [1.1-1.9] and 2.1 [1.4-3.1], respectively).

CONCLUSION: Women with one abnormal OGTT value, according to the C&C only, had worse outcome than normo-glycemic women or women with GDM. Those women should be considered as having GDM.

Table. Pregnancy and neonatal outcomes

Univariable analysis			
Number of abnormal OGTT values	0 N=14,450	1 N=661	2 N=904
Delivery week	39.4 ±1.6	39.1 ±1.6	38.7 ±1.5

641 Early versus late external cephalic version : A Retrospective Cohort Study

Fyrooz Yossef[1], Rami Samour[2], inna Bleicher[3]
[1]Bnai Zion Medical Center, Haifa, Hefa, [2]Bnai Zion, Haifa, Hefa, [3]Bnai Zion Medical Center, E Meadow, NY

OBJECTIVE: To compare the success rate and the cesarean delivery rate between early and late external cephalic version (ECV) in patients presenting with breech presentation at term.

STUDY DESIGN: This is a retrospective cohort study that included women undergoing a trial of external cephalic version (ECV). We included all patients with a singleton term pregnancy with a breech presentation who opted for ECV. We excluded patients with a nuchal cord, patients in labor, fetal heart rate abnormality, and patients with any contraindication for vaginal delivery. We compared the outcomes between ECV that was performed at 37+0 to 37+2 days (early ECV group) and ECV performed after 37+3 days (late ECV group). Our primary outcome was the rate of cesarean delivery among patients who had successful ECV. Secondary outcomes included success rate.

RESULTS: Between January 2021 and March 2023, a total of 100 patients had a trial of ECV, 45 in the early ECV group and 55 in the late ECV group. Baseline characteristics were similar between the two groups (Table 1). Late ECV group had significantly higher rate of successful version to cephalic presentation (82% vs. 60%, p=0.0156, OR-0.33, 95% CI 0.13-0.8) and significantly lower rate of cesarean delivery (34.6% vs 59.4%, p = 0.0202, OR 2.7, 95% CI 1.16-6.6) when compared to early ECV group.

CONCLUSION: External cephalic version performed at a later gestational age was associated with a higher rate of successful version to cephalic presentation and lower cesarean delivery rate.

Table 1: Patient characteristics and study outcomes

	Early ECV (n=45)	Late ECV (n=55)	P value	Effect size 95% CI
Maternal age	31.87 ± 4.65	31.93 ± 4.97	0.9	
Gestational age at ECV	37.2 ± 0.5	38.2 ± 0.8	0.0001	-0.9 (-1.2 - -0.7)
Gestational age at delivery after successful ECV	37.2±0.5	38.1± 0.7	**0.0001**	**-0.9 (-1.2-0.5)**
BMI	28.4 ±4.3	28.68 ± 4.1	0.81	N.S
Nulliparity	20 (44)	15 (27)	0.07	N.S
Prior cesarean	2 (4.4)	4 (7.2)	0.55	N.S
Cesarean delivery*	22 (59.4)	18 (34.6)	**0.0202**	**2.7 (1.16-6.6)**
Successful ECV	27 (60)	45 (82)	0.0156	0.33 (0.13-0.8)

642 Coping mechanisms and support systems of Black women after preterm birth: a qualitative study

Arthurine Zakama[1], Mlka Mengesha[2], Florence Momplaisir[3], Michal A. Elovitz[4], Jennifer Lewey[2], Michelle P. Debbink[5]
[1]University of California, San Francisco (UCSF), San Francisco, CA, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania School of Medicine, Philadelphia, PA, [4]Women's Biomedical Research Institute, Icahn School of Medicine at Mount Sinai, New York, NY, [5]University of Utah, Salt Lake City, UT

OBJECTIVE: Spontaneous preterm birth (sPTB) can have lasting impacts on the birthing person and the delivered child. Black women endure a higher prevalence of sPTB; however, there is a lack of data on how they cope with having a sPTB and the support symptoms they rely on to recover. Our study aimed to reveal the perspectives of Black women on coping mechanisms and their support systems after sPTB.

STUDY DESIGN: We conducted a qualitative interview study of self-identified Black women who had a sPTB at a large teaching hospital. We enrolled participants who had a sPTB between 24w0d and 33w6d from July 2020 to July 2022, spoke English, and were at least 18 years old. Interview participants were interviewed until thematic saturation was achieved. Data were analyzed using an inductive coding approach. Interrater reliability testing was performed. Standardized questions captured participants' perceptions of mental health symptoms, coping mechanisms, and support structures leveraged after sPTB.

RESULTS: Of 47 eligible participants, 13 (27.7%) completed the screening and interview process. Inter-rater reliability scores showed almost perfect coding agreement (mean kappa 0.99 (SD 0.01)). Participants found that psychological and spiritual connections helped them cope with the mental impact of sPTB; significant

themes are noted in Table 1. Support from partners, family members, and community members aided in participants building resiliency. However, participants perceived a lack of understanding of the sPTB from their partners and family members as less support, which negatively impacted their mental health.

CONCLUSION: Black women who had a sPTB coped through psychological and spiritual connections with support networks aiding in the development of resiliency. However, the lack of understanding of the sPTB within their support network, made participants feel unsupported. Interventions geared towards including patients' spiritual preferences and support networks in their pregnancy and postpartum management could increase perceived support after sPTB and improve mental health.

Table 1: Representative themes and quotes

Significant Themes	Representative Quotes
Coping Mechanism	
Psychological support	"I have the therapist that I've had for some time, so she was important and just talking to friends and family, my partner, because it was important" "I did have a counselor come down and talk to me. She brought me a couple of things for my hospital stay to make sure I was comfortable being there."
Spiritual connection	"A lot of prayer. A lot of prayer. I think sometimes I feel like bad situations happen and they draw you closer to God. And I definitely think that's what happened in this case. And I really feel like if I didn't have my faith, I would have dealt with it in unhealthy ways."
Support	
Impact of receiving social support	"Basically it helps to know that I can share my experience with other people who go through this [sPTB]. Let them know that it's okay, it's not always a bad feeling delivering a preterm baby" "It made a great impact. It made me more sensitive in a way. People and their kids, I'm young so the group that I hang with they're young but they have kids. I understand more the responsibility and like the caution and like, oh, I can't come out tonight. It gave me more understanding to understand what they did."
Lack of understanding from social support system	"I don't really feel like anybody ever paid any mind to it. Like, I don't think anybody really cares about a preemie baby being born until they have their own and they understand. So, I think it was just kind of ignored." "[My partner] didn't understand the emotions or the time wave that I was going through surrounding my daughter's birth. He had no idea. He didn't even know how to support me because he had no idea-to him this [sPTB] was normal. "They don't really understand the emotions and the decisions and the feelings and everything that we feel during the process" "I really cannot tell because I had my son all by myself and nobody was there."

643 Functional gut microbiome variation impacts iron deficiency and responsiveness to iron supplementation: An Interventional Trial

Maryshe S. Zietsman[1], Sarah E. Detlefs[2], Kjersti M. Aagaard[3], Michael D. Jochum Jr.[1]

[1]Baylor College of Medicine, Houston, TX, [2]Texas Children's Hospital, Houston, TX, [3]Texas Children's Hospital, Baylor College of Medicine, Houston, TX

OBJECTIVE: Careful regulation of iron absorption in the gut is mediated by key host and microbe molecular pathways controlling cellular function, metabolism, and DNA processing. Inconsistent response to oral iron supplementation (IS) suggests varying function in these molecular pathways. We hypothesized that the inferred functional gut microbiome would vary between iron sufficient and deficient participants, and responders vs non-responders following IS.

STUDY DESIGN: People who menstruate without a known history of anemia or iron deficiency were included in our open label, prospective, interventional trial (n=26). Participants received 14 days of 65mg elemental iron. Blood (Days (D) 0 & 14) & stool (8 samples including D0 & D14) were collected for iron & anemia indices and microbiome analyses. Stool sample DNA underwent 16S amplicon sequencing and bioinformatic analysis of microbial ASVs (DADA2). To characterize the gut microbiome composition, taxonomic comparisons, & unsupervised clustering with Dirichlet multinomial mixtures (DMM) were performed. Participants who were iron deficient on D0 (n=17) were later subdivided into iron supplement responders (ferritin $\geq$ 30 ng/mL, n=4) and non-responders (ferritin $<$ 30 ng/mL, n=12), based on their D14 ferritin.

RESULTS: Inferred functional microbiome comparisons at D0 found 13 significantly differentially expressed functions whose taxonomic abundances differed significantly in association with responder class (**Figure 1A**). In the D0 iron deficient group, 67 inferred microbial functions were identified in relation to response status. Analysis of the 67 functions at D14 detected 4 significantly differentially expressed functions whose taxonomic contributions differed significantly in association with responder class (**Figure1B,C**).

CONCLUSION: These data show significant differences between the inferred functional microbiomes of iron deficient and sufficient participants, and between IS responders and non-responders. Our findings provide insight into the functional impact of gut microbiome composition on iron deficiency and responsiveness to IS.

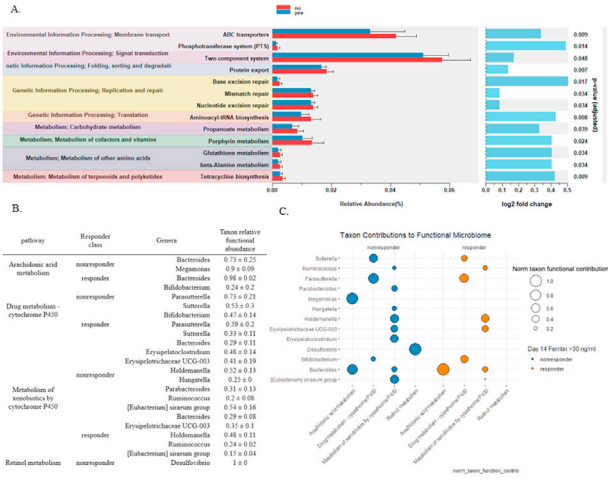

Figure 1. A) Heatmap represents the various microbial functions in individuals who were iron deficient at baseline (day 0) (<30 ng/mL). The x axis depicts the predicted and significant KEGG orthologs and the y axis is the samples. **B)** Taxon relative functional abundance in PICRUSt2 refers to the predicted proportion of functional genes present in a microbial community based on the relative abundance of taxonomic groups identified through 16S rRNA gene sequencing. **C)** x axis = significantly inferred functionally annotated microbiome KEGG pathways faceted by response to iron therapy defined at as Ferritin <30 ng/ml at Day 14. y axis = genera associated with significant contributions to the KEGG pathways.

644 Indicated versus universal third trimester ultrasound examination in low-risk pregnancies: a pre- and post-intervention trial

Aaron Roberts[1], John W. Hotra[2], Mason Collie[2], Shaun Smith[2], Allison Petronzio[2], Anjitha Saj[2], Claudia Pedroza[1], Baha M. Sibai[3], Sean C. Blackwell[4], Suneet P. Chauhan[5]
[1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [2]McGovern Medical School at UTHealth Houston, Houston, TX, [3]Hermann Memorial Hospital, Houston, TX, [4]Children's Memorial Hermann Hospital, Houston, TX, [5]University of Texas-Houston Medical School, Houston, TX

OBJECTIVE: In low-risk pregnancies, third trimester ultrasound examination (USE) are indicated if there is discordance between fundal height vs. gestational age. The primary objective was to compare the composite neonatal adverse outcomes (CNAO) with routine care vs. universal third trimester USE in low-risk pregnancies. The secondary objective was to compare the composite maternal adverse outcomes (CMAO).

STUDY DESIGN: Our multi-site quality improvement trial included low-risk women, defined as without medical or fetal indications for USE in the third trimester. Compared to routine care in pre-implementation, in the post-implementation period all patients were scheduled for USE at 36-37 weeks. Clinicians intervened based on abnormalities identified with these USE. CNAO was a composite of Apgar score $\leq$ 5 at 5 min, birth trauma, intubation for >24 hours, seizure, sepsis, meconium aspiration syndrome, IVH, PVL, NEC, or death. CMAO included chorioamnionitis, wound infection, PPH, blood transfusion, DVT, ICU admission, or death. We used Bayesian statistics to estimate a sample size of 600 individuals in each arm to detect >75% probability of any risk reduction in CNAO, (80% power; 50% risk reduction with USE). Posterior probability of risk reduction, posterior median relative risk (pRR) with 95% credible intervals (CrI), and number needed to treat (NNT) were calculated.

RESULTS: The primary outcome occurred in 15 of 568 (2.6%) individuals in the pre- and 12 of 661 (1.8%) in the post-intervention group, with an 83% posterior probability of risk reduction in CNAO (pRR 0.69, 95% CrI 0.34-1.42). CMAO occurred in 8.6% in the pre- and 6.5% in post-intervention group, with a 90% posterior probability of risk reduction in CMAO (pRR of 0.74, 95% CrI 0.49-1.15). The NNT to reduce CNAO was 121, to reduce CMAO was 46, and to reduce primary CD was 43 (Table).

CONCLUSION: Among low-risk pregnancies, compared to routine care with indicated USE, implementation of a universal third-trimester USE at 36-37 weeks was associated with an improvement in composite neonatal and maternal adverse outcomes.

Table: Indicated versus universal third trimester ultrasound examination in low-risk pregnancies

645 Perinatal effects of maternal cannabis and nicotine co-use in pregnancy

Adam Crosland[1], Ava Mandelbaum[1], Bharti Garg[1], Sarena Hayer[1], Kimberly Ryan[1], Cindy McEvoy[1], Lyndsey Shorey-Kendrick[2], Eliot Spindel[3], Aaron B. Caughey[1], Jamie Lo[1]
[1]Oregon Health & Science University, Portland, OR, [2]Oregon Health & Science University, Beaverton, OR, [3]Oregon National Primate Research Center, Beaverton, OR

OBJECTIVE: Prenatal cannabis use in the United States is rising and half of pregnant individuals who use cannabis also use nicotine-products. However, there is limited data regarding the combined effects of both cannabis and nicotine-products on perinatal outcomes. This study aims to assess the perinatal outcomes associated with prenatal cannabis and nicotine-product co-use, and use of either substance alone.

STUDY DESIGN: This is a retrospective cohort study of California linked hospital discharge-vital statistics data from 2012-2019. We included singleton, live-born infants with gestational age of 23-42 weeks. Pregnant individuals were classified into four categories: no-use (neither cannabis nor nicotine; reference group), cannabis use only, nicotine-product use only, and co-use (use of both cannabis and nicotine-products). Chi-squared and multivariable logistic regression were utilized for statistical analyses.

RESULTS: A total of 3,356,676 pregnant individuals were included: 25,168 used cannabis only, 62,199 used nicotine-products only and 11,401 co-used cannabis and a nicotine-product during pregnancy. After adjusting for maternal demographics, with 'no-use' as the reference group, hypertensive disease was significantly higher in patients with cannabis use (aOR=1.33; 95% CI: 1.27, 1.38), nicotine use (aOR=1.09 (1.06, 1.12) and co-use of cannabis and nicotine (aOR=1.13 (1.07, 1.22). Similarly, preterm delivery (<37 weeks and < 32 weeks) and severe maternal morbidity were higher with cannabis or nicotine use, but not with co-use. Neonatal outcomes including NICU admission, small for gestational age, respiratory

distress syndrome, infant deaths, and others were also higher with cannabis and nicotine use (Table 1).

CONCLUSION: Our study suggests that prenatal cannabis and nicotine-products, both independently and with co-use are associated with increased odds of maternal and neonatal morbidity compared to non-users. Given the growing prevalence of prenatal cannabis and nicotine co-use, our findings can help guide provider counseling.

646 Unintended consequences of inclusion of race in the TOLAC calculator, a birth certificate data study

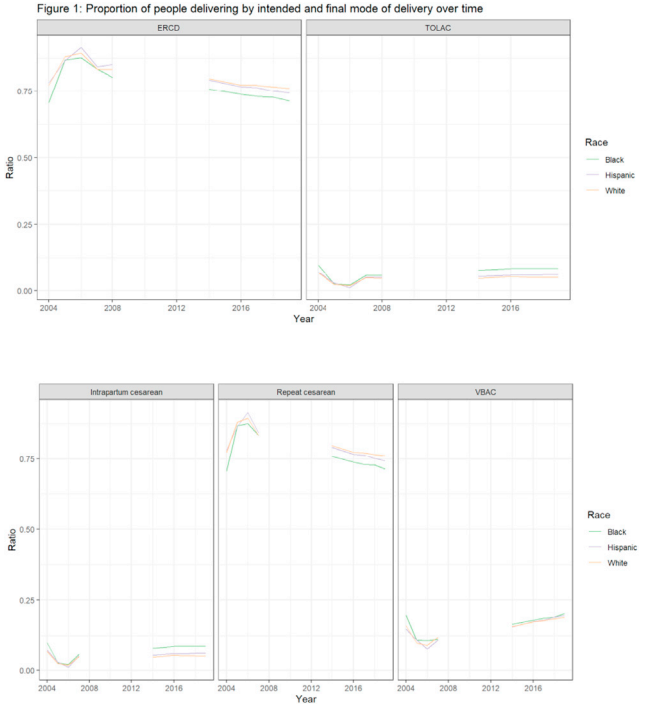
Ajleeta Sangtani[1], LeAnn A. Louis[2], Ashley Hesson[1], Anita M. Malone[1]
[1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Hospital System, Ann Arbor, MI

OBJECTIVE: In 2007, the Maternal Fetal Medicine Units Network published a widely available trial of labor after cesarean (TOLAC) calculator that included race as a data point. In 2021, the calculator was then revised to remove race from the calculator. The objective of this project was to determine if inclusion of race in the calculator changed TOLAC and vaginal birth after cesarean (VBAC) rates nationwide.

STUDY DESIGN: We conducted a retrospective study using data extracted from the Vital Statistics Natality Birth Data. Individuals were included if they delivered between 2003-2007 (the "early" group) or 2014-2019 (the "late" group), had a prior cesarean delivery, and were cephalic at the time of presentation. Patients delivering between 2008-2013 were excluded to allow for a washout period. Patients were also excluded if their TOLAC status was unknown. Three categories of race were analyzed: non-Hispanic White, Hispanic, and non-Hispanic Black. Statistical analysis was conducted using a Poisson regression and post-hoc testing with estimated marginal means in R.

RESULTS: 2,134,498 births met criteria during the two study periods, 22% of whom were in the early group and 78% were in the late group. Rates of TOLAC increased in all three groups, though the effect size was largest in the Hispanic population (P=0.01). Although intrapartum cesarean rates were not significantly different between race categories in the early group, Black patients were more likely to undergo intrapartum cesareans compared to White patients in the late group (p< 0.01). Likewise, Hispanic patients were more likely to undergo intrapartum cesareans in the late group (p=0.01). Figure 1 demonstrates the trend in intended and actual mode of delivery over time.

CONCLUSION: Nationally, intrapartum cesarean rates for Black and Hispanic patients significantly increased after original TOLAC calculator was released without increasing the rates of planned cesarean deliveries or changing the intrapartum cesarean rates in White patients. These findings highlight new, unintended bias associated with tools intended to enhanced clinical decision-making.



647 Patient cost willingness for diagnostic prenatal testing in a region with poor insurance coverage

Akila Subramaniam[1], Yuanfan Ye[1], Victoria C. Jauk[1], Fallon Brewer[2], Taylor Dunn[2], Anna Hurst[2], Brian M. Casey[2]
[1]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: Various tiers of diagnostic prenatal testing with karyotype, chromosomal microarray (CMA), next-generation sequencing (NGS) panels and whole exome/genome sequencing (WES/WGS) are available; however, insurance coverage for these tests is variable. We evaluated the costs that pregnant individuals were willing to pay for these various tests and compared costs by insurance and genetic-risk status.

STUDY DESIGN: We performed a prospective study of individuals seeking prenatal care at a large urban US academic center (3/2020-8/2022). Consenting persons were administered an electronic survey introducing the test types (i.e. karyotype, CMA, NGS, WES) and then assessing their attitudes regarding various levels of genetic information and willingness to obtain these tests, including costs. The primary outcome was cost range participants were willing to pay for karyotype, CMA, NGS panel, or WES/WGS (Figure). Frequencies of

cost ranges for each test were computed for the study population, and compared between insurance types (private vs public) and genetic risk levels (low vs high-risk [i.e. abnormal genetic screening, fetal anomalies]).

RESULTS: Of 1596 individuals approached for this study, 895 enrolled - 776 low-risk (54% public insurance) and 119 high-risk (55% public insurance). Our cohort was on average 27 ± 6yrs, primarily Black (55%) with ≥ high school education (92%). Most respondents (>50%) reported willingness to get any of the tests only if covered by insurance (Figure). This was similar for low and high-risk groups (p >0.05 for all test types). Publicly and privately insured patients had different cost willingness (all p< 0.001). While the majority of both groups were willing to get testing only if covered by insurance, >25% of publicly insured participants reported they would never get testing, regardless of cost. Others with public insurance were twice as likely to be willing to pay any cost vs. those with private insurance (Figure).

CONCLUSION: Financial willingness to obtain various diagnostic prenatal tests is based on insurance coverage, thus, efforts to universally improve coverage are needed.

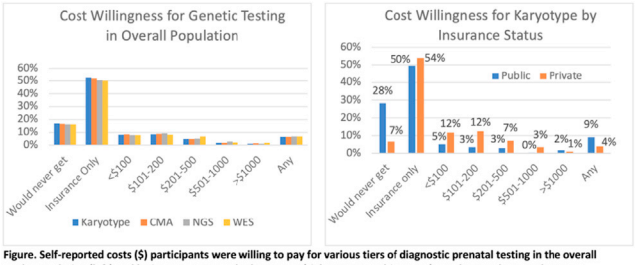


Figure. Self-reported costs ($) participants were willing to pay for various tiers of diagnostic prenatal testing in the overall study population (left) and by insurance status for karyotype (right, p<0.001 Chi-square) are shown. The costs by payor status for other testing (CMA, NGS, WES) are not shown but are consistent with karyotype as depicted on the right (p<0.001).

648 Indications for antenatal late preterm steroids and childhood neurodevelopmental outcomes

Alan T. Tita

University of Alabama at Birmingham, Birmingham, AL; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: Indications for late preterm steroids are heterogeneous. To evaluate whether there is an association between specific indications for late preterm steroids and adverse childhood neurodevelopment.

STUDY DESIGN: Secondary analysis of a prospective follow-up study of children ≥ 6 years old delivered without anomalies in the Antenatal Late Preterm Steroids trial. Indications included preterm labor with intact membranes (PTL), preterm PROM (PPROM), hypertensive disorders of pregnancy (HDPs), and fetal growth restriction or oligohydramnios without HDP (FGR/OLIGO). Certified psychologists performed neurocognitive testing using the Differential Ability Scales (DAS-II) core components of general conceptual ability (GCA): verbal, non-verbal reasoning, and spatial ability. The primary outcome was GCA score < 85 (-1 SD) and secondary outcomes were mean GCA and component scores, Social Responsiveness Scale, and Child Behavior Checklist (Table). Primary and secondary outcomes were compared in children with each indication relative to all others. Log-binomial regression calculated relative risks (RR) and mixed linear models and quantile regression estimated mean or median differences, respectively.

RESULTS: Among the 1,018 children, indications were as follows: 260 PTL, 267 PPROM, 353 HDPs and 60 FGR/OLIGO. Median GA at delivery was 36 weeks and age at follow-up was 7 years. The primary outcome, GCA < 85 (22.3%, 15.8%, 16.5% and 28.3%, for the respective indications) was not associated with any indication after adjustment (Table). Mean GCA and other secondary outcomes were associated with higher verbal ability for HDPs, worse externalizing behavior score for PTL, better anxious/depressed score for PPROM, and worse aggressive behavior score for both PTL and FGR/OLIGO.

CONCLUSION: Indications for late preterm steroids were not associated with the primary outcome (GCA) and most secondary outcomes. Some indications were associated with secondary outcomes but were inconsistent and few in number; given the number of comparisons, these associations may be due to chance.

Table. Adjusted primary and secondary outcome results by indication for late preterm steroids

Outcome	PTL (n=260)	PPROM (n=267)	HDPs (n=353)	FGR/OLIGO (n=60)
GCA < 85*	1.11 (0.80,1.53)	1.17 (0.83,1.66)	0.81 (0.56,1.16)	1.37 (0.89,2.12)

GCA denotes General Conceptual Ability, SRS Social Responsiveness Scale, and CBCL Child Behavior Checklist.
Data are adjusted RR (95% CI)* for categorical and mean or median difference (95% CI) for continuous outcomes. Adjusted for treatment assignment, maternal age, delivery GA, child's age, child sex, maternal education and if relevant for differences in pre-pregnancy BMI, chronic HTN, gestational DM, magnesium use, mode of delivery and NICU admission.

649 Intrapartum oral azithromycin to prevent maternal postpartum hemorrhage

Alan T. Tita

University of Alabama at Birmingham, Birmingham, AL; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: A single oral dose of azithromycin (AZI) given during labor in women planning a vaginal delivery reduced maternal infections including sepsis and the effect was stronger in Africa than Asia. Since maternal infection contributes to labor dysfunction and postpartum hemorrhage (PPH), we evaluated the association between AZI and PPH.

STUDY DESIGN: Secondary analysis of the A-PLUS trial in which women in labor at ≥28 weeks' gestation were randomized to either 2g AZI or placebo at 8 sites in 7 low- and middle-income countries (LMICs). The outcomes were: 1) PPH based on clinician diagnoses, and 2) postpartum blood transfusion, prior to hospital discharge. We compared rates of the outcomes and computed RR (95% CI) using Poisson regression as relevant. We also implemented subgroup analyses by Africa vs. Asia.

RESULTS: Of 29,278 participants randomized, 14590 to AZI and 14688 to placebo, 99.6% were followed to 42 days postpartum. Baseline characteristics were balanced between groups including overall from Africa (40%), Asia (55%) and Latin America (5%), nulliparous (43%) and labor induction (18%). PPH and blood transfusion did not differ significantly between groups (Table). The effect on blood transfusion appeared to be beneficial in Africa (RR=0.2; 0.07-0.59) but not in Asia (RR=1.22; 0.72-1.78); p-value for interaction = 0.002.

CONCLUSION: A single intrapartum oral dose of AZI did not significantly reduce the risk of PPH or blood transfusion. Further studies are needed to confirm whether there are benefits in Africa where use

of antibiotics in routine clinical care is less prevalent.

Table. Maternal Postpartum Hemorrhage and Blood Transfusion by Treatment

	Azithromycin	Placebo	RR (95% CI) or p-value
Maternal Outcome			
Postpartum hemorrhage	203/14,588 (1.4)	232/14,687 (1.6)	0.88 (0.73, 1.07)
Blood transfusion	68/14,588 (0.5)	76/14,687 (0.5)	0.90 (0.65, 1.25)
Number of packed red blood cells or whole blood units	66	74	
Median (P25, P75)	1.00 (1.00, 2.00)	1.00 (1.00, 2.00)	0.53

650 Reticulocyte hemoglobin equivalent in the iron deficiency spectrum

Lylach Haizler-Cohen[1], Haleema Saeed[1], Valencia Quiett[1], Gurpinder Kaur[1], Eshetu A. Tefera[2], Michael Auerbach[3], Nicholas Hazen[4]

[1]Medstar Washington Hospital Center, Washington, DC, [2]Medstar Health Research Institute, Hyattsville, MD, [3]Georgetown University School of Medicine, Baltimore, MD, [4]Medstar Georgetown University Hospital, Washington, DC

OBJECTIVE: Insufficient iron can lead to a spectrum of disorders including iron deficiency (ID) and iron deficiency anemia (IDA). IDA in pregnancy is associated with low birth weight, preterm birth and perinatal mortality. Screening all pregnant women for ID allows for timely iron supplementation before IDA develops. Ferritin, the gold standard for diagnosing ID, is an acute phase reactant, often leading to false elevations. Reticulocyte hemoglobin equivalent (Ret-He), the measure of functional iron in hemoglobin (Hgb) of reticulocytes, is rapid, cost effective and can be done on the same autoanalyzer as a complete blood count (CBC). Our objective was to describe the Ret-He values across the ID spectrum in the different trimesters of pregnancy.

STUDY DESIGN: Prospective cohort study which included 200 pregnant women recruited at any trimester if a CBC was drawn as part of routine prenatal care. Participants had their blood collected for Ret-He and ferritin at the same time. A ferritin level below 30 ng/mL was defined as ID and Hgb below 11 mg/dL (1st and 3rd trimesters) or 10.5 mg/dL (2nd trimester) was defined as anemia. Based on ferritin and Hgb values women were classified as having no ID, ID alone or IDA. Women were excluded for the following: age < 18, multifetal gestations, abnormal Hgb electrophoresis and anemia due to other etiologies than ID (n=4). A one-way ANOVA with post-hoc analysis was used to calculate the difference between groups.

RESULTS: Of 196 pregnant women included 35, 114 and 47 had no ID, ID and IDA, respectively. The rate of ID and IDA were 71% and 21% in the 1st trimester, 71% and 17% in the 2nd trimester, and 56% and 39% in the 3rd trimester. Across all trimesters Ret-He was statistically different between the three groups. Post-hoc analysis in all trimesters showed the Ret-He was significantly lower in the IDA compared to the ID group. However, there was only a trend of lower Ret-He in the ID compared to the non-ID group (except in the first trimester).

CONCLUSION: Ret-He may be useful in detecting severe ID resulting in anemia but not a mild iron deficient state resulting in ID only.

Table 1 – Reticulocyte hemoglobin equivalent levels in the iron deficiency spectrum groups across gestation

651 Lung size and doppler velocimetry after serial amnioinfusions in fetuses with renal agenesis/ dysplastic kidneys

Edgar Hernandez Andrade[1], Eric P. Bergh[2], Ramesha Papanna[1], Jimmy Espinoza[3], Suzanne Lopez[4], Percy Pacora[1], Anthony Johnson[1]

[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [3]McGovern Medical School at the University of Texas Health Science Center Houston, The Fetal Center- Children's Memorial Hermann Hospital, Houston, TX, [4]McGovern Medical School at The University of Texas, Health Science Center at Houston, Houston, TX

OBJECTIVE: To evaluate changes in fetal lung size/volume and intrapulmonary (IP) circulation after serial amnioinfusions (AI) in fetuses with bilateral renal agenesis/dysplasia and anhydramnios.

STUDY DESIGN: Seven fetuses with anhydramnios due to renal agenesis (n=4) or renal dysplasia (n=3) were managed with serial AI. Each AI targeted an AFI 15-17 cm and was repeated when AFI fell to 5-8 cm until the decision of delivery or PPROM occurred. Lungs size was measured before each AI via observed/expected lung-to-head (O/E LHR) and cardiothoracic ratios (CTR). Pulsatility index (PI) of the IP artery was also obtained. Expectation was to achieve O/E LHR 100% with 5th and 95th percentiles 67% and 133%. CTR, IP-IP values were plotted against reference standards.

RESULTS: No intrauterine deaths; 105 total (Median/case 16: range 11-21) AIs were performed between 17-32 weeks. PPROM occurred in one fetus at 28 weeks and in all others >31 weeks of gestation. All fetuses were born ≥32 weeks; 3/7 newborns (42.9%) survived and were discharged on dialysis until renal transplant. At first AI, all fetuses had low O/E LHR in both lungs (average left 64.2% [11.4]; right 61.4% [13.5]), which improved with repeated AI; however, the left O/E LHR was < 100% in 93.8% of subsequent AIs and < 5th percentile in 37.5% of measurements, and the right O/E LHR was < 100% in, 99% of measurements and < 5th percentile in 53.3% of subsequent AIs. CTR reduced after first AI but remained >90th percentile in 75% (89/120) of the evaluations (Fig. 1). Four fetuses had high IP-PI (>95th percentile) before first AI, which normalized after the second; in two fetuses, IP-PI increased >95th percentile after PPROM. Survivors had larger LHR and lower CTR than non-survivors (O/E LHR left 78.2 vs. 72.05%; right 71.4 vs 63.5%; CTR 0.56 vs. 0.58, respectively).

CONCLUSION: Fetal lung size increased after AI but remained below the expected mean for gestational age. Anhydramnios with severe

thoracic compression in the second trimester of pregnancy may reduce lung plasticity, limiting growth potential.

652 Opportunities to reduce inadequate treatment of syphilis in pregnancy associated with substance use disorder

Alesha M. White, Kristen Warncke, Jessica E. Pruszynski, Emily H. Adhikari

University of Texas Southwestern Medical Center, Dallas, TX

OBJECTIVE: Substance use disorder (SUD) has been identified as a barrier to adequate maternal syphilis treatment. The objective of this study was to evaluate missed opportunities in adequate treatment for syphilis in an urban, safety-net hospital system with a consistent practice of screening and referral for clinical staging and treatment.

STUDY DESIGN: We identified pregnant individuals with syphilis before or during pregnancy using reverse sequence screening followed by referral. Clinical staging for maternal syphilis, fetal evaluation, and treatment occurred in a specialized clinic for infectious diseases in pregnancy according to consistent protocol-driven practices across the healthcare system. SUD was identified by chart review and universal screening. We compared timing of penicillin treatment initiation among individuals with and without SUD. Groups included those treated prior to pregnancy, less than 30 or 30 or more days before delivery, or individuals lost to follow up before clinical staging.

RESULTS: From January 1, 2021 until December 31, 2022, 499 individuals were identified with syphilis prior to or during pregnancy, and 98(19.6%) had SUD. Primary substances used included 35 (35.7%) opioids, 19(19.4%) methamphetamines or stimulants, 19(19.4%) cocaine, 19(19.4%) cannabis, 5(5.1%) alcohol, and 1(1%) benzodiazepines. Compared to individuals without SUD, the frequency of treatment initiation less than 30 days before delivery, defined as inadequate maternal treatment, and the frequency of loss to follow up after referral was higher in individuals with SUD (Table). Among 8 with SUD lost to follow up before clinical staging evaluation and treatment initiation, 3 (38%) used methamphetamines, 3 (38%) opioids, and 2 (25%) cocaine.

CONCLUSION: Among individuals with syphilis prior to or during pregnancy identified in an urban, safety-net healthcare system, 20% have substance use disorders. Despite uniform referral and treatment services for syphilis in pregnancy, facilitating expedited linkages to clinical care for this group may help reduce missed treatment opportunities.

Table. Timing of treatment of syphilis prior to or during pregnancy according to presence of substance use disorder.

	No SUD	*SUD*	*P-value*
Treatment timing of syphilis			0.012
Treated prior to pregnancy	161 (40)	37 (38)	
Treated <30 days before delivery	39 (10)	14 (14)	
Treated 30 or more days before delivery	193 (48)	39 (40)	
Lost to follow up before clinical staging or treatment	8 (2)	8 (8)	
Total	401	98	

Data recorded as n(%). SUD, substance use disorder.

653 Timing of antenatal placenta accreta spectrum diagnosis and impact on clinical outcomes: a multicenter study

Alexa Cohen[1], Henri M. Rosenberg[2], Myah Griffin[3], Itamar Futterman[4], Thomas Owens[5], Nicola F. Tavella[6], Angela Bianco[2], Shoshana Haberman[4], Lois Brustman[7], Meghana Limaye[8], Rebecca H. Jessel[6], Pe'er Dar[9], Georgios Doulaveris[1]

[1]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [2]Mount Sinai Medical Center, New York, NY, [3]NYU Langone Health, Atlanta, GA, [4]Maimonides Medical Center, Brooklyn, NY, [5]Mount Sinai West, New York, NY, [6]Icahn School of Medicine at Mount Sinai Hospital, New York, NY, [7]St. Luke's Roosevelt Hospital Center, New York, NY, [8]NYU Langone Health, New York, NY, [9]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY; on behalf of the New York City MFM Research Consortium

OBJECTIVE: We sought to assess the impact of timing of antenatal diagnosis on management and outcomes in patients with placenta accreta spectrum (PAS).

STUDY DESIGN: This was a multicenter historic cohort of all patients $\geq$ 23 weeks with antenatal suspicion and histopathological confirmation of PAS at four tertiary care institutions from 1/2013 - 6/2022. Gravidas with suspected PAS on ultrasound at 20 weeks or less (early diagnosis) were compared to those diagnosed after 20 weeks (late diagnosis). Primary outcome was planned delivery by multidisciplinary specialists' team. Secondary outcomes were hemorrhage at delivery (defined as estimated blood loss $>$ 1,500L) and massive transfusion (defined as transfusion of 4+ units of packed red blood cells). Chi-square and Fisher's exact test were used as well as a multivariable logistic regression analysis.

RESULTS: 401 cases of histopathologically confirmed PAS were identified during the study period. Of them, 222 (55.36%) were diagnosed antenatally: 65 (29.3%) had early diagnosis and 157 (70.7%) late diagnosis, with mean gestational age at diagnosis of 24.8 weeks. Overall, 180 (44.9%) gravidas had ultrasound for placental assessment in the first trimester and 371 (92.5%) in the second or third trimester. PAS detection rate improved from 13/180 patients (7.2%) in first trimester to 131/341 (38.4%) in second trimester ($p < 0.01$). Pregnancy by assisted reproductive technology (ART) was the only predictor of early antenatal diagnosis (aOR 4.24, 95% CI 1.08-16.67, p=0.03). Delivery was planned in 71.2% of patients with prenatal PAS diagnosis. Patients with early prenatal diagnosis had similar rates of planned delivery (63.1% vs 73.5%, p=0.08), hemorrhage (70.8% vs 58.6%, p=0.08) and massive transfusion (46.2% vs 38.2%, p=0.2), compared to those diagnosed after 20 weeks.

CONCLUSION: In this historic cohort, most patients with antenatal diagnosis of PAS were diagnosed after 20 weeks. Approximately two thirds of patients with a prenatal PAS diagnosis had a planned delivery; diagnosis before 20 weeks did not appear to affect rates of planned delivery or adverse maternal outcomes.

654 Hemoglobin electrophoresis versus kleihauer betke to determine bone marrow suppression in fetuses undergoing intrauterine transfusion

Alexander M. Saucedo[1], Erin Moise[1], Mark Nwokocha[1], Michael Bebbington[1], Kenneth Moise Jr.[2]
[1]University of Texas at Austin, Dell Medical School, Austin, TX, [2]University of Texas Schooll of Medicine at Houston, Houston, TX

OBJECTIVE: The mainstay therapy for fetuses affected by red cell alloimmunization is serial intrauterine transfusions (IUTs). Confirmatory testing to determine when the fetal red cell pool has been replaced with donor cells historically involves the use of the Kleihauer-Betke (KB) stain. Hemoglobin (Hgb) electrophoresis testing may be more rapid with a reduced cost of analysis. We aim to determine the correlation between fetal Hgb electrophoresis versus the traditional KB stain.

STUDY DESIGN: This is a prospective cohort of all alloimmunized singleton pregnancies undergoing IUT between 1/1/2021 and 7/1/2023. Maternal and fetal characteristics were collected along with indication for IUT. A final fetal blood sample was obtained at the conclusion of each transfusion and sent for KB and Hgb electrophoresis. The primary outcome was the assessment of these parameters in their ability to predict replacement of the fetal circulating red cell population with donor cells. Linear regression analysis and repeated measures analysis of variance were performed, P values less than 0.05 were considered significant.

RESULTS: A total of 56 IUTs were performed in 16 patients. There were 39 (69.6%) final KB stain values collected and compared to 30 (53.6%) final Hgb electrophoresis values. Hgb electrophoresis when compared to the KB stain demonstrated a significant correlation (R^2 = 0.93; 95% CI, 0.61-0.76; P < 0.001). This same finding held true when examining correlation at each individual IUT as well. The final KB stain and Hgb electrophoresis value significantly decreased with each transfusion (P=0.003). A predominance of adult donor blood was noted by the third transfusion for both lab indices.

CONCLUSION: Fetal Hgb electrophoresis obtained at time of IUT demonstrates a significant correlation with the traditional KB stain. Given the increased cost, training, and time necessary to obtain a KB stain; substitution for an automated Hgb electrophoresis should be considered with comparable results.

Lab Indices per IUT Attempt								
Variable	1st IUT	2nd IUT	3rd IUT	4th IUT	5th IUT	6th IUT	7th IUT	P value
KB Stain [a]	19.90 (12.10)	9.14 (7.83)	1.78 (3.78)	0.64 (0.86)	1.36 (1.70)	3.86 (-)	0.03 (0.04)	0.003
Hgb Electrophoresis [b]	27.26 (7.21)	13.35 (10.61)	3.40 (6.80)	0.33 (0.70)	1.35 (1.61)	3.7 (-)	0 (-)	0.003

655 Inpatient early postpartum glucose tolerance testing in a large community hospital

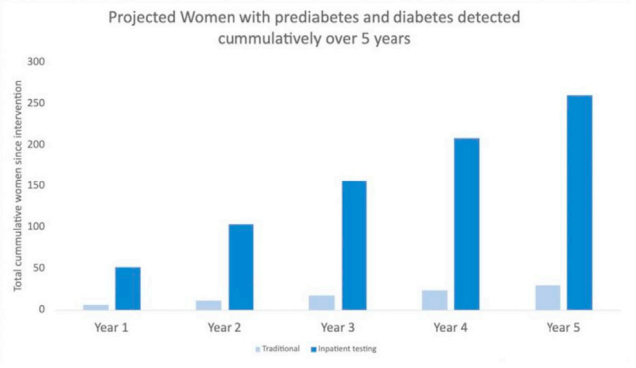
Alexandra Hammerquist[1], Tara Banaszek Daming[2]
[1]Mercy Hospital St Louis, St. Louis, MO, [2]Mercy Hospital St. Louis, St. Louis, MO

OBJECTIVE: Screening for gestational diabetes (GDM) in the postpartum period helps identify a population at risk for diabetes. To achieve greater compliance, it has been proposed that a 2-hour glucose tolerance test be performed inpatient on postpartum day 2. We hypothesize that implementation of this practice in a community hospital will improve postpartum testing compliance rates. The primary outcome is to compare pre-implementation compliance rates to post-implementation compliance rates. Secondary outcomes include determining the percentage of pre-diabetes and diabetes identified, and calculating the anticipated missed patients from previous testing strategies.

STUDY DESIGN: This is a retrospective cohort study performed after the completion of a quality improvement project. Patients included were diagnosed with GDM and delivered between 10/01/21 and 3/26/2023. The study was powered to detect a 10% or greater improvement rate (alpha =0.05, beta= 80%). The pre-intervention group included 437 patients and the post-intervention group included 203 patients. Data reports were obtained from the EMR and statistical analysis performed.

RESULTS: The pre-intervention group had a compliance rate of 15.3% and the post-intervention group had a compliance rate of 50.3% (p= 0.001). The pre-intervention group diagnosed 9% of women with pre-diabetes and diabetes whereas the post-intervention group diagnosed 26.4% (p= 0.004). Extrapolation of this data reveals that over a 5-year period, 240 patients with abnormal glucose metabolism may be missed utilizing only the previous testing strategy. Non-compliance with inpatient testing was associated with vaginal delivery (p=0.002) and increased gravidity and parity (p= 0.02 and p=0.001).

CONCLUSION: There was a greater than 300% improvement in compliance after implementation of an inpatient postpartum glucose tolerance test, and 9 times more women were diagnosed with abnormal glucose metabolism. While the compliance rate significantly improved, it is lower than pilot studies. This is likely multifactorial and further research is necessary to discern reasons for non-compliance.



656 Vasa previa management: analysis of maternal and neonatal outcomes between inpatient and outpatient approaches

Alexandria Weymon[1], Mary Benz[1], Katherine Huebner[1], Marcos Cordoba[2], Vivian Romero[2]
[1]Michigan State University College of Human Medicine, Grand Rapids, MI, [2]Corewell Health, Michigan State University College of Human Medicine, Grand Rapids, MI

OBJECTIVE: Vasa previa (VP) patients are commonly offered antenatal hospitalization because of the increased risk of fetal mortality. We aimed to compare obstetric and neonatal outcomes for VP patients managed inpatient and outpatient.

STUDY DESIGN: This is a retrospective study on singleton patients diagnosed with VP at a single institution over 5 years comparing obstetric history, transvaginal cervical length (TVCL) ultrasound measurements, and neonatal outcomes between inpatient and outpatient management groups determined by risk factors for preterm birth.

RESULTS: There were 42 patients with singleton pregnancies that had a VP diagnosis. Of these, 22 were managed inpatient and 20 managed outpatient. The groups had a statistically significant difference in history of PTD (7 vs 1; p=0.0471). Average TVCL measurements at 20-24 weeks and 30-34 weeks between the inpatient (39.7 ± 5.7 and 39.2 ± 6.0 mm) and outpatient groups (41.2 ± 9.0 and 36.7 ± 6.6 mm) were not statistically different (p=0.56 and 0.27). However, inpatients were delivered earlier than outpatients (34.4 vs 35.0 weeks, p< 0.0001) and had significantly smaller infants (2.37 kg vs 2.82 kg, p=0.001). More neonatal complications occurred in the inpatient group compared to the outpatient group (64% vs 30%, p=0.029) and the length of stay in the neonatal intensive care unit (NICU) was greater in the inpatient than outpatient group (16 vs 3 days, p=0.0013). See Table 1.

CONCLUSION: Our study found a higher risk of composite neonatal complications and a clinically significant difference in NICU length of stay in the inpatient group. A statistically significant difference in history of preterm delivery was noted between inpatient and outpatient managed VP patients which could have been an important factor in the incidence of complications noted in the inpatient group. Careful selection of candidates for outpatient management could be a favorable clinical approach based on this study's results.

Clinical Course and Neonatal Outcomes of Patients Managed Inpatient Vs. Outpatient for Vasa Previa

Variables	Inpatient (n=22)	Outpatient (n=20)	p-value
Maternal age (years)	32.4 ± 5.4	31.6 ± 4.0	0.5628
Gravida	3 [2, 4]	2 [1, 4]	0.3411
Parity	1 [0, 2]	1 [0, 1.5]	0.6434
History of PTD	7	1	0.0471
TVCL 20-24 weeks	N=19 39.7 ± 5.7	N=15 41.2 ± 9.0	0.5574
TVCL 30-34 weeks	N=17 39.2 ± 6.0	N=15 36.7 ± 6.6	0.2709
Gestational age at delivery (years)	34.4 [33.7, 34.9]	35 [35, 36.6]	<0.0001
Unscheduled Cesarean Section	8 (36%)	3 (15%)	0.1158
Infant birth weight (grams)	2366.6 ± 380.3	2821.6 ± 464.7	0.0012
Neonatal complications	14 (64%)	6 (30%)	0.0293
Neonatal age of discharge	16 [7, 23]	3 [3, 12.5]	0.0013

657 Timing of insulin initiation in Gestational Diabetes and fetal growth curves

Alina Tvina, Hannah McBride, Maria Brix, Sabrina Morales, Sadica Murphy, Anna Palatnik
Medical College of Wisconsin, Milwaukee, WI

OBJECTIVE: There is a large variation in clinical practices regarding the optimal insulin management of gestational diabetes (GDM). Data suggests earlier and tighter pharmacotherapy improves maternal and neonatal outcomes but can have different implications on fetal growth. We sought to explore the association between lower threshold for insulin initiation in GDM and fetal growth curves throughout pregnancy.

STUDY DESIGN: Retrospective cohort study comparing 2 groups of patients with GDM requiring insulin 2011-2019 in a single academic center. Group 1 was started on insulin when ≥ 40% of capillary blood glucose (CBG) values were above goal, and Group 2 when 20-39% of CBG values were above goal. Patients who received less than two ultrasounds (US) in the third trimester, GDMA1, and those who received oral antidiabetic medications were excluded. The primary outcome was estimated fetal weight using the Hadlock formula. Secondary outcomes were individual biometry indices (head circumference, biparietal diameter, abdominal circumference, and femur length) obtained during serial growth ultrasounds. Generalized linear models were used to model and compare the change in estimated fetal weight and in individual biometry indices as a function of gestational age between the two groups of GDM patients.

RESULTS: A total of 401 participants met all inclusion criteria. There were no significant differences in baseline maternal characteristics, gestational age at insulin initiation, or number of US performed throughout pregnancy between the groups. Estimated fetal weight and biometry indices were similar between the groups (Figure). The abdominal circumference curve demonstrated slower growth in the late third trimester in Group 2, the earlier insulin initiation group, but the difference did not reach statistical significance.

CONCLUSION: Tighter insulin therapy does not affect fetal growth curves throughout pregnancy. The effect of earlier insulin initiation on reducing the growth of the abdominal circumference should be examined in larger cohorts.

Figure: Fetal growth indices as a function of gestational age by two groups of insulin initiation in GDM: ≥ 40% vs. 20-39% abnormal CBG*.

658 Impact of an SMME committee on all cause and preventable maternal morbidity

Alison M. Kimura[1], Alex Ewing[1], Erin L. Thurston[1], Freda H. Kelley[1], Kacey Eichelberger[2]
[1]Prisma Health, Greenville, SC, [2]USC School of Medicine Greenville, Greenville, SC

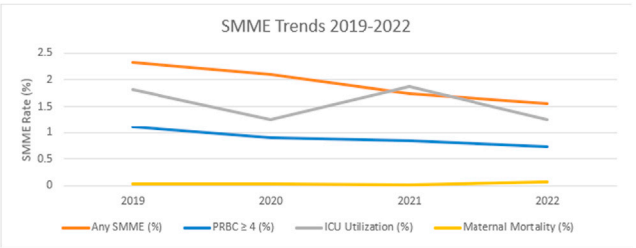
OBJECTIVE: An excess burden of maternal morbidity is experienced by pregnant people in the American south compared to other regions of the US. Implementation of a high fidelity, multidisciplinary severe maternal morbidity event (SMME) review committee may be

associated with reductions in preventable events over time. Our objective was to measure temporal changes in SMME at the state's largest delivery hospital after SMME committee implementation. We hypothesized that preventable SMME rates would decrease over time.

STUDY DESIGN: A cross-sectional study of cases reviewed at SMME committee from 2019-2022, including pregnant or postpartum people who received ≥4 units of PRBCs, had unplanned ICU admission, were diagnosed with eclampsia, were diagnosed with an infection with opportunity for improvement, underwent an unplanned hysterectomy, or were referred for review. We compared the rates of patients receiving ≥ 4 units of PRBCs, ICU utilization, and maternal mortality across years using Mann Kendall Trend Tests.chi squared trend tests.

RESULTS: 316 cases of SMME out of 16,501 total deliveries are included in this analysis (SMME rate, 1.9%). There was a significant reduction in the rate of SMME from 2019-2022 (p=0.04). The most common causes of SMME were postpartum hemorrhage (30.0%); "other events" including DKA, renal failure, solid organ arterial aneurysm rupture, and respiratory failure (21.8%); and pre-eclampsia/eclampsia (12.7%). The rate of ICU utilization significantly decreased over time (p=0.02), but blood product utilization did not. Forty-one percent of cases were considered preventable (n=130) and opportunity for improvement was identified largely at the provider level (30.8%, n=40) and combination provider-system level (13.8%, n=18). The rate of preventability did not change over the 4 years.

CONCLUSION: The implementation of an SMME review committee was associated with significant reductions in absolute SMME rate and ICU utilization over time.



659 Yield of serial prenatal ultrasounds for detection of congenital heart block in SSA/SSB antibody-positive patients

Alyssa Yeung[1], Justina Shafik[2], Alexa Cohen[1], Georgios Doulaveris[1], Pe'er Dar[3]
[1]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [2]MS, Bronx, NY, [3]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY

OBJECTIVE: Serial prenatal screening for fetal congenital heart block (CHB) has been suggested for gravidas with anti-Sjogren's syndrome-related antibody A (SSA) or B (SSB) by the American Heart Association. Recent guidelines released by the Society for Maternal and Fetal Medicine (SMFM) recommend against routine screening. This study sought to assess the yield of screening patients with SSA/SSB antibodies with fetal echo for the diagnosis of CHB.

STUDY DESIGN: This is a historical cohort study of all patients with positive SSA or SSB antibodies from 1/2010 to 10/2022 . Patients had ≥1 fetal mechanical Doppler PR interval screen and were followed to ≥ 34 weeks. Multiple gestations or known fetal anomalies were excluded. Screening protocol consisted of weekly screens from 16 to 28 weeks and monthly afterwards. A prolonged PR interval was >140 milliseconds and, if identified, a corticosteroid course was offered. The primary outcome was the diagnostic yield of screening for the diagnosis of at least first-degree CHB.

RESULTS: 124 patients met inclusion criteria and had a total of 1,628 ultrasounds for PR interval. The majority (69.4%) had systemic lupus erythematosus and 22.6% had Sjogren's syndrome. Median number of ultrasounds per patient was 10 (IQR 10). Three of 124 patients had prolonged PR intervals (2.4%). The false negative rate was 0%. There needed to be 43 patients screened and 542 ultrasounds done to detect one CHB case. Table 1 shows the outcomes of the screened positive patients. One patient was diagnosed with third-degree CHB and elected for termination. The other two had first-degree CHB, were treated with corticosteroids, did not progress to complete CHB and had healthy neonates with asymptomatic first-degree CHB.

CONCLUSION: In our historic cohort, the screen positive rate was 2.4%, similar to previous reports. Fetuses diagnosed with a first degree block had a successful therapeutic intervention. In light of conflicting recommendations from different organizations, large prospective studies are needed to evaluate PR interval screening for CHB and the effectiveness of treatment with corticosteroids.

Table 1. Characteristics and outcome of patients with positive PR interval screening

Patient	Age	Autoimmune disease	Gestational age at diagnosis	Fetal echocardiography finding	Intervention	Outcome
1	21	Systemic lupus	20 weeks	3rd degree AV block	Dexamethasone	Elective termination at 22 weeks gestation
2	29	Systemic lupus	31 weeks	1st degree AV block	Dexamethasone	Persisted after treatment. No progression to complete block. Delivered at 34 weeks, neonate with asymptomatic 1st degree block
3	33	Systemic lupus	33 weeks	1st degree AV block	Dexamethasone	Improved after treatment. Delivered at full-term, neonate with asymptomatic 1st degree block

660 Offspring long-term infectious morbidity following pregnancies with cervical cerclage

Amir Snir[1], Polina Schwarzman[2], Tamar Wainstock[3], Eyal Sheiner[4]
[1]Soroka University Medical Center, Beer-Sheva, HaDarom, Israel, [2]Soroka, Beer-Sheva, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom, [4]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: Cervical cerclage is an acceptable procedure in women with cervical insufficiency and known as effective in prevention of preterm delivery. Since the presence of foreign body during pregnancy may change the vaginal microbiom, we aimed to study whether a cervical cerclage is associated with long-term infectious morbidity of the offspring.

STUDY DESIGN: A population-based cohort study was performed at a tertiary medical center, including all singleton deliveries between the years 1991-2023. Long-term infectious morbidity was compared among offspring after pregnancies with and without cervical. A Cox proportional hazards model was used to control for confounders.

RESULTS: Out of 354,940 offspring included in the analysis, 0.4% (n=1416) were following pregnancies with cervical cerclage. Total infectious morbidity was comparable between the two study groups (OR 1.0, 95% CI 0.9 − 1.1; p = 0.369, Table). However, while controlling for confounders such as gestational age and mode of delivery, a significant association between cervical cerclage

placement during pregnancy and long term offspring's infectious morbidities **risk reduction** was demonstrated (adjusted HR 0.9, 95% CI 0.87 − 0.99, $p = 0.036$).

CONCLUSION: Cervical cerclage placement during pregnancy might have a protective effect for long-term infectious morbidity of the offspring. Further investigation regarding the influence of cervical cerclage on vaginal microbiome may be valuable.

Offspring long-term infectious morbidity after pregnancy with and without cervical cerclage

Infectious Morbidity	No Cerclage n = 354940	Cerclage n = 1416	OR (95% CI)	P Value
Respiratory infections	176546 (51.6)	730 (49.7)	1.1 (.09 – 1.2)	0.173
Viral infections	11450 (3.2)	42 (3.0)	0.9 (0.7 – 1.2)	0.581
Ophthalmic infections	6197 (1.7)	25 (1.8)	1.0 (0.7 – 1.5)	0.955
Skin infections	15672 (4.4)	63 (4.4)	1.0 (0.8 – 1.3)	0.951
Bacterial infections	5171 (3.0)	20 (3.2)	0.9 (0.7 – 1.2)	0.889

661 Offspring long-term morbidities in pregnancies with cervical cerclage

Amir Snir[1], Polina Schwarzman[2], Tamar Wainstock[3], Eyal Sheiner[4]

[1]Soroka University Medical Center, Beer-Sheva, HaDarom, Israel, [2]Soroka, Beer-Sheva, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom, [4]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: Cervical cerclage is a standard procedure used to reinforce the cervix in order to reduce pregnancy loss and preterm birth in patients with cervical insufficiency. Although cerclage is an accepted practice and profoundly investigated procedure, there is limited evidence regarding cerclage consequences on long-term neonatal outcomes. The present study was aimed to investigate the long-term morbidities of offspring following pregnancies with cervical cerclage.

STUDY DESIGN: A population-based cohort study was performed in a tertiary medical center including all deliveries between the years 1991-2023. Long-term neurological, endocrine, gastrointestinal and cardiac morbidities among offspring following pregnancy with and without cervical cerclage were compared. Diagnoses were predefined based on ICD-9 codes, as recorded in the hospital medical files. Multiple gestations and pregnancies with chromosomal abnormalities were excluded. Kaplan-Meier survival curves were used for cumulative long term morbidities over time and Cox proportional hazards models were constructed to control for confounders.

RESULTS: Out of 354,940 offspring included in the analyses, 0.4% (n=1416) were following pregnancies with cervical cerclage. The crude rates of long-term neurological morbidity (OR 1.4, 95% CI 1.3 − 1.6; p = 0.001), endocrine morbidity (OR 1.4, 95% CI 1.1 − 1.7; p = 0.001) and gastrointestinal morbidity (OR 1.3, 95% CI 1.1 − 1.4; p = 0.001) were ***higher*** among offspring following pregnancies with cervical cerclage. However, using Kaplan-Meier survival curve analyses, the association between cervical cerclage and all long-term morbidities was not significant (Table). Likewise, using Cox regression models, controlling for confounders such as gestational age, cervical cerclage was **not** associated with long-term neurological, endocrine, gastrointestinal and cardiac morbidities of the offspring (Table).

CONCLUSION: Cervical cerclage placement is not an independent risk factor for long-term neurological, endocrine, gastrointestinal and cardiac morbidities of the offspring.

Table. The association between cervical cerclage placement during pregnancy and offspring long-term morbidity

Morbidities	Cerclage n = 1416	No Cerclage n = 354940	P Value	Kaplan Meier Log-Rank Test	Adjusted HR* (95% CI)
Neurological Morbidities (%)	279 (19.7)	51465 (14.5)	0.001	0.13	1.07 (0.95 – 1.20)
Cardiac Morbidities (%)	24 (1.7)	7622 (2.1)	0.241	0.25	0.7 (0.47 – 1.05)
Endocrine Morbidities (%)	97 (6.9)	17703 (5.0)	0.001	0.48	1.02 (0.83 – 1.25)
Gastrointestinal Morbidities (%)	377 (26.6)	77919 (22.0)	0.001	0.55	0.93 (0.84-1.03)

663 ChatGPT promises but fails to correctly calculate pregnancy due dates

Amos Grünebaum[1], Moti Gulersen[2], Frank A. Chervenak[1], Eran Bornstein[3]

[1]Zucker School of Medicine at Hofstra of Northwell, New York, NY, [2]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA, [3]Lenox Hill Hospital, New York, NY

OBJECTIVE: "ChatGPT" refers to models in OpenAI's Generative Pre-trained Transformer (GPT) series that are designed for natural language understanding and generation. ChatGPT has swept the world since its launch in November 2022 and has quickly become the most disruptive and fastest growing new innovation including in medicine. When we asked ChatGPT if it was good in calculating the pregnancy due date, it answered: "I can provide general calculations for pregnancy due dates based on common methods, such as the date of the last menstrual period, ovulation date, conception date, or IVF transfer date." The objective of this study was to assess ChatGPT's ability to perform obstetric calculations, specifically calculating the estimated pregnancy due date (EDD).

STUDY DESIGN: Prospective study asking ChatGPT to calculate the EDD based on different parameters including the first day of the last menstrual period (LMP), different number of cycle days and LMP, fertilization day, ovulation day, implantation day, IVF transfer day of 5-day embryo. The same calculations were regenerated 10 times and the EDD calculated by ChatGPT as within 3 days of the correct EDD was deemed correct.

RESULTS: ChatGPT always calculated an EDD. though it calculated the EDD only 67.5% of the time correctly. Its accuracy was highest calculating the EDD by fertilization, conception, and IVF transfer dates, and lowest by LMP with different menstrual cycle lengths and by implantation date. Some of the estimated due dates which ChatGPT calculated were over 5 months inaccurate from the actual EDD.

CONCLUSION: It is no surprise that ChatGPT is not perfect. It all instances, ChatGPT returned a EDD using different ways and methods and explanations to arrive at its results, even fully explaining incorrect methods to calculate the incorrect EDD. ChatGPT is known to fail at basic math, and also can't seem to answer simple logic questions, arguing completely incorrect facts. In conclusion, we we have shown that ChatGPT users should not fully rely on its answers.

Due Date calculation based on	Correct due date calculated % (Correct/Total)
First day last menstrual period (LMP)	70% (7/10)
LMP and 21 cycle days	30 % (3/10)
LMP and 35 cycle days	0% (0/10)
Fertilization date	100% (10/10)
Ovulation date	80% (8/10)
Conception date	100% (10/10)
Implantation day	60% (6/10)
IVF transfer day	100% (10/10)
TOTAL	**67.5% (54/80)**

664 Occipital posterior vacuum assisted delivery: primiparity's impact on maternal and neonatal outcomes

Anat Pardo[1], Or Bercovich[2], Inbal Navon[3], Shir Nahum Fridland[3], Noam Pardo[4], Hadas Zafrir danieli[3], Ohad Houri[5], Eran Hadar[6], Sharon Perlman[3]

[1]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, Tel-Aviv, Israel, [2]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, HaMerkaz, [3]Helen Schneider Hospital for Women, Rabin Medical Center, Petach Tikwa, HaMerkaz, [4]Sheba Medical Center, Tel Hashomer, Ramat-Gan, Tel Aviv, [5]Rabin Medical Center, Tel Aviv, Israel, [6]Rabin Medical Center, Petach-Tikva, HaMerkaz

OBJECTIVE: Occipital posterior (OP) position presents unique challenges during delivery. Women with persistent OP facing vacuum-assisted delivery (VAD) are at a higher risk of failure and maternal and neonatal adverse outcomes. The precise impact of parity on the outcomes of VADs in the occipital posterior position remains an area of interest and requires in-depth investigation. We aimed to explore the influence of parity on VAD outcomes in fetuses presenting in the OP position.

STUDY DESIGN: Retrospective cohort study at a single tertiary center between 2012 and 2022 included 3,913 primiparous and 1,109 multiparous women who underwent VAD. The primary outcome was failed VAD. Secondary outcomes included maternal complications (postpartum hemorrhage, blood product transfusion, OASIS) and neonatal outcomes (umbilical cord pH $<$ 7.1, 5-minute Apgar score $<$ 7, NICU admission). Outcomes were compared between occiput anterior (OA) and OP vertex positions. Univariate analysis and multiple logistic regression were performed to identify independent predictors of the primary outcome.

RESULTS: 977 parturients in the Primiparous OP group (prim-OP) and 411 in the multiparous OP group (multi-OP) were compared to 2936 parturients in the prim- OA and 698 in the multi- OA group. Prim-OP had higher BMI, higher rates of spontaneous pregnancy, and higher birth weight than prim-OA ($p< 0.001$; $p=0.018$; $p=0.029$, respectively). Additionally, women in the prim- and multi-OP groups were significantly younger ($p< 0.001$; $p=0.039$) than their equivalents in the OA groups. The second stage of labor was longer in both OP groups compared to OA ($p< 0.001$). The prim-OP group demonstrated a higher rate of failed VAD and composite adverse maternal and maternal-neonatal outcomes (adjusted odds ratio 2.039, 95% CI 1.270 - 3.274; aOR 1.273, 95% CI 1.028 - 1.57; aOR 1.335, 95% CI 1.099 - 1.621, respectively). This effect was not observed in the multiparous OP group.

CONCLUSION: OP position during VAD in primiparous women is linked to higher failure risk and adverse outcomes for both mother and neonate, while no such effect is seen in multiparous women.

Table 1: Baseline characteristics and adverse pregnancy outcomes for occiput posterior versus occiput anterior in primiparous vs multiparous women

Variable	Primiparous				Multiparous			
	Occiput Anterior n=2,936	Occiput Posterior n=977	p-value	Adjusted OR (95% CI)	Occiput Anterior n = 698	Occiput Posterior n = 411	p-value	Adjusted OR (95% CI)

Composite maternal and neonatal includes 5-min Apgar <7, Umbilical Cord pH<7.1, NICU admission, PPH, blood products transfusion and OASIS

665 Widespread maternal immunity to RSV suggests naturally-occurring antibodies provide incomplete neonatal protection: implications for vaccination

Andrea G. Edlow[1], Paola Andrea Lopez Zapana[2], Lydia Shook[3], Olyvia Jasset[4], Kathryn J. Gray[5], Douglas L. Lauffenburger[2], Michal A. Elovitz[6]

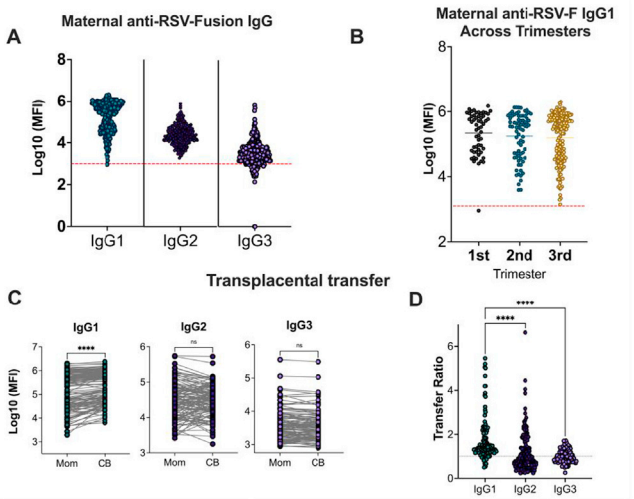
[1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Massachusetts General Hospital, Waban, MA, [4]Massachusetts General Hospital, Department of Obstetrics and Gynecology, Boston, MA, [5]Brigham and Women's Hospital, Boston, MA, [6]Women's Biomedical Research Institute, Icahn School of Medicine at Mount Sinai, New York, NY; on behalf of the Human Immunology Project Consortium and the Maternal 'Omics to Maximize Immunity (MOMI)

OBJECTIVE: RSV vaccination in pregnancy was recently demonstrated to significantly reduce neonatal morbidity and mortality from RSV infection. The known vulnerability of neonates to severe RSV disease suggests that either many pregnant individuals do not have anti-RSV antibodies, or the antibodies from natural infection do not confer protection against severe disease for all infants. Understanding maternal antibody response is critical to informing vaccination strategies that optimize neonatal protection, we sought to evaluate maternal immunity and transplacental transfer of maternal IgG from natural RSV infection in a large cohort of pregnant individuals.

STUDY DESIGN: Antibodies against RSV subtypes A and B pre-and post-fusion protein (RSV-F) were assayed in the plasma of 303 pregnant participants from geographically-distinct pregnancy cohorts, spanning all 3 trimesters of pregnancy, with a Luminex assay. In a subset of 126 participants, transplacental transfer of maternal anti-RSV IgG was assessed in paired maternal-cord plasma. Differences between IgG levels in maternal-cord pairs was determined by Wilcoxon signed rank tests.

RESULTS: Anti-RSV-F IgG1 was detectable in 99.6% (302/303) maternal and 100% (126/126) cord samples. All anti-RSV-F IgG subclasses were present in the majority of mothers (Fig 1A). IgG levels were stable across trimesters of pregnancy (Fig 1B). In the 126 maternal-cord pairs, anti-RSV IgG was efficiently transferred across the placenta in 99.2% (125/126) of pairs (Fig 1C). IgG1 transferred most efficiently (mean cord:maternal ratio of 1.7, Fig 1D).

CONCLUSION: Across multiple pregnancy cohorts, nearly all pregnant individuals have anti-RSV-F IgG that crosses the placenta and is detectable in cord blood. These findings suggest that naturally-acquired maternal antibodies do not confer complete protection to neonates. Understanding how antibody characteristics differ between naturally-acquired infection and vaccination in pregnant individuals is critical for the future optimization of maternal vaccination aimed at neonatal health.



(A) Maternal Log_{10}MFI levels of IgG subclasses against RSV-F. Red dashed line indicates detection level, which is defined as 5 SD above the PBS background. (B) Maternal anti-RSV-F IgG1 titers across trimesters of pregnancy. Red dashed line indicates 5 SD above the PBS background. (C) Dot plots demonstrate the relative RSV-F-specific IgG levels in maternal (M)-cord blood (CB) pairs. Significance was determined by Wilcoxon signed-rank test, ****p<0.0001. ns: not significant. (D) Cord:maternal transfer ratios for RSV-F-specific IgG subclasses. Gray line indicates expected/efficient transfer (transfer ratio ≥ 1). Significance was determined by Kruskal-Wallis test followed by Dunn's post-hoc comparisons. ****p<0.0001.

666 Improving compliance with umbilical cord management in vigorous term infants through a quality improvement initiative

Angela R. Seasely[1], Yuanfan Ye[1], Christianna Tu[2], Deepti Sharma[1], Colm P. Travers[2], Akila Subramaniam[1]

[1]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: Despite ACOG's recommendations in 2012, the implementation of delayed umbilical cord clamping (DCC) in term infants for at least 30-60 seconds as opposed to immediate cord clamping (ICC) < 30 seconds has not been universally adopted by providers. We sought to improve provider compliance with DCC among vigorous term infants.

STUDY DESIGN: Prospective cohort quality improvement study completed in two phases involving vigorous term infants (≥ 37 weeks). Patients with suspected placenta accreta spectrum and twin gestations were excluded. Pre-intervention data were collected from 4/1/2022-9/30/2022. Phase 1 was conducted from 10/1/2022-2/28/2023 and included implementing DCC of 30-60 seconds. Phase 2 was conducted from 3/1/2023-5/31/2023 and included implementing DCC of >60 seconds. We provided monthly education for providers and a multidisciplinary team reviewed outcomes and process measure data throughout the study. Our SMART aim was to decrease the relative rate of ICC of term infants by 75%. Our global aim was to decrease rates of NICU admission and unexpected need for pediatric providers at delivery. Mitigating maternal and neonatal factors that may deter providers from performing DCC were tracked. Comparisons between categorical and continuous variables were made with Chi-squared, ANOVA, and exact test as appropriate.

RESULTS: Of the 3303 term singleton deliveries during the study period, 282 infants were excluded due to non-vigorous status at delivery (8.4% pre-intervention, 9.0% Phase 1, 8.0% Phase 2, p=0.7). Thus, a total of 3021 patients were included in the analysis. No differences were seen in baseline characteristics (age, race, insurance status, mode of delivery, type of anesthesia) across the study period. The rate of ICC decreased by 91% from the baseline rate over 8 months (74.6% pre versus to 6.6% post). Maternal and neonatal outcome did not differ over the study period (Table).

CONCLUSION: We successfully implemented delayed cord clamping in vigorous term infants through a quality improvement initiative focused on provider education. The rate of ICC was decreased from baseline by 91%.

	Preintervention (n=1271)	Phase 1 (n=1096)	Phase 2 (n=654)	P-value
SMART AIM

667 Timing of postpartum pharmacologic thromboprophylaxis relative to delivery and anesthesia

Ann M. Bruno[1], Christine M. Warrick[2], Amanda A. Allshouse[1], Torri D. Metz[1]

[1]University of Utah Health, Salt Lake City, UT, [2]University of Utah, Park City, UT

OBJECTIVE: To describe the rate of adherence to obstetric (OB) and anesthesia (ANE) guidelines for timing of postpartum pharmacologic prophylaxis initiation. Secondarily, to evaluate the association between guideline adherence and venous thromboembolism (VTE) and complications.

STUDY DESIGN: Retrospective cohort of patients delivering at a single academic center from 2015-2023 receiving postpartum low molecular weight heparin (LMWH) prophylaxis. Those with an antepartum VTE or on therapeutic anticoagulation were excluded. OB guideline adherence was defined as LMWH initiation within 4-6 hours after vaginal, or 6-12 hours after cesarean, delivery. ANE guideline adherence was defined as LMWH initiation ≥12 hours post-neuraxial ANE placement and ≥4 hours post-neuraxial removal. Secondary outcomes included VTE (pulmonary embolism

or deep vein thrombosis), readmission, reoperation, and wound complications (hematoma, seroma, or infection) within 6 weeks postpartum. Median time from delivery and neuraxial ANE to LMWH initiation, and rate of adherence to guidelines was assessed. Multivariable models estimated the association between guideline adherence and outcomes.

RESULTS: Of 7,414 included, 4,894 (66%) underwent cesarean and 5,985 (95.8%) received neuraxial ANE. Median time from delivery to LMWH initiation was 15 hours (IQR 12-21) post-cesarean and 14 hours (IQR 11-20) post-vaginal delivery. Time from neuraxial placement and removal to LMWH initiation after cesarean was 21 hours (IQR 14-29) and 13 hours (IQR 9-17), respectively, and after vaginal was 24 hours (IQR 17-30) and 12 hours (IQR 8-18), respectively. Overall, 1,177 (16%) were OB guideline adherent, 4,816 (81%) ANE guideline adherent, and 739 (10%) both OB and ANE adherent. OB guideline adherence was associated with decreased readmission and wound complications, but no difference in VTE or reoperation (Table). ANE guideline or combined guideline adherence was not associated with any outcomes.

CONCLUSION: Adherence to OB and ANE guidelines for timing of postpartum pharmacologic prophylaxis was low. OB guideline adherence was associated with lower complications.

Table. Obstetric and anesthesia guideline adherence and the association between guideline adherence compared to non-adherence and outcomes

Guideline	Guideline Adherence		Adherence vs Non-Adherence	
Obstetric	**Yes (N= 1,177)**	**No (N= 6,237)**	**OR (95% CI)**	**aOR (95% CI)**
Venous thromboembolism	2 (0.2)	13 (0.2)	0.82 (0.18-3.62)	–
Readmission	17 (1.4)	177 (2.8)	0.50 (0.30-0.83)	0.52 (0.31-0.87)
Reoperation	10 (0.8)	64 (1.0)	0.83 (0.42-1.61)	1.26 (0.60-2.65)
Wound complication*	23/N=1098 (2.1)	126/N=3796 (3.3)	0.62 (0.40-0.98)	0.61 (0.39-0.96)

668 Validation of an extended maternal comorbidity index (MCI) for prediction of severe maternal morbidity

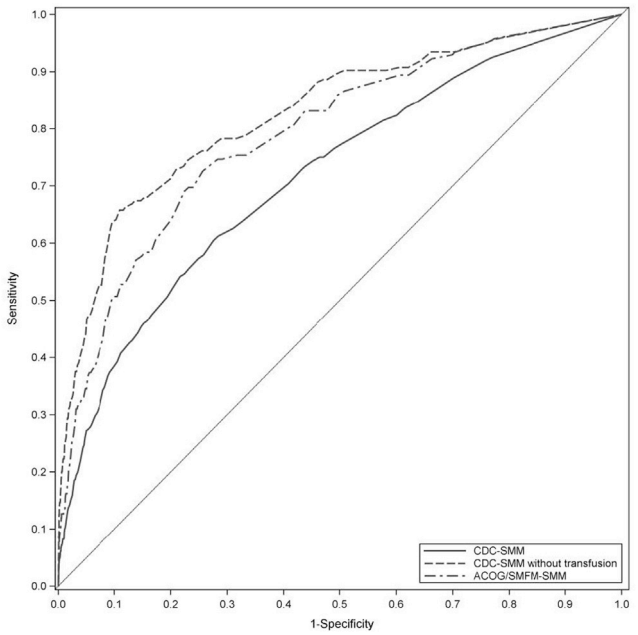
Ann M. Bruno
University of Utah Health, Salt Lake City, UT; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: The expanded maternal comorbidity index (MCI) developed by Leonard et al uses pre-existing maternal health conditions (e.g., hypertension, asthma, etc.) to produce a risk score that predicts severe maternal morbidity (SMM). This tool has been adopted into clinical and research use without external validation in a data source not reliant on administrative codes. We assessed the validity of the MCI to predict SMM in a modern obstetric cohort with detailed medical record abstraction.

STUDY DESIGN: Secondary analysis of a multicenter cohort of patients delivering on randomly selected days at 17 U.S. hospitals from 2019 through 2020. Data were manually abstracted from the medical record by trained staff. The MCI risk score was applied to all individuals within the cohort. The primary outcome was SMM as defined by the Centers for Disease Control and Prevention (CDC-SMM). Secondary outcomes included SMM without blood transfusion and the ACOG/SMFM definition of SMM (i.e., transfusion of ≥4 units of blood or intensive care unit admission). The median MCI score was calculated for the cohort, and the performance of the MCI risk score to predict SMM was assessed using the area under the receiver operating curve (AUC).

RESULTS: Of 20,898 eligible patients, 668 (3.2%, 95% CI 3.0-3.4%) experienced CDC-SMM, 184 (0.9%, 95% CI 0.8-1.0%) experienced CDC-SMM without transfusion, and 142 (0.7%, 95% CI 0.6-0.8%) experienced ACOG/SMFM-SMM. In this cohort, the most common comorbidities were anemia (22.7%), maternal age at least 35 years (22.2%), and previous cesarean delivery (18.4%). The median MCI score in the cohort was 57.5 (IQR 47.5-71.5), which corresponded to a SMM risk of 7.9% (IQR 5.3-13.5%). The AUC for the MCI to predict CDC-SMM was 0.72 (95% CI 0.70-0.74; compared to AUC 0.78 in Leonard et al), CDC-SMM without transfusion was 0.83 (95% CI 0.79-0.86) and ACOG/SMFM-SMM was 0.79 (95% CI 0.75-0.83; Figure).

CONCLUSION: We externally validated the expanded MCI for prediction of SMM in a contemporary obstetric cohort. These findings support the ongoing use of this tool in research and clinical settings.



669 National trends and outcomes for births requiring maternal transfers

Anna Farooqi[1], Alexander M. Friedman[2], Nasim C. Sobhani[3], Mary D'Alton[4], Timothy Wen[3]
[1]Texas Tech University Health Sciences Center, Amarillo, TX, [2]Columbia University, New York, NY, [3]University of California, San Francisco (UCSF), San Francisco, CA, [4]Columbia Presbyterian Medical Center, New York, NY

OBJECTIVE: With an increase in maternal care deserts expected data on maternal transfers prior to birth is critical. Using national data, we sought to assess national trends, epidemiology, and adverse outcomes in this cohort.

STUDY DESIGN: Birth hospitalizations were identified in the 2010-2020 Nationwide Readmissions Database for this cross-sectional analysis. Transfers were defined as admissions to a separate hospital with a patient disposition of hospital transfer immediately prior to

birth hospitalization. Trends analysis of maternal transport, outcomes by transfer status, and transfers to larger or teaching facilities was conducted using Joinpoint regression and expressed as annual average percent change (AAPC) and 95% confidence intervals (CI). Unadjusted and adjusted logistic regression models were fit to assess transfer status's association with adverse clinical outcomes adjusting from demographic, clinical, and hospital characteristics.

RESULTS: Of 37.4 million birth hospitalizations, 3,521 (9.4 per 100,000 births) births required transfer prior to birth at a stable rate of 8.4 to 8.9 transfers per 100,000 births from 2010 to 2020. Rates of transfers to larger hospitals increased from 15.7% to 23.6% (AAPC 5.7%, 95% CI: 1.8%, 10.4%) while transfers to teaching hospitals decreased from 65.6% to 45.3% (AAPC -3.4%, 95% CI: -4.6%, -2.4%) during this time. Births requiring transfers had higher rates of clinical factors such as hypertensive disorders of pregnancy (38% vs. 10%), multiple gestation (8% vs. 2%) and obesity (19% vs. 8%). Transferred birth hospitalizations had higher prevalence and adjusted odds of complications including non-transfusion severe maternal morbidity, needing critical care procedures, and shock/sepsis (Table).

CONCLUSION: Maternal transfers prior to birth are uncommon with a decreased trend of transfer to academic centers and disproportionate burden of adverse outcomes. As care continues to regionalize, maternal levels of care can aid in streamlining transfers and mitigating morbidity by enhancing coordination and appropriate resource allocation.

Table: Outcome Demographics and Analysis by Transport Status

	No Transfer		Transfer		Unadjusted		Adjusted	
Outcome	N	%	N	%	OR	95% CI	aOR	95% CI
Non-transfusion severe maternal morbidity	296,642	0.8%	243	6.9%	9.28	7.52, 11.47	3.00	2.36, 3.82
Transfusion	429,295	1.2%	194	5.5%	5.02	4.08, 6.18	2.03	1.63, 2.53

670 Peripartum factors associated with breastfeeding after cesarean birth

Anna Palatnik
Medical College of Wisconsin, Milwaukee, WI; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: Cesarean birth has been associated with lower rates of breastfeeding (BF) initiation, yet it is unknown what specific peripartum clinical factors are associated with likelihood of BF following a cesarean. Our objective was to analyze a large prospective and diverse contemporary cohort of cesarean births in the US and identify what factors among patients who had a cesarean are associated with lower rates of BF initiation. We hypothesized that perioperative anemia and postpartum hemorrhage (PPH) will be positively associated, and that receipt of tranexamic acid (TXA) will not be associated with BF initiation following cesarean birth.

STUDY DESIGN: Secondary analysis of participants with BF data who were enrolled in a randomized trial of tranexamic acid for prevention of postpartum hemorrhage at the time of cesarean. Those who experienced neonatal death within 24 hours of birth, delivery < 34 weeks, or had multifetal gestations were excluded. The primary exposures included third-trimester anemia (hemoglobin < 10g/dL), PPH (defined as estimated blood loss at >1L or receipt of packed RBCs intraoperatively), and receipt of TXA as the study drug. Multivariable logistic regression was performed adjusting for baseline maternal covariates and available social determinants of health.

RESULTS: Of 10,293 participants included in this analysis, 8119 (78.9%) initiated BF in the hospital. Those who did were older, more likely to be nulliparous, married, of White race, Hispanic ethnicity, and privately insured (p< 0.001 for all). Among those with third trimester anemia (n=915), the rate of starting BF in the hospital was 66.7% versus 80.1% among those without anemia (n=9371). In multivariable modeling, third-trimester anemia was associated with lower frequency of BF initiation (adjusted OR 0.68, 95% CI 0.58-0.80). Receipt of TXA and PPH were not (Table).

CONCLUSION: Third-trimester anemia, a modifiable risk factor, was associated with 32% lower odds of BF initiation after cesarean birth, but PPH and receipt of TXA were not.

Table. Peripartum factors associated with breastfeeding initiation in the hospital

	Breastfeeding started in hospital (n=8119)	No Breastfeeding in hospital (n=2174)	Unadjusted OR (95% CI)	Adjusted OR[1] (95% CI)
Third trimester anemia (Hb <10 g/dL)	610 (7.5)	305 (14.0)	0.50 (0.43, 0.58)	**0.68 (0.58, 0.80)**
Postpartum hemorrhage[2]	532 (7.9)	156 (8.4)	0.93 (0.77, 1.12)	0.97 (0.79, 1.18)
Receipt of tranexamic acid	4062 (50.0)	1113 (51.2)	0.95 (0.87, 1.05)	0.98 (0.89, 1.08)

CI, confidence interval; Hb, hemoglobin
1. Multivariable models were adjusted for maternal age, body mass index, race, ethnicity, nulliparous status, marital status, use of private insurance, tobacco use during pregnancy, scheduled vs. unscheduled cesarean status, hypertensive disorders of pregnancy, diabetes, gestational age at delivery, and anesthesia.
2. Postpartum hemorrhage was defined as intraoperative estimated blood loss >1L or receipt of packed red blood cells intraoperatively.

671 Impact of amniotomy timing after foley bulb on induction of labor outcomes in obese patients

Annabeth Brewton[1], Kristen Lilly[1], Jill Maples[2], Alicia Mastronardi[1], Megan L. Young[1], Summer Shore[1], Sarah Shelton[1]
[1]University of Tennessee Graduate School of Medicine, Knoxville, TN, [2]University of Tennessee Medical Center, Knoxville, TN

OBJECTIVE: Patients with obesity are less likely to spontaneously labor and more likely to require induction of labor (IOL) for pregnancy-related and comorbid conditions. Optimal timing of amniotomy in patients with obesity undergoing IOL is not well described and provider preference varies. We therefore aimed to describe the impact of timing of artificial rupture of membranes (AROM) on labor outcomes.

STUDY DESIGN: This retrospective cohort study involved nulliparous patients with term, singleton, vertex pregnancies undergoing IOL at a single academic center from January 2020-May 2021. Patients with pre-pregnancy body mass index (BMI) > 30 kg/m2 undergoing cervical ripening with a foley bulb were included. Patients were grouped into quartiles by timing of amniotomy, defined as the earliest 25th percentile to the later 75th percentile. The primary outcome was total induction time, defined as time of foley bulb placement to delivery. Additional secondary outcomes were measured for the first quartile of amniotomy timing in comparison to the remaining three quartiles (Table 1). Fisher's Exact, Two-Sided or Pearson Chi-Square tests were used for data analysis with p < .05 used to define significance.

RESULTS: Overall, 104 deliveries were analyzed with 26 patients in each quartile of amniotomy timing. Early amniotomy was associated with significantly less total induction time. There were no significant differences in rates of cesarean delivery, prolonged rupture of membranes, or chorioamnionitis (Table 1).

CONCLUSION: Among patients with a pre-pregnancy BMI > 30, earlier amniotomy may be associated with shorter overall induction times without increasing adverse outcomes. While retrospective, these data provide insight into the importance of amniotomy for

labor induction and suggest amniotomy should not be delayed out of concern for predisposing patients to chorioamnionitis or cesarean delivery. Future work should include rates of obstetric hemorrhage and NICU admission. Ultimately, randomized controlled trials should be performed to better guide decisions for amniotomy timing in patients with obesity.

Table 1: Labor outcomes by amniotomy quartile

Outcome	Early Amniotomy (<25th percentile; n=26)	Early-Mid Amniotomy (26th to 50th percentile; n=26)	Mid-Early Amniotomy (50th – 75th percentile n=26)	Mid-Late Amniotomy (>75th percentile; n=26)	P
Method of Delivery					1.000

672 Outcomes of operative vaginal deliveries by hospital volume status

Annika Willy, Alyssa R. Hersh, Bharti Garg, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

OBJECTIVE: It is unknown whether outcomes after operative vaginal delivery (OVD) differ by hospital characteristics, such as volume of operative vaginal deliveries in a hospital. Therefore, we sought to assess whether outcomes after OVD differ significantly between hospitals of different volumes of OVD.

STUDY DESIGN: This was a retrospective cohort study of singleton, non-anomalous, term deliveries in California between 2007 and 2019. We stratified hospitals into three categories based on proportion of OVD among all deliveries; the categories were low volume (< 5%), medium volume (5-7%) and high volume (≥7%). Chi-squared and multivariable logistic regression analyses were utilized to assess an association between OVD and adverse perinatal outcomes, among three hospital volumes separately.

RESULTS: In this study, we included 4,629,808 births, of which 31.7% were in low volume hospitals, 34.8% in medium-volume and 33.5% in high volume hospitals. Among low volume hospitals, OVD were associated with higher odds of obstetrics anal sphincter injuries (aOR=5.85 (5.68, 6.03)), cervical lacerations (1.33 (1.13, 1.56)), postpartum hemorrhage (1.21 (1.17, 1.26)), shoulder dystocia (3.81 (3.63, 4.00)), Apgar scores of < 7 at 5 minutes (1.92 (1.80 , 2.06)), NICU admissions (1.35 (1.31, 1.39)), facial nerve palsy (4.68 (3.18, 6.91)), scalp birth injuries (3.96 (3.85, 4.08)), and brachial plexus injury (5.07 (4.38, 5.87)). Medium-volume and high-volume hospitals had similar higher odds of perinatal outcomes too.

CONCLUSION: We found that obstetric outcomes were similar among births via OVD at hospitals of differing volumes. These findings illustrate the importance of ensuring providers at hospitals of all sizes are trained in operative deliveries, as low-volume settings can have outcomes consistent with hospitals of medium and high

v

Table 1: Perinatal Outcomes in Operative Vaginal Deliveries, stratified by hospitals volume of operative vaginal deliveries.

	Hospitals with low proportion of operative vaginal deliveries (<5%)			Hospitals with medium volume of operative vaginal deliveries (5-7%)			Hospitals with high volume of operative vaginal deliveries (≥7%)		
	No OVD	OVD	aOR (95% CI)	No OVD	OVD	aOR (95% CI)	No OVD	OVD	aOR (95% CI)

673 Mental health needs after preterm birth: A qualitative assessment of Black women's experiences

Arthurine Zakama[1], Mlka Mengesha[2], Florence Momplaisir[3], Michal A. Elovitz[4], Jennifer Lewey[2], Michelle P. Debbink[5]
[1]University of California, San Francisco (UCSF), San Francisco, CA, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania School of Medicine, Philadelphia, PA, [4]Women's Biomedical Research Institute, Icahn School of Medicine at Mount Sinai, New York, NY, [5]University of Utah, Salt Lake City, UT

OBJECTIVE: Black women (BW) face higher rates of spontaneous preterm birth (sPTB) than their White counterparts. BW endure a higher prevalence of perinatal mental health conditions with more debilitating symptoms; however, these often go unaddressed. Our study sought to reveal the perspectives of BW on the impact of sPTB on their mental health and their desired interventions.

STUDY DESIGN: We conducted a qualitative interview study of self-identified BW who delivered at one teaching hospital, had a sPTB between 24w0d and 33w6d from July 2020 to July 2022, spoke English, and were at least 18 years old. Interview participants were recruited and interviewed until thematic saturation was achieved. Data were analyzed through inductive coding. Interrater reliability testing was performed. Standardized questions captured participants' perceptions of mental health symptoms, barriers and facilitators to care seeking, and recommendations for improving mental health after sPTB.

RESULTS: Of 47 eligible participants, 13 (27.7%) completed screening and interviews. Interrater reliability scores showed almost perfect coding agreement (mean kappa 0.99 (SD 0.01)). Participants experienced self-blame, isolation, and prolonged duration of mental health symptoms (Table 1). Participants noted disrespectful communication and a lack of mental health resources. They felt dismissed and neglected while seeking care and experienced medical racism. These barriers negatively impacted their mental health and decreased their desire to re-engage with the healthcare system. Personalized care, family-centered communication, and racial representation facilitated care. Participants recommended improved

patient-provider communication, specialized mental health providers, support groups, and culturally sensitive care.

CONCLUSION: Black women with a sPTB endured prolonged mental health sequelae, worsened by neglect, dismissiveness, and medical racism. Implementing explanatory communication models, providing culturally responsive care, support groups, and sPTB-trained mental health providers are needed.

Table 1: Representative themes and quotes

Significant Themes	Representative Quotes
Mental Health Impact	
Self-Blame	"I didn't know what did I do wrong for my son to be born prematurely. I just felt like everything was my fault. Even though it wasn't, I had to learn that it wasn't my fault" "I kept asking, what did I do differently that I was able to have my son with no issues and then now I'm having my daughter at 32 weeks?"
Isolation	"I didn't really share it much with many people. There weren't really many people to talk to about it. And, yeah, I think I spoke to my doula about it. Sort of to my therapist. … the people that I pay to listen [to me], basically."
Prolonged duration of symptoms	"Still to this day. It was always that question of 'why me?' It's still like a mental battle to this day." "So it was a lot for me emotionally because I am still dealing with it at the moment, but at that time it was definitely overwhelming."
Barriers	
Neglect	"I sat in the waiting room and I literally had to scream at them, 'get me somewhere!' I was contracting, the pain was awful. I got rolled into the emergency department and they just left me there. I'm like yo, I'm literally pregnant. I'm in pain. Why is that not a red flag? Anything could be happening with my daughter on the inside. Why is it not a red flag?"
Dismissiveness	"I've given birthed five kids. So, I know when it's a contraction. So, I was telling her and she's like, 'Well, you're too -- you're too early to have contractions, ma'am. You're not having contractions.' Mind you, I had my daughter like an hour later."
Medical racism	"And yeah, I just felt like a lot of that could have been prevented, had leading up to it, they just checked me out in person. Or I also wonder if I was a white mom, if I told them that I felt like I was having contractions because I gave birth before I know what a contraction is. If they would have told me to just come in and just check just to see [what was happening]"
Facilitators	
Family-centered communication	"Just the amount of time that they spend with each of the babies and the families, explain the certain things. I think one night I left, she was burped in an incubator regularly and then the next day I came back and she had on goggles with a light on and the nurse said and explained to me her [bilirubin] levels, she helped me read the numbers. She explained to me why she was on the machine."
Personalized care	"I had one doctor…I felt she was amazing. She was calling on me. She was checking in on me. She was actually the one that was for NICU moms"
Racial representation	"[I connected to] a Black social worker, who I didn't feel like would've tried to make me feel badly or question what I did to cause this."
Recommendations	
Improved provider-patient communication	"I'd say just being a little more transparent. I guess [sometimes they think] withholding information…, it's easier. Because you don't know how some patients would react, but that wasn't the case for me. Uncertainty actually makes me more anxious than knowing what I face. So, I think it shouldn't be like a blanket response. I felt like it was a blanket response. They gave information [only] as needed."
Specialized mental health providers	"…Certain therapists that have been through [PTB] so they can really get deep and talk about it because I still got unfinished questions and answers - all of that in my head - that I want to talk to my therapist about, but she's no longer my therapist."
Support groups	"…maybe like a moms group for women who have had preterm labor or just some type of resources to connect to women who have already been there and experienced this. Because it's very isolating. I think that would have been the biggest help for me because I felt like I was like winging it a lot on my own."
Cultural sensitivity	"Labor itself especially being an African American woman is scary. My entire pregnancy I was explaining to my kids and I was explaining to my husband, this is life or death for me. There's not a guarantee that I'm going to walk out of this hospital after I have her, so I think just that in general is I just need them to be more understanding with the position that Black women are in." "Definitely a more diverse staff, not just in nursing, but in all aspects [would have helped me]"

674 Mean arterial pressure as an early predictor of preeclampsia: A retrospective cohort study

Ashten Waks[1], Gina F. Milone[2], Megan C. Oakes[3]

[1]University of California Irvine, Long Beach, CA, [2]University of California Irvine, Irvine, CA, [3]MemorialCare Miller Children's and Women's Hospital, Long Beach, Long Beach, CA

OBJECTIVE: To estimate the utility of early pregnancy mean arterial pressure (MAP) for predicting later preeclampsia diagnosis, and to compare the predictive ability of MAP with that of the risk categories recommended by the United States Preventive Services Task Force (USPSTF).

STUDY DESIGN: A retrospective cohort study of all pregnant patients with a first prenatal visit by 16 weeks' gestation and delivered in our system from 1/2021 – 12/2022. MAP was calculated using data captured at the initial visit. Patients' preeclampsia risk was assigned based on 2021 USPSTF guidance, in which elevated risk was defined as having 1 high risk or 2 or more moderate risk factors for the condition and low risk was defined as having none. The primary outcome was diagnosis of preeclampsia. The predictive abilities of MAP and the USPSTF risk categories were estimated using area under the receiver operating characteristic curves (AUROC). The Youden index was used to identify an optimal MAP cut-point, and the predictive characteristics of this value were compared to those associated with an elevated USPSTF risk category.

RESULTS: Of 1325 patients, 146 (11.0%) developed preeclampsia. MAP outperformed the USPSTF risk categories with respect to predicting this diagnosis, as evidenced by an AUROC of 0.73 compared to 0.64 ($X^2 = 2.70$, p = 0.10). The optimal MAP cut-point for predicting preeclampsia was 88.5 mm Hg. Contrasted with an elevated USPSTF risk category, MAP predicted preeclampsia with improved sensitivity (74.7 vs 61.6%), comparable specificity (62.3 vs 66.6%), and improved positive and negative predictive values (19.7 vs 18.6%; 95.2 vs 93.3%). MAP was similarly predictive of preeclampsia regardless of a patient's determined risk for the condition.

CONCLUSION: Early pregnancy MAP is a modest predictor of preeclampsia and has improved characteristics as a screening test relative to application of the USPSTF risk categories. Particularly among low-risk patients – who might not otherwise be prescribed aspirin for preeclampsia prophylaxis – early pregnancy MAP may be considered as an adjunct for preeclampsia risk stratification.

Predictive characteristics of 'optimal cut-points' of mean arterial pressure for predicting preeclampsia

Characteristic	Preeclampsia, any EGA	Preeclampsia, severe	Preeclampsia, ≤37w0d	Preeclampsia, ≤34w0d
Optimal cut-point, mm Hg	88.5	90.5	88.5	86.5
Area under ROC curve	0.73	0.67	0.72	0.69
Sensitivity (95% CI)	74.7% (66.8 – 81.5)	64.9% (52.9 – 75.6)	84.8% (71.1-93.7)	88.9% (51.8 – 99.7)
Specificity (95% CI)	62.3% (59.4 – 65.0)	68.4% (65.8 – 71.0)	59.7% (56.9 – 62.4)	48.3% (45.6 – 51.0)
Positive predictive value (95% CI)	19.7% (17.9 – 21.6)	10.8% (9.2 – 12.8)	7.0% (6.2 – 8.0)	1.2% (0.9 – 1.5)
Negative predictive value (95% CI)	95.2% (93.7 – 96.3)	97.1% (96.1 – 97.8)	99.1% (98.2 – 99.5)	99.8% (99.0 – 99.9)
Positive likelihood ratio (95% CI)	1.98 (1.76 – 2.23)	2.05 (1.70 – 2.48)	2.10 (1.83 – 2.42)	1.72 (1.36 – 2.18)
Negative likelihood ratio (95% CI)	0.41 (0.31 – 0.54)	0.51 (0.38 – 0.70)	0.25 (0.13 – 0.51)	0.23 (0.04 – 1.46)

675 Understanding Fluid Shifts in Hypertension: Postpartum Point-of-Care Ultrasound of the Inferior Vena Cava and Aorta

Awa Sanneh[1], Jenna L. Racine[1], Amy Godecker[1], Kara K. Hoppe[1], J. Igor Iruretagoyena[2]

[1]University of Wisconsin Madison, Madison, WI, [2]University of Wisconsin Meriter, Madison, WI

OBJECTIVE: Assessment of the inferior vena cava (IVC) and aorta using point-of-care ultrasound to estimate central venous pressure (CVP) is a commonly used practice across medical specialties. Our objective is to study postpartum fluid dynamics using IVC collapsibility and aorto-caval (IVC:Ao) indices measured on postpartum days (PPD) 1-3; and to compare changes in IVC collapsibility and IVC:Ao indices between postpartum patients with and without hypertensive disorders of pregnancy (HDP). Our hypothesis is postpartum patients with HDP will have lower IVC collapsibility and higher IVC:Ao indices than controls, signifying hypervolemia.

STUDY DESIGN: Prospective cohort study of postpartum singleton pregnancies delivered 24 to 41+6 weeks gestation with and without HDP conducted from 2020-23. Standardized ultrasound measurements of the IVC and aorta were performed daily starting PPD1 through PPD3. The primary outcomes were IVC collapsibility and IVC:Ao index. Individual IVC and aorta measurements were secondarily evaluated.

RESULTS: 123 (62 control and 61 HDP) postpartum participants were included in our analysis. HDP patients received more IV fluids than controls. IVC collapsibility was similar between groups across PPD 1-3. IVC:Ao index was significantly lower in hypertensive patients on PPD 1 (1.25 ± 0.3 vs 1.1 ± 0.3; p=0.003). HDP patients had significantly smaller IVC maximum diameter on PPD 1 (2.0 ± 0.4 cm vs 1.78 ± 0.5 cm; p=0.004). Indices between the two groups did not differ on PPD 2 and 3. Secondary analysis showed patients with preeclampsia with severe features had lower IVC:Ao indices compared to controls (1.25 ± 0.3 vs 1.03 ± 0.4; p=0.006).

CONCLUSION: Postpartum patients with HDP showed a lower IVC:Ao index and smaller IVC diameters on PPD 1, correlating with a lower CVP compared to controls despite receiving more IV fluids. The indices increased on PPD 2 and 3, which may signify fluid mobilizing to the intravascular space. Bedside point-of-care evaluation of the IVC and aorta can help providers understand postpartum fluid dynamics and may help identify candidates for diuresis.

Point-of-care Assessment of IVC and IVC:Aorta Indices from Postpartum Day 1 to 3

Postpartum Day 1			
	Control (n=62)	Hypertension (n=61)	p-value
IVC Collapsibility (%)	29.3 ± 12.3	30.1 ± 17.5	0.78
IVC:Ao Index	1.25 ± 0.3	1.1 ± 0.3	0.003
IVC maximum (cm)	2.0 ± 0.4	1.78 ± 0.5	0.004
Aorta (cm)	1.6 ± 0.2	1.6 ± 0.2	0.52
Postpartum Day 2			
	Control (n=60)	Hypertension (n=61)	p-value
IVC Collapsibility (%)	32.7 ± 16.8	31.3 ± 17.6	0.66
IVC:Ao Index	1.27 ± 0.3	1.2 ± 0.3	0.2
IVC maximum (cm)	1.96 ± 0.5	1.91 ± 0.5	0.53
Aorta (cm)	1.56 ± 0.2	1.63 ± 0.2	0.06
Postpartum Day 3			
	Control (n=6)	Hypertension (n=11)	p-value
IVC Collapsibility (%)	20.5 ± 13.8	33.2 ± 18	0.15
IVC:Ao Index	1.38 ± 0.3	1.14 ± 0.3	0.14
IVC maximum (cm)	2.13 ± 0.4	1.89 ± 0.5	0.37
Aorta (cm)	1.57 ± 0.2	1.65 ± 0.2	0.47

676 White coat hypertension validated on home blood pressure monitoring as predictor of adverse pregnancy outcomes

Beth Sobba[1], Naiha Mussarat[2], Mariella Gastanaduy[3], James D. Toppin[4], John A. Morgan[5], Shannon McCloskey[1], Joseph R. Biggio Jr.[6], F. B. Will Williams[1]

[1]Ochsner Clinic Foundation, New Orleans, LA, [2]Ochsner Clinical Foundation, New Orleans, LA, [3]Ochsner Clinic Foundation, LA, [4]Ochsner Health, New Orleans, LA, [5]Ochsner Clinic, Metairie, LA, [6]Ochsner Health System, New Orleans, LA

OBJECTIVE: White coat hypertension (WCH) is a common hypertensive disorder associated with cardiac morbidity in the non-pregnant population. Less described is WCH's impact on pregnancy outcomes. The advent of home blood pressure monitoring (HBPM) allows for comprehensive blood pressure assessment throughout pregnancy. Among pregnant patients undergoing HBPM, we aim to determine the impact of WCH on subsequent diagnosis of hypertensive disorders of pregnancy (HDP) and neonatal morbidity.

STUDY DESIGN: We performed a retrospective cohort study of singleton pregnancies receiving prenatal care and delivering in a large regional health system from October 2016 to March 2022. Documented pre-pregnancy chronic hypertension, antihypertensive use, severe BP elevations before 20 weeks gestation (EGA), multiple gestations, and any elevations on HBPM warranted exclusion. WCH was defined as clinic BP of either 140-159 mmHg systolic or 90-109 mmHg diastolic on two separate occasions prior to 20 weeks EGA without elevations on HBPM. The comparison group had no elevated BP in clinic or at home prior to 20 weeks EGA. Our primary outcome was diagnosis of HDP. Secondary outcomes included 5-minute Apgar score < 5, neonatal intensive care admission, small for gestational age (SGA), stillbirth, and preterm birth < 37 weeks EGA. Regression analyses controlling for obesity, maternal age, pre-gestational diabetes, and payer status generated adjusted odds ratios with 95% confidence intervals.

RESULTS: Of 18,916 eligible pregnancies, 3,177 (17%) were classified as WCH while 15,739 (83%) were classified as normotensive. WCH patients had higher median age and body mass index, and were more likely to have pre-gestational diabetes. HDP occurred in 33% of the WCH group compared to 13% in the normotensive group (aOR 2.97, 95% CI 2.71-3.26). Stillbirth, SGA, and preeclampsia with severe features were all increased in the WCH group (Table).

CONCLUSION: WCH, as defined by mild BP elevations early in pregnancy not-replicated on HBPM, was associated with increased risk for HDP and perinatal morbidity.

Table. Secondary outcomes by white coat hypertension status

	Normotensive	White Coat Hypertension	
	15,739	3,177	Odds Ratio
	N (%)	N (%)	(95% CI)
Gestational hypertension	1,418 (9.0%)	767 (24.1%)	**3.22 (2.92-3.55)**
Preeclampsia	1,090 (6.9%)	565 (17.8%)	**2.91 (2.61-3.25)**
Preeclampsia with severe features	603 (3.8%)	357 (11.2%)	**3.18 (2.77-3.65)**
5-minute Apgar < 5	264 (1.7%)	92 (3.0%)	**1.76 (1.38-2.24)**
Neonatal intensive care	766 (4.9%)	296 (9.3%)	**2.01 (1.75-2.31)**
Stillbirth	115 (0.7%)	49 (1.5%)	**2.13 (1.52-2.98)**
Small for gestational age	1,126 (7.2%)	315 (10.1%)	**1.45 (1.27-1.65)**
Preterm delivery	1,528 (9.7%)	597 (18.8%)	**2.15 (1.94-2.39)**

677 Unusual presentation of renal tubular dysgenesis: a case report and review of current literature

Bethany Erickson[1], Mary Best[1], Morgan Wallen[1], Norman Meyer[2]

[1]University of Tennessee, Memphis, TN, [2]Regional Medical Center, Memphis, Memphis, TN

OBJECTIVE: Renal tubular dysgenesis (RTD) is a rare disorder that arises from disruption of the renin-angiotensin system. This condition can result from maternal use of RAS-blocking agents or, more rarely, from a mutation in the genes encoding its components. The most common genes implicated include ACE, REN, AGT, and AGTR1. This condition typically presents as severe oligohydramnios or anhydramnios prior to 22-weeks gestation with subsequent pulmonary hypoplasia and associated Potter sequence.

STUDY DESIGN: In this report, we present a case of a novel mutation in the Angiotensin II Receptor Type 1 (AGTR1) gene and a review of the current literature.

RESULTS: A female infant born at 36-weeks to a multigravida mother with a history of two prior neonatal demises. The pregnancy was complicated by intrauterine growth restriction and anhydramnios beginning at 28-weeks gestation. Fetal kidneys, renal arteries, and bladder had all been unremarkable on previous imaging. However, upon further review, the fetal kidneys appeared homogenous with poorly differentiated calyces. At birth, the infant was anuric, and renal ultrasound revealed poor corticomedullary differentiation with increased bilateral renal echogenicity. Genetic evaluation of the infant revealed a novel mutation in the AGTR1 gene (c.704dup (p.Asn235Lysfs*28)) as the likely cause of Autosomal-recessive renal tubular dysgenesis (AR-RTD). This mutation is currently a variant of undetermined significance. Parental and sibling genetic analysis is

currently pending. However, if this mutation is present, it would reclassify this variant as pathogenic.

CONCLUSION: RTD most often presents with severe oligohydramnios prior to 22-weeks gestation, leading to severe pulmonary hypoplasia and Potter sequence. This, however, is not universal. A better understanding of the correlation between genotype and phenotype could help guide medical decision making and treatment for these infants. A potential new pathogenic mutation for AR-RTD may also be recognized.

678 Impact of body mass index and gestational weight-gain on neonatal outcomes in polycystic ovarian syndrome

Bharti Garg, Sacha Krieg, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

OBJECTIVE: Previous studies have shown that women with PCOS are more susceptible to overweight/obesity and experience higher gestational weight gain (GWG), however, none of the studies examined the interaction effect of BMI and GWG on adverse outcomes. In this study, we will examine association of BMI and GWG with neonatal outcomes in patients with PCOS.

STUDY DESIGN: This is a retrospective cohort study using California's linked vital statistics-hospital discharge data (2008-2019). We included patients with singleton births and gestational age of 37-42 weeks. Patients with PCOS were determined using ICD-9 and ICD-10 codes. GWG was used to group the subjects into below, within or above IOM guidelines. Multivariable logistic regression analyses were used to examine interaction between BMI and GWG; adjusted predicted probabilities were calculated and reported as cases per 1,000 births.

RESULTS: A total of 14,201 patients with PCOS were included, of whom 4,201 (29.6%) were normal weight, 3,676 (25.9%) were overweight and 6,324 (44.5%) were obese. In obese patients with GWG above guidelines, probability of macrosomia (204, 95% CI: 190, 218) vs 74, 95% CI: 62, 87) cases per 1000 births), large for gestational weight gain (215 (201, 228)) vs 68 (56, 80)), and shoulder dystocia (24 (18, 29) vs. 13 (7, 18)) were higher as compared to normal weight patients with GWG within guidelines (Table). Although obesity as well as GWG above guidelines were risk factors independently; however, when combined together, the risk of adverse outcomes was much higher.

CONCLUSION: Our study shows that excessive weight gain is associated with adverse neonatal outcomes. These results might be helpful for providers to provide counselling during pregnancy in PCOS patients.

Table: Multivariable logistic regression showing predicted probabilities from interaction term of pre-pregnancy BMI and gestational weight gain on the neonatal outcomes among PCOS patients in California (2008-2019).

	Macrosomia Cases per 1000 births (95% CI) *	Large for gestational age Cases per 1000 births (95% CI) *	Shoulder dystocia Cases per 1000 births (95% CI) *
Normal weight & below guidelines	43 (30, 56)	36 (24, 47)	12 (6, 19)
Normal weight & within guidelines	74 (62, 87)	68 (56, 80)	13 (7, 18)
Normal weight & over guidelines	134 (117, 152)	125 (108, 143)	27 (18, 35)
Overweight & below guidelines	41 (22, 60)	45 (25, 64)	25 (10, 39)
Overweight & within guidelines	82 (65, 100)	76 (59, 92)	18 (10, 27)
Overweight & over guidelines	153 (138, 168)	155 (140, 170)	15 (10, 21)
Obese & below guidelines	96 (80, 111)	105 (89, 121)	19 (9, 22)
Obese & within guidelines	138 (121, 155)	145 (128, 162)	21 (14, 29)
Obese & over guidelines	204 (190, 218)	215 (201, 228)	24 (18,29)

*Adjusted for maternal race and ethnicity, age, education, insurance, parity and smoking status.

679 Impact of amnioinfusions on the ultrastructure of the amnion in a rodent model

Samuel Martin[1], Jose L. Peiro[1], Marc Oria[2], Braxton Forde[3]
[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]University of Cincinnati College of Medicine, Cincinnati, OH, [3]University of Cincinnati Medical Center, Cincinnati, OH

OBJECTIVE: Amnioinfusions are an important part of many fetal therapy procedures. Prior research has shown that in vitro, amnioinfusions with normal saline (NS) and lactated ringer's (LR) leads to apoptosis of human amniotic membranes when compared with a novel synthetic amniotic fluid. We sought to evaluate the effect of amnioinfusions with commercially available fluids compared to a novel synthetic amniotic fluid ***in vivo*** in a rodent model.

STUDY DESIGN: This study was IACUC approved through Cincinnati Children's Hospital Medical Center. At day E17.5, pregnant rats underwent midline laparotomy to amnio exchange with removal of amniotic fluid around the rat fetus and 1 to 1 replacement of fluid with NS, LR, or a synthetic amniotic fluid, termed "amnio-well" (AW). As a control, some fetuses in each pregnant rat did not undergo amnio-exchange. Rats were harvested at day E20.5 and uterus and amnion specimens were evaluated via electron microscopy for ultrastructure changes as well as the rat amnions evaluating for matrix metalloproteinase 9 (MMP9) expression (a known executor of collagenase and amnion degradation in rodents) via Western Blot. Vinculin was used as a loading control. Western Blot images were analyzed via ImageJ® Software.

RESULTS: Under scanning electron microscopy, there was an increase in amniotic microfractures, as well as amniotic epithelial cellular shrinkage, signs indicative of impending rupture of membranes. These changes were not seen with amnio well nor control (Figure). The MMP9/Vinculin expression was noted to be 1.53 (IQR 1.09, 2.27) in control, compared with , with 2.82 (IQR 2.01, 3.09, $p = 0.072$) in NS, 5.86 (IQR 1.06, 6.72, $p = 0.038$) in LR and 1.58 (IQR 1.41, 1.74, $p = 0.395$) in AW.

CONCLUSION: The ultrastructure of the amnion, after amnio exchange with normal saline and lactated ringers, was notable for increased microfractures and cellular shrinkage, compared to use of a synthetic amniotic fluid. Increased MMP9 production was noted in LR when compared with control. Further study into the impact of amnioinfusions on the amniotic membrane is warranted.

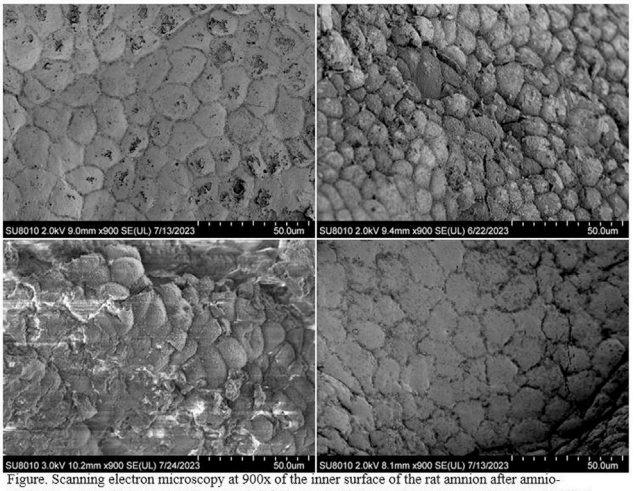

Figure. Scanning electron microscopy at 900x of the inner surface of the rat amnion after amnio-exchange. Top Left- Control without amnioinfusion. Top Right- amnio-exchange with Normal Saline (NS). Bottom Left- amnio-exchange with Lactated Ringer's (LR). Bottom Right- amnio-exchange with Amnio-well. Cells after exposure to NS and LR exhibit shrinking as well as microfractures between cells, with greater shrinkage in NS and greater microfractures in LR.

680 Impact of obesity class on unscheduled cesarean delivery outcomes

Bree A. Goodman[1], Shannon E. Beermann[1], Katherine Carbonell[1], Lucy Simpson[2], Katherine Massa[1], Ebony B. Carter[3], Jeannie C. Kelly[3], Antonina I. Frolova[4], Anthony O. Odibo[4], Nandini Raghuraman[4]

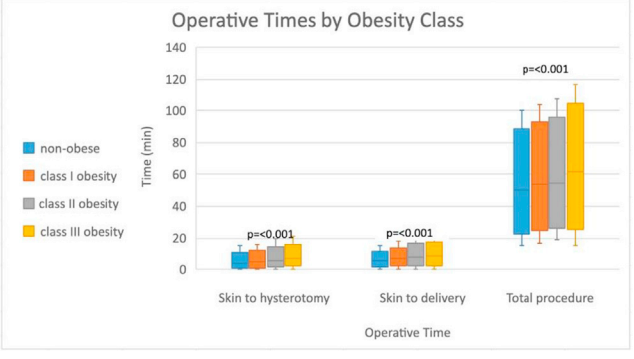
[1]Washington University in St. Louis, St. Louis, MO, [2]Mercy Hospital, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO, [4]Washington University School of Medicine in St. Louis, St. Louis, MO

OBJECTIVE: Obesity is a known risk factor for unplanned cesarean delivery (CD). In patients with obesity, perceived technical and surgical difficulty may influence decision-making on when to perform the CD. We sought to evaluate the impact of class of obesity on unscheduled CD outcomes.

STUDY DESIGN: This is a retrospective cohort study of all singleton, non-anomalous gestations delivered by unscheduled CD at a tertiary care center from 2018-2021. The primary outcome was time from skin incision to delivery. Secondary outcomes were composite measures of maternal (postpartum hemorrhage, transfusion, endomyometritis, ICU admission, readmission, wound complication requiring a hospital encounter, or bowel/bladder injury) and neonatal (NICU admission, respiratory support, therapeutic hypothermia, fetal acidemia) morbidity. We stratified patients according to obesity class (class I, class II, and class III at time of CD) and compared outcomes to non-obese patients. Multivariate logistic regression was used to control for potential confounders.

RESULTS: Of 1856 unscheduled CD, 569 (30.1%) were performed in non-obese patients and 452 (24.4%), 347 (18.7%), and 488 (26.3%) were in patients with class I, II, and III obesity, respectively. Operative times to delivery were significantly longer in patients with obesity (6 [IQR 3-9] min. in non-obese vs 7 [IQR 4-10], 8 [IQR 4-11], and 9 [IQR 5-12] min ($p< 0.001$). in patients with class I, II and II obesity respectively). Patients with Class I and II obesity had similar rates of composite maternal morbidity as non-obese patients. Patients with Class III obesity had a significantly increased risk of maternal morbidity compared to non-obese patients. (40.4 vs. 31.8%, aRR 1.19 95%CI 1.01-1.38.) Class of obesity was not significantly associated with neonatal morbidity.

CONCLUSION: Although maternal obesity was associated with longer operative times during unscheduled CD, the absolute difference in incision to delivery time of 1-2 minutes is unlikely to be clinically impactful as neonatal outcomes are similar. Maternal morbidity is only increased in patients with class III obesity.



681 Mifepristone pretreatment for second trimester induction, to wait or not to wait?

Bridget C. Huysman[1], Brittani Steinberg[2], Theresa Long[3], Emily Freeman[3], Jennifer Reeves[3], Dave Eisenberg[2], Jeannie C. Kelly[2], Katherine H. Bligard[1]

[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO, [3]Washington University in St. Louis, Barnes-Jewish Hospital, St. Louis, MO

OBJECTIVE: Mifepristone is administered 24 hours (hrs) before initiation of nonviable induction of labor in the second trimester (NIST) to reduce time from induction start to delivery. NIST is often performed in emergent cases, where expeditious care is vital. We hypothesized that mifepristone pretreatment compared misoprostol only would reduce time to delivery, time in labor, and need for dilation and curettage (D&C).

STUDY DESIGN: We conducted a retrospective chart review of patients with previable PPROM, IUFD, fetal anomalies, and maternal contraindications to pregnancy presenting at a single tertiary academic center for NISTs from 2018 to 2022. We compared the time to delivery, in labor, and need for D&C between those who received misoprostol only or mifepristone pretreatment. Stratification by time from first misoprostol or mifepristone pretreatment and an analysis excluding PPROM patients were performed.

RESULTS: Of 103 patients, 37 received mifepristone pretreatment, while 66 received misoprostol alone, and 56% of patients underwent NIST for IUFD. Comparing time from first NIST medication (misoprostol only or mifepristone pretreatment) to completion of delivery, there was a statistically significant increase in time when mifepristone was given (11.0 hrs [7.4, 20.0] vs. 34.4 hrs [28.7, 45.3], $p< 0.001$). There was a nonsignificant decrease in labor time ($p=0.91$) when mifepristone pretreatment time was excluded without a difference in need for D&C (12% vs. 13.5%, $p=1.00$). Stratification by time from no pretreatment or mifepristone pretreatment (< 24hrs or >24hrs) showed no difference in time in labor; but there was a statistically significant difference in total time from first medication to delivery (Table). Exclusion of PPROM patients did not change the results.

CONCLUSION: Mifepristone pretreatment increases the total time from first medication to delivery without a significant difference in labor duration. Our data suggests shortening the time from mifepristone to first dose of misoprostol administration could further expedite NIST care.

Table: Time to fetal and placental delivery from initiation of nonviable induction in the second trimester (hrs)

All Induction Indications*				
First medication administration (mifepristone pretreatment or misoprostol)	**Fetal Delivery**	**P value**	**Placental Delivery**	**P value**
No Mifepristone	10.9 hrs [6.1, 17.6]	**<0.001**	11.0 hrs [7.4, 20.0]	**<0.001**
Mifepristone >24hrs	41.7 hrs [35.8, 47.8]		44.0 hrs [35.8, 48.8]	
Mifepristone <24hrs	28.7 hrs [20.3, 41.4]		29.7 hrs [20.3, 41.5]

682 Neighborhood, race, or both? Impact on maternal and neonatal adverse outcomes

Bridget C. Huysman[1], Candice Woolfolk[1], Sarah Cohen[2], Sarah K. England[3], Jeannie C. Kelly[4], Ebony B. Carter[4], Antonina I. Frolova[1], Anthony O. Odibo[1], Nandini Raghuraman[1], Peinan Zhao[5]

[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Washington University in St. Louis, School of Medicine, St. Louis, MO, [3]Washington University in St. Louis, Barnes-Jewish Hospital, St. Louis, MO, [4]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO, [5]Washington University in St. Louis, St. Louis, MO

OBJECTIVE: Area deprivation index (ADI) is a measure that identifies neighborhoods experiencing socioeconomic disadvantage by considering factors independent of race such as income and education. We tested the hypothesis that patients living in deprived neighborhoods are at increased risk of adverse pregnancy outcomes and that this association is modified by race due to exposure to racism.

STUDY DESIGN: This is a secondary analysis of a prospective cohort study of singleton pregnancies at our academic center from 2017 to 2020. The parent study excluded non-English speaking patients and IVF pregnancies. The primary outcome for this analysis was composite adverse obstetric outcomes. The secondary outcome was composite neonatal adverse outcomes (Table). These outcomes were compared between patients with low ADI (< 75th percentile, representing affluence/ prosperity) and high ADI (≥75th percentile with cutoff of ADI≥9, adversity/ deprivation). Stratified analysis by race (Black vs. White), and interaction testing of ADI and race were performed.

RESULTS: Of 1260 birthing people, 1029 had ADI data for analysis. The median ADI for the cohort was 7 (IQR 3-9). Patients with high ADI were more likely to have composite adverse obstetric outcomes compared to those with lower ADI (aRR 1.17, 95%CI [1.02, 1.33]). There was no difference in composite neonatal adverse outcomes. After stratifying by race, there was no difference in risk of adverse outcomes in Black patients with low ADI vs. Black patients with high ADI. However, the p-value for interaction between race, ADI, and composite adverse obstetric outcome was significant (p=0.001) demonstrating that the association between ADI and adverse outcomes is modified by race, where Black patients are at higher risk than White patients.

CONCLUSION: More than half of patients living in deprived neighborhoods experience an adverse pregnancy outcome. Race modifies this risk where Black patients in deprived neighborhoods are at higher risk than White patients. Our results suggest that factors other than socioeconomics alone, such as systemic racism, contribute to adverse outcomes.

Table: Risk of composite obstetric and neonatal adverse outcomes by ADI and race

	Low ADI (less deprived) N= 663 Ref	**High ADI** (more deprived) N=366	**RR (95% CI)**	**aRR* (95% CI)**
Composite adverse obstetric outcome	290 (44%)	191 (52%)	1.19 (1.05, 1.36)	**1.17 (1.02, 1.33)**
Neonatal composite adverse outcome	166 (25%)	85 (23%)	0.93 (0.74, 1.17)	0.90 (0.71 ,1.14)
Black patients N=584				
Composite adverse obstetric outcome	136 (51%)	173 (54%)	1.06 (0.91, 1.23)	1.07 (0.93, 1.26)
White patients N=407				
Composite adverse obstetric outcome	140 (38%)	136 (38%)	0.99 (0.66, 1.49)	0.94 (0.59, 1.37)

P for interaction between race, ADI, and composite adverse obstetric outcome= 0.001
Composite OB outcome=hemorrhage or transfusion, wound infection, infectious endomyometritis, hypertensive disorder of pregnancy, unscheduled cesarean section, preterm delivery <37 weeks, maternal death, small for gestational age, stillbirth
Neonatal composite outcome=NICU admission, Umbilical artery pH <7.1, APGAR <7 at 5 mins, respiratory distress syndrome, hypoxic ischemic encephalopathy, neonatal death within 28 days.
*Adjusted RR: adjusted for age and obesity.

683 One year later: Comparison of care for nonviable second trimester pregnancies pre- and post-Dobbs decision

Brittani Steinberg[1], Theresa Long[2], Jennifer Reeves[2], Dave Eisenberg[1], Jeannie C. Kelly[1], Katherine H. Bligard[3], Bridget C. Huysman[3]

[1]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO, [2]Washington University in St. Louis, Barnes-Jewish Hospital, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, St. Louis, MO

OBJECTIVE: The Dobbs v. Jackson Women's Health Organization (Dobbs) decision may affect the care provision of patients with second trimester nonviable pregnancies (STNPs). We sought to compare differences in type of, indications for, and access to care of STNPs in the year before and after the Dobbs decision.

STUDY DESIGN: We conducted a retrospective cohort study of all patients who delivered following care for STNPs between 06/2021-07/2023 at a single, tertiary care center in a state where abortion became illegal, except in cases of medical emergency, immediately following Dobbs. We assigned patients to pre-Dobbs (June 2021-2022) or post-Dobbs (July 2022-2023) eras based on date of delivery. We compared differences in indication for care and procedure type pre- and post-Dobbs. We used multivariate logistic regression to determine the odds of obtaining a dilation and evacuation (D&E) pre- and post-Dobbs, adjusting for confounders.

RESULTS: We included 318 patients in the analysis (n=195 pre-Dobbs, n=123 post-Dobbs). There was no difference in gestational age between the groups (19.5 vs. 19.0, p=0.27), and no difference in distance traveled (24 vs. 21 miles, p=0.42). There was a significant difference in indication for care, with 0 STNP deliveries for fetal anomalies post-Dobbs (p< 0.001). There was also a significant decrease in D&Es post-Dobbs (p=0.01, Table). Patients receiving care post-Dobbs had 53% lower odds of obtaining D&E (aOR 0.47, 95% CI 0.29-0.78). When stratified by indication, there was no difference in odds for obtaining D&E for intrauterine fetal demise (IUFD) (aOR 0.81, 95% CI 0.42-1.56), but patients with an indication of medical emergency had an 83% lower odds of obtaining D&E post-Dobbs (aOR 0.17, 95% CI 0.06-0.47).

CONCLUSION: Provision of care for STNPs in the one year since the Dobbs decision in an abortion-restrictive state has significantly changed for patients with fetal anomalies and medical emergencies, but remains similar to the pre-Dobbs era for patients with IUFDs. Continued surveillance is necessary to understand how the evolving legal landscape may affect patients.

Table: Comparison of nonviable second trimester terminations (NSTT) by era

	Pre-Dobbs N=195 (Ref)	Post-Dobbs N=123	P-value
Gestational age (median [range]) Cohort: 19.2 [17.0-21.4]	19.5 [17.0-21.6]	19.0 [17.0-21.2]	0.27
State

IOL: induction of labor. D&E: dilation and curettage. IUFD: intrauterine fetal demise.

684 Natural Language Processing Analysis of TikTok's Most Popular #Pitocin Videos

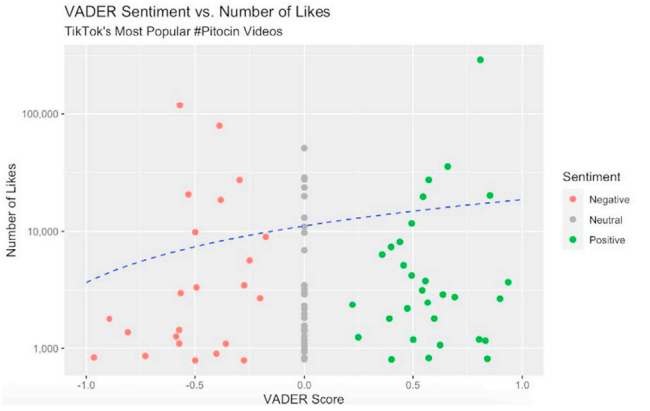
Bryan L. Aaron[1], Katherine Neff[1], Fei Cai[2], Luke P. Burns[3]
[1]University of Michigan Medical School, Ann Arbor, MI, [2]Oregon Health & Science University, Portland, OR, [3]University of Chicago Medicine, Chicago, IL

OBJECTIVE: Among TikTok's 150 million American users, an estimated 90 million reportedly consult the app for healthcare advice before seeing a physician. Patients may therefore rely on TikTok as a source of information on intravenous (IV) oxytocin use in labor, however, no studies exist describing the tone of popular TikTok videos available on this topic. We, therefore, used a natural-language processing tool to evaluate the tone and sentiment of popular TikTok videos tagged #Pitocin.

STUDY DESIGN: The application Apify was used to compile information about the most-liked videos with the #Pitocin tag on April 26th, 2023. Two reviewers assessed 169 videos for eligibility and excluded 73 videos due to irrelevance or unavailability, resulting in 96 videos for analysis. We used a natural language processing tool, Valence Aware Dictionary for sEntiment Reasoner (VADER) to assess the polarity (positive/negative) and intensity (strength) of emotion of the video description text. The VADER score range was -1 to 1, with -1 indicating a highly negative sentiment, and 1 indicating a highly positive sentiment. Regression modeling was performed with VADER score as the exposure variable and the number of likes on the video as the response variable.

RESULTS: The 96 reviewed videos with the #Pitocin tag had a total of 19,430,700 plays and 1,882,839 likes and averaged 60.4 seconds in length. 8 videos were removed from VADER analysis due to absent captions. Of the 88 video descriptions analyzed, 30 (34.1%) had values greater than 0, 23 (26.1%) had values less than 0, and 35 (39.8%) had values equivalent to 0. The adjusted R-squared value was equivalent to -0.002. VADER score did not significantly predict the number of likes on videos ($\beta_1 = 7463$, p-value = 0.89).

CONCLUSION: More than a quarter of the most popular TikTok videos tagged #Pitocin had negative sentiments regarding IV oxytocin infusion, based on video descriptions. There was no statistical association between the popularity of a video and its sentiment score.



685 Patient Perceptions Post Dobbs Decision

Bryce T. Munter[1], Claire Schenken[2], Angela R. Boyd[3]
[1]University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]University Hospital, San Antonio, TX, [3]The University of Texas Health Science Center at San Antonio, San Antonio, TX

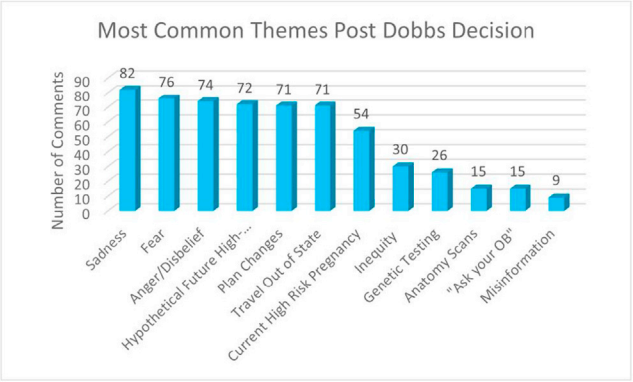
OBJECTIVE: In June 2022, the Supreme Court ruled in Dobbs v. Jackson's Women's Health Organization that the constitution does not confer a right to abortion. The objective of this study was to evaluate patients' perceptions and concerns regarding this ruling.

STUDY DESIGN: Reddit, a website for user-generated content and discussions, was searched for all communities specifically related to pregnancy. Each community was then searched for posts relating to the Dobbs v. Jackson case using key words "Roe v Wade" and "Dobbs." Thematic analysis was then performed using qualitative data analysis software.

RESULTS: A total of 5 posts with 1,061 associated comments were included. 102 commenters were currently pregnant. The most common emotions mentioned were sadness (82 posts), fear (76), and anger or disbelief (74). Many commented on uncertainties regarding the meaning of the new laws and possible future effects. Inequity and financial privilege were mentioned often (30), specifically relating to some not being able to travel outside of their state to receive necessary care. Many women currently or previously had high-risk pregnancies (54) and the maternal risks in a hypothetical future high-risk pregnancy was noted frequently (72). Many posts discussed plan changes (71), including moving to different states and decreasing family size goals. Additional common posts related to traveling out of state for abortion or emergency care (50), and others reported interest in moving before pursuing pregnancy (17). Fifteen posters listed a concern of lack of autonomy to pursue abortion if a severe anomaly was seen on early ultrasound. Posts including misinformation were rare (9) and few users urged others to speak to their obstetrician for clarification (15).

CONCLUSION: Patients feel afraid, angry, and sad after the Dobbs v. Jackson decision. Inequity, uncertainty, and hypothetical future high-risk pregnancies were discussed often. Unintended effects

include families electing to move to different states or changing their family planning goals.



686 Histopathologic placental findings in SARS-CoV-2 exposed gravida compared to unexposed controls

Burk Schaible[1], David M. Stamilio[2], Jeffrey Shenberger[3], Anna McDonald[1], Ingrid Tablason[4], Megan Seger[1]
[1]Atrium Wake Forest Baptist Health, Winston-Salem, NC, [2]Wake Forest University School of Medicine, Winston-Salem, NC, [3]Atrium Wake Forest Baptist Health, Connecticut Children's Specialty Group, Hartford, CT, [4]Atrium Wake Forest Baptist Health, Columbus, OH

OBJECTIVE: To estimate if SARS-CoV-2 maternal infection during pregnancy is associated with higher rates of placental abnormalities compared to unexposed controls.

STUDY DESIGN: We designed a single center retrospective cohort study of delivered patients with placental histopathologic results in exposed and unexposed to prenatal SARS-CoV-2 infection. Primary outcomes included select placental malperfusion abnormalities. Secondary outcomes included desired pregnancy outcomes. Data was obtained through automated chart extraction and verified manually. Bivariate and multivariable logistic regression analyses were performed. Subanalyses examined the effect of gestational timing and disease severity of SARS-CoV-2 infection on placental outcomes. Sensitivity analyses were performed to assess for confounding by indication.

RESULTS: Among the 1,923 pregnant patients in the cohort, 490 (25.5%) had prenatal SARS-CoV-2 infection. Study groups differed on several baseline characteristics, including higher rates of preterm birth, obesity, hypertension, fetal growth restriction, and fetal congenital anomalies in the unexposed group. In the unadjusted analysis, placental abnormalities, including MVM, FVM and inflammation, were similar between SARS-CoV-2 exposed and unexposed pregnant individuals. Findings were largely confirmed in the multivariable analyses adjusting for relevant confounding variables. Gestational timing and severity of infection did not appear to impact placental injury. However, a sub-cohort sensitivity analysis restricting to patients without potential confounding variables related to indications for ordering placental pathology revealed a higher rate of MVM in the SARS-CoV-2 exposed group.

CONCLUSION: Rates of specified placental histopathologic abnormalities were not increased in SARS-CoV-2 infection during pregnancy in this high-risk cohort. However, there is evidence of confounding by indication that may be masking an association between SARS-CoV-2 prenatal exposure and increased placental pathology.

Primary Placental Outcomes comparing SARS-coV2 prenatally exposed versus unexposed individuals

Variables	SARS-CoV-2 Exposed N= 490, n(%)	SARS-CoV-2 Unexposed N=1,433, n(%)	Unadjusted Relative Risk (95% CI)	Adjusted Odds Ratio (95% CI)
MATERNAL VASCULAR MALPERFUSION (MVM)	139 (28.4)	503 (34.8)	0.81 (0.69 - 0.95)	1.00 (0.79 - 1.28*)

Fetal inflammatory response	87 (17.8)	272 (18.9)		

*Multivariable model includes gestational and chronic hypertensive disorders and low birth weight
**No variables significantly impacted the association between SARS-CoV-2 and FVM
*** Multivariable model includes gestational and chronic hypertensive disorders

687 Immune Clock of Pregnancy: A Longitudinal Evaluation of Cervicovaginal Inflammation

Calvin L. Ward[1], Ashley Boerrigter[2], Heather True[2], Cynthia Cockerham[2], Asmita Shrestha[2], Sheridan Wagner[2], John O'Brien[2], Ilhelm Messaoudi[2]
[1]Baptist Health Lexington: Perinatal Diagnostic Center, Lexington, KY, [2]University of Kentucky, Lexington, KY

OBJECTIVE: Timed changes in circulating immune mediators have been reported to play a critical role in fetal tolerance and fetal growth while providing anti-microbial protection. However, similar longitudinal adaptations occurring in the cervicovaginal space are less well understood. Our goal was to evaluate inflammatory changes over time utilizing cervicovaginal lavage (CVL) in a normal patient population.

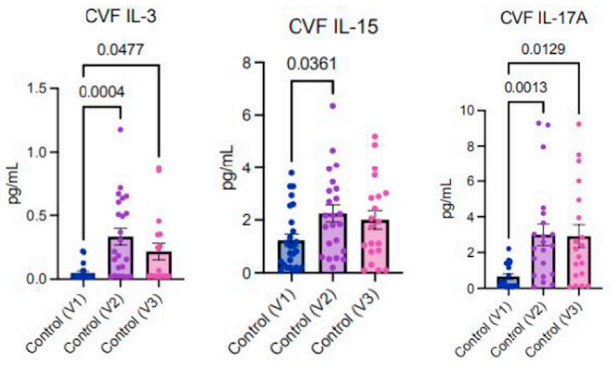
STUDY DESIGN: This is a single center, prospective case-control cohort study of pregnant patients at risk for spontaneous preterm birth (sPTB). The control cohort consists of nulliparous patients without a short cervix or symptoms of sPTB. All patients included were delivered at term. Enrollment occurred between 18-24 weeks (V1) with follow up at 27-29 weeks (V2) and 33-35 weeks (V3). CVL was obtained using 3cc of normal saline placed on the anterior lip of the cervix and collected in the posterior fornix of the vagina after 30 seconds. Twenty-eight CVL biomarkers were analyzed via Luminex platform. Statistical analysis utilized t-test and Mann-Whitney test to compare groups between time points.

RESULTS: 32 patients were included. Three cytokines varied significantly over the second and third trimester: IL-3, a colony stimulating factor promoting differentiation and a progesterone-responsive cytokine; IL-17A, a product of IL-6 /TGFb transformed Th17 lymphocytes; and IL-15, a regulator of NK cell activity demonstrated statistically significant differences when comparing the three visits. The first two cytokines demonstrated similar patterns with increases in IL-3 and IL-17A at V2 and V3 compared to V1, See Figure 1. IL-15 was higher at V2 compared to V1 (p=0.036). Although these

differences were statistically significant, the magnitude of the concentration change was modest using this methodology.

CONCLUSION: Modulation in the immune system was seen during pregnancy in this low-risk cohort in the cervicovaginal space. These changes appear hormonally mediated, in part, and were primarily evident during the midtrimester. These data should be considered as baseline for interpretations of further research.

Figure 1: Cervicovaginal Lavage Cytokine Changes Throughout Pregnancy



688 Impact of skin incision type on operative morbidity in cesarean hysterectomy for placenta accreta spectrum

Candace Levian, Mariam Naqvi, Gabriela Dellapiana
Cedars-Sinai Medical Center, Los Angeles, CA

OBJECTIVE: Vertical skin incision is often used for a planned cesarean hysterectomy (C-Hyst) for its improved visualization and conceivably fewer surgical complications. This study was designed to determine whether surgical complications for planned C-Hyst differ by skin incision type.

STUDY DESIGN: Cohort study of patients with planned C-Hyst for placenta accreta spectrum (PAS) stratified by skin incision (LT or vertical) from 2012-2023. Primary outcome was a composite of transfusion $\geq$ 4 units, intraoperative bowel or bladder injury, intensive care unit admission or wound complication. Comparisons performed using χ^2, t-test, rank sum test and multivariable logistic regression as appropriate.

RESULTS: We identified 53 patients with planned C-Hyst for PAS, of whom 37 (70%) had LT skin incision and 16 (30%) had vertical skin incision. Patients with LT incision were more likely to be $\geq$ 35 years old (76% vs 44%, P=0.02), have an antenatal diagnosis of accreta only (68% vs 38%, P=0.04) and deliver at a later gestational age (34.9 vs 33.7 weeks, P=0.01). The primary composite outcome was less common in those with LT incision than vertical incision (62% vs 94%, P=0.02). After adjusting for potential confounders, the odds of the primary outcome were the same (aOR 8.2, CI 0.8-89). However, vertical incision was more likely to have estimated blood loss $\geq$ 2500 cc (aOR 6.9, CI 1.2-38.5), operative time $\geq$ 120 minutes (aOR 8.9, CI 1.6-49.3) and discharge home with Foley catheter (aOR 13, CI 1.8-95.6), Table 1. There were no differences in wound complications, pain scores, opioid use or postpartum length of stay. There were also no differences in outcomes by skin incision when restricting the analysis to patients with percreta (8 LT incision; 4 vertical incision).

CONCLUSION: Vertical skin incision at time of planned C-Hyst for PAS is associated with higher blood loss, longer operative time and prolonged Foley catheter use as compared to LT incision, without a reduction in operative complications. For a surgeon skilled at either approach, LT skin incision should be considered a safe and effective option for treating PAS.

Table 1. Perioperative outcomes by skin incision for cesarean hysterectomy in patients with placenta accreta spectrum

Outcome	Low-Transverse Skin Incision N=37	Vertical Skin Incision N=16	P	Adjusted OR [a] (95% CI)	P
Composite primary outcome [b]	23 (62)	15 (94)	0.02	8.2 (0.8-89)	0.08
Transfusion ≥ 4 units	21 (57)	15 (94)	<0.01	10.5 (1-111.3)	0.05
Operative complications			0.22	3.2 (0.7-14.7)	0.14

Neonatal outcomes					
NICU admission	32 (86.5)	15 (94)	0.44	1.3 (0.1-31.2)	0.86
5-minute APGAR < 7	10 (27)	10 (62.5)	0.01	2.6 (0.6-11)	0.19

Data are N (%) or mean ± SD unless noted otherwise
[a] Adjusted for age ≥ 35, gestational age, antenatal diagnosis of placenta accreta and hysterotomy type
[b] Composite primary outcome consists of transfusion ≥ 4 units, intraoperative bowel or bladder injury, intensive care unit admission or wound complication
[c] There were 2 patients with skin and soft tissue infection and 1 patient with wound separation in the low-transverse skin incision group
ICU, intensive care unit; *EBL*, estimated blood loss; *PP LOS*, postpartum length of stay; *MME*, morphine milligram equivalents; *NICU*, neonatal intensive care unit

689 Maternal morbidity in postpartum severe preeclampsia by obstetric hospital volume

Carmen M. A. Santoli[1], Shakthi Unnithan[1], Tracy Truong[1], Sarah K. Dotters-Katz[1], Jerome J. Federspiel[2]
[1]Duke University Medical Center, Durham, NC, [2]Duke University Hospital, Durham, NC

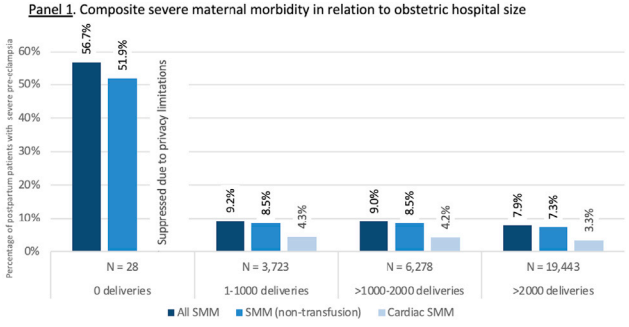
OBJECTIVE: Preeclampsia is a leading cause of maternal morbidity and mortality in the US. We investigated the relationship between facility delivery volume and rates of non-transfusion severe maternal morbidity (SMM) among patients readmitted postpartum for severe preeclampsia (SPREX).

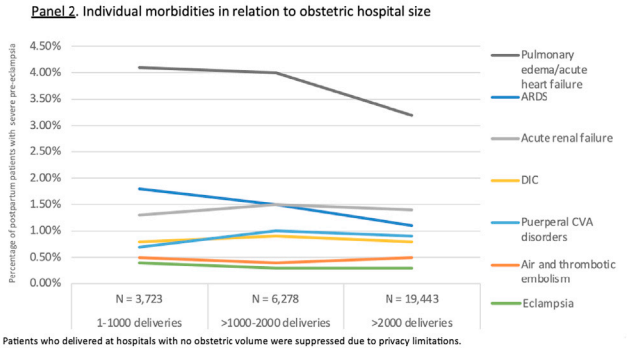
STUDY DESIGN: Retrospective cohort study using the Nationwide Readmissions Database (2015-2020), among patients readmitted for SPREX. Our primary outcome was non-transfusion SMM during readmission, defined per US Centers for Disease Control and Prevention criteria. We also evaluated SMM, cardiac SMM and individual morbidities. The exposure variable was the number of annual deliveries at the readmitting facility. Restricted cubic splines with 4 knots were used to assess the functional form of the relationship between obstetric volume and non-transfusion SMM; a linear relationship was identified as optimal. Logistic regression was used to generate adjusted odds ratios (aOR) which controlled for maternal age, non-transfusion SMM at delivery, expanded obstetric comorbidity index, and hypertensive disorder of pregnancy (HDP) during delivery.

RESULTS: The cohort included 29,472 patients readmitted postpartum with SPREX, of which the primary payer was 54.9% private and 41.7% governmental. Median age was 31.4 years. Most patients did not have prior HDP (64.7%) or chronic hypertension (85.6%). Non-transfusion SMM occurred in 7.3% readmitted to hospitals with >2,000 deliveries compared to 8.5% with 1-2,000 deliveries,

and 51.9% without any delivery hospitalizations (Panel 1). The most common SMM was pulmonary edema and heart failure (Panel 2). For every increase in 1,000 deliveries, the odds of a non-transfusion SMM at readmission decreased by 3.5% (aOR: 0.965; 95% confidence interval: 0.94, 0.99).

CONCLUSION: Non-transfusion SMM for postpartum readmissions with SPREX features were inversely associated with obstetric hospital volume. This information may guide risk-reducing initiatives for identifying strategies to optimize postpartum care at facilities with lower or no delivery volume.





690 Transport trends for early pregnancy evaluation before and after adoption of restrictive reproductive legislation

CeCe Cheng[1], Margaret M. Klausmeyer[2], Michaela Y. Lee[1], Dolores Perry[3], Alixandria F. Pfeiffer[4], Patrick S. Ramsey[2], John J. Byrne[2]

[1]University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]The University of Texas Health Science Center at San Antonio, San Antonio, TX, [3]University Health / San Antonio, San Antonio, TX, [4]UT Health, San Antonio, TX

OBJECTIVE: To evaluate the impact of the passage of restrictive abortion legislation in Texas and the federal Dobbs v Jackson Women's health decision on transports to our Level IV maternal center for early pregnancy evaluation.

STUDY DESIGN: We conducted a single-institution retrospective study on all transports to our center from 2/2021-2/2023, before and after the adoption of Texas restrictive abortion legislation (SB8—09/2021; SB4—12/2021) and the federal Dobbs decision (06/2022). Transports for early pregnancy evaluation including ectopic pregnancy, pregnancy of unknown location (PUL), miscarriage, and previable preterm prelabor rupture of membranes (PPROM). Demographics and transferring facility level of maternal care (LoMC) were compared between patients transported for early pregnancy evaluation versus transports for other indications. Severe morbidity and mortality (SMM; CDC definition) of transports were evaluated.

RESULTS: Of the 526 patients transferred, 63 (12%) were for early pregnancy evaluation. Of those, 21 (32%) were for ectopic pregnancy, 13 (20%) for PUL, 22 (33%) for miscarriage, and 9 (13%) for previable PPROM. Early pregnancy transports were significantly older, self-identify as Black, have lower body mass index, and be nulliparous when compared to other transports. Early pregnancy transports were also more likely to be via ground/ambulance (96 v 68%, $p< 0.0001$) and from a hospital/emergency room without a labor and delivery (59 v 24%, $p< 0.0001$). There were no differences in SMM rates ($p >0.05$). There was an increase in number of patients transferred from 2021-2022 (n=29) compared to 2022-2023 (n=36), though not significantly different (p=0.4). There were increases in transport rates after 09/21 and 06/22, particularly for miscarriage management (Figure).

CONCLUSION: Transports to a higher LoMC center for early pregnancy evaluation increased after passage of restrictive abortion legislation suggesting potentially unwarranted transports from centers with capability to manage early pregnancy evaluation.

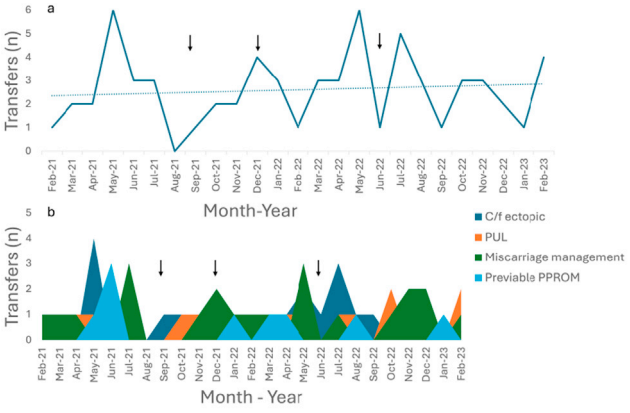


Figure. Transfers for a) early pregnancy evaluation from February 2021-February 2023 with trendline (dotted line) and b) by specific etiology – concern for (c/f) ectopic pregnancy, pregnancy of unknown location (PUL), miscarriage management (includes missed, incomplete, complete, septic abortion as well as retained products of conception) and previable preterm prelabor rupture of membranes (PPROM). Arrows indicate passage of SB8 (September 2021), SB4 (December 2021), and Dobbs (June 2022).

691 Neonatal outcomes in late preterm premature rupture of the membranes – subpopulation analysis

Chen Key Segal[1], Shay Kaufman[2], Hanoch Schreiber[3], Tal Biron-Shental[4], Michal Kovo[5], Sivan Farladansky Gershnabel[1]

[1]Meir Medical Center, Kfar Saba, HaMerkaz, [2]Meir medical center, Kfar Saba, HaMerkaz, [3]Meir Medical Centerartment of Obstetrics and Gynecology, Meir Medical Center, Kfar Saba, Israel, [4]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz, [5]Meir Medical Center, Macabim, HaMerkaz

OBJECTIVE: Following the PPROMT trial, our departmental protocol was revised in 2016, so that pregnant women with late preterm premature rupture of the membranes (PPROM), are managed conservatively up to 37 weeks. This study assessed neonatal outcomes according to clinical subpopulations, as various clinical scenarios in the face of late PPROM can affect outcomes and accordingly- clinical decisions.

STUDY DESIGN: The study included all women with late PPROM (defined as PPROM 34—37 weeks of gestation), during 2016-2022. The conservative management (CM) group (n=397) and the active management (AM) group (n=82) were compared according to neonatal outcomes (5-minute Apgar score ≤7, phototherapy, NICU

admission, neonatal respiratory support, and antibiotic treatment). Subpopulations were further analyzed: patients after cesarean delivery (CD) (n=66), twin pregnancy (n=24), diabetes mellitus (n=78), small for gestational age (SGA) (n=46), group B Strep carriers (n=15), and obesity (n=138).

RESULTS: When comparing active to conservative management, we found higher rates of CD (45.6% vs. 13.9%, p< 0.001), neonatal phototherapy (25.6% vs. 16.9%, p=0.05) and neonatal antibiotic treatment (6.6% vs. 1.4%, p=0.05), respectively.

Further analysis of patients after CD, twin pregnancy, diabetes or obesity, found vaginal delivery was more common in the CM compared to the AM group (P< 0.001). We also found higher rates of neonatal respiratory support in obese patients in the AM group (11.4% vs. 8.0%; P=0.002).

CONCLUSION: Patients with PPROM managed conservatively had a lower CD rate, which is particularly important when emphasizing the importance of preventing primary CD. Results were similar among the different subpopulations. Importantly, we found no differences in neonatal outcomes among diabetic patients and among twin pregnancies with late PPROM, where antenatal corticosteroid treatment was not used.

692 Genetic findings among neonates with perinatal hypoxic-ischemic encephalopathy

Christian M. Parobek[1], Matthew A. Shanahan[1], Roni Zemet Lazar[1], Brian Burnett[1], Elizabeth Mizerik[2], Jill Rosenfeld[3], Liesbeth Vossaert[3], Steven Clark[1], Jill Hunter[2], Seema Lalani[1]

[1]Baylor College of Medicine, Houston, TX, [2]Texas Childrens Hospital, Houston, TX, [3]Baylor Genetics, Houston, TX

OBJECTIVE: Neonatal encephalopathy (NE) occurs in 3 out of 1000 births, causing substantial morbidity and neurodevelopmental sequelae. Although more than 50% of NE cases are attributed to hypoxic-ischemic encephalopathy (HIE), most newborns with HIE have limited evidence of perinatal hypoxia. We hypothesized that some infants diagnosed with HIE have an identifiable genetic disorder with phenotypic features that resemble encephalopathy.

STUDY DESIGN: We reviewed HIE cases referred for genetic analysis in a clinical diagnostic laboratory between October 2014 - September 2022. Cases were included if they were given a diagnosis of HIE by the referring physician, were ≥35 wks at birth and < 1 yo at the time of genetic analysis, and if they underwent exome sequencing. Cases were excluded if there was significant cardiopulmonary pathology resulting in hypoxia or if clinical features or neuroimaging suggested a postnatal cause for hypoxic ischemic injury. This research was IRB approved (H-18414).

RESULTS: Twenty-three cases met inclusion criteria. A total of four (17.4%) had pathogenic or likely pathogenic variants linked to adverse neurologic outcomes with phenotypic features resembling encephalopathy (Table 1). Two additional neonates had pathogenic or likely pathogenic variants in genes associated with unrelated phenotypes, including congenital hypothyroidism and Noonan syndrome (Table 1). Two neonates had isolated HIE without significant comorbidities to suggest an underlying genetic disorder. There was no correlation between cord gas or Apgar values and genetic findings.

CONCLUSION: In this cohort, 17.4% of perinatal HIE cases had a genetic syndrome with a known neuromuscular or neurodevelopmental phenotype that overlaps with HIE. Notably, a subset of these neonates had isolated HIE without other clinical features to suggest that there may be an underlying genetic disorder. The variants identified in non-encephalopathy genes may be incidental or may represent a phenotypic expansion for these genes. These results, while limited by biases inherent in retrospective studies, call for prospective investigation.

Table 1. Pathogenic and likely pathogenic genetic findings in a cohort of neonates with hypoxic-ischemic encephalopathy.

ID	Phenotype	Cooling	Genetic variants having phenotypic overlap with encephalopathy:		Variant	Classification	Inheritance	OMIM Entry & Description
			Yes	No				
1	Static encephalopathy, GI dysmotility, hypertonia, motor delay, visual impairment, PFO, acute lactic acidemia, liver dysfunction.	NA	*KIF1A*		Heterozygous *de novo* c.757G>A (p.E253K)	Pathogenic	AD	Neurodegeneration and spasticity with or without cerebellar atrophy or cortical visual impairment [MIM:614255]

693 OBGYN shortage by Hospital Referral Region: Opportunities to reduce reproductive disparities

Christianna Tu[1], Neelu Varghese[1], Michael Holbert[2], Rachel Sinkey[3]

[1]University of Alabama at Birmingham, Birmingham, AL, [2]TriHealth Hospitals, Cincinnati, OH (retired), Cincinnati, OH, [3]University of South Florida, Tampa, FL

OBJECTIVE: To examine pre-Dobbs decision hospital referral region (HRR) characteristics and their association with OBGYN physician density outliers.

STUDY DESIGN: Data on active non-subspecialist OBGYNs and total Graduate Medical Education full-time equivalents were obtained from Centers for Medicare and Medicaid Services. Census and socioeconomic data for each zip code were abstracted from the US Census Bureau, including total female population, population by race, and percentage (%) of females by marital status, education, household income, insurance status/source, and public assistance factors. These data were then aggregated by HRR per the Dartmouth Atlas. Linear regression was performed comparing each HRR's female population to number of active OBGYNs to identify regions with the highest and lowest deciles of variance in expected compared to actual number of OBGYNs. Logistic regression was used to determine variable significance of demographic factors in the highest and lowest physician density deciles.

RESULTS: Of the 306 HRRs, the highest OBGYN density decile comprised 31,463,100 females and 11,914 OBGYNs for a density of 2,641 females per OBGYN. In the lowest decile, there were 41,549,887 females and 7,980 OBGYNs for a density of 5,207 females per OBGYN. In univariate analysis, the % of Hispanic females, ≥bachelor's degree, fulltime employment, private insurance, poverty, households receiving SNAP assistance, mean household income, and overall population density were significantly associated with OBGYN density outliers (Table). In multivariate analysis, HRRs with a higher percentage of Hispanic females (p=0.013) and those with less than a bachelor's degree (p< 0.001) were associated with more pronounced physician shortfalls.

CONCLUSION: HRRs with a higher proportion of Hispanic patients and lower educational attainment were more likely to have an OBGYN shortage. Policy aimed at recruitment and retention of

OBGYNs in HRRs with an OBGYN shortfall as well as innovative healthcare delivery solutions should be a public health priority to reduce disparities.

Table: Hospital Referral Region Characteristics and OB/GYN Density

	OB/GYN Density		Univariate		Multivariate	
Characteristic	**Low[1]**	**High[1]**	**z-value**	**p-value**	**z-value**	**p-value**
Race

694 Pregnancy Dysglycemia and Predicted Risk of Fatty Liver Disease 10-14 Years after Delivery

Christine P. Field[1], Vidya Mulangi[2], Jiqiang Wu[3], Patrick Catalano[4], Mark B. Landon[5], Denise Scholtens[6], William Lowe[6], William A. Grobman[2], Kartik Venkatesh[3]

[1]Ohio State University / Department of OB/GYN / Division of Maternal Fetal Medicine, Columbus, OH, [2]The Ohio State University, Columbus, OH, [3]Ohio State University, Columbus, OH, [4]Tufts Medical Center, Boston, MA, [5]The Ohio State University Wexner Medical Center, Columbus, OH, [6]Northwestern University, Chicago, IL

OBJECTIVE: To determine whether pregnancy dysglycemia is associated with higher 6-year predicted risk of non-alcoholic fatty liver disease (NAFLD), as quantified by the Framingham Risk Calculator, 10-14 years after delivery.

STUDY DESIGN: A secondary analysis from the prospective Hyperglycemia and Adverse Pregnancy Outcome (HAPO) Follow-up Study. The exposures examined were maternal dysglycemia defined by summary z-score using fasting, 1-, and 2-hour values of a 75-gram oral glucose tolerance test (OGTT) at 24-32 weeks' gestation, and secondarily by diagnosis of GDM per IADPSG criteria The primary outcome was the predicted 6-year NAFLD risk using the Framingham Risk Calculator modelled either as a continuous measure or in tertiles from lowest (tertile 1, [T1]) to highest predicted risk (T3). Linear and modified Poisson regression models adjusted for baseline covariates at the time of the OGTT, including study field center, age, parity, and gestational age at OGTT.

RESULTS: Of 4,697 individuals in the analytic sample, the median age was 30.5 (IQR: 26.0,34.1) and the median BMI was 26.6 (IQR: 24.1,29.9) at baseline. A total of 14.3% (n=672) developed GDM. At 10-14 years after delivery (median 11.6, IQR: 10.8, 12.4), the median predicted 6-year risk of NAFLD was 13% (IQR: 3, 13). Individuals with a higher OGTT summary z-score were at higher predicted risk of NAFLD (adj. beta coefficient: 3.1 per 1 SD; 95% CI: 2.7, 3.6), as were those who were diagnosed with GDM (adj. beta coefficient: 4.3; 95% CI: 3.1, 5.4). Individuals with higher OGTT summary z-scores were also more likely to be in the highest tertile of NAFLD predicted risk (adj. RR: 1.2 per 1 SD; 95% CI: 1.0, 1.3), but those who had GDM were not more likely to be in the highest tertile of predicted risk.

CONCLUSION: Increasing dysglycemia in pregnancy is associated with a higher predicted risk of NAFLD 10-14 years after delivery. Postpartum prevention of cardiometabolic risk factors for NAFLD among individuals with pregnancy dysglycemia requires further investigation.

TABLE. Association between pregnancy dysglycemia and 6-year predicted risk of Fatty Liver Disease (NAFLD) 10-14 Years after Delivery

	Unadjusted and adjusted analysis	
NAFLD predicted risk by 1% increase (continuous)		
	Unadjusted Percent Risk (95% CI)	Adjusted Percent Risk (95% CI)
OGTT summary z-score	**3.33 (2.86, 3.79)**	**3.14 (2.67, 3.61)**
GDM	**5.07 (4.02, 6.13)**	**4.25 (3.08, 5.42)**
NAFLD predicted risk by tertiles (categorical)		
	Unadjusted Risk Ratio (95% CI)	Adjusted Risk Ratio (95% CI)
OGTT summary z-score		
Tertile 1 (lowest NAFLD risk)	1.00	1.00
Tertile 2	**1.14 (1.05, 1.24)**	1.07 (0.98, 1.16)
Tertile 3 (highest NAFLD risk)	**1.24 (1.11, 1.38)**	**1.15 (1.03, 1.27)**
GDM		
Tertile 1 (lowest NAFLD risk)	1.00	1.00
Tertile 2	1.04 (0.86, 1.26)	0.97 (0.78, 1.16)
Tertile 3 (highest NAFLD risk)	1.18 (0.93, 1.51)	1.05 (0.80, 1.30)

Poisson and linear regression with robust error variance was used.
Model adjusted for baseline HAPO site, age, parity, gestational age at OGTT.
N=4,697.
Bold findings are statistically significant associations (p<0.05).

695 Maternal height and risk of neonatal morbidity in pregnancies complicated by fetal growth restriction

Christopher D'Esposito[1], Matthew A. Esposito[2], Megan G. Lord[1]

[1]Naval Medical Center Portsmouth, Portsmouth, VA, [2]Women and Infants Hospital, Providence, RI

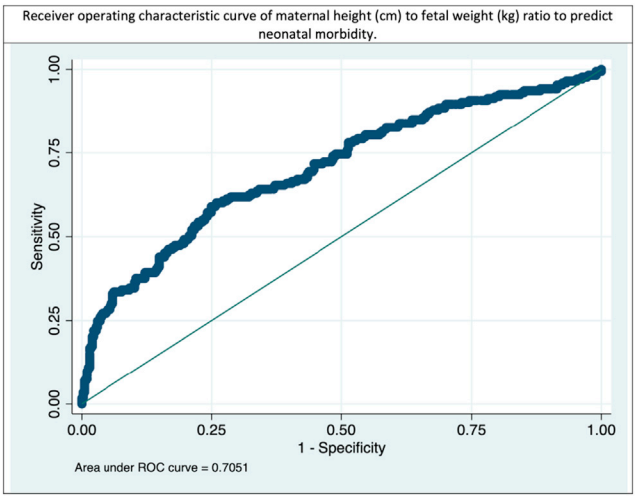
OBJECTIVE: To evaluate the role of maternal height in differentiating constitutionally small infants from pathologically growth-restricted infants who have not met their genetic growth potential by assessing risk of neonatal morbidity.

STUDY DESIGN: Pregnancies complicated by fetal growth restriction (FGR) were identified within a large, NIH-funded database of pregnancies resulting in delivery of live, singleton, non-anomalous infants at a single center 2002-2013. Neonatal morbidity was defined as one or more of the following: 5-minute Apgar < 7, arterial cord pH < 7.0, sepsis, neonatal death, or need for respiratory support, chest compressions, phototherapy, exchange transfusion, or hypoglycemia treatment. Maternal heights were compared between infants who experienced neonatal morbidity and those who did not, using raw height and the ratio of maternal height to infant birth weight.

RESULTS: Neonatal morbidity occurred in 174 of 575 eligible pregnancies (30%) and was associated with greater maternal height (160 vs 159cm, $p = 0.03$) and greater ratio of maternal height to infant birth weight (77 vs 66, $p < 0.01$) — an infant of a given birth weight was more likely to experience neonatal morbidity if delivered to a tall mother. Unadjusted odds ratio was 1.06 (95% confidence interval 1.04-1.08). Area under the received operating characteristic curve was 0.71 (Figure). This remained statistically significant after adjusting for umbilical artery Doppler findings, age, and insurance status (aOR 1.06, 95% CI 1.04-1.08, $p < 0.01$). There were no statistically significant differences in gestational age at delivery,

ultrasound estimated fetal weight centile, or rates of diabetes, hypertension, renal disease, cardiac disease, smoking, or illicit substance use.

CONCLUSION: Among pregnancies complicated by fetal growth restriction, neonatal morbidity occurred more frequently among infants delivered to taller mothers and in cases of a higher ratio of maternal height to infant birth weight. However, the effect size is modest and further study is needed.



696 Trends in Antepartum Pyelonephritis Hospitalizations and Risk for Associated Sepsis and Severe Maternal Morbidity

Christy Gandhi[1], Timothy Wen[2], Alexander M. Friedman[3]
[1]Columbia University Irving Medical Center, New York, NY, [2]University of California, San Francisco (UCSF), San Francisco, CA, [3]Columbia University, New York, NY

OBJECTIVE: To characterize trends in antepartum pyelonephritis hospitalizations in the United States and related sepsis and non-transfusion severe maternal morbidity (ntSMM).

STUDY DESIGN: The 2010-2020 Nationwide Readmissions Database was used for this retrospective cohort study. Delivery hospitalizations in October and November of each study year of patients aged 15-44 were identified. Linked antepartum admissions with a pyelonephritis diagnosis in the 9 months preceding delivery hospitalization were identified. Temporal trends in antepartum pyelonephritis admissions were analyzed using joinpoint regression to estimate the average annual percent change (AAPC) with 95% CIs. Risk for sepsis and ntSMM (excluding sepsis) among antepartum hospitalizations based on CDC criteria was similarly trended.

RESULTS: Of 10,158,939 delivery hospitalizations, 49,147 (0.48%) had an antepartum admission with a pyelonephritis diagnosis in the 9 months preceding delivery. Of these antepartum admissions, 4470 (9.1%) had a sepsis diagnosis and 5093 (10.4%) had a severe morbidity diagnosis other than sepsis. The rate of antepartum pyelonephritis hospitalizations declined over the course of the study period from 56.4 per 10,000 in 2010 to 40.2 per 10,000 in 2020. This trend was significant (AAPC -2.9%, 95% CI -4.0%, -1.9%). However, the proportion of antepartum pyelonephritis hospitalizations with a sepsis diagnosis increased over the study period from 3.7% to 8.5% (AAPC 10.4%, 95% CI 8.3%, 13.4%). Risk for ntSMM also increased significantly over the study period from 5.0% to 20.0% (AAPC 13.8%, 95% CI 10.7, 17.9%).

CONCLUSION: Rate of antepartum pyelonephritis hospitalizations has declined over the decade, likely reflecting an increased adaptation of prenatal screening for urinary tract infections, treatment of asymptomatic bacteriuria, and use of antibacterial suppression. Although antepartum hospitalizations have declined, the proportions of hospitalizations for pyelonephritis with sepsis and severe morbidity have increased. Further investigation is indicated to reduce morbidity associated with antepartum pyelonephritis.

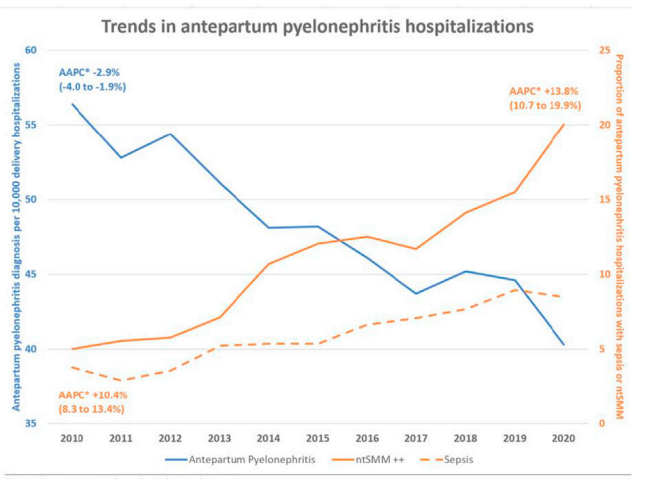


Figure: Antepartum pyelonephritis hospitalizations
* AAPC = average annual percent change
++ ntSMM = non-transfusion related severe maternal morbidity

697 Social determinants of health and hypertensive disorders of pregnancy in patients with heart disease

Claire A. McIlwraith[1], Christina T. Blanchard[2], Ayodeji Sanusi[3], John E. Scheinuk[1], Samantha Martin[3], Stephen A. Clarkson[1], Gretchen Wells[1], Marc Cribbs[1], Jeff M. Szychowski[1], Brian M. Casey[1], Alan T. Tita[1], Rachel Sinkey[4]
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [3]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [4]University of South Florida, Tampa, FL

OBJECTIVE: Hypertensive disorders of pregnancy (HDP) are a leading cause of maternal morbidity and mortality in the United States (US). We sought to examine the relationship between social determinants of health (SDOH) and HDP in patients with congenital or acquired maternal cardiac disease (MCD).

STUDY DESIGN: Retrospective cohort study of 156 MCD patients from 2015- 2019 at a single tertiary center. Patients with ≥1 visit in the cardio-obstetrics program and delivered at this center were included. The primary exposure was SDOH defined as a census tract level Area Deprivation Index (ADI) using a scale of 1 − 100 with social disadvantage worsening as numbers increase. ADI was divided into categories as follows: Low (0-33), Medium (34-66), High (67-100). The primary outcome was a composite of gestational hypertension, preeclampsia with and without severe features, HELLP syndrome, and eclampsia; secondarily, individual components of this composite were examined. Differences in outcomes were compared across ADI categories. A ROC curve and AUC examined the predictive ability of ADI.

RESULTS: On average, patients were obese (BMI 32.1±8.8), non-Hispanic White (55%), ≥ mWHO Class II (87%), publicly/self-

insured (61%), and 15% had chronic hypertension. Baseline characteristics across categories differed with respect to age, race, marital status, and payor. Delivery gestational age was no different (mean 37.0±3.3 weeks), and overall, 29.5% developed HDP. An increasing rate of HDP as ADI category increased was observed; however, the primary composite was not statistically significant between categories (Low: 18.8%, Medium: 22%, High: 34.3%; p= 0.21, Table 1). Additionally, no component of the HDP composite showed significance. ADI as a continuous variable was not predictive of HDP (AUC=0.5).

CONCLUSION: Nearly 1 in 3 patients in our cardio-obstetrics cohort developed HDP. HDP rates appeared to increase as SDOH worsened. While this was not significant, it should be further explored in a larger geographically and racially diverse sample.

Table. Baseline characteristics and incidence of hypertensive disorders of pregnancy in a cardio-obstetrics program by area deprivation index

Baseline Characteristics	Entire Cohort (n=156)	ADI 0 -- 33 (n=16)	ADI 34 – 66 (n=41)	ADI 67 – 100 (n=99)	p-value
Maternal age (years)	27.4 ± 6.4	31.8 ± 4.2	28.0 ± 6.6	26.4 ± 6.4	<0.01
Parity	1.0 ± 1.3	1.3 ± 2.1	0.9 ± 1.1	1.0 ± 1.2	0.58
BMI	32.1 ± 8.8	28.0 ± 6.3	31.9 ± 8.0	33.1 ± 9.3	0.10
Race					
Non-Hispanic Black	62 (39.7)	3 (18.8)	12 (29.3)	47 (47.5)	0.02
Non-Hispanic White	85 (54.5)	12 (75.0)	27 (65.9)	46 (46.5)	
Married / living with partner	65 (41.9)	12 (75.0)	23 (57.5)	30 (30.3)	<0.01
Insurance status					
Private	61 (39.1)	12 (75.0)	18 (43.9)	31 (31.3)	0.02
Public	88 (56.4)	4 (25.0)	22 (53.7)	62 (62.6)	
Self-pay	7 (4.5)	0 (0.0)	1 (2.4)	6 (6.1)	
NICU Admission	37 (23.9)	2 (12.5)	10 (25.0)	25 (25.3)	0.53

mWHO Class					
I	12 (7.7)	1 (6.3)	1 (2.4)	10 (10.1)	0.29
II	36 (23.1)	4 (25.0)	13 (31.7)	19 (19.2)	0.27
II – III	35 (22.4)	3 (18.8)	7 (17.1)	25 (25.3)	0.53
III	37 (23.7)	3 (18.8)	13 (31.7)	21 (21.2)	0.37
IV	27 (17.3)	3 (18.8)	7 (17.1)	17 (17.2)	0.99
Outcomes: Incidence of HDP					
Any HDP*	46 (29.5)	3 (18.8)	9 (22.0)	34 (34.3)	0.21
GHTN	21 (13.5)	1 (6.3)	3 (7.3)	17 (17.2)	0.20
Preeclampsia w/o SF	6 (3.9)	1 (6.3)	0 (0.0)	5 (5.1)	0.33
Preeclampsia w/ SF	19 (12.2)	1 (6.3)	6 (14.6)	12 (12.1)	0.75
HDP antenatal diagnosis	42 (91.3)	2 (66.7)	9 (100.0)	31 (91.2)	0.26
HDP PP diagnosis	4 (8.7)	1 (33.3)	0 (0.0)	3 (8.8)	0.26

ADI = Area Deprivation Index, a measure of social determinants of health, whereby 1 indicates that an individual lives in a resource rich community and 100 indicates that an individual lives in a resource poor community; BMI = body mass index, CHTN = chronic hypertension, GA = gestational age, HDP = hypertensive disorders of pregnancy, NICU = neonatal intensive care unit, mWHO.= modified WHO score, PP = postpartum, SF = severe features. *There were no cases of HELLP syndrome or eclampsia

698 Maternal Epigenetic Variation among women Experiencing Preterm Birth in Hawai'i

Corrie Miller[1], Paula Benny[2], Jonathan Riel[3], Men-Jean Lee[1]

[1]John A. Burns School of Medicine, University of Hawaii, Honolulu, HI, [2]National University of Singapore, Queenstown, Singapore, [3]University of Hawaii, Honolulu, HI

OBJECTIVE: Geographic level of deprivation may contribute to preterm birth risk. This study sought to identify epigenetic changes via methylation differences in women with high social vulnerability experiencing preterm birth vs. women who had term births.

STUDY DESIGN: Whole genomic DNA was isolated from peripheral blood from 160 participants of the Hawaii Reproductive Biorepository (biobanked from 2006-2013). Subjects who self-identified as Filipino and Native Hawaiian were selected due to overrepresentation of preterm birth in these ethnic subgroups. DNA was isolated and subjected to Illumina Epic Methylation Array. Data was processed according to EWAStools R package. Genome wide methylation differences (Limma) and regional differential methylation (DMRcate) were assessed among women who did and did not deliver preterm, and as well as according to level of high or low social vulnerability. EWAS model included Maternal Age, Ethnicity, Obesity, Cell Type Proportion and level of Social Vulnerability. DNA methylation age was calculated using the Horvath method, and compared to Age Acceleration among term vs. preterm births and those of high and low social vulnerability.

RESULTS: 149 samples (72 preterm, 71 term) passed quality control. There were no significant global methylation differences in the EWAS model between women who delivered term vs. preterm, nor those who lived in areas of high vs. low social vulnerability. Differentially methylation regional analysis demonstrated 512 areas of differential methylation among term vs. PTB participants; Overlapping genes in the top ten regions are listed in Table 1. Age acceleration residuals were greater among those who delivered preterm vs. term (p = 0.01762) but not among varying levels of social vulnerability (p = 0.081).

CONCLUSION: This pilot study identified areas of differential methylation in women who experienced PTB. A larger, validation cohort is needed to replicate the findings, as well as look for mechanistic causes for the interaction of these regions and PTB risk.

699 Inpatient versus outpatient/home initiation of medications for opioid use disorder (MOUD) in pregnancy

Courtney Birchall[1], Brittney Gaudet[1], Lindsey Issokson[1], Audrey Lang[1], Elizabeth Allocco[1], Katherine Leung[1], Katherine Callaghan[1], Ellen H. Delpapa[2]

[1]University of Massachusetts, Chan Medical School, Worcester, MA, [2]UMass Memorial Medical Center, Worcester, MA

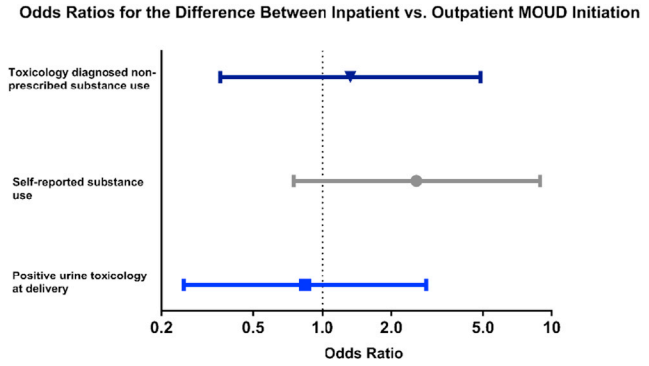
OBJECTIVE: To evaluate whether the location, inpatient versus outpatient/home, of MOUD initiation in pregnancy is associated with differences in non-prescribed substance use and neonatal outcomes.

STUDY DESIGN: This was an IRB-approved retrospective chart review conducted at a single academic center. We included patients with a diagnosis of opioid use disorder, who initiated MOUD in pregnancy, and received care in our comprehensive substance use in pregnancy clinic.

RESULTS: A total of 163 patients were identified as being treated with MOUD, 45 of whom initiated or re-initiated in pregnancy. Of the 45, 28 patients were initiated MOUD inpatient and 17 outpatient. There was no difference between groups for maternal age, self-reported race, ethnicity, parity and gestational age at delivery. Patients in the inpatient group were more likely to use methadone (inpatient 75%, outpatient 35%, p=0.008) and the average gestational age at initiation of MOUD between groups was different (inpatient 24.9, outpatient 18.5 weeks, p=0.023). There was no significant difference in the rate of self-reported substance use between group (inpatient 36%, outpatient 59%, p=0.216). The rate of urine toxicology diagnosed non-prescribed substance use was no different between groups (inpatient 64%, outpatient 71%, p=0.664), nor was there a difference in the number of weeks between MOUD initiation and

the first positive urine toxicology (inpatient 4.6 weeks, outpatient 4.3 weeks p=0.906). Finally, rates of positive urine toxicology at delivery were also similar (inpatient 57%, outpatient 53%, p=0.999). When examining neonatal outcomes there were no differences in birthweight percentiles or rates of diagnosis of neonatal abstinence syndrome.

CONCLUSION: Our data suggest that outpatient/home initiation of MOUD is not associated with significantly different rates non-prescribed substance or adverse neonatal outcomes. In an appropriately counseled patient with comprehensive substance use care in pregnancy outpatient/home MOUD initiation can be considered as an alternative to traditional inpatient initiation.



700 Timing of medication for opioid use disorder (MOUD) initiation in pregnancy and outcomes

Courtney Birchall[1], Elizabeth Allocco[1], Audrey Lang[1], Lindsey Issokson[1], Brittney Gaudet[1], Katherine Leung[1], Ellen H. Delpapa[2], Katherine Callaghan[1]

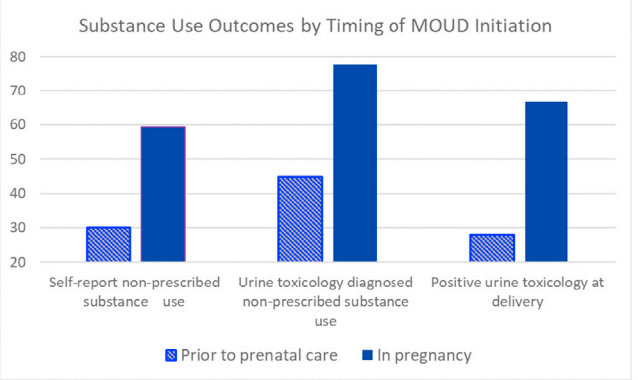
[1]University of Massachusetts, Chan Medical School, Worcester, MA, [2]UMass Memorial Medical Center, Worcester, MA

OBJECTIVE: Observe patterns of non-prescribed substance use in patients who start MOUD prior to prenatal care compared to those who begin treatment in pregnancy.

STUDY DESIGN: This is an IRB-approved retrospective cohort study conducted at a single academic center. We included patients taking MOUD in pregnancy and receiving care in our comprehensive substance-use in pregnancy clinic.

RESULTS: A total of 163 patients met inclusion criteria. Of these, 136 were identified as starting MOUD prior to their first prenatal visit in our clinic, and 27 as having started after initiating prenatal care. Patients starting MOUD prior to their first prenatal visit were older (31.6 vs 29.5 years) and had higher parity (81% vs 44% multiparous) than patients starting MOUD during pregnancy. There was no difference in the type of MOUD used. The rate of self-reported non-prescribed substance use was different between groups (prior 30.1%, during 59.3%, p=0.004). Rates of urine toxicology diagnosed non-prescribed substance use were also different between groups (prior 44.9%, during 77.8%, p=0.002). Average gestational ages at first and last non-prescribed substance use were similar (first: prior 26.4 weeks, during 26.5 weeks, p=0.976; last: 33.9 weeks, during 32.0 weeks, p=0.422). Finally, rates of positive urine toxicology at delivery were higher in the during pregnancy group (prior 27.9%, during 66.7%, p< 0.001). When examining neonatal outcomes there were no differences in birthweight percentiles or rates of diagnosis of neonatal abstinence syndrome.

CONCLUSION: Patients starting MOUD prior to their first prenatal visit had lower rates of non-prescribed substance use by self-report and urine toxicology antenatally, and by urine toxicology during their delivery admission. These findings highlight the importance of community MOUD resources for all females of childbearing age, especially for those considering pregnancy. The average gestational ages at first and last positive urine toxicology were similar between groups, suggesting times that patients may be at higher risk of use and benefit from additional support.



701 Hypertensive Disorders of Pregnancy and Childhood Growth

Cynthia Gyamfi-Bannerman

UC San Diego Health, La Jolla, CA; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: The fetal in utero environment is known to affect health outcomes in childhood and beyond. Hypertensive disorders of pregnancy (HDP) are associated with uteroplacental ischemia, small for gestational age (SGA) newborns, and accelerated childhood growth. We evaluated whether HDP, in women at risk for late preterm delivery, were associated with altered growth in childhood.

STUDY DESIGN: Secondary analysis of a prospective, follow-up study of children of mothers enrolled in a trial of late preterm steroids. To be eligible, children had to be $\geq$ 6 years old and have complete anthropometric measures. Participants with gestational hypertension, preeclampsia with or without severe features, HELLP or eclampsia at any time during pregnancy were considered to have a hypertensive disorder of pregnancy. Childhood height and weight were assessed at a study visit and BMI calculated. Z-scores were generated using the Centers for Disease Control and Prevention Growth Charts. Height, weight, and BMI z-score, along with measurements that were $< 5^{th}$ percentile or $\geq 95^{th}$ percentile, were compared in children of mothers with or without a hypertensive disorder of pregnancy. Univariable and multivariable analyses were performed, the latter adjusting for pre-specified characteristics (Table).

RESULTS: Of 2,422 eligible children, 1,026 were enrolled in the follow-up study and 1,020 were included in this analysis, of whom 353 (34.6%) had mothers with a HDP. Children in the hypertensive group were more likely to have been SGA at birth and their mothers were heavier and more likely to identify as White or Black race. There were no differences in the adjusted z-scores or the proportion $< 5^{th}$ percentile or $\geq 95^{th}$ percentile for height, weight or BMI at the time of follow-up for children from pregnancies affected by hypertensive disorders (Table).

CONCLUSION: Hypertensive disorders of pregnancy in women at risk for late preterm delivery were associated with small for gestational age infants, but not childhood growth at 6 years of age.

Table 1. Hypertensive Disorders of Pregnancy and Childhood Anthropometrics

Anthropometrics	Hypertensive Disorder of Pregnancy		Unadjusted	Adjusted*
	Yes (N=353)	No (N=667)		
Weight-for-age z-score	0.6 +/- 1.3	0.4 +/- 1.2	0.19 (0.03,0.34)	-0.07 (-0.22,0.09)
< 5th percentile	11 (3.1%)	18 (2.7%)	1.15 (0.55,2.42)	1.41 (0.65,3.02)
≥ 95th percentile	85 (24.1%)	113 (16.9%)	1.42 (1.11,1.83)	1.13 (0.87,1.46)
Height-for-age z-score	0.4 +/- 1.2	0.2 +/- 1.0	0.15 (0.01,0.29)	0.02 (-0.11,0.16)
< 5th percentile	10 (2.8%)	18 (2.7%)	1.05 (0.49,2.25)	0.97 (0.44,2.14)
≥ 95th percentile	46 (13.0%)	56 (8.4%)	1.55 (1.07,2.24)	1.25 (0.85,1.85)
BMI-for-age z-score	0.5 +/- 1.6	0.4 +/- 1.4	0.16 (-0.02,0.35)	-0.09 (-0.28,0.09)
< 5th percentile	17 (4.8%)	34 (5.1%)	0.94 (0.54,1.67)	1.15 (0.65,2.05)
≥ 95th percentile	85 (24.1%)	114 (17.1%)	1.41 (1.10,1.81)	1.11 (0.86,1.44)

Data are n (%), relative risk (95% CI), mean +/- standard deviation, or mean difference (95% CI).
*Adjusted by pre-specified characteristics including maternal weight, maternal height, maternal age, gestational age at delivery, child age, gender, private insurance, treatment assignment, and center.

702 Pain Management After Vaginal Birth: A Systematic Review To Support Clinical Practice Guideline Development

Dana Feldman[1], Bryan L. Aaron[2], Laura Peyton Ellis[3], Faith Gacheru[1], Holli Sharples[1], Michelle Moniz[1], Jennifer Waljee[1], Mark Bicket[1], Courtney Townsel[4], Lisa Kane Low[1], LaTeesa James[1], Alex Peahl[1]
[1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Medical School, Ann Arbor, MI, [3]University of Connecticut, Farmington, CT, [4]University of Maryland, Baltimore, MD

OBJECTIVE: To assess the evidence for key aspects of pain management following vaginal birth, higher-order perineal trauma, and peripartum tubal ligation to inform new clinical practice guidelines.

STUDY DESIGN: We conducted a systematic review and narrative synthesis of studies addressing post-vaginal birth pain management (opioid medications, non-opioid medications, and non-pharmacologic methods). Studies assessed opioid use, analgesia effects, patient-centered outcomes, and disparities in the general population, patients with opioid use disorder (OUD), chronic pain, and psychiatric conditions. Ovid MEDLINE, Elsevier's Scopus, Elsevier's Embase, Google Scholar, PubMed, and Web of Science were searched to identify relevant articles. Articles were screened and abstracted by two researchers. Quality was assessed using the RAND/UCLA Appropriateness Methodology approach.

RESULTS: Of 2,255 studies screened, 21 were included: 1 high-quality (clinical practice guideline); 7 moderate-quality (RCTs); and 13 low-quality (non-RCTs, observational studies). Two reported that multimodal, non-opioid interventions (e.g. scheduled ibuprofen and acetaminophen) reduced opioid use without increasing pain after vaginal birth. Inpatient strategies and nonpharmacologic studies were limited with mixed results. Three discharge prescribing studies after vaginal birth showed variability and racial/ethnic disparities. Receiving discharge opioid prescriptions was linked to persistent use and opioid-related adverse events. Higher-order perineal trauma and tubal ligation were associated with increased opioid use after discharge. Patients with chronic pain and psychiatric conditions had increased opioid exposure and persistent use.

CONCLUSION: Multimodal oral opioid-sparing strategies provide adequate pain control while limiting opioid use after vaginal birth. Nonpharmacologic methods may provide low-risk enhancement in pain management. There are significant evidence gaps for postpartum pain management in patients with OUD, chronic pain, and psychiatric conditions.

703 UCSD Health CardioObstetrics Initiative: A Multidisciplinary Team to Improve Outcomes in the Pregnant Cardiac Patient

Dana R. Canfield[1], Dora J. Melber[2], Lauryn C. Gabby[3], Colton Applegarth[4], Minhazur R. Sarker[5], Kelsey Pinson[6], Maryam Tarsa[7], Laith Alshawabkeh[8]
[1]University of California, San Diego, La Jolla, CA, [2]San Diego Perinatal Center, San Diego, CA, [3]UCSD Department of OBGYN & Reproductive Sciences, San Diego, CA, [4]UCSD School of Medicine, San Diego, CA, [5]University of California San Diego, San Diego, CA, [6]UC San Diego, La Jolla, CA, [7]UC San Diego Medical Center, San Diego, CA, [8]UC San Diego, San Diego, CA

OBJECTIVE: Cardiovascular disease is the leading cause of maternal death in the United States. Despite professional obstetric and cardiology societies advocating for multidisciplinary care of cardiac patients in pregnancy, this care is not often standardized even at large academic centers. In 2020, we established a monthly conference to review prenatal course and develop safe delivery plans for pregnant patients with cardiac disorders.

STUDY DESIGN: This is a description of our multidisciplinary program and summary of patients who have been enrolled in our CardioObstetrics Care Conference since 2020. Every patient discussed in our conference is assigned a class corresponding to the Modified World Health Organization (WHO) Classification of Maternal Cardiovascular Risk. These scores range from 1 to 5 with 1 denoting a low-risk lesion unlikely to cause problems in pregnancy (eg successfully repaired simple defect) and 5 corresponding to a high risk of mortality with termination recommended (eg pulmonary arterial hypertension). The data presented summarizes the demographics and birth outcomes of our cohort stratified by WHO Risk Class.

RESULTS: Since starting our program, we have enrolled 121 patients with the majority falling into WHO Risk Classes 1 to 3. Most of our patient cohort self-identified as White, around half as Hispanic, and roughly even numbers were covered by private and public insurance. While increasing BMI was statistically related with worsening pathology, other demographic characteristics and mode of delivery did not vary significantly by WHO Risk Class (Table 1).

CONCLUSION: In the 3 years since its inception, our CardioObstetrics Care Conference has facilitated care for a diverse group of 121 patients with cardiac disease in pregnancy. In our cohort, increasing BMI is statistically related to higher WHO Risk Class while mode of delivery appears unrelated.

704 Operative Vaginal Delivery Rates over two-decades: Instrument Choice and Neonatal Morbidity-Implications for Resident Training

Daniel Kane[1], Ronan Daly[2], Elizabeth Tunney[2], Eimear Wall[2], Enya Fullston[2], Roisin Gryson[3], Etaoin Kent[4], Fergal D. Malone[2]
[1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]Rotunda Hospital, Dublin, Ireland, [3]Rotunda Hospital, Dublin, Dublin, [4]Rotunda Hospital, Dublin, Dublin, Ireland

OBJECTIVE: Operative vaginal delivery (OVD) rates have shown a downward trend in contemporary obstetrics, paralleling the decline in the trainee experience of forceps in some hospitals. We conducted a 20-year single-center study to explore the trajectory of OVD rates as well as assessing the trend of instrument choice and associated neonatal morbidity and mortality rates.

STUDY DESIGN: This was a retrospective analysis of prospectively collected data at a single tertiary referral center from 2002-2021. All cases of OVD were included. The choice of instrument (forceps or vacuum), rate of hypoxic-ischemic-encephalopathy (HIE) and of neonatal death (NND) after OVD were also recorded. Linear regression analysis was used to determine trends.

RESULTS: During the study period, there was a total of 162,460 deliveries. The rate of OVD accounted for 17.4% (n=21,042) of all deliveries or 25.0% of all vaginal deliveries. The overall rate of OVD use showed a non-significant decrease (p=0.33, R^2=0.0528, slope=-0.2299) during the 20-year study period. Forceps were used in 4.4% of all deliveries (n=7,197), while vacuum was used in 13.0% (n=21,042). In contrast to other center's experience, the use of forceps significantly increased during the study period (p=0.006, R2=0.3491, slope=0.5908). There were no statistically significant difference in NND (p=0.067) or HIE (p=0.370) associated with OVD use.

CONCLUSION: Our analysis of OVD use at a single tertiary referral center revealed noteworthy trends. While the overall rate of OVD use showed a non-significant decline, the use of forceps increased significantly. The cause of this increase is likely to be multi-factorial and may reflect institutional commitment on the part of senior clinicians to optimizing forceps training for residents. Despite these shifts in delivery methods, there was no statistically significant difference in neonatal morbidity or mortality associated with OVD use. These findings should be useful for encouraging obstetric residency training programs to either commit to, or maintain, resident exposure to forceps as a useful obstetric skillset.

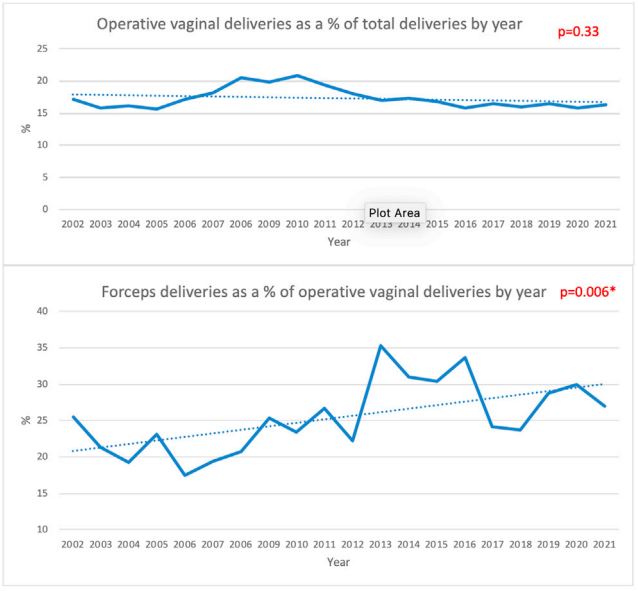

Fig1. % of forceps deliveries and % operative vaginal deliveries by year

705 Gestational diabetic CD4+ T-cells cause impaired glucose utilization, placental and pancreatic dysfunction, and hypertension

Danielle Frieson[1], Jan Michael Williams[1], Jean Vel[2], Baoying Zheng[1], Mariah Wilson[1], Nathan Campbell[1], Babbette LaMarca[1], Evangeline Deer[1]
[1]University of Mississippi Medical Center, Jackson, MS, [2]University of Mississippi Medical Center, Madison, MS

OBJECTIVE: Gestational diabetes mellitus (GDM) refers to glucose intolerance, insulin sensitivity and beta islet cell dysfunction during pregnancy. GDM pathogenesis is associated with hypertension, impaired placental and renal function, oxidative stress and increased circulating CD4+ T cells. Importantly, there are limited animal models available to explore GDM pathology and treatment. This study sought to determine a role for GDM patient placental CD4+ T cells to parallel the manifestations of GDM phenotype in pregnant athymic nude recipient rats.

STUDY DESIGN: GDM placental CD4+ T cells (GDM-CD4+ T cells) were magnetically isolated upon delivery and injected into pregnant nude athymic rats on gestational day (GD) 12. Mean arterial pressure (MAP) and markers of renal injury, proteinuria, kidney injury molecule-1 (KIM-1), and neutrophil gelatinase-associated lipocalin (NGAL) and placental mtROS were assessed on GD19. Glucose and Glucose tolerance tests (GTT) were performed on GD 19. Renal and pancreatic tissues were stained for Periodic acid Schiff (PAS) and

hematoxylin and eosin (H&E). A student's t-test was used for statistical analysis.

RESULTS: On GD19, MAP was higher in GDM-CD4+ T cell rats (121±3, n=8, p< 0.05) compared to pregnant athymic nude control rats (105±3 mmHg, n=8). Blood glucose was 201±46 mg/dl, (p< 0.05) in GDM CD4+T cell rats compared pregnant controls (82±9 mg/dl). GTT was impaired in GDM CD4+ T rats. Proteinuria and markers of renal injury were elevated in GDM-CD4+ T cell rats (5±0.8 ml/day (p< 0.05); 47±10 pg/mg, (p< 0.05); 28±4 pg/mg, (p< 0.05)) compared to controls (2±0.3 ml/day; 22±3 pg/mg; 12±1 pg/mg). Histological analysis showed increased glomerular damage and decreased beta islet number in GDM-CD4+T cell rats compared to controls. Placental mt ROS increased in GDM CD4+ T cells rats (291±47 FLU, p< 0.05) compared to controls (100±18 FLU).

CONCLUSION: Our findings indicate that GDM CD4+ T cells cause a diabetic phenotype during pregnancy suggesting a new model to investigate mechanisms and therapies for diabetes during pregnancy.

706 Insomnia in pregnancy: are hospitalized inpatients sleeping less than outpatients?

Danielle M. Panelli[1], Hayley E. Miller[2], Samantha L. Simpson[3], Janet Hurtado[4], Chi-Hung Shu[4], Ana C. Boncompagni[4], Jane Chueh[5], Fiona Barwick[4], Brendan Carvalho[4], Pervez Sultan[4], Nima Aghaeepour[4], Maurice L. Druzin[6]

[1]Stanford University, Palo Alto, CA, [2]Stanford University Hospital, San Francisco, CA, [3]Stanford, Mountain View, CA, [4]Stanford University, Stanford, CA, [5]Stanford, Menlo Park, CA, [6]Stanford University Medical Center, Palo Alto, CA

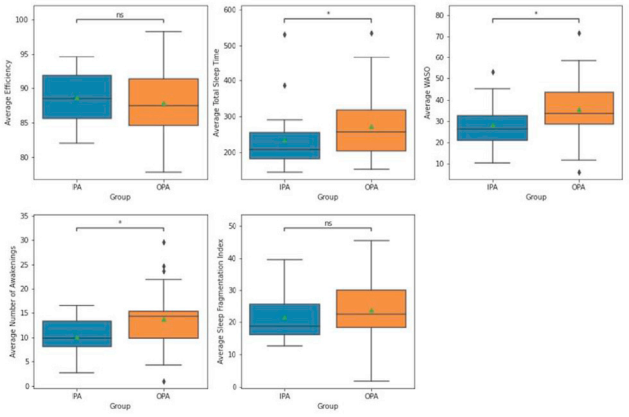
OBJECTIVE: Optimizing physical and mental health during antepartum hospitalization is critical, and understanding sleep quality is a key component of this. Since little is known about how antepartum hospitalization affects sleep, we compared sleep between pregnant inpatients and outpatients.

STUDY DESIGN: This was a prospective cohort between 2021-2022 including pregnant people aged 18-55 years with singleton gestations ≥16 weeks. Outpatients from obstetrics clinics were gestational age matched to antepartum inpatients. Participants responded to the Insomnia Severity Index (ISI) and wore Actigraph accelerometer watches up to 7 days to evaluate sleep. The primary outcome was mean total sleep duration per 24 hours. Secondary outcomes were sleep efficiency (time asleep/time in bed as a percentage), ISI score, clinical insomnia based on ISI score >15, short sleep duration (< 300 minutes per 24 hours), Wakefulness After Sleep Onset (WASO), number of awakenings, and sleep fragmentation index. Sleep parameters were compared using Wilcoxon rank sum tests and multivariable generalized estimating equations adjusting for body-mass index and use of sleep aid medication.

RESULTS: Data from 59 participants were analyzed. Inpatients were more likely to use sleep aids (39.9% versus 12.5%, p=0.03). Inpatients had significantly lower total sleep duration than outpatients (264.1 ± 97.5 minutes versus 309.4 ± 87.3 minutes, beta -62.8 [95% Confidence Interval -109.2 to -16.4], p=0.008). There were no differences in sleep efficiency, ISI score, clinical insomnia, or short sleep duration (Table 1). Number of awakenings and WASO were reduced among inpatients (p=0.01 and p=0.03, Figure 1).

CONCLUSION: Hospitalized pregnant inpatients slept 1 hour less than outpatients per day despite increased use of sleep aids, which is enough to have a clinically significant effect on health. Notably, average sleep time for inpatients was < 5 hours per day - well below the recommended 7 hours in pregnancy. Initiatives to improve sleep during pregnancy are warranted, particularly for antepartum inpatients.

Figure 1. Summary of sleep parameters compared between inpatients (IPA) and outpatients (OPA), N=59.



707 Patient factors associated with severe maternal morbidity by urban-rural designation in Georgia, United States

Danielle M. Vuncannon[1], Anne L. Dunlop[1], Marissa H. Platner[1], Sheree L. Boulet[1], Michael Kramer[1], Peter J. Joski[2], Denise Jamieson[3], E. Kathleen Adams[2]

[1]Emory University School of Medicine, Atlanta, GA, [2]Rollins School of Public Health at Emory University, Atlanta, GA, [3]University of Iowa, Iowa City, IA

OBJECTIVE: Georgia has among the highest rates of severe maternal morbidity (SMM) in the nation. Location of residence has been identified as a contributing factor for SMM, with those in metropolitan and rural Georgia at highest risk. To determine whether SMM risk factors differed by location of residence, we evaluated the association of maternal and pregnancy characteristics with SMM stratified by categories of urban-rural designation.

STUDY DESIGN: This population cohort study included all delivery hospitalizations in Georgia during 2016-2020 with birth record linked to hospital discharge data (n = 529,357). Multivariable robust Poisson regression analysis was used to estimate adjusted risk ratios (aRR) and 95% confidence intervals (CI) for the association of maternal and pregnancy characteristics with SMM at delivery admission or through 42 days postpartum, stratified by location of residence (categorized using the National Center for Health Statistics Urban-Rural Classification Scheme for Counties). SMM was identified using the 21 indicators defined by the Centers for Disease Control.

RESULTS: Across all residency categories, cesarean delivery was the factor most strongly associated with SMM (aRR 3.52, 95% CI 3.04-4.06 in small metro). Association of comorbidities varied by residency location. In metropolitan Georgia, severe mental illness (aRR 1.56, 95% CI 1.43-1.70), hypertension (aRR 1.40, 95% CI 1.28-1.53), and substance use (aRR 1.26, 95% CI 1.09-1.46) were the comorbidities most strongly associated. In rural Georgia, severe mental illness (aRR 1.40; 95% CI 1.05-1.86) and hypertension (aRR 1.39, 95% CI 1.08-1.80) were most strongly associated. The strength of association between hypertensive disorders of pregnancy and SMM increased as rurality increased (aRR 1.08, 95% CI 1.96-2.21 in metropolitan vs. aRR 2.53, 95% CI 2.01-2.13 in rural).

CONCLUSION: These findings demonstrate variation in factors associated with SMM by location of residence in Georgia and underscore the need for tailored prevention efforts within each location of residence.

Table 1. Multivariable robust Poisson analysis of SMM at delivery admission or through 42 days postpartum for maternal and pregnancy characteristics by location of residence.

Characteristic	Adjusted Relative Risk of Severe Maternal Morbidity				
	Large Metro	Medium Metro	Small Metro	Micropolitan	Rural
Mode of Delivery					
Cesarean	2.78 (2.62-2.95)	3.21 (2.63-3.93)	3.52 (3.05-4.06)	3.03 (2.58-3.56)	2.92 (2.43-3.51)
Comorbidities					
Diabetes Mellitus	1.11 (0.96-1.29)	1.40 (0.93-2.11)	1.53 (1.19-1.98)	0.85 (0.59-1.24)	1.42 (0.97-2.06)
Hypertension	1.40 (1.28-1.53)	1.12 (0.86-1.48)	1.54 (1.30-1.83)	1.29 (1.04-1.61)	1.39 (1.08-1.80)
Substance Use	1.26 (1.09-1.46)	1.32 (0.88-1.98)	1.41 (1.12-1.78)	1.14 (0.86-1.50)	1.19 (0.83-1.69)
Severe Mental Illness	1.56 (1.43-1.70)	1.65 (1.27-2.16)	1.27 (1.02-1.58)	1.05 (0.81-1.37)	1.40 (1.05-1.86)
Pregnancy Complications					
Hypertensive Disorder of Pregnancy	1.08 (1.96-2.21)	1.88 (1.54-2.30)	2.36 (2.07-2.69)	2.37 (2.05-2.75)	2.53 (2.13-3.01)
Preterm Delivery	1.84 (1.73-1.97)	3.01 (2.45-3.69)	1.92 (1.67-2.21)	2.32 (1.99-2.70)	1.77 (1.46-2.15)

Data are adjusted relative risk (95% confidence interval).
Adjusted models included age, race/ethnicity, level of education, marital status, insurance status, prenatal care utilization, parity, plurality, mode of delivery, comorbidities, and pregnancy complications.

708 Trends in placenta previa by age, race/ethnicity, and pre-pregnancy body mass index

Darios Getahun[1], Morgan Peltier[2], Nana Mensah[3], Vicki Y. Chiu[3], Meiyu Yeh[3], Nehaa Khadka[3], Yinka Oyelese[4], Michael J. Fassett[5]

[1]Kaiser Permanente Southern California Medical Group, Pasadena, CA, [2]NYU Long Island School of Medicine, Mineola, NY, [3]Kaiser Permanente Southern California, Pasadena, CA, [4]Beth Israel Deaconess Medical Center, Boston, MA, [5]Kaiser Permanente West Los Angeles Medical Center, Los Angeles, CA

OBJECTIVE: To characterize recent trends in placenta previa (PP) by maternal age, race/ethnicity, and pre-pregnancy body mass index (BMI).

STUDY DESIGN: Using Kaiser Permanente Southern California's electronic health records, we examined temporal trends in PP from 2009-10 through 2021-22 among singleton births at ≥20 weeks of gestation (N=507,494). Diagnosis of PP was based on the International Classification of Diseases Ninth/Tenth codes from routine clinical records of the electronic health records. We calculated the proportion of PP in the earliest (2009) versus most recent (2022) periods stratified by maternal age, race/ethnicity, and pre-pregnancy BMI. Poisson regression analysis was used to evaluate the adjusted p-values for temporal changes. Adjustments were made for maternal characteristics and behavioral factors.

RESULTS: The prevalence of PP was 10 per 1000 singleton pregnancies. Prevalence decreased from 11/1000 in 2009-10 to 8/1000 in 2021-22 (a relative decrease of 27.3%, $p < 0.001$). From 2009-10 to 2021-22, the PP rate decreased among women aged 30-34 years from 13/1000 to 8/1000, a relative decrease of 38.5% (adjusted p-value < 0.0001), and among women aged ≥35 years from 19/1000 to 14/1000, 26.3% decrease (adjusted p-value < 0.0001). Women aged < 30 years had the largest relative decrease (from 6/1000 to 3/1000; 50.0% [adjusted p-value < 0.0001]). Decreased rates of PP were observed for all race/ethnicity and BMI categories, but was largest for morbidly obese patients (41.7% relative reduction, adjusted p-value < 0.0001).

CONCLUSION: The prevalence of PP has decreased over the past decade. PP prevalence is disproportionately higher among racial/ethnic minorities and obese women. The drivers of these disparities are unclear and need to be investigated further. Although racial/ethnic disparities in rates of PP are persistent, they could be narrowing.

709 Impact of abortion bans on pregnancies with severe life-limiting fetal anomalies: a cost-effective analysis

David Monroe[1], Uma Doshi[1], Kimberley Bullard[2], Aaron B. Caughey[1]

[1]Oregon Health & Science University, Portland, OR, [2]University of Tennessee College of Medicine Chattanooga, Chattanooga, TN

OBJECTIVE: Since the US Supreme Court decision in *Dobbs v. Jackson Women's Health* to overturn a constitutional right to abortion in June 2022, 24 states have enacted laws prohibiting termination of pregnancy before most fetal anomalies are diagnosed. No exceptions are made for trisomy 13, trisomy 18, or anencephaly, which are severe life-limiting conditions with significant morbidity for survivors and their mothers. In this cost-effectiveness model, we estimated the difference in cost and maternal health outcomes associated with a termination ban for severe life-limiting fetal anomalies.

STUDY DESIGN: A decision-analytic model was built using TreeAge software to compare a total ban on termination in a theoretical cohort of 1038 women constructed from the annual incidence of trisomy 13, trisomy 18, or anencephaly (5.76/10000) and birth data from the 24 states with bans. All of these women were assumed to desire termination. Probabilities, utilities and costs were derived from the literature. National data was used to estimate the number of women who would travel out of state to obtain an abortion (27.2%). The threshold for cost-effectiveness was set at $100,000 per quality adjusted life year (QALY). Clinical outcomes included maternal death, stillbirth, birth of neonates with severe disease, severe preeclampsia, blood transfusion for hemorrhage, and infections.

RESULTS: Among the cohort, there would be 734 more live births affected by a severe life-limiting anomaly with an abortion ban in place. A policy restricting termination is associated with higher costs ($76,257,272) and decreased quality of life (4065 QALYs) annually. Two hundred and eighty-two women would travel out of state to obtain abortions.

CONCLUSION: Termination bans without exceptions for severe life-limiting fetal anomalies significantly restrict access to care for affected women and are associated with increased costs and worse health outcomes. Policies addressing abortion access should consider these health and cost impacts for both individuals and society.

Table 1.
Additional cases of each outcome in a theoretical cohort of 1038 women with trisomy 13, trisomy 18, or anencephalic pregnancies in states with abortion bans.

n=1038	Abortion Ban	No Abortion Ban	Difference
Maternal Mortality	0	0	0
Stillbirth	20	0	20
Birth of Neonate with Severe Disorder	734	0	734
Severe Preeclampsia	3	0	3
Hemorrhage Requiring Transfusion	5	3	2
Postpartum/Postoperative Infections	14	11	3
Abortions	282	1038	756
Cost	$84,431,573	$8,174,301	$76,257,272
Effectiveness (QALY)	22,608	26,673	4065

710 Variability in Epithelial DNA Yield Isolated from Cervical Mucosa During Pregnancy

Devon O'Brien[1], Julie Vircks[1], Brad Belden[2], Nick Nolte[2], Dan Louiselle[2], Elin Grundberg[2], Devika Maulik[1]
[1]University of Missouri-Kansas City School of Medicine, Kansas City, MO, [2]Children's Mercy Adele Hall - Genomic Medicine Center, Kansas City, MO

OBJECTIVE: There are ongoing challenges to studying pathophysiology of perinatal outcomes proximal to cervical architecture. However, epithelial DNA obtained from pregnant cervical mucosa offers a potentially noninvasive way of assessing gestational cervical changes at a genomic level. This study aims to evaluate the feasibility of isolating adequate cervical DNA during pregnancy and characterize the variability of DNA yields during routine clinical speculum exams at various gestational ages.

STUDY DESIGN: This is a prospective observational study, with patients recruited from an urban, safety-net hospital. During the prenatal visit, an additional cervical sample was obtained from routine speculum exams with a cytobrush; collected swabs were stored in a DNA transport medium. DNA was isolated using the DNeasy Blood & Tissue Kit (Qiagen) and banked in a -80 degree Celsius freezer. Demographics of participating subjects were collected. Descriptive statistics and multiple regression were utilized for data analyses.

RESULTS: Forty-three subjects were enrolled in the study, of which 40 had a cervical sample collected at the time of their initial obstetric visit. Gestational age ranged from 7 to 35 weeks with a median of 11.7 (IQR 9.8-16.3). Cervical epithelial DNA was successfully isolated in all viable samples, though the total yield varied widely across all gestational ages (Figure 1), with a median of 11ug (IQR 2,850-23,150). Gestational age, body mass index, and maternal age did not significantly predict the quantity of cervical DNA isolated (R^2=0.070, p=0.46).

CONCLUSION: Given that there was no correlation between multiple population characteristics and amount of DNA obtained, provider technique likely plays a role. However, this study did demonstrate that adequate cervical DNA can be easily obtained across a range of gestational ages and as part of a routine screening procedure in pregnancy (Pap smear) for downstream genomic analysis requiring typically only 100ng of DNA. Therefore, there could be utility in using this approach for future screening tools when identifying markers for adverse pregnancy outcomes.

711 Maternal endometriosis: an independent risk factor for long-term infectious morbidity of the offspring

Dor Marciano[1], Gil Gutvirtz[1], Tamar Wainstock[2], Eyal Sheiner[3]
[1]Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Metar, HaDarom, [2]Ben Gurion University, Beer-Sheva, HaDarom, [3]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: Endometriosis, a debilitating disease characterized by chronic inflammation, is associated with adverse pregnancy outcomes. However, the long-term health implications for offspring born to mothers with endometriosis remain inadequately explored. The maternal immune response in pregnancy is crucial for fetal development and growth, and the pro-inflammatory state of endometriosis may alter fetal immunologic programming. In this study, we aimed to assess an association between fetal exposure to maternal endometriosis and long-term risk of infectious morbidity for the offspring.

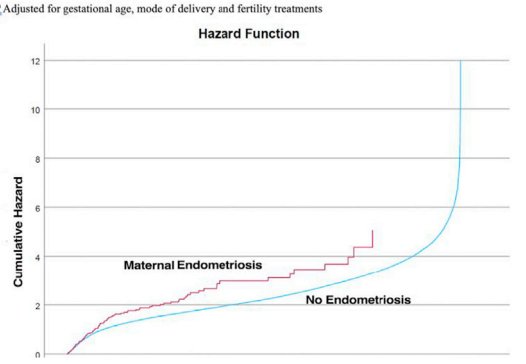
STUDY DESIGN: We conducted a retrospective population-based cohort study, comparing offspring of mothers diagnosed with endometriosis with those of mothers without the diagnosis. We followed the offspring longitudinally, tracking the time to their first diagnosis with an infectious disease made in a community-based clinics or hospitalization. A Kaplan-Meier survival curve was used to compare the cumulative incidence of offspring infectious morbidity between the study groups. A Cox regression model was constructed to evaluate an association between maternal endometriosis and offspring infectious morbidity, adjusting for possible confounders.

RESULTS: A total of 232,476 singleton deliveries were included. 224 deliveries of mothers diagnosed with endometriosis were compared to those without endometriosis. The total infectious morbidity rate was comparable between groups (70.5% vs. 68.0%, p=0.41). However, the Kaplan-Meier survival curve illustrated an elevated cumulative incidence of infectious morbidity in offspring born to mothers with endometriosis (Log-rank< 0.01, **Figure**). A Cox regression model, adjusted for gestational age, fertility treatments and mode of delivery, found that fetal exposure to maternal endometriosis was an independent risk factor for long-term infectious morbidity of the offspring (adjusted HR=1.17, 95%CI 1.00-1.36, p=0.05, **Figure**).

CONCLUSION: Fetal exposure to maternal endometriosis is an independent risk factor for long-term infectious morbidity of the offspring.

	Maternal endometriosis (N =224)	No maternal endometriosis (N = 232,252)	OR (95% CI)	Adjusted* HR (95% CI)
Infectious morbidity	158 (70.5%)	157,931 (68%)	1.12 (0.84-1.50)	1.17 (1.00 - 1.36)

*Adjusted for gestational age, mode of delivery and fertility treatments



712 Mode of delivery in preterm twin pregnancy and long-term cardiovascular morbidity of the offspring

Dor Nissim[1], Tamar Wainstock[2], Eyal Sheiner[3], Gali Pariente[4]
[1]Joyce and Irving Goldman Medical School, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, HaDarom, [2]Ben Gurion University, Beer-Sheva, HaDarom, [3]Soroka University Medical Center, Beer-Sheva, HaDarom, [4]Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Klahim, HaDarom

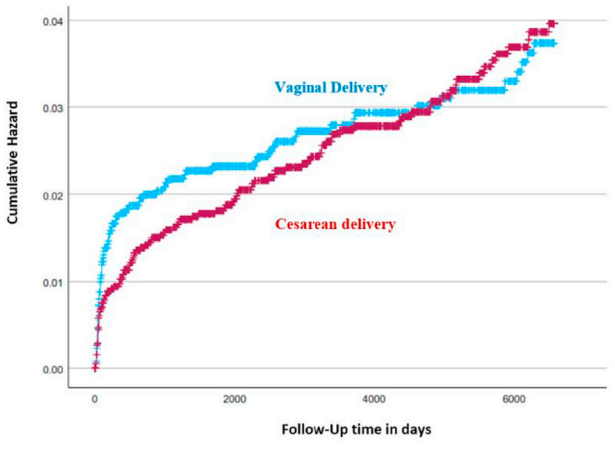
OBJECTIVE: Twin pregnancies are associated with higher rates of prematurity. The recommended mode of delivery in premature twin pregnancies is still under debate. Considering the known association between prematurity and long-term cardiovascular morbidity of the offspring, we opted to assess the association between mode of delivery of premature twins and long-term cardiovascular morbidity of the offspring.

STUDY DESIGN: A population-based retrospective cohort study, assessing the association between mode of delivery in preterm twin pregnancy and long-term cardiovascular morbidity of the offspring was conducted. Twins were born between the years 1991-2021 in a single tertiary medical center. The study groups were followed until 18 years of age for cardiovascular-related morbidity. A Kaplan-Meier survival curve was used to compare cumulative cardiovascular morbidity between the groups, and a multivariable Cox proportional hazard analysis was used to adjust for confounders.

RESULTS: During the study period 6,504 premature twins, born before 37 weeks gestation, were included, of which 3,868 (59.5%) were born through cesarean delivery (CD). Premature twins born through vaginal delivery did not demonstrate a significantly higher rate of long-term cardiovascular morbidity when compared with premature twins born through CD (2.9% vs. 2.8%, OR=0.96, 95% CI 0.71-1.30, p=0.82). Likewise, the cumulative incidence of long-term cardiovascular morbidity did not differ according to mode of delivery (Kaplan-Meier Log rank p=0.804, Figure). In a Cox proportional hazard model, the mode of delivery in premature twins was not associated with long-term cardiovascular morbidity of the offspring (adjusted HR=0.83, 95% CI 0.60-1.15, p=0.264).

CONCLUSION: In our population, no association was documented between mode of delivery in preterm twin pregnancies and long-term cardiovascular morbidity of the offspring. In the perspective of childhood cardiovascular morbidity, vaginal delivery in preterm twin pregnancies seems to be as safe as CD.

Figure: The cumulative incidence of long-term cardiovascular morbidity of premature twins according to mode of delivery (Log Rank p value= 0.804)



713 What blood bank preparation is appropriate for women giving birth?

Douglas S. Richards[1], Sarah Illstrup[1], Terry Rees[1], Sean Esplin[2], Donna Dizon-Townson[3], Erick Henry[4], Allison Butler[1], Brett D. Einerson[5]
[1]Intermountain Healthcare, Murray, UT, [2]Intermountain Medical Center, Murray, UT, [3]Intermountain Health, Sandy, UT, [4]Intermountain Health, Murray, UT, [5]University of Utah Health, Salt Lake City, UT

OBJECTIVE: Maximum surgical blood order schedules (MSBO) recommend T&S if the need for transfusion during an operative procedure is predicted to be > 5%. The type of blood bank preparation ordered for women giving birth (hold clot, type and screen, or crossmatch) is often determined according to the presence of hemorrhage risk factors. This approach does not quantify the chance for transfusion. The purpose of this study was to quantify the relative importance of risk factors for needing a blood transfusion and to develop a formula to define each individual's risk. This could then be used to decide an appropriate level of blood preparation for patients at different risk levels.

STUDY DESIGN: Risk factors for hemorrhage and the level of blood bank preparation were extracted from the medical records of a cohort of 89,239 women delivering in an 18-hospital health care system over 40 months. We tabulated the number who required at least one RBC transfusion or an urgent transfusion- defined as receiving blood during labor or within 4 hours after delivery. Odds ratios for requiring a transfusion were calculated for each risk factor. We then calculated the probability of a transfusion in deciles according to predicted risk of transfusion.

RESULTS: On admission, 66.3% of patients had a hold clot, 33.0% had a type and screen, and 0.7% had a crossmatch. 648 patients had any transfusion during their hospitalization (0.73% of deliveries), and 313 had an urgent transfusion (0.35% of deliveries). Odds ratios and frequency of risk factors are shown in the table. The mean probability of patients in the highest risk decile of having any transfusion was 3.4% (95% CI 3.0-3.8%).

CONCLUSION: In our cohort, the lowest 9 deciles risk of transfusion was < 1%, and even the highest risk decile had a predicted transfusion risk well below 5%. Based on the low chance of needing a transfusion for almost all obstetric patients, we suggest that a hold clot be used except for the highest risk patients- i.e. those with PAS, Hgb < 8, or placenta previa.

	Presence of Risk Factor		Tranfusion*		Urgent Transfusion*		Odds of transfusion
	n	%	*n*	%	*n*	%	*OR (95% CI)*

714 Neonatal Outcomes After Maternal versus Neonatal Transfers to a Level IV Perinatal Care Center

Drew M. Hensel[1], Janet Chandarlis[2], Josh Hernandez[2], Nandini Raghuraman[1], Roxane M. Rampersad[3], Ebony B. Carter[3], Anthony O. Odibo[1], Barbara Warner[2], Jeannie C. Kelly[3]

[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

OBJECTIVE: To access the highest levels of maternal and neonatal care, inpatient transfer to Level IV Perinatal Care Centers (PCC) is sometimes needed. We sought to compare neonatal outcomes between maternal and neonatal transfers to a Level IV PCC.

STUDY DESIGN: We performed a retrospective cohort study of all maternal and neonatal transfers to our Level IV PCC from January – December 2021. Maternal transfers who delivered during the transfer admission, and neonatal transfers within 24 hours of birth were included. Neonates were excluded if neonatal resuscitation was declined. The primary outcome was composite neonatal morbidity which included: respiratory distress syndrome (RDS), mechanical ventilation, sepsis, grade 3-4 intraventricular hemorrhage (IVH), chronic lung disease, necrotizing enterocolitis, patent ductus arteriosus, and stage 3-4 retinopathy of prematurity. Secondary outcomes included mode of delivery, APGAR < 7 at 5 minutes, length of neonatal stay, and each composite morbidity component. Chi-square, fisher exact, Mann-Whitney U, and multivariate logistic regression were used as appropriate.

RESULTS: 217 neonatal and 200 maternal transfers were included. Maternal transfers delivered at earlier gestational ages. Additionally, maternal transfers were less likely to have congenital anomalies, and more likely to receive antenatal steroids, be diagnosed with hypertensive disorders of pregnancy, and include racial minorities. For our primary outcomes, maternal transfers had significantly less odds of composite neonatal morbidity (aOR 0.79 [0.72-0.88]), specifically RDS (aOR 0.78 [0.70-0.86]), mechanical ventilation (aOR 0.84 [0.76-0.93]), and IVH (aOR 0.96 [00.92-0.99]), but their neonates had longer lengths of stay.

CONCLUSION: Maternal transfer to a Level IV PCC, compared to neonatal transfers, are associated with significantly lower odds of neonatal morbidity. These results underscore the importance of sustaining and expanding robust maternal transport programs to best access both maternal and neonatal expertise at Level IV PCCs.

715 Trends in Tdap and Flu Vaccination in Pregnant People in Relation to the COVID-19 Pandemic

Eesha Dave[1], Jennifer F. Culhane[1], Lisbet S. Lundsberg[2], Caitlin Partridge[1], Katherine Kohari[3], Anna Denoble[4]
[1]Yale University, New Haven, CT, [2]Yale, New Haven, CT, [3]Yale New Haven Hospital, New Haven, CT, [4]Yale University School of Medicine, New Haven, CT

OBJECTIVE: We aimed to understand how the COVID-19 pandemic impacted routine Tetanus, Diphtheria, and Pertussis (Tdap) and Influenza (Flu) vaccine administration in pregnancy.

STUDY DESIGN: This was a retrospective review of electronic medical records for Tdap and Flu vaccine administration for pregnant patients at a single institution from Mar 2018 to Dec 2022. Patients were assigned to the acute COVID epoch if their gestational age was < 20 weeks by 3/10/2020 and their estimated due date was before 1/1/2021. Pre-COVID and chronic COVID epochs comprised matched months for the two years before and after acute COVID. Bivariate associations between patient characteristics by COVID epoch (Table) and Tdap vaccination (data not shown) were assessed using X^2 and ANOVA. Associations between COVID epoch and Tdap vaccination, and COVID epoch and Flu vaccination, were evaluated using multivariable logistic regression.

RESULTS: Tdap vaccination rates varied across COVID epoch with a > 10% increase from pre-COVID (75.5%) to acute COVID (85.8%). The Tdap vaccine rate attenuated in the chronic COVID epoch (81.2%). A similar pattern was observed for Flu vaccination with an increasing rate from pre-COVID (48.1%) to acute COVID (53.3%). Flu vaccination rates fell dramatically in the chronic COVID epoch (38.5%) to below pre-COVID levels. Seven covariates were included in regression modeling. Compared to pre-COVID, the likelihood of Tdap vaccination was increased in both the acute COVID epoch [aOR= 2.01; CI 1.74-2.34] and the chronic COVID epoch [aOR = 1.38; CI 1.24-1.54]. The likelihood of Flu vaccination also significantly increased from pre-COVID to acute COVID [aOR=1.25; CI 1.2-1.39]. Notably, Flu vaccination uptake was dramatically reduced from pre-COVID to chronic COVID [aOR=0.67; CI 0.61-0.73].

CONCLUSION: Tdap and Flu vaccination rates peaked during acute COVID, likely correlating with amplified health concerns during the pandemic. After acute COVID, vaccination rates were sustained for Tdap, but decreased for Flu. Future studies are needed to elucidate health factors influencing rates of vaccination uptake.

Table 1: Tdap and flu vaccine administration rates and demographics by COVID-19 epoch

716 Outcomes from a 15 Year Review of Cystic Hygroma

Eimear Wall[1], Ciara M. Malone[2], Elizabeth Tunney[1], Ronan Daly[1], Daniel Kane[3], Alex Dakin[4], Sieglinde Mullers[5], Fergal D. Malone[1], Etaoin Kent[4]
[1]Rotunda Hospital, Dublin, Ireland, [2]Royal College of Surgeons in Ireland, Dublin, Ireland, [3]Royal College of Surgeons in Ireland, Dublin, Ireland, [4]Rotunda Hospital, Dublin, Dublin, Ireland, [5]RCSI, Dublin, Ireland

OBJECTIVE: Invasive genetic testing is routinely recommended to investigate aneuploidy as a cause of cystic hygroma in the first trimester. In the context of normal genetic testing, the predicted outcome is impacted by the presence of co-existing structural anomalies, particularly cardiac anomalies. We reviewed the diagnosis and outcome of these patients to establish contemporary outcome data to aid appropriate counseling.

STUDY DESIGN: This is a retrospective cohort study in a single large maternity hospital. Cases were identified using a fetal anomaly database and an electronic health record system. Data were collected on all patients with a fetal diagnosis of a nuchal translucency > 3mm with septations from 2007 to 2022. Results of chromosomal analysis, pregnancy outcomes and fetal outcomes were collated and described using summary statistics.

RESULTS: During the 15-year period, there were over 135,000 deliveries at our center. 677 cases of septated cystic hygroma were diagnosed. Pregnancy outcome was obtained in 97.5% (n=660) of cases, with 92% (621/677) undergoing invasive prenatal or postnatal testing. 39% (247/621) had a normal karyotype. 38% (249/660) of women underwent termination of pregnancy. In-utero demise occurred in 24% (159/660). Structural anomalies were found in 16% (39/247) of those with normal karyotype. In cases of cystic hygroma, normal invasive testing in the absence of structural anomalies carried a livebirth rate of 86% (164/191), in contrast to an overall livebirth rate of 38% (252/660) in all pregnancies affected by cystic hygroma.

CONCLUSION: Cystic hygroma is a significant finding in early pregnancy which confers a risk of aneuploidy of approximately 60% and is associated with adverse pregnancy outcomes. Outcomes of the study demonstrate a high livebirth rate in those with normal invasive testing and fetal echocardiography. This confirms the significance of appropriate counseling regarding confirmatory invasive testing, and highlights the value of follow-up with detailed anatomy ultrasound.

717 Is expectant management of late PPROM an option in patients with GBS colonization?

Elior Eliasi[1], Miriam Lopian[2], Ariel Many[3], Ronnie Cohen[4], Hadel Shabita[5], Olena Minich[5]
[1]Mayanei Hayeshua, Bnei Brak, HaMerkaz, [2]Mayanei Hayeshua Medical Center, Ra'anana, HaMerkaz, [3]Ma'ayne Hayeshua Medical Center Tel Aviv University, Bnei Brak, Tel Aviv, [4]Maaynei Hayeshua medical center Bnei Brak, Petach-Tikva, HaMerkaz, [5]Maynei Hayeshoa, Bnei Brak, HaMerkaz

OBJECTIVE: To determine if carriers of group B streptococcus (GBS) have adverse obstetric and neonatal outcomes when preterm premature rupture of membranes (PPROM) occurs between 34 to 37 weeks of pregnancy.

STUDY DESIGN: A retrospective cohort study was conducted at a single university-affiliated medical center between 2012 and 2022. Patients who had preterm premature rupture of membranes (PPROM) between 34 to 37 weeks of pregnancy carrying a singleton gestation, with no contraindications to expectant management were included in the study group. According to the department protocol, all patients with PPROM receive 1G of IV Azithromycin once and 4g of IV penicillin every 4 hours. Antibiotics are discontinued in patients negative for GBS and continued for one week in GBS positive patients. Outcomes were compared to those with a negative GBS culture. Baseline demographic characteristics were compared between the groups. The primary outcome was latency from PPROM till delivery. Secondary outcomes included cesarean delivery, composite adverse maternal outcome (PPH, chorioamnionitis, abruption of placenta) and composite neonatal outcome (NICU admission, respiratory distress syndrome, early onset GBS disease).

RESULTS: Two hundred and seventeen patients were included in the study. 98(45.2%) were GBS carriers and 119 (54.8%) were non-carriers. There were no significant between group differences in mean maternal age (GBS carriers: 27.3±6, noncarriers: 29.7±6.1; p=0.37) or gestational age at delivery (252 days±5 Vs 252

days±6;p=0.4),rate of diabetes (10.1% Vs 10.2%;p=0.97) neonatal mean birthweight (2602g ±36 Vs 2698g±56;p=0.32). There were no significant differences between the groups for the primary outcome of duration from membrane rupture until delivery (2.83 ± 2.9 days Vs 3.03 ± 2.9 days ;$P = 0.98$) nor the rate of cesarean delivery (9.8% Vs 10.9% ;p=0.45) or in composite maternal (2.7% Vs 1.9%;p=0.26) or neonatal outcomes(23% Vs 22%;p=0.34).

CONCLUSION: Expectant management of late PPROM in GBS carriers is not associated with an increased risk of adverse maternal or neonatal outcomes.

baseline demographic characteristics			
	GBS carriers	noncarriers	P value
Mean maternal age	27.3±6	29.7±6.1	0.37
Gestational age at delivery	252 days±5	252 days±6	0.4
Rate of diabetes	10.1%	10.2%	0.97
Hypertension disease	2%	1.7%	0.84
Neonatal mean birthweight	2602g±36	2698g±55	0.32
Maternal and neonatal outcomes			
Rate of cesarean delivery	9.8%	10.9%	0.45
PPH	4.2%	1.7%	0.27
Chorioamnionitis	2.1%	0.8%	0.45
Abruption of placenta	4.1%	3.4%	0.79
Composite maternal outcomes	2.7%	1.9%	0.26
NICU admission	30.6%	30.3%	0.95
Respiratory distress syndrome	17.3%	14.3%	0.53
Phototherapy	23.5%	22.7%	0.89
Early onset GBS disease	0	0	
Composite neonatal outcomes	23%	22%	0.34
Duration from membrane rupture until delivery	2.83 ± 2.9 days	3.03 ± 2.9 days	0.98

718 Identification of Black Birthing People at Highest Risk for Suicide

Emily S. Miller[1], Lighwah Ncube[2], Fatoumata Barry[2], Valerie Riis[2], Michal A. Elovitz[3]

[1]Alpert Medical School of Brown University and Women & Infants Hospital of Rhode Island, Providence, RI, [2]Women's Biomedical Research Institute; Icahn School of Medicine at Mount Sinai, New York, NY, [3]Women's Biomedical Research Institute, Icahn School of Medicine at Mount Sinai, New York, NY

OBJECTIVE: Suicide is one of the leading contributors to maternal mortality, however prediction of perinatal suicide remains poor. A history of prior suicide attempt is considered one of the most robust predictors of eventually completed suicide. We aimed to evaluate whether social determinants of mental health (SDoMH) can correctly classify birthing people at the highest risk of perinatal suicide.

STUDY DESIGN: This secondary analysis of a prospective cohort of Black birthing people. Individuals in the primary study were included in this analysis if they completed the Philadelphia ACE screen, which queried any prior history of attempted suicide. SDoMH, including age at pregnancy, parity, body mass index, ethnicity, insurance, marital status, and educational attainment, was obtained through self-report. Bivariable and multivariable models were used to identify SDoMH associated with a prior suicide attempt. A receiver operating characteristic curve for the outcome of prior suicide attempt was generated and the area under the curve (AUC) calculated.

RESULTS: Of the 592 Black birthing people included in the parent cohort, 487 (82%) met eligibility criteria. Forty-six people (9.5%) reported a history of a prior attempted suicide. In bivariable and multivariable analyses, none of the evaluated SDoMH were significantly associated with a history of attempted suicide (Table). SDoMH were unable to accurately classify which individuals had a prior history of suicide attempt (AUC 0.62, 95% CI 0.52-0.72).

CONCLUSION: Nearly one in ten Black birthing people in this cohort previously attempted suicide. While SDoMH have been implicated as risk factors for suicide in the general population, these determinants were not associated with a history of a suicide attempt in this perinatal cohort. These data demonstrate persistent gaps in our capacity to correctly identify birthing people at highest risk of suicide.

Table: Associations between social determinants of mental health and prior suicide attempt

Social Determinants of Mental Health	OR	95% CI	aOR	95% CI
Age at pregnancy (years)	0.97	0.92-1.03	0.99	0.92-1.07
Nulliparous	1.59	0.86-2.96	1.88	0.82-4.32
Body mass index ≥ 30 kg/m^2	0.80	0.43-1.48	0.89	0.44-1.81
Hispanic ethnicity	1.87	0.68-5.11	2.14	0.58-7.94
Public insurance	1.35	0.63-2.89	1.56	0.61-4.04
Married	0.77	0.31-1.89	0.69	0.21-2.23
Educational attainment				
High school or less	ref	ref	ref	ref
Some college	1.29	0.67-2.47	1.39	0.62-3.10
Completed college	2.76	0.85-8.94	7.55	1.43-39.63

719 Optimal Mode of Delivery for Term Breech Presentations: Emulating a Target Trial

Emily B. Rosenfeld[1], Ruchira Sharma[2], Cande V. Ananth[3]

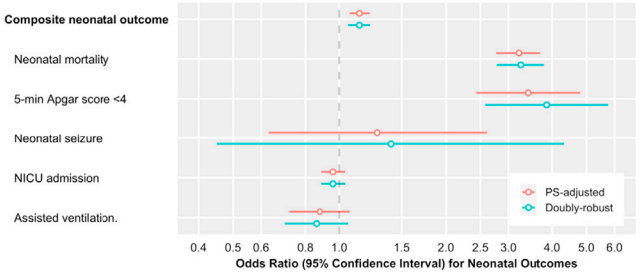
[1]Robert Wood Johnson Medical School, Rutgers University, New Brunswick, NJ, [2]Rutgers Robert Wood Johnson Medical School, Manhasset, NY, [3]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ

OBJECTIVE: Since the pivotal Term Breech Trial, global studies have demonstrated favorable neonatal outcomes for singleton vaginal breech deliveries. Despite changes in guidance from ACOG, current neonatal and maternal outcomes of those undergoing singleton breech deliveries at term in the US remain unknown. Since a randomized controlled trial (RCT) is ethically infeasible, we emulated a target trial to estimate the causal effect of vaginal versus cesarean delivery of term breech presentations in contemporary deliveries in the US.

STUDY DESIGN: We utilized the US vital records data of non-anomalous, singleton, term breech live births (2015 to 2020). We emulated a target RCT to contrast neonatal and maternal outcomes in vaginal versus cesarean delivery. To address confounding of the mode of delivery, we performed a propensity score (PS) analysis in a 1:5 match of vaginal to cesarean deliveries, and a doubly-robust estimation to account for confounding of the outcomes. Rates of neonatal and maternal complications were compared between the two groups.

RESULTS: Of 434,952 breech births, 4.4% (n = 19,256) were delivered vaginally. Composite adverse neonatal outcomes occurred in 7.6% of vaginal breech and 5.6% of cesarean breech deliveries (PS-matched, doubly robust odds ratio [OR] 1.14; 95% confidence interval [CI] 1.06, 1.22). Neonatal mortality occurred in 0.5% (n = 90) of vaginal and 0.1% (n = 373) of cesarean breech deliveries (OR 3.25; 95% CI 2.78, 3.79). Composite adverse maternal outcomes occurred in 0.3% of the vaginal breech and 0.5% of the cesarean (OR 0.43; 95% CI 0.31, 0.58) deliveries.

CONCLUSION: In a contemporary cohort of breech births in the US, vaginal delivery of breech presentations is associated with increased risks of composite neonatal adverse outcomes. This risk is over 3-fold higher for neonatal mortality. Although the findings are broadly similar to the landmark Term Breech Trial, the risks of both neonatal and maternal adverse outcomes are lower in this contemporary cohort. This present-day data should be considered when counseling patients who desire term vaginal breech births.



720 Perinatal suicidality among high-risk individuals: evaluating trends to inform policy

Emily S. Miller[1], Allie Sakowicz[2], Nina K. Ayala[3], Matthew M. Scarpaci[4], Crystal T. Clark[5]

[1]Alpert Medical School of Brown University and Women & Infants Hospital of Rhode Island, Providence, RI, [2]Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC, [3]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [4]Brown Univeristy School of Public Health, Providence, RI, [5]Women's College Hospital, Toronto, ON

OBJECTIVE: The CDC recently reported that mental health conditions, inclusive of suicide, were the leading contributor to maternal mortality from 2017-2019. Suicidal ideation (SI) is an antecedent to suicide and can serve as a proximate indicator of population-level trends to inform public health responses. We aimed to evaluate trends in SI among individuals enrolled in a collaborative care model (CCM) for mental health care.

STUDY DESIGN: This retrospective cohort study included all birthing people referred to a CCM for mental health care between 2017-2022. In the CCM, participants are asked to complete a PHQ-9 at least every 4 weeks, wherein SI is assessed. Any affirmative response, irrespective of frequency, was considered SI. Individuals enrolled in the CCM were divided into 6-month epochs based on their EDD, reflecting their general temporal engagement with the CCM. Tests of linear trend in SI over time were performed in both bivariate and multivariate modes. Linear trend curves of SI prevalence were created. Analyses were performed both for the overall sample and stratified by race/ethnicity.

RESULTS: Of the 2031 individuals enrolled in the CCM, 318 (11.7%) reported SI. The overall prevalence of SI decreased across each epoch (epochs 1 vs 10 = 12.8% vs 6.4%, respectively; aOR of SI by epoch = 0.92, 95% CI 0.88-0.97). Similar trends reflecting a steady linear decrease in SI were observed in the subset of individuals who identify as non-Hispanic Black (aOR = 0.90, 95% CI 0.83-0.98) and non-Hispanic White (aOR = 0.92, 95% CI 0.85 - 0.99). However, the prevalence of SI did not change over time among birthing people who identified as Hispanic (aOR = 1.01, 95% CI 0.84 − 1.22) or Asian (aOR = 0.97, 95% CI 0.84-1.11). Point estimates with overlayed linear trend curves are shown in the Figure.

CONCLUSION: SI is decreasing over time among high-risk perinatal individuals, mirroring recent population-level improvements in suicide rates across the United States. However, Latinx and Asian subgroups did not experience these same trends. These data can be used to inform targeted perinatal suicide prevention efforts.

Figure: Temporal Trends in the Prevalence of Suicidal Ideation

P-values represent tests of linear trend

721 Umbilical artery endocan level increases with maternal BMI

Emily Holthaus[1], Marim Zoma[2], Danielle McGinnis[2], Kailey Shine[3], Walter Jeske[4], Philip DeChristopher[4], Loretto Glynn[5], Jonathan Muraskas[3]

[1]UT Southwestern, Dallas, TX, [2]Loyola University Chicago Stritch School of Medicine, Maywood, IL, [3]Loyola University Medical Center, Maywood, IL, [4]Loyola University Chicago, Maywood, IL, [5]NYU Langone Health, New York City, NY

OBJECTIVE: Maternal obesity is strongly associated with offspring obesity and is potentially inherited through fetal programming, for which inflammation and endothelial dysfunction may play a mediating role. Endocan is a soluble biomarker linked to endothelial dysfunction and inflammation. We sought to determine whether umbilical artery endocan levels at birth differed between newborns born to mothers with and without obesity.

STUDY DESIGN: We conducted a prospective cohort study of term mother/fetus dyads who presented for delivery. We collected umbilical artery cord blood at delivery, and measured fetal/cord endocan levels by ELISA. We assessed differences using statistical regression modeling. A sample size of 168 was planned to detect a difference of 35% between infants born to obese and non-obese mothers.

RESULTS: We recruited 233 patients; following exclusion criteria and dropout, 148 remained. BMI of the included mothers ranged from 21 to 97 kg/m^2 (median 34, IQR 8). There were 36 patients with BMI $<$ 30 and 112 patients with BMI $\geqq$ 30. Bivariate analysis using obesity as a dichotomous variable showed no difference in cord endocan level between patients with BMI $<$ 30 and those with BMI $\geqq$ 30 (medians 272 pg/ml [IQR 113] vs. 299 [153], p=0.476). A

backward stepwise linear regression included the following candidate variables which were selected a priori: BMI at delivery, age, diabetes, hypertension, delivery mode, birthweight, sex. The final model reduced to BMI at delivery and maternal age. The overall regression was statistically significant (R^2=0.12, F(2,142)=9.22, p< 0.001). Endocan levels in newborn cord blood were positively and significantly associated with maternal BMI at delivery (p = 0.022), when controlling for maternal age.

CONCLUSION: Our results suggest that infants born to mothers with obesity may have higher levels of endothelial dysfunction and inflammation at birth, and may be affected in a dose-dependent manner with increasing BMI. These findings emphasize the importance of fetal programming in utero, prior to postnatal factors that contribute to downstream effects of maternal obesity.

Table 1. Backward stepwise linear regression modeled on umbilical artery endocan level

	Coefficient	Standard error	p
Maternal BMI at delivery	2.29	0.99	**0.022**
Maternal age	5.57	1.67	**0.001**
Constant	50.95	58.75	

Final model: F(2,142) = 9.22, R^2 = 0.12, **p < 0.001**

Candidate variables: Maternal BMI at delivery, maternal age, insulin controlled diabetes, hypertensive disorder of pregnancy, mode of delivery, birthweight, neonatal sex
Final variables: Maternal BMI at delivery, maternal age

723 Intrauterine vacuum-induced tamponade versus intrauterine balloon-tamponade for postpartum hemorrhage management

Emma Trawick[1], Amber Watters[2], Bethany T. Stetson[3]
[1]University of North Carolina at Chapel Hill, Durham, NC, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Northwestern Memorial, Chicago, IL

OBJECTIVE: To compare the effectiveness of intrauterine vacuum-induced tamponade device (IUVT) versus intrauterine balloon-tamponade device (IUBT) for postpartum hemorrhage (PPH) management.

STUDY DESIGN: This is a retrospective cohort study of patients who had an intrauterine tamponade device placed for management of PPH secondary to uterine atony from 4/2020-7/2023 at an academic medical center. Patients who underwent IUVT (Jada®) placement (n=152) were compared 1:1 to those who underwent IUBT (Bakri®) placement (n=152) prior to adoption of the Jada® device at the study institution. Primary outcomes were estimated blood loss (EBL), red blood cell (pRBC) transfusion, and failure of the device to control PPH. Secondary outcomes included time from hemorrhage identification to device placement, time spent in 1:1 nursing care, and length of stay. Cohorts were compared using bivariable and multivariable analyses.

RESULTS: Patients in both cohorts were similar in age, race, ethnicity, body mass index (BMI) and route of delivery (p >0.05). Patients who underwent IUVT placement had a significantly lower EBL and fewer units transfused that those who underwent IUBT placement (p< 0.01) (Table). Difference in EBL persisted in multivariable regression analysis (p< 0.01). There was no difference in failure between devices in controlling PPH (p >0.05). Of the IUVT that failed, 8 (53.3%) patients were subsequently managed with IUBT, and 6 (75%) of those then required further interventions. Patients underwent IUVT placement earlier, and IUVT remained in place for less time (p< 0.01). Patients who underwent IUVT placement spent less time in 1:1 nursing care and had shorter lengths of stay overall (p< 0.01). There was no difference between cohorts in admission to ICU, postpartum infection, or rates of readmission (p >0.05).

CONCLUSION: IUVT is similarly effective to IUBT in managing postpartum hemorrhage due to atony. IUVT is associated with less blood loss, fewer transfusions, lower nursing utilization, and shorter lengths of stay, which has significant implications for patient safety and costs of care.

Table. IUVT vs IUBT for PPH management.

Primary outcomes	IUVT (n=152)	IUBT (n=152)	OR (95%CI)	P value
EBL, median (IQR), mL	1583 (1200, 2099)	2090 (1599, 2657)	-	<0.01 *<0.01
pRBCs transfused, median (IQR), units	0 (0, 1)	1 (0, 2)	-	0.01 *0.05
Device failure in management of PPH	15 (9.9)	18 (11.8)	0.81 (0.39-1.62)	0.71
Hysterectomy	7 (4.6)	8 (5.3)	-	>0.99
UAE	4 (2.6)	10 (6.6)	-	0.17
IUBT	8 (5.3)	-	-	-
Secondary outcomes			**P value**	
Time of first uterotonic to device placement, median (IQR), minutes	19 (10, 37)	32 (19, 63)	<0.01	
Time device in place, median (IQR), minutes	180 (132, 248)	844.5 (717, 1178)	<0.01	
Time in 1:1 nursing, median (IQR), minutes	393 (314.8, 567.5)	1239 (973.3, 1548)	<0.01	
Length of stay, median (IQR), days	3 (2, 4)	3 (3, 5)	<0.01	

Results are shown as no. (%) unless otherwise indicated.
*adjusted for age, race, ethnicity, parity, cesarean, history of PPH, preeclampsia, multiples, macrosomia, neuraxial anesthesia
pRBC: pack red blood cells, Hgb: hemoglobin, BMI: body mass index, ICU: intensive care unit, UAE: uterine artery embolization
Patients who had an IUBT placed after Jada® adoption were excluded to minimize impact of provider preference.

724 Optimizing YouTube OB/GYN Video Search: The Impact of Adding Boolean Operators

Emma R. Herrero[1], Nicole Acero[2], Kaitlyn Voity[3], Jamie McIlvaine[4], Antonia F. Oladipo[5], Emre Kayaalp[6]
[1]Syracuse University, South Orange, NJ, [2]Hackensack Meridian School of Medicine, Nutley, NJ, [3]Hackensack Meridan School of Medicine, Hackensack, NJ, [4]Jersey City Medical Center RWJ Barnabas, Rutgers University, Jersey City, NJ, [5]Hackensack University Medical Center, Hackensack, NJ, [6]Atlantic Health System, Morristown, NJ

OBJECTIVE: YouTube is an accessible online resource for educational related information. A Boolean search uses specific search words and symbols known as Boolean operators (BO) to aid in limiting or expanding results. There is limited knowledge on the impact of boolean search terms on quality and accuracy of OB/GYN educational instructional video. Our objective is to examine the effect of Boolean searching on the quality and accuracy of YouTube OB/GYN video.

STUDY DESIGN: Surgical Curriculum of Obstetrics and Gynecology (SCOG) procedures in combination with BO were used in YouTube search queries. Results were screened with strict exclusion criteria and video characteristics were obtained. Videos were graded on accuracy and quality using the SCOG accuracy checklist and the validated Laparoscopic Surgery Video Educational Guidelines (LAP-VEGaS) video assessment tool. Results were analyzed using ANOVA statistical testing.

RESULTS: A total of 353 videos were screened, 89 were excluded and 264 were analyzed. For videos without BO, international organizations had highest % accuracy and only international healthcare organization videos met a quality score of 11.2. After using BO, average accuracy and quality scores increased by 54.6% and 37.7%, respectively. Videos with quality scores > 11 included multiple types of organizations (Table 1). BO videos had statistically significant

improvement in quality and accuracy separated by likes, views and affiliated organizations (p-value < 0.01). There was no statistically significant difference in accuracy and quality for BO videos based on number of subscribers and geographic location.

CONCLUSION: The user-friendly nature of YouTube allows OB/GYN providers the ability to access and learn from educational videos. Understanding characteristics associated with accurate and quality information ensures proper selection to precise and current educational resources. It is imperative that providers are aware of the importance and enhancement of BO when searching for OB/GYN educational content.

Table 1: Average Scores with and without Boolean Operators

SCOG Accuracy Score	Videos without Boolean Search	Videos with Boolean Search
average	35.00%	54.11%
LAP-VEGaS Quality Score (educational quality signified by score ≥ 11)		
average	7.809	10.75
Average by Affiliated Organizations:		
Academic Organizations	9.8	10.9
Non-Academic Organizations	6.9	11.69
Private Practices	7.3	11.31
International Healthcare Organizations	11.2	14.75
Commercial Organizations	7.3	10.87

725 Impact of maternal age on the risk for perineal injury and OASI in nulliparous women

Emmanuel Attali[1], Daniel Gabbai[2], Yariv Yogev[3], Yoav Baruch[4]

[1]Lis Maternity Hospital, Department of Obstetrics and Gynecology, Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel, [2]Tel Aviv Sourasky Medical Center, Tel Aviv, HaMerkaz, [3]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [4]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel, Tel Aviv, Tel Aviv

OBJECTIVE: We aimed to evaluate the association between maternal age and the incidence of perineal injury and obstetric anal sphincter injuries (OASI) in nulliparous women.

STUDY DESIGN: A retrospective, cohort population-based study was conducted in a tertiary, university-affiliated medical center from (January 2011- December 2020). The study included all nulliparous women with singleton pregnancies at term (37-41 weeks of gestation) in vertex and only with occiput anterior presentation who received epidural analgesia during labor. Exclusion criteria included stillbirth, and chronic and obstetric maternal conditions (hypertension, diabetes mellitus, etc.). Instrumental vaginal deliveries or deliveries in which episiotomy was performed were also excluded. The population was divided into two groups by age (20-25 vs 30-35 years old) and their characteristics were compared. The primary outcome was the incidence of perineal injury, defined as any spontaneous perineal tear, and/or OASI.

RESULTS: (1) Overall during the study period 39,596 nulliparas women delivered vaginally in our center. Of them 3,410 (8.61%) women met the study criteria, with 843 (24.72%) in the 20-25 age group and 2,567 (75.23%) in the 30-35 age group.

(2) Significant differences were observed between the two age groups in terms of ethnicity, maternal weight prior to pregnancy and at delivery, gestational glucose challenge test results, gestational age at delivery, duration of the second stage of labor, and birthweight (Table). (3) The incidence of perineal injury and OASI were significantly higher in the younger group (perineal injuries: 58% vs. 53.2%; p-value= 0.015) OASI (0.9% vs 0.4%, p-value: 0.04). (4) In multivariable logistic regression analysis for maternal age and perineal injury, the overall odds ratio for perineal injury in relation to age category was calculated as 1.22 (CI: 1.03-1.44; p-value: 0.023), indicating a higher risk of perineal injury in the 20-25 age group compared to the 30-35 age group.

CONCLUSION: This study suggests that young maternal age may be associated with an increased risk of perineal injury in nulliparous women.

Table 1: Demographics characteristics and pregnancy outcomes

	Age 20-25 N= 843	Age 30-35 N = 2567	P Value

726 Outcomes of fetoscopic laser surgery for twin-twin transfusion syndrome according to the presenting twin

Eric P. Bergh[1], Jimmy Espinoza[2], Sami Backley[1], Ramesha Papanna[3], Anthony Johnson[3]

[1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [2]McGovern Medical School at the University of Texas Health Science Center Houston, The Fetal Center-Children's Memorial Hermann Hospital, Houston, TX, [3]McGovern Medical School at UTHealth Houston, Houston, TX

OBJECTIVE: The major complications of fetoscopic laser surgery (FLS) for advanced twin-twin transfusion syndrome (TTTS) are prelabor premature rupture of membranes (PPROM) and preterm birth. We hypothesize that rupture of the amniotic sac of the recipient twin may present differently when a donor twin amniotic sac covers the cervical canal. We examined the incidence and complications of PPROM in patients who underwent FLS for TTTS according to the presenting twin.

STUDY DESIGN: This is a prospective observational cohort study of 660 monochorionic-diamniotic pregnancies with TTTS who

underwent FLS, performed at a single institution during 2011-2022. PPROM was defined as leakage of amniotic fluid documented prior to 34 weeks gestation. Study groups were assigned according to the presenting twin, either donor (D) or recipient (R). Baseline characteristics, gestational age (GA) at delivery and neonatal outcomes were compared between the two groups.

RESULTS: There were 204 cases with a D-presenting twin and 456 cases with a R-presenting twin. Baseline characteristics were similar between groups. The GA at FLS, incidence of PPROM, and GA at delivery were similar between the groups. The gestational age at PPROM was significantly later when the donor was presenting (median GA 28.6 weeks versus 27.0 weeks, p = 0.028). Among patients managed expectantly, there was no difference in GA at delivery nor was there any difference in twin survival or short-term neonatal outcomes between the groups.

CONCLUSION: FLS is associated with similar incidence of PPROM although PPROM occurs at a later GA when the donor twin is presenting, with similar GA at delivery than cases where recipient twin in presenting. This finding may represent a 'plugging' effect of the donor amniotic sac and should be considered when counseling patients undergoing FLS.

Figure 1: Baseline characteristics and outcomes based on presenting twin who underwent FLS for TTTS

	Presenting twin		
	Donor presenting N = 204	Recipient presenting N = 456	P-value

727 One laboratory's experience with prenatal cfDNA screening and incidental findings concerning for maternal neoplasia

Brittany Dyr[1], Erica Soster[2], Kimberly Fanelli[3], Samantha Caldwell[4], Philip Cacheris[5]
[1]Labcorp, San Diego, CA, [2]Labcorp, Westborough, MA, [3]Integrated Genetics, Manchester, NH, [4]LabCorp, Greensboro, NC, [5]LabCorp, San Diego, CA

OBJECTIVE: Cell-free DNA (cfDNA) prenatal screening has been increasingly utilized in pregnancies, and aims to provide fetal genetic information. However, incidental detection of maternal neoplasia has been reported by some cfDNA methodologies; particularly massively parallel sequencing (MPS). This cohort reviews cases submitted for cfDNA screening with nonreportable results by MPS due to multiple chromosome abnormalities, increasing concern for possible underlying maternal neoplasia.

STUDY DESIGN: Maternal blood samples submitted for cfDNA screening were subjected to DNA extraction, library preparation, and genome-wide MPS. Nonreportable cases with concerning sequencing profiles were identified by lab directors for discussion with the ordering provider. These cases were retrospectively analyzed. Outcome information for maternal and fetal health was collected from ordering providers.

RESULTS: From 2012 to 2019, 108 cases were nonreportable due to globally aberrant or chaotic genome-wide sequencing data in multiple chromosomes. This chaotic pattern of data was detected in ~1:10,000 samples. Maternal outcome was obtained in 92 cases (85%); all cases reported maternal neoplasia, many of which were malignant (n = 77/92; 84%). Of the maternal malignancies, breast cancer (n=20), lymphoma (n=28), and colorectal cancer (n=5) were most frequently reported. Other neoplasia cases (n=15) were thought to be benign, predominantly uterine fibroids (n = 12/15; 80%), but also included vestibular schwannoma, fibroadenoma, and ovarian teratoma. Of malignant cases, 54 (70%) had no clinical indication of malignancy and were diagnosed after cfDNA screening.

CONCLUSION: As part of evolving procedures, laboratories may contact the referring physician to discuss concerns and inquire about patient health history based on globally aberrant cfDNA sequencing profiles. As recommended by ACOG/ SMFM, pretest counseling should include the possibility of discovering a maternal incidental finding. Based on this cohort, when globally aberrant cfDNA sequencing data is observed on an MPS assay, the chance of a maternal neoplasia is significant.

728 Water birth youtube videos: understanding its accuracy in accordance to evidence-based guidelines

Erika Fleming[1], Jamie Chen[1], Katherine Collamore[1], Antonia F. Oladipo[2]
[1]Hackensack Meridian School of Medicine, Nutley, NJ, [2]Hackensack University Medical Center, Hackensack, NJ

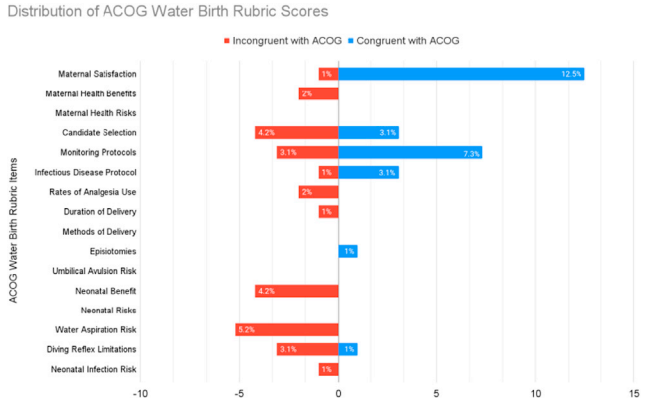
OBJECTIVE: YouTube is a frequently visited video platform for seeking and sharing advice during pregnancy, specifically around natural delivery methods such as water births. We aim to assess the most popular water birth videos on YouTube to determine how accurately these videos reflect published recommendations put forth by the American College of Obstetricians and Gynecologists (ACOG).

STUDY DESIGN: A YouTube "water birth" search was conducted on 3/9/2023 with a new profile and private browser using the filter "most viewed". The first 100 videos were selected and a strict inclusion criteria was followed. Video views ranged from 457,296 to 78,035,874. Reviewers scored videos in accordance with published guidelines using the "ACOG Water Birth Rubric".

RESULTS: 96 videos met criteria. 77.1% (n=74) scored neutral, 13.5% (n=13) accurate, and 9.4% (n=9) inaccurate. Accurately addressed guidelines include increased maternal satisfaction (12.5%), need for monitoring protocols (7.3%), and candidate selection and infectious disease protocols, (each 3.1%), limitations of the diving reflex and rates of episiotomies (each 1%). Inaccurate information included denying neonatal aspiration risk (5.2%), and need for candidate selection, neonatal benefit of water birth, (each 4.2%), denying the limitations of the diving reflex and the need for a monitoring protocol, (each 3.1%), false report of maternal health benefits and false information on rates of analgesia, (each 2%), neonatal infection risk, duration of delivery, and maternal satisfaction, (each 1%). No videos addressed alternative methods of delivery, avulsion, maternal health, or neonatal infection risk.

CONCLUSION: Caution is warranted viewing YouTube water birth videos as the most popular vastly overlooked ACOG recommendations. Some accurately emphasized increased maternal satisfaction, but inaccurately addressed neonatal aspiration risk, candidate selection, and neonatal benefits of water births. Future research should

assess the impact that such videos have on patients' perceptions of labor and delivery options compared to healthcare provided information.



gene functions may promote the increased anxiety observed in these offspring via altered microbe-to-host signaling in the gut.

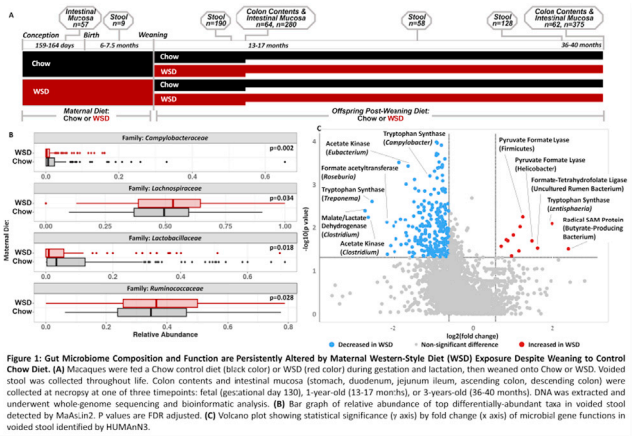


Figure 1: Gut Microbiome Composition and Function are Persistently Altered by Maternal Western-Style Diet (WSD) Exposure Despite Weaning to Control Chow Diet. (A) Macaques were fed a Chow control diet (black color) or WSD (red color) during gestation and lactation, then weaned onto Chow or WSD. Voided stool was collected throughout life. Colon contents and intestinal mucosa (stomach, duodenum, jejunum ileum, ascending colon, descending colon) were collected at necropsy at one of three timepoints: fetal (gestational day 130), 1-year-old (13-17 months), or 3-years-old (36-40 months). DNA was extracted and underwent whole-genome sequencing and bioinformatic analysis. **(B)** Bar graph of relative abundance of top differentially-abundant taxa in voided stool detected by MaAsLin2. P values are FDR adjusted. **(C)** Volcano plot showing statistical significance (y axis) by fold change (x axis) of microbial gene functions in voided stool identified by HUMAnN3.

729 Gut Microbiome is Persistently Altered by Maternal Western-Style Diet Exposure Despite Weaning Diet

Erin Bolte[1], Michael D. Jochum Jr.[1], Derek O'Neil[1], Olivia Stuyck[1], Maxim D. Seferovic[2], Min Hu[1], Kjersti M. Aagaard[3]

[1]Baylor College of Medicine, Houston, TX, [2]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [3]Texas Children's Hospital, Baylor College of Medicine, Houston, TX

OBJECTIVE: Gut microbes moderate and/or produce metabolites like serotonin and short-chain fatty acids (SCFAs) that are crucial for normal behavior. In a Japanese macaque model, offspring exposed to maternal Western-Style diet (mWSD) display anxiety, despite being weaned onto a control diet. We hypothesized that maternal mWSD alters the gut microbiome's ability to moderate the production of serotonin and SCFA pathway metabolites, contributing to the anxiety phenotype.

STUDY DESIGN: Dams were fed a Chow control diet or mWSD during pregnancy and lactation, then offspring were weaned onto Chow or Western-Style diet. Voided stool, colon contents, and intestinal mucosa were sampled throughout development ranging from fetal (gestational day 130) to pre-puberty (36-40 months) (Fig. 1A). DNA from these tissues (total n=1223 + n=27 kit negative controls) underwent whole-genome sequencing, taxonomic classification with MetaPhlAn4, functional classification with HUMAnN3, and differential abundance determination by MaAsLin2.

RESULTS: mWSD drove differential abundance of n=37 taxa in voided stool, independent of offspring sex, offspring diet, or repeat sampling. Presented at the family level, mWSD was associated with depleted *Campylobacteraceae* (p=0.002) and *Lactobacillaceae* (p=0.018), and enriched *Lachnospiraceae* (p=0.034) and *Ruminococcaceae* (p=0.028) (FDR adjusted p values) (Fig. 1B). At the functional level, mWSD was associated with suppression of gene expression, with n=395 genes down-regulated vs n=122 up-regulated (2-fold change threshold). Genes responsible for tryptophan (serotonin's precursor) availability and SCFA phosphorylation were persistently downregulated at all time points in stool from offspring of dams fed a mWSD (Fig. 1C).

CONCLUSION: Gut microbiome composition and bacterial gene function were found to be significantly altered by mWSD exposure, even when offspring were weaned onto and fed a control diet for 2.5 years. Downregulation of serotonin's precursor and SCFA-related

730 Vaginal progesterone treatment failure in otherwise low-risk patients with short cervix

Erinma P. Ukoha[1], Eve Overton[2], Shai Bejerano[3], Cynthia Masson[2], Uma M. Reddy[2], Mirella Mourad[1], Amy Turitz[4]

[1]Columbia University Medical Center, New York, NY, [2]Columbia University, New York, NY, [3]Vagelos College of Physician and Surgeons, Columbia University, New York, NY, [4]Greenwich Hospital, COS COB, CT

OBJECTIVE: Although vaginal progesterone is recommended for treatment in otherwise low-risk patients with cervical length (CL) ≤25mm, the data are limited on failed treatment, defined as the need for cerclage placement, cervical dilation, or spontaneous delivery prior to 24 weeks, particularly for the highest risk subgroup with CL ≤10mm.

STUDY DESIGN: This is a retrospective cohort study (2016-2022) at a single institution of individuals with singleton pregnancies, no history of spontaneous preterm birth, and started on vaginal progesterone for CL of ≤25mm between 16-24 weeks. The primary outcome was cerclage placement, cervical dilation, or spontaneous delivery prior to 24 weeks. Planned subgroup analysis was performed for those with CL ≤10mm. Baseline and sonographic characteristics were compared using chi-square, Fisher's exact, t-test, or Wilcoxon rank sum test as appropriate. Kaplan Meier survival curves were used to depict time to treatment failure stratified by CL ≤10mm.

RESULTS: Of 162 patients who met inclusion criteria, 41 (25.3%) failed treatment defined as cerclage placement (N=39), cervical dilation (N=16), or spontaneous delivery prior to 24 weeks (N=5). Baseline demographic characteristics were similar between groups. The relative risk of treatment failure for those with CL ≤10mm was 4.07 [2.61, 6.35] compared to those with CL >10mm. Individuals who experienced treatment failure were more likely to have initial sonographic findings of cervical funneling (81.6% vs 30.6%, p< 0.001), changes with Valsalva (46.7% vs 10.6%, p< 0.001), and dynamic changes (43.8% vs 18.8%, p=0.009) at their initial ultrasound diagnosing short cervix. Gestational age at diagnosis of short cervix did not differ between groups. Approximately 75% of patients with cervical lengths ≤10mm experienced treatment failure within 3 weeks of their initial short cervix ultrasound.

CONCLUSION: In otherwise low-risk patients with a short cervix on vaginal progesterone, the risk of cerclage placement, cervical dilation, or pregnancy loss prior to 24 weeks is significant (25%) and

approaches 75% in patients with cervical length ≤10mm.

Table: Sociodemographic characteristics and ultrasound findings of low-risk patients with short cervix on vaginal progesterone by treatment outcomes

731 Nationwide Trends in Periviable Preterm Birth Interventions

Ernesto Licon[1], Melissa Chambers[2], Jenny Chang[3], Fayez Bany-Mohammed[4], Afshan B. Hameed[5], Judith H. Chung[6]
[1]University of California Irvine, Pasadena, CA, [2]University of California Irvine, Whitter, CA, [3]University of California Irvine School of Medicine, Irvine, CA, [4]University of California Irvine, Irvine, CA, [5]UCI, Orange, CA, [6]UC Irvine Health, Orange, CA

OBJECTIVE: To examine differences in periviable preterm birth interventions in neonates born in 2021 compared to 2016 in the United States after implementation of the Obstetrics Care Consensus guidelines (introduced in 2015 with most recent revisions made in 2017).

STUDY DESIGN: This study is a retrospective analysis of the National Vitals Statistics Database, comparing obstetric (corticosteroids and cesarean delivery) and neonatal interventions (ventilation, surfactant use, NICU admission) for periviable preterm births (22 to 25 weeks' gestation) in the years 2016 and 2021. Adjusted odds ratios and 95% confidence intervals were calculated for the outcomes of interest, using the year 2016 as the reference group.

RESULTS: Table 1 presents a comparison of birth characteristics for the years 2016 and 2021. In 2016, preterm births accounted for 11.4% (450,225 cases). Among the preterm births, 15,668 (447/1000 births) were categorized as periviable births (between 22 to 25 weeks gestation). In 2021, preterm births slightly increased to 12.3% (450,318). Periviable births numbered 13,689 (425/1000 births), showing a small decrease compared to 2016. Table 2 provides the adjusted odds ratios for various outcomes in the year 2021 when compared to 2016 (reference group). Use of Corticosteroids for Fetal Lung Maturity showed an odds ratio of 1.51 (CI: 1.42-1.60) in 2021 and the odds of Cesarean Section rose to 1.20 (CI: 1.13-1.27) in 2021 compared to the reference year 2016. Additionally, the odds of Immediate-Assisted Ventilation were 1.35 times higher in 2021 compared to 2016, with a 95% CI of (1.27-1.43). Furthermore, the odds of Assisted ventilation exceeding 6 hours increased to 1.30 (CI: 1.22-1.38), NICU Admission to 1.31 (CI: 1.23-1.40), and Surfactant Use to 1.18 (CI: 1.10-1.27) in 2021.

CONCLUSION: These findings suggest that neonatal care interventions and medical practices for periviable preterm births have undergone substantial changes between 2016 and 2021. Further study is warranted to understand how current management of periviable preterm births impacts long term maternal and neonatal health outcomes.

Table 1. Comparison of neonatal preterm birth characteristics in year 2016 to 2021

Characteristic	Year 2016	Year 2021
Term Births	3,502,371 (88.5%)	3,216,483 (87.6%)
Preterm Births	450,225 (11.4%)	450,318 (12.3%)
Periviable Births (22-25 weeks)	15,668 (0.4%)	13,689 (0.4%)

Table 2. Adjusted odds ratios (OR) for year 2021 compared to year 2016 (reference group)

Outcomes	Year 2016	Year 2021	95% CI
Immediate-Assisted Ventilation	1.0	1.35	(1.27-1.43)
Assisted ventilation > 6 hours	1.0	1.30	(1.22-1.38)
NICU Admission	1.0	1.31	(1.23-1.40)
Surfactant Use	1.0	1.18	(1.10-1.27)
Corticosteroids for Fetal Lung Maturity	1.0	1.51	(1.42-1.60)
Cesarean Section	1.0	1.20	(1.13-1.27)

1. Each multivariate logistic model used stepwise model selection. First, characteristics including maternal age, nativity, race, marital status, education, paternal age, paternal race, paternal education, payment type, nulliparous status, participant in WIC, smoking, BMI, Pre-diabetes, gestational diabetes, chronic hypertension, gestational hypertension, eclampsia, prior preterm birth and prior cesarean section were included in the full model. Then, stepwise model selection used a significance level of entry=0.15 and significance level of stay =0.15 to select final model. Adjusted odds ratios listed here are from the final model.

732 Multi-disciplinary Review of International Guidelines on Iron Deficiency Anemia in Pregnancy

Fiona O'Toole[1], Rachel Sheane[2], Niamh Reynaud[2], Joan Fitzgerald[3], Annmarie MurphyCruse[3], Grace Mealy[4], Fionnuala M. Mcauliffe[5], Jennifer Walsh[6]
[1]National Maternity Hospital, Dublin, Ireland, [2]National Maternity Hospital, Dublin, Dublin, [3]UCD School of Medicine, Dublin, Dublin, [4]National Maternity Hospital, UCD Perinatal Research Centre, Dublin, [5]UCD NMH, Dublin, Ireland, [6]UCD School of Medicine, Dublin, Ireland

OBJECTIVE: Iron deficiency anemia (IDA) in pregnancy is a common diagnosis that is associated with adverse obstetric and neonatal outcomes. There is limited high-quality evidence to guide screening, prevention, and treatment of IDA in pregnancy. There is no consensus on benefits of routine iron supplementation, with concerns regarding potential harmful effects in women who are iron replete. The purpose of this review was to compare the content and appraise the quality of international guidelines on the screening and treatment of IDA in pregnancy.

STUDY DESIGN: Fourteen international guidelines were selected and appraised by a multidisciplinary team of 2 obstetricians, a hematologist and clinical dietician. International guidelines from the U.S., Europe, the U.K., Australia, New Zealand and Canada were reviewed. The AGREE II GRS tool was employed. Independent reviewer assessment collated scores from 1-7 for an overall score incorporating seven domains: process of development, clarity of presentation, completeness of reporting, clinical validity, and overall quality. The reviewers' mean scores were also individually compared according to discipline.

RESULTS: The mean score across all the guidelines was 4.4 (range 3.5-6.5). The median score was 4 (3.6-5.2 IQR). There was noted variation in overall scores among the different disciplines of the reviewers. Half of the guidelines recommended routine iron in pregnancy. Four guidelines recommended routine screening with ferritin in pregnancy, two recommended selective screening with ferritin for at risk groups only and one guideline suggested using ferritin where feasible. One guideline specifically advises against routine use of ferritin in pregnancy. While most of the guidelines recommended similar doses of oral elemental iron of 100-200mg daily, 2 guidelines recommend twice daily or three times daily dosing.

CONCLUSION: IDA in pregnancy is a common obstetric problem encountered in all populations. Despite this, there clearly remains a need to clarify the optimal screening method, dosing regimen, and timing of iron supplementation in pregnancy.

733 Perinatal outcomes in pregnancies complicated by a prenatal diagnosis of critical congenital heart disease (CCHD)

Fiona Cody[1], Orla Franklin[2], Nicola Mc Cay[3], Zara Molphy[1], Patrick Dicker[1], Fionnuala M. Breathnach[1]

[1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]CHI at Crumlin Children's Hospital, Trinity College Dublin, Dublin, Ireland, [3]CHI at Crumlin Children's Hospital, Dublin, Ireland

OBJECTIVE: Prenatal diagnosis of CCHD allows for optimal perinatal decision-making. We sought to examine care pathways and perinatal outcomes on prenatally and postnatally diagnosed cases over a four-year period.

STUDY DESIGN: This retrospective cohort study sought to determine the perinatal outcome of pregnancies complicated by CCHD detected prenatally and postnatally from 01/2019 to 12/2022. Patients attending a tertiary perinatology center in Ireland and its affiliated secondary centers underwent mid-trimester fetal cardiac ultrasound examination. All pregnancies diagnosed with CCHD were referred prenatally to the Fetal-medicine/cardiology service, offered genetic testing and counselling. Data sources included retrospective electronic chart and ultrasound report review and neonatology/pediatric records. All cases were treated in a single national pediatric cardiac center. CCHD was defined as duct-dependency or structural abnormality requiring urgent intervention in the 1st month of life.

RESULTS: Among 49,950 screened pregnancies, the incidence of CCHD was 0.21% (104/49,950) with a prenatal detection rate of 91% (95/104). In the prenatally diagnosed group, 41% of cases were complicated by extracardiac structural abnormalities, a genetic diagnosis or both. 10% chose pregnancy termination, 29% opted for perinatal palliation and 7% died in utero. Among 67 cases evaluated for neonatal cardiac intervention, 17 (25%) were deemed not surgical candidates. All remaining neonates 52/67 (78%) had surgery or catheterization or both in the first month of life. Survival to Day 30 of life was 88% (46/52) and 85% (44/52) at 1 year in the prenatally diagnosed cohort. All 9 cases of CCHD first diagnosed in the postnatal period (all of whom had aortic coarctation or critical pulmonary stenosis) were alive at 1 year.

CONCLUSION: 40% of all pregnancies complicated by CCHD will not undergo neonatal cardiac intervention, by virtue of parental choice determined either prenatally or after birth. Survival at one year for infants deemed suitable for CCHD surgery is in excess of 85%.

Table 1: Pregnancy Outcomes in prenatally diagnosed CCHD:

Outcome		All (N=95)	Left duct-dependant heart disease (N =39)	Right Duct - dependant heart disease (N=38)	Transposition of the great arteries (N=15)	Congenital heart block (N=3)

734 Uterine artery doppler, placental volume, and the risk for hypertensive disorders of pregnancy

Gabriel A. Arenas[1], Markolline Forkpa[1], Darleen Cioffi-Ragan[2], Nicholas Behrendt[3], John Hobbins[4], Lorraine Dugoff[5]

[1]Hospital of the University of Pennsylvania, Philadelphia, PA, [2]University of Colorado Anschutz Medical Campus, Aurora, CO, [3]University of Colorado, School of Medicine, Aurora, CO, [4]University of Colorado, Denver, CO, [5]University of Pennsylvania, Philadelphia, PA

OBJECTIVE: Hypertensive disorders of pregnancy (HDP) constitute a leading cause of maternal and perinatal morbidity and mortality worldwide. Early identification of pregnancies at risk for HDP could lead to improved risk stratification and surveillance to reduce morbidity and mortality. Our objective was to evaluate the risk for developing HDP by evaluating first trimester placental volume and uterine artery (UtA) Doppler velocimetry.

STUDY DESIGN: Retrospective case-control study of 664 patients with singleton gestations who presented for aneuploidy screening between 10 3/7 and 13 6/7 weeks' gestation. Each patient had three-dimensional placental volumes and bilateral UtA Doppler studies performed transabdominally with a Voluson E8 (GE Healthcare, Milwaukee, WI). UtA resistance index (RI) and notching were assessed. A placental quotient (PQ) was calculated by dividing the placental volume by the crown rump length. A UtA score was calculated by assigning one point for an RI >0.70 (>75th percentile) and one point for reproducible diastolic notching. The UtA score was calculated for each artery with points combined for a total score between 0-4. Next, UtA scores were grouped into three groups: score of 0, score of 1-2, and score of 3-4. Logistic regression was used to investigate the associations of PQ and UtA score groups with HDP.

RESULTS: PQ was not significantly associated with HDP ($p = 0.12$). The largest difference between UtA score groups occurred between groups 1-2 and 3-4 in predicting the development of preeclampsia (with and without severe features) (OR: 0.28, 95% CI: 0.12-0.66,$p = 0.003$). This relationship remained significant after adjusting for parity, body mass index, and chronic hypertension.

CONCLUSION: In this low-risk population, placental volume does not appear to be associated with HDP in the first trimester. A combination of increased RI and notching is associated with an increased risk of developing preeclampsia. Additional larger studies are warranted to confirm this finding in a low-risk patient population.

Table 1: Demographic Differences between Patients with no Preeclampsia and Patients with Preeclampsia (with and without Severe Features)

Variable		No Preeclampsia (n = 629)	Preeclampsia (n = 35)	Total	P-value
Maternal Age	Younger than 35	286 (94.7%)	16 (5.3%)	302 (46.0%)	0.969
	35 and above	335 (94.6%)	19 (5.4%)	354 (54.0%)	
Race	White	582 (94.5%)	34 (5.5%)	616 (92.8%)	0.305
	Black/Other	47 (97.9%)	1 (2.1%)	48 (7.2%)	
BMI	30kg/m^2 and below	554 (95.5%)	26 (4.5%)	580 (89.0%)	0.004
	Greater than 30kg/m^2	63 (87.5%)	9 (12.5%)	72 (11.0%)	
Parity	Multiparous	365 (97.1%)	11 (2.9%)	376 (57.3%)	0.001
	Nulliparous	256 (91.4%)	24 (8.6%)	280 (42.7%)

735 Mode of delivery does not impact cardiovascular morbidity in patients with prior cardiovascular disease

Gabriella Lobitz[1], Emily B. Rosenfeld[2], Rachel Lee[1], Deepika Sagaram[1], Cande V. Ananth[1]

[1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [2]Robert Wood Johnson Medical School, Rutgers University, New Brunswick, NJ

OBJECTIVE: Cardiovascular disease (CVD) affects up to 44% of women aged 20 years or older, making it an increasingly prevalent problem in persons of reproductive age. Patients with pre-existing CVD who become pregnant face an increased risk of adverse maternal and fetal outcomes. There is limited evidence available to guide the mode of delivery in persons with a history of CVD. The objective of this study is to determine if the mode of delivery affects CVD-related morbidity in a person with prior CVD. We hypothesize that patients with pre-existing CVD who undergo a cesarean delivery will be at increased risk of CVD morbidity in the first year after delivery.

STUDY DESIGN: We designed a retrospective cohort study utilizing the Nationwide Readmissions Database (2010-2018) to identify singleton births. ICD-9 and ICD-10 codes were used to identify patients with pre-existing CVD and who experience CVD morbidity within the calendar year of index delivery. Associations between mode of delivery and CVD morbidity were determined from Cox proportional hazards regression models before and after adjusting for potential confounders including hospital bed size, teaching status, patient insurance, and income.

RESULTS: Of the 19,217 patients with prior CVD who underwent delivery, 46% (n = 8,914) underwent a cesarean. Rates of CVD hospitalizations per 100,000 delivery discharges were 9,748 and 9,607 for cesarean and vaginal delivery (adjusted hazard ratio [HR] 0.98, 95% confidence interval [CI] 0.77, 1.11) (Table). The risk for stroke was highest in the first 30 days after the index delivery (adjusted HR 1.81, 95% CI 0.87-3.74) and diminished with increasing latency.

CONCLUSION: In patients with pre-existing CVD, the mode of delivery was not associated with the risk of CVD-related morbidity in the year following delivery. These findings support the recommendations that the usual obstetrical indications should be used to guide the mode of delivery in persons with pre-existing CVD.

Table 1

	Hazard ratio (95% confidence interval)	
	Unadjusted	Adjusted
Non-fatal complications		
Any cardiovascular disease	1.02 (0.84-1.23)	0.92 (0.77-1.11)
Any coronary heart disease	0.99 (0.81-1.21)	0.90 (0.74-1.09)
Ischemic heart disease	1.16 (0.77-1.76)	0.97 (0.64-1.47)
Atherosclerotic heart disease	0.83 (0.44-1.57)	0.90 (0.48-1.67)
Acute myocardial infarction	2.56 (0.83-7.88)	1.82 (0.56-5.90)
Hypertensive heart disease	1.57 (0.89-2.79)	1.20 (0.65-2.21)
Heart failure	0.99 (0.72-1.35)	0.88 (0.65-1.18)
Cardiomyopathy	1.27 (0.84-1.91)	1.16 (0.76-1.76)
Cardiac arrythmias	1.24 (0.95-1.62)	1.16 (0.88-1.54)
Any stroke	1.24 (0.79-1.95)	1.00 (0.70-1.71)
Ischemic stroke	1.25 (0.70-2.24)	1.10 (0.63-1.91)
Hemorrhagic stroke	1.21 (0.54-2.72)	1.10 (0.51-2.35)

736 Identifying women at high risk for preterm birth based on clinical data using machine learning

Gal Cohen[1], Tal Biron-Shental[2], Tal Meshali[3], Yoram Louzoun[3]

[1]Meir Medical Centerartment of Obstetrics and Gynecology, Meir Medical Center, Kfar Saba, Israel, [2]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz, [3]Bar Ilan University, Ramat Gan, HaMerkaz

OBJECTIVE: Existing models for predicting spontaneous preterm birth (delivery< 37 weeks, sPTB) are limited, relying mostly on a history of sPTB and multiple gestations, leaving the question of whether to screen the low-risk population for cervical dynamics during the 2nd trimester a matter of debate. Another challenge arises upon admission of patients presenting with suspected sPTB, regarding the need for corticosteroids or magnesium treatment for reducing prematurity complications. We aimed to develop a bedside tool using machine learning, to assist clinicians identify patients who justify cervical length screening, as well as identify those in need of corticosteroids or magnesium upon admission for suspected sPTB.

STUDY DESIGN: A data-based study of all live deliveries in a tertiary hospital between 2013-2023, of which 20% were used as a holdout test set, and 80% to train and validate a prediction model for sPTB using Xgboost. 1st trimester parameters were used to predict sPTB at 12 weeks. Within the population admitted with suspected sPTB (presenting with PMC, pPROM or cervical length< 20 mm), data available upon admission were used to predict sPTB within 2 or 7 days.

RESULTS: Included 63,937 deliveries, of whom 3,772 (5.9%) had a sPTB. Using 1st trimester parameters, 2% of the population were identified with a probability of 50% for having a sPTB that represent 25% of the sPTB cases. Excluding multiple gestations allowed to recognize 20% of the population having a 10% risk for sPTB representing over 40% of the sPTB cases. Including only singleton nulliparas, still allowed for some stratification; women with the highest 20% scores had a 1.5 risk factor for sPTB.

Within 3,718 patients who were admitted with suspected sPTB, 17% were recognized as high-risk patients, having a probability of practically 100% to deliver within 7 days (recall 0.5) and 10% were recognized as having a probability of 100% to deliver within 2 days (recall 0.3).

CONCLUSION: Implementation of machine learning can assist clinicians identify patients who are at higher risk for sPTB and justify cervical screening or medical interventions.

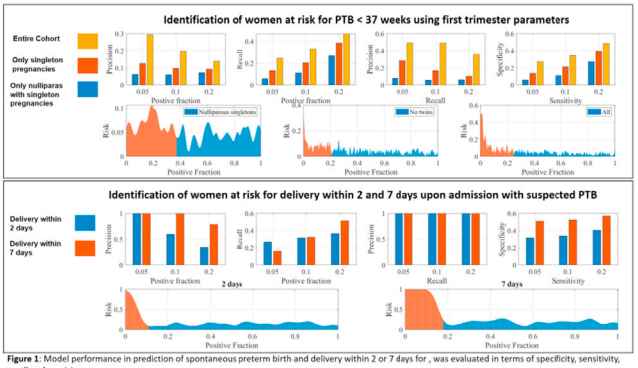

Figure 1: Model performance in prediction of spontaneous preterm birth and delivery within 2 or 7 days for , was evaluated in terms of specificity, sensitivity, recall and precision.

737 Trends and outcomes among pregnancy and non- pregnancy related hospitalizations with diabetic ketoacidosis

Ghamar Bitar[1], Han-Yang Chen[2], Sarah Nazeer[3], Suneet P. Chauhan[4], Sean C. Blackwell[5], Baha M. Sibai[6], Michal Fishel Bartal[7]

[1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [2]The University of Texas Health Science Center at Houston, Houston, TX, [3]McGovern Medical School at UTHealth Houston, Houston, TX, [4]University of Texas-Houston Medical School, Houston, TX, [5]Children's Memorial Hermann Hospital, Houston, TX, [6]Hermann Memorial Hospital, Houston, TX, [7]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX

OBJECTIVE: To evaluate temporal trends and outcomes related to diabetic ketoacidosis (DKA) in pregnancy and ascertain if it is associated with a higher rate of adverse outcomes than in non-pregnant reproductive age persons with DKA.

STUDY DESIGN: We conducted a retrospective cross-sectional study using the National Inpatient Sample to identify hospitalizations with DKA among reproductive age women (15-49 years) in the U.S. (2016-2020). DKA in pregnancy hospitalizations was compared to DKA in non- pregnant hospitalizations. Adverse outcomes evaluated included mechanical ventilation, coma, seizures, renal failure, prolonged hospital stay and death. Multivariable Poisson regression models with robust error variance were used to estimate adjusted relative risk (aRR) and 95% confidence interval (CI). Annual percent change (APC) was used to calculate change in DKA over time.

RESULTS: Among 35, 210,711 hospitalizations in reproductive age women, 447,600 (0.3%) were hospitalized with DKA. Of these, 13,390 (3%) hospitalizations occurred during pregnancy. Baseline characteristics differed in age, race and ethnicity, primary payer, household income, smoking status, location and teaching status of hospital, region of hospital bed size of hospital, heart disease, and baseline complications of diabetes. After adjustment, except for prolonged hospital stay, all adverse outcomes were more likely in non-pregnant DKA hospitalizations than in pregnant DKA hospitalizations (Table). Pregnancy related DKA hospitalizations were associated with a high rate of adverse outcomes including 12.5% renal failure, 2.1% seizures, 0.9% coma, and 0.2% mortality (Table). The rate of DKA increased over time (APC 3.8%, 95% CI 1.5 − 6.1), due to an increase in non-pregnancy related DKA (APC 4.7%, 95% CI 1.8 − 7.7).

CONCLUSION: A nationally representative sample of hospitalizations indicates higher risk of adverse outcomes in non-pregnancy related DKA hospitalizations as compared to pregnancy related DKA hospitalizations. DKA in pregnancy occurs at a rate of 68 per 100,000 hospitalizations with substantial adverse outcomes, including 0.2% mortality.

Table. Adverse outcomes associated with non- pregnancy hospitalizations with diabetic ketoacidosis and pregnancy hospitalizations with diabetic ketoacidosis

Outcomes	All	N	%	Crude RR (95% CI)	Adjusted RR* (95% CI)

738 Trends and outcomes among racial and ethnic groups in pregnancy associated stroke

Ghamar Bitar[1], Han-Yang Chen[2], Farah H. Amro[1], Suneet P. Chauhan[3], Sean C. Blackwell[4], Baha M. Sibai[5], Michal Fishel Bartal[6]

[1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [2]The University of Texas Health Science Center at Houston, Houston, TX, [3]University of Texas-Houston Medical School, Houston, TX, [4]Children's Memorial Hermann Hospital, Houston, TX, [5]Hermann Memorial Hospital, Houston, TX, [6]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX

OBJECTIVE: To compare trends of pregnancy associated stroke (PAS), risk factors, and adverse maternal outcomes among racial and ethnic groups.

STUDY DESIGN: This was a retrospective cross-sectional study of the National Inpatient Sample to identify hospitalizations with PAS in the U.S. (2016-2020). The inclusion criteria was PAS at any time. Race and ethnicity were categorized as non-Hispanic White, non-Hispanic Black, Hispanic, and non-Hispanic Other. We excluded those with unknown race/ethnicity. Demographics, clinical characteristics and adverse maternal outcomes (mechanical ventilation, seizure, pneumonia, prolonged hospital stay [> 7 days] and in hospital mortality) were compared among racial and ethnic groups. Multivariable Poisson regression models with robust error variance were used to estimate adjusted relative risk (aRR) and 95% confidence interval (CI). Annual percent change (APC) was calculated to assess changes in rates of PAS over time.

RESULTS: Among 19,717,450 pregnancy hospitalizations, 7,815 hospitalizations (0.04%) had pregnancy associated stroke. Of these, 3,390 (45.4%) identified as Non-Hispanic White, 1,865 (25%) as Non-Hispanic Black, 1,400 (18.8%) as Hispanic, 810 (10.9%) as

Non-Hispanic Other race and 350 (0.4%) were excluded given unknown race/ethnicity. The groups differed in age, primary payer, smoking status, location and teaching status of hospital, and region of hospital. Non-Hispanic Black PAS were more likely to have body mass index ≥ 30, diabetes, sickle cell disease, hypertensive disorder of pregnancy, and have postpartum stroke. After adjustment, there was no significant difference in the risk of in-hospital mortality, prolonged hospital stay, or mechanical ventilation. However, there was a higher risk in seizure in non−Hispanic Other group and pneumonia in non-Hispanic Black (Table). The rate of PAS remained stable over the 5-year analysis period in all racial and ethnic groups.

CONCLUSION: A nationally representative sample of hospitalizations in the U.S. indicates racial and ethnic differences in the risk of some adverse outcomes related to pregnancy associated stroke.

Table. Adverse outcomes in pregnancy associated stroke by race and ethnic group

Outcomes	All	N	%	Crude RR (95% CI)	Adjusted RR* (95% CI)
Mechanical ventilation					
Non-Hispanic White	3390	475	14.0	1.00	1.00

739 Maternal fertility treatments and the risk for celiac disease of the offspring

Gil Gutvirtz[1], Gali Pariente[2], Tamar Wainstock[3], Eyal Sheiner[4]

[1]Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Metar, HaDarom, [2]Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Klahim, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom, [4]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: Fertility treatments affect the female hormonal and immunological milieu, which also support the growing fetus. As celiac disease is known to be an immune-mediated disorder, we opted to investigate whether offspring of women conceived using fertility treatments are at higher risk to develop celiac disease.

STUDY DESIGN: A large population-based cohort study including all singleton deliveries in a tertiary medical center between the years 1991 and 2021 was conducted. The risk for celiac disease was compared between children (up to the age of 18 years) of women who conceived using fertility treatments (including ovulation induction with or without intrauterine insemination and in-vitro fertilization) and children born after spontaneously conceived pregnancies. Data for celiac disease diagnosis were extracted from community-based clinics and hospitalization records. Kaplan-Meier survival curve was used to compare the incidence of celiac disease between the study groups. A Cox proportional hazards model was used to control for possible confounders.

RESULTS: A total of 356,356 singleton deliveries were included in the study, of which 7,711 (2.2%) deliveries were pregnancies conceived using fertility treatments. Children born following fertility treatments had comparable rate of celiac disease as children who were born following spontaneously conceived pregnancies (0.6% vs. 0.5%, p=0.477, **Figure**). The Kaplan-Meier survival curve illustrated comparable cumulative incidence of celiac disease in both groups (Log Rank, p=0.285, **Figure**). Using a Cox proportional hazards model, controlling for maternal age and gestational age, fertility treatments were not associated with celiac disease of the offspring (adjusted hazard ratio (HR)=1.13, 95%CI 0.84-1.52, p=0.392, **Figure**).

CONCLUSION: Fertility treatments do not increase the risk for celiac disease of the offspring.

Figure. The association between being born using fertility treatments and celiac disease: Univariate analysis, Kaplan Meier survival curve and results from a Cox proportional hazards model

	Fertility treatments (n=7,711)	Spontaneously conceived pregnancy (n=348,645)	Odds Ratio (95% CI)	Adjusted* HR (95% CI)
Celiac disease	47 (0.6%)	1,914 (0.5%)	1.11 (0.83 – 1.48)	1.13 (0.84 – 1.52)

740 Maternal history of recurrent pregnancy loss and placental related complications

Gil Gutvirtz[1], Gali Pariente[2], Tamar Wainstock[3], Eyal Sheiner[4]

[1]Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Metar, HaDarom, [2]Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Klahim, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom, [4]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: Recurrent pregnancy loss (RPL) is a complex condition in which hematologic, endocrine and immunologic disorders have been identified as contributing factors. These disorders are also associated with suboptimal implantation and placentation. Hence, we sought to investigate whether maternal history of RPL is associated with placental-related complications in pregnancy.

STUDY DESIGN: A retrospective population-based cohort study of singleton deliveries was conducted to evaluate placental-related complications, including hypertensive disorders of pregnancy (gestational hypertension and preeclampsia), intra-uterine growth restriction (IUGR), placental abruption, placenta previa and preterm delivery, in mothers with and without a history of RPL. Generalized

estimating equation (GEE) models were used to control for potential confounders.

RESULTS: During the 30 years (1991-2021) study period, 356,356 singleton deliveries occurred; 14,235 deliveries (4.0%) occurred in women with a history of RPL. Placental complications were significantly more prevalent following RPL, including placental abruption, placenta previa and preterm delivery (**Table**). Using GEE models, controlling for siblings, maternal age, hypertensive disorders of pregnancy, pre-gestational and gestational diabetes mellitus, smoking and fertility treatments, maternal history of RPL was independently associated with IUGR, placental abruption, placenta previa and preterm delivery (**Table**).

CONCLUSION: Maternal history of RPL is an independent risk factor for placental-related complications in pregnancy, unrelated to maternal hypertensive disorders. Thus, emphasizing the need for specialized care and monitoring of these women.

Table. Placental-related complications in women with and without a history of RPL: Univariate analysis and results from a GEE model

	History of RPL (n=14,235)	No RPL (n=342,121)	Odds ratio (95%CI)	p value	Adjusted* OR (95%CI)	p value
Hypertensive disorders of pregnancy (%)	585 (4.1)	13,136 (3.8)	1.07 (0.98 – 1.16)	0.101	0.93** (0.85 – 1.03)	0.189

741 The association between hysterotomy extension and subsequent preterm birth

Giulia M. Muraca[1], Tzuria Peled[2], Abi Kirubarajan[1], Ari Weiss[2], Hen Y. Sela[3], Sorina Grisaru-Granovsky[2], Misgav Rottenstreich[1]

[1]McMaster University, Hamilton, ON, [2]Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim, [3]Shaare Zedek Medical Center, affiliated with the Hebrew University Hadassah School of Medicine, Jerusalem, Israel

OBJECTIVE: We aimed to quantify the association between uterine incision extensions and preterm birth (PTB) in a subsequent delivery.

STUDY DESIGN: We performed a retrospective cohort study using electronic perinatal data collected in 4 university-affiliated obstetrical centers, representing approximately 25% of all deliveries in the state of Israel. The study included patients with a primary cesarean delivery (CD) of a term, singleton live birth and a subsequent singleton birth in the same catchment (2006-2021). The primary outcome was subsequent PTB < 37 weeks; secondary outcomes included subsequent PTB < 34, < 32 and < 28 weeks. We assessed crude and adjusted associations between uterine incision extensions and subsequent PTB in multivariable regression models using odds ratios (ORs) and 95% confidence intervals (CIs). Adjusted models included several factors such as length of labour, indication for CD, chorioamnionitis, and smoking during pregnancy.

RESULTS: A total 4,827 patients met the study inclusion criteria. The overall rate of uterine incision extension was 6.0% and the total rate of PTB in the subsequent pregnancy was 4.9%. Patients with a uterine extension were more likely to have a longer duration of active labour, chorioamnionitis, failed vacuum delivery attempt, second stage CD, and persistent occiput posterior position of the fetal head in the primary CD and higher rates of smoking in the subsequent pregnancy. We found a higher, but statistically insignificant rate of subsequent PTB < 37 weeks among patients with vs without uterine incision extensions (adjusted OR 1.49, 95% CI 0.89-2.50; Table 1). However, a significantly higher rate of PTB < 34 weeks was found among patients with vs without extensions (adjusted OR 2.49, 95% CI 1.04-5.96; Table 1).

CONCLUSION: Patients with a hysterotomy extension have a 2.5-fold higher rate of PTB < 34 weeks compared with patients who do not sustain this injury. This association was not observed for PTB < 37 weeks.

Table 1. Crude and adjusted associations between hysterotomy extensions and preterm birth (PTB) in a subsequent pregnancy

	Rate (%)			
	With extension	Without extension	OR* (95% CI)	AOR† (95% CI)
PTB <37 weeks	6.6	4.8	1.40 (0.86-2.27)	1.49 (0.89-2.50)
PTB <34 weeks	2.4	1.1	**2.29 (1.03-5.11)**	**2.49 (1.04-5.96)**
PTB <32 weeks	1.4	0.6	2.36 (0.82-6.80)	2.53 (0.79-8.11)
PTB <28 weeks	0.7	0.3	2.44 (0.55-10.88)	3.05 (0.59-15.84)

*Deliveries without hysterotomy extension served as the referent group.
†Adjusted for the following characteristics of the primary CD: length of labour (no latent phase), CD type, CD indication, chorioamnionitis, failed vacuum attempt, persistent OP position and the following characteristics in the subsequent delivery: smoking during pregnancy.

742 Microwave ablation for selective fetal reduction in complicated monochorionic gestations

Gregory W. Kirschen[1], Bobby Brar[2], Camille Shantz[3], Ahmet A. Baschat[1], Michelle Kush[1], Sarah Millard[1], Mara Rosner[4], Jena L. Miller[4]

[1]Johns Hopkins Hospital, Baltimore, MD, [2]Tel Aviv University, Tel Aviv, Israel, [3]Johns Hopkins, Montreal, QC, [4]Johns Hopkins Center for Fetal Therapy, Baltimore, MD

OBJECTIVE: Second trimester selective fetal reduction (SFR) in monochorionic (MC) gestations has a cotwin loss rate of 18-40%. Microwave ablation (MA) is a newer technique for SFR with minimal thermal spread and a precise area of coagulation along the end of the needle and may result in lower preterm birth rates. We aimed to evaluate MA for SFR in MC gestations.

STUDY DESIGN: The surgical technique for MA is similar radiofrequency ablation. A 16-gauge microwave antennae is utilized under ultrasound guidance. Coagulation, tissue contact, and temperature are monitored. Demographics, procedure details and outcomes were evaluated for patients who underwent MA for SFR from 11/2017 to 4/2023 with available delivery outcomes. Our primary outcome was co-twin survival. Secondary outcomes included gestational age (GA)

at delivery and procedure to delivery interval. Continuous data were analyzed using Student's t-tests or Wilcoxon Rank Sum test. Categorical data were analyzed using Chi-square tests or Fisher's Exact.
RESULTS: Of 27 patients, 25 were MC twins, 1 was MC triplets and 1 was dichorionic triplets. MA was performed for twin reversed arterial perfusion in 14 (52%), discordant anomalies in 9 (33%), and twin to twin transfusion or selective fetal growth restriction in 6 (22%). Co-twin survival was 85%. Cotwin losses were due to previable birth (n=1), post operative intraventricular hemorrhage (n=1), septostomy with t cord entanglement (n=1), and post op day 1 demise (n=1). GA at delivery for 23 ongoing and delivered pregnancies was 37.7 [34-.1 - 38.9] weeks and interval to delivery was 17.2 [13.8 − 19.7] weeks. Between surviving and demised co-twins there was no difference in BMI, race, cervical length, gestational age, twin weight ratio, procedure time, or procedure energy. Transplacental entry was more frequent in co-twin demise (3/4 vs 5/23, p=0.03).
CONCLUSION: MA is a newer technique for SFR in MC twins thus far demonstrating favorable outcomes. Transplacental entry may be a risk factor for cotwin demise. Further studies are needed to evaluate outcomes and refine the technique.

743 Utility of genetic testing in fetuses with suspected lethal skeletal dysplasia on sonography

Haley Crane[1], Erica M. Schindewolf[2], Juliana S. Gebb[2], Natalie Burrill[2], Lisa Pilchman[2], Renee Wright[2], Suzanne DeBari[2], Beverly G. Coleman[3], Julie Moldenhauer[4]
[1]Richard D. Wood Jr. Center for Fetal Diagnosis and Treatment at CHOP, Philadelphia, PA, [2]Center for Fetal Diagnosis & Treatment, Children's Hospital of Philadelphia, Philadelphia, PA, [3]Richard D. Wood, Jr Center for Fetal Diagnosis and Treatment at CHOP, Perelman School of Medicine of the University of Pennsylvania, Philadelphia, PA, [4]Richard D. Wood, Jr. Center for Fetal Diagnosis & Treatment, Children's Hospital of Philadelphia, Perelman School of Medicine of the University of Pennsylvania, Philadelphia, PA

OBJECTIVE: Determining lethality in prenatally diagnosed skeletal dysplasia can be suspected using sonographic parameters with confirmation via molecular diagnosis. The challenge in the prenatal setting is that established ultrasound parameters are imperfect, while molecular diagnosis is not always achievable. We examined the added benefit of definitive genetic etiology in fetuses with suspected skeletal dysplasia when ultrasound was indicative of lethality.
STUDY DESIGN: A single-center retrospective chart review was conducted from 2013-2023 for pregnancies suspected to have a skeletal dysplasia. Fetuses were evaluated by ultrasound with attention to measurements predictive of lethality, including thoracic circumference/abdominal circumference < 0.6, femur length/abdominal circumference < 0.16, and thoracic circumference < 2.5%ile. Record review included demographics, imaging, genetic testing, and fetal/neonatal outcome.
RESULTS: Of 122 pregnancies that met inclusion criteria, 88 had at least 1 ultrasound criteria suggestive of lethality. Among suspected lethal cases, 79 underwent genetic screening/testing prenatally (64.6%), postnatally (20.3%), postmortem (10.1%), or at multiple points (5.1%). Genetic testing revealed non-lethal molecular diagnoses in 16 (20.3%) pregnancies thought to be lethal by ultrasound. In 39 cases with only 1 measurement in the lethal range, genetic testing identified lethal, non-lethal, and indeterminate results in 15 (38.5%), 14 (35.9%) and 10 (25.6%) patients, respectively. When presenting in the 3rd trimester, a higher portion of fetuses harbored non-lethal versus lethal genetic diagnoses, although this was not statistically significant (6/10 vs 4/10; p=0.25).
CONCLUSION: A discordant outcome from suspected lethal was revealed via non-lethal genetic diagnoses in 20.3% of cases. This data emphasizes the value of genetic testing in corroborating or refuting ultrasound prediction of lethality. A combination of ultrasound findings and molecular diagnosis can paint the clearest picture of prognosis, ultimately aiding in counseling, familial decision-making, and delivery planning.

Fetuses with suspected lethal skeletal dysplasias who underwent genetic testing (n=79)

744 Visual aids for induction of labor education: A randomized controlled trial

Halley Staples[1], Fan Zhang[2], Bridget C. Huysman[2], Bree A. Goodman[3], Rebecca R. Rimsza[4], Brianna Bradley[2], Lori Atwood[2], Jeannie C. Kelly[1], Ebony B. Carter[1], Anthony O. Odibo[2], Antonina I. Frolova[2], Nandini Raghuraman[2]
[1]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO, [2]Washington University School of Medicine in St. Louis, St. Louis, MO, [3]Washington University in St. Louis, St. Louis, MO, [4]St. Louis University, St. Louis, MO

OBJECTIVE: There are racial disparities in birth satisfaction among those undergoing induction of labor (IOL). Our objective was to develop a visual aid informed by the experience of historically marginalized pregnant people and test its ability to meet their IOL education needs.
STUDY DESIGN: This was a randomized trial of patients admitted for IOL. Those with prior cesareans, fetal anomalies, fetal growth restriction, and non-English speakers were excluded. Using data from an initial qualitative phase of semi-structured interviews and surveys of patients from marginalized backgrounds, we developed a visual aid handout on induction methods. On admission for IOL and prior to counseling on type of initial IOL method, patients were randomized to routine counseling or counseling with the visual aid. The primary outcome was patient knowledge, using a published IOL knowledge assessment tool. Secondary outcomes were Trust in Physician Scale scores and satisfaction with IOL counseling via Likert scale. A stratified analysis was performed by self-reported race (Black/Latinx/mixed race vs white). Eighty-four patients were required to detect a 25% difference in knowledge scores with 90% power. Analysis was performed using intention to treat approach.
RESULTS: Eighty-four patients were randomized: 42 to routine counseling, 42 to visual aid. 31% of patients self-identified as Black, Latinx, or mixed race. There was no significant difference in

knowledge score between routine counseling and visual aid groups (74.8% vs 68.3%, p=0.17). Trust in physician scores and satisfaction scores were also similar between groups. Although the visual aid increased knowledge scores in Black/Latinx/mixed race patients by 16%, there was no significant difference between routine counseling and visual aid groups.

CONCLUSION: The addition of a patient-informed visual aid to routine counseling at time of IOL did not significantly increase patient knowledge, trust in physician, or satisfaction scores. This calls for a broader investigation into contributors of birth dissatisfaction and consideration of earlier interventions prior to start of IOL.

Table: Impact of routine counseling vs counseling with patient-informed visual aid on knowledge scores, satisfaction, and trust in providers at time of induction of labor (IOL)

Outcomes	Routine counseling (n=21)	Visual Aid (n=21)	p-value
Satisfaction with quality of IOL counseling (0 to 10) Median (IQR)	9 (8, 10)	10 (9, 10)	0.08
Mean trust in physician scale (0-10) Mean (SD)	9.8 ± 0.4	10.0 ± 0.2	0.05
Average induction of labor knowledge score Mean % correct (SD)	68.3 ± 23.2	74.8 ± 19.4	0.17

745 Mode of delivery in FGR by EFW<10% vs. EFW≥10%ile and AC<10%ile undergoing trial of labor

Henri M. Rosenberg[1], Alexandra N. Mills[2], Ana Çapi[3], Elianna Kaplowitz[3], Daniel Kuhr[3], Sara Edwards[2], Calvin E. Lambert Jr.[4], Angela Bianco[1], Chelsea A. DeBolt[3]

[1]Mount Sinai Medical Center, New York, NY, [2]Icahn School of Medicine at Mount Sinai, New York, NY, [3]Mount Sinai Hospital, New York, NY, [4]Icahn School of Medicine at Mount Sinai, Richmond Hill, NY

OBJECTIVE: Per 2020 SMFM guidelines, fetal growth restriction (FGR) is diagnosed by estimated fetal weight (EFW) < 10%ile or abdominal circumference (AC) < 10%ile despite EFW. The objective was to investigate the difference in mode of delivery in patients undergoing a trial of labor between EFW < 10%ile versus AC< 10% ile but EFW ≥10%ile.

STUDY DESIGN: Retrospective cohort study including singleton, non-anomalous gestation, diagnosed with FGR prior to delivery undergoing trial of labor at Mount Sinai Hospital from 2021-2023. Patient characteristics were compared between groups using T-tests or Wilcoxon-Rank Sum tests for continuous measures and Chi-square or Fisher's exact tests for categorical measures. Primary outcome was mode of delivery. Primary and secondary outcomes were assessed using univariable and multivariable logistic regression, controlling for gestational age at delivery.

RESULTS: 141 patients (65%) were diagnosed with FGR based on EFW < 10%ile and 77 (35%) were diagnosed with FGR based on EFW ≥10%ile and AC < 10%ile. Those with EFW < 10%ile were more likely to have hypertensive disorders of pregnancy (p=0.03) and early onset FGR (p=0.003). The mean gestational age at delivery was 37 weeks versus 39 weeks for those with EFW < 10%ile compared to EFW ≥10%ile (p< 0.0001). There were no differences in the remaining maternal characteristics, including nulliparity and induction of labor. Overall cesarean delivery (CD) rate was 17.4%. There was no significant difference in CD rate in fetuses with EFW < 10%ile vs. EFW ≥10%ile and AC < 10%ile (aOR 0.90, 0.7-1.1). Those with EFW < 10%ile were at increased odds of CD for non-reassuring fetal status compared to those with EFW ≥10%ile and AC < 10%ile (OR 6.8, 1.6-29.8) and increased odds of NICU admission (OR 3.1, 1.2-7.7, Table 1).

CONCLUSION: There does not appear to be increased odds of CD in pregnancies complicated by FGR based on diagnostic parameters. However, future studies with larger sample sizes are warranted.

746 Peripartum cardiomyopathy delivery hospitalization and postpartum readmission trends, risk factors, and outcomes

Hooman Azad[1], Timothy Wen[2], Nicole Krenitsky[3], Natalie Bello[4], Whitney A. Booker[1], Stephanie Purisch[5], Mary D'Alton[6], Alexander M. Friedman[7]

[1]Columbia University Irving Medical Center, New York, NY, [2]University of California, San Francisco (UCSF), San Francisco, CA, [3]Columbia University Irving Medical Center, NewYork-Presbyterian, New York, NY, [4]Cedars-Sinai Medical Center, Los Angeles, CA, [5]New York Presbyterian Hospital, New York, NY, [6]Columbia Presbyterian Medical Center, New York, NY, [7]Columbia University, New York, NY

OBJECTIVE: To evaluate prevalence of peripartum cardiomyopathy (PPCM) during birth and postpartum hospitalizations, and to analyze associated trends, risk factors, and clinical outcomes.

STUDY DESIGN: Birth hospitalizations and postpartum readmissions within 5 months of delivery were analyzed from the 2010-2020 Nationwide Readmissions Database. Temporal trends in PPCM diagnoses were analyzed with joinpoint regression to estimate the average annual percent change (AAPC) with 95% confidence intervals (CI). Clinical, demographic, and hospital factors associated with PPCM, and odds for severe adverse outcomes including mortality were assessed using adjusted logistic regression models with odds ratios (OR) as measures of effect.

RESULTS: Of 39.8 million birth hospitalizations, 9,210 were complicated by PPCM (2.3 per 10,000 birth hospitalizations). Prevalence of PPCM among 5-month readmissions was 4.8 per 10,000. PPCM prevalence during birth hospitalization increased

from 2010 to 2020 (AAPC 2.2%, 95% CI 1.0%, 3.4%); prevalence of new PPCM diagnoses during readmissions did not (AAPC 0.0%, 95% CI -1.6%, 1.6%). Factors associated with peripartum cardiomyopathy (Table) include preeclampsia with severe features (aOR 13.9, 95% CI 12.5, 15.3), preeclampsia without severe features (aOR 6.0, 95% CI 5.3, 6.8), superimposed preeclampsia without severe features (aOR 10.2, 95% CI 8.5, 12.3), multiple gestation (aOR 2.7, 95% CI 2.3, 3.0), pre-gestational diabetes (aOR 1.8, 95% CI 1.6, 2.1), chronic hypertension (aOR 6.3, 95% CI 5.5, 7.2), and maternal age 40-54 years (aOR 1.9, 95% CI 1.7, 2.2, ref age 25-29). PPCM readmissions were associated with 10% of overall postpartum deaths, 21% of cardiac arrest/ventricular fibrillation diagnoses, 18% of extracorporeal membrane oxygenation cases, and 40% of cardiogenic shock cases.

CONCLUSION: PPCM prevalence during birth hospitalizations has increased over time. Preeclampsia and maternal chronic conditions were associated with the highest odds of PPCM. PPCM accounts for a significant proportion of severe postpartum adverse cardiopulmonary outcomes and death.

747 "Low-risk" and "High-risk" Nulliparous Term Singleton Vertex (NTSV) Cesarean Birth Rates Following the ARRIVE Trial

Itamar Futterman[1], Huda B. Al-Kouatly[2], Howard Minkoff[1], Rodney A. McLaren Jr.[3]

[1]Maimonides Medical Center, Brooklyn, NY, [2]Thomas Jefferson University, Philadelphia, PA, [3]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA

OBJECTIVE: The benefits of the ARRIVE trial for low-risk nulliparas, at ≥39 weeks, have been demonstrated. Given growing evidence that ARRIVE lowered the threshold for labor induction for all pregnant people, we sought to determine if the cesarean birth (CB) rate among "low-risk" and "high-risk" nulliparous term (≥37 weeks) singleton vertex (NTSV) pregnancies has changed since ARRIVE.

STUDY DESIGN: A population-based cohort study of all NTSV, non-anomalous live births using data from the US Natality database. Pre-ARRIVE included births between Jan-2015 and Dec-2017 and post-ARRIVE included births between Jan-2019 and Dec-2021. Low-risk births were without diabetes, hypertensive disorders of pregnancy, and prenatal care established < 12 weeks. Multivariable regression was performed to compare the mean NTSV CB rate between pre- and post-ARRIVE among births ≥37 weeks, adjusting for clinical differences. A logistic regression model was used to project the NTSV CB rate over time based on pre-ARRIVE rate and compare the rates, per year, using Wald confidence intervals.

RESULTS: There were 1,198,107 births pre-ARRIVE and 1,221,454 post-ARRIVE in the high-risk group and 2,413,279 births pre-ARRIVE and 2,226,433 post-ARRIVE in the low-risk group. After adjusting for clinical differences, the NTSV CB rate was lower post-ARRIVE compared to pre-ARRIVE in both the low-risk group (24.5% vs 24.3%, adjusted odds ratio (aOR) 0.92, 95% confidence interval (CI) 0.91-0.92) and the high-risk group (28.5% vs 29.0%, aOR 0.92, 95% CI 0.91-0.92). Low-risk pregnancies maintained a lower than projected NTSV CB rate based on pre-ARRIVE trends ($p < .05$), while there was no difference between projected and observed rates in the high-risk group (Figure 1).

CONCLUSION: There was a decrease in NTSV CB rate in the years following ARRIVE among both low-risk and high-risk pregnancies. However, among high-risk births, NTSV CB rates did not differ post-ARRIVE from what was projected based on pre-ARRIVE trends. These findings suggest that the ARRIVE protocol may not have the same benefits for high-risk pregnancies as it does for low-risk ones.

Figure 1: Rates of observed and projected NTSV CB rates pre-and post-ARRIVE among high-risk and low-risk groups:

748 Can Failed Vacuum Extraction Be Predicted?

Itamar Gilboa[1], Daniel Gabbai[2], Emmanuel Attali[3], Yariv Yogev[4], Anat Lavie[5]

[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel., Tel Aviv, Israel, [2]Tel Aviv Sourasky Medical Center, Tel Aviv, HaMerkaz, [3]Lis Maternity Hospital, Department of Obstetrics and Gynecology, Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel, [4]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [5]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel

OBJECTIVE: We aimed to determine risk factors for failed vacuum delivery among singleton pregnancies and to develop a prediction model.

STUDY DESIGN: A retrospective cohort study between the years 2011-2023, in a single university-affiliated medical center, with approximately 12,500 deliveries annually, was conducted. The study population included singleton pregnancies with a trial of vacuum extraction delivery and was divided into two groups; failed vacuum extraction (study group), defined as cases with an extraction duration exceeding 20 minutes or more than 2 cup detachments, leading to an urgent cesarean delivery (CD). The control group was comprised from women who had a successful vacuum extraction delivery. Pregnancy characteristics and outcomes were compared.

RESULTS: 1. Overall during the study period there were 133,024 deliveries, of them, 9,581 (7.2%) by vacuum extraction.

2. The rate of failed vacuum extraction was 186/9,581 (1.9%).

3. Multivariate analysis revealed an increased risk for a failed vacuum delivery associated with the following factors: patient's height < 160 cm. (OR=2.7, 95%CI [1.5-4.8], p< 0.001), induction of labor (OR=2.1, 95% CI [1.2-3.8], p=0.013), presenting part station < Sp+2 (OR=2.4, 95%CI [1.3-4.4], p=0.004), length of 2nd stage of delivery > 3.5 hours (OR=2.2, 95%CI [1.1-4.4], p=0.03), birthweight > 3750 gr (OR=2.4, 95%CI [1.2-5.1], p=0.02), and male gender (OR=2.1, 95%CI [1.1-4.0], p=0.024).

4. Newborns in the study group had increased rates of NICU hospitalization (20.4% vs. 5.6%, p< 0.001), subgaleal hematoma (5.4% vs. 0.3%, p< 0.001), and neonatal death (0.5% vs. 0.1%, p=0.015).

5. The prediction score model, incorporating these risk factors, demonstrated predictive performance with an AUC of 0.727 (95%CI 0.66-0.80), p-value < 0.001).

CONCLUSION: Using a prediction model for failed vacuum delivery may assist for caregivers to identify high risk patients for complicated delivery.

OBJECTIVE: We have previously demonstrated that maternal anatomical position changes directly affect the fetal middle cerebral artery (MCA) Doppler pulsatility indices (PI) and may serve as a predictor for adverse pregnancy outcomes. After power analysis of

pilot data, we sought to determine if these PI changes were associated with adverse pregnancy outcomes.

STUDY DESIGN: A prospective cohort study of pregnant people with a singleton, non-anomalous fetus, recruited between 18 and 24 weeks of gestation, in a single tertiary care center from 12/2021- 2/2022. MCA Dopplers were obtained and PI indices were measured and recorded, first in the supine position and then in the maternal left lateral position. Based on our prior findings suggesting a PI Δ of 0.22 being associated with adverse composite pregnancy outcomes (pre-eclampsia, fetal growth restriction and oligohydramnios), we divided the cohort into two groups, those above and below the cutoff of Δ =0.22. Demographic characteristics were compared using univariable analyses. Multivariable logistic regression was performed to compare the composite and individual pregnancy outcomes, adjusting for significant demographic differences between the groups.

RESULTS: We recruited 228 patients and followed them to delivery. There were 107 that had a PI $\Delta < 0.22$ and 121 that had PI $\Delta > 0.22$. Demographics and outcomes are seen in Table 1. The primary outcome of composite adverse outcomes did not differ between the groups. However, among pregnancies with PI $\Delta < 0.22$, pre-eclampsia was more likely to develop than pregnancies with PI $\Delta >$ 0.22 [aOR 95%CI 3.30 (1.02-10.69)].

CONCLUSION: We found that a second trimester fetal MCA PI $\Delta <$ 0.22 with maternal position changes at anatomy ultrasound was associated with developing preeclampsia. This data suggests that there may be an association of early decreased feto-placental reserve and the development of preeclampsia later in the pregnancy.

750 The Effect of the ARRIVE Trial on Nulliparous Term Singleton Vertex (NTSV) Cesarean Birth Rate

Itamar Futterman[1], Huda B. Al-Kouatly[2], Howard Minkoff[1], Rodney A. McLaren Jr.[3]
[1]Maimonides Medical Center, Brooklyn, NY, [2]Thomas Jefferson University, Philadelphia, PA, [3]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA

OBJECTIVE: The ARRIVE trial showed lower cesarean birth rates with labor induction at ≥39 weeks among low-risk nulliparas. These findings lowered the threshold for labor induction across all pregnant people, but little is known regarding the effects on nulliparous term (≥37 weeks) singleton vertex (NTSV) cesarean birth rate. Thus, we sought to determine how the cesarean birth rate among all NTSV pregnancies has changed after the ARRIVE trial.

STUDY DESIGN: We conducted a population-based, cohort study of all NTSV (≥37 weeks), non-anomalous births using data from the US Natality database. The pre-ARRIVE group included births between Jan-2015 and Dec-2017 and the post-ARRIVE group included births between Jan-2019 and Dec-2021. We compared the mean NTSV cesarean birth rate between both groups. Multivariable logistic regression was performed to adjust for clinical differences. A logistic regression model was used to project the NTSV cesarean birth rate over time based on the pre-ARRIVE rate and compare the rates, per year, using Wald confidence intervals.

RESULTS: There were 3,611,386 births in the pre-ARRIVE group, and 3,447,887 in the post-ARRIVE group. The NTSV cesarean birth rates pre- and post-ARRIVE were 25.8% and 25.9%, respectively. After adjusting for clinical differences between the groups, there was a decrease in the NTSV cesarean birth rate post-ARRIVE (adjusted odds ratio (aOR) 0.91, 95% confidence interval (CI) 0.908- 0.915). The NTSV cesarean birth rates (both observed and projected) are summarized in Figure 1. The absolute NTSV cesarean birth rate post-ARRIVE remained lower compared to the projected rate based on pre-ARRIVE trends ($p< 0.05$).

CONCLUSION: Despite a lower than projected rate of NTSV cesarean birth, the overall rate continued to increase. This rate increase warrants further investigation into the effects of the ARRIVE trial findings on populations outside the ARRIVE's inclusion criteria.

Figure 1: Observed and projected NTSV cesarean birth rates pre-and post-ARRIVE

751 Improving participation in postpartum remote blood pressure monitoring collaborating with community doulas for Black women

Jackie Powell[1], Tia Murray[1], Uchenna Jones[2], Erin Bailey[1], Kristin Hildebrandt[1], Megan Knutson Sinaise[3], Kara K. Hoppe[3]
[1]University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]Harambee Village, Madison, WI, [3]University of Wisconsin Madison, Madison, WI

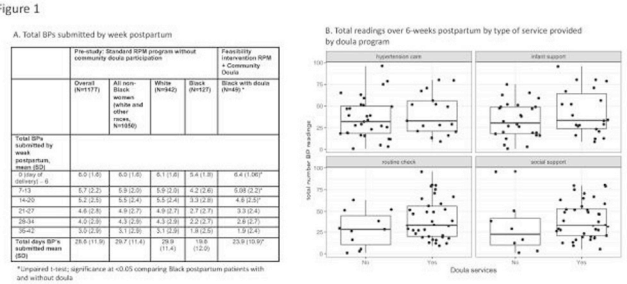
OBJECTIVE: Black persons have a higher incidence of hypertension disorders of pregnancy (HDP) and are 3-4 times more likely to experience mortality than non-Black persons. In an established postpartum (PP) remote patient monitoring program (RPMP) for HDP, daily BP submission was inequitable between non-Black and Black persons through 42-days PP. We aimed to increase participation equity for BP submission by incorporating community-based doulas with the RPMP.

STUDY DESIGN: A prospective feasibility study was performed at a single site from 1/21-10/22. The existing RPMP partnered with a community doula program focused on supporting Black birthing persons. Patients enrolled in the standard RPMP were approached for study participation prior to discharge and if consented were paired with a full service PP doula. Quantitative data was analyzed, and summary data generated. Non-paired t-test was performed comparing the pre-post study periods for BP submission of Black participants with standard RPM compared to RPM with the addition of a doula.

RESULTS: Of eligible Black PP persons, 49/153 (32%) enrolled. Over 42-days PP the mean total BPs submitted were significantly increased from 19.6 ± 12.0 prior to the study compared to 23.9 ± 10.9 when paired with a doula ($p < 0.05$). The percentage of patients who reported ≥ one BP by postpartum week was (week; %): 1; 96.1%, 2; 94.1%, 3; 86.3%, 4; 80.4%, 5; 68.6%, 6; 52.9%.) Of the types of doula services offered, social support was most associated with an increase in total BP submission. BP control improved PP, however 30% of patients continued to have stage 2 hypertension or worse at 6-weeks PP.

CONCLUSION: This study achieved an increase in participation of daily BP submission for Black PP persons through a community-based doula partnership within an established RPMP for HDP. Doula services involving social support were most impactful in increasing the total submissions. Community engagement and social support can improve health engagement of PP Black persons in the first 6-weeks PP.

Figure 1



752 Universal use of aspirin prenatally: Benefit to patients at high-risk for preeclampsia

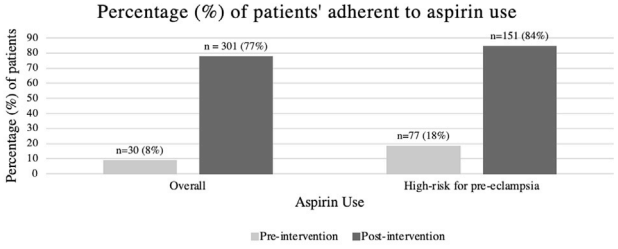
Jaclyn Del Pozzo, Insaf Kouba, Kristen H. Demertzis, Quratulain Zeeshan, Matthew J. Blitz
Zucker School of Medicine at Hofstra of Northwell, Bay Shore, NY

OBJECTIVE: The objective of this study was to evaluate if aspirin (ASA) administration to all obstetric patients increases use. Specifically, we assessed compliance rates in patients at high-risk for preeclampsia.

STUDY DESIGN: A prospective cohort of all obstetric patients who initiated prenatal care from January 2022 – December 2022 at a federally funded health care center and delivered at an academic health institution in New York. ASA 81mg daily was prescribed to all patients initiating care from 12 to 28 weeks' gestation beginning January 2022. Compliance with ASA use was verified at each prenatal visit. Patients who had a contraindication to ASA use, missed abortion, initiated care after 28 weeks' gestation and/or transferred care were excluded. Data was compared to a retrospective cohort of all obstetric patients from January 2021 – December 2021. The included patients were divided into two groups: pre- and post-intervention. Patient characteristics were obtained from the electronic medical record system. In addition to comparing maternal ASA use between the pre- and post-intervention groups, a separate analysis was performed to assess ASA use among patients at high risk for preeclampsia based on ACOG and USPTF guidelines.

RESULTS: A total of 765 patients were included: 373 pre-intervention and 392 post-intervention. Patients were predominately Hispanic, Spanish-speaking, single, and maternal age < 35 years old. The rate of ASA use increased significantly when comparing the pre-intervention to the post-intervention group [8% (n= 30) vs 77% (n=301), p< 0.001; Graph]. 228 patients were classified as high-risk for developing pre-eclampsia: 77 pre-intervention and 151 post-intervention. The rate of ASA use in the high-risk post-intervention group increased [18% (n= 14) vs 84% (n=127), p< 0.001].

CONCLUSION: When ASA is administered universally, patients at high-risk for preeclampsia were four times more likely to adhere to use. Further studies are needed to evaluate preeclampsia outcomes in this patient population.



753 Obstetrical and Perinatal Trends in Hawai'i from 2019 to 2023

Jacob Garcia[1], Laurito Jodie[2], Kelly Yamasato[3], Tiannah Ohta[4], Carrie Caeton[5], Jonathan Riel[6], Men-Jean Lee[3]
[1]University of Hawaii-JABSOM, Honolulu, HI, [2]Hawai'i Pacific Health, Honolulu, HI, [3]John A. Burns School of Medicine, University of Hawaii, Honolulu, HI, [4]Hawaii Pacific Health, Honolulu, HI, [5]Kapi'olani Medical Center for Women and Children, Honolulu, HI, [6]University of Hawaii, Honolulu, HI

OBJECTIVE: The State of Hawai'i is known to have one of the most diverse populations in the Unites States and faces unique social,

cultural, and geographic barriers that impact maternal health. We aimed to assess the most recent pregnancy outcomes in Hawai'i to identify communities at higher risk.

STUDY DESIGN: Pregnancy outcomes were abstracted from the EHR at Kapiolani Medical Center for Women & Children (KMC) from January 2019 to June 2023 as part of Hawai'i Pacific Health Quality Improvement. KMC is the only tertiary mother-baby referral hospital in the Pacific Basin. A total of 24,303 singleton deliveries with gestational age greater than 20 weeks and birth weight greater than 400g were analyzed. Clinical diagnoses were grouped by ICD-10 codes: e.g., hypertensive disorders (pre-existing and gestational), diabetic disorders (pre-gestational and gestational), and pre-eclampsia. Preterm births were defined as < 37 weeks and very preterm < 32 weeks. Growth disturbances were defined by low birth weight < 2500g and macrosomia >4000g. Descriptive analysis, Chi-square tests, and ANOVA were performed on Intellectus Statistics software.

RESULTS: Table 1 summarizes the results. Pregnant persons identifying as Native Hawaiian and Other Pacific Islander (NHOPI) experienced the highest rate of preterm delivery. Both NHOPI and Black or African American pregnant people had similarly high rates of hypertensive disorders. Asians experienced the highest rate of diabetic disorders in pregnancy. In fact, Asians were diagnosed with diabetes at a much lower BMI than all other racial/ethnic groups.

CONCLUSION: NHOPI people experience the highest rates of preterm birth. Asian pregnant persons experience diabetic disorders at much lower BMI than all other groups. Further studies are necessary to elucidate the pathophysiology of these observations in order to promote health equity.

754 Ultrasound and Clinical Characteristics of Congenital Pulmonary Airway Malformations (CPAM) and Neonatal Care Needs

James D. Doss[1], Anthony O. Odibo[1], Sherri Jackson[2], Jesse Vrecenak[3], Katherine H. Bligard[1]

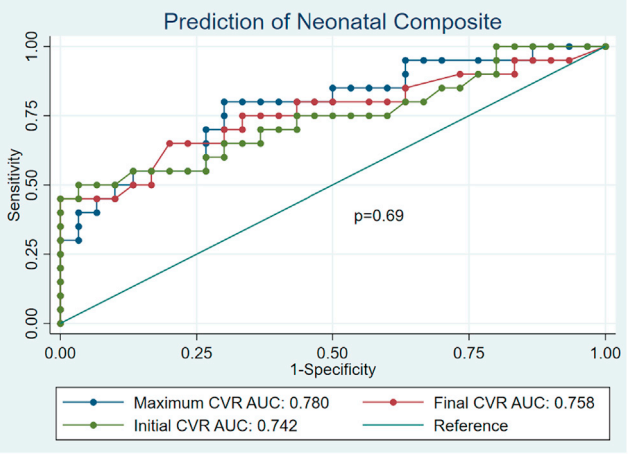
[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Barnes-Jewish Hospital, St. Louis, MO, [3]Washington University in St. Louis, St. Louis, MO

OBJECTIVE: CPAM are a heterogeneous group of congenital abnormalities, with increased prevalence given improvements in ultrasound (US) technology. Clinical factors influence recommendations regarding delivery, but more data is needed to establish a systematic approach to delivery planning. This study aimed to assess the prognostic utility of clinical characteristics to anticipate neonatal support needs.

STUDY DESIGN: We performed a retrospective case control study of patients with fetal CPAM from December 2010 to March 2023. The primary outcome was an adverse neonatal outcome composite (NICU admission, neonatal respiratory distress, respiratory support, neonatal surgery, and death). Receiver operating characteristic (ROC) curves compared the ability of CPAM volume ratio (CVR) and other US factors to predict the neonatal composite. The Liu method was used to determine a CVR cutoff to predict the neonatal composite outcome. CVR cutoff comparisons were performed by the Fisher exact test for categorical variables and the Mann-Whitney-U test for continuous variables. Statistical significance was defined as P value < 0.05.

RESULTS: 68 patients were included in the initial analysis, with 18 patients excluded. The composite neonatal outcome was seen in 18 patients (36%). Analysis using ROC curves found that initial, maximum, and final CVR were equally adequate predictors of the neonatal composite outcome. An initial CVR cutoff of 0.8 (sensitivity 50%, specificity 97%, AUC 0.73), maximum CVR cutoff of 0.8 (sensitivity 80%, specificity 70%, AUC 0.75), and final CVR cutoff of 0.4 (sensitivity 65%, specificity 80%, AUC 0.73) optimized ability to predict the neonatal composite outcome. Type of lesion and the percent change of CVR over the pregnancy were not predictive of adverse neonatal outcome. Likewise, the gestational age at max CVR and US evidence of compression were poor predictors of the neonatal composite outcome.

CONCLUSION: Our study validates the use of CVR to predict outcome and proposes CVR cutoffs that can predict adverse neonatal outcomes and help guide decisions to deliver at a higher level of neonatal care.



755 Increased prevalence of neural tube defects in industrial area in Northwestern Netherlands in 2020-2021

Jana M. de Vries[1], Liesbeth van Leeuwen[1], Anita C. Ravelli[2], Bernadette de Bakker[3], Eva Pajkrt[3]

[1]Amsterdam University Medical Center, Amsterdam, Noord-Holland, [2]Amsterdam University Medical Center, Amsterdam, the Netherlands and Amsterdam Reproduction & Development, Amsterdam, Amsterdam, Noord-Brabant, [3]Amsterdam UMC, location AMC, Amsterdam, Noord-Holland

OBJECTIVE: In the first year of the COVID-19 pandemic, 2020, we perceived an unexpected increase of prenatal diagnosis of neural tube defects (NTDs) in the Northwest region of the Netherlands. Environmental pollutants and exposure to heavy metals are associated with NTDs. The aim of this study is to evaluate the association of possible risk factors to the unexpected increase of prenatal diagnosis of NTDs in our region.

STUDY DESIGN: We performed a retrospective cohort study to examine the prevalence of isolated NTDs in the Northwest region of the Netherlands from 2010-2022. We looked into all possible risk factors for NTDs, including COVID-19. Zipcodes were used to examine exposure to pollution on municipal level. The region was separated into three areas according to levels of pollution: IJmond area (industrial area), Amsterdam (urban area), and all other municipalities. Poisson regression was employed to calculate crude prevalence ratios (PR) and 95% confidence intervals [CI]. PR were described per 10,000 births.

RESULTS: We diagnosed 203 isolated NTDs between 2010 and 2022 of which 41 cases (20%) were in 2020 and 2021. The PR of NTDs between 2010-2022 was 4.4 (95% CI 3.8, 5.1) per 10,000 births on average. In 2020 and 2021 the PR significantly increased to 5.4 (95%-CI 3.2, 8.5) and 7.5 (95%-CI 4.9-11.0) per 10,000 births, respectively (p=0.005). There was no change in lifestyle, obstetric or social-demographic risk factors such as use of folic-acid supplements, medication e.g.. Areal differences were evident only in 2020-2021 (p=0.001).The PR of NTDs in 2020 and 2021 was the highest in IJmond area with 21.0 (95%-CI 7.6, 45.8) NTDs per 10,000 births. Amsterdam and other municipalities of Northwest Netherlands had lower PRs of 7.3 (95%-CI 4.1, 12.1) and 4.5 (95%-CI 2.7, 6.9) per 10,000 births, respectively.

CONCLUSION: There was an increase of NTD prevalence in 2020 and 2021 in the Northwest region of the Netherlands. NTDs were most prevalent in the industrial area (IJmond area), and also increased in the very urban city of Amsterdam. We hypothesize that COVID-19 lockdown measures increased individual exposure of pregnant women to industrial pollution.

756 Perceived Discrimination, Adverse Childhood Experiences, Depression, and Perception of Care in Low Socioeconomic Obstetric Patients

Jasmaine Coleman[1], Kristina A. Roloff[1], Dotun A. Ogunyemi[2], Preeanka Mazumder[1], Guillermo Valenzuela[1]

[1]Arrowhead Regional Medical Center, Colton, CA, [2]California University of Science & Medicine, San Bernardino, CA

OBJECTIVE: To examine the associations of perceived discrimination, perception of care, Adverse Childhood Experiences (ACE), depression and the impact on obstetrical and neonatal outcomes in a cohort of pregnant patients.

STUDY DESIGN: This is a prospective observational cohort study of obstetric patients from 2022-2023. At initial prenatal care visit, participants completed baseline questionnaires on ACE; Ethnic Discrimination (PEDQ) analyzed by total score and components of Exclusion/rejection, Stigmatization/devaluation, Threat/aggression, and Discrimination at work; Person-Centered Prenatal Care Scale (PCPC) analyzed by total score and components of Responsive/supportive care, and Communication/autonomy and Dignity/Respect; and Edinburgh Postnatal Depression Scale (EPDS). Obstetrical complications included diabetic and hypertensive disorders and neonatal complications were fetal demise, preterm birth, low birth weight and low Apgar scores.

RESULTS: Of 104 participants; 62% were Hispanic, 23% Black, and 9% White. There was a significant negative correlation between PEDQ, and PCPC (rho= -0.355; p= 0.001). Results showed a positive correlation between PEDQ and ACEs, (r= 0.430; p< 0.001). Black compared to white patients, had lower total mean PCPC scores, (51.4 vs. 71.0, p=0.032), as well as in the domains of responsiveness/support (12.79 vs. 21.17, p=0.047), and dignity/respect (13.21 vs. 18.00, p=0.037). Black compared to Hispanic patients had higher mean scores of discrimination in the domains of stigmatization/devaluation (5.60 vs. 4.57, p= 0.046), and exclusion/rejection (9.60 v. 6.47, p=0.003). Patients with obstetrical complications had lower mean scores in the domain of responsive/supportive (2.361 v 1.423, p=0.037). No differences found in relation to neonatal complications.

CONCLUSION: Our results suggest that experiences of discrimination negatively affect perceptions of person-centered care. Black pregnant patients experienced more discrimination and had lower baseline person-centered prenatal care scores compared to other races.

Table: By Race/Ethnicity and Obstetrical Complications

Variable	White [mean (SD)]	Black [mean (SD)]	P value
Birthweight	3505.00 (241)	3009.83 (639)	0.035
Person-Centered Perception of care score	73.00 (4.98)	51.43(22.18)	0.032
Responsive and supportive positive score	21.17 (3.7)	12.79 (9.2)	0.047
Dignity and respect positive score	18.00 (0.0)	13.21 (5.1)	0.037
	Hispanic [mean (SD)]	Black [mean (SD)]	P value
Exclusion rejection score	6.47 (2.69)	9.60 (5.07)	0.003
Stigmatization devaluation score	4.57 (1.25)	5.60 (2.53)	0.046
	No complications [mean (SD)]	Obstetrical complications [mean (SD)]	P value
Responsive and supportive negative scores	1.42(2.01)	2.36(2.46)	0.037
	No complications [mean (SD)]	Hypertensive disorders [mean (SD)]	P value
Person Centered Perception of care negative score	3.68 (3.80)	6.81 (9.40)	0.027

757 Maternal, Neonatal and Delivery Outcomes Following a SARS-CoV-2 Moratorium on Elective Deliveries

Jayne Caron[1], Gabriela Dellapiana[2], Naomi Greene[2], John A. Ozimek[2]

[1]Cedars-Sinai Health System, Los Angeles, CA, [2]Cedars-Sinai Medical Center, Los Angeles, CA

OBJECTIVE: During the Omicron surge, hospitals experienced staffing shortages. To compensate for the diminished workforce, our institution cancelled *elective* inductions of labor (IOL) and *elective* cesarean deliveries (CD). The purpose of this study was to determine the impact of this moratorium on labor and delivery outcomes.

STUDY DESIGN: Retrospective cohort study of patients with singleton full-term deliveries: (1) three months prior to implementation of the moratorium, (2) the month of the moratorium, and (3) three months following the moratorium. The primary outcome was the rate of nulliparous term singleton vertex (NTSV) CD. Secondary outcomes included select maternal and neonatal outcomes. Outcomes were compared between the three time periods using Chi-square, Kruskal-Wallis, and one-way ANOVA tests as appropriate.

RESULTS: During the study period, 3248 patients meeting inclusion criteria delivered. There were no differences in maternal age, body mass index, race, insurance status, nulliparity, or overall induction of labor across the time periods. NTSV CD rates did not differ across the three time periods (Table 1). There were also no differences in rates of operative vaginal deliveries, trial of labor after CD, vaginal birth after CD, or overall CD rates. Maternal outcomes were similar with no differences in chorioamnionitis, hypertensive disorders of pregnancy, or higher order perineal lacerations. Lastly, there were no differences in neonatal outcomes including 5-minute Apgar < 7, neonatal intensive care unit admission, shoulder dystocia, or Unexpected Term Newborn Complications.

CONCLUSION: Previous studies have evaluated the impact of modifications to labor and delivery practices in response to SARS-CoV-2 and the impact of lockdown measures on preterm birth and CD rates; however, this is the first study to our knowledge to specifically

look at the impact of cancellations of elective IOL or CD. These findings are relevant in the context of potential future surges. It is reassuring that in this analysis there were no significant impacts on maternal, neonatal or delivery outcomes during the moratorium.

Table 1: Delivery-related maternal and neonatal outcomes for patients pre-, post-, and during the moratorium on elective deliveries

758 Increased Risk of Metabolic Syndrome Following Delivery of Abnormal Birthweight Babies

Jeesun Lee[1], Young Mi Jung[2], Jihye Bae[3], Haemin Kim[4], Sang-Hyuk Jung[5], Manu Shivakumar[5], Dokyoon Kim[5], Chan-Wook Park[1], Jong Kwan Jun[1], Jae-Seung Yun[6], Seung Mi Lee[1]

[1]Seoul National University College of Medicine, Seoul, Seoul-t'ukpyolsi, [2]Korea University College of Medicine, Seoul, Republic of Korea, Seoul, Seoul-t'ukpyolsi, [3]Seoul National University Hospital, Seoul, Seoul-t'ukpyolsi, [4]Seoul National University College of Medicine, Daegu, Taegu-jikhalsi, [5]University of Pennsylvania, Philadelphia, PA, [6]St. Vincent's Hospital / College of Medicine, The Catholic University of Korea, Kyonggi-do

OBJECTIVE: The history of delivering babies with abnormal birthweights has been reported to be associated not only with adverse perinatal outcomes but also with long-term metabolic complications of offspring. However, the potential impact of abnormal birthweight on maternal long-term health has not been well evaluated. This study aimed to evaluate the influence of delivering babies with abnormal birthweights on the long-term development of metabolic syndrome.

STUDY DESIGN: This study was conducted using data from the UK Biobank, which is a large cohort that includes participants in age 40 to 69 years recruited between 2006 and 2010, with ongoing follow-up. Women with at least one livebirth were included in the analysis. The study population was divided into three groups according to the birthweight of their first baby: low birthweight, normal birthweight, and macrosomia. Metabolic syndrome was defined by the presence of 3 or more diagnostic components: abdominal obesity, hypertriglyceridemia, low high-density lipoprotein cholesterol, high blood pressure, and hyperglycemia. The risk of metabolic syndrome and each component were evaluated for both low birthweight and macrosomia cases.

RESULTS: The analysis included 215,882 women, among whom 18,255 had delivered low birthweight babies, and 19,376 had delivered babies with macrosomia. At 40-60 years old, the prevalence of metabolic syndrome was 25.7% (55,517/215,882). Both delivering babies with low birthweight and macrosomia increased the risk of developing metabolic syndrome in middle-aged women.

CONCLUSION: This study highlights that delivering abnormal birthweight babies increase the risk of long-term development of metabolic syndrome, with different effect on each metabolic component. These findings imply the importance of considering both ends of the birthweight spectrum as potential risk factors of adverse maternal health outcomes.

Figure. Adjusted hazard ratio of metabolic syndrome and each components according to the birthweight of offspring

759 Outcomes of fetoscopic laser surgery across the spectrum of the transfusion syndromes

Jena L. Miller[1], Joyce Cheng[2], Mara Rosner[1], Michelle Kush[3], Camille Shantz[4], Katelyn Uribe[3], Alexandra D. Forrest[2], Angie Jelin[2], Marika Toscano[5], Ahmet A. Baschat[3]

[1]Johns Hopkins Center for Fetal Therapy, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins Hospital, Baltimore, MD, [4]Johns Hopkins, Montreal, QC, [5]Johns Hopkins University School of Medicine, Baltimore, MD

OBJECTIVE: Twin Twin Transfusion Syndrome (TTTS) and Twin Anemia Polycythemia Sequence (TAPS) are distinct clinical conditions across the spectrum of the transfusion syndromes. Both can present in isolation or in association with other complications specific to monochorionic twins. Fetoscopic laser surgery (FLS) aims to treat both TTTS and TAPS in a single procedure. We sought to understand if the outcome after FLS was worse in the setting of co-existing or isolated TAPS compared to TTTS.

STUDY DESIGN: Single site secondary analysis of patients presenting with isolated TTTS, TAPS, and TTTS with TAPS. TTTS was defined by Quintero staging and TAPS by middle cerebral artery peak systolic velocity (MCA PSV) discordance criteria. Pregnancy and ultrasound characteristics, primary treatment modality and perinatal outcomes were evaluated using Fisher's exact, Chi-square, Kruskal-Wallis and Mann-Whitney-U tests.

RESULTS: Of 431 patients treated with fetoscopic laser surgery, 371 had TTTS and 12 had TAPS alone, while 48 had both TTTS and TAPS. For cases of isolated TAPS, 9 were stage 2, 1 was stage 3 and 2 were stage 4. There was no difference in maternal body mass index (BMI), gestational age (GA) or fetal size discordance at the time of FLS. Preoperatively, cases with TTTS and TTTS/TAPS had shorter cervical length (CL), higher recipient and lower donor maximum vertical pockets (MVP) than those with isolated TAPS. GA at FLS, fetoscopy time, and joules were not different among groups. Total

number of artery to vein (AV) anastomoses were fewer in TAPS but total AV anastomoses number was not different. The Solomon technique was achieved in 92-98% of cases and recurrence was ≤5% across all groups. Median GA at birth and survival after FLS, birth and >28 days were not different (Table).

CONCLUSION: Despite differences in preoperative characteristics across the spectrum of monochorionic transfusion syndromes of TTTS and TAPS, FLS performs similarly with an overall favorable outcome.

Obstetric outcomes after fetoscopic laser surgery for TTTS, TAPS, and TTTS with TAPS

Characteristic	TTTS (n=371)	TAPS (n=12)	TTTS & TAPS (n=48)	p

760 Trends in delayed cord clamping documentation and performance at an urban hospital

Jenna Silverstein[1], Gurpreet Kaur[2], Lenora Codrington-Ennis[3], Jessica A. Meyer[1], Purnahamsi V. Desai[3], Lisa Shanahan[4]

[1]NYU Langone Health, New York, NY, [2]Nationwide Childrens, Columbus, OH, [3]NYU Grossman SOM, Department of Pediatrics, New York, NY, [4]New York University School of Medicine, New York, NY

OBJECTIVE: Delayed cord clamping (DCC) has beneficial effects on neonates, specifically in preterm infants where it has been shown to decrease the incidence of necrotizing enterocolitis, intracranial bleeds, anemia and subsequent need for blood transfusions, and hospital mortality. Despite these well studied effects, DCC is not universally performed or documented. We aimed to evaluate the trends in DCC documentation and performance with the goal of identifying areas for improvement.

STUDY DESIGN: This is a retrospective study of DCC documentation and performance at our urban hospital. In October 2022 we implemented formal documentation of DCC performance and duration - documentation was performed by the primary nurse and verified by the primary obstetrician.

RESULTS: From October 2022 – July 2023, 4352 deliveries of live neonates were performed. Throughout the study period documentation improved from 73.8% to 93.7%. Documentation was more commonly performed in vaginal deliveries (VD) compared to cesarean deliveries (CD) (91.5% vs. 73.8%; Figure 1). When documented, the rate of DCC performance was high in both VD and CD (98.0% vs. 94.4%; Figure 1). When comparing extremely preterm (22-27+6w), very preterm (28-31+6w), moderately preterm (32-33+6w), late preterm (34-36+6w) and term (37+w) deliveries, DCC was less likely to be performed at earlier gestational ages (87.5% vs. 89.5% vs. 95.2% vs. 95.8% vs. 97.2%) and more likely to be performed for shorter duration than in term infants (data not shown).

CONCLUSION: Documentation and performance of DCC was overall high, but documentation was lower for cesarean deliveries and performance was poorer and of shorter duration at earlier gestational ages. We identified cesarean deliveries and preterm gestations as areas for improvement in documentation and performance, respectively, and plan to develop educational curricula to improve these measures as well as evaluate the associated neonatal outcomes.

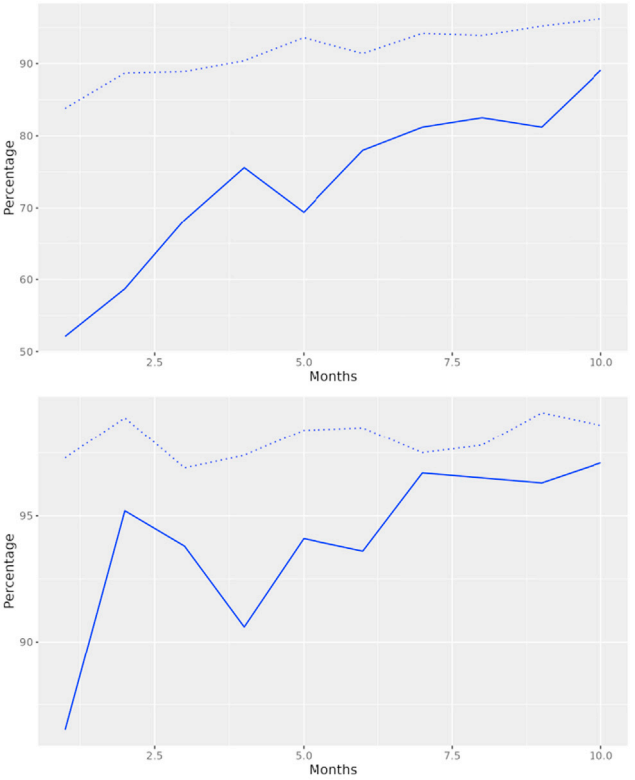

Figure: Documentation and performance of delayed cord clamping by mode of delivery over the study period

761 Impact of Retained Placenta on Breastmilk Production in Individuals Undergoing Conservative Management of PAS

Jennie Coselli[1], Elias Kassir[2], Rylee Trotter[3], Katherine Lambert[2], Baha M. Sibai[4], Pamela Berens[1]

[1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [2]McGovern Medical School at UTHealth Houston, Houston, TX, [3]University of Texas-Houston Medical School, Houston, TX, [4]Hermann Memorial Hospital, Houston, TX

OBJECTIVE: Conservative management of placenta accreta spectrum (PAS) includes delivery of the infant with retention of the placenta in situ. It has been suggested that retained placenta may adversely impact milk supply. There is insufficient data on the impact of leaving the placenta in situ with PAS and ability to establish lactation. Progesterone is believed to disrupt prolactin binding to alveolar cell

receptors within the breast. Placenta delivery with subsequent fall in progesterone removes this inhibitory effect and allows full milk supply. Our objective is to gather information related to lactation in women with planned placental retention.

STUDY DESIGN: We performed a prospective cohort study among pregnant individuals diagnosed with PAS in a tertiary county hospital system. We obtained progesterone and beta hCG levels for individuals undergoing either conservative management (with placenta left in situ and delayed hysterectomy) or cesarean hysterectomy. Chart review of lactation notes from each individual's inpatient hospitalization assessed whether they were breastfeeding or not, and, if breastfeeding, the approximate time for milk production to come in.

RESULTS: The percentage of individuals who breastfed in the cesarean hysterectomy group was 62.5%. The percentage of individuals who breastfed in the conservative management group was 66.7%. The average progesterone levels postpartum were 62.9 ng/mL in the conservative management group compared to 1.86 ng/mL in the cesarean hysterectomy group. The average time for milk supply to come in was 5.6 days for conservative management and 3 days for cesarean hysterectomy.

CONCLUSION: This information is important for future counseling on the impact of retained placenta on breastfeeding outcomes among the pregnant individuals considering conservative management of PAS. Continued research efforts are needed to better understand changes in progesterone and beta hCG levels associated with planned placental retention and implications on breastfeeding and milk supply.

Table 1: Differences in lactation in subjects opting for conservative management of placenta accreta spectrum vs. cesarean hysterectomy

	Conservative Management (n= 30)	Cesarean Hysterectomy (n= 96)
Number breastfeeding (n, %)	20, 66.7	60, 62.5
Progesterone level pre-delivery in ng/mL (mean, SD)	115.6, 63.1	138, 10.2
Progesterone level post-delivery in ng/mL (mean, SD)	62.9, 31.3	1.86, 2.1
hCG level in mIU/mL (mean, SD)	11410.9, 10143.0	15848.5, 12282.6
Number of days for milk supply to come in (mean, SD)	5.6, 2.8	3.5, n/a
Gestational age at delivery (mean, SD)	33w4d, 8.4 days	32w2d, 7.2 days

762 Neonatal intensive care unit admission and maternal postoperative pain experience

Jennifer L. Grasch

The Ohio State University Wexner Medical Center, Columbus, OH; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: To evaluate whether there is a relationship between newborn admission to the neonatal intensive care unit (NICU) and maternal pain experience and analgesic requirements after cesarean delivery (CD).

STUDY DESIGN: Secondary analysis of a multicenter randomized trial of individuals who underwent CD at 31 US hospitals (2020-22). Those whose pregnancies were complicated by major congenital anomalies, fetal or immediate neonatal death, or with missing data on the level of neonatal care required were excluded. The primary outcome was severe pain in the 24 hours prior to discharge: ≥7 on a scale from 0-10 on the Brief Pain Inventory. Secondary outcomes included assessments of opioid use and pain at defined time points. Univariable and multivariable analyses were performed.

RESULTS: 5265 individuals (95% of parent study participants) were included in this analysis. The 1348 (25.6%) participants whose newborns were admitted to the NICU were younger, of higher BMI, more likely to self-identify as non-Hispanic Black and to have comorbidities. There was no difference in the primary outcome (54.9 vs 57.2%, aOR 0.87, 95% CI 0.75-1.00) or rates of severe pain at 1 (Table), 2, 6 weeks, or 90 days postoperatively between the two groups (data not shown). Rates of moderate pain (≥4) at enrollment (88.1 vs 90.4%, aOR 0.70, 95% CI 0.57-0.88) and 1 week postpartum (57.5 vs 60.9%, aOR 0.81, 95% CI 0.70-0.94) were lower for people with infants in NICU.

Despite similar pain scores, people with infants in NICU had higher average daily and total postoperative inpatient opioid use (adjusted median difference 13.2 morphine milligram equivalents, 95% CI 7.8-18.7; Table).

CONCLUSION: In the postoperative period, parents whose infants were admitted to the NICU required higher doses of opioids to achieve similar pain control after CD.

Table. Maternal postoperative pain outcomes by highest level of neonatal care required

Outcome	Infant admitted to NICU (n=1348)	Infant not admitted to NICU (n=3917)	OR (95% CI)	Adjusted OR (95% CI)[a]
At enrollment, self-rated worst pain in last 24 hours				
Severe (≥7)	740 (54.9)	2238 (57.2)	0.91 (0.80, 1.03)	0.87 (0.75, 1.00)
Moderate or severe (≥4)	1188 (88.1)	3538 (90.4)	0.79 (0.65, 0.96)	0.70 (0.57, 0.88)
One week postpartum, self-rated worst pain in last 24 hours				
Severe (≥7)	233 (18.8)	657 (18.2)	1.04 (0.88, 1.23)	0.96 (0.79, 1.16)
Moderate or severe (≥4)	712 (57.5)	2192 (60.9)	0.87 (0.76, 0.99)	0.81 (0.70, 0.94)
			Median difference (95% CI)	Adjusted median difference (95% CI)[a]
Total inpatient opioid use, *MME*	45 (7.5, 101.3)	30 (0, 67.5)	15.0 (9.0, 21.0)	13.2 (7.8, 18.7)
Daily inpatient opioid use, *MME*	14 (3.1, 28.3)	10.5 (0, 25.2)	3.6 (2.0, 5.1)	2.0 (0.5, 3.6)

Data are reported as n (%), median (IQR) or OR (95% CI).

763 Obstetric Care and Pregnancy Health among Autistic Individuals in an Integrated Healthcare Setting in California

Jennifer Ames[1], Meredith Anderson[1], Emily Cronbach[2], Dena Gassner[3], Catherine Lee[1], Morénike Giwa Onaiwu[4], Lisa Croen[1]

[1]Kaiser Permanente Northern California, Oakland, CA, [2]The Permanente Medical Group, Walnut Creek, CA, [3]Adelphi University, Garden City, NY, [4]Rice University Center for the Study of Women, Gender, and Sexuality, Houston, TX

OBJECTIVE: Early evidence, mainly from European samples, suggests that individuals with autism spectrum disorder (ASD) face unique challenges around reproductive health, including increased risks of perinatal depression and pregnancy complications. Autistic people also commonly report traumatic experiences in healthcare, particularly in obstetric care. Our study aimed to describe pregnancy health and obstetric care utilization in autistic individuals in the United States.

STUDY DESIGN: Among members of Kaiser Permanente Northern California (KPNC) who had a clinician-documented ASD diagnosis,

we identified all pregnancies that occurred between January 1997 and July 2022 (n=235). From electronic health records, we extracted data on sociodemographic factors, diagnoses during pregnancy and postpartum, birth outcomes, and obstetric care utilization. We matched pregnancies among non-autistic members 100:1 on birth year to the autistic group (n=235,000). We used adjusted logistic regression to compare outcomes and utilization between the two groups.

RESULTS: Autistic individuals were more likely than non-autistic peers to be younger at pregnancy onset (average age 26 vs. 30 years old), White, non-Hispanic (58% vs. 35%), and to have government-subsidized insurance (25% vs. 10%). Autistic individuals also had higher rates of therapeutic abortion (27% vs. 15%), depression during pregnancy (54% vs. 14%) and postpartum (20% vs. 9%), and pre-term birth (13% vs. 6%). Pregnancy conditions such as gestational diabetes and pre-eclampsia, and prenatal care utilization, such as timing of prenatal care initiation, screenings, and C-section, did not significantly differ between the groups. However, autistic individuals were more likely to visit the emergency department within 6 months postpartum (Adjusted-OR: 1.56, 95% CI: 1.00, 2.46).

CONCLUSION: These findings emphasize the importance of addressing the obstetric needs of autistic individuals, including improving access to family planning services, enhancing the quality of prenatal and postpartum care, and providing adequate perinatal mental health support.

764 Optimizing Glucose Control and User Satisfaction with a Diabetes in Pregnancy Order Set Algorithm

Jenny Y. Mei[1], Tina A. Nguyen[2]

[1]University of California, Los Angeles, Los Angeles, CA, [2]David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA

OBJECTIVE: Correctional insulin is frequently ordered for pregnant patients on Labor and Delivery however preexisting insulin order sets are designed for non-pregnant patients. We aimed to create an obstetrics specific insulin order set in our electronic health record to improve efficiency, standardization, and user satisfaction.

STUDY DESIGN: With joint collaboration between maternal-fetal medicine, endocrinology, and nursing, we created a standardized insulin order set for use in pregnant patients with antepartum, intrapartum, and postpartum orders for each phase of care. A 20-item REDCAP survey was administered to MD and RN providers prior to and after implementation. Users rated on a Likert scale various statements assessing user satisfaction across 4 domains: usability of orders, communication between providers, clarity of orders, and efficiency of use. Chi-square or independent samples t-test were used to compare groups as appropriate. The study was deemed IRB exempt #22-000102.

RESULTS: Total 59 providers completed the survey prior to implementation of the order set and 24 completed it up to 12 months post-implementation. Demographics of survey participants did not vary between groups. After implementation of the new order set, there was significant improvement in perceived usability of the orders interface, including adaptability, clarity, and standardization of instructions across patients ($p< 0.001$). Providers reported decreased rates of miscommunication, incorrect orders, avoidable mistakes, and safety concerns ($p< 0.001$). Providers felt improved clarity of orders including blood glucose checks and insulin coverage ($p< 0.001$). There was also reported improvement in efficiency, with decreased amounts of time spent on orders and overall increased satisfaction with the orders interface ($p< 0.001$).

CONCLUSION: Implementation of a standardized obstetric specific insulin order set can significantly improve provider satisfaction on Labor and Delivery, helping improve usability, communication, and efficiency.

Table 1: Pre- and Post-Implementation Survey Results

Survey Question	Pre (n=59)	Post (n=24)	P-value[a]
Usability			
The orders interface is user-friendly.	2.46±0.92	4.13±1.03	**<0.001**
The orders interface is easy to adapt to pregnant patients.	2.31±0.88	3.92±1.21	**<0.001**
The orders interface is clear in the instructions.	2.34±0.90	4.13±1.03	**<0.001**
The orders interface is standardized between patients.	2.24±1.04	4.17±1.09	**<0.001**
The orders interface is efficient to use.	2.36±1.0	4.17±1.05	**<0.001**
Communication			
There is frequent miscommunication between providers.	3.69±0.88	2.88±1.33	**0.002**
There is frequent need to clarify orders.	4.41±0.53	3.0±1.45	**<0.001**
There are often incorrect orders.	3.78±0.94	2.42±1.28	**<0.001**
There are avoidable mistakes that happen.	3.52±1.01	2.46±1.10	**0.002**
There are safety concerns that arise.	3.74±1.00	2.38±1.24	**<0.001**
Clarification of Orders			
It is clear how often to check blood sugars.	2.60±0.92	3.88±1.26	**<0.001**
It is clear when to continue or discontinue standing insulin.	2.41±0.90	3.92±1.18	**<0.001**
It is clear how much insulin coverage to give.	3.0±0.99	4.33±0.82	**<0.001**
It is clear how often insulin coverage should be given.	2.78±0.97	4.29±0.81	**<0.001**
It is clear when to start pregnant patients on an insulin drip.	2.72±0.97	4.21±0.88	**<0.001**
Efficiency			
It is difficult identifying the orders needed.	3.69±0.75	2.0±1.02	**<0.001**
It is time consuming clarifying orders.	4.12±0.86	2.42±1.32	**<0.001**
It is frustrating taking care of diabetic pregnant patients.	3.69±0.99	2.25±1.26	**<0.001**
The amount of time I spend on the EHR for diabetic pregnant patients is significantly greater than for other patients.	3.78±0.90	2.79±1.22	**<0.001**
I am overall satisfied with the orders interface for diabetes management in our pregnant patients.	2.26±0.85	4.04±1.04	**<0.001**

765 Intended conservative management versus cesarean hysterectomy for known/suspected placenta accreta spectrum: a cost-effectiveness analysis

Jessica Morgan[1], Erika Hripko[2], Brett D. Einerson[3], Ashish Premkumar[2]

[1]The University of Chicago, NorthShore University Health Systems, Chicago, IL, [2]University of Chicago, Chicago, IL, [3]University of Utah Health, Salt Lake City, UT

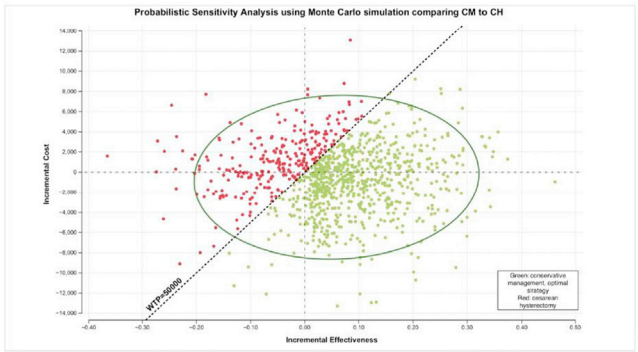
OBJECTIVE: Although the standard of treatment for placenta accreta spectrum (PAS) is planned cesarean hysterectomy (CH), an alternative approach in which the placenta and uterus are left in situ, conservative management (CM), is gaining acceptance. CM reduces immediate PAS morbidity, but delayed morbidity may lead to greater costs over time. We examined the cost-effectiveness of offering CM compared to CH as standard treatment for PAS.

STUDY DESIGN: A decision analysis (DA) compared CH with CM for 1000 persons with known or suspected PAS > 20 weeks gestation. In the base case analysis, we assumed 20-40% of patients with PAS would be eligible for CM and 50% would accept the intervention. Using probabilities derived from the literature, 78% would achieve successful CM at delivery and 82% would meet their intended delivery date. The DA was conducted from a healthcare system perspective with the analytic horizon the first postpartum year. Incremental cost-effectiveness ratios (ICER) for each strategy were calculated and compared. Utilities and costs were derived from the literature and Healthcare Cost and Utilization Project and adjusted to 2023 US dollars. An ICER of $50,000 per QALY defined cost-effectiveness. Standard sensitivity analyses were performed.

RESULTS: For base-case estimates, CM was the dominant strategy. Compared to CH, CM resulted in 905 fewer hysterectomies, 80 fewer instances of surgical site infection, and 5 fewer deaths. CM resulted in 149 more admissions with length of stay >5 days and 25 more ICU admissions. CM was the cost-effective strategy in 72% of runs and the dominant strategy in 41% of runs. In our threshold analysis, 23% of patients would need to accept and undergo successful CM

for it to be cost-effective, while it would remain cost-effective if no more than 51% were admitted to the ICU.

CONCLUSION: CM was the cost-effective or cost-saving management strategy compared to CH for PAS. However, modeling demonstrated significant uncertainty in the comparative effectiveness of the two strategies, highlighting the need for prospective research evaluating the effectiveness of CM.



766 Obstetric and fetal outcomes with high risk and non-reportable low fetal fraction cell-free DNA results

Jessica Barry[1], Amanda Boyer[1], Natasha Combs[1], Mikayla Deluca[1], Meredith Rochon[2]

[1]Lehigh Valley Health Network, Allentown, PA, [2]Lehigh Valley Hospital, Allentown, PA

OBJECTIVE: Low fetal fraction of cell-free fetal DNA (cfDNA) is associated with a risk for adverse pregnancy outcomes and aneuploidy. This study compares outcomes for pregnancies with non-reportable low fetal fraction (NR-LFF) versus high-risk low fetal fraction (HR-LFF) results.

STUDY DESIGN: Retrospective study of singleton pregnancies with LFF cfDNA results from a SNP-based platform from 1/2020 to 1/2023 at a single institution. Patients received a HR result (1/17 risk for trisomy 18, trisomy 13 or triploidy) or a NR result based on a fetal fraction-based risk (FFBR) model that incorporates maternal age, weight and gestational age into risk assessment. Primary outcomes included aneuploidy and live birth rate. Secondary outcomes included preterm delivery (PTD), small for gestational age (SGA) and preeclampsia (preE).

RESULTS: There were 214 women with LFF during the study period: 61 HR-LFF and 152 NR-LFF. Women in the HR-LFF group were older, had lower BMI, and lower fetal fraction (table). Those in the NR-LFF group were more likely to repeat the screen and those in the HR-LFF group were more likely to pursue diagnostic testing, likely representing differences in counseling. Aneuploidy rates were comparable between the two groups, including no pregnancies with trisomy 18, trisomy 13 or triploidy in the HR-LFF group. Pregnancy outcomes were available for 204 (95.3%) of the cohort and were similar between groups, although there was a trend towards a lower rate of liveborn neonates in the HR-LFF group. Rates of PTD and preE were high. Most miscarriages in the cohort did not have genetic testing, which may have limited sensitivity to detect aneuploidy.

CONCLUSION: Rates of aneuploidy were low in both HR-LFF and NR-LFF groups, although they may be underestimated due to incomplete genetic testing. Live birth rates trended lower in the HR-LFF group suggesting a greater risk for pregnancy loss. Overall rates of adverse pregnancy outcomes were relatively high, although there was no difference in outcomes between the HR-LFF and NR-LFF groups, suggesting these metrics are not influenced by the FFBR model.

Table 1. Maternal and pregnancy outcomes

	Non-reportable LFF N=152	High Risk LFF N=61	P value
Maternal Characteristics			
Maternal age (year)	28.97 ± 4.90	34.03 ± 6.45	<0.00001

767 Differential Packaging of Nuclear and Membrane Progesterone Receptors in Myometrial and Decidual Cell Exosomes

Jessica O. Selim[1], Lauren Richardson[2], Ananth Kumar Kammala[2], Enkhtuya Radnaa[3], RamKumar Menon[4]

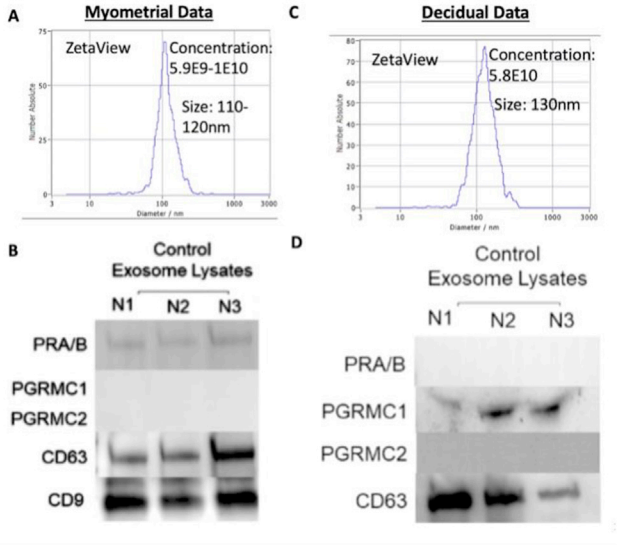
[1]University of Texas Medical Branch, Houston, TX, [2]University of Texas Medical Branch, Galveston, TX, [3]University of Texas Medical Branch at Galveston, Galveston, TX, [4]University of Texas Medical Branch, League City, TX

OBJECTIVE: Progesterone and its receptors (progesterone receptor membrane components-1/2 [PGRMC1/2] and nuclear progesterone receptors A/B [PRA/B]) play a crucial role in pregnancy maintenance by promoting decidualization, immunomodulation, uterine quiescence, and cervical integrity. The paracrine signaling functions they may provide when propagated via uterine cell-derived exosomes are unclear.

STUDY DESIGN: Lysates of myometrial and decidual cells grown in a 2D culture were prepared, and extracellular vesicles (exosomes) were isolated from media using differential ultracentrifugation and size exclusion chromatography. Immunocytochemistry and western blots localized receptors within cells and exosomes. ZetaView determined exosome size, concentrations, and exosomal-enriched CD markers.

RESULTS: Immunocytochemistry and western blot analysis of myometrial and decidual cell lysates confirmed the expression of both membrane (PGRMC1/PGRMC2) and genomic receptors (PRA/PRB). Myometrial and decidual cell-derived exosomes were around 110-130nm (**Fig.1A; Fig.1C**), concentrated within 10^9 -10^{10} per/ml (**Fig.1A; Fig.1C**), and expressed CD63 or CD9 (**Fig.1B; Fig.1D**). Myometrial exosomes predominantly expressed genomic receptors PRA/B (**Fig.1B**), while decidual exosomes expressed PGRMC1 (**Fig.1D**). These differences highlight the potential distinction in progesterone paracrine signaling and could be later used to target either cell type depending on the pathology.

CONCLUSION: We confirmed the expression of progesterone receptors and report their differential expressions in exosomes from myometrial and decidua cells. Given that a subset of pregnant women does not respond to progesterone treatment due to functional progesterone withdrawal, PR-containing exosomes could be utilized to deliver these receptors to gestational tissues during pregnancy. Potentially making them responsive to progesterone. Functional studies are still needed to understand the role of exosome-derived progesterone receptors.



768 Mid-gestation pregnancy serum level of placenta-specific miR-519c is inversely associated with infection-related preterm birth risk

Jessica A. Meyer[1], Agata Kantorowska[2], Jenna Silverstein[1], Whitney Cowell[1], Xinhua Lin[3], Leonardo Trasande[1], Ashley S. Roman[1], Shilpi Mehta-Lee[4], Nazeeh Hanna[3]

[1]NYU Langone Health, New York, NY, [2]NYU Grossman Long Island School of Medicine, Mineola, NY, [3]NYU Langone Health, Mineola, NY, [4]NYU Langone Health, Brooklyn, NY

OBJECTIVE: Placenta-specific miRNA-519c plays a crucial role in mitigating excessive placental inflammatory responses to repeated infections. Due to its predominant expression in the placenta, it has the potential to serve as a valuable maternal serum biomarker reflecting placental immune status. This study aimed to explore the association of low mid-gestation serum miR-519c with subsequent infection-related preterm birth.

STUDY DESIGN: This was a multicenter case-control study of pregnant patients for whom serum was collected during a routine prenatal visit ≤24 weeks and the placenta was histopathologically examined for chorioamnionitis postnatally. Preterm birth (< 37 weeks) cases were compared to term birth controls. miR-519c expression was assessed by qRT-PCR and presented as -dCt using cel-miR-39-3p as a control. The relationship between serum miR-519c level and the outcome of infection-related preterm birth was examined using unpaired t-test, ANOVA, and receiver operating characteristic curves as applicable.

RESULTS: Sera from 114 patients were analyzed: 54 preterm deliveries (13 with chorioamnionitis) and 60 term controls (21 with chorioamnionitis). Lower miR-519c levels were found among those with eventual preterm chorioamnionitis compared to term births (p=0.03) and uninfected preterm births (p< 0.01), as shown in Figure Panel (a). Preterm birth was not associated with lower miR-519c levels in the absence of peripartum infection compared to term birth (Panel (a)), nor was the presence of chorioamnionitis alone associated with lower miR-519c levels among those who delivered at term (Panel (b)). Mid-gestation serum miR-519c level was a good predictor of infection-related preterm birth (Panel (c): AUC 0.76, 95% CI 0.62-0.90).

CONCLUSION: Decreased levels of mid-gestation anti-inflammatory miR-519c were associated with subsequent development of infection-related preterm birth. Further investigation is warranted to explore the role of miR-519c in obstetrical outcomes and its utility as a pregnancy biomarker of placental immune status.

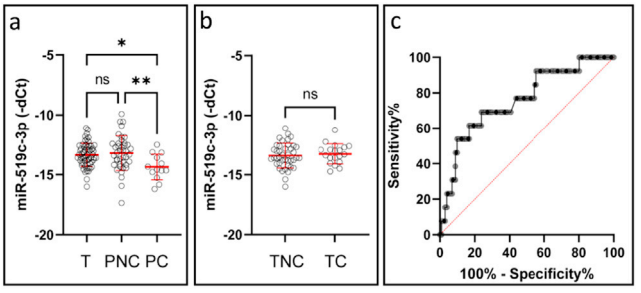


Figure: Mid-gestation pregnancy serum miR-519c-3p levels in relation to pregnancy outcomes

a) Relative mid-gestation expression of serum miR-519c-3p among patients that ultimately delivered at term (T, n=60), preterm without chorioamnionitis (PNC, n=41), or preterm with chorioamnionitis (PC, n=13). Analysis via one-way ANOVA with Turkey's multiple comparisons test; * (p<0.05), ** (p<0.01), and ns (p>0.05).

b) Relative mid-gestation expression of serum miR-519c-3p among patients that ultimately delivered at term without chorioamnionitis (TNC, n=41) or term with chorioamnionitis (TC, n=19). Analysis via unpaired t-test; ns (p>0.05).

c) Receiver operating characteristic curve (ROC) for serum miR-519c-3p levels predictive of infection-related preterm birth. Area Under the Curve (AUC) was 0.76 (95% CI 0.62–0.90, p=0.003). Generated using GraphPad Prism v 10.0.1 with Wilson/Brown method.

769 Rationalization of obstetric hysterectomy trays: A quality-improvement initiative

Jessica A. Meyer, Sepideh Mehri, Sharon Patrick, Ashley S. Roman

NYU Langone Health, New York, NY

OBJECTIVE: While obstetric hysterectomy is a rare event, it is associated with high morbidity and possible mortality. Surgical instrument trays with inappropriate instruments may contribute to intraoperative disorganization, causing increased costs and delays during these critical cases. We aimed to improve OR efficiency by rationalizing surgical instrument trays for obstetric hysterectomy cases.

STUDY DESIGN: This is a prospective quality improvement study critically appraising obstetric hysterectomy instrument trays at a single urban academic institution. Qualitative surveys were distributed to surgical technicians and senior surgeons (Maternal-Fetal Medicine and Gynecologic Oncology) to identify targets for

improvement. Existing obstetric trays were inventoried and compared to gynecologic hysterectomy trays to facilitate removal of unnecessary instruments and supplementation of necessary missing instruments. Post-rationalization instrument lists were approved by senior surgeons prior to tray modification and cost analysis.

RESULTS: A total of 4 trays containing 176 instruments were rationalized to 2 trays containing 129 instruments (27% reduction). Nearly one third of instruments (N=55/176) in the pre-rationalization trays were deemed unnecessary. The post-rationalization trays had 77% crossover (N=99/129) with the pre-rationalization obstetric hysterectomy trays and 23% crossover (N=30/129) with gynecologic hysterectomy trays, reflecting the inadequacy of the original trays to include all necessary instruments. Based on institutional case volume for obstetric hysterectomies, tray rationalization amounted to $4075.91 savings in purchase costs and $690 annual savings in tray processing costs.

CONCLUSION: Interdisciplinary appraisal of surgical instrument trays can effectively improve their clinical appropriateness while also reducing costs. Future steps for quality improvement will integrate the rationalized trays into a simulation curriculum to ensure familiarity and competency of all operating room staff and surgeons with the updated obstetric hysterectomy trays.

Table: Pre- and post-rationalization instrument use, costs, and savings

Tray Name	SIs per Tray	SIs per Case	SITs per Case	Cost per Case [a]	Annual Savings [b]
Pre-rationalization Trays					
L&D Z Clamps	29	176	4	Purchase $9938.29 Processing $115	$4765.91
L&D Abdominal Hysterectomy Clamp A	46				
L&D Abdominal Hysterectomy Clamp B	71				
L&D Abdominal Retractor	30				
Post-rationalization Trays					
L&D Hysterectomy Clamps	113	129	2	Purchase $5862.38 Processing $115	
L&D Hysterectomy Retractors	16				

Abbreviations: Surgical Instruments (SIs), Surgical Instrument Trays (SITs)
a Cost including purchase cost of all instruments in tray and cleaning/processing cost per case
b Savings calculated per year, assuming average case volume of 3 obstetric hysterectomies annually

770 Neonatal outcomes associated with clinically significant red blood cell antibody seroconversion in pregnancy

Jia Jennifer Ding[1], Elizabeth Abels[1], Jeremy Jacobs[1], Katherine Kohari[2]
[1]Yale University School of Medicine, New Haven, CT, [2]Yale New Haven Hospital, New Haven, CT

OBJECTIVE: To determine neonatal outcomes associated with clinically significant red blood cell (RBC) antibody seroconversion in pregnancy.

STUDY DESIGN: This is a retrospective cohort study of all pregnant patients who delivered at a multi-hospital system from 2016-2023. In this system, a type and screen (T&S) is obtained at entry to prenatal care, at time of admission for delivery, prior to administration of Rh(D) immune globulin (RhIG), or as clinically indicated. Patients with missing RBC antibody screen at delivery or no record of T&S at entry to prenatal care were excluded. All other patients with a positive screen at delivery were categorized as passively immunized due to RhIG, alloimmunized (antibody previously identified during the pregnancy), or seroconverted (antibody not previously identified in the pregnancy). Antibodies were described as clinically significant if associated with hemolytic disease of the fetus and newborn (HDFN) to any degree per ACOG Practice Bulletin 192. For neonates born to seroconverted patients with clinically significant antibodies, neonatal outcomes were chart abstracted. The highest total bilirubin was recorded prior to 96 hours of life as was phototherapy for hyperbilirubinemia, need for RBC transfusion, and neonatal intensive care unit (NICU) admission.

RESULTS: There were 58,912 pregnant individuals with 71,384 eligible deliveries. 351 (0.5%) deliveries had clinically significant antibodies associated with HDFN, and among those, 168 (0.2%) seroconverted in pregnancy. Among those deliveries, there was one case of unexplained stillbirth at 29 weeks and another pregnancy loss at 19 weeks. Of the remaining 166 liveborn neonates, 78 had a total bilirubin level drawn (median 9.1, ranged from 1.1 to 30.1) and 22 required phototherapy. 27 neonates required NICU admission, 5 of which were primarily due to hemolytic disease (Table).

CONCLUSION: Development of new clinically significant RBC antibody in pregnancy occurred at a rate of 0.2% with low incidence of associated neonatal morbidity. Routine third trimester assessment of maternal antibody status may not be indicated.

Table: Characteristics of neonatal cases admitted to NICU with component of hemolytic anemia

Case	Maternal antibodies	Antepartum PUBS/IUT	GA at birth	Neonatal DAT	Highest total bilirubin (mg/dL)	Time of bilirubin (hours of life)	Photo-therapy	First Hgb (mg/dL)	Transfusion	NICU LOS (days)	Comments
1	Anti-JkA	IUT x5, hydrops fetalis	33w2d	Negative	9.9	76	Yes	10.1	Simple pRBC and platelet	52	Prenatal diagnosis of pathogenic variants associated with bone marrow failure
2	Anti-D, anti-S, Anti-C, anti-JkA	IUT x5	35w2d	Negative	5.6	32	Yes	10.6	Simple pRBC	38	Abnormal microarray, congenital hydrocephalus

771 TTTS staging stratification for fetal death with donor twin middle cerebral artery evaluation without TAPS

Jimmy Espinoza[1], Neha Das Agarwal[2], Anthony Johnson[2], Ramesha Papanna[2], Edgar Hernandez Andrade[2], Eric P. Bergh[3]
[1]McGovern Medical School at the University of Texas Health Science Center Houston, The Fetal Center- Children's Memorial Hermann Hospital, Houston, TX, [2]McGovern Medical School at UTHealth Houston, Houston, TX, [3]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX

OBJECTIVE: To determine the association of elevated (> 1.5 MoMs) middle cerebral artery peak systolic velocity (MCA-PSV) with fetal demise in donor twins among twin-to-twin transfusion syndrome (TTTS) cases without twin anemia polycythemia sequence (TAPS).

STUDY DESIGN: This prospective cohort study included TTTS cases that underwent laser surgery from 2011 to 2022 at a single center. The distribution of donor fetal demise was stratified according to TTTS staging and elevated donor MCA-PSV without TAPS. Regression analysis was done to determine the association of isolated increased donor MCA-PSV and fetal demise, adjusted for TAPS, TTTS stage, selective fetal growth restriction (sFGR), and other confounders (Table 1). A cox regression model was used to evaluate the association of elevated donor MCA-PSV without TAPS and surgery-to-delivery interval adjusting for confounders.

RESULTS: Out of 660 TTTS cases, donor MCA-PSV was unavailable in 46 (7%) cases. Of the remaining 614 patients, 9 (1.5%) were lost

to follow up. High donor MCA-PSV without TAPS was seen in 5.6% (34/605) of the study population and its frequency doubled with each TTTS stage (1.2%, 3.6%, 6.9%, and 16.7%; at stages I, II, III, and IV, respectively; p=0.003). Among donor fetal demise cases (n=85) the percentage of elevated donor MCA-PSV without TAPS was 0% (0/6), 7.1% (1/14), 22.6% (14/62), and 100% (3/3) at TTTS stages I, II, III, and IV, respectively (p=0.005). High donor MCA-PSV without TAPS was an independent factor for donor fetal demise (aOR: 10.7; 95 % CI: 4.84-23.6; p< 0.001), after adjusting for confounders (Table 1). Elevated donor MCA-PSV without TAPS was independently associated with shorter surgery-to-delivery interval (Hazard ratio: 0.38; 95% CI: 0.22-0.67).

CONCLUSION: Elevated donor MCA-PSV without TAPS prior to laser surgery is associated with shorter procedure-to-delivery interval and with an 11-fold increased risk for donor fetal demise, adjusted for TAPS, sFGR, TTTS stage, and other confounders. Doppler evaluation of donor MCA PSV prior to laser surgery can further stratify TTTS staging to evaluate the risk for donor fetal demise.

Table 1. *Logistic regression analysis to identify variables determining donor fetal death*

Predictor Variables	Crude Odds Ratio (95% CI)	p	Adjusted Odds Ratio (95% CI)	p
Maternal age (years)	0.98 (0.95-1.02)	0.362	1.01 (0.97-1.06)	0.591

Donor MCA-PSV >1.5 MoM without TAPS	9.37 (4.59-19.1)	<0.001	10.69 (4.84-23.62)	<0.001

GA: gestational age, BMI: body mass index; sFGR: selective fetal growth restriction (EFW or birthweight discordance ≥25% and EFW < 10th percentile); MCA: middle cerebral artery; PSV: peak systolic velocity. TAPS: twin anemia polycytemia sequence [donor MCA-PSV>1.5 multiples of the median (MoMs) and recipient MCA-PSV< 1 MoM]; CI: confidence interval.

772 Hypertensive disorders of pregnancy and severe maternal morbidity according to race/ethnicity, California 2007-2018

Jonathan A. Mayo, Nicola Perlman, Anna Girsen, Suzan L. Carmichael, Stephanie A. Leonard
Stanford University, Palo Alto, CA

OBJECTIVE: The goal of this study was to assess the relationship between hypertensive disorders of pregnancy (HDP) and severe maternal morbidity (SMM) at delivery through 6-weeks postpartum (PP) by race/ethnicity. Racial/ethnic disparities in HDP and SMM are well known, and HDP confers increased risks of SMM and PP readmission.

STUDY DESIGN: This historical cohort study contained birth and fetal death certificates linked to hospital discharge records for the delivery admission and PP readmissions up to 6 weeks after delivery, for nearly all inpatient deliveries in California from 2007-2018. PP readmissions excluded transfers from the delivery hospitalization. HDP were identified by International Classification of Diseases codes from the delivery hospitalization. SMM was defined by the Centers for Disease Control and Prevention index and analyzed as any SMM from delivery up to 6 weeks PP as well as by time of occurrence: at delivery only, PP only, or delivery and PP SMM. We calculated the frequency of SMM among people with and without HDP stratified on race/ethnicity. We performed logistic regression to assess the association of HDP and SMM by race/ethnicity and adjusted confounders.

RESULTS: The frequency of SMM by race/ethnicity was between 1-2% of people without HDP and 4-7% of those with HDP (Table 1). SMM by each time of occurrence was highest among non-Hispanic Black people both with and without HDP. The highest odds ratio (OR) for HDP and SMM was observed among Hispanic people (OR=4.26, 95% confidence interval (4.17, 4.36), but the associations were similar and significantly elevated for all race/ethnicities (Table 1).

CONCLUSION: SMM at delivery or up to 6-weeks postpartum was 3 to 4 times more likely among pregnant people with HDP compared to those without HDP. The magnitude of the relationship between HDP and SMM was similar for all race/ethnicities although the absolute percentage of SMM was the highest among non-Hispanic Black people. These results confirm that HDP is a major risk factor for SMM, regardless of race/ethnicity.

Table 1. Frequency of severe maternal morbidity by time of occurrence and odds ratios for all severe maternal morbidity (SMM) at delivery through 6-weeks postpartum, by race/ethnicity and hypertensive disorders of pregnancy status at delivery

773 Utility of maternal cultures In laboring patients with isolated maternal fever or suspected intra-amniotic infection

Shay Dekel[1], Hila Hochler[2], Michal Lipschuetz[2], Shay Porat[2], Keren Olshtain-Pops[2], Gilad Karavani[2], Joshua I. Rosenbloom[3]
[1]Hebrew University School of Medicine, Jerusalem, Yerushalayim, [2]Hadassah Medical Center, Jerusalem, Yerushalayim, [3]Hadassah-Hebrew University Medical Center, Jerusalem, Yerushalayim

OBJECTIVE: There are no guidelines regarding the practice of taking cultures in laboring parturients with isolated intrapartum fever or suspected intra-amniotic infection. The objective of this study was to determine the utility of maternal cultures in febrile parturients and to examine risk factors for positive cultures.

STUDY DESIGN: In this retrospective cohort study from 2005-2015, all parturients at term at a tertiary medical center with a fever of ≥ 38°C during a trial of labor of a singleton fetus were included. In our institution, urine, blood, and vaginal cultures are routinely taken in all laboring patients with isolated intrapartum fever or suspected intra-amniotic infection. Clinical and demographic data, including results of cultures and neonatal results, were collected by chart review. Routine statistical tests were applied and multivariable logistic regression was performed to identify risk factors for positive cultures.

RESULTS: There were 1813 febrile patients included, with a mean maximum fever of 38.2°C; of these 1734 (95.6%) had blood cultures taken, 1327 (73.2%) had vaginal cultures, and 1612 (88.9%) had urine cultures, and 288 had placental cultures. Of the blood cultures, 1653 (95.3%) were negative and 25 (1.4%) were likely contaminated; leaving 56 (3.2%) positive cultures. Of the vaginal cultures, 1158 (87.3%) were negative; the majority of the positive cultures were GBS. Of the urine cultures, 1442 (89.4%) were negative, and the majority of the positive cultures were either GBS, Klebsiella, or E. coli. Neonatal cultures were taken in 1668 (92%) of cases, of these, 1645 (98.7%), were negative. In multivariable analysis, patients with higher fever were more likely to have positive blood cultures aOR 2.9 (95%CI 1.7, 5.2).

CONCLUSION: The yield of maternal blood cultures in labors complicated by fever is extremely low. The organisms identified in the 10.6% of positive urine cultures are treated by the empiric antibiotics started in cases of suspected chorioamnionitis. The practice of routinely collecting maternal cultures in all labors complicated by fever is not supported by evidence.

TABLE: Culture Results

Type of culture	Result	Frequency
Vaginal (n=1327)	Negative	1111(83.7%)
	Candida albicans	49(3.7%)
	GBS	134(10.1%)
	Other	33(2.5%)
Maternal blood (n=1734)	Negative	1653(95.3%)
	GBS	9(0.5%)
	Contaminated	16(0.9%)
	Streptococcus mitis\oralis	9 (0.5%)
	Other	47(2.7%)
Maternal urine (n=1612)	Negative	1444 (89.6%)
	GBS	33(2%)
	Escherichia coli	38(2.4%)
	Klebsiella pneumoniae	9(0.6%)
	Other	88(5.5%)
Placenta (n=288)	Negative	199(69.1%)
	GBS	14(4.9%)
	Enterococcus faecalis	8(2.8%)
	Escherichia coli	14(4.9%)
	Lactobacillus	18(5.3%)
	Other	35(12.2%)
Neonatal blood (n=1668)	Negative	1651 (99%)
	Other	17(1%)

774 Hospital-level variation in cesarean birth after nulliparous term induction of labor

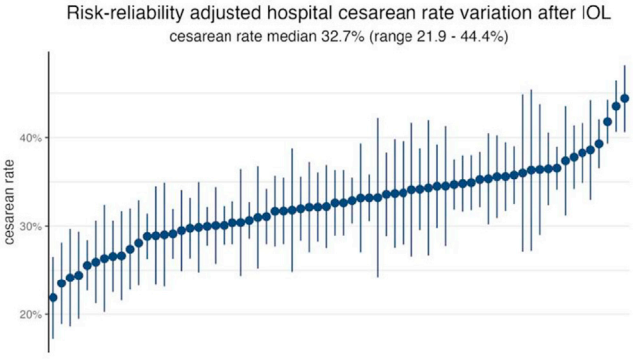
Jourdan E. Triebwasser[1], Xilin Chen[2], Michelle Moniz[2], Nicolina Smith[3], Lisa Kane Low[2], Molly J. Stout[2]
[1]University of Michigan , Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]Henry Ford Health System, Detroit, MI

OBJECTIVE: To estimate the variation in cesarean birth rates among nulliparous, term, singleton, vertex (NTSV) births that 1) underwent induction of labor (IOL) and 2) had an elective IOL.

STUDY DESIGN: This is a cross-sectional study across 68 birthing hospitals using clinically abstracted values from the Obstetrics Initiative, a quality improvement initiative supported by Blue Cross Blue Shield of Michigan. We included NTSV births undergoing IOL from 01/2020 to 12/2022. Risk and reliability adjusted cesarean rates were calculated using logistic linear mixed models with random intercepts for hospitals. The model included age, admission BMI, pre-gestational diabetes, gestational diabetes, hypertensive disorders of pregnancy, substance use disorder, social vulnerability index (SVI), hospital teaching status, and neonatal care level.

RESULTS: Among 39,139 NTSV patients undergoing IOL, 13,364 (34.1%) had a cesarean birth. Most births occurred in a teaching hospital (87%). The median number of IOL per hospital was 352 (IQR: 192-844) with high variation in observed cesarean rates ranging from 18.8% to 46.3% (median 33.4%). In the model-based analysis, pre-pregnancy diabetes (aOR: 2.09), higher SVI (aOR: 1.57), older age (aOR: 1.06) and higher BMI (aOR: 1.06) were associated with cesarean birth ($p < 0.05$). Variation in cesarean was only slightly reduced after risk and reliability adjustment (median adjusted cesarean rate, 32.7%, range 21.9% to 44.4% [**Figure**]). In a sensitivity analysis among 10,971 elective IOL, we found similar results with risk and reliability adjusted cesarean rates ranging from 22.1% to 44.1% (median 30.2%).

CONCLUSION: High variability in risk-adjusted cesarean rates across hospitals after IOL highlights that lower rates of cesarean are achievable. Practice sharing regarding IOL management may lead to lower cesarean rates.



775 Optimizing latent phase duration during inductions to minimize morbidity and cesarean delivery

Julia Burd[1], Michael Dombrowski[2], Jeannie C. Kelly[3], Ebony B. Carter[3], Anthony O. Odibo[1], Antonina I. Frolova[1], Nandini Raghuraman[1], Candice Woolfolk[1]
[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

OBJECTIVE: A prolonged latent phase (PLP) is associated with maternal/neonatal morbidity. Although ACOG recommends against cesarean for PLP, the rising rate of patients undergoing induction of labor (IOL) demands identification of meaningful latent phase timepoints that can guide counseling/management. We aim to define the optimal latent phase length during IOL using maternal, neonatal, and cesarean risks.

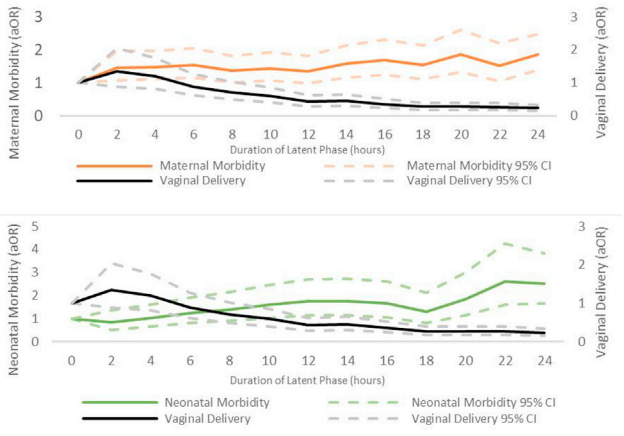
STUDY DESIGN: This was a secondary analysis of the Consortium for Safe Labor study, a multicenter retrospective study of consecutive

births at 19 hospitals from 2002-2008. We included singleton, cephalic gestations at ≥ 37 weeks who underwent IOL and completed the latent phase. Pregnancies with prior uterine incisions, major congenital anomalies, and incomplete labor curve information were excluded. Composite maternal and neonatal morbidities (see figure) and likelihood of vaginal delivery (VD) were analyzed at each four-hour interval of latent phase past 12 hours. Results were stratified by parity. Multivariable logistic regression was used to determine adjusted odds ratios for cumulative risk.

RESULTS: 13,161 patients were included with 6128 (47%) nulliparas and 7033(53%) multiparas. The composite maternal and neonatal morbidities were seen in 13% and 8% of patients, respectively. Among nulliparas undergoing IOL, cumulative risks of maternal and neonatal morbidity consistently increased after 16 and 20 hours, respectively. Although the odds of a VD decreased consistently with each time extension past 12 hours, the absolute chance of VD remained high at 74% even at >24 hours of latent phase for nulliparas. Among multiparas undergoing IOL, the odds of neonatal morbidity increased at 12 hours but then remained stable, whereas maternal morbidity did not increase with time. The odds of VD decreased at each time point after 12 hours, but VD rates remained >78% at >24 hours for multiparas.

CONCLUSION: In nulliparous patients undergoing IOL, 20 hours of latent labor is a reasonable timepoint to engage in shared decision-making about increased risks of maternal and neonatal morbidity and chances of VD.

Comparison of adjusted odds ratio of maternal and neonatal morbidity and vaginal delivery throughout the latent phase for induction of labor in nulliparous patients



Composite maternal morbidity is defined as chorioamnionitis, endometritis, postpartum hemorrhage, blood transfusion, third-or-fourth degree perineal lacerations, or ICU admissions. **Composite neonatal morbidity** is defined as respiratory distress syndrome, sepsis, mechanical ventilation, birth trauma, seizures, hypoxic ischemic encephalopathy, NICU admission, or neonatal death.
Adjusted odds ratio (aOR): Morbidity adjusted for obesity and delivery mode. Vaginal delivery adjusted for obesity

776 Maternal-Perinatal Outcomes in Pregnancies Exposed to Hydroxyurea

Julie Barbera[1], Rebecca Horgan[2], Rachel Madding[3], Vincenzo Berghella[4], Melissa L. Russo[5], Rodney A. McLaren Jr.[1], Huda B. Al-Kouatly[6]

[1]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA, [2]Eastern Virginia Medical School, Norfolk, VA, [3]Oregon Health & Science University, Portland, OR, [4]Jefferson Medical College, Philadelphia, PA, [5]Women and Infants Hospital, Providence, RI, [6]Thomas Jefferson University, Philadelpia, PA

OBJECTIVE: Hydroxyurea (HU) is an oral chemotherapeutic agent. Despite therapeutic efficacy, it is not recommended during pregnancy due to concerns of potential teratogenicity. Our objective was to assess maternal-perinatal outcomes among patients exposed to HU during pregnancy.

STUDY DESIGN: A systematic literature review using PubMed, Scopus, CINAHL, Clinicaltrials.gov and the Cochrane library was performed from inception through January 2023. This systematic review was performed according to the Preferred Reporting Item for Systematic Reviews and Meta-Analyses (PRISMA) statement and the protocol was registered with PROSPERO (CRD42020203416). All studies that reported outcomes in pregnancy exposed to HU, including case reports and case series, were included. Exclusion criteria included patient self-reported outcomes. Pregnancy outcomes were live birth, early pregnancy loss (< 20 weeks), stillbirth, infant death, or termination of pregnancy (TOP). Perinatal outcomes were presence of congenital anomaly, fetal growth restriction (FGR), and preterm birth (PTB).

RESULTS: A total of 225 pregnancies exposed to HU across 35 publications were included. HU indications were sickle cell disease 142 (61.3%), chronic myeloid leukemia 35 (15.6%), essential thrombocytopenia 28 (12.4%), and other conditions 15 (6.7%). First trimester exposure was documented in 195 (86.7%). Among continuing pregnancies (n=185), outcomes included live birth (84.3%), early pregnancy loss (13.5%), stillbirth (2.2%), and infant death (0.5%) (Table 1). Among continuing pregnancies at > 20 weeks (n=160), perinatal outcomes included FGR 7 (4.4%), PTB 22 (13.8%) and congenital anomaly 3 (1.9%) including pilonidal cyst, unilateral renal dilatation, and hip dysplasia. Of these 160 pregnancies, 125 (78.1%) had no reported adverse perinatal outcomes.

CONCLUSION: Pregnant patients should be counseled that exposure to HU does not appear to increase the risk of early pregnancy loss nor congenital malformation. Additionally, the rate of stillbirths, FGR and PTB appear favorable in the context of high-risk pregnancy with sickle cell disease or malignancy.

Table 1. Pregnancy Outcomes with Exposure to Hydroxyurea

Pregnancy Outcomes	Any Exposure (N=225)	1st Trimester Exposure (N=195)	2nd/3rd Trimester Exposure (N=21)
Live Births	156 (84.3)	130 (82.8)	17 (89.5)
Early Pregnancy Loss	25 (13.5)	24 (15.3)	0 (0.0)
Stillbirth	4 (2.2)	3 (1.9)	1 (0.5)
Infant Death	1 (0.5)	1 (0.5)	0 (0.0)
Termination of Pregnancy	40 (17.8)	38 (19.5)	2 (9.5)

*Data presented as n (%). Percentages of outcomes calculated based on pregnancies that were not terminated

777 Normative values of monocyte distribution width in pregnancy

Julie Vircks[1], Devon O'Brien[1], Eva Kaufman[1], Kiersten Herzog[1], Christine Henricks[1], Anna Ilivicky[1], Imaima Casubhoy[1], Julia Dahlke[1], Subhjit Sekhon[1], Tanvi Karmarkar[1], Madison Brown[1], Jared Bodine[1], Jeffrey Kelleher[2], Nanette West[2], David Mundy[2], Devika Maulik[1]
[1]University of Missouri-Kansas City School of Medicine, Kansas City, MO, [2]University Health, Kansas City, MO

OBJECTIVE: The volumetric measurement of the monocyte, known as the monocyte distribution width (MDW), has been shown to increase as the infection severity increases in the nonpregnant population. However, there is an absence of data regarding baseline values in pregnancy and whether a normal value of less than 20 units applies to pregnancy. The primary aim of this study was to define monocyte distribution width values in each trimester of pregnancy. The secondary analysis sought to correlate MDW with other infection-associated markers, specifically white blood cell (WBC) and neutrophil counts.

STUDY DESIGN: In 2023, we performed a retrospective electronic chart review of outpatient antepartum visits over a 2-month interval in an urban safety net hospital. Subjects were included in the data analysis if a complete blood count with MDW was performed. Exclusion criteria were the presence of an active or recent infection (including COVID-19) and antibiotic, immunotherapy, or corticosteroid use in the 14 days before the lab results. Chi-square, Spearman's rank-order, and Kruskal-Wallis tests were utilized for statistical analyses.

RESULTS: Seven hundred eighty-four charts were reviewed, and 259 were included in the analysis. First-trimester MDW values were significantly lower than the second and third-trimester values ($p< 0.001$). However, there was no significant difference between second and third-trimester values on post hoc analysis ($p=0.85$) (Table 1). MDW values greater than 20 U also differed between trimesters, notably increasing in the second and third trimesters ($p=0.03$) (Table 1). The participants had no correlation between MDW values and WBC or neutrophil counts ($r=0.171$, 0.124, respectively).

CONCLUSION: This is the first study that describes normative MDW values in pregnancy and suggests that several normal gravidas without clinical evidence of infection have MDW values above the nonpregnant upper limit of normal (20 U). Further studies are needed to prospectively analyze MDW values in pregnancy to identify values indicative of infection and sepsis.

Table 1: Monocyte distribution width (MDW), white blood cell (WBC), and neutrophil values per trimester*

	First trimester (n=89)†	Second trimester (n=76)†	3rd trimester (n=94)†	p value
Gestational age (weeks)	10.4 (8.2-11.9)	23.3 (17.2-26.9)	30.3 (28.5-33.7)	--
Body mass index (kg/m^2)	28.0 (23.8-37.7)	29.1 (26.3-34.6)	30.8 (26.4-37.6)	0.20
MDW (U)	17.0 (15.5-18.3)	18.4 (17.0-19.9)	18.5 (17.3-19.8)	<0.001
MDW values >20 U, n (%)	8 (9.0)	17 (22.4)	20 (21.3)	0.03
WBC	8.3 (6.7-10.5)	9.1 (7.6-11.1)	8.8 (7.3-10.3)	0.14
Neutrophil count	5.9 (4.2-7.6)	6.6 (5.1-8.2)	6.1 (4.8-7.7)	0.84

778 Obstetrical patient comorbidity according to hospital volume of delivery: a retrospective cohort study

Juliette St-Georges[1], Nicholas Czuzoj-Shulman[2], Andrea R. Spence[2], Haim A. Abenhaim[3]
[1]Université de Montréal, Montréal, QC, [2]Jewish General Hospital, QC, [3]Jewish General Hospital, Montreal, QC

OBJECTIVE: Our study objective is to determine whether obstetrical patients with more comorbidities are more likely cared for at hospitals with higher patient loads.

STUDY DESIGN: A retrospective cohort study was conducted on all admissions with a delivery or maternal death from October 2015 to December 2019 from the American database Healthcare Cost and Utilization Project-Nationwide Inpatient Sample. The cohort was weighted to be representative of the entire population and births in the United States. The cohort was stratified using the validated Expanded Obstetric Comorbidity Scoring System, a tool designed to predict the risk of severe maternal morbidity. The cohort was divided in four categories of scores. The strata were then divided by hospital sizes at which the births were recorded. Frequencies were calculated for each sub-category of maternal comorbidity index and hospital size.

RESULTS: The cohort included 15,669,785 deliveries. Of those, 45.0% had a comorbidity score of 0, 19.2% had a score of 1-10, 19.2% had a score of 11-20 and 16.5% had a score of 21+. In hospitals with less than 500 deliveries annually, 48.2% had a score of 0, 20.2% had a score of 1-10, 18.40% had a score of 11-20 and 13.3% had a score of 21 or higher. In hospitals with 500-< 1000 deliveries annually, for the same score categories, the frequencies were as follow: 46.3%, 19.9%, 18.8% and 15.1%. In hospitals with 1000 to < 2000 deliveries, the frequencies were as follow: 44.5%, 19.1%, 19.4% and 17.0%. Lastly, in hospitals with >2000 deliveries, the frequencies were as follow: 44.1%, 18.7%, 18.7% and 17.8%.

CONCLUSION: In conclusion, more than 50% of women delivering at American hospitals have comorbidity increasing the risk of severe maternal morbidity. As hospital volume of deliveries increases, the proportion of comorbid patients delivering also increases. Nonetheless, all hospital sizes care for patients of every risk level.

779 Patient Perspectives on Sources of Conflict and Support During Periviability Counseling: A Qualitative Analysis

Katarina Schneiderman[1], Alexa Morrison[2], Katherine Himes[3]
[1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]University of Pittsburgh Medical Center, Magee-Women's Hospital, Pittsburgh, PA, [3]Magee-Womens Research Institute, Pittsburgh, PA

OBJECTIVE: Families facing delivery during the periviable period must make high-stakes, time-sensitive, and often irrevocable decisions about how to care for their infant after birth. There is a paucity of literature regarding patients' experiences with periviable counseling. Understanding patient experience can help us improve communication and may aid high-quality decision making. The purpose of this study was to highlight patient-identified sources of support and conflict from conversations with their health care team when delivering during the periviable period.

STUDY DESIGN: We contacted birthing people who delivered between 22 - 25 weeks gestational age from 2011 - 2014. We conducted semi-structured interviews focused on counseling and decision-making at the time of periviable birth. Interviews were transcribed and coded to perform thematic analysis.

RESULTS: We interviewed 20 women who delivered during the periviable period and 6 important others. Average age was 27.3, 35% identified as Black and 50% had private insurance. The average gestational age at delivery was 24 weeks. We identified 14 themes during our analysis. Here, we focus on sources of conflict and support which were most frequently coded and actionable. Sources of conflict included a mismatch between patients' and providers' understanding of prognosis, patient perception of excessive hopelessness by providers, and lack of provider acknowledgement of family values. Sources of support included relationships with and understanding from nursing and ancillary staff, providers acknowledging family emotional processing, as well as patient's perception of time and effort spent by provider.

CONCLUSION: Our findings suggest areas for improvement in our periviablity counseling include provider acknowledgement of patient hope and family values, whilst ensuring patient understanding of prognosis. Our findings emphasize adequate time for counseling and addressing patient emotions throughout, with potential benefit in providing nursing training in patient support during the periviable period.

Theme	Representative Quote
Sources of Conflict	
Understanding of prognosis	*"If I knew then what I know now...I probably would've been pushing...for the [corticosteroid] shots...for more than I got but I didn't know. And I didn't know what I didn't know."*
Lack of acknowledgement of family values	*"I wish I had been armed with information... I could feel differently about what decisions I made if the outcome had been different, but I have a great deal of regret for giving up my ability to give birth for a baby that was not viable..."*
Emphasis on hopelessness	*"I totally understand they have to tell you the possibilities...but I feel like you can't just be like 'IF your baby even lives, it's going to be all doom and you have no hope of anything'...And honest to god I laid in that bed and I just quit listening to him."*
Sources of Support	
Importance of nursing	*"The nurses they were wonderful...Even in the operating room, I'm like 'hold my hand don't leave'. Because it's so scary and the one nurse was there all the time."*
Acknowledging family emotional processing	*"The difference...was the way they laid it out to me and the way they presented the information while still being honest but being encouraging as well..."*
Perceived time spent/effort of provider	*"it was helpful that she just sat down...she wasn't getting on to the next room. she just took as much time as we needed...which I don't think we needed much time. But you know, just if we needed it then she would've stayed there for an hour, it felt like that to us."*

780 Resolution of fetal discordance after laser is predicted by twin growth before twin-to-twin transfusion syndrome

Katelyn Uribe[1], Abby Birk[2], Jena L. Miller[3], Ahmet A. Baschat[1], Michelle Kush[1], Valeria Pasuizaca[4], Sam Suh[4], Kristin Voegtline[2], Sarah Olson[2], Mara Rosner[3]

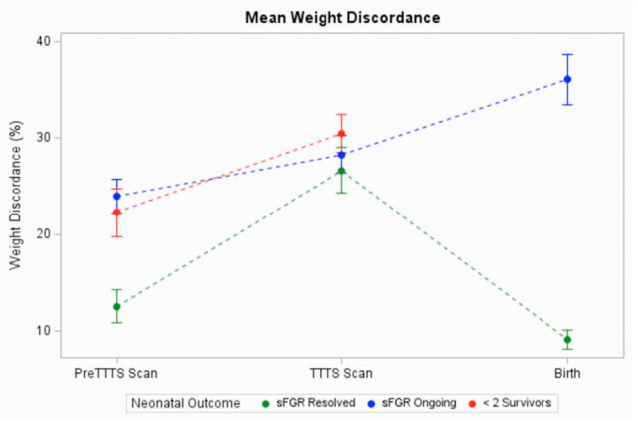
[1]Johns Hopkins Hospital, Baltimore, MD, [2]Johns Hopkins School of Medicine, Baltimore, MD, [3]Johns Hopkins Center for Fetal Therapy, Baltimore, MD, [4]Johns Hopkins University, Baltimore, MD

OBJECTIVE: To determine if resolution of fetal growth discordance after laser surgery for Twin-to-Twin Transfusion Syndrome (TTTS) with concurrent selective fetal growth restriction (sFGR) is predicted by estimated fetal weight discordance (EFWD) prior to the development of TTTS (pre TTTS).

STUDY DESIGN: This is a single center, retrospective analysis of monochorionic twins with TTTS and sFGR who underwent laser surgery and had available growth ultrasound records at a pre-TTTS scan. Demographics, pregnancy characteristics, and outcomes were compared between 3 outcome groups: double survival (DS) with birth weight discordance (BWD) < 20%, DS with ongoing BWD ≥ 20%, or demise after laser. Continuous data were analyzed using Student's t-tests or Wilcoxon Rank Sum test. Categorical data were analyzed using Chi-square test orFisher's Exact test. A multivariate logistic regression model was constructed based on univariate associations.

RESULTS: Ninety-seven patients underwent laser at 19.1 [17.4-22.1] weeks with a mean EFWD of 28.7%. The pre-TTTS scan occurred at 16.9 [16.1-19.6] weeks. After laser, 34 (35.1%) had resolved BWD (mean 9%), 34 (35.1%) had ongoing BWD (mean 36.5%), and 29 (29%) had a single or double fetal demise. Demographics, TTTS stage, recipient umbilical artery Dopplers, and donor middle cerebral artery Dopplers did not differ by patient groups. Pre-TTTS EFWD was significantly lower among cases with resolved BWD relative to persistent BWD (P< .0001). EFWD at the time of TTTS diagnosis did not differ between patient groups (P=0.071). Donor umbilical artery qualitative flow (P=0.0087) and pulsatility index (P=0.0061) were associated with ongoing BWD and fetal loss following laser therapy; however, after logistic regression, EFWD at the pre-TTTS scan was the only predictor of growth resolution at birth (p = 0.0063).

CONCLUSION: Concordant growth prior to the development of TTTS is associated with resolution of fetal growth discordance after laser treatment. These findings suggest that TTTS pathophysiology also contributes to growth discordance noted at the time of TTTS diagnosis.



781 Multiethnic Growth Standards for Fetal Body Composition and Organ Volumes Derived from 3D Ultrasonography

Katherine Grantz[1], Wesley Lee[2], Lauren Mack[3], Magdalena Sanz Cortes[4], Luis Goncalves[5], Jimmy Espinoza[6], Roger Newman[7], William A. Grobman[8], Ronald J. Wapner[9], Karin Fuchs[10], Mary D'Alton[11], Daniel Skupski[12], John Owen[13], Anthony C. Sciscione[14], Deborah Wing[15], Michael P. Nageotte[16], Angela Ranzini[17], Edward Chien[18], Sabrina Craigo[19], Seth Sherman[20], Dian He[21], Stefanie Hinkle[22], Cuilin Zhang[23], Jagteshwar Grewal[24], Zhen Chen[25]

[1]National Institute of Child Health and Development, National Institutes of Health, Bethesda, MD, [2]Baylor College of Medicine, Houston, TX, [3]GE Healthcare, Houston, TX, [4]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [5]Phoenix Children's Hospital, Phoenix, AZ,

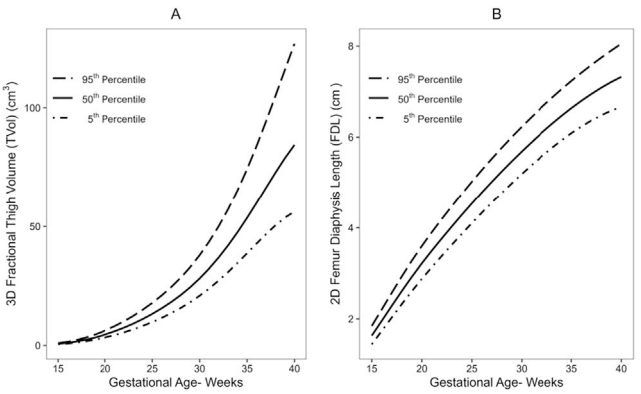
[6]McGovern Medical School at the University of Texas Health Science Center Houston, The Fetal Center- Children's Memorial Hermann Hospital, Houston, TX, [7]Medical University of South Carolina, Charleston, SC, [8]The Ohio State University, Columbus, OH, [9]Columbia University Irving Medical Center, New York, NY, [10]Columbia University Medical Center, New York, NY, [11]Columbia Presbyterian Medical Center, New York, NY, [12]Weill Cornell Medicine, Flushing, NY, [13]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [14]Delaware Center for Maternal & Fetal Medicine of Christiana Care, Inc., Newark, DE, [15]Korn Ferry, Pasadena, CA, [16]Miller Children's and Women's Hospital, Long Beach, Long Beach, CA, [17]MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH, [18]Cleveland Clinic, Lakewood, OH, [19]Tufts Medical Center, Boston, MA, [20]The Emmes Company, MD, [21]The Prospective Group, Inc; NICHD, NIH, Bethesda, MD, [22]University of Pennsylvania, Philadelphia, PA, [23]National University of Singapore, Queenstown, Singapore, [24]NICHD, NIH, Bethesda, MD, [25]Quest Diagnostics, Secaucus, NJ

OBJECTIVE: For three-dimensional (3D) ultrasound to live up to its potential to improve estimated fetal weight precision and characterize fetal growth abnormalities, it is first necessary to establish population-based standards for 3D measures including indicators of body composition (fractional limb volumes (arm [AVol], thigh [TVol])) and organ volumes. Growth in fat and lean mass and organ size may be differentially altered by nutritional, metabolic or environmental influences and in complicated pregnancies, in ways not identifiable using corresponding 2D measures. Our objective was to create standards for fetal 3D measures and compare with traditional 2D measures.

STUDY DESIGN: The Fetal 3D Study included banked research-quality images of singletons from 12 U.S. sites, up to 5 scans per fetus, and was racially and ethnically diverse. All gravidas had low-risk profiles, and their neonates had normal outcomes (N=1,730). Volumes were measured by protocol and estimated, weighted curves (5^{th}, 50^{th}, 95^{th} percentiles) derived from 15-41 wks using mixed models with cubic splines.

RESULTS: Subcutaneous thickness of abdomen, arm, and thigh increased linearly, with slight acceleration around 27-29 wks. AVol, TVol, and lean limb volume increased along a quadratic curvature, with acceleration around 29-30 wks.(Fig A) In contrast, 2D humerus and femur lengths demonstrated a logarithmic shape, with fastest growth in the 2^{nd} trimester.(Fig B) Cerebellar 2D diameter increased linearly, while cerebellar 3D volume growth gradually accelerated until 32 wks and then decelerated. Lung, kidney, and liver volumes all had gradual early growth followed by a linear acceleration beginning at 25 wks for lungs, 26-27 wks for kidneys, and 29 wks for liver.

CONCLUSION: Growth patterns and timing of maximal growth for 3D limb (lean and fat tissue) and organ volumes differed from traditional 2D growth measures. Multiethnic standards for 3D growth measures may complement 2D, particularly in the 3^{rd} trimester. Future studies will investigate 3D as potential indicators of abnormal growth and association with adverse pregnancy outcomes.



782 Phenotyping Labor Dystocia: A Pilot Study Triangulating Cytokines and Uterine EMG Parameters

Katherine J. Kissler[1], Elise N. Erickson[2], Shalom Darmanjian[3], Julien Penders[3], Leah Holmes[4], Ellen L. Tilden[4]

[1]University of Colorado, Aurora, CO, [2]University of Arizona College of Nursing, Tucson, AZ, [3]Bloomlife, San Francisco, CA, [4]Oregon Health & Science University, School of Nursing, Portland, OR

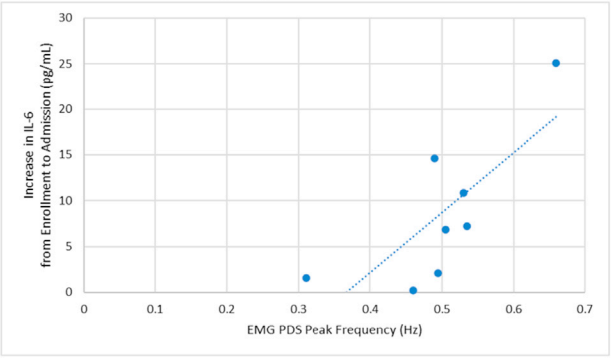
OBJECTIVE: The purpose of this pilot study is to evaluate feasibility of triangulating physiologic data to differentiate etiologies of labor dystocia. We aimed to establish preliminary data on associations and correlations of biomarkers with labor outcomes to support hypothesis development.

STUDY DESIGN: In this prospective pilot, we measured IL-6 at ~37 weeks gestation and upon admission for labor and analyzed a 30-minute segment of uterine electromyography (EMG) during labor using the 128hz 12bit Lovelace FT device (Bloomlife) in (N = 8) low-risk nulliparas planning vaginal birth. The three EMG channels were band pass filtered between 0.1 and 1 Hz using a second order Butterworth filter, then adaptively combined based on their signal-to-noise ratio. The output was then down-sampled at 16 Hz and normalized and the mean contraction duration and power density spectrum (PDS) median and peak frequency were calculated for each contraction.

RESULTS: Change in IL-6 from enrollment to admission was associated with the EMG PDS peak frequency (Spearman's Rho = .593, p = .044); admission IL-6 also trended toward correlation with EMG PDS peak frequency (Spearman's Rho = .733, p = .079) (Figure 1). Although not statistically significant, IL-6 on admission, change in IL-6, and EMG PDS peak frequency were lower in those with induction, dystocia, and cesarean.

CONCLUSION: Generalizability is limited by small sample size, multiple exploratory comparisons, and incomplete timing data to link the EMG data to labor events. Despite the limitations of the data, the significant association between EMG PDS peak frequency and IL-6 supports our original hypothesis and suggests that IL-6 may have a role in uterine contractility during labor. Researchers can improve quality of intrapartum EMG data by reducing skin impedance < 10kOhms, utilization of hardware to log accelerometer data and electrode locations, and real-time synchronous logging of the labor events (including medications).

Figure 1: EMG PDS Peak Frequency is Correlated with Change in IL-6



Note: 1. IL-6 on enrollment (~37 weeks gestation) was often below the lowest detectable limit (6.14 pg/ml)
2. For most patients, IL-6 increased between enrollment and admission to the hospital. Patients in spontaneous labor had a great change in IL-6.
3. EMG PDS Peak Frequency is correlated with change in IL-6 (p = .044) and trends toward a correlation with admission IL-6 (p = .079).

783 Risk of Severe Maternal Morbidity among Pregnancies complicated by Pregestational Diabetes

Katherine Reckamp, Emily A. DeFranco, Heather R. Masters
University of Cincinnati College of Medicine, Cincinnati, OH

OBJECTIVE: Severe Maternal Morbidity (SMM) is an indicator of pregnancies at risk of mortality and is an important indicator of the health of a population. High-risk pregnancies with pregestational diabetes (PGDM) are also at risk of adverse pregnancy outcomes, however there is a paucity of data on its relationship with severe maternal complications, SMM.

STUDY DESIGN: Retrospective population-based cohort study of all US live births using vital statistics birth certificate records, 2014-2019. Demographic, medical, and pregnancy factors were compared between mothers with PGDM and those without. The primary outcome was composite SMM, defined as maternal ICU admission, eclampsia, blood transfusion, unplanned hysterectomy, or ruptured uterus. Multivariate logistic regression estimated the relative influence of risk factors associated with SMM in pregnancies complicated by PGDM.

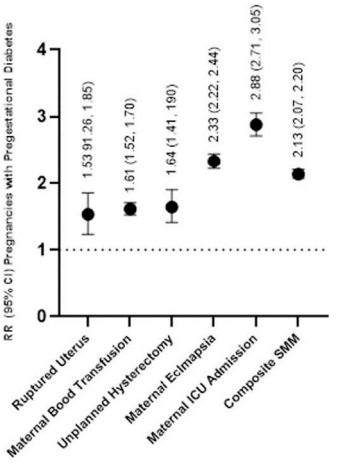
RESULTS: Of 23,839,716 live births in the US during the study period, 439,895 (1.8%) had pregnancies complicated by PGDM. The overall rate of the primary outcome in the population, composite SMM was 0.71% in pregnancies with no diabetes, and significantly higher (2.2%) among those with PGDM, adjRR 2.13 (95%CI 2.07, 2.20). PGDM was also associated with significantly increased risk of all individual measures of SMM, even after adjustment for the confounding influences of advanced maternal age, Non-Hispanic Black race, chronic hypertension, and obesity, see figure.

CONCLUSION: Pregestational diabetes is associated with over 2-fold increased risk for severe maternal morbidity even after accounting for the influence of co-existing risk factors. These findings highlight the importance of individualizing care among pregnancies with PGDM and consider delivery at higher level maternity centers with capacity to provide care to the most complex pregnancies, especially when co-existing risk factors are present.

Figure 1: Rate and risk of severe maternal morbidity associated with pregestational diabetes.

	Pregnancies without diabetes n=21,738,321	Pregnancies with pregestational diabetes n=439, 895	Adjusted RR (95% CI)
Composite SMM	150,405 (0.71%)	4,349 (2.2%)	2.13 (2.07 – 2.20)
Maternal Eclampsia	49,733 (0.24%)	1,832 (0.92%)	2.33 (2.22 – 2.44)
Maternal ICU Admission	31,143 (0.15%)	1,332 (0.67 %)	2.88 (2.71 – 3.05)
Unplanned Hysterectomy	8,713 (0.04%)	198 (0.10%)	1.64 (1.41 – 1.90)
Ruptured Uterus	6,459 (0.03%)	112 (0.06%)	1.53 (1.26 – 1.85)
Maternal Blood Transfusion	72,395 (0.34%)	1,332 (0.67%)	1.61 (1.52 – 1.70)

Severe Maternal Morbidity defined as: blood transfusion, ICU admission, unplanned hysterectomy, maternal eclampsia or ruptured uterus.
All RRs in this table are adjusted for Non-Hispanic Black race, advanced maternal age, obesity and chronic hypertension.



784 Neonatal Outcomes Among Individuals with Depressed Fetal Heart Tracings at Methadone and Buprenorphine Peak Levels

Kathleen J. Koenigs[1], Molly R. Siegel[1], Kaitlyn E. James[1], Haylie Butler[2], Mark A. Clapp[1], Davida M. Schiff[3], Sarah N. Bernstein[1]
[1]Massachusetts General Hospital, Boston, MA, [2]Harvard Medical School, Boston, MA, [3]Massachusetts General Hospital for Children, Boston, MA

OBJECTIVE: Medications for opioid use disorder (MOUD) have been shown to have depressive effects on the fetal heart tracing (FHT) in the antenatal setting however the impact of these findings at the time of labor and delivery is not well characterized. We evaluated a cohort of birthing persons administered MOUD during the delivery hospitalization and compared neonatal outcomes in those with and without fetal heart tracing alterations at peak dose.

STUDY DESIGN: We studied a retrospective cohort of term singleton pregnancies with MOUD administration during labor and delivery at an academic urban hospital from 2016-2023. MOUD dose, dosing time, psychotropic medications, non-prescribed substance exposures, pregnancy complications, and mode of delivery were obtained via chart review. Clinically documented FHT variability and accelerations were collected at pharmacological trough and peak levels. FHTs with greater than 45 minutes of minimal variability during the peak period were characterized as minimal, and those without accelerations for more than 1 hour were characterized as absent. Tracings with minimal variability and absent accelerations were compared to reassuring tracings for differences in neonatal outcomes.

RESULTS: Of the 77 dyads who met inclusion criteria, 15 (19%) had fetal heart tracings with minimal variability and 43 (56%) had absent accelerations. Individuals who received methadone at delivery were more likely to exhibit minimal variability at peak dose (p= .03). Individuals cotreated with SSRIs/SNRIs were more likely to exhibit absent accelerations at peak dose (p=.001). However, there were no statistically significant difference in APGARS, NICU admission, respiratory distress or cesarean section rates in the cohort with reassuring fetal heart tracings versus those with predominantly minimal variability or absent accelerations.

CONCLUSION: Fetal heart rate tracing depression should be interpreted with caution among birthing individuals receiving methadone or buprenorphine treatment at the time of labor and delivery.

	Overall cohort* (n=77)	Reassuring variability during peak (n=62)	Minimal variability during peak** (n=15)	p-value	Reassuring accelerations during peak (n=34)	Absent accelerations during peak*** (n=43)	p-value

**Greater than 45 minutes of FHT categorized as such
***Greater than 1 hour of FHT categorized as such

785 Utilizing ecological momentary assessment in the postpartum evaluation of patients with hypertensive disorders of pregnancy

Kay Roussos-Ross, Tony S. Wen, Tianze Jiao, Deepthi Varma, Amie Goodin
University of Florida, Gainesville, FL

OBJECTIVE: Hypertensive disorders of pregnancy affect 10-20% of pregnancies, and are a leading cause of maternal mortality in the United States. A subset of women will develop worsening hypertension after delivery with resultant increased risk of morbidity and mortality. A smartphone-based application utilizing ecological momentary assessment (EMA) technology was developed for monitoring and intervention of postpartum patients with a history of hypertension in pregnancy. This innovative method allows for frequent evaluations and timely interventions of positive screens.

STUDY DESIGN: A prospective study was conducted at a quaternary care academic hospital from November 2021 through June 2023. Inclusion criteria included: postpartum status, delivery of liveborn neonate, English-speaking, aged 18 and above, owning a smartphone, agreeing to download app, and prenatal diagnosis of gestational/chronic hypertension, or pre-eclampsia/eclampsia. Participants received a blood pressure cuff and were prompted to assess blood pressure via the app daily for 2 weeks, then weekly for 4 weeks. A positive screen was defined as a blood pressure $\geq$ 140/90 and resulted in nurse follow-up contact.

RESULTS: A total of 545 participants were enrolled. Clinical and demographic characteristics revealed: 57% enrolled in Medicaid, 58% white, 30% black, 15% Hispanic, 57% delivered vaginally, and 43% had Covid-19 in pregnancy. There were a total of 7,578 in-app assessments resulting in 219 positive screens (40.2% of the total enrolled) that prompted contact by the study nurse. Of positive screens, 74.9% required no referrals, 8.7% had medication adjustments/referred for clinic visit, 6.4% were sent to Labor & Delivery, and 6.4% were admitted to the hospital.

CONCLUSION: This smartphone-based EMA app allowed for prompt assessment and intervention of postpartum patients with hypertension, and resulted in 40.2% of participants requiring follow-up contact after an elevated blood pressure reading. Further studies are needed to assess the impact of the intervention with respect to morbidity, mortality, and health-system related cost savings.

Table: Follow-Up Actions Due to Postpartum Hypertension Positive Screens Recorded in the App

Actions from Positive Screens (enrolled=545)	Number of Participants with Action (%)
Follow-up resulted in hospital admission	14 (6.4%)
Clinic referrals or medication adjustments	19 (8.7%)
Referred to Labor & Delivery	14 (6.4%)
Offered appointment but declined	2 (0.9%)
Follow-Up resulted in unable to contact	6 (2.7%)
Other follow-up	6 (2.7%)
No referral necessary (continued monitoring)	164 (74.9%)
Number of Participants Receiving Any Follow-Up Contact (of % enrolled)	**219 (40.2%)**

786 Hemoglobin A1c among patients without diabetes and risk of large for gestational age neonates

Kelly Zafman[1], Ximena van Tienhoven[2], Whitney Bender[3], Celeste Durnwald[1]
[1]University of Pennsylvania, Philadelphia, PA, [2]Universidad Anáhuac, Pinecrest, FL, [3]Thomas Jefferson University Hospital, Haddonfield, NJ

OBJECTIVE: To describe the association between an early pregnancy Hemoglobin A1c (HbA1c) as obtained on universal screening with large for gestational age (LGA) neonates among patients without a diagnosis of diabetes.

STUDY DESIGN: This is a retrospective cohort study of patients with a singleton pregnancy who underwent universal HbA1c screening in early pregnancy ($\leq$16 weeks) at a single urban tertiary care center between 2016 and 2018. We included those who delivered $\geq$32 weeks with documented maternal weight at the first prenatal visit and at delivery. We excluded patients with preexisting or gestational diabetes, fetal demise, or those without glucose tolerance screening. The exposure of interest was an elevated A1c (5.7-6.4%). The primary outcome was a diagnosis of LGA, defined by a birthweight $\geq$90thile by INTERGROWTH-21.

RESULTS: Of 2594 eligible patients, 2272 (87.6%) had normal HbA1c levels (< 5.7%) and 322 (12.4%) had elevated HbA1c (5-7-6.4). Patients with an elevated HbA1c were more likely to be older, Black, multiparous, publicly-insured, obese at the initial prenatal visit, or have chronic hypertension compared to those with a normal HbA1c level. There was no significant difference in the rate of LGA neonates between patients with an elevated compared to normal HbA1c (12.7% vs. 11.9%, p=0.67). Among patients with obesity (BMI $\geq$30), however, an increasing HbA1c was significantly associated with LGA (OR=1.95, 95% CI 1.04-3.678). This remained significant after adjusting for maternal age, parity, insurance status, and chronic hypertension (aOR=2.85, 95% CI 1.41-5.74). The relationship between HbA1c and LGA remained regardless of whether Institute of Medicine gestational weight gain guidelines were met or exceeded.

CONCLUSION: In obese patients, an elevated HbA1c in early pregnancy increases the risk of delivering an LGA infant in the absence of diabetes and irrespective of weight gain in pregnancy. This underscores the importance of achieving normal HbA1c levels prior to pregnancy for improved neonatal outcomes.

Table 1: Baseline characteristics and birthweight outcomes for patients with normal vs. elevated HbA1c

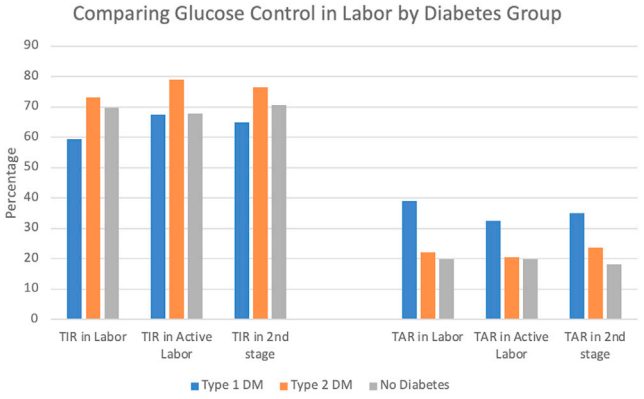
* Median [IQR]

multivariable analysis, higher birthweight, T1DM, and T2DM were associated with neonatal hypoglycemia with T1DM conferring the most risk (OR 13.2, 95% CI 2.0-89.6).

CONCLUSION: Hyperglycemia in labor was common and did not differ in gravidas with and without diabetes. Neonatal hypoglycemia was more common in gravidas with T1DM, T2DM, and in heavier neonates. Further study is needed to define optimal glucose in labor among gravidas with diabetes.



787 Glycemic control in labor: Comparing time in range (TIR) among gravidas with and without pre-gestational diabetes

Kelsey Pinson[1], Jane J. Kim[2], Bethany Gottesman[3], Valentina Stanley[2], Navyaa Sharma[1], Emily Kobayashi[1], Amit Majithia[4], Gladys A. Ramos[5]
[1]UC San Diego, La Jolla, CA, [2]UC San Diego, San Diego, CA, [3]Phoenix Children's Hospital, Phoenix, AZ, [4]University of California, San Diego School of Medicine, San Diego, CA, [5]University of California, San Diego, San Diego, CA

OBJECTIVE: Hyperglycemia in labor is associated with adverse neonatal outcomes in gravidas with diabetes (DM) including neonatal hypoglycemia. Our objective was to use continuous glucose monitors (CGM) to compare glucose control in gravidas in labor with and without DM. We hypothesized that gravidas without DM would have higher TIR compared to gravidas with DM.

STUDY DESIGN: Prospective cohort study of term gravidas with CGM placed in early labor. TIR was defined as 70-120 mg/dl with time above range (TAR) >120 mg/dL and time below range (TBR) < 70mg/dL assessed at several labor stages. Gravidas with DM and their neonates were managed per standard institutional monitoring protocols with treatment of hyper- and hypoglycemia. Gravidas without DM and their neonates had glucose tested only if clinically indicated. CGM values were blinded. Chi-square, ANOVA and Python 3.10.4 were used for analysis.

RESULTS: 90 gravidas were included: 72/90 (80%) without diabetes, 11/90 (12%) with type 1 diabetes (T1DM), and 7/90 (7.8%) with type 2 (T2DM). Mean TIR from CGM placement to delivery was 68.8%, 68.6% in active labor, and 70.5% in 2nd stage and did not differ between groups (Fig 1). The mean TAR from CGM placement to delivery was 22.4%, 21.2% in active labor, and 20.4% in 2nd stage and did not differ between groups. The glucose at delivery was highest in T1DM at 118±25 mg/dl and lowest in those without DM at 109±27 mg/dl (p=0.02). Overall, 11/90 (12%) of neonates were treated for hypoglycemia: 4/11 (36%) in the T1DM group, 2/7 (28.5%) in the T2DM group, and 5/72 (6.9%) in group without DM (p=0.008). Mean birthweight did not differ between groups. In

788 Impact of anemia on perinatal outcomes by race and ethnicity

Kimberly Ryan, Bharti Garg, Martens Kylee, Shatzel Joseph, Aaron B. Caughey, Jamie Lo, Ashley E. Benson
Oregon Health & Science University, Portland, OR

OBJECTIVE: Anemia in pregnancy is common and associated with substantial morbidity. Racial and ethnic disparities in recognition and treatment of anemia exist, despite routine screening. The objective of this study was to evaluate perinatal outcomes associated with anemia in pregnancy, stratified by race and ethnicity in a large US-based cohort.

STUDY DESIGN: Secondary analysis of California linked hospital discharge-vital statistics data from 2016-2019 was performed. Deliveries 23-42 weeks' gestation were included and anemia was identified using birth certificate and International Classification of Disease (ICD-10) codes. Race and ethnicity were categorized into Non-Hispanic White (NHW), non-Hispanic Black (NHB), Hispanic, Asian/Pacific Islander (API), and American-Indian and Alaskan Native (AIAN). Multivariable logistic regressions were created to assess the association of anemia with adverse perinatal outcomes in the total cohort and by race and ethnicity.

RESULTS: A total of 1,719,596 births met inclusion criteria; 303,718 (18%) had maternal diagnosis of anemia. Anemia prevalence was highest among NHB (31%), followed by AIAN (20%), Hispanic (19%), and NHW (16%; p< 0.001). Anemia was significantly associated with hypertensive disease in NHW (aOR=1.44, 95% CI: 1.40, 1.48), NHB (aOR=1.47 (1.40, 1.53), Hispanic (aOR=1.53 (1.50, 1.56), API (aOR=1.62 (1.54, 1.69), and AIAN (aOR=1.31 (1.05, 1.64). Similarly, across all racial categories, individuals with anemia had higher rates of preterm delivery (< 37 weeks and < 32 weeks), NICU admission, small for gestational age, respiratory distress syndrome, hypoglycemia, and low birth weight compared to those without anemia (Table 1).

CONCLUSION: Anemia in pregnancy is associated with increased odds of adverse perinatal outcomes, that were overall similar among diverse racial and ethnic backgrounds. Given higher rates of anemia

in Hispanic, AIAN, and NHB pregnant individuals in this cohort, further investigation is warranted.

789 Perinatal Cannabis Use Adversely Impacts Pregnancy and Neonatal Outcomes

Kimberly Ryan, Bharti Garg, Sarena Hayer, Kristin Prewitt, Ashley E. Benson, Aaron B. Caughey, Jamie Lo
Oregon Health & Science University, Portland, OR

OBJECTIVE: Cannabis use in pregnancy has been markedly rising. There is an existing gap in knowledge regarding the safety of prenatal cannabis use, partly because prior studies had either small sample size or did not adjust for potential cofounders. The purpose of this study is to examine recent data from a large, population-based birth cohort to understand the impact of maternal cannabis use on perinatal outcomes.

STUDY DESIGN: This is a retrospective cohort study of California linked hospital discharge-vital statistics data from 2012-2019. We included singleton, live-born infants with gestational age of 23-42 weeks. Our maternal outcomes of interest included hypertensive disease, preterm delivery (PTD) of < 37 weeks & < 32 weeks), severe maternal morbidity (SMM). As blood transfusion is the major contributor to SMM, we also examined non-transfusion SMM. Neonatal outcomes included NICU admission, small for gestational age (SGA), respiratory distress syndrome (RDS), and infant death. Chi-squared and multivariable logistic regression were utilized for statistical analyses.

RESULTS: A total of 3,551,167 pregnant people were included. 37,417 (1.05%) had a cannabis related diagnosis at delivery. Patients with cannabis related diagnosis were more likely to experience SMM (aOR 1.35; 99% CI: 1.26,1.46), non-transfusion SMM (aOR 1.40; 99% CI:1.24, 1.58), PTD< 37 weeks (aO 1.68; 99% CI:1.62, 1.73), PTD< 32 weeks (aOR 1.86; 99% CI:1.73, 2.00) and hypertensive disease (aOR1.36; 99% CI: 1.31, 1.40). Neonatal outcomes were also significantly higher for those with a cannabis related diagnosis (Table), including NICU admission (aOR 1.43; 99% CI: 1.39, 1.47), SGA (aOR1.48;1.43, 1.52), RDS (aOR 1.50; 99% CI: 1.43, 1.57), and infant death (aOR 1.93; 99% CI:1.69, 2.20).

CONCLUSION: Our study suggests that use of prenatal cannabis is associated with increased odds of maternal and neonatal morbidity. Given the legislative changes to cannabis legalization and the prevalence of use, our results can inform prenatal care and counseling.

Table 1. Multivariable logistic regression models showing association of cannabis related diagnosis with perinatal outcomes.

	Cannabis related diagnosis	No cannabis related diagnosis	Cannabis related diagnosis** aOR (99% CI)
Hypertensive disease	13.0%	8.1%	1.36 (1.31, 1.40)
Preterm delivery (<37 weeks)	14.0%	6.8%	1.68 (1.62, 1.73)
Very Preterm delivery (<32 weeks)	2.5%	0.9%	1.86 (1.73, 2.00)
Severe maternal morbidity (SMM)*	2.4%	1.3%	1.35 (1.26, 1.46)
Non-transfusion SMM	0.89%	0.42%	1.40 (1.24, 1.58)
NICU admission	17.9%	10.3%	1.43 (1.39, 1.47)
Small for gestational age	15.3%	8.7%	1.48 (1.43, 1.52)
Respiratory distress syndrome	6.3%	3.4%	1.50 (1.43, 1.57)
Infant deaths	0.8%	0.2%	1.93 (1.69, 2.20)

aOR = Adjusted odds ratio, CI=Confidence interval
* Severe maternal morbidity (SMM) was defined using a published and previously validated list of ICD codes from the center of Disease Control and Prevention.
**Adjusted for maternal race/ethnicity, age, education, pre-pregnancy BMI, insurance, parity, smoking, alcohol use, nicotine use, chronic hypertension, pre-existing diabetes, anxiety, depression and bipolar disorders.

790 Opioid Use in Pregnancy Adversely Affects Perinatal Outcomes

Kristin Prewitt, Sarena Hayer, Bharti Garg, Kimberly Ryan, Aaron B. Caughey, Ashley E. Benson, Jamie Lo
Oregon Health & Science University, Portland, OR

OBJECTIVE: Perinatal opioid use affects almost 4 million pregnancies annually and has become a leading cause of maternal mortality. Studies on prenatal opioid use are limited by varying methodology, inconsistently controlling for confounders, and focusing on a narrow scope of outcomes. Existing population-based data is largely from outside the United States (US) with different demographics. The objective of this study is to examine US-based population-level associations between perinatal opioid use, and maternal and neonatal outcomes.

STUDY DESIGN: This is a secondary data analysis using California linked vital statistics and hospital discharge data from 2008-2019. We included singleton, live-born infants with gestational age of 23-42 weeks. Opioid-related diagnosis during pregnancy was identified using ICD-9 and ICD-10 codes from hospital discharge data. Chi-squared and multivariable logistic regression were utilized for statistical analyses.

RESULTS: A total of 5,470,747 pregnancies met inclusion criteria, and 13,026 (0.24%) had opioid-related diagnosis. Opioid use was associated with higher risk of hypertensive disorders (aOR 1.57; 95% CI: 1.48-1.67), severe maternal morbidity (aOR 2.36; 95% CI: 2.14-2.62), blood transfusion (aOR=2.29, 95% CI: 2.06-2.56)), venous thromboembolism (aOR 2.34; 95% CI: 2.09-2.62), and primary cesarean delivery (aOR 1.21; 95% CI: 1.13-1.29). Neonates exposed to *in utero* opioids had higher risks of neonatal intensive care unit admission (aOR 5.08; 95% CI: 4.89-5.29), respiratory distress syndrome (aOR 2.24; 95% CI: 2.09-2.39), neonatal opioid withdrawal syndrome (aOR 137.1; 95% CI 129.1-145.7), small for gestational age (aOR 1.71; 95% CI: 1.62-1.79), and infant death (aOR 1.51; 95% CI 1.23-1.85).

CONCLUSION: Our study suggests that a prenatal opioid-related diagnosis is associated with a significantly increased risk of maternal and neonatal morbidity. As the perinatal opioid crisis persists, our findings can help inform patient care and counseling.

Table 1: Logistic regression model showing raw percentages and adjusted odds ratios for perinatal outcomes among patients with and without opioid-related diagnoses in California

	No opioid use disorder N=5,457,721	Opioid use disorder N=13,026	p*	aOR (95% CI)[a]
Maternal outcomes				
Hypertensive disease of pregnancy	7.0%	11.3%	<0.001	1.57 (1.48, 1.67)
Severe maternal morbidity	1.2%	3.7%	<0.001	2.36 (2.14, 2.62)
Venous thromboembolism	0.0%	0.2%	<0.001	4.21 (2.86, 6.19)
Maternal Blood transfusion	1.0%	2.9%	<0.001	2.34 (2.09, 2.62)
Cesarean in nulliparous	30.3%	34.2%	<0.001	1.21 (1.13, 1.29)
Cesarean in multiparous with prior cesarean	90.3%	92.1%	0.001	1.25 (1.09, 1.44)
Cesarean in multiparous without prior cesarean	9.1%	15.1%	<0.001	1.54 (1.42, 1.66)
Postpartum hemorrhage	3.3%	4.3%	<0.001	1.25 (1.14, 1.37)
Preterm premature rupture of membranes	1.8%	5.1%	<0.001	2.18 (2.00, 2.37)
Neonatal outcomes				
Preterm delivery<37 weeks	6.9%	19.7%	<0.001	2.59 (2.47, 2.72)
Preterm delivery<32 weeks	0.9%	2.9%	<0.001	2.35 (2.09, 2.64)
NICU admission	10.5%	43.2%	<0.001	5.08 (4.89, 5.29)
Small for gestational age	8.7%	15.9%	<0.001	1.71 (1.62, 1.79)
Respiratory distress syndrome	2.6%	10.0%	<0.001	2.24 (2.09, 2.39)
Infant deaths (Death within one year of birth)	0.2%	0.9%	<0.001	1.51 (1.23, 1.85)
Congenital anomalies	9.8%	12.3%	<0.001	1.18 (1.12, 1.25)
Hypoglycemia	1.7%	5.1%	<0.001	1.86 (1.71, 2.02)
Neonatal opioid withdrawal	0.1%	26.1%	<0.001	137.1 (129.1, 145.7)

aOR=Adjusted odds ratio, CI-Confidence interval

791 Timing of exam-indicated cerclage and pregnancy outcomes: To emergently or urgently schedule?

Kristine E. Brown[1], Selin Everett[2], Elizabeth Vitaro[2], Shai Bejerano[3], Amy Turitz[4], Alexander M. Friedman[5], Mirella Mourad[2]

[1]New York Presbyterian/Columbia, New York, NY, [2]Columbia University Medical Center, New York, NY, [3]Vagelos College of Physician and Surgeons, Columbia University, New York, NY, [4]Greenwich Hospital, COS COB, CT, [5]Columbia University, New York, NY

OBJECTIVE: Exam-indicated cerclage (EC) is an important treatment for cervical insufficiency with the goal of preventing preterm birth (PTB). How the interval from diagnosis of cervical dilation to EC affects pregnancy outcomes is not known.

STUDY DESIGN: A retrospective cohort study was conducted at a single academic center from 2015-2023. Patients with a dilated cervix < 24 weeks gestation (GA) recommended for EC were included. Multiples and patients with incomplete delivery data were excluded. The time interval (hours) from ultrasound with dilated cervix to operating room anesthesia was calculated and analyzed categorically (< 12, 12-24, > 24). Age, parity, GA at EC, cervical length, dilation, and prior PTB were collected. The primary outcome was GA at delivery. Secondary outcomes included latency from EC to delivery, PTB, PPROM, and NICU admission. Categorical variables were analyzed by Fisher's exact test. Continuous variables were assessed by ANOVA or Kruskal-Wallis test. Time-to-event curves were created to display time-to-delivery by group. Linear regression was used to assess the association between interval to EC and the primary outcome after adjusting for potential confounders.

RESULTS: 155 patients with EC were identified. The median GA at diagnosis was 21.0 weeks (IQR 19.7-21.9) and cervical dilation 1.0cm (IQR 0.5-1.0). The median GA at delivery was 37.1 weeks (IQR 30.0-39.1). As a continuous variable, there was no correlation between interval to EC and GA at delivery (ρ=-0.02, p=0.83). Comparing groups, baseline characteristics were not significantly different aside from parity (p=0.048) and pre-EC amniocentesis (p=0.001). Linear regression showed no significant difference in GA at delivery between those receiving EC < 12 (β [95% CI]: 0.36 [-1.87,2.59]) or 12-24 hours (β [95% CI]: 0.83 [-1.75,3.41]) from diagnosis, compared to those at > 24 hours. There was no difference in secondary outcomes.

CONCLUSION: We observed no significant correlation between interval to EC placement and GA at delivery. These results suggest that EC can be scheduled urgently rather than emergently with similar outcomes.

792 Medium postpartum hemorrhage risk: do multiple medium risk factors increase risk to high?

Laura Chahin[1], Rachel L. Wiley[2], Ipsita Ghose[3], Han-Yang Chen[4], Hector Mendez Figueroa[5], Suneet P. Chauhan[6]

[1]McGovern Medical School, Houston, TX, [2]McGovern Medical School at UTHealth Houston, Houston, TX, [3]University of Texas Medical School at Houston, Houston, TX, [4]The University of Texas Health Science Center at Houston, Houston, TX, [5]University of Texas Health Science Center at Houston, Houston, TX, [6]University of Texas-Houston Medical School, Houston, TX

OBJECTIVE: The ACOG Practice Bulletin on Postpartum hemorrhage (PPH; #183) suggests that all parturients be risk stratified into low-, medium- and high-risk. We noticed that within medium-risk, the composite maternal hemorrhagic outcome (CMHO) rate varied by the number of risk factors. Thus, we hypothesized that parturient with 2 or more medium risk factors would have significantly higher rates of CMHO compared to those with only one medium risk factor.

STUDY DESIGN: This is a retrospective cohort study of all singleton gestations delivered at a Level-IV center within one year. The components of CMHO are described in the table. Chi-squared and Kruskal Wallis analysis was used to compare categorical variables. The adjusted relative risks (aRR) of CMHO and its components were calculated between the studied groups using Poisson regression, adjusted for confounders from the univariate analysis.

RESULTS: Of the 4,544 deliveries, 1,376 (30%) were cataloged as medium risk, and within those, 1,132 (82%) had one medium risk factor and 244 (18%) had more than 1. Patents were significant different in maternal age, race, Marial status, insurance type, BMI at delivery, gestational age, diabetes and hypertension diagnosis. The three most common "medium" risk factors were: prior uterine surgery (n-738, 54%), prolonged oxytocin use (292, 21%) or magnesium sulfate use at delivery (n=282, 20%). The risk for CMHO was significantly higher in those with two or more medium risk factors compared to a single risk factor (aRR 0.78, 95% CI (0.63-0.98). This difference is largely driven by uterotonic use, which was significantly higher in the multiple medium risk factor group compared to the single medium risk factor groups (aRR 0.67, 95% CI 0.51 − 0.88

CONCLUSION: In our study population, participants with two or more medium PPH risk factors had a higher rate of CMHO than those with a single medium risk factor, largely driven by treatment for atony, and may be more appropriately treated as high-risk.

Table 1: Composite Maternal Hemorrhagic Outcome

	1 Medium Risk Factor n = 1,132 (%)	≥2 Medium Risk Factors n = 244	Adjusted RR**	(95% CI)	
Composite Maternal Hemorrhagic Outcome	238 (21.0%)	81 (33.2%)	**0.78**	**0.63**	**0.98**

793 Maternal risk factors for preeclampsia and prescription practices of low dose aspirin for preeclampsia prophylaxis

Lauren Stewart[1], Lena Woo[2], Bijal Parikh[3], Cassandra Heiselman[3], David Garry[3], Kimberly Herrera[1]
[1]Stony Brook University Hospital, Stony Brook, NY, [2]Renaissance School of Medicine at Stony Brook University, Stony Brook, NY, [3]Stony Brook Medicine, Stony Brook, NY

OBJECTIVE: To determine how prophylactic low dose aspirin (LDA) prescription rates differed across different maternal risk factors for preeclampsia.

STUDY DESIGN: Retrospective study of patients that met SMFM criteria to initiate LDA ppx who received prenatal care and delivered at a single academic center between January - May 2021. Exclusion criteria: age < 18 years old, transfer of care >28 weeks, and delivery < 20 weeks gestation. Patient characteristics, moderate risk (MR) and high risk (HR) criteria, and pregnancy outcomes were collected. Rate of aspirin prescription across different MR and HR factors for preeclampsia groups were compared. Statistical analysis was performed using Chi square and univariate analysis with significance defined as $p < 0.05$.

RESULTS: Of the 622 patients who were included in the study, 60.3% of patients met criteria to initiate LDA prophylaxis with either 2 MR factors or at least 1 HR factor. Risk factors that were more likely to be prescribed LDA were a history of preeclampsia, chronic hypertension, pregestational diabetes, autoimmune disease, and APLS (Table 1). 82 patients (67.8%) with 1 high risk factor were prescribed LDA, compared to only 13.8% (n=35) of patients with 2 moderate risk factors (OR 13.15, 95% CI 7.8-22.2). When comparing patients with 2 or more high risk factors to patients with 1 high risk factor or 2 moderate risk factors only, providers prescribed LDA at a rate of 92.3% vs. 29.0% (OR 29.4, 95% CI 3.8-228.7), respectively. Risk factors with no significant differences in rates of LDA prescription included obesity (BMI >30), class III obesity (BMI >40), kidney disease, cardiac disease, gestational diabetes, thrombophilia, obstructive sleep apnea, hypothyroidism, AMA, and interpregnancy interval >10 years.

CONCLUSION: Patients with 2 or more high risk factors for preeclampsia were more likely to be appropriately prescribed LDA than patients with only 1 high risk factor or only moderate risk factors.

Table 1. Individual Maternal Risk Factors Associated with Higher Low Dose Aspirin Prescription

Factor	Prescribed Aspirin (n = 117)	Not Prescribed Aspirin (n = 258)	p-value
High Risk Factors

794 MRI After Ultrasound Consistent with Accreta Incorrectly Changes Diagnosis to Negative in up to One-Third

Lauren Kucirka[1], Alexandria Kraus[2], William Goodnight[3]
[1]University of North Carolina, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Durham, NC, [3]UNC Hospitals, Chapel Hill, NC

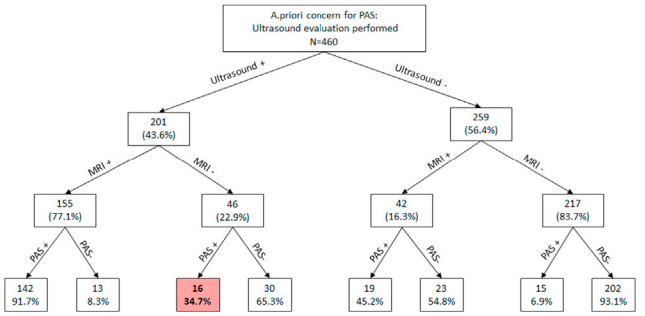
OBJECTIVE: Many studies have demonstrated similar sensitivity of MRI and ultrasound (US) for placenta accreta spectrum (PAS) detection; however, since all patients get an ultrasound, the relevant clinical question is not if MRI is more sensitive but whether it adds value to ultrasound in PAS diagnosis or management. **Our goal was to evaluate the added value of obtaining an MRI after ultrasound in suspected PAS.**

STUDY DESIGN: We reviewed 21 references from 2 recently published systematic reviews comparing the sensitivity and specificity of MRI and US in patients with clinical risk factors for PAS. Included studies reported, either directly or in a way that it could be mathematically derived, 1) # of patients with discordant or concordant MRI and US results and 2) pathologic presence or absence of PAS at delivery. Data were abstracted as follows: Discordant: 1) # MRI true positive(TP) /US false negative(FN), 2) # MRI true negative(TN) /US false positive(FP), 3) # MRI FP / US TN, 4) # MRI FN / US TP). Concordant: 1) # MRI TP/ US TP, 2) # MRI TN / US TN, 3) # MRI FP / US FP, 4) # MRI FN / US FN). We created pooled estimates for each category to estimate the added value of MRI under different scenarios.

RESULTS: 460 patients with suspected PAS from 10 studies met inclusion criteria. 201 (43.6%) were US+ and 259 (56.4%) US(-) for PAS (Figure). MRI was concordant with US in 155 (77.1%) of US+ and 217 (83.7%) US(-) (Figure 1). In 46 US+ patients (22.9%), MRI was negative for PAS. Of those US+/MRI-, MRI incorrectly changed the diagnosis to negative in 16 (34.7%), and correctly changed to negative in 30 (65.3%). Of those US− /MRI+, MRI correctly

changed the diagnosis to positive in 45.2% of cases and incorrectly confirmed the negative diagnosis in 23 (54.8%) of cases.

CONCLUSION: Routinely obtaining an MRI after a positive US can lead to incorrectly changing the diagnosis to negative in up to 1/3 of patients. MRI thus may be best utilized in cases of negative ultrasound where PAS is strongly suspected or US imaging is suboptimal.



795 High school diploma rate is associated with neonatal glucose Instability and macrosomia among non-diabetic patients

Leah M. Savitsky, Rachel Budker, Allen Ghareeb, Anjali N. Mitra, Mindy Pike, Shani Delaney, Catherine M. Albright
University of Washington, Seattle, WA

OBJECTIVE: To characterize the impact of high school (HS) diploma rates in a patient's home zip code on the development of neonatal glucose instability and macrosomia in non-diabetic patients.

STUDY DESIGN: We conducted an IRB-approved retrospective cohort study using the Obstetrical Care Outcomes Assessment Program (OBCOAP) at the University of Washington Medical Center. We included the first pregnancy in the data set for each non-diabetic patient with complete data on neonatal glucose instability, birthweight, and patient home zip code. We evaluated the association between the percent of people in the patient's home zip code with a HS diploma and a composite variable of neonates with glucose instability and/or macrosomia. Multiple logistic regression was used to adjust for maternal age and body mass index.

RESULTS: There were 8026 patients in the cohort, of which 660 (18.5%) had a neonate with either glucose instability or macrosomia. Compared to patients living in zip codes where >95% of people have a HS diploma, patients living in zip codes with lower educational rates have an increased risk of neonatal glucose instability or macrosomia (adjusted OR [aOR] 1.69, 95% CI 1.35-2.13 for 85-95% HS diploma rate and aOR 1.84, 95% CI 1.38-2.46 for < 85% HS diploma rate.) (Table 1). When evaluated individually, the association appears to be driven by glucose instability, with aOR 1.68 (95% CI 1.33-2.14) and 1.87 (95% CI 1.38-2.52) for zip codes with 85-95% and < 85% HS diploma rates, respectively.

CONCLUSION: Among non-diabetic patients, living in a zip code with lower rates of obtaining a HS diploma is associated with an increased risk of having neonatal glucose instability and/or macrosomia. HS education is an indicator of socioeconomic status, nutritional education, and availability of healthy foods as well as literacy rates, all of which likely contribute to this finding. This finding gives insight into additional avenues to direct efforts to prevent adverse neonatal outcomes.

Table 1. Association between high school diploma rate by zip code and neonatal glucose instability or macrosomia among non-diabetic patients

Percent with a HS diploma	Unadjusted		Adjusted*	
	OR (95% CI)	p-value	OR (95% CI)	p-value
>95%	1.0 (ref)	-	1.0 (ref)	-
85-95%	1.80 (1.48-2.19)	<0.001	1.69 (1.35-2.13)	<0.001
<85%	1.98 (1.55-2.51)	<0.001	1.84 (1.38-2.46)	<0.001

796 Impact of Oxytocin Timing and Duration on TOLAC Outcomes: A Retrospective Study

Lee Rak[1], Hadar Amdursky[2], Eran Hadar[2], Alexandra Berezowsky[3]
[1]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, HaMerkaz, [2]Rabin Medical Center, Petach-Tikva, HaMerkaz, [3]Sunnybrook Health Sciences Centre, Toronto, ON

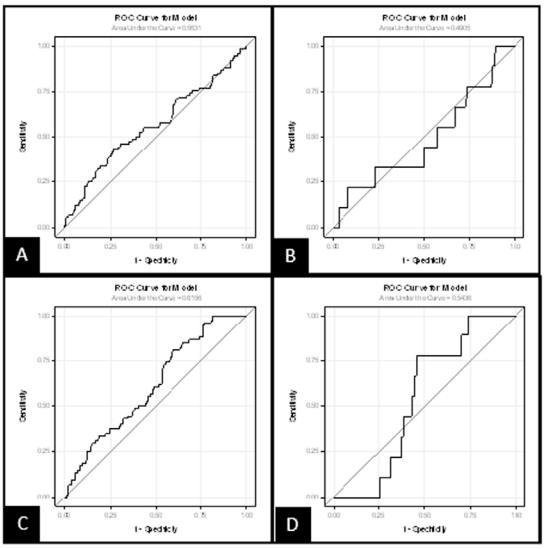
OBJECTIVE: Oxytocin is commonly used to enhance labor progression. Its application in Trial of Labor after Cesarean Section (TOLAC) requires special considerations, due to the risk of uterine rupture. Currently, limited data exists on the influence of oxytocin administration timing and duration on adverse outcomes during TOLAC. Our study aims to explore the correlation between the timing of oxytocin initiation, the duration of oxytocin administration, and the rates of uterine rupture and successful vaginal deliveries during TOLAC.

STUDY DESIGN: In this retrospective cohort study conducted from 2012 to 2020 at a single tertiary medical center, we included women with a prior single cesarean delivery attempting their first TOLAC and with no history of vaginal deliveries. Exclusions were made for women with multiple gestations or those who underwent cervical ripening. Outcome evaluation was performed using Receiver Operating Characteristic (ROC) curves.

RESULTS: A total of 385 women met the inclusion criteria. The mean age was 31.8 (±4.3) and Median gestational age at delivery was 40+3 weeks (37+0 - 41+6). Of women, 311 (80.78%) achieved successful vaginal delivery, while nine (2.34%) experienced uterine rupture. ROC analysis did not reveal significant associations between the timing of oxytocin administration and the primary outcomes: successful vaginal delivery (AUC= 0.56, p= 0.244) [Fig. 1A] and uterine rupture (AUC= 0.49, p= 0.902) [Fig. 1B]. However, the duration of oxytocin administration demonstrated a noteworthy correlation with successful vaginal delivery (AUC= 0.62, p= 0.008) [Fig. 1C], but not with uterine rupture (AUC= 0.54, p= 0.354) [Fig. 1D].

CONCLUSION: Early initiating of oxytocin did not contribute to a higher rate of vaginal delivery during TOLAC. However, extended use of oxytocin was associated with improved success rates. Importantly, commencing oxytocin early and using it for an extended period did not elevate the risk of uterine rupture. Further extensive studies are required to comprehend the potential risks and benefits of early or prolonged oxytocin administration during TOLAC.

Figure 1: Receiver Operating Characteristic (ROC) Curves for Oxytocin Timing and Duration in Relation to Vaginal Delivery and Uterine Rupture.



A) ROC Curve for Oxytocin Timing and Vaginal Delivery

B) ROC Curve for Oxytocin Timing and Uterine Rupture

C) ROC Curve for Duration of Oxytocin Administration and Vaginal Delivery

D) ROC Curve for Duration of Oxytocin Administration and Uterine Rupture

2. Higher cholesterol (205±35 vs 190±27, mg/dl*), triglycerides (127±70 vs 92±40, mg/dl*) and lower HDL (50±11 vs 60±12, mg/dl*)

3. Higher values across 20 indexes of glucose control and variability of continuous glucose monitoring (CGM) indicating increased glucose fluctuation and longer durations of hyperglycemia

4. Body composition (DXA scan) showed higher visceral fat mass (901±320 vs 590±230 gr*)

5. Sleep monitoring indicated a higher rate of sleep apnea (Oxygen Desaturation Index, number of desaturation episodes per hour) (4±5 vs 2.8±4*)

6. Microbiome: lower bacterial richness which is associated with obesity and metabolic disorders

CONCLUSION: GDM has long lasting effects on multiple physiological systems relating to metabolic syndrome. Insights provided can aid long-term monitoring and interventions to reduce cardiovascular and metabolic disease risks linked to GDM

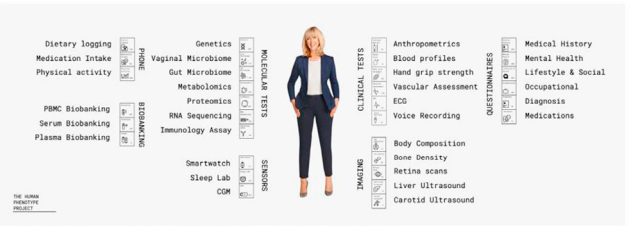


Figure | Data collected or analyzed in the Human Phenotype Project
The project combines innovative medical tests and wearables (such as CGM, and sleep monitoring). It profiles participants at unprecedented depth, including physiological assessment of their muscular, skeletal, liver, blood, heart, vascular, immune, gastrointestinal, and cognitive body systems. The multi-omics profiling of each participant includes genetics, microbiome, metabolomic, transcriptomic, proteomic, and immune system evaluation. A life-style questionnaire and medical records are obtained.

797 Molecular and Physiological Profile of Women with a History of Gestational Diabetes Mellitus

Lee Reicher[1], Michal Rein[2], Nastya Godneva[2], Adina Weinberger[2], Yariv Yogev[3], Eran Segal[2]

[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel, [2]Weizmann Institute of Science, Rehovot, HaMerkaz, [3]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

OBJECTIVE: Gestational diabetes mellitus (GDM) can be a risk factor for subsequent cardiovascular and metabolic diseases. However, there is a paucity of information regarding diverse cardiovascular, metabolic and multi-omic measurements in elderly women after GDM. We assessed the molecular and physiological profile of women with a history of GDM

STUDY DESIGN: Data collected as part of large-scale, prospective, longitudinal study with more than 10,000 healthy adults aged 40−70 years, between the years 2019 and 2022. The participants underwent physiological assessments through special medical tests and wearables, molecular profiling and collection of medical records and lifestyle questionnaires (**Figure**). We included women who reported at least one live birth and compared the profiles of women with a history of GDM to control subset, matched by the number of pregnancies and the time elapsed since the GDM pregnancy

RESULTS: Our study consisted of 300 and 800 women in GDM and the control group, respectively (mean of 17 years post-pregnancy). Women with a history of GDM displayed notable findings compared to the control group (*p< 0.001 for all)

1. Higher sonographic liver attenuation; indicative of fatty liver

798 Personalized Machine Learning Model for Predicting Successful Vaginal Delivery during the Active Phase of Labor

Lee Reicher[1], sharon Napadenski[2], Emmanuel Attali[3], Nadav Rappoport[2], Yariv Yogev[4]

[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel, [2]Ben Gurion University of the Negev, Beer-Sheva, HaDarom, [3]Lis Maternity Hospital, Department of Obstetrics and Gynecology, Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel, [4]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

OBJECTIVE: Accurate personalized prediction of delivery mode during the active stage improves resource allocation, reduces unnecessary interventions, and enhances patient-centered care. However, current machine learning models lack focus on active labor and effective use of labor-related data. The "black box" problem further impedes understanding, accuracy, and patient safety. We developed a personalized model using real-time data to predict successful vaginal delivery in the active phase and provide an explanation of the model's decision-making process.

STUDY DESIGN: Labor records from a single university affiliated tertiary medical center with approximately 12,500 deliveries annually, over a 10-year period. Three models were trained using both "static features" (e.g demographics) and "dynamic features" (e.g cervical dilatation, efficacy, and newly derived features calculated as ratios between adjusted dynamic measures and time differences). To assess the explainability of the best-performing model, we employed SHAP (SHapley Additive exPlanations) analysis, which is used to explain model prediction and show which features had most influenced the prediction.

RESULTS: 1. A total of 94,386 cases in which a trial of labor was attempted were identified. Of them 70,000 admitted to the active phase of labor (6 cm dilatation).

2. We trained three types of classifier models predicting successful vaginal delivery: Random Forest classifier, Histogram-Based Gradient Boosting classifier, and neural network model

3. Histogram-Based Gradient Boosting model achieved the highest scores: ROC AUC score and Precision recall AUC score was 0.87 (95% confidence interval, 0.858-0.892) and 0.52 (95% confidence interval, 0.511-0.542) respectively (Figure)

4. SHAP analysis of the best model revealed key contributing features: rate of fetal descent, cervical opening rate, maternal age, and clinical fetal weight estimation.

CONCLUSION: Our model accurately predicts delivery mode during active labor and and enhances decision-making by providing insights into prediction factors, improving transparency and validation

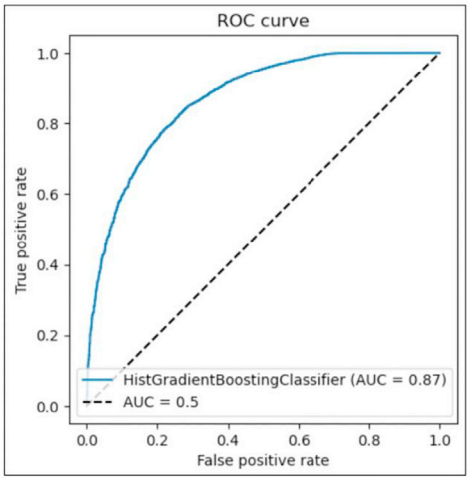

Figure | ROC curve plot with AUC of 0.87 indicates a high classifier performance and that it can distinguish between the classes.

Model's performance for binary classification of vaginal vs. CS Labor outcome classification task. The histogram-Based Gradient Boosting model achieved the highest scores in the combination of precision-recall and ROC AUC.

799 Prophylactic Aspirin Treatment for Preeclampsia Prevention in Dichorionic-Diamniotic Twin Pregnancies

Anat Pardo[1], Or Bercovich[2], David Danon[3], Yuval Gielchinsky[3], Shiri Barbash Hazan[2], Sharon Sigal-Kaplun[3], tal resnick[3], Yael Haring[3], Noam Pardo[4], Eran Hadar[5], kinneret tenenbaum gavish[3]

[1]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, Tel-Aviv, Israel, [2]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, HaMerkaz, [3]Helen Schneider Hospital for Women, Rabin Medical Center, Petach Tikwa, HaMerkaz, [4]Sheba Medical Center, Tel Hashomer, Ramat-Gan, Tel Aviv, [5]Rabin Medical Center, Petach-Tikva, HaMerkaz

OBJECTIVE: Preeclampsia (PE) is a pregnancy-related hypertensive disorder associated with significant maternal and neonatal morbidity and mortality. Definitive treatment requires delivery, hence primary prevention is crucial. Aspirin has shown success in preventing early PE in singleton pregnancies. However, its efficacy in twin gestation is unknown.

We aimed to evaluate whether prophylactic use of aspirin initiated prior to 16 weeks gestation reduces PE incidence in dichorionic (DC) pregnancies

STUDY DESIGN: Retrospective cohort study of 1,008 DC pregnancies between 2015 and-2022 in a single tertiary center, of whom 180 (90 treated vs 90 untreated) were compered using propensity score matching to estimate the effect of aspirin treatment on PE occurrence. The propensity scores were estimated using logistic regression based on maternal age, BMI, chronic hypertension, antiphospholipid antibodies syndrome (APLA), parity, in vitro fertilization (IVF), smoking status, history of PE, history of preterm delivery and history of gestational diabetes

RESULTS: We found no significant difference between the groups in the rate of PE with or without severe features (8.9% vs 12% p=0.467 ;8.9% vs 4.4%, p=0.232), respectively. Furthermore, the groups did not differ in the incidence of gestational hypertension, superimposed PE, HELLP syndrome, gestational diabetes, and fetal growth restriction. When comparing gestational age at PE diagnosis, no difference was found between the groups before and after 37 weeks gestation (16% vs 22%, p=0.253; 2.2% vs 1.1%, p >0.999), respectively (Table 1). Further logistic regression analysis failed to demonstrate that aspirin treatment reduces rates of any hypertensive disorders, PE with or without severe features (OR 1.496 95% CI 0.762 - 2.937; OR 0.701 95%CI 0.267 -1.841; OR 2.098 CI 95% 0.651 - 6.760), respectively, independent of the differences of gestational ages at birth. The need for induction due to PE did not differ between the groups (OR 0.551 CI 95% 0.169 - 1.801)

CONCLUSION: Administration of prophylactic aspirin in DC pregnancies did not result in a reduction of PE incidence

Table 1: Hypertensive Disorders Outcome in DC Twins with and without Aspirin

Variable	No Aspirin n = 90	Aspirin n = 90	p-value
Gestational Hypertension	0 (0%)	2 (2.2%)	0.497
PE with severe features (All):	13 (14%)	13 (14%)	>0.999
PE with severe features	11 (12%)	8 (8.9%)	0.467
HELLP syndrome	2 (2.2%)	5 (5.6%)	0.444
PE without severe features	4 (4.4%)	8 (8.9%)	0.232
Superimposed PE	0 (0%)	3 (3.3%)	0.246
Fetal growth restriction	12 (13%)	14 (16%)	0.672
Gestational diabetes mellitus	22 (24%)	21 (23%)	0.861
Gestational age at PE diagnosis			
After 37 Weeks	2 (2.2%)	1 (1.1%)	>0.999
Before 37 Weeks	14 (16%)	20 (22%)	0.253
Before 34 Weeks	6 (6.7%)	9 (10%)	0.418
Before 32 Weeks	3 (3.3%)	3 (3.3%)	>0.999

800 Variation in genetic workup of polyhydramnios: An international and inter-specialty survey

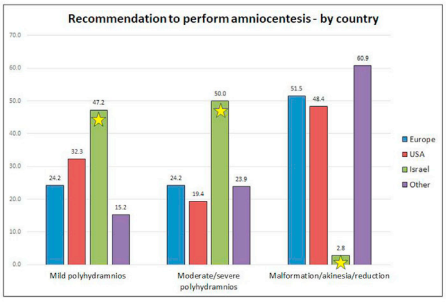
Lena Sagi-Dain[1], Yuval Yaron[2], Roni Zemet Lazar[3]
[1]Carmel Medical Center, Haifa, Hefa, [2]Tel Aviv Sourasky Medical Center, Tel Aviv, HaMerkaz, [3]Baylor College of Medicine, Houston, TX

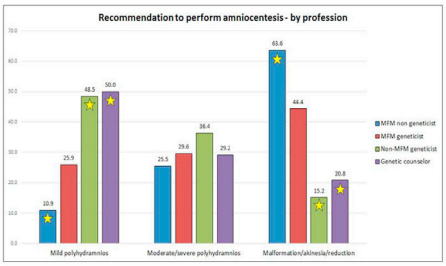
OBJECTIVE: To evaluate the opinions of health professionals regarding the definition of polyhydramnios in which invasive testing is considered, as well as the optimal genetic testing in such cases.

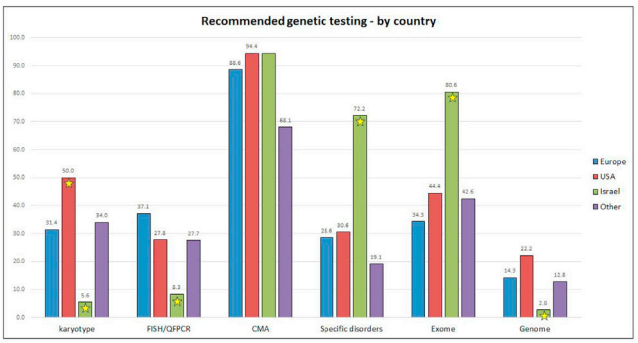
STUDY DESIGN: This anonymous electronic survey was conducted using the Fetal Sequencing Consortium and COGEN mailing list. The survey included questions about the country of origin, the main specialty of the respondent (i.e., clinical geneticist, MFM geneticist, MFM non-genetics professional, genetic counselor, and others), sonographic criteria for recommendation of invasive testing in cases of polyhydramnios (i.e., mild polyhydramnios, moderate/severe polyhydramnios or only in the presence of additional sonographic aberrations such as fetal akinesia or malformations), as well as the recommended genetic testing in such cases.

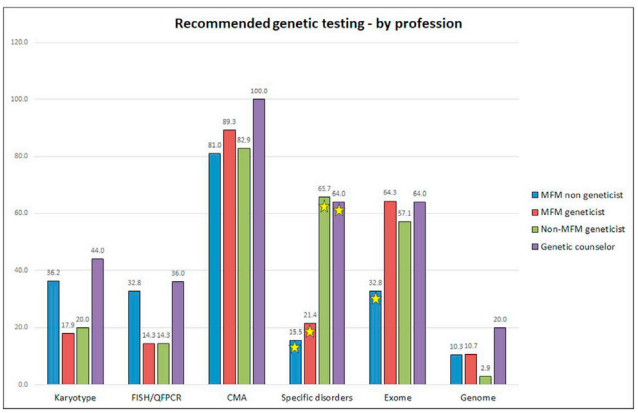
RESULTS: Of the 154 healthcare practitioners participatung in the survey, 17.8% would recommend invasive testing in any case of mild polyhydramnios (defined as amniotic fluid index (AFI) of ≥24 cm or maximal vertical pocket (MVP) of ≥8 cm), 19.9% - only in moderate and severe polyhydramnios (AFI of ≥30cm or MVP ≥12 cm), while 41.8% - only in the presence of additional sonographic anomalies. 30.5% recommend fetal karyotyping for genetic testing, 25.3% - FISH/QF-PCR, 85.1% - chromosomal microarray analysis, 50.0% - exome sequencing, 13.0% - genome, and 36.3% - genetic testing for specific genetic disorders (Myotonic Dystrophy, Spinal Muscular Atrophy and Prader-Willi syndrome). The answers differed by country of origin, as well as the medical specialty of the respondents (Figure 1, statistically significant differences noted by star).

CONCLUSION: Pronounced differences in the genetic management of polyhydramnios were noted, partly depending on geographic and professional factors. Large-scale studies should be performed to facilitate the establishment of uniform guidelines on this matter.









801 Moderate to severe thrombocytopenia is associated with postpartum hemorrhage but not increased anemia

Lisa R. Thiele[1], Donald D. McIntire[2], Elaine L. Duryea[3], David B. Nelson[3], Catherine Y. Spong[3]
[1]UT Southwestern Medical Center, Dallas, TX, [2]University of Texas Southwestern Medical Center, Richardson, TX, [3]University of Texas Southwestern Medical Center, Dallas, TX

OBJECTIVE: Recent studies have demonstrated an increased incidence of postpartum hemorrhage (PPH) among patients presenting for delivery with mild thrombocytopenia. Our objective was to evaluate

the effect of thrombocytopenia at delivery on rates of PPH and anemia in the immediate postpartum period.

STUDY DESIGN: This was a retrospective cohort study of all patients delivering at a single academic institution. Patients with HELLP syndrome and pre-eclampsia with severe features were excluded. Cohorts included normal platelet count (^{3}150k), mild thrombocytopenia (100k−149k), and moderate/severe thrombocytopenia (< 100k) on admission for delivery. Perinatal outcomes were obtained from an obstetric database with clinical data entry by trained research nurses. The primary analysis was to evaluate the frequency of PPH according to platelet count on admission. Secondary outcomes included hematocrit levels, anemia prior to discharge, and transfusion. Outcomes were compared using chi-square for categorical measures and ANOVA for continuous measures. Multiple comparisons were made using the Tukey-Kramer adjustment.

RESULTS: Between Jan 2019 and Dec 2020, 21,640 met inclusion criteria with 133 (6/1,000) patients having moderate/severe thrombocytopenia. Patients with moderate/severe thrombocytopenia on admission had significantly higher rates of PPH compared with those with normal or mildly decreased platelet levels. (Table) Patients with moderate/severe thrombocytopenia had higher average hematocrit levels (32.0 ± 3.4%) immediately postpartum and lower anemia rates (30%) compared with patients with normal platelet levels (30.9 ± 3.6%, 35%). Rate of transfusion postpartum was similar among all three cohorts.

CONCLUSION: Patients with moderate/severe thrombocytopenia on admission for delivery had significantly higher rates of PPH compared with patients with normal or mildly decreased platelet levels. However, this increase did not translate to increased rates of transfusion or postpartum anemia.

	Normal Platelet Count	Mild Thrombocytopenia	Moderate to Severe Thrombocytopenia	P value
Patients delivered (n)	18,639 (86.1%)	2,868 (13.3%)	133 (0.6%)

802 Nausea and vomiting during pregnancy, cannabis use, and health implications among an international Latina subgroup

Lizbeth S. Becerra[1], Erin Gould[1], Amal Roble[1], Ryan M. Nguyen[1], Christine Okemkpa[1], Rachel C. Ceasar[1], Jennifer Laughter[2], Shreya Tamatam[1], Marlena Fejzo[1], Kimber MacGibbon[3]

[1]University of Southern California, Los Angeles, CA, [2]California State University, Fullerton, CA, [3]Hyperemesis Education and Research Foundation, Clackamas, OR

OBJECTIVE: Nausea and vomiting during pregnancy (NVP) can result in severe weight loss and affect maternal and fetal health. Hispanic/Latinas (HL) experience a higher prevalence of NVP than White women and are more likely to use cannabis to self-medicate NVP symptoms. This study investigated the prevalence of HL who took medication as prescribed for NVP yet also used cannabis.

STUDY DESIGN: This prospective study used data from the HER Foundation that anonymously surveys women internationally about NVP symptoms, treatment for NVP, and cannabis use during their most recent pregnancy. Data were responses collected electronically between April 2022 to June 2023.

RESULTS: Data were collected from HL experiencing NVP (N=283). Respondents were from 18 countries, nearly half lived in suburban regions, and had a mean age of 29.63 (SD=4.83). On average, most HL were about 15 weeks pregnant at the time of completing the survey and 28% self-reported that they had lost about 10% of their pre-pregnancy weight due to NVP. The majority had been prescribed medication for NVP (95%) with 84% reporting that they had taken the medication as prescribed. About 17% of HL self-reported using cannabis products (THC/CBD) during their pregnancy. Adjusting for residential context and age, there was a trend toward an inverse association between using NVP medication as prescribed and using cannabis to self-medicate for NVP. Although not statistically significant, women who used NVP medication as prescribed were less likely to use cannabis than women who did not use medication (OR: -0.13, 95% CI: [0.33−2.32], p >.05).

CONCLUSION: Based on these preliminary findings, more research with large, diverse participants are needed to better understand cannabis use among pregnant women of color. Qualitative analysis can support reasons why women are using cannabis and inform tailored educational approaches to treat weight loss caused by NVP.

803 Impact of labor and delivery unit acuity on labor length and risk of cesarean delivery

Logan Mauney, Kaitlyn E. James, Damilola M. Shobiye, Sarah Rae Easter, Christina M. Duzyj Buniak, Mark A. Clapp

Massachusetts General Hospital, Boston, MA

OBJECTIVE: Extensive research has investigated the impact of individual patient- and hospital-level factors such as delivery volume on labor management and perinatal outcomes. Our objective was to understand the impact of labor and delivery unit acuity and patient volume on labor management.

STUDY DESIGN: This is a retrospective cohort study between 3/2021 and 11/2022 at 8 hospitals in an integrated healthcare system. All laboring patients with viable, liveborn deliveries with an admission Obstetric Comorbidity Index (OB-CMI) score recorded were included. We measured the association of unit acuity (mean patient OB-CMI score on a unit in a 24-hour period) on length of labor and cesarean delivery (CD) using multivariable linear and logistic regressions. Fixed effects for hospital were included, and standard errors were clustered by hospital. Models were adjusted for volume (number of deliveries in 24-hour period) and patient factors. These analyses were also performed in the subset of nulliparous patients with term, singleton, vertex-presenting fetuses (NTSV). As sensitivity analyses, we assessed other measures of unit acuity, including relative unit acuity, proportion of patients with OB-CMI >5, maximum OB-CMI, and unit presence of a patient with OB-CMI >5.

RESULTS: There were 22,159 patients included, of which 11,766 (53.1%) were NTSV patients. In models with only hospital fixed effects, mean daily OB-CMI was associated with length of labor (β=1.21, 95%CI 0.40-2.01) and unscheduled CD (OR 1.18, 95% CI 1.12-1.23). The association was not affected by delivery volume. After adjusting for patient characteristics, there was no longer an association (Table 1). This pattern persisted for all alternate measures of unit acuity and among NTSV patients.

CONCLUSION: In a large healthcare system, measures of daily unit acuity were not associated with length of labor or risk of CD after controlling for hospital- and patient-level factors. This suggests that despite higher patient acuity or delivery volume, unit resources can compensate such that other patients' outcomes are unaffected.

Table 1 - Association of mean daily unit OB-CMI with length of labor and cesarean delivery

	Length of labor		Cesarean Delivery	
	All deliveries N=22,159	NTSV N=11,741	All deliveries N=22,159	NTSV N=11,741
Mean OB-CMI	Coef (95% CI)	Coef (95% CI)	OR (95% CI)	OR (95% CI)
Model adjusted for fixed effects of hospital	1.21 (0.40-2.01)	1.35 (1.05-1.64)	1.18 (1.12-1.23)	1.13 (1.05-1.22)
Model further adjusted for delivery volume[a]	0.96 (0.70-1.22)	1.35 (1.05-1.64)	1.17 (1.12-1.23)	1.13 (1.05-1.22)
Model further adjusted for delivery volume and patient characteristics[b]	-0.15 (-0.51-0.22)	-0.04 (-0.37-0.30)	1.00 (0.92-1.08)	0.98 (0.89-1.08)

a - Delivery volume defined as number of patients delivered on the unit in 24 hour period

b - Patient characteristics include patient OB-CMI, preterm, nulliparity, induced labor, and neonatal birthweight in length of labor model and OB-CMI, nulliparity, and preterm in cesarean delivery model (excluding nulliparity and preterm for NTSV)

Abbreviations: OB-CMI, Obstetric Comorbidity Index; NTSV, Nulliparous, term, singleton, vertex; Coef, coefficient; OR, odds ratio

804 Women with one previous preterm delivery or second-trimester loss: history-indicated-cerclage versus ultrasound cervical length screening

Lola Loussert[1], Mathilde Terral[1], François Goffinet[2], Paul Guerby[3], Chloe Lieng[4], Yoann Athiel[4]

[1]Toulouse University Hospital, France, Toulouse, Midi-Pyrenees, [2]Maternité Port Royal, Groupe hospitalier Paris Centre, APHP, Paris, Ile-de-France, [3]Hopital Paule de Viguier, CHU Toulouse, Toulouse III University, Toulouse, Midi-Pyrenees, [4]Maternité Port-Royal, Groupe hospitalier Paris Centre, AP—HP, Paris, Ile-de-France

OBJECTIVE: International guidelines regarding the management of women with one unique previous preterm delivery (PTD) or second-trimester loss are inconsistent.

Our objective was to compare history-indicated cerclage to ultrasound cervical length screening in women with one previous severe PTD or second-trimester loss.

STUDY DESIGN: We conducted a retrospective bicentric cohort study from 01/2015 to 12/2022. We compared two French tertiary care maternity units with different standards of care for women with one previous severe PTD or second-trimester loss: history-indicated cerclage in the 1st trimester in center 1, and ultrasound cervical length screening, with cerclage placement reserved for women whose cervical length shortens in center 2. We included women with one unique previous spontaneous PTD before 28 weeks or second-trimester loss. We excluded women whose previous PTD was not evocative of cervical insufficiency: bleeding from placenta previa or placental abruption, intrauterine fetal death, delivery following invasive prenatal testing. We also excluded women with more than one previous PTD or second-trimester loss and women with multiple pregnancies. Our primary outcome was delivery before 34 weeks, including second-trimester loss. We performed a sensitivity analysis after excluding the women who were not treated according to the protocol of their center.

RESULTS: The study included 314 women: 165 in center 1 and 149 in center 2. Twenty-six (15.8%) women delivered before 34 weeks in center 1 versus 38 (25.5%) in center 2 (p=0.032). In the multivariable analysis, the risk of delivery before 34 weeks was significantly lower for women with history-indicated cerclage compared to ultrasound screening (adjusted OR 0.47[0.23—0.97]). The results were unchanged in the sensitivity analysis. In center 2, 73 (49%) women underwent cerclage due to cervical shortening.

CONCLUSION: In women with one previous PTD or second-trimester loss, history-indicated cerclage is associated with a lower risk of delivery before 34 weeks compared to ultrasound screening of cervical length.

Outcome	Group 1 n=165 History indicated cerclage n (%)	Group 2 n=149 US cervical length screening n (%)	OR (IC 95%)	ORa* (IC 95%)
PTD < 34 WG or second trimester loss	26 (15.8)	38 (25.5)	0.55 (0.31 – 0.95)	0.47 (0.23 – 0.97)
Second trimester loss	10 (6.1)	14 (9.4)	0.62 (0.27 – 1.45)	0.63 (0.20 – 1.99)
sPTD < 34 WG or second trimester loss	24 (14.6)	37 (24.8)	0.52 (0.29 – 0.91)	0.45 (0.21 – 0.94)
PTD < 28 WG or second trimester loss	17 (10.3)	29 (19.5)	0.48 (0.25 – 0.91)	0.50 (0.22 – 1.17)
PTD < 37 WG or second trimester loss	46 (27.9)	55 (36.9)	0.66 (0.41 – 1.06)	0.78 (0.43 – 1.43)

Gestational age at delivery according to cervical insufficiency management

US: ultrasound, OR: odd ratio, aOR: adjusted odd ratio, PTD: preterm delivery, sPTD: spontaneous preterm delivery, WG: weeks of gestation

805 Morphometric analysis of spina bifida (SB) to associate pre-operative severity and clinical outcomes after fetal repair

Lovepreet Mann[1], Shreya Pandiri[1], Jeannine Garnett[1], Jong Won[1], Eric P. Bergh[2], Hope Northrup[1], Kit Sing Au[1], Elin Grundberg[3], Brandon Miller[1], Mary Austin[1], Kuojen Tsao[4], Stephen A. Fletcher[1], Ramesha Papanna[1]

[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [3]Children's Mercy Adele Hall - Genomic Medicine Center, Kansas City, MO, [4]McGovern Medical School at Houston, UTHealth Houston, Houston, TX

OBJECTIVE: Spina bifida lesions have conventionally been categorized into two types: with sac (myelomeningocele) and without sac (myeloschisis). However, the correlations of these types with baseline status and outcomes remains unknown. This study utilized the unique opportunity provided by in-utero fetoscopic repair to assess spina bifida lesions directly and to correlate with pre-operative presentation and post-operative outcomes.

STUDY DESIGN: We studied a prospective cohort of patients who underwent fetoscopic spina bifida repair from 2020-2023. We used high-resolution images and videos obtained during surgery to categorize lesions into 5 types (Table) based on placode exposure and stretching nerve roots. Pre-operative baseline characteristics such as ventricle measurement, tonsillar herniation level, lower extremities movement, and lesion dimensions were compared. Also, surgical time, need for patch for skin closure, gestational age at delivery, PPROM, and neonatal CSF diversion were compared. The reproducibility of the lesion classification was confirmed via Kappa inter-rater agreement.

RESULTS: 57/60 lesions had available images of sufficient quality for classification. The most common lesion type was Type 2. Baseline characteristics show greater lateral ventricle dimensions in Type 2 than in Type 1 and Type 4 lesions (Table), but no differences in other variables. Type 4 and 5 lesions received patch skin closure. However, the PPROM rate was high in Type 1 lesion pregnancies, which resulted in earlier gestational age at delivery. For lesion classification, there was 96.4% agreement between examiners ($p < 0.0001$).

CONCLUSION: Type 2 lesions present with severe ventriculomegaly; plausible explanation is nerve roots stretching and placode exposure leading to altered CSF dynamics or vice a versa. The surgical approach for skin closure varies based on the type. Also, the unusually high rate of PPROM and preterm birth in Type 1 lesions

needs further investigation. Findings have important implications in patient counseling.

	Type 1	Type 2	Type 3	Type 4	Type 5	P-value
Placode Exposure /length of lesion	None/minimal	>1/2	<1/2	<1/2	>1/2

806 Validation of the fetal lamb model of complex gastroschisis

Luc Joyeux[1], David Basurto[2], Kanokwaroon Watananirun[2], Tom Bleeser[2], Ignacio J. Valenzuela[2], Tomohiro Arai[2], Inge Depoortere[2], Alison Accarie[2], Tim Vanuystel[2], Michael Aertsen[2], Alex Menys[3], Paolo De Coppi[4], Larry H. Hollier[1], Michael A. Belfort[5], Jan Deprest[6], Sundeep Keswani[1]

[1]Texas Children's Hospital, Baylor College of Medicine, Houston, TX, [2]KU Leuven, Leuven, West-Vlaanderen, [3]Motilent, London, England, [4]Great Ormond Street Hospital, NHS, London, England, [5]Texas Children's Hospital, Houston, TX, [6]University Hospitals Leuven, Leuven, Vlaams-Brabant

OBJECTIVE: Despite perceived favorable outcomes, complex Gastroschisis (cGS) has a significant morbidity such as sepsis, necrotizing enterocolitis, short bowel syndrome and bowel obstruction. A realistic animal model is lacking to enable further investigation of the pathogenesis of bowel dysfunction and development of novel prenatal therapies. We aimed to develop and validate a fetal lamb model of cGS.

STUDY DESIGN: In fetal lambs at 75 days' gestation, a 1cm abdominal incision was made, a 1cm diameter rigid silicone constrictive ring was fixed to the abdominal wall and the small bowel was exteriorized through the standardized defect. At term (145d), lambs were delivered and compared to normal control lambs. Outcomes were small bowel gross examination, *in vivo* motility (primary) and structure on MRI, *ex vivo* contractility and permeability, and histological analysis.

RESULTS: 5 of the 11 (45%) fetal lambs who underwent cGS induction survived to term. Compared to normal lambs (n=6), all lambs displayed a macroscopic phenotype of cGS (n=5): the small bowel and most of the large bowel were eviscerated, distended, thick and inflamed; there was small bowel obstruction with stenosis, atresia, necrosis and/or perforation (Fig.1A). On MRI, cGS lambs showed significantly decreased small bowel motility (motility GI-Quant score) and increased proximal bowel obstruction (motility contrast score), intra-abdominal bowel dilation and wall thickness (Fig.1B). They also had a reduced bowel contractility with significant decrease in smooth muscle contractions (Fig.1C). There were trend toward increased bowel permeability and increased integrity (Fig.1D). Histological analysis confirmed the abnormal architecture including thickening of all layers especially of proximal jejunum smooth muscle, serosal vascular proliferation, inflammatory cellular infiltrates in the serosa and submucosa, and shorter mucosal villi and crypts (Fig.1E-G).

CONCLUSION: The fetal lamb model of cGS accurately replicates at term the structural and functional phenotype observed in human neonates with complex GS.

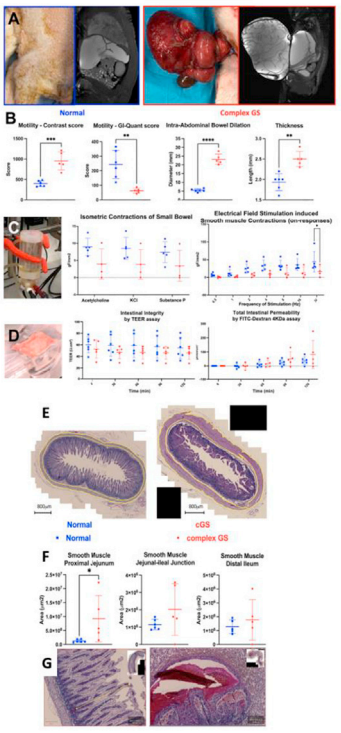

Figure 1 - Bowel structure and function in complex GS lambs (red, n=5) at term, compared to normal controls (blue, n=6).
(A) Gross examination: no eviscerated intestines in the control animals with representative MRI at term with normal large fluid filled stomach and smaller diameter intestines (blue). Thick matted intestines with evidence of bowel obstruction, atresia, necrosis and perforation consistent with complex GS and dilated bowel on term MRI.
(B) MRI examination: complex GS lambs have a significant increase in proximal bowel motility (contrast score 954 vs. 395, p<0.001), decrease in small bowel motility (GI-Quant score 63 vs. 243, p<0.01) and increase in intraabdominal bowel dilation (IABD; 23.3. vs. 5.4mm, p<0.001) and wall thickness (2.5 vs. 1.9mm, p<0.01).
(C) Ex vivo contractility assay: complex GS lambs have reduced smooth muscle contractions at a maximum intensity of 32 Hz (16.5±15.1 vs. 44.4±28.0 gF/mm², p=0.038) and trend toward lower isometric contractions.
(D) Ex vivo permeability assay: complex GS lambs demonstrate a trend toward decreased TransEpithelial Electrical Resistance (TEER) and increased total permeability of 4KDa Fluorescein IsoThioCyanate (FITC) Dextran.
(E-G) Histology: **(E)** All cGS lambs have an abnormal bowel architecture with loss of the normal crypt and villi architecture and **(F)** thickened smooth muscle especially in the proximal jejunum (9.26±8.30 vs. 1.27±0.54 x10⁶ um², p=0.041) compared to normal controls (blue, n=6). **(G)** all lambs display complex GS with stenosis, atresia, necrosis or perforation (right) compared to controls (left). The jejunal-ileal junction, proximal jejunum, and distal ileum exhibit abnormal architecture with serosal vascular proliferation, inflammatory cellular infiltrates.

807 Utility of reticulocyte hemoglobin equivalent in screening for iron deficiency in pregnancy

Lylach Haizler-Cohen[1], Haleema Saeed[1], Valencia Quiett[1], Gurpinder Kaur[1], Eshetu A. Tefera[2], Michael Auerbach[3], Nicholas Hazen[4]

OBJECTIVE: Reticulocyte hemoglobin equivalent (Ret-He) is the measure of functional iron available in hemoglobin of reticulocytes and may be an early indicator of iron deficiency (ID) prior to other red blood cell parameters. It has gained popularity in screening for ID in non-pregnant populations due to its convenience of testing, rapidity of results and cost-effectiveness. Unlike ferritin, Ret-He is not an acute phase reactant and not affected by inflammation. The objective of this study was to determine the accuracy of Ret-He in detecting ID in pregnancy compared to ferritin.

STUDY DESIGN: This was a prospective cohort study which included 200 pregnant patients. Participants were recruited in any trimester if a complete blood count (CBC) was drawn as part of routine prenatal care. For those who agreed to participate, Ret-He and ferritin were collected simultaneously with the CBC. Exclusion criteria included age < 18 , multifetal gestations, thalassemia or sickle cell disease and chronic kidney or liver disease. Ferritin level below 30 ng/mL was considered the gold standard for diagnosing ID. Spearman correlation was conducted to test the association between Ret-He and ferritin. Sensitivity and specificity were calculated for different Ret-He cutoff points. Receiver Operating Curve (ROC) analysis with area under the curve (AUC) was performed to assess the value of Ret-He in identifying ID.

RESULTS: Of 200 pregnant women recruited, 52, 72 and 76 were enrolled in the first, second and third trimesters, respectively. There was a weak but statistically significant correlation between ferritin and Ret-He (r_s=0.48, p< .0001). A Ret-He cutoff of 30.3, the lower threshold used by our laboratory for non-pregnant individuals, had a sensitivity of 30% and specificity of 90%. Alternatively, a Ret-He cutoff point of 34.0 had a sensitivity of 72% and specificity of 54%. The AUC for Ret-He was 0.65, predicting poor discrimination between patients with and without ID.

CONCLUSION: Ret-He is a poor predictor of ID in pregnancy. If it is used, a higher cutoff value may be more appropriate for diagnosing ID.

Table 1 – Reticulocyte hemoglobin equivalent cutoffs and their respective sensitivity and specificity

Cutoff point	Sensitivity	Specificity
30.3	0.298	0.897
31.9	0.441	0.769
32.9	0.522	0.641
33.5	0.652	0.590
34.0	0.721	0.539
35.0	0.795	0.282

808 Timing of aspirin discontinuation prior to delivery and risk of peripartum bleeding complications

Macie L. Champion

University of Alabama at Birmingham, Birmingham, AL; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: There are limited data to guide timing of aspirin discontinuation prior to delivery. We assessed whether there was an association between timing of aspirin discontinuation and maternal and peripartum bleeding complications.

STUDY DESIGN: This was a secondary analysis of a large multicenter RCT of prophylactic tranexamic acid versus placebo in patients undergoing cesarean delivery. Participants taking daily oral aspirin during pregnancy whose discontinuation date was known were included. Participants were grouped by days of aspirin discontinuation in relation to their delivery date: on the day of delivery, 1-7 days prior to delivery, or >7 days prior to delivery. The primary outcome was a composite of transfusion of packed red blood cells or EBL >1L. Secondary outcomes were individual components of the primary outcome. Outcomes were compared across discontinuation timing groups. Adjusted ORs (95% CIs) were calculated using backwards elimination logistic regression (using characteristics associated with primary outcome) with >7 days prior to delivery as the reference group.

RESULTS: Of 10,993 patients in the parent trial, 1614 (15%) were on aspirin and 1571 with a known discontinuation date were included: 164 (10%) discontinued aspirin on day of delivery, 1064 (68%) from 1-7 days, and 343 (22%) >7 days prior to delivery. The primary outcome was observed in 244 (16%) of patients. After adjustments for differences in baseline characteristics (footnote), there were no significant differences in adjusted odds of outcomes by timing of aspirin discontinuation (Figure).

CONCLUSION: The timing of discontinuation (in days) of aspirin prior to cesarean delivery was not associated with postpartum hemorrhage or blood transfusion.

	Day of Delivery (n=164)	1-7 Days (n=1064)	>7 Days (n=343)
Transfusion or EBL >1L	0.92 (0.51, 1.66)	1.16 (0.81, 1.67)	Referent
Transfusion	0.34 (0.07, 1.57)	1.61 (0.86, 3.03)	Referent
EBL >1L	1.09 (0.59, 1.99)	1.10 (0.75, 1.62)	Referent

Odd ratios with 95% confidence intervals with adjustment for maternal age, body mass index, twin pregnancy, preoperative hemoglobin level, thrombocytopenia, cesarean for labor arrest, duration of oxytocin, reached second stage of labor, suspected accreta, and tranexamic acid study medication.

809 Vaginal misoprostol versus vaginal dinoprostone for labor induction: Individual participant data meta-analysis of randomized trials

Malitha Patabendige[1], Fei Chan[2], Christophe Vayssiere[3], Virginie Ehlinger[4], Nicolette van Gemund[5], Saskia Le Cessie[5], Martina Prager[6], Lena Marions[6], Patrick Rozenberg[7], Sylvie Chevret[8], David Young[9], Paul A. le Roux[10], Sarah Gregson[11], Mark Waterstone[11], Daniel L. Rolnik[12], Ben Willem W. Mol[12], Wentao Li[13]

OBJECTIVE: To compare the effectiveness and maternal and perinatal safety with vaginal misoprostol versus vaginal dinoprostone for induction of labor (IOL).

STUDY DESIGN: In this individual participant data meta-analysis, we identified randomised controlled trials comparing vaginal misoprostol to vaginal dinoprostone for IOL in women with a live singleton gestation. Ovid MEDLINE, Ovid Embase, Ovid Emcare, CINAHL Plus, Scopus, Cochrane Library of registered trials, WHO ICTRP and clinicaltrials.gov were searched from inception to March 2023. We approached the authors of each study to share individual-level data. Primary outcomes were vaginal birth and composites for adverse perinatal and maternal outcomes. For the main analysis, data were analysed by the intention-to-treat principle. The primary meta-analysis used two-stage random-effects models, and the sensitivity analysis used one-stage mixed models. This meta-analysis is registered with PROSPERO (CRD42022321378).

RESULTS: Ten out of 52 eligible trials provided individual participant data, of which two were excluded after concerns about data integrity. The eight trials (4,180 participants) compared low-dose vaginal misoprostol (n= 2,077) and dinoprostone (n=2,103) (Table 1). Compared to vaginal dinoprostone, low-dose vaginal misoprostol had a comparable rate of vaginal birth (77.4% vs 77.6 %, adjusted odds ratio (aOR) 0.95, 95% CI 0.80 to 1.13, p=0.51, I^2=0%) and comparable composite adverse perinatal outcomes (11.8% vs 11.8%, aOR 0.96, 95% CI 0.74 to 1.25, p=0.74, I^2=36%). Composite adverse maternal outcomes were significantly lower with low-dose vaginal misoprostol (10.4% vs 8.96%, aOR 0.80, 95% CI 0.65:0.98, p=0.04, I^2=0.0%). Sensitivity analysis for the primary outcomes revealed similar findings.

CONCLUSION: Low-dose vaginal misoprostol and vaginal dinoprostone for IOL are comparable in terms of effectiveness and perinatal safety. However, low-dose vaginal misoprostol is likely to lead to a lower rate of composite adverse maternal outcomes than vaginal dinoprostone.

Table 1. Vaginal misoprostol compared to vaginal dinoprostone

810 Performance of four methods for urine-protein estimation compared to the standard 24-hours for proteinuria diagnosis

Manal Massalha[1], Efrat Yanai[2], Mysalon Mahajna[3], Noah Zafran[4], gali Garmi[4], Raed Salim[5]
[1]Emek medical center, Afula, HaZafon, [2]The Ruth and Bruce Rappaport Faculty of Medicine, Technion, Haifa, HaZafon, [3]emek medical center, Afula, HaZafon, [4]Emek Medical Center, Afula, HaZafon, [5]Holy Family Hospital, Nazareth, Nazareth, HaZafon

OBJECTIVE: To assess the accuracy of a 6-h, 12-h urine collection, and protein/creatinine ratio (PCR) to diagnose proteinuria in women with gestational hypertension, and to determine if diurnal vs nocturnal collection affects the performance of the test.

STUDY DESIGN: A prospective observational study conducted at a University Teaching institution in Israel, between May 2013 and July 2023. Pregnant women >20 weeks hospitalized for preeclampsia workup were eligible. Three consecutive urine samples were collected for each woman; 06:00-12:00 h, 06:00-18:00 h, and 18:00-06:00 h. Protein levels were measured in each sample, as well as in a 24-h pooled sample. The diagnostic cut-off values for proteinuria were ≥75mg (6-h samples), ≥150 mg (12-h samples) and ≥300 mg (24-h sample). Moreover, PCR was also measured at the first urine sample and a ratio of ≥300 was diagnostic. The validity of each sample as opposed to 24-h sample, was evaluated by determination of sensitivity, specificity, positive predictive value, negative predictive value, and accuracy.

RESULTS: Overall, 258 women were included, and proteinuria was confirmed in 80 (31%) according to 24-h sample. The reliability and validity of the 6-h, diurnal and nocturnal 12-h and PCR versus the 24-h sample for a diagnosis of proteinuria are shown in Table 1. Cohen's kappa indicated a moderate agreement for the 6-h and the PCR diagnostic tests while a substantial agreement in both 12-h samples was observed. Paired sample AUC test revealed no statistically significant difference in AUC between 12-h diurnal and nocturnal results. ROC curve analysis did not show improved in sensitivity and specificity of any of the diagnostic tests when the analysis was stratified according to maternal weight, gestational age, number of fetuses, parity, or the existence of severe features.

CONCLUSION: The 12-h test showed adequate accuracy for detecting proteinuria, regardless of the time of collection. The 12-h test perform better than the 6-h and PCR tests.

Table 1. Comparison of the Diagnostic tests

	Proteinuria, mg	Positive Proteinuria*	Cohen κ	P value	Sensitivity (95% CI), %	Specificity (95% CI), %	PPV (95% CI), %	NPV (95% CI), %	Accuracy (95% CI), %

24 hours (n=251)	205.2±233.7 (15.4-7727.4)	77 (30.7)	substantial						
Protein/creatinine/ ratio (n=239) 24 hours (n=239)	182.9±192.9 (9.9-8864.2)	64 (26.8) 75 (31.4)	.605	<.001	63.3 (51.7-77.1)	91.5 (86.1-95.2)	78.1 (67.8-85.8)	83.8 (79.4-87.4)	82.3 (76.9-86.9)

CI, confidence interval; NPV, negative predictive value; PPV, positive predictive value.
Values are given as mean±SD (range) or number (%), unless indicated otherwise.
Proteinuria is defined as a protein level of ≥75 mg/6 h, ≥150 mg/12 h, ≥300 mg/24 h, and protein/creatinine ratio ≥300.

811 Does risk of postpartum hemorrhage increase in twin pregnancies with birthweights greater than 4000g?

Manasa G. Rao[1], Kelly Wang[2], Sonia Khurana[3], Isabelle C. Band[2], Alexandra N. Mills[2], Joanne Stone[3], Chelsea A. DeBolt[4]
[1]Columbia University, Icahn School of Medicine at Mount Sinai, New York, NY, [2]Icahn School of Medicine at Mount Sinai, New York, NY, [3]Icahn School of Medicine at Mount Sinai Hospital, New York, NY, [4]Mount Sinai Hospital, New York, NY

OBJECTIVE: Twin pregnancy carries a unique increased risk of postpartum hemorrhage (PPH) when compared to singleton gestations. Increased fetal weight in twin pregnancy may exacerbate uterine distension and result in increased risk of PPH secondary to uterine atony. In singletons, macrosomia is defined as a birthweight of 4000 grams (g) and is associated with risk of PPH. While prior studies have concluded PPH increases linearly with increasing birthweight in

twins, our aim was to examine whether patients with a sum birthweight >4000g were at increased odds of PPH when compared to those with a sum birthweight < 4000g.

STUDY DESIGN: Retrospective review of patients who delivered dichorionic-diamniotic twins at a single academic institution from 2013-2021. The primary outcome was PPH, defined as quantitative blood loss ≥ 1000mL in either vaginal or cesarean delivery. Secondary outcomes included PPH due to atony and use of uterotonic medications. Outcomes were assessed using univariable and multivariable logistic regression.

RESULTS: Among 431 twin gestations, 94 (21.8%) had a sum of birthweights ≤ 4000g and 337 (78.2%) had a sum of birthweights > 4000g. PPH occurred in 24.8% of individuals overall. There was no significant difference in odds of PPH in the ≤4000g group compared to the >4000g group (20.2% vs. 26.1%, p=0.24). There also was no significant difference in PPH due to atony or use of uterotonics between the two groups. After adjusting for age, insurance type, BMI, IVF, multiparity, history of cesarean delivery or uterine surgery, fibroids, and placenta accreta spectrum, there was insufficient evidence to conclude an association between PPH and the allotted birthweight categories (p=0.11).

CONCLUSION: In this retrospective study, risk of PPH does not appear to increase in patients with combined birthweights of greater than 4000g when compared to those ≤ 4000g.

Table Outcomes based on sum of birthweight cutoff

OBJECTIVE: Current ACOG guidelines regarding management of patients with obesity are based on pre-gravid body mass index (BMI). It is unclear if and how management recommendations should change when BMI class increases during pregnancy.

STUDY DESIGN: This is a retrospective cohort study from 2009—2022 of patients with singleton gestations and BMI ≥35kg/m^2. We included those who maintained or increased (≥3 BMI points) BMI class during pregnancy and excluded those that decreased BMI class. The primary outcome was a composite of growth abnormalities (FGR/LGA), cesarean delivery, oligohydramnios, polyhydramnios, and stillbirth. A superiority analysis was performed for the composite outcome between patients who increased BMI class IIàIII and class II using a repeated measures logistic regression model adjusting for a history of the primary outcome, race/ethnicity, marital status, insurance, nulliparity, chronic hypertension and pregestational diabetes. The adjusted odds ratio was reported with the respective 95% confidence interval and p-value. An equivalence test was performed for the composite outcome between patients who increased BMI class IIàIII and class III using two one-sided tests from a repeated measures model with an equivalence margin of 4%, and adjusting for same characteristics as in the superiority analysis. The adjusted 90% confidence interval and the higher p-value of the two one-sided tests were reported. A p-value < 0.05 was considered significant.

RESULTS: 9,117 pregnancies were included: 2,481 (class II), 4,154 (class III), 2,482 (class IIàIII). Patients who increased from BMI class IIàIII had more adverse outcomes than those who maintained class II BMI (aOR 1.60, CI 1.36-1.89) and were similar to those with class III BMI (adjusted 90% CI -0.013-0.022, adjusted equivalence p-value < 0.01).

CONCLUSION: For patients that increase BMI class from IIàIII, it is reasonable to manage their pregnancies (with regards to antenatal surveillance and delivery timing) according to ACOG and institutional guidelines for patients with pre-gravid BMI class III.

Table 1: Composite adverse outcomes

	Class II > III (N=2482)	Class II (N=2481)	Adjusted OR (95% CI)	Adjusted p-value[1]	Class III (N=4154)	Equivalence Margin	Adjusted 90% CI[2] Class II-III v. Class III	Adjusted Equivalence p-value[2]
Composite adverse outcomes	502 (20.2)	328 (13.2)	1.62 (1.37-1.91)	<0.01	820 (19.7)	+/- 4%	(-0.013-0.022)	<0.01

Results reported as n (%) unless otherwise specified. OR: Odds ratio, CI: Confidence Interval

Composite adverse outcome: fetal growth restriction, large for gestational age, cesarean delivery, oligohydramnios, polyhydramnios, and stillbirth.

[1]Repeated measures, logistic regression model adjusted for history of the primary outcome, race/ethnicity, marital status, insurance, nulliparity, chronic hypertension and pregestational diabetes

[2]Two one-sided tests were performed for equivalence using a repeated measures analysis and adjusting for the above characteristics. 90% confidence interval and the higher of the two p-values are reported. Repeated measures analysis was utilized.

813 Trends in Hypertensive Disorders in the United States Post Aspirin Recommendation Guidelines: A Nationwide Study

Mariam Ayyash[1], Rodney A. McLaren Jr.[2], Huda B. Al-Kouatly[3], Majid Shaman[4]

[1]Columbia University Irving Medical Center, New York, NY, [2]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA, [3]Thomas Jefferson University, Philadelpia, PA, [4]Henry Ford Health, W Bloomfield, MI

OBJECTIVE: To determine if there were changes in the rates of hypertensive disorders of pregnancy (HDP) in the United States after the publication of aspirin recommendation guidelines by the United States Preventive Services Task Force (USPSTF) and the American College of Obstetricians and Gynecologists (ACOG).

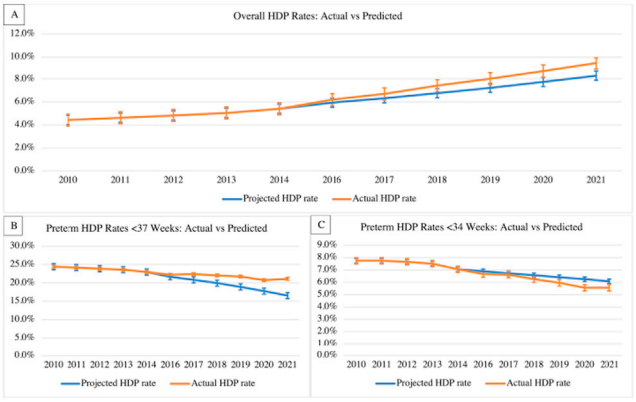
STUDY DESIGN: A population-based retrospective cohort study was performed using the US Natality database. The pre-aspirin recommendation guidelines (pre-ASA) group were births from 2010-2014. The post-aspirin recommendation guidelines (post-ASA) group - including both the USPSTF and ACOG guidelines - were births from 2016-2021. Births that occurred in 2015 were excluded. Outcomes were rates of HDP. Univariable and multivariable analyses were

performed. A logistic regression was used to project the HDP rate over time based on the pre-ASA group rate and was compared, per year, using Wald confidence intervals.

RESULTS: There were 12,127,659 births in the pre-ASA group and 17,665,217 births in the post-ASA group. After adjusting for baseline clinical differences, the post-ASA group had a higher rate of overall HDP than the pre-ASA group (7.7% vs 4.9%; aOR 1.58 [1.57-1.59]). However, the post-ASA group had a lower rate of preterm birth complicated with HDP prior to 37 weeks (21.6% vs 23.7%; aOR 0.90 [0.89-0.91]) and prior to 34 weeks (6.0% vs 7.5%; aOR 0.79 [0.78-0.81]) than the pre-ASA group. The observed HDP rate post-ASA implementation was higher than projected for overall HDP and preterm birth with HDP < 37 weeks, but not different for the preterm birth with HDP < 34 weeks. Both preterm periods showed a downtrending pattern.

CONCLUSION: While HDP remains on the rise overall, the rates are downtrending among preterm births. This observed trend, however, remains either higher or no different compared to the projected trend post-ASA implementation guidelines. While aspirin may provide some efficacy for HDP prophylaxis, it is worthwhile to continue focusing on public health efforts to address known modifiable risk factors for preeclampsia such as obesity, chronic hypertension, and diabetes.

Figure 1. Trends in Hypertensive disorders in the pre-ASA and post-ASA groups



814 Impact of quality improvement efforts at a population level: evidence from cesarean birth trends

Marie Boller[1], Bharti Garg[2], Aaron B. Caughey[2]
[1]Oregon Health & Science University, Portland, OR, [2]Oregon Health & Science University, Portland, OR

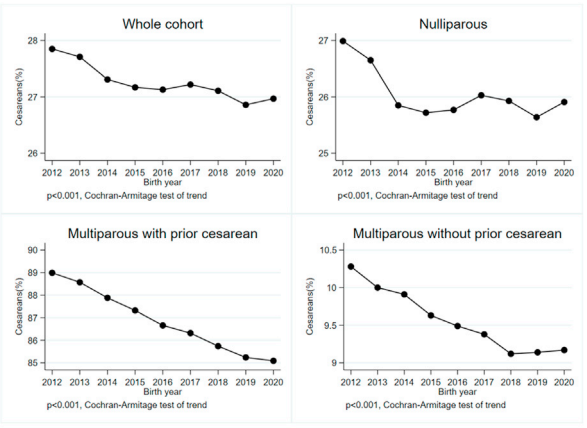
OBJECTIVE: In response to rising cesarean birth rates, the American College of Obstetricians and Gynecologists and the Society for Maternal-Fetal Medicine published guidance for prevention of the primary cesarean in 2014. Our objective was to evaluate trends in cesarean birth rates in the United States from 2012-2020.

STUDY DESIGN: Retrospective observational study of delivery data from National Vital Statistics System. Inclusion criteria were singleton, non-anomalous, term (37w0d-42w0d) gestation, vertex deliveries. We examined trends in rates of cesarean birth from 2012-2020 in nulliparas, multiparas without prior cesarean, and multiparas with prior cesarean utilizing Cochrane-Armitage test of trend. Risk ratios (95% Confidence interval) comparing cesarean rates for 2020 with 2012 were estimated.

RESULTS: In total, 27,221,575 cesarean births were included. Overall, the rate of cesarean birth decreased from 27.8% (95% confidence interval 27.7%, 27.9%) in 2012 to 26.9% (95% confidence interval 26.9%, 27.0%) in 2020 with a risk ratio (RR) of 0.97 (95% confidence interval 0.97, 0.98). Cesareans were decreased in nulliparous (26.9% (26.9%, 27.1%) in 2012 to 25.9% (25.8%, 25.9%) in 2020 with a RR of 0.96 (0.95, 0.96)), multiparous with prior cesarean (88.9% (88.8%, 89.1%) in 2012 to 85.1% (84.9%, 85.2%); RR (0.97 (0.97, 0.97)) and multiparous without prior cesarean (10.3% (10.2%, 10.3%) in 2012 to 9.16% (9.12%, 9.21%) in 2012; RR=0.97 (0.97, 0.97). Cesarean birth rates declined across subgroups stratified by parity: in nulliparas as well as multiparas both with and without prior cesarean (p< 0.001, Cochran Armitage test of trend) (Figure 1).

CONCLUSION: Quality improvement bundles aimed at safe prevention of primary cesarean birth may be associated with a reduction in overall cesarean birth including in multiparas with and without prior cesarean birth.

Figure 1. Trends in cesarean birth in the United States, 2012-2020



815 Treatment effect heterogeneity of antenatal steroids among late preterm births

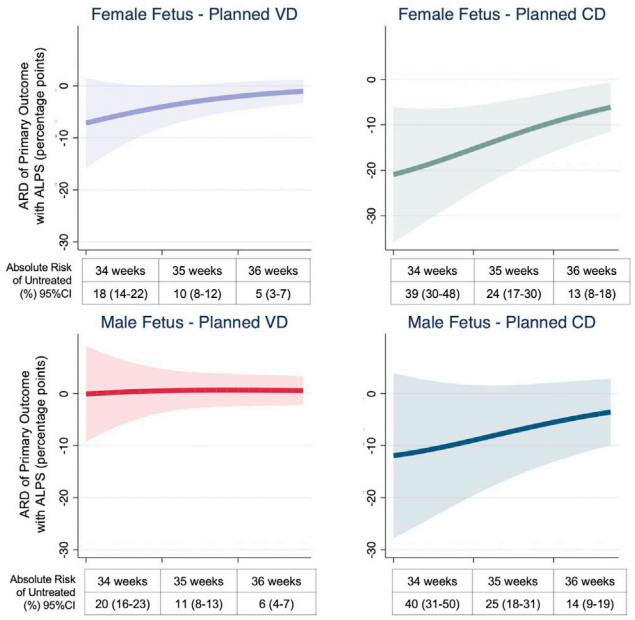
Mark A. Clapp[1], Cynthia Gyamfi-Bannerman[2], Anjali J. Kaimal[3], Jessica Cohen[4], Scott Lorch[5], Jason D. Wright[6], Alexander Melamed[1]
[1]Massachusetts General Hospital, Boston, MA, [2]UC San Diego Health, La Jolla, CA, [3]University of South Florida Morsani College of Medicine, Tampa, FL, [4]Harvard TH Chan School of Public Health, Boston, MA, [5]Children's Hospital of Philadelphia, Philadelphia, PA, [6]Columbia University Medical Center, New York, NY

OBJECTIVE: To determine if there is treatment effect heterogeneity for late preterm steroids among factors previously reported to be associated with a neonate's risk of respiratory morbidity.

STUDY DESIGN: This is an exploratory secondary analysis of the Antenatal Late Preterm Steroid (ALPS) Trial. The primary outcome was the same composite of respiratory morbidity used in the trial. The primary exposure was antenatal steroid exposure vs. placebo. Treatment heterogeneity of antenatal steroids was assessed across 3 factors: gestational age at trial enrollment, fetal sex, planned cesarean delivery. A logistic regression model with interaction terms between the exposure and each factor was fit. Predicted probabilities of the primary outcome were compared across all potential possible combinations, and the absolute risk difference (ARD) between ALPS vs. placebo was plotted across days of gestation, stratified by sex and mode of delivery.

RESULTS: There were 2,825 participants included. The distribution of gestational age, fetal sex, and planned mode of delivery was not different between the groups. The Figure shows the ARD for respiratory morbidity over the late preterm period by fetal sex and planned mode of delivery. The absolute risk of the outcome in the untreated group is shown below the x-axis for each week of gestation. Patients with a planned cesarean delivery and presenting at 34+0 weeks had the highest baseline risk of respiratory morbidity (49.6% (95% CI 39.1, 59.9%)) and demonstrated the greatest ARD with ALPS. In comparison, the absolute risk for patients presenting at 36+5 weeks and having planned vaginal delivery was 5.9% (95% CI 4.1, 7.6%) with no observed ARD with steroid exposure, though the analysis was limited by small sample sizes.

CONCLUSION: These findings suggest there is treatment heterogeneity for ALPS depending on fetal sex, gestational age, and mode of delivery, with the largest benefit for patients with presenting at 34 weeks having a planned CD. Studies with larger sample sizes are needed to better inform shared decision-making around the practice of late preterm steroids.



ARD, absolute risk difference. CD, cesarean delivery. VD, vaginal delivery.
Note: The x-axis displays the gestational age at time of randomization into the ALPS trial.

816 Gut microbiome impacts iron deficiency and responsiveness to iron supplementation in a prospective, interventional trial

Maryshe S. Zietsman[1], Sarah E. Detlefs[2], Kjersti M. Aagaard[3], Michael D. Jochum Jr.[1]

[1]Baylor College of Medicine, Houston, TX, [2]Texas Children's Hospital, Houston, TX, [3]Texas Children's Hospital, Baylor College of Medicine, Houston, TX

OBJECTIVE: Oral iron absorption in the gut is regulated to optimize bioavailability & overcome iron losses. However, response to iron supplementation (IS) is unpredictable. We hypothesized that variation in the composition of the gut microbiome would vary between responders vs non-responders following IS.

STUDY DESIGN: People who menstruate without a known history of anemia or iron deficiency were included in our open label, prospective, interventional trial (n=26). Participants received 14 days of 65mg elemental iron. Blood (Days (D) 0 & 14) & stool (8 samples including D0 & D14) were collected for iron & anemia indices and microbiome analyses. Stool sample DNA underwent 16S amplicon sequencing and bioinformatic analysis of microbial ASVs (DADA2). To characterize the gut microbiome composition, taxonomic comparisons, & unsupervised clustering with Dirichlet multinomial mixtures (DMM) were performed. Participants who were iron deficient on D0 (n=17) were later subdivided into iron supplement responders (ferritin $\geq$ 30 ng/mL, n=4) and non-responders (ferritin $<$ 30 ng/mL, n=12), based on their D14 ferritin.

RESULTS: Three taxa were associated with D0 iron deficiency (ferritin $<$ 30 ug/L): *Bacteroides, Streptococcus* and *Tyzzerella* (p=0.021, 9.3e-05, 0.0024; Fig1A). Unlike *Streptococcus* and *Tyzzerella*, *Bacteroides* was inversely associated with baseline ferritin levels. In the D0 iron deficient group, IS response was associated with six keystone taxa: *Ruminococcus, Bacteroides, Gordonibacter, Lachnoclostridium, Lactobacillus*, and *Lactococcus* (p=0.013, 0.006, 0.008, 0.003, 0.004, 0.005; Fig1B). Increases in *Ruminococcus, Gordanibacter*, and *Lactobacillus* were associated with responders. *Bacteroides* remained more abundant in non-responders throughout the IS period.

CONCLUSION: Significant gut microbiome taxonomic differences were observed when comparing iron deficient and sufficient participants, and between IS therapy responders and non-responders. Thus, there is evidence for an impact of gut microbiome composition on iron deficiency and responsiveness to IS.

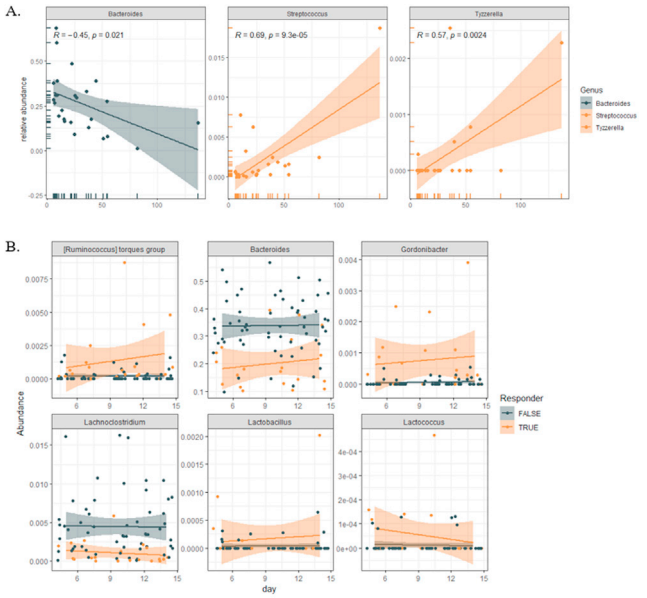


Figure 1. (A) Relative abundance scatterplots for keystone taxa associated with baseline iron deficiency where the x axis represents serum ferritin levels at Day 0, the y axis represents the relative abundance for each keystone and the color represents the associated with iron deficiency at Day 0. **(B)** Relative abundance scatterplots for keystone taxa associated with response to iron therapy post treatment where the x axis represents time in days, the y axis represents the relative abundance for each keystone and the color represents either non-responder (blue) or responder (gold) status for subjects that were originally iron deficient.

817 Trans-placental transport of a novel fluorescent lipid nanoparticle in a pre-clinical fetal therapy murine model

Maryshe S. Zietsman[1], Matthew A. Shanahan[1], Enrico R. Barrozo[2], Maxim D. Seferovic[2], Rohan Bhavane[3], Prajwal Bhandari[3], Ketan Ghaghada[3], Magdalena Sanz Cortes[4], Christopher Ward[1], Michael A. Belfort[3], Kjersti M. Aagaard[5]

[1]Baylor College of Medicine, Houston, TX, [2]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [3]Texas Children's Hospital, Houston,

TX, [4]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [5]Texas Children's Hospital, Baylor College of Medicine, Houston, TX

OBJECTIVE: *In utero* therapies allow for prevention of irreversible fetal morbidity. While preferential transplacental delivery for fetal treatment is challenging, lipid nanoparticles (LNPs) offer an established safety profile, and lipoprotein-rich fetal blood provides a compatible environment. Since modifications in LNP composition allow for fetal tissue target specificity, we hypothesized that a specialized LNP delivery vehicle with near infrared (NIR) fluorescence detection would enable targeted fetal delivery which could be readily visualized *in vivo* after peripheral administration to a gravid mouse.

STUDY DESIGN: DiR, a NIR fluorescent dye, and other lipids dissolved in EtOH were rapidly mixed with buffer and sonicated to form DiR LNPs at 6 mM lipid concentration. 1.7 mg/uL DiR LNPs were injected into the tail veins of e14.5 gravid mice (n=2). Images were obtained at 4 timepoints before removing the maternal uterus, liver, kidneys, and viscera for imaging. The fetuses and placentae were subsequently imaged as well.

RESULTS: As anticipated, maternal *in vivo* images demonstrated strong fluorescent LNP signal in the liver at all timepoints (Fig1A). Initial faint LNP signal in the maternal uterus became concentrated in the distribution of the L uterine horn (Fig1B). Excitingly, the fluorescent LNP signal was observed in every placenta and fetus (Fig1C), and honed to the fetal liver. At high resolution, revealing there was preferential LNP signal in the fetal live over the other abdominal viscera (Fig1D).

CONCLUSION: These data show, for the first time, successful *in vivo* trans-placental LNP delivery to fetal mice via intravenous injection of a gravid mouse, with preferential uptake in the fetal liver. These findings are an exciting next step in the development of a novel, maternal peripherally delivered yet transplacental LNP delivery of cargo to the fetal liver for *in utero* fetal therapies.

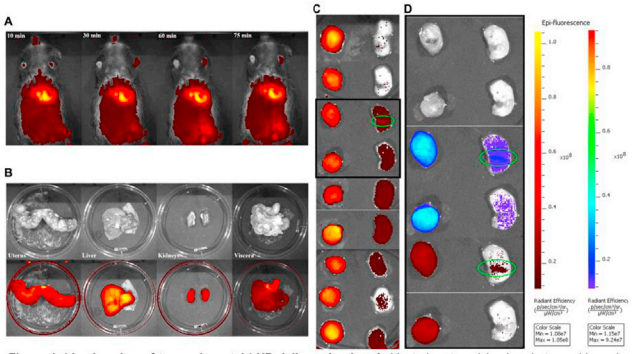

Figure 1. Live-imaging of trans-placental LNP delivery *in vivo*. A, Ventral maternal *in vivo* photographic and fluorescent overlay images at 4 timepoints (10, 30, 60, and 75 minutes) post-DiR LNP injection. **B,** Maternal uterus, liver, kidneys, and viscera 90 minutes post-DiR LNP injection. **C,** Photographic and fluorescent overlay of individual placenta and fetus pairs from Litter 1. **D,** High resolution photographic and fluorescent overlay images of placenta and fetus pairs 3 and 4 from Litter 1 to show detailed fluorescence distribution in the fetus. All images obtained with IVIS Lumina X5; 700/790 nm ex/em. C57Bl/6 mice used for all studies; Mice were euthanized by IACUC standards via cervical dislocation under inhaled isoflurane anesthesia.

818 MRI Markers of PAS in Individuals Without PAS

Matthew B. Givens[1], Paula Woodward[1], Anne Kennedy[1], April Griffith[1], Michelle P. Debbink[1], Christine M. Warrick[2], Amanda A. Allshouse[3], Robert M. Silver[3], Brett D. Einerson[3]
[1]University of Utah, Salt Lake City, UT, [2]University of Utah, Park City, UT, [3]University of Utah Health, Salt Lake City, UT

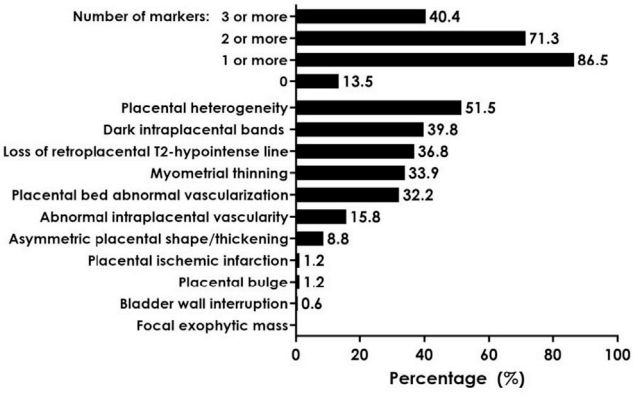
OBJECTIVE: The imaging diagnosis of placenta accreta spectrum (PAS) is challenging. Ultrasound markers of PAS are often seen in unaffected individuals but the prevalence of MRI markers in unaffected pregnancies is unknown. We evaluated the prevalence of MRI PAS markers in patients without PAS.

STUDY DESIGN: Retrospective analysis of MRIs performed at greater than 20 weeks gestation for non-PAS indications at a single institution from Jan 2019 to June 2022. Our institution obtains placental evaluation sequences for all MRIs obtained during pregnancy. Individuals with clinical or pathologic PAS or missing delivery data were excluded. Three experienced radiologists blinded to patient history, independently assessed for 11 markers of PAS as defined by the Society of Abdominal Radiology and the European Society of Urogenital Radiology guidelines. The prevalence of markers was compared between patients with and without a prior cesarean. Ten percent of cases were examined by all radiologists for consistency.

RESULTS: 171 MRIs performed at a median GA of 29 weeks (IQR 6.3 weeks) were included. 3.5% of fetuses were confirmed genetically abnormal and 66% had normal aneuploidy testing. At least one marker of PAS was seen in 86.5% of MRIs. The most prevalent markers were placental heterogeneity (51.5%), dark intraplacental bands on T2 weighted images (39.8%), loss of the retroplacental T2-hypointense line (36.8%), myometrial thinning (33.9%), and abnormal vascularization of the placental bed (32.2%). Three markers were uncommon: placental bulge (1.2%), placental ischemic infarction (1.2%), and focal exophytic mass (0%). Myometrial thinning was significantly more likely to be seen in those with a prior cesarean section than those without (55.2% vs 29.6%, p=0.008).

CONCLUSION: Similar to ultrasound, MRI markers of PAS are frequently seen in patients without PAS. Overreliance upon these markers in isolation is likely to lead to overdiagnosis of PAS.

Figure 1. Prevalence of MRI Markers of PAS in Individuals Without PAS



819 Trends and outcomes in deliveries affected by maternal fatty acid oxidation defects

Matthew Shear[1], Teresa N. Sparks[2], Renata Gallagher[1], Kate Swanson[1], Mary E. Norton[1], Anna Farooqi[3], Timothy Wen[1]
[1]University of California, San Francisco (UCSF), San Francisco, CA, [2]University of California, San Francisco (UCSF), School of Medicine, San Francisco, CA, [3]Texas Tech University Health Sciences Center, Amarillo, TX

OBJECTIVE: Improved detection and management of fatty acid oxidation defects (FAOD) over time has led to increased survival to reproductive age. National data is needed on the prevalence and obstetric outcomes for this group of patients, given the potential increased risk of complications such as hypoglycemia or rhabdomyolysis related to the metabolic stress of labor and delivery.

STUDY DESIGN: Deliveries of patients with FAOD were identified using ICD-10CM codes from the 2016-2020 abstracts of the Nationwide Inpatient Sample. Trends in the rates of maternal FAOD delivery hospitalizations were assessed using Joinpoint regression with measured association expressed as annual average percent change (AAPC). Baseline patient demographics, obstetric outcomes, and health care resource utilization were compared using Chi-square or Wilcoxon rank sum where appropriate. Unadjusted logistic regression models were fit comparing risks of obstetric complications in patients with and without FAOD, expressed as odds ratios (OR) and 95% confidence intervals (CI).

RESULTS: 492 births affected by maternal FAOD were identified, with an increasing incidence over time from 20 to 45 cases per million birth hospitalizations (AAPC 24.8%, 95% CI: 11.6%, 42.7%). Deliveries with FAOD were associated with statistically significant higher mean length of stay (LOS) (3.6 versus 2.7 days) and delivery costs ($8,248 vs. $6,642). Births with FAOD were at higher odds of postpartum hemorrhage (PPH) (OR 1.76, 95% CI: 1.05, 2.95) but were not at higher likelihood of transfusion, non-transfusion severe maternal morbidity, preterm delivery, chorioamnionitis, hypertensive disorders of pregnancy, placental abruption, or cesarean delivery.

CONCLUSION: The prevalence of deliveries affected by a known maternal FAOD is increasing and associated with increased LOS, costs, and likelihood of PPH, although with no observed increased odds of other birth complications. These outcomes are helpful when counseling patients with FAOD considering pregnancy. Further research is needed to understand drivers of PPH and increased costs among these patients beyond LOS.

Table 1: Trends and outcomes in maternal fatty acid oxidation defect delivery hospitalizations

	FAOD deliveries		non-FAOD deliveries		
Year	N		N		Rate per million
2016	74		3781749		19.7

820 High-Risk Pregnancy in North Carolina: Predictors of High Efficacy Postpartum Contraception Use

Maya Cox-Terry[1], James Edwards[2], Godwin Dogbey[1]
[1]Campbell University School of Osteopathic Medicine, Lillington, NC, [2]WakeMed, Raleigh, NC

OBJECTIVE: Postpartum high efficacy contraception use is particularly recommended for patients with a history of high-risk pregnancy. Several studies on high-risk pregnancy and high efficacy contraceptive use have shown inconsistent results. This study examined factors that influence the use of high efficacy contraception postpartum in respondents with reported high-risk pregnancy at a state population level.

STUDY DESIGN: North Carolina Pregnancy Risk Assessment Monitoring System data for 2012-2020 was analyzed. High efficacy contraceptive (IUD, implant, tubal ligation, vasectomy) use postpartum was the outcome of interest. The predictors and covariates included: demographics, high-risk pregnancy history, parity, pregnancy intention, infant mortality, interpersonal violence during pregnancy, and prenatal and postpartum counseling. High-risk pregnancy was defined as a history of preterm birth, low birth weight infant, obesity, diabetes, hypertension, depression, or no prenatal care. A multivariable logistic regression analysis was conducted with adjusted odds ratios (aORs) determined.

RESULTS: Significant predictors of high efficacy contraception use: history of high-risk pregnancy, multiparity, trying to get pregnant with their most recent pregnancy, living infant, postpartum contraception counseling, postpartum visit inquiry about depression, Black and Asian races, attainment of a bachelor's or master's degree, and age groups 30-34 and 35-39 years-old. (See Table 1 for aORs, p-values, and Confidence Intervals.)

CONCLUSION: At a state population level, high-risk pregnancy history is associated with high efficacy contraception use postpartum. Patients who use high efficacy contraception are more likely to plan their pregnancies and have multiple children. Postpartum contraception counseling is a predictor of high efficacy contraception use. Thus, based on the study findings, patients who are younger, have lower education levels, and have a history of unplanned pregnancy should be identified and provided comprehensive postpartum contraception counseling.

Variable	aOR	p-value	95% CI
History of high-risk pregnancy	1.182	.046	[1.003 to 1.394]
Multiparity	2.005	< .001	[1.703 to 2.362]
Trying to get pregnant with recent pregnancy	0.723	< .001	[0.619 to 0.845]
Living infant	2.846	.003	[1.416 to 5.720]
Postpartum contraception counseling	0.355	< .001	[0.282 to 0.446]
Postpartum visit inquiry about depression	1.404	.023	[1.049 to 1.880]
Black race	0.780	.014	[0.641 to 0.951]
Asian race	0.364	< .001	[0.226 to 0.586]
Bachelor's degree	0.642	< .001	[0.502 to 0.821]
Master's degree	0.655	.007	[0.482 to 0.892]
30-34 years-old	1.307	.007	[1.075 to 1.590]
35-39 years-old	1.504	< .001	[1.194 to 1.893]

Table 1. Significant predictors of high efficacy contraception use postpartum.

821 Impact of fetal sex on neonatal outcomes in gestational diabetes mellitus

Maya ben zion[1], Gal Cohen[2], Hila Shalev[3], Gil Shechter Maor[1], Tal Biron-Shental[4], Michal Kovo[5]
[1]Meir Medical Center, Kfar Saba, HaMerkaz, [2]Meir Medical Centerartment of Obstetrics and Gynecology, Meir Medical Center, Kfar Saba, Israel, [3]Meir Medical Center, Kfar sava, HaMerkaz, [4]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz, [5]Meir Medical Center, Macabim, HaMerkaz

OBJECTIVE: A growing body of evidence suggest that maternal adaptation to pregnancy complications differs based on fetal sex chromosomes, indicating sexual dimorphisms in maternal pregnancy complications. This study aimed to investigate the disparities

in outcomes between pregnancies with female and male fetuses in patients with gestational diabetes mellitus (GDM).

STUDY DESIGN: The medical files of all diagnosed GDM patients delivered between 2018-2020, were reviewed. GDM was diagnosed based on oral glucose tolerance test. Women with GDMA1 achieved sufficient glycemic control without medical treatment, and GDMA2 required medical treatment to control their blood glucose levels. Maternal characteristics, pharmacological treatment, delivery and neonatal outcome were compared between the "male GDM group" and the "female GDM group" (patients with male or female fetuses respectively). Composite averse neonatal outcome included at least one of the following: hypoglycemia, sepsis, respiratory distress, anemia/blood transfusion, cerebral hemorrhage, HIE, or convulsions.

RESULTS: A total of 1587 GDM patients were included. As compared to the female GDM group (n=763) the male GDM group (n=824) was characterized by higher maternal age (p=0.046), a higher rate of cesarean deliveries (CD) (p=0.027), vacuum extractions (p=0.001), increased neonatal birthweight (p=0.001), macrosomia (birthweight >4000 gr) (p=0.001) and a higher rate of adverse composite neonatal outcome (0.004). Multivariable logistic regression analysis revealed that having a male fetus was independently associated with composite adverse neonatal outcome, with an odds ratio of **1.68**, 95% CI 1.16-2.42, p=0.006. Among GDMA2 cases there were no differences regarding the total dose of insulins or oral hypoglycemic medications between pregnancies with female and male fetuses.

CONCLUSION: The higher rate of adverse neonatal outcome observed in pregnancies with male fetuses among GDM patients corresponds with sex-specific differences in maternal pathophysiological adaptation during complicated pregnancies.

Table 2- Logistic regression model for composite adverse neonatal outcome

	Adjusted Odds Ratio	95% CI	P value
Maternal age (every added year)	0.98	0.95-1.02	0.260
Nulliparity	1.08	0.74-1.57	0.681
Obesity (BMI>30)	0.98	0.58-1.64	0.935
GDMA2	1.21	0.82-1.79	0.338
Hypertensive disorders	1.56	0.79-3.06	0.201
Male fetus	**1.68**	**1.16-2.42**	**0.006**
Fetal macrosomia	1.02	0.45-2.31	0.971
Fetal weight (every added gram)	1.00	1.00-1.00	0.990

822 Implications of intravenous paracetamol prior labor induction by catheter balloon insertion: a randomized controlled trial

Maya Wolf[1], Inshirah Sgayer[2], Raneen Abu Shqara[1], Karina Naskovica[3], Fatina Kassis[4], Nataly Kushnir[4], Miri Lavinsky[4], Nasra Idilbi[3], Lior Lowenstein[5]

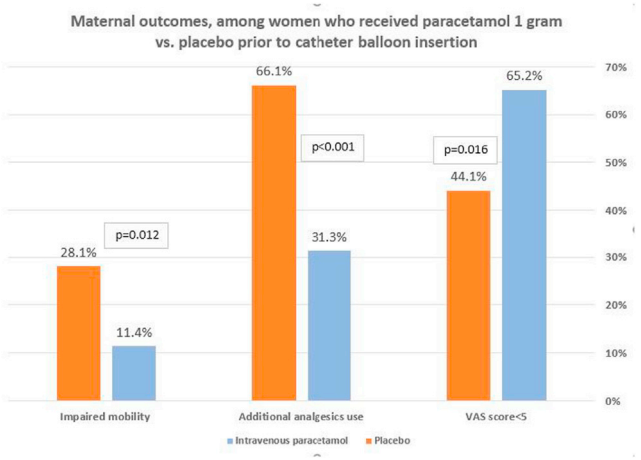
[1]Galilee Medical Center, Nahariya, HaZafon, [2]Galilee Medical Center, Nahariya, and Azrieli Faculty of Medicine, Bar Ilan University, Safed, Israel, Nahariya, HaZafon, [3]Galilee Medical Center, Nahariya, and Azrieli Faculty of Medicine, Bar Ilan University, Safed, Israel, Nahariya, Israel, HaZafon, [4]Galilee Medical Center, Nahariya, Israel, Nahariya, Israel, HaZafon, [5]Galilee Medical Center, Nahariya, Israel Azrieli Faculty of Medicine, Bar Ilan University, Safed, Israel, Naharyia, HaZafon

OBJECTIVE: For women with an unfavorable cervix, mechanical ripening by catheter balloon is common, but studies of pain relief during balloon insertion are lacking. This study aimed to assess maternal pain and satisfaction following paracetamol vs. placebo, prior to catheter balloon insertion.

STUDY DESIGN: Primiparous women at term who were admitted for medically indicated labor induction were randomized to receive intravenous paracetamol 1 gram in 100 cc normal saline or placebo (100 cc normal saline) prior to catheter balloon insertion. The primary outcomes were visual analog scale (VAS) scores and maternal satisfaction, as assessed in a questionnaire.

RESULTS: Overall, 141 women were included: 71 received paracetamol 1 g and 70 received placebo prior catheter balloon insertion. Background characteristics and pre-induction maternal pain did not differ between the groups. The median VAS scores at 2, 30 and 60 minutes after catheter insertion were comparable between the paracetamol and placebo groups, 6.46±2.77 vs. 6.66±2.78, p=0.68; 5.53±3.2 vs. 5.93±3.01, p=0.46; and 5.83±3.25 vs. 6.49±2.88, p=0.26, respectively. For the paracetamol vs. placebo group, the proportion with a mean VAS score < 5 was higher (65.2% vs. 44.1%, p=0.016) and the mean sum of the VAS scores was lower (4.39 vs. 5.37, p=0.045). After the balloon insertion, women in the paracetamol vs. placebo group showed greater maternal mobility (p=0.012), and a smaller proportion needed analgesics (31.3% vs. 66.1%, p(0.001) (figure). The maternal satisfaction score was similar between the groups (P=0.877). In multivariate analysis, advanced maternal age (p=0.034) independently decreased the VAS score. Cervical ripening, the duration from catheter insertion to delivery, and labor and neonatal outcomes did not differ significantly between the groups.

CONCLUSION: Paracetamol use prior to catheter balloon insertion was associated with reduced VAS score and reduced analgesic use after catheter balloon insertion, and improved maternal mobility compared with placebo



823 Virtual care in maternal fetal medicine: A patient and provider perspective

Megan McNitt-Johnson[1], Mariam Ayyash[2], Raminder Khangura[3]

[1]Henry Ford Hospital, Detroit, MI, [2]Columbia University Irving Medical Center, New York, NY, [3]Henry Ford Health, Detroit, MI

OBJECTIVE: The purpose of this study is to evaluate provider and patient perspectives on virtual maternal-fetal medicine (MFM) consultation visits.

STUDY DESIGN: Patient satisfaction surveys were collected between 2020 and 2023 for patients who received MFM consultation care at a tertiary health system. A satisfaction survey was also distributed to MFM specialists across the country to evaluate providers' perspective on virtual care. Univariate analysis of data included means and standard deviation, and percentages. Comparison of continuous variables was performed using a two tailed t-test.

RESULTS: Patients reported no changes (on a scale of 0-3) in how their providers explained their diagnosis (1.86+/-0.34 virtual vs 1.93 +/-0.29 in-person; p=0.149), the respect they felt the providers showed (1.92+/-0.28 vs 1.91+/-0.37; p=0.900), or the likelihood they would recommend the office (1.75+/- 0.46 vs 1.81+/-0.53; p=0.42). From the providers standpoint, 46.6% either strongly disagreed or disagreed that they were motivated to incorporate telehealth into their practice prior to the COVID-19 pandemic when virtual care was not a popular option. However, the pandemic changed this mindset as most providers (86.7%) were motivated to continue using telehealth with 66.2% liking or strongly liking telehealth. Providers also strongly felt that telehealth improves access to care (54.7%), provides adequate care (54.7%), and is convenient for patients (61.3%). The biggest concern providers had for telehealth was that it decreased rapport with their patients (34.7%).

CONCLUSION: Overall the results from this survey study showed that virtual care has been well received by patients and providers. Maternal fetal medicine as a consultation service lends itself nicely to the ability to provide patients with telehealth services without compromising patientcare. Such services are of particular benefit to patients facing barriers to social drivers of health such as transportation limitations and can be a solution to improving patient-provider communication.

824 MD vs. ML: Comparing clinician intuition to machine learning to predict mode of delivery

Melissa S. Wong[1], samira torna[1], Matthew Wells[1], Alex AT Bui[2], Kimberly D. Gregory[1]

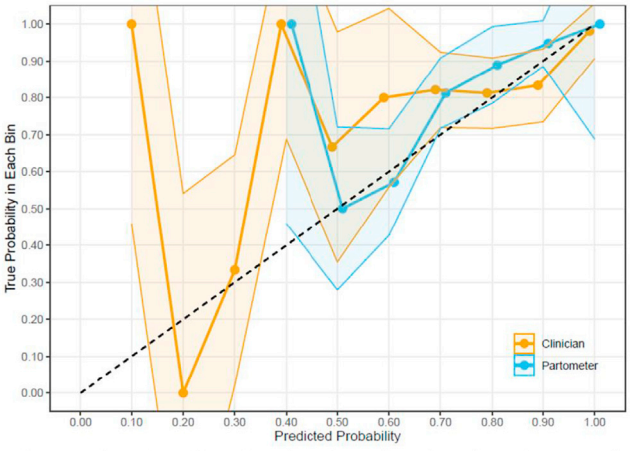
[1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]University of California Los Angeles, Los Angeles, CA

OBJECTIVE: Integration of machine learning (ML) models in healthcare remains rare. One reason is uncertainty regarding these models' predictive abilities compared to clinical intuition. We previously developed the Partometer, an ML model that passively collects both admission and intrapartum data to calculate accurate, q5 minute predictions of a patient's probability of vaginal delivery. The objective of this study is to assess if the Partometer is able to predict as well as a patient's obstetrician the probability of a vaginal delivery.

STUDY DESIGN: A prospective cohort study to evaluate calibration of the Partometer compared to clinician intuition. 42 clinicians agreed to participate. Patients admitted to these physicians, laboring and planning a vaginal delivery were the subjects for the prediction model. At 4 hours (a previously tested threshold time), we queried both the Partometer for a prediction of vaginal delivery likelihood (0 = likely cesarean to 1 = likely vaginal delivery) and concurrently asked the patient's physician (blinded to the Partometer's prediction). The calibration of each method's prediction was then compared to the final outcome by fitting a linear mixed model for the difference in the Brier scores between the two methods with random intercept to account for the predictions made by the same clinician. Calibration results were stratified for age, race and ethnicity, parity, and BMI.

RESULTS: 159 deliveries were included. Approximately half of subjects were nulliparous (55.3%), ≥35 years old (44%), and a third had BMI ≥30 (32.7%). The Partometer's predictions (mean Brier score = 0.11) were as well calibrated as clinicians' (mean Brier score = 0.12) in determining if the patient would have a vaginal delivery (estimated intercept = 0.01, p=0.343 from the mixed model). The demonstrated equivalence did not differ when stratifying by other predictive variables.

CONCLUSION: Our ML model, the Partometer, was able to predict as well as the patient's clinician the likelihood of a vaginal delivery, laying foundational work for integration of ML into obstetric decision making.



Predicted Probability	0.00	0.10	0.20	0.30	0.40	0.50	0.60	0.70	0.80	0.90	1.00
Clinician	0	1	1	3	3	3	5	28	32	30	53
Partometer	0	0	0	0	1	6	14	32	27	76	3

Figure 1: Calibration curves comparing clinician estimation of probability of vaginal delivery (orange line, shaded 95% confidence interval) to Partometer predictions (blue, shaded 95% confidence interval). The table describes the number of predictions made in each bin.

825 What are patient perspectives on research participation during labor and delivery

Melissa Cantave[1], Brianna Bradley[1], Nicole McCandless[1], Lori Atwood[1], Alicia Collins[1], Jessica Battle[1], Kristina Allen[1], Paige Wilder[1], Jamie Strickland[1], Ebony B. Carter[2], Jeannie C. Kelly[2], Nandini Raghuraman[1]

[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

OBJECTIVE: Pregnant people are underrepresented in clinical trials. Black patients only represent 5% of clinical trial participants in the US due to historic injustices that have led to research mistrust. Our objective was to assess the barriers, facilitators, and race-specific perspectives of research participation on labor and delivery (L&D).

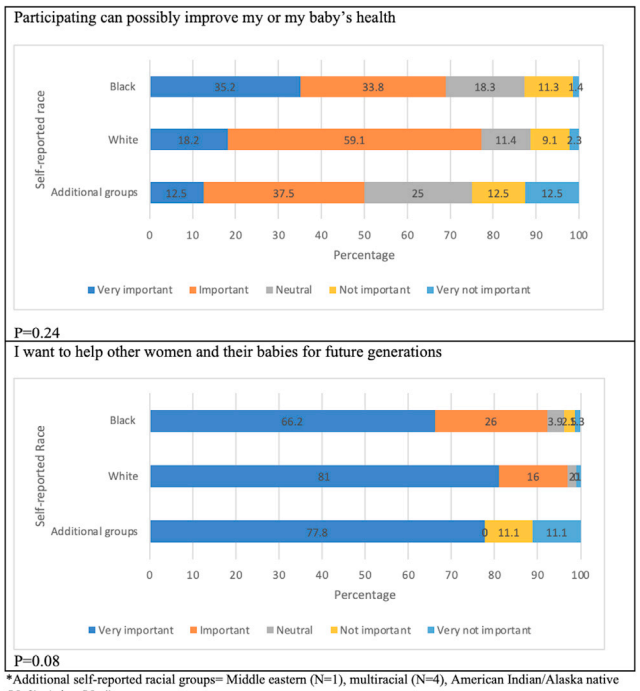
STUDY DESIGN: A prospective cross-sectional survey study of pregnant patients admitted for delivery at a single academic hospital with a high volume of L&D research studies. Inclusion criteria were all patients approached for research participation. An electronic survey was administered via tablet to patients who consented or declined L&D research participation. Descriptive and univariate analyses were used to compare characteristics of patients who consented vs declined research participation and compare motivators/barriers by self-reported race: Black/Afro-Caribbean, White, and additional groups [Middle Eastern, multi-racial, Asian, or American Indian].

RESULTS: We surveyed 221 patients (91%) who consented to research participation and 81 patients (52%) who declined. Self-identified race did not differ between consent and decline groups: 43.6% of

those who consented identified as Black, 50% White, and 6.4% as an additional group, while those who declined identified as Black (58.4%), White (33.8%), and members of an additional group (7.8%)(P=0.10). The most common reasons for declining research participation were concerns regarding health risks and confidentiality and these reasons for declining were similar across all races. Among patients who consented, the most common motivator for participation was a desire to help other pregnant people followed by the possibility of improving one's own health. These motivators were similar across all races.

CONCLUSION: Black patients are just as likely to participate in L&D research and share similar concerns regarding research participation as other racial groups. Researchers should address safety and confidentiality to maximize patient engagement, while simultaneously emphasizing how research can help other pregnant people.

Figure: Most common motivators for research participation among those who consented to research studies stratified by race



*Additional self-reported racial groups= Middle eastern (N=1), multiracial (N=4), American Indian/Alaska native (N=2), Asian (N=4)

826 Integrating maternal genotypes to improve birth weight prediction in low-risk pregnancies

Merry Joseph[1], Lisa Pappas[1], Maryam Zeinomar[1], Joseph R. Mims Jr.[1], Rafael Guerrero[2], Marvin B. Moore[1], Nathan R. Blue[3]

[1]University of Utah, Salt Lake City, UT, [2]North Carolina State University, Raleigh, NC, [3]University of Utah Health, Salt Lake City, UT

OBJECTIVE: Fetal growth potential is thought to be genetically driven, yet growth assessment tools do not utilize genetic data. Our aim was to determine whether integration of a maternal genetic risk score for birth weight (GRS-BW) would improve BW prediction in low-risk pregnancies.

STUDY DESIGN: This was a secondary analysis of a prospective observational cohort of 10,038 nulliparas who underwent detailed clinical characterization. To predict "ideal" BW, we included births without risk factors for abnormal fetal growth: preterm birth, pregestational diabetes, chronic hypertension, chromosomal abnormalities, and stillbirth. We randomly selected 60% of participants as a training set and utilized log linear regression to derive a new model for ideal BW prediction using established variables (gestational age (GA), sex) and assessing new variables with evidence for effects on growth beyond transmitted alleles: GRS-BW, prepregnancy nutrition (Healthy Eating Index-2010), exercise during pregnancy (weekly metabolic equivalents), maternal weight, and gestational weight gain. Maternal SNP arrays were used to compute GRS-BW from 84 published BW-associated loci. We compared the performance of models with and without GRS-BW in the validation set.

RESULTS: We analyzed N=7,816 births. In the training set, the "base model" (GA and sex only) had modest prediction of BW (R^2=0.598). GRS-BW, early pregnancy weight, and final pregnancy weight were independently associated with BW ($p< 0.001$ for all), and their addition to the model increased the R^2 to 0.644. Prepregnancy nutrition and pregnancy exercise were not independently associated with BW. In the validation set, the model with GA, sex, GRS-BW, and early pregnancy weight decreased the mean absolute error from 10.2% to 9.9% over the base model, while the model with all significant variables did not yield further improvement.

CONCLUSION: Integrating a maternal genetic risk score for BW marginally improved BW prediction in low-risk pregnancies. Further work is needed to determine whether genetic personalization of fetal growth potential can offer any clinical benefit.

Table 1. Validation of BW prediction models

Validation data	RMSE	RRSE	MAE
1. Base model (GA, sex)			
Ln(BW) = -1.654 + 0.443*GA -0.005*GA^2	0.133	0.622	0.102
2. Early pregnancy model: adds GRS + early pregnancy maternal weight			
Ln(BW) = -1.921 + 0.448*GA -0.005*GA^2 +0.05*GRS + 0.001*V1Wt	0.129	0.597	0.0987
3. Full model: adds final pregnancy weight			
Ln(BW) = -1.860 + 0.445*GA -0.005*GA^2 +0.045*GRS + 0.002*V1Wt - 0.001*V4wt	0.128	0.591	0.0979

The inclusion of GRS and early pregnancy maternal weight improved the prediction of BW compared to the base model as calculated by the root mean square error (RMSE), the root residual standard error (RRSE), and Mean Absolute Error (MAE), where lower error scores reflect better performance. The full model which also included final pregnancy weight did not yield further improvement.

827 Outcomes of Adolescent Pregnancies with Diabetes

Michael Richley[1], Christina S. Han[2], Lauren E. Wisk[3], Tannaz Moin[3], Timothy Copeland[4], Estelle Everett[3]

[1]University of Washington, Seattle, WA, [2]David Geffen School of Medicine at UCLA, Los Angeles, CA, [3]David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, [4]Fielding School of Public Health at UCLA, Los Angeles, CA

OBJECTIVE: National trends in obesity and metabolic syndrome have resulted in increasing rates of diabetes (DM) in pregnancy. These trends in pregestational comorbidities also affect the teenage populations. However, the potential additive effect of DM and adolescent status on pregnancy risks remains poorly elucidated. We sought to evaluate rates of adverse outcomes from adolescent pregnancies (AP) with DM.

STUDY DESIGN: We performed a retrospective cohort study using the Kids' Inpatient Database (KID) to identify pediatric admissions (≤20 years old) with ICD codes pertaining to Labor and Delivery and diabetes during five periods in the past decade (2006, 2009, 2012, 2016, 2019) in the United States. We used appropriate bivariate (e.g., chi-square) and multivariate (e.g., logistic regression) statistics to evaluate differences in obstetrics outcomes by diabetes status.

RESULTS: We identified 1,823,854 AP without DM, 3327 AP with type 1 (T1) DM, 3050 AP with type 2 (T2) DM, and 12,909 with gestational DM (GDM). Table 1 shows rates of outcomes by DM type. Compared to AP without diabetes, preterm delivery (T1: OR 4.53, 95% CI 4.09-50.2; T2: OR 3.35, 95% CI 2.96-3.78: GDM: 1.18,

95% CI 1.08-1.28), hypertensive disorders of pregnancy (T1: OR 4.32, 95% CI 3.95-4.74; T2: OR 4.18, 95% CI 3.79-4.61; GDM: OR 1.99, 95% CI 1.89-2.10), and cesarean delivery increased for all types of DM ($p< 0.001$ for all). Length of stay and cost of admission were also increased for any DM diagnosis ($p< 0.001$). Fetal anomaly rates remained unchanged for GDM, but increased for T1 and T2 DM ($p< 0.001$).

CONCLUSION: Diabetes in pregnancy potentiates the risks associated with adolescent pregnancies. This data highlights the need for targeted public health interventions to counteract both the rates of teen pregnancies and the epidemic of metabolic dysfunction in adolescent populations with rising rates of both T2DM and GDM. Public health and nutrition programs are needed to address the intersection of these epidemics.

Table 1: Adverse Pregnancy Outcomes in Adolescent Pregnancies with Diabetes

N (%)	No DM	T1DM	T2DM	GDM	p
Total N	1,823,854 (99.0%)	3,327 (0.2%)	3,050 (0.2%)	12,909 (0.7%)	--

829 Cost-effectiveness of exome and genome sequencing for low-risk pregnancies

Michal Rosenberg[1], Yariv Yogev[2], Sharon Maslovitz[3], Moshe leshno[4], Lee Reicher[5]

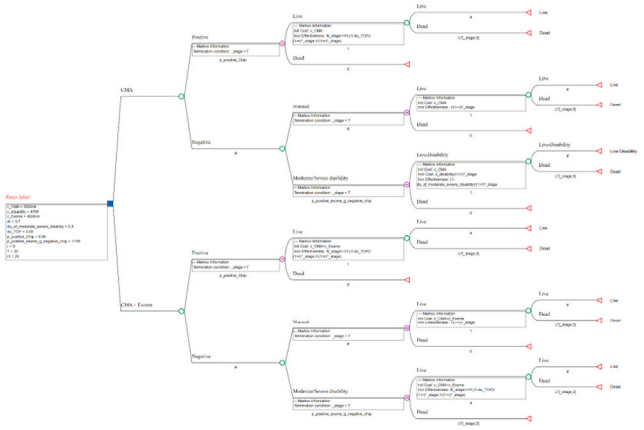
[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel, Tel Aviv, Israel, [2]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [3]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University Israel, Tel aviv, Israel, [4]Tel Aviv University, Tel Aviv, Israel, [5]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel

OBJECTIVE: Chromosomal microarray (CMA) is positive in about 1% of fetuses without a specific indication, even with apparent normal anatomy scans. Hence, CMA has become a widely accepted practice upon "parental request". However, it is evident that normal CMA analysis cannot exclude a single nucleotide variant (SNV) that is below the detection limit of CMA. Among low risk pregnancies with normal CMA 1/160 will have pathogenic variant for a severe disorder in exome sequencing (ES). We assessed the cost-effectiveness of ES in low-risk pregnancies

STUDY DESIGN: Costs, utility and quality adjusted life years (QALY) were modelled for prenatal testing with CMA or CMA+ES. Two strategies were compared using Markovian decision analysis model: (1) CMA only- abnormal result culminating in termination of pregnancy and normal test has a 1/160 chance for severe disorder. (2) ES after a negative CMA, for positive result a termination of pregnancy is conducted. Outcome measures included the QALYs after abortion, cost of CMA and ES test and the health expenses of a critically ill infant. The time horizon of the model was 20 years

RESULTS: Testing costs were $1,479 and $3,108 for CMA and CMA+ES strategies respectively. The QALY with time horizon of 20 years were 18.768 and 18.819 QALY for CMA and CMA+ES strategies respectively with incremental cost-effectiveness ratio (ICER) of 32,368$/QALY. The commonly accepted threshold for cost-effectiveness in many healthcare systems is an ICER of less than $50,000/QALY. Sensitivity analysis revealed that the time horizon and the dis-utility of moderate/sever disability of the genetic disorder has an impact on the ICER. For example, with a relatively small disutility of moderate/sever disability, the ICER is 58,822$/QALY and for a shorter time horizon of 10 years, the ICER is 80,024$/QALY

CONCLUSION: ES has the potential to be cost-effective compared with CMA alone. Our research provides data regarding the cost-effectiveness of ES in low-risk pregnancies that will become increasingly important in the near future as whole genome sequencing becomes the first-tier test in prenatal diagnosis



830 How does social vulnerability influence substance use patterns in pregnant persons with substance use disorder?

Michelle R. Petrich, Irena Kuan, Justine Keller, Marissa Turkin, Amy DeVeydt, Sophia Izhar, Samuel Kruger, Niraj R. Chavan

St Louis University, St. Louis, MO

OBJECTIVE: This study was undertaken to evaluate the impact of extremes of social vulnerability on substance use patterns in pregnant persons with substance use disorder (SUD).

STUDY DESIGN: We conducted a retrospective cohort analysis of mother-neonate dyads who received prenatal care through a specialized perinatal SUD program at a tertiary academic center from December 2019 to March 2023. Overall as well as subcomponent Social Vulnerability Index (SVI) scores were assigned based on zip code, as defined by the CDC. Information pertaining to demographic characteristics, prenatal care utilization and substance use patterns during pregnancy, were abstracted from electronic records and compared across 2 subgroups − the lowest and highest overall SVI quartiles. Student's t test and chi2 / Fisher's exact tests were used to compare continuous and categorical data, respectively. Statistical significance was set at $p\leq.05$.

RESULTS: Of 491 pregnant persons, 124 (25%) were in the lowest SVI and 106 (22%) in the highest SVI quartile. Mean SVI scores were 0.131 ± 0.099 vs 0.849 ± 0.012 (mean $\pm$ SD) in the lowest and highest quartile categories, respectively. Patients in the high SVI category had higher parity ($p< .01$), were more likely to be non-hispanic Black ($p< .01$) and have lower median income ($p< .01$).

The high social vulnerability subgroup also notably had higher rates of any current substance use (p=< .01), specifically opioid (p=.03) and cocaine (p< .01) use as well as DSM-V defined cocaine use disorder (p=.03). Patients in the high SVI group had limited prenatal care utilization as evidenced by - later presentation to prenatal care (p=.02), with fewer prenatal care visits (p=.04) which translated into higher rates of positive urine drug screens (UDS) for illicit substances upon admission to L&D (p=.05).

CONCLUSION: Pregnant persons with SUD exposed to high SVI environments are at increased risk for continued use, relapse and limited healthcare utilization. Addressing determinants of social vulnerability is a critical need for achieving perinatal health equity and addressing disparities in care.

831 Neonatal Hypoglycemia at Term: Unraveling the Impact of Maternal Glycemic Status and Fetal Growth Patterns

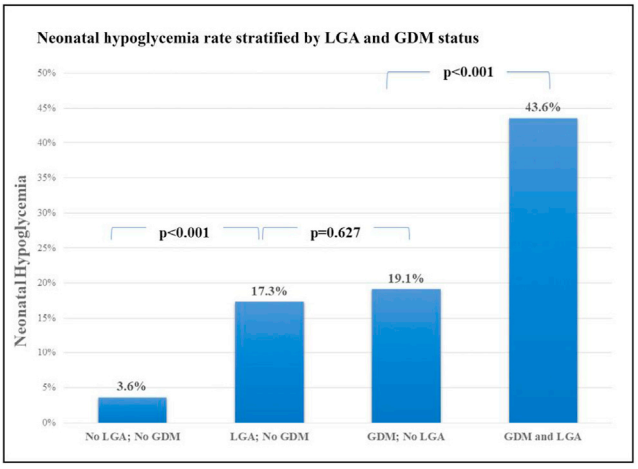
Misgav Rottenstreich[1], Howard Berger[2], Swati Agrawal[3], Homero Flores Mendoza[1], Gharid Nourallah Bekdache[1], Ipsita Goswami[1], Bryon DeFrance[1], Jon F. Barrett[4], Eran Ashwal[5]
[1]McMaster University, Hamilton, ON, [2]University of Toronto, Thornhill, ON, [3]Hamilton Health Sciences, Toronto, ON, [4]Sunnybrook Health Science, University of Toronto, Toronto, ON, [5]McMaster University, North York, Tel Aviv

OBJECTIVE: Neonatal hypoglycemia is closely linked to abnormal maternal glycemic control and aberrant fetal growth. To delve deeper into this relationship, our study aims to evaluate the influence of two significant factors - gestational diabetes (GDM) and large-for-gestational-age (LGA) status - on the risk of neonatal hypoglycemia at term.

STUDY DESIGN: This retrospective cohort study enrolled liveborn singleton pregnancies born at term (≥37 weeks) in a tertiary center (2011-2022). Exclusion criteria included pre-gestational diabetes mellitus, neonatal birthweight < 10th centile, and known fetal genetic/structural abnormalities. The study population was categorized into four distinct groups: (1) Pregnancies without GDM or LGA (birthweight > 90th centile) – reference group; (2) pregnancies without GDM, but with LGA neonate; (3) pregnancies complicated with GDM, without LGA neonate; and (4) pregnancies with GDM and LGA neonate. The primary outcome of interest was the occurrence of neonatal hypoglycemia. Multivariable logistic regressions were performed.

RESULTS: A total of 22,836 patients were included in the study, with 18,889 (82.7%) pregnancies without GDM or LGA (group 1 – reference group), 1,640 (7.2%) with LGA (group 2), 1,947 (8.5%) with GDM (group 3), and 360 (1.6%) with both GDM and LGA. Notably, the groups exhibited variations in sociodemographic and obstetrical characteristics. The rates of neonatal hypoglycemia were 3.6%, 17.3%, 19.1%, and 43.6%, without significant differences between groups 2 and 3. The multivariate analysis, which controlled for hypertensive disorders of pregnancy, gestational age at delivery, mode of delivery, and birth injury, found that both LGA and GDM were significantly and independently associated with neonatal hypoglycemia. Interestingly, when presented together, LGA and GDM exhibited a synergistic effect.

CONCLUSION: The findings underscore the importance of considering maternal glycemic control and fetal growth patterns in assessing neonatal hypoglycemia risk and highlight the need for targeted interventions and monitoring strategies to optimize neonatal health outcomes.



832 Trial of labor outcomes after knotless-barbed vs. conventional suture for closure of cesarean uterine incision

Michal Novoselsky Persky[1], Tzuria Peled[2], Ari Weiss[2], Hen Y. Sela[3], Sorina Granovsky Grisaru[2], Eran Ashwal[4], Misgav Rottenstreich[5]
[1]Hadassah Medical Center, Jerusalem, Yerushalayim, [2]Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim, [3]Shaare Zedek Medical Center, affiliated with the Hebrew University Hadassah School of Medicine, Jerusalem, Israel, [4]McMaster University, North York, Tel Aviv, [5]McMaster University, Hamilton, ON

OBJECTIVE: To assess the effect of knotless barbed suture use for uterine incision closure at cesarean delivery on maternal and neonatal outcomes during the subsequent trial of labor.

STUDY DESIGN: We analyzed data from women with singleton pregnancies who underwent their first trial of labor after cesarean delivery between 2005 and 2021 at two large obstetrical centers. Trial of labor outcomes were compared between those with knotless barbed

sutures vs. conventional sutures for uterine incision closure in their primary cesarean. The primary outcome was trial of labor failure, with secondary outcomes including adverse maternal and neonatal outcomes. Univariate analysis was performed, followed by multivariable logistic regression while adjusting for relevant covariates.

RESULTS: During the study period, 5,087 patients met inclusion and exclusion criteria. Among them, 174 (3.4%) had prior use of knotless barbed sutures, while 4913 (96.6%) had conventional sutures. Maternal demographic characteristics did not differ between the groups. Univariate analysis revealed no significant differences in trial of labor failure between women with previous knotless barbed sutures and conventional sutures use (16.7% vs. 19.9%, p=0.30), the composite adverse maternal outcome, uterine scar disruption (rupture or dehiscence), and adverse neonatal outcome rates (TABLE). Multivariable analyses confirmed no association between knotless suture use and trial of labor failure (adjusted Odds Ratio (aOR) 0.79, 95% CI 0.41-1.52, p=0.48) or the composite adverse maternal outcome (aOR 0.80, 95% CI 0.52-1.23, p=0.31).

CONCLUSION: Knotless barbed suture use for uterine incision closure at cesarean delivery is associated with comparable vaginal birth rates and maternal and neonatal outcomes during the subsequent trial of labor. Further larger studies are needed to assess the incidence of more rare outcomes and to provide more robust evidence regarding the safety and efficacy of knotless sutures in this context.

Table: Obstetric maternal outcomes among the study groups

	Conventional suture use N=4913	Barbed suture use delivery N=174	p value
Primary outcomes			
TOLAC failure (intrapartum cesarean delivery)	976 (19.9%)	29 (16.7%)	0.30
Secondary outcomes			
Composite adverse maternal outcomes*	984 (20.0%)	32 (18.4%)	0.60

Encephalopathy	10 (0.2%)	0 (0%)	0.55
Intracranial hemorrhage	26 (0.5%)	0 (0%)	0.34
Birth asphyxia	35 (0.7%)	1 (0.6%)	0.83

Data are mean ± standard deviation; number (%); ICU Intensive Care Unit. TOLAC Trial of labor after cesarean. NICU Neonatal intensive-care unit, TTN Transient tachypnea of the newborn.
* Composite of adverse maternal outcome was defined as involving one or more of the following: uterine rupture or uterine scar dehiscence, postpartum hemorrhage, blood products transfusion, maternal ICU admissions, prolonged hospitalization (≥ 7 days after cesarean >5 days after vaginal delivery), chorioamnionitis, puerperal fever, laparotomy, and hysterectomy. ** Hospitalization > 7 days after cesarean >5 days after vaginal delivery

833 Outpatient versus inpatient management of premature prelabour rupture of membranes: A systematic review and meta-analysis

Monica L. Williamson[1], Zi Yang (Susan) Dong[1], Rohan D'Souza[2], Romina Brignardello-Petersen[3], Stefania Ronzoni[4]
[1]University of Toronto, Toronto, ON, [2]Center for fetal care and high-risk pregnancy, University Hospital of Chieti, Chieti, Emilia-Romagna, [3]McMaster University, Hamilton, ON, [4]Sunnybrook Health Sciences Centre, Toronto, ON

OBJECTIVE: We aimed to compare the neonatal, obstetric, and maternal outcomes associated with outpatient management of pregnancies complicated by premature prelabour rupture of membranes (PPROM) against inpatient management.

STUDY DESIGN: We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) and cohort studies. We searched MEDLINE, EMBASE, Cochrane Database and Central Register, and PubMed from 1990 until July 2023 with no language restrictions for eligible studies. Random effects model was used for meta-analysis. The GRADE approach was used to assess quality of evidence.

RESULTS: Of 2,825 records identified, 14 publications (two RCTs, twelve cohort studies) were included, representing 6,010 patients. Management protocols were varied, generally including brief initial hospitalization, strict outpatient eligibility criteria, and surveillance with lab and ultrasound investigations. The RCTs were judged to have very low certainty of evidence due to small sample sizes and limited details available regarding their protocols. Based on data from cohort studies, outpatient management may be associated with lower rates of respiratory distress syndrome (RDS) (RR = 0.63 [0.52 to 0.77, very low certainty of evidence]), longer latency (MD 8.78 days, [2.29 to 15.26 days, low certainty of evidence]), higher gestational age (GA) at delivery (MD = 7.70 days [2.02 to 13.38 days, low certainty of evidence]), and lower rates of histologic chorioamnionitis (RR 0.74 [0.62 to 0.89, low certainty of evidence]) without meaningfully increased risks of other adverse neonatal, obstetric, or maternal outcomes.

CONCLUSION: Outpatient management may be a viable option for select patients affected by PPROM. The meta-analyzed data indicated that outpatient care may be at least as safe as inpatient management, with no demonstrated difference in risk of severe maternal, obstetric, or neonatal outcomes, and with potential benefits in reduced rates of RDS, longer latency, higher GA at delivery, and lower rates of histologic chorioamnionitis. This opportunity should be explored further in RCTs.

834 Vacuum delivery for "Maternal Exhaustion" has distinctive characteristics

Naama Farago[1], Gal Bachar[2], Yoav Siegler[3], avia Amir[4], Yuval Ginsberg[5], Nadier ghanim[4], Dana Vitner[6], Nizar Khatib[7], Ron Beloosesky[8], Zeev Weiner[1], Yaniv Zipori[9]
[1]Rambam Medical Health Campus, Haifa, HaZafon, [2]Rambam Healthcare Campus, Haifa, Hefa, [3]Rambam Medical Center, Haifa, Hefa, [4]Technion, Haifa, HaZafon, [5]Rambam Health Care Campus, Haifa, HaZafon, [6]Rambam Medical Health Campus, Toronto, ON, [7]Rambam health care campus, Haifa, Israel, Acre, Hefa, [8]Harbor UCLA Medical Center, Los Angeles, CA, [9]Rambam Healthcare Campus, BINYAMINA, Hefa

OBJECTIVE: Prolonged labor can be physically and emotionally exhausting and is associated with an increased risk of vacuum extraction (VE). Effective pushing and cooperation throughout the VE procedure are crucial for a favorable outcome. We aimed to characterize women at risk for VE indicated for "Maternal Exhaustion."

STUDY DESIGN: A retrospective cohort study of all singletons, term VEs in a tertiary center between 2011 and 2022. Patients were allocated into two groups based on the indication for VD, exhaustion (group 1) versus non-exhaustion (group 2). Exhaustion was based on the operator's discretion. The primary outcome was to investigate potential risk factors for exhaustion before VE.

RESULTS: We analyzed 2,950 VEs; 819 (27.8%) were indicated for exhaustion and 2,131 (72.2%) for non-exhaustion (Table 1). The features of the VE procedure, such as the number of pulls or detachments and the duration of the procedure, were not different between the groups. In univariate analysis, exhausted mothers were more likely to be nulliparous (75% vs. 71%, p=0.028), have diabetes in pregnancy (7.7% vs. 5.4%, p=0.047), use regional anesthesia (92.4% vs. 89.1%, p=0.006), have a longer duration of premature rupture of membranes [9.8 h (5.5-19.6) vs. 8.3 h (4.12-15.7), p< 0.001], longer second-stage duration (2.86 h ± 1.2 vs. 2.54 h ± 1.3, p< 0.001), and spend an extended time in the labor-ward [15.8 h (11.0-22.2) vs. 13.4 h (9.4-19.4), p< 0.001]. Using multivariable logistic regression, the duration of the second stage was the most statistically significant variable to predict "Maternal Exhaustion." as an indication for VE, an increment of 27.4% with every hour in the second stage (OR 1.274 [95% CI 1.146-1.416]).

CONCLUSION: Longer second-stage duration and extended time in the delivery room increase the risk of VE for the indication of maternal exhaustion. Better identification and support for prone gravidas may decrease VE rates and improves the birth experience.

Table 1. Characteristics of the groups based on Exhaustion vs. Non-Exhaustion in women undergoing Vacuum delivery.

Variable	Exhausted (n=819)	Non-Exhausted (n=2131)	P-value*	Odds Ratio	95% CI Lower	95% CI Upper

835 Optimizing the 4th Trimester: Factors That Drive Attendance to a Comprehensive Postpartum Cardiometabolic Clinic

Natalie E. Poliektov[1], Asmita Gathoo[1], Kaitlyn Stanhope[1], Suchitra Chandrasekaran[2]

[1]Emory University School of Medicine, Atlanta, GA, [2]Emory University School of Medicine, Decatur, GA

OBJECTIVE: Gestational adverse metabolic outcomes (AMO), including hypertension (HTN) & diabetes (DM), impact maternal cardiometabolic (CM) health. The current practice of a ~6-week (wk) postpartum (PP) visit is insufficient to address all necessary long-term issues. We initiated a 12-wk Postpartum Cardiometabolic Clinic (PPMC) for patients with a gestational AMO to provide comprehensive/individualized guidance & noted that attendance increases follow-up with primary/specialty care. We therefore investigated what factors impact attendance to PPMC.

STUDY DESIGN: This retrospective cohort study included those with a gestational AMO referred to PPMC between 8/22-7/23. We compared demographic/CM factors between attendees/non-attendees of PPMC. Continuous variables were compared using Wilcoxon Rank Sum Tests. Categorical variables were compared using Chi-Square/Fisher's exact tests. Log binomial regressions calculating adjusted risk ratios (ARR) were performed.

RESULTS: 150 patients were referred to PPMC. Attendees were more likely to be referred > 2wks PP; non-attendees were more likely to be referred from L&D *(Table 1)*. Attendees were more likely to have a PP readmission *(26.9% vs. 10.5%, p< 0.05)* & routine PP visit *(90.3% vs. 70.2%, p< 0.01)* compared to non-attendees. Those with preeclampsia (PRE) w/ severe features (SF) were more likely to attend vs. no-show PPMC *(75.5% vs. 25.5%, p< 0.05)* whereas those with gestational HTN or PRE w/o SF were less likely to attend *(33.3% vs 66.6%, p< 0.01)*. After controlling for confounders (age, race, education, insurance & parity), those w/ a routine PP visit or readmission had a 1-2-fold higher likelihood of attending PPMC *(**ARR 1.9**, 95% CI 1.1-3.3, p=0.02; **ARR 1.3**, 95% CI 1.0-1.8, p=0.04)*.

CONCLUSION: Understanding factors impacting attendance to PP care is imperative. Here we demonstrate that referral timing & routine PP visit attendance significantly affect PPMC attendance. Our innovative data underscore the need to investigate factors driving these differences in PP clinic attendance as the 4th trimester is a critical gateway in the continuum of long-term maternal health.

Table 1: Characteristics of persons who attended vs. did not attend a comprehensive Postpartum Cardiometabolic Clinic.

	Overall (n=150)	Attended PPMC (n=93)	Did not attend PPMC (n=57)	p-value

836 Ultrasonographic fetal lung texture analysis in twin and singleton gestations

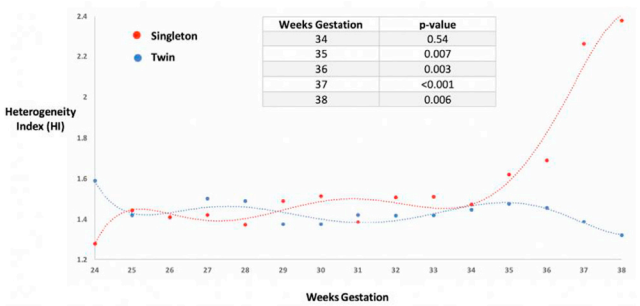
Nathan A. Keller[1], Luis A. Bracero[2], Matthew J. Blitz[3], Christina Karras[3], Insaf Kouba[3], Frank I. Jackson[3], Sleiman R. Ghorayeb[3]

[1]Zucker School of Medicine at Hofstra of Northwell, Lindenhurst, NY, [2]South Shore University Hospital, Bay Shore, NY, [3]Zucker School of Medicine at Hofstra of Northwell, Bay Shore, NY

OBJECTIVE: The objective of this study was to determine whether fetal lung ultrasound heterogeneity index (HI) differs between twin and singleton gestations during the late second and third trimesters.

STUDY DESIGN: This prospective cohort study included women with singleton and twin gestations who had scheduled medically indicated ultrasound examinations at 24 weeks gestation or later in a large healthcare system from 2017 through June 2023. Grayscale fetal lung images were acquired with Voluson E8 and E10 ultrasound machines (GE Healthcare, Milwaukee, WI) using convex array transducers with a frequency range of 3-7.5 MHz. A region of interest was selected in each fetal lung image with a transverse view at the level of the 4-chamber heart excluding areas with shadow. HI was determined with MATLAB software (The Math Works, Inc, Natick, MA). This program converts the intensity of each pixel to a binary 1 (white) and 0 (black), and then calculates the percentage of white pixels with respect of the total number of pixels. Ineligible patients included those with fetal malformations and screening tests suggestive of aneuploidy. Exclusion criteria included low image quality.
RESULTS: During the study period, lung images were analyzed from 240 twin fetuses and 425 singleton fetuses. In total 2,151 images were analyzed. The fetal lung HI was determined for each collected image. The mean HI at each gestational week was compared between singleton and twin fetuses with two sample t-tests. Fetal lung HI throughout gestation for both groups are shown in Figure 1. There is a statistically significant divergence in mean HI beginning at 35 weeks gestational age between singleton and twin fetuses such that HI sharply increases in singleton fetuses.
CONCLUSION: A significant divergence in HI was observed between twin and singleton fetuses at and beyond 35 weeks of gestation. This finding may reflect previously reported differences in fetal lung maturity between twins and singletons during these gestational ages.

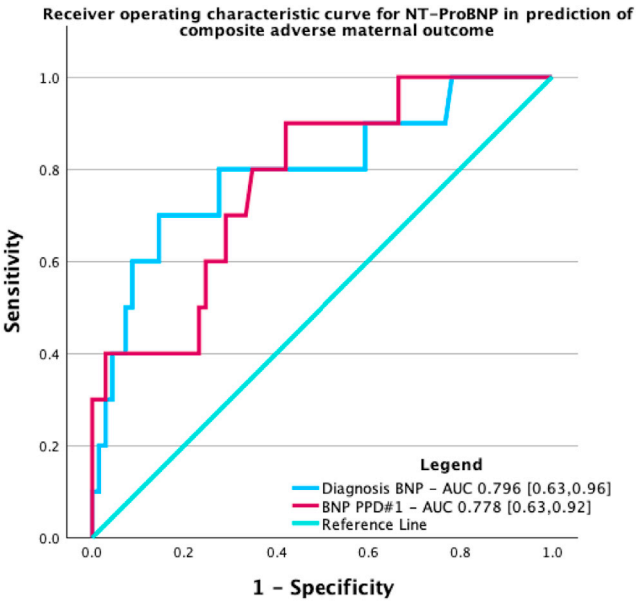
Figure 1 - Average fetal lung HI for twins and singletons from 24 to 38 weeks gestation



837 NT-ProBNP in preeclampsia with severe features as a predictor of adverse maternal cardiac outcomes

Neel Iyer[1], Julie Gomez[2], Indranee Rajapreyar[2], Rupsa C. Boelig[1], Huda B. Al-Kouatly[3]
[1]Thomas Jefferson University Hospital, Philadelphia, PA, [2]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA, [3]Thomas Jefferson University, Philadelphia, PA

OBJECTIVE: N-terminal brain natriuretic peptide (NT-ProBNP) is secreted by cardiac myocytes when exposed to excess myocardial stretching or ischemia and is predictive of heart failure in non-pregnant adults. We aimed to evaluate the predictive value of NT-ProBNP for adverse maternal cardiac outcomes among patients with preeclampsia with severe features (PreESF).
STUDY DESIGN: This was a prospective cohort study of singleton pregnant patients diagnosed with PreESF from 1/2022 to 7/2023. Patients with pre-existing cardiac diseases were excluded. NT-ProBNP was drawn at diagnosis and postpartum day one (PPD#1). The primary outcome was a composite of peripartum cardiomyopathy (PPC) or postpartum readmission (PPR) within 6 weeks for a preeclampsia-related complication. Diagnosis and PPD#1 NT-ProBNP levels were analyzed using multivariable logistic regression with backwards selection and receiver operating characteristic curves to evaluate the association and predictive value. Maximum Youden indices were calculated to identify optimal NT-ProBNP cutoffs.
RESULTS: 80 patients were included. Mean maternal age was 31.8±7.1 years and mean gestational age at preeclampsia diagnosis was 34.7±3.2 weeks. Sixty percent identified as Black (n=48) and 15% (n=12) as Hispanic. Ten patients (12.5%) experienced the composite outcome: PPC n=6 and PPR n=4. Multivariable logistic regression identified diagnosis NT-ProBNP (p=0.02) and PPD#1 NT-ProBNP (p=0.04) as associated with the composite outcome. Diagnosis NT-ProBNP and PPD#1 NT-ProBNP were similarly predictive of outcome with an area under the curve (AUC) of 0.796 (p=0.0001, 95% CI [0.63,0.96]) and 0.778 (p=0.0001, 95% CI [0.63,0.92]) respectively. Youden index for diagnosis NT-ProBNP was 274.5 pg/mL (sensitivity 70%, specificity 81.2%, PPV 41.1%, NPV 95.2%) and for PPD#1 NT-ProBNP was 102 pg/mL (sensitivity 90%, specificity 58%, PPV 23.7%, NPV 97.6%).
CONCLUSION: Elevated NT-ProBNP at diagnosis or after delivery of PreESF is predictive of adverse maternal cardiac outcomes and may be a useful marker to identify patients in need of additional cardiac evaluation and follow-up.



838 Transvaginal/Transvesical Ultrasound (TVUS) to Diagnose Placenta Accreta Spectrum (PAS), its Severity & to Predict Blood Loss

Neha Das Agarwal[1], Michal Fishel Bartal[2], Jennie Coselli[3], Eleazar E. Soto Torres[1], Edgar Hernandez Andrade[1], Dejian Lai[1], Ashley Salazar[1], Sami Backley[3], Farah H. Amro[3], Anthony Johnson[1], Jimmy Espinoza[4], Eric P. Bergh[3], Rosa Guerra[1], Vahed Maroufy[1], Baha M. Sibai[5], Sean C. Blackwell[6], Ramesha Papanna[1]
[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer,

Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX, [3]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [4]McGovern Medical School at the University of Texas Health Science Center Houston, The Fetal Center-Children's Memorial Hermann Hospital, Houston, TX, [5]Hermann Memorial Hospital, Houston, TX, [6]Children's Memorial Hermann Hospital, Houston, TX

OBJECTIVE: Diagnosing PAS disorders and their severity using imaging technology remains a challenge. TVUS (full bladder) offers a unique opportunity to evaluate the anatomy, including cervical region involvement and vascular flow. Our study developed and evaluated semi-quantitative score, based on TVUS, to accurately diagnose PAS and predict blood loss during surgery in pregnant women with clinical and ultrasound evidence of PAS.

STUDY DESIGN: A prospective cohort study was performed from 2018 -2023 of patients referred to a quaternary center with suspected PAS on 2D ultrasound and clinical suspicion. A pre-determined scoring system was applied based on uterine wall, arterial vascularity, and cervical involvement. Each of three categories was scored 0-3, yielding a cumulative score of 0-9. Patients with score of 0 were recommended c-section with placenta removal. Scores from 1-9 were managed on multidisciplinary discussion and patient preference among the following options: c-section with placenta removal, c-section with placenta in-situ (conservative) with or without interval hysterectomy, or c-hysterectomy. Multivariate linear regression analysis was performed to predict blood loss using evaluated risk factors and PAS scoring.

RESULTS: 73 patients were evaluated and categorized by score (Table1). These categories differed significantly in terms of management type, estimated blood loss, ICU admission and hospital length of stay. All patients in Category 0 (score 0) were successfully managed as c-section with placenta removal. On multivariate analysis, Category 3 (score 7-9) and c-hysterectomy were associated with significantly higher blood loss; prior history of c-section deliveries was not associated with estimated blood loss (EBL). Excluding the conservative management group, EBL was directly correlated with the scoring category.

CONCLUSION: Our TVUS-based scoring accurately diagnosed PAS. Cases with a score of 0 had a successful c-section with placenta removal. The complexity of management, blood loss and morbidity increased with higher scores.

Table 1. Comparison of demographics and outcomes based on PAS Categories.

Variables	Category 0 (PAS 0) (n =11)	Category 1 (PAS 1-3) (n=17)	Category 2 (PAS 4-6) (n=27)	Category 3 (PAS 7-9) (n=18)	P value
GA at delivery (weeks)	37.2 (34-40)	35 (26-39)	34.3 (25-38)	32.5 (26-35)	<0.001
C-section with removal of placenta	11 (100%)	10 (58.8%)	5 (18.5%)	0 (0%)	<0.001
C-section with conservative management	0 (0%)	4 (23.5%)	6 (22.2%)	9 (50%)

839 Unexpected UDS: Impact on Neonatal and Maternal Outcomes in Opioid Use Disorder

Neil Bharat Patel[1], John O'Brien[1], Nancy Hendrix[1], Cynthia Cockerham[1], Gregory Hawk[1], Abigail Leonhard[1], Asmita Shrestha[1], Barbara V. Parilla[2]

[1]University of Kentucky, Lexington, KY, [2]UK Albert B. Chandler, Lexington, KY

OBJECTIVE: Evaluate the effects of unexpected Urine Drug Screens (UDS) on neonatal and maternal outcomes in pregnant patients on Medications for Opioid Use Disorder (MOUD).

STUDY DESIGN: Prospective cohort of pregnant patients on MOUD enrolled in a multidisciplinary treatment program between 2015 and May 2023. Patients had at least 2 prenatal visits with at least two UDS. Experimental group contained at least 2 unexpected UDS outcomes, while the control group had at least 2 expected UDS outcomes. Primary outcomes assessed were Neonatal Opioid Withdrawal Syndrome (NOWS). Secondary outcomes included prenatal care compliance, maternal obstetric outcomes, and birth weight. Categorical outcomes are compared between groups using Fisher's exact tests. Quantitative data were analyzed using Poisson regression or two-sample t-tests with transformations included as appropriate.

RESULTS: 266 patients met the inclusion criteria. 51 of 266 (19%) were on Buprenorphine prior to pregnancy vs 215 of 266 (81%) were started during pregnancy. 68 of 266 (26%) had at least 2 unexpected UDS outcomes vs 198 of 266 (74%) had expected UDS. The median buprenorphine dose at delivery was 12 mg [IQR: 8 to 16] vs 12 mg [8 to 16], P=.654. Demographic data was similar including overdose history.

Hypertensive disorders were higher in the unexpected UDS group at 26.5% vs 15.2%, P=.044. NOWS treatment was similar in unexpected UDS at 56.7% vs 46.7%, P=.161, although the Finnegan score was higher in unexpected UDS 13.3 +/- 3.9 vs 12.1 +/- 3.9, P=.034. Prenatal and postpartum visits were lower in unexpected UDS group 14.6+/-7.9 v 18.9+/-7.1, P<.0001. Patients with unexpected UDS were less likely to be on buprenorphine at the time of delivery 77.9% v 94.4%, P=.0005. Rooming in and breastfeeding rates at discharge were lower in unexpected UDS at 45.3% v 64%, P=.012 and 7.4% vs 22.8%, P=.004 respectively, Table.

CONCLUSION: Unexpected UDS results in pregnant patients with OUD were associated with higher rates of hypertensive disorders, lower prenatal and postpartum visit attendance, fewer on MOUD at delivery, and lower rates of mother-infant bonding.

Table 1. Maternal and Neonatal delivery data with P value calculated by Fisher's exact test or two-sample t-test.

	Unexpected (n=68)	Expected (n=198)	P value

840 How Much Oxytocin Do We Give? Cumulative Doses for Labour Acceleration

Nicola O. Riordan, Michael Robson, Declan Keane
National Maternity Hospital, Dublin, Ireland

OBJECTIVE: Recent publications call for more detailed data regarding the cumulative doses of oxytocin (CDOs) given over the course of labour, to increase our understanding of the drug. We aimed to evaluate the CDOs given for labour acceleration with a high dose regimen (HDR), to compare these to CDOs possible within low dose regimens (LDRs), and to evaluate if HDRs translate to high CDOs.

STUDY DESIGN: We conducted a retrospective cohort study of all Robson Group 1 patients over a one-year period who had been commenced on oxytocin for labour acceleration (augmentation) in the first stage (n=414). Labours were accelerated if progress was < 1cm/hour over a two-hour period. A HDR of oxytocin was given, commencing at 5mU/min and increasing by 5mU every 15 minutes to a maximum of 30mU/min. CDOs were manually calculated to account for all dose titrations, duration of each titration and labour duration. The CDOs given with our HDR were then compared to those permissible within a LDR, commencing at 2mU/min and increasing by 2mU every 30 mins to a maximum of 15mU/min.

RESULTS: CDOs spanned a wide, right skewed range (75 - 17,325mU) when recorded as a continuous variable. The mean (SD) CDO for our study cohort was 3006mU (±2992mU). 0.9% (4/414) of the population reached the maximum CDO permitted by the HDR. 57.2% (237/414) of the CDOs given were within the range permitted by LDRs. At 8-hours of oxytocin acceleration the mean (SD) CDO was 4468mU (±2729mU), less than 1/3 of the maximum permitted dose of 13,280mU over that duration.

CONCLUSION: Previous studies of CDOs comment on maximum permitted doses of oxytocin within HDR and LDRs, rather than true doses given. Our study shows that using a HDR, the true CDO given falls within the range of doses permitted by LDRs for the majority of cases. We report a mean CDO of 3006mU, which is lower than previous studies of with LDRs which quote 3437mU as the mean CDO for Group 1 labour acceleration. We conclude that CDOs reflect an institutions readiness to downward titrate, and safe, judicious use of oxytocin. Without knowledge of CDOs, debate regarding HDR and LDR is trivial.

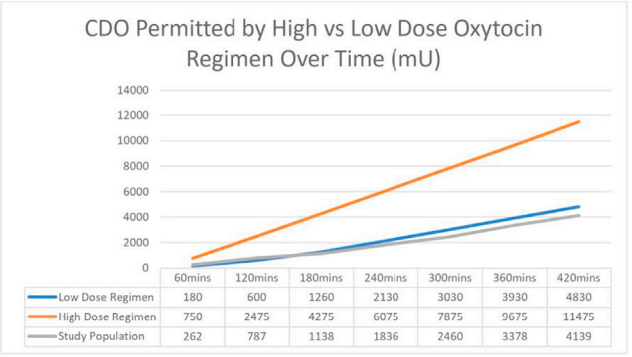

Figure 1. Maximum permitted CDO in a high vs a low dose oxytocin regimen, and CDO given in a high dose regimen (i.e. study population).

841 To Push or Not to Push: Passive Descent and the Second Stage

Nicola O. Riordan, Michael Robson, Declan Keane
National Maternity Hospital, Dublin, Ireland

OBJECTIVE: Guidelines vary widely regarding management of the second stage (SS), with recommendations focusing on duration of active pushing (DOAP) and passive descent (PD). We evaluated the impact of oxytocin on DOAP and mode of delivery. We aimed to evaluate if management in the SS should vary depending on first stage (FS) progress/oxytocin use.

STUDY DESIGN: This was a retrospective cohort study of 300 SS Robson Group 1 patients in an Irish tertiary referral centre. The study had three arms, 100 consecutive patients were recruited to each arm: oxytocin acceleration in the FS, oxytocin de novo in the SS, and no oxytocin. Patients were grouped according to PD or active pushing. DOAP and mode of delivery were recorded.

RESULTS: Operative intervention rates were higher, and DOAP was longer for those with PD, p=.00, with an increase of 16.8 ± 2.7 minutes (95% C.I. = 11.5 − 22.1). When analyzed in terms of oxytocin use, the findings remained significant only for those with oxytocin acceleration in the FS.

Those with PD had higher rates of malposition (OP/OT) (22.3%) than those immediately pushing (18.7%). This did not reach statistical significance (p=.46). Station was higher for those with PD (p= .00). Adjusting for these confounding factors, both oxytocin use in the FS (p=.04) and PD (p=.00) predicted the duration of AP, explaining for 14% of the variance in DOAP (r2 = .14).

CONCLUSION: Our findings agree with previous studies demonstrating a longer duration of the second stage has a significant impact on the

mode of delivery. Our findings are novel in their differentiation by oxytocin use. The impact of PD on mode of delivery only retains significance for those with oxytocin in the FS, suggesting that for this cohort, limiting the duration of the SS is more important. PD may therefore be less beneficial for those with a dystocic FS and should the position and station of the vertex be suitable, AP should be encouraged. This may also limit pelvic floor damage secondary to both a prolonged FS and SS.

842 Maternal Morbidity and Health Services Outcomes Following Combined Vaginal-Cesarean Twin Births

Nicole Krenitsky[1], Anna Farooqi[2], Hooman Azad[3], Russell S. Miller[3], Lynn Simpson[3], Mary D'Alton[4], Alexander M. Friedman[5], Timothy Wen[6]

[1]Columbia University Irving Medical Center, NewYork-Presbyterian, New York, NY, [2]Texas Tech University Health Sciences Center, Amarillo, TX, [3]Columbia University Irving Medical Center, New York, NY, [4]Columbia Presbyterian Medical Center, New York, NY, [5]Columbia University, New York, NY, [6]University of California, San Francisco (UCSF), San Francisco, CA

OBJECTIVE: Maternal complications and healthcare costs of combined twin deliveries are not well defined. We sought to assess national trends and costs of combined deliveries and to analyze their association with adverse maternal outcomes.

STUDY DESIGN: Monochorionic (MCDA) and dichorionic (DCDA) diamniotic twin births were abstracted from the 2016-2020 Nationwide Readmissions Database. Mode of delivery (MOD) was defined using procedure codes and combined deliveries (CoD) as having both vaginal (VD) and cesarean delivery (CD) codes in the same hospitalization. CoD trends analyses by twin type were conducted using joinpoint regression to estimate the average annual percent change (AAPC) with 95% confidence intervals (CI). Adjusted logistic regression models were performed to evaluate associations between MOD and non-transfusion severe maternal morbidity (ntSMM) and other clinical outcomes adjusting for demographic, clinical, and hospital factors. Mean hospitalization costs and postpartum length of stay (ppLOS) were stratified by MOD.

RESULTS: Of 277,172 twin births, 72,536 (26.2%) resulted in VD, 8,845 (3.2%) in CoD, and 195,791 (70.6%) in CD. From 2016 to 2020, CoD prevalence for MCDA twins remained stable at 2.3% (AAPC 0.2%, 95% CI -2.6%, 3.0%) while decreasing significantly for DCDA twins from 3.6% to 3.2% (AAPC -2.4%, 95% CI -2.9%, -2.0%). CoD conferred higher odds of ntSMM (aOR 1.88, 95% CI 1.51- 2.34), transfusion, reoperation, wound infection, critical care interventions and intrauterine infection compared to VD (Table). Compared to CD, CoD were at higher odds of transfusion (aOR 1.63, 95% CI 1.44, 1.84), postpartum hemorrhage (aOR 1.50, 95% CI 1.34, 1.68), intrauterine infection (aOR 2.38, 95% CI 2.03, 2.79) and dilation and curettage (aOR 1.61, 95% CI 1.02, 2.53). Among the three modes of delivery, mean total costs adjusted for inflation were highest for CoD at $13,838 ($8,016 VD, $11,589 CD) with no difference in CoD versus CD ppLOS (3.3 days).

CONCLUSION: Combined vaginal-cesarean twin births are associated with higher odds of severe maternal complications and lead to higher hospitalization costs.

Table: Maternal morbidity of twin births in the United States stratified by mode of delivery

	Combined Delivery				Cesarean Delivery

*Reference group = vaginal twin deliveries. Adjusted for maternal age, payer, median income quartile, twin type, gestational age, hospital location and teaching status, hospital size, year of delivery, and clinical factors (hypertension, gestational and pre-gestational diabetes, obesity, history of cesarean delivery, placental abruption). SMM = severe maternal morbidity, DVT = deep vein thrombosis, PE = pulmonary embolism.

843 Patient Perception of Gestational Diabetes Mellitus And Its Influence on Adherence to Postpartum Diabetes Screening

Nicole Feigenblum[1], Tamar Itzkowitz[2], Colette Knight[3], Toni Isabella[4], Christine Moore[3], Antonia F. Oladipo[3]

[1]Hackensack University Medical Center, Englewood, NJ, [2]Hackensack Meridian School of Medicine, Nutley, NJ, [3]Hackensack University Medical Center, Hackensack, NJ, [4]Molly Diabetes Education Center, Maywood, NJ

OBJECTIVE: Patients with Gestational Diabetes Mellitus (GDM) are at increased risk for developing Type II Diabetes Mellitus (T2DM). Postpartum screening for T2DM is lacking and presents challenges, with less than 50% of patients undergoing recommended follow up. We aim to understand risk perception and knowledge surrounding screening adherence to T2DM.

STUDY DESIGN: An IRB-approved, prospective study between August 1, 2022 to July 31, 2023 surveying patients diagnosed with GDM in a single hospital system. Data was collected at three timepoints - twice at antenatal diabetes education appointments and once postpartum prior to discharge from hospital. The survey was adapted from the Risk Perception Survey for Developing Diabetes (RPS-DD).

RESULTS: A total of 136 individuals participated in the study at least one time point. Twenty-two of these participants completed the survey at two time points. A total of 158 surveys were collected. Prior to study participation, 51.3% of patients had formal diabetes education. Patients believed that factors associated with T2DM development include previous GDM (66.9%), family history of T2DM (56.3%), and lifestyle factors (25.2%). Knowledge on racial discrepancies and diabetes diagnosis was limited, with only one third of respondents stating that non-white races (including Asian American, Black, Hispanic, and American Indian) are associated with increased risk of developing T2DM. Additionally, in comparison to women in their age group, 74.7% of GDM patients believe they are more likely to develop T2DM. Interestingly, only 50.7% believe they have increased immediate risk of developing T2DM over the next 10 years.

CONCLUSION: Understanding patient's perception and ensuring that we continue to educate and raise awareness surrounding their immediate and long-term risks related to development of T2DM is paramount. Education should highlight the increased risk of T2DM development in the 3-10 years post delivery. Further research is needed to understand how risk perception influences screening adherence.

844 Timeliness of diagnosis and treatment of postpartum hypertensive disorders in the Emergency Department

Nicolina Smith[1], Gabrielle Ezell[2], Mary Condon[2], Katherine Joyce[2], John Joseph[2], D'angela S. Pitts[2]
[1]Henry Ford Health System, Detroit, MI, [2]Henry Ford Health, Detroit, MI

OBJECTIVE: This study aims to assess the time to diagnosis and treatment of hypertensive disorders during the postpartum period in the Emergency Department, particularly focusing on potential disparities in care and identify areas for quality improvement.

STUDY DESIGN: The study was conducted at a multi-centered large medical institution in the metro-Detroit area, analyzing postpartum ED visits from November 2015 to December 2022. The primary analysis focused on the time elapsed between severe range blood pressure readings and the administration of antihypertensives. Secondary analyses included the presence of essential laboratory work up such as complete blood count, complete metabolic panel, urine protein and creatinine.

RESULTS: Among the 430 women who presented to the ED during the postpartum period with hypertension, 72.6% had preeclampsia with severe features, and 13% had chronic hypertension with superimposed severe preeclampsia. Of the patients with severe hypertension, only 72% received a complete blood count, 66% underwent evaluation of creatinine and liver profile, and 4% had a urine protein ordered. The average time from severe range blood pressure to antihypertensive administration was 189 minutes for Black patients and 370 minutes for White patients. There were no statistically significant differences in the time of first blood pressure reading, laboratory evaluation, or treatment of severe range blood pressure between racial groups.

CONCLUSION: This study identified the most significant area for improvement in the timely administration of antihypertensive medication following severe range blood pressure readings. Additional areas for improvement were observed in ordering essential laboratory tests to assess the severity of preeclampsia. Surprisingly, our institution demonstrated equal expeditious care for both white and black patients, contrary to existing literature indicating potential disparities. Based on these findings, a targeted quality improvement plan will be implemented to enhance the identified areas of concern.

845 Mode of delivery and postpartum depressive symptoms among nulliparous people with antenatal depression

Nina K. Ayala[1], Lauren Schlichting[2], Emily S. Miller[3], Anna Whelan[4], Martha B. Kole-White[1], Adam K. Lewkowitz[5]
[1]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [2]Hassenfeld Child Health and Innovation Institute of Brown University, Providence, RI, [3]Alpert Medical School of Brown University and Women & Infants Hospital of Rhode Island, Providence, RI, [4]Grafton, MA, [5]Warren Alpert Medical School of Brown University, Women & Infants Hospital Rhode Island, Providence, RI

OBJECTIVE: Antenatal depression (AD) and cesarean delivery (CD) are both independent risk factors for postpartum depression (PPD); however, it is unknown whether mode of delivery impacts progression from AD to PPD.

STUDY DESIGN: The 2016-2019 Multistate Pregnancy Risk Assessment Monitoring System (PRAMS) data was used to identify first-time parturients with AD (reported depression in the 3 months prior to or at any point during pregnancy). Mode of delivery was obtained through the birth record. The primary outcome was self-reported PPD symptoms (positive response on the PHQ-2) and was compared between those undergoing a spontaneous vaginal delivery (SVD) to those who underwent operative birth (CD plus operative vaginal delivery). Maternal demographics, pregnancy characteristics and delivery characteristics were compared between groups. Population-weighted multivariable regression was performed, adjusting for a priori confounders.

RESULTS: Of the 15,317 people who met the inclusion criteria, 9,405 (63.6%) had a SVD and 5,912 (36.4%) had an operative birth. Parturients who underwent operative birth were older, had higher levels of education, were more likely to be married, had higher BMIs, more medical comorbidities (hypertension and diabetes), and higher rates of preterm birth than those who had a SVD (Table). After adjustment for confounders, there was no difference in the odds of PPD symptoms between those with AD who had a vaginal delivery compared with operative birth (aOR 1.08, 95% CI 0.95-1.24).

CONCLUSION: In this large, population-based, nationally representative study of first-time parturients with AD, there was no association between mode of delivery and risk of PPD symptoms. This is important for counseling those with AD, who are often concerned about the risk for development or progression of PPD.

846 Obstetric and neonatal outcomes in clinically diagnosed placental abruption with and without placental histopathological confirmation

Liat Mor[1], Daniel Rabinovich[1], Ilia Kleiner[2], Elad Barber[3], Giulia Barda[4], Eran Weiner[5], Noa Gonen[2]
[1]Wolfson Medical Center, Holon, HaMerkaz, [2]Edith Wolfson Medical Center, Holon, HaMerkaz, [3]Wolfson Medical Center, Ramat Hasharon, HaMerkaz, [4]Edith Wolfson Medical Center, Petach Tikva, IL, [5]Wolfson Medical Center, Tel Aviv, HaMerkaz

OBJECTIVE: Placental abruption (PA) is a severe obstetric complication. The diagnosis of PA is a clinical one, while placental histopathology (PH) is used to support the diagnosis. It is not yet clear whether PH findings consistent with PA are a marker of severity of abruption, and whether it correlates with maternal and neonatal

outcomes. Our aim was to compare obstetric and neonatal outcomes in clinically diagnosed PA cases with and without PH confirmation
STUDY DESIGN: All clinically diagnosed PA cases between 2008-2020 were reviewed. Obstetrics and neonatal outcomes, and PH were compared between patients with a clinically diagnosed PA with and without PH of retroplacental hematoma. Placental lesions were classified according to the current "Amsterdam" criteria. Composite of neonatal morbidity included one or more of the following complications: seizures, IVH, HIE, PVL, blood transfusion, NEC, or neonatal death
RESULTS: A total of 305 clinically diagnosed PA cases were included for analysis, of them 95 (31.3%) had PH lesions consistent with PA and 210 (68.8%) did not.

The group with PH lesions was characterized by higher rates of vaginal bleeding at presentation (51.6% vs. 36.2%, p=0.012), a higher rate of prematurity (61% vs. 34.2%, p< 0.001), and a higher incidence of the composite neonatal outcomes (27.3% vs. 13.4%, p=0.005). The group with PH retroplacental hematoma had substantially higher rates of concurrent maternal vascular malperfusion (MVM) lesions (31.6% vs. 11.9%, p< 0.001)
CONCLUSION: Approximately 1/3 of PA cases were confirmed by histopathology and were associated with worse obstetric and neonatal outcomes as well as placental MVM lesions

Table - Selected obstetric, neonatal, and placental outcomes

	Clinical PA & Histopathology confirmation (n=95)	Clinical PA (n=210)	P Value
Maternal age (years)	36.6 ± 6.01	35.3 ± 6.2	0.078
Nulliparity (%)	19 (20)	63 (30)	0.071
BMI (kg/m^2)	22.8 ± 8	23.5 ± 5.7	0.384
Preterm delivery <37 weeks (%)	58 (61)	72 (34.2)	**<0.001**
Gestational age at delivery (weeks)	34.8 ± 4.5	37.1 ± 3.7	**<0.001**
Presenting symptom vaginal bleeding (%)	49 (51.6)	76 (36.2)	**0.012**
Cesarean delivery (%)	64 (67.3)	164 (78.1)	0.064
Birthweight (gr)	2266.7 ± 827	2684.9 ± 785.7	**<0.001**
Small for gestational age (%)	14 (14.7)	29 (13.8)	0.859
Neonatal death (%)	4 (4.2)	3 (1.4)	0.209
Composite adverse neonatal outcome (%)	26 (27.3)	28 (13.4)	**0.005**
Placental weight <10th percentile (%)	19 (20)	48 (22.8)	0.655
Vascular lesions of maternal malperfusion (%)	30 (31.6)	25 (11.9)	**<0.001**
Villous lesions of maternal malperfusion (%)	26 (27.3)	70 (33.3)	0.352
Vascular lesions consistent with FTOD (%)	5 (5.2)	13 (6.2)	>0.999
Villous lesions consistent with FTOD (%)	2 (2.1)	14 (6.7)	0.162
MIR (stage 1-3) (%)	18 (18.9)	46 (21.9)	0.649
FIR (stage 1-3) (%)	6 (6.3)	15 (7.1)	>0.999

Continuous variables are presented as mean ± SD and categorical variables as n (%). p-values in bold are statistically significant. SGA- Birthweight < 10th centile; Composite adverse neonatal outcomes - One or more of the following severe complications: Neonatal seizures, intra-ventricular hemorrhage, hypoxic-ischemic encephalopathy, periventricular leukomalacia, the need for blood transfusion, necrotizing enterocolitis, or neonatal death; disease; MIR- maternal inflammatory response; FIR- fetal inflammatory response

847 One hour versus two hours postprandial glucose monitoring in gestational diabetes-mellitus: a prospective clinical trial

Giulia Barda[1], Noa Ben Shoshan[2], Yossi Mizrachi[3], Ann Dekalo[2], Liliya Tamayev[4], Eran Weiner[5]
[1]Edith Wolfson Medical Center, Petach Tikva, IL, [2]Edith Wolfson Medical center, Holon, HaMerkaz, [3]Wolfson, Holon, HaMerkaz, [4]Wolfson Medical Center, Holon, Tel Aviv, [5]Wolfson Medical Center, Tel Aviv, HaMerkaz

OBJECTIVE: We aimed to compare perinatal outcomes and patient satisfaction in patients with gestational diabetes mellitus (GDM) monitored by 1-hour versus 2-hours postprandial glucose measurements (PPG1 vs PPG2).
STUDY DESIGN: A prospective control trial at a single tertiary center. The study population included patients with GDM, diagnosed by the two-step approach. Patients diagnosed with gestational diabetes who were referred to our ambulatory patient clinics were asked to participate in the trial. Patients were placed in one of two groups Group 1 —PPG1 group 2- PPG2 according to their preference. All patients otherwise were managed according to our GDM-clinic protocol: patients were placed on appropriate diet by a dietitian and were instructed to self-monitor and document their blood glucose measurements using a glucose meter 4 times a day (fasting + either PPG1 or PPG2 with the appropriate normal and abnormal cutoffs). As per our protocol patients were evaluated every 2 weeks from time of diagnosis to 32 weeks gestation and every one week afterward. Insulin or oral medications were administered as per clinic protocol as well as decisions regarding timing or mode of delivery. Patients were asked to fill in a detailed satisfaction and questionnaire in the last prenatal visit. The study was powered to detect a 25% difference in the primary outcome of composite of adverse neonatal outcomes.
RESULTS: Overall, 99 patients were recruited 50 in the PPG1 group and 49 in the PPG2 group. Baseline characteristics were comparable between the study groups. The rate of the primary outcome, as well as glycemic control, induction of labor, mode of delivery, and birth weights were comparable between the groups — (Table). All parameters of patient satisfaction were also comparable.
CONCLUSION: PPG1 and PPG2 postprandial glucose monitoring had comparable outcomes and patient satisfaction. Therefore, we recommend counseling patients to choose either strategy based on personal preference.

Table – Selected neonatal and pregnancy outcomes

	PPG1 group (n=50)	PPG2 group (n=49)	p-value
Composite neonatal complications (primary outcome)			0.27
Neonatal hypoglycemia	11 (22.0)	17 (34.7)	
Neonatal jaundice	0	1 (2.0)	
NICU admission	2 (4.0)	4 (8.2)	
Respiratory morbidity	5 (10.0)	2 (4.1)	
Balances glycemic control (<20% abnormal values)	41 (82.0)	39 (79.6)	0.76
Induction of labor	17 (34.0)	21 (42.9)	0.36
Mode of delivery			0.14
Normal vaginal delivery	22 (44.0)	30 (61.2)	
Cesarean delivery	26 (52.0)	16 (32.7)	
Assisted vaginal delivery	2 (4.0)	3 (6.1)

NICU – neonatal intensive care unit.

848 Outcomes in pregnancies complicated with preterm hypertensive disorders with and without late antenatal corticosteroids

Noam Regev[1], Michal Axelrod[2], Rakefet Yoeli[3], Shali Mazaki-Tovi[4], Eyal Sivan[5], Baha M. Sibai[6], Michal Fishel Bartal[7]

[1]Obstetrics and Gynecology, Sheba Medical Center, Tel-Hashomer, Ramat Gan, HaMerkaz, [2]Sheba Medical Center, Ramat-Gan, HaMerkaz, [3]Sheba Medical Center, Tel-Hashomer, Kiriat Ono, HaMerkaz, [4]Chaim Sheba Medical center, Tel HaShomer, Ramat Gan, HaMerkaz, [5]Sheba Medical Center, Tel-Hashomer, Ramat-Gan, Israel, [6]Hermann Memorial Hospital, Houston, TX, [7]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX

OBJECTIVE: To determine whether late preterm (34-36 weeks) course of antenatal corticosteroids (ACS) is associated with improved short-term neonatal outcomes among pregnancies complicated with hypertensive disorders of pregnancy (HDP) who delivered in the late preterm period.

STUDY DESIGN: A single tertiary center retrospective study (11/2011 to 05/2023), including all individuals with singleton, non-anomalous fetuses who delivered between 34.0-36.6 weeks of gestation following a diagnosis of HDP. Individuals with missing delivery data and those who received only a single dose of ACS were excluded. The primary outcome was a composite adverse neonatal outcome, including intensive care unit (NICU) admission, oxygen treatment, non-invasive positive pressure ventilation, mechanical ventilation, respiratory distress syndrome, or transient tachypnea of the newborn. Secondary neonatal outcomes included Apgar score, intraventricular hemorrhage, surfactant use, hypoglycemia, hyperbilirubinemia, and sepsis. Multivariable regression models were used to estimate adjusted odds ratio (aOR) and 95% confidence intervals (CI).

RESULTS: Of 7624 preterm deliveries during the study period, 262 (3.4%) individuals were diagnosed with HDP and delivered between 34+0 to 36+6 weeks. Of them, 73 (28%) received ACS in the late preterm period. Those treated with ACS were more likely to have a history of HDP (12.3% vs5.3%. , p=0.05), to be diagnosed with fetal growth restriction (19.2% vs7.4%. , p=0.006), delivered earlier (35.4 vs. 36.1 weeks, p=0.001), and to have a Cesarean delivery (67.1% vs48.9%. , p=0.008). After adjustments, the composite neonatal morbidity was similar between the two groups (aOR 0.87, 95% CI 0.44,1.72). Other secondary outcomes, including hypoglycemia requiring treatment, were also similar between the groups (Table).

CONCLUSION: Exposure to a late preterm ACS does not improve neonatal morbidity in newborns born in the late preterm period following HDP. Additional studies with larger cohorts in this specific population are required.

Table: Neonatal outcomes in relation to antenatal corticosteroids exposure

Outcome	No ACS (n=189)	Late Preterm ACS (n=73)	P-value	aOR (95% CI) #
Composite neonatal morbidity*	48 (25.4)	22 (30.1)	0.44	0.87 (0.44-1.72)
NICU admission	31 (16.8)	18 (24.7)	0.15	
Oxygen treatment	25 (13.5)	8 (11.0)	0.58	
NIPPV treatment	7 (3.8)	1 (1.4)	0.45	
Mechanical ventilation	5 (2.7)	1 (1.4)	1.00	
TTN	19 (10.3)	7 (9.6)	0.87

IVH	1 (0.5)	0 (0.0)	1.000	
Hypoglycemia**	56 (30.3)	30 (41.1)	0.097	
Hypoglycemia requiring treatment***	38 (20.5)	21 (28.8)	0.156	
Hyperbilirubinemia	87 (47.0)	39 (53.4)	0.35	
Neonatal sepsis	0 (0.0)	0 (0.0)	NC	

Dichotomous variables are presented as n(%), continuous variables are presented as mean (±standard deviation)

aOR: adjusted odds ratio, CI: confidence interval, IVH: intraventricular hemorrhage, NC: not calculated, NICU: neonatal intensive care unit, NIPPV: non-invasive positive pressure ventilation, RDS: respiratory distress syndrome, TTN: transient tachypnea of the newborn.
* Defined as any of the following: NICU admission, oxygen treatment, NIPPV, mechanical ventilation, RDS, or TTN
** Defined as serum glucose lower than 40 mg/dl at first 24 hours and lower than 50 mg/dl afterwards.
*** Defined as the need for oral or parenteral treatment.
# Adjusted to mode of delivery and gestational age at birth.

849 Macrosomia prediction via sonographic and obstetrical parameters using machine learning

Asaf Romano[1], Gil Zeevi[2], Asnat Walfisch[3], Eran Hadar[4], Rotem Yedidia Moser[5], Shir Gruber[6], Joshua Guedalia[7], Ohad Houri[8]

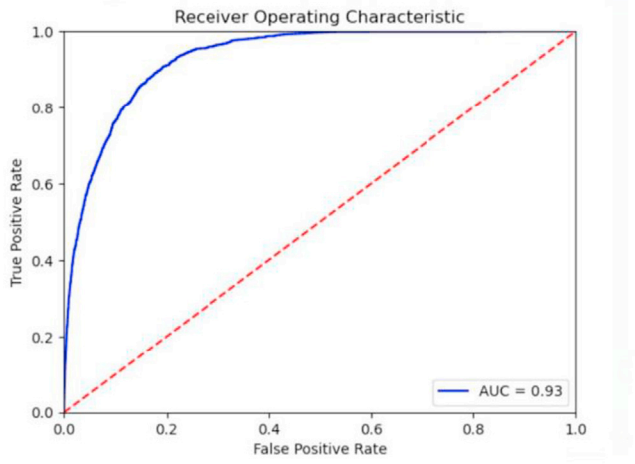
[1]Rabin medical center, Hertzelia, HaMerkaz, [2]Rabin Medical Center, Tel aviv, Israel, [3]Hadassah Mount Scopus, Petach-Tikva, Israel, [4]Rabin Medical Center, Petach-Tikva, HaMerkaz, [5]Rabin Medical Center, HaMerkaz, Israel, [6]Helen Schneider Hospital for Women, Rabin Medical Center, Tel Aviv, Israel, [7]Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim, [8]Rabin Medical Center, Tel Aviv, Israel

OBJECTIVE: Assessing the predictive capacity of machine learning (ML) algorithm, incorporating sonographic and obstetrical parameters, in predicting macrosomia

STUDY DESIGN: Retrospective cohort study including all parturients at a single tertiary university who had a singleton live birth at $\geq$ 36 gestational weeks between July 2012 and September 2020, in whom a sonographic estimated fetal weight (EFW) 14 days prior birth was available. The study employed a total of 39 features, comprising biometry sonographic measurements such as abdominal circumference (AC), femur length (FL), bi-parietal diameter (BPD), and head circumference (HC), along with maternal data encompassing demographic information, anthropometric measurements, obstetrical history, chronic and gestational morbidity, and glucose values for gestational diabetes screeaining and diagnosis. Gradient boosting-catboost was utilized to estimate birth weight $\geq$ 4000 grams. The predictive capacity of the algorithm was then compared to the Hadlock EFW formula accuracy

RESULTS: A total of 20,468 parturients met the inclusion criteria, and 9.29% of the neonates were classified as macrosomic, defined by a birth weight of $\geq$ 4000 grams. Notably, the algorithm's performance was influenced most significantly, in descending order, by AC, FL, BPD, fetal gender, HC, gestational age, and parity. The algorithm's predictive capacity for macrosomia exhibited an area under the curve (AUC) of 0.93 (95% CI 0.927-0.936), outperforming the AUC of 0.89 observed for the Hadlock's EFW formula (Figure 1). When employing Youden's index, the algorithm demonstrated a positive predictive value (PPV) of 0.32 and a negative predictive value (NPV) of 0.99.

CONCLUSION: The predictive algorithm demonstrated superior accuracy compared to the traditional EFW formula in predicting macrosomia, resulting in a remarkably high NPV. The incorporation ML algorithm into clinical care has the potential to greatly assist in patient counseling regarding the optimal timing and mode of delivery, thereby potentially reducing neonatal morbidity risks.



850 Timing of the diagnosis of fetal growth restriction: better early or better late?

Olivia Grubman[1], Thomas Owens[2], Mia A. Heiligenstein[3], Kelly Wang[4], Graham Ashmead[5], Zainab Al-Ibraheemi[6], Lois Brustman[7]

[1]Mount Sinai West, New York, NY, [2]Mount Sinai West, New York, NY, [3]Stony Brook University Hospital, Amityville, NY, [4]Icahn School of Medicine at Mount Sinai, New York, NY, [5]Roosevelt Hospital, New York, NY, [6]Mount Sinai West, N Caldwell, NJ, [7]St. Luke's Roosevelt Hospital Center, New York, NY

OBJECTIVE: SMFM defines early-onset fetal growth restriction(FGR) when diagnosed < 32 weeks(wks) of gestation. The implication of the gestational age(GA) at the time of diagnosis of FGR (based on estimated fetal weight(EFW) or abdominal circumference(AC)) in regards to neonatal outcomes is unclear. The objective of the study was to assess whether the severity of neonatal outcomes was associated with the GA at the time of diagnosis of FGR.

STUDY DESIGN: A retrospective cohort study, from 3/2018-12/2022, on singleton gestations, with FGR, delivered at term. Fetuses were stratified into groups based on GA at diagnosis: < 24 wks, 24-32 wks, and >32 wks. Groups were further stratified into FGR based on overall EFW< 10% and those that were diagnosed based on an isolated AC< 10th%. The primary outcome was a neonatal composite outcome: NICU Admission, APGAR < 5 at 5 minutes, neonatal hypoglycemia & small for GA.

RESULTS: Of 529 patients, 20 patients were diagnosed with FGR < 24 wks (17 by EFW, 3 by AC), 126 diagnosed 24-32 wks (78 by EFW, 48 by AC) & 382 diagnosed >32 wks (141 by EFW, 241 by AC). Individuals diagnosed at < 24 weeks had a higher likelihood of having an adverse event compared to individuals who were diagnosed at GA >32 wks (90% vs. 60.5%, p=0.0003). In regards to the 24-32 wks group, there was no statistically significant difference in the composite outcomes when compared to < 24 wks or >32 wks groups. Furthermore, regardless of the mode of diagnosis (EFW vs AC) there were more adverse composite neonatal outcomes when FGR was diagnosed < 24 wks compared to >32 wks (Table 1). There is a trend of improvement of outcomes in the 24-32 wks period, but it does not reach statistical significance.

CONCLUSION: Our data implies that the diagnosis of FGR, at any GA, regardless of the mode of diagnosis, is associated with neonatal morbidity of >50%. However, those infants diagnosed < 24 weeks GA, have a significantly higher risk of morbidity than any other GA. Therefore, it is our contention that the definition of early FGR should be expanded upon to reflect the severity of the disease at this periviable time.

Table 1. Primary Outcome – Composite Fetal/Neonatal Outcome by GA.

All Patients Diagnosed with FGR					
Variable	ALL (n=528)	<24 WEEKS (n=20)	24-32 WEEKS (n=126)	>32 WEEKS (n=382)	p-value
Composite Fetal/Neonatal Outcome –no. (%)	353 (66.9)	18 (90.0)	104 (82.5)	231 (60.5)	<.0001
Patients diagnosed with FGR by: AC < 10%, EFW >10%					
Variable	ALL (n=292)	<24 WEEKS (n=3)	24-32 WEEKS (n=48)	>32 WEEKS (n=241)	p-value
Composite Fetal/Neonatal Outcome –no. (%)	159 (54.5)	2 (66.7)	35 (72.9)	122 (50.6)	0.009
Patients diagnosed with FGR by: EFW <10%

851 Neonatal outcome in late preterm twin gestation: impact of antenatal corticosteroids before 34 weeks

Eliner[1], Efrat Sagy-Dicker[2], Hanoch Schreiber[3], Gal Cohen[3], Tal Biron-Shental[4], Michal Kovo[5]

[1]Meir Medical Center, Kfar Saba, HaMerkaz, [2]Tel Aviv University, Tel Aviv, Israel, [3]Meir Medical Centerartment of Obstetrics and Gynecology, Meir Medical Center, Kfar Saba, Israel, [4]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz, [5]Meir Medical Center, Macabim, HaMerkaz

OBJECTIVE: This study aims to investigate the impact of antenatal corticosteroids (ACS) treatment before 34 weeks on neonatal outcome of dichorionic diamniotic (DCDA) twins born at late preterm (gestational age (GA) 34-36.6 weeks).

STUDY DESIGN: This retrospective study examined all DCDA twin gestations born during the late preterm period between 2014 to 2020. Maternal and neonatal outcomes were compared between twin gestations treated with ACS (before 34 weeks) (ACS group) and those who were not exposed to ACS (control group). Sub-analysis was performed to compare neonatal outcome between those treated with ACS during the 14 days prior to delivery and those treated more than 14 days before delivery. Composite adverse neonatal outcome included: hypoglycemia, sepsis, respiratory morbidity, blood transfusion, cerebral morbidity.

RESULTS: A total of 297 twin pregnancies were included, with 122 in the ACS group and 175 in the control group. Maternal age, BMI, hypertensive disorders, diabetes mellitus and mode of delivery did not differ between groups. GA at delivery was lower in the ACS group compared to the control group (35.06 ± 0.8 weeks vs. 35.49 ± 0.69 weeks, p< 0.001). The ACS group had higher rates of nulliparity (46.7% vs. 33.1%, p=0.018), induction of labor (13.1% vs. 5.1%, p=0.015), and neonatal NICU admission (p< 0.001). Composite adverse neonatal outcome did not differ between the groups. Within the ACS group, neonates delivered within 14 days from ACS

treatment had higher rates of NICU admission compared to those who were born >14 days from ACS treatment (p< 0.004), yet adverse composite neonatal outcome did not differ between the groups. By multivariable logistic regression analysis ACS treatment was not found to be independently associated with composite adverse neonatal outcome.

CONCLUSION: Twin pregnancies treated with ACS before 34 weeks but delivered in the late-preterm period, showed similar outcomes compared to those who were not treated with ACS. Clinical judgment for ACS treatment should consider the GA and its proximity to 34 weeks of gestation.

Table- Comparison of neonatal outcome of twin gestations according to ACS

	Control group (n=350)	ACS group (n=244)	P value
Birth weight (gram)	2317.3±329.5	2168.9±360.3	**0.0001**
5-min Apgar score < 7	3 (0.9)	3 (1.2)	0.69
Admission to NICU	58 (16.6)	88 (36.1)	**0.0001**
Hypoglycemia	3 (0.9)	3 (1.2)	0.69
Respiratory distress	5 (1.4)	0	0.082
Composite adverse neonatal outcome	15 (4.2)	10 (4.09)	0.9
	ACS ≤ 14 days (n= 46)	**ACS > 14 days (n= 198)**	**P value**
Birth weight (gram)	2175.8±362	2139.3±351.5	0.643
GA (weeks)	34.57±0.58	35.17±0.79	**<0.0001**
5-min Apgar score < 7	1 (0.5)	2 (4.3)	0.092
Admission to NICU	25 (54.3)	63 (31.8)	**0.004**
Hypoglycemia	3 (1.5)	0	1
Composite respiratory morbidity	0	0	
Composite adverse neonatal outcome	0	10 (5.05)	0.216

Data are mean± standard deviation, n (%). NICU- neonatal intensive care unit. Composite outcome included at least one of the following- hypoglycemia, sepsis, respiratory morbidity, anemia/blood transfusion, cerebral hemorrhage, HIE or convulsions, Intraventricular hemorrhage (IVH).

852 Utility of a standardized reporting system in prenatal ultrasound for placenta accreta spectrum disorder

Oxana M. Zarudskaya[1], Shriya Devkumar Das[2], Nina Kumar[2], Michael D. Berkus[2], John J. Byrne[2], Angela R. Boyd[2], Theresa Stewart[2], Christina Hill[2], Nora M. Doyle[2], Patrick S. Ramsey[2]

[1]University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]The University of Texas Health Science Center at San Antonio, San Antonio, TX

OBJECTIVE: Prenatal diagnosis of placenta accreta spectrum disorders (PASD) has become essential to allow for a well-conducted multidisciplinary management plan before the onset of labor to reduce maternal and fetal morbidity and mortality. In addition to risk-factor assessment, first-line modalities for predicting PASD are two-dimensional grayscale ultrasound (US) and color Doppler. Inconsistency and variability of reported US descriptors complicate multidisciplinary collaboration and research communication within and between institutions nationally and internationally.

STUDY DESIGN: We conducted a retrospective review of patients evaluated and delivered for PASD at the University Health System in San Antonio, Texas. In January 2023 our institution implemented a standardized reporting protocol for prenatal ultrasound descriptors of PASD. We compared the rate of reported standardized ultrasound descriptors and PASD type from January to July 2022 and the same period in 2023, before and after the implementation of this tool.

RESULTS: Of the 30 cases included, 17 (56.7%) pre-implementation and 13 (43.3) post-implementation. Pre-implementation, PASD was histologically confirmed as percreta in 69.2%, increta in 15.4%, and accreta in 15.4%. Post-implementation, PASD histological confirmation revealed of placenta percreta in all cases (100%). The type of placenta accreta based on prenatal ultrasound was reported only in 35% of cases in the pre-implementation period compared to post-implementation 85% (p=0.007). The rate of reported standardized ultrasound descriptors before and after implementation of our protocol is demonstrated in Table 1.

CONCLUSION: Implementation of standardized protocol into routine practice of prenatal maternal-fetal ultrasound for PASD improves reporting rate of ultrasound descriptors, and a priori risk and placenta accreta index (PAI) score, both of which facilitate multidisciplinary collaboration and surgical planning for patients with PASD.

853 Outcomes of Stevens-Johnson syndrome and toxic epidermal necrolysis in pregnant women, 2009-2020

Paul Wasuwanich[1], Joshua So, MS[1], Kiran Motaparthi[1], Robert Egerman[2], Tony S. Wen[2]

[1]University of Florida College of Medicine, Gainesville, FL, [2]University of Florida, Gainesville, FL

OBJECTIVE: Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) are rarely described in the pregnant population, and little is known about their impact on the mother and developing fetus. We aim to describe SJS/TEN in pregnant women and to investigate the risk factors for developing SJS/TEN in pregnancy.

STUDY DESIGN: We utilized hospitalization data from the 2009-2020 National Inpatient Sample. Pregnancy hospitalizations and SJS/TEN involvement were identified by ICD-9/10 codes and analyzed by chi-square and logistic regression.

RESULTS: We identified 650 pregnancies complicated by SJS/TEN requiring hospitalization. The median age was 28 (IQR: 23-32) years, and the majority of patients were non-Hispanic white (55.2%). There were ≤10 cases of mortality in the cohort. Among cases with trimester data, 73.9% of SJS/TEN cases occurred during the third trimester. In the multivariable logistic regression model, HIV infection (OR=9.49; 95% CI=1.24-7.24; p=0.030), herpes simplex virus (HSV) infection (OR=2.49; 95% CI=1.15-5.41; p=0.021), genitourinary tract (GU) infections (OR=3.80; 95% CI=2.01-7.16; p< 0.001), malignant neoplasm (OR=8.67; 95% CI=1.22-61.39; p=0.031), and lupus (OR=41.94; 95% CI=20.78-84.66; p< 0.001) were associated with increased odds of developing SJS/TEN in pregnancy. Of 650 pregnant patients with SJS/TEN, 378 delivered during the hospitalization. The rates of preterm births were higher in the SJS/TEN cohort, 16.9% versus 8.2% (p< 0.001). There were no significant differences in frequency of pre-eclampsia, stillbirths, and post-term births compared to the non-SJS/TEN pregnancy cohort.

CONCLUSION: Although rare, SJS/TEN in pregnancy is associated with favorable perinatal outcomes aside from an increase in preterm birth. The high prevalence of SJS/TEN in the third trimester may reflect the inflammatory state of the late third trimester. Lupus, malignancy, HIV, and to lesser degrees, HSV and GU infection should be considered in the differential diagnosis.

Table 1: Logistic regression risk factors for association with developing Stevens-Johnson syndrome and toxic epidermal necrolysis in pregnancy (2009-2020).

Risk Factors		Crude Odds Ratio (95% CI)	Crude P-Value	Adjusted Odds Ratio (95% CI)	Adjusted P-Value
Demographics					
Age	≥30 (vs <30)	0.99 (0.70-1.41)	0.973	0.96 (0.65-1.28)	0.821

854 Inositols pathway is altered in placental tissue of obese women

Pierluigi Di Vinci[1], Fabio Facchinetti[2], Bénazir Siddeek[3], Umberto Simeoni[3]

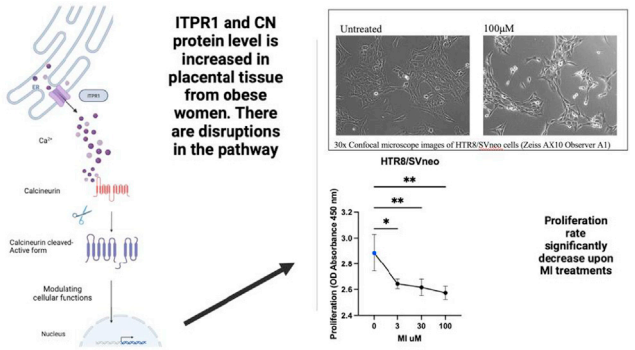
[1]University of Modena and Reggio Emilia, Emilia-Romagna, [2]Policlinico di Modena, University of Modena and Reggio Emilia, Emilia-Romagna, [3]Centre hospitalier universitaire vaudois, Vaud

OBJECTIVE: Obesity in pregnancy has significant short- and long-term consequences for both women and their neonates as well for long-life metabolic disorders. Myo-Inositol (MI) has a pivotal role in Insulin/glucose metabolism interacting with Inositol 3 phosphate receptor 1 (ITPR1) in endoplasmic reticulum. This pathway influences also cellular functions. The objective was to investigate potential changes of MI pathway in placental tissue of obese women, investigating its role in cellular proliferation.

STUDY DESIGN: In a non-randomized experimental study, placental explants were collected from uncomplicated obese (OB) and normal weight (CTRL) women undergoing elective cesarean section, at term. Tissues were snap frozen in liquid nitrogen. Critical proteins involved in Ins regulation and pathway including SMIT1, SMIT2, ISYNA1, MIOX, ITPR1 and CN were analyzed. Total proteins were extracted with RIPA buffer, their concentrations measured with BCA assay and quantified by Western Blot (WB). To investigate the effect of MI treatment on placental cells, a trophoblast human cell line (HTR8/SVneo) was used for proliferation assay study (Immunological science). Student's t test was used for single comparison analysis and ANOVA for multiple comparisons. Data were significant if p< 0.05.

RESULTS: Thirty-four placenta samples (18 OB vs 16 CTRLs) were analyzed by WB. Data were normalized on GAPDH protein level. ITPR1 was upregulated in OB group (p=0.002) compared to CTRLs, as well as the active cleaved form of calcineurin (CN) (p=0.004). We did not observed alteration in SMITs, MIOX and ISYNA1 protein levels. "*In vitro*" MI treatment, in a dose-dependent way, decreased proliferation of trophoblast cells (Fig).

CONCLUSION: An alteration of the MI pathway within placenta tissue of OB women was demonstrated as revealed by significant increase in ITPR1 protein level and active CN. No changes instead occurred in MI cellular intake, synthesis and catabolism. MI inhibited trophoblast cell proliferation. In women with pre-pregnancy obesity up-regulation of placental MI activity could affect placenta development.



855 Incidence of Dysphoric Milk Ejection Reflex

Rachel Solmonovich[1], Insaf Kouba[2], Christine Bailey[3], Wendi Andria[1], Kristen H. Demertzis[2], Matthew J. Blitz[2], Jolene Muscat[2]

[1]South Shore University Hospital of Northwell Health, Bay Shore, NY, [2]Zucker School of Medicine at Hofstra of Northwell, Bay Shore, NY, [3]Huntington Hospital of Northwell Health, Huntington, NY

OBJECTIVE: Dysphoric Milk Ejection Reflex (DMER) is a condition described as brief, abrupt, negative emotions experienced by breastfeeding individuals prior to milk letdown. It may negatively impact the breastfeeding relationship. Our primary objective was to determine the incidence of DMER.

STUDY DESIGN: A prospective cohort study with English speakers who delivered a liveborn infant between December 2022-May 2023 at two hospitals within a large healthcare system in New York. Patients who elected to breastfeed were eligible for the study. Participants were emailed an initial survey at the time of consent. The following morning, they started receiving surveys three times daily for one week assessing for DMER symptoms, with symptom severity rated on a Likert scale. Medical records were reviewed to obtain patient demographics, antepartum course, and obstetrical and fetal outcomes. Descriptive statistics were performed to determine incidence and characterize the patient population.

RESULTS: 203 patients were approached for participation. 151 consented and 1 withdrew, leaving 150 participants in the study. Of those, 59 did not complete any surveys, and 73 were lost to follow up. The 18 remaining participants completed the initial survey and >50% of the surveys assessing for DMER symptoms, for a total of

321 surveys completed. 33.% (n=6) screened positive for DMER in more than 50% of breastfeeding episodes. Patients who screened positive were more likely to be <35 years old, non-Hispanic white, married, obese, privately insured, and delivered at term by cesarean section. Amongst those who screened positive for DMER, no one had a history of psychiatric disorders. DMER symptom severity was mostly very mild to moderate (Table 1). One patient reported severe symptoms.

CONCLUSION: More than 1 in 4 breastfeeding women screened positive for DMER. It is important to extend this research to better define, quantify, qualify, and publicize this condition in an effort to inform clinical practices to facilitate successful, healthy, breastfeeding relationships.

	% Patients Reporting DMER Symptom Severity (n=6)			
Symptoms	Very Mild	Mild	Moderate	Severe
Aggression	66.7	50.0	16.7

856 Intrapartum Maternal Fever and Severe Maternal Morbidity

Rachel P. Gerber[1], Insaf Kouba[2], Frank I. Jackson[2], Matthew J. Blitz[2]

[1]Zucker School of Medicine at Hofstra of Northwell, Manhasset, NY, [2]Zucker School of Medicine at Hofstra of Northwell, Bay Shore, NY

OBJECTIVE: To determine the association between severity of intrapartum maternal fever and severe maternal morbidity (SMM).

STUDY DESIGN: Retrospective cohort of all deliveries that occurred at 7 hospitals within a large health care system in New York from 2019-2022. Pregnancies without intrapartum temperature data were excluded. Clinical and sociodemographic data were obtained from the electronic medical record system. The primary exposure was maximum temperature prior to delivery. The cohort was divided into three groups: afebrile (<38.0 °C), mild fever (≥ 38.0°C – 39.0°C), moderate-severe fever (≥ 39.0°C). The primary outcome was SMM, defined using the Centers for Disease Control and Prevention (CDC) criteria. Multivariable logistic regression was used to evaluate the association between maximum maternal temperature and SMM, adjusting for potential confounders.

RESULTS: A total of 65,246 deliveries were included for analysis: 96.4% (n=62,918) afebrile, 3.2% (n=2,092) mild fever, and 0.4% (n=236) moderate-severe fever. The overall rate of SMM was 4.3% (n=2,780), which occurred in 4.0%, 9.3%, and 22.9% of the afebrile, mild fever, and moderate-severe fever groups, respectively ($p < 0.001$). On multivariable logistic regression analysis, SMM was 2.41 and 7.55 times more likely in pregnancies complicated by mild or moderate-severe fever compared to afebrile patients (95% CI 2.03-2.86 and 5.36-10.47, respectively).

CONCLUSION: Maternal intrapartum fever is an independent predictor of SMM. Further investigation is warranted to determine the optimal timing of antibiotic administration to effectively reduce this risk.

Table 1. Multivariable logistic regression analysis.

Characteristic	aOR (95% CI)
Temperature	
<38 °C	REFERENCE
38 - 39°C	2.41 (2.03-2.86)
≥39°C	7.55 (5.36-10.47)
Maternal Age (≥ 35yo)	1.18 (1.07-1.30)
Race-Ethnicity other than Non-Hispanic White	1.42 (1.30-1.56)
Obesity	1.00 (0.92-1.10)
Multiparity	0.63 (0.57-0.70)
Public Insurance	1.15 (1.05-1.26)
Multiple Gestation	2.79 (2.30-3.37)
Pre-eclampsia with severe features	4.24 (3.77-4.77)
Other hypertensive disorders	1.75 (1.56-1.96)
Placental Abnormalities	5.00 (4.28-5.81)
Prior Uterine Surgery	2.19 (1.95-2.45)

* Logistic regression model included 56,500 deliveries and adjusted for all above variables.

857 Validation of the PROMIS© Medication Adherence Scale for Aspirin Among Pregnant Patients

Rachel S. Ruderman[1], Emily White VanGompel[2], Ashish Premkumar[1], Jungeun Lee[2], Olivert Mbah[3], Melinique Walls[4], Sunitha C. Suresh[5]

[1]University of Chicago, Chicago, IL, [2]NorthShore University HealthSystem, Chicago, IL, [3]NorthShore University HealthSystem, Evanston, IL, [4]Pritzker School of Medicine, Chicago, IL, [5]NorthShore University Health System, Evanston, IL

OBJECTIVE: Low-dose aspirin is an essential tool to prevent preeclampsia. A measure validated in the prenatal setting to evaluate adherence, which is essential to efficacy, is lacking. We investigated the validity and performance of an instrument validated outside a pregnant population to measure medication adherence among pregnant patients of low socioeconomic status who were recommended low-dose aspirin.

STUDY DESIGN: This was a cross-sectional analysis using the National Institutes of Health (NIH) Patient-Reported Outcomes Measurement Information Systems (PROMIS©) Medication Adherence Scale (PMAS), which contains two subscales, Medication Beliefs and Knowledge (MBK) and Medication Taking Behaviors (MTB). This was assessed among pregnant people who were recommended low-dose aspirin at an urban tertiary care center clinic between April and July 2023. We assessed internal consistency and reliability, and compared mean PMAS scores using Mann-Whitney U and Kruskal-Wallis tests by self-reported maternal race/ethnicity, history of adverse pregnancy outcome (APO), or history of pre or gestational diabetes.

RESULTS: Among 40 patients surveyed, the mean PMAS score was overall high at 41.18 (SD 3.90) and the internal consistency reliability was strong at 0.83. Item-to-total PMAS score correlations demonstrated a moderate to good fit (r range 0.39-0.80) for all items except two in the MTB subscale which focused on medication side effects (MedAd7) and cost (MedAd9) (Table 1). Self-reported race, ethnicity, history of APO, or history of diabetes were not associated

with a significant difference in PMAS score (p = 0.62, 0.40, 0.36, 0.70 respectively).

CONCLUSION: This study revealed that use of PMAS in this population is reliable, but that the MTB subscale may be weakened by inherent characteristics of low-dose aspirin (e.g., few side effects and low cost). It may be preferable to use MedAd5 as a stand-alone item along with the MBK subscale in future evaluations of this population. There was no statistically significant difference in PMAS score by any demographic or clinical characteristic.

Score Totals & Narratives		Mean Score (SD)	Max Score	Cronbach's Alpha
Medication Beliefs & Knowledge		17.53(2.10)	20	0.78
MedAd1	*"I know how to take this medication as recommended"*			
MedAd2	*"I understand why I need to take this medicine"*			
MedAd3	*"I believe it is important to take this medicine"*			
MedAd4	*"I believe this medicine is working"*			
Medication Taking Behaviors[1]		23.65(2.33)	25	0.74
MedAd5	*"I took this medicine as recommended"*			
MedAd6	*"I remembered to take this medication"*			
MedAd7	*"I did not take this medicine because it caused side effects that bothered me"*			
MedAd8	*"I stopped taking this medicine because I thought I did not need it"*			
MedAd9	*"I did not take this medicine because of the cost"*			
PMAS Total Score		41.18(3.90)	45	0.83

858 Applying machine-learning models to successful Vaginal Birth after two Cesarean Deliveries

Rachel S. Griffin[1], Emanuelle S. Hay[2], Itai Braude[3], Ron Rosenberg[1], Amir Weintraub[2], Nir R. Duvdevani[1], Yael Pasternak[2]

[1]Laniado Medical Center, Netanya Israel, Netanya, HaMerkaz, [2]The Adelson School of Medicine, Ariel University, Netanya, HaMerkaz, [3]Emek medical center, Afula, HaZafon

OBJECTIVE: Applying machine-learning models to clinical features of women attempting Trial of Labor after two Cesarean deliveries to predict success rate.

STUDY DESIGN: A Retrospective Cohort Study was conducted between the years 2009 -2021 at a University- affiliated Medical Center. Data was extracted from records and included maternal demographics and clinical features. The primary outcome was Vaginal Birth After Two Cesarean deliveries (VBAC2) without uterine rupture or dehiscence. Secondary outcomes were APGAR scores at 1 and 5 minutes, neonatal pH values below 7.1, Neonatal Intensive Care Unit admissions, maternal need for blood transfusion, and intrapartum, neonatal and maternal mortality. We used different machine-learning models and statistical regression to predict the outcome class.

RESULTS: Among a total of 91196 singleton deliveries, 2472 of women underwent two prior Cesarean sections. Of these, 475 deliveries were approved for and attempted trial of labor. Of them, 408 (86%) had successful VBAC2, 406 without uterine rupture or dehiscence. In total, 10 women had uterine rupture (2.1%) and 4 (0.8%) had dehiscence of uterine scar. There were no mortalities, neonatal or maternal. The most accurate classifier model was the XGBoost Classifier (ROC AUC 81%), followed by the Randon Forest Classifier (ROC AUC 80%) and then by the Logistic Regression Classifier (ROC AUC 72%). The sensitivity and specificity of the XGBoost were 25.0% and 96.4%, respectively, defining the prediction probability threshold as 0.25, with high specificity. The parameters with the highest importance for successful VBAC2 XGBoost Classifier are presented in figure 1.

CONCLUSION: Machine-learning models trained with clinical data may be useful in predicting safety and success for vaginal delivery after two Cesarean sections with a relatively high degree of certainty. Using these models may aid in counseling women before delivery and help patients and physicians make more informed decisions regarding mode of delivery choices in the case of two previous Cesarean sections.

859 Neonatal and Maternal Outcomes Following Implementation of Expectant Management of Late Preterm PROM

Rafaela Germano Toledo, Anna M. Modest, Emily Whitesel, Cassandra R. Duffy

Beth Israel Deaconess Medical Center, Boston, MA

OBJECTIVE: Recent evidence suggests that both immediate delivery and expectant management until 37 weeks are reasonable options for stable preterm premature rupture of membranes (PPROM) in the late preterm period. We compared maternal and neonatal outcomes pre- and post-implementation of a January 2021 institutional guideline which introduced the option of expectant management after 34 weeks' gestation.

STUDY DESIGN: This was a retrospective cohort study of patients admitted with PPROM between 28 – 36 6/7 weeks' gestation from May 2019 to December 2020 (pre-implementation) and from April 2021 to December 2022 (post-implementation). Pregnancies with fetal anomalies and multiple fetuses were excluded. The primary outcome was neonatal intensive care unit (NICU) length of stay (LOS). Secondary outcomes included neonatal sepsis, maternal LOS, and chorioamnionitis.

RESULTS: Data were collected from 170 patients pre-implementation and 180 post-implementation. The median gestational age at the time of PPROM was the same between groups (34 weeks, IQR 32 – 35.3 vs. 34 weeks, IQR 32.1 – 35.1). NICU LOS was similar in both pre- and post-groups (14.7 days, IQR 4.4 - 29.7 vs. 12.7 days, IQR 4.0 - 23.4, p=0.35). When patients in active labor at the time of admission were excluded, results remained similar (13.5 days, IQR 4.0 - 27.7 vs. 11.0 days, IQR 4.0 - 22.9, p=0.35). The incidence of neonatal sepsis was similar between groups (1.8% vs. 3.9%, p=0.22), as was the incidence of chorioamnionitis (6.5% vs. 8.3%, p=0.51). There was a statistically significant increase in maternal LOS (3 days (IQR 3-5) vs. 4 days (IQR 3-7), p=0.02) in the post-implementation period. There were no significant differences in need for neonatal respiratory support, stillbirth or neonatal demise, maternal

postpartum antibiotics, postpartum hemorrhage, or blood transfusion (Table 1).

CONCLUSION: Offering expectant management of late PPROM at a tertiary care academic center led to similar maternal and perinatal outcomes with no change in neonatal NICU LOS and a modest increase in maternal LOS.

Table 1. Neonatal and Maternal Outcomes by Implementation Period.

	Pre-implementation (n=170)	Post-implementation (n=180)	p-value
Gestational age at PPROM	34.0 (32.0 – 35.3)	34.0 (32.1 – 35.1)	0.96
GBS status			0.26

Maternal length of stay (days)	3 (3 – 5)	4 (3 – 7)	0.02
Maternal postpartum antibiotics	17 (10.0)	16 (8.9)	0.72
Postpartum hemorrhage	9 (5.3)	9 (5.0)	0.58
Blood transfusion	2 (1.2)	1 (0.6)	0.53

Data presented as median (interquartile range) or n (%).

*Defined as a neonatal intensive care unit (NICU) stay for ≥ 4 hours.
**Defined as a positive blood culture and/or use of antibiotics for ≥ 7 days.
***Includes mechanical ventilation/intubation or continuous positive airway pressure (CPAP) use.

860 Increasing postpartum hemorrhage and blood product transfusion at delivery in the United States, 2016-2020

Rauvynne N. Sangara[1], Shakeela Faulkner[2], Emi Komatsu[3], Kazuhide Matsushima[3], Rachel S. Mandelbaum[3], Brendan Grubbs[3], Marc H. Incerpi[3], Joseph G. Ouzounian[3], Koji Matsuo[3]

[1]University of Southern California, Pasadena, CA, [2]Keck School of Medicine of USC, Los Angeles, CA, [3]Los Angeles General Hospital + USC Medical Center, Los Angeles, CA

OBJECTIVE: To evaluate temporal trends of postpartum hemorrhage (PPH) and blood product transfusion at delivery in the United States.

STUDY DESIGN: This cross-sectional study queried the Healthcare Cost and Utilization's National Inpatient Sample. The study population was 18,067,310 hospital deliveries from 1/2016-12/2020. The main outcome measures were incidence of PPH and performance of blood product transfusion at delivery according to the Center for Disease Control and Prevention (CDC) definition, including red blood cells, fibrinogen, plasma, platelets, cryoprecipitate, and whole blood. Temporal trends were assessed with the Cochran-Armitage test.

RESULTS: Annual delivery volume decreased from 3,754,681 to 3,427,085 from 2016-2020 (8.3% relative-decrease). The incidence of PPH was 400.0 per 10,000 deliveries. The diagnosis of PPH at delivery increased from 337.2 to 463.4 per 10,000 deliveries during the 5-year period (37.4% relative-increase, *P-trend*< 0.001). During the study period, 205,720 (113.9 per 10,000) patients received blood transfusion with any product type, including single product (n=180,415 [99.9 per 10,000]), two type products (n=15,270 [8.5 per 10,000]), and three or more type products (n=10,035 [5.6 per 10,000]). The number of patients receiving any blood product at delivery increased from 102.9 to 125.4 per 10,000 deliveries from 2016-2020 (21.9% relative-increase, *P-trend*< 0.001), including two product types from 7.7 to 9.6 per 10,000 deliveries (24.7% relative-increase, *P-trend*< 0.001) and three or more product types from 4.5 to 6.0 per 10,000 deliveries (33.3% relative-increase, *P-trend*< 0.001).

CONCLUSION: This nationwide analysis demonstrates an increasing trend of PPH diagnosis and utilization of blood transfusion at delivery, particularly with multiple products, despite an overall decrease in delivery volume in the recent years in the United States. In 2020, one in 80 patients received blood transfusion at delivery.

861 Timing of history-indicated cerclage placement and pregnancy outcomes

Rebecca Fleenor[1], John Owen[2], Gabriella D. Cozzi[1], Claire A. McIlwraith[1], Joseph T. Edwards Jr.[3], Dhong-Jin Kim[2], Victoria C. Jauk[2], Alan T. Tita[1], Akila Subramaniam[2]

[1]University of Alabama at Birmingham, Birmingham, AL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [3]UAB, Birmingham, AL

OBJECTIVE: Patients with history of cervical insufficiency are offered a history (Hx)-indicated cerclage in a future pregnancy; however, data on timing of placement is limited. We compared the relationship between gestational age (GA) at cerclage placement to selected perinatal outcomes in patients undergoing a Hx-indicated vaginal cerclage.

STUDY DESIGN: Retrospective cohort study of patients with non-anomalous singleton gestations who underwent Hx-indicated vaginal cerclage (between 11-20 wks GA) and delivery at a single tertiary center 1/2013-4/2021. At our institution, Hx-indicated cerclages are typically placed at 12-14 wks, but can vary upon GA at entry to prenatal care. The primary exposure was GA at cerclage placement. Primary outcome was birth GA. Secondary outcomes included preterm birth (PTB), operative morbidities, and select pregnancy outcomes. Linear and logistic regression modeled the relationship between GA at cerclage placement and primary and secondary outcomes, and OR and β with 95% CI were calculated.

RESULTS: Of 542 cerclages performed in our study period, 175 cases were analyzed. The mean GA of Hx-indicated cerclage placement was 13 ± 1.4 wks. Our cohort were largely obese, publicly insured, non-married, non-Hispanic Black, and had high rates of intramuscular progesterone use. There was no significant association between GA at cerclage placement and birth GA (p=0.72, b 0.13 [-0.57, 0.82], Table). While there was a significant association between GA at placement and readmission within 7 days (p=0.048, OR 1.7 [1.01, 3.1]), there was no significant relationship between GA at placement and PTB (at any GA cut-off), intraoperative complications, or other studied maternal or neonatal outcomes (Table).

CONCLUSION: GA at time of Hx-indicated cerclage placement up to 20 wks was not associated with birth GA, PTB, or intraoperative complications. However, for each additional wk of GA at cerclage placement, there were increased odds of post-operative readmission. Future studies should evaluate if there an optimal GA for Hx-indicated cerclage placement.

Table. Pregnancy and operative outcomes among cases of non-emergent Hx-indicated vaginal cerclage 2013-2021 by timing of cerclage placement (weeks of gestation)

OUTCOMES	History-indicated cerclage (n=175)	OR or β (95% CI)
Cerclage procedure		
Intraoperative composite[1]	1.7	OR 0.97 (0.42, 2.2)[3]
Operative blood loss (mL)	15 (5, 25)	β -0.51 (-4.2, 3.2)[4]
Operative time (min)	23 (14)	β 0.24 (-1.3, 1.8)[4]
Maternal postoperative LOS (hrs)	4.0 (4.2)	β -0.003 (-0.44, 4.4)[4]
Readmission within 7 days	1.1	OR 1.8 (1.0, 3.1)[3]
Number of postoperative triage visits	1 (0, 2)	β 0.11 (-0.12, 0.34)[4]
Pregnancy Outcomes		
GA of rupture of membranes (wks)	34 (7.0)	β 0.94 (-0.64, 0.83)[4]
GA at cerclage removal (wks)	32 (6.3)	β 0.16 (-0.49, 0.82)[4]

862 Virtual reality for pain reduction during episiotomy and perineal tear repair

David Peleg[1], Reem Yassin[1], Inbar Ben Shachar[1], Steven Warsof[2]
[1]Ziv Medical Center, Azrieli Faculty of Medicine, Bar-Ilan University, Safed, HaZafon, [2]Eastern Virginia Medical School, Norfolk, VA

OBJECTIVE: Virtual Reality (VR) is being used as a non-pharmacological tool for pain relief and anxiety reduction. Our objective was to determine the impact of VR during episiotomy and perineal tear repair.

STUDY DESIGN: A prospective, randomized control trial was performed from September 2022 to February 2023. Delivered women were randomly allocated to undergo episiotomy or perineal tear repair with or without the use of VR. The primary outcome was pain evaluated by the Visual Analogue Scale (VAS) at the end of the repair. A validated questionnaire was used to evaluate anxiety which included 20 questions.

RESULTS: Eighty-eight women were included in this study, 44 were randomly included in each group., There was no statistically significant differences between the demographics and characteristics of the participants. VR was effective in significantly reducing the pain in the study group. There was no difference in the level of anxiety between groups.

CONCLUSION: VR was effective in reducing pain but not anxiety during episiotomy and perineal tear repair.

	VR Group (N=44)	Control (N=44)	P
Age	28.9 ± 3.9	29.4 ± 5.1	0.61
BMI	28.7 ± 5.0	28.7 ± 4.2	0.89
First delivery	21	17	0.52

863 Outcomes after fetoscopic laser photocoagulation for TTTS with or without concomitant selective fetal growth restriction

Romain Corroenne[1], Jessian L. Munoz[2], Cara Buskmiller[2], Ahmed A. Nassr[2], roopali V. donepudi[2], Michael A. Belfort[3], Magdalena Sanz Cortes[4]
[1]Angers University Hospital, Angerd, Pays de la Loire, [2]Baylor College of Medicine, Houston, TX, [3]Texas Children's Hospital, Houston, TX, [4]Baylor College of Medicine and Texas Children's Hospital, Houston, TX

OBJECTIVE: To compare outcomes after fetoscopic laser photocoagulation (FLP) for twin-twin transfusion (TTTS) with or without concomitant selective fetal growth restriction (SFGR) based on single or dual survival postlaser.

STUDY DESIGN: Retrospective cohort study of patients with TTTS treated by FLP in 1 institution between 11/2011 and 04/2023.SFGR was defined by a fetal weight < 10 percentile in 1 fetus and intertwin discordance of ≥25%. Outcomes were compared between TTTS with no SFGR and TTTS+SFGR.

RESULTS: 186/422(44.1%) patients presented TTTS+SFGR and 236/422(55.9%) presented with isolated TTTS.

Gestational age(GA) (20.1[15.9-29.0] vs 20.1[15.9-27.9] weeks, p=0.53), cervical length at the time of FLP (38[10-70] vs 37[11-57] mm, p=0.3) and rate of PPROM (16/226[7.1%] vs 17/183[9.4%], p=0.19) were similar between TTTS and TTTS+SFGR.

Postlaser dual survival was higher in cases of isolated TTTS (200/236[84.7%] vs TTTS+SFGR 142/186[76.3%], p=0.03).

There were some relevant differences when outcomes between single survivor after FLP with TTTS vs TTTS+SFGR where compared: Main difference before FLP was a higher proportion of stage 3 TTTS in the latter group (83.8% vs 34.6%, p< 0.01), as the proportion of anterior placentas, GA at laser and surgical time were similar. PPROM was more frequent in the TTTS+SFGR group (0 vs 16%, p=0.03), and they delivered at an earlier GA than compared to those with isolated TTTS (33.4 vs 30.0weeks, p=0.04). There were also differences in the proportion of surviving ex donor fetuses at birth (44% vs 12.5%, p< 0.01) and at 30 days of life (50% vs 11.1%, p< 0.01), with higher rates in the isolated TTTS group. In case of dual survival post laser, the proportion of surviving ex-donor were significantly higher at birth and at 30 days in the isolated TTTS group.

CONCLUSION: FLP for TTTS+SFGR was associated with a decreased rate in dual survival with an increased risk of donor demise. Outcomes in cases of TTTS+SFGR where there was a single survivor were worse than if isolated TTTS was the indication for FLP. Specific explanation of these adverse results need to be elucidated.

Table 1. Comparison between isolated TTTS and TTTS with concomitant sFGR according to the immediate post-laser survival

	Isolated TTTS (n=236)		TTTS with concomitant sFGR (n=186)		p*	P**
	Single survivor post laser (n=26)	Dual survivor post laser (n=200)	Single survivor post laser (n=37)	Dual survivor post laser (n=142)

**represents the comparison between dual survivor post laser for TTTS+SFGR versus dual survivor post laser for TTTS with no SFGR

864 Maternal Rates of Alloimmunization at Initiation of Pregnancy Care: Insights from a National Cohort

Ronan P. Sugrue[1], Kenneth Moise Jr.[2], Jerome J. Federspiel[3], Elizabeth Abels[4], Judy Louie[5], Zhen Chen[5], Damian Alagia[5], Harvey Kaufman[5]

[1]Duke University, Durham, NC, [2]University of Texas Schooll of Medicine at Houston, Houston, TX, [3]Duke University Hospital, Durham, NC, [4]Yale University School of Medicine, New Haven, CT, [5]Quest Diagnostics, Secaucus, NJ

OBJECTIVE: Hemolytic disease of fetus and newborn (HDFN) is a life-threatening disease mediated by maternal alloimmunization. Published prevalence studies of maternal antibodies in the United States (US) include single center reports but no national data. This study describes contemporary prevalence and temporal trends in alloimmunization in early pregnancy in the US.

STUDY DESIGN: Red blood cell antibodies (RBC Abs) in obstetric panels during 2010-2021 were identified in a national commercial laboratory database. The Overall Cohort comprised pregnant patients screened for RBC antibodies in an initial obstetric panel; Continuity Cohort included those who had additional 3rd trimester oral glucose challenge. Data were normalized based on US Centers for Disease Control live births and weighted by year and census division to estimate the national prevalence of alloimmunization. Cochrane-Armitage tests were used to assess for alloimmunization temporal trends.

RESULTS: Of 9,876,196 pregnancies, 1.5% screened positive for RBC Abs; 0.9% (914/100,000 pregnancies) identified and 0.6% (604/100,000) unidentified. Of identified RBC Abs, anti-D comprised 64%, corresponding to an estimated national rate of 586/100,000 pregnancies. Prevalence of other high-risk RBC Abs for HDFN included anti-E (110/100,000), anti-K (68/100,000), and anti-c (29/100,000) (**Table**). Similar results were observed in the continuity cohort. There was an increasing temporal trend for all four high risk antibodies (all $P < .001$).

CONCLUSION: Among nearly 10 million pregnancies in the US from 2010 to 2021, 1.5% screened positive for RBC Abs. Over 50% (793/100,000) had RBC Abs known to be high risk for HDFN with an increasing temporal trend. Though overall prevalence of anti-D is difficult to interpret without ability to distinguish active from passive presence, it likely remains problematic in HDFN as demonstrated by ranking second only to anti-K in critical titers. Given the severity of HDFN, new initiatives may be required to reduce alloimmunization incidence in patients of reproductive potential.

Table 1: Estimates of national prevalence of alloimmunization in early pregnancy

	Rate per 100,000 pregnancies (95% Confidence Interval)			
	Overall Cohort (Number = 9,876,196)		Continuity Cohort (Number = 3,926,094)	
	RBC Antibody Detected	Critical Titer*	RBC Antibody Detected	Critical Titer
High risk of HDFN				
anti-D	586 (553 - 618)	21 (20 - 22)	516 (484 - 548)	12 (11 - 14)
anti-K	68 (64 - 71)	46 (44 - 48)	49 (45 - 52)	32 (30 - 35)
anti-c	29 (26 - 31)	1.9 (1.5 - 2.2)	23 (21 - 25)	1 (0.7 - 1.4)
anti-E	110 (105 - 116)	8 (7 - 9)	90 (85 - 96)	4.5 (3.7 - 5.2)
Moderate risk of HDFN				
anti-C	30 (26 - 33)	2.6 (2.2 – 3.0)	21 (18 - 24)	1.5 (1.1 - 1.9)
anti-e	4 (3 - 5)	0.06 (0.01 - 0.12)	3 (2 - 4)	0.06 (0 - 0.15)
anti-k	0.01 (0 - 0.03)	0.01 (0 - 0.03)	0	0

865 Toll-like Receptor 9 (TLR9) suppression restores endothelial function in the maternal placental microvasculature in preeclampsia

Rosinda De La Pena[1], Kaleigh Kozak[2], David D. Gutterman[2], Curt D. Sigmund[2], Andreas M. Beyer[2], Michael E. Widlansky[2], Julie Freed[2], Meredith Cruz[2], Jennifer J. McIntosh[2]

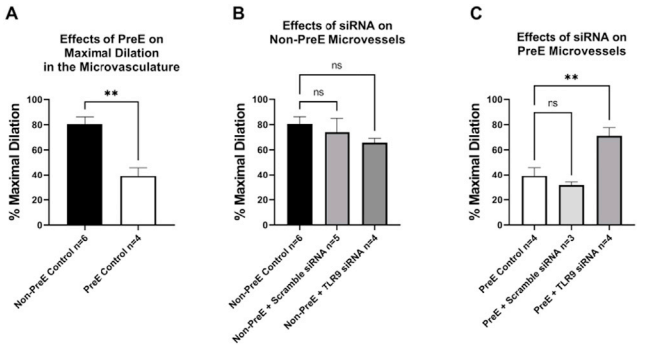
[1]Hospital, Wauwatosa, WI, [2]Medical College of Wisconsin, Milwaukee, WI

OBJECTIVE: We have previously shown that endothelial function in the human placental microcirculation is impacted by excessive oxidative stress and TLR9 may be part of this mechanism. Therefore, to evaluate whether TLR9 knockdown restores vascular function in preeclamptic microvessels.

STUDY DESIGN: Placental microvessels (< 150μM diameter) were dissected from the maternal side of control or preeclamptic placentas and then incubated with media and scrambled siRNA or TLR9-specific siRNA (50nM) for 12-16 hours. Vessels were cannulated on glass micropipettes, pressurized to 60mmHg, and then pre-constricted with 0.1-2.0 nM endothelin-1. A pressure gradient was applied to induce flow and vessel inner diameters were measured by videomicroscopy. Flow-mediated dilation (FMD) was calculated as a % of maximum diameter and expressed as mean ± SEM. Results were analyzed by two-way ANOVA with Dunnett's multiple comparisons. The maximum dilation values were evaluated by a Kruskal-Wallis test with Dunn's multiple comparative test or t-test as appropriate.

RESULTS: Preeclamptic microvessels demonstrated impaired endothelium-dependent vasodilation compared to healthy controls (Fig. A, p=0.0018). Vasodilator capacity in healthy controls was not significantly impacted by siRNA treatment (Fig. B, p=0.4429). TLR9 siRNA restored impaired endothelium-dependent vasodilation to flow compared to both untreated and scrambled siRNA-transfected vessels from patients with preeclampsia (Fig. C, p=0.0082).

CONCLUSION: Suppression of TLR9 expression restores endothelium-dependent vasodilation to flow in preeclamptic vessels and merits further evaluation.



866 Zygosity-based Twin Pregnancy Outcomes: Insights from SNP-Based cfDNA Screening

Ruben A. Quintero[1], Joseph Hurt[2], Neeta L. Vora[3], Neil S. Seligman[4], Gerard Reilly[5], Myra Wick[6], Samuel Wolf[7], Maeve Hopkins[8], Tom Westover[9], Homa K. Ahmadzia[10], Camille Kanaan[11], Andrei Rebarber[12], Eftichia V. Kontopoulos[1], Jingwen Zhang[13], Melissa Egbert[13], Sophia Vourthis[13], Vivienne Souter[13], Clark T. Johnson[14]

[1]USFetus Research Consortium, Coral Gables, FL, [2]University of Colorado, School of Medicine, Aurora, CO, [3]University of North Carolina, Chapel Hill, NC, [4]University of Rochester Medical Center, Rochester, NY, [5]Seven Hills Women's Health Center, Cincinnati, OH, [6]Mayo Clinic, Rochester, MN, [7]Emerald Coast Obstetrics and Gynecology, Panama City, FL, [8]Cleveland Clinic, Rocky River, OH, [9]Capital Health, Trenton, NJ, [10]George Washington University, Washington, DC, [11]Eastern Virginia Medical School, Norfolk, VA, [12]Icahn School of Medicine at Mount Sinai, New York, NY, [13]Natera, Inc., Austin, TX, [14]Sinai Hospital of Baltimore, Baltimore, MD

OBJECTIVE: To evaluate outcomes in twin pregnancies stratified by zygosity based on SNP-based cell-free DNA screening (cfDNA).

STUDY DESIGN: Prospective study of twin pregnancies undergoing SNP-based cfDNA following prenatal ultrasound (< 20 weeks' gestation) at 13 US sites (Oct 2021-March 2023). Pregnancies with twin-to-twin transfusion syndrome (TTTS) prior to enrollment or a contraindication to cfDNA screening were excluded. cfDNA results, ultrasound findings, placental pathology, and maternal and newborn outcomes were collected. Dizygotic twins (DZ) on cfDNA were classified as dichorionic (DC). Monozygotic (MZ) twins on cfDNA were classified as monochorionic (MC) or DC based on placental pathology. Odds ratios (95% confidence intervals) were calculated to compare the pregnancy outcomes for MZ MC and MZ DC twins with those of DZ twins.

RESULTS: 137 patients enrolled in the study. After exclusions for undetermined cfDNA (1), incomplete follow-up (11), and MZ twins with no placental pathology (2), 123 patients remained in the cohort: 76 DZ, 31 MZ MC, and 16 MZ DC. Placental pathology was available for 63/76 (82.9%) DZ twins and was DC in all. Median gestation at cfDNA was 12^{+5} weeks. Pregnancy outcomes by zygosity and chorionicity are shown in Table 1. TTTS occurred in 3.2%, selective intrauterine growth restriction (SIUGR) in 22.6%, and twin-anemia-polycythemia sequence (TAPS) in 9.7% of MC twins. MZ MC twins had the highest incidence of pregnancy complications including preterm birth and NICU admission. The incidence of small-for-gestational age (SGA) (birth weight < 10th percentile) was higher in the MZ DC group compared to the DZ group (OR=2.51; 95% CI 1.08,5.87).

CONCLUSION: SNP-based cfDNA in twin pregnancies can be used to determine the rate of complications by zygosity. This may help establish the actual rates of specific complications of MC twins, such as TTTS, SIUGR, and TAPS. The finding of a high incidence of SGA in MZ DC vs DZ DC twins may have important research and clinical implications, particularly on the frequency of growth surveillance.

Table 1. Newborn outcomes Comparison of pregnancy outcomes in MZ MC and MZ DC twins with those in the referent group, DZ twins.

867 Impact of BMI and Mode of Delivery on Neonatal and Maternal Outcomes of Nulliparas

Rula Atwani, George R. Saade, Tetsuya Kawakita
Eastern Virginia Medical School, Norfolk, VA

OBJECTIVE: To compare neonatal and maternal outcomes based on the attempted mode of delivery stratified by body mass index (BMI kg/m^2).

STUDY DESIGN: This was a repeated cross-sectional analysis of US vital statistics Live Birth/Infant Death linked data from 2011 to 2020. We limited analyses to nulliparas with singleton pregnancies and cephalic presentation who delivered at 20 weeks or greater. Our primary outcome was a composite neonatal outcome defined as any neonatal death, neonatal intensive care unit (ICU), surfactant use, ventilation use, or seizure. Our secondary outcome was severe maternal morbidity (SMM) defined as any maternal ICU, transfusion, uterine rupture, and hysterectomy. Outcomes were compared according to BMI category (< 18.5, 18.5-24.9, 25-29.9, 30-39.9, 40-49.9, and 50-59.9) between individuals who attempted labor and individuals who opted for non-labor cesarean delivery. Adjusted relative risks (aRR) with 99% confidence intervals were calculated using modified Poisson regression.

RESULTS: Of 9,711,230 individuals, 462,201 had BMI < 18.5, 4,882,537 had BMI 18.5-24.9, 2,342,705 had BMI 25-29.9, 1,663,303 had BMI 30-39.9, 317,913 had BMI 40-49.9, and 42,571 had BMI 50-59.9. Table 1 shows the aRRs for each BMI class, with individuals who attempted labor being the referent group. Compared to attempting labor, non-labor cesarean was associated with an increased risk of the composite neonatal outcome in all BMI classes-BMI < 18.5, 18.5-24.5, 25-29.9, 30-39.9, 40-49.9, and 50-59.9 (range of aRRs 1.12-1.44). Compared to attempting labor, non-labor cesarean was associated with an increased risk of SMM in BMI < 18.5, 18.5-24.5, 25-29.9, and 30-39.9 (range of aRR 1.20-1.77). However,

there was no significant difference in severe maternal morbidity in BMI 40-49.9, and 50-59.9.

CONCLUSION: Attempting labor was associated with improved neonatal outcomes in all BMI classes as well as improved maternal outcomes except for BMI 40-49.9 and 50-59.9 compared to non-labor cesarean. Even for individuals with high BMI, it is reasonable to allow an attempt for vaginal delivery.

Table 1

	Severe Maternal Morbidity		Neonatal Composite Outcome

868 Impact of the ARRIVE Trial in Nulliparous Individuals with Morbid Obesity: Interrupted Time Series Analysis

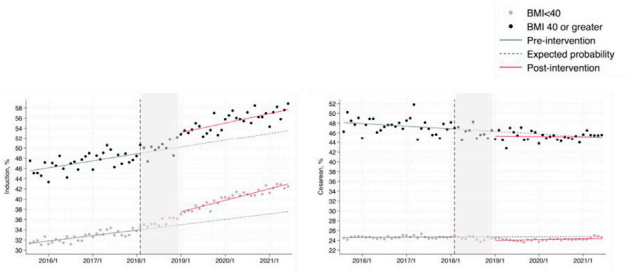
Rula Atwani, George R. Saade, Tetsuya Kawakita
Eastern Virginia Medical School, Norfolk, VA

OBJECTIVE: Since the ARRIVE trial (A Randomized Trial of Induction Versus Expectant Management) was published in 2018, the number of induction of labor (IOL) in nulliparas has increased. Given that the median body mass index (BMI) in the ARRIVE trial was 30.5 kg/m^2, the generalizability of the benefits of elective induction to patients with morbid obesity (BMI≥40kg/m^2) is not clear. We aimed to examine rates of induction of labor (IOL) and cesarean delivery (CD) before and after the ARRIVE trial stratified by BMI category at the population level.

STUDY DESIGN: This was a repeated cross-sectional analysis of publicly available US birth certificate data from 2015 to 2021. We limited analyses to nulliparas with singleton pregnancy without chronic hypertension and diabetes (gestational or pregestational) who delivered between 39 and 42weeks' gestation. The dissemination period of the ARRIVE trial was from Feb 2018 to Dec 2018. The pre-ARRIVE period was from Aug 2015 to Jan 2018. The Post-ARRIVE trial period was from Jan 2019, to June 2021. We conducted an interrupted time series analysis after stratifying by BMI (< 40 or ≥40). Poisson regression to calculate adjusted incident rate ratios (aIRR) with 95% confidence intervals (95%CI).

RESULTS: Of 2,666,235 individuals 2,578,484(96.7%) had BMI< 40 and 87,751(3.3%) had BMI ≥40. In nulliparas with BMI< 40, the post-ARRIVE period compared to the pre-ARRIVE period was associated with increased rates of IOL (37.0% observed vs. 35.0% expected; aIRR, 1.06; 95%CI 1.05-1.08) and decreased rates of CD (24.4% observed vs. 24.7% expected; aIRR, 0.97; 95%CI, 0.96-0.99). On the other hand, in nulliparas with BMI≥40, there was a significant increase in IOL (52.8% observed vs. 50.2% expected; aIRR, 1.06 95%CI, 1.01-1.11); however, the decrease in CD was not significant (44.7% observed vs. 46% expected; aIRR, 0.97; 95%CI, 0.92-1.02).

CONCLUSION: The dissemination of the ARRIVE trial had the expected impact on IOL rates in nulliparas with and without morbid obesity. Only nulliparas without morbid obesity benefited from decreased CD rates.



869 The Impact of Obstetrician's Gender on Maternal and Neonatal Outcomes in Vacuum-Assisted Deliveries

Anat Pardo[1], Michal Axelrod[2], Or Bercovich[3], Inbal Navon[4], Shir Nahum Fridland[4], Noam Pardo[5], Ohad Houri[6], Hadas Zafrir danieli[4], Eran Hadar[7], Sharon Perlman[4]
[1]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, Tel-Aviv, Israel, [2]Sheba Medical Center, Ramat-Gan, HaMerkaz, [3]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, HaMerkaz, [4]Helen Schneider Hospital for Women, Rabin Medical Center, Petach Tikwa, HaMerkaz, [5]Sheba Medical Center, Tel Hashomer, Ramat-Gan, Tel Aviv, [6]Rabin Medical Center, Tel Aviv, Israel, [7]Rabin Medical Center, Petach-Tikva, HaMerkaz

OBJECTIVE: To investigate the association between obstetrician's gender and maternal and neonatal outcome following vacuum-assisted deliveries (VAD)

STUDY DESIGN: Retrospective cohort study at a single tertiary center between 2012 and 2022 included 5328 VADs. The outcomes of 2659 VADs performed by women obstetricians were compared to 2669 VADs performed by men obstetricians. The primary outcome was failed VAD. Secondary outcomes included maternal complications (Post Partum Hemorrhage, blood products transfusion, and OASIS) and neonatal complications (5-min Apgar< 7, umbilical cord pH< 7.1, and NICU admission).

The groups were compared using demographic and clinical independent variables in a univariate and multivariate analysis

RESULTS: Demographic characteristics did not significantly differ between the groups, except for body mass index (BMI) which was lower for mothers in the women obstetricians' group (23.07±4.40 vs 23.30±4.27, p=0.045). There were no between-group variations for regional analgesia, indication for intervention, and neonatal birthweight. Women obstetricians used more often metal caps than men (86.6% vs. 84%, p=0.009). Failed VADs analysis displayed gender-based differences: women obstetricians exhibited lower rates of failure compared to men (1.7% vs. 2.8%; p=0.08). This association was further supported by multivariate analysis (OR 1.57, 95% CI 1.047-2.366) with p< 0.029. However, these differences were not associated with increased adverse maternal or neonatal outcomes. When analyzing the final mode of delivery, women obstetricians achieved higher rates of vaginal deliveries (0.3% vs. 0%), while men obstetricians had higher rates of cesarean deliveries (2.3% vs. 1.2%; p< 0.001) (Table 1)

CONCLUSION: Women obstetricians demonstrated a notably lower rate of failed VAD compared to their men counterparts. These findings highlight the necessity for additional research and targeted interventions to understand the underlying factors contributing to this gender-based discrepancy

Table 1: Baseline characteristics, delivery characteristics and maternal and neonatal outcomes

Variables	Women operator N=2659	Men operator N=2669	p-value
Demographic and clinical characteristics			
Maternal Age, years	30.03±5.13	30.19±5.21	0.275

870 MicroRNAs as Markers of Aspirin Response and Pregnancy Outcome in High Risk Singletons

Rupsa C. Boelig[1], James Michael[2], Antonios Tawk[3], Walter Kraft[3], Steven McKenzie[3]

[1]Thomas Jefferson University Hospital, Philadelphia, PA, [2]Thomas Jefferson University, Philadelphia, PA, [3]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA

OBJECTIVE: Aspirin decreases the risk of preeclampsia and preterm birth in high risk pregnancies, but individual response to aspirin varies and has not been correlated with outcomes. MicroRNAs (miRNA) are non-coding RNAs that regulate gene expression. Circulating miRNAs are associated with aspirin response and cardiovascular risk in non-pregnant adults, and placental miRNAs with preeclampsia and preterm birth. We sought to evaluate selected miRNAs associated with platelet activity and preeclampsia/preterm birth to determine whether they are markers of response to aspirin in pregnancy and predictors of adverse outcomes

STUDY DESIGN: This is a prospective study of singletons at high risk for preeclampsia taking aspirin daily. Blood was drawn at baseline prior to aspirin (10-16 weeks'), 2-4 weeks after aspirin initiation (follow-up 1), and at 28-32 weeks' (follow-up 2). PFA-100 epinephrine closure time (PFA-100 (epi)) is a known marker of aspirin response that increases with platelet inhibition. miRNAs (16, 18a, 181a, 126, 155, 223) were quantified in highly purified platelets and reported as fold-change from baseline. Pearson correlation coefficient was used to correlate PFA-100(epi) and miRNA fold change. Regression analysis was used to correlate fold-change in miRNAs and outcome of preeclampsia and preterm birth.

RESULTS: Of N=130 participants in parent study, N=57 had sufficient sample for miRNA extraction and reliable, reproducible quantification. At follow up-1, an increase in PFA-100(epi) was associated with a reduced miRNAs 223 (r=-0.33, p=0.017), 18a (r=-0.29, p=0.035), and 181a(r=-0.28, p=0.046). No miRNA at follow up-1 was associated with outcomes. At follow up-2, increased miRNA 223 was associated with preterm birth (B=6.5 (1.5-27.2), p=0.01) but not preeclampsia (B=2.0 (0.7-6.3, p=0.22).

CONCLUSION: MicroRNAs are markers of both aspirin response in pregnancy and adverse pregnancy outcome. Platelet derived miRNA 223 has been associated with platelet activity and activation of inflammatory pathways, and is a promising marker for both tracking aspirin response and prediction of adverse pregnancy outcome.

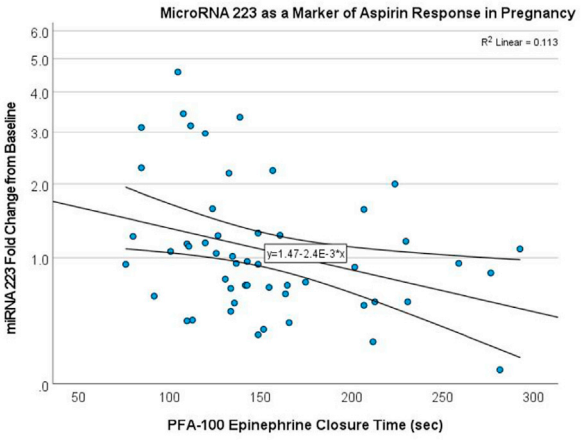

Figure: Correlation between PFA-100 epinephrine closure time and fold change in miRNA223 in purified platelets in singleton pregnancies 2-4 weeks after aspirin initiation. Pearson correlation coefficient r=-0.33, p=0.017.

871 Maternal Fetal Medicine Unit (MFMU) vaginal birth after cesarean calculator validation at academic community hospital

Salam Syed[1], Morgan McFadden[1], Meredith Rochon[2], Travis Dayon[1], Joanne Quiñones[1]

[1]Lehigh Valley Health Network, Allentown, PA, [2]Lehigh Valley Hospital, Allentown, PA

OBJECTIVE: The MFMU vaginal birth after cesarean (VBAC) calculator was revised in 2021 due to concerns that the original 2007 calculator propagated health disparities by including race and ethnicity. The objective of our study was to compare predicted success rates of the 2007 vs 2021 calculators in a population who underwent a trial of labor after cesarean (TOLAC).

STUDY DESIGN: This is a retrospective cohort study of pregnant individuals ≥ 18 years who underwent TOLAC after 1 cesarean (CD) at our institution between 9/1/19-8/31/2022. Success scores were calculated using both calculators, categorized (< 50%, 50-59%, 60-69%, and ≥70% success), and compared, stratifying by race. Receiver operating characteristic (ROC) curves were created to compare the overall performance of both calculators using these predicted success categories.

RESULTS: 2009 individuals with a history of CD delivered during the study period, of which 1291 had one previous CD and no contraindication to TOLAC. Of these, 457 attempted TOLAC, with an overall VBAC success rate of 76.4%. Success rates by race are shown in Table 1. When applying both calculators to this population, a higher proportion of Black individuals had lower predicted success score categories compared to other races when using the 2007

calculator but not the 2021 calculator (Table 2). The overall ability to predict VBAC success was similar for the two calculators (area under the curve for the 2007 calculator 0.70 vs 0.72 for the 2021 calculator, p=0.27).

CONCLUSION: In our population, predicted VBAC success rates were lower for Black women when using the 2007 vs 2021 MFMU VBAC calculator, while both calculators performed similarly in predicting overall VBAC success. Our data validate the 2021 revised MFMU VBAC calculator without race or ethnicity.

Table 1. Successful VBAC rates by race & ethnicity in our population

Race	VBAC rate	p value
White	200 (78.4%)	
Black	15 (40.5%)	
Asian	17 (85.0%)	p<0.001
Other	108 (81.2%)	
Unknown	9 (75.0%)	
Hispanic ethnicity	**VBAC rate**	**p value**
Yes	127 (82.5%)	0.03
No	222 (73.3%)	

Table 2. Comparison of 2007 and 2021 MFMU VBAC calculator scores among our population by race and ethnicity

2007 calculator predicted success	White (n=255)	Black (n=37)	Other (n=145)	p value
<50%	24 (9.4%)	11 (29.8%)	32 (22.1%)	<0.001
50-59%	28 (11.0%)	6 (16.2%)	21 (14.5%)	
60-69%	44 (17.3%)	6 (16.2%)	25 (17.2%)	
≥70%	159 (62.4%)	14 (37.8%)	67 (46.2%)	
2021 calculator predicted success	**White (n=255)**	**Black (n=37)**	**Other (n=145)**	**p value**
<50%	30 (11.8%)	8 (21.6%)	21 (14.5%)	0.53
50-59%	38 (14.9%)	5 (13.5%)	25 (17.2%)	
60-69%	57 (22.4%)	7 (18.9%)	23 (15.9%)	
≥70%	130 (51.0%)	17 (46.0%)	76 (52.4%)	

872 Validation and clinical case report in non invasive prenatal testing for all chromosomes

Sam Martin[1], Hyuk Jung Kwon[1], Dabin Park[1], Woo Jung Do[1], Min Seob Lee[2]

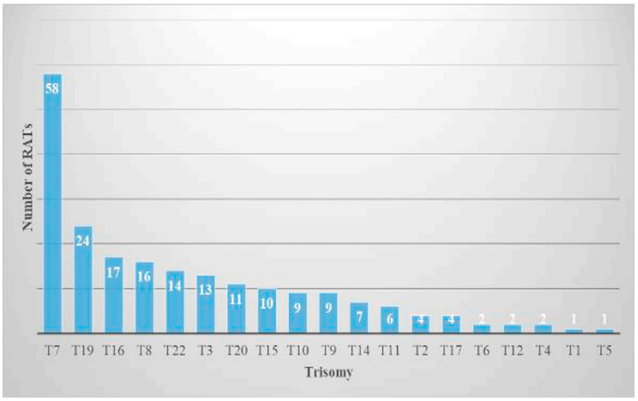
[1]Eone Diagnomics Genome Center, Inc., Incheon, Inch'on-jikhalsi, [2]Diagnomics, Inc., San Diego, CA

OBJECTIVE: Whole-Genome Sequencing (WGS)-based bioinformatics algorithms have a potential advantage to detect the aneuploidies for all chromosomes. Despite this advantage, chromosome 21, 18, 13 and sex chromosome have typically been applied for Non-invasive prenatal testing (NIPT) and have sufficient validation results. As Rare Autosomal Trisomies (RATs) research helps the understanding of feto-placental biology, a detection algorithm with higher accuracy is also importantly required.

STUDY DESIGN: We first searched for RAT cases from the literature and generated artificial data for each case, according to various fetal fraction. We used an in-house pipeline, which applied the z-score twice to maximize the sensitivity and set the threshold. Finally, we calculated the demographic statistics using clinical data.

RESULTS: Depending on the fetal fraction, the accuracy varies for each chromosome. In most chromosomes, the proposed algorithm showed high accuracy (> 99%) with 10% fetal fraction, and most of chromosomes had high accuracy (> 95%) even at 5% fetal fraction, while chromosome 19 showed low accuracy as 80%. One hundred eighty-seven RATs were identified in 30,364 clinical samples, and Trisomy 7 (n=58) was the most frequent, followed by Trisomy16 (n=17), Trisomy 8 (n=16). Amniotic karyotyping was performed in 23 cases, with 6 confirming an abnormality (mosaic or trisomy). The other 17 cases were normal amniocentesis results, which may suggest confined placental mosaicism (CPM).

CONCLUSION: Our results show that we have developed an algorithm, with well-designed artificial samples for detecting all chromosomes aneuploidies. All chromosome testing can help to detect the presence of RATs that may adversely affect pregnancy outcomes, with respect to placental dysfunction, fetal growth restriction and potential uniparental disomy (UPD).



873 Timing of antenatal steroid administration in twin gestations

Sara Edwards[1], Medhavi Bhasin[2], Alexandra J. D. Phelps[3], Calla Holmgren[4], Rachel Harrison[5]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]Advocate Lutheran General Hospital, Park Ridge, IL, [3]Vanderbilt University Medical Center, Nashville, TN, [4]AAH Lutheran General Hospital, Park Ridge, IL, [5]Advocate Christ Hospital, Oak Lawn, IL

OBJECTIVE: The administration of antenatal steroids to improve neonatal outcomes is common in situations of anticipated preterm delivery both before and after 34 weeks. Our objective was to evaluate maternal and neonatal outcomes in twin gestations delivered after 34 weeks.

STUDY DESIGN: We conducted a retrospective cohort study of twin gestations delivered at ≥ 34 weeks gestation within our health system from 2020-2021. Subjects were excluded if they delivered before 34 weeks gestation. Included subjects were categorized based upon presence and timing of antenatal steroid administration (< 34 weeks, ≥ 34 weeks, or none). Our primary outcome was presence of respiratory distress syndrome. Secondary outcomes included other adverse neonatal outcomes, including use of surfactant, use of supplemental oxygen with a fraction of inspired oxygen of 30% for at least 24 hours, neonatal hypoglycemia, and birthweight < 10th percentile. Groups were compared via t-tests, chi-square analysis, Fisher's exact test, and linear and logistic regression.

RESULTS: 522 subjects were included, of which 374 (71.6%) did not receive steroids, 66 (12.6%) received steroids < 34 weeks, and 82 (15.7%) received steroids ≥ 34 weeks. When controlling for other factors that differed among groups with p< 0.05, those receiving steroids < 34 weeks demonstrated significantly lower rates of respiratory distress syndrome (aOR 0.32, 95%CI 0.12-0.85), but higher rates of transient tachypnea of the newborn (aOR 2.42, 95%CI 1.16-5.04) when compared to those who did not receive steroids. This significant improvement was not noted in cases of steroids received ≥ 34 weeks gestation. Additional neonatal complications were not significantly different between groups when controlling for other factors.

CONCLUSION: Rates of respiratory distress syndrome were significantly lower in twin gestations who received steroids < 34 weeks gestation, without similar significant improvement seen with steroid administration ≥ 34 weeks gestation.

Adjusted Regression comparing steroids given ≥ 34 weeks or < 34 weeks versus no steroids		
	Steroids < 34 weeks	Steroids ≥ 34 weeks
	aOR / aRC (95% CI)	aOR / aRC (95% CI)
Respiratory distress syndrome	**0.32 (0.12-0.85)**	0.57 (0.27-1.20)
Surfactant use	0.35 (0.04-2.99)	0.81 (0.22-3.03)
FiO2 >30% for at least 24 hours	0.39 (0.04-3.64)	0.81 (0.15-4.48)
Transient tachypnea of the newborn	**2.42 (1.16-5.04)**	1.27 (0.59-2.74)
Apnea	0.59 (0.15-2.37)	0.50 (0.14-1.80)
Apgar < 7 at 5 minutes	0.73 (0.22-2.45)	0.53 (0.14-2.01)
Birth weight < 10th %ile		
Twin A	1.85 (0.65-5.26)	1.40 (0.48-4.08)
Twin B	1.54 (0.69-3.44)	1.19 (0.53-2.65)
Hypoglycemia	1.01 (0.55-1.83)	1.52 (0.88-2.64)
Neonatal intensive care unit admission	0.74 (0.38-1.41)	0.92 (0.51-1.65)
Controlled for hypertensive disorders of pregnancy, chorionicity/amnionicity, preterm labor, preterm premature rupture of membranes, gestational age at delivery		

874 How common are fetal genetic abnormalities in "low-risk" patients undergoing genetic testing?

Sarah J. Weingarten[1], Brittany Roser[2], Luiza Perez[3], Sarah Heaps[4], Rana K. Fowlkes[4], Stephen T. Chasen[1]
[1]Weill Cornell Medicine, New York, NY, [2]Weill Cornell, New York, NY, [3]Weill Cornell Medical College, New York, NY, [4]Weill Cornell Medicine at New York Presbyterian Hospital, New York, NY

OBJECTIVE: While amniocentesis and chorionic villus sampling (CVS) are typically performed in those with risk factors, they should be offered to all patients. Our aim was to evaluate the rate of chromosomal abnormalities or copy number variants (CNVs) in patients at low risk who chose to undergo diagnostic testing.

STUDY DESIGN: This was a retrospective review of low-risk patients who underwent invasive testing from 2016-2022. "Low-risk" was defined as those without abnormal screening tests for aneuploidy or single gene disorders. Those with ultrasound abnormalities prior to invasive testing, no prior genetic screening test, and those who terminated for reasons unrelated to genetic diagnosis were excluded. Advanced maternal age (AMA) (age ≥35) patients with normal non-invasive prenatal test (NIPT) were considered low-risk, due to the high sensitivity of NIPT for age-related chromosomal abnormalities. The primary outcome was the rate of genetic abnormalities in low-risk patients. Analysis was done using Fisher's exact.

RESULTS: 668 patients at a median age of 37 (35-40) underwent invasive testing. 77.2% underwent amniocentesis, 21.9% CVS, and 0.9% both. 97% had normal karyotype and microarray. 20 patients (3%) had abnormal genetic testing, including 4 with abnormal karyotype (all inherited rearrangements) and 16 with abnormal microarray. Of the 16 abnormal microarrays, two (12.5%) were considered pathogenic or potentially pathogenic. Genetic findings are shown in Table 1. Overall, three patients (0.4%) chose to terminate the pregnancy due to genetic results. The rate of AMA was not different in those with and without genetic abnormalities (86.9% vs 75%; p=0.25).

CONCLUSION: Genetic screening can identify a population at very low-risk of abnormalities on karyotype or microarray. While most patients in this population had normal genetic testing, clinically significant abnormalities were encountered. These results reinforce the importance of offering invasive testing to all patients, regardless of risk, especially in those who would consider abortion.

Table 1: Demographics and Genetic Outcomes for "low-risk" patients

		Total patients N=668
Abnormal Karyotypes		
	Autosomal trisomy	0 (0%)
	Sex chromosome aneuploidy	0 (0%)
	Inherited inversion or translocation	4 (0.6%)
	De novo inversion or translocation	0 (0%)
Abnormal Microarrays		
	CNV (pathogenic)	2 (0.3%)
	Inherited VUS	14 (2.1%)
	De novo VUS	0 (0%)

Abbreviations: CNV – copy number variant; VUS – variant of uncertain significance

875 Nocturnal Time Above Range with Continuous Glucose Monitoring and Large for Gestational Age Newborn

Sarah Nazeer[1], Rafael Santos[2], Claudia Pedroza[2], Sean C. Blackwell[3], Baha M. Sibai[4], Michal Fishel Bartal[5]
[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [3]Children's Memorial Hermann Hospital, Houston, TX, [4]Hermann Memorial Hospital, Houston, TX, [5]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX

OBJECTIVE: Recent data suggests a correlation between nighttime maternal blood sugars and neonatal birthweight. We aimed to examine the association between nighttime continuous glucose monitor (CGM) metrics and neonatal birthweight among individuals using CGM during gestational diabetes (GDM) screening.

STUDY DESIGN: This was a secondary analysis of the prospective study (06/2020 to 01/2022) of individuals who underwent 2-step GDM screening at ≤ 30 weeks. Participants wore a blinded CGM (Dexcom G6 Pro) for ten days during the 1-hour glucose challenge test (GCT). We evaluated nocturnal TAR defined as the percentage of time >140 mg/dL between midnight to 6:00 am. The primary outcome was the rate of large for gestational age, defined as >90th percentile on the Duryea et al. nomogram. TAR was expressed as a percentage of all CGM readings, mean glucose and standard deviation (SD) were analyzed. Spearman's rank correlation coefficient test was used to examine nocturnal TAR and neonatal birthweight; p value of < 0.05 was considered as a statistically significant value.

RESULTS: Of the 92 recruited participants, 6 (6.5%) had a LGA neonate. Individuals with LGA did not have a significantly increased nocturnal TAR as compared to those without LGA (p= 0.24). A correlation between increasing nocturnal TAR and increasing birthweight was not significant (p=0.51).

CONCLUSION: An association between increased nocturnal TAR and neonatal birthweight was not found. Larger studies are needed to investigate the role of nocturnal hyperglycemia and other adverse outcomes, as well as other maternal outcomes related to neonatal birthweight.

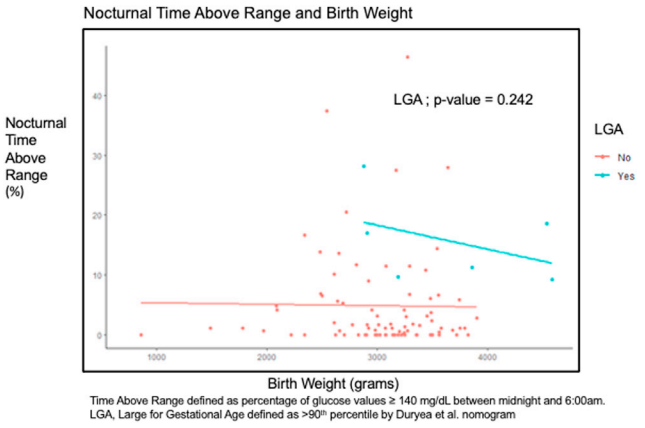


Table 1. Outcomes in a theoretical cohort of 3,664,292 live births

	Screening	No Screening	Difference (Screening-No Screening)
Correct Primary CMV Diagnoses	28,475	0	28,475
Vertical Transmission	6,128	15,687	-9,559
Abortion	877	492	385
Stillbirths	12,000	12,043	-43

876 Universal Screening and Valacyclovir for Maternal Primary CMV in the First Trimester: A Cost-Effectiveness Analysis

Sarah K. Dzubay, Amelia H. Gagliuso, Megha Arora, Uma Doshi, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

OBJECTIVE: Universal prenatal screening for CMV is not recommended in the United States as, historically, no effective interventions were available. With growing evidence that valacyclovir treatment in first trimester primary infections reduces vertical transmission, universal screening may become an important tool in congenital CMV prevention. This study examined the cost-effectiveness of universal screening for first trimester primary CMV and subsequent valacyclovir treatment for congenital CMV prevention in the United States.

STUDY DESIGN: A decision-analytic model was constructed to compare outcomes of universal screening and valacyclovir treatment in a theoretical cohort of 3,664,292 individuals, the estimated number of annual live births in the United States. Individuals found to be IgG+, IgM+, and to have low IgG avidity were considered to have primary CMV infection and received valacyclovir. Outcomes included correctly diagnosed primary CMV infections, cases of vertical CMV transmission, abortions, stillbirths, neonatal deaths, hearing loss, neurodevelopmental disabilities, costs, and quality adjusted life years (QALYs). Model inputs were derived from literature.

RESULTS: In our study, universal screening in the first trimester for primary CMV and subsequent treatment with valacyclovir in positive cases correctly diagnosed 28,475 cases of primary CMV, led to 385 additional abortions, and decreased adverse outcomes by 9,559 vertical transmission cases, 43 stillbirths, 40 neonatal deaths, 1,238 cases of hearing loss, and 276 cases of neurodevelopmental disability. Universal screening and subsequent treatment was the dominant strategy as it saved $608,668,546 and led to 6,222 additional QALYs.

CONCLUSION: Our results demonstrate that screening for first trimester primary CMV may be a cost-saving intervention, as identification of cases allows for the provision of treatment, which in turn reduces CMV transmission and costly sequelae.

877 Resource Utilization in Abdominal Hysterectomy for Placenta Accreta Spectrum versus other Benign Indications

Hope Y. Yu, Sarah E. Miller, Daniela A. Carusi
Brigham and Women's Hospital, Boston, MA

OBJECTIVE: Placenta Accreta Spectrum (PAS) patient outcomes are significantly improved under the care of multidisciplinary teams. Currently, hysterectomies for PAS management are billed under the same codes as benign non-obstetric abdominal hysterectomies, though we hypothesized that more surgeon resources are used for the former. We compared the required operating room times and number of attending OBGYNs between hysterectomies for PAS and benign gynecologic (GYN) indications.

STUDY DESIGN: Hysterectomies performed between 2015-2023 at a single institution were included. GYN hysterectomies included scheduled cases with procedure codes for abdominal hysterectomy (total or supracervical). Laparoscopic and robotic hysterectomies as well as those including other unrelated procedures were excluded. PAS hysterectomies included cesarean hysterectomies with pathology-confirmed PAS. Wilcoxon rank sum and Chi-squared analyses were used for continuous and categorical variables, respectively.

RESULTS: Three-hundred twenty-three hysterectomies were included, 147 PAS and 176 GYN. Cases of PAS comprised of 54 grade 1 (36.7%) and 93 grade 2 or above (63.3%). PAS hysterectomies were significantly more likely to require >1 attending OBGYN than GYN hysterectomies (29.9% vs 3.98%, OR 10.3 [4.48-23.8]). Compared to GYN hysterectomies (median 184 min, IQR 156, 235), attending OBGYN time in the operating room (OR) was similar when compared to all PAS hysterectomies (median 198 min, IQR 160, 240, p=0.78). However, this time was significantly greater for PAS hysterectomies grade 2 or above (median 214 min, IQR 167, 252, p=0.02) and those with placenta previa (median 222 min, IQR 192, 256, p< 0.01).

CONCLUSION: PAS hysterectomies are more likely to require multiple attending OBGYNs, and in cases with placenta previa or invasive PAS, longer time in the OR. As multidisciplinary delivery care is now the standard of care for PAS management, reimbursement rates for PAS hysterectomies should better reflect the resources and personnel required to care for these complex patients.

878 Intimate partner violence is associated with increased adverse perinatal outcomes

Sarena Hayer, Bharti Garg, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

OBJECTIVE: Pregnancy is a high-risk time for intimate partner violence (IPV), with varying estimates of IPV prevalence globally. Existing population-level research on IPV in pregnancy often examines cohorts outside of the United States (US). The objective of this study is to examine the association between IPV in pregnancy and perinatal outcomes in a large, US-based cohort.

STUDY DESIGN: This is a retrospective cohort study using California linked vital statistics and hospital discharge data from 2016-2019. We included singleton, non-anomalous births with gestational age 23-42 weeks. IPV was identified using International Classification of Diseases (ICD-10-CM) codes. Chi-square tests and multivariable logistic regression models were to determine association of IPV in pregnancy with perinatal outcomes.

RESULTS: A total of 1,518,741 births were included, of which 2,756 (0.2%) had reported IPV in pregnancy. Compared with no reported IPV, pregnancies with IPV had higher proportions of chorioamnionitis (6.6% vs. 3.3%; p< 0.001), severe maternal mortality (SMM) (2.5% vs. 1.3%; p< 0.001), preterm delivery < 37 weeks (9.1% vs. 6.8%; p< 0.001), and neonatal intensive care unit (NICU) admission (11.8% vs. 8.6%; p< 0.001). Pregnancies with reported IPV had increased odds of preeclampsia (aOR=1.41, (1.21, 1.65)), chorioamnionitis (aOR=2.23, (1.90, 2.61)), placental abruption (aOR=1.68, (1.27, 2.24)), and SMM (aOR=1.73, (1.35, 2.21)). With regards to neonatal outcomes, reported IPV in pregnancy was associated with increased odds of Apgar score < 7 at 5 minutes (aOR=2.02, (1.58, 2.59)) and NICU admission (aOR=1.23, (1.09, 1.38)). We did not find a statistically significant difference in preterm birth < 32 weeks, small for gestational age, stillbirth, or infant death.

CONCLUSION: IPV in pregnancy is associated with increased odds of adverse maternal outcomes, as well as increased odds of Apgar score < 7 at 5 minutes and NICU admission. The results of this study reinforce the need for universal screening for IPV in pregnancy to inform care in during this high-risk period.

Table 1: Multivariable logistic regression analyses showing adjusted odds ratios (aOR) for perinatal outcomes among patients with reported IPV in California (2016-2019)

	Births with reported IPV N=2,756 (0.2%)	Births with no report of IPV N=1,515,985 (99.8%)	p-value*	Adjusted odds ratio (aOR (95% CI)**
Maternal outcomes				
Preeclampsia	6.8%	4.5%	<0.001	1.41 (1.21, 1.65)
Chorioamnionitis	6.6%	3.3%	<0.001	2.23 (1.90, 2.61)
Pyelonephritis	0.3%	0.1%	<0.001	3.85 (1.91, 7.74)
Antepartum hemorrhage	0.3%	0.1%	0.002	2.82 (1.46, 5.45)

879 Perinatal outcomes of methamphetamine use in pregnancy in California, 2008-2019

Sarena Hayer[1], Bharti Garg[1], Jessica D. Wallace[2], Kristin Prewitt[1], Aaron B. Caughey[1], Jamie Lo[1]
[1]Oregon Health & Science University, Portland, OR, [2]University of Colorado, Aurora, CO

OBJECTIVE: While methamphetamine use has been rising in recent years, occurring amongst a wider demographic and in broader geographical areas, there is limited research on its use in pregnancy. The objective of this study is to examine the association between prenatal methamphetamine use and perinatal outcomes in a large, recent birth cohort.

STUDY DESIGN: This is a retrospective cohort study using California linked vital statistics and hospital discharge data from 2008-2019. We included singletons with gestational age 23-42 weeks. We further excluded cocaine, opioid, or other substance use. Methamphetamine use was identified using ICD-9 and ICD-10 codes. Chi-square tests and multivariable logistic regression models were used to evaluate associations of methamphetamine use with perinatal outcomes.

RESULTS: A total of 5,148,972 births were included, of which 6,056 (0.12%) had prenatal methamphetamine use. Compared with no use, individuals with methamphetamine use had higher proportions of severe maternal morbidity (3.1% vs. 1.2%; p< 0.001), preterm delivery < 37 weeks (16.0% vs. 6.7%; p< 0.001), and neonatal intensive care unit (NICU) admission (21.6% vs. 10.2%; p< 0.001). Individuals with methamphetamine use had increased odds of gestational hypertension (aOR=1.63, (1.44, 1.83)), preeclampsia (aOR=1.65, (1.48, 1.85)), placental abruption (aOR=2.09, (1.76, 2.48)), cardiovascular morbidity (aOR=2.11, (1.61, 2.77)), and severe maternal morbidity (aOR=2.11, (1.81, 2.47)). Hispanic patients and those with public insurance had higher odds of adverse maternal outcomes. With regards to neonatal outcomes, methamphetamine use was associated with increased odds of preterm birth < 37 weeks (aOR=2.10, (1.95, 2.26)), NICU admission (aOR=1.99, (1.87,

2.12)), small for gestational (aOR=1.30, (1.20, 1.41)), and infant death (aOR=3.29, (2.56, 4.23)).

CONCLUSION: Methamphetamine use in pregnancy is associated with increased odds of both adverse maternal and neonatal outcomes. The results of this study can inform care in pregnancy and postpartum for this high-risk, socioeconomically vulnerable population.

Table 1: Multivariable logistic regression analyses showing adjusted odds ratios (aOR) for perinatal outcomes among patients with methamphetamine use in California (2008-2019)

	Pregnant individuals with methamphetamine use N=6,056 (0.12%)	Pregnant individuals with no methamphetamine use N=5,142,916 (99.88%)	p-value*	Adjusted odds ratio (aOR (95% CI)**

880 Paracetamol versus Ibuprofen for Postpartum Pain control: A Randomized Controlled Trial

Shai Ram[1], Dotan Madar[2], Yotam Lior[3], Goni Peleg[4], Ayelet Greenfeld[2], Gala Yakov[2], Yariv Yogev[5], Ariel Many[6]

[1]Lis Hospital for Women, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, Ra'anana, Tel Aviv, [2]Lis Hospital for Women, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, Ichilov, Tel Aviv, [3]Intensive Care, and Pain Medicine, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, Ichilov, Tel Aviv, [4]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [5]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [6]Ma'ayne Hayeshua Medical Center Tel Aviv University, Bnei Brak, Tel Aviv

OBJECTIVE: The use of opioids for postpartum pain control raises concerns regarding their transfer through breastfeeding and potential side effects. We aimed to compare the pain control efficacy between paracetamol and ibuprofen during the immediate postpartum period.

STUDY DESIGN: A randomized controlled interventional study was conducted, including women who underwent vaginal delivery and provided informed consent for participation. When participants requested pain relief at any time during their hospitalization, they were randomly assigned treatment in a double-blind manner using pre-prepared envelopes containing either 400 mg of Ibuprofen or 1000 mg of paracetamol. Women who had undergone a cesarean section had a known sensitivity to any of the study drugs, had preeclampsia, pre or gestational diabetes, a history of depression, or chronic pain or fibromyalgia, were excluded from participation in the study.

Pain level was reported using the Numeric Rating Scale (NRS) at various time points immediately after treatment (T0), one, four, and six hours after treatment (T1, T4, and T6, respectively). The indicated site of the most intense pain and the need for additional analgesia were recorded. The study also evaluated the impact of pain control on breastfeeding initiation, mobilization, and urination.

RESULTS: 1. There were no differences in demographic characteristics and perinatal outcomes between the two study groups.

2. No significant differences were found in the interval from delivery to demand for pain control between the groups (8±6-10.5 hours and 11±6-16 hours for the paracetamol and ibuprofen groups respectively, p-value = 0.13).

3. Pain scores by NRS were similar between the groups for the paracetamol and ibuprofen groups (table)

4. No significant differences were noted in breastfeeding initiation, mobilization, urination, or the need for additional analgesia between the groups.

CONCLUSION: This study suggests comparable effectiveness of paracetamol and Ibuprofen for immediate postpartum analgesia and both medications can be considered as a non-opioid alternative for postpartum pain control.

Table - Analgesia effectiveness

Variable			All population (n=107)	paracetamol (n=52)	ibuprofen (n=55)	p-value
T0	Time delivery to analgesia request, mean (SD), hours		9 (6-12.5)	8 (6-10.5)	11 (6-16)	0.13

881 Gestational inflammation induces a cyclooxygenase-2 dependent disruption of vascular integrity of the placental barrier

Shakeela Faulkner[1], Qiuying Zhao[2], Hana Horackova[2], Thea Tagliaferro[3], Weiye Dai[2], Cara Monroe[1], Sue Ellen Martin[1], William Dean Wallace[1], Saloni Walia[1], Axel Montagne[4], Alexandre Bonnin[2]

[1]Keck School of Medicine of USC, Los Angeles, CA, [2]Zilkha Neurogenetic Institute, Keck School of Medicine, University of Southern California, Los Angeles, CA, [3]Neonatal Intensive Care Unit, Memorial Care Miller Children's and Women's Hospital, Long Beach, CA, [4]UK Dementia Research Institute and Centre for Clinical Brain Sciences, Edinburgh Medical School, University of Edinburgh,, Edinburgh, Scotland

OBJECTIVE: This study aimed to identify cellular and molecular pathways mediating severe maternal immune activation (MIA) effects on placental permeability and vasculature in a mouse model. Pharmacological and immunohistological methods identified the role of cyclooxygenase-2 (COX2) pathway and cellular localization of COX2 molecular pathway components to identify key players and potential therapeutic targets.

STUDY DESIGN: Pregnant mice were injected with saline or a viral mimetic, polyinosinic-polycytidylic acid (polyI:C; 10 mg/kg), to induce inflammation on gestational day 13. After 24 hours, mice

either received celecoxib (20 mg/kg) or vehicle only. On gestational day 15, live MRI was performed and specimens collected. Immunohistochemistry was used to evaluate placental pericyte coverage of endothelial cells and cellular localization of key elements of the COX 2 pathway.

RESULTS: Live MRI revealed that severe MIA increases placental permeability to a gadolinium contrast agent. In vivo pharmacological inhibition experiments demonstrated that this effect is from a COX2-dependent signal which increases macrophage activity and decreases pericyte coverage of endothelial cells in the placental villi. Similar responses were observed in human placental histological samples from patients with infections. Immunohistological studies revealed COX2 expression in decidual cells, microsomal Prostaglandin E synthase-1 (mPGES1) in syncytiotrophoblasts, and Prostaglandin E_2 receptor 3 (EP3) in adjacent pericytes.

CONCLUSION: Our results suggest that severe gestational MIA activates a decidual COX2 pathway leading to immune activation in placental villi and disruption of the blood-placental barrier integrity via EP3 receptor signaling in pericytes. Disruption of placental vascular structure and permeability may increase the risk of abnormal fetal development and negatively impact long-term health due to exposure to pathogens and inflammatory molecules. These results have implications extending beyond infection as COX2-mediated disruption of pericyte coverage of endothelial cells is observed in in vivo models of preeclampsia.

882 Impact of continuous glucose monitoring on glycemic control in type 1 diabetes in pregnancy

Shannon McCloskey[1], Joseph R. Biggio Jr.[2], Naiha Mussarat[3], John A. Morgan[4], James D. Toppin[5], Sarah Sternlieb[6], Nicholas Manuel[6], Kali Juracek[6], Sharon Shu[6], Jesse Stone[6], Frank Williams[7]

[1]Ochsner Clinic Foundation, New Orleans, LA, [2]Ochsner Health System, New Orleans, LA, [3]Ochsner Clinical Foundation, New Orleans, LA, [4]Ochsner Clinic, Metairie, LA, [5]Ochsner Health, New Orleans, LA, [6]Ochsner, New Orleans, LA, [7]Ochsner Clinic, New Orleans, LA

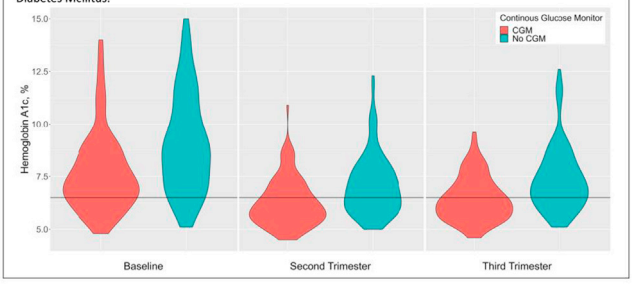
OBJECTIVE: Continuous glucose monitoring (CGM) is an expanding technology with potential benefits in pregnancy related outcomes. We aim to determine the effect of CGM use on glycemic control in patients with type 1 diabetes mellitus (T1DM) in pregnancy.

STUDY DESIGN: This was a retrospective cohort study of patients with T1DM with singleton pregnancy who received prenatal or diabetes care and delivered within a single large hospital system from 1/2016 - 1/2023. Patients using CGM were compared to those using traditional blood glucose monitoring (TBGM). Patients were excluded if missing delivery information, care was established after 20 weeks, or if unable to determine CGM status in pregnancy. Logistic regression was used to control for maternal age, body mass index, chronic hypertension, and insurance. Primary outcome was glycemic control in pregnancy, with on-target defined as hemoglobin A1c (HgA1c) $<$ 6.5%. Secondary outcomes included baseline poor glycemic control (HgA1c $\geq$10%), DKA admission, hypertensive disorders of pregnancy, indicated preterm birth, and primary cesarean delivery.

RESULTS: Among 288 patients with T1DM, 145 (50.3%) used CGM compared to 143 using TBGM monitoring. Patients using CGM were more likely to use insulin pumps and were less likely to be Black, nulliparous, or to use publicly funded insurance. On-target baseline glycemic control was more common in the CGM group (24.8% vs 9.8%, aOR 2.15, 95% CI 1.04-4.46) while poor glycemic control at baseline was less common in the CGM group (10.3% vs 28.7%, aOR 0.26, 95% CI 0.13-0.51). Differences in glycemic control persisted through pregnancy with on-target A1C values more common in the CGM group in second (55.2% vs 25.2%, OR 3.28, 95% CI 1.88-5.71) and third trimesters (42.1% vs 18.2%, OR 3.44, 95% CI 1.90-6.24). Persistent suboptimal or worsening glycemic control was less common in the CGM group (31% vs 46.2%, OR 0.29, 95% CI 0.16-0.53). Non-glycemic outcomes were similar between groups.

CONCLUSION: CGM use in T1DM is predictive of glycemic control throughout pregnancy, even when controlling for factors associated with poor glycemic outcomes.

Figure. Hemoglobin A1c through Pregnancy by Continuous Glucose Monitor Use Among Patients with Type 1 Diabetes Mellitus.



883 Impact of continuous glucose monitoring on non-glycemic perinatal outcomes in type 1 diabetes in pregnancy

Shannon McCloskey[1], Joseph R. Biggio Jr.[2], Naiha Mussarat[3], John A. Morgan[4], James D. Toppin[5], Sarah Sternlieb[6], Nicholas Manuel[6], Kali Juracek[6], Sharon Shu[6], Jesse Stone[6], Frank Williams[7]

[1]Ochsner Clinic Foundation, New Orleans, LA, [2]Ochsner Health System, New Orleans, LA, [3]Ochsner Clinical Foundation, New Orleans, LA, [4]Ochsner Clinic, Metairie, LA, [5]Ochsner Health, New Orleans, LA, [6]Ochsner, New Orleans, LA, [7]Ochsner Clinic, New Orleans, LA

OBJECTIVE: Continuous glucose monitoring (CGM) is an expanding technology with potential benefits in glycemic and non-glycemic perinatal outcomes. We aim to determine the impact of CGM use in type 1 diabetes mellitus (T1DM) on non-glycemic perinatal outcomes.

STUDY DESIGN: This was a retrospective cohort study of patients with type 1 diabetes who received prenatal or diabetes care and delivered within a single large hospital system from January 2016 to January 2023. Patients using CGM were compared to those using traditional capillary blood glucose monitoring (BGM). Inclusion criteria included diagnosis of type 1 diabetes prior to pregnancy and singleton gestation. Patients were excluded if missing delivery information, care was established after 20 weeks, or if unable to determine CGM status in pregnancy. Logistic regression was used to control for maternal age, body mass index, and insurance type. Primary outcome was prenatally diagnosed fetal anomalies. Secondary outcomes included stillbirth, perinatal death, small for gestational age (SGA), large for gestational age (LGA), neonatal intensive care (NICU), and 5-minute Apgar $<$4.

RESULTS: Among 288 patients with type 1 diabetes, 145 (50.3%) used CGM compared to 143 using traditional BGM monitoring. Patients using CGM were more likely to use insulin pumps and were less likely to be Black, nulliparous, or use publicly funded insurance. Median baseline hemoglobin A1c was lower in the CGM group (7.3 vs 8.8%, p$<$ 0.001). Fetal anomalies were less common in the CGM group compared to the traditional BGM group (3.4 vs 10.5%, aOR

0.27, 95% CI 0.09-0.81). Antenatal stillbirth (excluding those with congenital anomalies) was also less common in the CGM group (0.7% vs 6.3%, aOR 0.12, 95% CI 0.01-0.98). Secondary outcomes including LGA, SGA, NICU admission, perinatal death, and 5-minutes Apgar <4 were similar between groups (Table).

CONCLUSION: Preconception and pregnancy CGM use in T1DM is associated with a lower rate fetal anomalies and antenatal stillbirth, even when controlling for factors associated with adverse glycemic outcomes.

Table. Non-glycemic perinatal outcomes.

	All N = 288	CGM N = 145	TBGM N = 143	OR (95% CI)
Congenital anomaly	20 (6.9%)	5 (3.4%)	15 (10.5%)	0.27 (0.09-0.81)
Stillbirth	10 (3.5%)	1 (0.7%)	9 (6.3%)	0.12 (0.01-0.98)
Perinatal death	15 (5.2%)	4 (2.8%)	11 (7.7%)	0.33 (0.1-1.13)
LGA	96 (33.3%)	50 (34.5%)	46 (32.2%)	1.09 (0.66-1.78)
SGA	12 (4.2%)	5 (3.4%)	7 (4.9%)	0.68 (0.21-2.21)
5-minute Apgar <4	18 (6.2%)	7 (4.8%)	11 (7.7%)	0.62 (0.23-1.64)
NICU admission	164 (56.9%)	77 (53.1%)	87 (60.8%)	0.69 (0.42-1.11)

884 Influence of growth restriction on perinatal outcomes in singleton pregnancies with fetal congenital heart disease

Shelly Soni[1], Juliana S. Gebb[2], Nahla Khalek[2], Christina Paidas Teefey[1], Serena Wu[1], Kayla Neary[1], Kathleen Gianforcaro[1], Lisa Pilchman[2], Jack Rychik[1], Julie Moldenhauer[3]

[1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Center for Fetal Diagnosis & Treatment, Children's Hospital of Philadelphia, Philadelphia, PA, [3]Richard D. Wood, Jr. Center for Fetal Diagnosis & Treatment, Children's Hospital of Philadelphia, Perelman School of Medicine of the University of Pennsylvania, Philadelphia, PA

OBJECTIVE: To evaluate perinatal outcomes in singleton fetal congenital heart disease (CHD) cases with and without fetal growth restriction (FGR).

STUDY DESIGN: Single center retrospective analysis of singleton pregnancies with diagnosis of fetal CHD delivering at ≥ 37 weeks between July 1, 2020 and July 31, 2022. Cardiac anomalies were stratified by the neonatal level of care plan and graded from 1-4 in increasing order of complexity. The primary outcomes were birth-surgery interval and survival to hospital discharge. The FGR group was compared to the appropriately grown (AGA) group.

RESULTS: 389 pregnancies delivered during the study period. Of these, 61 (15.7%) were FGR and 328 (84.3%) were AGA. Pregnancies with FGR delivered at an earlier gestational age (p< 0.0001). Induction of labor rates were higher in the FGR group (69% vs 51%). Mode of delivery and NICU length of stay were comparable in both groups. On univariate analysis, birth-surgery interval was significantly greater (p=0.02), and neonatal survival rate was lower in the FGR group (p=0.03). On multiple regression (Table 2), the diagnosis of FGR did not influence birth-surgery interval (p=0.29) which was driven by the complexity of cardiac anomaly (p< 0.0001). However, FGR diagnosis along with the complexity of cardiac anomaly had a significant impact on the survival rate on logistic regression (p=0.03 and 0.007) (Table 3). Upon stratification of the FGR pregnancies by gestational age at delivery, 10 pregnancies delivered beyond 39 weeks and were not included due to small sample size. Outcomes were compared for gestational age at delivery between 37-37.6 weeks and 38-38.6 weeks. Gestational age at delivery influenced birth-surgery interval (p=0.008) and survival rate (p=0.04) in the FGR group on regression analysis.

CONCLUSION: In singleton term pregnancies with fetal CHD, FGR was associated with a lower neonatal survival rate. In the FGR group, early gestational age at delivery had greater birth-surgery interval and lower neonatal survival rates.

Table 1: Univariate analysis in term CHD pregnancies with and without FGR

	FGR (n=61)	AGA (n=328)	p-value
Extra-cardiac anomalies, N(%)	19 (31.1)	68 (20.7)	0.09

885 Outcomes in monochorionic diamniotic pregnancies with proximate placental cord insertions

Shelly Soni[1], Juliana S. Gebb[2], Julie Moldenhauer[3], Christina Paidas Teefey[1], Kendra Miller[4], Nahla Khalek[2]

[1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Center for Fetal Diagnosis & Treatment, Children's Hospital of Philadelphia, Philadelphia, PA, [3]Richard D. Wood, Jr. Center for Fetal Diagnosis & Treatment, Children's Hospital of Philadelphia, Perelman School of Medicine of the University of Pennsylvania, Philadelphia, PA, [4]Richard D. Wood Jr. Center for Fetal Diagnosis and Treatment at CHOP, Philadelphia, PA

OBJECTIVE: To evaluate outcomes in monochorionic diamniotic (MCDA) pregnancies with proximate placental cord insertions (pPCI).

STUDY DESIGN: Single center retrospective analysis of MCDA pregnancies between 2014-2022. Distance between placental cord insertions (PCI) was defined by ultrasound examination. Outcomes of pregnancies with pPCI (≤ 4 cm) were compared to those with intermediate PCI or iPCI (4.1-6.0 cm) from the same study period. For each pPCI pregnancy, 2 controls with PCI distance > 6 cm (normal or nPCI) were selected after matching for the diagnosis and the type of intervention.

RESULTS: 60 pregnancies with pPCI and 46 with iPCI were evaluated. More than 90% of pregnancies were twins in both groups. The rate of pathologies related to monochorionic placentation like TTTS was

similar between groups. There was a non-significant trend towards a greater number of type III sFGR cases in the pPCI group (37% vs 22%). The rate of intervention was similar in both groups, though there were a smaller number of cases that underwent laser in the pPCI group (3.3% vs 10.8%). The intertwin estimated fetal weight (EFW) discordance was lower in the pPCI group (18% vs 22%, p=0.04). Upon comparing pPCI and nPCI group, the rate of intervention was similar though the percentage of cases undergoing laser were greater in the nPCI group (3.3% vs 14.2%, p=0.04). A greater number of cases were managed with "amnioreduction (AR) only" in the pPCI group (8.3 vs 1.7, p=0.04). The EFW discordance was considerably lower in the pPCI group (18% vs 26%, p< 0.0001) though perinatal outcomes were similar in both groups. Linear regression model included all patients (n=226) and the distance between PCI significantly influenced EFW discordance after controlling for sFGR and gestational age at initial evaluation.

CONCLUSION: Presence of pPCI was associated with lower EFW discordance likely due to even distribution of placental share. Lower rates of laser and higher rates of AR management in this group suggests technical challenges associated with laser though the overall outcomes are comparable likely driven by the underlying diagnosis.

	pPCI (n=60)	nPCI (n=120)	p-value

886 Non-Criteria Obstetrics Antiphospholipid Syndrome is an independent risk factor for adverse pregnancy outcome

Shir Luvaton[1], Anat Rabinovich[2], Ran Abuhasira[3], Shayna Miodownik[4]

[1]Soroka University Medical Center, Beer-Sheva, HaDarom, [2]Thrombosis and Hemostasis Unit, Hematology Institute, Soroka University Medical Center, Beer Sheva, HaDarom, [3]Clinical Research Center, Soroka University Medical Center, Beer Sheva, HaDarom, [4]Hematology Institue, Soroka University Medical Center, HaDarom

OBJECTIVE: Non-Criteria Obstetric Antiphospholipid Syndrome (NC-OAPS) includes individuals who fit OAPS clinical criteria but not the Sydney laboratory requirements. The aims of the study were to determine the prevalence of NC-OAPS, antiphospholipid antibodies (APLab) profile, pregnancy outcomes among NC-OAPS and long-term thrombotic and obstetric complications.

STUDY DESIGN: A population-based retrospective cohort study included all singleton gestations (n=116,409) delivered at our medical center from 1998 to 2020. We defined NC-OAPS patients according to low titers of IgM/IgG anticardiolipin (aCL) or anti-β2-glycoprotein (aβ2GP) antibodies, a single positive lupus anticoagulant test (LAC) or positive IgA antibodies present on two or more occasions at least 12 weeks apart; together with at least one clinical criterion.

RESULTS: The rate of NC-OAPS was 0.22% (258/116409) and of OAPS 0.04% (49/116,409). The most frequent APLab tests were low titers of IgM & IgG aCL and LAC antibodies (33.7%, 35.3, and 35.3% respectively). Women with NC-OAPS had a higher rate of chronic hypertension, hypercholesterolemia, lupus, and aspirin and LMWH treatments than those in the general obstetrical population (GOP) (p< 0.001 for all). In comparison to women with OAPS, the NC-OAPS group had lower median gravidity and parity, a lower rate of lupus and aspirin or LMWH treatments. The rate of obstetric complications prior to and following the diagnosis of OAPS or NC-OAPS did not differ between the groups. The rate of DVT was lower in the NC-OAPS group (p=0.01). In a multivariable Generalized Estimating Equation model adjusting for maternal age, gravidity, and ethnicity, NC-OAPS patients had an independent risk to develop fetal loss, stillbirth, preeclampsia, placental abruption, fetal growth restriction and preterm birth than those in the GOP, which was similar to those with OAPS (Table).

CONCLUSION: NC-OAPS carries an independent risk for the development of pregnancy complications. These findings have implications on the prenatal follow-up and prevention strategies among women with NC-OAPS.

887 Perinatal outcomes of Small-for-Gestational-Age (SGA) newborns to mothers with and without a Müllerian anomaly

Sivan Chocron[1], Polina Schwarzman[2], Tamar Wainstock[3], Eli H. Bernstein[4], Eyal Sheiner[5]
[1]Soroka University Medical Center, Omer, HaDarom, [2]Soroka, Beer-Sheva, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom, [4]Bay State Medical Center, White Plains, NY, [5]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: Müllerian anomalies contribute to a distinct uterine environment which influence fetal development and have implications for both fetal growth and obstetrical outcomes. The current study aimed to compare the immediate perinatal outcomes of SGA newborns after development in a uterus with a Müllerian anomaly to SGA newborns who developed in a normal uterus.

STUDY DESIGN: A retrospective population-based cohort study was conducted including all SGA infants born between 1991 and 2021 in a tertiary medical center. The delivery data were collected from the institutional computerized database. Multiple gestations and chromosomal abnormalities were excluded. The study group included SGA newborns from uterus with a Müllerian anomaly compared to a group of SGA newborns from a normal uterus. Maternal characteristics and immediate perinatal outcomes were evaluated. Multiple logistic regression models were used for statistical analysis.

RESULTS: During the study period, 16,210 SGA neonates delivered in our medical center; 0.61% (n = 99) were born to mothers with Müllerian anomalies and 99.39% (n=16,111) were born to mothers with a normal uterus. Müllerian anomalies were related to higher rates of cesarean delivery (OR 20.4; 95% CI [12.3-33.7]; p < .001), preterm delivery < 37 weeks (OR 4.3; 95% CI [2.7-6.7]; p < .001), preterm delivery< 34 weeks (OR 4.1; 95% CI [2.2-7.7]; p < .001) and very low birth weight (< 1500g) (OR 3.5; 95% CI [1.9-6.3]; p < .001). However, perinatal outcomes, such as Apgar score < 7 at 5 minute and pH < 7 were comparable between the study groups.

CONCLUSION: Offspring with SGA that developed in a uterus with a Müllerian anomaly have a higher risk of cesarean delivery, preterm delivery and very low birth weight compared to SGA offspring developed in a normal uterus. However, there were no significant differences regarding adverse perinatal outcomes between the study groups.

Obstetric and perinatal outcomes of SGA newborns after gestation in Müllerian anomaly uterus versus newborns with SGA in normal uterus.

888 Vaginal progesterone effects at the endocervical epithelium in cell culture and preterm birth mouse model

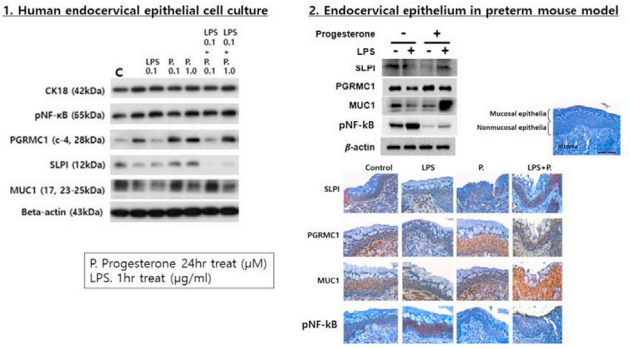
Soo Ran Choi[1], Suyeon Park[2]
[1]Inha University Hospital, Incheon, Republic of Korea, [2]Inha university hospital, Jung-gu, Inch'on-jikhalsi

OBJECTIVE: The vaginal progesterone has used to decrease preterm birth in women with short cervical length. The mechanism of progesterone on short cervix is not understood clearly. In this study, we investigated the effects of vaginal progesterone at the uterine endocervical epithelium in cell culture and preterm birth mouse model.

STUDY DESIGN: First, endocervical epithelial cell culture from human (hysterectomy due to postpartum hemorrhage) was conducted and treated with lipopolysaccharide (LPS) and progesterone. Second, the C57BL/6 mice (n = 7/group) were used. On days 13 -15 of gestation, mice received intrauterine injections of either LPS or sterile medium. Vaginal progesterone supply into upper vagina through vaginal plug. Four groups of mice were experimented, the controlled group, vaginal progesterone group, LPS group, and LPS with vaginal progesterone group. The expressions of progesterone receptor membrane component-1 (PGRMC1), secretory leukocyte protease inhibitor (SLPI), mucin-1, and phosphate nuclear factor-kB (pNF-kB) were determined by WB and IHC.

RESULTS: First, in cell culture, the expression levels of PGRMC1, SLPI, and mucin-1 were decreased after LPS treatment, but pNF-kB level was increased. After LPS pretreat and progesterone treat, PGRMC1 and SLPI levels were decreased and lower than that after progesterone treat, but mucin-1 level was increased. Second, in group of LPS treat, the expression of pNF-kB was increased and mucin-1 and SLPI and PGRMC1 expressions were decreased. In group of vaginal progesterone, pNF-kB expression was decreased and PGRMC1 expression was increased. In LPS with vaginal progesterone group, compare to LPS group, the expressions of PGRMC1, SLPI, and mucin-1 were increased, and pNF-kB expression was decreased.

CONCLUSION: Vaginal progesterone showed anti-inflammatory effects at the endocervical epithelium by increased expression of mucin-1, SLPI, and PGRMC1 and decreased expression of pNF-kB.



889 Measurements of pregnancy-related anxiety in sub-saharan africa: A scoping review

Tanvi Sharma[1], Ibrahim Khan[1], Emma Lawrence[2], Sophia Fraga[1]
[1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI

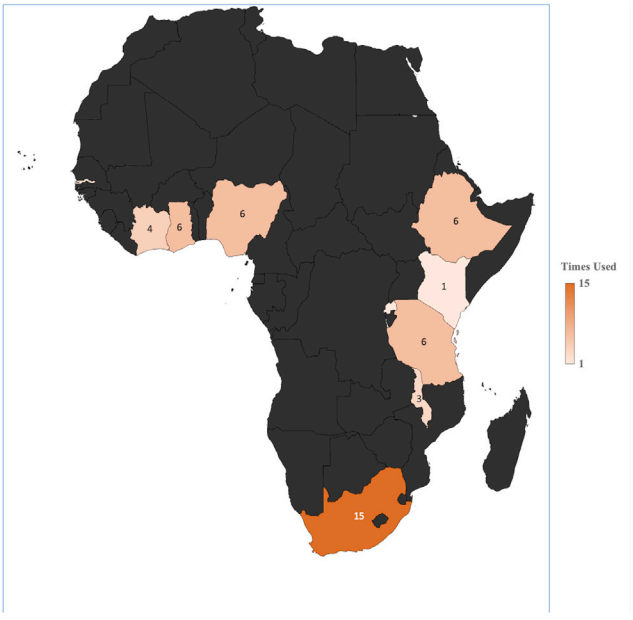
OBJECTIVE: This paper intends to evaluate existing literature to determine which pregnancy-related anxiety scales have been used in Sub-Saharan Africa.

STUDY DESIGN: PubMed, Health and Psychosocial Instruments (HaPI), and APA PsycNet were searched systematically for relevant studies in the English language. Eligible studies (1) screened for anxiety; (2) examined anxiety specifically in pregnant people; (3) were conducted in Sub-Saharan Africa; and (4) specified a validated measurement or scale used to evaluate pregnancy-related anxiety.

Articles were evaluated blindly by three researchers for inclusion in two stages: An abstract and title review, followed by a full text review. Screening tools and evaluation of validity were extracted for each study, as well as region, country, clinical population, and number of participants.

RESULTS: Of the 271 articles screened for inclusion, 37 full-text articles were included in the final paper. These articles yielded 25 different screening tools used to evaluate anxiety in pregnant women in Sub-Saharan Africa. The most frequent location for the study administrations was South Africa (11 studies), with Tanzania (5 studies), Ethiopia (5 studies), Nigeria (4 studies), and Ghana (4 studies) being other common study locations. The most commonly used tools to evaluate pregnancy-related anxiety in Sub-Saharan Africa were the GAD-7 (8 studies), STAI (6 studies), SRQ-20 (5 studies), and EPDS (5 studies).

CONCLUSION: In conclusion, this scoping review sheds light on the current state of research on pregnancy-related anxiety in Sub-Saharan Africa. There remains a significant need for further investigation into the impact of pregnancy on mental health in Sub-Saharan Africa and this study emphasizes the importance of developing and validating culturally sensitive scales that consider the local contexts and challenges faced by pregnant women in Sub-Saharan Africa. Addressing these gaps will contribute to the development of improved interventions for pregnancy-related anxiety in Sub-Saharan Africa, ultimately improving the mental health outcomes of pregnant women in these regions.



890 Oxytocin regimens to prevent postpartum hemorrhage: Comparison of two cohorts matched by propensity score analysis

Giovanni Morganelli[1], Stefania Fieni[2], Gabriella Maria Celora[3], Elvira di Pasquo[1], Andrea Dall'Asta[3], Tullio Ghi[3]

[1]Azienda Ospedaliera Universitaria di Parma, Parma, Emilia-Romagna, [2]University of Parma, Parma, Italy, [3]Università di Parma, Emilia-Romagna

OBJECTIVE: To compare the efficacy of two different prophylactic oxytocin regimens (10 IU intramuscular injection vs 5 IU intravenous bolus) in preventing postpartum hemorrhage (PPH) after vaginal delivery.

STUDY DESIGN: Single-center retrospective cohort study including all vaginal deliveries between June 1st 2022 and January 31st 2023 at a tertiary referral unit. On October 1st 2022 the oxytocin regimen for PPH prophylaxis after vaginal delivery was switched from 10 IU intramuscular injection to 5 IU intravenous bolus, administered at the time of shoulder delivery. This amendment was introduced as standard of care in the local protocol for active management of the third stage of labor. The incidence of PPH > 500 mL was compared between the patients who gave birth before and after the implementation of the new protocol. A 1:1 propensity score matching of the 2 groups was done for the variables that proved to be independently associated with PPH.

RESULTS: In the study period, 1509 patients had a vaginal birth at our tertiary care unit (753 in the standard-care group and 756 in the new protocol group) and were enrolled in the study population. Of these, 262 (17.4%) had postpartum hemorrhage > 500 mL. At binomial analysis, nulliparity (48.6% vs 68.7%, P < .001), labor induction (31.4% vs 46.9%, P < .001), manual placenta removal (0.6% vs 9.5%, P < .001) and birthweight (3310 ± 518 vs 3528 ± 512, P < .001) were independently associated with the incidence of PPH. Following propensity score matching for the above cited factors, 294 patients from the standard protocol group vs 294 exposed to the new protocol were compared. A significant decrease in the incidence of PPH was noted with the use of intravenous vs intramuscular oxytocin (18.4% vs 8.8%, P < .001) although after matching a higher rate of perineal tears was allocated in the former group.

CONCLUSION: Administering an intravenous bolus of 5 IU of oxytocin seems more effective than an intramuscular injection of 10 IU in preventing PPH after vaginal delivery.

891 Maternal risk factor clusters and risk of infant congenital heart disease and maternal morbidity

Stephanie Tseng[1], Kimberley Miles[2], Emily A. DeFranco[3], Allison Divanovic[2], Elaine Urbina[2], James Cnota[2]

[1]Nationwide Children's Hospital, COLUMBUS, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]University of Cincinnati College of Medicine, Cincinnati, OH

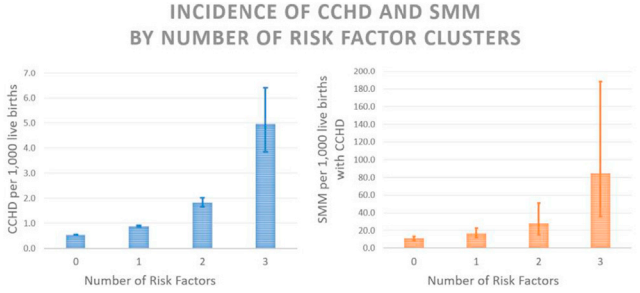
OBJECTIVE: Clustering of cardiovascular disease (CVD) risk factors is associated with greater CVD incidence. In pregnant women, such risk factors are associated with congenital heart disease in the infant. This study aimed to determine the association of maternal clustered CVD risk with infant critical congenital heart disease (CCHD) and associated severe maternal morbidity (SMM).

STUDY DESIGN: This retrospective cohort study used Centers for Disease Control birth certificate data for all live births from 2014-2018. Maternal CVD risks factors (yes/no) included pregestational

diabetes and hypertension, pre-pregnancy smoking status, and history of preterm delivery. SMM was defined as maternal intensive care unit admission, ruptured uterus, unplanned hysterectomy, or maternal transfusion. Cases were grouped as having 0, 1, 2, or 3 maternal CVD risk factors. Incidence and relative risk (RR) of infant CCHD and SMM were calculated for each cluster group and compared to a group with no risk factors.

RESULTS: The cohort included 11,638 infants with CCHD (0.06%) and 19,329,552 without. CCHD incidence increased with a greater number of maternal CVD risk factors (Figure). When compared to the group with no risk factors, the RR for infant CCHD in groups with 1, 2, or 3 risk factors were RR 1.63 (1.56-1.71), RR 3.37 (3.04-3.75), and RR 9.22 (7.15-11.91) respectively. SMM was more common in mothers with infant CCHD (1.30% vs 0.51%, p< 0.001) and incidence increased with additional maternal risk factors (Figure). In mothers with infant CCHD, the RR for SMM in groups with 1, 2, or 3 risk factors were RR 1.52 (1.05-2.20), RR 2.54 (1.33-4.82), and RR 7.74 (3.27-18.31) respectively when compared to the group with no risk factors.

CONCLUSION: CVD risk clustering in mothers of CCHD infants suggests that biological mechanisms underlying CVD may also disturb fetal cardiac development and contribute to poor maternal outcomes. These findings could inform CHD screening and delivery planning. Prevention strategies targeting these risks may benefit both mother and child.



892 Time to Resolution of Low Lying Placentas

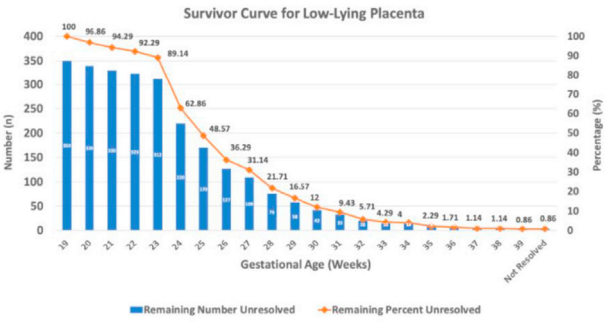
Stephanie Hopp[1], John Palmieri[2], Barak Rosenn[1]
[1]Jersey City Medical Center, Jersey City, NJ, [2]Rutgers New Jersey Medical School, Jersey City, NJ

OBJECTIVE: Most pregnant women who have a 2nd-trimester ultrasound (US) also undergo trans-vaginal US to determine cervical length. A low-lying placenta (edge measuring ≤2cm from the cervix) is a frequent finding. Although most low-lying placentas will resolve by term, there is limited information on the time to resolution. The objective of this study was to determine the timeline to resolution of a low-lying placenta and the optimal timing of follow-up US examinations.

STUDY DESIGN: IRB approved retrospective cohort study of singleton pregnancies who had a trans-vaginal US between 16-6/7 to 24-0/7 weeks gestation from 1/2019-12/2022. Potential subjects were identified by querying the US database for ICD-10 code O44.42. Patients were included if they had follow-up transvaginal scans until resolution (placental edge >2cm from the cervix) or within 4 weeks of delivery. Patients were excluded if their low lying placenta resolved before 20 weeks. The proportion of resolved low-lying placentas at weekly intervals and mean and median weeks to resolution were calculated.

RESULTS: 626 patients were identified, of which 350 patients met inclusion criteria. Three (3) patients had an unresolved low lying placenta by time of delivery, leaving 347 patients with a resolved low lying placenta (99.14%). The mean (± SD) gestational age at diagnosis was 20-3/7 (±1-5/7) weeks. The mean (± SD) time to resolution was 6-3/7 (± 3-2/7) weeks. The median time to resolution was 5-1/7 weeks (range 1-1/7 to 19-0/7 weeks). A survival curve analysis was performed demonstrating that over 60% of low lying placentas had resolved by 26 weeks gestation and 88% had resolved by 30 weeks.

CONCLUSION: The vast majority of low-lying placentas diagnosed in the second trimester resolve by 30 weeks gestation. This information may help alleviate patient anxiety and direct optimal timing of follow-up US examinations.



893 What's the optimal threshold? Association of continuous glucose monitoring thresholds with adverse perinatal outcomes

Stephanie A. Fisher[1], Emily Kobayashi[2], Natalie Conboy[1], Jingtong Huang[3], Charlotte M. Niznik[4], Amit Majithia[5], David C. Klonoff[3], Lynn M. Yee[4]
[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]UC San Diego, La Jolla, CA, [3]Diabetes Technology Society, Burlingame, CA, [4]Northwestern University, Chicago, IL, [5]University of California, San Diego School of Medicine, San Diego, CA

OBJECTIVE: Continuous glucose monitor (CGM) goals in pregnancy have been extrapolated from the American Diabetes Association (ADA) guidelines from those for nonpregnant adults (time-in-range, TIR >70%; time-above-range, TAR < 25%; time-below-range, TBR < 4%; and glycemic variability, GV ≤36%) with limited supporting data. We sought to determine risk of adverse perinatal outcomes (APOs) in people with type 1 diabetes mellitus (T1DM) using various CGM thresholds across gestation.

STUDY DESIGN: In a retrospective analysis (2019-22) of gravidas with T1DM using CGM, we determined average TAR, TIR, TBR, and GV per trimester using a target range 70-140 mg/dL. Generalized estimating equations determined odds ratios adjusted for microvascular complications (aOR) and 95% confidence intervals for hypertensive disorders of pregnancy (HDP), large-for-gestational age (LGA, birthweight ≥90%ile) and neonatal intensive care unit (NICU) admission at varying thresholds for each CGM metric in the 1st and 3rd trimesters. Receiver operating characteristic analysis determined area under the curve (AUC) for each metric at each threshold.

RESULTS: Among 92 gravidas with CGM data, HDP, LGA, and NICU admission occurred in 30 (33%), 29 (32%), and 20 (23%). For HDP, the 20% threshold for 3rd trimester TAR and 32% threshold for 1st trimester GV had the greatest adjusted odds (TAR: aOR 6.5, GV:

aOR 7.5), and 3rd trimester TAR < 20% had the greatest discriminatory ability (AUC 0.68, Table). For LGA, the 70% threshold for 1st trimester TIR had the greatest adjusted odds (aOR 27.1) and discriminatory ability (AUC 0.73) of any metric. For NICU admission, the 40% threshold for 1st trimester TAR had the greatest odds and discriminatory ability (aOR 9.1, AUC 0.74). TBR at any threshold has poor discriminatory ability (AUC ≤ 0.54) for all outcomes.

CONCLUSION: In this cohort, the optimal discriminatory ability for CGM thresholds and risk of APOs in pregnancy diverge from ADA guidelines, with the exception of the 1st trimester 70% TIR threshold for LGA risk. Larger studies should determine optimal CGM goals in pregnancy and corresponding risk of APOs.

Table. Association of continuous glucose monitoring thresholds with odds of perinatal outcomes

	n (%)		HDP aOR (95% CI)		LGA aOR (95% CI)		NICU admission aOR (95% CI)

aOR—odds ratio adjusted for microvascular complications; CI—confidence interval; GV—glycemic variability, assessed by the coefficient of variation for glucose; HDP—hypertensive disorders of pregnancy, LGA—large-for-gestational age, NICU—neonatal intensive care unit, ref—reference, TIR—time-in-range, TAR—time-above-range, TBR—time-below-range

TIR: percentage of time with capillary blood glucose 70-140 mg/dl; TAR: percentage of time with capillary blood glucose above 140 mg/dL
TBR: percentage of time with capillary blood glucose below 70 mg/dl; GV: measure of fluctuations of capillary blood glucose levels over 24 hours.

894 Neighborhood deprivation is not associated with abortion consideration or completion in patients with fetal myelomeningocele

Steven T. Papastefan[1], Yuqi Bian[1], Manmeet Singh[2], William S. Marriott[2], Joy Ito[2], Jessica T. Fry[3], Aimen Shaaban[2], Ashish Premkumar[4]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]The Chicago Institute for Fetal Health, Chicago, IL, [3]Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [4]University of Chicago, Chicago, IL

OBJECTIVE: Social determinants of health are key drivers of maternal morbidity and adverse pregnancy outcomes, but the relationship to abortion decision-making for severe fetal anomalies is not known. We hypothesized that higher neighborhood deprivation index (NDI) is associated with abortion consideration and completion for pregnant patients with fetal myelomeningocele (fMMC).

STUDY DESIGN: In this retrospective cohort study, patients with fMMC presenting to a tertiary fetal treatment center (FTC) in Illinois between 2018-2023 were identified. The exposure was NDI, calculated from patient zip codes. NDI was analyzed as both a dichotomous (i.e., above average to most v. average to least deprivation) and ordinal exposure. The co-primary outcomes were abortion consideration prior to FTC consultation, ascertained by nurse intake, and abortion completion after FTC consultation. Bivariate and log-binomial regression analyses were performed. Covariates were selected based on P< .10 on bivariate analyses. A subgroup analysis was performed on individuals residing only in Illinois. P< .05 indicated statistical significance.

RESULTS: 124 patients were included. In evaluating NDI as a dichotomous exposure, NDI was not associated with abortion consideration or completion (Table 1). On log binomial modeling, after controlling for confounders of GA and ethnicity, NDI was also not significantly associated with abortion consideration (aRR 0.93, 95% CI 0.57-1.52) or completion (aRR 0.98, 95% CI 0.51-1.87). For a subgroup of individuals residing in Illinois (n = 83 [63.5%]), NDI was also not significantly associated with consideration (aRR 0.84, 95% 0.53-1.32) or completion (aRR 1.07, 95% CI 0.52-2.19). These results were similar when treating NDI as an ordinal exposure.

CONCLUSION: Contrary to our hypothesis, NDI is not associated with abortion consideration or completion in patients with fMMC. While NDI has traditionally been associated with adverse pregnancy outcomes, the lack of relationship with abortion for severe fetal anomalies underscores the importance of comprehensive counseling for all patients presenting to FTCs.

895 Induction of labor at 40 weeks of gestation after the ARRIVE trial dissemination

Taylor S. Freret[1], Anjali J. Kaimal[2], Alexander Melamed[1], Mark A. Clapp[1]

[1]Massachusetts General Hospital, Boston, MA, [2]University of South Florida Morsani College of Medicine, Tampa, FL

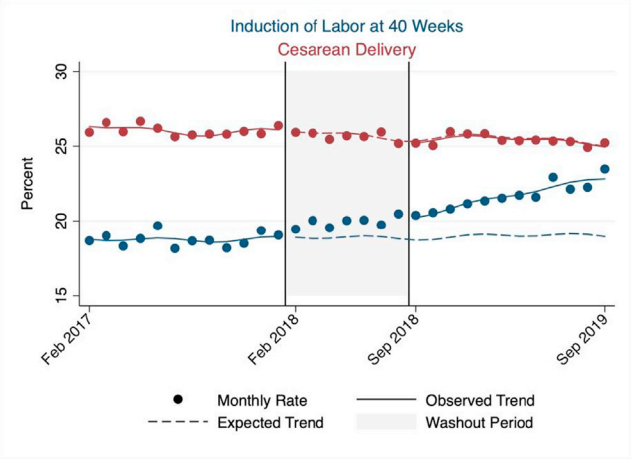
OBJECTIVE: The ARRIVE trial showed that induction of labor at 39 weeks among low-risk nulliparous patients led to a lower rate of

cesarean delivery. We sought to determine if the trial's dissemination was associated with a change in the rate of induction of labor at 40 weeks and associated outcomes.

STUDY DESIGN: This was a repeated cross-sectional analysis using US natality data of patients who gave birth to cephalic, non-anomalous, non-small-for-gestational age infants between 40-43 completed weeks of gestation without hypertension or diabetes from Feb 2017-Aug 2019. A population-level interrupted time series (ITS) analysis was performed using Poisson regression. The period from Feb 2018-Aug 2018 was excluded from the analysis due to ongoing evidence dissemination. Level change and temporal trends in the rate of induction, induction at 40 weeks of gestation, cesarean delivery, and adverse neonatal outcome were compared before and after the dissemination period. Seasonality was accounted for with sine and cosine terms.

RESULTS: A total of 870,217 births were included (367,062 in the pre-period, 312,676 in the post-period). In the immediate post-period, the rate of induction increased from a predicted rate of 36.4%, had the trial not been disseminated, to 37.7% (IRR 1.04, 95% CI 1.00-1.07); the rate of induction at 40 weeks increased from 18.7% predicted to 20.2% (IRR 1.08, 95% CI 1.05-1.12) (Figure). The rate of cesarean delivery and adverse neonatal outcome did not change (cesarean delivery: 25.3% predicted vs 25.2% observed, IRR 1.00, 95% CI 0.96-1.03; adverse neonatal outcome: 5.3% predicted vs 5.0% observed, IRR 0.95, 95% CI 0.87-1.02). Changes in the trend of induction over time were also noted, with an additional 21 inductions/10,000 births at 40 weeks occurring per month (95% CI 2.8-40.0 inductions/10,000 births).

CONCLUSION: Following the dissemination of the ARRIVE trial, induction of labor increased among low-risk patients at 40 weeks of gestation. However, there was no observed decrease in cesarean delivery, suggesting the benefits of induction of labor at 39 weeks may not extrapolate to this cohort.



896 Induction of labor in low-risk patients with pre-pregnancy obesity after the ARRIVE trial

Taylor S. Freret[1], Anjali J. Kaimal[2], Alexander Melamed[1], Mark A. Clapp[1]

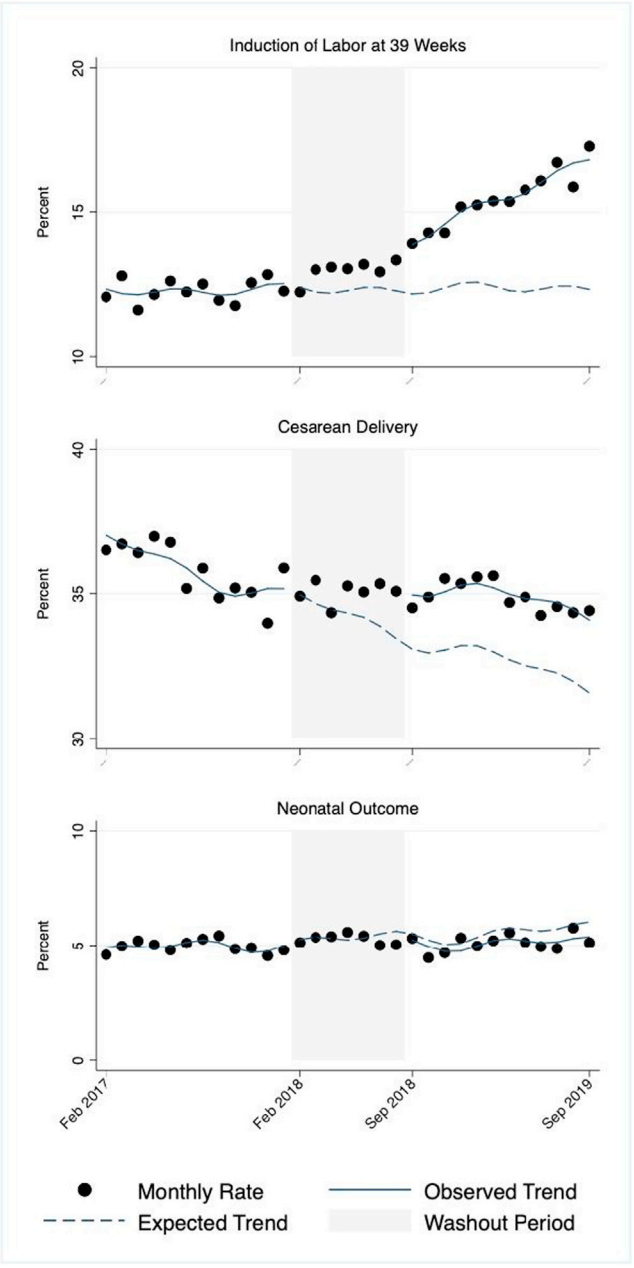
[1]Massachusetts General Hospital, Boston, MA, [2]University of South Florida Morsani College of Medicine, Tampa, FL

OBJECTIVE: The ARRIVE trial showed that induction of labor (IOL) at 39 weeks among low-risk nulliparous patients led to decreased cesarean delivery (CD) rates, with similar results in a subgroup analysis that stratified by obesity (BMI≥30) at randomization (38 weeks). We sought to determine if the trial was associated with changes in IOL, CD, or neonatal outcome among patients with pre-pregnancy obesity.

STUDY DESIGN: This repeated cross-sectional analysis used US natality data of nulliparous patients with a pre-pregnancy BMI ≥30 kg/m^2 who gave birth to cephalic, non-SGA infants between 39 and 43 completed weeks of gestation from Feb 2017-Aug 2019. Patients with hypertension or diabetes were excluded. A population-level interrupted time series analysis was performed using Poisson regression. The primary outcome was 39-week IOL. Secondary outcomes included CD and a composite neonatal outcome (perinatal death, respiratory support, seizures, antibiotic treatment, or 5-min Apgar ≤3). Feb to Aug 2018 was excluded from the analysis as a time of active trial dissemination. The pre-period occurred from Feb 2017 to Jan 2018; the post-period from Sep 2018 to Aug 2019.

RESULTS: The study included 286,576 patients; 111,502 in the pre-period, 63,690 in the dissemination period, and 111,384 in the post-period. In the first month after the dissemination, the rate of 39-week IOL increased from 12.2% (expected) to 13.9% (incidence rate ratio 1.14, 95% CI 1.07-1.22, p< 0.001). The monthly rate of change also increased (IRR 1.02, 95% CI 1.01-1.03, p=0.001). However, CD also increased, from 33.1% expected to 35.0% observed, (IRR 1.06, 95% CI 1.01-1.11, p=0.03). There was no significant difference in the rate of change of CD over time or in composite adverse neonatal outcome (Figure).

CONCLUSION: Dissemination of the ARRIVE trial resulted in a 14% increase in the rate of 39-week IOL among low-risk patients with pre-pregnancy obesity. However, this was associated with a 6% increase in cesarean delivery, suggesting that the reduction in cesarean anticipated with elective induction may not be observed in this group.

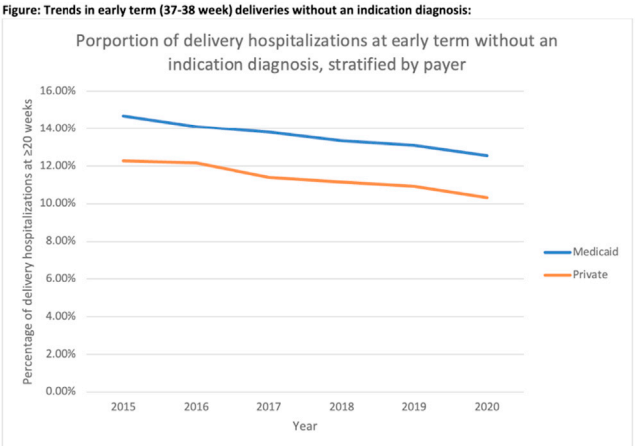


STUDY DESIGN: We conducted a repeated cross-sectional analysis of 18.8 million delivery hospitalizations in the National Inpatient Sample from October 2015-December 2020 at ≥20 weeks gestation. We identified those hospitalizations with a medical indication for early delivery as defined by ACOG/SMFM criteria or which occurred to patients who presented in spontaneous labor at 37-38 weeks gestation. We then described temporal trends in 37-38 week delivery without such indication, reporting average annual percent change (AAPC). Using survey-adjusted logistic regression, we calculated adjusted odds ratios (aOR) for the association between demographic and hospital factors and unindicated early term delivery.

RESULTS: Of 5.1 million 37-38 week deliveries, 2.3 million had no associated indication. The percentage of unindicated early term deliveries was higher among Medicaid-paid births as compared to those with private insurance for every year in our study interval, decreasing from 14.1% to 12.6% of Medicaid-paid births over 2015-2020 for an AAPC of -2.9% [95% confidence interval (CI) (-3.3%, -2.4%)] as compared to 12.3% to 10.3% of privately-insured births for an AAPC of -3.5% [95% CI (-4.6%, -2.5%)]. Deliveries to Black [aOR 1.15 95% CI 1.13, 1.16] and Hispanic [aOR 1.25 95% CI 1.23, 1.26] patients, deliveries paid for by Medicaid [aOR 1.10 95% CI 1.09, 1.11], and deliveries in the South [aOR 1.24 95% CI 1.21, 1.26] were more likely to be unindicated and at early term.

CONCLUSION: While early elective deliveries are decreasing nationally, these deliveries remain common. Disparities in these deliveries by race and payer have persisted despite nearly a decade of target Medicaid quality improvement initiatives.

Figure: Trends in early term (37-38 week) deliveries without an indication diagnosis:



Average annual percent change (AAPC) per 10,000 delivery hospitalizations with 95% confidence interval (CI) for the proportion of deliveries at early term without an indication diagnosis:
Among births paid for by Medicaid: AAPC -2.9% 95% CI (-3.3%, -2.4%)
Among births paid for by private insurance: AAPC -3.5% 95% CI (-4.6%, -2.5%)

897 Trends in and factors associated with early term deliveries without indication

Teresa Logue[1], Timothy Wen[2], Alexander M. Friedman[3]
[1]Christiana Care Health Systems, Newark, DE, [2]University of California, San Francisco (UCSF), San Francisco, CA, [3]Columbia University, New York, NY

OBJECTIVE: Since 2009, ACOG and SMFM have recommended against induction or cesarean at 37-38 weeks without indication. Reducing nonmedically indicated early term deliveries has also been a priority over the past decade for state Medicaid programs seeking to improve neonatal outcomes. The purpose of this analysis is to describe current trends in and factors associated with these deliveries.

898 Early vs. late amniotomy following cervical ripening in individuals undergoing induction of labor: a meta-analysis

Maya Diab[1], Yara Hage Diab[2], Antonio F. Saad[3], Marissa J. Berry[4], George R. Saade[2], Tetsuya Kawakita[2]
[1]University of Michigan, Ann Arbor, MI, [2]Eastern Virginia Medical School, Norfolk, VA, [3]University of Texas Medical Branch, Galveston, TX, [4]The Ohio State University, Columbus, OH

OBJECTIVE: A meta-analysis found that early amniotomy shortened the duration of labor without impacting cesarean rates. However, the review was not adequately powered to detect infectious morbidity and included a limited number of women who had Foley balloon for cervical ripening methods. Moreover, two U.S. trials utilizing Foley

balloon have been completed since then. Our objective was to perform a systematic review and meta-analysis to evaluate the impact of early amniotomy on outcomes of induction of labor.

STUDY DESIGN: A literature search was conducted using various electronic databases from the inception of each database through July 2023. We included all randomized controlled trials (RCTs) that compared early amniotomy with late amniotomy (including spontaneous rupture of membranes) in women who underwent pre-induction cervical ripening by either Foley balloon or prostaglandins (PG). The primary outcome was chorioamnionitis. Secondary outcomes included cesarean delivery, delivery within 24 hours, induction to delivery time, intrapartum fever, neonatal intensive care unit (NICU) admission, and neonatal sepsis. Findings were summarized as relative risk (RR) or mean difference (MD) with 95% confidence interval (CI) using the random effects model of Restricted Maximum Likelihood.

RESULTS: Eight trials included 1,954 women who underwent induction of labor and cervical ripening by either Foley or PG (5 Foley, 2 PG, and 1 both). Outcomes are presented in Table 1. There were no differences in chorioamnionitis between early and late amniotomy (7.5% vs. 6.9%; RR 1.06 [0.72-1.58]; Figure 1). Similarly, there were no differences in other neonatal and maternal outcomes except for induction to delivery time (weighted MD -4.2 [-7.3 to -1.0] favoring early amniotomy). Heterogeneity was high (>70%) for many of the outcomes.

CONCLUSION: Early amniotomy after cervical ripening in women with singleton gestations and cephalic presentation at term does not decrease cesarean rates but reduces the duration from induction to delivery without impacting neonatal and maternal outcomes.

Table 1. Outcomes

Outcome	Early amniotomy	Control	I^2, %	RR or weighted MD (95%CI)
Chorioamnionitis	53/706 (7.5)	49/708 (6.9)	9.8	1.06 (0.72-1.58)
Cesarean delivery	273/972 (28.1)	291/982 (29.6)	45.2	0.92 (0.78-1.09)
Delivery within 24 hours	561/706 (79.5)	463/708 (65.4)	91.5	1.29 (0.99-1.68)
Induction to delivery (hr)	NA	NA	89.9	-4.2 (-7.3 - -1.0)
Intrapartum fever	70/793 (8.8)	61/801 (7.6)	49.6	1.21 (0.68-2.14)
NICU	91/822 (11.1)	97/824 (11.8)	0	0.95 (0.72-1.25)
Neonatal sepsis	54/632 (8.5)	51/634 (8.0)	26.0	1.11 (0.69-1.79)

Abbreviations: MD (mean difference); NA (not applicable); NICU (neonatal intensive care unit); RR (relative risk)

899 Glucose Monitoring in Labor: Does the Frequency Matter?

Thomas Owens[1], Olivia Grubman[2], Xiteng Yan[3], Eric Reynolds[4], Mia A. Heiligenstein[5], Tirtza Spiegel Strauss[6], Graham Ashmead[7], David Cole[8], Zainab Al-Ibraheemi[9], Lois Brustman[10]

[1]Mount Sinai West , New York, NY, [2]Mount Sinai West, New York, NY, [3]Mount Sinai South Nassau, Oceanside, NY, [4]Icahn School of Medicine, New York, NY, [5]Stony Brook University Hospital, Amityville, NY, [6]Maimonides Medical Center, New York, NY, [7]Roosevelt Hospital, New York, NY, [8]Mt. Sinai West, New York, NY, [9]Mount Sinai West, N Caldwell, NJ, [10]St. Luke's Roosevelt Hospital Center, New York, NY

OBJECTIVE: In patients with gestational diabetes (GDM), there are limited protocols of intrapartum glucose monitoring with minimal guidance from obstetrical societies. Neonatal hypoglycemia is a complication of the maternal glucose levels intrapartum, with an incidence as high as 40%. The hypothesis of this study is that there is no difference in the rates of neonatal hypoglycemia with differing protocols in frequency of glucose monitoring during labor.

STUDY DESIGN: A retrospective cohort study of patients with GDM that were diet controlled (A1) and medication controlled (A2) undergoing labor/induction from 2020-2023 were studied. Two groups were identified: Group 1(infrequent) had blood glucose(BG) levels every 4 hours in latent labor, and 2 hours in active labor, and Group 2(frequent) had BG levels every 2 hours in latent labor, and 1 hour in active labor. Primary outcome was to assess rates of neonatal hypoglycemia between these 2 groups at delivery. Demographics as seen in table 1 were studied. Wald Confidence Limits of the Odds Ratio estimates were used to test for non-inferiority. Variables were compared using Chi-square and Mann-Whitney U test. $p< 0.05$ was considered significant.

RESULTS: Of 508 subjects, 285(56%) had infrequent monitoring, and 223(44%) had frequent monitoring. Patients with infrequent testing were more likely to have A1GDM($p< .01$), have better diabetic control($p< .01$), lower BMI($p< .01$), less likely to have LGA($p< .01$), and less likely to be induced($p< .01$). Neonatal hypoglycemia did not differ between the two groups($p=0.11$), as seen in table 1. Adjusting for control, compliance, type of GDM, age, BMI, and need for insulin drip showed infrequent monitoring was non-inferior to frequent monitoring in relation to neonatal hypoglycemia(aOR 0.56[90% 0-1.35]).

CONCLUSION: Our study suggests there is no difference in rates of neonatal hypoglycemia regardless of these glucose monitoring protocols intrapartum. This study can lay the foundation for future studies to provide intrapartum glucose monitoring protocols, which would lessen invasive testing and improve patient satisfaction.

900 What is the clinical utility and accuracy of single gene NIPT for recessive mendelian disorders?

Thomas Westover[1], Nicole Rook[2], Sandra James[2], Dineli Lewke[2], Jess Murawsky[2]

[1]Capital Health, Pennington, NJ, [2]Capital Health, Trenton, NJ

OBJECTIVE: We sought to evaluate the clinical utility and accuracy of commercially available single gene NIPT (sgNIPT) for sickle cell, thalassemia, cystic fibrosis and SMA in at-risk preg pts

STUDY DESIGN: The MFM dept in our USA regional perinatal ctr performs primary genetic screening/US for nearly 4000 births annually. In 2022, we began offering sgNIPT (Unity) to ethnically diverse patients who were known to be carriers of, or who had family history of SMA, CF, sickle or alpha/beta thal. Fetal/newborn status was assessed via CVS/amnio or newborn screening. The biologic father was routinely offered carrier screening when available. sgNIPT results are designated increased/high risk (> 1/100; range 1/100 to 9/10) vs decreased/low risk. Small sample size precluded exact estimation of assay accuracy; wide confidence intervals were noted

RESULTS: During 2022-23, 135 preg pts desired sgNIPT (median gest 18 wks; range 12-36) after the preg pt was found to be a carrier of, affected by, or had family hx of one or more of the above recessive conditions. 80 pts were a carrier of 1 condition, 20 pts were a carrier of 2 dx and 1 pt was a carrier of 3 dx (total 101 carrier pts). 34 pts were not a carrier. 3/143 (2.1%) assays were uninformative. Outcome data was available for all preg. All 5 affected fetuses were classified as high risk while 1 unaffected fetus was labeled high risk (sens 100%, PPV 83%). 129/130 unaffected fetuses were labeled low risk (false pos rate 0.7%) in samples reporting informative results. Two affected preg were terminated while 3 affected preg were continued

CONCLUSION: sgNIPT for recessive conditions offers refined risk assessment that complements traditional carrier screening and may reliably inform fetal risk status when 1: partner carrier status is unknown/unavailable; 2: paternity is uncertain 3: both partners are carriers. Noninvasive sgNIPT analysis may result in a more precise risk assessment than traditional parental carrier screening alone. Further research with larger populations is needed to rigorously assess the sens/spec and accuracy of sgNIPT for recessive mendelian disorders

901 National trends and outcomes in births with co-occurring hypertensive disorders of pregnancy and gestational diabetes

Timothy Wen[1], Audrey Kim[2], Kartik Venkatesh[3], Mark A. Clapp[4], Isabel Fulcher[5]

[1]University of California, San Francisco (UCSF), San Francisco, CA, [2]Delfina Care Inc., San Francisco, CA, [3]Ohio State University, Columbus, OH, [4]Massachusetts General Hospital, Boston, MA, [5]Delfina Care, Sunnyville, CA

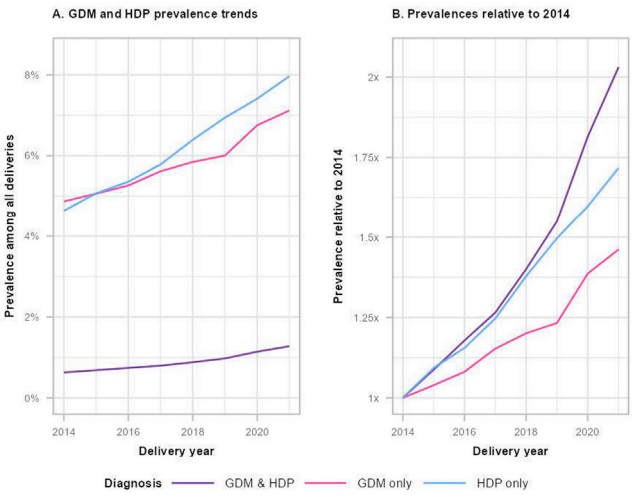
OBJECTIVE: To describe trends of births with co-occurring gestational diabetes (GDM) and hypertensive disorders of pregnancy (HDP) and estimate associated odds of maternal and neonatal adverse outcomes.

STUDY DESIGN: The 2014-2021 National Vital Statistics System data was used for this analysis, excluding those with pregestational diabetes, congenital anomalies, or missing diagnoses. Trends analysis for GDM, HDP, and co-occurring GDM/HDP were conducted using Joinpoint regression with measures of association expressed as annual average percent change (AAPC) and 95% confidence intervals (CI). Unadjusted and adjusted logistic regression models were fit to assess the exposure of GDM, HDP, co-occurring GDM/HDP on composite maternal (Cesarean delivery, transfusion, perineal laceration, unplanned hysterectomy, ICU admission) and neonatal (preterm birth < 37 weeks, large/small for gestational age, NICU admission) outcomes adjusting for demographic and other clinical variables.

RESULTS: 29.9 million births were included with prevalence of co-occurring GDM/HDP, GDM alone, and HDP alone at 0.9%, 5.7%, and 6.0%, respectively. The prevalence of co-occurring GDM/HDP increased from 0.6% to 1.3% (AAPC 10.8%, 95% CI: 9.4-12.2%), and GDM alone and HDP alone increased from 4.9% to 7.1% (AAPC 5.6%; 95% CI: 4.7-6.6%) and from 4.6% to 8.0% (AAPC 8.1%; 95% CI: 7.4-8.9%), respectively (Figure 1A). Co-occurring GDM/HDP rates showed the highest rate of increase; more than doubling from 2014 to 2021 (Figure 1B). Births with co-occurring diagnoses had higher odds of adverse maternal complications (aOR 1.85, 95% CI: 1.83-1.87; versus neither) which is marginally higher in magnitude than GDM alone (aOR 1.45, 95% CI: 1.44-1.47) and HDP alone (aOR 1.20, 95% CI: 1.19, 1.21). Similar findings were noted among neonatal outcomes.

CONCLUSION: The prevalence of patients with co-occurring GDM/HDP is increasing and is associated with higher odds of maternal and neonatal complications compared to either condition alone. These findings provide real-world evidence and highlight the need for additional for this growing high-risk cohort.

Figure 1: Trends of gestational diabetes (GDM) and hypertensive disorders of pregnancy (HDP) among US deliveries, 2014-2021



902 Impact of method of fetal extraction in second stage cesarean delivery on subsequent preterm delivery

Tzuria Peled[1], Giulia M. Muraca[2], Miri Ratner[3], Hen Sela[3], Abi Kirubarajan[2], Ari Weiss[1], Sorina Grisaru-Granovsky[1], Misgav Rottenstreich[2]

[1]Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim, [2]McMaster University, Hamilton, ON, [3]Shaare Zedek Medical Center, Jerusalem, Yerushalayim

OBJECTIVE: Second-stage cesarean delivery (CD) is associated with subsequent preterm birth (PTB). Previous studies have shown that reverse breech extraction is associated with lower rates of uterine incision extensions compared to the "push" method. We aimed to investigate the association between the mode of fetal extraction during second stage CD and the rate of spontaneous PTB (sPTB), as well as other maternal and neonatal outcomes during the subsequent pregnancy.

STUDY DESIGN: A multi-center retrospective cohort study. The study population included women in their subsequent singleton pregnancy following a second-stage CD between 2004 and 2021. The main exposure of interest was the method of fetal extraction in primary CD ("push" method vs reverse breech extraction). The primary outcome of this study was sPTB< 37 weeks. Secondary outcomes were overall PTB, vaginal birth rate and other adverse maternal and

neonatal outcomes. Univariate analysis was followed by multiple logistic regression modeling.

RESULTS: During the study period, 615 women met inclusion criteria, of whom 275 (44.7%) had fetal extraction using the reverse breech extraction technique, while 340 (55.3%) had the "push" method for extraction. In univariate analysis, women the "push" method had similar rates of sPTB and overall PTB (< 37, < 34 and < 32 weeks), as well as other maternal outcomes except of higher rates of overall CD. This was confirmed by multivariate analyses with adjusted odds ratio of 0.64 (95% CI 0.23-1.75) for sPTB.

CONCLUSION: Among women with a previous second-stage cesarean, no significant difference was observed in the rates of PTB in subsequent pregnancies following the "push" method compared to the reverse breech extraction technique.

Table: Crude rate, odds ratio (OR) adjusted OR and 95% confidence intervals (CI) of preterm birth among women with the push method vs reverse breech extraction technique during section stage cesarean delivery for impacted fetal head in primary cesarean delivery

Outcome	Method of extraction at primary delivery		OR* (95% CI)	aOR** (95% CI)
	Push method n=340	Reverse breech extraction n=275		
Spontanous preterm delivery <37 weeks	9 (2.6%)	10 (3.6%)	0.72 (0.29-1.80)	0.64 (0.23-1.75)
All Preterm birth <37 weeks	21 (6.2%)	18 (6.5%)	0.94 (0.49-1.80)	0.8 (0.38-1.67)
Preterm birth <34 week	7 (2.1%)	3 (1.1%)	1.91 (0.49-7.44)	2.7 (0.51-14.38)
Preterm birth <32 week	3 (0.9%)	3 (1.1%)	0.81 (0.16-4.03)	1.21 (0.2-7.5)

*Reverse breech extraction serves as the referent group. ** Adjusted for inter-pregnancy interval, maternal age, and preterm birth <37 weeks in primary delivery.

903 Impact of Pre-Pregnancy Depressive Disorders on Adverse Perinatal Outcomes

Uma Doshi, Bharti Garg, Olivia J. Curl, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

OBJECTIVE: The rate of mental health disorders continues to rise in the United States. While post-partum mental health for pregnant patients is often examined, the impact of pre-pregnancy mental health on perinatal outcomes is also large. We sought to examine the impact of a pre-pregnancy depressive disorder diagnosis on adverse perinatal outcomes.

STUDY DESIGN: This is a retrospective cohort study of singleton non-anomalous pregnancies from 23-42 weeks gestation in the state of California from 2008-2019. We further excluded patients with Type 1 diabetes and Type 2 diabetes mellitus. Multivariable logistic regressions were also conducted to further evaluate the relationship between a diagnosed depressive disorder and adverse perinatal outcomes while controlling for maternal age, BMI, race/ethnicity, education, prenatal care, insurance status, and parity.

RESULTS: In our cohort of 4,902,521 pregnancies, 87,556 (1.79%) had a diagnosis of a prenatal depressive disorder. Patients with a pre-pregnancy depressive disorder had increased odds of delivery before 32 weeks (1.65 (1.55, 1.76), delivery before 37 weeks (1.54 (1.51, 1.58)), preeclampsia (1.42 (1.38, 1.47)) as well as severe maternal morbidity (1.83 (1.74, 1.93)). Odds of cesarean delivery were found to be decreased in multiparous women who had a prior cesarean delivery (0.76 (0.71, 0.81)), and increased in those without a prior cesarean delivery (1.71 (1.13, 1.21)). When examining neonatal outcomes, patients with a pre-pregnancy depressive disorder had increased odds of NICU admission (1.15 (1.12, 1.18)), APGAR scores of < 7 at 5 minutes (2.00 (1.89, 2.10)), hypoglycemia (1.58 (1.51, 1.65)), respiratory distress syndrome (1.78 (1.72, 1.85)), neonatal death (1.59 (1.30, 1.95)) and infant death (1.59 (1.39, 1.81)) (Table 1).

CONCLUSION: Depressive disorders are associated with significantly increased risks of several adverse maternal and neonatal outcomes. This indicates that prioritizing mental health treatment can lead to improved perinatal outcomes.

Table 1: Adverse outcomes in those with and without pre-pregnancy depressive disorder diagnoses

	No Depressive disorder diagnosis N%	Depressive disorder diagnosis N%	aOR (95%CI)
Preterm Delivery <32 weeks	0.71%	1.23%	1.65 (1.55-1.76)*
Preterm Delivery <37 weeks	6.38%	9.62%	1.54 (1.51-1.58)*

904 Transient Ischemic Attack and Obstetric and Neonatal Outcomes - A Population-Based Study

Uri Amikam[1], Ahmad badeghiesh[2], Haitham Baghlaf[3], Richard Brown[3], Michael H. Dahan[3]
[1]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv, Israel, [2]Department of Obstetrics and Gynecology, Western University, London, ON, [3]McGill University, Montreal, QC

OBJECTIVE: Transient ischemic attack (TIA) is rare in women of reproductive age. We aimed to compare pregnancy, delivery, and neonatal outcomes between women who suffered from TIA to those who did not.

STUDY DESIGN: We conducted a retrospective population-based cohort study using the Healthcare Cost and Utilization Project, Nationwide Inpatient Sample (HCUP-NIS). Included in the study were all pregnant women who delivered or had a maternal death in the US between 2004-2014. We compared women with an ICD-9 diagnosis of TIA to those without. Pregnancy, delivery, and neonatal outcomes were compared between the two groups using multivariate logistic regression models adjusting for baseline maternal characteristics.

RESULTS: A total of 9,096,788 women met the inclusion criteria. Amongst them, 203 women (2.2/100,000) had a diagnosis of TIA (either prior to or during pregnancy). Women with TIA, compared to those without, were more likely to be older than 35 years of age; Caucasian; in the highest income quartile; be insured by private insurance; and suffer from obesity and chronic hypertension (P< 0.001, all). Patients in the TIA group, compared to those without, had a higher rate of pregnancy-induced hypertension (aOR 2.5, 95%

CI 1.55-4.05, p< 0.001), preeclampsia (aOR 3.77, 95% CI 2.15-6.62, p< 0.001, and eclampsia (aOR 28.05, 95% CI 6.91-113.95, p< 0.001). Additionally, they had a higher rate of preterm delivery (aOR 1.78, 95% CI 1.03-3.07, p=0.039) and maternal complications such as venous thromboembolism (aOR 22.66, 95% CI 5.49-93.48, p< 0.001). Regarding neonatal outcomes, patients with a TIA, compared to those without, had a higher rate of congenital anomalies (aOR 7.04, 95% CI 2.86-17.32, p< 0.001).

CONCLUSION: Women diagnosed with a TIA before or during pregnancy had a higher incidence of maternal complications, including hypertensive disorders of pregnancy and venous thromboembolism, as well as an increased risk of congenital anomalies.

Table 1 Pregnancy and perinatal outcomes

	TIA (%)	No TIA (%)	Crude OR (95% CI)	Adjusted OR (95% CI)	Adjusted p-value
Pregnancy outcomes [a]

a- Adjusted for Age, Race, Plan type, Income quartiles, Obesity, and Chronic hypertension.
b- Adjusted for Age, Race, Plan type, Income quartiles, Obesity, Chronic hypertension, Pregnancy-induced hypertension, Preeclampsia, and Eclampsia.
Abbreviations and definitions: TIA – transient ischemic attack; GDM – gestational diabetes mellitus; CD – cesarean delivery; PPH – post-partum hemorrhage; VTE – venous thromboembolism; DIC – disseminated intravascular coagulation; SGA – small for gestational age; IUFD – intrauterine fetal death.
Per convention of the HCUP database when N<11, absolute cell number of subjects was not provided to protect patient anonymity.

905 Mode of delivery in chorioamnionitis: impact on neonatal and parturient outcomes

Vanessa Kay[1], **Isabella Liang**[1], **Jennifer Twiss**[1], **Michelle Morais**[2]
[1]McMaster University, Hamilton, ON, [2]McMaster University, Burlington, ON

OBJECTIVE: The impact of mode of delivery in chorioamnionitis on neonatal outcomes is unclear. This retrospective cohort study compares risk of early onset neonatal sepsis between vaginal delivery and cesarean section. Subgroup analysis was done by indication for cesarean section.

STUDY DESIGN: Singleton pregnancies at greater than 24+0 weeks gestation with live birth and clinical chorioamnionitis from January 1, 2019 to December 31, 2021 were included. Cases with multiple gestations, terminations or histological chorioamnionitis alone were excluded. Risk of early onset neonatal sepsis and a composite outcome of parturient infectious morbidity were compared using propensity score weighting.

RESULTS: 378 cases were included with 197 delivering vaginally and 181 delivering via cesarean section. The groups differed on age, parity, hypertension, renal disease, gestational age, corticosteroid use, magnesium sulfate use, presence of meconium and percentage meeting Gibb's criteria. Risk of early onset neonatal sepsis was greater in the cesarean section group (13.8% versus 3.1%, adjusted risk difference 8.3% [3.5-13.1], p=0.0007). Secondary neonatal outcomes were similar between groups. When compared by indication, risk of early onset neonatal sepsis was greater in the cesarean section for abnormal fetal surveillance group compared to vaginal delivery but not in the cesarean section for other reasons group. In parturients, the risk of infectious morbidity was greater with cesarean section (13.8% versus 1.5% [adjusted risk difference 13.0% [7.1-18.9], p < 0.0001). No other difference in parturient secondary outcomes was identified except a longer hospital stay after cesarean section (2.3days ±0.93 versus 1.6days ±0.92, p < 0.0001).

CONCLUSION: The risk of early onset neonatal sepsis was highest in the cesarean section group, particularly in those with abnormal fetal surveillance. Neonates affected by or vulnerable to sepsis likely have a greater need for cesarean section. The evidence supports cesarean section only for routine obstetrical indications in chorioamnionitis.

906 Patient Weight, Not Height, Significantly Influences cfDNA Screening Performance

Vanessa Nitibhon[1], **Brittany Dyr**[2], **Erica Soster**[3]
[1]Labcorp, Portland, OR, [2]Labcorp, San Diego, CA, [3]Labcorp, Westborough, MA

OBJECTIVE: Asses the role of patient weight, versus height and BMI, in influencing the performance of cell-free DNA (cfDNA) screening, with a focus on fetal fraction and the rate of no calls due low fetal fraction.

STUDY DESIGN: Retrospective study of 7606 consecutive patient samples submitted for cfDNA screening at one laboratory. The samples were subjected to DNA extraction, library preparation, and whole-genome massively parallel sequencing, as outlined by Jensen et al. These samples were systematically sorted into BMI groups as per the World Health Organization criteria. Fetal fraction and samples reported as QNS across each BMI category were reviewed.

RESULTS: A strong inverse relationship between patient weight and fetal fraction across all BMI categories was identified (correlation coefficient -0.993). The highest average fetal fraction (10.6%) was observed in the Underweight category, while the lowest average fetal fraction (6.0%) was noted in the Obesity Class III category. Conversely, patient BMI and height exhibited only a weak relationship across the BMI categories, with a correlation coefficient of -0.44. The average patient height stayed relatively constant across all BMI categories, ranging from a low of 64.3 inches in the Pre-obesity and Obesity Class I categories to a high of 64.9 inches in the Underweight category. The overall QNS rate was 0.41% (n=31) across all BMI categories, with the most frequent occurrence in the Obesity Class III category (1.58%, n=8).

CONCLUSION: This analysis highlights that patient weight significantly influences the performance of cfDNA screening, particularly in terms of fetal fraction and the rate of QNS results. While BMI can be used to make similar comparisons, it does so primarily because it includes weight as a variable. These findings highlight the importance of focusing on patient weight when discussing the performance of cfDNA screening.

907 Hereditary Hemorrhagic Telangiectasia: pregnancy and delivery-specific considerations and outcomes

OBJECTIVE: Prior studies have evaluated maternal outcomes in patients with hereditary hemorrhagic telangiectasia (HHT), yet

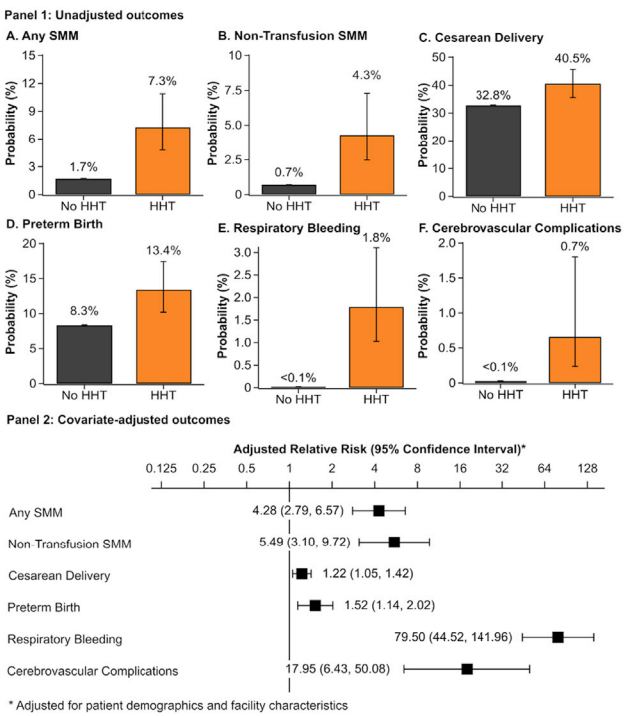
pregnancy and delivery specific data remains limited in this patient population. This study aims to evaluate pregnancy and delivery outcomes in patients with HHT.

STUDY DESIGN: This retrospective study used the National Readmissions Database to identify patients with HHT diagnosis on delivery hospitalizations between 2010-2020. The primary outcome was severe maternal morbidity (SMM). Secondary outcomes included non-transfusion SMM, preterm birth, cesarean delivery, respiratory bleeding, and cerebrovascular complications. Trends in the prevalence of HHT at delivery hospitalization were assessed with logistic regression. Logistic regression analyses, adjusting for age, payer, zip code income, hospital size and teaching status, were also used to produce adjusted relationships between HHT status and outcomes.

RESULTS: The cohort of 19,812,073 delivered pregnancies corresponded to a national estimate of 40,819,063. Of those, 1,132 (2.7 per 100,000) had a diagnosis of HHT. A steady rise in HHT diagnosis rate during pregnancy from 2010 to 2020 (1.7 per 100,000 in 2010, 4.0 per 100,000 in 2020, $p< 0.001$ for trend) was seen. Patients with HHT were significantly more likely to experience SMM compared to patients without HHT (7.3% vs 1.7%, $p< 0.001$). Additionally, rates of preterm birth (13.4% vs 8.3%), cesarean delivery (40.8% vs 32.9%), respiratory bleeding (1.8% vs < 0.1%) and cerebrovascular complications (0.7% vs < 0.1%) were higher in patients with HHT than non-HHT patients (all $p< 0.001$; Panel A). After adjusting for patient and facility characteristics, these associations remained significant (Panel B).

CONCLUSION: Patients with HHT have higher rates of severe maternal morbidity and adverse delivery outcomes when compared to the baseline population. As the prevalence of HHT during pregnancy is increasing, guidelines for pregnancy and delivery management in these patients are warranted.

Figure 1: Primary and secondary outcomes



908 Maternal outcomes by mode of delivery among pregnant patients with eclampsia: a retrospective cohort study

Virginia Y. Watkins[1], Jerome J. Federspiel[1], Ronan P. Sugrue[2], Matthew Fuller[1], Karthik Raghunathan[1], Tetsu Ohnuma[1], Vijay Krishnamoorthy[1], Sarah K. Dotters-Katz[3], Marie Louise Meng[1]

[1]Duke University Hospital, Durham, NC, [2]Duke University, Durham, NC, [3]Duke University Medical Center, Durham, NC

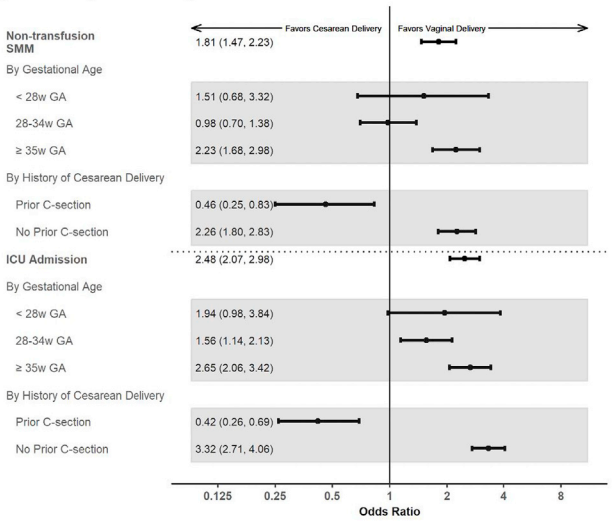
OBJECTIVE: For most patients with preeclampsia, cesarean delivery can be reserved for usual obstetric indications, but data are limited for patients with eclampsia. The goal of this study is to evaluate maternal outcomes by intended mode of delivery in patients with eclampsia.

STUDY DESIGN: This retrospective cohort study used the Premier Healthcare Database. Patients delivered between 2016-2020 with a diagnosis of eclampsia prior to delivery were included. The primary analysis compared intended cesarean delivery (non-intrapartum cesarean) to intended vaginal delivery (vaginal delivery and intrapartum cesarean) using a target trial emulation strategy. The primary outcome was non-transfusion severe maternal morbidity (SMM). The secondary outcome was ICU admission. We performed two subgroup analyses evaluating outcomes by gestational age (< 28 weeks, 28-34 weeks, ≥ 35 weeks) and history of cesarean delivery. Logistic regression models were used to compare outcomes.

RESULTS: The cohort included 3,491 patients. Patients with eclampsia who underwent intended cesarean delivery had significantly increased rates of non-transfusion SMM (16.0% vs 9.4%, OR 1.81 [1.47, 2.23]) and ICU admission (27.8% vs 13.1%, OR 2.48 [2.07, 2.98]) compared to patients with a trial of labor (Figure 1). These results remained significant with adjustment for patient demographic and facility characteristics as well as comorbid diagnoses. There was evidence of effect measure modification noted based on gestational age at delivery and history of prior cesarean delivery – for the latter, patients with a history of prior cesarean delivery who underwent intended vaginal delivery had *higher* rates of both SMM and ICU admission than those undergoing planned cesarean delivery.

CONCLUSION: While intended vaginal delivery is associated with *decreased* risk of non-transfusion SMM and ICU admission in patients with eclampsia, particularly if ≥ 35 weeks, TOLAC is associated with *increased* morbidity in this population. These results speak to a personalized approach to delivery route planning in patients with eclampsia.

Figure 1: Primary and secondary outcomes



909 Optimally timed antenatal corticosteroids over a 5-year period in a large US birth cohort

Vivienne Souter[1], Ian Painter[2], Andreas Höhn[3]
[1]Natera, Inc., Austin, TX, [2]Foundation for Health Care Quality, Seattle, WA, [3]MRC/CSO Social and Public Health Sciences Unit, University of Glasgow, Glasgow, Scotland

OBJECTIVE: Antenatal corticosteroids (ACS) improve outcomes for preterm neonates and are most effective when administered within the 7 days preceding preterm birth. ACS also have an uncertain long term safety profile for babies born at term. Optimizing ACS is therefore important to maximize benefits and minimize potential harm. Our objective was to evaluate optimal ACS use in a contemporary US birth cohort over a 5-year period.

STUDY DESIGN: This retrospective observational study included consecutive births (24^{+0}-42^{+6} weeks' gestation) at 12 hospitals in the Northwest US (Jan 2017-Dec 2021). Pregnancies missing data for ACS (n=153) were excluded. ACS exposure was based on >=1 dose of a first course of ACS. Clinical data were collected from medical records. The outcomes evaluated were: optimally timed ACS in *early preterm* births (ACS given within 7 days of live births < 34 weeks, expressed as a % of all live births < 34 weeks); % of *term* births given ACS; and % of *late preterm* (34^{+0}-36^{+6}weeks) live births given ACS within 7 days. Overall and annual rates of each outcome were calculated. Univariate estimates of Odds Ratios (OR) and 95% Confidence Intervals (95% CI) were calculated for change over time with 2017 as the reference year.

RESULTS: Our study comprised 106,146 births: 10,112 preterm and 96,034 term births. In all, 54.8% of early preterm and 27.2% of late preterm births were given ACS within 7 days; 1.3% of term births also received ACS. Between 2017 and 2021, the annual rate of optimally timed ACS in *early preterm* births remained unchanged while ACS within 7 days of *late preterm* births increased (OR 1.38; 95% CI 1.17, 1.63) (Table 1). ACS exposure in *term* births also increased from 1.0% to 1.7% (OR 1.66; 95% CI 1.39, 1.98). Of 1250 *term* births with timing of ACS, 41.3% received ACS at 34^{+0}-36^{+6} weeks and 3.7% at term.

CONCLUSION: Given the suboptimal timing of ACS in preterm births and increasing ACS exposure in term births, our study highlights a need for greater focus on optimal timing of ACS and on strategies to avoid unnecessary ACS in term births.

Table 1. Delivery within 7 days of antenatal corticosteroids (ACS) in early and late preterm births. Time interval from ACS to birth was missing for 34 (1.5%) early preterm and 45 (0.7%) late preterm births and these cases were excluded from the analysis.

Year of birth	% of early preterm births (<34 weeks) given antenatal corticosteroids: within 7 days of birth % (OR; 95% CI)	% of late preterm births (34^{+0}-36^{+6} weeks) given antenatal corticosteroids within 7 days of birth % (OR; 95%CI)	Balancing measure: % of term births (>=37 weeks) given antenatal corticosteroids % (OR; 95%CI)
All, % (n/N)	55.45% (1,466/2,644)	27.26% (1,947/7,143)	1.34 (1,285/96,034)
2017	57.86% (Reference group)	23.25% (Reference group)	1.02% (Reference group)
2018	54.20% (0.86; 0.68, 1.09)	25.76% (1.15; 0.97, 1.36)	1.28% (1.26; 1.04, 1.51)

910 Performance of SNP-based cell-free DNA prenatal screening for 22q11.2 deletion syndrome in a commercial population

Wendy DiNonno, Melissa Maisenbacher, Georgina Goldring, Melda Balcioglu, Kayla Turner, M. Caleb Meads, Kayla Ruiz, Priyanka Arya, Jeffrey Meltzer, Katherine Howard
Natera, Inc., Austin, TX

OBJECTIVE: Evaluate positive predictive value (PPV) of 22q11.2 deletion syndrome (22q del) with SNP-based prenatal cfDNA screening in a commercial population.

STUDY DESIGN: Included all domestic SNP-based prenatal cfDNA screening with a high-risk result for a fetal 22q del over a 21 month period. Suspected maternal 22q del results were excluded from analysis. Diagnostic testing and ultrasound (u/s) results were collected. PPVs were calculated for samples with genetic truth via microarray (CMA) performed prenatally, postnatally or on products of conception.

RESULTS: Out of 1,057,710 cases, 753(0.071% or 1/1400) were high-risk for fetal 22q del. Average (avg) maternal age was 30.2 yrs(range 18-46); avg maternal weight 165.6 lbs(91-321 lbs, n=723); avg gestational age 14.0 wks(7.0-35.4); avg fetal fraction 7.9%(2.8-28.6%). Outcomes obtained in 155 cases(20.6%, table 1).

PPV was 47.0%. Including cases with suggestive u/s findings raised the PPV to 56.7%. 46.3% of CMA-positive cases did not have u/s finding(s). For cases with u/s anomalies(n=73), PPV was 78.4%. When u/s findings were limited to a cardiac(CHD) or renal anomaly(n=51), PPV was 92.6%.

CONCLUSION: The 22q del affects ~1/1,500-2000 pregnancies and is a common cause of developmental delay and CHDs. Early diagnosis allows for better pregnancy management and improves neonatal outcomes. This study shows a PPV ~50% in the general population and >90% in fetuses with cardiac and/or renal abnormalities. Importantly, less than 50% of true positive cases had u/s findings typically associated with 22q del. Without prenatal cfDNA screening, cases lacking u/s findings may be missed leading to delayed postnatal diagnosis (diagnostic odyssey) with previously reported median time to diagnosis of 4.7 yrs.

A previous prospective study (SNP-based Microdeletion and Aneuploidy RegisTry: SMART) showed a similar PPV of 52.6% in a cohort of 12 affected pregnancies. Results of this study confirm a

PPV of ~50% in a larger, real-world study and illustrate the limitations of u/s findings as a screening tool for the 22q del.

Table 1. Results of Follow-up

Follow-up Status	Cases (n)	Cases without Ultrasound Anomalies (n, %)	Cases with Ultrasound Anomalies (n, %)	Cases with Heart Defects (n)	Cases with Renal Anomalies (n)

Figure. Percentage of pregnant patients with early-stage (primary, secondary, early latent) syphilis, late-stage (late latent, unknown duration) syphilis or syphilis reinfection who received PrEP counseling in an antepartum clinic, March 2022 – February 2023

911 High acceptance of PrEP prescriptions among pregnant patients regardless of syphilis stage

Whitney Kleinmann, Kristen Warncke, Emily H. Adhikari
University of Texas Southwestern Medical Center, Dallas, TX

OBJECTIVE: HIV preexposure prophylaxis (PrEP) is an underutilized tool in the fight to end the HIV epidemic — especially in pregnant populations. We implemented an intervention to counsel and offer PrEP to all pregnant patients treated for syphilis in our high-risk ambulatory clinic. The purpose of this study was to determine if patients with early-stage syphilis are more likely to accept PrEP than those with late-stage syphilis or syphilis reinfection.

STUDY DESIGN: This was an observational cohort study of HIV-negative pregnant patients who were treated for syphilis at an antepartum clinic. Standardized PrEP counseling was provided at the time of each bicillin injection. Prescriptions were sent to our institutional ambulatory pharmacy for those who accepted. Demographics were collected including stage of syphilis at treatment. Medication dispensation was verified by chart review. Acceptance and dispensation rates of patients with primary, secondary, or early latent syphilis (early-stage) were compared to those with late latent or syphilis of unknown duration (late-stage) or syphilis reinfection. Statistical methods included use of chi-square with $p < 0.05$ considered significant.

RESULTS: From March 1, 2022 through February 28, 2023, 107 patients were treated for syphilis and received PrEP counseling with 8 (8%) with early-stage syphilis, 86 (80%) with late-stage syphilis, and 13 (12%) with syphilis reinfection. Fifty-five (51%) patients accepted PrEP, and acceptance rates by stage were 75%, 51%, and 38% respectively, although this was not statistically significant ($p = 0.26$). Thirty (55%) patients picked up PrEP and dispensation rates by stage were 50%, 57%, and 40% respectively ($p = 0.75$).

CONCLUSION: Pregnant patients treated for early-stage syphilis were more likely to accept a PrEP prescription than those with late-stage syphilis or syphilis reinfection, although these results were not statistically significant. Over half of all patients who received standardized PrEP counseling accepted a prescription. Further opportunities to increase acceptance and dispensation should be pursued.

912 Oxytocin versus oral misoprostol for PROM induction in nulliparas with unfavorable cervix: A randomized trial

Whitney Bender[1], Jennifer A. McCoy[2], Lisa D. Levine[3]
[1]Thomas Jefferson University Hospital, Haddonfield, NJ, [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA

OBJECTIVE: To determine if oxytocin or oral misoprostol (miso) results in a shorter time to delivery after induction of labor (IOL) for premature rupture of membranes (PROM) in nulliparas with an unfavorable cervical exam.

STUDY DESIGN: This randomized trial was conducted at an urban tertiary care center from 2019-2023. For nulliparas with a singleton gestation undergoing PROM IOL, we compared time from IOL to delivery (hours, h) between oxytocin vs oral miso (50 mcg q4h). Subjects were $\geq$ 36 wks with an unfavorable starting cervical exam ($\leq$ 2 cm and Bishop $<$ 8). Secondary outcomes included intraamniotic infection, cesarean, composite maternal and neonatal morbidity, and patient satisfaction. Sub-group analyses for those with BMI $\geq$ 30kg/m^2 and cervical dilation $\geq$ 1cm were performed. We needed 148 subjects to have 80% power to detect a 2-hour difference in time to delivery. The study was stopped early by the DSMB due to feasibility concerns in recruiting desired sample size.

RESULTS: 108 subjects were randomized: 56 oxytocin; 52 oral miso. There were no differences in demographic or baseline characteristics (Table 1). For time to delivery, there was no statistical difference between groups (14.9h oxytocin vs. 18.1h miso, p =0.06). In subgroup analyses with oxytocin compared to miso, there was a 5h shorter time to delivery for those with a BMI $\geq$ 30kg/m^2 and 4.5h shorter time to delivery for those with cervix $\geq$ 1cm. There was no difference in intraamniotic infection, cesarean, maternal or neonatal morbidity (Table 1). Satisfaction was higher for those receiving oxytocin compared to miso (29.0 vs. 26.3, p=0.03).

CONCLUSION: There was no overall difference in time to delivery between oxytocin and oral miso in this group of nulliparas with PROM and an unfavorable cervix. There was, however, a shorter time to delivery with oxytocin in obese patients and those with cervical dilation of at least 1 cm. Additionally, patient satisfaction was increased with oxytocin with no difference in cesarean or morbidity.

[f] Composite outcome of neonatal care unit admission greater than 48 hours, neonatal blood transfusion, hypoxic ischemic encephalopathy, grade III or IV intraventricular hemorrhage, neonatal cooling, severe respiratory distress syndrome, necrotizing enterocolitis, neonatal sepsis, or death
[g] Missing data on 9 subjects (n=99). Assessed via Birth Satisfaction Scale-Revised (BSS-R) with higher score indicating greater satisfaction. The BSS-R is subdivided into 3 domains: 1. Stress experienced during labor, 2. Birthing person's personal attributes, and 3. Quality of care provided.

913 Use of postpartum text-based support platform is not associated with breastfeeding outcomes

Whitney Bender[1], Celeste Durnwald[2]
[1]Thomas Jefferson University Hospital, Haddonfield, NJ, [2]University of Pennsylvania, Philadelphia, PA

OBJECTIVE: To describe the relationship between utilization of a text-based breastfeeding support platform and feeding outcomes at 6 weeks postpartum.

STUDY DESIGN: This is a secondary analysis of a randomized controlled trial (RCT) conducted at an urban tertiary care center from January 2020 to January 2021 comparing (1) a control group (2) an intervention group receiving weekly educational text messages and personalized text-based breastfeeding support as needed. Only patients randomized to intervention arm were included. The exposure of interest was engagement with the breastfeeding support platform as defined by asking one or more questions on the platform during 6 postpartum weeks of trial enrollment. The primary outcome was breastfeeding exclusivity at 6 weeks postpartum.

RESULTS: Of the 216 subjects in the RCT, 106 were randomized to the intervention arm, and 93 subjects had data on the primary outcome. Clinical characteristics of the cohort included a mean age of 31.9 years, 46.2% self-identified Black, 51.6% nulliparous and 58.1% had commercial insurance. Fifty (53.8%) of the subjects asked at least one breastfeeding question of the platform. Nulliparous subjects and those who saw a lactation consultant in the hospital were more likely to ask a question. There was, however, no difference in the primary outcome between those who queried the platform and those who did not (48% v. 48.8% p =0.94). This remained true after adjustment for prior lactation consultation (aOR 0.80, 95% CI 0.34-1.86). Number of interactions with the platform ranged from 0-21 with a median of 1; there was also no difference in breastfeeding exclusivity by number of interactions (p=0.69). There were no differences in measured secondary outcomes (Table).

CONCLUSION: There was no relationship between utilization of a personalized text-based breastfeeding support platform and breastfeeding outcomes at 6 weeks postpartum. This finding warrants further exploration as we consider innovative ways to improve breastfeeding rates.

914 Once GDM, always GDM? Pregnancy with GDM preceding non-GDM pregnancy- A retrospective cohort study

Yael Shalev Rosenthal[1], Eran Hadar[2], Adam Rosenthal[3], Shai Ram[4], Hila Shalev[5], Shir Gruber[6], Anat Pardo[7], Anat Shmueli[1]
[1]Rabin medical center, Petach-Tikva, HaMerkaz, [2]Rabin Medical Center, Petach-Tikva, HaMerkaz, [3]Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim, [4]Lis Hospital for Women, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, Ra'anana, Tel Aviv, [5]Meir Medical Center, Kfar sava, HaMerkaz, [6]Helen Schneider Hospital for Women, Rabin Medical Center, Tel Aviv, Israel, [7]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, Tel-Aviv, Israel

OBJECTIVE: To investigate whether women previously diagnosed with gestational diabetes mellitus (GDM) but not in a subsequent pregnancy present similar diabetes-related complications, despite the lack of diagnosis.

STUDY DESIGN: A retrospective cohort design was employed, including women with at least two consecutive births at Rabin Medical Center between July 2012 and December 2022. Participants were categorized into three groups: GDM in both pregnancies (group 1), GDM in the first but not in the subsequent pregnancy (group 2), and no GDM in both pregnancies (group 3). Groups were compared for various diabetes-related complications.

RESULTS: The study population comprised 19,703 women. Group 2 showed higher rates of macrosomia (OR 1.4, 95% CI 1.01-1.92, p=0.03), large-for-gestational-age (LGA) (OR 1.6, 95% CI 1.2-2.0, p< 0.01) and preeclampsia (OR 2.35, 95% CI 1.32-4.15, p< 0.01) when compared to group 3. Rates of LGA, macrosomia and preeclampsia were similar between group 1 and 2. Both Group 1 and Group 2 exhibited significantly elevated composite maternal-neonatal outcomes compared to Group 3 (OR 1.91, 95% CI 1.58-2.3, p< 0.01 and OR 1.48, 95% CI 1.23-1.77, p< 0.01 , respectively).

In a multivariate logistic regression, the adjusted OR (accounting for age, BMI and parity) for composite maternal-neonatal outcomes was 1.75 (95% CI 1.36-2.25, p< 0.01) and 1.30 (95% CI 1.01-1.67, p=0.03) in groups 1 and 2 respectively, compared to group 3. Elective cesarean delivery rate was higher in groups 1 (22%) and 2 (13%) compared to group 3 (8.7%). However, the rate was also significantly higher in group 1 versus 2. Preterm birth rates were higher in group 1 (OR 1.7, 1.2-2.3, p< 0.01) but not 2, when compared to group 3.

CONCLUSION: Women with a history of GDM in a previous pregnancy but not in subsequent pregnancy are at increased risk of diabetes-related complications, including preeclampsia, macrosomia, and LGA. The findings suggest that these women may have underlying insulin resistance, as well as other, still occuring, risk factors; and their lack of diagnosis does not withhold adverse outcome.

915 Health Inequity Observed in Demographic Correlations with Pregnancy-Associated Hypertensive Morbidity During the Coronavirus Pandemic

Yanling Dong[1], Stefanie J. Hollenbach[2]

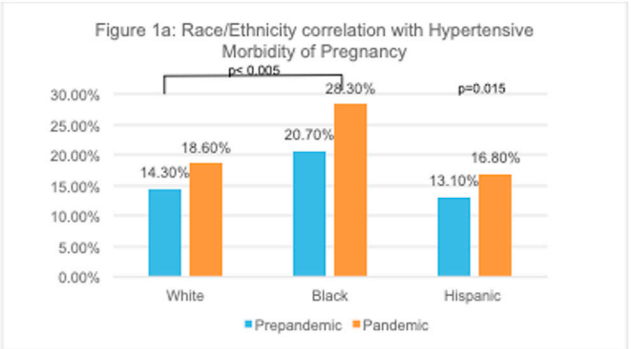
[1]University of Rochester Medical Center, Rochester, NY, [2]The University of Rochester Medical Center, Rochester, NY

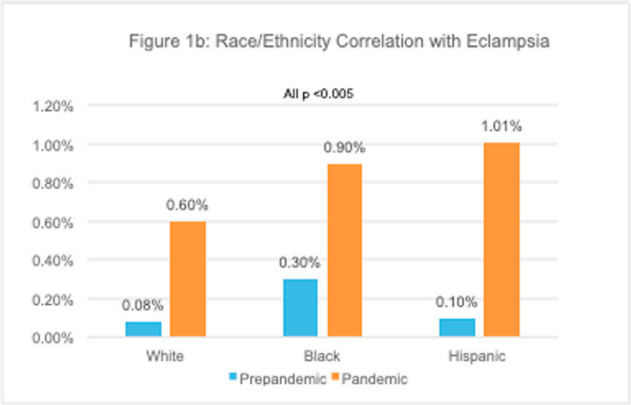
OBJECTIVE: To characterize race and ethnicity associations with the prevalence of hypertensive (HTN) morbidity during pregnancy in relationship to the COVID-19 pandemic.

STUDY DESIGN: Retrospective, ecological cohort study of a 10-county birth certificate database with a pre-pandemic cohort from April 2018 to February 2019 and a pandemic cohort from April 2020 to February 2021, excluding transitional deliveries during the emerging pandemic. Cohorts were analyzed for the primary outcome of diagnosed HTN morbidity in pregnancy (including pregnancy related HTN and chronic HTN) and eclampsia among different ethnicity groups, as well as a secondary outcome of neonatal morbidities. Data analysis was performed via T-Test and Chi-squared Test.

RESULTS: 19062 deliveries were included, 9726 in the pre-pandemic and 9335 in the pandemic cohorts. Patient demographics, including maternal age, gestational age and BMI were not significantly different between the two cohorts. Prevalence of HTN morbidity (from 14.9% to 20.2%, OR 1.45, CI 1.34-1.56, p< 0.05) and eclampsia (from 0.1% to 0.7%, OR 6.8, CI 3.50-13.3, p< 0.05) during the COVID pandemic increased. The increased prevalence of HTN morbidity persisted among patients identifying as non-Hispanic White (from 14.3% to 18.6%, OR1.37, CI 1.24-1.50, p< 0.005), non-Hispanic Black (from 20.7% to 28.3%, OR 1.51, CI 1.29-1.78, p< 0.005), and Hispanic (from 13.1% to 16.8%, OR 1.34, CI 1.05-1.71, p=0.015). The increased prevalence of eclampsia was also persistent and profound (Figure 1). There was no clinically significant change in neonatal outcomes, including birth weight, preterm delivery rate, APGAR scores and NICU admission rates.

CONCLUSION: These data demonstrate an increased prevalence of HTN morbidity and eclampsia during the COVID-19 pandemic across different race/ethnicity groups, with most significant increase of HTN morbidity experienced in those identifying as non-Hispanic Black and eclampsia in Hispanic populations. These trends reveal disparate concentrations of morbidity across populations that may be a reflection of differing burden of baseline health disparities.





916 Nutrition Pattern and Adverse Pregnancy Outcomes in nulliparous individuals: A cluster analysis

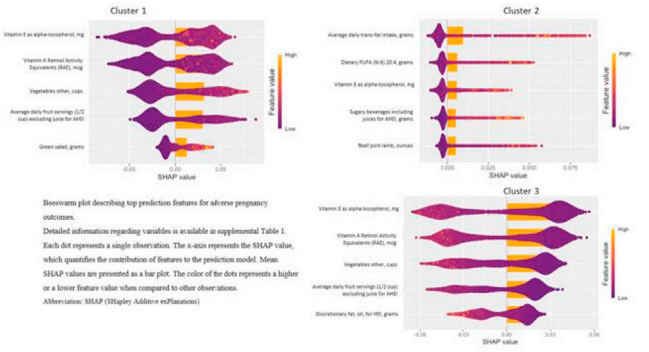
Yara Hage Diab, Kazuma Onishi, George R. Saade, Tetsuya Kawakita
Eastern Virginia Medical School, Norfolk, VA

OBJECTIVE: Studies evaluating association between nutrition and pregnancy outcomes did not take into consideration the various aspects of each patient diet or the large amount of variables within each dietary exposure. Our objective was to use unsupervised machine learning models to characterize dietary profiles and determine their associations with pregnancy outcomes.

STUDY DESIGN: This was a secondary analysis of the Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-to-Be. The primary outcome was a composite of preterm birth, stillbirth, eclampsia, preeclampsia, gestational hypertension, and small for gestational age. An unsupervised machine learning algorithm was developed (k-means). A total of 335 clustering variables were considered. The proportion of the primary outcome was examined within each cluster. Multivariable logistic regression was performed to obtain adjusted odds ratios (aOR) with 95% confidence intervals (95%CI), controlling for predefined confounders.

RESULTS: Of 7074 individuals, there were 2593 (36.7%) in cluster 1, 546 (7.7%) in cluster 2, and 3935 (55.6%) in cluster 3. Cluster 2 was associated with increased odds of adverse pregnancy outcomes (22.4% vs.31.3%; aOR 1.35 [95%CI 1.06-1.71]) and gestational diabetes (3.9% vs.6.0%; aOR 1.86 [95%CI 1.15-3.01]). Cluster 3 was not associated with adverse pregnancy outcomes (22.4% vs. 25.6%; aOR 1.13 [95%CI 0.99-1.29]). Cluster 1 was characterized by higher intake of vitamin E, vitamin A, fruits, vegetables, and green salad. Cluster 2 was characterized by higher intake of trans-fat, polyunsaturated fatty acids, red meat, sugar beverages, and theobromine intake. Cluster 3 was characterized by lower intake of vitamin E, vitamin A, vegetables, fruits, and fat or oil consumption.

CONCLUSION: We were able to use machine learning to categorize food intake into clusters, each with its own risk of adverse pregnancy outcome. Food intake pattern that is characterized by higher intake of trans-fat, polyunsaturated fatty acids, red meat, and sugar beverage intake was associated with adverse pregnancy outcomes.



917 Incidence of umbilical cord accidents as a cause of fetal death and associated histologic characteristics

Yevgenia Y. Fomina[1], Isabelle Mulder[2], Alesha M. White[1], Nicole Seyfried[1], Jessica E. Pruszynski[1], Anne M. Ambia[1], Elaine L. Duryea[1]
[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]University of Texas Southwestern Medical Center, Bellaire, TX

OBJECTIVE: The underlying mechanisms of umbilical cord accidents (UCA) as the cause of fetal death are poorly understood. We aim to report the incidence of fetal death due to UCAs at a large, urban hospital and identify the associated histologic characteristics.

STUDY DESIGN: This is a retrospective cohort study of all singleton fetal deaths $\geq$ 24 weeks that were attributed to umbilical cord accidents at a large, urban health system that serves medically-indigent patients. Each fetal death underwent a complete cause of death analysis by a multi-disciplinary committee of neonatologists, genetic counselors, obstetricians, and pathologists. Diagnosis of fetal death due to umbilical cord accidents was made by committee consensus opinion after review of the antepartum pregnancy course, fetal autopsy, chromosomal microarray, placental pathology, and fetal surveys. The placental slides for each case were reviewed by two pathologists and a consensus report was issued. The pathology reports were systematically reviewed and tabulated.

RESULTS: Between January 2010 and December 2022 there were 150,090 singleton births at our facility, 782 of which were fetal deaths $\geq$ 24 weeks and weighing $\geq$ 500 grams at delivery. After case review by the committee, 31 (4%) of the fetal deaths were attributed to umbilical cord accidents. Fetal survey at time of delivery and subsequent pathologic cord evaluation was notable for a nuchal cord in 15 patients (48.4%), a true knot in 7 patients (22.6%), and cord hyper-coiling in 7 patients (22.6%) (Table). Placental pathology was notable for vasculopathy in 16 patients (51.6%) and villitis in 7 patients (22.6%) (Table).

CONCLUSION: Umbilical cord abnormalities are an important risk factor for stillbirth. Umbilical cord accidents account for

approximately 4% of fetal deaths at a large urban hospital system. Associated histologic findings include cord hyper-coiling, placental vasculopathy, and placental villitis.

Perinatal characteristics	Patients (n)
Maternal age (mean + SD)	27.8 y/o (5.6)

918 Parental Acceptance of Fetal Tissue Donation: Insights from the Dutch Fetal Biobank

Yousif Dawood, Marieke Buijtendijk, Bernadette de Bakker, Maurice van den hoff, Eva Pajkrt
Amsterdam UMC, location AMC, Amsterdam, Noord-Holland

OBJECTIVE: Traditionally parents have had two options after termination of pregnancy. Either they take the fetal remains home for burial/cremation or the fetus remains in the hospital for collective cremation. Since 2017, a new choice emerged in the Netherlands: donation to the Dutch Fetal Biobank. This shift in options has led to an exploration of parents' willingness to contribute to research through donation.

STUDY DESIGN: We performed a cohort study at the Amsterdam UMC aimed to understand the impact of this new choice on post-termination decision-making. From 2008 to 2022, we included maternal age, ethnicity, gestational age, reason for termination, and post-termination decision in our analyses.

RESULTS: Prior to the introduction of the Dutch Fetal Biobank (DFB), of 689 terminations, 40.8% of parents took remains home, 55.3% chose collective cremation, 1.3% donated to science, and for 2.6% data was not available. After introduction of the DFB, of 459 terminations, 44.2% took remains home, 30.7% chose collective cremation, 21.4% donated to science, and for 1.7% information was missing. When we omitted those uninformed about the DFB or excluded from donation, 31.4% consented to donate.

Maternal age, ethnicity, and termination reason did not significantly influence the likelihood of donation. However, gestational age negatively impacted donation likelihood, reducing odds of donation by a factor of 0.986 with each additional day.

CONCLUSION: The considerable uptake of the Biobank donation option illustrates broad acceptability of this choice among parents. The increased donation rates, uninfluenced by maternal age, ethnicity, or termination reason, suggest potential for the establishment of more fetal biobanks globally. Our results indicate donation is increasingly chosen and acceptable, thus providing an opportunity to expand this service, offering additional support for parents post-termination and valuable contributions to scientific research.

919 Retrospective analysis of opioid prescribing following obstetric procedures in patients with and without opioid exposure

Bryan L. Aaron[1], Dana Feldman[2], Jennifer Waljee[2], Mark Bicket[2], Michelle Moniz[2], Vidhya Gunaseelan[2], Alex Peahl[2]
[1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI

OBJECTIVE: To compare opioid prescribing practices following obstetric procedures in pregnancy across opioid-naive patients and patients diagnosed with opioid use disorder (OUD).

STUDY DESIGN: We performed a retrospective cohort study using claims data from *Truven Medicaid* and *Truven Marketscan* for patients aged 18-55 who gave birth from 1/1/2016 to 12/31/2020. We included patients who underwent an obstetric procedure in pregnancy from 270 to 4 days prior to childbirth admission. We compared opioid-naive patients (i.e., patients with no opioid prescriptions or diagnoses of OUD in pregnancy) to patients with OUD (i.e., patients with a diagnosis of OUD or who received medication for OUD). Outcomes included receipt of an opioid and prescription size (standardized to 5 mg tabs of oxycodone). Descriptive statistics between patients' insurance type and opioid exposure were used to summarize the data.

RESULTS: Among all patients that underwent an obstetric or non-obstetric procedure, 16,028 of 20,782 patients (77.1%) underwent obstetric procedures in pregnancy (opioid naive: 15,858/20,521; OUD: 170/261). The most common obstetrical procedure was amniocentesis (opioid-naive: 44.4%, OUD: 53.5%), followed by transvaginal cerclage (opioid-naive: 39.3%, OUD: 38.2%), and chorionic villus sampling (CVS; opioid-naive: 15.9%, OUD: 7.6%). Across all procedures, the rate of opioid prescribing was higher for patients with OUD than for opioid-naive patients and higher for patients with public insurance versus private insurance. For example, following amniocentesis, rates of opioid prescribing for patients with OUD with public (32.4%) and commercial (23.5%) insurance were higher than for opioid-naive patients with public (1.0%) or commercial (0.2%) insurance.

CONCLUSION: Patients with OUD and public insurance were more likely to receive opioid prescriptions following obstetric procedures in pregnancy than opioid-naive and commercially insured patients. Future work is needed to define appropriate, tailored prescribing recommendations for these groups that balance opioid stewardship with the need for excellent pain management.

920 Retrospective analysis of opioid prescribing following surgical procedures in patients with commercial vs. public insurance

Bryan L. Aaron[1], Dana Feldman[2], Jennifer Waljee[2], Mark Bicket[2], Michelle Moniz[2], Vidhya Gunaseelan[2], Alex Peahl[2]
[1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI

OBJECTIVE: To compare opioid prescribing practices following non-obstetrical procedures in pregnancy among public versus private insurance enrollees.

STUDY DESIGN: We performed a retrospective cohort study using claims data from *Truven Medicaid* (public) and *Truven Marketscan* (private) for all opioid-naive patients aged 18-55 undergoing a procedure in pregnancy from 01/01/2016 to 12/31/2020. We included opioid-naive patients (e.g., no opioid prescription in pregnancy) who underwent 6 common procedures from 270 to 4 days prior to childbirth admission. Outcomes included opioid prescribing characteristics (e.g., receipt of opioid, prescription size in 5 mg tabs of oxycodone). Descriptive statistics and tests of comparison were used to summarize the data.

RESULTS: Among those undergoing all procedure types, 10.1% (2,080 of 23,396 patients) had non-obstetrical procedures and were opioid-naive (Public: 790 of 7,324 [10.8%]; Private 1,290 of 16,072 [8.0%]). The most common procedures differed by insurance type (public: laparoscopic (lap.) cholecystectomy [54.1%], lap. appendectomy [21.4%], lap. oophorectomy [17.3%]; private: lap. cholecystectomy [40.1%], lap. oophorectomy [25.8%], lap. appendectomy [25.5%]). The procedure with the highest proportion of opioid prescribing for public enrollees was lap. oophorectomy (84.7%, Median: 20); For private enrollees, this was lap. cholecystectomy (77.0%, Median: 14.5). Of those who received opioid prescriptions, the proportion of patients who received a prescription and prescription size were higher for five of the six procedures for patients with public compared to private insurance.

CONCLUSION: Compared to patients with private insurance those with public insurance more commonly received an opioid prescription following procedures in pregnancy and received larger prescription sizes. Because one in 25 patients who receive an opioid prescription during pregnancy will develop new-persistent opioid use, standardized pain management guidelines for pregnant patients may reduce this observed inequity and reduce the risk of harm from opioid overprescribing.

921 Maternal and fetal outcomes among pregnant women with endometriosis

Sara Abdessamie[1], Nicholas Czuzoj-Shulman[2], Haim A. Abenhaim[3]
[1]McGill University, Montreal, QC, [2]Jewish General Hospital, QC, [3]Jewish General Hospital, Montreal, QC

OBJECTIVE: Endometriosis, a prevalent disorder affecting approximately 10% of women of reproductive age which has been associated with obstetric complications during pregnancy. The primary objective of this study was to evaluate the prevalence of endometriosis in pregnancy and explore the maternal and newborn outcomes of pregnant women diagnosed with endometriosis.

STUDY DESIGN: A retrospective cohort study was conducted using data from the Healthcare Cost and Utilization Project, Nationwide Inpatient Sample (HCUP-NIS) database of the United States between 1999 and 2019. Multivariate logistic regression analysis, controlling for diverse baseline maternal characteristics were used to investigate pregnancy and newborn outcomes in births to women diagnosed with endometriosis as compared to those without.

RESULTS: The study cohort consisted of 16,911,497 births to women without endometriosis and 14,956 pregnant women diagnosed with

endometriosis. Over the 20-year period, there was a significant upward trend in the prevalence of endometriosis among births, rising from 34.9 to 160.6 per 100,000 births. Births to women with endometriosis exhibited distinctive demographic characteristics, being of advanced maternal age, predominantly of Caucasian ethnicity, belonging to higher income quartiles, obese, smokers, and having private insurance coverage. Births to women with endometriosis were at heightened risk of experiencing obstetric complications, including gestational diabetes, preeclampsia, preterm birth, and postpartum hemorrhage. Neonates born to mothers with endometriosis also demonstrated an elevated likelihood of growth restriction and congenital anomalies.

CONCLUSION: This study provides comprehensive insights into the baseline characteristics of pregnant women with and without endometriosis. Moreover, it establishes a compelling association between endometriosis and elevated risks of adverse maternal and newborn outcomes. These findings emphasize the significance of early interventions and vigilant monitoring to ameliorate obstetrical and fetal outcomes in pregnant women diagnosed with endometriosis.

922 Temporal, regional and hospital-type variation in EMTALA violations involving obstetric emergencies, 2018-2023

Sameer Ahmed[1], Rauvynne N. Sangara[2], Carmen Toomer[1], Olivia Sison[1], Zach Reichert[1], Brian Nguyen[1], Michael Menchine[1], Seth A. Seabury[3], Sophie Terp[1], Sarah Axeen[1]

[1]Keck School of Medicine of USC, Los Angeles, CA, [2]University of Southern California, Pasadena, CA, [3]USC Mann School of Pharmacy, Los Angeles, CA

OBJECTIVE: The Emergency Medical Treatment and Labor Act (EMTALA) requires hospitals to screen, stabilize, and, if appropriate, transfer patients presenting to emergency departments (EDs) seeking emergency care and/or labor evaluation. EMTALA is enforced by the 10 regional offices of the Centers for Medicare & Medicaid Services (CMS), which may vary in their processes. We aim to describe regional variations in EMTALA enforcement related to obstetric (OB) emergencies in the United States from 2018 to 2023, with attention to temporal variations related to the COVID-19 pandemic.

STUDY DESIGN: This is a retrospective study of 2837 EMTALA violations from 2018 to March 2023 obtained from CMS, including dates, locations, and hospital types. Inspection text was systematically reviewed for keywords for the involvement of pregnant patients and/or OB emergencies. We compared temporal and regional variations in EMTALA violations involving OB versus non-OB emergencies.

RESULTS: During the study period, 294 (10.4%) violations involved OB emergencies. Rates of clinical deficiencies were 11 percentage points higher in OB violations versus non-OB violations. OB-related violations accounted for 12% of EMTALA-related violations prior to the COVID-19 pandemic versus 8.7% from 2020 to 2021. While violations from 2022 and 2023 are incompletely reported, available data note a continued downtrend to 8.3%. By CMS region, regions 4 (South Atlantic), 9 (Southwest), and 10 (Northwest) contributed to disproportionately more OB-related violations (differences of 2.8, 2.5, and 2.1 percentage points, respectively). Critical Access Hospitals (CMS-designated eligible rural hospitals) account for 20.7% of OB-related violations but only 17.5% of non-OB-related violations in contrast to short-term hospitals with near-identical proportions.

CONCLUSION: The proportion of EMTALA violations involving OB emergencies decreased over time. Proportions additionally varied by CMS region and hospital type. Recent changes in legislation impacting access to reproductive services may impact future temporal and regional variations in OB-related EMTALA violations.

923 The July Phenomenon and Postpartum Hemorrhagic Morbidity

Naahanna B. Akahara[1], Rachel L. Wiley[1], Ipsita Ghose[2], Saloni Kumar[1], Rylee Trotter[3], Emily Johnson[1], Yossi Bart[1], Hector Mendez Figueroa[4], Suneet P. Chauhan[3]

[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]University of Texas Medical School at Houston, Houston, TX, [3]University of Texas-Houston Medical School, Houston, TX, [4]University of Texas Health Science Center at Houston, Houston, TX

OBJECTIVE: The "July Phenomenon" refers to the time of year when inexperienced physicians begin training and there is a concern for increase in adverse outcomes. We aimed to evaluate differences in composite of maternal hemorrhagic morbidity (CMHM) over four calendar quartiles to determine the putative impact of the "July Phenomenon".

STUDY DESIGN: Our retrospective cohort study included all singleton deliveries at an academic Level IV center from July 2020 to June 2021. A total of 4,151 deliveries were included and divided into four quartiles designed to follow one academic year**:** Quartile 1 (July to September, n=1073), Quartile 2 (October to December, n=1066), Quartile 3 (January to March, n=1011), and Quartile 4 (April to June, n=1001). The data was collected by trained clinicians. CMHM was defined as blood loss $\geq$ 1000 mL, use of uterotonics (excluding prophylactic oxytocin), mechanical tamponade, surgical techniques for atony, transfusion, venous thromboembolism, intensive care unit (ICU) admission, hysterectomy, or maternal death. CMHM in Quartiles 1, 2, and 3 were compared to Quartile 4 (when residents are most experienced) using multivariate Poisson regression with robust error variance, adjusted for variables identified in the univariate analysis.

RESULTS: Compared to Quartile 4, there was no significant difference in CMHM with Quartile 1 (aRR 1.01, 95% CI 0.86 − 1.2), Quartile 2 (aRR 0.95, 95% CI 0.8 − 1.12) or Quartile 3 (aRR 1.13, 95% CI 0.96 − 1.33) (Figure 1). Majority of the components of the composite investigated did not differ between the Quartiles, except in surgical techniques where there was a significant increase in Quartile 4. Admission to ICU was significantly lower in Quartile 2, however this was no longer significant when admissions for COVID were excluded.

CONCLUSION: There was no "July phenomenon" for obstetrical hemorrhagic morbidity at our institution. Whilst surgical techniques differ as residents get more experienced, most components of the composite remained unchanged during a year.

	Quartile 1	Quartile 2	Quartile 3	Quartile 4
*CMHH Rate	20.3% (218/1073)	19.6% (209/1066)	23.6% (239/1011)	21.3% (213/1001)
aRR†	1.01	0.95	1.13	1.00
95% CI	0.86 - 1.20	0.80 - 1.12	0.96 - 1.33	

Figure 1. CMHM in relationship to delivery quartile, with reference group as Quartile 4 when residents are most experienced.

* CMHH included blood loss ≥ 1000 mL, uterotonic use (excluding initial oxytocin), surgical techniques for atony (uterine artery ligation, B-lynch or uterine artery embolization), mechanical tamponade, transfusion, hysterectomy, DVT/PE, ICU admission or maternal death

† adjusted Risk Ratio - Adjusted for race/ethnicity, diabetes, hypertension, induction of labor, abnormal vital signs at admission, low hematocrit and prolonged oxytocin use

924 Serum magnesium levels: does maternal weight matter?

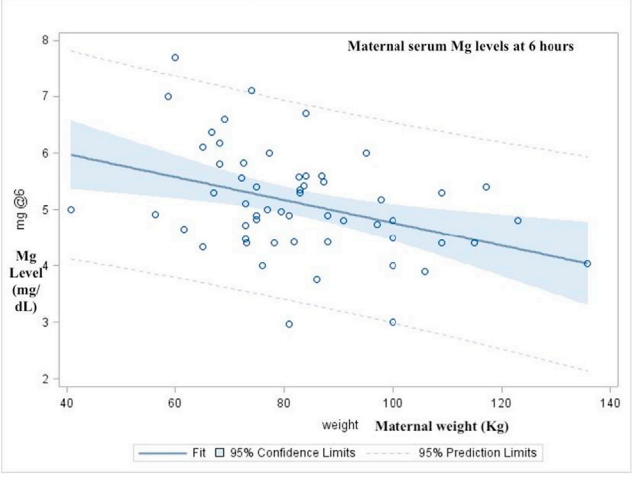
Islam Aly[1], Barak Rosenn[2]
[1]NYU Langone Health, Brooklyn, NY, [2]Jersey City Medical Center, Jersey City, NJ

OBJECTIVE: Standard management of preeclampsia with severe features includes the administration of Magnesium Sulfate (Mg) for the prevention of eclamptic seizures. Most institutions employ a protocol that includes an intravenous loading dose of 4-6 g followed by continuous infusion of 2g/hour. The purpose of this study was to test the hypothesis that maternal serum concentration of Mg is inversely correlated with maternal weight.

STUDY DESIGN: This retrospective cohort study included women who received I/V Mg for preeclampsia between January 2017 and January 2022 and had a 6-hour Mg serum level determined before delivery. Patients were identified by the hospital pharmacy and their medical records were reviewed. Data reviewed included age, gestational age at presentation, blood pressure on admission, weight (kg), and Mg concentrations. Statistical analysis involved t-test, Pearson correlation, and linear and multiple regression.

RESULTS: 1036 records were reviewed, of these, 56 (5.4%) patients received at least 6 hours of Mg prior to delivery and had a 6-hour determination of Mg level. Mean (±SD) Mg level was 5.11+0.94 mg/dL. Maternal Mg level was inversely correlated with maternal weight (r=0.385; p=0.0034). Multiple regression adjusting for gestational age, systolic, and diastolic blood pressures did not alter this result (p=0.0184). Nineteen of the 56 patients (34%) had a Mg level < 4.8 mg/dL, considered sub-therapeutic. Mean weight of patients with sub-therapeutic and therapeutic Mg levels were 79.64+16.33 Kg vs. 89.45±18.99 Kg, respectively (p=0.025).

CONCLUSION: Antepartum Mg concentration is inversely correlated with maternal weight. Loading and maintenance doses of Mg may need to be adjusted based on maternal weight.



925 Risk factors for the need for repeated surgical intervention after a cesarean delivery

Uri Amikam[1], Yael Botkovsky[2], alyssa Hochberg[3], Aviad Cohen[4], Ishai Levin[4], Yariv Yogev[5], Liran Hiersch[6], Anat Lavie[7]
[1]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv, Israel, [2]Tel-Aviv University, Tel-Aviv, Israel, [3]Helen Schneider Hospital for Women, Rabin Medical Center, Petach Tikva, Israel, Petach Tikva, Israel, HaMerkaz, [4]Lis Hospital for Women's Health, Sourasky Medical Center, Tel Aviv, Israel, Tel-Aviv, Israel, [5]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [6]Sourasky Medical Center, Tel-Aviv, Israel, [7]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel

OBJECTIVE: To determine risk factors for re-surgery following a cesarean delivery (CD).

STUDY DESIGN: A retrospective case-control study at a single tertiary university-affiliated medical center (2013-2023). Women who had a repeat surgery up to 6 weeks of the CD (re-surgery group) were compared to a control group of women with a CD without re-surgery in a 1:2 ratio. Controls were women who had a CD before and after each case in the re-surgery group. Maternal characteristics, obstetrical and surgical data were compared. Inclusion criteria were CD occurring ≥24 gestational weeks and opening of the fascia at the repeat surgery. CD performed at different centers and indications for repeat surgery unrelated to the primary surgery (appendicitis, etc.) were excluded. Logistic regression was used to adjust for potential confounders.

RESULTS: 1. Overall, 138,765 women delivered during the study period. Of them, 27,302 (19.7%) delivered by CD; and 101 (3.7/1,000) underwent re-surgery in the postpartum period.

2. 87/101 (86.2%) were operated by relaparotomy, and 14/101 (13.8%) by laparoscopy. The median time for re-operation was 27 hours (IQR 29-143 hours).

3. There were no significant differences between the groups regarding maternal age, body mass index, gravidity, parity, rate of previous CD, gestational diabetes mellitus, and gestational age at delivery (p > 0.05 for all).

4. There were significantly higher rates of multiple pregnancies (11.9% vs. 2.5%, p< 0.001), low molecular weight heparin (LMWH) use during pregnancy (9.9% vs. 2%,p=0.02), and hypertensive disorders of pregnancy (HDP) (13.9% vs. 4.5%,p=0.003) in the study compared to the control group.

5. In a multivariable logistic regression, multiple pregnancies, LMWH use, HDP, estimated blood loss at CD, and the use of a hemostatic dressing, were all found to be significant independent predictors of the need for re-operation following CD (Table).

CONCLUSION: Several pregnancy and intra-operative risk factors can be identified for the need for re-surgery following a CD, requiring appropriate diligent care and management.

Table - Multivariable analysis of factors associated with repeated surgery

Characteristic	Adjusted OR	95% Confidence Interval	p-value
LMWH during pregnancy	5.9	1.6-21.6	**0.007**
Multiple pregnancy	5.4	1.6-18.2	**0.024**
Hypertensive disorder of pregnancy	2.8	1.1-7.9	**0.049**
Preterm labor (<37 weeks)	1.1	0.5-2.3	0.81
Second stage CD	2.4	0.9-6.2	0.078
EBL	1.5	1.2-3.9	**0.035**
Duration of surgery	1.02	0.99-1.04	0.091
Intraabdominal adhesions	1.4	0.7-2.7	0.37
Use of a hemostatic dressing	2	1.03-3.9	**0.039**

LMWH – low molecular weight heparin; CD – cesarean delivery; EBL– estimated blood loss.

926 Psychological impact of medical termination of pregnancy: secondary analysis of the multicenter randomized trial DILATOP

OBJECTIVE: To evaluate the psychological impact of medical termination of pregnancy (TOP) and to determine factors associated with severe psychological impact.

STUDY DESIGN: Secondary analysis of a multicenter (n= 10 centers) randomized controlled trial comparing the efficacy of cervical dilators inserted concurrently with misoprostol with that of misoprostol alone for women undergoing TOP between $15^{0/7}$ and $27^{6/7}$ weeks of gestation. Psychological impact was evaluated by the impact of event scale revised (IES-R) questionnaire self-administered 1 to 4 months after TOP. IES-R is a 22-items scale designed to assess subjective distress caused by traumatic events, validated for use in perinatal medicine. A score $^{3}33$ corresponds best to the diagnosis of PTSD and a score $^{3}37$ to severe psychological impact. Maternal and obstetrical characteristics associated with a score $\geq$37 were studied using mixed models. We present results for complete cases and after multiple imputation to account for selective dropouts and missing information at follow-up.

RESULTS: Between November 2017 and September 2019, 347 women were enrolled; 247 IES-R questionnaires were available and 219 fully completed. Median time between TOP and completion of the questionnaire was 7 weeks (IQR 4.9-13.3). The median IES-R score was 31 (IQR 22-42), 46% of women had a score ^{3} 33 and 37% ^{3} 37. After multivariable analysis, the only maternal factor associated with an IES-R ^{3}37 was occupation as a blue-collar worker or commercial employee compared to manager. Obstetric or labor-related characteristics as well as parity, gestational age over 22 weeks, use of cervical dilators, labor > 12h, pain or complications during delivery or post-partum were not associated with an IES-R ^{3}37. The results were similar after multiple imputation.

CONCLUSION: A high proportion of women experiencing medical TOP had a major psychological impact. The absence of vulnerability factors besides occupation, underlines the importance of psychological evaluation after TOP for all women to improve global care.

Table 1: Maternal, obstetric and labor-related characteristics associated with a severe psychological impact (IES-R ≥37) in women with medical TOP

927 The impact of cup size on complications in vacuum-assisted deliveries: A retrospective case-control matching analysis

Matan Anteby[1], Tally Pinchas-Cohen[2], Anat Lavie[2], Sharon Maslovitz[3], Liran Hiersch[4], Yariv Yogev[5]

[1]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv, and Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [2]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel, [3]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University Israel, Tel aviv, Israel, [4]Sourasky Medical Center, Tel-Aviv, Israel, [5]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

OBJECTIVE: While previous research compared different Vacuum Assisted Delivery (VAD) devices (e.g. soft vs. rigid), scarcity of data exists regarding the association between vacuum cup size and perinatal complications.

We aimed to assess the association of vacuum cup size on maternal and neonatal morbidity in vacuum-assisted deliveries (VAD).

STUDY DESIGN: A retrospective cohort study at a single university-affiliated tertiary medical center (2011-2022). The metallic Malmström device, with cup sizes of 50 or 60 mm, was used for VAD. Cup size choice was based on physician preference and with both sizes an external force pressure of 550-600 mm Hg was used. Neonatal and maternal outcomes were compared between VAD using 50 vs 60 mm cup sizes. In order to ensure comparability between the groups, we conducted a case-control matching analysis with a 1:1 ratio based on age, BMI, analgesia, nulliparity, gestational age, baby weight, episiotomy, VAD indication, fetal station, and presentation.

RESULTS: 1. Overall, 4,703 women underwent VAD with a 50 mm Malmström cup, and 1,541 with a 60 mm cup.

2. The matching analysis included a total of 782 well-balanced cases in each group.

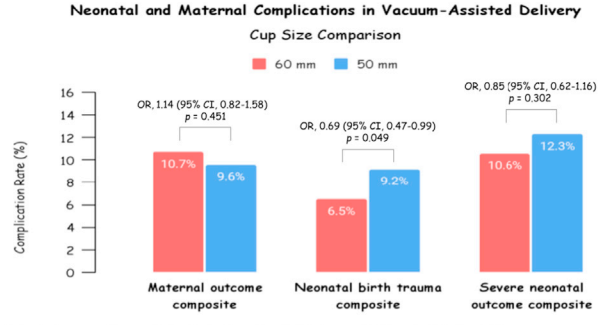
3. A 60mm cup was associated with a shorter mean interval from VAD initiation to delivery (4.31± 1.88 minutes vs 4.65±2.406 minutes, p=0.003) and reduced risk of cup detachment [OR 0.52 (0.31-0.89), p=0.015], with a comparable cesarean delivery rate compared to the 50mm cup (0.6% vs 0.9%); OR 0.71 [0.22-2.25], p=0.56.

4. Risk of neonatal birth trauma (brachial plexus injury, cephalohematoma, subgaleal hematoma or subdural hematoma) was higher in the 50mm group [Figure].

5. Composite severe neonatal outcome did not differ significantly between the groups [Figure].

6. Composite maternal outcome was similar between the groups [Figure]. However, the risk of perineal tears was lower in the 60 compared to the 50 mm group [306 (39.1%) vs 369 (47.2%), OR 0.72 (0.59-0.88), p=0.001].

CONCLUSION: A larger Malmström cup size (60 mm) during VAD is associated with a decreased risk of neonatal birth trauma compared to a 50 mm diameter.



928 Sexual dimorphism in chorion trophoblastic cells

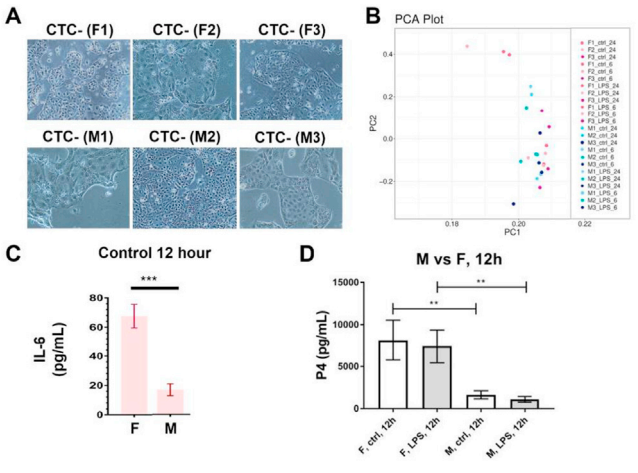
Daphne D. Arena Goncharov[1], RamKumar Menon[2], Enkhtuya Radnaa[3], Lauren Richardson[1], Ryan Lintao[4]
[1]University of Texas Medical Branch, Galveston, TX, [2]University of Texas Medical Branch, League City, TX, [3]University of Texas Medical Branch at Galveston, Galveston, TX, [4]University of Texas - Medical Branch, Manila, TX

OBJECTIVE: Differences in clinical premature birth outcomes and intrauterine tissue inflammation have been observed between male (M) and female (F) neonates. These observations have been identified in placental trophoblast tissue, but sexual-level differences are unknown to occur within the fetal membrane trophoblast layer (chorion trophoblasts [CTC]). This study examined whether there is evidence for sex-based differences in gene expression and inflammatory marker expression in CTCs, and their differential response due to infectious stimuli, modeling infection-associated preterm birth.

STUDY DESIGN: CTC from six different patient-derived fetal membrane samples (three M and three F) (Fig. 1A) were cultured and divided into experimental and control groups. Lipopolysaccharide (LPS) was a proxy for infection, and CTC were stimulated for 6, 12, or 24H (hours). RNA from Cells were subjected to RNA-seq. Multiplex cytokine kits or ELISA detected secreted pro- and anti-inflammatory cytokines (IL-6, IL-8, TNFα, GM-CSF; IL-10), progesterone (P4), and soluble HLA-G in cell supernatants to determine inflammatory status and endocrine responses.

RESULTS: CTC-M & CTC-F showed sex, time, and stimulant-dependent differential gene expression profiles (Fig. 1B). Cytokine analysis demonstrated a significantly lower IL-6 production in control CTC-M than in CTC-F (Fig. 1C). No sex-dependent responses were observed in CTCs after LPS treatment regarding pro- or anti-inflammatory cytokines. CTC-M produced significantly lower P4 than CTC-F (Fig. 1D).

CONCLUSION: The theories of sexual dimorphism linked to placental inflammation do not extend to fetal membrane trophoblasts. This study supports current evidence that the chorion acts as a "great wall" which protects the fetus from external infection by being refractory to insults. Further examination into the weaknesses of the chorion barrier and redirection of study efforts that examine sex-dependent responses of fetal membranes is needed.



929 Low-dose aspirin usage during pregnancy: A retrospective structured electronic medical record data study

Rula Atwani[1], Barbara Levy[2], Greg Poorman[2], Patrick Edmundson[2], Michael Padmanabhan[2], Brandon Boswell[2], Amanda Elfman[2], George R. Saade[1], Tetsuya Kawakita[1]
[1]Eastern Virginia Medical School, Norfolk, VA, [2]Dorsata, Washington, DC

OBJECTIVE: To examine the impact of reminder software to prescribe low-dose aspirin when indicated at the point-of-care on aspirin prescription in high-risk individuals.

STUDY DESIGN: This was a retrospective study of individuals who were eligible for low-dose aspirin during pregnancy according to ACOG guidelines from 2019 to 2023 in the State of Connecticut. Data were extracted from centers that used Dorsata Prenatal with its Care Plan technology within the athenahealth EMR. Dorsata Prenatal is a software that notifies physicians within their workflow when individuals are clinically eligible for low-dose aspirin. We limited the analysis to individuals who met ACOG criteria for low-dose aspirin. The primary outcome was the prescription of low-dose aspirin. The secondary outcomes were preterm delivery < 32 weeks, preterm delivery < 28 weeks, postpartum hemorrhage, cesarean delivery, eclampsia, gestational hypertension, preeclampsia, and low birthweight. Outcomes were compared between individuals whose physicians acknowledged the Care Plan within Dorsata Prenatal and those whose physicians did not acknowledge the Care Plan. Logistic regression was used to obtain crude odds ratio (cOR) with 95% confidence intervals.

RESULTS: Of 41963 individuals, 23258 had their Care Plan acknowledged and 18705 did not. Table 1 shows the cORs for each outcome. Compared to individuals whose Care Plan was not acknowledged, those with an acknowledged Care Plan had increased odds of being started on low-dose aspirin (cOR 5.79 [5.40-6.20]), cesarean delivery (cOR 1.07 [1.03-1.12]), and gestational hypertension (cOR 1.32 [1.16-1.49]), but had decreased odds of preterm delivery< 32 weeks (cOR 0.42 [0.39-0.46]), preterm delivery < 28 weeks (cOR 0.36 [0.33-0.40]), and postpartum hemorrhage (cOR 0.77 [0.65-0.92]).

CONCLUSION: Dorsata Prenatal Care Plan can enhance the prescription of low-dose aspirin for individuals who meet the criteria for low-dose aspirin.

Table 1. Comparison of care plan acknowledged with not acknowledged

930 The maternal implications of congenital malformations: A cross-sectional study

Rula Atwani[1], **Michael M. Aziz**[2], **George R. Saade**[1], **Tetsuya Kawakita**[1]

[1]Eastern Virginia Medical School, Norfolk, VA, [2]Allegheny Health Network, Pittsburgh, PA

OBJECTIVE: To evaluate relationships between congenital malformation types and adverse maternal outcomes.

STUDY DESIGN: This was a repeated cross-sectional analysis of US vital statistics Live Birth/Infant Death linked data from 2011 to 2020. All pregnancies at 20 weeks or greater were included. Our primary outcome was severe maternal morbidity (SMM) defined as any maternal intensive care unit admission, transfusion, uterine rupture, and hysterectomy. Secondary outcomes were cesarean delivery (CD), preeclampsia, and preterm delivery. Pregnancy outcomes were compared for each type of congenital malformation with the referent group of pregnancies without congenital malformation. Congenital malformations available in the dataset included spina bifida, congenital heart disease, diaphragmatic hernia, omphalocele, gastroschisis, limb defect, cleft lip/palate, chromosomal anomaly, and hypospadias. If a fetus had more than one malformation, it was classified as multiple malformation. Adjusted relative risks (aRR) with 99% confidence intervals were calculated using modified Poisson regression.

RESULTS: Of 34,747,260 pregnancies that were included in our study, 34,645,400 pregnancies had no congenital malformation and 101,860 had isolated or multiple congenital malformation. Outcomes are presented in Table 1. Compared to pregnancies without congenital malformation, all congenital malformations were associated with an increased risk of SMM except for gastroschisis and limb anomaly (range of aRR 1.60-2.66). All malformations were associated with an increased risk of CD and preterm delivery (range of aRR 1.14-2.36 and 1.64-7.91, respectively). Congenital heart disease, omphalocele, cleft lip/palate, chromosomal anomaly, hypospadias, and multiple malformation were associated with an increased risk of preeclampsia (range of aRR 1.24-1.63) and gastroschisis was associated with a decreased risk of preeclampsia (aRR 0.52).

CONCLUSION: The maternal implications of congenital malformation should be included in informed consent when making decisions regarding continuation of pregnancy.

Table 1. Maternal outcomes of congenital malformation

	SMM	Cesarean	Preeclampsia	Preterm delivery

Abbreviations: SMM (severe maternal morbidity); RR (relative risk)
Adjusted relative risks were controlled for age, race, parity, history of cesarean, insurance, infertility treatment, chronic hypertension, and pregestational diabetes.

931 Risk of cesarean delivery stratified by BMI at delivery

Brittany Austin[1], **Ralitza H. Peneva**[2], **Matthew M. Finneran**[1]

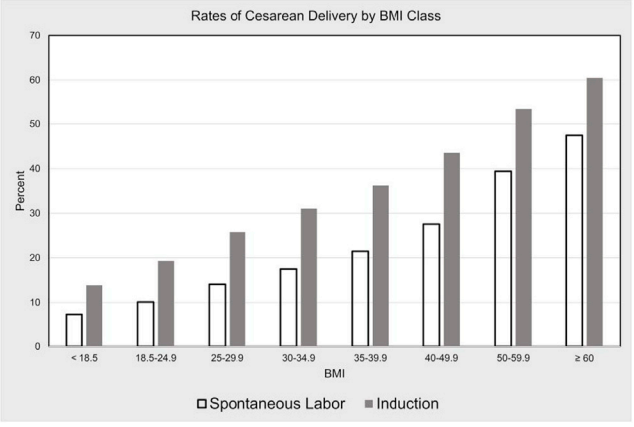
[1]Medical University of South Carolina, Charleston, SC, [2]MUSC, Johns Island, SC

OBJECTIVE: Studies have shown that obesity increases overall risk of cesarean delivery (CD) in a dose dependent fashion, but are often underpowered to assess higher stratifications of body mass index (BMI), particularly in super obese women (BMI > 50). The objective of this study is to evaluate overall risk of CD in super obese women and the impact on maternal and neonatal outcomes.

STUDY DESIGN: This was a population based retrospective study of all nulliparous women who delivered in the United States in 2021. Patients were stratified by BMI category at delivery excluding patients undergoing cesarean without labor. The primary outcome was the overall rate of CD, which was further stratified among inductions versus spontaneous labor. Secondary outcomes included maternal (transfusion, hysterectomy, ICU admission) and neonatal (NICU admission, mechanical ventilation, surfactant administration) composite adverse outcomes. Poisson regression with robust error variance was used to generate adjusted risk ratios (aRR) for each study outcome using normal BMI (18.5-24.9) as the referent adjusting for confounders.

RESULTS: There were 1,147,941 nulliparous women included in the analysis with 5,820 patients with BMI 50-59.9 and 594 patients with BMI ≥ 60. There was an increasing rate of CD with increasing BMI at delivery (range 7.3%-60.5%) with the highest risk among induced (aRR 1.35, CI 1.31-1.39) and spontaneously laboring (aRR 1.35, CI 1.28-1.42) women with BMI > 60; Figure 1. Similarly, the highest rate of both the maternal (range 0.57-1.16%) and neonatal (range 9.3-19.5%) composite adverse outcomes were in the highest BMI categories. Adverse outcomes remained significant after adjustment for gestational age at delivery.

CONCLUSION: There is a substantial increased risk of CD as well as both adverse maternal and neonatal outcomes among nulliparous super obese women undergoing a labor trial. It is unknown whether these risks would be mitigated by elective cesarean delivery.



932 Publication rate of oral presentations at the society for maternal-fetal medicine annual meeting

Mariam Ayyash[1], Catherine Y. Spong[2]
[1]Columbia University Irving Medical Center, New York, NY, [2]University of Texas Southwestern Medical Center, Dallas, TX

OBJECTIVE: To evaluate publication status for oral presentations at the Society for Maternal-Fetal Medicine (SMFM) annual meetings.

STUDY DESIGN: Data from the 2018 and 2019 SMFM annual meetings were evaluated. The data was publicly available via the American Journal of Obstetrics & Gynecology (AJOG) SMFM supplements. Included were all oral presentations at the annual meetings. Abstract titles and authors were queried on PubMed to evaluate the publication status.

RESULTS: Of 231 oral presentations, the publication rate was 73.6% (170/231). Among the 170 published presentations**:** 42.4% were published within the same year of presentation, 24.1% in the following year, 21.2% two years later, 11.8% within three to five years, and 0.6 % were published prior to the timing of the oral presentation. The top five journals of publications were**:** Am J Obstet Gynecol (22.4%), Obstet Gynecol (14.7%), Am J Perinatol (9.4%), Am J Obstet Gynecol MFM (5.9%), and Ultrasound Obstet Gynecol (4.1%). The remainder of the publications were published in 50 other journals.

CONCLUSION: Publication rate for oral presentations was high, with the majority being within the first two years from presentation. Timely manuscript publication is reassuring and valuable for prompt dissemination of research findings and advancing clinical practice within the high-risk pregnancy community.

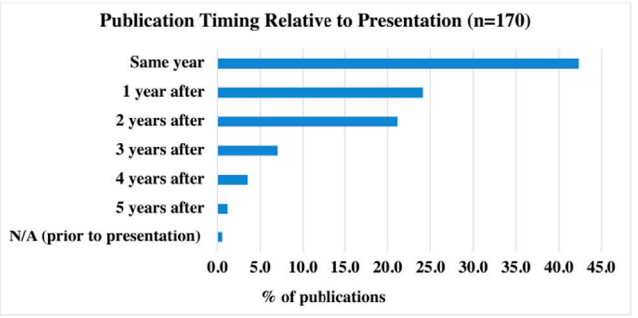


Figure 1. Publication timing relative to presentation

933 Policy change combined with clinical decision support improves equity and yield of L&D UDS testing

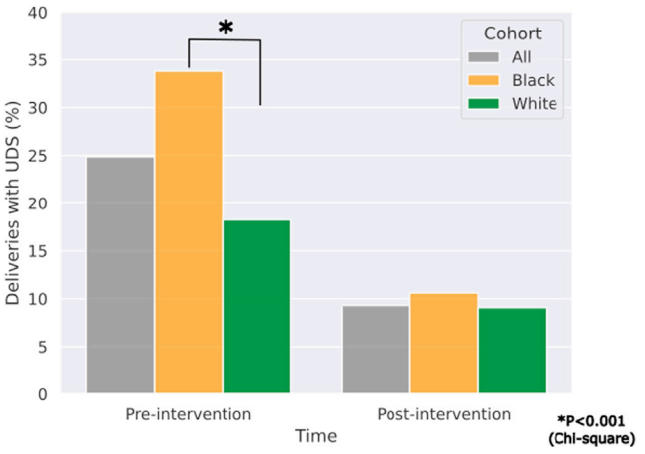
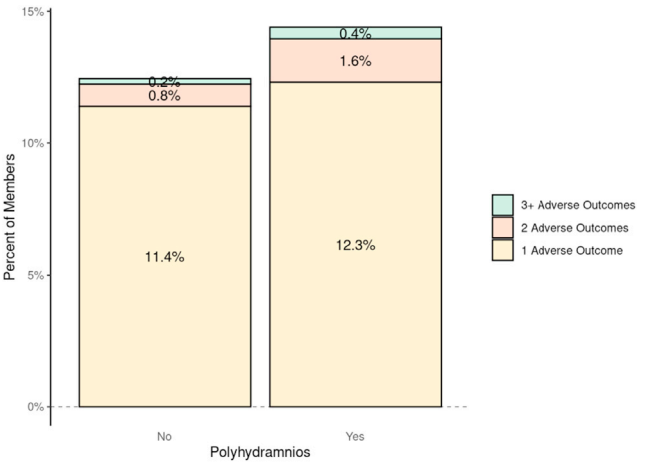
OBJECTIVE: An indication of isolated tetrahydrocannabinol (THC) use for urine drug screening (UDS) in labor and delivery units is a poor predictor of other substance exposure and leads to inequities in downstream harms (e.g. reporting to state child abuse hotline). In September 2022, the Labor and Delivery unit at an urban tertiary care center removed isolated THC use as an indication for UDS. Concurrently, an electronic health record (EHR)-based order question was implemented requiring providers to select an indication for testing. We sought to assess the impact of these changes on UDS ordering practices.

STUDY DESIGN: We performed a retrospective cohort study of all UDS results from an inpatient obstetric unit at an urban tertiary care center from June 2020-July 2023. Urine drug screening is performed based on verbal screening of all admitted patients. Statistical testing for comparing pre- vs. post-testing periods was performed using Pearson's chi-square.

RESULTS: 2056/8271 (24.9%) and 209/2247 (9.3%) of all deliveries in the pre- and post-implementation periods had UDS performed, respectively ($p < 0.001$). 1356/4013 (33.8%) and 665/3647 (18.2%) ($p < 0.001$) of deliveries in the pre-implementation period had UDS performed for Black and White patients, respectively, vs. 107/1008 (10.6%) and 97/1070 (9.1%) of deliveries in the post-implementation period ($p=0.32$). The rate of UDS results positive only for THC decreased from 512/2056 (24.9%) to 22/209 (10.5%) ($p < 0.001$) in the pre- vs. post-implementation periods.

CONCLUSION: Following the interventions, significantly fewer UDS's were performed overall and a race-based difference in the rate of UDS was significantly reduced. Additionally, a significant decrease was observed in the UDS positivity rate for non-THC substances in the pre- vs. post-intervention periods, suggesting that the removal of the isolated THC use order indication led to fewer THC-only positive UDS results. These results suggest that removal of isolated THC use as an indication and implementation of an indication order question can reduce low-yield UDS and reduce race-based UDS disparities.





934 Long-term childhood outcomes after pregnancy complicated by isolated polyhydramnios

Michael M. Aziz[1], Tyson S. Barrett[2], Ahizechukwu Eke[3], Kent Willis[4]

[1]Allegheny Health Network, Pittsburgh, PA, [2]Highmark Health, Pittsburgh, PA, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: While most cases of polyhydramnios are mild and of unknown etiology, some cases are indicative of underlying congenital anomalies or genetic syndromes. Antenatal counseling is compounded by the lack of long-term outcomes from children born after isolated polyhydramnios.

STUDY DESIGN: We performed a case-control study utilizing a blended database of linked pregnancy-to-pediatric medical records and insurance claims from 2014-2022 from a multi-state health insurance and delivery organization. Propensity score (PS) matching was performed based upon sex of the infant, the mothers' comorbidities (Charlson comorbidity index), and number of months of follow-up. Cases and controls were matched with replacement with a 1:1 ratio with preference given to exact matches. We excluded patients with diabetes. The primary exposure was isolated polyhydramnios. Long-term outcomes include fetal death, PICU admission, neurologic diagnosis, developmental delay, and therapy (speech, occupational, or physical). Demographics and individual outcomes were analyzed using Chi-squared tests, whereas the composite outcome was examined with Poisson regression.

RESULTS: From a total population of approximately 5 million individuals, we identified 3,182 pregnancies complicated by polyhydramnios. These were PS matched to 2,955 control pregnancies. There were no significant demographic differences between groups. Individually, polyhydramnios was a significant risk factor for PICU admission (2.7% vs 1.6%, OR 1.7 [95% CI 1.2-2.5]) and developmental delay (9.6% vs 8.0%, OR 1.2 [95% CI 1-1.5]). No other measured adverse outcomes were different. Polyhydramnios was significantly associated with increased rates of any adverse outcome as well as two adverse outcomes and three or more (see Figure 1).

CONCLUSION: Long-term childhood outcomes are higher for polyhydramnios-complicated pregnancies. Future research should study this association and the effects of polyhydramnios severity and prematurity on outcomes.

935 Retain products of conception following cesarean delivery: Characteristics and risk factors

Gal Bachar[1], Noa Arbel[2], Hiba Abu-Rass[2], Naphtali Justman[3], Dana Vitner[4], Yuval Ginsberg[5], Ron Beloosesky[6], Zeev Weiner[2], Nizar Khatib[7]

[1]Rambam Healthcare Campus, Haifa, Hefa, [2]Rambam Medical Health Campus, Haifa, HaZafon, [3]Rambam Medical Center, Haifa, Hefa, [4]Rambam Medical Health Campus, Toronto, ON, [5]Rambam Health Care Campus, Haifa, HaZafon, [6]Harbor UCLA Medical Center, Los Angeles, CA, [7]Rambam health care campus, Haifa, Israel, Acre, Hefa

OBJECTIVE: Untreated Retained products of conception (RPOC) may cause bleeding, infection and intrauterine adhesions which may jeopardize the woman's fertility. Literature is scarce in addressing RPOC after Cesarean delivery (CD). In this study we aimed to clarify the risk factors and prevalence of PROC after CD.

STUDY DESIGN: We performed a retrospective cohort study at a single tertiary care center from 2010 to 2022. Enrolled women, delivered by CD and diagnosed with PROC confirmed by hysteroscopy. A control group of patients who had CD without RPOC was matched, in 1:4 ratio.

RESULTS: Sixty-six women out of 14631 CDs had a hysteroscopic diagnosis of RPOC; 295 controls were matched. Table 1 provides the maternal and pregnancy characteristics. RPOC following CD was related to older age (33.42±5.38 vs. 30.59±5.08, p< 0.001), higher BMI (35.42±3.20 vs. 29.5±3.49, p=0.01), IVF conception (16.7% vs. 7.1%, p=0.01) and was less common among nulliparous patients (39.4% vs. 71.9%, p< 0.001). In addition, gestational week at delivery was earlier (37.84±2.34 vs. 40.04±1.07, p< 0.001) and most CDs were elective (62.1%). Chorioamnionits was related to higher cases of RPOC (9.1% vs. 2.4%, p=0.008), although water break duration was similar (18.44±15.83 vs. 17.83±14.16, p=0.93).

CONCLUSION: Nulliparity, advanced maternal age and increased BMI are among risk factors increasing the probability of RPOC after CD delivery. This data can help gynecologists in postpartum follow-up.

Table 1. Comparison maternal and delivery characteristics of women with or without retained products of conception following Cesarean delivery

Variable	RPOC N=66	No RPOC N=295	P-Value
General Maternal Characteristics			
Age, years, mean +/- SD	33.42±5.38	30.59±5.08	**<0.001**
Body Mass Index, kg/m^2, mean +/- SD	35.42±3.20	29.5±3.49	**0.01**

SD, standard deviation; n, number. P < 0.05 was considered significant.

936 Testing transcriptional regulatory pathway in early-onset FGR using patient-specific human trophoblast stem cells

Juliana Bakk[1], Soumen Paul[2], Soma Ray[2], Marc Parrish[2]
[1]The University of Kansas Medical Center, Kansas City, KS, [2]University of Kansas Medical Center, Kansas City, KS

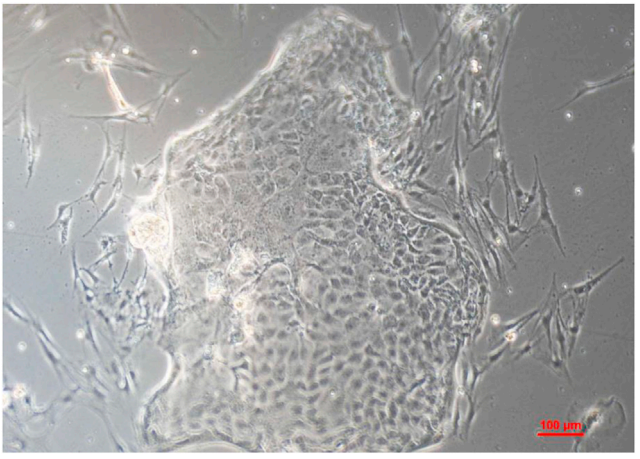
OBJECTIVE: Human Trophoblast stem cells (hTSC) are an excellent model system to understand trophoblast development during human pregnancy. However, most of previously studied hTSCs were established from 1st trimester placentas, which limits evaluation of mechanisms underlying development of early-onset FGR. We hypothesize that a defect in trophoblast progenitor self-renewal and differentiation can result in a pathologic pregnancy, such as FGR. Components of Hippo signaling pathway are essential for optimization of trophoblast progenitor self-renewal. Our objective was to establish patient-specific hTSCs from early-onset FGR placentas and controls to determine differences in expression in transcription factors and cofactors in the Hippo signaling pathway.

STUDY DESIGN: Patients were identified as early-onset FGR when diagnosis was prior to 32wks and had a typical pattern of progression resulting in preterm delivery. Excluded**:** Non-English/Spanish speaking, other fetal anomalies, multifetal gestation, declined participation. The controls delivered by c-section before labor, had no medical problems or fetal abnormalities.

Cytotrophoblasts (CTBs) were isolated from placentas and plated in stem media in a hypoxic chamber. Qualitative speed of growth of hTSC colonies was noted, comparing control to FGR. mRNAs were isolated from growing cells to determine expressions of Hippo signaling transcription factors, TEAD4/TEAD1 and cofactors YAP1/WWTR1.

RESULTS: CTBs of 8 early-onset FGR placentas were isolated to establish hTSC lines. FGR-hTSCs were slower growing compared to controls. Expression of TEAD4, which is an important regulator for CTB proliferation, was suppressed in several FGR-hTSCs.

CONCLUSION: Due to our successful establishment of hTSCs from early-onset FGR placentas, we have provided a novel way of understanding underlying mechanisms of FGR. TEAD4 expression is decreased in early-onset FGR placentas. In the future, WES will aid in discovery of specific mutations that may result in this abnormality along with other pathways affecting trophoblast development leading to early-onset FGR.



937 The rate of maternal comorbidities among different body mass index groups

Kimen Singh Balhotra[1], Ipsita Ghose[2], Rachel L. Wiley[1], Yossi Bart[1], Hector Mendez Figueroa[3], Suneet P. Chauhan[4], Baha M. Sibai[5]
[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]University of Texas Medical School at Houston, Houston, TX, [3]University of Texas Health Science Center at Houston, Houston, TX, [4]University of Texas-Houston Medical School, Houston, TX, [5]Hermann Memorial Hospital, Houston, TX

OBJECTIVE: The purpose of this study was to describe the association between body mass index (BMI) at delivery and the rates of different maternal comorbidities among obese pregnant individuals.

STUDY DESIGN: This is a retrospective cohort study of all singletons ≥14 weeks that were delivered between March 2020 and February 2022 at a single Level IV center. We categorized the cohort by different BMI classes**:** overweight (25−29.9 kg/m^2), class I/II (30-39.9 kg/m^2), class III (40-49.9 kg/m^2), and class IV ≥ 50 kg/m^2. The reference group was the overweight cohort. The rates of composite comorbidities (hypertensive disorder of pregnancy, diabetes, asthma, cardiac disease, mental illness, or venous thromboembolism (VTE)) were ascertained. Poisson regression was used to calculate adjusted relative risks for each comorbidity by class, adjusted for age given that age is most likely to influence rate of comorbidities.

RESULTS: Of 8,623 deliveries, 7618 (88.3%) met inclusion criteria. 29.2% were overweight (n=2221), 51.2% were class I/II (n =3900),16% were class III (n=1220), and 3.6% were class IV

(n=277). Compared to overweight, class I/II, III and IV were significantly more likely to have composite co-morbidities (aRR 1.37 (1.29-1.46), aRR 1.82 (1.70-1.95), and 2.18 (2.01-2.35), respectively.) After adjusting for maternal age, class IV obesity demonstrated statistically significant higher risk of hypertensive disorders (aRR 3.09, 95% CI 2.77 -3.45), diabetes (aRR 3.99, 95% CI 3.16-5.03), asthma (aRR 2.03, 95% CI 1.44-2.88), and mental illness (aRR 1.58, 95% CI 1.11-2.25) (Table 1.).

CONCLUSION: As BMI increases, the rate of several maternal comorbidities increases, with composite morbidity reaching 66% in class III individuals and 90% in Class IV individuals. Obese patients are an increasing constituent in contemporary obstetric populations and BMI alone does not accurately reflect the medical complexity and subsequent challenges in care. Given the increased risk of maternal comorbidities in Class IV obesity, frequent maternal surveillance should be considered for early detection and management of comorbidities.

Table 1: BMI and Risk of Co-morbidities

Outcomes	Group	Total	N	%	Unadjusted RR (95% CI)	Adjusted RR [a] (95% CI)
Composite of co-morbidities	BMI 25-29.9	2221	822	37.0	1.00	1.00
	BMI 30-39.9	3900	1961	50.3	1.36 (1.28-1.45)	**1.37 (1.29-1.46)**
	BMI 40-49.9	1220	813	66.6	1.81 (1.69-1.93)	**1.82 (1.70-1.95)**
	BMI ≥ 50	277	224	80.9	2.19 (2.03-2.37)	**2.18 (2.01-2.35)**
Hypertensive disorders [a]	BMI 25-29.9	2221	498	22.4	1.00	1.00
	BMI 30-39.9	3900	1367	35.1	1.56 (1.43-1.71)	**1.57 (1.44-1.72)**
	BMI 40-49.9	1220	638	52.3	2.33 (2.12-2.56)	**2.35 (2.14-2.59)**
	BMI ≥ 50	277	193	69.7	3.11 (2.78-3.47)	**3.09 (2.77-3.45)**
Diabetes mellitus [b]	BMI 25-29.9	2221	158	7.1	1.00	1.00
	BMI 30-39.9	3900	485	12.4	1.75 (1.47-2.08)	**1.76 (1.48-2.08)**
	BMI 40-49.9	1220	244	20.0	2.81 (2.33-3.39)	**2.84 (2.36-3.42)**
	BMI ≥ 50	277	84	30.3	4.26 (3.38-5.38)	**3.99 (3.16-5.03)**
Asthma	BMI 25-29.9	2221	140	6.3	1.00	1.00
	BMI 30-39.9	3900	300	7.7	1.22 (1.01-1.48)	1.22 (1.00-1.48)
	BMI 40-49.9	1220	136	11.1	1.77 (1.41-2.22)	**1.76 (1.41-2.21)**
	BMI ≥ 50	277	35	12.6	2.00 (1.41-2.84)	**2.03 (1.44-2.88)**
Cardiac disease [c]	BMI 25-29.9	2221	30	1.4	1.00	1.00
	BMI 30-39.9	3900	60	1.5	1.14 (0.74-1.76)	1.15 (0.74-1.78)
	BMI 40-49.9	1220	22	1.8	1.34 (0.77-2.30)	1.36 (0.78-2.35)
	BMI ≥ 50	277	8	2.9	2.14 (0.99-4.62)	2.02 (0.94-4.33)
Mental illness [d]	BMI 25-29.9	2221	167	7.5	1.00	1.00
	BMI 30-39.9	3900	335	8.6	1.14 (0.96-1.37)	1.15 (0.96-1.37)
	BMI 40-49.9	1220	137	11.2	1.49 (1.20-1.85)	**1.50 (1.21-1.87)**
	BMI ≥ 50	277	33	11.9	1.58 (1.11-2.25)	**1.58 (1.11-2.25)**
Venous thromboembolism	BMI 25-29.9	2221	10	0.5	1.00	1.00
	BMI 30-39.9	3900	35	0.9	1.99 (0.99-4.02)	2.01 (1.00-4.05)
	BMI 40-49.9	1220	11	0.9	2.00 (0.85-4.70)	2.03 (0.87-4.78)

938 The association of Social Vulnerability Index (SVI) with acuity of presentation to obstetric triage

Tracy Caroline Bank

The Ohio State University Wexner Medical Center, Columbus, OH; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: To assess the association between CDC Social Vulnerability Index (SVI) with acuity of presentation to obstetric triage.

STUDY DESIGN: Secondary analysis of a retrospective cohort study of all triage visits occurring from 20 0/7 through 34 6/7 weeks' gestation on randomly selected dates from 1/1/2019 through 3/31/2019 at 34 hospitals across the US. Individuals enrolled with geocode and CDC SVI data available were eligible for analysis. The primary exposure was the CDC SVI with a higher number indicating greater vulnerability. The primary outcome was high acuity at presentation to triage, defined as preeclampsia with severe features (for those presenting with hypertensive disorders of pregnancy), cervical dilation >3 cm, or chorioamnionitis (for those presenting with threatened preterm labor or preterm premature rupture of membranes), or delivery within 48 hours of presenting to triage. Additional adverse maternal and neonatal outcomes were compared. All outcomes were also analyzed by the four themes within SVI. Baseline characteristics were compared using Cochran-Armitage or Jonckheere-Terpstra trend tests. Logistic and quantile regressions were used with the lowest SVI quartile (Q1) group as referent.

RESULTS: Among 2,666 individuals eligible for analysis, 554 (20.8%) were in SVI Q1, 672 (25.2%) in Q2, 649 (24.3%) in Q3, and 791 (29.7%) in Q4. Individuals with higher overall SVI scores were younger, had higher BMI, and were more likely to be multiparous, use tobacco, drugs, and live with co-morbidities. SVI quartiles were not associated with acute presentation to triage (Q1 reference; Q2 aOR 0.91, 95% CI 0.65-1.28; Q3 aOR 1.09, 95% CI 0.78-1.54; Q4 aOR 1.03, 95% CI 0.73-1.44) . Higher SVI was associated with an increased odds of receipt of a complete course of betamethasone and decreased odds of adverse respiratory outcomes (Table). There was no association between the individual themes of SVI and the primary outcome, or between SVI and acuity of different presenting concerns.

CONCLUSION: We found no association between SVI and acuity of presentation to triage.

Table. Maternal and Neonatal Outcomes by SVI Quartile

Outcomes	n / N (%) or Median (Q1-Q3)	OR (95% CI) or Difference (95% CI)	aOR (95% CI) or Adjusted Difference (95% CI)
Primary Outcome			
High acuity at presentation to triage			
Quartile 1	80 / 554 (14.4)	1.0 (Reference)	1.0 (Reference)
Quartile 2	81 / 672 (12.1)	0.81 (0.58 - 1.13)	0.91 (0.65 - 1.28)
Quartile 3	85 / 649 (13.1)	0.89 (0.64 - 1.24)	1.09 (0.78 - 1.54)
Quartile 4	95 / 791 (12.0)	0.81 (0.59 - 1.11)	1.03 (0.73 - 1.44)
Secondary Outcomes			
Time from triage to delivery (days)			
Quartile 1	46 (17 - 80) [n=553]	0 (Reference)	0 (Reference)
Quartile 2	50 (23 - 78) [n=671]	4 (-1 - 9)	2 (-4 - 8)
Quartile 3	44 (21 - 71) [n=649]	-2 (-7 - 3)	-4 (-10 - 2)
Quartile 4	44 (23 - 73) [n=791]	-2 (-7 - 3)	-4 (-9 - 2)
Preterm delivery less than 37 weeks			
Quartile 1	223 / 554 (40.3)	1.0 (Reference)	1.0 (Reference)
Quartile 2	248 / 672 (36.9)	0.87 (0.69 - 1.09)	0.93 (0.73 - 1.17)
Quartile 3	242 / 649 (37.3)	0.88 (0.70 - 1.11)	0.98 (0.77 - 1.25)
Quartile 4	309 / 791 (39.1)	0.95 (0.76 - 1.19)	1.14 (0.90 - 1.44)
Complete course of betamethasone for lung maturity			
Quartile 1	30 / 554 (5.4)	1.0 (Reference)	1.0 (Reference)
Quartile 2	35 / 672 (5.2)	0.96 (0.58 - 1.58)	1.10 (0.66 - 1.82)
Quartile 3	51 / 649 (7.9)	1.49 (0.93 - 2.37)	**1.85 (1.14 - 2.99)**
Quartile 4	48 / 791 (6.1)	1.13 (0.71 - 1.80)	1.49 (0.91 - 2.44)
Early preterm morbidity composite			
Quartile 1	26 / 573 (4.5)	1.0 (Reference)	1.0 (Reference)
Quartile 2	21 / 693 (3.0)	0.65 (0.36 - 1.19)	0.70 (0.38 - 1.28)
Quartile 3	33 / 675 (4.8)	1.05 (0.61 - 1.81)	1.19 (0.68 - 2.08)
Quartile 4	32 / 811 (3.9)	0.85 (0.49 - 1.46)	0.94 (0.54 - 1.66)
Respiratory Distress Syndrome or Transient Tachypnea of the Newborn			
Quartile 1	161 / 576 (28.0)	1.0 (Reference)	1.0 (Reference)
Quartile 2	160 / 700 (22.9)	0.76 (0.58 - 0.99)	0.79 (0.60 - 1.04)
Quartile 3	149 / 687 (21.7)	0.71 (0.54 - 0.92)	0.77 (0.58 - 1.02)
Quartile 4	160 / 818 (19.5)	0.62 (0.48 - 0.81)	**0.73 (0.55 - 0.96)**

Data are n / N (%), median (Q1 - Q3), or unless otherwise specified.
Early preterm morbidity composite = fetal or neonatal death, severe BPD (Grade 3), intraventricular hemorrhage (Grades 3-4), NEC (Bell 2A or greater), periventricular leukomalacia, retinopathy of prematurity (Stage III-V), proven sepsis (early and late) within 120 days of delivery

939 Stages of HPV Cervical Cancer Discerned by Integrated Host-viral Single-cell and Spatial Biology

Khanh L. Tran[1], David N. Moorshead[1], Maryshe Zeitsman[1], Michael D. Jochum Jr.[2], Kjersti M. Aagaard[3], Enrico R. Barrozo[1]

[1]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [2]Baylor College of Medicine, Houston, TX, [3]Texas Children's Hospital, Baylor College of Medicine, Houston, TX

OBJECTIVE: Cervical cancer damages cervical integrity and may necessitate invasive surgical procedures that negatively impact the likelihood of future successful pregnancies. Over 99% of cervical cancer cases are associated with human papillomavirus (HPV). The temporal transition and spatial distribution of cellular subsets during cervical cancer progression provide valuable insights into HPV disease development. A recent study examined HPV-induced malignant transformation and immune remodeling with single-cell and spatial transcriptomics. However, viral gene expression was not directly assessed. Therefore, we hypothesized that host immune response programs successfully restrict, or fail to control, HPV gene expression in the cervix, ultimately correlating with cancer progression.

STUDY DESIGN: To address this hypothesis, we analyzed the single-cell and spatial transcriptomics data from HPV+ subjects with known clinical phenotypes (n= 9;) and aligned them to our custom HPV16 and human reference.

RESULTS: Out of the 88,743 total single-cell and spatial transcriptomes yielded 16 cell types and spatial niches, and we detected 4,710 transcriptomes with HPV gene expression (Fig. 1A). We identified 2,883 significant DEGs (Fig. 1B; $q< 0.05$) associated with controlling (28% of DEGs), or failing to control (72%), HPV. HPV gene expression correlated with high-grade intraepithelial lesions, specifically in a subset of epithelial cells. Host gene expression was significantly perturbed in a cervical cancer specimen and negatively correlated with HPV transcription (Fig. 1C). Restriction of HPV gene expression correlated with normal and cervical cancer phenotypes, and the gene signatures aligned with immune cell populations (Fig. 1D). Specifically, cervical cancer outcomes were associated with the B-to-plasma cell transition.

CONCLUSION: By integrative host-viral analyses, we identified gene signatures that may lead to potentially novel targets for therapeutic strategies combating HPV persistence and cervical cancer progression, which in turn may positively impact future pregnancies.

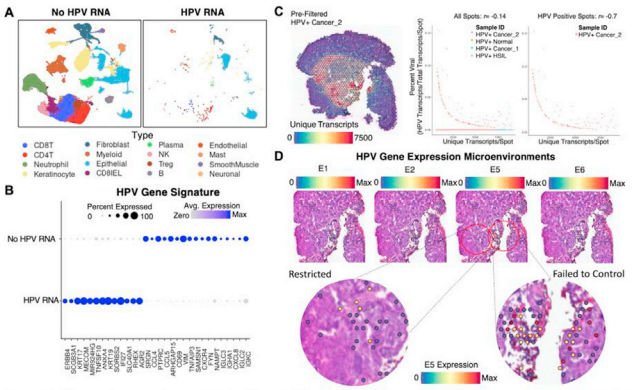

Figure 1. Microenvironments associated with restricting, or failing to control, HPV gene expression. A, UMAP split by HPV RNA detection labeled by single-cell type and spatial niche annotation. **B,** All transcriptomes were subject to differential expression analysis based on HPV gene expression status (positive for viral RNA or negative). Differential expression analyses identified 2,883 significant DEGs comparing transcriptomes with HPV RNA (72% of DEGs) or without (28%), including 1,580 DEGs that align to specific cell types. The top 30 markers of the HPV gene signatures are visualized by HPV status. **C,** Unique transcripts in the HPV+ Cancer_2 sample before applying standard QC filters removed 41% of the spatial transcriptomes. To determine if this was a biological or technical error, we correlated viral transcription with unique transcripts per spot in all 4,560 spatial transcriptomes or the 150 spots with virus, revealing a significant reduction in host gene expression in spots with viral transcription. **D,** Visualization of the 150 spots with HPV spatial gene expression detected. Insets zoom in on microenvironments where HPV gene expression was restricted, or the immune system presumably failed to viral gene expression.

940 Predictors of maternal morbidity among individuals at low-risk of postpartum hemorrhage

Yossi Bart[1], Rachel L. Wiley[1], Ipsita Ghose[2], Baha M. Sibai[3], Suneet P. Chauhan[4]

[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]University of Texas Medical School at Houston, Houston, TX, [3]Hermann Memorial Hospital, Houston, TX, [4]University of Texas-Houston Medical School, Houston, TX

OBJECTIVE: To identify risk factors for maternal morbidity among individuals categorized as low-risk for postpartum hemorrhage (PPH) according to ACOG Practice Bulletin (#183), a modification of the California Maternal Quality Care Collaborative (CMQCC) version 2 schema.

STUDY DESIGN: A case-control study of all singleton births between March 2020 and February 2022 at a single Level IV center. Individuals deemed at moderate or high risk for PPH according to the ACOG risk stratification and those with missing body-mass index (BMI) data were excluded. Cases were individuals who experienced maternal hemorrhagic morbidity, defined as a composite maternal hemorrhagic outcome (CMHO). Controls were individuals without the composite morbidity. Variables previously associated with maternal morbidity, not included in the ACOG stratification, were analyzed. Multivariable logistic regression was applied to identify factors independently associated with the outcome. The predictive values of the possible risk factors were assessed using a receiver operating characteristic (ROC) curve.

RESULTS: Of the 8,623 consecutive deliveries in the study period 3,465 (40%) met inclusion criteria, and among them 173 (5%) had a CHMO. Individuals with CHMO were older, had a higher BMI, and were more likely to be of Hispanic race/ethnicity, have diabetes mellitus, post-term pregnancy, and a large for gestational age newborn. In the multivariable analysis, all factors but diabetes remained significantly associated with the CHMO. The combined presence of any of these 3 risk factors was associated with a CHMO rate of 28% (13/46) and yielded a positive likelihood ratio of 7.50 (95% confidence interval [CI] 4.02-13.98; Table 1). The ROC curve generated an area under the curve of 0.63 (95% CI 0.62-0.65). Subgroup analyses of individuals that underwent either labor (3,022; 87%) or planned cesarean delivery (443; 13%) yielded similar results.

CONCLUSION: Among individuals identified with low-risk for PPH according to the ACOG risk stratification, several risk factors of maternal morbidity were identified, albeit of low predictive value.

Table 1. Composite maternal hemorrhagic outcome among parturients at low-risk

Risk factors [a]	All individuals (n)	CMHO [b] (n [%])	Sensitivity (95% CI)	Specificity (95% CI)	Positive LR (95% CI)	Negative LR (95% CI)
Total	3,465	173 (5.0)	--	--	--	--
None	1,821	60 (3.3)	--	--	--	--
At least one risk factor	1,644	113 (6.9)	65.3 (57.7-72.4)	53.5 (51.8-55.2)	1.40 (1.25-1.58)	0.65 (0.53-0.80)
At least two risk factors	374	51 (13.6)	29.5 (22.8-36.9)	90.2 (89.1-91.2)	3.00 (2.33-3.87)	0.78 (0.71-0.86)
At least three risk factors	46	13 (28.3)	7.5 (4.1-12.5)	99.0 (98.6-99.3)	7.50 (4.02-13.98)	0.93 (0.90-0.97)

CMHO, composite maternal hemorrhagic outcome; CI, confidence interval; LR, likelihood ratio.

[a] The possible risk factors included: maternal age ≥ 35 years, Hispanic race/ethnicity, body mass index at delivery ≥ 40 kg/m², post-term delivery ≥ 41.0 weeks, and large for gestational age (birthweight ≥ 90th percentile for gestational age, using nomogram published by Duryea EL et al.).

[b] The composite maternal hemorrhagic outcome included: blood loss ≥ 1000 mL, mechanical tamponade, use of surgical techniques (O'Leary, B-Lynch or uterine artery embolization) for atony, transfusion, venous thromboembolism, intensive-care unit admission, hysterectomy, or maternal death.

941 Single betamethasone dose for late prematurity and neonatal morbidity

Yossi Bart[1], Suneet P. Chauhan[2], Michal Fishel Bartal[3], Sean C. Blackwell[4], Baha M. Sibai[5]

[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]University of Texas-Houston Medical School, Houston, TX, [3]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX, [4]Children's Memorial Hermann Hospital, Houston, TX, [5]Hermann Memorial Hospital, Houston, TX

OBJECTIVE: Although the standard regimen for late preterm birth (LPTB) antenatal corticosteroids involves two doses of betamethasone given 24 hours apart, not all women remain pregnant long enough to receive a second dose. We sought to compare neonatal

morbidity among individuals at risk of LPTB following a single dose of betamethasone (BMZ) versus placebo.

STUDY DESIGN: We performed a secondary analysis of the ALPS trial (Gyamfi-Bannerman C. et al., NEJM; PMC4823164). All individuals enrolled in the parent trial that received a single dose of either BMZ or placebo were included. Individuals with randomization-to-delivery interval > 24 hours were excluded. Primary outcome was a composite of respiratory support at 72 h, including continuous positive airway pressure or high flow nasal cannula ≥ 2 h, oxygen with an inspired fraction of ≥ 30% for ≥ 4 h, or mechanical ventilation.

RESULTS: Of the 2,831 individuals in the parent trial, 1,083 (38%) met inclusion criteria; of them 539 (50%) received BMZ. The placebo and BMZ groups had similar clinical characteristics; rates of premature rupture of membranes (41% vs. 43%), spontaneous labor (50% vs. 50%), and cesarean delivery (18% vs. 17%) did not differ between groups. Age and race were balanced as well. Table 2 describes neonatal outcomes for the study population. Compared to placebo, the primary respiratory outcome was not lower among those who received a single BMZ dose (aRR 1.10, 95% CI 0.84-1.46). Furthermore, a single dose of BMZ was associated with neonatal hypothermia compared to placebo (aRR 1.55, 95% CI 1.07-2.26). Stratification by randomization-to-delivery intervals of 12-hour increments also showed no differences between groups.

CONCLUSION: In individuals with LPTB pregnancies who received betamethasone and delivered prior to a second dose, there were no differences in neonatal respiratory morbidities compared to placebo. Our analysis supports the concept that the optimal timing of benefit for BMZ is greater than 48 hours of administration.

Table – Neonatal outcomes.

Outcome	Placebo (N=544)	BMZ (N=539)	Adjusted RR [a] (95% CI)
Primary respiratory outcome [b]	14.7	15.6	1.10 (0.84-1.46)
CPAP / HFNC ≥ 2h	13.8	13.9	1.05 (0.79-1.41)
Inspired oxygen fraction ≥ 30% for ≥ 4 h	2.9	5.6	**1.98 (1.09-3.58)**
Mechanical ventilation	3.5	3.2	0.96 (0.50-1.83)
Severe respiratory complication [b,c]	12.1	12.1	1.05 (0.76-1.44)
CPAP / HFNC ≥ 12 continuous hours	10.8	10.4	1.01 (0.72-1.42)
Inspired oxygen fraction ≥ 30% for ≥ 24 h	2.0	2.2	1.11 (0.50-2.49)
Hypothermia (< 36.0 Celsius degrees)	7.5	11.3	**1.55 (1.07-2.26)**
Respiratory distress syndrome	5.9	8.2	1.46 (0.94-2.25)
NICU hospitalization	55.5	53.1	0.99 (0.90-1.10)

Data presented as %.

[a] Adjusted for gestational diabetes mellitus, gestational age at randomization < 35 weeks, and cesarean delivery.

[b] If occurred within the first 72 hours after birth.

[c] A severe respiratory complication was defined as any of the following: CPAP or high-flow nasal cannula for at least 12 hours, supplemental oxygen with a fraction of inspired oxygen of 0.30 or more for at least 24 hours, or mechanical ventilation.

CPAP, continuous positive airway pressure; HFNC, high flow nasal cannula; NICU, neonatal intensive care unit.

942 Periviable Outcomes stratified by Mode of Delivery

Amanda M. Baucom[1], Emily A. DeFranco[1], Robert M. Rossi[1], Megan Jiang[2]

[1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]University of Cincinnati, Cincinnati, OH

OBJECTIVE: Periviable birth, defined by ACOG as delivery at 20 0/7 - 25 6/7 weeks is associated with high maternal and neonatal morbidity. Counseling regarding outcomes is typically based upon data from the Neonatal Outcome Trajectory Tool. We sought to obtain hospital specific data regarding outcomes stratified by mode of delivery (MOD) and gestational age (GA) to assist in counseling patients at risk of periviable birth.

STUDY DESIGN: Retrospective cohort study of all livebirths from 22 0/7- 25/ 6/7 at a single tertiary academic medical center, 2012-2021. The objective was to assess infant outcomes with periviable birth stratified by MOD and GA.

RESULTS: There were 207 periviable liveborn infants delivered during the study period. 144 (70%) delivered via cesarean and 63 (30%) by vaginal delivery with 98 infants surviving to discharge. Mean GA at delivery was 24 0/7 ± 0.8 weeks. Infants born by cesarean were less likely to survive to discharge (39.6% vs 65.1%, p=0.001; aRR 0.49, 95% CI 0.19-1.23). Multivariable regression estimating association between cesarean and survival was performed, adjusting for HTN disorders, birthweight, and indication for delivery. There was no significant association between cesarean section and survival. There were similar neonatal ICU lengths of stay (164 vs 187 days, p=0.329) and rates of neonatal morbidities including BPD, high grade IVH, cerebral palsy, and retinopathy of prematurity between delivery cohorts, however the rate of necrotizing enterocolitis following cesarean was lower (7.0 vs 22.5%, p=0.036) compared to vaginal delivery, see Table 1. There was high but similar rate of tracheostomy (28.1% vs 30.0%, p=1.0) and gastrostomy tube (36.8% vs 23.7%, p=0.260) placement in neonates delivered by cesarean and vaginal route respectively.

CONCLUSION: Within the study population, no statistically significant differences were observed for survival or postnatal complications between 22 0/7 and 25 6/7 weeks gestation based on MOD, other than a lower risk of necrotizing enterocolitis.

Neonatal interventions	**All (n=207)**	**Cesarean delivery (n=144)**	**Vaginal delivery (n=63)**	**p-value**
Discharged alive	98 (47.4)	57 (39.6)	41 (65.1)	0.001
Postnatal Outcomes	**All (n=98)**	**Cesarean Delivery (n=57)**	**Vaginal Delivery (n=41)**	**p-value**
NEC	13 (13.4)	4 (7.0)	9 (22.5)	0.036
Gastrostomy tube	30 (31.6)	21 (36.8)	9 (23.7)	0.260
Tracheostomy tube	28 (28.9)	16 (28.1)	12 (30.0)	1.000
Neonatal LOS (days)	174±111	164±95	187±131	0.329

943 Risk factors for surgical morbidity following unscheduled cesarean delivery

Shannon E. Beermann[1], Katherine Carbonell[1], Lucy Simpson[2], Ebony B. Carter[3], Jeannie C. Kelly[3], Antonina I. Frolova[4], Anthony O. Odibo[4], Megan L. Lawlor[4], Nandini Raghuraman[4], Bree A. Goodman[1]

[1]Washington University in St. Louis, St. Louis, MO, [2]Mercy Hospital, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO, [4]Washington University School of Medicine in St. Louis, St. Louis, MO

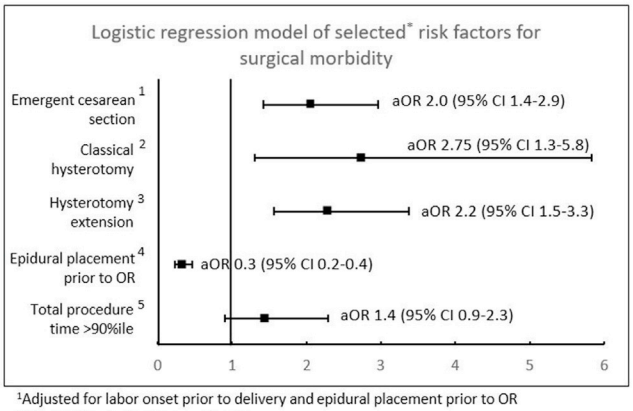
OBJECTIVE: Approximately one in three births in the United States is via cesarean delivery (CD). Unscheduled CD are associated with increased maternal morbidity. Our objective was to identify risk factors for maternal surgical morbidity at the time of unscheduled CD.

STUDY DESIGN: This is a case-control study of all patients delivering live, non-anomalous, singleton neonates by unscheduled CD at ≥37 weeks gestation from 2018-2021 at a single tertiary care center. Cases were patients with composite maternal surgical morbidity, defined as blood transfusion, intubation, postoperative ICU admission, bowel/bladder injury, wound complication requiring hospital encounter, and endomyometritis. Controls were patients who did not experience these measures of surgical morbidity. We compared baseline and

intraoperative characteristics between cases and controls using bivariate analyses and used multivariable logistic regression to identify factors independently associated with surgical morbidity.

RESULTS: Of 1025 patients who underwent unscheduled CD, 211 (20.1%) were cases complicated by serious surgical morbidity. In the regression model, emergent CD (aOR 2.06, CI 1.42-2.97), classical hysterotomy (aOR 2.75, CI 1.30-5.83), and hysterotomy extension (aOR 2.29, CI 1.56-3.38) were associated with surgical morbidity, while epidural placement prior to operating room (OR) transfer was associated with decreased morbidity (aOR 0.46, CI 0.34-0.63). Other factors including BMI, cesarean section history, comorbidities, labor characteristics (rupture of membranes, cervical dilation, and labor arrest) and operative times were not associated with surgical morbidity.

CONCLUSION: Emergent delivery, classical hysterotomy, and hysterotomy extension are risk factors for surgical morbidity associated with unscheduled CD. Neuraxial anesthesia placement prior to OR transfer is protective against maternal morbidity, identifying a potential opportunity to modify risk in patients at high risk of unscheduled CD.



[1]Adjusted for labor onset prior to delivery and epidural placement prior to OR
[2]Adjusted for hysterotomy extension
[3]Adjusted for second stage cesarean section
[4]Adjusted for labor, general anesthesia, emergent procedure
[5]Adjusted for classical hysterotomy and hysterotomy extension
*Other clinical factors including maternal BMI, cesarean section history, comorbidities, labor characteristics, and operative times were not associated with maternal morbidity

944 Physical activity during pregnancy. A step-by-step towards reduced rate of C-sections

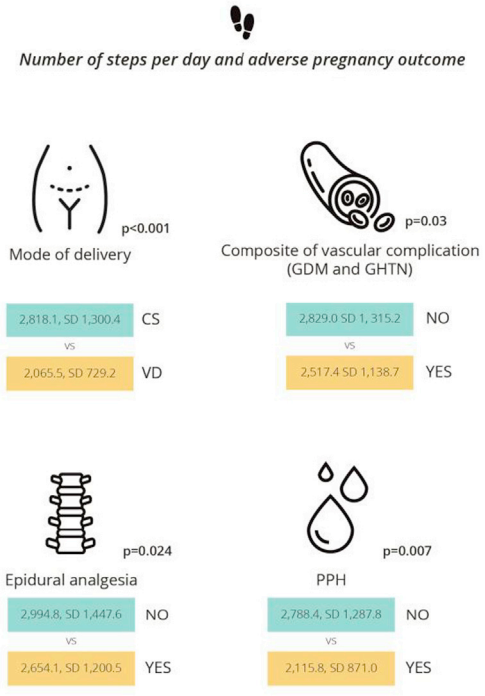
Chen Ben David[1], Rayna Boyarsky[2], Devorah Rozenberg[2], Yaniv Zipori[3], Naphtali Justman[4], Gal Bachar[1], Nizar Khatib[5], Yuval Ginsberg[6], Zeev Weiner[7], Ron Beloosesky[8]
[1]Rambam Healthcare Campus, Haifa, Hefa, [2]Technion University, Haifa, Hefa, [3]Rambam Healthcare Campus, BINYAMINA, Hefa, [4]Rambam Medical Center, Haifa, Hefa, [5]Rambam health care campus, Haifa, Israel, Acre, Hefa, [6]Rambam Health Care Campus, Haifa, HaZafon, [7]Rambam Medical Health Campus, Haifa, HaZafon, [8]Harbor UCLA Medical Center, Los Angeles, CA

OBJECTIVE: This study explores the association between maternal physical activity, as indicated by the number of steps taken daily during pregnancy and adverse pregnancy outcomes.

STUDY DESIGN: A prospective observational study in a tertiary center (January-July 2023). Only women with singleton pregnancies attempting vaginal delivery were included. The number of steps taken during gestation (STDG) was measured using validated phone apps. Regression models and correlation tests investigated the association between the mean number of STDG and perinatal outcomes. Results were adjusted for age, parity, body mass index, medical and obstetric history. The primary outcome was mode of delivery. The secondary outcomes included adverse neonatal and maternal complications.

RESULTS: A total of 401 patients met the inclusion criteria. We observed a gradual decrease in maternal physical activity as pregnancy progressed (mean of 3,184, 2,700, and 2,152 daily steps in the first trimester, mid-pregnancy, and third-trimester, respectively). The overall incidence of intrapartum cesarean section (CS) was 10.5%. More active patients (higher mean daily steps during gestation) had a significantly lower incidence of CS (2,818.± 1,300.4 vs. 2,065.± 729.2 steps, p< 0.001). The area under the ROC curve, with a cut-off set at 2,093.5 daily steps, was 0.694 (95% CI, 0.615−0.773), resulting in a significant risk reduction in the CS rate (odd ratio of 0.22, 95% CI 0.104-0.465). More active patients also showed: 1. reduced composite outcome of gestational diabetes, gestational hypertension and pre-eclampsia; 2. epidural analgesia use; 3. and postpartum hemorrhage (figure 1). Preterm birth, labor induction, neonatal weight, and neonatal intensive care unit admission were not significantly affected.

CONCLUSION: Increased physical activity during pregnancy, as reflected by a higher STDG, significantly improves perinatal outcome, including decreased rates of C-section, gestational hypertension, gestational diabetes, epidural use, and postpartum hemorrhage. Maintaining an active lifestyle during pregnancy should be strongly encouraged.



The mean number of steps per day and pregnancy outcome are presented. SD, standard deviation; PPH, postpartum hemorrhage; GDM, gestational diabetes mellitus; GHTN, gestational hypertension; VD, vaginal delivery; CS, cesarean section.

945 The effect of COVID-19 pandemic on pregnancy outcomes – A Population-Based study

Atar Ben- Shmuel[1], Howard Berger[2], Elad Mei-Dan[3], Nir Melamed[4], Jon F. Barrett[1], Amir Aviram[5]
[1]Sunnybrook Health Science, University of Toronto, Toronto, ON, [2]University of Toronto, Thornhill, ON, [3]North York General Hospital, Toronto, ON, [4]Sunnybrook Health Sciences Centre, Toronto, ON, [5]Rabin Medical Center, Toronto, ON

OBJECTIVE: The COVID-19 pandemic affected the entire world, and numerous countries implemented various measures to reduce the

spread of the virus. Challenging times characterized by heightened stress levels, limited access to healthcare resources, and strained healthcare systems might lead to adverse pregnancy outcomes. We aimed to evaluate the impact of COVID-19 on the incidence of preterm birth and other adverse pregnancy outcomes.

STUDY DESIGN: A population-based, provincial-level, retrospective study of all individuals who gave birth in hospitals in Ontario, Canada, during January-December 2020. The comparator group included all individuals who delivered between January 2017 and December 2019. The primary outcomes were preterm birth (PTB) < 37 weeks of gestation. Additionally, we analyzed several secondary maternal outcomes, including PTB at different gestational ages, preeclampsia, HELLP syndrome, eclampsia, and perinatal morbidity. Secondary analysis was performed by geographical area (rural/urban), and annual quartiles.

RESULTS: Overall, 116,244 births were included in the study group, and 363,650 in the control group. Delivery during the pandemic was not found to be associated with PTB. Yet, it was associated with a higher risk for neonatal morbidity (aRR 1.06, CI 1.04-1.08) and gestational diabetes (aOR 1.07, 95% CI 1.05-1.10), and a lower risk for preeclampsia and eclampsia (aRR 0.90, 95% CI 0.86-0.95 and RR 0.68, 95% CI 0.53- 0.87, respectively) (Table). Secondary analysis by quartiles and geographical distribution did not yield any significant standardized differences.

CONCLUSION: The COVID pandemic was not associated with an increased risk of preterm birth, but it was associated with an increase in neonatal morbidity and gestational diabetes.

Table 1: Relative risk of selected outcomes before and after Jan 1st 2020

Outcome	Jan 2020-Dec 2020 (N=116,244)	Jan 2017-Dec 2019 (N=363,650)	Adjusted RR (95%-CI)*
PTB < 37 weeks	8,933 (7.57)	27,937 (7.57)	1.00 (0.98, 1.02)
PTB < 34 weeks	2,038 (1.73)	6,486 (1.76)	0.99 (0.94, 1.04)
PTB < 32 weeks	1,130 (0.96)	3,557 (0.96)	1.01 (0.94, 1.08)
PTB < 28 weeks	466 (0.39)	1,490 (0.40)	1.01 (0.91, 1.13)
PTB < 26 weeks	273 (0.23)	928 (0.25)	0.94 (0.82, 1.08)
Preeclampsia	1,740 (1.50)	5,506 (1.51)	0.90 (0.86, 0.95)
Preeclampsia<37 weeks	649 (0.56)	1,957 (0.54)	0.95 (0.88, 1.04)
Eclampsia	77 (0.07)	340 (0.09)	0.68 (0.53, 0.87)
HELLP syndrome	156 (0.13)	491 (0.14)	0.93 (0.78, 1.11)

*Adjusted for maternal age, nulliparity, pre-pregnancy BMI, smoking, pre-existing diabetes and pre-existing hypertension.

**Adjusted for maternal age, nulliparity, pre-pregnancy BMI, smoking and preexisting hypertension.

***Composite severe morbidity defined as any of the following: admission to neonatal intensive care unit (NICU) > 24 hours, 5-minutes Apgar score <5, respiratory distress syndrome or need for mechanical ventilation and hypoxic ischemic encephalopathy.

946 Single hypoglycemic value during oral glucose tolerance test

Dafna Ben Yehuda Raz[1], inna Bleicher[2], Rami Samour[3], Shlomi Sagi[1]

[1]Bnai Zion Medical Center, Haifa, Hefa, [2]Bnai Zion Medical Center, E Meadow, NY, [3]Bnai Zion, Haifa, Hefa

OBJECTIVE: The American College of Obstetricians and Gynecologists (ACOG) defines Gestational Diabetes Mellitus (GDM) as ≥ 2 abnormal values during Oral Glucose Tolerance Test (OGTT) and suggests that 1 abnormal value may also be sufficient for diagnosis. Abnormal values are usually considered as hyperglycemia, while the significance of hypoglycemia remains uncertain. We sought to evaluate whether single hypoglycemic value during OGTT is comparable to a single hyperglycemic value.

STUDY DESIGN: This was a retrospective cohort study conducted in a single tertiary medical center during the years 2021-2022. We included patients with singleton pregnancies who had a single abnormal value, either high or low, during OGTT, with the 3 remaining values being normal. We compared birth outcomes between patients with a single hyperglycemic value (hyperglycemia group) and patients with a single hypoglycemic value (hypoglycemia group). Hypoglycemia was defined as plasma glucose ≤ 70 mg/dL at any value, while hyperglycemia was defined according to Carpenter and Coustan criteria. The primary outcome was the rate of small for gestational age (SGA) and large for gestational age (LGA) infants at delivery. Secondary outcomes included mode of delivery, postpartum hemorrhage (PPH), neonatal intensive care unit (NICU) admission, and length of hospital stay.

RESULTS: Three hundred and seventy-three patients were included in the analysis, 186 in the hypoglycemia group and 187 in the hyperglycemia group. The rate of SGA and LGA were comparable between the groups, and so was the mode of delivery. Hypoglycemia was associated with greater gestational age at delivery and higher mean birthweight. Other obstetric and neonatal outcomes including mode of delivery were similar. (Table 1).

CONCLUSION: A single hypoglycemic value during OGTT leads to similar rates of LGA and SGA, and could be considered equally abnormal as hyperglycemia.

Table 1 – Group Characteristics and Study Outcomes:

	Hypoglycemia group (N=186)	Hyperglycemia group (N=187)	P-value	OR (95% CI)
Maternal age			0.915	1 (1 - 1)
Mean (SD)	32.4 (4.96)	32.3 (5.05)		
Median [Min, Max]	32.0 [21.0, 52.0]	32.0 [22.0, 52.0]		
Gestational age (weeks)			0.025	1.2 (1 - 1.4)
Mean (SD)	39.3 (1.47)	39.0 (1.47)		
Median [Min, Max]	39.4 [28.1, 41.5]	39.1 [32.0, 42.4]		
Induction of labor	52 (28.0%)	53 (29.4%)	0.551	0.9 (0.5 - 1.4)
Normal GCT	33 (17.7%)	14 (7.5%)	0.002	3 (1.5 - 5.9)
GCT value			<0.001	1 (1 - 1)
Mean (SD)	141 (25.7)	156 (18.7)		
Median [Min, Max]	144 [48.0, 196]	157 [94.0, 197]		
GCT hyperglycemia	86 (46.2%)	112 (59.9%)	<0.001	0.3 (0.2 - 0.6)
SGA	3 (1.6%)	6 (3.2%)	0.502	0.5 (0.1 - 2)
LGA	35 (18.8%)	33 (17.6%)	0.79	1.1 (0.6 - 1.8)

Mean (SD)	3.05 (1.05)	3.66 (1.65)		
Median [Min, Max]	2.94 [0.840, 9.76]	3.19 [1.38, 13.2]		
Delivery to discharge (days)			<0.001	0.6 (0.5 - 0.8)
Mean (SD)	2.60 (0.920)	3.14 (1.50)		
Median [Min, Max]	2.46 [0.800, 9.72]	2.75 [1.30, 12.1]		
NICU	2 (1.1%)	5 (2.7%)	0.45	0.4 (0.1 - 2.2)

Numbers are mean (SD), median or n (%).

Abbreviations: GCT – Glucose Challenge Test (50 grams), SGA – Small for Gestational Age, LGA – Large for Gestational Age, CS – Cesarean Section, PPH – Post Partum Hemorrhage, NICU – Neonatal Intensive Care Unit

947 Placental complications in patients with Mullerian anomalies

Anastasia Bendet[1], Eyal Sheiner[2], Tamar Wainstock[3], Eli H. Bernstein[4], Polina Schwarzman[1]
[1]Soroka, Beer-Sheva, HaDarom, [2]Soroka University Medical Center, Beer-Sheva, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom, [4]Bay State Medical Center, White Plains, NY

OBJECTIVE: Mullerian anomalies are associated with adverse pregnancy outcomes and specifically preterm deliveries. However, scarce data exists regarding placental complications. This study aimed to determine whether women with Mullerian anomalies have a higher rate of placental complications.

STUDY DESIGN: A retrospective population-based cohort study was conducted comparing placental complications in women with and without Mullerian anomalies. We evaluated all deliveries that occurred between the years 1991 and 2021 at a tertiary medical center. Multiple gestations and chromosomal abnormalities were excluded. Multiple logistic regression models were used to control for confounding variables.

RESULTS: During the study period, 356,356 deliveries met inclusion criteria, 0.4% (n=1283) of whom were diagnosed with Mullerian anomalies. Placental complications, including placenta previa, placenta accreta, placental abruption, residua and also the need for blood transfusion were significantly more prevalent in women with Mullerian anomalies (Table). Using multiple logistic regression models, Mullerian anomalies were found as an independent risk factor for placenta previa (adjusted OR 1.82; 95% confidence interval(CI) , 1.12-2.97; p< 0.001), placenta accreta (adjusted OR 1.66 ; 95% CI, 1.01-2.74; p=0.004), abruption (adjusted OR 2.66 ; 95% CI, 1.84- 3.86; p< 0.001), residua (adjusted OR 1.43; 95%, (1.01- 2.03); p=0.002) and receiving blood transfusion (adjusted OR 1.47; 95% CI, 1.05-2.06; p< 0.001; Table), while controlling for maternal age and gestational age.

CONCLUSION: Mullerian anomalies are associated with placental complications. Women with Mullerian anomalies should receive meticulous care during pregnancy and delivery to address potential placental complications.

Table: Placental complications of women with and without Mullerian anomalies

Placental abnormality and adverse effect	Mullerian Anomalies n= 1283 (0.4%)	No Mullerian Anomalies n= 355073 (99.6%)	OR (95% CI)	Adjusted OR (95% CI)[a]
Placenta previa (N, %)	20 (1.6)	1446 (0.4)	3.87 (2.48-6.04)	1.82 (1.12-2.97)

948 Postpartum health-care utilization and blood pressure control by antihypertensive agent in hypertensive disorders of pregnancy

Carrie Bennett[1], Lara S. Lemon[2], Kripa Venkatakrishnan[2], Hannah Wichmann[2], Sanjana Ghosh[2], Hyagriv Simhan[2], Alisse Hauspurg[3]
[1]University of Pittsburgh Medical Center, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]UPMC Magee-Womens Hospital, Pittsburgh, PA

OBJECTIVE: To evaluate rates of postpartum hospital readmission and emergency room (ER) utilization for individuals with a hypertensive disorder of pregnancy (HDP) after discharge on labetalol versus nifedipine XL.

STUDY DESIGN: We evaluated outcomes associated with antihypertensive at discharge in a cohort of postpartum individuals delivering from 4/2019-6/2023 at a single institution. Individuals were included who were diagnosed with hypertension (HTN) in pregnancy (including chronic HTN), were discharged on labetalol or nifedipine XL and were enrolled in our institution's remote blood pressure (BP) management program. Individuals were excluded if they were prescribed antihypertensives antenatally. We compared demographics, inpatient and outpatient BP and clinical outcomes between groups. The primary outcome was postpartum hospital readmission within 8 weeks of delivery. Multivariate logistic regression models adjusted for age, self-identified race, BMI and type of HTN.

RESULTS: 1775 individuals were included; 694 (39.1%) were discharged on labetalol and 1081 (60.9%) on nifedipine XL. Those discharged on labetalol had higher BMIs and higher rates of chronic HTN. Maximum postpartum outpatient systolic BPs were higher in those discharged on labetalol compared to nifedipine (BP 149±15 v 147±13, p=0.03); conversely, maximum diastolic BPs were lower for those on labetalol (BP 96±9 v 98±9, p=0.0002). Compared to individuals discharged on labetalol, those discharged on nifedipine were less likely to have a postpartum hospital readmission (7.3% v 4.3%, p=0.001). In multivariate logistic regression models, discharge on nifedipine was associated with an aOR 0.51 (95%CI 0.31-0.83) decreased odds of postpartum hospital readmission. These findings were similar when stratified by type of HDP (no chronic HTN: aOR 0.54 (95%CI 0.29-0.98); chronic HTN: aOR 0.46 (95%CI 0.20-1.06).

CONCLUSION: Despite minimal differences in peak postpartum BPs, discharge on nifedipine was associated with less postpartum hospital readmission following a HDP compared to discharge on labetalol, which was robust across type of HDP.

Table 1. Patient Characteristics by Antihypertensive Agent

	Labetalol (N=694)	Nifedipine XL (N=1081)	p-value
Age (yrs)	31 ± 6	30.8 ± 6	0.51

949 Pregnancy outcomes in people with spinal cord injury

Claire J. Mazzia[1], Anne Berndl[2], Sarah Daisy Kosa[3], Anne Harris[4]

[1]Temerty Faculty of Medicine, University of Toronto, Toronto, ON, [2]Sunnybrook Research Institute, Toronto, ON, [3]McMaster University, Hamilton, ON, [4]Toronto Metropolitan University, Toronto, ON

OBJECTIVE: To understand the obstetrical and neonatal outcomes of people with spinal cord injury (SCI).

STUDY DESIGN: This is part of an international observational questionnaire examining reproductive and urogenital health outcomes in people with SCI. It was developed with input from people with SCI, and distributed electronically in four languages in collaboration with social media and SCI organizations. Self-identified people over the age of 18 who were assigned female at birth were included. This study assessed key obstetrical and neonatal outcomes in this population. Descriptive analysis was used.

RESULTS: Responses were received from 33 countries; the recruitment rate was 85.4% (1056/1237) and the completion rate was 73.8% (780/1056). Of these, 216 people reported having 392 pregnancies following SCI, 5 of which were twin pregnancies. There were 265 live births, 3 stillbirths, 71 miscarriages, 38 terminations, 3 ectopics and 17 people who were currently pregnant. Of the pregnancies resulting in live births and stillbirths, there were 99 cesarean sections and 161 vaginal births, 3 did not report mode of delivery. Preterm birth (PTB) occurred in 64/263 (24.3%) of pregnancies ending in births. Bladder infections occurred in 80/263 (30.4%), kidney infection in 16/263 (6.1%), hospital admission in 44/263 (16.7%) and ICU admission in 5/263 (1.9%) of pregnancies ending in births. 39/263 (14.8%) pregnancies resulted in NICU admission.

CONCLUSION: This is the largest and most detailed assessment to date of pregnancy outcome in people with SCI. It supportsa previously reported concern for a risk of PTB in this population, as well as high incidence of bladder and kidney infections, and hospital admission. This information is of value to people with SCI who are contemplating pregnancy or are currently pregnant, and the physicians who care for them. Although the majority of pregnancies resulted in term, vaginal deliveries, this study suggests a need for future research into the causes of, and ways to prevent PTB and urologic infection in people with SCI, as well as possible links between these two outcomes.

950 Maternal and neonatal outcomes of implementation of a computer-based software for intrapartum glucose management

Margarita Berwick, Lauren Silva, Miranda Solly, Xuban Palau, Kayleigh Porritt, Cathleen Mestre, Tony S. Wen

University of Florida, Gainesville, FL

OBJECTIVE: The objective of the present study was to determine whether rates of neonatal hypoglycemia and maternal glucose levels differed among patients managed with conventional insulin dose calculation versus Glucommander insulin management software.

STUDY DESIGN: Outcomes pre- and post-implementation of Glucommander were analyzed. Inclusion criteria included type 1, type 2, or gestational diabetes, prenatal care at our center after 26 weeks of gestation, and vaginal delivery. Maternal characteristics including age, body mass index, type of diabetes, and third trimester treatment were obtained. Percentages of values in euglycemic (100-140 mg/dL), target (70-110 mg/dL pre- / 100-140 mg/dL post-intervention), hypoglycemic (less than 70 mg/dL), and hyperglycemic (greater than 140 or 180 mg/dL) ranges were calculated. Neonatal data points used in analysis included gestational age at delivery, delivery weight, initial neonatal glucose reading, and neonatal intensive care admission. Analyses included t-test and Chi-square.

RESULTS: 108 pregnancies met inclusion criteria in pre-intervention group and 39 in post-intervention group. Summary of findings is presented in table 1. Total time in target glycemic range and rates of maternal hyperglycemia were similar between groups. Severe neonatal hypoglycemia was significantly less common among patients managed with Glucommander (p=0.034) with no difference in NICU admissions for hypoglycemia. In sub-analyses of pre-term and term deliveries, greater incidence of maternal hypoglycemia was observed among patients delivering after 37 weeks managed with conventional insulin drip (4.29 vs 0.99 %, p =0.005). In ANCOVA analysis accounting for gestational age, association between mode of insulin dosing and neonatal glucose remained significant.

CONCLUSION: Glucommander insulin management software shows similar time in target glucose range compared with conventional insulin drip dosing with lower rates of maternal hypoglycemia in term patients. Lower rates of neonatal hypoglycemia were noted with no difference in rates of neonatal intensive care admission due to low blood glucose.

951 Preeclampsia in patients with adult congenital heart disease

Medhavi Bhasin[1], Rachel Harrison[2], Kavya Shivashankar[3], Yara El Helou[4], Michael Earing[5], Calla Holmgren[6]

[1]Advocate Lutheran General Hospital, Park Ridge, IL, [2]Advocate Christ Hospital, Oak Lawn, IL, [3]University of Illinois Hospital, Chicago, IL, [4]University of Illinois at Chicago, Chicago, IL, [5]Advocate Aurora Health, Chicago, IL, [6]AAH Lutheran General Hospital, Park Ridge, IL

OBJECTIVE: To determine the rate of hypertensive disorders of pregnancy (HDP) among women with adult congenital heart disease (ACHD).

STUDY DESIGN: This is a retrospective cohort study performed using the National Inpatient Sample Database from the Healthcare Cost

and Utilization Project from 2017-2019. ICD-10 codes were used to identify subjects with and without ACHD for comparison. Subjects with delivery encounters associated with their admission were included. Subjects were excluded if gestational age was unknown or < 20 weeks. 2,214,562 patients were included in the analysis, 2,409 (0.1%) of whom had ACHD. Baseline characteristics and the presence and type of HDP in the two groups were compared via t-tests, chi-squared analysis, and logistic regression analysis.

RESULTS: Those with ACHD were more likely to be younger, non-Hispanic white, obese, tobacco users, or to have diabetes or a hypertensive disorder. They were less likely to have public insurance and more likely to deliver at large, private, and urban teaching hospitals. ACHD was associated with increased rates of HDP; HDP affected 16.4% of subjects with ACHD vs. 12.0% of subjects without ($p< 0.001$). When stratifying by type of HDP, the difference between the two groups was only statistically significant for severe HDP − preeclampsia with severe features (3.2% vs. 2.3%, p=0.003), superimposed preeclampsia with severe features (2.7% vs. 1.0%, $p< 0.001$), and HELLP/eclampsia (0.9% vs. 0.3%, $p< 0.001$) − not for gestational hypertension or preeclampsia without severe features (6.8% vs 6.1%, p=0.177 & 1.9% vs 1.7%, p=0.411). In adjusted analysis, subjects with ACHD remained more likely than non-ACHD subjects to have any HDP (aOR 1.23, 95% CI 1.10-1.38), superimposed preeclampsia with severe features (aOR 1.77, 95% CI 1.33-2.37), and HELLP/eclampsia (aOR 2.46, 95% CI 1.60-3.79) compared to non-ACHD subjects.

CONCLUSION: Pregnant patients with ACHD have an increased risk for HDP and are specifically at higher risk for development of superimposed preeclampsia with severe features and HELLP/eclampsia compared to patients without ACHD.

Adult congenital heart subjects compared to non-ACHD subjects

952 The association of sociodemographic differences with clinical management following a diagnosis of short cervix

Joseph R. Biggio Jr.
Ochsner Health System, New Orleans, LA; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: To evaluate the association of sociodemographic (SD) factors and related systemic bias with variation in clinical management following diagnosis of a short cervix.

STUDY DESIGN: Secondary analysis of a randomized trial in which singletons with a cervical length (CL) ≤ 20 mm were randomized to pessary vs. usual care. We assessed recommendations for vaginal progesterone (vag P), additional CL surveillance, pelvic rest, bedrest, and cerclage. Additional CL assessment was discouraged and cerclage allowed only for cervical dilation; activity modification and vag P were at provider discretion. SD factors were race and ethnicity, marital status, employment status, years of education, and type of insurance. Multivariable regression models examined the association between each SD factor and recommendation adjusting for other SD factors, CL at enrollment, clinical center, and treatment arm; odds ratios and 95% CI were determined.

RESULTS: Of the 446 patients (82% of 544 enrolled) with at least one post enrollment visit, 95.5% received vag P, 28% had additional CL assessment, 55.8% were on pelvic rest, 19.5% on activity restriction, and 7.4% had cerclage. The high rate of vag P usage precluded evaluation of association with SD factors. Non-Hispanic Black and Hispanic patients had lower odds of repeat CL assessment compared with Non-Hispanic White patients (aOR 0.47, 95% CI 0.24, 0.91; aOR 0.45, 95% CI 0.21, 0.99, respectively). No other SD factors were associated with repeat CL (Table 1). Patients with private insurance, but no other SD factor, had higher odds of pelvic rest recommendation (aOR 2.08, 95% CI 1.25, 3.45). None of the examined SD factors were associated with recommendations for bedrest or cerclage.

CONCLUSION: Non-Hispanic Black and Hispanic patients were less likely to have a repeat CL assessment following diagnosis of a short cervix and pelvic rest was more likely to be recommended to patients with private insurance. Variation in the frequency of these interventions raises questions about differences in intervention use based on race and ethnicity and insurance coverage.

953 Quantitative blood loss and hemorrhage risk in patients taking antepartum SSRI and aspirin

Courtney Birchall, Rose Cohen-Sandler, Rebecca Chernick, Katherine Leung, Heidi K. Leftwich
University of Massachusetts, Chan Medical School, Worcester, MA

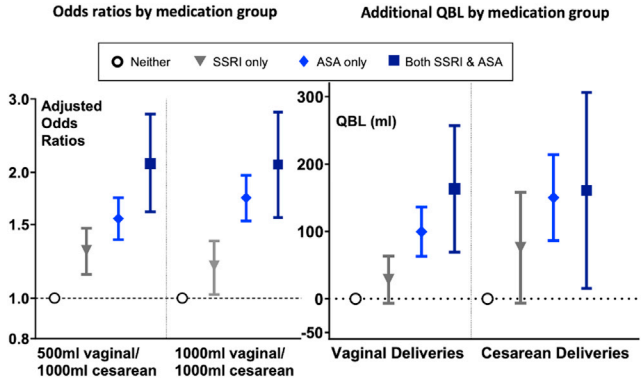
OBJECTIVE: Studies have shown taking an SSRI and an NSAID together increases the risk of bleeding events in other disciplines. The objective of this study was to investigate whether a similar relationship exists with SSRI and aspirin use and post-partum bleeding.

STUDY DESIGN: This was an IRB-approved retrospective chart review conducted at a single academic center. Data was abstracted from a total of 17,512 pregnancies between 2018 and 2023. Patients were characterized based on their medication use in pregnancy as documented in the electronic medical record.

RESULTS: Of these patients 1,283 took an SSRI alone, 1,541 took aspirin alone and 232 took both an SSRI and aspirin antepartum. Pre-delivery hemorrhage risk scores between groups showed high risk scores of: 26.5% neither medication, 28.7% SSRI only, 34.4% aspirin only, and 26.4% SSRI and aspirin. For patients with a vaginal delivery our analysis showed that patients taking an SSRI and aspirin

had the highest average quantitative blood loss (QBL) with a mean of 492 mL. This relationship remained in a model adjusting for maternal age, parity, and gestational age (p=0.001). This group also had highest QBL in those with cesarean delivery, with average QBL of 928.5 mL. This relationship remained significant in our adjusted analysis. In all delivery types, patients taking aspirin and SSRI were most likely group to have a QBL > 500 for vaginal delivery and >1000 for cesarean delivery, in both an adjusted and unadjusted model (rate 38.8%, adj OR 2.10, 1.61-2.76, p< 0.001). A similar result was seen when looking at QBL > 1000 for all delivery types (adj OR 2.09, 1.56-2.79, p< 0.001).

CONCLUSION: Patients taking an SSRI and aspirin in pregnancy had the highest average QBL, regardless of mode of delivery and were the most likely group to experience a post-partum hemorrhage in both unadjusted and adjusted models. Our study shows patients taking SSRI and aspirin may be at an increased likelihood of post-partum hemorrhage. Knowing this relationship can allow providers to appropriately counsel and monitor these patients during their delivery and in the post-partum period.



954 Second trimester fetal growth restriction and small for gestational age

Ghamar Bitar[1], Kyung Hyun Lee[2], Hailie Ciomperlik[3], Emily S. Miller[4], Shruti Natarajan[5], Suneet P. Chauhan[6], Sean C. Blackwell[7], Baha M. Sibai[8], Eleazar E. Soto Torres[5], Edgar Hernandez Andrade[5]

[1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [2]Center for Clinical Research & Evidence-Based Medicine, McGovern Medical School at UTHealth Houston, Houston, TX, [3]University of Texas, McGovern School of Medicine, Houston, TX, [4]Alpert Medical School of Brown University and Women & Infants Hospital of Rhode Island, Providence, RI, [5]McGovern Medical School at UTHealth Houston, Houston, TX, [6]University of Texas-Houston Medical School, Houston, TX, [7]Children's Memorial Hermann Hospital, Houston, TX, [8]Hermann Memorial Hospital, Houston, TX

OBJECTIVE: Among individuals with fetal growth restriction (FGR) diagnosed in the mid second trimester (18-24 weeks), we assessed risk factors and associated outcomes with and without small for gestational (SGA).

STUDY DESIGN: This was a single center retrospective study (1/2018 – 2/2021) of singletons with FGR (estimated weight [EFW] and/or abdominal circumference [AC] < 10th percentile for gestational age, Hadlock) identified at 18 – 24 weeks' with reliable estimated delivery date. We compared maternal and pregnancy characteristics as well as outcomes in pregnancies that were SGA (< 10% birth weight, by Fenton) versus not SGA (10-99% birthweight). We excluded anomalous gestations and those without delivery outcomes. Primary outcome was a composite neonatal outcome including neonatal intensive care unit admission (NICU), respiratory distress syndrome, mechanical ventilation, continuous positive airway pressure, hypoglycemia or neonatal death prior to discharge. Secondary outcomes included other neonatal and maternal outcomes.

RESULTS: During the study period, 28,703 ultrasounds were performed between 18 – 24 weeks' gestation, with 398 (1.4%) singleton gestations diagnosed with FGR. 159 patients (39.9%) met all inclusion criteria. Of these, 78 (49.1%) were not SGA at delivery and 81 (50.9%) were SGA. Maternal characteristics were similar between groups. Those with SGA at delivery were more likely to have EFW ≤ 3rd percentile at diagnosis than those not SGA. The primary outcome occurred more frequently in those SGA at delivery (24.7% not SGA vs. 52.9% SGA, p < 0.001), likely driven by gestational age difference at delivery. Maternal hypertensive disorders of pregnancy occurred more frequently in those SGA (17.9% not SGA vs. 33.3% SGA; p=0.03).

CONCLUSION: 1 in 2 patients diagnosed with FGR at 18 – 24 weeks' gestation will be SGA at delivery. Fetuses diagnosed with FGR having an EFW ≤ 3rd percentile are more likely to be SGA at delivery. These pregnancies are also more likely to be associated with maternal hypertensive disorders of pregnancy.

Table. Fetal growth restriction in second trimester

Characteristic	Not small for gestational age (n = 78)	Small for gestational age (n= 81)	P value
Diagnostic Ultrasound Descriptors			
Gestational age at first diagnostic ultrasound	21.1 ± 1.43	20.9 ± 1.28	0.55
FGR by EFW <10% at diagnosis	50 (86.2)	85 (83.3)	0.82
FGR by EFW ≤ 3% at diagnosis	21 (27.3)	45 (55.6)	**<0.001**
FGR by AC <10% at diagnosis	24 (41.4)	48 (47.1)	0.51
FGR by both EFW and AC at diagnosis	16 (27.6)	33 (32.4)	0.60
Abnormal Doppler (UA, MCA or CPR) at diagnosis [a]	8 (16.3)	16 (30.2)	0.10
Delivery Characteristics			
Gestational age at delivery	37.5 ± 3.6	34.4 ± 5.4	**<0.001**
Preterm Delivery < 37 weeks	13 (16.7)	32 (39.5)	**0.002**
Preterm Delivery < 34 weeks	8 (10.3)	24 (29.6)	**0.003**

955 Second trimester fetal growth restriction with estimated fetal weight 3rd percentile or less

Ghamar Bitar[1], Kyung Hyun Lee[2], Hailie Ciomperlik[3], Emily S. Miller[4], Shruti Natarajan[5], Suneet P. Chauhan[6], Sean C. Blackwell[7], Baha M. Sibai[8], Eleazar E. Soto Torres[5], Edgar Hernandez Andrade[5]

[1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [2]Center for Clinical Research & Evidence-Based Medicine, McGovern Medical School at UTHealth Houston, Houston, TX, [3]University of Texas, McGovern School of Medicine, Houston,

TX, [4]Alpert Medical School of Brown University and Women & Infants Hospital of Rhode Island, Providence, RI, [5]McGovern Medical School at UTHealth Houston, Houston, TX, [6]University of Texas-Houston Medical School, Houston, TX, [7]Children's Memorial Hermann Hospital, Houston, TX, [8]Hermann Memorial Hospital, Houston, TX

OBJECTIVE: Among individuals with fetal growth restriction (FGR) diagnosed in the mid second trimester (18-24 weeks), we assessed risk factors and associated outcomes with estimated fetal weight (EFW) 3rd percentile or less versus 4 - 9th percentile at diagnosis.

STUDY DESIGN: This was a single center retrospective study (2018 - 2021) of singletons with FGR (estimated weight [EFW] and/or abdominal circumference [AC] < 10th percentile for gestational age, Hadlock) identified at 18 – 24 weeks' with reliable estimated delivery date. We compared maternal and pregnancy characteristics as well as outcomes in pregnancies that were EFW ≤ 3rd percentile at initial diagnosis versus 4 - 9th percentile. We excluded anomalous gestations and those without delivery outcomes. Primary outcome was small for gestational age (SGA, birthweight < 10th percentile, Fenton) with secondary outcomes including other neonatal and maternal outcomes.

RESULTS: During the study period, 28,703 ultrasounds were performed between 18 – 24 weeks' gestation, with 398 (1.4%) singleton gestations diagnosed with FGR. 160 patients (40.2%) met all inclusion criteria. Of these, 93 (58.1%) were EFW 4 - 9th percentile and 67 (41.9%) were EFW ≤ 3rd percentile. Maternal characteristics were similar between groups. Those with EFW ≤ 3rd percentile were more likely to meet criteria for FGR by AC and EFW than those with EFW 4 - 9th percentile (Table). The primary outcome of SGA was more likely in those with EFW ≤ 3rd percentile (38.7% EFW 4-9th % vs. 61.5% EFW ≤ 3rd %,Table). All intrauterine fetal demises occurred in those with EFW ≤ 3rd percentile. Maternal hypertensive disorders of pregnancy were similar between groups (Table).

CONCLUSION: Six in 10 fetuses with EFW ≤ 3rd percentile at mid-trimester ultrasound will be SGA and are at higher risk of intrauterine fetal demise than those meeting criteria for FGR with EFW 4 - 9th percentile.

956 The impact of cut-off values on the prevalence of short cervical length in pregnancy

Sofie H. Breuking[1], Charlotte E. van Dijk[1], Annabelle L. van Gils[1], Maud D. van Zijl[2], Brenda M. Kazemier[3], Eva Pajkrt[1]
[1]Amsterdam UMC, location AMC, Amsterdam, Noord-Holland, [2]Amsterdam UMC, location AMC, IJsselstein, Utrecht, [3]Wilhelmina's Children Hospital, Utrecht, Utrecht; on behalf of the Quadruple P Research Group

OBJECTIVE: Previous literature demonstrated that the use of a cut-off value may manipulate the distribution of cervical length(CL) measurements and introduce potential selection bias. Therefore, the objective of this study is to assess the distribution of CL using a cut off value for a short CL of ≤35mm.

STUDY DESIGN: This is a secondary analysis of the Quadruple P (QP) Screen study; a prospective cohort study that included low-risk women with singleton pregnancies undergoing fetal assessment at 18-22 weeks of gestation with a CL measurement. Women with a short cervix, defined as ≤35mm, were subsequently counseled for the QP trial; a multicenter randomized controlled trial that compared vaginal progesterone and cervical pessary in the prevention of preterm birth in women with a short cervix.

In this present study, normal distributions for CL were simulated based on mean and standard deviation (SD) of the original data. The Kolmogorov-Smirnov test was used to evaluate the distribution of the CL measurements.

RESULTS: The total cohort included 19.364 women who underwent CL measurement, with a total mean CL of 43.8mm (±8.1 SD). A total of 2031(10.5%) women had short cervix of ≤35mm. The observed distribution of all CL measurements was not normally distributed(P < 0.001; Figure 1A). When comparing the data to the simulated normal distribution, a decrease in the distribution of CL measurements was seen within the range of 26-35 mm. Conversely, CL measurements at ≤25 mm showed an increase compared to the normal distribution (Figure 1B).

CONCLUSION: In line with previous literature, we did find the use of a cut-off value for a short CL influences the CL distribution. The increase in CL measurements at ≤25mm appears to be influenced by the cut-off value for treatment with progestogens, while the measurements ≤35mm is influenced by the cut-off value for study eligibility. This study highlights the risk of selection bias and importance of measuring CL with caution when essential decisions are depending on a specific cut-off value for the CL.

B. Number of cervical length(CL) measurements as a percentage of number of simulated CL measurements (red line).

957 The impact of gestational weight gain on total labor length among patients with obesity

Annabeth Brewton[1], Alissa Paudel[2], Alicia Mastronardi[1], summer Shore[1], Jill Maples[3], Nikki B. Zite[1], Megan L. Young[1], Kimberly B. Fortner[3]

[1]University of Tennessee Graduate School of Medicine, Knoxville, TN, [2]University of Tennessee Medical Center Knoxville, Knoxville, TN, [3]University of Tennessee Medical Center, Knoxville, TN

OBJECTIVE: Excessive gestational weight gain (GWG) and pre-pregnancy obesity are associated with decreased rates of spontaneous labor and increased cesarean birth. Current Institute of Medicine (IOM) guidelines establish a single recommendation for GWG in patients with obesity of all classes. We sought to assess the impact of increasing GWG on labor length and time from rupture of membranes (ROM) to vaginal delivery in patients with pre-pregnancy obesity undergoing induction of labor.

STUDY DESIGN: This retrospective cohort study included nulliparous, term, singleton, vertex presentation patients that underwent induction of labor at our institution between January 2020-May 2021 and had a vaginal delivery. Patients with pre-pregnancy BMI < 30 and who delivered via cesarean were excluded. GWG was calculated based on difference between pre-pregnancy weight and weight at delivery admission. Outcomes included total labor length (i.e., time of initial induction agent to delivery time) and ROM time (i.e., time of ROM to delivery). Univariable and multivariable linear regression models tested for the impact of severity of maternal obesity, gestational weight gain, and maternal age on mean differences in total labor length and ROM time.

RESULTS: Pre-pregnancy class of obesity was not a significant predictor of total labor length or ROM time. Conversely, increasing GWG was associated with increased total labor length in both adjusted and unadjusted models (Table 1). Increasing maternal age was also associated with increased labor length time in both models. GWG was not a significant predictor of ROM time when adjusting for other variables in the model. Models controlled for gestational age at delivery and neonatal birth weight.

CONCLUSION: Our data indicate that increasing GWG is a risk factor for longer labor inductions in the obese population. Class of obesity did not impact labor outcomes, reinforcing current IOM guidelines for patients with BMI > 30. These data also inform patient counseling on impact of GWG on labor timing. Future work should aim to create standardized induction protocols for patients with obesity.

Table 1. Mean differences in total labor length (in minutes) and time with ruptured membranes (in minutes) by maternal age, gestational weight gain, and class of obesity in patients with successful vaginal deliveries.

958 Pre-cerclage amniotic fluid glucose levels, white blood cell count and pregnancy outcomes

Kristine E. Brown[1], Selin Everett[2], Elizabeth Vitaro[2], Shai Bejerano[3], Amy Turitz[4], Alexander M. Friedman[5], Mirella Mourad[2]

[1]New York Presbyterian / Columbia, New York, NY, [2]Columbia University Medical Center, New York, NY, [3]Vagelos College of Physician and Surgeons, Columbia University, New York, NY, [4]Greenwich Hospital, COS COB, CT, [5]Columbia University, New York, NY

OBJECTIVE: Exam-indicated cerclage (EC) is an important treatment for cervical insufficiency, with the goal of preventing preterm birth (PTB). Given the risk of intra-amniotic infection (IAI) with cervical dilation, amniocentesis may be considered prior to EC to rule out IAI. In addition to bacterial culture, commonly tested amniotic fluid components include white blood cell count (WBC) and glucose. However, the utility of these tests in predicting pregnancy outcomes has not been demonstrated.

STUDY DESIGN: A retrospective cohort study was conducted at a single academic center from 2015-2023. Patients undergoing amniocentesis prior to EC were identified. Multiples and patients with incomplete delivery data were excluded. Amniotic fluid was sent for gram stain, culture, WBC and glucose levels. Patients with positive culture did not proceed to cerclage. The primary outcome was gestational age (GA) at delivery. Spearman correlation was used to assess for correlation between amniotic fluid WBC or glucose and the primary outcome. WBC (< 20, ≥ 20) and glucose (≤ 14, > 14) were also analyzed categorically by t-test or Wilcoxon rank sum test.

RESULTS: 155 patients underwent EC. Of those, 77 proceeded with amniocentesis prior to EC. Median GA at diagnosis was 21.0 weeks (IQR 19.9-21.9). Median cervical dilation was 1.0cm (IQR 0.5-1.0). 21 patients (30.4%) had prolapsing membranes and 45 (61.6%) had intra-amniotic debris present prior to EC. Median amniotic WBC was 5.0 x10^3/uL (IQR 2.0-14.2) and mean glucose 36.5 mg/dL (SD 13.0). The median GA at delivery was 37.1 weeks (IQR 29.9-39.0). No correlation was found between either WBC (ρ=0.04, p=0.70) or glucose (ρ=-0.13, p=0.26) and GA at delivery. Assessed by group, patients with glucose ≤ 14 delivered later (p=0.03) than glucose > 14 (Table 1), though there was a limited number of patients in the ≤ 14 group.

CONCLUSION: In patients receiving EC, there is no statistically significant correlation between either amniotic WBC or glucose level and GA at delivery. In patients receiving cerclage, WBC and glucose may be of limited clinical utility in predicting pregnancy outcome.

Table 1. Amniotic fluid WBC and glucose level and gestational age at delivery

	WBC < 20 N = 59	WBC ≥ 20 N = 17	p	Glucose ≤ 14 N = 2	Glucose > 14 N = 75	p
Gestational Age at Delivery Median (IQR)	37.0 (29.1 - 39.0)	37.7 (35.1 - 38.9)	0.75	40.3 (40.0 - 40.6)	37.1 (29.5 - 39.0)	0.03

959 The association between cervical cerclage and offspring long-term neurological morbidity among twin pregnancies

Adva Bugaiski Shaked[1], Gali Pariente[2], Tamar Wainstock[3], Eyal Sheiner[4]

[1]Emory University, Atlanta, GA, [2]Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Klahim, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom, [4]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: The body of evidence does not support the efficacy of routine cerclage in multiple gestations, but it may be useful in patients with a history of cervical insufficiency or a short cervix.

Preterm delivery, commonly associated with twin pregnancies, was found to be linked to long-term neurologic impairment in the offspring. We aimed to study the association between twin pregnancies with and without cervical cerclage and the risk for offspring long-term neurological morbidity.

STUDY DESIGN: A population-based retrospective cohort study was conducted, comparing the long-term neurological morbidity among twins born after pregnancies with and without cervical cerclage, between the years 1991-2021 in a tertiary medical center. The study groups were followed until 18 years of age for neurological-related morbidity. Data for the diagnosis of neurological morbidity of the offspring was extracted from community-based clinics and hospitalization records. A Kaplan-Meier survival curve was used to compare cumulative incidence, and multivariable Cox proportional hazard model was used to adjust for confounders.

RESULTS: The study included 11,986 twins in which 180 (1.5%) were born in pregnancies with cervical cerclage. Being born after pregnancy with cerclage was not significantly associated with higher risk for neurological morbidity of the offspring (15.3% vs. 13.3% p=0.471, Table). Likewise, the cumulative incidence of long-term neurological morbidity was not significantly higher among twins born after pregnancies with cerclage (Kaplan-Meier survival curve, Log rank p=0.435, Figure). In the Cox proportional hazard regression model, after adjusting for gestational age at birth, being born after a pregnancy with cervical cerclage was not associated with long-term neurological morbidity (adjusted HR 1.16, 95% CI 0.77-1.73, p=0.467, Table).

CONCLUSION: Twins who are born after cerclage placement were not found to be in higher risk for long-term neurological morbidity.

The association between cervical cerclage and offspring long-term neurological morbidity among twin pregnancies; univariable analysis, Kaplan-Meier survival curve and Cox proportional hazard regression model

	Cervical cerclage (n=180) n (%)	Without cervical cerclage (n=11,806) n (%)	OR (95% CI)	P value	Adjusted HR* (95% CI)	P value*

960 Sonographic predictors of mirror syndrome in cases of hydrops fetalis

Brian Burnett[1], Matthew A. Shanahan[1], Romain Corroenne[2], Kristi Poling[3], Christian M. Parobek[1], Jessian L. Munoz[1], Cara Buskmiller[1], Kelly Albrecht[1], roopali V. donepudi[1], Magdalena Sanz Cortes[4], Michael A. Belfort[5], Ahmed A. Nassr[1]
[1]Baylor College of Medicine, Houston, TX, [2]Angers University Hospital, Angerd, Pays de la Loire, [3]University of Arizona College of Medicine, Tuscon, AZ, [4]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [5]Texas Children's Hospital, Houston, TX

OBJECTIVE: Mirror syndrome (MS), is a rare life-threatening condition in which a pregnant person develops edema, "mirroring" that of their hydropic fetus. Data is limited with less than 120 cases of MS described in the literature. This study sought to determine sonographic predictors for development of MS in cases of hydrops fetalis (HF).

STUDY DESIGN: Retrospective cohort study of participants with HF at our center from 2012-2023. Participant history, pregnancy outcome, and ultrasound data were obtained. MS was defined clinically as worsening edema in combination with new-onset hypertension, lab abnormality (proteinuria, anemia, thrombocytopenia, elevated liver enzymes) or symptoms (headache, visual changes or dyspnea secondary to pulmonary edema). All participants were classified as having a cardiogenic or non-cardiogenic etiology for HF, defined as presence of high cardiac output pathophysiology and evidence of cardiovascular compromise. Bivariate analyses were performed comparing those with and without MS, and logistic regression was used to evaluate the association of affected fetal fluid compartments, placental thickness ($\geq$ 4 cm in second or $\geq$ 6 cm in third trimester) and etiology of HF in those who developed MS.

RESULTS: Among 201 cases of HF, MS was diagnosed in 22/201 (10.9%). HF due to a cardiogenic etiology was more common in MS, 15/22 (68.2%) compared to HF without MS, 60/179 (33.5%, p=0.002). Of those with cardiogenic etiology for hydrops, 15/60 (20%) developed MS versus 7/119 (5.6%) who did not. Both pericardial effusion and placental thickening concurrently remained significantly associated with MS after adjusting for cardiogenic etiology and elevated blood pressure at time of diagnosis, aOR [95% CI]=43.8 [5.5-348.9], p=< 0.01.

CONCLUSION: The presence of both fetal pericardial effusion and placental thickening concurrently on ultrasound were significantly associated with the development of MS. Those with HF due to a cardiogenic etiology were nearly four times as likely to be complicated with MS, suggesting a potential common pathophysiology between fetal cardiovascular compromise and MS.

Table 1. Maternal demographics and rate of mirror syndrome in participants with hydrops fetalis, classified by etiology and fetal compartment.

961 Predictive value of neutrophil-lymphocyte ratio for intraamniotic infection in preterm premature rupture of membranes

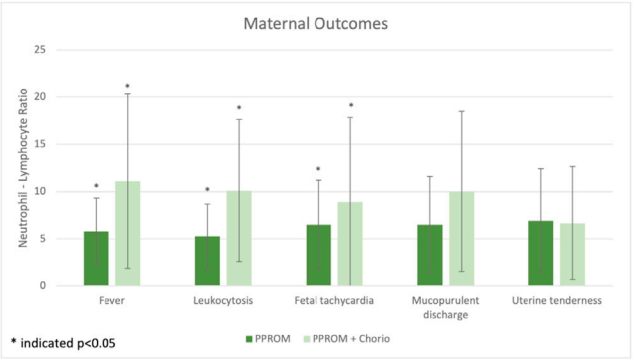
Julianne Byun[1], Ruofan Yao[2]
[1]Loma Linda University Health, Loma Linda University Health, CA, [2]Loma Linda University, Loma Linda, CA

OBJECTIVE: The purpose of our study is to assess whether an elevated neutrophil-lymphocyte ratio (NLR) is associated with intraamniotic infection (Triple I) in patients with preterm premature rupture of membranes (PPROM) and subsequent adverse neonatal outcomes.

STUDY DESIGN: We conducted a retrospective cohort study focused on women diagnosed with PPROM before 34 weeks, with or without Triple I based on ICD-10 codes at a tertiary US hospital. The NLR was calculated from complete blood counts obtained prior to delivery. Triple I was defined as maternal temperature ≥39.0°C or 38.0−38.9°C accompanied by at least one additional clinical risk factor such as maternal leukocytosis, fetal tachycardia, mucopurulent discharge, or uterine tenderness. Fetal outcomes included respiratory distress syndrome, bronchopulmonary dysplasia, necrotizing enterocolitis, intraventricular hemorrhage, sepsis, and mortality. T-test was used to determine the association between NLR and intraamniotic infection and neonatal outcomes.

RESULTS: One hundred and thirty-three women were diagnosed with PPROM. Forty-six out of the 133 (34.6%) women were diagnosed with Triple I at the time of delivery. Patients diagnosed with triple I had higher mean NLR compared to PPROM patients without triple I *[p=0.026]*. Patients with fever had a significantly elevated NLR when compared to patients without fever *[mean: 11.1 vs 5.8, SD: 1.9 vs 0.4, p< 0.001]*. A similar trend was observed with maternal leukocytosis *[10.1 vs 5.3, 1.2 vs 0.4, p< 0.001]* and fetal tachycardia *[8.9 vs 6.5, 2.2 vs 0.5, p=0.111]*. However, an elevated NLR was not associated with mucopurulent discharge, uterine tenderness, or adverse neonatal outcomes in this population when controlled for gestational age.

CONCLUSION: Patients with PPROM and an elevated NLR have an increased risk of Triple I and should be closely monitored for symptoms. However, the NLR did not have any predictive value of adverse neonatal outcomes in this population.



962 Social determinants of health impact the development of new-onset postpartum hypertension

Camila Cabrera[1], Teresa Janevic[2], Frances Howell[3], Natalie Boychuk[4], Sarah Nowlin[3], Sheela Maru[3], Micki Burdick[5], Oluwadamilola Oshewa[5], Maria Monterroso[5], Katharine McCarthy[1], Daniel Gundersen[6], Alva Rodriguez[7], Cecilia Katzenstein[3], Regina Longley[3], Jennifer A. McCoy[8], Jennifer Lewey[5], Elizabeth A. Howell[5], Lisa D. Levine[5], Jill Berkin[1], Lauren Ferrara[9]
[1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]Mt. Sinai, New York, NY, [3]Mount Sinai, New York, NY, [4]Mt. Sinai, Mt. Sinai, NY, [5]University of Pennsylvania, Philadelphia, PA, [6]Harvard, Harvard, MA, [7]Mount Sinai Hospital, Mount Sinai, NYC, NY, [8]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [9]Mount Sinai School of Medicine, New York, NY

OBJECTIVE: Hypertension (HTN) that is diagnosed postpartum (ppHTN) is understudied. Although more commonly diagnosed in women with hypertensive disorders of pregnancy (HDP), it can occur de novo postpartum (PP). There are no guidelines for BP surveillance after normotensive pregnancies; therefore, data on the incidence and risk factors for new-onset ppHTN is limited. We aimed to prospectively examine incidence and risk factors for ppHTN, and the impact of social determinants of health (SDoH).

STUDY DESIGN: We performed a secondary analysis of participants without chronic HTN or HDP (n=244) from the coronaVirus Impact on Birth Equity (VIBE) Study, which enrolled patients in 2022 from four hospitals in Philadelphia and New York City. Participants reported PP BP on a text-messaging platform for 90 days and provided demographic and SDoH information via survey. The primary outcome was Stage 1 or Stage 2 ppHTN defined as ≥2 BP ≥130/80 or receiving new medications or diagnosis of HTN within 12 weeks PP. We examined SDoH measures and their impact on ppHTN diagnosis including rent/food insecurity, housing status, education, gendered racial microaggressions during obstetric care, postpartum visit attendance, neighborhood racial-economic segregation, language, race, ethnicity, and nativity. Multivariable logistic regression was used to adjust for BMI, parity and age.

RESULTS: 71 (29.1%) participants met criteria for Stage 1 ppHTN, 5 (2.1%) met criteria for Stage 2 ppHTN, and 3 (1.2%) received new medication or diagnosis for HTN. Those in highly segregated neighborhoods were more likely to develop ppHTN compared to those in less segregated neighborhoods (unadjusted OR: 1.97, 95% CI: 1.07, 3.73). This finding was sustained after adjusting for BMI, parity, age, and all other SDoH (aOR: 2.21, 95% CI: 1.06, 4.64). The only other risk factor identified was BMI (aOR: 1.09, 95% CI: 1.04, 1.15).

CONCLUSION: In a diverse low-risk population, 32.4% of participants developed new-onset ppHTN. Higher BMI and living in highly segregated neighborhoods were significantly associated with the development of new-onset ppHTN.

Table 1. Multivariable logistic regression of SDoH and the development of postpartum stage I or II HTN.

963 The impact of patient experiences and perceptions of pregnancy risk on postpartum follow up patterns

Lauren Callans[1], Lisa D. Levine[1], Rebecca F. Hamm[2], Adina R. Kern Goldberger[3]
[1]University of Pennsylvania, Philadelphia, PA, [2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [3]Cleveland Clinic Lerner College of Medicine, Cleveland, OH

OBJECTIVE: A significant proportion of severe maternal morbidity (SMM) occurs after delivery, but postpartum follow-up is challenged by low patient engagement. This study evaluated whether subjective perceptions of pregnancy risk and/or actual experiences of adverse outcomes impacts participation in postpartum follow up.

STUDY DESIGN: This prospective observational study at an urban, academic hospital enrolled a convenience sample of 500 consecutive postpartum patients (6-11/2022). Prior to postpartum discharge, we evaluated patients' perceptions of their own antenatal risk and experience of peripartum complication (via a survey using Likert scales) and compared these to risks and outcomes derived from the EHR (including obstetric co-morbidity index and SMM). The primary outcome was attendance at any visit with an obstetric provider within 6 weeks of delivery.

RESULTS: 501 patients participated [(60.7% Black, 6.5% Hispanic, median age 31 (IQR 26-34) median gestational age at delivery 39 wks (IQR 38-39)]. 40.6% delivered by cesarean and median obstetric co-morbidity index (OB-CMI) was 1 (IQR 0-3); 11.6% with high-risk score $\geq$ 6). 8 patients experienced SMM without transfusion [CDC definition] and 30 had a postpartum hemorrhage. 288 patients (57.5%) attended any visit within 6 weeks postpartum, 80.6% of which were 3-6 weeks postpartum and 64% virtual. There were no differences in attendance of a 6-week postpartum visit based on OB-CMI, incidence of SMM, or subjective descriptions of risk or pregnancy complications (Table).

CONCLUSION: Neither perceived risk nor actual complications impacted participation in postpartum care, suggesting that under-appreciation of pregnancy-related risk is not a primary driver of postpartum visit attendance. Efforts to optimize postpartum care delivery should target other factors that may contribute to suboptimal follow up, with specific focus on high-risk patients, to prevent morbidity over the extended postpartum period.

OBJECTIVE: In women with a singleton pregnancy and a short cervical length (CL), cervical pessary and vaginal progesterone are both used in preterm birth (PTB) prevention. We performed a head-to-head comparison between these two treatments.

STUDY DESIGN: We conducted a multi-center, randomized clinical trial (NCT04300322) at three hospitals in Vietnam. Asymptomatic women with a singleton pregnancy and a CL $\leq$ 25mm (at 16-22 weeks) were randomized (1:1 ratio) to receive either an Arabin® cervical pessary or 200-mg vaginal progesterone daily. Primary outcome was PTB $<$ 37 weeks of any cause. Secondary outcomes were maternal and neonatal complications. We planned to recruit 804 women to assess a 10% absolute risk reduction in PTB $<$ 37 weeks (alpha-error 0.05, power 80%, 5% lost to follow-up). Analysis was by intention-to-treat. In view of the potential harm of pessary on

perinatal mortality and PTB < 28 weeks reported recently in two trials (NTR 4414; NCT02901626), our study was halted in June 2023.

RESULTS: Between May 2020 and May 2023, we randomized 301 women to pessary (N=150) and progesterone (N=151). Seven women withdrew consent and 13 were lost to follow-up, resulting in 281 women available from analysis (Arabin group N=139; progesterone group N=142). The primary outcome PTB < 37 weeks rate occurred in15.1% in the pessary group versus 14.1% in the progesterone group (RR 1.1, 95%CI 0.61 to 1.9). PTB < 28 weeks and perinatal death rates were almost doubled in the pessary group, although these differences did not reach statistical significance(7.9% versus 4.2%, RR 1.9, 95%CI 0.71 to 4.9 and 4.3% versus 2.8%, RR 1.5, 95%CI 0.44 to 5.3; respectively). Other secondary outcomes are presented in the Table.

CONCLUSION: In women with a singleton pregnancy and a CL ≤ 25 mm, pessary was not superior over progesterone in the PTB prevention and might increase the risk of perinatal death and PTB < 28 weeks.

965 Predictive youtube video characteristics as indicators for adherence to accurate water birth guidelines

Erika Fleming[1], Jamie Chen[1], Katherine Collamore[1], Antonia F. Oladipo[2]

[1]Hackensack Meridian School of Medicine, Nutley, NJ, [2]Hackensack University Medical Center, Hackensack, NJ

OBJECTIVE: The accessibility of YouTube videos has made it a popular platform for seeking and sharing pregnancy advice, especially experiences related to "natural" delivery methods like water births. Therefore, it is important to understand which characteristics amassed more views as well as explore the relationship between characteristics and accuracy of information. We aim to assess what components of water birth YouTube videos are predictive of more accurate content with evidence based American College of Obstetricians and Gynecologists (ACOG) guidelines.

STUDY DESIGN: A YouTube search on "water birth" was conducted on 3/9/2023 with a new profile and private browser using the filter "most viewed". The first 100 videos were selected using a strict inclusion criteria, and video characteristics were recorded. Video views ranged from 457,296 to 78,035,874. Reviewers scored videos in accordance with published guidelines using the "ACOG Water Birth Rubric." Chi-square goodness-of-fit and independence tests were performed to assess significance of differences between groups.

RESULTS: Out of 96 videos,13.1% from North America were scored as accurate, versus 15% from other continents (p = 0.575). Only 14.4% of videos from personal channels were accurate, despite comprising 71.8% of all videos in the top 100. All videos from doulas and midwives scored neutral, and there were no videos from healthcare professionals with advanced degrees. Commercial videos had the highest amount of accurate videos at 16.6%. Videos with a supportive figure in the thumbnail had significantly less videos graded as inaccurate (3.5%) compared to those without (18%, p = 0.0003).

CONCLUSION: Patients use YouTube videos as a resource for pregnancy information, particularly for alternative birthing practices. North America has some of the most popular videos and personal channels that often deviate from ACOG guidelines. Our findings highlight an urgent need for healthcare professionals to guide patients towards evidence-based resources, especially for alternative birth practices, and contribute accurate and informative content on such platforms.

966 Seasonality and the causes of spontaneous preterm birth

Ahyoung Choi[1], Han Sung Hwang[2], Han Sung KWON[1], In Sook Sohn[1], Seung-Woo Yang[3], Dong Wook Kwak[4]

[1]Konkuk University Hospital, Seoul, Seoul-t'ukpyolsi, [2]Konkuk University Hospital, Seoul, Seoul Teugbyeolsi, [3]Inje University Sanggye Paik Hospital, Seoul, Seoul-t'ukpyolsi, [4]Ajou University Hospital, Suwon, Kounggi-do

OBJECTIVE: The objective of this study was to investigate the relationship between the four seasons in the northern hemisphere and spontaneous preterm birth (SPB).

STUDY DESIGN: The retrospective study was performed between January 2009 and December 2021. The data of all electronic medical records were retrospectively reviewed in Konkuk University Medical Center, Seoul, Korea. Average temperature and humidity data were obtained from Korea Meteorological Administrations. We excluded the data from women with multi-fetal gestations, pre-eclampsia, gestational hypertension, oligohydramnios, polyhydramnios, GDM, any fetal anomalies, and medico-surgical illnesses that can cause preterm birth. The four seasons are defined as follows: spring (March, April, and May), summer (June, July, and August), fall (September, October, and November), and winter (December, January, and February). The SPB was defined as a fetus born before 36 weeks and 6 days of gestation. SPBs were grouped by the causes of preterm birth: incompetent internal os of the cervix (IIOC), spontaneous preterm labor (PTL), and preterm premature rupture of membranes (PPROM).

RESULTS: The SPB rate in relation to IIOC was highest in the summer and lowest in the fall. SPB incidence due to PTL was higher in the fall and winter. SPB incidence due to preterm premature rupture of membranes was highest in spring and summer.

CONCLUSION: The rate of SPB, by considering the etiologies, had different patterns based on the season. Therefore further studies related to seasonal patterns should consider the etiologies of SPB. The unique seasonal characteristics of the region are closed related to the pregnancy outcome of pregnant women, and further studies are required to help improve pregnancy prognosis.

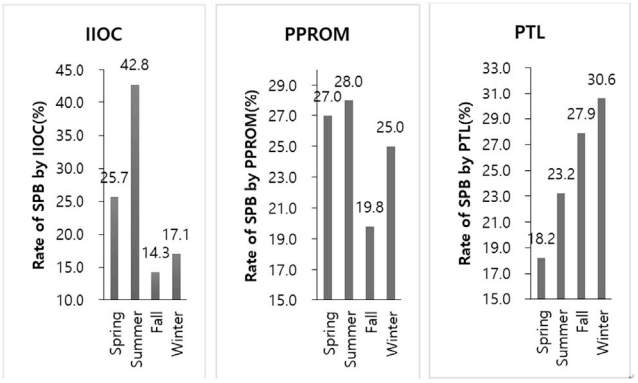

Figure 1 : Rate of cesarean delivery in patients with a prior vaginal delivery across increasing interpregnancy intervals

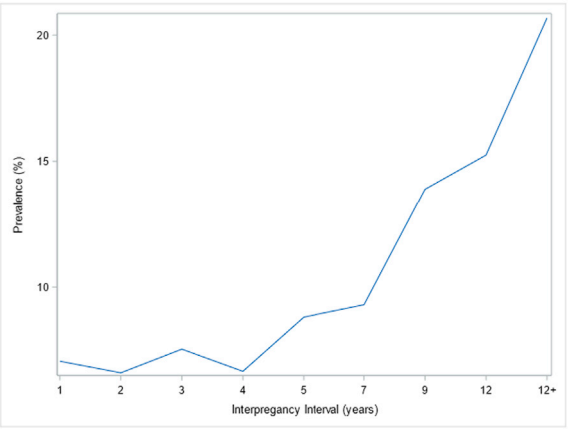

967 The risk for cesarean delivery after prior successful vaginal delivery according to interpregnancy interval

Henry Lesser[1], David Chromey II[2], Celia Gray[3], Priyanka Pawar[3], A Dhanya Mackeen[3]
[1]Geisinger Medical Center, DANVILLE, PA, [2]Gesinger Medical Center, Danville, PA, [3]Geisinger Medical Center, Danville, PA

OBJECTIVE: A history of vaginal delivery is the strongest predictor of future successful vaginal delivery. However, prolonged interpregnancy intervals may reduce the likelihood of success. We sought to determine the pregnancy interval at which the rate of cesarean delivery (CD) in the setting of a prior successful vaginal delivery approaches that of a nulliparous patient.

STUDY DESIGN: We performed a retrospective cohort study between 10/01/2007-12/31/2022. We included those with a successful vaginal delivery and a subsequent delivery-both of which needed to have occurred within our health system. We excluded those with a history of or planned CD, as well as any deliveries complicated by being multifetal or preterm. The primary outcome was the interpregnancy interval at which the rate of CD was similar to that of nulliparous patients. Within this time frame, there were 19,551 nulliparous patients with an overall CD rate of 26.4%. Interpregnancy intervals were grouped by years 1 to 12 and over. The risk of CD was adjusted for age and BMI of the subsequent pregnancy. Frequencies and percentages were used to describe categorical variables. The Cochran-Armitage test of trend was used to assess the rate of CD as the interpregnancy interval increased; the Kruskal Wallis Test was used for continuous variables. P-values <0.05 were considered significant.

RESULTS: 20,331 multiparous patients were included with an interpregnancy interval that ranged from 0.08 years to 22.6 years. The overall CD rate was 8.0%. There was a significant rise in the rate of CD as the interpregnancy interval increased from approximately 7% from years 1-4 to up to 21% at greater than 12 years, $p< 0.01$ (Figure 1).

CONCLUSION: As the interpregnancy interval increases past 4 years, there is a significant rise in the rate of CD; however, even at an interval of 12 years, this rate does not exceed that of a nulliparous patient.

968 Post-Partum Hemorrhage Morbidity Among Obese versus Non-Obese Individuals

Hailie Ciomperlik[1], Rachel L. Wiley[2], Ipsita Ghose[3], Anna Whelan[4], Hector Mendez Figueroa[5], Suneet P. Chauhan[6]
[1]University of Texas, McGovern School of Medicine, Houston, TX, [2]McGovern Medical School at UTHealth Houston, Houston, TX, [3]University of Texas Medical School at Houston, Houston, TX, [4]Grafton, MA, [5]University of Texas Health Science Center at Houston, Houston, TX, [6]University of Texas-Houston Medical School, Houston, TX

OBJECTIVE: Obesity in pregnancy has been an unclear risk factor for postpartum hemorrhage (PPH) risk stratification, and ACOG Obesity in Pregnancy (#230) suggests that body mass index (BMI) $\geq$40 kg/m^2 is a risk factor for atonic PPH only in vaginal deliveries. This study aimed to determine the effect of BMI $\geq$30 kg/m^2 on PPH.

STUDY DESIGN: This retrospective cohort study was conducted on all singletons $\geq$14 weeks with recorded BMI who delivered at a Level IV center for two consecutive years. The exposure group was subcategorized into BMI 30-39 and BMI $\geq$ 40 kg/m^2, with a planned subgroup looking at route of delivery. Data was collected by clinicians, and the composite maternal hemorrhagic outcome (CMHO) was defined as: blood loss $\geq$ 1000 mL, interventions for atony including use of uterotonics (excluding prophylactic oxytocin), mechanical tamponade, surgical intervention, venous thromboembolism, admission to the intensive care unit, hysterectomy, or maternal death. Adjusted relative risks (aRR) with 95% confidence intervals (CI) were calculated using multivariate Poisson regression with robust error variance.

RESULTS: Of 8,623 deliveries in the study period, 8,340 (96.7%) met inclusion criteria, with 2943 (35%) having BMI $<$ 30.0, 3,900 (46%) had a BMI of 30-39.9 kg/m^2, and 1497 (17%) had a BMI of $\geq$40 kg/m^2. CHMO was increased for BMI 30-39.9 (aRR 1.19, 95% CI 1.08-1.31) and $\geq$40.0 (aRR 1.22, 95% CI 1.09-1.38) (Table 1), largely due to increased risk of blood loss $\geq$ 1,000 mL (BMI 30-39.9: aRR 1.45, 95% CI 1.1901.75, BMI $\geq$40: aRR 1.67, 95% CI 1.35-2.07) and uterotonic use (BMI 30-39.9: aRR 1.24, 95% CI 1.11-1.4, BMI $\geq$40: aRR 1.37, 95% CI 1.04-1.59). A subgroup analysis of obese individuals and route of delivery noted that cesarean delivery compared to vaginal delivery among BMI 30-39.9 had an increased risk of CMHO in BMI 30-39.9 (aRR 1.61, 95% CI 1.41-1.85), but had no effect on BMI $\geq$40 (aRR 1.05, 95% CI 0.85-1.30).

CONCLUSION: Obese parturient had a higher risk of hemorrhage related morbidity compared to non-obese patients, with implications for counseling, risk stratification, and intervention trials

969 Prediction of adverse neonatal outcomes at the start of the second stage of labor

Mark A. Clapp[1], Siguo Li[1], Kaitlyn E. James[1], Emily Reiff[2], Sarah E. Little[2], Thomas H. McCoy[3], Roy H. Perlis[3], Anjali J. Kaimal[4]

[1]Massachusetts General Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Massachusetts General Hospital, Center for Quantitative Health, Boston, MA, [4]University of South Florida Morsani College of Medicine, Tampa, FL

OBJECTIVE: To develop a risk stratification for unexpected adverse neonatal outcomes at the start of the second stage of labor.

STUDY DESIGN: This is a retrospective cohort study of individuals at term who reached the second stage or labor and delivered at two hospitals between July 1, 2016, and June 30, 2020. The outcome was unexpected newborn complication, modeled after the Joint Commission metric. Predictor variables included only information that would be known at the start of the second stage, including maternal history, pregnancy characteristics, vital signs, and patterns observed in the nursing documentation of the fetal heart rate tracing (full list below Table). Data were divided into a training and testing sets. Multiple machine-learning variable selection techniques were compared, in addition to standard logistic regression modeling. Discrimination and calibration were assessed between models in the testing set. In the final model (chosen after comparing discrimination and considering parsimony), sensitivity, specificity, negative and positive predictive values were calculated for those in the top 10% and 5% of predicted probabilities in the testing set to better assess model performance.

RESULTS: 19,091 patients were included: 12,994 (68%) in the training and 6,097 (32%) in the testing sets. The prevalence of the outcome in both groups was 4.3%. Random forest, extreme gradient boosting, and Latent Dirichlet Allocation modeling approaches did not result in improved discrimination compared to the logistic regression model. The overall discrimination (AUC 0.65 (95%CI 0.62-0.69)) and calibration were poor, attributed to the rarity of the outcome. However, when examining performance among individuals predicted to be at the highest risk, the model identified patients with >2-3x increased risk of adverse neonatal outcomes.

CONCLUSION: A model constructed using information available at the start of the second stage can be used stratify patient risk for adverse neonatal events. Future work should focus on how this information could be presented and used in clinical practice to improve neonatal outcomes.

Performance of a Prediction Model of Adverse Neonatal Outcomes at the Start of the Second Stage of Labor

Model Characteristic	Predicted High Risk (Top 10%)	Predicted Very High Risk (Top 5%)
Sensitivity	28.3%	18.1%
Specificity	90.3%	95.5%
Positive Predictive Value	11.5%	15.2%
Negative Predictive Value	96.6%	96.3%

Logistic regression prediction model included the following terms:

1) Fetal heart rate tracing: number of observations of absent variability, presence of late decelerations, presence of variable decelerations, presence of minimal variability, presence of fetal tachycardia
2) Maternal characteristics: age, gestational age, BMI, height, hypertension, diabetes, obesity, prior vaginal deliveries, anxiety
3) Labor characteristics: length of labor, use of oxytocin, artificial rupture of membranes, epidural, provider type, presence of blood or meconium-stained amniotic fluid, number of exams, rate of dilation, station at start of second stage, max temperature

970 The effectiveness of a CD bundle with vaginal preparation, Cefazolin and Azithromycin in reducing infections

Gal Cohen[1], Hanoch Schreiber[1], Yakin Amer[2], Hila Shalev-Ram[3], or Eliner[4], Tal Biron-Shental[5], Michal Kovo[6]

[1]Meir Medical Centerartment of Obstetrics and Gynecology, Meir Medical Center, Kfar Saba, Israel, [2]Meir Medical Center, Kfar Saba, Israel, HaMerkaz, [3]Tel-Aviv University, Ra'anana, Israel, [4]Meir Medical Center, Kfar Saba, HaMerkaz, [5]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz, [6]Meir Medical Center, Macabim, HaMerkaz

OBJECTIVE: Recent data suggest that vaginal preparation and adjunctive macrolide administration reduce the risk of infectious morbidity in non-elective cesarean deliveries (CD). We aimed to evaluate the effectiveness of a CD bundle including preoperative vaginal preparation, Cefazolin and Azithromycin administration, as compared to Cefazoline alone, in reducing post-operative infections in CD performed in the second stage of labor.

STUDY DESIGN: As of August 2016, our departmental treatment protocol for prevention of infectious morbidity in second stage CD has been replaced from preoperatively IV 2g Cefazolin alone, to preoperatively IV 2g Cefazolin, IV 500 mg Azithromycin and vaginal preparation (vaginal wash with povidone-iodine). The medical records of all women who underwent CD during the second stage of labor were reviewed, comparing two time periods: 01.2014-08.2016 (control group, Cefazoline alone) and 11.2016-1.2021 (CD bundle group). Obstetric characteristics, post-op infections and neonatal outcomes were compared between the groups. Composite infectious morbidity was defined as the occurrence of one or more of the following: endometritis, surgical site infection (SSI), abscess, urinary tract infection and post-partum fever.

RESULTS: The CD bundle group (n=331) group had lower rates of endometritis, SSI, and composite infectious morbidity compared to the control group (1.2% vs 4.8%, p=0.03; 3.0% vs 7.1%, p=0.049, 6.9% vs 14.3%, p=0.014, respectively). Neonatal outcomes did not

differ between groups. Multivariable regression analysis adjusted for confounders revealed that the CD bundle reduced the risk for the composite infection outcome, with an adjusted OR of 0.30, (95% CI 0.09-0.92).

CONCLUSION: In second stage CD, the addition of preoperative Azithromycin and vaginal preparation to Cefazolin, is efficacious in reducing post-operative infections.

Table 1: Multivariable logistic regression analysis for the composite infection outcome

Variable	adjusted Odds Ratio	95% Confidence Interval	P-value
CD bundle compared to Cefazolin alone	0.30	0.09-0.92	0.036
Maternal age	0.97	0.87-1.08	0.600
Nulliparity	1.00	0.17-5.89	0.998
Gestational hypertensive disorders	0.98	0.10-9.54	0.985
Diabetes Mellitus[a]	0.88	0.16-4.78	0.884
Obesity (BMI>30 kg/m^2)	0.81	0.20-3.30	0.773
Time from rupture of membranes to delivery	0.97	0.88-1.07	0.531
Maternal anemia[b]	0.84	0.16-4.38	0.831
GBS carrier	0.55	0.10-2.93	0.485
Epidural anesthesia (compared to general anesthesia)	1.11	0.33-3.88	0.866

Factors included in the multivariable regression model were independent variables found significantly different between groups in the univariate analysis or thought to have a possible effect on infections rate. Results are reported as adjusted odds ratios and 95% confidence intervals.

[a]Diabetes mellitus includes pregestational and gestational diabetes

[b]Maternal anemia was defined as hemoglobin < 10 g/dL at admission

971 Race and quantitative blood loss in postpartum hemorrhage

Aidan Coon[1], Bhavana Janga[2], Xi D. Plummer[3], Hannah Hill[4], Kelly S. Gibson[5]

[1]Case Western Reserve University School of Medicine, Cleveland, OH, [2]MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH, [3]MetroHealth, Cleveland, OH, [4]MetroHealth Medical Center, Population Health and Equity Research Institute, Cleveland, OH, [5]The MetroHealth System, Cleveland, OH

OBJECTIVE: Black patients are at a higher risk of morbidity and mortality from postpartum hemorrhage (PPH) than White patients in pregnancy. Inadequate estimation of blood loss (EBL) has been suggested as one possible contributing factor which could be mitigated with the adoption of quantitative blood loss (QBL). This study examined whether the transition from EBL to QBL impacted disparities in the magnitude of PPH. We hypothesized that the magnitude of PPH in Black patients with QBL would be higher, reflecting an underassessment with EBL.

STUDY DESIGN: A retrospective cohort study of pregnant patients with documented PPH during delivery at a tertiary safety-net hospital between 2019-2021; QBL was formally implemented at the institution in April 2020. PPH was defined as > 1000mL for C-sections and > 500mL for vaginal deliveries. Patients with chorioamnionitis, macrosomia, multiple gestation, treatment with magnesium, or other diagnoses that influence blood loss were excluded. Included patients underwent chart review for demographic information and documented blood loss. Wilcox rank sum testing and transformation of the outcome variable via natural logarithms with subsequent t-testing were performed comparing EBL to QBL for Black and White patients.

RESULTS: 429 patients were included. 192 patients delivered via C-section (50% Black) and 237 delivered vaginally (43% Black). When comparing QBL to EBL there was a statistically significant increase in average blood loss for C-sections in all patients. The difference was greater in Black (+167mL,p=0.004) versus white patients (+46mL,p=0.004). There was no statistically significant increase in average blood loss for spontaneous vaginal deliveries in Black (+34mL,p=0.5) or White women (-137mL,p=0.2).

CONCLUSION: While EBL tended to underestimate blood loss during C-sections for all patients, the difference was greater for Black patients. Objective tools such as QBL may impact disparities by reducing the potential for individual bias in patient assessment and should continue to be an important tool in PPH bundles of care.

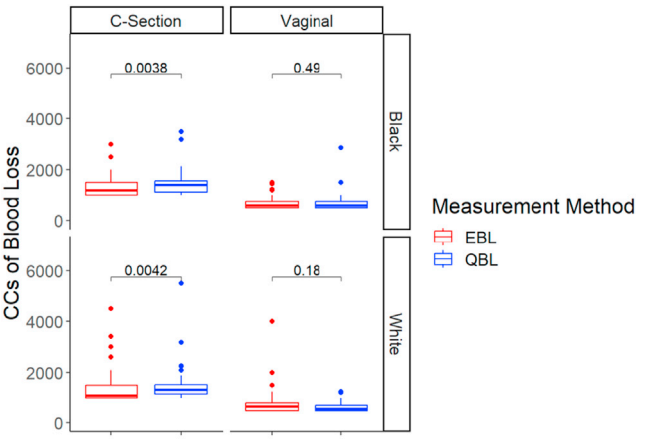

Figure 1. Estimated vs. quantitative blood loss stratified by race and delivery method.

972 Prolonged antepartum admission as an independent risk factor for perinatal depression in patients with PPROM

Rachel Crebessa

University of Tennesse COM, Chattanooga, TN

OBJECTIVE: The objective is to assess antepartum length of stay (LOS) as an independent risk factor for postpartum depression (PPD). Preterm premature rupture of membranes (PPROM) is a known risk factor for PPD- little is known about the effects of prolonged hospitalization on maternal mental health, a widely practiced part of management in this population. If a relationship exists between prolonged hospitalization and PPD, providers may more easily identify patients at risk and offer interventions to improve maternal and neonatal outcomes.

STUDY DESIGN: This is a retrospective cohort study of patients admitted to a single hospital for PPROM from January 2018 to March 2023. Patients were stratified based on antepartum LOS and Edinburgh Postnatal Depression (EPDS) score in the immediate postpartum period were compared. Chart review collected data regarding comorbid maternal and neonatal complications. The following exclusion criteria were used**:** delivery at non-viable gestational age (less than 22 weeks 0 days for this study), beyond 34 weeks 0 days, and fetal demise. We used descriptive and inferential statistics to characterize the population and determine if a relationship exists between prolonged hospitalization and EPDS score in the postpartum period.

RESULTS: 168 patients were eligible for review. Average antepartum LOS was 9 days, average EPDS score was 5.1. Incidence of stay 7 days or greater was 43.4% and 21% of patients had EPDS score greater than 9, indicating moderate to severe symptoms. There was no

significant difference in the incidence of EPDS greater or equal to 9 based on LOS more than 7 days. (OR 0.79, 95% CI 0.37-1.69).

CONCLUSION: This study doesn't suggest a statistically significant relationship between prolonged LOS and EPDS score. Analysis shows prolonged LOS may be protective against depression, a direct opposition to the original hypothesis. Investigators reason this could be due to better neonatal outcomes associated with longer latency periods and delivery at later gestational ages. More studies reviewing larger samples are needed to fully assess this patient population.

973 Placental gene expression: histologic evidence of maternal vascular malperfusion and small for gestational age newborns

Alexa A. Freedman[1], Megan Choi[2], Steve Cole[3], Renee Odom[1], Lauren S. Keenan-Devlin[1], Janedelie Romero[1], Greg E. Miller[1], Jessica Britt[4], Britney P. Smart[1], Linda M. Ernst[5], Ann Borders[6], Amy Crockett[7]

[1]NorthShore University HealthSystem, Evanston, IL, [2]Northwestern University, Evanston, IL, [3]University of California, Los Angeles, Los Angeles, CA, [4]Prisma Health Upstate, Greenville, SC, [5]NorthShore University HealthSystem, University of Chicago Pritzker School of Medicine, Evanston, IL, [6]NorthShore University HealthSystem, Evanston Hospital, Evanston, IL, [7]Prisma Health, University of South Carolina School of Medicine Greenville, Greenville, SC

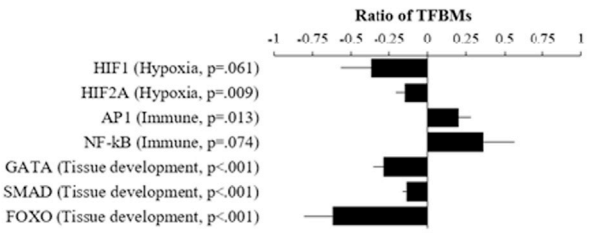
OBJECTIVE: Placental maternal vascular malperfusion (MVM) is a common pathologic histologic finding associated with adverse birth outcomes, including increased risk of delivering a small for gestational age (SGA, < 10% for GA) newborn. Measuring placental gene expression is an innovative approach to evaluate pathways that may increase SGA risk. We investigated differently expressed genes in MVM placentas from newborns with and without SGA.

STUDY DESIGN: This is a secondary analysis of a prospective randomized controlled trial of a racially diverse, low-income sample. Placentas were collected at delivery. A trained perinatal pathologist conducted histologic placental evaluations. Our sample included placentas with ≥1 MVM lesion. Placental genome-wide mRNA profiles were analyzed to identify transcripts showing >1.5-fold differential expression in SGA vs non-SGA newborns, controlling for potential confounders, including GA at delivery, hypertension, newborn sex, race/ethnicity, smoking, and first prenatal BMI. TELiS analyzed transcription factor activity.

RESULTS: Of 700 placentas assessed, 195 exhibited MVM. Among these, 32 (16.4%) delivered an SGA newborn. Bioinformatic analyses for participants with SGA newborns showed elevated activity of key pro-inflammatory signaling pathways (AP1↑15%, p=.013; NF-kB↑29%, p=.074) and unexpected reductions in hypoxia-signaling pathways (HIF1↓23%, p=.061; HIF2A↓10%, p=.009) (Figure 1). Exploratory results showed reduced activity of gene regulation pathways involved in tissue differentiation (GATA↑18%, p< .001; SMAD ↑9%, p< .001; FOXO↑35%, p< .001).

CONCLUSION: Participants with MVM lesions that delivered SGA newborns showed increased inflammatory pathway activity, decreased tissue differentiation and development pathway activity, and an unexpected decrease in hypoxia-associated pathways. These results suggest that inflammation and dysregulated tissue development may play a more prominent role than hypoxia in MVM associated with SGA newborns.

Figure 1. Differential Transcription Factor Activity in Placentas with Maternal Vascular Malperfusion that gave birth to a Small for Gestational Age newborn



X axis is the log2 ratio of transcription factor-binding motifs (TFBMs) in core promoter sequences of differentially expressed genes in those who gave birth to a small for gestational age newborn as compared to those who gave birth to an appropriate for gestational age newborn (reference), among those with placental maternal vascular malperfusion. Error bars reflect standard error.

974 Racial Trends in Opioid Use Disorder (OUD) at Delivery Hospitalization in the U.S. (2010-2020)

Heather N. Czarny[1], Emily A. DeFranco[2], Robert M. Rossi[2]

[1]University of Cincinnati Medical Center, Cincinnati, OH, [2]University of Cincinnati College of Medicine, Cincinnati, OH

OBJECTIVE: Data are lacking on OUD racial and ethnic disparities in pregnancy. We evaluated trends in OUD by race and ethnicity at delivery.

STUDY DESIGN: Retrospective cohort study of U.S. delivery hospitalizations with OUD using data from the National Inpatient Sample. ICD9-10 codes were used to identify OUD diagnoses. OUD rates between racial groups (Asian and Pacific Islander; API; American Indian; AI; non-Hispanic Black; NHB, Hispanic, and non-Hispanic White; NHW) were compared from 2010-2020. The OUD annual percent change (APC) was determined by Joinpoint regression. Adjusted RR of OUD by region (Northeast; NE, Midwest; MW, South, and West) were discerned using the lowest risk region as the referent group.

RESULTS: From 2010-2020, there were 272,610 (0.80%) delivery hospitalizations with OUD in the U.S. OUD rates increased significantly among AI (APC 23.2, CI 18.2-43.9; 2010-2017), NHW (APC 15.2, CI 13.0-18.3; 2010-2016), and NHB (APC, 15.0, CI 9.9-32.6; 2010-2017) groups before stabilizing (Figure). OUD rates increased linearly for API (APC 21.5, CI 17.8-27.6) and Hispanic (APC 11.7, CI 10.5-13.2) groups (2010-2020).

Region of lowest aRR for OUD was determined for each racial group (NHW; West, NHB, Hispanic, and AI; South, API; NE). NHW OUD risk was highest in the NE (aRR 2.1 CI 2.0-2.2) and South (aRR 1.2 CI 1.1-1.3) and similar in the MW and West. NHB OUD risk was increased in the West (aRR 2.2 CI 1.3-1.7), MW (aRR 2.1 CI 1.8-2.4) and NE (aRR 1.5 CI 1.3-1.7) compared to the South. Hispanic OUD risk was increased in the West (aRR 1.2 CI 1.0-1.3) but similar in the MW, NE, and South. AI OUD risk was higher in the MW (aRR 1.83 CI 1.5-2.5) and West (aRR 1.8 CI 1.5-2.1) and similar in the NE and South. API OUD risk was higher in the South (aRR 1.9 CI 1.3-2.6), MW (aRR 1.6 CI 1.1-2.4), and West (aRR 1.5 CI 1.1-2.1) relative to the NE.

CONCLUSION: Rate of OUD peaked among NHW and AI delivery hospitalizations, however it continues to rise among NHB, Hispanic, and API populations with significant regional variation.

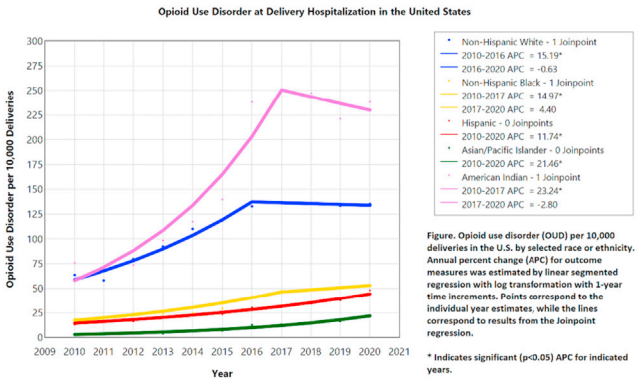


Figure. Opioid use disorder (OUD) per 10,000 deliveries in the U.S. by selected race or ethnicity. Annual percent change (APC) for outcome measures was estimated by linear segmented regression with log transformation with 1-year time increments. Points correspond to the individual year estimates, while the lines correspond to results from the Joinpoint regression.

* Indicates significant (p<0.05) APC for indicated years.

975 Racial Trends in Severe Maternal Morbidity Among Parturients With Opioid use disorder in the U.S.

Heather N. Czarny[1], Emily A. DeFranco[2], Robert M. Rossi[2]
[1]University of Cincinnati Medical Center, Cincinnati, OH, [2]University of Cincinnati College of Medicine, Cincinnati, OH

OBJECTIVE: Opioid use disorder (OUD) is an epidemic in the U.S. and associated with increased risk for severe maternal morbidity (SMM). We evaluated temporal trends and associated risk of SMM among delivery hospitalizations with OUD by race and ethnicity in the U.S. from 2010 to 2020.

STUDY DESIGN: Retrospective cohort study of U.S. delivery hospitalizations utilizing discharge data from the Healthcare Cost and Utilization Project National Inpatient Sample. ICD9-10 codes were used to identify OUD and SMM diagnoses. The primary aim was to compare the rate of SMM among those with OUD over a 10-year period (2010 vs 2020) by racial group (non-Hispanic White; NHW, non-Hispanic Black; NHB, and Hispanic). The annual percent change (APC) in SMM was determined by Joinpoint regression analysis. The adjusted RR of SMM among those with OUD by racial group was determined through multivariate regression analysis adjusting for co-existing risk factors.

RESULTS: From 2010-2020, delivery hospitalizations with OUD accounted for 272,610 (0.8%) births in the U.S. The rate of SMM per 10,000 delivery hospitalizations with OUD significantly increased in NHW (135 to 243; APC 5.9 CI 4.2-8.0) and NHB (385 to 720; APC 9.6 CI 4.3-19.5) parturients (Figure). There was no significant difference observed in the Hispanic parturients (APC 3.8 CI -4.3-16.4).

As compared to the NHW group with OUD, the NHB group with OUD had an increased risk of SMM (aRR 2.3, CI 1.9-2.7). This was not observed among the Hispanic group (aRR 1.1, CI 0.9-1.4) after adjusting for demographic and comorbidity differences. When directly compared to NHB, Hispanic deliveries had a lower risk of SMM (aRR 0.5 CI 0.4-0.6).

CONCLUSION: The rate of SMM at delivery hospitalization has significantly increased among NHB and NHW people with OUD, with SMM increasing disproportionately faster and higher among NHB people. This research can help guide future studies and initiatives on reducing and addressing disparities in maternal screening and delivery of care among those with OUD.

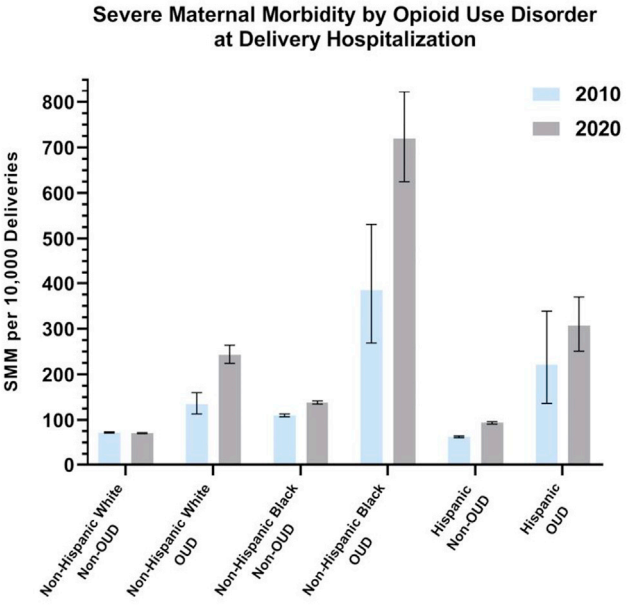

Figure. Severe maternal morbidity (SMM) rate with corresponding 95% CI (per 10,000 deliveries) among non-Hispanic White, non-Hispanic Black, and Hispanic groups with opioid use disorder (OUD) in the U.S. in 2010 compared to 2020. SMM rates of deliveries without OUD by race and ethnicity included for comparison. SMM ICD-9 and ICD-10 diagnosis codes as defined by the Center for Disease Control and Prevention. Transfusion codes were excluded from this analysis to minimize overestimation of SMM.

976 Pregnancy related extracellular vesicles induce breast cancer cell migration and proliferation

Ayelet Dangot[1], Anat Aharon[2], Mor Zavaro[2], Tali hana Ba-Lev[1], Eliana Pickholz[2]
[1]Tel Aviv Sourasky Medical Center, Tel Aviv, HaMerkaz, [2]Israel Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

OBJECTIVE: Pregnancy-associated breast cancer (PABC) is associated with an aggressive disease and shorter survival, indicating that pregnancy itself may promote cancer progression through unidentified mechanisms.

Extracellular vesicle (EVs) are lipid membrane vesicles involved in both tumor progression and modulation of the immune system in cancer as well as induction of angiogenesis in pregnancy. EVs may support cancer growth by inducing immunosuppression and creating a conducive pre-cancerous niche.

Placental EVs compose ~10% of the EV population in pregnant women. The placenta and malignant tumors share several properties, including a high rate of tissue proliferation, invasion, angiogenesis, and immune modulation. We propose a model whereby EVs that normally mediate placental-maternal crosstalk can also promote the aggressive nature of PABC. The study aimed to explore the effects of pregnancy-related EVs on breast cancer cell growth.

STUDY DESIGN: EVs obtained from placental human villous trophoblast cells (HVT) and EVs obtained from plasma of healthy pregnant (HP) and non-pregnant (NP) women were isolated and incubated with target cells. The effects of placental HVT-EVs or pregnancy related EVs on breast cancer cell lines MCF7, luminal (ER+, PR+) and MDA-231, triple negative aggressive cell lines and their related cancer stem cells (CSC), isolated by FACS sorting of ALDH+CD24-CD44+ cells, were compared to the response of a benign cell line, MCF10a. The effects of EVs on cell proliferation and migration were assessed.

RESULTS: Co-culture of placental EVs (HVT-EVs or HP-EVs) with BC cell lines increased migration of MCF7 cells, MDA-231 cells and their related cancer stem cells compared to NP-EVs or untreated wells (Figure 1).

MCF7 CSC and MDA-231 CSC show increased proliferation in XTT tests when exposed to HVT EVs or HP EVs compared to exposure to NP EVs or no EVs. This response was not evident in MCF10a benign breast cancer cells.

CONCLUSION: Pregnancy related extracellular vesicles may contribute to the aggressive nature of pregnancy-associated breast cancer.

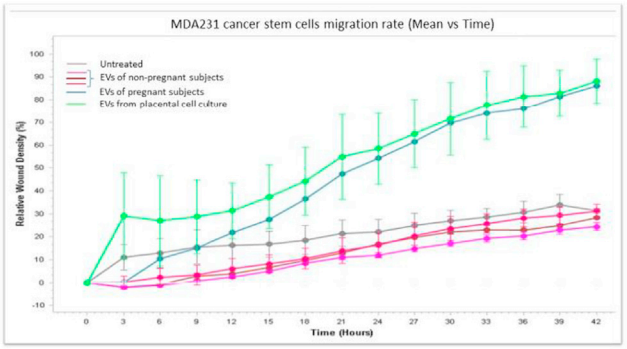

Figure 1: Placental EVs accelerate MDA231 Cancer Stem Cells (ALDH+CD44+CD24-) migration- scratch model. Cells were seeded on a 96 well plate. Scratches were performed in each well, and EV pellets of: 3 non-pregnant subjects (pink lines), pregnant subject (blue line) and placental cells (green line) were added and compared to untreated wells (gray line). The wells were photographed every 3 hours during 42 hours using Incucyte platform. Cell migration and area occupation percentage by migratory cells were calculated.

977 Severe maternal morbidity and 5-year transplant rejection in pregnant patients with history of solid-organ transplant

Kristin C. Darwin, Shridda Nayak, Arthur J. Vaught, Marika Toscano

Johns Hopkins University School of Medicine, Baltimore, MD

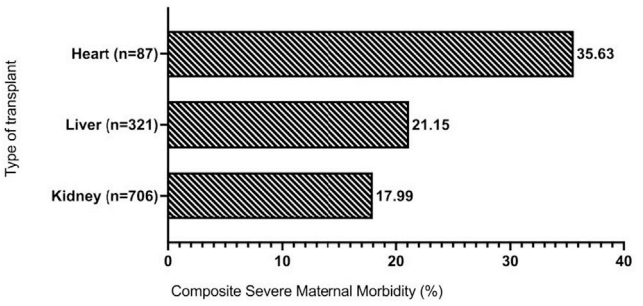
OBJECTIVE: To determine rates of severe maternal morbidity (SMM) and 5-year transplant rejection in pregnant patients with history of kidney, liver, or heart transplant.

STUDY DESIGN: This descriptive study was conducted using the TriNetX Diamond Network, a health research network with data from 92 health care organizations from inception in 2009-8/2023. Patients aged 12-55 years were included if they received a single solid organ transplant prior to pregnancy and had no prior history of transplant rejection. SMM was defined using Centers for Disease Control (CDC) ICD-10 codes for 21 indicators of SMM. The primary outcome was composite SMM. Secondary outcomes included rates of individual indicators of SMM and transplant rejection over time.

RESULTS: A total of 706 kidney, 321 liver, and 87 heart transplant recipients met inclusion criteria. Mean age at index was 31.8, 28.7, and 32.2 years for kidney, liver and heart transplant recipients, respectively. Baseline rates of comorbidities were different between cohorts (chronic hypertension: 52%, 16%, and 30% and diabetes mellitus: 14%, 8%, and 13% for kidney, liver, and heart, respectively). Rates of composite SMM were greatest for heart transplant recipients (35.63%), with morbidity most often from pulmonary edema/acute heart failure (26.43% (n=23)). This was followed by kidney transplant recipients (composite SMM: 17.99%), with acute renal failure occurring in 10.91% (n=77). Liver transplant recipients had the lowest composite SMM (12.15%). Rates of solid organ transplant rejection progressively increased at 1-, 2-, and 5-years post-delivery for all cohorts. Solid organ transplant rejection at 5-years was highest for heart transplant recipients (14.94%), followed by kidney (11.48%), and liver (7.48%).

CONCLUSION: Patients with history of heart transplant had highest composite SMM and highest rates of transplant rejection 5-years post-delivery. The potential impact of pregnancy on long-term outcomes in cardiac transplantation should be further explored.

Figure 1. Rates of composite severe maternal morbidity by type of solid organ transplant



978 Severe maternal morbidity and adverse pregnancy outcomes in patients with history of kidney transplant

Kristin C. Darwin, Shridda Nayak, Arthur J. Vaught, Marika Toscano

Johns Hopkins University School of Medicine, Baltimore, MD

OBJECTIVE: To determine the odds of severe maternal morbidity (SMM) in patients with a pre-pregnancy history of kidney transplant.

STUDY DESIGN: This study was conducted using the TriNetX Diamond Network, a health research network with data from 92 health care organizations from inception in 2009-8/2023. Pregnant patients aged 12-55 years with pre-pregnancy history of kidney transplant and no history of transplant rejection/other transplant complication were compared to those without a history of kidney transplant. Primary outcome was composite SMM defined using Centers for Disease Control ICD-10 codes. Individual indicators of SMM and other adverse pregnancy outcomes (preeclampsia, postpartum hemorrhage, cesarean delivery, and spontaneous preterm delivery) were investigated as secondary outcomes. The TriNetX platform was used to run 1:1 propensity score matching and logistic regression. Variables included in propensity score matching were age, race, ethnicity, chronic hypertension, history of heart disease, diabetes mellitus, and obesity.

RESULTS: After propensity score matching, there were 706 individuals included in each cohort (Table). Patients with history of kidney transplant had higher odds of composite SMM (OR 4.62, 95% CI 3.09-6.92), acute renal failure (OR 8.52, 95% CI 4.37-16.61), sepsis (OR 2.77, 95% CI 1.33-5.76), spontaneous preterm delivery (OR 1.86, 95% CI 1.20-2.89), and preeclampsia (OR 2.32, 95% CI 1.51-3.57). When acute renal failure was removed from composite SMM, there were still increased odds of SMM in the renal transplant group (OR 2.59, 95% CI 1.68-3.99). There was no significant difference between groups in odds of cardiac arrest/ventricular fibrillation (OR 1.17, 95% CI 0.54-2.55), blood transfusion (OR 1.72, 95% CI 0.78-3.78), cesarean section (OR 1, 95% CI 0.81-1.24), or postpartum hemorrhage (OR 1.64, 95% CI 0.90-2.98).

CONCLUSION: Patients with a history of kidney transplant have increased odds of composite SMM, primarily driven by increased odds of acute renal failure.

Table: Cohort comparison before and after propensity score matching

	Before matching			After matching		
	No transplant history	History of kidney transplant	p-value	No transplant history	History of kidney transplant	p-value
Number of patients	9,679,835	706	--	706	706	--
Age, mean (SD)	28.7 (6.27)	31.8 (6.58)	<0.01	31.7 (6.54)	31.8 (6.58)	0.87
Race, n (%)						
White	1,375,548 (14.21)	116 (16.43)	0.09	117 (16.57)	116 (16.43)	0.94
Black	314,661 (3.25)	40 (5.67)	<0.01	40 (5.67)	40 (5.67)	1.00

979 Severe maternal morbidity and adverse pregnancy outcomes in patients with isolated obesity

Kristin C. Darwin, Shridda Nayak, Janice Henderson, Arthur J. Vaught, Marika Toscano

Johns Hopkins University School of Medicine, Baltimore, MD

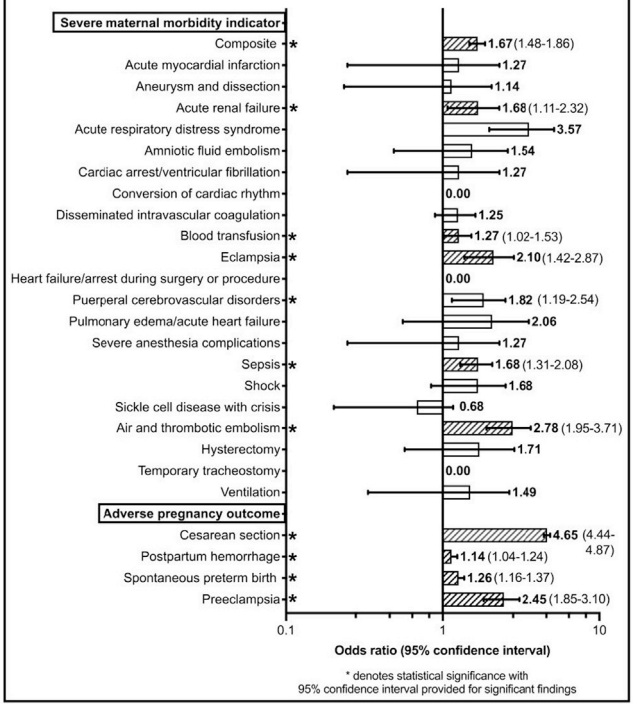
OBJECTIVE: Pregnancy outcomes of people with obesity but without other significant pre-pregnancy comorbidity are not well characterized. The objective of this study was to determine rates of severe maternal morbidity (SMM) and adverse pregnancy outcomes in patients with isolated obesity.

STUDY DESIGN: This study was conducted using the TriNetX Diamond Network, a research network comprising data from 92 health care organizations, from inception in 2009-8/2023. Patients 12-55 years with isolated obesity (body mass index (BMI) greater than or equal to 30 kg/m2 and without other comorbidity) at least one year before delivery encounter were compared to non-obese patients (BMI less than 30 kg/m2). Patients were excluded from both cohorts for any history of hypertension, diabetes mellitus, hyperlipidemia, bariatric surgery, heart disease, prior cesarean section (C/S), multiple gestation, or systemic lupus erythematosus. The primary outcome was composite severe maternal morbidity (SMM), defined using Centers for Disease Control ICD-10 codes. Individual indicators of SMM and adverse pregnancy outcomes (C/S, postpartum hemorrhage, spontaneous preterm birth, preeclampsia) were secondary outcomes. The TriNetX platform was used to perform 1:1 propensity score matching (age, race, ethnicity) and logistic regression. Comorbid conditions were not used to match, as patients with significant comorbidity had been already excluded from the cohort.

RESULTS: After propensity score matching, 46,862 individuals of similar age, race, and ethnicity were included in each cohort. Compared to a healthy, non-obese cohort, pregnant patients with isolated obesity had significantly increased odds of composite SMM. Obese patients also had significantly increased odds of renal failure, blood transfusion, preeclampsia, eclampsia, cerebrovascular disorders (e.g., stroke), sepsis, embolism, C/S, postpartum hemorrhage, and spontaneous preterm birth (Figure).

CONCLUSION: Pregnant patients with isolated obesity are more likely to experience SMM and adverse pregnancy outcomes compared to non-obese, healthy patients.

Figure: Odds of severe maternal morbidity or adverse pregnancy outcome of healthy obese patients compared to healthy non-obese patients



980 Prevention of Obstetric Hemorrhage in Moderate and High Risk Patients: Addition of Prophylactic Misoprostol

Ashlesha K. Dayal[1], Daniel Skupski[2], Liping Lu[3], Shai Bejerano[4], Rosalyn Chan-Akeley[5], Dinakar Velagala[5], Dena Goffman[6]

[1]NYP Queens/ Weill Cornell Medicine, Flushing, NY, [2]Weill Cornell Medicine, Flushing, NY, [3]Columbia University Dept Epidemiology Mailman School of Public Health, Columbia University, New York, NY, [4]Vagelos College of Physician and Surgeons, Columbia University, New York, NY, [5]NYP Queens, Flushing, NY, [6]New York Presbyterian, Columbia University Medical Center, New York, NY

OBJECTIVE: We sought to evaluate the impact of dual pharmacologic prophylaxis with oxytocin and misoprostol for patients at moderate or high risk for postpartum hemorrhage (PPH) on PPH rates, quantitative blood loss (QBL) amounts, and morbidities.

STUDY DESIGN: A quality improvement initiative was undertaken including the addition of buccal misoprostol prophylaxis immediately after delivery for all patients with moderate or high risk for hemorrhage during pre-birth PPH risk assessment, 200 micrograms for moderate risk and 400 micrograms for high risk. 'Oxytocin only' prophylaxis was administered 6/2021 to 4/2022 and 'dual agent' prophylaxis was given 4/2022 to 3/2023. Inclusion criteria: deliveries $\geq$ 20 weeks' gestation with moderate or high-risk pre-birth PPH risk assessment. Exclusion criteria: missing QBL, gestational age $<$ 20 weeks or low PPH risk. The primary outcome was QBL at delivery and total postpartum blood loss (PPBL). Secondary outcomes were PPH rate ($\geq$ 1000 ml) and composite morbidity including hysterectomy, unanticipated surgical intervention, uterine artery embolization, coagulopathy, acidemia (pH $\leq$ 7.35), hypothermia (Temp $\leq$ 36.0), intubation $>$ 24 hours, transfusion of $\geq$ 4u RBC, ICU

admission. Demographic, QBL and morbidity data were captured electronically with morbidities confirmed by chart review.

RESULTS: With dual agent prophylaxis, multiple linear regression analysis showed significantly less QBL at delivery and total PPBL within 24 hours in those having cesarean delivery (Table) and logistic regression analysis showed a significant reduction in composite morbidity (Table).

CONCLUSION: Dual agent prophylaxis with oxytocin and misoprostol immediately after delivery was associated with a significant reduction in PPH rates and composite morbidity in patients undergoing cesarean birth. Prospective studies are warranted to assess replicability and safety.

Adjusted logistic regression analysis for postpartum hemorrhage rate and composite morbidity between time periods and adjusted linear regression analysis stratified by mode of delivery for quantitative blood loss at delivery and quantitative total postpartum blood loss within 24 hours

Logistic regression						
Outcome	Adjusted OR (95% CI)[a]		P value			
PPH rate	0.87 (0.72, 1.06)		0.16			
Composite morbidity	0.32 (0.14, 0.71)		0.005			
Multiple linear regression						
Outcomes	**Total (n=4397)[b]**		**Vaginal (n=2714)[b]**		**Cesarean (n=1683)[b]**	
	β for predictor of time period (95% CI)	**P value**	**β for predictor of time period (95% CI)**	**P value**	**β for predictor of time period (95% CI)**	**P value**
Log-transformed PPBL	-0.02 (-0.07, 0.03)	0.46	0.02 (-0.05, 0.08)	0.58	-0.11 (-0.16, -0.06)	<0.0001
			P for interaction = 0.0097[c]			
Log-transformed QBL	-0.02 (-0.07, 0.03)	0.48	0.01 (-0.05, 0.08)	0.66	-0.10 (-0.15, -0.06)	<0.0001
			P for interaction = 0.0188[c]			

'Oxytocin only' time period is the reference group for both logistic and linear regression analyses.

[a]Adjusted variables for logistic regression: age, BMI, gestational age, race, and insurance status.

[b]Adjusted variables for multiple linear regression: age, BMI, gestational age, race, and insurance status.

[c]Adjusted variables in interaction analyses: age, BMI, gestational age, race, insurance status, delivery method, and an interaction term between time period and delivery method.

β evaluates difference between time periods; the negative result indicates a decrease for the dual prophylaxis time period.

PPBL=total postpartum blood loss within 24 hours. QBL=quantitative blood loss at delivery

982 Maternal and neonatal outcomes associated with route of progesterone administration in frozen embryo transfers

Jaclyn Del Pozzo[1], Insaf Kouba[1], Nicholas Dilena[1], Alexandra Peyser[1], Julia Katz[2], Matthew J. Blitz[1]

[1]Zucker School of Medicine at Hofstra of Northwell, Bay Shore, NY, [2]Zucker School of Medicine at Hofstra of Northwell, Uniondale, NY

OBJECTIVE: To determine if the route of progesterone administration in medicated single euploid frozen embryo transfers (FET) affects the incidence of adverse maternal and neonatal outcomes.

STUDY DESIGN: This was a retrospective cohort of all patients who underwent a single euploid FET at a single IVF center resulting in delivery at one of seven hospitals within a large academic health system in New York from January 2020-July 2023. For patients with more than one pregnancy during the study period, only the first was included for analysis. Patients with multiple gestation pregnancies and those who delivered at less than 23 weeks of gestation were excluded. Patients were divided into three groups based on route of progesterone administration: intramuscular progesterone only (IM), vaginal progesterone only (Vag), and combination of IM and Vag progesterone (IM+Vag). Demographic information, clinical characteristics and pregnancy outcomes were obtained. Maternal and neonatal outcomes were compared between the three groups using ANOVA with $p < .05$ considered significant.

RESULTS: A total of 335 patients were included in the study (Table): 234 IM, 74 Vag, 27 IM+Vag. The patients in all groups were mostly non-Hispanic white, >35 years old, overweight, married, and English speaking. There were no differences in maternal or neonatal outcomes between the three groups.

CONCLUSION: The route of progesterone administration in pregnancies achieved via FET is not associated with adverse maternal or neonatal outcomes. Vaginal progesterone may be considered to minimize discomfort for patients undergoing fertility treatment. Larger prospective studies are still warranted.

Table: Maternal and neonatal outcomes by route of progesterone administration

Characteristics	IM (n=234)	Vag (n=74)	IM+Vag (n=27)	P value
Maternal Outcomes				
Preeclampsia with severe features	17 (7.3)	3 (4.1)	5 (18.5)	0.05

983 Maternal characteristics associated with delivery versus expectant management when presenting with term decreased fetal movement

Jia Jennifer Ding[1], Lisbet S. Lundsberg[2], Jennifer F. Culhane[3], Caitlin Partridge[3], Sarah N. Cross[1]

[1]Yale University School of Medicine, New Haven, CT, [2]Yale, New Haven, CT, [3]Yale University, New Haven, CT

OBJECTIVE: To compare maternal characteristics among patients presenting to triage with decreased fetal movement (DFM) at term who were either admitted for delivery within 24 hours, between 24-48 hours, or after 48 hours.

STUDY DESIGN: This was a retrospective cohort study of patients with singleton gestations delivering at a large hospital system from 2013-2023. Using electronic medical records, patients presenting with the chief complaint of DFM at ≥37 weeks gestation were identified. Using timestamps, latency between DFM presentation and delivery admission was calculated. Patients were grouped into 3 categories: 1) < 24 hours, 2) 24-48 hours, 3) >48 hours. For patients who presented with DFM more than once beyond 37 weeks, the presentation most proximal to delivery was used to calculate time to admission. Comparisons across the categorical measure of time to admission were performed using chi-square tests and multinomial logistic regression, where delivery admission >48 hours is the referent category.

RESULTS: Of the 2,015 patients, 193 (9.6%) were admitted for delivery at < 24 hours, 131 (6.5%) between 24-48 hours, and 1,691 (83.9%) at >48 hours. Patients with non-commercial insurance, Black non-Hispanic or Hispanic, BMI ≥30 at delivery, non-English speaking, with chronic hypertension or hypertensive disorders of pregnancy or with pregestational diabetes were significantly more likely to be admitted >48hours than within 24 hours or within 24-48 hours. Conversely, patients who conceived via IVF were more likely to be admitted within 24 hours than within 24-48 hours or after 48 hours. Following adjustment, non-commercial insurance was

associated with reduced odds of admission < 24 hours, aOR=0.47 (95% CI 0.30-0.71) and reduced odds of admission 24-48 hours, aOR=0.20 (95%CI 0.12-0.32).

CONCLUSION: Among patients presenting with DFM to triage at term, there are significant sociodemographic and clinical variations between those admitted < 24 hours, 24-48 hours, and >48 hours. Even after adjustment, non-commercial insurance was significantly associated with decreased likelihood of admission prior to 48 hours.

Table 1: Maternal characteristics among patients presenting to triage with DFM at term who were admitted for delivery within 24 hours, between 24-48 hours, or after 48 hours

Patient characteristics	Delivery admission within 24h (n=193)	Delivery admission 24-48h (n=131)	Delivery admission >48h (n=1691)	p-value

Data are presented as n (%)

BMI=body mass index; HDP=hypertensive disorders of pregnancy which includes gestational hypertension, preeclampsia with or without severe features, eclampsia, and hemolysis, elevated liver enzymes and low platelets; IVF=in vitro fertilization

984 Rate of clinically significant red blood cell antibody seroconversion in pregnancy

Jia Jennifer Ding[1], Elizabeth Abels[1], Jeremy Jacobs[1], Katherine Kohari[2]

[1]Yale University School of Medicine, New Haven, CT, [2]Yale New Haven Hospital, New Haven, CT

OBJECTIVE: To determine the rate of clinically significant red blood cell (RBC) antibody seroconversion in pregnancy.

STUDY DESIGN: This is a retrospective cohort study of all pregnant patients who delivered at a large multi-hospital system from 2016-2023. In this system, a type and screen is obtained at entry to prenatal care, at time of admission for delivery, prior to administration of Rh(D) immune globulin (RhIG), or as clinically indicated. Patients with missing RBC antibody screen at delivery or no record of type and screen at entry to prenatal care were excluded. All other patients with a positive screen at delivery were categorized as passively immunized due to RhIG, alloimmunized (antibody previously identified during the pregnancy), or seroconverted (antibody not previously identified in the pregnancy). Antibodies were described as clinically significant if associated with hemolytic disease of the fetus and newborn (HDFN) to any degree per ACOG Practice Bulletin 192.

RESULTS: There were 58,912 pregnant individuals with 71,384 eligible deliveries in the time period. 66,615 (93.3%) deliveries had negative RBC antibody screen at delivery and 4,176 (5.9%) deliveries had a positive antibody screen only due to passive immunity from RhIG. Of the remaining 593 (0.8%) deliveries, 351 (0.5%) had clinically significant antibodies associated with HDFN, and among those, 168 (0.2%) seroconverted in pregnancy. 148 (88.1%) of these seroconverted deliveries were Rh positive and 20 (11.9%) of them were Rh negative. The most common antibodies newly acquired in pregnancy were anti-E, anti-c, anti-JkA, anti-C, anti-C, anti-M, and anti-Kell (Figure).

CONCLUSION: Development of new clinically significant RBC antibody in pregnancy occurred at a rate of 0.2% in this large cohort study. Routine third trimester assessment of maternal antibody status may not be indicated due to low likelihood for new clinically significant seroconversion.

Figure: Count of new RBC antibodies developed in pregnancy among seroconverted patients (Some pregnancies were associated with development of multiple new antibodies)

985 Magnetic resonance imaging predicts severe placenta accreta spectrum (PAS) resulting in hysterectomy

Quyen N. Do[1], Christina L. Herrera[1], Yin Xi[1], Catherine Y. Spong[2], Diane M. Twickler[1]

[1]UT Southwestern Medical Center, Dallas, TX, [2]University of Texas Southwestern Medical Center, Dallas, TX

OBJECTIVE: Recent guidelines have identified magnetic resonance (MR) placenta accreta spectrum (PAS) markers. The purpose of this study is to evaluate these markers ability to predict need for cesarean hysterectomy due to PAS.

STUDY DESIGN: This was a single-center retrospective study of pregnancies referred with suspected PAS between September 2019-February 2023. MR reports were prospectively interpreted by two investigators, and MR parameters were extracted from the clinical reports, blinded to clinical outcomes. Medical records were reviewed to determine surgical outcomes, and patients were grouped according to the outcome of hysterectomy. Patient demographics were compared between those who required hysterectomy and those that did not using T-tests and Fisher's Exact test. Univariate logistic regression models and area under the receiver operating characteristics curve (AUC) for MRI variables were generated.

RESULTS: Of 82 pregnant patients with suspicion for PAS and available MR scan, 41 (50%) required cesarean hysterectomy for PAS. No differences in age, race, or gestational age at MR were found (Table 1A). Eleven MR parameters were significantly predictive of the outcome of hysterectomy, with greatest dimension of invasion by MR and radiologist impression the most predictive (Table 1B).

CONCLUSION: MR parameters correlate to severe PAS requiring cesarean hysterectomy, especially greatest dimension of invasion, radiologist impression of invasion, and placental heterogeneity. Further studies with standardized MR reporting of PAS are needed to compare the predictive value to ultrasound, develop an MRI predictive index for severe PAS, and ultimately automate these processes for reproducibility.

Table 1. (A) Demographic characteristics of the suspected PAS study cohort undergoing magnetic resonance imaging (MRI). (B) AUC values of PAS MRI parameters for predicting hysterectomy in pregnant individuals with suspected placenta accreta spectrum.

(A)

Characteristic	Hysterectomy (n = 41)	No hysterectomy (n = 41)	P value
Age at delivery (years)	33.6±5.6	33.0±5.7	0.653
Race/ethnicity			1.0
Black	9	7	
Hispanic	30	32

986 Prospective validation of a Vital-sign augmented Peripartum Risk Stratification Model to predict severe maternal morbidity

Nikolina Docheva[1], Urmila Ravichandran[1], Marci Adams[1], Constandina Kapogiannis-Politis[1], Ekaterina Livschiz[1], Richard Chesis[1], Nirav Shah[1], Richard Silver[1], Beth Plunkett[2]
[1]NorthShore University HealthSystem, Evanston, IL, [2]Evanston Hospital, NorthShore University HealthSystem, Evanston, IL

OBJECTIVE: To build and validate an equitable Vital-sign augmented Peripartum Risk Stratification Model (VPRSM) in the electronic medical record (EMR) to identify in real-time patients at highest risk for severe maternal morbidity (SMM) during delivery admission.

STUDY DESIGN: Using deliveries/terminations from 1/1/13-10/31/20, CDC-defined SMM were identified by ICD9/10 codes, audited and time-stamped using pre-specified diagnostic criteria. Patients with SMM prior to/on admission were excluded. Demographic and clinical (including laboratory and vital sign) data informed the model. One variable from highly correlated pairs (Pearson's r $\geq$0.6) and those without a univariable signal were removed and logistic regression conducted. VPRSM was built on a discrete time-framework and ran continuously behind the scenes in the EMR (7/21/22-12/26/22) for prospective validation. Area under the receiver operating characteristic curve (AUC) was calculated 1 hour before a SMM (for patients with SMM) or at a randomly chosen time point for those without. SMM was characterized as Composite (any SMM), Minor (transfusion < 3 units of blood) and Major (transfusion $\geq$3 units or any non-transfusion SMM). Model data and equity were analyzed by race/ethnicity with White as reference. Fairness metrics were calculated. False Negative Rate (FNR) was chosen to define fairness, with a tolerance of 1.3 times smaller or larger than reference.

RESULTS: 39,521 patients were included of which 2,940 comprised the prospective cohort (Table). The AUC 1 hour before an event was 0.84 (95%CI: 0.80-0.88) for Composite, 0.87 (95%CI: 0.81-0.93) for Major and 0.83 (95%CI: 0.78-0.88) for Minor SMM. Hispanic and Black met fairness criterion. Asian and Other both had FNR lower than White (better performance) but fell outside the tolerance range (Table).

CONCLUSION: VPRSM is a highly predictive equity-based model that incorporates real-time vital sign data to identify patients at highest risk for SMM during delivery admission.

Table. Demographics, clinical characteristics, severe maternal morbidity outcomes and fairness metrics among race/ethnic groups in the prospective validation cohort

BMI: body mass index kg/m², SMM: severe maternal morbidity; N/A: not applicable
a: Minor SMM is defined as <3 units of blood transfused.
b: Major SMM is defined as ≥3 units of blood transfused OR other non-transfusion SMM. Minor and Major SMM are not mutually exclusive.
c: All fairness metrics calculated using the top 15% of VPRSM scores.
d: Disparity is the ratio of parity measure of a group to the reference group i.e., White
Note: Asian, Black, Other and White groups are Non-Hispanic groups

987 Prospective validation of an automated Peripartum Risk Score Model to predict severe maternal morbidity (SMM)

Nikolina Docheva[1], Urmila Ravichandran[1], Marci Adams[1], Constandina Kapogiannis-Politis[1], Ekaterina Livschiz[1], Richard Chesis[1], Nirav Shah[1], Richard Silver[1], Beth Plunkett[2]
[1]NorthShore University HealthSystem, Evanston, IL, [2]Evanston Hospital, NorthShore University HealthSystem, Evanston, IL

OBJECTIVE: To create and validate an automated Peripartum Risk Score Model (PRSM) in the electronic medical record (EMR) to identify patients at highest risk for SMM during delivery admission.

STUDY DESIGN: Using health-system data from all deliveries/terminations from 1/1/13-10/21/20, a retrospective cohort was used to build/validate the PRSM model. A separate prospective cohort (7/21/22-12/26/22) was used for prospective validation. The 21 CDC-defined SMM were identified by ICD9/10 codes, audited and time-stamped using pre-specified diagnostic criteria. Excluded from both cohorts were patients with an SMM prior to/on admission. Model includes demographic and clinical data. One variable from all pairs of highly correlated variables (Pearson's r $\geq$0.6) was removed as were variables without a univariable signal. Logistic regression model was built/ validated to predict SMM using the retrospective cohort and then validated prospectively. SMM was characterized as Composite (any SMM), Minor (transfusion of < 3 units of blood) and Major (transfusion of $\geq$3 units of blood or any non-transfusion SMM).The area under the receiver operating characteristic curve (AUC) was used to assess goodness of fit. Sensitivity and precision were determined.

RESULTS: Descriptive characteristics were similar between the retrospective (n=36,581) and prospective (n=2,940) cohorts with some exceptions.(Table) For Composite SMM, the PRSM had an AUC of 0.8 (95%CI: 0.76-0.84) on retrospective data and an AUC of 0.76 (95% CI: 0.7-0.82) on prospective validation. When the top 30% of prospective PRSM scores were flagged, the sensitivity for the

prediction of Major SMM was 74% and 69% for both Composite and Minor SMM. The sensitivity increased to 90% for Major and 82% for Composite and Minor SMM when the top 40% of patients were flagged with a precision of 8%.

CONCLUSION: We have built and prospectively validated an automated PRSM in the EMR to identify pregnant patients at highest risk for SMM during their delivery admission.

988 Tetanus-diptheria-acellular pertussis (Tdap) vaccine receipt in pregnancy and its association with community-level socioeconomic vulnerability

Sarah G. Downs[1], Caitlin Tedeschi[2], Michelle Hsia[2], David Kline[2], David M. Stamilio[2]

[1]Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC, [2]Wake Forest University School of Medicine, Winston-Salem, NC

OBJECTIVE: To estimate the association between prenatal Tdapvaccine receipt and measures of community-level socioeconomic deprivation, as limitations of existing research preclude an accurate characterization of the relationship.

STUDY DESIGN: A retrospective cohort study of pregnant women who delivered at ≥ 28 weeks at a single tertiary care center between September 1, 2019 and November 30, 2022 for whom prenatal records were available. The primary exposure was socioeconomic vulnerability as measured by the CDC's Social Vulnerability Index (SVI). Patient addresses were geocoded and linked at the census tract level to assign their SVI values. SVI scores are composed of 15 variables organized into 4 themes**:** socioeconomic status, household composition/disability, minority status/language, and housing type/transportation. Scores range from 0-1; greater values indicate greater socioeconomic disadvantage. Automated data abstraction was used to obtain discrete variables from the medical record, including demographics and the primary outcome, Tdapvaccine receipt. The primary exposure was assessed as a continuous and categorical quartile variable. We used multivariable logistic regression to estimate the independent association between SVI and Tdap vaccine receipt.

RESULTS: Of 5190 pregnant women included, the rate of Tdap vaccine receipt was 57%. Women with higher SVI scores had lower odds of Tdap vaccination (aOR 0.51, 95%CI 0.42-0.62). Women in the highest quartile for SVI themes 3 and 4 had lower odds of Tdap vaccination (aOR 0.63, 95%CI 0.50-0.79, aOR 0.69, 95%CI 0.57-0.85, respectively) (Table). Non-English language and public insurance were also associated with lower odds of Tdap vaccine receipt.

CONCLUSION: Pregnant women living in areas with greater socioeconomic disadvantage are less likely to receive the Tdap vaccine. Among SVI themes, racial/ethnic minority status and housing type/transportation appear to drive the inverse relationship between SVI and Tdap vaccine receipt. SVI may be used to identify barriers to prenatal vaccine receipt and thereby guide interventions that seek to enhance vaccine equity.

OBJECTIVE: Vanishing twins (VTs) occur in up to 30% of early twin pregnancies and are associated with increased fetal aneuploidy and challenges for aneuploidy screening in the living twin (LT). These include potential for inaccurate cell-free (cf)DNA results due to a persistent cfDNA signal from the VT for up to 15 weeks. We sought to identify maternal and ultrasound (US) characteristics associated with persistence of cfDNA from a VT.

STUDY DESIGN: Planned secondary analysis of data from a prospective study of VTs at 17 centers between August 2021 – February 2023

aimed to develop a cfDNA algorithm for the LT in pregnancies with a LT and a VT. Monochorionicity, use of a donor egg, or iatrogenic fetal demise were excluded. SNP-based cfDNA screening at ≥9 weeks' gestation evaluated the presence of one or two distinct sets of fetal alleles (signals). Univariate analysis was used to compare maternal and US characteristics among patients with one fetal signal, two fetal signals, or no-call results. Multivariable logistic regression was used to account for confounding.

RESULTS: Of 101 VT pregnancies, 42 had 1 fetal signal, 49 had 2, and 10 could not be determined due to very low fetal fractions . Median maternal age was 34.4 years and 20% conceived with assistance (IVF, ovulation induction and/or intrauterine insemination). Median GA of the LT at VT diagnosis was 9.4 weeks and median GA at cfDNA screening was 13 weeks. A non-viable fetus was visible in 54 and an empty sac in 47 cases (Table 1). Detection of two signals was associated with increasing GA at VT diagnosis (aOR = 1.66; 95%CI 1.19-2.49), a visible non-viable fetus on US (aOR = 3.48, 95%CI 1.05-12.60) and assisted conception (aOR = 6.10; 95%CI 1.19-47.50).

CONCLUSION: Persistence of a second fetal signal was present in approximately half of VT pregnancies in our study and was more common with assisted conception, VT diagnosis after 8 weeks' gestation, cfDNA within 3 weeks of VT diagnosis, and a visible non-viable fetus on US. This information may be helpful in optimizing timing of cfDNA screening in pregnancies with a VT.

Table 1. Maternal and vanishing twin characteristics and number of distinct cell-free DNA signals

990 The impact of pregnancy, maternal and neonatal complications on breastfeeding at the time of discharge

Yael Eliner[1], Moti Gulersen[2], Jordan Eisenberg[1], Marlee Hirsch[3], Erez Lenchner[4], Amos Grunebaum[3], Frank A. Chervenak[3], Eran Bornstein[5]

[1]Lenox Hill Hospital, Northwell Health, New York, NY, [2]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA, [3]Zucker School of Medicine at Hofstra of Northwell, New York, NY, [4]New York University Rory Meyers College of Nursing, New York, NY, [5]Lenox Hill Hospital, New York, NY

OBJECTIVE: Breastfeeding has been associated with significant benefits for both the infant and the mother. Such benefits include, for example, lower risk of childhood infections, obesity, and SIDS, for the infant, and lower risk of developing type 2 diabetes, breast cancer, and ovarian cancer for the mother. We aimed to assess the impact of different pregnancy, maternal and neonatal complications on the prevalence of breastfeeding at the time of hospital discharge.

STUDY DESIGN: A retrospective analysis of the Centers for Disease Control and Prevention, Natality Live Birth database (2019-2021). We compared the prevalence of breastfeeding at the time of hospital discharge between birthing individuals who had a specific pregnancy, maternal or neonatal complication and those who did not using Pearson's chi-square test. We then conducted a multivariate regression analysis to account for potential confounding variables. The results are presented as adjusted odds ratios (aOR) and 95% confidence intervals (CI), with the statistical significance set to 0.05.

RESULTS: A total of 9,104,236 live births were analyzed. The overall prevalence of breastfeeding at the time of discharge from the hospital was 83.3%. The prevalence of breastfeeding and the aORs for different maternal, neonatal and pregnancy complications are displayed in the table.

CONCLUSION: As expected, most pregnancy, maternal and neonatal complications were associated with a decreased prevalence of breastfeeding. Specifically, preterm delivery, pre-gestational diabetes, chronic hypertension, gestational hypertension, eclampsia, cesarean delivery, blood transfusion, unplanned hysterectomy, maternal ICU admission, 5-min Apgar score, neonatal ICU admission, suspected neonatal sepsis, neonatal seizures and congenital anomalies were all associated with decreased prevalence of breastfeeding. These findings may help in guiding hospital and obstetric providers on allocating resources, such as lactation consultants, to this high-risk population.

991 Racial and ethnic disparities in post-cesarean opioid prescribing and pain experiences

Mariana Espinal[1], **Hyagriv Simhan**[2]

[1]for the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD, [2]University of Pittsburgh, Pittsburgh, PA; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: To evaluate whether there are racial and ethnic disparities in post-cesarean delivery (CD) inpatient opioid administration and, among participants assigned to an individualized opioid prescription protocol (IOPP), discharge opioid prescribing and pain experience.

STUDY DESIGN: Secondary analysis of a multicenter trial of participants post-CD randomly assigned to an IOPP or fixed quantity of opioids upon discharge. We included participants who self-reported as non-Hispanic White (NHW), non-Hispanic Black (NHB), or Hispanic. The primary outcome was morphine milligram equivalents (MMEs) used in 24 hours prior to randomization (all participants). Secondary outcomes (IOPP participants) were number of tablets recommended (based on MMEs use in 24 hours prior to randomization) and requested, and pain experience outcomes at 1-week post-discharge. Outcomes were compared by race and ethnicity using bivariable and multivariable analyses.

RESULTS: Of 5464 individuals, 43% identified as NHW, 28% NHB, and 21% Hispanic. Pain score prior to randomization was similar among groups (median 7). MMEs used in 24 hours prior to randomization was higher in NHB and lower in Hispanic vs. NHW individuals (Table). In adjusted analyses, MME use was lower for Hispanic participants (median difference -8.3, CI [-10.2, -6.3]) but similar for NHB (median difference 1.1, CI [-1.8, 4.0]) vs. NHW participants. Hispanic IOPP participants were recommended and requested fewer tablets and were less likely to request an opioid prescription after discharge. In contrast, NHB IOPP participants were more likely to request an opioid prescription after discharge, more likely to have pain and pain interference scores ≥4 on Brief Pain Inventory, and less likely to report improved global impression of change with treatment.

CONCLUSION: Race and ethnicity were associated with post-CD inpatient opioid administration and post-discharge pain experiences. Contrary to prior literature, NHB participants used similar MMEs post-CD and were more likely to request an opioid prescription after discharge, yet still had poorer pain experience-related outcomes.

Table. Primary and secondary outcomes by self-reported maternal race and ethnicity

992 Plasma sFlt-1/PlGF ratio as MoM improves prediction of preeclampsia with severe features within two weeks

Jimmy Espinoza[1], **Vinicius Calsavara**[2], **Elizabeth Lemoine**[3], **Sarah Kilpatrick**[4], **Ravi Thadhani**[5], **S. Ananth Karumanchi**[4]

[1]McGovern Medical School at the University of Texas Health Science Center Houston, The Fetal Center- Children's Memorial Hermann Hospital, Houston, TX, [2]Cedars-Sinai Health System, Los Angeles, CA, [3]University of North Carolina, Durham, NC, [4]Cedars-Sinai Medical Center, Los Angeles, CA, [5]Emory University, Atlanta, GA; on behalf of the PRAECIS Study Group

OBJECTIVE: Cut-off values of the ratio of soluble fms-like tyrosine kinase 1 (sFlt-1) to placental growth factor (PlGF) as preeclampsia biomarker vary with assay platforms. This study compares multiples of the median (MoM) of maternal plasma sFlt-1/PlGF ratio, sFlt-1, PlGF, and conventional clinical and laboratory values to predict preeclampsia with severe features (PSF).

STUDY DESIGN: Secondary data analysis of a cohort study across 18 U.S. centers involving hospitalized hypertensive patients between 23-35 weeks' gestation. Receiver operating characteristic curve (ROC) analyses of maternal plasma biomarkers, highest systolic or diastolic blood pressures, and laboratory values were performed for the prediction of PSF. Their areas under the curve (AUC) were compared and quasi-Poisson regression models were done. Primary outcome**:** PSF within two weeks. Secondary outcomes**:** composite of severe adverse maternal outcomes (HELLP syndrome, placental abruption, eclampsia, DIC, and pulmonary edema) and composite of severe adverse neonatal outcomes [birthweight< 3rd percentile, very preterm birth (< 32 weeks) and fetal/neonatal death].

RESULTS: A total of 543 patients were included. ROC-derived cut-off of 11.5 MoM for sFlt-1/PlGF plasma ratio provided sensitivity (90.6%), specificity (76.9%), PPV (66%), NPV (94.3%) and accuracy for PSF (81.4%) akin to FDA-approved predictive values. This cut-off was used to compare cases (≥ cut-off) and controls (< cut-off). PSF within two weeks was observed in 66% of cases vs. 5.7% in controls (IRR**:** 1.001; p< 0.001). Higher proportion of cases developed composites of severe adverse maternal (IRR**:** 1.001; p=0.028) or neonatal outcomes (IRR**:** 1.002; p< 0.001) than controls (Table 1). The AUC of sFlt-1/PlGF plasma ratio in MoM (0.91) for PSF within two weeks was significantly higher (< 0.05 for all comparisons) than either plasma biomarker alone or any of the other parameters.

CONCLUSION: sFlt-1/PlGF plasma ratio ≥11.5 MoM among hospitalized, hypertensive patients prior to 35 weeks of gestation is independently associated with PSF within two weeks and severe a

993 Plasma sFlt-1/PlGF ratio in mom and severe adverse neonatal outcomes in non-preeclamptic patients

Jimmy Espinoza[1], Vinicius Calsavara[2], Elizabeth Lemoine[3], Sarah Kilpatrick[4], Ravi Thadhani[5], S. Ananth Karumanchi[4]
[1]McGovern Medical School at the University of Texas Health Science Center Houston, The Fetal Center- Children's Memorial Hermann Hospital, Houston, TX, [2]Cedars-Sinai Health System, Los Angeles, CA, [3]University of North Carolina, Durham, NC, [4]Cedars-Sinai Medical Center, Los Angeles, CA, [5]Emory University, Atlanta, GA; on behalf of the PRAECIS Study Group

OBJECTIVE: The adoption of ever-changing clinical criteria to diagnose preeclampsia has hindered progress in the prevention of adverse maternal and neonatal outcomes associated with it. This study compares the ratio of maternal plasma soluble fms-like tyrosine kinase 1 (sFlt-1) to placental growth factor (PlGF), sFlt-1 or PlGF alone, and conventional clinical or laboratory values in the prediction of adverse perinatal outcomes in hospitalized patients with the suspicion of preeclampsia.

STUDY DESIGN: Secondary data analysis of a cohort study across 18 U.S. centers involving hospitalized hypertensive patients between 23-35 weeks' gestation. Areas under the curve (AUC) of multiple of the median (MoM) values of maternal plasma sFlt-1/PlGF ratio, maternal plasma sFlt-1 or PlGF alone, highest systolic or diastolic blood pressures, and laboratory values were compared for the prediction of severe adverse neonatal outcomes [birthweight< 3rd percentile, very preterm birth (< 32 weeks) and fetal/neonatal death]. Quasi-Poisson regression models were done to determine the value of sFlt-1/PlGF ratio in MoM for the prediction of adverse perinatal outcomes adjusted for clinical or laboratory values.

RESULTS: A total of 330 hypertensive patients whose diagnosis of preeclampsia was not confirmed were included. The AUC of sFlt-1/PlGF plasma ratio in MoM (0.73) for the prediction of severe adverse perinatal outcomes was modest but it was significantly higher than highest systolic (0.60, p=0.01) or diastolic blood pressures (0.58, p=0.002), platelet count (0.59, p=0.04), and creatinine (0.59, p=0.01), AST, or ALT (both 0.53, p=0.001) concentrations. However, the AUC of sFlt-1/PlGF plasma ratio in MoM was similar than that of sFlt-1 (0.71) or PlGF (0.73) alone in the prediction of study outcomes. Regression analysis demonstrated that sFlt-1/PlGF ratio in MoM is independently associated with severe adverse perinatal outcomes (IRR**:** 1.002; 95% CI**:** 1.001-1.003; p< 0.001).

CONCLUSION: Angiogenic imbalances is associated with severe adverse perinatal outcomes even if the diagnosis of preeclampsia is not confirmed.

994 The effect of addition of intrauterine suction device to treat postpartum hemorrhage on composite morbidity

Sean Esplin[1], Donna Dizon-Townson[2], Erin A. Clark[3], Brett D. Einerson[4], Lindsey Carlson[5], Li Dong[6], Flint Porter[7], Alexandra G. Eller[5], Jessica Page[6]
[1]Intermountain Medical Center, Murray, UT, [2]Intermountain Health, Sandy, UT, [3]University of Utah, Salt Lake City, UT, [4]University of Utah Health, Salt Lake City, UT, [5]Intermountain Health, Murray, UT, [6]Intermountain Health, Salt Lake City, UT, [7]Intermountain Healthcare, Salt Lake City, UT

OBJECTIVE: We sought to determine if addition of Jada, an intrauterine suction device (ISD), to a standardized algorithm for treatment of postpartum hemorrhage (PPH) as a third line option would result in improved outcomes.

STUDY DESIGN: We performed a retrospective review of outcomes associated with a standard PPH clinical decision support algorithm

with, and without the ISD. All women who delivered in one of 5 hospitals from a single, large healthcare system between 1/1/2022-6/1/2023 who suffered a PPH, defined as quant blood loss ≥ 1000 cc during 24 hr. after delivery, or who received either uterine balloon tamponade (UBT) or ISD due to concern for PPH, were included. Women in the Control Group delivered between 1/1/2022-9/30/2022 when the ISD was not available while those in the Study Group delivered between 10/1/22-6/1/23 after ISD was implemented as third line therapy (1st line - pharmacologic and 2nd line - UBT as needed). The primary outcome was a maternal morbidity composite of blood transfusion, surgical/IR intervention (D&C, B-Lynch, Hysterectomy, or uterine art embolization), need for ICU admit, or massive blood loss (≥ 2,000 cc). Demographic and outcome data were compared using Student t-test, chi-square test and Fisher's Exact Test as indicated.

RESULTS: The overall rate of PPH for the control group vs. the study group was 2.1% (241 PPH/10,925 total del) vs. 3.0% (285 PPH/9,461 total del) and the rate of the primary outcome was 0.8% (161/20,238) vs. 0.92% (167/18,034) respectively. Maternal demographic information and outcomes are in Table 1. There was no significant difference in the rate of the primary composite outcome after implementation of the ISD in the study group compared to the control group [106 cases/9,461 del (1.1%) vs. 95 cases/10,925 del (0.87%); p=0.6].

CONCLUSION: Introduction of the ISD as a third line of treatment for PPH was not associated with a reduction of the composite morbidity of PPH.

Maternal Characteristics PPH Cases	Control Group ISD not available N=241	Study Group ISD available N= 285	P Value

995 The impact of art therapy in women at risk for postpartum depression: a pilot study

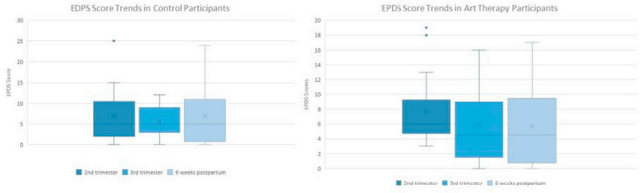
Fatimah Z. Fahimuddin[1], Kathryn Tedeschi[2], Alanna Betts[2], Kelley Kuchinov[2], Noha Ahmed[3], Ria Richards[3], Rachel Paquette[3]
[1]MedStar Washington Hospital Center, Arlington, VA, [2]Sage House Therapy, Reston, VA, [3]MedStar Washington Hospital Center, Washington, DC

OBJECTIVE: Postpartum depression results in great distress for mothers and leads to impaired bonding with newborns. Finding useful interventions and prevention strategies are needed to decrease the growing incidence of postpartum depression.

STUDY DESIGN: A randomized control trial was completed to assess how art therapy during pregnancy may impact women at risk for postpartum depression. Inclusion criteria included age greater than eighteen years, having at least one risk factor for postpartum depression, and receiving prenatal care with plans for delivery at our medical center. Participants were randomized into either the control or intervention group. The intervention group attended six online art therapy sessions during the late second trimester through the early third trimester. All participants completed Edinburgh Postnatal Depression Scale (EPDS) screenings at time of enrollment, in the third trimester, and at six weeks postpartum. Comparison between groups was completed to assess differences.

RESULTS: Of the forty-three participants in the pilot study, twenty-one were in the control arm of the study and twenty-two participants were in the intervention arm. There were no significant differences of characteristics between the groups. The average EPDS score for the control group was 7 and was 8 for the intervention group. Figure 1 shows the ranges of EPDS scores. When comparing differences between the average EPDS scores at the start of participation, in the third trimester, and at six weeks postpartum, there were no statistically significant differences between groups [X^2 (1, N=43)=0.14, p=0.93]. Furthermore, participants' depression screen results did not significantly differ from the controls' when comparing results from the start of participation to the conclusion [X^2 (1, N=43)= 0.03, p=0.86].

CONCLUSION: Participating in art therapy during pregnancy did not have a significant role in reducing EPDS scores in women who are at risk for postpartum depression. However, this is a small pilot study and further investigation on the use of art therapy in the pregnant population is needed.



996 Maternal and neonatal outcomes of pregnancies with PPROM following expectant management or elective termination

Eva Fandozzi[1], Alexandria Sasaki[1], Danielle Browning[2], Christina J. Megli[3]
[1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA, [3]Magee- Womens Hospital UPMC, Pittsburgh, PA

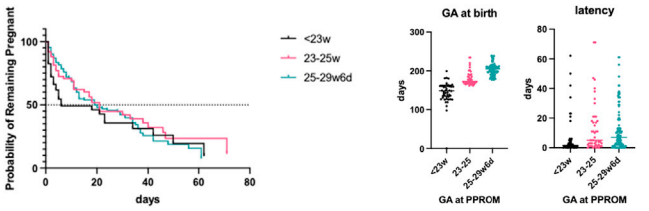
OBJECTIVE: Preterm premature rupture of membranes (PPROM) accounts for one third of preterm deliveries and is associated with significant perinatal morbidity. Neonatal resuscitation has been extended to earlier gestational ages, including for patients with PPROM, but maternal and neonatal outcomes are not well characterized. Our objective is to compare patient outcomes following PPROM at 25-29 weeks to previable and periviable PPROM.

STUDY DESIGN: A retrospective cohort of 233 pregnancies with 256 neonates were identified by maternal ICD-9/10 codes for PPROM who delivered at UPMC between 2015 and 2019. Patients were excluded with congenital anomalies. Detailed chart review was performed. Patients were stratified by gestational age (GA) at

PPROM. Chi square test was used for dichotomous variables and t-test for continuous variables.

RESULTS: Neonatal demographics did not vary by cohort with the exception of GA at PPROM. In the previable and periviable cohorts, 77 pregnancies in our cohort (58%) ended in termination, fetal or neonatal demise. Significantly fewer maternal complications including chorioamnionitis, sepsis, endometritis, and death were observed in patients who underwent elective termination for previable PPROM (p= 0.0053). In our previable cohort, 100% of neonates from pregnancies that were expectantly managed had severe outcomes including late onset sepsis, intraventricular hemorrhage, and chronic lung disease. Neonatal outcomes were statistically significantly different across all cohorts, with increased morbidity associated with earlier GA at PPROM. Maternal morbidity rates were similar across cohorts. All cohorts achieved similar mean latencies.

CONCLUSION: Despite achieving similar GA at birth and latency, earlier GA at PPROM is associated with higher neonatal death rates and severe morbidity in survivors. Moreover, neonatal morbidity is greater than has been reported by gestational age. Maternal morbidity was similar across all cohorts. However, significantly fewer maternal complications were seen in pregnancies with previable PPROM that were electively terminated.



997 The impact of ACOG's 39-week rule on fetal death rates in america: a systematic review

Michael T. Finlan[1], Alisha Goyal[2], Yingting Zhang[3], Vincenzo Berghella[4], Justin S. Brandt[5]

[1]Rutgers Robert Wood Johnson Medical School, Asbury Park, NJ, [2]Sydney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA, [3]Rutgers Biomedical and Health Sciences, New Brunswick, NJ, [4]Jefferson Medical College, Philadelphia, PA, [5]Johns Hopkins Hospital, Baltimore, MD

OBJECTIVE: The "39-week rule," implemented in August 2009, strongly discouraged early term deliveries before 39 weeks without accepted ACOG indications. In this study, we evaluated fetal death rates before and after the 39-week rule in the United States (US) by review of published series.

STUDY DESIGN: Systematic literature searches were performed in PubMed, Cochrane Central Register of Controlled Trials, Embase, Cumulative Index to Nursing and Allied Health Literature, Web of Science, and Scopus databases (January 2009-June 2023). Searches were focused on the 39-week rule and fetal death. In each concept, we identified keywords, subject headings, synonyms, and other related terms to exhaust search results in accordance with PRESS guidelines. We included observational studies that examined fetal death risk pre- and post-implementation of the 39-week rule. Articles were excluded if they were non-English, included non-US population, and included multiple gestations. Two blinded authors reviewed the titles (and the abstract, when necessary). The study was prospectively registered in PROSPERO.

RESULTS: Of 833 articles identified after initial search, 6 peer-reviewed studies met the inclusion criteria. There were 8,726 fetal deaths/7,267,648 total births (0.12%) post-implementation of the 39-week rule, and 8,523 fetal deaths/7,622,439 total births (0.11%) pre-implementation (p< 0.001) (TABLE). Compared to pre-implementation, the odds of fetal death after the 39-week rule were 1.07 (95% confidence interval 1.04-1.11).

CONCLUSION: Implementation of ACOG's 39-week rule, currently used as a quality indicator, resulted in an 7% increased risk of fetal death, compared to pre-implementation of the 39-week rule. Further study is needed to identify other unintended consequences, such as the impact on maternal and neonatal morbidity and mortality, associated with adoption of this policy.

TABLE
Impact of the 39-week rule on fetal death rates in America: results of a systematic review

998 Relationship between intrapartum blood glucose values and adverse outcomes in individuals with diabetes

Michal Fishel Bartal[1], Sarah Nazeer[2], Joy A. Ashby Cornthwaite, RD, CDE[3], Ghamar Bitar[3], Sean C. Blackwell[4], Claudia Pedroza[3], Suneet P. Chauhan[5], Antonio F. Saad[6], George R. Saade[7], Baha M. Sibai[8]

[1]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX, [2]McGovern Medical School at UTHealth Houston, Houston, TX, [3]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [4]Children's Memorial Hermann Hospital, Houston, TX, [5]University of Texas-Houston Medical School, Houston, TX, [6]University of Texas Medical Branch, Galveston, TX, [7]Eastern Virginia Medical School, Norfolk, VA, [8]Hermann Memorial Hospital, Houston, TX

OBJECTIVE: Patients with diabetes mellitus (DM) are typically managed with frequent monitoring and tight control of blood glucose (BG) during labor to reduce adverse outcomes, notably neonatal hypoglycemia (NH). However, there is limited evidence to support this method. Continuous glucose monitoring (CGM) is becoming more ubiquitous for managing DM and may soon replace fingerstick (FS). We sought to evaluate the relationship between intrapartum glucose levels and outcomes using FS and CGM.

STUDY DESIGN: We conducted a multicenter prospective study (11/2021-12/2022) of parturients with pregestational or gestational DM at $\geq$ 34 wks. Cohorts had a blinded CGM (Dexcom G6 PRO) placed from admission through delivery and were monitored with FS according to usual care. Time in the target range (TIR; range 70−110 mg/dL), time above the target range (TAR; >110mg/dL) expressed as % of all CGM readings, and mean glucose was obtained for both CGM and FS. We evaluated the association of these measures with NH and compared CGM versus FS in the prediction of NH and outcomes related to glucose control. Youden index was used to choose the cut-off point for TAR and prediction of NH.

RESULTS: Of 9,479 deliveries during the study period, 202 (2.1%) met inclusion criteria, and 112 (56%) were enrolled (n=7 did not have CGM data). Of these, 45 (40%) had pregestational DM, and 65 (60%) had gestational DM. The mean BG using a CGM was 102 mg/dL (IQR: 89.9,113.5 mg/dL), and the average TIR was 62.1% (IQR:

36.9,85.6). CGM and FS were poor predictors of NH, with no differences in AUC (0.61, 95% CI: 0.49,0.73 vs. 0.54, 95% CI: 0.43,0.65). Using a threshold of time >120 mg/dL (AUC: 0.58, 95% CI: 0.46,0.70) or >130 mg/dL (AUC: 0.55, 95% CI: 0.43,0.67) did not improve prediction of NH. The best cutoff for the prediction of NH was a TAR of 61%, with 23% being above the threshold. The rate of NH was similar for TAR ≥61% vs < 61% (45.8% vs 25.9%, p=0.06) (Table).

CONCLUSION: We could not find a glucose measure by CGM or FS associated with or predictive of neonatal hypoglycemia. Intrapartum management of diabetic patients may need to be re-evaluated.

Table: Neonatal and maternal outcomes by CGM time above range < or ≥ 61%

999 Proof-of-concept testing of vascular closure devices for use in fetal surgery

Braxton Forde[1], Samuel Martin[2], Marc Oria[3], Jordan Kapke[4], Jose L. Peiro[2]
[1]University of Cincinnati Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]University of Cincinnati College of Medicine, Cincinnati, OH, [4]Wisconsin Radiology Specialists, Milwaukee, WI

OBJECTIVE: Prior clinical findings have demonstrated that maternal laparotomy with trans-amniotic trans-uterine suturing of the fetoscopic port site during in utero myelomeningocele repair reduces the risk of membrane rupture. However, due to laparotomy-associated morbidity, we aimed to explore the feasibility of using a vascular closure device for percutaneous trans-amniotic trans-uterine suturing.

STUDY DESIGN: This IRB and IACUC-exempt study utilized sheep undergoing cesarean delivery for other research purposes. At the time of cesarean, size 12 French Checkflo® were inserted in different approaches: (1) Seldinger technique, (2) Seldinger technique insertion of Checkflo® cannula and subsequent use of the Abbott Perclose® device to suture the port site after check flow removal, (3) Abbott Perclose® device utilized in what is described as a "pre-close" technique, where prior to catheter placement, trans-uterine trans-amniotic stitches are placed and the 12 French Checkflo® cannula is inserted over the same guidewire. H&E staining was performed to assess uterine hole closure and amnion-to-uterus fixation.

RESULTS: The Perclose® device effectively sutured the amnion to the uterus in both pre-close and post-close fashion, but the pre-close technique achieved better amnion-to-uterus approximation and more appropriate uterine hole closure (see representative Figure 1). H&E staining revealed that without suturing, amnion separation from the chorion layer occurred, and the uterine hole persisted. The second technique showed partial connection between the amnion and chorion, but inadequate uterine hole closure with amnion shift into the defect. Optimal closure, with secure amnion-to-chorion fixation and uterine closure, was achieved through the pre-close technique (Figure).

CONCLUSION: This proof-of-concept study suggests the potential viability of using vascular closure devices for percutaneous trans-amniotic trans-uterine suturing during fetoscopic surgery. Further animal studies are required to investigate the feasibility of this technique during mid-pregnancy procedures.

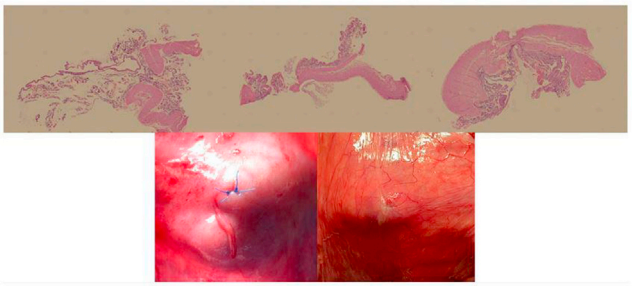

Figure A-F. A. Histology of sheep amnion and uterus after 12 F Checkflo® insertion, with a persistent defect in the myometrial layers and separation of the amnion from uterus. B. Histology of sheep amnion and uterus after 12 F Checkflo® insertion and site closure with Perclose®. The amnion layer remains in proper location and contact with the uterus, however the defect is not appropriately closed. C. Histology of sheep amnion and uterus after placement of sutures with Perclose® used in "pre-close" fashion and subsequent 12 F Checkflo® insertion. The amnion is secured in proper location and the uterine defect is closed. E&F. The uterine and amnion side of the sheep uterus after placement of Perclose® sutures with a well closed fetoscopic port site.

1000 Surgical antibiotic prophylaxis among patients treated for intraamniotic infection

Taylor S. Freret[1], Kaitlyn E. James[1], Mark A. Clapp[1], Anjali J. Kaimal[2], Malavika Prabhu[1]
[1]Massachusetts General Hospital, Boston, MA, [2]University of South Florida Morsani College of Medicine, Tampa, FL

OBJECTIVE: Patients with intraamniotic infection (IAI) are at increased risk of postpartum infection. For patients with IAI receiving broad-spectrum antibiotics and undergoing cesarean delivery (CD), the optimal surgical antibiotic prophylaxis is unknown. We sought to determine if preoperative cefazolin in patients with IAI is associated with reduced postpartum infection.

STUDY DESIGN: Retrospective cohort study of patients with IAI (from ICD10 codes) undergoing unscheduled CD for a ≥24-week singleton between 2017-2022 within one healthcare system. Exclusion criteria were PPROM. The primary exposure was cefazolin administration at delivery; antibiotics received before or on the day of delivery were obtained from the medical record. The primary outcome was a composite of infection within 6 weeks postpartum (ICD10 codes for endometritis, SSI, sepsis, or postoperative infection; or post-delivery positive blood, wound, respiratory, or urinary cultures). Secondary outcomes included incisional complications (cellulitis, disruption, or positive wound culture) and need for oral antibiotics after delivery. Multivariable logistic regression analysis

controlled for delivery BMI, smoking, pregestational diabetes, failure to progress CD indication, duration of membrane rupture (hours), and use of adjunctive azithromycin.

RESULTS: During the study, 1,306 patients with IAI delivered. Pre-delivery antibiotic regimens received varied widely; most included ampicillin and gentamicin (70.5%). Cefazolin was administered to 1,040 (79.6%) of patients. The primary outcome occurred in 227 (17.4%) patients; 51 (3.9%) had an incisional complication and 156 (11.9%) received oral antibiotics after delivery. In the adjusted model, receipt of cefazolin was associated with lower odds of the primary outcome (aOR 0.80, 95% CI 0.69-0.93, p< 0.01), incisional complications (aOR 0.48, 95% CI 0.30-0.76, p< 0.01), and post-delivery oral antibiotic use (aOR 0.82, 95% CI 0.74-0.90, p< 0.01) (Table).

CONCLUSION: Cefazolin surgical prophylaxis for patients with IAI undergoing CD is associated with a reduction in postoperative infection.

1001 Post-traumatic stress disorder two months after a cesarean delivery: a multicenter prospective study

Alizée Froeliger[1], Catherine Deneux-Tharaux[2], Lola Loussert[3], Hugo Madar[4], Loïc SENTILHES[5]

[1]CHU Bordeaux, Bordeaux University Hospital, Bordeaux, Aquitaine, [2]Université Paris Cité, Perinatal Obstetrical and Pediatric Epidemiology Research Team (EPOPé), Center for Research on Epidemiology and Statistics (CRESS), INSERM, Paris, Ile-de-France, [3]Toulouse University Hospital, France, Toulouse, Midi-Pyrenees, [4]Bordeaux University Hospital, France, Bordeaux, Aquitaine, [5]CHU Bordeaux, Bordeaux University Hospital, Aquitaine, France

OBJECTIVE: The prevalence and risk factors of post-traumatic stress disorder (PTSD) after cesarean delivery outside high-risk contexts, remain unclear. Our objectives were to assess the prevalence and risk factors of PTSD two months after cesarean delivery.

STUDY DESIGN: Prospective ancillary cohort study of the TRAAP2 trial, conducted in 27 French hospitals in 2018-2020.

Women expected to undergo cesarean delivery before or during labor at 34 or more weeks of gestation were enrolled.

After randomization, characteristics of the cesarean delivery were prospectively collected. PTSD profile and provisional diagnosis were assessed two months after childbirth by two self-administered questionnaires (IES-R and TES). The corrected prevalence of PTSD was estimated with inverse probability weighting to account for non-respondents. Associations between potential risk factors and PTSD were analyzed by multivariate logistic or linear regression.

RESULTS: Questionnaires were returned by 2,785/4,431 and 2,792/4,431 women for the IES-R and TES, respectively (62.9% and 63.0% response rate). Prevalences of PTSD profile and provisional diagnosis were respectively 9.0% (95%CI 7.8-10.3%) and 1.7% (95%CI 1.2-2.4%). Characteristics associated with a higher risk of PTSD profile were prepregnancy vulnerability factors - young age, high BMI and Africa-born migrant — and obstetric factors related to the context of the cesarean - cesarean delivery after an induced labor (aOR 1.81 95%CI 1.14-2.87), postpartum hemorrhage (aOR 1.61 95%CI 1.04-2.46) and high intensity of pain during the postpartum stay (aOR 1.90 95%CI 1.17-3.11). Women who had immediate skin-to-skin contact with their newborn had a lower risk of PTSD (aOR 0.66 95%CI 0.46-0.98). Women with bad memories of delivery at day 2 postpartum were at increased risk of PTSD (aOR 3.20 95%CI 1.97-5.12). Results were consistent with the IES-R and the TES scales.

CONCLUSION: Around one of eleven women with cesarean delivery have PTSD profile at two months postpartum. Certain obstetric interventions and management of cesarean may influence the risk of PTSD.

Table 1. Factors associated with PTSD profile (defined as IES-R score above the 95th percentile) at two months after a cesarean delivery (n=2,785).

b model with postpartum anemia (defined as hemoglobin level <9 g/dL at day 2);
c model with bad memories of delivery (defined as "bad" or "very bad" memories of childbirth);
d univariate and multivariate logistic regression model after multiple imputation of missing data and multilevel mixed-effects with the random intercept on the center;
e defined as pain assessed at 7/10 or higher by caregivers via the visual analog scale or digital visual scale.

1002 Maternal diet, physical activity, and perinatal outcomes

Ilit Furman[1], Tamar Wainstock[2], Eyal Sheiner[3]

[1]Ben Gurion University of the Negev, Beer-Sheva, HaDarom, [2]Ben Gurion University, Beer-Sheva, HaDarom, [3]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: Maternal physical activity may be associated with significant health consequences to the mother and offspring. The current research aimed to study the association between engagement in physical activity before or during early pregnancy and the risk for adverse pregnancy outcomes including gestational diabetes mellitus (GDM), hypertensive disorders, anemia, preterm delivery (PTD) and low birth weight.

STUDY DESIGN: A prospective cohort study was conducted, consisting of women recruited from two medical centers. Medical records were summarized and self-completed questionnaires regarding physical activity were administered. Pregnancy outcomes were compared between women who engaged or not engaged in physical activity before and during early pregnancy. Multivariable logistic models were used to study the association between engaging in physical activity and pregnancy outcomes, while adjusting for body mass index, maternal age, and socioeconomic status.

RESULTS: The study included 514 pregnant women, 69.5% (n=244) were physically active before or during early pregnancy. The incidence of the studied outcomes are presented in the Table. Women who engaged in physical activity *before* pregnancy were less likely to

suffer from GDM (15.4% vs 2.0%, p=0.022) and PTD (10.2% vs 4.4%, p=0.038). This association was also significant in the multivariable model for engaging in physical activity before pregnancy (adjusted OR for GDM= 0.092 95%CI 0.01 − 0.82 and adjusted OR for PTD95%= 0.375 CI 0.15 − 0.92). Engaging in physical activity *during* early pregnancy was also associated with lower risk for GDM (adjusted OR=0.098 95%CI 0.017 − 0.56) but not for PTD (adjusted OR=0.872 95%CI 0.36 − 2.11).

CONCLUSION: Engaging in physical activity, either before or during the first trimester, is associated with a reduced risk for GDM and PTD.

1003 Prenatal polycystic ovarian syndrome is associated with an increase in severe maternal morbidity

Bharti Garg, Sacha Krieg, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

OBJECTIVE: It has been well known that polycystic ovary syndrome (PCOS) is associated with adverse perinatal outcomes such as pre-eclampsia, preterm birth, gestational diabetes and low birth weight; however, association between PCOS and severe maternal morbidity (SMM) is not well studied. The objective of this study is to examine the association between PCOS and SMM.

STUDY DESIGN: This is a retrospective cohort study using California's linked vital statistics- hospital discharge data (2008-2019). We included singletons, non-anomalous births with gestational age of 23-42 weeks. Outcome of interest was SMM, which was defined as the published list of ICD-9 and ICD-10 diagnoses and procedure codes, provided by Center for Disease Control and Prevention (CDC). As blood transfusion is known to be a major contributor to SMM, we classified non-transfusion SMM (ntSMM) by excluding blood transfusion from the composite score of SMM. Chi-square and multivariable logistic regression analyses were used for analyses.

RESULTS: A total of 4,674,311 patients were included, of whom 14,274 (0.31%) had PCOS. Majority of patients with PCOS were non-Hispanic white (38.9% vs 26.5%; p< 0.001), with private insurance (82.5% vs 47.5%; p< 0.001) and gestational diabetes (23.2% vs 9.4%; p< 0.001). After adjusting for demographics, patients with PCOS had higher odds of SMM (aOR=1.61; 95% CI: 1.42, 1.83) and ntSMM (aOR=2.09 (1.74, 2.51). Among SMM indicators, we found higher odds of blood products transfusion (aOR=1.42 (1.22, 1.65), disseminated intravascular coagulation (DIC) (aOR=1.41 (1.04, 1.92), acute renal failure (ARF) (aOR=2.68; 95% CI: 1.90, 3.80), sepsis (aOR=1.87 (1.30, 2.68), eclampsia (aOR=2.06 (1.39, 3.04), hysterectomy (aOR= 1.68 (1.07, 2.64)), shock (aOR=1.97 (1.11, 3.49)) and pulmonary edema (aOR=2.33 (1.37, 3.96)).

CONCLUSION: Our study found higher odds of SMM in patients with PCOS. The clinicians should keep in mind these complications while treating patients with PCOS. These patients need additional care during pregnancy and parturition.

Table: Associaticn of polycystic ovarian syndrome with severe maternal morbidity using multivariable logistic regression model.

	No PCOS N=4,660,037	PCOS N=14,274	P*	Adjusted odds ratio (95% Confidence interval)**

**Adjusted for maternal race and ethnicity, age, body mass index, education, insurance, parity and smoking status, gestational diabetes and macrosomia.

1004 Postpartum discharge opioid prescribing in nulliparous, term, singleton, vertex pregnancies in opioid-naive birthing people

Joshua George[1], Alex Peahl[1], Daria Stelmak[1], Hsou Mei Hu[1], Chiao-Li Chan[1], Courtney Townsel[2]
[1]University of Michigan, Ann Arbor, MI, [2]University of Maryland, Baltimore, MD

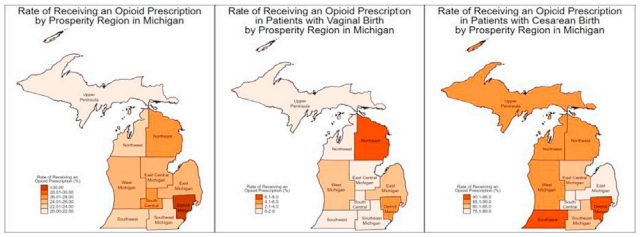
OBJECTIVE: To describe the patient, provider, hospital, and regional predictors of postpartum opioid prescribing for birthing people who had no prior opioid exposure.

STUDY DESIGN: We conducted a retrospective cohort analysis of 89,721 opioid-naive, nulliparous, term, singleton, vertex (NTSV) births from 1/1/2020-1/1/2023, using registry data obtained from a Michigan statewide maternity care collaborative, the Obstetrics Initiative. Patient demographics and clinical data were obtained from registry data. We assessed variation in postpartum prescribing by region. Then, using models adjusted for patient, prescribing provider, hospital, and regional characteristics, we assessed the factors most associated with receipt of a discharge opioid prescription following vaginal and cesarean birth.

RESULTS: Of the 89,721 opioid- naive birthing people, 24,317 (27%) received an opioid prescription at discharge. The prescription rates for Cesarean births was 88% and for vaginal births was 3%. For vaginal births, the prescription rate varied across regions from 0.14% to 6.9%. The regional variation in prescription rates for cesarean birth ranged from 76.4% to 92.8%. In adjusted models, region of childbirth was a predictor of opioid prescribing for vaginal births but not cesarean births. The strongest predictors of receiving an opioid prescription after vaginal birth were 3rd and 4th degree laceration (aOR 7.23, 95% CI 6.12-8.55) and hysterectomy (aOR 7.69, 95% CI 1.33-44.28). The strongest predictors of receiving an opioid

prescription after cesarean birth were non-Hispanic Black (aOR 1.27, 95% CI 1.08-1.49) and Asian race (aOR 1.27, 95% CI 1.02-1.58) and postpartum hemorrhage (aOR 1.15, 95% CI 1.02-1.30).

CONCLUSION: Opioid prescribing after vaginal birth was low, and largely driven by delivery related morbidity. Prescribing after cesarean birth was high and variable, and driven in part by non-clinical factors. Future work is needed to identify and address discrepancies that result in inequitable prescribing patterns.



1005 The clinical experience of prenatal whole genome sequencing in a maternal fetal medicine practice

Jessalyn Gerber[1], Eva Kaplan[1], Erika Pavilus[1], Paddy Tung[1], Edwin Guzman[1], Susan Lashley[1], Leena Shah[2], Natalie Porat[3], Asha Rijhsinghani Bhatia[1], Karen Russo Stieglitz[1], Dyese Taylor[4], David Mclean[1]

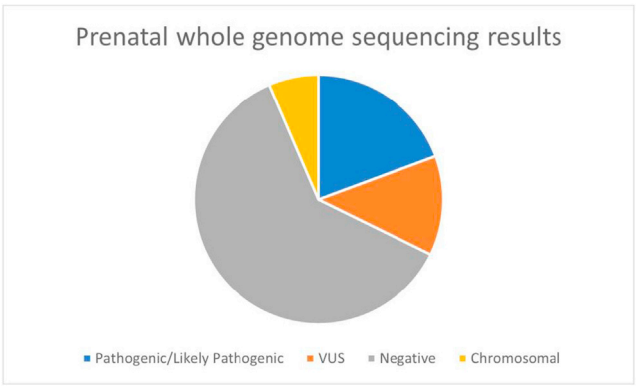
[1]Atlantic Maternal Fetal Medicine, Morristown, NJ, [2]Atlantic Maternal Fetal Medicine, Summit, NJ, [3]Atlantic Maternal Fetal Medicine, N Caldwell, NJ, [4]Atlantic Health Maternal Fetal Medicine, Morristown, NJ

OBJECTIVE: Prenatal whole genome sequencing (WGS) recently became commercially available for patients undergoing CVS and amniocentesis procedures. We sought to characterize the clinical experience and evaluate the results of patients who elected to pursue prenatal WGS.

STUDY DESIGN: Pregnant patients undergoing diagnostic procedures from April 2022 to June 2023 were retrospectively studied. All patients underwent genetic counseling to discuss benefits and limitations of diagnostic testing and to obtain written consent. Inclusion criteria for WGS: patients undergoing CVS/amniocentesis with negative NIPT and at least one structural abnormality and/or a first trimester nuchal translucency measurement $\geq$ 3mm.

RESULTS: A total of 149 CVS/amniocentesis specimens were obtained. Of these, 31 patients elected to pursue WGS. Of the 31 cases, 6 (19%) were found to have a pathogenic or likely pathogenic mutation, 4/31 (13%) were found to have a variant of uncertain significance (VUS) related to clinical phenotype, 2/31 (6%) were found to have an abnormality that would have been detected through standard karyotype and/or chromosomal microarray (one case with 47,XXY and one with a 862 kb deletion within the region of 16p11.2) and 19/31 (62%) were negative.

CONCLUSION: Thirty-two percent of samples yielded a pathogenic/likely pathogenic variant or a VUS in a gene related to a clinical phenotype that would have been missed on chromosomal microarray analysis. These results suggest that WGS should be offered to patients undergoing diagnostic procedures when there is an anomaly noted on fetal ultrasound.



1006 The impact of screening for preeclampsia and preterm birth in nulliparous women: the PREVENTION-pilot study

Louise Ghesquiere[1], Paul Guerby[2], Jean-Claude Forest[3], Yves Giguère[4], Chantale Vachon-Marceau[3], Caroline Carpentier[3], Emmanuel Bujold[1]

[1]Centre de recherche du CHU de Québec-Université Laval, Quebec, QC, [2]Hopital Paule de Viguier, CHU Toulouse, Toulouse III University, Toulouse, Midi-Pyrenees, [3]CHU de Québec, Quebec City, QC, [4]Research Center of the CHU de Québec-Université Laval, QC

OBJECTIVE: Vaginal progesterone in women with a short cervix reduces spontaneous preterm births (sPTB) and particularly the early forms of sPTB. Aspirin initiated in the first-trimester can reduces preeclampsia (PE), particularly early PE, but also other outcomes related to deep placentation disorders (Great Obstetrical Syndromes). We wanted to study the impact of combined 1st trimester (early PE) and 2nd trimester (sPTB) screening on pregnancy outcomes.

STUDY DESIGN: We carried out an historical comparative study. From 2014 to 2017, we recruited nulliparous pregnant women with a singleton pregnancy in the 1st trimester of pregnancy. The 1st trimester FMF screening was performed, but the result remained secret and no intervention was proposed. From 2020 to 2022, we recruited nulliparous pregnant women with the same criteria in the same center to whom we gave the result of the FMF screening (giving aspirin in high-risk women) and to whom we performed a mid-trimester assessment of cervical length (giving vaginal progesterone in cases of short cervix). We compared the pregnancy outcomes, including PTB, sPTB before 37 weeks, 34 weeks, and before 32 weeks along with PE, PE $<$ 37 weeks, and PE$\leq$ 34 weeks, and intra-uterine fetal death (IUFD).

RESULTS: We compared the pregnancy outcomes of 5593 participants who did not receive screening results (2014-2017) with 1703 participants who received screening results (2021-2022). We observed no significant change in terms of PTB and PE overall, but a significant reduction of sPTB$<$ 32 weeks – RR : 0.32; 95%CI 0.13 – 0.83 (p=0.01), and a favorable trend for the other outcomes: all sPTB – RR : 0.83; 95%CI 0.63 – 1.09; sPTB $<$ 34 weeks – RR : 0.60; 95%CI 0.36 – 1.03, p=0.06; early PE – RR : 0.86; 95%CI 0.32 – 2.31; IUFD – RR: 0.75 95%CI : 0.22 – 2.65.

CONCLUSION: The introduction of 1st trimester PE screening combined to a 2nd trimester sPTB screening does not reduce the overall rates of PTB and PE, but can have a significant impact on the most

severe forms of those diseases, particularly sPTB < 32 weeks. A randomized trial with larger number of participants is warranted.

1007 Racial trends in severe maternal morbidity in the US

Kriti M. Goel[1], Heather N. Czarny[1], Emily A. DeFranco[2], Robert M. Rossi[2]
[1]University of Cincinnati Medical Center, Cincinnati, OH, [2]University of Cincinnati College of Medicine, Cincinnati, OH

OBJECTIVE: Racial disparities in severe maternal morbidity (SMM) are well known, however, data regarding temporal trends and regional variation are limited. We sought to evaluate these trends by race and ethnicity.

STUDY DESIGN: Retrospective cohort study of SMM using data from the National Inpatient Sample of US delivery hospitalizations (2010-2020). ICD9-10 codes identified SMM diagnoses as defined by the CDC (excluding transfusion). SMM rates by racial group (American Indian; AI; Asian and Pacific Islander; API; non-Hispanic Black; NHB; Hispanic; non-Hispanic White; NHW) were compared. Joinpoint regression determined annual percent change (APC) and average APC (AAPC) in SMM. Adjusted relative risk of SMM by region (Northeast; NE, Midwest; MW, South, and West) were ascertained using NHW (lowest SMM risk) as the referent group.

RESULTS: Of all US deliveries (2010-2020), the overall rate of SMM (per 100,000) was 673, 1183, 755, 811, and 999 among NHW, NHB, Hispanic, API, and AI cohorts respectively. SMM rate increased for all races (2010-2020 AAPC; NHB 2.3, CI 1.4-3.3, Hispanic 4.6, CI 3.3-6.2, API 2.8, CI 0.6-5.1, AI 3.8, CI 0.5-7.8) except NHW (AAPC -0.1 CI -0.8-0.7).

NHW SMM APC increased significantly after 2017. NHB and API groups had significant APC increases beginning in 2018 while Hispanic APC increased significantly during 2010-2011 and again during 2017-2020. AI SMM APC was significant and constant throughout.

SMM risk was higher in NHB compared to NHW parturients in the NE (aRR 1.8, CI 1.7-1.9), MW (aRR 1.7, CI 1.6-1.7), South (aRR 1.4, CI 1.3-1.4), and West (aRR 1.6, CI 1.5-1.6). SMM risk was likewise significantly higher for the Hispanic cohort (aRR range 1.1-1.4) in all regions except the South. For API, SMM risk was higher (aRR range 1.1-1.2) in every region outside the NE. AI had higher SMM risk (aRR range 1.1-1.2) in the NE and West but not MW and South.

CONCLUSION: All racial groups other than NHW had a significant increase in average APC of SMM (2010-2020). Significant regional and temporal variation in SMM exists between racial groups in the US.

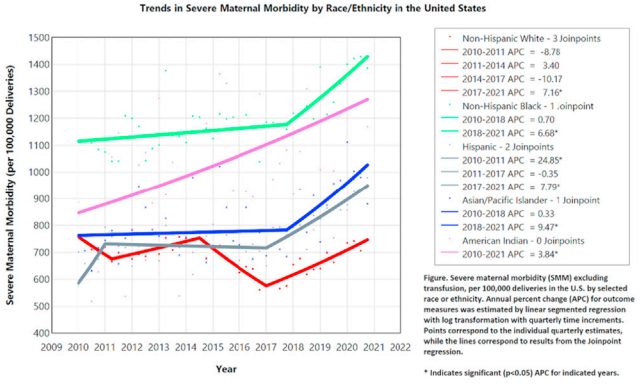


Figure. Severe maternal morbidity (SMM) excluding transfusion, per 100,000 deliveries in the U.S. by selected race or ethnicity. Annual percent change (APC) for outcome measures was estimated by linear segmented regression with log transformation with quarterly time increments. Points correspond to the individual quarterly estimates, while the lines correspond to results from the Joinpoint regression.

* Indicates significant (p<0.05) APC for indicated years.

1008 Risk of severe maternal morbidity among pregnancies resulting from infertility treatment

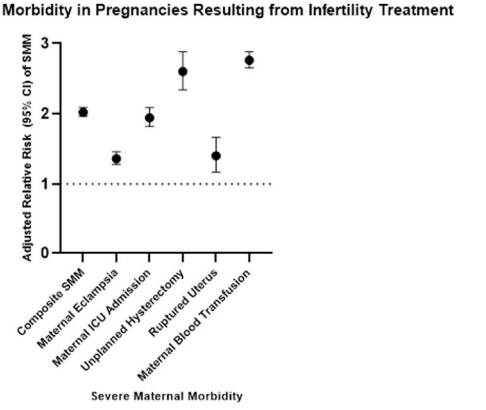
Kriti M. Goel[1], Emily A. DeFranco[2]
[1]University of Cincinnati Medical Center, Cincinnati, OH, [2]University of Cincinnati College of Medicine, Cincinnati, OH

OBJECTIVE: As infertility rates rise in the US, more women are seeking infertility treatment. Though there is much to gain from infertility treatments (IT), there are well-documented risks associated with resulting pregnancies. Despite the rising number of IT pregnancies, data on the relationship between IT and severe maternal morbidity (SMM) are limited.

STUDY DESIGN: Retrospective population-based cohort study of all singleton US live births using vital statistics birth certificate records, 2014-2019. Demographic, medical, and pregnancy factors were compared between pregnancies resulting from infertility treatment and those not. The primary outcome was composite SMM, defined as maternal ICU admission, eclampsia, blood transfusion, unplanned hysterectomy, or ruptured uterus. Multivariate logistic regression estimated the relative influence of infertility treatment on SMM risk in pregnancies after adjustment for co-existing risks.

RESULTS: Of 22,568,980 singleton live births, 299,069 (1.8%) resulted from IT. Composite SMM rate was 0.70% in pregnancies without IT, and 2-fold higher (1.4%) among those with IT, adjRR 2.02 (95% CI 1.96, 2.09). IT was also associated with significantly increased risk of all individual measures of SMM, even after adjusting for confounding variables (figure). IT pregnancies resulting specifically from fertility enhancing drugs (FED) had 60% increased risk of composite SMM, adjRR 1.62 (95%CI 1.53, 1.71) and those with assisted reproductive technology (ART) had 50% increased risk, adjRR1.51 (95%CI 1.22, 1.89) compared to pregnancies without IT. Unplanned hysterectomy and blood transfusion risks were over 3-fold increased with ART, adjRR 3.25 (95% CI 2.89, 3.65) and adjRR 3.43 (95% CI 3.26, 3.61), respectively.

CONCLUSION: Pregnancies achieved following infertility treatment in the US are associated with significantly increased risk of SMM. These findings may inform counseling on pregnancy risks among those seeking fertility treatment and decisions regarding acuity level of care access for prenatal care and delivery planning.



Referent group: pregnancies without infertility treatment
Adjusted RR: covariates included maternal black race, maternal age 35 years and greater, and Medicaid status

1009 Surgical site infection severity in patients receiving non-cephalosporin antibiotics at time of cesarean section

Clara Grayhack[1], Mary Angelides[1], Kristin C. Darwin[2], Marie Bielman[2], Devon Ramaeker[3], Michael M. Aziz[3], Jaden Kohn[2], Jeanne Sheffeild[2], Arthur J. Vaught[2]
[1]West Penn Hospital- Allegheny Health Network, Pittsburgh, PA, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Allegheny Health Network, Pittsburgh, PA

OBJECTIVE: To determine severity of surgical site infections (SSI) occurring in patients receiving cephalosporin versus non-cephalosporin based prophylaxis at time of cesarean section (CS).

STUDY DESIGN: This is a retrospective chart review of all SSIs occurring at two tertiary care centers. Inclusion criteria included women who had CS from 1/1/2016 to 12/31/2022. Exclusion criteria included combined delivery of multiples. Our primary outcome was development of organ space SSI. Secondary outcomes included postpartum endometritis, incisional infection, postpartum readmission, and other indicators of maternal morbidity data was analyzed using standard statistical tests.

RESULTS: We identified 134 patients with SSI**:** 112 received a standard (cephalosporin-based) regimen and 22 received a non-standard (non-cephalosporin-based regimen). Cohorts were similar in demographics and medical co-morbidities (Table). Those in non-standard cohort were more likely to develop an organ/space SSI ($p = 0.04$) and require hospital readmission ($p = 0.05$). There were also higher rates of composite procedures (return to OR, hysterectomy, drain placement) in the non-standard group, but did not reach significance. 59% (n=13) of patients in the non-standard group went on to receive a penicillin analogue for subsequent treatment without allergic reaction.

CONCLUSION: Patients with SSI who received non-standard (non-cephalosporin antibiotics) regimens at CS were more likely to develop organ/space SSI and experience hospital readmission. Further, the majority of the non-standard cohort subsequently received penicillin analogues noting the importance of allergy testing in reducing SSI related morbidity and associated resource utilization.

1010 The relationship between platelets indices and hypertensive disorders of pregnancy

Myah Griffin[1], Anais Hausvater[2], Ariel Schaap[2], Ashley S. Roman[2], Yuhe Xia[2], Dana R. Gossett[2], Gwendolyn Quinn[2], Jeffrey Berger[2], Christina A. Penfield[2]
[1]NYU Langone Health, Atlanta, GA, [2]NYU Langone Health, New York, NY

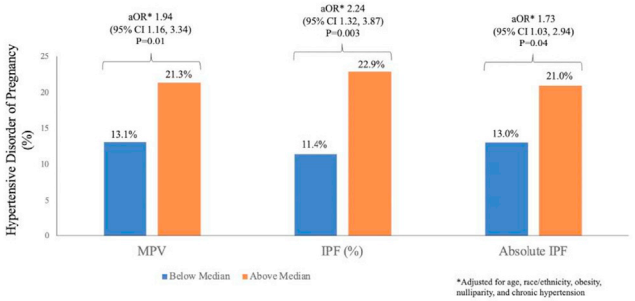
OBJECTIVE: The underlying mechanism of hypertensive disorders of pregnancy (HDP) is unclear. Aspirin, a well-known platelet function inhibitor, is indicated in high-risk pregnancies for the prevention of preeclampsia. We sought to investigate the relationship between platelet indices (count, size, and production/immaturity) and HDP.

STUDY DESIGN: This was a prospective cohort of pregnant participants followed from the 1st trimester between 2/2022 to 6/2022. Routine platelet indices obtained prospectively during prenatal care and delivery were compared between those who developed HDP and those who did not. We assessed platelet count (by trimester), mean platelet volume (MPV, an assessment of platelet size), and immature platelet function (IPF, an assessment of platelet production/immaturity) measured as percent (%) and absolute count. Platelet indices are presented as median (25th,75th %ile) and compared between groups via Mann-Whitney U test. Data are presented as adjusted odds ratio (95% CI) following multivariable logistic regression.

RESULTS: Overall, 78 of 459 (17.0%) developed HDP. While age and race/ethnicity did not differ, obesity (29.5% v. 13.6%, $p< 0.01$) and chronic hypertension (12.8% v. 5.8%, $p< 0.05$) were more frequent in those who developed HDP. There was no significant difference in platelet count in the 1st trimester, 2nd trimester, or at delivery in those with or without HDP. In contrast, people who developed HDP had higher MPV (11.7 fL [10.8,12.4] v. 11.1 fL [10.5,12.0], $P_{adj}=0.005$), IPF% (7.3% [4.9,10.7] v. 5.9% [4.2,9.2], $P_{adj}=0.025$), and absolute IPF (16.4 $x10^9$ [11.2,20.4] v. 13.3 $x10^9$ [9.3,17.4], $P_{adj}=0.022$) than those without. When stratified by the median, the prevalence and adjusted odds of HDP increased with increasing MPV, IPF (%), and absolute IPF. (Figure).

CONCLUSION: Platelet indices of size and production/immaturity were significantly increased in those with HDP, suggesting that platelets play an important role in HDP development. These data support further investigation into platelet activity and the role of targeting platelets with aspirin to prevent HDP.

Figure. Prevalence and Adjusted Odds of HDP with Increased Markers of Platelet Size and Immaturity



1011 Routine TVUS at the time of anatomy scan: to do or not to do?

Olivia Grubman[1], Mackenzie Mitchell[2], Thomas Owens[3], Mia A. Heiligenstein[4], Tirtza Spiegel Strauss[5], Elianna Kaplowitz[6], Zainab Al-Ibraheemi[7], Graham Ashmead[8], Lois Brustman[9], Farrah N. Hussain[1]

[1]Mount Sinai West, New York, NY, [2]Mount Sinai, New York, NY, [3]Mount Sinai West, New York, NY, [4]Stony Brook University Hospital, Amityville, NY, [5]Maimonides Medical Center, New York, NY, [6]Mount Sinai Hospital, New York, NY, [7]Mount Sinai West, N Caldwell, NJ, [8]Roosevelt Hospital, New York, NY, [9]St. Luke's Roosevelt Hospital Center, New York, NY

OBJECTIVE: There are no universal guidelines for transvaginal ultrasound (TVUS) at time of anatomy scan. TVUS can provide information on placental location and cervical length (CL), but may lead to more interventions. As a quality assurance initiative, a universal TVUS (UTVUS) protocol at the time of anatomy scan was started at our institution. This study was conducted to assess whether there was a decrease in preterm birth (PTB), postpartum hemorrhage (PPH), and neonatal intensive care unit (NICU) admission once UTVUS was implemented.

STUDY DESIGN: This was a retrospective cohort study performed on singleton gestations from February 2021-January 2022. During the first six months of the study period, patients only had a TVUS based on risk factors (history of cervical procedure, history of prior PTB, placenta appears low lying or cervix appears short on abdominal ultrasound) (pre group). The second half of the study period, UTVUS was implemented at the time of anatomy scan (post group).

RESULTS: A total of 2118 patients were included. There were 1037 patients in the pre group, of which 161 underwent TVUS based on high risk factors. The post group/UTVUS included 1081 patients. Regarding patient characteristics, patients in the pre group had statistically significant earlier gestational age at first TVUS ($p< 0.0001$), were less likely to have had a prior PTB < 36 weeks ($p=0.03$), and were more likely to have a history of cervical procedure ($p=0.0006$) than patients in the post group. However, the proportion of patients with PTB, PPH, or NICU admission did not significantly differ between the two groups even after adjusting for cofounders ($p >0.05$).

CONCLUSION: Our data shows that UTVUS did not decrease adverse pregnancy outcomes. In addition, the implementation of UTVUS increases discomfort for the patient, duration of the scan and is an additional cost. Therefore, surveillance by abdominal ultrasound may be reasonable with addition of TVUS based on risk factors.

Table 1. Patient Demographics & Univariable and Multivariable Analysis of Primary Outcomes

	Pre UTVUS (n=1037)		Post UTVUS (n=1081)		P-Value

1012 The association between uterine fibroid size and number and risk of preterm birth

Moti Gulersen[1], David Krantz[2], Burton Rochelson[3], Matthew J. Blitz[4]

[1]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA, [2]Zucker School of Medicine at Hofstra of Northwell, Melville, NY, [3]Zucker School of Medicine at Hofstra of Northwell, Manhasset, NY, [4]Zucker School of Medicine at Hofstra of Northwell, Bay Shore, NY

OBJECTIVE: While the association between uterine fibroids and preterm birth (PTB) is well known, data regarding whether fibroid characteristics such as size or number modifies such risk are limited. Therefore, we aimed to evaluate the association between uterine fibroid size and number and risk of PTB.

STUDY DESIGN: Multicenter retrospective cross-sectional study of all patients who had a prenatal ultrasound at ≥ 18 weeks and delivered from 2019-2022. When fibroids were identified on ultrasound, their characteristics were documented. Patients with more than one delivery during the study period had only their first included for analysis. The risk of PTB, stratified by gestational age (< 37, < 34, and < 28 weeks), was assessed based on fibroid number (1, 2, ≥3) and size (largest dimension < 5cm, 5-10cm, >10cm) compared to patients with no fibroids. Multivariate logistic regression was performed to adjust for potential confounders. Data were presented as adjusted odds ratios (aOR) with 95% confidence intervals (CI).

RESULTS: Among the 65,590 patients studied, 4,421 (6.7%) had at least one fibroid. The prevalence of PTB was 8.7%. The presence of any fibroid, regardless of size or number, was associated with an increased risk of PTB < 37 weeks (Table). Increasing fibroid number and size were associated with higher risks of PTB < 37 weeks. Patients with 2 and ≥3 fibroids were at increased risk of PTB < 34 and

< 28 weeks compared to those with no fibroids. Increasing fibroid size was also associated with an increased risk of PTB < 34 weeks. Patients with fibroids >10cm were at increased risk of PTB < 28 weeks compared to those with no fibroids.

CONCLUSION: Data from this large cohort suggest that fibroid characteristics such as size and number are associated with the PTB and impact the severity of PTB. Providers should consider and inform these risks while caring for pregnancies with prenatally detected uterine fibroids.

Table 1. Association between fibroid number and size and preterm birth.

		aOR* (95% CI)

1013 Preterm delivery and the risk for childhood celiac disease of the offspring

Gil Gutvirtz[1], Gali Pariente[2], Tamar Wainstock[3], Eyal Sheiner[4]

[1]Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Metar, HaDarom, [2]Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Klahim, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom, [4]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: Preterm delivery is the endpoint of a multifactorial process resulting in a premature birth of the neonate. Some immunological disorders causing an immune-mediated inflammation, have been linked to preterm delivery, and women carrying these traits may pass them along to their offspring. As celiac disease is an immune-mediated disease, we investigated whether children born preterm (< 37 weeks) are at an increased risk to develop celiac disease.

STUDY DESIGN: A large population-based cohort study of singleton deliveries in a tertiary hospital between the years 1991 and 2021 was conducted. The risk of celiac disease was compared between children (up to the age of 18 years) born preterm and children born at term. Data for celiac disease diagnosis of the offspring were extracted from community-based clinics and hospitalization records. Kaplan-Meier survival curve was used to compare the incidence of celiac disease between the study groups. A multivariable Cox proportional hazards model was used to control for confounders.

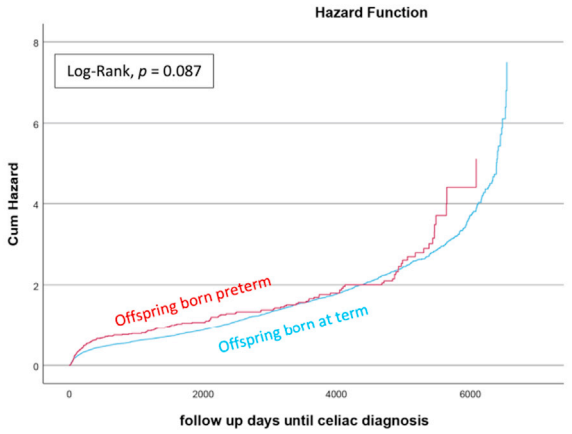
RESULTS: A total of 356,109 singleton deliveries were included, of which, 24,511 deliveries (6.9%) were preterm. Children born preterm had higher rates of celiac disease as compared to children born at term (0.7% vs 0.5%, p=0.012, Figure). However, the Kaplan-Meier survival curve illustrated comparable cumulative incidence of celiac disease in preterm and term born offspring (Log Rank, p=0.087, Figure). When using a Cox proportional hazards model, controlling for maternal celiac disease, maternal age and small for gestational age (SGA) neonates, being born prematurely was not associated with celiac disease (adjusted hazard ratio (HR)=1.14, 95%CI 0.97-1.34, p=0.103, Figure).

CONCLUSION: Being born prematurely is not a risk factor to develop childhood celiac disease.

Figure. The association between being born prematurely and celiac disease: Univariate analysis, Kaplan Meier survival curve and results from a Cox proportional hazards model

	Preterm delivery (n=24,511)	Term delivery (n=331,598)	Odds Ratio (95% CI)	Adjusted* HR (95% CI)
Celiac disease	163 (0.7%)	1797 (0.5%)	1.22 (1.04 – 1.44)	1.14 (0.97 – 1.34)

* Adjusted for maternal celiac disease, maternal age and SGA (<5th percentile for gestational age and gender)



1014 Predictors of antibiotic redosing in cesarean deliveries with excessive blood loss

Laura C. Ha[1], Naomi Greene[2], John A. Ozimek[2]

[1]Cedars-Sinai Health System, Los Angeles, CA, [2]Cedars-Sinai Medical Center, Los Angeles, CA

OBJECTIVE: Surgical site infections occur in up to 15% of patients after cesarean delivery, and elevated blood loss during surgery is associated with postoperative infectious complications. Multiple societies recommend that surgical patients who experience excessive blood loss should receive an additional intraoperative dose of the pre-incision antibiotic. However, these guidelines are not consistently followed. We sought to examine factors associated with receiving a redose of preincision antibiotic in cesarean deliveries with excessive blood loss.

STUDY DESIGN: A retrospective cohort study of all patients who underwent cesarean delivery at a single site from October 2018 - April 2022 with an estimated or quantitative blood loss > 1.5 liters. Demographic and pregnancy data were abstracted from the electronic medical record. The relationship between blood loss, baseline characteristics, and antibiotic redose was described by univariable analysis. We identified factors associated with antibiotic redose using multivariable logistic regression.

RESULTS: Of 113 patients who met criteria for redose, 35 (31.0%) were given an additional dose of preincision antibiotic. The median blood loss was 2000 mL (IQR 1800 - 3000mL). 44 (38.9%) patients underwent a cesarean hysterectomy. Patients were more likely to receive a redose if they had higher blood loss (p=.0002), cesarean hysterectomy (p< .0001), or delivered at an earlier gestational age (p=.007) (Table). After adjusting for confounders, only cesarean hysterectomy was still an independent predictor of antibiotic redose (aOR 4.56, 95% CI 1.59 - 13.06).

CONCLUSION: Patients with blood loss > 1.5 liters during cesarean delivery were more likely to receive the recommended redose of

preincision antibiotics if they underwent cesarean hysterectomy. Overall compliance with the recommendation to redose antibiotics in cesarean deliveries with excessive blood loss was suboptimal, and measures should be taken to improve redosing in all patients who meet criteria.

1015 The Effect of latent-phase duration on pregnancy outcomes in nulliparas undergoing induction of labor: Meta-analysis

Yara Hage Diab[1], Misooja Lee[2], George R. Saade[1], Tetsuya Kawakita[1]

[1]Eastern Virginia Medical School, Norfolk, VA, [2]Kindai University, Sayama city, Osaka

OBJECTIVE: Failed induction of labor (IOL) is defined as failure to deliver or achieve active labor after an adequate period of oxytocin and rupture of membrane (ROM). Previous studies showed an association between adverse maternal outcomes and longer duration of oxytocin and rupture of membranes (ROM). However, neonatal outcomes were not well-described. We sought to perform a meta-analysis of studies that evaluated outcomes according to the duration of oxytocin and ROM.

STUDY DESIGN: Studies were included in the meta-analysis if they were observational studies that examined a cohort of nulliparous individuals undergoing IOL with cephalic presentation and singleton pregnancies at 36 weeks or greater. The primary outcome was admission to the neonatal intensive care unit (NICU). Secondary outcomes included rates of chorioamnionitis, endometritis, cesarean delivery, and postpartum hemorrhage (PPH). Outcomes were compared between individuals who remained in latent labor and those who exited the latent phase (active labor or delivered) at 6, 9, 12, 15, and 18 hours of oxytocin and ROM. Findings were summarized as relative risk (RR) with 95% confidence interval (CI) using the random effects model.

RESULTS: Of 1364 studies found on the initial search, 4 studies and 22,184 nulliparous individuals were included in the meta-analysis. Compared to individuals who exited the latent labor, those who remained in latent labor at 12, 15, and 18 hours after oxytocin and ROM had an increased risk of NICU admission (range of RR 1.48-1.82; Table 1). All adverse maternal outcomes were increased in those who remained in latent labor at all time points (6, 9, 12, 15, and 18 hours) except for endometritis and PPH which were not significantly different after 18 hours of oxytocin and ROM.

CONCLUSION: In nulliparous individuals undergoing IOL, adverse neonatal outcomes increase significantly after 12 hours in those who do not deliver or achieve active phase. A definition of failed IOL as failure to achieve active labor after 12 hours of oxytocin and ROM is appropriate to minimize adverse outcomes.

Table 1. Outcomes for individuals who remained in latent labor vs. those who exited latent labor

1016 The T rend in Maternal Morbidity

Yara Hage Diab, Lea Nehme, George R. Saade, Tetsuya Kawakita

Eastern Virginia Medical School, Norfolk, VA

OBJECTIVE: Multiple reports indicate that severe maternal morbidity (SMM) is increasing. Whether this increase is due to change in patient characteristics or practice patterns is not adequately evaluated. Our objective was to examine the temporal trends of SMM in the US population in relation to trends in maternal characteristics.

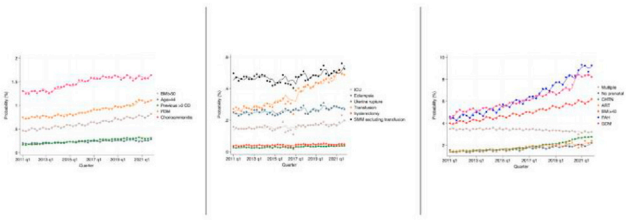
STUDY DESIGN: We performed a repeated cross-sectional analysis of US birth certificate data from 2011 to 2021. Our primary outcome was SMM defined as the occurrence of intensive care unit admission (ICU), eclampsia, uterine rupture, blood product transfusion, and hysterectomy. We also examined the proportions of age (> 44 years), BMI (>40 kg/m^2 and >50 kg/m^2), > 3 prior cesareans, pregestational diabetes, multiple gestation, no prenatal care, chronic hypertension, and assisted reproductive technology. The incidence rate ratio per year (IRR) was calculated using negative binomial regression.

RESULTS: There were 42,519,424 births from 2011 to 2021. Figure 1 shows statistically significant increases in the rates of patient with age >44 years (IRR 1.03 [95% CI 1.03-1.04]), BMI >40 kg/m2 (IRR 1.06 [95% CI 1.06-1.06]), BMI >50 kg/m2 (IRR 1.07 [95% CI 1.07-1.07]), no prenatal care (IRR 1.04 [95% CI 1.04-1.05]), chronic hypertension (IRR 1.07 [95% CI 1.06-1.07]), pregestational diabetes (IRR 1.06 [95% CI 1.06-1.06]), and >3 prior cesarean (IRR 1.08 [95% CI 1.07-1.08]). There were statistically significant increases in SMM (IRR 1.03 [95% CI 1.02-1.03]), ICU (IRR 1.04 [95% CI 1.03-

1.05]), eclampsia (IRR 1.02 [95% CI 1.01-1.02]), hysterectomy (IRR 1.04 [95% CI 1.03-1.05]), uterine rupture (IRR 1.05 [95% CI 1.04-1.06]), and transfusion (IRR 1.09 [95% CI 1.08-1.09]). However, these were no longer significant after adjusting for the increase in BMI >40 kg/m2, age >44 years, and no prenatal care.

CONCLUSION: SMM increased over the past decade, but this increase was not out of proportion to the temporal trends in maternal characteristics. Addressing SMM requires tackling issues that are not directly related to the index pregnancy.

Figure 1: Trends in maternal morbidities



1017 Late preterm antenatal steroids in women with gestational diabetes mellitus

Lylach Haizler-Cohen[1], Maria C. Alzamora[2], Nicole Legro[1], Leila Eter[3], Tasha Freed[3], Suditi Rahematpura[3], Ayah Arafat[4], Victoria R. Greenberg[5], Sara Iqbal[6]

[1]Medstar Washington Hospital Center, Washington, DC, [2]MedStar Washington Hospital Center, Washington, DC, [3]Georgetown University School of Medicine, Washington, DC, [4]MedStar Health Research Institute, Hyattsville, MD, [5]Medstar Washington Hospital Center, Middletown, CT, [6]Washington Hospital Center, Washington, DC

OBJECTIVE: Pregnant people with gestational diabetes mellitus (GDM) were included in the ALPS study but represented only 11% of the sample. Additionally, neonatal outcomes were not stratified based on maternal diabetes status. The objective of this study was to examine the rate of neonatal hypoglycemia, NICU admission, and respiratory morbidity in neonates of pregnant individuals with GDM who were exposed to late preterm antenatal steroids (AS) and those who were not.

STUDY DESIGN: This was a retrospective cohort study in four hospitals in one healthcare system between 2016-2021. Pregnant people with either GDMA1 (diet controlled) or GDMA2 (requiring medication) who presented in the late preterm period with concern for preterm delivery were included. The indication for preterm delivery was classified as preterm labor (PTL), preterm pre-labor rupture of membranes (PPROM), or maternal/fetal indication. Exclusion criteria included multifetal gestations, prior course of AS or no anticipation of delivery in the next 7 days. Adjusted odds ratios with 95% confidence intervals were calculated for neonatal outcomes.

RESULTS: The sample included 199 women in the AS group and 123 women in the non-AS group. Of those in the AS and non-AS groups, 92 and 61 had GDMA1; 107 and 62 had GDMA2. The indication for admission was PTL (22.1%, 26.8%), PPROM (21.6%, 35.8%) and maternal/fetal indication (56.3%, 37.4%) in the AS and non-AS groups respectively. In the AS group, 40% received one dose of steroids and 60% received two doses. After adjusting for gestational age at birth and birth weight, there were no significant differences in hypoglycemia (0.87 [0.53-1.43]) and NICU admission (1.03 [0.62-1.70]). Respiratory distress syndrome was lower in the AS group (0.50 [0.27-0.95]) but there was no difference in the composite respiratory score (0.93 [0.57-1.54]).

CONCLUSION: Administration of late preterm AS to women with GDM does not increase the risk of hypoglycemia or NICU admission. AS reduce the risk of respiratory distress syndrome but not other respiratory or neonatal morbidity.

1018 Late preterm antenatal steroids in women with pregestational diabetes mellitus

Lylach Haizler-Cohen[1], Maria C. Alzamora[2], Nicole Legro[1], Tasha Freed[3], Leila Eter[3], Suditi Rahematpura[3], Ayah Arafat[4], Victoria R. Greenberg[5], Sara Iqbal[6]

[1]Medstar Washington Hospital Center, Washington, DC, [2]MedStar Washington Hospital Center, Washington, DC, [3]Georgetown University School of Medicine, Washington, DC, [4]MedStar Health Research Institute, Hyattsville, MD, [5]Medstar Washington Hospital Center, Middletown, CT, [6]Washington Hospital Center, Washington, DC

OBJECTIVE: Pregnant people with pregestational diabetes mellitus (PGDM) were excluded from the ALPS study due to concern for worsening hypoglycemia in neonates exposed to antenatal steroids (AS). However, AS may improve neonatal respiratory outcomes, which are compromised in neonates of diabetic mothers. The objective of this study was to examine the rate of neonatal hypoglycemia, NICU admission and respiratory morbidity in neonates exposed to late preterm AS compared to those who were not.

STUDY DESIGN: This was a retrospective cohort study in four hospitals in one healthcare system between 2016-2021. Pregnant people with either Type 1 or 2 diabetes (T1DM, T2DM) who presented in the late preterm period with concern for preterm delivery were included. The indication for preterm delivery was classified as preterm labor (PTL), preterm pre-labor rupture of membranes (PPROM), or maternal/fetal indication. Exclusion criteria included multifetal gestations, prior course of AS, or no anticipation for delivery in the next 7 days. Adjusted odds ratios with 95% confidence intervals were calculated for neonatal outcomes.

RESULTS: The sample included 65 women in the AS group and 58 women in the non-AS group. Of mothers in the AS and non-AS

groups, 12 and 14 had T1DM and 53 and 44 had T2DM, respectively. The indication for admission was PTL (12.3%, 10.3%), PPROM (12.3%, 22.4%) and maternal/fetal indication (75.4%, 67.2%) in the AS and non-AS groups, respectively. In the AS group, 38% received one dose of steroids and 61% received two doses. After adjusting for gestational age at birth and birth weight, there were no significant differences in hypoglycemia (1.54 [0.71-3.41]) and NICU admission (0.81 [0.31-2.06]). There was a trend toward decreased composite respiratory score in the AS group (0.456 [0.19-1.05]) as well as a significant reduction in supplemental oxygen and need for resuscitation.

CONCLUSION: Administration of late preterm AS to women with PGDM does not increase the risk of hypoglycemia or NICU admission in our retrospective cohort. Neonatal respiratory morbidity with AS may be decreased.

1019 Multi-country trial of intrapartum oral azithromycin: cultures of maternal infections

Alan T. Tita
University of Alabama at Birmingham, Birmingham, AL; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: An intrapartum oral dose of azithromycin (AZI) reduced maternal death or sepsis (by WHO clinical criteria). Herein, we compare the frequency of cultures, organisms and antimicrobial resistance from maternal infections by AZI vs. placebo groups.

STUDY DESIGN: Ancillary study of the NICHD A-PLUS trial in which women in labor, ≥28 weeks' and planning vaginal delivery were randomized to a 2g dose of AZI or placebo at 8 sites in 7 low- and middle-income countries (LMICs). Culture specimens from suspected infections were tested when feasible using standard of care clinical microbiological procedures at each site supplemented by AZI susceptibility testing. Cultures were encouraged for suspected sepsis (blood), cesarean or perineal wound infection, abdominopelvic or breast abscess (free pus from sites), mastitis (breast milk) and pyelonephritis (urine).

RESULTS: Of 29,278 women randomized, 14,590 had AZI vs. 14,688 placebo. Among randomized, AZI group was associated with fewer maternal clinical cultures (any source), culture positivity, and AZI resistance **(Table 1A)**. Among actual maternal cultures, AZI was not significantly associated with culture positivity or AZI resistance. The most prevalent organisms (Table 1B) were gram-negative rods (GNRs - *E. coli* and *K. pneumoniae*) and gram-positive cocci (GPCs - *S. aureus* and MRSA). GNRs and GPCs were also the most prevalent among 325 blood cultures, 168 perineal wounds and 94 cesarean wounds, while GPCs (Staph) were predominant in breast abscess and GNRs (*E. coli*) in pyelonephritis.

CONCLUSION: A single intrapartum oral dose of AZI was associated with a lower prevalence of cultures and culture-positivity in LMICs and less AZI resistant organisms.

1020 The four critical components of an induction of labor protocol to reduce cesarean delivery

Rebecca F. Hamm[1], Nia Flynn[2], Sindhu K. Srinivas[2], Samuel Parry[2], Lisa D. Levine[2]
[1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: Standardized protocols for management of labor induction (IOL) may reduce cesarean delivery (CD). However, it is unclear if there is a specific threshold of adherence to protocol components or if specific components themselves are associated with reduced CD.

STUDY DESIGN: This is a secondary analysis of a prospective cohort study evaluating standardized IOL management at 2 sites from 2018-2022. Singletons ≥37 weeks with intact membranes receiving cervical ripening were included. Adherence was measured to 8 IOL protocol components (Table). CD rate was evaluated by percent of the 8 protocol components each IOL was adherent to (< 50%, 50-74.9%, 75-99.9%, 100%) and tests for trends by group were calculated using Mantel-Haenszel. Next, we aimed to see if there were individual protocol components critical to reducing CD. Poisson regression with relative risk evaluated independent association of adherence to each component with CD while controlling for confounders. Finally, CD rate was evaluated for IOLs adherent to the four protocol components found to be independent predictors in modeling.

RESULTS: 8509 IOLs were included with an overall CD rate of 21.7%. Median protocol adherence was 80%. Increasing adherence to the

protocol was associated with decreasing CD rate (< 50% adherence: CD 45.4%; 50-74.9% adherence: CD 23.7%; 75-99.9% adherence: CD 18.6%; 100% adherence: CD 14.2%; p< 0.001). In multivariable modeling, 4 protocol components were independently associated with reduced CD even when controlling for covariates: "if misoprostol is utilized, it should not be continued >6 doses or >24h; transition to oxytocin", "if a Foley is utilized, remove at 12h or when falls out", "cervical exams q2-4h in latent labor", and "q1-2h in active labor". Notably, for IOLs adherent to all 4 of these components, CD rate was similar to IOLs adherent to all 8 components (15.0% vs. 14.2%, p=.46).

CONCLUSION: There are 4 critical components of this IOL protocol which, when adhered to, were associated with decreased risk of CD. These components include not continuing "futile" cervical ripening and frequent cervical exams.

Table: IOL protocol adherence and associations with CD

Percent adherence to protocol components					OR [IQR]
	<50%	50-74.9%	75-99.9%	100%

1021 Preterm delivery risk in women with a prior pregnancy complicated by previable PPROM (pPPROM)

Marissa A. Hand[1], Catherine Klammer[1], Meng Yao[2], Amol Malshe[2]

[1]Cleveland Clinic Foundation, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH

OBJECTIVE: Preterm delivery (PTD), defined by ACOG as delivery from 20w0d to 36w6d, can be a devastating finding often associated with severe fetal morbidity and mortality. In addition, these pregnancies have a heightened risk for preterm delivery in a subsequent pregnancy. A method to reduce this elevated risk is to offer cervical length screening and possible cerclage in a subsequent pregnancy. However, in women who rupture prior to 20w, data and guidance are sorely lacking.

STUDY DESIGN: This was a multi-center, retrospective cohort study of women with previable PPROM divided into < 20w (16w0d -19w6d) and ≥20w (20w0d -22w6d) collected from 1/1/2010-12/31/2020. Exclusion criteria included fetal demise prior to PPROM, multiples, and PPROM at < 16w or ≥23w. Primary outcome was gestational age (GA) at delivery (>37w vs ≤37w) in a subsequent pregnancy. Secondary outcomes included the rate of chorioamnionitis, placental abruption in the index pregnancy, rate of PPROM and PTB in the immediately ensuing pregnancy, progesterone use (intramuscular or vaginal), and neonatal outcomes.

RESULTS: 133 patients with pPPROM met criteria, 67 patients < 20w vs 66 patients ≥20w. 63 of these women had a recorded subsequent pregnancy. The rate of PTD was similar between < 20w and ≥20w group, 33% vs 41.7% (p = 0.50) respectively. Within these two gestational cohorts, both groups suffered comparable rates of PPROM, 19.4% (< 20w) vs 18.2% (≥20w) (p = 0.99), at subsequent pregnancy. Diagnosis of chorioamnionitis and placental abruption in the index pregnancy was similar between the two cohorts (p = 0.61 and 0.11, respectively). Progesterone use (IM vs vaginal vs none) was similar between cohorts in both the index and subsequent pregnancy (p = 0.10 and 0.98, respectively). Neonatal demise at index pregnancy was markedly different with 91.0% suffering mortality < 20w compared to 69.7% ≥20w (p = 0.002).

CONCLUSION: The rate of recurrent preterm birth in < 20w parallels those who deliver ≥20w. This finding would suggest that women who suffer pPPROM prior to 20 weeks should also be offered similar treatment.

1022 Progesterone Use Following Previable Prelabor Rupture of Membranes

Marissa A. Hand[1], Catherine Klammer[1], Meng Yao[2], Amol Malshe[2]

[1]Cleveland Clinic Foundation, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH

OBJECTIVE: Many preterm intervention studies, including the Meis trial, do not include women with history of preterm birth (PTB) less than 20 weeks of gestation. Research looking at subsequent pregnancy outcomes in women with a history of previable PPROM is limited. We explored progesterone use in women with a history of previable preterm prelabor rupture of membranes (PPROM) between 16 and 23 weeks of gestation and the effect of progesterone use on reduction of preterm delivery in a subsequent pregnancy.

STUDY DESIGN: We conducted a multi-center, retrospective study of women with previable PPROM between 16w0d and 22w6d of gestation occurring between 1/1/2010-12/31/2020. Exclusion criteria included cases of IUFD prior to PPROM, twins or multiples. The first subsequent pregnancy reaching the second trimester was then selected for review. Investigators searched the EMR for documentation of intramuscular (IM) and vaginal progesterone use in both the index and subsequent pregnancy. Pearson's chi-squared test was used to determine the effect of progesterone use on PTB in subsequent pregnancies.

RESULTS: 133 patients had previable PPROM between 16w0d-22w6d of gestation, with 27.3% of women having documented progesterone

use in this pregnancy (12.9% IM vs 14.4% vaginal, p = 0.10). 63 women had a subsequent pregnancy reaching the second trimester, with 69.8% using progesterone (65.9% IM vs 34.1% vaginal). Of the subsequent pregnancies using progesterone, 65.9% (52.5% IM vs 20.0% vaginal) delivered at a gestational age >37w compared to 34.1 (34.8% IM vs 30.4 vaginal) at ≤37w (p=0.54).

CONCLUSION: The majority of patients with a history of previable PPROM used progesterone in some form in the following pregnancy. However, treatment with progesterone in the subsequent pregnancy (IM or vaginal) did not significantly change whether the patient delivered at term.

1023 Preterm premature rupture in patients with adult congenital heart disease

Rachel Harrison[1], Yara El Helou[2], Kavya Shivashankar[3], Medhavi Bhasin[4], Michael Earing[5], Calla Holmgren[6]
[1]Advocate Christ Hospital, Oak Lawn, IL, [2]University of Illinois at Chicago, Chicago, IL, [3]University of Illinois Hospital, Chicago, IL, [4]Advocate Lutheran General Hospital, Park Ridge, IL, [5]Advocate Aurora Health, Chicago, IL, [6]AAH Lutheran General Hospital, Park Ridge, IL

OBJECTIVE: Women with adult congenital heart disease (ACHD) are at risk for endocarditis in labor. We sought to identify whether rates of preterm premature rupture of membranes (PPROM) were higher, potentially increasing risk of bacterial exposure in these patients.

STUDY DESIGN: This is a retrospective cohort study evaluating pregnant patients with a delivery encounter in the National Inpatient Sample database through AHRQ-HCUP from 2017 to 2019. Women were included if they delivered greater than 20 weeks gestation and excluded if gestational age at delivery was unknown or the hospital encounter was not linked to a delivery. Women with ICD10 codes specific to congenital heart disease were compared to those without. The primary outcome was PPROM. Secondary outcomes included PPROM and delivery at less than 34 and 28 weeks as well as other infectious morbidity including endocarditis. T-tests, chi2 analysis, and logistic regression were used to compare groups.

RESULTS: A total of >2.2 million subjects were included with 2,409 affected by ACHD. ACHD subjects were more likely to identify as non-Hispanic white, be younger, obese, privately insured and have more comorbidities (p< 0.05). They also delivered at larger, urban teaching and private hospitals (p< 0.05) via cesarean (39.5% vs 33.1%) (p< 0.001). Rates of PPROM overall (3.2% vs 1.7%, p< 0.001) and at < 37 weeks and < 34 weeks gestation (3.1% vs 1.6 and 1.6% vs 0.7%, respectively) was higher in those with ACHD. Rates of endocarditis were significantly higher (0.3% vs < 0.0%, p< 0.001) and so were rates of endometritis and other postpartum infections, but not chorioamnionitis. PPROM at less than 37 weeks, endocarditis, endometritis and other infections remained significantly associated with ACHD after controlling for confounders that differed between groups at baseline with p< 0.05.

CONCLUSION: ACHD is associated with higher rates of PPROM and other infectious morbidity at the time of delivery admission, including endocarditis.

1024 Pigment epithelium derived-factor (PEDF), a potent anti-angiogenic protein, is elevated in fetal growth restriction

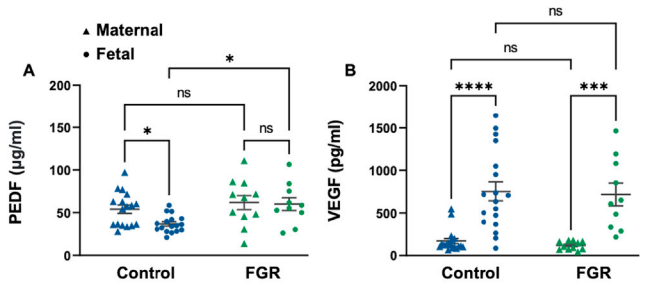
Noa Hasky[1], Luba Nemerovsky[2], Hadas Bar-Joseph[3], Anat Eldar-Boock[3], Lisa Barchilon-Tiosano[1], Sivan Farladansky Gershnabel[1], Gil Shechter Maor[1], Ruth Shalgi[3], Tal Biron-Shental[4]
[1]Meir Medical Center, Kfar Saba, HaMerkaz, [2]Meir Medical Center, Tel Aviv, Tel Aviv, [3]Faculty of Medicine, Tel Aviv, Tel Aviv, [4]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz

OBJECTIVE: To examine pigment epithelium-derived factor (PEDF) expression in pregnancies complicated by fetal growth restriction (FGR). PEDF is a pleiotropic protein with anti-angiogenic and anti-oxidative properties, known to negate vascular endothelial growth factor (VEGF) and regulate trophoblast function under hypoxia.

STUDY DESIGN: Maternal sera, cord blood and placentas from pregnancies complicated by FGR (n=12) and normal controls (n=18) were obtained following deliveries. Changes in PEDF, PEDF receptors and VEGF mRNAs, were quantified using qPCR. Sera levels of PEDF and VEGF were quantified using ELISA and compared to clinical parameters such as birth-weight percentile and doppler measurements of fetal umbilical and middle cerebral arteries.

RESULTS: VEGF and PEDF mRNA level were significantly elevated (p=0.016; p=0.009) in placentas from FGR pregnancies compared to controls. PEDF receptors showed differential expression in FGR placentas; LRP6, was upregulated (p=0.046) and Laminin receptor was downregulated (p< 0.0001). PEDF was also elevated in cord blood of FGR pregnancies compared to normal pregnancies (p=0.02) while VEGF displayed low concentrations in maternal sera (p=0.0001) and a wide range in cord blood with no significant difference between FGR and controls. Due to the small sample size, no significant correlation was found when comparing clinical parameters to PEDF protein level in cord blood of FGR pregnancies. Data was analyzed by one-way ANOVA with FDR correction.

CONCLUSION: Elevated level of PEDF in cord blood and placentas from FGR pregnancies may represent trophoblast response to chronic hypoxic stress in the fetal-placental interphase.



Maternal serum and cord blood concentration of PEDF (A) and VEGF (B) in normal and FGR pregnancies measured by ELISA. A) Elevated PEDF in maternal sera compared to cord blood of normal pregnancies (blue; n=18). Elevated PEDF in cord blood of FGR pregnancies (green; n=12) compared to normal pregnancies, thus resembling the level of PEDF in maternal sera. **B)** Low VEGF in maternal sera compared to cord blood levels which showed a wide range. No significant difference in VEGF blood concentration was found comparing control and FGR pregnancies. Data expressed as mean±SEM. PEDF indicates pigment epithelium derived factor and VEGF, vascular endothelial growth factor. *P<0.05, ***P<0.001 and ****P<0.0001.

1025 Pigment epithelium derived-factor (PEDF), a potent anti-angiogenic protein, is upregulated in women with preeclampsia

Noa Hasky[1], Luba Nemerovsky[2], Hadas Bar-Joseph[3], Anat Eldar-Boock[3], Lisa Barchilon-Tiosano[1], Sivan Farladansky Gershnabel[1], Tal Biron-Shental[4], Gil Shechter Maor[1], Ruth Shalgi[3]

[1]Meir Medical Center, Kfar Saba, HaMerkaz, [2]Meir Medical Center, Tel Aviv, Tel Aviv, [3]Faculty of Medicine, Tel Aviv, Tel Aviv, [4]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz

OBJECTIVE: Maternal endothelial dysfunction due to circulating angiogenic factors such as vascular endothelial growth factor (VEGF) and its soluble receptor sFlt-1 are the hallmark of pre-eclampsia (PE) pathophysiology. Pigment epithelium derived-Factor (PEDF) is a potent anti-angiogenic glycoprotein that negates VEGF activity and elicits sFlt-1 cleavage. Recent studies have unraveled a potential role for PEDF as a regulator of anti-angiogenic processes at the fetoplacental interface.

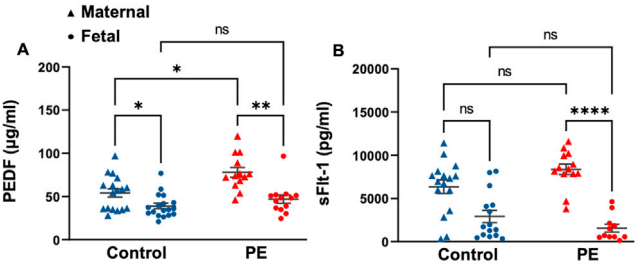
Our goal was to investigate PEDF expression in placentas of pregnancies complicated by PE compared to controls and in maternal and fetal sera.

STUDY DESIGN: Maternal sera, cord blood and placentas of women with PE (n=16) and controls (n=18) were obtained following deliveries.

Changes in vascular effectors were quantified by qPCR (mRNAs) and Western blotting (proteins) and serum levels of PEDF, VEGF and sFlt-1 measured by ELISA. Protein expression was determined by immunofluorescence in histological sections using antibodies against PEDF, pan-cytokeratin and CD31.

RESULTS: PEDF is expressed in the placenta by trophoblasts, stromal and endothelial cells. Placental PEDF mRNA ($p< 0.0001$) and protein level ($p=0.01$), as well as PEDF serum concentration ($p=0.025$) were significantly higher in women with PE compared to control. LRP6, a PEDF receptor was also significantly upregulated in PE placentas ($p=0.038$). Additionally, PEDF concentration was significantly higher in maternal sera compared to their matched cord-blood samples in both normal ($p=0.026$) and PE pregnancies ($p=0.004$), representing a differential expression pattern between mothers and their fetuses. Data was evaluated by one-way ANOVA with FDR correction.

CONCLUSION: PEDF expression is eminently elevated in placentas and sera of women with PE compared to healthy controls, presenting PEDF as a potential novel biomarker for PE.



Maternal serum and cord blood concentration of PEDF (A) and sFlt-1 (B) in normal pregnancies and preeclampsia measured by ELISA.
A) Elevated PEDF level in women with PE (red triangles; n=16) compared to healthy controls (blue triangles; n=18), whereas no difference was detected between cord blood of healthy and PE pregnancies (spheres). PEDF level in maternal sera was higher than cord blood level in both groups. **B)** In PE, sFlt-1 was higher in maternal blood compared to cord blood and only a trend was observed when comparing sFlt-1 serum level of women with PE to controls. Data expressed as mean±SEM. PEDF indicates pigment epithelium derived factor; sFlt-1, fms-like tyrosine kinase-1. *P<0.05; **P<0.01; ****P<0.0001.

1026 Plasminogen Activator Inhibitor 1 promotes endothelial cell inflammatory response

Rachel Hauschel[1], Nabil Boutagy[2], William Sessa[2], Molly McAdow[2]

[1]University of Texas, McGovern School of Medicine, Houston, TX, [2]Yale University School of Medicine, New Haven, CT

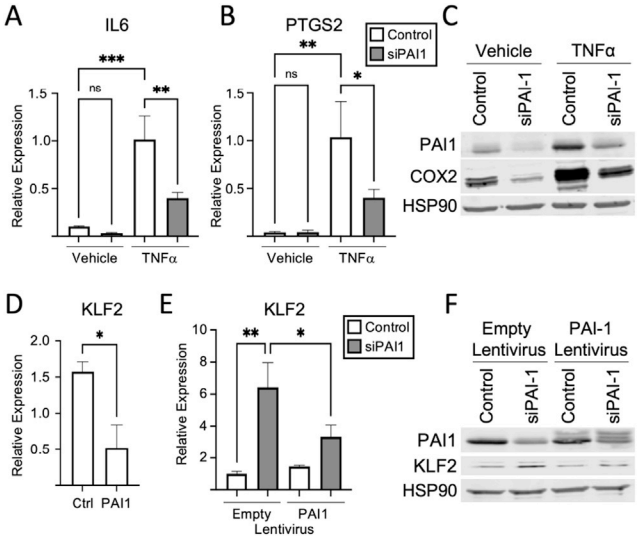
OBJECTIVE: Plasminogen Activator Inhibitor 1 (PAI1) is elevated in preeclampsia. In addition to its prothrombotic activity, emerging evidence suggests that PAI-1 directly contributes to endothelial dysfunction. Our objective was to determine whether PAI1 modulates the endothelial cell response to tumor necrosis factor alpha (TNFα), an inflammatory cytokine that is elevated in preeclampsia.

STUDY DESIGN: Human umbilical vein endothelial cells (HUVECs) were transfected with PAI1-specific silencing RNA or non-targeting control, followed by treatment with TNFα (1 ng/mL) for 16 hours. In other experiments, HUVECs were treated with purified recombinant PAI1 (40 ng/µL) prior to TNFα. To rescue the phenotype, HUVECs were infected with a lentivirus that over-expresses PAI1 prior to RNA silencing and TNFα treatment. Gene expression was measured by reverse transcription polymerase chain reaction (RT-PCR). Protein levels were determined by Western blot. Statistical analysis was performed in GraphPad Prism 9. Between-group differences were analyzed by two-way analysis of variance (ANOVA) with post-hoc analysis using Sidak's test for multiple comparisons. Differences were considered significant if $P < 0.05$.

RESULTS: HUVECs treated with TNFα have upregulation of pro-inflammatory genes, but silencing PAI1 significantly blunted the TNFα response for genes including *IL6* (Figure a), *PTGS2* (b), *CXCL8*, and *EDN1*. Reduction of COX2 was confirmed by Western blot (c). Reciprocally, addition of recombinant PAI-1 increased the expression of *PTGS2*, *CXCL8*, and *IL6*. KLF2 is a transcription factor that promotes endothelial cell homeostasis. Silencing PAI-1 increased KLF2 transcription, and addition of recombinant PAI-1 decreased KLF2 transcription (d). Lentiviral over-expression of PAI-1 partially restored the response to TNFα by significantly reducing

KLF2 expression in response to TNFα as seen by RT-PCR and Western blot (e, f).

CONCLUSION: PAI-1 promotes the endothelial cell response to TNFα, which may be mediated by suppressing KLF2. These findings suggest that PAI-1 may contribute directly to endothelial dysfunction in preeclampsia.



1027 The effect of rooming-in on postpartum hemorrhage: A propensity score analysis

Natav Hendin[1], Ohad Houri[2], Yossi Geron[3], Shiran Loewenstein[4], Eran Hadar[5], Asnat Walfisch[6], Rony Chen[7]

[1]The Sackler Faculty of Medicine, Tel-Aviv University, Tel Aviv, Israel, [2]Rabin Medical Center, Tel Aviv, Israel, [3]Rabin medical center, Petach-Tikva, HaMerkaz, [4]Rabin Medical Center, HaMerkaz, Israel, [5]Rabin Medical Center, Petach-Tikva, HaMerkaz, [6]Hadassah Mount Scopus, Petach-Tikva, Israel, [7]Rabin medical center, Israel, Petach-Tikva, HaMerkaz

OBJECTIVE: We aimed to investigate the effect of rooming-in on postpartum hemorrhage (PPH) and other immediate post-partum complications.

STUDY DESIGN: Retrospective study conducted at a high-volume tertiary obstetric center. All healthy women with a singleton uncomplicated pregnancy and childbirth, between 2012 and 2022 were included. Women were categorized into 2 groups based on their choice of neonatal care method: rooming-in vs. hospital nursery. Propensity score matching was used to create comparable groups in a 2:1 ratio. The matching was based on the following parameters: age, body mass index (BMI) at birth, total pregnancy days, newborn weight, parity, prior cesarean section, epidural and perineal lacerations. The primary outcome measure was defined as PPH or the need for postpartum blood transfusion. Secondary outcomes included breastfeeding, postpartum fever, postpartum preeclampsia, and duration of hospitalization.

RESULTS: A total of 79,936 women delivered during the study period, of which 16,201 met the inclusion criteria. After propensity score matching, 15,459 women were included in the analysis, of whom 10,306 chose nursery care and 5,153 rooming-in. Rooming-in was associated with lower odds of PPH (1.71% Vs. 2.43%, OR 0.7, 95% CI 0.55-0.89, p= 0.004), postpartum blood transfusion (0.60% Vs. 1.13%, OR 0.51, 95% CI 0.36-0.79, p=0.001) and a lower likelihood of postpartum hospitalization exceeding 48 hours (82.42% Vs. 86.81%, OR 0.71, 95% CI 0.65-0.78, p< 0.001) and 72 hours (12.17% Vs. 13.75%, OR 0.87, 95% CI 0.79-0.96, p=0.006). Rooming-in was also associated with a higher rate of breastfeeding (92.66% Vs. 85.79%, OR 2.09, 95% CI 1.86-2.36, p< 0.001). Choice of immediate neonatal care was not associated with postpartum fever or preeclampsia.

CONCLUSION: This study provides evidence of an association between rooming-in and a decreased risk of PPH and the need for blood transfusion.

These findings highlight the potential benefits of the rooming-in practice and can assist in making more informed decisions regarding postpartum care.

Table 2: Rooming-in vs. hospital nursery - obstetrical outcomes

	Rooming-in n=5,153	Hospital nursery n=10,306	P value	OR (95% CI)
Postpartum Hemorrhage	88 (1.71%)	250 (2.43%)	0.004	0.7 (0.55-0.89)
Postpartum Blood Transfusion	31 (0.60%)	116 (1.13%)	0.001	0.51 (0.36-0.79)
Postpartum Preeclampsia	4 (0.08%)	9 (0.09%)	1.000	0.89 (0.44-1.81)
Postpartum Fever	38 (0.74%)	80 (0.78%)	0.845	0.95 (0.65-1.40)
Postpartum Hospitalization > 48hr	4247 (82.42%)	8947 (86.81%)	<0.001	0.71 (0.65-0.78)
Postpartum Hospitalization > 72hr	627 (12.17%)	1417 (13.75%)	0.006	0.87 (0.79-0.96)
Breastfeeding	4775 (92.66%)	8842 (85.79%)	<0.001	2.09 (1.86-2.36)

1028 The impact of placental cord drainage on third stage of labor: A randomized controlled trial

Natav Hendin[1], Michal Grosvald[2], Ilana Shemesh[2], Adi Borovich[3], Rony Chen[4], Eran Hadar[5], Ohad Houri[6]

[1]The Sackler Faculty of Medicine, Tel-Aviv University, Tel Aviv, Israel, [2]Rabin Medical Center, HaMerkaz, Israel, [3]Rabin Medical Center, Tel Aviv, HaMerkaz, [4]Rabin medical center, Israel, Petach-Tikva, HaMerkaz, [5]Rabin Medical Center, Petach-Tikva, HaMerkaz, [6]Rabin Medical Center, Tel Aviv, Israel

OBJECTIVE: We aimed to investigate the impact of placental drainage during the third stage of labor on key obstetric outcomes, specifically third-stage length, maternal blood loss and postpartum hemorrhage (PPH) incidence.

STUDY DESIGN: In a randomized controlled trial at a high-volume tertiary obstetric center between 2021-2022, 212 pregnant women with a singleton uncomplicated pregnancy were enrolled. They were randomly assigned to two groups: an intervention group of 104 women receiving placental drainage and a control group of 108 women receiving standard care without drainage. Placental drainage involved unclamping the cut umbilical cord, allowing blood to drain into a plastic bag placed below, which was weighed after placenta removal. All participants received 10 units of oxytocin immediately after delivery, according to department's standard care. The allocation was concealed and blinded to the participants but not to the care providers.

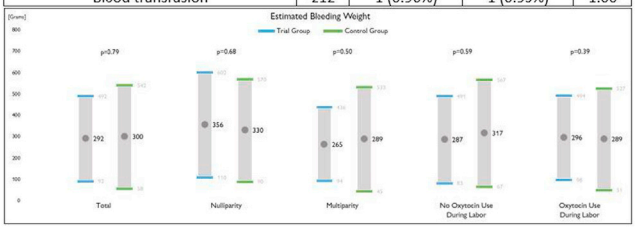
RESULTS: The two groups were similar in their baseline characteristics. No significant differences were observed between the intervention and control groups regarding the duration of the third stage of labor (10.56 minutes ± 6.12 vs. 10.95 ± 6.33, p=0.65), the incidence of PPH (3.84% vs. 7.41%, p=0.38) or the amount of bleeding during the third stage of labor (292 grams ± 200 vs. 300 ± 242, p=0.79).

Furthermore, no significant differences were observed in the amount of bleeding in a subgroup analysis for nulliparity (356 ± 246 vs. 330 ± 240, p=0.68), multiparity (265 ± 171 vs. 289 ± 244, p=0.50), women who received oxytocin during labor (296 ± 198 vs. 289 ± 238, p=0.39) or not (287 ± 204 vs. 317 ± 250, p=0.59).

CONCLUSION: Placental drainage during the third stage of labor offers no benefit on third-stage length, PPH incidence or maternal blood loss.

Table 1. Delivery third stage outcomes among women with or without placental cord drainage

outcome		N	Trial group n=104	Control group n=108	P value
Third stage of labor length [minutes]		212	10.56 ± 6.12	10.95 ± 6.33	0.65
Postpartum hemorrhage		212	4 (3.84%)	8 (7.41%)	0.38
Maternal blood loss, [grams]	Total	212	292 ± 200	300 ± 242	0.79
	Nulliparity	61	356 ± 246	330 ± 240	0.68
	Multiparity	151	265 ± 171	289 ± 244	0.50
	No Oxytocin use during labor	87	287 ± 204	317 ± 250	0.59
	Oxytocin use during labor	125	296 ± 198	289 ± 238	0.39
Revision/Manual lysis of placenta		212	1 (0.96%)	5 (4.63%)	0.21
Blood transfusion		212	1 (0.96%)	1 (0.93%)	1.00



1029 Postpartum preeclampsia readmissions- Is de novo postpartum hypertension worse?

Bonnie L. Hermann[1], Baha M. Sibai[2], Khalil Chahine[1], Yossi Bart[1], Ayokunle A. Ogunye[1], Nahla Daye[3], Sandra Sadek[3], Estefania Guthrie[4], Farah H. Amro[3]

[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]Hermann Memorial Hospital, Houston, TX, [3]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [4]The University of Texas Health Science Center at Houston, Houston, TX

OBJECTIVE: To determine if maternal outcomes vary between individuals readmitted with de novo postpartum hypertension compared to individuals with underlying hypertensive disease of pregnancy.

STUDY DESIGN: This is a retrospective cohort analysis of postpartum preeclampsia readmission (up to 6 weeks postpartum) between 2017-2023 at a tertiary medical center. Subjects were stratified based on underlying hypertensive status: 1. de novo postpartum hypertension (de novo PP HTN) and 2. those with a known diagnosis of hypertensive disorder of pregnancy or chronic hypertension (HDP). Our primary outcome was composite maternal morbidity: acute kidney injury, pulmonary edema, stroke, eclampsia, ICU admission, maternal death, and thromboembolism. Data were analyzed using Chi-squared and Fisher's exact tests for categorical variables and Poisson regression model was used for calculating relative risk.

RESULTS: Of 359 included subjects, 83 (23%) had de novo PP HTN; 276 (77%) had HDP. Individuals with HDP had higher rates of obesity, diabetes mellitus, and a history of preeclampsia in prior pregnancies (Table 1). Composite maternal outcomes did not differ between the groups (P=0.324), however rates of stroke and ICU admission during readmission were increased among individuals with de novo PP HTN (4.8% vs 0.4%, p= 0.01; and 6% vs 1.8%, p=0.04) (Table 1). Time from delivery discharge to readmission and length of stay during readmission were not different between the groups (Table 1).

CONCLUSION: Individuals readmitted with de novo PP HTN and those with HDP have similar composite maternal morbidity, however rates of stroke and ICU admission are increased among those with de novo PP HTN. Thus, there is a need to identify risk factors for de novo PP HTN in order to facilitate closer monitoring postpartum in this population.

Table 1. Baseline Characteristics and Maternal Outcomes in Postpartum Preeclampsia Readmissions

	De Novo PP HTN N=83[1]	HDP N=276[1]	p-value
Age	31.4 (5.69)	31.96(5.53)	0.304

1030 Outcomes of non-participants in a chronic hypertension in pregnancy treatment trial: CHAP ancillary observational study

Alan T. Tita

University of Alabama at Birmingham, Birmingham, AL; on behalf of the Chronic Hypertension and Pregnancy (CHAP) Consortium

OBJECTIVE: In CHAP, treatment of pregnant women with mild chronic (C) HTN to a BP goal < 140/90 mmHg (vs. no treatment unless BP ≥160/105) was beneficial and safe. Since only 1:12 screened women participated in the trial, we implemented an ancillary study to compare characteristics and outcomes of non-participants without severe CHTN to randomized participants.

STUDY DESIGN: Retrospective observational cohort (OC) study of patients with new or known CHTN who were screened but not randomized in CHAP. We included patients who were excluded due to advanced gestational age (GA), BP not ≥140/90 mmHg off medication or who declined randomization. Those with severe or secondary CHTN, FGR, kidney disease, diabetes class D or greater and/or stillbirth/pregnancy loss remained excluded. Patients were randomly selected per site in a ratio of 1 OC: 2 randomized. Outcomes were ascertained by abstraction of records without adjudication. The primary outcome was a composite of preeclampsia + severe features, perinatal death, indicated preterm birth (PTB) < 35 weeks or abruption. The sample size of 1100-1200 in the OC would provide 80-85% power to estimate a 25-30% difference in the outcome from a reference >30%.

RESULTS: A total of 1102 patients were included in the OC; compared to randomized groups, they were more likely to be NH white, non-diabetic and have private insurance with lower mean systolic and diastolic BP (4-5 mmHg) and mean BMI (2 kg/m^2). The primary composite was more frequent in the control but not the active group compared to the OC (Table). Perinatal death, PTB, GA at delivery and preeclampsia were more frequent in both active and control groups. Additional components of the primary and secondary

outcomes were more frequent in the control group (Table). Results were consistent in covariate-adjusted models.

CONCLUSION: CHAP screened non-participants without severe HTN had a more favorable risk profile than participants and better pregnancy outcomes than active and control CHAP participants even after adjustments.

Table. Outcome results of observational cohort compared to CHAP randomized groups

	Study Groups and Comparisons*				
	Active (n=1208)	Control (n=1200)	Observational (O) (n=1102)	Active vs. O RR (95% CI)	Control vs. O RR (95% CI)

1031 Premature rupture of membranes after serial amnioinfusions in fetuses with anhydramnios due to renal agenesis/dysplasia

Edgar Hernandez Andrade[1], Kevin Magee[2], Paxton Alexander[3], Eric P. Bergh[4], Ramesha Papanna[1], Jimmy Espinoza[5], Anthony Johnson[1]

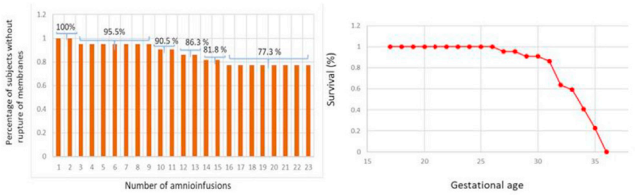
[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]Fetal Care Center Dallas, Dallas, TX, [3]Fetal Care center Dallas, Dallas, TX, [4]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [5]McGovern Medical School at the University of Texas Health Science Center Houston, The Fetal Center- Children's Memorial Hermann Hospital, Houston, TX

OBJECTIVE: To estimate the frequency of preterm premature rupture of membranes (PPROM) in fetuses with anhydramnios managed with serial amnioinfusions (AIs).

STUDY DESIGN: Nineteen fetuses with anyhydramnios due to dysplastic kidneys or bilateral renal agenesis were treated in utero with serial AIs to prevent lung hypoplasia and Potter sequence. Fetuses with associated structural or chromosomal anomalies were not included. The first AI was performed for detailed anatomic evaluation; the amount of fluid infused targeted an amniotic fluid index (AFI) of 15-20 cm. Subsequent AIs were performed when AFI was between 5-8 cm. The initial goal was to reach 32 weeks of gestation. Patients with PPROM were managed expectantly until 32 weeks or until labor, fetal distress, or signs of clinical chorioamnionitis were noted.

RESULTS: 279 AIs in 19 fetuses were performed (median n=15, range 3-22). Median gestational age (GA) at first AI was 22 weeks (range 17-25) and at last AI was 33 weeks (range 26-35). Four patients (21%) had PPROM**:** two at 26 weeks, one at 28 weeks, and one at 29 weeks. Seventeen of 19 cases reached at least 28 weeks, and 15/19 reached at least 30 weeks of gestation without PPROM. Fig1 shows the percentage of fetuses without PPROM after each AI. All cases underwent at least two AIs without PPROM; 95.4% underwent 3 to 9 AIs without PPROM. After the 10th AI, the prevalence of PPROM increased by 4.5% for every two additional AI; 77.3% of subjects who underwent 16 or more AIs did not have PPROM. No women < 26 weeks of gestation had PPROM despite some having up to 6 AIs before that GA.

CONCLUSION: The risk of PPROM < 32 weeks of gestation after serial AIs is approximately 20%. The risk increases after 10 AIs or after 26 weeks of gestation, whichever comes first.



1032 The volume of fluid corresponding to each centimeter of amniotic fluid index changes throughout pregnancy

Edgar Hernandez Andrade[1], Kevin Magee[2], Paxton Alexander[3], Ramesha Papanna[1], Eric P. Bergh[4], Jimmy Espinoza[5], Anthony Johnson[1]

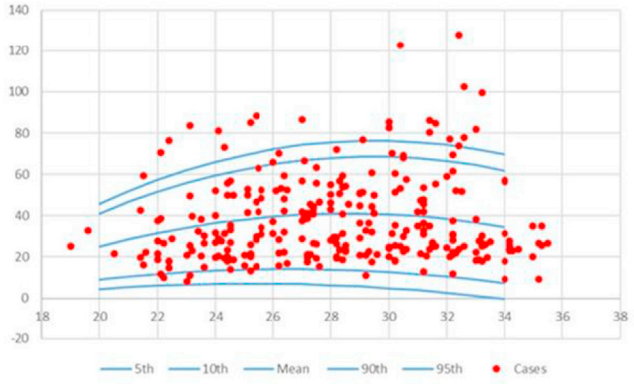
[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]Fetal Care Center Dallas, Dallas, TX, [3]Fetal Care center Dallas, Dallas, TX, [4]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [5]McGovern Medical School at the University of Texas Health Science Center Houston, The Fetal Center- Children's Memorial Hermann Hospital, Houston, TX

OBJECTIVE: The most frequently used metric to estimate amniotic fluid (AF) volume is the amniotic fluid index (AFI). Normal values range from 5-25 cm, using these same thresholds throughout pregnancy to define normal AF or oligo/polyhydramnios. However, a similar AFI may correspond to different AF volume at different gestational ages. Our aim was to estimate the amount of fluid corresponding to1 cm of AFI when a known amount of fluid is infused in the amniotic cavity as treatment of fetuses with anhydramnios due to bilateral renal agenesis or severe dysplastic kidneys.

STUDY DESIGN: Serial amnioinfusions (AIs) were performed to promote lung development and reduce fetal thorax compression. AFI was measured before and after AI and the difference (increment) was calculated in relation to the amount of infused fluid (Infused fluid/(AFI final-AFI initial). Mean and standard deviation were calculated and 5th, 10th 50th, 90th and 95th percentiles estimated using regression models.

RESULTS: *Results* 279 AIs in 19 fetuses were performed (median/case n=15, range 3-22). The volume of infused fluid ranged from 250 to 500 mL at 20-35 weeks, 700 to 800 mL at 27-29 weeks, and 800 to 1000 mL at 30-32 weeks. There was a mild increment in volume per AFI cm from 20 to 30 weeks, with a subsequent mild reduction at 34 weeks (Fig 1). The mean volume of fluid per cm of AFI at 20 weeks was (mean) 25.1 mL (10th 9.0 mL, 90th 41.2 mL), whereas at 30 weeks 1 cm of AFI corresponded to (mean) 40.6 mL (10th 12.8 mL - 90th 68.4mL). There was 66% increment in AF fluid per cm of AFI from 20 to 30 weeks of gestation. Extrapolating these calculations, a normal AFI at 20 weeks (5-25 cm) could range from 125 mL (AFI=5 cm) to 627 mL (AFI=25 cm), and at 30 weeks from 203 mL (AFI=5 cm) to 1015 mL (AFI=25 cm).

CONCLUSION: The volume of amniotic fluid per cm of AFI changes during gestation. The definition of poly or oligohydramnios based on the same AFI can vary up to 66% in fluid volume from 20-30 weeks of gestation



1033 Regional diffusion of the chronic hypertensive placenta

Christina L. Herrera[1], **Quyen N. Do**[1], **Catherine Y. Spong**[2], **Diane M. Twickler**[1], **Yin Xi**[1]
[1]UT Southwestern Medical Center, Dallas, TX, [2]University of Texas Southwestern Medical Center, Dallas, TX

OBJECTIVE: In placental disease, spiral artery remodeling is thought to be more aberrant at the periphery but remains normal in the central area near the cord. Considering this pathology, we aimed to investigate the impact of chronic hypertension (cHTN) during pregnancy on placental diffusion *in vivo*. Water diffusion is relatively stable against aging changes represented by connective tissue or calcifications, making diffusion mapping a tool to evaluate placenta pathology.

STUDY DESIGN: In this prospective study, pregnant individuals with and without chronic hypertension were imaged at 16-20 (visit 1) and 24-28 (visit 2) weeks gestation on a Phillips 3T Ingenia MRI. Sagittal diffusion weighted-imaging (DWI) was obtained during free breathing with 7 b-values - 0, 50, 100, 150, 400, 700, 1000 sec/mm2. Apparent diffusion coefficient (ADC) map was generated using mono-exponential fit.

Placental volumes and cord location region of interests (ROIs) were drawn on the ADC maps. The Euclidian distance between center of mass of the cord insertion and placental image voxels was calculated. Association between the distance and ADC value for each patient was evaluated using linear regression. The slope coefficient (change in ADC value per mm away from cord insertion) was estimated and compared between those with and without cHTN for each visit using Wilcoxon rank sum test.

RESULTS: Analysis included 33 pregnant individuals. At time point 1, 17 had cHTN, and 15 did not; at time point 2, 18 had cHTN, and 14 did not. Subjects with cHTN had significantly lower slope values at visit 2 compared to those without cHTN, with matched gestational age (P = 0.049). At visit 2, we observed a decrease in ADC value in tissue farther from the cord insertion, indicating an increase in tissue diffusivity (reduced tissue compactness) in placental periphery.

CONCLUSION: Regional diffusion may correlate with placental health changes in pregnancies with chronic hypertension. Regional differences may implicate pathology for fetal/neonatal findings. Further study is needed to determine if ADC mapping may be useful indicator of placental pathology.

Figure. (A) Sagittal ADC map of a 27-week gestational age pregnant chronic hypertension patient with overlayed placenta ROI. Heat map demonstrates distance from cord insertion location. Red indicates closer to cord insertion; blue indicates furthest away from cord insertion. (B) Summary statistics for the association between distance from cord insertion to ADC value.

1034 Predictors of fetal growth in patients with maternal cardiovascular disease- cardiac medications are protective

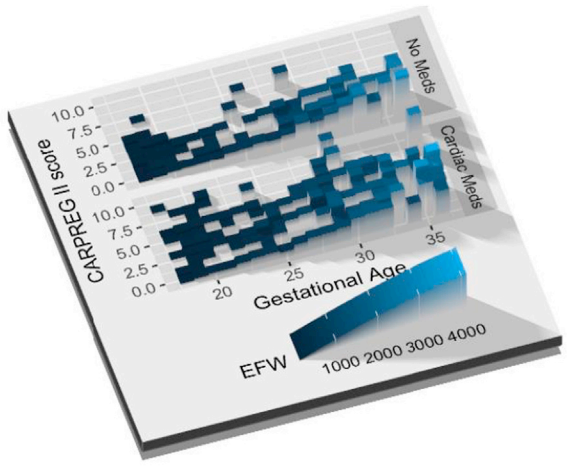
Ashley Hesson, Melinda B. Davis, Elizabeth S. Langen
University of Michigan, Ann Arbor, MI

OBJECTIVE: Fetal growth restriction is a possible complication of maternal cardiovascular disease. It remains unclear what characteristics of a given cardiac condition confer risk: lesion, severity, or functional status. The role of cardiac medications in mediating risk is also poorly understood. We aim to assess the impact of maternal cardiac disease and use of cardiac medications on fetal growth.

STUDY DESIGN: We conducted a retrospective cohort study of singleton gestations managed in a high volume Cardio-Obstetrics program from 2018-2022. Cardiovascular variables (primary lesion type, lesion severity [CARPREG II score], functional status [NYHA class], cardiac medications) and all 2nd and 3rd trimester Hadlock estimated fetal weights (EFW) along with their respective gestational ages at collection were reviewed for this cohort. Multivariate linear regression was used to model EFW, the primary outcome, as a function of lesion type, lesion severity, functional status, the use of any cardiac medication, and gestational age (GA). Interactions were stipulated between (GA), functional status, and lesion severity. Lesion type was modeled separately from severity due to concern for collinearity.

RESULTS: We identified 250 pregnancies and 935 ultrasounds. There were significant main effects on EFW from GA (P< 0.01), CARPREG II score (P=0.02), and use of cardiac medications (P=.005). Interactional effects were significant for: 1) GA and CARPREG II score (P=.004), 2) CARPREG II score and NYHA class (P=0.05), 3) GA, CARPREG II score, and NYHA class (P=0.02). Worse functional status and increasing lesion severity had a negative impact on fetal growth; taking cardiac medications (most commonly beta blockers) was protective (Fig 1).

CONCLUSION: Maternal functional status significantly impacts the influence of CARPREG II score on fetal growth. Importantly, use of cardiac medications is associated with more normal fetal growth. Cardiac medications used to optimize maternal functional status may improve both maternal and neonatal outcomes.



A multi-dimensional plot of fetal growth (EFW, z-axis) by gestational age (GA, x-axis), CARPREG II score (y-axis), and the use (lower pane) vs non-use (upper pane) of cardiac medications. The slope of increasing fetal weight with gestational age is steeper for those on cardiac medications, representing relatively preserved fetal growth in this cohort compared to those not on any cardiac medications in pregnancy.

CONCLUSION: Racial disparities were present in initial therapy for GDM, with NHW more likely to receive insulin and Hispanic more likely to receive oral therapy. Initial insulin therapy was associated with a higher risk of preeclampsia, which may reflect underlying health status.

1035 Racial and ethnic disparities in treatment strategies and pregnancy outcomes of women with gestational diabetes

Rachel L. Hill[1], Emily A. DeFranco[2], Heather R. Masters[2]
[1]University of Cincinnati, Cincinnati, OH, [2]University of Cincinnati College of Medicine, Cincinnati, OH

OBJECTIVE: Rate of gestational diabetes (GDM) is disparate among racial and ethnic backgrounds (R/E). Guidelines vary regarding oral medication as first-line therapy. We investigated R/E disparities in GDM by initial treatment and pregnancy outcomes.

STUDY DESIGN: Single-institution retrospective cohort of 543 patients with GDM, 2015—2019. Patients were stratified by R/E based on self-report: non-Hispanic white (NHW, referent), non-Hispanic Black (NHB), Hispanic, and Asian. Diet-treated GDM and pre-pregnancy diabetes were excluded. Pregnancy outcomes and initial therapy regimen (insulin versus oral) were compared between R/E using generalized linear modeling. Multinomial logistic regression was used to determine relative risk (RR) of pregnancy outcomes after adjusting for relevant factors (aRR).

RESULTS: Cohort was 44.6% NHW, 29.7% NHB, 14.7% Hispanic, and 11.1% Asian. Highest rate of initial insulin therapy was in NHW (26%), compared with 24%, 8%, and 18% in NHB, Hispanic, and Asian R/E, respectively, RR: 1.4 (1.03-2.0). Initial oral therapy was highest in Hispanic (93%), compared with 74%, 76%, and 82% in NHW, NHB, and Asian R/E, RR: 1.3 (1.1-1.4).

Pregnancy outcomes were compared after stratifying by initial treatment and R/E (Table 1). Cesarean and large for gestational age differed significantly between R/E (p=0.010 and 0.007, respectively) in those with oral therapy. Hispanic with oral treatment had greater risk of birth injury, RR: 3.6 (1.04-12.3) compared to other R/E.

Compared to oral treatment, initial insulin treatment was associated with greater risk of preeclampsia (aRR: 1.75, 1.1-2.8) after adjusting for tobacco, obesity and chronic hypertension. When included in the logistic model, R/E did not significantly impact this outcome. Chronic hypertension was a significant predictor of insulin therapy, aRR: 2.7 (1.7-4.4).

1036 The impact of social vulnerability data while utilizing machine learning to predict preeclampsia

Carly I. Hirschberg[1], Marek Sirendi[2], Christina Howe[2], Ipsita Chatterjee[3], Adriann Combs[4], Matthew J. Blitz[5], Michael Nimaroff[6], Burton Rochelson[6]
[1]Zucker School of Medicine at Hofstra of Northwell, New York, NY, [2]Aegis Ventures, New York, NY, [3]Northwell Holdings at Northwell Health, New York, NY, [4]Northwell Health, Manhasset, NY, [5]Zucker School of Medicine at Hofstra of Northwell, Bay Shore, NY, [6]Zucker School of Medicine at Hofstra of Northwell, Manhasset, NY

OBJECTIVE: We aimed to develop a machine learning model that utilizes social vulnerability data along with clinical information to predict the risk of preeclampsia. Additionally, we sought to analyze the impact social vulnerability data has in determining risk.

STUDY DESIGN: A multi-center analysis of patients who received prenatal care at Northwell Health from January 2018 to August 2023. Medical and social vulnerability data collected at the initial prenatal visit were used for the prediction models. Social vulnerability data included both individual demographics and neighborhood-level factors based on census tracts and social vulnerability index (SVI) published by the CDC in 2022. All data was available at the initial prenatal care visit. The algorithms to predict preeclampsia were trained using a gradient boosted decision tree model.

RESULTS: The dataset comprised of 106,626 patients, of whom 7.3% were diagnosed with preeclampsia during their pregnancy. The algorithm was fixed with a 10% false positive rate to enable comparison of predictive ability (Table 1). This predictive algorithm both with and without social vulnerability data (AUROC 0.8 vs. 0.82) exceeds the performance of current clinical guidelines (AUROC 0.68) as well as previously published models (the Mount Sinai — Sema4 consortium (AUROC = 0.70) and the Karolinska — Uppsala joint study (AUROC = 0.69)). Including social vulnerability data improves the specificity of the model by six percentage points leading to 74 fewer false positives in the test set of 1,281 patients. This difference is statistically significant with a p-value of 0.0017.

CONCLUSION: By using machine learning models that employ both clinical and social vulnerability data, preeclampsia can be predicted with greater accuracy than by using clinical information alone. These models could be applied to personalize risk assessment following a routine first prenatal office visit, without additional workup. Utilizing this model could allow for the targeting of high-risk patients with appropriate antepartum monitoring and counseling.

ECV, external cephalic version

1037 Screening for developmental dysplasia of the hip following external cephalic version

Alison M. Hoffer[1], Jonathan Hunt[2], Brianne Morrow[3], Andrea McGlynn[4]
[1]Naval Medical Center Portsmouth, Portsmouth, VA, [2]Naval Medical Center Portsmouth, CHESAPEAKE, VA, [3]Naval Medical Center Portsmouth, Norfolk, VA, [4]NMCP, Portsmouth, VA

OBJECTIVE: Breech presentation in the third trimester is an indication for screening for developmental hip dysplasia (DDH); however, external cephalic version (ECV) can obscure this information. The objective of this study was to identify whether a successful ECV delivered in cephalic presentation impacts rate of screening for and time-to-diagnosis of DDH compared to those delivered in breech presentation following an unsuccessful ECV.

STUDY DESIGN: IRB approval number NMCP.2023.0002. We performed a retrospective cohort study of all patients undergoing ECV at a single tertiary-care military treatment facility from 2016 to 2022 and assessed screening rates and time-to-imaging for DDH. The primary outcome for this analysis was whether a screening imaging study for DDH was ordered before six months of age.

RESULTS: Successful ECV was associated with a decreased likelihood of appropriate screening imaging study being ordered (60.7% vs 95.6%, $p < .001$). However, in those circumstances in which appropriate screening was ordered, there was no difference in completion rates (P=.42) or age at completion of the screening imaging study (P=.13). Nor was there a difference in rates of DDH diagnosed in either cohort (P=.67).

CONCLUSION: In a cohort of ECV procedures performed for a singleton fetus 34 weeks gestation or more, we found that a successful ECV was associated with a reduced rate of appropriate screening for DDH. This may be due to silos in care limiting transmission of relevant clinical information from the maternal care team to the pediatric care team, likely exacerbated by divides in data access within the electronic medical record.

1038 Population-based incidence of obstetric anal sphincter injuries and associated risk factors

Christopher X. Hong[1], Pamela S. Fairchild[1], Payton C. Schmidt[1], Jourdan E. Triebwasser[2]
[1]University of Michigan, Ann Arbor, MI, [2]University of Michigan , Ann Arbor, MI

OBJECTIVE: Although systematic reviews and meta-analyses have provided insight on the incidence and risk factors of obstetric anal sphincter injuries (OASIS), there are few contemporary population-based studies. Our aim was to assess the population-based incidence of OASIS and its associated risk factors.

STUDY DESIGN: We performed a retrospective case-control study using birth certificate data from the National Vital Statistics System from 2016 to 2021, which encompasses all recorded births in the United States. The incidence of OASIS among vaginal births was determined. Logistic regression was used to assess the relationship between risk factors and OASIS. The pseudo-R^2 (pR^2) was used to estimate the goodness of fit of univariate models, enabling a comparative assessment of the factors' association with OASIS.

RESULTS: A total of 15,413,957 were vaginal births were analyzed after excluding a negligible proportion (30,211; < 0.01%) for unknown data. The overall incidence of OASIS was 1.1%. The factors that exhibited the strongest predictability for OASIS were birth history (pR^2 5.8%) and operative birth (pR^2 4.8%), followed by infant weight (pR^2 1.5%); all other factors had a pR^2 of 0.5% or lower. Compared to primiparous patients, multiparous patients with a history of only cesarean birth(s) had a higher likelihood of OASIS (aOR 1.11, 95% CI 1.08-1.15), while those with any history of vaginal birth were approximately five times less likely to have an OASIS. Compared to spontaneous births, forceps-assisted births had the highest risk of OASIS (13.0% vs. 0.9%; OR 14.51, 95% CI 14.24-14.79), and this risk remained substantially elevated in a multivariable regression model (aOR 8.76, 95% CI 8.58-8.93). Vacuum-assisted births were also associated with an increased risk of OASIS (aOR 3.73, 95% CI 3.68-3.79).

CONCLUSION: In this population-based study of over 15 million vaginal births, birth history and operative birth were most strongly

predictive of OASIS, which occurred in 1.1% of births. Notably, use of forceps was independently associated with a 9-fold increase in the risk of OASIS, higher than previously cited.

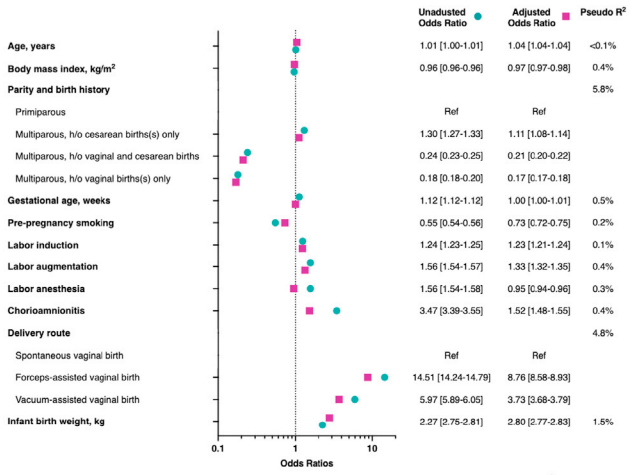

Figure 1. Odds ratios for obstetric anal sphincter injury following univariable and multivariable logistic regression modeling. The pseudo R^2 represents the proportion of overall variability that can be explained by each univariable model (ie, goodness of fit) and enables comparative assessment between risk factors.

1039 Resolution of low lying placentas:Does the distance matter?

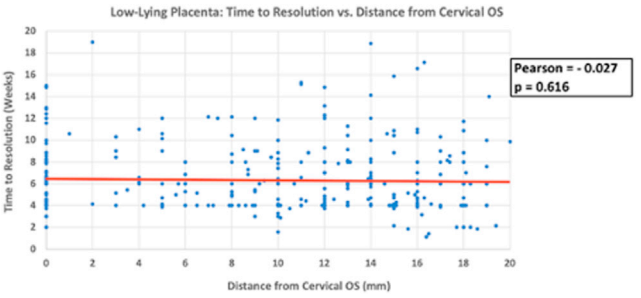
Stephanie Hopp[1], **John Palmieri**[2], **Barak Rosenn**[1]
[1]Jersey City Medical Center, Jersey City, NJ, [2]Rutgers New Jersey Medical School, Jersey City, NJ

OBJECTIVE: Most pregnant women undergo a 2nd-trimester trans-vaginal ultrasound (US) that often includes a trans-vaginal scan to determine cervical length and placental location relative to the cervix. A low-lying placenta (edge measuring ≤2cm from the cervix) is a frequent finding. Although most low-lying placentas will resolve by term, there is limited information on whether the distance from the cervical os at time of diagnosis affects time to resolution. The objective of this study was to test the hypothesis that the distance from the edge of a low-lying placenta to the cervical os at time of diagnosis is inversely correlated with the time to resolution**:** the shorter the distance, the longer it takes for the low-lying placenta to resolve.

STUDY DESIGN: IRB approved retrospective cohort study of singleton pregnancies who had a transvaginal US between 16-0/7-24-0/7 weeks gestation from 1/2019-12/2022. Subjects were identified by querying the US database for ICD-10 code O44.42. Patients were included if they had follow-up transvaginal scans until resolution (placental edge >2cm from the cervix) or within 4 weeks of delivery. Patients were excluded if their low lying placenta resolved before 20 weeks. Statistical analysis included Pearson correlation.

RESULTS: 626 patients were identified, of which 350 patients met inclusion criteria. Three (3) patients had an unresolved low lying placenta by time of delivery, leaving 347 patients with a resolved low lying placenta (99.14%). The mean (± SD) gestational age at diagnosis was 20-3/7 (±1-5/7) weeks, and the mean (±SD) time to resolution was 6-3/7 (± 3-2/7) weeks. The mean distance (±SD) of the placental edge from the cervical os at diagnosis was 9.6mm (±6.4mm), with a median distance of 11mm [range 0-20mm]. Pearson correlation showed no correlation between the distance and time to resolution (r = -0.027, p=0.616).

CONCLUSION: The vast majority of low lying placentas will resolve by time of delivery, but the distance from the placental edge to the cervical os at time of diagnosis does not impact time to resolution.



1040 The relation between maternal spiral artery perfusion in early pregnancy and subsequent adverse pregnancy outcomes

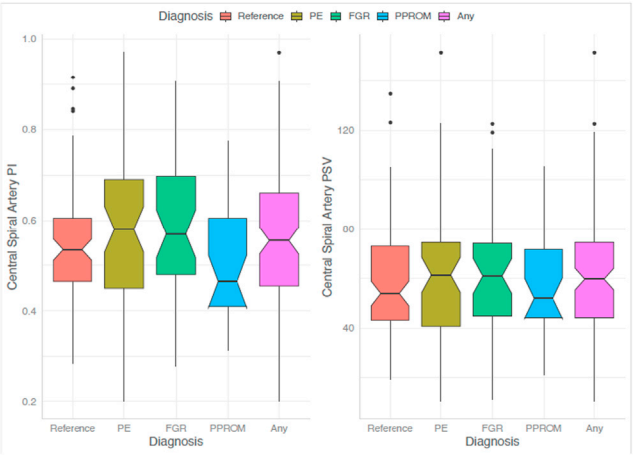
Rebecca Horgan[1], **Elena Sinkovskaya**[1], **Erkan Kalafat**[2], **George R. Saade**[1], **Alfred Abuhamad**[1]
[1]Eastern Virginia Medical School, Norfolk, VA, [2]Koc University School of Medicine, Istanbul, Istanbul

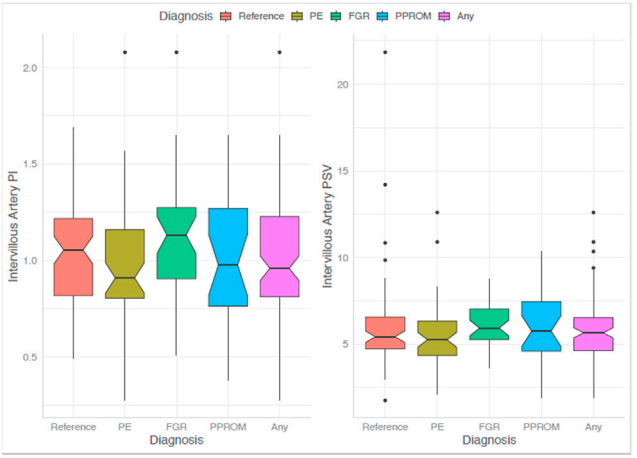
OBJECTIVE: To evaluate the relation between maternal spiral artery perfusion in early pregnancy and subsequent adverse pregnancy outcomes.

STUDY DESIGN: Patients with non-anomalous pregnancies at < 13+6 weeks gestation without umbilical cord or placental abnormalities were enrolled in a longitudinal cohort study to evaluate the relation between placental novel sonographic markers and pregnancy outcomes. Ultrasounds were performed and data were ascertained by certified and trained sonographers and research coordinators. Superb Microvascular Imaging (SMI®) ultrasound technology was used to obtain spiral artery pulsatility index (SA-PI) and peak systolic velocity (SA-PSV) on first trimester ultrasound. Data was compared between patients who developed subsequent adverse pregnancy complications including preterm prelabor rupture of membranes (PPROM), fetal growth restriction (FGR) or pre-eclampsia (cases) and normal low risk patients (controls aged 18-35 years, with a body mass index (BMI) < 30, without existing comorbidities, who conceived spontaneously and had an uncomplicated pregnancy, with delivery >37 weeks' gestation). Multinominal logistic regression tests were used for statistical analysis, with $p < 0.05$ used to denote statistical significance (R for Statistical Computing v.4.2.0).

RESULTS: Amongst the 610 included pregnancies, 125 patients (20.5%) developed one of our adverse pregnancy outcomes**:** PPROM (n=30), preeclampsia (n=60) and FGR (n=45).There was no difference in mean central spiral artery PI in the first trimester amongst patients who developed PPROM 0.46 (p=0.29), FGR 0.57 (p=0.10) or preeclampsia 0.58 (p=0.24) compared to the controls. There was no difference in mean central spiral artery PSV in the first trimester amongst patients who developed PPROM 52.0 cm/sec (p=0.78), FGR 61.0 cm/sec (p=0.71) or preeclampsia 61.4 cm/sec (p=0.63) compared to the controls.

CONCLUSION: Mean SA-PI and SA-PSV in the first trimester are not associated with subsequent PPROM, FGR or preeclampsia.





1041 The relation between placental intervillous perfusion in early pregnancy and subsequent adverse pregnancy outcomes

Rebecca Horgan[1], Elena Sinkovskaya[1], Erkan Kalafat[2], George R. Saade[1], Alfred Abuhamad[1]
[1]Eastern Virginia Medical School, Norfolk, VA, [2]Koc University School of Medicine, Istanbul, Istanbul

OBJECTIVE: To evaluate the relation between placental intervillous perfusion in early pregnancy and subsequent adverse pregnancy outcomes.

STUDY DESIGN: Patients with non-anomalous pregnancies at < 13+6 weeks gestation without umbilical cord or placental abnormalities were enrolled in a longitudinal cohort study to evaluate the relation between placental novel sonographic markers and pregnancy outcomes. Ultrasounds were performed and data were ascertained by certified and trained sonographers and research coordinators. Superb Microvascular Imaging (SMI®) ultrasound technology was used to obtain intervillous arteriole pulsatility index (IA-PI) and peak systolic velocity (IA-PSV) on first trimester ultrasound. Data was compared between patients who developed subsequent adverse pregnancy complications including preterm prelabor rupture of membranes (PPROM), fetal growth restriction (FGR) or preeclampsia (cases) and normal low risk patients controls (aged 18-35 years, with a body mass index (BMI) < 30, without existing comorbidities, who conceived spontaneously and had an uncomplicated pregnancy, with delivery >37 weeks' gestation). Multinominal logistic regression tests were used for statistical analysis, with $p < 0.05$ used to denote statistical significance (R for Statistical Computing v.4.2.0).

RESULTS: Amongst the 610 included pregnancies, 125 patients (20.5%) developed one of our adverse pregnancy outcomes**:** PPROM (n=30), preeclampsia (n=60) and FGR (n=45). There was no difference in mean IA-PI in the first trimester amongst patients who developed PPROM 0.98 (p=0.60), FGR 1.13 (p=0.20) or preeclampsia 0.91 (p=0.15), compared with controls(n=90). There was no difference in mean IA-PSV in the first trimester amongst patients who developed PPROM 5.75 cm/sec (p=0.77), FGR 5.92 cm/sec (p=0.79) or preeclampsia 5.25 cm/sec (p=0.26) compared with controls (n=90).

CONCLUSION: Mean IA-PI and IA-PSV in the first trimester are not associated with subsequent PPROM, FGR or preeclampsia.

1042 Racial disparities in maternal transfusion in the United States by mode of delivery

Parnian Hossein Pour, Maya Rajasingham, Giulia M. Muraca
McMaster University, Hamilton, ON

OBJECTIVE: To assess racial disparities in maternal transfusion in the United States (US) overall and stratified by mode of delivery.

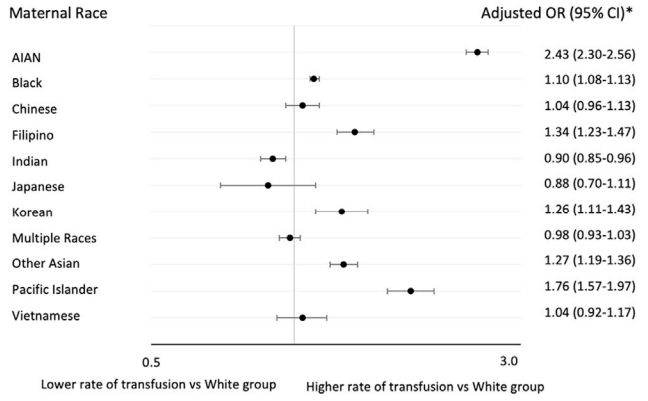
STUDY DESIGN: We performed a population-based, retrospective cohort study of full term, live births in 2016-2021 using CDC US Natality Files. Regression models were constructed to estimate adjusted odds ratios (aORs) and 95% confidence intervals (CIs) of maternal transfusion by self-identified maternal race in the total population, as well as among subgroups stratified by mode of delivery. Model adjustments are described in Figure 1.

RESULTS: The study included 16,339,947 patients; maternal transfusion occurred in 3.7 per 1000 deliveries. Compared with White patients (3.5 per 1000 transfusion rate), higher odds of transfusion were seen among American Indian and Alaska Native (AIAN), Black, Filipino, Korean, and Pacific Islander patients, while lower odds were found among Indian patients (Figure 1).

Rates of transfusion varied by mode of delivery**:** 2.3, 9.2, 5.3, 9.2, 5.1 per 1000 among spontaneous vaginal delivery (SVD), forceps, vacuum, cesarean deliveries (CD) with labor, and CD without labor, respectively. Among forceps deliveries, compared with White patients (9.1 per 1000 transfusion rate), Chinese patients had a nearly two-fold higher rate of transfusion (aOR 1.93, 95% CI 1.30-2.87), while Black patients had a nearly 30% lower rate of transfusion (aOR 0.71, 95% CI 0.56-0.91). Lower rates of transfusion in Black vs White patients were also observed in the SVD (2.2 vs 2.3 per 1000; aOR 0.93, 95% CI 0.90-0.97), vacuum (4.4 vs 5.3 per 1000; aOR 0.82, 95% CI 0.72-0.94), and CD with labor (9.0 vs 9.1 per 1000; aOR 0.91, 95% CI 0.87-0.95) groups, while a higher rate was shown among CDs without labor (7.0 vs 4.6 per 1000; aOR 1.39, 95% CI 1.34-1.44).

CONCLUSION: Racial disparities in maternal transfusion in the US are evident and vary by mode of delivery. Disaggregation by mode of delivery showed the increase in transfusion among Black vs. White patients was confined among CDs without labor; Black patients had lower rates of transfusion in all other mode of delivery groups.

Figure 1. Maternal transfusion by maternal race compared with White race, full term, live births, United States, 2016-2021



OR, odds ratio; CI, confidence interval; AIAN, American Indian and Alaskan Native.

1043 Magnesium sulfate administration in preeclampsia without severe features and perinatal outcomes

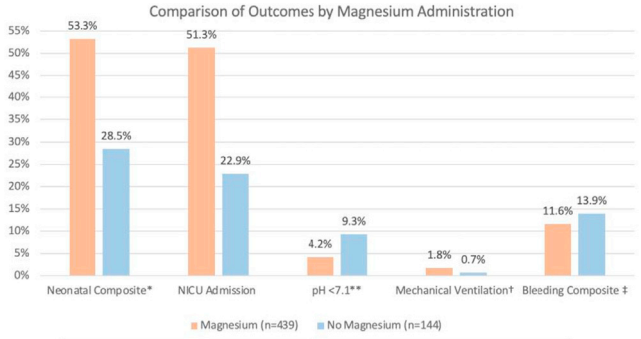
Samantha E. Howell[1], Christina T. Blanchard[2], Morgan Jenkins[1], Grace M. Lee[1], Macie L. Champion[1], Michelle Y. Lu[1], Ashley N. Battarbee[1], Brian M. Casey[1], Akila Subramaniam[2]
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: Magnesium sulfate (Mg) for seizure prophylaxis is recommended for patients with preeclampsia with severe features. There is no consensus for preeclampsia without severe features (mild preeclampsia), and thus is often left to the discretion of the provider. Our objective was to evaluate neonatal outcomes according to whether Mg was administered for seizure prophylaxis in patients with mild preeclampsia.

STUDY DESIGN: Retrospective cohort study of patients with mild preeclampsia who delivered at our institution between November 2021, and May 2022. Patients with fetal anomalies and those delivering at < 32 weeks gestation, given Mg for cerebral palsy prophylaxis, were excluded. The primary outcome was a composite of adverse neonatal outcomes (Figure*). Secondary outcomes included the individual components of the neonatal composite and a maternal bleeding composite (Figure†). Outcomes were compared using chi-squared test and multivariable logistic regression estimated the association between Mg and the outcomes, adjusting for baseline characteristics that were unbalanced between groups.

RESULTS: Of 583 patients included, 439 (75%) received Mg and 144 (25%) did not. Patients receiving Mg were more likely to have public insurance, comorbidities (cHTN, GDM), aspirin use, earlier GA at delivery, and chorioamnionitis. The composite adverse neonatal outcome was more frequent in patients who received Mg (53% vs. 29%, aOR 1.85, 95% CI 1.13-3.04) than those who did not receive Mg. This was primarily driven by an increase in NICU admission (Figure). While rates of neonates with pH < 7.1 was higher in the no Mg group, there was no difference in other secondary outcomes including maternal bleeding outcomes (Figure).

CONCLUSION: We found an increase in adverse neonatal outcomes, primarily NICU admission, in patients receiving Mg for mild preeclampsia. While this data is limited by undetermined indications for NICU admission, further studies are warranted regarding the short and long-term benefits and risks of Mg for mild preeclampsia given the potential for adverse neonatal consequences.



Outcome	aOR (95% CI) No magnesium as referent group
Neonatal Composite*	1.85 (1.13-3.04)
NICU admission	2.46 (1.46-4.14)
pH <7.1**	0.36 (0.15-0.88)
Base excess > 12**	0.60 (0.10-3.54)
5-minute Apgar < 3**	0.19 (0.03-1.15)
Mechanical ventilation**	1.30 (0.15-11.34)
Bleeding Composite†	0.88 (0.47-1.66)

*Neonatal composite: NICU admission, pH <7.1, base excess > 12, 5-minute apgar <3, neonatal death, culture proven sepsis, mechanical ventilation
**Baseline characteristics used in adjusted models include public insurance, married, BMI, alcohol use, aspirin use, cHTN, pregestational DM, GA at delivery, and chorioamnionitis
†Bleeding composite: EBL >1L, transfusion of pRBC

1044 Predicting fetal weight with umbilical cord and umbilical vessel diameter

Amy Hua[1], David Garry[2], Ivan Ngai[3]
[1]Flushing Hospital Medical Center, Department of Obstetrics and Gynecology, Long Island, NY, [2]Stony Brook Medicine, Stony Brook, NY, [3]Flushing Hospital Medical Center, Flushing, NY

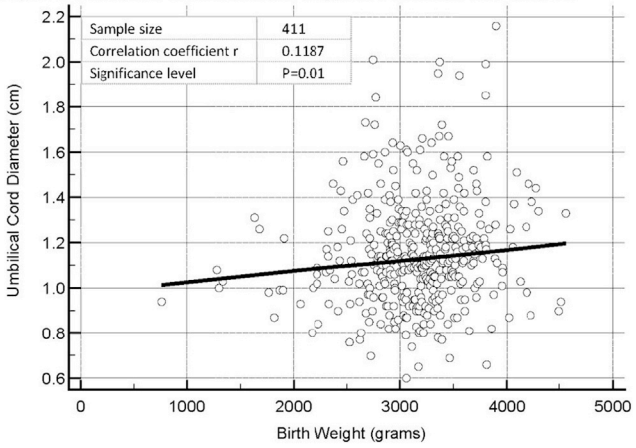
OBJECTIVE: Fetal growth and development depends on the delivery of nutrients by the placenta from the mother to the fetus. Accordingly, the size of the umbilical cord has the potential to predict fetal outcomes. We sought to evaluate the association between umbilical cord diameter and birth weight.

STUDY DESIGN: A free floating umbilical cord cross-section was evaluated in all patients from June 2021 to June 2022 during the standard second trimester anatomy ultrasound. The entire umbilical cord diameter, individual umbilical arteries and vein diameters were measured in the sagittal view. Only patients who delivered a live infant and had a fetal anatomy ultrasound performed at our institution were included. Patients with two vessel cords, fetal demise, aneuploidy and twin gestations were excluded. Demographic and clinical data were extracted from the electronic medical records. Umbilical vessel diameters to newborn birth weight were compared using linear regression. Statistical significance was set at $p < 0.05$.

RESULTS: During the study period, 1043 patients with a second trimester anatomy ultrasound performed between 18-22 weeks (Mean: 21.4; SD: +2.11) were evaluated with 410 patients having the umbilical vessels measured and met inclusion criteria. There was a positive correlation between umbilical cord diameter and birth weight (r-value: 0.118, p-value 0.01). Figure 1. In the linear regression model, umbilical cord diameter was a significant independent predictor of newborn birth weight (β=225.3; p=0.023). Individual cord vessels, umbilical vein diameter (r-value: 0.10; p-value 0.05), and umbilical artery (r-value: 0.02, p-value 0.73) did not correlate with birth weight.

CONCLUSION: There is a significant positive correlation between umbilical cord diameter and birth weight, and a potential for a second trimester variable to predict newborn birth weight.

Figure 1. Correlation of newborn birth weight and umbilical cord diameter



1045 The dose-dependent effect of obesity on maternal and neonatal outcomes

Sara I. Jones[1], Elise A. Rosenthal[1], Jessica E. Pruszynski[1], Gary Cunningham[2]
[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Parkland Hospital, Dallas, TX

OBJECTIVE: To evaluate the prevalence of adverse maternal and neonatal outcomes associated with obesity. We hypothesized that obesity confers a dose-dependent risk for these outcomes.

STUDY DESIGN: This was a retrospective cohort study of singleton pregnancies delivered between 24 and 42 weeks gestation at an urban county hospital between 2013 and 2021. Body mass index (BMI) at first prenatal visit was used as a proxy for pre-pregnancy weight. Patients were excluded if no first trimester BMI was available.

RESULTS: During the study period, 58497 patients delivered a singleton infant, of which 12365 (21.1%), 5429 (9.3%), and 3482 (6.0%) had class I, II, and III obesity, respectively. Non-obese patients were more likely to be younger and nulliparous with a mean delivery gestational age of 39 weeks across all groups. Increasing obesity was associated with a dose-dependent increase in cesareans (27% for non-obese versus 46% for class III obesity). There was an association between increasing obesity and peripartum complications, including severe preeclampsia (8% in non-obese versus 19% in class III obesity) and gestational diabetes (5% in non-obese versus 15% in class III obesity). Infants born to patients with class III obesity versus non-obese patients were more likely to develop grade III-IV intraventricular hemorrhage (RR 4.58, 95%, CI 2.10-9.99), sepsis (RR 3.76, 95% CI 2.00-7.06), respiratory distress syndrome (RDS) (RR 2.66, 95% CI 2.15-3.29), and have an initial cord gas pH < 7 (RR 2.48, 95%CI 1.68-3.66) (Figure).

CONCLUSION: Increasing BMI is associated with a dose-dependent increase in associated adverse maternal and neonatal outcomes. Infants born to patients with higher classes of obesity have significant associated morbidity including a 2 to 4 times increased risk of neonatal acidosis, grades III-IV IVH, sepsis, and RDS.

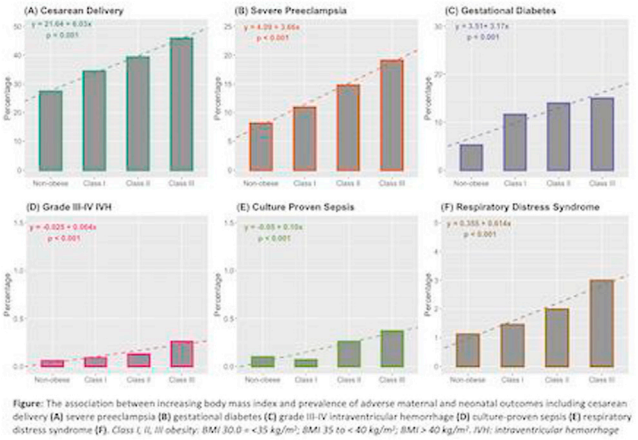


Figure: The association between increasing body mass index and prevalence of adverse maternal and neonatal outcomes including cesarean delivery (A) severe preeclampsia (B) gestational diabetes (C) grade III-IV intraventricular hemorrhage (D) culture-proven sepsis (E) respiratory distress syndrome (F). *Class I, II, III obesity: BMI 30.0 = <35 kg/m²; BMI 35 to < 40 kg/m²; BMI > 40 kg/m². IVH: intraventricular hemorrhage*

1046 Socioeconomic insecurity and pregnancy outcomes: A case for comprehensive social services to improve obstetric care

Adina R. Kern Goldberger[1], Kirat Sandhu[2], Stacey Ehrenberg[2], Cara D. Dolin[3]
[1]Cleveland Clinic Lerner College of Medicine, Cleveland, OH, [2]Cleveland Clinic Foundation, Cleveland, OH, [3]Cleveland Clinic, Pepper Pike, OH

OBJECTIVE: Social determinants of health (SDoH) impact risk for maternal and perinatal morbidity and contribute to health inequity. Systematic screening for SDoH in routine pregnancy care could target "wrap around" services to improve long-term wellness and short-term obstetric outcomes. This study investigates the association between SDoH and pregnancy outcomes.

STUDY DESIGN: This retrospective cohort study evaluated all patients who delivered 1/1/18-6/30/23 in a multi-hospital health system in a single metropolitan area and underwent SDoH screening. The primary exposure, "socioeconomic insecurity" (SEI) was a composite of SDoH elements from the screening template including housing instability, poor access to transportation, financial strain, food insecurity, and intimate partner violence. The primary outcome was preterm birth < 37 weeks (secondary outcomes in Table). All data were extracted from the EMR, patient demographics and clinical characteristics were compared in univariable analysis, and multivariable logistic regression was used to evaluate the association of SEI with outcomes.

RESULTS: 15,763 patients had comprehensive SDoH screening (23.4% of deliveries, with 20.2% screening positive for at least one element of the composite). Patients with SEI were more likely to be younger, Black, Hispanic, insured by Medicaid, and multiparous, and to have higher pregravid BMI (mean 30.0 [8.1] vs 27.6 [6.8]) and a high obstetric co-morbidity index (≥ 6; 6.9 vs 4.3%) [$p < 0.01$ for all]. Adjusted analysis demonstrated higher odds of preterm birth < 37 weeks for patients with SEI, even when accounting for other relevant health determinants, though not for the other outcomes [Table].

CONCLUSION: Socioeconomic security may independently increase risk for preterm birth and could amplify the risks levied by other social determinants such as race. Universal SDoH screening in pregnancy could better identify patients at risk of preterm birth and direct appropriate social services to optimize outcomes.

Table. Association of Socioeconomic Insecurity with Preterm Birth and Other Obstetric Outcomes

	aOR*	95% Confidence Interval	P-Value
Preterm delivery < 37 weeks	1.24	1.07 – 1.42	**< 0.01**
Preterm delivery < 34 weeks	1.11	0.87 – 1.43	0.40
Severe preeclampsia	0.84	0.65 – 1.09	0.18
SMM without transfusion	0.91	0.57 – 1.45	0.70
Maternal ICU admission	1.09	0.56 – 2.14	0.79
Postpartum length of stay ≥ 5 days	0.90	0.63 – 1.31	0.59
NICU admission**	1.10	0.94 – 1.27	0.23

*Adjusted Odds Ratio: Model adjusted for race, ethnicity, insurance type, diabetes, chronic hypertension, and obesity (BMI ≥ 30) based on results of univariable analyses
**Model also adjusted for gestational age at delivery (unadjusted OR of NICU admission 1.34, 95% CI 1.20-1.53, p < 0.01)

1047 The role of incorporating MFM physicians onto labor and delivery in reducing maternal morbidity

Adina R. Kern Goldberger[1], Megan Ansbro[2], Cara D. Dolin[3], Edward Chien[4], Justin R. Lappen[5]

[1]Cleveland Clinic Lerner College of Medicine, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic, Pepper Pike, OH, [4]Cleveland Clinic, Lakewood, OH, [5]Cleveland Clinic Foundation, Cleveland, OH

OBJECTIVE: With expertise in complex deliveries, maternal-fetal disease, and obstetric emergencies, MFM physicians can contribute meaningfully to labor and delivery (L&D) care. There is variability in the role of MFM physicians on delivery units. This study evaluated the impact on severe maternal morbidity (SMM) of a health system change to add an MFM physician to the L&D team.

STUDY DESIGN: This is a retrospective cohort study of all deliveries > 20 weeks from 1/1/2018-12/31/2022 at 2 academic hospitals in a large health system. Both hospitals previously had consultative-only MFM involvement on L&D, but added an MFM attending to the L&D team 4/2021. Patient-level clinical data were extracted from the medical record and compared pre/post. The only other systemic change during this time was adoption of a hypertension care bundle, so a planned sensitivity analysis excluding patients with chronic hypertension/preeclampsia was conducted. The primary outcome was SMM without transfusion (Table). Multivariable logistic regression was used to evaluate SMM pre- and post-MFM presence on L&D.

RESULTS: There were 31,680 deliveries in the pre-MFM period and 21,292 in the post-period with no differences in patient characteristics across period including race/ethnicity, insurance status, pregravid BMI, parity, plurality, gestational age at delivery, or mode of delivery – other than higher mean maternal age [31.9 (SD 5.3) v. 29.7 (5.6), $p < 0.01$] and higher OB-CMI in the post-period (Table). There were significantly decreased odds of SMM, hemorrhage, and maternal ICU admission in the post-period on adjusted analysis (Table), with similar findings excluding patients with hypertension/preeclampsia.

CONCLUSION: Adding an MFM physician to L&D was associated with reduced SMM, despite increased maternal age and co-morbidities in the post-group. These findings suggest the impactful role that the perspective and knowledge of MFM physicians can have in reducing morbidity in real-time on L&D.

Table. Impact of MFM Coverage of Labor & Delivery on Severe Maternal Morbidity & Other Maternal Outcomes

	Full Cohort			Cohort Excluding Patients with Chronic Hypertension/Gestational Hypertension/Preeclampsia+		
	aOR*	95% CI	P-Value	aOR*	95% CI	P-Value
SMM without transfusion**	0.74	0.58 – 0.93	**0.01**	0.70	0.51 – 0.95	**0.03**
Postpartum hemorrhage (EBL ≥ 1L)	0.90	0.84 – 0.96	**<0.01**	0.89	0.82 – 0.96	**< 0.01**
Maternal ICU admission	0.62	0.42 – 0.92	**0.02**	0.59	0.37– 0.95	**0.03**

1048 Population attributable risk proportion of modifiable and non-modifiable risk factors for stillbirth

Sameer Khan[1], Padmalatha Gurram[2], Sara Brescia[2], Andrew Nyein[2], Katherine Livatova[2], Jessica Abruzzese[2], Kiran Trivedi[2]

[1]Good Samaritan University Hospital, Roslyn, NY, [2]Good Samaritan University Hospital, West Islip, NY

OBJECTIVE: Many risk factors are attributed to stillbirth, however, the exact proportion of stillbirths explained by these factors are unknown. We examined the proportions of stillbirths that are attributable to established modifiable and non-modifiable risk factors.

STUDY DESIGN: This is a retrospective case-control study. Eligible cases include women with stillbirths from January 2013 to July 2022. The cases were matched to controls based on the year of stillbirth and gestational age at the time of delivery. Stillbirths at or greater than 20 weeks gestation and fetal weight greater than or equal to 350 g if the gestational age is not known are included. Stillbirths with congenital anomalies and chromosomal abnormalities and miscarriages before 20 weeks of gestation were excluded.

The risk factors selected for analysis were women less than 20 and greater than 35 years of age, non-Hispanic black race, BMI greater than 30, nulliparity, short inter pregnancy interval (less than 18 months), insufficient prenatal care (less than 3 prenatal visits), illicit substance use (alcohol and drug), smoking, preexisting medical conditions such as diabetes, hypertension and anemia and In vitro fertilization. The main outcome measure is the population attributable risk proportion (PARP) of stillbirth. The PARP is calculated for individual risk factors.

RESULTS: There are 44,286 livebirths and 175 stillbirths (0.40%). 175 stillbirths and 154 controls were studied. Most of the women with stillbirths are between 20 to 35 years of age (77.7%), predominantly Caucasian (44.6%), 38% were between 20 to 25 weeks and 24% were between 36 to 40 weeks at diagnosis. When considering modifiable risk factors, insufficient prenatal care has the highest PARP% followed by age less than 20 , illicit substance use and diabetes (Table 1). The most important non- modifiable risk factor is nulliparity (Table 1).

CONCLUSION: Changes to modifiable risk factor profiles especially focusing on insufficient prenatal care, teenage pregnancies, substance use disorders and diabetes could potentially reduce stillbirth rates.

Table 1: PARP for Combination of Risk Factors	
2 Risk Factors	Cases (stillbirths) N = 175 PARP % (95%CI)
Age <20, Non-Hispanic Black Race	2.78 (-2.29 - 7.85)
Age >35, Non-Hispanic Black Race	-68.5 (-71.9 - -65.2)
Age <20, BMI >30	-147.2 (-155.2 - -139.1)
Age >35, BMI >30	40.7 (39.1 - 42.3)
Non-Hispanic Black Race, BMI >30	-2.4 (-4.0 - -0.8)
Age <20, Smoking	NA: NO PATIENTS
Age >35, Smoking	NA: NO PATIENTS
BMI >30, Smoking	-69.7 (-73.1 - -66.3)
Age <20, Illicit Drug Use	NA: NO PATIENTS
Age >35, Illicit Drug Use	-107.9 (-116.2 - -99.6)
Age >35, IVF Pregnancy	27.5 (22.6-32.4)
BMI >30, IVF Pregnancy	-101.2 (-107.5 - -94.8)
BMI >30, Primiparous	35.0 (34.2 - 35.8)
Age >35, Primiparous	3.4 (1.2 - 5.5)
IVF Pregnancy, Primiparous	-13.4 (-21.0 - -5.8)
Age <20, No Prenatal visits	74.8 (72.3 - 77.4)
Age >35, Short Interpregnancy Interval (<18 months)	NA: NO PATIENTS
Age >35, Hypertension	29.6 (27.0 - 32.1)
BMI > 30, Hypertension	37.1 (36.0 - 38.2)
Non-Hispanic Black Race, Hypertension	39.6 (37.9 – 41.3)
Primiparous, Hypertension	-131.4 (-137.3 - -125.6)
Age >35, Diabetes Mellitus	45.7 (43.6 – 47.7)
BMI >30, Diabetes Mellitus	30.5 (29.3 – 31.7)
Non-Hispanic Black Race, Diabetes Mellitus	-13.2 (-16.2 - -10.3)
Primiparous, Diabetes Mellitus	13.5 (11.1 – 15.8)

1049 The association between stillbirth and maternal serum analyte levels

Kavisha Khanuja[1], Lucy Qi[2], Tracy Gao[2], Sascha Wodoslawsky[2], Mariella Toro[2], Moti Gulersen[2], Huda B. Al-Kouatly[1], Rodney A. McLaren Jr.[2]

[1]Thomas Jefferson University, Philadelphia, PA, [2]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA

OBJECTIVE: Abnormal maternal serum analytes measured during prenatal screening have been associated with adverse pregnancy outcomes. We sought to examine the association between first and second trimester maternal serum analyte levels obtained for prenatal aneuploidy screening and stillbirth (fetal loss >20 weeks gestation).

STUDY DESIGN: Retrospective cohort study of all singleton, non-anomalous pregnancies with no known genetic disorders dated by first-trimester ultrasound with available serum analyte data who delivered between from 3/1/2017 to 12/31/2022. Multiple of the median (MoM) values for free beta-human chorionic gonadotropin (β-hCG), pregnancy-associated plasma protein A (PAPP-A), maternal serum alpha-fetoprotein (AFP), unconjugated estriol, and inhibin A) were compared between two groups**:** patients with stillbirths (i.e. study group) and those with live births (i.e. control group) using variable analyses. Standard cutoffs for abnormal analyte levels were also compared between the two groups. Multivariable analyses were performed to adjust for potential confounders.

RESULTS: Of the 5,092 pregnancies included in the study, 45 (1.1%) had a stillbirth. After adjusting for potential confounders, there were no statistically significant differences in mean serum analyte levels between the two groups (Table 1). Additionally, the proportions of abnormal analyte levels were similar between the two groups.

CONCLUSION: The results of this large cohort demonstrated no association between serum analyte levels and stillbirth. Our data does not support use of these biochemical markers as a screening tool for stillbirth.

Table 1: Serum Analytes in Patients with Stillbirth vs Livebirth

Baseline Characteristics			
	Stillbirth n=45	Livebirth n=5,047	P-value
Maternal age (y)	30.1±5.8	30.3±5.6	0.828
GA at delivery (wk.d)	**29.6±6.6**	**38.7±1.9**	**<0.001**
Birthweight (g)	**1205 (445, 2640)**	**3210 (2890, 3530**	**<0.001**
Body mass index (kg/m^2)	32.4±5.7 [44]	32.3±7.1 [4,972]	0.895
Chronic hypertension	12 (26.7%)	1,007 (26.7%)	0.997
Preeclampsia	7 (17.1%) [41]	622 (13.2%) [4,725]	0.462
Diabetes	5 (11.1%)	592 (15.7%)	0.400
Serum Analytes			
PAPP-A MoM	1.21 (0.60, 1.82) [24]	1.23 (0.83, 1.82) [2,665]	0.714
Abnormal PAPP-A	5 (20.8%) [24]	593 (22.3%) [2,665]	0.868
AFP MoM	1.09 (0.97, 1.43) [33]	1.09 (0.88, 1.37) [3,189]	0.417
Abnormal AFP	4 (12.1%) [33]	410 (12.9%) [3,189]	0.990
β-hCG 1st MoM	1.08 (0.81, 1.43) [23]	1.07 (0.80, 1.39) [2,636]	0.920
β-hCG 2nd MoM	1.12 (0.84, 1.72) [23]	1.09 (0.74, 1.52) [2,144]	0.549
Abnormal β-hCG	2 (4.4%)	234 (4.6%)	>0.99
Estriol MoM	1 (0.77, 1.26) [23]	1.01 (0.83, 1.21) [2,457]	0.979

Abnormal Inhibin	2 (8.7%) [23]	171 (7.0%) [2,456]	0.745

Abbreviations: AFP, alpha-fetoprotein; β-hCG, beta-human chorionic gonadotropin; GA, gestational age; MoM, multiple of the median; PAPP-A, pregnancy-associated plasma protein A. Data presented as mean±standard deviation, N(%) [N, if missing], or median (interquartile range)

*Adjusted for maternal age, body mass index, male fetal sex, gestational age at delivery.

1050 Stillbirth as a risk factor for dementia: a prospective population-based UK Biobank study

Haemin Kim[1], Mi-Young Oh[2], Young Mi Jung[3], Jeesun Lee[4], Sang-Hyuk Jung[5], Manu Shivakumar[5], Dokyoon Kim[5], Chan-Wook Park[4], Joong Shin Park[4], Jong Kwan Jun[4], Seung Mi Lee[4]

[1]Seoul National University College of Medicine, Daegu, Taegu-jikhalsi, [2]Bucheon Sejong Hospital, Bucheon, Kyonggi-do, [3]Korea University College of Medicine, Seoul, Republic of Korea, Seoul, Seoul-t'ukpyolsi, [4]Seoul National University College of Medicine, Seoul, Seoul-t'ukpyolsi, [5]University of Pennsylvania, Philadelphia, PA

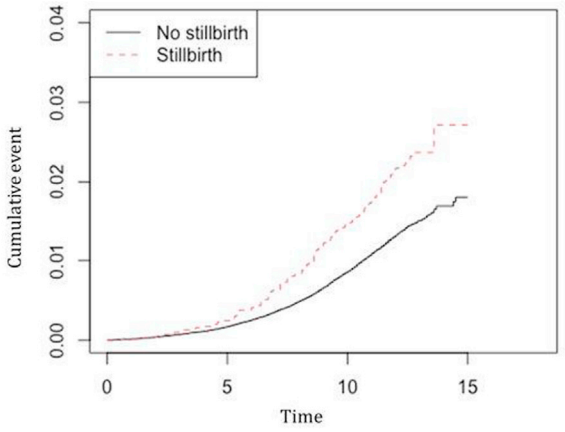
OBJECTIVE: Adverse pregnancy outcomes (APO) have been reported to increase the risk of long-term cardiovascular or metabolic disease later in life. In the current study, we tried to evaluate the risk of dementia in middle-aged women according to the history of APO.

STUDY DESIGN: The UK Biobank is a prospective cohort study from 2006 to 2010, encompassing > 500,000 individuals at 40-60 years from the United Kingdom. Among them, we included 220,395 women and compared the new onset of dementia according to the history of APO using the Cox proportional hazard model.

RESULTS: In middle-aged women, dementia has newly occurred in a total of 3,047 women (1.38%) during follow up. Among APOs, only history of stillbirth increased the risk of dementia whereas other APOs such as hypertensive disease in pregnancy, gestational diabetes mellitus, and recurrent spontaneous abortion was not associated with the risk of dementia. Even after adjusting the confounding variables, women who had a history of stillbirth increased risk of a new onset of dementia. (HR 1.1855, p=0.048).

CONCLUSION: History of stillbirth was associated with an increased risk of dementia and should be also considered as a risk factor for dementia.

Figure. Kaplan-Meier survival curves of dementia according to the history of stillbirth



1051 The burden of substance use associated stigma in pregnancy

Alison M. Kimura[1], Melissa L. Fair[2], Kara Davis[3], Hannah McKinnon[2], Kacey Eichelberger[4]

[1]Prisma Health, Greenville, SC, [2]Furman University Institute for the Advancement of Community Health, Greenville, SC, [3]University of South Carolina Upstate, Spartanburg, SC, [4]USC School of Medicine Greenville, Greenville, SC

OBJECTIVE: Stigma is a predictor of the quality and quantity of prenatal care among patients with substance use disorder (SUD). The Substance Use Stigma Mechanism Scale (SU-SMS), a previously validated scale, measures 3 domains of substance use related stigma: enacted, anticipated, and internalized stigma. Our objective was to quantify the burden of stigma among a cohort of patients at a perinatal addiction medicine collaborative care clinic, evaluating differences by age, SUD type, and trimester of prenatal care initiation. Our hypothesis was that older patients, patients with stimulant use disorders, and those who delayed prenatal care will report higher levels of stigma.

STUDY DESIGN: This is a prospective cohort study of all patients who received prenatal care at our addiction medicine collaborative care clinic, were at least 18 years old, and completed the SU-SMS tool. ANOVAs were used to compare domain-specific stigma scores by age (> 25 years, 25-29.99, 30-34.99, equal or > 35), SUD type (opioid only, stimulant only, combined opioid/stimulant, all other SUD diagnoses), and trimester of prenatal care initiation.

RESULTS: 166 patients completed the SU-SMS tool and are included in this analysis. Patients reported highest levels of internalized stigma, (M =3.14, SD=1.06), followed by enacted (M=2.31, SD=1.0) and anticipated stigma (M=1.81, SD=0.90). Those who initiated prenatal care in the third trimester had significantly higher internalized stigma scores compared to those who initiated in the first trimester (3.76 vs 2.90, $p<0.01$). Patients with stimulant or combined opioid/stimulant use disorders reported significantly higher anticipated (F=3.48, p=0.02) and enacted (F=6.21, $p<0.001$) stigma when compared to patients with other SUD diagnoses.

CONCLUSION: This study supports previous research on the association between stigma and delayed entry to prenatal care and enhances understanding of differences in stigma by SUD type among pregnant individuals with SUD. Future research should explore ways to reduce community level stigma and incorporate patient care models that address different domains of stigma.

1052 Smoking Reduction in Gravid Patients with Substance Use Disorders (SIGS): A Randomized Controlled Trial

Rubymel Jijon Knupp[1], Christina T. Blanchard[2], Annkay Alexander[3], Jordan Garcia[3], Jenna Stanford[3], Kevin S. Shrestha[3], Kaitlyn Kincaid[3], William Andrews[3], Lorie M. Harper[4], Jeff M. Szychowski[3], Brian M. Casey[3], Alan T. Tita[3], Rachel Sinkey[5]

[1]University of Alabama at Birmingham, Jacksonville, FL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham, AL, [4]University of Texas at Austin, Dell Medical School, Austin, TX, [5]University of South Florida, Tampa, FL

OBJECTIVE: To determine if measuring exhaled carbon monoxide (eCO) at prenatal visits (PNV) is associated with cigarette smoking cessation or reduction as estimated by eCO.

STUDY DESIGN: Single-center, parallel randomized trial including pregnant individuals 14-45 years old < 24 weeks gestational age (GA) who self-reported smoking ≥10 cigarettes/day. Multiples, fetal growth restriction (FGR), anomalies/aneuploidy, demise, or e-cigarette use were exclusions. All participants measured eCO at PNV but were randomized 1:1 to either eCO disclosure or no disclosure (control). Primary outcome was prevalence of smoking ≥10 cigarettes/day at final measurement (FM) per eCO. With 90% power and 2-sided α of 0.05, a sample size of 74 was estimated to detect a 50% reduction in smoking ≥10 cigarettes/day from a rate of 90%. Secondary outcomes were self-reported smoking and average # of cigarettes smoked/day per eCO, average %fetal carboxyhemoglobin (% FCH) at FM, FGR, GA at delivery, birthweight (BW), and Apgars.

RESULTS: From 2/2021 to 2/2023, 74 patients were randomized. eCO values at randomization were higher in the intervention group (15.4±8.8 vs 11.3±5.6, p=0.02). Thirty in the intervention and 32 in the control arm had delivery data available for analysis. Prevalence of smoking ≥10 cigarettes/day at FM per eCO was not different (73% vs 50%, p=0.06). Prevalence of self-reported ≥10 cigarettes/day (39% vs 52%, p=0.30), average # of self-reported cigarettes/day (8.1±8.5 vs 7.8±5.2, p=0.90), average # of cigarettes per eCO (18.3±9.4 vs 14.6±9.6; p=0.12), and average %FCH (4.3±4.8 vs 2.6±1.9, p=0.08), all at FM, were not different between the intervention and control groups, respectively (Table). Clinical outcomes including FGR (3% vs 0%, p=0.49), GA at delivery (35±5.8 vs 36±4.0, p=0.29), BW (2396±1129 vs 2785±722g p=0.27) and 5-minute Apgars (7±3 vs 8±2, p=0.73) were not different. Despite this, most participants in the intervention and control arms (83% vs 60%, p=0.14) report planning future device use.

CONCLUSION: Exhaled carbon monoxide monitoring in pregnancy did not improve smoking cessation or clinical outcomes.

Table. Outcomes Among Pregnant Participants in the SIGS Randomized Trial

	Intervention (N = 30)	Control (N = 32)	*p* value
Primary outcome			
≥10 cigarettes/day per eCO	22 (73.3)	16 (50.0)	0.06
Secondary outcomes			
≥10 cigarettes/day per patient report	12 (38.7)	17 (51.5)	0.30
# of cigarettes/day per patient report	8.1 ± 8.5	7.8 ± 5.2	0.89
Average # of cigarettes smoked/day per eCO			0.12
Non-smoker	4 (13.3)	5 (15.6)	
Lighter smoker	4 (13.3)	11 (34.4)	
Heavy smoker	22 (73.3)	16 (50.0)	
Average % fetal carboxyhemoglobin per eCO	4.3 ± 4.8	2.6 ± 1.9	0.09
Hypertensive Disorders of Pregnancy	10 (28.6)	14 (38.9)	0.36
Gestational Hypertension	2 (5.7)	6 (16.7)	0.26
Preeclampsia	8 (22.9)	8 (22.2)	0.95
Gestational Diabetes			0.61
Yes	2 (5.7)	1 (2.8)	
No	33 (94.3)	35 (97.2)

Use eCO monitoring in the future?			0.14
Yes	19 (82.6)	12 (60.0)	
Unsure	4 (17.4)	6 (30.0)	
No	0 (0.0)	2 (10.0)	

All eCO smoking measurements and self-reported smoking values obtained at last prenatal visit or delivery.
eCO = exhaled carbon monoxide, GA = gestational age; IUFD = intrauterine fetal demise

1053 Postpartum visit timing and the effect on visit attendance: A randomized controlled trial

Martha B. Kole-White[1], Lauren Schlichting[2], Nina K. Ayala[1], Renee R. Eger[1], Margaret Howard[3], Srilakshmi Mitta[1], Adam K. Lewkowitz[4]

[1]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [2]Hassenfeld Child Health and Innovation Institute of Brown University, Providence, RI, [3]Department of Psychiatry & Human Behavior, Brown University, Providence, RI, [4]Warren Alpert Medical School of Brown University, Women & Infants Hospital Rhode Island, Providence, RI

OBJECTIVE: More than 60% of maternal deaths in the US occur postpartum (PP). Optimal PP care may reduce mortality, but ~40% of women do not attend the standard 6-week PP visit. We sought to examine if adding an early PP visit improves PP visit attendance.

STUDY DESIGN: We conducted a randomized controlled trial (RCT) at a single tertiary care center at which PP visits are scheduled prior to discharge from birth hospitalization. Patients were excluded if they planned to obtain PP care at non-hospital-based clinics or had pregnancies complicated by hypertension, 3rd- or 4th-degree lacerations, blood transfusion, intensive care unit admission or were prescribed anxiolytic or antidepressant medication in the antepartum period. Consenting patients were randomized to routine care (6-week PP visit) or to receive an additional visit 2-3 weeks PP. The primary outcome was attending any PP visit. Secondary outcomes included number of topics addressed in PP care, and PP Emergency Department (ED) visits or readmissions. To detect a difference of 20% in PP visit attendance with an alpha of 0.05 and power of 80%, 81 patients per group were required. Outcomes were compared between those randomized to two versus one PP visits via Fisher's exact test.

RESULTS: Among the 162 patients who were enrolled, those randomized to two PP visits were not more likely to attend any PP visit compared to those randomized to one PP visit (n=63 (78%) vs n=65 (80%), 0=0.85). Among participants who attended any PP care (n=128), there was no difference between groups in term of number of PP topics addressed (5 vs 5, p=0.49). Of patients randomized to 2 PP visits, 36% attended 1 visit and 37% attended both visits. There was no difference in PP ED visits (11% vs 9%, p=0.79) or PP readmission rates (3% vs 1%, p=0.99) between groups.

CONCLUSION: In this RCT, being scheduled for two PP visits was not associated with increased PP visit attendance, differences in number of PP topics addressed, or PP ED utilization. Thus, adding an additional PP visit does not facilitate improved PP outcomes in low-risk patients.

1054 Reassessing the strength and attributable fraction of clinical risk factors for preeclampsia: a nationwide study

Diane Korb[1], Vassilis Tsatsaris[2], valérie Olié[3], grégory Lailler[3], Camille Le Ray[1], Catherine Deneux-Tharaux[4]

[1]APHP, APHP, Ile-de-France, [2]Maternité Port Royal, Groupe hospitalier Paris Centre, APHP, APHP, Ile-de-France, [3]Santé Publique France, Ile-de-France, [4]Université Paris Cité, Perinatal Obstetrical and Pediatric Epidemiology Research Team (EPOPé), Center for Research on Epidemiology and Statistics (CRESS), INSERM, Paris, Ile-de-France

OBJECTIVE: Available evidence about risk factors for preeclampsia is limited by the study design, data source, lack of appropriate adjustment and outdated data. A better knowledge of the main subgroups at risk could help define preventive strategies. The study objective was to determine the strength and attributable fraction of clinical risk factors for preeclampsia.

STUDY DESIGN: Data from the French national perinatal surveys, repeated cross-sectional surveys including all women delivering during one week in all maternity units in France in 2016 (n=13896) and 2021 (n=13404) was used. After exclusion of women without data on the occurrence of hypertensive disorders of pregnancy (HDP), 25941 women were included. Multivariable Poisson regression models with adjusted relative risks (aRR) were used to identify risk factors in two steps: 1/present at antenatal care booking, 2/those emerging as pregnancy progresses. We calculated population attributable fractions (PAF) for each factor, to consider both its prevalence and aRR.

RESULTS: The incidence of preeclampsia was 2.0%(1.8-2.2)(n=508). Risk factors for preeclampsia present at antenatal care booking were: chronic hypertension (aRR(95%CI):11.1(7.3-16.8)), previous HDP (aRR:10.2(7.4-14.5)), chronic kidney disease (aRR:8.8(3.0-25.3)), non-spontaneous and spontaneous multiple pregnancy (aRR:4.8(2.9-8.1), aRR:4.2(2.7-6.6)) nulliparity (aRR:3.5(2.8-4.4)), diabetes (aRR:3.0(1.7-5.6)), previous neonatal complication (aRR:1.8(1.3-2.5)), obesity (aRR:1.7(1.3-2.3)), overweight (aRR:1.3(1.0-1.7)), Sub-Saharan Africa-born women (aRR:1.7(1.2-2.3)); and emerging during pregnancy: excessive weight-gain (aRR:1.6(1.3-2.1)). Risk factors with the higher PAF were nulliparity (43.8%), excessive weight gain (22.9%), obesity (10.8%).

CONCLUSION: Identifying the major risk factors based on the strength of the association makes it possible to identify the women most at risk at an individual level, which is different from prioritising the risk factors according to their PAF which can be taken into account to define preventive strategies in the population in a public health perspective

Table: Risk factors for preeclampsia (N = 25,941 women)

1055 The association of free fluid in the abdomen after cesarean delivery and postpartum pain

Chaitali Korgaonkar-Cherala[1], Ingy Khattaby[2], Lena Woo[3], Jane Burgan[3]

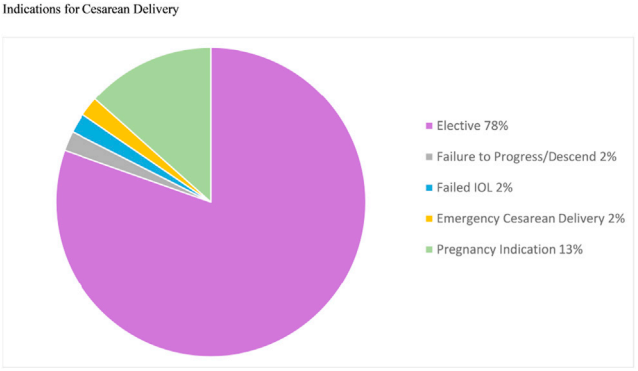
[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel, [2]Stony Brook University Hospital, Stony Brook, NY, [3]Renaissance School of Medicine at Stony Brook University, Stony Brook, NY

OBJECTIVE: The primary outcome is to evaluate the correlation between free fluid in the abdomen postop after cesarean delivery and postpartum opioid use. Secondary outcomes are correlation between free fluid levels postop and postpartum pain scores, and whether cleaning of the paracolic gutters intraop affects free fluid levels postop. We utilize a modified FAST scan to evaluate levels of free fluid in the abdomen after cesarean delivery.

STUDY DESIGN: This is a prospective observational study of women undergoing cesarean delivery for any indication (N=38). Patients are recruited and consented upon admission to labor and delivery or upon decision for C-section. Women are excluded from the study if they have a vaginal delivery followed by any surgical procedure, or if they are under 18 years. The sonographer of this study was trained and validated by a registered diagnostic medical sonographer. Patients undergo a modified FAST scan within 2 hours postop and again 36-48 hours postop.

RESULTS: In this small cohort, the presence of free fluid did not correlate with the amount of opioid use while inpatient (immediate postop p=.319; delayed postop p=.166) or postpartum pain scores at 2, 24, or 48 hours postop (immediate postop p=.639, .981, .765 respectively; delayed postop p=.631, .459, .878 respectively). Cleaning of the paracolic gutters was not significantly associated with the presence of free fluid in the abdomen (immediate postop p=.728; delayed postop p=.449).

CONCLUSION: In our initial study population, free fluid in the abdomen detected by FAST scan does not correlate with postpartum opioid use or pain scores. Cleaning of the paracolic gutters is not associated with the amount of free fluid detected on FAST scan. The main strength of this study is that this is the first study to examine the relationship between free fluid in the abdomen postop and postpartum opioid use and pain scores. The main limitation of this study is the small sample size. Additionally, documentation of postpartum pain scores and operative report documentation on cleaning of the paracolic gutters is inconsistent in the EMR.



1056 The anti-inflammatory and antioxidant effects of exogenous oxytocin on human placental cells

Insaf Kouba[1], Xiangying Xue[2], Matthew J. Blitz[1], Luis A. Bracero[3], Christine Metz[2]

[1]Zucker School of Medicine at Hofstra of Northwell, Bay Shore, NY, [2]Zucker School of Medicine at Hofstra of Northwell, The Feinstein Institutes for Medical Research, Hempstead, NY, [3]South Shore University Hospital, Bay Shore, NY

OBJECTIVE: Oxytocin (OXT) has been shown to ameliorate oxidative stress (OS) in non-placental cells such as cases of atherosclerosis and cisplatin-induced nephrotoxicity. No studies have demonstrated this effect in human placentas. The objective of this study was to investigate how OXT affects oxidative stress and inflammation in human placental cells using JAR and JEG-3 placental cell lines.

STUDY DESIGN: Inflammatory response**:** JAR and JEG-3 cells (ATCC) were plated at $2x10^5$ cells per mL**:** JAR cells were plated in RPMI 10% Fetal bovine serum (FBS) PSQ and JEG-3 cells were plated in DMEM 10%FBS PSQ. All assays were performed in triplicate and repeated three times. At confluence, cells were treated with vehicle (HBSS), OXT (,125500nM) or N-acetyl cysteine (NAC, 5mM). After 24 hours, the cells were then washed, collected, resuspended in 2 mL HBSS and labeled with 20 μM DCF-DA. After 24 hours, cells were treated with TNF (20ng/ml) to induce a pro-inflammatory response. After 24 hr., culture supernatants were analyzed for IL-6 by ELISA.

Oxidative stress**:** The cells were set up as described above and were then treated with vehicle (HBSS) or OXT (125-500nM). The plates were read in a VICTOR3™ plate reader after 10 min (basal reading). Hydrogen peroxide (H_2O_2) was then added to induce oxidative stress and the plates were re-read 1 hr. later.

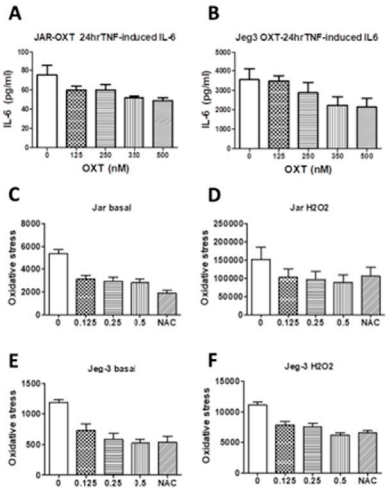
Cell viability**:** JAR and JEG-3 cells were plated in media as described above. The cells were then treated with vehicle (HBSS) or OXT (125-500nM) and cytotoxicity was measured using the neutral red assay 48 hr. later.

RESULTS: OXT does not induce cytotoxic effects on JAR or JEG-3 cells. OXT significantly reduced TNF induced IL-6 production by JAR (p=0.006) and JEG-3 (p=0.002) cells (Figure 1A-B). Similar to

NAC (a well-known antioxidant), OXT exerts dose-dependent antioxidant effects by JAR and JEG-3 cells under basal and following H_2O_2 stimulation ($p < 0.001$; Figure 1C-F). The anti-inflammatory and antioxidant effects of OXT are not accompanied by cytotoxicity.

CONCLUSION: Exogenous OXT has strong anti-inflammatory and antioxidant effects on human placental cell lines.

Figure: Effect of oxytocin (OXT) on placental cells: **A-B)** anti-inflammatory effect in JAR and Jeg-3 cells. **C-D)** anti-oxidative effect in JAR cells. **E-F)** anti-oxidative effect in Jeg-3 cells.



1057 Redefining birth weight centiles: Parity is more significant than gender

Ariel Lasry[1], Ariel Many[2], Ella Segal[3], Lior Kashani Ligumsky[4], Adi Ashkenazi Katz[1], Elad Miron[5], Ioana Olteanu[1], Miriam Lopian[6]

[1]Mayanei Hayeshua Medical Center, Bnei Brak, HaMerkaz, [2]Ma'ayne Hayeshua Medical Center Tel Aviv University, Bnei Brak, Tel Aviv, [3]Tel Aviv University, Tel Aviv, Israel, [4]Mayanei Hayeshua Medical Center, Tel-Aviv, Israel, [5]Mayanei Hayeshua Medical Center, Bnei Brak, Tel Aviv, [6]Mayanei Hayeshua Medical Center, Ra'anana, HaMerkaz

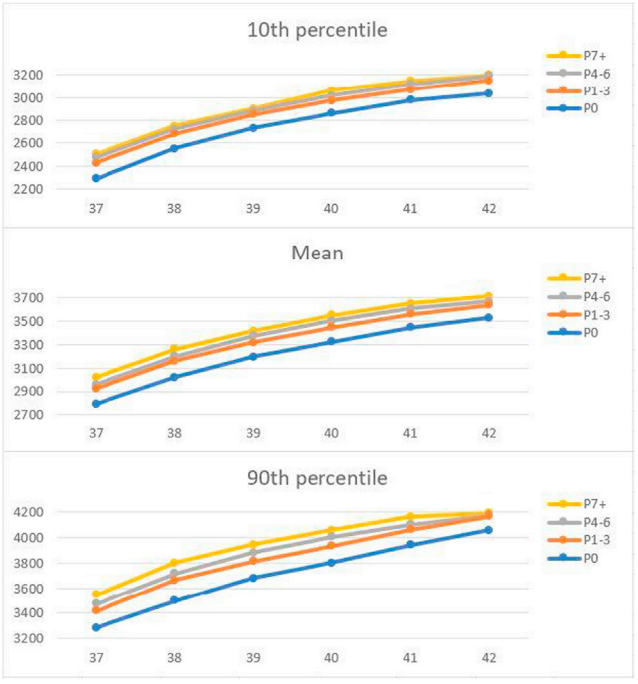
OBJECTIVE: To determine the impact of parity on birth weight patterns at term.

STUDY DESIGN: A retrospective cohort study was conducted between 2012-2023 at a single university-affiliated medical center characterized by a highly parous population with over 12,000 deliveries per year. The study group was comprised of patients who delivered liveborn singletons at term. The cohort was divided into 4 groups: Group 1—nulliparous patients, Group 2-parity of 1-3, Group 3-parity of 4-6 and Group 4-parity of ≥7. We calculated the 10th, 50th and 90th centile of birth weights for each of the study groups delivering at 37, 38, 39, 40, 41 and 42 weeks. Data was analyzed using ANOVA and Tukey-Kramer test for post-hoc analysis.

RESULTS: 129,752 patients were included in the study group. Group 1-23,331 patients, Group 2-56,240 patients, Group 3—31,779 patients, Group 4-14,740 patients.

Increasing parity was significantly associated with increasing neonatal birthweight across the 10th, 50th and 90th centiles ($p< 0.0001$). The results of the post-hoc analysis revealed statistically significant differences for all pairwise comparisons between the four groups ($p< 0.0001$) and these differences persisted when stratifying for each week of gestation (Graph). The mean birthweight for Nulliparas (Group 1) was 155g lower than Multiparas (3209g vs. 3364g) (95% CI 149-161 $p< 0.0001$). Similarly, the mean birthweight of male neonates was 128g greater than female neonates (3397g vs. 3269g) (95% CI 123-133 $p< 0.0001$).

CONCLUSION: There is a positive correlation between increasing parity and neonatal birthweight for each week of gestation at term across the 10th, 50th and 90th centiles This relationship is consistent across all parity groups. Moreover, birthweights for nulliparous women were significantly lower than their multiparous counterparts. The effect of nulliparity on birthweight is greater than that of fetal gender for which growth curves are commonly adjusted. Parity should be taken into consideration in the clinical decision-making process when a diagnosis of either growth restriction or Large for Gestational Age is established at term.



1058 PROMPT-AID: Predicting obstetric morbidity from postpartum hemorrhage through artificial intelligence

Cecilia B. Leggett[1], Elaine Albertson[2], Benison Pang[2], Matthew Wells[2], Melissa S. Wong[2]

[1]Stanford University , Palo Alto, CA, [2]Cedars-Sinai Medical Center, Los Angeles, CA

OBJECTIVE: Postpartum hemorrhage (PPH) is a leading cause of maternal morbidity, complicating about 25% of deliveries. Most PPH patients lack identifiable risk factors (RF); when present, RF are not accurate predictors of severe morbidity from PPH. This study validates an AI model that makes continuous predictions using iterative data throughout a labor course to predict likelihood of severe morbidity from PPH.

STUDY DESIGN: An automated machine learning (AML) platform was used to develop a model to predict severe morbidity (defined as occurrence of unscheduled hysterectomy, uterine artery embolization, massive transfusion protocol, ICU admission, takeback to the operating room, or in-hospital death) using continuously updated data based on electronic health record for all delivering patients at a large academic hospital from 01/01/2013 through 12/31/2022. The primary outcome is ROC-AUC in predicting severe morbidity from PPH. A sequential approach was used to develop admission, intrapartum, and postpartum models using continuously updated data throughout a patient's hospital course. Time-series engineering was applied to transform individual timelines into statistics to describe trends during intrapartum and postpartum periods.

RESULTS: 12,807 patients were included in the study and used in the training algorithm with 386 events of severe morbidity from PPH identified. The features of highest importance (with the highest permutation index) for each model are described in Figure 1. Each model demonstrated continuous improvement through the postpartum period which showed the highest discriminatory ability (ROC AUC 0.88).
CONCLUSION: AI incorporating time-series engineering has improved AUC, precision, and sensitivity when compared to relying on patient risk factors alone for prediction of severe morbidity from PPH. AI-based predictions could identify patients at risk of severe morbidity and provides opportunity for proactive intervention to reduce morbidity associated with PPH.

1059 Maternal Angiogenic Imbalance & Placental Sexual Dimorphism

Elizabeth Lemoine[1], Vinicius Calsavara[2], Ravi Thadhani[3], Sarah Kilpatrick[4], S. Ananth Karumanchi[4], Kim Boggess[5]
[1]University of North Carolina, Durham, NC, [2]Cedars-Sinai Health System, Los Angeles, CA, [3]Emory University, Atlanta, GA, [4]Cedars-Sinai Medical Center, Los Angeles, CA, [5]University of North Carolina, Chapel Hill, NC

OBJECTIVE: Sex-based responses to the in-utero environment & resultant infant outcomes are reported. While preeclampsia occurs more frequently in patients carrying a male fetus, carrying a female fetus is associated with higher odds of preterm preeclampsia. We hypothesize that fetal sex differences in maternal serum sFLT-1/PlGF contribute to differences in sex differences in preterm preeclampsia. We sought to compare maternal serum sFLT-1/PlGF ratio within 2 weeks of delivery in hypertensive patients between those with a male vs. female fetus.
STUDY DESIGN: This is a secondary analysis of data from a prospective cohort study in 18 US centers of hospitalized patients with hypertensive disorders of pregnancy & a singleton fetus between 24 & 35-weeks' gestation. We compared maternal characteristics with student t-test or chi-square tests. We calculated the median (95% CI) of maternal sFlt-1/PlGF ratios & compared between those with a female vs. male fetus using Mann Whitney U tests. All analyses were performed in R.
RESULTS: Of 551 patients without missing data, 260 (47%) had a male & 287 (52%) a female. Demographic and clinical characteristics were comparable by fetal sex. Compared to male group, maternal sFLT-1/PlGF ratio was significantly higher in the female group [224.7 vs. 181.8, P = 0.024]. Severe maternal adverse outcomes (HELLP syndrome, abruption, DIC, eclampsia, pulmonary edema) & severe fetal/neonatal adverse outcomes (fetal/neonatal death, birthweight < 3% percentile & delivery < 32 weeks) were not different between groups. Pregnancies with female fetuses were more likely than male to be delivered for worsening hypertension or non-reassuring fetal status (97.56 vs. 87.69%, P < 0.001).
CONCLUSION: Our data support that placental sexual dimorphism in angiogenic imbalance occurs in preterm preeclampsia. Further studies are needed to determine if sexual dimorphism impacts response to prevention or treatment strategies.

1060 Postnatal Incidence and Prenatal Detection of Twin Anemia Polycythemia Sequence (TAPS) among Monochorionic Twin Gestations

Felicia V. LeMoine[1], Alana Diedrick[2], Angela Ranzini[3]
[1]The MetroHealth System/ Case Western University Program, Cleveland, OH, [2]Purdue University, Lafayette, IN, [3]MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH

OBJECTIVE: International screening recommendations for TAPS varyand are infrequently assessed by postnatal diagnostic criteria. Our study aims investigate the accuracy of prenatal sonography in the prediction of postnatal TAPS (pnTAPS) and serious neonatal morbidity in uncomplicated monochorionic, diamniotic (MCDA) twin gestations.
STUDY DESIGN: A retrospective cohort study was performed via EMR query of single, tertiary center. PnTAPS was defined as neonatal intertwin hemoglobin discordance ≥8g/dL within 24 hours of delivery and placental vascular anastomoses (≤1mm). Serious neonatal morbidity included respiratory distress, culture-proven sepsis, intraventricular hemorrhage (grade III/IV), necrotizing enterocolitis (Stage II/III), periventricular leukomalacia (III/IV) or neonatal death. Outcomes were compared using Student's *t*-test and Fisher's exact/Chi-square test where appropriate. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were used to compared diagnostic accuracy of prenatal sonographic criteria.
RESULTS: 73 MCDA pregnancies were identified; 65 met eligibility criteria. Postnatal diagnostic criteria were available in 39/65 (60%). Two (5.1%) were diagnosed with postnatal TAPS; neither were diagnosed prenatally. Those with postnatal diagnostic criteria available delivered at an earlier gestational age (33.9 [30,25] weeks versus 36.3 [36,37] weeks, p< 0.05) and experienced higher rates of serious neonatal morbidity (49.4% versus 1.9%, p< 0.05). There were no differences in maternal, obstetric, or neonatal variables. There was no difference in serious neonatal morbidity between those with and without pnTAPS. Table 1 demonstrates sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of prenatal diagnostic criteria.
CONCLUSION: Of those with postnatal testing, the prevalence of pnTAPS is 5.1% of MCDA twin gestations. However, both the prevalence of pnTAPS and assessment of prenatal diagnostic accuracy are limited by inconsistent neonatal blood sampling. Prenatal screening criteria were poor predictors of pnTAPS.

Table 1. Diagnostic accuracy of prenatal diagnostic criteria in the prediction of pnTAPS

	Sensitivity	Specificity	PPV	NPV
MCA-PSV ≥ 1.5 MoM for the donor twin and MCA-PSV ≤ 1.0 MoM for the recipient twin	0% (0, 84.2)	95.8% (78.9, 99.9)	0%	92% (91.4, 92.6)
MCA-PSV ≥ 1.5 MoM for the donor twin and MCA-PSV ≤ 0.8 MoM for the recipient twin	0% (0, 84.2)	100% (86.8, 100)	0%	92.3% (92.3, 92.3)
Δ MCA-PSV MoM ≥ 1.0	0% (0, 84.2)	100% (86.8, 100)	0%	92.3% (92.3, 92.3)
Δ MCA-PSV MoM ≥ 0.8	0% (0, 84.2)	95.8% (78.9, 99.9)	0%	92% (91.4, 92.6)
Δ MCA-PSV MoM ≥ 0.5	0% (0, 84.2)	75% (53.3, 90.2)	0%	90% (87.7, 91.9)

1061 Short cervical length in asymptomatic twin pregnancies and optimal timing of antenatal corticosteroid therapy

Anne Leostic[1], Anne Rousseau[1], Alexandra Benachi[2], patrick rozenberg[3], Alexandre Vivanti[2], Paul Berveiller[4]
[1]Intercommunal Hospital of Poissy Saint Germain-en-Laye, Paris Saclay University Hospital, Poissy, Ile-de-France, [2]Antoine Béclère Hospital, Paris Saclay University Hospital, Clamart, Ile-de-France, [3]American Hospital of

Paris, France, Neuilly-sur-Seine, Ile-de-France, [4]Centre Hospitalier Intercommunal de Poissy Saint Germain, Poissy, France

OBJECTIVE: Identification of an ultrasonographic short cervical length (CL) is useful to predict a spontaneous preterm delivery in asymptomatic twin pregnancies, but data are sparce regarding relation between short CL and risk of PB in the forthcoming 7 days. Therefore, there is no evidence that a diagnosis of short CL in asymptomatic twin pregnancy may justify the administration of antenatal corticosteroid (ACS) therapy. We aimed to assess whether a short CL in asymptomatic twin pregnancies was associated with a significant risk of delivery within 7 days following CL measurement.

STUDY DESIGN: We performed a retrospective cohort study of twin pregnancies followed and delivered in a referral university hospital from January 1, 2007, to December 31, 2017. Asymptomatic twin pregnancies had sequential ultrasound measurements of the CL every four weeks from 21 to 34 weeks of gestation. The primary outcome was the delivery in the forthcoming 7 days after first CL measurement < 25 mm. Secondary outcomes included interval between first CL measurement < 25 mm and delivery, and preterm delivery rate before 34 and 37 weeks of gestation. In addition to the 25 mm CL threshold, we evaluated theses outcomes according to the thresholds of 20, 15 and 10 mm.

RESULTS: Of 1,285 asymptomatic twin pregnancies, a short CL of $<$ 25 mm was observed in 28.1 % (n = 361) women at mean gestational age of 29.0 +/- 3.4 weeks, and was not associated with a significant rate of delivery in the forthcoming 7 days after first CL measurement < 25 mm (2.8 %). The mean interval between first CL measurement < 25 mm and delivery was 47 days (+/- 24). No difference was observed in theses outcomes for any of the thresholds. Moreover, 77.6 % of women followed for a CL of < 25 mm finally delivered after 34 weeks.

CONCLUSION: In this retrospective cohort study of asymptomatic twin pregnancies, CL measurement of < 25 mm by routine transvaginal ultrasound was not associated with a significant risk of delivery in the forthcoming 7 days (only 2.8 %). Therefore, we cannot recommend its use in routine follow-up in order to indicate properly ACS therapy.

Table 2. Primary and secondary outcomes for overall population of asymptomatic twin pregnancies according to the chosen threshold to define short CL

Twin pregnancies with short CL < 25 mm				
	CL < 25 mm n = 361 (100 %) n (%)	CL < 20 mm n = 170 (47.1 %) n (%)	CL < 15 mm n = 64 (17.7 %) n (%)	CL < 10 mm n = 20 (5.5 %) n (%)
Delivery < 7 days	10 (2.8)	10 (5.9)	1 (1.6)	0 (0)
Delivery < 14 days	29 (8.0)	18 (10.6)	5 (7.8)	2 (10.0)
Delivery < 34 WG	81 (22.4)	47 (27.6)	21 (32.8)	12 (60.0)
Delivery < 37 WG	236 (65.4)	121 (71.2)	46 (71.9)	17 (85.0)
Duration between short CL diagnosis and delivery (days)				
Mean +/- SD	45 +/- 23	43 +/- 24	43 +/- 22	40 +/- 22
Median [1st Q; 3thd Q]	42 [28; 60]	40 [27; 58]	39 [29; 54]	37 [25; 49]

Abbreviations: CL: Cervical length; PB: Preterm Birth; SD: Standard Deviation; WG: weeks of gestation.

1062 Prospective Study on the Duration of Cervical Ultrasound Measurement on the Prevalence of Short Cervix

Lauriane Lessard[1], Brielle Demuth[1], Louise Ghesquiere[1], Mario Girard[1], Geneviève Marcoux[1], Annie Beaudoin[1], Carolanne Morin[1], Chantale Vachon-Marceau[2], Paul Guerby[3], Emmanuel Bujold[1]

[1]Centre de recherche du CHU de Québec-Université Laval, Quebec, QC, [2]CHU de Québec, Quebec City, QC, [3]Hopital Paule de Viguier, CHU Toulouse, Toulouse III University, Toulouse, Midi-Pyrenees

OBJECTIVE: To assess the impact of examination duration for mid-trimester cervical length (CL) assessment on the prevalence of short cervix (CL $\leq$ 25 mm).

STUDY DESIGN: A prospective study on asymptomatic nulliparous women with a singleton pregnancy at 20-23 weeks. Certified sonographers performed transvaginal ultrasound examination of the cervix (AIUM guidelines). After an initial CL measurement (T-0), the sonographer observed the cervix for 3 minutes and collected the shortest measurement (T-3min). For all cases with CL $\leq$ 30 mm, the observation was prolonged for another 3 minutes (total of 6 minutes, T-6min) along with 200 participants with CL $>$ 30 mm. A MFM subspecialist verified all measurements and performed his own assessment for all cases with CL $\leq$ 30 mm (T-MFM). We compared the proportion of CL $\leq$ 25mm according to the shortest CL obtained at T0, T3min and T6min. Vaginal progesterone was prescribed in case of CL $\leq$ 25mm and all participants were followed for spontaneous preterm birth (sPTB) $<$ 35 weeks.

RESULTS: We recruited 1644 participants at a median gestational age of 23 [interquartile (IQ): 22 − 23] weeks with a median CL of 35 (IQ: 32 − 39) mm and 100 (6.1%) cases of CL $\leq$ 25mm. The initial measurement (T0) would have identified 35 (2.1%) cases of short cervix, compared to 69 (4.2%) at T-3min and 95 (5.8%) at T-6min ($p < 0.001$). An extra 5 (0.3%) cases were observed by the MFM. ($p < 0.001$). No (0%) short cervix were observed at T-6min in the selection of participants with CL $>$ 30mm at T-3min. Of note, the rate of spontaneous PTB $<$ 35 weeks was 0.8% in women with CL $>$ 25 mm; 5.7% among women with CL $\leq$ 25mm at T0; 2.9% among women with CL $\leq$ 25mm at T-3min; 3.8% among women with CL $\leq$ 25 mm at T-6min, and 0/5 (0%) among those with CL $\leq$ 25mm according to the MFM only (p=0.01).

CONCLUSION: Midtrimester cervical examination duration influences the proportion of short cervixes. For optimal diagnosis, the examination should last 3 minutes after the first measurement and 6 minutes when CL $\leq$ 30 mm. Extending the examination beyond these limits is not necessary.

1063 Prenatal Exome in low-risk pregnancies and apparently normal fetuses — the rate of abnormal findings

Michal Levy[1], Shira Lifshitz[2], Mirela Goldenberg-Fumanov[2], Lily Bazak[2], Rayna Joy Goldshtein[2], Uri Hamiel[2], Yael Wilnai Ziskind[2], Rachel Berger[2], Shlomo Lipitz[3], Mordechai Shohat[2]

[1]The Genetic Institute of Maccabi Health Services, Rehovot, Israel, Tel Aviv Yafo, Israel, [2]The Genetic Institute of Maccabi Health Services, Rehovot, Israel, Rehovot, HaMerkaz, [3]Chaim Sheba Medical Center, Tel-Hashomer, Israel, Rehovot, HaMerkaz

OBJECTIVE: This study aims to assess the diagnostic yield of prenatal exome sequencing (ES) in a clinical setting for structurally normal fetuses, without major/minor abnormalities or family history indicative of monogenic disease.

STUDY DESIGN: This retrospective analysis encompasses prenatal ES conducted at a single center between January 2020 and July 2023. Genetic counselling was provided to all couples, and detailed medical histories were obtained. The exome analysis focused on a curated list of ~2100 genes associated with Mendelian early-onset genetic disorders. Variant analysis and genetic counseling were conducted by a multidisciplinary team comprising bioinformaticians and clinicians.

Pregnancies with indications for monogenic disease, such as major ultrasound findings, sonographic soft markers, abnormal maternal biochemical screening, or suggestive family history, were excluded, as well as cases with abnormal chromosomal microarray (CMA) results. In all cases, CMA was done prior to ES. Only pathogenic and likely pathogenic (P/LP) variants, classified according to the American College of Medical Genetics and Genomics (ACMG) guidelines, were reported.

RESULTS: From January 2020 to July 2023, a total of 1910 fetal ES cases were conducted.

After exclusion, in 1029 prenatal ES cases, 20 fetuses (1.9%) were identified with P/LP variants, indicating the presence of known monogenic diseases. Among these cases, 9 fetuses (8%0.) had the potential for severe phenotypes, including shortened lifespan and intellectual disability, and 11 had the potential for milder phenotypes.

Out of the 20 cases, 11 (55%) were determined to be de novo. 19 cases (95%) showed dominant/X linked inheritance patterns.

CONCLUSION: The 1.9% diagnostic yield highlights the great contribution of ES in structurally normal fetuses. However, it necessitates rigorous analysis, and comprehensive genetic counseling before and after testing.

1064 Risks of hospitalization for cardiovascular disease in the first year after delivery of twin pregnancies

Ruby Lin[1], Jessica C. Fields[2], Rachel Lee[1], Emily B. Rosenfeld[3], Emily E. Daggett[4], Ruchira Sharma[5], Cande V. Ananth[1]

[1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [2]Christiana Health, Jersey City, NJ, [3]Robert Wood Johnson Medical School, Rutgers University, New Brunswick, NJ, [4]Rutgers Robert Wood Johnson Medical School, CLEVELAND HTS, OH, [5]Rutgers Robert Wood Johnson Medical School, Manhasset, NY

OBJECTIVE: Compared to singletons, patients carrying twins face increased risks of hypertensive disorders of pregnancy (HDP). We hypothesized that the increased plasma volume and cardiac output in twin pregnancies pose a greater risk of cardiovascular complications. We determined the risk of cardiovascular disease (CVD) related hospitalizations within the year following delivery in relation to HDP, comparing twin with singleton pregnancies.

STUDY DESIGN: We performed a retrospective cohort study of hospitalized singleton and twin births in the United States from 2010-2018, using the Healthcare Cost and Utilization Project Nationwide Readmissions Database. Using ICD coding, we identified all hospitalizations for CVD complications during the same calendar year after delivery in singleton versus twin pregnancies with and without HDP. We calculated rates of CVD readmission and expressed associations based on a confounder-adjusted hazard ratio (HR) with a 95% confidence interval (CI).

RESULTS: Of a total of 30,606,363 delivery hospitalizations, 565,306 (1.8%) were twin births, of which 135,910 (24%) were affected by HDP. The rate of CVD readmission in twin and singleton pregnancies were 376.3 and 162.6 per 100,000 delivery admissions, respectively. Compared with singletons without HDP, the adjusted risk of CVD readmission was highest for twins with HDP (HR 5.12, 95% CI 4.43, 5.92), followed by singletons with HDP (HR 3.95, 95% CI 3.76-4.16) (Table). The increased risk of CVD readmission persisted among twins without HDP (HR 1.84, 95% CI 1.62, 2.09). The adjusted HRs for twins with HDP were substantially high for hypertensive heart disease (23.29, 95% CI 15.69, 34.57), heart failure (12.11, 95% CI 10.06, 14.58), and cardiomyopathy (9.47, 95% CI 6.72, 13.34).

CONCLUSION: Compared to singletons without HDP, twin pregnancies in general, and more so with HDP, are associated with increased risks for CVD complications in the first year postpartum. These findings underscore the increased strain twin pregnancies place on the maternal cardiovascular system and the need for short-term follow-up in this population.

Table
Maternal readmission within one year of delivery for cardiovascular disease complications for twin versus singleton pregnancies with and without hypertensive disorders of pregnancy (HDP) in the United States, 2010-2016

	Adjusted hazard ratio (95% confidence interval)			
	Singleton without HDP	Singleton with HDP	Twin without HDP	Twins with HDP
Any cardiovascular disease	1.00 (Reference)	3.95 (3.76-4.16)	1.84 (1.62-2.09)	5.12 (4.43-5.92)
Coronary heart disease	1.00 (Reference)	3.91 (3.69-4.13)	1.87 (1.64-2.12)	5.58 (4.79-6.49)
Acute myocardial infarction	1.00 (Reference)	3.73 (3.06-4.48)	1.75 (1.08-2.84)	5.40 (3.52-8.28)
Ischemic heart disease	1.00 (Reference)	3.73 (3.16-4.40)	1.40 (0.91-2.15)	5.28 (3.09-9.03)
Atherosclerotic heart disease	1.00 (Reference)	3.40 (2.63-4.40)	1.44 (0.72-2.89)	3.07 (1.62-5.84)
Hypertensive heart disease	1.00 (Reference)	11.59 (10.07-13.35)	3.48 (1.77-6.83)	23.29 (15.69-34.57)
Heart Failure	1.00 (Reference)	6.24 (5.76-6.76)	2.28 (1.91-2.73)	12.11 (10.06-14.58)
Cardiomyopathy	1.00 (Reference)	4.82 (4.19-5.56)	1.60 (1.21-2.13)	9.47 (6.72-13.34)
Cardiac arrhythmias	1.00 (Reference)	2.45 (2.26-2.65)	1.76 (1.49-2.08)	2.26 (1.64-3.11)
Any stroke	1.00 (Reference)	4.21 (3.75-4.73)	1.61 (1.17-2.23)	2.69 (1.90-3.81)
Ischemic Stroke	1.00 (Reference)	4.55 (3.92-5.28)	1.88 (1.27-2.78)	3.36 (2.21-5.09)
Hemorrhagic Stroke	1.00 (Reference)	3.24 (2.80-3.74)	1.29 (0.76-2.19)	1.56 (0.89-2.76)

HDP: Hypertensive disorders of pregnancy (Includes gestational hypertension, preeclampsia, eclampsia, and superimposed preeclampsia)
Hazard ratios were adjusted for maternal age, insurance status, income quartile, hospital bed size, hospital type, hospital teaching status, chronic hypertension, and pregestational diabetes in a weighted Cox-proportional regression model

1065 The risk of mortality from cardiovascular disease differs depending on the mode of delivery

Gabriella Lobitz[1], Emily B. Rosenfeld[2], Rachel Lee[1], Deepika Sagaram[1], Cande V. Ananth[1]

[1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [2]Robert Wood Johnson Medical School, Rutgers University, New Brunswick, NJ

OBJECTIVE: Cardiovascular disease (CVD) mortality is responsible for up to 22% of maternal deaths and up to 4% of pregnancies are affected by pre-existing CVD. The purpose of this study is to determine if the mode of delivery affects a person's risk of CVD-related mortality in the year following delivery. We hypothesized that patients, both with and without prior CVD, that undergo a cesarean delivery will be at increased risk of CVD-related death.

STUDY DESIGN: We designed a retrospective cohort study utilizing the Nationwide Readmissions Database (2010-2018) to identify singleton births. ICD-9 and ICD-10 codes were used to identify patients with CVD mortality within the calendar year of index delivery. Associations between mode of delivery and CVD mortality were determined from Cox proportional hazards regression models before and after adjusting for potential confounders.

RESULTS: In persons without pre-existing CVD, CVD-related hospital mortality among the cesarean and vaginal delivery groups were 3.8 and 2.9 per 100,000 delivery discharges, respectively (hazard ratio [HR] 1.19, 95% confidence interval [CI] 0.97, 1.46) (Figure). The risk for CVD mortality was highest in the first 30 days after the delivery hospitalization (HR 1.58, 95% CI 1.01, 2.47) and diminished with time. Risk of stroke mortality increased two-fold in the first 30 days (HR 2.11, 95% CI 1.03-4.32) and remained elevated for one year after delivery. In patients with pre-existing CVD, CVD-related mortality among the cesarean and vaginal delivery groups were 231.8 and 157.9 per 100,000 delivery discharges, respectively (HR 1.35, 95% CI 0.44, 4.14), although the risk estimate was imprecise.

CONCLUSION: Persons without pre-existing CVD have an increased risk of CVD-related mortality after cesarean delivery. This may be due to the unmasking of undiagnosed CVD. Mortality risk in persons with prior CVD is not affected by the mode of delivery. These findings suggest that attempting vaginal delivery among persons

with and without a history of CVD may be beneficial insofar as mortality from CVD within the first year.

1066 Serial measurements of ultrasonic dimensions of gravid maternal anatomy and aspirated cervical stiffness

Erin Louwagie[1], Serena Russell[1], Jacqueline C. Hairston[2], Chia Ling Nhan Chang[3], Karin Fuchs[2], Cynthia Gyamfi-Bannerman[4], Whitney A. Booker[3], Maria Andrikopoulou[5], Alexander M. Friedman[1], Noelia Zork[6], Ronald J. Wapner[3], Joy Vink[7], Mirella Mourad[2], kristin Myers[1]

[1]Columbia University, New York, NY, [2]Columbia University Medical Center, New York, NY, [3]Columbia University Irving Medical Center, New York, NY, [4]UC San Diego Health, La Jolla, CA, [5]Columbia University New York Presbyterian Hospital, New York, NY, [6]New York Presbyterian, Columbia University Medical Center, New York, NY, [7]Hawaii Pacific Health, Honolulu, HI

OBJECTIVE: Reproductive tissues grow and remodel during pregnancy to accommodate the developing fetus. With little known about this process in normal human pregnancy, delineating abnormalities in preterm birth (PTB) is challenging. This study serially assessed maternal anatomy size and cervical stiffness for patients at low risk for PTB.

STUDY DESIGN: This was a prospective observational study of patients at low risk for PTB. Patients (n = 47, all delivered at term) were asked to attend four research visits: late 1st (L1, 9^{3}-15^{3} weeks), middle 2nd (M2, 17^{3}-20^{5} weeks), late 2nd (L2, 23^{3}-27^{1} weeks), and middle 3rd trimester (M3, 33^{4}-38^{0} weeks). Cervical stiffness and maternal dimensions were measured via aspiration and ultrasound, respectively. The primary outcomes were linear regression slopes (accounting for patient correlation) for dimension measurements of intrauterine diameter (UD), uterine wall thickness (UT), cervical length (cm/week), and aspirated cervical stiffness (aCS, mbar/week) (fig. 1). The overall slope (all four visits) and slope between visits were found.

RESULTS: The inferior-superior UD increased fastest between L1 and M2 (slope = 0.80 cm/week). The anterior-posterior UD increased fastest between L2 and M3 (slope = 0.26 cm/week) and left-right UD between M2 and L2 (slope = 0.86 cm/week). The fundal and left/right UT increased during pregnancy (slope = 0.01 and 0.02 cm/week, respectively), whereas the lower uterine thinned (slope = -0.02 cm/week). No significant slope value was found for the anterior UT. The cervical length decreased (slope = -0.04 cm/week), with the largest rate of decrease between L2 and M3 (slope = -0.06 cm/week). aCS decreased as pregnancy progressed (slope = -3 mbar/week), with the largest decrease between L1 to M2 (slope = -5 mbar/week).

CONCLUSION: This novel dataset shows the rate of lower uterine segment thinning, cervical length shortening, and decreases in cervical stiffness are gestational age-dependent. These data is vital to further developing computational models to understand how the uterus and cervix function in normal and abnormal pregnancies leading to PTB.

	Overall Slope (cm/week)	L1 - M2 Slope (cm/week)	M2 - L2 Slope (cm/week)	L2 - M3 Slope (cm/week)

1067 Preeclampsia associated genetic variants near FLT1 are associated with elevated late pregnancy maternal serum sFLT1

Jasmine A. Mack[1], Ulla Sovio[2], Emma Cook[2], Felix Day[2], Alison Motsinger-Reif[3], John Perry[2], D. Stephen Charnock-Jones[2], Gordon Smith[2]

[1]National Institutes of Health and The University of Cambridge, Cambridge, England, [2]University of Cambridge, Cambridge, England, [3]National Institute of Environmental Health Sciences, Research Triangle Park, NC

OBJECTIVE: It is hypothesized that increased placental release of soluble fms-like tyrosine kinase-1 (sFLT1) is causally related to the pathophysiology of preeclampsia (PE). Genome-wide association studies identified four PE-associated fetal variants near the *FLT1* gene: rs4769612, rs4769613, rs7318880, and rs12050029, but previous studies have failed to show associations between these variants in the mother and sFLT1 levels in the first and second trimester of pregnancy. We sought to determine the association between maternal or fetal carriage of these variants and maternal circulating levels of sFLT1 across all three trimesters of pregnancy.

STUDY DESIGN: We analyzed data from the Pregnancy Outcome Prediction study, a prospective cohort of nulliparous women, where 3,968 mother-child pairs passed genotyping quality control. Maternal serum sFLT1 levels were measured at 12-, 20-, 28-, and 36 weeks of gestational age (wkGA) using a Roche Cobas e411 analyzer. In cross-sectional and longitudinal regression models, the dependent variable was the z-score of log-transformed sFLT1 at each wkGA or the change in z-score between 28- and 36wkGA, adjusted for fetal sex, age, BMI, maternal race/ethnicity, alcohol use, smoking, deprivation index, and the top 10 genetic principal components.

RESULTS: There was no association between the maternal variants and sFLT1 levels at any individual wkGA ($P > 0.05$). There was no association between fetal variants and sFLT1 levels at 12, 20 or 28wkGA ($P > 0.05$). However, all four fetal variants were positively associated with the sFLT1 z-score at 36wkGA (Figure 1). All maternal and fetal variants except rs12050029 were associated with increased change in the sFLT1 z-score from 28 to 36wkGA. Fetal associations with third trimester sFLT1 z-score change were consistently stronger than maternal associations ($P < 1 \times 10^{-5}$).

CONCLUSION: Fetal variants near *FLT1* associated with an increased risk of PE are associated with higher maternal serum sFLT1 levels in the third trimester, supporting a causal role for placentally derived sFLT1 in the pathophysiology of PE.

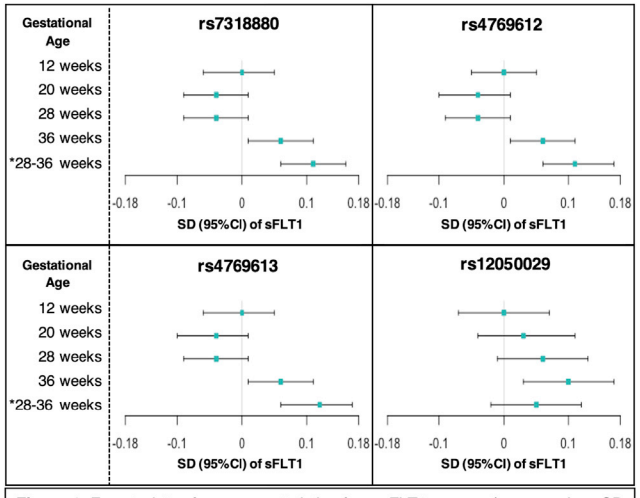

Figure 1. Forest plots of summary statistics from sFLT1 z-score (expressed as SD with 95% CI) and fetal genotype association across gestation for Pregnancy Outcome Prediction study participants without preeclampsia. Four genetic variants near the *FLT1* gene previously found to be associated with preeclampsia (SNP_Effect Allele): rs7318880_T; rs4769612_C; rs4769613_C; rs12050029_G. SD = Standard Deviation; CI = Confidence Interval; *change in z-score between 28- and 36-weeks' gestation

1068 Pregnancy Outcomes in Severe Early-Onset Fetal Growth Restriction: Results from the Multicenter PERIMETER Study

David Mackin[1], Rocco Cuzzilla[1], Roisin McConnell[2], Karen O'Neill[3], Ronan Daly[4], Laura Ryan[2], Zara Molphy[1], Denisa Ramona Asandei[5], Elizabeth Murphy[3], Rebecca Hunter[3], Genevieve Leon[4], Anne Doolan[3], Stephen Carroll[2], Michael Boyle[4], Carmen Regan[3], Anne Twomey[2], Fergal D. Malone[4]

[1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]National Maternity Hospital, Dublin, Ireland, [3]Coombe Womens and Infants University Hospital, Dublin, Ireland, [4]Rotunda Hospital, Dublin, Ireland, [5]RCSI Rotunda, Dublin, Ireland

OBJECTIVE: Severe, early-onset fetal growth restriction (EO-FGR) represents a particularly challenging obstetric cohort. There remains a paucity of data to address optimal timing of delivery, balancing the risk of fetal demise with the potential benefits of advancing gestation. This analysis describes pregnancy outcomes for all cases at one center of EO-FGR due to uteroplacental causes to assist in perinatal counseling.

STUDY DESIGN: The PERIMETER Study collected all singleton cases of EO-FGR confirmed by ultrasound between 18^0 and 27^6wks, at the three largest tertiary referral obstetric hospitals in one city from July 2016 to June 2020. FGR diagnosis was confirmed using electronically-stored ultrasound data, with international Delphi consensus criteria used for diagnosis, including biometry and Doppler data. Cases were considered to be uteroplacental in the absence of structural or genetic abnormality or infection, and in the presence of umbilical artery (UA) Doppler abnormality.

RESULTS: Severe EO-FGR was diagnosed in 250 cases, with uteroplacental cause identified in 154 (62%). Pregnancy outcomes were confirmed for 111 cases, including livebirth (99, 89%) and stillbirth (12, 11%). Liveborn cases were diagnosed later compared with stillbirth (mean (SD) 24.6 (2.4) v 22.2 (1.8) wks, p< 0.001). Liveborn infants < 34wks were more likely to be delivered for abnormal CTG or deteriorating Doppler parameters, and more likely to have UA AEDF or REDF and/or oligo- or anhydramnios pre-delivery, compared with those born later (Table). All but one liveborn infant < 34wks was delivered by cesarean (39/40, 98%), including 4 by classical CS. Amongst stillbirths (n=12), median gestation at confirmed fetal demise was 24.9wks (range 22.3-30.9), including 8 (67%) cases with EFW < 400g. Almost one third of patients required delivery in the maternal interest.

CONCLUSION: Almost 50% of severe EO-FGR cases deliver < 34wks, with no cases resulting in stillbirth thereafter. Most stillbirths occurred at previable weight. These data will be useful for counseling patients regarding the timing of delivery of EO-FGR pregnancies.

Table: Pregnancy outcomes for livebirths by gestational age at delivery

Pregnancy outcome	Gestational age at delivery (wks)			
	All gestations, n=99	<28wks, n=19	28^0 – 34wks, n=22	>34^0wks, n=58
Gestation at diagnosis (wks), mean (SD)	24.6 (2.4)	23.9 (2.5)	26.0 (1.9)	24.4 (2.3)
Gestation at delivery (wks), mean (SD)	34.0 (5.1)	26.6 (1.2)	30.5 (1.7)	37.8 (2.3)

1069 Risk of perinatal mortality associated with expectant management in patients who used nicotine products

Rachel Madding, Alyssa R. Hersh, Kimberly Ryan, Bharti Garg, Jamie Lo, Aaron B. Caughey

Oregon Health & Science University, Portland, OR

OBJECTIVE: Prior studies have demonstrated an association between maternal nicotine use and adverse neonatal outcomes. Balancing the risk of stillbirth and infant death with increasing gestational age (GA) is nuanced and an important aspect of decision making around delivery timing. There is limited guidance regarding timing of delivery and whether earlier delivery reduces overall perinatal mortality rate in patients who used nicotine products. Therefore, we sought to compare the risk of perinatal death associated with each additional week of expectant management to that of immediate delivery.

STUDY DESIGN: This was a retrospective cohort study of singleton non-anomalous term births in California between 2016 and 2019. We included patients who used nicotine products during any trimester of pregnancy. Pregnancies complicated by pre-existing diabetes and chronic hypertension were excluded. To determine the optimal GA for delivery, we compared the risk of delivery, which represented the risk of infant death at each week, with the fetal/infant mortality risk of expectant management for an additional week. The risk of expectant management was the sum of the risk of stillbirth during a subsequent week plus the risk of infant death in the subsequent week.

RESULTS: In this study, 24,895 births were included who had tobacco use during pregnancy. At 37 weeks' gestation, the risk of immediate delivery was greater than one week of expectant management (64.2 vs. 48.0 deaths per 10,000 births) (Table 1). At 38 weeks' gestation the risks were not different (42.1 vs. 41.0 deaths per 10,000 births). At 39 weeks, the risk of immediate delivery was lower than expectant management (30.8 vs. 54.7) and remained lower at 40 and 41 weeks' gestation.

CONCLUSION: In this study of those who used nicotine during pregnancy, we found that the risk of perinatal mortality was increased with expectant management at 39 weeks and beyond. These findings can be used to guide clinical counseling and care in the context of ongoing prenatal care.

Table 1 **Risk of infant death and stillbirth vs. composite perinatal mortality risk stratified by gestational age in patients who used nicotine products**

Gestational age (weeks)	Stillbirths per 10,000 ongoing pregnancies	Infant deaths per 10,000 live births	Composite perinatal mortality risk
37	5.96 (3.26, 10.00)	64.17 (38.07, 101.22)	48.03 (47.90, 48.16)
38	10.16 (6.21, 15.69)	42.08 (25.72, 64.92)	41.01 (40.91, 41.10)
39	19.32 (12.38, 28.74)	30.84 (20.82, 44.00)	54.68 (54.51, 54.86)
40	24.72 (12.78, 43.14)	35.36 (21.30, 55.17)	64.22 (63.73, 64.73)
41	69.86 (30.21, 137.20)	39.51 (17.07, 77.69)	69.89 (65.63, 74.30)

1070 Rising cesarean delivery rates in contemporary obstetric practice - Suboptimal obstetric practice or perfectly justifiable?

Ciara M. Malone[1], Catherine Finnegan[2], Patrick Dicker[1], Karen Flood[1], Fionnuala M. Breathnach[1], Fergal D. Malone[2]
[1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]Rotunda Hospital, Dublin, Ireland

OBJECTIVE: The WHO has suggested that the "ideal" cesarean delivery (CD) rate should be < 15%, and that CD rates >10% are not associated with mortality reduction. Obstetricians have been criticized for rising CD rates possibly being associated with higher uterine rupture (UtRu) during VBAC attempts, and higher peripartum hysterectomy (PH) due to placenta accreta spectrum. Our objective was to quantify the association between increasing CD rate, hypoxic ischemic encephalopathy (HIE), perinatal mortality rate (PMR), UtRu, and PH at a single tertiary obstetric unit over a 20-year time period.

STUDY DESIGN: A prospectively maintained database of all cases of HIE, perinatal mortality, uterine rupture and peripartum hysterectomy was interrogated for the 2003-2022 time period. HIE (grades 2 or 3) and corrected perinatal mortality rates (cPMR) were expressed per 1,000 births, and excluded cases with congenital malformation. UtRu and PH rates were expressed per 1,000 mothers delivered.

RESULTS: Over 20 years, 163,604 mothers delivered 167,005 babies, for an average of 8,180 mothers per year. The table demonstrates a significant increase in CD from 28.2% in 2003 to 39.0% in 2022 (38% increase), and was accompanied by a highly significant reduction in cPMR from 5.2 to 3.5 per 1,000, (33% decrease), with Spearman rank correlation of -0.83 ($p< 0.001$). Rates of UtRu and PH did not change significantly, at 0.00 and 0.30 per 1,000 in 2003, to 0.25 and 1.47 per 1,000 in 2022 respectively, with Spearman rank correlation of 0.33 ($p=0.154$). The rate of HIE did not change significantly, with a persistently low rate ranging from 1.47 to 1.21 per 1,000 from 2003 to 2022 respectively.

CONCLUSION: Contrary to some prior claims, the 38% increase in CD rate noted at a single maternity hospital was associated with a highly significant improvement in perinatal outcome (33% reduction in PMR, and persistently low HIE rate) but without any negative impact on uterine rupture or peripartum hysterectomy. A higher CD rate than an assumed WHO "ideal" of < 15% is in fact associated with persistently low rates of perinatal mortality and HIE.

Table 20 year trends in CD, HIE, corrected PMR, uterine rupture, and peripartum hysterectomy at a single large obstetric hospital.

Year	Number babies born	CD rate %	HIE rate per 1,000*	cPNM per 1,000*	UtRu rate per 1,000#	Hyst rate per 1,000#
2003	6,790	28.2	1.47	5.2	0.00	0.30
2004	6,731	26.6	1.63	6.1	0.46	1.06
2005	6,804	25.6	1.03	5.4	0.00	0.15

1071 Marked 21-year decline in infectious diseases in pregnancy at the busiest maternity hospital in Europe

Emma C. Malone[1], Aaron Ryan[1], Patrick Dicker[2], Maeve Eogan[1], Mairead Lawless[1], Wendy Ferguson[1], Jack Lambert[1], Fergal D. Malone[3]
[1]Rotunda Hospital Dublin, Dublin, Dublin, [2]Royal College of Surgeons in Ireland, Dublin, Ireland, [3]Rotunda Hospital, Dublin, Ireland

OBJECTIVE: As the busiest obstetric hospital in Europe, with an established multidisciplinary specialist Infectious Diseases Service, we sought to evaluate trends in incidence of selected infectious diseases in pregnancy and their rate of associated neonatal infection.

STUDY DESIGN: This hospital provides a specialist multidisciplinary service to manage pregnancies complicated by certain infectious diseases. We interrogated a prospectively collected database for prevalence of these infections in pregnancy, incidence of newly diagnosed cases, and data on infected neonates. Comparisons were made across a 21 year time period using the Cochran-Armitage Test of Trend.

RESULTS: Figure 1 demonstrates the incidence of new cases of Hepatitis B (HBV), Hepatitis C (HCV), syphilis and HIV in

pregnancy during the last 21 years of operation of this specialist clinic, while Figure 2 shows the prevalence of each infection (new and pre-existing). There has been a significant decrease in the prevalence of all infections, with HBV declining from 14.5/1,000 in 2002 to 4.2/1,000 in 2022 (p< 0.0001), HCV declining from 11.5/1,000 in 2002 to 2.0/1,000 in 2022 (p< 0.0001), syphilis declining from 5.6/1,000 in 2002 to 2.5/1,000 in 2022 (p< 0.0001), and HIV declining from 7.3/1,000 in 2002 to 1.4/1,000 in 2022 (p< 0.0001). Similarly, declines were noted in the number of newly diagnosed cases for all infections over the 21 year time period. The number of infected neonates has remained low, with only one case of a neonate infected with HCV and one with syphilis in the last five years from 2018-2022 and no cases of neonates infected with HBV or HIV.

CONCLUSION: There has been a marked reduction in incidence of HBV, HCV, syphilis and HIV in pregnancy over the last 21 years at the largest obstetric hospital in Europe. While it is reassuring to note such a significant drop in maternal infection, it is even more reassuring to see an almost complete absence of congenital infection with these infections. This likely underscores the critical importance of maintaining such a multidisciplinary specialist infectious diseases in pregnancy service.

Figure 1: Incidence of new cases of maternal HBV, HCV, syphilis and HIV in pregnancy, 2002-2022

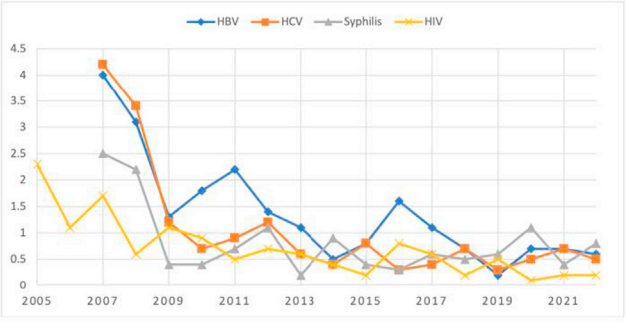

Figure 2: Prevalence of new and pre-existing cases of maternal HBV, HCV, syphilis and HIV in pregnancy, 2002-2022

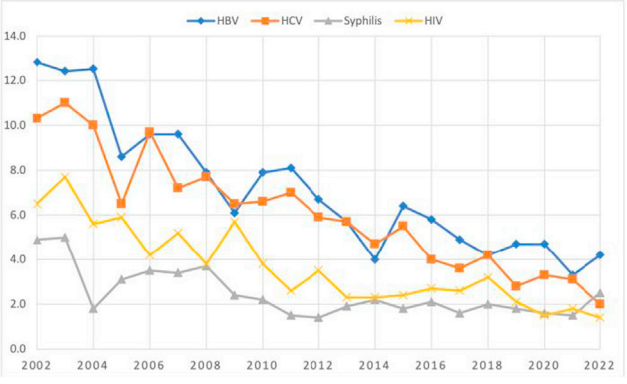

1072 The association between maternal preeclampsia and long-term offspring respiratory disease- sibling matched analysis

Dor Marciano[1], **Eyal Sheiner**[2], **Tamar Wainstock**[3]

[1]Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Metar, HaDarom, [2]Soroka University Medical Center, Beer-Sheva, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom

OBJECTIVE: To assess the association between maternal preeclampsia and long-term respiratory morbidity in offspring. While short-term neonatal complications of preeclampsia are well understood, its influence on long-term respiratory outcomes remains unclear. Prior research suggests an increased risk of respiratory diseases, but these studies lacked comprehensive control for confounding factors. Our sibling-matched analysis addresses this gap, providing insights into the long-term respiratory impact of preeclampsia.

STUDY DESIGN: A retrospective study was conducted, including parous women who were diagnosed with preeclampsia in one pregnancy. Using a sibling-matched analysis, we compared prenatally preeclampsia-exposed siblings with their unexposed counterparts. Incidence of the offspring's hospitalization with specific respiratory morbidities were compared between the siblings, as well as the time to first hospitalization with such a diagnosis. Multivariable generalized estimation equation (GEE) analysis was performed to adjust for confounding variables.

RESULTS: Our cohort included 8,544, half of whom were exposed to maternal preeclampsia. Higher cumulative respiratory hospitalization rates were noted in the preeclampsia group, using a Kaplan-Meier survival curve (log-rank, p< 0.019; Figure). However, crude rates of total respiratory hospitalizations were not statistically different between the groups, (5.2% vs 4.5% respectively; OR= 1.13; 95% CI 0.72-1.06, P=0.202; Table). The GEE model which adjusted for maternal and gestational age, and time of exposure, did not show a significant association between preeclampsia and offspring's risk for long-term respiratory hospitalization (adjusted HR = 1.11; 95% CI 0.91-1.33, P =0.305; Table).

CONCLUSION: In this study, through sibling analysis and confounder adjustment, we discovered no increased risk of respiratory morbidity for offspring born from pregnancies complicated with preeclampsia. Our results underscore the importance of confounder consideration and sibling correlation when estimating the long-term impacts of preeclampsia on offspring's respiratory health.

Table – Crude and adjusted rates of respiratory hospitalizations by exposure to preeclampsia

Preeclampsia N= 4272 %(N)	No preeclampsia N= 4272 %(N)	OR; 95% CI	Adjusted HR[a]
5.2% (221)	4.5% (194)	1.13; (0.72, 1.06)	1.11; (0.91, 1.33)

[a] Adjusted for maternal age, gestational age, and time of exposure

1073 Placenta Accreta Spectrum and Endometriosis

Valerie Martin[1], Matt Givens[2], Michelle P. Debbink[1], Robert M. Silver[2], Brett D. Einerson[2]
[1]University of Utah, Salt Lake City, UT, [2]University of Utah Health, Salt Lake City, UT

OBJECTIVE: The chronic pelvic inflammation and endometrial dysfunction that characterize endometriosis may predispose those affected by it to placenta accreta spectrum (PAS). Prior small studies suggest there may be an association between endometriosis and PAS. We aimed to evaluate this association in a nationwide sample to better understand the etiology and risk factors for PAS.

STUDY DESIGN: We performed a retrospective cohort study using the U.S. National Inpatient Sample from 2017-2020 including individuals delivering after 20 weeks' gestation. ICD-10 codes were used to determine exposure and outcomes. A logistic regression model controlling for confounding variables was constructed. As placenta previa is a mediating effect, it was not included as a confounding factor in our main regression model. A mediation analysis was performed using the counterfactual approach. Data were weighted according to NIS reported sampling weights.

RESULTS: Of 14,154,044 (2,833,010 unweighted) individuals included, 0.12% had PAS and 0.15% had endometriosis. Baseline characteristics are shown in Table 1. In the unadjusted regression model, endometriosis was associated with an increased odds of PAS (OR 5.4; 95% CI 3.7-7.8) (Table). When controlling for confounding factors (age, prior cesarean section, and obesity) the odds of having PAS was higher in patients with endometriosis (OR 3.2, 95% CI 2.3-4.8, p=0.01). In the mediation analysis, placenta previa was found to be an indirect mediator (percent of the total effect that is mediated is 0.49). A second regression model including placenta previa as a covariate was constructed and included in the Table.

CONCLUSION: There is an association between endometriosis and PAS. Further research into the causal pathway between these two disease entities is warranted and may help shed further light onto the role of inflammatory mediators in the development of PAS.

1074 The impact of post-epidural hypotension requiring vasopressor treatment on mode of delivery

Andrew R. Mather[1], Erica K. Nicasio[2], Carrie Irvine[3], Sarah Caveglia[3], Amol Malshe[4], Courtney Olson-Chen[3]
[1]Prisma Health, Midlands, West Columbia, SC, [2]University of Rochester, Pittsford, NY, [3]University of Rochester Medical Center, Rochester, NY, [4]Cleveland Clinic, Cleveland, OH

OBJECTIVE: To investigate the impact of post-epidural hypotension on the risk of cesarean delivery and, secondarily, to assess the impact of post-epidural hypotension on perinatal outcomes.

STUDY DESIGN: Retrospective cohort study of intrapartum individuals with post-epidural hypotension requiring treatment with either ephedrine or phenylephrine between 2015-2021 at a single institution. A control group who received an epidural without need for vasopressors was randomly selected in a 4:1 ratio compared to the exposure group. Individual characteristics and perinatal outcomes were collected from the electronic medical record. A chi-square test was used to analyze categorical outcomes including the primary outcome of mode of delivery, and a logistic regression was performed to assess confounding by covariates including age, BMI, nulliparity, induction and premature rupture of membranes.

RESULTS: A total of 3474 subjects were included in the cohort with 694 having post-epidural hypotension and 2780 without hypotension. Post-epidural hypotension requiring treatment with vasopressors was associated with a nearly 3 times increased risk of cesarean delivery compared to no hypotension requiring vasopressors after epidural (24.6% vs. 8.2%; RR 2.99, 95% CI 2.5- 3.6). This finding persisted in the logistic regression model (aOR 3.29, 95% CI 2.6-4.1). Additionally, post-epidural hypotension increased the risk for adverse neonatal outcomes including NICU admission (RR 3.39, 95% CI 2.4-4.9) and neonatal oxygen requirement (RR 2.45, 95% CI 1.6-3.7) compared to no hypotension after epidural placement.

CONCLUSION: Individuals with post-epidural hypotension requiring vasopressor treatment have an increased risk of cesarean delivery compared to those who do not have epidural hypotension requiring treatment. These findings are relevant for patient counseling, and future studies are needed to develop strategies to prevent post-epidural hypotension.

1075 Male fetal sex associated with maternal respiratory failure in infection: a health records-based cohort study

Logan Mauney[1], Matthew H. Mossayebi[2], Andrea G. Edlow[1], Lydia Shook[3]
[1]Massachusetts General Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Massachusetts General Hospital, Waban, MA

OBJECTIVE: Pregnancy is an immunologically complex state, requiring maternal adaptations to both tolerate the semi-allogeneic fetus and protect the dyad from infections. Biological evidence suggests that pregnancies carrying a male fetus may have altered inflammatory responses to immune challenges. We aimed to assess the impact of fetal sex on severe maternal respiratory morbidity as a proxy for severe immune response in pregnancies complicated by viral and/or bacterial infections.acute re.

STUDY DESIGN: This is a retrospective cohort study of pregnant individuals with a live singleton birth and known fetal sex occurring at two large academic medical centers in Boston between January 2020 and July 2023. We examined features associated with maternal respiratory failure (ICD-10 J96.*) or acute respiratory distress syndrome (ARDS, ICD-10 J80.*) in individuals with a diagnosis of viral respiratory infection (SARS-CoV-2, influenza, parainfluenza, rhinovirus, adenovirus), disseminated varicella, pneumonia, or upper urinary tract infection/pyelonephritis during pregnancy. The primary exposure of interest was fetal sex. Multiple logistic

regression was used to assess maternal and fetal factors associated with maternal respiratory failure/ARDS.

RESULTS: 3,903 pregnant individuals met inclusion criteria. Of 33 individuals with respiratory failure/ARDS, 26 (79%) had a male fetus, compared with 1,993/3,870 (52%) in those without respiratory failure/ARDS; unadjusted odds ratio (OR) 3.5, 95% CI: 1.8-6.8 (Fig. 1A). Male sex, pre-existing airway disease, and presence of a hypertensive disorder were significantly associated with maternal respiratory failure/ARDS in a logistic regression model (Fig. 1B); adjusted OR male sex: 4.5, 95% CI: 3.5-5.6, p< 0.001.

CONCLUSION: In this large retrospective cohort, male sex was a significant risk factor for severe maternal respiratory morbidity following both respiratory and urinary tract infections. These data add to the growing literature that fetal sex plays an important role in modulating the maternal immune response.

A Cohort clinical information by outcome.

	No respiratory failure	Respiratory failure	P*
N	3870	33	
Male fetal sex	1993 (52)	26 (79)	0.002
Maternal age	34 (30, 37)	36 (31, 40)	0.07
Pre-existing airway disease	406 (11)	14 (42)	<0.001

1076 Risk Factors Predictive of Cesarean Section for Non-reassuring Fetal Heart Tracing among Inductions

Elizabeth Maxwell[1], Alberto Muniz Rodriguez[1], Zoe Kibbelaar[2], Andrea Pelletier[1], Sarah E. Little[1]

[1]Brigham and Women's Hospital, Boston, MA, [2]Harvard Medical School, Boston, MA

OBJECTIVE: To identify risk factors for patients needing a cesarean delivery for fetal distress while undergoing induction of labor.

STUDY DESIGN: In a retrospective case-control study design, every patient undergoing induction of labor and who delivered via a cesarean section for a non-reassuring fetal heart tracing (FHT) over a 12-month period at Brigham and Women's Hospital were included as cases. Patients who were attempting a trial of labor after a prior cesarean section were excluded. Controls were defined as the next scheduled induction who delivered either vaginally or via cesarean delivery for other indications. A multivariate logistic regression model was built based on significant univariate findings to identify risk factors for needing a cesarean delivery for fetal distress during induction.

RESULTS: A total of 142 cases and 148 controls were included. The significant associations are reported in the table below. Spanish speakers, nulliparity, need for cervical ripening, fetal growth restriction, and having a category II FHT within the first hour of induction were independent significant predictors of having cesarean delivery for fetal distress. When these risk factors were combined, it was found that nulliparous patients who require cervical ripening and have a category II FHT within the first hour of induction have an adjusted OR of 3.7 (95% CI 1.8-7.6, p< 0.001).

CONCLUSION: These findings suggest that certain maternal, fetal, and labor factors at the start of induction may be predictive of needing a cesarean delivery for fetal distress later in induction. Additionally, the cumulative effect of these factors suggests that a certain patient population (i.e. nulliparous patients with an unfavorable cervix and a category II FHT within the first hour of induction) may have a higher risk of ultimately needing a cesarean section during induction, which can help inform and guide patient counseling. These findings could be used to help build a predictive model that combines variables prior to induction of labor to identify pregnancies at increased risk of cesarean delivery for fetal distress.

1077 Sphingolipid profile in human uterus at term.

Magdaleena Naemi Mbadhi[1], Kaci Martin[1], Ruth Gill[1], Nandini Raghuraman[2], Kumar Saurabh[1], Antonina I. Frolova[2]

[1]Washington University in St. Louis, School of Medicine, St. Louis, MO, [2]Washington University School of Medicine in St. Louis, St. Louis, MO

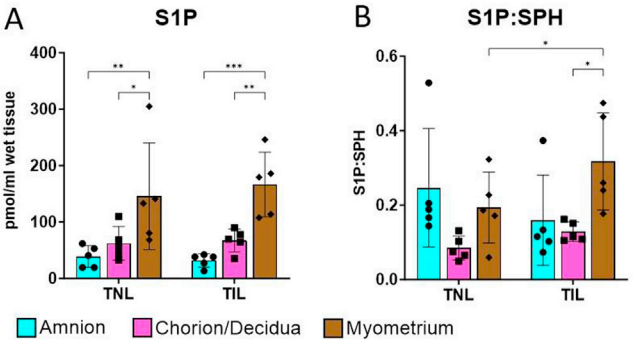
OBJECTIVE: Sphingolipids are a diverse class of bioactive lipids that have emerged with essential regulatory roles in various physiological and pathological processes. Prior work has shown that the bioactive sphingolipid, sphingosine-1-phosphate (S1P), activates a pro-inflammatory phenotype in human myometrium. This study examined the concentrations and distribution of sphingolipids in human term non-labor (TNL) and labor (TIL) amnion, chorion/decidua, and myometrium.

STUDY DESIGN: This prospective study included 5 term TNL and 5 term TIL tissue samples collected during cesarean at ^{3}37 weeks gestation. Samples were flash-frozen within one hour of delivery and stored at -80^{o}C until processing. Sphingolipids were extracted from the tissues and quantitated using high-performance liquid chromatography-mass spectrometry (HPLC-MS/MS). Two-way ANOVA was used to compare lipids between TNL and TIL samples. Tukey post-hoc test was used to adjust for multiple comparisons.

RESULTS: Concentrations of S1P were significantly more abundant in the myometrium compared to the chorion/decidua and amnion at TNL and TL (Fig A). There was no significant difference in S1P levels between TNL and TIL in any of the three tissue types. The levels of sphinganine (SPA), a ceramide and sphingosine (SPH) precursor, were higher in the chorion/decidua than in the amnion and myometrium in TNL and TIL. Levels of SPH, the direct precursor of S1P, were significantly higher in the chorion/decidua and myometrium compared to amnion in both TNL and TL. To understand the S1P turnover rate, we looked at the ratio of S1P to its

precursors. S1P:SPH (Fig B) and S1P:SPA ratios were both significantly higher in the TIL compared to TNL myometrium.

CONCLUSION: Our study presents a quantitative profile of the major sphingolipids in human uterine tissues at parturition. The active metabolite, S1P, is highest in the myometrium. Additionally, S1P:SPH and S1P:SPA ratios suggest a higher turnover rate of S1P during labor. These data suggest a potential role for S1P in myometrial contractility during parturition.



1078 The Association Between Driving Distance to Obstetric Care Centers and Perinatal Outcomes in Alabama

Charlotte McCarley[1], Christina T. Blanchard[2], Ariann Nassel[3], Ashley N. Battarbee[4], Akila Subramaniam[2]

[1]University of Alabama at Birmingham, Hoover, AL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [3]School of Public Health, University of Alabama at Birmingham, Birmingham, Alabama, Birmingham, AL, [4]University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: Maternal care deserts are increasing. We evaluated if driving distance to obstetric (OB) care is associated with perinatal morbidity and if this association differs based on social vulnerability.

STUDY DESIGN: Retrospective cohort of patients delivering a singleton ≥ 22 weeks at a tertiary care center in central Alabama (2014-2018). Patients were excluded if their home address was unavailable or outside Alabama. Driving distance from home address to the nearest OB center and our center was determined using ArcGIS Network Analyst. Patients were secondarily categorized by their social vulnerability index (SVI); high SVI defined as 1 standard deviation above our population mean. Co-primary outcomes were composites of adverse maternal and neonatal outcomes (Table). The odds of our outcomes by driving distance (kilometers) to nearest OB center and our center were estimated using logistic regression models. Tests of interaction explored differential effects on outcomes by SVI (high SVI vs. not).

RESULTS: A total of 12,697 patients were analyzed**:** 65% publicly insured, 46% Non-Hispanic Black, and 60% single. Median driving distance to nearest OB center was 11km (IQR 6-21) and to our center 19km (10-34). The maternal composite occurred in 32% and neonatal composite in 25% of our cohort. There was no association between driving distance to nearest OB center for either outcome in the overall cohort (Table). In the subgroup of patients with high SVI (n=2885) there was a 2.5-fold increased odds of neonatal morbidity (aOR 2.51 [95% CI 1.60-3.94]) for every 50km further from the nearest OB center. When examining distance to our center, there was a 5% increased odds of maternal and a 25% increased odds of neonatal morbidity for every 50km further from our center (Table); results did not differ by SVI.

CONCLUSION: Patients living further from our tertiary care center have higher odds of maternal and neonatal morbidity regardless of SVI. Additionally, living further from the nearest OB center increases neonatal morbidity for those with high SVI. Interventions for high SVI patients living in remote areas are needed.

Table. Logistic regression model for association of driving distance to obstetric center and tertiary care center with maternal and neonatal outcomes

Outcome	aOR (95% CI)[a,b]	Interaction p-value (high vs not-high SVI)
Nearest Obstetric Center		
Maternal Composite	1.02 (0.96-1.08)	0.22
Neonatal Composite	1.06 (0.99-1.14)	<0.001
Tertiary Care Center		
Maternal Composite	1.05 (1.02-1.08)	0.76
Neonatal Composite	1.25 (1.21-1.30)	0.30

Maternal composite: ICU admission, death, unplanned surgery, postpartum hemorrhage, blood transfusion, puerperal infection, wound complication, postpartum readmission or hospital encounter, abruption, fetal death
Neonatal composite: preterm delivery, NICU admission, neonatal death, Apgar < 4 at 5 min, umbilical artery pH < 7.0.
[a]Odds Ratio per 50 kilometer interval
[b]Maternal composite adjusted for race, alcohol use, and chronic hypertension. Neonatal Composite adjusted for race, chronic hypertension, fetal anomaly, and mode of delivery.

1079 The Impact of Physical Activity During Pregnancy on Peripartum Depression

Charlotte McCarley[1], Yumo Xue[2], Ashton Robinson[3], Chase Cawyer[4], Sara Gould[4], Ashley N. Battarbee[4]

[1]University of Alabama at Birmingham, Hoover, AL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL, [4]University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: Physical activity during pregnancy reduces perinatal depression in low risk patients, however, its effect in patients with medical co-morbidities is not known. We aimed to evaluate this association.

STUDY DESIGN: Retrospective cohort of patients included in the Nulliparous Pregnancy Outcomes Study Monitoring Mothers-to-Be with ≥1 medical comorbidity (Table footnote). Activity logs reporting type and amount of activity for the previous month were completed at 3 study visits**:** 6.0-13.6, 14.0-21.6, and 22.0-29.6 weeks. Patients were characterized based on if they met ACOG recommendation of 150 minutes of moderate or 75 minutes of vigorous activity per week averaged across all visits (active versus not active). The primary outcome was EPDS score >10 (indicating perinatal depression) at visit 3. Secondary outcomes included change in EPDS score between visit 1 and 3, treatment for depression, and perinatal outcomes. Outcomes were compared between groups and multivariable logistic regression was used to adjust for covariates.

RESULTS: Overall, 7,486 patients were included, 4092 (55%) were active and 3394 (45%) were not active during pregnancy. History and treatment of mental health disorder before pregnancy, chronic hypertension, and pregestational diabetes were less common in those

who were active compared to those who were not. EPDS score >10 was 15% less likely in those who were active compared to those who were not (aOR 0.85 [95% CI 0.72-0.99]; Table). The average change in EPDS score from visit 1 to 3, treatment for perinatal depression, and adverse perinatal outcomes including preterm birth and SGA did not differ by activity (Table).

CONCLUSION: Patients with medical co-morbidities who were active during pregnancy had lower odds of depression than those who were not active. Treatment of perinatal depression did not differ between groups, however there was not an increase in adverse perinatal outcomes with physical activity. Prospective studies are needed to evaluate the potential benefits of physical activity during pregnancy for perinatal depression in patients with medical co-morbidities.

Association between physical activity and peripartum depression in women with medical comorbidities[a]

Outcome	Active[b]	Not Active	aOR (95% CI)[c]
EPDS >10	371 (9%)	409 (12%)	0.85 (0.72-0.99)
Treatment for PD	279 (7%)	278 (8%)	0.94 (0.76-1.17)
Suspected FGR	103 (3%)	95 (3%)	0.92 (0.68-1.24)
Preterm birth	261 (7%)	282 (8%)	0.82 (0.68-0.99)
Oligohydramnios/ anhydramnios	171 (4%)	139 (4%)	1.02 (0.81-1.30)
SGA	130 (17%)	429 (13%)	1.09 (0.82-1.45)

[a]Medical co-morbidities include: chronic hypertension, pregestational diabetes, asthma, cardiac disease, systemic lupus erythematosus, renal disease, history of mental health disease, hyperthyroidism

[b]Active indicates average of 150 minutes of moderate or 75 minutes of vigorous activity per week

[c]Adjusted for age, insurance type, body mass index, chronic hypertension, pregestational diabetes, history of mental health disorder, treatment of mental health disorder prior to pregnancy.

EPDS, Edinburg Postnatal Depression Scale; PD, perinatal depression; FGR, fetal growth restriction; SGA, small for gestational age

1080 Provider-level disparities in delivery outcomes among patients with a history of Cesarean

Lily McCarthy[1], Sara Wetzler[2], Nicola F. Tavella[3], Lily Ardente[1], Toni Stern[1], Angela Bianco[4]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]Mount Sinai, New York, NY, [3]Icahn School of Medicine at Mount Sinai Hospital, New York, NY, [4]Mount Sinai Medical Center, New York, NY

OBJECTIVE: The decision about whether to pursue a trial of labor after cesarean (TOLAC) or elective repeat cesarean delivery (ERCD) requires assessment of risks and benefits prenatally [1]. Providers play a central role in this counseling process [2, 3]. However, the influence of provider-associated characteristics on delivery methods remains unclear [4]. These include specific provider type, practice setting, and patients' cultural beliefs [5-11]. We aimed to address these knowledge gaps by analyzing the impact of provider-level differences on delivery choice and delivery outcome in a cohort of patients with a prior history of cesarean delivery (CD).

STUDY DESIGN: This was a retrospective cohort study of 1,661 deliveries between April 29, 2015 — April 29, 2020. Subjects were divided into either TOLAC or ERCD, and they either delivered a vaginal birth after Cesarean (VBAC) or a repeat CD. The primary outcomes were a cohort of delivery choice and delivery outcomes. Disparities in these outcomes were reviewed between different obstetric providers, examining proportional differences through Chi-squared tests. The delivering provider was determined from a breakdown of different providers delivering at the study site during the study period.

RESULTS: There were significant proportional disparities between patients in the TOLAC and ERCD groups, as well as between patients in the VBAC and repeat CD groups. Specifically, patients with a provider specializing in midwifery were significantly more likely to undergo TOLAC and deliver by VBAC, while patients seeing an OBGYN in private practice were more likely to deliver by elective repeat CD ($p < 0.001$).

CONCLUSION: Given the evidence of increased risk of morbidity with multiple CDs, examining factors that influence repeat CDs is critical. This study suggests that provider-level differences relating to specialty may be one such factor. These data also illuminate underresearched areas in which culture influences maternal and neonatal delivery outcomes. These findings help to guide future investigations to improve outcomes among patients with a history of CD.

Table:

	TOLAC Total = 1,294 *n (%)*	ERCD Total = 367 *n (%)*	χ^2	*p*
Delivering Provider			150.47	< 0.001

1081 The Impact of Removing Abortion Access to Patients with Chronic Kidney Disease: A Cost-Effectiveness Analysis

Sydney McCarthy, Olivia J. Curl, Sarah K. Dzubay, Uma Doshi, Aaron B. Caughey

Oregon Health & Science University, Portland, OR

OBJECTIVE: In the 2022 ruling in Dobbs v Jackson Women's Health, the United States Supreme Court returned abortion access back to where it was in 1973, constitutionally unprotected. This has had wide-reaching impacts on people capable of becoming pregnant, potentiates deadly outcomes, and inflicts costs on our health system. The current study focuses on how abortion access affects people who

are pregnant, have chronic kidney disease (CKD), and desire an abortion. With both maternal and fetal/neonatal health in mind, we will examine the outcomes and costs associated with providing or refusing in-state access to abortions for this population.

STUDY DESIGN: A decision-analytic model was built to compare the costs associated with providing abortions in-state compared to the costs associated with a statewide abortion ban. The model considers documented outcomes of pregnancy with CKD (preeclampsia, preterm birth, maternal mortality) and considers the progression of kidney disease. The model also considers the likelihood and costs associated with traveling to another state for an abortion.

RESULTS: In a cohort of 31,243 pregnant people with CKD, providing abortions resulted in 1,130 fewer cases of preeclampsia, 2,264 fewer preterm births, 6,411 fewer cases of chronic kidney disease stage progression, 731 fewer cases of ESRD requiring dialysis, and 139 fewer maternal deaths. Due to the increased incidence of perinatal complications and a progression of maternal chronic kidney disease, an absence of in-state abortion access was associated with an increased cost of $470,769,524 and a decrease of 14,997 QUALYs compared to those in states with abortion access.

CONCLUSION: Providing in-state abortion access to pregnant people with chronic kidney disease is a cost-effective strategy. Due to the direct decrease in preeclampsia, preterm birth, maternal mortality, and progression of kidney disease, allowing these patients to terminate their pregnancies saves a considerable amount of money. Jurisdictions that have restricted abortion access should consider implementing increased access to lower both medical and societal costs.

Table 1. Outcomes in a cohort of 31,243 pregnant people with CKD

Outcome	In-State Abortion Access	No in-State Abortion Access	Difference
Preeclampsia (cases)	0	1,130	-1,130
Preterm Birth (cases)	0	2,264	-2,264
CKD Progression (cases)	0	6,411	-6,411
ESRD (cases)	0	731	-731
Maternal Mortality (cases)	167	306	-139
Cost ($)	$549,189,454	$1,019,958,978	-$470,769,524
Effectiveness (QUALY)	490,828	475,831	+14,997

1082 Resolution of postpartum hypertension among Asian, Black, and Hispanic patients with hypertensive disorders of pregnancy

Jennifer A. McCoy[1], Teresa Janevic[2], Frances Howell[3], Natalie Boychuk[4], Katharine McCarthy[5], Micki Burdick[6], Sarah Nowlin[3], Sheela Maru[3], Oluwadamilola Oshewa[6], Maria Monterroso[6], Alva Rodriguez[7], Cecilia Katzenstein[3], Regina Longley[3], Elizabeth A. Howell[6], Lisa D. Levine[6]

[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [2]Mt. Sinai, New York, NY, [3]Mount Sinai, New York, NY, [4]Mt. Sinai, Mt. Sinai, NY, [5]Icahn School of Medicine at Mount Sinai, New York, NY, [6]University of Pennsylvania, Philadelphia, PA, [7]Mount Sinai Hospital, Mount Sinai, NYC, NY

OBJECTIVE: Persistent postpartum hypertension is a risk factor for maternal morbidity and future cardiovascular disease. We sought to (1) evaluate the time to resolution (TTR) of hypertension among patients with a hypertensive disorder of pregnancy (HDP) and (2) determine which characteristics were associated with resolution in a cohort of high-risk patients.

STUDY DESIGN: We conducted a secondary analysis of a prospective cohort study of Asian, Black, and Hispanic patients who delivered from April-October 2022 at 4 hospitals in Philadelphia and New York City. Participants reported postpartum blood pressures (BPs) twice daily through a texting platform until 10 weeks postpartum. We included participants diagnosed with HDP prior to discharge. Resolution of HDP was defined as BP< 140/90 for ^{3}48 hours within 10 weeks postpartum. Survival curves were generated to assess TTR and Cox proportional hazards was used to compute hazard ratios.

RESULTS: Of 419 patients in the cohort, 120 had HDP and were included. 80 (67%) achieved resolution of HDP. The median TTR among all participants was 7.0 days (SD**:** 3.4). A higher BMI and higher systolic BP at discharge were associated with a lower rate of resolution (Table). Non-Hispanic Black and "other" race were also associated with a lower rate of resolution compared to Hispanic patients. Participants with a high school degree/GED experienced a lower rate of resolution compared to those with a college degree. When adjusting for confounders (BMI and race and ethnicity), each 1 mmHg increase in systolic BP at delivery resulted in an approximately 2% lower rate of resolution (aHR**:** 0.98, 95% CI**:** 0.96, 0.99). Similarly, each 1 mmHg increase in diastolic BP resulted in an approximately 3% lower rate of resolution (aHR**:** 0.97, 95% CI**:** 0.95, 0.99).

CONCLUSION: In this high-risk cohort of Asian, Black, and Hispanic patients with HDP, BMI, race/ethnicity, education level and BP at discharge were all associated with lower rates of resolution of BP. Given the high maternal morbidity in this group, these factors should be considered when determining length of time for postpartum BP monitoring.

1083 Risk of Severe Maternal Morbidity in Polycystic Ovary Syndrome

Kathryn M. McKenney[1], Jennifer F. Culhane[2], Moeun Son[3], Kevin Dysart[4]

[1]University of Colorado Anschutz School of Medicine, Aurora, CO, [2]Yale University, New Haven, CT, [3]Weill Cornell Medical College, New York, NY, [4]Nemours Children's Hospital, Wilmington, DE

OBJECTIVE: Patients with Polycystic Ovary Syndrome (PCOS) are more likely to have preexisting medical comorbidities and experience pregnancy related complications. We aimed to describe and compare severe maternal morbidity (SMM) rates during the delivery

encounter in patients with and without a diagnosis of PCOS in a large national electronic health record database.

STUDY DESIGN: This is a retrospective cohort study of singleton deliveries from 2018-2022 using Epic's Cosmos platform. PCOS was defined by ICD-10 codes. The primary outcome was SMM, defined by CDC's criteria. Secondary outcomes were SMM types. We evaluated maternal age, race and ethnicity, insurance, social vulnerability index, obesity, smoking, preexisting and pregnancy related hypertension (HTN) and diabetes mellitus (DM), congenital and acquired heart disease, chronic renal disease, use of metformin, antihypertensives, and magnesium, and delivery mode. Logistic regression was used to calculate crude and adjusted odds of SMM by PCOS status.

RESULTS: Of 1,817,361 deliveries, 61,485 (3.5%) patients had PCOS. Those with PCOS were more likely to be White, commercially insured, and obese; have pre-existing and pregnancy related HTN and DM; and deliver by cesarean. The SMM rate among those with PCOS was 262.7 per 10,000 (95% CI 250.3-275.6) compared to 214.8 (212.7-216.9) among non-PCOS. Unadjusted odds of SMM in patients with PCOS was 1.24 (95% CI 1.18-1.30); however, after adjusting for confounders, this was no longer statistically significant (aOR 1.01, 95% CI 0.96-1.06). Types of SMM differed between those with PCOS and those without (Table).

CONCLUSION: Individuals with PCOS experience higher rates and differing types of SMM compared to those without PCOS. The association between PCOS and SMM appears to be driven by demographic factors and medical comorbidities and not as an independent effect of PCOS. To improve pregnancy outcomes in patients with PCOS, clinicians should target modifying these risk factors.

Table: Severe Maternal Morbidity (SMM) in those with versus without PCOS.

	PCOS *rate per 10,000 (95% CI)*	No PCOS *rate per 10,000 (95% CI)*
SMM	262.7 (250.3-275.6)	214.8 (212.7-216.9)
SMM without blood transfusion	141.1 (132.0-150.8)	95.1 (93.6-96.5)
Acute Myocardial Infarction	2.3 (1.3-3.9)	1.4 (1.2-1.6)
Acute Renal Failure	31.2 (27.1-36.0)	21.4 (20.8-22.2)
Adult Respiratory Distress Syndrome	19.4 (16.2-23.2)	13.9 (13.4-14.5)
Pulmonary Embolism – Air or Thrombus	12.7 (10.1-15.8)	6.9 (6.5-7.3)
Pulmonary Embolism – Amniotic Fluid	1.9 (1.1-3.5)	1.2 (1.1-1.4)

1084 Physician and Hospital Characteristics Associated with Vaginal Delivery in Nulliparous Patients Receiving Magnesium Sulfate

Jenny Y. Mei[1], Daniel Lee[2], Masaru Negi[3]
[1]University of California, Los Angeles, Los Angeles, CA, [2]UCLA Medical Center, Los Angeles, CA, [3]UCLA David Geffen School of Medicine, N Hollywood, CA

OBJECTIVE: Magnesium sulfate administration for preeclampsia with severe features during labor induction has been associated with increased risk of cesarean delivery (CD). We aim to evaluate provider and hospital associations with successful vaginal delivery (VD) in nulliparous patients undergoing labor induction while receiving magnesium sulfate.

STUDY DESIGN: This was a secondary analysis from the Consortium on Safe Labor, a multicenter cohort study of 228,438 deliveries in 19 U.S. hospitals. The analysis included nulliparous women $\geq$ 18 years old with singleton gestation undergoing induction of labor for preeclampsia with severe features and receiving magnesium sulfate. Primary outcome was physician and hospital characteristics associated with successful VD. Chi-square and independent samples t-test were used to compare groups. The study was deemed IRB exempt #20-000360.

RESULTS: Total 4,122 women met inclusion criteria, of whom 2256 (54.7%) had a successful VD. Patients who had a VD were more likely to have had a female physician ($p< 0.001$), midwife or resident involvement ($p< 0.001$), government, OB hospitalist, or university practice model over private practice ($p< 0.001$), and government or hospital insurance over group or self-pay model ($p=0.003$). Hospital type, level of care, or types of physician coverage (MFM, hospitalist, midwife) did not differ between groups. NICU level of care did not differ between groups. The number of hospital deliveries per year was slightly lower in those with successful VDs ($p< 0.001$).

CONCLUSION: Rates of cesarean delivery are high in patients undergoing induction of labor for severe preeclampsia receiving magnesium sulfate. Various physician and hospital characteristics are associated with increased rate of successful VD. These findings suggest the need to study practice patterns by different providers in various settings to appropriately manage labor in this high risk patient cohort.

1085 Remote Blood Pressure Monitoring for Postpartum Hypertension: A Cost-Effectiveness Analysis

Jenny Y. Mei[1], Alisse Hauspurg[2], Kate Corry-Saavedra[3], Tina A. Nguyen[3], Aisling M. Murphy[3], Emily S. Miller[4]
[1]University of California, Los Angeles, Los Angeles, CA, [2]UPMC Magee-Womens Hospital, Pittsburgh, PA, [3]David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, [4]Alpert Medical School of Brown University and Women & Infants Hospital of Rhode Island, Providence, RI

OBJECTIVE: Recognizing the importance of close follow-up after hypertensive disorders of pregnancy (HDP), many centers have initiated programs to support postpartum remote blood pressure monitoring (RBPM). We aim to evaluate the cost-effectiveness to inform scalability of these programmatic interventions.

STUDY DESIGN: We conducted a cost-effectiveness analysis of utilizing RBPM to manage postpartum hypertension versus usual care. The modeled RBPM included provision of home blood pressure (BP) cuff, guidance on warning symptoms, instructions on BP self-monitoring twice daily, and clinical staff to monitor population-level BPs and provide clinical recommendations. Usual care was defined as guidance on warning symptoms and recommendation for one outpatient visit for BP monitoring within a week of discharge. We designed a Markov model that ran over 14 one-day cycles. QALYs were calculated over the first year postpartum and reflected the short-term morbidities associated with HDP that, for most birthing people, resolve by two weeks postpartum. Sensitivity analyses were performed to assess strength and validity of the model. Primary outcome was incremental cost effectiveness ratio (ICER) defined as cost needed to gain one quality adjusted life year (QALY). Secondary outcome was incremental cost per readmission averted.

RESULTS: In the base case scenario, utilizing RBPM was the dominant strategy [Table 1a]. In univariate sensitivity analyses, the most cost-effective strategy was sensitive to baseline probability of normotensive BPs, mild range BPs, or severe range BPs [Table 1b]. Assuming a willingness-to-pay of $100,000 per QALY, utilizing RBPM was cost-effective in 99.96% of simulations in a Monte Carlo analysis. Using readmissions averted as a secondary effectiveness outcome, the incremental cost per readmission averted was $118.23.

CONCLUSION: Remote blood pressure management of postpartum hypertension is cost saving with better outcomes compared to usual care. These data support broad implementation of RBPMs for birthing people with hypertensive disorders of pregnancy.

Table 1a: Cost-Effectiveness Outcomes Based on Strategy Per Patient for Base Case

	RBPM	No RBPM
Total Cost (USD) over 14 days	$2,982.92	$4,213.99
Total QALYs over 14 days	15	14.99
ICER	Dominant strategy	--
Readmissions	0.01	0.05
Incremental cost per readmission averted	$118.23	--

Table 1b: Univariate Sensitivity Analyses Evaluating When the Most Cost-Effective Strategy Shifted to Usual Care

Baseline Parameter	Base Estimate	Range	One-Way Sensitivity Threshold
Probability of Normotensive BP	0.96	0.95-0.98	Less than 0.95
Probability of Mild Range BP	0.03	0.02-0.08	Less than 0.023
Probability of Severe Rane BP	0.008	0.006-0.012	Less than 0.0014

1086 Risk Factors for Post-Acute Sequelae of SARS-CoV-2 Infection (PASC) Symptoms Among Postpartum Birthing People

Emily S. Miller[1], Lutfiyya N. Muhammad[2], Torri D. Metz[3], Siyuan Dong[2], Young Lee[4], Jaqueline Gollan[2], Craig Garfield[2]
[1]Alpert Medical School of Brown University and Women & Infants Hospital of Rhode Island, Providence, RI, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]University of Utah Health, Salt Lake City, UT, [4]Northwestern University, Chicago, IL

OBJECTIVE: Approximately 10% of people with SARS-CoV-2 will experience PASC, which has been characterized by symptoms such as malaise, fatigue, and cough, among others. PASC symptoms are particularly difficult for postpartum people as they navigate their own physical and emotional transition to new parenthood. We sought to evaluate risk factors for PASC in postpartum people.

STUDY DESIGN: This secondary analysis of a randomized trial of a digital health intervention to support new parents. The parent trial recruited birthing people after delivery, prior to hospital discharge. At the time of consent, birthing people were asked to answer additional questions surrounding prior SARS-CoV-2 infection, its timing, vaccination status, co-morbidities, and whether they were experiencing any of the 44 symptoms of PASC described within the NIH RECOVER cohort. Those who reported prior SARS-CoV-2 infection were included. A PASC score was calculated using

previously published criteria and a cut-off of ≥ 12 used to define PASC. Multivariable models were used to identify risk factors for PASC.

RESULTS: Of the 284 postpartum people who met inclusion criteria, 137 (48.2%) reported prior SARS-CoV-2. A total of 27 (9.5%) met criteria for PASC. In multivariable models, non-Hispanic Black race was associated with having a lower PASC score whereas having a chronic medical condition was associated with a higher PASC score. For multivariable models with the outcome of PASC (i.e., PASC score ≥ 12), having a chronic medical condition was the only risk factor associated with PASC. Notably, SARS-CoV-2 infection during pregnancy (vs outside of pregnancy) was not associated with PASC. While point estimates for PASC score and PASC were lower for those vaccinated for SARS-CoV-2 compared to those unvaccinated, these estimates did not reach statistical significance.

CONCLUSION: For postpartum birthing people with SARS-CoV-2, having a chronic medical condition is a risk factor for PASC symptoms postpartum. Recognizing the particular burden of PASC on new parents, these data amplify the importance of ongoing public health prevention efforts.

Table: Multivariable analyses for the outcome of PASC score and PASC

	PASC Score		Screen-Positive for PASC (PASC Score ≥ 12)	
	aβ	95% CI	aOR	95% CI

1087 Placental histopathological lesions and adverse neonatal outcomes in patients with Inflammatory Bowel Diseases

Liat Mor[1], Ann Dekalo[2], Ohad Feldstein[2], Meital Levin[2], Letizia Schreiber[2], Yael Ganor Paz[3], Eran Israeli[2], Giulia Barda[4], Eran Weiner[5]

[1]Wolfson Medical Center, Holon, HaMerkaz, [2]Edith Wolfson Medical center, Holon, HaMerkaz, [3]Edith Wolfson Medical Center, Shoham, HaMerkaz, [4]Edith Wolfson Medical Center, Petach Tikva, IL, [5]Wolfson Medical Center, Tel Aviv, HaMerkaz

OBJECTIVE: To investigate the relationship between inflammatory bowel diseases (IBD), including Crohn's disease and Ulcerative Colitis, and adverse pregnancy outcomes by comparing neonatal outcomes and placental histopathology in two matched groups of patients with and without IBD.

STUDY DESIGN: In this retrospective study, data of all patients who gave birth between 2008-2021 in a single tertiary center and were diagnosed with IBD were reviewed and matched in a 2:1 ratio with a control group based on maternal age, gestational age, and pregnancy complications. Neonatal outcomes and placental pathology were compared between cases with and without IBD.

RESULTS: Compared to the control group (n=76), the placentas of patients with IBD (n=36) were characterized by significantly lower placental weight ($p < 0.001$), and higher rates of several placental lesions including lesions associated with maternal vascular malperfusion (MVM, $p < 0.001$) and maternal and fetal inflammatory response lesions ($p < 0.001$) – Table.

Small for gestational age (SGA) birthweight was more prevalent in the IBD compared with the control group (p=0.01). Additionally, neonates of patients with IBD suffered from an increased need for phototherapy ($p = 0.03$), increased respiratory morbidity and NICU admission rates (both $p < 0.001$).

Multivariate logistic regression analyses confirmed the independent association between IBD and composite MVM lesions (aOR 4.2, $p = 0.01$), maternal inflammatory responses (aOR 4.8, $p < 0.001$) and SGA infants (aOR 4.0, $p = 0.05$) after controlling for possible confounders.

CONCLUSION: IBD is associated with increased rates of placental histopathological lesions and adverse pregnancy outcomes, including SGA infants. These novel findings demonstrate the role of placental malperfusion and inflammatory processes in pregnancy complications of IBD patients, which should be followed accordingly.

Placental histopathological lesions and neonatal outcomes of the study groups

	IBD (n = 38)	Controls (n = 76)	p-value
Placental histopathological lesions			
Placental weight (grams)	405.08 ± 110.27	485.63 ±94.33	**< 0.001**
Placental weight < 10th percentile	20 (52.63%)	17 (22.37%)	**0.001**
Maternal vascular malperfusion (MVM) lesions			
Retroplacental hemorrhage	3 (7.89%)	3 (3.95%)	0.37
Vascular lesions of MVM	1 (2.63%)	2 (2.63%)	1.00
Villous lesions of MVM	19 (50%)	14 (18.42%)	**< 0.001**
Composite lesions of MVM	21 (55.26%)	17 (22.37%)	**< 0.001**
Fetal vascular malperfusion (FVM) lesions			
Vascular lesions of FVM	6 (15.79%)	4 (5.26%)	0.06
Villous lesions of FVM	4 (10.53%)	7 (9.21%)	0.82

1088 Single Institution Implementation of a Stillbirth Evaluation Quality Improvement Initiative

John A. Morgan[1], Alexia Novara[2], Kaitlyn M. Dorn[2], Shannon McCloskey[3], James D. Toppin[4], Joseph R. Biggio Jr.[5], Frank Williams[2]

[1]Ochsner Clinic, Metairie, LA, [2]Ochsner Clinic, New Orleans, LA, [3]Ochsner Clinic Foundation, New Orleans, LA, [4]Ochsner Health, New Orleans, LA, [5]Ochsner Health System, New Orleans, LA

OBJECTIVE: The relative infrequency of stillbirths and lack of uniform protocols leads to inconsistency in providing an optimal, cost-effective evaluation. We implemented a quality improvement (QI) initiative to standardize and optimize stillbirth evaluation.

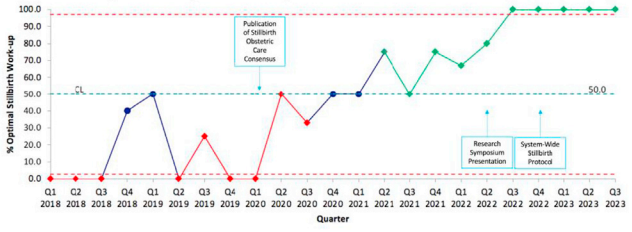
STUDY DESIGN: Two phase QI initiative targeting stillbirth evaluation at a single academic center between 1/2018 and 7/2023. Phase 1 was

a cohort study evaluating the proportion of optimal stillbirth evaluations before and after the publication of the ACOG/SMFM Obstetric Care Consensus (OCC) in 3/2020. Phase 2 involved presentation of findings to faculty and residents at our Annual Research Symposium in 6/2022. Publication of a hospital specific stillbirth protocol followed in 11/2022. Stillbirths included were singleton, non-anomalous fetuses > 20 weeks gestation or > 350 grams. Severe anomalies, spontaneously ruptured membranes, and stillbirths diagnosed intrapartum were excluded. Primary outcome was optimal stillbirth evaluation, defined as placental pathology, counseling on genetic testing & autopsy, and antiphospholipid syndrome testing. Secondary outcome examined unnecessary testing (infectious titers and/or inherited thrombophilia work up). Analysis was performed using student's t test and chi square test.

RESULTS: There were 41 total stillbirths divided into three groups, with 26 stillbirths occurring in the pre-OCC group, 11 occurring in the post-OCC group, and 4 stillbirths occurring in the post-protocol group. Washout periods were observed following the OCC publication and from presentation of phase 1 to publication of the site wide protocol. The post-protocol group had a higher maternal age at delivery; there were no other differences between the three groups. We observed a stepwise improvement in the optimal stillbirth evaluation over time (15.4% vs 72.7% vs 100%, p=< 0.01, figure 1). Likewise, we saw a decline in unnecessary test performance over time (61.5% vs 0% vs 0%, p=< 0.01).

CONCLUSION: Our quality improvement initiative resulted in 100% compliance with optimal stillbirth evaluation and a reduction in unnecessary testing.

Figure 1: Proportion of Optimal Stillbirth Evaluation



1089 Smoking During Pregnancy in an Irish Obstetric Population: Prevalence, Maternal and Ethnic Factors

Julia C. Morrison, Mark A. Dempsey, John J. Morrison
University Hospital Galway, Galway

OBJECTIVE: Maternal smoking during pregnancy is associated with fetal and maternal adverse outcomes. It has been reported that the prevalence of smoking during pregnancy in Ireland is one of the highest worldwide. While the prevalence of smoking during pregnancy in the USA has dropped in recent years, there are no recent data relevant to an Irish obstetric population. The aims of this study were: 1. To evaluate the prevalence of maternal smoking in Ireland during 2015-2022; 2. To investigate the maternal and ethnic factors associated with smoking.

STUDY DESIGN: The data were obtained from the Euroking Obstetric Database at Galway University Hospital. Data was entered prospectively for women booked at the hospital during 2015-2022. Maternal smoking was recorded at antenatal booking in the first trimester. Descriptive statistics were calculated and prevalence rates were compared using Chi^2 for proportions and trend.

RESULTS: The total number of pregnancies was 19,247. There was a stepwise reduction in the prevalence of smoking from 8.3% in 2015 to 6.0% in 2022 (P< 0.001). Smoking rates were 25.9% ≤20yrs, 13.3% aged 21-30 years, 4.2% aged 31-40 years, and 3.1% ≥41 years, with a significant downward trend with maternal age (P< 0.001). The greatest reduction in smoking was observed among those aged 21-30yrs, from 15.3% to 10.1% (P< 0.001). Increasing parity was associated with a higher prevalence of smoking as follows: PO 5.8%, PI 5.7% and P >1 10.8% (P< 0.001). The ethnic breakdown of smokers was: white Irish 69.1%, other white background 19.4%, white traveller 9.5%, and 2% for all other ethnic groups. Initiation of breastfeeding rates were 32.0% for smokers and 70.1% among non-smokers (P< 0.001).

CONCLUSION: These findings outline a reduction in maternal smoking during pregnancy in Ireland over the past decade, particularly in the 21-30 year age group. Maternal smoking during pregnancy is associated with younger age, higher parity, white race and lower breast feeding initiation rates. These data provide information for strategies aimed at prevention of smoking during pregnancy.

1090 The association of social vulnerability index and trial of labor after cesarean

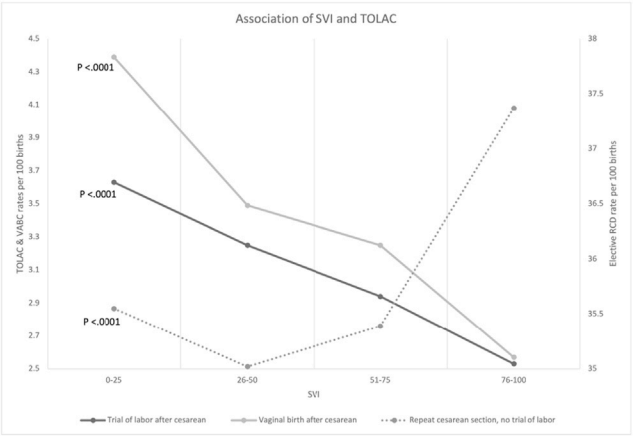
Lauren M. Murphy[1], Ntami P. Echeng[1], Matthew M. Scarpaci[2], Margaret Thorsen[3], Victoria Adewale[1], John R. Soehl[1], Anna Whelan[4], Alexis C. Gimovsky[1], Brock Polnaszek[1]
[1]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [2]Brown Univeristy School of Public Health, Providence, RI, [3]Women and Infants Hospital, Providence, RI, [4]Grafton, MA

OBJECTIVE: The objective of this study was to evaluate the association of the social vulnerability index (SVI) and rates of trial of labor after cesarean section (TOLAC).

STUDY DESIGN: The number of births per mode of delivery were extracted from the publically available Center for Disease Control and Prevention (CDC) natality WONDER database from 2019-2021. Delivery county's were linked to nationally ranked county SVI scores from the CDC/SVI. SVI scores were stratified into quartiles with higher quartiles representing greater social vulnerability. Outcomes were rates of elective repeat cesarean (RCD), attempted TOLAC, successful vaginal birth after cesarean (VBAC), and unsuccessful TOLAC.

RESULTS: Patients who delivered in areas with the highest quartile SVI scores were significantly more likely to undergo an elective RCD (RR 1.04 CI 1.03- 1.05), less likely to achieve a VBAC (RR 0.60 CI 0.50- 0.61), and less likely to undergo a TOLAC (RR 0.71 CI 0.70- 0.72) compared to the lowest quartile. Tests for linear trend across quartiles were significant for RCD, successful VBAC, and attempted TOLAC (P < 0.0001). Rates of unsuccessful TOLAC were not different across SVI quartiles (Figure 1.).

CONCLUSION: This study demonstrates disparities in mode of delivery illustrated by increased rates of elective RCD and lower rates of VBAC and TOLAC among those delivering in areas of greater social vulnerability. In order to improve cesarean morbidity and increase equity, future studies should assess the cause of these disparities and develop interventions to address them.



1091 The effect of aspirin treatment on obstetric complications in twin gestations in a retrospective cohort

Lauren M. Murphy[1], Melissa L. Russo[2], Lauren Schlichting[3], Lorraine Dugoff[4]

[1]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [2]Women and Infants Hospital, Providence, RI, [3]Hassenfeld Child Health and Innovation Institute of Brown University, Providence, RI, [4]University of Pennsylvania, Philadelphia, PA; on behalf of the Twin Cell-free Study Consortium

OBJECTIVE: Pregnant persons with twin gestations are at increased risk for obstetric complications including preeclampsia, gestational hypertension, gestational diabetes, and preterm birth. Low dose aspirin (ASA) has been shown to decrease rates of preeclampsia in singleton pregnancies and recent studies suggest the benefits of ASA may extend beyond preeclampsia. We aimed to evaluate if ASA use reduces preeclampsia or other obstetric complications in twin gestations.

STUDY DESIGN: Planned secondary analysis of a 17-center, retrospective cohort of twin pregnancies aimed to study cell-free DNA screening performance. The primary exposure was ASA use at cell-free DNA blood draw. The primary outcome was preeclampsia. Secondary outcomes included preeclampsia< 34 weeks, preeclampsia with severe features, preterm birth, spontaneous preterm birth, fetal death and gestational diabetes. Those with unknown ASA use status, unknown chorionicity, and vanishing twins were excluded. Baseline characteristics and obstetric outcomes were compared amongst pregnancies taking vs not taking ASA. Outcomes were further analyzed using logistic regression.

RESULTS: Of the 1335 included subjects twin gestations, 320 took ASA and 1015 did not take ASA. Demographic and medical differences existed between the groups (Table 1). There was no difference in preeclampsia < 34 weeks, preeclampsia with severe features, preterm birth, fetal death, and gestational diabetes with respect to ASA exposure. There was a higher risk of preeclampsia in those who took ASA, however after adjustment for BMI, race, pre-gestational diabetes, cHTN and preeclampsia in a prior pregnancy, this association was no longer significant (RR 1.36 95% CI 1.04-1.77; aRR 1.11 95% CI 0.81-1.54).

CONCLUSION: In this cohort, prophylactic ASA did not significantly decrease risk for preeclampsia or spontaneous preterm birth. This information may prove to be helpful in counseling; additional prospective studies are indicated regarding ASA indications and benefits.

Table 1:Outomces in pregnancies who took aspirin (ASA) versus not

Outcome	ASA N (%) N=320	No ASA N (%) N=1015	p-value	RR	aRR*

1092 Postponing early intrauterine transfusion with IVIG treatment in severe hemolytic disease: Individual patient data meta-analysis

Hiba J. Mustafa[1], Giorgio Pagani[2], Enaja Sambatur[3], Francesco D'Antonio[4], Emeline Maisonneuve[5], Paul Maurice[6], Carolien Zwiers[7], Joanne Verweij[8], Alireza A. Shamshirsaz[9], Jean-Marie Jouannic[10], Asma Khalil[11]

[1]Indiana University, Riley Children's Hospital, Carmel, IN, [2]Maternal Fetal Medicine Unit, Department of Obstetrics and Gynecology, ASST-Papa Giovanni XXIII, Bergamo, Lombardia, [3]Maternal-Fetal Care Center, Boston Children's hospital, Boston, MA, [4]McMaster University, Hamilton, ON, [5]Materno-Fetal and Obstetrics Research Unit, Woman-Mother-Child Department, Lausanne University Hospital, Lausanne, Bern, [6]Fetal Medicine Department and French Referral National Centre for Perinatal Hmobiology Armand Trousseau Hospital. APHP Sorbonne University, Paris, Lorraine, [7]Leiden University Medical Center, Leiden, Flevoland, [8]Leiden University Medical Center, Leiden, Gelderland, [9]Maternal Fetal Care Center (MFCC), Boston Children's Hospital, Harvard Medical School, Boston, MA, [10]Fetal Medecine Department, Armand Trousseau Hospital, APHP, Sorbonne Université, Paris, Ile-de-France, [11]Fetal Medicine Unit, St. George's Hospital, St. George's University of London, London, England

OBJECTIVE: To determine whether maternal administration of intravenous immunoglobulin (IVIG) in high-risk red blood cell alloimmunized pregnancies is effective in delaying the gestational age (GA) at the first intrauterine transfusion (IUT) and the onset of severe hemolytic disease of fetus and newborn (HDFN).

STUDY DESIGN: We systematically searched Medline, Embase and Cochrane Library until June 2023. We included studies reporting on pregnancies with severe Rhesus alloimmunization which was defined as either a previous fetal or neonatal death as a result of HDFN or the need for IUT prior to 24 weeks' gestation in the previous pregnancy. Cases included pregnancies receiving IVIG aiming to delay IUT, while controls were pregnancies receiving IUT only. Following inclusion, individual patient data (IPD) were obtained and authors were contacted for missing data. Primary outcome was GA at first IUT. IPD Meta-Analysis was performed using the Bayesian framework.

RESULTS: 11 studies were included in the systematic review of which IPD were obtained for 9 studies. Data were available for 90 controls and 97 cases. GA at first IUT mean difference was significantly earlier in the IUT only group compared to IVIG group (MD -1.29, 95%

CI -2.49, -0.13). Hemoglobin level was significantly lower in the IUT only group compared to IVIG at time of first IUT (MD -2.19, 95% CI -3.18, -1.24). GA at delivery was also significantly different between groups reflecting earlier GA in the IUT only group compared to IVIG (MD -4.99, 95% CI -6.79, -3.23). There were no significant differences in numbers of IUTs, hemoglobin level at birth, or bilirubin level at birth between groups.

CONCLUSION: IVIG treatment in pregnancies at risk of severe early HDFN seems to have a potential clinically relevant beneficial effect on the course and severity of the disease.

Outcome	Number of studies	IUT-only Total N	IVIG+IUT Total N	Pooled RR or MD (95% CI)
GA at first IUT	9	90	97	-1.29 (-2.49, -0.13)
Hg level at time of first IUT	9	87	88	-2.19 (-3.18, -1.24)
Number of IUTs	9	90	97	-0.10 (-0.25, 0.06)
GA at delivery	9	46	50	-4.99 (-6.79, -3.23)
Hg level at time of delivery	9	46	50	-0.47 (-2.04, 1.04)
Bilirubin level at time of delivery	9	46	50	17.64 (-27.50, 61.77)

GA: gestational age, Hg: hemoglobin, IUT: intrauterine transfusion, IVIG: intravenous immunoglobulin, RR: relative risk, MD: mean difference

1093 Management and Core Outcomes Set of Fetal Lower Urinary Tract Obstruction: Delphi Consensus

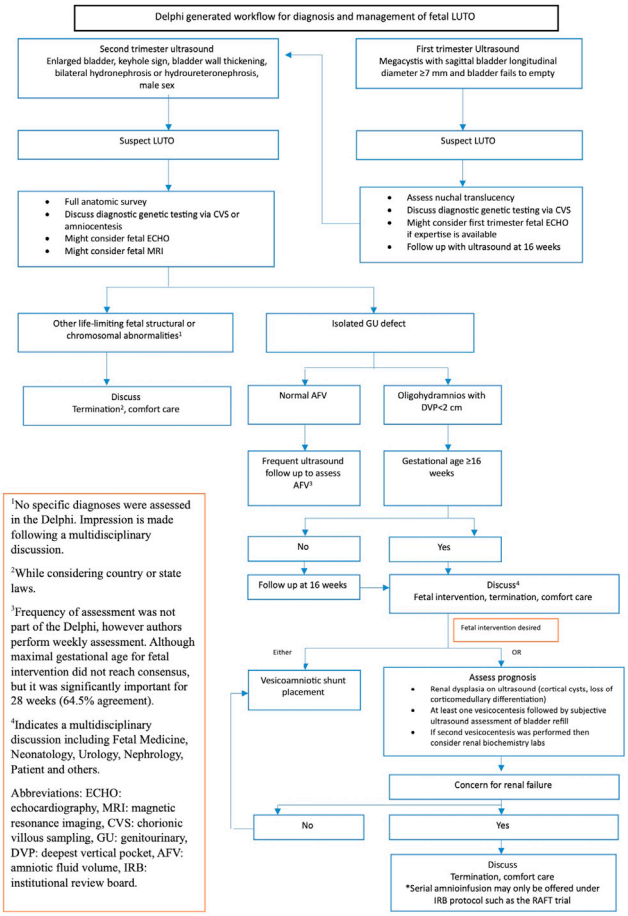
Hiba J. Mustafa[1], Sonia Johnson[2], Sanne J. Gordijn[3], Wessel Ganzevoort[4], Chester Koh[5], George T. Mandy[6], Charlotte Melling[7], Asma Khalil[8], Ahmed A. Nassr[9]
[1]Indiana University, Riley Children's Hospital, Carmel, IN, [2]Oxford University, England, [3]UMCG, Groningen, Groningen, [4]University of Amestrdam, Amestrdam, Limburg, [5]Professor of Urology, Pediatrics, and OB/GYN. Director, Pediatric Robotic Surgery Program Executive Director, SouthWest national Pediatric Device innovation Consortium (SWPDC) Texas Children's Hospital | Baylor College of Medicine, Houston, TX, [6]Texas Children's Hospital, Baylor College of Medicine, Houston, TX, [7]Consultant Paediatric Surgeon & Urologist Honorary Clinical Lecturer University of Liverpool, Liverpool, England, [8]Fetal Medicine Unit, St. George's Hospital, St. George's University of London, London, England, [9]Baylor College of Medicine, Houston, TX

OBJECTIVE: We aimed to reach a Delphi-generated international expert consensus on the diagnosis, management and core outcomes set (COS) of Fetal Lower urinary tract obstruction (LUTO).

STUDY DESIGN: A three-round Delphi procedure was conducted among international panel of LUTO experts from Fetal Medicine and subspecialties of Pediatrics. Panel was provided with a list of literature review generated parameters for diagnosing and management. A parallel procedure was conducted along with patient groups to produce COS.

RESULTS: A total of 160 experts were approached, of whom 99 completed the first round and 80 (80/99, 80.8%) completed all three rounds. Regarding diagnosis, in the first trimester, objective assessment with a longitudinal bladder diameter of ≥7 mm should be used to suspect LUTO. While in the second trimester, imaging parameters of obstructive uropathy include enlarged bladder, keyhole sign, bladder wall thickening, bilateral hydronephrosis and male sex. There was lack of consensus on the current prognostic scoring literature, however, experts agreed on the value of amniotic fluid volume < 24 weeks to predict survival. While experts endorsed the role of sonographic parameters of renal dysplasia (cortical cysts, loss of corticomedullary differentiation), at least one bladder tap, and renal biochemistry for counselling, these items did not reach consensus for fetal intervention candidacy. Consensus for fetal intervention candidacy were absence of life-limiting fetal anomalies, imaging parameters of obstructive uropathy, minimum gestational age of 16 weeks, and oligohydramnios with DVP < 2 cm. If bladder refill was assessed, it should be assessed subjectively. In the presence of suspected renal failure, serial amnioinfusion should only be offered under IRB protocols. Core outcome set for future studies was agreed upon.

CONCLUSION: International diagnostic, prognostic and management criteria for fetal LUTO have reached consensus. Consensus-based criteria and the Core Outcome Set should inform clinical care and research to optimize perinatal outcomes.



1094 Postpartum Hemorrhagic Morbidity in Those With Versus Without Diabetes Mellitus

Sarah Nazeer[1], Rachel L. Wiley[1], Ipsita Ghose[2], Ghamar Bitar[3], Michal Fishel Bartal[4], Yossi Bart[1], Hector Mendez Figueroa[5], Baha M. Sibai[6], Suneet P. Chauhan[7]
[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]University of Texas Medical School at Houston, Houston, TX, [3]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [4]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX, [5]University of Texas Health Science Center at Houston, Houston, TX, [6]Hermann Memorial Hospital, Houston, TX, [7]University of Texas-Houston Medical School, Houston, TX

OBJECTIVE: There is conflicting evidence on the role of hyperglycemia and postpartum hemorrhage. Due to vascular and perfusion abnormalities, we hypothesized that post-partum hemorrhagic morbidity would be higher among those with versus without diabetes mellitus (DM—gestational or pregestational). Our objective was to compare the composite of maternal hemorrhagic morbidity (CMHM) in those with and without DM.

STUDY DESIGN: This was a retrospective cohort study of all singleton deliveries ≥ 14 weeks at a Level IV center between March 2020 and February 2022. Inclusion criteria were those with known DM status. The primary outcome was a composite maternal hemorrhagic-morbidity (CMHM) defined as: blood loss ≥ 1000 mL, use of uterotonics (excluding prophylactic oxytocin), mechanical tamponade, surgical intervention for atony (O'Leary, B-Lynch, or uterine artery embolization), blood transfusion, venous thromboembolism, admission to the intensive care unit, hysterectomy, or maternal death. Multivariable Poisson regression models were used to estimate adjusted relative risks (aRR), adjusted with variables identified in the univariate analysis.

RESULTS: Of the 8,623 deliveries during the study period, 8,357 (97%) met the inclusion criteria. and among them 1,003 (12.0%)—632 (63%) with GDM and 371 (37%) with pregestational—had DM and the remaining 7,354 (88.0%) individuals did not. There were no significant differences in CMHM between the groups (without diabetes 20.6% vs. with diabetes 27.3%; aRR 1.08, 95% CI 0.96-1.22). In subgroup analysis comparing those without diabetes compared to those with gestational diabetes, there was no significant difference (20.6% v. 25.2%; aRR 1.09, 95% CI 0.95-1.26). Similarly, examining those without diabetes compared to those with pregestational diabetes, there was no significant difference (20.6% v. 31.0%; aRR 1.05, 95% CI 0.89-1.24) (Table 1).

CONCLUSION: In our population, pregnancies complicated by diabetes were not at a significantly higher risk of hemorrhagic-related morbidity compared to those without diabetes.

Table 1. Composite Maternal Hemorrhagic-Morbidity Outcomes Stratified by Diabetes Status

Outcomes	No Diabetes (N=7354)	Diabetes (N=1003)	Unadjusted RR (95% CI)	Adjusted RR [a] (95% CI)

Data presented as N (%).

Bolded if significant.

* Stillbirths and malformations excluded for neonatal outcome analysis.

[a] Adjusted for: maternal age, race/ethnicity, marital status, prenatal care provider, nulliparity, body-mass index at delivery, hypertensive disorders, postpartum hemorrhage risk score, cesarean delivery, and gestational age at delivery.

1095 The Role of Long-Acting Antihypertensives in Preeclampsia with Severe Features

Ann Nguyen Pham[1], Oluwatoni Okuyemi[1], Gina F. Milone[2], Jenny Chang[3], Argyrios Ziogas[2], Pranathi Rao[2], Kenneth Chan[4]

[1]University of California, Irvine, Orange, CA, [2]University of California Irvine, Irvine, CA, [3]University of California Irvine School of Medicine, Irvine, CA, [4]Long Beach Memorial Medical Center Women's Hospital, Long Beach, CA

OBJECTIVE: To determine whether initiation of long-acting antihypertensives achieves pregnancy prolongation in preeclamptic patients with severe features and, if so, whether there is significant neonatal benefit gained and maternal risk incurred by this prolongation.

STUDY DESIGN: This was a retrospective cohort study conducted at a single site between 2015-2022. The charts of preeclamptic patients diagnosed with severe features (de novo or superimposed) between 23w0d-33w6d were reviewed and separated into two cohorts: those diagnosed between 23-28 weeks gestation (extremely preterm, or EP) and those diagnosed between 28-34 weeks gestation (preterm, or P). Each cohort was then divided into a traditional subcohort who received only urgent short-acting antihypertensives and a novel subcohort who received both short-acting and long-acting antihypertensives. The primary outcome was pregnancy prolongation, defined as days elapsed between diagnosis of preeclampsia with severe features and delivery. The secondary outcomes were maternal composite outcome and neonatal composite outcome (Table 1). Two sample t-tests and Chi squared analyses with multivariate analysis were utilized.

RESULTS: A total of 288 patients were included. Demographics did not differ significantly. Long-acting antihypertensives prolonged pregnancy by 7 days in the EP cohort (9 days vs 2 days, $p < 0.0001$) and by 3 days in the P cohort (6 days vs 3 days, $p < 0.0001$). Further, use of long-acting antihypertensives provided clinical and statistical benefits in neonatal composite outcomes for the EP neonates (Table 1). Such was not seen in the P neonates, and no changes in maternal composite outcomes were noted in either cohort.

CONCLUSION: The initiation of oral long-acting antihypertensives for preeclamptic patients with severe features prolonged pregnancy sufficiently to improve newborn outcomes in the 23-28-week cohort but not in the 28-34 week cohort. Doing so did not result in maternal harm. Randomized-controlled-trial results are needed to confirm these findings and to potentially adopt this clinical approach.

1096 The HOME INDUCTION Randomized Controlled Trial – Logistics for achieving delivery

Sarah M. Nicholson[1], Orla Smith[2], Corina Oprescu[2], Eimear Wall[2], Sara El Nimr[2], Geraldine Gannon[2], Susan Hatt[2], Ita Shanahan[3], Bernard Kennedy[2], Ronan Daly[2], Claudia Looi[2], Elena Fernandez[2], Zara Molphy[1], Patrick Dicker[1], Karen Flood[1], Fergal D. Malone[2]

[1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]Rotunda Hospital, Dublin, Ireland, [3]Rotunda, Rotunda, Dublin

OBJECTIVE: The ARRIVE Trial has resulted in an increased demand for 39 week induction of labour (IOL) in normal-risk nulliparous

patients, but this creates significant logistical challenges for already busy Labor Wards. A potential solution is commencing induction by means of outpatient cervical ripening at home (H-IOL), using vaginal prostaglandin (Propess/Cervidil) or osmotic cervical dilator (Dilapan-S). This secondary analysis evaluates the logistics of achieving vaginal delivery, including time taken and need for additional ripening modality.

STUDY DESIGN: We randomized healthy nulliparous women, who agreed to elective IOL at 39 weeks, to one of three forms of initial cervical ripening at home: 12 hours of Dilapan (D12), 24 hours of Dilapan (D24), or 24 hours of Propess/Cervidil (P24). Patients returned to the hospital after 12 or 24 hours for either amniotomy or, if the cervix remained unripe, additional doses of prostaglandin E2 gel (Prostin, 1mg). Time to delivery and need for additional Prostin were assessed as part of this secondary analysis.

RESULTS: Patients randomized to Dilapan (D12/D24) were significantly more likely to require an additional agent (Prostin, 1mg) prior to amniotomy being possible (64.5% vs 34%, $p< 0.001$). There was no difference in oxytocin use between groups. Table 1 also shows the timeframe of delivery for each group. 66% of all nulliparous women delivered within 48 hours after IOL commenced, and 94% delivered within 72 hours, inclusive of the time period spent at home.

CONCLUSION: Home IOL is an efficient and useful option for dealing with logistical challenges in busy Labor Wards, with the majority of nulliparous patients delivering within 48 hours. However, there are significant differences in performance characteristics of different modalities for H-IOL, with the majority of Dilapan patients requiring additional Prostin. Outpatient Propess appears to have the most favorable, successful vaginal delivery profile. These RCT data will be useful for Labor Ward planning, including optimizing staffing levels and bed availability.

Reason	All (N=271)	Dilapan 24hr (N=96)	Dilapan 12hr (N=88)	Propess (N=87)	P-value
Prostin given	149 (55%)	68 (71%)	51 (58%)	30 (34%)	<0.001
Oxytocin augmentation	202 (75%)	74 (77%)	67 (76%)	61 (70%)	0.511
Prostin subgroup	***N=149***	***N=68***	***N=51***	***N=30***	
Vaginal delivery rate	92 (62%)	48 (71%)	28 (55%)	16 (53%)	0.125
Time to delivery (hours)	47 [40,58]	49 [44,59]	39 [33,48]	52 [48,59]	<0.001
No Prostin subgroup	***N=122***	***N=28***	***N=37***	***N=57***	
Vaginal delivery rate	102 (84%)	24 (86%)	28 (76%)	50 (88%)	0.288
Time to delivery	34 [26,45]	42 [35,52]	30 [26,35]	34 [23,43]	<0.001
Vaginal delivery	**All**	**Dilapan 24hr**	**Dilapan 12hr**	**Propess**	**Difference: Dilapan - Propess (95% CI)**
Within 48 hours	180 (66%)	53 (55%)	72 (82%)	55 (63%)	-5% (-7%, 17%)
Within 72 hours	254 (94%)	85 (89%)	86 (98%)	83 (95%)	-2% (-8%, 3%)

Table 1 shows the need for second modality within groups; oxytocin use within groups; and the vaginal delivery rate as well as time from initiation of induction to delivery stratified by group/Prostin administration.
< 12 hours for Dilapan 12hr, < 24 hours for Dilapan 24hr and Propess

1097 Prediction of placental chorioamnionitis in active labor utilizing platelets and complete blood count indices

Devon O'Brien, Julie Vircks, Christine Henricks, Eva Kaufman, Imaima Casubhoy, Subhjit Sekhon, Anna Ilivicky, Julia Dahlke, Tanvi Karmarkar, Kiersten Herzog, Emily Gharabegi, Devika Maulik

University of Missouri-Kansas City School of Medicine, Kansas City, MO

OBJECTIVE: The complete blood count (CBC) has been utilized for decades in pregnancy, but only recently have indices and their ratios been studied for their association with intraamniotic infection and adverse pregnancy outcomes. Platelets actively engage in the immune response to acute infections and are anticipated to increase. This study aimed to describe the utility of platelet to white blood cell (PW), platelet to neutrophil (PN), and platelet to lymphocyte (PL) ratios in predicting chorioamnionitis identified on placental pathology. White blood cell (WBC), neutrophil, lymphocyte, and platelet counts were analyzed secondarily.

STUDY DESIGN: A retrospective electronic chart review was performed at an urban safety net hospital for 6 months from 2022-2023. Subjects in active labor beyond 20 weeks of gestation were included in the study if a CBC was performed at admission with placental pathology available. Exclusion criteria were extrauterine infection or platelet count of less than 100,000. Preterm labor (PTL) was defined as less than 37 weeks of gestation. Descriptive and Mann-Whitney U statistical tests were utilized for analyses.

RESULTS: One thousand seventy-nine subject charts were reviewed, with only 35.1% of those with placental pathology available. Of those, 37 subjects admitted with PTL and 81 subjects with term labor were included in the final analysis. There was a significantly higher PL ratio as well as neutrophil count in subjects admitted with PTL who had chorioamnionitis on placental pathology (Table 1). The PL ratio and neutrophil count were moderate predictors of chorioamnionitis in the PTL group, with an area under the curve of 0.724 (95% CI [0.559, 0.888]) and 0.720 (95% CI [0.528, 0.913]), respectively.

CONCLUSION: Platelet to lymphocyte count ratio and neutrophil count may serve as more effective indicators of histopathologic chorioamnionitis in preterm labor patients less than 37 weeks of gestation compared to the traditional use of the WBC count. Larger studies that include neonatal outcomes are warranted to examine if targeted treatment can improve maternal and neonatal outcomes.

Table 1: Complete blood count indices at admission in preterm and term labor analyzed by placental pathology*

1098 Pregnancy related acute kidney injury leads to chronic kidney disease in the postpartum

Gail Ohaegbulam[1], Brittany Berry[1], Angelica J'Mere[1], Shauna-Kay Spencer[1], Terryn Railey[1], Kedra Wallace[2], Ashley Griffin[1]

[1]University of Mississippi Medical Center, Jackson, MS, [2]UMiss, Rockford, IL

OBJECTIVE: Rates of Pregnancy Related-Acute Kidney Injury (PR-AKI) and hospitalizations due to PR-AKI have increased in the past two decades in the United States. Acute kidney injury (AKI) outside

the context of pregnancy has been associated to the progression of chronic kidney disease (CKD). This study has two objectives. The first is to test the hypothesis that PR-AKI leads to the development CKD (Study 1). The second is to test the hypothesis that treatment of AST-120, oral carbon absorbent of uremic toxin precursor, will slow the development of CKD in rats following PR-AKI (Study 2).

STUDY DESIGN: Time pregnant Sprague Dawley rats arrive on gestational day (GD) 11, and PR-AKI is induced on GD18 via a 45-min bilateral renal ischemic reperfusion surgery. Animals are allowed to delivered without intervention on GDs 21-22. Throughout the study, animals had their urine collected via metabolic cages. These measurements were collected at the following timepoints**:** GD15. GD19, Postpartum week (PPW 1), PPW5, PPW9, PPW12, and PPW16. Urinary protein and creatinine were measured via commercially bought assays. For the second objective, animals followed a similar time course with the exception that AST-120 treatment began on PPW2 until PPW11.

RESULTS: Study 1 results urine output is decreased in PR-AKI animals at GD19, PPW1 and at PPW16 compared to normal pregnant (NP). In addition, urinary protein was increased at GD19, PPW1, and PPW16. Compared to NP, at PPW12 and PPW16 PR-AKI animals had a decrease in NP. Study 2 results showed that AST-120 treatment improved urine output at PPW16 compared in PR-AKI animals compared to untreated PR-AKI animals. AST-120 treatment decreased urinary protein in PR-AKI animals at PPW16. AST-120 treatment doesn't affect urinary creatinine values at PPW16.

CONCLUSION: PR-AKI led to evidence of long-term effects of renal damage through decreased urine output, increased urinary protein, and decreased urinary creatinine. AST-120 was able to improve 2 of 3 outcomes by increasing urine output and decreasing urinary protein.

1099 Placenta accreta spectrum (PAS) diagnosis timing and its effect on maternal and neonatal outcomes

Thomas Owens[1], Henri M. Rosenberg[2], Eric Reynolds[3], Alexa Cohen[4], Nicola F. Tavella[5], Myah Griffin[6], Itamar Futterman[7], Pe'er Dar[8], Meghana Limaye[9], Angela Bianco[2], Georgios Doulaveris[4], Lois Brustman[10], Rebecca H. Jessel[5]

[1]Mount Sinai West , New York, NY, [2]Mount Sinai Medical Center, New York, NY, [3]Icahn School of Medicine, New York, NY, [4]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [5]Icahn School of Medicine at Mount Sinai Hospital, New York, NY, [6]NYU Langone Health, Atlanta, GA, [7]Maimonides Medical Center, Brooklyn, NY, [8]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY, [9]NYU Langone Health, New York, NY, [10]St. Luke's Roosevelt Hospital Center, New York, NY; on behalf of the New York City MFM Research Consortium

OBJECTIVE: Expert opinion exists that antenatal diagnosis results in improved maternal and neonatal outcomes. Our aim was to retrospectively compare perinatal outcomes in antenatally diagnosed PAS cases versus those identified at the time of delivery.

STUDY DESIGN: Multicenter retrospective cohort study of 400 histopathologically confirmed PAS cases 1/1/2013 - 6/30/2022 at four New York academic institutions diagnosed both antenatally and at the time of delivery. The primary outcomes were composite maternal morbidity (≥4 RBC units, vasopressor use, organ injury, ICU admission, and mechanical ventilation/intubation), and composite neonatal outcome morbidity (necrotizing enterocolitis (NEC), respiratory distress syndrome (RDS), Intraventricular hemorrhage (IVH), and seizures). Univariate analysis was done using Wilcoxon rank sum analysis and chi-square. Odds ratio (95% CI) P< 0.05 was considered significant. Multivariate logistic regression was used to control confounders.

RESULTS: Of 400 cases, 223 (56%) were found prenatally and 177 (44%) at the time of delivery. Those diagnosed prenatally were less likely to receive vasopressors (aOR 3.5 [95%1.2-10.3]), p=0.02). However, the overall maternal composite morbidity showed no significant difference in the two groups (aOR 2.1 [95% 0.5-8.4]), p=0.31). Neonatal composite morbidity was found to be significantly worse in patients with known PAS (OR 3.2 [95% 1.8-5.5]), p< 0.01). Of note, prenatally diagnosed cases of PAS were delivered more preterm. (33 w SD +/- 3.9 vs 36 SD +/- 3.3 w), p< 0.001.

CONCLUSION: Our data confirms expert opinion that undiagnosed PAS cases have more "surgical" morbidity based on the increased use of vasopressors at the time of delivery. While there was no difference in the overall composite maternal morbidity, this could have been related to fact that these patients were delivered at large academic institutions. Even though there was a significant difference composite neonatal morbidity this could be secondary to the significant difference in gestational age at the time of birth.

Table 1

			Crude		Adjusted	
	Diagnosed prenatally (N=183)	Not Diagnosed prenatally (N=140)	Odds Ratio (95% CI)	P-values	Odds Ratio (95% CI)	P-values [a]

1100 Major congenital malformation in an experimental mouse model of COVID-19

Michael Paidas[1], Hussain Hussain[2], Rajalakshmi Ramamoorthy[1], Andrew D. Masciarella[1], Dibe Di Gregorio[3], Natalia Ravelo[4], Pingping Chen[1], Jaclyn kwal[4], Arumugam Jayakumar[1]

[1]University of Miami Miller School of Medicine, Miami, FL, [2]Larkin Community Hospital, Miami, FL, [3]University of Miami College of Arts & Sciences, Miami, FL, [4]University of Miami, Jackson Memorial Hospital, Miami, FL

OBJECTIVE: We recently reported the first-ever case of maternal second-trimester SARS-CoV-2 infection resulting in severe neonatal brain damage and associated placental abnormalities (Pediatrics, 2023). We, therefore, explored whether we could induce major congenital malformation (MCM) in our established murine hepatitis coronavirus (MHV-1) mouse model of COVID-19 using a high viral load.

STUDY DESIGN: Pregnant A/J mice (N=26, Jackson Laboratories, ME, USA) were divided into 2 groups**:** Group 1, control (CON), pregnant mice without virus inoculation (N=14), and Group 2, pregnant mice which were inoculated at day 15 of pregnancy (equivalent to second trimester in humans) with 5000 PFU MHV-1 intranasally (N=12) (Viruses, 2021). On days 20 and 21 of pregnancy (expected delivery timepoint), pups delivered spontaneously, and were collected from CON and MHV-1-infected pregnant mice. Clinical evaluation was performed on the mother and pups for MCM, and the MCM and survival rates for the pups were calculated. Data were analyzed by unpaired t-test (two-tailed) using GraphPad 9.5.1 software. Four independent examiners performed clinical evaluation postnatally.

RESULTS: CON mice had higher live birth rates compared to MHV-1 infected mice (39/62, 62.9% in CON, vs. 5/12, 41.6% in MHV-1, $p< 0.008$) (Fig. 1). MHV-1 infected mice pups had MCM when compared to no MCM in the CON group (7/12, 58.3% in MHV-1-infected vs. 0/62, 0% in CON, $p< 0.0001$). In the MHV-1 infected group (N=12), pups with MCM were all stillborn (6/6, 100%), compared to stillborn pups without MCM (1/7, 14.3%, $p< 0.0001$) (Fig. 1). Interestingly, of the 6 MCM, there were 3 cases central nervous system malformations (brain/face, craniothoracopagus twinning, and neural tube defect), and 2 abdominal wall defects (gastroschisis/omphalocele).

CONCLUSION: Our findings strongly suggest that MCM can be induced in the second trimester in our established MHV-1 mouse model of COVID-19, which replicates both acute and long COVID in Biosafety Level 2 conditions. Our model is useful to evaluate pathophysiology in COVID and affords an opportunity to evaluate therapeutic agents.

Major congenital malformation (MCM) in MHV-1-infected mice

Animal#	Live	Dead	Congenital Malformation
1		X	Facial and brain malformation, bilateral nephromegaly
2		X	Craniothoracopagus conjoined twins, lower limb hypoplasia
3		X	Craniothoracopagus conjoined twins, lower limb hypoplasia
4		X	Sacral agenesis, intestinal atresia
5		X	Omphalocele, diaphragmatic hernia
6		X	Pulmonary and intestinal atresia, aortic dilation, bilateral nephromegaly, right lower limb hypoplasia
7		X	No anomalies
8	X		Gastroschisis
9	X		No anomalies
10	X		No anomalies
11	X		No anomalies
12	X		No anomalies

Examples of MCM in MHV-1-infected mice

1101 Physical activity among pregnant inpatients and outpatients and associations with anxiety

Danielle M. Panelli[1], Hayley E. Miller[2], Samantha L. Simpson[3], Janet Hurtado[4], Chi-Hung Shu[4], Ana C. Boncompagni[4], Jane Chueh[5], Brendan Carvalho[4], Pervez Sultan[4], Nima Aghaeepour[4], Maurice L. Druzin[6]

[1]Stanford University, Palo Alto, CA, [2]Stanford University Hospital, San Francisco, CA, [3]Stanford, Mountain View, CA, [4]Stanford University, Stanford, CA, [5]Stanford, Menlo Park, CA, [6]Stanford University Medical Center, Palo Alto, CA

OBJECTIVE: Physical activity is linked to lower anxiety, but little is known about the association during pregnancy. This is especially important for antepartum inpatients, who are known to have increased anxiety during hospitalization. We compared physical activity between pregnant inpatients and outpatients and explored correlations with anxiety.

STUDY DESIGN: This was a prospective cohort between 2021 and 2022 of pregnant people aged 18-55 years carrying singleton gestations ≥16 weeks. Three exposure groups were matched for gestational age**:** 1) outpatients from low-risk obstetric clinics (LOPA); 2) outpatients from high-risk obstetric clinics (OPA); and 3) antepartum inpatients (IPA). Participants wore Actigraph accelerometer watches for 7 days to measure physical activity. The primary outcome was mean daily step count. Secondary outcomes were metabolic equivalent tasks (METs), hourly kcals, moderate to vigorous physical activity (MVPA), and anxiety (State-Trait Anxiety Inventory [STAI]). Physical activity parameters were compared using Wilcoxon rank sum tests, then using multivariable generalized estimating equations adjusting for maternal age and body-mass index. Spearman correlations were used to correlate STAI scores with step counts.

RESULTS: 59 participants were analyzed. Inpatients had significantly lower mean daily steps (adjusted beta -2394, 95% Confidence Interval [CI] -3381, -1407, $p< 0.001$), METs (adjusted beta -0.20, 95% CI -0.26, -0.13, $p< 0.001$), and MVPA (adjusted beta -43.6, 95% CI -61.2, -25.9, $p< 0.001$) than outpatients (Figure 1). Over the course of the week, steps progressively decreased for inpatients (p-interaction 0.009). Lower steps correlated with higher STAI scores ($r=0.30$, $p=0.02$).

CONCLUSION: We present antenatal population norms and variance for step counts, METS, and MVPAs as well as correlation with STAI scores. Antepartum inpatients had significantly lower physical activity than outpatients, and lower step counts correlated with higher anxiety. Physical activity may be a potential target for anxiety reduction interventions.

Figure 1. Summary of physical activity parameters among general Ob/Gyn low-risk outpatients (LOPA), Maternal-Fetal Medicine clinic high-risk outpatients (OPA), and antepartum inpatients (IPA, total N=59).

1102 Prenatal Mobile Self-Operated Home Ultrasound Service Impact on Birth Outcomes

Anat Pardo[1], Emilie Klochendler Frishman[2], Rachel Gomez-Tolub[2], Monica Pailis[2], Or Lee Rak[2], Ofri Samueloff[2], Shiri Barbash Hazan[3], Arnon Wiznitzer[2], Asnat Walfisch[4], Eran Hadar[5]

[1]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, Tel-Aviv, Israel, [2]Helen Schneider Hospital for Women, Rabin Medical Center, Petach Tikwa, HaMerkaz, [3]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, HaMerkaz, [4]Hadassah Mount Scopus, Petach-Tikva, Israel, [5]Rabin Medical Center, Petach-Tikva, HaMerkaz

OBJECTIVE: A leading HMO (Clalit Health Services, Israel) launched a home-ultrasound service (Pulsenmore's Ltd.) enabling parturients to perform a basic sonographic assessment and to have it interpreted by a clinician via asynchronous teleconsultation.

Our aim was to examine whether the use of the device and its adjunct medical service can enhance pregnancy outcomes.

STUDY DESIGN: Retrospective cohort study between 2021 and 2023, comparing 4,460 women using Clalit's home ultrasound service with a control group of 102,707 pregnant women with an equal HMO status, who did not obtain this service. Demographic characteristics, obstetrical and neonatal outcomes were compared between the groups.

RESULTS: Compared to the control group, women in the study group were older, more likely to be primiparous, had higher incidence of chronic illness, were more often considered to be at high risk pregnancy and were of higher socio-economic score as presented in the univariate analysis (Table 1). Body mass index (BMI) did not differ between the groups, although more women in the study group had a normal BMI category. Univariate analysis demonstrated no significant difference in early preterm birth (PTB $<$ 32 and $<$ 34 weeks gestation) and high risk for PTB$<$ 37 weeks gestation ($p<$ 0.0007). However, multivariate analysis adjusted by age, BMI, parity, socio economic score, and chronic illness demonstrated lower risk of PTB in the study group compared to controls at $<$ 37, 34 and 32 gestational weeks (adjusted OR 0.51, 95% CI 0.42-0.63 aOR 0.46, 95% CI 0.30-0.69, aOR 0.47, 95% CI 0.26-0.84, respectively) as well as lower risk of small gestational age neonates (aOR 0.64, 95% CI 0.49-0.83), birthweight $<$ 2500g (aOR 0.49, 95% CI 0.40-0.59) and $<$ 1500g (aOR 0.38, 95% CI 0.20-0.74).

CONCLUSION: Prenatal mobile self-operated home ultrasound may provide a feasible solution for remote fetal surveillance. In a large-scale utilization, the service may potentially reduce the risk for adverse pregnancy outcomes

Table 1: Baseline characteristics and adverse pregnancy outcomes, stratified according to prenatal utilization of Home Ultrasound

Variable	Control n=102,707	Study n=4460	p-value

1103 Prenatal Mobile Self-Operated Home Ultrasound Service Impact on Heath Care Resources Utilization

Anat Pardo[1], Shiri Barbash Hazan[2], Riki Bergel-Bson[3], Ohad Houri[4], Sivan Zuarez Easton[3], Noam Pardo[5], Arnon Wiznitzer[3], Asnat Walfisch[6], Eran Hadar[7]

[1]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, Tel-Aviv, Israel, [2]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, HaMerkaz, [3]Helen Schneider Hospital for Women, Rabin Medical Center, Petach Tikwa, HaMerkaz, [4]Rabin Medical Center, Tel Aviv, Israel, [5]Sheba Medical Center, Tel Hashomer, Ramat-Gan, Tel Aviv, [6]Hadassah Mount Scopus, Petach-Tikva, Israel, [7]Rabin Medical Center, Petach-Tikva, HaMerkaz

OBJECTIVE: Mobile medical devices for self-patient use are rapidly evolving. A leading HMO (Clalit Health Services, Israel) launched a home-ultrasound (Pulsenmore Ltd.) service enabling a basic sonographic assessment interpreted by a clinician via asynchronous teleconsultation.

We aimed to examine whether the use of the device and its adjunct medical service can provide financial benefits for both patients and the healthcare system.

STUDY DESIGN: Retrospective cohort between 2021 and 2023, comparing 4,460 women using Clalit's home ultrasound service with a control group of 102,707 women with an equal HMO status, who did not obtain this service. Demographic characteristics, number (№) of emergency room (ER) visits, № of hospitalizations, № of hospital stay days and № of OBGYN primary caregiver visits were compared between the groups as well as composite outcome of these variables.

RESULTS: Women in the study group were older, more likely primiparous, had higher incidence of chronic illness, more often considered to be at high-risk pregnancy and had higher socio-economic score in comparison to controls (Table 1). Univariate analysis demonstrated lower rates of ER visits, hospitalizations and in-hospital days in favor of the study group ($p<$ 0.0001). № of OBGYN primary caregiver visits were higher among the study group ($p<$ 0.0001), however it embodies administrative and phone call appointments, making it difficult to estimate the exact in-person visits. Furthermore, higher rates of chronic illnesses and high-risk pregnancies likely requires closer surveillance. In a multivariate analysis for age, BMI, parity, socioeconomic score, and chronic illness the calculated adjusted value of ER visits, № of hospitalization, № of in-hospital days and a composite score of ER visits and in-hospital days were all lower in the study group compared to controls (2.24 vs 2.38, p=0.0268; 0.34 vs 1.53, $p<$ 0.0001; 0.95 vs 4.75, $p<$ 0.0001 and 3.17 vs 7.6, $p<$ 0.0001).

CONCLUSION: Prenatal mobile self-operated home ultrasound service may ease the burden of healthcare resource utilization, mainly emergency visit and in-hospital stay

Table 1: Baseline characteristics and use of health care resources, stratified according to prenatal utilization of Home Ultrasound Service

1104 Personalized Machine Learning Model for Predicting Time to Delivery in Active Labor

Lee Reicher[1], Emmanuel Attali[2], sharon Napadenski[3], Nadav Rappoport[3], Yariv Yogev[4]
[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel, [2]Lis Maternity Hospital, Department of Obstetrics and Gynecology, Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel, [3]Ben Gurion University of the Negev, Beer-Sheva, HaDarom, [4]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

OBJECTIVE: Prolonged labor has significant associations with an increased rate of operative delivery and adverse maternal and neonatal outcomes. To optimize resource management, physicians should assess and predict the course of labor. We aim to develop a personalized machine learning model using real-time data to predict time to delivery in the active phase of labor.

STUDY DESIGN: Labor records from a single university affiliated tertiary hospital with approximately 12,500 deliveries annually were analyzed over a 10-year period. We trained logistic regression models using both "static features" (e.g demographics) and "dynamic features" (e.g cervical dilatation, efficacy, and newly derived features calculated as ratios between adjusted dynamic measures and time differences) to predict time to delivery (min). To assess the explainability of the model, we employed SHAP (SHapley Additive exPlanations) analysis.

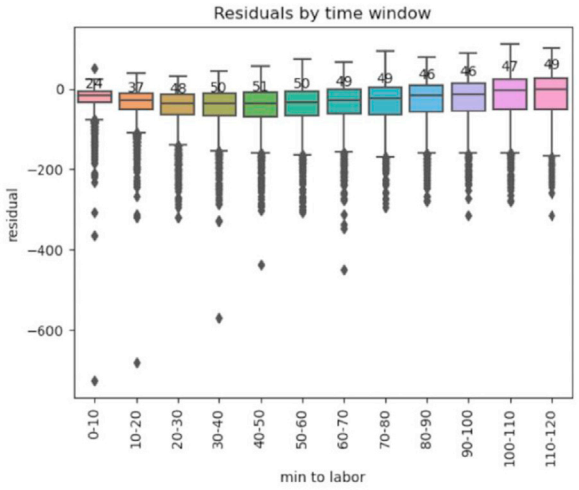
RESULTS: 1. A total of 94,386 cases in which a trial of labor was attempted were identified. Of them approximately 70,000 cases were admitted to the active phase of labor (6 cm dilatation).

2. Histogram-Based Gradient Boosting regressor trained on the dataset with the demographic, static, dynamic, and aggregative features achieved higher results in terms of overall MAE and R2 metrics than a baseline of Lasso linear regression model**:** The model scores were mean absolute error of 62.64, and R2 0.51.

3. Next, we present a residual box plot focusing on the time range between 0-120 minutes to labor (Figure).

4. Explainability of the best model was analyzed using SHAP. SHAP provides insights into the "why" behind a model's decisions, making it easier to interpret and trust the model's results. The features that contributed the most for the model prediction were**:** current cervical opening rate, maximal cervical opening rate and clinical fetal weight estimation.

CONCLUSION: Our personalized machine learning model holds promise in predicting time to delivery during active labor using real time data, aiding physicians in making informed decisions and potentially improving outcomes.



Figure

Residuals by time to labor range for Histogram Based Gradient Boosting model. The 'time to labor' continuous values were gathered into bins in the range of 10 minutes under the x-axis and the residual is presented for each range of minutes to labor on the y-axis. Mean absolute error is also presented for each time window box plot and was placed onto the Q3 upper edge of the box.

1105 Neonatal and Maternal Outcomes in Nulliparas According to Prepregnancy Body Mass Index: A Population-Level Analysis

Rula Atwani, George R. Saade, Tetsuya Kawakita
Eastern Virginia Medical School, Norfolk, VA

OBJECTIVE: To compare neonatal and maternal outcomes between BMI (body mass index kg/m^2) categories using population-level data and determine the impact lowering or increasing BMI would have on these outcomes.

STUDY DESIGN: This was a repeated cross-sectional analysis of US vital statistics Live Birth/Infant Death linked data from 2011 to 2020. We limited analyses to nulliparas with singleton pregnancies who delivered at 20 weeks or greater. Our primary outcome was a composite neonatal outcome defined as any neonatal death, neonatal intensive care unit (ICU), surfactant use, ventilation use, or seizure. Our secondary outcome was severe maternal morbidity defined as any maternal ICU, transfusion, uterine rupture, and hysterectomy. Outcomes were compared according to BMI category (< 18.5, 18.5-24.9, 25-29.9, 30-39.9, 40-49.9, 50-59.9, and 60-69.9) with each of the other categories as the referent. Adjusted relative risks (aRR) with 99% confidence intervals were calculated for each BMI category as a referent group, using modified Poisson regression.

RESULTS: Of 11,174,890 individuals, 537,541 had BMI < 18.5, 5,569,307 had BMI 18.5-24.9, 2,688,070 had BMI 25-29.9, 1,944,535 had BMI 30-39.9, 382,139 had BMI 40-49.9, 48,432 had BMI 50-59.9 and 4,866 had BMI 60-69.9. Table 1 shows the aRRs for a starting BMI category (referent, column) compared with each of the other categories (row). The following are a few comparisons provided to illustrate the use of the heatmap. Starting with a normal BMI (18.5-24.9), the aRR of the primary outcome increases from 1.02 (yellow) to 2.04 (red) as BMI increases. Starting with a BMI of 60-69.9 the aRR of severe maternal morbidity decreases from 0.51

(or 49% decrease; lime) to 0.34 (or 66% decrease; turquoise) with each decrease in BMI category.

CONCLUSION: We provide population-level estimates of the impact of policies to address the obesity epidemic on maternal and neonatal outcomes. Lowering the BMI by even one category would have a tremendous impact on obstetrical outcomes, likely larger than any other proposed intervention.

Table 1. Heat map

aRR (99%CI)	Referent (starting BMI)						
	BMI <18.5 (n=537,541)	BMI 18.5-24.9 (n=5,569,307)	BMI 25-29.9 (n=2,688,070)	BMI 30-39.9 (n=1,944,535)	BMI 40-49.9 (n=382,139)	BMI 50-59.9 (n=48,432)	BMI 60-69.9 (n=4,866)
Primary outcome, n (%)	50961 (9.5)	515546 (9.3)	283309 (10.5)	241180 (12.4)	57140 (15.0)	8811 (18.2)	1073 (22.1)

1106 Preventing Hypothermia in Moderate and Late Preterm Neonates: A delivery room randomized controlled pilot trial

Pavan Parikh[1], Rodney Edwards[2], Jennifer Peck[3], Birju Shah[3]
[1]Oregon Health & Science University, Portland, OR, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [3]University of Oklahoma, Oklahoma City, OK

OBJECTIVE: Neonatal hypothermia (< 36.5C) at admission has been associated with an increased risk of morbidity and mortality. This study evaluated the safety and efficacy of warming moderate and late preterm neonates delivered via cesarean during delayed umbilical cord clamping (dUCC).

STUDY DESIGN: Parallel group randomized controlled pilot trial with block randomization stratified for two gestational age groups–32w0d-34w6d and 35w0d-36w6d. The control and intervention groups underwent dUCC for 60 seconds at the time of cesarean; if considered safe by both pediatric and obstetric providers. Neonates in the intervention group were placed in a polyethylene suit above a chemical warming mattress during the dUCC period. The devices were removed at the resuscitation warmer. Axillary temperature was measured at arrival to the warmer, completion of resuscitation and arrival to the neonate's room. All providers were trained using a standardized video.

RESULTS: 52 patients were randomized, 26 to each group and two were excluded prior to delivery. Modified Poisson regression, adjusting for stratum and time from delivery to the warmer, demonstrated no difference in the risk of hypothermia at the warmer, RR 2.71 (95% CI 0.70-10.51). Of note, RR of hypothermia at arrival to the neonate's room was 0.60 (95% CI 0.28-1.29) and NICU admission was 0.81 (95% CI 0.64-1.02). The effect was mostly attributed to a lower risk of moderate hypothermia (< 36.0C) at arrival to neonate's room, RR 0.24 (95% CI 0.03-1.92). Other secondary outcomes including hypoglycemia, highest bilirubin level, form of respiratory support, pulmonary hemorrhage, hyperthermia (>37.5C), length of stay, and neonatal composite (outcomes of death, intraventricular hemorrhage and/or sepsis) did not reach significance and had wide confidence intervals.

CONCLUSION: While there was no difference in temperature at the warmer or safety signals, there may be an improvement in admission hypothermia and NICU admissions. These pilot results will inform the design of a well-powered multi-center trial for hypothermia prevention.

Table 1. Primary and secondary outcomes among patients treated with the warming intervention during delayed cord clamping compared to controls

Outcome	Treatment (n=25) n (%)	Controls (n=25) n (%)	Unadjusted Risk Ratio (95% CI)	Adjusted Risk Ratio* (95% CI)
Hypothermia at Warmer	6 (24.0)	2 (8.0)	3.00 (0.67, 13.46)	2.71 (0.70, 10.51)
Hypothermia at Completion of Resuscitation**	6 (28.6)	3 (15.8)	1.81 (0.52, 6.25)	1.78 (0.44, 7.11)
Hypothermia at Admission	7 (28.0)	11 (44.0)	0.64 (0.30, 1.37)	0.60 (0.28, 1.29)
Hyperthermia (>37.5C)	2 (8.0)	1 (4.0)	2.00 (0.19, 20.67)	--
Hypoglycemia	4 (16.0)	3 (12.0)	1.33 (0.33, 5.35)	--
NICU Admission	16 (64.0)	18 (72.0)	0.89 (0.61, 1.30)	0.81 (0.64, 1.02)
Composite	1 (4.0)	1 (4.0)	1.00 (0.07, 15.11)	--

*Risk ratios adjusted for stratum and time from delivery to the warmer using modified Poisson regression
** Among n=21 in treatment group and n=19 in control group with temperature data available at completion of resuscitation
-- Adjusted risk ratios cannot be calculated due to sparse data

1107 The role of MSAFP screening in prenatal diagnosis of omphalocele

Christian M. Parobek, Matthew A. Shanahan, Brian Burnett, Simon Dadoun, April Adams
Baylor College of Medicine, Houston, TX

OBJECTIVE: As serum screening for aneuploidies becomes less prevalent due to the uptake of non-invasive prenatal testing and improved prenatal imaging, it is unclear whether continued maternal-serum alpha-fetoprotein (MSAFP) screening results in earlier omphalocele detection compared to ultrasound alone. We explored whether MSAFP screening results in earlier omphalocele detection.

STUDY DESIGN: This is an IRB-approved retrospective cohort study of prenatally detected omphalocele cases at our fetal referral center, from 08/2007-05/2023. Maternal, fetal, and neonatal outcomes were abstracted. We explored the association between MSAFP screening and gestational age at omphalocele diagnosis using bivariate analyses and the Mann-Whitney U test for nonparametric comparisons.

RESULTS: Among 102 pregnancies with prenatally diagnosed omphalocele, 27 (26.4%) had MSAFP screening. Of these, 11 (41%) had MSAFP values ≥2.5 MoM and 16 (59%) did not have an elevated MoM; these findings did not correlate with omphalocele rupture or additional major anatomic defects (phi=0.368). The median gestational age at MSAFP screening was 17w3d. Among pregnancies with MSAFP screening, the median GA at first sonographic suspicion of omphalocele was 18w2d; however, among pregnancies without MSAFP screening the median GA was slightly earlier at 17w5d though this was not significant (p=0.75). There was also no difference between MSAFP and no-MSAFP cases in GA at sonographic confirmation of the omphalocele (p=0.87).

CONCLUSION: In this cohort of prenatally diagnosed omphaloceles, MSAFP was abnormally elevated in approximately 40% of cases. MSAFP screening was not associated with earlier sonographic suspicion for or prenatal confirmation of omphalocele. While there is a paucity of consistent data regarding whether MSAFP still aids in prenatal detection of gastroschisis and neural tube defects, MSAFP screening in this population did not lead to earlier omphalocele detection.

Antenatal diagnostic characteristics	MSAFP Screening (n=27)	No MSAFP Screening (n=75)	*p*-value

1108 Sharing or not-sharing individual participant data: how valid are randomized trials evaluating induction of labor?

Malitha Patabendige[1], Daniel L. Rolnik[2], Ben Willem W. Mol[2], Wentao Li[3]
[1]Monash University, Oakleigh East, Victoria, [2]Monash University, Clayton, Victoria, [3]Monash University, Melbourne, Victoria

OBJECTIVE: To compare characteristics, trustworthiness of randomized controlled trials (RCTs) and outcomes on labor induction that shared individual participant data (IPD) versus those that did not.

STUDY DESIGN: In this meta-epidemiological study, RCTs included in five IPD-MAs comparing different methods of labor induction were evaluated using published data. We used Monte Carlo simulation with baseline characteristics to assess randomization. Trustworthiness of RCTs was evaluated using the TRACT checklist (pubmed.ncbi.nlm.nih.gov/37337220/). Agreement in outcomes (cesarean delivery and hyperstimulation) between shared and non-shared was done with random-effects meta-analysis.

RESULTS: Of 112 RCTs, 29 (25.9%) shared data and 83 (74.1%) did not. Median year of publication of the shared group was 2015 (range 1996-2023) versus 2008 (1983-2021) for non-sharing RCTs. Shared RCTs were larger median (range) compared to the non-shared; 339 (101-1859) versus 126 (38-1358).

Studies that did not share data had a small probability of having proper randomization (p=0.03), whereas shared group seems to be having proper randomization (p=0.85). In non-shared group, authors who refused to share were less likely (p=0.003) to have proper randomization than authors who could not share data as data were not available (p=0.14).

Proportion of RCTs with 'concerns' under seven domains of the TRACT checklist between shared vs non-shared was: Governance 36.8% vs 75.1%; Author Group 2.3% vs 11.2%; Plausibility of Intervention 0% vs 16.9%; Timeframe 3.4% vs 21.1%; Drop-Out Rates 0% vs 27.7%; Baseline Characteristics 0% vs 11.7%; Outcomes 12.6% vs 32.1%.

According to random-effects meta-analysis, only one comparison showed comparable effect estimates for cesarean delivery and uterine hyperstimulation between shared and non-shared groups (Table 1).

CONCLUSION: In studies on labor induction, RCTs without IPD sharing have lower quality and more trustworthiness concerns than those who shared IPD. The availability of IPD and willingness to share is a good indicator of the quality and trustworthiness.

Table 1 shows the results of aggregate data random-effects meta-analyses in the shared and nonshared groups.

Comparison	Outcome	Group	No.of trials	OR (95% CI)	P-value	I^2
Balloon catheter versus low-dose oral misoprostol	Cesarean delivery	Shared	4	0.77 (0.64;0.92)	0.02	0.0 (0 -90)
		Non-shared	3	1.47 (0.06; 33.49)	0.36

		Non-shared	20	1.24 (0.81;1.92)	0.29	19.6 (0 - 55)
Outpatient versus inpatient methods	Cesarean delivery	Shared**	8	1.22 (1.03;1.44)	0.03	0 (0-68)
		Non-shared	7	0.84 (0.67;1.05)	0.10	0 (0 - 71)
	Uterine hyper-stimulation	Shared	3	0.39 (0.01;12.05)	0.36	53 (0 - 87)
		Non-shared	4	1.33 (0.21;8.43)	0.67	0 (0 - 90)

*One shared trial and **two shared trials were published as abstracts and only included for the meta-analysis, not for the other assessments.

1109 THC Impact in Urine Drug Screens on Maternal and Neonatal Outcomes in Substance Use Disorder

Neil Bharat Patel[1], John O'Brien[1], Nancy Hendrix[1], Cynthia Cockerham[1], Gregory Hawk[1], Abigail Leonhard[1], Asmita Shrestha[1], Barbara V. Parilla[2]
[1]University of Kentucky, Lexington, KY, [2]UK Albert B. Chandler, Lexington, KY

OBJECTIVE: Evaluate the effects of tetrahydrocannabinol (THC) presence in urine drug screens (UDS) on neonatal and maternal outcomes in patients with substance use disorder.

STUDY DESIGN: Prospective cohort study of pregnant patients enrolled in a multidisciplinary treatment program between 2015 and May 2023. Patients had at least 2 prenatal visits. Unexpected UDS group contained at least 2 UDS positive for THC, while the control group had no UDS with THC. Primary outcomes included decreased birth weight, decreased head circumference, NICU admission, and NICU length of stay. Secondary outcomes assessed were tobacco use, Neonatal Abstinence Syndrome (NAS), a composite of various neonatal outcomes, prenatal care compliance, maternal obstetric outcomes, return to opioid use, and unexpected UDS. Categorical outcomes displayed counts, percentages and Fisher's Exact test p-values. Quantitative outcomes showed summary stats with respective Poisson regression p-values or t-test. Analyses were done in SAS 9.4.

RESULTS: 382 patients enrolled in the multispecialty treatment program met inclusion and exclusion criteria. 114 of 382 (30%) had a positive UDS for THC vs 268 of 382 (70%) patients had no THC on any UDS. Tobacco use during pregnancy was similar in THC group 90% vs 84%, P=.316. Demographic data was similar including age at e-cigarette use and overdose history.

Prenatal and Postnatal visit compliance was lower in THC group 57% ± 30% vs 77% ±28%, < .0001. Compliance was defined as the number of appropriate visits (without a positive UDS for any drugs) divided by the total number of potential visits). Mean Buprenorphine dose at delivery was similar for THC group 12 mg ± 4 vs no THC at 12 mg ± 4, P=.648. Maternal complications, GA at delivery,

head circumference, birth weight, NOWS rates and NICU admissions were similar between groups, Table 1.

CONCLUSION: The presence of THC in urine pregnancy tests of women with OUD did not appear to significantly affect maternal delivery complications, birth weight or head circumference. However, it was associated with lower compliance with prenatal and postnatal visits.

Table 1. Maternal and Neonatal delivery data with P value calculated by Fisher's Exact Test.

	THC (n=114)	No THC (n=268)	P value

1110 The Effect of Second Provider Consultation and Checklist Utilization on the Cesarean Delivery Rate

Jessica Peterson[1], Cody Goldberger[2], Morgan Steelman[1], Kelly Wang[3], Angela Bianco[4]

[1]Icahn School of Medicine, New York, NY, [2]NYU Grossman School of Medicine, New York, NY, [3]Icahn School of Medicine at Mount Sinai, New York, NY, [4]Mount Sinai Medical Center, New York, NY

OBJECTIVE: Effect of mandatory second provider consultation using California Maternal Quality Care Collaborative (CMQCC) checklist on the Nulliparous, Term, Singleton, Vertex (NSTV) cesarean rate.

STUDY DESIGN: Prospective cohort study conducted 3/1/2021-2/28/2022. Unscheduled cesareans required consutation with second attending and use of CMQCC checklist. The primary provider ultimately decided whether to proceed with cesarean. Nulliparous patients with vertex, term, singleton pregnancies were included. Multiple gestations, preterm pregnancy, scheduled cesarean, malpresenting fetus were excluded. The primary outcome was NTSV cesarean rate. The study period was compared to a pre-COVID (3/1/2019-2/29/2020) and COVID cohort (3/1/2020-2/28/2021).

RESULTS: 1365 patients were included, 10.8% Asian/Pacific Islander, 11.0% Black, 55.5% White and 20.1% Other. 50.5% were non-Hispanic. English was the primary language for 96.6%. 23.4% had public insurance. During the study period, NTSV cesarean rate was 25.6% (vs 29.4% COVID, p=0.01; vs 31.1% pre-COVID, p=0.0002). Black patients had a higher NTSV cesarean rate in all cohorts. Within the study period, the rate was 32.7% for Black, 22.7% for White, 31.8% for Asian/Pacific Islander and 27.0% for Other (p=0.01). Second opinion/checklist did not modify the relationship between race and NTSV cesarean rate (p= 0.69). Over all cohorts, the privately insured had a higher NTSV cesarean rate compared to the publicly insured (p< 0.0001). During the study period, the privately insured had a rate of 28.2% (vs 18.2% publicly insured). Second opinion/checklist did not modify the relationship between insurance and NTSV cesarean rate (p= 0.14). There was no association between ethnicity or primary language and NTSV cesarean rate. The neonatal composite outcome was 6.8% (vs 39.6% pre COVID, p< 0.0001; vs 36.1% COVID, p< 0.0001).

CONCLUSION: Pre-cesarean checklist with second provider consultation reduced the NTSV cesarean rate without increasing neonatal morbidity, but disparities based on race and insurance persist.

1111 The Effect of Pregnancy Complications on Quality of Life with Placenta Accreta Spectrum

Kripa Philip[1], Uma Deshmukh[1], Bridget M. Donovan[2], Guadalupe Arambula[1], Helena C. Bartels[3], Donal Brennan[4], Kristen Terlizzi[5], Brianna Evans[5], Naomi Cooney[6], Scott A. Shainker[7], Anna M. Modest[1]

[1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Beth Israel Deaconess Medical Center, Brookline, MA, [3]National Maternity Hospital, Dublin, Ireland; UCD School of Medicine, National Maternity Hospital, Dublin, Ireland, Dublin, Ireland, [4]National Maternity Hospital, Dublin, Ireland; UCD School of Medicine, National Maternity Hospital, Dublin, Ireland, Dubllin, Ireland, [5]National Accreta Foundation, Saratoga, CA, [6]Placenta Accreta Ireland, Dublin, Ireland, [7]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

OBJECTIVE: Placenta accreta spectrum (PAS) is associated with significant pregnancy and postpartum complications. We evaluated the effect of pregnancy complications during a PAS pregnancy on quality of life (QOL).

STUDY DESIGN: This was a retrospective survey from February-May 2023 of patients with a PAS pregnancy enrolled in the National Accreta Foundation or Placenta Accreta Ireland. QOL was assessed using the validated SF-36 Short Form measuring physical functioning, role limitations due to physical health, role limitations due to emotional problems, energy/ fatigue, emotional well-being, social functioning, pain, general health, and health change. Participants were asked to compare their current health to one year prior to their PAS pregnancy.

RESULTS: Of the 448 respondents, the median age at delivery was 34 years (interquartile range (IQR) 31 − 37). Gestational age at delivery was 35 weeks (IQR 34-38). Participants were mostly white (89.5%), had private health insurance (69%), a history of depression (17.4%) and anxiety (23.4%). Surveys were completed at a median of 3 years (IQR 2−6) after PAS. Participants who had a hemorrhage vs. no hemorrhage reported lower QOL; specifically in social functioning, general health, and health change (all $p \leq 0.02$). Peripartum hysterectomy vs. no hysterectomy was associated with a lower; specifically in energy/fatigue, emotional well-being, social functioning, and pain (all $p \leq 0.04$). Antenatal suspicion of PAS was associated with better QOL; specifically in role functioning/physical and pain (both $p \leq 0.02$). This pattern was not seen across all subscales between those who had an unplanned vs. planned delivery; however, those with unplanned delivery reported a better QOL in role functioning/physical and general health (both $p=0.04$).

CONCLUSION: Postpartum hemorrhage and hysterectomy resulting from a PAS pregnancy are associated with a lower QOL, even years after their delivery. Differences were also seen in those with and without an antenatal diagnosis, and those with unplanned vs. planned delivery.

1112 Prevalence rates of chronic hypertension and hypertensive disorders of pregnancy: US national trends 2015-2020

Sara EK. Phillips, Bharti Garg, Amy M. Valent
Oregon Health & Science University, Portland, OR

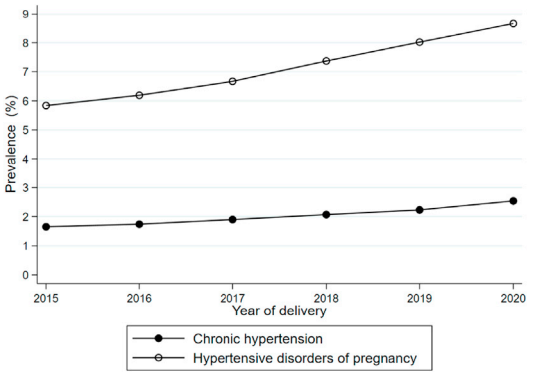
OBJECTIVE: Chronic hypertension (cHTN) and hypertensive disorders of pregnancy (HDP) represent one of the leading causes of severe maternal morbidity and mortality in the United States (US). However, data on the population burden of these disorders is lacking. We sought to quantify recent prevalence rates and trends of cHTN and HDP among pregnant patients.

STUDY DESIGN: We performed a retrospective cohort study of all US pregnancies between 2015 to 2020 using the National Vital Statistics. Annual prevalence rates were calculated for cHTN and HDP and visualized graphically. Risk difference (RD), relative risk (RR), and their 95% confidence intervals (CI) comparing cHTN and HDP rates for 2020 with 2015 were estimated.

RESULTS: A total of 23,027,245 births were included in the analysis. In the US, rates of cHTN increased from 1.65% (95% CI: 1.63%, 1.66%) in 2015 to 2.54% (2.52%, 2.56%) in 2020 with a statistically significant RR of 1.54 (95% CI: 1.52, 1.56) and an absolute RD of 0.89% (95% CI: 0.87%, 0.91%). During the same period, rates of HDP increased from 5.84% (95% CI: 5.81%, 5.86%) in 2015 to 8.65% (95% CI: 8.62%, 8.68%) in 2020 with a RR of 1.48 (1.47, 1.49) and an absolute RD of 2.81% (2.77%, 2.85%).

CONCLUSION: National prevalence of cHTN and HDP have increased in recent years. This trend underscores the need for targeted interventions to address perinatal cardiometabolic health. More studies are needed to explore the factors influencing the rise of hypertensive disorders nationally.

Figure 1. Annual US prevalence rates of chronic hypertension and hypertensive disorders of pregnancy between 2015 and 2020.



1113 The 4th Trimester and Beyond: Optimizing Maternal Health Through a Novel Postpartum Clinic Service Line

Natalie E. Poliektov[1], Asmita Gathoo[1], Kaitlyn Stanhope[1], Suchitra Chandrasekaran[2]
[1]Emory University School of Medicine, Atlanta, GA, [2]Emory University School of Medicine, Decatur, GA

OBJECTIVE: Adverse metabolic outcomes (AMO) during pregnancy increase future risks of chronic metabolic diseases, including heart disease, diabetes (DM) & hypertension (HTN). The postpartum (PP) period is when transitions to primary/specialty care services are imperative & often lacking. As such, we established a Postpartum Cardiometabolic Clinic (PPMC) for patients at 12 weeks PP with a gestational AMO to bridge gaps in care transitions. We investigated if PPMC attendance improves follow-up with primary/specialty providers.

STUDY DESIGN: This retrospective cohort study included patients referred to PPMC between 8/22-7/23 for diagnoses of chronic HTN/ hypertensive disorders of pregnancy or pre-gestational/gestational DM. We compared follow-up with primary/specialty care services among those who attended vs. did not attend PPMC. Continuous variables were compared using Wilcoxon Rank Sum Tests. Categorical variables were compared using Chi-Square/Fisher's exact tests. Log binomial regressions calculating adjusted risk ratios (ARR) were performed.

RESULTS: Of N=150 referrals, 62% (n=93) attended PPMC (Table 1). Persons who attended PPMC vs. those who did not were more likely to have follow-up within 6 months PP with any provider *(73.1% vs. 36.8%, $p< 0.001$)*, Primary Care *(40.9% vs. 22.8%, $p< 0.05$)*, or Cardiology *(51.6% vs. 17.5%, $p< 0.001$)*, & have lipids/

triglycerides *(29.0% vs. 7.0%, p< 0.01)* & HgbA1c *(28.0 vs. 7.0%, p< 0.01)* assessed. After controlling for confounders (age, race, parity, education & insurance), those attending PPMC had a 2-fold higher likelihood of follow-up with any provider ***(ARR 1.9**, 95% CI 1.3-2.6, p< 0.01)* or Cardiology ***(ARR 1.8**, 95% CI 1.4-2.4, p< 0.001)*. There was no difference in follow-up with Endocrinology or 2-hour Glucose Tolerance Test completion between groups (Table 1).

CONCLUSION: We innovatively demonstrated that a PPMC service *significantly* improved PP follow-up with primary/specialty care. With rates of gestational AMOs increasing & impacting long-term maternal metabolic health, our data support the need for serious considerations to change current 4th trimester standards-of-care.

Table 1. Demographic characteristics and postpartum follow-up of persons who attended vs. did not attend a comprehensive Postpartum Cardiometabolic Clinic.

1114 Link between adiposity distribution and cytokine signaling in offspring brains of exercised versus sedentary mice

Danielle M. Prentice[1], Sarah Bingaman[2], Serdar Ural[3], Kirsteen Browning[2], Rebecca Fleeman[2], Elizabeth Proctor[2], Amy Arnold[2]

[1]Oregon Health & Science University, Portland, OR, [2]Penn State University College of Medicine, Hershey, PA, [3]Penn State College of Medicine, Hummelston, PA

OBJECTIVE: Human epidemiological and animal studies have shown that the maternal *in utero* environment significantly impacts offspring development. This maternal environment includes a sedentary (SED) lifestyle, which is linked to developmental programming of metabolic dysfunction. Our previous study showed significant differences in adiposity distribution in offspring from SED versus exercised (EX) dams, with EX increasing brown adipose and decreasing white adipose tissue weight. The aim of this study was to investigate if cytokine signaling in the brains of offspring could predict adiposity distribution in mice born to either EX or SED dams.

STUDY DESIGN: C57BL/6J female mice were placed on a control diet and allocated to SED or voluntary running wheel EX cages. Voluntary wheel running was allowed for 2 weeks prior to breeding and throughout weaning. Offspring were euthanized at 16 weeks of age. Adipose tissue depots were dissected and weighed. Offspring brains were harvested, and hypothalamus was dissected for Luminex cytokine quantification and analysis. We performed partial least squares (PLS) analysis to create predictive models.

RESULTS: Using the supervised machine learning tool PLS, we found that cytokine signaling in the hypothalamus of offspring could predict the quantity of brown and white adipose tissue. Offspring with higher levels of brown adipose tissue had upregulated cytokine secretion (Accuracy**:** RMSECV 0.0357, Confidence 100%), and those with higher levels of white adipose tissue had downregulated cytokine secretion (Accuracy**:** RMSECV 0.0748, Confidence**:** 100 %).

CONCLUSION: A connection exists between hypothalamic cytokine profiles and adiposity distribution in mice, which may be altered by maternal programming of either EX or SED behavior. Future studies will investigate if this altered cytokine profile and adiposity distribution protects against the deleterious effects of high fat diet throughout the offspring's life.

1115 The Impact of COVID-19 Infection on Neonatal Birth Parameters and Outcomes

Advaita Punjala-Patel[1], Sophia Alvarado[2], Austin French[2], Rebekah Lassiter[2], David M. Stamilio[2]

[1]Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC, [2]Wake Forest University School of Medicine, Winston-Salem, NC

OBJECTIVE: We aimed to estimate the association between antenatal maternal COVID-19 (C-19) infection and the risk for small-for-gestational-age (SGA) neonatal birthweight. We also sought to assess if gestational timing or severity of C-19 infection differentially impacts the risk of SGA.

STUDY DESIGN: This retrospective cohort study included all pregnant patients with C-19 infection and randomly selected unexposed controls who delivered at a tertiary care center from 10/1/2020 to 6/1/2022. We also assessed C-19 exposure by trimester of infection and disease severity. The primary outcome, SGA, was defined as neonatal birthweight < 10th percentile for gestational age based on a standard growth curve. Secondary outcomes included birth length and head circumference (HC) percentiles, APGAR scores and neonatal hospital length of stay (LOS). We used chi-squared and t-tests to estimate differences between C-19 exposed and unexposed groups, and multivariable logistic regression analysis to estimate the association between C-19 and SGA.

RESULTS: Among 1011 patients, 502 had C-19 infection and 509 did not. Baseline demographics between groups were similar. Overall C-19 was not associated with increased risk of SGA adjusting for confounding by maternal age, hypertension and race. Among patients with C-19, 15.2%, 31.1% and 53.7% had infection in the 1st, 2nd, and 3rd trimester and 68.4%, 25.4% and 6.2% had mild, moderate, or severe disease respectively. First trimester C-19 infection was associated with a 2-fold increase in SGA (aOR 2.3, 95% CI 1.1-5.1), compared to 2nd or 3rd trimester infection. Stratifying by C-19 disease severity, moderate-severe disease was associated with a 2-fold increase in SGA (aOR 2.1, 95% CI 1.1-3.5), but mild disease did not increase this risk. C-19 exposure was not associated with increased risk of any other secondary neonatal outcomes (Table 1).

CONCLUSION: When stratifying by antenatal C-19 disease severity and timing of infection, we observed a two-fold increased risk of SGA in patients with severe C-19 disease and with infection in the 1st trimester.

	COVID-19 exposed (n= 502)	COVID-19 unexposed (n = 509)	Adjusted OR (95% CI)

1116 The profile of fetuses with growth restriction with and without growth recovery

Manesha Putra[1], Emma E. Peek[2], Greggory R. DeVore[3], John Hobbins[2]

[1]University of Colorado, Aurora, CO, [2]University of Colorado, Denver, CO, [3]University of California Los Angeles, David Geffen School of Medicine, Pasadena, CA; on behalf of the Perelman Family Foundation

OBJECTIVE: We aimed to compare the cardiac size and shape and functional parameters, thigh volumes, and neurodevelopmental outcomes of growth restricted fetuses whose estimated fetal weight (EFW) and abdominal circumference (AC) later exceed the 10th percentile.

STUDY DESIGN: This was a retrospective cohort study of singleton non-anomalous pregnancies with fetal growth restriction initially diagnosed after 20 weeks of gestation. Fetuses who then had growth recovery define as EFW and AC greater than 10th percentile were compared to the growth restricted cohort. Cardiac size, shape, and functional parameters were obtained using speckle tracking. Thigh volumes calculation were measured using 3-dimentional ultrasound and calculated according to Lee et al. Bayley-III scores were measured at 2-3 years of age. The percentiles of these parameters were compared using Mann-Whitney U tests.

RESULTS: There were a total of 95 fetuses included in the cohort with 15 (15.8%) who showed growth recovery and 80 (84.2%) who remained growth restricted. Cardiac data was available in 95 patients, thigh volume data was available in 75 patients, and Bayley-III scores were available in 34 patients. There were no differences in size and shape, and functional parameters between the recovered and growth restricted cohorts except for a decreased fractional left ventricular shortening of segment 12 (L FS T12) percentile (Figure 1a). Left ventricular cardiac output (LVCO) was < 10% for both groups. Total thigh and lean thigh volumes were smaller in growth restricted cohort (Figure 1b). The recovered growth children had higher motor and language percentiles on the Bayley-III (Figure 1c).

CONCLUSION: Traditionally, growth recovery in growth restricted fetuses may result in reduced to no surveillance given the perceived overall improved outcomes in this group. While thigh volumes and neurodevelopmental outcomes were improved in the recovered group, cardiac parameter similarity and low LVCO in both the recovered and growth restricted groups may suggest residual risk to the recovered growth fetuses.

Figure 1a. Cardiac size, shape, and functional parameters in recovered EFW and AC fetuses compared to IUGR fetuses.

1117 SNP-based Prenatal Cell-free DNA Screening in Twin Pregnancies: A New Standard of Care?

Ruben A. Quintero[1], Joseph Hurt[2], Neeta L. Vora[3], Neil S. Seligman[4], Gerard Reilly[5], Myra Wick[6], Samuel Wolf[7], Maeve Hopkins[8], Tom Westover[9], Homa K. Ahmadzia[10], Camille Kanaan[11], Andrei Rebarber[12], Eftichia V. Kontopoulos[1], Jingwen Zhang[13], Melissa Egbert[13], Sophia Vourthis[13], Vivienne Souter[13], Clark T. Johnson[14]

[1]USFetus Research Consortium, Coral Gables, FL, [2]University of Colorado, School of Medicine, Aurora, CO, [3]University of North Carolina, Chapel Hill, NC, [4]University of Rochester Medical Center, Rochester, NY, [5]Seven Hills Women's Health Center, Cincinnati, OH, [6]Mayo Clinic, Rochester, MN, [7]Emerald Coast Obstetrics and Gynecology, Panama City, FL, [8]Cleveland Clinic, Rocky River, OH, [9]Capital Health, Trenton, NJ, [10]George Washington University, Washington, DC, [11]Eastern Virginia Medical School, Norfolk, VA, [12]Icahn School of Medicine at Mount Sinai, New York, NY, [13]Natera, Inc., Austin, TX, [14]Sinai Hospital of Baltimore, Baltimore, MD

OBJECTIVE: Prenatal diagnosis of chorionicity is critical for the management of twin pregnancies. Although ultrasound has been recommended for this, it has not been thoroughly validated. SNP-based cell-free DNA (cfDNA) can determine zygosity from 9 weeks' gestation. Dizygotic cfDNA infers dichorionicity (DC). Monozygotic (MZ) cfDNA results may require managing the pregnancy as monochorionic (MC), regardless of chorionicity. The purpose of this study was to assess the accuracy of the diagnosis of chorionicity by ultrasound (C-US) prior to knowledge of cfDNA results.

STUDY DESIGN: Prospective observational registry multi-institutional study (13 sites in the USA). Inclusion criteria were an ongoing twin pregnancy (< 20 weeks' gestation) with C-US prior to cfDNA. Exclusion criteria were higher order multiples, contraindication for cfDNA, and twin to twin transfusion syndrome prior to enrollment. C-US, cfDNA results, perinatal outcome and placental pathology reports were collected.

RESULTS: A total of 137 twin pregnancies were enrolled in the study. After exclusions for undetermined zygosity on cfDNA (1), missing placental pathology (15), incomplete follow-up (11), and unreported chorionicity on ultrasound (4), 106 pregnancies remained. Median gestation at C-US was 11 weeks. Two of 28 (7.1%) pregnancies reported to be MC on pathology were DC on C-US. All were monozygotic on cfDNA. One in 78 pregnancies (1.3%) reported to be DC on pathology was MC on C-US and was dizygotic on cfDNA. Overall, chorionicity was misdiagnosed by C-US in 2.8% (3/106) of twin pregnancies. Of the MZ-cfDNA twins (41.5%, 44/106), 36% were DC and 64% were MC on pathology. All DZ cfDNA twins (62/106, 58.5%) were DC on pathology. Surgical pathology confirmed the cfDNA zygosity diagnosis in all cases.

CONCLUSION: Ultrasound assessment of chorionicity may be inaccurate in approximately 3% of twins. False negative MC diagnosis may preclude timely management of typical MC complications. False positive MC diagnosis may result in unnecessary surveillance or interventions. cfDNA screening for zygosity is essential in the management of twin pregnancies.

1118 Postpartum Antihypertensive Choice and Readmission Outcomes

Anne Reed-Weston[1], Lauren Roby[2], Dianne Holleran[1], Matthew Hoffman[1]

[1]Christiana Care Health Systems, Newark, DE, [2]Christiana Care Health Services, Newark, DE

OBJECTIVE: Postpartum women with hypertensive disorders are routinely discharged on Labetalol, Nifedipine, and Lasix; however, the impact of antihypertensive selection on readmission is not well understood.

STUDY DESIGN: We performed a retrospective cohort study of all pregnancies at a single institution who delivered from 07/31/2012 to 01/31/2023 who had a hypertensive disorder during pregnancy. Discharge antihypertensive medications were recorded along with other demographic data. Readmission within 42 days was then ascertained for the cohort. Our primary outcome was the readmission rate. Univariate analysis was performed.

RESULTS: A total of 11192 pregnancies met study criteria. The average maternal age was 30.1 and the study population was 55.78% white and 34.57% Black. 35.35% of the study cohort received health insurance funded by the government. A total of 491 patients were readmitted within 42 days of discharge, for a total readmission rate of 4.39%. Both Nifedipine and Lasix were associated with a statistically significant decreased risk of readmission, with readmission rates of 2.97% (p=0.04) and 3.45% (p=0.045) respectively. Receipt of labetalol was not associated with a change in readmission rate (5.12%, p=0.174).

CONCLUSION: Discharge on Nifedipine or Lasix was associated with a statistically significant decrease in readmission rate, while receipt of Labetalol did not change readmission rates.

1119 Routine use of the Detailed First Trimester Ultrasound (DFTU) and Associated Outcomes

Anne Reed-Weston[1], Lauren Roby[2], Philip Shlossman[3], Anthony C. Sciscione[3]

[1]Christiana Care Health Systems, Newark, DE, [2]Christiana Care Health Services, Newark, DE, [3]Delaware Center for Maternal & Fetal Medicine of Christiana Care, Inc., Newark, DE

OBJECTIVE: As many states incorporate gestational age limits on elective termination, the identification of congenital anomalies (3-5% in the general population) in the first trimester becomes paramount to having the ability to choose elective termination. We sought to determine the anomaly rate, types of anomalies, and outcomes detected on the DFTU.

STUDY DESIGN: At our large, academic teaching hospital, we offer all pregnant patients a DFTU regardless of risk. We performed a retrospective cohort study of our database between February 23, 2022 and March 31, 2023. All examinations were performed by the division of Maternal Fetal Medicine.

RESULTS: A total of 3748 pregnant patients received a DFTU exam, of which 3715 (99.1%) were available for analysis. 41 (1.10%) had at least one fetal anomaly noted. There were demographic differences between the two cohorts. Anomaly detection rate on second trimester anatomy ultrasound was significantly higher in the anomaly on DFTU group (41.7% versus 1.3%, $p < 0.001$). Additionally, anomaly on DFTU was associated with a significantly higher risk of high risk NIPT testing (47.2% versus 1.30%, $p< 0.001$), as well as higher rates of invasive testing using chorionic villous sampling (CVS) (9.75% versus 0.16%, $p< 0.001$) and amniocentesis (14.6% versus 0.49%, $p< 0.001$). The most common anomaly identified on DFTU was cystic hygroma, which was seen 58.5% of DFTUs with an abnormality. Less than half of DFTU abnormalities were revisualized on a detailed second trimester ultrasound, however 20% of DFTU revealed a different anomaly than was previously seen on the DFTU. Of patients with an anomaly, 36/41 (87.8%) elected to have cell free DNA (cfDNA) screening, and of those who did have cfDNA screening 19/36 (52.8%) were negative.

CONCLUSION: The rate of detecting an anomaly on the DFTU exam in our cohort was approximately 1 in 90 (1.1%). Of those, over half had negative cfDNA screening.

1120 The Impact of Age on Adverse Obstetrical Outcomes among Pregnant Women with COVID-19 Infection.

Yael Reicher[1], Lior Yahav[2], Alla Saban[3], Noa Leybovitz-Haleluya[4], Reli Hershkovitz[5], Adi Y. Weintraub[2], Tamar Eshkoli[3]

[1]Soroka University Medical Center, Givat shmuel, HaMerkaz, [2]Soroka Medical Center, Beer-Sheva, HaDarom, [3]Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Beer Sheva, HaDarom, Israel, [4]Soroka University Medical Center, Meitar, HaDarom, [5]Soroka Medical Center, Omer, HaDarom

OBJECTIVE: Pregnant individuals experienced a more severe course of COVID-19 infection. Advanced age is widely recognized as a risk factor for severe disease and its complications, as well as for adverse obstetrical complications.

Therefore, our study aimed to investigate the association between maternal age at the time of COVID-19 infection and obstetrical adverse outcomes.

STUDY DESIGN: We conducted a retrospective cohort study at a tertiary single medical center, which included all singleton gestations of women with COVID-19 infection within a week prior to or after delivery, who delivered between 2020 and 2022. Exclusion criteria included women with incomplete medical records, multiple gestations and nulliparity. The women were categorized into two groups: below and above 35 years old. A multivariable logistic regression model was used to adjust for confounders such as obesity, cesarean delivery, induction of labor, epidural analgesia and birthweight.

RESULTS: Our study included 443 patients with peripartum COVID-19 infection, of whom 354 were younger than 35 years and 89 were 35 years or older. We observed an increased risk of cesarean delivery (Table 1: 28.1% Versus 16.1%, P value= 0.01) and an increased risk of preterm delivery before 34 weeks (8% Versus 1.7%, P Value= 0.006) among the older age group.

Using multivariate logistic regression model after adjusting for maternal obesity, induction of labor, epidural analgesia and neonatal birthweight, the association between preterm delivery before 34 weeks and advanced maternal age remained significant (Adjusted Odd Ratio 8.04, P value=0.021).

CONCLUSION: Maternal age over 35 years is a risk factor for preterm delivery before 34 weeks in pregnant women with peripartum COVID-19 infection.

Table 1: Obstetrical characteristics and perinatal outcomes of women with COVID-19 diagnosis under 35 Years old or 35 and above.

1121 Prenatal Diagnosis Post-Dobbs in an Abortion-Banned State: A Retrospective Cohort Study

William L. Riley[1], Alixandra Hunzicker[2], Nikki B. Zite[3], Jill Maples[4], Alicia Mastronardi[3], Alissa Paudel[5], Rebecca Purvis[5], Kimberly B. Fortner[4], Kristina Carter[6]

[1]University of Tennessee Knoxville, Knoxville, TN, [2]UT Medical Center Knoxville, Knoxville, TN, [3]University of Tennessee Graduate School of Medicine, Knoxville, TN, [4]University of Tennessee Medical Center, Knoxville, TN, [5]University of Tennessee Medical Center Knoxville, Knoxville, TN, [6]UTMCK, Knoxville, TN

OBJECTIVE: Following the ruling of Dobbs v. Jackson Women's Health Organization (Dobbs), Tennessee became an abortion-banned state. The impact of abortion bans on diagnostic prenatal genetic testing was unknown. We sought to examine the frequency and characteristics of women undergoing prenatal diagnostic genetic testing before and after Dobbs.

STUDY DESIGN: A retrospective cohort study (IRB #5070) examined viable pregnancies electing diagnostic genetic testing by either chorionic villus sampling (CVS) or amniocentesis during two 9-month periods before and after Dobbs at our regional MFM practice. Cases were identified by CPT codes; demographic information, procedure details, and results were collected for comparison. Area deprivation index (ADI) rankings and cross tabulation tables were created; chi-square tests were used to determine significance.

RESULTS: 119 patients underwent diagnostic genetic testing during the periods studied (7/1/18 to 3/31/19 = 48; 7/1/22 to 3/31/23 = 71). Demographic characteristics are shown in Table 1. No difference in race, age at delivery, or gestational age (GA) at the time of testing

were noted; however, GA at the time of testing for CVS procedures was statistically lower post Dobbs (12.88 vs. 11.99 weeks, p=.024). Prior to Dobbs, CVS accounted for 16.7% of diagnostic procedures (11.2 per thousand 1st trimester exams (76801)), compared to 26.8% post-Dobbs (19.5 per thousand 76801). After Dobbs, a significantly higher proportion of patients undergoing CVS for diagnostic testing were publicly insured (0% vs. 52.6%, p=.012) while ADI ranking did not differ.

CONCLUSION: Following events that limited access to in-state abortion, we observed an increase in the number of patients seeking diagnostic genetic testing and a larger proportion undergoing CVS. We also observed an increase in pre-pregnancy BMI and public insurance status with a decrease in GA at the time of CVS. Further work will be aimed at determining the impact of this increased and earlier testing and explore the association with insurance status and BMI.

1122 Revisiting low-lying placenta: internal os distance and pregnancy outcomes

Andrea Rizkallah[1], Ellery Cohn[1], Lisa R. Thiele[2], Milan Ho[1], Catherine Y. Spong[1], Donald D. McIntire[3], Christina L. Herrera[2]
[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]UT Southwestern Medical Center, Dallas, TX, [3]University of Texas Southwestern Medical Center, Richardson, TX

OBJECTIVE: Low-lying placenta is diagnosed when the internal os distance (IOD) is 2 centimeters or less without any part covering the os and has been associated with antepartum and postpartum hemorrhage, hospitalization, cesarean delivery and small for gestational age neonates. The management of a low-lying placenta remains undefined. A recent study suggested using >5 mm as a cutoff for trial of labor. We sought to report outcomes associated with this cutoff.

STUDY DESIGN: Pregnant people diagnosed with placenta previa or low-lying placenta in the second trimester who underwent a follow-up examination in the third trimester and delivered at our institution between January 2012 and March 2023 were included. The last scan with an IOD on transvaginal imaging prior to delivery was used. Outcomes were grouped based on IOD as 0-5, 6-20, and >20 mm. Maternal and neonatal outcomes were collected from an available obstetric database and electronic chart review. Patients with placenta previa, other placental abnormalities (e.g. placenta accreta spectrum) or cord abnormalities near the cervix (e.g. vasa previa) were excluded from the analysis. Statistical analysis included χ^2 for categorical measures and ANOVA for continuous measures, with $P < 0.05$ considered significant.

RESULTS: A total of 344 patients met inclusion criteria for analysis. Third trimester follow-up sonography was performed at a mean gestational age of 33.5±2.0 weeks. Maternal age was significantly different between groups but not race/ethnicity, BMI, or parity (Table). Compared to normal implantation, a low-lying placenta was delivered at a lower relative gestational age; had increased rates of antepartum hemorrhage, hospitalization, and cesarean; and a decreased induction rate. No differences were observed for small for gestational age, postpartum hemorrhage, or maternal transfusion.

CONCLUSION: Low-lying placenta at < 5 and 6-20 mm demonstrated increased pregnancy morbidity. Patients attempting trial of labor should be counseled on these risks and shared decision making pursued.

Table. Maternal demographics and selected pregnancy outcomes based on third trimester transvaginal internal os distance (IOD).

[1]Bleeding was restricted to second and third trimester and quantified based on subject report or objective assessment. Spotting was based on report or an exam with <10 cc bleeding. Mild uterine hemorrhage was based on the report of saturating 1-2 pads or exam with 10-25 cc bleeding. Significant hemorrhage was based on the report of multiple pads, passage of clots, or >25 cc bleeding on exam).

1123 The Value of Extending Maternal Care of Diabetes Mellitus After Delivery in Underserved Areas

Andrea Rizkallah[1], Robert Martin[1], Elaine L. Duryea[1], Ashlyn Lafferty[1], Donald D. McIntire[2], Kristie R. Wilburn-Wren[1], Catherine Y. Spong[1], David B. Nelson[1]
[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]University of Texas Southwestern Medical Center, Richardson, TX

OBJECTIVE: Postpartum care for patients with diabetes mellitus (DM) is challenging for underserved communities. The aim of this study is to compare glycemic control for patients enrolled in a dedicated postpartum care program to those living in other areas of an urban region.

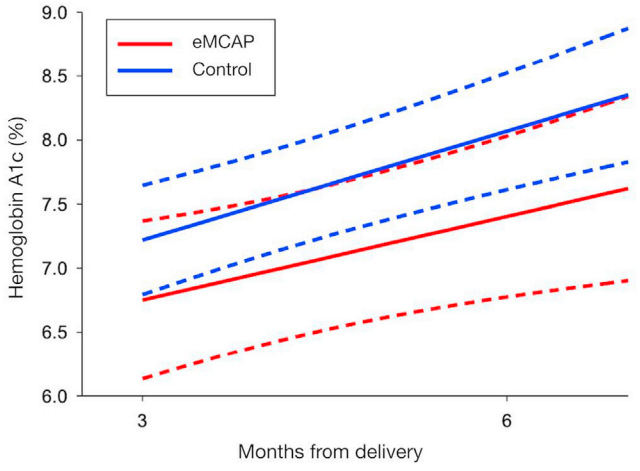
STUDY DESIGN: This was a prospective cohort study of postpartum individuals with pregestational DM who delivered at a large, safety-net hospital. Patients living within a group of zip codes with identified health disparities are offered enrollment into the extending

Maternal Care After Pregnancy (eMCAP) program, which provides management of chronic health conditions including access to a mobile health unit for a year after delivery. Patients living outside the target zip codes receive routine referral to a primary care provider postpartum. Patients in eMCAP with DM were matched 1:2 for maternal age, race/ethnicity, and delivery date to non-eMCAP (control) DM cases. Statistical analysis included Pearson's chi-square and Student's t-test. A mixed effects repeated measures regression model was used to compare the change in hemoglobin A1c (HbA1c) over time (a random effect) between cases and controls (a fixed effect).

RESULTS: Between Oct 2020 - Dec 2022, 50 patients with DM were enrolled into eMCAP compared to 100 controls. The majority of eMCAP patients identified as Hispanic (72%) and Black (24%) with mean BMI 37.4 ± 8.5 kg/m^2. Patients enrolled in eMCAP had significantly higher rates of follow-up at 3, 6 and 12 months postpartum (all P< 0.01). As a corollary, HbA1c values were significantly lower at 3 and 6 months in patients followed in eMCAP compared to controls, a finding that persisted at 1-year postpartum (P< 0.01, Figure).

CONCLUSION: Patients with DM enrolled in a dedicated postpartum care program had significantly higher follow-up rates and lower postpartum HbA1c values after delivery. Improving access to postpartum DM care is critical to improve maternal health and reduce future maternal cardiometabolic disease.

Figure. Estimated Hemoglobin A1c (%) by months from delivery (with 95% confidence intervals)



1124 Reproductive Outcomes with Universal Detailed First Trimester Ultrasound

Lauren Roby[1], Anne Reed-Weston[2], Philip Shlossman[3], Anthony C. Sciscione[3]

[1]Christiana Care Health Services, Newark, DE, [2]Christiana Care Health Systems, Newark, DE, [3]Delaware Center for Maternal & Fetal Medicine of Christiana Care, Inc., Newark, DE

OBJECTIVE: In a political climate where reproductive autonomy is being challenged and earlier decisions are key to access in many states, we sought to determine the effect on termination rates of performing routine detailed first trimester ultrasounds (DFTUs).

STUDY DESIGN: At our institution, we offer all pregnant patients DFTU's and cell free DNA screening (cfDNA). We performed a retrospective cohort study of all pregnancies who received a DFTU between February 23, 2022 and March 31, 2023. All exams were performed by the Division of Maternal-Fetal Medicine at our large academic teaching hospital. The cohort was divided into two groups: those with fetal anomalies found on DFTU and those without. Our primary outcome was the rate of termination. Univariate analysis was performed.

RESULTS: A total of 3715 patients had a DFTU, of which 41 (1.10%) of DFTUs had at least one fetal anomaly noted. There was no difference in maternal BMI between the groups. Maternal age was greater in the abnormal DFTU group (33.1 versus 30.7, p = 0.004), as was gravidity (3.54 versus 2.57, p = 0.0003). Gestational age at time of DFTU performance was lower in the abnormal DFTU group (12.7 weeks versus 13.0 weeks, p < 0.001). 18/41 (43.9%) chose elective termination versus 11/3674 (0.30%) without an anomaly (P< 0.001). Of the 18 who chose elective termination 14/18 (77.8%) did so based on the results of the DFTU, terminating prior to their routine second trimester ultrasound. Of the patients who shared the gestational age at which they terminated, the average gestational age at termination with abnormal DFTU was 15.6 weeks (SD 3.99) versus 19.8 weeks (SD 2.86) for those with normal DFTU. Of those 18, 13/18 (72.2%) also had a genetic anomaly identified on a genetic test (cfDNA, CVS, or amniocentesis).

CONCLUSION: Patients who have an abnormal DFTU are likely to pursue an elective termination, and the majority of those happen before a routine second trimester sonogram is performed.

1125 Residential Proximity to Hydraulic Fracturing Wells Increased the Risk for Low Birth Weight

Emily Root[1], Brian Guinn[1], David Harris[2], William Haneberg[2], Edward Miller[3], Caitlin Thomas[3]

[1]University of Louisville, Louisville, KY, [2]University of Kentucky, Kentucky Geological Survey, Lexington, KY, [3]University of Louisville Hospital, Louisville, KY

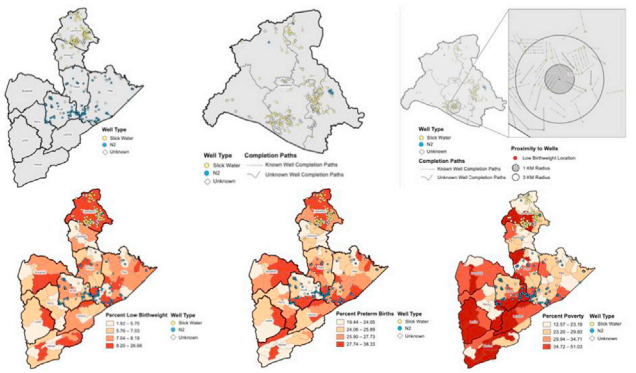
OBJECTIVE: Exposure to hydraulic fracturing (HF), an oil and gas extraction method, may be associated with adverse birth outcomes. Nitrogen (N2) HF uses nitrogen gas to extract natural gas, whereas

slick water HF uses a combination of chemicals, water and sand. By differentiating outcomes by type of HF performed, recommendations can be made on the methods of gas extraction which confer the lowest risk to pregnant patients. Our aim is to demonstrate the impact of residential proximity to slick water versus N2 based HF wells and preterm birth and low birth weight.

STUDY DESIGN: This is an ecological study. Ten eastern Kentucky (KY) counties that contain both slick water and N2 fracking were identified. Data from the KY Public Health Department included: demographics, gestational age (GA), and birth weight for singleton pregnancies over 20 years. Individual births were categorized by term (GA > 37weeks) or preterm (GA < 37 weeks) as well as LBW (< 2500g) or VLBW (< 1500g). The KY Geologic survey provided location data for HF wells in 10 eastern KY counties. KY county shapefiles were downloaded from the US Census Bureau's TIGER/Line Shapefile repository. Data for percent poverty was downloaded from the American Community Survey 2019 5-year estimates. Choropleth maps are expressed by quantiles. All maps were produced in ESRI ArcGIS Pro version 2.8.4.

RESULTS: There were 29,360 unique births during the study period. A total of 398 HF wells were identified in all counties, 45.7% were slick water HF and the vast majority were in Lawrence county (n=160). Lawrence county had the highest prevalence of low birth weight (15.37%, n=166). The 9 remaining counties did not show a spatial association between residential proximity and low birth weight. There was no association between preterm birth and slick water or N2 well location.

CONCLUSION: There appears to be a spatial association between slick water HF, and low and very low birth weight. This spatial correlation is not present for preterm birth.



1126 The Placenta Accreta Index: Potential cutoffs for clinical management

Elise A. Rosenthal[1], Quyen N. Do[2], Ashlyn Lafferty[1], Catherine Y. Spong[1], Diane M. Twickler[2], Yin Xi[2], Christina L. Herrera[2]

[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]UT Southwestern Medical Center, Dallas, TX

OBJECTIVE: The placenta accreta index (PAI) is a standardized method for the ultrasound (US) prediction of placenta accreta spectrum (PAS). Since 2019, we have prospectively applied the PAI in pregnancies in the second and third trimester identified to be at risk for PAS due to prior history of cesarean and placenta previa or low-lying placenta or other sonographic signs of PAS. We sought to determine clinically meaningful cutoffs to guide the decision to obtain adjunct magnetic resonance imaging (MRI).

STUDY DESIGN: We analyzed pregnant individuals who underwent assessment with the PAI from 2019-2023. The last PAI prior to delivery was analyzed for prediction of hysterectomy. Two cut off values were determined for a 96% sensitivity and specificity for the outcome of cesarean hysterectomy. Associated sensitivity, specificity, positive predictive and negative predictive values were determined.

RESULTS: Of 126 with a PAI in the third trimester, 45/126 (36%) required a hysterectomy at delivery. PAI was performed at a mean gestational age of 31.2 ± 2.6 weeks. Mean gestational age at delivery was 36.8 ± 2.0 weeks. The cutoff value for a sensitivity of 96% for cesarean hysterectomy was a PAI of 3.5. The cutoff value for a specificity of 96% for cesarean hysterectomy was a PAI of 8.

CONCLUSION: Our proposed cutoffs of 3.5 and 8 can provide excellent sensitivity and specificity respectively for predicting hysterectomy. The PAI range of 3.5 to 8 was indeterminate, with potential added value of MRI. Future studies will explore the value added of MRI within this PAI range.

Table. Sensitivity, specificity, positive and negative predictive values based on PAI for 96% sensitivity and specificity of cesarean hysterectomy in pregnant individuals at risk for PAS.

96% sensitivity for cesarean hysterectomy PAI optimal cut off: 3.5			
	Value	Lower Limit	Upper Limit
Sensitivity	0.956	0.849	0.995
Specificity	0.593	0.478	0.701
Positive Predictive Value	0.566	0.450	0.917
Negative Predictive Value	0.960	0.862	0.975
96% specificity for cesarean hysterectomy PAI optimal cut off: 8			
	Value	Lower Limit	Upper Limit
Sensitivity	0.511	0.358	0.663
Specificity	0.988	0.933	1.000
Positive Predictive Value	0.958	0.800	0.977
Negative Predictive Value	0.784	0.660	0.993

1127 Prenatally Diagnosed Genetic Anomalies, Anticipated Phenotypes, and Pregnancy Outcomes

Brittany Roser[1], Sarah J. Weingarten[2], Natalie Suder[3], Brittany Dodson[4], Stephen T. Chasen[2]

[1]Weill Cornell, New York, NY, [2]Weill Cornell Medicine, New York, NY, [3]Lenox Hill Hospital Northwell Health, Lenox Hill Hospital Northwell Health, NY, [4]Weill Cornell Medicine at New York Presbyterian Hospital, New York, NY

OBJECTIVE: Phenotypic severity ranges broadly among genetic anomalies and should inform decisions about pregnancy termination. Our objective was to explore phenotype severity and pregnancy outcomes in those with abnormal genetic results.

STUDY DESIGN: This is a retrospective cohort study at a tertiary care center from 2016-2022. Pregnant patients who underwent invasive testing with abnormal results were included. Those with incomplete data or miscarriages were excluded. Phenotypes were categorized into "Severe" (e.g. Trisomy 13/18, OI Type II) "Moderate" (e.g. Trisomy 21, Noonan Syndrome), "Mild" (e.g. sex chromosome aneuploidy, Stargardt Disease), and "Unknown" (e.g. copy number variant of unknown significance) based on anticipated degree of

cognitive impairment, morbidity and longevity. All patients underwent post-test genetic counseling. Analysis was done with Chi-square, Fisher Exact, or T-Test as appropriate.

RESULTS: 202 patients were included. Demographic information and the distribution of diagnoses and phenotypes between pregnancies that were terminated vs continued are in Table 1. Patients who underwent termination were more likely to undergo CVS vs amniocentesis (71% vs 38%) ($p< 0.001$). The overall rate of abortion following prenatal diagnosis was 64.8%. Autosomal trisomy was the most common diagnosis and was more common in pregnancies undergoing termination (50.4% vs 5.6%) ($p< 0.001$). There was a strong correlation between phenotype severity and the decision to undergo abortion. The rates of abortion were 92.8%, 90.1%, and 60.4% for those with severe, moderate, and mild phenotypes, respectively ($p< 0.001$). Only 15.6% of those with an uncertain phenotype terminated the pregnancy.

CONCLUSION: In patients with prenatal diagnosis of genetic anomalies, we saw a strong correlation between phenotype severity and the rate of pregnancy termination. This highlights the importance of appropriate genetic counseling following prenatal diagnosis. Rates of termination were high even with milder phenotypes, indicating that most individuals in our population who choose invasive testing would consider abortion.

Title: Distribution of Prenatal Diagnoses and Phenotypes in Pregnancies undergoing Termination vs Continuation

	Pregnancy Outcome		P-value
	Pregnancy Termination (N = 131)	Pregnancy Continuation (N = 71)	
Maternal Age *(median [IQR])*	37 (33-40)	36 (34-38)	0.43
Insurance Type (%)			0.35
Public	15 (11.5%)	5 (7.0%)	
Private	116 (88.5%)	67 (93.0%)	
Invasive Testing Type (%)			**<0.001**
CVS	93 (71.0%)	27 (38.0%)	
Amniocentesis	36 (27.5%)	43 (60.6%)	
Genetic Diagnosis (%)			**<0.001**
Trisomy 13/18	23 (17.6%)	2 (2.8%)	
Trisomy 21	43 (32.8%)	2 (2.8%)	
Sex Chromosome Abnormality	21 (16.0%)	7 (9.9%)	
Affected Fetus of Carrier Couple	15 (11.5%)	12 (16.9%)	
Single Gene Disorder	7 (5.3%)	0 (0.0%)	
Copy Number Variant (Pathogenic)	7 (5.3%)	4 (5.6%)	
Variant of Uncertain Significance	8 (6.1%)	43 (60.6%)	
Other	7 (5.3%)	1 (1.4%)	
Phenotype (%)			**<0.001**
Mild	29 (22.1%)	20 (28.1%)	
Moderate	55 (42.0%)	6 (8.5%)	
Severe	39 (29.8%)	2 (2.8%)	
Uncertain	8 (6.1%)	43 (60.6%)	

1128 Reliability of FISH by Testing Indication

Brittany Roser[1], Onyedikachi Aligbe[2], Sonali Iyer[2], Stephen T. Chasen[3]

[1]Weill Cornell, New York, NY, [2]Weill Cornell Medicine at New York Presbyterian Hospital, New York, NY, [3]Weill Cornell Medicine, New York, NY

OBJECTIVE: With gestational age limits on abortion, expediting results of prenatal testing is important. Florescence in situ hybridization (FISH) can provide rapid results following CVS or amniocentesis. Our objective was to explore the reliability of FISH in prenatal diagnosis.

STUDY DESIGN: This was a retrospective cohort study from 2020-2021. All patients undergoing invasive testing with FISH were included. Patients with uninformative FISH results were excluded. The positive predictive value (PPV) of FISH was calculated for each testing indication, considering only the chromosomes evaluated by FISH (13, 18, 21, X, Y). Fisher's Exact test was used for statistical comparison.

RESULTS: 703 patients (483 CVS/220 amniocentesis) met inclusion criteria, with 146 abnormal FISH results (20.8%). The most common indication for invasive testing was abnormal NIPT ($n = 225$) followed by AMA ($n = 206$). 27 had chromosomal abnormalities beyond the scope of FISH. Results of FISH and karyotype based on procedure and indication are in Table 1. Overall, FISH was not consistent with karyotype in 8 cases (1.1%), all from CVS There were 2 false positive and 6 false negative results. Discrepancy between FISH and karyotype was seen in 8 of 459 CVS vs 0 of 217 amniocentesis (1.7% vs 0%; $p = .06$). Both false positive results were in cases with abnormal NIPT and normal NT. The 6 false-negative FISH results included one case of T18, one of 47XXY, and four mosaic results, two confined to the placenta based on normal karyotypes on amniocentesis. The PPV of FISH for all indications was 98.6%. PPV was 100% in those with abnormal NT or ultrasound. The overall NPV was 98.9% (524/530), with NPV of 100% with amniocentesis. NPV was lower when CVS was done for abnormal NT than for other conditions (93.6% vs. 99.0%, $p = .04$).

CONCLUSION: While most FISH findings are confirmed by karyotype, PPV with CVS is less than for amniocentesis. Normal FISH results are less reliable with abnormal NT. When NIPT is abnormal but NT is normal, awaiting confirmation with karyotype is recommended.

Table 1: Results of FISH and karyotype based on procedure and indication

			Karyotype Result				
			Abnormal (n=150)		Normal (n=526)		Other (n=27)
	Testing Indication		CVS (n=130)	Amniocentesis (n=20)	CVS (n=329)	Amniocentesis (n=197)	
FISH Result	Abnormal NIPT (n=225)	Abnormal	99	17	2	0	0
		Normal	1	0	36	66	4
	Advanced Maternal Age (n=206)	Abnormal	3	0	0	0	0
		Normal	2	0	144	47	10
	Abnormal NT (n=84)	Abnormal	16	1	0	0	0
		Normal	3	0	44	14	6
	Prior Abnormal Pregnancy (n=41)	Abnormal	1	0	0	0	0
		Normal	0	0	38	1	1
	Abnormal Serum Screen (n=39)	Abnormal	3	0	0	0	0
		Normal	0	0	13	23	0
	Abnormal Anatomy (n=22)	Abnormal	0	2	0	0	0
		Normal	0	0	0	20	0

		Normal	0	0	52	26	6

1129 Let's talk about twin survival after fetal therapy...the same way

Mara Rosner[1], Michelle Kush[2], Ahmet A. Baschat[2], Jena L. Miller[1]

[1]Johns Hopkins Center for Fetal Therapy, Baltimore, MD, [2]Johns Hopkins Hospital, Baltimore, MD; on behalf of the Kelly Family

OBJECTIVE: To understand the various measurement constructs that can be used describe twin outcomes after fetal therapy and demonstrate how these methods can represent the same data differently.

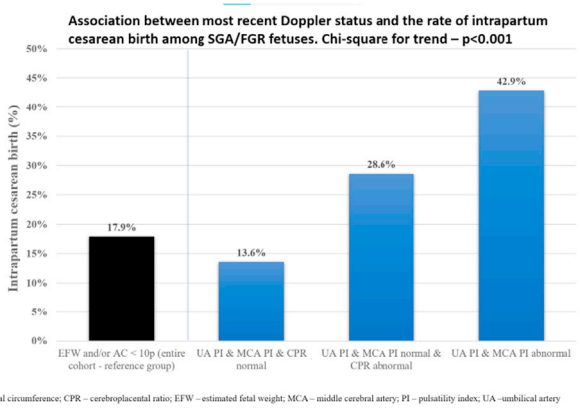
STUDY DESIGN: We evaluated all patients who underwent fetoscopic laser for twin to twin transfusion syndrome (TTTS) from 2014 to 2023 using commonly described outcome measures. Double twin survival (DS) is the percentage of pregnant patients who have two surviving twins. At Least One Survivor (ALOS) describes the sum of the percentage of pregnant patients with DS plus the percentage of those with a single survivor (SS). Perinatal survival (PS) considers each twin as a separate patient and potential survivor which is DS x2 + SS x 1 / all patients x 2. We compared DS to ALOS at the time of birth within our own cohort using Chi squared analysis. We also calculated the PS at birth for the same cohort.

RESULTS: 408 patients underwent laser surgery for TTTS. The median gestational age at birth was 32.3 [29.2-34.2] weeks. 314/408 (77%) had double survival. An additional 65 (17.2%) patients had SS therefore 379/408 (93%) had ALOS which was statistically different from DS, p< 0.001. Perinatal survival was 693/816 (85%).
CONCLUSION: Amongst a cohort of 408 consecutive patients undergoing laser surgery, birth survival could be described as 77% (double survival), 93% (at least one survivor), or 85% (perinatal survival). These findings emphasize the importance of previously stated goals to harmonize and understand outcome measures, as well as outcomes. We recommend DS and PS as the most useful survival measures as ALOS underemphasizes the significance of single fetal demise.

1130 Sonographic parameters associated with mode of delivery among small for gestation and growth-restricted fetuses

Misgav Rottenstreich[1], Swati Agrawal[2], Homero Flores Mendoza[1], Bryon DeFrance[1], Jon F. Barrett[3], Eran Ashwal[4]
[1]McMaster University, Hamilton, ON, [2]Hamilton Health Sciences, Toronto, ON, [3]Sunnybrook Health Science, University of Toronto, Toronto, ON, [4]McMaster University, North York, Tel Aviv

OBJECTIVE: Doppler measurements play a crucial role in managing fetuses with impaired fetal growth. However, the existing evidence on their association with the mode of delivery is limited. This study aims to identify the sonographic parameters associated with intrapartum cesarean section among patients with small-for-gestational-age (SGA) or fetal growth-restricted (FGR) fetuses.
STUDY DESIGN: A retrospective cohort study was conducted, including all singleton pregnancies ≥ 32 wks that experienced a trial of labor. All cases completed Doppler assessment (umbilical artery pulsatility index (UA-PI) and middle cerebral artery (MCA) PI, and cerebroplacental (CPR) within 14 days before birth. Eligible fetuses had either EFW and/or AC < 10% for gestational age without known genetic or structural anomalies. The study compared patients who achieved a successful vaginal birth with those who ultimately underwent an intrapartum cesarean birth. Univariate and multivariable logistic regressions were utilized.
RESULTS: In total, 632 patients with SGA/FGR fetuses participated in a trial of labor. Among them, 519 (82.1%) had a vaginal birth, while 113 (17.9%) underwent intrapartum cesarean birth. Gestational age at the most recent ultrasound, ultrasound-to-birth interval, rates of EFW < 3%, and rates of umbilical artery PI >95% were comparable between the groups. The Doppler status was significantly associated with the mode of delivery (p< 0.001; Figure) Multivariable logistic regressions adjusted for parity, obesity, history of cesarean birth, hypertensive disorders, labor induction, and gestational age at birth identified several sonographic parameters associated with an intrapartum cesarean birth. These included AC < 3% (adjusted odds ratio 1.63; 95% confidence interval 1.03-2.58) and CPR < 5% centile (2.02; 1.28-3.19).
CONCLUSION: Sonographic measurements have been found to be significantly associated with the mode of delivery in SGA/FGR fetuses. These findings highlight the importance for caregivers to consider those parameters when counseling the mode of delivery with patients who have SGA/FGR fetuses.



1132 Lived experiences of pregnant patients with COVID-19 requiring ICU admission

Amrita Roy, Courtney Olson-Chen
University of Rochester Medical Center, Rochester, NY

OBJECTIVE: We sought to understand the lived experiences of pregnant patients requiring ICU admission due to severe COVID-19 infection including their familiarity with their diagnosis and hospital course, and the impact of their ICU stay on peripartum wellbeing.
STUDY DESIGN: A qualitative descriptive study was performed using semi-structured interviews at a single tertiary care medical center. All pregnant subjects had a diagnosis of COVID-19 requiring ICU admission between March 2020 and October 2022. Interviews were conducted via Zoom, transcribed verbatim, identifiers removed, and coded thematically using the Dedoose data analysis software.
RESULTS: A total of 17 subjects were approached and 9 were enrolled. 8 of 9 subjects (88.9%) required intubation and 3 (33.3%) received ECMO while in the ICU. Our study identified four themes describing the experiences of pregnant patients requiring ICU admission due to severe COVID-19**:** (a) intense loneliness and confusion due to the pandemic, hospitalization, and visitor restrictions (b) depersonalization and feeling absent during a key life event (c) complex birth trauma with several subjects reporting new debilitating psychiatric diagnoses after their ICU admissions and (d) resiliency from either religious beliefs, strengthened family relationships, or the need to survive for their newborn.
CONCLUSION: Pregnant patients admitted to the ICU with COVID-19 experience unique physical, cognitive, and mental challenges secondary to their hospitalization and transition into the fourth trimester. Our subjects felt fear, confusion, and a painful absence from a major life event, with an increase in psychiatric diagnoses following hospitalization. Many patients described a reinvigoration of spiritual faith and maintaining family relationships. Pregnant patients surviving critical illness may benefit from additional tailored support, and a detailed review of their complex courses with their medical team.

1135 The Effect of Preoperative Music and Conversation on Anxiety in Women Undergoing Elective Cesarean Delivery

Masho Salomon[1], zehava Yohay[2], Sapir Ellouk[1], Yael Baumfeld[1], Alina Kopitman[1], Eyal Sheiner[3]
[1]Soroka Medical Center, Beer-Sheva, HaDarom, [2]Pain Unit, Soroka University Medical Center, Beer Sheva, Israel, Soroka medical center, HaDarom, [3]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: Anxiety is a common mental health condition affecting a significant number of individuals, especially pregnant women. Mind-body techniques may be helpful to reduce anxiety before surgeries. Our study aimed to investigate the effect of preoperative music and brief preparatory conversation on anxiety in women undergoing elective cesarean delivery (CD).

STUDY DESIGN: A prospective study in a tertiary referral hospital was conducted between the years 2022-2023, investigating preoperative anxiety of women undergoing elective CD. All patients attended a preoperative clinic (team consisting of a nurse and physician) with explanations regarding the procedure. In addition, the intervention group received a message with detailed information accompanied by relaxing music and a brief conversation. The State-Trait Anxiety Inventory (STAI) was used to measure the level of anxiety in both groups during the morning before the operation. Multivariable linear analysis was conducted to control for potential confounding variables.

RESULTS: The analysis included a total of 130 women undergoing elective CD, with 65 women in each group. No significant difference in maternal age, level of education, religion, financial status, parity, previous CD were noted between the groups. Preoperative anxiety and stress levels were significantly **lower** following the intervention with preoperative music and a brief conversation, compared with patients who underwent preoperative clinic alone (Table). Specifically, women in the intervention group were less anxious and expressed happier feelings as compared to women in the non-intervention group (Table). Two linear regression models were constructed for the prediction of both positive and negative feeling composites, controlling for age, parity, previous CD, education, ethnicity, and financial status. The music intervention significantly improved the positive composite (B=7.23, SD 0.91; $p< 0.001$) and reduced the negative composite stress outcome (B=-7.07, SD 0.75; $p< 0.001$).

CONCLUSION: Intervention with preoperative music and a brief conversation may reduce anxiety before an elective CD.

Table. Preoperative anxiety levels, using the State-Trait Anxiety Inventory

	Pre-operative clinic and music Intervention group (n=65)	Preoperative clinic alone (n=65)	P-value
State-Trait Anxiety Inventory (STAI)			
I feel calm	3 (3-3)	2 (1.75-3)	<0.001
I feel secure	3 (3-4)	3 (2-3)	<0.001

I feel upset	1 (1-1)	1 (1-2)	<0.001
I am presently worrying over possible misfortunes	2 (1-2)	2 (2-3)	<0.001
I feel satisfied	3 (2-3)	2 (2-3)	<0.001
I feel frightened	2 (1-2)	3 (2-4)	<0.001
I feel uncomfortable	3 (3-3)	2 (2-3)	<0.001
I feel self-confident	3 (3-4)	2 (2-3)	<0.001
I feel nervous	1 (1-1)	1 (1-2)	<0.001
I feel jittery	2 (1-2)	3 (2-3)	<0.001
I feel indecisive	1 (1-2)	3 (2-4)	<0.001
I am relaxed	2 (2-3)	1 (1-2)	<0.001
I feel content	3 (3-4)	3 (2-3)	<0.001
I am worried	2 (2-2)	3 (2-4)	<0.001
I feel confused	2 (1-2)	2 (2-3)	0.03
I feel steady	4 (3-4)	3 (2-4)	<0.001
I feel pleasant	3 (3-4)	2 (2-3)	<0.001

1136 The Cost-Effectiveness of Access to Termination for Pregnancies Affected by Trisomy 13

Kirat Sandhu[1], Belinda Udeh[1], Lorraine Dugoff[2], Maeve Hopkins[3]

[1]Cleveland Clinic Foundation, Cleveland, OH, [2]University of Pennsylvania, Philadelphia, PA, [3]Cleveland Clinic, Rocky River, OH

OBJECTIVE: We aimed to evaluate the cost of restrictive abortion bans in pregnancies diagnosed with fetal trisomy 13 in the first trimester. A secondary aim was to compare costs between access to termination versus restrictive abortion ban in pregnancies affected by trisomy 13.

STUDY DESIGN: Using a decision analytic model, we assessed the cost-effectiveness of two strategies for managing pregnancy with trisomy 13 diagnosed in the first trimester: legal access to pregnancy termination versus restrictive abortion ban. Costs included were abortion procedures, travel, abortion complications, pregnancy complications, and medical care of the infant including palliative care. Effects included decision to terminate pregnancy, stillbirth, and maternal preeclampsia. The costs and effects of the two strategies were compared with the primary outcome being the cost per stillbirth averted and sensitivity analysis conducted. Variables were abstracted from published literature and the analysis was conducted from the healthcare perspective.

RESULTS: In the base case, access to termination was less costly ($20,2016 vs $63,103) and resulted in fewer stillbirths than restricted abortion access and was, therefore, the choice strategy. The model was most sensitive to the cost of stillbirth and the probability of live birth but there were no thresholds identified in any of the variables where the choice strategy would change. Assuming current Trisomy 13 prevalence and national birthrates, access to termination would result in 222 fewer stillbirths annually and $9,520,914 lower costs.

CONCLUSION: For pregnancies diagnosed with fetal trisomy 13 in the first trimester, access to termination results in fewer stillbirths and reduced costs.

Base case Trisomy 13	Probability (low, high)	Cost, (low, high $ US Dollars)
Elective termination (access)	0.73 (0.71-0.78)	388 (161-528)
Travel termination (no access)	0.15 (0.1-0.3)	2473 (1,350-4,992)
Abortion complication	0.126 (0.0014-0.0138)	669 (546-749)
Live Birth	0.368 (0.2-0.43)	29,524 (26,598-32,451)
Stillbirth	0.6436 (0.8-0.57)	9756 (857-100,336)
Preeclampsia	0.12 (0.09-0.26)	49334 (25,527-110,702)
Palliative care	0.75 (0.52-0.77)	23,214 (10,555-67,577)
Life-prolonging care	0.25 (0.48-0.33)	468,945 (369,044-568,846)

Table 1, costs and probabilities for base-case analysis. US: United States

1137 Pregnancy hormones effects on coronary artery cellular gene regulation and functional correlates of SCAD

Ajleeta Sangtani[1], Cameron Pinnock[2], Kristina Hunker[2], Santhi K. Ganesh[2]

[1]University of Michigan, Ann Arbor, MI, [2]Michigan Medicine, Ann Arbor, MI

OBJECTIVE: Spontaneous coronary artery dissection (SCAD) occurs during hormonal-mediated events such as pregnancy. The objective of this study was to determine the effect of pregnancy-level estradiol and progesterone on coronary artery smooth muscle cells

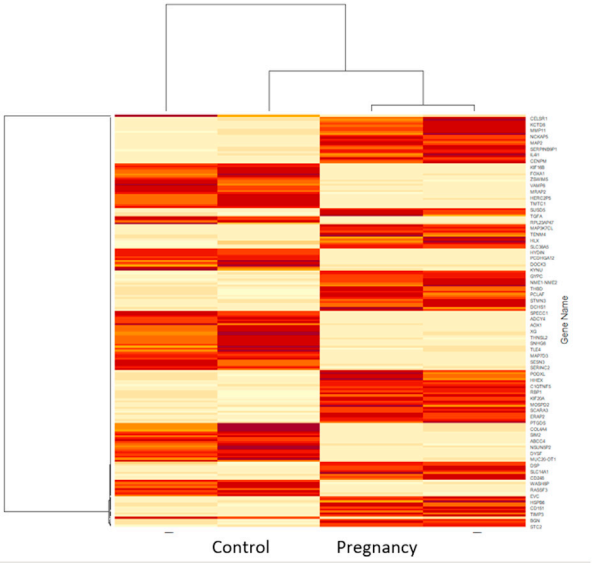
(huCASMCs) and cellular behavior relevant to arterial destabilization such as in SCAD.

STUDY DESIGN: Human CASMCs were propagated and incubated with either control media or 100nM estradiol plus 1000nM progesterone (pregnancy) for 48 hours. Experiments were performed in triplicate. To query transcriptional activation by hormone exposure, RNA sequencing (RNASeq) was analyzed to detect differentially expressed genes and processes. To validate transcriptomic findings on functional models, traction force microscopy (TFM) was performed on the hormone and control cells using a polydimethylsiloxane (PDMS) layer with a predefined elasticity modulus and fluorescent nanoparticles with deflections measured to quantify force generation. A wound healing assay was performed to assess cellular migration. Bromodeoxyuridine (BrdU) incorporation was measured to determine cellular proliferation. Analyses were performed using DESeq2 in R, Friedman tests, and Kruskal-Wallis tests where appropriate.

RESULTS: Over 100 transcripts were differentially expressed between the control and pregnancy conditions (Fig.1). Significant biologic processes identified by gene ontology analysis included cell proliferation (p=0.01), cell adhesion (p=0.02) and cell movement (p=0.01). TFM showed increased force in the pregnancy condition when induced with KCl (263±11 N/m^2 versus 181±8 N/m^2, p=0.01). Although the pregnancy cells were less proliferative (24 hours of BrdU incorporation, p=0.03), they showed increased migration in the wound healing assay (p=0.01).

CONCLUSION: Results from this in vitro study highlight candidate transcriptional and cellular behavior of the vascular smooth muscle induced by estradiol and progesterone that support specific mechanistic hypotheses for the regulation coronary artery smooth muscle cells that may have relevance to pregnancy-related cardiovascular events.

Figure 1: Heatmap of differentially expressed genes



1138 Prediction of pregnancy outcomes by various blood pressure metrics among patients with mild chronic hypertension

Ayodeji Sanusi
Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; on behalf of the Chronic Hypertension and Pregnancy (CHAP) Consortium

OBJECTIVE: To assess the ability of various blood pressure (BP) measures to predict adverse pregnancy outcomes in patients with mild chronic hypertension (CHTN).

STUDY DESIGN: Secondary analysis of an open label RCT of antihypertensive treatment (vs. none) in pregnant patients with mild CHTN (BPs < 160/105 mmHg) and singleton pregnancies < 23 weeks' gestation. All enrolled patients with ascertained outcomes were included. The primary exposures were average mean arterial pressure (MAP) compared to mean systolic (SBP) and mean diastolic (DBP) blood pressures in pregnancy. The primary outcome was a composite of severe preeclampsia, preterm birth < 35weeks, placental abruption, and fetal or neonatal death. Receiver operating curves (including c-statistics and 95% CI) from adjusted multivariable logistic regression models were used to compare predictive ability of the various BP measures with respect to adverse outcomes.

RESULTS: Participants were included if they had at least 1 prenatal blood pressure measurement and the primary composite (N=2,267). Mean age was 32.3 ± 5.6 years, 1075 (47.4%) were Black and >50% had public insurance. Over half (n=1,233, 54.4%) were on anti-HTN medications at baseline and >80% were multiparous. Average mean MAP, SBP and DBP in pregnancy were 97.2 ± 7.6, 130.7 ± 10.1, and 80.5 ± 7.7mmHg respectively. All BP measures were modest predictors of the primary outcome, however, MAP was a significantly better predictor of the primary outcome compared to SBP and DBP (mean difference: MAP vs. SBP 0.02, 95% 0.01-0.04; MAP vs. DBP 0.02, 95% CI 0.01-0.03). For all other secondary outcomes except SGA and respiratory support, MAP was marginally better at predicting outcomes. DBP was the best predictor of small for gestational age < 10th percentile, while SBP best predicted any neonatal respiratory support.

CONCLUSION: Compared to SBP and DPB, MAP is a better predictor of most adverse outcomes in pregnant patients with mild chronic hypertension.

Table: Mean Blood Pressure Measures and their Association with Outcomes in Pregnant Patients with Mild Chronic Hypertension

Outcome	MAP	SBP	DBP	MAP vs SBP	MAP vs DBP
Primary Composite	0.71	0.69	0.69	0.02 (0.01-0.04)	0.02 (0.01-0.03)
Severe Preeclampsia	0.71	0.68	0.69	0.03 (0.01-0.04)	0.02 (0.01-0.03)
Preterm Birth (<35 weeks)	0.75	0.73	0.72	0.02 (0-0.03)	0.02 (0.01-0.03)
Fetal/Neonatal Death (<28 days)	0.60	0.58	0.58	0.02 (-0.03-0.07)	0.02 (-0.02-0.05)
Placental Abruption	0.64	0.62	0.63	0.02 (-0.03-0.06)	0.02 (-0.02-0.05)
SGA < 10th Percentile	0.54	0.51	0.55	0.03 (0.01-0.05)	-0.009 (-0.02-0.005)
NICU Admission	0.71	0.67	0.70	0.04 (0.02-0.05)	0.006 (-0.004-0.02)
Low Birth Weight <2500g	0.63	0.63	0.61	-0.003 (-0.01-0.02)	0.03 (0.008-0.03)
Composite Neonatal Morbidity	0.72	0.70	0.69	0.02 (-0.02-0.06)	0.02 (-0.008-0.06)

Numbers are AUC and Mean difference (95% confidence interval) as appropriate; Confidence intervals in bold do not cross the null.

1139 Risk factors of uterine rupture in individuals attempting TOLAC in the setting of stillbirth

Alyssa Savelli Binsted[1], Elizabeth Miller[2], George R. Saade[1], Tetsuya Kawakita[1]
[1]Eastern Virginia Medical School, Norfolk, VA, [2]Eastern Virginia Medical Center, Norfolk, VA

OBJECTIVE: TOLAC counseling is based on the risk and benefits gathered from multiple cohort studies. However, the evidence may not apply in the setting of stillbirth when perinatal outcome is not considered in the evaluation, and the available data is limited. Our study aimed to assess risk factors for uterine rupture in individuals who attempted TOLAC in the setting of stillbirth.

STUDY DESIGN: This was a case-control study using Fetal Death Data from the National Vital Statistics System from 2014 to 2021. We limited analysis to individuals with stillbirth at 20 weeks or greater and a history of cesarean delivery and those who underwent TOLAC. Variables were compared between individuals who had uterine rupture and those who did not using bivariate analysis. Those with P-value < 0.1 were included in multivariable logistic regression to calculate adjusted odds ratios (aOR) with 95th confidence intervals (95% CI).

RESULTS: Of 11,550 eligible for inclusion, 147 (1.3%) had uterine rupture. Compared to individuals who did not have uterine rupture, those who had uterine rupture were less likely to be Hispanic, deliver at term, and have greater number of prior cesarean delivery. Risk factors for uterine rupture included greater gestational age (20-23 weeks 0.5% [referent]; 24-27 weeks 0.6% [aOR 1.19, 95%CI 0.57-2.49]; 28-36 weeks 1.4% [aOR 2.78, 95%CI 1.71-4.51]; 37 weeks or greater 3.7% [aOR 8.12, 95%CI 5.00-13.18]), pregestational diabetes (2.2% [aOR 1.73, 95%CI 1.03-2.91]), and number of cesarean delivery (1 previous cesarean 1% [referent]; 2 previous 2.1% [aOR 2.68, 95%CI 1.87-3.84]; 3 previous 2.0% [aOR 2.58, 95%CI 1.51-4.42]). Hispanic compared to non-Hispanic ethnicity was associated with decreased odds of uterine rupture (0.9% vs. 1.4% [aOR 0.57, 95%CI 0.36-0.92]).

CONCLUSION: Overall, the rate of uterine rupture in individuals who attempted TOLAC in the setting of stillbirth was comparable to overall historical data, even in the setting of multiple cesarean deliveries. Individuals considering the mode of delivery after stillbirth at term should be counseled on a potentially increased odds of uterine rupture.

Table 1. Risk factors for uterine rupture after TOLAC in the setting of fetal demise

	Uterine rupture n (%)	Crude OR (95%CI)	Adjusted OR (95%CI)
Gestational age			
20-23	24/4588 (0.5)	Reference	Reference
24-27	10/1559 (0.6)	1.23 (0.59-2.57)	1.19 (0.57-2.49)
28-36	55/3818 (1.4)	**2.78 (1.72-4.50)**	**2.78 (1.71-4.51)**
37 or greater	58/1585 (3.7)	**7.22 (4.47-11.66)**	**8.12 (5.00-13.18)**

1140 Retroverted uterus in the first trimester and associated pregnancy outcomes

Emily Schneider[1], Agata Kantorowska[2], Joanna Clough[3], Erin Miller[3], Emmanuella Kobara[2], Jasmine Brite[2], Meredith Akerman[2], Wendy Kinzler[4], Anju Suhag[2], Martin Chavez[4], Patricia Rekawek[5]
[1]NYU Grossman Long Island School of Medicine, Larchmont, NY, [2]NYU Grossman Long Island School of Medicine, Mineola, NY, [3]NYU Langone Hospital-Long Island, Mineola, NY, [4]Winthrop University Hospital, Mineola, NY, [5]NYU Langone Health- Long Island/ NYU Grossman Long Island School of Medicine, Mineola, NY

OBJECTIVE: To determine if retroverted (RV) uterus diagnosed at the time of nuchal translucency (NT) ultrasound is associated with second trimester pregnancy loss and other adverse pregnancy outcomes.

STUDY DESIGN: This is a retrospective cohort study of patients with RV uterus documented on NT ultrasound at a single institution from 10/2019 to 03/2023. Subjects were identified using a query for "retroverted" uterus within the obstetric ultrasound imaging program. Two subjects with anteverted (AV) uterus were selected for every RV case and used as a comparison group. Patients with multiple gestation, Mullerian anomalies, fetal aneuploidy, or those who delivered at an outside institution were excluded. Maternal demographics, obstetrical, and neonatal outcomes were obtained by chart review. Chi-square test or Fisher's exact test were used for categorical variables, and t-test or Mann-Whitney test were used for continuous variables, with p value < 0.05 denoting significance. Multivariable logistic regression was used to adjust for possible confounding variables.

RESULTS: There were 249 subjects included: 83 in the RV group and 166 in the AV group. Most RV subjects (98%) had resolution of retroversion by the second trimester. Uterine incarceration requiring intervention occurred in three subjects. Significantly more RV subjects conceived by in vitro fertilization (IVF), 11% vs 3% (p=0.02). There was no difference in second trimester pregnancy loss between groups, 0% vs 1.2% (p=0.55). After adjusting for IVF, RV subjects were four times more likely to have first trimester vaginal bleeding (OR=4.1, p=0.001). There were no other differences in adverse outcomes, including first trimester pregnancy loss.

CONCLUSION: Persistent RV uterus in the first trimester is associated with increased risk of first trimester vaginal bleeding. However, rates of first and second trimester pregnancy loss were similar between groups, providing valuable information for patient counseling. Significantly more RV subjects conceived by IVF, highlighting the need for further study in this patient population.

Table 1. Pregnancy outcomes of patients with RV versus AV uterus on NT ultrasound

Total n=249	Retroverted (n=83)	Anteverted (n=166)	P value
Cesarean section	32 (38.5%)	68 (41%)	0.91
First trimester bleeding	14 (16.9%)	7 (4.2%)	**0.001**
First trimester spontaneous abortion	2 (2.4%)	2 (1.2%)	0.60
Second trimester pregnancy loss	0 (0%)	2 (1.2%)	0.55
Short cervix	2 (2.4%)	7 (4.2%)	0.72
Composite adverse maternal outcomes*	18 (21.7%)	51 (30.7%)	0.13
Composite adverse fetal outcomes†	9 (10.8%)	11 (6.6%)	0.25
Composite adverse neonatal outcomes‡	22 (26.5%)	42 (25.3%)	0.83

*Composite adverse maternal outcomes include hypertensive disorders of pregnancy, spontaneous preterm labor, preterm prelabor rupture of membranes, placental abruption, postpartum hemorrhage, retained placenta
†Composite adverse fetal outcomes include growth restriction, oligohydramnios, and intrauterine fetal demise
‡Composite adverse neonatal outcomes include low birth weight (LBW), very LBW, extremely LBW, preterm delivery, 5-minute APGAR score < 7, NICU admission, neonatal death

1141 T2DM identified as risk factor for IHCP using a machine learning approach with pregnancy records

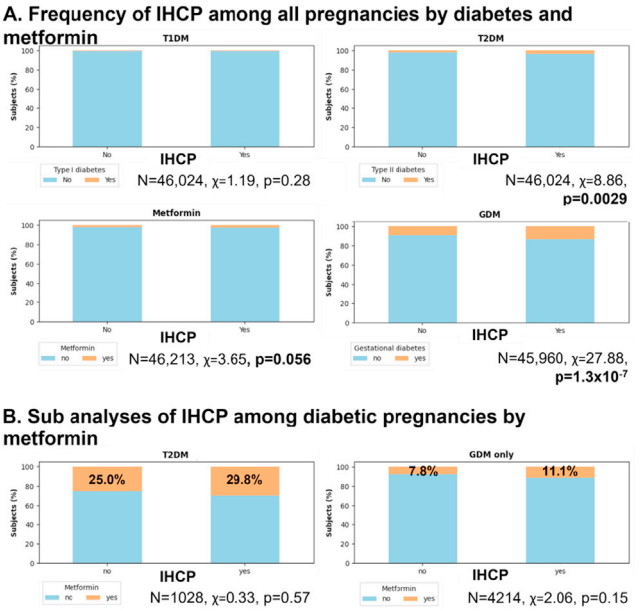
Maxim D. Seferovic[1], Kjersti M. Aagaard[2]
[1]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [2]Texas Children's Hospital, Baylor College of Medicine, Houston, TX

OBJECTIVE: Intrahepatic cholestasis of pregnancy (IHCP) is a poorly understood disease known to have hormonal and metabolic links. In a discovery approach, we sought to naively assess a large database of pregnancies using machine learning and natural language processing (NLP) for novel insights into pathology and risk.

STUDY DESIGN: Peribank, a research database of 46,641 pregnancies containing 12,017 data entry fields, was natural language processed using *spaCy* pretrained models, with Boolean and scalar data retained. Medications were corrected against MEDI-Ensemble using Levenshtein distance *fuzzy* matching. Post processing filtering left ~450,000 unique features that were assessed for predictive feature selection with *scikit-learn*. Logit regression was used for select features.

RESULTS: There were 1374 IHCP pregnancies discovered in the database. Feature selection revealed top scoring predictors of IHCP (positive or negative) in decreasing score as T2DM as indication for antenatal testing, T2DM, metformin use at conception, white maternal race, white paternal race (both inclusive of Hispanic ethnicity), no medications at conception, tetanus vaccination, high alkaline phosphatase, high glucose, flu vaccination, and GA at admittance. Diabetes and metformin use were then assessed independently for risk. T2DM patients had increased risk for IHCP (OR 1.44, 95% CI 1.05-1.98, p=0.023) as did GDM (1.54, CI 1.31-1.81, $p=3.5x10^{-7}$), while there was no association with Type I diabetes or metformin use independently. The associations were confirmed by X^2 for T2DM (p=0.0029), GDM ($p=1.3\ x10^{-7}$) and metformin use (p=0.056) (Fig. A). A sub analyses of only diabetic patients of all types (n=5110) found metformin treated patients more likely to develop IHCP than others (14.0% vs. 10.8%) though it did not reach significance (p=0.17, X^2) (Fig. B).

CONCLUSION: The novel association of risk for IHCP with T2DM adds to the known association of GDM. Given the absence of association with T1DM, and the possible influence of metformin, the results support the theory that IHCP pathology is linked to hepatic insulin resistance.



1142 Long- term infectious morbidity of offspring born to women with psoriasis

Moran Shahar[1], Gil Gutvirtz[2], Tamar Wainstock[3], Gali Pariente[4], Eyal Sheiner[5]
[1]Soroka, Carmit, HaDarom, [2]Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Metar, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom, [4]Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Klahim, HaDarom, [5]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: Psoriasis is a common skin disease with prevalence of 1.5-2.2% in the adult population. About half of psoriasis patient are women, presenting usually before the age of 40. Limited data exists regarding long-term morbidity of the offspring in women with psoriasis. The objective of this study was to assess long-term infectious morbidity of the offspring born to women with psoriasis.

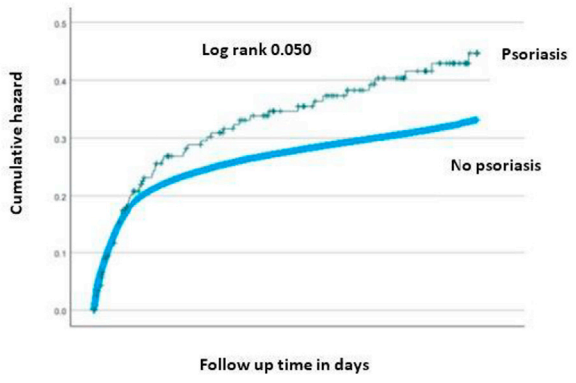
STUDY DESIGN: In a population-based cohort study, long- term infectious hospitalizations of the offspring were compared between singletons born to mothers with and without psoriasis. Deliveries occurred between the years 1991-2021 in a regional tertiary medical center. Infectious related morbidity up to the age of 18 years was assessed according to a predefined set of ICD-9 codes associated with offspring hospitalizations. A Kaplan-Meier survival curve was used to assess cumulative incidence of infectious related morbidity of the offspring and a Cox proportional hazards model was performed to control for confounders.

RESULTS: During the study period 356,356 deliveries met the inclusion criteria, 240 (0.07%) occurred in women with psoriasis. Rates of long- term infectious hospitalizations of the offspring were comparable between the groups (30.4% vs 24.1% for offspring to mothers with and without psoriasis, respectively, p=0.129). However, the cumulative incidence of long- term infectious morbidity was higher among offspring born to women with psoriasis (Kaplan-Meier Log -rank = 0.050, Figure). In a Cox proportional hazards model, controlling for birth-weight, being born to a woman with psoriasis was independently associated with long term infectious

morbidity of the offspring (adjust HR = 1.2, 95% CI 1.01-1.58; p=0.049).

CONCLUSION: Being born to a mother with psoriasis is an independent risk factor for long-term infectious morbidity of the offspring.

Figure: Kaplan-Meier survival curve for cumulative incidence of long-term infectious morbidity of the offspring born to mothers with and without psoriasis (Log Rank P= 0.050)



1143 Social determinants of health and stillbirth evaluation

Lena A. Shay, Jannie Matar, Sarah Tounsi, Jennifer R. McKinney, April Adams
Baylor College of Medicine, Houston, TX

OBJECTIVE: Intrauterine fetal demise (IUFD) is defined as fetal death at ≥20 weeks' gestation and complicates about 1 in 160 pregnancies. Several important social determinants of health (SDOH) have been associated with higher rates of stillbirth, such as race, income, education, and access to antenatal care, however SDOH haven't been examined relative to stillbirth evaluation. Our objective was to examine the role of SDOH factors on post-delivery evaluation of stillbirth.

STUDY DESIGN: Retrospective cross-sectional analysis was conducted to examine IUFD deliveries occurring at two tertiary care centers from 2016 to 2022. Cases included IUFD occurring ≥20 weeks gestation. Exclusion criteria were elective termination, pre-viable preterm premature rupture of membranes, or multiple gestation. 340 cases were included. Descriptive statistics were calculated for study variables and Student's T-test and Chi-squared tests used for analysis.

RESULTS: The stillbirth rate (7.2 per 1000 live births) was comparable to the 2020 US stillbirth rate of 5.7 per 1000 live births. Higher rates of stillbirth were observed for non-Hispanic Black women and Hispanic women, compared to White women. Fewer non-Hispanic Black women received diagnostic genetic testing (27%) and autopsy (30%) following IUFD compared to non-Hispanic White women (54%, 46%, respectively) (p=0.0005, p=0.037). There were no other factors associated with a difference in rate of diagnostic testing or autopsy. Additionally, non-Hispanic Black women were administered urine toxicology testing 3X as often as non-Hispanic White women (39% vs. 11%) (p=0.016), despite lower positivity rates (24% vs. 50%).

CONCLUSION: Our data shows that disparities are present in both the occurrence of stillbirth and the evaluation performed thereafter, particularly for diagnostic genetic testing and autopsy. Further studies are needed to elucidate the reasons behind observed differences in stillbirth evaluation. Future efforts should focus on standardization of the counseling recommended for stillbirth evaluation and elimination of testing that is neither helpful nor equitably performed.

1144 Predicting preeclampsia and gestational hypertension using the vasculature of the eye

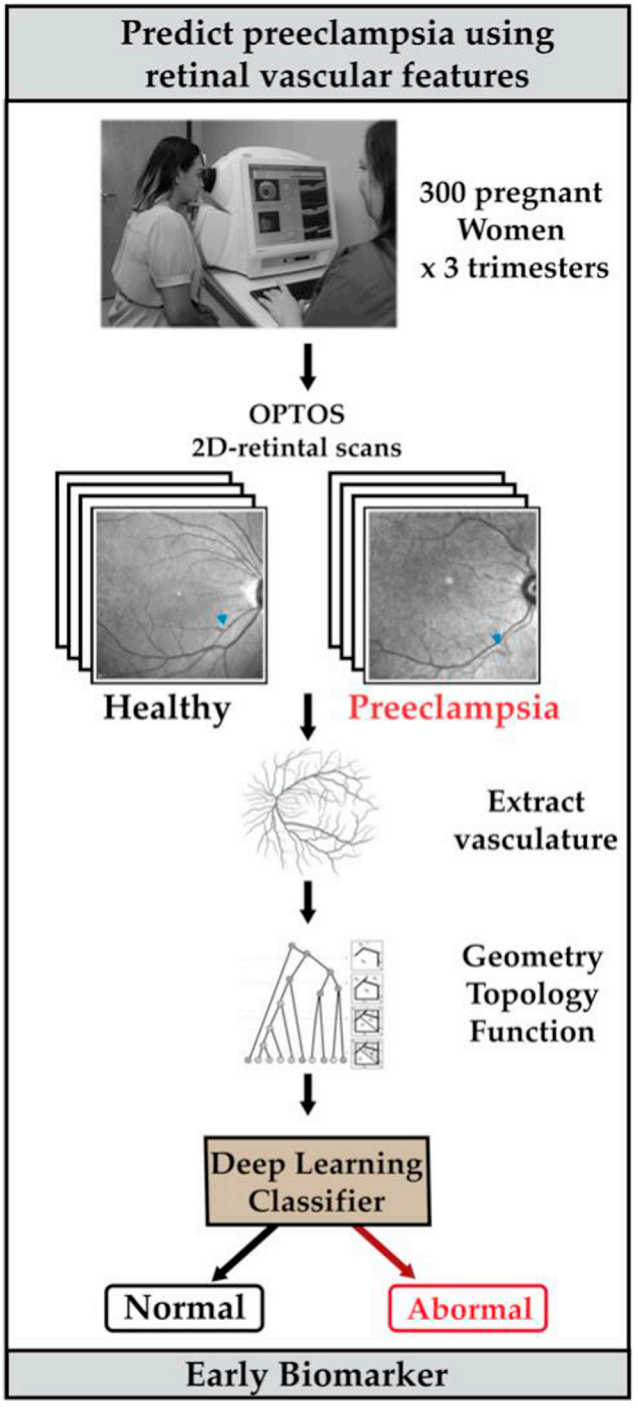
Liat Shenav[1], Andrew Laine[2], Kaveri Thakoor[2], Ye Tian[2], Geoffrey Wu[2], Zoilo Castillo[2], Yessenia Gutierrez[2], Lisa Hark[3], Ronald J. Wapner[4], Srilaxmi Bearelly[5]
[1]Rockefeller University, New York, NY, [2]Columbia University, New York, NY, [3]Columbia University Medical Center, New York, NY, [4]Columbia University Irving Medical Center, New York, NY, [5]Columbia University, Stony Brook, NY

OBJECTIVE: Preeclampsia is one of the most severe pregnancy complications and a leading cause of maternal death. Notably, the initial vascular alterations leading to preeclampsia occur in the placenta and maternal vasculature well before symptoms develop. This observation is **key to novel diagnostics.** Here we evaluate, for the first time, changes in the retinal vasculature occurring prior to the patient becoming symptomatic and use an Artificial Intelligence (AI) framework to develop and test a vascularity based predictive algorithm.

STUDY DESIGN: Recent advancements in ocular imaging now provide high-resolution, cheap, and non-invasive imaging of the retina. Using the Optos Daytona machine, we collected retinal images from 300 pregnant women at 1st, 2nd and 3rd trimester visits. We further developed an AI framework, combining topological data analysis and deep learning termed DVT-Net (Deep Vascular Topology Network), suitable to characterize the topological and geometrical changes in the retinal vasculature to predict preeclampsia (Figure 1).

RESULTS: From the cohort of 300 pregnancies, 12 women were diagnosed with preeclampsia, 40 with gestational hypertension and 248 had neither. Using images from the first and second trimesters, our computational framework (DVT-Net) and a 10-fold cross validation, we achieved an accuracy of 0.813 (95% CI [0.76, 0.91]) in predicting the above-mentioned pregnancy-disorders.

CONCLUSION: Our approach provides a nuanced description of the retinal vasculature topology in normal and hypertensive pregnancies and serves as an accessible and sensitive imaging surrogate of placental vasculature changes. This may allow early prediction of preeclampsia and gestational hypertension.



1145 Postnatal growth trajectories of offspring exposed to maternal SARS-CoV-2 infection: a pandemic era cohort study

Lydia Shook[1], Victor Castro[2], Roy H. Perlis[2], Andrea G. Edlow[3]
[1]Massachusetts General Hospital, Waban, MA, [2]Massachusetts General Hospital, Center for Quantitative Health, Boston, MA, [3]Massachusetts General Hospital, Boston, MA

OBJECTIVE: Prior birth cohorts have suggested an association between maternal infection in pregnancy and offspring risk for childhood obesity. The objective of this study is to determine whether *in utero* exposure to SARS-CoV-2 is associated with differences in offspring weight, length, BMI, systolic and diastolic blood pressure at 12 months of age.

STUDY DESIGN: This electronic health records-based cohort study included the live offspring of all individuals who delivered during the COVID-19 pandemic (March 1, 2020 - May 31, 2021) at any of 8 hospitals within the Mass General Brigham network. Exposure was defined as a positive SARS-CoV-2 PCR during pregnancy. Offspring weight, length, and BMI percentiles for age were determined using sex-specific WHO growth curves at birth and 12 months (+/- 30 days). Differences in mean offspring weight-for-age, length-for-age, and BMI-for-age percentiles and mean systolic and diastolic blood pressure (BP) between groups were compared at birth and 12 months (Welch's two sample t-test).

RESULTS: The study cohort included 18,323 pregnancies (17,446 unexposed and 877 exposed offspring). Maternal age, gestational age, public insurance, and diabetes were significantly different in SARS-CoV-2 positive pregnancies (Fig. 1A). At birth, weight-for-age percentiles were lower in exposed infants ($p< 0.001$, Fig. 1B); no difference was observed in mean length-for-age or BMI-for-age percentiles. At 12 months of age, mean BMI-for-age percentiles and weight-for-age percentiles were significantly higher in exposed vs. unexposed offspring ($p=0.005$ and $p=0.03$, respectively, Fig. 1B). No significant differences in mean systolic or diastolic BP were observed between groups at 12 months.

CONCLUSION: Altered growth patterns with lower weight-for-age percentiles at birth and higher weight- and BMI-for age percentiles at 12 months of age were observed in infants with in utero exposure to maternal SARS-CoV-2 infection. Larger cohorts and longer follow-up will be necessary to assess the clinical significance of these findings and evaluate risk across the lifespan.

A

Cohort clinical/demographic characteristics

	SARS-CoV-2 negative	SARS-CoV-2 positive	P*
N	17,446	877	
Maternal age, yrs	33 (30, 36)	32 (28, 35)	<.001

"Negative" and "Positive" reflect maternal SARS-CoV-2 PCR test result during pregnancy.

1146 Single-cell transcriptomic profiling of Hofbauer cells reveals varied baseline functions and cluster-specific responses to SARS-CoV-2

Lydia Shook[1], Rebecca Batorsky[2], Rose De Guzman[3], Olyvia Jasset[3], Brittany Goods[4], Roy H. Perlis[5], Andrea G. Edlow[6]
[1]Massachusetts General Hospital, Waban, MA, [2]Tufts University, Data Intensive Studies Center, Medford, MA, [3]Massachusetts General Hospital, Department of Obstetrics and Gynecology, Boston, MA, [4]Dartmouth College, Thayer School of Engineering, Hanover, NH, [5]Massachusetts General Hospital, Center for Quantitative Health, Boston, MA, [6]Massachusetts General Hospital, Boston, MA

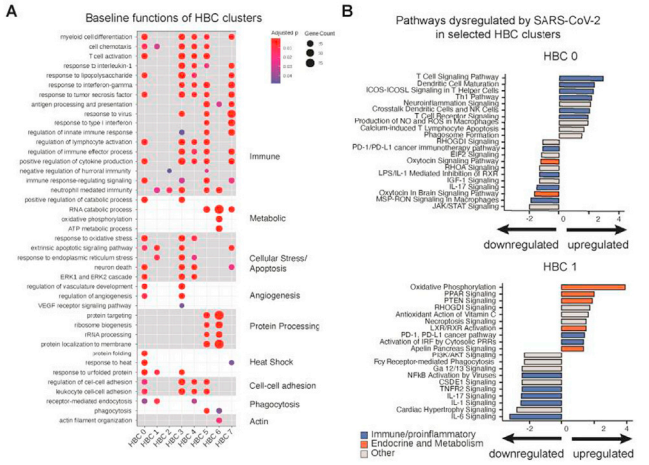
OBJECTIVE: Immune activation at the maternal-fetal interface has the potential to impact fetal development. Hofbauer cells (HBCs) are fetal placental macrophages that play diverse roles in placental immunity and homeostasis. To gain insight into the potential impact of

maternal SARS-CoV-2 infection on fetoplacental immunity, we examined HBC gene expression profiles.

STUDY DESIGN: We performed single-cell RNA sequencing (scRNA-seq, 10x Genomics) on placental macrophage suspensions from individuals with SARS-CoV-2 infection during pregnancy (N=4) and uninfected controls (N=8). Graph-based clustering was performed to identify cell types based on marker gene expression. To characterize unique functions of HBC clusters, Gene ontology (GO) pathway analysis of top marker genes was performed (log fold-change >0.25, Benjamini-Hochberg (BH) p< 0.05). Differentially expressed genes (DEGs) by SARS-CoV-2 status were identified (BH-p < 0.05), and Ingenuity Pathway Analysis (IPA) was used to predict signaling pathways dysregulated by SARS-CoV-2.

RESULTS: 31,719 high-quality cells were identified as macrophages. 8 HBC clusters were identified by expression of distinct marker genes; GO analysis of marker genes revealed variable enrichment in pathways involved in immune, metabolic, angiogenesis, and cellular stress responses by cluster (Fig. 1A). Number of DEGs by SARS-CoV-2 status was highest in clusters HBC0-3 and HBC5. IPA analysis of DEGs by SARS-CoV-2 reveals upregulation of pro-inflammatory responses and phagocytic pathways in two HBC clusters (0, 3) and downregulation in three (1, 2, 5). Pathways involved in T-cell communication are upregulated in HBC 0 in SARS-CoV-2, whereas in HBC 1, metabolic processes are upregulated and innate immune pathways are downregulated (Fig. 1B).

CONCLUSION: ScRNA-seq reveals varied gene programs in HBC subclusters at baseline and differences in response to maternal infection with SARS-CoV-2, with unique clusters engaged in both pro- and anti-inflammatory functions. These data can inform future studies of mechanisms underlying fetoplacental programming in response to maternal viral infection.



1147 The use of intrapartum ultrasound in operative vaginal delivery: a cohort study

Sasha M. Skinner[1], Peter Neil[2], Ryan J. Hodges[2], Nadine murray[2], Cecile Carbonnel[3], John Regan[2], Ben Willem W. Mol[4], Daniel L. Rolnik[4]

[1]Monash Health, Monash Medical Centre, Clayton, Victoria, [2]Monash Health, Clayton, Victoria, [3]Victorian Managed Insurance Authority, Victoria, [4]Monash University, Clayton, Victoria

OBJECTIVE: Operative vaginal birth (OVB) is associated with higher maternal and perinatal morbidity. A safety bundle, including routine intrapartum ultrasound (IPUS), a structured time-out and procedural checklist, aims to improve accuracy of assessing fetal position, interdisciplinary communication and adherence to guidelines at OVB. We aim to compare deliveries where IPUS was and was not used during the safety bundle implementation period at Monash Health.

STUDY DESIGN: We performed a prospective cohort study of OVB and second-stage caesareans with a term singleton cephalic fetus at Monash Health. We compared deliveries when IPUS was and was not used. To control confounding by indication, we estimated propensity scores (PS) for the probability of using IPUS for each case and adjusted the effect estimates for the PS using multivariable logistic regression models. The primary outcome was neonates delivered in an unexpected position. Neonatal and maternal morbidity were also assessed.

RESULTS: There were 1077 second stage operative births from August 2022 to June 2023, of which IPUS was used in 432, and not used in 645. In deliveries where IPUS was used, there was more often fetal malposition (34% vs 23%, p< 0.001) and mid-cavity station (49% vs. 35%, p< 0.001), and greater use of the time-out (56 vs 37%, p< 0.001) and checklist (77% vs 56%, p< 0.001). IPUS was associated with more forceps (66% vs. 58%, adjusted OR [adjOR] 1.35, 95%CI 1.03-1.77, p = 0.028) and a trend to less vacuum births (25% vs. 33%, adjOR 0.75, 95%CI 0.56-1.00, p = 0.052). IPUS was associated with significantly less infants delivered in an unexpected position (0.2% vs. 2.2%, adjOR 0.09, 95% CI 0.01-0.70, p=0.021) and reduced composite neonatal morbidity including Apgar 5 min < 7, cord lactate >8mmol/L, need for resuscitation, birth trauma or neonatal intensive care unit admission (20.6% vs. 25.3%, adjOR 0.66 [95%CI 0.48-0.91], p = 0.011).

CONCLUSION: Use of IPUS as part of an OVB safety bundle was associated with less infants delivered in an unexpected position and reduced neonatal morbidity.

Table 1. Results

1148 Politics v. Applicants: Effects of the Roe v. Wade overturn on prospective MFM fellowship applicants

Megan M. Smith[1], Adam K. Lewkowitz[2], Dayna Burrell[2]
[1]Alpert Medical School of Brown University and Women & Infants Hospital of Rhode Island, Providence, RI, [2]Warren Alpert Medical School of Brown University, Women & Infants Hospital Rhode Island, Providence, RI

OBJECTIVE: The overturn of Roe v. Wade continues to have a dramatic effect on MFM clinical practices, especially in abortion restrictive states. We aimed to assess how the overturn of Roe v. Wade affected application decisions of prospective MFM fellowship applicants.

STUDY DESIGN: This is a cross-sectional survey distributed to prospective MFM fellowship applicants in the 2023 application cycle. A survey link was sent to US residency program directors to distribute to senior residents planning to apply into MFM in the 2023 application cycle and circulated electronically to all SMFM members in March 2023. The dual primary outcome was whether the overturn of Roe v. Wade affected the number and geographic distribution of MFM programs to which the applicants planned to apply. Secondary outcomes included applicants' desires to receive dilation and evacuation (D&E) training during MFM fellowship. In the past five years, 153 to 192 residents applied to MFM fellowship per cycle. Assuming a 60% response rate, we aimed to survey 100 prospective applicants. Anonymous survey data without participant identifiers was collected; thus a waiver of consent from our institution's IRB was obtained.

RESULTS: Among 37 responders, most identified as women (83.8%) and white (73.0%). The majority of survey participants were from the Midwest (41.7%) or the Northeast (36.1%). The majority of participants planned to apply to the same number of programs (64.9%), but 67.6% of participants planned to apply to fewer programs located in abortion-restrictive states and 97.3% of participants planned to apply to the same or more programs in abortion accessible states. A large majority of participants (86.5%) were interested in receiving D&E training during fellowship.

CONCLUSION: Though the low survey response rate introduces risk of selection bias, the overturn of Roe v. Wade has affected how prospective MFM fellowship applicants plan to apply. Given that most respondents desired D&E training during MFM fellowship, applicants may disproportionately avoid seeking training in abortion restrictive states.

Table 1: Survey responses

	N=37 (%)
Has the overturn of Roe affected how you are planning to apply into MFM fellowship?	
Yes	21 (56.8%)
No	12 (32.4%)
Unsure	4 (10.8%)
Overall, I plan to apply to:	
Fewer programs	6 (16.2%)
More programs	7 (18.9%)
The same number of programs	24 (64.9%)
When considering applying to fellowships in abortion restrictive states, I plan to apply to:	
Fewer programs	25 (67.6%)
More programs	1 (2.7%)
The same number of programs	11 (29.7%)
When considering applying to fellowships in abortion accessible states, I plan to apply to:	
Fewer programs	1 (2.7%)
More programs	18 (48.6%)
The same number of programs	18 (48.6%)
What types of abortion education/training have you received in residency (select all that apply):	
Medical management of abortion	36 (97.3%)
Manual vacuum aspiration	37 (100%)
Suction dilation & curettage	36 (97.3%)
Dilation & evaluation	33 (89.2%)
Are you interested in receiving dilation & evacuation training during your fellowship?	
Yes	32 (86.5%)
No	3 (8.1%)
Undecided	2 (5.4%)

1149 The Impact of Obstetric Risk Factors for Preterm Delivery among Women with Cervical Cerclage

Amir Snir[1], Polina Schwarzman[2], Tamar Wainstock[3], Eyal Sheiner[4]
[1]Soroka University Medical Center, Beer-Sheva, HaDarom, Israel, [2]Soroka, Beer-Sheva, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom, [4]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: Cervical cerclage is considered as an effective procedure for patients with cervical insufficiency. However, these patients still remain at a higher risk for preterm delivery. Several studies have attempted to ascertain predictors for preterm delivery among patients with cervical cerclage with mixed findings. We aimed to study the impact of obstetric risk factors for preterm delivery among women with cervical cerclage.

STUDY DESIGN: A population-based cohort study was performed including all patients with cervical cerclage. Deliveries occurred between the years 1991-2023 in a tertiary medical center. Multiple gestations and pregnancies with chromosomal abnormalities were excluded from the study. Diagnoses were pre-defined based on ICD-9 codes, as recorded in the hospital medical files. A multiple linear regression model was used to assess the impact of maternal characteristics as well as pregnancy complications on the length of pregnancy.

RESULTS: A total of 1416 deliveries following a pregnancy with cervical cerclage were included in the study. After univariate analysis, the following factors were found to be associated with preterm delivery in our study group**:** fetal growth restriction, placental abruption, nulliparity and advanced maternal age. Using a multiple linear regression model, with backward elimination, the impact of these variables on the length of pregnancy was assessed ($R^2 = 0.18$, $p < 0.001$). The mean gestational age at birth among patients ***without*** risk factors was 38.4 weeks. Placental abruption reduced gestational age by 7 weeks, chorioamnionitis reduced gestational age by 6.27 weeks, fetal growth restriction reduced gestational age by 1.2 weeks, nulliiparity reduced gestational age by 0.89 weeks, and maternal age over 35 years reduced gestational age by 0.21 weeks (Table).

CONCLUSION: Placental abruption, chorioamnionitis, fetal growth restriction, nulliiparity and maternal age over 35 years are independent risk factors for preterm delivery among patients with cervical cerclage.

The impact of obstetric risk factors and complications on the length of pregnancy among patients with cervical cerclage.

Characteristics	B (CI 95%)	SE	P Value

1150 Risk factors for preterm delivery in monochorionic diamniotic pregnancies undergoing selective cord occlusion

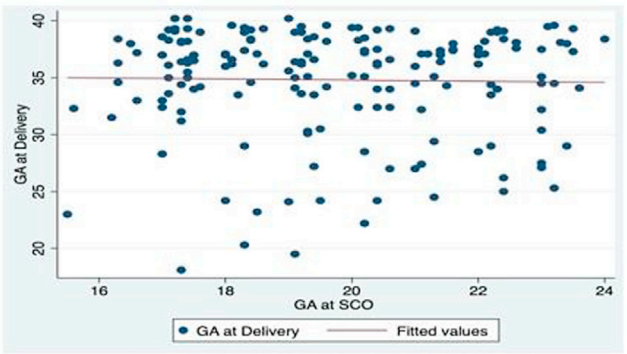
Shelly Soni[1], Juliana S. Gebb[2], Christina Paidas Teefey[1], Julie Moldenhauer[3], Nahla Khalek[2]
[1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Center for Fetal Diagnosis & Treatment, Children's Hospital of Philadelphia, Philadelphia, PA, [3]Richard D. Wood, Jr. Center for Fetal Diagnosis & Treatment, Children's Hospital of Philadelphia, Perelman School of Medicine of the University of Pennsylvania, Philadelphia, PA

OBJECTIVE: To review risk factors for preterm delivery in a cohort of monochorionic diamniotic twin pregnancies undergoing selective cord occlusion (SCO) using radiofrequency ablation (RFA).

STUDY DESIGN: Single center retrospective analysis of complex monochorionic pregnancies managed with SCO via RFA between 2014-2022. The spontaneous preterm group was compared to the full-term delivery group. Correlation analysis between gestational age at SCO and gestational age at delivery was performed. Kaplan-Meier survival analysis was created for time to delivery between different diagnostic indications and log-rank test was performed.

RESULTS: Total live birth rate in the twin population undergoing RFA was 86% (160/186) with a median gestational age at delivery of 36.1 weeks. Total survivor to discharge rate was 82.3% (153/186). To evaluate risk factors for premature birth, pregnancies with dual demise within the first post-operative week and iatrogenic preterm deliveries were excluded. A total of 155 pregnancies were evaluated - 76 (49%) had spontaneous preterm delivery and 79 (51%) delivered full term. Preoperative variables were comparable in the two groups. A higher proportion of women undergoing RFA for TTTS had spontaneous preterm delivery (34.2% versus 19%, $p< 0.05$). Adding amnioreduction in conjunction with RFA did not increase the risk of preterm delivery (13.2% vs 10.1%). The rest of the operative variables did not influence the rates of premature delivery. Gestational age at procedure did not correlate with gestational age at delivery ($p=0.78$). Kaplan−Meier curves showed that the proportion of pregnancies remaining undelivered from the time of radiofrequency ablation until 37 weeks' gestation was lower for the indication of TTTS.

CONCLUSION: Most perioperative variables did not influence the rates of spontaneous premature delivery in the monochorionic twin population undergoing RFA. Preoperative indication of TTTS was associated with an increased risk of preterm birth, possibly suggesting the underlying diagnosis increasing risk for prematurity rather than the procedure.



Graph 1 Correlation analysis of gestational age at SCO and gestational age at delivery

1151 Promoting Timely Treatment of Severe Hypertension with Live Visual Metric on Labor and Delivery

Monica Sosa, Nadine Martinez, La Vone Simmons, Ralph N. Burns
University of Washington Medical Center, Seattle, WA

OBJECTIVE: To assess if a live visual metric in common work areas would improve timely treatment of severe hypertension (sHTN) episodes, as defined by the Society for Maternal-Fetal Medicine's suggested sHTN quality metric.

STUDY DESIGN: This is a single institution prospective observational quality improvement study. The visual metric is a g-chart, converted to a 'scoreboard'-poster that displays (1) the number of consecutive days sHTN episodes were managed appropriately and (2) the best streak without metric failure. The AdaptX platform tracked these episodes. On March 9, 2023 the visual metric was displayed in the Labor and Delivery and Postpartum multidisciplinary team-rooms. The primary outcome was the rate of timely treatment of sHTN episodes, aiming to increase our success rate from 93% to 100% in the following five months post-implementation.

RESULTS: In the 23 months prior to implementation, from April 1, 2021 to March 8, 2023, there were a total of 535 sHTN episodes, 93.6% with successful timely treatment. This represented an average of 18 days between metric failures (+/- 22.4; upper control limit 189) and a median of 8 sHTN cases between failure events (IQR 10; upper control limit 51). In the five months after implementation of the visual metric, from March 9, 2023 to August 6, 2023, there were a total of 102 sHTN episodes, 99.0% with successful timely treatment.

Only one failure occurred in this time period, with a best streak of 104 consecutive days (74 consecutive cases) without metric failure. The poster continues to be regularly updated.

CONCLUSION: A low cost, live visual metric in common work areas appears to be a promising motivator for multi-disciplinary clinical performance to enhance patient safety. We hope to implement standing order sets that would improve timely treatment of sHTN episodes, assess staff attitudes after implementation of the visual metric and further analyze the location and time of day in which metric failures occurred.

Table 1.1 Baseline Characteristics

	Pre-Visual Metric Implementation (*n*=535) Mean (Range) or *n* (%)	Post-Visual Metric Implementation (*n*=102) Mean (Range) or n (%)
Age (years)	32.98 (17-53)	33.19 (19-48)
Gravidity	2.65 (1-15)	2.69 (1-7)
Parity	0.93 (0-10)	0.81 (0-5)
Maternal Race

Asian	82 (15.33)	13 (12.75)
Black/African American	78 (14.58)	19 (18.63)
Unknown	50 (9.35)	7 (6.86)
American Indian/Alaskan Native	12 (2.24)	
Other	6 (1.12)	
Hispanic ethnicity	53 (9.91)	16 (15.69)

Table 1.2 Timely treatment of severe HTN episodes

	Pre-Visual Metric Implementation (*n*=535) *n* (%) or Mean (SD) or Median (IQR)	Post-Visual Metric Implementation (*n*=102) *n* (%)
Timely treatment of sHTN episode		
Yes	501 (93.6)	101 (99.0)
No	34 (6.4)	1 (1.0)
Average of days between metric failures	18 (+/- 22.4)	104*
Median of sHTN cases between metric failures	8 (10)	74‡

*Only one failure has occurred since the implementation of the visual metric (from March 9, 2023 to August 6, 2023) thus an average of days between metric failures unable to be calculated

‡Given only one failure has occurred since the implementation of the visual metric (March 9, 2023 to August 6, 2023) this represents the number of cases prior to the failure, a median of cases unable to be calculated

1152 Positive Carrier Screening for Alport Syndrome: A Need for Greater Awareness

Vivienne Souter[1], Lisa Johnson[1], Sarah Keilman[1], Emily Becraft[1], Elizabeth Repass[1], Brittany Prigmore[1], Yang Wang[1], Hossein Tabriziani[1], Peter Benn[2]

[1]Natera, Inc., Austin, TX, [2]University of Connecticut Health Center, Farmington, CT

OBJECTIVE: Alport syndrome can be inherited as an autosomal recessive, dominant or X-linked condition. *COL4A3* and *COL4A4* genes are included in some carrier screening panels due to their association with autosomal recessive Alport syndrome. Carriers for pathogenic (P) or likely pathogenic (LP) variants in these genes have a frequency of approximately 1 in 279 and 1 in 332, respectively (Souter et al., Obstet Gynecol; In Press), and these individuals can also express symptoms, including hematuria and progressive renal disease. We present follow up data for pregnant people identified through carrier screening as carriers for P/LP variants in one of these two genes.

STUDY DESIGN: This retrospective observational study included follow-up of pregnant people (aged 18-55 years) identified as heterozygous for a P/LP variant in *COL4A3* or *COL4A4* through a 274 gene panel ordered from a US commercial laboratory (01/2020-09/2022). Pregnancy outcomes were requested from providers offices. Data were de-identified prior to analysis. Pre-pregnancy health, hematuria, specialist consults, and pregnancy complications were evaluated.

RESULTS: To date, outcomes are available for 76 pregnant people: 45 were heterozygous for a *COL4A3* variant and 31 for a *COL4A4* variant. Hematuria or a pre-pregnancy history of renal disease was present in 6.6% and pre-pregnancy hypertension was reported in 3.9%, but only a minority of patients with these symptoms had a nephrology referral. Preeclampsia in the most recent pregnancy was reported in 11.8%. Overall, 1 in 15 patients were referred to a nephrologist, 13 (17.1%) to maternal fetal medicine, and 23 (30.3%) were referred for comprehensive genetic counseling.

CONCLUSION: Our preliminary data showing low specialist referral rates suggest that the potential for developing Alport syndrome in people identified as carriers might not be widely recognized among obstetric professionals. The significance of symptoms such as hematuria might not be recognized and the opportunity for nephrology care and early intervention could be missed.

1153 Progression in AHA stage of hypertension and cardiovascular disease risk among ACOG-defined normotensive individuals

Anna P. Staniczenko[1], Jessica Pudwell[2], Christina M. Ackerman-Banks[3], Shelby Smith[4], Heather S. Lipkind[5]

[1]Columbia University Irving Medical Center, New York, NY, [2]Queen's University, Kingston, ON, [3]Baylor College of Medicine, Houston, TX, [4]Yale University, New Haven, CT, [5]Weill Cornell, New York, NY

OBJECTIVE: Antenatal and postpartum hypertension (HTN) are associated with long-term cardiovascular disease (CVD) risk. We aimed to analyze the prevalence of worsening blood pressure (BP) during low-risk pregnancies and implications for long-term CVD risk.

STUDY DESIGN: This retrospective study included singleton pregnancies and excluded those with CVD, diabetes, renal disease, chronic HTN as defined by ACOG, or using anti-HTN medication antenatally (AN: prior to gestation or < 20w gestation). Participants were categorized as Normal, Elevated, or Stage 1 HTN AN based on AHA guidelines, and again categorized postpartum (PP, measured at 6-12 months), with additional categories of Stage 2 HTN and use of anti-HTN medication. The exposure was persistent or worsening HTN (PWH), defined as unchanged not-normotensive category when comparing AN and PP BP, worsening in category of HTN when comparing AN and PP BP, or using an anti-HTN medication PP. The comparison group was those who remained normotensive or had improved BP PP. The primary outcome was prevalence of high lifetime CVD risk at 6-12 months PP. Prevalence of metabolic syndrome and 30-year CVD risk scores were also calculated. Outcomes were compared using chi-squared or Mann-Whitney U tests.

RESULTS: Of 485 participants, 186 (38.4%) had worsening AHA Stage of HTN at 6-12 months PP and 72 (14.8%) had persistently abnormal BP (Table), so that 53.2% of the cohort had the exposure of PWH. Those with PWH were more likely to have high BMI (28.8 [24.0-34.6] vs. 24.5 [21.9-28.5]; $p< 0.01$) and a HTN disorder of pregnancy (90.7% vs. 64.8%; $p< 0.01$). Participants with PWH were more likely to have high lifetime risk of CVD (79.3% vs. 37.8%; $p< 0.01$). Participants with PWH had higher prevalence of metabolic syndrome and higher 30-year CVD risk scores (Table).

CONCLUSION: Blood pressure worsened in a high fraction of participants after "low-risk" pregnancies: more than a third progressed in AHA Stage of HTN. Those with persistently abnormal or worsening BP at 6-12 months PP are at significantly elevated risk of long-term CVD and may benefit from targeted postpartum follow-up.

Table: Progression in AHA Stage of HTN from antenatal (pre-gestation or <20w gestation) to postpartum (6-12 months postpartum) and long-term risk of cardiovascular disease

Antenatal Blood Pressure (Pre-gestation or <20 weeks GA) ↓ / Postpartum Blood Pressure (6-12 months postpartum) →	Normal SBP <120 and DBP <80	Elevated SBP 120-129 and DBP <80	Stage 1 HTN SBP 130-139 or DBP 80-89	Stage 2 HTN SBP ≥140 or DBP ≥90	Antihypertensive Medication
Normal SBP <120 and DBP <80	157	11	53	26	10
Elevated SBP 120-129 and DBP <80	41	9	30	14	3
Stage 1 HTN SBP 130-139 or DBP 80-89	29	6	57	32	7

1	Improved: abnormal stage antenatal, normotensive postpartum	70 (14.4%)
2	Normal: normotensive antenatal, normotensive postpartum	157 (32.4%)
3	Persistent: abnormal stage antenatal, unchanged stage postpartum	72 (14.8%)
4	Worsening: increased by one or more AHA category postpartum	186 (38.4%)

	Blood Pressure Change from Antenatal (pre-gestation to <20w GA) to Postpartum (6-12 months postpartum)

1154 Prenatal Vitamins: An Analysis of Most Common Ingredients and Cost

Nicholas Stansbury, Katie Kolp
UTHealth, San Antonio, TX

OBJECTIVE: Prenatal vitamins are a multi-million-dollar industry and are recommended for every pregnancy. However, ingredients, dosages, and costs vary widely. This study identifies the most common active ingredients and cost range in popular prenatal vitamins in order to evaluate if common over-the-counter prenatal vitamins meet the America College of Obstetricians and Gynecologists (ACOG) vitamin and mineral recommendations during pregnancy.

STUDY DESIGN: The Amazon July 2023 best-seller list for prenatal vitamins was analyzed. The top 50 products were reviewed. The ingredient list and cost per serving was collected for each prenatal vitamin and these ingredients were compared against the ACOG vitamin and mineral recommendations. Descriptive statistics were used to analyze the data.

RESULTS: 48 prenatal vitamins were included with 58 different active ingredients. The top 5 most common were**:** Vitamin D (94%), Vitamin B6 (94%), Vitamin C (92%), Vitamin E (92%), and Vitamin B12 (92%). Folate and Iron were contained in 89% and 75%, respectively. 44% of prenatal vitamins contained all ingredients recommended by ACOG and only 31% contained all the vitamins and minerals in the recommended dosages. The prices ranged from 0.11-2.98$ per-serving.

CONCLUSION: While they are many prenatal vitamins that contain a wide variety of supplements, only about 1/3 of the top 50 prenatal vitamins listed on Amazon contained the recommended vitamins and minerals at recommended doses in accordance with the ACOG recommendations. Furthermore, some of the most well-studied prenatal ingredients including folate and iron were only contained in 10 and 25% of the most common prenatal vitamins, respectively. In a time when many patients utilize online shopping for their basic needs, including prenatal vitamins, practitioners need to be aware that not all prenatal vitamins are created equally. Moreover, there is a wide range of costs per serving associated with prenatal vitamins with no correlation between cost and recommended ingredients or dosages. Practitioners should educate themselves on common vitamins with the recommended dosages.

1155 Prenatal evaluation of fetal abdominal calcifications in the age of advanced sonographic and genetic screening

Aneesa T. Stewart[1], Erin Morris[2], Aina Rattu[2]
[1]University of Vermont, Shelburne, VT, [2]University of Vermont, Burlington, VT

OBJECTIVE: The advent of maternal cell free DNA (cfDNA) screening has led to early detection of fetuses with chromosomal abnormalities. Similarly, prenatal ultrasound technique and equipment have advanced leading to increased detection of soft markers of aneuploidy such as abdominal calcifications (AC). The purpose of our study was to assess neonatal outcomes after detection of fetal ACs.

STUDY DESIGN: This is a retrospective case series of patients diagnosed with fetal abdominal calcifications at a single center between 2016 and 2023. A query was created within our ultrasound software (Viewpoint 2.0). Presence, location, number and size of ACs, presence of other soft markers and abnormalities were collected. Chart review was used to determine gestational age (GA) of diagnosis, maternal demographics, viral serologies, genetic/ carrier screening and pregnancy outcomes.

RESULTS: 130 patients had fetal ACs. Prenatal detection of ACs increased steadily within the study period. 73.5% of patients had low risk cfDNA screening, 6.1% had abnormal cfDNA with increased risk of Trisomy 21 and 20.9% of patients opted out of screening. All genetic screening results were known at the time of identification of ACs. Table 1 shows evaluation and outcomes of ACs based on genetic testing. 120 patients (92%) had extrahepatic ACs in the left upper quadrant adjacent to the stomach with other locations including intrahepatic and gastric foci. Patients who had low risk cfDNA underwent the same evaluation (maternal fetal medicine consultation, viral serologies, cystic fibrosis testing and further ultrasounds) as those that did not have testing completed. 95.7% of all patients underwent follow up ultrasound which showed either stable or resolved ACs. The mean GA of delivery was 38 6/7 weeks with mean birthweight and 1 and 5 minute APGAR scores of 2973 gm and 8/8.86 respectively. No neonates in our series had follow up imaging of prenatally diagnosed ACs by 1 month or 1 year of life.

CONCLUSION: Ultrasound identification of fetal ACs resulted in increased testing and follow-up without clinically relevant abnormalities in any infants.

1156 Preeclamptic or History-of-COVID-19 CD4+ T Cells Contribute to Hypertension, Neurovascular Dysfunction Postpartum and in Offspring

Kimberly S. Sullivan[1], Evangeline Deer[1], Owen Herrock[1], Baoying Zheng[1], Rachael Morris[2], Richard Roman[1], T. Y. Turner[1], Nathan Campbell[1], Mariah Wilson[1], Lorena M. Amaral[1], Babbette LaMarca[1]

[1]University of Mississippi Medical Center, Jackson, MS, [2]University of Mississippi Medical Center, Flora, MS

OBJECTIVE: Preeclampsia (PE), new hypertension (HTN) in pregnancy, and COVID-19 infection (CV Hx) are associated with activated CD4+ T cells and neurological dysfunction. We examined the contribution of CD4+ T cells from PE and CV Hx to PE phenotype, maternal neurovascular function, fetal growth, and offspring cognitive function.

STUDY DESIGN: One million placental CD4+ T cells from PE and normotensive (NT) patients with or without CV Hx in pregnancy were injected i.p. into nude athymic rats on gestational day (GD) 12. Memory navigation errors were assessed by Barnes maze and novel object recognition on GD 19 and 12 weeks postpartum (PP) in dams and offspring, and cerebral blood flow (CBF) was measured by Doppler flowmetry. A two-way ANOVA was used for statistical analysis.

RESULTS: MAP (mmHg) increased in PE CV Hx (113±2, n=8) and PE (115±2, n=10) compared to NT CV Hx (104±4, n=7) and NT (98±2, n=7 $p< 0.05$) during pregnancy and remained increased 12 weeks PP in PE CV Hx (111±4, n=4) and PE (115±2, n=5) compared to NT CV Hx (100±4, n=5) and NT (99±3, n=4 $p< 0.05$). PE groups exhibited short term memory dysfunction and greater latency ($P< 0.05$) with more errors in the maze compared to NT groups as well as impaired CBF autoregulation at 3 months PP. No differences in weight, MAP, or latency at age 3 months were observed among the offspring groups. CV Hx offspring had more errors in the Barnes maze compared to offspring of PE and NT without CV Hx.

CONCLUSION: CD4+ T cells from PE with or without CV Hx in pregnancy cause HTN, impaired CBF autoregulation, and cognitive dysfunction during pregnancy and PP in recipients compared to recipients of NT CD4 + T cells. CD4+ T cells from either CV Hx group results in cognitive dysfunction in offspring. This data corroborates the important role of CD4+ T cells in development of long-term sequalae from HTN, including impaired maternal neurological function in pregnancy and PP and cognitive decline in her offspring.

1157 Placental lipid content is associated with neonatal adiposity independent of maternal obesity

Deanna Sverdlov, Lema Abuoqab, Patrick Catalano, Tomoko Kaneko-Tarui, Perrie O'Tierney-Ginn

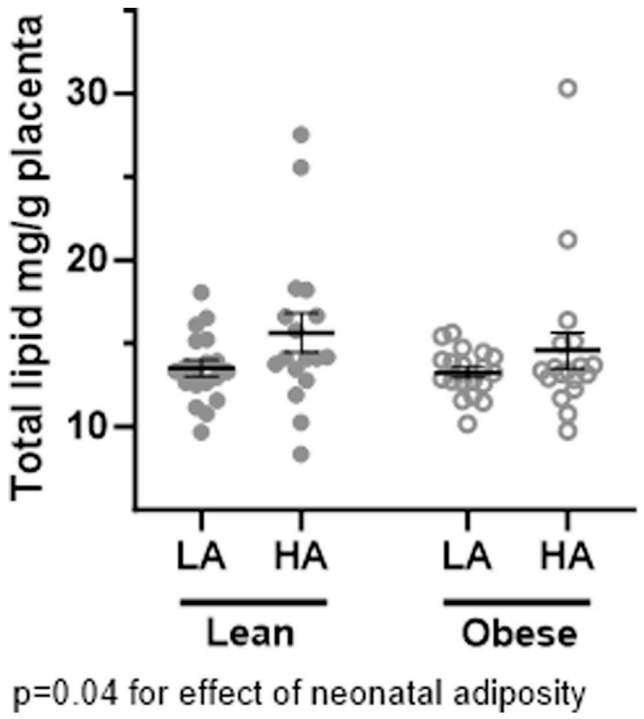
Tufts Medical Center, Boston, MA

OBJECTIVE: Research has shown that placental lipid metabolism is altered in obese patients and that neonates exposed to obesity *in utero* have higher adiposity at birth on average. However, lean patients may also have infants with high adiposity, suggesting that other factors may modulate this relationship. The objective of this study was to examine the relationship between placental lipid composition and neonatal adiposity in patients with and without obesity.

STUDY DESIGN: Placental samples (N=77) were collected from healthy participants delivered via scheduled cesarean at term and grouped by maternal pre-pregnancy body mass index (BMI) (lean (LE), BMI 18 – 24.9 kg/m^2 vs. obese (OB), BMI 30-40 kg/m^2) and then by tertiles of % body fat at birth measured by skinfold (low adiposity (LA), 1st tertile vs. high adiposity (HA), 3rd tertile) resulting in 4 groups**:** LELA, LEHA, OBLA, OBHA. Total lipids were extracted from the placenta using the Folch method. Placental lipids were separated into lipid species using thin layer chromatography. The effect of maternal obesity and neonatal adiposity on placental lipid composition was analyzed using 2-way ANOVA.

RESULTS: High neonatal adiposity was associated with increased total placental lipid content (p=0.04), cholesterol ester (p=0.015), total phospholipid (p=0.019), and triglyceride (p=0.02), independent of maternal obesity. Maternal obesity had no significant effect on placental lipid content when neonatal adiposity was accounted for, and no interaction between the two variables was detected. No differences in free cholesterol or free fatty acid content was detectable between groups.

CONCLUSION: High total placenta lipid content was associated with high neonatal adiposity at birth, but not to maternal obesity. Esterified lipid species comprised the main differences between groups, whereas no differences were seen among non-esterified lipids. These findings suggest that placental lipid metabolism may modulate fetal fat accrual independent of maternal BMI.



1158 The placental drainage effect on quantitative blood loss after vaginal delivery in an urban population

Emma J. Swayze, Ethelin Cammock, Sierra Bishop, Natalie Oxley, Kristen Wyckoff, Marina Santa Cruz Terrazas
University of Tennessee Health Science Center, Memphis, TN

OBJECTIVE: Postpartum hemorrhage (PPH) is the leading cause of maternal morbidity and mortality. Placental cord drainage (PCD) is the unclamping of the umbilical cord to allow drainage of blood from the placenta, intended to minimize PPH. This technique has been studied predominantly among healthy patients, so this trial was designed to investigate the effect of PCD in a high-risk population.

STUDY DESIGN: We conducted a randomized controlled trial examining the impact of PCD prior to placental delivery on quantitative blood loss (QBL) in women ages 18 to 45 undergoing term vaginal delivery at a safety-net, county hospital in Memphis, TN. Women were randomly assigned to one of two groups: 1. PCD prior to placental delivery and 2. Immediate delivery of the placenta. Two-sided t testing and Mann Whitney U testing were used to compare QBL, change in hematocrit, and duration of third stage of labor, as appropriate. Analyses were performed on Stata version 16.1 (StataCorp, College Station, Texas).

RESULTS: Between January 2022 and January 2023, 49 total patients met inclusion criteria. 88.6% of participants identified as Black, and 79.2% of participants were enrolled in Medicaid insurance plans. The average body mass index was 34.1. The average gestational age at delivery was 39.0 weeks. There was no significant difference in baseline characteristics between groups ($p > 0.05$ for all comparisons). At time of delivery, 21 (42.9%) patients underwent placental drainage and 28 (57.1%) did not. The average QBL was 273.3 mL in group 1 and 377.8 in group 2 ($p=0.01$). The average percent change in hematocrit before and after delivery was -3.2% in group 1 versus -3.5% in group 2 ($p=0.71$). There was no significant change in the average duration of the third stage of labor (5.8 minutes in group 1 versus 7.4 minutes in group 2; $p=0.95$).

CONCLUSION: PCD is a low cost, simple intervention that may be utilized to reduce average QBL after a vaginal delivery in high-risk populations.

Table 1: Delivery outcomes in patients with placental drainage versus no placental drainage

	Group A: Placental Drainage: Mean (SE), N=21	Group B: No Placental Drainage: Mean (SE), N=28	Mean Difference (SD)	95% CI	P value
Average % change in hematocrit	3.2 (0.6)	3.5 (0.5)	3.4 (2.7)	(2.62-4.20)	0.71
Average QBL (mL)	273.3 (30.0)	377.8 (32.0)	333.3 (23.3)		**0.01**
Average duration of third stage of labor (minutes)	5.8 (0.34)	7.4 (1.4)	6.6 (0.8)	(5.04- 8.21)	0.95
Blood loss >1000 mL	0 (0)	0 (0)			n/a
Blood loss >500 mL	1 (5.3)	3 (11.1)			0.49
Use of uterotonics	11 (57.9)	13 (48.2)			0.52
Post-delivery transfusion	2 (10.0)	1 (4.2)			0.58

1159 Reducing blood transfusion administration by introducing a structured intravenous iron protocol for maternal postpartum anemia

Liliya Tamayev[1], Kira Nahum Sacks[2], Tamar Shyldkrot[2], Moran Shmilovitz[2], Asher Winder[2], Anat Engel[2], Eran Weiner[3]
[1]Wolfson Medical Center, Holon, Tel Aviv, [2]Wolfson Medical Center, Ra'anana, Tel Aviv, [3]Wolfson Medical Center, Tel Aviv, HaMerkaz

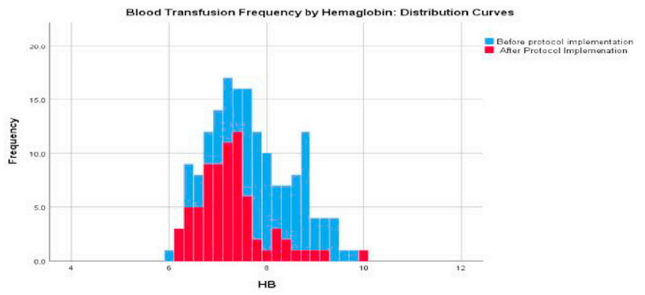
OBJECTIVE: To investigate the effect of implementation of an institutional protocol targeting postpartum anemia with intravenous iron sucrose infusion (Venofer), on the use of red blood cell transfusions (RBCT).

STUDY DESIGN: A detailed structured protocol for managing maternal anemia was introduced starting July 2021 in a single tertiary center based on different hemoglobin (Hb) concentrations, symptoms, and vital signs. The protocol aimed to educate and encourage the routine use of Venofer instead of RBCT in patients with Hb concentrations between 7-10 g/dL.

A comparative analysis was conducted across two distinct time frames: the year preceding the protocol implementation (July 2020 to June 2021), a transitional period (which was excluded from analysis), and the year of protocol implementation (January 2022 to December 2022). All maternal cases that underwent RBCT were enrolled in the study.

RESULTS: Over the course of 24 months in this study, a total of 94 women underwent RBCT prior to the introduction of the protocol, with this number decreasing to 73 after protocol implementation. A comparative analysis between women who received RBCT prior to and following protocol implementation, revealed that the proportion of women receiving RBCT for Hb levels between 8-10 g/dl, dropped from 41.5% to 13.7%. The average Hb for initiating RBCT was lowered from 7.9 to 7.2 following the introduction of the protocol ($pv< .001$). Moreover, there was a significant decrease in RBCT use in each Hb concentration separately (Figure 1). Furthermore, after adjusting for the difference in the number of deliveries during each study period, there was a notable 41% reduction in the utilization of RBCT in the year after protocol implementation, yielding an odds ratio of 0.59 [CI: 0.44-0.79] of receiving RBCT.

CONCLUSION: The implementation of a simple management protocol targeting postpartum anemia using Venofer was associated with a significant 41% decrease in the utilization of RBCT in our center.



1160 The impact of 'low sugar diet' on amniotic fluid index in patients with idiopathic polyhydramnios

Liliya Tamayev[1], Ayala Shevach Alon[1], Eva Dadush[1], Eran Weiner[2], Liat gindes[1]
[1]Wolfson Medical Center, Holon, Tel Aviv, [2]Wolfson Medical Center, Tel Aviv, HaMerkaz

OBJECTIVE: Polyhydramnios is involved in approximately 2% of pregnancies. The leading known cause is gestational diabetes, and a strict diet resolved the problem in most cases. However, in about 60% of the patients, the cause is not identified. The aim of the study is to evaluate the influence of a low simple carbohydrate, high vegetable and fiber diet consumption on the amniotic fluid index (AFI) in women with idiopathic polyhydramnios.

STUDY DESIGN: A total of 50 pregnant women were randomly divided into two groups. The intervention group received dietary recommendations aimed at promoting a healthy diet, including a low simple carbohydrate and high vegetable and fiber diet. The control group was given a normal diet for pregnant women. The AFI was measured after two weeks blindly by a different sonographer. The primary outcome was the AFI measured two weeks after the implementation. Maternal and neonatal outcomes were compared as secondary outcomes.

RESULTS: AFI decreased on average by 18.4% and 4.8%, respectively, in favor of the intervention group (p-value=0.003). A statistically significant difference was found between the two groups when measured after two weeks (22.7 cm and 25.9 cm, respectively) (table 1). A significant decrease of 6.7% was shown in neonatal weight at birth in the intervention group. In 15 of 22 patients in the study group, AFI returned to normal after 2 weeks, a reduction from 27 cm at enrollment in the study, to an average of 20 cm (a decrease of 25.7% in AFI). No difference was seen in maternal or neonatal outcomes.

CONCLUSION: 'Idiopathic Polyhydramnios' in most cases is due to high sugar levels in the blood of pregnant women and can be treated by a proper diet of complex carbohydrates, vegetables, and fruits and a reduction in free sugar. We offer a therapeutic alternative without any danger or potential harm and with a positive effect for the pregnant woman and the newborn.

Table 1

	Control group [n=25]	Study group [n=22]	P_value
The reduction in AFI between 2 measurements (%)	4.8%	18.4%	**0.0026**
Average of first AFI measurement (cm)	27.3	27.9	0.539
Average of second AFI measurement (cm)	25.9	22.7	**0.022**
Gestational week on first measurement	31.6	30.4	0.281
Gestational week on second measurement	34.3	32.7	0.124

1161 Prostaglandin administration and cesarean for non-reassuring fetal status in preterm induction of labor

Rachel A. W. Taylor[1], David M. Stamilio[2]
[1]ECU Brody School of Medicine Department of Ob/Gyn, ECU Health, Greenville, NC, [2]Wake Forest University School of Medicine, Winston-Salem, NC

OBJECTIVE: The primary objective was to estimate the association between prostaglandin administration in preterm labor induction and cesarean for non-reassuring fetal status. An *a priori* secondary aim was to assess this association in the subgroup of preterm patients with fetal growth restriction (FGR).

STUDY DESIGN: This was a retrospective cohort study using the NICHD Consortium for Safe Labor (CSL) database. Only patients undergoing preterm labor induction were included for analysis. The exposure was prostaglandin E as an induction agent. The primary outcome was cesarean performed for non-reassuring fetal status. Secondary outcomes included rate of cesarean for all indications as well as specified maternal and neonatal adverse outcomes. We used unadjusted and multivariable analyses to estimate the independent effect of prostaglandins on the primary outcome. Multiple imputation was performed to address missing data for maternal body mass index.

RESULTS: Among 228,438 patients in the CSL cohort, 4789 patients underwent preterm labor induction and 833 (17%) of these received prostaglandins. After adjusting for confounding variables, rate of cesarean for non-reassuring fetal status was increased nearly 75% in the prostaglandin-exposed population and the cesarean rate for all indications more than doubled (Table 1). Prostaglandin-exposed patients had lower rates of chorioamnionitis (1.7% v. 4.0%, $p < 0.0001$). Neonates in the prostaglandin-exposed group had longer NICU admissions (22.65±21.71 days v. 17.16±22.16 days, p=0.0003) but lower rates of sepsis (4.0% v. 6.1%, p=0.017). In comparison to the total cohort, the FGR subcohort had increased risk for cesarean for non-reassuring fetal status but not for cesarean for other indications.

CONCLUSION: Prostaglandin administration in preterm induction of labor is associated with increased rate of cesarean for non-reassuring fetal status as well as for cesarean overall. The association between prostaglandin use and cesarean for non-reassuring fetal status is amplified in preterm pregnancies complicated by FGR.

Table 1. Outcome of Cesarean for Preterm IOL

	PG Exposure	Non-PG Exposure	aOR	CI
Preterm birth cohort	**N = 833**	**N = 3956**		
Cesarean for NRFS	130 (15.6)	335 (8.5)	1.73	1.38-2.17
Cesarean for any indication	340 (40.8)	853 (21.6)	2.35	2.00-2.77
Fetal growth restriction subcohort	**N = 52**	**N = 224**

1162 Prenatal predictors of survival in isolated congenital diaphragmatic hernia undergoing expectant management

Alena Tofte[1], Faezeh Aghajani[2], Mohammad Jawwad[3], Anna Flood[4], Francesco D'Antonio[5], Asma Khalil[6], Hiba J. Mustafa[7]

[1]Dartmouth Hitchcock Medical Center, Lebanon, NH, [2]BCNatal Fetal Medicine Research Center, Hospital Clínic and Hospital Sant Joan de Déu, Universitat de Barcelona, Barcelona, Islas Baleares, [3]Dow University of Health and Sciences, Karachi, Sindh, [4]Indiana University School of Medicine, Indianapolis, IN, [5]McMaster University, Hamilton, ON, [6]Fetal Medicine Unit, St. George's Hospital, St. George's University of London, London, England, [7]Indiana University, Riley Children's Hospital, Carmel, IN

OBJECTIVE: To investigate prenatal predictors of survival to hospital discharge in fetuses with isolated congenital diaphragmatic hernia (CDH) undergoing prenatal expectant management.

STUDY DESIGN: We performed a systematic review and meta-analysis on prenatal diagnostic tests in fetuses with isolated CDH undergoing expectant management. Cases undergoing FETO were excluded. Primary outcome was survival to hospital discharge. Subgroup analysis was performed according to the side of CDH when feasible. Pooled effect sizes were presented using mean difference (MD) or odds ratio (OR), using the Mantel-Haenszel test, with 95% confidence interval (CI) for continuous and categorical variables, respectively.

RESULTS: A total of 161 full text articles were assed for eligibility between 2000 and 2023. Forty-five studies encompassing 3977 isolated CDH were included. Pooled proportion for survival was 71.2%, (95% CI 69.8%-72.6%). Index tests that were significantly associated with survival included**:** 1) Total fetal lung volume (TFLV) (MD 13.42, 95% CI 11.22, 15.62), 2) o/e TFLV < 30% (OR 0.09 , 95% CI 0.05, 0.17), 3) o/e TFLV (MD 14.73, 95% CI 11.62,17.84, I2 46%), 4) Liver intra-thoracic ratio (LiTR) (MD 9.59, 95% CI -15.73,-3.46), 5) o/e LHR (MD 14.03, 95% CI 12.69, 15.36), 6) o/e LHR < 25% (OR 0.07, 95% CI 0.04, 0.13), 7) Mediastinal shift angle (MD -6.17, 95% CI -7.70,-4.64), 8) Stomach position in mid-chest (OR 0.14, 95% CI 0.06, 0.36), and 9) intrathoracic liver (OR 0.23, 95% CI 0.15, 0.35), subgroup analysis to the left side remained significant in all the aforementioned tests.

CONCLUSION: In fetuses with CDH, fetal lung size measurements by ultrasound including LHR cut-off of 25% or MRI including TFLV cut-off of 30%, and liver herniation are good predictors for survival in isolated CDH.

10

Table : Proposed predictors of survival until hospital discharge in fetuses with congenital diaphragmatic hernia

1163 Maternal and neonatal outcomes with severely elevated 1-hour glucose challenge test

James D. Toppin[1], Erika Pettis[1], John A. Morgan[2], Shannon McCloskey[3], Meenakshi Mishra[4], Roberto X. Calix[1], Joseph R. Biggio Jr.[5], Frank Williams[4]

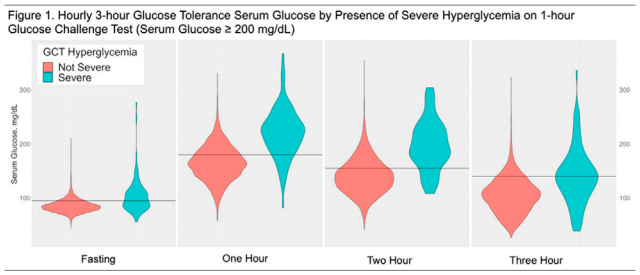
[1]Ochsner Health, New Orleans, LA, [2]Ochsner Clinic, Metairie, LA, [3]Ochsner Clinic Foundation, New Orleans, LA, [4]Ochsner Clinic, New Orleans, LA, [5]Ochsner Health System, New Orleans, LA

OBJECTIVE: Strategies to diagnose gestational diabetes mellitus (GDM) remain contentious. Severe hyperglycemia (≥ 200 mg/dL) on a 1-hour glucose challenge test (GCT) is associated with high risk for failed 3-hour glucose tolerance test (GTT). We compare perinatal outcomes for those managed as GDM by severe hyperglycemia on GCT alone to those diagnosed by full two-step assessment.

STUDY DESIGN: We performed a retrospective cohort study of pregnant patients with late second or early third trimester GCT > 140 mg/dL in a large healthcare system from 2016-2021. Those with pregestational diabetes, early GDM diagnosis, higher order multiples, preexisting cardiac or renal disease, chronic steroid use, and serious fetal anomalies were excluded. Patients managed as GDM based on severe hyperglycemia by GCT alone were compared to those diagnosed by two-step Carpenter-Coustan criteria. The primary outcome was a composite of primary cesarean delivery, macrosomia, shoulder dystocia, neonatal hypoglycemia, or neonatal hyperbilirubinemia. T-test and X^2 analyses compared outcomes.

RESULTS: Among 4415 positive GCT, 296 (7%) had GCT ≥ 200 mg/dL. Of those with severe hyperglycemia, 205 (69%) were managed empirically as GDM, while 91 underwent GTT. Severe hyperglycemia on GCT was associated with 12-fold increased odds of failed GTT (82% vs 18%, OR 12.0, 95% CI 6.9-20.6); such patients more likely to have blood glucose > 300 mg/dL during GTT (figure 1). Patients managed as GDM by severe hyperglycemia on GCT alone had increased body mass index (33 vs 29 kg/m^2, p< 0.001). The primary outcome was similar between groups (30% vs 33%, OR 0.9, 95% CI 0.6-1.2). Compared to GDM patients diagnosed by two-step, those diagnosed by GCT alone had higher incidence of GDM A2 (24% vs 8%, OR 3.6, 95% CI 2.5-5.2) and were more likely to deliver preterm (27% vs 14%, OR 2.25, 95% CI 1.61-3.15).

CONCLUSION: Severe hyperglycemia on GCT is associated with low likelihood of normal GTT and increased risk for GTT serum glucose > 300 mg/dL. With similar outcomes via either diagnostic method, empiric treatment based on the GCT alone seems reasonable.



1164 The Impact of an Independent, Academic Midwifery Practice on Labor and Delivery Unit Culture

Marika Toscano[1], Stefanie J. Hollenbach[2], Heather Lane[3], Helene Thompson-Scott[3], Megan Hogan-Roy[3], Clare Lennon[3], Eva K. Pressman[3]

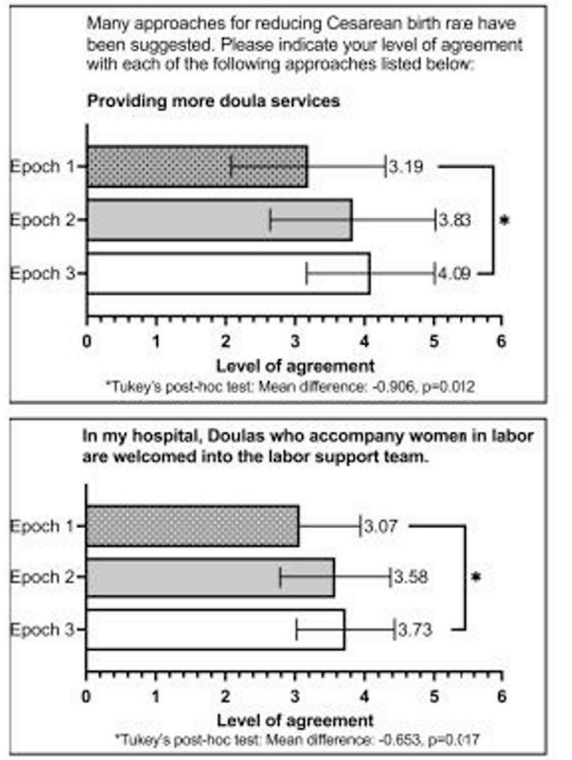
OBJECTIVE: To explore how the addition of an independent, academic, midwifery-only practice group to a traditional physician-led Labor & Delivery (L&D) unit may shift the cultural environment and impact the beliefs and attitudes about childbirth and L&D practices among Obstetrics providers.

STUDY DESIGN: Single center, longitudinal prospective cohort study of L&D providers following a natural "intervention" consisting of the addition of an independent, academic, midwifery-only practice group (not supervised by Obstetricians) to the traditional University hospital physician-led L&D unit. The Labor Culture Survey (VanGompel et al. 2018) was administered to L&D providers longitudinally at baseline (May 2020), 1 year (June 2021), and 2 years (June 2022) after this "intervention" (referred to as epochs 1, 2 and 3). Surveys were completed voluntarily, electronically via RedCap and scored on a Likert-type scale (5: strongly agree; 1: strongly disagree). The primary outcome, difference in mean score over time, was analyzed using one-way ANOVA and Tukey's post-hoc test for significance. Cesarean birth rates pre- and post-intervention were compared as a secondary outcome.

RESULTS: 91 total surveys were completed (response rate: 37%). Respondents were majority female physicians (91.2%) aged 39.3±0.5 years. Following the "intervention", physicians were more likely to welcome doulas as members of the labor support team (p=0.017), support more doula services (p=0.013), and more midwifery services (p=0.042) (Figure 1) as strategies to reduce Cesarean birth rates. Simultaneously, the University hospital saw a decrease in the total Cesarean birth rate from 37.5% in 2019 to 31.9% in 2021 (p< 0.001).

CONCLUSION: Midwifery-style L&D care is known to promote and support physiologic birth in uncomplicated pregnancies. Changing L&D culture and subjective norms via the addition of a midwifery-only practice to a traditional L&D unit has the potential for meaningful changes in perceptions, actions, and behaviors by physician providers.

Figure: Selected responses by Obstetrics physicians to the Labor Culture Survey following addition of an independent, academic, midwifery-only practice group to the traditional University hospital physician-led L&D unit



1165 The impact of early amniotomy on delivery outcomes in pregnancies with fetal macrosomia

Or Touval[1], Gal Cohen[2], Lior Heresco[3], Tal Biron-Shental[4], Michal Kovo[5], Hanoch Schreiber[2]

[1]Meir Medical Center, affiliated with Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [2]Meir Medical Centerartment of Obstetrics and Gynecology, Meir Medical Center, Kfar Saba, Israel, [3]Meir Medical Center, Tel Aviv, HaMerkaz, [4]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz, [5]Meir Medical Center, Macabim, HaMerkaz

OBJECTIVE: The optimal timing for amniotomy during labor is controversial. Early amniotomy (EA), defined as amniotomy performed at cervical dilation < 4 cm, has been shown to shorten labor duration without increasing cesarean delivery (CD) rate, in the general pregnant population. However, its impact in deliveries with fetal macrosomia is unknown. We aimed to investigate the effects of early vs. late amniotomy on delivery outcomes in pregnancies with fetal macrosomia.

STUDY DESIGN: A retrospective cohort study of all women who delivered neonates with a birthweight of ≥ 4,000 g., between 01/2014 to 10/2020. We included parturients admitted in latent phase of labor (< 6 cm dilation), that underwent amniotomy during labor. The study cohort was divided into two groups: the early amniotomy (EA group) and the late amniotomy (LA group), based on the cervical dilation at which amniotomy was performed, (≤ 4 cm

or > 4 cm, respectively). Delivery and neonatal outcomes were compared between the groups.

RESULTS: A total of 797 women were included. There were no differences in the pre-labor fetal-weight estimation between the groups (3,928±273 vs. 3,945±271 g., p=0.61 in the EA and LA group, respectively). Compared to the LA group (n=438), the EA group (n=359) had higher rates of nulliparity (p< 0.001), diabetes mellitus (p< 0.001), induction of labor (p< 0.001), epidural analgesia (p< 0.001) intrapartum fever (6.1% vs. 2.3%, p=0.006) and CD (13.1% vs. 5.7%, p< 0.001). Neonatal birthweights were similar between the EA and LA groups, (4,185±169 g. vs. 4191±181, p=0.61). Composite adverse neonatal outcome was higher in the EA group compared to the LA group (11.8% vs. 6.9%, p=0.046). A multivariable logistic regression analysis adjusted for confounders (table 1) revealed that EA was independently associated with increased risk for CD (aOR 2.13, p=0.014, 95% CI 1.16-3.9).

CONCLUSION: The timing of amniotomy in deliveries of suspected fetal macrosomia should be carefully considered, as early amniotomy may increase the rate of CD.

Table 1. Multivariable logistic regression of factors associated with cesarean delivery during labor.

Variable	Adjusted Odds Ratio (aOR)	95% CI	*P-value*
Early amniotomy	2.13	1.16-3.90	0.014
Nulliparity	9.79	5.38-17.80	<0.001
Diabetes mellitus*	1.54	0.72-3.32	0.267
Induction of labor	1.22	0.67-2.20	0.516
Epidural analgesia	3.30	1.64-6.63	<0.001
Intrapartum fever	4.81	1.99-11.67	<0.001

Factors included in the multivariable regression model were variables found as significantly different between groups in the univariate analysis. Results are reported as adjusted odds ratios (OR) and 95% confidence intervals (CI); *pregestational and gestational diabetes.

1166 Statewide Patterns of Opioid Use Disorder Diagnosis and Treatment in Nulliparous, Term, Singleton, Vertex Pregnancies

Courtney Townsel[1], Joshua George[2], Daria Stelmak[2], Chiao-Li Chan[2], Hsou Mei Hu[2], Alex Peahl[2]

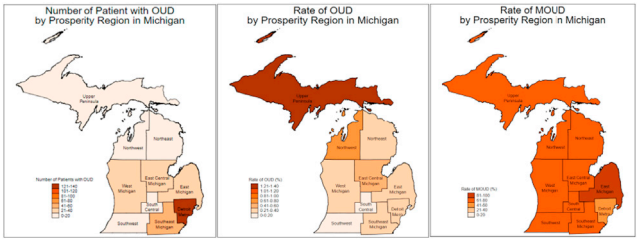
[1]University of Maryland, Baltimore, MD, [2]University of Michigan, Ann Arbor, MI

OBJECTIVE: To assess regional variation in rates of identified opioid use disorder (OUD) and treatment for OUD with medication for OUD (MOUD) in birthing people across Michigan.

STUDY DESIGN: We performed a retrospective cohort study of 90,217 birthing people with a nulliparous, term, singleton, vertex (NTSV) pregnancy. Eligible individuals had a vaginal or cesarean birth at one of 62 Michigan birthing hospitals between 1/1/2020 and 1/31/2023. Birthing people were categorized by status of OUD, treatment with MOUD, and MOUD type. Individuals with a postpartum length of stay > 7 days were excluded. We used basic descriptive statistics and tests of comparison between groups based on OUD diagnosis and type of MOUD. We created geocoded heat maps of OUD diagnosis and receipt of MOUD by region.

RESULTS: The rate of OUD was 0.33% (300/90,217). Patients with OUD were older, more likely to have Medicaid insurance, and use other substances (alcohol, tobacco and marijuana) compared to the general population (p< 0.01). Among patients with OUD, 69% (207/300) received MOUD. The most common MOUD was buprenorphine (62%, 129/207), followed by methadone (36%, 75/207) and naltrexone (1.5%, 3/207). The proportion of patients with diagnosed OUD ranged from 0.35-1.36%. The proportion of patients with OUD receiving MOUD ranged from 58.6-95.5%. The region with the highest number of birthing patients with OUD (n=128/300) had one of the lowest rates of MOUD (n= 75/207, 58.6%).

CONCLUSION: There is a mismatch between regions with the highest burden of OUD and utilization of MOUD. Though the majority of NTSV patients with OUD received MOUD, almost one-third of patients did not. Future work is needed to understand the individual and system-level factors that influence patients' access to MOUD.



1167 Sentinel Biomaterials Remotely Monitor The Placental Microenvironment

Russell Urie, Lauren Hesse, Chengchuan Xiao, Elizabeth Lombard, Elizabeth Hughes, Ariella Shikanov, Lonnie Shea

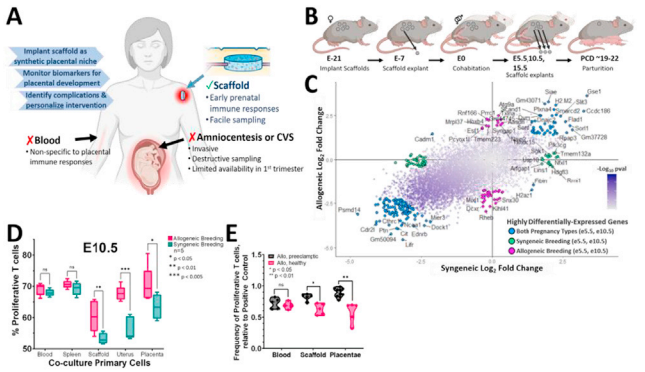
University of Michigan, Ann Arbor, MI

OBJECTIVE: In this work, we employ microporous scaffolds as a synthetic immunological niche to remotely capture the longitudinal immune domain of healthy and preeclamptic-like, miscarriage-prone rodent pregnancies with greater specificity than blood (Fig 1A).

STUDY DESIGN: Microporous poly(ε-caprolactone) (PCL) scaffolds were implanted subcutaneously in C57BL/6 female mice prior to cohabitation with BALB/c (allogeneic) or C57BL/6 (syngeneic) males (FIg 1B). For preeclamptic-like pregnancies, CBA females were bred with DBA/2 males. Scaffolds were serially explanted prior to cohabitation and on embryonic days (E) 5.5, 10.5, and 15.5, along with age-matched non-breeders. Blood, spleen, uterus, placentae, and implanted scaffold cells were processed for flow cytometry, T cell activation, and trophoblast migration. Scaffolds were also sequenced for differential gene expression and pathway enrichment.

RESULTS: In both healthy and preeclamptic-like pregnancies, the scaffold implant recapitulates tissue-resident immune cell phenotypes (including NK cell and macrophage phenotypes) and the immune microenvironment of the uterus and placentae with greater tissue specificity than found in circulation (Fig 1D, E). In addition to the innate immune cell phenotypes in the scaffold, gene expression in the scaffold can be used to distinguish between gestational stages and states (Fig 1C). Through an Elastic Net regression, we identified 8 genes that differentiate between allogeneic-bred and syngeneic-bred mice at embryonic day 5.5 (E5.5), prior to fetal or placental organogenesis, to construct a predictive biomarker panel for the risk of preeclampsia. Lastly, scaffolds capture a population of fetal cells identified in the placentae at E15.5.

CONCLUSION: We have developed scaffold implants to remotely monitor immunological markers of prenatal progression which recapitulate aspects of the uterine microenvironment. Scaffold gene expression can differentiate the prenatal immune state, and scaffolds capture a population of fetal cells from circulation. These scaffolds act as a minimally invasive prenatal monitoring tool.



1168 Quadruple P screening study: risk factors associated with a short mid-pregnancy cervical length in singletons

Charlotte E. van Dijk[1], Annabelle L. van Gils[1], Maud D. van Zijl[2], Benjamin Gravesteijn[3], Brenda M. Kazemier[4], Eva Pajkrt[1]

[1]Amsterdam UMC, location AMC, Amsterdam, Noord-Holland, [2]Amsterdam UMC, location AMC, IJsselstein, Utrecht, [3]Amsterdam University Medical Center, Amsterdam, the Netherlands and Amsterdam Reproduction & Development, Amsterdam, Amsterdam, Noord-Holland, [4]Wilhelmina's Children Hospital, Utrecht, Utrecht; on behalf of the Quadruple P Research Group

OBJECTIVE: Mid-pregnancy short cervical length (CL) ≤35mm has been associated with increased risk for spontaneous preterm birth (sPTB) in singleton pregnancies. However, CL screening is not universal and targeted risk-profiles are not yet established. In this prospective cohort study we aim to identify risk factors for a short mid-pregnancy CL.

STUDY DESIGN: We performed a multicenter prospective cohort study in 25 hospitals and midwifery practices in the Netherlands. We included low-risk, asymptomatic women with a singleton pregnancy undergoing a transvaginal midtrimester CL measurement during the fetal anomaly scan between 18^{+0} -22^{+0} weeks of gestation. The primary outcome is the association between maternal and obstetric characteristics for a CL ≤ 35mm. Secondary outcomes included the association for a CL ≤ 25mm and a multivariable logistic regression was performed. Odds ratio (OR) calculation with a 95 % confidence interval (CI) and binomial logistic regression analyses were used to identify the associations.

RESULTS: Overall, 19,364 women were included in analysis of which 2031 (10.5 %) had a CL ≤35 mm and 269 (1.4 %) a CL ≤ 25 mm. Multiple maternal and obstetrical characteristics were individually significantly associated with a short cervical length (Table 1). In a multivariable logistic regression nulliparity (OR 1.9, CI 1.3 − 2.7) and cervical excisional procedures (OR 3.2, CI 1.8 − 5.5) remained statistically significant. Similar results were found for nulliparity (OR1.3, CI 1.0 − 1.7) and cervical excisional procedures (OR 5.1, CI 3.7 − 7.2) in women with a CL ≤ 25 mm.

CONCLUSION: Nulliparity, a history of cervical excisional procedures and uterine excavation with curettage are associated with increased odds of short mid-trimester CL ≤ 35mm. We advocate for the implementation of universal CL screening during pregnancies, with a particular emphasis on screening women with known risk factors. This facilitates appropriate interventions and personalized care for those at higher risk for sPTB.

1169 Postpartum Beat-to-Beat Systolic Blood Pressure Variability in Preeclampsia with Severe Features

Anne-Sophie van Wingerden[1], Maria Katsidoniotaki[2], Noora Haghighi[1], Casandra Almonte[1], Helen Woolcock[1], Eduard Valdes[1], Aymen S. Alian[3], Whitney A. Booker[1], Natalie Bello[4], Randolph Marshall[1], Ioannis Kougioumtzoglou[2], Nils Petersen[3], Eliza C. Miller[1]

[1]Columbia University Irving Medical Center, New York, NY, [2]Columbia University, New York, NY, [3]Yale University School of Medicine, New Haven, CT, [4]Cedars-Sinai Medical Center, Los Angeles, CA

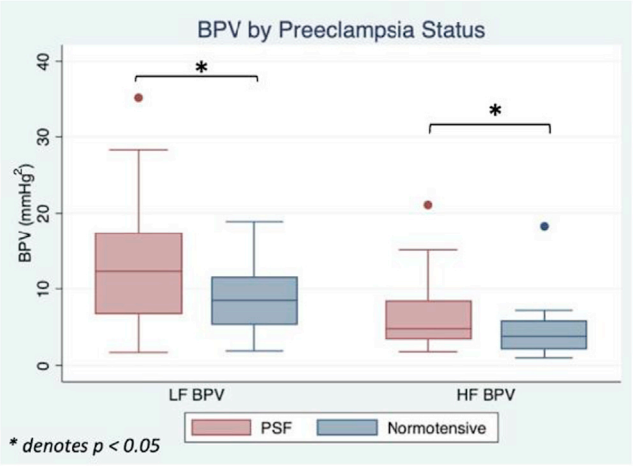
OBJECTIVE: Beat-to-beat blood pressure variability (bbBPV) has been correlated with adverse outcomes including stroke in non-pregnant populations. bbBPV increases throughout healthy pregnancy and to a greater extent in preeclampsia. However, it is unknown whether elevated bbBPV persists in the immediate postpartum period. We compared differences in bbBPV within 8 days postpartum between patients with preeclampsia with severe features (PSF) and normotensive postpartum controls.

STUDY DESIGN: We prospectively recruited individuals with PSF and normotensive pregnant individuals delivering at an urban academic medical center. We measured continuous blood pressure over 10 minutes using finger plethysmography within 8 days postpartum. Systolic bbBPV was calculated using spectral analysis in low frequency (LF, 0.04-0.15 Hz) and high frequency (HF, 0.15-0.40 Hz) bands. Results were compared using parametric or non-parametric tests depending on the distribution.

RESULTS: Subjects were 51 women with PSF, of whom 21 (41%) had chronic hypertension with superimposed preeclampsia (siPEC), and 19 normotensive controls. All PSF subjects had been treated at the time of the study; 10 (20%) had received magnesium sulfate (Mg) and 44 (86%) had received antihypertensive medications

(antiHTNs) within 24 hours before bbBPV was measured. Subjects with PSF had significantly higher LF (median 12.3 vs. 8.5 mmHg^2, p = 0.038) and HF (median 4.8 vs. 3.8 mmHg^2, p = 0.029) systolic bbBPV compared to controls. Within the PSF group, bbBPV did not differ in patients who received Mg or antiHTNs within 24 hours of the study. Subgroup analysis showed no difference in bbBPV in the siPEC group compared to control and non-superimposed PSF groups. LF/HF ratio did not differ significantly among groups.

CONCLUSION: The increase in bbBPV seen in preeclampsia patients during pregnancy persists during the first week postpartum. Standard treatment with Mg and antiHTNs is intended to reduce mean blood pressure but may not address elevated bbBPV in the postpartum period.



1170 Linking patients to primary and subspecialty care through a high-risk fourth trimester clinic

Kavita Vani[1], Cien Huang[2], Jessica Hecht[2], Matthew Lootens[2], Chavi Eve Karkowsky[3], Edith Gurewitsch Allen[4], Kevin Fiori[4], David Lounsbury[2]

[1]Albert Einstein College of Medicine, Montefiore Medical Center, Great Neck, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Albert Einstein College of Medicine, Montefiore Medical Center, New York, NY, [4]Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY

OBJECTIVE: To describe the primary care (PC) and subspecialty needs of high-risk patients seen at a specialized postpartum clinic within a racially and ethnically diverse urban health system and to determine associations between having a preexisting primary care provider (PCP) and clinic referral indication and postpartum care utilization.

STUDY DESIGN: An observational cohort of high-risk patients was followed for 12 months (6/2022 to 6/2023) at a dedicated postpartum clinic that provides care-coordination. High-risk indications for clinic referral included a chronic medical condition and/or adverse delivery or immediate postpartum event. All patients were asked about their PC and subspecialty needs. A care coordinator helped schedule PCP and subspecialty follow-ups if indicated. Summary statistics described patients' PC and subspecialty needs. Bivariate analyses comparing postpartum attendance characteristics and clinic referral indication by identification of a PCP at entry to postpartum care were performed using chi-square and Mann-Whitney U tests.

RESULTS: Out of N=143 patients seen at the Fourth Trimester clinic, 78.3% (n=112) were publicly insured and 95.1% (n=136) identified as non-white. 52.5% (n=75) identified a PCP at entry to postpartum care. Among the 47.6% (n=68) without a PCP, 73.1% (n=49) received care coordination to schedule a PCP visit and, of these, 63.2% (n=31) attended their appointment. 51.0% (n=73) of patients needed to see at least one subspecialist. 16.7% (n=24) received care coordination to schedule a subspecialty visit; 58.3% (n=14) attended their appointment. No statistically significant difference was found in clinic referral indication, number of postpartum visits attended, or attendance within 21 days postpartum between those with and without a preexisting PCP.

CONCLUSION: Almost half of high-risk patients seen for care at our specialized Fourth Trimester clinic did not identify a PCP at entry to postpartum care. Care coordination linked the majority of these patients to a PCP after delivery, demonstrating its importance in the transition from postpartum to PC.

1171 The need for mental health screening and care at a high-risk fourth trimester clinic

Kavita Vani[1], Jessica Hecht[2], Cien Huang[2], Matthew Lootens[2], Chavi Eve Karkowsky[3], Edith Gurewitsch Allen[4], Kevin Fiori[4], David Lounsbury[2]

[1]Albert Einstein College of Medicine, Montefiore Medical Center, Great Neck, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Albert Einstein College of Medicine, Montefiore Medical Center, New York, NY, [4]Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY

OBJECTIVE: To describe depression screening and referral to mental health (MH) services among high-risk individuals receiving care at a dedicated postpartum (PP) clinic within a racially and ethnically diverse urban health system and their associations with clinic referral indication.

STUDY DESIGN: An observational cohort of high-risk patients was followed for 12 months (6/2022 to 6/2023) at a specialized PP clinic where universal PP depression screening is performed at least once using the Edinburgh Postnatal Depression Scale (EDPS) as per clinic protocol. High-risk indications for clinic referral included a chronic medical condition and/or an adverse delivery or immediate PP event. All patients were offered referral to MH services regardless of their PP depression screen. Summary statistics described depression screening and referral to MH services. Chi-square test ($p < 0.05$) compared depression screen characteristics and MH referrals by clinic referral indication.

RESULTS: 143 patients, 90.9% (n=130) of whom identify as non-white and 78.3% (n=112) of whom are publicly insured, were seen at our Fourth Trimester clinic. 87.4% (n=126) were screened for depression at least once. Among the 27% (n=34) who screened positive, 88.2% (n=30) were referred to MH services, 52.9% (n=18) of which attended an appointment. An additional 28 patients (19.6%) who screened negative for depression desired referral to MH services. Among those, 67.9% (n=19) attended at least one MH appointment. Performance of depression screening, positive screen prevalence, referral to MH services and attendance of a MH appointment were similar regardless of clinic referral indication.

CONCLUSION: Over 25% of high-risk patients screened positive for depression and an additional 20% without positive screens desired MH referral. A standardized workflow including depression screening and universal referral to MH services can maximize identification of high-risk patients in need of mental health services.

1172 The Integration of Prenatal Data Into the Neonatal Research Network (NRN) Survival Probability Estimator

Michael W. Varner
Eunice Kennedy Shriver National Institute of Child Health and Human Development, Salt Lake City, UT; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: Neonatal survival probabilities are important in shared decision-making considerations for peri-viable deliveries. The NICHD NRN Survival Probability Estimator has been used for counseling and treatment decisions but considers very few prenatally available data. We asked whether**:** 1) using an ultrasonographic estimated fetal weight (EFW) within one week of delivery rather than birthweight resulted in significantly different predicted survival probabilities, or 2) predicted probabilities were different based on the indication for delivery.

STUDY DESIGN: Secondary analysis of an observational cohort of deliveries from 16 0/7 through 34 6/7 weeks from January-August 2019 at 34 U.S. hospitals. Patients were included if they had an ultrasonographic estimated fetal weight (EFW) within one week of delivery and a live birth of a non-anomalous infant from 22 0/7 through 25 6/7 weeks. The primary outcome was neonatal survival as estimated from the NRN Estimator. The Estimator uses birthweight, newborn sex, plurality, and antepartum steroid exposure to generate the survival probability. We assessed whether predicted survival was significantly altered after substituting birthweight for EFW, and after partitioning of the cohort by whether 1) PPROM (as primary reason for delivery admission), 2) hypertensive disorders of pregnancy (HDP), or 3) spontaneous premature birth (SPTB) had occurred.

RESULTS: 275 neonates met inclusion criteria. At each week of gestational age the median survival estimate using EFW was not statistically different from that estimated using birthweight. However, the predicted survival was dependent upon whether the selected obstetric complications had occurred. Specifically, birth after SPTB or PPROM identified a group of neonates with a higher probability of predicted survival after 23 weeks.

CONCLUSION: EFW instead of birthweight does not alter NRN Estimator survival probabilities. The findings that predicted survival probabilities varied by indication for delivery warrants further assessment.

Neonatal Predicted Survival^ (22 0/7 to 25 6/7 weeks) with Integration of Prenatal Data

* PPROM as primary reason for hospital admission
+ Includes individuals admitted with PPROM who labored spontaneously
EFW = ultrasonographic estimated fetal weight; PPROM = preterm premature rupture of membranes; HDP = hypertensive disorders of pregnancy; SPTB = spontaneous preterm birth

1173 Three-dimensional fetal body composition and organ volume growth patterns in hypertensive disorders of pregnancy

Kathryn A. Wagner[1], Katherine Grantz[1]
[1]Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD; on behalf of the NICHD Fetal 3D Study and the NICHD Fetal Growth Studies

OBJECTIVE: Hypertensive disorders of pregnancy (HDP) complicate 5-8% of pregnancies and are associated with lower birthweight and fetal growth restriction. No studies have evaluated the association between HDP and three-dimensional (3D) measures of fetal body composition, such as lean and fat tissue, and organ volumes across pregnancy. Differential accumulation of fetal lean and fat tissue, or organ volume growth, may be a more sensitive marker for abnormal fetal growth.

STUDY DESIGN: In the NICHD Fetal 3D Study (n=2430 pregnancies), fetal body composition and organ volumes were measured at up to five 3D ultrasounds between 15 to 40 weeks by certified sonographers per protocol. Women were identified as having severe preeclampsia (PE) (n=32, 1.3%), mild PE (n=52, 2.1%), gestational hypertension (GH) (n=84, 3.5%), or no hypertension (referent; n=2262, 93.1%). Trajectories of 3D fetal measures were modeled using linear mixed effect models. Overall and weekly mean differences in the trajectories, by hypertensive status, were tested after adjustment for covariates.

RESULTS: Compared to pregnancies without hypertension, fetuses of women who developed severe PE had smaller fractional lean arm and thigh volumes starting at 15 and 18 weeks, respectively, prior to PE diagnosis and continuing through term, reaching statistical significance at 15-17 and 28-34 weeks for arm and 27 weeks for thigh (Table). Fetuses of women who developed mild PE had larger maximum abdominal and thigh SCTT starting, on average, at 23 weeks through term, and larger cerebellar volume starting at 19 weeks (Table). Lastly, fetuses of women who developed GH had smaller fractional arm and thigh volumes (overall and lean) and abdominal area starting in the 2nd half of pregnancy, larger maximum abdominal SCTT starting at 29 weeks, and larger cerebellar volume at 17-23 weeks (Table).

CONCLUSION: Patterns of lean and fat tissue growth and cerebellar volume varied across HDP categories. Future investigation is needed to determine whether these findings have clinically important implications for offspring cardiometabolic function and health.

Table. Summary of overall and weekly comparisons of fetal 3D body composition and organ volumes across hypertensive disorders of pregnancy; NICHD Fetal 3D Study.

		Weekly Comparisons		
Outcome	Global Comparison	Gestational Hypertension	Mild PE	Severe PE

PE = preeclampsia
Linear mixed models were adjusted for: maternal age, race/ethnicity, parity, pre-pregnancy BMI, education, infant sex, insurance, marital status, and full-time employment status
Dashes indicate no gestational age for which pairwise comparisons were different
Women without hypertension during pregnancy were the referent group for all analyses

1174 Placental Inflammation is More Common in A2 versus A1 Gestational Diabetes

Morgan Wasickanin[1], Joshua Monson[2], Sarah Ligon[1], Jennifer Damicis[3], Marit K. Bastian[1], Katherine E. Free[1], Emily Sheikh[4], Jason Pates[5], Peter Napolitano[6], Nicholas Ieronimakis[1]

[1]Madigan Army Medical Center, Tacoma, WA, [2]Madigan Army Medical Center, Gig Harbor, WA, [3]Madigan Army Medical Center, WA, [4]Madigan Army Medical Center, Lacey, WA, [5]Madigan Army Medical Center, Steilacoom, WA, [6]University of Washington, Seattle, WA

OBJECTIVE: It is well-known that worse obstetric outcomes are observed in pregnancies complicated by A2 compared to A1 gestational diabetes mellitus (GDM). Insulin resistance is thought to exaggerate placental immune responses. We hypothesize that there is greater placental inflammation in patients with A2GDM compared to A1GDM. Inflammatory responses in the placenta are mediated, in part, by macrophages (aka Hofbauer cells). To test our hypothesis, we compared macrophage abundance and proinflammatory gene expression in placentas from patients with A2GDM versus A1GDM.

STUDY DESIGN: Intervillous placental biopsies were collected and analyzed from term, unlabored patients delivered by planned cesarean. Insulin was the sole treatment modality for all A2GDM patients in this analysis. Histological analysis by CD163 staining was conducted to quantify the number of macrophages. The expression of 732 macrophage-related genes were compared between placentas from pregnancies complicated by A2GDM versus A1GDM (n=12/condition). Gene expression was also referenced to uncomplicated pregnancies using the NanoString nCounter system.

RESULTS: The number of macrophages (CD163+ cells) did not differ between A2GDM and A1GDM (Figure 1.A). However, in placentas from patients with A2GDM, 47 genes were significantly upregulated, and 3 downregulated when compared to those with A1GDM (Figure 1.B). The most significantly upregulated genes promote macrophage inflammation, including *LTB4*, *CD160* and *IRF5*.

CONCLUSION: While that the number of macrophages did not differ between groups, significant upregulation of macrophage associated inflammatory genes was observed in placentas from patients with A2GDM. Placental inflammation is thought to contribute to adverse obstetric outcomes such as preeclampsia. Further research is warranted to evaluate if placental inflammation is associated with specific adverse outcomes observed in GDM.

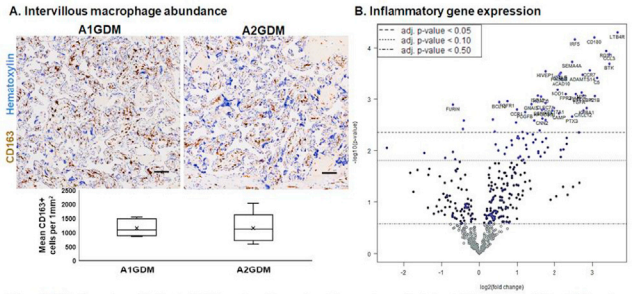

Figure 1. A. Staining and quantification for CD163 a marker of human placental macrophages. Scale bar = 100um. Box and whisker plot shows the number of CD163+ macrophages counted within 1mm² areas of tissue. Means are denoted by x's within each box. No significance was observed between A2GDM compared A1GDM. **B.** Volcano plot for differential expression between A2GDM versus A1GDM placentas (n=12/condition). Horizontal axis represents log transformed fold change, vertical depicts log transformed p-values. Horizontal lines denote Benjamin-Hochberg adjusted p-values, legend in top left of plot. The top 20 genes are annotated with abbreviations and fall above the line for adj p<0.05.

1175 Pregnancy outcomes in hepatitis E-associated hospitalizations in the United States: a nationwide study

Paul Wasuwanich[1], Wikrom Karnsakul[2], Robert Egerman[3], Tony S. Wen[3]

[1]University of Florida College of Medicine, Gainesville, FL, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]University of Florida, Gainesville, FL

OBJECTIVE: Hepatitis E virus (HEV) is typically asymptomatic in developed countries but can be severe in certain populations including pregnancy. However, in the U.S. there is limited data on the effects of the endemic genotype of HEV on the pregnant population, thus, we aim to investigate a large cohort of pregnant women and describe the characteristics and pregnancy outcomes in those with HEV from 1998-2020.

STUDY DESIGN: We utilized the National Inpatient Sample and extracted cases of HEV-associated hospitalizations using ICD-9/10 diagnostic codes. Demographic, clinical, and pregnancy data were extracted and analyzed by chi-square.

RESULTS: We identified 3,354 cases of HEV-associated hospitalizations, among those, 226 (6.7%) involved pregnant women. The median age was 30 years compared to 28 years in the non-HEV pregnant cohort (p=0.021). The race/ethnic distribution was 35.0% non-Hispanic White, 15.0% non-Hispanic Black, 10.6% Hispanic, 13.3% Asian/Pacific Islander. There were no cases of maternal death in the HEV pregnant cohort. Diabetes was found to be more common in the HEV pregnant cohort, 6.2% versus 1.1% (p< 0.001). Additionally, hepatitis B co-infection (31.9% vs 0.1%, p< 0.001), hepatitis C co-infection (11.1% vs 0.3%, p< 0.001), intravenous drug use (6.6% vs 0.6%, p< 0.001), coagulopathy (4.0% vs 0.3%, p< 0.001), and thrombocytopenia (6.2% vs 0.9%, p< 0.001) were significantly more common in the HEV pregnant cohort compared to the non-HEV pregnant cohort. Fetal heart rate/rhythm abnormalities were more frequent in the HEV pregnant cohort, 24.3% versus 12.4% (p=0.015). There were no differences in frequency of obesity, HIV infection, and pre-eclampsia (p >0.05). Among the 226 HEV pregnancies, 172 (76.1%) were hospitalized for delivery. There were no cases of stillbirth, and the frequencies of preterm and post-term births were similar to non-HEV pregnant cohort.

CONCLUSION: Among U.S. pregnant patients with hepatitis E, comorbidities such as co-infection with other hepatitis viruses were more common, but maternal and fetal outcomes were favorable and similar to the non-HEV pregnant population.

1176 Risk factors associated with intensive care unit admission during the Peripartum period: A retrospective study

Hadel Watad[1], Anat Kalter-Ferber[2], Yael Haviv[2], Shali Mazaki-Tovi[3]

[1]Sheba Medical Center, Jatt Village, HaMerkaz, [2]Sheba Medical Center, Ramat Gan, HaMerkaz, [3]Chaim Sheba Medical center, Tel HaShomer, Ramat Gan, HaMerkaz

OBJECTIVE: The aim of this study was to identify risk factors associated with peripartum admission to intensive care unit (ICU) including baseline characteristics, pregnancy data, and delivery outcomes.

STUDY DESIGN: This was a retrospective cohort study. Study group consisted of all patients admitted to the ICU during the peripartum period between January 2011 and January 2022. A control group included individuals who delivered at the same medical center during the specified time frame. We matched each study case with

five control cases according to medical staff and delivery day. Baseline characteristics, pregnancy and delivery outcomes were compared between the two groups. Additionally, we analyzed the indications for ICU admission. Nonparametric statistics were applied for analysis.

RESULTS: A total of 113 patients were admitted to the ICU, which accounted for 0.1% of all births at our medical center during the same period. The controls consisted of 565 individuals. The median maternal age was significantly higher in the ICU group than in the control group. Patients admitted to the ICU had a significantly lower rate of spontaneous conception and higher rates of multifetal gestation, hypertensive diseases, preterm labor (PTL), and Cesarean sections (CS) (Table). Neonates born to patients admitted to the ICU tended to have a lower median birth weight and a longer hospitalization period, with higher rates of low Apgar scores, stillbirth, NICU admission, mechanical ventilation and cooling treatment (Table). Among the study group, observation for background disease was the leading cause for ICU admission (34.5%), followed by hematological complications (14.2%). Ten patients (8.8%) had hysterectomies, 5 (4.4%) had cardiac arrest and one patient (0.9%) had anoxic brain damage. Maternal death rate was 2.65%.

CONCLUSION: Advanced maternal age, multifetal pregnancy, and hypertensive diseases are associated with peripartum maternal ICU admission. Patients admitted to ICU have higher rates of PTL, CS and neonatal complications. Identifying these risk factors may help in the early detection of high-risk individuals.

Table. Baseline demographic, pregnancy characteristics and neonatal outcomes

1177 Low maternal cardiac index is associated with a high rate of fetal growth restriction

Cynthie Wautlet[1], Emma E. Peek[2], John Hobbins[2], Greggory De Vore[3]

[1]University of Colorado Denver, Aurora, CO, [2]University of Colorado, Denver, CO, [3]Fetal Diagnostic Center, Pasadena, CA; on behalf of the Perelman Family Foundation

OBJECTIVE: A paucity of prior studies has described a relationship between maternal cardiac function and fetal growth using equipment not accessible to obstetricians. Our objective was to determine whether a low maternal cardiac index (CI) is associated with fetal growth restriction (FGR) in gravidas with and without hypertension (HTN) using a readily available adult cardiac probe compatible with obstetrical ultrasound machines.

STUDY DESIGN: We conducted a prospective cross-sectional study of healthy gravidas and those with FGR with or without HTN recruited from two outpatient clinics and one antepartum hospital ward. The maternal descending aorta was imaged via the suprasternal notch using a Samsung P2-4BQ Cardiac Sector probe. The aortic diameter distal to the left subclavian artery was measured and the pulsed Doppler waveform obtained. Maximum velocity, velocity time integral, ejection time, and R-R interval were measured. Maternal CI ($L/min/m^2$) was calculated and z-scores and their corresponding centiles were computed using a recently reported calculator derived from 400 control patients (Am J Obstet Gynecol. 2023 Aug;229(2):155.e1-155.e18.) Charts were abstracted for maternal characteristics, fetal biometry and Dopplers. Mann-Whitney and Fisher's exact tests were used for comparisons.

RESULTS: Thirty-six gravidas (control 21; FGR 15) between 24-37 weeks of gestation met inclusion criteria. Two cases of FGR had chronic HTN and 1 had preeclampsia. The relationship between CI and EFW is shown in Figure 1a. Mean CI centile was significantly lower in the FGR group (control 26.8 $\pm$ 16.0 vs FGR 12.4 $\pm$ 13.0; p=.0112). In gravidas with CI $< 20^{th}$ centile, the rate of FGR was higher (p=.0022; Figure 1b). In the low CI FGR group, 8 of 13 (62%) had EFW $< 3\%$ and/or abnormal Dopplers.

CONCLUSION: Maternal CI $< 20^{th}$ centile for gestational age is associated with a higher rate of FGR. Simple assessment of maternal cardiovascular parameters using a readily available adult cardiac ultrasound probe in FGR pregnancies is feasible and holds promise as a strategy for risk stratification and development of novel treatments.

Figure 1a - Maternal Cardiac Index and Estimated Fetal Weight Centiles

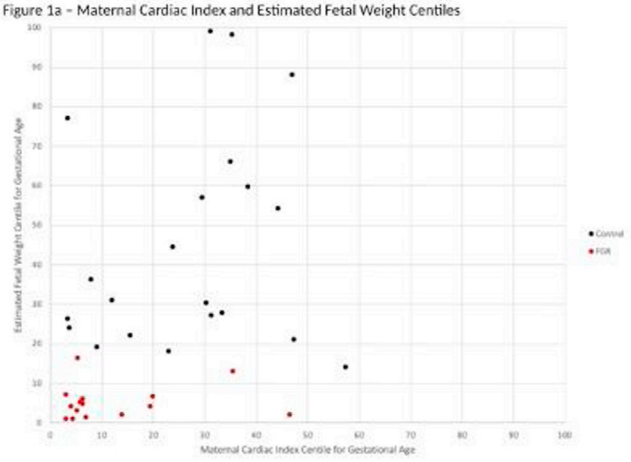

Figure 1b - Maternal Cardiac Index and Fetal Growth Restriction

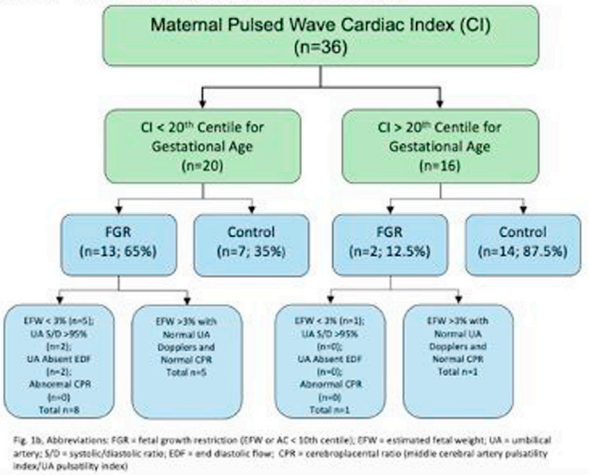

Fig. 1b. Abbreviations: FGR = fetal growth restriction (EFW or AC < 10th centile); EFW = estimated fetal weight; UA = umbilical artery; S/D = systolic/diastolic ratio; EDF = end diastolic flow; CPR = cerebroplacental ratio (middle cerebral artery pulsatility index/UA pulsatility index)

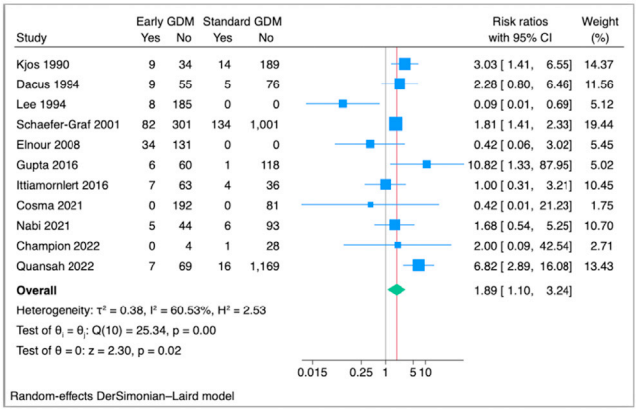
used, results were presented as relative risk (RR), 95% confidence intervals (CI). Post-hoc subgroup analyses were performed for the primary outcome among studies in the USA, used 2-hour or 3-hour oral glucose tolerance test (oGTT) for GDM screening, and early GDM diagnosed at < 24 weeks or < 20 weeks.

RESULTS: Of 5682 studies screened, 11 met inclusion criteria. Seven were prospective cohorts, two were retrospective cohorts and two were secondary analyses of RCTs. Of 1305 patients with early GDM, 248 (19.0%) had DM compared to 181 (6.1%) of 2972 with standard GDM (RR 1.89, 95% CI 1.10-3.24). This persisted for the primary outcome among studies in the USA (RR 2.04, 95% CI 1.53-2.73), used 3-hour oGTT (RR 1.95, 95% CI 1.31-2.90), and defined early GDM < 20 weeks (RR 2.31, 95% CI 1.09-4.87). However, this was no longer significant with studies that used 2-hour oGTT (RR 1.08, 95% CI 0.17-6.73) or defined early GDM < 24 weeks (RR 1.39, 95% CI 0.50-3.87).

CONCLUSION: The rate of DM diagnosed postpartum was higher in patients with early GDM compared to standard GDM diagnosis. Although at higher risk, the majority (81%) of patients with early GDM were not found to have DM postpartum. Thus, early GDM should not be a presumed diagnosis of DM.

Figure 1 – Forest plot of the frequency of diabetes mellitus diagnosis on postpartum screen



1178 Postpartum diabetes mellitus among patients with early gestational diabetes mellitus: A systematic review and meta-analysis

Sarah J. Weingarten[1], Ariel Levy[2], Huda B. Al-Kouatly[3], Rodney A. McLaren Jr.[4]

[1]Weill Cornell Medicine, New York, NY, [2]Weill Cornell Medicine at New York Presbyterian Hospital, New York, NY, [3]Thomas Jefferson University, Philadelpia, PA, [4]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA

OBJECTIVE: Patients diagnosed with early gestational diabetes mellitus (GDM) are commonly managed as pregestational DM. However, little is known whether early GDM is gestational or pregestational DM diagnosed in pregnancy. Our objective was to assess if the rate of DM diagnosed postpartum differs between patients with early GDM (< 24 weeks) and those with standard GDM (24-28 weeks).

STUDY DESIGN: This was a systematic review and meta-analysis registered with Prospero (CRD42022372568). An electronic search was conducted of PubMed, EMBASE, World Health Organization International Clinical Trials Registry Platform, Clinicaltrials.gov, and Cochrane Library through March 2023. Randomized controlled trials (RCTs) or observational studies of postpartum patients with early diagnosis of GDM were included. The primary outcome was rate of DM diagnosed postpartum. DerSimonian-Laird method was

1179 Risk of recurrent spontaneous preterm birth among those with persistent cervical HPV infection

Jessica Weng[1], Megan Branda[2], Maryam Shahi[3], Andrew Norgan[3], Elizabeth Enninga[3], Margaret Long[3], Alyssa Larish[3]

[1]Mayo Clinic Alix School of Medicine, Rochester, MN, [2]University of Iowa, Iowa City, IA, [3]Mayo Clinic, Rochester, MN

OBJECTIVE: This retrospective cohort study aims to determine the risk of recurrent preterm premature rupture of membranes (PPROM) or preterm labor (PTL) among those with cervical high-risk human papillomavirus (cHPV) infection and a history of previous PPROM/PTL; and examine clinical characteristics of cHPV infection among patients with PTL/PPROM.

STUDY DESIGN: Following IRB approval we performed a chart review of obstetric at Mayo Clinic Rochester or Mayo Clinic Health System, included patients with ≥ 1 spontaneous birth due to PPROM/PTL and positive cHPV testing from 5/1/2018- 12/31/2021. Demographics, cervical cytology, and placental pathology from the index and subsequent pregnancies were abstracted. cHPV persistence (testing during obstetric care) was defined as >1 pregnancy with positive cHPV testing.

RESULTS: Of 164 eligible patients, 54/164, 18/54, and 3/18 had one, two, and three subsequent pregnancies (Table 1). 21/75 (28%) had recurrence of PPROM/PTL which occurred in 8/32(25%) with persistent cHPV and 13/43(31%) without (p=0.57). HPV strain (16,18, or other high risk) was available for 99 patients, and 0/32 (0%) of patients with subsequent pregnancies and cHPV persistence changed strain type. Progression of CIN occurred in 9/16(56%), 5/9(56%), 1/2(50%) of those with persistent cHPV in subsequent pregnancies; 61/77(79%) in patients with no subsequent pregnancies. 53% of patients in index and subsequent pregnancies (1st 51%, 2nd 53%, 3rd 67%) underwent pre-pregnancy cervical excisional procedures. Histologic evidence of chorioamnionitis in the placenta was noted in 20/139(14%) of index pregnancies and 5/12 (42%) of subsequent pregnancies with persistent cHPV, but 0/19 patients without persistent cHPV (p=0.005).

CONCLUSION: High rates of PPROM/PTL recurrence, chorioamnionitis and CIN progression were noted in patients with persistent cHPV. No difference in rates of recurrent PPROM/PTL were noted in those whose cHPV testing transitioned to negative. Study of a larger population with higher cHPV prevalence may provide more clarity.

1180 Social Disparities in Patients with a history of prior Cesarean

Nicola F. Tavella[1], Sara Wetzler[2], Lily McCarthy[3], Lily Ardente[3], Toni Stern[3], Angela Bianco[4]

[1]Icahn School of Medicine at Mount Sinai Hospital, New York, NY, [2]Mount Sinai, New York, NY, [3]Icahn School of Medicine at Mount Sinai, New York, NY, [4]Mount Sinai Medical Center, New York, NY

OBJECTIVE: Since ACOG's call to decrease incidence of non-medically indicated cesarean deliveries (CDs), many providers encourage trial of labor after cesarean (TOLAC). Since social factors impact TOLAC and vaginal birth after cesarean (VBAC), this study reviewed disparities in characteristics of patients choosing a TOLAC vs. elective repeat cesarean delivery (ERCD) at a single New York hospital.

STUDY DESIGN: This was a retrospective cohort of 1,369 deliveries of patients with a history of prior CD between April 29, 2015 – April 29, 2020. Subjects were divided by delivery choice (opting for a TOLAC or ERCD) and had one of two delivery outcomes (VBAC or a repeat CD). Disparities were examined among different social categories including race/ethnicity (White, Asian, Black/ African American, Hispanic/ Latina, Other), health insurance (commercial, public), and pre-pregnancy body mass index (BMI) (< 30, 30-39.9, >40). Chi-squared tests examined proportional differences.

RESULTS: There were significant disparities between patients regarding both cohort and delivery outcome. Patients with a race/ethnicity of "Hispanic/Latina" or "Other" more often opted for and delivered by CD ($p < 0.001$). Patients with public insurance more often chose TOLAC and delivered by VBAC ($p < 0.001$). Patients with a pre-pregnancy BMI of 40+ more often chose TOLAC ($p < 0.001$) but had a lower VBAC rate ($p < 0.01$). Intersections of these categories exist such that publicly insured patients had higher BMI ($p < 0.001$) and certain racial/ethnic groups were more likely to be publicly or privately insured ($p < 0.001$).

CONCLUSION: These findings suggest that certain patients more often elect for repeat CD while others more often choose TOLAC and deliver by VBAC. Race and ethnicity reflect social determinants of health such that disparities may reflect systemic racism within the delivery space. The picture is more complicated at the intersection of insurance and BMI. Additional research among patients with a history of CD is needed.

1181 Maternal and fetal tissue specific response to phthalate exposure in the third trimester

Alexandria Williams[1], David E. Cantonwine[2], Amber Cathey[3], Morten Rasmussen[4], Maneesh Jain[4], John Meeker[5], Kelly Ferguson[6], Thomas McElrath[2]

[1]Brigham and Women's Hospital, Brookline, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]University of Michigan, Ann Arbor, MI, [4]Mirvie, Inc., South San Francisco, CA, [5]University of Michigan School of Public Health, Ann Arbor, MI, [6]National Institute of Environmental Health Sciences, Durham, NC

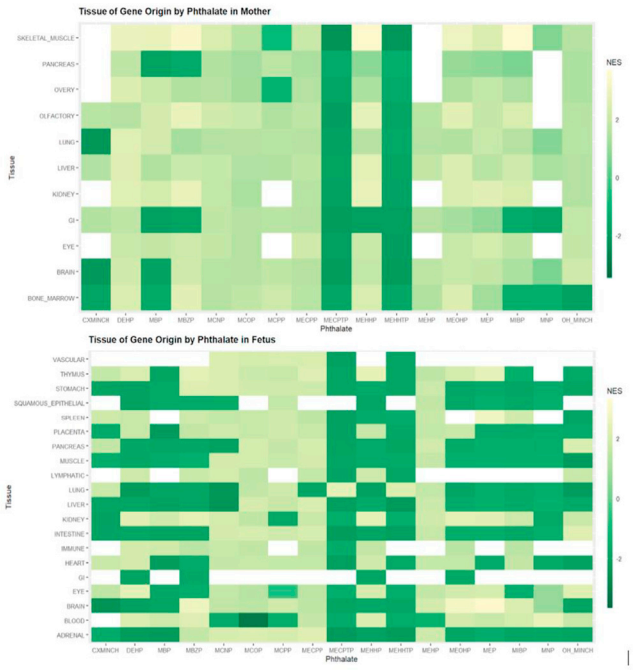
OBJECTIVE: Exposure to phthalates, a class of endocrine disruptors, is pervasive in the modern environment. Exposure during pregnancy has been associated with outcomes like preterm birth, gestational diabetes, and preeclampsia. We hypothesized that high exposure levels will yield specific responses in maternal and fetal tissues.

STUDY DESIGN: Using matched urine and plasma samples collected in 57 singleton women (median 25 weeks gestation), the

concentrations of 17 urinary phthalate metabolites were measured using quantitative mass spectrometry, and maternal cell free RNA was characterized via RNA sequencing. Samples above and below the median for each metabolite were considered high and low exposure, respectively. The fgsea package from Bioconductor was used for gene set enrichment analysis. The cell type signature gene set collection (C8 v2023.1.Hs) from the Molecular Signatures Database was used to identify affected maternal and fetal tissues. Normalized enrichment scores (NES) were compared by high vs low exposure level for each phthalate metabolite. P-values adjusted for multiple testing.

RESULTS: The heat maps displayed NES significance at an adjusted p-value < 0.01 for tissue-specific gene sets by phthalate metabolite. Tissues with altered NES in both maternal and fetal tissues included pancreas, brain, gastrointestinal, kidney, liver, lung, eye. Among fetal gene sets, adrenal, blood, heart, immune, lymphatic, muscle, placental, splenic, stomach, thymic, and vascular showed altered NES. Among maternal gene sets bone marrow, olfactory, ovary, and skeletal muscle showed altered NES. Affected tissues were primarily endocrine and high metabolizing tissues.

CONCLUSION: This novel analysis of gene set expression in response to high vs. low phthalate exposure during the early third trimester demonstrated both up and down regulation in gene expression across a wide variety of fetal and maternal tissues. The patterns of gene set alteration differed between the maternal and fetal context and may suggest potential mechanisms that underly observed associations between phthalate exposure and pregnancy outcomes.



1182 Racial Disparities Impact on Perinatal Outcomes in Patients with Twin-Twin Transfusion Syndrome

Kedeja V. Williams[1], Michelle Kush[2], Jena L. Miller[3], Arthur J. Vaught[4], Andrew J. Satin[5], Camille Shantz[6], Elena R. Taylor[7], Mara Rosner[3], Ahmet A. Baschat[2]

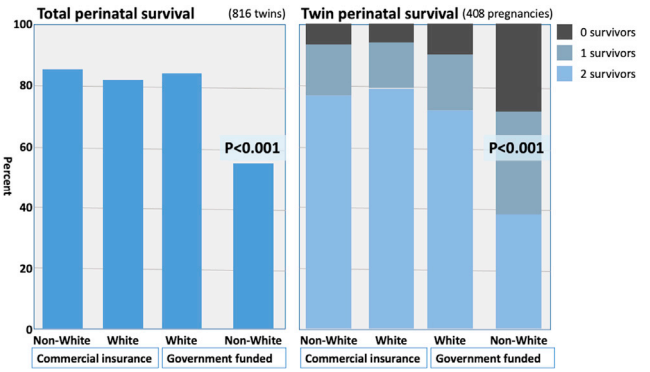
[1]Johns Hopkins Hospital, CHARLOTTE, NC, [2]Johns Hopkins Hospital, Baltimore, MD, [3]Johns Hopkins Center for Fetal Therapy, Baltimore, MD, [4]Johns Hopkins University School of Medicine, Baltimore, MD, [5]Johns Hopkins University, Baltimore, MD, [6]Johns Hopkins, Montreal, QC, [7]Johns Hopkins School of Medicine, Baltimore, MD

OBJECTIVE: Racial disparities are a recognized factor for adverse outcomes in medicine. The impact of racial disparities on fetal therapy outcomes is largely unexplored. We sought to evaluate the impact of race on outcome in patients with Twin-Twin Transfusion Syndrome (TTTS) presenting for fetoscopic laser surgery (FLS).

STUDY DESIGN: Single site secondary analysis of patients presenting for TTTS evaluation between July 2014 to March 2023. Groups were compared between 5 race categories (White, Black, Hispanic, Asian, and other) and then compared between White and nonwhite groups. Demographics, TTTS characteristics, and FLS outcomes were compared using Fisher's exact Chi-square, Kruskal-Wallis and Mann-Whitney U-tests. Logistic regression was performed based on significance at univariate analysis.

RESULTS: Of 408 patients with TTTS, 301 (73.8%) were White, 47 (11.5%) Black, 38 (9.3%) Hispanic, 20 (4.9%) Asian, and 2 (0.5%) were classified as other. Prior preterm birth was more common in Black patients ($p = 0.04$). Nonwhite patients presented for evaluation later (20.1 [13 − 28.1] vs 18.6 [12.4-28.1] weeks, $p=0.011$) and at more advanced TTTS stages ($p=0.001$). Evaluation to laser interval was 0-1 day for all groups (NS). There was no difference in gestational age (GA) at delivery however perinatal survival was lower in nonwhite patients (160/214 (74.8%) vs 516/602 (85.4%), $p< 0.001$) due to lower double birth survival, 71/107 (66.4%) vs 243/301 (80.7%), $p=0.007$, and they were twice as likely to have no survivors at birth, 15/107 (14%) versus 21/301 (7%), $p=0.01$. The two greatest determinants of laser survival were insurance type and race ($p< 0.001$) [Figure].

CONCLUSION: Nonwhite patients with government insurance have the lowest perinatal survival after laser. Disparities significantly contribute to worse outcomes in patients with TTTS. The reason for these findings is likely complex and multifactorial, skewed by the nature of fetal therapy referral patterns, and demands further study.



1183 The Impact of Body Mass Index on Cesarean Delivery Duration

Mary Taylor Winsten[1], Alexandra Piselli[2], Kylie Mulvaney[1], Babatamilore Alade[2], Taylor Martin[2], Julisa Nunez[2], Fatimah Z. Fahimuddin[3], Gerald Kolm[4], Felicia Hamilton[1]

[1]MedStar Washington Hospital Center, Washington, DC, [2]Georgetown University School of Medicine, Washington, DC, [3]MedStar Washington Hospital Center, Arlington, VA, [4]Georgetown University, Washington, DC

OBJECTIVE: Prolonged operative durations are known to increase complications. In obstetrics, prolonged operative times in repeat cesarean deliveries (CD) are known to be a marker for adverse maternal outcomes, with higher maternal body mass index (BMI) potentially being a risk factor. In this study, we sought to compare the length of operative times of CDs across various BMI categories to determine how elevated BMI impacts operating time.

STUDY DESIGN: We performed a single center, retrospective study comparing CD operating times and maternal BMI from July 2021 to December 2022. In this review, we compared total length of time in the operating room (OR), time from skin closure to OR exit, and time from placental delivery to exit. BMI ranges were defined as $<30 m/kg^2$, 30-39.9 m/kg^2, 40-49.9 m/kg^2, and ≥ 50 m/kg^2. Patient exclusion criteria included multifetal gestation and emergent CD. Linear regression models compared BMI categories. Covariates included the total blood loss, concern for bladder or bowel injury, and number of prior CDs.

RESULTS: A total of 1647 patients were included in the study, with 47 being omitted due to missing data. Regression analysis comparing total OR times showed BMI <30 m/kg^2 required significantly less OR time than the 40-49.9 m/kg^2 [95%CI (6.83-19.85), $p=< 0.001$] and ≥ 50 m/kg^2 [95%CI (39.67-61.79), $p=< 0.001$]. Patients with BMI ≥ 50 m/kg^2 had significantly greater total time in the OR compared to BMI 40-49.9 m/kg^2. For placental delivery to exit, the BMI of < 30 m/kg^2 group was significantly less than all other categories. Skin closure to exit times was significantly faster than the group of BMI ≥ 50 m/kg^2 [95%CI (24.58-34.46), $p=< 0.001$], but there was no significant difference between patients with BMIs $<30 m/kg^2$ and those with BMIs of 30-39.9 m/kg^2 or 40-49.9 m/kg^2.

CONCLUSION: Operative times vary based on patients' BMI, with heavier patients having significantly longer procedures. Body mass index ≥ 50 m/kg^2 had the greatest impact on increased total OR time. Given this data, increased BMI may be associated with an increased risk of operative complications and hospital costs.

Table 1. Linear Regressions of Stages of Cesarean Delivery by BMI Categories

1184 The association between being born small for gestational age and childhood inflammatory bowel disease

Orit Wissotzky Broder[1], Gali Pariente[2], Tamar Wainstock[3], Eyal Sheiner[4]

[1]Soroka Medical Center, Kibutz Lahav, HaDarom, [2]Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Klahim, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom, [4]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: The pathogenesis of inflammatory bowel disease (IBD) is considered multifactorial. Genetic changes, environmental factors and mostly dysregulated immunity, all play a role in the pathogenesis of IBD. Being born small for gestational age (SGA) is known to be related to immunologic aberrations and endothelial dysfunction leading to abnormal placentation. As both IBD and being born SGA share common pathophysiologic features, we sought to investigate the association between being born SGA and childhood IBD.

STUDY DESIGN: A population-based cohort study was conducted. Deliveries occurred between the years 1991-2021 in a tertiary medical center, infants followed up to the age of 18 years. Data for the diagnosis of IBD was extracted from community-based clinics and hospitalization records. Kaplan-Meier survival curve was used to compare the cumulative incidence of childhood IBD of SGA and

non-SGA infants. A Cox proportional hazard model was used to control for confounders.

RESULTS: During the study period, 356,356 singleton deliveries occurred, of which 16,210 (4.5%) infants were born SGA. Being born SGA, was not associated with childhood IBD (0.2% vs. 0.1%, p=0.118, Table). The Cox proportional hazard model adjusted for maternal and gestational age demonstrated that being born SGA was not independently associated with childhood IBD (Adjusted HR 0.94, 95% CI 0.63-1.39, p=0.761, Table).

CONCLUSION: Being born SGA is not a risk factor for childhood IBD.

Table. The association between SGA and childhood IBD; Univariate analysis and results from a Cox proportional hazard model

	SGA infant (n=16,210) n (%)	Non- SGA infant (n=340,146) n (%)	Odds Ratio	95%CI	p value	Adjusted* HR	95%CI	p value
Inflammatory bowel disease	27 (0.2%)	416 (0.1%)	1.36	0.92-2.01	0.118	0.94	0.63-1.39	0.761

* Adjusted for gestational age, maternal age at birth

Outcomes	Balloon (n=40)	Dilapan-S (n=40)	P value
Change in Bishop score	3.0 (2.0,4.5)	3.0 (2.0,5.0)	0.91
Overall patient satisfaction[γ]	8 (5,9)	9 (8,10)	<0.01
Cervical ripening failure*	15 (37.5%)	7 (17.5%)	0.045
Unscheduled medical contact	14 (35.0%)	3 (7.5%)	<0.01

Time to delivery (hours)	17.0 (11.7,28.4)	20.1 (13.9,26.2)	0.89
Maternal length of stay (days)	2.9 (2.7,3.9)	3.2 (2.7,4.7)	0.98
Maternal morbidity composite[α]	8 (20%)	8 (20%)	1
Neonatal morbidity composite[β]	0 (0%)	1 (2.5%)	1

Data are presented as number (percentage) or median (quartile 1, quartile 3).
[γ] On scale of 0-10
* Defined as inability to place CR or need for further cervical ripening post removal
[α] Maternal composite: transfusion, chorioamnionitis, endometritis, wound infection, venous thromboembolism, hysterectomy, or ICU admission
[β] Neonatal composite: sepsis, transfusion, therapeutic hypothermia/HIE, or IVH

1185 Single-balloon catheter versus Dilapan-S placement for outpatient cervical ripening: A single-blind randomized controlled trial

Rachel L. Wood[1], Clarissa Bluemm[2], Sarah Lassey[2], Julianna Schantz-Dunn[2], Sarah E. Little[2]
[1]Duke University Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA

OBJECTIVE: To compare Dilapan-S to cervical balloon for outpatient cervical ripening (CR).

STUDY DESIGN: This was a single-blind, randomized controlled trial at a single tertiary hospital between May 2022 and July 2023. Term patients with no prior c-section and a singleton, vertex fetus scheduled for outpatient CR per hospital policy were eligible. Prior to CR, an NST and exam to confirm Bishop score < 6 were performed. Patients were then consented and randomized to CR catheter with 60mL in the intrauterine balloon or 3 to 5 Dilapan-S hydroscopic dilators then discharged home. Patients returned in 6-24 hours per policy or if clinically indicated. CR agent was removed, blinded exam performed, and patients completed a satisfaction survey. Further induction was per the obstetrical provider. Primary outcome was change in Bishop score. Secondary outcomes included patient satisfaction, time to delivery, mode of delivery, cervical ripening failure (failure to place or need for further ripening) and composite maternal and neonatal morbidity.

RESULTS: 80 patients were randomized with no difference in baseline demographic data, percent nulliparous, starting dilation, or Bishop score. There was no significant difference in change in Bishop score between Dilapan-S and balloon (median change 3 (interquartile range (IQR) 2-5) vs 3 (IQR2-4.5) respectively, p=0.91). There was no difference in time to delivery, mode of delivery or maternal or neonatal outcomes (Table 1). Patients with Dilapan-S were significantly more satisfied with their experience (scale 0-10, median 9(IQR 8-10) vs 8(IQR 5-9), p=0.008) and significantly less likely to experience cervical ripening failure (7(17.5%) vs 15(37.5%), p=0.045) or have unscheduled contact with the medical team (3(7.5%) vs 14(35%);p< 0.01).

CONCLUSION: Dilapan-S was non-inferior to cervical balloon catheter for outpatient cervical ripening based on change in Bishop score. Patients were significantly more satisfied with Dilapan-S and significantly less likely to experience cervical ripening failure or have unscheduled contact with the medical team compared to single balloon catheter.

1186 Pre-Pregnancy BMI Associated with Increased Perceived Stress During Pregnancy and Adverse Pregnancy and Neonatal Outcomes

S Taylor Woollen[1], Carol L. Wagner[1], Myla D. Ebeling[1], Anna L. Vestergaard[2], Judy R. Shary[1], Bruce W. Hollis[1], Donna Johnson[1]
[1]Medical University of South Carolina, Charleston, SC, [2]Aarhus University, Aarhus, Midtjylland

OBJECTIVE: The association between Body Mass Index (BMI) and perceived stress is understudied. We hypothesized that a greater BMI is associated with increased maternal stress and adverse pregnancy and neonatal outcomes.

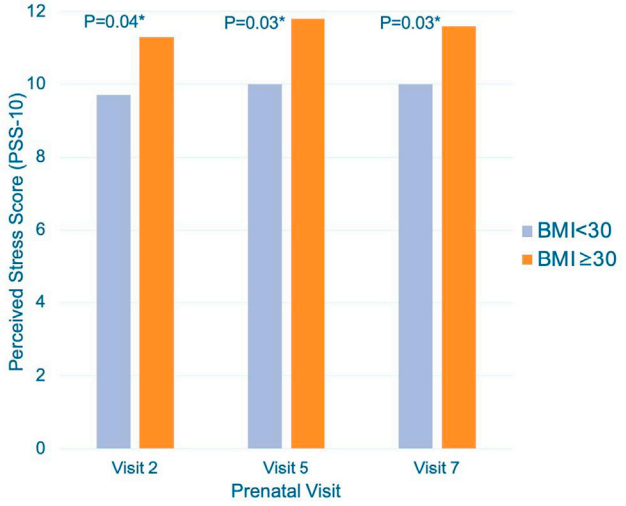
STUDY DESIGN: This 2° retrospective analysis of the Kellogg Vitamin D Pregnancy Study included women aged 18−45 who presented to MUSC obstetric clinics within 14 weeks' gestation between January 2013−May 2016. Baseline maternal health and sociodemographic information was collected during first study visit. Birth outcomes and infant parameters were collected at birth. Linear regression analyses used to show association between maternal Perceived Stress Scale (PSS-10) scores and maternal and infant characteristics; and logistic regression analyses used to show factors associated with pregnancy outcomes and maternal PSS-10 scores. Generalized linear mixed effect models created to measure the relationship between maternal PSS-10 scores and BMI, marital status, race, education, insurance status, planned pregnancy, gestational diabetes, and visit.

RESULTS: 212 women completed PSS-10 at 16, 28, and 36 wks GA and were the basis for these analyses (154 had BMI< 30, 58 had BMI ≥30). BMI≥30 associated with increased PSS-10 scores at each visit (p< 0.05). Women with BMI≥30**:** more likely unmarried, Black/Hispanic, less college, Medicaid insurance, and lower 25(OH)D (p< 0.05). In mixed effect models, increased PSS-10 scores associated with BMI≥30, unmarried, planned pregnancy, and decreased maternal 25(OH)D. BMI≥30 associated with lower maternal weight gain, lower maternal 25(OH)D 1 month before delivery, and AUC (p< 0.05). Neonates born to women with BMI≥30 were more likely admitted to higher acuity care, had shorter gestational age, and lower 25(OH)D (p< 0.05).

CONCLUSION: Pregnant women with BMI≥30 had sociodemographic differences and greater vitamin D deficiency, perceived stress, and adverse neonatal outcomes. BMI remained a strong predictor of

higher neonatal acuity and shorter gestational age. Public health efforts should be directed at effective, sustained treatment to reduce BMI prior to pregnancy.

Figure 1. Perceived Stress Scores at Visits 2, 5, and 7



BMI ≥30 associated with increased perceived stress scores at visits 2, 5, and 7.

1187 Placental abruption and antepartum hemorrhage delivery hospitalization trends, risk factors, and outcomes

Gillian Wright[1], Timothy Wen[2], Cande V. Ananth[3], Alexander M. Friedman[4]

[1]New York Presbyterian-Columbia, New York, NY, [2]University of California, San Francisco (UCSF), San Francisco, CA, [3]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [4]Columbia University, New York, NY

OBJECTIVE: Placental abruption is a serious condition involving early separation of the placenta. The objective of this study was to identify trends and adverse outcomes associated with placental abruption.

STUDY DESIGN: The 2000-2020 National Inpatient Sample was used for this repeated cross-sectional study. Delivery hospitalizations to women age 15-54 years were identified. Temporal trends in abruption were analyzed with joinpoint regression to determine the average annual percentage change (AAPC) with 95% CIs. The association between hospital, demographic, and clinical factors and placental abruption was analyzed with logistic regression models. Logistic regression models were then used to assess odds of adverse outcomes associated with placental abruption accounting for demographic, hospital, and patient factors.

RESULTS: Of 80.2 million deliveries from 2000 to 2022, 1.1 million had an abruption diagnosis. Placental abruption risk increased from 1.2% of deliveries in 2000 to 1.6% in 2020 (AAPC 0.5). Placental abruption was associated with multiple gestation, hypertensive diagnoses, diabetes, asthma, and Medicaid insurance. In unadjusted and adjusted analyses, placental abruption was associated with a range of adverse outcomes with adjusted odds highest for transfusion (aOR 6.9, 95% CI 6.7, 7.0) and preterm birth (aOR 8.4, 95% CI 8.2, 8.5) (Table). Risk for several adverse outcomes associated with abruption increased over the study period including postpartum hemorrhage (from 4.4% to 9.2%, AAPC 4.1%) and transfusion (3.9% to 6.2%, AAPC 2.7%).

CONCLUSION: Risk for placental abruption increased over the study period and was associated with several adverse outcomes. Among deliveries with abruption, risk for several complications increased significantly including transfusion and postpartum hemorrhage. Given trends in both increasing incidence and related complications, placental abruption is likely to continue to be a significant source of adverse obstetric outcomes.

Table. Risk for adverse obstetric outcomes associated with placental abruption

Adverse outcomes	No Abruption		Abruption		Unadjusted model		Adjusted model	
	N	%	N	%	OR	95% CI	aOR	95% CI

[1]Tzafon Medical Center, Afula, HaZafon, [2]Emek medical center, Afula, HaZafon, [3]Emek medical center, Timrat, HaZafon, [4]Sourasky Medical Center, Tel-Aviv, Israel, [5]Rambam Medical Center, Haifa, Hefa, [6]Rambam Medical Health Campus, Toronto, ON, [7]Edith Wolfson Medical Center, Shoham, HaMerkaz, [8]Samson Assuta Ashdod University Hospital, Ashdod, HaMerkaz, Israel, [9]Galilee Medical Center, Nahariya, Israel Azrieli Faculty of Medicine, Bar Ilan University, Safed, Israel, Nahariya, HaZafon, [10]Galilee Medical Center, Nahariya, HaZafon, [11]Mayanei Hayeshua Medical Center, Tel-Aviv, Israel, [12]Mayanei Hayeshua Medical Center, Ra'anana, HaMerkaz, [13]Tzafon Medical Center, Poriya, HaZafon, [14]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz, [15]Meir Medical Center, Kfar Saba, HaMerkaz, [16]Soroka University Medical Center, Beer Sheva, HaDarom, [17]Hillel Yaffe Medical Center, Hadera, Hefa, [18]Hillel Yaffe Medical Center, Ramat Gan, Hefa

OBJECTIVE: Twin gestations are subjected to higher rates of growth abnormalities. Accurate locally customized reference values may contribute to accurately diagnosing abnormal fetal growth. We aimed to determine reference values for ultrasound-based estimated fetal weight (EFW) and compared them to the actual birth-weight curve for twins.

STUDY DESIGN: A multicenter retrospective longitudinal analysis of sonographically EFW evaluations of twin gestations performed between 2009 and 2022 in 10 medical centers in Israel. Estimated fetal weight at 14-40 gestational weeks was calculated using the Hadlock 1985 formula. No exclusions were made on grounds of chorionicity. The non-parametric Quantile Generalized Additive Model (QGAM) approach was employed. Following the calculation of the 10th, 50^{th,} and 90th percentile for each gestational week and the construction of ultrasound-based curves, we compared the 10th percentile at 22 to 37 gestational weeks with that calculated using the Israeli local twin specific actual birth weight curve.

RESULTS: After cleaning procedures, the dataset comprised data from 5,506 mothers with approximately 26,500 sonographic evaluations of EFW (median 5 evaluations per pregnancy). Values corresponding to the 50th, 10^{th,} and 90th percentiles were calculated with the construction of the ultrasound-based reference curve. The 10th percentile of the sonographic EFW curve was about 100-200 grams

higher than the 10th percentile of the birth-weight curve, matching the 15-20 growth percentiles (figure).

CONCLUSION: The sonographic EFW curve and the actual birth-weight curve established different cutoff values for the 10th percentile in twin gestation. Choosing the appropriate growth curve is important to avoid misdiagnosis of growth abnormalities.

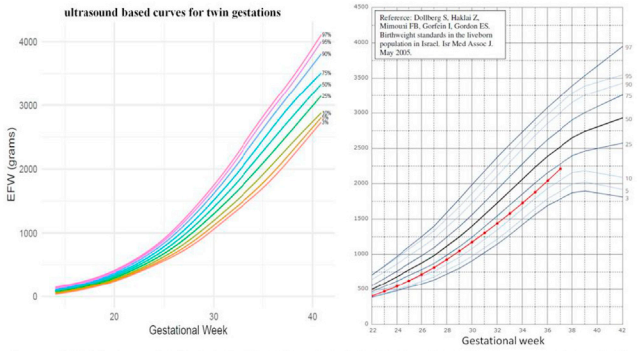

Figure. Left panel: The sonographic estimated fetal weight . Right panel: The birth-weight curve (blue and black lines) and the 10th percentile of the calculated sonographic estimated fetal weight (red line)

1189 The effect of fetal surveillance on fetal outcomes in pregnancies with fetal growth restriction

Enav Yefet[1], Yahel Shohat[2], Bili Gasman[2], Revital Vinitski[2], Netaly Faramand[2], Manal Massalha[3], Ali Massalha[4], Zohar Nachum[5]

[1]Tzafon Medical Center, Afula, HaZafon, [2]Tzafon Medical Center, Poriya, HaZafon, [3]Emek medical center, Afula, HaZafon, [4]Emek medical center, Emek, HaZafon, [5]Emek medical center, Timrat, HaZafon

OBJECTIVE: There is no consensus regarding the appropriate follow-up frequency in fetal growth restriction (< 10th percentile; FGR). We examined whether FGR would benefit from careful monitoring with stratification for normal and pathological cerebro-placental ratio (CPR).

STUDY DESIGN: This was a retrospective cohort study conducted between 2016 and 2020 in two medical centers. Women with suspected FGR (with (N=135) and without (N=269) pathological CPR underwent a strict monitoring regimen (1-2 well being assessments per week and Doppler flows once a week). These groups were compared to two control groups - fetuses identified only after birth as small for gestational age (SGA; N=693), and fetuses appropriate for gestational age (AGA; N=864) in which routine follow-up was done. Twins were excluded. The primary outcomes were (1) a composite outcome of cesarean deliveries (CD) due to suspected fetal distress, Apgar score< 7 at 5 min, cord pH< 7.1, neonatal intensive care unit admission, need for neonatal oxygen support and intrauterine fetal death, and (2) The rate of women in whom the strict follow-up led to induction of labor/CD before 37 weeks.

RESULTS: Study outcomes are presented in the table. The composite outcome was significantly different between the pathological CPR, normal CPR, SGA and AGA groups (61%, 34%, 24%, 12% respectively; P< 0.0001). Following logistic regression to control for background characteristics, the difference in the rate of the composite outcome was statistically significant between all groups except from the normal CPR group versus the SGA group (table). The strict follow-up led to a higher rate of induction of labor/CD before week 37 in the group with the pathological CPR (23 [18%]) compared to those with normal CPR (11 [4%]), P< 0.0001.

CONCLUSION: The knowledge of FGR led to additional interventions, but without improving the outcomes of the newborn. CPR measurement may have a role in the assessment and adjustment of the follow-up plan. In cases where the CPR was normal, the rate of interventions before week 37 was low, and close follow-up may not be necessary in these cases.

1190 Presence of SSA/SSB antibodies and risk of preeclampsia in patients with autoimmune disease

Alyssa Yeung[1], Justina Shafik[2], Alexa Cohen[1], Pe'er Dar[3], Georgios Doulaveris[1]

[1]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [2]MS, Bronx, NY, [3]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY

OBJECTIVE: The presence of anti-Sjogren's syndrome-related antibody A (SSA) or B (SSB) in pregnant patients is associated with neonatal lupus and heart block. However, data on adverse maternal outcomes is limited. We hypothesized these antibodies are associated with a higher risk of adverse maternal outcome. We sought to assess

the association of SSA/SSB antibodies with the development of preeclampsia and other adverse obstetric outcomes in gravidas with autoimmune disease.

STUDY DESIGN: This is a historical matched case-control study of all patients with positive SSA or SSB antibodies from 1/2010 to 8/2022 who delivered at a tertiary referral center. The study group was matched by age, parity, and autoimmune disease to gravidas with autoimmune disease without SSA/SSB antibodies. Primary outcome was preeclampsia with or without severe features. Secondary outcomes were gestational hypertension, cesarean delivery and spontaneous preterm birth. Categorical variables were compared using Chi-square and Fisher's exact test. Student t-test or Mann Whitney test were used for continuous variables. Multivariable logistic regression analysis was performed to adjust for confounders (age, obesity, parity, antiphospholipid syndrome, chronic hypertension, pregestational diabetes).

RESULTS: 124 SSA/SSB antibody positive patients were compared to 86 SSA/SSB negative patients. The characteristics and outcomes are presented in Table 1. The incidence of preeclampsia was significantly higher in patients with positive SSA/SSB antibodies compared to those without antibodies (21.0% vs 10.5%, p=0.04). There was no difference in the incidence of gestational hypertension, spontaneous preterm birth or cesarean delivery. After adjusting for confounders, positive SSA/SSB antibodies remained an independent risk factor for preeclampsia (OR 2.66, 95% CI 1.04-6.84, p=0.04).

CONCLUSION: In our historic cohort, the presence of SSA/SSB antibodies in patients with autoimmune disease appears associated with an increased incidence of preeclampsia. Additional larger and prospective studies are necessary to further examine this possible association.

Table 1. Characteristics and outcome of patients with autoimmune disease and positive versus negative SSA or SSB antibodies

	SSA/B positive (n=124)	SSA/B negative (n=86)	P value
Age, years (mean ±SEM)	30.5 ±0.5	31.5 ±0.6	0.2

1191 Prophylactic TXA prior to skin incision in high-risk cesarean deliveries: Does it make a difference?

Emily Zantow[1], Olivia Wilson[2], Elena Jenkins[3], Joseph Polcaro[2], Niraj R. Chavan[4]

[1]Mercy Hospital St. Louis, St. Louis, MO, [2]St. Louis University School of Medicine, St. Louis, MO, [3]SSM Health St. Mary's Hospital, St. Louis, MO, [4]St. Louis University, St. Louis, MO

OBJECTIVE: The objective of this study was to evaluate the implementation and impact of a quality improvement (QI) protocol focused on prophylactic tranexamic acid (TXA) administration prior to skin incision in cesarean deliveries (CD) at high-risk for postpartum hemorrhage (PPH).

STUDY DESIGN: We undertook a QI initiative centered on prophylactic TXA given prior to skin incision in CDs at medium to high risk for PPH. We evaluated perioperative outcomes in 2 successive cohorts – 3 months before and after implementation, from November 2022 to April 2023. Our protocol entailed: 1 gm IV infusion 10 minutes prior to skin incision in CDs with no contraindications to TXA. Demographic characteristics and perioperative outcomes were abstracted from electronic records and compared across the 2 groups using Student's t-test and c^2 or Fischer's exact test for continuous and categorical data, respectively. Statistical significance was set at $p \leq .05$. Our primary implementation outcome was % of eligible CDs receiving prophylactic TXA per protocol and primary effectiveness outcomes were quantitative blood loss (QBL) and need for transfusion.

RESULTS: 250 patients were included in this analysis: 125 each, pre and post-implementation. Demographic characteristics were similar across both groups, including BMI, number of prior CDs, type of anesthesia, uterine incision, timing, type and duration of CD, and gestational age at delivery. Of all eligible patients, 62.1% (n=72) in the pre- and 90.4% (n=103) in the post-implementation group received TXA per protocol ($p < .01$). QBL was similar across groups; however, the post-implementation group had lower rates of transfusion, including number of packed red blood cells (PRBC), total units transfused, and cases requiring >2 units PRBC, which trended towards significance (p=.07). Changes in hemoglobin, need for additional uterotonic agents, and arterial embolization/cesarean hysterectomy rates were similar.

CONCLUSION: Prophylactic TXA administration may have limited clinical utility in high-risk CDs, however the optimal timing of administration and effectiveness needs further evaluation.

Table 1: Perioperative Outcomes from Prophylactic TXA Administration Prior to Skin Incision

Outcome	Pre-Protocol n=125	Post-Protocol n=125	P
Eligible candidate for TXA	116 (92.8)	114 (91.2)	.64
TXA administered	75 (60.0)	109 (87.2)	<.0001

1192 The Evolving Landscape of Biomedical Informatics for Postpartum Hypertension: A Scoping Review

Ruben Zapata, Michaela Rechdan, Lindsey Brinkley, Adetola Louis-Jacques, Francois Modave, Dominick J. Lemas

University of Florida, Gainesville, FL

OBJECTIVE: Postpartum hypertension (PPHTN) affects more than 10% of deliveries and can affect multiple systems such as neurological and renal systems in the mother while also affecting the infant negatively. The objective of this scoping review is to investigate the role of biomedical informatics in the identification and management

of PPHTN, with a focus on the use of machine learning/artificial intelligence (ML/AI) for early identification.

STUDY DESIGN: A structured search was used to query Scopus, PubMed, IEEE Xplore for relevant articles. The scoping review identified studies that described the application of ML/AI for prediction, prevention, or early detection of adverse events in each of the harm domains. Inclusion criteria**:** Included PPHTN or high blood pressure occurring within the first six weeks following childbirth, studies based on humans, ML studies with PPHTN, and ML studies in postpartum related complications. Exclusion criteria removed papers unrelated to the postnatal period, meta-analyses, any review, prenatal or gestational only studies.

RESULTS: A total of 462 articles were obtained with the keywords "machine learning", "artificial intelligence", with the following keywords "postpartum hypertension", "high blood pressure", "postnatal hypertension". Four articles were selected after screening according to the inclusion and exclusion criteria. Data used to predict PPHTN were electronic health records (EHR) (75%), medical records (25%). In 3 studies, the main metrics used were**:** Area under the curve, sensitivity, specificity, and accuracy. Most common ML methods used were logistic regression and XGBoost. Out of the ML approaches used, the best results were found using XGBoost technique with an AUC score of 0.85.

CONCLUSION: Our results demonstrate that AI-based methods to reduce PPHTN have been limited to a small number of studies that focus on structured EHR data elements. In conclusion, our findings highlight the potential for AI to improve diagnosis and treatment of patients with PPHTN by overcoming various problems related to early identification, and management of postnatal hypertension.

1193 The Yield of Amnioinfusion in the Prevention of Postpartum Hemorrhage

Keren Zloto[1], Eyal Sivan[2], Rakefet Yoeli[3], Shali Mazaki-Tovi[4], Suneet P. Chauhan[5], Michal Fishel Bartal[6]

[1]Sheba Medical Center, Tel Aviv, Israel, [2]Sheba Medical Center, Tel-Hashomer, Ramat-Gan, Israel, [3]Sheba Medical Center, Tel-Hashomer, Kiriat Ono, HaMerkaz, [4]Chaim Sheba Medical center, Tel HaShomer, Ramat Gan, HaMerkaz, [5]University of Texas-Houston Medical School, Houston, TX, [6]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX

OBJECTIVE: Previous report highlighted the role of amnioinfusion in the prevention of uterine atony (Wetta et al., AJOG 2013). However, whether or not amnioinfusion decreases the risk of postpartum hemorrhage (PPH) is unknown. This study aimed to determine whether amnioinfusion reduces the risk of PPH.

STUDY DESIGN: This was a retrospective study of all laboring individuals at a single tertiary center between 01/2013 and 12/2022 at $\geq$ 34 weeks. Individuals with planned cesarean delivery (CD), known major fetal anomalies, stillbirth, or missing delivery records were excluded. The primary outcome was a composite outcome including any of the following**:** PPH (estimate blood loss of $\geq$1,000 mL or blood loss accompanied by signs or symptoms of hypovolemia within 24 hours from delivery) blood transfusion, need for uterotonic (in addition to oxytocin), mechanical tamponade, surgical management of PPH, or relaparotomy or hysterectomy. Multivariable regression models were used to estimate adjusted odd risks (aOR), controlling for variables identified in the univariate analysis.

RESULTS: Of 109,989 deliveries during the study period, 89,321 (81%) met the inclusion criteria. Of those, 4,452 (5%) had amnioinfusion during labor. Laboring individuals with amnioinfusion, compared to those without, were more commonly nulliparous (61.2% vs. 34.7%; P< 0.01), had polyhydramnios (3.8% vs. 2.7%; P< 0.01), had a higher rate of labor induction (56.0% vs. 28.8%; P< 0.01), and had a higher CD rate (35.3% vs. 10.4%; P< 0.01). Following a multivariable regression, there was no difference in the rate of composite outcome among individuals that had an amnioinfusion versus those that did not. The rates of infectious morbidity, including surgical site infection and postpartum fever, were higher among individuals with amnioinfusion than those without (Table).

CONCLUSION: Among laboring individuals $\geq$ 34 weeks, intrapartum amnioinfusion was not associated with a significant reduction in the rate of postpartum hemorrhage, though amnioinfusion was associated with a higher likelihood of infectious morbidity.

Table: Intrapartum amnioinfusion during labor and maternal outcomes

Hypertension: Treatment/management 41, 42, 44, 145, 288, 352, 408, 481, 870, 924, 948, 1082
Infectious Diseases: Chorioamnionitis/endometritis 54, 97, 98, 185, 773, 905, 1097
Infectious Diseases: CMV 50
Infectious Diseases: Group B streptococcus 611
Infectious Diseases: Hepatitis 188, 468, 1071
Infectious Diseases: HIV 478
Infectious Diseases: Other 265, 551, 711, 777
Infectious Diseases: Other viral 51, 307, 350, 431, 549, 554, 591, 628, 665, 939, 1086, 1100
Infectious Diseases: Surgical site/postoperative 65, 164, 1000, 1009
Infectious Diseases: Syphilis 198, 333, 380, 629, 911
Infectious Diseases: Toxoplasmosis 298
Intrapartum Fetal Assessment: Fetal heart rate monitoring 79, 245, 460, 497, 784
Intrapartum Fetal Assessment: Other 342, 373
Labor: Abnormal labor 75, 127, 203, 457, 524, 545, 775, 782, 803
Labor: Abnormal position/presentation 719
Labor: Anesthesia 273, 1074
Labor: Cervical ripening 77, 78, 192, 237, 241, 393, 578, 822
Labor: Induction/augmentation 10, 12, 16, 81, 82, 83, 251, 289, 418, 449, 512, 543, 608, 671, 757, 774, 809, 840, 841, 895, 898, 912, 957, 1015, 1020, 1076, 1096
Labor: Operative vaginal delivery 748, 927

Labor: Other 6, 57, 84, 446, 492, 561, 637, 641, 717, 728, 965
Labor: Perineal trauma 56, 725, 862
Labor: Postpartum hemorrhage 7, 72, 171, 521, 971, 1094
Medical/Surgical/Diseases/Complications: Anesthesia 583
Medical/Surgical/Diseases/Complications: Cardiovascular 52, 344, 379, 426, 466, 634, 746, 1023, 1030, 1034
Medical/Surgical/Diseases/Complications: Critical care 625
Medical/Surgical/Diseases/Complications: Endocrinologic 950, 1083
Medical/Surgical/Diseases/Complications: Gastrointestinal 581, 694, 1087
Medical/Surgical/Diseases/Complications: Hematologic/thrombocytopenia 49, 133, 336, 392, 650, 732, 807, 907, 984
Medical/Surgical/Diseases/Complications: Immunologic 53, 1075
Medical/Surgical/Diseases/Complications: Malignancy 181
Medical/Surgical/Diseases/Complications: Neurologic 105, 329, 390, 576, 588, 738, 904, 949, 959
Medical/Surgical/Diseases/Complications: Non-obstetric surgery 96
Medical/Surgical/Diseases/Complications: Obesity 356, 442, 721, 896, 931, 937, 979, 1045
Medical/Surgical/Diseases/Complications: Other 71, 204, 853, 880, 901, 947
Medical/Surgical/Diseases/Complications: Psychiatric 162, 330, 365, 448, 506, 706, 718, 845, 995, 1001
Medical/Surgical/Diseases/Complications: Pulmonary/asthma 502
Medical/Surgical/Diseases/Complications: Thromboembolic 667
Medical/Surgical/Diseases/Complications: Transplants 218, 219, 977, 978
Neonatology: Birth trauma 969
Neonatology: Hypoxia/ischemia 692
Neonatology: Late preterm/early term infants 134, 473
Neonatology: Neurologic injury 286
Neonatology: Other 438, 558, 585, 770
Obstetric Quality and Safety: Clinical communication/decision-making 246, 544, 604, 764, 1061
Obstetric Quality and Safety: Clinical policies and guidelines 193, 562, 618, 702, 713, 814, 890, 919, 920, 997, 1014
Obstetric Quality and Safety: Maternal morbidity/mortality 66, 156, 163, 242, 303, 439, 494, 495, 496, 584, 658, 668, 703, 707, 785, 844, 856, 986, 987, 1007, 1008, 1047, 1065
Obstetric Quality and Safety: Patient related outcomes (e.g. Quality of life) 260, 321, 458, 1037
Obstetric Quality and Safety: Qualitative research 215, 779, 820
Obstetric Quality and Safety: Quality improvement 59, 61, 243, 312, 340, 353, 396, 430, 501, 572, 609, 666, 769, 1088
Obstetric Quality and Safety: Quality measures 606, 607, 760, 793, 857, 1070
Operative Obstetrics: Cervical cerclage 660, 661, 861
Operative Obstetrics: Cesarean delivery 13, 67, 73, 363, 434, 440, 444, 491, 559, 567, 605, 680, 741, 902, 935, 943, 970, 1055
Operative Obstetrics: Cesarean hysterectomy 165, 166, 320
Operative Obstetrics: Operative vaginal delivery 479, 664, 672, 704, 834, 869
Operative Obstetrics: Surgical site/postoperative 106, 762, 925
Operative Obstetrics: Uterine rupture 276
Operative Obstetrics: VBAC 130, 170, 179, 301, 302, 470, 796, 832, 858, 1080
Physiology/Endocrinology: Fetal 211, 421
Physiology/Endocrinology: Maternal 441, 687, 761, 801
Practice Management: Patient flow/wait times/satisfaction 823
Practice Management: Physician compensation 877
Prematurity: Cervical insufficiency 9, 20, 21, 24, 229, 436, 730, 791, 958, 964
Prematurity: Corticosteroids 19, 121, 154, 413, 536, 648, 848, 873, 909, 1018, 1022
Prematurity: Neonatal outcomes 701, 714, 815, 942
Prematurity: Preterm labor 23, 187, 213, 272, 337, 397, 429, 619, 731, 736
Prematurity: PROM 202, 394, 401, 505, 636, 833, 859, 996, 1021
Prematurity: Risk assessment/screening 174, 315, 364, 368, 371, 422, 530, 531, 698, 952, 1006, 1012
Prematurity: Tocolysis/treatment 22, 269, 525
Public Health/Global Health: Ethical, legal and social issues 217, 295, 366, 469, 515, 518, 623, 915, 1089
Public Health/Global Health: Global health 4, 18, 48, 76, 103, 104, 277, 294, 569, 574, 622, 649, 802, 889, 945, 966, 1019
Ultrasound/Imaging: 3D/4D ultrasound 210, 613, 781
Ultrasound/Imaging: Cervical length 257, 409, 956, 1062
Ultrasound/Imaging: Doppler 89, 261, 374, 375, 575, 734, 749
Ultrasound/Imaging: Fetal anomalies 15, 92, 510
Ultrasound/Imaging: Fetal echocardiography 95, 538
Ultrasound/Imaging: Fetal growth/weight 91, 128, 142, 173, 296, 369, 465, 504, 522, 548, 644, 849, 850, 1044
Ultrasound/Imaging: Interventional procedures 264, 385, 771
Ultrasound/Imaging: Maternal imaging 114, 266, 592
Ultrasound/Imaging: Multifetal gestation 836, 885, 1060
Ultrasound/Imaging: Nuchal translucency 716
Ultrasound/Imaging: Other 88, 94, 381, 553, 960, 1102
Ultrasound/Imaging: Placenta/membranes 146, 207, 240, 291, 313, 818, 838, 852, 892, 985, 1033, 1039, 1040, 1041
Ultrasound/Imaging: Vaginal sonography 1011

Numbers represent abstract numbers of presentations at this meeting.
