AJOG American Journal of Obstetrics & Gynecology

Information for Readers

Manuscript submissions

Address editorial queries to either of the managing editors: Donna L. Stroud, ajog@rrohio.com, and Sandra Perrine, ajogsp@gmail.com.

For mailing address, telephone and fax numbers, e-mail address, and detailed instructions on manuscript submission, see the Information for Authors at ajog.org and at www.editorialmanager.com/AJOG.

Customer service (orders, claims, online access, change of address)

Please visit our Support Hub page https://service.elsevier.com for assistance.

One-year subscription rates

United States and its commonwealths, territories, and possessions: individual, $523; student/resident, $242. All other countries (prices include airspeed delivery): individual $644; student/resident, $305. To receive student/resident rate, order must be accompanied by name of institution, date of term, and signature of program/residency coordinator on institution letterhead. Orders will be billed at the individual rate until proof of status has been received. No student discount applies for back volumes or back issues.

Advertising

Display advertising rates and requirements: Jessica Sneathen, Advertising Sales Representative, Elsevier Inc., 230 Park Avenue, New York, NY 10169-0901, USA. Phone: 267-226-8166. E-mail: j.sneathen@elsevier.com.

Classified advertising orders and inquiries: Kenneth Naylor, Advertising Sales Representative, Elsevier Inc., 230 Park Avenue, Suite 800, New York, NY 10169-0901, USA. Phone: 212-633-3835. Fax: 212-633-3820. E-mail: K.Naylor@elsevier.com.

For more information

Additional information about the Journal is available from the publisher or at ajog.org. Information on other Elsevier products is available at www.elsevier.com.

Author inquiries

You can track your submitted article at http://www.elsevier.com/track-submission. You can track your accepted article at http://www.elsevier.com/trackarticle. You are also welcome to contact Customer Support via http://support.elsevier.com. These sites enable authors to track accepted articles and to request e-mail alerts to be sent whenever an article's status has changed. Also provided are detailed guidelines for the submission of artwork, copyright information, FAQ, and more. Once an article has been submitted, the corresponding author will be advised to contact the editors for questions that may arise if the article is accepted.

Reprints

To order 100 or more reprints of any single article for educational, commercial, or promotional use, contact Derrick Imasa, Commercial Reprints Department, Elsevier Inc., 230 Park Avenue, New York, NY 10169-0901, USA. Phone: 212-633-3874. Fax: 212-462-1935. E-mail: reprints@elsevier.com. For queries about authors' discounts for reprints of their own articles: authorsupport@elsevier.com. Reprints of single articles available online to subscribers only may be obtained via Pay-Per-View access ($36 per article) at ajog.org.

Copyright

Copyright © 2024 Elsevier Inc. All rights reserved.

Electronic availability

The Journal is available online from Elsevier Inc. at ajog.org. All material is free to signed-in subscribers. Some material is free to all.

Photocopying

One photocopy of each article may be made for personal use as permitted by national copyright law. Permission of the publisher and payment of a fee is required for all other photocopying, including multiple or systematic copying, copying for advertising or promotional purposes, resale, and all forms of document delivery. Special rates are available for educational institutions that wish to make photocopies for nonprofit educational classroom use.

Derivative works

Subscribers may reproduce tables of contents from the Journal and prepare lists of Journal articles, including abstracts, for circulation within their institutions. Permission of the publisher is required for resale or distribution of such material outside the institution and for all other derivative works, including compilations and translations.

Permission requests

Permissions may be sought from the Elsevier Rights Department. Phone: 215-239-3804 (Philadelphia, PA) or 44 (0) 1865 843830 (Oxford, England). Fax: 44 (0) 1865 85333 (Oxford). E-mail: permissions@elsevier.com. Requests may also be completed online at www.elsevier.com/authors/obtaining-permission-to-re-use-elsevier-material, where requirements are described.

Permissions may be cleared and payments made in the US through the Copyright Clearance Center, Inc., 222 Rosewood Drive, Danvers, MA 01923. Phone: 978-750-8400. Fax: 978-750-4744. In the UK, this may be done through the Copyright Licensing Agency Rapid Clearance Service (CLARCS), 90 Tottenham Court Road, London W1P 0LP, England, UK. Phone: (44) 20 7631 5555. Fax: (44) 20 7631 5500. In other countries where a local copyright clearance center exists, please contact that center for information about permissions and payments.

Electronic storage or use

Permission of the publisher is required to store or use electronically any material contained in the Journal, including any article in full or in part. Except as outlined above, no part of this publication may be reproduced, stored in a retrieval system, or transmitted in any form or by any means, electronic, mechanical, photocopying, recording or otherwise, without written permission of the publisher. Address requests for such permissions to the Elsevier Rights Department as indicated above under "Permission requests."

Notice

No responsibility is assumed by the publisher or its affiliated societies and organizations for any injury and/or damage to persons or property as a matter of product liability, by negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein. Rapid advances in the medical sciences demand independent verification of diagnoses, drug dosages, and other health-related information provided herein.

Although all advertising material is expected to conform to ethical standards, inclusion in this publication does not constitute a guarantee or endorsement of the quality or value of any such product or of claims made by its manufacturer.

All abstract presentations take place at the Gaylord National Resort and Convention Center

Schedule of oral presentations 5A

MONDAY, February 12

3:15 PM–3:45 PM — **Opening Addresses from Program Chair & President; Honorary, Lifetime Achievement, and President's Awards**

3:45 PM–6:00 PM — **Oral Plenary Session I and Late Breaking**
Abstracts 1-8, and LB1 | *Potomac Ballroom* S1

TUESDAY, February 13

7:00 AM–7:30 AM — **Foundation for SMFM Chair Address**
Potomac Ballroom, Ballroom Level

7:30 AM–8:00 AM — **Keynote Address by Secretary Xavier Becerra**
Potomac Ballroom, Ballroom Level

8:00 AM–10:30 AM — **Oral Plenary Session II - Fellows Plenary and Late-Breaking**
Abstracts 9-16 | *Third Floor* S7

10:30 AM–12:00 PM — **Poster Session I**
Abstracts 95-369 | *Exhibit Hall* S70

1:30 PM–3:30 PM — **Oral Concurrent Sessions**

Session 1 Prematurity
Abstracts 17-24 | *Potomac Ballroom AB* S14

Session 2 Diabetes
Abstracts 25-32 | *Potomac Ballroom C* S20

Session 3 Basic Science
Abstracts 33-40 | *Potomac Ballroom D* S26

3:30 PM–5:00 PM — **Poster Session II**
Abstracts 370-643 | *Exhibit Hall* S208

Congratulations to Our Abstract Awards Winners

Bruce A. Work Award for Best Research by a Practicing or Training Maternal-Fetal Medicine Physician outside of the US

72: Increased risk of postpartum hemorrhage in women with resolved low placentation: a multicenter prospective study

Ornaghi Sara, MD, PhD

Disparities Award for Best Research on Diversity/Disparity in Health Outcomes

64: Exploring Black birthing people's perspectives on racial concordance with obstetric care providers

E. Nicole Teal, MD, MPH

Dru Carlson Memorial Award for Best Research in Ultrasound and Genetics

1: Multicenter, prospective cohort of genome sequencing in 750 fetal structural anomalies

Ronald J. Wapner, MD

Norman F. Gant Award for Best Research in Maternal Medicine

42: Clinical Outcomes Following Remote Hypertension Monitoring Program for Postpartum Individuals with Hypertensive Disorders of Pregnancy

Lara S. Lemon, PhD, PharmD

Best Abstract in Fetal Therapy Award *supported by NAFTNet in memory of Elizabeth Thom*

11: Donor velamentous cord insertion: an omen for poor laser outcomes?

Christy Gandhi, MD

MONDAY, February 12, 2024 • 3:45 PM - 6:00 PM

Time	Abstract	Oral Plenary Session I and Late-Breaking
3:45 PM	1	**Multicenter, prospective cohort of genome sequencing in 750 fetal structural anomalies** **Ronald J. Wapner**[1]; Jessica L. Giordano[2]; Jessica de Voest[3]; Kelly L. Gilmore[4]; Lauren Westerfield[5]; Alexandra Tinfow[6]; Stephanie Galloway[2]; Leandra Tolusso[7]; Beatrix Wong[8]; Farrah Jackson[7]; Grant Bonesteele[5]; Theresa Wittman[9]; Blair Stevens[10]; Samantha Stover[11]; Anthony Johnson[12]; Nancy Doan Leslie[7]; Daniel Swarr[7]; Aaron B. Caughey[13]; Wendy Chung[14]; Rebecca Clifton[15]; Ignatia B. Van den Veyver[16]; Neeta L. Vora[4] [1]Columbia University Irving Medical Center, New York, NY; [2]Columbia University, New York, NY; [3]George Washington University, Rochester, MD; [4]University of North Carolina at Chapel Hill, Chapel Hill, NC; [5]Baylor College of Medicine and Texas Children's Hospital, Houston, TX; [6]Columbia University, New York City, NY; [7]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [8]Cincinnati Children's Hospital, Cincinnati, OH; [9]UT Health, Houston, TX; [10]UTPhysicians, Houston, TX; [11]Texas Children's Hospital, Houston, TX; [12]McGovern Medical School at UTHealth Houston, Houston, TX; [13]Oregon Health & Science University, Portland, OR; [14]Harvard and Boston Children's Hospital, Boston, MA; [15]George Washington University, Washington, DC; [16]Baylor College of Medicine, Houston, TX
4:00 PM	2	**Association between HDP and GDM and Child Cardiovascular Health in Early Adolescence** **Kartik Kailas Venkatesh**[1]; Amanda Perak[2]; Sadiya S. Khan[3]; Jiqiang Wu[4]; Patrick Catalano[5]; Mark B. Landon[6]; Denise Scholtens[2]; William Lowe[2]; William A. Grobman[1] [1]The Ohio State University, Columbus, OH; [2]Northwestern University, Chicago, IL; [3]Northwestern University Feinberg School of Medicine, Oak Park, IL; [4]Ohio State University, Columbus, OH; [5]Tufts Medical Center, Boston, MA; [6]The Ohio State University Wexner Medical Center, Columbus, OH
4:15 PM	3	**Evaluation of a more restrictive, heparin-based, obstetric thromboprophylaxis protocol** **Macie L. Champion**[1]; Christina T. Blanchard[2]; Anna Lively[1]; Morgan Jenkins[1]; Samantha E. Howell[1]; Grace M. Lee[1]; Brian M. Casey[1]; Akila Subramaniam[2] [1]University of Alabama at Birmingham, Birmingham, AL; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL
4:30 PM	4	**Cost-effectiveness of Azithromycin for the Prevention of Maternal Sepsis or Death in Planned Vaginal Births** Jackie Patterson[1]; Simon Neuwahl[2]; Janet Moore[3]; Elizabeth M. McClure[3]; Waldemar Carlo[4]; Melissa Buserman[5]; **Alan T. Tita**[6] [1]University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, NC; [2]RTI International, Atlanta, GA; [3]RTI International, Durham, NC; [4]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [5]University of North Carolina at Chapel Hill, Chapel Hill, NC; [6]University of Alabama at Birmingham, Birmingham, AL; on behalf of the NICHD Global Network for Women's and Children's Health Research APLUS Trial.
4:45 PM	5	**Peripartum dapagliflozin improves late life cardiovascular outcomes in a mouse model of superimposed preeclampsia** **Ashley Hesson**[1]; Ajleeta Sangtani[1]; Elizabeth S. Langen[1]; Kristina Hunker[2]; Nitin Kumar[1]; Santhi K. Ganesh[2] [1]University of Michigan, Ann Arbor, MI; [2]Michigan Medicine, Ann Arbor, MI
5:00 PM	6	**Effect of supplemental oxygen for Category II resuscitation on oxidative stress: a randomized controlled trial** **Nandini Raghuraman**[1]; Fan Zhang[1]; Brianna Bradley[1]; Antonina I. Frolova[1]; Ebony B. Carter[2]; Jeannie C. Kelly[2]; Anthony O. Odibo[1]; Molly J. Stout[3]; D Michael Nelson[4]; Methodius G. Tuuli[5]; Alison G. Cahill[6] [1]Washington University School of Medicine in St. Louis, St. Louis, MO; [2]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO; [3]University of Michigan, Ann Arbor, MI; [4]Washington University in St. Louis, St. Louis, MO; [5]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI; [6]University of Texas at Austin, Dell Medical School, Austin, TX
5:15 PM	7	**Association of Postpartum Oxytocin Dose and Postpartum Hemorrhage** **Ashley E. Shea**[1]; Candice Woolfolk[2]; Vasiliki B. Orfanakos[1]; Alison G. Cahill[3]; Methodius G. Tuuli[4]; Sindhu K. Srinivas[5]; George A. Macones[6]; Alan T. Tita[1]; Akila Subramaniam[7] [1]University of Alabama at Birmingham, Birmingham, AL; [2]Washington University School of Medicine in St. Louis, St. Louis, MO; [3]University of Texas at Austin, Dell Medical School, Austin, TX; [4]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI; [5]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [6]The University of Texas at Austin, Austin, TX; [7]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL
5:30 PM	8	**A Randomized Controlled Trial (RCT) of Laser Surgery in Twin-Twin Transfusion Syndrome: The Sequential Trial** **Ramen H. Chmait**[1]; Arlyn Llanes[1]; Lisa M. Korst[2]; Kristine B. Rallo[1]; Andrew H. Chon[3]; Martha A. Monson[4]; Ruben A. Quintero[5] [1]University of Southern California, Los Angeles, CA; [2]Childbirth Research Associates, North Hollywood, CA; [3]Oregon Health & Science University, Portland, OR; [4]Intermountain Healthcare, Salt Lake City, UT; [5]USFetus Research Consortium, Coral Gables, FL, on behalf of USFetus.
5:45 PM	LB01	**Development of post-acute sequelae of SARS-CoV-2 (PASC) after infection in pregnancy: NIH RECOVER-Pregnancy Cohort** **Torri D. Metz**[1]; Harrison Reeder[2]; Rebecca G. Clifton[3]; Valerie Flaherman[4]; Leyna V. Aragon[5]; Leah Castro Baucom[6]; Alexis Braverman[7]; Tingyi Cao[2]; Jodie A. Dionne[8]; Andrea S. Foulkes[2]; Rachel S. Gross[9]; Jenny Han[10]; Rachel Hess[1]; Leora I. Horwitz[9]; Xiaolin Jia[11]; Minal Kale[12]; Alem Mehari[13]; Jonathan S. Monteiro[2]; Deepti Pant[2]; Patrick S. Ramsey[14]; Vanessa Jacoby[4] [1]University of Utah Health, Salt Lake City, UT; [2]Massachusetts General Hospital, Boston, MA; [3]George Washington University, ROCKVILLE, MD; [4]University of California at San Francisco, San Francisco, CA; [5]University of New Mexico, Albuquerque, NM; [6]RECOVER Patient, Caregiver, or Community Advocate Representative, New York, NY; [7]University of Illinois Chicago, Chicago, IL; [8]Department of Medicine, Division of Infectious Diseases, University of Alabama at Birmingham, BIRMINGHAM, AL; [9]New York University Grossman School of Medicine, New York, NY; [10]Emory University, Atlanta, GA; [11]Stanford University, Palo Alto, CA; [12]Mount Sinai Medical Center, New York, NY; [13]Howard University, Washington DC, DC; [14]UTHSCSA, UTHSCSA, TX

Blue type in each byline indicates the presenting author.

TUESDAY, February 13, 2024 • 8:00 AM - 10:30 AM

Time	Abstract	Oral Plenary Session II - Fellows Plenary and Late-Breaking
8:00 AM	9	**Pessary or Cerclage (PC Study) to prevent recurrent preterm delivery – a randomized controlled trial** **Annabelle L. van Gils**[1]; Charlotte E. van Dijk[1]; Bouchra Koullali[1]; M.A. Lugthart[1]; B.B. Bet[1]; Maud D. van Zijl[2]; H M. Knol[3]; Begoña Martinez de Tejada[4]; Sanne J. Gordijn[5]; Marieke Sueters[6]; Marjon A. de Boer[1]; Eline S. van den Akker[7]; Brenda J. Hermsen[8]; Yolanda M. de Mooij[9]; Sabina de Weerd[10]; Wilhelmina M. van Baal[11]; Marion E. van Hoorn[12]; Martine C. van der Weide[1]; Martijn A. Oudijk[1]; Brenda M. Kazemier[13]; Ben Willem W. Mol[14]; Eva Pajkrt[1] [1]Amsterdam UMC, location AMC, Amsterdam, Noord-Holland; [2]Amsterdam UMC, location AMC, IJsselstein, Utrecht; [3]Isala Hospital, Isala, Overijssel; [4]University Hospitals of Geneva and Faculty of Medicine, Geneva, Geneve; [5]UMCG, Groningen, Groningen; [6]Leiden University Medical Center, Leiden, Netherlands; [7]Onze Lieve Vrouwe Gasthuis Oost, Amsterdam, Noord-Holland; [8]Onze Lieve Vrouwe Gasthuis West, Amsterdam, Noord-Holland; [9]Zaans Medical Center, Zaandam, Noord-Holland; [10]Albert Schweitzer Hospital, Dordrecht, Zuid-Holland; [11]Flevoziekenhuis, Almere, Flevoland; [12]Haga Hospital, Den Haag, Zuid-Holland; [13]Wilhelmina's Children Hospital, Utrecht, Utrecht; [14]Monash University, Clayton, Victoria
8:15 AM	10	**Optimal Misoprostol Dosing Among Patients with a BMI Greater Than 30: A Randomized Controlled Trial** **Alexander M. Saucedo**[1]; Miriam Alvarez[1]; George A. Macones[2]; Alison G. Cahill[1]; Lorie M. Harper[1] [1]University of Texas at Austin, Dell Medical School, Austin, TX; [2]The University of Texas at Austin, Austin, TX
8:30 AM	11	**Donor velamentous cord insertion: an omen for poor laser outcomes?** **Christy Gandhi**; Noelle Breslin; Russell S. Miller; Rosalie Ingrassia; Chia Ling Nhan Chang; Lynn Simpson Columbia University Irving Medical Center, New York, NY
8:45 AM	12	**Outpatient Induction of Labor – Primary Outcome Results from the HOME INDUCTION Randomized Controlled Trial** **Sarah M. Nicholson**[1]; Orla Smith[2]; Corina Oprescu[2]; Eimear Wall[2]; Sara El Nimr[2]; Geraldine Gannon[2]; Susan Hatt[2]; Ita Shanahan[3]; Bernard Kennedy[2]; Ronan Daly[2]; Claudia Looi[2]; Elena Fernandez[2]; Zara Molphy[1]; Patrick Dicker[1]; Karen Flood[1]; Fergal D. Malone[2] [1]Royal College of Surgeons in Ireland, Dublin, Ireland; [2]Rotunda Hospital, Dublin, Ireland; [3]Rotunda, Rotunda, Dublin
9:00 AM	13	**The effect of enhanced recovery after surgery (ERAS) on neonatal glucose: A randomized, equivalence trial** **Amanda McWhirter**[1]; Maria Ruiz[2]; Autri Hafezi[2]; Ethan Manninen[3]; Eli Lefkowitz[2]; Benjamin Manninen[4]; Karen Lesser[2] [1]University of Arizona, Tucson College of Medicine, Tucson, AZ; [2]University of Arizona, Tucson, AZ; [3]Harvard University, Cambridge, MA; [4]Cornell University, Ithaca, NY
9:15 AM	14	**Persistent Programming of Offspring Gut Serotonin Pathway by Maternal Western-Style Diet in Non-Human Primates** **Erin Bolte**[1]; Derek O'Neil[1]; Rene Lindsley[2]; Melissa Kirigiti[2]; Paul Kievit[3]; Mindy Engevik[4]; Kjersti M. Aagaard[5] [1]Baylor College of Medicine, Houston, TX; [2]Ohio State University, Beaverton, OR; [3]Oregon National Primate Research Center, Beaverton, OR; [4]Texas Children's Hospital, Houston, TX; [5]Texas Children's Hospital, Baylor College of Medicine, Houston, TX
9:30 AM	15	**Panniculus retractor use for visualization of fetal anatomy: a randomized controlled trial** **Melissa L. Wise**[1]; Marvin Okon[2]; Katelyn Pratt[1]; Andrew Lane[3]; Laura Carlson[1]; Amy Crockett[1]; Lu Zhang[2]; Daniel Pasko[1] [1]Prisma Health, University of South Carolina School of Medicine Greenville, Greenville, SC; [2]Clemson University, Clemson, SC; [3]Prisma Health, Greenville, SC
9:45 AM	16	**Early amniotomy after Foley balloon in labor induction: a randomized clinical trial** **Marissa J. Berry**[1]; Kelly Lamiman[2]; Megan Slan[3]; Xue Zhang[2]; Daphne D. Arena Goncharov[2]; Yihharn P. Hwang[2]; Jennifer Rogers[2]; Luis D. Pacheco[4]; George R. Saade[5]; Antonio F. 10:15 AM	LB03	**Randomized trial of screening for preterm birth in low-risk women. The Preterm Birth Screening Study** **Gabriele Saccone**[1]; Daniele Di Mascio[2]; Fabrizio Zullo[3] [1]Università degli studi di Napoli Federico II, PHILADELPHIA, PA; [2]Policlinico Umberto I - University Hospital, Rome, Piemonte; [3]University of Rome, Roma, AL

Blue type in each byline indicates the presenting author.

TUESDAY, February 13, 2024 • 1:30 - 3:30 PM

Time	Abstract	Oral Concurrent Session 1 - Prematurity
1:30 PM	17	**Risk markers for recurrent adverse pregnancy outcomes** **William A. Grobman**[1]; Beth Wiener[2]; Rebecca B. McNeil[3]; Hyagriv Simhan[4]; Bob M. Silver[5]; Philip Greenland[6]; Noel Bairey Merz[7]; George R. Saade[8]; Matthew Hoffman[9]; Victoria Pemberton[10]; Lynn M. Yee[11]; Lisa D. Levine[12]; Brian M. Mercer[13]; David M. Haas[14]; Judith H. Chung[15]; Uma M. Reddy[16]; Janet M. Catov[17] [1]The Ohio State University, Columbus, OH; [2]RTI, Chapel Hill, NC; [3]RTI, Durbam, NC; [4]University of Pittsburgh, Pittsburgh, PA; [5]University of Utah, School of Medicine, Salt Lake City, UT; [6]Northwestern University Feinberg School of Medicine, Evanston, IL; [7]Cedars-Sinai Medical Center, Los Angeles, CA; [8]Eastern Virginia Medical School, Norfolk, VA; [9]Christiana Care Health Systems, Newark, DE; [10]National Institutes of Health, Bethesda, MD; [11]Northwestern University, Chicago, IL; [12]University of Pennsylvania, Philadelphia, PA; [13]MetroHealth Medical Center, Cleveland, OH; [14]Indiana University, Carmel, IN; [15]UC Irvine Health, Orange, CA; [16]Columbia University, New York, NY; [17]Magee-Womens Research Institute, Pittsburgh, PA
1:45 PM	18	**Prenatal heat stress and birth outcomes in a rural Ghanaian cohort** **Blair Wylie**[1]; Alison Lee[2]; Aalekhya Reddam[3]; Mohammed Mujtaba Nuhu[4]; Cascade Tuholske[5]; Kaali Seyram[6]; Kennetha A. Ae-Ngibise[4]; Danielle Medgyesi[3]; Ellen Boamah[6]; Andrea Baccarelli[3]; Oscar Agyei[4]; Steven Chillrud[7]; Kwaku Poku asante[6]; Darby Jack[8]; Prince Darko Agyapong[4]; Abubakari Sulemana[4] [1]Columbia University, New York, NY; [2]Mount Sinai Hospital, New York, NY; [3]Columbia Mailman School of Public Health, New York, NY; [4]Kintampo Health Research Centre, Kintampo, Brong-Ahafo; [5]Montana State University, Billings, MT; [6]Kintampo Health Research Centre, Brong Ahafo, Ghana; [7]The Earth Institute, New York, NY; [8]Mailman School of Public Health, New York, NY
2:00 PM	19	**Neonatal Hypoglycemia in Pregnancies at Risk for Late Preterm Birth: Childhood Neurodevelopmental Outcomes** **Cynthia Gyamfi-Bannerman** UC San Diego Health, La Jolla, CA, for the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network
2:15 PM	20	**Pessary versus cerclage with/without progesterone in twin pregnant women and a short cervix: a RCT** **Yen TN He**[1]; Ha NH Pham[2]; Tri C Nguyen[3]; Trung Q Bui[2]; Nhu T Vuong[2]; Diem TN Nguyen[3]; Thanh V Le[2]; Wentao Li[4]; Cam H Le[1]; Tuong M Ho[2]; Ben Willem W. Mol[5]; Vinh Q Dang[6]; Lan N Vuong[7] [1]My Duc Phu Nhuan Hospital, Ho Chi Minh, Ho Chi Minh; [2]My Duc Hospital, Ho Chi Minh, Ho Chi Minh; [3]HOPE Research Center, Ho Chi Minh, Ho Chi Minh; [4]Monash University, Melbourne, Victoria; [5]Monash University, Clayton, Victoria; [6]My Duc Hospital, Ho Chi Minh, Vietnam; [7]University of Medicine and Pharmacy at Ho Chi Minh City, Ho Chi Minh, Vietnam
2:30 PM	21	**Vaginal polyamines mitigate inflammasome activation: potential immune mechanisms governing barrier function in preterm birth** Briana Ferguson[1]; Aaron Loder[1]; Scott M. Gordon[2]; Lauren Anton[1]; **Kristin D. Gerson**[3] [1]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA; [2]Children's Hospital of Philadelphia, Philadelphia, PA; [3]Hospital of the University of Pennsylvania, Philadelphia, PA
2:45 PM	22	**Vaginal progesterone for the prolongation of pregnancy after arrested pre-term labor-multicenter randomized controlled trial** **Enav Yefet**[1]; Yael Ganor Paz[2]; Malak Wattad[3]; Noa Harel[4]; Manal Massalha[5]; Zohar Nachum[6] [1]Tzafon Medical Center, Afula, HaZafon; [2]Edith Wolfson Medical Center, Shoham, HaMerkaz; [3]Emek Medical Center, Afula, Israel; [4]Tzafon Medical Center, Poriya, HaZafon; [5]Emek medical center, Afula, HaZafon; [6]Emek medical center, Timrat, HaZafon
3:00 PM	23	**Investigating the Association between Preterm Delivery and Autism Spectrum Disorder in Childhood** **Sapir ELLOUK**[1]; Omri Zamstein[2]; Tamar Wainstock[3]; Eyal Sheiner[2] [1]Soroka Medical Center, Beer-Sheva, HaDarom; [2]Soroka University Medical Center, Beer-Sheva, HaDarom; [3]Ben Gurion University, Beer-Sheva, HaDarom
3:15 PM	24	**Vaginal putrescine attenuates microbe-mediated inflammation in the cervical epithelium** Briana Ferguson[1]; Aaron Loder[1]; Scott M. Gordon[2]; Lauren Anton[1]; **Kristin D. Gerson**[3] [1]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA; [2]Children's Hospital of Philadelphia, Philadelphia, PA; [3]Hospital of the University of Pennsylvania, Philadelphia, PA

TUESDAY, February 13, 2024 • 1:30 - 3:30 PM

Time	Abstract	Oral Concurrent Session 2 - Diabetes
1:30 PM	25	**Initiation of Metformin in Pregnancy Results in Fetal Bioaccumulation, Growth Restriction & Renal Dysmorphology** **Kjersti M. Aagaard**[1]; Paul Kievit[2]; Maureen Gannon[3]; Carrie McCurdy[4]; Stephanie Wesolowski[5]; Jed Friedman[6]; Tyler Dean[2]; Kristin Sauter[2]; Maxim D. Seferovic[7]; Brandon T. Garcia[7]; Feng Li[8]; John Hicks[1]; Xuan Qin[9]; Erin Bolte[9]; Gwendolynn Hummel[9]; Melissa Suter[1] [1]Texas Children's Hospital, Baylor College of Medicine, Houston, TX; [2]Oregon National Primate Research Center, Beaverton, OR; [3]Vanderbilt University Medical Center, Nashville, TN; [4]University of Oregon, Eugene, OR; [5]University of Colorado Health Sciences Center-Anschulz, Denver, CO; [6]University of Oklahoma Health Sciences Center & Hamm Diabetes Center, Oklahoma City, OK; [7]Baylor College of Medicine and Texas Children's Hospital, Houston, TX; [8]University of North Carolina at Chapel Hill, Chapel Hill, NC; [9]Baylor College of Medicine, Houston, TX
1:45 PM	26	**IRELAnD—Investigating the Role of Early Low-dose Aspirin in Diabetes: a multicenter placebo-controlled blinded randomized trial** **Catherine Finnegan**[1]; Patrick Dicker[2]; Denisa Ramona Asandei[3]; Mary Higgins[4]; Neil O'Gorman[5]; Fidelma Dunne[6]; Geraldine Gaffney[7]; Christine Newman[8]; Fionnuala M. Mcauliffe[9]; Mairead O'Riordan[10]; Vineta Ciprike[11]; Elena Fernandez[1]; Fergal D. Malone[1]; Fionnuala M. Breathnach[12] [1]Rotunda Hospital, Dublin, Ireland; [2]Royal College of Surgeons in Ireland, Dublin, Ireland; [3]RCSI Rotunda, Dublin, Ireland; [4]National Maternity Hospital, Dublin, Ireland; [5]Coombe Hospital, Dublin, Dublin; [6]NUI Galway, NIUG, Galway; [7]NUI Galway, NUIG, Galway; [8]UHG, UHG, Galway; [9]UCD NMH, Dublin, Ireland; [10]UCC, Cumh, Cork; [11]OLOL Drogheda, Louth; [12]Royal College of Surgeons in Ireland, Dublin, Dublin

Blue type in each byline indicates the presenting author.

TUESDAY, February 13, 2024 • 1:30 - 3:30 PM *(continued)*

Time	Abstract	Oral Concurrent Session 2 - Diabetes
2:00 PM	27	**Relationship between metformin use and preterm preeclampsia in pregnancies with type 2 diabetes** **Maya Patel**[1]; Ashley N. Battarbee[2]; Jerrie Refuerzo[3]; Noelia Zork[4]; Kacey Eichelberger[5]; Gladys A. Ramos[6]; Gayle Olson[7]; Celeste Durnwald[8]; Mark B. Landon[9]; Kjersti M. Aagaard[10]; Kedra Wallace[11]; Christina Scifres[12]; Todd J. Rosen[13]; Wadia Mulla[14]; Amy M. Valent[15]; Sherri Longo[16]; Kim Boggess[1] [1]UNC at Chapel Hill, Chapel Hill, NC; [2]University of Alabama at Birmingham, Birmingham, AL; [3]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX; [4]New York Presbyterian, Columbia University Medical Center, New York, NY; [5]USC School of Medicine Greenville, Greenville, SC; [6]University of California, San Diego, San Diego, CA; [7]University of Texas Medical Branch, Galveston, TX; [8]University of Pennsylvania, Philadelphia, PA; [9]The Ohio State University Wexner Medical Center, Columbus, OH; [10]Texas Children's Hospital, Baylor College of Medicine, Houston, TX; [11]UMiss, Rockford, IL; [12]Indiana University School of Medicine, Indianapolis, IN; [13]Robert Wood Johnson Medical School, Rutgers University, New Brunswick, NJ; [14]Temple University Hospital, Philadelphia, PA; [15]Oregon Health & Science University, Portland, OR; [16]Ochsner Medical center, New Orleans, LA
2:15 PM	28	**Oral antihyperglycemic agent strategy versus insulin for gestational diabetes mellitus – a randomized controlled trial** **Doortje Rademaker**[1]; Leon de Wit[2]; Ruben G. Duijnhoven[1]; Daphne N. Voormolen-van Münster[2]; Joris van der Post[1]; Judith E. Bosmans[3]; Harold W. de Valk[2]; Inge M. Evers[4]; Ben Willem W. Mol[5]; Arie Franx[6]; Hans de Vries[1]; Rebecca Painter[7]; Bas van Rijn[8]; SUGAR-DIP Investigator Group[9] [1]Amsterdam UMC, location AMC, Amsterdam, Noord-Holland; [2]UMC Utrecht, UMC Utrecht, Utrecht; [3]Vrije Universiteit, Vrije Universiteit, Noord-Holland; [4]Meander MC, Meander MC, Noord-Holland; [5]Monash University, Clayton, Victoria; [6]Erasmus MC, Erasmus MC, Zuid-Holland; [7]Amsterdam UMC, location AMC, Amsterdam, Netherlands; [8]Maxima Medisch Centrum, Noord-Brabant; [9]Netherlands, Netherlands, Noord-Holland
2:30 PM	29	**Permissive Glucose Control Versus Usual Care for Diabetes in Labor: An Equivalence Randomized Control Trial** **Ghamar Bitar**[1]; Rafael Santos[1]; Claudia Pedroza[1]; Sarah Nazeer[2]; Suneet P. Chauhan[3]; Sean C. Blackwell[4]; Baha M. Sibai[5]; Michal Fishel Bartal[6] [1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX; [2]McGovern Medical School at UTHealth Houston, Houston, TX; [3]University of Texas-Houston Medical School, Houston, TX; [4]Children's Memorial Hermann Hospital, Houston, TX; [5]Hermann Memorial Hospital, Houston, TX; [6]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX
2:45 PM	30	**Breastfeeding and Long-Term Maternal and Child Cardiometabolic Health at 10-14 years after delivery** **Yiwen Cui**[1]; Kartik Kailas Venkatesh[2]; Anna Palatnik[1] [1]Medical College of Wisconsin, Milwaukee, WI; [2]The Ohio State University, Columbus, OH
3:00 PM	31	**Association of glucose profiles based on daily continuous glucose monitoring metrics with adverse perinatal outcomes** **Ashley N. Battarbee**[1]; Ayodeji Sanusi[2]; Isabel Fulcher[3]; Sara Sauer[4] [1]University of Alabama at Birmingham, Birmingham, AL; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [3]Delfina Care, Sunnyville, CA; [4]Delfina Care, San Francisco, CA
3:15 PM	32	**Classifying patients based on weekly continuous glucose monitoring metrics and their association with pregnancy outcomes** **Sara Sauer**[1]; Ayodeji Sanusi[2]; Isabel Fulcher[3]; Ashley N. Battarbee[4] [1]Delfina Care, San Francisco, CA; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [3]Delfina Care, Sunnyville, CA; [4]University of Alabama at Birmingham, Birmingham, AL

TUESDAY, February 13, 2024 • 1:30 - 3:30 PM

Time	Abstract	Oral Concurrent Session 3 – Basic Science
1:30 PM	33	**Bioaccumulation of Microplastics in Placentae Associated with Environmental Chemical Exposures and Obstetrical Outcomes** **Enrico R. Barrozo**[1]; Marcus A. Garcia[2]; Michael D. Jochum, Jr.[3]; Eliane El Hayek[2]; Eliseo F. Castillo[2]; Jorge Gonzalez-Estrella[2]; Cynthia Shope[3]; Melissa Suter[4]; Matthew J. Campen[2]; Kjersti M. Aagaard[4] [1]Baylor College of Medicine and Texas Children's Hospital, Houston, TX; [2]University of New Mexico, Albuquerque, NM; [3]Baylor College of Medicine, Houston, TX; [4]Texas Children's Hospital, Baylor College of Medicine, Houston, TX
1:45 PM	34	**Safety and efficacy of open fetal repair of complex gastroschisis in the fetal lamb model** **Luc Joyeux**[1]; David Basurto[2]; Kanokwaroon Watananirun[2]; Tom Bleeser[2]; Tomohiro Arai[2]; Inge Depoortere[2]; Alison Accarie[2]; Tim Vanuystel[2]; Michael Aertsen[2]; Alex Menys[3]; Paolo De Coppi[4]; Larry H. Hollier[1]; Michael A. Belfort[5]; Jan Deprest[6]; Sundeep Keswani[1] [1]Texas Children's Hospital, Baylor College of Medicine, Houston, TX; [2]KU Leuven, Leuven, West-Vlaanderen; [3]Motilent, London, England; [4]Great Ormond Street Hospital, NHS, London, England; [5]Texas Children's Hospital, Houston, TX; [6]University Hospitals Leuven, Leuven, Vlaams-Brabant
2:00 PM	35	**Potential mechanism of neuroprotection by magnesium sulfate and betamethasone in microglia and neural stem cells** **Sarah Ligon**[1]; Jennifer Damicis[1]; Marit K. Bastian[1]; Katherine E. Free[1]; Irina Burd[2]; Peter Napolitano[3]; Nicholas Ieronimakis[1] [1]Madigan Army Medical Center, Tacoma, WA; [2]University of Maryland, Baltimore, MD; [3]University of Washington, Seattle, WA
2:15 PM	36	**Evaluation of transplacental transfer of cancer therapies in melanoma via the perfused human placental model** Estelle Heggarty[1]; David Combarel[2]; Francois Vialard[3]; yoann rodriguez[3]; Stanislas Grassin-Delyle[3]; Elodie lamy[4]; Olivier Mir[2]; Angelo Paci[5]; **Paul Berveiller**[6] [1]CHIPS Poissy Hospital, Paris Saclay University, Ile-de-France; [2]Gustave Roussy Cancer Campus, Villejuif, Ile-de-France; [3]Université Paris-Saclay, Jouy-en-Josas, Ile-de-France; [4]Université Paris-Saclay, Montrigny-le-Bretonneux, Ile-de-France; [5]Gustave Roussy, Villejuif, Ile-de-France; [6]Centre Hospitalier Intercommunal de Poissy Saint Germain, Poissy, France

Blue type in each byline indicates the presenting author.

TUESDAY, February 13, 2024 • 1:30 - 3:30 PM *(continued)*

Time	Abstract	Oral Concurrent Session 3 — Basic Science
2:30 PM	37	**Refractoriness of chorion trophoblast cells to epithelial mesenchymal transition (EMT) by pPROM risk factors** **Benjamin A. Bush**[1]; Enkhtuya Radnaa[2]; Ryan Lintao[3]; Mary Severino[4]; RamKumar Menon[5] [1]UTMB-Galveston, Friendswood, TX; [2]University of Texas Medical Branch at Galveston, Galveston, TX; [3]University of Texas - Medical Branch, Manila, TX; [4]University of Texas - Medical Branch, Galveston, TX; [5]University of Texas Medical Branch, League City, TX
2:45 PM	38	**Impact of Gestational E-Cigarette Aerosols on Uterine Artery Function in Rats** **Alexander Juusela**[1]; Vishal D. Naik[2]; Alexander Carabulea[2]; Joseph Janeski[2]; Hong Jiang[2]; Jayanth Ramadoss[2] [1]Wayne State University, Detroit, MI; [2]C.S. Mott Center for Human Growth and Development, School of Medicine, Wayne State University, Detroit, MI
3:00 PM	39	**Developing an Approach for In Utero Gene Editing: Lessons Learned** **Courtney Breckenfelder**[1]; Patrick McGrath[1]; Jennifer Matsuda[2]; Ganna Bilosouva[1]; Paul Rozance[1]; Russell Anthony[3]; Michael V. Zaretsky[4] [1]University of Colorado Denver Anschutz Medical Campus, Aurora, CO; [2]National Jewish Health, Denver, CO; [3]Colorado State University, Fort Collins, CO; [4]University of Colorado, School of Medicine, Aurora, CO
3:15 PM	40	**Increased Offspring Anxiety Following Maternal Western-Style Diet Exposure During Gestation and Lactation in Non-Human Primates** **Erin Bolte**[1]; Geoff Dunn[2]; Thomas Horvath[3]; Maxim D. Seferovic[4]; Sigmund Haidacher[5]; Kathleen Hoch[5]; Derek O'Neil[1]; Anthony Haag[3]; Kjersti M. Aagaard[6] [1]Baylor College of Medicine, Houston, TX; [2]Ohio State University, Beaverton, OR; [3]Texas Children's Microbiome Center Mass Spectrometry Laboratory, Texas Children's Hospital, Houston, TX; [4]Baylor College of Medicine and Texas Children's Hospital, Houston, TX; [5]Texas Children's Hospital, Houston, TX; [6]Texas Children's Hospital, Baylor College of Medicine, Houston, TX

WEDNESDAY, February 14, 2024 • 10:00 AM - 12:00 PM

Time	Abstract	Oral Concurrent Session 4 — Hypertension
10:00 AM	41	**ASpirin in Placental and maternal Endothelial cell Regulation IN pre-eclampsia (ASPERIN Trial): Primary Outcome** **John O'Brien**; Aarthi Srinivasan; Katherine Vignes; Cynthia Cockerham; Wendy Whitley; Hong Huang; Arnold J. Stromberg; John A. Bauer University of Kentucky, Lexington, KY
10:15 AM	42	**Clinical Outcomes Following Remote Hypertension Monitoring Program for Postpartum Individuals with Hypertensive Disorders of Pregnancy** **Lara S. Lemon**[1]; Beth Quinn[2]; Anna Binstock[1]; Jacob Larkin[2]; Hyagriv Simhan[1]; Alisse Hauspurg[3] [1]University of Pittsburgh, Pittsburgh, PA; [2]Magee-Womens Hospital, University of Pittsburgh Medical Center, Pittsburgh, PA; [3]UPMC Magee-Womens Hospital, Pittsburgh, PA
10:30 AM	43	**162 mg versus 81 mg Aspirin for High-risk Obese Individuals: An Open Label RCT (ASPREO)** **Farah H. Amro**[1]; Michal Fishel Bartal[2]; Claudia Pedroza[1]; Sami Backley[1]; Ghamar Bitar[1]; Joseph Lucci IV[1]; Nahla Daye[1]; Sandra Sadek[1]; Suneet P. Chauhan[3]; Sean C. Blackwell[4]; Baha M. Sibai[5] [1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX; [2]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX; [3]University of Texas-Houston Medical School, Houston, TX; [4]Children's Memorial Hermann Hospital, Houston, TX; [5]Hermann Memorial Hospital, Houston, TX
10:45 AM	44	**Platelet Response to Aspirin Therapy in Pregnancy and Association with Pregnancy Outcome** **Rupsa C. Boelig**[1]; Emily Foecke Munden[2]; Tingting Zhan[3]; Steven McKenzie[4]; Walter Kraft[4] [1]Thomas Jefferson University Hospital, Philadelphia, PA; [2]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadlephia, PA; [3]Thomas Jefferson University, Philadelphia, PA; [4]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA
11:00 AM	45	**Optimal Gestational Age for Delivery of Pregnant Individuals with Mild Chronic Hypertension** **Torri D. Metz** University of Utah Health, Salt Lake City, UT, on behalf of the Chronic Hypertension and Pregnancy (CHAP) Trial Consortium
11:15 AM	46	**Subtypes of hypertension years after a hypertensive disorder of pregnancy** **Laura H. Brubaker**[1]; Janet M. Catov[2]; Natalie Bello[3]; Judith H. Chung[4]; Bethany Gibbs[5]; Philip Greenland[6]; William A. Grobman[7]; Abbi Lane-Cordova[8]; Lisa D. Levine[9]; Rebecca B. McNeil[10]; Brian M. Mercer[11]; Noel Bairey Merz[3]; Eliza C. Miller[12]; Mitali Ray[13]; Uma M. Reddy[14]; George R. Saade[15]; Sadiya S. Khan[16]; Christina Scifres[17]; Robert M. Silver[18]; Hyagriv Simhan[13]; Lauren H. Theilen[18]; Jasmina Varagic[19]; Lynn M. Yee[20]; Alisse Hauspurg[1] [1]UPMC Magee-Womens Hospital, Pittsburgh, PA; [2]Magee-Womens Research Institute & Foundation, Pittsburgh, PA; [3]Cedars-Sinai Medical Center, Los Angeles, CA; [4]UC Irvine Health, Orange, CA; [5]West Virginia University, Morgantown, WV; [6]Northwestern University Feinberg School of Medicine, Evanston, IL; [7]The Ohio State University, Columbus, OH; [8]University of South Carolina, Columbia, SC; [9]University of Pennsylvania, Philadelphia, PA; [10]RTI, Durbam, NC; [11]MetroHealth Medical Center, Cleveland, OH; [12]Columbia University Irving Medical Center, New York, NY; [13]University of Pittsburgh, Pittsburgh, PA; [14]Columbia University, New York, NY; [15]Eastern Virginia Medical School, Norfolk, VA; [16]Northwestern University Feinberg School of Medicine, Oak Park, IL; [17]Indiana University School of Medicine, Indianapolis, IN; [18]University of Utah Health, Salt Lake City, UT; [19]National Institutes of Health, Bethesda, MD; [20]Northwestern University, Chicago, IL, on behalf of RTI International.
11:30 AM	47	**Subclinical Cardiovascular Alterations and Molecular Signatures in Women with History of Hypertensive Disorders in Pregnancy** **Lee Reicher**[1]; Nastya Godneva[2]; Adina Weinberger[2]; Yariv Yogev[3]; Eran Segal[2] [1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel; [2]Weizmann Institute of Science, Rehovot, HaMerkaz; [3]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Blue type in each byline indicates the presenting author.

WEDNESDAY, February 14, 2024 • 10:00 AM - 12:00 PM *(continued)*

Time	Abstract	Oral Concurrent Session 4 — Hypertension
11:45 AM	48	**Lower thresholds for diagnosing hypertension in pregnancy and perinatal outcomes in large Tanzanian cohort** **Andrea Barnabas Pembe**[1]; Christopher Sudfeld[2]; Alfa Muhihi[3]; Amani Kikula[1]; Nandita Perumal[4]; Heavenlight Paul[3]; Honorati Masanji[5]; Mary Mwanyika-Sando[3]; Wafaie Fawzi[2]; Blair Wylie[6] [1]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Dar es Salaam; [2]Harvard T.H. Chan School of Public Health, Boston, MA; [3]Africa Academy for Public Health, Dar es Salaam, Dar es Salaam; [4]Harvard T.H.Chan School of Public Health, Boston, MA; [5]Ifakara Health Institute, Dar es Salaam, Dar es Salaam; [6]Columbia University, New York, NY

WEDNESDAY, February 14, 2024 • 10:00 AM - 12:00 PM

Time	Abstract	Oral Concurrent Session 5 — Medical & Surgical Complications
10:00 AM	49	**Early pregnancy reticulocyte hemoglobin content as a marker for iron deficiency by BMI category** **Kaitlyn P. Casper**[1]; Kimberly Moyle[1]; Amanda A. Allshouse[1]; Ashley E. Benson[2]; Timothy M. Bahr[1]; Robert D. Christensen[1]; David Branch[1] [1]University of Utah Health, Salt Lake City, UT; [2]Oregon Health & Science University, Portland, OR
10:15 AM	50	**Frequency of cytomegalovirus reinfection during pregnancy: a prospective cohort study** **Juliette St-Georges**[1]; Safari Joseph Balegamire[1]; Suresh Boppana[2]; Mi-Suk Kang Dufour[3]; Ariane Larouche[3]; Barbora Knoppova[2]; Misty Latting[2]; Christian Renaud[3]; Benoit Masse[4]; Yves Giguère[5]; Jean-Claude Forest[6]; Soren Gantt[3]; Isabelle Boucoiran[7] [1]Université de Montréal, Montréal, QC; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Centre Hospitalier Universitaire Sainte-Justine, Montréal, QC; [4]University of Montréal, Montréal, QC; [5]Research Center of the CHU de Québec-Université Laval, QC; [6]CHU de Québec, Quebec City, QC; [7]CHU Sainte-Justine, Center for Maternal-Fetal Medicine, Montréal, QC
10:30 AM	51	**Association of SARS CoV-2 infection in pregnancy and placental gene expression at delivery** **Sunitha C. Suresh**[1]; Alexa A. Freedman[2]; Steve Cole[3]; Renee Odom[2]; Megan Choi[4]; Lauren S. Keenan-Devlin[2]; Britney P. Smart[2]; Greg E. Miller[2]; Jessica Britt[5]; Janedelie Romero[2]; Linda M. Ernst[6]; Ann Borders[7]; Amy Crockett[8] [1]NorthShore University Health System, Evanston, IL; [2]NorthShore University HealthSystem, Evanston, IL; [3]University of California, Los Angeles, Los Angeles, CA; [4]Northwestern University, Evanston, IL; [5]Prisma Health Upstate, Greenville, SC; [6]NorthShore University HealthSystem, University of Chicago Pritzker School of Medicine, Evanston, IL; [7]NorthShore University HealthSystem, Evanston Hospital, Evanston, IL; [8]Prisma Health, University of South Carolina School of Medicine Greenville, Greenville, SC
10:45 AM	52	**Short term risk of cardiovascular disease complications differs depending on the mode of delivery** **Gabriella Lobitz**[1]; Emily B. Rosenfeld[2]; Rachel Lee[3]; Deepika Sagaram[1]; Cande V. Ananth[1] [1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Robert Wood Johnson Medical School, Rutgers University, New Brunswick, NJ; [3]Flushing Hospital Medical Center, Bayside, NY
11:00 AM	53	**Systematic review of recipient alloimmunization using standard ABO+D versus an extended donor match protocol** **Ronan P. Sugrue**[1]; Marie Elise Abi Antoun[2]; Jaxon Olsen[3]; Alexandra Stonehill[4]; Jennifer J. Cate[1]; Virginia Y. Watkins[5]; Lesley Skalla[4]; Marilyn Telen[4]; Andra H. James[6]; Jerome J. Federspiel[5] [1]Duke University, Durham, NC; [2]Tufts University School of Medicine, Boston, MA; [3]Duke University School of Medicine, Salt Lake City, UT; [4]Duke University School of Medicine, Durham, NC; [5]Duke University Hospital, Durham, NC; [6]Duke University Medical Center, Durham, NC
11:15 AM	54	**Azithromycin to Reduce Maternal Infections in Planned Vaginal Birth: Secondary Analysis of the A-PLUS Trial** **Waldemar Carlo**[1]; Alan T. Tita[2]; Elizabeth M. McClure[3] [1]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]RTI International, Durham, NC, on behalf of NICHD Global Network for Women's and Children's Health Research
11:30 AM	55	**Infant developmental delays at well visit encounters in infants exposed to MOUD: buprenorphine or methadone** **Chaitali Korgaonkar-Cherala**[1]; Emily H. Stetler[2]; Lauren Stewart[2]; Oladunni Ogundipe[2]; Julia Kim[2]; Rakasa Pattanaik[2]; David Garry[3]; Kimberly Herrera[2]; Diana Garretto[4]; Cassandra Heiselman[3] [1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel; [2]Stony Brook University Hospital, Stony Brook, NY; [3]Stony Brook Medicine, Stony Brook, NY; [4]Stony Brook University Hospital, E Northport, NY
11:45 AM	56	**Transperineal ultrasound-based algorithm advising women after obstetric anal sphincter injury regarding their subsequent delivery mode** **Tamar Katzir**; Gil Friedman; Edi Vaisbuch; Moshe Gillor Kaplan Medical Center, Rehovot, HaMerkaz

WEDNESDAY, February 14, 2024 • 10:00 AM - 12:00 PM

Time	Abstract	Oral Concurrent Session 6 — Quality, Equity & Public Health
10:00 AM	57	**Inter-pregnancy interval and uterine rupture among more than 500,000 Trials of Labor after Cesarean (TOLAC)** **Bradley de Vries**[1]; Pejman Adily[2]; Travis Bettison[3]; Vincenzo Berghella[4]; Adam Mackie[3]; Rajit Narayan[3]; George Johnson[1]; Marjan Mosalman Haghighi[1] [1]Sydney Institute for Women, Children and their Families, Camperdown, New South Wales; [2]Sydney Institute for Women, Children and their Families, Sydney, New South Wales; [3]Royal Prince Alfred Hospital, New South Wales; [4]Jefferson Medical College, Philadelphia, PA, on behalf of the Sydney Institute for Women, Children and their Families.

Blue type in each byline indicates the presenting author.

WEDNESDAY, February 14, 2024 • 10:00 AM - 12:00 PM *(continued)*

Time	Abstract	Oral Concurrent Session 6 — Quality, Equity & Public Health
10:15 AM	58	**Prenatal herbicide exposure and newborn size in a Ghanaian cohort** Kwaku Poku asante[1]; Kaali Seyram[1]; Mohammed Mujtaba Nuhu[2]; Elizabeth Gibson[3]; Alison Lee[4]; Kennetha A. Ae-Ngibise[2]; Anna M. Modest[5]; Ellen Boamah[1]; Jones Opoku-Mensah[2]; Austin M. Oberlin[6]; Oscar Agyei[2]; Russ Hauser[3]; Abena Konadu Yawson[2]; Darby Jack[7]; Brent Coull[3]; **Blair Wylie**[8] [1]Kintampo Health Research Centre, Brong Ahafo, Ghana; [2]Kintampo Health Research Centre, Kintampo, Brong-Ahafo; [3]Harvard T.H. Chan School of Public Health, Boston, MA; [4]Mount Sinai Hospital, New York, NY; [5]Beth Israel Deaconess Medical Center, Boston, MA; [6]Columbia University Irving Medical Center, New York, NY; [7]Mailman School of Public Health, New York, NY; [8]Columbia University, New York, NY
10:30 AM	59	**Assessment of Labor Unit Culture as a Factor in Safely Reducing Cesarean Births** Althea Bourdeau[1]; Emily White VanGompel[2]; Elizabeth S. Langen[1]; **Lisa Kane Low**[1] [1]University of Michigan, Ann Arbor, MI; [2]NorthShore University HealthSystem, Chicago, IL
10:45 AM	60	**Predicting chorioamnionitis using AI-based methods: a retrospective cohort study** **Anne R. Waldrop**[1]; Tomin K. OBJECTIVE: The incremental value of exome sequencing (ES) over chromosomal microarray (CMA) in the evaluation of fetal structural anomalies has been demonstrated. Genome sequencing (GS) is now utilized for postnatal genomic diagnostic evaluation given GS has a higher yield over other technologies (ES, CMA). We prospectively evaluated the diagnostic yield of trio GS in pregnancies with major structural fetal anomalies referred to five tertiary care centers.

STUDY DESIGN: From August 2019 to July 2023, pregnancies $<$ 36 weeks with major fetal structural anomalies, isolated fetal growth restriction $<$ 5th percentile identified $<$ 24 weeks, and/or an elevated nuchal translucency of $\geq$ 3.5mm were screened for eligibility into this five-center prospective cohort study. Exclusions included an explanatory CMA/karyotype and planned termination based on imaging findings. Prenatal diagnosis by either CVS or amniocentesis and consent of both parents was required. GS was performed at 1 of 4 diagnostic laboratories using local bioinformatic tools. Pathogenic (P), likely pathogenic (LP), and uncertain variants (VUS) related to the phenotype meeting specific study protocol criteria were reported.

RESULTS: 5495 pregnancies with anomalies were screened; 2147 were eligible and 750 (34.9%) were enrolled. The main reasons for ineligibility were $>$ 36 weeks (16.4%) and planned termination or fetal demise (16.2%). A P/LP finding causative of the phenotype was identified in 117 (15.6%) and a VUS related to the phenotype was found in 21 (2.8%). There were causative P/LP findings in 41 (9.5%) cases with a single organ system involved and in 76 (23.8%) cases with multiple organ system involvement (table). Recurrent diagnoses included *PTPN11* (8), *NIPBL* (5), *CHD7* (5), *MYRF* (4), *PIEZO1* (4). Notably, no case with NT >= 3.5 mm to $<$ 4.5 mm without evidence of cystic hygroma had a GS finding. The positivity rate for findings related to the phenotype was not significantly different between the 4 labs (p=0.09).

CONCLUSION: Prenatal trio GS provides incremental diagnostic information in pregnancies with fetal structural anomalies and a non-causal CMA.

Table. Reported Variants Related to the Phenotype by Organ System (n=750)

	Single Organ System			Multiple Organ Systems (most severely affected system)		
	Total (N=431)	Pathogenic/likely pathogenic (N=41)	VUS (N=13)	Total (N=319)	Pathogenic/likely pathogenic (N=76)	VUS (N=8)
CNS	52	7 (13.5%)	2 (3.8%)	50	14 (28.0%)	1 (2.0%)
Ear/Neck/Eye/Face/Nose	25	3 (12.0%)	0	18	6 (33.3%)	1 (5.6%)
Gastro-intestinal tract	24	0	0	14	1 (7.1%)	0
Genitourinary	41	4 (9.8%)	2 (4.9%)	58	9 (15.5%)	1 (1.7%)
Cardiac	84	9 (10.7%)	3 (3.6%)	41	12 (29.3%)	2 (4.9%)
Osteoarticular (includes arthrogryposis)	54	3 (5.6%)	1 (1.9%)	41	15 (36.6%)	0
Thorax/Respiratory	1	0	0	7	1 (14.3%)	0
Effusion/Hydrops	23	5 (21.7%)	3 (13.0%)	31	10 (32.3%)	2 (6.5%)
Nuchal translucency (NT) >= 3.5 mm to < 4.5 mm without evidence of cystic hygroma	18	0	0	0	0	0
Fetal growth restriction < 5th percentile	20	1 (5.0%)	1 (5.0%)	1	0	0
Cystic hygroma (NT >= 4.5 mm)	39	6 (15.4%)	1 (2.6%)	8	2 (25.0%)	0
Congenital diaphragmatic hernia	14	2 (14.3%)	0	29	6 (20.7%)	1 (3.4%)
Spina bifida	34	1 (2.9%)	0	20	0	0

Data are n (%).

2 Association between HDP and GDM and Child Cardiovascular Health in Early Adolescence

Kartik Kailas Venkatesh[1], amanda Perak[2], Sadiya S. Khan[3], Jiqiang Wu[4], Patrick Catalano[5], Mark B. Landon[6], Denise Scholtens[2], William Lowe[2], William A. Grobman[1]
[1]The Ohio State University, Columbus, OH, [2]Northwestern University, Chicago, IL, [3]Northwestern University Feinberg School of Medicine, Oak Park, IL, [4]Ohio State University, Columbus, OH, [5]Tufts Medical Center, Boston, MA, [6]The Ohio State University Wexner Medical Center, Columbus, OH

OBJECTIVE: To examine the association of hypertensive disorders of pregnancy (HDP) and gestational diabetes (GDM) with child cardiovascular health (CVH) in early adolescence.

STUDY DESIGN: A secondary analysis from the prospective Hyperglycemia and Adverse Pregnancy Outcome (HAPO) Follow-up Study. The exposure (expressed as a multiple dichotomous variable) was HDP alone, GDM alone, or both HDP and GDM, compared with none of these (reference). The primary outcome was child CVH at ages 10 to 14 years, based on four metrics: body mass index, blood pressure, total cholesterol level, and glucose level. Each metric was categorized as ideal, intermediate, or poor using pediatric guidelines. The primary outcome was having at least one metric that was non-ideal versus all ideal (reference). We also secondarily examined to what extent the exposures were associated with progressive decrements in CVH by categorizing CVH according to the number of non-ideal metrics: at least one intermediate metric, one poor metric, or at least two poor metrics versus all ideal. Modified Poisson models adjusted for field center, parity, maternal age at enrollment, gestational age at enrollment, pregnancy alcohol or tobacco use, child's sex, and child's age at CVH assessment.

RESULTS: Among 3,317 assessed maternal-child dyads, 7.9% (n=263) pregnant individuals developed HDP alone, 12.1% (n=402) GDM alone, and 2.5% (n=82) both HDP and GDM. When the children were at a median age of 11.6 years, 55.5% (n=1808) had at least one metric that indicated less-than-ideal CVH. In adjusted models, individuals with HDP alone (aRR 1.16; 95% CI 1.04, 1.28), GDM alone (aRR 1.11; 95% CI 1.02, 1.21), and both HDP and GDM (aRR 1.17; 95% CI 1.00, 1.38) were more likely to have children with less-than-ideal CVH 10-14 years after delivery. Secondary analyses

revealed that the associations strengthened in magnitude as the adverse CVH metrics increased in number and severity (TABLE).

CONCLUSION: Pregnant individuals in the HAPO FUS cohort with HDP, GDM, or both were more likely to have children with worse CVH 10 to 14 years after their delivery.

TABLE. Frequency and association between HDP and GDM and Child Cardiovascular Health (CVH)

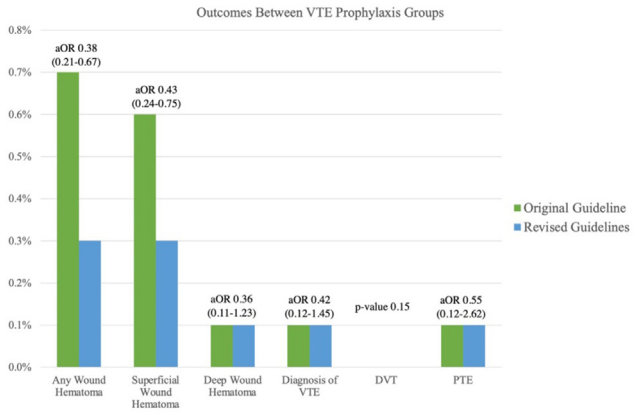
Frequency of child CVH (by composite of 4 metrics: body mass index, blood pressure, total cholesterol level, and glucose level) by HDP and GDM status (row percentage)

	All ideal	Any not ideal	≥ 1 intermediate	1 poor	≥ 2 poor
	n (%)	n (%)	n (%)	n (%)	n (%)
No HDP/GDM (n=2,570)	1,214 (47.2)	1,356 (52.8)	911 (35.4)	398 (15.5)	47 (1.8)
HDP alone (n=263)	103 (39.2)	160 (60.8)	96 (36.5)	58 (22.1)	6 (2.3)
GDM alone (n=402)	161 (40.0)	241 (60.0)	149 (37.1)	81 (20.1)	11 (2.7)
Both HDP and GDM (n=82)	31 (37.8)	51 (62.2)	26 (31.7)	22 (26.8)	3 (3.7)

Association between HDP and GDM and child CVH at 10 to 14 years[1,2]

	Any not ideal vs. all ideal (ref)	≥ 1 intermediate vs. all ideal (ref)	1 poor vs. all ideal (ref)	≥ 2 poor vs. all ideal (ref)
	aRR (95% CI)	aRR (95% CI)	aRR (95% CI)	aRR (95% CI)
No HDP/GDM	Ref	Ref	Ref	Ref
HDP alone	**1.16 (1.04, 1.28)**	1.28 (0.94, 1.73)	**1.82 (1.26, 2.62)**	1.55 (0.62, 3.87)
GDM alone	**1.11 (1.02, 1.21)**	1.19 (0.93, 1.52)	**1.48 (1.09, 2.01)**	1.57 (0.78, 3.18)
Both HDP and GDM	**1.17 (1.00, 1.38)**	1.11 (0.64, 1.93)	**2.37 (1.30, 4.30)**	2.82 (0.79, 10.06)

[1]Poisson regression with robust error variance was used.
[2]Models adjusted field center, parity, maternal age at enrollment, gestational age at enrollment, pregnancy alcohol and tobacco use, child sex, and child age at CVH assessment.
Final N=3,317 mother-child dyads without maternal chronic hypertension in pregnancy and with child outcome data.
Bold findings are statistically significant associations (p<0.05).



3 Evaluation of a more restrictive, heparin-based, obstetric thromboprophylaxis protocol

Macie L. Champion[1], Christina T. Blanchard[2], Anna Lively[1], Morgan Jenkins[1], Samantha E. Howell[1], Grace M. Lee[1], Brian M. Casey[1], Akila Subramaniam[2]
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: In 2016 our institution adopted VTE prophylaxis guidelines based on ACOG recommendations. These guidelines recommended heparin-based chemoprophylaxis for those with ≥ 2 VTE risk factors (e.g. obesity, chorioamnionitis, preeclampsia). As institutional data showed increased wound hematomas and no difference in VTEs, we adopted a more restricted approach requiring ≥ 3 risk factors with fewer conditions considered risk factors (severe preeclampsia vs. all preeclampsia). Our objective was to evaluate outcomes after the implementation of this revised, more restrictive obstetric thromboprophylaxis protocol.

STUDY DESIGN: Retrospective cohort study of patients who delivered at our institution between January 1, 2016 and December 31, 2018 (original guidelines) and between December 1, 2021 and May 31, 2023 (revised guidelines). High-risk patients (thrombophilia, prior/current VTE) on antepartum anticoagulation were excluded. Our primary outcome was clinical diagnosis of wound hematoma up to 6 weeks postpartum. Secondary outcome was new diagnosis of postpartum VTE. We compared baseline characteristics and outcomes between groups and estimated adjusted odds ratios (aOR) with 95% confidence intervals (CI) of primary and secondary outcomes using the original guideline group as reference.

RESULTS: Of 17,489 patients included in our analysis, 12,430 (71%) were in the original guidelines group, and 5,029 (29%) in the revised group. Rates of chemoprophylaxis decreased by 50% - from 16% during the original guidelines to 8% after revision. Groups differed in baseline characteristics including age, race, insurance status, and comorbidities. Compared to the original guidelines, more restrictive guidelines were associated with a > 50% significant decrease in any wound hematoma (0.7% vs. 0.3%, aOR 0.38, [0.21-0.67]), specifically due to a 50% reduction in superficial wound hematomas (0.6% vs. 0.3%, aOR 0.43 [0.24-0.75]). There was no increase in VTE, DVT, or PTE (Figure).

CONCLUSION: A more conservative approach to VTE prophylaxis decreased rates of wound hematomas without an increase in postpartum VTE.

4 Cost-effectiveness of Azithromycin for the Prevention of Maternal Sepsis or Death in Planned Vaginal Births

Jackie Patterson[1], Simon Neuwahl[2], Janet Moore[3], Elizabeth M. McClure[3], Waldemar Carlo[4], Melissa Buserman[5], Alan T. Tita[6]
[1]University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, NC, [2]RTI International, Atlanta, GA, [3]RTI International, Durham, NC, [4]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [5]University of North Carolina at Chapel Hill, Chapel Hill, NC, [6]University of Alabama at Birmingham, Birmingham, AL; on behalf of the NICHD Global Network for Women's and Children's Health Research APLUS Trial

OBJECTIVE: Maternal sepsis is one of the top three causes of maternal death globally. In a multi-country randomized trial performed by the National Institute of Child Health and Human Development's Global Network for Women's and Children's Health Research, a single oral dose of azithromycin significantly reduced the risk of maternal sepsis or death in low- and middle-income countries (LMICs). To support policymakers considering recommendations regarding intrapartum azithromycin in LMICs, we estimate the cost per case of maternal sepsis or death averted, and the incremental cost of the intervention after accounting for cost-savings from reduced healthcare use.

STUDY DESIGN: In this cost-effectiveness analysis, we compared the costs and effects of azithromycin versus standard care using a probabilistic decision tree model informed by published results and primary data from the Azithromycin Prevention in Labor Use (A-PLUS) trial. From a healthcare sector perspective, we considered the costs of azithromycin treatment and its effect on maternal outcomes and healthcare use related to infection. We used country-specific costs and considered Zambia the median country based on the cost per day for hospital stays. Our model results represent the average of 100,000 model runs, each using a randomly selected set of parameters drawn from model distributions.

RESULTS: Azithromycin resulted in 769 maternal sepsis or death cases averted, 809 maternal infections averted and 495 maternal hospitalizations averted per 100,000 pregnancies (Table). The cost of the intervention was $90,963 per 100,000 pregnancies, or $0.91 per pregnancy. The reduction in healthcare use resulted in cost-savings for all countries except Bangladesh (which had the lowest cost for healthcare use). The median country cost-savings was $18,451 per 100,000 pregnancies.

CONCLUSION: Azithromycin in women planning a vaginal birth is a cost-saving, effective treatment to reduce maternal sepsis or death and maternal infection. This cost-savings strengthens the evidence in

support of implementing azithromycin in intrapartum care in LMICs.

Table: **Cost-effectiveness of intrapartum azithromycin expressed per 100,000 pregnancies**

	Overall						
Health outcomes (95% CI)							
Cases of sepsis or death averted	768.1 (682.6 - 821.9)						
Cases of infection averted	808.5 (688.4 - 896.7)						
Hospitalizations averted*	494.9 (525.5 - 459.7)						
Unplanned care visits averted*	859.1 (852.7 - 851.9)						
Antibiotic regimens averted (without hospitalization or unplanned care)	1,976.4 (1956.8 - 1976.5)						
YLDs averted	10.4 (11.2 - 9.3)						
Intervention cost in USD	$90,963						
	Bangladesh	**Kenya**	**DRC**	**Zambia**	**Pakistan**	**India**	**Guatemala**
Country-specific costs							
Hospital cost per day	$9.96	$21.67	$21.60	$28.00	$45.45	$48.43	$85.42
Clinic visit cost	$3.03	$11.56	$10.20	$10.64	$17.87	$13.62	$34.46
Antibiotic cost	$3.17	$7.22	$10.20	$4.87	$10.58	$7.26	$10.77
Cost-effectiveness outcomes in USD (95% CI)							
Incremental cost	$47,968	-$8,352	-$13,815	-$18,451	-$80,229	-$89,889	-$231,105
Cost per sepsis or death averted	$62	Cost-saving					
Cost per infection averted	$59	Cost-saving					
Cost per DALY averted	$4,592	Cost-saving					

Model results are based on maternal outcome and healthcare utilization probabilities and treatment effects from the A-PLUS trial, and azithromycin pricing from the 2015 International Medical Products Price Guide. All results represent the average with 95% CI of 100,000 model simulations, each using a randomly selected set of parameters drawn from model distributions. Country-specific analyses reflect healthcare utilization costs from that country. *Each hospitalization and unplanned care visit included one course of antibiotics. DRC=Democratic Republic of the Congo; CI=confidence interval; YLD=years lived with disability; USD=United States dollars; DALY=disability-adjusted life year.

5 Peripartum dapagliflozin improves late life cardiovascular outcomes in a mouse model of superimposed preeclampsia

Ashley Hesson[1], Ajleeta Sangtani[1], Elizabeth S. Langen[1], Kristina Hunker[2], Nitin Kumar[1], Santhi K. Ganesh[2]
[1]University of Michigan, Ann Arbor, MI, [2]Michigan Medicine, Ann Arbor, MI

OBJECTIVE: Dapagliflozin (DAPA), an SGLT2 inhibitor, has been shown to improve outcomes in heart failure. We hypothesized that peripartum treatment with DAPA in a mouse model of chronic hypertension with superimposed preeclampsia would lead to a more favorable cardiovascular profile of blood pressure and potentially adverse cardiac remodeling in pregnancy and reduce the risk of later life cardiovascular pathology.

STUDY DESIGN: BPH/2J mice have chronic hypertension that worsens in pregnancy with proteinuria and elevated sFLT level (Fig.1). We randomly assigned 14 BPH/2J mice to dapagliflozin chow (N=7) versus control chow (N=7) from early gestation (E4) through the postpartum period (E21 + 21 days). Blood pressures were measured by an implanted telemetry device. Echocardiograms were obtained pre-pregnancy, in late gestation (E18), and in late life (9 months aged) along with obstetric ultrasounds.

RESULTS: Mid-gestation systolic blood pressures were higher in the control group than the DAPA group (Fig.1, P=2.53e-05), but comparable in early and late gestation. Controls had higher aortic peak velocities in late pregnancy compared to the DAPA group (745.8 vs 596.5 mm/s, P=0.02). Left ventricular base strain in pregnancy was higher in the control group (5.2 vs -1.7% in the DAPA group, P=3.58 e-03), though left ventricular ejection fractions were similar. There were no differences in estimated fetal weights or amniotic fluid levels between groups. In late life, the control group had a significant loss of left ventricular function from their pre-pregnancy baseline, whereas mice treated with DAPA during pregnancy had relatively preserved left ventricular function (-17% vs -5% change, P=0.02, Fig,1). There was no difference in late life systolic blood pressure or pulse pressure between groups.

CONCLUSION: DAPA treatment only during the peripartum period results in subtle differences in blood pressure and cardiac function during pregnancy for mice with superimposed preeclampsia, but is associated with a significant improvement in both clinical and echocardiographic measures of late life cardiovascular function.

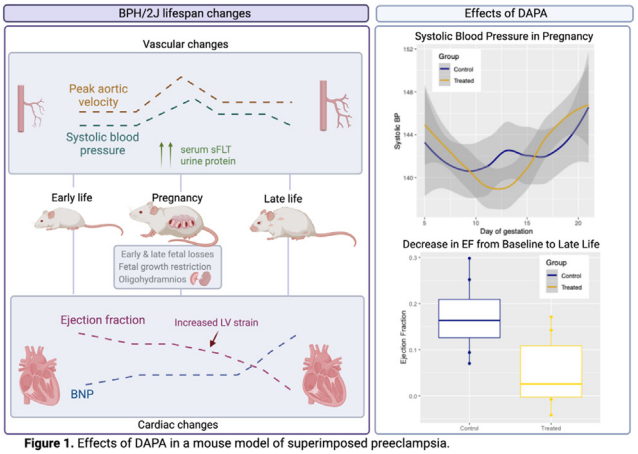


Figure 1. Effects of DAPA in a mouse model of superimposed preeclampsia.

6 Effect of supplemental oxygen for Category II resuscitation on oxidative stress: a randomized controlled trial

Nandini Raghuraman[1], Fan Zhang[1], Brianna Bradley[1], Antonina I. Frolova[1], Ebony B. Carter[2], Jeannie C. Kelly[2], Anthony O. Odibo[1], Molly J. Stout[3], D Michael Nelson[4], Methodius G. Tuuli[5], Alison G. Cahill[6]
[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO, [3]University of Michigan, Ann Arbor, MI, [4]Washington University in St. Louis, St. Louis, MO, [5]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [6]University of Texas at Austin, Dell Medical School, Austin, TX

OBJECTIVE: The Association of Women's Health, Obstetric and Neonatal Nurses recently recommended continued use of supplemental oxygen (O_2) for intrauterine resuscitation despite ACOG recommendations to the contrary. There is a need to address the safety of this practice given neonatal and adult literature that demonstrate a link between excess O_2 exposure and free radical-mediated oxidative cell damage. We tested the hypothesis that O_2, compared with room air (RA), for Category II fetal heart tracings (FHT) is associated with an increase in umbilical artery (UA) and maternal measures of oxidative stress.

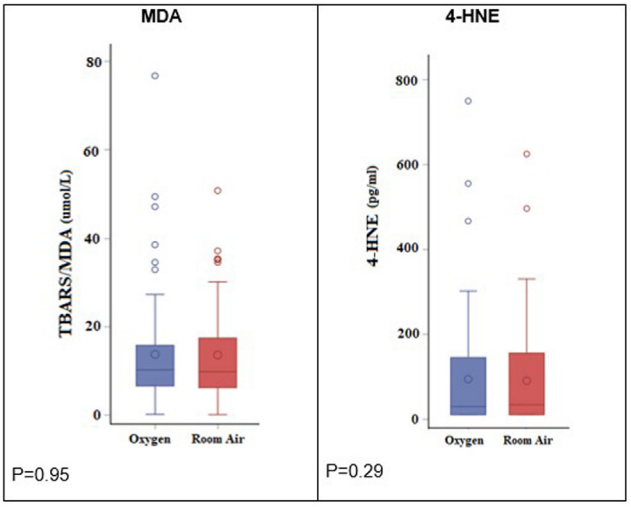
STUDY DESIGN: This was a single-center randomized controlled trial. Singleton pregnancies ^{3} 37 weeks with Category II FHT necessitating intrauterine resuscitation in active labor were randomized to RA or 10L/min O_2 by face mask until delivery. The primary outcomes were two UA markers of oxidative stress via free radical-mediated lipid peroxidation: malondialdehyde (MDA) and 4-hydroxynonenal (4-HNE). They were measured using commercially available thiobarbituric acid and competitive ELISA reactive substances' assays. Secondary outcomes were maternal plasma MDA and 4-HNE at time of delivery, UA cord gases, and mode of delivery.185 patients were needed for 80% power to detect a 10% difference in UA MDA levels between groups. We increased the sample size to 212 to accommodate 15% loss to unattainable UA samples. Analysis was by intention-to-treat.

RESULTS: Of the 212 patients randomized, 153 had UA samples that were adequate for oxidative stress analysis; 74 O_2 and 79 RA. Baseline characteristics and alternate intrauterine resuscitation techniques were similar between groups. There was no difference in median UA MDA or 4-HNE between O_2 and RA groups (**Figure**).

There was no difference in maternal MDA or 4-HNE, UA gases, or mode of delivery between groups.

CONCLUSION: Among patients with Category II FHT in active labor, intrauterine resuscitation with supplemental O_2 is not associated with an increase in fetal or maternal lipid peroxidation markers. Clinical outcomes were similar between O_2 and RA groups.

Figure: Umbilical artery malondialdehyde (MDA) and 4-hydroxynonenal (4-HNE) in patients randomized to Oxygen versus Room air



7 Association of Postpartum Oxytocin Dose and Postpartum Hemorrhage

Ashley E. Shea[1], Candice Woolfolk[2], Vasiliki B. Orfanakos[1], Alison G. Cahill[3], Methodius G. Tuuli[4], Sindhu K. Srinivas[5], George A. Macones[6], Alan T. Tita[1], Akila Subramaniam[7]

[1]University of Alabama at Birmingham, Birmingham, AL, [2]Washington University School of Medicine in St. Louis, St. Louis, MO, [3]University of Texas at Austin, Dell Medical School, Austin, TX, [4]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [5]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [6]The University of Texas at Austin, Austin, TX, [7]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

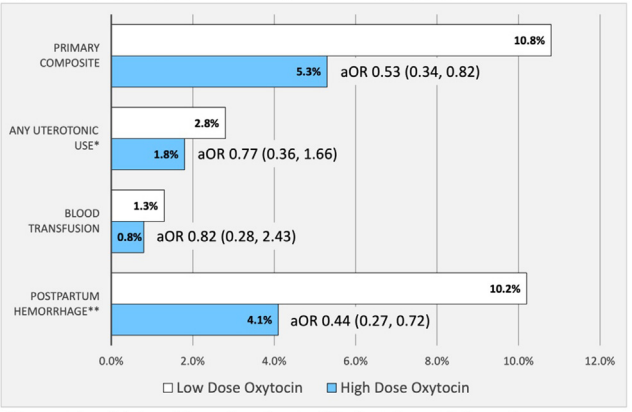
OBJECTIVE: The most effective dose of prophylactic oxytocin for the prevention of postpartum hemorrhage (PPH) is unknown. Our objective was to compare rates of PPH and the need for additional PPH interventions between postpartum (PP) high dose (80 units) and lower dose (10-30 units) oxytocin regimens.

STUDY DESIGN: Secondary analysis of a multicenter randomized control trial of 2,404 nulliparous women between 5/2014-12/2017 with term singleton pregnancies that investigated immediate versus delayed pushing in women in the 2nd stage. PP oxytocin regimens were ascertained from each of the 6 participating centers and categorized as high dose (80 units/500 mL over 1 hour after placental delivery) and lower dose (10-30 units/500-1000 mL over 1-4 hours). The primary outcome was a composite of uterotonic use, any blood transfusion, and PPH (see figure footnote). Secondary outcomes included individual composite components. Outcomes were compared between groups and logistic regression was used to estimate adjusted odds ratios and 95% confidence intervals using the lower dose group as the reference.

RESULTS: All 2,404 patients from the primary RCT were included: 455 (19%) in the high dose group and 1,949 (81%) in the lower dose group. Women in the high dose group were more likely to be younger, African American, obese, have magnesium sulfate exposure, and achieve vaginal delivery. Compared to lower dose oxytocin, patients receiving higher oxytocin doses had nearly a 50% reduction in odds of the primary composite outcome (aOR 0.53 [95% CI 0.34, 0.82]), primarily driven by a >50% decreased odds of PPH (aOR 0.44 [0.27-0.72])(Figure). While frequencies of other secondary outcomes were lower in the high dose group; there was no difference in odds of these outcomes after multivariable adjustment. Stratified analysis of low (10-20 units), moderate (30 units), and high dose (80 units) was consistent with primary results.

CONCLUSION: High dose PP oxytocin was associated with lower rates of PPH than traditional oxytocin doses. Future multicenter trials of PP oxytocin dose should be performed to improve outcomes.

Figure. Percentage of postpartum bleeding outcomes with adjusted odds ratios



*Any uterotonic use includes methylergonovine, carboprost, additional oxytocin, or rectal misoprostol.
**Postpartum hemorrhage is defined by EBL >500 mL for vaginal delivery and >1000 mL for cesarean section.
***Odds ratios are adjusted for delivery mode and race based on parsimonious modeling. Odds ratios are listed as aOR (95% CI).

8 A Randomized Controlled Trial (RCT) of Laser Surgery in Twin-Twin Transfusion Syndrome: The Sequential Trial

Ramen H. Chmait[1], Arlyn Llanes[1], Lisa M. Korst[2], Kristine B. Rallo[1], Andrew H. Chon[3], Martha A. Monson[4], Ruben A. Quintero[5]

[1]University of Southern California, Los Angeles, CA, [2]Childbirth Research Associates, North Hollywood, CA, [3]Oregon Health & Science University, Portland, OR, [4]Intermountain Healthcare, Salt Lake City, UT, [5]USFetus Research Consortium, Coral Gables, FL, on behalf of USFetus

OBJECTIVE: Sequential laser surgery in TTTS has been associated with improved donor twin survival in observational studies compared with the conventional selective technique (91% vs. 80%). In the sequential technique the arteriovenous (AV) communications from the volume-depleted donor to the volume-overloaded recipient twin are occluded before those from recipient to donor. In the selective technique, the anastomoses are occluded in no particular sequence. The trial tested whether: (1) the sequential technique improves donor survival compared to the selective technique; (2) intraoperative timing of laser ablation of superficial anastomoses (arterioarterial/venovenous) affects donor twin survival.

STUDY DESIGN: TTTS patients were randomized to sequential vs selective surgery. The study had >80% power to detect a 10% difference in donor survival. Nested within the trial, a second RCT randomized patients with superficial anastomoses to ablation of these connections first (before ablating the AV anastomoses) vs last. Trial registration: NCT02122328.

RESULTS: Over 12 years, 642 patients were randomly allocated to sequential vs selective techniques. The frequency of donor survival was 85.6% (274/320) and 84.2% (271/322), respectively (OR 1.12

[0.73-1.73], p=0.60). Thirty-day survival did not differ between the two groups (Table). The postoperative mean peak systolic velocity in the middle cerebral artery (MCA-PSV) was lower in the sequential vs selective group (1.00 ± 0.30 vs 1.06 ± 0.30 MoM, p=0.003). Superficial anastomoses occurred in 27.4% (176/642) of cases; donor survival was 71.0% (125/176) in those with superficial anastomoses vs 90.1% (420/460) in those without (OR 0.27 [0.17-0.42], p< 0.0001). In cases with superficial anastomoses, donor survival was independent of timing of ablation or surgical technique.

CONCLUSION: The primary outcome, donor survival, did not differ between the sequential and the selective techniques. Superficial anastomoses were associated with lower donor survival, which was independent of timing of occlusion or technique. The significance of the MCA-PSV results is unknown.

Table. Perinatal outcomes.

Outcome	Sequential Group N=320	Selective Group N=322	p-value
Alive at birth			
Donor (primary outcome)	85.6% (274)	84.2% (271)	0.7
Recipient	94.1% (301)	93.5% (301)	0.9
30-day survival			
Donor	82.2% (263)	80.7% (260)	0.7
Recipient	90.6% (290)	89.4% (288)	0.7
Dual survival	79.1% (253)	76.7% (247)	0.5
At least 1 survivor	93.8% (300)	93.5% (301)	0.9
30-day survival of donor by Stage			
Stage I	90.0% (45/50)	92.6% (50/54)	0.7
Stage II	87.8% (72/82)	84.5% (60/71)	1.0
Stage III D, D/R	73.1% (38/52)	64.1% (41/64)	1.0
Stage III R	79.5% (93/117)	78.5% (84/107)	0.8
Stage IV	78.9% (15/19)	96.2% (25/26)	0.2

LB01 Development of post-acute sequelae of SARS-CoV-2 (PASC) after infection in pregnancy: NIH RECOVER-Pregnancy Cohort

Torri D. Metz[1], Harrison Reeder[2], Rebecca G. Clifton[3], Valerie Flaherman[4], Leyna V. Aragon[5], Leah Castro Baucom[6], Alexis Braverman[7], Tingyi Cao[2], Jodie A. Dionne[8], Andrea S. Foulkes[2], Rachel S. Gross[9], Jenny Han[10], Rachel Hess[1], Leora I. Horwitz[9], Xiaolin Jia[11], Minal Kale[12], Alem Mehari[13], Jonathan S. Monteiro[2], Deepti Pant[2], Patrick S. Ramsey[14], Vanessa Jacoby[4]

[1]University of Utah Health, Salt Lake City, UT, [2]Massachusetts General Hospital, Boston, MA, [3]George Washington University, ROCKVILLE, MD, [4]University of California at San Francisco, San Francisco, CA, [5]University of New Mexico, Albuquerque, NM, [6]RECOVER Patient, Caregiver, or Community Advocate Representative, New York, NY, [7]University of Illinois Chicago, Chicago, IL, [8]Department of Medicine, Division of Infectious Diseases, University of Alabama at Birmingham, BIRMINGHAM, AL, [9]New York University Grossman School of Medicine, New York, NY, [10]Emory University, Atlanta, GA, [11]Stanford University, Palo Alto, CA, [12]Mount Sinai Medical Center, New York, NY, [13]Howard University, Washington DC, DC, [14]UTHSCSA, UTHSCSA, TX

OBJECTIVE: To estimate the prevalence of post-acute sequelae of SARS-CoV-2 infection (PASC or long COVID) after infection with SARS-Cov-2 during pregnancy, and characterize associated risk factors.

STUDY DESIGN: In a prospective, multicenter observational cohort study, individuals who had SARS-CoV-2 infection during pregnancy were enrolled across 41 sites from December 2021 through August 2023. The primary outcome was presence of PASC, as defined by the NIH RECOVER Consortium based on symptoms and severity, at least 6 months after first SARS-CoV-2 infection. Risk factors for PASC were evaluated including sociodemographic and pre-existing clinical characteristics, and SARS-CoV-2 infection severity (oxygen requirement). Univariable and multivariable logistic regression models, with multiple imputation for missing data, were fitted to estimate associations between these characteristics and presence of PASC.

RESULTS: Overall 1,503 participants were included; 61% had an index SARS-CoV-2 infection on or after December 1, 2021 (i.e., during Omicron variant dominance); and 51% were fully vaccinated prior to infection. The prevalence of PASC at first study visit 6 months or more after infection was 9.3% (95% CI 7.9-10.9%). The most common defining symptoms among individuals with PASC were post-exertional malaise (82%), fatigue (75%) and dizziness (62%). In a multivariable model, obesity (aOR 1.63, 95% CI 1.13-2.44), preexisting depression or anxiety disorder (aOR 2.64, 95% CI 1.80-3.87), economic hardship (self-reported difficulty covering expenses) (aOR 1.66, 95% CI 1.11-2.48), and treatment with oxygen during infection (aOR 1.88, 95% CI 1.01-3.50), were associated with increased odds of developing PASC in a multivariable model (Table).

CONCLUSION: PASC prevalence after SARS-CoV-2 infection during pregnancy was lower than published NIH RECOVER-Adult cohort estimates of 23%. This finding may reflect differential immune response in pregnancy, differences in sampling strategies, or lower rates of pre-existing comorbidities. Several socioeconomic and clinical characteristics were associated with the development of PASC.

Table. Demographic and Clinical Characteristics by PASC Status and Modeling Results

Characteristic	PASC Positive (n=140)	PASC Indeterminate (n=1363)	Unadjusted OR (95% CI)	aOR (95% CI)
Age at index infection, mean (SD)	32 (5)	32 (5)	1.00 (0.96, 1.03)	1.03 (0.99, 1.07)
Index infection pre-Omicron era (<2021/12/01)	72/140 (51%)	513/1363 (38%)	1.75 (1.24, 2.49)	1.38 (0.84, 2.28)
Medicare or Medicaid or No Insurance reported at enrollment	49/140 (35%)	377/1360 (28%)	1.40 (0.97, 2.03)	1.02 (0.64, 1.63)
Covering expenses reported Somewhat or Very Difficult at enrollment	81/140 (58%)	550/1360 (40%)	2.02 (1.42, 2.88)	1.66 (1.11, 2.48)
Discrimination index at enrollment, mean (SD) [OR for a 10-point increase]	2 (1)	1 (1)	1.44 (1.16, 1.78)	1.15 (0.91, 1.46)
Not fully vaccinated two weeks prior to index infection	87/140 (62%)	644/1361 (47%)	1.83 (1.28, 2.61)	1.41 (0.83, 2.42)
Any tobacco use (or prefer not to answer) in year prior to index infection	24/140 (17%)	154/1352 (11%)	1.61 (1.01, 2.58)	1.04 (0.62, 1.74)

OBJECTIVE: Women with previous spontaneous preterm birth (sPTB) are at increased risk of recurrent PTB. Cervical cerclage has been proven effective in preventing recurrent PTB in women with multiple preterm births (history indicated) or a previous sPTB and a midpregnancy short cervix ≤ 25 mm (ultrasound indicated). We hypothesized that a cervical pessary might be non-inferior to cerclage.

STUDY DESIGN: This was an international, open-label, multi-center, non-inferiority, randomized controlled trial in 21 hospitals in the Netherlands and Switzerland. We included women with a singleton pregnancy with prior sPTB < 34 weeks and an obstetric history or ultrasound guided indication for an intervention. Participants were randomised (1:1 ratio) to pessary or cerclage, stratified per centre and indication. Primary outcome was PTB < 32 weeks. Secondary outcomes included obstetric, neonatal and maternal outcomes. Analysis was by intention-to-treat. Treatment effect was expressed as relative risk (RR) and 95% confidence intervals (CI). The non-inferiority margin for pessary was set at 10%, resulting in a sample size of 400 women. After the third interim analysis, recruitment was halted due to safety concerns and the apparent challenge in establishing non-inferiority of pessary treatment. (ICTRP Trial registration: NTR4415)

RESULTS: From March 2014 to December 2022, we randomized 261 participants to pessary (n=133) or cerclage (n=128). The primary outcome PTB < 32 weeks occurred in 33.8 % after pessary versus 24.0 % after cerclage (RR 1.4 , 95 % CI 0.95 – 2.1, p-value 0.09). Nearly all other PTB rates and obstetric outcomes significantly favored cerclage. Neonatal outcomes favored cerclage, although not statistically significant (Table).

CONCLUSION: In women with a singleton pregnancy, previous sPTB and an indication for an additional intervention based on obstetric history or a short cervix, we could not proof non-inferiority of cervical pessary compared to cerclage in preventing recurrent PTB. Women with an indication for additional treatment should be treated with cerclage.

10 Optimal Misoprostol Dosing Among Patients with a BMI Greater Than 30: A Randomized Controlled Trial

Alexander M. Saucedo[1], Miriam Alvarez[1], George A. Macones[2], Alison G. Cahill[1], Lorie M. Harper[1]
[1]University of Texas at Austin, Dell Medical School, Austin, TX, [2]The University of Texas at Austin, Austin, TX

OBJECTIVE: Patients with obesity have longer lengths of labor with increased risk of perinatal morbidity. It is unclear whether the same dose of misoprostol should be used for induction of labor in obese compared to non-obese women. We aimed to determine if 50mcg (compared to 25mcg) of vaginal misoprostol reduces the time from induction start to delivery in obese patients.

STUDY DESIGN: Double-blinded, pragmatic randomized controlled trial, between June 2022, and July 2023. Patients with a BMI ≥ 30 kg/m^2 undergoing labor induction ≥ 36 weeks, singleton gestations, and a cervical dilation ≤ 3cm on admission, were included. Patients were randomized to 25 or 50 mcg of vaginal misoprostol. The primary outcome was time from induction to delivery. A priori, we estimated 90 subjects per group (N=180). This is based on 18 +/- 6 hours for time to delivery in the control (25mcg), alpha of 5%, and an 85% power to detect a 3-hour difference. Analysis was intention-to-treat. A two-sample t-test was used for the primary outcome, Cohen's *d* as a measure of effect, and P values were reported. Logistic regression was used to analyze secondary outcomes.

RESULTS: Of the 180 patients, 88 were assigned to the 25mcg group and 92 were assigned to the 50mcg group. Baseline characteristics were similar between groups. No difference was found in the primary outcome of time to delivery (21.59 hrs vs. 18.56 hrs; $d = 0.28$; 95% CI, -0.02-0.57). In a planned subgroup analysis, multiparous patients delivered faster in the 50mcg group (15.19 hrs. vs. 11.97 hrs; $d = 0.51$; 95% CI, 0.04-0.97). The rate of tachysystole was rare overall (2.2%) and non-significant between groups. No differences in maternal or neonatal adverse effects were observed.

CONCLUSION: Obese patients undergoing cervical ripening with 50mcg of vaginal misoprostol experienced similar time to delivery when compared to 25mcg. However, multiparous patients had a significantly reduced time to delivery when 50mcg was used. A higher dose of misoprostol may be a promising intervention for reducing time in labor by an average of 3 hours which warrants further study.

11 Donor velamentous cord insertion: an omen for poor laser outcomes?

Christy Gandhi, Noelle Breslin, Russell S. Miller, Rosalie Ingrassia, Chia Ling Nhan Chang, Lynn Simpson
Columbia University Irving Medical Center, New York, NY

OBJECTIVE: Velamentous cord insertion (VCI) occurring in monochorionic diamniotic (MCDA) pregnancies has been associated with the occurrence of twin-twin transfusion syndrome (TTTS) and adverse outcomes. However, literature associating VCI with TTTS fetoscopic laser surgery (FLS) outcomes is limited. This study aims to determine the impact of donor twin VCI (dVCI) detected on sonogram in a cohort of twin pregnancies that underwent FLS for TTTS.

STUDY DESIGN: This is a retrospective cohort study of MCDA twins that underwent FLS at a single fetal care center from 2009-22. Pregnancies with dVCI were compared to those without dVCI. Primary outcome was dual survival at time of first sonogram done after FLS. Secondary outcomes included gestational age (GA) at time of TTTS diagnosis, at time of FLS, and at time of delivery, as well as survival to neonatal intensive care unit (NICU) discharge. Categorical values were compared using chi-square or Fisher's exact test while continuous variables were compared using Kruskal-Wallis test.

RESULTS: Of the 226 MCDA pregnancies that underwent FLS, 57 were excluded (12 triplet gestations, 39 without documented cord insertion data, and 6 with incomplete data after FLS). Of the 169 remaining twins, there were 62 (37%) dVCI and 107 (63%) without dVCI. TTTS staging distribution and GA at time of diagnosis were similar between groups. Pregnancies with dVCI underwent FLS at an earlier GA compared to pregnancies without dVCI (19.5 weeks vs 20.4 weeks, $p< 0.05$). There was no difference in GA at time of delivery between groups.

Dual twin survival at first sonogram post-FLS was 71% in the dVCI group, compared to 89% without dVCI ($p< 0.01$). Subgroup analysis of 127 pregnancies (75%) with complete delivery data demonstrated the rate of dual twin survival to NICU discharge was 54% in the dVCI group compared to 73% without dVCI ($p< 0.05$).

CONCLUSION: In MCDA twin pregnancies undergoing FLS for TTTS, dVCI was associated with earlier fetal intervention and decreased likelihood of dual twin survival. These findings can help guide counseling of patients with MCDA twins with dVCI affected by TTTS.

12 Outpatient Induction of Labor – Primary Outcome Results from the HOME INDUCTION Randomized Controlled Trial

Sarah M. Nicholson[1], Orla Smith[2], Corina Oprescu[2], Eimear Wall[2], Sara El Nimr[2], Geraldine Gannon[2], Susan Hatt[2], Ita Shanahan[3], Bernard Kennedy[2], Ronan Daly[2], Claudia Looi[2], Elena Fernandez[2], Zara Molphy[1], Patrick Dicker[1], Karen Flood[1], Fergal D. Malone[2]
[1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]Rotunda Hospital, Dublin, Ireland, [3]Rotunda, Rotunda, Dublin

OBJECTIVE: The ARRIVE Trial has resulted in an increased demand for 39 week induction of labor (IOL) in normal-risk nulliparous patients, but this creates significant logistical challenges for over-stretched delivery units. A potential innovation is commencing induction by means of outpatient cervical ripening at home(H-IOL), using vaginal prostaglandin(Propess/Cervidil) or osmotic cervical dilator(Dilapan-S). Before widespread implementation however, there is a critical need for prospective data on safety and efficacy of H-IOL methods.

STUDY DESIGN: We randomized healthy nulliparous women, who had agreed to elective IOL at 39 weeks, to one of 3 forms of initial cervical ripening at home: 12 hours of Dilapan(D12), 24 hours of Dilapan(D24), or 24 hours of Propess(P24). Participants began the IOL process in hospital and returned home for 12/24 hours, following which they returned to the hospital to complete their delivery. The primary objective was to confirm relative safety and efficacy of the 3 protocols, using a non-inferiority analysis of Dilapan to Propess within a 10% margin. The primary outcome was failure to achieve vaginal delivery.

RESULTS: 327 women were recruited and randomised at 38 weeks, with 271 completing induction. D24 and P24 had similarly high rates of vaginal delivery of 75% vs 76%, respectively. D12 had a lower vaginal delivery rate of 64% and the criteria for non-inferiority of Dilapan to P24 were not met (difference of -6%, 95% CI= -17%,5%). While hyperstimulation was more likely with P24, this had no clinical consequences.

CONCLUSION: This RCT has confirmed similarly high vaginal delivery rates for both D24 and P24, with 75% of patients successfully delivering vaginally, and with no significant adverse maternal or

neonatal outcomes. This study empowers obstetricians to embrace outpatient H-IOL as a highly effective solution for handling the increasing numbers of nulliparous patients requesting 39 week induction. Use of either cervical ripening method enables patients to stay home for a large part of the IOL process, thereby significantly reducing resource demands in the Labor Ward.

13 The effect of enhanced recovery after surgery (ERAS) on neonatal glucose: A randomized, equivalence trial

Amanda McWhirter[1], Maria Ruiz[2], Autri Hafezi[2], Ethan Manninen[3], Eli Lefkowitz[2], Benjamin Manninen[4], Karen Lesser[2]

[1]University of Arizona, Tucson College of Medicine, Tucson, AZ, [2]University of Arizona, Tucson, AZ, [3]Harvard University, Cambridge, MA, [4]Cornell University, Ithaca, NY

OBJECTIVE: Enhanced recovery after surgery (ERAS) is a protocol aimed at improving surgical recovery and is becoming the standard of care for women undergoing cesarean delivery. The protocol includes a pre-operative carbohydrate-containing drink. While the protocol appears to benefit the mother, the potential effects on the neonate are unknown. Our objective was to determine if administration of a pre-operative carbohydrate drink prior to cesarean delivery influences neonatal blood glucose.

STUDY DESIGN: We performed a randomized, controlled, equivalence trial of non-diabetic patients with term, non-anomalous pregnancies undergoing cesarean delivery. Participants were randomized to receive a pre-operative drink containing 50-g of carbohydrate or to a control group, who remained fasting. The primary outcome was neonatal glucose at 1-2 hours of life. Secondary outcomes included neonatal glucose at 24 hours of life, neonatal hypoglycemia (glucose $<$ 45 mg/dL), NICU admission, and other maternal and neonatal outcomes. *A priori* sample size of 108 was calculated using an equivalence margin of 10 mg/dl, and a power of 90%.

RESULTS: From October 2021 to April 2023, of 352 scheduled cesarean deliveries, 214 were eligible, and 108 agreed to enrollment and randomization with two withdrawals. Clinical characteristics were similar between groups (Table). Neonatal glucose at 1-2 hours of life was not equivalent between groups (TOST upper, $P = .366$; TOST lower, $P < .001$). Additionally, the incidence of neonatal hypoglycemia increased in the drink group (Table). No neonate had an Apgar score < 7 at 5 minutes of life and neonatal glucose at 24 hours of life was equivalent (TOST upper, $P < .001$; TOST lower, $P < .001$).

CONCLUSION: Neonatal glucose at 1-2 hours of life after maternal consumption of a carbohydrate drink was not equivalent to fasting. Maternal benefit should be weighed against the risk of neonatal hypoglycemia when considering adopting the ERAS protocol for cesarean delivery.

Table: Clinical characteristics and outcomes

Characteristics	Control (n=53)	Drink (n=53)	*P*-value
Age (years)	30.36 ± 5.9	29.68 ± 5.83	0.553

14 Persistent Programming of Offspring Gut Serotonin Pathway by Maternal Western-Style Diet in Non-Human Primates

Erin Bolte[1], Derek O'Neil[1], Rene Lindsley[2], Melissa Kirigiti[2], Paul Kievit[3], Mindy Engevik[4], Kjersti M. Aagaard[5]

[1]Baylor College of Medicine, Houston, TX, [2]Ohio State University, Beaverton, OR, [3]Oregon National Primate Research Center, Beaverton, OR, [4]Texas Children's Hospital, Houston, TX, [5]Texas Children's Hospital, Baylor College of Medicine, Houston, TX

OBJECTIVE: Anxiety is a mood disorder associated with low levels of serotonin. Over 95% of the body's serotonin is produced in the gut by enterochromaffin cells, and it affects the brain and behavior via signaling at the vagus nerve (the gut-brain axis). We have previously shown that non-human primate offspring exposed to maternal Western-Style diet (WSD) display anxiety persistent into juvenile life. To investigate the connection between maternal WSD and serotonin as a mechanism for the observed anxiety, we hypothesized that maternal WSD can persistently program offspring gut enterochromaffin cells.

STUDY DESIGN: Macaques were fed WSD or Chow control diet during gestation/lactation. Offspring were sampled at fetal necropsy (late third-trimester, n=4) or born vaginally and weaned onto a Chow diet for sampling at 3 years of age (peripuberty, n=8) (Fig. 1A). *Ex vivo* intestinal organoids were generated from fresh descending colon biopsy tissue at both timepoints and differentiated to contain serotonin-producing enterochromaffin cells. Secreted serotonin and serotonin-related gene expression were measured.

RESULTS: Maternal WSD-programmed fetal and juvenile intestinal organoids secreted decreased serotonin compared to Chow control organoids (fetal 0.006 versus 0.011 pg/cells, p= 0.021, Fig. 1B; 3 year-olds 0.010 versus 0.014 pg/cells, p= 0.033, Fig. 1C). At the Fetal stage, maternal WSD-programmed intestinal organoids expressed increased enterochromaffin cell marker expression (*CHGA* p= 0.0004) and decreased serotonin transporter expression (*SERT*, p=0.0009), with no statistical difference in serotonin rate limiting enzyme expression (*TPH1*) (Fig. 1D).

CONCLUSION: We have observed that maternal WSD exposure disrupts enterochromaffin cell secretion of serotonin in the colon beginning in fetal life. This disruption is not normalized by a normal offspring diet, as low serotonin secretion is still observed when offspring are 3-years-old. Maternal WSD programs an altered serotonin pathway gene expression equilibrium, which may predispose the gut-brain axis of these offspring towards anxiety.

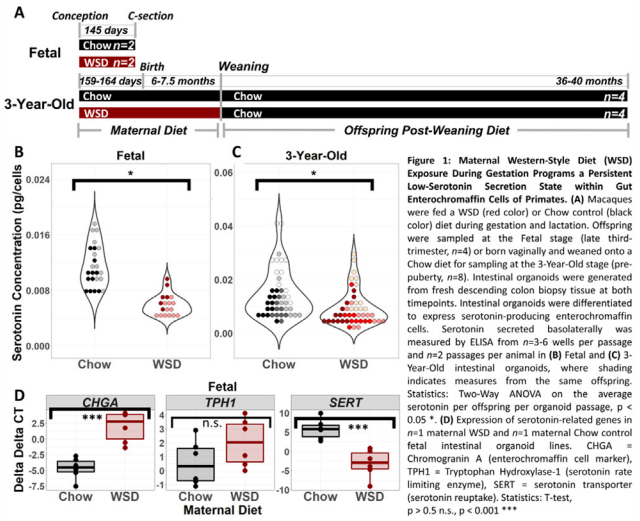

Figure 1: Maternal Western-Style Diet (WSD) Exposure During Gestation Programs a Persistent Low-Serotonin Secretion State within Gut Enterochromaffin Cells of Primates. (A) Macaques were fed a WSD (red color) or Chow control (black color) diet during gestation and lactation. Offspring were sampled at the Fetal stage (late third-trimester, *n*=4) or born vaginally and weaned onto a Chow diet for sampling at the 3-Year-Old stage (pre-puberty, *n*=8). Intestinal organoids were generated from fresh descending colon biopsy tissue at both timepoints. Intestinal organoids were differentiated to express serotonin-producing enterochromaffin cells. Serotonin secreted basolaterally was measured by ELISA from *n*=3-6 wells per passage and *n*=2 passages per animal in **(B)** Fetal and **(C)** 3-Year-Old intestinal organoids, where shading indicates measures from the same offspring. Statistics: Two-Way ANOVA on the average serotonin per offspring per organoid passage, $p < 0.05$ *. **(D)** Expression of serotonin-related genes in *n*=1 maternal WSD and *n*=1 maternal Chow control fetal intestinal organoid lines. CHGA = Chromogranin A (enterochromaffin cell marker), TPH1 = Tryptophan Hydroxylase-1 (serotonin rate limiting enzyme), SERT = serotonin transporter (serotonin reuptake). Statistics: T-test, $p > 0.5$ n.s., $p < 0.001$ ***

15 Panniculus retractor use for visualization of fetal anatomy: a randomized controlled trial

Melissa L. Wise[1], Marvin Okon[2], Katelyn Pratt[1], Andrew Lane[3], Laura Carlson[1], Amy Crockett[1], Lu Zhang[2], Daniel Pasko[1]

[1]Prisma Health, University of South Carolina School of Medicine Greenville, Greenville, SC, [2]Clemson University, Clemson, SC, [3]Prisma Health, Greenville, SC

OBJECTIVE: The detection of fetal anomalies decreases as maternal body mass index (BMI) increases. Panniculus retraction provides access to the suprapubic acoustic window and could improve sonographer ergonomics. We tested the hypothesis that use of a panniculus retractor during the detailed fetal anatomic survey improves visualization of fetal anatomy for participants with obesity and a panniculus.

STUDY DESIGN: This was a randomized controlled trial conducted at a single academic center (NCT05764408). Pregnant participants with a BMI $\geq$ 40 kg/m^2 and a panniculus were randomized 1:1 to undergo a detailed anatomy ultrasound with or without use of a panniculus retractor. The primary outcome was adequate visualization of 16 prespecified anatomic views. Secondary outcomes included adequate visualization of all detailed anatomic views, detection of fetal anomalies, and survey satisfaction for participants and sonographers. A sample size of n=150 provided 80% power to detect a two-fold improvement in the primary outcome, assuming a historical baseline visualization rate of 23% and 2-sided alpha of 0.05. Analysis was by intention-to-treat.

RESULTS: 2123 participants were screened from March 2023 to July 2023, of which 216 met inclusion criteria and 150 were randomized (n=74 to retractor, n=76 to no retractor). Baseline characteristics were similar between groups apart from panniculus grade. Adequate visualization of the 16 prespecified anatomic views did not differ between groups (25.7% retractor vs. 31.6% no retractor, RR 0.81; 95% CI 0.49-1.35). This finding persisted after adjusting for panniculus grade. There were also no differences in adequate visualization of all detailed anatomic views (13.5% retractor vs. 15.8% no retractor, RR 0.86; 95% CI 0.39-1.86). No major fetal anomalies were detected in either group. Sonographer and participant survey scores were similar between groups (Table).

CONCLUSION: Use of a panniculus retractor during the detailed fetal anatomic survey for participants with a BMI $\geq$ 40 kg/m^2 and a panniculus did not improve visualization of 16 prespecified fetal anatomic views.

Table: Primary and Secondary Outcomes

Outcome	Retractor (n=74)	No retractor (n=76)	Relative risk (95% CI)	P value
Primary Outcome				
Adequate visualization of 16 prespecified views [a]	19 (25.7)	24 (31.6)	0.81 (0.49-1.35)	0.47
Secondary Outcomes				
Adequate visualization of all anatomic views	10 (13.5)	12 (15.8)	0.86 (0.39-1.86)	0.82
Sonographer survey [b]				
Pain while performing ultrasound	3.7 ± 1.21	3.9 ± 1.03	-	0.41
Body habitus affected ultrasound	4.1 ± 1.05	4.3 ± 0.94	-	0.20
Confidence about image quality	3.8 ± 0.99	3.6 ± 0.98	-	0.18
Participant survey [b]				
I felt comfortable	4.6 ± 0.84	4.8 ± 0.44	-	0.06
I am satisfied with the quality of pictures	4.6 ± 0.70	4.5 ± 0.60	-	0.37
I enjoyed the ultrasound experience	4.6 ± 0.69	4.7 ± 0.52	-	0.54

Data presented as n(%) or mean ± standard deviation.
[a] Prespecified views: lateral ventricles, cerebellum, cavum septum pellucidum, face, four chamber heart view, right and left ventricular outflow tracts, three vessel view, three vessel trachea view, spine, ventral wall, umbilical cord, stomach, kidneys, and bladder.
[b] Responses recorded as Likert scale ranging from strongly disagree (1) to strongly agree (5).

16 Early amniotomy after Foley balloon in labor induction: a randomized clinical trial

Marissa J. Berry[1], Kelly Lamiman[2], Megan Slan[3], Xue Zhang[2], Daphne D. Arena Goncharov[2], Yihharn P. Hwang[2], Jennifer Rogers[2], Luis D. Pacheco[4], George R. Saade[5], Antonio F. Saad[2]

OBJECTIVE: To investigate if early amniotomy (within two hours) post-Foley balloon expulsion shortens active labor and quickens vaginal delivery compared to amniotomy after greater than four hours.

STUDY DESIGN: In a single-center, randomized trial of 150 participants undergoing labor induction with Foley balloon from October 2020 to March 2023, subjects were categorized into early or delayed amniotomy post-Foley balloon removal. Primary outcome: time between Foley balloon placement and active labor initiation. Secondary outcomes: time to delivery, rates of vaginal delivery within set intervals, cesarean section rates, maternal complications, and neonatal outcomes. Outcomes were analyzed both with intention-to-treat and per-protocol analyses.

RESULTS: 149 out of 150 participants were analyzed. Protocol adherence was 90.7% of subjects in the early amniotomy group and 77% in the delayed amniotomy group. The most common reason for protocol non-adherence was spontaneous rupture of membranes. Both groups had comparable characteristics. Early amniotomy led to quicker progression to active labor (312.5 vs. 442.5 mins, P=0.02) and delivery (484 vs. 587 mins, P=0.03). Moreover, a higher proportion delivered within 36 hours (96% vs. 85%, P=0.03). The early group advanced to active labor and delivery 1.5 times faster post-Foley balloon placement (HR, 1.5; 95% CI, 1.1-2.2; P = 0.02). The delayed group had more cases of postpartum hemorrhage (0% vs. 9.5%, P=0.01), but other outcomes, like cesarean rates and maternal/neonatal outcomes, did not differ significantly.

In the per-protocol analysis, early amniotomy consistently resulted in quicker progression to active labor and delivery and higher delivery rates within specific timeframes. Postpartum hemorrhage was again more common with delayed amniotomy (0% vs. 8.8%, P=0.02).

CONCLUSION: Early amniotomy post-Foley balloon promotes faster active labor onset and time to delivery without increasing adverse outcomes. Additionally, it is associated with reduced postpartum hemorrhage risk.

Table 1. Study outcomes in the intent-to-treat population.

	Early N=75	Delayed N=74	P
Time from Foley balloon placement to active labor (minutes)	885 (161-2340)	975 (250-2760)	0.08

OBJECTIVE: In our initial trial (Katheria et al), umbilical cord milking (UCM) compared to early cord clamping (ECC) in non-vigorous term and near-term newborns, reduced delivery room cardiorespiratory support, hypoxic-ischemic encephalopathy, and therapeutic hypothermia. However, long-term safety of UCM in term infants is not known. We investigated if infants randomized to UCM would have better scores on the Ages & Stages Questionnaire, third Edition (ASQ-3) and a lower frequency of medium or high scores on the Modified Checklist for Autism in Toddlers (M-CHAT-R) compared to ECC at 22 to 26 months.

STUDY DESIGN: In a cluster-randomized crossover trial of non-vigorous infants born at 35 to 42 weeks, 10 hospitals were randomized to UCM or ECC for 1 year and then crossed over until study completion. Waiver of consent was approved in all centers, families consented for long term neurodevelopmental follow-up via the ASQ-3 and the M-CHAT-R at 22-26 months of age.

RESULTS: Among 1730 newborns in the primary trial, 1207 consented for long term follow-up, 4 infants died in the hospital and 3 post discharge. 971 infants (81%) had ASQ-3 scores available for analysis, and 927 parents (77%) completed the M-CHAT-R. There were no major differences in maternal and neonatal characteristics (Table 1). Median (IQR) ASQ-3 total scores (UCM: 255 (225-280) vs ECC 255 (230-280), p=0.49) or any of its 5 sub-domains (Table 2). Medium to high M-CHAT-R scores (UCM 9.3% vs ECC 8.4%, p=0.59) were similar between groups. No interaction between treatment group, maternal education or sex was observed.

CONCLUSION: Among non-vigorous infants born at 35 to 42 weeks' gestation, neurodevelopmental scores at 22-26 months of age were similar between the UCM and ECC groups. These data, combined with the previously reported short-term benefits, suggest that UCM is a safe intervention. UCM is a no-cost intervention that can be easily implemented even in resource-limited settings and may improve short-term outcomes without long-term neurodevelopmental risks to development.

Data are n (%) or median (IQR), unless otherwise noted. P-value from a Wilcoxon test or Chi-square test evaluating differences between the two groups. The interaction between randomization group and sex was not significant (P-value >.05) for any of the ASQ-3 or M-CHAT-R measures. Additional analyses accounting for the clustered and crossover study design provided similar to the unadjusted analyses shown in the above table. Results were similar in models adjusted for sex and maternal education
*Defined as n (%) with score ≥2 standard deviations below the mean in at least one domain or death before 2 years of age.

LB03 Randomized trial of screening for preterm birth in low-risk women. The Preterm Birth Screening Study

Gabriele Saccone[1], Daniele Di Mascio[2], Fabrizio Zullo[3]
[1]Università degli studi di Napoli Federico II, PHILADELPHIA, PA, [2]Policlinico Umberto I - University Hospital, Rome, Piemonte, [3]University of Rome, Roma, AL

OBJECTIVE: It is unclear whether the introduction of a universal transvaginal ultrasound cervical length screening program in women at low risk for preterm delivery is associated with a reduction in the frequency of preterm birth.

STUDY DESIGN: This was a multicenter non-blinded randomized trial of screening, of asymptomatic singleton pregnancies without prior spontaneous preterm birth, who were randomized to either transvaginal ultrasound cervical length screening program (i.e. intervention group) or no screening (i.e. control group). Participants were consented and randomized at the time of their routine anatomy scan between 18 0/7 and 23 6/7 weeks. Women randomized in the screening group received a single transvaginal ultrasound cervical length measurement. Those who were found to have cervical length ≤25 mm were offered 200 mg vaginal progesterone daily along with cervical pessary. The primary outcome was preterm birth < 37 weeks. The risk of primary outcome was quantified by the relative risk (RR) with 95% confidence interval (CI), and was based on the intention-to-screen principle.

RESULTS: 1,334 asymptomatic women with singleton pregnancies and without prior preterm birth, were included in the trial. Out of the 675 women randomized in the TVU CL screening group, 13 (1.9%) were found to have TVU CL ≤25 mm during the screening. Preterm birth at less than 37 weeks of gestation occurred in 48 women in the TVU CL screening group (7.5%), and 54 women in the control group (8.7%) (RR 0.86, 95% CI 0.59 to 1.25). Women randomized in the TVU CL screening group had no significant differences in the incidence of preterm birth at less than 34, 32, 30 weeks, 28, and 24 weeks of gestation. Perinatal outcomes were also not different between the two groups.

CONCLUSION: The introduction of a universal cervical length screening program at 18 0/6 – 23 6/7 weeks in singleton pregnancies without a history of spontaneous preterm birth, with treatment for those with transvaginal ultrasound cervical length ≤25 mm, did not result in lower incidence of preterm delivery than the incidence without the screening program.

OBJECTIVE: Nulliparas are at increased risk of adverse pregnancy outcomes [APOs]; once an individual has an APO, they are at risk of recurrence. Little is known about markers, independent of prior APO, that are associated with recurrent APO. This analysis proposed to ascertain factors identified early in a first pregnancy that are associated with an APO in a second pregnancy.

STUDY DESIGN: The nuMoM2b Heart Health Study is a cohort of nulliparas followed from the first trimester through delivery who attended an in-person visit 2-7 years after their pregnancy. This analysis is restricted to those who had two pregnancies that extended to at least 20 weeks' gestation. Demographics, clinical measures, and laboratory values from the first trimester of the first pregnancy were considered as potential risk markers. Race and ethnicity, as social constructs, were evaluated given known disparities in APO. An APO was defined as any of the following: hypertensive disorders of pregnancy, preterm birth < 37 weeks', small-for-gestational-age birth (< 5th%ile), fetal demise, or gestational diabetes. Logistic regression estimated the association between risk markers and APO in a second pregnancy, controlling for a first pregnancy APO, in order to identify risk markers independent of prior APO.

RESULTS: Of 4484 participants, the 2830 who met inclusion criteria and comprised the analytic population had a mean (SD) time between pregnancies of 2.9 (1.3) years. Of the 32% with an APO in the first pregnancy, 40% had an APO in the second pregnancy. Of those without an APO in the first pregnancy, 15% developed an APO in a second pregnancy. Multiple markers from the first trimester of the first pregnancy (BMI, race/ethnicity, blood pressure, and cardiometabolic serum analytes) were associated with an APO in the second pregnancy. The magnitude of APO recurrence risk associated with having had an APO in the first pregnancy varied by race/ethnicity (TABLE).

CONCLUSION: Multiple markers in a first pregnancy, including some that are modifiable, are associated with an APO in a second pregnancy, suggesting potential targets for intervention.

Association of Maternal Characteristics with Adverse Pregnancy Outcomes during a Second Pregnancy

Characteristics during nuMoM2b Index Pregnancy	Prevalence of Second Pregnancy APO	Second Pregnancy APO vs no APO
	% (n/N)	aOR (95% CI)
APO at nuMoM2b Index Pregnancy (vs no APO)	40% (364/910)	3.39 (2.79, 4.12)
Maternal race and ethnicity*		
White, Non-Hispanic	21% (407/1970)	4.11 (3.23, 5.22)
Black, Non-Hispanic	32% (92/287)	1.79 (1.05, 3.05)
Hispanic	27% (101/375)	2.41 (1.44, 4.03)
Asian	27% (23/86)	3.36 (1.14, 9.92)
Other	28% (31/112)	1.75 (0.73, 4.22)
BMI (kg/m^2), category		
<18.5	25% (13/52)	1.81 (0.92, 3.58)
18.5 to <25	17% (252/1479)	ref
25 to <30	26% (174/667)	1.27 (1.00, 1.63)
30 to <35	31% (97/315)	1.40 (1.01, 1.92)
≥35	40% (108/272)	1.48 (1.04, 2.13)
SBP, per 5 mmHg		1.04 (0.99, 1.10)
DBP, per 5 mmHg		1.09 (1.01, 1.17)
Glucose, per 10 mg/dL		1.03 (0.97, 1.10)
hsCRP, per doubling in value[1/]		1.08 (1.00, 1.16)
Triglycerides, per doubling in value[1/]		1.41 (1.16, 1.71)

Abbreviations: APO = adverse pregnancy outcome; BMI = body mass index; CI = confidence interval; DBP = diastolic blood pressure; hsCRP = high sensitivity C-reactive protein; aOR = adjusted odds ratio; SBP = systolic blood pressure.

Note: Eligibility for this analysis includes nuMoM2b-HHS1 participants who participated in the 2-7 year postpartum in-person visit and who carried their nuMoM2b pregnancy to at least 20 weeks gestation. This analysis cohort is comprised of eligible participants with a documented second pregnancy carried to at least 20 weeks gestation and nonmissing composite APO information for the first (index) and second pregnancy.

Note: Explanatory variables are included in the statistical model as measured at the time of the first (nuMoM2b index) pregnancy: presence of any APO in the first pregnancy, maternal race, BMI category, SBP, DBP, glucose, hsCRP, and triglycerides. *An interaction term for (maternal race) × (presence of any APO in the first pregnancy) is also included in the model.

[1/] This characteristic is included in statistical models after a log2 (logarithm with base 2) transformation. Odds ratios for log-transformed quantities are interpreted on the multiplicative scale.

^ Indicates confidence interval excludes the null value.

18 Prenatal heat stress and birth outcomes in a rural Ghanaian cohort

Blair Wylie[1], Alison Lee[2], Aalekhya Reddam[3], Mohammed Mujtaba Nuhu[4], Cascade Tuholske[5], Kaali Seyram[6], Kennetha A. Ae-Ngibise[4], Danielle Medgyesi[3], Ellen Boamah[6], Andrea Baccarelli[3], Oscar Agyei[4], Steven Chillrud[7], Kwaku Poku asante[6], Darby Jack[8], Prince Darko Agyapong[4], Abubakari Sulemana[4]

[1]Columbia University, New York, NY, [2]Mount Sinai Hospital, New York, NY, [3]Columbia Mailman School of Public Health, New York, NY, [4]Kintampo Health Research Centre, Kintampo, Brong-Ahafo, [5]Montana State University, Billings, MT, [6]Kintampo Health Research Centre, Brong Ahafo, Ghana, [7]The Earth Institute, New York, NY, [8]Mailman School of Public Health, New York, NY

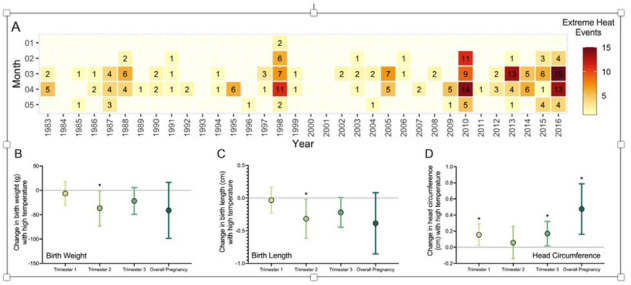
OBJECTIVE: Climate change is increasing exposures to higher ambient temperatures, particularly for rural developing communities where people have limited access to indoor cooling. We aimed to examine associations between prenatal heat exposure with birth outcomes in rural Ghana.

STUDY DESIGN: We leveraged the GRAPHS prenatal cohort recruited from 35 rural communities in the Brong Ahafo East Region of Ghana between 2013-2015. We assigned prenatal heat stress from conception to delivery using weekly averages of satellite-derived daily Wet Bulb Globe Temperature (WBGT) estimates corresponding to the community of each participant. We performed multivariable linear regression with both WBGT averaged over pregnancy and trimester (TM)-specific

averages included in the same model to understand associations with birth weight, length, head circumference, SGA, and LBW.

RESULTS: 1,173 pregnant individuals with delivery ≥ 28 weeks were available for analysis. Weekly prenatal WBGT averages in the cohort ranged from 22.7-30.8°C. Extreme heat events (WBGT >30°C) are occurring with increasing frequency (Figure A); 82% of participants experienced ≥ 1 extreme heat event in pregnancy. Increasing WBGT in the 2nd TM was associated with lower mean birth weight (β = -36.5 g per 1°C increase in average 2nd TM exposure, 95% CI: -72.9, -0.2) and birth length (β = -0.32 cm, 95% CI: -0.61, -0.02). Third TM exposure was suggestive of similar reductions, although not statistically significant (Figure B&C). Increasing WBGT across gestation, and in 1st and 3rd TMs, was associated with increased head circumference, possibly a head sparing effect (Figure D). No significant associations of WGBT with SGA or LBW were identified.

CONCLUSION: We demonstrate impacts of heat stress on newborn anthropometrics in this rural Ghanaian population where the range of temperatures is relatively narrow. Given the link between size at birth and future disease, it is critical to better understand how rising global temperatures impacts newborn health, and more importantly, identify interventions to mitigate these effects.



19 Neonatal Hypoglycemia in Pregnancies at Risk for Late Preterm Birth: Childhood Neurodevelopmental Outcomes

Cynthia Gyamfi-Bannerman

UC San Diego Health, La Jolla, CA, for the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network

OBJECTIVE: Persistent neonatal hypoglycemia is related to adverse neurodevelopment in infants born preterm, but it is unknown whether late preterm hypoglycemia, often transient and more frequent with maternal antenatal steroid treatment, is similarly related. Our objective was to evaluate whether hypoglycemia in neonates at risk for late preterm delivery was related to adverse childhood neurodevelopment.

STUDY DESIGN: Secondary analysis of a prospective, follow-up study of ≥ 6 year-old children delivered in the NICHD Antenatal Late Preterm Steroids study, which excluded patients with pregestational diabetes. Certified psychologists performed neurocognitive testing using the Differential Ability Scales, 2nd Edition (DAS-II) core components of general conceptual ability (GCA): verbal, non-verbal reasoning, and spatial ability. Hypoglycemia was defined as blood glucose concentration < 40 mg/dL within 24 hours of birth. Primary and secondary outcomes were compared in children with and without hypoglycemia and by severity: 25-39 mg/dL (moderate) and < 25 mg/dL (severe) vs none. The primary outcome was the proportion of GCA scores < 85 (-1 standard deviation) and secondary outcomes included the Gross Motor Function Classification System, Social Responsiveness Scale, and Child Behavior Checklist. Log-binomial regression was used to calculate relative risks (RR) and quantile regression and mixed linear models to estimate differences.

RESULTS: Of 1,026 children enrolled, 1,020 (99.4%) had blood glucose data. 234 (22.9%) had hypoglycemia, 852 (83.5%) delivered late preterm and 97 (41.5%) with hypoglycemia were treated. Those with hypoglycemia were more likely to have private insurance, older mothers, received betamethasone, and identify as White. There were no differences in the primary, GCA score < 85 (15.9% vs 18.5%; aRR 1.03; 95% CI: 0.74, 1.45), or secondary outcomes. Severity of hypoglycemia was also not associated with primary or secondary outcomes.

CONCLUSION: Hypoglycemia was not associated with neurodevelopmental outcomes in children born predominantly late preterm.

Table 1. Primary and Secondary Outcomes by Neonatal Hypoglycemia

Outcome	Hypoglycemia (< 40 mg/dL) (N=234)	No Hypoglycemia (N=786)	Adjusted RR or Mean/Median Difference*
GCA < 85	33/208 (15.9%)	136/736 (18.5%)	1.03 (0.74,1.45)
GCA	97.0 +/- 13.4	96.4 +/- 13.9	-0.10 (-1.93,1.74)
Verbal ability	99.0 +/- 18.4	96.8 +/- 20.3	0.65 (-2.09,3.39)
Nonverbal reasoning	95.9 +/- 15.7	95.8 +/- 15.1	-0.09 (-2.30,2.12)
Spatial ability	97.8 +/- 13.1	98.0 +/- 14.7	-0.55 (-2.60,1.49)
SRS t-score > 65	35/233 (15.0%)	106/783 (13.5%)	1.18 (0.83,1.69)
GMFCS > Level I	0	2 (0.3%)	
CBCL			
Total problems t-score	49.0 +/- 11.2	48.6 +/- 11.1	0.09 (-1.55,1.73)
Internalizing behavior t-score	50 (43-58)	48 (41-57)	0.56 (-1.19,2.32)
Externalizing behavior t-score	48 (41-54)	48 (41-56)	-1.42 (-3.31,0.48)
Dysregulation profile t-score	157 (152-170)	156 (151-169)	-0.14 (-2.03,1.75)
Anxious/depressed t-score	51 (50-57)	51 (50-54)	0.04 (-0.31,0.40)
Attention problems t-score	52 (50-57)	52 (50-57)	0.08 (-0.44,0.61)
Aggressive behavior t-score	51 (50-55)	51 (50-56)	0.00 (-0.36,0.36)

GCA denotes General Conceptual Ability, SRS Social Responsiveness Scale, GMFCS Gross Motor Function Classification System, and CBCL Child Behavior Checklist.
Data are n (%), mean +/- standard deviation, median (Q1-Q3), relative risk (95% CI), mean difference (95% CI) or median difference (95% CI).
CBCL missing in 3.
*Adjusted by pre-specified characteristics including maternal age, gestational age at delivery, child age, gender, maternal education, treatment assignment, and center.

20 Pessary versus cerclage with/without progesterone in twin pregnant women and a short cervix: a RCT

Yen TN. He[1], Ha NH. Pham[2], Tri C. Nguyen[3], Trung Q. Bui[2], Nhu T. Vuong[2], Diem TN. Nguyen[3], Thanh V. Le[2], Wentao Li[4], Cam H. Le[1], Tuong M. Ho[2], Ben Willem W. Mol[5], Vinh Q. Dang[6], Lan N. Vuong[7]

[1]My Duc Phu Nhuan Hospital, Ho Chi Minh, Ho Chi Minh, [2]My Duc Hospital, Ho Chi Minh, Ho Chi Minh, [3]HOPE Research Center, Ho Chi Minh, Ho Chi Minh, [4]Monash University, Melbourne, Victoria, [5]Monash University, Clayton, Victoria, [6]My Duc Hospital, Ho Chi Minh, Vietnam, [7]University of Medicine and Pharmacy at Ho Chi Minh City, Ho Chi Minh, Vietnam

OBJECTIVE: Women with a twin pregnancy and a short cervical length (CL) are at increased preterm birth (PTB) risk. We aimed, in a factorial randomized clinical trial (RCT), to compare the effectiveness of pessary versus cerclage, with or without 400mg-progesterone for PTB prevention in these women.

STUDY DESIGN: We conducted a multi-center, two-by-two factorial RCT at two hospitals in Vietnam. The protocol has been published (Dang et al, 2020). Asymptomatic twin pregnant women with a CL

≤ 28mm (at 16-22 weeks) were randomized (1:1:1:1 ratio) to pessary alone, cerclage alone, pessary+progesterone or cerclage+progesterone. Primary outcome was PTB < 34 weeks. Secondary outcomes were maternal and neonatal complications. We planned to recruit 340 women to assess a 50% reduction in PTB < 34 weeks (alpha-error 0.05, power 80%, 5% lost to follow-up/protocol deviation). Analysis was by intention-to-treat. The recruitment was terminated in July 2023 given advice by the Data Safety Monitoring Committee because women had a higher rate of perinatal deaths and deliveries < 28 weeks in the pessary group.

RESULTS: Between March 2019 and January 2023, we randomized 219 women to pessary alone (N=54), cerclage alone (N=54), pessary+progesterone (N=56) or cerclage+progesterone (N=55). Two women withdrew consent while 11 women were lost to follow-up. The PTB < 34 weeks rates occurred in 19% women receiving pessary versus 19.8% women receiving cerclage (RR 0.96, 95%CI 0.55-1.7) and in 18.4% women treated with progesterone versus 20.4% women without progesterone (RR0.9, 95%CI 0.52-1.6). Perinatal death occurred in 12 (5.7%) babies in the pessary group versus two (1%) in the cerclage group (RR 5.8, 95%CI 1.3-26). Secondary outcomes are presented in the Table.

CONCLUSION: Since in women with a twin pregnancy and a short cervix, pessary resulted in a higher rates of PTB < 28 weeks and perinatal death compared to cerclage, we recommend cerclage as the treatment of choice. Addition of vaginal progesterone to cerclage/pessary probably has no beneficial effect.

		Pessary vs Cervical cerclage				Progesterone vs No Progesterone			
	All women (N=206)	Pessary (N=105)	Cervical cerclage (N=101)	RR (95% CI)	p-values	Progesterone (N=103)	No Progesterone (N=103)	RR (95% CI)	p-values

21 Vaginal polyamines mitigate inflammasome activation: potential immune mechanisms governing barrier function in preterm birth

Briana Ferguson[1], Aaron Loder[1], Scott M. Gordon[2], Lauren Anton[1], Kristin D. Gerson[3]

[1]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Hospital of the University of Pennsylvania, Philadelphia, PA

OBJECTIVE: Vaginal metabolomics from our group previously identified a role for polyamines in delineating preterm birth (PTB) risk among pregnant individuals with a *Lactobacillus*-deplete or high-risk microbiota, suggesting that spermine and spermidine may function in a protective capacity. As immune perturbations contribute to barrier dysfunction and tissue remodeling on the pathway to PTB, we sought to explore whether polyamines mitigate these molecular processes. We investigated the innate immune system, including the inflammasome, which is heavily regulated by metabolic cues in other systems and emerging as a key first line of defense in epithelial barriers.

STUDY DESIGN: Ectocervical and endocervical epithelial cells were treated with 10^7 CFUs *Gardnerella vaginalis* (GV), an anaerobe prevalent in a *Lactobacillus*-deplete microbiota. THP-1 monocytes were activated into macrophages with PMA and treated with 10^5 CFUs GV or NLRP3 inflammasome agonist nigericin 5mM. Treatments occurred in the presence or absence of polyamines at concentrations ranging from 50-400uM. Inflammatory cytokine IL-8 and inflammasome activation marker IL-1β were measured in cell culture media by ELISA. One-way ANOVAs with Dunnet's multiple comparisons tests were performed.

RESULTS: Spermidine and spermine partially mitigate GV-induction of IL-8 and IL-1β-in ectocervical and endocervical cells ($p < 0.05$ for all, Fig. 1A and B). Spermine partially mitigates GV-induction of IL-1β in macrophages ($p < 0.001$, Fig. 1C). Spermidine and spermine partially mitigate nigericin-activation of NLRP3 as measured by IL-1β induction in macrophages ($p < 0.001$ for both, Fig. 1D).

CONCLUSION: Our data support the paradigm that low concentrations of vaginal spermidine and spermine may contribute to increased inflammation and inflammasome activation in the cervicovaginal space, thereby rendering the barrier more suspectable to microbial challenge. These findings carry translational potential — vaginal polyamine repletion may serve as a novel postbiotic strategy to reduce PTB risk in the setting of a *Lactobacillus*-deplete microbiota. SMFM-AAOGF Award (KDG)

22 Vaginal progesterone for the prolongation of pregnancy after arrested pre-term labor-multicenter randomized controlled trial

Enav Yefet[1], Yael Ganor Paz[2], Malak Wattad[3], Noa Harel[4], Manal Massalha[5], Zohar Nachum[6]

[1]Tzafon Medical Center, Afula, HaZafon, [2]Edith Wolfson Medical Center, Shoham, HaMerkaz, [3]Emek Medical Center, Afula, Israel, [4]Tzafon Medical Center, Poriya, HaZafon, [5]Emek medical center, Afula, HaZafon, [6]Emek medical center, Timrat, HaZafon

OBJECTIVE: To evaluate the efficacy of vaginal micronized progesterone 200 mg given twice daily for the prolongation of pregnancy after arrested pre-term labor.

STUDY DESIGN: Multicenter randomized controlled trial was conducted during 2018-2022 at three university affiliated medical

centers. Women with a history of preterm delivery or cervical shortening in the current pregnancy were excluded. Patients with arrested pre-term labor following tocolytics at 24-34 gestational weeks were randomly allocated to receive vaginal micronized progesterone 200 mg twice daily or no treatment until 36.6 weeks. The primary outcomes were the number of days from enrollment to delivery and the rate of spontaneous preterm delivery prior to 37 weeks of gestation. A sample size of 128 women was required to detect a difference of 7 ± 14 days in pregnancy prolongation and a reduction from 50% to 25% in the rate of spontaneous preterm delivery (5% two-sided alpha, 80% and 84% power, respectively).

RESULTS: Sixty four and 65 women were allocated to the no treatment and treatment groups, respectively. Demographic characteristics were similar. Study outcomes are presented in the table. Comparing no treatment with treatment, there was no difference in the number of days from enrolment to delivery (37.4±20.3 versus 40.0±17.8, respectively; P=0.44), the overall rate of preterm delivery (28 (44%) versus 19 (30%), respectively; P=0.09), and the rate of spontaneous preterm delivery (19 (30%) versus 16 (25%), respectively; P=0.52). In twins (table), compared with no treatment, micronized progesterone was associated with increased number of days from enrolment to delivery (26.1±15.2 versus 43.7±18.1, respectively; P=0.02), later delivery week (34.7±2.2 versus 36.5±1.4, respectively; P=0.01) and increased birth weight (2018±430 versus 2444±528 gr, respectively; P=0.01).

CONCLUSION: Vaginal micronized progesterone following arrested preterm labor was not an effective treatment to prolong pregnancy or prevent spontaneous preterm delivery. Further research should be conducted regarding possible favorable effect in twins.

Table. Study outcomes

	No treatment	Micronized progesterone	P value
Entire group	N=64	N=65	
Delivery week	36.9±2.4	37.4±2.8	0.28
Pregnancy prolongation from recruitment (days)	37.4±20.3	40±17.8	0.44
Pregnancy prolongation beyond 7 days	59 (92%)	62 (95%)	0.49
Overall preterm delivery	28 (44%)	19 (29%)	0.09
Spontaneous preterm delivery	19 (30%)	16 (25%)	0.52

Apgar score at 1 minute	8.9±1	8.7±1.1	0.51
Apgar score at 5 minutes	9.6±0.7	9.7±0.6	0.67
Cord pH	7.3±0.1	7.3±0.1	0.42

Values are presented as mean±SD or number (percent)
One woman with twins in the no treatment group gave birth in another medical center. Data regarding neonatal outcomes were missing.
Neonatal outcomes were analyzed for all neonates (N=28 and N=24 in the no treatment and treatment groups, respectively).

23 Investigating the Association between Preterm Delivery and Autism Spectrum Disorder in Childhood

Sapir ELLOUK[1], Omri Zamstein[2], Tamar Wainstock[3], Eyal Sheiner[2]

[1]Soroka Medical Center, Beer-Sheva, HaDarom, [2]Soroka University Medical Center, Beer-Sheva, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom

OBJECTIVE: Preterm infants are at an increased risk for neurodevelopmental outcomes. Autism spectrum disorder (ASD) is a neurodevelopmental condition clinically evident from early childhood. The association between preterm birth and the risk of ASD is unclear. In this study, we have examined the contributory role of preterm birth on ASD diagnosis.

STUDY DESIGN: We conducted a cohort analysis using population-based data from community clinics and a tertiary referral hospital, encompassing deliveries between 2005-2017. This time frame was selected since children born after 2017 have not yet been diagnosed with ASD in our population. Our study aimed to compare the occurrence of ASD diagnoses in offspring based on their delivery period: early preterm (< 34w), late preterm (34-37w) or term (37-42w). To assess the cumulative incidence of ASD, we employed a Kaplan-Meier survival curve. A Cox proportional hazards model was utilized to account for potential confounding variables.

RESULTS: The analysis included 139,859 pregnancies, 1.2% delivered before 34 gestational weeks, 4.1% at 34-37w and the remaining delivered at term. Earlier gestational age at delivery was linked with certain obstetrical characteristics; primiparity, lower 5-minute Apgar score and male gender (p< 0.001 for all). There was no significant association between preterm delivery and the occurrence of ASD (0.4% vs. 0.5% vs. 0.5% for early preterm, late preterm, and term deliveries, respectively; p< 0.961). This finding was supported by a Kaplan-Meier survival curve, which demonstrated comparable cumulative morbidity across the groups (log-rank p=0.74). When adjusting for ethnicity, SGA, maternal age, and fetal gender using a Cox proportional hazards model, no significant association was observed between any preterm delivery group and ASD (adjusted HR = 1.24 for < 34w vs. term, 95% CI 0.58-2.64, p=0.58 and adjusted HR = 0.98 for 34-37w vs. term, 95% CI 0.67-1.44, p=0.92).

CONCLUSION: There appears to be no discernible association between preterm birth and the diagnosis of ASD.

Table. Selected obstetrical and perinatal outcomes of pregnancies, according to gestational age group at delivery.

	Early preterm (<34 gestational weeks) (n= 1,609)	Late preterm (34-37 gestational weeks) (n= 5,734)	Term (37-42 gestational weeks) (n=132,516)	P-value
Obstetrical outcomes				
Maternal age (years ± SD)	27.0 ± 6.2	27.4 ± 6.0	28.1 ± 5.6	<0.001
Primiparity (%)	37.3	33.9	24.4	<0.001

24 Vaginal putrescine attenuates microbe-mediated inflammation in the cervical epithelium

Briana Ferguson[1], Aaron Loder[1], Scott M. Gordon[2], Lauren Anton[1], Kristin D. Gerson[3]

[1]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Hospital of the University of Pennsylvania, Philadelphia, PA

OBJECTIVE: A *Lactobacillus*-deplete vaginal microbiota confers increased risk of preterm birth (PTB). Our group previously uncovered a role for vaginal polyamines in distinguishing individuals at greatest risk of PTB among those with similar microbiota-related risk. Putrescine is a polyamine primarily produced by anaerobes and abundant in a *Lactobacillus*-deplete microbiota. We have shown that vaginal metabolites, including select polyamines, can modify immune responses at the host-microbial interface. As immune perturbations can contribute to cervical remodeling preceding PTB, we hypothesized that putrescine promotes inflammation in the cervical epithelium as a mechanism underlying barrier disruption.

STUDY DESIGN: Ectocervical and endocervical epithelial cells were treated with putrescine (500-4000uM) for 24h. For microbial experiments, cells were treated with 10^7 CFUs *Gardnerella vaginalis* (GV), an anaerobe prevalent in a *Lactobacillus*-deplete microbiota, in the presence or absence of putrescine. Inflammatory cytokines IL-8 and IL-1β were measured in cell culture media by ELISA. One-way ANOVAs with Dunnet's multiple comparisons tests were performed.

RESULTS: Putrescine has no effect on basal levels of IL-8 or IL-1β in ectocervical and endocervical cells (Fig. 1). Putrescine partially mitigates GV-induction of IL-8 in ectocervical and endocervical cells in a dose-dependent manner (Fig. 1A). Putrescine partially mitigates GV-induction of IL-1β in endocervical cells in a dose-dependent manner (Fig. 1B). While a similar trend was observed in ectocervical cells, putrescine did not significantly modify GV-induction of IL-1β (Fig. 1B).

CONCLUSION: Contrary to our hypothesis, vaginal putrescine exerts an anti-inflammatory effect on the cervical epithelium. Our data suggest that this microbial metabolite may blunt host immune responses and promote tolerance of a *Lactobacillus*-deplete anaerobe-rich microbiota. The extent to which this molecular process may modify epithelial barrier stability, cervical remodeling, and PTB risk warrants future investigation. SMFM-AAOGF Award (KDG)

25 Initiation of Metformin in Pregnancy Results in Fetal Bioaccumulation, Growth Restriction & Renal Dysmorphology

Kjersti M. Aagaard[1], Paul Kievit[2], Maureen Gannon[3], Carrie McCurdy[4], Stephanie Wesolowski[5], Jed Friedman[6], Tyler Dean[2], Kristin Sauter[2], Maxim D. Seferovic[7], Brandon T. Garcia[7], Feng Li[8], John Hicks[1], Xuan Qin[9], Erin Bolte[9], Gwendolynn Hummel[9], Melissa Suter[1]

[1]Texas Children's Hospital, Baylor College of Medicine, Houston, TX, [2]Oregon National Primate Research Center, Beaverton, OR, [3]Vanderbilt University Medical Center, Nashville, TN, [4]University of Oregon, Eugene, OR, [5]University of Colorado Health Sciences Center-Anschulz, Denver, CO, [6]University of Oklahoma Health Sciences Center & Hamm Diabetes Center, Oklahoma City, OK, [7]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [8]University of North Carolina at Chapel Hill, Chapel Hill, NC, [9]Baylor College of Medicine, Houston, TX

OBJECTIVE: Traditional maternal drug toxicity studies focus on fetal malformations, overlooking potential childhood outcomes not recognized at birth. Metformin evades 1st pass liver metabolism & crosses the placenta. Based on its pharmacodynamics & limited clinical studies suggesting risk for childhood obesity & insulin resistance, we hypothesized that metformin initiated periconception would lead to fetal bioaccumulation with aberrant fetal growth. We developed a highly novel primate model and applied triple-quadruple pole LC mass spectrometry (UHPLC-QQQ) for direct quantitation of maternal and fetal metformin levels with detailed fetal biometry & histopathology.

STUDY DESIGN: Within 30d of confirmed conception, n=19 Rhesus macaque dams fed a control chow or Western style diet (mWSD) were initiated on twice daily, human dose-equivalent (10mg/kg) metformin or vehicle control (dose weight-adjusted Q trimester). G145 fetuses were delivered via Cesarean, measured, and necropsied by primate center experts. All fetal organs & tissue were processed per pediatric clinical pathology standards. Fluid and tissue metformin levels were assayed using UHPLC-QQQ.

RESULTS: Of n=19 pregnancies, 3 were late-term stillbirths unrelated to drug exposure. Viable pregnancies demonstrated significant bioaccumulation of metformin within the fetal kidney, urine, amniotic fluid, & placenta (Fig1A-D). These findings were associated with significant ($p < .05$) and specific restriction of overall growth, and decreased kidney, liver, skeletal muscle & retroperitoneal fat mass (Fig1E), driving significantly lower birthweight. Fetal kidney sagittal sections demonstrated delayed maturation with disorganized glomeruli & increased cortical thickness (Fig1F,G).

CONCLUSION: We are the first to directly demonstrate fetal bioaccumulation of metformin driving fetal growth restriction & significant renal dysmorphology. These findings are consistent with limited clinical trial data suggesting risk of SGA leading to paradoxical childhood obesity & insulin resistance. Additional investigation of the enduring effects of prenatal metformin use is warranted.

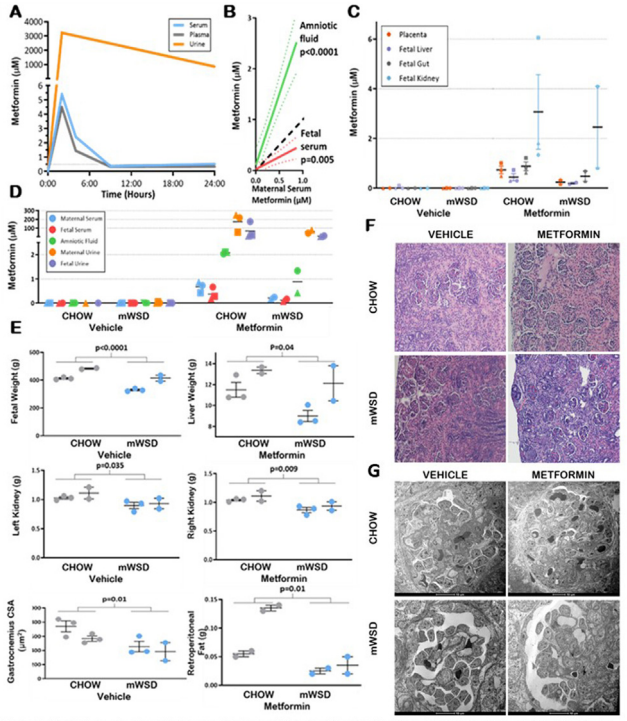

Figure. Metformin does not undergo first pass metabolism and bioaccumulates in maternal-equivalent concentrations in fetal kidney, urine and amniotic fluid and is associated with a significantly reduced fetal weight, and restricted fetal skeletal muscle and visceral growth with fetal renal dysmorphology. (A) Orally administered Metformin at a clinically relevant standard dose of 10 mg/kg (112.5mg=840μM) in adult rhesus macaques every 9 hours, with urine concentrations at log-fold higher than serum or plasma. (B-H). Dams initiated on 10 mg/kg twice daily metformin or vehicle control at G30, and fetuses were delivered via Cesarean at G145. (B-C) Serum, urine, amniotic fluid & fetal tissues (colors and symbols/shapes) from paired maternal-fetal dyads compared within treatment groups. Metformin was not detected with vehicle alone, and levels did not differ by maternal diet. (E) Significantly decreased fetal body weight, liver weight & mass, gastrocnemius muscle cross sectional area & volume, retroperitoneal fat mass, and right and left kidney weight & mass were observed independently of fetal sex. (F) Fetal kidney H&E and (G) electron microscopy was read by blinded-to-treatment pediatric renal pathologist examination. *Spearman's correlation, dashed colored lines for 95% CI.

26 IRELAnD—Investigating the Role of Early Low-dose Aspirin in Diabetes: a multicenter placebo-controlled blinded randomized trial

[1]Rotunda Hospital, Dublin, Ireland, [2]Royal College of Surgeons in Ireland, Dublin, Ireland, [3]RCSI Rotunda, Dublin, Ireland, [4]National Maternity Hospital, Dublin, Ireland, [5]Coombe Hospital, Dublin, Dublin, [6]NUI Galway, NIUG, Galway, [7]NUI Galway, NUIG, Galway, [8]UHG, UHG, Galway, [9]UCD NMH, Dublin, Ireland, [10]UCC, Cumh, Cork, [11]OLOL Drogheda, Louth, [12]Royal College of Surgeons in Ireland, Dublin, Dublin

OBJECTIVE: Aspirin is widely advocated for obstetric risk modification, yet trials rarely include pre-gestational diabetes (PGDM). The aim of this study was to assess the effect of aspirin on adverse perinatal outcome (APO) in pregnancies complicated by PGDM.

STUDY DESIGN: We conducted a double-blinded, placebo-controlled RCT at 6 university-affiliated centers. Type 1 or 2 DM patients were randomly allocated to aspirin 150mg daily or placebo from 11-14 weeks' gestation until 36 weeks. The primary outcome was a composite measure of APO (PET, FGR, PTB < 34 weeks' gestation or

perinatal mortality). Secondary endpoints were composite maternal morbidity, composite neonatal morbidity and glycemic control. A sample size of 328 was required for 35% reduction in the primary outcome with 85% power (2-sided type I error 0.05), however the trial was stopped for recruitment challenges within the study timeframe. Treatment groups were compared using t-tests, chi-square tests and Repeated Measures analysis for longitudinal data.

RESULTS: 191 patients were eligible; 134 were enrolled (67 randomized to aspirin and 67 placebo). Baseline characteristics were similar between groups. Treatment compliance was very high (97% for aspirin, 94% for placebo). The composite measure of APO did not differ between groups (25% aspirin vs 21% placebo, $p = 0.796$).

The aspirin group required significantly lower insulin dosing throughout pregnancy. On average, a 86% increase in insulin requirements was observed in the placebo group, compared to a 57% increase for aspirin-treated patients over the same gestational period ($p = 0.002$, Fig 1). Serial HbA1c measurements across gestation were observed to be lower in the aspirin group, although this was not statistically significant.

CONCLUSION: In this double-blinded, placebo-controlled RCT, aspirin did not reduce the risk of APO. Compared to placebo, aspirin-treated patients required significantly less insulin throughout pregnancy, indicating a beneficial effect of aspirin on DM control. Aspirin may exert a plausibly placenta-mediated effect on PGDM that is not limited to its antithrombotic properties.

Table 1. Study Outcomes

Primary Outcome		Aspirin (N=65)	Placebo (N=61)	P-value
Preeclampsia *[1]*		11 (17%)	7 (11%)	0.382
Preterm birth (< 34+0 weeks) *[2]*		3 (5%)	4 (7%)	0.634
Low birthweight (<10th centile) *[3]*		0	1 (2%)	0.304
Stillbirth *[4]*		2 (3%)	1 (2%)	0.597
Primary outcome: Composite of placental dysfunction: *[1],[2],[3]or[4]*		14 (22%)	12 (20%)	0.796
Secondary Outcomes				
Gestational age at delivery (weeks)		37.3 (2.1)	37.3 (2.4)	0.911
Mode of delivery	SVD	14 (22%)	14 (23%)	0.975
	OVD	5 (8%)	5 (8%)	
	CS	46 (71%)	42 (69%)	
Birthweight (g)		3661 (738)	3495 (774)	0.221

OBJECTIVE: Pregnant patients with type 2 diabetes (T2DM) are at increased risk of preeclampsia, and both T2DM and preeclampsia increase risk for cardiovascular disease (CVD). Metformin is used to treat T2DM in nonpregnant patients. In addition to hypoglycemic effects, metformin may lower preeclampsia risk in pregnancy and CVD risk in non-pregnant patients. Our objectives were 1) to estimate the association between maternal metformin use for T2DM and preterm preeclampsia, and 2) to measure the effect of metformin use for T2DM in pregnancy on maternal CVD biomarkers.

STUDY DESIGN: Secondary analysis of data collected from an RCT comparing the effect of metformin vs placebo on composite neonatal outcome in singleton pregnancies with insulin-treated early diabetes or T2DM. Participants were randomized at 11 - 23 weeks to 1000 mg metformin BID or placebo until delivery. In a subset, maternal blood was collected at 24-30 wks for CVD biomarker measurement. We defined preterm preeclampsia as preeclampsia or HELLP syndrome requiring delivery at < 34 or < 37 wks. We used multivariable regression analysis to estimate the association between metformin use and preterm preeclampsia and maternal CVD biomarker levels.

RESULTS: Of 831 participants, 119 (14.3%) developed preeclampsia requiring delivery < 37 weeks: 57 (13.7%) of 416 in the placebo group and 62 (14.9%) of 415 in the metformin group. 37 (4.4%) of 831 developed preeclampsia requiring delivery < 34 weeks: 15 (3.6%) of 416 in placebo group and 22 (5.3%) of 415 in metformin group. Metformin did not significantly reduce the odds of early preeclampsia (Table). There was also no association between metformin and maternal soluble endoglin, apolipoprotein B, VCAM-1, or hsCRP level (Table).

CONCLUSION: Among pregnant patients with diabetes early in pregnancy or T2DM, the addition of metformin to insulin does not reduce odds of developing preterm preeclampsia or improve maternal serum CVD biomarker measurements in the early third trimester.

Table

Association Between Metformin Use and Preterm Preeclampsia		
	Unadjusted OR (95% CI)	***Adjusted OR (95% CI)**
Preeclampsia < 37 wks	0.96 (0.65-1.41)	1.06 (0.71-1.57)
Preeclampsia < 34 wks	1.43 (0.73-2.81)	1.44 (0.73-2.28)
Association Between Metformin Use and Maternal CVD Biomarkers		
	Unadjusted β (95% CI)	****Adjusted β (95% CI)**
Soluble endoglin (ng/mL)	-0.21 (-2.06 to 1.64)	-0.17 (-2.01 to 1.67)
Apolipoprotein B (mcg/mL)	-0.02 (-0.12 to 0.07)	-0.02 (-0.12 to 0.07)
VCAM-1 (ng/mL)	-82.69 (-292.0 to 126.7)	-90.29 (-298.0 to 117.5)
hsCRP (mcg/mL)	-4.22 (-12.0 to 3.59)	-4.03 (-11.87 to 3.81)

[1]Amsterdam UMC, location AMC, Amsterdam, Noord-Holland, [2]UMC Utrecht, UMC Utrecht, Utrecht, [3]Vrije Universiteit, Vrije Universiteit, Noord-Holland, [4]Meander MC, Meander MC, Noord-Holland, [5]Monash University, Clayton, Victoria, [6]Erasmus MC, Erasmus MC, Zuid-Holland, [7]Amsterdam UMC, location AMC, Amsterdam, Netherlands, [8]Maxima Medisch Centrum, Noord-Brabant, [9]Netherlands, Netherlands, Noord-Holland

OBJECTIVE: Metformin and glibenclamide monotherapy as first-line treatment for gestational diabetes (GDM), are often used as a patient-friendly alternative to insulin. However, whether a combination of these agents offers perinatal outcomes comparable to insulin alone is unknown.

STUDY DESIGN: In this multicenter, non-inferiority randomized controlled open-label trial, participants with singleton pregnancies between 16-34 weeks of gestation, who had insufficient glycemic control by diet, were randomly assigned to a treatment strategy with oral antihyperglycemic agents (OAS), starting with metformin and, if needed, additional glibenclamide and/or supplemental insulin, or treatment with insulin alone. The primary outcome was neonatal large-for-gestational age (LGA), with a non-inferiority margin of 8%. Secondary outcomes included patient preference and other perinatal and maternal endpoints.

RESULTS: Between 2016 and 2022 we randomized 821 women, 409 to OAS and 412 to insulin. The LGA rate was 23.9% versus 19.9% (absolute risk difference 4.0% (95% CI -1.7% - 9.8%, p=0.09 for non-inferiority, p=0.17 for superiority). In the OAS group, neonates more often required intravenous glucose therapy (6.4% vs 3.2% p=0.04). Gestational weight gain was lower after OAS than insulin treatment (9.2 kg vs 10.4 kg p=0.03). Maternal hypoglycemia affected 21% of those allocated to OAS and 11% of those allocated to insulin (p=0.003). Eighty-two (20%) of OAS participants received insulin therapy. Participants receiving OAS reported more gastrointestinal adverse events. Serious adverse events were similar between groups. Overall, participants in both groups were satisfied with treatment, but participants assigned to OAS would more often recommend their treatment to others (5.1 vs 4.1, scale 0-6), and were more inclined to continue their current treatment (4.7 vs 3.9, both p< 0.001).

CONCLUSION: In this study, a treatment strategy for GDM using metformin and additional glibenclamide if needed, did not show non-inferiority to insulin for the primary outcome of LGA infants.

	Oral treatment N=407	Insulin N=403	Rel. risk (95% CI) or Absolute difference	p-value

29 Permissive Glucose Control Versus Usual Care for Diabetes in Labor: An Equivalence Randomized Control Trial

Ghamar Bitar[1], Rafael Santos[1], Claudia Pedroza[1], Sarah Nazeer[2], Suneet P. Chauhan[3], Sean C. Blackwell[4], Baha M. Sibai[5], Michal Fishel Bartal[6]

[1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [2]McGovern Medical School at UTHealth Houston, Houston, TX, [3]University of Texas-Houston Medical School, Houston, TX, [4]Children's Memorial Hermann Hospital, Houston, TX, [5]Hermann Memorial Hospital, Houston, TX, [6]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX

OBJECTIVE: There is limited high quality data to determine best practices for maternal blood glucose (BG) management during labor. We compared permissive control (target maternal BG 70−180mg/dL) to usual care (BG 70−110mg/dL) among laboring individuals with diabetes (DM).

STUDY DESIGN: We performed a multi-site equivalence RCT (NCT05553275) for individuals with DM (pregestational or gestational) at ≥ 34 weeks in labor. Individuals were randomly allocated to usual care or permissive control. Capillary BG monitoring was performed in latent and active labor every 4 and 2 hours, respectively. Insulin drip was initiated if maternal BG exceeded the upper bounds of the allocated target. Primary outcome was neonatal heel stick BG within two hours of birth. For usual care, we assumed a mean neonatal BG of 50 ± 10 mg/dL (standard deviation). To ensure that use of permissive control did not increase or decrease the mean neonatal BG > 10 mg/dL (two-tailed, α= 0.05, β= 0.2), 96

participants total were required. We calculated relative risk (RR) and 95% confidence intervals (CI) in an intention-to-treat analysis. A Bayesian analysis was preplanned to estimate the probability of equivalence with a neutral informative prior.

RESULTS: Of 6,628 deliveries (10/2022 - 6/2023), 280 (4.2%) met eligibility criteria, and 96 (34.3%) agreed and were randomized, with similar baseline characteristics between groups. 17% of individuals in the usual care required an insulin drip compared to none in permissive care. There was equivalence in the primary outcome between usual and permissive care (57.9 vs. 57.1 mg/dL, mean difference [MD] -0.72, 95% CI -8.87,7.43). Bayesian analysis indicated 89% posterior probability of MD not being greater than ±10 mg/dL and 99% probability of the MD not being more than 10 mg/dL lower (95% credible interval -3.5,13.2). There was no difference in other neonatal or maternal outcomes (Table).

CONCLUSION: In this RCT, while almost 1 in 6 individuals with DM required an insulin drip during usual maternal BG care in labor, permissive BG care was associated with equivalent neonatal BG when compared to usual care.

Table. Intrapartum characteristics followed by neonatal and maternal outcomes in usual versus permissive blood glucose care in labor

Outcome	Usual care N = 48	Permissive care N = 48	Relative Risk (95% CI)
Intrapartum and Delivery Characteristics			
Gestational age at delivery	37.7 (36.7, 38.9)	37.5 (36.1, 38.4)	-
Insulin drip utilization	8 (16.7)	0 (0.0)	-
Hours of insulin drip utilization	5.9 (2.7, 9.5)	-	-
Any glucose > 110 mg/dL	17 (35.4)	24 (50.0)	1.39 (0.87, 2.23)

30 Breastfeeding and Long-Term Maternal and Child Cardiometabolic Health at 10-14 years after delivery

Yiwen Cui[1], Kartik Kailas Venkatesh[2], Anna Palatnik[1]
[1]Medical College of Wisconsin, Milwaukee, WI, [2]The Ohio State University, Columbus, OH

OBJECTIVE: To examine the association between breastfeeding and maternal and child cardiometabolic health 10-14 years after delivery in the Hyperglycemia and Adverse Pregnancy Outcome (HAPO) Follow-up Study.

STUDY DESIGN: Secondary analysis of maternal-child dyads from HAPO Follow-up Study. The primary exposure was self-reported breastfeeding. Cardiometabolic outcomes included maternal measures of prediabetes, diabetes, hypertension, and hyperlipidemia, and child measures of glucose metabolism disorders, defined as either type 2 diabetes or impaired glucose tolerance, increased body fat defined as >85%tile, and increased body mass index (BMI) defined as BMI >85%tile. Multivariate logistic regression was used and adjusted for baseline maternal covariates at HAPO enrollment.

RESULTS: Of 4,685 assessed maternal-child dyads, 79.7% reported breastfeeding. Mothers who breastfed were older at the time of follow-up (42.4y [38.8, 45.9] vs. 41.4y [37.1, 45.4], p=0.012), less likely to smoke (5.9% vs. 15.4%, p< 0.001), and more likely to use alcohol (35.0% vs. 22.9%, p< 0.001). When looking at the outcomes, mothers who breastfed had lower HOMA insulin resistance (1.8 [1.2, 2.8] vs. 1.9 [1.3, 3.0], p=0.001) and body fat percentage (34.9% vs. 35.9%, p=0.013). In multivariate analysis, breastfeeding was not associated with maternal cardiometabolic outcomes (Table). However, breastfeeding was associated with improved child cardiometabolic health, including lower rates of glucose metabolism disorders (10.7% vs. 13.7%; aOR 0.77, 95% CI 0.62, 0.96), impaired fasting glucose (6.1% vs. 9.4%; aOR 0.67, 95% CI 0.51, 0.88), HOMA insulin resistance >85% (13.0% vs. 15.6%; aOR 0.79, 95% CI 0.64, 0.98), body fat >85%, (13.6% vs. 17.5%; aOR 0.79, 95% CI 0.65, 0.97), and BMI >85% (26.6% vs. 30.0%; aOR 0.81, 95% CI 0.69, 0.96) (Table).

CONCLUSION: Breastfeeding was associated with improved child but not maternal cardiometabolic health 10-14 years postpartum, including lower rates of glucose metabolism disorders and lower rates of body fat and BMI being >85%tile.

Table 1. Association of breastfeeding with maternal and childhood metabolic measures

	No Breastfeeding N = 950	Breastfed N = 3,735	Odds Risk (95% CI)	Adjusted odds risk* (95% CI)
Maternal				
Type 2 diabetes	26 (2.7%)	108 (2.9%)	1.06, (0.69, 1.64)	1.12 (0.71, 1.76)

HOMA, homeostatic model assessment, CI, Confidence Interval, BMI, body mass index.
*Adjusted for age, tobacco, alcohol use, and history of hypertensive disorder of pregnancy.
Additionally adjusted for birthweight for child outcomes.
Bolded results were statistically significant (p<0.05).

31 Association of glucose profiles based on daily continuous glucose monitoring metrics with adverse perinatal outcomes

Ashley N. Battarbee[1], Ayodeji Sanusi[2], Isabel Fulcher[3], Sara Sauer[4]
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [3]Delfina Care, Sunnyville, CA, [4]Delfina Care, San Francisco, CA

OBJECTIVE: While individual continuous glucose monitoring (CGM) metrics are associated with pregnancy outcomes, the combination of CGM metrics is more difficult to study. Our goal was to 1) identify discrete glucose profiles based on daily CGM metrics among pregnant individuals with pregestational diabetes and 2) investigate their association with adverse perinatal outcomes.

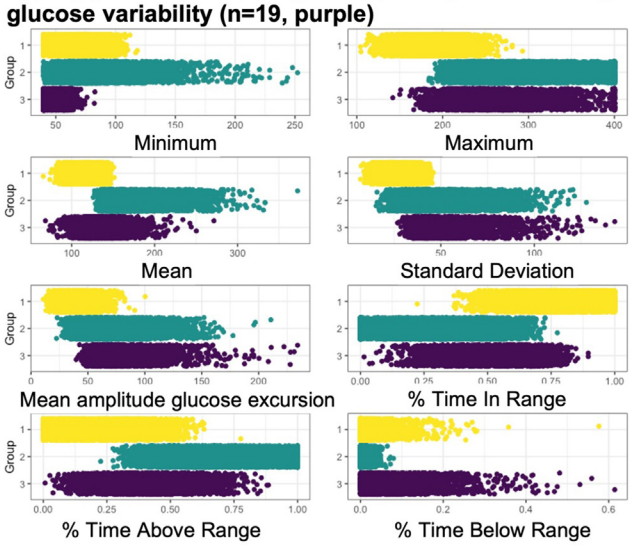
STUDY DESIGN: Retrospective cohort study of pregnant individuals with type 1 or type 2 diabetes who used Dexcom G6 CGM from at least 24-30wga and delivered at a tertiary center (2019-2023). CGM data was transformed into eight daily CGM metrics: minimum, maximum, mean, standard deviation, mean amplitude of glucose excursion, and time spent in range (65-140 mg/dL), above range, and below range. K-means clustering identified distinct glucose profiles, and individuals were classified based on which profile best summarized their CGM data. Last, the association between glucose profiles and outcomes was estimated using logistic regression

adjusted for diabetes type, maternal age, insurance, CGM use before pregnancy, and parity.

RESULTS: Of 90 pregnant individuals, 53 (58.9%) had type 1 diabetes and 47 (41.1%) had type 2 diabetes. We identified three glucose profiles: 1) well-controlled, 2) suboptimal control with hyperglycemia, and 3) suboptimal control with high glucose variability (Figure). Compared to the well-controlled profile, the hyperglycemia profile had higher odds of preterm birth (aOR 3.23, 95%CI 1.04-11.0), cesarean (aOR 3.42, 95%CI 1.09-11.9), LGA (aOR 3.88, 95% CI 1.14-15.1), neonatal hypoglycemia (aOR 4.10, 95%CI 1.36-13.5), and NICU admission (aOR 7.82, 95%CI 2.44-29.0). Compared to the well-controlled profile, the high variability profile had higher odds of preterm birth (aOR 5.49, 95%CI 1.34-25.8) and NICU admission (aOR 10.7, 95%CI 2.41-58.5). Neither was associated with preeclampsia.

CONCLUSION: In addition to avoiding maternal hyperglycemia in pregnant individuals with pregestational diabetes, high glucose variability with excursions in both directions should be minimized given high risk of preterm birth and NICU admission.

Glycemic characteristics of 3 glucose profiles: 1) well-controlled (n=33, yellow), 2) suboptimal with hyperglycemia (n=38, teal), and 3) suboptimal with high glucose variability (n=19, purple)



32 Classifying patients based on weekly continuous glucose monitoring metrics and their association with pregnancy outcomes

Sara Sauer[1], **Ayodeji Sanusi**[2], **Isabel Fulcher**[3], **Ashley N. Battarbee**[4]
[1]Delfina Care, San Francisco, CA, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [3]Delfina Care, Sunnyville, CA, [4]University of Alabama at Birmingham, Birmingham, AL

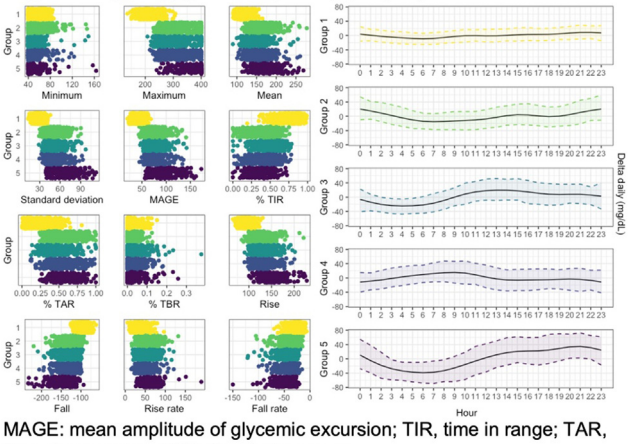
OBJECTIVE: Continuous glucose monitoring (CGM) data is complex and can be difficult to interpret. Using machine learning techniques, we sought to 1) identify groups of patients based on CGM metrics, and 2) compare patient characteristics and outcomes across groups.

STUDY DESIGN: Retrospective cohort study of patients with type 1 or type 2 diabetes who used real-time CGM during pregnancy and delivered at a tertiary center (2019-2023). CGM data were collapsed into weekly glycemic summaries related to centrality, spread, excursions, and circadian cycle patterns. Principal component analysis and k-means clustering were used to identify 5 discrete groups, and patients were assigned to the group that best represented their CGM patterns. Finally, patient characteristics and outcomes were compared across groups.

RESULTS: We identified five glucotype groups using 2040 weeks of CGM data from 145 patients: 1) well-controlled and sub-optimally controlled with 2) nocturnal hyperglycemia, 3) daytime hyperglycemia, 4) early morning hyperglycemia, and 5) high variability with fasting hypoglycemia and daytime hyperglycemia (Figure). Patients in groups 1 and 2 were more likely to be older and have type 2 diabetes whereas groups 3, 4 and 5 more likely to be younger and have type 1 diabetes ($p< 0.01$ for both). Groups 1, 2 and 5 were more likely to be non-Hispanic Black and groups 3 and 4 non-Hispanic White ($p< 0.05$). Insurance and parity were similar between groups ($p=0.44$ and 0.87). With regards to outcomes, groups 2 and 5 were most likely to have NICU admission and neonatal hypoglycemia ($p< 0.01$ for both). Groups 2 and 4 were most likely to have preterm birth, with group 5 next ($p< 0.01$). Preeclampsia and cesarean delivery did not differ ($p=0.08$ and 0.40).

CONCLUSION: Weekly CGM metrics successfully classified pregnant patients into discrete glucotype groups integrating glycemic excursions and circadian cycle patterns. Nocturnal hyperglycemia and high glycemic variability with hypo- and hyperglycemia should be avoided as these patients appear most likely to experience adverse outcomes.

Characteristics of 5 glucotype groups: 1) well-controlled (n=47, yellow), 2) nocturnal hyperglycemia (n=29, green), 3) daytime hyperglycemia (n=24, teal), 4) early morning hyperglycemia (n=32, blue), 5) high glucose variability with morning hypoglycemia and daytime hyperglycemia (n=13, purple)



MAGE: mean amplitude of glycemic excursion; TIR, time in range; TAR, time above range; TBR, time below range

33 Bioaccumulation of Microplastics in Placentae Associated with Environmental Chemical Exposures and Obstetrical Outcomes

Enrico R. Barrozo[1], Marcus A. Garcia[2], Michael D. Jochum Jr.[3], Eliane El Hayek[2], Eliseo F. Castillo[2], Jorge Gonzalez-Estrella[2], Cynthia Shope[3], Melissa Suter[4], Matthew J. Campen[2], Kjersti M. Aagaard[4]

[1]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [2]University of New Mexico, Albuquerque, NM, [3]Baylor College of Medicine, Houston, TX, [4]Texas Children's Hospital, Baylor College of Medicine, Houston, TX

OBJECTIVE: Inhalation and ingestion of millions of microplastics (particles < 20 μm) occur annually in people. Microplastic exposures have been linked to increased levels of inflammatory markers in experimental animal models. Given the putative role of disrupted inflammatory pathways in preterm birth risk, we hypothesized that microplastics quantitatively differ in human placentae.

STUDY DESIGN: We visualized and quantified cumulative microplastics (Fig. 1A) by Fourier-transformed infrared microscopy (FTIR; n=31), quantified microplastics species by pyrolysis followed by quantitative time of flight gas chromatography-mass spectrometry (pyro-qTOF/GC-MS; n=10), and quantified polycyclic aromatic hydrocarbons (PAHs; n=70) BaP, BbF, and DBA by GC/MS. We then applied machine learning algorithms correlating environmental toxicants (n=24 with PAH and microplastics data) with social deprivation scores and obstetrics outcomes.

RESULTS: Microplastics were detected in 100% of placentae (1.45-26.3 mg/g, mean 6.91 mg/g ±1.1 SEM). With pyro-qTOF/GC-MS, we detected 12 polymers with high specificity, with polyethylene being the most prominent (Fig. 1B). There was more variation between placentae in terms of the total plastics (p=0.002), compared contributions from individual plastic types (p< 0.0001). Machine learning identified the top predictive features of microplastics were gestational age and APGAR scores. Pearson's correlation analysis (Fig. 1C) revealed significantly higher polyethylene in the placentae of male offspring compared to females (Fig. 1D; p=0.032). Bulk and spatial transcriptomics (n=10) identified significant (q< 0.05) gene expression alterations associated with quartile distributions of toxicants.

CONCLUSION: To our knowledge, this is the first study to quantitate and speciate the bioaccumulation of microplastics in placentae. Further, we utilized these data to train a predictive model of environmental exposures at the maternal-fetal interface, which will only become more translational with additional integration.

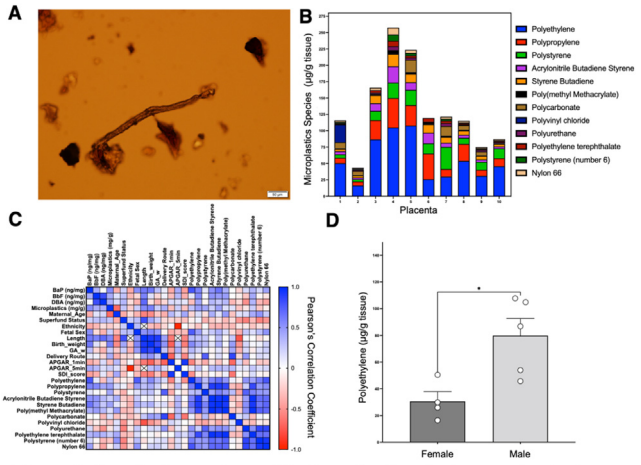

Figure 1. Visualization and quantification of microplastics species in human placentae. A, Human placentae were digested and visualized by FTIR. **B,** Individual microplastic species were quantified by pyro-GC/MS. **C-D,** Specimen with PAH, microplastics, and corresponding subject metadata were analyzed by Pearson's correlation analysis (**C**), revealing a significant increase in polyethylene associated with fetal biological sex (**D**; p=0.032, Mann-Whitney).

34 Safety and efficacy of open fetal repair of complex gastroschisis in the fetal lamb model

Luc Joyeux[1], David Basurto[2], Kanokwaroon Watananirun[2], Tom Bleeser[2], Tomohiro Arai[2], Inge Depoortere[2], Alison Accarie[2], Tim Vanuystel[2], Michael Aertsen[2], Alex Menys[3], Paolo De Coppi[4], Larry H. Hollier[1], Michael A. Belfort[5], Jan Deprest[6], Sundeep Keswani[1]

[1]Texas Children's Hospital, Baylor College of Medicine, Houston, TX, [2]KU Leuven, Leuven, West-Vlaanderen, [3]Motilent, London, England, [4]Great Ormond Street Hospital, NHS, London, England, [5]Texas Children's Hospital, Houston, TX, [6]University Hospitals Leuven, Leuven, Vlaams-Brabant

OBJECTIVE: *In utero* repair of complex gastroschisis (cGS) may prevent progressive and irreversible bowel damage due to inflammation and ischemia. We aimed to assess the safety and efficacy of open fetal repair of cGS in a previously validated fetal lamb model.

STUDY DESIGN: Standardized cGS was induced in fetal lambs at 75 days' gestation (Fig.1A). At 90 days, we repaired the defect using a stepwise fetal procedure that involved reducing the bowel into the abdominal cavity and suturing of the abdominal wall. At term (143d), we compared the outcomes of repaired cGS lambs to unrepaired and normal lambs. Outcomes were survival, small bowel gross examination, *in vivo* motility (primary) and structure on MRI, *ex vivo* contractility and permeability, and histological analysis.

RESULTS: 71% (n=5/7) of repaired cGS fetal lambs survived to term compared to 45% (n=5/11) unrepaired lambs. At term, there was no macroscopic evidence of stenosis, atresia, necrosis, perforation, or volvulus in repaired lambs, whereas 100% of the non-repaired lambs exhibited one or more of these features (Fig.1A). Repaired cGS lambs had significantly improved bowel motility and decreased bowel dilation and wall thickness on postnatal MRI to levels that were not significantly different from normal lambs (Fig.1B).

Repaired lambs had increased bowel contractility on *ex vivo* analysis with an increase in smooth muscle contractions comparable to normal lambs (Fig.1C). There was no difference in small bowel permeability and integrity. Histological examination revealed that repaired lambs exhibited restoration of smooth muscle architecture mainly in the proximal jejunum with a trend toward normal crypt and villi architecture, compared to the characteristic thickened and inflamed bowel in unrepaired cGS (Fig. 1D).

CONCLUSION: Open fetal repair of cGS in the fetal lamb model is safe and effective. Prenatal intervention improves bowel anatomy and physiology in cGS. Future studies will investigate the feasibility and safety of fetoscopic repair before envisioning clinical implementation.

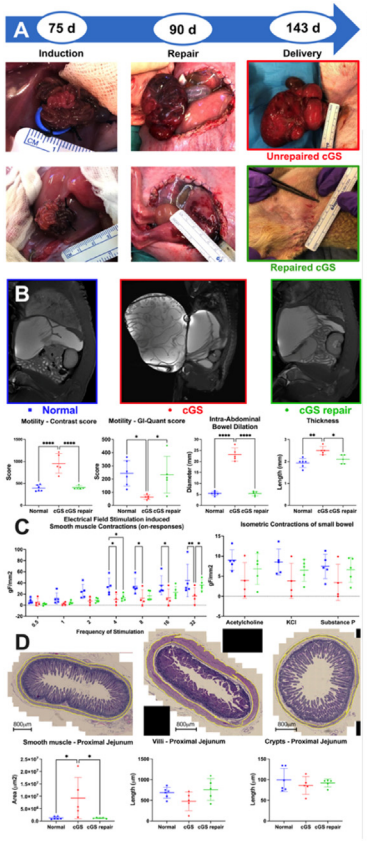

Figure 1 - Bowel structure and function after fetal repair in cGS lambs (green, n=5) at term, compared to unrepaired cGS (red, n=5) and normal controls (blue, n=6).
(A) Experimental timeline from induction until term delivery. Standardized cGS was induced in fetal lambs using a 1cm abdominal incision and a 1cm diameter silicone constrictive ring fixed to the abdominal wall followed by small bowel evisceration through the defect.
(B) *In vivo* bowel MRI: in repaired cGS lambs, significant decrease in motility contrast score of the proximal jejunum (406±39, vs. 954±223, p<0.0001), increase in GI-Quant motility score of the entire small bowel (233±139, vs. 63±17, p<0.05), and decrease in intra-abdominal bowel dilation (5.4±1.0 vs. 23.2±3.0 mm, p<0.0001) and thickness (2.1±0.2 vs. 2.5±0.2 mm, p<0.05).
(C) Ex vivo contractility assay: in repaired cGS lambs , increase in smooth muscle contractions at a maximum intensity of 4, 8, 16 and especially 32 Hz (36.1±20.1 vs. 16.5±30.1, p<0.05) and trend toward increase in isometric contractions.
(D) Quantitative histological analysis: decrease in smooth muscle area of the proximal jejunum (1.19±0.18 vs. 9.26±8.30 x10^6 um2, p<0.05), and trend toward increase of villi and crypt lengths.
One- or two-way ANOVA to compare the outcomes of repaired lambs n=5 to control lambs (*n*=6); p<0.05 is significant.

35 Potential mechanism of neuroprotection by magnesium sulfate and betamethasone in microglia and neural stem cells

Sarah Ligon[1], Jennifer Damicis[1], Marit K. Bastian[1], Katherine E. Free[1], Irina Burd[2], Peter Napolitano[3], Nicholas Ieronimakis[1]
[1]Madigan Army Medical Center, Tacoma, WA, [2]University of Maryland, Baltimore, MD, [3]University of Washington, Seattle, WA

OBJECTIVE: The use of antepartum magnesium sulfate ($MgSO_4$) and corticosteroids is associated with reductions in developmental disability among preterm infants. The protective mechanisms of these drugs remain unclear but may relate to neurodevelopment. As the brain grows in-utero, neural stem cells (NSCs) decline in number while microglia increase. We hypothesize that the mechanism of $MgSO_4$/corticosteroids relate to drug interactions in these cells and their proportion within the fetal brain at the time of preterm birth. We aimed to characterize the neuroprotective actions of these drugs by evaluating cytokine production in stimulated human fetal microglia and NSCs *in-vitro*.

STUDY DESIGN: Commercially available fetal derived microglia (HMC3) and NSCs (ReNcells) were given PBS as a control or stimulated for 24-hours with IL-1B, a mediator of perinatal neuroinflammatory injury. Cells were also given the vehicle, $MgSO_4$, betamethasone (BTMZ) or $MgSO_4$/BMTZ. The production of twelve cytokines/chemokines were compared in cell media collected 24-hours post exposure using a Milliplex immunology assay.

RESULTS: In controls, cytokines/chemokines were absent or at low levels. With IL-1B exposure, the production of five cytokines/chemokines was elevated by NSCs (Figure 1) while microglia upregulated 11 of the 12 (Figure 2). Substantial production of pro-inflammatory IL-6 and IL-8 was observed by both cell types yet only microglia produced the anti-inflammatory cytokine IL-10. Treatment with $MgSO_4$ but not BTMZ or $MgSO_4$/BTMZ lowered IL-8 but not IL-6 in IL-1B exposed NSCs. For microglia, BTMZ alone and $MgSO_4$/BTMZ reduced most cytokines upregulated by IL-1B.

CONCLUSION: In stimulated microglia and NSCs, proinflammatory cytokines were lowered selectively by each drug. BTMZ reduces inflammatory responses in microglia whereas NSCs are incrementally affected by $MgSO_4$. Further research is needed to determine whether neuroprotection by these drugs relates to gestational age, as there are differences in the brain's composition of microglia and NSCs at different times of exposure.

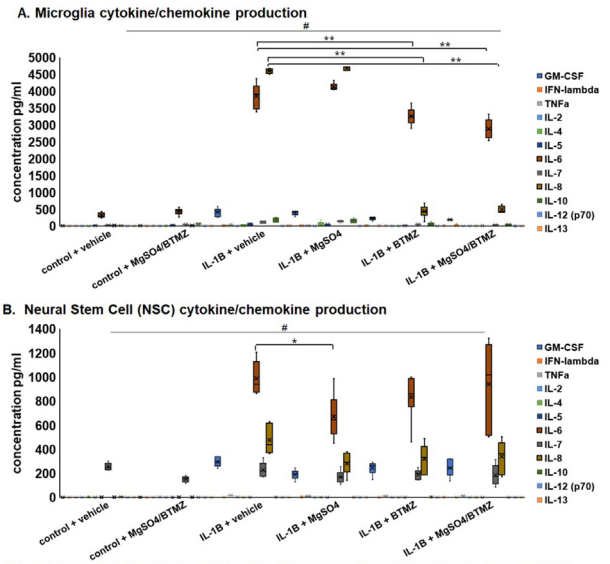

Figure 1. Box and whisker plots show cytokines/chemokine measured in media from cultured microglia and NSCs collected 24-hours following exposure to IL-1B or PBS (controls), in combination with normal saline (vehicle), MgSO4, Betamethasone (BTMZ) or MgSO4/BTMZ. Errors bars reflect the standard deviation, center lines within each box the medians, x's denote means. The horizontal axis specifies exposure-treatment (n=4-6 technical replicates per condition), vertical axis the absolute concentration. **Panel A Microglia.** # p<0.05 by ANOVA for all cytokines/chemokines across all conditions with exception to IL-4 which was not detected. ** p<0.005 by Tukey's post hoc test for IL-6 and IL-8 between IL-1B + vehicle vs. IL-1B + BTMZ and IL1B + MgSO4/BTMZ. **Panel B NSCs.** # p<0.05 by ANOVA for GM-CSF, TNF, IL-6, IL-7 and IL-8 across all conditions. * p<0.05 by Tukey's post hoc test for IL-8 between IL-1B + vehicle vs. IL-1B + MgSO4.

36 Evaluation of transplacental transfer of cancer therapies in melanoma via the perfused human placental model

Estelle Heggarty[1], David Combarel[2], Francois Vialard[3], yoann rodriguez[3], Stanislas Grassin-Delyle[3], Elodie lamy[4], Olivier Mir[2], Angelo Paci[5], Paul Berveiller[6]
[1]CHIPS Poissy Hospital, Paris Saclay University, Ile-de-France, [2]Gustave Roussy Cancer Campus, Villejuif, Ile-de-France, [3]Université Paris-Saclay, Jouy-en-Josas, Ile-de-France, [4]Université Paris-Saclay, Montrigny-le-

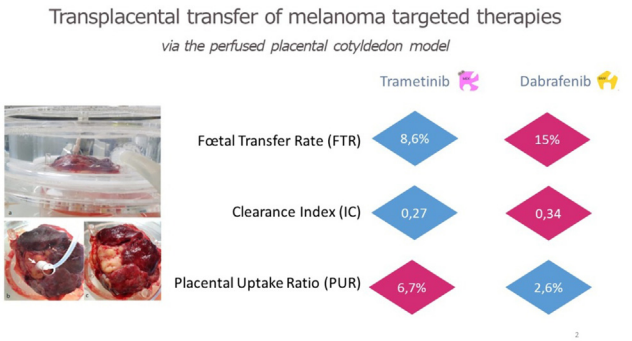
Bretonneux, Ile-de-France, [5]Gustave Roussy, Villejuif, Ile-de-France, [6]Centre Hospitalier Intercommunal de Poissy Saint Germain, Poissy, France

OBJECTIVE: Treating melanoma during pregnancy is becoming increasingly common. The targeted therapies directed at the mutations that cause 50% of melanomas, including dabrafenib (anti-BRAF) and trametinib (anti-MEK), have revolutionized the prognosis of advanced cancers. However, there are scarce on their use during pregnancy. It is essential to provide clinicians with preliminary data on the placental passage of these molecules. The objective of our study is to determine the Foetal Transfer Rate (FTR), Clearance Index (CI) and Placental Uptake Ratio (PUR) of dabrafenib and trametinib using the experimental ex vivo reference model of the human perfused cotyledon.

STUDY DESIGN: Placentas from normal term pregnancies were collected immediately after delivery. Cotyledons were placed in a 37°C perfusion chamber and perfused in a double open circuit with a solution containing trametinib or dabrafenib and its metabolites (hydroxy-dabrafenib and desmethyl-dabrafenib). The concentration found in the foetal circulation was evaluated by mass spectrometry, on samples taken every 5 minutes for 90 minutes. The validity of the manipulations was verified by the determination of antipyrine concentration, of which the transfer rate is known.

RESULTS: In the trametinib arm, 11 placentas were successfully tested. The trametinib FTR was 8.6%, the CI was 0.27, and the PUR was 6.7%. In the dabrafenib and metabolites arm, 12 placentas were successfully tested. The FTR for dabrafenib was 14.9%, the CI was 0.34, and the PUR was 2,6%. Analyses for hydroxy-dabrafenib and desmethyl-dabrafenib are ongoing.

CONCLUSION: There is a significant passage of the 2 molecules through the placental barrier, less for trametinib. These results are the first pharmacokinetic data on the placental passage of targeted melanoma therapies, an essential prerequisite for the treatment of pregnant women. Comparing this molecules will help oncologists and obstetricians chosing the best individual treatment plan for each pregnant cancer patient.



37 Refractoriness of chorion trophoblast cells to epithelial mesenchymal transition (EMT) by pPROM risk factors

OBJECTIVE: Fetal membrane inflammation is one of the drivers of pPROM. Epithelial-mesenchymal transition (EMT) of amnion epithelial and chorion trophoblast cells (CTC) at cellular-level generate inflammation that can weaken the membranes. In amnion, progesterone (P4) through receptor membrane components (PGRMC 1 and 2) restricts EMT to avoid inflammation. CTCs at the fetomaternal interface are vulnerable to maternal risk factors that can cause EMT. This study tested the influence of PGRMC 1 and 2 on EMT of CTCs in response to stressors associated with pPROM.

STUDY DESIGN: PGRMC1 or PGRMC2 knock out (KO) CTCs were prepared by CRISPR/Cas9 (Fig 1). The cells were treated with stressors Bafilomycin (BafA1) and TGF-β (EMT inducers), immunogens lipopolysaccharide (LPS), chlamydial antigen, and Ureaplasma-conditioned media (UP) to simulate various infections known to be associated with pPROM. Primary endpoints included morphologic evidence of EMT, cell-shape index, N-Cadherin to E-Cadherin ratio, TNF-α, IL-6, and progesterone production (P4).

RESULTS: Progesterone from chorion self regulates, providing anti-inflammatory barrier function. In PGRMC1 KO, there was no difference in EMT compared to wild type (WT) under normal conditions (Fig 1). In PGRMC2 KO, only LPS, but no other agent, induced EMT compared with WT ($p=0.045$) and an increase in P4 ($p=0.033$). Inflammatory cytokines (TNF-α, IL-6) significantly increased in PGRMC1 and PGRMC2 KO in response to BafA1, TGF-β, LPS, and UP ($p< 0.05$) (Table 1). P4 and PGRMC do not impact CTC EMT. CTCs are refractory to EMT in response to risk factors of pPROM (LPS, Chlamydia and U parvum antigens) and inducers of EMT (TGF-β). Increases in proinflammatory cytokines in PGRMC KO compared to WT suggest P4-PGRMC axis regulating CTC inflammation, which is independent of EMT.

CONCLUSION: CTCs are resistant to EMT to maintain its barrier functions. Chorionic inflammation, independent of EMT, is regulated by P4/PGRMC mediated autocrine signaling. Risk factors of pPROM do not induce chorion cell derangements and membrane dysfunctions are likely resulting from EMT of the amnion cells.

Table 1. Genotype-specific response to inflammatory and non-inflammatory stressors

Treatment	WT *vs.* PGRMC1 KO				WT *vs.* PGRMC2 KO			
	EMT	TNF-α	IL-6	P4	EMT	TNF-α	IL-6	P4
BafA1	-	↑↑	↑↑	-	-	↑↑	↑	-

LPS	-	↑↑↑	↑↑	-	↑	↑↑	↑↑	↑
Chl	-	-	-	-	-	-	-	-
UP	-	↑↑↑↑	↑	-	-	↑	↑	-

Summary table of EMT, progesterone release, TNF-α release, and IL-6 release differences in genotype-specific responses. ↑ = increased ($p \le 0.5$), ↑↑ = increased ($p \le 0.01$), ↑↑↑ = increased ($p \le 0.001$), and ↑↑↑↑ = increased ($p \le 0.0001$).

38 Impact of Gestational E-Cigarette Aerosols on Uterine Artery Function in Rats

Alexander Juusela[1], Vishal D. Naik[2], Alexander Carabulea[2], Joseph Janeski[2], Hong Jiang[2], Jayanth Ramadoss[2]

[1]Wayne State University, Detroit, MI, [2]C.S. Mott Center for Human Growth and Development, School of Medicine, Wayne State University, Detroit, MI

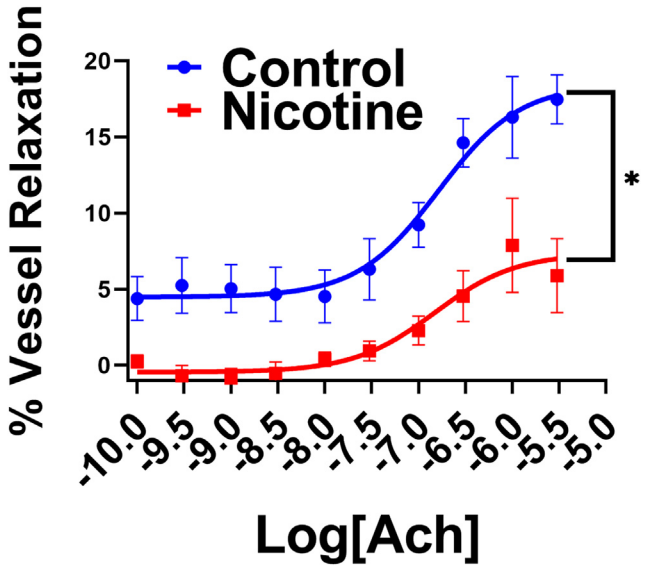
OBJECTIVE: Many perceive e-cigarettes (e-cig) as safer than cigarettes. There is a major knowledge gap surrounding the effects of e-cig aerosols (AE) on pregnancy and fetal development. We hypothesized that e-cig vaping during pregnancy will result in endothelium-dependent uterine artery (UA) dysfunction mediated by the nitric oxide system (NOS).

STUDY DESIGN: In a validated Sprague-Dawley rat model system, a custom-engineered vaping system was used to generate and deliver e-cig AE that mimic the AEs produced by commercial e-cigs. E-cig

aerosols and blood nicotine concentrations were characterized by mass spectrometry. UA function was measured via pressure arteriography. Immunoblotting and histology approaches were used to assess and validate the role of endothelial NO system.

RESULTS: Mass spec identified major AE constituents including vegetable glycerin, propylene glycol, nicotine, and carcinogenic compounds. Median peak serum nicotine concentration in dams=27.7 ng/mL, comparable to moderate/high level human smokers. As compared to the pair-fed control group, mean fetal weight (↓16.9%, one-way ANOVA P< 0.001), CRL (↓13.0%, P=0.019), and placental weight (42.3%, P=0.488). Pair-wise comparisons showed a concentration-dependent vasodilatory effect on UAs of the e-cig exposed rats, with vessel relaxation improved (P< 0.0001), treatment effect (P=0.0010). Acetylcholine induced UA relaxation was impaired in e-cig exposed rats ([1e-5 M] Control 16.3% vs. E-cig 7.89%, ↓69.5%). L-NAME↓UA vasodilation in both control and e-cig (P=0.09). The ↓ in vessel dilation due to NO inhibition in control was higher than the e-cig group, suggesting that the ↓ was due to the NO component. Immunoblotting showed that e-cig exposure↓P-Ser1177 eNOS levels in the UAs. L-NAME treatment inhibited P-Ser1177 eNOS levels in both control and e-cig exposed UAs, showing that L-NAME inhibited eNOS. Histology validated immunoblot data.

CONCLUSION: E-cig exposure during pregnancy decreases endothelial-dependent vascular relaxation in the rat UA by impairing NO-mediated vasodilation via alteration of eNOS excitatory post-translational modification.



39 Developing an Approach for In Utero Gene Editing: Lessons Learned

Courtney Breckenfelder[1], Patrick McGrath[1], Jennifer Matsuda[2], Ganna Bilosouva[1], Paul Rozance[1], Russell Anthony[3], Michael V. Zaretsky[4]

[1]University of Colorado Denver Anschutz Medical Campus, Aurora, CO, [2]National Jewish Health, Denver, CO, [3]Colorado State University, Fort Collins, CO, [4]University of Colorado, School of Medicine, Aurora, CO

OBJECTIVE: Cystic fibrosis is a genetic disorder resulting from mutations in the CFTR gene, and CRISPR/Cas9 genome editing offers potential treatment. Our objective was to develop CRISPR/Cas9 constructs targeting the F508 codon of the CFTR gene, deliver them to wild-type fetal sheep in utero, and assess the efficiency of CRISPR/Cas9-mediated genome editing in vivo to provide insights into its future feasibility.

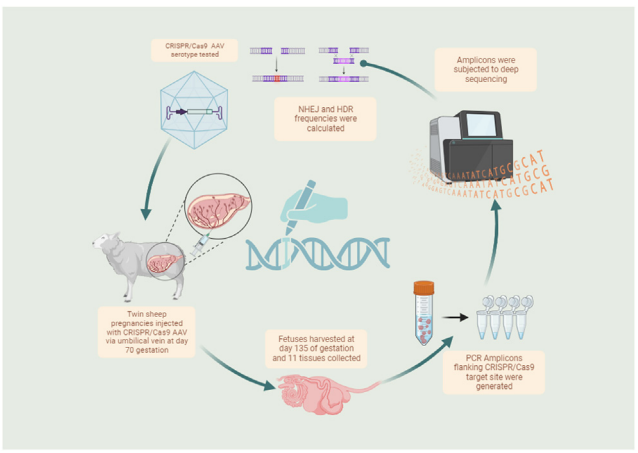
STUDY DESIGN: Several CRISPR/Cas9 orthologs were designed to target the F508 codon. The gene editing efficiency was determined in fetal sheep trophoblasts utilizing T7 endonuclease I assay. The CRISPR/Cas9 ortholog with the highest nuclease activity, smallest size and cuts closest to F508 codon was packaged into a single AAV[9]. Four fetuses from two twin sheep pregnancies at day 70 of gestation were injected with 0.5 mL of 1.5 x 10^{12} viral particles injected via the umbilical vein. The fetuses were harvested on day 135.

Eleven tissues of interest underwent genomic DNA extraction, PCR amplicons flanking the CRISPR/Cas9 target site were generated and amplicons were subjected to deep sequencing by Quintara Biosciences, NGS Division. NHEJ and HDR frequencies were calculated using the CRISPResso webtool.

RESULTS: All 4 fetuses successfully received injections and survived to term. No evidence of adverse effects were observed in treated fetuses. Amplicon NextGen sequencing revealed that CRISPR/Cas9 construct was unsuccessful at inducing indel formation in the target site. There was no significant evidence of NHEJ nor HDR.

CONCLUSION: Despite promising in vitro work, in vivo delivery of CRISPR-Cas9 systems remains complex. Off-target effects may cause unsuccessful results when using the CRISPR/Cas9 system, despite its high specificity in targeting specific genes. It is also possible that the stage of fetal development at which the gene editing is performed may impact its efficacy.

Strategies such as lipid nanoparticles for packaging and delivery as well as ongoing work in organoids is expected to provide valuable insights into the safety and efficacy of CRISPR-Cas9 editing prior to further in vivo work.



40 Increased Offspring Anxiety Following Maternal Western-Style Diet Exposure During Gestation and Lactation in Non-Human Primates

Erin Bolte[1], Geoff Dunn[2], Thomas Horvath[3], Maxim D. Seferovic[4], Sigmund Haidacher[5], Kathleen Hoch[5], Derek O'Neil[1], Anthony Haag[3], Kjersti M. Aagaard[6]

[1]Baylor College of Medicine, Houston, TX, [2]Ohio State University, Beaverton, OR, [3]Texas Children's Microbiome Center Mass Spectrometry Laboratory, Texas Children's Hospital, Houston, TX, [4]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [5]Texas Children's Hospital, Houston, TX, [6]Texas Children's Hospital, Baylor College of Medicine, Houston, TX

OBJECTIVE: Maternal Western-Style diet (mWSD) feeding and obesity during pregnancy/breastfeeding have been linked to increased offspring anxiety. Anxiety is the result of decreased serotonin, an important neurotransmitter in mood regulation. Serotonin is synthesized from tryptophan and degraded into 5-hydroxyindoleacetic acid (5-HIAA). We hypothesized that mWSD feeding in a primate model would alter her offspring's serotonin pathway metabolites, leading to persistent and evident offspring anxiety at 3 years of age (peripuberty).

STUDY DESIGN: Japanese macaque dams were fed a Chow control diet or mWSD during gestation and lactation, then offspring were weaned onto Chow or Western-Style diet (Fig. 1A). Anxiety was tested by multiple validated measures at 34 months and scored by blinded reviewers. Serum was collected at 36-40 months and analyzed by targeted liquid chromatography-mass spectrometry of all known serotonin pathway metabolites and other metabolites known to affect behavioral neuroactivity (gamma-aminobutyric acid and short-chain fatty acids).

RESULTS: Anxiety was calculated as the sum of four components: high energy outbursts and reactive, ritualized, and inactive behaviors (Fig. 1B). Total anxiety scores display a right shift (more frequent occurrence) in males (Z-test p= 0.005, Fig. 1C). We detected 18 neuroactive metabolites in serum which withstood confirmatory factor analysis, revealing statistically significant inverse relationships between 5-HIAA levels and ritualized anxiety (p=0.004) and high energy outbursts (p=0.048, Fig. 1D).

CONCLUSION: We demonstrated that mWSD feeding programs male offspring with persistently increased anxiety, despite 2.5 years of control diet feeding. Analysis of serotonin metabolites showed an inverse correlation between 5-HIAA and anxiety, indicating low levels of serotonin inferred from its degradation product that correspond with higher levels of anxiety. These data underscore the importance of dietary counseling during pregnancy and lactation to potentially prevent unintended programming of offspring neuroactivity and anxiety behavior.

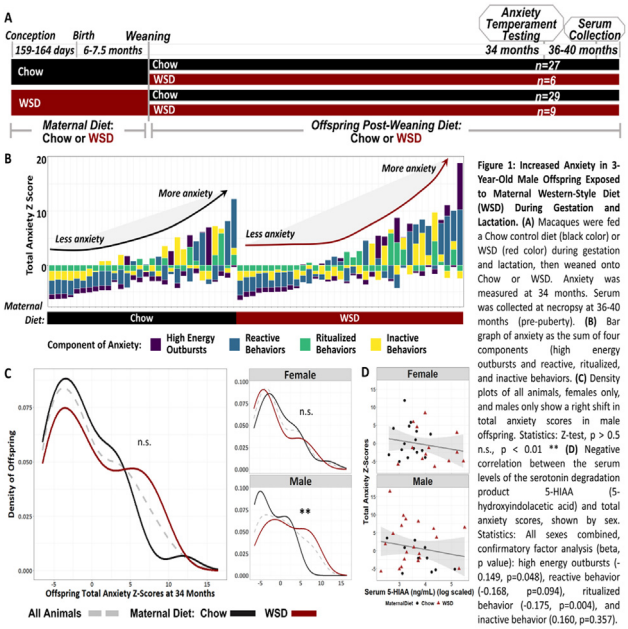


Figure 1: Increased Anxiety in 3-Year-Old Male Offspring Exposed to Maternal Western-Style Diet (WSD) During Gestation and Lactation. (A) Macaques were fed a Chow control diet (black color) or WSD (red color) during gestation and lactation, then weaned onto Chow or WSD. Anxiety was measured at 34 months. Serum was collected at necropsy at 36-40 months (pre-puberty). **(B)** Bar graph of anxiety as the sum of four components (high energy outbursts and reactive, ritualized, and inactive behaviors. **(C)** Density plots of all animals, females only, and males only show a right shift in total anxiety scores in male offspring. Statistics: Z-test, $p > 0.5$ n.s., $p < 0.01$ ** **(D)** Negative correlation between the serum levels of the serotonin degradation product 5-HIAA (5-hydroxyindolacetic acid) and total anxiety scores, shown by sex. Statistics: All sexes combined, confirmatory factor analysis (beta, p value): high energy outbursts (-0.149, p=0.048), reactive behavior (-0.168, p=0.094), ritualized behavior (-0.175, p=0.004), and inactive behavior (0.160, p=0.357).

41 ASpirin in Placental and maternal Endothelial cell Regulation IN pre-eclampsia (ASPERIN Trial): Primary Outcome

John O'Brien, Aarthi Srinivasan, Katherine Vignes, Cynthia Cockerham, Wendy Whitley, Hong Huang, Arnold J. Stromberg, John A. Bauer
University of Kentucky, Lexington, KY

OBJECTIVE: Recent findings suggest biophysical differences in uterine artery Doppler profile can be identified with exposure to low dose aspirin. Dose effects however have not been adequately investigated. We hypothesized variations in uterine artery pulsatility index (UtA PI) may be identified based on dose.

STUDY DESIGN: Between April 2019 and July 2022, a phase II open-label, randomized trial was performed to compare UtA PI in three subpopulations: high-risk randomly assigned to 81 mg aspirin daily, high-risk randomly assigned 162 mg of aspirin daily, and a convenience control group (no risk factor) (NCT03893630). Singletons with or without a major criterion risk factor defined by the USPSTF were enrolled and randomized by a scheme stratified by BMI. Patients initiated treatment after first trimester measurement of UtA PI. Serial UtA PI assessments were performed at 18-22 weeks and 28-32 weeks. Repeated measures using a mixed model analysis was performed to assess the effect of dose over time.

RESULTS: The ASPERIN trial enrolled 209 subjects (69 treated with 81 mg, 75 to 162 mg, and 65 controls). Demographics differed between groups (Table). Analysis of change in UtA PI over time which incorporated aspirin exposure, BMI, and trimester revealed a significant interaction between exposure in the three groups, P=.02. However, excluding controls, a significant difference was not observed in UtA PI based on dose, P=0.416. In a post hoc analysis limited to the obese subpopulation, BMI ≥30, the UtA PI did not identify differences between the high-risk subgroups at 28-32 weeks, 1.0 ± 0.09 SE vs 1.14 ± .08 SE, P=.24; and at 18-22 weeks 1.16 ± .097 SE vs 1.13 ± 0.085, P=0.78. The aspirin-exposed high-risk groups had a cumulative non-significant increase in perinatal mortality, p=0.327, but a dose effect on mortality was not present.

CONCLUSION: A change in UtA PI over time was observed as expected; however, in a trial population enrolled by risk factors, dose of aspirin did not demonstrate a significant treatment effect on UtA PI in a phase II study.

42 Clinical Outcomes Following Remote Hypertension Monitoring Program for Postpartum Individuals with Hypertensive Disorders of Pregnancy

Lara S. Lemon[1], Beth Quinn[2], Anna Binstock[1], Jacob Larkin[2], Hyagriv Simhan[1], Alisse Hauspurg[3]
[1]University of Pittsburgh, Pittsburgh, PA, [2]Magee-Womens Hospital, University of Pittsburgh Medical Center, Pittsburgh, PA, [3]UPMC Magee-Womens Hospital, Pittsburgh, PA

OBJECTIVE: We sought to evaluate outcomes following implementation of a remote monitoring program for postpartum individuals with a hypertensive disorder of pregnancy (HDP).

STUDY DESIGN: We evaluated the impact of engagement in a remote hypertension management program in a cohort of postpartum individuals with a HDP delivering from 1/2018 - 6/2023 at a single institution. We compared postpartum readmission, office visit within 6 weeks, BP measurement within 10 days, and postpartum initiation of antihypertensive medication among those who participated to controls who did not participate. Program participation was at the discretion of the care provider and patient. We performed multivariate logistic regression and conditional regression in a propensity score matched cohort. Adjustment variables were included in propensity score modeling likelihood of program participation.

Propensity scores were assessed for even distribution by group and ensuring standardized bias < 10% after matching.

RESULTS: We included 14,382 eligible individuals (6501 participants, 7881 controls). Program participants were more likely to be white, commercially insured, reside in a more disadvantaged neighborhood, have a higher BMI, have preeclampsia, and have higher prenatal and inpatient postpartum BPs. These factors were well-balanced after implementation of propensity score. Program participants had lower 6-week postpartum readmission rates, demonstrating 16 fewer readmissions for every 1000 individuals in the program [adjRD=-1.6 (-2.5, -0.80); aRR 0.77 (0.68, 0.88)]. For every 100 individuals in the program, 85 more had a BP recorded within 10 days [adjRD=85.9 (85.1, 86.8)] and 7 more were adherent with 6-week postpartum office visit [adjRD=7.9 (6.4, 9.5)]. Participants were 3-4 times more likely to initiate an antihypertensive medication postpartum [ajdRR=3.79 (3.42, 4.19)].

CONCLUSION: Participation in a postpartum remote BP monitoring program was associated with fewer postpartum hospital readmissions, higher attendance at postpartum visits, improved guideline adherence, and higher rates of antihypertensive use after implementation.

43 162 mg versus 81 mg Aspirin for High-risk Obese Individuals: An Open Label RCT (ASPREO)

Farah H. Amro[1], Michal Fishel Bartal[2], Claudia Pedroza[1], Sami Backley[1], Ghamar Bitar[1], Joseph Lucci IV[1], Nahla Daye[1], Sandra Sadek[1], Suneet P. Chauhan[3], Sean C. Blackwell[4], Baha M. Sibai[5]

[1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [2]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX, [3]University of Texas-Houston Medical School, Houston, TX, [4]Children's Memorial Hermann Hospital, Houston, TX, [5]Hermann Memorial Hospital, Houston, TX

OBJECTIVE: Low dose aspirin is recommended for preeclampsia prevention; however, the optimal dose is debated. We evaluated whether daily dose of aspirin (162 mg) compared to routine dose (81 mg) decreases the rate of preeclampsia (PE) with severe features in high-risk obese individuals.

STUDY DESIGN: Pregnant individuals 12-20 weeks with a BMI ≥ 30 kg/m^2 and at least one high-risk factor (history of PE, pregestational diabetes, gestational diabetes diagnosed < 20 weeks, or at least stage I hypertension [≥130/80]) were randomly allocated to aspirin dose of 81 mg or 162 mg (ClinicalTrials.gov: NCT03961360). Adherence to medications was assessed at 4 weeks after enrollment and at 32-36 weeks. Primary outcome was rate of PE with severe features based on physician diagnosis in those delivered ≥ 20 weeks. We used Bayesian methodology to determine a total sample size of 220 subjects needed to determine whether higher aspirin dosing would decrease the primary outcome, assuming 80% power, a neutral informative prior, and 75% certainty. An intention-to-treat analyses was used to calculate relative risk (RR), 95% credible intervals (CI).

RESULTS: Over the study period (05/2019 to 11/2022) 343 eligible women were approached and 220 (64%) agreed. High risk factors were similar between groups (history of prior PE: 34% vs 29%, diabetes mellitus: 42% vs 46%, Stage I HTN: 29% vs 32%). Primary outcome was unavailable for 7 (3%) participants,4 (1.8%) delivered prior to 20 weeks.Thus, we analyzed:107 on 162 mg and 102 on 81 mg.PE with severe features occurred in 35% in 162 mg compared to 40% in the 81 mg group(RR, 0.88, 95% credible interval, 0.64-1.22) with a posterior probability for treatment benefit of 78% (Table).The median gestational age at delivery was lower in 162 mg group (p=0.04), however there were no differences in other secondary outcomes or medication adverse events (Table).

CONCLUSION: Among high-risk obese individuals our trial suggests with 78% certainty that 162 mg aspirin compared to 81 mg, decreases PE with severe features.This trial supports doing a larger phase III multicenter trial.

Table. Maternal Characteristics and Outcomes

	ASA 162 mg N=107	ASA 81 mg N=102	RR (95% CI)	p-value	Bayesian (Prob RR<1)

44 Platelet Response to Aspirin Therapy in Pregnancy and Association with Pregnancy Outcome

Rupsa C. Boelig[1], Emily Foecke Munden[2], Tingting Zhan[3], Steven McKenzie[4], Walter Kraft[4]

[1]Thomas Jefferson University Hospital, Philadelphia, PA, [2]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA,

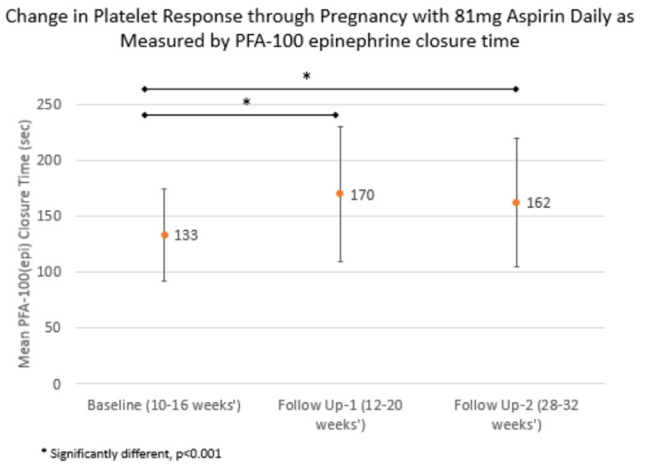
[3]Thomas Jefferson University, Philadelphia, PA, [4]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA

OBJECTIVE: Low dose aspirin is recommended for prevention of preeclampsia in high risk patients, but individual response to aspirin is highly variable and there is no marker established to measure aspirin response in pregnancy. A commercially available assay PFA-100 epinephrine closure time (PFA-100(epi)), is used to measure aspirin response in non-pregnant adults. Increased PFA-100(epi) result indicates increased platelet inhibition, and a threshold of 150 seconds has been described for aspirin response. We aimed to characterize the response to aspirin in pregnancy with use of PFA-100(epi) and identify whether it was associated with hypertensive disorders of pregnancy (HDP).

STUDY DESIGN: This is a prospective cohort study of singletons at high risk for preeclampsia taking 81mg aspirin daily. Blood was drawn at baseline prior to aspirin (10-16 weeks'), 2-4 weeks after aspirin initiation (follow-up 1), and at 28-32 weeks' (follow-up 2). We evaluated PFA-100(epi) across visits as well as rate of PFA-100(epi)< 150. Primary outcome was HDP. Secondary outcomes included preterm delivery for preeclampsia (preterm preE). Multivariable logistic regression was used to evaluate the relationship between PFA-100 (epi) and outcomes, adjusting for age, BMI, and preexisting hypertension or diabetes.

RESULTS: 103 participants had >75% adherence and completed all visits. 26% were Black, 30% had hypertension, and 10% had diabetes. PFA-100(epi) increased with aspirin through gestation (Figure). Predictors of aspirin response included diabetes; patients with diabetes had reduced PFA-100(epi) (log corrected adjusted MD -0.23 (- 0.46 to -0.01)) and higher rate of PFA-100(epi)< 150 seconds (adjusted OR 4.9 (1.1-34.3)) compared to non-diabetics. In multivariable logistic regression neither PFA-100(epi) at follow up-1 nor follow up-2 were associated with risk of HDP or preterm preE (p >0.10).

CONCLUSION: Low dose (81mg) aspirin therapy in pregnancy results in platelet inhibition through gestation as measured by PFA-100(epi), but PFA-100 response was not associated with the risk of hypertensive disorders of pregnancy



45 Optimal Gestational Age for Delivery of Pregnant Individuals with Mild Chronic Hypertension

Torri D. Metz
University of Utah Health, Salt Lake City, UT, on behalf of the Chronic Hypertension and Pregnancy (CHAP) Trial Consortium

OBJECTIVE: ACOG recommends delivery as early as 37w0d gestation to as late as 39w6d for chronic hypertension (CHTN). Our aim was to investigate the optimal gestational age to deliver pregnant people with CHTN to improve perinatal outcomes.

STUDY DESIGN: Secondary analysis of a randomized controlled trial of CHTN treatment to different blood pressure goals. Participants with a term, singleton gestation were included. Pregnancies with fetal anomalies and those with a diagnosis of preeclampsia (preE) or gestational HTN < 37 weeks were excluded. The primary maternal composite outcome included death, serious morbidity (heart failure, stroke, encephalopathy, MI, pulmonary edema, ICU, intubation, renal failure), preE with severe features, hemorrhage requiring blood transfusion, or abruption. The primary neonatal outcome included fetal or neonatal death, respiratory support beyond oxygen mask, Apgar < 3 at 5 minutes, neonatal seizures, proven sepsis. Secondary outcomes included cesarean birth, length of stay, NICU admission, suspected sepsis, RDS, TTN, hypoglycemia. Those with a planned delivery were compared with those expectantly managed at each gestational week. Adjusted odds ratios with 95% CIs are reported.

RESULTS: 1,417 participants with mild CHTN were included; 305 (21.5%) with a new diagnosis in pregnancy and 1112 (78.5%) with known pre-existing HTN. Groups differed by BMI and pre-existing diabetes. In adjusted models, there was not an association between planned delivery and the maternal composite outcome in any gestational age week compared with expectant management (Table). Planned delivery in week 37 was associated with cesarean birth. Planned delivery in week 37 and 38 was associated with adverse neonatal outcomes (Table).

CONCLUSION: Planned delivery in the early term period compared with expectant management was not associated with a reduction in adverse maternal outcomes and increased the odds of cesarean delivery. Early term delivery was also associated with an increase in neonatal complications. Delivery timing should weigh maternal and neonatal outcomes in each gestational week.

Table. Maternal and neonatal outcomes of those with planned delivery versus expectant management

Outcome	37w0d-39w6d (n=1417)			38w0d-39w6d (n=961)			39w0d-39w6d (n=460)		
	Planned Delivery[c] (n=171)	Expectant Management (n=1246)	[b]aOR (95% CI)	Planned Delivery[c] (n=177)	Expectant Management (n=784)	[b]aOR (95% CI)	Planned Delivery[d] (n=306)	Expectant Management (n=154)	[b]aOR (95% CI)
Maternal primary composite outcome and components of the outcome, n(%)									
Primary composite maternal outcome	26 (15.2)	174 (14.0)	1.11 (0.71-1.75)	20 (11.3)	93 (11.9)	0.90 (0.53-1.52)	35 (11.4)	14 (9.1)	1.22 (0.63-2.35)
Serious maternal morbidity	0 (0)	14 (1.1)	N/A[e]	1 (<1)	9 (1.1)	N/A[e]	5 (1.6)	1 (<1)	N/A[e]

Hypoglycemia, n(%)	32 (18.7)	134 (10.8)	**1.87 (1.20-2.91)**	25 (14.1)	60 (7.7)	**1.73 (1.02-2.92)**	16 (5.2)	11 (7.1)	0.44 (0.18-1.06)

[a] Planned delivery group included anyone with a scheduled induction of labor or cesarean without labor from 37w0d to 37w2d. Other participants who were still pregnant at or beyond 37w0d were considered expectantly managed.
[b] Adjusted odds ratio with 95% confidence interval was obtained by multivariable logistic regression models for binary outcomes. Covariates included maternal BMI and pre-existing diabetes which were different between groups at baseline. The difference for length of neonatal stay between planned delivery and expected management with 95% confidence interval was estimated by generalized linear mixed model.
[c] Planned delivery group included anyone with a scheduled induction of labor or cesarean without labor from 38w0d to 38w2d. Other participants who were still pregnant at that time were considered expectantly managed.
[d] Planned delivery group included anyone with a scheduled induction of labor or cesarean without labor from 39w0d to 39w2d. Other participants who were still pregnant at that time were considered expectantly managed.
[e] N/A: Multivariable modeling if count less than 5

46 Subtypes of hypertension years after a hypertensive disorder of pregnancy

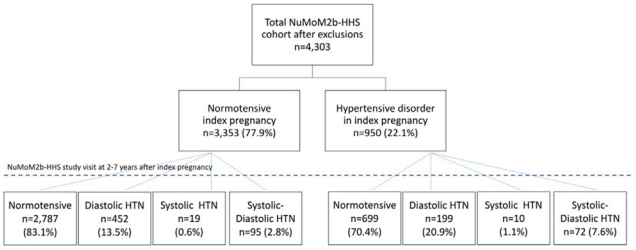
OBJECTIVE: Isolated diastolic hypertension (HTN) is prevalent in young adults and imparts increased cardiovascular risk. Our objective was to determine whether subtypes of HTN (isolated diastolic, isolated systolic, and combined systolic-diastolic) differ years after index pregnancy complicated by hypertensive disorder of pregnancy (HDP, including preeclampsia, eclampsia, gestational hypertension) compared with normotensive pregnancy.

STUDY DESIGN: This analysis utilized data from NuMoM2b-Heart Health Study (NuMoM2b-HHS), a multi-site cohort during which 4,312 individuals completed a follow-up visit at 2-7 years postpartum after index delivery (HHS visit). Individuals with preexisting chronic HTN or diabetes or on antihypertensive medications at HHS visit were excluded from this analysis. Combined HTN was defined as systolic blood pressure (SBP) $\geq$ 130 mmHg and diastolic BP (DBP) $\geq$ 80 mmHg; isolated systolic or diastolic HTN was either SBP $\geq$ 130 or DBP $\geq$ 80 mmHg, respectively. Multinomial logistic regression models adjusted for age, BMI at HHS visit, years from index delivery until HHS visit, and self-reported race and ethnicity (social constructs).

RESULTS: 4,303 individuals met inclusion criteria and had BP measurement at HHS visit with mean of 3.2 (SD 0.9) years since index pregnancy; 950 (22.1%) had history of HDP during that pregnancy. Among 847 (19.7%) with HTN at HHS visit and not on medications, isolated diastolic HTN was the predominant subtype (651 cases; 76.9%), followed by combined HTN (167; 19.7%) and isolated systolic HTN (29; 3.4%). When compared to those without HDP, those with history of HDP had an increased risk of isolated diastolic and combined HTN subtypes (isolated diastolic: aRR 1.58 [CI 1.30, 1.92]; isolated systolic: aRR 1.85 [0.85, 4.03]; systolic-diastolic: aRR 2.70 [1.95, 3.74]).

CONCLUSION: HDP are associated with both isolated diastolic HTN and combined systolic-diastolic HTN; further study in this population on the role of isolated diastolic HTN on future cardiovascular risk is warranted.

Figure 1. Subtypes of hypertension in NuMoM2b-HHS cohort at 2 to 7 years postpartum by hypertensive disorder of pregnancy



47 Subclinical Cardiovascular Alterations and Molecular Signatures in Women with History of Hypertensive Disorders in Pregnancy

Lee Reicher[1], Nastya Godneva[2], Adina Weinberger[2], Yariv Yogev[3], Eran Segal[2]

[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel, [2]Weizmann Institute of Science, Rehovot, HaMerkaz, [3]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

OBJECTIVE: Hypertensive disorders of pregnancy (HDP) are associated with increased risk for long-term cardiovascular (CV) complications. During the postpartum years, these women experience subclinical CV changes with potential implications for CV diseases. Yet, the characterization of these changes remains limited. We investigated the long term molecular and physiological profiles of women with a history of HDP

STUDY DESIGN: Data collected as part of large-scale longitudinal study with over 10,000 healthy adults aged 40−70 years, between the years 2019 and 2022. The participants underwent physiological assessments through special tests and wearables, multi-omic profiling, and medical records were collected (**Figure**). Profiles of women with a history of HDP (hypertension occurring after 20 weeks of gestation, gestational hypertension and pre-eclampsia) were compared to a matched control subset (by number of pregnancies and the time elapsed since the HDP pregnancy)

RESULTS: Our study consisted of 200 women in the HDP group and 600 women in the control group (mean of 18 years post-pregnancy). Women with a history of HDP displayed notable findings compared to the control group (all *p< 0.001)

1. Higher sonographic liver viscosity and lower speed of sound index indicating liver fibrosis and steatosis, respectively.
2. Higher triglycerides (110±50 vs 99±50, mg/dl*)
3. Higher BMI (28±5 vs 25±5*) and systolic (122±17 vs 114±15*) and diastolic (89±11 vs 80±11*) blood pressure
4. Higher visceral fat percentage (822±550 vs 627±420 gr*)
5. Sleep monitoring indicated a higher rate of sleep apnea; higher Oxygen Desaturation (number of desaturation episodes per hour) (4.5±5 vs 3±4*) and Apnea-Hypopnea Index (18±14 vs 13±12*)
6. Retinal imaging: fractal artery dimension is reduced (associated with hypertension)
7. Lower levels of LysoPC, a vasoprotective metabolite

CONCLUSION: These findings offer valuable insights into long-term CV processes post pregnancy complicated with hypertensive dusease and can aid in personalized monitoring, guiding targeted interventions to proactively reduce the risk of CV complications

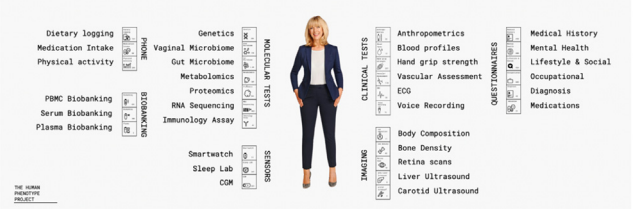


Figure | Data collected or analyzed in the Human Phenotype Project
The project combines innovative medical tests and wearables (such as CGM, and sleep monitoring). It profiles participants at unprecedented depth, including physiological assessment of their muscular, skeletal, liver, blood, heart, vascular, immune, gastrointestinal, and cognitive body systems. The multi-omics profiling of each participant includes genetics, microbiome, metabolomic, transcriptomic, proteomic, and immune system evaluation. A life-style questionnaire and medical records are obtained.

48 Lower thresholds for diagnosing hypertension in pregnancy and perinatal outcomes in large Tanzanian cohort

Chan School of Public Health, Boston, MA, [3]Africa Academy for Public Health, Dar es Salaam, Dar es Salaam, [4]Harvard T.H.Chan School of Public Health, Boston, MA, [5]Ifakara Health Institute, Dar es Salaam, Dar es Salaam, [6]Columbia University, New York, NY

OBJECTIVE: The American Heart Association now defines stage 1 hypertension (HTN) as a systolic blood pressure (BP) of 130-139 mmHg, a diastolic BP of 80-89 mmHg, or both, based on association with long-term cardiovascular risk. Whether lower thresholds should be adopted for diagnosing hypertensive disorders of pregnancy (HDPs) is not clear, particularly in low- and middle-income country settings where data are limited. We aimed to estimate perinatal risks associated with using stage 1 BP cutoffs after 20 weeks' gestation compared with traditionally defined cutoffs in a large Tanzanian cohort.

STUDY DESIGN: We performed a secondary analysis of a randomized noninferiority trial comparing 500 mg calcium vs 1500 mg daily for preeclampsia prevention among nulliparous women (n=11,000 pregnancies) in Dar es Salaam (2019-2023). After excluding 59 participants with BP $\geq$ 130/80 $<$ 20 weeks, we compared risks of perinatal outcomes associated with a lower cutoff (130/80) for gestational HTN >20 weeks versus traditional cutoffs. A normotensive group ($<$ 130/$<$ 80) throughout gestation served as the reference group in multivariable regression models.

RESULTS: A total of 10,941 pregnancies and 10,891 offspring with birth outcome data available were included analysis. 466 pregnancies (5.0%) were diagnosed with GHTN or PE using standard definitions while an additional 1,190 (10.9%) were categorized as reaching stage I thresholds at $\geq$20 weeks' gestation. There were no differences in birth weight, gestational age at birth, or other perinatal outcomes (perinatal mortality, PTB, SGA, LBW) for those reaching stage 1 HTN thresholds compared to normotensive women (TABLE). In contrast, higher risks of adverse outcomes were observed for those reaching the >140/ >90 threshold with or without proteinuria and with or without severe features.

CONCLUSION: Lowering blood pressure thresholds in pregnancy to define HDPs in Tanzania does not identify a population at higher risk for adverse perinatal outcomes. Limited resources in these settings may be better directed to management of women reaching traditional thresholds for HTN in pregnancy.

TABLE: Multivariable association of stage I GHTN, traditional GHTN, traditional PE w/o severe features and PE w/severe features with birth outcomes

	Normotensive (<130/<80 mmHg)	Stage I GHTN (130-139/80-89 mmHg w/ or w/o proteinuria)	Traditional GHTN (140-159/90-109 mmHg w/o proteinuria)	Traditional PE without severe features (140-159/90-109 mmHg w/ proteinuria)	PE with severe features (160+/110+ mmHg or other severe features)

49 Early pregnancy reticulocyte hemoglobin content as a marker for iron deficiency by BMI category

Kaitlyn P. Casper[1], Kimberly Moyle[1], Amanda A. Allshouse[1], Ashley E. Benson[2], Timothy M. Bahr[1], Robert D. Christensen[1], David Branch[1]
[1]University of Utah Health, Salt Lake City, UT, [2]Oregon Health & Science University, Portland, OR

OBJECTIVE: Iron deficiency (ID) in pregnancy is common, affecting up to 45% of individuals. ACOG recommends ferritin to screen for ID; however, ferritin may be elevated in inflammatory conditions, such as obesity, obscuring the diagnosis of ID. Reticulocyte hemoglobin concentration (RET-He), a readily available assay, is not affected by inflammation and may be an alternative measure of iron status. We describe the diagnostic properties of early pregnancy ferritin and RET-He in identifying ID for all-comers and by BMI category.

STUDY DESIGN: Prospective cohort of pregnant individuals enrolled at $\leq$ 14 weeks' GA, stratified 1:1 by obesity . Serum transferrin saturation (Tsat), ferritin, and RET-He were measured at enrollment. ID was defined as Tsat $\leq$ 20%. ROC analysis assessed the diagnostic properties of ferritin and RET-He for ID within the cohort as well as by BMI category. The ferritin and Ret-He value with maximum potential effectiveness was identified using Youden index.

RESULTS: A total of 165 individuals were included, 83 with BMI $<$ 30 and 82 with BMI $\geq$ 30. Diagnostic properties of RET-He for ID by ROC analyses were consistently reasonable overall and in both obesity groups, whereas ferritin was less discriminatory among people with obesity (Figure 1). For RET-He, cut points were: 33.0, 32.8 and 33.2 for BMI $\geq$ 30, BMI $<$ 30, and the whole cohort respectively. The optimal cut points of ferritin for identification of ID were 18, 51 and 25 ng/mL. Sensitivity of these values for RET-He and ferritin for ID for those with BMI $\geq$ 30 were 59 and 31, and specificity 92 and 100. For those with BMI $<$ 30: sensitivity was 56 and 78, and specificity 96 and 72. For the whole cohort: sensitivity was 63 and 34, specificity 91 and 94.

CONCLUSION: Early pregnancy RET-He performs better than ferritin in identification of ID in pregnancy. This difference is greater in those with BMI $\geq$ 30. The optimal ferritin value for identifying ID varied significantly by BMI, whereas RET-He did not.

50 Frequency of cytomegalovirus reinfection during pregnancy: a prospective cohort study

Juliette St-Georges[1], Safari Joseph Balegamire[1], Suresh Boppana[2], Mi-Suk Kang Dufour[3], Ariane Larouche[3], Barbora Knoppova[2], Misty Latting[2], Christian Renaud[3], Benoit Masse[4], Yves Giguère[5], Jean-Claude Forest[6], Soren Gantt[3], Isabelle Boucoiran[7]
[1]Université de Montréal, Montréal, QC, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Centre Hospitalier Universitaire Sainte-Justine, Montréal, QC, [4]University of Montréal, Montréal, QC, [5]Research Center of the CHU de Québec-Université Laval, QC, [6]CHU de Québec, Quebec City, QC, [7]CHU Sainte-Justine, Center for Maternal-Fetal Medicine, Montréal, QC

OBJECTIVE: To identify reinfection with cytomegalovirus (CMV) during pregnancy and determine the proportion of congenital CMV infections (cCMV) associated with these reinfections.

STUDY DESIGN: We used the biobank of the prospective cohort Grossesse en santé, collected between 2005 and 2010 in Quebec City, Canada and selected cases with positive CMV IgG serology (Abbott Architect platform) in the first trimester. CVM primary infections were excluded based on IgG avidity less than 60%. Antibody response to CMV strain-specific epitopes on glycoproteins B and H (gB and gH) from laboratory strains (AD169 and Towne) were measured by enzyme-linked immunosorbent assay using serum samples collected in the first and third

trimester. CMV reinfection was defined as the appearance of an antibody response targeting a new CMV epitope in the third trimester. cCMV infections were identified by CMV polymerase chain reaction (PCR) on cord blood using the AltoStar CMV PCR Kit 1.5 (Altona) platform.

RESULTS: Among 7855 participants, 4111 had first and third trimester sera available, from which 965 were seropositive for CMV (+IgG) in the first trimester (23%) and 9 were excluded because of first trimester primary infection. Among the remaining 956 participants, 16 reinfections were identified (1.7%), and 21 cases of cCMV were identified (2.2%). Of cCMV cases, 3 (14.3%) and 18 (85.7%) occurred among participants with and without evidence of reinfection during pregnancy, respectively. This corresponds to a 18.7% risk of transmission with reinfection during pregnancy, compared to 1.9% in the absence of reinfection.

CONCLUSION: CMV reinfection in pregnancy is rare but is associated with 18.7% risk of vertical transmission. The number of reinfections during pregnancy may have been underestimated because CMV is extremely variable, and the assay used in our study only identifies antibody response against 4 antigenically distinct epitopes from 2 viral strains highlighting the critical need for the development of an assay to accurately estimate the rate of CMV reinfection in pregnancy.

51 Association of SARS CoV-2 infection in pregnancy and placental gene expression at delivery

[1]NorthShore University Health System, Evanston, IL, [2]NorthShore University HealthSystem, Evanston, IL, [3]University of California, Los Angeles, Los Angeles, CA, [4]Northwestern University, Evanston, IL, [5]Prisma Health Upstate, Greenville, SC, [6]NorthShore University HealthSystem, University of Chicago Pritzker School of Medicine, Evanston, IL, [7]NorthShore University HealthSystem, Evanston Hospital, Evanston, IL, [8]Prisma Health, University of South Carolina School of Medicine Greenville, Greenville, SC

OBJECTIVE: SARS CoV-2 infection during pregnancy has been associated with varying degrees of placental inflammation, with an unknown underlying mechanism. We utilized the novel approach of placental gene expression analysis to examine possible mechanistic differences induced by SARS CoV-2 infection during pregnancy by trimester.

STUDY DESIGN: In this prospective dual site cohort study, placentas were biopsied at delivery in patients infected with SARS CoV-2 during pregnancy. Placental biopsies collected prior to the SARS CoV-2 pandemic were controls. Placental biopsies underwent novel genome-wide mRNA profiling and bioinformatics were used to assess transcription factor activity and immune cell activation, controlling for study site, age, parity, BMI, race/ethnicity, and insurance status. Transcripts with >2-fold differential expression between infected and uninfected placentas were considered significant.

RESULTS: 886 uninfected and 68 infected placentas were analyzed. Of the affected samples, 8 were infected in the 1st, 24 in 2nd and 36 in 3rd trimester. Marked transcriptional alterations were identified in 3rd trimester infections, including upregulation of mesenchymal transcripts, elevated expression of Type I interferon/innate antiviral signaling (IRF, STAT family transcription factors), glucocorticoid receptor activity, macrophage activation, and downregulation of epithelial gene transcripts (Figure 1). Classical and non-classical monocytes were both upregulated. 2nd trimester infection demonstrated less significant interferon signaling, but additional inflammatory activation (NF-kB). These effects were not seen in 1st trimester SARS CoV-2 infection apart from macrophage activation, although sample size limits results.

CONCLUSION: SARS CoV-2 infection was associated with multiple alterations in placental gene regulation with differential activity by trimester of infection. These differences could be related to the severity and timing of infection, and future research should clarify the impact of these factors.

52 Short term risk of cardiovascular disease complications differs depending on the mode of delivery

Gabriella Lobitz[1], Emily B. Rosenfeld[2], Rachel Lee[3], Deepika Sagaram[1], Cande V. Ananth[1]

[1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [2]Robert Wood Johnson Medical School, Rutgers University, New Brunswick, NJ, [3]Flushing Hospital Medical Center, Bayside, NY

OBJECTIVE: Cardiovascular disease (CVD) is an increasingly prevalent problem in females of reproductive age, affecting up to 4% of pregnancies in previously healthy persons. While the physiologic relationship remains unclear, increased fluid shifts, prolonged hypomobility, higher blood loss, hypothermia, and overall stress state triggered by cesarean surgery may affect CVD risk in the postpartum period. The objective of this study is to determine if the mode of delivery affects CVD-related morbidity in a person without prior CVD. We hypothesized that patients that undergo a cesarean delivery (CD) will be at increased risk of non-fatal CVD readmissions one year following delivery.

STUDY DESIGN: We designed a retrospective cohort study utilizing the Nationwide Readmissions Database (2010-2018) to identify singleton delivery hospitalizations. ICD-9 and ICD-10 codes were used to identify patients with readmission for CVD within the calendar year of index delivery. Patients with preexisting CVD hospitalization prior to or during delivery were excluded. Associations between mode of delivery and CVD complications were determined from Cox proportional hazards regression models before and after adjusting for potential confounders.

RESULTS: Of the 30,039,844 deliveries, 32% (n = 9,613,039) underwent a cesarean. CVD readmissions occurred in 255.2 per 100,000 cesarean deliveries compared with 133.9 per 100,000 vaginal deliveries. After controlling for patient and hospital characteristics, as well as hypertensive and diabetic disorders, there remained an increase in readmission for CVD (adjusted hazard ratio [HR] 1.42, 95% confidence interval [CI] 1.35, 1.50), coronary heart disease (adjusted HR 1.46, 95% CI 1.38, 1.50), and stroke (adjusted HR 1.17, 95% CI 1.05, 1.31). The risk of CVD in relation to CD was strongest for heart failure (HR 1.50, 95% CI 1.36, 1.65). The risk of readmission for CVD persisted for one year after delivery (figure 1).

CONCLUSION: Despite the low rates of CVD readmissions overall, cesarean is associated with an increase in cardiovascular morbidity in previously healthy patients.

53 Systematic review of recipient alloimmunization using standard ABO+D versus an extended donor match protocol

Ronan P. Sugrue[1], Marie Elise Abi Antoun[2], Jaxon Olsen[3], Alexandra Stonehill[4], Jennifer J. Cate[1], Virginia Y. Watkins[5], Lesley Skalla[4], Marilyn Telen[4], Andra H. James[6], Jerome J. Federspiel[5]

[1]Duke University, Durham, NC, [2]Tufts University School of Medicine, Boston, MA, [3]Duke University School of Medicine, Salt Lake City, UT, [4]Duke University School of Medicine, Durham, NC, [5]Duke University Hospital, Durham, NC, [6]Duke University Medical Center, Durham, NC

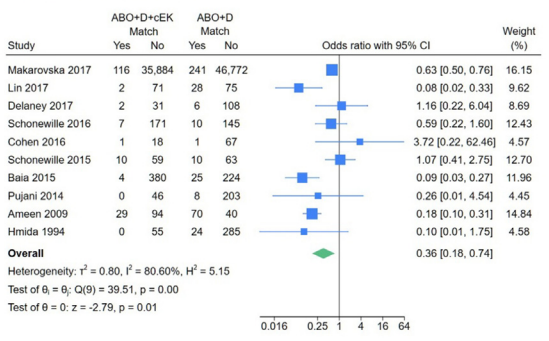
OBJECTIVE: Red blood cell alloimmunization (AI) limits transfusion options and confers risk of hemolytic disease of the fetus and newborn (HDFN). Antigens D, c, E and Kell are particularly pathogenic. Few institutions in the United States routinely match donors for more than ABO and D antigen (ABO+D) when alloantibodies are absent. Several studies have compared new AI among recipients of blood matched for ABO+D to blood additionally matched for c, E and Kell (ABO+D+cEK). The aim of this study was to systematically review and meta-analyze their outcomes.

STUDY DESIGN: Three online databases (Medline via PubMed, Scopus, Embase) were searched for prospective and retrospective cohort studies comparing ABO+D and ABO+D+cEK donor match protocols where new AI was a primary outcome. Case reports, literature reviews and studies of non-human subjects were excluded. The search protocolwas peer-reviewed and published on the PROSPERO international database of meta-analyses (CRD42023411620). Two teams of two reviewers independently screened studies; conflicts resolved by a fifth reviewer. Data were extracted according to Cochrane guidelines; risk of bias measured using ROBINS-I and RoB-2 tools. Random effects meta-analysis was used to combine effect estimates.

RESULTS: In total, 3,533 studies were reviewed. Among 10 that met inclusion criteria, 85,385 patients were transfused, of whom 43.3% (36,980) received only ABO+D+cEKmatched blood. ABO+D+cEK was associated with significantly lower rate of new AI compared with ABO+D (OR: 0.36, 95% CI: 0.18-0.74). Secondary analyses showed similar reductions when excluding studies of intrauterine fetal transfusions (OR 0.27, 95% CI: 0.13-0.58) and when only examining c, E or Kell antigen AI (OR 0.26, 95% CI: 0.13-0.53). As expected, no reduction in D antigen AI was noted (OR 0.77, 95% CI: 0.24-2.52).

CONCLUSION: New alloimmunization is significantly reduced when using an ABO+D+cEK match protocol. Given sequelae of alloimmunization in pregnancy and thereafter, establishing routine use of ABO+D+cEKdonor match in adults of pregnancy potential merits consideration.

Figure 1: Forest plot of effect sizes of extended ABO+D+cEK match versus standard ABO+D match on recipient alloimmunization



54 Azithromycin to Reduce Maternal Infections in Planned Vaginal Birth: Secondary Analysis of the A-PLUS Trial

Waldemar Carlo[1], Alan T. Tita[2], Elizabeth M. McClure[3]

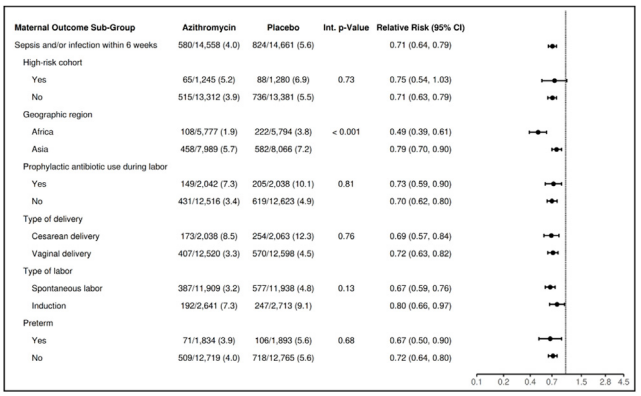
[1]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]RTI International, Durham, NC, on behalf of NICHD Global Network for Women's and Children's Health Research

OBJECTIVE: The intrapartum azithromycin trial (A-PLUS Trial) showed a reduction in maternal sepsis or death mainly driven by sepsis. To test the hypothesis that a single oral dose of intrapartum 2g azithromycin (AZI) in women in labor planning a vaginal delivery reduces the incidence of any maternal infection

STUDY DESIGN: This is a secondary analysis of the A-PLUS Trial involving 29,278 women in seven countries who were randomized to a single oral dose of 2g of AZI vs. placebo. The primary outcome was any maternal infection defined as one or more of any of the following infections after randomization: sepsis (by WHO clinical criteria), chorioamnionitis, endometritis, perineal or cesarean wound infection, abdominopelvic abscess, mastitis/breast abscess, pyelonephritis, pneumonia, and other bacterial infections (meningitis, etc). The relative risk (RR) and 95% confidence interval (CI) of each outcome comparing the azithromycin arm to the placebo arm was estimated using a Poisson model adjusted for treatment arm and site. Subgroup analyses were conducted by: high- and low-risk delivery (high-risk if membrane ruptured ≥8 hours and/or in labor ≥18 hours prior to randomization), region (Africa or Asia), prophylactic antibiotic, delivery mode, type of labor, and preterm/term status. Subgroup analyses included a two-way interaction test between intervention arm and subgroup.

RESULTS: Maternal sepsis or death occurred less often in the azithromycin arm (580/14,558, 4.0%) compared to the placebo arm to 824/14,661, 5.6% in the placebo arm (RR=0.71; 95% CI: [0.64, 0.79], Figure 1). The number needed to treat was 62.

CONCLUSION: In women in labor in low-resource settings planning a vaginal delivery, intrapartum azithromycin was associated with a lower rate of any maternal infection compared to the placebo group and the NNT was 62 or half of the NNT for maternal death and/or sepsis (NNT 125) in the A-PLUS Trial.



55 Infant developmental delays at well visit encounters in infants exposed to MOUD: buprenorphine or methadone

Chaitali Korgaonkar-Cherala[1], Emily H. Stetler[2], Lauren Stewart[2], Oladunni Ogundipe[2], Julia Kim[2], Rakasa Pattanaik[2], David Garry[3], Kimberly Herrera[2], Diana Garretto[4], Cassandra Heiselman[3]
[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel, [2]Stony Brook University Hospital, Stony Brook, NY, [3]Stony Brook Medicine, Stony Brook, NY, [4]Stony Brook University Hospital, E Northport, NY

OBJECTIVE: Infant outcomes as they relate to type of maternal medication for OUD (MOUD) are not well-studied. This study examines differences in social/emotional, language/communication, cognitive, and movement/physical delays in infants exposed to buprenorphine (Bup) versus methadone (Meth) at sequential infant wellness visits.

STUDY DESIGN: This is a retrospective study of patients (N=302) on MOUD who delivered at a single institution between Jan 2017 and Dec 2022. Patients were divided based on MOUD, Bup or Meth. Data was collected including medical comorbidities, parity, psychiatric diagnoses, race, ethnicity, BMI, age, gestational age at birth, and mode of delivery. Infant data included NOWS, NICU admission, and developmental delays noted at infant well visits (2-mo, 4-mo, 6-mo, 9-mo, 12-mo, and 18-mo).

RESULTS: There were 220 (72.8%) patients taking Bup and 82 (27.1%) patients taking Meth. Groups were similar in maternal/neonatal characteristics. NOWS requiring morphine was more likely with Meth than Bup (41.5% v 19.5%, p< 0.01). Compliance with the 12-mo wellness visit was higher in the Bup group than the Meth group (38.4% v 27%, p=0.04); however, there was no difference in compliance between groups at the 18-mo visit (p=0.11). Groups were similar in identification of any delay at visits through 12-mo and 18-mo (p=0.10 and 0.75). A composite infant delay through the 12-mo and 18-mo visit (p=0.22 and 0.74) were also similar. (Table 1) When individualizing specific delays, cognitive delay at the 18-mo visit was significantly higher in the Meth group than the Bup group (17.4% v 2.6%, p=0.02).

CONCLUSION: Infant composite delays were similar based on MOUD, Bup or Meth. When individualizing delays, MOUD with Bup had a lower incidence of cognitive delays at 18-mo compared with Meth. Infant well visit compliance was similar in both groups. Early psychomotor evaluation is important in these MOUD exposed infants.

Table 1: Infant Well Visit Compliance and Developmental Delays at 12-month and 18-month visits with divided based on maternal MOUD: Buprenorphine and Methadone

	Buprenorphine (n=220)	Methadone (n=82)	p-value
12 month wellness visit (n=120)			
Visit compliance	94 (38.4)	27 (27)	0.04
Infant with any delay at visit	9 (9.6)	6 (22.2)	0.10
Social/emotional delay	3 (3.2)	0 (0)	0.81
Language/communication delay	5 (5.3)	4 (14.8)	0.11
Cognitive delay	5 (5.3)	3 (11.1)	0.38
Movement/physical	5 (5.3)	3 (11.1)	0.38
Compliance for all wellness visits through 12 months (n=120)	55 (59.1)	17 (63)	0.72
Any delay at any wellness visit up to 12 months	24 (17.4)	12 (25.5)	0.22
18 month wellness visit (n=140)			
Visit compliance	78 (31.7)	23 (23)	0.11
Infant with any delay at visit	23 (29.5)	6 (26.1)	0.75
Social/emotional delay	3 (3.8)	3 (13)	0.13
Language/communication delay	21 (26.9)	6 (26.1)	0.94
Cognitive delay	2 (2.6)	4 (17.4)	0.02
Movement/physical	3 (3.8)	3 (13)	0.13
Compliance for all wellness visits through 18 months	49 (46.2)	10 (29.4)	0.08
Any delay at any wellness visit up to 18 months	41 (28.9)	16 (31.4)	0.74

56 Transperineal ultrasound-based algorithm advising women after obstetric anal sphincter injury regarding their subsequent delivery mode

Tamar Katzir, Gil Friedman, Edi Vaisbuch, Moshe Gillor
Kaplan Medical Center, Rehovot, HaMerkaz

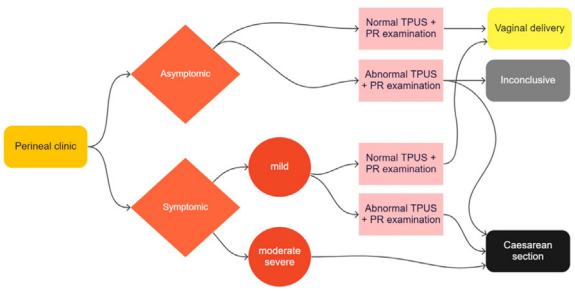
OBJECTIVE: Obstetric anal sphincter injury (OASI) is a severe complication of vaginal delivery (VD) that increases the risk of anal incontinence. Limited validated data is available on the optimal mode of subsequent delivery following OASI, leading to the potential overuse of elective cesarean deliveries (CD). Since 2020, within a dedicated "Perineal trauma" clinic, we have developed and implemented an algorithm utilizing transperineal ultrasound (TPUS), rather than the conventional and commonly used transrectal ultrasound, for consulting women with a history of OASI on the preferred mode of delivery (Figure 1). This study aimed to assess our algorithm's impact on subsequent OASI and elective CD rates.

STUDY DESIGN: This retrospective cohort study included women diagnosed with OASI between 5/2015 and 4/2022 in our hospital. Demographic and delivery data were collected from the electronic medical charts. The study group included women who delivered after 2019 and underwent an assessment according to the TPUS algorithm in our dedicated perineal trauma clinic. The control group included women who delivered before the clinic's establishment and consulted regarding the preferred future delivery mode based on the attending physician's subjective impression. Recommendations for future delivery mode, actual subsequent delivery mode, and recurrent OASI rates were compared between the groups.

RESULTS: Demographic characteristics were comparable between the study (n=57) and control (n=73) groups. The rate of 3a-degree perineal tear was higher, and unclassified 3rd-degree perineal tear was lower in the study group (52% vs. 7%, p=0.001 and 7% vs. 18%, p=0.07). Women in the study group were more reassured to deliver vaginally (66% vs. 10%, p< 0.001). Indeed, their subsequent VD rate was higher (53% vs. 21%, p< 0.001) without an increase in the recurrent OASI rate (0% vs. 9%, p=0.24).

CONCLUSION: Consulting women after OASI regarding their preferred mode of subsequent delivery in a dedicated perineal trauma clinic, using a TPUS-based algorithm, reduced elective CD rates without increasing the rate of recurrent OASI.

Figure 1: Algorithm advising women after vaginal delivery with OASI on the subsequent mode of delivery



TPUS, Trans Perineal ultrasound; PR, per rectum; SMIS, St Mark's score of anal incontinence; EAS, external anal sphincter

Mild symptoms were defined as SMIS≤2 with a visual analog scale (VAS) of anal incontinence ≤3. Abnormal TPUS was defined as a defect of ≥30° in the EAS in ≥4/6 slices. Abnormal PR was defined as a weak anal sphincter contraction during rectal examination (3 or less on a scale of 0-5).

57 Inter-pregnancy interval and uterine rupture among more than 500,000 Trials of Labor after Cesarean (TOLAC)

Bradley de Vries[1], Pejman Adily[2], Travis Bettison[3], Vincenzo Berghella[4], Adam Mackie[3], Rajit Narayan[3], George Johnson[1], Marjan Mosalman Haghighi[1]

[1]Sydney Institute for Women, Children and their Families, Camperdown, New South Wales, [2]Sydney Institute for Women, Children and their Families, Sydney, New South Wales, [3]Royal Prince Alfred Hospital, New South Wales, [4]Jefferson Medical College, Philadelphia, PA, on behalf of the Sydney Institute for Women, Children and their Families

OBJECTIVE: To describe the association between inter-pregnancy interval (IPI) and uterine rupture among individuals attempting TOLAC.

STUDY DESIGN: This retrospective cohort study used US CDC data including birth and fetal death data files (2011-2021) and Period/Cohort Linked Birth-Infant Death Data Files (2014-2019). Participants had one previous livebirth by cesarean delivery (CD), no previous vaginal births and an immediately subsequent TOLAC. Rates of uterine rupture were described by IPI group and univariable logistic regression with first-order splines with one knot. Multiple imputation and multivariable logistic regression were used.

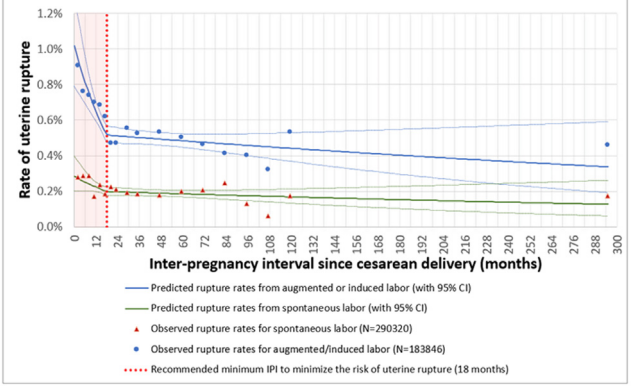
RESULTS: Among 42.5 million births, 506 666 TOLACs immediately after a CD were included in the multivariable logistic regression.

The raw rate of uterine rupture was 0.40% for IPIs < 18 months (95%CI 0.37-0.44%) and 0.30% for IPIs ≥18 months (95%CI 0.28-0.32%). The Figure shows rates of uterine rupture by IPI and the predicted probabilities of rupture in the univariable spline regression for induced/augmented and spontaneous labors. There was a linear decrease with increasing IPI until 18 months and subsequent relatively constant rates.

The odds ratio was 1.94 for an IPI < 3 months (95%CI 1.73 to 2.06), progressively decreasing to 1.15 for an IPI from 15 to < 18 months (95%CI 1.10 to 1.21) compared with IPI 4-5 years after adjusting for confounders. Uterine rupture was associated with increasing age, decreasing height, higher gestation, higher birthweight, and induced/augmented labors. It was not associated with hypertension, gestational diabetes or smoking. The rate of uterine rupture with stillbirth or neonatal death was 0.012% (1:8413) for IPI < 18 months (95%CI 0.00-0.02%) and 0.018% (1:5614) for IPI ≥18 months (95%CI 0.01-0.02%).

CONCLUSION: Shorter IPI is strongly associated with an increase in uterine rupture in TOLAC with the odds ratio falling sharply between 0 and 18 months. An IPI of at least 18 months should be recommended to achieve the lowest incidence of uterine rupture during TOLAC.

Figure: Predicted (solid curve) and observed (point estimates) uterine rupture rates versus inter-pregnancy interval by onset of labour type among 506,666 trials of labor for parturients with one previous cesarean delivery and no previous vaginal births



58 Prenatal herbicide exposure and newborn size in a Ghanaian cohort

Kwaku Poku asante[1], Kaali Seyram[1], Mohammed Mujtaba Nuhu[2], Elizabeth Gibson[3], Alison Lee[4], Kennetha A. Ae-Ngibise[2], Anna M. Modest[5], Ellen Boamah[1], Jones Opoku-Mensah[2], Austin M. Oberlin[6], Oscar Agyei[2], Russ Hauser[3], Abena Konadu Yawson[2], Darby Jack[7], Brent Coull[3], Blair Wylie[8]

[1]Kintampo Health Research Centre, Brong Ahafo, Ghana, [2]Kintampo Health Research Centre, Kintampo, Brong-Ahafo, [3]Harvard T.H. Chan School of Public Health, Boston, MA, [4]Mount Sinai Hospital, New York, NY, [5]Beth Israel Deaconess Medical Center, Boston, MA, [6]Columbia University Irving Medical Center, New York, NY, [7]Mailman School of Public Health, New York, NY, [8]Columbia University, New York, NY

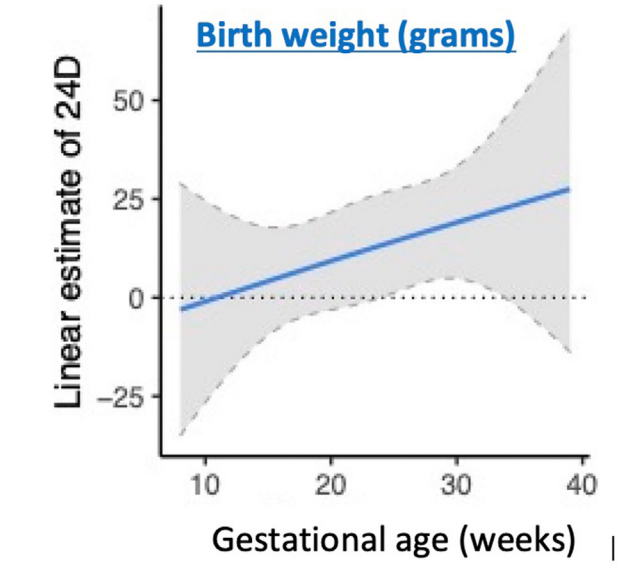
OBJECTIVE: Widely used herbicides may act as endocrine disruptors. Herbicide biomarkers are routinely detected, and levels are increasing, among pregnant people around the globe. Epidemiologic studies evaluating the impacts of herbicides during pregnancy are limited. We aimed to determine associations between urinary prenatal herbicide concentrations and newborn size, an important marker of future infant health, and to identify critical windows of vulnerability.

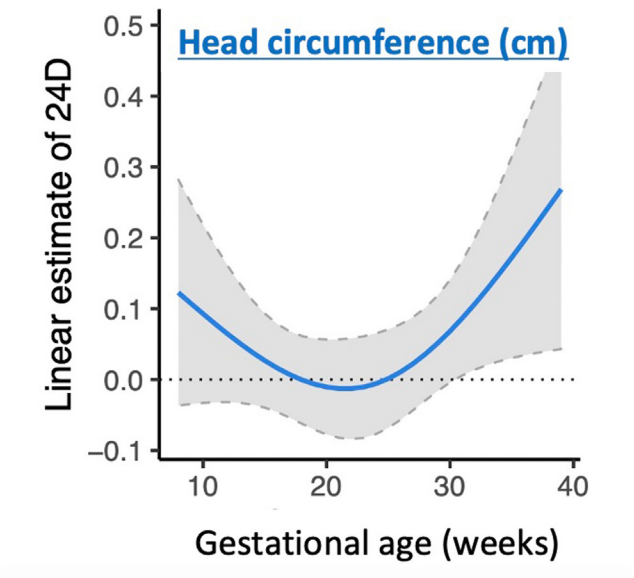
STUDY DESIGN: In a prospective Ghanaian prenatal cohort using repeated urine samples across pregnancy, we measured 2,4-dichlorophenoxyacetic acid (2,4D), a widely used weed killer. We extended multiple informant models with time-varying coefficients to account for the short $^1/_2$ -life of 2,4D and examined variable associations of creatinine-corrected 2,4D concentrations across pregnancy with newborn weight, length, and head circumference. We adjusted for key environmental co-exposures (air pollution, pesticides) and confounders (parity, BMI, wealth, malaria) and examined effect modification by infant sex.

RESULTS: Among samples from 1,152 pregnant participants, 58% had detectable 2,4D with median prenatal exposure of 0.19 μcg/mL (IQR 0.11-0.49). Prenatal 2,4D exposure was associated with significant increases in birth weight during weeks 24-33 and head

circumference during weeks 31-39 (Figure). Averaged across pregnancy, a doubling of exposure in any given week increased birth weight by 11.5 grams (95%CI 1.5, 21.5) with a stronger association among males (16.8; 95%CI 2.2, 31.4). The average association between 2,4D and head circumference was not statistically significant. We found no evidence of a relationship with birth length.

CONCLUSION: Prenatal exposure to 2,4D, a widely used herbicide, was associated with increased birth weight and head circumference in this Ghanaian cohort. While the increase is modest for a given week, repeated exposures may result in larger cumulative effects. Follow up during childhood is ongoing to determine whether this chemical is acting as an *in utero* obesogen.





59 Assessment of Labor Unit Culture as a Factor in Safely Reducing Cesarean Births

Althea Bourdeau[1], Emily White VanGompel[2], Elizabeth S. Langen[1], Lisa Kane Low[1]

[1]University of Michigan, Ann Arbor, MI, [2]NorthShore University HealthSystem, Chicago, IL

OBJECTIVE: To assess the association between maternity unit culture and the rate of nulliparous, term, singleton, vertex cesarean births (NTSV CB) at the hospital level.

STUDY DESIGN: Clinicians at Michigan birthing hospitals participating in the Obstetrics Initiative perinatal quality collaborative funded by Blue Cross Blue Shield of Michigan, were invited to complete the Labor Culture Survey (LCS). The LCS includes 28 Likert-style items covering 7 subscales measuring individual attitudes, beliefs and perceptions of unit practices. Descriptive statistics and multivariate Poisson regression (controlling for hospital birth volume, location, nursery acuity level, BMI $>$ 30, age $>$ 35 years, and Medicaid as primary insurance) were conducted to measure association between hospital-level means on each subscale and hospital-level NTSV CB rates. Sites with abstracted data in 2020 and 2021 (n = 67) were included in descriptive analyses, and sites that had $\geq$ a 30% response rate and one OBGYN responder ("responder sites"; n = 53) were included in Poisson modeling.

RESULTS: The LCS was completed by 3,222 clinicians.The Fear, Unit Microculture, and Cesarean Safety subscales were associated with hospital NTSV CB rates (Table 1). A one point increase in the Fear subscale (personal concerns) was associated with a relative 51.3% increase ($p< 0.001$) and a one-point increase in the Cesarean safety (estimation of birth risk) subscale was associated with a relative 44.5% increase in the NTSV CB rate ($p< 0.001$); conversely, a one-point increase in the Unit Microculture subscale (assessment of unit practices that support vaginal birth) was associated with a relative 29.6% decrease in the NTSV CB rate (p=0.049).

CONCLUSION: Understanding unit culture is an important step in addressing NTSV CB rates. While individual attitudes such as fear of vaginal birth and perception of Cesarean safety may be deeply entrenched, improving unit microculture (e.g. use of evidence based practices/policies, nurses providing labor support) may represent a key focus area for quality improvement champions.

Relationship between Labor Culture Survey subscale score and NTSV CB rate

LCS subscale	Estimate (95% CI)	Relative risk
Best Practices	-0.29 (-0.65, 0.08)	0.748
Fear`	-0.67 (-1.01 ,- 0.33)	0.513**
Unit Microculture	-0.35 (-0.70 , 0.00)	0.704*
Physician Oversight	-0.08 (-0.43, 0.27)	0.923
Maternal Agency	-0.34 (-0.67, 0.00)	0.712
Cesarean Safety`	-0.81 (-1.23, -0.39)	0.445**
Unit Norms	-0.11 (-0.36, 0.14)	0.896
Vaginal Birth Microculture	-0.13 (-0.39, 0.13)	0.878
Patient Safety Culture	-0.06 (-0.29, 0.16)	0.942

`Subscale is reverse-coded

*P < 0.05; **P < 0.001

Includes hospitals with at least one OBGYN survey respondent and a response rate >= 30%. Adjusted for hospital annual birth volume, geographic location, nursing acuity level, birthing person % BMI > 30, birthing person % age > 35y, and birthing person % Medicaid as primary insurance.

60 Predicting chorioamnionitis using AI-based methods: a retrospective cohort study

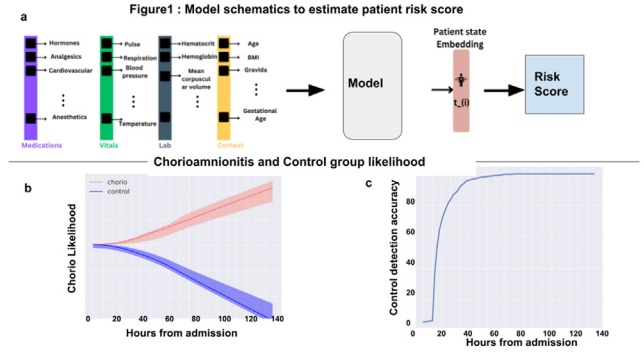
Anne R. Waldrop[1], Tomin K. James[1], Sanaa Suharwardy[2], Manual Studer[1], Alan Chang[1], Camilo Espinosa Bernal[1], Feng Xie[1], Sayane Shome[1], Debapriya Hazra[1], Yera Kim[1], Geetha Clarke[1], Dipro Chakraborty[1], Samson Mataraso[1], Eloise Berson[1], Lei Xue[1], Seyedeh Payrovnaziri[1], Neshat Mohammadi[1], William Haberkorn[1], Ivana Maric[2], Yasser Y. El-Sayed[2], Brendan Carvalho[2], Nima Aghaeepour[2]
[1]Stanford University, Palo Alto, CA, [2]Stanford University, Stanford, CA

OBJECTIVE: Diagnosing chorioamnionitis remains challenging due to its non-specific clinical manifestations and the reliance on invasive testing. This study introduces a state-of-the-art machine learning model designed to diagnose chorioamnionitis early and accurately by harnessing the power of routinely collected Electronic Health Record (EHR) data.

STUDY DESIGN: EHR data collected from inpatient delivery admission from 2012-2018 at Stanford Hospital were utilized to devise a mathematical model representing patient health.The timing of clinical chorioamnionitis diagnosis was determined by the initiation of chorioamnionitis specific antibiotics. Utilizing over 75 variables including birthing parent demographics, inpatient vital signs, labor interventions, administered medications, and laboratory test results from the delivery admission, we created birthing parent representations through a transformer encoder-based neural network (Figure 1. a). This model was combined with a Hidden Markov Model for real-time chorioamnionitis risk assessment during a patient's stay (Fig 1.a).

RESULTS: Our analysis included 25,723 pregnant persons, of which 12% were diagnosed with chorioamnionitis during their delivery admission. Our model demonstrated an 80% success rate in pre-empting the conventional, clinical diagnosis of chorioamnionitis (Fig 1. b). On average, our model diagnosed chorioamnionitis 4.5 hours earlier than the clinical diagnoses. Moreover, 90% of unaffected patients were correctly identified within their initial 24 hours of hospital admission (Fig 1.c).

CONCLUSION: This study serves as a proof-of-concept that the application of artificial intelligence with delivery admission EHR data may aid in the accurate and more timely diagnosis of chorioamnionitis. By transcending the limitations of traditional diagnostic methods, our approach offers a data-driven tool capable of generating individualized risk profiles. Pending external validation, this methodology could usher in more personalized, timely interventions, with the potential to enhance both maternal and neonatal outcomes.



61 A Pilot Study for Implementation of a Virtual Group Prenatal Genetics Counseling Program

Sarah J. Weingarten[1], Erika Brockhoff, MS[1], Eliana Spielman[1], Heather S. Lipkind, MD, MS[1], Jessica Scholl, MD[1]
[1]Weill Cornell Medicine, New York, NY

OBJECTIVE: ACOG endorses nondirective pretest counseling regarding prenatal genetic testing options. Pretest counseling is often performed by the obstetrician at the first prenatal visit. To provide more standardized and available genetic counseling, we initiated free monthly group genetics virtual sessions. Using survey data, we aimed to determine whether the sessions improved patients' knowledge and comfort levels surrounding prenatal testing.

STUDY DESIGN: All English-speaking obstetric patients were encouraged to enroll in a virtual 60-minute webinar, led by a certified genetic counselor and an MFM. Pre- and post-session surveys were provided to all attendees, which included sociodemographics and a questionnaire modified from validated scales. Survey data were collected from March to June 2023. Patients were divided into two groups for score comparison, depending on whether they had prior pretest counseling as part of standard prenatal care. Statistical analyses included Mann-Whitney U, Chi-square, and ANOVA modeling for comparison of score changes.

RESULTS: Of the 231 patients who attended a webinar, 40% completed the surveys (Table 1). Prior to the sessions, 59% of patients reported feeling comfortable understanding their prenatal testing options compared to 99% after the sessions ($p< 0.001$). There was an increase in those reporting having the tools to make decisions about genetic testing (54% pre- vs 99% post-session, $p< 0.001$) and reporting that their decisions reflect what is important to them (64% pre- vs 81% post-session, $p=0.009$). The session was valuable to 96% of participants. There were no differences in pre- vs post-session scores related to anxiety. When comparing survey data among those who had prior standard counseling to those who had not, the improvement in scores remained present after adjusting for covariates (Table 1).

CONCLUSION: Standardized group genetic counseling appears beneficial to patients, even among those with prior counseling by their obstetric providers. Future directions include assessment of a larger, more diverse patient population to support broader implementation.

Table 1: Demographics and survey data among patients participating in virtual group genetics counseling

	Patients with prior counseling (n = 34)	Patients without prior counseling (n = 53)	p-value
Maternal age, years	35	34	0.74
Gestational age at virtual session	10w2d	6w6d	< 0.001
Nulliparity	25 (73.5)	43 (81)	0.70

[a]When asked, "Using a scale of 1-5, I feel comfortable understanding the prenatal testing options available to me" (1=extremely uncomfortable, 5=extremely comfortable).
[b]When asked, "Using a scale of 1-5, I feel I have the tools to make decisions around genetic testing that will influence my family's future." (1=strongly disagree, 5=strongly agree).
[c]When asked, "Using a scale of 1-5, My decisions around genetic testing reflect what is important to me." (1=strongly disagree, 5=strongly agree).
[d]When asked, "Using a scale of 1-5, I am worried about making decisions regarding genetic testing." (1=not worried, 5=very worried).
[e]When asked, "Using a scale of 1-5, I am worried about what I will do if a genetic test shows an abnormality." (1=not worried, 5=very worried).

62 Genetic Health Literacy in an Urban Southeastern Population

Akila Subramaniam[1], Yuanfan Ye[1], Victoria C. Jauk[1], Fallon Brewer[2], Taylor Dunn[2], Anna Hurst[2], Brian M. Casey[2]
[1]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: As prenatal genetic screening and diagnostic testing is recommended for all pregnant persons, we sought to evaluate genetic literacy in an urban population in the Southeast.

STUDY DESIGN: Prospective study of all individuals seeking prenatal care at the University of Alabama at Birmingham from 3/2020-8/2022. Consenting individuals were administered a computer-based survey which included an introduction to genetic screening/diagnostic testing and assessed patient attitudes towards genetic testing. Genetic literacy was assessed using two validated measures: the Genetic Literacy and Comprehension (GLAC), which assesses a patient's self-reported familiarity with 8 genetics terms, and the Genetic Knowledge Survey (GKS) which assesses correctness on 16 genetics questions. Mean scores for both instruments as well as GKS score ranges (Table) were computed for the overall population. Scores were compared between private vs. public insured groups and low-risk vs. high-risk populations (referred for potential genetic abnormalities e.g., abnormal genetic screening, fetal anomalies) using appropriate tests.

RESULTS: A total of 1596 people were approached for this study, of whom 895 enrolled. Of these, 776 were low-risk (53.6% publicly insured) and 119 high-risk (54.5% publicly insured). Our cohort was on average 27±6 yrs old, primarily Black (55%), with at least a high school education (92%). The overall mean GLAC score was 5.2±2.3 and was significantly higher in privately insured patients and those with high genetic risk (Table). GKS scores were overall low in our cohort (6.9 ± 4.7), with lower scores among publicly insured participants (Table). GKS scores were similar among low and high-risk groups (p=0.095). While rates of high knowledge were greatest in those with private insurance (13.9%), high GKS scores were infrequent (Table).

CONCLUSION: While pregnant individuals report familiarity with genetic terms, they do not have high genetic knowledge. Efforts to improve genetic knowledge are urgently needed, so that pregnant patients can make informed decisions about prenatal genetic screening and diagnosis.

	Overall Cohort (n=895)	Low-Risk (n=776)	High-Risk (n=119)	p-value*	Low-Risk Public Insurance (n=416)	Low-Risk Private Insurance (n=360)	p-value**
GLAC Score (mean ± SD)	5.2 ± 2.3	5.2 ± 2.3	5.7 ± 2.1	0.031	4.2 ±2.4	6.2 ± 1.7	<0.0001
GKS Score (mean ± SD)	6.9 ± 4.7	6.8 ± 4.7	7.5 ± 4.5	0.095	5.0 ± 3.9	8.8 ± 5.0	<0.0001
GKS Score Range				0.018			<0.0001
<7 (low)	42.3%	43.9%	31.9%		58.2%	27.5%

63 A Novel Index to Assess Association Between Structural Racism and Black/White Stillbirth Rate Disparities

Sebastian Ramos[1], Erika F. Werner[1], Chloe E. Bird[2], Ndidiamaka Amutah-Onukagha[3], Michael B. Siegel[1]
[1]Tufts University School of Medicine, Boston, MA, [2]Center for Health Equity Research, Boston, MA, [3]Department of Public Health and Community Medicine, Boston, MA

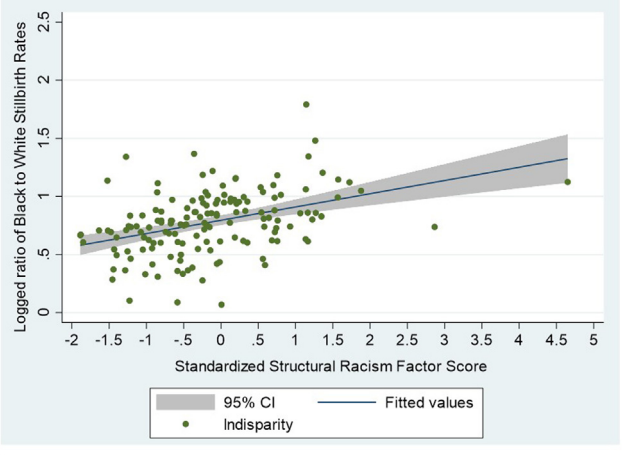
OBJECTIVE: Racial disparities in stillbirth rates are well-documented but the association with structural racism has not been adequately studied. Using the Structural Racism Index, a novel index that assesses Black/White disparities in multiple socioeconomic indicators and quantifies exposure to systemic inequalities, this study investigates the relationship between structural racism and Black/White stillbirth rate disparities across US counties.

STUDY DESIGN: Using CDC Vital Statistics data from 2016 - 2019, stillbirth rates were calculated for non-Hispanic Black (NHB) compared to non-Hispanic White (NHW) populations at the county level. The Structural Racism Index (SRI) and its relationship to differences in stillbirth rates by race was studied. Analyses were restricted to counties with more than 50,000 Black residents and at least 10 stillbirths to assure model stability. Linear regression of the stillbirth rate were performed and adjusted for county level access to resources using the CDC's Social Vulnerability Index (SVI) and other county level socioeconomic factors.

RESULTS: A total of 149 counties, representing 1.5 million residents and 70% of the US Black population, met inclusion criteria. The average stillbirth rate was 10.4 in the NHB population versus 5.3 per 1000 in the NHW population. After adjusting for SVI, each standard deviation increase in the SRI score still resulted in a 12% increase in the rate of stillbirth disparity (aOR 1.12, 95% CI 1.07-1.17). The disparity in rates was not explained by county level differences in social vulnerability as measured by the SVI or county level factors like education, unemployment, or poverty.

CONCLUSION: There are significant racial disparities in rates of stillbirth between NHB and NHW populations at the US county level and structural racism as measured by the Structural Racism Index is strongly associated with these differences. Measures such as the CDC's SVI do not adequately account for the differences observed thus other measures such as the SRI should be considered to better understand how exposure to structural racism leads to worse health outcomes.

Figure 1: Correlation between county structural racism factor scores and the logged ratio of county-level Non-Hispanic Black to Non-Hispanic White stillbirth rates in US counties[1], 2016-2019 (N=149)



[1]Counties with > 50,000 Black residents and more than 10 stillbirths

64 Exploring Black birthing people's perspectives on racial concordance with obstetric care providers

E. Nicole Teal, Aryana Daye, Kayla Blades, Kathryn Menard, Karen Sheffield-Abdullah
University of North Carolina at Chapel Hill, Chapel Hill, NC

OBJECTIVE: The qualitative aim of this multi-method study was to explore Black birthing people's lived experiences within obstetric care and their perspectives on racial concordance with obstetric providers.

STUDY DESIGN: In this study, we used a qualitative descriptive approach to conduct 1-on-1 semi-structured interviews (n=16) and 5 focus groups (FGs; n=16) in a sample of individuals who self-identified as Black or African American, were $\geq$ 18 years of age, delivered a baby with the university health system between 2019-2021, and were English-speaking. Potentially eligible individuals were identified via electronic health record data then recruited and consented electronically. Interview and FG guides were co-created by the research team and were utilized to elicit discussion regarding lifetime experiences with racism and discrimination, experiences with the healthcare system during pregnancy, and perspectives on racial concordance with obstetric providers. Interviews and FGs were conducted by experienced researchers who identify as Black women. They were audio-recorded, transcribed, and data was de-identified for analysis. Thematic analysis was used to group codes into larger themes.

RESULTS: All 32 participants included in the analysis identified as non-Hispanic Black women. Their mean age was 34 years, nearly 63% were married, and 72% had a bachelor's degree or higher. Themes that emerged were: (1) desire for racially concordant providers, (2) difficulty finding racially concordant providers, (3) experience of stereotyping during obstetric care, (4) not being heard by obstetric providers and staff, and (5) fear of dying in pregnancy/childbirth. Representative quotes for each theme are presented in Table 1.

CONCLUSION: Black birthing people in this study shared a clear preference for racially concordant obstetric providers, citing experiences of discrimination and racism in their lifetimes and during obstetric care as driving factors, and lamented how difficult it is to find this. Increasing opportunities for racially concordant obstetric care may be one strategy for improving care for Black birthing people.

Table 1. Themes and representative quotes

	Themes	Quotes
1	Desire for racially concordant providers	"I really would have loved to have a couple of Black midwives... I would have loved to have had **somebody that looked like me.**" (P241) "**I was actually a little hesitant to see the providers who were White in the office**, just because of the... discrimination that I have experienced throughout my lifetime and the discrimination that I see my friends and my family experience and also the discrimination that you witness on the news and see on TV." (P126) "There's just an innate knowledge and understanding that you would have for someone [of the same race]." (P376) "So because I was terrified, and this was my fourth C-section, I told my doctors because my doctor is a White woman and I told her **I really would like a Black woman in there.** Because you know, I'm just afraid." (FG5E) "Then this last labor was a rainbow coalition of people and **I had more Black women involved in the pregnancy and delivery process and it made so much of a difference** that I would say it was definitely mandatory." (FG5E)
2	Difficulty finding racially concordant providers	"I was actually trying to find African American or Black physician doctor [that was] female, preferably for high risk. **That was so hard. Oh, so hard.**" (P376) "**I didn't have anybody that actually looked like me.**" (P405)
3	Not being heard	"**I did not feel heard**. I didn't feel like they were taking me seriously." (P165) "I was talking to a White provider. And I felt like I was I was trying to express my concerns, but I felt like she wasn't listening to them, and she was just kind of brushing them off as in **not taking me seriously.**" (P126) "I've run into a lot of White male doctors that clearly were **not listening and did not take me seriously.** I've also run into a lot of female, White female nurses that **clearly did not care.**" (P165)
4	Stereotyping	"She's like, you know, well, abortion is an option especially if you don't know the dad. I'm just like, wait a minute, I do know who my child's dad is... 'Oh, so y'all actually managed to stay together?' Just like why is it so much of a surprise? **I'm sorry, am I meant to be a single mother?**" (P220) "This one nurse... kept asking me do I need a social worker? Do I need WIC? Did I need all these things? And I'm like, what, what in my profile is making you ask these questions, are these normal questions? **Or are you asking me this because I'm Black?**" (P241)
5	Fear of dying	"I was so scared because I'm like, **I might die with this pregnancy**. Like that was the first thought in my head. I could very well die just from simply getting pregnant and because I decided to have a child." (FG2A) "**I was definitely concerned about dying in childbirth or afterwards.**" (P165)

65 Prophylactic Antibiotics after Cesarean Trial (PACT): A Randomized Control Trial

Brett Goldman[1], Nicholas Spencer[2], Maggie Kuhlmann[3], Mollie McDonnold[4], George R. Saade[5], Antonio F. Saad[2]
[1]University of Texas Medical Branch, Dickinson, TX, [2]University of Texas Medical Branch, Galveston, TX, [3]University of Nebraska Medical Center, Omaha, NE, [4]St. David's Women's Center of Texas, Austin, TX, [5]Eastern Virginia Medical School, Norfolk, VA

OBJECTIVE: A trial of postoperative antibiotics as prophylaxis for post-cesarean surgical site infections (SSI) noted a benefit in obese patients with ruptured membranes. However, this was before pre-incision extended antibiotic prophylaxis with adjunctive azithromycin. We sought to assess if 48-hour post-cesarean antibiotics reduce infectious morbidity in the era of extended pre-operative prophylaxis.

STUDY DESIGN: Between 8/2017 to 3/2023, we conducted a double-blinded randomized clinical trial that included obese patients undergoing cesarean with > 4 hours of ruptured membranes. section following the administration of extended-spectrum pre-operative prophylaxis. Participants with chorioamnionitis, immunosuppression, antibiotic contraindications, or planned post-operative antibiotics were excluded. Subjects were assigned randomly to cephalexin 500mg and metronidazole 500mg PO q8hrs for 48 hours post-operatively (cefalexin-metronidazole) vs. placebo (control). Per clinical practice, both groups received extended-spectrum pre-skin incision prophylaxis with cephazolin and azithromycin. The primary outcome was a composite of endometritis, SSI, or other post-cesarean infections within 30 days of delivery. Secondary outcomes included incisional morbidity, fevers, and other surgical wound complications. Analysis was performed by intention-to-treat as well as per protocol.

RESULTS: Among 321 randomized participants, 284 (88.4%) completed the 30-day follow-up. The median age was 27.8 years, and BMI was 38 kg/m2. Baseline characteristics were balanced between the 2 groups. There was no difference in the primary outcome between the active and placebo groups (5.0% vs 6.9%, RR 0.71, 95% CI, 0.26-1.91]. No significant differences were found between groups for other prespecified secondary outcomes, including rates of incisional morbidity, fever, wound separation, or endometritis (Table).

CONCLUSION: The previously noted benefit of postoperative antibiotics for post-cesarean prophylaxis in obese patients was not seen in the pre-incision extended antibiotic regimen era. A larger trial is unlikely to find differences.

Study Outcomes				
Intention to Treat	Cephalexin-Metronidazole (n=160)	Placebo (n= 161)	Relative Risk (95% CI)	P Value
Primary Outcomes	n (%)	n (%)

66 Oral Analgesia in Fixed-Time Interval vs. On-Demand following Vaginal Delivery: A Randomized Controlled Trial

Gal Bachar[1], Naphtali Justman[2], Gili Buchnik Fater[3], Naama Farago[3], Chen Ben David[1], Hiba Abu-Rass[3], Yoav Siegler[2], Areen Hajaj[1], Yaniv zipori[4], Nizar khatib[5], Zeev Weiner[3], Dana Vitner[6]
[1]Rambam Healthcare Campus, Haifa, Hefa, [2]Rambam Medical Center, Haifa, Hefa, [3]Rambam Medical Health Campus, Haifa, HaZafon, [4]Rambam Health Care Campus, Haifa, Israel, [5]Rambam Healthcare Campus, Acre, Israel, [6]Rambam Medical Health Campus, Toronto, ON

OBJECTIVE: To compare the efficacy of a fixed-time-interval oral analgesia compared to on-demand protocols for the management of post-vaginal delivery pain in the first 24 hours postpartum.

STUDY DESIGN: We performed a randomized, prospective, controlled trial, at a single tertiary medical center, between June 2020 to June 2022. Vaginally delivered women were randomly assigned to one of two groups: group 1: oral analgesics of Paracetamol 1 g + Ibuprofen 400 mg every 6 h for the first 24 hours postpartum (per-protocol analgesia group); group 2: same oral analgesics according to maternal request (on-demand group). The primary outcome was pain level during the 1st 24 hours post-delivery, measured on a 10-point visual analog scale (VAS). We estimated that 100 women per group would provide 80% power to identify a 20% difference in the primary outcome.

RESULTS: From 2020-2022, 200 women were enrolled and included in the analysis: 100 (50%) in study group (per-protocol analgesia) and 100 (50%) in control group (on-demand analgesia). Baseline and delivery characteristics were comparable for all relevant variables, including oxytocin augmentation, epidural anesthesia, episiotomy rate and neonatal weight. VAS score was comparable between study groups (5.31±1.92 vs. 5.29±1.67, p=0.626), even following sub-analysis for nulliparity, episiotomy, and vacuum assisted delivery. However, breastfeeding rates were higher in the per-protocol analgesia group (98% vs. 88%, p=0.006). Additionally, higher satisfaction rates were found among the per-protocol analgesia

group (p< 0.05). Women in the per-protocol group received more analgesic treatment with no reported side effects.

CONCLUSION: A fixed analgesic protocol for postpartum pain management, compared with an on-demand protocol, following vaginal delivery, is associated with higher breastfeeding rates and better maternal satisfaction though similar VAS scores.

Table 1. Pain management characteristics and outcomes.

Variable	Per-protocol analgesia n=100	As-needed analgesia n=100	P-value
Analgesics ≤ 24h, mean ± SD			
Paracetamol	2.9 ± 1.3	0.8 ± 1.1	< 0.001
Ibuprofen	2.9 ± 1.2	0.7 ± 1.1	
Analgesics > 24h, mean ± SD			
Paracetamol	2.9 ± 2.3	0.9 ± 1.3	< 0.001
Ibuprofen	5.9 ± 4.5	0.5 ± 1.1	
Average VAS, 24 h, mean ± SD			
All patients	5.31 ± 1.92	5.29 ± 1.67	0.626
Episiotomy	5.38 ± 1.91	5.17 ± 1.84	0.326
Nulliparous	5.53 ± 1.71	5.39 ± 1.78	0.878
Vacuum assisted delivery	4.28 ± 1.89	6.27 ± 1.79	0.126
Infant Feeding status, n (%)			
Breastfeeding	88 (88)	98 (98)	0.006

VAS, visual analog scale.

+BSS-30 (Birth Satisfaction Scale) is a valid and reliable scale designed to assess women's experiences of labor and childbirth. The questionnaire has 3 components: quality control (QC), women's attributes (WA) and stress experienced (SE).

P < 0.05 is considered significant.

67 Association of body mass index with pain and opioid use after cesarean delivery

Hyagriv Simhan[1], **Hector Mendez Figueroa**[2]

[1]University of Pittsburgh, Pittsburgh, PA, [2]University of Texas Health Science Center at Houston, Houston, TX, for the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: To ascertain whether the amount of opioid analgesia used after cesarean delivery (CD) differed among those with body mass index (BMI) < 30 vs. ≥ 30 m/kg2

STUDY DESIGN: Secondary analysis of a multicenter randomized trial of individuals who had undergone CD and were randomly assigned, within 1 day prior to planned discharge to an individualized opioid prescribing plan (IOPP) or a fixed quantity of opioids upon discharge at 31 U.S. hospitals (2020-22). The primary exposure was delivery BMI. The primary outcome was inpatient oral opioid use in morphine milligram equivalents (MME) in the 24 hours prior to randomization. Secondary outcomes included outpatient opioid use calculated as number of tablets taken through 6 weeks postpartum and moderate-severe (score ≥4) perceived pain and interference in daily activities on the Brief Pain Inventory (BPI, 1-10) at 1-week postpartum. Multivariable modeling evaluated the association between BMI (with BMI < 30 kg/m2 as referent group) and opioid use and pain scores.

RESULTS: Of 4,768 included individuals, 3,556 (74.6%) had BMI ≥ 30 m/kg2. Those with BMI ≥ 30 m/kg2 were more likely to have government assisted insurance, diabetes, and hypertension/pre-eclampsia, and less likely to be £ 19 years old or nulliparous. Individuals with BMI ≥ 30 m/kg2 used more opioids in the 24h prior to discharge and requested more oxycodone tablets at discharge. They used more oxycodone tablets at 1, 2 and 6 weeks post discharge, and reported a higher frequency of moderate to severe pain at baseline and at all time points assessed through 6-weeks. (Table). The association between obesity and the magnitude of pain relief did not differ by opioid use prior to discharge (p=0.56) or at the 1-week visit (p=0.45).

CONCLUSION: Individuals with BMI ≥ 30 m/kg2 use more opioids post-cesarean and after hospital discharge than individuals with BMI < 30 kg/m2. Despite this greater use, they demonstrate slightly poorer pain relief than subjects with BMI < 30 kg/m2.

Body Mass Index Category, opioid use and pain

	Body mass index ≥ 30 kg/m² (N=3,556)	Body mass index < 30 kg/m² (N=1,212)	p	Adjusted median difference & 95% CI
MMEs consumed in 24 hours prior to randomization	15 (0, 37.5)	10 (0, 30)	< 0.001	5 (2.8, 7.2)
Number of Oxycodone 5 mg tablets requested at discharge (IOPP group only)	15 (8, 20)	10 (5, 20)	< 0.001	3.5 (2.1, 4.9)
Number Oxycodone 5 mg tablets used at 1-week, N=4,273	5 (0, 10)	3 (0, 10)	< 0.001	1 (0.4, 1.6)
Number Oxycodone 5 mg tablets used at 2-weeks, N=4,373	5 (0, 14)	3 (0, 12)	< 0.001	1.7 (0.9, 2.4)
Number Oxycodone 5 mg tablets used at 6-weeks, N=3,862	6 (0, 15)	3 (0, 12)	< 0.001	2 (1.3, 2.7)
	Body mass index ≥ 30 kg/m² (N=3,556)	Body mass index < 30 kg/m² (N=1,212)	p	Adjusted odds ratio & 95% CI

BPI Moderate to severe pain 1-week, N=4,396	1,996 (60.8)	624 (56.0)	0.005	1.11 (0.96, 1.28)
BPI Moderate to severe pain 2-weeks, N=4,333	1,076 (33.1)	279 (25.8)	< 0.001	1.22 (1.04, 1.44)
BPI Moderate to severe pain 6-weeks, N=4,328	390 (12.0)	100 (9.2)	0.01	1.08 (0.84, 1.37)
BPI Moderate to severe pain 90-days, N=4,148	170 (5.5)	55 (5.2)	0.75	0.88 (0.63, 1.22)

Data are n (%) or median (IQR). IOPP = individualized opioid prescribing plan. Multivariate analyses are adjusted for advanced maternal age, parity, diabetes, hypertension, private insurance, and primary indication for cesarean delivery.

68 Prospective multicenter trial comparing balloon versus suction hemorrhage control devices for postpartum hemorrhage

Laurence E. Shields[1], **Mindy Foster**[2], **Catherine Klein**[2], **Jennie Torti**[2], **Curtis Cook**[3]

[1]CommonSpirit Health, Santa Maria, CA, [2]CommonSpirit Health Women and Infant Clinical Institute, Denver, CO, [3]Dignity Health Medical Group, Chandler, AZ

OBJECTIVE: Postpartum hemorrhage (PPH) is the leading cause of severe maternal morbidity. Two devices, balloon (Bakri) and suction (Jada), are available for treatment of PPH, but there is limited data directly comparing their efficacy against each other. The purpose of this study was to prospectively compare these two devices within a large multi-center hospital system using a standardized 3 stage PPH response algorithm.

STUDY DESIGN: PPH and use of hemorrhage control devices was assessed at 65 facilities through detailed case audits. Use of PPH control devices is recommended for stages 2 and 3 of the algorithm. Case audits included all cases of stage 3 PPH, if a PPH device was used, or there was transfusion. The primary outcomes were: 1) need for any transfusion; 2) use of ^{3} 3 units of red blood cells (pRBC); and 3) quantitative blood loss (QBL) after device placement. Other variables assessed were length of stay (LOS), mode of delivery, admission Hct, abnormal DIC labs (INR, platelets, and fibrinogen), use of tranexamic acid (TXA), and discharge Hct. Data was analyzed using t-test and z-ratios.

RESULTS: During the 11-month observation period there was 80,049 deliveries and PHH occurred in 3,894 (4.9%). PPH control devices (Bakri, n=183 and Jada, n=195) were used in 378 cases (10.3%). The Bakri group had a higher rate of cesarean delivery (36.1% v. 25.1%, p=0.02), rate of abnormal DIC panel (29.2% v. 16.8%, p<

0.01), and a higher QBL at time of device placement (1729 v 1538 ml, p=0.01). There was no difference between devices for Hct at admission, use of TXA, QBL after device placement, rate of transfusion, the number requiring ³ 3 units of pRBC, or discharge Hct, Table 1.

CONCLUSION: Despite higher QBL at placement, abnormal DIC labs, and the rate of cesarean section in the Bakri group both devices were equally effective with regards to mitigating transfusion requirements and blood loss after device placement. With similar efficacy when used as part of a standardized PPH response other factors, such as cost of the device, availability and ease of use, will need to be considered.

	Bakri	Jada	p-value
Length of stay (days)	3.3	3.2	0.56
Admission Hct	34.1	34.9	0.18
Cesarean Delivery	36.1%	25.1%	0.02
Abnormal DIC labs	28.4%	16.4%	0.005
TXA use	83.1%	86.2%	0.4
QBL at device placement (ml)	1729	1537	0.01
QBL after device placement (ml)	418	435	0.82
Received transfusion	56.3%	51.3%	0.33
Received ≥ 3pRBC	27.3%	25.6%	0.71
Discharge Hct	27.0	27.3	0.84

69 Derivation and validation of an intrapartum algorithm to predict postpartum hemorrhage risk using photoplethysmography data

Kimberly K. Trout[1], Stefanie Modri[2], Harish M. Sehdev[1], James Weimer[3]

[1]Pennsylvania Hospital, Philadelphia, PA, [2]University of Pennsylvania, School of Nursing, Philadelphia, PA, [3]Vanderbilt University, School of Computer Science and School of Biomedical Engineering, Nashville, TN

OBJECTIVE: Postpartum hemorrhage (PPH) is the leading cause of maternal mortality. Uterine atony accounts for most PPH, where myometrial fatigue is a significant and unobservable indictor.

OBJECTIVE: The primary aim was to develop an algorithm using non-invasive photoplethysmography (PPG) data to provide intrapartum decision support indicating subjects at high-risk of requiring postpartum nonprophylactic intervention for hemorrhage. The algorithm was designed using machine learning, with the goal to constrain the learning process such that the resulting model targets myometrial fatigue for predicting need for PPH intervention.

STUDY DESIGN: This study was a primary, prospective, observational study at a single academic hospital. Patients with a live, term singleton pregnancy were eligible upon admission for a non-planned cesarean. A wearable PPG device was placed on the participant's wrist from active labor through 24 hours postpartum and collected data at 5Hz.The algorithm was designed to recognize PPG waveform signatures that corresponded to specific variations in heart rate timing modeled to correlate with myometrium fatigue. Since myometrial fatigue was not observable, administration ofnonprophylactic uterotonic was recorded as a reference standard. Admission PPH risk score was recorded for each subject as a baseline.

RESULTS: PPG data was obtained from 403 participants. Subjects receiving nonprophylactic postpartum uterotonics were labeled as case subjects (190). Subjects were randomly divided into 202 training subjects (87 cases) for designing the algorithm and 201 test subjects (103 cases). Test subject evaluations demonstrated the system could predict PPH intervention 1-6 hours before delivery with a >2.5x improvement in sensitivity (40% vs. 15%) compared to PPH risk score, with no decrease in positive predictive value.

CONCLUSION: Elevated risk for PPH intervention was identified 1 to 6 hours ahead of delivery with significantly higher sensitivity than admission PPH risk scores. Advanced warning for PPH would allow time to mobilize resources for appropriate and timely treatment.

70 Management Approaches for Placenta Accreta Spectrum – Not a one size fits all approach

Farah H. Amro[1], Michal Fishel Bartal[2], Edgar Hernandez Andrade[3], Elizabeth Nugent[3], Lavanya Palvalli Parsons[3], Jennie Coselli[1], Nahla Daye[1], Sandra Sadek[1], Ramesha Papanna[3], Sean C. Blackwell[4], Baha M. Sibai[5]

[1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [2]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX, [3]McGovern Medical School at UTHealth Houston, Houston, TX, [4]Children's Memorial Hermann Hospital, Houston, TX, [5]Hermann Memorial Hospital, Houston, TX

OBJECTIVE: The incidence of placenta accreta spectrum (PAS) has increased, and it causes substantial morbidity and mortality. Cesarean hysterectomy is the standard treatment for PAS in the United States, however it frequently leads to major morbidity. At our center we offer three approaches to manage PAS, and the objective of this study was to compare maternal outcomes as a result of these different management strategies.

STUDY DESIGN: Prospective cohort study at a Level IV academic center (January 2020 to July 2023) of individuals with ultrasound suspected PAS that had three different planned PAS management approaches:1. Cesarean hysterectomy (CH), 2. Delayed Interval hysterectomy (hysterectomy performed 4-5 weeks after delivery) (DH) 3. Conservative Management (no planned hysterectomy) (CM). The data was analyzed according to planned management protocol. As an alternative option to CH, CM was offered starting in 2020 and DH as of 2022. The primary outcome was composite acute morbidity (within 24 hours from cesarean delivery or hysterectomy) and composite delayed morbidity (>24 hours postoperative).

RESULTS: A total of 60 individuals had ultrasound suspected PAS, management planned was: CH for 29 (48%), DH for 16 (27%), CM for 15 (25%). There were no differences in baseline maternal characteristics between the groups (age, race, BMI, chronic hypertension, diabetes mellitus). The type of PAS by ultrasound and placental pathology was similar between all groups, although there was a trend towards more placenta increta and percreta in the DH and CM groups (Table).The planned procedure was performed in 26/29 (90%) CH group, 13/16 (81%) DH group, 4/15 (27%) CM group (3/15 in CM group had a delayed hysterectomy due to patient request). DH and CM groups were less likely to require a blood transfusion, and had significantly less composite acute morbidity. The composite postoperative morbidity was similar between the three groups (Table).

CONCLUSION: Our results suggest that delayed hysterectomy and conservative management can be considered as viable approaches for management of PAS.

Table. Baseline Characteristics and Maternal Outcomes stratified by PAS management strategy

	Planned Cesarean Hysterectomy N=29[1]	Planned Interval Hysterectomy N=16[1]	Planned Conservative Management N=15[1]	p-value

**Composite Delayed Morbidity: bleeding, UTI, pneumonia, ileus, wound infection, operating room take back, venous thromboembolism

71 Reoperation following cesarean delivery: an analysis of incidence, indications, and procedures using a national database

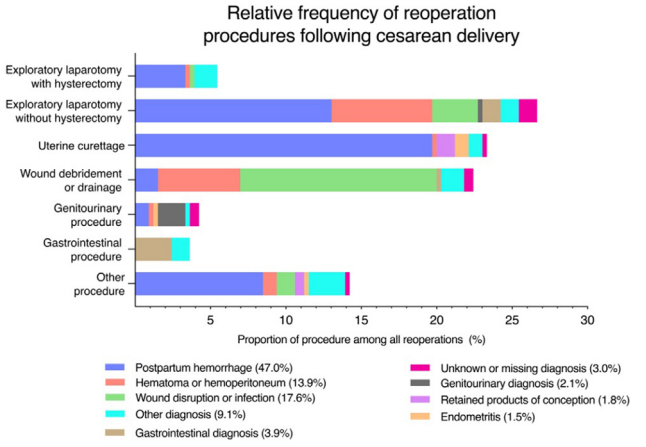
Luke P. Burns[1], Jourdan E. Triebwasser[2], Christopher X. Hong[3]
[1]University of Chicago Medicine, Chicago, IL, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI

OBJECTIVE: Prior studies have described reoperation rates after cesarean birth (CB) but primarily focus on relaparotomy and were conducted at single centers. The types of procedures and indications for reoperation in a more generalizable population remains unclear. Our objective was to determine the incidence of reoperation after uncomplicated CB, describe the types of procedures and indications for reoperation, and identify risk factors associated with reoperation using the National Surgical Quality Improvement Program (NSQIP) database.

STUDY DESIGN: The NSQIP database was queried to identify patients who underwent CB between 2019-2021, based on International Classification of Diseases 10th Revision (ICD-10) codes. Cases involving non-gynecologic concurrent procedures or hysterectomy were excluded. Reoperations within 30 days of the CB were identified using Current Procedural Terminology (CPT) codes for the reoperation procedure and ICD-10 codes for the associated diagnosis. Patient characteristics were analyzed, and multivariable logistic regression models were used to identify risk factors associated with reoperation.

RESULTS: A total of 43,113 CB were analyzed, among which 397 (0.88%) required reoperation. Out of these, 330 (87%) reoperations were performed for indications associated with the CB. Postpartum hemorrhage was the most common diagnosis for reoperation (47%), followed by wound disruption or infection (18%), and hematoma or hemoperitoneum (14%). The main types of reoperation included exploratory laparotomy without hysterectomy (27%), uterine curettage (23%), and wound debridement and drainage (22%). In the final multivariable model, several risk factors were independently associated with a higher likelihood of reoperation: smoking (aOR 1.96, 95% CI 1.49-1.56), hypertension (aOR 1.83, 95% CI 1.27-2.62), bleeding disorders (aOR 2.11, 95% CI 1.15-3.89), ASA) class >3 (aOR 2.23, 95% CI 1.29-3.84), and concurrent myomectomy (aOR 4.39, 95% CI 1.06-18.2).

CONCLUSION: Reoperation after cesarean birth is uncommon but associated with identifiable perioperative risk factors.



72 Increased risk of postpartum hemorrhage in women with resolved low placentation: a multicenter prospective study

Ornaghi Sara[1], Francesca Arienti[2], Federica Fernicola[3], Alessandra Abbamondi[1], Sofia Giani[4], Elisabetta Colciago[1], Simona Fumagalli[5], Anna Catalano[6], Meroni Mario Giuseppe[7], Sara Benedetti[7], Camilla Bulfoni[7], Clelia Callegari[8], Andrea Sala[8], Edoardo Barbolini[6], Giulia Zangheri[9], Giulia Dal Molin[9], Michele Vignali[9], Mirko Pozzoni[10], Maria Castoldi[10], Massimo Candiani[10], Sara Consonni[11], Irene Cetin[12], Elisa Fabbri[12], Valentina Sala[12], Anna Locatelli[5]
[1]University of Milan-Bicocca, Monza, Lombardia, [2]University of Milano Bicocca, Milano, Lombardia, [3]University of Milano-Bicocca, School of Medicine and Surgery, Monza, Lombardia, [4]University of Milan-Bicocca, School of Medicine and Surgery, Monza, Lombardia, [5]University of Milano-Bicocca, Monza, Lombardia, [6]Hospital Poliambulanza Foundation, Brescia, Lombardia, [7]Niguarda Hospital, Milan, Lombardia, [8]Alessandro Manzoni Hospital, Lecco, Lombardia, [9]Macedonio Melloni Hospital, Milan, Lombardia, [10]San Raffaele Hospital, Milan, Lombardia, [11]Carate Hospital, Carate Brianza, Lombardia, [12]Children Hospital Vittore Buzzi, Milan, Lombardia

OBJECTIVE: Low placentation (placenta previa and low-lying at 1-20 mm from the internal os) is a well-known risk factor for PPH when present at delivery. However, conflicting data are available on the risk of PPH in women with low-positioned placenta resolved during gestation, with evidence coming mostly from dated or retrospective research.

The aim of our study was to determine whether resolution of low placentation is associated with PPH.

STUDY DESIGN: A prospective, multicenter, 1:3 matched-control cohort study of singleton women with diagnosis of low placentation by transvaginal scan at 19- to 24-weeks. Controls were women with normally located placenta at the same time range, matched for parity.

Low placentation was defined as resolved when placenta was at > 20 mm from the internal os at transvaginal scan (cases). Early resolution was considered < 34 weeks. Exclusion criteria were persistent low placentation at birth and PAS. Enrollment occurred between 1/2021 and 6/2023.

PPH was defined as blood loss ≥ 1,000mL, severe PPH as ≥ 1,500mL.

Multivariable logistic regression was used to estimate the independent association between outcomes after controlling for confounders.

RESULTS: During the study period, 186 women with low placentation and 445 controls were enrolled. Sixty-three cases were excluded because of persistent low placentation or PAS, thus leaving 123 women for analyses. In 84 (68.3%) cases, there was early resolution of low placentation. At multivariate logistic regression, cases displayed a 3- and 5-fold increased risk of PPH and severe PPH (Table). No differences were identified in PPH rate between early and late resolved cases (16.1% vs 20.5% for PPH and 6% vs 7.7% for severe PPH). Women with resolved low placentation were more likely to be admitted for antepartum bleeding and receive 2nd line uterotonic drugs, balloon tamponade, and blood transfusions (Table).

CONCLUSION: Women with a resolved low placentation are at substantially increased risk of PPH and bleeding-related complications when compared with those who always had a normally located placenta.

73 Endocannabinoids and Related Lipids are Associated with Postoperative Opioid Use in Patients Undergoing Cesarean Delivery

Amelie Pham[1], Sarah S. Osmundson[1], Phillip J. Kingsley[1], Sachin Patel[2], Alex Pedowitz[3], Laura Sorabella[1], Stephen Bruehl[1]

[1]Vanderbilt University Medical Center, Nashville, TN, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]University of Miami, Leonard M. Miller School of Medicine, Miami, FL

OBJECTIVE: Endocannabinoids (EC) are endogenous cannabinoid receptor agonists that modulate pain and are potential targets for opioid-sparing therapies. We evaluated whether levels of EC and related lipids (structurally related non-EC lipids) in cerebral spinal fluid (CSF) and plasma predict outpatient postoperative opioid use and pain after cesarean delivery.

STUDY DESIGN: Between 2021-2022, we enrolled pregnant patients without opioid use disorder or chronic pain and collected plasma and CSF at the time of scheduled cesarean delivery under regional anesthesia. Preoperatively, EC levels in plasma (2-AG, AEA) and CSF (2-AG), and plasma related lipids (OG, OEA) were measured. All patients received the same opioid prescription at discharge and completed surveys 2 weeks post-delivery reporting number of outpatient opioid tablets used, duration of use, and pain, which was assessed using the McGill Pain Questionnaire (MPQ-2) . We evaluated associations between EC and related lipid levels and outpatient opioid tablets used (primary outcome), duration of outpatient opioid use, and postoperative pain at 2 weeks. Linear regression was used to examine these associations controlling for maternal age, body mass index (BMI) at delivery, and race.

RESULTS: Complete follow up data were available for 136 patients – mean age 31.1 years (SD 5.3), mean BMI 34.4 kg/m^2 (SD 8.6), 27.1% publicly insured, and 77.6% non-Hispanic white. Of the five EC and related lipids studied, three were associated with decreased opioid use after discharge (CSF 2-AG and plasma 2-AG and OG). Higher CSF levels of 2-AG were also associated with decreased duration of outpatient opioid use. No EC or related lipids were associated with measures of postoperative pain intensity (Table).

CONCLUSION: Higher endogenous EC may be associated with reduced outpatient opioid use but not pain after cesarean delivery. These data enhance understanding of mechanisms underlying differential opioid requirements and risk for opioid-related adverse sequelae and could be potential targets for opioid-sparing therapeutics.

Table. Association between endocannabinoid levels and postoperative opioid use and pain

Bold: statistically significant at p<0.05
Hierarchical linear regressions controlled for the potential confounding effects of maternal age, body mass index at delivery, and race.
[*]MPQ-2 is a validated questionnaire for measuring neuropathic and nonneuropathic pain qualities. It contains 22 items divided into 4 subscales (continuous, intermittent, neuropathic, and affective pain) to described different qualities of pain felt in the last 7 days, rated using a numeric rating scale (0 = none and 10 = worst possible).

74 Predictors of intrauterine vacuum-induced device failure in management of postpartum hemorrhage: a multicenter experience

Candace Levian[1], Logan Mauney[2], Matthew H. Mossayebi[3], Katherine Moran[4], Andrew Florin[1], Naomi Greene[1], Ilona Goldfarb[5], Mariam Naqvi[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Massachusetts General Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Cedars-Sinai Medical Center, W HOLLYWOOD, CA, [5]Massachusetts General Hospital, Newton, MA

OBJECTIVE: A novel intrauterine vacuum-induced hemorrhage control device (Jada System) is being increasingly used in the management of postpartum hemorrhage (PPH). Our objective was to describe maternal outcomes with use of a vacuum-induced hemorrhage control device and to identify predictors of device failure.

STUDY DESIGN: Retrospective multicenter cohort study of patients who delivered at two metropolitan medical centers since introduction of a vacuum-induced hemorrhage control device. Patients were identified either using a natural language search engine, DEEP-6, and/or through institutional quality review of cases with PPH. The primary outcome was device failure, defined as need for additional surgical interventions. Univariable and multivariable logistic regression was performed to determine independent predictors of device failure. Secondary adverse maternal outcomes were also described.

RESULTS: During the study period, there were a total of 11,124 deliveries across sites and 55 (0.49%) patients received an intrauterine vacuum-induced hemorrhage control device for PPH management. Of the 55 patients, 22 (40%) had a total estimated blood loss of over 2 liters, and 12 (22%) required additional interventions, including hysterectomy (n=2), uterine artery embolization (n=7), and dilation & curettage (n=2) (Table). Patients who had device failure were more likely to have delivered via cesarean delivery (67% vs 21%, p=0.002), have abnormal placentation (25% vs 2%, p=0.007), have PPH secondary to coagulopathy (25% vs 0%, p=0.001), and were less likely to be of white race (17% vs 54%, p=0.024). After adjustment for advanced maternal age, obesity, race, and site, both cesarean delivery and abnormal placentation were associated with device failure (aOR 7.9, 95% CI 1.4-46.1 and aOR 26.8, 95% CI 1.5-484). There were 5 (9%) admissions to the intensive care unit, 2 postpartum readmissions (4%), and no maternal deaths.

CONCLUSION: Cesarean delivery and abnormal placentation were associated with need for additional interventions following use of a vacuum-induced hemorrhage control device in the management of PPH.

Table. Predictors of additional interventions following placement of vacuum-induced device for postpartum hemorrhage.

	Total (n=55)	No additional interventions (n=43)	Additional interventions[a] (n=12)	p
Maternal age ≥ 35 years	29 (52.7)	24 (55.8)	5 (41.7)	0.39
Gestational age < 37 weeks	12 (21.8)	9 (20.9)	3 (25)	0.76

LABOR & DELIVERY

Abstracts 75-84

75 A contemporary assessment of uterine contractility in labor: what is adequate?

Nandini Raghuraman[1], Candice Woolfolk[1], Nicole McCandless[1], Brianna Bradley[1], Jeannie C. Kelly[2], Ebony B. Carter[2], Anthony O. Odibo[1], Antonina I. Frolova[1]
[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

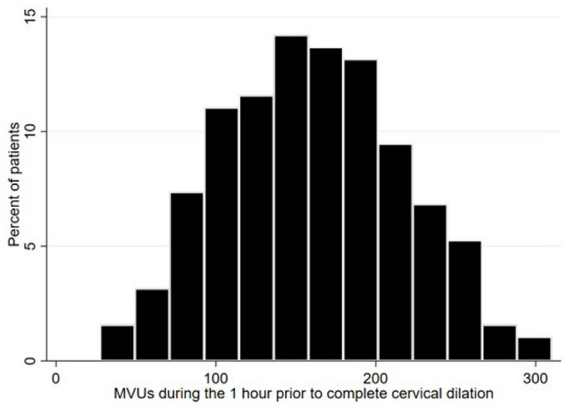
OBJECTIVE: Labor arrest disorders account for over a third of cesarean deliveries. The diagnosis of arrest requires assessment of contraction adequacy, defined in national guidelines as a minimum of 200 Montevideo units (MVU) in the active phase. This MVU cutoff is derived from a historic cohort of 109 patients in the 1980s. We re-assessed uterine contractility measures in a contemporary cohort of patients with universal intrauterine pressure catheter (IUPC) placement.

STUDY DESIGN: This was a prospective cohort study of singleton pregnancies ≥37 weeks gestation admitted in spontaneous labor or for induction of labor. All enrolled patients had IUPCs placed at time of amniotomy regardless of preceding labor pattern. For this analysis, we only included patients who had a vaginal delivery. Contraction data were collected by obstetric nurses blinded to outcomes in ten-minute epochs and averaged over 1 hour. MVUs in the 1 hour before 10 centimeters (cm) dilation were assessed to best represent MVU requirements in the active phase of labor.

RESULTS: Of 224 enrolled patients, 190 (84.8%) had a vaginal delivery and IUPC data within 1 hour of 10cm dilation, and were included in this analysis. 170 (89.5%) underwent IOL, 93 (49%) were nulliparas, and 178 (93.7%) received oxytocin. Among those with vaginal deliveries, the median [5th, 95th percentile] MVU was 163 [63, 260]. Using current definitions of adequacy, 7.4% of patients were adequate for all 60 minutes prior to complete dilation and 50% of patients were never adequate in the 60 minutes before 10 cm dilation. Nulliparous patients had a lower median MVU compared to multiparous patients (145.8 [105.8, 188.3] vs 171.7 [128.3, 213.0], P< 0.01).

CONCLUSION: In this contemporary prospective study with universal IUPC placement not subject to selection bias, there is a wide range of MVUs among patients with successful vaginal deliveries. 50% of patients with vaginal deliveries do not achieve 200 MVUs prior to complete dilation. MVU may be a poor marker of adequacy. If MVUs remain the standard, parity-based stratification of adequacy should be considered.

Figure: Histogram of Montevideo units (MVUs) in the 1 hour prior to 10 centimeters dilation among those with vaginal deliveries



76 Multi-Country Trial of Intrapartum Oral Azithromycin: Cultures of Neonatal Infections

Alan T. Tita
University of Alabama at Birmingham, Birmingham, AL; for the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network

OBJECTIVE: An intrapartum oral dose of azithromycin (AZI) reduced maternal but not neonatal/fetal death or sepsis. Herein, we compare the frequency of neonatal cultures, organisms and antimicrobial resistance from neonatal infections by AZI vs. placebo groups.

STUDY DESIGN: Ancillary study of the NICHD A-PLUS trial in which women in labor, ≥28 weeks' and planning vaginal birth were randomized to 2g AZI vs. placebo at 8 sites in 7 low- and middle-income countries (LMICs). Culture specimens from suspected newborn infections including sepsis (blood), meningitis (cerebrospinal fluid, CSF), umbilical stump, eye or skin infections (free pus) were evaluated using standard of care clinical microbiological procedures with the addition of AZI susceptibility testing.

RESULTS: Of 29,278 women (29,354 fetuses) randomized, 14,628 had AZI vs. 14,726 placebo. The AZI group was not associated with frequency of neonatal cultures (any source), culture positivity or AZI resistance among those randomized nor with actual neonatal cultures (Table 1A). The most prevalent neonatal pathogens (Table 1B) were gram positive-cocci (GPCs - S. aureus and MRSA) followed by gram-negative rods (GNRs - E. coli, K. pneumonia and Acinetobacter species). The findings were similar when specimens were limited to blood and CSF only.

CONCLUSION: A single intrapartum oral dose of AZI was not associated with the frequency of cultures, culture-positivity or baseline AZI resistance in LMICs. The organisms identified were predominantly expected gram-positive cocci and gram-negative rods with overall AZI resistance of ranging from 60-90%.

Table 1. Neonatal Clinical Cultures, Organisms and AZI Resistance by Group

[1]Assuta Ashdod Medical Center, Ashdod, HaDarom, [2]Samson Assuta Ashdod University Hospital, Ashdod, HaDarom, [3]Assuta Ashdod University Hospital, Ben Gurion University of the Negev, Ashdod, Israel, [4]Tzafon Medical Center, Afula, HaZafon, [5]Tzafon medical center, Poriya, Israel, Poria, HaZafon, [6]Rambam Medical Health Campus, Toronto, ON, [7]Sheba Medical Center, Tel Hashomer, Toronto, ON, [8]Wolfson Medical Center, Tel Aviv, HaMerkaz, [9]Edith Wolfson Medical Center, Shoham, HaMerkaz

OBJECTIVE: Extra amniotic balloon (EAB) is a widespread mechanical method for cervical ripening. Following EAB the clinician may choose the method for induction of labor - either artificial rupture of membranes or oxytocin infusion, delaying amniotomy to a later stage of labor. We aimed to examine the effectiveness of early versus late amniotomy following balloon cervical ripening for labor induction at term.

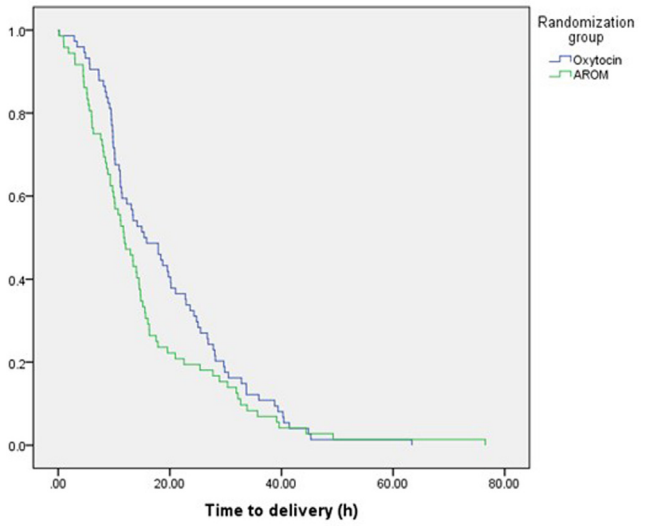
STUDY DESIGN: A prospective, multi center randomized controlled trial included patients underwent labor induction , using an EAB for cervical ripening. Patients were randomly assigned to two groups based on the primary intervention: Early amniotomy group, in which amniotomy was performed as the primary intervention. Oxytocin infusion was begun no earlier than 2 hours following amniotomy. For the late amniotomy group oxytocin infusion was begun as per local protocol. Amniotomy was performed no earlier than 2 hours following commence of oxytocin infusion.

Included were patients at 37-42 weeks gestational age, singleton pregnancy, vertex presentation and medical indication for labor induction. Exclusion criteria included multiple pregnancies, preterm pregnancy, previous cesarean section and uterine malformation.

Primary outcome was interval from primary intervention to delivery. Secondary outcomes were intrapartum and neonatal fever.

RESULTS: Of 146 eligible patients, 72 had early amniotomy as primary intervention and 72 had oxytocin infusion. There was no significant difference between groups in the rate of primiparous patients, achieved Bishop score , or management not by intention to treat. Time to delivery was significantly shorter among patients in the early amniotomy group (15.6 hours (range 9.8-26.9) VS 11.8 hours (range 7-17.7), P=0.025). This difference was significant for intervention to delivery interval above 18 hours, but not longer then 24 hours (Figure). There was no difference in the rate of intrapartum or neonatal fever.

CONCLUSION: After EAB ripening, opting for an early rupture of membranes to induce labor enhances the likelihood of labor occurring within 24 hours of induction.



78 Foley catheter+oral misoprostol versus misoprostol for cervical ripening in nulliparous-obese women: a French multicenter RCT

OBJECTIVE: Nulliparous obese women are at higher risk of cesarean delivery (CD) for failed induction of labor (IOL) and of other adverse outcomes. Our objective was to evaluate if adding Foley catheter to oral misoprostol (PGE1) reduce CD rate compared to PGE1 alone

STUDY DESIGN: Multicenter randomized controlled 2-stage group sequential design trial in nulliparous obese women (BMI $\geq$30 kg/m^2)

from June 2020 to December 2022 at 17 academic hospitals from the French Research Group (GROG). Inclusion criteria were singleton cephalic pregnancy, intact membranes, GA ≥36 wks, Bishop score ≤5. Exclusion criteria were stillbirth, major fetal anomalies, or contraindication to PGE1. Women received either a 20-Fr 60 cc Foley catheter vaginally + 25 mcg oral PGE1 every 2 hours (max 8 pills) or the same dose of oral PGE1 alone. A minimum latent phase of labor of 12 hours was requested. CD was the primary outcome (PO). Main secondary outcomes (SOs) were CD for abnormal FHR, oxytocin use during labor, and delivery < 24 h after first PGE1 intake. Sample size was 774, based on a 10% decrease between arms assuming a 40% rate in the control arm (CYTOPRO trial) with 80% power and .05 overall α. An interim efficacy/futility analysis was planned once half the women had been randomized and followed up until discharge

RESULTS: The study was stopped after the prespecified interim analysis for ethical considerations due to an unfavorable trend for the PO and the other outcomes. The efficacy analysis included 379 patients (191 in the Foley+PGE1 arm vs 188 in the control arm) and 395 in the safety analysis (190 vs 205 respectively). Baseline characteristics and indications for IOL were similar. A higher CD rate was found in the Foley+PEG1 arm (47.1% vs 42.0%, risk difference of 5.1% with 95% RCI of -10.2 to 20.4, 2-sided p=.32 [significance level of .00267]) as well as unfavorable results for the main SOs (Table) and postpartum hemorrhage ≥1l, 9.0% and 6.3% respectively. Neonatal morbidity was similar between arms

CONCLUSION: In this RCT, adding Foley catheter to oral PGE1 was not associated with decreased CD in obese nulliparous women

Table: Main secondary efficacy endpoints - ITT population

	Balloon catheter + oral misoprostol (N=191)	Oral misoprostol alone (N=188)
Occurrence of cesarean delivery because of abnormal FHR		
n / N (%)	26 / 189 (13.8)	16 / 187 (8.6)
95% CI (a)	(9.2 to 19.5)	(5.0 to 13.5)
Use of oxytocin during labor		
n / N (%)	147 / 188 (78.2)	154 / 186 (82.8)
95% CI (a)	(71.6 to 83.9)	(76.6 to 87.9)
Delivery less than 24 hours after first administration of misoprostol		
n / N (%)	53 / 185 (28.6)	33 / 187 (17.6)
95% CI (a)	(22.3 to 35.7)	(12.5 to 23.9)

79 Evaluation of standardized management of category II tracings: Category II action plan study (CAP Study)

Alexandra G. Eller[1], Sean Esplin[2], Donna Dizon-Townson[3], Cempaka Martial[4], Erick Henry[1], Jessica Page[4], Brett D. Einerson[5], Flint Porter[6]

[1]Intermountain Health, Murray, UT, [2]Intermountain Medical Center, Murray, UT, [3]Intermountain Health, Sandy, UT, [4]Intermountain Health, Salt Lake City, UT, [5]University of Utah Health, Salt Lake City, UT, [6]Intermountain Healthcare, Salt Lake City, UT

OBJECTIVE: To determine the effect of system-wide implementation of and compliance with a standardized algorithm for the management of category II (cat II) FHR tracings on rates of composite neonatal morbidity associated with intrapartum hypoxia.

STUDY DESIGN: We performed a pre (Pre-I)- and post (Post-I)-implementation study following initiation of a standardized approach to management of cat II FHR tracings at 21 hospitals from a single healthcare system. The program included education/training, published algorithm with specific indications for team communication, and time frames for intervention. All singleton, nonanomalous pregnancies at > 35 wk were included. The primary outcome was a neonatal morbidity composite including unexpected admission to the NICU and at least 1 of the following: Need for cooling, art pH < 7.10, base deficit > 12, 5-min Apgar < 7, or documented HIE. Logistic regression was performed to control for GA, parity, OB complications, and race-ethnicity between Pre-I and Post-I groups and to assess the effect of compliance (defined as receiving intervention when indicated) on the composite outcome among the Post-I group alone.

RESULTS: There were 34,754 pregnancies in the Pre-I group (1/1/20-6/1/21) and 33,146 pregnancies in the Post-I group - (1/1/22-6/1/23). Table 1 compares demographics and outcomes. There were significantly fewer admissions to the NICU in the Post-I group. There was a small but significant increase in delivery by CS and operative vaginal delivery after implementation. Logistic regression confirmed the absence of significant difference in the primary outcome (aOR 1.03; CI 0.88-1.20) between the Pre-I and Post-I groups. Although compliance with the algorithm increased from 15% to 61% in the Post-I group across the study we could not confirm an association with lower rates of the composite outcome (aOR 0.79; CI 0.61-1.03).

CONCLUSION: Implementation of a standardized approach to management of cat II FHR tracing in a large healthcare system was not associated with reduced rates of the composite outcome among Pre-I and Post-I groups.

80 Vaginal dinoprostone versus Foley catheter for induction of labor: a randomized controlled trial

Xiaohua Liu[1], Ding Huang[2], Yang Liu[3], cuicui Qu[4], Huiqin Mo[3], Xin Zhao[3], Wentao Li[5], Ben Willem W. Mol[6], Hong Shen[2], Weiwei Cheng[7], Hao Ying[4]

[1]Shanghai First Maternity & Infant Hospital, Tongji University School of Medicine, Shanghai, [2]International Peace Maternity & Child Health Hospital, Shanghai Jiaotong University, Shanghai, Shanghai, [3]Shanghai Key Laboratory of Maternal and Fetal Medicine, Shanghai First Maternity & Infant Hospital, Tongji University School of Medicine, Shanghai, Shanghai, [4]Shanghai First Maternity & Infant Hospital, Tongji University School of Medicine, Shanghai, Shanghai, [5]Monash University, Melbourne, Victoria, [6]Monash University, Clayton, Victoria, [7]International Peace Maternity & Child Health Hospital, Shanghai Jiaotong University, Shanghai, China (People's Republic)

OBJECTIVE: The effectiveness and safety of pharmacological versus mechanical agents for induction of labour (IOL) remains a matter of debate. We compared the effectiveness and safety of dinoprostone versus transcervical Foley catheter for IOL in term pregnant women with an unfavorable cervix.

STUDY DESIGN: We performed a parallel, open-label randomized controlled trial in two maternal centers in Shanghai, China. Individuals with a singleton pregnancy in cephalic presentation at term and an unfavorable cervix (Bishop score < 6) scheduled for IOL. After informed consent, participants were randomly allocated to cervical ripening with either a dinoprostone vaginal insert (10mg) or a 60cc Foley catheter for up to 24 hours. The primary outcomes were vaginal delivery rate and time to vaginal delivery. Secondary outcomes included time to delivery and composites for maternal and neonatal morbidity. A sample size of 1,836 women was planned. Analysis was done by intention-to-treat (China trial registry CTR2000038435).

RESULTS: Between October 2019 and July 2022, we randomly assigned 1,860 women to vaginal dinoprostone (n = 930) or Foley catheter (n = 930). The vaginal birth rates were 72.8% (677/930) vs. 69.9% (650/930) in vaginal dinoprostone and Foley catheter, respectively (aRR 1.04, 95% CI 0.98 to 1.10), with no difference in time to vaginal delivery. The composite poor perinatal outcomes were not significantly different between the two groups (4.5% vs. 3.8%, aRR 1.21, 95% CI 0.78 to 1.88), but more neonatal asphyxia occurred in the dinoprostone group (1.2% vs. 0.2%, aRR 5.39, 95% CI 1.22 to 23.92). Dinoprostone was less likely complicated with suspected intrapartum infection (aRR: 0.62, 95% CI 0.44-0.88) and postpartum infection (aRR: 0.38, 95% CI 0.20-0.72).

CONCLUSION: In term pregnant women with an unfavorable cervix, IOL with vaginal dinoprostone or Foley catheter has similar effectiveness. Foley catheter is safer for neonates, while it may result in a higher risk of maternal infection.

Note: Trial registration was prospectively, but due to a mistake in the trial register it is not correctly projected.

Table 1. Delivery, neonatal and maternal outcomes

	Dinoprostone (n=930)	Foley catheter (n=930)	Relative risk (95% CI)	Adjusted relative risk (95% CI) *	*p* value
Vaginal delivery	677 (72.8%)	650 (69.9%)	1.04 (0.98-1.10)	1.04 (0.98-1.10)	0.172
Indication for caesarean section

81 The HOME-INDUCTION Randomized Controlled Trial — Women's Opinions on Outpatient Induction of Labor

Sarah M. Nicholson[1], Orla Smith[2], Corina Oprescu[2], Eimear Wall[2], Sara El Nimr[2], Geraldine Gannon[2], Sirisha Bellamkonda[3], Ita Shanahan[4], Bernard Kennedy[2], Ronan Daly[2], Claudia Looi[2], Elena Fernandez[2], Patrick Dicker[1], Zara Molphy[1], Karen Flood[1], Fergal D. Malone[2]

[1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]Rotunda Hospital, Dublin, Ireland, [3]RCSI, Dublin, Dublin, [4]Rotunda, Rotunda, Dublin

OBJECTIVE: A major challenge following the ARRIVE Trial has been how to safely accommodate increasing numbers of nulliparous patients on the Labor Ward for induction of labour (IOL). Outpatient induction at home (H-IOL) has been suggested for normal-risk women, but there is a paucity of data regarding women's experience of the process. Our objective was to perform a detailed survey of participants in the HOME INDUCTION RCT, who received either prostaglandin (Propess/Cervidil) or osmotic cervical dilator (Dilapan) to commence their induction at home.

STUDY DESIGN: Normal-risk nulliparous women were randomized at 39 weeks to outpatient cervical ripening with 12 hours of Dilapan, 24 hours of Dilapan, or 24 hours of Propess. A questionnaire was administered (in person/by post) after delivery to assess patients' experience with the process.

RESULTS: Of 271 randomized patients, 113 (41%) completed the survey, with 104 (92%) recommending H-IOL, and 96 (85%) reporting no safety concerns with induction being initiated at home. On a scale of 1-10, (with 10 representing highest discomfort on insertion), patients regarded both methods favorably, rating Dilapan insertion 3.6/10 and Propess insertion 2.8/10 (p=0.46). Patients receiving Propess were significantly more likely to experience contractions at home (58% vs 10%, p< 0.001), and return to the hospital before 24 hours had passed (53% vs 9%, p< 0.001). A total of 82/113 (73%) respondents found the overall induction process to be a positive experience, 18% were unsure, and only 10% disagreed. There were no other significant differences between groups in terms of satisfaction scores.

CONCLUSION: This RCT patient satisfaction data has confirmed that women find elective home IOL to be a positive experience, and almost all would recommend the experience to others. Our data also confirm that some negative commentary expressed about routine 39 week IOL after publication of the ARRIVE Trial, is not supported by prospectively collected data on patients' own opinions and experiences, thereby supporting outpatient initiation of IOL amongst nulliparous patients.

Yes/No questions from the HOME INDUCTION RCT Questionnaire							
Question		All (N=113)	Dilapan 24hr (N=43)	Dilapan 12hr (N=27)	Dilapan All (N=70)	Propess (N=43)	P-value#
Did you experience regular contractions at home?	Yes	32 (29%)	5 (12%)	2 (8%)	7 (10%)	25 (58%)	<0.001
	No	79 (71%)	37 (88%)	24 (92%)	61 (90%)	18 (42%)	
Did you have to return to hospital before the allocated 12 or 24hours?	Yes	29 (26%)	5 (12%)	1 (4%)	6 (9%)	23 (53%)	<0.001
	No	83 (74%)	37 (88%)	26 (96%)	63 (91%)	20 (47%)	
Were you aware that returning home for IOL was an option?	Yes	58 (54%)	25 (60%)	14 (54%)	39 (57%)	19 (49%)	0.621
	No	49 (46%)	17 (40%)	12 (46%)	29 (43%)	20 (51%)	
Would you recommend outpatient IOL to others?	Yes	98 (92%)	37 (95%)	24 (92%)	61 (94%)	37 (90%)	0.735
	No	8 (8%)	2 (5%)	2 (8%)	4 (6%)	4 (10%)	

Agree/Disagree statements from the HOME INDUCTION RCT Questionnaire				
Statement	N	Disagree	Unsure	Agree
I felt I was treated as an individual	107	3 (3%)	7 (6%)	97 (91%)
Staff always took my concerns and questions seriously	113	1 (1%)	5 (4%)	107 (95%)
Staff reassured me	113	2 (2%)	5 (4%)	106 (94%)
I felt safe going home	112	2 (2%)	3 (2%)	107 (96%)
I felt like I got more rest due to going home	113	7 (6%)	8 (7%)	98 (87%)
I felt that I was well looked after	113	7 (6%)	4 (4%)	102 (90%)
I found the overall induction process to be a positive experience	113	11 (10%)	20 (17%)	82 (73%)

82 Obesity remains associated with cesarean delivery despite a standardized protocol for labor induction

Melissa Riegel[1], Lisa D. Levine[1], Samuel Parry[1], Celeste Durnwald[1], Rebecca F. Hamm[2]
[1]University of Pennsylvania, Philadelphia, PA, [2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

OBJECTIVE: Patients with obesity are at increased risk for cesarean delivery (CD), with failed induction of labor (IOL) as a leading indication. Possible explanations for differences in CD include physiologic differences and variation in provider care. We aimed to evaluate CD for patients with obesity before and after implementation of a standardized protocol for IOL. We hypothesized that if differences in CD remained after standardizing labor induction, this would support factors other than variations in care contributing to the risk, such as underlying biological factors.

STUDY DESIGN: This is a secondary analysis of a prospective cohort study conducted at 2 sites comparing 2 years before (PRE) to 2 years after (POST) implementation of an IOL protocol from 2018-2022. This analysis included term, nulliparous, singleton gestations undergoing IOL with unfavorable cervices, intact membranes, and BMI $\geq$30 kg/m^2 at delivery. The standardized IOL protocol recommended active labor management, including frequent cervical exams, amniotomy by first exam $\geq$4cm, and intervention when no cervical change was made after two hours (e.g. oxytocin and IUPC). Patients were stratified by obesity class: 30-34.9; 35-39.9; $\geq$40. The primary outcome was CD. Poisson regression with robust error variance was used to calculate adjusted relative risks (aRR).

RESULTS: 5131 patients were included (PRE: n=2480, POST: n=2651). While patients in the POST group had increased maternal age, less favorable cervical exams, differences in IOL indication, and cervical ripening agent used, there was no difference in BMI class. There were no differences in risk of CD in any obesity class from PRE to POST implementation, even when controlling for confounders (Table). There were also no differences in labor length, maternal, or neonatal morbidity in any obesity class from PRE to POST-implementation.

CONCLUSION: In this work, minimizing variation in IOL management did not impact the relationship between obesity and CD, supporting underlying physiologic explanations.

Table: CD rate for patients with obesity before and after implementation of a standardized labor induction protocol

Group (BMI Range)	PRE N(%)	POST N(%)	p-value	aRR [IQR]*
Class I Obesity (30-34.9)	243/1137(21.4)	272/1213 (22.4)	0.54	1.02 (0.86-1.21)
Class II Obesity (35-39.9)	172/697 (24.7)	181/712 (25.4)	0.75	1.02 (0.83-1.25)
Class III Obesity (≥40)	202/646 (31.3)	237/726 (32.6)	0.59	1.00 (0.83-1.21)

* Variables controlled for: modified Bishop score, maternal age, indication for IOL, starting induction agent utilized

83 Application of Tension on Transcervical Foley Catheter for Induction of Labor in Term Nulliparous Women

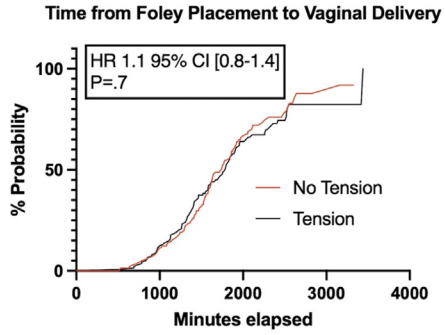
Meagan V. Benson[1], Lena Younes[1], Alisha Watson[2], George R. Saade[3], Antonio F. Saad[1]
[1]University of Texas Medical Branch, Galveston, TX, [2]UTMB, Galveston, TX, [3]Eastern Virginia Medical School, Norfolk, VA

OBJECTIVE: To determine whether applying tension to the catheter decreases delivery times in term nulliparous women undergoing pre-induction cervical ripening with a transcervical Foley catheter.

STUDY DESIGN: This cluster randomized trial included nulliparous patients aged 18 to 49 years with singleton gestation presenting for labor induction with a plan for cervical ripening via transcervical Foley catheter placement. Patients with stillbirth, non-cephalic presentation, prior cesarean, or contraindications for transcervical balloon placement were excluded. Participants were assigned to either the tension or no-tension group based on randomized, weekly clusters (26 total clusters). The primary outcome was the time from initial Foley balloon insertion to delivery. Secondary outcomes included cesarean delivery rates, peripartum infections, and NICU admissions.

RESULTS: 279 subjects were enrolled (138 in the tension and 141 in the no-tension groups). Protocol adherence was 92% in the no-tension and 100% in the tension groups. The baseline characteristics were similar for both groups. In the intent-to-treat population, the median time from Foley placement to delivery was 1596 (range: 430-3438) minutes for the tension group and 1621 (range: 488-3323) minutes for the no-tension group (p=0.8). Results did not differ in the per-protocol analysis. Similar results were noted for time to vaginal delivery (Table). The Log Rank Mantel-Cox test for time to vaginal delivery after Foley balloon placement demonstrated a hazard ratio of HR 1.1; 95% CI [0.8-1.4]; p = 0.7 (Figure). No significant differences were observed in the secondary outcomes, including the incidence of primary cesarean delivery (34 % vs. 30%, p=0.7), peri-partum infections (36 % vs. 31%, p=0.6), and NICU admissions (10% vs. 10%, p=1) between the two groups

CONCLUSION: Applying tension to the catheter during pre-induction cervical ripening with a Foley in term nulliparous women does not reduce delivery times or improve outcomes. It is, therefore, appropriate to forgo tension to improve patient satisfaction and facilitate outpatient cervical ripening.



Outcomes	Intent to Treat Analysis			Per Protocol Analysis		
	Tension (n=138)	No Tension (n=141)	*P*	Tension (n=138)	No Tension (n=130)	*P*
Time Foley balloon in place (min)	720 [75-900]	725 [45-945]	0.6	720 [75-900]	725 [45-945]	0.4
Time from Foley placement to delivery (min)	1596 [430-3438]	1621 [488-3323]	0.8	1596[430-3438]	1608 [507-3323]	1
Time from Foley placement to vaginal delivery (min)	1438 [430-3438]	1542 [522-3159]	0.4	1438 [430-3438]	1542 [522-3159]	0.7

84 Increasing Number of Cervical Examinations in Labor: Does a Risk of Intrapartum Fever Actually Exist?

Chase Calvert[1], Miriam Alvarez[1], Jeny Ghartey[2], Emily Hall[1], Elaine Avshman[3], Sama Jwaied[1], Nandini Raghuraman[4], Lorie M. Harper[1], Alison G. Cahill[1]

[1]University of Texas at Austin, Dell Medical School, Austin, TX, [2]Seton Medical Center Austin, UT Austin, Dell Medical School, Austin, TX, [3]Texas A&M School of Medicine, Bryan, TX, [4]Washington University School of Medicine in St. Louis, St. Louis, MO

OBJECTIVE: Intrapartum fever is a significant contributor to maternal and neonatal morbidity. Theory persists that laboring patients who receive multiple cervical examinations are at increased risk of intrapartum fever. A prior single center study suggested that no such relationship exists once accounting for time in labor, possibly due to unique, homogeneous labor management at that center. We assessed the relationship between cervical exams and intrapartum fever among a diverse population at a tertiary center with a wide spectrum of labor management approaches by both private and university providers.

STUDY DESIGN: A retrospective cohort of singleton pregnancies delivering at ≥37 weeks over a 3yr period. Patients who developed intrapartum fever (> 38.0C) were compared to afebrile ones. Patients were included if they reached the second stage of labor. Patients were stratified into three groups of number of cervical exam by tertials. Time-to-event analyses were used to account for length of labor; Cox proportional hazard models adjusted for induction, bishop score >5 and rupture of membranes.

RESULTS: Of the 3,627 patients, 160 (4.1%) developed intrapartum fever. Women who developed fever had a greater number of cervical exams (median 7, interquartile range [IQR] 5-9) compared to women without fever (median 5, IQR 4-6). However, when accounting for labor duration, the risk of fever significantly *decreased* as the number of cervical exams *increased*; women who had ≥7 exams had the lowest risk (HR 0.24, 95% CI 0.13-0.43), compared to women with 1-4 exams.

CONCLUSION: After accounting for time in labor, increasing number of cervical exams in term labor management does not increase risk of maternal fever. Misconception that increasing number of cervical exams increases the risk of febrile morbidity is most likely due to the confounding of time in labor. Our data suggest that clinically indicated cervical exams should not be avoided due to concern of fever, and that the literature should be collectively evaluated to analyze these findings with those from prior studies to assess the strength of this relationship.

Overall Final Cox Proportional Hazard Model for Intrapartum Fever

Time From Admission to Fever or Delivery		
Number of cervical exams	Hazard Ratio [HR] (95% CI)*	P-value
1-4 (n=1370)	*reference*	--
5-6 (n=1140)	0.54 (0.31 - 0.94)	0.03
= or > 7 (n=856)	0.21 (0.11 - 0.39)	<.0.01
Time from Rupture of Membranes to Fever or Delivery		
Number of cervical exams	Hazard Ratio [HR] (95% CI)*	P-value
1-4 (n=1347)	*reference*	--
5-6 (n=1110)	0.99 (0.54 - 1.81)	0.98
= or > 7 (n=848)	0.50 (0.27 - 0.95)	0.03

*Adjusted for labor induction, Bishop score >5, ROM on admission, ROM-time interaction

85 Clinical Utility of Genome Sequencing in Prenatal Diagnosis

Allan Fisher[1], Jane Schuette[2], Kendall Kaufmann[2], Nicolette Sookar[2], Reena Ray Sisk[2], Christine Stanley[2]
[1]St. Louis University, St. Louis, MO, [2]Variantyx, Inc., Framingham, MA

OBJECTIVE: The diagnostic capabilities of chromosomal microarray (CMA) and exome sequencing (ES) have been described in the prenatal (PN) diagnosis arena. However, there is minimal data demonstrating the utility of genome sequencing (GS) in establishing a diagnosis for fetal anomalies identified by ultrasound. This is the first report to explore the diagnostic capability of a large PN cohort.

STUDY DESIGN: PN and POC samples with anomalies were accepted for GS and HPO terms placed after record review. Whole genome short read sequencing was performed using the Illumina DNA PCR-free sequencing NovaSeq 6000 system. Small sequence changes, all copy number variants (including *SMN1/SMN2* and UPD), mitochondrial variants, and short tandem repeats (*FMR1, AR, FXN, DMPK*) were analyzed. Maternal cell contamination analysis was performed on all specimens.

RESULTS: GS was performed on 331 fetuses over 19.5 months at a single laboratory (Variantyx, Inc. Framingham, MA). Results for 13 (3.9%) samples were deemed indeterminate due to high MCC or poor DNA quality. Of the remaining cases, 82.8% were PN and 17.2% were POC. The overall positive rate was 42.8% for Pathogenic/Likely Pathogenic, Candidate, and Uncertain disease-causative variants, consistent with the fetal phenotype. POC samples had a 28.1% positive rate whereas PN samples had a 44.3% detection rate. In the anomaly categories, hydrops, musculoskeletal, CNS, and CVS had the highest positive rates- 56.1, 53.1, 48.1, 44.0%, respectively. GS detected 20 (14.7% positives) more cases than what would be expected, technologically, by ES+CMA. Turnaround time for results was 17 days in 95% of cases received in the last 12 months.

CONCLUSION: The use of WGS in the PN arena is a new technology. Proof of concept of this technology is apparent with a potential higher diagnostic yield than ES+CMA due to more complete coverage. Turnaround time is comparable to other conventional modalities used in PN diagnosis.

86 Genome sequencing as a first-tier prenatal diagnostic test: Is it time to change?

Vaidehi Jobanputra[1], Jessica L. Giordano[2], Josie Pervola[3], Volkan Okur[1], Amanda Thomas-Wilson[1], Saurav Guha[1], Atteeq U. Rehman[1], Ashley Wilson[1], Alexandra Tinfow[3], Stephanie Galloway[2], Avinash Abhyankar[1], Vanessa Felice[1], Cecilia Esteves[1], Endre Hegedus[1], Shruti Phadke[1], Sowmya Thirumalai Srinivasa[1], Shahid Y. Khan[1], Caroline Nava[1], Qi Yan[2], Brynn Levy[3], Ronald J. Wapner[4]
[1]New York Genome Center, New York City, NY, [2]Columbia University, New York, NY, [3]Columbia University, New York, NY, [4]Columbia University Irving Medical Center, New York, NY; on behalf of the Women's Genetics Center

OBJECTIVE: Current standard of care (SOC) for routine prenatal testing includes karyotype, FISH, and/or chromosomal microarray (CMA). Exome sequencing is recommended for fetuses with ultrasound anomalies. Evidence demonstrating the utility of genome sequencing (GS) as a single prenatal diagnostic test for structural anomalies and standard indications is limited. We investigated GS as an alternative to SOC testing in a prospective blinded study.

STUDY DESIGN: 218 fetuses undergoing routine diagnostic SOC testing had GS performed; 132 with ultrasound anomalies and 86 without anomalies. Trio GS testing was performed in 98.6%. Fetuses with aneuploidy detected by FISH were excluded. SOC results were blinded to the laboratory performing GS. SOC reporting criteria followed local clinical laboratory guidelines. Reporting criteria for GS were established by a multidisciplinary team. Reportable variants include clinically significant findings related to the fetal phenotype and/or associated with a severe neonatal, pediatric, or maternal health outcome. Detection rates of reported variants were compared between testing approaches by McNemar analysis.

RESULTS: Overall yield for GS was significantly higher than that of SOC, at 23% compared to 7.3% ($p < .0001$). In anomalous cases, 31% had reportable findings by GS and 7.6% had reportable findings by SOC ($p < .0001$). 76% of findings reported by GS and 30% of findings reported by SOC were related to the fetal phenotype. In non-anomalous cases, 10.5% had reportable findings by GS and 7% had reportable findings by SOC ($p < .0001$). Overall, 4 fetuses had reportable SOC findings missed by GS (2 mosaic tetraploidy, 1 mosaic monosomy X, and 1 balanced translocation) and 47 fetuses had reportable GS findings missed by SOC (single nucleotide variants, indels, copy number variants < 300 kb, uniparental heterodisomy, and repeat expansions).

CONCLUSION: GS identifies most disorders detected by SOC testing and reveals additionally relevant genetic findings in the fetus and mother. GS has the potential to become the superior first-tier prenatal diagnostic test, replacing SOC.

Comparison of Genome Sequencing and Standard of Care (McNemar analysis)

Overall Cohort with GS and SOC (n=218) (p <0.0001)		
	Genome Sequencing	**SOC (Karyotype and/or CMA)#**
Reportable Findings*	50 (23%)	16 (7.3%)
Anomalous (n=132) (p <0.0001)		
	Genome Sequencing	**SOC (Karyotype and/or CMA)**
Reportable Findings	41 (31%)	10 (7.6%)
Non-Anomalous (n=86) (p <0.0001)		
	Genome Sequencing	**SOC (Karyotype and/or CMA)**
Reportable Findings	9 (10.5%)	6 (7.0%)

*Reportable findings = at least one reportable finding based on GS protocol or SOC clinical laboratory guidelines
#SOC = Karyotype and/or CMA: 3 patients had karyotype and no CMA (2 declined CMA due to cost and 1 sample was inadequate); 11 patients had CMA and no karyotype (2 culture failures and 9 declined karyotype)

87 Preoperative Predictors of Survival in Twin-Twin Transfusion Syndrome Undergoing Fetoscopic Laser Treatment

Henry L. Galan[1], Michael V. Zaretsky[1], Nicholas Behrendt[1], Zhaoxing Pan[2], Anthony Johnson[3], Greg Ryan[4], William Goodnight[5]

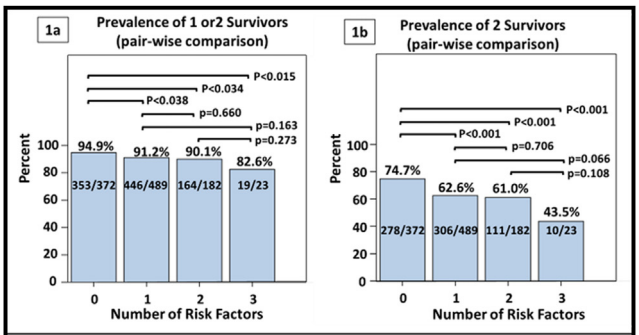
[1]University of Colorado, School of Medicine, Aurora, CO, [2]University of Colorado, School of Medicine, School of Public Health, Aurora, CO, [3]McGovern Medical School at UTHealth Houston, Houston, TX, [4]Sinai Health Center, Toronto, ON, [5]UNC Hospitals, Chapel Hill, NC; on behalf of NAFTNet

OBJECTIVE: Limited data exist regarding the influence of preoperative risk factors (PreopRF) on survival for patients undergoing fetoscopic laser photocoagulation (FLP) for twin-twin transfusion syndrome (TTTS). The objective of this study was to determine preoperative variables predictive of single and dual survival at birth for those subjects treated with FLP for TTTS.

STUDY DESIGN: TTTS pregnancies treated with FLP between 2001-2023 were identified through an international complicated monochorionic twin pregnancy registry (North American Fetal Therapy Network) containing maternal, obstetric, fetal/newborn outcomes, and multiple PreopRF (BMI, gestational age (GA) at FLP, selective fetal growth restriction (sFGR) $< 10^{th}$ and $< 3^{rd}$ percentiles, cervical length (CL) $< <$ 25 and $<$ 15mm, anterior placental location (AP), cardiomyopathy markers, and Quintero TTTS stage). Higher order multiples, fetal anomalies and karyotypic abnormalities were excluded. Predictive rates of single/dual survival based on PreopRF and uni- and multivariate regression analyses were performed with $p < 0.05$ taken as significant.

RESULTS: Of 2728 TTTS cases treated with FLP, 1066 met inclusion criteria. Sequential addition of any Preop RF progressively reduces survival of 1 or 2 twins (Figure 1a) or 2 twins (Figure 1b). Figure 1c shows progressive reduction in predicted survival rates for 1 or 2 twins or 2 twins based on individual and combinations of PreopRF. After uni- and multivariate analyses, the only Preop RF with significant reductions in survival were CL $<$ 25mm for 1 or 2 twins and AP location for 2 twins. Compared to stage I & 2 TTTS, only dual survival is reduced in stage 3 & 4 disease (OR 1.32: 1.02, 1.71; p=0.032)

CONCLUSION: In this large registry, a CL $<$ 25mm was the most predictive PreopRF reducing survival for one or both twins, while AP location was most predictive in reducing survival for both twins. As the number of PreopRF increases for a given TTTS case, there is a progressive reduction in survival. Calculated survival rates based on the presence of one or more PreopRF is useful in the counseling of patients with TTTS.



1c TTTS Survival with and without Preoperative Complications

88 An assessment of the relation between first trimester fetal cardiac function and subsequent preeclampsia

Rebecca Horgan[1], George R. Saade[1], Alfred Abuhamad[1], Erkan Kalafat[2], Elena Sinkovskaya[1]

[1]Eastern Virginia Medical School, Norfolk, VA, [2]Koc University School of Medicine, Istanbul, Istanbul

OBJECTIVE: To compare fetal first trimester right ventricular (RV) cardiac function in uncomplicated pregnancies and in pregnancies who subsequently develop preeclampsia.

STUDY DESIGN: This prospective longitudinal cohort study on the Human Placenta Project (HD 086313-01) included 610 pregnancies at $<$ 13+6 weeks' gestation without fetal, umbilical cord or placental abnormalities. At the first trimester ultrasound, the fetal RV Tei index was measured. The Tei index is a noninvasive Doppler index of combined systolic and diastolic function, calculated by isovolumic contraction time divided by ejection time. Study subjects were followed for the reminder of pregnancy and outcomes were evaluated by trained and certified research coordinators.Patients who ultimately developed preeclampsia (cases) were compared to those who had low risk pregnancies with normal outcomes (controls: aged 18-35 years, with a body mass index (BMI) $<$ 30, without existing comorbidities, who conceived spontaneously and had an uncomplicated pregnancy, with delivery $>$37 weeks' gestation). We compared fetal RV Tei index measurements on first trimester ultrasound between cases and controls.

RESULTS: Amongst the 610 included pregnancies, 60 patients (9.8%) developed preeclampsia (n=60) and 90 patients were in the control group. Mean RV Tei index in the first trimester was significantly lower in cases versus controls (0.42 vs 0.49, p=0.025). Multinominal logistic regression tests were used for statistical analysis, with $p < 0.05$ used to denote statistical significance (R for Statistical Computing v.4.2.0).

CONCLUSION: Compared with normal patients, fetuses of patients who ultimately develop preeclampsia show changes in cardiac function early in pregnancy. We speculate that this represents early fetal adaptation to the previously described utero-placental-fetal vascular perturbation that precedes preeclampsia.

89 Umbilical arteries resistance indices in the management of FGR fetuses- Only half of the story?

Misgav Rottenstreich[1], Swati Agrawal[2], Homero Flores Mendoza[1], Sarah D. McDonald[1], Bryon DeFrance[1], Jon F. Barrett[3], Eran Ashwal[4]

[1]McMaster University, Hamilton, ON, [2]Hamilton Health Sciences, Toronto, ON, [3]Sunnybrook Health Science, University of Toronto, Toronto, ON, [4]McMaster University, North York, Tel Aviv

OBJECTIVE: Assessing the umbilical artery pulsatility index (UA PI) through Doppler measurement is crucial in evaluating fetuses with impaired fetal growth. This study aims to examine the perinatal outcomes associated with discordant PIs of the UAs in small-for-gestational-age and fetal growth-restricted fetuses.

STUDY DESIGN: A retrospective cohort study from a major university hospital including all singleton pregnancies without fetal genetic/structural anomalies and EFW and/or AC below the 10th centile for gestational age (2017-2022). Only cases in which both UAs were concurrently sampled within 14 days from birth were considered. The study compared cases with discordant UA PI values (defined as one UA-PI $\leq$ 95th centile and the other UA-PI $>$ 95th centile for gestational age) to pregnancies where both UAs had normal PI values and those where both UAs had abnormal PI values. The primary outcome focused on the occurrence of composite adverse neonatal outcomes. Multivariable logistic regressions were conducted, adjusting for relevant covariates.

RESULTS: The study included a total of 1,014 patients, among whom 194 (19.1%) had discordant UAs PI values, 671 (66.2%) had both UAs PI within the normal range, and 149 (14.7%) had both UAs PI indicating abnormal values. Pregnancies with discordant UAs PI demonstrated a worsened fetoplacental phenotype compared to those with both UAs showing normal PI values. Similarly, those cases presented worse perinatal outcomes than those with both UAs displaying normal PI values (Table). Notably, cases with discordant UAs PI demonstrated a more benign fetoplacental status and perinatal outcomes compared to those with both abnormal UAs PI. The multivariate analysis indicated that discordant UAs PI was independently associated with composite adverse perinatal outcomes, with an aOR of 1.67 (95% CI 1.16-2.41).

CONCLUSION: Assessing the resistance indices of both umbilical arteries provide additional essential data and is useful as there was an association of adverse perinatal outcomes among SGA/FGR fetuses with discordant US PIs.

Characteristics and outcomes between cases with discordant UA PI, and those with both normal umbilical arteries pulsatility index, and between cases with both abnormal umbilical arteries pulsatility index

	Discordant UA PI n=194	Both normal UAs PI n=671	p-value[a]	Both abnormal UAs PI n=149	p-value[b]

90 Three-dimensional fetal body composition and organ volumes in pregnancies complicated by gestational diabetes mellitus

Kathryn A. Wagner[1], Katherine Grantz[2]

[1]Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD, [2]National Institute of Child Health and Development, National Institutes of Health, Bethesda, MD; on behalf of the NICHD Fetal 3D Study and the NICHD Fetal Growth Studies

OBJECTIVE: Gestational diabetes mellitus (GDM) complicates 6-8% of pregnancies and increases the risk of fetal overgrowth and development of obesity and type 2 diabetes in offspring. Two-dimensional (2D) ultrasound measures of abdominal circumference and fat thickness are greater in fetuses of women with GDM. Three-dimensional (3D) ultrasound, however, provides superior capability in characterizing lean and fat mass and can also measure limb and organ volumes, potentially making it more appropriate for identifying fetal growth abnormalities linked to maternal hyperglycemia. Therefore, we evaluated longitudinal 3D fetal body composition, limb, and organ volumes among normoglycemic women and women who developed GDM, enrolled in a diverse, prospective US pregnancy cohort.

STUDY DESIGN: In the NICHD Fetal 3D Study, fetal body composition and organ volumes were measured in up to five 3D ultrasounds from 15 to 40 weeks by certified sonographers. Women were identified as having GDM (n=130, 6%) or normal glucose tolerance (NGT, n=2,205) using standard diagnostic criteria. Trajectories of 3D fetal measures were modeled using linear mixed effect models. Overall and weekly mean differences in fetal growth were tested by glycemic status, adjusted for covariates including maternal age and body mass index.

RESULTS: Fetuses of women who developed GDM, versus NGT, had larger fractional arm and fractional fat arm volumes on average starting at 27 through 35 weeks, reaching statistical significance at 30-31 and 29-31 weeks, respectively, and larger abdominal area starting at 28 weeks, continuing through the end of gestation (Table). No overall differences were observed among the thigh or organ volumes.

CONCLUSION: Fetal body composition differed in fetuses of women who developed GDM, including larger arm volumes manifested by increases in fat volume. Additional investigation is needed to explore how interventions to treat GDM, including lifestyle and medication, may alter the trajectory of fetal fat accumulation in GDM pregnancies.

Table. Summary of overall and weekly comparisons of fetal 3D body composition and organ volumes across maternal glycemic status; NICHD Fetal 3D Study.

	Global Comparison	Weekly Comparisons	
Outcome	Adjusted p-value	GDM vs. NGT Gestational Weeks	Direction of Assocation
Body Composition			
Fractional arm volume, cm^3	**0.00002**	30-31	Larger
Fractional lean arm volume, cm^3	**0.00002**	17-21	Smaller
Fractional fat arm volume, cm^3	**0.03**	29-31	Larger
Maximum arm SCTT, cm	0.54	-	-
Abdominal area, mm^2	**0.0001**	28-34, 39-40	Larger
Maximum abdominal SCTT, mm	**0.01**	34-36	Larger
Fractional thigh volume, cm^3	0.63	-	-
Fractional lean thigh volume, cm^3	0.48	-	-
Fractional fat thigh volume, cm^3	0.92	-	-
Maximum thigh SCTT, cm	0.12	22-25	Smaller
Organ Volumes			
Cerebellar volume, cm^3	0.65	-	-
Average lung volume, cm^3	0.38	27	Smaller
Average kidney volume, cm^3	0.32	-	-
Liver volume, cm^3	0.15	19-23	Smaller

GDM = gestational diabetes mellitus; NGT = normal glucose tolerance
Linear mixed models were adjusted for: maternal age, race/ethnicity, parity, pre-pregnancy BMI, education, and infant sex
Dashes indicate no gestational age for which weekly pairwise comparisons were different

91 Quantitative Vessel Assessment for Fetal Growth Restriction using 3D Ultrasound Microvessel Imaging

Janelle Santos, Hannah Scott, U Wai Lok, Ping Gong, Elizabeth Cheek-Norgan, Shanshan Tang, Michael Nienow, Krystal Ruka, Mauro Schenone, Sihgao Chen, Chengwu Huang, Elizabeth Enninga, Jingke Zhang, Reade Quinton
Mayo Clinic, Rochester, MN

OBJECTIVE: Fetal growth restriction (FGR) is managed using ultrasonography measurements including estimated fetal weight, abdominal circumference, and Doppler measurements (e.g., uterine artery flow). Ultrasound microvessel imaging could be a useful adjunct to assess abnormal placental development associated with FGR. We used 3D scanning to collect microvessel data to assess microvasculature in placentas of both normal and FGR fetuses.

STUDY DESIGN: Subjects having normal (n=13) and FGR (n=21) pregnancies were enrolled and scanned between 32-36 weeks gestation. A Verasonics Vantage 256-channel ultrasound system equipped with a GE-9L was used in this study. Realtime version of highly sensitive Doppler imaging using randomized SVD-based clutter filtering was applied to find a proper scanning location for a placental villous tree. Step-by-step scanning was performed to acquire 3D data, as illustrated in Fig. A. For the post-processing, the SVD-based clutter filtering with background noise suppression was applied to reconstruct all 2D microvessel images from different step scanning. Additionally, we created a user-interface for the physician to select the region of interest (ROI). The 3D vessel density was computed as a percentage ratio of the total vessel volume within the ROI and the total ROI volume. The 3D vessel densities of the placental microvasculature of FGR subjects were then quantified and compared to those of control groups.

RESULTS: Figure B demonstrates 1 slice of microvessel images (overlaid on the B-mode) with and without FGR, demonstrating fewer vessels in the FGR group. Quantification of vessel density detected a significant difference between the FGR and control groups, as shown in Fig C. The median value of mean vessel densities for the FGR and control groups were 8.9% and 19.1%, respectively ($p < 0.01$).

CONCLUSION: This novel ultrasound method detected significant difference in vessel density for the FGR group compared to control group. Further research is needed to determine how 3D microvessel imaging could improve the detection and management of growth restricted pregnancies.

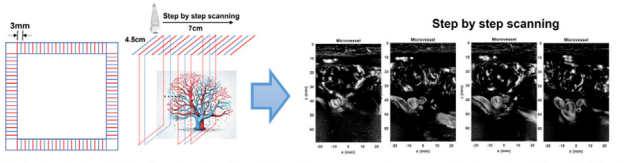

Fig. A. Step-by-step 2D imaging at each position, followed by manual probe movement to the next position guided by the rectangle marker. To cover a 3D volume of scanning, 2D imaging is repeated plane-to-plane for a certain number of planes.

92 Functional deterioration in fetuses with spina bifida on ultrasound

Lennart Van der Veeken[1], Luc De Catte[2], An Hindryckx[3], Johannes van der Merwe[3], Adalina Sacco[4], Felix Debie[5], Katrien Jansen[3], Jan Deprest[6], Francesca M. Russo[7]
[1]Catholic University Leuven, Toronto, ON, [2]Cluster Woman and Child, Biomedical Sciences, KU Leuven, Leuven, Belgium, [3]UZ Leuven, Leuven, Belgium, [4]University College London Hospitals, London, England, [5]UZ Leuven, Leuven, Oost-Vlaanderen, [6]University Hospitals Leuven, Leuven, Vlaams-Brabant, [7]KULeuven, KULeuven, Vlaams-Brabant

OBJECTIVE: Open spina bifida (OSB) is associated with lower limb and bladder dysfunction. We describe bladder and lower limb function over gestational age in a longitudinal cohort of OSB fetuses.

STUDY DESIGN: Prospective cross-sectional study of all fetuses with isolated OSB who had two or more ultrasound evaluation at a single center (2015-2019). Gestational age at assessment was categorized into four groups: (< 24, 25-28, 29-31, ≥32 weeks). 3D-volumes of the bladder were taken every 5-10 minutes during US examination. Volumes were measured using VOCAL method. Bladder filling and voiding was calculated and compared to control fetuses matched for gestational age (1:1). The anatomical level of the lesion was determined on ultrasound. The fetal motor functional level was determined by ultrasound based on joint movement of hip, knee, ankle and toes. Correlation between the postnatal and prenatal functional and anatomical level was calculated using weighted kappa. The presence of talipes was assessed as a prognostic factor.

RESULTS: We included 122 examinations from 69 OSB fetuses. Bladder volumes were smaller in fetuses with OSB compared to controls ($p< 0.0001$) and were correlated to gestational age, but not to the level of the lesion. Also urinary flow was lower compared to controls ($p=0.049$). Lower limb motor dysfunction was more frequent at higher gestational ages (simple linear regression: $p=0.0004$) but it was not correlated to the level of the lesion. In utero motor function was a better predictor for postnatal function than the anatomical level (weighted κ 0.33 vs 0.10 at 21-24w and 0.69 vs 0.41 after 32w) however this only became a strong prediction after 29 weeks. Lastly, the presence of talipes at 25 weeks was a negative predictive factor for postnatal motor function, decreasing the in utero motor function with 2 levels compared to the postnatal function.

CONCLUSION: In OSB, bladder volume and function changes are seen prenatally. In utero lower limb function is a good predictor of postnatal function. Conversely the presence of talipes has an adverse effect.

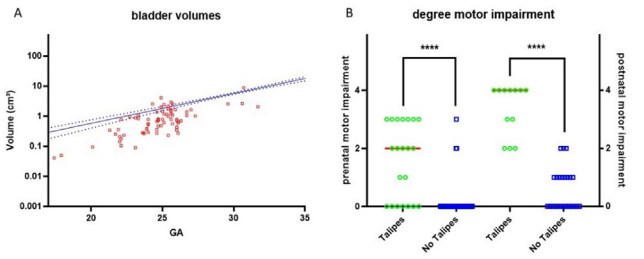

Figure: A) bladder volumes throughout gestation for fetusus with open spina bifida (red) compared to normal controls (bleu line) with 95% CI (dotted line). B) Functional motor impairment assessed prenatally on ultrasound (left) and postnatal (right) for fetuses with talipes (green) and fetuses without talipes (bleu). Red line indicates median. The median anatomic level of both groups was similar. The pre- and postnatal functional level was defined as a score as follows: toe movement or ankle plantar flexion = 0 ; ankle dorsi-flexion = 1 ; knee flexion = 2 ; knee extension = 3 ; hip movement = 4. **** indicates p<0.0001. All data are plotted as individual values.

93 Reliability of "lethal" ultrasound markers in identifying fetuses with truly life-limiting skeletal dysplasia

Haley Crane[1], Erica M. Schindewolf[2], Julie Moldenhauer[3], Natalie Burrill[2], Suzanne DeBari[2], Nahla Khalek[1], Christina Paidas Teefey[4], Shelly Soni[4], Beverly G. Coleman[5], Juliana S. Gebb[2]

[1]Richard D. Wood Jr. Center for Fetal Diagnosis and Treatment at CHOP, Philadelphia, PA, [2]Center for Fetal Diagnosis & Treatment, Children's Hospital of Philadelphia, Philadelphia, PA, [3]Richard D. Wood, Jr. Center for Fetal Diagnosis & Treatment, Children's Hospital of Philadelphia, Perelman School of Medicine of the University of Pennsylvania, Philadelphia, PA, [4]Children's Hospital of Philadelphia, Philadelphia, PA, [5]Richard D. Wood, Jr Center for Fetal Diagnosis and Treatment at CHOP, Perelman School of Medicine of the University of Pennsylvania, Philadelphia, PA

OBJECTIVE: Several ultrasound markers have been proposed to identify fetuses with life-limiting skeletal dysplasia. We sought to determine their diagnostic performance in a fortified cohort.

STUDY DESIGN: A single-center retrospective chart review was conducted from 2013 to 2023 for pregnancies suspected to have a skeletal dysplasia. Fetuses were evaluated by ultrasound with attention to measurements predictive of lethality, including thoracic circumference/abdominal circumference (TC/AC) < 0.6, femur length/abdominal circumference (FL/AC) < 0.16, and thoracic circumference (TC) < 2.5%ile. Record review included demographic information, imaging, genetic testing, and fetal/neonatal outcome. Statistical analysis included Mann Whitney U and Fisher's exact tests. Calculation of sensitivity, specificity, positive predictive value, and negative predictive value was also undertaken.

RESULTS: 122 fetuses were identified with prenatal ultrasound findings consistent with a skeletal dysplasia. Of those, 34 (27.9%) had no lethal markers, 52 (42.6%) had one lethal marker, 31 (25.4%) had two lethal markers, and 5 (4.1%) had three lethal markers. Outcomes based on number of lethal markers are detailed in Table 1. 96 (78.7%) patients had complete outcome data. In those, FL/AC ratio < 0.16 and TC < 2.5%ile were associated with death or a life-limiting genetic diagnosis ($p< 0.001$; $p< 0.001$) while TC/AC < 0.6 was not ($p=0.056$) (Table 2). The positive predictive value for predicting death or a life-limiting genetic diagnosis increased from 50.0% with one lethal ultrasound marker to 76.9% with two lethal markers to 100% with three lethal markers. The negative predictive value of no lethal markers was 90.9%.

CONCLUSION: In our cohort, ultrasound markers of lethality did not necessarily portend a life-limiting postnatal diagnosis until three lethal parameters were present and absence of lethal markers did not guarantee a non-lethal dysplasia. This highlights the importance of the combination of thorough ultrasound examination, genetic testing, and balanced parental counseling.

	Alive or non-lethal genetic diagnosis n=47	Deceased or lethal genetic diagnosis n=49	p-value
Gestational age at US	27.1 [21-32]	23.3 [21-26.6]	0.072
TC/AC < 0.6	0	5 (10.2%)	0.056

94 Fully quantitative operator-independent numeric cervical softening device: Cervical softening rate associated with mode of delivery

Molly J. Stout[1], Methodius G. Tuuli[2], Adam K. Lewkowitz[3], Julie Tumbarello[1], Emily Diveley, BSN[4], Wendy Sparks[1], Maya Diab[1], Michelle Moniz[1], AnneMarie E. Opipari[1], Jourdan E. Triebwasser[5], Peinan Zhao[4]

[1]University of Michigan, Ann Arbor, MI, [2]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [3]Warren Alpert Medical School of Brown University, Women & Infants Hospital Rhode Island, Providence, RI, [4]Washington University in St. Louis, St. Louis, MO, [5]University of Michigan, Ann Arbor, MI

OBJECTIVE: To utilize a novel, fully quantitative cervical elastography system (FQ-CES) to numerically measure cervical stiffness at term to predict mode of delivery.

STUDY DESIGN: This is a prospective longitudinal cohort study of pregnant patients who underwent FQ-CES starting 37 weeks and weekly thereafter until delivery occurred. We invented FQ-CES, which modifies a transvaginal ultrasound probe to quantify both pressure applied and tissue deformation, thereby yielding a fully quantified strain-based elastography system that provides a numeric quantification (Young's modulus) of cervical tissue stiffness. This system is operator independent and can be compared across patients and within patients over time. Singleton pregnancies at 37 weeks

awaiting spontaneous labor and vaginal delivery were enrolled and had FQ-CES measured weekly until delivery occurred. Patients remained enrolled regardless of their eventual timing or indications for delivery. Young's modulus was log transformed to achieve normality of distribution (logYM). Cervical tissue logYM from FQ-CES and CL were analyzed over pregnancy using linear mixed effect models.

RESULTS: A total of 122 patients were included, 109 vaginal births and 12 cesarean births. Cervical tissue stiffness (logYM) decreased from 37 weeks until delivery at a rate of 13% per week (P=0.005). In patients with eventual vaginal birth the softening rate is 15% per week (P=0.001) whereas those with cesarean birth did not soften. The trend lines for rate of softening significantly differed (P=0.02) by eventual mode of delivery.

CONCLUSION: FQ-CES detects different cervical softening patterns at term associated with eventual mode of delivery, which may provide opportunity to define normal and abnormal cervical remodeling ahead of birth.

95 Application of machine learning in the detection of four chamber abnormalities

Paola Abi Habib[1], Reza Shirkavand[2], Samantha Selhorst[1], Ozhan M. Turan[3], Heng Huang[2], Sifa Turan[3]
[1]University of Maryland School of Medicine, Baltimore, MD, [2]University of Maryland, College Park, MD, [3]University of Maryland Medical Center, Baltimore, MD

OBJECTIVE: Identification of the normal cardiac landmarks excludes major cardiac defects. Congenital heart defects (CHD) often go undetected in low-risk settings despite having a high incidence, due to training and resource substandardization. The use of Machine learning (ML) in cardiovascular disease has been newly implemented and has the potential to overcome this limitation. We hypothesize that ML technology accurately detects normal vs. abnormal four-chamber views.

STUDY DESIGN: MobileNet is a lightweight neural network model that has an innate understanding of general visual features. We employed an architecture similar to a MobileNet pretrained on the ImageNet dataset and subsequently applied it to our previously collected fetal ultrasound scans. The characteristics of MobileNet are well-suited for small datasets, as its efficiency allows practical training even with limited data. Our data comprised 150 normal and 50 abnormal four-chamber heart views (4ChV) collected between 20-28 weeks of gestation, in patients with a median BMI of 27.9 (17.2-50.2). Normal 4ChV is defined as two equal size atria and ventricles, intact septum, different positions of the crux, and visualization of two pulmonary veins into the left atrium. This dataset was used for training and validation through a 5-fold cross-validation process. The metrics were subsequently compared to other mainstream models using F1 scores (combination of precision and recall).

RESULTS: This model demonstrates excellent proficiency in accurately interpreting normal vs. abnormal 4ChV of the fetal heart images, yielding an F1 score of 0.758±0.038 and an Area Under the Receiver Operating Characteristic curve (AUROC) of 0.884±0.032. These metrics were also higher compared to other existing mainstream ML models (Table).

CONCLUSION: Our study demonstrates the efficacy of integrating advanced deep learning, specifically the MobileNet model, into fetal echocardiography for identifying abnormal 4ChV. The model performs remarkably and offers a promising solution to enhance the clinical diagnosis of fetal cardiac defects.

Table 1: Performance Metrics of Various Deep Learning Models on Fetal Heart Abnormality Detection. AUROC: Area Under Receiver Operating Characteristic, F1: F1 Score, Accuracy: Classification Accuracy, Precision: Positive Predictive Value, Re- call: Sensitivity. 96 Maternal and pregnancy outcomes following management of acute appendicitis during pregnancy in the United States

May Abiad, Emanuele Lagazzi, Wardah Rafaqat, Jefferson A. Proaño-Zamudio, Anne Hoekman, Ikemsinachi C. Nzenwa, Micheal DeWane, George Velmahos, John O. Hwabejire, Emily Naoum, Malavika Prabhu, Casey Luckhurst
Massachusetts General Hospital, Boston, MA

OBJECTIVE: To compare maternal and pregnancy outcomes according to management strategy for acute appendicitis during pregnancy.

STUDY DESIGN: This retrospective cohort study was conducted using data from the 2016-2019 Nationwide Readmissions Database. Pregnant patients admitted with acute appendicitis were identified and categorized based on the initial management strategy: operative management (OM) vs. non-operative management (NOM). The primary outcomes evaluated were adverse maternal and perinatal outcomes: intrauterine fetal death (IUFD), intrauterine growth restriction (IUGR), spontaneous abortion, preterm delivery, C-section, obstetric bleeding, venous thromboembolism (VTE), chorioamnionitis. Propensity score matching was used to control for confounders including maternal age, gestational age at index admission, maternal comorbidities, maternal obstetric history, multiple gestation, and appendiceal disease severity.

RESULTS: Among 2184 patients identified, 340 (15.6%) underwent NOM for acute appendicitis. At index admission, NOM patients were more likely to be in their first trimester, have Medicaid as primary insurance, and less likely to have a history of previous C-section (all $p < 0.001$). NOM patients were also less likely to have presented with complicated appendicitis. After propensity score-matched analysis, no significant differences were observed in IUFD, IUGR, spontaneous abortion, obstetric bleeding, VTE, or chorioamnionitis between the two groups. Patients who underwent OM had a higher likelihood of preterm delivery (16.0% vs. 9.0%, $p = 0.007$) and C-section (44.9% vs. 35.2%, $p < 0.011$) [Table 1]. NOM patients were more likely to have genitourinary complications during index admission, particularly pyelonephritis (7.8% vs. 0.0%, $p < 0.001$).

CONCLUSION: While operative management of appendicitis is the historical standard of care, this study suggests that there may be an increased risk of adverse maternal or perinatal outcomes with operative management.

Table 1. Clinical Outcomes at Index Admission and Delivery Readmission, in a National Sample of Pregnant Patients Admitted with Acute Appendicitis, by Management Approach in Matched Pairs.

	Non-operative Management (N=332)	Operative Management (N=332)	p-value
Outcomes at Index Hospitalization

97 Induction of labor at 12 vs. 24-hours for prelabor rupture of membranes: a retrospective study

Raneen Abu Shqara[1], Liron Rosso[1], Lior Lowenstein[2], Maya Frank Wolf[3]

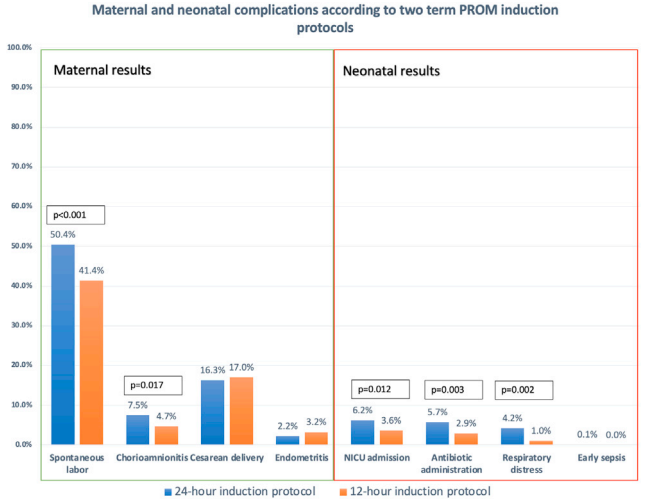
[1]Galilee Medical Center, Nahariya, HaZafon, [2]Galilee Medical Center, Nahariya, Israel Azrieli Faculty of Medicine, Bar Ilan University, Safed, Israel, Naharyia, HaZafon, [3]Galilee Medical Center, Nahariyya, Israel and Azrieli Faculty of Medicine, Bar Ilan University, Safed, Israel, Nahahriyya, HaZafon

OBJECTIVE: The management of term prelabor rupture of membrane (PROM) is controversial. As spontaneous labor occurs in 60% and 95% of women at 12 and 24-h post PROM, respectively, we changed our department protocol from induction at 12 to 24-h following PROM. We aimed to investigate maternal and neonatal morbidity according to the two induction protocols.

STUDY DESIGN: This retrospective study was conducted in a single tertiary university-affiliated hospital (2020-2023). On 01 July, 2021, we extended the conservative management duration of our term PROM protocol, such as to administer oxytocin after 24 rather than 12 h. We compared the rate of chorioamnionitis between the two induction protocols, among women at term with PROM and without evidence of active labor at admission. Exclusion criteria were complications requiring prompt delivery, and multiple pregnancies.

RESULTS: Following the protocol of 24-h (n=962) versus 12-h (n=802) induction, the proportions were higher of women who labored spontaneously (50.4% vs 41.5%, p< 0.001), and who had chorioamnionitis (7.5% vs 4.7%, p=0.017); cesarean deliveries (CD) occurred similarly. Following the 24-h versus 12-h induction protocol, the rates were higher of neonatal intensive care unit admission (6.2% vs 3.6%, p=0.012), antibiotic administration (5.7% vs 2.9%, p=0.003), and respiratory distress (4.2% vs 1.0%, p=0.002) (Figure). Among women with a previous vaginal delivery, the rate of inductions was lower following the 24-h than 12-h protocol (46.5% vs 57.3%, p=0.041); maternal and neonatal outcomes were similar. Among women with a previous CD, the rates were lower following the 24-h vs. 12-h protocol, for oxytocin use (20.3% vs 43.2%, p=0.003) and CD (28.9% vs 48.6%, p=0.016).

CONCLUSION: Our results advocate shared decision-making in the management of term PROM. Women should be informed of the lower chance for induction and the higher risk of chorioamnionitis, with a 24-h induction protocol approach. Parous women and those with previous CD might benefit from longer expectant management.



98 Is subfebrile fever during prolonged ROM (>12 hours) related to infectious outcomes?

Raneen Abu Shqara[1], Yara Nakhlah[2], Lior Lowenstein[3], Maya Frank Wolf[4]

[1]Galilee Medical Center, Nahariya, HaZafon, [2]Galilee Medical Center, Nahariya, Israel, HaZafon, [3]Galilee Medical Center, Nahariya, Israel Azrieli Faculty of Medicine, Bar Ilan University, Safed, Israel, Naharyia, HaZafon, [4]Galilee Medical Center, Nahariyya, Israel and Azrieli Faculty of Medicine, Bar Ilan University, Safed, Israel, Nahahriyya, HaZafon

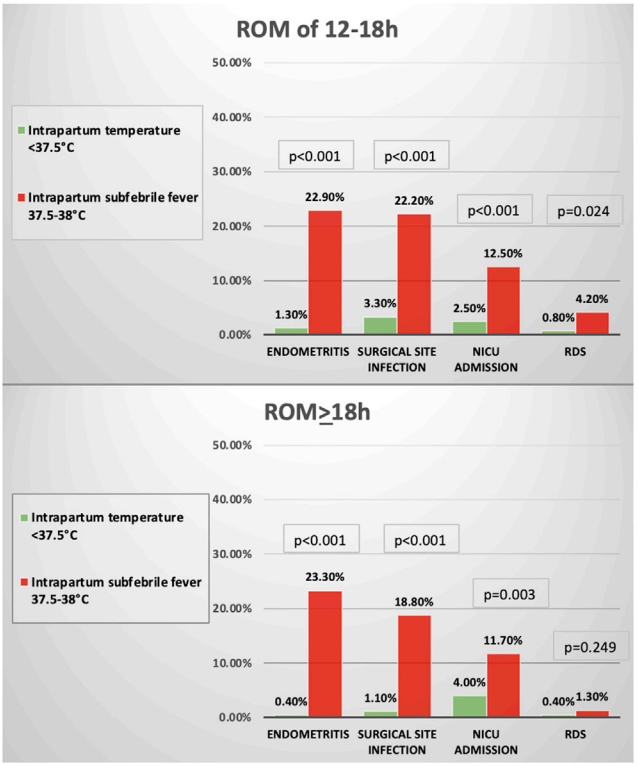
OBJECTIVE: Women with prolonged rupture of membranes (ROM) are at higher risk for peripartum infections. Definitions for intrapartum fever vary. Generally, when intrapartum fever is ≥38°C, antibiotic treatment should be considered. We compared maternal and neonatal outcomes of women with prolonged ROM (>12h), between those with subfebrile fever (37.5-37.9°C) and with normal body temperature (< 37.5°C).

STUDY DESIGN: This retrospective study included women hospitalized in a tertiary university-affiliated hospital between July 2021 and May 2023. The primary outcome, the endometritis rate, was compared between women with intrapartum subfebrile fever and with normal body temperature. Singleton term, ROM >12h and maximal body temperature of 37.9°C were inclusion criteria. The data were analyzed according to two latency period groups: ROM of 12-18h and ROM >18h. Women with ROM >18h received intrapartum ampicillin for group B streptococcus prophylaxis. Chorioamniotic-membrane swabs were obtained in ROM >18h.

RESULTS: Included were 1796 women: 687 with ROM 12-18h and 1109 with ROM >18h. For both latency groups, among women with subfebrile fever vs. normal body temperature, the rates were higher of endometritis (p< 0.001), surgical site infections (p< 0.001), neonatal intensive care admission (p=0.003) and neonatal fever (p< 0.001) (figure). Respiratory distress syndrome rates were higher

among women with subfebrile than normal fever in the ROM 12-18h group (p=0.024). Among women with ROM >18h group, the rates were higher of Enterobacteriaceae isolates in chorioamniotic-membrane cultures, among those who were subfebrile than with normal intrapartum temperature (22% vs 11%, p< 0.001).

CONCLUSION: We report higher maternal and neonatal morbidity among women with subfebrile fever and ROM >12h. Subfebrile fever might be the initial presentation of peripartum infection. This is supported by the higher rates of endometritis and surgical site infection. Clinical trials should focus on whether antibiotic treatment should be considered in this context.



99 A meta-analysis on the impact of doula care on Cesarean section rates

Nnenna E. Achebe[1], Yasmin Dias[2], Michelle M. Doering[3], Rachel Paul[3], Megan L. Lawlor[3], Nandini Raghuraman[3], Jeannie C. Kelly[4], Ebony B. Carter[4]

[1]Meharry Medical College, Nashville, TN, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, St. Louis, MO, [4]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

OBJECTIVE: Cesarean section account for nearly one-third of all deliveries in the United States. We aimed to pool results from extant literature to determine whether the addition of doula services decreases caesarean delivery rates.

STUDY DESIGN: We conducted a systematic review and meta-analysis by searching electronic databases for randomized controlled trials (RCT) and observational studies comparing prenatal care plus doula services (PC+) to standard prenatal care (PC). The primary outcome was caesarean delivery (CD). Secondary outcomes included instrument assisted vaginal delivery (IAVD-forceps or vacuum) and epidural placement. We conducted a stratified analysis by study type (RCT or observational). Pooled relative risks (RRs) and weighted mean differences were calculated using random-effects models. The Q-test and I2 statistics assessed heterogeneity.

RESULTS: Sixteen studies (8 RCTs and 8 observational studies) met study criteria. Patients receiving PC+ were significantly less likely to have a CD overall (n=16 pooled rates 18.7% PC+ vs. 30.7% PC; pooled RR 0.32; 95% CI 0.25-0.40) and in stratified analysis of RCTs (8 studies: pooled rates 14.4% PC+ vs. 21.9% PC; pooled RR 0.25; 95% CI 0.17-0.37) and observational (8 studies: pooled rates 19.7% PC+ vs. 30.7% PC; pooled RR 0.37; 95% CI 0.27-0.50) studies. There was no difference in rate of epidural placement but those with PC+ were more likely to have an IAVD.

CONCLUSION: Pregnant patients supported by doulas services are 68% less likely to undergo CD than those receiving standard prenatal care, more likely to have IAVD, and have no difference in epidural rates. Additional research is needed to elucidate the impact of doula services on neonatal outcomes. Nonetheless, doula support services represent a promising intervention to decrease the high rates of caesarean section in the United States.

100 Artificial intelligence (machine learning) and molecular classification of sibling twin (TW) placentas in preeclampsia (PE).

William E. Ackerman IV[1], Hongwu Jing[2], Guomao Zhao[2], Catalin S. Buhimschi[2], Irina A. Buhimschi[2]

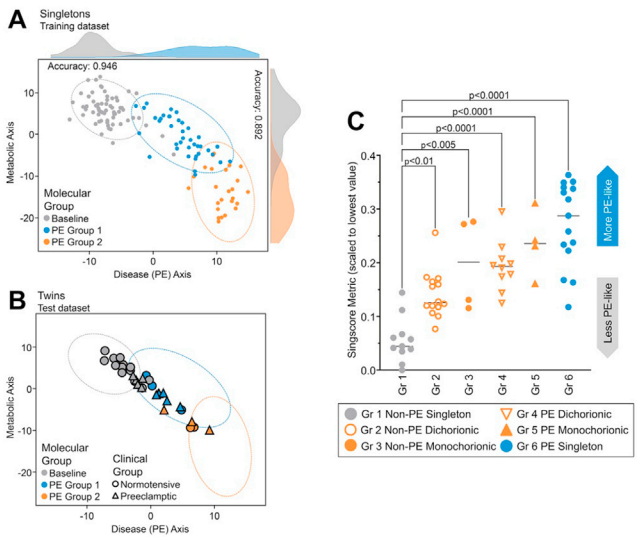
[1]University of Illinois at Chicago College of Medicine, Chicago, IL, [2]University of Illinois at Chicago, Chicago, IL

OBJECTIVE: TW pregnancies are at increased risk for PE. Glycolytic metabolic shift is a key transcriptomic signature in PE placenta. Here, we explored transcriptomic features of the TW placenta using artificial intelligence (AI) tools to understand its contribution to the pathobiology of PE.

STUDY DESIGN: RNAseq was performed on villous tissue of TW pregnancies grouped by chorionicity and PE diagnosis: **1)** dichorionic (dc) PE (n=5, GA 33±2 w); **2)** dc non-PE (n=7, GA 32±1 w); **3)** monochorionic (mc) PE (n=2, GA 33±3 w); **4)** mc non-PE (n=2, GA 32±1 w). Placentas from mc cases were sampled twice. A 3-cohort early-onset PE dataset from 127 singleton PE and non-PE placentas (GSE114691, GSE148241, GSE203507) was mined using machine learning (DaMiRseq) and used to train support vector machine (SVM) classifiers (caret R package). A gene-signature scoring (singscore) algorithm quantified molecular phenotypes along a continuum.

RESULTS: In the learning phase, SVM had accuracies of 94.6% and 89.2% for PE and glycolytic metabolic shift, respectively (Fig. A), segregating singleton data in 3 clusters: normal (baseline), disease group 1 (PE, no metabolic shift), and disease group 2 (PE with metabolic shift). In twin pairs, 56% (9/16; dc n=7, mc n=2) had inter-TW placental transcriptional discordance. Individually, 27% (5/18) of clinically non-PE TW placentas were reclassified to a diseased molecular class (group 1 or 2), while 35% (5/14; dc n=4, mc n=1) of clinically PE TW placentas were categorized as baseline (Fig. B). The TW PE placentas had higher (more PE-like) singscores (p< 0.001, ANOVA). Non-PE TW placentas also had elevated scores compared to non-PE singleton placentas (p< 0.01, ANOVA; Fig. C). Among dc pregnancies, only 42% (5/12) of cases had both placentas displaying the same molecular signature simultaneously.

CONCLUSION: Our novel AI approach demonstrates that placental transcriptional metabolic stress and discrepancy between clinical and molecular classification is common in TW. In dc TW one placenta carrying the molecular PE signature may be sufficient to trigger the hypertensive phenotype.



101 Impact of treatment for prenatal depression on cardiovascular disease 24 months after delivery

Christina M. Ackerman-Banks[1], Kristin Palmsten, ScD[2], Heather S. Lipkind[3], Katherine Ahrens[4]

[1]Baylor College of Medicine, Houston, TX, [2]Health Partners Institute, Health Partners Institute, MN, [3]Weill Cornell, New York, NY, [4]Muskie School of Public Health, ME; for the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

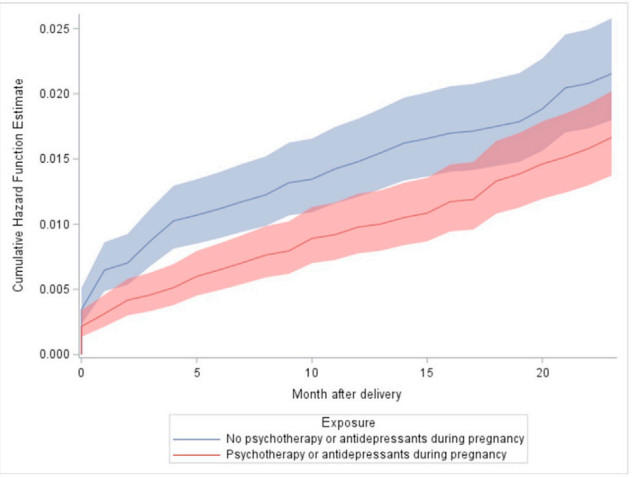
OBJECTIVE: Prenatal depression is associated with an increased risk of new cardiovascular disease (CVD). However, It is unclear how treatment of prenatal depression impacts CVD risk. We sought to determine if treatment of prenatal depression reduces the risk of new CVD within 24 months postpartum.

STUDY DESIGN: Our longitudinal population-based study included pregnant individuals with deliveries in the Maine Health Data Organization's All Payer Claims Data, 2007-2019. We excluded those with pre-pregnancy CVD, multifetal gestations, or no continuous health insurance during pregnancy. Prenatal depression was identified with ICD9/10 diagnosis codes, psychotherapy was identified with CPT procedure codes, and antidepressant medications were identified from pharmacy dispensing data. All were identified using claims with service dates between 6 and 34 weeks' gestation. Primary outcomes were a composite CVD outcome (heart failure, ischemic heart disease, cerebrovascular disease, arrythmia/cardiac arrest, and cardiomyopathy) and new chronic hypertension (cHTN). Cox models were used to estimate hazard ratios, adjusting for potential confounding factors. Censoring events were loss of health insurance or next pregnancy, whichever was earlier.

RESULTS: Of the 15,895 pregnancies with prenatal depression, 54% (n=8517) had antidepressants or psychotherapy visits (34% had antidepressants and 30% had psychotherapy). The cumulative risk of the composite CVD outcome and new cHTN within 24 months postpartum was 1.9% and 3.3%, respectively. Antidepressant medications and/or psychotherapy visits were associated with a decreased risk of the composite CVD outcome (aHR 0.73 [95% CI 0.56-0.96]). (Figure) The risk of new cHTN within 24 months postpartum was not impacted (aHR 1.04 [95% CI 0.83-1.32]).

CONCLUSION: The cumulative risk of new cardiovascular disease within 24 months postpartum was decreased in patients with antidepressant and/or psychotherapy use. This association requires further exploration, but suggests that prioritizing treatment of prenatal depression both improves mood and mitigates cardiovascular disease risk.

Figure: Risk of New Cardiovascular Disease (CVD)[a] in the first 24 months' postpartum among people with Prenatal Depression



[a] Cardiovascular disease = composite outcome (heart failure, ischemic heart disease, cerebrovascular disease, arrythmia/cardiac arrest, and cardiomyopathy)
*Adjusted for maternal age at time of delivery, pre-pregnancy depression, pre-pregnancy hypertension, pre-pregnancy diabetes, obesity, smoking, nulliparity, pregnancy number in dataset, year of delivery, Medicaid coverage during pregnancy, county-level measures, zip-code level measures, hypertensive disorders of pregnancy, gestational diabetes, use of psychotropic medication during 6-34 weeks' gestation, any depression-related hospital or emergency department encounter during 6-34 weeks' gestation.
Data source: Maine Health Data Organization's All Payer Claims Database

102 Circulating EV-miRNA profile in pregnant persons with opioid use disorder treated with buprenorphine

Maricedes Acosta-Martinez[1], Christelle Jean-Baptiste[1], Zijian Shao[1], Omar Abuzeid[2], Cassandra Heiselman[1], David Garry[1]

[1]Stony Brook Medicine, Stony Brook, NY, [2]Stony Brook University Hospital, Stony Brook, NY

OBJECTIVE: Maternal OUD has increased with a related rise in NOWS. Buprenorphine has become one of the mainstays for MOUD. The effects of OUD and MOUD on maternal and fetal physiology are not well understood. Because circulating extracellular vesicle miRNAs (EV-miRNAs) from pregnant patients have both a maternal and fetal (placental) origin, they may serve as biomarkers of maternal and fetal health. Hence, we examined the impact of buprenorphine on circulating EV-miRNA cargo in pregnant patients.

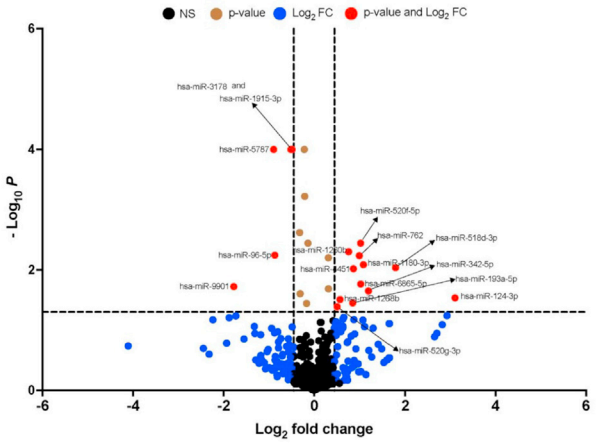
STUDY DESIGN: EV-miRNAs were isolated from the plasma of pregnant women during the 3rd trimester (12 buprenorphine-treated and 12 healthy controls) and small RNA-sequencing was performed to identify miRNAs in both groups. For miRNAs differential presence analysis, read counts were log-10 normalized and 2-way ANOVA comparisons between groups performed with Benjaminini and Hochberg method used to control the false discovery rate (FDR). Targeted biological pathways and disease-associations were assessed with DIANA-miRpath and RNADisease, respectively.

RESULTS: Maternal age and BMI were similar in both groups. There was no difference in timing of maternal blood for EV-miRNAs

evaluation (30.7±2.7 v 31.4±2.9; p=0.56) for controls and buprenorphine respectively. A total of 508 EV-miRNAs were detected, of which 16 were differentially abundant between buprenorphine and control groups (Figure 1). Among the EV-miRNAs enriched in the buprenorphine group, hsa-miR-520f-5p, hsa-miR-520g-3p, and hsa-miR-518d-3p, belong to the placenta-specific, chromosome 19 miRNA cluster (C19MC). RNA-disease prediction analysis revealed *hsa-miR-520g-3p, hsa-miR-124-3p, has-miR-1260b* to be associated with preeclampsia. Moreover, many differentially present EV-miRNAs were linked to cardiovascular disease, stroke, and myocardial infarction. Targeted biological pathways linked to the EV-miRNAs included pathways in cancer, cellular senescence, regulation of actin cytoskeleton, and neurotrophin signaling.

CONCLUSION: This is a novel study which identified unique alterations in circulating EV-miRNAs in buprenorphine treated patients with OUD.

Figure 1. Volcano plot of differentially expressed EV-miRNAs between buprenorphine-exposed pregnant patients and healthy controls. Each dot corresponds to a miRNA. The log2fold change is represented in the x-axis, while the negative log (base 10) of the p-value in the y-axis. The horizontal dashed line represents the threshold with a p-value cutoff <0.05, while the vertical bars represent the absolute log2fold change ≥0.5. The 16 differentially expressed miRNAS (DEMIs) are labeled in the plot (red). The left panel (0 to −6 of log2fold change) is downregulated, while the right panel (0–6 of log2fold change) is upregulated EV-miRNAs.



103 Assessing tranexamic acid utilization for management of postpartum hemorrhage at referral facilities in Ghana

Kwame Adu-Bonsaffoh[1], Paola Del Cueto[2], Kate Obayagbona[3], Rohini Dutta[4], Mehreen Zaigham[3], Grace Newman[5], Henry Kumi[6], Abonie Maclean[7], Solomon Armah[6], Henry Mark Mark Lugobe[8], Isaac Nsiah[6], Nicholas Musinguzi[9], Chris Fofie[10], Adeline A. Boatin[11]

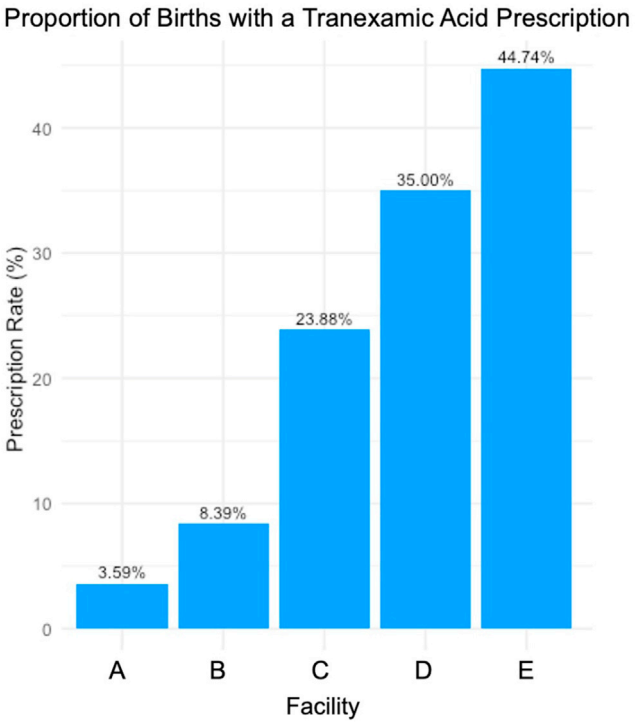
[1]University of Ghana Medical School, Greater Accra, [2]Massachusetts General Hospital, Boston, MA, [3]Program for Surgery and Social Change and, Boston, MA, [4]Program in Global Surgery and Social Change, Brookline, MA, [5]Korle-Bu Teaching Hospital, Accra-North, Armed Forces Africa, Canada, Europe, Middle East, [6]Korle-Bu Teaching Hospital, Accra, Greater Accra, [7]Korle-Bu Teaching Hospital, Accra, Ghana, [8]Mbarara University of Science and Technology, Mbarara, Mbarara, [9]Center for Global Health, Boston, MA, [10]Ghana Health Services, Accra, Greater Accra, [11]Massachusetts General Hospital, BOSTON, MA

OBJECTIVE: Postpartum hemorrhage (PPH) is the leading cause of maternal mortality worldwide. Tranexamic acid (TXA) is a promising intervention for excessive bleeding after childbirth, and is recommended by the World Health Organization for the treatment of PPH. However, there is limited real-world data on current use patterns of TXA in low and middle-income countries, including Ghana. We aimed to assess the utilization of tranexamic acid among women delivering at referral-level facilities in Ghana using electronic medical record (EMR) data and describe variation in use by facility, delivery volume at each facility, and mode of delivery.

STUDY DESIGN: Data was obtained from Lightwave Health Information System (LHIMS), an EMR system implemented across referral facilities in Ghana in 2018. Clinical information is entered into LHIMS by clinicians engaged in patient care. We retrieved data on medicines prescribed, mode of delivery and patient demographics on all births occurring at five regional referral hospitals between August and November 2022. We compared the proportion of births in which TXA was prescribed by facility, delivery volume, patient demographics, and mode of delivery.

RESULTS: Data were available on 3723 births from five facilities. The overall proportion of births in which TXA was prescribed was 20.9% and varied significantly across facilities from 3.5% to 45%. Prescription rates were higher among women delivered by cesarean section compared to those delivered vaginally (51.4% vs 4.3%; p< 0.001). We found no differences in prescription of TXA by age, education or occupation of women delivered, or by delivery volume.

CONCLUSION: We demonstrate the use of a national-level EMR to assess peripartum TXA prescription patterns in Ghana, revealing significant variation in TXA use across referral hospitals in the country and by mode of delivery. Further work is needed to understand variation in practice by facilities and mode of delivery to optimize adherence to recommended practice guidelines



104 Adverse maternal obstetric outcomes by HIV status in Botswana: Data from the 'Treat-All' HIV Era

J. Sroda Agudogo[1], Maya Jackson-Gibson[2], Annliz Macharia[1], Indira Ranaweera[1], Katlego Boikanyo[3], Modiegi Diseko[3], Judith Mabuta[3], Sarah Hanson[1], Dudu Rubgega[4], Bridgette Wamakima[1], Joseph Makhema[3], Michele R. Hacker[1], Rebecca Zash[1], Justus Hofmeyr[4], Roger L. Shapiro[1], Rebecca Luckett[1]

[1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Botswana Harvard Health Partnership, Gaborone, Botswana, [4]University of Botswana, Botswana, South-East

OBJECTIVE: Botswana has achieved 90-90-90 targets to eliminate HIV and led the region in initiating antiretroviral therapy (ART) at the time of HIV diagnosis ('treat-all'). The impact of HIV and ART on neonatal outcomes have been extensively studied, yet data on maternal obstetric outcomes are limited. This study aimed to evaluate maternal outcomes in a large cohort with high HIV prevalence after implementation of a 'treat-all' policy.

STUDY DESIGN: Data were collected at the time of delivery from the medical record between November 2021 to February 2023; outcomes were recorded in the Tsepamo Birth Outcomes Surveillance and Safe Birth studies at Princess Marina Hospital in Botswana. We evaluated maternal obstetric morbidities and maternal mortality at the time of hospital discharge by HIV status.

RESULTS: We included 6982 participants; 1336 (19%) were pregnant people with HIV (PHIV). 1288 (96%) were on ART, and 439 (93%) of those with known ART regimen were on tenofovir, lamivudine, and dolutegravir (TLD). Of 473 with known CD4 counts, 325 (69%) were >500 cells per μL, 128 (27%) were 200-500 cells per μL, and only 20 (4%) were < 200 cells per μL. Of 898 with known viral loads, 836 (93%) were undetectable. Overall rates of pre-eclampsia were the same between groups (p=0.47). There were no differences in rates of hemorrhage, infections, acute pulmonary or cardiac conditions, or death in people with and without HIV (all p≥0.24). Although an overall rare outcome, acute kidney injury was slightly more common in PHIV (0.4% versus 0.1%, p = 0.04).

CONCLUSION: Rates of adverse maternal obstetric outcomes were similar in people with and without HIV in the treat-all ART era where a majority were virally suppressed on TLD, except for a 3-fold increased risk of AKI for PHIV though numbers were small. This study demonstrates that treat-all with first-line TLD leads to similar maternal obstetric outcomes for PHIV.

Table 1: Adverse maternal obstetric outcomes by HIV status

Complication	People without HIV (n=5646)	People with HIV (n=1336)	P value
Pre-eclampsia	548 (9.7)	121 (9.1)	0.47
Pre-eclampsia without severe features[1]	234 (42.9)	59 (48.8)	0.24
Pre-eclampsia with severe features[1]	312 (57.1)	62 (51.2)	0.24
HELLP syndrome[1]	22 (4.0)	7 (5.8)	0.39
Superimposed preeclampsia[1]	90 (16.4)	24 (19.8)	0.37
Acute kidney injury[2]	8 (0.1)	6 (0.4)	0.04
Obstetric hemorrhage	210 (3.7)	54 (4.0)	0.58
Infection[3]	57 (1.0)	17 (1.3)	0.40
Acute cardiac and pulmonary events[4]	28 (0.5)	7(0.5)	0.89
Maternal death in hospital	4 (0.1)	2 (0.1)	0.32

Data presented as n (%)
[1]denominator is total cases of pre-eclampsia in each group, definitions of categories according to American College of Obstetrics and Gynecology
[2] defined clinically as elevated creatinine > 104 µmol/L or urine output < 30 milliliters / hour
[3] composite outcome of chorioamnionitis, sepsis, wound infection, urinary tract infection, pneumonia

105 Medication effectiveness in the treatment of Insomnia in 3rd trimester pregnancies

Daniel Martingano[1], Andrea Ouyang[2], Marwah Al-Dulaimi[1], Jessica Marshall[1], Rachel Amuzu[3], Shavana Singh[4], Alexander Ulfers[5], Benjamin Dribus[6], Kristin Cohen[7], Shailini Singh[8], Jacqueline Marecheau[1], Antonia F. Oladipo[9], Donald Morrish[1]

[1]St. John's Episcopal Hospital-South Shore, Far Rockaway, NY, [2]William Carey University College of Osteopathic Medicine, Baton Rouge, LA, [3]Rutgers Health, Jersey City Medical Center, Elizabeth, NJ, [4]Lake Erie College of Osteopathic Medicine, Far Rockaway, PA, [5]Walter Reed National Military Medical Center, Bethesda, MD, [6]William Carey University, Hattiesburg, MS, [7]RWJBarnabas Health, Trinitas Regional Medical Center, Elizabeth, NJ, [8]Hackensack Meridian Health, JFK University Medical Center, Edison, NJ, [9]Hackensack University Medical Center, Hackensack, NJ

OBJECTIVE: Pregnant patients experiencing insomnia in the 3rd trimester is a common occurrence, yet management approaches are highly varied and medication efficacy remains unclear. This study sought to determine which medication proved most effective for patients with insomnia in the 3rd trimester.

STUDY DESIGN: We conducted a multi-center, prospective observational study from 7/2021 to 7/2023 comparing all pregnant patients who received treatment of insomnia at a gestational age range of 28 0/7 to 40 0/7 weeks. Monotherapy medications dimenhydrinate, diphenhydramine, melatonin, gabapentin, benzodiazepines, and magnesium oxide were included as covariates. Patients taking overlapping medications or with allergies to any included medications were excluded. Primary outcomes included the need to switch medication, patient-reported resolution confirmed by provider assessment, patient-reported increased energy level due to adequate sleep, and patient-reported ability to fall asleep reliably with medication as discrete events.

RESULTS: The study included 686 patients who required pharmacologic treatment for insomnia in the 3rd trimester. Baseline demographics were not significantly different. Patients who received magnesium oxide at doses of 800mg or greater were less likely to switch to an alternative medication (61.2% v. 33.1%, $p = 0.03$) with a 68% decreased risk in adjusted models (RR 0.32, 95% CI 0.21-0.73, $p = 0.004$). Patients taking gabapentin at doses exceeding 1200mg (59.1% v. 17.9%, $p = 0.003$) or melatonin at doses of 40mg or greater (49.2% v. 11.5%, $p = 0.01$) had higher rates of increased energy levels due to adequate sleep. Adjusted models demonstrated an additional 44% and 21% increased likelihood when taking gabapentin (RR 1.44, 95% CI 1.23 − 1.77, $p = 0.002$) or melatonin (RR 1.21, 95% CI 1.11 − 1.53, $p = 0.007$), respectively.

CONCLUSION: Magnesium oxide, melatonin, and gabapentin are reasonable medical therapies in the treatment of insomnia for 3rd-trimester pregnant patients.

106 Comparison of surgical techniques for subcutaneous closure during cesarean deliveries complicated by super obesity

Daniel Martingano[1], Rachel Amuzu[2], Sheida Rodriguez[1], Andrea Ouyang[3], Marwah Al-Dulaimi[1], Shavana Singh[4], Jacqueline Marecheau[1], Jessica Marshall[1], Alexander Ulfers[5], Donald Morrish[1], Francis X. Martingano[6], Kristin Cohen[7], Antonia F. Oladipo[8], Shailini Singh[9]

[1]St. John's Episcopal Hospital-South Shore, Far Rockaway, NY, [2]Rutgers Health, Jersey City Medical Center, Elizabeth, NJ, [3]William Carey University College of Osteopathic Medicine, Baton Rouge, LA, [4]Lake Erie College of Osteopathic Medicine, Far Rockaway, PA, [5]Walter Reed National Military Medical Center, Bethesda, MD, [6]NYU Grossman School of Medicine, Department of OB/GYN, Brooklyn, NY, [7]RWJBarnabas Health, Trinitas Regional Medical Center, Elizabeth, NJ, [8]Hackensack University Medical Center, Hackensack, NJ, [9]Hackensack Meridian Health, JFK University Medical Center, Edison, NJ

OBJECTIVE: Super obesity is defined as BMI ≥50 kg/m^2 and is increasingly prevalent among pregnant patients nationwide, requiring unique surgical considerations. This study sought to

evaluate the differences between subcutaneous closure techniques for cesarean deliveries complicated by super obesity.

STUDY DESIGN: We conducted a multicenter, prospective observational study from 7/2021 to 7/2023 comparing all pregnant patients with super obesity who required a cesarean delivery between 37 0/7 and 41 0/7 weeks gestational age. Patients were divided into two groups for subcutaneous layer closure: one group received an interrupted technique, and the second received a running technique. Both groups used plain gut sutures and subcuticular skin closures. Surgical technique was determined by surgeon preference. Primary outcomes included wound seroma, dehiscence, wound infection, postoperative pain, compositive wound complication (CWC, including all former outcomes), and surgical time.

RESULTS: The study included 197 patients: 101 receiving an interrupted technique and 96 receiving a running technique. Baseline demographics, use of electrocautery, cesarean order, and use of negative-pressure wound vacuum dressings were not significantly different. Surgical time was less in the running technique group (8.3 v. 13.2 minutes, $p < 0.001$). Rates of wound seroma within 2 weeks postoperative were less in the running suture group (2.1% v. 4.9%, $p = 0.004$) with a 27% decreased risk in adjusted models (RR 0.73, 95% CI 0.39-0.91, $p = 0.003$). Rates of dehiscence, wound infection, postoperative pain, and CWC within 2 or 6 weeks postoperative were not significantly different.

CONCLUSION: Running surgical techniques may have benefits in the 2-week postoperative period for patients needing cesarean deliveries complicated by super obesity.

107 The association of dody mass index with engagement in a perinatal collaborative care model

Kathryn Anderson[1], Anna Whelan[2], Emily S. Miller[3], Allie Sakowicz[4], Esther Son[5], Mayán Alvarado-Goldberg[6]

[1]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [2]Grafton, MA, [3]Alpert Medical School of Brown University and Women & Infants Hospital of Rhode Island, Providence, RI, [4]Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC, [5]Northwestern Feinberg School of Medicine, Chicago, IL, [6]Northwestern University, Chicago, IL

OBJECTIVE: Individuals with a higher body mass index (BMI) are less likely to engage in routine healthcare due to the experience of weight stigma. Whether this applies to mental health care, and specifically, the collaborative care model of delivery, remains unknown. This study evaluated the association of BMI with engagement in a perinatal collaborative mental health care model (PCCM).

STUDY DESIGN: This secondary analysis of a prospective cohort study included individuals referred to PCCM at a quaternary care hospital in Chicago, IL from 2017-2022. Individuals were grouped by pre-pregnancy BMI using the World Health Organization classification (class 1: 30-34.9kg/m^2, class 2: 35-39.9kg/m^2, class 3: $\geq$40kg/m^2). The primary outcome, engagement, was defined as the completion of $\geq$2 mental health assessments within the PCCM. Maternal demographics, comorbidities, obstetric factors, and baseline Patient Health Questionnaire-9 (PHQ-9) scores were compared across BMI strata. Multivariable regression accounting for differences in race/ethnicity, parity, mental health history, and tobacco use was performed.

RESULTS: Of the 2,614 individuals included, 1,921 (73.5%) had a BMI< 30, 362 (13.8%) class 1 obesity, 184 (7.0%) class 2 obesity, and 147 (5.6%) class 3 obesity. Myriad differences were observed in sociodemographic and clinical characteristics across BMI categories, aligning with prior literature. Compared to individuals with BMI< 30, individuals with BMI$\geq$30 had higher baseline PHQ-9 scores (median 8 [IQR 5,14], vs. median 7 [IQR 4,12], p=.025) but no difference in engagement (76.2% vs. 78.9%, p=.16). On multivariate regression, having a BMI > 40 kg/m^2 was associated with higher engagement in PCCM (Table 1).

CONCLUSION: Although individuals with a pre-pregnancy BMI$\geq$30 had more baseline depressive symptoms, there was no difference in engagement in PCCM compared to those with BMI < 30. Those with the highest BMI category were found to have paradoxically increased engagement, suggesting that the equity-centered principles of the PCCM extend to the area of weight bias.

Table 1: Engagement with the Perinatal Collaborative Care Model by BMI Class

	BMI < 30kg/m^2 (N=1,921)	BMI 30-34.9kg/m^2 (N=362)	BMI 35-39.9kg/m^2 (N=184)	BMI ≥40kg/m^2 (N=147)
Engagement	76.2%	75.7%	80.4%	85.0%
OR (95% CI)	ref	0.97 (0.75-1.26)	1.28 (0.88-1.87)	**1.76 (1.10-2.80)**
aOR (95% CI)	ref	0.97 (0.73-1.27)	1.32 (0.88-1.96)	**1.73 (1.06-2.82)**

BMI = body mass index; OR = odds ratio; aOR = adjusted odds ratio

108 Unique maternal immunoproteomic signatures by trimester and in response to de novo mRNA vaccination

Paola Andrea Lopez Zapana[1], Lydia Shook[2], Olyvia Jasset[3], Kathryn J. Gray[4], Michal A. Elovitz[5], Douglas L. Lauffenburger[1], Andrea G. Edlow[6]

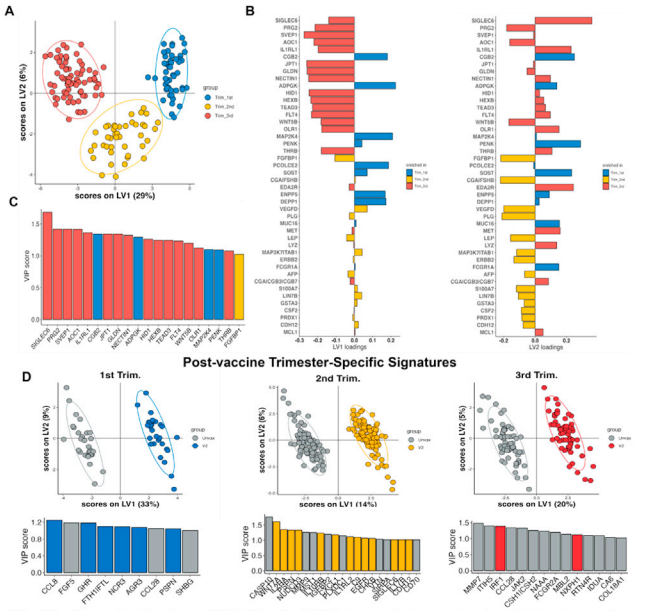
[1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts General Hospital, Waban, MA, [3]Massachusetts General Hospital, Department of Obstetrics and Gynecology, Boston, MA, [4]Brigham and Women's Hospital, Boston, MA, [5]Women's Biomedical Research Institute, Icahn School of Medicine at Mount Sinai, New York, NY, [6]Massachusetts General Hospital, Boston, MA; on behalf of Human Immunology Project Consortium, Maternal 'Omics to Maximize Immunity (MOMI)

OBJECTIVE: Use of COVID-19 mRNA vaccines in pregnant individuals presents a unique opportunity to define baseline trimester-specific immunoproteomic signatures, and to examine how de novo vaccines might perturb these signatures across trimesters (TMs).

STUDY DESIGN: The maternal proteome was profiled across TMs at baseline and in response to COVID-19 vaccination (vax) in 466 samples from 296 pregnant individuals, including 104 from 1st, 198 from 2nd, and 164 from 3rd TM, using an aptamer-based proteomics assay. Maternal plasma samples were collected prevax/baseline (V0, N=182), 3-4 weeks after 1stmRNA vax (V1, N=120) and 2-6 weeks after 2nd mRNA vax (V2, N=164). Effects of TM, maternal age, BMI, and infant sex on protein expression were evaluated by a local inverse Simpson's Index. Partial least squares discriminant analyses with regularization determined proteins best defining the TMs prevax. Generalized additive modeling (GAM) evaluated TM-specific responses to vaccination, and pathways analysis (IPA) inferred biological implications of differentially-expressed proteins by TM.

RESULTS: 44 proteins distinguished baseline samples across TMs (Fig 1A/B). Variable of importance analysis identified top proteins that distinguished TMs prevax (Fig 1C). IPA analyses demonstrated that the 1st TM was defined by mitogenesis, chemotaxis, and apoptotic signaling; 2nd by pathways of NK- and T-cell survival and differentiation; and 3rd by pro-inflammatory cytokine signaling, immunogenic cell death signaling, and nervous system development. GAM modeling demonstrated TM-specific responses to vaccination after both 1st and 2nd dose of mRNA vax (Fig 1D), including dysregulation of proteins involved in interferon, WNT and apoptosis signaling, and cell-cell adhesion.

CONCLUSION: In normal pregnancy, trimesters were defined by a specific immunoproteomic signature. De novo mRNA vaccination altered expression of proteins in a trimester-specific manner. Enhanced understanding of how vaccines and other exposures alter the immune proteome by trimester may provide new opportunities to optimize maternal and neonatal health.



(A) Partial Least Squares Discriminant Analysis (PLSDA) followed by LASSO feature regularization was performed, resulting in a reduced set of features that were consistently in at least 80 of the 100 LASSO models. Trimester had the strongest impact of all covariates on the baseline maternal proteome. All models had 5-Fold CV: 0.99 and p<0.01 when compared to permutated label model. (B) The bar plots show the loadings of the 44 LASSO-selected proteins on the (left) 1st Latent Variable (LV), and the (right) 2nd LV, with the colors indicating the trimester of collection (1st trim = blue, 2nd trim = yellow, and 3rd trim = red). (C) Variable of importance analysis demonstrates the top proteins that distinguish the maternal proteome across trimesters. (D) Generalized additive modeling (GAM), followed by PLSDA and LASSO feature regularization was used to determine the post-vaccination proteomic signature. Only the post-2nd mRNA vax or V2 signature is shown due to space constraints, but the same approach was performed for the V1 timepoint, demonstrating a well-defined and trimester-specific signature characterized by unique key proteins in each trimester of de novo COVID-19 mRNA vaccination.

109 Prenatal diagnostic testing trends in the era of cell-free DNA screening

Eliza R. McElwee, Elizabeth A. Arruda, Kayla Shine, Jamison Lee, Roger Newman

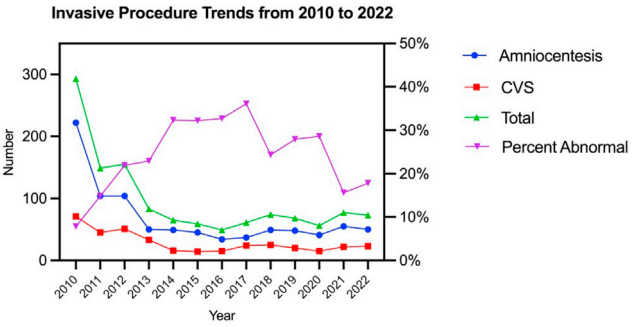
Medical University of South Carolina, Charleston, SC

OBJECTIVE: According to the American College of Obstetrics and Gynecology, all pregnant patients should be offered testing for fetal aneuploidy. Cell-free DNA screening became available at our institution in 2012. We investigated the trends of diagnostic testing, diagnostic yield, and indications for procedure in the era of cell-free DNA.

STUDY DESIGN: In this observational retrospective study, all invasive prenatal procedures from 2010 to 2022 were evaluated at a single institution. Indication for procedure was determined (advanced maternal age alone, ultrasound findings, abnormal prenatal screen, single gene testing). Results of diagnostic testing were reviewed and stratified by result and type of genetic abnormality. Categorical variables were assessed using X^2 or Fishers Exact test as appropriate and comparisons of column proportions; continuous variables were analyzed with Wilcoxon rank-sum test.

RESULTS: A total of 1262 invasive procedures were performed in the study period, with 888 (70.4%) amniocentesis procedures and 374 (29.6%) chorionic villus sampling procedures (Figure 1). There was a significant decline in total procedures over time (p< .001). Fifty one percent of patients had prenatal genetic screening, with 28.2% of patients having diagnostic testing for abnormal prenatal screen. In 2017, cell free DNA analysis surpassed analyte testing as the primary genetic screening modality. Overtime, percentage of abnormal diagnostic result increased (Fig 1). There was a significant change in indication over time; advanced maternal age alone declined from 45% to 5.6% during the study period(p< .001).

CONCLUSION: Performance of invasive testing for prenatal chromosomal disorders has dramatically decreased since cell-free DNA testing became universally available. This has resulted in a shift in indication for diagnostic testing and higher diagnostic yield.



111 Establishing a risk score for prediction of intrapartum cesarean delivery among elderly gravidae

Daniel Gabbai[1], Yael Reichman[2], Lee Reicher[3], Sharon Maslovitz[4], Yariv Yogev[5], Emmanuel Attali[6]

[1]Tel Aviv Sourasky Medical Center, Tel Aviv, HaMerkaz, [2]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Tel Aviv, [3]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel, [4]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University Israel, Tel aviv, Israel, [5]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [6]Lis Maternity Hospital, Department of Obstetrics and Gynecology, Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel

OBJECTIVE: We aimed to determine risk factors for intrapartum cesarean delivery (CD) in women over 40 years old, and to develop a risk prediction score for this outcome.

STUDY DESIGN: We conducted a retrospective cohort study, in a single university-affiliated tertiary medical center with approximately 12,500 deliveries annually (2012-2022). We included all women aged 40 years old or more, who planned a trial of labor and excluded women who opt for an elective CD or those with non-viable fetuses. Maternal and neonatal characteristics of women who delivered vaginally were compared to those who underwent an intrapartum CD. Risk factors were examined using univariate analysis as well as multivariate logistic regression. A specific risk prediction score was developed in accordance with the relative risk, to predict the need for CD. The ROC curve was assessed utilizing the performance of our model.

RESULTS: (1) During the study period, 6,122 women aged 40 years old or more attempted a trial of labor. Of them, 428 (7%), underwent an intrapartum CD.

(2) Using multivariate analysis, several independent risk factors for intrapartum CD were identified, including nulliparity, multiple gestations, induction of labor, epidural anesthesia, preeclampsia, gestational diabetes, and previous CD. We attributed a risk score for each risk factor and included them in our score model. [Table]

(3) Our score model, employing a cut-off of 7, demonstrated successful prediction of intrapartum CD with an area under the curve of 0.85 (95%CI [0.83-0.87], p=0.009).

CONCLUSION: Assessment of risk factors before and during labor, using our risk score, can be used by caregivers to offer a more informed consultation to patients facing the decision among mode of delivery.

	aOR (95% CI)	p-value	Score	
			Yes	No
Age > 45	1.4 (0.9-2.1)	0.13	-	-
BMI >35	1.1 (0.5-2.3)	0.68	-	-
Nulliparity	4.9 (3.7-6.5)	<0.001	5	0
Multiple gestation	5.1 (2.8-9.2)	<0.001	5	0
Delivery before 37 weeks	0.7 (0.4-1.1)	0.177	-	-
Previous Cesarean Delivery	7.5 (5-11)	<0.001	7	0
Pre-gestational DM	1.5 (0.6-3.8)	0.3	-	-
Gestational DM	1.4 (1.03-1.8)	0.028	1	0
Pre-Eclampsia	2.3 (1.3 – 3.8)	0.002	2	0
Epidural Anesthesia	2.3 (1.5-3.5)	<0.001	2	0
Induction of Labor	1.8 (1.4-2.4)	<0.001	2	0
Antibiotics use during labor	4.3 (3.3-5.5)	<0.001	4	0
Oxytocin use	0.9 (0.6-1.2)	0.5	-	-

112 Impact of the ARRIVE trial on stillbirth rates in nulliparous individuals

Rula Atwani, George R. Saade, Tetsuya Kawakita
Eastern Virginia Medical School, Norfolk, VA

OBJECTIVE: Following the publication of the ARRIVE trial, rates of induction of labor (IOL) increased, even as early as 37 weeks. We aimed to examine the rate of stillbirth at term before and after the ARRIVE trial.

STUDY DESIGN: This was a cross-sectional analysis of US vital statistics Live Birth and Fetal Death certificates data from 2016 to 2020. We limited analyses to nulliparas with singleton gestation and cephalic presentation who delivered at term (37-42 weeks). The pre-ARRIVE period was from Jan 2016 to Dec 2017. The post-ARRIVE trial period was from Jan 2019 to Dec 2020. Stillbirth and induction rates at each gestational age were calculated based on the number of ongoing pregnancies. Modified Poisson regression was used to calculate adjusted relative risks (aRR) with 95% confidence intervals (95%CI). We performed a secondary analysis in nulliparas without hypertension, preeclampsia, diabetes, or fetal anomaly (low-risk group).

RESULTS: Of 4,077,674 births, 5,200 were stillbirths during our study period. There were 2,087,960 births in the pre-ARRIVE period and 1,989,714 in the post-ARRIVE period. Compared to the pre-ARRIVE period, the rate of stillbirths, per 1000 births, in the post-ARRIVE period was significantly lower at term (1.4 vs. 1.2; aRR 0.84 [95% CI 0.79-0.89]), at 37 weeks (0.4vs. 0.3; aRR 0.79 [0.71-0.88]), and at 38 weeks (0.4 vs. 0.3; aRR 0.89 [0.80-0.95]) (Table 1). However, the change in stillbirth rates at 39 weeks and 40-42 weeks were not statistically significant. Rates of IOL increased at all gestational ages. The findings were similar in low-risk individuals. We estimated that 228 additional IOL were needed to prevent 1 additional stillbirth at 37 weeks whereas 5234 additional IOL were needed at 39 weeks.

CONCLUSION: Despite increased rates of IOL at all gestational ages, stillbirth rates only decreased at 37-38 weeks. An increase in IOL at 39 weeks was not large enough to impact the stillbirth rate at 39 weeks or greater.

Table 1

	Pre-ARRIVE (n = 2,087,960)		Post-ARRIVE (n = 1,989,714)

113 Women's representation in major obstetrics and gynecology journals

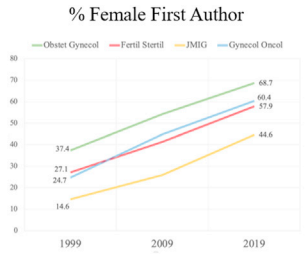
Rula Atwani[1], Jessie Jones[2], Katherine McLaughlan[1], George R. Saade[1], Tetsuya Kawakita[1]
[1]Eastern Virginia Medical School, Norfolk, VA, [2]UCONN Health, Hartford, CT

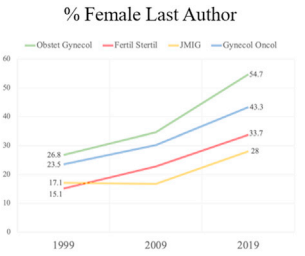
OBJECTIVE: To examine the number of women as first and senior authors in four journals in obstetrics and gynecology over two decades.

STUDY DESIGN: This bibliometric analysis included all original research articles published in 1999, 2009, and 2019 in four obstetrics and gynecology journals—*Gynecologic Oncology (Gynecol Oncol), Obstetrics and Gynecology (Obstet Gynecol), Journal of Minimally Invasive Gynecologic Surgery (JMIGS)*, and *Fertility and Sterility (Fertil Steril)*. Other types of publications including case reports, reviews, and editorials were excluded. The sex of the author was determined by a Google-based webtool. For inconclusive results, a Google search of the authors was attempted to identify gender. If we were not able to identify the sex of the authors, they were excluded from the analysis. Proportions of female first and senior authors were assessed yearly. Interrupted time-series analysis was performed using an autoregressive integrated moving average.

RESULTS: A total of 2,781 articles were analyzed, with a total of 5562 authors. 518 authors (9.3%) were excluded. Over two decades, the proportions of both first and senior authors nearly doubled in all four journals. For example, in 1999, the proportions of the first author were 24.7%, 37.4%, 14.6%, and 27.1% in Gynecol Oncol, Obstet Gynecol, JMIGS, and Fertil Steril, respectively. In 2019, the proportions of the first author were 60.4%, 68.7%, 44.9%, and 57.9% in Gynecol Oncol, Obstet Gynecol, JMIGS, and Fertil Steril, respectively. This increase in proportions was statistically significant (all $P < 0.001$).

CONCLUSION: Proportions of female first and senior authors nearly doubled over two decades.





114 Ultrasound assessment of upper abdominal free fluid after uncomplicated cesarean delivery

Nicholas Baranco[1], Catherine Baril[1], Robert Silverman[2]
[1]SUNY Upstate Medical University, Syracuse, NY, [2]Crouse Hospital, Syracuse, NY

OBJECTIVE: Ultrasound measurement of upper abdominal fluid is commonly used to assess for intraabdominal bleeding after trauma, but it has not been studied after cesarean delivery. We sought to define normal measurements after scheduled cesarean delivery.

STUDY DESIGN: After IRB approval, a prospective cohort of patients undergoing scheduled cesarean delivery was recruited. Ultrasound measurements of fluid in the hepatorenal (RUQ) and splenorenal (LUQ) fossa in were taken in supine position immediately after surgery and repeated on postoperative day #1. Information on medical history, prenatal care, and postoperative course were abstracted from the medical record. Continuous variables were compared with t-test and categorical compared with chi squared.

RESULTS: 42 patients without concern for postoperative complication were included. The immediate postoperative RUQ and LUQ measurements were mean (SD [standard deviation]) 1.2 (1.8) mm and 1.3 (1.4) mm, 90th percentile 2.9 mm and 3.8 mm, and no measurable fluid in 48% and 45% respectively. On postoperative day #1 the RUQ and LUQ measurements were mean (SD) 1.6 (1.2) mm and 1.0 (1.3) mm, 90th percentile 3.5 mm and 3.7 mm, and no measurable fluid in 44% and 53%. Measurements were not obtained due to patient discomfort in 0 to 9.5% of cases. Change from initial to day #1 measurements were calculated, and the 90th percentiles were RUQ 2.0 mm and LUQ 2.2 mm. On postoperative day #1, 28.6% of patients had a composite of at least one measurement or change in a measurement greater than the 90th percentile (table 1). This composite outcome was associated with repeat cesarean (p=.03) and with increased operative time (37 vs 53 minutes, mean difference 15.3 minutes [95% CI 5.8, 24.8], p=.002), but was not otherwise associated with maternal or surgical characteristics.

CONCLUSION: Measurements of fluid in the RUQ and LUQ were easily obtained and well tolerated after routine cesarean delivery, and our data show that finding more than 3.8 mm of fluid is abnormal and may help diagnose intraabdominal bleeding as it does after trauma.

Table 1. Rate of at least 1 measurement of upper abdominal fluid > 90th percentile by maternal and surgical characteristics

Characteristic	No Elevated Measurements	1 or More Elevated Measurement	P-value

115 Prolonged second stage of labor (P2S) in primipara, and perinatal outcomes

Shira Fridman Lev, Yair gotlib, rivka Farkash, Sorina Grisaru-Granovsky, Arnon Samueloff, Maayan Bas Lando
Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim

OBJECTIVE: Duration and optimal management of prolonged second stage (P2S) in the primipara is still controversial and represents a source for primary cesarean deliveries. We assessed maternal and neonatal outcome when the second stage of labor was prolonged according to American College of Obstetricians and Gynecologists guidelines.

STUDY DESIGN: Electronic medical record data from a retrospective cohort (2005—2022) at a tertiary medical center. All nulliparous births with term live singleton vertex fetus that reached full dilation were included. P2S was defined: with epidural > 3 hours, without > 2 hours.

Statistics: Comparisons, adjusted multivariate model; Odds Ratio (OR 95%CI), p< 0.05

RESULTS: Study population included 55309 primiparous deliveries who reached full dilation. P2S occurred in 13.1% of nulliparas, with and without an epidural. Cesarean delivery rates with P2S compared to normal second stage (N2S) were 8.5% vs. 0.8% respectively. Vaginal delivery and assisted vaginal delivery rates were 48.4% vs. 85.6% and 43.1% vs. 13.6% for P2S compared to N2S, respectively. P2S was associated with higher maternal and neonatal morbidity when compared to N2S including PPH (1.1% vs 0.8%), and third-degree or fourth-degree perineal lacerations (1.8% vs 1.0%), Shoulder Dystocia (0.5% vs. 0.1%), NICU admissions >72 hours (3.6% vs. 2.4%), clavicular fracture (0.7% vs. 0.4%) and Apgar score at 5 minutes < 7 (1.3% vs. 0.7%), p< 0.0001 for all. Arrest of descent was the leading indication for CD. Multivariate analyses revealed independent association (OR 2.2 95% CI [2.1-2.4] between prolonged second stage and higher rates of composite maternal adverse outcome (27.9% vs. 13.6%), and composite neonatal adverse outcome 16.8% vs. 11%, p< 0.0001 for all.

CONCLUSION: P2S for primiparous women at term, according to the traditional definition, is associated with adverse maternal and neonatal outcomes. Even with the benefits of increased rate of vaginal delivery, implementation of new relaxed guidelines for 2nd stage of labor might lead to additional health costs.

116 Pregnancy & power: understanding instagram sentiments on weight & strength training using artificial intelligence (MonkeyLearn)

Grace Basralian[1], Kaitlyn Voity[2], Sharon Galperin[3], Antonia F. Oladipo[3]
[1]Hackensack Meridian School of Medicine, Hackensack, NJ, [2]Hackensack Meridan School of Medicine, Hackensack, NJ, [3]Hackensack University Medical Center, Hackensack, NJ

OBJECTIVE: Exercise in pregnancy, specifically strength training, is safe and encouraged. However, limited and controversial guidelines across social media platforms leads to confusion and misinformation for pregnant patients. We aim to assess the sentiments of Instagram comments concerning weight and strength training during pregnancy, using natural language processing tools (Monkey Learn).

STUDY DESIGN: A cross-sectional analysis of Instagram comments via hashtags #pregnancystrengthtraining and #pregnancyweightlifting was conducted on August 3, 2023. The first 100 posts for each hashtag were reviewed. Content characteristics were obtained. Comments were input into MonkeyLearn Sentiment Analyzer (2023), to assess their sentiments. The confidence percentage of the sentiment was recorded. Chi-square goodness-of-fit test was performed to assess observed proportions of sentiments compared to expected distribution.

RESULTS: 200 Instagram posts were identified, 31 posts were excluded, and 169 were analyzed. For"#pregnancyweightlifting" (n=83), sentiments were 75% positive, 5% negative and 1% neutral ($p< 0.0001$). Confidence levels of positive sentiments ranged from 45.4% to 99.6%, with a mean of 87.0%. Confidence levels of negative sentiments ranged from 43.5% to 77.0%, with a mean of 51.0%. For "#pregnancystrengthtraining"(n=86), sentiments were 80% positive, 4% negative and 2% neutral ($p< 0.0001$). The confidence level of neutral sentiments was 43.4% to 46.0%, with a mean of 44.6%. Confidence levels of positive sentiments ranged from 35.6% to 99.6%, with a mean of 86.3%. Confidence levels of negative sentiments ranged from 49.2% to 91.5%, with a mean of 66.7%

CONCLUSION: Instagram is a unique social platform that pregnant patients can learn about their bodies. Prenatal exercise including weight and strength training show comment sentiment that are significantly positive compared to negative/neutral, thus healthcare providers should continue to encourage, educate, and safely guide patients on the health benefits of prenatal exercise.

117 Pregnancy and delivery outcomes of women who underwent a VBAC with and without epidural analgesia

Merav jacobs[1], Tamar Eshkoli[2], Alla Saban[2], Yael Baumfeld[3], Renana Ben shushan Amor[1], zehava Yohay[4], Adi Y. Weintraub[3]
[1]Soroka University Medical Center, Beer-Sheva, HaDarom, [2]Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Beer Sheva, HaDarom, Israel, [3]Soroka Medical Center, Beer-Sheva, HaDarom, [4]Pain Unit, Soroka University Medical Center, Beer Sheva, Israel, Soroka medical center, HaDarom

OBJECTIVE: To evaluate whether there is an association between Epidural Analgesia (EA) during VBAC (vaginal birth after cesarean) and pregnancy and delivery outcomes.

STUDY DESIGN: In this retrospective population-based cohort study, all women who underwent a VBAC with and without EA, between the years 1996-2016 at the Soroka University Medical Center (SUMC) were included. Women who delivered by cesarean section (elective and non-elective) and those who gave birth to a newborn with chromosomal abnormalities or major malformations, and multifetal gestations were excluded. Demographical, clinical, and obstetrical characteristics were recorded, and pregnancy complications and adverse perinatal outcomes were compared between the groups. Univariate analysis was followed by a multivariate analysis to control for confounders. A p-value of < 0.05 was considered statistically significant.

RESULTS: During the study period 17,516 women who have had a previous CS met the inclusion criteria, of which 15% (n= 2652) used EA during labor, while the rest of the cohort 85% (n= 14,864) were non-EA users. Women in the EA group had higher rates of instrumental delivery and postpartum hemorrhage (PPH) as well as higher rates of oxytocin augmentation and a longer second stage of labor . The use of EA was found to be an independent risk factor for instrumental delivery after controlling for maternal age, ethnicity, parity, DM (diabetes mellitus), hypertensive disorders of pregnancy, oxytocin augmentation and prolonged second stage of labor . However, no significant differences were observed regarding neonatal outcomes including perinatal mortality, birth weight, Apgar scores and shoulder dystocia rates.

CONCLUSION: EA for women undergoing a VBAC was associated with higher rates of instrumental delivery and PPH, oxytocin augmentation and a longer second stage of labor compared with women without EA. However, neonatal outcomes did not differ between the groups.

Instrumental vs. spontaneous vaginal mode of delivery in the presence of epidural analgesia: multivariate analysis

	aOR	95%CI	P value
Epidural analgesia	3.09	2.58-3.69	<0.001

Parity	0.40	0.33-0.49	<0.001

118 Mediolateral episiotomy and obstetric anal sphincter injuries in nullipara: A propensity score matching study

Or Bercovich[1], Daniela Chen[1], Bar Narkis[1], Anat Pardo[2], Eran Hadar[3], Ohad Houri[4]
[1]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, HaMerkaz, [2]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, Tel-Aviv, Israel, [3]Rabin Medical Center, Petach-Tikva, HaMerkaz, [4]Rabin Medical Center, Tel Aviv, Israel

OBJECTIVE: The potential protective effect of mediolateral episiotomy against obstetric anal sphincter injuries (OASIs) is controversial. We aimed to investigate mediolateral episiotomy's role in preventing OASIs during vaginal deliveries (VD) or vacuum-assisted deliveries (VAD).

STUDY DESIGN: Retrospective observational study at a tertiary center, from August 2007 to September 2019. Inclusion criteria were for all nulliparous women with a singleton gestation who underwent VD or VAD at ≥ 37 gestational weeks. To adjust for confounding, propensity score matching with a 1:1 ratio was employed. The primary outcome was the incidence of OASIs, and the secondary outcome was a composite of immediate neonatal outcomes (umbilical artery pH < 7.1, neonatal intensive care unit admission, and 5-minute Apgar score < 7).

RESULTS: The study cohort comprised 22,787 deliveries: 17,546 VD (77%) and 5,241 VAD (23%). Episiotomy rates were 38.5% and 75.9% in VD and VAD, respectively. After matching, both groups showed good balance in body mass index, post-term pregnancy, oxytocin use, neuraxial anesthesia, and birth weights. Separate analyses were conducted for the matched VD group (n = 13,500) and the matched VAD group (n = 2,518). Episiotomy was associated with a lower risk of grade 1 and 2 tears in VD (OR 0.110, 95% CI 0.100 − 0.121) and VAD (OR 0.472, 95% CI 0.378 − 0.590). Regarding OASIs, no significant differences were observed in VD (OR 1.147, 95% CI 0.779-1.688) or VAD (OR 0.581, 95% CI 0.324-1.039). However, in VAD, episiotomy demonstrated a borderline protective effect against OASIs with a number needed to treat = 104.917 (95% CI 42.640 - 167.194). Conversely, episiotomy in NVD was associated with a higher rate of composite neonatal outcome (OR 1.227, 95% CI 1.036-1.453), while VAD showed no such association (OR 1.115, 95% CI 0.871-1.426).

CONCLUSION: Propensity score matching reveals no significant protective effect of mediolateral episiotomy on OASIs in women undergoing VD. However, there is a possible benefit in VAD.

119 Transplacental transfer of alectinib and osimertinib using an ex vivo human placental perfusion model

Laure Benoit[1], David Combarel[2], Marie-Noëlle Dieudonné[3], yoann rodriguez[3], Olivier Mir[2], Stanislas Grassin-Delyle[3], Elodie lamy[4], Angelo Paci[5], Francois Vialard[3], Paul Berveiller[6]

[1]Department of Gynecology and Obstetrics, Poissy, Ile-de-France, [2]Gustave Roussy Cancer Campus, Villejuif, Ile-de-France, [3]Université Paris-Saclay, Jouy-en-Josas, Ile-de-France, [4]Université Paris-Saclay, Montrigny-le-Bretonneux, Ile-de-France, [5]Gustave Roussy, Villejuif, Ile-de-France, [6]Centre Hospitalier Intercommunal de Poissy Saint Germain, Poissy, France

OBJECTIVE: Non-small cell lung cancer is a rare diagnosis in pregnant women but its incidence is increasing during pregnancy. Recent protein kinase inhibitors have improved the prognosis of specific molecular subtypes (epidermal growth factor receptor-mutant and anaplastic lymphoma kinase-rearranged), but little is known about their use during pregnancy. Thus, we aimed to determine transplacental transfer and cotyledon accumulation of osimertinib and alectinib, using the human perfused placental cotyledon model.

STUDY DESIGN: Human term placentas from normal pregnancies were collected after delivery and were perfused with osimertinib or alectinib associated with its principal active metabolite M4 at targeted maternal concentrations. We evaluated transport parameters such as fetal transfer rate (FTR) and clearance index (CI), as well as cotyledon accumulation. Antipyrine was used as a control marker. Samples were collected during a 90 minute-procedure.

RESULTS: Mean FTR and mean CI of osimertinib were 9.5% and 0.42, respectively. Mean osimertinib cotyledon accumulation index was 28.9 % i.e. 116,7 μg/100 mg. Conversely, nor alectinib neither M4 were detected in fetal samples. However, mean alectinib cotyledon accumulation index was 370.7 % i.e., 574 μg/100 mg and mean M4 cotyledon accumulation index was 178.5 % i.e. 79.3 μg/100 mg.

CONCLUSION: Our results suggest that osimertinib significantly crosses the placenta with a moderate placental uptake. Conversely, alectinib and its metabolite M4 do not cross the placental barrier and massively accumulate in placental tissue.

Characteristics of osimertinib, alectinib and M4 transplacental transfer using an *ex vivo* human placental perfusion model

Characteristic	Osimertinib	Alectinib	M4
No. of perfused placentas	6	12	12
Fetal transfer rate (%), median (range)	9,55 (4,5-32)	/	/
Clearance index, median (range)	0,42 (0,2-0,58)	/	/
Placental uptake (µg/100mg), median (range)	116,7 (84,9-545,2)	574 (76,9-2671)	79,3 (22,5-346,2)
Accumulation index (%)	28,9	370,7	178,5

120 Association between distance to fetal treatment center and abortion consideration among people with fetal myelomeningocele

Yuqi Bian[1], Steven T. Papastefan[1], Manmeet Singh[2], William S. Marriott[2], Joy Ito[2], Jessica T. Fry[3], Aimen Shaaban[2], Ashish Premkumar[4]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]The Chicago Institute for Fetal Health, Chicago, IL, [3]Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [4]University of Chicago, Chicago, IL

OBJECTIVE: The relationship between geographic distance and abortion for individuals with fetal myelomeningocele (fMMC) has not yet been elucidated. Thus, we aimed to evaluate the association between distance traveled to fetal treatment center (FTC) and consideration of abortion among patients with fMMC.

STUDY DESIGN: We performed a retrospective cohort analysis of all fMMC consultations at a FTC in Illinois from 2018-2023. The exposure was distance traveled to FTC, collected as miles from patient's zip code of residence to FTC. Distance was analyzed categorically, dichotomized based on median value, and continuously. The primary outcome was abortion consideration, ascertained by a nurse during FTC intake. Bivariate and multivariate log-binomial regression analyses were performed, treating distance traveled as an

interaction factor with state of residence. P< 0.05 indicated statistical significance.

RESULTS: 100 patients were available for analysis. Median distance traveled was 62.2 miles (range 1.2-928.2). On bivariate analysis, people traveling below the median distance were more likely to identify as Latinx, reside within Illinois, and present at an earlier gestational age when compared with those traveling above the median distance (Table). On regression modeling, when compared with individuals living below the median distance and outside Illinois, both living above the median distance and outside Illinois (aRR 0.36, 95% CI 0.17-0.75) and within Illinois (aRR 0.40, 95% CI 0.18-0.79) were independently associated with a lower risk of considering abortion after controlling for maternal ethnicity. On regression modeling after controlling for ethnicity, for every mile traveled, the risk of considering abortion decreased by 1% (aRR 0.99, 95% CI 0.98-1, p = 0.003 for in-state, p = 0.01 for out-of-state).

CONCLUSION: Increased distance traveled is associated with lower risk of abortion consideration prior to presenting to an FTC for fMMC consultation. These data emphasize the nuanced relationship between fetal diagnosis and abortion and importance of providing comprehensive reproductive counseling to FTC patients.

Table. Biomedical and sociodemographic data of pregnant people with fetuses with myelomeningocele, by distance travelled

121 Antenatal corticosteroid exposure in late preterm small for gestational age: A population cohort study

Ghamar Bitar[1], Han-Yang Chen[2], Sarah Nazeer[3], Suneet P. Chauhan[4], Sean C. Blackwell[5], Baha M. Sibai[6], Michal Fishel Bartal[7]

[1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [2]The University of Texas Health Science Center at Houston, Houston, TX, [3]McGovern Medical School at UTHealth Houston, Houston, TX, [4]University of Texas-Houston Medical School, Houston, TX, [5]Children's Memorial Hermann Hospital, Houston, TX, [6]Hermann Memorial Hospital, Houston, TX, [7]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX

OBJECTIVE: To examine outcomes in parturients who delivered a small for gestational age (SGA) newborn in the late preterm period and who either received antenatal corticosteroids (ANCS) or did not.

STUDY DESIGN: This population-based retrospective cohort study used U.S. Vital Statistics dataset (2016-2020). The inclusion criteria were singleton, liveborn non-anomalous individuals delivering between 34.0 − 36.6 weeks' gestation with SGA neonate (birth weight < 10% for gestational age, Duryea EL et al) and known status of exposure to ANCS at any time in gestation. The primary outcome was a composite neonatal adverse outcome including Apgar score < 5 at 5 min, immediate assisted ventilation, assisted ventilation > 6 hrs., surfactant use, seizure, or neonatal mortality. Multivariable Poisson regression models were used to estimate adjusted relative risks (aRR) and 95% confidence intervals (CI). A subgroup analysis by gestational age was performed. Annual percent change (APC) was calculated to assess changes in rates of ANCS exposure over study period.

RESULTS: Of 19 million live births during the study period, 109,985 (0.6%) met inclusion criteria, and among them, 26,151 (24%) individuals with SGA neonates received ANCS. After adjustment, the composite neonatal adverse outcome, mainly driven by respiratory complications, was higher among those who received ANCS than those who did not (aRR 1.31, 95% CI 1.27-1.35). This difference persisted in gestational age subgroup analysis at 34 (aRR 1.35, 95% CI 1.29 − 1.42), 35 (aRR 1.27, 95% CI 1.21 − 1.35) and 36 weeks' gestation (aRR 1.31, 95% CI 1.24 − 1.38). The rate of ANCS exposure remained stable over the 5 years period (APC 14.2 95% CI -1.1 − 31.9).

CONCLUSION: Among individuals with late preterm neonates and small for gestational age, 1 out of 4 had exposure to antenatal corticosteroids, and it was associated with a higher risk of neonatal morbidity.

Table. Late preterm birth and small for gestational age

Outcomes	Antenatal steroids	Total live births	n	Rate per 1,000 live births	Crude RR (95% CI)	Adjusted RR* (95% CI)

122 Association between partner factors on continued substance use among pregnant people with opioid use disorder

Lillian B. Boettcher[1], Jessica N. Sanders[1], Kara McKinney[2], Kristin Ashford[3], Sherry Weitzen[4], Amanda Fallin-Bennett[3], Jessica L. Coker[5], Marcela C. Smid[6]

[1]University of Utah, Salt Lake City, UT, [2]University of New Mexico, Albuquerque, NM, [3]College of Nursing, University of Kentucky, Lexington,

KY, [4]University of New Mexico, Health Sciences Center, Albuquerque, NM, [5]College of Medicine, University of Arkansas for Medical Sciences, Little Rock, AR, [6]University of Utah Health, Salt Lake City, UT

OBJECTIVE: To explore associations between intimate partner factors and continued substance use among pregnant people with opioid use disorder (OUD).

STUDY DESIGN: This is a multi-center prospective cohort study of pregnant people with OUD. We recruited participants >20 weeks' gestation from four clinics specializing in perinatal addiction. We collected data at baseline and at follow-up three months later. At baseline, we collected participant demographics and intimate partner factors including substance use. Intimate partner violence (IPV) was assessed using the validated HARK (humiliation, afraid, rape, kick) questionnaire plus a financial abuse question. We defined continued use as maternal unexpected urine toxicology results at follow-up. We compared participant and partner characteristics between those with and without continued use using chi-square and Fisher's exact test. Multivariable logistic regression was used to explore associations of partner factors with continued use while adjusting for potential confounders.

RESULTS: Eighty participants were enrolled at four sites and 62 (77.5%) completed 3-month follow up. At baseline, 37% of participants (n=22/74 with available urine sample) had unexpected use compared to 32.3% (n=20/62) at follow-up. At baseline, 30% of participants (n=22/73) reported that their partner used substances and 64% (n=50/78) reported partner used alcohol. Many participants (36%, n=29/80) reported IPV at baseline (humiliation 29%, afraid 22%, sexual assault 10%, physical assault 17%, financial 31%). In the adjusted model, participant substance use at baseline (aOR 11.6, 95% CI 2.21, 62.2) and 3-month medication for opioid use disorder (aOR 0.03 95% CI 0.01-1) were associated with continued use at follow-up (Table). Partner factors were not significantly associated with continued use.

CONCLUSION: While limited by small sample size and attrition, this study found that partner factors were not associated with continued use. However, IPV was frequent and systemic screening for financial abuse should be considered in this population.

Table: Participant characteristics and partner factors among pregnant people with opioid use disorder by continued substance use at follow-up

Characteristics n (%)	Baseline n = 80	Follow-up available n=62		Adjusted odds ratio (95% confidence interval)
		No continued use at follow-up	Continued substance use at follow-up

123 Is maternal intrapartum low-grade fever a risk factor for maternal and neonatal adverse outcomes?

Rona Bogin Greenfield[1], Gal Cohen[2], Offra Julia Engel[3], Ofer Markovitch[4], Michal Kovo[5], Tal Biron-Shental[6], Hanoch Schreiber[2]

[1]Meir Medical Center, Tel Aviv, Israel, [2]Meir Medical Centerartment of Obstetrics and Gynecology, Meir Medical Center, Kfar Saba, Israel, [3]Meir Medical Center, Tel Aviv, Tel Aviv, [4]Meir Medical Center, Kfar Saba, Tel Aviv, [5]Meir Medical Center, Macabim, HaMerkaz, [6]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz

OBJECTIVE: Intrapartum fever (IF) is defined as maternal temperature ≥38°C during labor and is a known risk factor for maternal and neonatal morbidity. Maternal fever between 37.5-37.9°C, although considered as low-grade fever (LG fever), could also be indicative of an underlying maternal infection. This study aims to assess the association between intrapartum LG fever and adverse maternal and neonatal outcomes.

STUDY DESIGN: This retrospective study included all nulliparous women with a singleton pregnancy who gave birth between 2014-2020. The study cohort was divided into three groups: women with low grade intrapartum fever (LG fever group), women with intrapartum fever (IF group) and a control group comprising women with a normal-range body temperature. Maternal and neonatal outcomes were compared between the groups.

RESULTS: A total of 15,093 nulliparous were included, with 1,294 in the LG fever group, 934 in the IF group and 12,865 controls. Compared to the control group, the IF and the LG fever groups had higher rates of post term deliveries (P< 0.001 for all). The LG fever group had higher rates of labor induction (p< 0.001), epidural (P< 0.001), longer duration of the second stage (142 ± 71 vs 109 ± 73, P< 0.001) and vacuum extractions (VE) (27% vs 17%, P< 0.001) compared to the control group. The rate of cesarean delivery (CD) did not differ between the control group and the LG fever group (p= 0.237), but was significantly increased in the IF group (p< 0.001). Compared to the control group the LG fever group had higher neonatal birth weights (3,272 ± 429 vs 3,136 ± 467, P< 0.001), higher rates of shoulder dystocia (1.3% vs 0.4%, P< 0.001) and 5 minutes Apgar score< 7 (0.9% vs 0.4%, p=0.034). Multivariate logistic regression analysis adjusted for confounders revealed that low-grade fever was independently associated with increased likelihood to deliver by VE and to have 5 minutes Apgar score < 7.

CONCLUSION: Intrapartum maternal low-grade fever is associated with maternal and neonatal adverse outcomes and therefore should be taken into consideration during labor.

Maternal and neonatal outcomes in relation to maternal intrapartum fever status

	LG fever 37.5-37.9°C (n=1294)	IF (n=934)	Normal range fever (n=12865)	P-value IF vs normal range fever	P-value LG fever vs normal range fever

124 Prescription opioid exposure and risk of spontaneous preterm delivery

Olivia Bosworth, Margaret Adgent, Andrew Spieker, Maria Catalina Padilla-Azain, Amelie Pham, Ashley Leech, Andrew Wiese, Carlos Grijalva, Sarah S. Osmundson
Vanderbilt University Medical Center, Nashville, TN

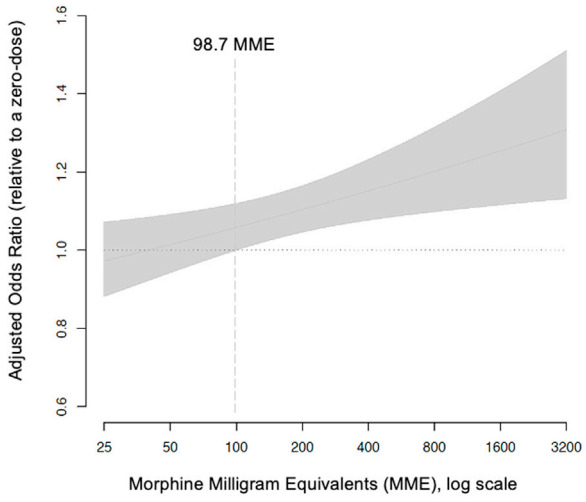
OBJECTIVE: Prior studies that reported associations between opioid exposure during pregnancy and preterm birth did not differentiate between spontaneous and indicated preterm birth or fully investigate a potential dose-dependent relationship with opioid exposure. We investigated the association between prescription opioid exposure proximate to delivery and spontaneous preterm birth, and whether the association is dose-dependent.

STUDY DESIGN: We performed a nested case-control study of pregnant patients enrolled in TN Medicaid. Enrollment files were linked to healthcare encounters, hospital discharge data, birth certificate data, and prescription fill records. We included patients aged 15-44 years with a singleton livebirth at 24 weeks or greater between 2007 and 2019 with linked birth certificate data in the parent cohort. We identified cases of spontaneous preterm birth using a validated algorithm and matched up to 10 controls on case delivery date (index date), conception date, race, ethnicity, maternal age at delivery (±2 years), and preterm birth history. The exposure was total opioid morphine milligram equivalents (MME) filled within the 60 days prior to the index date. We used conditional logistic regression to estimate adjusted odds ratios (aOR) and obtained 95% confidence intervals (95% CI).

RESULTS: We identified 25,383 patients with spontaneous preterm birth (cases) and matched them to 225,436 controls (N=250,819 total). Overall, 8.8% of case patients filled an opioid prescription (median MME 150, IQR 75-338) versus 7.3% of controls (median MME 135, IQR 72-270). Total opioid MME prescribed within 60 days prior to index date was continuously associated with higher odds of spontaneous preterm birth, adjusting for relevant confounders (aOR=1.03 95% CI: [1.07-1.13] per opioid MME). Total opioid doses >98.7 MME were significantly associated with spontaneous preterm birth.

CONCLUSION: We identified an association between higher total opioid exposure and spontaneous preterm birth. Our findings support guidance to minimize opioid exposure proximate to delivery and prescribe the lowest dose necessary.

Figure: Association between total opioid MME prescribed and spontaneous preterm birth



>98.7 MME is the point where the lower bound of the 95% confidence interval becomes statistically significant

Model adjusted for parity, pre-pregnancy body mass index (BMI), education level, tobacco use, hepatitis infections, and pain indications

125 Adverse labor events and childhood autism- is there a link?

Hagar Brami[1], Omri Zamstein[2], Tamar Wainstock[3], Eyal Sheiner[2]
[1]Soroka University Medical Center, Beer-Sheva, [2]Soroka University Medical Center, Beer-Sheva, HaDarom, [3]Ben Gurion University, Beer-Sheva, HaDarom

OBJECTIVE: While the global interest and prevalence of autism spectrum disorder (ASD) are on the rise, the underlying mechanism and potential perinatal risk factors for its development are yet to be fully elucidated. In this study, we have sought to examine the potential association between unfavorable perinatal outcomes and ASD during childhood.

STUDY DESIGN: A population-based cohort analysis was conducted that included deliveries at a tertiary referral hospital occurring between 2005 to 2017 (selected following initial analysis that revealed a lower incidence of ASD diagnoses after 2017). The incidence of offspring diagnosed with ASD (both community and hospital-based diagnoses) was compared based on exposure (or lack thereof) to the composite variable "adverse perinatal outcomes" (comprising of 5-min Apgar scores < 7, umbilical cord blood pH < 7.0, and non-reassuring fetal heart rate). A Kaplan-Meier survival curve was used to assess cumulative ASD incidence. A Cox proportional hazards model was used to control for confounders.

RESULTS: Out of the 165,989 births included in the study, 11,070 (6.7%) had adverse perinatal outcomes. These births were more commonly complicated by intra-uterine growth restriction (4.1% vs.

1.8%), preterm delivery (9.6% vs. 6.6%), and cesarean delivery (45.3% vs. 13.4%; p< 0.001 for all). 862 offspring of the cohort were diagnosed during childhood with ASD. Overall, the cumulative incidence of ASD diagnoses was equivalent comparing "adverse perinatal outcomes" exposure status (Kaplan-Meier log-rank p=0.690), while the total ASD diagnoses were higher among offspring of complicated deliveries (0.7% vs. 0.5% respectively; p=0.012; Table). A Cox proportional hazards model, controlling for ethnicity, gestational age, maternal age, cesarean delivery, and gender, found no association between adverse perinatal outcomes and the risk of ASD (adjusted HR = 0.96, 95% CI 0.75−1.22, p=0.72; Table).

CONCLUSION: Adverse labor events, although concerning in terms of immediate neonatal health, do not appear to contribute to a higher risk of ASD in children as they grow older.

Table. The association between adverse perinatal outcomes (i.e., 5-min Apgar score <7, umbilical cord blood pH <7.0, and non-reassuring fetal heart rate) and autism spectrum disorder (ASD) in the offspring.

	Adverse perinatal outcomes (n=11,070)	No adverse perinatal outcomes (n=154,619)	Odds ratio (95% CI)[b]	Adjusted hazard ratio (95% CI)[a,]

126 A qualitative study of patient experiences and burdens of antenatal testing

Alexis Bridges, Lucy Ward, Karen J. Gibbins
Oregon Health & Science University, Portland, OR

OBJECTIVE: Expanded outpatient antenatal testing recommendations were released in 2021. Recommendations include individualizing care due to potential negative outcomes including the psychosocial impacts to patients, however limited information is available describing patient experiences and burdens when completing recommended antenatal testing. We sought to better understand patient experiences and potential burdens to those undergoing outpatient antenatal testing.

STUDY DESIGN: A single-center cross-sectional survey was administered to those attending an antenatal testing appointment. A 55-question electronic survey assessing patient knowledge, experience, and potential burdens surrounding completion of antenatal testing was self-administered by the patients. Demographics and survey responses were analyzed using descriptive statistics. Qualitative questions were analyzed with thematic analysis.

RESULTS: 124 patients were approached with 122 agreeing to participate. 103 completed the survey, resulting in 84% survey response rate. Overall, most participants did not consider it difficult to complete testing (86.8%). Missing work was required by 45.9% and obtaining childcare by 34.9%. When rating level of burden experienced, financial burden rated highest for those with household income < $100K with missed work highest for those with household income of $200k+ (Table 1). The median patient non-medical expense for each antenatal testing appointment was $20 (IQR = $5, $80). Thematic analysis of responses identified the following themes related to patient burdens: scheduling availability, requirement for missed work and childcare, high cost, increased stress and anxiety, and inconvenience.

CONCLUSION: For participants completing antenatal testing at our institution, burdens commonly experienced included financial, need for missed work and childcare. For some these negative psychosocial impacts are not insignificant and should be considered when individualizing care.

Table 1. Median [IQR] rating of participant burdens experienced by annual income with "0" signifying no burden and "10" signifying most burdensome.

	Financial	Childcare	Missed Work
< 100k	4 [1 – 6.5]	1 [0 – 6]	1 [0 – 7.25]
100-200k	3 [1 – 4.5]	1 [0 – 4]	4 [0 – 8]
200k +	1 [0 – 2]	1 [0 – 4]	4 [1.25 – 6]

127 Among patients undergoing induction who reach active phase, does prolonged latent phase matter?

Kira A. Bromwich[1], Rebecca F. Hamm[2], Lisa D. Levine[3], Jennifer A. McCoy[4]
[1]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, [2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

OBJECTIVE: While guidelines exist for diagnosing a failed induction of labor (IOL), there is little data assessing the impact of a prolonged, but not failed, latent phase on the remainder of the IOL trajectory. Therefore, we sought to assess if a prolonged latent phase is associated with an increased risk of Cesarean delivery (CD) or labor arrest among patients undergoing IOL.

STUDY DESIGN: This was a secondary analysis of a large prospective cohort study of term, singleton inductions with intact membranes and an unfavorable cervix at 2 sites from 2018-2022. Only patients who reached active phase (defined as ≥6cm dilation) were included. Prolonged latent phase was defined as < 6 cm dilation after ≥12 hours with ruptured membranes and receiving oxytocin infusion. The primary outcome was CD for any indication. Generalized estimating equations were used to calculate relative risk (RR) and adjust for confounders.

RESULTS: Of 8,509 patients in the cohort, 7,451 (87.6%) reached active phase and were included. 472 (6.3%) had a prolonged latent phase with demographic and clinical characteristic differences noted in the Table. There was a higher rate of CD for those with a prolonged latent phase compared to those without, which remained after adjusting for BMI, insurance type, diabetes, and Bishop score at the start of IOL (25.2% vs 9.9%, p< 0.001, aRR 1.69 95%CI [1.41-2.01]). This increased risk was noted among nulliparous patients (27.8% vs. 14.3%, p< 0.001, aRR 1.67 95%CI [1.39-2.00]) but not multiparous patients (8.1% vs. 3.2%, p=0.03, aRR 2.13 95%CI [0.88-5.12]). In those with a CD, there was a higher rate of CD for labor arrest among patients with prolonged latent phase compared to those without (19.5% vs. 6.3%, p< 0.001), with an increased risk of CD for labor arrest noted among nulliparous (21.7% v. 9.4%, p< 0.001), but not multiparous patients (4.8% v. 1.5%, p=0.07).

CONCLUSION: While the majority of patients with a prolonged latent phase of labor ultimately have a vaginal delivery, it is an independent risk factor for CD in active phase, both overall and among nulliparous patients.

128 Association of borderline fetal growth with progression to fetal growth restriction

Baillie Bronner[1], Margaret Schermerhorn[2], Monique Holod[3], Juliana Sung[1], Anna McCormick[1], Samantha de los Reyes[4]

[1]Rush University Medical Center, Chicago, IL, [2]Rush University Medical Center, Chiicago, IL, [3]Rush Medical College, Chicago, IL, [4]Rush University Medical Center, Evanston, IL

OBJECTIVE: To evaluate if an estimated fetal weight (EFW) between the 10-15th percentiles at time of anatomy ultrasound, referred to as borderline fetal growth, is associated with progression to fetal growth restriction (FGR) on subsequent ultrasound, delivery of a SGA neonate or neonatal intensive care (NICU) admission.

STUDY DESIGN: We performed a secondary analysis using the Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-to-Be data (NuMom2b). The exposures were normotensive pregnancies with non-anomalous singleton gestations with normal growth, defined as EFW >15th percentile at the anatomy scan compared to borderline fetal growth fetuses defined as those with an EFW in the 10-15th percentile. The primary outcome was FGR at subsequent ultrasound, defined as EFW or AC < 10%. The secondary outcomes were NICU admission and small for gestational age (SGA) neonate. Univariable analyses were performed comparing maternal baseline demographic and clinical characteristics. Multivariable analysis was performed for the primary outcome with variables adjusted a priori for body mass index, smoking status, race/ethnicity, insurance status, and drug use.

RESULTS: 4986 patients met inclusion criteria with 114 in the borderline fetal growth group and 4769 in the normal growth group. There were no significant differences in maternal demographic or medical characteristics (Table 1). In adjusted multivariable analysis, patients with borderline growth had significantly higher odds of being diagnosed with FGR at their subsequent scan (aOR 6.68, CI 3.98-11.20) compared to those with normal growth. For secondary outcomes, patients with borderline fetal growth were significantly more likely to have SGA neonates (6.14% vs. 2.67%, p= 0.025). There was no difference in admissions to the NICU between groups.

CONCLUSION: Diagnosis of borderline fetal growth at time of anatomy scan was associated with a significantly increased odds of progression to FGR at subsequent scan and delivery of a SGA neonate.

129 Impact of group prenatal care on postpartum contraception choice and rapid repeat pregnancy

Laura Gorham[1], Jessica Britt[1], Baylee Brown[1], Hannah Cain[2], Melissa Weisberg[2], Eliza Hardy[1], Daniel Pasko[3], Chelsea Fox[1], Liwei Chen[4], Emily Heberlein[5], Lu Zhang[6], Moonseong Heo[6], Amy Crockett[3]

[1]Prisma Health Upstate, Greenville, SC, [2]University of South Carolina, Greenville, SC, [3]Prisma Health, University of South Carolina School of Medicine Greenville, Greenville, SC, [4]University of California, Los Angeles, Los Angeles, CA, [5]James Bell Associates, Atlanta, GA, [6]Clemson University, Clemson, SC

OBJECTIVE: Group prenatal care (GPNC) offers extended time for health education on topics including family planning (contraception methods, healthy pregnancy spacing). Patients who receive evidence-based family planning counseling often choose long acting reversible contraceptive (LARC) options. We sought to compare the initiation rates of postpartum LARC in patients participating in GPNC versus individual prenatal care (IPNC).

STUDY DESIGN: This was a secondary analysis of a single-center 1:1 randomized controlled trial comparing pregnancy outcomes for patients in GPNC versus IPNC, stratified by self-reported race and ethnicity. Patients with a spontaneous abortion, fetal demise, or who were lost to follow-up after delivery were excluded. The primary outcome was initiation of LARC by 8 weeks postpartum. Secondary outcomes included initiation of LARC across racial and ethnic groups, initiation of LARC prior to hospital discharge, and short-interval pregnancies. A sensitivity analysis compared outcomes in per compliance (>5 visits in assigned arm, PC) groups. Multivariable logistic regression was used to adjust for baseline differences between groups.

RESULTS: 1,998 (85.0%) of the Centering and Racial Disparities (CRADLE) participants met inclusion criteria for this analysis. Demographic characteristics were similar between treatment groups with the exception of tobacco use prior to pregnancy. There was no

significant difference in the rates of LARC initiation between GPNC and IPNC participants at 8 weeks postpartum (adjusted odds ratio [aOR] 1.08, 95% confidence interval [CI] 0.89, 1.30). LARC initiation did not differ by racial and ethnic groups across exposures. There was also no significant difference between the rate of LARC initiation at hospital discharge (aOR 1.05, 95% CI 0.87, 1.26) nor the frequency of short-interval pregnancies (odds ratio 1.04, 95% CI 0.81, 1.33). These findings did not differ when comparing PC groups.

CONCLUSION: In this secondary analysis, participation in GPNC was not associated with increased rates of LARC initiation or decreased rates of short-interval pregnancies.

130 Vaginal birth after cesarean (VBAC) success and uterine rupture among twin compared to singleton gestation

Taylor L. Lendrum[1], Joshua Horns[2], Torri D. Metz[3], Ann M. Bruno[3], Lenz Ignace[2]
[1]University of Utah, Salt Lake City, UT, [2]University of Utah, Salt Lake City, UT, [3]University of Utah Health, Salt Lake City, UT

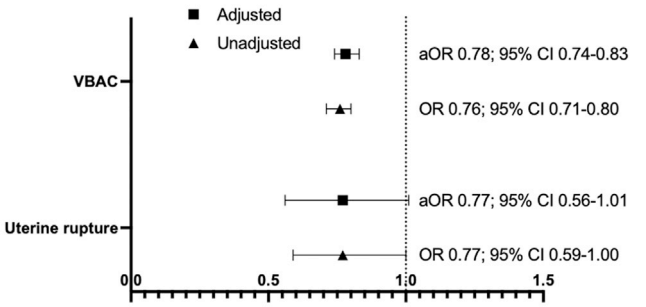
OBJECTIVE: Rates of vaginal birth after cesarean (VBAC) success and uterine rupture risk are well described for singleton gestations undertaking a trial of labor after cesarean (TOLAC). However, data are limited for twin gestations. We aimed to evaluate rates of VBAC success and uterine rupture among twin compared to singleton gestations undergoing TOLAC.

STUDY DESIGN: Retrospective cohort study including deliveries >20 weeks' gestation from 2016-2018 with data available in the MarketScan Research Database. Individuals with prior cesarean delivery and undertaking TOLAC were included. Those with contraindication to vaginal delivery or higher order multiples were excluded. The primary outcome was successful VBAC, defined as vaginal delivery among those with history of cesarean. The secondary outcome was uterine rupture. Outcomes and covariates were identified using ICD-10 codes. Univariate analyses compared baseline characteristics for twins compared to singleton gestations. Multivariate logistic modeling estimated the association between twin compared to singleton TOLAC and the outcomes.

RESULTS: Of 51,214 eligible deliveries, 10,368 (20.2%) were twin gestations. Twin compared to singleton gestations were more likely to have chronic hypertension (10.3% vs 8.1%, p< 0.001) and gestational diabetes (14.6% vs 12.5%, p< 0.001). In unadjusted and adjusted modeling, twin compared to singleton TOLAC was associated with lower VBAC success (14.40% vs 18.18%; OR 0.76, 95% CI 0.71-0.80; aOR 0.78, 95% CI 0.74-0.83) but no statistically significant difference in uterine rupture (0.65% vs 0.84%; OR 0.77, 95% CI 0.59-1.0; aOR 0.77, 95% CI 0.56-1.01; Figure).

CONCLUSION: TOLAC in twin gestations compared to singletons was associated with decreased VBAC success but no difference in rates of uterine rupture. This information may be used to help counsel patients with twin gestations considering TOLAC.

Figure. Vaginal birth after cesarean (VBAC) success and uterine rupture among twin compared to singleton pregnancies undertaking trial of labor after cesarean (TOLAC)



Adjusted for maternal age, gestational or preexisting diabetes mellitus, chronic hypertension or hypertensive disorders of pregnancy, class III obesity (body mass index >40 kg/m^2), and placental abruption.

131 Urinary immune complexome profiling allows for clinical subphenotype differentiation in preeclampsia (PE)

Hongwu Jing[1], Catalin S. Buhimschi[1], Guomao Zhao[1], William E. Ackerman IV[2], Irina A. Buhimschi[1]
[1]University of Illinois at Chicago, Chicago, IL, [2]University of Illinois at Chicago College of Medicine, Chicago, IL

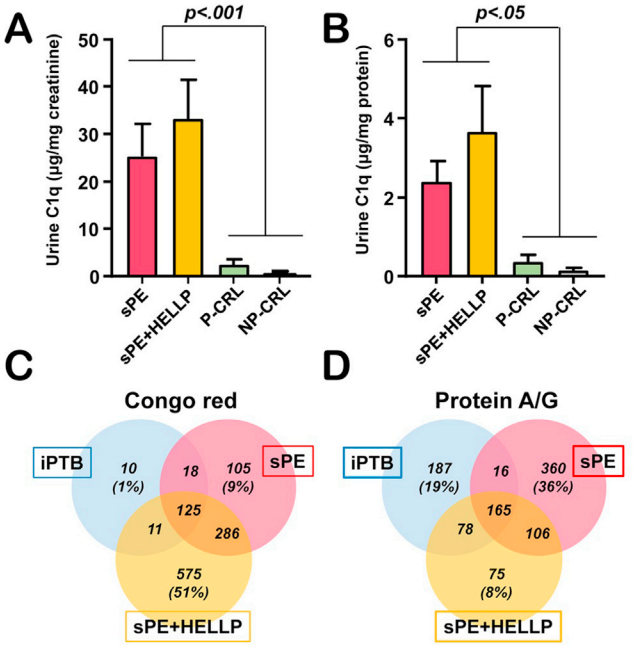
OBJECTIVE: Urine of patients with PE harbors unique antigenic proteins in the form of conformational neoepitopes reactive with monoclonal antibodies raised against prototype pre-fibrillar amyloid proteins. The objectives of this study were to discover if **1)** the counterpart conformational autoantibodies and immune complexes (ICs) binding to the amyloid neoepitopes are also present in PE urine and **2)** if PE clinical subphenotypes are linked to specific antigenic neoepitopes peptides.

STUDY DESIGN: In a cross-sectional study design we analyzed urine samples of 77 subjects as follows: **1)** normotensive nonpregnant (NP-CRL, n=9) or **2)** non-PE pregnant persons (P-CRL, n=17, GA: 28±1w); **3)** early-onset severe features PE (sPE, n=28, GA: 29±1w) without and **4)** with clinically manifest HELLP (sPE+HELLP, n=23, GA: 29±1w). Urine ICs were assayed by ELISA employing C1q (subcomponent of ICs) and normalized to creatinine or total protein levels. Urine ICs of a subset of sPE, sPE+HELLP or spontaneous preterm birth (sPTB, n=5) patients were precipitated with polyethylene glycol (PEG), Protein A/G or the amyloidophilic dye Congo red and then subjected to LC/MSMS. Protein identities (IDs) were assigned to functional classes using Scaffold, g:Profiler, Cytoscape with STRING and ClueGO Apps for further analysis.

RESULTS: Compared to CRLs, sPE and sPE+HELLP patients had significantly higher urine IC concentration (Figs. A&B). While quantitatively, there was no difference in IC output between sPE and sPE+HELLP, we observed that different IC enrichments captured distinct ID repertoires. Congo red identified the highest proportion of unique IDs in sPE+HELLP (Fig. C). Protein A/G captured the highest proportion of unique IDs in sPE (Fig. D). Compared to sPE and iPTB, the non-immunoglobulin ID repertoire in sPE+HELLP

had higher representation of proteins involved in extracellular processes, hemostasis and protein-lipid interactions.

CONCLUSION: Our findings highlight the importance of the autoimmune response in PE pathogenesis and support the notion that sPE and HELLP may associate with different repertoires of autoantigens.



132 Time to intervention or delivery in monochorionic diamniotic twins with abnormal screening ultrasound findings

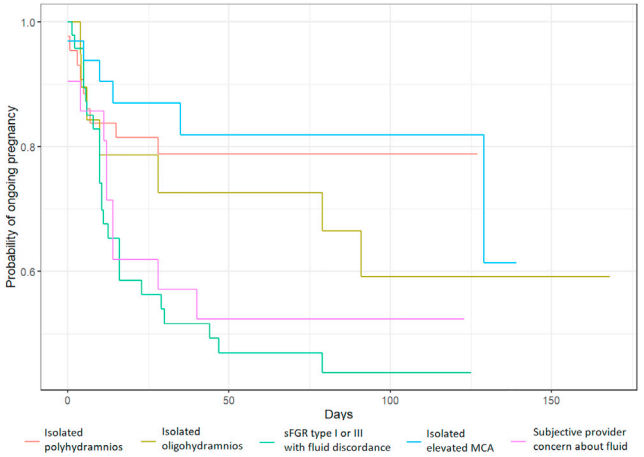
Cara Buskmiller[1], Linda Alpuing Radilla[1], Luis Delgadillo Chabolla[1], Divya Chilukuri[2], Daniel Arnaud Dominguez[1], Jessian L. Munoz[1], Ahmed A. Nassr[1], Magdalena Sanz Cortes[3], Michael A. Belfort[4], roopali V. donepudi[1]
[1]Baylor College of Medicine, Houston, TX, [2]Case Western, MetroHealth, Cleveland, OH, [3]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [4]Texas Children's Hospital, Houston, TX

OBJECTIVE: This study sought to examine the natural history of monochorionic diamniotic (MCDA) twins that do not meet criteria for twin-twin transfusion syndrome (TTTS), twin anemia-polycythemia sequence (TAPS), or selective fetal growth restriction (sFGR) but have an abnormal finding during screening for these conditions.

STUDY DESIGN: This retrospective case-control study longitudinally reviewed all MCDA twins between 2018-2022 at a tertiary fetal care center. Twins with normal imaging acted as controls, and those with abnormalities on screening ultrasounds (US) were included as cases. Excluded were twins with clear diagnostic findings of TTTS, TAPS, or sFGR as well as higher-order multiples, anomalies which could affect fluid or Dopplers, and having only one US. Cases were divided into subgroups including those with polyhydramnios of one twin, oligohydramnios of one twin, sFGR with fluid discrepancy, subjective provider concern about fluid discrepancy, and middle cerebral artery (MCA) Doppler $\geq$ 1.5 MoM without fluid abnormalities. The primary outcome was time from an abnormal finding to laser or to delivery. Kaplan Meier (KM) curves were generated with cases censored at laser, delivery, or at last scan when delivery records were unavailable.

RESULTS: Of 751 gestations, 227 were excluded for clear diagnosis, 19 for fetal anomaly 10 for higher order multiples, and 44 for having only one US. Of the remaining 438, 224 with normal imaging became controls, and the remaining 214 were cases. The probability of two ongoing weeks of pregnancy without fetal intervention or delivery differed between controls and case subgroups (control, 100%; isolated polyhydramnios, 83%; isolated oligohydramnios, 77%; sFGR with fluid discrepancy, 65%; abnormal MCA, 87%; provider concern, 62%, p = 0.01). KM curves demonstrate that sFGR with fluid discrepancy and subjective provider concern were the most morbid findings; elevated MCA Doppler was the least.

CONCLUSION: Families of MCDA twins with abnormal ultrasound findings can be counseled on the likelihood of ongoing uncomplicated pregnancy based on their condition.



133 Anemia negatively impacts perinatal outcomes in a large cohort of 1,724,828 pregnancies in California.

Kimberly Ryan, Bharti Garg, Martens Kylee, Shatzel Joseph, Aaron B. Caughey, Jamie Lo, Ashley E. Benson
Oregon Health & Science University, Portland, OR

OBJECTIVE: Anemia is common in pregnancy and associated with maternal and fetal morbidity. However, the incidence and risk factors of perinatal outcomes are largely derived from international cohorts with higher rates of anemia and are less representative of pregnancies within the United States (US). The objective of this study was to evaluate perinatal outcomes associated with anemia diagnosis in pregnancy in a modern, large California-based cohort.

STUDY DESIGN: We performed a cohort study of California-linked hospital discharge-vital statistics data from 2016-2019. Deliveries 23-42 weeks' gestation were included and anemia was identified using birth certificate and International Classification of Disease (ICD-10) codes. Chi-squared and multivariable logistic regression were utilized for statistical analyses.

RESULTS: A total of 1,724,828 births met study inclusion criteria; 303,718 (18%) had a maternal diagnosis of anemia. Pregnancies affected by anemia compared to those without anemia were associated with a higher frequency of hypertensive disease (12.1% vs 8.1%, aOR: 1.51 (1.49-1.53)), preterm delivery (10.4% vs 7.7%, aOR: 1.30 (1.28-1.32)), and very preterm delivery (1.8% vs 1.1%, aOR: 1.49 (CI: 1.45-1.54). Neonatal morbidity was increased in the presence of maternal anemia with more NICU admissions (11.5% vs 9.5%, aOR: 1.12 (1.11-1.14)), respiratory distress syndrome (7.5% vs

5.6%, aOR: 1.33, (1.31-1.35)), hypoglycemia (3.8% vs 2.8%, aOR 1.34 (1.31-1.37)) and low birth weight infants (< 2500 gm) (7.9% vs 6.1%, aOR 1.22 (1.20-1.24)).

CONCLUSION: Anemia during pregnancy is associated with numerous adverse perinatal outcomes. These findings support anemia as a potentially modifiable risk factor in maternal and neonatal morbidity. Increased screening for anemia may provide timely intervention and mitigation of associated morbidity

Table 1. Multivariable logistic regression models showing association of anemia with perinatal outcomes.

Perinatal Outcome	No anemia N=1,724,828	Anemia N= 303,718	Adjusted odds ratio (95% Confidence interval)†
Hypertensive disease	115,363 (8.1%)	36,636 (12.1%)	1.51 (1.49, 1.53)
Preterm birth (<37 weeks)	110,014 (7.7%)	31,546 (10.4%)	1.30 (1.28, 1.32)
Very preterm birth (<32 weeks)	14,967 (1.1%)	5,335 (1.8%)	1.49 (1.45, 1.54)
NICU admission	135,124 (9.5%)	34,959 (11.5%)	1.12 (1.11, 1.14)
Respiratory distress syndrome	79,112 (5.6%)	22,724 (7.5%)	1.33 (1.31, 1.35)
Infant deaths	3,749 (0.3%)	1,020 (0.3%)	1.15 (1.07, 1.24)
Hypoglycemia	39,283 (2.8%)	11,425 (3.8%)	1.34 (1.31, 1.37)
Low birth weight (<2500 gm)	87,083 (6.1%)	23,879 (7.9%)	1.22 (1.20, 1.24)

†Adjusted for maternal race and ethnicity, age, level of education, body mass index, parity, insurance, prenatal visits, chronic hypertension and pre-existing diabetes.

134 Late preterm antenatal corticosteroids and neonatal hypoglycemia: a cohort study

Mauricio Carrillo[1], Fernando Castañeda[2], Nicolas Rodriguez[1], Ivana Moyano[3]

[1]Fundación Santa Fé de Bogotá, Department of Gynecology and Obstetrics, Bogota, Distrito Capital de Bogota, [2]Universidad El Bosque, Gynecology and Obstetrics, Bogota, Distrito Capital de Bogota, [3]Universidad del Rosario, School of Medicine, Bogota, Distrito Capital de Bogota

OBJECTIVE: To determine associations between antenatal corticosteroid (AC) administration in late preterm fetuses with presence of neonatal hypoglycemia (NH).

STUDY DESIGN: Retrospective cohort study in pregnant women with late preterm deliveries at University Hospital Fundación Santa Fe de Bogotá 2019−2022. The exposure of interest was AC administration of betamethasone during pregnancy between 34 0/7 and 36 6/7 weeks in singleton and twin gestations. The primary outcome was NH. Descriptive analysis based on averages and percentages, and multivariable logistic regression were used to estimate the association between AC exposure and NH. We stratified the study by singleton and twin gestations, corticosteroids dose, maternal outcomes and neonatal outcomes. Statistical analysis was performed using Odds Ratio(OR), confidence intervals and *p* values.

RESULTS: 6017 total deliveries, 528 (8.7%) late preterm, 378 (71,5%) singleton and 150 (28.5%) twin pregnancies. 330 mothers received AC, 260 (78.8%) were singleton and 70 (21.3%) were twin pregnancies. There were no statistical differences between all late preterm fetuses who received AC and those who did not received and developed NH (OR=1.09, 95% CI [0.71-1.67], p=0.699), no significant statistically relationship between AC and NH when we adjusted by: singleton (OR= 0.78, 95%CI[0.43-1.43], p=0.428), or twins (OR=1.12, 95%CI[0.56-2.25], p=0.742). There were no association when we adjusted by number of corticosteroids dose, full course, or partial course (OR=0.96, 95%CI[0.62-1.48], p=0.860). There were no significant statistically relationship between AC and NH adjusted by maternal and neonatal clinical conditions such as preeclampsia, premature rupture of membranes, gestational diabetes, fetal growth restriction, oligoamnios, neonatal sepsis, polycythemia, jaundice, and respiratory distress syndrome.

CONCLUSION: Exposure to AC in singletons and twins during late preterm period is not associated with increased odds of hypoglycemia. In our population several maternal and neonatal clinical conditions do not change the significant statistical relationship between AC and NH.

135 Distressed community index and the association with preterm birth

Allen Ghareeb, Lindsay Cheu, Leah M. Savitsky, Mindy Pike, Shani Delaney, Catherine M. Albright

University of Washington, Seattle, WA

OBJECTIVE: To determine whether more socioeconomically distressed communities experience higher rates of preterm birth or earlier gestational age at delivery at a tertiary care hospital in Washington state.

STUDY DESIGN: We conducted an IRB-approved retrospective cohort study using the Obstetrical Care Outcomes Assessment Program (OBCOAP) at the University of Washington Medical Center. We included the first pregnancy in the dataset for each individual with complete data on gestational age (GA) at delivery and distressed community index (DCI), a tool for measuring the comparative economic well-being of U.S. communities. We evaluated the association between DCI quintile and GA at delivery using linear regression, adjusting for pre-pregnancy substance use, smoking, diabetes, hypertension, and urban/rural class. Chi-square test and Kruskal-Wallis rank test were used for comparison of outcomes across quintiles.

RESULTS: A total of 10,143 individuals were included for analysis, with 39.0% of individuals living in the least distressed communities (DCI quintile =1), and 2.9% in the most distressed communities (DCI quintile = 5). For individuals in the least distressed quintile, gestational age at delivery was 2.5 weeks (95% CI: 2.06, 2.93) later than for individuals in the most distressed quintile, after adjustment for confounders. Individuals in the most distressed communities experienced significantly higher rates of extremely preterm, very preterm, moderate preterm, and late preterm birth compared to the least distressed communities (Table 1).

CONCLUSION: Our findings indicate that the DCI has the potential to identify patient populations at risk for preterm birth independent of classic risk factors such as smoking, diabetes, substance use, and hypertension. Promising DCI applications could include the creation of neighborhood-specific interventions for addressing the rising rates of preterm deliveries in vulnerable communities.

Table 1. Gestational age and preterm birth status by distressed community quintile

	Quintile 1 (n=3,959)	Quintile 2 (n=3,163)	Quintile 3 (n=1,764)	Quintile 4 (n=964)	Quintile 5 (n=293)	p-value

136 A systematic review of interventions for opioid use disorder during the first year postpartum

Pranaya Chilukuri[1], Charlotte McCarley[2], Juliann Wang[3], Brian M. Casey[4], Rachel Sinkey[5], Caitlin Clevenger[4]

[1]University of Kentucky Albert B. Chandler Hospital, Lexington, KY, [2]University of Alabama at Birmingham, Hoover, AL, [3]University of Alabama at Birmingham School of Medicine, Birmingham, AL, [4]University of Alabama at Birmingham, Birmingham, AL, [5]University of South Florida, Tampa, FL

OBJECTIVE: Opioid use disorder (OUD) is a leading cause of maternal mortality, particularly postpartum (PP). The objective of this systematic review is to provide a qualitative summary of published interventions for PP opioid abstinence or reduction.

STUDY DESIGN: This systematic review was registered with PROSPERO (ID CRD42023405688). A comprehensive search of CINAHL, MEDLINE, PsycINFO, and EMBASE was conducted for intervention trials with $\geq$ 5 subjects aimed at opioid use reduction or abstinence in the first year PP. Studies without a comparison group or interventions continued PP were excluded. All abstracts were summarized, if eligible, by 2 independent reviewers. Risk of bias was assessed with the Cochrane Risk of Bias or Newcastle-Ottawa Scale.

RESULTS: Of 812 articles screened, 14 were assessed for full-text eligibility and 3 were included for full-text review (Table). Study 1 assessed a therapeutic workplace (TW) that provided a job with reimbursement for opioid abstinence. Abstinence was increased in TW (n=20) compared to usual care (UC) (n=20) in the first 6 months PP, but the change was not significant (52% vs 33%, p=0.06). Study 2 assessed a comprehensive perinatal clinic's effect on patients with substance use and demonstrated drug use abstinence during pregnancy in 93/97 (96%) of participants. However, only 10% of patients in the study had OUD, 22% were lost to follow up PP, and 13% relapsed to heavy drug use by 6 months PP. Study 3 compared motivational interviewing to UC in 60 participants and found a significant reduction in PP opioid use (23% vs 60%, p=0.004).

CONCLUSION: Despite the large contribution of OUD to maternal mortality, only 3 intervention studies have assessed strategies to reduce opioid use PP. Existing studies vary widely in intervention type and effect. Our systematic review illustrates the paucity of evidence-based interventions for PP OUD. This underscores the pressing need to further address this significant public health concern and contributor to maternal mortality.

Table: Opioid use disorder interventions identified in systematic review

Methods	Study Result
1. Silverman et al. A reinforcement-based therapeutic workplace for the treatment of drug abuse: six-month abstinence outcomes. Exp Clin Psychopharmacol. 2001 Feb;9(1):14-23.	
Study Type: RCT, n = 40 **Intervention:** Therapeutic workplace **Outcome:** Opioid abstinence **Inclusion criteria:** Pregnant or PP women 18-50 years, unemployed, on methadone maintenance with ≥1 UDS + for opiates or cocaine within 6 weeks of enrollment **Exclusion criteria:** At risk for suicide or had psychiatric disorder that might disrupt ability to work or provide informed consent	Increase in opioid abstinence after 6 months (UC 33% vs TW 52%, p = 0.060)
2. Wright et al. Implementation and evaluation of a harm-reduction model for clinical care of substance using pregnant women. *Harm reduction journal*, 2012. 9(1), 1-10.	
Study Type: Prospective Cohort Study, n = 213 **Intervention:** Comprehensive perinatal care **Outcome:** Substance use reduction **Inclusion criteria:** Pregnant and PP women with SUD	Abstinence at delivery (93/97, 96%) Lost to follow up PP (n/n, 22%) Relapse rate to heavy substance usage at 6 months PP (n/n, 13%)
3. Esmaeilinejad et al. Effect of Motivational Enhancement Therapy on Patterns of Substance Abuse in Postpartum Women: A Randomized Clinical Trial. J of Holistic Nursing and Midwifery 2022	
Study Type: RCT, n = 60 **Intervention:** Motivational-Enhancement Therapy **Outcome:** Substance use reduction **Inclusion criteria:** PP women age 15-45 years with SUD **Exclusion criteria:** Absence from one session, committing a crime, using other counseling services	Reduction in the number of opium (p=0.008) and methadone (p=0.003) users. Reduction in the *amount* of opium and methadone use (p<0.05). Opium usage decreased significantly in the intervention group (p=0.01).

RCT, randomized controlled trial; TW, therapeutic workplace; UC, usual care; SUD, substance use disorder; UDS, urine drug screen; Postpartum, PP

137 Outcomes of twin patients referred for shunt placement: a single institution's 16-year experience

Dani R. Chmait[1], Arlyn Llanes[1], Lisa M. Korst[2], Andrew H. Chon[3], Martha A. Monson[4]

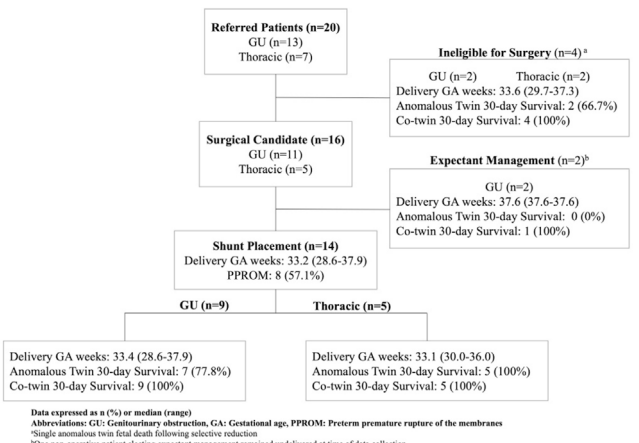
[1]University of Southern California, Los Angeles, CA, [2]Childbirth Research Associates, North Hollywood, CA, [3]Oregon Health & Science University, Portland, OR, [4]Intermountain Healthcare, Salt Lake City, UT

OBJECTIVE: Fetal shunt placement in twins remains controversial due to technical difficulties and potential procedure-related risks to the healthy co-twin. We report outcomes following referral for possible shunt placement in twins.

STUDY DESIGN: Retrospective case series of twin gestations referred for shunt placement at a single center (2007-2023). Conditions eligible for shunt placement included: cystic fetal lung lesions or pleural effusion(s) with secondary fetal hydrops, and genitourinary (GU) tract obstructionwith oligohydramnios. Results are reported as n (%) or median (range).

RESULTS: Among the 20 patients referred for possible shunt surgery, 4 were not eligible [chest lesion without hydrops (n=2), GU obstruction without oligohydramnios (n=2)]. Of the 16 eligible patients, 14 underwent shunt placement (9 GU, 5 thoracic) and 2 elected expectant management (2 GU). Gestational age (GA) at initial surgery was 21.9 (17.7-33.7) weeks. Four (28.6%) patients underwent a second procedure for displaced shunt. No intra-operative complications (e.g., incidental septostomy) occurred. Latency from initial surgery to delivery was 12.3 (2.43-20.0) weeks. Pregnancy outcomes are described in the Figure. Delivery GA was 33.2 (28.6-37.9) weeks in shunted patients vs. 35.5 (29.7-37.6) for all non-operative referred patients. All 20 unaffected co-twins were 30-day survivors. Twelve (85.7%) shunted twins were 30-day survivors with 100% co-twin 30-day survival. Significant co-twin prematurity related morbidity after shunting was rare (necrotizing enterocolitis and late onset sepsis after 28 and 34-week preterm births, respectively). Non-operative anomalous and healthy co-twin 30-day survival was 2 (50%) and 5 (100%), respectively.

CONCLUSION: Shunt placement in twins meeting surgical criteria can be accomplished with relatively minimal risk to the co-twin. Well-counseled patients with twin gestations should not be excluded from undergoing fetal shunt placement at experienced centers.



138 Late prenatal repair of open spina bifida (OSB) and postnatal cerebrospinal fluid (CSF) diversion

Ramen H. Chmait[1], Jason Chu[2], Alexander L. Van Speybroeck[2], Huyen Q. Pham[1], Arlyn Llanes[1], Lisa M. Korst[3], HaiThuy N. Nguyen[2], Eftichia V. Kontopoulos[4], Ruben A. Quintero[4]

[1]University of Southern California, Los Angeles, CA, [2]Children's Hospital Los Angeles, Los Angeles, CA, [3]Childbirth Research Associates, North Hollywood, CA, [4]USFetus Research Consortium, Coral Gables, FL; on behalf of the USFetus Research Consortium

OBJECTIVE: Risk factors for postnatal CSF diversion after prenatal OSB repair were identified in a meta-analysis from 2002-2021. These included lateral ventricle ≥ 15 mm, lesion level T12-L2, myeloschisis, and gestational age (GA) at surgery ≥ 25 weeks. The aim of this study was to assess the risk factors for CSF diversion by 12 months of life after percutaneous fetoscopic OSB repair performed ≥ 25 weeks' gestation.

STUDY DESIGN: This was a prospective study of patients who underwent percutaneous fetoscopic OSB repair from 2019-2023 at GA ≥ 25 weeks. The decision to offer CSF diversion was based on postnatal MRI and clinical findings. Preoperative, operative, and neonatal characteristics were examined as predictors for a CSF diversion procedure (ventriculoperitoneal shunt or endoscopic third ventriculostomy) within the first 12 months of life, using bivariate analyses and multiple logistic regression models.

RESULTS: Of 47 patients that had prenatal repair ≥ 25 weeks' gestation, some degree of hindbrain herniation (HBH) reversal was noted at birth in 41 (87.2%) and complete HBH reversal in 22 (46.8%). CSF diversion by 12 months of age was required in 14 cases (29.8%). In bivariate analysis ($p < 0.05$), both fetal ventricular measurement ≥ 15 mm prior to surgery and lack of complete hindbrain HBH reversal at neonatal assessment were associated with a CSF diversion procedure. Multiple logistic regression showed that cases with a lateral ventricle ≥ 15 mm were 7 times more likely to have CSF diversion (OR 7.63, 95%CI 1.52-38.20, $p = 0.0134$), and cases lacking complete HBH reversal were 5 times more likely to have CSF diversion (OR 5.25, 95%CI 1.07-25.83, $p = 0.0414$).

CONCLUSION: Percutaneous fetoscopic repair of OSB at 25-27 weeks was associated with a 29.8% risk of postnatal CSF diversion at 12 months of life. This compares favorably to the ~40% risk in the published literature in which prenatal repair is typically done £ 25 weeks. Further study is required to assess the risks/benefits of postponing prenatal repair of OSB beyond 25 weeks' gestation.

Table 1. Bivariate analysis of cases that underwent percutaneous fetoscopic repair of open spina bifida (OSB) and requirement for CSF diversion procedure by 12 months of age. Data are expressed as n (%) or mean ± standard deviation.

139 The impact of maternal depression and fetal attachment on fetal heart rate variability

Hee Young Cho[1], Sehwan Park[2], Kyungun Jhung[3], Jin Young Park[4]

[1]Seoul National University College of Medicine, Seoul, Seoul-t'ukpyolsi, [2]Biomedical Research Institute, Catholic Kwandong University International St. Mary's Hospital, Inch'on-jikhalsi, [3]International St. Mary's Hospital, Catholic Kwandong University College of Medicine, Inch'on-jikhalsi, Inch'on-jikhalsi, [4]Yongin Severance Hospital, Yonsei University College of Medicine, Yongin, Kyonggi-do

OBJECTIVE: The purpose of this study is to investigate the association between mental health of pregnant women and fetal heart rate variability (HRV).

STUDY DESIGN: A total of 92 normal pregnant women at third trimester (28 to 40 weeks of gestation) participated. The maternal and fetal HRV were measured by the software-based instrument, Philips HR, by a standard protocol that calculates the time and frequency domain during a rest period of approximately 30 minutes. The sociodemographic and obstetric measures, as well as psychological measures including depression, maternal-fetal attachment, mental health well-being, and sleep were conducted. Statistical analysis was conducted through Pearson r and spearman correlation coefficient.

RESULTS: In fetal HRV, total score of maternal-fetal attachment scale, its two subscales and self-rating scores of fetus' moods from mother were positively correlated with time domain indices (sdnn; sdann, $p < 0.05$). Sleep disturbance (rmssd; sdsd, $p < 0.01$), sleep latency (sdnn; $p < 0.05$), sleep quality (rmssd; sdsd, $p < 0.05$), the stress level within a year (sdnn; sdann, $p < .05$) and age (sdann; $p < 0.01$)

were negatively correlated with time domain indices. The number of artificial abortion was negatively correlated with frequency domain measures (lf; hf, $p < 0.05$). In mother's HRV, one of the subscales of maternal-fetal attachment scale (sdann; $p < 0.05$) and the number of artificial abortion (sdnn; sdann; rmssd; sdsd, $p < 0.01$) was positively correlated with time domain indices. Habitual sleep quality was negatively correlated with frequency domain indicator (hf; $p < 0.05$).

CONCLUSION: This study suggests that indices of fetal HRV have significant association with the mental health of the mother and mental health in the perinatal period plays a major role in considering the overall health of the fetus and the development of autonomic nervous system of fetus.

140 Association of neighborhood walkability with adverse pregnancy outcomes in gestational diabetes

Yiwen Cui[1], Yuhong Zhou[1], Meredith Cruz[1], Bethany Canales[1], Kartik Venkatesh[2], Anna Palatnik[1]

[1]Medical College of Wisconsin, Milwaukee, WI, [2]Ohio State University, Columbus, OH

OBJECTIVE: To examine the association of neighborhood walkability with adverse pregnancy outcomes (APO) in patients with gestational diabetes (GDM).

STUDY DESIGN: Retrospective cohort study of pregnancies with GDM at a Midwestern academic center. Participants' primary residential addresses were geocoded at the census tract level to the 2018 Environmental Protection Agency (EPA) National Walkability Index. The exposure of neighborhood walkability was analyzed continuously and categorically per EPA recommendations as block groups: least walkable (score 1-5), below average (6-10), above average (11-15), and most walkable (16-20). APO included maternal composite outcome of preeclampsia, preterm birth, cesarean birth, 3rd/4th degree laceration, postpartum hemorrhage, wound infection, and neonatal composite outcome of LGA, SGA, LBW< 2500g, fetal or neonatal death, shoulder dystocia, brachial nerve palsy, hypoglycemia, RDS, and NICU admission. These composite outcomes were chosen as they are associated with GDM and were utilized by us in prior work.

RESULTS: Of 892 patients with GDM, 6.4% lived in least walkable, 39.1% in below average walkable, 38.1% in above average walkable, and 16.4% in most walkable neighborhoods. Non-Hispanic White patients were more likely to live in less walkable neighborhoods (43.2% in most walkable vs. 93.0% in least walkable, p< 0.001), while the opposite was observed for non-Hispanic Black patients (1.8% in least walkable vs. 26.7% in most walkable, p< 0.001). Nulliparity (p=0.02), being single (p< 0.001) and public insurance (p< 0.001) increased with higher neighborhood walkability. In adjusted analyses, higher neighborhood walkability as a continuous measure was associated with lower odds of composite maternal APO (aOR 0.96, 95% CI 0.92, 0.99). When analyzed as EPO block groups, neighborhood walkability was not associated with APO (Table).

CONCLUSION: Among pregnant patients with GDM, neighborhood walkability was associated with sociodemographic characteristics. Those who lived in most walkable neighborhoods were at lower likelihood of maternal APOs.

Table. Association of national walkability index with adverse pregnancy outcomes in gestational diabetes

	Unadjusted Odds Ratio (95% CI)	[a]Adjusted Odds Ratio (95% CI)
Composite maternal APO with walkability index analyzed as a continuous variable	0.99 (0.96, 1.03)	**0.96 (0.92, 0.99)**
Composite neonatal APO with walkability index analyzed as a continuous variable	**1.03 (1.00, 1.07)**	1.02 (0.98, 1.06)
[b]Composite maternal adverse outcome analyzed as EPA block groups		
Block 1: Least walkable (1-5)	Ref	Ref
Block 2: Below average (6-10)	1.53 (0.85, 2.74)	1.36 (0.74, 2.52)
Block 3: Above average (11-15)	1.33 (0.74, 7.38)	0.88 (0.47, 1.68)
Block 4: Most walkable (16-20)	1.25 (0.66, 2.37)	0.81 (0.40, 1.62)
[c]Composite neonatal adverse outcome analyzed as EPA block groups		
Block 1: Least walkable (1-5)	Ref	Ref
Block 2: Below average (6-10)	**0.51 (0.29, 0.90)**	0.55 (0.30, 0.95)
Block 3: Above average (11-15)	**0.74 (0.42, 1.29)**	0.67 (0.17, 1.22)
Block 4: Most walkable (16-20)	**0.93 (0.51, 1.73)**	0.83 (0.46, 1.59)

APO, Adverse pregnancy outcomes; CI, Confidence Interval.
[a]Adjusted for age, race, nulliparity, marital status, insurance type and pre-pregnancy BMI
[b]Composite of hypertensive disorder of pregnancy, preterm birth, operative or cesarean delivery, 3rd or 4th degree perineal laceration, postpartum hemorrhage, wound infection
[c]Composite of large for gestational age, small for gestational age, low birthweight <2500 grams, fetal or neonatal death, shoulder dystocia, brachial nerve palsy, hypoglycemia, respiratory distress syndrome, NICU admission

141 Adrenomedullin upregulates mRNA expression of nutrient transporters in human trophoblast cell line: implications for GDM

Simon Dadoun, Yuanlin Dong, Allyson Nevins, Antonio H. Ruano, Moises Tacam, Jon A. Fuson, Simone Hernandez, Chandrasekhar Yallampalli, Kathleen A. Pennington

Baylor College of Medicine, Houston, TX

OBJECTIVE: Mechanisms underlying the pathophysiology of Gestational Diabetes Mellitus (GDM) and its adverse effects on mother and fetus remain poorly understood. Adrenomedullin (ADM) is elevated in pregnancies complicated by GDM. Studies from our laboratory previously showed elevated ADM levels play a role in maternal dyslipidemia and defective β-cell adaptation associated with GDM. However, the effects of increased circulating ADM levels on placental function and nutrient transport are still unknown. We performed a series of in vitro experiments investigating the effects of increased ADM on the expression of trophoblast cell nutrient transporters.

STUDY DESIGN: First-trimester human trophoblast cell line HTR8/SVneo was cultured with increasing doses of ADM (0, 0.1, 1.0, or 10 nM) for 24 hours. Cells were then harvested, mRNA extracted, cDNA synthesized, and real-time qPCR performed for genes related to lipid, glucose, and amino acid transport, that have previously been shown to be upregulated in placentas with GDM.

RESULTS: Treatment with ADM increased the expression of several transporter genes: lipid transporters EL (p=0.03), FABP3 (p=0.0002), FABP5 (p=0.006), FABP7 (p=0.02), FATP1 (p=0.01), FATP6 (p=0.01), and CD36 (p=0.0087); glucose transporters GLUT3 (p=0.02) and GLUT4 (p=0.002); amino acid transporters SNAT1 (p=0.04), SNAT2(p=0.03), and LAT2 (p=0.001). LAT1 (p=0.06) was downregulated. These effects in gene expression progressed in a dose-dependent fashion.

CONCLUSION: These studies demonstrate in vitro treatment with ADM upregulates the expression of trophoblast cell nutrient transporters in a dose-dependent fashion. Data from this study further implicates ADM in the pathogenesis of fetal macrosomia associated with GDM. Future in vivo studies will explore the possibility of using ADM as a biomarker of GDM. By increasing our understanding of molecular pathways involved in placental nutrient transport, we may be able to develop future therapies to reduce the maternal and fetal complications associated with GDM.

142 Estimated fetal weight versus abdominal circumference in predicting adverse outcome in fetal growth restriction

Lydia DeAngelo[1], Justin D. Moore[2], Meng Yao[2], Sarah C. Graves[3], Catherine Klammer[3], Lauren Buckley[2], Oluyemi Aderibigbe[4], Amol Malshe[2], Maeve Hopkins[5]
[1]Cleveland Clinic Lerner College of Medicine of Case Western Reserve University School of Medicine, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic Foundation, Cleveland, OH, [4]Cleveland Clinic Obstetrics and Gynecology, Cleveland, OH, [5]Cleveland Clinic, Rocky River, OH

OBJECTIVE: To identify fetal growth restriction (FGR) based on estimated fetal weight (EFW)< 10%ile, abdominal circumference (AC)< 10%ile or both AC and EFW< 10%ile (AC/EFW< 10%ile). To determine whether EFW< 10%ile, AC< 10%ile or both EFW and AC< 10%ile are associated with adverse neonatal outcomes in singleton FGR pregnancies.

STUDY DESIGN: Retrospective cohort study of singleton deliveries with prenatal FGR diagnosis at single tertiary hospital system 1/1/2021-12/31/2021. FGR was defined at earliest abnormal ultrasound by: EFW < 10%ile only, AC < 10%ile only, or both AC/EFW < 10th% ile. Adverse outcomes included premature delivery, neonatal intensive care unit (NICU) admission, APGAR < 7 at 1 or 5 minutes, neonatal cooling, arterial pH < 7.1, stillbirth, and neonatal death.

RESULTS: 647 patients met inclusion criteria, 340 with AC/EFW < 10%ile, 168 with only EFW < 10%ile, and 139 with only AC < 10% ile. Maternal demographics did not differ between groups. Premature delivery occurred at a higher frequency in patients meeting EFW< 10%ile (21.4%) and AC/EFW < 10%ile (25.6%) compared to AC < 10%ile alone (12.2%) (p= 0.006). Higher rates of NICU admission were observed in EFW < 10%ile (25.6%) and AC/EFW< 10%ile (27.4%), in contrast to AC < 10%ile alone (14.4%) (p = 0.009). Gestational age at delivery in days was earlier in patients with AC/EFW < 10%ile (264 [258, 273]) compared to AC < 10%ile (269 [264, 274]) (p< 0.001). FGR diagnostic group was not associated with other differences in neonatal outcomes. Although not reaching statistical significance, there was higher rate of severe preeclampsia in the AC/EFW < 10%ile (20%) compared to the EFW < 10%ile or AC < 10%ile (13.1%, 13.7%) (p= 0.078).

CONCLUSION: In pregnancies diagnosed with FGR, AC/EFW < 10% ile and EFW < 10%ile had increased rates of preterm delivery and NICU admission compared to those with AC < 10%ile alone. Delivery occurred earlier in pregnancies diagnosed with FGR based on AC/EFW < 10%ile and EFW < 10%ile compared to AC < 10%ile. These findings can inform risk counseling in pregnancies diagnosed with fetal growth restriction.

Table 1. Outcomes in fetal growth restricted pregnancies diagnosed by estimated fetal weight versus abdominal circumference

		Overall				
Factor	N	Total	EFW less than 10%ile (N=168)	AC less than 10%ile (N=139)	Both AC and EFW less than 10%ile (N=340)	p-value

Stillbirth	646	2 (0.31)	0 (0.00)	0 (0.00)	2 (0.59)	0.99[d]
Neonatal death	645	7 (1.09)	4 (2.4)	0 (0.00)	3 (0.89)	0.12[d]

Statistics presented as Median [P25, P75], N (column %).
p-values: aoKruskal-Wallis test, boPearson's chi-square test, coFisher's Exact test.
1: Significantly different from EFW less than 10th%ile
2: Significantly different from AC less than 10th%ile
3: Significantly different from both EFW and AC less than 10th%ile met
Post-hoc pairwise comparisons were done using Bonferroni adjustment.
Hypertension (HTN), Hemolysis, Elevated Liver enzymes and Low Platelets Syndrome (HELLP), Gestational hypertension (gHTN), Gestational Age (GA), Neonatal Intensive Care Unit (NICU)

143 Accuracy of fetal fraction measurements in SNP-based non-invasive prenatal testing (NIPT)

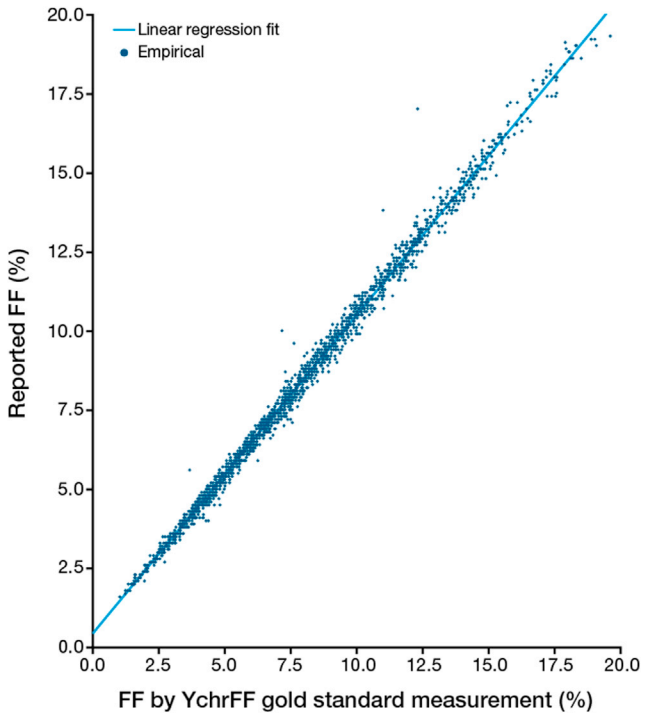
Daniel Lyons[1], Jingwen Zhang[1], Wenbo Xu[1], Zachary Demko[1], Peter Benn[2]
[1]Natera, Inc., Austin, TX, [2]University of Connecticut Health Center, Farmington, CT

OBJECTIVE: Measuring fraction of cell free-DNA (cfDNA) that is fetal/placental in origin (fetal fraction (FF)) is an important, guideline-supported, quality assurance metric in non-invasive prenatal testing (NIPT). We assessed the accuracy of FF measurements for a SNP-based NIPT using measures of Y-chromosome DNA as a reference standard.

STUDY DESIGN: We reviewed a total of 3,046 pregnancies (1,886 low-risk by SNP-based NIPT singleton male fetus cases with reported FF≥2.8%, and 1,150 cases with low FF (< 2.8%)). Each cohort was from randomly selected referrals between March-May 2022. A published maximum likelihood method, considering 9,267 SNPs exclusively from autosomal chromosomes, provided the "Reported FF". FF was also assessed by considering 277 SNPs from homologous non-recombinant regions (HNRs) of the Y chromosome that must be fetal in origin ("YchrFF"). We calculated the Pearson correlation coefficient between the ReportedFF and YchrFF; the accuracy standard deviation (SD) defined as SD (ReportedFF-YchrFF); and bias defined as mean (ReportedFF-YchrFF).

RESULTS: Linear regression showed a very strong correlation between ReportedFF and YchrFF across the YchrFF range of 0.6% to 20% (r squared = 0.996). The accuracy standard deviation was 0.14% for samples with a Reported FF between 0.6%-2.8%; 0.19% for FF between 2.8%-5.0%%; 0.20% for FF between 5.0-7.0%; 0.26% for FF between 7.0-10.0%; and 0.38% for FF >10%.

CONCLUSION: Using Y-chromosome DNA as a reference standard, this SNP-based NIPT had reported FF's that were substantially more accurate (accuracy SD=0.14-0.38%) than those previously reported for other NIPT methods (accuracy SD 1.3%-2.5%) (Persson and Prensky, Clin Chem 2021;67:863-6). Reported FF for the SNP-based NIPT can be reliably interpreted at values as low as 0.6% which is well below the 2.8% FF threshold used by this laboratory for interpreting SNP data. FF is an important quality assurance metric and all laboratories should be held to a high standard in its measurement.



144 Changes in cytokine levels during progression in twin gestations and association with pregnancy outcome

Mariarosaria Di Tommaso[1], Angela Silvano[2], Giovanni Sisti[3], Viola Seravalli[2], Noemi Strambi[2], Astrid Parenti[2], Amedeo Amedei[2], Steven S. Witkin[4]
[1]Azienda Ospedaliero-Universitaria Careggi, Firenze, Toscana, [2]University of Florence, Florence, Toscana, [3]College of Medicine, University of Arizona, Tucson, AZ, [4]Weill Cornell Medicine, New York, NY; on behalf of the Fondazione Ente Cassa di Risparmio Firenze

OBJECTIVE: To evaluate the plasma concentrations of multiple cytokines during each trimester of twin pregnancies and identify associations with preterm birth and gestational age at delivery.

STUDY DESIGN: This prospective, observational study was conducted at Careggi University Hospital, Florence, Italy. Plasma from 82 women with twin pregnancies was collected in each trimester for measurement of multiple cytokines (IL-1β, IL-6, IL-10, IL-12p70, TNF-α). Demographic and clinical outcome data were subsequently obtained by chart review. Data were analyzed by Friedman pairwise comparison or Wilcoxon analysis with the Bonferroni correction and the Mann-Whitney test.

RESULTS: 78 women were White, 2 were Asian and 2 were African. Their median (interquartile range) age was 35 (33, 38) years old. Body mass index was 21.5 (19.6, 23,9) kg/m^2. Thirty of the women (36.6%) conceived by assisted reproduction technology, either intrauterine insemination or in vitro fertilization. The mean age at sample collection was 12.2 weeks in the first trimester, 22.0 weeks in the second trimester and 31.0 weeks in the third trimester. Gestational diabetes mellitus was diagnosed in 17 (21.0%) of the women. The mean (standard deviation) gestational age at delivery was 36.0 (1.6) weeks and 9 women (11.0%) had a spontaneous preterm birth. Gestational age at delivery was inversely correlated with the TNF- α concentration in the second ($p = 0.015$) and third ($p< 0.002$) trimester. TNF- α was also positively associated with preterm birth in the second and third trimester ($p = 0.042$ and 0.023, respectively). The IL-6 level in the third trimester was also associated with gestational age at delivery ($p < 0.002$). The IL-1 β concentration in 3rd trimester was positively associated with gestational diabetes mellitus (p=0.022). Additionally, plasmatic cytokines concentrations and their comparison between the three trimesters were reported in Table 1. Values are reported as median and interquartile range.

CONCLUSION: Quantitation of TNF-a and IL-6 in plasma are predictors of earlier gestational age at delivery in multifetal gestations.

Maternal plasma cytokines (pg/ml)	I Tr	II Tr	III Tr	Comparison between 3 trimesters overall (Friedman test)	P value I tr vs II tr (Wilcoxon test with Bonferroni correction)	P value I tr vs III tr (Wilcoxon test with Bonferroni correction)	P value II tr vs III tr (Wilcoxon test with Bonferroni correction)
IL-1β	3.18 (1.66-5.63)	5.53 (3.72-8.61)	7.6 (5.53-12.05)	< 0.001	< 0.001	< 0.001	< 0.001
IL-6	0.3 (0.21-0.44)	0.3 (0.23-0.64)	0.6 (0.3-1.07)	< 0.001	0.086	<0.001	< 0.001

145 Acute treatment of severe hypertension in pregnancies with fetal growth restriction: Does medication choice matter?

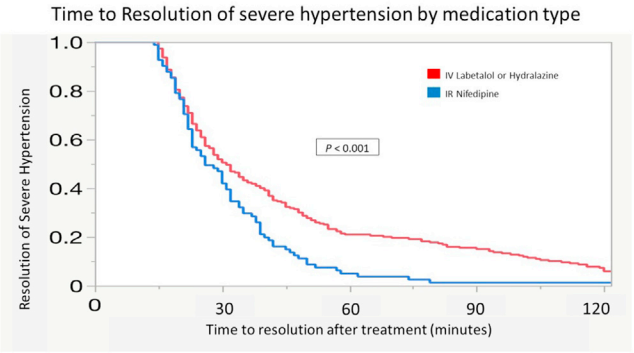
Tucker Doiron[1], Niraj R. Chavan[1], Jennifer E. Powel[2], Samantha J. Mullan[3], Tracy M. Tomlinson[1]
[1]St. Louis University, St. Louis, MO, [2]Hackensack Meridian Health - Jersey Shore University Medical Center, Neptune, NJ, [3]Tri Health Women's Services, Cincinnati, OH

OBJECTIVE: To evaluate whether medication type affects time to resolution of acute severe hypertension (HTN) in pregnancies complicated by fetal growth restriction (FGR).

STUDY DESIGN: Passive prospective cohort analysis of patients with their first singleton gestations in which they received acute treatment for severe HTN at a single academic tertiary care center (2011-2020). This subanalysis of duration of severe HTN after acute treatment was limited to pregnancies meeting Delphi consensus criteria for FGR. Those initially treated with either intravenous (IV) labetalol or hydralazine were compared with those treated with immediate release oral nifedipine. This study design was the result of visual inspection of nonparametric survival curves that revealed violation of the proportional hazards assumption when analyzing the three agents individually or combining pregnancies with and without FGR in the same analysis. A Cox proportional hazards model incorporated factors associated with time to resolution of severe hypertension up to two hours after treatment.

RESULTS: Of 998 patients with severe HTN, 331 (33%) met Delphi consensus criteria for FGR and, of these 301 underwent acute treatment of severe HTN with either IV labetalol (n=151), IV hydralazine (n=69), or oral nifedipine (n=81) as the initial medication of choice. Median time to resolution was 26 (IQR 23,31) vs 31 (IQR 27,35) minutes with nifedipine vs the IV agents respectively (Log-rank $P < .001$). After adjustment for pre-gravid BMI, treatment postpartum, and pre-treatment pulse pressure, 2 factors were independently associated with longer time to resolution of severe HTN: pre-treatment mean arterial pressure (MAP) >125 mmHg [adjusted hazard ratio (aHR) 0.63, 95%CI 0.49-0.80)] and requiring ^{3} 2 medication doses (aHR 0.53, 95%CI 0.41-0.69). The bias-corrected bootstrapped (1000 replicates) aHR for acute treatment with nifedipine is 1.48 (95% CI 1.13-1.95).

CONCLUSION: Acute treatment with nifedipine is associated with a shorter time to resolution of severe hypertension compared to IV hydralazine and labetalol in pregnancies complicated by FGR.



146 A novel first-trimester ultrasound marker for cesarean scar pregnancy: the tadpole sign

Bridget M. Donovan[1], Laura A. Smith[2], Guadalupe Arambula[2], Anna M. Modest[2], Olga Brook[2], Uma Deshmukh[2], Yinka Oyelese[2], Cassandra R. Duffy[2], Scott A. Shainker[3]

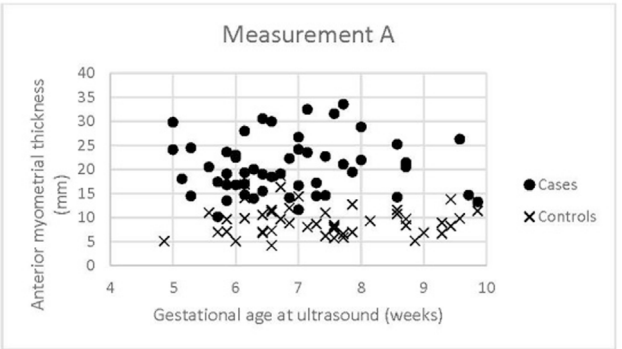
[1]Beth Israel Deaconess Medical Center, Brookline, MA, [2]Beth Israel Deaconess Medical Center, Boston, MA, [3]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

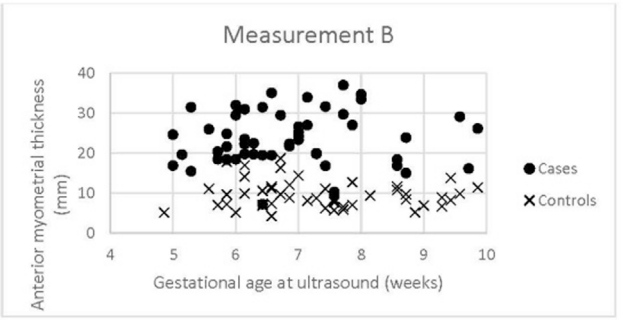
OBJECTIVE: We aim to describe a first trimester ultrasound marker for cesarean scar pregnancy (CSP) diagnosis and compare it to the currently used "crossover sign".

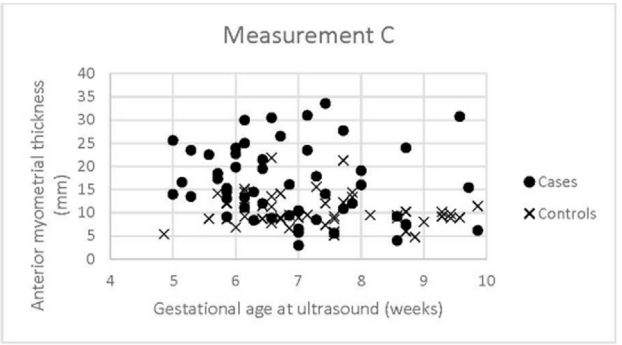
STUDY DESIGN: This is a retrospective case-control study of first trimester transvaginal ultrasound (TVUS) images from obstetric imaging databases. All images were in the midsagittal plane of the uterus with visualization of cervix to fundus. Cases were those with suspected CSP diagnosed radiographically. Controls were the next available first trimester TVUS of a viable singleton intrauterine pregnancy with prior cesarean delivery matched for gestational age. Images were independently reviewed by two experts. The distance from point "M" (as defined by the crossover sign) to the fundus was divided into thirds, with point A closest to fundus, B in the middle, and C at the "M-line". At each point the anterior myometrial thickness was measured and compared between cases and controls. The visual "tadpole sign" is the presence of the gestational sac (the "head") fixed anteriorly towards the cesarean scar, with closed uterine cavity extending cephalad towards the fundus (the "tail"). Analyses included interclass correlation coefficient (ICC) and area under the curve (AUC) with 95% confidence intervals (CI).

RESULTS: We identified 52 CSP cases and 52 controls. Distribution of the myometrial thickness measurements at each of the three points are presented in image 1. The ICC for the measurements at points A, B and C were 0.88, 0.95, 0.86, respectively. The AUC and 95% CI for each measurement was 0.96 (95% CI 0.93-0.99), 0.98 (95% CI 0.94-1.0), 0.75 (95% CI 0.65-0.85), respectively. There was 100% agreement between the crossover sign and tadpole sign in identifying CSPs. Both the tadpole sign and crossover sign identified all CSPs accurately except one case.

CONCLUSION: The tadpole sign highly correlates with the crossover sign for diagnosis of CSP. Myometrial thickness correlates well to the presence of the tadpole sign. This novel sign is easily identified and carries strong interrater reliability without need for additional ultrasound image manipulation.







147 Letters of recommendation for MFM fellowship: What are program directors looking for?

Sarah K. Dotters-Katz[1], Matthew R. Grace[2], Lisa Hofler[3], Lorene Temming[4], Rachel A. Pilliod[5], Anthony L. Shanks[6]

[1]Duke University Medical Center, Durham, NC, [2]Vanderbilt University Medical Center, Nashville, TN, [3]University of New Mexico, Albuquerque, NM, [4]Atrium, Charlotte, NC, [5]Allina Health, Minneapolis, MN, [6]Indiana University School of Medicine, Indianapolis, IN

OBJECTIVE: Letters of recommendation(LOR) for MFM fellowship are a critical part of the applicant evaluation process. Data regarding best practices for LOR writing for MFM is limited. This study aimed to describe what MFM program directors(PDs) value in a LOR.

STUDY DESIGN: Subject matter experts used research from obstetrics/gynecology residency and other specialties to develop an e-survey querying the importance of various LOR 'best practices' described by other specialties, and deployed it to MFM PDs using the SMFM PD listserv in February 2023, with 2 reminder emails. The primary outcome was the importance of various practices to PDs queried on a Likert scale of 1-5. Responses of important or very important were grouped.

RESULTS: Of 104 MFM PDs sent the survey, 70 (67%) responded.

MFM PDs reviewed an average of 78 applications(SD ± 30)/cycle, 60% wrote≥3 letters/year, and 91% noted that LOR are important/

very important in shaping impression of the applicant. 93% stated that **well-crafted** LOR convinced them to consider a **weaker** candidate more favorably while 66% stated a **poorly** crafted LOR convinced them to consider a strong candidate **less** favorably.

LOR characteristics that were most important to PDs included: descriptions of the depth of interaction with applicant, the specific behavior traits of the applicant, and the applicant's abilities(Table). A summative statement about the strength of the recommendation was also important(Table). Other "less important" letter writing 'techniques' include: use of bold/italics, use of competency-based framework and use of personal stories about the applicant. Only half of PDs felt letter length of 1 page or less was important, and 22.4% felt including highlights from the applicant CV was important.

CONCLUSION: From the MFM PD perspective, descriptions of applicants' abilities, behavior traits, and depth of the writer's interactions with applicant are important aspects of a MFM LOR, while letter length, use of bold/italics, and including highlights form the CV are not. These LOR-writing practices should be incorporated by those writing MFM LOR.

Importance of letter-writing practices*	Median (% rated important)
Description of the depth of interaction with applicant	5 (94.0)
Description of behavior traits	5 (91.0)
Description of applicant's ability	4 (97.0)
Use of summative statement about strength of recommendation	4 (82.1)
Description of letter writer's role/experience with residents	4 (62.7)
Academic rank of letter writer	4 (56.7)
Use of competency based framework	4 (54.7)

148 Trends in the MFM fellowship match: How should we counsel applicants?

Sarah K. Dotters-Katz[1], Lorene Temming[2], Sarah Ellestad[1], Matthew R. Grace[3], Anthony L. Shanks[4]

[1]Duke University Medical Center, Durham, NC, [2]Atrium, Charlotte, NC, [3]Vanderbilt University Medical Center, Nashville, TN, [4]Indiana University School of Medicine, Indianapolis, IN

OBJECTIVE: Maternal Fetal Medicine (MFM) Fellowship match process is complicated, Limited resources exist to guide applicants and fellowship program leadership regarding this trend. This study seeks to illuminate data aspects of the application and match in MFM.

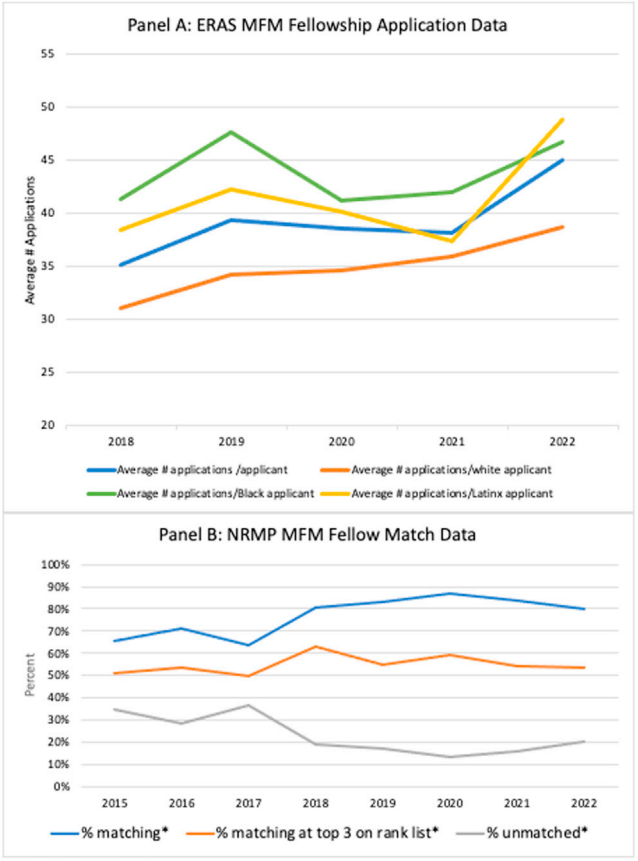
STUDY DESIGN: After IRB exemption, publicly available data were obtained from the Electronic Residency Application Service(ERAS) website and from the National Residency Match Program(NRMP) website. Applicants registering for MFM fellowship in ERAS in 2018-22 included in application analysis. Applicants registering for MFM match with NRMP from 2015-22 included in match phase analysis. Descriptive and bivariate statistics were used to analyze data. Cochrane-Armitage test performed to assess for change over time.

Primary outcome was % of applicants matching and % matching at top choice. Secondary outcomes include % matching at top 3, % not matching, and total number of programs applied to overall, stratified by URM status. URM status match data not publicly available for NRMP data.

RESULTS: From 2018-22, 840 applicants applied for MFM fellowship in ERAS(average:168/yr). Applicants applied to an average 39 programs/yr. URM applicants applied to more programs than white applicants (average 9 apps/yr, SD:3 for Black applicants; 6/yr, SD:3 for LatinX applicants(Panel A).

In the past 8 yrs, 1,171 applicants entered the NRMP match, (avg 146/yr), with an increase in positions from 97→137. The average MFM match rate is 76.7%(range 63.5-86.6, p-trend=0.07, Panel B), with an average of 37.3% matching at #1 choice annually(range 31.6,42.9). An average of 54.9% of applying applicants are matching in their top 3 annually(range 50,63.2,p-trend=0.38, Panel B)

CONCLUSION: The overall match rates for MFM fellowship is high, with over $^1/_2$ applicants matching in their top 3. These data may be helpful for those counseling individuals applying for MFM fellowship.



*P-for-trend NS for all

149 Association between postpartum continuous glucose monitoring and oral glucose tolerance testing for screening after GDM

Kathleen Drexler[1], Kim Boggess[1], Ashley N. Battarbee[2]

[1]University of North Carolina, Chapel Hill, NC, [2]University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: ACOG/ADA recommend diabetes screening after GDM pregnancies; however, only half complete postpartum oral glucose tolerance testing (OGTT). Given high satisfaction with continuous glucose monitoring (CGM) for diabetes management, we aimed to determine the association between postpartum CGM and OGTT.

STUDY DESIGN: Prospective observational study of pregnant individuals with GDM who wore a masked Dexcom G6 CGM for 10 days and completed a 75g, 2hr OGTT at 3 study visits postpartum—immediate (< 48hr), 6wk, and 6mo. Participant satisfaction was also surveyed. Using ACOG/ADA criteria, OGTT results were categorized as normal, prediabetes (preDM) or type 2 diabetes (T2DM). Ordinal

logistic regression estimated the association between average glucose on CGM and OGTT diagnosis, adjusted for study visit timing and clustering by individual. Secondary outcomes (normal OGTT, T2DM, fasting and 2hr glucose) were analyzed using logistic and linear regression. In sensitivity analyses, we evaluated the association between other CGM metrics and OGTT diagnosis.

RESULTS: 32 participants completed CGM and OGTT at 53 visits (27 immediate, 20 at 6wk, and 6 at 6mo). Average prepregnancy BMI was 35±9kg/m^2 with 7.5kg gestational weight gain. For every 10mg/dL increase in average glucose on CGM, there was 1.83 times higher odds of preDM or T2DM vs normal GTT and 1.83 times higher odds of T2DM vs normal or preDM (Table). Study visit timing did not modify this effect (interaction p=0.10). With increasing average glucose on CGM there were lower odds of normal OGTT, higher odds of T2DM, and higher fasting and 2-hour glucose levels (Table). While other CGM metrics (TIR, TAR, TBR, and variability) were not associated with OGTT, the % time >250mg/dL was associated with higher odds of preDM or T2DM (aOR 5.63, 95%CI 2.06-15.4). Finally, 87% preferred CGM, 13% had no preference and none preferred OGTT.

CONCLUSION: Postpartum average glucose on CGM was associated with OGTT. Validation of these findings and development of diagnostic CGM criteria may provide a more acceptable alternative to postpartum OGTT for diabetes screening after GDM.

Table. Association between average glucose on postpartum continuous glucose monitoring and oral glucose tolerance test results

	Adjusted Odds Ratio (95% CI)*
2-hour OGTT Diagnosis† Normal Prediabetes Type 2 Diabetes	1.83 (1.29-2.61)
Normal OGTT	0.63 (0.45-0.88)
Type 2 Diabetes by OGTT	2.32 (1.42-3.78)
	Adjusted Beta Coefficient (95% CI)*
Fasting glucose (mg/dL)	3.65 (1.56-5.75)
2-hour glucose (mg/dL)	14.4 (8.57-20.15)

*For every 10mg/dL increase in average glucose on CGM, adjusted for timing of study visit and clustering by individual
†Normal=FBG<100 and 2hr<140; Prediabetes=FBG 100-125 or 2hr 140-199; Type 2 Diabetes=FBG≥126 or 2hr≥200

150 Looking for a blueprint for changing patient behavior: Group Prenatal Care improves breastfeeding knowledge

Meghan Dubose[1], Jessica Britt[2], Moonseong Heo[3], Liwei Chen[4], Lu Zhang[3], Emily Heberlein[5], Lauren S. Keenan-Devlin[6], Amy Crockett[7]

[1]Prisma Health, Greenville, SC, [2]Prisma Health Upstate, Greenville, SC, [3]Clemson University, Clemson, SC, [4]University of California, Los Angeles, Los Angeles, CA, [5]James Bell Associates, Atlanta, GA, [6]NorthShore University HealthSystem, Evanston, IL, [7]Prisma Health, University of South Carolina School of Medicine Greenville, Greenville, SC

OBJECTIVE: Despite providing both maternal and neonatal benefits, breastfeeding rates remain lower than goal targets. Prior research suggests that breastfeeding initiation rates are higher for group prenatal care (GPNC) compared to individual care (IPNC), but little is known about its effectiveness for improving breastfeeding knowledge and self-efficacy.

STUDY DESIGN: This is a secondary analysis of the Centering and Racial Disparities (CRADLE) randomized control trial comparing the impact of GPNC vs IPNC on preterm birth. The primary analysis used an intent-to-treat (ITT) approach and the primary outcome was breastfeeding at hospital discharge. Patient surveys administered prior to delivery included questions on breastfeeding knowledge (adapted from the Infant Feeding Practices II Survey) and self-efficacy (adapted from Wells' 20-item Prenatal Breast-feeding Self-efficacy Scale). A subgroup analysis was conducted on primigravid patients.

RESULTS: 2350 participants were enrolled and 80.4% (1890) completed the surveys. Participants identified as either African American (40.6%), Hispanic (21.4%), White (36.8%), or Other race/ethnicity (1.3%) and 62.7% were primigravid. Compared with IPNC, GPNC did not improve breastfeeding at hospital discharge (71.7% IPNC vs 72.0% GPNC; OR 1.02, 95% CI 0.84 − 1.23). Participants assigned to GPNC were more likely to provide correct answers for all knowledge questions ($p \leq 0.04$) except one item and scored higher (p=0.007) on the composite knowledge score when compared to IPNC (Table 1). These findings were consistent for primigravid participants, but no significant differences were noted for multigravid participants. There was no difference ($p > 0.29$) in self-efficacy questions by prenatal care type.

CONCLUSION: GPNC increased breastfeeding knowledge, especially for primigravid patients, but this did not translate into increased rates of breastfeeding at hospital discharge.

	IPNC	GPNC	p value
Breastfeeding Knowledge	51.8 (976)	48.2 (914)	
Infant formula is as good as breast milk[a]	1.76 ± 1.27	1.70 ± 1.28	0.38
If a baby is breastfed, he or she will be less likely to get sick with ear infections, diarrhea, and breathing infections	3.16 ± 1.11	3.30 ± 1.00	0.003
Babies who are breastfed have a lower risk of SIDS (sudden infant death syndrome)	2.93 ± 1.14	3.07 ± 1.09	0.005
Moms who breastfeed are more likely to return to their pre-pregnancy weight	3.04 ± 1.03	3.19 ± 0.96	0.002
Any amount of breastfeeding is good	3.24 ± 1.00	3.33 ± 0.96	0.03
For the first six months, it is best to only breastfeed	3.07 ± 1.01	3.16 ± 1.03	0.04
Composite Knowledge Score	17.52 ± 4.39	18.07 ± 4.48	0.007
Breastfeeding Self-Efficacy			
I can make time to breastfeed my baby even when I feel busy	3.02 ± 1.13	3.05 ± 1.13	0.60
I can breastfeed my baby even when I am tired	3.04 ± 1.12	3.08 ± 1.10	0.48
I can find out what I need to know about breastfeeding my baby	3.26 ± 0.95	3.30 ± 0.92	0.38
I can breastfeed my baby without feeling embarrassed	3.20 ± 1.06	3.25 ± 1.00	0.29

151 A comparison of techniques for antibody titers in screening for hemolytic disease of the fetus

Suzanne Dysart[1], Braxton Forde[2], Kara Markham[3]

[1]University of Cincinnati, Cincinnati, OH, [2]University of Cincinnati Medical Center, Cincinnati, OH, [3]Allo Hope Foundation, Tulscaloosa, AL

OBJECTIVE: To compare the relationship between titer concentrations via gel microcolumn agglutination (GMA) and conventional tube

testing (CTT) methods to examine if critical titer thresholds should differ between the two techniques.

STUDY DESIGN: Retrospective chart review on all obstetric patients treated at a single tertiary care center with RBC antibodies from November 2018 to October 2022. Patients were included in the statistical analysis if there were parallel CTT and GMA titration studies available. GMA vs CTT titers were graphed via bubble plots, and polynomial regression analysis was used to evaluate the correlation between the two methods. Logistical regression was used to evaluate the sensitivity and specificity of GMA titers for prediction of a critical CTT titer of 16.

RESULTS: **166** GMA titers from 87 patients had corresponding CTT titers. The most common antibody was anti-Rh(D) (76) followed by anti-Kell (29). Polynomial regression indicated a relationship between GMA titers and CTT titers ($R2 = 0.5325$, $p < 0.001$). The relationship changed significantly with removal of anti-Kell antibodies ($R2 = 0.6733$, $p < 0.001$). GMA titers were predictive of a critical CTT (AUC 0.97, $p< 0.001$) for non-anti-Kell antibodies but not predictive for anti-Kell antibodies ($p = 0.134$). Overall a GMA titer of 64 was predictive of a CTT titer of 16 or higher with 90.7% (95% CI 82.5-95.9%) sensitivity and 85.0% (95% CI 75.3-92.0%) specificity (Table 2). All GMA results of 32 or higher for anti-Kell antibodies had CTT of at least 16, whereas the same could not be said of the non-anti-Kell antibodies until GMA titers reached at least 512.

CONCLUSION: There is a correlation between GMA and CTT titers. GMA titers are consistently higher than CTT titers in all antibodies tested in our study except for anti-Kell. A predictive table was created for provider reference if their hospital's blood bank only employs GMA techniques.

GMA titer	Sensitivity of prediction of CTT of at least 16 (with 95% CI)	Specificity of prediction of CTT of at least 16 (with 95% CI)	Predictive value that GMA at or below this threshold will yield a CTT < 16	Predictive value that GMA above this threshold will yield a CTT > 16
All antibodies				
16	41.86% (31.3-52.99)	97.5% (91.26-99.7)	94.74% (82.25-99.36)	60.94% (51.92-69.44)

152 Impact of WIC on hypertensive disorders in pregnancy, stratified by BMI category, among medicaid participants

Sarah K. Dzubay, Uma Doshi, Megha Arora, Bharti Garg, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

OBJECTIVE: To investigate whether participation in the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) has differential impacts on gestational hypertensive disorders for individuals of different BMI categories.

STUDY DESIGN: A retrospective cohort study was performed using 2012-2020 national vital statistics patient discharge data from the Centers for Disease Control and Prevention (CDC). The analysis was restricted to data from Medicaid recipients without pre-existing or gestational diabetes, who had non-anomalous, singleton births between 23 and 42 weeks. We compared hypertensive disorders between those who did and did not receive WIC benefits, and further stratified by BMI categories (underweight, normal weight, overweight, and obese). Participants were excluded if they had missing WIC status or BMI data. The outcome of interest was gestational hypertension or pre-eclampsia, which are collapsed in CDC vital statistics. We performed a multivariable logistic regression, controlling for race/ethnicity, age, education, prenatal care, and smoking.

RESULTS: Of the 12,245,325 Medicaid recipients meeting inclusion criteria, 8,556,373 (69.87%) received WIC benefits. Compared to those without WIC benefits, WIC recipients of all BMI categories had a lower prevalence of gestational hypertension (Figure 1). Multivariable logistic regression demonstrated that the adjusted odds of gestational hypertension or preeclampsia in those who received WIC benefits, relative to those who did not receive WIC benefits, were 0.953 (95% CI: 0.919, 0.989) in underweight individuals, 0.951 (95% CI: 0.941, 0.961) in normal weight individuals, 0.911 (95% CI: 0.902, 0.921) in overweight individuals, and 0.925 (95% CI: 0.917, 0.933) in obese individuals.

CONCLUSION: Among Medicaid recipients, WIC had a small, inverse association with hypertensive disorders in pregnancy across all BMI categories, with the strongest association demonstrated in overweight and obese individuals.

Figure 1. Gestational hypertension among Medicaid recipients who do and do not receive WIC, stratified by BMI Category

BMI Category	WIC	No WIC	Adjusted Odds Ratio (95% CI)
Underweight	2.92%	2.95%	0.953 (0.919, 0.989)
Normal Weight	3.65%	3.80%	0.951 (0.941, 0.961)
Overweight	5.07%	5.67%	0.911 (0.902, 0.921)
Obese	8.33%	9.20%	0.925 (0.917, 0.933)

153 Impact of WIC benefits on neonatal outcomes, stratified by BMI category, among medicaid participants

Sarah K. Dzubay, Megha Arora, Uma Doshi, Bharti Garg, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

OBJECTIVE: To investigate whether participation in the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) has differential impacts on neonatal outcomes for mothers of different BMI categories.

STUDY DESIGN: A retrospective cohort study was performed using 2012-2020 national vital statistics patient discharge data from the

Centers for Disease Control and Prevention (CDC). The analysis was restricted to data from Medicaid recipients without pre-existing or gestational diabetes, who had non-anomalous, singleton births between 23 and 42 weeks. We compared pregnancy outcomes between those who did and did not receive WIC benefits, and further stratified by pre-pregnancy BMI category (underweight, healthy weight, overweight, and obese). Participants were excluded if they had missing WIC or BMI data. Outcomes of interest were preterm delivery (< 37 weeks) and NICU admission. We performed a multivariable logistic regression, controlling for race/ethnicity, age, education, prenatal care, and smoking.

RESULTS: Of the 12,245,325 Medicaid recipients meeting inclusion criteria, 8,556,373 (69.87%) received WIC benefits. Compared to infants whose parents did not receive WIC benefits, infants whose parents did receive WIC benefits were less likely to be delivered preterm or be admitted to the NICU across all BMI categories (Figure 1).

CONCLUSION: Among Medicaid participants, WIC participation demonstrated a mildly inverse association with preterm delivery and NICU admission, with similar effects seen in all BMI categories. These results further support the body of evidence that WIC participation during pregnancy is associated with fewer adverse neonatal outcomes, and provide evidence that the benefit of WIC is seen across people of varying body size.

Figure 1. Neonatal Outcomes among Medicaid recipients who do and do not receive WIC, stratified by BMI Category

Preterm Delivery Under 37 Weeks			
BMI Category	**WIC**	**No WIC**	**Adjusted Odds Ratio (95% CI)**
Underweight	12.01%	13.91%	0.909 (0.892, 0.926)
Normal Weight	9.30%	10.52%	0.911 (0.905, 0.917)
Overweight	8.72%	10.01%	0.910 (0.902, 0.918)
Obese	9.36%	10.81%	0.909 (0.901, 0.916)
Preterm Delivery Under 32 Weeks			
BMI Category	**WIC**	**No WIC**	**Adjusted Odds Ratio (95% CI)**
Underweight	1.71%	2.44%	0.818 (0.783, 0.855)
Normal Weight	1.30%	1.84%	0.794 (0.781, 0.807)
Overweight	1.29%	1.86%	0.797 (0.781, 0.813)
Obese	1.52%	2.25%	0.787 (0.773, 0.801)
NICU Admissions			
BMI Category	**WIC**	**No WIC**	**Adjusted Odds Ratio (95% CI)**
Underweight	8.38%	10.35%	0.861 (0.843, 0.880)
Normal Weight	7.26%	8.72%	0.869 (0.863, 0.876)
Overweight	7.15%	8.53%	0.878 (0.870, 0.887)
Obese	7.96%	9.44%	0.881 (0.874, 0.889)

154 Antenatal late preterm steroids in twin gestations

Sara Edwards[1], Medhavi Bhasin[2], Alexandra J. D. Phelps[3], Rachel Harrison[4], Calla Holmgren[5]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]Advocate Lutheran General Hospital, Park Ridge, IL, [3]Vanderbilt University Medical Center, Nashville, TN, [4]Advocate Christ Hospital, Oak Lawn, IL, [5]AAH Lutheran General Hospital, Park Ridge, IL

OBJECTIVE: The administration of antenatal steroids in the late preterm period (34+0 to 36+6 weeks gestation) to improve neonatal outcomes is now common. Our objective was to evaluate maternal and neonatal outcomes in twin gestations who received antenatal steroids in the late preterm period.

STUDY DESIGN: We conducted a retrospective cohort study of twin gestations delivered between 34+0 and 36+6 weeks gestation within our health system from 2020-2021. Subjects were excluded if they received steroids before 34 weeks gestation or had Type 2 diabetes. Our primary outcome was a composite of respiratory treatment for either or both twins (continuous positive airway pressure or high-flow nasal cannula for at least 2 hours, supplemental oxygen with a fraction of inspired oxygen of 30% for at least 4 hours, extracorporeal membrane oxygenation, mechanical ventilation, or death). Secondary outcomes included other adverse neonatal outcomes and maternal infection and length of stay. Groups were compared via t-tests, chi-squared analysis, Fisher's exact test, and linear and logistic regression.

RESULTS: 205 patients delivered in the late preterm period without administration of steroids before 34 weeks gestation. Of these, 71 (34.63%) received steroids in the late preterm period. Those receiving steroids were older (32.0 vs. 30.6 years, $p < 0.05$), more likely to have a hypertensive disorder of pregnancy (43.7% vs. 29.9%, $p < 0.05$), and delivered earlier (35.6 vs. 35.9 weeks, $p < 0.05$). Between the two groups, there was no difference in the primary composite outcome of respiratory support requirement, neonatal intensive care unit admission, neonatal hypoglycemia, or other neonatal outcomes. Those who received steroids had longer maternal postpartum stays (3.2 vs. 2.7 days, $p < 0.05$), including when controlling for other factors.

CONCLUSION: There was no difference in neonatal outcomes with administration of late preterm steroids to multiple gestations. Maternal postpartum length of stay was longer, suggesting patients receiving antenatal steroids may have been more unwell at baseline.

156 Post partum maternal readmission rates using the Robson classification groups

Zvi Ehrlich, rivka Farkash, Ari Weiss, Shirley Shapira, Sorina Granovsky Grisaru, Shunit Armon

Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim

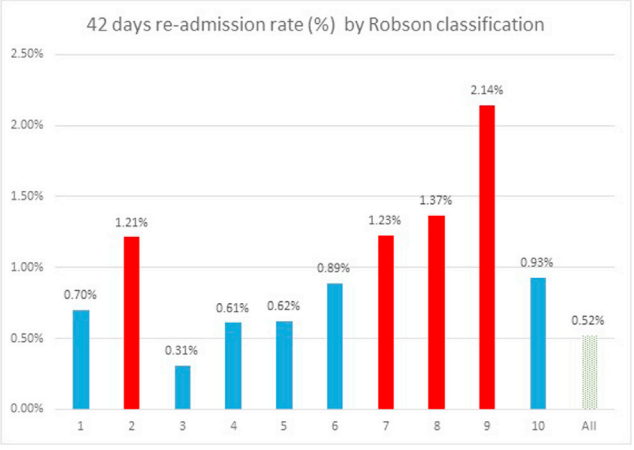
OBJECTIVE: Post partum maternal readmission is a significant burden for mother, neonate and family as well as health system. The postpartum readmission rate is used to evaluate quality of care and to guide beneficial interventions. Thus, identifying women at risk for readmission is of high value. The WHO established the internationally used Robson group (RG) classification as an optimal measure of caesarean section (CS) rates. Although intended for evaluation of CS rates, in recent years the utilization of the RG classification has been expanded to evaluate other obstetrical outcomes.

We aim to describe the rates of postpartum maternal readmission across RG classification and to identify risk groups.

STUDY DESIGN: Retrospective register-based cohort study of women who delivered at a tertiary medical center. All women were classified into 1 of the 10 RGs. Rates of post-partum readmission within 42 days of delivery were calculated for each group.

RESULTS: A total of 295,215 deliveries were classified to the 10 Robson classification groups. The 42-day readmission rate for the whole database was 0.52%. Maternal readmission rate varied significantly between RGs. Groups identified with a significant rate of maternal readmission were RG 9 (transverse lie) 2.14%, RG 8(multifetal pregnancies)1.37%, RG 7 (multiparous breech pregnancies)1.23% and RG2 (nulliparous pregnancies $\geq$ 37 w, labor induction' or prelabor cesarean) 1.21%.

CONCLUSION: Post partum readmission rates varies among the RGs. Interventions aimed to lower the number of women in RG 2,7,8 and 9; such as use of external cephalic version, vaginal delivery of breech and multifetal pregnancies may be beneficial. The neonatal impact of such policy remains to be considered for each center.



157 Another reason to address social determinants and disparities: It saves money

Mark I. Evans[1], Gregory F. Ryan[2], George Mussalli[3], David W. Britt[4], Jaqueline Worth[3], Lawrence D. Devoe[5]
[1]Mount Sinai Hospital, New York, NY, [2]Fetal Medicine Foundation of America, Burlington, MA, [3]Icahn School of Medicine at Mount Sinai, New York, NY, [4]Fetal Medicine Foundation of America, New York, NY, [5]Medical College of Georgia at Augusta University, Augusta, GA

OBJECTIVE: Inherent in healthcare policy/medical practice changes are 2 components: 1. Does it improve care, & 2. How much does it cost? Serious attention is finally being paid to medical ramifications of Social Determinants of Healthcare, racism, and resultant inequitable care. This study focuses on the second question: What are the short and long-term financial consequences (FC) of disparate care? Cesarean delivery rates (CDR) by race/ethnic group, have higher levels of morbidity and mortality and serve as a surrogate for quality of care.

STUDY DESIGN: Using a GDP-based statistical dollar value metric of each life, we calculate long-term FC of disparate care. We compare representative states having generally perceived high and low spending on obstetrical care infrastructures and posed the following question: if CDR for Black patients were reduced to that of white patients, what FC would there be for short-term and long-term care. Long term costs are calculated as (additional hospital stay days X avg. cost per day) + (additional avg. recovery days X avg. daily GDP contribution).

RESULTS: Most states show considerably higher CDR and morbidity/mortality for Black patients vs. white. Reducing Black CDR to white levels, short-term US savings would be $263M. Maternal and neonatal mortality rates (MMR and NMR) for Blacks are also higher [excess cost for Black MMR = $224M]. States with higher maternal and neonatal MR have significant impact on lifetime economic productivity. Nationally, the annual cost of excess MMR & NMR is $3.147 Billion from increased costs, reduced incomes, and tax revenues. In CA economic reductions are $471 per delivery; in GA it's $1665.

CONCLUSION: In addition to general societal deleterious effects of disparities, the perception of "saving" money by not spending for better care is wrong. Long term State FC show no short-term savings and increased long term expenses. Ignoring (momentarily) the commonly articulated quality of care reasons for fixing the provision of care, it costs the US $ 3.634 Billion per year that could be better allocated.

STATE	White CDR%	Black CDR%	$XS Cost Black CDR	XS Cost per C-Delivery	White MMR	Black MMR	$XS Cost Black MMR	White NMR	Black NMR	$XS Cost Black NMR	XS Long Term YLL Costs	$XS Cost/ Delivery
CA	30.00	36.5	$ 16,495,000	$ 4,648	12.6	45.8	$ 10,417,000	3.06	9.04	$ 187,707,000	$ 198,124,000	$ 471

158 Nulliparas with term PROM and an unfavorable cervix, induction of labor with prostaglandin or oxytocin

Maayan Bas Lando[1], Majida Ewida[2], Sarit Helman[1], Sorina Grisaru-Granovsky[1], Orna Reichman[3]
[1]Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim, [2]Shaare Zedek Medical Center, Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Yerushalayim, [3]Shaare Zedek Medical Center, affiliated with the Hebrew University Medical School of Jerusalem, Jerusalem, Israel

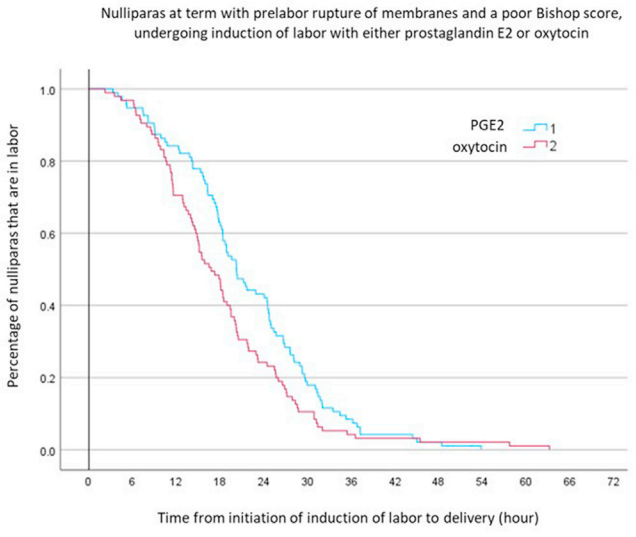
OBJECTIVE: To study whether the time from induction of labor (IOL) to delivery differs between nulliparas with premature rupture of membrane (PROM) and an unfavorable cervix induced by prostaglandins (PGE2) versus oxytocin.

STUDY DESIGN: A retrospective matched cases study. Data were extracted from a validated real-time computerized data base. All nulliparas with term PROM who underwent induction between January 2006 to April 2023 were identified. Cases induced by either PGE2 or oxytocin were matched on the following criteria (1) time

from PROM to IOL, (2) modified Bishop score defined by cervix dilatation and effacement prior to induction, (3) newborn birthweight, and (4) vertex position *Statistics*: Descriptive, means±SDs, medians+IQR. Comparisons: chi-square, independent samples T-test and Kaplan Mayer survival curve.

RESULTS: Ninety-five matched cases were identified. Maternal age (26±4.7 years old, p=0.203) and gestational age at delivery (38.6±0.6, p=0.701) were similar between the groups. Matched factors including modified Bishop score (2.0 versus 2.3, p=0.187), time from PROM to IOL (23.5 ± 19.2 versus 24.3 ± 21.4 p=0.780), birth weight of newborn (3111g versus 3101g, p=0.842) and occiput anterior position (present on 98% in both groups p=0.687) were also comparable . Time from IOL to delivery was significantly shorter by 3 hours and 36 minutes in the group induced by oxytocin compared to PGE2, (p=0.029). The Kaplan-Meier survival curve demonstrated a significant difference between time from IOL to delivery. Within 24 hours, 55(58%) of those induced with PGE2 delivered compared to 72(76%) of those induced by oxytocin, (p=0.033), see figure. Cesarean delivery rate [17(18%) versus 18(19%)], blood transfusion rates [3(3%) versus 2(2%)], and Apgar scores (8.9 versus 8.8) were similar between the groups, p≥0.387.

CONCLUSION: Among nulliparas with term PROM and an unfavorable cervix, induction with oxytocin results in a shorter time from IOL to delivery and a higher rate of vaginal delivery within 24 hours, with no elevated risk for cesarean delivery.



159 Amnion mesenchymal macrophages: characterization and response to infection

Eva Fandozzi[1], Taylor Snisky[2], Gideon Hillebrand[3], Thomas Hooven[4], Christina J. Megli[5]

[1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]MWRI, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA, [4]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA, [5]Magee- Womens Hospital UPMC, Pittsburgh, PA

OBJECTIVE: The primary organ of pregnancy, the placenta, exists as a maternal-fetal barrier and displays remarkable immunoactivity. However, the underlying mechanisms of immune regulation are not well understood. We previously identified the presence of CD14+ cells localized to the mesenchymal layer of the amnion, a distinct population of macrophages referred to as Amnion Mesenchymal Macrophages (AMMs). We hypothesize that these are regulated by the amnion and play a key role in pathogen clearance for *S. agalactiae* (GBS).

STUDY DESIGN: Fetal membranes were collected from cesarean sections in the absence of labor or inflammation. The amnion and chorion were cultured separately to generate conditioned media, and cytokine response was measured by ELISA. Sections of amnion were fixed for IF staining and imaged using a Nikon A1. Explants were infected using GBS and infectivity was quantified by CFUs.

RESULTS: Amnion explants have decreased colonization of GBS in comparison to chorion, intact fetal membrane, and chorionic villi. We found that the amnion secretes the cytokine IL-11 in greater abundance than chorion and chorionic villi. IL-11 secretion is responsive to TGFβ and colocalizes with AMMs. IL-11 secretion was reduced with treatment of cytochalasin D. Using conditioned media exposed to macrophages, we found that amnion conditioned macrophages (ACMs) have decreased infection with GBS suggesting that the secretory activity of the amnion regulates GBS clearance by macrophages. ACMs have decreased alpha-defensin and increased IL-11 production when exposed to GBS compared to chorion conditioned macrophages and chorionic villi conditioned macrophages.

CONCLUSION: AMMs produce IL-11 and restrict GBS at the maternal-fetal interface. ACMs also restrict GBS, suggesting that they may function as a model for AMMs *in vitro*. Our data suggest that macrophage function at the maternal fetal interface is spatially distinct and tightly regulated. Further work elucidating the functional regulation of AMMs may provide insight into vertical transmission of pathogens across fetal membranes.

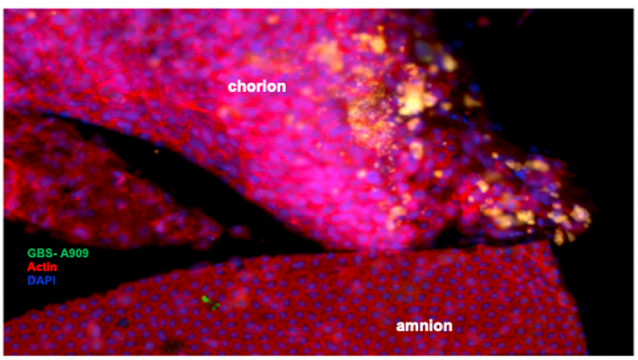


Figure 1. Immunofluorescence staining of human fetal membrane infected with GBS. GBS (green) shows increased colonization of the chorion compared to the amnion. Nuclei and cytoplasmic actin are stained with DAPI (blue) and phalloidin (red) respectively.

160 Blood pressure levels in pregnancy and adverse maternal metabolic health 10-14 years postpartum

Christine P. Field[1], William A. Grobman[2], Sadiya S. Khan[3], Jiqiang Wu[4], Alan Kuang[5], Mark B. Landon[6], Denise Scholtens[5], William Lowe[5], Kartik Venkatesh[4]

[1]Ohio State University / Department of OB/GYN / Division of Maternal Fetal Medicine, Columbus, OH, [2]The Ohio State University, Columbus, OH, [3]Northwestern University Feinberg School of Medicine, Oak Park, IL, [4]Ohio State University, Columbus, OH, [5]Northwestern University, Chicago, IL, [6]The Ohio State University Wexner Medical Center, Columbus, OH

OBJECTIVE: Guideline changes from the American College of Cardiology/American Heart Association (ACC/AHA) have shown that

blood pressure (BP) < 140/90 increases the risk of adverse health in non-pregnant adults. We examined the associations between BP levels during pregnancy and long-term postpartum metabolic health.

STUDY DESIGN: A secondary analysis from the prospective Hyperglycemia and Adverse Pregnancy Outcome (HAPO) Follow-Up Study. The exposure was hypertension status in the early third trimester per ACC/AHA thresholds: normal BP < 120/80 mmHg (reference), elevated BP 120-129/< 80 mmHg, stage 1 hypertension 130-139/80-89 mmHg, and stage 2 hypertension ≥140/≥90 mmHg. Outcomes assessed 10-14 years after the index pregnancy were type 2 diabetes, prediabetes, metabolic syndrome, and measures of dyslipidemia. Modified Poisson models adjusted for baseline pregnancy covariates: field center, age, parity, BMI, height, family history of hypertension and diabetes, smoking and alcohol use, and OGTT summary z-score.

RESULTS: Among 4,697 pregnant individuals in the early third trimester, 70.0% (n=3,290) had normal BP, 8.5% (n=399) had elevated BP, 14.9% (n=701) had stage 1 hypertension, and 6.4% (n=302) had stage 2 hypertension. At a median follow-up of 11.6 years, individuals with elevated BP (4.7%; aRR: 2.06; 95% CI: 1.51, 2.61), stage 1 hypertension (5.7%; aRR: 2.65; 95% CI: 2.20, 3.10), and stage 2 hypertension (9.2%; aRR: 2.87; 95% CI: 2.35, 3.39) were at greater risk of developing type 2 diabetes compared with those with normal BP (1.5%). Similarly, individuals with elevated BP, stage 1 hypertension, and stage 2 hypertension were at greater risk of developing prediabetes and metabolic syndrome. There was no increased risk between increasing BP category and LDL cholesterol, HDL cholesterol, and triglycerides.

CONCLUSION: Pregnant individuals with elevated BP ≥120/80 are at increased risk of adverse metabolic health 10-14 years postpartum. BP categories with lower thresholds (AHA/ACC) than those currently used for hypertension in pregnancy may identify individuals at risk for adverse long-term metabolic health.

Table. Frequency and association between pregnancy blood pressure and adverse maternal metabolic health 10-14 years postpartum

	Outcome frequency (row percentage)	Unadjusted and adjusted analysis	
		Unadjusted risk ratio, RR (95% CI)	Adjusted risk ratio, aRR (95% CI)[1,2]

161 Amniotic fluid sCD14, presepsin (sCD14-ST), intraamniotic infection/inflammation and early onset neonatal sepsis (EONS)

Michelle Firlit[1], Guomao Zhao[1], Irina A. Buhimschi[1], Mert Ozan Bahtyiar[2], Catalin S. Buhimschi[1]
[1]University of Illinois at Chicago, Chicago, IL, [2]Yale University, New Haven, CT

OBJECTIVE: Soluble CD14 (sCD14) is a monocyte/macrophage activation marker and mediator of bacterial lipopolysaccharide (LPS) action. Presepsin (sCD14-ST) is a cleavage product of sCD14. Elevated cord blood (CB) presepsin were proposed as a biomarker for EONS. We aimed to determine if amniotic fluid (AF) presepsin is elevated in the context of IAI and could serve as a biomarker of EONS.

STUDY DESIGN: Presepsin and sCD14 were evaluated by ELISA in AF of 29 randomly selected singleton pregnancies who had transabdominal amniocentesis to rule out infection. Pregnancy outcomes were grouped as: 1) preterm birth (PTB) positive IAI (PTB+IAI, n=11, [mean±SE] GA: 26±1 wks]; 2) idiopathic PTB absent IAI [PTB-IAI, n=10, GA: 29±1 wks]; 3) term birth absent IAI [TB-IAI, n=8, GA: 29±1 wks). AF interleukin-6 (IL-6) and matrix metalloprotease-9 (MMP9) levels were measured as indicators of inflammation and proteolytic activity, respectively. Matched CB from fetuses with EONS and maternal blood (MB) samples were analyzed for a subset of PTB groups. We used parametric statistics (1-way ANOVA) after log transformation, correlation and regression analyses.

RESULTS: AF sCD14 was significantly elevated in the context of IAI [PTB+IAI: 1,090±255 ng/mL vs. PTB-IAI: 443±96 ng/mL, ANOVA p=.017; vs. TB-IAI 393±49 ng/mL, p=.013). Generally, presepsin was detectable in AF, at similar levels with MB, but at 10-fold lower than in CB. Following adjustment for GA and membrane status, AF presepsin did not differ among the groups [PTB+IAI: 5.3±1.6 ng/mL vs. PTB-IAI: 3.8±0.6 ng/mL, vs. TB-IAI 5.4±1.4 ng/mL, p >0.05 for all). AF sCD14 was positively correlated with AF IL-6 (r=0.619, p< .001) and AF MMP9 (r=0.714, p< .001) concentrations. There were no significant correlations of AF presepsin with sCD14, IL-6 or MMP-9.

CONCLUSION: sCD14 is significantly elevated in IAI. Yet, AF may carry inhibitory properties that neutralize cleavage of sCD14, thereby limiting the ability of AF presepsin to be used as biomarker of IAI or EONS.

162 Anxiety trends during pregnancy

Yevgenia Y. Fomina[1], Kristen Warncke[1], Aldeboran N. Rodriguez[2], Anne M. Ambia[1], Tina Wolfson[1], Meitra Doty[1], Rebecca Corona[1], Jeanette Dominguez[1], Mark Peters[1], Donald D. McIntire[3], David B. Nelson[1]
[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]University of Texas Southwestern, Dallas, TX, [3]University of Texas Southwestern Medical Center, Richardson, TX

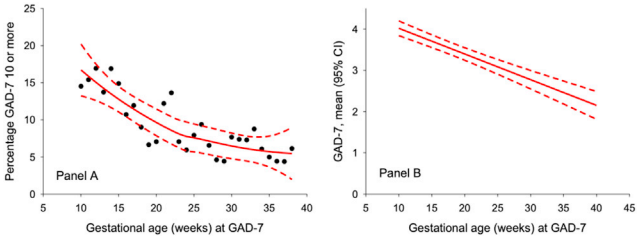
OBJECTIVE: National guidelines recommend that treatment for perinatal mood and anxiety disorders be equitably available to all pregnant individuals, however, the trend of anxiety symptomology across gestation is not known. Our aim was to examine trends in anxiety scores over time throughout pregnancy among underserved patients living in an urban community.

STUDY DESIGN: This was a secondary analysis of a prospective observational study of system-based Generalized Anxiety Disorder 7-

item screening questionnaire (GAD-7). The setting was a neighborhood-based community clinic in a large, urban health system that serves medically-indigent patients. GAD-7 screening was initiated at the first prenatal visit and repeated during prenatal care visits with those having two or more GAD-7 screens included in the analysis. Patients with multiple gestations, congenital anomalies, or those who established care after 34 weeks were excluded. To examine GAD-7 scores during gestation, linear regression was used for patients with multiple GAD-7 scores to calculate the direction of change over pregnancy course with $P < 0.05$ considered significant.

RESULTS: Between Sept 2020 and Dec 2022, a total of 1197 patients completed serial GAD-7 screens (range: 2-6) during the antepartum period. Mean GAD-7 scores were highest at the first prenatal visit, with an average score of 4.0 (CI 3.8, 4.2) at 10 weeks gestation. The highest percentage of GAD-7 scores ≥ 10 were observed at 14 weeks gestation (17.4%) as shown in Figure 1a. When evaluating the trend of GAD-7 over time, scores down-trended during pregnancy course as shown in Figure 1b (p-value for slope < 0.001).

CONCLUSION: Anxiety symptomatology is highest in the first trimester and down-trends over the pregnancy course. These findings support GAD-7 screening early in pregnancy.



163 Focused assessment with sonography for trauma associated with faster time to intervention for postpartum hemorrhage

Yaneve N. Fonge[1], Helen Gomez[2], Shanice Akoto[2], John Dibato[3], Matthew Hoffman[2]

[1]University of Pittsburgh, Pittsburgh, PA, [2]Christiana Care Health Systems, Newark, DE, [3]Cooper University Medical Center, Camden, NJ

OBJECTIVE: We sought to identify if using Focused Assessment with Sonography for Trauma (FAST) exams during the evaluation of postpartum hemorrhage (PPH) following cesarean delivery affects the time to interventions.

STUDY DESIGN: This is a retrospective cohort study of cesarean deliveries (CD) between 2016-2020. Women ages 14-51 with a diagnosis of PPH were included. Patients with placenta accreta spectrum disorder identified at the time of CD were excluded. Demographic and outcome data were compared between those who had a FAST exam for PPH evaluation and those who did not. The primary outcome was the time to a composite of interventions, including intensive care unit admission, reoperation, and interventional radiology procedure within 48hrs of delivery. Group allocation and outcomes were determined through chart review. Survival Models were used to assess differences in time to intervention between the two groups, while adjusting for potential confounders.

RESULTS: A total of 1,128 women with PPH following CD were included in this analysis. 113 (10.0%) had a FAST exam as part of their evaluation for hypotension (18%), tachycardia (11%), dizziness (5%), abdominal pain (21%), larger than expected decrease in hemoglobin (23%), or bleeding from the vagina or incision (18%). 18% of FAST exams were positive for hemoperitoneum. The FAST group had a higher estimated blood loss (EBL) (1,952 mL vs 1,340 mL $p < 0.0001$) and more PPH related significant maternal morbidity (SMM). All other demographic variables were balanced between groups. The mean time to intervention was 8 hours shorter in the FAST group. FAST patients received interventions on average 39.2 hrs after delivery and non-FAST patients received interventions 47.2 hrs after delivery ($p < .0001$). After adjusting for age, EBL, multiple gestation, fibroids, reason for PPH, and PPH related SMM, the FAST group still received interventions on average 5.5 hrs faster than those who did not ($p < 0.0001$).

CONCLUSION: Providers should utilize FAST exams as a first-line approach in the evaluation of PPH to decrease time to interventions and reduce maternal morbidity.

164 Adjunctive azithromycin for unscheduled cesarean delivery complicated by intraamniotic infection

Taylor S. Freret, Kaitlyn E. James, Alexander Melamed, Mark A. Clapp, Malavika Prabhu

Massachusetts General Hospital, Boston, MA

OBJECTIVE: Adjunctive azithromycin at the time of unscheduled cesarean delivery (CD) reduces postoperative infection. Patients with intraamniotic infection (IAI) were excluded in the original trial. We sought to determine if azithromycin is associated with reduced postoperative infection in this population.

STUDY DESIGN: Retrospective cohort study of patients with IAI and a singleton delivered by unscheduled CD at $\geq$24 weeks between 2017-2022 in one healthcare system. IAI was diagnosed using ICD10 codes. Exclusion criteria were PPROM or macrolide allergy. The primary exposure was administration of IV azithromycin 500mg at

delivery. The primary outcome was a composite of infection (ICD10 codes for endometritis, SSI, sepsis, or postoperative infection; or post-delivery positive blood, wound, respiratory, or urinary cultures within 6 weeks postpartum). Secondary outcomes included oral antibiotic use after delivery or any urgent (ED or readmission) visit for infection. Patients were matched on delivery BMI, failure to progress CD indication, smoking status, duration of rupture of membranes (h), and pregestational diabetes using coarsened exact matching. Weighted simple logistic regression was performed on matched patients.

RESULTS: During the study period, 1,366 patients with IAI delivered; 1,158 (84.8%) patients were matched. The overall rate of the primary outcome was 16.7%; 113 patients (9.8%) received oral antibiotics after delivery; and 11 (1.0%) had an urgent postpartum visit for infection (Table). Adjunctive azithromycin was not associated with a lower rate of the primary outcome (OR: 0.88, 95% CI 0.64 − 1.2, p=0.46). It was associated with decreased oral antibiotic use (OR: 0.50, 95% CI 0.39-0.65, p< 0.001) and fewer urgent postpartum visits (OR: 0.22, 95% CI 0.07 − 0.69, p=0.01).

CONCLUSION: Adjunctive azithromycin at the time of CD delivery among patients with IAI is not associated with lower rates of postpartum infection. However, it is associated with a reduction in oral antibiotic use, which may suggest a decrease in less severe postoperative infection rates.

Outcome*	No Azithromycin (n=761)	Azithromycin (n=397)	Post-Match OR [95% CI]†	p-value†

165 Machine learning for the prediction of surgical morbidity in placenta accreta spectrum

Itamar Futterman[1], Olivia Sher[1], Chaskin Wells Saroff[2], Alexa Cohen[3], Georgios Doulaveris[3], Pe'er Dar[4], Myah Griffin[5], Meghana Limaye[6], Thomas Owens[7], Lois Brustman[8], Henri M. Rosenberg[9], Nicola F. Tavella[10], Rebecca H. Jessel[10], Angela Bianco[9], Shoshana Haberman[1]

[1]Maimonides Medical Center, Brooklyn, NY, [2]Biotics AI, Oakland, CA, [3]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [4]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY, [5]NYU Langone Health, Atlanta, GA, [6]NYU Langone Health, New York, NY, [7]Mount Sinai West, New York, NY, [8]St. Luke's Roosevelt Hospital Center, New York, NY, [9]Mount Sinai Medical Center, New York, NY, [10]Icahn School of Medicine at Mount Sinai Hospital, New York, NY; on behalf of the New York City MFM Research Consortium

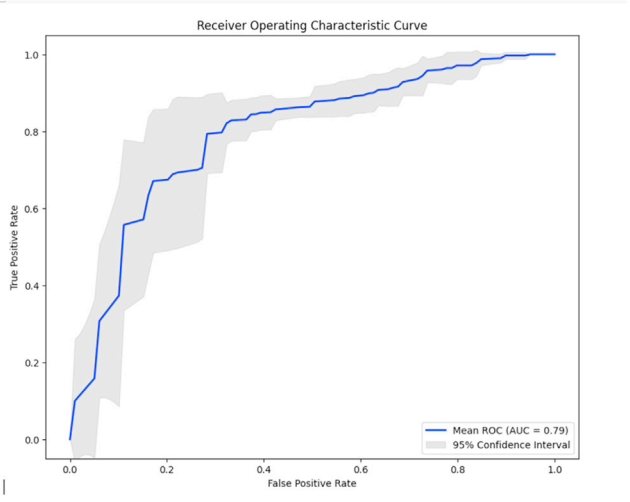
OBJECTIVE: We sought to create a machine learning (ML) model to identify variables that would aid in the prediction of surgical morbidity in cases of Placenta Accreta Spectrum (PAS).

STUDY DESIGN: A multicenter analysis including all cases of PAS across five tertiary care perinatal centers and members of the New York City Maternal Fetal Medicine research consortium, from 2013-2022. We developed models to predict operative morbidity using 213 variables including demographics, obstetrical information and limited imaging findings detailing placental location. Our primary outcome was prediction of a surgical morbidity composite defined as including any of the following: ICU admission, transfusion of >4 units of packed red blood cells, organ injury, vasopressor use, intubation or mechanical ventilation and maternal mortality. A nested, stratified, cross-validation approach was used to tune model hyperparameters and estimate generalizability. XGBoost classifiers models incorporated preprocessing steps of standard scaling for numerical variables and one-hot encoding for categorical variables. Model performance was evaluated using area under the receiver operating characteristic curve (AUC), positive and negative predictive values (PPV, NPV), and F1 score. Variable importance ranking was also determined.

RESULTS: Among 401 PAS cases, 326 (81%) underwent hysterectomy. Of the 401 cases of PAS, 309 (77%) had at least one event defined as surgical morbidity. Our predictive model had an AUC of 0.79 (95% CI: 0.69,0.89), PPV 0.79, NPV 0.76 and F1 score of 0.88.

The variables most predictive of surgical morbidity were completion of a hysterectomy, pre-pregnancy BMI, absence of a 2nd trimester ultrasound, SES zip code, BMI at delivery, number of prenatal visits and delivery time of day.

CONCLUSION: By identifying social and obstetrical characteristics that increase patients' risk, ML models are useful in predicting PAS-related surgical morbidity. Utilizing ML could serve as a foundation for risk and complexity stratification in cases of PAS to optimize surgical planning.



166 Planned hysterectomy vs. conservative management for placenta accreta spectrum − a systematic review meta analysis

Itamar Futterman, Olivia Sher, Cintia Gomes, julia Fisher, Shoshana Haberman, Scott Chudnoff

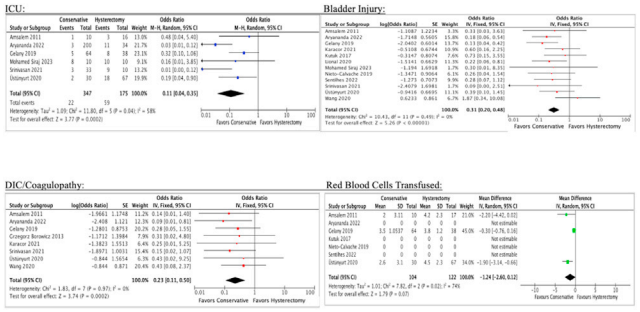
Maimonides Medical Center, Brooklyn, NY

OBJECTIVE: In recent years, management of Placenta Accreta Spectrum (PAS) has fallen into two categories: planned hysterectomy vs. conservative management to preserve fertility. However, optimal management remains unclear. Therefore, we conducted a systematic review and meta-analysis comparing the two to evaluate which approach offers lower surgical morbidity.

STUDY DESIGN: Systematic review was conducted using PRISMA guideline. MEDLINE, Scopus, the Cochrane Library, and ClinicalTrials.gov were searched from inception to June 30, 2023 for trials comparing conservative management versus hysterectomy. Surgical morbidity was defined as rates of ICU admission, Disseminated Intravascular Coagulation (DIC)/coagulopathy, bladder injury and number of units of packed red blood cells transfused (pRBC). Odds ratios (OR) were computed with 95% confidence intervals (CI) using a fixed or random effects model.

RESULTS: Among 839 studies initially retrieved, 14 were included with a total of 1193 patients. Of these, 753 (63.1%) underwent conservative management and 440 (36.9%) underwent planned hysterectomy. Conservative management resulted lower rates of ICU admission (OR 0.11; 95% CI 0.04,0.35), lower rates of bladder injury (OR 0.31; 95% CI 0.2,0.48), and lower incidence of DIC or coagulopathy (OR 0.23; 95% CI 0.11,0.50). No difference was found in the total number of pRBC units transfused (OR -1.24; 95% CI -2.60-0.12).

CONCLUSION: Our findings suggest that conservative management of PAS may lead to reduced surgical morbidity. Further research is needed to better define those who are potential conservative management candidates for PAS.



167 Do recommended continuous glucose monitoring thresholds apply to type 2 and gestational diabetes in pregnancy?

Stephanie A. Fisher[1], Emily Kobayashi[2], Natalie Conboy[1], Jingtong Huang[3], Charlotte M. Niznik[4], Amit Majithia[5], David C. Klonoff[3], Lynn M. Yee[4]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]UC San Diego, La Jolla, CA, [3]Diabetes Technology Society, Burlingame, CA, [4]Northwestern University, Chicago, IL, [5]University of California, San Diego School of Medicine, San Diego, CA

OBJECTIVE: Continuous glucose monitor (CGM) goals applied to pregnant people with type 1 diabetes include time-in-range (TIR) > 70%, time-above-range (TAR) < 25%, and glycemic variability (GV) ≤ 36%. Limited data support CGM use for gravidas with type 2 diabetes (T2DM) or gestational diabetes (GDM). We sought to determine risk of adverse perinatal outcomes (APOs) using various CGM thresholds in gravidas with T2DM/GDM.

STUDY DESIGN: In a retrospective analysis (2019-22) of gravidas at a single large center who used CGM for T2DM/GDM, we determined median 3rd trimester TAR, TIR, and GV in those with and without APOs using a target range 70-140 mg/dL. Generalized estimating equations determined odds ratios and 95% confidence intervals (CI) for hypertensive disorders of pregnancy (HDP), large-for-gestational age (LGA, birthweight ≥90%ile), neonatal intensive care unit (NICU) admission, neonatal hypoglycemia (NH, glucose ≤ 40 in first 24 hours), and jaundice (requiring phototherapy) at varying thresholds for each CGM metric in the 3rd trimester. Receiver operating characteristic analysis determined area under the curve (AUC) for varying thresholds for each metric.

RESULTS: Among 70 gravidas using CGM (T2DM: 48, GDM: 22), APOs occurred frequently (HDP, 43%; LGA, 13%; NICU admission, 29%; NH, 29%; and jaundice, 17%). For HDP, the TIR 90% (OR 3.3) and GV 20% (OR 5.3) thresholds were associated with the greatest odds of HDP. For LGA, TIR ≤ 75% (OR 7.2; AUC 0.73) and TAR ≥ 25% (OR 6.7; AUC 0.72) were associated with the greatest odds and discriminatory ability, while TIR 85% and TAR 15% had the greatest odds for NICU admission. Only TIR 75% was significantly associated with NH. Except for the aforementioned metrics for LGA, all other CGM metric thresholds had poor discriminatory ability for APOs (AUC < 0.7). GV thresholds were not associated with other APOs aside from HDP (GV > 20% vs. ≤ 20%: OR 5.3, CI 1.6-18.1).

CONCLUSION: In this cohort, recommended CGM thresholds for glycemic optimization during pregnancy had limited ability to distinguish risk of common APOs, beyond LGA, that complicate pregnancies with T2DM/GDM.

Table. Association of CGM thresholds with odds of perinatal outcomes

*CGM—continuous glucose monitoring, CI—confidence interval; HDP—hypertensive disorders of pregnancy, LGA—large-for-gestational age, NICU—neonatal intensive care unit, OR—odds ratio, ref—reference, TAR—time-above-range (*percentage of time with capillary blood glucose above 140 mg/dl), *TIR—time-in-range (*percentage of time with capillary blood glucose 70-140 mg/dl)*

Data for glycemic variability (the measurement of fluctuations of capillary blood glucose levels over 24 hours, assessed by the coefficient of variation for glucose) are not shown in the table.

168 Perinatal outcomes in pregnancies affected by early abnormal glucose tolerance

Erin Gallent[1], Qiaowu Li[2], Brianne Bimson[1]

[1]Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA, [2]Kaiser Permanente Southern California Department of Research and Evaluation, Pasadena, CA

OBJECTIVE: Abnormal glucose tolerance (AGT) in the third trimester, defined as 1 of 4 elevations on an oral glucose tolerance test (OGTT), is associated with increased risk for adverse pregnancy outcomes. Using universal rather than risk-based screening, we aimed to determine if AGT in early pregnancy was similarly associated with perinatal complications.

STUDY DESIGN: This study was a retrospective cohort study that reviewed 70,921patients with pregnancy data from three hospitals in

the greater Los Angeles area that employ universal gestational diabetes mellitus (GDM) screening in early pregnancy between the years 2010 and 2020. Per protocol, all patients are screened for GDM at the time of prenatal intake using the 2-step method. The primary outcome was large for gestational age (LGA) neonate. Secondary outcomes were a maternal composite and a neonatal composite.

RESULTS: 56,266 patients were identified who successfully completed the 1 hour 50-gram oral glucose challenge screening prior to 18 weeks gestational age. 6,294 patients met criteria for AGT on diagnostic evaluation with the 3 hour 100-gram OGTT using Carpenter-Coustan criteria. 6,294 matched controls with normal screening were identified. There were no significant differences in the primary outcome of LGA between groups (4% vs 4.1%, p=0.7186). Regression analyses revealed patients with early AGT were more likely to develop GDM compared to controls (29% vs 9.6%, OR 3.95 CI 3.55-4.40, p< 0.0001). There was also a significant difference in the rate of primary cesarean section for patients with early AGT (OR 1.11 CI 1.00-1.22, p=0.045).

CONCLUSION: Using universal GDM screening in early pregnancy, we found no association between early AGT and increased incidence of LGA newborns. However, early AGT was associated with an increased risk for GDM diagnosis in the third trimester as well as primary cesarean section. Further investigation into the use of risk based GDM screening in early pregnancy is warranted, as well as early implementation of healthy lifestyle counseling.

Adverse Perinatal Outcomes	Odds Ratio for Women with Early AGT	95% Confidence Intervals	*p* value
LGA	0.97	0.83-1.12	0.64
GDM	3.95	3.55-4.40	<0.0001
PIH	1.09	1.00-1.20	0.06
Chorioamnionitis	1.05	0.93-1.18	0.47
Shoulder dystocia	0.88	0.62-1.25	0.48
Operative VD	1.16	0.93-1.45	0.2
Primary CS	1.11	1.00-1.22	0.045
Repeat CS	1.01	0.91-1.12	0.84
Apgar 1 min	0.87	0.66-1.14	0.3
Apgar 5 min	1.07	0.77-1.48	0.68
Neonatal hypoglycemia	0.92	0.40-2.08	0.83
Neonatal RDS	0.79	0.61-1.02	0.07

AGT: abnormal glucose tolerance, LGA: large for gestational age (birth weight > 90%ile), GDM: gestational diabetes mellitus, PIH: pregnancy-induced hypertension, Operative VD: operative vaginal delivery including vacuum-assisted and forceps, primary CS: primary cesarean section, repeat CS: repeat cesarean section, neonatal RDS: neonatal respiratory distress syndrome

169 Curating the fetal genome: experience of the ClinGen prenatal gene curation expert panel (GCEP)

Stephanie Galloway[1], Jessica L. Giordano[1], Amanda Thomas-Wilson[2], Volkan Okur[2], Carrie J. Shawber[1], Kelly L. Gilmore[3], Julie Ratliff[4], Roni Zemet Lazar[5], Mythily Ganapathi[1], Natalie Chandler[6], Neeta L. Vora[7], Avinash V. Dharmadhikari[8], Jessica Van Ziffle[9], Teresa N. Sparks[10], David Chitayat[11], Lyn Chitty[12], Erin Riggs[13], Alicia B. Byrne[14], Ronald J. Wapner[15], Wendy Chung[16], Ignatia B. Van den Veyver[5]

[1]Columbia University, New York, NY, [2]New York Genome Center, New York City, NY, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]Broad Institute of MIT and Harvard, Cambridge, MA, [5]Baylor College of Medicine, Houston, TX, [6]North Thames Genomic Laboratory Hub, London, England, [7]University of North Carolina, Chapel Hill, NC, [8]USC, Los Angeles, CA, [9]University of California, San Francisco (UCSF), San Francisco, CA, [10]University of California, San Francisco (UCSF), School of Medicine, San Francisco, CA, [11]Mount Sinai Hospital, Toronto, ON, [12]Great Ormond Street NHS Foundation Trust, London, England, [13]Geisinger, Lewisburg, PA, [14]Broad Institute of MIT and Harvard, Boston, MA, [15]Columbia University Irving Medical Center, New York, NY, [16]Harvard and Boston Children's Hospital, Boston, MA

OBJECTIVE: Prenatal genetic diagnosis now includes genomic sequencing. Interpretation of variants is more challenging prenatally than post-natally as fetal phenotypic information is limited to structural/growth abnormalities. Unique fetal phenotypes of genetic diseases and genotype-phenotype associations are underreported, leading to more genes of uncertain significance in the prenatal setting. This uncertainty negatively impacts confidence in reporting prenatal sequencing results by laboratories and the clinical management of pregnancies. To address the limited evidence for prenatal gene-disease associations, we assembled the ClinGen Prenatal GCEP.

STUDY DESIGN: The initial focus is on genes previously reported as associated with unique prenatal phenotypes: non-immune fetal hydrops (NIHF) and stillbirth (SB). All curators and experts trained in the standardized ClinGen tools to score genetic and functional evidence for gene-disease association. Paired curators and clinical experts focused on one assigned gene. Evidence was reviewed at weekly meetings and published on the ClinGen website.

RESULTS: Genes selected for curation include 151 implicated in NIHF and 221 implicated in SB; 34 overlap between these phenotypes. Pre-curation to assess initial evidence has been completed for 8 genes; primary curation has been completed for 5 genes associated with 7 phenotypes. These include *EPHB4*, *PIEZO1*, *FLT4*, *GRIP1*, and *TUBGCP6*, with confirmed causative evidence for hydrops, stillbirth, and prenatally observable fetal anomalies. A secondary curation has been completed for *TAFAZZIN*; primary curation was done by the Inborn Errors of Metabolism GCEP. Overall, this process has provided international prenatal providers with further clarity about unique fetal features of many genetic diseases, and will translate to more accurate prenatal diagnosis.

CONCLUSION: Our experience supports the importance of gene curation for prenatal phenotypes. The continuously updated data, which are publicly available online through ClinGen, will significantly facilitate uniformity in diagnostic prenatal sequencing and improve pregnancy management.

170 Successful trial of labor after cesarean prediction utilizing machine learning frameworks

Reetam Ganguli[1], Stephen M. Wagner[2]

[1]Warren Alpert Medical School of Brown University, Women & Infants Hospital Rhode Island, Providence, RI, [2]Beth Israel Deaconess Medical Center, Brookline, MA

OBJECTIVE: Vaginal birth after cesarean section (VBAC) is associated with reduced maternal morbidity and improved outcomes in future pregnancies. Planned c-section leads to better outcomes over an unplanned c-section following failed TOLAC.

Recent literature has shown that clinicians overestimate the likelihood of successful VBAC (AUC=0.60). Identifying best candidates for TOLAC can guide clinical decision making and reduce emergency cesarean section. We aimed to develop and validate a machine learning framework utilizing non-invasive data to accurately predict successful VBAC.

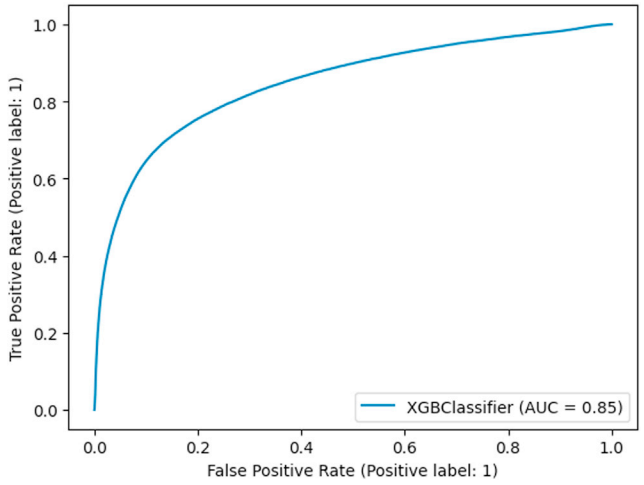
STUDY DESIGN: All patients from 2018-2020 in the National Vital Statistics System who had undergone a previous cesarean section met the inclusion criteria. Clinical variables studied included patient demographics, obstetric history, and clinical risk factors. The primary outcome predicted was successful VBAC. An extreme gradient boosting machine learning model was developed on the data. Weight scaling algorithms were utilized to improve representation of patients who underwent sucessful VBAC. The model was trained on all patients from 2018-2020, as well as VBAC patients from years 2014, 2016, and 2017 and was tested on a hold-out set of patients from the year 2021.

RESULTS: 43 variables across 1,948,912 obstetric patients were included in the training data, of which 453,085 successfully had a VBAC.

The model was tested on 561,717 patients from the 2021 year, of which 79,558 patients had a successful VBAC. The extreme gradient boosting model had an area under the receiver operating characteristic curve of 0.85, specificity of 0.89, with an accuracy of 85.4%, and F1 score of 0.85.

The highest weighted factors in the model were interval since last live birth, prepregnancy weight, and paternal age.

CONCLUSION: Machine learning models using routinely collected clinical data can accurately predict the probability of successful TOLAC. This could optimize counseling for pregnant patients considering TOLAC versus repeat cesarean delivery and have the potential to reduce unnecessary operative deliveries and associated costs for hospital systems.



171 Machine learning methods to identify severe postpartum hemmorrhage requiring transfusion prior to delivery

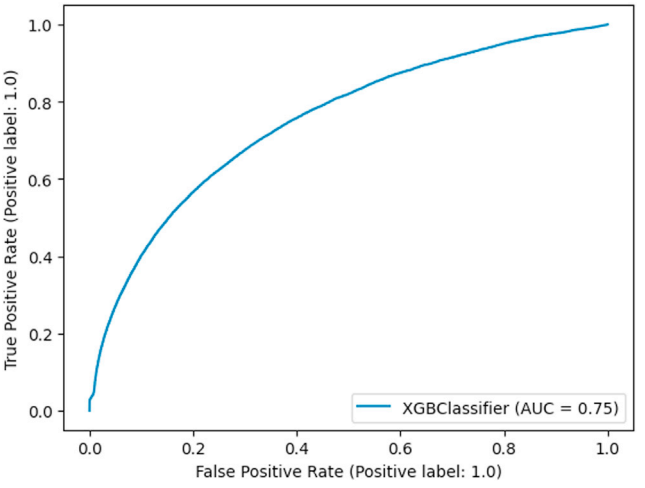
Reetam Ganguli[1], Stephen M. Wagner[2]
[1]Warren Alpert Medical School of Brown University, Women & Infants Hospital Rhode Island, Providence, RI, [2]Beth Israel Deaconess Medical Center, Brookline, MA

OBJECTIVE: Postpartum hemorrhage (PPH) is a leading cause of maternal mortality in the United States. The widely adopted PPH risk assessment tool developed by the California Maternal Quality Care Collaborative only classifes 22% of severe PPH patients as high risk and includes variables only accessible during the labor period. We developd a machine learning (ML) model to identify patients at risk for severe PPH requiring transfusion using data available prior to delivery. Early recognition could signal providers to schedule deliveries in higher-resourced hospital systems for patients in rural regions and enable earlier coordination with blood banks to prepare antigen matched blood prior to delivery.

STUDY DESIGN: We conducted a retrospective cohort study using the the Center for Disease Control's (CDC) Vital Statistics System. All patients from the 2018-2020 years as well as PPH patients from the 2014, 2016, and 2017 years without missing data for the PPH outcome were included. Variables with >50% missing data were omitted and training variables consisted of demographics, medical history, and prenatal data. An extreme gradient boosting ML algorithm was validated on CDC data from the 2021 year. Youden's J statistic value was calculated to set the classification threshold. The primary outcome was severe PPH requiring intrapartum maternal transfusion.

RESULTS: 7,728,892 patients were used to train the model. The incidence of severe PPH necessitating a transfusion was 1.2% (n=89,819). The gradient boosting model was trained across 39 variables and achieved an AUC of 0.75 with a 78.2% accuracy, and 0.78 F1 score. The sensitivity was 0.65 after setting the optimal threshold at 0.46. The highest weighted factors for the model were body mass index and maternal age.

CONCLUSION: ML methods can be utilized to identify patients at risk for severe PPH with nearly 3-fold greater high-risk sensitivity than the current PPH risk assessment system. Our model has the potential to improve care, avoid preventable PPH deaths, and reduce associated health services costs for PPH patients.



172 Continuous glucose monitoring in type 2 and gestational diabetes in pregnancy: better than hemoglobin A1c?

Stephanie A. Fisher[1], Emily Kobayashi[2], Natalie Conboy[1], Jingtong Huang[3], Charlotte M. Niznik[4], Amit Majithia[5], David C. Klonoff[3], Lynn M. Yee[4]
[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]UC San Diego, La Jolla, CA, [3]Diabetes Technology Society, Burlingame, CA,

[4]Northwestern University, Chicago, IL, [5]University of California, San Diego School of Medicine, San Diego, CA

OBJECTIVE: In gravidas with type 2 diabetes (T2DM) and gestational diabetes (GDM), we sought to determine the ability of continuous glucose monitoring (CGM) metrics (time-in-range, TIR; time-above-range, TAR; time-below-range, TBR; glycemic variability, GV) and hemoglobin A1c (HbA1c) to distinguish those at risk of adverse perinatal outcomes (APOs).

STUDY DESIGN: In a retrospective study (2019-22) of gravidas with T2DM/GDM who used CGM with target range 70-140 mg/dl, we assessed average 3rd trimester TIR, TAR, TBR, GV, and HbA1c in those with (vs. without) the following APOs: hypertensive disorders of pregnancy (HDP), large-for-gestational age neonate (LGA, birthweight $\geq$ 90%ile), neonatal intensive care unit (NICU) admission, neonatal hypoglycemia (NH, glucose $\leq$ 40 within 24 hours of birth), and jaundice (requiring phototherapy). For each outcome, the Mann-Whitney U test compared median CGM metrics and HbA1c, and receiver operating characteristic (ROC) analysis determined the optimal cut-point and area under the curve (AUC) for each metric.

RESULTS: Of 48 and 22 eligible gravidas with T2DM and GDM, respectively, lower TIR ($p \leq 0.03$) and higher TAR ($p \leq 0.04$) was associated with both HDP and NICU admission. HbA1c was higher in gravidas who had LGA infants and NICU admission ($p \leq 0.02$), and discriminatory ability of HbA1c exceeded that of all CGM metrics assessed (AUC for HbA1c: LGA 0.75, NICU 0.71). However, for HDP, a difference in HbA1c was not observed ($p=0.26$) and HbA1c had poor discriminatory ability (AUC 0.61). Neither HbA1c nor any of the CGM metrics differed among those with (vs. without) neonatal hypoglycemia or jaundice, and discriminatory ability of all metrics for these outcomes was poor (AUC $\leq$ 0.7).

CONCLUSION: In this cohort, HbA1c had superior discriminatory ability than CGM metrics for LGA and NICU admission among pregnancies affected by T2DM/GDM, but further investigation is warranted to identify the optimal measure of glycemic control that can prognosticate risk of other APOs in this population.

Table. Continuous glucose monitoring metrics and adverse perinatal outcomes

	Median		Cut-point	AUC
	No APO	*+APO*		
HDP (n, %)	40 (57.1)	30 (42.9)		
TIR	0.84	0.75*	0.79	0.44
TAR	0.13	0.20*	0.12	0.62
TBR	0.011	0.015	0.013	0.57
GV	0.21	0.24*	0.20	0.68
HbA1c	5.8	5.9	5.6	0.61
LGA (n, %)	61 (87.1)	9 (12.9)		
TIR	0.82	0.70	0.94	0.52
TAR	0.16	0.30	0.35	0.74
TBR	0.014	0.006	0.10	0.40
GV	0.22	0.25	0.22	0.64
HbA1c	5.8	6.4*	6.1	0.75
NICU (n, %)	50 (71.4)	20 (28.6)		
TIR	0.84	0.73*	0.69	0.44
TAR	0.12	0.27*	0.17	0.68
TBR	0.014	0.010	0.018	0.46
GV	0.22	0.24	0.23	0.62
HbA1c	5.7	6.3*	5.9	0.71
Neonatal hypoglycemia (n, %)	50 (71.4)	20 (28.6)		
TIR	0.73	0.84	0.89	0.50
TAR	0.13	0.25	0.23	0.65
TBR	0.015	0.009	0.026	0.54
GV	0.22	0.23	0.23	0.54
HbA1c	5.7	6.1	5.9	0.62
Neonatal jaundice (n, %)	58 (82.9)	12 (17.1)		
TIR	0.84	0.74	0.73	0.50
TAR	0.14	0.24	0.19	0.69
TBR	0.012	0.011	0.009	0.58
GV	0.22	0.25	0.24	0.67
HbA1c	5.7	6.0	5.9	0.70

AUC—area under the curve, GV—glycemic variability, HbA1c—hemoglobin A1c, HDP—hypertensive disorders of pregnancy, LGA—large-for-gestational age, NICU—neonatal intensive care unit, TAR—time-above-range,
TBR—time-below-range, TIR—time-in range
TIR: percentage of time with capillary blood glucose 70-140 mg/dl.
TAR: percentage of time with capillary blood glucose above 140 mg/dl.
TBR: percentage of time with capillary blood glucose below 70 mg/dl.
GV: the measurement of fluctuations of capillary blood glucose levels over 24 hours
HbA1c: average blood glucose level over the prior 3 months
Cut-point: blood glucose value whose sensitivity and specificity are the closest to the value of the area under a receiver operating characteristic curve, and the absolute value of the difference between the sensitivity and specificity values is minimum.
*Indicates significant p-value (< 0.05) for those with (vs. without) each APO for each exposure.

173 Accuracy of estimated fetal weight based on provider training level

Helen Gao[1], Nandini Raghuraman[2], Anthony O. Odibo[2], Jeannie C. Kelly[3], Katherine H. Bligard[2]
[1]Washington University in St. Louis, St. Louis, MO, [2]Washington University School of Medicine in St. Louis, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

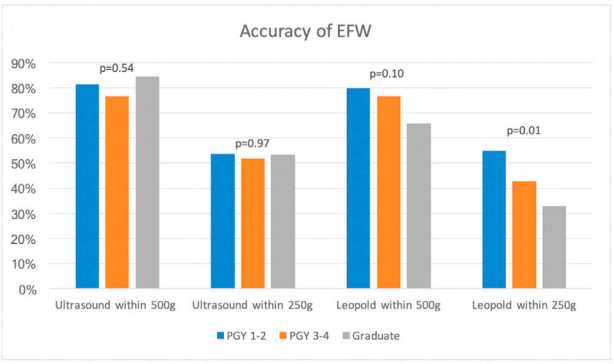
OBJECTIVE: Ultrasound (US) and clinical palpation can be used to determine an estimated fetal weight (EFW). We aimed to determine the accuracy of these measures performed by providers at various training levels.

STUDY DESIGN: This is a secondary analysis of a prospective cohort study of term singleton gravidas with obesity admitted for delivery. EFW was obtained with US-derived biometry and clinician palpation via Leopold's maneuvers. The primary outcome was prediction of birthweight within 500g. Secondary outcomes included accuracy within 250g and prediction of small-for-gestational age (SGA, < 10%ile) and large-for-gestational age (LGA, >90%ile) birthweight as measured by area under receiver-operating characteristic curves. (AUCs). These outcomes were compared by provider level of training: post-graduate years (PGY) 1-2, PGY 3-4, and post-residency (fellows and attendings).

RESULTS: Of 243 patients, 46.9% of EFW were performed by PGY 1-2, 23.0% by PGY 3-4, and 30.0% by post-residency providers. Baseline characteristics were similar. There was no difference in accuracy of US or palpation within 500g or US within 250g between the groups (Figure). However, the more junior providers were more likely to accurately predict birthweight within 250g by palpation (p=0.01). SGA was most likely to be accurately predicted by PGY3-4 providers via US (AUC 0.94 [0.90-0.99] vs 0.74 [0.50-0.98] for PGY1-2 and 0.66 [0.43-0.88] for post-residency, p=0.02) and by PGY1-2 providers by palpation (AUC 0.77 [0.53-1.00] vs 0.62 [0.37-0.86] for PGY3-4 and 0.49 [0.46-0.51] for post-residency, p=0.04). There was no difference in LGA prediction by training level.

CONCLUSION: Overall accuracy of EFW by US is similar across training levels, however accurate prediction of SGA by US is highest among PGY3-4 providers. By clinical palpation, PGY 1-2 providers are most likely to accurately assess fetal weight. This may suggest that as training progresses, US replaces palpation as preferred EFW method. Overall, trainees' estimates of fetal weight are similarly accurate to post-residency providers' and can be used to guide clinical management.

Figure: Accuracy of US- and palpation-derived estimated fetal weight by provider training level



174 Physical activity and sedentary behavior and spontaneous preterm birth (SPTB): Insights from Fitbit tracker data

Emily Gascoigne[1], Catherine Vladutiu[2], Abbie Smith-Ryan[1], Annie Dude[3], Tracy Manuck[1]
[1]University of North Carolina, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Rockville, MD, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

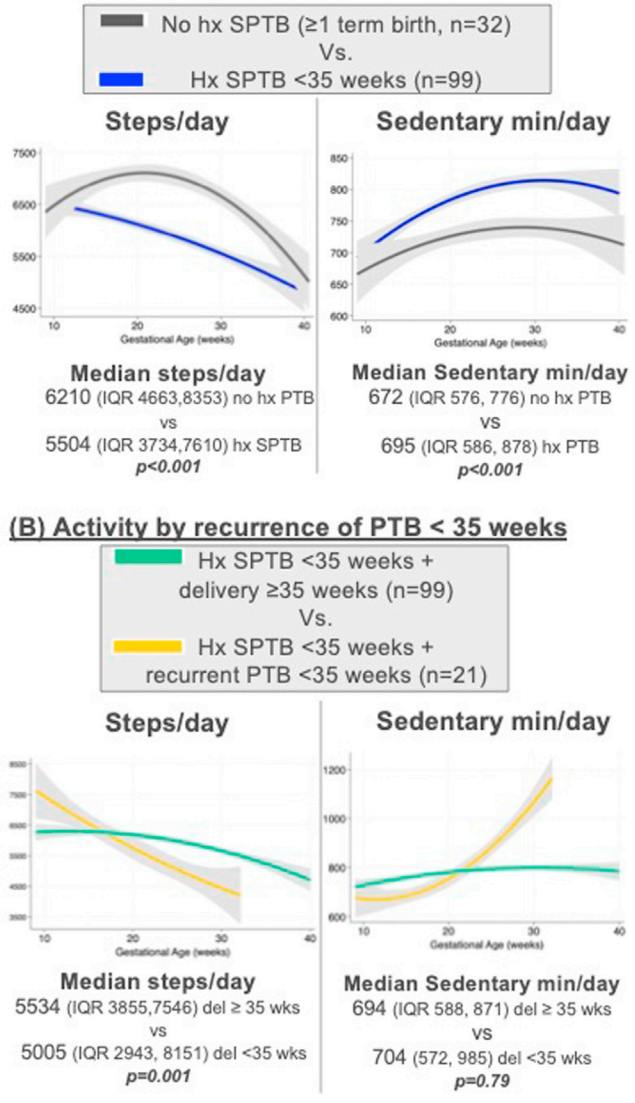
OBJECTIVE: We sought to assess if objectively quantified physical activity amount and intensity differ throughout gestation by history of SPTB and by recurrent PTB in the current pregnancy.

STUDY DESIGN: Primary analysis of a prospective observational cohort designed to identify factors associated with recurrent SPTB. Patients with singleton, non-anomalous gestations and ≥1 prior SPTB 16.0-34.9 wks (***hx SPTB***) and a smaller subset of individuals with ≥1 prior births ≥ 37 wks and no prior PTB (***no SPTB hx***) were recruited, 9.0-13.9 wks, 2017-2022. Physical activity was quantified using study-provided FitBit activity trackers. Subjects were instructed to maintain their 'usual activity.' Those with ≥7 valid monitoring days (FitBit recorded heart rate for ≥80% of the day) were included. Daily steps and activity intensity (sedentary, light, fairly/very active minutes) were compared by hx SPTB. For those with a hx SPTB, steps and activity intensity were also evaluated by recurrent PTB < 35 wks. Fixed-effects regression was used to account for varying numbers of obs/subject and adjust for confounders.

RESULTS: **131** patients met inclusion criteria. 99 (76%) had a hx SPTB < 35 wks; 18/99 (18%) had recurrent PTB < 35 wks (median 31.9 wks). All 32 patients with no hx SPTB delivered at term. The cohort was racially (37% Black) and ethnically (16% Hispanic) diverse. There were 9,401 Fitbit wear days (median 63 days/person). Those with hx PTB were less active and more sedentary than those with no hx SPTB (all p< 0.001), Figure Panel A. Among those with hx PTB, those with recurrent PTB < 35 wks were less active but not more sedentary than those with hx SPTB who delivered ≥ 35 wks, Figure Panel B. In separate adjusted models, median steps/day (β=-0.04, 95% CI -0.007, -0.001, p=0.003) and sedentary minutes (β=0.002, 95% CI 0.0006, p=0.009) were associated with recurrent PTB < 35 wks.

CONCLUSION: Patients with hx SPTB < 35 wks are less active and more sedentary than those with only prior term births. Fewer median steps per day and increased sedentary minutes are associated with recurrent PTB.

Figure. Physical activity across gestation, measured by FitBit activity tracker. Fitted values are shown. *Trends were similar for other activity intensities (data not shown due to space limitations).*



175 Physical activity guidelines are infrequently met during pregnancy, regardless of SPTB history or antepartum hospitalization

Emily Gascoigne[1], **Catherine Vladutiu**[2], **Abbie Smith-Ryan**[1], **Annie Dude**[3], **Tracy Manuck**[1]

[1]University of North Carolina, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Rockville, MD, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

OBJECTIVE: National guidelines recommend pregnant persons obtain ≥ 150 min of ≥moderate intensity activity/week (~7,000-10,000 steps/day). We sought to quantify physical activity to assess adherence to recommended guidelines among pregnant outpatients (outpt) with and without a prior SPTB, and those cared for inpatient (inpt) on the antepartum unit.

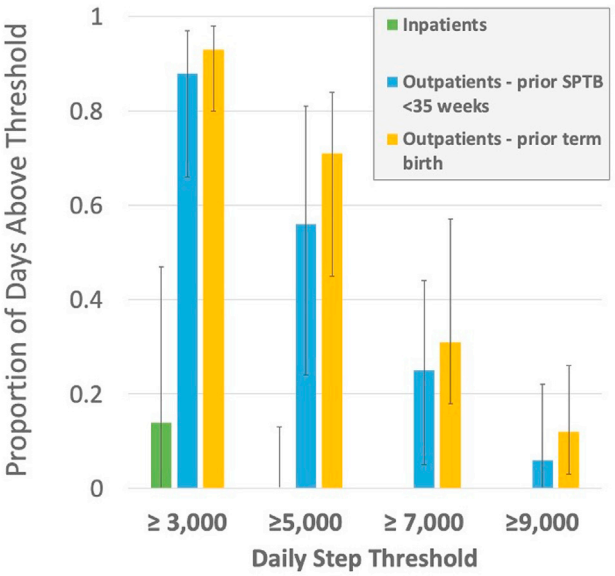
STUDY DESIGN: Analysis of 2 prospective observational cohorts. In study #1 (outpt), patients were recruited from OB clinics, 9-13 wks; most had a prior SPTB < 35 wks; a subset had ≥1 prior term delivery. In study #2 (inpt), patients were recruited while admitted to antepartum, 20-33 wks. Physical activity was quantified using study-provided FitBit activity trackers throughout pregnancy (study #1) or while inpt and undelivered (study #2). Subjects were instructed to maintain 'usual activity.' Those with ≥7 valid study days (FitBit recorded heart rate for ≥80% of the day) were included. The primary outcomes were the % of days each participant (a) took ≥7,000 steps/day; (b) had ≥ 21 minutes of ≥ moderate activity. Secondary outcomes were the % of days each participant took ≥ 3000, 5000, and 9000 steps. Data were analyzed by ANOVA, chi2, and t-test.

RESULTS: **201** patients met inclusion criteria, including 131 outpts (32 prior term birth, 99 prior PTB; median 63 days of monitoring) and 70 inpts (median 14 days of monitoring). There were 11,914 Fitbit wear days. 73/201 (36%) patients had no days with ≥ 7,000 steps recorded (14 outpts, 59 inpts). Inpts had a median of zero FitBit monitoring days with ≥ 7000 steps; only 11/70 inpts had ≥ 1 FitBit day with ≥7000 steps. Outpts with a hx of SPTB achieved each step threshold less frequently than outpts with only prior term births (Figure). Similarly, outpts with a hx of SPTB achieved ≥ 21 minutes of ≥ moderate activity a median of 5.3% of days (vs. 9.6% for those with only prior term deliveries, and 0% for inpts).

CONCLUSION: Pregnant persons infrequently achieve recommended national physical activity goals. Activity levels are lower in individuals with a prior SPTB, and lowest in those hospitalized on the antepartum service.

Figure. Proportion (%) of FitBit monitoring days with daily step count above the thresholds of ≥ 3000, 5000, 7000, and 9000 daily steps. Data are stratified by subject type; inpatients were the least likely to achieve each of the daily step thresholds.

Note: p<0.001 for all 3-way comparisons



176 Continuous glucose monitoring metrics and perinatal morbidity in pregnancies with type 1 diabetes

Stephanie A. Fisher[1], Emily Kobayashi[2], Natalie Conboy[1], Jingtong Huang[3], Charlotte M. Niznik[4], Amit Majithia[5], David C. Klonoff[3], Lynn M. Yee[4]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]UC San Diego, La Jolla, CA, [3]Diabetes Technology Society, Burlingame, CA, [4]Northwestern University, Chicago, IL, [5]University of California, San Diego School of Medicine, San Diego, CA

OBJECTIVE: To examine the discriminatory ability of continuous glucose monitoring (CGM) metrics (time-in-range, TIR; time-above-range, TAR; time-below-range, TBR; glycemic variability, GV) across gestation and hemoglobin A1c (HbA1c), for adverse perinatal outcomes (APOs) in pregnant people with type 1 diabetes (T1DM).

STUDY DESIGN: This is a retrospective study (2019-22) of gravidas with T1DM using CGM with target range 70-140 mg/dl. Exposures were average TIR, TAR, TBR, GV, and HbA1c per trimester. Primary maternal and neonatal outcomes were hypertensive disorders of pregnancy (HDP) and large-for-gestational age neonate (LGA, birthweight $\geq$ 90%ile). Secondary neonatal outcomes were neonatal intensive care unit (NICU) admission, neonatal hypoglycemia (NH, glucose $\leq$ 40 mg/dl in first 24 hours), and jaundice (requiring phototherapy). The Mann-Whitney U test compared median CGM metrics and HbA1c by outcome each trimester. Receiver operating characteristic (ROC) analysis determined the optimal cut-point with the greatest sensitivity and specificity and area under the curve (AUC) for each metric.

RESULTS: Among 92 patients using CGM for T1DM, the majority were multiparous (58%) and used insulin pumps (60%). Pregnancies with HDP, NICU admission, and jaundice had lower TIR each trimester ($p \leq 0.01$); lower TIR was associated with LGA only in the first trimester (p=0.01). Pregnancies with (vs. without) HDP (41% vs. 28%), LGA (36% vs. 27%), NICU admission (46% vs. 30%), and jaundice (46% vs. 29%) had higher median TAR in the first trimester ($p \leq 0.01$), with similar findings in the 2nd and 3rd trimester ($p < 0.05$). Median HbA1c was also higher every trimester for those with HDP, LGA, NICU admission, and jaundice ($p < 0.05$). For NH, we did not identify a difference in CGM metrics or HbA1c. Among CGM metrics, TAR had the greatest discriminatory ability for APOs (AUC 0.63-0.90, Table), but its discriminatory ability was similar to that of HbA1c for HDP, LGA and NICU across gestation.

CONCLUSION: TIR is inversely associated with APOs in people with T1DM, but has poor discriminatory ability for APOs compared to TAR and HbA1c.

Table. Discriminatory ability of continuous glucose monitoring metrics for adverse perinatal outcomes

	HDP		LGA		NICU		Neonatal Hypoglycemia		Neonatal Jaundice	
n/N (%)	*30/92 (32.6)*		*29/92 (31.5)*		*20/92 (22.5)*		*33/89 (37.1)*		*16/89 (18.0)*

HbA1c	6.0%	0.75	5.9%	0.66	6.1%	0.74	6.1%	0.59	6.5%	0.79

AUC—area under the curve, GV—glycemic variability, HbA1c—hemoglobin A1c, HDP—hypertensive disorders of pregnancy, LGA—large-for-gestational age, NICU—neonatal intensive care unit, TAR—time-above-range, TBR—time-below-range, TIR—time-in range

TIR: percentage of time with capillary blood glucose 70-140 mg/dl. TAR: percentage of time with capillary blood glucose above 140 mg/dl.
TBR: percentage of time with capillary blood glucose below 70 mg/dl.
GV: the measurement of fluctuations of capillary blood glucose levels over 24 hours
HbA1c: average blood glucose level over the prior 3 months
Cut-point: blood glucose value whose sensitivity and specificity are the closest to the value of the area under a receiver operating characteristic curve, and the absolute value of the difference between the sensitivity and specificity values is minimum.

177 Value of "lethal" ultrasound markers identifying fetuses with lethal skeletal dysplasia before/after 28 weeks

Haley Crane[1], Erica M. Schindewolf[2], Julie Moldenhauer[3], Natalie Burrill[2], Suzanne DeBari[2], Nahla Khalek[2], Christina Paidas Teefey[4], Shelly Soni[4], Beverly G. Coleman[5], Juliana S. Gebb[2]

[1]Richard D. Wood Jr. Center for Fetal Diagnosis and Treatment at CHOP, Philadelphia, PA, [2]Center for Fetal Diagnosis & Treatment, Children's Hospital of Philadelphia, Philadelphia, PA, [3]Richard D. Wood, Jr. Center for Fetal Diagnosis & Treatment, Children's Hospital of Philadelphia, Perelman School of Medicine of the University of Pennsylvania, Philadelphia, PA, [4]Children's Hospital of Philadelphia, Philadelphia, PA, [5]Richard D. Wood, Jr Center for Fetal Diagnosis and Treatment at CHOP, Perelman School of Medicine of the University of Pennsylvania, Philadelphia, PA

OBJECTIVE: Several ultrasound markers have been proposed to identify fetuses with lethal skeletal dysplasia. We sought to determine their utility in fetuses < vs >= 28 weeks.

STUDY DESIGN: Single-center retrospective review of pregnancies with suspected fetal skeletal dysplasia from 2013-2023. Ultrasound was performed with attention to measurements predictive of lethality, including thoracic circumference/abdominal circumference (TC/AC)< 0.6, femur length/abdominal circumference (FL/AC)< 0.16, and thoracic circumference (TC)< 2.5%ile. Fetuses were grouped based on gestational age at diagnosis. Demographic information, imaging, genetic testing, and outcome were collected. Statistical analysis included Fisher's exact test and calculation of sensitivity, specificity, positive predictive value, and negative predictive value.

RESULTS: 122 fetuses had a prenatal ultrasound consistent with a skeletal dysplasia between 16-38 weeks. Of those, 88 (72%) were < 28 weeks and 34 (28%) were >= 28 weeks. Outcomes are detailed in Table 1. Complete outcome data was available for 96 patients. In the cohort diagnosed at < 28 weeks, FL/AC ratio < 0.16 and TC < 2.5% ile were associated with death or a lethal genetic diagnosis (p< 0.001; p< 0.001) while TC/AC < 0.6 was not (p=0.280) (Table 2). In the cohort diagnosed at >= 28 weeks, only TC < 2.5%ile was associated with death or a lethal genetic diagnosis (p=0.006) (Table 2). The positive predictive value of one, two and three "lethal" ultrasound markers for predicting death or a lethal genetic diagnosis went from 58%, 90%, and 100% at < 28 weeks to 27%, 43%, and 100% at >= 28 weeks, respectively. The negative predictive value of no lethal markers was 91% in both groups.

CONCLUSION: In our cohort, the positive predictive value of one or two "lethal" ultrasound markers was lower in fetuses diagnosed at >= 28 weeks compared to those diagnosed earlier in pregnancy. This highlights the importance of thorough ultrasound examination, genetic testing, and balanced parental counseling particularly in patients presenting later in gestation.

178 Comparative transcriptomic analysis of the ectopic vs. physiologically implanted trophoblast

Jessica George[1], Irina A. Buhimschi[1], Guomao Zhao[1], Erica Hinz[1], Jonah Fleischer[1], Sami Heywood[1], William E. Ackerman IV[2], Catalin S. Buhimschi[1]

[1]University of Illinois at Chicago, Chicago, IL, [2]University of Illinois at Chicago College of Medicine, Chicago, IL

OBJECTIVE: Eutherian development needs complex molecular dialogs between trophoblast and maternal decidua/endometrium. The ancestrally invasive phenotypic trophoblastic behavior is likely dependent on intra-uterine or extra-uterine epithelium differentiation. Our transcriptomic comparison of normally vs extra-uterine implanted human trophoblast aimed to discover differentially and similarly expressed genes that are likely to underlie distinct features of human placentation based on implantation environment.

STUDY DESIGN: RNAseq was performed on surgically excised ectopic pregnancy (EP) chorionic villi (n=6, GA:5.6±0.4 w). As reference tissues we used trophoblast obtained from early intrauterine pregnancies (IUP) via surgical abortion (n=5, GA:8.2±3.2 w), chorionic villus sampling (CVS, n=5, GA:12.6±1.1w), idiopathic preterm birth placentas (iPTB, n=7, GA:25.9±1.6 w) and term placentas (n=5, GA:39±1w). Differential abundance was calculated using DESeq2. Computational deconvolution on a dataset (PRJEB33665, n=8) estimated relative decidual composition in tissue isolates. Analyzed samples had a decidual transcriptional program < 12%. Data were compared to an existing independent EP vs IUP RNAseq dataset (GSE183319, n=10). ClusterProfiler for pathway enrichment and Therapeutic Target Database identified pharmacologically relevant tissue effectors.

RESULTS: Controlling for embryologic sex, 4,632 differentially abundant transcripts (2,130 increased, FDR< 0.05) were identified in EP vs IUP, of which 641 were common with the external cohort (Fig A). EP trophoblast was enriched for inflammatory and metabolic pathways and deficient in cell adhesion pathways (Fig B). The 404 transcripts commonly increased in EP vs IUP in both cohorts included sero-diagnostic markers and 101 cancer-related druggable targets.

CONCLUSION: EP chorionic villi transcriptome is remarkably different from that of the IUP trophoblast. Our data reveal for the first time that aberrant implantation triggers robust trophoblast inflammation and cell adhesion downregulation which could be therapeutically targeted to prevent EP or enhance IUP implantation.

179 A novel and modern VBAC calculator for use prior to labor

Alexis C. Gimovsky[1], Silas Monje[2], Jack Dunn[3], Jordan Levine[4]

[1]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [2]Alpert Medical School of Brown University, Providence, RI, [3]Interpretable AI, Cambridge, MA, [4]Dynamic Sky, Providence, RI

OBJECTIVE: To develop a prediction model for individualized risks and benefits of a trial of labor after cesarean using modern mathematical techniques.

STUDY DESIGN: This was a secondary analysis of the Cesarean Registry database. Primary outcome: prediction of success of vaginal birth after cesarean (VBAC). Secondary outcomes: prediction of uterine rupture, maternal complications, neonatal complications. Inclusion criteria: term, singletons, cephalic presentation, one prior low transverse cesarean delivery. Exclusion criteria: intrauterine fetal demise, planned cesarean, prior myomectomy. Univariate comparisons identified variables that were independently associated with VBAC. An optimal decision tree was used to create a prediction model. A test set was withheld for validation. A risk calculator tool was developed for prediction of successful VBAC and adverse perinatal outcomes. Adverse maternal outcomes: uterine dehiscence, hysterectomy, postpartum hemorrhage, endometritis, intensive care unit admission, thromboembolic event, readmission, organ injury. Adverse neonatal outcomes: hypoxic ischemic encephalopathy, respiratory distress, seizures, apnea, respirator use, death, cord blood ph < 7.1.

RESULTS: The study population included 73262 deliveries; 12942 patients met inclusion and exclusion criteria. After removing cases for the test set, the included patients were 8078 patients, of which 5970 people had a successful VBAC (73.9%). Parity, number of years since prior cesarean delivery, pre-pregnancy body mass index (BMI), delivery BMI, maternal age, previous VBAC were associated with successful VBAC. A risk predictor calculator was created, and a ROC curve was developed with AN AUC was 0.72. The tool was also developed to identify a person's risk of uterine rupture, composite maternal morbidity and neonatal morbidity.

CONCLUSION: VBAC for patients with term, cephalic, singleton gestations were associated with several variables. This advanced calculator tool will facilitate shared decision making about the value of a TOLAC regarding the personalized risks of maternal and neonatal morbidity.

Table: Case examples using calculator tool

	Case 1	Case 2	Case 3	Case 4
○ Parity	1	1	3	4
○ Pre-pregnancy BMI	20	50	29	22
○ Delivery BMI	25	56	36	28
○ Maternal Age	22	40	30	35
○ Interval since prior cesarean (years)	1	3	11	3
○ Prior VBAC	No	No	Yes	Yes
✓ VBAC probability	76%	24%	78%	95%
✓ Uterine rupture probability	0%	3%	1%	0%
✓ Adverse maternal outcome probability	2%	3%	12%	2%
✓ Adverse neonatal outcome probability	7%	10%	9%	5%

Abbreviations: VBAC (vaginal birth after cesarean), BMI (body mass index)

Red = < 50% chance of VBAC, or ≥ 10% or higher risk of morbidity

Green = ≥ 50% chance of VBAC, or < 10% chance of morbidity

180 Personalized approach to predict twin mode of delivery

Alexis C. Gimovsky[1], Silas Monje[2], Jack Dunn[3], Jordan Levine[4]

[1]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [2]Alpert Medical School of Brown University, Providence, RI, [3]Interpretable AI, Cambridge, MA, [4]Dynamic Sky, Providence, RI

OBJECTIVE: The reported incidence of combined twin delivery (vaginal delivery of twin A followed by cesarean of twin B) ranges between 5% and 10%. These estimates can be useful overall, but personalized predictions are more clinically valuable for patient centered counseling. We aimed to develop a model that predicts the chance of successful vaginal delivery of twins based on pre-labor patient characteristics for an individual patient using a modern machine learning approach.

STUDY DESIGN: Secondary analysis of the Consortium for Safe Labor data set. Women with non-anomalous, diamniotic twins with a cephalic presenting twin between 32 0/7 and 38 6/7 weeks gestation were included. Only women attempting vaginal birth of twins were analyzed. We performed a retrospective cohort study, using optimal classification trees to predict twin mode of delivery (both vaginal, both cesarean or combined vaginal/cesarean). Pre-labor patient characteristics were examined to identify variables significantly associated with the success or failure of twin vaginl birth.

RESULTS: 830 patients met were analyzed after removing test set patients. Pre-labor characteristics associated with delivery mode included parity, pre-pregnancy body mass index, maternal age, history of prior cesarean and presentation of baby B. Using these characteristics, a predictive model was developed. A test set was withheld and then utilized to create a receiver operator curve. Accuracy was assessed with an area under the curve of AUC of 0.65.

CONCLUSION: We report the successful development of a predictive calculator for delivery mode in diamniotic twin pregnancy. This tool will be useful in patient counseling regarding mode of delivery.

Table: Case examples using calculator tool

	Case 1	Case 2	Case 3	Case 4
○ Parity	0	0	1	3
○ Pre pregnancy BMI	24	30	23	25
○ Maternal age	32	35	27	36
○ Prior cesarean	No	No	No	Yes
○ Presentation of baby B	Transverse	Cephalic	Breech	Cephalic
✓ Vaginal delivery of both twins probability	70.7%	26.3%	55.6%	28.6%
✓ Cesarean delivery of both twins probability	25.5%	71.3%	32.3%	64.3%
✓ Combined vaginal/cesarean probability	3.8%	2.5%	12.1%	7.1%

Abbreviations: BMI (body mass index)

○ Calculator Input

• Calculator Output

Red = < 50% chance of vaginal birth, or ≥ 5% chance of combined delivery

Green = >50% chance of vaginal birth, or < 5% chance of combined delivery

181 An association between advanced maternal age at first delivery and long-term risk for gynecological cancer

Noa Gohar-Portnoy[1], Sharon Davidesko[2], Eyal Sheiner[3], Tamar Wainstock[4], Ruslan Sergienko[5], Roy Kessous[3]

[1]Soroka University Medical Center, Givot Bar, HaDarom, [2]Soroka University Medical Center, Omer, HaDarom, [3]Soroka University Medical Center, Beer-Sheva, HaDarom, [4]Ben Gurion University, Beer-Sheva, HaDarom, [5]Ben Gurion University of the Negev, Beer-Sheva, HaDarom

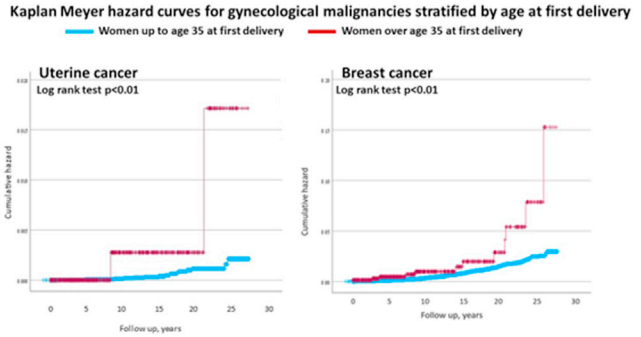
OBJECTIVE: Global trends indicate women increasingly delaying childbirth. This study aims to assess the impact of advanced maternal age at first delivery on the long-term incidence of gynecological cancers.

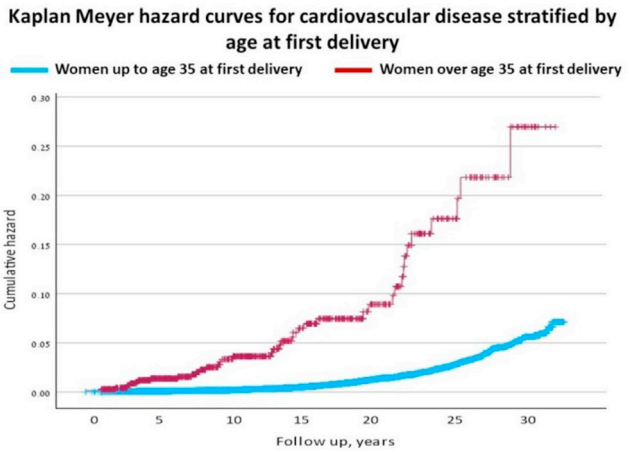
STUDY DESIGN: A population-based cohort study including all primigravida delivering between the years 1991-2019, stratified by age (up to vs. over 35 years at delivery). Data were collected retrospectively from medical records according to pre-defined ICD-9 codes. The incidence of gynecological cancers were compared and analyzed. Kaplan-Meier survival curves compared malignant morbidity controlling for time, and a Cox regression model controlled for confounders.

RESULTS: Among 44,230 first deliveries, 71.8%88 () were in elderly primigravida who were more likely to have undergone fertility treatment (29.1%vs. 3.1%, p< 0.01) as well as higher prevalence of diabetes (18.4% vs. 3.8%, p< 0.01), hypertension (16.6% vs. 6.9%, p<0.01), and pre-pregnancy obesity (2.3% vs. 0.9%, p< 0.01). The overall incidence of gynecological malignancies was higher in elderly primigravida (1.8% vs. 0.8%, p=0.003) and specifically, breast and endometrial (1.5% vs. 0.7%, p=0.003 and 0.3% vs. 0.0%, p=0.004 respectively). No differences were noted in the incidence of cervical and ovarian cancer. Kaplan-Meier survival curves reiterated these findings (Figure, log-rank test p< 0.01 for endometrial and breast cancers).

Multivariate analysis controlling for other risk factors such as hypertension, pre-eclampsia, diabetes and fertility treatment showed that elderly primigravida had an adjusted HR of 1.792 (95%CI 1.030-3.118, p=0.001) for composite malignancy, 3.398 (95%CI 0.700-16.504, p=0.129) for uterine cancer and 1.905 (95%CI 1.045-3.470, p=0.035) for breast cancer.

CONCLUSION: First pregnancy at advanced age is associated with increased lifetime risk for breast and endometrial malignancies, an additional factor to consider in family planning decisions.





182 Advanced maternal age among primigravida as a risk factor for long-term cardiovascular disease

Noa Gohar-Portnoy[1], Sharon Davidesko[2], Eyal Sheiner[3], Tamar Wainstock[4], Ruslan Sergienko[5], Roy Kessous[3]

[1]Soroka University Medical Center, Givot Bar, HaDarom, [2]Soroka University Medical Center, Omer, HaDarom, [3]Soroka University Medical Center, Beer-Sheva, HaDarom, [4]Ben Gurion University, Beer-Sheva, HaDarom, [5]Ben Gurion University of the Negev, Beer-Sheva, HaDarom

OBJECTIVE: The rising global trend of women delaying childbirth has prompted investigation into the impact of advanced maternal age at first delivery on long-term maternal health. This study focuses on the influence on maternal cardiovascular diseases.

STUDY DESIGN: A retrospective population-based cohort study including all primigravida between the years 1991-2019, stratified by age (up to vs. over 35 years at delivery) was conducted. Women with cardiovascular disease prior to delivery were excluded as were those with preeclampsia. Data were collected from medical records according to pre-defined ICD-9 codes. The incidence of cardiovascular outcomes were compared and analyzed according to maternal age. Kaplan-Meier survival curves compared cardiovascular morbidity, and a Cox regression model controlled for confounders.

RESULTS: Of 43,344 first deliveries, 749 (1.7%) were over age 35. Elderly primigravida suffered from a higher incidence of hypertension (5.7% vs 1.0%, p< 0.01) as well as ischemic heart disease (IHD, 0.6% vs. 0.2%, p=0.024) and composite cardiovascular diseases (5.8% vs 1.1%, p< 0.01). The Kaplan-Meier survival curves confirmed an increased risk of cardiovascular disease among elderly primigravida (Figure, log-rank test p< 0.01). Multivariate analysis, controlling for gestational hypertension, preeclampsia, diabetes, and fertility treatment showed that elderly primigravida had an adjusted hazard ratio (aHR) of 4.935 (95%CI 3.443-7.073, P< 0.001) for long-term cardiovascular disease compared to those up to age 35 at first delivery.

CONCLUSION: Our study highlights that elderly primigravida face an elevated lifetime risk of cardiovascular disease, specifically hypertension and IHD. These findings underscore the importance of family planning decisions in relation to long-term health.

183 Is preeclampsia with low sodium levels associated with preterm birth?

Cody Goldberger[1], Isabelle C. Band[2], Rebecca M. Cohen[2], Alexis L. Zachem[2], Alexandra N. Mills[2], Kelly Wang[2], Angela Bianco[3], Chelsea A. DeBolt[4]

[1]NYU Grossman School of Medicine, New York, NY, [2]Icahn School of Medicine at Mount Sinai, New York, NY, [3]Mount Sinai Medical Center, New York, NY, [4]Mount Sinai Hospital, New York, NY

OBJECTIVE: Preeclampsia (PEC) complicates 5-10% of all pregnancies. Preeclampsia and low sodium (PALS) has been previously reported; however, additional risks of low sodium levels in these patients is not well understood. We hypothesize PALS is associated with preterm birth (PTB).

STUDY DESIGN: Single center retrospective cohort of patients with PEC and a documented sodium level during delivery admission at Mount Sinai Hospital between 2013 and 2021. Demographic, obstetric, and neonatal outcomes of patients with and without low sodium, defined as sodium < 135 mmol/L, were compared. Primary outcome was PTB < 37 weeks. Secondary outcomes include gestational age at delivery, NICU admission, neonatal hyponatremia, mode of delivery, and indication for delivery. Primary and secondary outcomes were assessed using multivariable regression models, adjusting for history of preeclampsia in prior pregnancies, chronic hypertension, multiple gestation, aspirin use, history of PTB, and subtype of PEC.

RESULTS: Patients with PALS were more likely to be nulliparous (p=0.002), have a history of PEC (p=0.04), history of PTB (p=0.048), and history of prior cesarean delivery (CD) (p=0.01). The odds of PTB < 37 weeks among individuals with PALS is 1.76 times the odds among individuals with normal sodium levels (95% CI 1.09 − 2.83, Table 1). The odds of PTB < 34 weeks is 2.09 times the odds among individuals with low sodium levels compared to individuals with normal sodium levels (95% CI 1.17 − 3.75, Table 1). A trend towards earlier gestational age at delivery (36.9 vs 37.7 weeks, p=0.06) and higher rate of NICU admission (p=0.06) was noted in the hyponatremia group compared to the normal sodium group, although these associations were not statistically significant. Patients with PALS experienced higher rates of CD (p=0.03). Neonates born to patients with PALS experienced higher odds of hyponatremia (p=0.0009).

CONCLUSION: Hyponatremia in patients with preeclampsia is associated with preterm birth < 37 weeks. These findings may prompt closer attention to sodium levels in the identification and management of patients with preeclampsia.

Table 1. Univariable and Multivariable Logistic Regression Analyses

	PEC with Normal Sodium (n=398)	PEC with Hyponatremia (n=103)	Crude* Odds Ratio (Hyponatremia vs Normal) (95% CI)	Crude* P value	Adjusted** Odds Ratio (Hyponatremia vs Normal) (95% CI)	Adjusted** P value
Primary Outcome Variable:						
Preterm birth <37 Weeks—no. (%)	161 (40.5)	53 (51.5)	1.56 (1.01, 2.41)	0.045	1.76 (1.09, 2.83)	0.02
Preterm birth <34 weeks—no. (%)	55 (13.8)	23 (22.3)	1.79 (1.04, 3.09)	0.04	2.09 (1.17, 3.75)	0.01
Preterm birth <32 weeks—no. (%)	24 (6.0)	10 (9.7)	1.68 (0.77, 3.63)	0.19	--	--
Preterm birth <28 weeks—no. (%)	3 (0.8)	3 (2.9)	3.95 (0.79, 19.87)	0.10	--	--
Secondary Outcome Variable:						
Cesarean delivery (yes vs no)—no. (%)	207 (52.0)	65 (63.1)	1.58 (1.01, 2.47)	0.045	1.67 (1.06, 2.65)	0.03
NICU admission—no. (%)	143 (35.9)	47 (45.6)	1.50 (0.97, 2.32)	0.07	1.57(0.98, 2.52)	0.06
Neonatal hyponatremia –no. (%)	56 (14.1)	30 (29.1)	2.51 (1.51, 4.18)	0.0004	2.52 (1.46, 4.35)	0.0009

*Non-adjusted odds ratio estimated with the use of a simple logistic regression model.
**The final models for Preterm Delivery was adjusted by history of preeclampsia in prior pregnancies, aspirin use in pregnancy, multiple gestations (twins, triplets, etc.), chronic hypertension, history of preterm delivery in previous pregnancy, and subtype of PEC (preeclampsia with severe features, preeclampsia without severe features, and superimposed preeclampsia). There were not enough preterm infants <28 and <32 weeks to allow for multivariable regression using proposed confounders.

184 Risk factors for postpartum refractory hypertension and consequent pregnancy outcomes

Naphtali Justman[1], Roee Goldfreind[2], chen ben-david[1], Yoav Siegler[1], Gilad Shahak[1], Gal Bachar[3], Yuval Ginsberg[4], Yaniv Zipori[5], Zeev Weiner[6], Dana Vitner[7], Nizar Khatib[8], Ron Beloosesky[9]

[1]Rambam Medical Center, Haifa, Hefa, [2]Rambam Medical Center, Haifa, HaZafon, [3]Rambam Healthcare Campus, Haifa, Hefa, [4]Rambam Health Care Campus, Haifa, HaZafon, [5]Rambam Healthcare Campus, BINYAMINA, Hefa, [6]Rambam Medical Health Campus, Haifa, HaZafon, [7]Rambam Medical Health Campus, Toronto, ON, [8]Rambam health care campus, Haifa, Israel, Acre, Hefa, [9]Harbor UCLA Medical Center, Los Angeles, CA

OBJECTIVE: To identify risk factors for refractory postpartum hypertension (RPHTN) in women with gestational hypertension (GH) and preeclampsia (PE), and to report outcomes of subsequent pregnancies.

STUDY DESIGN: A retrospective cohort study of singleton pregnancies diagnosed with GH or PE between 2006-2022, at a single tertiary care center. We compared pregnancy outcomes between RPHTN patients (requiring >1 antihypertensive treatment) and those with an adequate response. The primary outcome was the rate of severe preeclampsia in subsequent pregnancies. The secondary outcomes included subsequent pregnancy cesarean delivery (CD) rate, gestational age at delivery, and birthweight. Chi-square or fisher exact test were used to analyzed categorical variables, and student's t-test or Mann-Whiteny test were used for continuous variables. $p< 0.05$ was considered statistically significant.

RESULTS: A total of 3,735 gravidas were included in our study, 3457 in the non-RPHTN group and 278 in the RPHTN group. Women with RPHTN were more likely to be older than 35 years (31.7% vs. 24.6%, p=0.009), had a lower rate of BMI > 30 (56.8% vs. 68.7%, $p < 0.008$), and a higher rate of severe preeclampsia (54.3% vs. 12.4%, $p< 0.001$) compared with women with non RPHTN. At the subsequent pregnancy the rate of severe preeclampsia, and cesarean delivery were higher in the RPHTN group (12.2% vs. 4.3%, $p< 0.001$; 66.1% vs. 36.1%, $p< 0.001$, respectively) compared with the non RPHTN group. Birth weight was lower in the RPHTN group (3,028+682 vs. 3,216+592 grams, $p< 0.001$) compared with the non RPHTN group.

CONCLUSION: RPHTN is associated with advanced maternal age, severe preeclampsia, and low BMI. Subsequent pregnancies in RPHTN patients are linked to higher rates of severe preeclampsia, CD, and low birthweights. Vigilant monitoring in subsequent pregnancies is recommended

Table 1. Comparison of baseline demographic characteristics and pregnancy outcomes of women with non-refractory versus refractory hypertension.

		Variable	Non-Refractory HTN n= 3548	Refractory HTN n= 284	P-Value

185 A novel, validated calculator for predicting chorioamnionitis in laboring patients

Helen B. Gomez Slagle[1], Tetsuya Kawakita[2], Yaneve N. Fonge[3], Richard Caplan[4], Anthony C. Sciscione[5], Matthew Hoffman[6]

[1]Columbia Irving Medical Center, New York, NY, [2]Eastern Virginia Medical School, Norfolk, VA, [3]University of Pittsburgh, Pittsburgh, PA, [4]Christiana Care iREACH, Newark, DE, [5]Delaware Center for Maternal & Fetal Medicine of Christiana Care, Inc., Newark, DE, [6]Christiana Care Health Systems, Newark, DE

OBJECTIVE: Chorioamnionitis is associated with neonatal morbidity and infection-related mortality, but our ability to predict intrapartum infection is limited. We sought to derive and validate a prediction model for chorioamnionitis among patients presenting to labor and delivery at term.

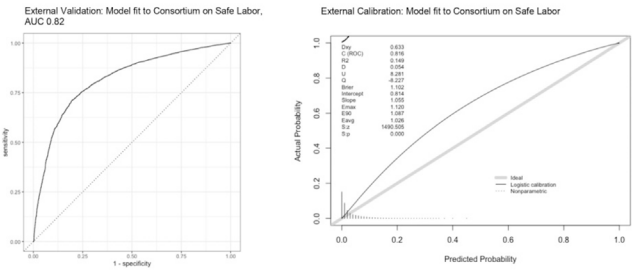
STUDY DESIGN: This was a planned secondary analysis of a large cohort study from 2014 through 2018 at an academic tertiary care center. To derive a prediction model for chorioamnionitis, we limited our analysis to full-term (≥37 weeks) patients with a singleton gestation undergoing labor induction. Both nulliparous and multiparous patients were included. Patients with a planned cesarean delivery, fever on admission, or missing data were excluded. The model was derived using multivariable logistic regression. Refinement of the prediction model with internal calibration was performed. External validation was performed utilizing a publicly available database (Consortium on Safe Labor) and applying the same inclusion and exclusion criteria.

The discriminative power of each model was assessed using a bootstrap, bias-corrected area under the curve.

RESULTS: The chorioamnionitis rates in the derivation and external validation groups were: 5% (1,005/19,966) and 5.8% (n = 3,005/52,171), respectively. In multivariable modeling, maternal age, nulliparity, gestational age, smoking status, group B streptococcus colonization, hours ruptured, number of cervical exams, length of labor, epidural use, internal monitoring, and meconium were significantly associated with infection. A calculator was created and externally validated with an area under the curve of 0.82 (95% confidence interval, 0.81-0.82). External validity was further confirmed with a calibration intercept of 0.81.

CONCLUSION: This is the first infection calculator created and validated for the prediction of developing chorioamnionitis in patients undergoing induction of labor at term. This calculator can be used to augment patient counseling and guide intrapartum infection surveillance in laboring patients.

Figure 1: Receiver Operating Curve of Internal and External Validation to Predict Intrapartum Chorioamnionitis



186 A randomized trial of spaced versus massed simulation in forceps assisted vaginal deliveries

Andrew Greene[1], Matthew Zuber[1], Joshua F. Nitsche[1], Mark Newman[1], Brian C. Brost[2]

[1]Wake Forest University School of Medicine, Winston-Salem, NC, [2]University of Kansas Medical Center, Kansas City, KS

OBJECTIVE: We tested the effects of clustered versus spaced training sessions to teach trainees forceps assisted vaginal delivery (FAVD) and hypothesized that spaced training sessions would lead to superior retention of skill. We used a commercially available pelvic trainer (Lucy's Mum, MODEL-med®) and measured objective structured assessment of technical skills (OSATS) scores at >1 month post-intervention.

STUDY DESIGN: This was a randomized controlled trial of clustered versus spaced FAVD simulation sessions. Thirty-five (n=35) participant enrollment gave 80% power to detect a difference of OSATS score of 6. Trainees and medical providers who do not independently perform FAVD were randomized in blocks to a single learning session (30 minutes of hands-on teaching with a model; n=17) or three individual learning sessions (10 minutes each x3; n=18) spaced one week apart. Participants completed an online module introducing FAVD and completed skillset questionnaires pre- and post- simulation. We used a chest-mounted GoPro™ camera to capture point-of-view technique in order to blind expert adjudicators to participants' identities and blinded footage was used to grade average OSATS scores.

RESULTS: Both clustered and spaced simulation training led to improved FAVD OSATS score post-intervention (4.8 vs. 5.9), however the median change was not different between randomization group (Wilcoxon Rank Sum p= 0.78). Both simulation groups had higher confidence to apply forceps, perform safety checks, and independently/safely perform FAVD (t test p< 0.05).

CONCLUSION: We describe a novel use of point-of care video and simulator application to improve FAVD simulation training. OSATS scores and provider self-assessment of training improved regardless of clustered vs. spaced simulation sessions.

187 Development of predictive model for preterm dirth using machine learning with US CDC data

Jessica Gulati[1], Gloria Khafif[1], Rosalie DePaola[2], Maria Teresa Benedetto[2], Teresa Cheon[2], Mio Sawai[2], Christine Yang[2], Yuzuru Anzai[3]

[1]University of Chicago, Chicago, IL, [2]Lenox Hill Hospital, New York City, NY, [3]Lenox Hill Hospital, New York, NY

OBJECTIVE: This study aims to create a prognostic model for predicting preterm birth using automated machine learning algorithms.

STUDY DESIGN: Using US CDC natality data (2016-2019), a multiple regression analysis identified significant risk factors for preterm birth. These factors included gestational diabetes, gestational hypertension, pre- and during pregnancy smoking status, maternal age, multifetal gestation, BMI, prepregnancy hypertension, maternal race, prepregnancy diabetes, previous preterm births, interpregnancy interval, insurance type, and maternal presence of STIs. Using 756,288 randomly selected individuals from 2018-2019, two sets of multiple logistic regression (LR) and decision tree (DT) models were generated to predict preterm birth: early screening (in first trimester) and late screening (in third trimester). The early screening model excluded risk factors that had a later onset in pregnancy. For the LR models, we set the threshold to 10% probability, reflecting the national preterm birth rate. An 80-20 train-test split was performed to validate the model.

RESULTS: The DT and LR models performed similarly with accuracies of > 75%. However, the LR models had greater predictive power with F1 (harmonic mean of positive predictive value and sensitivity) scores of 0.333 for early and 0.304 for late screening compared to 0.229 and 0.237, respectively, for the DTs (Table 1). The early screening LR model (threshold = 0.1) had an accuracy of 83.5% and the late screening LR model (threshold = 0.1) had an accuracy of 75.1%. The LR models can also calculate an individual probability percentage for preterm birth based on the risk factors inputted.

CONCLUSION: The prognostic models were trained on a large, diverse national dataset, affirming their strength. Their high negative predictive value, high specificity and accuracy, and the LR models' ability to output a probability for preterm birth support that the

models can complement physician expertise in determining risk for preterm birth. Their limitations include low sensitivity and low positive predictive value, necessitating further model development.

188 Adverse pregnancy outcomes associated with hepatitis C in pregnancy: a population-based study

Moti Gulersen[1], Erez Lenchner[2], Amos Grunebaum[3], Frank A. Chervenak[3], Eran Bornstein[4]

[1]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA, [2]New York University Rory Meyers College of Nursing, New York, NY, [3]Zucker School of Medicine at Hofstra of Northwell, New York, NY, [4]Lenox Hill Hospital, New York, NY

OBJECTIVE: The prevalence of hepatitis C virus (HCV) infection during pregnancy in the United States (US) continues to increase at an alarming rate. Data regarding the association of HCV with adverse pregnancy outcomes are limited. Therefore, we set out to evaluate adverse pregnancy outcomes associated with HCV during pregnancy in a current US population.

STUDY DESIGN: Retrospective analysis of the US Centers for Disease Control and Prevention Natality Live Birth database (2016-2021). All live births were eligible for inclusion. Deliveries with missing data on HCV were excluded. The rates of several adverse pregnancy and neonatal outcomes were compared between two groups: pregnancies complicated by maternal HCV infection and those without HCV. Multivariable logistic regression was performed to adjust outcomes for potential confounders. Data were presented as adjusted odds ratios (aOR) with 95% confidence intervals (95% CI) and statistical significance set at $P < 0.05$.

RESULTS: Of the 22,604,938 included, 107,761 (0.48%) were complicated by maternal HCV infection. Adverse pregnancy and neonatal outcomes associated with HCV during pregnancy are presented in the Table.

CONCLUSION: Based on this large US population cohort, HCV infection during pregnancy is associated with an increased risk of several adverse pregnancy outcomes and neonatal complications. Specifically, the risk of preterm birth, congenital malformations, low birthweight, NICU admission, low Apgar score, need for ventilation, and antibiotics for suspected neonatal sepsis were significantly higher in pregnancies complicated by HCV. Understanding the impact of HCV on pregnancy outcomes in a current US population is important to better manage and optimize care for these pregnancies.

Table. Adverse pregnancy and neonatal outcomes associated with HCV during pregnancy.

	HCV Group (n=107,761)	No HCV Group (n=22,497,177)	aOR (95% CI)
Preterm birth < 37 weeks	20,406 (18.9)	2,250,590 (10.0)	1.99 (1.96-2.03)
Preterm birth < 32 weeks	4,058 (3.8)	459,893 (2.0)	1.86 (1.80-1.93)
Hypertensive disorders of pregnancy	7,334 (6.8)	1,442,413 (6.4)	1.07 (1.04-1.09)
Gestational diabetes	5,928 (5.5)	1,589,770 (7.1)	0.93 (0.90-0.95)
Congenital malformations	688 (0.6)	77,274 (0.3)	1.67 (1.53-1.81)
Low birthweight	18,725 (17.4)	1,848,423 (8.2)	2.40 (2.35-2.44)
5-minute Apgar < 7	3,703 (3.4)	458,360 (2.0)	1.67 (1.61-1.73)
NICU admission	25,752 (23.9)	2,041,241 (9.1)	3.06 (3.01-3.11)
Immediate ventilation	11,214 (10.4)	1,049,418 (4.7)	2.08 (2.04-2.13)
Prolonged ventilation	4,729 (4.4)	360,002 (1.6)	2.35 (2.27-2.43)
Administration of antibiotics for suspected neonatal sepsis	6,256 (5.8)	471,499 (2.1)	2.56 (2.48-2.63)

Data presented as n (%).
Models adjusted for maternal age, body mass index, race or ethnic group, history of preterm birth, chronic hypertension, and pregestational diabetes.

189 Pre-labor sonographic assessment of fetal station as a predictor of cesarean delivery

Dillon Gurciullo[1], Noel Cercizi[2], Jessica Gulati[2], Gloria Khafif[2], Maria Teresa Benedetto[3], Teresa Cheon[3], Mio Sawai[3], Yuzuru Anzai[4]

[1]Lenox Hill Hospital, Department of Obstetrics and Gynecology, New York, NY, [2]University of Chicago, Chicago, IL, [3]Lenox Hill Hospital, New York City, NY, [4]Lenox Hill Hospital, New York, NY

OBJECTIVE: This study aims to determine if sonographic evaluation of fetal station before the onset of labor has an association with mode of delivery.

STUDY DESIGN: This prospective cohort study enrolled pregnant patients who are nulliparous, singleton, with vertex presentation and no contraindication to labor. IRB approval was obtained. Transperineal sonography was performed after 36 weeks before the onset of labor with patients' written consent. We measured angle of progression (angle between the long axis of pubic bone and fetal skull) and distance (distance between perineum and fetal skull). Additional data included in the analysis were maternal age, height, prepregnancy weight, weight gain, BMI, birth weight, and mode of delivery. Multivariate and univariate logistic regression analyses were run on SPSS. A decision tree model with a train-test split of 0.5 was created using python machine learning algorithms.

RESULTS: The study enrolled 220 patients, but 4 Cesarean deliveries (CD) were excluded due to fetal status prior to labor. 216 patients remained, with 18 CD, 149 spontaneous vaginal deliveries, 46 forceps assisted deliveries, and 2 vacuum assisted deliveries. Multivariate logistic regression showed distance was the most significant factor in determining CD ($p = 0.013$), followed by birth weight ($p = 0.031$) and height ($p = 0.034$). The decision tree model created using these three variables had an accuracy of ~90% with a specificity of 98% and sensitivity of 11%. Figure 1 displays the correlation between distance and CD.

CONCLUSION: Short distance was strongly associated with vaginal delivery, consistent with a lower station of the fetal head in the pelvis, indicating low risk of inlet or mid-pelvis dystocia. The CD rate in this study is lower than the national average. However, since most CDs in this series were due to arrest disorder, this data may be better suited to characterize the effect of distance on mode of delivery. This measurement could provide clinically useful information to physicians. A larger dataset can further validate this analysis and allow for a more precise predictive model.

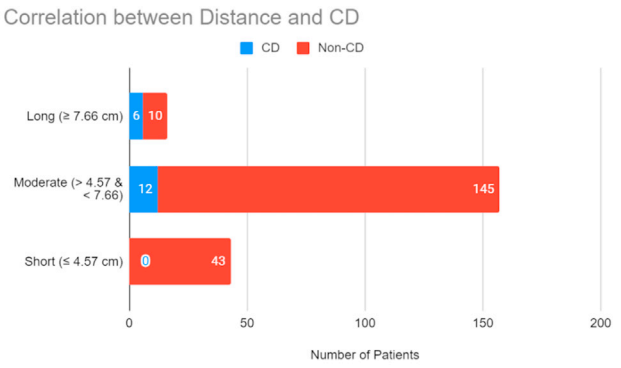

Figure 1: Zero of 43 patients with a distance less than 4.57 cm had CD, 12 out of 157 patients with a distance between 4.57 and 7.66 cm had CD, six out of 16 patients with a distance more than 7.66 cm had CD. There is a positive correlation between distance and proportion of CDs.

190 Modulation of dysbiotic vaginal complications by cervical mucus revealed in linked human-vagina and cervix-chips

Ola Gutzeit, Aakanksha GULATI, Zohreh IZADIFAR, Anna STEJSKALOVA, Hassan RHBINY, Justin COTTON, Bogdan BUDNIK, Sanjid SHAHRIAR, Girija GOYAL, Abidemi JUNAID, Donald INGBER

Wyss Institute, Harvard Medical School, Boston, MA; on behalf of the Bill and Melinda Gates Foundation and the Wyss Institute for Biologically Inspired Engineering

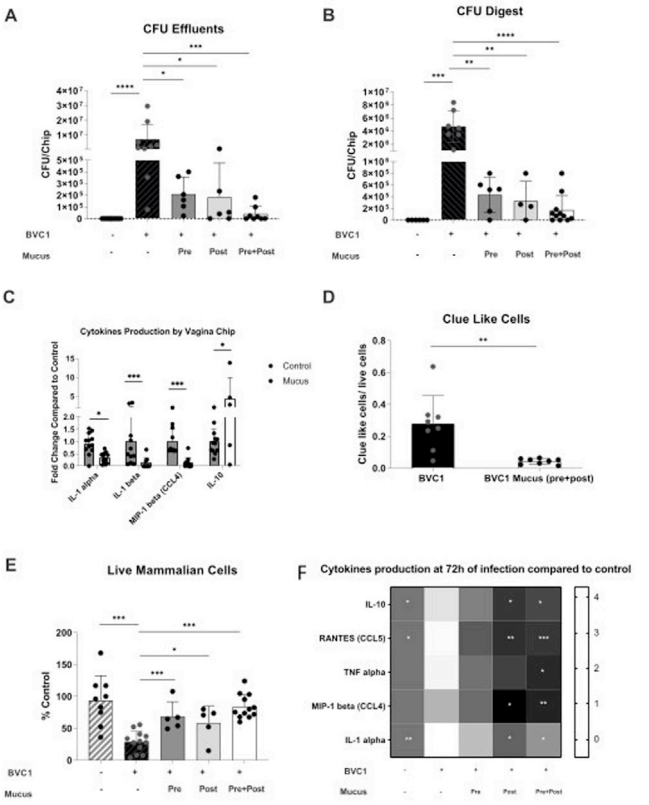
OBJECTIVE: Background: The cervicovaginal mucus that coats the upper surface of the vaginal epithelium is thought to serve as a selective barrier that helps to clear pathogens, however, its role in modulating the physiology and pathophysiology of the human vagina is poorly understood. Bacterial vaginosis (BV), a common disease of the female reproductive tract that increases susceptibility to sexually transmitted infections, pelvic inflammatory disease, infertility, preterm birth, and both maternal and neonatal infections is characterized by the presence of a wide array of strict and facultative anaerobes, often including *Gardnerella vaginalis*.

OBJECTIVE: To assess the role of cervical mucus in preventing dysbiosis-associated complications and preserving vaginal health.

STUDY DESIGN: To better understand the role of cervicovaginal mucus in vaginal health, we used human organ-on-a-chip (Organ Chip) microfluidic culture technology to analyze the effects of cervical mucus produced in a human Cervix Chip when transferred to a human Vagina Chip BV model. Both chips are lined by primary human organ-specific (cervical or vaginal) epithelium interfaced with organ-specific stromal fibroblasts.

RESULTS: Our data show that mucus-containing effluents from Cervix Chips protect Vagina Chips from inflammation and epithelial cell injury caused by co-culture with dysbiotic microbiome containing *G. vaginalis*. Proteomic analysis of proteins produced by the Vagina Chip following treatment with the Cervix Chip mucus also revealed a collection of differentially abundant proteins that may contribute to the vaginal response to dysbiotic microbiome, which could represent potential diagnostic biomarkers or therapeutic targets for management of BV.

CONCLUSION: This study highlights the importance of cervical mucus in control of human vaginal physiology and pathophysiology, and demonstrates the potential value of Organ Chip technology for studies focused on health and diseases of the female reproductive tract.



191 Intersectionality of individual- and neighborhood-level adverse social determinants of health in pregnancy

Jameaka L. Hamilton[1], William A. Grobman[1], Jiqiang Wu[2], Courtney Denning-Johnson Lynch[1], Kartik Venkatesh[2]

[1]The Ohio State University, Columbus, OH, [2]Ohio State University, Columbus, OH

OBJECTIVE: Individual- and neighborhood-level social determinants of health (SDOH) typically have been assessed separately in pregnancy, and their relationship to one another remains uncertain. We examined the intersectionality of individual- and neighborhood-level SDOH in early pregnancy.

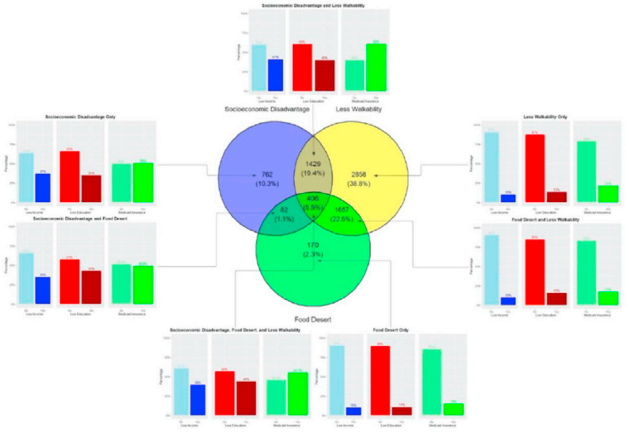
STUDY DESIGN: A secondary analysis from the prospective cohort Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-To-Be. Participant home addresses in the first trimester were geocoded at the census-tract level. We compared the overlap in frequency of three individual-level adverse SDOH (low income, low education, and Medicaid insurance) with three validated neighborhood-level adverse SDOH measures (socioeconomic disadvantage per the highest tertile by the 2015 Area Deprivation Index, food desert by the USDA *Food Access Research Atlas*, and less walkability by the EPA National Walkability Score).

RESULTS: Of 9,588 nulliparous individuals, individual-level adverse SDOH (low income, low education, and Medicaid insurance) were more prevalent among the 6% (406/7,282) of individuals who lived in a neighborhood with all three adverse SDOH (socioeconomic disadvantage, food desert, and less walkability) (low income: 39%;

low education: 44%; Medicaid: 55%) compared with the individuals who lived in neighborhoods with either two (43% of the population: low income: 22%; low education: 27%; Medicaid: 37%) or one adverse neighborhood SDOH (51% of the population: low income: 14%; low education: 17%; Medicaid: 27%) ($p< 0.001$ for all).

CONCLUSION: Among nulliparous individuals, individual-level adverse SDOH factors increased in frequency as individuals lived in neighborhoods with a greater number of neighborhood-level adverse SDOH. Approaches that identify both individual- and neighborhood-level adverse SDOH and relate these to pregnancy outcomes are needed.

Figure. Venn diagram of the relationship between individual- and neighborhood-level adverse social determinants of health in pregnancy



192 Labor length differences with 30cc versus 60cc Foley inflation when combination ripening methods are utilized

Rebecca F. Hamm[1], Jennifer A. McCoy[2], Antoilyn Nguyen[3], Lisa D. Levine[3]

[1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA; for the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

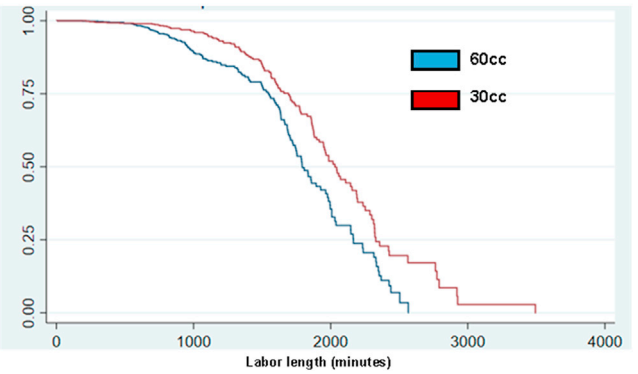
OBJECTIVE: Data supports shorter time to delivery with 60cc vs. 30cc Foley inflation for labor induction (IOL). Similarly, combination cervical ripening has a shorter time to delivery compared to single-agents. To date, no study has evaluated incremental benefit of higher Foley volume in the setting of combination ripening methods.

STUDY DESIGN: This is a secondary analysis of a prospective cohort study evaluating standardized IOL management at 2 sites. Any cervical ripening method could be used. Site#1 used 60cc Foley inflation, while Site#2 used 30cc. For this analysis, patients were included if they underwent a term ($\geq$37 week) IOL from 2020-2022 with a singleton, intact membranes, and received combination methods of Foley and misoprostol or oxytocin. Standardized IOL included regular cervical exams, amniotomy if $\geq$4cm, and active management of dystocia. 1:1 propensity score matching balanced baseline parameters (age, race/ethnicity, insurance, BMI, parity, and IOL indication). Time-to-event regression analyses for labor length, censored for CD, was modeled with a Cox proportional hazard model. Secondary outcomes included CD and maternal/neonatal morbidity.

RESULTS: Of 4295 inductions, 2117 (49.3%) utilized combined cervical ripening methods. After propensity score matching, 1480 were included. Even in the context of combined ripening and standardized IOL, Foley inflation to 60cc was associated with 3-hour shorter labor than 30cc (14.6h[10.4-21.3] v. 17.7h[12.4-24.4], $p< 0.001$). When censored for CD, patients who received 60cc Foley inflation delivered 70% faster than those who received 30cc (Hazard Ratio, HR 1.73[1.36-2.21]). 60cc inflation was also associated with reduced time to amniotomy (6.6h[4.5-9.8] v. 9.1h[6.4-12.4], $p< 0.001$). There was no difference in CD (18.9% v. 17.7%, $p=0.55$), maternal morbidity (15.5% v. 18.0%, $p=0.21$), or neonatal morbidity (3.4% v. 2.6%, $p=0.36$).

CONCLUSION: Even when using combined cervical ripening methods, 60cc Foley inflation is associated with reduced time to delivery as compared to 30cc without increasing morbidity, and should be considered to optimize labor length.

Figure: Kaplan-Meier curve of labor length by Foley inflation volume, censored for cesarean



193 Implementation of a standardized protocol for labor induction: a type I hybrid effectiveness-implementation trial

Rebecca F. Hamm[1], Janice A. Benny[2], Rinad S. Beidas[3], Knashawn H. Morales[2], Sindhu K. Srinivas[2], Samuel Parry[2], Lisa D. Levine[2]

[1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Northwestern University, Chicago, IL; for the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: Retrospective data have shown standardization of induction of labor (IOL) may reduce cesarean delivery (CD). Here, we evaluated the impact of prospectively implementing a standardized IOL protocol on obstetric outcomes.

STUDY DESIGN: This type I hybrid effectiveness-implementation trial compared 2 years before (PRE) and 2 years after (POST) implementation of a standardized IOL protocol at 2 sites (2018-2022). The protocol had 8 components and recommended active management of labor, frequent cervical exams, and amniotomy by first exam >=4cm. All singletons $\geq$37 weeks with intact membranes requiring cervical ripening were eligible; prior CD was excluded. The primary effectiveness outcome was CD. Secondary effectiveness outcomes included labor length, chorioamnionitis, and maternal/neonatal morbidity. Poisson regression with robust error variance was used to calculate adjusted relative risks (aRR), with planned stratified analyses by site and parity. Implementation outcomes included fidelity to each protocol component. Feedback on protocol fidelity was distributed to site clinicians POST-implementation every 3 months.

RESULTS: 8509 patients were included (PRE: n=4214, POST: n=4295). Patients in the POST group had higher BMI and age, more hypertension, less favorable cervices, and differed in IOL indication.

There was no difference in CD (PRE: 21.6% v. POST: 21.8%, p=0.85), even when controlling for confounders (aRR 0.99 95%CI [0.90-1.09]; Table). There were no differences in labor length, chorioamnionitis, or neonatal morbidity. Maternal morbidity decreased PRE to POST (21.1% v. 18.0%, p< 0.001; aRR 0.83 95%CI[0.76-0.92]). Stratified results were similar. POST-implementation, fidelity to 4 of 8 protocol components increased significantly, evidenced by more frequent cervical exams, earlier dilation at amniotomy, higher oxytocin doses, and increased IUPC use.

CONCLUSION: Despite increasing standardization of active IOL management, no significant difference in CD was found. The observed decrease in maternal morbidity was unlikely to be a result of the IOL protocol without a change in CD or labor length.

Table: Demographic characteristics and outcomes compared pre- to post-implementation of a standardized labor induction protocol at 2 labor and delivery sites (2018-2022)

194 Fetal fraction amplification dramatically increases PPV for 22q11.2 deletion syndrome in prenatal cell-free DNA screening

Carly Hammer[1], Summer Pierson[1], Devika Chawla[1], Sarah Ratzel[1], Katie Johansen Taber[1], Dale Muzzey[2]

[1]Myriad Genetics, Inc., Salt Lake City, UT, [2]Myriad Gentics, Inc., Salt Lake City, UT

OBJECTIVE: 22q11.2 deletion syndrome occurs in approximately 1 in 2,000-4,000 births. Prenatal cell-free DNA screening (pcfDNA) can detect fetuses affected by deletions as small as 2.5 Mb. Fetal fraction amplification (FFA), which has been shown to yield an average fetal fraction (FF) in excess of 20%, may further enhance pcfDNA detection of these deletions. Positive predictive values (PPV) of pcfDNA screening for 22q11.2 microdeletion have been reported between 20%-50%. Here, we sought to describe the impact of FFA on the PPV of 22q11.2 microdeletion screening using a whole-genome sequencing (WGS)-based pcfDNA platform.

STUDY DESIGN: We retrospectively analyzed data from patients who underwent WGS-based pcfDNA screening with FFA (Prequel™, Myriad Genetics, Inc.) between 8/20-10/22. For screen-positive cases, pregnancy outcome data were requested via a routine HIPAA-compliant process. All samples with diagnostic confirmation were used to calculate PPV, defined as: true positives/(true positives + false positives). Confidence interval (CI) was estimated using the Exact Binomial Test.

RESULTS: Complete outcomes were obtained for 54 cases that screened positive for 22q11.2 microdeletion; 21 underwent molecular diagnostic testing. All 21 were confirmed as true positives, for a PPV of 100% (21/21; 95% CI 83.9%-100%). Among the 33 cases that declined molecular confirmation, 17 had ultrasound findings that are either strongly or moderately associated with 22q11.2 deletion syndrome (e.g., cardiac defects, polyhydramnios, skeletal defects, intrauterine growth restriction). The average FF of true positive samples was 23.0%. For screen-positive patients who declined diagnostic testing, the average FF was 21.6%.

CONCLUSION: The increased FF levels conferred by FFA yield a PPV for 22q11.2 microdeletion higher than any previous studies have reported, and comparable to that for common autosomal trisomies. Because respective FF levels were comparable in patients with and without diagnostic confirmation, PPV is likely to be comparable in patients with and without diagnostic confirmation.

195 Endocannabinoid effects on myometrial expression of contraction associated proteins

Zaid Haque, Jie Zhang, Saraswatie Rambaran, Chad Grotegut, Melissa L. Kozakiewicz

Wake Forest University School of Medicine, Winston-Salem, NC

OBJECTIVE: The endocannabinoid system (ECS) is an endogenous cell-signaling system that plays a significant role in embryo development, implantation, and early pregnancy maintenance. Animal models indicate a potential role of the ECS in the initiation of labor. The endogenous cannabinoid, anandamide, rises in human plasma prior to the onset of labor. The objective of this study was to evaluate the effects of anandamide on the myometrial expression of the contraction associated proteins connexin-43 (Cx 43) and oxytocin receptor (OTR).

STUDY DESIGN: Using an immortalized myometrial cell line derived from term human pregnancy myometrium (PHM1-41), the effects of anandamide treatment on Cx 43 and OTR expression were determined. Cells were treated with methanandamide, a more stable analogue of anandamide, for various time intervals ranging from 0 to 20 hours. Cellular expression of Cx 43 and OTR was determined using western blot and real-time quantitative polymerase chain reaction (qPCR). Experiments were repeated using a cannabinoid type 1 receptor (CB_1R) antagonist to determine receptor selectivity.

RESULTS: A significant increase in Cx 43 mRNA was detected after 8 (p=0.01), 12 (p=< 0.01), 16 (p=< 0.01), and 20 (p=< 0.01) hours of methanandamide exposure when compared to the no-treatment control. With the addition of a CB_1R inhibitor (SR141716A), a significant increase in Cx 43 mRNA was still detected after 12 (p=< 0.01), 16 (p=< 0.01), and 20 (p=< 0.01) hours of methanandamide treatment. There was no significant difference in OTR mRNA with methanandamide treatment. There was no significant difference in the protein expression of Cx 43 or OTR using western blot.

CONCLUSION: Methanandamide treatment of myometrial cells results in an increase in Cx 43 mRNA expression. Surprisingly, this effect does not appear to be CB_1R mediated. Additional studies are needed to examine the potential signaling pathways through which this occurs.

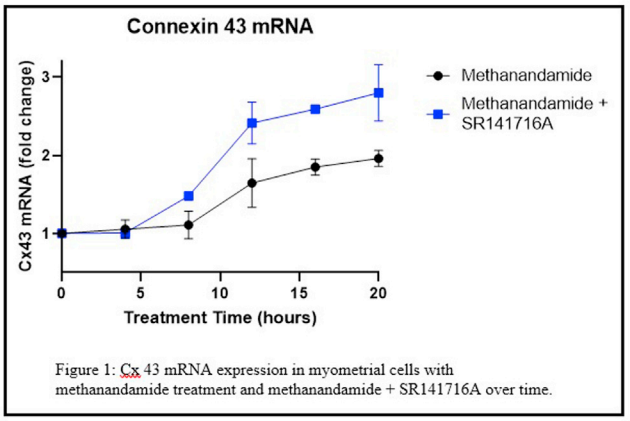

Figure 1: Cx 43 mRNA expression in myometrial cells with methanandamide treatment and methanandamide + SR141716A over time.

196 Association between trunk muscle mass and persistent postpartum low back and pelvic pain

Katsuhito Hayashi[1], Megumi Koga[1], Kotaro Takazawa[2], Ichiro Yasuhi[1]
[1]NHO Nagasaki Medical Center, Omura-City, Nagasaki, [2]Shinjuen Hospital, Saikai, Nagasaki

OBJECTIVE: Low back and pelvic pain (LBPP) is commonly experienced during pregnancy and the postpartum period, accounting for 15% of chronic lumbar pain in women unrelated to pregnancy. Although the association of LBPP with reduced trunk muscle mass (TMM) are considered out of pregnancy, few studies have examined this association in relation to pregnancy and the postpartum period, especially regarding persistent postpartum LBPP. The aim of the study was to investigate whether early postpartum TMM was associated with LBPP four months after delivery.

STUDY DESIGN: This prospective observational study recruited singleton pregnant women with LBPP at 35 weeks' gestation and measured their TMM using a body composition analyzer (Tanita MC780A-N) four weeks after delivery. Women who still experienced LBPP at four months postpartum were defined as having persistent postpartum (pp)-LBPP. Risk factors associated with pp-LBPP were identified among baseline and perinatal characteristics, including age, parity, body mass index, pre-pregnancy history of LBPP and physical activity, delivery methods, and breastfeeding. We investigated whether TMM was associated with pp-LBPP after adjusting these risk factors.

RESULTS: Among 209 women with LBPP during pregnancy, 101 women (48%) had pp-LBPP. In a multivariate analysis, age (adjusted odds ratio 1.10/year [95% confidence interval 1.03-1.17/year]), primipara (2.40 [1.21-4.75]), cesarean section (3.39 [1.51-7.64]), and the lack of pre-pregnancy athletic activity (2.04 [1.01-4.12]) were identified as independent risk factors associated with pp-LBPP. TMM was significantly higher in women with pp-LBPP than in women without pp-LBPP (19.5±1.2 vs 19.1±1.1 kg, $p < .001$), and was not found to be associated with pp-LBPP in the multivariate model.

CONCLUSION: In this prospective study, women with traditional risk factors, including older age, primiparity, lack of pre-pregnancy athletic activity, and cesarean section appear to be at high risk for developing pp-LBPP. However, no association was found between early postpartum TMM and pp-LBPP.

197 Is umbilical artery Doppler improvement following steroid administration associated with improved fetal growth?

Jaclynne Hedge[1], Bree A. Goodman[2], Jeffrey Dicke[1], Diana Gray[2], Roxane M. Rampersad[3], Nandini Raghuraman[4], Katherine H. Bligard[4]
[1]Barnes-Jewish Hospital, St. Louis, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO, [4]Washington University School of Medicine in St. Louis, St. Louis, MO

OBJECTIVE: Betamethasone (BMZ) is given for fetal growth restriction (FGR) with abnormal umbilical artery Doppler (UAD) velocimetry. Improvement of UAD can be seen after BMZ, but the impact on fetal growth and other outcomes is unclear. We tested the hypothesis that UAD improvement after BMZ is associated with improved fetal growth.

STUDY DESIGN: This was a retrospective cohort study of pregnancies with FGR from 2014 to 2020 with abnormal UAD between 240-336 weeks gestational age (GA). Abnormal UAD included elevated (pulsatility index >95%ile), absent end diastolic flow (EDF), or reversed EDF. We included patients who received BMZ within 1 week of abnormal UAD and had growth assessments performed before and after BMZ administration. Improvement was defined as any improvement in a category of UAD within 2 weeks of BMZ. The primary outcome was small-for-GA (SGA) at birth. Secondary outcomes included growth trends, GA at delivery, and birthweight. Outcomes were compared between patients with and without UAD improvement after BMZ. Sensitivity analyses among those with sustained and non-sustained UAD improvement and subgroup analysis of absent or reversed EDF were performed.

RESULTS: Of 102 pregnancies, UAD improved in 58 (59.1%) after BMZ. There was no difference in SGA between the two groups. The initial growth velocity (rate of change in fetal weight (EFW) immediately before and after BMZ administration) was higher in patients with UAD improvement; however there was no difference in final growth velocity (rate of change in EFW from BMZ administration to birth) between groups. Patients with improved UAD delivered at a significantly later GA with higher birthweight. The rate of SGA was similar between those with sustained vs non-sustained UAD improvement and in patients with absent or reversed EDF.

CONCLUSION: UAD improved in more than half of FGR cases after BMZ and was associated with initial improvement in growth velocity, but this improvement was not sustained over pregnancy. While UAD improvement after BMZ appears to be associated with improved pregnancy outcomes, the impact on growth patterns seems transient.

All patients			
Outcomes	UAD improved (n=58)	UAD not improved (n=44)	P-value

198 Impact of pregnancy on ceftriaxone pharmacokinetics and treatment of syphilis: physiologic-based population PK modeling approach

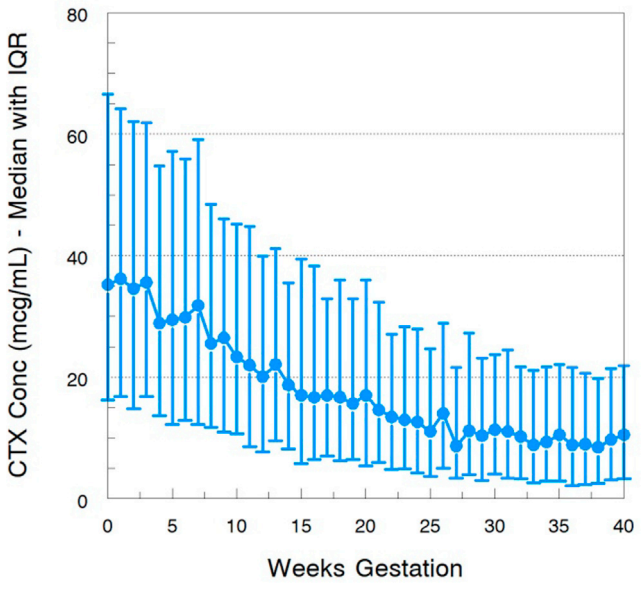
Cassandra Heiselman[1], Jeremiah Momper[2], Sharon Nachman[3], Patrick Jean-Philippe[4], Edmund Capparelli[2]
[1]Stony Brook Medicine, Stony Brook, NY, [2]UC San Diego, San Diego, CA, [3]Renaissance School of Medicine at Stony Brook University, Stony Brook, NY, [4]NIAID, NIH, Rockville, MD, on behalf of the IMPAACT (International Maternal Pediatric Adolescent AIDS Clinical Trials) Network

OBJECTIVE: Cases of congenital syphilis are rapidly rising. For pregnant women, penicillin G benzathine is the only endorsed treatment option; however, global shortages of penicillin are restricting supply to critical populations. Ceftriaxone (CTX) is a WHO alternative treatment, with limited data on pharmacokinetics (PK) and optimal dosing in pregnancy. Our objective was to characterize expected CTX PK changes during pregnancy using a physiologic-based population PK (PopPK) model to optimize CTX dosing for syphilis treatment.

STUDY DESIGN: A PopPK CTX model was developed for simulations from existing literature (Pollack 1982, Garot 2011). These limited CTX PK data in pregnancy were leveraged (Bourget 1993, Poavic 2007) with established PopPK pregnancy models that utilize a large repository of anatomic, physiologic, and biologic parameters that change with gestational age, e.g., plasma volume, GFR (Dallmann 2018). Steady-state CTX exposures were predicted in pregnant and non-pregnant persons with different dosing strategies (1g vs 2g IV/IM; q24h, q48h, vs q72h).

RESULTS: With all dosing strategies, concentrations were highly variable with lower CTX concentrations in the 3rd trimester compared to non-pregnant persons. Following a 1g IM q24h regimen, as gestation increased, the CTX trough decreased by 58% to 11.7 mcg/mL, 5.9-21.5 (median, IQR) at 40 wks gestation (Figure). The predicted concentration of unbound CTX trough also decreased quicker than in non-pregnancy to < 1% of non-pregnant adult levels due to non-linear binding. Cord blood troughs were predicted to be only 22% of non-pregnant plasma trough levels. Increasing the CTX dose to 2g did not compensate for the changes between pregnant and nonpregnant states nor allow for infrequent dosing.

CONCLUSION: There is a significant decrease in CTX exposure to the mother and fetus in the 3rd trimester regardless of dosing strategy. Currently, effective CTX dosing in vivo is unknown against T. *pallidum* in pregnancy, however late pregnancy may require different dosing approaches than non-pregnant persons to maintain adequate concentration in the mother and fetus.



199 Preterm low segment transverse cesarean delivery and the risk of uterine rupture in subsequent delivery

Shira Fridman Lev[1], Sarit Helman[1], Orna Reichman[2], rivka Farkash[1], Sorina Grisaru-Granovsky[1], Maayan Bas Lando[1]
[1]Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim, [2]Shaare Zedek Medical Center, affiliated with the Hebrew University Medical School of Jerusalem, Jerusalem, Israel

OBJECTIVE: Background: Preterm cesarean delivery (CD) is a common mode of preterm delivery and most often recorded as a low segment transverse uterine section. We hypothesized that the reduced uterine size, non-vertex presentation and absence of labor process are associated with a poorly developed lower uterine segment, leading to misidentification of the lower segment, and thus posing an increased risk for uterine rupture (UR) in subsequent delivery. The literature is conflicting regarding this question, and there is need for further research.

STUDY DESIGN: Methods: A retrospective cohort study. Women after a previous primary preterm low segment CD (pCD) between 24-32 weeks with subsequent delivery were compared with women who had primary term low segment cesarean section LSTCS with subsequent delivery. Primary outcome: UR, defined as full thickness uterine wall defect. Secondary outcomes: severe maternal, fetal, and neonatal morbidities. Statistics: Descriptive, means±SDs, medians+IQR. Comparisons: chi-square, Fisher's exact test, Mann-Whitney Test.

RESULTS: Study cohort included 5340 women, 186 women in the pCD group and 5145 in the control group. The average gestational age at the first delivery was 28 weeks in pCD compared to 39 weeks in the control group. Women in the pCD group had more hypertensive disorders during their first delivery (20.4% vs. 2.5%; p< 0.001). There were no significant differences in the incidence of uterine rupture at subsequent delivery between groups (0% vs 0.5% p NS). At the subsequent delivery There were more preterm deliveries in the pCD group (19.9% vs. 4.7%; p< 0.01) and more successful vaginal deliveries (86.1% vs 77.3%; p=0.015).

CONCLUSION: Women with a previous preterm LSTCS delivery, did not exhibit an increased risk of uterine rupture in subsequent delivery. Considering these results, it might be reasonable to offer trial of labor to these patients.

201 Digital health utilization during pregnancy and the likelihood of preterm birth

Alison Brinson, Hannah R. Jahnke, Natalie Henrich, Smriti Karwa, Christa Moss, Neel Shah
Maven Clinic, New York, NY

OBJECTIVE: Research suggests interventions to reduce rates of preterm birth should be multifaceted. Maven, a comprehensive digital platform for women's and family health, offers continuous access to virtual providers, patient education, and care coordination. This analysis explored the association between Maven use and odds of preterm birth among a sample of nulliparous, low-risk individuals.

STUDY DESIGN: Data for this retrospective analysis came from 3491 low-risk pregnant Maven users who gave birth between 1/1/2020 and 9/19/2022. The sample excluded parous users, and users pregnant with multiple gestation, conceived with fertility treatment, or reported cigarette, drug, or alcohol use during pregnancy. Chi-square and Fisher's exact tests compared characteristics between users who developed gestational conditions and users who did not. Adjusted multivariable logistic regression models estimated the association between the number of hours of Maven use and odds of preterm birth, stratified by presence of gestational conditions.

RESULTS: Compared to those without gestational conditions, individuals who developed gestational conditions were more likely to have a preterm birth (8.7% vs. 3.4%; p< 0.001). For every 1 hour of Maven use, users experienced a 2% reduction in their odds of experiencing a preterm birth [AOR (95% CI) = 0.98 (0.95, 0.998), p = 0.043]. Adjusted models revealed that among individuals who developed gestational conditions, every 1 hour increase in Maven use was associated with a 5% reduction in the odds of experiencing a preterm birth [AOR (95% CI) = 0.95 (0.91, 0.99), p = 0.037] (Table 1). Among individuals who did not develop gestational conditions, there was no statistically significant association between use and preterm birth.

CONCLUSION: Among those who developed gestational conditions, increased use of a digital health platform was associated with a decreased likelihood of preterm birth. A digital health platform that provides continuous care coordination, access to providers, and educational information has the potential to support disease management and reduce preterm births.

Table 1. Adjusted association between digital health utilization (hours) and likelihood of preterm birth among Maven users, stratified by presence of gestational conditions (N=3326)[a]

	Overall (N=3326)		No gestational conditions (N=1936)		≥1 gestational conditions (N=1390)[b]	
	Adjusted OR (95% CI)	p-value	Adjusted OR (95% CI)	p-value	Adjusted OR (95% CI)	p-value
Digital health utilization (hours)	0.98 (0.95, 0.998)	0.043	0.99 (0.96, 1.01)	0.31	0.95 (0.91, 0.99)	0.037

[a]All models were adjusted for maternal age, race and ethnicity, presence of chronic medical conditions, history of anxiety or depression, mode of delivery, and the number of days enrolled in the Maven Clinic

[b]Gestational conditions include diagnosis of high blood pressure (diagnosed during pregnancy), gestational diabetes, problems with the placenta, Preeclampsia, Eclampsia, or HELLP, vaginal blood loss (excluding labor), infant large for gestational age, excess or diminished amniotic fluid, issues with the cervix, intrauterine growth restriction, perinatal mood disorder, and cholestasis.

202 Neonatal and maternal outcomes after betamethasone administration for late-preterm premature rupture of membranes (PROM).

Richard Benoit[1], Adrian L. Hernandez Lopez[2], Joanie Chung[3], Kiran Magee[4]
[1]Kaiser Los Angeles Medical Center, Los Angeles, CA, [2]University of California, San Francisco (UCSF), San Francisco, CA, [3]Kaiser Permanente Research, Los Angeles, CA, [4]Kaiser Permanente School of Medicine, Pasadena, CA

OBJECTIVE: Assess the impact of betamethasone administration in the management of late-preterm premature rupture of membranes (PROM).

STUDY DESIGN: Retrospective review of singleton pregnancies with PROM delivering at 34 to 36 weeks gestation within a health maintenance organization, 2017 to 2019. Treatment with one or two doses of betamethasone prior to delivery was compared with no treatment. The primary outcome was a composite of neonatal respiratory complications of one or more: respiratory distress syndrome, respiratory arrest, transient tachypnea, use of CPAP or HFNC. Statistical analysis utilized Chi-square and multivariate logistic regression.

RESULTS: The primary composite outcome occurred in 44 of 328 (13.4%) in the betamethasone group versus 122 of 699 (17.5%) in the control group (relative risk 0.77; 95% CI, 0.5 to 1.1; P=0.1). The primary outcome occurred more often following cesarean than spontaneous vaginal delivery (OR 2.5; 95% CI, 1.7 to 3.7, p < .001). The mean gestational age (35.4 wks) and median time from ROM to delivery (17 hours), did not differ between groups, indicating immediate delivery management. The rate of chorioamnionitis was lower in the betamethasone group, 3.4% versus 6.6%, (relative risk 0.51; 95% CI 0.2 to 0.97, p=0.04). Endometritis following delivery did not differ between groups. Neonatal sepsis occurred more often in the betamethasone group, 1.5 % versus 0.3%, (relative risk 5.3; 95% CI, 1 to 27, p=0.04). A higher rate of neonatal hypoglycemia was also observed in the betamethasone group (15.5% vs. 10.7%; relative risk 1.4, 95% CI, 1.0 to 2.0; p=0.03).

CONCLUSION: Betamethasone administration with immediate delivery management for late-preterm PROM was associated with a reduction in the rate of neonatal respiratory complications, although not

statistically significant. Maternal infectious morbidity was not increased, although higher rates of neonatal sepsis and hypoglycemia were observed following betamethasone exposure. Cesarean delivery remains a significant risk factor for neonatal respiratory morbidity in the late preterm, regardless of steroid administration.

Table 1: Maternal and neonatal outcomes after delivery

Outcome	Betamethasone (N=328)	Control (N=699)	p-value[†]
Primary outcome:			0.1
Composite of neonatal respiratory disorders[*]			
0 or none	284 (86.6%)	577 (82.6%)

203 Predicting prolonged pushers: risk factors for prolonged second stage at the time of full dilation

Rachel Herz-Roiphe[1], Alexandria Williams[2], Mark A. Clapp[3], Emily Reiff[4], Sarah E. Little[4]
[1]New York Presbyterian - Columbia, New York, NY, [2]Brigham and Women's Hospital, Brookline, MA, [3]Massachusetts General Hospital, Boston, MA, [4]Brigham and Women's Hospital, Boston, MA

OBJECTIVE: A prolonged second stage of labor is associated with increased maternal and neonatal morbidity. Identifying patients at the start of the second stage at high risk for a prolonged second stage may help inform targeted clinical management strategies.

STUDY DESIGN: Retrospective cohort of 1000 nulliparous patients with an epidural who reached full dilation at a single academic hospital in 2022. Patient characteristics were collected and charts reviewed to identify intrapartum factors. Active labor was considered protracted if time from the first exam at >/=6 cm to full dilation was > the 95% per contemporary labor nomograms. Contractions were considered adequate if at least every 3 minutes, lasting 1 minute and moderate or strong. Station was considered high if < +1/5. Head position was determined by documentation at delivery accounting for earlier documentation of spontaneous/manual rotation. Statistical analysis performed in STATA; p< 0.05 used for statistical significance.

RESULTS: The median length of the second stage was 1.5 hours (IQR 0.7-3.0). 132 patients (13.2%) had a prolonged second stage (>4 hours), which was associated with higher rates of chorioamnionitis (28% vs. 11%), postpartum hemorrhage (16% vs. 5%), and NICU evaluation (39% vs. 18%) [p< 0.01 all]. Several factors were independently associated with prolonged second stage: birthweight > 4000g (aOR 2.2; 95%CI 1.2-4.1), protracted active labor (aOR 1.7 [1.2-2.6]), inadequate contractions (aOR 2.0 [1.3-3.0]), high station (aOR 2.4 [1.4-4.0]) and OP position (aOR 4.4 [2.8-7.0]). Using these factors, the risk of a prolonged second stage ranged from 5 to 83% in our cohort with 10% of patients at >30% risk.

CONCLUSION: Risk factors known at the start of the second stage (OP position, protracted labor, LGA, inadequate contractions, and high station) can identify patients at the highest risk for a prolonged second stage which may allow for targeted management strategies, such as active coaching, manual rotation, oxytocin titration, or an earlier threshold for operative delivery in high risk patients to reduce maternal/neonatal morbidity.

		Second Stage Length <4 Hours N=868	Second Stage Length >4 Hours N=132	P-Value

204 Symphysiolysis in pregnancy: Is there an impact on obstetric outcomes?

Hila Shalev-Ram[1], Yael Shalev Rosenthal[2], Gal Cohen[3], Hanoch Schreiber[3], Michal Kovo[4], Tal Biron-Shental[5], Gil Shechter Maor[6]
[1]Tel-Aviv University, Ra'anana, Israel, [2]Rabin medical center, Petach-Tikva, HaMerkaz, [3]Meir Medical Centerartment of Obstetrics and Gynecology, Meir Medical Center, Kfar Saba, Israel, [4]Meir Medical Center, Macabim, HaMerkaz, [5]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz, [6]Meir Medical Center, Kfar Saba, HaMerkaz

OBJECTIVE: Symphysiolysis commonly induces significant pain and intermittent anxiety during pregnancy. However, there is a scarcity of information regarding the impact of this condition on labor outcomes and birth outcomes. We aimed to compare obstetrical and neonatal outcomes, in affected women compared to women without this condition.

STUDY DESIGN: This retrospective cohort study included women with a singleton pregnancy, no prior cesarean delivery (CD), who attempted vaginal delivery at 37 weeks or later in a tertiary medical center between 2013 and 2021. The cohort comprised nulliparous and multiparous, each further divided into two groups: those diagnosed with symphysiolysis during pregnancy and a control group.- Maternal and delivery characteristics, as well as obstetric and neonatal adverse outcomes, were compared between the two groups.Adjusted odds ratios (aOR) with 95% confidence intervals (95%CI) were calculated, controlling for confounding variables.

RESULTS: A total of 15,557 nulliparous and 27,477 multiparous women were included in the study, among whom 233(1.5%) nulliparous and 515(1.9%) multiparous were diagnosed with symphysiolysis. As compared to controls, both nulliparous and multiparous women with symphysiolysis were younger (27.5±4.4 vs. 28.5±5.0, p=0.002 for nulliparous,31.1±4.9 vs. 32.2±4.8, p=0.000 for multiparous), had a higher body mass index (BMI) prior to pregnancy (25.0±5.2 vs. 23.5±5.0,p=0.000 and 25.3±5.5 vs. 25.3±5.5,p=0.000 respectively), and had a higher prevalence of smoking during pregnancy (7.3% vs. 4.4%, P=0.036 and 9.3% vs. 4.7%,P=0.000, respectively).No differences were found between both groups in obstetric outcomes such the rate of vacuum extractions, CDs or perineal lacerations (see Table 1). Moreover, there were no significant differences observed between the groups in rates of low Apgar scores (< 7) at 5 minutes, low arterial pH (< 7.1), or admissions to the neonatal intensive care unit.

CONCLUSION: Women who are diagnosed with symphysiolysis during pregnancy, along with their fetuses, do not have an increased risk of obstetrical or neonatal complications during labor.

205 Predicting miscarriage risk in individuals with chronic illnesses

Hila Shalev-Ram[1], Nofar Gabay[2], Shai Ram[3], Gal Cohen[4], Netanella Miller[5], Tal Biron-Shental[6], Michal Kovo[7], Yael Yagur[8]
[1]Tel-Aviv University, Ra'anana, Israel, [2]Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim, [3]Lis Hospital for Women, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, Ra'anana, Tel Aviv, [4]Meir Medical Centerartment of Obstetrics and Gynecology, Meir Medical Center, Kfar Saba, Israel, [5]Meir Hospital, Kfar Saba, HaMerkaz, [6]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz, [7]Meir Medical Center, Macabim, HaMerkaz, [8]Meir Medical Center, Kfar Saba, HaMerkaz

OBJECTIVE: This study aimed to predict the risk of spontaneous abortion associated with pre-existing chronic illnesses and other known risk factors before pregnancy.

STUDY DESIGN: We conducted an observational retrospective study using extensive data from all live births and abortions between the years 2010 to 2019 in a big health maintenance organization (HMO). By analyzing diagnostic codes from patient registries, we identified 18 chronic diseases relevant only if diagnosed before the pregnancy of interest. Miscarriage risk according to underlying diseases and other risk factors were estimated using odds ratios (ORs) using logistic regression adjusting for woman's age, BMI, socioeconomic status, and smoking. Based on the ORs, we created a risk score ranging from 0 to 20.

RESULTS: During the study period, a total of 359,983 live births and 39,475 abortions were included. We observed an increased risk of miscarriage among women with diabetes type 2 (OR 1.23, 95% CI 1.12 to 1.35), neurology diseases (OR 2.38, 95% CI 1.79 to 3.14), depression (OR 1.43, 95% CI 1.33 to 1.54), polycystic ovary syndrome (OR 1.4, 95% CI 1.27 to 1.54), rheumatology diseases (OR 1.48, 95% CI 1.3 to 1.67), hypothyroidism (OR 1.31, 95% CI 1.28 to 1.33), hyperthyroidism & parathyroid diseases (OR 1.25, 95% CI 1.06 to 1.47), and cardiac diseases (OR 1.39, 95% CI 1.31 to 1.47). Additionally, we identified other known risk factors. The final multivariate model, as presented in Figure 1, exhibits a strong predictive ability with a mean-squared error (MSE) of 0.088. According to this model, a 37-year-old IVF patient with a BMI of 39 and two chronic diseases is subject to a 26.4% risk of abortion. In contrast, a 22-year-old woman with a BMI of 18 and no underlying chronic conditions has a significantly lower abortion risk at 8.8%.

CONCLUSION: We have identified several chronic diseases and other risk factors associated with spontaneous abortion and developed a highly predictive model. However, validation of the model in an independent population is required.

OBJECTIVE: The aim of our study is to evaluate both the overall and organ-specific teratogenic risk in pregnant women with overt diabetes mellitus based on their pre-pregnancy fasting blood sugar (FBS) levels.

STUDY DESIGN: In this a national population-based retrospective cohort study, we included women diagnosed with diabetes before pregnancy who underwent health examinations and had FBS measurements within one year before conception. The participants were grouped based on FBS levels into well-controlled (FBS $<$ 100 mg/dL), less-controlled (FBS: 100-125 mg/dL), and poorly-controlled (FBS $\geq$ 126 mg/dL) groups. Additionally, the well-controlled group was further subdivided into four subgroups based on FBS levels (table). Using the reference group, the relative risk of overall fetal malformations and organ-specific malformations was calculated for the other groups using multivariable analysis.

RESULTS: A total of 5,687 women were included in this study. The well-controlled group had a 10% overall rate of fetal malformations,

while the less controlled group had a 13.6% overall rate, and the poorly controlled group had an 18.6% overall rate of fetal malformations ($p< 0.001$). In the subgroups with FBS levels < 100 mg/dL, there was no significant increase in the overall or organ-specific teratogenic risk compared to the reference group. However, the overall teratogenic risk was 1.3 times higher in the less controlled group and 1.8 times higher in the poorly controlled group than in the reference group (table). Specifically, the risk of cardiac malformations was 2.5 times higher, and the risk of skeletal malformations was 3.3 times higher than reference group.

CONCLUSION: Our national population-based study demonstrates that when FBS levels are ≥ 100 mg/dL during the pre-conceptional period in women with pre-gestational diabetes, there is an elevated risk of fetal malformations, particularly concerning cardiac and skeletal malformations. However, some changes of FBS within 100 mg/dL during the pre-conceptional period may not increase the teratogenic risk during pregnancy (grant number: HC23C0124).

Table. Teratogenic risk based on the pre-pregnancy FBS in women with overt DM

	Overall malformation		Cardiac malformation		Skeletal malformation	
	Unadjusted OR	Adjusted OR*	Unadjusted OR	Adjusted OR*	Unadjusted OR	Adjusted OR*
Reference group (FBS ≤83 mg/dL)	(REF)	(REF)	(REF)	(REF)	(REF)	(REF)

207 An assessment of the relation between first trimester placental microcalcifications and adverse pregnancy outcomes

Rebecca Horgan[1], Elena Sinkovskaya[1], Erkan Kalafat[2], George R. Saade[1], Alfred Abuhamad[1]

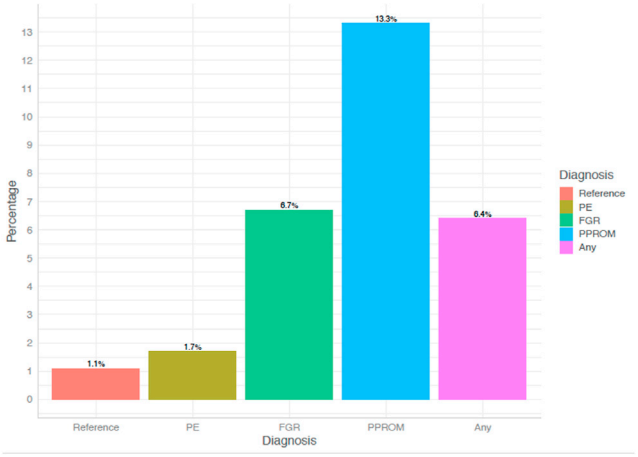
[1]Eastern Virginia Medical School, Norfolk, VA, [2]Koc University School of Medicine, Istanbul, Istanbul

OBJECTIVE: To evaluate the relation between placental microcalcifications in early pregnancy and subsequent adverse pregnancy outcomes.

STUDY DESIGN: Patients with non-anomalous pregnancies at < 13+6 weeks gestation without umbilical cord or placental abnormalities were enrolled in a longitudinal cohort study to evaluate the relation between placental novel sonographic markers and pregnancy outcomes. Ultrasounds were performed and data were ascertained by certified and trained sonographers and research coordinators. Micropure ultrasound technology was used to assess the presence of placental microcalcifications on first trimester ultrasound. Data was compared between patients who developed subsequent adverse pregnancy complications including preterm prelabor rupture of membranes (PPROM), fetal growth restriction (FGR) or preeclampsia (cases) and normal low risk patients (controls aged 18-35 years, with a body mass index (BMI) < 30, without existing comorbidities, who conceived spontaneously and had an uncomplicated pregnancy, with delivery >37 weeks' gestation). Multinominal logistic regression tests were used for statistical analysis, with $p < 0.05$ used to denote statistical significance (R for Statistical Computing v.4.2.0).

RESULTS: Amongst the 610 included pregnancies, 125 patients (20.5%) developed one of our adverse pregnancy outcomes: PPROM (n=30), preeclampsia (n=60) and FGR (n=45). Microcalcifications on first trimester ultrasound were noted in 13.3% (4/30) of patients who developed PPROM (OR 12.1, 95% CI 1.59-341.7, p=0.003), 6.7% (3/45) patients who developed FGR (OR 5.77, 95% CI 0.65-168.9, p=0.072) and 1.7% (1/60) of patients who developed preeclampsia (OR 1.5, 95% CI 0.04-59.4, p=0.771) compared to 1.1% (1/90) in the control group.

CONCLUSION: Compared to normal pregnancies, placentas in pregnancies who ultimately develop PPROM are more likely to demonstrate the presence of placental microcalcifications in early pregnancy.



208 Next generation sequencing application in congenital fetal anomalies

Hyewon HUR

Severance Hospital, Yongin-si, Seoul-t'ukpyolsi

OBJECTIVE: The purpose of this study is to investigate the diagnostic yiled of the application of NGS for fetuses with congenital anomalies.

STUDY DESIGN: Retrosective review of 32 fetuses with congenital anomalies with normal karyotype and negative chromosomal microarray results underwent NGS. The detected variants were classified as pathogenic, likely pathogenic, of uncertain significance, likely benign or benign, following the guidelines recommended by the American College of Medical Genetics and Genomics.

RESULTS: The detection rates of targeted NGS for pathogenic and likely pathogenic variations were 14.2% and 4.3%, respectively. The turnaround time of the test was 4 weeks. The likely pathogenic variation was detected on JAG1, which is associated with tetralogy of Fallot and Alagille syndrome. Variations of uncertain significance were detected in 78.2% of cases.

CONCLUSION: NGS in fetuses with congenital anomalies achieved a high diagnostic yield, with an acceptable turnaround time for the prenatal setting.

209 Validation of calculator for cesarean delivery during induction of labor

Claudia Ibarra[1], Rachel L. Wiley[1], Ipsita Ghose[2], Estefania Guthrie[3], Baha M. Sibai[4], Suneet P. Chauhan[5]

[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]University of Texas Medical School at Houston, Houston, TX, [3]The University of Texas Health Science Center at Houston, Houston, TX, [4]Hermann Memorial Hospital, Houston, TX, [5]University of Texas-Houston Medical School, Houston, TX

OBJECTIVE: We aimed to validate a published risk calculator to predict cesarean delivery (CD) among people undergoing induction of labor (IOL; Rossi, et al. PMID: 32028500) in an external cohort, and to evaluate if a higher predicted CD risk score was associated with a higher likelihood of cesarean or a composite maternal adverse outcome (CMAO).

STUDY DESIGN: Our retrospective cohort study included consecutive singleton IOL from 3/2020 to 9/2020. A predicted CD score was calculated using the coefficients of the calculator developed by Rossi et al. External validation of the calculator was assessed by the discriminative power of the model using area under the receiver operating characteristic curve (AUC), and by graphically displaying a calibration curve. The predicted CD score was further categorized as $< 20\%$, 20-40%, and $\geq 40\%$. The primary outcome was CD, the secondary outcomes was CMAO. Multivariable Poisson regression models with robust error variance estimated the association; adjusted relative risk (aRR) with 95% confidence interval (CI) was calculated.

RESULTS: Among 548 IOL, 159 (29%) had CD. External validation noted the AUC was 0.77 (95% CI 0.73-0.81) and calibration curve and its 95% confidence band had good calibration (Fig 1A-B). Overall, 277 (50%), 177 (33%), and 94 (17%) had a predicted CD score of $< 20\%$, 20-40%, and $\geq 40\%$, respectively. After adjustment, compared to individuals with a CD score of $< 20\%$, the likelihood of having a CD was higher in those with a score between 20-40% (aRR 2.40, 95% CI 1.68-3.34) and with a score $\geq 40\%$ (aRR 4.36, 95% CI 3.12-6.10). Compared to those who had a score $< 20\%$, the risk of the CMAO was higher in those with a score $\geq 40\%$ (aRR 1.62, 95% CI 1.10-2.40).

CONCLUSION: Our external validation suggests that the use of a calculator for predicting CD is feasible. There was a direct correlation between the score and likelihood of CD. A higher CD score was also associated with an increased likelihood of CMAO.

Fig 1A. Receiver-operating characteristic curve

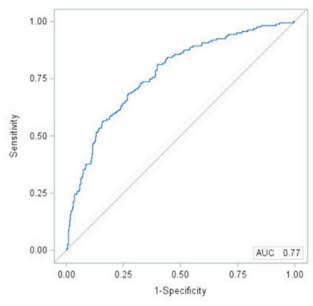


Fig 1A. Receiver operating characteristic curve of the prediction model. The area under the receiver operating characteristic curve (AUC) was 0.77 (95% confidence interval=0.73-0.81)

Fig 1B. Calibration cure

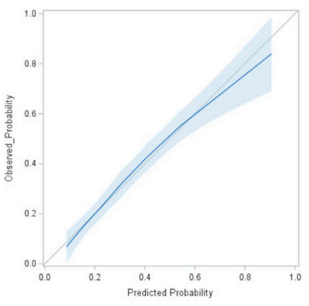

Fig 1B. Calibration curve (with 95% confidence interval) of model validation. The grey straight line is the line of perfect calibration. The blue line is the calibration curve generated by the prediction model, which is surrounded by light blue area that represent the 95% confidence band of the calibration curve.

210 Association of maternal serum insulin-like growth factor-1 and fetal fractional thigh volume

Keisuke Akita[1], Satoru Ikenoue[2], Junko Tamai[3], Keita Hasegawa[3], Kaoru Kajikawa[2], Marina Takahashi[2], Kunio Tanaka[3], Yuka Fukuma[3], Yuya Tanaka[3], Toshimitsu Otani[3], Yoshifumi Kasuga[3], Mamoru Tanaka[3]

[1]Keio University School of Medicine, Shinjuku-ku, Tokyo, [2]Keio University School of Medicine, Tokyo, Tokyo, [3]Keio University School of Medicine, Shinanomachi, Tokyo

OBJECTIVE: Insulin-like growth factor-1 (IGF-1) is one of the growth factors that promote protein and carbohydrate metabolism, and consequently affects birth weight. Fetal fractional thigh volume has been proposed as a useful parameter for predicting birth weight and quantifying fetal soft tissue development. However, the association between maternal serum IGF-1 and fetal fractional thigh volume remains unclear. This study aimed to investigate the association of maternal serum insulin-like growth factor-1 and fetal fractional thigh volume.

STUDY DESIGN: A prospective study was conducted in a cohort of 24 singleton pregnancies. Maternal blood sample was obtained at 24 weeks' gestation, and fetal ultrasonography was performed at 24-, 30-, and 36-weeks' gestation. Fractional thigh volume was assessed as cylindrical limb volumes based on 50% of the fetal total diaphysis length using 3D ultrasonography. The association between maternal serum IGF-1 and fetal fractional thigh volume was examined using Pearson product moment correlations.

RESULTS: Maternal serum IGF-1 at 24 weeks was 140.0±5.7 ng/ml (mean±S.E.). Maternal IGF-1 was not associated with fetal fractional thigh volume at 24 weeks ($r = 0.016$, $p = 0.930$) and 30 weeks ($r = 0.229$, $p = 0.216$). Maternal IGF-1 significantly correlated with fetal fractional thigh volume at 36 weeks ($r = 0.475$, $p = 0.019$).

CONCLUSION: Maternal serum IGF-1 at 24 weeks significantly correlated with fetal fractional thigh volume in late gestation. Maternal serum IGF-1 in mid-gestation could be a marker for predicting fetal growth in late gestation.

211 Artificial intelligence-driven precision pathology identifies distinct placental findings in severe fetal growth restriction or hypertension

Anna K. Jacobs[1], Saif I. Al-Juboori[2], Evgenia Dobrinskikh[2], Matthew A. Bolt[3], Mary Sammel[3], Virginia Lijewski[4], Miriam D. Post[2], James M. Small[1], Emily Su[5]

[1]Rocky Vista University College of Osteopathic Medicine, Englewood, CO, [2]University of Colorado, School of Medicine, Aurora, CO, [3]Colorado School of Public Health, Aurora, CO, [4]University of Colorado Anschutz, Denver, CO, [5]University of Colorado Denver Anschutz Medical Campus, Aurora, CO

OBJECTIVE: To leverage artificial intelligence (AI)-driven precision pathology to quantify the effects of severe FGR, pregnancy-related HTN, or their interaction on placental villus and vascular properties. We hypothesize that while only villi are affected in HTN, both villous and vascular structures are diminished in severe FGR with no additional effect of concomitant HTN.

STUDY DESIGN: In this retrospective cohort study, paraffin-embedded placental sections were obtained from four groups: [1] Severe FGR with HTN (n=11) [2] Severe FGR with normotension (n=14) [3] Appropriately grown, gestational age (GA)-matched pregnancies with HTN (n=12) and [4] Appropriately grown, GA-matched pregnancies with normotension (n=14). These underwent immunodetection for cytokeratin-7 (trophoblast) and CD34 (endothelium) followed by AI-driven image analyses. Number of villi and placental vessels, total villous area and total vascular area were quantified. Outcomes were normally distributed, and quantitative analyses were modeled with linear regression models.

RESULTS: Pregnancies with HTN exhibited significantly less stem villi ($p< 0.01$), stem villous area ($p< 0.01$), and stem villous vessels ($p< 0.01$), with no difference in vascular area. In contrast, abnormalities in severe FGR were limited to terminal villi, with fewer villi and vessels ($p< 0.01$) and decreased villous area ($p< 0.01$) and vascular area ($p=0.02$). No significant effects were found with the interaction of HTN and severe FGR.

CONCLUSION: Pregnancy-related HTN and severe FGR are associated with stem and terminal villus anomalies, respectively, suggesting that perturbations in placental development may be occurring at different gestational periods for each condition.

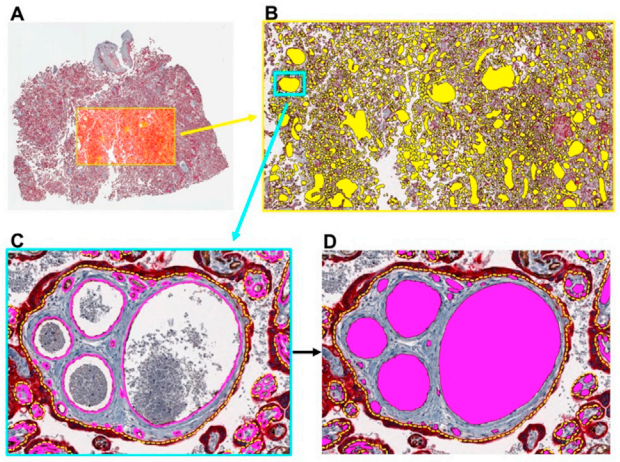

Figure 1. Identification and quantification of placental villi and vasculature. (A) The annotated ROI (yellow box) was scanned, and this annotation area was calculated. **(B)** Placental villi were recognized and outlined (yellow labels) using a series of designed protocols within the Visiopharm™ platform. The number of villi (3647 total villi within this representative ROI) and areas of each individual villus were calculated. **(C)** Magnification of the cyan box within the overall ROI shows individual villi outlined by yellow lines. Within each villus, fetoplacental blood vessels were identified and delineated by the magenta line using a separate series of designed protocols in Visiopharm™. **(D)** Blood vessels were separated using yet another series of designed protocols in Visiopharm™. Number of blood vessels and total blood vessel area in each villus was calculated.

212 Implication of cervical microbiomes including DNA Viromes in patients with cervical insufficiency

Seri Jeong[1], Won Kyong Cho[2], Kyong-No Lee[3], Yeonhwa Jo[2], Keun Young Lee[4]

[1]Kangnam Sacred Heart Hospital/Hallym University College of Medicine, Seoul, Seoul-t'ukpyolsi, [2]Sungkyunkwan University, Suwon, Kyonggi-do, [3]Chungnam National University Hospital, Daejeon, Ch'ungch'ong-namdo, [4]Kangnam Sacred heart hospital, Hallym university, Seoul, Seoul-t'ukpyolsi; on behalf of the National Research Foundation of Korea

OBJECTIVE: Cervical microbiomes and viromes have been associated with cervical insufficiency (CI) and pregnancy maintenance. These factors are incompletely understood. This study aimed to investigate them in pregnant women, with a specific focus on patients with CI.

STUDY DESIGN: A total of 232 cervical swab samples from 116 pregnant women were collected from the endocervix and exocervix. The location of the endocervix is around the internal cervical os and the exocervix is near the vaginal fornix. The participants were categorized into three groups: normal, prophylactic cerclage, and cervical insufficiency (CI) groups. DNA shotgun sequencing and two analytical approaches, Kraken2 and *de novo* assembly, were applied to reveal a comprehensive overview of cervical microbiomes and viromes in pregnant women.

RESULTS: Our results indicated significant differences in evenness and richness for alpha diversity between the endocervix and exocervix, as well as between the normal and CI groups, suggesting the influence of different cervical regions and the potential impact of CI on microbiome diversity. Beta-diversity analysis further elucidated the significance of cervical location and patient groups. (Figure 1). The utilization of both Kraken2 and *de novo* assembly approaches allowed us to characterize a diverse range of bacterial and viral species present in the cervix. Notably, *de novo* assembly revealed the presence of several DNA viruses, including bacteriophages, human papillomaviruses, and human herpesviruses. Furthermore, we annotated *de novo* assembled contigs according to KEGG, COG, and Pfam databases, revealing enriched functions regulated by different groups of microbiomes.

CONCLUSION: In conclusion, our study provides the data for cervical microbiomes and DNA viromes in pregnant women, especially for patients with CI. We focus on these factors to aid in the comprehensive understanding and therapeutic modulation of local microbial composition for enhancing safer and healthier pregnancies.

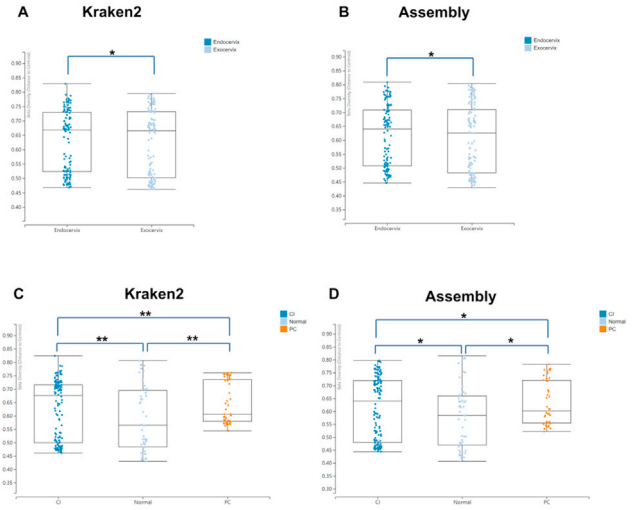

Figure 1. Comparison of beta diversity analysis using Kraken2 and *de novo* assembly. Plots for **A,** comparison of endocervix and exocervix samples obtained from data processed with Kraken2; **B,** comparison of endocervix and exocervix samples obtained from data processed with *de novo* assembly; **C,** comparison of normal, prophylactic cerclage, and CI (cervical insufficiency) groups derived from data processed with Kraken2; **D,** comparison of normal, prophylactic cerclage, and CI groups derived from data processed with *de novo* assembly.
Statistical significance is denoted by * ($p < 0.05$) and ** ($p < 0.01$) indicating the significance levels between the respective groups.

213 Maternal lactobacillus crispatus abundance in early gestation associated with decreased incidence of preterm birth

Michael D. Jochum Jr.[1], Maxim D. Seferovic[2], Gwendolynn Hummel[1], Erin Bolte[1], Lori Showalter[1], Cynthia Shope[1], Melissa Suter[3], RamKumar Menon[4], Kjersti M. Aagaard[3]

[1]Baylor College of Medicine, Houston, TX, [2]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [3]Texas Children's Hospital, Baylor College of Medicine, Houston, TX, [4]University of Texas Medical Branch, League City, TX

OBJECTIVE: Although *Lactobacillus spp.* are prevalent members of the vaginal and gut microbiomes, their role in birth outcomes has received little attention. Recently, *L. crispatus* has been associated with decreased risk of spontaneous PTB. *Lactoplantibacillus plantarum* has also been implicated in attenuating the somatotropic axis, indicating a potential role in PTB outcomes. We sought to determine the role of the six most prevalent *Lactobacilli spp.* of the microbiome on birth outcomes in a large, prospective, longitudinal cohort (BaBs, Bacteria and Birth study).

STUDY DESIGN: The BaBs study prospectively enrolled gravidae (n=585) at risk for preterm birth at 11-19 6/7 wks, and longitudinally sampled maternal and applicable neonatal infant sites to 1mo

postpartum. Sampling timepoints included enrollment, early 3rd trimester (27-28wks), delivery (term or preterm), and within 6wks postpartum. A total of 52116 maternal and 14350 neonatal/infant samples were collected and subjected to metagenomics sequencing (MGS) and rigorous bioinformatics analysis for delineation of species via taxonomic classification of human filtered read counts using kraken2, TaxonKit, and bitTools.

RESULTS: A total of n= 328 subjects delivered at term, and n= 78 preterm, and n=179 were lost to followup/ dropout. Comparisons across timepoints revealed a statistically significant higher relative abundance of *L.crispatus* was present as early as 11 weeks in births destined to deliver at term (>37 weeks), but not preterm. This was true for the number of *L.crispatus* MGS reads in not only the vaginal posterior from the initial visit (11-20 weeks) & early 3rd trimester (27-29wks), but in the oral microbiome and stool (Figure); these findings persistent post-partum.

CONCLUSION: In the largest longitudinal microbiome in pregnancy study to date, *L. crispatus* dominated microbiome communities in the vagina, oral and gut, from the first trimester were protective and predicted term birth. This was unique to *Lactobacillus crispatus,* indicating a likely functional role for this beneficial microbe in early gestation and successful gestation to term.

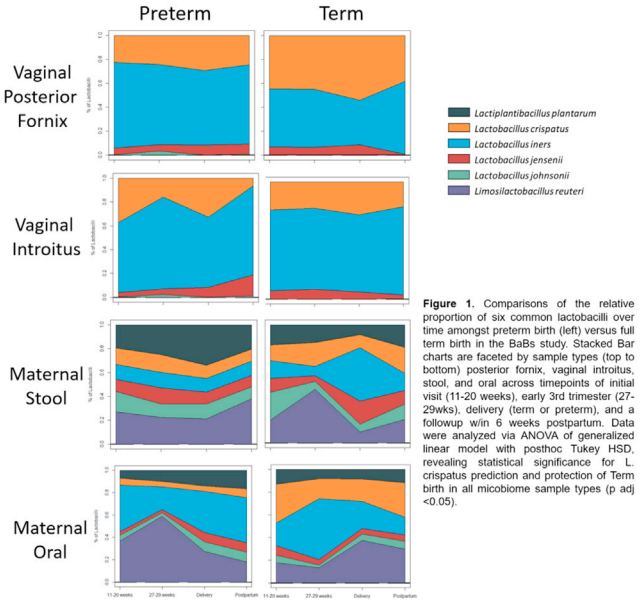

Figure 1. Comparisons of the relative proportion of six common lactobacilli over time amongst preterm birth (left) versus full term birth in the BaBs study. Stacked Bar charts are faceted by sample types (top to bottom) posterior fornix, vaginal introitus, stool, and oral across timepoints of initial visit (11-20 weeks), early 3rd trimester (27-29wks), delivery (term or preterm), and a followup w/in 6 weeks postpartum. Data were analyzed via ANOVA of generalized linear model with posthoc Tukey HSD, revealing statistical significance for L. crispatus prediction and protection of Term birth in all micobiome sample types (p adj <0.05).

214 Newborn anthropometric alternations are associated with second-trimester exposure to low-levels air pollution

Rotem Kabir[1], Tal Michael[1], Amalia Levy[1], Elkana Kohn[2], Ariela Hazan[2], Matitiahu Berkovitch[2], Ori Hochwald[3], Liron Borenstein[4], Moshe Betser[5], Miki Moskovich[5], Ayelet Livne[6], Rimona Keidar[6], Adi Malkoff[7], Zeev Weiner[8], Itai Kloog[1], ido Solt[9]

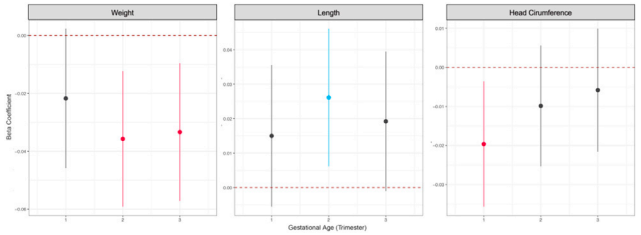
[1]Ben Gurion University of the Negev, Beer-Sheva, HaDarom, [2]Clinical Pharmacology and Toxicology Unit, Shamir (Assaf Harofeh) Medical Center, HaMerkaz, [3]Neonatal ICU, Rambam Health Care Campus, Haifa, Israel, [4]Rambam Health Care Campus, Haifa, Israel, [5]Shamir (Assaf Harofeh) Medical Center, HaMerkaz, [6]Neonatal Intensive Care Uni, Shamir (Assaf Harofeh) Medical Center, HaMerkaz, [7]Rambam Health Care Campus, Bynyamina, HaMerkaz, [8]Rambam Medical Health Campus, Haifa, HaZafon, [9]Rambam health care campus, Haifa, Israel, Haifa, Hefa

OBJECTIVE: Accumulating evidence suggests that prenatal exposure to fine particulate matter ($PM_{2.5}$) is largely associated with adverse newborn's health outcomes. However, the relevant timing of exposures varies between studies and is yet unclear. Hence, we examined the association of several anthropometric measures with weekly $PM_{2.5}$ exposure throughout weeks of gestation.

STUDY DESIGN: We recruited 1060 mother-infant pairs from two major hospitals in Israel. Data regarding daily $PM_{2.5}$ predictions were estimated on a $1_{km}X1_{km}$ grid from satellite-based models, geocoded and overlaid geographically per each mother using ArcGIS. We conducted Linear Mixed-Effects Models to examine the association between birth weight, length, and head circumference and trimestral as well as weekly exposures to $PM_{2.5}$ from the last menstrual period to the day of delivery.

RESULTS: Comparing to $PM_{2.5}$ exposure levels measured worldwide in a global analysis of air pollution conducted by the WHO, our study showed relatively moderate levels of daily mean PM2.5 concentrations (18.34 $\pm$1.45 $\mu g/m^3$). Prenatal exposure to $PM_{2.5}$ throughout the 2nd and 3rd trimesters (Figure 1) was significantly associated with decreased birthweight ($\beta_{trimester1}$= -0.021, CI: -0.046 to 0.002; $\beta_{trimester2}$= -0.035, CI: -0.059 to -0.012; β =-0.033$_{trimester3}$, CI:-0.057 to -0.0095 respectively), with the most noticeable effect between the 15th to the 35th gestational weeks. While head circumference was negatively associated with exposure to $PM_{2.5}$ in the first trimester (β= -0.019, CI:-0.035 to -0.0036), birth length was positively associated with exposures during the second trimester (β=0.026, CI:0.006-0.046).

CONCLUSION: Our findings suggest that $PM_{2.5}$ is significantly associated with a reduction in birth weight, with higher susceptibility between the 15th to the 35th gestational weeks. This critical window should be carefully assessed and could be the grounds for future clinical interventions. The trimestral associations of $PM_{2.5}$ with decreased head circumference and increased length could shed light on uncovered biological mechanisms that should be further studied.



215 Experience, training, tools: A mixed-methods study of decision-making for obstetric transport in New Mexico

Madhurima Keerthy, Bailee Miller, Payton Sandoval-Belt, juhee Patel, Avalon Yi, Trevor Quiner

University of New Mexico, Albuquerque, NM

OBJECTIVE: New Mexico relies heavily on emergency obstetric transport due to the widely separated rural communities and limited centers for providing advanced maternal, fetal, and neonatal care. Emergency transport requires careful decision-making and efficient use of resources. This study aims to evaluate perceived adequacy with respect to training, experience, and resources for obstetricians who make transport decisions.

STUDY DESIGN: An interview guide and survey questions were developed to evaluate the perception of different aspects of emergency obstetric transport in New Mexico. Interviews were performed

with OB/GYN providers who participate in emergency obstetric transport, both sending and receiving, throughout the state of New Mexico in both rural and urban communities. Interviews were recorded, transcribed, and coded for qualitative analysis.

RESULTS: The majority (75%) of participating providers had no formal training in emergency transport during their medical education and there was a common sentiment that targeted training in obstetric transports would be beneficial. However, providers who reported being uncomfortable in making transport decisions at the beginning of their current positions reported quickly gaining the experience needed to feel comfortable. While tools to assess preterm labor are extremely limited in some settings (transvaginal cervical length available to only 40% of interviewees), all providers felt that they had the necessary tools to make transport decisions.

CONCLUSION: Obstetric transport is essential in rural obstetric care. While experience is an excellent teacher, obstetric training is generally lacking in transport focused education. Development of obstetric transport-centered training may improve the comfort level of providers in new settings.

Table 1. Perinatal Outcomes Among Patients with SUD and Co-Occurring Psychiatric Comorbidities

	Total (N=466)	With co-occurring psychiatric disorder N=410 (88)	Without co-occurring psychiatric disorder N=56 (12)	p-value

216 Perinatal substance use programming: impact on maternal and neonatal outcomes among women with psychiatric comorbidities

Amy DeVeydt, Justine Keller, Marissa Turkin, Irena Kuan, Sophia Izhar, Krithika Narayana Kumanan, Niraj R. Chavan
St. Louis University, St. Louis, MO

OBJECTIVE: The objective of this study was to evaluate the impact of participation in a comprehensive perinatal substance use disorder (SUD) program on maternal and neonatal outcomes among women with SUD and co-occurring psychiatric diagnoses.

STUDY DESIGN: We conducted a retrospective cohort study of women receiving prenatal care through a specialized perinatal SUD program at an academic tertiary center from December 2019 to March 2023. Demographic characteristics, substance use patterns, maternal and neonatal outcomes were abstracted from electronic records and compared across 2 groups — women with SUD with and without co-occurring psychiatric disorders. Our study outcomes were — an adverse maternal composite, including antepartum and postpartum — relapse, overdose and severe maternal morbidity (SMM), and an adverse neonatal composite including Neonatal Abstinence Syndrome (NAS) requiring pharmacologic treatment, NICU stay >7 days, SGA at birth and neonatal demise. Student's t-test and chi^2/Fisher's exact tests were used to compare continuous and categorical data, respectively. Statistical significance was set at $p \leq .05$.

RESULTS: Of the 466 pregnant women with a DSM-V defined SUD, 410 (88%) had co-occurring psychiatric disorder(s) and 56 (12%) did not. Those with co-occurring psychiatric disorders were more likely to be white (P< .01), married (p=.02), had higher rates of history of IV drug use (p< .01), participation in inpatient rehabilitation (p< .01), prior overdose (p< .01), history of sexual trauma (p=0.04) and prior arrest/incarceration (p=.02). While Opioid use disorder (OUD) was the predominant SUD in 85% (n=396) of the overall cohort, the subset with psychiatric comorbidities had higher rates of benzodiazepine (p=.04) and amphetamine use disorder (p< .01). Gestational age at care initiation, number of prenatal visits as well as rates of adverse maternal and neonatal composite outcomes were similar across both groups.

CONCLUSION: Participation in a comprehensive prenatal substance use recovery program can potentially improve clinical outcomes for women with SUD and co-occurring psychiatric diagnoses.

217 Assessing healthcare worker stigma toward pregnant persons with opioid use disorder

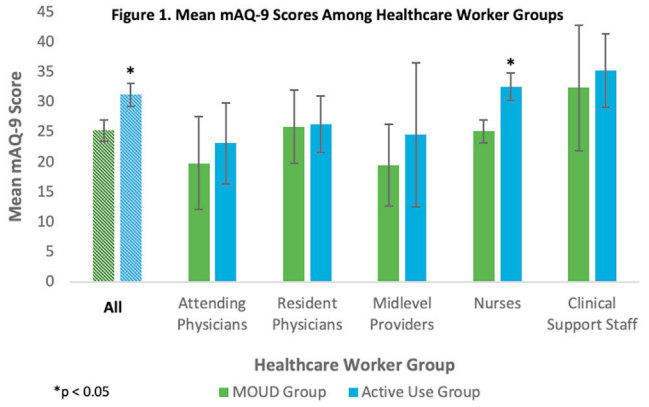
Anthony Kendle, Katherine Pressman, Margaret Cornwall, Marcia Kneusel, Tanner G. Wright
University of South Florida Morsani College of Medicine, Tampa, FL

OBJECTIVE: Stigma toward pregnant people with opioid use disorder (OUD) is a significant barrier to treatment and quality care. We aimed to assess the degree of stigma that exists among healthcare workers who care for these families in hospital settings.

STUDY DESIGN: This is a cross-sectional analysis of survey responses from healthcare workers at a single tertiary care center. We collected participant demographics as well as responses to the modified Attribution Questionnaire 9 (mAQ-9) to assess stigma toward pregnant people with OUD. Participants were randomized to two versions of the mAQ-9: a pregnant person with OUD receiving methadone ("MOUD") or a pregnant person with continued, active heroin use ("Active Use"). The questionnaire assesses 9 stereotypes using a nine Likert scale items of agreement, such that higher scores indicate more stigma. Mean mAQ-9 scores were compared between groups using a two-sided t-test. A p-value of < 0.05 was considered significant.

RESULTS: A total of 294 participants completed the survey, with 144 in the "MOUD" group and 150 in the "Active Use" group. The mean mAQ-9 score for all participants was 28.3 (range of scores 9-72). Mean mAQ-9 score was higher for the Active Use group compared to the MOUD group among all participants (31.2 vs. 25.3, p< 0.001) and among nurse participants (32.5 vs. 25.1, p< 0.001). Clinical Support Staff had the highest mean scores for both groups whereas mid-level providers had the lowest mean scores. Healthcare workers in pediatric units had higher mean mAQ-9 scores compared to those in obstetric units (29.6 vs 25.8, p=0.006). Pity was the stereotype most implicated in stigma toward pregnant people with OUD. Of all respondents, 22% felt a pregnant person with OUD should be forced into treatment.

CONCLUSION: Healthcare workers hold stigma toward pregnant people with OUD, especially toward those with active opioid use in pregnancy. Stigma is greatest among clinical support staff and nurses, and workers in pediatric units have higher degrees of stigma. This supports a role for anti-stigma efforts to improve care for pregnant people with OUD.



218 Preeclampsia in kidney transplant recipients during pregnancy and its impact on graft survival

Vanessa Kirschner[1], Ophelia Yin[2], Lisa Coscia[3], Serban Constantinescu[4], Michael Moritz[3], Roxanna Irani[2], Yalda Afshar[1]

[1]David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, [2]University of California San Francisco, San Francisco, CA, [3]Transplant Pregnancy Registry International, Gift of Life Institute, Philadelphia, PA, [4]Lewis Katz School of Medicine, Temple University, Philadelphia, PA

OBJECTIVE: Preeclampsia affects ≥ 25% of kidney transplant recipients during pregnancy, but its impact on longitudinal graft survival are unclear. We aim to characterize longitudinal graft survival from the time of delivery and investigate maternal and neonatal outcomes in kidney transplant recipients who experienced preeclampsia.

STUDY DESIGN: Retrospective cohort study of kidney transplant recipients enrolled in an international transplant registry with a pregnancy of ≥ 20 weeks' gestation between 1967-2019. Primary outcome was graft loss after delivery. Secondary outcomes included severe maternal and neonatal composite morbidity. Univariate, Kaplan-Meier curves, and Cox proportional-hazards models were constructed for statistical analysis using Rstudio v.2023.06.1.

RESULTS: There were 2,106 kidney transplant recipients, of which 1,574 pregnancies and 1,641 neonates met inclusion criteria. Preeclampsia was reported in 447 (28.4%) of pregnancies. Recipients with preeclampsia were more likely to be nulliparous, self-identify as white, report tacrolimus use during pregnancy, have cesarean births, and have a multiple gestation. Preeclampsia was associated with higher creatinine during pregnancy ($p< 0.01$) and after pregnancy ($p=0.02$), but there was no difference in pre-pregnancy creatinine ($p=0.80$). Severe maternal morbidity was higher in those with preeclampsia (4.7% vs 2.5%, $p=0.02$). Preeclampsia was associated with higher neonatal composite morbidity (23.5% vs 9.6%, $p< 0.01$), as well as higher rates of NICU stays (33% vs 16%, $p< 0.01$). Preeclampsia was associated with a shorter interval to graft loss after delivery (8.9, vs 14.4 years, $p< 0.01$); however, on survival analysis there was no increased risk of graft loss from delivery (aHR: 1.22, [0.99, 1.49]) after adjusting for covariates.

CONCLUSION: In kidney transplant recipients who developed preeclampsia during pregnancy, a shorter time to graft loss and increased severe maternal and neonatal composite morbidity was observed. There was no difference in kidney graft survival based on a history of preeclampsia in a post-transplant pregnancy.

219 Pregnancies in heart transplant recipients: the impact of preeclampsia on pregnancy outcomes and graft loss

Vanessa Kirschner[1], Ophelia Yin[2], Lisa Coscia[3], Serban Constantinescu[4], Michael Moritz[3], Roxanna Irani[2], Yalda Afshar[1]

[1]David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, [2]University of California San Francisco, San Francisco, CA, [3]Transplant Pregnancy Registry International, Gift of Life Institute, Philadelphia, PA, [4]Lewis Katz School of Medicine, Temple University, Philadelphia, PA

OBJECTIVE: Heart transplant recipients have an increased risk of hypertension, with a prevalence of 72% at 1 year after transplant. Pre-pregnancy hypertension elevates risk of preeclampsia, with >25% of heart recipients experiencing this complication. The impact of preeclampsia on heart transplant recipients is unknown. We describe heart transplant recipients who developed preeclampsia and the effect of preeclampsia on graft and pregnancy outcomes.

STUDY DESIGN: This is a retrospective cohort study of adult heart transplant recipients with subsequent pregnancy of ≥ 20 weeks' gestation enrolled in an international transplant registry between 1967- 2022. Primary outcome was graft loss within 2 years from delivery. Secondary outcomes included pregnancy and neonatal outcomes. Statistical comparisons were made with Wilcoxon rank sum and Fisher's exact tests in Rstudio v.2023.06.1.

RESULTS: 146 pregnancies and 149 neonates met inclusion criteria. All were livebirths. 42 pregnancies (28.8%) developed preeclampsia. Cardiomyopathy was the leading diagnosis for transplantation in both cohorts. Baseline characteristics of age, BMI, race, and multiple gestation were similar, with the majority self-identifying as white. The preeclampsia group had higher rates of nulliparity (81.0% vs

54.8%, p< 0.01), chronic hypertension (73.8% vs 34.6%, p< 0.01), and repeat transplant (11.9% vs 1.9%, p< 0.05). Immunosuppressant regimens were similar between cohorts; notably there were mycophenolate and sirolimus exposures in both groups (p >0.05). Incidence of graft loss at 2 years was similar with (4.8%) or without (2.9%) preeclampsia, p=0.72. Preeclampsia was associated with lower gestational age at birth (35.0 vs 37.0 weeks, p< 0.01) and lower birth weight (2310 vs 2801 grams, p< 0.01).

CONCLUSION: There was no difference in graft loss within 2 years from delivery in heart transplant recipients who developed preeclampsia. Risk factors for preeclampsia included nulliparity, chronic hypertension, and repeat heart transplant. These data provide pertinent information for counseling heart transplant recipients who pursue pregnancy.

220 Telehealth use and patient care utilization within one year postpartum

Thomas P. Kishkovich[1], Kaitlyn E. James[2], Katie Camacho Orona[3], Jessica Cohen[3], Mark A. Clapp[2]

[1]Massachusetts General Hospital, Department of Obstetrics and Gynecology, Boston, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Harvard TH Chan School of Public Health, Boston, MA

OBJECTIVE: Telehealth is now widely used in obstetrics. Our objective was to examine the relationship between exclusive telehealth vs. in-person postpartum visits and healthcare utilization within the first year postpartum.

STUDY DESIGN: We performed a retrospective cohort study of individuals receiving postpartum care at a single institution between 7/1/2020—6/30/2021. The primary exposure was exclusive use of telehealth vs. in-person visit for postpartum care. Primary outcomes were use of long-acting reversible contraception (LARC) and pap smear screening within 1 year postpartum, services that require an in-person visit and can be provided outside of routine obstetric care (i.e., by a primary care provider). Secondary outcomes included weight assessment, prescription contraception use, primary care visits, and pregnancy within 1 year postpartum. Logistic regressions were performed to assess the association between the outcomes and telehealth vs. in-person postpartum care.

RESULTS: Of the 3,407 individuals who delivered, 3,096 (90.9%) had a postpartum visit; 1,304 (33.4%) utilized telehealth exclusively. Those who used telehealth exclusively were more likely to self-identify as White (69.2 vs. 61.4%, p< 0.001), report English as their primary language (93.3 vs. 87.9%, p< 0.001), and not have pregnancy-related hypertension (13.8 vs. 18.5%, p< 0.001), gestational diabetes (6.7 vs. 11.3%, p< 0.001), and mental health conditions (15.9 vs. 18.8%, p=0.03). The telehealth users were less likely to have a pap smear (22.5 vs. 47.0%, p< 0.001) or use LARCs (8.7 vs. 21.9%, p< 0.001) than those receiving in-person care. There were reduced odds of all services in the telehealth compared to the in-person cohort, except subsequent pregnancy within 1 year (Table).

CONCLUSION: There was lower utilization of commonly recommended services within the first year postpartum for individuals who utilize telehealth services for postpartum care. As telehealth has become for patients to access medical care, these findings should prompt clinicians to consider what services may be delayed or missed by the exclusive use of telehealth.

Odds of Health Care Utilization and Screening Services within 1 year of Delivery for Exclusive Telehealth Use compared to In-Person Postpartum Care

Outcomes	Unadjusted Odds Ratio for Exclusive Telehealth vs. In-Person Postpartum Care (95% CI)	Adjusted Odds Ratio for Exclusive Telehealth vs. In-Person Postpartum Care (95% CI) [3]
Primary		
Pap Smear [1]	0.33 (0.25-0.42)	0.30 (0.23-0.39)
Long-Acting Reversible Contraception [2]	0.34 (0.27-0.43)	0.35 (0.27-0.44)
Secondary		
Any Prescribed Contraception [2]	0.72 (0.62-0.83)	0.72 (0.62-0.84)
Blood Pressure Assessment	0.03 (0.02-0.05)	0.03 (0.02-0.05)
Weight Assessment	0.15 (0.13-0.19)	0.16 (0.13-0.19)
Primary Care Visit	0.77 (0.67-0.89)	0.81 (0.70-0.94)
Subsequent Pregnancy within 1 Year	0.98 (0.73-1.33)	1.00 (0.74-1.36)

CI, confidence interval.

[1] Denominator for comparison: individuals without pap smear in the 3 years prior to delivery.

[2] Denominator for comparison: individuals who did not receive long-acting reversible contraception or have a sterilization procedure during the delivery hospitalization.

[3] The adjusted logistic regression model included the following covariates that were defined a priori: age (continuous), parity (nulliparous vs. multiparous), preterm birth, primary language (English vs. non-English), self-identified race, self- identified ethnicity (Hispanic vs. non-Hispanic), primary payer for delivery admission, delivery mode, and maternal comorbidities (pre- and gestational diabetes, chronic and pregnancy-related hypertension, mental health conditions).

221 Sex-specific placental histopathology effects on newborn cytokine-chemokine levels in a cohort with universal placental examination

Carolyn M. Salafia[1], Dvora Kluwgant[2], Caitlin Rukat[3], Beata Dygulska[2], Serena Chen[4], Sylvia Dygulski[5]

[1]Institute for Basic Research, New York, NY, [2]NYP-Brooklyn Methodist Hospital, Brooklyn, NY, [3]Placental Analytics, Placental Analytics, NY, [4]Placental Analytics LLC, New Rochelle, NY, [5]Touro College of Osteopathic Medicine, NYP-Brooklyn Methodist Hospital, Brooklyn, NY

OBJECTIVE: To determine the association(s) of placental histopathology types with levels of developmentally important regulatory molecules assayed in newborn dried blood spots (DBS), and whether any associations differ by infant sex.

STUDY DESIGN: 1809 children with complete placental evaluation by a single pathologist (CMS) had DBS retained as part of the New York State Newborn Screening Program. Assays were performed using the Bio-Rad 40-plex Illumina assay. Histopathology types were considered as binary (present/absent), and Mann Whitney U tests compared their relationships with DBS analyte levels. Results were stratified by sex. Acronyms for placental histopathology types with at least one significant association with a DBS analyte in either sex are as follows:

MAIR	Any versus no maternal inflammatory responses
FAIR-UC, FAIR-CV	Any versus no fetal inflammatory responses in umbilical cord (UC) or chorionic plate vessels (CV)
MVP-RVA	Any versus no maternal malperfusion pathology: reduced villous arborization
MVP-INF	Any versus no maternal malperfusion pathology: infarction
MVP-IVT with INF	Any versus no maternal malperfusion pathology: intervillous thrombus with peripheral infarct
FVP-Macro	Any versus no fetal vascular pathology in chorionic plate or fetal stem vessels
FVP-Micro	Any versus no fetal vascular pathology in villous capillaries
Dysmaturity	Immature and/or edematous appearing villi with decreased vasculosyncytial membranes
CPI-Mat	Any versus no chronic inflammation in maternal tissues
CPI- Fet	Any versus no chronic inflammation in placental villi

RESULTS: Multiple significant associations were observed between placental histopathology types and DBS analytes, and the majority were seen either in males or females, but not both (Table).

CONCLUSION: The dramatic sex-specific differences in associations linking placental histopathology types and DBS analytes make infant sex a critical variable in any study of placental histopathology and its potential downstream and lifelong effects.

222 Early postpartum appendicular skeletal muscle mass in Japanese women with gestational diabetes

Megumi Koga, Katsuhito Hayashi, Hiroshi Yamashita, Ichiro Yasuhi

NHO Nagasaki Medical Center, Omura-City, Nagasaki

OBJECTIVE: Gestational diabetes (GDM) is strongly associated with the development of type 2 diabetes mellitus (T2DM) and it is suggested that, in addition to obesity, reduced appendicular skeletal muscle mass (ASM) may be a risk factor for T2DM, particularly in lean populations such as East Asians. However, few studies have investigated the association between ASM and GDM. This study aimed to investigate the volume of ASM in Japanese women with GDM.

STUDY DESIGN: In this prospective study, singleton pregnant women with or without GDM were recruited at 35 weeks' gestation. ASM was measured using a body composition analyzer (Tanita MC780A-N), along with body mass index (BMI), four weeks postpartum. We compared the early postpartum body fat mass (BFM), ASM/body weight (BW), and ASM/BMI between women with and without GDM.

RESULTS: A total of 118 women with GDM and 426 women without GDM were included in the study. Compared with women without GDM, women with GDM had significantly higher BMI and BFM. Regarding ASM, although the absolute ASM did not differ between the groups, the ASM/BW and ASM/BMI in the GDM group were significantly lower than those in the non-GDM group (**Table**).

CONCLUSION: This is the first report to demonstrate that women with GDM were associated with the reduced ASM during the early

postpartum period compared to those without GDM. It suggests that not only obesity but also reduced ASM may be associated with the development of GDM in Japanese women.

Table: Comparison of BFM and ASM between women with or without GDM

	GDM (n=118)	Non GDM (n=426)	P value
Hight (cm)	158.0 ± 5.1	157.6 ± 5.6	0.56

223 Uterine rupture among patients with placenta accreta spectrum: pre-labor vs. in -labor

Emi Komatsu[1], Shinya Matsuzaki[2], Genevieve R. Mazza[1], Rachel S. Mandelbaum[1], Doerthe Brueggmann[3], Joseph G. Ouzounian[1], Koji Matsuo[1]

[1]Los Angeles General Hospital + USC Medical Center, Los Angeles, CA, [2]Osaka International Cancer Institute, Osaka, Osaka, [3]University of Frankfurt Faculty of Medicine, Frankfurt, Hessen

OBJECTIVE: There is to date limited data examining uterine rupture in placental accreta spectrum (PAS). This study examined clinical and pregnancy characteristics related to uterine rupture among patients with PAS.

STUDY DESIGN: This serial cross-sectional study queried the Healthcare Cost and Utilization Project's National Inpatient Sample. The study population was 18,180 patients with diagnosis of PAS from 2017-2020. Patient and pregnancy characteristics were assessed for uterine rupture type (pre-labor or in-labor) in multivariable analysis.

RESULTS: Uterine rupture occurred in 220 patients (12.1 per 1,000 PAS diagnoses), including 110 (6.1 per 1,000) pre-labor uterine ruptures and 110 (6.1 per 1,000) in-labor uterine ruptures. Patients who had pre-labor uterine rupture were older compared to those without uterine rupture (rupture (age ≥35 years, adjusted-odds ratio [aOR] 2.05, 95% confidence interval [CI] 1.37-3.05). Patients with placenta percreta were four times more likely to have pre-labor uterine rupture compared to those with placenta accreta (adjusted-odds ratio [aOR] 4.26, 95% confidence interval [CI] 2.81-6.46). Prior vertical or low-transverse uterine incision was not associated with pre- or in-labor uterine rupture. Pre-labor uterine rupture occurred more in extreme-preterm (< 28 vs ≥36 weeks, aOR 13.35, 95%CI 6.71-26.57) followed by early-preterm (28-35 vs ≥36 weeks, aOR 5.61, 95%CI 3.09-10.16). In-labor uterine rupture occurred more in extreme-preterm (aOR 2.66, 95%CI 1.38-5.14) but not in early-preterm (aOR 1.28, 95%CI 0.81-2.03). Pre-labor uterine rupture, but not in-labor uterine rupture, was associated with fetal demise or stillbirth (aOR 3.69, 95%CI 1.93-7.05).

CONCLUSION: This nationwide analysis suggests that uterine rupture can occur in one in nearly 80 patients with PAS and that pre- and in-labor uterine ruptures have distinct differences in clinical and pregnancy characteristics.

224 Umbilical cord occlusion of twin reversed arterial perfusion (TRAP) sequence: laser photocoagulation vs radiofrequency ablation

Emi Komatsu[1], Catherine Hamzeh[2], Arlyn Llanes[2], Lisa M. Korst[3], Ramen H. Chmait[2]

[1]Los Angeles General Hospital + USC Medical Center, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, [3]Childbirth Research Associates, North Hollywood, CA

OBJECTIVE: TRAP sequence is rare (1:30,000 pregnancies) and associated with poor perinatal outcomes in high-risk cases. Surgical management via umbilical cord occlusion (UCO) has been shown to improve pump twin survival, but limited data are available comparing surgical techniques. The study objective was to review perinatal outcomes of patients with high-risk TRAP sequence who underwent mid-trimester UCO via laser photocoagulation vs radiofrequency ablation (RFA).

STUDY DESIGN: This is a retrospective cohort study of all patients seen between 2006-2023 with high-risk TRAP sequence who underwent UCO at a gestational age (GA) of 16-26 weeks. Criteria used to classify TRAP sequence patients as high-risk and eligible for UCO included: (1) abdominal circumference of the acardiac twin greater than or equal to that of the pump twin, (2) polyhydramnios (maximum vertical pocket ≥ 8 cm), (3) critically abnormal Doppler studies in the pump twin, (4) pump twin hydrops, or (5) monoamniotic twins. The primary outcome was 30-day survival of the pump twin.

RESULTS: Of 77 consecutive high-risk TRAP sequence patients that underwent UCO, perinatal outcomes were available in 74, of which 37 underwent UCO by laser and 37 by RFA. All gestations had at least 1 high-risk characteristic (Table); 63 were twins, 10 were triplets and 1 was quadruplets. The average GA of UCO was similar between the laser and RFA groups (20.5 ± 2.3 vs 20.7 ± 3.1 weeks, p=0.987). Five fetal demises occurred, 1 in the laser group (1/37, 2.7%) and 4 in the RFA group (4/37, 10.8%) (p=0.358). Postoperative pump twin membrane detachment was a risk factor for demise (4/7 [57.1%] vs 10/67 [14.9%], OR 7.69 [1.47-33.33], p=0.015). The average GA at delivery was similar between groups (35.2 ± 4.6 vs 34.5 ± 5.7 weeks, p=0.812) groups. The 30-day neonatal survival rate was 91.9% (34/37) in the laser group and 89.2% (33/37) in the RFA group (aOR: 1.42 [0.27-7.46], p= 0.677).

CONCLUSION: No significant differences in perinatal outcomes were identified in patients with high-risk TRAP sequence who underwent UCO by laser vs RFA.

Table 1. Characteristics of umbilical cord occlusion patients by surgical technique.*

TRAP high-risk factors	Laser photocoagulation (n=37)	RFA (n=37)
(1) Abdominal circumference of acardiac greater than or equal to pump twin	89.1% (33)	89.1% (33)
(2) Pump twin polyhydramnios	70.3% (26)	51.4% (19)
(3) Critically abnormal Doppler studies in pump	27.0% (10)	16.2% (6)
(4) Pump twin hydrops	0	2.7% (1)
(5) Monoamniotic twins	0	0

*Patients may have more than 1 characteristic.

225 Evaluation for congenital infections in late-onset small for gestational age (SGA) neonates

Kavitha Konduru, Rewa Repala, Alessandro Ghidini

Inova Alexandria Hospital, Alexandria, VA

OBJECTIVE: Symmetric SGA neonates are thought to be small due to familial, genetic, or infectious causes. The association of maternal infections with early-onset SGA is controversial and SMFM recommends against screening for congenital infections in SGA in the absence of other risk factors (strong recommendation, low-quality evidence). We have evaluated the utility of routine investigation for late-onset symmetric SGA infants.

STUDY DESIGN: Cohort study of all infants with birth weight $< 10^{th}$ centile born at >35 weeks over a 2-year period (2021-2022). Symmetric SGA was defined as both birth weight and head circumference < 10 centile. Excluded were infants with congenital anomalies, genetic syndromes, and those transferred to high acuity neonatal intensive care units. Birth weight centile were evaluated according to Fenton growth curves to include late preterm infants. SGA infants were recommended testing for congenital infections, head ultrasound (US), complete blood cell count, and glucose testing.

RESULTS: Of the 6075 babies born at >35 weeks during the study period, 339 (5.6%) were SGA and 116 of them (34%) were symmetric SGA. Urine CMV PCR was done on 67/116 (58%) babies with symmetric SGA, and all results were negative. TORCH IgM/Total IgM was done on 65 babies (56%), and only 1 had a mild elevation in Total IgM. Head US was done on 67 babies (58%); it was normal in 60 (89%). Seven babies had abnormal US findings: 2 with increased echogenicity in the periventricular matter, 1 with small periventricular calcifications, and 4 with grade 1 IVH (one of which had a small periventricular calcification). Repeat head US or brain MRI 3 months later was normal. Urine CMV PCR was negative in all these babies.

CONCLUSION: Extensive laboratory work-up for congenital infections in symmetric SGA babies at >35 weeks is not useful or cost effective.

226 Family separation at birth: impact of marijuana-only positive urine drug screening on the parent-neonatal dyad

Elizabeth Kravitz[1], Lakeisha Mulugeta-Gordon[1], Nia Bhadra-Heintz[1], Caroline Antonacci[1], Olivia Palmer[1], Rebecca Schapiro[1], Sindhu K. Srinivas[2], Sarita Sonalkar[1], Abike James[1]

[1]Hospital of the University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA

OBJECTIVE: This study described and compared the neonatal outcomes and interventions for pregnant patients with a positive marijuana-only UDS compared to those with a negative UDS after implementation of a urine drug screening protocol.

STUDY DESIGN: This is a retrospective cohort study comparing pregnant patients with a positive marijuana-only UDS result and those with a negative UDS admitted to the labor floor from 9/1/2020 to 6/1/2022. Patient demographics and neonatal outcomes were collected from the electronic medical record (Table 1). Chi square analysis was used to evaluate the association between categorical variables.

RESULTS: Of 7022 births during the study period, 127 (1.8%) patients had a UDS collected. Patients who identified as Black were significantly more likely to have a UDS collected (P< 0.0001). Of the 127 patients with a UDS result, 55 (43%) had a negative UDS, 28 (22%) had a marijuana-only positive result, 44 were positive for other substances (34.6%). Of the patients with marijuana-only positive results, 12 were sent for no prenatal care, 1 for altered mental status, 4 for use of illicit substances, 3 for treatment with medications for opioid use disorder, 1 for suspicion of abruption, 4 for intrauterine fetal demise, and 1 undocumented indication. There was no difference in neonatal outcomes between the two groups, however, significantly more in the marijuana only group were referred to DHS (44% versus 16%).Of the 28 patients with marijuana-only results with a DHS referral, 4 were discharged home without custody of their neonates.

CONCLUSION: No significant differences in neonatal outcomes were observed between patients with and without a positive marijuana-only UDS result. Nonetheless, current UDS testing practices have significant adverse impact on parent-baby dyad and may lead to family separation and its associated downstream health effects. Given the legality of marijuana in much of the U.S., and its lack of medical significance, we recommend that its detection should be removed from the UDS for birthing parents.

	Positive THC (n=28)	Patients with negative UDS (n=55)	p-value

227 Satisfaction of placenta accreta training during maternal-fetal medicine versus gynecologic oncology fellowship.

Oxana M. Zarudskaya[1], Nina Kumar[2], Shriya Devkumar Das[2], Michael D. Berkus[2], Angela R. Boyd[2], John J. Byrne[2], Nora M. Doyle[2], Patrick S. Ramsey[2], Nicole M. P. Spencer[2], Georgia A. McCann[2]

[1]University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]The University of Texas Health Science Center at San Antonio, San Antonio, TX

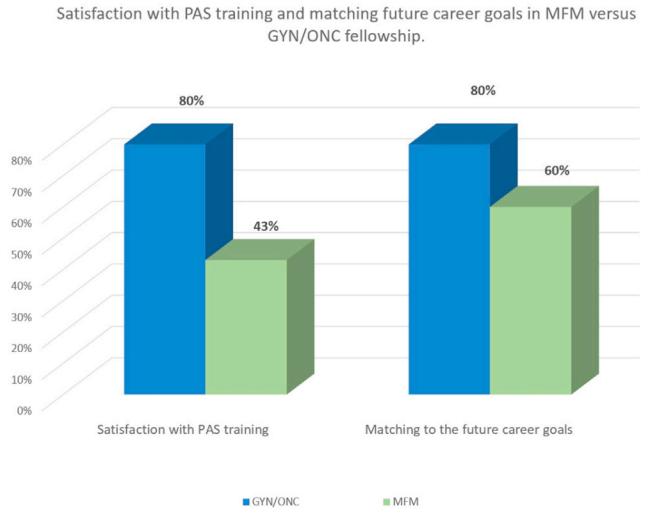
OBJECTIVE: Training in placenta accreta spectrum disorder (PASD) is essential to Maternal-Fetal Medicine (MFM) and Gynecology Oncology (Gyn/Onc) fellowships. Our objective was to assess the satisfaction and alignment with future career goals of placenta accreta training during MFM and Gynecology Oncology fellowship.

STUDY DESIGN: An anonymous survey was distributed to all ACGME-accredited MFM and Gyn/Onc fellowship programs between 04.08.23-07.30.23. The survey contained demographic information, and questions reflecting satisfaction with PASD training during

fellowship and matching future career goals. This was assessed with modified 5-point Likert scale.

RESULTS: We received 43 responses, 28 (65.1%) responders were from MFM fellows, and 15 (35.9%) were from Gyn/Onc fellows. Out of all responders, satisfaction with PASD training in their fellowship was greater in Gyn/Onc fellows compared to MFM fellows (80% vs. 42.9%, p=0.02). Conversely, MFM fellows reported that they were not satisfied with their PASD-related training more frequently than Gyn/Onc fellows (32.1% vs 13.3%, p=0.39) PASD training in MFM fellowship matched trainees' future career plans in 60.1% in contrast to 80% of Gyn/Onc fellows (p=0.19).

CONCLUSION: Satisfaction with PAS training and alignment with future career goals were higher in Gyn/Onc fellowship programs compared with MFM fellowship.



228 Utility of standardized FIGO descriptors for reporting of intra-operative findings of placenta accreta spectrum disorders.

Oxana M. Zarudskaya[1], Nina Kumar[2], Shriya Devkumar Das[2], Nicole M. P. Spencer[2], Georgia A. McCann[2], Caitlin E. Martin[2], Patrick S. Ramsey[2]

[1]University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]The University of Texas Health Science Center at San Antonio, San Antonio, TX

OBJECTIVE: Proper reporting of placenta accreta spectrum disorder (PASD) findings intra-operatively allows consistency of communications between multidisciplinary teams within the institution and improves research opportunities on national and international levels. The universal use of the International Federation of Gynecology and Obstetrics (FIGO) classification for a description of intra-operative findings is an important tool for potential use in this standardization.

STUDY DESIGN: We conducted a retrospective chart review of patients delivered for PASD at the University Health System in San Antonio, TX in twelve-month period between 2022 and 2023. We compared the reported rate of intra-operative findings and reported standardized FIGO descriptors before and after the implementation of standardized use of the FIGO criteria.

RESULTS: A total of 30 cases were evaluated: 17 pre-implementation and 13 post-implementations. Pre-implementation, cesarean hysterectomy was performed in 13 out of 17 cases (76.5%) with histological confirmation of placenta percreta in 69.2%, increta in 15.4%, and accreta in 15.4%. Post-implementation, cesarean hysterectomy was performed in 10 out of 13 (76.9%) cases with histological confirmation of placenta percreta in all cases (100%). Intraoperative findings were documented in all (100%) charts. FIGO staging classification was not used in the pre-implementation period and was utilized in 69.2% of cases after the implementation. The reporting of "bluish/purple coloring, distention or bulge" increased from 41.2% to 84.6%, "hypervascularity" description improved from 52.9% to 76.9%, "placenta tissues in the uterus or clear plane between the uterus and bladder" improved from 41.2% to 84.6%, "invasion into the bladder or nearest organs" improved from 41.2% to 69.2% in 2022 and 2023 respectively. Table 1 demonstrated a reported rate of standardized intra-operative descriptors.

CONCLUSION: The use of a standardized FIGO classification approach for reporting intra-operative findings during PASD cases in our institution significantly improved the quality of reported findings.

Table 1. Report rate of standardized intra-operative FIGO descriptors before and after implementation of the universal protocol.

Positive or negative description of findings	2022 N=17 (%)	2023 N=13 (%)	P*
Intra-operative findings described in the operative report	17 (100)	13 (100)	-
FIGO staging of intra-operative findings	0	9 (69.2)	0.0001
Bluish /purple coloring and distention or "bulge"	7 (41.2)	11 (84.6)	0.02
Hypervascularity	9 (52.9)	10 (76.9)	0.18
Placenta tissues in the uterus or clear plane between the uterus and bladder	7 (41.2)	11 (84.6)	0.02
Invasion into the bladder or nearest organs	7 (41.2)	9 (69.2)	0.13

229 Biomechanical modeling of cervical support during pregnancy: implications for the treatment of cervical insufficiency

Abigail Laughlin[1], Erin Louwagie[1], Devon Campbell[2], Michael House[3], kristin Myers[1]

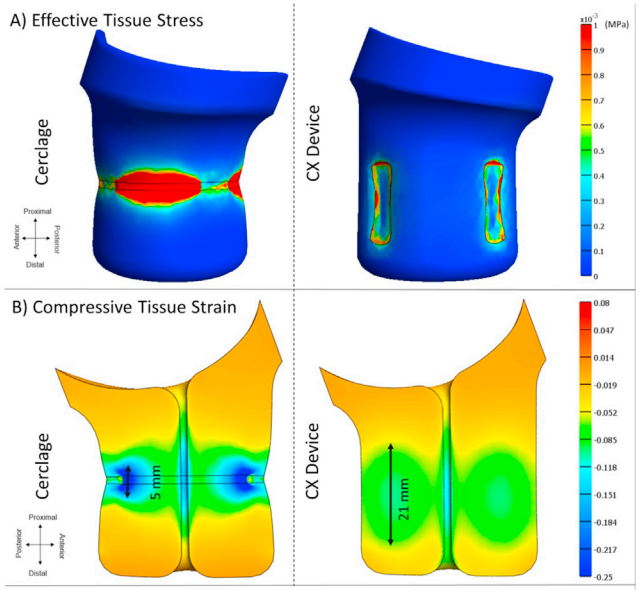
[1]Columbia University, New York, NY, [2]Prodct, LLC, Lexington, MA, [3]Tufts Medical Center, Boston, MA

OBJECTIVE: A cerclage supports the cervix by applying compression to the cervical stroma. However, the biomechanics of cervical compression are not well understood. In this study, we aimed to investigate the biomechanics of cerclage support by modeling cerclage compression. We also examined cervical compression using the Cx Device, a medical device currently in development as an alternative to cerclage. The Cx Device is designed to distribute cervical compression over a larger contact area. Our hypothesis was that our models would show a wider distribution of compression with the Cx Device compared to the cerclage.

STUDY DESIGN: Three-dimensional ultrasound measurements of the uterus and cervix were taken from a patient at 21 weeks of gestation. The ultrasound anatomy was then converted into a computer-aided design (CAD) model, which included the cervix, uterus, fetal membranes, and abdomen. The model was meshed using tetrahedral elements in Hypermesh and imported into FEBio for finite element analysis. Material properties for the maternal reproductive tissue were assigned based on previously published mechanical data, and appropriate boundary conditions were applied. A force of 0.85 N was applied to the areas where the Cx Device and cerclage contact the cervix. The distribution of tissue stretch and stress in the cervix was computed for both the cerclage and Cx Device, allowing for a comparison of their biomechanical function.

RESULTS: Biomechanical modeling shows that cerclage is associated with areas of high stress concentration in the region where the suture is placed (Figure). Cervical compression is concentrated over a distance of 5 mm with a cerclage (blue color). In contrast, the Cx Device spreads cervical compression over a wider distance of 21 mm (green color), resulting in decreased stress concentrations.

CONCLUSION: Biomechanical modeling has demonstrated that the distribution of cervical compression is directly influenced by the method of cervical support used. This study provides valuable insight into the mechanism of mechanical support for the cervix.



A) Effective tissue stress and B) compressive tissue strain on cervix as cerclage and CX Device are applied to the model and loaded with the same force.

230 Trial of labor or repeat caesarean delivery in women with morbid obesity

Misooja Lee[1], Tawany C. Almeida[2], George R. Saade[2], Tetsuya Kawakita[2]

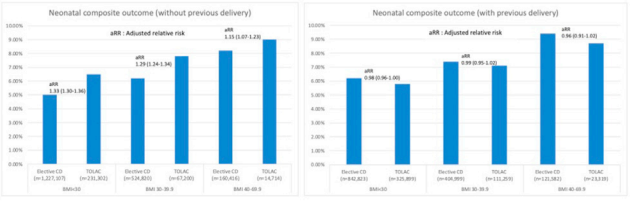
[1]Kindai University, Sayama city, Osaka, [2]Eastern Virginia Medical School, Norfolk, VA

OBJECTIVE: Given that obesity affects vaginal delivery rates (VD), which impact trial of labor after cesarean (TOLAC) success and safety, we aimed to evaluate the impact of BMI on adverse neonatal outcomes associated with TOLAC, after accounting for prior VD.

STUDY DESIGN: This was a repeated cross-sectional analysis of individuals with singleton, cephalic, and term deliveries with a history of one or two cesarean deliveries in the Linked Birth/Infant Death data from 2011 to 2020. Outcomes were examined according to the BMI category including BMI < 30, 30-39.9, and 40-69.9 kg/m^2. The primary outcome was a composite neonatal outcome, defined as any presence of neonatal death, neonatal intensive care unit admission, assisted ventilation, surfactant therapy, or seizures. Outcomes were compared between TOLAC and elective repeat cesarean delivery (eRCD) after stratifying by BMI category and previous VD. Log-binomial regression was performed to obtain adjusted relative risk (aRR) with 99% confidence intervals, controlling for covariates.

RESULTS: Of 4,055,440 individuals, 2,627,131 had BMI$<$ 30, 1,108,278 had BMI 30-39.9, and 320,031 had BMI 40-69.9 kg/m^2. In individuals with no prior VD, VD rates after TOLAC were 66.7%, 57.2%, and 48.1%, respectively. In individuals with prior VD, VD rates after TOLAC were 81.4%, 74.7%, and 67.3%, respectively. In the subgroup without prior VD, TOLAC was associated with the primary outcome in individuals with BMI < 30 kg/m^2 (5.0% vs. 6.5%; aRR 1.33 [1.30-1.36]), BMI 30-39.9 kg/m^2 (6.2% vs. 7.8%; aRR 1.29 [1.24-1.34]), and BMI 40-69.9 kg/m^2 (8.2% vs. 9.0%; aRR 1.15 [1.07-1.23]) compared with eRCD. In the subgroup with prior VD, there were no differences in the primary outcomes between TOLAC and eRCD across BMIs (BMI < 30: (6.2% vs.5.8%; aRR 0.98 [0.96-1.00]), BMI 30-39.9: (7.4% vs.7.1%; aRR 0.99 [0.95-1.02]), and BMI 40-69.9: (9.4% vs. 8.7%; aRR 0.96 [0.91-1.02]).

CONCLUSION: Neonatal outcome in TOLAC is impacted by prior VD rather than BMI. Prior studies regarding the safety of TOLAC in obese patients are likely confounded by prior VD.



231 Impact of OBTeleflex program on delivery outcomes at an academic urban center

Devika Lekshmi[1], Sophie Nader[2], Jennifer Roberts-Barry[1], Laura E. Baecher-Lind[1], Sebastian Ramos[2], Erika F. Werner[2]

[1]Tufts Medical Center, Boston, MA, [2]Tufts University School of Medicine, Boston, MA

OBJECTIVE: Studies have shown that telehealth can improve obstetric outcomes such as smoking cessation and breastfeeding rates. However, the effect of telehealth on outcomes such as mode of delivery has not been adequately investigated.

STUDY DESIGN: We performed a retrospective cohort study of all patients who initiated prenatal care between October 1st 2021 and September 30th 2022 at a major urban academic center. Patients were included if they were eligible for OBTeleflex, a hybrid telemedicine/in-person prenatal program that provides flexible, education-oriented prenatal care where 6 traditional antepartum/postpartum visits are replaced by remote visits with an OB nurse navigator. Low risk patients were eligible for OBTeleflex and included in this study if they had a singleton, viable, non-anomalous fetus, and did not have hypertension requiring medication. The primary outcome was mode of delivery. Patients who elected to participate in OBTeleflex were compared to those who opted for routine care. Standard labor management were per hospital protocol and maternal characteristics and pregnancy outcomes were collected from the EMR.

RESULTS: Of the 351 patients eligible for the OB Teleflex program, 63 (18%) chose to participate. The groups differed by race but other maternal characteristics did not differ significantly (Table). OBTeleflex participation was associated with a significantly higher rate of vaginal delivery compared to routine prenatal care (81% vs. 68%, p $= 0.04$) and lower rates of perineal tears (p=0.02). Rates of vaginal delivery did not differ significantly between OBTeleflex and routine prenatal care when comparing only nulliparous patients (78% vs. 66%, p $= 0.14$).

CONCLUSION: In this small cohort, a hybrid prenatal telemedicine program was associated with similar delivery outcomes in nullips and an increased rate of vaginal delivery in all comers compared to routine prenatal care. A randomized trial may help to elucidate

whether the increased flexibility and education in programs like OBTeleflex can lead to improved delivery outcomes.

232 Nipocalimab pharmacokinetic/pharmacodynamic and exposure-response modeling in pregnancies at risk for early-onset severe (EOS) HDFN

Jie Zhou[1], Jocelyn H. Leu[1], Yuan Xiong[1], Edwin Lam[1], Leona Ling[2], Umair Amin[1], Waheeda Sirah[1], Shumyla Saeed-Khawaja[2], Arpana Mirza[1], Yosuke Komatsu[1], Jannine Williams[1], Kattayoun Kordy[1], Ricardo Rojo Cella[1], An Vermeulen[3], Mahesh N. Samtani[1]

[1]Janssen Research & Development, LLC, Spring House, PA, [2]Janssen Research & Development, LLC, Cambridge, MA, [3]Janssen Research & Development, a division of Janssen Pharmaceutica NV, Beerse, Antwerpen

OBJECTIVE: Hemolytic disease of the fetus and newborn (HDFN) is a rare, immune-mediated red blood cell (RBC) disorder, where maternal IgG alloantibodies attack fetal RBCs. Nipocalimab is a fully human monoclonal antibody designed to selectively block the IgG binding site on neonatal Fc receptors (FcRn). Modeling approaches were used to characterize the pharmacokinetic/pharmacodynamic (PK/PD) and exposure-response (E-R) relationships of nipocalimab in the Phase 2 UNITY study in pregnancies at risk for EOS-HDFN.

STUDY DESIGN: UNITY is a multicenter, open-label, single-arm study evaluating the safety, efficacy, and PK/PD of nipocalimab in pregnant individuals at risk for EOS-HDFN. Data from three Phase 1 studies in healthy volunteers and the UNITY study were combined and utilized for the PK/PD and E-R modeling. Nipocalimab PK and FcRn occupancy (RO) were characterized by a 2-compartment target-mediated-drug-disposition (TMDD) model following intravenous (IV) doses. A PK/PD model was established to describe the observed longitudinal IgG data following IV doses. E-R relationships were explored to correlate nipocalimab PK or total IgG with efficacy and safety endpoints.

RESULTS: Nipocalimab PK exhibited nonlinear behavior. The developed TMDD PK model characterized the time courses of nipocalimab PK and FcRn RO. The PK/PD model indicated high potency of nipocalimab to reduce the maternal total IgG levels. Similar to total IgG, maternal alloantibodies decreased and showed a correlation with maternal total IgG. At the studied dose levels in UNITY, nipocalimab fully saturated FcRn, leading to decreased maternal alloantibodies and inhibition of their placental transfer. E-R modeling for primary efficacy and selected safety (ie, infection) endpoints showed that optimal responses have been achieved in EOS-HDFN participants.

CONCLUSION: This study demonstrates the correlation of nipocalimab PK and FcRn RO with reduction in total IgG and alloantibodies, as well as with clinical efficacy and safety endpoints. These relationships inform the appropriate dose regimen for evaluation in the pivotal Phase 3 study in EOS-HDFN.

233 Is ethnicity associated with different rates of engagement with remote postpartum blood pressure monitoring?

Adam K. Lewkowitz[1], Nina K. Ayala[2], Lauren Schlichting[3], Crystal F. Ware[2], Janet Rousseau[2], Amanda O'Neill[2], Katherine D. McCleary[2], Megan L. Ranney[4], Methodius G. Tuuli[2]

[1]Warren Alpert Medical School of Brown University, Women & Infants Hospital Rhode Island, Providence, RI, [2]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [3]Hassenfeld Child Health and Innovation Institute of Brown University, Providence, RI, [4]Yale School of Public Health, New Haven, CT

OBJECTIVE: Remote postpartum blood pressure (ppBP) programs reduce racial disparities in ppBP assessment. Their effect on ethnic disparities in ppBP assessment is less clear. We examined whether ppBP assessment differed among participants in remote ppBP monitoring programs who self-reported being Hispanic versus non-Hispanic.

STUDY DESIGN: This is a planned secondary analysis of a RCT including women in our tertiary care center's postpartum unit who had chronic or pregnancy-related hypertension (HTN) and were enrolled into our remote ppBP program, in which they manually enter BPs into a patient portal for 6 weeks. In the parent trial, consenting patients were randomized to remain in this program or be enrolled in another remote ppBP program, in which a Bluetooth-enabled BP cuff synched to an app utilizing AI to respond to each BP/symptom and flag abnormalities for providers. For this study, women who self-reported their ethnicity were stratified into two ethnic groups—Hispanic and non-Hispanic—regardless of randomization group. The primary outcome was ≥1 BP assessment 3-7 days after discharge. Secondary outcomes are listed in the Table. Odds ratios (OR) were calculated for categorical and betas for continuous outcomes.

RESULTS: Among 119 women in the parent study, 83 (70%) self-reported ethnicity, and the proportion of Hispanic people was similar in both groups. This study included 21 Hispanic (19% monolingual in Spanish) and 62 non-Hispanic women. Rates of BP assessment 3-7 days after discharge were similar (Hispanic 71% vs Non-Hispanic 79%; OR 0.7 (95% CI 0.2, 2.0). There were no

differences in mean number of remote ppBP assessments and rates of remote BP medication initiation or titration and HTN-related ED visits or readmission. Patients rated their remote ppBP program highly favorably, with median Likert scale scores of 10 (out of 10) in both groups.

CONCLUSION: Hispanic and non-Hispanic women in remote ppBP monitoring had similar HTN-related outcomes and favorable patient perceptions. These findings suggest the impact of remote ppBP programs on perinatal equity may not be limited to race-based disparities.

Table 1: Outcomes among Hispanic versus non-Hispanic postpartum women participating in a randomized trial comparing remote blood pressure monitoring programs

	Hispanic (n=21)	Non-Hispanic (n=62)	Odds Ratio or Beta (95% Confidence Interval (CI))
Primary Outcome			
Assessment of BP 3-7 days after discharge	15 (71)	49 (79)	0.7 (0.2-2.0)
Secondary Blood Pressure Outcomes			
BP max systolic (mmHg)	143 (139-152)	146 (134-154)	0.1 (-7.2-7.4)
BP max diastolic (mmHg)	98 (94-104)	97 (9)	2.0 (-3.7-7.7)
Number of remote BP assessments	14 (7-45)	23 (12-37)	0.1 (0-0.2)
Secondary Outcomes: Health Care Utilization			
Remote BP medication initiation within 6 weeks	0 (0)	6 (10)	---
Remote BP medication titration within 6 weeks	3 (14)	16 (26)	0.5 (0.1-1.8)
Presentation to ED within 30 days for hypertension	3 (14)	11 (18)	0.8 (0.2-3.1)
Readmission within 30 days for hypertension	2 (10)	7 (11)	0.8 (0.2-4.3)
Secondary Outcomes: Patient experience/mood			
"Using any number from 0 to 10 where 0 is the worst possible experience and 10 is the best possible experience, please rate your experience in the postpartum hypertension program"*	10 (9-10)	10 (9-10)	0.4 (-0.7-1.4)

Data are presented as n (%) or median (interquartile range)

234 Expanded carrier screening for genetic conditions with clinical trials in-utero therapy

Billie R. Lianoglou[1], Vivienne Souter[2], Brittany Prigmore[2], Elizabeth Repass[2], Yang Wang[2], Tippi C. MacKenzie[1]
[1]University of California, San Francisco (UCSF), Center for Maternal-Fetal Precision Medicine, San Francisco, CA, [2]Natera, Inc., Austin, TX

OBJECTIVE: Molecular fetal therapies for monogenetic conditions are an emerging area of care with the potential to transform outcomes. Identifying pregnancies eligible for treatment is challenging for conditions with no ultrasound manifestations. We evaluated carrier frequency for 9 conditions identifiable through reproductive carrier screening, focusing on conditions with active in-utero (IU) clinical trials.

STUDY DESIGN: This retrospective observational study included carrier screening tests from female patients, aged 18-55 years, ordered from a US commercial laboratory (Jan 2020-Sept 2022). Samples were tested for a variety of panels ranging from 2 to 421 genes. We calculated the proportion of samples that included screening for any of the conditions with IU therapy trials and the gene-specific carrier frequency for 7 autosomal recessive (AR) conditions and 2 X-linked (XL) conditions (Table 1). To focus on severe subtypes eligible for IU therapy, we excluded pseudodeficiency variants in IDUA, GAA, and ARSB and the neuronopathic protective variant (p.N409S) of Gaucher disease.

RESULTS: Of 822,155 samples screened, 228,720 (28%) were for a panel that included *none* of the conditions and were excluded from the analysis. 15,237 (1.9%) were for a panel with all of the relevant conditions with clinical trials of IU therapy. For the 7 AR conditions, the carrier frequency ranged from 1 in 77 for Pompe disease (GAA) to 1 in 1693 for MPS VII (GUSB) (Table 1). For the XL conditions, the carrier frequency was 1 in 5580 for X-linked Hypohidrotic Ectodermal Dysplasia (EDA) and 1 in 19274 for Hunter syndrome (IDS).

CONCLUSION: Our study highlights that carriers for these individually "rare" conditions are, collectively, not uncommon. However, many patients have screening with panels that detect *none* of the conditions and few have panels that detect all. As fetal and early postnatal treatment options expand for rare genetic conditions, we should reconsider the paradigm of screening (currently based on carrier frequency) to also include conditions with actionable findings.

Table 1. Gene specific carrier frequencies

	Gene (Condition)	Number Screened	Positive n (%)	95% CI
autosomal recessive	ARSB (MPS VI or Maroteaux-Lamy syndrome)	124,032	154 (0.124%; 1 in 805)	0.106%, 0.145% (1 in 943, 1 in 688)
	GAA (GSD II or Pompe)	101,350	1,310 (1.293%; 1 in 77)	1.225%, 1.364% (1 in 82, 1 in 73)
	GALNS (MPS IVA or Morquio syndrome)	15,237	28 (0.184%; 1 in 544)	0.127%, 0.265% (1 in 786, 1 in 377)
	GBA* (Gaucher)	593,435	2,679 (0.451%; 1 in 222)	0.435%, 0.469% (1 in 230, 1 in 213)
	GUSB (MPS VII or Sly syndrome	15,237	9 (0.059%; 1 in 1693)	0.031%, 0.112% (1 in 3218, 1 in 891)
	IDUA (MPS Type I Or Hurler syndrome)	155,859	744 (0.477%; 1 in 209)	0.444%, 0.513% (1 in 225, 1 in 195)
	LIPA (Wolman disease)	132,557	257 (0.194%; 1 in 516)	0.172%, 0.219% (1 in 583, 1 in 457)
X-linked	EDA (Hypohidrotic X-Linked ectodermal dysplasia)	111,608	20 (0.018%, 1 in 5580)	0.012%, 0.028% (1 in 8620, 1 in 3613)
	IDS (Hunter syndrome)	96,371	5 (0.005%; 1 in 19274)	0.002%, 0.012% (1 in 45123, 1 in 8233)

MPS= Mucopolysaccharidosis. GSD = Glycogen storage disease. *Excludes cases with the p.N409S variant which protects against neuronopathic Gaucher (Types 2 or 3). Pseudodeficiency variants in IDUA, GAA, and ARSB were excluded from the carrier frequency.

235 Endometriosis and adverse pregnancy outcomes: a nation-wide population-based study

Sun Min Kim, Byoung Jae Kim, Seo Hyun Choi, Hee Jeung Lim
Seoul National University College of Medicine, Seoul, Seoul-t'ukpyolsi

OBJECTIVE: Endometriosis is one of the main causes of infertility and pelvic pain; however, there are insufficient data about pregnancy outcomes in women with endometriosis. This study aimed to evaluate the relationship between endometriosis and adverse pregnancy outcomes

STUDY DESIGN: Data on singleton pregnancy deliveries between January 2014 and October 2019 were obtained from the Korean Health Insurance Review and Assessment Service database. The index date was defined as 266 days before delivery, and the follow-up end date was 42 days after delivery. Women with diagnostic codes for endometriosis within 3 years of the follow-up end date were classified into the endometriosis group. We compared the clinical characteristics and adverse pregnancy outcomes between women with endometriosis and those without endometriosis.

RESULTS: In total, 1,251,597 pregnant women were enrolled, of which 32,951(2.6%) were assigned to the endometriosis group. The mean maternal age was higher, and the rates of nulliparity and assisted reproductive technology were higher in the endometriosis group than in the non-endometriosis group. Women with endometriosis had significantly higher adverse pregnancy outcomes than those without endometriosis after adjusting for confounding factors. Adverse pregnancy outcomes associated with endometriosis included preterm labor, preterm birth, gestational hypertensive disorders, fetal growth restriction, placenta previa, placental abruption, antepartum and postpartum hemorrhage, and stillbirth. Additionally, cesarean delivery was significantly associated with endometriosis. The cesarean delivery rate was significantly higher in the endometriosis group than in the non-endometriosis group even when excluding cases with antenatal obstetric complications that could increase the risk of cesarean delivery.

CONCLUSION: Women with endometriosis have a significantly higher risk of adverse pregnancy outcomes even after successful conception.

236 Implementation study of early postpartum glucose tolerance test

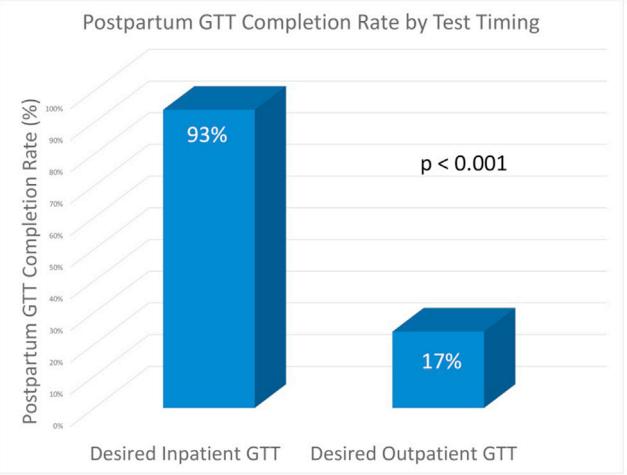
Jennifer Ludgin[1], Alysa St. Charles[1], Devika Lekshmi[1], Erika F. Werner[2]
[1]Tufts Medical Center, Boston, MA, [2]Tufts University School of Medicine, Boston, MA

OBJECTIVE: Recent data have shown that inpatient glucose tolerance tests (GTTs) >24 hours after delivery have similar diagnostic utility as the standard of care 4-12 weeks postpartum GTT to identify prediabetes and diabetes after gestational diabetes mellitus (GDM). Given low completion of the 4-12 week postpartum GTT, we sought to assess completion rate of the inpatient postpartum GTT in clinical care.

STUDY DESIGN: A prospective, single-center implementation study was performed at a tertiary care, urban hospital. Implementation strategy included interdisciplinary clinical protocol development, staff education, electronic health record modifications, and direct patient communication. All admitted postpartum patients with GDM were eligible for enrollment in the study and inpatient GTTs unless they received steroids in the prior 7 days, were critically ill, or could not tolerate a glucose load. The primary outcome assessed was postpartum GTT completion. Individuals who elected inpatient testing were compared to those who deferred testing to 4-12 weeks postpartum.

RESULTS: Between June 2022 and July 2023, 94% (161/171) of patients with GDM receiving postpartum care at our center were eligible for inpatient postpartum GTTs. Following implementation of the inpatient GTT option, 75% (n=120) of eligible postpartum patients elected inpatient testing. Postpartum GTT completion was significantly higher among those who elected inpatient GTTs compared to those who deferred testing (93% v 17%, p< 0.001, Figure). Maternal characteristics did not differ between those who desired inpatient GTTs and those who deferred testing except that those requiring medication management for GDM were more likely to elect inpatient GTTs (p=0.01). Among those whose GTT was deferred, 76% cited personal preference, 5% cited medical recovery needs, and 19% were not offered early testing. Postpartum visit attendance did not differ by timing of the GTT (57% v 59%, p=0.90).

CONCLUSION: When postpartum GTTs are offered as part of routine inpatient care after GDM, >90% test completion can be achieved with simple implementation strategies.



237 Mifepristone as an adjunct to transcervical balloon for labor induction (MiLI): a randomized controlled trial

Hayley E. Miller[1], Michael T. Jennings[2], Stephanie A. Leonard[3], Jonathan A. Mayo[3], Deirdre J. Lyell[4], Yasser Y. El Sayed[5], Paul Blumenthal[2], Kate Shaw[2]
[1]Stanford University Hospital, San Francisco, CA, [2]Stanford University Hospital, Palo Alto, CA, [3]Stanford University, Palo Alto, CA, [4]Stanford University Medical Center, Palo Alto, CA, [5]Stanford University, Stanford, CA

OBJECTIVE: Additional options for outpatient cervical preparation prior to term labor induction are needed. Mifepristone decreases induction times by nearly half in the second trimester when used for cervical preparation. We sought to assess uterine and fetal heart tracing (FHT) response to mifepristone in term, inpatient, labor induction.

STUDY DESIGN: We conducted an exploratory, unmasked, randomized controlled trial that enrolled nulliparas 18 to 45 years old at 37 to 42 weeks' gestation undergoing induction with a transcervical balloon. Participants were randomized to receive either oral mifepristone 200 mg or oral misoprostol 50 mcg within three hours of balloon placement. Clinicians managed labor and delivery using standard care. We assessed presence of uterine contractions while the balloon was in place, and uterine tachysystole and category II FHT in the 12 hours following study medication and induction duration.

RESULTS: We enrolled and randomized 30 participants between July 2022 and April 2023. Of the participants who received misoprostol, 86% received one dose and 14% received two doses. In the 12 hours after medication administration, participants who received mifepristone had a median number of contraction 38% lower than those who received misoprostol (p< 0.001) and zero incidence of tachysystole versus five among those who received misoprostol (p=0.04). No category II FHT occurred in either group in the first 12 hours after medication administration. Compared to misoprostol, mifepristone had longer median times with a balloon (2.6 hours, p=0.01) and to complete dilation (8 hours, p=0.01), with a similar proportion delivering by 24 hours (p=0.45).

CONCLUSION: In this exploratory study, when used with a balloon at term, compared to misoprostol, mifepristone induced fewer median number of contractions and less tachysystole in the 12 hours following administration. Category II FHT did not occur in the 12

hours following medication administration in both groups. These data may help inform future studies on the safety and efficacy of outpatient mifepristone for pre-induction cervical preparation.

Table 1. Obstetric and neonatal outcomes among participants who were randomized to receive mifepristone 200 mg versus misoprostol 50 mcg in conjunction with a transcervical balloon.

Obstetric outcomes	Mifepristone N=15	Misoprostol N=15	P-value

238 Optimal timing of delivery in pregnancies complicated by pregestational diabetes: a population-based study

Mona M. Makhamreh[1], Huda B. Al-Kouatly[2], Moti Gulersen[3], Rodney A. McLaren Jr.[3]
[1]Maimonides Medical Center, Brooklyn, NY, [2]Thomas Jefferson University, Philadelphia, PA, [3]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA

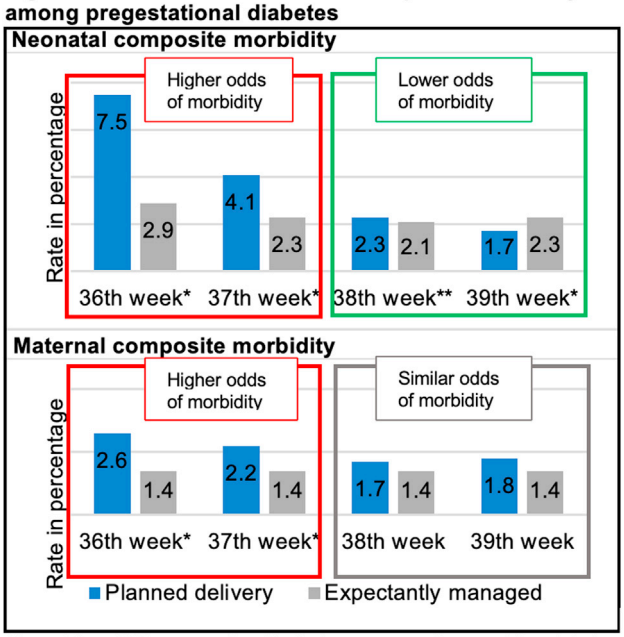
OBJECTIVE: The American College of Obstetricians and Gynecologists recommend delivery 36 0/7-39 6/7 weeks for pregnancies complicated with pregestational diabetes mellitus (PGDM) based on limited data. Our objective was to assess neonatal and maternal morbidity at birth for each week of gestation in pregnancies complicated with PGDM to determine risk versus benefit between 36 0/7-39 6/7 weeks.

STUDY DESIGN: This was a population-based cohort study of non-anomalous, singleton, live births complicated by PGDM between 36 and 41 completed weeks using data from the U.S. Natality Vital Statistics (2015-2021). Planned delivery group were births at each completed week from 36 to 39 weeks that had a labor induction or pre-labor cesarean delivery, excluding spontaneous labor. Expectant management group included all births that delivered on or after the following week (i.e., planned birth at 36 0/7-36 6/7 was compared to all births ≥ 37 0/7 weeks). The primary outcomes were neonatal and maternal adverse composites (Figure 1). These outcomes were compared between both groups at each week using multivariable analyses.

RESULTS: There were 173,822 births. Before 38 weeks, planned delivery had higher odds of neonatal morbidity than those expectantly managed (planned 36 weeks births: 7.5% vs expectant births ≥37 weeks: 2.9%, aOR 1.81, 95% CI 1.61-2.04; planned 37 weeks birth: 4.1% vs expectant births ≥38 weeks: 2.3%, aOR 1.34, 95% CI 1.21-1.48). Planned delivery at 38 weeks and 39 weeks had lower odds of neonatal morbidity than those expectantly managed (38 weeks: 2.3% vs ≥39 weeks 2.1%, aOR 0.88, 95% CI 0.77-0.99; 39 weeks: 1.7% vs ≥40 weeks: 2.3, aOR 0.71, 95% CI 0.61-0.83). Planned delivery at ≥38 weeks had similar odds of maternal morbidity to those expectantly managed.

CONCLUSION: For pregnancies complicated with PGDM, planned delivery at 38 0/7-39 6/7 weeks had lower odds of neonatal morbidity and no difference in maternal morbidity compared to expectant management. This data suggests optimal delivery timing for pregnancies with PGDM is 38 0/7-39 6/7 weeks. A randomized trial is needed to confirm this finding.

Figure 1: Neonatal and maternal composite morbidity among pregestational diabetes



Neonatal morbidity composite: 5-min Apgar score <5, neonatal assisted ventilation use >6 hours, neonatal seizures, 10-min Apgar score =0, and neonatal death
Maternal morbidity composite: third- and fourth-degree perineal lacerations, maternal ICU admission, maternal transfusion, and unplanned hysterectomy.

239 Perinatal outcomes of myelomeningocele by mode of delivery in the United States

Mona M. Makhamreh[1], Rodney A. McLaren Jr.[2], Moti Gulersen[2], Melissa L. Russo[3], Huda B. Al-Kouatly[4]
[1]Maimonides Medical Center, Brooklyn, NY, [2]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA, [3]Women and Infants Hospital, Providence, RI, [4]Thomas Jefferson University, Philadelphia, PA

OBJECTIVE: The optimal mode of delivery for fetuses with myelomeningocele remains uncertain. Our study aimed to compare perinatal outcomes of newborns with myelomeningocele by mode of delivery in a contemporary United States (US) cohort.

STUDY DESIGN: A retrospective cohort used population-based data from the US Natality Database on live singleton births complicated by myelomeningocele (2017-2021). Data was stratified to vaginal versus planned cesarean delivery. Cases delivered by cesarean after a failed trial of labor or unknown trial of labor attempt were excluded. The primary outcome was adverse perinatal composite, including preterm birth < 37 and < 34 weeks, chorioamnionitis, 5-minute Apgar score < 3, NICU admission, immediate and >6 hour assisted ventilation use, surfactant use, neonatal seizures, and neonatal mortality. Our secondary outcome included each component of the composite. Neonatal death was defined at the time of the birth certificate reporting. Multivariable logistic regression compared outcomes between vaginal and cesarean groups, adjusting for potential confounders.

RESULTS: Of the 13,368,848 births included, 1,559 (0.012%) were affected by myelomeningocele. Delivery mode was planned cesarean in 939 (60%) and vaginal in 492 (32%). Examining gestational age at birth in newborns with myelomeningocele, 457 (29%) were < 37 weeks, and 179 (39%) < 34 weeks. Vaginal birth was associated with lower odds of adverse perinatal composite compared with planned cesarean birth (Table 1). Evaluating individual components of the composite, vaginal delivery was associated with a higher rate of chorioamnionitis and planned cesarean delivery was associated with high rate of respiratory adverse outcomes. Additionally, vaginal delivery was associated with higher odds of seizures and neonatal death compared to planned cesarean delivery.

CONCLUSION: Patient counseling on delivery planning for pregnancies complicated by myelomeningocele should include a discussion of potential adverse outcomes individualized to patients in the shared-decision-making process.

Table 1. Perinatal outcomes of births complicated by myelomeningocele by mode of delivery

Outcomes	Vaginal delivery N=492	Planned cesarean delivery N=939	*P*	aOR, 95% CI*
Perinatal adverse composite	376 (76.4%)	881 (93.8%)		0.21 (0.15-0.30)
Mean GA at delivery, weeks	37.4±3.8	36.6±3.1	<0.001

240 Isthmocele in patients with history of cesarean delivery followed by pregnancy complicated with placenta accreta

Staci Marbin[1], Fielding Stephen[2], brian druyan[3], eva hoffmann[4], catherine Marudo[2], Meghana Chapalamadugu[2], Kathy Truong[2], Nidhi Gajakas[2], Christina Yarborough[2], Grace Sarris[2], Kelby Hunt[2], Maria Mantero[2], Pasquale Patrizio[2], jose carugno[5], Anna K. Sfakianaki[6]

[1]Jackson Memorial Hospital, Miami, FL, [2]University of Miami, Miami, FL, [3]University of Miami School of Medicine, Miami, FL, [4]University of Miami School of Medicine, Jackson Memorial Health System, Miami, FL, [5]Univeristy of Miami, Miami, FL, [6]Yale University School of Medicine, Miami, FL

OBJECTIVE: Isthmocele, a complication of Cesarean Delivery (CD), is associated with postmenstrual spotting, secondary infertility, cesarean scar pregnancies, and abnormal placentation. The extent isthmocele is associated with development of placenta accreta spectrum (PAS) is unknown and existing data is mostly retrospective. This study aims to determine the relationship between isthmocele and development of PAS.

STUDY DESIGN: A retrospective study was conducted at a National Accreta Center from January 1, 2012 through September 30, 2022. All patients with a history of CD and confirmed PAS were identified and compared to patients who did not develop PAS and underwent repeat CD. Ultrasounds were reviewed for presence, size, and appearance of isthmocele, as well as associated prenatal and demographic information. Statistical analysis included T test and Chi square with $P < 0.05$ considered significant when comparing the two study groups.

RESULTS: We identified 137 patients with a history of CD who went on to develop PAS. Among those who had early ultrasound images for review, there were 23 patients who developed PAS after CD compared to 70 patients who had normal placentation. There were no differences in age and number of prior CDs across study groups. Patients who developed PAS were nearly 6 times as likely to have an isthmocele on early US ($p=0.002$). Notably, every patient with early implantation in the lower half of the uterus ultimately developed PAS whereas those patients with implantation in the upper half of the uterus did not irrespective of isthmocele diagnosis.

CONCLUSION: Isthmoceles diagnosed on early US are associated with a significantly increased risk of PAS. Our study highlights the importance that accurate identification of early implantation in the lower uterine segment has in prediction of development of PAS in patients with history of CD. Prospective studies are critically necessary in order to evaluate isthmocele as an independent risk factor for development of PAS.

241 Efficacy of non-pharmacologic interventions for antepartum cervical ripening in term pregnancies

Daniel Martingano[1], Rachel Amuzu[2], Andrea Ouyang[3], Marwah Al-Dulaimi[1], Shavana Singh[4], Jessica Marshall[1], Sheida Rodriguez[1], Alexander Ulfers[5], Benjamin Dribus[6], Jacqueline Marecheau[1], Donald Morrish[1], Kristin Cohen[7], Shailini Singh[8], Antonia F. Oladipo[9]

[1]St. John's Episcopal Hospital-South Shore, Far Rockaway, NY, [2]Rutgers Health, Jersey City Medical Center, Elizabeth, NJ, [3]William Carey University College of Osteopathic Medicine, Baton Rouge, LA, [4]Lake Erie College of Osteopathic Medicine, Far Rockaway, PA, [5]Walter Reed National Military Medical Center, Bethesda, MD, [6]William Carey University, Hattiesburg, MS, [7]RWJBarnabas Health, Trinitas Regional Medical Center, Elizabeth, NJ, [8]Hackensack Meridian Health, JFK University Medical Center, Edison, NJ, [9]Hackensack University Medical Center, Hackensack, NJ

OBJECTIVE: While various non-pharmacologic interventions for antepartum cervical ripening (NPACR) are widely utilized, their effectiveness remains unknown. This study sought to evaluate the effects and potential benefits of commonly used interventions for ACR for pregnant patients at term.

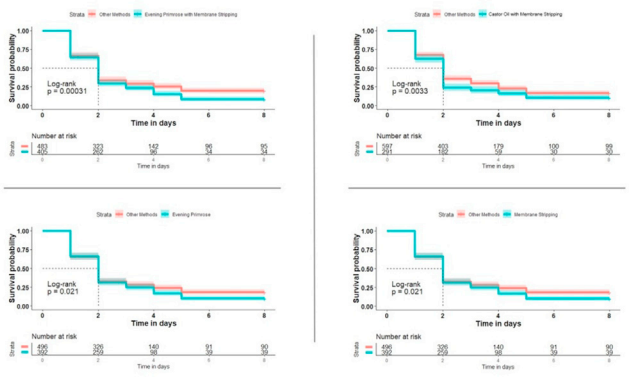
STUDY DESIGN: We conducted a multi-center, prospective observational study from 7/2021 to 7/2023 comparing all pregnant patients who received any form of NPACR within the gestational age range of

40 0/7 to 41 0/7 weeks. Interventions considered for analysis included exercise, sexual intercourse, membrane stripping (MS), diet modifications, nipple stimulation, castor oil, evening primrose, and black cohosh. Patients less than 40 0/7 weeks gestation, multiple gestations, or utilized more than one mechanical or dietary intervention were excluded. The primary outcomes included time to spontaneous labor (SL) and the need for pharmacologic induction of labor at late term as a discrete event.

RESULTS: The study included 888 patients who reported using an NPACR. Study groups' demographics were not significantly different. Patients using either evening primrose (2.6 v. 3.1 days, p=0.020) or MS (2.7 v. 3.9 days, $p<$ 0.001) had lower times to SL as compared to non-use. Combinations of MS with primrose (2.5 v. 3.2 days, $p<$ 0.001) or MS with castor oil (2.5 v. 3.0 days, p=0.01) had lower times to SL. Kaplan-Meier survival analysis also demonstrated significantly less time to SL (Figure 1.) Nipple stimulation (4.9 v. 2.8 days, $p<$ 0.001) and sexual intercourse (4.2 v. 2.7 days, $p<$ 0.001) were associated with increased times to SL. In adjusted models, a 35%, 49%, 46%, and 37% decreased risk of needing pharmacologic induction of labor was noted with use of primrose (RR 0.65, 95%CI 0.47-0.9, p=0.010), MS (RR 0.49, 95%CI 0.45-0.76, $p<$ 0.001), combinations of MS with primrose (RR 0.54, 95%CI 0.38-0.77, $p<$ 0.001), or MS with castor oil (RR 0.67, 95%CI 0.45-0.76, $p<$ 0.001), respectively.

CONCLUSION: Antepartum use of primrose oil and/or membrane stripping is a potentially efficacious method of NPACR for pregnant patients at term.

Kaplan Meier Survival Analysis for Non-Pharmacologic Methods of Cervical Ripening



242 Impact of unit acuity on postpartum hemorrhage and severe maternal morbidity

Logan Mauney, Kaitlyn E. James, Damilola M. Shobiye, Sarah Rae Easter, Christina M. Duzyj Buniak, Mark A. Clapp
Massachusetts General Hospital, Boston, MA

OBJECTIVE: Many have investigated the impact of individual patient and hospital factors on maternal morbidity. We sought to understand the impact of labor and delivery unit acuity and patient volume on a patient's risk of postpartum hemorrhage (PPH) and severe maternal morbidity (SMM).

STUDY DESIGN: This is a retrospective cohort study between 3/2021 and 11/2022 at 8 hospitals and included laboring patients with viable, liveborn deliveries with an Obstetric Comorbidity Index (OB-CMI) score recorded on admission. We measured the association of unit acuity (mean OB-CMI score on a unit in a 24-hour period) on PPH and SMM using logistic regressions. Fixed effects for hospital were included to account for fixed hospital-specific characteristics, and standard errors were clustered by hospital. Models were adjusted for volume (number of deliveries in 24-hour period) and patient factors (OB-CMI, parity, and gestational age). We performed this analysis in a subset of patients at low risk of morbidity (OB-CMI $\leq$2). As sensitivity analyses, we assessed other measures of unit acuity (relative unit acuity, maximum OB-CMI, and unit presence of a patient with OB-CMI >5), and an outcome of non-transfusion SMM.

RESULTS: Of 22,159 patients included, 713 (3.2%) had SMM, and 1,921 patients (8.6%) had a PPH. In unadjusted models, mean daily OB-CMI was associated with PPH (OR 1.19, 95% CI 1.14-1.24) and SMM (OR 1.26, 95% CI 1.17-1.36). The association was not affected by delivery volume in a 24-hour period. However, after adjusting for patient factors, there was no association with SMM; the association with PPH was weak (Table 1). For the adjusted analysis in the low-risk cohort, unit acuity was not associated with PPH or SMM. This pattern persisted for alternative measures of unit acuity and for non-transfusion SMM.

CONCLUSION: In a large healthcare system, measures of unit acuity were not associated with a patient's risk of PPH or SMM after controlling for patient-level factors. This suggests individual outcomes are not significantly affected by unit acuity or volume, rather most risk is related to individual patient factors.

Table 1 - Association of mean daily unit OB-CMI with PPH and SMM

	Postpartum hemorrhage		Severe maternal morbidity	
	All deliveries N=22,159	OB-CMI ≤2 N=17,348	All deliveries N=22,159	OB-CMI ≤2 N=17,348
Mean OB-CMI	OR (95% CI)	OR (95% CI)	OR (95% CI)	OR (95% CI)
Model with fixed effects of hospital	1.19 (1.14-1.24)	1.11 (1.05-1.18)	1.26 (1.17-1.36)	1.08 (0.91-1.3)
Model further adjusted for delivery volume[a]	1.19 (1.15-1.24)	1.11 (1.05-1.18)	1.26 (1.17-1.36)	1.08 (0.91-1.3)

243 A standardized anemia protocol and obstetric clinic-based intravenous iron center reduces anemia at delivery admission

Logan Mauney[1], Kaitlyn E. James[1], Jonathan Y. siden[2], Mark A. Clapp[1], Sarah N. Bernstein[1]
[1]Massachusetts General Hospital, Boston, MA, [2]Mass General Brigham, Boston, MA

OBJECTIVE: Protocols for diagnosis and management of antepartum anemia increase use of intravenous (IV) iron and improve pre-delivery hematocrit (Hct). IV Fe use is limited, however, by delays in diagnosis and administration restricted to infusion centers or inpatient units. To address these issues, we launched a standardized protocol for diagnosis and management of anemia across our practice as well as an IV iron center in our obstetrics clinic. We sought to study the impact of the protocol and onsite IV iron center on rates of IV iron administration and anemia diagnosis at the time of delivery.

STUDY DESIGN: Our retrospective cohort study included patients admitted for delivery at an urban academic hospital during a 10-month period pre- and post-intervention (3/2021-12/2021 and 8/2022-6/2023) that had a Hct recorded prenatally and at delivery hospitalization. Patients with a comorbidity contributing to anemia (hemoglobinopathy, bleeding disorder, renal disease, bleeding in pregnancy) were excluded. Anemia was defined as Hct < 33% at any point during pregnancy. The primary outcome was anemia on

admission. Secondary outcomes were the receipt of IV iron and blood transfusion at delivery.

RESULTS: There were 2,704 and 2,624 patients in the pre- and post-intervention groups of which 765 (28.3%) and 998 (38.0%) had antepartum anemia (P< 0.001). Of patients with anemia, 47/765 (6.1%) and 162/998 (16.2%) received IV Fe pre- and post-intervention (P=0.001) with no significant change in the rate of PO Fe (24.5% vs. 27.5%, P=0.17). Anemia on admission was lower in the post-intervention group (34.7% vs. 39.5%, P=0.04) and persisted at a threshold of Hct < 30% (4.5% vs. 6.7%, P=0.05). The rate of transfusion also decreased during the study period (2.5% vs. 4.6%, P=0.02).

CONCLUSION: The creation of an anemia protocol and obstetrics based IV iron center drastically increased utilization of IV Fe and decreased rates of anemia and blood transfusions at delivery at our institution. Given these findings, OB practices should strongly consider integrating similar interventions into their practices.

Table 1 - Rates of anemia and treatment before and after intervention

	Pre-intervention	Post-intervention	
	All patients		
	N=2,704	N=2,624	P-value
Hct <33%	765 (28.3)	998 (38.0)	<0.001
Hct <30%	163 (6.0)	205 (7.8)	0.01
Hct <27%	29 (1.1)	28 (1.1)	0.98
GA at anemia diagnosis (weeks)	27.8 (7.7)	27.0 (8.0)	0.041
	Patients with anemia		
	N=765	N=998	
IV iron (patients)	47 (6.1)	162 (16.2)	0.001
PO iron (patients)	210 (27.5)	245 (24.5)	0.17
Anemia on delivery admission			
Hct <33%	296 (39.5)	338 (34.7)	0.04
Hct <30%	50 (6.7)	44 (4.5)	0.05
Blood transfusion	35 (4.6)	25 (2.5)	0.02

244 An anemia protocol and obstetric clinic-based iron infusion center decreases disparities in IV iron access

Logan Mauney[1], Jonathan Y. siden[2], Kaitlyn E. James[1], Mark A. Clapp[1], Sarah N. Bernstein[1]

[1]Massachusetts General Hospital, Boston, MA, [2]Mass General Brigham, Boston, MA

OBJECTIVE: Racial disparities in antepartum anemia exist with Black pregnant people experiencing 2x greater prevalence of anemia than non-Hispanic Whites. The use of protocols for the diagnosis and management of anemia increases the use of intravenous (IV) iron and delivery hematocrit, but it is unknown if all racial and ethnic groups benefit. IV iron can be difficult to access because it is often administered in IV infusion centers or inpatient. To improve access, our institution established a standardized anemia protocol and infusion center housed in the obstetrics clinic.

STUDY DESIGN: This retrospective cohort study examined patients admitted for delivery at a large academic hospital in the 10 months pre- and post-intervention (3/2021-12/2021 and 8/2022-6/2023). Patients with Hct < 33% at any point in pregnancy were included. Those with hemoglobinopathy, renal disease, and bleeding in pregnancy were excluded. Self-reported race/ethnicity data was abstracted from the EMR. The primary outcome was anemia on admission and secondary outcomes were rates of IV iron and blood transfusion during the delivery encounter.

RESULTS: There were 2,704 and 2,624 patients in the pre- and post-intervention groups respectively, including 1,772 White (78%) and 206 Black (8%). Black patients had higher baseline rates of anemia than White patients (39% vs 27%). All racial and ethnic groups saw increases in IV iron administration after the intervention (p< 0.05), with Black patients experiencing an 11-point increase compared to a 10-point increase among White patients. The rates of anemia on admission for delivery and transfusion were not statistically different for any racial or ethnic groups pre- or post-intervention but were significant for the cohort as a whole.

CONCLUSION: Implementation of a standardized anemia protocol and an obstetrics clinic-based infusion center improved access to IV iron administration for all racial and ethnic groups, including for black patients. Given the urgent need to address disparities in maternity care, practices should consider implementation of similar interventions.

Table 1 - Rates of anemia and treatment by race and ethnicity before and after intervention

	Pre-intervention (%)		Post-intervention (%)	
	All patients N=2704	With anemia N=765	All patients N= 2624	With anemia N=998

245 Accuracy of deep learning models in interpreting intrapartum fetal monitoring to predict fetal acidemia

Jennifer A. McCoy[1], Guangya Wan[2], Lisa D. Levine[3], Joseph Teel[3], John Holmes[3], William LaCava[2]

[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [2]Harvard University, Boston, MA, [3]University of Pennsylvania, Philadelphia, PA

OBJECTIVE: Up to 30% of cesareans in the US are performed due to false-positive interpretations of intrapartum electronic fetal monitoring (EFM). EFM interpretation is subjective and vulnerable to bias. Novel deep learning techniques can improve complex data processing and pattern recognition in medicine. We sought to apply deep learning approaches that could interpret EFM data to predict fetal acidemia.

STUDY DESIGN: The database was created using intrapartum EFM data from 2006-2020 at a large, multi-site academic health system. We included patients ≥34 weeks with a singleton, vertex fetus with EFM data available for ≥1 hour prior to delivery and an umbilical cord blood pH result available. We excluded those with >30% missingness in EFM data. Data pre-processing removed noise and artifact. Data was divided into training and testing sets with equal distribution of acidemic cases. Several different deep learning architectures were explored, including transformers, convolutional neural networks (CNNs), and long short-term memory (LSTM) networks. The primary outcome was low cord blood pH, investigated at four clinically meaningful thresholds: 7.2, 7.15, 7.1, and

7.05. Receiver operating characteristic (ROC) curves were generated with area under the curve (AUC) assessed to determine the performance of the models.

RESULTS: A total of 124,776 fetal monitoring files were available, 35,604 had a corresponding umbilical cord gas pH result, and the final sample size was 10,176. The prevalence of the outcome in the data was 20.9% with pH < 7.2, 9.1% < 7.15, 3.3% < 7.10, and 1.3% < 7.05. The median AUC values for each deep learning model at each different pH threshold are shown in Figure 1. The best performance was achieved with the CNN multiscale model and a pH threshold of 7.10, with an AUC of 0.82 95% CI [0.82-0.83].

CONCLUSION: A novel application of deep learning methods achieves excellent performance in predicting fetal acidemia on umbilical cord blood pH. This technology could improve the accuracy and consistency of EFM interpretation to prevent unnecessary cesarean deliveries and avoidable intrapartum fetal injury.

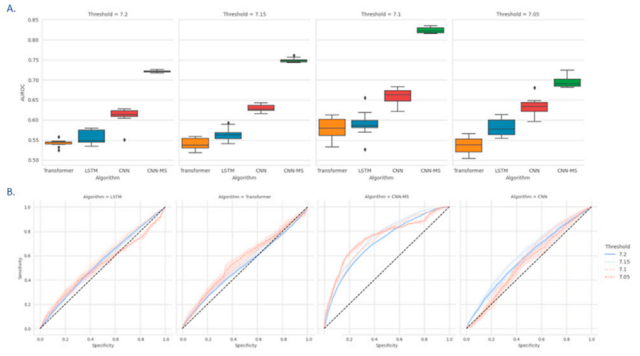

Figure 1. Panel A: box plots depicting area under the curve and 95% confidence intervals of each model type at each umbilical cord blood pH threshold. Panel B: ROC curves for each model type at each umbilical cord blood pH threshold. *LSTM: long short term memory; CNN: convolutional neural network; CNN-MS: convolutional neural network multiscale.*

246 The fragility index of randomized controlled trials in obstetrics

Jordan A. McKinney[1], Kelcey Day[1], Lifeng Lin[2], Luis Sanchez Ramos[1]

[1]University of Florida College of Medicine, Jacksonville, FL, [2]University of Arizona, Tucson, AZ

OBJECTIVE: To assess the fragility index (FI) and fragility quotient (FQ) of recently published obstetric randomized controlled trials (RCTs) in order to evaluate the robustness of study results beyond conventional statistical significance testing.

STUDY DESIGN: A retrospective analysis was conducted to identify obstetric RCTs published between 2018 and 2022 in the top medical and obstetric journals, based on impact factor. Eligible studies included those with at least one statistically significant binary primary outcome. Two independent reviewers extracted data on sample size, event and control group sizes, loss to follow-up, blinding status, type of intervention, and other relevant factors. The FIs and FQs were calculated for each study.

RESULTS: A total of 245 RCTs were identified, and 31 met the eligibility criteria. The median and interquartile range FI for all studies was 6 (2-20), while the median FQ was 0.011 (0.004-0.034). Of the studies, 39% had an FI < 5. RCTs with placebo control groups demonstrated greater robustness compared to those with active control groups (5 [2-12]; P=0.028). Otherwise, no statistically significant relationships were observed between FI or FQ and other variables. Loss to follow-up exceeded the FI in 39% of the studies.

CONCLUSION: Incorporating the FI and FQ as complementary measures to traditional statistical significance testing is crucial for assessing the robustness of trial results in obstetrics. These metrics offer valuable insights into study reliability and can guide informed decisions regarding the safety and efficacy of interventions. By considering the FI and FQ, clinicians and researchers can navigate uncertainties associated with the evidence more effectively.

247 Exploring the limits of artificial intelligence for referencing scientific articles

Emily Graf[1], Jordan A. McKinney[1], Alexander Dye[1], Lifeng Lin[2], Luis Sanchez Ramos[1]

[1]University of Florida College of Medicine, Jacksonville, FL, [2]University of Arizona, Tucson, AZ

OBJECTIVE: To evaluate the reliability of three artificial intelligence (AI) chatbots (ChatGPT, Google Bard, and Chatsonic) in generating accurate references from existing obstetric literature.

STUDY DESIGN: Between mid-March and late April 2023, ChatGPT, Google Bard, and Chatsonic were prompted to provide references for specific obstetrical randomized controlled trials (RCTs) published in 2020, adhering to the AMA Manual of Style guidelines. RCTs were considered for inclusion if they were mentioned in a previous article that primarily evaluated RCTs published by the top medical and obstetrics and gynecology journals with the highest impact factors in 2020, as well as RCTs published in a new journal focused on publishing obstetric RCTs. The selection of the three AI models was based on their popularity, performance in natural language processing, and public availability. Data collection involved prompting the AI chatbots to provide references according to a standardized protocol. The primary evaluation metric was the accuracy of each AI model in correctly citing references, including authors, publication title, journal name, and DOI. Statistical analysis was performed using a permutation test to compare the performance of the AI models.

RESULTS: Among the 44 RCTs analyzed, Google Bard demonstrated the highest accuracy, correctly citing 13.6% of the requested RCTs, while ChatGPT and Chatsonic exhibited lower accuracy rates of 2.4% and 0%, respectively. Google Bard often substantially outperformed Chatsonic and ChatGPT in correctly citing the studied reference components. The majority of references from all AI models studied were noted to provide DOIs for unrelated studies or DOIs that do not exist.

CONCLUSION: To ensure the reliability of scientific information being disseminated, authors must exercise caution when utilizing AI for scientific writing and literature search. However, despite their limitations, collaborative partnerships between AI systems and researchers have the potential to drive synergistic advancements, leading to improved patient care and outcomes.

Summary of permutation analysis

248 Changes in low-dose aspirin eligibility and use among nullips after updated USPSTF guidance

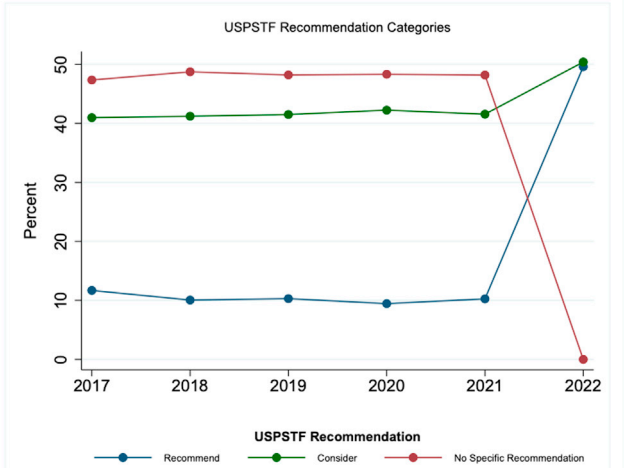
Taylor S. Freret[1], Kaitlyn E. James[1], Anjali J. Kaimal[2], Mark A. Clapp[1]
[1]Massachusetts General Hospital, Boston, MA, [2]University of South Florida Morsani College of Medicine, Tampa, FL

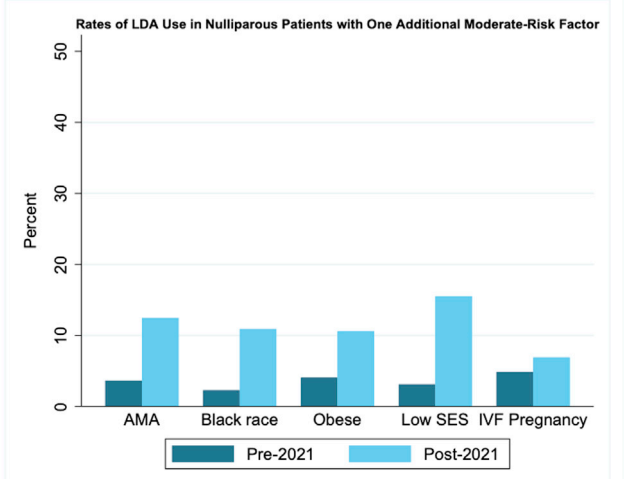
OBJECTIVE: The USPSTF recommends low-dose aspirin (LDA) for patients at risk of preeclampsia. Guidance from 2014 was updated in 2021, expanding recommendations for LDA. We sought to determine how the updated recommendation changed LDA use.

STUDY DESIGN: Retrospective cohort study of nulliparous patients with ≥2 moderate-risk factors and no high-risk factors delivering at ≥24 weeks gestation from 2017-2022 at four hospitals in one healthcare system. Patients were included if they established care before 14 weeks. USPSTF risk factors and aspirin use were obtained from the medical record. The primary outcome was LDA use, determined by presence on the medication list. Analyses used chi square test, with $p< 0.05$ considered significant.

RESULTS: The cohort included 31,555 patients, of whom 19,070 (60.4%) had risk factors for which LDA was recommended or should be considered. Of 5,473 patients for whom LDA was recommended, only 1,431 (26.2%) had use documented; this rate was 678/13,597 (5.0%) for patients in whom LDA should be considered. There was a significant change the makeup of USPSTF categories before and after the 2021 recommendation ($p< 0.001$, Figure). In 2022, 5,633 patients delivered; 2,369 (42.1%) patients had a new recommendation for LDA and 14.8% of these had LDA listed; 2,625 (46.6%) had a new indication for considering LDA and only 4.1% had LDA listed. Among nulliparous patients with no high-risk and one additional moderate-risk factor (to nulliparity), rates of LDA use increased after the updated guidelines: Medicaid insurance (as a proxy for lower income) (13.0 vs 2.0%, $p< 0.001$), advanced maternal age (12.4 vs 3.8%, $p< 0.001$), Black race (as a proxy for racism)(10.7 vs 2.7%, $p< 0.001$), and obesity (10.6 vs 3.6%, $p< 0.001$). There was no change for IVF pregnancies (6.3 vs 4.0%, $p=0.19$).

CONCLUSION: Despite updated recommendations from USPSTF in 2021 expanding recommendations for LDA, documented use of LDA remains low. The additional single moderate risk factors associated with the lowest absolute LDA rates were Black race, obesity, and IVF pregnancy.





249 Assessing the social network structure of high risk patients: A novel research method in obstetrics

Rachel Meislin[1], Angela Bianco[2], Corrine Hanson[3], Rachel Potter[1], Jana Ponce[4], Courtney Juliano[1], Amar Dhand[5], Sonali Bose[1]
[1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]Mount Sinai Medical Center, New York, NY, [3]University of Nebraska Medical Center, Omaha, NE, [4]University of Nebraska, Omaha, NE, [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

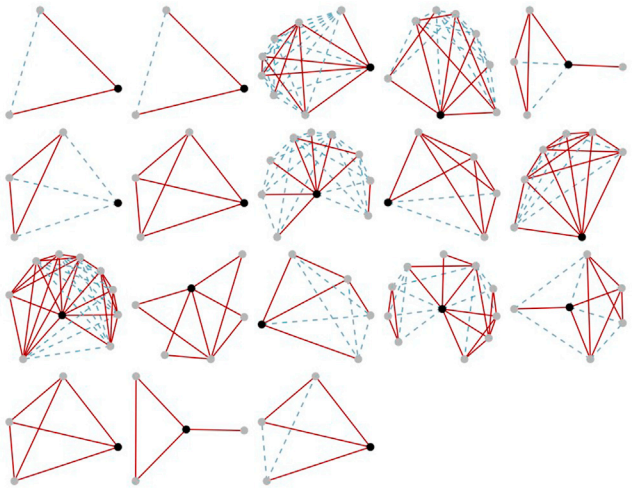
OBJECTIVE: Maternal psychosocial health has been associated with adverse pregnancy outcomes including preterm birth. Quantitative tools to measure an individual's social network have been demonstrated to predict health outcomes (e.g. stroke) in nonpregnant patients. The Surgeon General's 2023 advisory on the loneliness epidemic highlights the research gap in social connectivity as a possible determinant of obstetric outcomes. The objective of this study was to investigate the applicability of a novel quantitative approach to assess social networks within a population of high risk pregnant patients.

STUDY DESIGN: Patients with asthma participating in a longitudinal pregnancy cohort were interviewed in their second or third trimester of pregnancy using an established social network analysis instrument (PERSNET). PERSNET measures components of one's social

network including density (how each tie in the network is related to all ties), constraint (closeness of people to the participant and each other), and size (number of ties). Statistical and graphical analyses were generated using R software.

RESULTS: Eighteen participants completed the PERSNET survey with 100% participation rate. All reported active asthma with medication use in the last three months. The mean age of participants was 28.7 years (SD 3.73). The majority (n=16, 88.9%) reported non-white race. Black race was reported by n=7 (38.8%) and Hispanic ethnicity by n=7 (38.8%). Thirteen (72.2%) completed some college or less. Network structures are depicted in Figure 1. Mean (SD) network density was 0.82 (0.253), mean (SD) constraint was 0.67 (0.22), and the range of network size was 2-12 people [median (IQR) 4, 3.75].

CONCLUSION: Social network structure among a high risk pregnant cohort was highly variable in size, density, and interconnectedness. Smaller networks tended to be more interconnected. Because social capacity may influence health behaviors, these findings represent a rigorous way to capture a critical part of the prenatal social environment. Future research is needed to explore how social network structures may impact reproductive outcomes.



250 Preimplantation genetic testing (PGT) for non-homologous Robertsonian translocation carriers: a twelve-year laboratory experience

Katrina Merrion[1], Carrie Chou[2], Jeannie Klavanian[2], Emily Boniferro[2], Erin Armenti[2], Sarah Stueber[2], Jeffrey Meltzer[2], Karine Hovanes[2], Peter Benn[3]

[1]Natera, San Carlos, CA, [2]Natera, Inc., Austin, TX, [3]University of Connecticut Health Center, Farmington, CT

OBJECTIVE: Report preimplantation genetic testing (PGT) results for trophectoderm (TE) embryo biopsies from patients carrying a balanced non-homologous Robertsonian translocation (RT).

STUDY DESIGN: Retrospective review of results from single nucleotide polymorphism-based PGT performed at a lab between 2011-2023. Results were classified as 'euploid' for normal or balanced chromosomes; 'unbalanced/uniparental disomy (UPD)' for monosomy or trisomy of a translocation chromosome (with or without unrelated aneuploidy) or if UPD for an imprinted translocation chromosome was present; or 'unrelated aneuploid' for aneuploidy that did not involve a translocation chromosome.

RESULTS: PGT results were obtained on 2157/2240 (96.3%) TE biopsies from 301 patients who completed 436 in vitro fertilization cycles (Table 1). Mean maternal age was 34.8 years (range 22-44). Female RT carriers produced a higher rate of embryos with unbalanced translocations compared to male carriers (37.0% vs. 15.8%; p< 0.05%). The rates for normal/balanced embryos were 37.1% for female carriers versus 46.9% for male carriers (p< 0.05%).

CONCLUSION: The risk for unbalanced RTs is dependent on which parent is the carrier. Despite the high rates of abnormality, carriers of non-homologous RTs can be reassured that they can produce normal/balanced embryos.

Table 1. TE results by translocation type.

Type of translocation	IVF-PGT cycles (n)	Mean MA (years)	Embryo biopsies (n)	Euploid (normal or balanced) (%)	Unbalanced/ UPD (%)	Unrelated Aneuploid (%)
Mat 13;14	164	35.4	749	36.7	36.3	27.0

251 LEEPs and cones: Do they impact labor induction duration?

Jessica A. Meyer, Jenna Silverstein, Sara G. Brubaker, Namita Kansal, Iffath A. Hoskins, Christina A. Penfield, Ashley S. Roman

NYU Langone Health, New York, NY

OBJECTIVE: Cervical excision via loop electrocautery procedure (LEEP) or cold knife cone (CKC) is associated with subsequent preterm birth, but these procedures may also lead to cervical scarring and stenosis. We aimed to evaluate how the post-excision healed cervix functions during labor in response to induction.

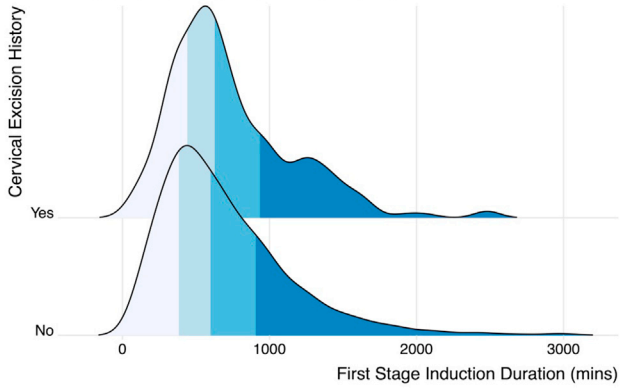
STUDY DESIGN: This is a retrospective cohort study of pregnant patients being induced at a single academic center between 7/2013 and 10/2018. We compared duration of the 1st stage of labor (from induction start to full dilation) among patients with and without prior cervical excision (via LEEP or CKC). We excluded those with multiple gestation, spontaneous labor, or urgent delivery before full dilation. The primary outcome was time from induction initiation to full dilation. Data were analyzed using Chi square, Fischer's exact, Mann-Whitney-U test, and non-parametric signed rank test.

RESULTS: A total of 228 patients with history of cervical excision (223 LEEPs, 6 CKCs) and 5995 patients without such history were studied. Patients with excision history were more likely to be White (82% vs 69%), to have a short cervix (4.4% vs 1.3%), and to have less favorable starting cervical dilation (2.25 cm [IQR 1-3.5] vs 2.5

cm [IQR 1-4]); clinical features (such as median parity) and obstetrical outcomes (such as median blood loss) were similar between groups. Median duration of 1st stage of labor was longer among patients with vs without excision history (Figure: 624 min [IQR 439-935] vs 600 min [IQR 385-907], pvalue < 0.001).

CONCLUSION: Patients with a history of cervical excision experienced a longer duration of the first stage of labor compared to those without excision history. Future studies, such as in the setting of induction failure, may help further explore the differential impact of cervical excision on subsequent labor, possibly informing individualized induction guidelines for these patients.

Figure 1: Ridgeline density plots of the distribution of 1st stage labor durations among patients with and without history of cervical excision procedure



252 Prenatal styrene and ethylbenzene exposures are associated with decreased birth weight and head circumference

Tal Michael[1], Amalia Levy[1], Elkana Kohn[2], Sharon Daniel[1], Ariela Hazan[2], Matitiahu Berkovitch[2], Ori Hochwald[3], Liron Borenstein[4], Moshe Betser[5], Miki Moskovich[5], Ayelet Livne[6], Rimona Keidar[6], Frieda Schwartsburd[7], Adi Malkoff[8], Zeev Weiner[9], ido Solt[10]

[1]Ben Gurion University of the Negev, Beer-Sheva, HaDarom, [2]Clinical Pharmacology and Toxicology Unit, Shamir (Assaf Harofeh) Medical Center, HaMerkaz, [3]Neonatal ICU, Rambam Health Care Campus, Haifa, Israel, [4]Rambam Health Care Campus, Haifa, Israel, [5]Shamir (Assaf Harofeh) Medical Center, HaMerkaz, [6]Neonatal Intensive Care Uni, Shamir (Assaf Harofeh) Medical Center, HaMerkaz, [7]National Residue Control Laboratory, HaMerkaz, [8]Rambam Health Care Campus, Bynyamina, HaMerkaz, [9]Rambam Medical Health Campus, Haifa, HaZafon, [10]Rambam health care campus, Haifa, Israel, Haifa, Hefa

OBJECTIVE: Prenatal exposure to aromatic hydrocarbons has been associated with adverse health outcomes in animal studies; However, there have been limited studies of the associations between prenatal exposure to these compounds and measurable outcomes in human newborns.

STUDY DESIGN: We recruited pregnant women who lived in urban areas in Israel and were admitted to the delivery rooms of two major hospitals between 2016 and 2020. The primary outcomes were newborn birthweight, length, and head circumference, measured by neonatologists in delivery rooms. Urine samples were collected from all mothers within 24 hours of admission for further BTEX analysis.

RESULTS: A total of 883 women and their term-born infants (n(%) 462 (52%) male; mean±SD infant gestational age, 39.5±1.3 weeks) were recruited; Traces of toluene, xylene, and ethylbenzene metabolites were detected in all samples and were lower than those previously reported among worldwide population, with mean (±SD) concentrations of benzylmercapturic-acid (23.8±51.5 μg/g creatinine); methylhippuric-acid (292.5±527.2 μg/g creatinine); and phenylglyoxylic-acid (555.2±737.7 μg/g creatinine), respectively. An increase in phenylglyoxylic-acid levels was found to be associated with a decrease in males birthweight (b= -40.856 g; 95% confidence interval (CI) -73.073 to -8.639). Further exclusion of newborns considered small and large for gestational age resulted in an association between an increase in phenylglyoxylic-acid levels and head circumference of males (b= -.07 cm; 95%CI:-.146 to -.005).

CONCLUSION: Prenatal exposure to Styrene and Ethylbenzene in relatively low levels is associated with decreased birth weight and head circumference among males by a mechanism that is yet to be fully understood and requires further analysis.

253 Aspirin dose effect on uterine artery Doppler in patients stratified by biomarkers: ASPERIN secondary analysis

Elizabeth L. Mirsky, Katherine Vignes, Aarthi Srinivasan, Cynthia Cockerham, Wendy Whitley, Hong Huang, Brandon Schanbacher, John A. Bauer, Arnold J. Stromberg, John O'Brien

University of Kentucky, Lexington, KY

OBJECTIVE: To determine if there is a dose-effect of aspirin on uterine artery Doppler over time, when groups were stratified by Fetal Medicine Foundation (FMF) criteria to define risk for preeclampsia.

STUDY DESIGN: This was a planned secondary analysis of The ASpirin in Placental and maternal Endothelial cell Regulation IN preeclampsia (ASPERIN) trial which enrolled a study population as high versus low risk based on the United States Preventive Services Task Force (USPSTF) major criteria. We reclassified the entire population by FMF guidelines with a cutoff of less than 1:100 for further analysis. Criteria for discrimination included mean arterial pressure (MAP), uterine artery pulsatility index (UtA PI), and clinical factors in the first trimester before initiation of treatment. High risk subjects were randomly assigned to 81 mg versus 162 mg daily aspirin in the parent trial. UtA PI was measured at baseline to define risk and subsequently at 20-22 weeks and 28-32 weeks. A mixed model analysis was performed to assess for dose-response, with ANOVA, T test and nonparametric analyses performed where applicable.

RESULTS: Of the 209 patients enrolled in the ASPERIN Trial, 57 assigned to 81 mg, 54 to 162 mg aspirin, and 16 controls were restratified as high risk. Demographics differed between subgroups (see table). In the model, significant interactions were identified in UtA PI related to treatment group (p=0.0002), risk calculation (p=< 0.0001), and time, (p< 0.0001). First and second trimester UtA PI did not differ between aspirin subgroups by dose (p=0.160 and p=0.153, respectively). A significant difference was noted in the third trimester between the subgroups (p=0.024). The difference between enrollment and third trimester UtA PI was significantly greater in the 81 mg group versus 162 mg (0.766 and 0.573, respectively, p=0.040).

CONCLUSION: A dose-effect of aspirin on UtA PI was identified over time, supporting evidence this biomarker is informative in assessing treatment response when discriminating candidates for therapy based on FMF criteria.

254 Social determinants of health improves prediction for postpartum readmissions due to preeclampsia

Lihong Mo, Shivam RaiSharma, Nimerta Sandhu, Herman L. Hedriana, Zahabiya H. Chithiwala, Anna Curtin, Chen-Nee Chuah

University of California Davis, Sacramento, CA

OBJECTIVE: Strong associations exist between social determinants of health (SDOH) and preeclampsia. We hypothesize that socially disadvantaged patients are more likely to be readmitted for worsening preeclampsia in the postpartum period. The objective of this study is to compare the performance of 2 machine learning (ML) models where zip code related SDOH variables are added to the basic model.

STUDY DESIGN: This is a retrospective analysis of 146 patients who had the diagnosis of hypertensive disorder of pregnancy (HDP) in a single tertiary medical center from 2020-2023. Two supervised ML models were created using four different ML methods (Random Forest, XGBoost, Logistic Regression, and Support Vector Machines). Model 1 only utilized clinically available variables. Model 2 uses the same variables as Model 1 and the zip codes related Area Deprivation Index (ADI) and SDOH variables from Agency of Healthcare Research and Quality database.

RESULTS: Among the HDP cohort of 73 readmissions and 73 non-readmissions, 51 EMR variables and 175 zip code related variables were included in the models. The best performance was achieved using a two-sample Kolmogorov-Smirnov and correlation reduction-based feature selection method and Random Forest ML method in Model 2 (Table). Adding zip code related variables (Model 2) was able to improve the sensitivity by 65% (Model 1: 0.43; Model 2: 0.71), and area under the curve (AUC) by 30% (Model 1: 0.56; Model 2: 0.73). The top features associated with readmissions are the increase of body mass index in pregnancy, the distance from a tertiary center, the unemployment rate in the neighborhood, the percentage of non-English speakers in the neighborhood, and whether an electrocardiogram was ordered in the pregnancy.

CONCLUSION: Adding zip code related ADI and SODH variables can improve the ML model prediction. The performance of models should be further validated by a multicenter or state database. With greater insights regarding the geographic hot spots for preeclampsia readmissions, new guidelines for targeted intervention and resource allocation may be implemented.

Table: The performance comparison between ML models with and without zip code related variables

Dataset used	Feature selection method	Accuracy	AUC	Sensitivity	Specificity	PPV	NPV	AUC Increase	Sensitivity increase

255 A prospective pilot study to investigate physical activity levels during pregnancy in an Irish cohort

Zara Molphy[1], Lea Stuart[2], David Gaul[3], Niamh Daly[2]

[1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]Royal College of Surgeons in Ireland, Dublin, Dublin, [3]Technological University Dublin, Dublin, Dublin

OBJECTIVE: Physical activity (PA) during pregnancy has been associated with decreased risks of adverse health outcomes for the pregnant woman and their babies. Attitudes toward and engagement in PA during pregnancy vary considerably among women and change pregnancy. Despite the health benefits for mothers and babies, considerable numbers of women fail to achieve the recommended levels of PA during pregnancy. The objective of this pilot study was to examine the level and types of PA participation during each trimester of pregnancy and whether research subjects meet ACOG guidelines of "moderate intensity exercise on most days of the week".

STUDY DESIGN: Of 107 recruited prospectively, 90 low-risk women attending antenatal midwifery led clinics in a tertiary maternity unit in a diverse socio-economic catchment area were included (17 incomplete questionnaires). The International Physical Activity Questionnaire (IPAQ) was administered to evaluate during pregnancy: i) whether expectant mothers meet ACOG guidelines for PA, ii) change in PA levels and iii) changes in choice of type of PA. Chi-squared and linear analysis were conducted.

RESULTS: Of 90 women over three trimesters, 16/90 (17.8%) women met ACOG exercise recommendations. Moderate exercise reduced from 30% to 20% to 16% over the first to third trimesters respectively (p=0.14). While walking rates over pregnancy did not change (but was neither moderate nor vigorous), rates of cycling, swimming

and yoga decreased. As recommended, all contact sports ended in the first trimester.

CONCLUSION: This prospective pilot study identified that the vast majority of low-risk women do not meet the ACOG guidelines for PA during pregnancy. This study also highlights the need for a larger study to gain additional understanding of PA patterns in a low-risk Irish community to develop future interventions and emhasizes the urgent need for an increase in frequency, intensity and type of PA in pregnancy in this cohort.

Table 1: 16/90 (17.78%) women who met ACOG guidelines for "moderate intensity exercise on most days of the week"

256 Activity restriction and time from diagnosis to delivery among patients with preterm pre-eclampsia

Matthew H. Mossayebi[1], Kaitlyn E. James[2], Peter James[3], Mark A. Clapp[2]

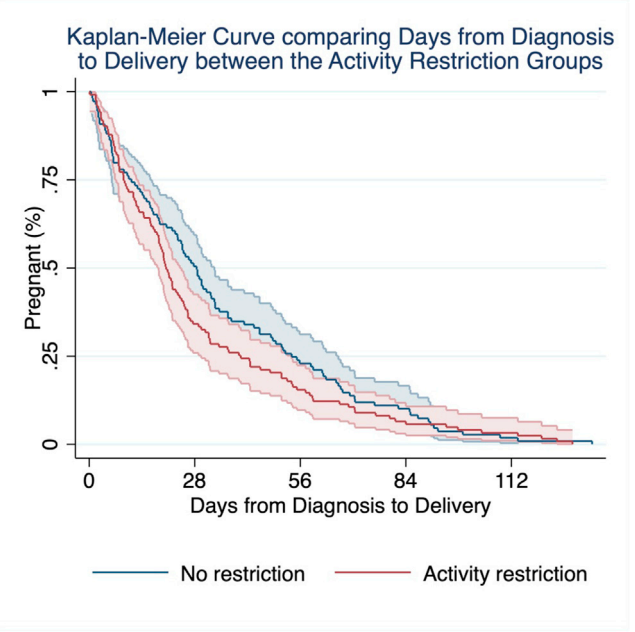
[1]Brigham and Women's Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA

OBJECTIVE: To determine the association between activity restriction and time from diagnosis to delivery among patients diagnosed with gestational hypertension (gHTN) or pre-eclampsia without severe features.

STUDY DESIGN: This is a secondary analysis of nulliparous patients enrolled in the nuMoM2b study. Individuals with gHTN or pre-eclampsia without severe features diagnosed < 37 weeks were included. Individuals with other forms of hypertensive disorders of pregnancy (HDP) were excluded because their management is more dependent on the timing of diagnosis and severity of disease. The primary outcome was days between diagnosis and delivery. The secondary outcome was development of pre-eclampsia with severe features or eclampsia. The exposure was patient report of a recommendation for activity restriction. Cox proportional hazard and logistic regression models adjusted for gestational age at diagnosis, age, diabetes, and fetal growth restriction were performed.

RESULTS: Of 9,289 patients, 299 (3%) were first diagnosis gHTN or pre-eclampsia without severe features prior to 37 weeks; 232 (78%) responded to the survey question about activity restriction. Of respondents, 53% reported being instructed to restrict their physical activity. There was no difference in the gestational age at diagnosis between the activity restriction vs. no restriction groups: median 33.9 (IQR 30.6, 35.9) vs. median 33.1 (IQR 29.8, 36.1), p=0.72. Activity restriction was associated with an increased risk of delivery (adjusted hazard ratio 1.42 (95%CI 1.09, 1.86)) but not with the development of more severe disease (adjusted odds ratio 1.24 (95% CI 0.70, 2.20)).

CONCLUSION: Activity restriction was commonly recommended but not associated with an increased time between diagnosis and delivery or the development of severe features for individuals with gHTN or pre-eclampsia without severe features. The increased risk of delivery for activity restriction may represent confounding (e.g., severity) not captured by the initial diagnosis. Given the lack of evidence, larger studies are needed to evaluate the role for activity restriction in HDP.



257 Aspirated and computed cervical stiffness throughout gestation for patients with and without a pessary

Mirella Mourad[1], Jacqueline C. Hairston[1], Abigail Laughlin[2], Erin Louwagie[2], Chia Ling Nhan Chang[3], Qi Yan[2], Uma M. Reddy[2], kristin Myers[2]

[1]Columbia University Medical Center, New York, NY, [2]Columbia University, New York, NY, [3]Columbia University Irving Medical Center, New York, NY; for the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

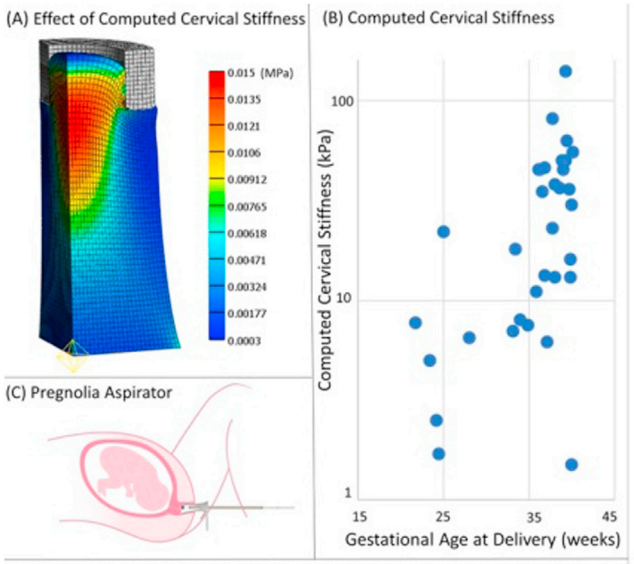
OBJECTIVE: Short cervical length is a risk factor for spontaneous preterm birth (sPTB). This study measured cervical stiffness in patients with a short cervix as an additional assessment to estimate sPTB risk. We also compared the change in cervical stiffness throughout pregnancy for patients with a short cervix with and without a pessary. Lastly, we compared cervical stiffness between patients who delivered preterm versus term.

STUDY DESIGN: Single-site ancillary study to a randomized-controlled trial of usual care versus pessary placement among patients with a singleton gestation and a short cervix (≤2 cm). Aspirated cervical stiffness (aCS) was measured at baseline visit 1 (16w-23w6d) using the Pregnolia aspiration device and again at visit 2 (26-30w0d). At both visits, the cervical shape was obtained using transvaginal ultrasound. Computer-aided design and finite element analysis software combined these measurements with aCS to generate computed CS (cCS). Welch's t-tests compared the baseline aCS and cCS and the difference in visit 2 and baseline aCS and cCS between patients in each treatment group. Lastly, aCS and cCS were compared between patients who delivered term or preterm, regardless of treatment.

RESULTS: At baseline, there was no difference in aCS between patients randomized to pessary (n=17) or usual care (n=16)

(aCS=78mbar ± 40 vs 76mbar ± 39, p >0.05). At visit 2, patients randomized to pessary (n=10) had an increase in aCS and cCS compared to baseline value, while the patients randomized to usual care (n=8) had a decrease. However, this result was not statistically significant (aCS=7mbar ± 40 vs -18mbar ± 28 p >0.05; cCS=8kPa ± 67 vs -13kPa ± 23, p >0.05). Regardless of the treatment group, patients who delivered before 37 weeks (n=17) had lower cCS than those who delivered at term (n=18) (cCS =18kPa ± 16 vs 38kPa ± 33, p< 0.05).

CONCLUSION: There was no significant difference in cervical stiffness between patients who received a pessary and those who did not. When not accounting for the treatment arms, patients with lower cervical stiffness delivered preterm.



A) Effect of computed cervical stiffness on cervix in finite element analysis. B) Gestational age at delivery versus computed cervical stiffness. C) Schematic of pregnolia aspirator measuring cervical stiffness. (Badir, et al., *BMC Pregnancy & Childbirth* 2020)

258 Implementation and outcomes of a stratified patient post-operative relocation protocol after fetoscopic spina bifida repair

Jessian L. Munoz[1], Cara Buskmiller[1], Rebecca Johnson[2], William Whitehead[2], Ahmed A. Nassr[1], roopali V. donepudi[1], Michael A. Belfort[3], Magdalena Sanz Cortes[4]

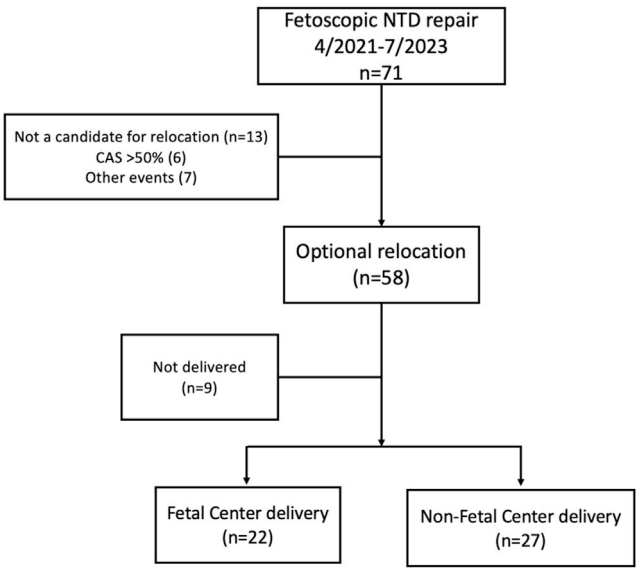
[1]Baylor College of Medicine, Houston, TX, [2]Texas Childrens Hospital, Houston, TX, [3]Texas Children's Hospital, Houston, TX, [4]Baylor College of Medicine and Texas Children's Hospital, Houston, TX

OBJECTIVE: In utero spina bifida repair has been shown to improve neonatal outcomes. Traditionally, antenatal repair requires patient relocation resulting in additional patient financial burden and disruption of family units. In 2021, we developed a protocol for post-operative assessment and safe patient relocation home with support of local institutions. Our primary objective was to assess the perinatal outcomes of this approach to patient centered care.

STUDY DESIGN: This study is a post-implementation analysis of a protocol for patient assessment and relocation after fetoscopic spina bifida repair at our fetal center from 4/2021-7/2023. After surgical recovery, patients followed up at our fetal center for 2 weeks undergoing post-operative assessment and antenatal testing. Patients were then notified if relocation to a home institution was advisable. Clinically relevant outcomes were obtained from electronic medical records.

RESULTS: During the 2-year study period, 71 patients underwent fetoscopic spina bifida repair at our fetal center. Surgical gestational age was 25 ±1 weeks with an average 4 ±1 days post operative stay. Following planned 2-week evaluation, 81% (58/71) of patients met criteria to return home, 38% (22/58) elected to deliver at our fetal center while 47% (27/58) delivered at their local institution. 18.3% (13/71) did not meet criteria for relocation and 9 patients were undelivered at time of study assessment. The average gestational age at delivery (37 [35, 38] vs 36 [34, 39] wk, p=0.54), rates of premature rupture of membranes (32% vs 33%, p=1.0), abruption (0% vs 7%, p=0.49) and vaginal delivery (45% vs 52%, p=0.78) were similar. Neonatal birthweight (2870 ± 425g vs 2670 ± 609g, p=0.18) and NICU stay (14 ± 11 vs 16 ± 20 days, p=0.45) were equivalent.

CONCLUSION: Our study shows the feasibility of implementing a standardized protocol for patient relocation home after fetoscopic spina bifida repair with equivalent perinatal outcomes. This approach provides an evidence-based, patient-centered and collaborative approach to fetal care while focusing on patient desires and optimal outcomes.



259 A comprehensive early pregnancy access clinic increases first trimester care in an underserved urban population

Celia Muoser[1], Hannah Rosenthal[1], Ioanna Katehis[2], Chavi Eve Karkowsky[1], Elizabeth P. Gurney[1], Antoinette Danvers[1], Kavita Vani[3]

[1]Albert Einstein College of Medicine, Montefiore Medical Center, New York, NY, [2]NYU Grossman Long Island School of Medicine, Flushing, NY, [3]Albert Einstein College of Medicine, Montefiore Medical Center, Great Neck, NY

OBJECTIVE: To assess the gestational age at which prenatal care (PNC) was initiated in an underserved urban population, and to compare the proportion of patients receiving first trimester PNC in a comprehensive Early Pregnancy Access Clinic (EPAC) versus traditional care model.

STUDY DESIGN: This retrospective cohort study included patients initiating PNC at multiple faculty practice sites within a large urban medical center in the Bronx, NY from February to May 2023. Our

EPAC offers multidisciplinary early pregnancy care at one location. During a single encounter, patients seen in EPAC are screened for medical comorbidities, have an ultrasound to confirm dating and viability, receive initial prenatal counseling/labs, and are scheduled for appropriate follow-up including routine obstetric care, high-risk obstetric care, or complex family planning care. Bivariate analyses comparing patient demographics and gestational age at entry into PNC by site of care were performed using Chi Square, Mann Whitney U, and t-tests. We used a multiple logistic regression model to estimate the adjusted odds ratio of attending PNC in the first trimester (< 14 weeks).

RESULTS: Of 698 patients, 392 patients were seen in EPAC and 306 patients received routine PNC at other sites. Patients in both groups were largely non-White and publicly insured. EPAC patients initiated PNC earlier than patients at traditional PNC sites (10.6 vs. 14.0 weeks, $p < 0.001$). More EPAC patients were seen in the first trimester (73.0% vs. 49.7%, $p < 0.001$). After adjusting for age, BMI, race, and preferred language, EPAC patients had a 2.76 increased odds of initiating care in the first trimester (aOR 2.76, 95% CI 1.93-3.94).

CONCLUSION: Patients who initiated PNC at EPAC were more likely to be seen at an earlier gestational age. EPAC is a novel, patient-centered approach consolidating multiple facets of early pregnancy care into a single encounter and, thereby, increasing access in the first trimester for an underserved obstetric population.

Table 1 Maternal demographics and entry into prenatal care

	EPAC (n = 392)	Routine prenatal care (n = 306)	p-value

260 Quantitative analysis of birth experience narratives identifies drivers of trauma among parturients with hypertensive pregnancy

Hana G. Murphy[1], Ashley Hesson[2], Angelina Noll[2], Hannah Slater[1], Haley White[1], Elizabeth S. Langen[2]
[1]University of Michigan School of Medicine, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI

OBJECTIVE: Hypertensive disorders of pregnancy (HDP) are associated with traumatic birth experiences. We aim to identify obstetric, interactional, and relational predictors of traumatic experiences as potential targets for quality improvement.

STUDY DESIGN: Participants were recruited nationally via social media. Semi-structured interviews were conducted and transcripts were reviewed for patient-reported birth events. Analysts subjectively assessed participants' characterization of their birth experience as "positive", "neutral", or "negative". Logistic regression was used to predict birth experience based on intrapartum events. Sentiment analysis was used to quantify patterns in words and phrases with specific emotive or relational content. A custom lexicon was built from an independent training dataset of parturients recalling their self-identified traumatic births, in addition to a validated set of emotive terms representing joy, trust, anticipation, surprise, sadness, disgust, fear, and anger. Natural language processing techniques were used to extract these sentiments from participants' descriptions of their birth.

RESULTS: A total of 67 interviews were analyzed; 74.6% (N=50) of respondents had inductions, 50.7% (N=34) received magnesium, and 35.8% (N=27) were delivered preterm. None of these intrapartum events were significantly associated with a negatively framed birth story. Among people with negative birth experiences, fear was the dominant negative emotion in their birth narratives, driven by discussion of the "hospital" environment. "Medical", "emergency", "pain", and "healthy" also contributed to sentiments of Trauma and Sadness (Fig 1).

CONCLUSION: For patients with HDP, expressed fears of medicalized birth were associated with negatively framed birth experiences, as opposed to specific interventions (e.g., magnesium infusion, preterm induction). Supportive and proactive counseling on the birth process may decrease medical anxiety and the experience of birth trauma.

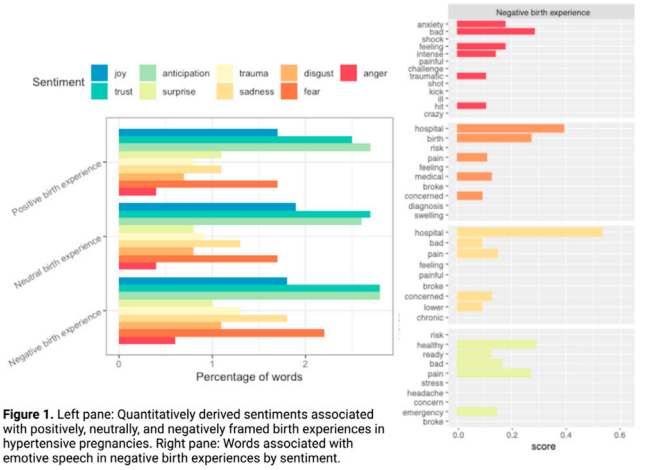

Figure 1. Left pane: Quantitatively derived sentiments associated with positively, neutrally, and negatively framed birth experiences in hypertensive pregnancies. Right pane: Words associated with emotive speech in negative birth experiences by sentiment.

261 Maternal administration of oxygen to predict respiratory morbidities among growth restricted infants

Sebastian Nasrallah[1], Laura Sanapo[2], Laura Hitchings[3], Joanna Marroquin[4], Luis M. Gomez[5]
[1]Inova Health System, Falls Church, VA, [2]Brown University, Providence, RI, [3]Advarra, Falls Church, VA, [4]George Mason University, Fairfax, VA, [5]Inova Health System, FairFax, VA

OBJECTIVE: Maternal hyperoxygenation (MH) decreases the fetal pulmonary vasoreactivity (PVR) and increases the pulmonary blood flow in normally grown fetuses. Considering that fetal growth restriction (FGR) negatively affects the pulmonary development and increases the risk for neonatal respiratory morbidities, we sought to

evaluate the role of MH and PVR in identifying newborns at risk for respiratory morbidities among pregnancies complicated by FGR.

STUDY DESIGN: Case series where singleton pregnancies complicated by FGR underwent MH testing every 1-2 weeks from enrollment to delivery. The pulsatility index (PI) of the middle branch of the pulmonary arteries (mPA) was obtained by ultrasound as a baseline, during MH, and after 15 minutes of MH. MH consisted of maternal administration of 8 L/min of 100% oxygen through a non-rebreathing face mask. A reactive PVR test was defined as any decrease in mPA-PI during MH compared to baseline. PVR results of newborns requiring respiratory support at delivery or admission to the neonatal intensive care unit (NICU) due to respiratory morbidity (Group I) were compared to those in no need of respiratory support at birth (Group II). Results of the last PVR test prior to delivery were compared with neonatal outcomes.

RESULTS: Among 32 subjects enrolled from July 2018 to July 2019, 28 participants were eligible for analysis (Group I=12; Group II=16). Among Group I, 7 fetuses had a non-reactive PVR (NR-PVR) test, while 1 fetus in Group II had a NR-PVR test; P=0.008. When subdivided by early (N=23) or late FGR (N=5) FGR, NR-PVR was seen only on the early FGR subgroup. Sensitivity, specificity, positive (PPV) and negative predictive (NPV) values were 58%, 93%, 87% and 75%, respectively. At 6-mo age, WIDEA-FS was comparable among both groups.

CONCLUSION: PVR tested by MH is a non-invasive test with high specificity and PPV in anticipating respiratory morbidity in early FGR when antenatal NR-PVR is observed. PVR by MH does not predict infant outcomes at 6-mo age.

262 Antenatal corticosteroid exposure in those with hypertensive disorders of pregnancy: a population cohort study

Sarah Nazeer[1], Han-Yang Chen[2], Suneet P. Chauhan[3], Ghamar Bitar[4], Farah H. Amro[4], Sean C. Blackwell[5], Baha M. Sibai[6], Michal Fishel Bartal[7]

[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]The University of Texas Health Science Center at Houston, Houston, TX, [3]University of Texas-Houston Medical School, Houston, TX, [4]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [5]Children's Memorial Hermann Hospital, Houston, TX, [6]Hermann Memorial Hospital, Houston, TX, [7]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX

OBJECTIVE: To examine the association between antenatal corticosteroid (ANCS) exposure and adverse neonatal outcomes among those with hypertensive disorders of pregnancy (HDP) who delivered in the late preterm period.

STUDY DESIGN: This population-based, retrospective cohort study used U.S. Vital Statistics dataset between 2016-2020. Inclusion criteria were those with a diagnosis of HDP (defined as chronic hypertension, gestational hypertension, pre eclampsia and eclampsia), who delivered between 34.0 to 36.6 weeks gestation and known ANCS exposure status. The primary outcomes were a composite neonatal adverse outcome, included: Apgar score < 5 at 5 minutes, immediate assisted ventilation, assisted ventilation > 6 hours, surfactant use, seizure, neonatal or infant mortality. Multivariable Poisson regression models with robust error variance were used to estimate adjusted relative risks (aRR) and 95% confidence intervals (CI).

RESULTS: Between 2016-2020, upwards of 19 million live births occurred in the U.S. Of those, 182,014 (1%) met our inclusion criteria and among them, 130,133 (71.5%) did not receive ANCS and 51,881 (28.5%) received ANCS. After adjustment, the risk of composite neonatal morbidity (aRR 1.32, 95% CI 1.30-1.35) was significantly higher among those with HDP who received ANCS compared to those without ANCS exposure. A subgroup analyses in those with preexisting hypertension, also showed an increase in both neonatal adverse outcome (aRR 1.36, 95% CI 1.30-1.42).

CONCLUSION: In pregnancies with HDP and delivery in the late preterm period, the risk of composite neonatal morbidity was higher in those with ANCS exposure compared to those without ANCS administration. These findings suggest further need of trials investigating the role of ANCS in those with HDP.

Table 1. Composite and individual Neonatal and Maternal Adverse Outcomes among pregnancies with HDP and Antenatal Corticosteroid Exposure

Outcomes	Antenatal steroids	Total live births	n	Rate per 1,000 live births	Crude RR	(95% CI)		Adjusted RR	(95% CI)	
Composite neonatal adverse outcome	Total	181,610	30,376	167.3						
	Did not receive	129,807	18,640	143.6	1.00			1.00

	Received	51,869	4,978	96.0	1.86	1.80	1.93	1.46	1.41	1.52
Surfactant use	Total	181,968	2,425	13.3						
	Did not receive	130,099	1,417	10.9	1.00			1.00		
	Received	51,869	1,008	19.4	1.78	1.65	1.93	1.45	1.34	1.58
Seizure	Total	181,968	125	0.7						
	Did not receive	130,099	84	0.6	1.00			1.00		
	Received	51,869	41	0.8	1.22	0.84	1.78	1.32	0.90	1.95
Neonatal death	Total	180,014	235	1.3						
	Did not receive	130,133	173	1.3	1.00			1.00		
	Received	51,881	62	1.2	0.90	0.67	1.20	0.85	0.63	1.15
Infant mortality	Total	182,014	670	3.7						
	Did not receive	130,133	477	3.7	1.00			1.00		
	Received	51,881	193	3.7	1.01	0.86	1.20	0.99	0.83	1.17

RR: relative risk; CI: Confidence interval.
Composite neonatal adverse outcome includes immediate assisted ventilation, assisted ventilation > 6 hours, NICU admission, surfactant use, transient tachypnea of the newborn and need for IV glucose-minute Apgar < 5. Adjusted for maternal age, race and ethnicity, education, marital status, insurance type, pre-pregnancy body mass index, prior preterm birth, hypertensive disorders and gestational age
Bold indicated statistically significant results.

263 The utility of PlGF as a "rule-out" test: examining outcomes after triage testing

Natalie Neff[1], Han-Yang Chen[2], Baha M. Sibai[3], Jacqueline G. Parchem[1]

[1]University of Texas Health Science Center at Houston, Houston, TX, [2]The University of Texas Health Science Center at Houston, Houston, TX, [3]Hermann Memorial Hospital, Houston, TX

OBJECTIVE: Despite the release of a new preeclampsia biomarker test in the United States, the clinical application of PlGF-based testing is unclear as few have examined adverse outcomes or assessed the test's ability for timely risk stratification in the triage setting. Therefore, we sought to evaluate the outcomes of patients with suspected preeclampsia according to PlGF value, stratified by inpatient vs. outpatient status to evaluate PlGF as a "rule-out" test.

STUDY DESIGN: This is a secondary analysis of the Preeclampsia Triage by Rapid Assay Trial, a prospective, multicenter, observational study that enrolled patients with suspected preeclampsia aged 18-45 with a singleton pregnancy between 20-35 weeks gestation. Plasma PlGF was measured at enrollment and defined as normal > 100 pg/mL, indeterminate 12-100 pg/mL and abnormal < 12 pg/mL. Our primary outcome was a composite adverse outcome (maternal or neonatal) and delivery within 7 days. A secondary outcome was a diagnosis of severe preeclampsia and delivery within 7 days. Data were analyzed within two disposition groups, inpatient and outpatient. Analysis was performed with use of Fisher's exact or chi-square tests as appropriate.

RESULTS: Of 601 patients who met inclusion criteria, 260 were managed as inpatient and 341 as outpatient. Demographic characteristics were similar between groups. A normal PlGF was identified in 59 (22%) of the inpatient group and 190 (55%) of the outpatient group. Among patients with a normal PlGF, the primary adverse composite neonatal outcome was only identified in 1 (1.7%)

inpatient, and was not observed in the outpatient group. The primary adverse composite maternal outcome was not observed in either disposition group. The secondary outcome did not occur in the outpatient group with a normal PlGF.

CONCLUSION: A normal PlGF may provide reassurance and allow for outpatient surveillance within an interval of 7 days. Our findings suggest PlGF as a "rule-out" test and could strengthen clinical decision making and potentially limit unnecessary hospitalizations.

Table 1. Adverse outcome and preterm delivery within 7 days of PLGF measurement

Inpatient	PlGF < 12 n = 200	PlGF 12-100 n = 82	PlGF > 100 n = 59	P value[a]
Composite Maternal Morbidity[b]	21 (10.5)	3 (3.7)	0 (0.0)	0.08
Composite Neonatal Morbidity[c]	42 (21)	4 (4.9)	1 (1.7)	<0.001
Preeclampsia with severe features[d]	154 (77)	37 (45)	10 (17)	<0.001
Outpatient	**n = 23**	**n = 47**	**n = 190**	
Composite Maternal Morbidity[b]	0 (0)	0 (0)	0 (0.0)	N/A
Composite Neonatal Morbidity[c]	2 (8.7)	0 (0)	0 (0.0)	0.005
Preeclampsia with severe features[d]	2 (8.7)	1 (2.1)	0 (0.0)	0.008

[a]*Chi-square or fishers exact used as appropriate, P < 0.05 considered statistically significant*

[b]Composite maternal morbidity: Maternal death, eclampsia, HELLP syndrome, pulmonary edema or ARDS, placental abruption, need for 3rd IV anti-hypertensive agent, other severe maternal morbidity (acute renal failure, retinal detachment, stroke, DIC, microangiopathy, acute fatty liver of pregnancy).
[c]Composite neonatal morbidity: 5 minute Apgar score < 4, fetal demise, neonatal death, seizure, grade III/IV intraventricular hemorrhage, retinopathy of prematurity, bronchopulmonary dysplasia, necrotizing enterocolitis.
[d]Secondary outcome: superimposed preeclampsia with severe features or Preeclampsia with severe features without history of chronic hypertension.

264 BhCG decline following intrasac methotrexate for the management of cesarean-scar ectopic pregnancy: An 11-year experience.

Bianca Nguyen[1], Sebastian Nasrallah[1], Masooma Raza[2], Ankit Shah[3], Francine McLeod[4], Luis M. Gomez[3]

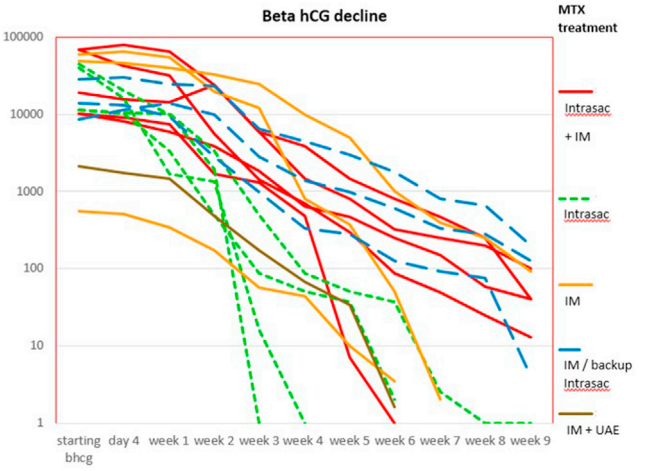
[1]Inova Health System, Falls Church, VA, [2]Inova Health System, Chantilly, VA, [3]Inova Health System, FairFax, VA, [4]Johns Hopkins Medicine, Baltimore, MD

OBJECTIVE: We sought to compare the rate of beta human chorionic gonadotropin (BhCG) levels decline of a protocol of transvaginal intrasac MTX injection to other non-surgical treatment modalities for the management of cesarean scar ectopic pregnancy (CSEP).

STUDY DESIGN: We conducted a case control of CSEP cases at INOVA Fairfax Hospital from September 2012 to March 2023. We abstracted demographic, medical, and obstetric information from medical records. BhCG levels were trended to determine the rate of decline following our protocol of outpatient local intrasac injection of 2.5 mL MTX treatment (IS-MTX) under transvaginal ultrasound guidance compared to (i) only intramuscular methotrexate (IM-MTX), (ii) simultaneous intra-gestational sac methotrexate injection and intramuscular methotrexate (IS-MTX + IM-MTX); (iii) backup intra-gestational sac methotrexate injection given after intramuscular methotrexate treatment failure (IM-MTX / backup IS-MTX); and (iv) simultaneous uterine artery embolization and intramuscular methotrexate (UAE + IM-MTX). Intrasac 1.5 mL KCl was injected prior to IS-MTX whenever a live embryo was present.

RESULTS: Among 920 ectopic pregnancies reported during the study period, we identified 23 cases of CSEP (2.5%) of which 16 cases had complete data and were included in our study. The fastest rate of BhCG decline was seen in the IS-MTX group and in UAE + IM-MTX. A rapid BhCG decline followed rescue IS-MTX when IM-MTX failed. All treatment modalities did not differ in grouped comparison (P=0.095); nonetheless, individual group comparisons showed significant BhCG decline in the IS-MTX group compared to IM-MTX (P=0.047), and in UAE + IM-MTX compared to IM-MTX (P=0.019) and to IM-MTX / backup IS-MTX (P=0.025). The presence of live embryo did not influence the rate of BhCG decline following IS-MTX.

CONCLUSION: IS-MTX alone is superior to IM-MTX. IM-MTX did not accelerate the decline of BhCG when used simultaneously with intrasac MTX (IS-MTX + IM-MTX group) compared to IS-MTX alone. UAE + IM-MTX is a useful non-surgical alternative when IS-MTX is not available.



265 Patient-level trends in vaccine uptake during the COVID pandemic

Ravyn Njagu[1], Amanda Brucker[2], Kelvin Feng[2], Siera Lunn[2], Melissa Greene[2], Geeta K. Swamy[1], Sarah K. Dotters-Katz[3]

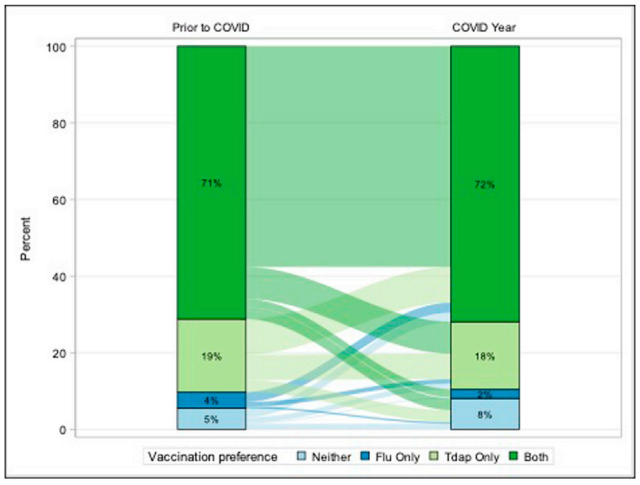
[1]Duke University, Durham, NC, [2]Duke University School of Medicine, Durham, NC, [3]Duke University Medical Center, Durham, NC

OBJECTIVE: Influenza and tetanus toxoid reduced diphtheria toxoid, acellular pertussis(TDaP) vaccines are safe, effective, and recommended in pregnancy. Despite this, significant vaccine hesitancy exists in pregnancy. The impact of the COVID-19 pandemic on vaccine hesitancy is not well understood. Wedescribe impact of the COVID-19 pandemic on patient-level influenza, TDaP, and dual vaccination trends.

STUDY DESIGN: Retrospective cohort study of patients delivering at single academic center with pregnancies in both pre-COVID(10/1/17-8/31/19) and mid-COVID(10/1/20-8/31/21) periods. Demographic and vaccine data abstracted. Primary outcome was change in vaccine choice between epochs. Generalized estimating equations repeated measures framework used to model changes in patient vaccine choices comparing across race/ethnicity. Analyses adjusted for payor, maternal age, and gestational age, calculating odds ratios and 95% confidence intervals.

RESULTS: Of 420 patients with at least one pregnancy in both periods, 49.8% were NH white, 28.4% NH black, and 14.9% Hispanic. Across all vaccines, the majority of patients had consistent vaccination preferences across both periods. 315/420(75%) the same flu vaccination preference, 353/420(84%) the same TDaP preference, and 242/420(58%) received both vaccinations(Figure). However, NH Black patients had significantly lower odds of flu vaccination mid-COVID vs pre-COVID (aOR: 0.60, 95%CI:0.38, 0.95). NH White patients had significant increase in receiving both vaccinations mid-COVID (aOR:1.61, 95%CI:1.03, 2.53).

CONCLUSION: Majority of vaccination decisions remained consistent despite the pandemic. However, in response to the pandemic NH black patients were less likely to receive influenza vaccination while NH white patients were more likely to receive dual vaccination. These data emphasize the importance of continued counseling and education efforts to better understand societal and cultural norms that impact patient hesitancy during pandemic-mediated prenatal care.



266 The association between post-delivery inferior vena cava diameter and Postpartum hemoglobin levels

Ariel Noy[1], Eran Barzilay[2], Anna Babakine Sason[2], alisa sadon[2]
[1]Samson Assuta Ashdod University Hospital, Ashdod, Israel, [2]Samson Assuta Ashdod University Hospital, Ashdod, HaMerkaz, Israel

OBJECTIVE: Inferior vena cava (IVC) diameter has been suggested as a useful sonographic tool for estimation of blood loss. To this date, it has been investigated only in an acute or massive hemorrhage setting. The aim of the present study was to determine whether IVC diameter can be an effective prognostic tool for predicting postpartum hemoglobin (Hb) level drop 24-48 hours after delivery.

STUDY DESIGN: A single center prospective cohort study, included postpartum women who delivered at 37 to 41 weeks of gestation. Cesarean delivery, multiple pregnancies, Patients with known coagulation disorders or hepatic failure and those using anti-coagulation drugs were excluded from the study. Abdominal ultrasonography measurements were performed 24-48 hours after delivery, Hb levels were taken before delivery and 24-48 hours after delivery to assess blood loss. Delta-IVC was defined as the difference between IVC diameter at expirium (IVCe) and at inspirium (IVCi). Spearman correlation test was used to assess for correlation between Hb levels and IVC diameter. Man-Whitney's U test was used to compare IVC diameters in cases with Hb drop of above 2g gr\dl and below.

RESULTS: We found no significant correlation between Hb levels and IVCi, IVCe or delta-IVC. Moreover, there was no difference in IVC diameters between parturients with a Hb drop of more than 2 gr/dl and those with a Hb drop of less than 2 gr/dl

CONCLUSION: Our findings did not show a significant association between IVC diameters and Hb levels. This may indicate that IVC diameter measurement, though useful in an acute setting, is not suitable for follow-up in stable patients.

Table 1: Spearman's correlation tests

		HB pre-delivery	HB post-delivery (up to 24 h)	1st delta HB	HB post del (up to 48 h)	Total HB drop
IVCe (mm)	Correlation Coefficient	.048	.058	.026	.115	-.032
	Sig. (2-tailed)	.684	.651	.839	.492	.804
	N	73	63	63	38	64
IVCi (mm)	Correlation Coefficient	.045	-.012	.085	.124	-.001
	Sig. (2-tailed)	.707	.928	.509	.460	.995
	N	73	63	63	38	64
delta IVC	Correlation Coefficient	-.068	.032	-.065	-.084	-.031
	Sig. (2-tailed)	.565	.804	.611	.615	.806
	N	73	63	63	38	64

Table 2: IVC diameters in high vs. low blood loss.

	Overall HB Loss > 2 gr (n=23)	Overall HB Loss ≤ 2 gr (n=41)	p value
IVC expirium	1.61 (1.38-1.98)	1.74 (1.42-2.01)	0.45
IVC inspirium	1.24 (0.98-1.45)	1.27 (1.07-1.41)	0.585
delta IVC	0.37 (0.26-0.56)	0.36 (0.21-0.63)	0.967

Data is presented as median (IQR). Comparisons wre performed using Mann-Whitney's U test.

267 Differences in dosing strategies and perinatal outcomes for pregnant patients on buprenorphine compared with methadone

Oladunni Ogundipe[1], Chaitali Korgaonkar-Cherala[2], Julia Kim[1], Lauren Stewart[1], Emily H. Stetler[1], Kimberly Herrera[1], David Garry[3], Cassandra Heiselman[3]
[1]Stony Brook University Hospital, Stony Brook, NY, [2]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel, [3]Stony Brook Medicine, Stony Brook, NY

OBJECTIVE: There is limited data evaluating differences in dosing and outcomes of patients on methadone and buprenorphine, two common medications for opioid use disorder (MOUD). This study sought to evaluate dosing alterations in pregnancy as well as to compare perinatal outcomes between buprenorphine based MOUD and methadone.

STUDY DESIGN: Retrospective cohort study comprised of patients with opioid use disorder (OUD) during their pregnancy who delivered at a single institution between January 2017 and July 2023. Patients were divided according to their prescribed MOUD: buprenorphine-based and methadone. Exclusion criteria: patients with OUD who were not described MOUD during their prenatal care. These groups were compared using Chi-square, McNemar test, t-tests with statistical significance defined as $p < 0.05$.

RESULTS: With respect to dosing, more patients in the methadone group required dosage changes (n=50, 78.1%) vs buprenorphine group (n=62, 51.7%), $p< 0.01$. In buprenorphine based MOUD, there was no statistically significant difference in the total milligrams prescribed at the beginning of pregnancy compared to the dose at the time of delivery. Comparatively, patients who were prescribed methadone had a statistically significant increase in milligrams prescribed from their dose at the beginning of pregnancy (72.0mg

±43.8) to dose at delivery (106.2mg±50.5, p< 0.01). When comparing maternal and neonatal outcomes across groups, the methadone patients had fewer postpartum follow up visits at 6 weeks, increased risk of NOWS requiring morphine, and lower birth weights (p < 0.01). See Table 1.

CONCLUSION: In our study, compared to buprenorphine, patients with OUD that were treated with methadone needed an increase in dose by delivery. Additionally, they had an increased rate of infants with NOWS, lower birth weights, and less postpartum follow up.

Table 1: Maternal and Neonatal Outcomes Compared between Patients on Buprenorphine versus Methadone

	Buprenorphine (n=257)	Methadone (n=105)	p-value
Pregnancy induced hypertension	34 (13.2)	14 (13.6)	0.92
Gestational diabetes	16 (6.2)	5 (4.9)	0.63
Fetal Growth Restriction	14 (5.4)	5 (4.8)	0.79
Any OB complication	22 (8.6)	9 (8.6)	0.99
PTB <37 weeks	33 (12.9)	20 (19.2)	0.12
Cesarean Delivery	111 (43.7)	50 (48.1)	0.45
Birth weight (g)	3020 (±615)	2810 (±586)	<0.01
NOWS requiring morphine	55 (21.4)	50 (47.6)	<0.01
Admitted to NICU	155 (60.8)	70 (68.0)	0.20
Infant hospital LOS (days)	12.0 (±20.2)	14.9 (±13.1)	0.16
Postpartum visit compliance	52 (20.4)	18 (17.7)	<0.01
Relapse postpartum	8 (3.6)	6 (7.4)	0.21

268 Association between social vulnerability and severe maternal morbidity

Andria Li, Andrew Spieker, Margaret Adgent, Amelie Pham, Andrew Wiese, Ashley Leech, Carlos Grijalva, Sarah S. Osmundson

Vanderbilt University Medical Center, Nashville, TN

OBJECTIVE: The Social Vulnerability Index (SVI) measures community-level factors associated with health outcomes, but few studies have measured their contribution to perinatal morbidity. We examined the association between SVI and severe maternal morbidity (SMM).

STUDY DESIGN: We included patients 15-44 years enrolled in Tennessee Medicaid who delivered between 2007-2019. Enrollment files were linked to healthcare encounters and prescription fill data, hospital discharge and birth certificate data. The primary exposure was SVI ranging from 0 to 100 (lower to higher SVI) and assigned based on residential address at delivery. Secondary exposures included SVI subthemes: socioeconomic status, household characteristics, racial and ethnic minority status, and housing type and transportation. The primary outcome was SMM as defined by Centers for Disease Control and Prevention criteria using diagnosis codes for 21 conditions. We employed multivariable logistic regression to estimate the association between SVI and SMM, adjusting for covariates selected *a priori*. We stratified by race/ethnicity and rural versus metro residence to test whether the association between SVI and SMM varied by these subgroups.

RESULTS: We identified 369,465 births meeting eligibility criteria, of which 8,057 (2.2%) experienced SMM. SVI quartiles were Q1 0-41, Q2 42-67, Q3 68-87, and Q4 87-100. Increasing SVI was associated with increasing odds for SMM (aOR 1.018 [1.013-1.023] per 5 unit increase in SVI). Increasing SVI was associated with SMM for each subtheme except housing type and transportation. When analyses were stratified by Black or non-Black race, SVI was significantly associated with SMM only among Black patients (adjusted OR 1.013 [95% CI 1.004-1.021] per 5 unit increase in SVI). The association between overall SVI and SMM did not vary significantly by rurality.

CONCLUSION: We demonstrated a positive association between SVI and SMM, especially among Black patients. Greater investment in vulnerable communities may help reduce large disparities in pregnancy outcomes in the United States.

Figure 1: Stratified associations[1] between severe maternal morbidity and social vulnerability index

269 Stress-reducing interventions in pregnancy for prevention of preterm birth: a systematic review and meta-analysis.

Laura Janssen[1], Adelia Gieskes[1], Marjolein Kok[1], Christianne J. de Groot[2], Martijn A. Oudijk[1], Marjon A. de Boer[1]

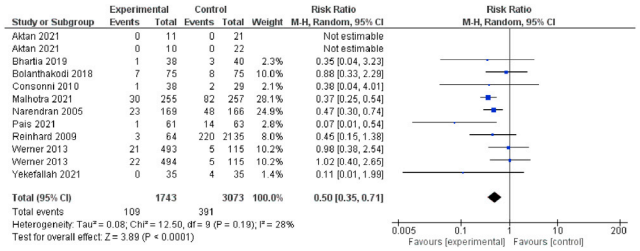
[1]Amsterdam UMC, location AMC, Amsterdam, Noord-Holland, [2]Amsterdam University Medical Center, Amsterdam, the Netherlands and Amsterdam Reproduction & Development, Amsterdam, Amsterdam, Noord-Holland

OBJECTIVE: Preterm birth (PTB) is the leading cause of neonatal morbidity and mortality. Maternal stress during pregnancy is an established risk factor for PTB. Therefore, our primary aim was to assess whether stress-reducing interventions during pregnancy can reduce the incidence of PTB.

STUDY DESIGN: This systematic review and meta-analysis searched MEDLINE, Embase, ClinicalTrials.gov, Cumulative Index to Nursing and Allied Health Literature, and the Cochrane Library for (randomized) controlled trials (RCTs), cohort studies, and observational studies reporting on stress-reducing interventions during pregnancy and PTB rates. Studies investigating women already in preterm labor, or aiming at women at high risk of PTB or depression, or with a history of depression or anxiety disorders, were excluded.

RESULTS: Ten studies with a total of 4.816 women were included, with five studies on yoga, two on hypnosis, and three multidisciplinary programs with a mindfulness and psychosomatic approach. The incidence of PTB was significantly lower in the intervention group (RR 0.50, 95% CI 0.35 − 0.71). The incidence of LBW was significantly lower, and mean gestational age was significantly higher in the intervention groups. Our subgroup analysis focusing on the intervention type yoga (N= 5; 757 women), showed a significant reduction in PTB and LBW rates (RR 0.30, 95% CI 0.13 − 0.71, RR 0.57, 95% CI 0.41 − 0.81 respectively). Two studies on maternal anxiety and two studies on maternal stress could not be meta-analyzed due to incomplete data. The overall quality of the included studies was low and risk of bias was high. When excluding high risk studies (N=3; 3046 women), the previously significant associations could no longer be confirmed.

CONCLUSION: This study provides substantial evidence supporting the efficacy of stress-reducing interventions, in particular yoga, in reducing the incidence of PTB in low risk women. Given the low quality and high risk of bias in the included studies, yet promising results, we propose a RCT of high quality to determine the effectiveness of stress-reducing interventions in reducing PTB risk.



270 A cost-effectiveness analysis of neuraxial anesthesia and number of attempts for external cephalic version

Claire H. Packer[1], Thomas P. Kishkovich[2], Mark A. Clapp[3], Sarah E. Little[4]

[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Massachusetts General Hospital, Department of Obstetrics and Gynecology, Boston, MA, [3]Massachusetts General Hospital, Boston, MA, [4]Brigham and Women's Hospital, Boston, MA

OBJECTIVE: ECV is a key tool in management of presentation and reducing cesarean deliveries. There is debate regarding the optimal use of neuraxial anesthesia for ECV procedures, and whether it is beneficial to offer a second ECV attempt for patients with persistently breech fetuses. Studies have found ECVs with neuraxial anesthesia to be the cost-effective strategy, however this is the first study to directly compare both the use of neuraxial anesthesia and the number of attempts.

STUDY DESIGN: A cost-effectiveness model was built using TreeAge 2023 software to compare outcomes and costs of one or two attempts of ECV with or without use of neuraxial anesthesia. We used a theoretical cohort of 100,000 nulliparous women with non-vertex presenting singletons. The model accounted for costs and quality adjusted life years (QALYs) for the mother and the neonate. Outcomes included unsuccessful ECV, cesarean delivery, maternal death, neonatal death, and major neurodevelopmental disability. Probabilities were derived from the literature, and a cost-effectiveness threshold was set at $100,000/QALY.

RESULTS: In our theoretical cohort of 100,000 pregnant women, we found that two attempts, the first without neuraxial anesthesia, and the second with neuraxial anesthesia to be the most cost-effective strategy with an ICER of $27,874. Two attempts with both under neuraxial anesthesia was the most effective option with 3000 fewer cesarean deliveries, 5 fewer cases of neonatal death and 1 fewer case of major neurodevelopmental disability. However, in our cohort, two attempts under neuraxial anesthesia was 24 million dollars more expensive. With sensitivity analysis, two attempts with neuraxial becomes the dominant strategy if the rate of successful ECV with neuraxial anesthesia were greater than 0.62.

CONCLUSION: Two attempts for ECVs with and without neuraxial anesthesia is optimal when compared to one attempt. The most cost-effective option is to perform the first ECV without neuraxial anesthesia and the second attempt with neuraxial anesthesia at the time of possible cesarean delivery.

	One ECV attempt without NA	One ECV attempt with NA	Two ECV attempts: both with NA	Two ECV attempts: first without NA, second with NA
Cesarean delivery	65,000	53,000	28,000	31,000
Maternal death	2	2	2	2
Neonatal death	292	275	240	245
Neonatal morbidity	93	92	92	93
Cost	$83M	$87M	$86M	$83M
Effectiveness	664,401	664,579	664,713	664,635
ICER				$27,874/ QALY

271 The effects of pregnancy conceived after fertility treatment on perinatal outcomes; a sibling analysis.

Oren Malka[1], Tamar Wainstock[2], Eyal Sheiner[3], Atif Zeadna[3], Gali Pariente[4]

[1]Joyce and Irving Goldman Medical School Ben Gurion University, Beer-Sheva, HaDarom, [2]Ben Gurion University, Beer-Sheva, HaDarom, [3]Soroka University Medical Center, Beer-Sheva, HaDarom, [4]Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Klahim, HaDarom

OBJECTIVE: Recent studies have reported an association between fertility treatments and adverse perinatal outcomes. However, the precise contribution of maternal factors versus the fertility treatments per-se to these adverse outcomes remains unclear. This study used a unique sibling analysis method to investigate perinatal outcomes between pregnancies conceived using fertility treatment and spontaneously conceived pregnancies. Using sibling analysis as a study approach allows thorough examination of the association between conception mode and adverse perinatal outcomes while omitting unmeasured potential confounders.

STUDY DESIGN: In a population-based retrospective cohort study, perinatal outcomes of pregnancies conceived following fertility treatment were compared to spontaneously conceived pregnancies of the same women. The study population included all mothers who had at least two deliveries between the years 1991-2021 at a tertiary medical center, with one pregnancy conceived following fertility treatments and another spontaneously conceived pregnancy. The comparison was done using maternal clusters analysis. Generalized linear models were used to control for confounders.

RESULTS: During the study period 12,755 deliveries were included, of which 7,711 (60.5%) were conceived following fertility treatments. Using generalized linear models, controlling for maternal age, pregnancies conceived following fertility treatments were independently associated with adverse perinatal outcomes including hypertensive disorders (9.9% vs. 5.8%, $p< 0.001$), gestational diabetes mellitus (12.7% vs. 7.1%, $p< 0.001$), placenta previa (1.4% vs. 0.5%, $p< 0.001$), preterm delivery (11.7% vs. 7.5%, $p< 0.001$), cesarean delivery (34.1% vs. 21.1%, $p< 0.001$) and small for gestational age (5.3% vs. 3.3%, $p< 0.001$, Table 1).

CONCLUSION: Using maternal clusters analysis, pregnancies conceived following fertility treatments were found to be independently associated with higher risk for adverse perinatal outcomes.

Table 1: The association between conception method and perinatal outcomes; Univariable analysis and generalized linear models controlling for maternal age.

Characteristics	Pregnancy conceived following fertility treatment (n=7,711) n (%)	Spontaneously conceived pregnancy (n= 5,044) n (%)	OR (95% CI)	Adjusted OR* (95% CI)	P* value
Hypertensive disorders	765 (9.9%)	293 (5.8%)	1.78 (1.55-2.05)	1.78 (1.47-2.15)	<0.001
Gestational diabetes mellitus	982 (12.7%)	356 (7.1%)	1.92 (1.69-2.18)	1.79 (1.47-2.17)	<0.001
Placenta previa	106 (1.4%)	25 (0.5%)	2.79 (1.80-4.33)	2.43 (1.57-3.78)	<0.001
Preterm delivery <37	902 (11.7%)	376 (7.5%)	1.64 (1.45-1.86)	1.37 (1.05-1.79)	0.017
Cesarean delivery	7,711(34.1%)	5,044 (21.1%)	1.93 (1.78-2.10)	1.40 (1.31-1.50)	<0.001
Small for gestational age	406 (5.3%)	164 (3.3%)	1.65 (1.37-1.99)	1.72 (1.44-2.06)	<0.001

*Adjusted for maternal age.

272 Appropriate timing of steroid administration in pregnancies at risk for preterm delivery

Michelle Lende, Dhara Patel, Amanda Vinner, Tara A. Lynch
Albany Medical Center, Albany, NY

OBJECTIVE: The objective of this study was to evaluate the timing of steroid administration in both the preterm and late preterm pregnancies and to evaluate the impact of timing on adverse neonatal outcomes.

STUDY DESIGN: This was a retrospective chart review of all pregnant individuals who delivered at a single academic hospital between 1/1/2016 to 12/31/2016. Non-anomalous, singleton gestations who received antenatal steroids and had available delivery information were included. Maternal demographics, indications for steroid administration, delivery information, and neonatal outcomes were all collected. Latency from steroids to delivery was calculated and analyzed as >7 days or ≤7 days and >14 days or ≤14 days. Statistical analysis with descriptive statistics and logistic regression was done.

RESULTS: Of 1986 deliveries at our institution, 211 (10.6%) met inclusion criteria. A total of 87 (41.2%) delivered >7 days from early steroid administration with the most common indications for steroids being hypertension, preterm prelabor rupture of membranes, and preterm labor. Of those >7 days and >14 days from steroids, 29 (50.9%) and 23 (62.2%) received a rescue course, respectively. In the late preterm period, 35 (92.1%) delivered ≤7 days. An interval of >7 days from steroids was not associated with composite adverse perinatal outcomes as compared to those ≤7 days (OR 1.34, CI 0.58-3.12). Regression analyses showed that greater delivery gestational age was associated with less adverse neonatal outcomes in both the early (OR 0.83, CI 0.79-0.89) and late preterm period (OR 0.79, CI 0.66-0.95). When evaluating for delivery predictors, a regression showed that maternal race (OR 0.31, CI 0.12-0.83), prior preterm birth (OR 0.45, CI 0.22-0.95), and cervical dilation (OR 1.65, CI 1.2-2.2) had an impact on steroid timing >7 days from delivery.

CONCLUSION: Our results were consistent with prior literature indicating that objective criteria need to be developed for optimally timed steroids within seven days of delivery.

273 Pain medication utilization in the obese population after implementation of multimodal pain regimen post-cesarean delivery

CeCe Cheng[1], Isha B. Patel[2], Shriya L. Veluri[2], Seoyon Lee[2], Autumn B. Chidester[2], Camille B. Marquez[3], Patrick S. Ramsey[2], Angela R. Boyd[2]
[1]University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]The University of Texas Health Science Center at San Antonio, San Antonio, TX, [3]University Health, San Antonio, TX

OBJECTIVE: High body mass index (BMI) or obesity is not only a risk factor for cesarean delivery (CD), but also associated with high opioid consumption after surgery. We sought to determine whether differences exist in the use of non-opioid and opioid medications across different BMI categories in patients undergoing CD after implementation of a standardized pain regimen.

STUDY DESIGN: This was a single-institution, retrospective cohort of 907 patients who underwent CD from 01/9/22-12/31/22. A representative sample of patients from 7/2021-12/2021 was obtained for baseline comparison. A standardized pain regimen was implemented in 1/2022. Post-intervention, patients were divided into four BMI cohorts: Non-obese (BMI < 30 kg/m^2), Class 1 obesity (30-34.9), Class 2 obesity (35-39.9) and Class 3 obesity (≥40). Non-opioid analgesia use was quantified over the course of the hospital stay in milligrams while opioid use was quantified in morphine milligram equivalents (MME).

RESULTS: Of the 907 patients, 253 (28%) were non-obese, 258 (28%) were Class 1, 175 (19%) were Class 2, and 221 (24%) were Class 3. Non-obese patients were significantly younger and less likely to identify as Hispanic/LatinX than the other groups. Patients with Class 3 Obesity were more likely to deliver at an earlier gestational age, have pre-existing hypertension, diabetes and asthma, and more likely to have a combined spinal epidural for intra-operative analgesia compared to the other groups. Implementation of a standardized pain regimen decreased total median MMEs in the post-operative period from 50 to 7.5 (p< 0.0001). Post-implementation, although there were some significant differences between BMI groups related to oral acetaminophen and ibuprofen use, overall there was no difference in total MME use between BMI groups (Figure).

CONCLUSION: There is no difference in post-operative opioid pain medication use in patients with higher BMIs undergoing CD in the setting of a standardized multimodal pain regimen, which provides further evidence for the use of a multimodal pain regimen in the obstetric patient population.

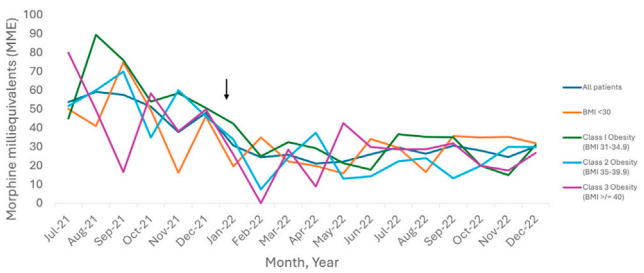


Figure. Run chart of MMEs for all patients and each BMI class before and after implementation of standardized pain regimen. Arrow indicates implementation of standardized pain regimen.

274 Quantifying the operational impacts of varying patient-provider continuity policies in prenatal care

Alex Peahl, Natalia Eddy, Leena Ghrayeb, Arman Getzen, Cynthia Joy Johnson Monickaraj, Amber Campbell, Molly J. Stout, Amy Cohn
University of Michigan, Ann Arbor, MI

OBJECTIVE: To describe how different policies of patient-provider continuity in prenatal care affect clinical operations.

STUDY DESIGN: We conducted a simulation study of an appointment scheduling policy at an academic medical center with 12 ambulatory sites. Each site maintains 40% capacity for obstetric appointments, 20% of which is used for telemedicine. Data inputs were derived from a data set of 4,992 patients at a single academic institution from March 1, 2022 to March 1, 2023. Of the 4,992 patients, 62% were medically high risk, and 38% were medically low-risk. Prenatal schedules are tailored to medical need (high-risk: 13 visits; low-risk 9 visits) and patient preference for modality (in-person or virtual), and patients can transition from low to high-risk with changing diagnoses. We tested 3 scheduling policies: 1) provider continuity: patients are booked only with their provider, and overbooked if there are no available appointments; 2) advanced rescheduling: if a patient's primary provider does not have capacity, the patient is booked with another provider; 3) just-in-time rescheduling: if an appointment is still overbooked the week of the visit, the patient is rescheduled with another provider. The simulation was run in C++ for a 92 week horizon over 100 replications to assess effects on clinic utilization, overbooking, and patient delays. All metrics were reported as an average across all clinics.

RESULTS: The overbooking rate was higher for the policy that favored provider continuity compared to rescheduling (Policy 1: 16.9%; Policy 2: 0.9%; Policy 3: 0.9%). Capacity utilization was similar across all policies (Policy 1: 80.7%; Policy 2: 81.2%; Policy 3: 81.4%). On average, patient delays measured in weeks were low over the course of their care pathways for all policies (Policy 1: 0.24, Policy 2: 0.61, Policy 3: 0.24).

CONCLUSION: Policies that favor provider continuity result in significantly higher overbooking rates for providers, without improving overall clinic utilization. Policies that favor more even distributions of patient loads may result in more effective, efficient clinical operations.

275 The effects of dynamic patient trajectories on prenatal care utilization and clinical operations

Amber Campbell, Leena Ghrayeb, Cynthia Joy Johnson Monickaraj, Arman Getzen, Natalia Eddy, Molly J. Stout, Amy Cohn, Alex Peahl
University of Michigan, Ann Arbor, MI

OBJECTIVE: To assess the effects of a new tailored prenatal care policy on clinical capacity and efficiency, accounting for dynamic patient trajectories in pregnancy.

STUDY DESIGN: We conducted a discrete event simulation study of traditional versus tailored prenatal care policies. We compared the traditional care model (14 in-person visits for all patients), to a schedule tailored to medical risk (high-risk: 13 visits; low-risk: 9 visits), and preference for care modality (in-person vs. virtual). We also introduced dynamic patient trajectories to account for medically low-risk patients who develop complications (e.g. gestational diabetes, gestational hypertension) in pregnancy, requiring transition to the high-risk schedule. Data inputs were derived from 4,992 real patients who received prenatal care and gave birth at a single academic institution from March 1 2022 to March 1 2023. Simulation parameters included probability of diagnosis of complications, preference for hybrid care (derived from local survey data), patient risk level, and dynamic patient arrival times. The simulation was run in C++ for 100 replications of 92 weeks each. We reported on measures of clinical operations including capacity utilization, patient delay, and overbooking.

RESULTS: In the dynamic patient simulation, 12.18% of low-risk patients became high-risk. Of patients who switched, the average number of appointments added to the pathway was 1. Following a traditional visit schedule showed in-person capacity utilization of 107%, implying overbooking, and patient delay of 0.41 weeks per patient on average. When compared to a traditional visit schedule, implementing a tailored prenatal care policy showed average capacity utilization of 92% (including in-person and virtual appointments), eliminating overbooking. Patient delay was reduced to 0.36 weeks per patient.

CONCLUSION: The implementation of tailored prenatal visit schedules allowing for a dynamic patient type model eliminates in-person overbooking and reduces patient delays. Further study is needed to determine the optimal proportion of clinic capacity to allocate to virtual care.

276 Pregnancy following uterine rupture - maternal and neonatal outcomes

eliel shapira[1], Tzuria Peled[1], rivka Farkash[1], Hen Y. Sela[2], Sorina Grisaru-Granovsky[1], Maayan Bas Lando[1]
[1]Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim, [2]Shaare Zedek Medical Center, affiliated with the Hebrew University Hadassah School of Medicine, Jerusalem, Israel

OBJECTIVE: Uterine rupture is a severe obstetrical complication that is associated with increased immediate maternal and neonatal morbidity. However, the literature regarding subsequent pregnancy outcome is scant and inconclusive. This study aims to investigate maternal and neonatal outcomes in the pregnancy following uterine rupture

STUDY DESIGN: A multicenter retrospective study between 2005 to 2022 that included cases (exposed) of subsequent singleton pregnancies following uterine rupture- defined as a full-thickness defect in the uterine wall. Labor, maternal, and neonatal characteristics were compared to a matched control group (not exposed), in a ratio of 1 to 4 (maternal age, parity and number of previous CD) of subsequent pregnancies following previous CDs with no history of uterine rupture. main outcome: uterine rupture, secondary outcomes: other maternal and neonatal complications Statistics: Descriptive, means±SDs, medians+IQR. Comparisons: chi-square, Fisher's exact test, Mann-Whitney Test, multivariate logistic models

RESULTS: During the study period there were 33 subsequent pregnancies following uterine rupture with one case of recurrent uterine rupture while the control group included 132 pregnancies without any event if uterine rupture (p=0.2). In the exposed group there were higher rates of composite adverse maternal outcomes (41.9% vs 18.6%; p=0.006), preterm delivery < 37 weeks (54.5% vs 10.6%; p< 0.001), NICU hospitalization >72 hours (29% vs 12.7%; p=0.026) and neonatal composite adverse outcomes (51.6% vs 30.4%; p=0.026 multivariate analysis revealed that previous uterine rupture was not associated with composite adverse neonatal outcome (OR= 1.085 95%CI [0.408-2.882] p=0.870). rather, the only association was found with preterm delivery < 37 weeks (OR=6.520 95%CI [2.257-18.838]; P< 0.001)

CONCLUSION: past uterine rupture is not associated with an increased risk of uterine rupture in the following pregnancy. However, other

maternal and neonatal morbidities are increased mostly due to preterm delivery. Balancing timing of delivery vs concern for uterine rupture may improve obstetric outcomes

Table: maternal demographics and maternal and neonatal outcomes

Characteristics	Past uterine rupture (N=33)	Past CD without uterine rupture (n=132)	P value
Maternal age (mean, years)	31.6±5	31.6±5	0.962
Prior CS (Median [IQR])	2[2-2]	2[2-2]	0.992
Parity (Median [IQR])	3[3-5.5]	3[3-5]	0.411
Gestational age (median [IQR])	36[36-37]	38[37-38]	<0.001
Preterm delivery<37 weeks (N, %)	18(54.5%)	14(10.6%)	<0.001
Extension of uterine scar (N, %)	5(15.2%)	6(4.2%)	0.044
Recurrent uterine rupture (N, %)	1(3%)	0(0%)	0.200
Dehiscence (N, %)	3(9.1%)	17(12.9%)	0.400
* Composite adverse Maternal outcome (N, %)	13(41.9%)	24(18.6%)	0.006
Newborn weight (Mean, grams)	2727.2±402	3069.7±537	<0.001
Newborn Apgar 5minutes <7 (N, %)	4(12.1%)	1(0.8%)	0.006
NICU>72 Hours (N, %)	9(29%)	16(12.7%)	0.026
** Composite adverse Neonatal outcome (N, %)	16(51.6%)	38(30.4%)	0.026

* Composite adverse Maternal outcome – defined by one or more of the following: Extension of uterine scar, uterine rupture, accreta, hysterectomy, dehiscence, bladder injury, readmission in 42 days, Puerperal Fever, massive PPH.
** Composite adverse Neonatal outcome - defined by one or more of the following: NICU>72 Hours Newborn Apgar 5minutes <7, jaundice, hypoglycemia, sepsis.

277 Early-onset hypertensive disorders of pregnancy associated with high perinatal mortality in Dar es Salaam, Tanzania

Amani Kikula[1], Christopher Sudfeld[2], Alfa Muhihi[3], Andrea Barnabas Pembe[1], Nandita Perumal[4], Heavenlight Paul[3], Honorati Masanji[5], Mary Mwanyika-Sando[3], Wafaie Fawzi[2], Blair Wylie[6]

[1]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Dar es Salaam, [2]Harvard T.H. Chan School of Public Health, Boston, MA, [3]Africa Academy for Public Health, Dar es Salaam, Dar es Salaam, [4]Harvard T.H.Chan School of Public Health, Boston, MA, [5]Ifakara Health Institute, Dar es Salaam, Dar es Salaam, [6]Columbia University, New York, NY; on behalf of the Bill and Melinda Gates Foundation

OBJECTIVE: To estimate the risk of adverse perinatal outcomes associated with early (< 34 weeks) vs late (≥ 34 weeks) presentation of hypertensive disorders of pregnancy (HDPs) in a resource-limited setting.

STUDY DESIGN: We performed a secondary analysis of a randomized noninferiority trial comparing 500 mg vs 1500 mg calcium supplementation daily for preeclampsia (PE) prevention among nulliparous women (n=11,000) in Dar es Salaam, Tanzania (2019-2023). Women were followed monthly during antenatal visits through delivery with serial measurements of blood pressure and urine dipstick for protein. We compared risk of adverse perinatal outcomes associated with early (< 34 weeks) vs late (≥ 34 weeks) presentation of HDPs in multivariable regression models.

RESULTS: Of the 11,000 women enrolled in the trial, 162 (1.5%) were diagnosed with GHTN, 121 (1.1%) with PE without severe features and 194 (1.8%) with PE w/ severe features. Early (< 34 weeks) presentation was associated with a marked increase in the risk of adverse perinatal outcomes across all HDP categories (TABLE). The prevalence of perinatal mortality for early compared to late onset of GHTN was 32.0% vs 5.0% (aRR 5.0; 95% CI: 2.2, 11.1); for PE without severe features 26.1% vs 4.6% (aRR: 8.5; 95% CI: 2.0, 36.7); and for PE with severe features 47.5% vs 8.8% (aRR: 5.8; 95% CI: 3.0, 11.4). Early onset HDP also was strongly associated with preterm birth and low birthweight across HDP phenotypes.

CONCLUSION: Adverse perinatal outcomes were significantly higher among pregnancies with HDPs that presented earlier in gestation (< 34 weeks) compared to later in this large pregnancy cohort from Tanzania. Our findings confirm the importance of early detection and management of HDP. The high rates of perinatal mortality and other adverse outcomes underscore the critical need for scaling up interventions, such as prophylactic aspirin or calcium supplementation, that can prevent or delay the onset of HDP in settings where access to routine neonatal intensive care is limited or currently unavailable.

TABLE: Perinatal outcomes associated with early (<34 wks) vs late (≥34 wks) presentation of HTN in pregnancy

	GHTN (140-159/90-109 mmHg w/o proteinuria)		PE without severe features (140-159/90-109 mmHg w/ proteinuria)		PE with severe features (160+/110+ mmHg or other severe features)

*Birth outcomes are reported per infant rather than per pregnancy. The denominator for perinatal mortality includes both live births and stillbirths whereas the denominator for other perinatal outcomes is restricted to live births. Relative risks adjusted for age, education, wealth quintile, BMI, anemia, HIV, family h/o HTN, trial regimen.

278 Is age just a number? advanced maternal age and stillbirth risk

Ralitza H. Peneva[1], Matthew M. Finneran[2]

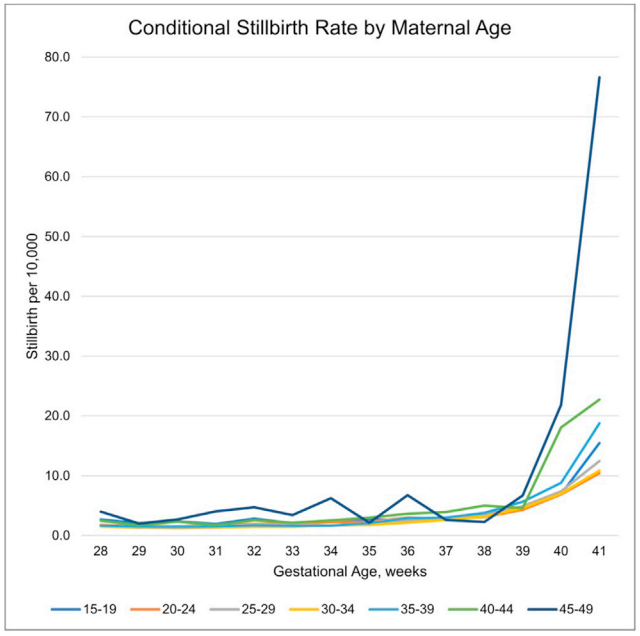
[1]MUSC, Johns Island, SC, [2]Medical University of South Carolina, Charleston, SC

OBJECTIVE: Advanced maternal age (AMA) has been associated with an increased risk of stillbirth, but it is unclear whether this is an independent effect or represents risk of higher baseline morbidity with increasing age. Further, it is not obvious whether these stillbirths are preventable either by antenatal testing or indicated delivery. The objective of this study is to assess risk of stillbirth in a large population among women classifying as AMA.

STUDY DESIGN: This was a population based retrospective study of all singleton, non-anomalous, genetically normal gestations ≥ 20 weeks gestational age in a national registry of live birth vital statistics data from 2020-2022. Women were stratified by age categories in five-year increments from 15-49 years old. Conditional stillbirth rates were calculated per 10,000 women for each gestational age week between 28-41 weeks. Poisson regression with robust error variance was used to calculate adjusted risk ratios (aRR) for still birth overall and ≥ 32 weeks in ongoing pregnancies adjusting for chronic hypertension, pregestational diabetes, and birthweight percentile with age 25-29 as the referent. A secondary analysis restricted the regression to patients with delivery <40 weeks.

RESULTS: A total of 7,032,369 pregnancies were included in this analysis with 15.8%, 3.4%, and 0.2% with maternal age of 35-39, 40-44, and 45-49, respectively. Conditional stillbirth rates increased with advancing gestational age in all groups, with a notable increase following 39; Figure 1. Absolute overall risk of stillbirth was small (range 0.42%-0.85%) with the highest rate at 45-49 years old. The risk of stillbirth after 32 weeks was only significant in women age 40-44 (aRR 1.18, CI 1.07-1.29) and age 45-49 (aRR 1.49, CI 1.10-1.99) after adjustment. However, when further adjusting to exclude deliveries occurring after 39 weeks there were no significantly increased risks of stillbirth across any age category.

CONCLUSION: A small but significant increased risk of stillbirth was seen in women 40 to 49 years old. However, this was not significant restricting to women delivered < 40 weeks.



279 Advanced maternal age and risk of pathologic fetal growth

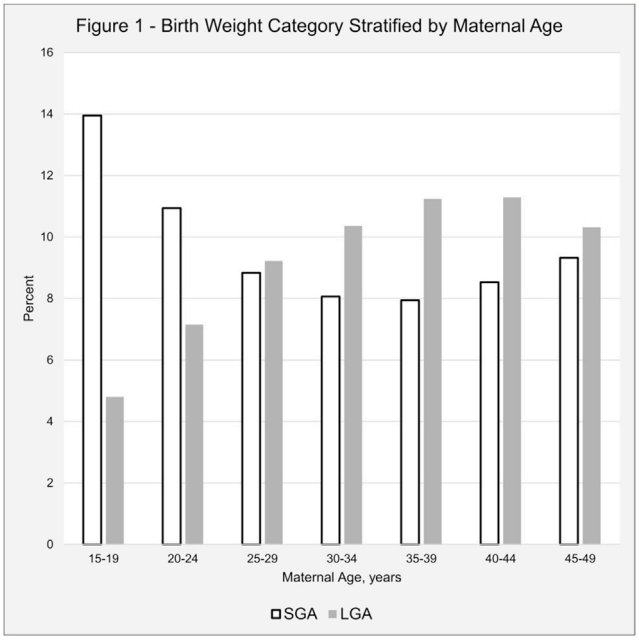
Ralitza H. Peneva[1], Brittany Austin[2], Matthew M. Finneran[2]
[1]MUSC, Johns Island, SC, [2]Medical University of South Carolina, Charleston, SC

OBJECTIVE: Advanced maternal age is associated with an increased risk of underlying comorbid disease and pregnancy complications, which are associated with both small (SGA) and large (LGA) for gestational age birth weight. For this reason, some centers perform serial growth surveillance in all AMA women, but the independent affect of age on birth weight is unclear. The objective of this study was to analyze a large population of AMA women and assess risk of SGA and LGA accounting for known confounders.

STUDY DESIGN: This was a population based retrospective study of all singleton, non-anomalous, genetically normal gestations $\geq$ 20 weeks gestational age in a national registry of live birth vital statistics data from 2020-2022. Women were stratified by age categories in five-year increments from 15-49 years old. The primary outcome was risk of large (LGA, birth weight >90%) and small (SGA, birth weight < 10%) for gestational age birth weight assigned by sex-specific Fenton criteria. Poisson regression with robust error variance was performed to generate adjusted risk ratios (aRR) among age categories using ages 25-29 years old as the referent adjusting for chronic hypertension, hypertensive disorders of pregnancy, pregestational and gestational diabetes.

RESULTS: A total of 7,022,461 pregnancies were included in this analysis with 9.4% and 9.1% classifying as LGA and SGA, respectively. In unadjusted analysis, rates of SGA decreased and rates of LGA increased with advancing maternal age; Figure 1. The risk of LGA was elevated for all age categories above age 25 and highest among ages 35-39 (aRR 1.20, CI 1.19-1.21). Conversely, the risk of SGA was highest for ages less than 25, and highest among age 15-19 (aRR 1.57, CI 1.55-1.58) and age 20-24 (aRR 1.23, CI 1.23-1.24).

CONCLUSION: Advancing maternal age is associated with decreasing rates of SGA and increasing rates of LGA birth weight that was independent of known comorbid conditions and pregnancy complications.



280 Joint effects of epilepsy and mental health on severe maternal morbidity

Nicola Perlman[1], Jonathan A. Mayo[1], Stephanie A. Leonard[1], Suzan L. Carmichael[1], Thomas McElrath[2], Kimford Meador[1], Maurice L. Druzin[3], Danielle M. Panelli[1]
[1]Stanford University, Palo Alto, CA, [2]Brigham and Women's Hospital, Boston, MA, [3]Stanford University Medical Center, Palo Alto, CA

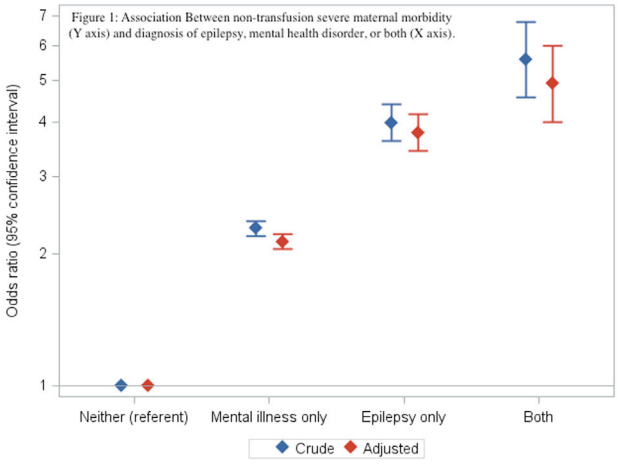
OBJECTIVE: Mental illness and epilepsy are each associated with increased maternal morbidity and mortality, yet their joint effects are unknown. We evaluated the impact of concurrent mental illness on the relationship between epilepsy and non-transfusion severe maternal morbidity (SMM).

STUDY DESIGN: We conducted a population-based cohort study of birth certificate (both live birth and fetal death) and hospital discharge records in California in 2007-2018. Epilepsy and mental health disorders at delivery hospitalization were identified using ICD-CM codes. Mental health disorders included depression, anxiety, bipolar disorder, post-traumatic stress disorder, and psychosis/delusions. Exposures were no epilepsy or mental health disorder (referent), mental health disorder alone, epilepsy alone, or both epilepsy and mental health disorder. The outcome was SMM—defined as presence of 1 of 20 indicators not including blood transfusion—during delivery hospitalization or hospitalization within 6-weeks postpartum. The associations between exposure groups and SMM were modeled by multivariable logistic regression, adjusting for age, race/ethnicity, education, delivery payment, initiation of prenatal care, delivery BMI, and parity.

RESULTS: 5,275,994 people were included. The prevalence of mental health disorder without epilepsy was 296 patients per 10,000, epilepsy without a mental health disorder was 28 per 10,000, and epilepsy with mental health disorder was 5 per 10,000. Within these groups, there was higher incidence of SMM (1.75%, 3.00%, 4.15%) compared to the referent group (SMM: 0.77%). Logistic regression showed increased odds of SMM with each respective diagnosis

compared to the referent group. Patients with both epilepsy and mental health disorder had highest odds of SMM (aOR 4.91 (95% CI 4.01,6.00) Figure 1). An interaction term of epilepsy and mental health disorder on SMM was significant (p=0.005).

CONCLUSION: Independently, epilepsy and mental health disorders were confirmed as drivers of maternal morbidity. Patients with both diagnoses carried even higher odds of experiencing SMM during delivery or postpartum.



281 Association between Medicaid coverage of dental services and dental hygiene during pregnancy

Madeline F. Perry[1], Lynn M. Yee[2], Joe M. Feinglass[2]
[1]Northwestern University, CHICAGO, IL, [2]Northwestern University, Chicago, IL

OBJECTIVE: Poor oral hygiene has been associated with adverse pregnancy outcomes. Unlike prenatal care, dental care is not required to be covered by Medicaid and coverage may change when people become pregnant. We evaluated the association between state Medicaid coverage of dental services and receipt of teeth cleaning during pregnancy among those covered by Medicaid and those privately insured.

STUDY DESIGN: Using 2016-20 data from the Pregnancy Risk Assessment Monitoring System including 44 states, linked with data from the Medicaid and CHIP Payment and Access Commission (MACPAC), we analyzed state-level differences in dental care during pregnancy. Utilizing multivariable Poisson regression, we assessed the association between Medicaid coverage of dental services and the likelihood of teeth cleaning during pregnancy separately among Medicaid and privately-insured populations, controlling for respondent sociodemographic characteristics.

RESULTS: The analysis included 149,748 respondents representing a weighted 7,520,502 population. Teeth cleaning during pregnancy was reported for 34% of Medicaid respondents and 56% of privately-insured respondents. Among Medicaid respondents, in states with the no Medicaid coverage of dental services, there was a 41% lower likelihood of teeth cleaning during pregnancy (aOR 0.59, 95% CI 0.52, 0.67) compared with states with the most generous Medicaid coverage of dental services (Table). The likelihood of dental cleaning during pregnancy for privately-insured respondents was not associated with state Medicaid policies.

CONCLUSION: Minimal or no Medicaid coverage of dental services is associated with a significantly lesser likelihood of receiving teeth cleaning during pregnancy in a Medicaid-only population. This relationship did not exist in a privately insured population, suggesting that receipt of teeth cleaning is not due to state-level differences but rather associated with insurance coverage. Findings demonstrate the importance of dental insurance coverage specifically in pregnant, low-income populations.

Table. Association of Medicaid coverage of dental services and receipt of teeth cleaning during pregnancy

State Medicaid Coverage of dental services[1]	Percent of respondents living in Medicaid coverage category (%)[2]	Percent of Medicaid respondents reporting teeth cleaned during pregnancy[3,4]	Percent of privately insured respondents reporting teeth cleaning during pregnancy[5,7]
No coverage	3.9	21.1	50.8
Emergency coverage	5.8	25.5	56.0
Coverage of 1-4 dental services	9.6	26.3	50.5
Coverage of ≥5 dental services	80.7	36.1	57.2
State Medicaid Coverage of dental services[1]		**Teeth cleaning during pregnancy among Medicaid respondents, aIRR 95% CI[3,4,6]**	**Teeth cleaning during pregnancy among privately insured respondents, aIRR 95% CI[5,6,7]**
No coverage		0.59 (0.52, 0.67)	0.95 (0.90, 0.99)
Emergency coverage		0.71 (0.66, 0.77)	1.01 (0.99, 1.04)
Coverage of 1-4 dental services		0.73 (0.68, 0.79)	0.93 (0.90, 0.96)
Coverage of ≥5 dental services		Referent	Referent

282 State conservative ranking and prevalence of intimate partner violence before and during pregnancy

Madeline F. Perry[1], Lynn M. Yee[2], Joe M. Feinglass[2]
[1]Northwestern University, CHICAGO, IL, [2]Northwestern University, Chicago, IL

OBJECTIVE: An estimated 2 to 9 percent of people who are pregnant experience intimate partner violence (IPV), increasing their risk of adverse pregnancy outcomes. We hypothesize that states with a more progressive political culture will have lower rates of IPV than more conservative states. We aimed to evaluate the association between state conservative ranking and state IPV rates before and during pregnancy.

STUDY DESIGN: We used 2016-20 data from the Pregnancy Risk Assessment Monitoring System, linked to published state conservative ranking scores based on the percent of total votes in a state legislature cast for conservative causes. States were grouped into

tertiles of most to least conservative. Using multivariable Poisson regression, we assessed the association between state conservative ranking and the frequency of self-reported IPV before (within 12 months) and during pregnancy, controlling for individual-level sociodemographic variables.

RESULTS: This analysis included 194,334 respondents representing a population of 9,785,771. In total, 3.1% of respondents reported experiencing IPV before or during pregnancy. Pearson correlation coefficients demonstrated a significant linear association (0.57, $p < 0.001$), with states that had a higher proportion of conservative votes associated with higher reported prevalence of IPV (Figure). In multivariate Poisson regression, there was a 14% lower likelihood of IPV in the 14 states with the least conservative (most liberal) state legislative voting records in comparison to a referent group of moderately conservative states (aIRR 0.86, 95% CI 0.79-0.95). However, the risk of IPV was not significantly different between those in highly versus moderately conservative states.

CONCLUSION: Birthing individuals in states with the least conservative (most liberal) policy environment were significantly less likely to report IPV in the 12 months before or during pregnancy. While evaluation of individual-level factors dominates research about IPV, we advocate for a better understanding of how political environments influence the prevalence of IPV in order to reduce IPV rates.

283 A Prenatal lead screening and intervention program in a high risk obstetrical population

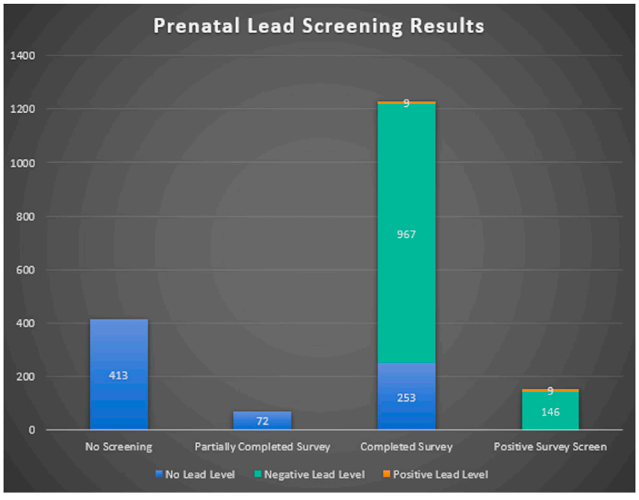
Maria Phillis[1], Natalie Harper[2], Jennifer Conti[3], Kelly S. Gibson[3]
[1]The MetroHealth System/Case Western Reserve University Program, Cleveland, OH, [2]The MetroHealth System, Institute for HOPE, Cleveland, OH, [3]The MetroHealth System, Cleveland, OH

OBJECTIVE: Prenatal lead exposure in pregnancy has known adverse effects on maternal health and infant outcomes. We aimed to assess the efficacy of a prenatal screening and intervention program for lead exposure. We hypothesized that in a city with high rates of lead exposure, blood lead levels drawn in pregnancy would identify additional patients with elevated levels, beyond those discovered via survey screening.

STUDY DESIGN: A prospective quality intervention study of lead exposure in pregnant patients at a tertiary urban center with high lead rates in the city. We screened patients at their first prenatal visit with a survey of their exposure and a blood lead level. "Yes" to any question or a blood lead level >5mg/dL were considered screening positive. Patients with positive screens were referred to the Community Health Worker for intervention, a detailed interview, in depth education on the risks of lead exposure, nutrition education and referrals to a dietician and a lead cleaning kit for use at home. Patients deemed appropriate by the Community Health Worker were also offered a home lead inspection and assessment.

RESULTS: In 2022-2023, the intervention clinic had 1717 new pregnancy encounters. 1229 completed surveys (71.6%) and 72 partially completed a survey (4.2%). Of those surveys, 155 patients (11.9%) screened positive for possible lead exposure. A total of 976 blood lead levels were drawn and resulted in 9 (0.9%) elevated lead levels, all of whom also screened positive for possible exposure on the survey. Of the 155 patients who screened positive, 70 kits were offered for lead intervention. 55 total kits were distributed. Of the patients with the home kits, 18 (33.3%) were referred for inspections. A third of the inspections required intervention.

CONCLUSION: The rate of elevated lead levels in pregnant patients living in areas with high lead exposure is low. It is feasible to conduct a screening protocol for lead exposure using a survey at the obstetric intake visit. The addition of serum lead screening did not increase the identification of high risk patients.



284 Postpartum diabetes screening rates and 1-year outcomes for individuals with early onset gestational diabetes

Benjamin Pifer[1], Bertie Geng[1], Lisbet S. Lundsberg[2], Jennifer F. Culhane[3], Caitlin Partridge[3], Audrey A. Merriam[4]
[1]Yale New Haven Hospital, New Haven, CT, [2]Yale, New Haven, CT, [3]Yale University, New Haven, CT, [4]Yale University School of Medicine, New Haven, CT

OBJECTIVE: ACOG recommends early gestational diabetes (GDM) screening for at risk patients. GDM increases the subsequent risk of developing diabetes mellitus (DM) however compliance with postpartum DM screening is low. Current data does not stratify which GDM patients are at greatest risk of developing postpartum DM. We aim to summarize postpartum screening practices and outcomes for patients with 3 or 4 abnormal values on early 3-hour GTT.

STUDY DESIGN: This is a retrospective study of individuals delivering at a tertiary hospital from 2013 to 2021 with a 3-hour GTT

completed before 26 weeks. Patients with pregestational DM, multifetal gestations, or who delivered before 24 weeks were excluded. Data was extracted from the electronic medical record. Frequencies and chi-square tests of association were performed using SAS.

RESULTS: In our analysis of 151 patients, 111 had 3 and 40 had 4 abnormal values. There were no differences in patient characteristics. 84 (55.63%) had a 2-hour GTT or A1c within 1 year of delivery. 63 patients completed either a 2-hour GTT or A1c within 6 weeks postpartum. Of those, 5 (7.94%) met criteria for DM. 46 patients completed either a 2-hour GTT or A1c after 6 weeks postpartum but up to 1 year post-delivery. Of those, 13 (28.26%) met criteria for DM. Those with 4 abnormal values were more likely to have completed postpartum 2-hour GTT compared to those with 3 abnormal values, p=0.016 (Table). Those who had 4 abnormal values were more likely to be diagnosed with DM postpartum with OR 4.31 (CI 1.49-12.53) compared to those with 3 abnormal values.

CONCLUSION: Patients with 4 abnormal early 3-hour GTT values were more likely to undergo postpartum DM screening and screen positive for DM compared to those with 3 abnormal values. Many patients with 3 or 4 abnormal values did not complete postpartum DM screening. This work emphasizes the importance of adherence to recommended screening guidelines postpartum and the need for close communication with primary care providers to ensure adequate postpartum DM follow up.

Table: Patient characteristics and postpartum diabetes evaluation for individuals with 3 or 4 abnormal values on early glucose tolerate testing

	Number of abnormal glucose values on early GTT		
Patient characteristics	**3 abnormal values n=111 n (%)**	**4 abnormal values n=40 n (%)**	p-value
Age <35 years old	49 (44.1)	19 (47.5)	0.72
Nulliparous	80 (72.7)	24 (60.0)	0.14
Postpartum BMI ≥30	89 (81.2)	37 (92.5)	0.07
Baseline cHTN	24 (21.6)	8 (20.0)	0.83
HDP	32 (28.8)	14 (35.0)	0.47
Type of evaluation			
A1c	36 (32.4)	13 (32.5)	0.99
fasting glucose	40 (36)	22 (55.0)	**0.04**
2-hour GTT	37 (33.3)	22 (55.0)	**0.02**
random glucose	26 (23.4)	16 (40.0)	**0.04**
Diagnosed with DM postpartum°	**7 (6.3)**	**9 (22.5)**	**0.004**

° DM diagnosed by a hemoglobin A1c values >6.4, fasting glucose value of >125 mg/dl, 2-hour post 75g glucose load value of >199mg/dl, or random glucose ≥200 mg/dL

285 Safety and performance of a cloud-based fetal and maternal monitoring system

Mindy A. Ditch[1], Benjamin A. Teplitzky[1], Carrie McKenzie[1], Beth Plunkett[2]

[1]Marani Health, Oakdale, MN, [2]Evanston Hospital, NorthShore University HealthSystem, Evanston, IL

OBJECTIVE: To demonstrate the safety and performance of a remote, wireless, cloud-based monitoring system for fetal and maternal heart rate (FHR and MHR). Uterine activity (UA) monitoring was assessed as a secondary objective.

STUDY DESIGN: A multi-center, single-arm, prospective paired comparison study was conducted to evaluate safety and compare FHR and MHR acquired with a new antenatal monitoring system (M•care System, Marani Health) to simultaneously acquired FHR and MHR measured with a standard cardiotocography (CTG) device and pulse-oximetry, respectively. UA was compared against tocodynamometry (TOCO). Eligible subjects had singleton pregnancies with gestations ≥ 32 weeks and BMI between 15 and 45 kg/m^2. Recruitment occurred on Labor and Delivery units, antepartum floors and outpatient settings across three sites. Bland-Altman 95% Limits of Agreement (LoA_{95}) between the M•care System and CTG measures and pulse oximetry were compared against equivalence thresholds of 15 beats per minute (BPM) for FHR and 10 BPM for MHR. Three blinded physicians independently assessed M•care UA in comparison to TOCO.

RESULTS: Performance data was available for 80 subjects. Demographic and clinical characteristics of the study population are displayed (Table). Between device FHR differed by 0.18±4.77 (mean±SD) BPM, with a lower LoA_{95} [95% CI] of -4.45 [-5.26, -3.61] and upper LoA_{95} of 6.64 [5.25, 8.45] BPM. Between device MHR differed by 0.28±2.48 (mean±SD) BPM, with a lower LoA_{95} [95% CI] of 2.26 [-2.74, -1.95] and upper LoA_{95} of 2.93 [2.52, 3.32] BPM. However, only 57% of TOCO contractions were detected in M•care UA. One mild adverse event occurred, a skin reaction to the exfoliating agent, prior to placement of the study device.

CONCLUSION: The M•care System is safe and its performance is comparable to CTG and pulse oximetry. It is not sufficiently sensitive to measure UA. This technology could support home-based antenatal maternal and fetal monitoring to enable patients and providers to connect efficiently and potentially reduce patient travel and childcare burden.

Table: Subject Demographic and Clinical Characteristics

	Subjects (N=80)
Demographics	
Age	32.0 (22.0, 41.0)
Gestational age (weeks)	39.1 (32.6, 41.4)
Ethnicity	
Not Hispanic or Latino	93.5% (72/77)
Hispanic or Latino	6.5% (5/77)
Race	
White	77.5% (62/80)
Black or African American	5.0% (4/80)
American Indian or Alaska Native	3.8% (3/80)
Asian	5.0% (4/80)
Other	2.5% (2/80)
Unknown	6.3% (5/80)

286 Amnioinfusion for intrauterine neuroprotection: A pilot randomized feasibility trial

Brock Polnaszek[1], Julia Rossen[1], Lauren M. Murphy[1], Anna Whelan[2], Maureen Hamel[1], Dwight J. Rouse[1], Methodius G. Tuuli[1], Adam K. Lewkowitz[3]

[1]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [2]Grafton, MA, [3]Warren Alpert Medical School of Brown University, Women & Infants Hospital Rhode Island, Providence, RI

OBJECTIVE: Amnioinfusion (AI) has the potential to reduce neurologic injury in at risk fetuses via in-utero hypothermia. We performed a pilot randomized controlled trial to assess the feasibility and effects of AI with room-temperature fluid in such fetuses.

STUDY DESIGN: Participants in labor with term singleton pregnancies who developed risk factors for fetal neurologic injury (chorioamnionitis or Category 2 fetal heart tracing) underwent intrauterine pressure catheter placement and randomization to continuous AI of room-temperature fluid or no AI until delivery. Intrauterine temperature (IUT) was monitored with a temperature probe (DataTherm II, Medline). The primary outcome was umbilical artery lactate (UAL). Secondary outcomes included neonatal core temperature within 10 minutes of birth, IUT at 10 minute intervals, composite maternal and neonatal morbidity, decisional self-efficacy and labour agentry scores. To detect a 50% difference in UAL (similar to fetal morbidity data from intrauterine ischemia), 13 participants were needed in both groups (2-tailed test, alpha 0.5, 10% attrition). Analysis was by intention-to-treat. ClinicalTrials.gov Identifier: NCT05513690

RESULTS: Of 226 women approached, 85 (37.6%) were consented with 26 randomized. At baseline, the study groups were similar. UAL did not significantly differ between the AI (median [interquartile range] 5.1 [4.5-7] mmol/L) and no AI group (4.4 [3.6-5.6] mmol/L; p=0.18). IUT, neonatal core temperature, and composite maternal and neonatal morbidity did not significantly differ. Decisional self-efficacy and labour agentry scores were similarly high between groups.

CONCLUSION: Continuous AI with room-temperature fluid in fetuses at risk for neurologic injury is feasible but did not lower neonatal core temperature or UAL. Future research should examine whether AI with cold-fluid will achieve in-utero hypothermia and reduce neurologic injury.

Table 1. Effects of room temperature amnioinfusion in fetuses at risk for neurologic injury.

Feasibility Outcomes	Amnioinfusion N=13 (Intervention)	No Amnioinfusion N=13 (Control)	p-value

287 Aspirin restores preeclamptic placental mesenchymal stem cells for licensing to immune suppressor cells

Kimone Powell, Lauren Sherman, Shauna F. Williams, Pranela Rameshwar, Bobak Shadpoor

Rutgers New Jersey Medical School, Newark, NJ

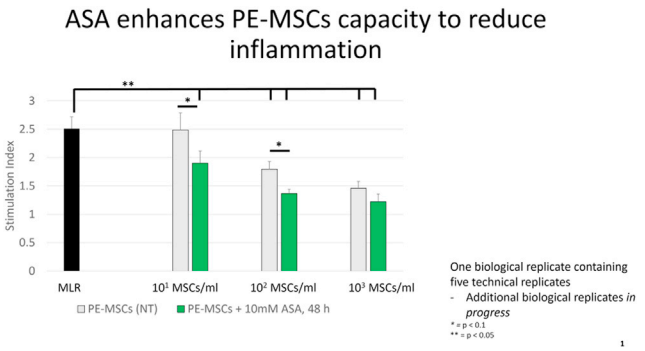
OBJECTIVE: Preeclampsia (PE) affects 2-8% of pregnancies globally and can lead to serious complications. Pregnancy depends on the maternal immune system's ability to tolerate the allogeneic fetus.-Transforming growth factor β (TGF-β) plays a role in this process. MSCs are normally licensed, or educated, by inflammation to act as anti-inflammatory cells. Omics studies in our group identified increased TGF-β signaling when PE-derived placental mesenchymal stem cells (PE-MSCs) were treated with aspirin (ASA). We tested the hypothesis that PE-MSCs restored with ASA can mitigate inflammation.

STUDY DESIGN: We obtained placentas from singleton pregnancies at or near term from healthy and PE patients; excluding subjects with abnormal placentas, infections or preexisting medical comorbidities. MSC identity was confirmed by flow cytometry and multilineage differentiation capacity. We tested the density of TGF-β receptor and amount of active cytokine induced by ASA treatment. Immune suppression by ASA-treated MSCs was assessed in a 2-way mixed lymphocyte reaction (MLR) in which PE-MSCs were added as third-party cells after ASA treatment.

RESULTS: ASA increased TGF-β receptor density, with untreated PE-MSCs expressing undetectable TGF-β receptor and ASA treatment yielding strong expression. ASA treatment led to a >100 fold increase in active TGF-β cytokine production. Functionally, the ASA-treated PE-MSCs were 30% more effective at suppressing T-cell proliferation than untreated PE-MSCs.

CONCLUSION: The data illustrate a possible mechanism through which ASA enhances PE-MSCs' anti-inflammatory capacity through TGF-β. Specifically, ASA treatment yields increased levels of active TGF-β cytokine with concomitant increased TGF-β receptor expression, suggesting that not only are the MSCs producing more of

this anti-inflammatory cytokine, but are more susceptible to it as well. The findings support our hypothesis that the newly licensed ASA-treated PE-MSCs can mitigate inflammation in subjects with PE to decrease the clinical phenotype.



288 Amlodipine versus nifedipine ER for the management of postpartum hypertension: a noninferiority randomized controlled trial

Katelyn Pratt[1], Ross Lordo[1], Stella Self[2], Laura Carlson[1]
[1]Prisma Health, University of South Carolina School of Medicine Greenville, Greenville, SC, [2]University of South Carolina, Greenville, SC

OBJECTIVE: Hypertensive disorders of pregnancy (HDP) are a leading cause of maternal morbidity, yet data comparing postpartum hypertension (PPHTN) medications are limited. We sought to compare the effectiveness of 2 dihydropyridine calcium channel blockers: amlodipine, which is often used as first-line monotherapy for non-obstetric hypertension, and nifedipine ER, which is frequently used for PPHTN. We hypothesized that amlodipine is non-inferior to nifedipine ER for PPHTN control, as defined by time from delivery until discharge (PPLOS).

STUDY DESIGN: This was a pragmatic, noninferiority RCT at a single regional perinatal center. Patients with unmedicated HDP were randomized 1:1 to postpartum treatment with amlodipine or nifedipine ER, stratified by underlying chronic hypertension (CHTN). The primary outcome was PPLOS with a non-inferiority limit of 24 hrs. Secondary outcomes included readmission rate, side effects, and medication discontinuation. Primary analysis was intent-to-treat; secondary analysis was performed on an as-treated cohort (AT). Wilcoxon rank sum, ANOVA, and logistic regression were utilized as appropriate.

RESULTS: **175** patients met inclusion criteria and were randomized, 87 to amlodipine and 88 to nifedipine ER. 120 were evaluated in the AT cohort. Baseline characteristics were balanced (Table). Median PPLOS was 73.5 hrs. for amlodipine and 72 hrs. for nifedipine ER, consistent with noninferiority ($p< 0.001$). Noninferiority was maintained in the AT cohort and in those with CHTN. There was no difference in readmission (4.1% amlodipine vs 5.1% nifedipine ER, $p=0.77$). Patients exposed to nifedipine ER experienced more hypotension (OR 4.6, 95% CI 1.72-14.63) and tachycardia (OR 2.25, 95% CI 1.08-4.78) compared to patients exposed to amlodipine. Seven patients (10%) exposed to nifedipine ER discontinued medication due to side effects, compared to none exposed to amlodipine.

CONCLUSION: Amlodipine is non-inferior to nifedipine ER in managing PPHTN as measured by PPLOS. Readmission rates were similar and amlodipine discontinuation was lower. Amlodipine should be considered for PPHTN management.

Characteristic	Amlodipine (n = 87)	Nifedipine ER (n = 88)
Maternal age	27.9 (6.8)	27.8 (5.9)
BMI at delivery	36.8 (9.3)	37.0 (10.1)

289 Is duration of labor during induction termination associated with adverse maternal outcomes?

Ashish Premkumar[1], Vanya Manthena[1], Jocelyn Wascher[1], Emily Barker[2], Laura Laursen[3], Leanne McCloskey[4], Joseph Michalski[5]
[1]University of Chicago, Chicago, IL, [2]Washington University in St. Louis, St. Louis, MO, [3]Rush University, Chicago, IL, [4]Northwestern University, Chicago, IL, [5]Rush University Medical Center, Chicago, IL

OBJECTIVE: Though duration of labor is associated with adverse maternal outcomes in term labor, there are scant data to evaluate this association during induction termination (IT). We evaluated the relationship between duration of labor during IT and adverse maternal outcomes.

STUDY DESIGN: We performed a retrospective cohort analysis of all individuals undergoing IT with a singleton gestation with no evidence of rupture of membranes, preterm labor, or cervical insufficiency at 3 tertiary care centers in Chicago, IL from 2009-2019. The primary exposure was the duration of labor for complete fetal expulsion in hours, analyzed categorically (duration of labor < 18 hours v. ≥ 18 hours) and continuously. The primary outcome was composite maternal morbidity (i.e., uterine rupture, need for blood transfusion, suspected intraamniotic infection [IAI], and/or intensive care unit admission). Bivariate and multivariate regression analyses were performed. A priori covariates included gestational age and use of mifepristone. Other covariates were included if $p < 0.10$ on bivariate analysis. Tests of homogeneity were performed based on prior history of cesarean birth. A Kaplan-Meier curve was generated, censoring at the time the primary outcome was met.

RESULTS: 506 individuals were included (Table). When evaluating duration of labor continuously, longer duration was associated with increased frequency of maternal morbidity on bivariate (β coefficient 0.05, 95% CI 0.02-0.07) and multivariate analyses, after additionally adjusting for nulliparity and maternal age (aβ coefficient 0.04, 95%

CI 0.02-0.07, see Figure). When evaluating duration of labor categorically, those with labor ≥ 18 hours had an elevated risk for maternal morbidity on bivariate (RR 2.55, 95% CI 1.61-4.06) and multivariate analyses (aRR 2.70, 95% CI 1.70-4.28). Tests of homogeneity showed no difference in risk based on history of cesarean birth.

CONCLUSION: Duration of labor is independently associated with risks for adverse maternal outcomes during IT. Further research should evaluate interventions to reduce the duration of labor in the setting of IT.

290 Analysis of the plan of safe care for parent-child dyads affected by opioid use

Katherine Pressman, Margaret Cornwall, Tanner G. Wright, Anthony Kendle
University of South Florida Morsani College of Medicine, Tampa, FL

OBJECTIVE: In an effort to address the opioid epidemic, the Comprehensive Addiction and Recovery Act of 2016 (CARA) was passed as a provision of the Child Abuse Prevention and Treatment Act (CAPTA), which expanded use of Plans of Safe Care (POSC) for all infants affected by substance use in pregnancy. There is limited data on parent-child outcomes as it relates to this federal mandate. The goal of this study was to evaluate the outcomes of POSC, specifically the use of medications for opioid use disorder (MOUD) at time of delivery, return to opioid use, and custody of infant at discharge.

STUDY DESIGN: This is a retrospective cohort study of pregnant person-infant dyads who delivered at a tertiary care hospital from January 2019-July 2023. Medical records were reviewed for demographics and clinical characteristics as well as documentation of a POSC. Univariate analysis was completed using chi-square tests and Student's t-test where appropriate. Bivariate logistic regression was used to generate odds ratios (OR) and 95% confidence intervals (CI). Significance was pre-specified as $p < 0.05$.

RESULTS: Of 274 dyads analyzed, 72 had a documented POSC. There was no difference in rates of MOUD or removal of parental custody at discharge between the groups. In a subgroup analysis of dyads with complete data for 12 months after delivery, there was no difference in rates of return to opioid use. On multivariate analysis, we found that any maternal psychiatric condition (OR 2.92, 95% CI [1.03-8.28], $p = 0.044$) or Hispanic ethnicity (OR 3.87 95% CI [1.54-9.73], $p = 0.004$) was associated with having a POSC. Having a documented POSC ultimately increased the odds of a child protective services (CPS) case (OR 2.71, 95% CI [1.328-5.513], $p = 0.006$).

CONCLUSION: A documented POSC is not associated with MOUD utilization in pregnancy, loss of custody, or rate of return to opioid use. However, POSC is associated with a 2.7-fold increase in CPS involvement. These data support a need to refocus POSC efforts to align with the original goals of the policy, generate supportive and evidence-based services, and avoid discriminatory application.

	Plan of safe care (N = 72)	No plan of safe care (N = 202)	p-value

291 Association of resolving placenta previa and other early sonographic markers with postpartum hemorrhage

Teresa Qi[1], Alexa Cohen[2], Christine Miguel[3], Melissa Peskin-Stolze[4], Pe'er Dar[1], Georgios Doulaveris[2]
[1]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY, [2]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [3]Montefiore Medical Center, Albert Einstein College of Medicine, Manhasset, NY, [4]New York University Grossman Long Island School of Medicine, New York, NY

OBJECTIVE: Low placentation is associated with increased risk of postpartum hemorrhage (PPH). There is a paucity of data on the association between low placentation on second trimester ultrasound that later resolves, and PPH. We hypothesized that due to lower uterine segment neovascularization seen with low placentation, it's resolution before labor does not eliminate the increased risk of PPH. Aim of this study was to investigate association of low placentation and other early prenatal ultrasound markers, and future development of PPH.

STUDY DESIGN: This was retrospective matched case-control (1:1) study of full term, singleton pregnancies complicated by PPH who delivered vaginally at our regional perinatal referral center between 2018 - 2022. PPH was defined as blood loss > 1L within 24 hours of delivery. Primary exposure variable was second trimester placenta previa (defined as complete or marginal previa, or low-lying placenta within 10mm from internal os) that resolved prior to labor. Additional exposure variables included leiomyoma, first trimester subchorionic hematoma, and second trimester cervical length< 25mm, polyhydramnios or estimated fetal weight over 90%tile. Chi-square test and unpaired student t-test were used to compare categorical and continuous variables, respectively. Multivariable logistic regression was also performed.

RESULTS: We compared 400 gravidas with PPH to 400 without. They were matched by age, parity, gestational age at delivery and mode of delivery. PPH occurred more often in cases with resolved previa versus controls (12% vs 4.6%, $p < 0.01$). On multivariate analysis, those with resolved previa were 2.85 times more likely to have PPH, compared to controls, (95%CI 1.52-5.31, $p < 0.01$). PPH rate was also higher in those with leiomyoma (aOR 3.03, 95%CI 1.25-7.39, $p=0.01$). Rates of subchorionic hematoma, short cervical length,

polyhydramnios and estimated fetal weight >90% were similar between groups.

CONCLUSION: A finding of low placentation on second trimester ultrasound is associated with increased risk of PPH, even when it appears to resolve in the third trimester.

292 Adverse pregnancy outcomes with stimulant and opioid use disorder: costs of care and health-system implications

Alexandra Schroeder[1], Noor Al-Hammadi[2], Tucker Doiron[2], Niraj R. Chavan[2]

[1]St. Louis University School of Medicine, St. Louis, MO, [2]St. Louis University, St. Louis, MO

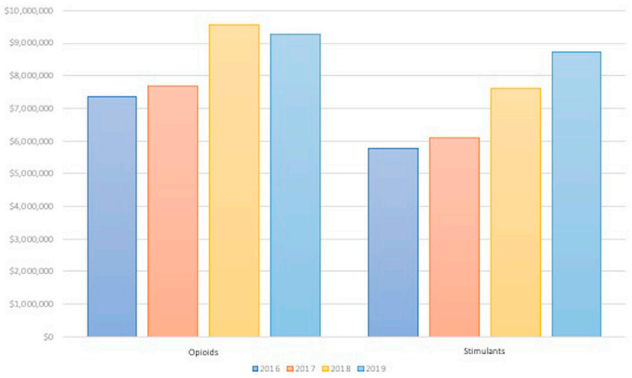
OBJECTIVE: This study was undertaken to identify the current public health cost burden of inpatient hospitalizations for adverse pregnancy outcomes (APO) in the context of stimulant and opioid use disorder (OUD).

STUDY DESIGN: We conducted a cross-sectional analysis of inpatient delivery admissions from the Healthcare Cost and Utilization Project (HCUP) National Inpatient Sample (NIS) from 2016 to 2019. APO was defined as a composite to include hypertensive disorders, antepartum or postpartum hemorrhage, preterm birth, and fetal growth restriction. Inpatient delivery admissions of patients with a stimulant or OUD and concomitant APO diagnosis were identified from NIS using ICD-10 codes and diagnosis related group (DRG) codes. Our primary outcome was total charges of the hospital stay with inflation related adjustments. Survey-weighted means and the percentage of change in total charges over time was calculated and compared across study years.

RESULTS: Inpatient delivery related hospitalizations for APO with stimulant or OUD increased from 2,212 in 2016 to 3616 in 2019. The median hospital charges for admissions with APOs with stimulant use disorder had an 8% increase ($22,108 to $23,827) and those with OUD had a 6% increase ($20,226 to $21,452) from 2016 to 2019. In comparison, delivery admissions with APOs in the absence of stimulant or OUD were noted to have a 1% increase ($21,686 to $21,965) from 2016 to 2019. Evaluation of the aggregate charges and costs, or the "National Bill" revealed that in 2019 the total costs of hospitalizations with APOs with stimulant use disorder was $8,727,192 and with OUD was $9,258,586. The total cost increase for inpatient management of APOs with stimulant use disorder was nearly 3 million dollars compared to an increase of 2 million dollars with OUD from 2016 to 2019 (Figure 1).

CONCLUSION: Our work provides an appreciation of the cost burden from APOs associated with opioid and stimulant use disorder, as an essential first step for designing system-level interventions for addressing the escalating costs of care associated with perinatal substance use disorder.

Figure 1. Aggregate Total Charges of Adverse Pregnancy Outcomes with Opioid and Stimulant Use Disorder in Pregnancy (2016-2019)



293 Cell-free RNA detection of "placental" and immunologic differentially-expressed genes in healthy pregnant vs. non-pregnant individuals

Nathaniel Delaney-Busch, Alison Cowan, Carrie Haverty, Arkady Khodursky, Maneesh Jain, Eugeni Namsaraev, Ilma Abbas, Alison Moe, Kay Mekaru, Mitsu Reddy, Morten Rasmussen

Mirvie, Inc., South San Francisco, CA

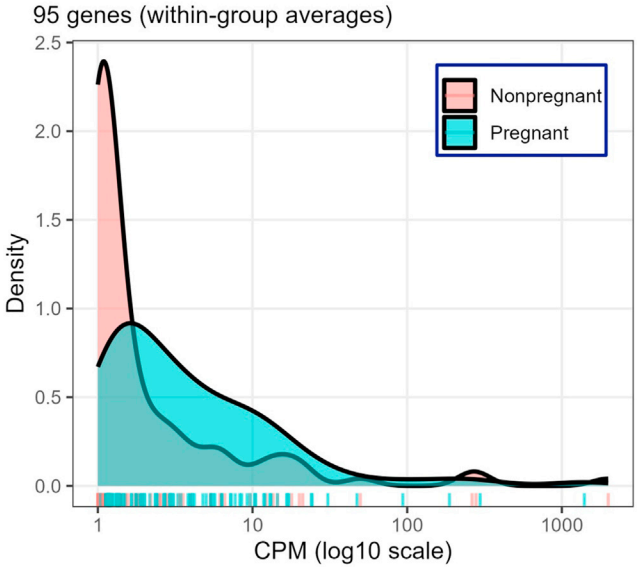
OBJECTIVE: A healthy pregnancy requires extensive physiological adaptations systemically and locally at the maternal-fetal interface. An inability to test all tissues during a pregnancy limits understanding of the transcriptomic shifts that occur from the non-pregnant (NP) to pregnant state. Using cfRNA from maternal blood, we sought to reveal changes in global gene patterns in diverse NP and pregnant individuals.

STUDY DESIGN: For pregnant participants (N=231), individuals had a median age of 32 (range: 20-45) years, BMI of 24 (15 - 60), had no comorbidities and delivered at term without any known pregnancy complications. Maternal blood was drawn at 19 (18-22) weeks. NP individuals (N=49) were 32 (22-40) years, BMI 32 (19-61) and were collected by Discovery Life Sciences. All samples were collected and processed using the same protocol. Differentially expressed genes (DEG) were determined by spearman correlation and gene set overrepresentation by msigdbr v7.5.1.

RESULTS: Pregnancy was associated with 7,301 DEG (adj $p < 0.001$), 38.5% of all plasma-detected genes. Top DEG are known pregnancy genes (top 3: CGA, CSH1, CSH2), with placental genes showing some of the largest differential expression, but 53 of 95 placental genes are also expressed in NP females, with 5 being significantly higher (fig1). Gene set analyses reveal overrepresentation of gene ontologies (GO) linked with immune genes, and even after excluding placental genes, the GO term for inflammatory response is the most overrepresented in pregnancy, demonstrating cfRNA can monitor immune modulation in addition to the fetal/placental genes.

CONCLUSION: Cell-free RNA demonstrates DEG between pregnant and NP individuals, providing insights into underlying biological changes. Placental genes are often expressed in NP females suggesting caution around analyses based on annotations. With several adverse pregnancy outcomes tied to immune response and the inflammatory response observed in these healthy pregnancies, cfRNA offers a comprehensive non-invasive approach to track physiologic changes, including immune response, in pregnancy.

Fig. 1 - Annotated placental genes detected in pregnant and non-pregnant individuals



294 Differences in demographic and obstetrical characteristics among pregnant women with and without COVID-19 vaccination

Alla Saban[1], Yael Reicher[2], Noa Leybovitz-Haleluya[3], Lior Yahav[4], Adi Y. Weintraub[4], Reli Hershkovitz[5], Tamar Eshkoli[1]

[1]Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Beer Sheva, HaDarom, Israel, [2]Soroka University Medical Center, Givat shmuel, HaMerkaz, [3]Soroka University Medical Center, Meitar, HaDarom, [4]Soroka Medical Center, Beer-Sheva, HaDarom, [5]Soroka Medical Center, Omer, HaDarom

OBJECTIVE: Coronavirus disease 2019(COVID-19) infection posed elevated risks of severe illness and adverse obstetrical outcomes for pregnant women. Limited data is available regarding women who have been vaccinated but remained uninfected. Therefore, our study aimed to compare demographic and clinical characteristics of vaccinated and unvaccinated pregnant women without COVID19 infection during the peripartum period.

STUDY DESIGN: We conducted a population-based study at a tertiary medical center, enrolling all women with singleton pregnancies who delivered between 2020 and 2022 and were uninfected with COVID-19. Exclusion criteria included women with incomplete medical records, multiple gestations, and fetal malformations. The study group consisted of women who had received the COVID-19 vaccine, the comparison group consisted of women who had not been vaccinated. We studied the differences in demographic and obstetrical characteristics between both groups. Women with peripartum infection with COVID-19 were excluded.

RESULTS: The study included a total of 26,250 women who met the inclusion criteria. Among them, 3,379 received COVID-19 vaccination. Among vaccinated women, there was significantly higher rate of women with Jewish ethnicity and women above the age of 35. In addition, women with COVID-19 vaccination were found to be significantly associated with an increased risk of cesarean delivery, gestational diabetes, oligohydramnios, induction of labor and epidural anesthesia. However, after conducting a multivariable logistic regression analysis and controlling for confounders the association remained significant only between COVID -19 vaccination and the use of epidural anesthesia (adjusted OR 1.46, 95% CI 1.31-1.63; p< 0.001).

CONCLUSION: In the vaccinated group, there was a significantly greater proportion of women aged 35 and above, as well as those of Jewish ethnicity. Additionally, pregnant women who received the COVID-19 vaccination demonstrated a notable increase in the use of epidural anesthesia.

Table: Demographic and obstetrical characteristics of pregnant women not infected with COVID-19: Comparison between Vaccinated and Non-Vaccinated Groups

Characteristics	Unvaccinated Women without COVID-19 Illness n=22871	Vaccinated Women without COVID-19 Illness n=3379	P- value

295 Adolescent pregnancies between 2006-2019: Temporal trends, risk factors and adverse pregnancy outcomes

Michael Richley[1], Christina S. Han[2], Lauren E. Wisk[3], Tannaz Moin[3], Timothy Copeland[4], Estelle Everett[3]

[1]University of Washington, Seattle, WA, [2]David Geffen School of Medicine at UCLA, Los Angeles, CA, [3]David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, [4]Fielding School of Public Health at UCLA, Los Angeles, CA

OBJECTIVE: Adolescent pregnancies (AP) pose significant psychosocial, economic and intergenerational burdens on the health system and society. While teens tend to be healthier at baseline, adverse pregnancy outcomes (APO) are a known risk. Trends, risk factors, and rates of these APO have not been quantified in the last decade. Given the increasing restrictions in reproductive options for pregnant individuals, we sought to evaluate modern trends in AP rates and associated APO.

STUDY DESIGN: We performed a retrospective cohort study using the Kids' Inpatient Database (KID) to identify pediatric admissions (9-20 years old) with ICD-9 and -10 codes pertaining to Labor and Delivery in years 2006, 2009, 2012, 2016, 2019 in the United States. We used descriptive statistics and Pearson's correlation to measure the association between each year analyzed and APO.

RESULTS: 1,840,913 AP were reported over the study period. AP disproportionately affects the South (44.5%), urban populations (80.4%), Caucasian and Hispanic (35.6% and 27.1%, respectively), lowest quartile of median household income (41.2%), public insurance (72.4%). AP rates have decreased over time (p=< 0.001), but mortality rates remained stable (p=0.04; Figure). Increasing trends (all p=< 0.0001) were noted for obesity (from 1% to 9.3%), type 2 diabetes (from 1.4% to 1.9%), hypertensive disorders (from 8% to 15%), multiple gestations (from 0.3% to 0.8%), length of stay (from 2.54 to 2.70 days), and severity of illness. Cesarean rates decreased from 19.5% to 16.8% (p=< 0.0001) Overall rates of gestational hypertension, preeclampsia, and eclampsia are 5.8%, 6.4%, and 0.14% respectively.

CONCLUSION: Despite decreasing rates, AP continues to disproportionately affect the South and lower income individuals and yield high rates of APO. These trends highlight the need to focus on preventative health, sex education, access to contraceptive and reproductive options, and prenatal care for this high-risk teen population.

296 Large-for-gestational age with polyhydramnios on late third-trimester ultrasound is associated with cesarean delivery.

Heather Moss[1], William L. Riley[2], Christiana Coonradt[1], Alicia Mastronardi[1], Leanne Brechtel[1], Jill Maples[3], Jaclyn van Nes[4], Mithil Patel[5], Sydney Stewart[6], Samson Lopez-Schultz[6], Louis Brown[6], Landon Carroll[6], Nikki B. Zite[1], Callie Reeder[1]

[1]University of Tennessee Graduate School of Medicine, Knoxville, TN, [2]University of Tennessee Knoxville, Knoxville, TN, [3]University of Tennessee Medical Center, Knoxville, TN, [4]UTMC, Knoxville, TN, [5]University of Tennessee, Memphis, TN, [6]University of Tennessee Health Science Center, Memphis, TN

OBJECTIVE: While not routinely performed in uncomplicated pregnancies, late third-trimester ultrasounds could be useful in improving maternal health outcomes. The purpose of this study was to determine the utility of late third-trimester ultrasound findings in predicting cesarean delivery (CD).

STUDY DESIGN: This is a retrospective cross-sectional study (IRB #4869) of singleton pregnancies with large-for-gestational age (LGA, defined as >90% Estimated Fetal Weight) and/or polyhydramnios (AFI ≥25 or MVP ≥8)findings on late third-trimester ultrasound delivered at a single academic medical center from April 2020 to April 2022. Patients were grouped according to ultrasound findings: 1) LGA or polyhydramnios alone and 2) LGA with polyhydramnios. Demographics and outcome data were analyzed using Fisher's exact tests and binary regression in SPSS.

RESULTS: A total of 220 patients were noted to have LGA and/or polyhydramnios on ultrasound performed between 34 and 38-weeks gestation. A significantly higher rate of cesarean delivery (CD) was seen among those patients with LGA and polyhydramnios (62.5%) compared to those with LGA or polyhydramnios alone (41.5%) (p=0.034) (data not shown). After controlling for maternal pre-pregnancy weight status, age, diabetes in pregnancy, gestational age at delivery, and infant sex, the odds of CD among patients with late ultrasound findings of LGA with polyhydramnios was 2.241 (CI .991-5.068, p=0.052) (Table 1).

CONCLUSION: LGA with polyhydramnios is associated with CD and can be evaluated on late third-trimester ultrasound. This information could be valuable in counseling patients on mode of delivery and its potential complications. Further investigation is warranted to establish whether late third-trimester ultrasound should be standard.

297 12 versus 24 hours of postpartum magnesium sulfate for seizure prophylaxis: a cost-effective analysis

Andre Robinson[1], Olivia J. Curl[2], Uma Doshi[2], Aaron B. Caughey[2], Christina A. Penfield[3]

[1]NYU Grossman School of Medicine, New York, NY, [2]Oregon Health & Science University, Portland, OR, [3]NYU Langone Health, New York, NY

OBJECTIVE: To assess the cost-effectiveness of using 12 hours versus 24 hours of postpartum magnesium sulfate for preeclampsia with severe features to prevent eclampsia.

STUDY DESIGN: We developed a decision-analysis model to determine the cost-effectiveness of 12 versus 24 hours of postpartum magnesium sulfate to prevent eclampsia using TreeAge software. Outcomes

included maternal death, eclampsia, eclampsia within 0-12 hours postpartum, eclampsia within 12-24 hours postpartum, and magnesium toxicity in a theoretical cohort of 47,000 patients diagnosed with preeclampsia with severe features. Probability estimates for seizure, magnesium side effects, toxicity, and the cost of nursing ratios were determined from the literature. The cost-effectiveness threshold was set to $100,000/QALY.

RESULTS: 12 hours of postpartum magnesium sulfate results in 88 more instances of eclampsia in our theoretical cohort compared to 24 hours. However, 12 hours has 169 more QALYs than 24 hours and costs $15 million less than 24 hours. Overall, this is a cost-saving strategy: -$88k/QALY. NNT: 531 people with preeclampsia with severe features treated with 24 hours of postpartum magnesium sulfate to prevent 1 instance of eclampsia.

CONCLUSION: Though there are more instances of eclampsia, and 1-2 additional maternal deaths in the 12-hour group compared to the 24-hour group, the possibility of time not on magnesium sulfate, with its toxicity risk and disutility, is driving the overall relative QALY increase and cost savings of the 12-hour treatment dose. The routine use of 12 hours of postpartum magnesium sulfate should be considered for patients with preeclampsia with severe features in a shared decision-making approach.

Table 1. Outcomes associated with 12 versus 24 hours of postpartum magnesium sulfate with a theoretical cohort of 47,000.

Variable	*12 hours*	*24 hours*	*Difference*
Maternal death	17	15	2
Eclampsia	409	321	88
Eclampsia 0-12 hours	256	256	0
Eclampsia 12-24 hours	153	64	89
Magnesium toxicity	3489	4024	-535
Cost (USD)	$97,616,625	$112,564,683	-$14,948,058
Effectiveness (QALYs)	251	81	170

QALYs, quality-adjusted life-years.

298 Alternative regimens in the treatment of toxoplasmosis during 2nd & 3rd trimester pregnancies

Daniel Martingano[1], Marwah Al-Dulaimi[1], Andrea Ouyang[2], Sheida Rodriguez[1], Jessica Marshall[1], Rachel Amuzu[3], Shavana Singh[4], Alexander Ulfers[5], Jacqueline Marecheau[1], Benjamin Dribus[6], Kristin Cohen[7], Shailini Singh[8], Donald Morrish[1], Antonia F. Oladipo[9]

[1]St. John's Episcopal Hospital-South Shore, Far Rockaway, NY, [2]William Carey University College of Osteopathic Medicine, Baton Rouge, LA, [3]Rutgers Health, Jersey City Medical Center, Elizabeth, NJ, [4]Lake Erie College of Osteopathic Medicine, Far Rockaway, PA, [5]Walter Reed National Military Medical Center, Bethesda, MD, [6]William Carey University, Hattiesburg, MS, [7]RWJBarnabas Health, Trinitas Regional Medical Center, Elizabeth, NJ, [8]Hackensack Meridian Health, JFK University Medical Center, Edison, NJ, [9]Hackensack University Medical Center, Hackensack, NJ

OBJECTIVE: In high-risk and underserved communities, treatment of otherwise uncommon diseases like toxoplasmosis for pregnant patients poses a significant challenge given limited medication availability, cost, and lack of subspecialty providers. This study sought to evaluate the safety and effectiveness of alternative antibiotic regimens in the treatment of toxoplasmosis for 2nd and 3rd trimesters.

STUDY DESIGN: We conducted a multicenter, prospective observational study from 7/2021 to 7/2023 comparing all pregnant patients who were diagnosed with toxoplasmosis in the 2nd or 3rd trimester and completed treatment. Patients were divided into two treatment groups: those who received pyrimethamine/leucovorin (PL) and those who received amoxicillin/clavulanic acid plus azithromycin (ACA). The treatment method was determined by medication availability, where the first attempt was always the preferred regimen through the Centers for Disease Control and Prevention. If there were barriers to obtaining such treatments, those patients were included in the alternative group. Patients were excluded if there was insufficient treatment compliance or immunosuppressive medical conditions. Primary outcomes included the resolution of maternal symptoms by physician clinical assessment, development of fetal hydrocephalus, clearance of maternal IgM serology, and 1 and 5-minute APGAR scores less than 7, as discrete events.

RESULTS: The study included 88 patients: 52 receiving PL regimens and 36 receiving ACA regimens. Baseline demographics, method of delivery, and rates of fetal hydrocephalus were not significantly different. Rates of treatment compliance were higher in the alternative regimen group (91.7% v. 88.5%, $p = 0.002$). Rates of fetal hydrocephalus, clearance of IgM, and APGAR scores were not significantly different. No adverse medication events were noted in either group.

CONCLUSION: Amoxicillin/clavulanic acid plus azithromycin treatment regimens are safe and effective for toxoplasmosis in pregnancy, with potential added benefits for underserved populations, including decreased barriers to use and increased compliance.

299 Acute post-neuraxial hypotension in patients with hypertensive disorder is associated with fetal acidemia

Minhazur R. Sarker[1], Daniella Rogerson[2], Jenny B. Koenig[2], Lauren Ferrara[3], Angela Bianco[4], Gladys A. Ramos[5], Chelsea A. DeBolt[6]

[1]University of California San Diego, San Diego, CA, [2]UC San Diego, San Diego, CA, [3]Mount Sinai School of Medicine, New York, NY, [4]Mount Sinai Medical Center, New York, NY, [5]University of California, San Diego, San Diego, CA, [6]Mount Sinai Hospital, New York, NY

OBJECTIVE: Maternal hypotension is a common complication of neuraxial anesthesia, and maternal hypotension has been associated with fetal acidemia. We aimed to determine if pregnancies with hypertensive disorders (HDP) that experienced acute post-neuraxial hypotension were associated with fetal acidemia.

STUDY DESIGN: Retrospective cohort study of non-labor, term, singleton, non-anomalous births via cesarean delivery under neuraxial anesthesia from 2013-2019 that experienced acute post-neuraxial hypotension (systolic blood pressure < 100 mmHg recorded prior to delivery). We compared rates of adverse outcomes in pregnancies with or without HDP defined as gestational hypertension, chronic hypertension, and pre-eclampsia without severe features. Primary outcome was umbilical artery pH < 7.1. Secondary outcomes included umbilical artery pH < 7.2, umbilical cord base deficit of > 8, umbilical cord base deficit of > 12, 5-minute APGAR < 7, neonatal intensive care unit (NICU) admission, and meconium-stained amniotic fluid. Chi-square and multivariate regression tests determined the strength of association.

RESULTS: Of 2851 included subjects, 189 (6.63%) had an HDP while 2662 (93.37%) did not. Pregnancies with HDP had higher BMI, higher rates of diabetes, more often received combined spinal-epidural analgesia, and had longer procedural time from neuraxial placement to delivery (all $p < 0.01$). After adjusting for confounders including maternal BMI, type of neuraxial anesthesia, and time from neuraxial anesthesia to delivery, pregnancies complicated by HDP with acute post-neuraxial hypotension were associated with

umbilical artery pH < 7.1 (aOR 1.75; 95% CI 1.02-3.06) and umbilical cord base deficit >8 (aOR 1.76; 95% CI 1.04-2.98).

CONCLUSION: Findings suggest that among pregnancies that experience an acute post-neuraxial hypotensive episode, those complicated by HDP are associated increased odds of fetal acidemia compared to normotensive pregnancies. Further studies are needed to better determine the effect of hypotensive insult on fetal academia in pregnancies complicated by HDP.

Univariate analysis of post-neuraxial hypotension and adverse outcomes

	No HDP (n=2662)	HDP (n=189)	p-value

300 Association between fetal anomalies and rurality

Jordan Rossi[1], Bo Park[2], Ruofan Yao[3]

[1]Loma Linda University Hospital, Jurupa Valley, CA, [2]University of California, State Fullerton, Fullerton, CA, [3]Loma Linda University, Loma Linda, CA

OBJECTIVE: To determine if there is an association between fetal anomalies and rural versus urban areas.

STUDY DESIGN: Retrospective cohort analysis using data abstracted from the California Office of Statewide Health Planning and Development (OSHPD) Linked Birth File with hospital discharge International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) diagnoses between 2007 and 2012. Pregnancies in women were stratified into three community types: metropolitan, small town, and rural. The primary outcome of interest was risk of all fetal anomalies. Secondary outcomes included risk of individual anomalies including abdominal wall defects, anencephaly, neural tube defects, diaphragmatic hernia, heart defects, cleft lip and palate, limb defects, down syndrome, chromosomal defects, and other anomalies. Logistic regression analysis was performed to estimate the odds ratio of the outcome of interest for each community type while adjusting for confounding variables.

RESULTS: There were a total of 1,831,360 pregnancies. Pregnant women living in small town areas had the largest percentage of women with fetal anomalies at 0.48%. Women in metropolitan areas had the lowest percentage of women with fetal anomalies at 0.3%. Pregnancies in small town areas had increased risk of fetal anomalies with OR 1.6 (p-value < 0.001; CI 1.29-1.99). The risk of fetal anomalies in rural areas was OR 1.51 (p-value < 0.001; CI 1.14-2.00). There was a higher risk of down syndrome (OR 3.32 p-value < 0.001; CI 2.07-5.30) and cleft palate (OR 3.39, p-value < 0.001; CI 1.59-7.19) in small town areas. Rural areas had an increased risk of chromosomal anomalies (OR 3.69, p-value =0.001; CI 1.74-7.81). There was no significant association with the other individual anomalies.

CONCLUSION: There is a higher risk of overall fetal anomalies, including down syndrome and cleft palate, for pregnant women living in small town areas. Rural areas have higher risk of chromosomal anomalies.

301 Trial of labor after two-previous cesareans, can we predict a failure? A large multicenter study

Yael Zamir[1], Tzuria Peled[2], Hila Hochler[3], Ari Weiss[2], Michal Lipschuetz[3], Eran Ashwal[4], Hen Y. Sela[5], Sorina Grisaru-Granovsky[2], Misgav Rottenstreich[6]

[1]Mayanei Hayeshua Medical Center, Bnei Brak, HaMerkaz, [2]Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim, [3]Hadassah Medical Center, Jerusalem, Yerushalayim, [4]McMaster University, North York, Tel Aviv, [5]Shaare Zedek Medical Center, affiliated with the Hebrew University Hadassah School of Medicine, Jerusalem, Israel, [6]McMaster University, Hamilton, ON

OBJECTIVE: Trial of labor after cesarean (TOLAC) after two cesarean deliveries (CDs) is linked to a lower success rate of vaginal delivery and higher rates of adverse obstetrical outcomes compared to TOLAC after one previous cesarean. We aimed to investigate the factors associated with failed TOLAC among women with two previous CDs.

STUDY DESIGN: We conducted a multicenter retrospective cohort study, which included all women with singleton pregnancies 34-42 weeks attempting TOLAC after two previous CDs between the years

2003 and 2021 from four large university affiliated medical center in Israel accounted for approximately 25% of all deliveries in the country. We compared labor, maternal, and neonatal characteristics between women with failed TOLAC and those with successful TOLAC. Univariate analysis was initially performed, followed by multivariable analysis (adjusted odds ratios [aORs]; [95% CI]).

RESULTS: The study included a total of 1181 women attempting TOLAC after two previous CDs. Among these cases, vaginal birth after cesarean was achieved in 973 (82.4%). Several factors were found to be associated with failed TOLAC, including longer inter-pregnancy and inter-delivery intervals, lower gravidity and parity, lower rates of previous successful vaginal delivery, smoking, earlier gestational age at delivery, preterm delivery (34- 37 gestational weeks), lower cervical dilation on admission, non-use of epidural, and smaller neonatal birthweight. Our multivariable model revealed that preterm delivery (aOR=3.79, 95% CI 1.37-10.47) and cervical dilation on admission of labor < 3 cm (aOR=2.58, 95% CI 1.47-4.54) were associated with higher odds of failed TOLAC.

CONCLUSION: In the investigated population of women with two previous CDs undergoing TOLAC, admission at active labor at term may elevate the chances of successful TOLAC and reduce the risk of repeated cesarean delivery.

Multivariate logistic regression analysis for the association between labor and delivery characteristics and failed TOLAC (Adjusted Odds Ratio)

	p value	aOR	95%CI	
Cervical dilation on admission<3 cm	<0.01	2.58	1.47	4.54

302 Maternal and neonatal outcomes of trial of labor after cesarean in parturients with oligohydramnios

Ari Weiss[1], Tzuria Peled[1], Yael T. lerner[2], Zvi Ehrlich[1], Eran Ashwal[3], Hen Y. Sela[4], Sorina Granovsky Grisaru[1], Misgav Rottenstreich[5]

[1]Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim, [2]Israel, Givot Bar, HaDarom, [3]McMaster University, North York, Tel Aviv, [4]Shaare Zedek Medical Center, affiliated with the Hebrew University Hadassah School of Medicine, Jerusalem, Israel, [5]McMaster University, Hamilton, ON

OBJECTIVE: Oligohydramnios is considered a determinant of adverse perinatal outcomes. However, information on trial of labor after cesarean (TOLAC) for parturients with oligohydramnios is limited. This study aims to evaluate the maternal and neonatal outcomes of parturients with oligohydramnios attempting TOLAC versus those who underwent planned repeat cesarean delivery (PRCD).

STUDY DESIGN: We conducted a retrospective cohort study of women with a term singleton pregnancy and a live fetus following a single low-segment transverse cesarean delivery (CD) and a diagnosis of oligohydramnios (maximal vertical pocket < 2 cm and/or Amniotic Fluid Index < 5 cm) within 14 days from birth between 2017 and 2021. Maternal and neonatal outcomes were compared between parturients attempting TOLAC and those opting for PRCD. Univariate analysis was conducted, followed by a multivariate analysis.

RESULTS: A total of 409 eligible births were included, of which 321 (78.4%) attempted TOLAC. The successful vaginal delivery rate for women who attempted TOLAC was 85%. There were no cases of hysterectomy in either group. Uterine rupture and dehiscence of uterine scar rates did not significantly differ between those who had TOLAC vs. PRCD (0.9% vs. 0%, p=0.36 vs. 0.3% vs. 1.3%, p=0.06, respectively). However, the rate of hypoglycemia (2.5% vs. 6.8%, p=0.049) and composite adverse neonatal outcome was higher among women with PRCD (11.5% vs. 21.6%, p=0.01). Nevertheless, after controlling for potential confounders, including hypertensive disorders of pregnancy, diabetes, and SGA, no independent association between composite adverse neonatal outcome and PRCD was demonstrated (adjusted odds ratio 0.50, 95% CI 0.17-1.41, p=0.19).

CONCLUSION: TOLAC for parturients with oligohydramnios appears to be a reasonable alternative and is associated with favorable outcomes. Further large and prospective research in this area may lead to improved management strategies and better maternal and neonatal outcomes.

Baseline and labor characteristics and maternal and neonatal outcomes of the study population

303 Analyzing the utility of ecological momentary assessment in the evaluation of postpartum depression

Kay Roussos-Ross, Tony S. Wen, Deepthi Varma, Amie Goodin
University of Florida, Gainesville, FL

OBJECTIVE: Postpartum depression (PPD) affects up to 20% of women in the initial 12 months after delivery. Maternal suicide is a leading cause of maternal mortality in the United States. A smartphone-based application using ecological momentary assessment

(EMA) technology was developed for monitoring and intervention of PPD during the initial 6 weeks after delivery. This innovative method allows for frequent evaluations and interventions when positive findings are noted.

STUDY DESIGN: All postpartum English-speaking women, aged 18 and above, owning a smartphone, agreeing to download the app, and who delivered a liveborn neonate at a quaternary care academic hospital were offered participation in this prospective study. Enrollment occurred between November 2021 and June 2023. Participants received notifications to complete mood evaluations via marking "happy" or "sad" faces and by completing the Edinburgh Postpartum Depression Scale (EPDS) in the app. Following discharge, notifications were sent at least 3 times weekly in weeks 1 and 2, and once per week from weeks 3 to 6. When EPDS scores were ≥12, follow-up contact via phone was made where action was taken based on nurse assessment.

RESULTS: A total of 1430 participants were enrolled, resulting in 3,552 assessments via the app. 232 participants reported feeling "sad" (16.2% of enrolled), and 189 were noted to have an EPDS score ≥12, which was considered positive and alerted the study team (13.2% of those enrolled). The outcomes of the alerts resulted in: 220 completed follow up contacts from a study nurse, 50 clinic referrals, 1 hospitalization, and 2 referrals to Labor & Delivery. Nearly a quarter (24.1%, or 53/220) of follow-up contacts from app positive screens resulted in clinical intervention.

CONCLUSION: The ability to monitor postpartum women continually and intervene in real-time allows for more rapid identification and management of PPD. This intervention may decrease undiagnosed PPD and lessen the mental health burden of new mothers. More studies are required to determine if this application is effective in decreasing maternal morbidity.

304 Examining the impact of antenatal small for gestational age prediction on pregnancy outcomes

Erika Ilatov[1], Alla Saban[2], Rachel Rappaport[3], Efrat Spiegel[4], Reli Hershkovitz[5], Adi Y. Weintraub[6], Tamar Eshkoli[2]

[1]Soroka Hospital, HaDarom, [2]Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Beer Sheva, HaDarom, Israel, [3]Soroka Hospital, Beer Sheva, HaDarom, [4]Soroka University Medical Center, Omer, HaDarom, [5]Soroka Medical Center, Omer, HaDarom, [6]Soroka Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: Fetal growth restriction (FGR) affects 5%-10% of pregnancies and raises the risk of maternal and neonatal mortality and morbidity. Given the difficulty of accurate fetal weight assessment in FGR, we aim to assess its impact on these outcomes.

STUDY DESIGN: A retrospective study performed on June 2020 to January 2022 at a large tertiary hospital, focusing on term singleton deliveries with small gestational age (SGA) birthweights. We compared delivery traits and outcomes between women with sonographically estimated fetal growth restriction (FGR) and those mistakenly assessed as appropriate-for-gestational-age (AGA). Definitions for SGA and FGR were birthweight under 2500 gr and estimated fetal weight in the < 10th percentile,respectively, using the Israeli population's standard growth curve referred to as a Dolberg curve. Logistic regression models were used for confounder adjustment.

RESULTS: During the study, 1,173 SGA birthweight deliveries were recorded, with 674 and 499 suspected as being appropriate and restricted growth, respectively. Patients with suspected FGR showed higher frequencies of cesarean deliveries, labor induction, maternal stays over 4 days, and more adverse maternal outcomes. Similarly, neonatal outcomes were worse in suspected FGR cases, with longer stays, higher perinatal mortality, and hypoglycemia. After multivariate analysis, only extended neonatal stay remained significant. Predicting SGA resulted in increased neonatal stays over 4 days, with an adjusted OR=1.41 (CI=1.07-1.87, p-value=0.016).

CONCLUSION: Prediction of SGA before birth was found as associated with neonatal length of stay exceeding 4 days. This unfortunate outcome seems to correlate with an increased frequency of interventions. The complexities surrounding this issue necessitate further research to enhance our understanding and improve clinical approaches.

Table: Results of a multivariable logistic regression analyses

Outcome variable analyzed	Adjusted OR* (95% CI)	P
CD	1.25 (0.90-1.73)	0.179
Maternal length of stay > 4 days	1.26 (0.94-1.67)	0.119
Composite of adverse maternal outcomes[a]	1.11 (0.82-1.49)	0.506
Perinatal mortality	2.85 (0.86-9.50)	0.088
Hypoglycemia	1.95 (0.75-5.12)	0.173
Neonatal length of stay > 4 days	1.41 (1.07-1.87)	0.016
Composite of adverse neonatal outcomes[b]	1.22 (0.94-1.58)	0.142

OR odds ratio, CI confidence interval, P P-value, CD cesarean delivery
*aOR adjusted OR. Models were adjusted for parity, gestational age and oligohydramnios. All variables, excluding CD, were also adjusted for CD performance.
[a]Defined as composite of emergent surgery, hemorrhagic complications, peripartum infections and wound complications and maternal length of stay > 4 days. [b]Defined as composite of 1 & 5 APGAR scores ≤7, PH <7, phototherapy, NICU admission, neonatal length of stay > 4 days, perinatal mortality, asphyxia, hypothermia, hypoglycemia, polycythemia, hypocalcemia, Hyperbilirubinemia, HIE, RDS, NEC, sepsis, IVH, meconium aspiration syndrome and pulmonary hypertension.

305 A multi-organ fetal membrane-placenta-on-chip platform to study the transmission of infection and inflammation during pregnancy

Melody Safarzadeh[1], Lauren Richardson[1], Ananth Kumar Kammala[1], Enkhtuya Radnaa[2], Sungjin Kim[3], Po Yi Lam[3], Arum Han[3], RamKumar Menon[4]

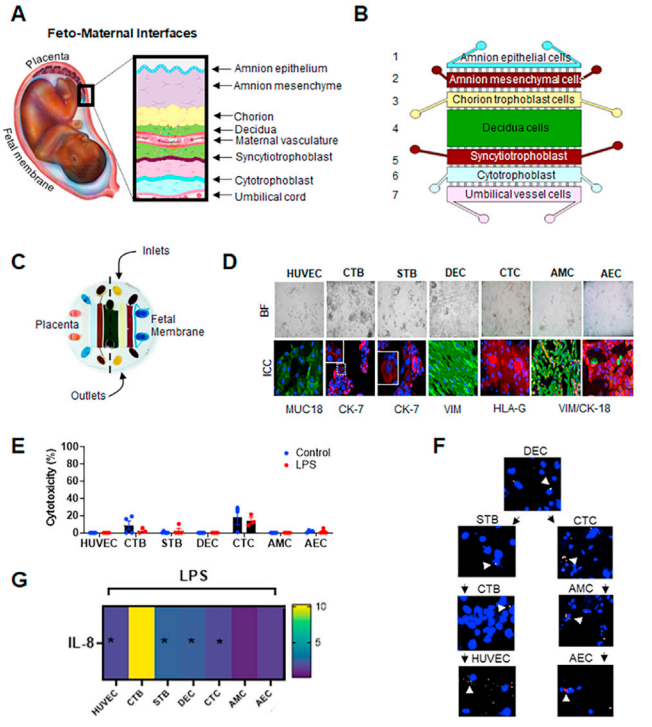
[1]University of Texas Medical Branch, Galveston, TX, [2]University of Texas Medical Branch at Galveston, Galveston, TX, [3]Texas A&M University, College Station, TX, [4]University of Texas Medical Branch, League City, TX

OBJECTIVE: Infection and inflammation are risk factors for spontaneous preterm birth. However, the spread of infection and inflammatory mediators at the two feto-maternal interfaces (FMi; placenta and fetal membranes with decidua [Fig 1A]) are difficult to study due to the limitations of animal models and the lack of comprehensive *in-vitro* models. We developed a humanized multi-organ fetal membrane-placenta organ-on-chip (FMi-PLA-OOC) (**Fig 1B-C**), established physiologic and pathologic models of the FMi, and determined the responses of FMis to infection and inflammation.

STUDY DESIGN: FMi-PLA-OOC contained cells from human umbilical cord endothelium, cyto- and syncytiotrophoblasts, decidua, chorion, and amnion (mesenchyme and epithelium) in seven cell chambers connected by arrays of collagen-filled microchannels.To validate FMi-PLA-OOC, we determined cell viability (cytotoxicity - lactate dehydrogenase [LDH] assay) and confirmed that *in utero* cellular characteristics (immunocytochemistry [ICC]) were maintained during culture on-chip. We also determined lipopolysaccharide (LPS; 100ng/mL) propagation (immunostaining) and inflammation (multiplex cytokine assay).

RESULTS: Cell markers and viability in the FMi-PLA-OOC were similar to *in-utero* FMi, validating the physiological relevance of the device (Fig 1D-E). LPS propagated from maternal to fetal cells within 6 days(Fig 1F), inducing an increase in pro-inflammatory cytokine concentrations (IL-6, IL-8, TNF-a) and a decrease in anti-inflammatory cytokine production (IL-10) across the fetal membrane and placenta layers(Fig 1G; [Heat map is normalized to control. *- p< 0.05]).

CONCLUSION: Healthy and disease models of FMis on a chip demonstrated differential responses of the placental and fetal membrane to infection and inflammation. This platform provides broad utility in obstetrics research.



306 A multi-organ-on-chip model to study the efficacy of exosomal therapeutics in treating inflammation-associated adverse pregnancies

Melody Safarzadeh[1], Lauren Richardson[1], Ananth Kumar Kammala[1], Angela Mosebarger[1], Mohamed Bettayeb[2], Enkhtuya Radnaa[3], Sungjin Kim[4], Po Yi Lam[4], Arum Han[4], RamKumar Menon[5]

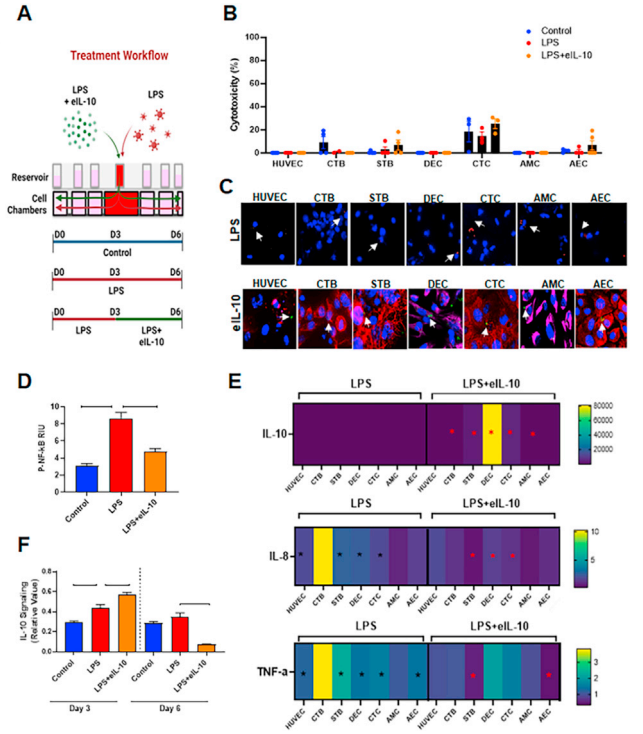
[1]University of Texas Medical Branch, Galveston, TX, [2]University of Texas - Medical Branch, Galveston, TX, [3]University of Texas Medical Branch at Galveston, Galveston, TX, [4]Texas A&M University, College Station, TX, [5]University of Texas Medical Branch, League City, TX

OBJECTIVE: Infection and inflammation are two major risk factors for preterm birth. There is a lack of physiologically-relevant human models of the two feto-maternal interfaces (FMi; placenta and fetal membranes with decidua) to test anti-inflammatory drug efficacy and functions in an *in vitro* setting. We used a fetal membrane-placenta organ-on-chip (FMi-PLA-OOC) to mimic infectious inflammation of the FMiand conduct pre-clinical drug testing (cytotoxicity, mechanism of action, and efficacy) using a novel anti-inflammatory compound, exosomal-derived interleukin-10 (eIL-10), engineered to facilitate drug passage across FMi barriers.

STUDY DESIGN: FMi-PLA-OOC contained cells from human umbilical cord endothelium, cyto- and syncytiotrophoblasts, decidua, chorion, and amnion (mesenchyme and epithelium) in seven cell chambers connected through collagen-filled microchannels.The decidual cells were treated with lipopolysaccharide (LPS; 100ng/mL) followed by a co-treatment of LPS and eIL-10 (500ng/mL) (Fig 1A).LPS and eIL-10 propagation and P-NF-kB expression were determined by immunostaining, functional IL-10 signaling (Quant blue assay), and inflammation (multiplex cytokine assay).

RESULTS: Maternal-to-fetal propagationof LPS occurred within 6 days without inducing cytotoxicity of cells in the FMi-PLA-OOC (Fig 1B-C). LPS induced P-NF-kB expression (Fig 1D) and induced pro-inflammatory cytokines (IL-6, IL-8, TNF-a) across the fetal membrane and placenta layers (Fig 1E; [black *-p< 0.05 normalized to control]). eIL-10 did not induce cytotoxicity (Fig 1B) within the maternal or fetal cells and propagated to distal chambers within 3 days (Fig 1C). LPS+eIL-10 co-treatment induced IL-10 signaling pathways (Fig 1F), reduced P-NF-kB expression (Fig 1D), and suppressed LPS-induced pro-inflammatory cytokine production in the fetal membranes and placenta (red *-p< 0.05 normalized to LPS) (Fig 1E).

CONCLUSION: Using thismodel, we successfully tested the ability of eIL-10 to suppress LPS-induced inflammation at the FMi. FMi-PLA-OOC is an alternative to animal models for preclinical testing of drugs during pregnancy.



307 Absence of SARS-CoV-2 in second trimester amniotic fluid during SARS-CoV-2 virus pandemic: a prospective study

Ying Chan[1], Poonam Samyal[1], Luis A. Bracero[2], Andrew S. Quinn[3], Huifang Xiao[4], jonathan Williams[5]

[1]Comprehensive Perinatal Medicine PLLC, Flushing, NY, [2]South Shore University Hospital, Bay Shore, NY, [3]Northwell, Forest Hills, NY, [4]Huifeng Xiao MD PC, Flushing, NY, [5]Labcorp, Burlington, NC

OBJECTIVE: To determine the presence or absence of severe acute respiratory syndrome-coronavirus-2 (SARS-CoV-2) in second trimester amniotic fluid during the 2020-2022 SARS-CoV-2 virus pandemic in patients undergoing genetic amniocentesis.

STUDY DESIGN: Women undergoing genetic amniocentesis between September 2020 and April 2022 were asked to participate in the study. On the day of amniocentesis, an additional 5 mL of amniotic fluid, 5 mL of a maternal blood sample, and nasal swabs were collected from each participant. After July 2021, vaccination status was obtained. Amniotic fluid was tested for the presence of the virus by RT-PCR test using an automated bead-based method for extracting total nucleic acid. An electrochemiluminescence immunoassay on maternal blood was used to detect SARS-CoV-2 total (IgG/IgM) antibodies against nucleocapsids. A positive result indicates an immune response to a recent or prior infection with SARS-CoV-2. A molecular PCR, nucleic acid amplification test was also used to detect SARS-CoV-2 antigen using maternal nasal swabs.

RESULTS: The present study enrolled 92 patients. There were 16 patients who had a history of SARS-CoV-2 virus infection: eight of them contracted SARS-CoV-2 virus infection during the first and second trimester, and eight had SARS-CoV-2 virus infection before pregnancy. Forty-nine patients were vaccinated prior to amniocentesis. All 92 amniotic fluid samples tested negative for the SARS-CoV-2 virus. There were 5 positive and 3 negative SARSC-CoV-2 maternal nucleocapsid antibody tests among the eight patients who had SARS-CoV-2 during the 1st and 2nd trimester of pregnancy. All 8 patients had negative swab tests for the SARS-CoV-2 virus antigen.

CONCLUSION: In the eight patients who had SARS-CoV-2 virus infection during the first and second trimester there was no SARS-CoV-2 virus in the second trimester amniotic fluid samples. This finding suggests that after a first and second trimester SARS-CoV-2 virus infection, it is highly unlikely to find the SARS-CoV-2 virus in the amniotic fluid.

Clinical characteristics and outcomes of eight patients who had SARS-CoV-2 in the 1st and 2nd trimester:

Case #	GA at the time of SARS-CoV-2	GA at Delivery	Birth Weight	Amnio Results	Nasal Swabs Results	SARS-CoV-2 total (IgG/IgM) Antibodies

308 Investigating gaps filled by perinatal patient navigation to address social determinants of health in pregnancy

Kirat Sandhu[1], Cara D. Dolin[2], Adina R. Kern Goldberger[3]
[1]Cleveland Clinic Foundation, Cleveland, OH, [2]Cleveland Clinic, Pepper Pike, OH, [3]Cleveland Clinic Lerner College of Medicine, Cleveland, OH

OBJECTIVE: Social determinants of health (SDoH) contribute to disparities in maternal and neonatal morbidity and mortality. Community-based patient navigators (PN) may be an important intervention to provide comprehensive health and social services for vulnerable pregnant patients. This study describes the patients referred to a novel perinatal PN program based in a high social vulnerability index county and the patient-driven SDoH needs targeted during its initial instigation.

STUDY DESIGN: This is a descriptive cohort study of patients referred to a novel PN program from 1/2023-4/2023 based on a structured SDoH assessment during the initial prenatal visit. Data regarding patient demographics, referral criteria, resources provided, and PN-reported barriers to intervention were assessed descriptively through EMR review and the PN program records.

RESULTS: 227 patients were referred to the perinatal PN program (3170 total deliveries; 7.2%). The median maternal age was 25, and the median gestational age at referral was 18 weeks. 61% of patients had Medicaid insurance, 63% were Black, and 7.4 % were Hispanic. A description of referral criteria and resources provided is in the Table. The majority of patients were referred for food insecurity (15 %) and the top 3 needs identified were food (44%), doula support (17.1%), and mental health (11.8%). The primary barriers identified were inability to reach the patient via phone (15%) and patients who did not speak English as a primary language (5.7%).

CONCLUSION: Understanding the types of social service needs during pregnancy, and the barriers in connecting patients to these services, allows this and similar programs to effectively target gaps in comprehensive support for socially vulnerable pregnant patients. Optimization of resources to meet the actual needs of patients facing modifiable social barriers may improve perinatal outcomes and decrease disparities.

Table. Referral Criteria and Additional Needs Addressed by Perinatal Patient Navigator Program

	Referral criterion N (%)	Need Identified by Patient Navigator N (%)
Desire for Centering prenatal care*	2 (.08%)	6 (2.6 %)
WIC**	34 (14.9%)	75 (33.0%)
SNAP***	3 (1.3%)	25 (11.0%)
Doula services	20 (8.8%)	39 (17.1%)
Mental health services	4 (1.7%)	27 (11.8%)
Insurance challenges	14 (6.2%)	6 (2.6%)
Domestic violence	8 (3.5%)	3 (1.3%)
Transportation difficulties	12 (5.2%)	10 (4.4%)

*Centering is a form of community-based, holistic, group prenatal care
**WIC (Women, Infants, and Children) is a federal social support program that provides supplemental food, health care referrals, and nutrition education during pregnancy/postpartum and for children up to age 5 ***SNAP (Supplemental Nutrition Assistance Program) is a federal food assistance program (food stamps)

309 Aspirin decreases triglycerides in the development of preeclampsia

Kelsey Blocklinger[1], Tarynne E. Kinghorn[1], Kaylee Weaver[2], Ashlyn S. Mulcahey[2], Wendy S. Hamilton[2], Sydney Pearl[2], Meghan L. Funk[2], Dane D. Sweezer[2], Alexis J. Faudel[2], Sophia T. Schnoebelen[2], Amy K. Stroud[2], Stephen K. Hunter[3], Gary L. Pierce[2], Heath A. Davis[2], Boyd Knosp[1], Debra S. Brandt[4], Mark K. Santillan[2], Donna A. Santillan[2]
[1]University of Iowa Carver College of Medicine, Iowa City, IA, [2]University of Iowa, Iowa City, IA, [3]University of Iowa Hospitals and Clinics, Iowa City, IA, [4]New York University, New York, NY

OBJECTIVE: Preeclampsia is associated with higher triglyceride and copeptin levels. Low-dose aspirin (ASA, 81 mg) is routinely prescribed in pregnancy to prevent the development of preeclampsia. However, the mechanism of this remains poorly understood. The objective of this study was to determine if ASA is effective in lowering triglyceride (TG) and copeptin levels in association with preeclampsia.

STUDY DESIGN: In this retrospective case control study, subjects were selected from the Perinatal Family Tissue Bank (IRB#200910784) based on ASA use and preeclampsia diagnosis. Demographics were collected from the electronic health record using the Intergenerational Health Knowledgebase. TG and copeptin were measured using commercial assays. T test, chi square tests, and ANOVA were performed as appropriate. Alpha was set at 0.05.

RESULTS: Preeclampsia pregnancies were associated with a higher rate of ASA use in comparison to controls (47% vs. 25%, $p< 0.001$). Maternal age, race/ethnicity, BMI, and gravida were similar between groups. The combined interaction of ASA use and preeclampsia was significant ($p< 0.05$) demonstrating a larger decrease in mean TG between the first and 3rd trimester with ASA treatment in those with preeclampsia (105.2 ± 25.1 vs 11.1 ± 43.4 mg/dL) vs. controls (71.8 ± 8.4 vs. 88.0 ±26.6 mg/dL). This interaction was not observed in the difference in copeptin levels ($p=0.311$).

CONCLUSION: These data suggest that aspirin may decrease triglycerides in pregnancy in patients who develop preeclampsia. Exploring this mechanism further may lead to a more efficacious preventative for preeclampsia.

310 Risk of hypertension progression after pregnancies complicated by American Heart Association (AHA) stage 1 hypertension

Ayodeji Sanusi[1], Yumo Xue[2], Victoria C. Jauk[2], Ashley N. Battarbee[3], Akila Subramaniam[2], Jeff M. Szychowski[3], Brian M. Casey[3], Alan T. Tita[3], Rachel Sinkey[4]

[1]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham, AL, [4]University of South Florida, Tampa, FL

OBJECTIVE: Data on long-term cardiovascular risks of AHA stage 1 chronic hypertension (CHTN) in pregnancy are limited. We quantified the risk of progression to ≥ stage 2 CHTN among patients with stage 1 CHTN in pregnancy.

STUDY DESIGN: Retrospective cohort study of singleton deliveries at a single US center from 2010- 2022 with at least 2 follow up blood pressures (BP) >12 weeks' postpartum (PP). Stage 2 CHTN (BP≥140/90mmHg) or anti-HTN medication at index pregnancy were excluded. The primary outcome was progression to stage 2 or higher CHTN (BP ≥140/90mmHg, ≥2 occasions, 4 hours apart) at >12weeks PP or at < 20 weeks' gestation in a subsequent pregnancy within 5 years. Secondary outcomes included severe CHTN (BP ≥160/110mmHg). Multivariable logistic regression estimated the yearly cumulative odds of outcomes in patients with stage 1 CHTN compared to normal BP, and identified risk factors for progression.

RESULTS: Of 6,184 included patients, 3,871 (62.6%) had normal BPs and 2,313 (37.4%) had stage 1 CHTN during the index pregnancy. Patients with stage 1 CHTN were older, more likely to be White, privately insured, nulliparous, obese, initiate prenatal care earlier and have medical comorbidities. Over 5 years, 622 (26.9%, 95% CI 25.1-28.8%) with stage 1 CHTN had the primary outcome, compared to 502 (13.0%, 95% CI 11.9-14.1%) with normal BP($p< 0.01$). Median time to ≥ stage 2 CHTN was shorter in patients with stage 1 CHTN, compared to normal BP (1.7 vs. 1.9yrs, $p=0.03$). In each successive year after pregnancy, patients with stage 1 CHTN had approximately 2-fold higher adjusted odds of developing ≥ stage 2 CHTN, compared to normal BP(Table). In contrast, the odds of severe CHTN with stage 1 CHTN only increased after 3 years. Black race (OR 1.88, 95% CI 1.52-2.33), obesity (OR 1.88, 95% CI 1.48-2.40), tobacco use (OR 1.56, 95% CI 1.15-2.12) and prior preeclampsia (OR 1.88, 95% CI 1.38- 2.56) were also risk factors for progression.

CONCLUSION: Pregnant patients with stage 1 CHTN have a significant risk of progression to ≥ stage 2 CHTN as early as the first year postpartum.

Table: Cumulative Prevalence and Adjusted Odds Ratios of ≥ Stage 2 Chronic Hypertension among Patients with American Heart Association Stage 1 Chronic Hypertension and Normal BPs in Pregnancy

	Normal BP (n=3871)	Stage 1 CHTN (n=2313)	Unadjusted Odds Ratio (95% CI)	Adjusted Odds Ratio (95% CI)
Stage 2 or greater CHTN				
≤1 year	153 (4.0)	206 (8.9)	2.38 (1.92-2.95)	1.89 (1.48-2.42)
≤2 years	258 (6.7)	363 (15.7)	2.61 (2.20-3.09)	2.08 (1.72-2.51)
≤3 years	362 (9.4)	485 (21.0)	2.57 (2.22-2.98)	2.08 (1.76-2.46)
≤4 years	445 (11.5)	570 (24.6)	2.52 (2.20-2.89)	2.05 (1.75-2.39)
≤5 years	502 (13.0)	622 (26.9)	2.47 (2.17-2.82)	2.03 (1.75-2.37)
Severe CHTN				
≤1 year	16 (0.4)	22 (1.0)	2.31 (1.21-4.41)	1.73 (0.84-3.56)

≤3 years	41 (1.1)	53 (2.3)	2.19 (1.45-3.30)	1.43 (0.90-2.28)
≤4 years	51 (1.3)	69 (3.0)	2.30 (1.60-3.32)	1.54 (1.02-2.32)
≤5 years	59 (1.5)	82 (3.6)	2.38 (1.69-3.33)	1.54 (1.05-2.25)

Data are N (percentage) or Odds Ratio (95% Confidence Intervals) as appropriate
Models adjusted for age, nulliparous, BMI category, insurance, race, first encounter GA, preeclampsia, aspirin and baseline blood pressure at index (first captured) pregnancy

311 Biomarkers of poor volume handling predict preeclampsia in a symptomatic population

Zoe Sayler[1], Brandon Schickling[1], Erica Testani[1], Heath A. Davis[1], Boyd Knosp[2], Donna A. Santillan[1], Mark K. Santillan[1]

[1]University of Iowa, Iowa City, IA, [2]University of Iowa Carver College of Medicine, Iowa City, IA

OBJECTIVE: Copeptin, a marker of vasopressin secretion and fluid volume handling, is robustly predictive of the development of preeclampsia (PreE) in all three trimesters. Other markers of poor volume handling such as Brain Natriuretic Peptide (BNP) and Atrial Natriuretic Peptide (ANP) may also predict PreE. This translational, prospective cohort study aimed to evaluate these markers in a symptomatic population. We hypothesize that BNP, ANP, and Copeptin will be associated with those diagnosed with PreE.

STUDY DESIGN: In this Rule Out PreEclampsia (ROPE) Study (IRB# 201611746), birthing parents who presented for evaluation of PreE in the 3rd trimester due to signs or symptoms at a university medical center provided access to clinical information and plasma samples. Copeptin and ANP were measured using Time Resolved Amplified Cryptate Emission (TRACE) using a Kryptor Clinical Analyzer (ThermoFisher) and BNP was measured by commercial Enzyme-linked immunosorbent assays (ELISA). T tests, chi square, and logistic regression analyses were performed with a=0.05.

RESULTS: A total of 55 control and 104 PreE participants were recruited. Maternal age, race, body mass index, gravida, para, rate of chronic hypertension and diabetes were similar between the 2 groups. Copeptin (14.3 ± 2.9 vs. 7.3 ± 0.7, p=0.02), BNP (362.2 ± 52.1 vs. 182.0 ± 52.1, p=0.03), and ANP (93.8 ± 6.4 vs. 62.4 ± 8.8, p=0.005) values were all significantly higher in those diagnosed with PreE. After controlling for chronic hypertension and diabetes diagnoses, Copeptin (p=0.05), BNP (p=0.04), and ANP (p=0.009) remained significantly associated with the development of PreE. In addition, BNP values (r^2=0.7, p=0.04) was significantly, positively correlated with Copeptin levels.

CONCLUSION: These data suggest that Copeptin, BNP, and ANP may be adjunct diagnostic tools for PreE in a symptomatic population. In addition, the poor fluid handling these analytes indicate in the 3rd trimester provides further evidence that fluid imbalance may provide a molecular mechanism for the later stages of the disease.

312 Assessing immediate-acting antihypertensive therapy on severely elevated peripartum blood pressures through balancing measures

Patrick Schneider[1], Anna Muraveva[2], Michelle Menegay[2], Hallie Kerr[3], Justin R. Lappen[4]

[1]The Ohio State University, Columbus, OH, [2]Government Resources Center for the Ohio Colleges of Medicine, Columbus, OH, [3]Ohio Department of Health, Columbus, OH, [4]Cleveland Clinic Foundation, Cleveland, OH

OBJECTIVE: The timely treatment of severely elevated peripartum blood pressures (BP) within 60 minutes of identification is advocated as a strategy to decrease severe morbidity and mortality from hypertensive disorders of pregnancy. However, concerns about too rapidly decreasing BP results in delays in care as providers do not want to potentially induce hypotension or changes in the fetal status.

STUDY DESIGN: As part of a state-wide quality improvement initiative, 29 hospitals submitted data on an initial severely elevated BP episode, defined as a systolic BP (SBP) ≥160 or diastolic BP (DBP) ≥110 occurring sequentially and 15 minutes apart, and subsequent management of the episode. BPs following treatment were collected to assess the response to immediate-acting antihypertensive therapy with the next three BPs collected at 15-minute intervals. The primary measure was fetal heart rate (FHR) changes within 1 hour of the initial severely elevated BP (among pregnant patients) with secondary measure assessing whether hypotension (SBP < 90 or DBP < 60) occurred among pregnant or postpartum patients.

RESULTS: Overall, 3,230 pregnant or postpartum patients were treated for a severe hypertensive event. Mean initial SBP was 170.9mmHg and mean initial DBP was 96.1mmHg. Following BP treatment and normalization, the mean SBP and DBP decreased to 145.1 and 83.1, respectively. A small proportion of patients (13.8%) had mean arterial pressure (MAP) decrease of ≥30% following treatment. Among 2,396 pregnant patients, those with a MAP decrease of ≥30% (compared to those with MAP decrease of < 30%) were more likely to require intervention for FHR changes (8.5% vs. 4.3%, p=.001). Patients with MAP decrease of ≥30% had higher rates of hypotension compared to those with MAP decrease of < 30% (42.3% vs. 1.6%), p< .001).

CONCLUSION: MAP decreases of ≥30% were associated with FHR changes requiring intervention and hypotension. These findings suggest that strategies towards effective BP control should be cognizant of how rapidly and profoundly BP is decreased to avoid potential harm.

[i] Patients that were pregnant or up to 6 weeks postpartum during their severe hypertensive event (n=3,230)

[ii] Limited to patients that were pregnant during their severe hypertensive event (n=2,396)

[iii] Defined as systolic blood pressure after normalization less than 90mmHg or diastolic blood pressure after normalization less than 60mmHg

313 Is there an association between lateral placenta and pregnancy adverse outcomes?

Hanoch Schreiber[1], Gal Cohen[1], Sivan Farladansky Gershnabel[2], Lior Heresco[3], or Eliner[2], Michal Kovo[4], Tal Biron-Shental[5], Ofer Markovitch[6]

[1]Meir Medical Centerartment of Obstetrics and Gynecology, Meir Medical Center, Kfar Saba, Israel, [2]Meir Medical Center, Kfar Saba, HaMerkaz, [3]Meir Medical Center, Tel Aviv, HaMerkaz, [4]Meir Medical Center, Macabim, HaMerkaz, [5]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz, [6]Meir Medical Center, Kfar Saba, Tel Aviv

OBJECTIVE: Compared to the anterior or posterior uterine walls, the lateral uterine walls may differ in their anatomical curve and blood supply, potentially affecting implantation and pregnancy outcome. The effect of lateral placentation on pregnancy outcomes is controversial, with several studies suggesting an association with small for gestational age (SGA), hypertensive (HTN) disorders, and preterm deliveries. Data regarding its impact on maternal bleeding and residual placenta are scarce. We aimed to evaluate the association between lateral placentation and adverse obstetrics outcomes.

STUDY DESIGN: This retrospective study included all women with singleton pregnancies, who underwent a trial of labor. All patients had a sonographic assessment of the placental location. The study cohort was divided into two groups: those with uterine lateral placentation (lateral placenta group) and those with all other possible placentation types including anterior, posterior, or fundal placentation (control group). Maternal, obstetrics, and neonatal outcomes were compared between the groups. A power analysis determined that a total of 882 women in each group would be sufficient to detect a significant increase in the rate of the primary outcomes, including preterm delivery, HTN disorders, or SGA in the lateral placenta group.

RESULTS: Overall 23,808 women met the inclusion criteria, with 1817 (7.6%) in the lateral placenta group and 21,991 (92.4%) in the control group. No significant differences were found between the groups regarding the rate of HTN disorders, SGA, or preterm delivery. The lateral placenta group had a higher rate of retained placenta (5.7% vs. 4.2%, p=0.002), however, using multivariate regression analysis adjusted for maternal age, nulliparity, second and third stage duration, there was no difference in the rate of retained placenta between the groups.

CONCLUSION: Contrary to previous studies, the lateral location of the placenta is not associated with any clinically significant adverse maternal, obstetric, or neonatal outcome.

314 Pilot study to assess non-adherence to daily low dose aspirin in patients with pregestational diabetes

Hayley J. Schultz[1], Marni B. Jacobs[1], Elizabeth Spooner[1], Gladys A. Ramos[2]
[1]University of California, San Diego, La Jolla, CA, [2]University of California, San Diego, San Diego, CA

OBJECTIVE: Daily low-dose 81mg aspirin (LDASA) is recommended for those with pregestational diabetes to reduce risk for hypertensive disorders of pregnancy (HDP). High adherence to daily dosing is necessary to achieve prophylactic benefit. We investigated the non-adherence rate of daily LDASA in gravidas with pregestational diabetes at 28 and 36 weeks gestational age (GA) to determine if an intervention is needed to improve adherence.

STUDY DESIGN: This was a prospective cohort study performed between 1/2022 and 7/2023 of gravidas with type 1 (T1DM) or 2 diabetes (T2DM) enrolled at 12-24 weeks GA. Participants were recommended LDASA per standard of care. Adherence was surveyed using the validated simplified medication adherence questionnaire (SMAQ) at 28 and 36 weeks. Non-adherence was defined as responding "yes" to any survey question or reporting more than two missed doses in the past week or past three months. Demographic and pregnancy data were collected. Univariate analysis was performed utilizing Stata.

RESULTS: Seventy-one participants were enrolled in the study, with a mean age of 31.2±5.0 years and mean GA 15.7±3.96 weeks. The majority had T2DM (77.5% (55/71)) and 22.5% (16/71) had T1DM. Most of the cohort (69% (49/71)) identified as Latinx and 82.6% (57/71) spoke English as a primary language. Of the 58 participants who completed the SMAQ either at 28 or 36 weeks, 40 (69.0%) demonstrated non-adherence to daily low dose aspirin at one or both time points (62.3% at 28 weeks and 69.0% at 36 weeks). This was significantly greater than the expected literature rate of 45% (p=0.0002). Non-adherence did not differ by diabetes type, insulin use or any other demographic factor. The rate of HDP in the delivered participants in this cohort was 48.9% and did not differ by LDASA adherence.

CONCLUSION: In this population of gravidas with diabetes at high risk of HDP who were recommended LDASA, 69% were non-adherent by self-report through SMAQ, which is far higher than expected. A strong intervention is needed to improve adherence to optimize HDP risk reduction in this population.

315 Activity in women at risk for early delivery: A prospective observational study

Anthony C. Sciscione
Delaware Center for Maternal & Fetal Medicine of Christiana Care, Inc., Newark, DE

OBJECTIVE: Activity restriction is commonly employed in pregnancy without evidence that it prolongs pregnancy or improves outcomes. We sought to evaluate whether physical activity in patients at high risk for preterm birth was associated with pregnancy prolongation.

STUDY DESIGN: An ancillary study of preterm birth prevention in patients with a short cervical length. Participants were enrolled from 16.0 to 25.6 weeks and were instructed to wear a wrist accelerometer (Fitbit Flex 2) until delivery. Physical activity data (steps per day) were reviewed weekly by research nurses along with a monthly interview. Sedentary activity is commonly defined as $< 3{,}500$ or $< 5{,}000$ steps per day (SPD). We compared outcomes between < 3500 median SPD vs ≥ 3500 median SPD; and < 5000 median SPD vs. ≥ 5000 median SPD. The primary outcome was time from enrollment to delivery.

RESULTS: Overall 120 patients were enrolled and 117 (97.5%) had accelerometer data. Median gestational age at entry was 22.5 weeks (IQR 21.3, 23.7). At enrollment, a quarter of patients (25.8%) were placed on activity restriction (AR) by their provider. Median cervical length at baseline did not differ by SPD. Time from enrollment to delivery did not differ by SPD group. However, participants with $<$ 3500 median SPD delivered earlier and were more likely to deliver at $<$ 34 weeks vs. $\geq$ 3500 median SPD (Table). Of 104 patients with accelerometer and study visit data, 39 (37.5 %) were ultimately placed on AR. Of patients prescribed AR, 51.3% reported modifying their work schedule vs. 27.7% who were not prescribed on AR.

CONCLUSION: Among individuals with a short cervix in the second trimester, physical activity level was not associated with time to

delivery. However, the risk of preterm delivery at < 34 weeks was significantly higher with less activity (< 3500 steps per day). Patients are still being placed on AR and even when not placed on AR patients are still modifying their work schedules.

316 Spatial placental PSG4 gene expression profiling in spontaneous preterm labor

Karl E. Seif[1], Mary Mangione[1], Jun Lei[1], Ashley Cellini[1], Sifa Turan[1], Peixin Yang[1], Irina Burd[2], BingBing Wang[1]
[1]University of Maryland Medical Center, Baltimore, MD, [2]University of Maryland, Baltimore, MD

OBJECTIVE: A better understanding of the biology of spontaneous preterm labor (SPTL) could help elucidate new treatments. Accelerated placental senescence (PS) is known to cause certain obstetrical complications, but studies have not clearly demonstrated a relationship between accelerated PS and SPTL. Recently, Pregnancy Specific Beta-1-Glycoprotein 4 (PSG4) has been found to be a potent molecular driver for PS. Our hypothesis is that PSG4 is overexpressed in chorionic villi of SPTL placenta samples compared to those at full term (FT) and may represent one of the key players of SPTL.

STUDY DESIGN: Post-partum placental samples were collected from 18 to 45 year old patients who delivered at a single medical center between 2021 and 2022. Exclusion criteria included multiple gestations, fetal structural anomalies and aneuploidies, and presence of maternal hypertension or diabetes, infectious diseases including COVID-19, and autoimmune diseases. PSG4 RNA in-situ hybridization was then conducted in formalin-fixed paraffin-embedded slides with the use of the RNAScope for Multiplex Fluorescent Reagent Kit v2. RNA expression was then quantified using QuPath software. The mean mRNA signal counts/cell were then obtained and compared between SPTL and FT samples.

RESULTS: 40 samples met inclusion criteria. 31 (77.5%) were SPTL placentas, and 9 (22.5%) were FT controls. The mean PSG4 mRNA signal counts/cell in the SPTL samples was 7.1 ± 4.5 compared to 0.6 ± 0.3 in the FT samples ($p < 0.05$). Of the SPTL placentas, 21 (68%) were < 34 weeks, 10 (32%) were 34-37 weeks. The mean PSG4 mRNA signal counts/cell was not different in those 2 subgroups: 7.5 ± 4.7 v. 6.4 ± 4.1, p=0.49 (Figure 1). PSG4 mRNA signals were predominantly detected in syncytiotrophoblast as well as the discontinuous monolayer of cytotrophoblast.

CONCLUSION: PSG4, a known potent molecular driver of PS, is overexpressed in SPTL placentas compared to FT placentas. Thus, accelerated PS may play an important role in the pathophysiology of SPTL and may serve in the future as a target for novel therapeutics.

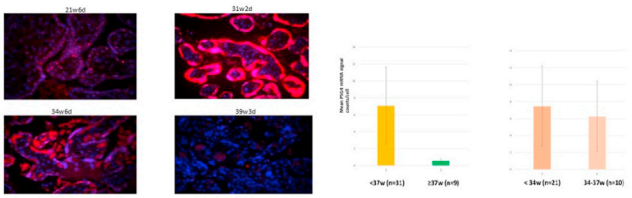

Figure 1: Quantification of PSG4 mRNA signal counts per cell in SPTL and FT placentas and representation of PSG4 mRNA expression (Red) in SPTL and FT placentas

317 A 3D printed device for electrophysiological measurement of myometrial smooth muscle cell contractions in vitro

Jessica O. Selim[1], Rahul Cherukuri[2], Ourlad Alzeus G. Tantengco[3], Lauren Richardson[4], Ananth Kumar Kammala[4], RamKumar Menon[5]
[1]University of Texas Medical Branch, Houston, TX, [2]Texas A&M University, College Station, TX, [3]University of the Philippines Manila, Manila, National Capital Region, [4]University of Texas Medical Branch, Galveston, TX, [5]University of Texas Medical Branch, League City, TX

OBJECTIVE: Current methods for determining uterine cell contractions using in vitro cell models are insufficient for preclinical drug trials as the 2D environment do not mimic intercellular interactions. To address this, we developed a non-invasive and functional model for recording uterine muscle contractions using a 3D-printed device incorporated with an isometric force transducer and measured real-time contractions and assessed the device's functionality in vitro.

STUDY DESIGN: Myometrial cells were 3D printed using a combination of GelMA (gelatin methacryloyl) and collagen, along with an isometric force transducer to enable real-time recording of uterine muscle contractions. Cell viability within the different biocompatible materials (GelMA and Collagen) was assessed using live-dead staining. In vitro, experiments were conducted with the device to evaluate myometrial cell contractility by stimulating the cells with acetylcholine at a concentration of 1μM.

RESULTS: The 3D-printed device model provided a suitable platform for culturing uterine muscle cells and mimicking their physiological environment. Myometrial cells were viable (green) in biocompatible materials like GelMA and collagen-1 (**Fig 1A**). With a 3D printed device (Fig 1B), we could record the cyclical contraction and relaxation of the 3D myometrial cell culture, using an isometric transducer and LabChart software (Fig 1B). The device successfully replicated the architectural and contractile properties of the native myometrial tissue, providing a conducive environment for culturing uterine muscle cells.

CONCLUSION: This non-invasive tool presents a promising avenue for studying uterine physiology and conducting preclinical trials, such as uterotonics, tocolytics, and treatments for postpartum bleeding. The tool allows real-time monitoring of drug responses to uterine contractions, enabling researchers to study drug efficacy and safety more effectively. Further research and validation will contribute to obstetric advancements, benefitting maternal and fetal healthcare and the development of new therapeutics.

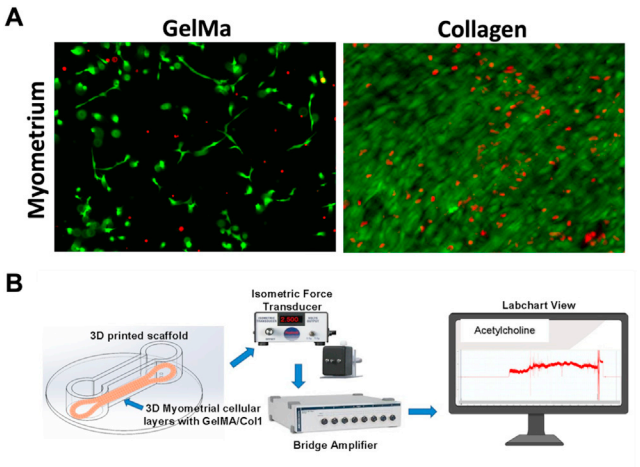

Table – Neonatal and perinatal outcomes, comparing participants with and without metformin use during the current pregnancy. Significance denoted by **bold** type.

318 Association between prenatal metformin exposure and birthweights in a cohort of gravidae with mild hypertension

Matthew A. Shanahan[1], **Kjersti M. Aagaard**[2]
[1]Baylor College of Medicine, Houston, TX, [2]Texas Children's Hospital, Baylor College of Medicine, Houston, TX; on behalf of the Chronic Hypertension and Pregnancy (CHAP) Consortium

OBJECTIVE: Metformin is currently the most commonly used oral antihyperglycemic agent for diabetes (DM) in pregnancy. Metformin crosses the placenta and is associated in several trials with a higher incidence of small for gestational age (SGA) births. Given the elevated risk of adverse outcomes with multiple maternal comorbidities, we hypothesized that in the setting of maternal chronic hypertension (cHTN) and DM, metformin use during pregnancy would be associated with decreased birthweights and risk of adverse outcomes.

STUDY DESIGN: This was a secondary analysis of the CHAP trial, a multi-center randomized trial where pregnant participants with cHTN were randomized to antihypertensive agents to maintain goal blood pressure (BP) < 140/90 mm Hg (active treatment) or deferred treatment until BP ≥160/105 mm Hg (control). Participants in the CHAP trial with DM (gestational or type 2) with and without metformin use were compared. Participants were included if their metformin exposure was known, and excluded if enrolled in a metformin and diabetes management trial. The primary outcome was birthweight and secondary outcomes included neonatal & placental outcomes.

RESULTS: 452 gravidae with DM were included, n=170 (37.6%) exposed to metformin and n=282 not. Participants with and without metformin exposure were similar at baseline. While neither birthweights nor incidence of SGA significantly differed with metformin exposure (Table), neonatal outcomes & placental morphology did. Specifically, the proportion of neonates with a 5-minute Apgar < 7 was higher with metformin exposure (12.9% vs 6.4%, p=0.03). Placental thickness was increased with metformin use, but placental weights were not different.

CONCLUSION: Among a cohort of gravidae with cHTN and DM, metformin use during pregnancy was not associated with a significant change in birthweight, but was associated with an increase in the amount of neonates with 5 minute Apgar of < 7. Further work regarding the long-term safety of fetal metformin exposure is warranted.

319 Impact of the oxytocin shortage on postpartum bleeding outcomes

Ashley E. Shea[1], **Christina T. Blanchard**[2], **Victoria C. Jauk**[2], **Vasiliki B. Orfanakos**[1], **Brian M. Casey**[1], **Alan T. Tita**[1], **Akila Subramaniam**[2]
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: National oxytocin shortages led our institution to modify our postpartum (PP) oxytocin protocol. Our objective was to compare rates of postpartum hemorrhage (PPH) and the need for additional PPH interventions before and during the oxytocin shortage.

STUDY DESIGN: We performed a retrospective cohort study of all deliveries >22 weeks at a large academic referral center from 4/2022-1/2023. Prior to oxytocin shortages, we utilized a high-dose PP oxytocin regimen of 80 units/500 mL after vaginal deliveries and two bags of 80 units/500 mL after cesareans. With the shortage, we transitioned on 10/12/22 to 60 units/1000 ml after vaginal deliveries and one bag of 80 units/500 ml after cesareans. The primary outcome was a composite of activation of the institution's quantitative PPH protocol, any uterotonic use, any blood transfusion, and PPH based on EBL (see Table footnote). Secondary outcomes included individual constituents in the composite and other bleeding outcomes (Table). Outcomes were compared between pre-shortage and during shortage groups and logistic regression was used to estimate adjusted odds ratios (aORs) and 95% confidence intervals (CI) using the pre-shortage group as reference.

RESULTS: Of 2988 deliveries in our study period, 2422 deliveries were included- 1747 pre-shortage and 675 during. Individuals before the shortage were more likely to have a BMI >30, be nulliparous, have a prior cesarean, undergo cesarean, have antepartum magnesium use, have preeclampsia, and less likely to have intrapartum oxytocin. There was no significant difference in the primary composite outcome between time periods (pre-shortage 15.0% vs shortage 12.2%; aOR 0.92 [0.70-1.22]) (Table). Secondary outcomes were also similar between groups. Results were unchanged when stratified by delivery mode.

CONCLUSION: Rates of PPH and postpartum bleeding interventions were unchanged after PP oxytocin dose reduction during the oxytocin shortage at our institution. When using a high-dose

postpartum prophylactic oxytocin regimen, slight reductions in oxytocin did not alter bleeding outcomes.

Table. Primary and secondary outcomes before and during the oxytocin shortage

	Prior to oxytocin shortage (n=1747) n (%)	During oxytocin shortage (n=675) n (%)	aOR† (95% CI)
Primary composite	262 (15.0%)	82 (12.2%)	0.92 (0.70-1.22)
Activation of the PPH protocol*	152 (8.7%)	46 (6.8%)	0.90 (0.63-1.29)
Any uterotonic administered **	73 (4.2%)	31 (4.6%)	1.17 (0.75-1.82)
Transfusion of any blood product	101 (5.8%)	25 (3.7%)	0.75 (0.47-1.21)
Postpartum hemorrhage***	78 (4.6%)	25 (3.8%)	0.85 (0.52-1.36)
Hematocrit decline >6%	25 (5.7%)	4 (2.9%)	0.37 (0.11-1.28)

†Reference group: Prior to oxytocin shortage. Odds ratios are adjusted for BMI >30, prior cesarean delivery, nulliparity, magnesium sulfate use, intrapartum oxytocin use, and mode of delivery.
*Activation of the PPH protocol occurred if any of the following were met – vaginal delivery with EBL >500 and/or >5 surgical laps used, cesarean section with EBL >1000 and/or >30 surgical laps used, or any provider with clinical concern/desire for closer patient monitoring. Patients on protocol received more frequent vital and lab monitoring.
**Any uterotonic administered included any dose of carboprost, methylergonovine, or vaginal misoprostol
***Postpartum hemorrhage was defined as an EBL >500 mL for vaginal delivery and EBL >1000 mL for cesarean section

320 Machine learning for the prediction of placenta accreta spectrum- systematic review and diagnostic meta analysis

Olivia Sher[1], Itamar Futterman[1], Cintia Gomes[1], julia Fisher[1], Rodney A. McLaren Jr.[2], Shoshana Haberman[1]
[1]Maimonides Medical Center, Brooklyn, NY, [2]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA

OBJECTIVE: Antenatal detected placenta accreta spectrum disorder (PAS) is associated with improved outcomes compared with first recognized PAS at delivery. We conducted a systematic review and diagnostic meta-analysis assessing the ability of machine learning (ML) for the prediction of placenta accreta spectrum disorders (PAS) from MRI-based texture data.

STUDY DESIGN: Systematic review was conducted using PRISMA guidelines. MEDLINE, Scopus, the Cochrane Library, and ClinicalTrials.gov were searched from inception to June 30, 2023, for studies that described the use of ML for the prediction of PAS. We then conducted a diagnostic meta-analysis to assess the validity of ML algorithms for prediction PAS and reported their respective sensitivity and specificity. Finally, a pooled sensitivity and specificity and area under the curve (AUC) were computed as well as diagnostic odds ratio (OR) with 95% confidence intervals (CI) using a random effects model.

RESULTS: Among 15 studies initially retrieved, three were included with a total of 201 patients. We were able to identify five different ML algorithms used to predict PAS from MRI-based texture data points. The five algorithms and their respective sensitivities and specificities are reported in Figure 1. In the reported trials, the ML algorithm successfully predicted 88 patients and successfully excluded 87 patients. The ML algorithm falsely predicted 15 patients and falsely excluded 11 patients. The AUC of the pooled trial was (diagnostic OR: 47; 95% CI 20.42,107.87).

CONCLUSION: ML-base MRI texture algorithms were predictive of PAS with high specificity. Our findings suggest that ML-based MRI texture algorithms have the potential to improve antenatal detection and ultimately pregnancy outcomes.

321 Alloimmunization in pregnancy: Patient-reported quality of care, mental health effects, and impact upon daily life

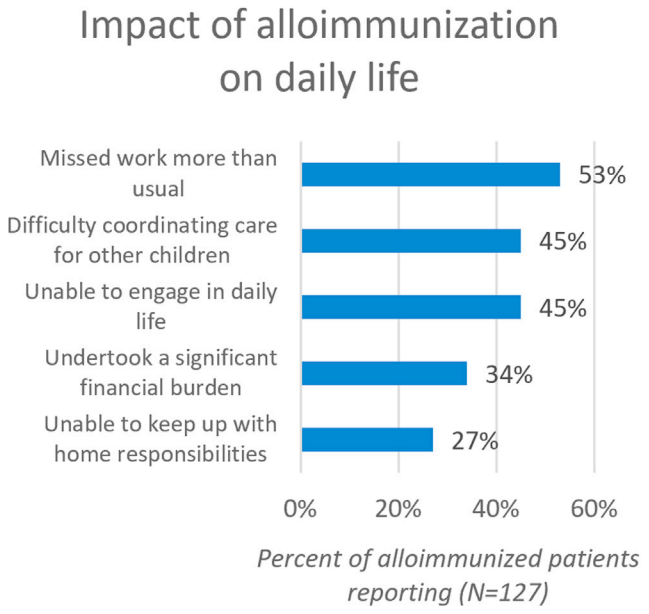
Molly R. Sherwood[1], Bethany Weathersby[1], Kara Markham[2], Marion E. Granger[3]
[1]Allo Hope Foundation, Tuscaloosa, AL, [2]Allo Hope Foundation, Tulscaloosa, AL, [3]University of South Carolina, Columbia, SC

OBJECTIVE: The objective of this study was to examine the perceived quality of care and impact upon mental health and daily living in pregnancies complicated by red blood cell alloimmunization.

STUDY DESIGN: This investigation was an IRB-approved structured survey of individuals reporting a history of alloimmunization in pregnancy. Recruitment took place November 2022 to February 2023 through Allo Hope Foundation's social media channels and private patient support group. In addition to inquiring about disease presentation, management and outcomes, respondents were asked about their perceived quality of care and the impact of their condition on their mental health and daily lives.

RESULTS: **127** respondents detailing 200 pregnancies reported new or worsening feelings of anxiety (91%), guilt (75%), self-doubt (68%), isolation (71%), depression (68%) and symptoms of PTSD (61%) during their pregnancies. When asked to rate the quality of care they received during their pregnancies, individuals who rated their care as 8/10 or above reported significantly lower rates of guilt (p=0.004), self-doubt (p=0.003), depression (p=0.011), and symptoms of PTSD (p=0.006) compared to those with quality care ratings of 7/10 or below. Respondents were offered mental health support in 25% of alloimmunized pregnancies. Respondents were satisfied with the continuity of care across providers in 40% of pregnancies, with 37% and 67% reporting satisfaction with obstetrician/midwife and maternal fetal medicine specialist knowledge of alloimmunization respectively. 53% of respondents reported changing doctors to find better care. Self-reported impact upon daily living is depicted in the Figure.

CONCLUSION: Alloimmunization imposes a high emotional burden on patients. The obstetric and high-risk fetal medicine community must turn its attention to offering mental health support and bolstering its understanding of this complicated disease to minimize the patient burden.



322 A randomized trial of a simulation-based resuscitation curriculum for maternal cardiac arrest

Andrea Shields[1], Jacqueline Battistelli[2], Kristen Annis[1], Charles Minard[2], Brook Thomson[3], Peter D. Nielsen[3]
[1]University of Connecticut School of Medicine, Farmington, CT, [2]Baylor College of Medicine, Houston, TX, [3]University of Texas Health Science Center at San Antonio, San Antonio, TX; on behalf of the Obstetric Life Support Consortium

OBJECTIVE: Obstetric Life Support (OBLS) is a simulation-based blended learning curriculum on managing maternal cardiac arrest that consists of self-guided pre-course work and an instructor-led simulation course using a customized low-fidelity simulator. Our objective was to assess course pass rates and performance on cognitive and Megacode assessments following completion of the course.

STUDY DESIGN: We performed a randomized, controlled, single-blinded trial of the OBLS curriculum versus no education between May 2022 - July 2023. Eligible participants were healthcare professionals in active practice in prehospital and hospital-based settings who respond to maternal medical emergencies, were English-speaking, and were at least 18 years old. Megacode evaluators were blinded to assignment groups. Our primary outcomes were overall course pass rates determined by performance on validated cognitive and Megacode assessments. The secondary outcome was self-efficacy in clinical, procedural, knowledge, and communication skills following completion of the course.

RESULTS: We consented and randomized 49 participants. Seven participants withdrew before the intervention. The final analysis included 42 participants, 22 in the control group (c-OBLS) and 20 in the intervention group (i-OBLS). c-OBLS participants were older than i-OBLS participants (46.1 versus 33.6 years old, P=0.0182). There was no other difference in baseline demographics, and all but one c-OBLS participant had current training in basic (BLS) and advanced cardiac life support (ACLS). OBLS course pass rates were higher in the i-OBLS compared with c-OBLS (90.5% and 9.5%, P< 0.0001), Table 1. Mean cognitive scores were higher in i-OBLS than in c-OBLS (78.5 versus 64.9%, P=0.0003). Mean confidence scores were higher in i-OBLS versus c-OBLS (192.5 versus 160.4, P=0.0016).

CONCLUSION: OBLS-trained participants achieved higher course pass rates and cognitive and Megacode scores as team leaders than participants without additional training. Self-efficacy scores were much higher in those completing OBLS training than those without additional training.

Table. Baseline Characteristics and Outcomes of Obstetric Life Support Participants.

Baseline Variable	Summary Statistic[1]	All (N=49)	Control (N=26)	Intervention (N=23)	P-value[2]
Age (years)	n (n missing)	36 (13)	19 (7)	17 (6)	
	Mean (sd)	40.2 (16.1)	46.1 (18.6)	33.6 (9.5)	0.0182
Gender identity	n (n missing)	47 (2)	25 (1)	22 (1)	0.2864

[1]Categorical variables are summarized by frequencies (%). Continuous measures are summarized by mean (sd).
[2]P-value for parameteric analysis using Chi-Square test or t-test/ANOVA and nonparametric analysis using Fisher's exact test or Wilcoxon rank sum test (t-approximation with continuity correction)/Kruskal-Wallis test (chi-square approximation).

323 Satisfaction with continuous glucose monitoring in pregnant patients with type 1 and type 2 diabetes

Kevin S. Shrestha, Ashley N. Battarbee
University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: Continuous glucose monitoring (CGM) improves pregnancy outcomes in type 1 diabetes. Given rapid uptake of CGM in pregnancies complicated by both type 1 and type 2 diabetes, our objective was to determine if CGM satisfaction and use differed between type 1 and type 2 diabetes.

STUDY DESIGN: Cross-sectional survey study of 100 patients with pregestational diabetes who used Dexcom G6 CGM during pregnancy and received prenatal care at a single tertiary care center (2021-2023). Participants completed the validated 15-question Glucose Monitoring Satisfaction Survey (GMSS) and other questions about CGM use. The primary outcome was high satisfaction with

CGM, defined as total GMSS score of 4 or greater (calculated as average of all questions on 5-point Likert scale). Secondary outcomes included GMSS subscales, frequency of CGM app use (< 6 times/day, 6-10 times/day, all the time), and CGM features used (numbers only, arrows or graphs, both arrows and graphs). Outcomes were compared between type 1 and type 2 diabetes, and logistic and ordinal regression estimated the association between type 2 diabetes and outcomes.

RESULTS: Of 100 surveyed patients, 45 had type 1 and 55 had type 2 diabetes. Patients with type 1 diabetes were more likely to use CGM before pregnancy and use insulin pump. CGM satisfaction did not differ between type 1 and type 2 diabetes (74.5% vs 56.6%; aOR 0.54, 95%CI 0.21-1.36; Figure). High openness, low behavioral burden, low emotional burden, and high worthwhileness also did not differ between groups after adjustment for CGM use before pregnancy (Figure). Reported CGM app use was high and did not differ between groups (aOR 0.80, 95%CI 0.33-1.95). Patients with type 2 diabetes were less likely to use arrows and/or graphs on CGM app compared to type 1 diabetes (aOR 0.34, 95%CI 0.11-0.98).

CONCLUSION: In this cohort, patients with type 2 diabetes appear to be similarly satisfied with CGM compared to those with type 1 diabetes. Future efforts focused on CGM education for new users may help increase use of CGM app features, maximize satisfaction and minimize technology burden.

	OR (95%CI)	aOR (95%CI)
High total satisfaction	0.45 (0.19-1.05)	0.54 (0.21-1.36)
High openness	0.46 (0.20-1.07)	0.46 (0.18-1.16)
Low emotional burden	0.37 (0.16-0.88)	0.49 (0.19-1.24)
Low behavioral burden	0.98 (0.33-2.96)	0.79 (0.22-2.79)
High worthwhileness	1.05 (0.43-2.61)	1.22 (0.45-3.29)

324 Assessing provider confidence in counseling patients about peripartum toxicology testing

Molly R. Siegel[1], Sabine Berry[2], Sarah N. Bernstein[1]
[1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Department of Obstetrics and Gynecology, Boston, MA

OBJECTIVE: To evaluate provider comfort in discussing peripartum toxicology testing with patients.

STUDY DESIGN: Semi-structured virtual interviews were performed with a convenience sample of obstetric providers in a single hospital system. Interviews assessed provider comfort with consenting for testing, disclosing toxicology test results, reviewing implications for maternal and infant health, and referring to treatment. Responses were assessed using descriptive statistics.

RESULTS: Of 20 participants, 5 (25%) were trainees, 6 (30%) were attending midwives, and 11 (55%) were attending obstetricians. 10 (50%) had been in practice for at least 10 years. Most participants reported that they counsel patients about substance use in pregnancy less than once per week (15/20, 75%), and 6/20 (30%) of participants reported that they do not always obtain consent before toxicology testing in pregnancy, despite a hospital policy and the United States Supreme Court ruling requiring such consent. While participants expressed high confidence in counseling peripartum patients on the implications of positive toxicology test results on neonatal health, only half reported that they understood the implications of a positive test on maternal health and breastfeeding or that they understood the treatment options available to patients with a positive toxicology test (Figure). Only two participants (10%) agreed that they understood and could counsel patients on the implications of a positive toxicology test on child welfare reporting.

CONCLUSION: Providers expressed low confidence in counseling pregnant patients on the implications of a positive toxicology test for maternal health, breastfeeding, treatment referrals, and child welfare, which may explain the suboptimal rates of providers obtaining consent for toxicology testing in this cohort. Educational initiatives to improve provider comfort with discussing implications of a positive test are imperative and planned by these authors.

325 Adverse pregnancy outcomes in patients with congenital uterine anomalies: evaluation of a large population database

Zoe O. Silsby[1], Stephen Rhodes[2], David C. Kaelber[3], David Sheyn[2], Justin R. Lappen[4]

[1]Case Western Reserve University School of Medicine, Cleveland, OH, [2]University Hospitals, Cleveland, OH, [3]Center for Clinical Informatics Research and Education, The MetroHealth System, Cleveland, OH, [4]Cleveland Clinic Foundation, Cleveland, OH

OBJECTIVE: Published literature has established an increased risk of some adverse pregnancy outcomes in patients with congenital uterine anomalies (CUA); however, prior studies are limited by small sample sizes. Our aim was to better characterize the risk of adverse pregnancy outcomes among patients with CUA.

STUDY DESIGN: We performed a retrospective cohort study of female patients aged 10-55 with a documented pregnancy outcome in the TriNetX Analytics Research Network. Congenital uterine anomalies were identified using ICD-10 codes Q51.x and O34.0. Patients with multiple conflicting diagnosis codes were excluded from analysis. We assessed the risk of adverse pregnancy outcomes in patients with and without an encounter diagnosis of CUA. Outcomes of interest included pregnancy outcome (i.e. abortion, ectopic pregnancy, live birth, stillbirth) and Severe Maternal Morbidity (SMM), using ICD-10 indicator codes selected by the Centers for Disease Control and Prevention (CDC). Descriptive statistics and chi-squared tests were used to analyze differences between groups.

RESULTS: 2,217,222 patients met inclusion criteria, 16,413 of whom had a one or more encounter diagnoses codes for CUA. Baseline differences between groups are shown in Table 1. Compared to patients with no encounter diagnoses for CUA, patients with CUA had higher rates of spontaneous abortion (14% vs 6.8%, $p < 0.001$) and stillbirth (1.2% vs 0.45%, $p < 0.001$). SMM was also increased in patients with CUA. Specifically, these patients had statistically significantly higher rates of blood products transfusion (1% vs 0.79%) hysterectomy (0.21% vs 0.10%), and DIC (0.46% vs 0.26%, all $p < 0.001$) within 30 days of delivery.

CONCLUSION: Patients with CUA are at higher risk of adverse pregnancy outcomes compared to patients with normal uterine anatomy, including for SMM and severe hemorrhage. Patients with CUA should be counseled about these pregnancy-associated risks, and CUA should be incorporated into risk-stratification and prevention strategies.

Table 1: Baseline Characteristics

	CUA (16,413 patients)	Control group (2,200,809 patients)
Mean Age	29.1 years (SD 6.0)	28.8 years (SD 6.3)
Chronic hypertension	870 (5.3%)	82,507 (3.7%)
Maternal BMI > 30	951 (5.8%)	96,048 (4.4%)
Type I Diabetes	119 (0.7%)	10,581 (0.5%)
Type II Diabetes	365 (2.2%)	35,771 (1.6%)
Gestational diabetes	1,171 (7.1%)	135,867 (6.2%)
History of uterine scar	1,016 (6.2%)	72,932 (3.3%)
History of preterm labor	206 (1.3%)	11,240 (0.5%)

326 Postpartum complications and delivery costs associated with births at term in the United States

Vanessa Perez Patel[1], Eric Zuk[2], Matthew Davis[2], Jim Li[1], Damien Croft[1], Kara M. Rood[3], Hyagriv Simhan[4]

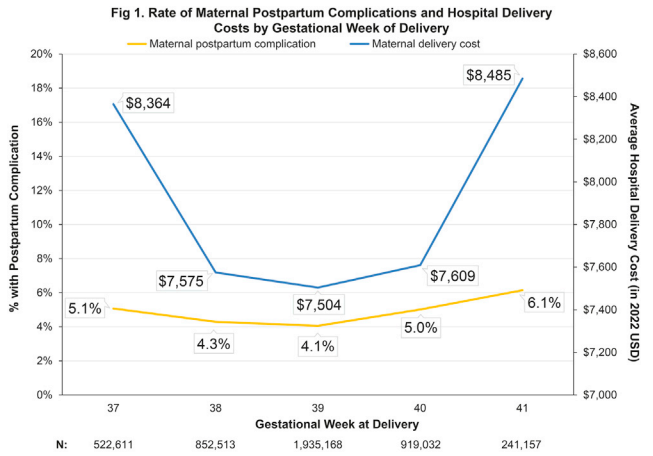
[1]Organon & Co, Jersey City, NJ, [2]Medicus Economics, Boston, MA, [3]The Ohio State University, Columbus, OH, [4]University of Pittsburgh, Pittsburgh, PA

OBJECTIVE: To assess maternal postpartum (PP) complication rates and delivery costs for individuals delivering across the spectrum of gestational age (GA) at term (37–41 weeks GA [wGA]) in the United States.

STUDY DESIGN: A population-based cohort study of the Premier Healthcare Database (Jan 2016–Sep 2021) was conducted. Eligible individuals aged 12–55 years old who had a live birth at $\geq$ 37 wGA were included; trends in rates of maternal PP complications and cost of care during the delivery hospitalization were examined. Severe maternal morbidity (SMM) scores were calculated using the expanded obstetric comorbidity scoring system (Leonard et al, Obstet Gynecol 2020). Maternal PP complications were a composite of sepsis, shock, acute renal failure, cardiac and thromboembolic events, acute respiratory distress, or hemorrhage. Trends by maternal age were explored.

RESULTS: A total of 4,470,481 term deliveries were included. Mean±SD age at delivery was 28.9±5.7 years; the obstetric comorbidity score for SMM was 11.0±15.2. U-shaped trends were observed in the frequency of complications and per-person costs for 37 to 41 wGA (Fig 1), with inflection points at 39 wGA: 4.1% of individuals delivering at 39 wGA had a complication; associated per-person costs were $7,504. Complications and costs increased after 39 wGA, with estimates highest at 41 wGA: 6.1% had a complication; per-person costs were $8,485. Compared to individuals $\leq$ 35 years old at delivery, costs were consistently highest across all wGA for individuals > 35 years old. PP complication frequency was consistently highest among individuals < 17 years old and lowest among individuals 17–35 years old.

CONCLUSION: Late-term deliveries exhibited the highest level of patient and hospital cost burden. Individuals > 35 years old at delivery did not have the highest frequency of complications, but their cost of care was consistently the highest, suggesting perhaps more severe complications were experienced.



327 Amphiregulin downregulation during preeclampsia may have long lasting cardiovascular effects

Caroline Smith[1], Carrie Bennett[2], Taylor Snisky[3], Alisse Hauspurg[4], Christina J. Megli[5]
[1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]University of Pittsburgh Medical Center, Pittsburgh, PA, [3]MWRI, Pittsburgh, PA, [4]UPMC Magee-Womens Hospital, Pittsburgh, PA, [5]Magee- Womens Hospital UPMC, Pittsburgh, PA

OBJECTIVE: There are fundamental knowledge gaps in the molecular mechanisms underlying preeclampsia pathogenesis. Even less is understood on how dysregulated signaling contributes to adverse cardiovascular outcomes postpartum. We hypothesize that macrophages, which regulate vascular function and inflammation play a key role.

STUDY DESIGN: Serum (n=80) and fresh full thickness placental biopsies (n=60) were obtained from our institution's biorepository. Serum was obtained 2 years postpartum (n=40) in individuals with a hypertensive disorder of pregnancy (HDP). Chorionic villi were dissected and used to generate placental conditioned media (CM) as previously described or fixed in formalin. THP-1 macrophages were incubated with CM for 24 hours to generate placental conditioned macrophages (PCM). Cytokine concentration was measured with ELISA. Immunofluorescence and confocal microscopy were used to localize proteins in samples. Clinical variables collected include: HDP diagnosis, blood pressure (BP). Ordinary one-way ANOVA was used to compare serum amphiregulin across HDP severity and diagnoses.

RESULTS: AREG was the most induced gene in placental conditioned macrophages (Figure 1a). PCM expression of AREG was reduced with HDP. Amphiregulin was present in the serum of HDP patients and strongly correlated strongly with disease severity ($p< 0.0001$), Figure 1b. These differences persisted 2 years postpartum ($p=0.03$), Figure 1c, but did not correlate with BP. Amphiregulin was abundant in placental conditioned media; however, levels did not correlate with HDP severity. Macrophage secretion of amphiregulin was not dependent on placental amphiregulin, suggesting an alternative pathway of regulation. Immunofluorescence localized amphiregulin to maternal macrophages on the surface of the syncytiotrophoblast in placental explants (Figure 1d).

CONCLUSION: Our data implicate macrophage-dependent regulation of amphiregulin in the development of hypertensive disorders during pregnancy with persistence postpartum. Future studies examining amphiregulin as a predictor of HDP and postpartum endothelial dysfunction are warranted.

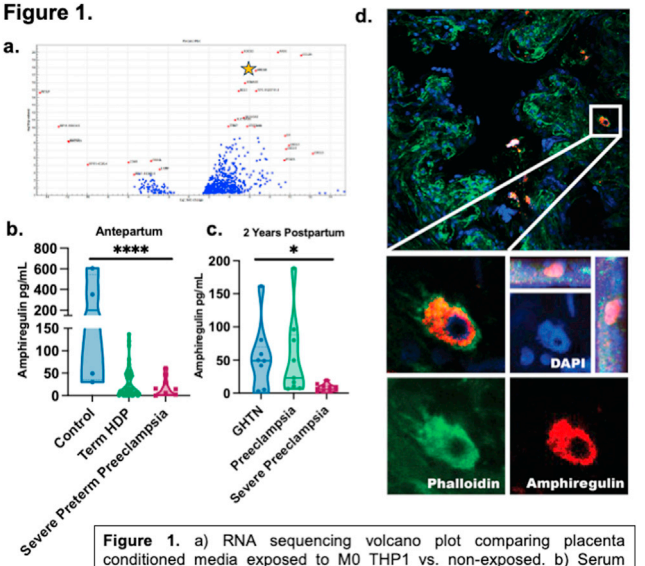


Figure 1. a) RNA sequencing volcano plot comparing placenta conditioned media exposed to M0 THP1 vs. non-exposed. b) Serum amphiregulin concentration at time of delivery by HDP severity. c) Serum amphiregulin concentration at 2 years postpartum by HDP diagnosis. d) Immunofluorescence staining of fixed chorionic villi tissue.

328 Activin A as a marker of postpartum hypertension following a hypertensive disorder of pregnancy.

Caroline Smith[1], Carrie Bennett[2], Lara S. Lemon[3], Agnes Koczo[4], Taylor Snisky[5], Christina J. Megli[6], Alisse Hauspurg[4]
[1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]University of Pittsburgh Medical Center, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA, [4]UPMC Magee-Womens Hospital, Pittsburgh, PA, [5]MWRI, Pittsburgh, PA, [6]Magee- Womens Hospital UPMC, Pittsburgh, PA

OBJECTIVE: Activin A is a pleotropic protein and marker of endothelial dysfunction and cardiac fibrosis in pregnant and non-pregnant individuals. We sought to assess the relationship between maternal serum activin A concentration at delivery, severity of hypertensive disorder of pregnancy (HDP) and postpartum blood pressure (BP) following a HDP.

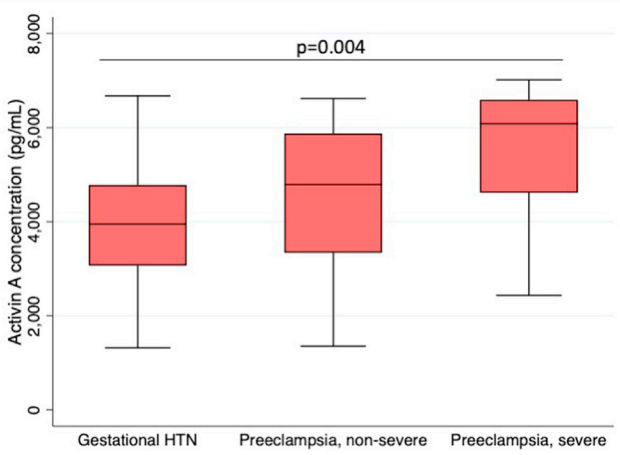
STUDY DESIGN: We conducted a cohort study of individuals with a HDP who delivered between 3/2019 and 3/2022 co-enrolled in our institution's biospecimen repository and our remote (BP) monitoring program. Eligible individuals had a physician adjudicated HDP diagnosis, no pre-pregnancy hypertension, a serum specimen collected at the time of delivery and reported at least five home BPs in the first six weeks postpartum. Serum activin A was measured by R&D Systems ELISA. Aspirin use during pregnancy was ascertained from the medical record. We used nonparametric Spearman correlations to compare activin concentrations and continuous variables and Wilcoxon rank sum and non-parametric test for trend to compare concentrations across categorical variables.

RESULTS: We included 76 individuals who contributed 2121 home BPs to this analysis. Maternal serum activin concentration increased in a stepwise fashion with severity of HDP (non-parametric test for trend $p< 0.01$) but did not differ significantly by aspirin use in

pregnancy. Activin concentration was also significantly correlated with peak systolic (r:0.33, p< 0.01) and diastolic (r: 0.24, p=0.03) postpartum BP, but was not correlated with pre-delivery peak systolic (r: 0.11, p=0.35) or diastolic BP (r: 0.06, p=0.58). Individuals requiring initiation of anti-hypertensive medications had higher activin concentrations compared to those never requiring medications (p=0.001).

CONCLUSION: In our study, higher serum activin concentrations at the time of delivery were related to increasing severity of HDP, higher peak postpartum BP and need for anti-hypertensive medication. Our results suggest the potential of activin A as a promising biomarker for improving postpartum risk stratification among individuals with HDP.

Figure 1. Activin concentration by HDP severity.



329 Prenatally identified congenital aqueductal stenosis: short- and long-term neurodevelopmental outcomes

Noah J. Smith[1], Charu Venkatesan[2], Beth Kline-Fath[2], Mounria Habli[2], Usha Nagaraj[2], Karin Bierbauer[2]
[1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

OBJECTIVE: Assess short- and long-term neurodevelopmental outcomes in patients with prenatally identified congenital aqueductal stenosis (CAS) with and without ventricular rupture to improve counseling for patients and families.

STUDY DESIGN: This was an IRB-approved, retrospective-cohort study of 140 CAS patients who underwent fetal MRI (87 also received postnatal brain imaging) at Cincinnati Children's Hospital Medical Center between 2003 and 2023. Patients were grouped according to etiology and ventricular rupture status. Patients were deemed to have "syndromic CAS" if there was a coexisting diagnosis of a malformation (e.g., rhombencephalosynapsis, Dandy-Walker malformation, etc.) or genetic syndrome (e.g., X-linked hydrocephalus, Walker-Warburg, etc.). Otherwise, they were classified as "isolated CAS." Patient records were analyzed for metrics such as length of NICU stay, seizures, respiratory and feeding support, speech capabilities, and gross motor function score (GMFCS).

RESULTS: Of 140 patients with fetal imaging, 18 died in the fetal or immediate neonatal period, and 14 pregnancies were terminated. 108 and 88 patients were available to analyze short- and long-term outcomes, respectively. The mean age was 7.23 years (range: [1.04, 18.74]) for long-term outcomes. Long-term motor outcomes were not correlated with ventricular rupture. There were no differences when comparing patients with rupture to those without rupture. However, poor motor outcomes were correlated with syndromic CAS with a statistically significant difference ($p< .001$) in GMFCS compared to isolated CAS; 65.9% of syndromic CAS required assistance with ambulation vs. 6.67% of those with isolated CAS. Similarly, the risk for future epilepsy and the requirement for feeding assistance was significantly increased with syndromic CAS.

CONCLUSION: These findings challenge the conventional counseling that ventricular rupture is a reliable predictor of poor prognosis. Instead, distinguishing syndromic from isolated CAS is more fruitful for personalizing treatment and informing care decisions.

330 Anxiety and depression treatment in birthing people experiencing antepartum hospitalization: a systematic review and meta-analysis

John R. Soehl[1], Kathryn E. Anthony[2], Adam K. Lewkowitz[3], Lauren Fletcher[4], L. G. Ward[5], Emily S. Miller[6]
[1]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [2]Women and Infants Hospital, E Providence, RI, [3]Warren Alpert Medical School of Brown University, Women & Infants Hospital Rhode Island, Providence, RI, [4]Brown University Library, Providence, RI, [5]Department of Psychiatry and Human Behavior, Alpert Medical School of Brown University, Providence, RI, [6]Alpert Medical School of Brown University and Women & Infants Hospital of Rhode Island, Providence, RI

OBJECTIVE: Birthing people who experience pregnancy complications are at a higher risk of developing perinatal anxiety or depression. Antepartum hospitalization due to these complications enhances the risk, with one in every three birthing people hospitalized reporting anxiety or depression. Our objective was to evaluate interventions for anxiety or depression for birthing people experiencing antepartum hospitalization for perinatal or fetal complications.

STUDY DESIGN: Searches were conducted in Ovid MEDLINE, Embase, CINAHL Plus, Cochrane CENTRAL, and PsycINFO to identify randomized controlled trials (RCTs) comparing any intervention against treatment as usual (TAU) for management of anxiety or depression among birthing people admitted to a hospital's antepartum unit for pregnancy complications. Two authors independently reviewed abstracts for eligibility and potentially eligible full-text articles for inclusion. The primary outcome was a measurement of anxiety or depression symptoms using a validated scale following the intervention. The Hedges method was used to detect standardized mean difference (SMD) in studies using different psychometric scales.

RESULTS: Of 877 articles identified, two RCTs—consisting of total of 161 and 123 participants randomized to intervention and TAU, respectively—were included. The pooled intervention group included daily meditation programs or other mind-body interventions such as education on stress reduction techniques and individualized patient support. Compared to TAU, interventions significantly reduced mean scores assessing anxiety and depression symptoms (Figure 1).

CONCLUSION: Few RCTs have been published examining the effect of interventions on symptoms of anxiety or depression among birthing people who experience antepartum hospitalization. Nevertheless, mental health interventions yielded modest yet significant reduction in both perinatal anxiety and depression symptoms in this

population. These promising results and shortage of data highlight a need for further high-quality trials to support the mental health needs of this high-risk population.

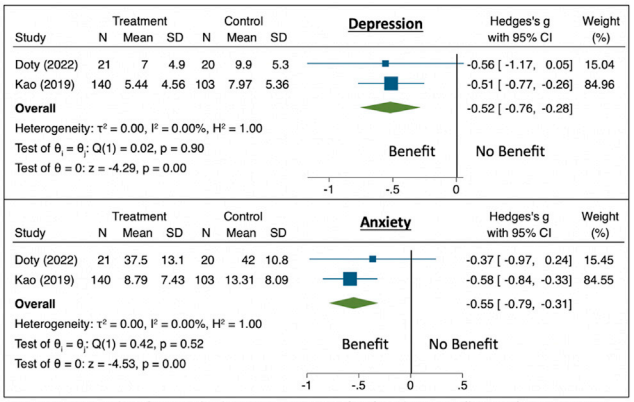


Figure 1: Forest plots for standard mean Depression (top) and Anxiety (bottom) symptoms as assessed on validated scales

331 Subsequent pregnancies after conservative placenta accreta management: systematic review and meta-analysis

Shmuel Somer[1], Doron Kabiri[2], Shay Porat[3], Yossef Ezra[4], Aharon Tevet[3], Joshua I. Rosenbloom[4]

[1]Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Hefa, [2]Hadassah, Jerusalem, Yerushalayim, [3]Hadassah Medical Center, Jerusalem, Yerushalayim, [4]Hadassah-Hebrew University Medical Center, Jerusalem, Yerushalayim

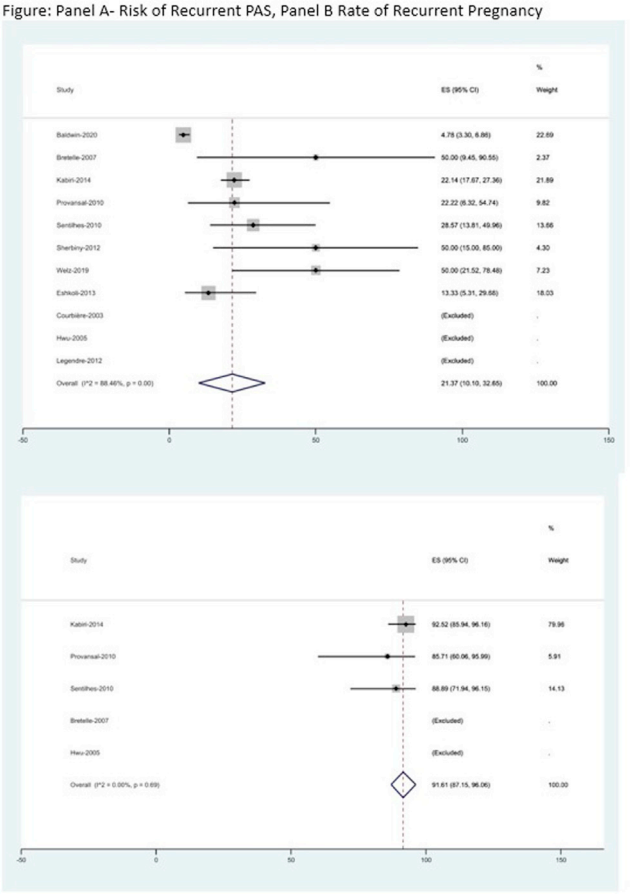
OBJECTIVE: This study aimed to assess the recurrence rate and obstetric outcomes in patients with a history of placenta accreta spectrum (PAS) who underwent conservative management with uterine preservation.

STUDY DESIGN: This systematic review and meta-analysis was conducted according to PRISMA guidelines. Titles and abstracts retrieved by a trained research librarian were screened by two authors. Studies were included that reported subsequent pregnancy outcomes including recurrence rate of PAS for patients who underwent conservative uterine-sparing management of PAS in the index pregnancy. Studies that did not report subsequent pregnancies were excluded. The primary outcome was the risk of recurrent PAS in subsequent pregnancies. The secondary outcomes were rates of achieved pregnancies and rates of pregnancies resulting in live births. Random effects meta-analysis was used to compute the rates of recurrent PAS and other pregnancy outcomes.

RESULTS: There were 1020 studies screened, and the final analysis included eight studies with 888 live births. There was heterogeneity with respect to the type of conservative management performed, length of follow up time, and definitions of PAS. Of the 888 patients there were 105 (21.4%, 95%CI (10.1, 32.7)) cases of recurrent PAS (Figure). There were six studies which reported a total of 152 women who attempted pregnancy, 140 of whom (91.6%, 95%CI (87.2, 96.1)) achieved pregnancies including some with multiple subsequent pregnancies: however, not all of these studies reported the outcomes of these pregnancies. There were six studies that reported the outcomes of subsequent pregnancies including 51 pregnancies resulting in 33 live births, 13 spontaneous abortions, 3 termination of pregnancies, and 2 ectopic pregnancies.

CONCLUSION: The quality of existing literature on recurrent PAS is low. There is a high pregnancy rate after conservative treatment of PAS with a risk of recurrent PAS of 21%. Patients undergoing conservative management of PAS should be appraised of these risks.

Figure: Panel A- Risk of Recurrent PAS, Panel B Rate of Recurrent Pregnancy



332 IGF-1 mediates ID2 in trophoblast differentiation

Feng Li, Rebecca Ssengonzi, WH Davin Townley-Tilson, Yukako Kayashima, Nobuyo Maeda-Smithies

University of North Carolina at Chapel Hill, Chapel Hill, NC

OBJECTIVE: In preeclampsia (PE), impaired trophoblast proliferation and differentiation is thought to cause abnormal placentation and consequent fetal growth restriction. Insulin-like growth factor 1 (IGF-1) promotes trophoblast proliferation and differentiation, however the mechanisms of these processes are not well understood. The IGF-1 receptor regulates inhibitor of DNA binding 2 (ID2), but it is unclear how. ID2 functions as a negative regulator of bHLH transcription factors. ID2 is involved in trophoblast differentiation and implicated in many processes disrupted in PE—placental development, vascular differentiation, and angiogenesis. We hypothesize that IGF-1 promotes trophoblast differentiation via ID2—a relationship that has not been tested before in trophoblasts.

STUDY DESIGN: Immortalized human first trimester trophoblast cells (HTR-8/SVneo) were treated with IGF-1 for 24 hours after serum starvation. ID2 and MKI67 (marker of proliferation Ki67) expression was quantified by qRT-PCR and Western blot. Treated cells were visualized for tube formation as an index of differentiation. A wound healing assay was used to visualize cell migration and CCK-8 was used to enzymatically quantify viable cells.

RESULTS: Cell viability, migration, and differentiation were significantly increased in high doses (100 and 1000 ng/mL) of IGF-1 compared to low doses (0 and 10 ng/mL). *ID2* and *MKI67* mRNA levels were significantly lower in high *IGF-1* doses compared to lower doses. As IGF-1 increased from 0 to 100 ng/mL, ID2 protein increased significantly. But when IGF-1 increased from 100 to 1000 ng/mL, ID2 protein decreased significantly.

CONCLUSION: These data suggest IGF-1 may regulate trophoblast proliferation and differentiation through ID2. Increased IGF-1 may increase differentiation by decreasing ID2 expression. Futures studies will investigate mechanisms by which IGF-1 influences ID2, and if there are ID2-independent pathways of IGF-1 trophoblast regulation.

333 A molecular diagnostic assay for syphilis infection among a high-risk pregnant cohort.

Irene A. Stafford[1], Myra Kurjee[2], Nikita Ghosh[2], Ana Davie[2], Juan Camilo Padilla Ruiz[2], Erik Munson[3]

[1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [2]The University of Texas Health Science Center at Houston, Houston, TX, [3]Marquette University, WI

OBJECTIVE: Recommended syphilis screening during pregnancy relies on a serologic test to determine the host response towards antigenic components of the causative agent, *Treponema pallidum*. A novel research-use only transcription mediated amplification assay (TMA) targeting 16S rRNA of *T. pallidum* collected from mucosal tissue has demonstrated organism detection prior to seroconversion in rectal swabs collected from men. The aim of this pilot study is to determine detection rates of *T. pallidum* in provider or self-collected vaginal swab samples from pregnant women with syphilis.

STUDY DESIGN: A prospective cohort study was conducted for all pregnant individuals who underwent routine syphilis screening via the recommended reverse or traditional screening methods between 01/23-06/23 at a high-risk obstetrical clinic. Vaginal swabs were collected by the provider or the patient at the same visit the syphilis screen was performed. All swabs were subjected to automated *T. pallidum* TMA (Hologic,Inc). Syphilis status was confirmed with the health department.

RESULTS: Of 210 eligible patients, 191 (90%) underwent a provider collected or self-collected vaginal swab. Of those, 32 (16.7%) had detectable T. pallidum rRNA. Of these, 5 (15.6%) patients were positive for syphilis using the reverse algorithm with a reactive treponemal antibody and a confirmatory nontreponemal (NT) titer. The stage of syphilis varied, and NT titers ranged from 1:1-1:128. Nine (28.1%) with detectable T. pallidum RNA were screened by the traditional algorithm and yielded a nonreactive NT titer, and 8 (25%) were negative by the reverse algorithm (nonreactive treponemal antibody). The remaining 10 (31%) are pending testing for discordant results. None of the patients with nondetectable T. pallidum RNA tested positive using syphilis serology, yielding a 100% positive predictive value and 85% specificity.

CONCLUSION: The research-use only TMA test targeting 16S rRNA of *T. pallidum* demonstrated pathogen detection from vaginal mucosal specimens in pregnant individuals with syphilis. Further research is needed to determine its utility as a screening test.

334 Is there clinical utility of PAPP-A in the age of cell free DNA?

Tirtza Spiegel Strauss[1], Phuong Chi Nguyen[2], Dhara Kadakia[3], Anna Eberwein[3], Alexandra N. Mills[4], Shobha Jagannatham[5], Ariel Coughlin[3], Olivia Grubman[6], Thomas Owens[7], Guillaume Stoffels[8], Farrah N. Hussain[6], David Cole[9], Graham Ashmead[10], Zainab Al-Ibraheemi[11], Lois Brustman[12]

[1]Maimonides Medical Center, New York, NY, [2]Mount Sinai South Nassau, Oceanside, NY, [3]Mount Sinai West, Icahn School of Medicine at Mount Sinai, New York, NY, [4]Icahn School of Medicine at Mount Sinai, New York, NY, [5]Icahn School of Medicine at Mount Sinai West/Morningside, New York, NY, [6]Mount Sinai West, New York, NY, [7]Mount Sinai West, New York, NY, [8]Mount Sinai Hospital, New York, NY, [9]Mt. Sinai West, New York, NY, [10]Roosevelt Hospital, New York, NY, [11]Mount Sinai West, N Caldwell, NJ, [12]St. Luke's Roosevelt Hospital Center, New York, NY

OBJECTIVE: SMFM recommends against performing first trimester screen(FTS) with cell free DNA(cfDNA). However PAPP-A≤0.4 multiples of the mean(MoM) has been associated with adverse perinatal outcomes. We aimed to prove there was additional clinical utility of analytes, specifically PAPP-A, in FTS. We hypothesized that FTS+cfDNA, compared to NT+cfDNA, would increase sensitivity to detect adverse outcomes, guide aspirin initiation, and thus decrease rates of adverse maternal outcomes such as preeclampsia and placental abruption.

STUDY DESIGN: This was a prospective observational cohort study comparing patients at 2 hospitals from 2021-2022. Site 1 received NT+cfDNA, while site 2 received FTS+cfDNA or NT+cfDNA. Those with PAPP-A≤0.4 were recommended aspirin and fetal surveillance. Demographics, aspirin use, and outcomes were reviewed. The McNemar test was performed on FTS+cfDNA group to determine additional sensitivity that PAPP-A≤0.4 had to detect adverse outcomes, while adjusting for treatment.

RESULTS: FTS+cfDNA was sent on 688 and NT+cfDNA on 701 patients. In the FTS+cfDNA group patients were older, lower BMI, predominantly White, more in vitro fertilization(IVF), less hypertension, more nulliparous, and less publicly insured compared to NT+cfDNA group ($p < 0.01$). After adjusting for hypothetical proportions of prevented outcomes with the McNemar test in FTS+cfDNA group, PAPP-A added additional sensitivity to detect adverse maternal outcomes compared to only NT+cfDNA(Table 1). 78% PAPP-A≤0.4 took aspirin compared to 33% of those recommended aspirin for ACOG risk factors. Adverse maternal outcomes were similar between FTS +cfDNA group and NT+cfDNA group (10.6% vs 11.8%, p=0.46).

CONCLUSION: Our data suggests PAPP-A has additional sensitivity to detect adverse maternal outcomes and increases aspirin compliance. Though we anticipated decreased adverse outcomes in the FTS+cfDNA group, it is possible that differing group demographics lead to similar rates of adverse maternal outcomes. As preeclampsia causes maternal and fetal morbidity, all known noninvasive interventions to increase detection should be considered.

Table 1: McNemar Test for screening performance of PAPP-A among the FTS+cfDNA group

Outcome	Hypothetical proportion of prevented outcomes‡	Sensitivity		
		No PAPP-A	PAPP-A	P value†
Maternal adverse outcome	0%	0.01 (1/73)	0.15 (11/73)	0.002
	10%	0.01-0.03 (1-2/74)	0.16 (12/74)	0.001-0.002
	20%	0.01-0.05 (1-4/76)	0.18 (14/76)	0.0002-0.001

† Sensitivity was compared using the McNemar test on case patients.
‡ The hypothetical proportion of prevented outcomes corresponds to the proportion of cases that would have been avoided by treatment after PAPP-A<0.4 MoM. Note that 10% and 20% of prevented outcomes were equivalent to 1 and 3 cases, respectively.

335 Efficacy of glycated albumin in the management of gestational diabetes

Yusen Sugimura[1], Misao Fukuoka[1], Kensuke Ashimoto[2], Hiroshi Yamashita[1], Ichiro Yasuhi[1]
[1]NHO Nagasaki Medical Center, Omura-City, Nagasaki, [2]Kameda Medical Center, Kamogawa City, Chiba

OBJECTIVE: While glycated albumin (GA) can be used for blood glucose management in patients with diabetes, the role of GA in assessing glycemic status in gestational diabetes (GDM) has been controversial. This study aimed to investigate the efficacy of GA measurements in predicting the need for insulin therapy at GDM diagnosis and assessing glycemic status during the early third trimester in women with GDM.

STUDY DESIGN: This retrospective study included singleton pregnant women with GDM who had both GA and self-monitoring of blood glucose (SMBG) measured at the time of diagnosis and between 31-33 weeks' gestation. SMBG measurements were taken four times a day (before breakfast [fasting] and 2 hours after each meal), and the respective mean values of fasting and postprandial glucose measurements over consecutive seven days were calculated. We investigated whether GA was correlated with SMBG values and whether GA values at diagnosis and during the early third trimester effectively predicted insulin therapy and poor glycemic control (defined as fasting ≥95 mg/dL and postprandial ≥120 mg/dL, respectively.

RESULTS: We measured GA in 190 patients at diagnosis and in 153 patients during the early third trimester. While GA values were significantly and negatively associated with prepregnancy body mass index (BMI) (p< .0001), they did not show significant associations with mean fasting or postprandial glycemic values of the SMBG measurements, either at diagnosis or during the early third trimester after controlling BMI. GA did not differ significantly between women with and without insulin therapy or those with poor and good control (**Table**).

CONCLUSION: GA measurements seem to be ineffective in assessing glycemic control status in women with GDM and therefore should be abandoned.

Table. Comparison of GA values in the various glycemic statuses

(A) At diagnosis of GDM				
	Insulin therapy (n=82)	Diet alone (n=108)	Crude p value	BMI-adjusted p value
GA value (%)	13.4±1.2	13.4±1.1	0.79	0.20
(B) Between 31-33 weeks' gestation				
Fasting	Poor control (n=24)	Good control (n=129)	Crude p value	BMI-adjusted p value
GA value (%)	12.8±1.1	13.1±1.1	0.24	0.45
Postprandial	Poor control (n=82)	Good control (n=71)	Crude p value	BMI-adjusted p value
GA value (%)	13.1±1.1	13.0±1.1	0.58	0.30

336 Differences in pharmacologic management of postpartum hemorrhage in patients with and without thrombocytopenia

CeCe Cheng[1], Claire D. Sundjaja[1], Michaela Y. Lee[1], Bryce T. Munter[1], B. Kate Neuhoff[2], Patrick S. Ramsey[3], John J. Byrne[3]
[1]University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]UTHSCSA, San Antonio, TX, [3]The University of Texas Health Science Center at San Antonio, San Antonio, TX

OBJECTIVE: Low platelet count at delivery is a risk factor for postpartum hemorrhage (PPH). We sought to evaluate if patients with thrombocytopenia < 150,000 platelets/μl require different uterotonic management in the setting of postpartum hemorrhage (PPH).

STUDY DESIGN: We performed a single-institution, retrospective cohort study on patients whose deliveries were complicated by PPH from 8/2020-11/2021. Inclusion criteria included quantitative blood loss ≥1000ml within 24 hours of delivery as defined by ACOG's reVITALize criteria for PPH. Patients were stratified into two groups: those with thrombocytopenia on delivery admission with platelets < 150,000 per μl and those with platelets ≥150,000 per μl. The primary outcome was number of types of uterotonics used and number of administered doses for each uterotonic in PPH management. The secondary outcome was number of doses of tranexamic acid (TXA). All patients received standardized postpartum oxytocin regimen per institutional protocol.

RESULTS: μOf the 4298 patients who delivered during the study period, 529 (12%) patients experienced PPH. In patients who experienced PPH, 61 (11.5%) met definition for thrombocytopenia on admission. Body mass index was significantly lower in patients with thrombocytopenia, but otherwise, all other demographics were similar. Patients with thrombocytopenia were more likely to require 4 different types of uterotonics only if they underwent CD (14% vs 3%, p = 0.008). In addition, they were more likely to require more doses of carboprost (0 [0, 1.75] vs 0 [0, 0], p=0.04) and methylergonovine (0 [0, 1] vs 0 [0, 1], p=0.007) compared to patients without thrombocytopenia only if they required CD. There were no differences in the number of types of uterotonics used or doses of each uterotonic administered when patients underwent SVD. Rates of TXA administration were similar between groups.

CONCLUSION: Patients with thrombocytopenia (platelets < 150,000 per μl) require significantly more types of uterotonics and doses of carboprost and methylergonovine for pharmacologic management of PPH when undergoing CD.

Table. Number of types of uterotonics* used and number of doses of each uterotonic administered in the thrombocytopenia v non-thrombocytopenia cohorts

	Spontaneous Vaginal Delivery			Cesarean Delivery		
	Thrombocytopenia (n=25)	Non-thrombocytopenia (n=192)	P value	Thrombocytopenia (n=37)	Non-thrombocytopenia (n=275)	P value
1	9 (36)	67 (35)	>0.99	15 (41)	168 (61)	0.02
2	5 (20)	57 (30)	0.36	9 (24)	67 (24)	>0.99
3	9 (36)	37 (19)	0.06	7 (19)	31 (11)	0.18
4	2 (8)	28 (15)	0.54	5 (14)	7 (3)	0.008
Misoprostol	0 [0, 0]	0 [0, 1]	0.35	5 (14)	22 (8)	0.34
Carboprost	1 [0, 2]	0 [0, 1]	0.13	0 [0, 1.75]	0 [0, 0]	0.04
Methylergonovine	1 [0, 1]	0 [0, 1]	0.75	0 [0, 1]	0 [0, 1]	0.007
TXA	1 [0, 1]	1 [0, 1]	0.34	0 [0, 1]	0 [0, 1]	>0.99

*Uterotonics include oxytocin, carboprost, methylergonovine, and misoprostol. TXA=Tranexamic acid.

337 Acute inflammation is associated with reduced basal decidua progesterone receptor density in spontaneous preterm birth

Sunitha C. Suresh[1], Alexa A. Freedman[2], Emmet Hirsch[3], Linda M. Ernst[4]
[1]NorthShore University Health System, Evanston, IL, [2]NorthShore University HealthSystem, Evanston, IL, [3]Evanston Northwestern Healthcare, Northwestern University, Evanston, IL, [4]NorthShore University HealthSystem, University of Chicago Pritzker School of Medicine, Evanston, IL

OBJECTIVE: A functional progesterone withdrawal has been thought to contribute to the pathophysiology of preterm birth (PTB), a process potentially mediated in part by alterations in the progesterone receptor (e.g. isoform abundance, tissue distribution,

quantity). We sought to understand the relationship between density of progesterone receptor in the decidua and placental pathology patterns.

STUDY DESIGN: This is a retrospective cohort study leveraging a prior null result case-control study of 40 patients with spontaneous PTB < 37 weeks. The exposure of placental pathology was evaluated as absence/ presence of each of the major recognized patterns of placental injury including acute inflammation, chronic inflammation, maternal vascular malperfusion, and fetal vascular malperfusion. Slides containing basal decidua were stained for progesterone receptor (mouse monoclonal anti-human progesterone receptor antibody Clone PgR 1294, diluted 1:50), which stains for both PR-A and PR-B. 10 representative images were obtained for each sample and QuPath was utilized to determine the outcome of % positive stained cells for progesterone receptor. The average percentage of positive cells across the representative images was compared by t-tests for each pattern of placental injury.

RESULTS: Average gestational age at index birth was 31 weeks per design of primary study. Among patients with acute inflammation (AI), there was a lower density of progesterone receptor staining (% positive cells 12.9 without AI vs 9.1 with AI, p= 0.03). There was no difference based on chronic inflammation, maternal vascular malperfusion, or fetal vascular malperfusion (Table 1).

CONCLUSION: The presence of acute inflammation may be associated with lower density of progesterone receptor expression in the basal decidua. Further research is needed to investigate these findings in the context of spontaneous PTB and potential prevention of preterm birth. These findings may also be further explored in the setting of progesterone supplementation in pregnancies threatened by PTB.

338 Application of the solomon laser technique to dichorionic-triamniotic triplet gestations with twin-to-twin transfusion syndrome

Elena R. Taylor[1], Anjali Varghese[1], Abby Birk[1], Kenae Thompson[2], Sarah Olson[1], Kristin Voegtline[1], Michelle Kush[3], Ahmet A. Baschat[3], Jena L. Miller[4], Mara Rosner[4]

[1]Johns Hopkins School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins Hospital, Baltimore, MD, [4]Johns Hopkins Center for Fetal Therapy, Baltimore, MD

OBJECTIVE: The Solomon technique for laser surgery in monochorionic (MC) twins with twin to twin transfusion syndrome (TTTS) may be associated with higher survival but also an increased risk for placental abruption. Dichorionic triamniotic (DCTA) triplets with TTTS are candidates for Solomon laser surgery, however, Solomon outcomes have not been directly studied for triplet gestations. We evaluated the outcomes of Solomon laser in DCTA triplets compared to MCDA twins.

STUDY DESIGN: Triplets were matched 4:1 with twins for TTTS Stage III, co-existing selective fetal growth restriction (sFGR), cervical length (CL) (< 20 or ≥20 mm), and gestational age (GA) at laser (< 18, 18-24, >24 weeks). Patients were compared for maternal demographics, pretreatment characteristics, procedural details, and post-treatment outcomes. Our primary outcome was gestational age (GA) at birth. Continuous data were analyzed using student's t or Wilcoxon Rank-Sum test. Categorical data were analyzed using Pearson's chi squared or Fisher's Exact test.

RESULTS: Ten triplets were matched to 40 twins after Solomon laser. The median GA at delivery was lower in triplets (30.6 vs 33.3 weeks, p=0.04) and the interval from laser to delivery was shorter (9.1 vs 12.3 weeks, p=0.04). There was no difference in laser energy, fetoscopy time, PPROM, fetal demise within 48 hours of laser, septostomy, birth survival, or abruption (see table).

CONCLUSION: When matched for known TTTS risk modifiers such as stage, sFGR, CL and GA at laser, DCTA triplets undergoing Solomon laser for TTTS deliver about 3 weeks earlier than MCDA twins due to a shorter laser to delivery interval. However, intraoperative parameters and survival are similar and overall favorable for both groups after Solomon laser.

	MCDA Twins N=40	DCTA Triplets N=10	p
Maternal Age, mean (SD)	31.9 (5.8)	32 (3.1)	0.9
GA laser (weeks), mean (SD)	19.8 (2.6)	20.7 (3.2)	0.4
Total anastomoses, mean (SD)	17.8 (10.3)	16.1 (6.3)	0.6

339 An evolving epidemic: xylazine incidence in opioid-positive drug screens in an inpatient pregnant population

Cassandra Trammel[1], Vahid Azimi[2], Nandini Raghuraman[2], Ebony B. Carter[3], Antonina I. Frolova[2], Anthony O. Odibo[2], Megan L. Lawlor[2], Jeannie C. Kelly[3]

[1]Washington University in St.Louis, St. Louis, MO, [2]Washington University School of Medicine in St. Louis, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

OBJECTIVE: Opioid use disorder (OUD) is associated with significant maternal morbidity. Recent reports have highlighted the rise of xylazine, a non-opioid veterinary sedative, in the nonprescribed fentanyl supply. Outside of pregnancy, complications of xylazine exposure may include naloxone-refractory respiratory depression, prolonged loss of consciousness, and skin ulcers. The frequency with which pregnant patients with opioid use disorder are exposed has not been characterized. We sought to describe the incidence of xylazine detected in urine drug screens (UDS) from obstetric patients admitted to a labor unit.

STUDY DESIGN: We performed a cross sectional study of all UDS results from an inpatient obstetric unit at an urban tertiary care center from December 2022, when xylazine was added to the detection panel, through July 2023. Urine drug screening is performed based on verbal screening of all admitted patients. The trend of opioid-positive urine drug screens also positive for xylazine from December to July was measured with the Cochran-Armitage test.

RESULTS: Of 138 UDS sent, 98 (71%) were positive for nonprescribed substances. Of positive UDS, 36 (37%) were positive for nonprescribed opioids, and of these, 16 (44%) were positive for xylazine. The trend of UDS positive for opioids that are also positive for xylazine increased significantly over time (Figure 1, p=0.009), from 0% in the first month to 100% in the last month.

CONCLUSION: In less than one year, xylazine has significantly increased in prevalence among patients admitted to an obstetric inpatient unit who have UDS positive for nonprescribed opioids. This is consistent with national trends, with increasing rates of xylazine identified on post-opioid overdose autopsy. These results underscore the critical need to further study the impact of xylazine on obstetric outcomes.

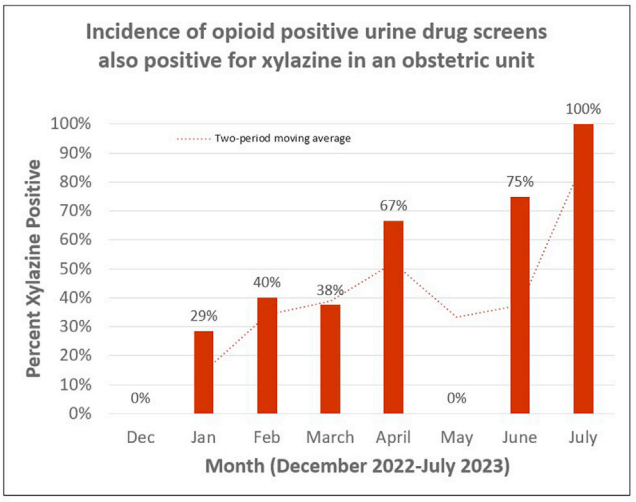

Figure 1: Incidence of xylazine positivity in opioid-positive urine drug screens by month. Testing began December 2022. Statistically significant increase by Cochran-Armitage test, p=0.009.

340 Implementation and clinical impact of evidence-based induction of labor practices

Jourdan E. Triebwasser[1], Leah Mitchell Solomon[2], Joanne M. Bailey[3], Rebecca F. Hamm[4], Michelle Moniz[3], Molly J. Stout[3]

[1]University of Michigan, Ann Arbor, MI, [2]University of MIchigan, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI, [4]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

OBJECTIVE: To assess effectiveness and implementation outcomes after standardizing induction of labor (IOL) practices.

STUDY DESIGN: We conducted a quality improvement project in a high volume, academic medical center to increase utilization of 3 evidence-based IOL practices: 1) dual agent ripening; 2) vaginal misoprostol instead of buccal; 3) early amniotomy (≤ 4 cm). Singletons with intact membranes and initial cervical dilation ≤2 cm were included. Prior cesarean and stillbirth were excluded. We assessed effectiveness (IOL length, cesarean birth) and implementation outcomes (utilization, adoption by admitting services) pre-implementation (PRE; 11/1/21-1/31/22) vs. post-implementation (POST; 3/1/22-4/30/22). Cox proportional hazards models, stratified by parity, and adjusted for age, BMI, dilation, and epidural, were used to test the association between time period and IOL length.

RESULTS: Among 495 patients (PRE, n=293, POST, n=202) there were no differences in baseline characteristics other than epidural use (66.9% vs. 78.2%, p=0.006). IOL length was shorter POST (22.0 vs. 18.3 h, p=0.003) with no difference in cesarean (27.7 vs. 26.7%, p=0.82). Time to delivery was faster POST for nulliparas (HR 1.5, 95% CI 1.2-1.9; **Figure**) and multiparas (HR 1.5, 95% CI 1.1-2.0). Use of each practice increased POST: dual ripening (31.1 vs. 42.6%, p=0.009), vaginal misoprostol (34.5 vs. 68.3%, p< 0.001), and early amniotomy (19.1 vs. 31.7%, p=0.001). Adoption differed across services: Obstetrics increased use in all practices (32.1 vs. 43.5%, p=0.02; 37.1 vs. 70.8%, p< 0.001; 20.4 vs. 33.9%, p=0.003, respectively); Family Medicine increased use of dual ripening (0.0 vs. 40.0%, p=0.001) and vaginal misoprostol (11.1 vs. 60.0%, p=0.001), but not early amniotomy (11.1 vs. 20.0%, p=0.43); and Midwifery did not increase use of any practice (44.4 vs. 36.8%, p=0.57; 35.6 vs. 52.6%, p=0.20; 17.8 vs. 21.1%, p=0.76, respectively).

CONCLUSION: Standardizing IOL practices leads to shorter IOL without increasing cesarean birth providing the opportunity to improve obstetric outcomes, decrease morbidity, and maximize system efficiency.

341 Amylase and phospholipase A2 levels in human amniotic fluid of fetuses with open spina bifida

Tess N. van Schoor[1], Matthew E. Thornton[2], J. C. Rodman[3], Arlyn Llanes[4], Catherine Hamzeh[4], R. H. Chmait[5], Brendan Grubbs[6]

[1]Keck School of Medicine, Los Angeles, CA, [2]Maternal Fetal Medicine Division, Department of Obstetrics and Gynecology, Keck School of Medicine, Los Angeles, CA, [3]USC CTSI, Los Angeles, CA, [4]University of Southern California, Los Angeles, CA, [5]Los Angeles Fetal Surgery, Los Angeles, CA, [6]Los Angeles General Hospital + USC Medical Center, Los Angeles, CA

OBJECTIVE: Fetuses with open spina bifida (OSB) incur ongoing neurologic injury throughout gestation. We previously demonstrated elevated levels of Phospholipase A2 (PLA2) and Amylase in the amniotic fluid (AF) of a fetal rat Retinoic Acid Induced (RA) OSB model. The objective of this study was to determine whether levels of amylase and PLA2 were similarly elevated in the AF of human fetuses with OSB.

STUDY DESIGN: AF was collected at the time of diagnosis (Early 21-22 weeks, n=6) or immediately prior to fetoscopic repair (Late 26-27 weeks, n=7). Control samples (21-22 weeks, n=3) were amniocentesis samples collected for advanced maternal age and did not have OSB. Activity levels of amylase and PLA2 were measured in control, early gestation, and late gestation groups utilizing commercial assay kits. The Wilcoxon-Signed Rank Test was used to compare amylase activity in the control vs. early groups and the early vs. late groups. A one-sided T-Test was used to compare PLA2 activity the control vs. early groups and the early vs. late groups.

RESULTS: The Amylase Activity of the early group (median=0.204 nmol/ml/min) was not significantly different from that of the control group (median= 0.183 nmol/ml/min); p=0.4, but was significantly less than that of the Late Group (median=0.253 nmol/ml/min); p< 0.0045. The PLA2 Activity of the early group (mean=3.84 nmol) was not significantly different from that of the control group (mean=4.1 nmol); p=0.3, and was not significantly less than that of the Late Group (mean=5.09 nmol); p=0.892.

CONCLUSION: Amylase activity levels in the AF of human fetuses with MMC appear to increase throughout the 2nd trimester. The increase in PLA2 activity did not reach statistical significance and may be due to a lack of power. These, as well as other neurotoxic enzymes may contribute to the "second hit" of OSB and suggest the RA rat as a valid model for the human defect.

342 Fetal outcomes in growth restriction with expansion of abdominal circumference diagnostic criteria

Kyle Varon[1], Olivia Peters[2], Heath A. Davis[2], Boyd Knosp[3], Stephen K. Hunter[1], Aaron Trask[4], Donna A. Santillan[2], Mark K. Santillan[2]

[1]University of Iowa Hospitals and Clinics, Iowa City, IA, [2]University of Iowa, Iowa City, IA, [3]University of Iowa Carver College of Medicine, Iowa City, IA, [4]The Ohio State University College of Medicine, Columbus, OH

OBJECTIVE: This retrospective cohort study assessed the effect of changing fetal growth restriction (FGR) diagnostic criteria to include abdominal circumference (AC) less than the 10th %ile on the occurrence of adverse neonatal outcomes (ANO) in a single institution. We hypothesized that this protocol change would not affect ANO rates.

STUDY DESIGN: We utilized the Intergenerational Health Knowledgebase (IHK) which extracts clinical data from electronic health record with high fidelity (IRB# 201902830). Demographic and pregnancy outcome data were extracted for birth parents and babies. AC< 10th percentile was added as diagnostic criteria for FGR on 6/22/20. Pregnancy episodes with a known diagnosis of FGR were categorized as pre-protocol (delivered prior to 6/22/20) and post-protocol (delivered after 1/1/21). Pre-protocol criteria included EFW< 10%ile and/or AC< 5%ile. Post-protocol criteria included EFW< 10%ile and/or AC< 10th %ile. A combined ANO variable included admission to NICU, PTX, RDS, IVH, PVL, NEC, Pulm HTN, sepsis, and HIE. T tests, chi square, and logistic regression analyses were performed with a=0.05.

RESULTS: 1548 pre-protocol and 242 post-protocol unique FGR pregnancies were identified. Maternal age, race, rate of hypertensive disease in pregnancy (HDP) and diabetes were similar between cohorts. Birthweights, 1 and 5 min. APGARs, gestational age of delivery (37.1 vs. 36.6, p=0.9), and ANO rate (49% vs. 43%, p=0.1) were also similar between groups. When controlling for HDP, DM, and maternal age, change in FGR diagnostic protocol (OR 0.795, P = 0.13) was not associated with increased development of ANO in FGR fetuses. The model did identify a statistically significant increase in ANO among FGR neonates where HDP was also present in the pregnancy episode (OR 2.12, P < 0.001).

CONCLUSION: Expansion of FGR diagnostic criteria to include AC< 10th %ile demonstrated no difference in fetal outcomes despite increased surveillance and ultrasound burden. Further work to evaluate the cost effectiveness of this strategy will further elucidate the potential effects of this FGR diagnostic criteria change.

343 Timing of delivery in women with pre-existing hypertension and stillbirth risk: A retrospective population-based study

Èvicka Veilleux[1], Nicholas Czuzoj-Shulman[2], Haim A. Abenhaim[3]

[1]McGill University, Brossard, QC, [2]Jewish General Hospital, QC, [3]Jewish General Hospital, Montreal, QC

OBJECTIVE: To evaluate the risk of stillbirth at term, in women with pre-existing hypertension, to determine if earlier induction of labour (IOL) decreases the risk of stillbirth.

STUDY DESIGN: A retrospective population-based cohort study was conducted using the CDC's Fetal Death Public Use Files and linked data from Period Linked Birth-Infant Death Public Use Files, including all births between 2010 and 2019. Maternal and fetal outcomes among deliveries to women with pre-existing hypertension (exposed) were compared to women without pre-existing hypertension (unexposed). Multivariate logistic regression models, adjusted for maternal age, race, education and smoking were used to estimate the risk of stillbirth and the risk of IOL at each gestational age, as of 37 weeks, compared to women without pre-existing hypertension at the same gestational ages.

RESULTS: Of 39,757,769 births in our cohort, 98.42% were to women without pre-existing hypertension and 1.58% were to women with pre-existing hypertension. Pre-existing hypertension was associated with an increased risk of adverse maternal and fetal outcomes. The incidence of stillbirth amongst the general population experienced a marginal decrease from 1.43 in 2010, to 1.21 in 2019. The risk of stillbirth increased with gestational age in women with pre-existing hypertension compared to women without, of the same gestational age. The most pronounced rises in risk began at 39 weeks (OR 1.92, 95% CI 1.64-1.24), 40 weeks (OR 1.86 95% CI 1.50-2.35) and 41 weeks (OR 2.74, 95% CI 2.30-3.27). In turn, rates of IOL amongst women with pre-existing hypertension were most elevated between 37 and 39 weeks: 37 weeks (OR 2.46, 95% CI 2.43-2.49), 38 weeks (OR 2.84, 95% CI 2.81-2.87), 39 weeks (OR 2.42, 95% CI 2.39-2.44).

CONCLUSION: While women with pre-existing hypertension, with no other complications at term, have increased risk of stillbirth as of 39 weeks, American practice has developed such that this population is undergoing preventive IOL earlier (37-39 weeks), reflecting an overall decrease in stillbirths.

344 Adverse pregnancy outcomes and predicted 30-year risk of maternal cardiovascular disease 2-7 years after delivery

Kartik Venkatesh[1], Sadiya S. Khan[2], Janet M. Catov[3], Jiqiang Wu[1], Rebecca B. McNeil[4], Victoria Pemberton[5], Philip Greenland[6], Judith H. Chung[7], Lisa D. Levine[8], Lynn M. Yee[9], Hyagriv Simhan[10], David M. Haas[11], George R. Saade[12], Noel Bairey Merz[13], William A. Grobman[14]

[1]Ohio State University, Columbus, OH, [2]Northwestern University Feinberg School of Medicine, Oak Park, IL, [3]Magee-Womens Research Institute, Pittsburgh, PA, [4]RTI, Durbam, NC, [5]National Institutes of Health, Bethesda, MD, [6]Northwestern University Feinberg School of Medicine, Evanston, IL, [7]UC Irvine Health, Orange, CA, [8]University of Pennsylvania, Philadelphia, PA, [9]Northwestern University, Chicago, IL, [10]University of Pittsburgh, Pittsburgh, PA, [11]Indiana University, Carmel, IN, [12]Eastern Virginia Medical School, Norfolk, VA, [13]Cedars-Sinai Medical Center, Los Angeles, CA, [14]The Ohio State University, Columbus, OH

OBJECTIVE: To determine whether adverse pregnancy outcomes (APOs) are associated with higher 30-year predicted risk of cardiovascular disease (CVD) 2-7 years after delivery.

STUDY DESIGN: This was a secondary analysis from the prospective Nulliparous Pregnancy Outcomes Study-Monitoring Mothers-to-Be Heart Health Study cohort. The primary exposures included APOs modelled individually: abnormal fetal growth (i.e., either SGA (< 10th percentile) or LGA (≥ 90th percentile)), hypertensive disorder of pregnancy (HDP), gestational diabetes (GDM), and preterm birth (PTB) < 37 weeks; and secondarily, we examined the total number of APOs (0, 1, ≥2) that were found to be significantly associated with CVD risk. The primary outcome was high predicted 30-year

CVD risk defined ≥10%; secondarily, we evaluated CVD risk as a continuous measure. Predicted risk was quantified by the Framingham Risk Score for atherosclerotic CVD (i.e., coronary heart disease and/or stroke).

RESULTS: Among 4,299 individuals, 12.8% had an SGA infant, 7.6% had a LGA infant, 13.4% developed HDP, 4.3% developed GDM, and 8.3% had a PTB. At 2-7 years after delivery (median: 2.7 years), the median predicted 30-year ASCVD risk was 2.2% (IQR: 1.4, 3.4). Individuals who experienced HDP (aRR: 1.88; 95% CI: 1.15, 3.07), GDM (aRR: 1.95; 95% CI: 1.10, 3.47), and PTB (aRR: 2.26; 95% CI: 1.32, 3.88) were more likely to have a high predicted risk for CVD (i.e., ≥10%) 2-7 years postpartum. High CVD risk increased with the number of APOs experienced (1: aRR: 2.32; 95% CI: 1.40, 3.85; ≥2: aRR: 3.45; 95% CI: 1.76, 6.76). These results were similar when the predicted probability was analyzed as a continuous outcome. Neither having a LGA nor an SGA infant was associated with CVD risk.

CONCLUSION: Two-to-seven years after a first pregnancy, individuals who had APOs, including HDP, GDM, and PTB, were more likely to have a higher predicted 30-year risk of CVD. High risk status increased with the number of APOs experienced. These results suggest research is needed to examine the value of APO history in CVD risk scores.

TABLE. Association between adverse pregnancy outcomes and predicted 30-year risk of maternal cardiovascular disease 2-7 years after delivery

		Unadjusted analysis[1]	Adjusted analysis[1,2]
Outcome: 30-year CVD risk ≥ 10% (binary)			
	≥10% CVD risk, %	RR (95% CI)	aRR (95% CI)
Abnormal fetal growth vs. AGA			
SGA	0.7	0.41 (0.15, 1.11)	0.48 (0.18, 1.33)

[1]Modified Poisson and linear regression models were used.
[2]Models adjusted for baseline (at cohort enrollment) age, body mass index, smoking status, and health insurance status.
Abbreviations: Adverse pregnancy outcomes (APOs), small-for-gestational-age (SGA), large-for-gestational-age (LGA), appropriate-for-gestational-age (AGA), hypertensive disorder of pregnancy (HDP), gestational diabetes (GDM), and preterm birth (PTB), CVD (cardiovascular disease).
Bolded results were statistically significant finings (p<0.05).

345 Association of county-level WIC enrollment and adverse pregnancy outcomes in the U.S. from 2016-2019

Kartik Venkatesh[1], Xiaoning Huang[2], Natalie Cameron[3], lucia Petito[3], jennifer garner[4], amy Headings[5], William A. Grobman[4], Sadiya S. Khan[6]
[1]Ohio State University, Columbus, OH, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Northwestern University, Chicago, IL, [4]The Ohio State University, Columbus, OH, [5]Mid-Ohio Food Collaborative, Columbus, OH, [6]Northwestern University Feinberg School of Medicine, Oak Park, IL

OBJECTIVE: Food and nutrition insecurity are associated with adverse pregnancy outcomes (APOs). We evaluated, at the county-level, whether changes in WIC enrollment were associated with the rate of APOs among nulliparous individuals eligible for WIC.

STUDY DESIGN: Using U.S. National Center for Health Statistics Natality data between 2016-2019, we conducted a longitudinal, county-level analysis. The exposure was the change in county-level WIC enrollment from 2016 to 2019 (increase [>0%] versus no change or decrease [≤0%]) among those eligible for WIC (i.e., U.S. resident and Medicaid insured). APOs were measured in 2019, and included maternal (CD, HDP, GDM, ICU admission, and transfusion) and infant (PTB < 34 weeks, NICU admission, SGA, and LGA) measures. Hierarchical logistic regression was used and adjusted for baseline county-level mean WIC enrollment and APOs in 2016 and individual-level covariates, including mean age at delivery, and proportion of the population that self-identified as non-Hispanic White, had competed college education, and enrolled in prenatal care in the first trimester.

RESULTS: Among 1,945,914 WIC-eligible nulliparous individuals from 3,120 U.S. counties, the county-level age-standardized rate of WIC enrollment decreased from 2016 (73.1%) to 2019 (66.1%) (average annual percent change, AAPC: -3.2%; 95% CI: -3.7, -2.9). WIC enrollment increased in 27.4% of counties. Compared with counties in which WIC enrollment decreased or did not change, counties in which WIC enrollment increased had lower rates of multiple maternal [GDM (aOR: 0.71; 95% CI: 0.57, 0.89), ICU admission (aOR: 0.47; 95% CI: 0.34, 0.65), transfusion (aOR: 0.68; 95% CI: 0.53, 0.88)], and infant [PTB (aOR 0.71; 0.56, 0.90); NICU admission (aOR: 0.77; 95% CI: 0.60, 0.97)] APOs.

CONCLUSION: As a greater proportion of eligible nulliparous individuals within a county enrolled in WIC, the likelihood of APOs decreased. In an era where WIC enrollment has decreased and food and nutrition insecurity has increased, efforts are needed to increase WIC enrollment among eligible individuals in pregnancy.

TABLE. Association between county-level change (increase versus no change or decrease) in WIC enrollment and adverse pregnancy outcomes[1]

	Unadjusted odd ratios OR (95% CI)[2]	Adjusted odds ratio AOR (95% CI)[3]
Maternal Outcomes		
Cesarean delivery	0.56 (0.37, 0.85)*	1.00 (0.68, 1.48)

346 HDP and GDM and predicted risk of maternal cardiovascular disease 10-14 years after delivery

Kartik Venkatesh[1], William A. Grobman[2], Maged M. Costantine[2], Jiqiang Wu[1], Patrick Catalano[3], Mark B. Landon[4], Denise Scholtens[5], William Lowe[5], Sadiya S. Khan[6]
[1]Ohio State University, Columbus, OH, [2]The Ohio State University, Columbus, OH, [3]Tufts Medical Center, Boston, MA, [4]The Ohio State University Wexner Medical Center, Columbus, OH, [5]Northwestern University, Chicago, IL, [6]Northwestern University Feinberg School of Medicine, Oak Park, IL

OBJECTIVE: To determine whether hypertensive disorders of pregnancy (HDP) and gestational diabetes mellitus (GDM) are associated with a higher 10- and 30-year predicted risk of atherosclerotic cardiovascular disease (ASCVD), as quantified by the Framingham Risk Score 10-14 years after delivery.

STUDY DESIGN: A secondary analysis from the prospective Hyperglycemia and Adverse Pregnancy Outcome (HAPO) Follow-up Study. The exposure (expressed as a multiple dichotomous variable) was HDP alone, GDM alone, or both HDP and GDM, compared with none of these (reference). The primary outcomes were high predicted 10- and 30-year ASCVD risk (composite of fatal and non-fatal coronary heart disease and stroke). We used the Framingham Risk Score defined as ≥7.5% at 10 years and ≥20% at 30 years per current guidelines. Secondarily, we examined predicted ASCVD risk as a continuous measure. Modified Poisson and linear regression models adjusted for baseline covariates: field center, age, BMI, height, smoking and alcohol use, and parity, all measured at the OGTT during pregnancy.

RESULTS: Of 4,432 assessed individuals, the median age was 30.5 and the median BMI was 26.5 at baseline. A total of 8.2% (n=364) developed HDP alone, 11.2% (n=497) developed GDM alone, and 2.5% (N=112) developed both HDP and GDM. At 10-14 years after delivery (median 11.6), individuals with HDP alone (aRR: 1.02; 95% CI: 1.01-1.04) and GDM alone (aRR: 1.02; 95% CI: 1.01-1.04) were at higher predicted 10-year ASCVD risk compared with those with neither HDP nor GDM. Individuals with HDP alone (aRR: 1.01; 95% CI: 1.01-1.03), GDM alone (aRR:1.04; 95% CI: 1.02-1.06), and both HDP and GDM (95% CI: 1.06; 95% CI: 1.01-1.10) were at higher predicted risk of 30-year CVD compared with those with neither HDP nor GDM. These results were similar when modeling ASCVD risk as a continuous percentage (TABLE).

CONCLUSION: Pregnant individuals with HDP and GDM in the HAPO FUS cohort who were 10-14 years after delivery were more likely to be at high predicted risk of ASCVD.

TABLE. Association between HDP and GDM and 10- and 30-year predicted risk of ASCVD

Both HDM and GDM	13.6 (9.8)	6.48 (4.71, 8.25)	3.35 (1.98, 4.73)

Poisson regression with robust error variance and linear regression were used. Missing imputation for covariates was performed.
Models adjusted for maternal variables at oral glucose tolerance test during pregnancy: study field center, age (continuous), BMI (continuous), height (continuous), smoking status (yes/no), alcohol use (yes/no), and parity (0, >1).
Final N=4,432 individuals without chronic hypertension in pregnancy.
Abbreviations: Hypertensive disorders of pregnancy (HDP), gestational diabetes mellitus (GDM), and atherosclerotic cardiovascular disease (ASCVD).

347 Hyperemesis gravidarum: investigating pregnancy outcomes by severity and time of diagnosis

Omri Porgador[1], Eyal Sheiner[2], Gali Pariente[3], Tamar Wainstock[4]
[1]Joyce & Irving Goldman Medical School, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva, Israel., Lehavim, HaDarom, [2]Soroka University Medical Center, Beer-Sheva, HaDarom, [3]Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Klahim, HaDarom, [4]Ben Gurion University, Beer-Sheva, HaDarom

OBJECTIVE: With inconsistencies regarding the possible effect of hyperemesis gravidarum on the course of pregnancy, this research aimed to study the association between hyperemesis gravidarum and pregnancy outcomes, while addressing the trimester of diagnosis and severity of the disease.

STUDY DESIGN: A population-based retrospective cohort study was conducted, including all singleton deliveries of mothers from the largest health maintenance organization in the country, in a single tertiary hospital between the years 1991-2021. Incidence of adverse pregnancy outcomes was compared between pregnancies with and without hyperemesis gravidarum diagnosis, including preterm birth, low birth weight, cesarean delivery, and perinatal mortality. Severe cases were defined as hyperemesis gravidarum with metabolic disturbances. Multivariable Generalized Estimation Equation binary models were used to study the association between maternal hyperemesis gravidarum, trimester of diagnosis and severity, and the studied outcomes while adjusting for smoking, nulliparity, fertility treatments, ethnicity, gender, maternal age, and maternal recurrence in the cohort.

RESULTS: The study population included 232,476 pregnancies, of which 3227 (1.4%) were complicated with hyperemesis gravidarum. Women with hyperemesis gravidarum were more likely to deliver preterm (adjusted OR=1.30, 95%CI 1.14-1.47), a newborn with low birth weight (adj. OR=1.52, 95%CI 1.16-1.98, only if diagnosed in the second trimester), and to have a cesarean delivery (adj. OR=1.22, 95%CI 1.10-1.35). They were less likely to experience perinatal mortality (adj. OR=0.54, 95%CI 0.31-0.93, among mild cases only). A dose-response association was observed between preterm birth and hyperemesis gravidarum severity (Table).

CONCLUSION: Hyperemesis gravidarum is associated with an increased risk for preterm birth, low birth weight, and cesarean delivery, specifically among women diagnosed during the second trimester. However, it is associated with a lower risk for perinatal mortality.

Table. Adjusted* Odds ratios and 95%CI for the association between HG and pregnancy outcomes, by severity and by time of diagnosis

348 Is insufficient prenatal protein consumption a risk for adverse pregnancy outcomes? A prospective multicenter study

Tamar Wainstock[1], Eyal Sheiner[2]
[1]Ben Gurion University, Beer-Sheva, HaDarom, [2]Soroka University Medical Center, Beer-Sheva, HaDarom

OBJECTIVE: During pregnancy, there is an increase in nutritional requirements, including the macronutrient Protein, to maintain maternal metabolism while supporting fetal growth and development. Studies in low and middle income countries have suggested that insufficient protein consumption is associated with low birthweight (LBW) and small for gestational age (SGA). The aim of the

current study was to study the association between insufficient protein consumption and adverse pregnancy outcomes in a high-income country.

STUDY DESIGN: A prospective multicenter cohort study was conducted, in which pregnant women completed a detailed food frequency questionnaire (FFQ) regarding their dietary habits during pregnancy. The adequacy of protein consumption was defined based on the international Recommended Dietary Allowance, which are 1.1 g of protein/kg/day among pregnant women. The following pregnancy outcomes were compared between women with sufficient and insufficient protein consumption (>1.1 or < 1.1 protein/kg/day): SGA, LBW, preterm deliveries (PTD), gestational diabetes mellitus, gestational hypertension and anemia. Multivariable logistic models were used to study the association between the study groups and each adverse pregnancy outcome, while adjusting for pre-pregnancy BMI and maternal age.

RESULTS: The study included 219 women who fully completed the FFQ, of which 29.7% (n=65) were with insufficient protein consumption. Insufficient protein consumption was not associated with socioeconomic status or age, however women with insufficient protein consumption were more likely to be overweight (BMI > 25). Insufficient protein consumption was not associated with the studied adverse pregnancy outcomes (Table), including PTD and LBW. The multivariable models have revealed similar results (adj.OR=2.18; 95%CI 0.69-6.84 and adj.OR=0.70; 95%CI 0.19-2.62, for PTD and LBW respectively).

CONCLUSION: Insufficient protein consumption in high income countries may not be associated with adverse pregnancy outcomes. However, further research is recommended regarding the protein quality rather than its quantity.

Table: Demographic and clinical characteristics and pregnancy outcomes by protein intake

	Insufficient Protein intake (n=65, 29.7%)	Sufficient Protein intake (n=154, 70.3%)	p-value

349 Antenatal aspirin prescription following the United States preventive services task force's (USPSTF) 2021 practice update

Ashten Waks[1], **Gina F. Milone**[2], **Megan C. Oakes**[3]
[1]University of California Irvine, Long Beach, CA, [2]University of California Irvine, Irvine, CA, [3]MemorialCare Miller Children's and Women's Hospital, Long Beach, Long Beach, CA

OBJECTIVE: To compare the odds of antenatal aspirin prescription between patients with moderate risk factors for preeclampsia and patients with high risk factors for preeclampsia, as defined by the USPSTF.

STUDY DESIGN: A retrospective cohort study of all pregnant patients with a documented prenatal care visit prior to 16 weeks' gestation and delivered in our health care system between 1/1/2021 – 12/31/2022. Patients' preeclampsia risk was stratified according to 2021 USPSTF guidance using data from the initial prenatal visit. The primary outcome was appropriate prescription of antenatal aspirin, defined as prescription by 16 weeks' gestation to any patient with 1 high risk factor or 2 or more moderate risk factors for preeclampsia, and assessed using chi-square tests. Odds of correct antenatal aspirin prescription were also compared between risk groups using log-binomial regression.

RESULTS: Of 1325 patients, 167 (12.6%) were found to have 1 or more high risk factor for preeclampsia and 316 (23.8%) were found to have 2 or more moderate risk factors for preeclampsia. Patients with just 1 high risk factor were significantly more likely to be prescribed antenatal aspirin than those with a combination of moderate risk factors (76.1% vs 38.9%, $p < 0.05$). The odds of correct antenatal aspirin prescription were over 5 times greater among patients with at least 1 high risk factor relative to those with multiple moderate risk factors (OR = 5.02, 95% CI 3.30 – 7.66). Adjusted for covariates of maternal age, parity, and blood pressure at the initial prenatal visit, the odds of antenatal aspirin prescription were unchanged between groups (aOR = 5.36, 95% CI 3.32 – 8.63).

CONCLUSION: Since publication of the USPSTF's 2021 practice update on aspirin use for preeclampsia prophylaxis, less than 50% of eligible patients in our health care system have been correctly prescribed this medication. This trend was more pronounced among patients considered moderate risk, highlighting an opportunity for healthcare provider education on the utility of aspirin in this population.

Baseline characteristics of the study population by risk			
	Number (%)[a]

OBJECTIVE: Prior studies of the effects of SARS-CoV-2 (COVID) infection on pregnancy have mixed results. Our objectives were to determine characteristics of pregnant women with and without COVID and maternal and neonatal outcomes

STUDY DESIGN: A prospective observational cohort study of pregnant women (age ≥18 years) between May 2020 and August 2021 was conducted in a single center. COVID infection was diagnosed by the detection of viral RNA on nasal pharyngeal swabs during gestation.

Demographics, gestational age, comorbidities, maternal and newborn outcomes were abstracted. The primary outcome was the rate of COVID infection in pregnancy during the first 18 months of the Pandemic. Secondary outcomes included cesarean delivery (CD), hospital admission, and preeclampsia; newborn outcomes included prematurity, NICU admission, and evidence of vertical transmission.Continuous variables were analyzed using t-tests and categorical variables were tested by Chi-square.

RESULTS: Among 916 participants, 114 (12.3%) were diagnosed with COVID infection (Table 1). Women who contracted COVID infection were more likely to be Hispanic (6.7% vs 40.1%, $p < 0.001$); have a BMI ≥ 35 (35.0% vs 22.9%, p=0.005); although the mean BMI was similar (35.1 ± 7.9 vs, 33.2 ± 6.9, p=0.06). There were no differences in comorbidities, pregnancy complications, CD, or preterm birth (PTB). Women with symptomatic COVID infection were more likely to be admitted to the ICU. No newborns had evidence of vertically acquired COVID. However, infants born to COVID infected women were more likely to fail their hearing screening exam (11.3% vs 2.5%, $p < 0.001$).

CONCLUSION: Perinatal infection with COVID infection did not increase CD, PTB, nor obstetrical complications. Symptomatic women had higher rates of ICU admissions. Newborn outcomes were generally good. However, the higher rates of failed newborn hearing tests following maternal COVID infection is concerning as the virus has been reported to cause adverse neurological sequalae in adults. This new finding requires confirmation and followup. If confirmed, early identification and treatment is critical.

351 Is periodontitis such a big hit to pregnancy outcomes? a bench study in rat model

Xiaoxu Liu[1], Issotina Zibrila Abdoulaye[2], Meng Yuan[2], Chunfang Li[2], Jinjun Liu[2], Zheng Wang[2]

[1]Xi'an Jiaotong University, X'i'an, Shaanxi, [2]Xi'an Jiaotong University, Xi'an, Shaanxi

OBJECTIVE: Periodontitis (PD) is plaque bacteria-induced chronic inflammation and contributes numerous systemic diseases. Previous epidemiological studies and meta-analysis also reported the association between PD and adverse pregnancy outcomes, however, few mechanistic studies have been conducted. Here we aimed to investigate the mechanistic actions of PD in pregnancy outcomes.

STUDY DESIGN: Forty female SD rats were randomly divided into Control or PD group, the rats in PD underwent four-week bilateral ligation of maxillary second molar. Fetal weight, litter size, placental weight, ultrasound blood flow signals were recorded. The offspring was also subjected to the Morris Water Maze test and placental tissues were performed with CD31and CK-7 staining.

RESULTS: Compared with Control, maternal blood pressure, fetal weight , litter size, and long-term learning and memory ability of offspring in PD group showed declining tendencies but didn't achieve any statistical significances. However, significant alterations in uteroplacental unit were observed: PD group exhibited increased placental weight, decreased CD31 and CK-7 intensity in mesometrial triangle of placenta, suggesting impaired trophoblast invasion and defective angiogenesis; ultrasound examination revealed steady blood flow signal in uterine artery but significantly increased systolic/diastolic velocity (S/D) values in umbilical artery and fetal middle cerebral artery in PD group, indicating compromised fetoplacental perfusion.

CONCLUSION: In current study, we didn't observe any PD-induced significantly detrimental effects on pregnancy outcomes. Nevertheless, our data showed that PD were associated with pathological features in placenta and defective perfusion in fetoplacental unit. The current study, while preliminary and limited, gives us a hint that PD may be a potential risk factor to good pregnancy outcomes.

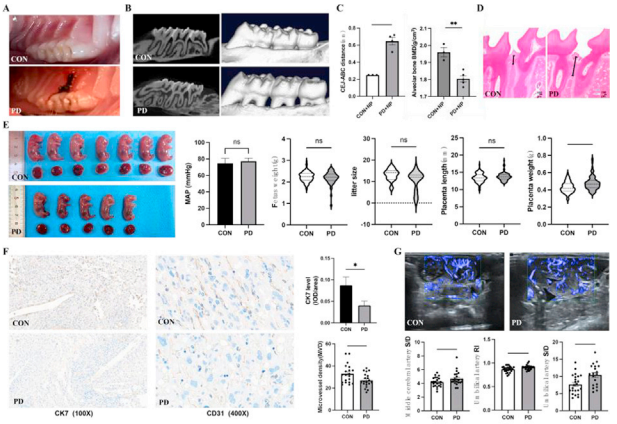

Figure1: A: Gingival manifestations in the CON and PD groups. (CON) Control group; (PD) Periodontitis group. B: The maxillary alveolar bone of CON and PD Nonpregnant rats were taken micro-computed tomography (micro-CT) scan. On the right panel, there is the 3D reconstruction of maxilla. C: Results are expressed as mean ± standard error of the distance of cementum-enamel junction to alveolar bone crest in mm and alveolar bone mineral density obtained by micro-CT. D: HE staining in maxilla of CON and PD Nonpregnant rats. E: Morphology and weight of the fetus and placenta in the two groups of rats and results of blood pressure in pregnant rats. F: Immunohistochemical staining of CK7 in the interstitial triangle of the uterus and CD31 in the placenta tissue of pregnant rats. G: The RI and S/D of fetal umbilical artery and S/D of fetal middle cerebral artery were measured by Aplio i900.

352 Remote blood pressure monitoring during pregnancy: Comparing patient engagement between connected and unconnected device users

Mia Charifson[1], Timothy Wen[2], Bonnie Zell[1], Priyanka Vaidya[1], Cynthia I. Rios[3], Funsho Fagbohun[3], Isabel Fulcher[4]

[1]Delfina Care Inc., San Francisco, CA, [2]University of California, San Francisco (UCSF), San Francisco, CA, [3]Center for Women's Health, TX, [4]Delfina Care, Sunnyville, CA

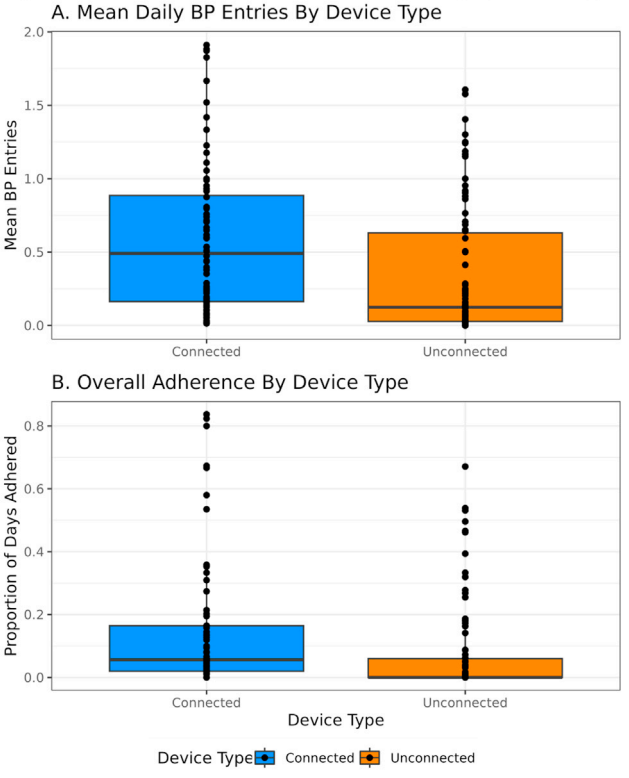
OBJECTIVE: Remote patient monitoring (RPM) for blood pressure (BP) is increasingly used for monitoring patients with hypertensive disorders of pregnancy (HDP). Connected RPM devices automatically sync values at the time of measurement, unlike unconnected devices, which require the patient to manually record values after measurement. It is unclear if connected devices have advantages over existing modalities. We sought to compare patient engagement with BP RPM between connected and unconnected devices.

STUDY DESIGN: In January 2023, Delfina Care, a comprehensive pregnancy care platform, was launched for pregnant patients at a community practice in Texas. Eligible patients were initially provided unconnected BP RPM devices, requiring patients to manually log BP measures in the Delfina Care patient application. In April 2023, connected BP devices were introduced, which automatically synchronized measures to the application. Data on the number of measures recorded and patient adherence (at least 2 BP measures/day for the duration of their pregnancy) were collected. Poisson and logistic regressions were fit to model the effect of device type on the number of BP measures and adherence, respectively. Both models controlled for relevant confounders (age, parity, weeks since enrollment, primary clinic and preferred language) and included a random effect for repeated measures from patients.

RESULTS: A total of 4,381 BP measures were recorded from 152 patients. Patients with connected devices had more mean entries/day (0.57 vs. 0.35) and higher adherence rates (15% vs. 8%) compared to those with unconnected devices (Figure 1). Adjusted analyses noted 2.28 (95% CI: 1.44-3.61) times more BP measure per day and 6.28 (95% CI: 2.62-15.05) higher odds of adherence among connected versus unconnected device users.

CONCLUSION: Patients with connected devices entered more BP measures per day and had higher adherence to the RPM protocol. These findings suggest that automated recording facilitates RPM of BP and ultimately has the potential to improve care among pregnant patients at high risk for HDP.

Figure 1: Remote Blood Pressure (BP) Monitoring by Device Type



Caption: The boxplot shows the median for each group as the black horizontal line and the interquartile range for each group as the upper and lower bound of the box.

353 Changing labor unit culture and cesarean delivery: a prospective study

Emily White VanGompel[1], Lavisha Singh[2], Althea Bourdeau[3], Elizabeth S. Langen[3], Lisa Kane Low[3]

[1]NorthShore University HealthSystem, Chicago, IL, [2]NorthShore University Health System, Evanston, IL, [3]University of Michigan, Ann Arbor, MI

OBJECTIVE: To assess the association between maternity unit culture change and improvement in hospital nulliparous, term, singleton, vertex cesarean birth (NTSV CB) rates.

STUDY DESIGN: Clinicians at 69 Michigan birthing hospitals participating in the Obstetrics Initiative (OBI) funded by Blue Cross Blue Shield of Michigan were invited to complete the Labor Culture Survey (LCS) in 2020 and 2022 as a part of a statewide initiative to lower the NTSV CB rate.The LCS includes 28 Likert-style items covering 7 subscales measuring individual attitudes, beliefs and perceptions of unit norms. We examined the relationship between changing LCS scores and reduction of the NTSV CB rate. Excluding hospitals with a 2020 NTSV CB rate below the Healthy People 2030 (HP2030) goal (≤23.6%) we defined "successful" hospitals as those that either (a) achieved the HP2030 goal, or (b) reduced their NTSV CB rate by ≥5 percentage points by 2022. We compared differences in LCS scale means using Wilcoxon rank sum tests.

RESULTS: 57 hospitals participated in the LCS both years, 44 (77%) of which had an NTSV CB rate above the HP2030 goal in 2020. Of these, 8 met criteria for "successful" hospital designation. There were no significant baseline differences in LCS scores between groups. In 2022, successful hospitals had significantly lower fear of vaginal birth (Fear) and significantly higher estimation of unit microculture supportive of vaginal birth (Table 1). Fear decreased over time at successful hospitals (-0.07, 95% CI -0.16 to 0.02, p< .05) and increased at unsuccessful hospitals (0.04, 95% CI -0.01 to 0.09, p< .05).

CONCLUSION: Over the two year period, decreasing clinicians' fear of vaginal birth was most predictive of successfully improving NTSV CB rates. Clinicians' fear, as a barrier to change, may impact the success of initiatives to safely reduce NTSV CB rates and should be considered in hiring decisions, training activities, and peer-support processes.

2022 Labor Culture Survey subscale scores by Hospital Success in Reducing NTSV CB Rates

	Unsuccessful	Successful	
LCS Subscale	Mean (95% CI)	Mean (95% CI)	P-value
Best Practices	3.16 (3.11-3.21)	3.17 (3.01-3.34)	0.82
Fear	1.44 (1.40-1.49)	1.35 (1.28-1.42)	**0.04**
Unit Microculture	2.72 (2.67-2.78)	2.87 (2.70-3.04)	**0.02**
Physician Oversight	3.10 (3.05-3.15)	3.06 (2.93-3.20)	0.50
Maternal Agency	2.82 (2.75-2.88)	2.76 (2.57-2.94)	0.55
Cesarean Safety	1.86 (1.82-1.91)	1.93 (1.81-2.06)	0.46

354 Invasive testing for abnormal NIPT before and after the texas heartbeat act

Anne H. Mardy, Rosemary Rogers, Madeline Whitney
University of Texas at Austin, Dell Medical School, Austin, TX

OBJECTIVE: Texas passed the "Texas Heartbeat Act", also known as Senate Bill 8, in 2021, which effectively banned abortions in the state of Texas after a fetal heartbeat is detected. This law was enacted on September 1st, 2021. Whether this law has impacted patient decision-making regarding invasive testing is unknown. We sought to determine the rate of uptake of invasive testing after an abnormal cell free DNA (cfDNA) before and after the enactment of the Texas Heartbeat Act on September 1st, 2021.

STUDY DESIGN: This was a retrospective cohort study of all genetic counseling visits for an abnormal cfDNA at our institution in Austin, Texas between 2019-2022. Information regarding demographics, abnormal cfDNA results, invasive testing, ultrasound anomalies, and pregnancy outcomes was collected. Chi square tests were used to compare groups before and after September 1st, 2021.

RESULTS: 146 patients had genetic counseling visits for an abnormal NIPT between 2019-2022, 81 were done prior to September 1, 2021, and 65 after. Patient demographics were similar between groups, including maternal age, abnormal cfDNA result, language and public or private insurance. The rate of invasive testing did not change after the Texas Heartbeat Act (44% before, 37% after, p value 0.21). The type of invasive testing and the rate of pregnancy terminations also did not change. When stratifying by insurance status (public versus private), the rate of invasive testing and pregnancy termination did not change after the law was passed.

CONCLUSION: Restrictive laws in Texas have not changed the likelihood of patients to undergo invasive testing in our population. The rate of terminations for abnormal pregnancies also has not changed, including for those using public insurance or who are uninsured.

Table 1: Demographics and Outcomes

	Pre- Sept 1, 2001 (n=81)	Post- Sept 1, 2001 (n=65)	p-value
Age at EDD (mean, range)	34 (29-39)	33 (26-37)	0.33

355 Body composition vs. traditional weight and BMI for assessing hypertensive disorders of pregnancy (HDOP) risk

Tenisha Wilson[1], Heather Barrera-Ramirez[2], Sierra Parkinson[2], Abbie Smith-Ryan[2], Ebony B. Carter[3], Tracy Manuck[2]
[1]Johns Hopkins, Durham, NC, [2]University of North Carolina, Chapel Hill, NC, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

OBJECTIVE: Clinical history (hx) and BMI are established risk factors for HDOP. We sought to evaluate if incorporation of body composition parameters improves HDOP prediction compared to traditional clinical hx and weight/BMI.

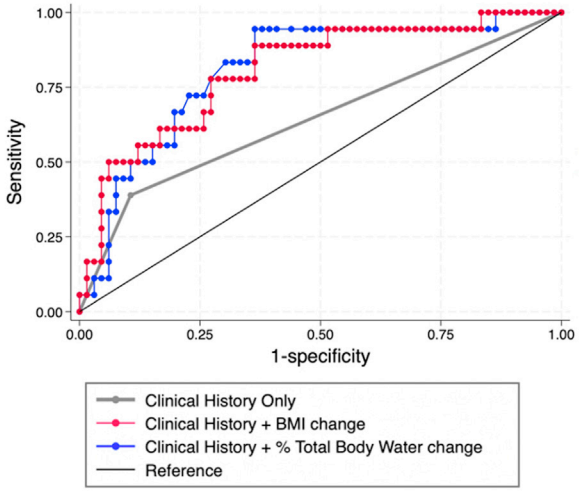
STUDY DESIGN: Primary analysis of a prospective cohort. Pregnant individuals at high risk for medically-indicated or spontaneous PTB were recruited from a MFM outpatient clinic, 2021-2023. Direct segmental multi-frequency bioelectrical impedance analysis technology measured each participant's body composition (% body fat, skeletal muscle mass, total body water, lean body mass) up to 4 times during pregnancy using the non-invasive InBody 270 scale-type device. Those with ≥ 2 InBody measurements were included in this analysis. The primary outcome was development of HDOP. Logistic regression models were constructed to select the top: (1) clinical hx (2) clinical hx + weight/BMI; (3) clinical hx + body composition parameters to predict HDOP. Area under the receiver operating

characteristics curves (AUC) were used to select the model that best predicted HDOP.

RESULTS: 88 study participants were included; 18 (20.5%) developed HDOP. The cohort was racially and ethnically diverse (38% Black, 9% Latinx); most (93%) were multiparous. First InBodys were at a median 18.2 (IQR 14.7-22.4) wks' and last Inbodys were at a median 29.1 (IQR 25.3, 32.7) wks.' The most predictive clinical factor for HDOP was hx of preeclampsia (AUC 0.64, 95% CI 0.52, 0.76). The most predictive weight/BMI factor was BMI change between the first & last InBody; adding this to hx of preeclampsia improved model prediction (AUC 0.809, 95% CI 0.694, 0.923) vs. clinical hx, p=0.009. The most predictive body comp factor was total body water change between the first & last InBody; adding this to hx of preeclampsia also improved model prediction (AUC 0.816, 95% CI 0.706, 0.926) vs. clinical hx, p=0.003, Figure. The BMI and total body water models similarly predicted HDOP (p=0.93).

CONCLUSION: Adding mid-pregnancy changes in BMI or total body water to clinical factors significantly improves prediction of HDOP beyond clinical factors.

Figure. Receiver operating characteristic (ROC) curves, comparing sensitivity vs. 1-specificity, for the prediction of hypertensive disorders of pregnancy.



***BMI change** = BMI as measured at last InBody during pregnancy minus BMI as measured at first InBody during pregnancy
***% Total Body Water change** = % Total Body Water as measured at last InBody during pregnancy minus % Total Body Water as measured at first InBody during pregnancy
- Median gestational age of first InBody = 18.2 (IQR 14.7, 22.4) weeks
- Median gestational age of last InBody = 29.1 (IQR 25.3, 32.7) weeks

356 Changes in maternal body composition parameters across gestation vary by prepregnancy BMI

Tenisha Wilson[1], Sierra Parkinson[2], Heather Barrera-Ramirez[2], Abbie Smith-Ryan[2], Ebony B. Carter[3], Tracy Manuck[2]
[1]Johns Hopkins, Durham, NC, [2]University of North Carolina, Chapel Hill, NC, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

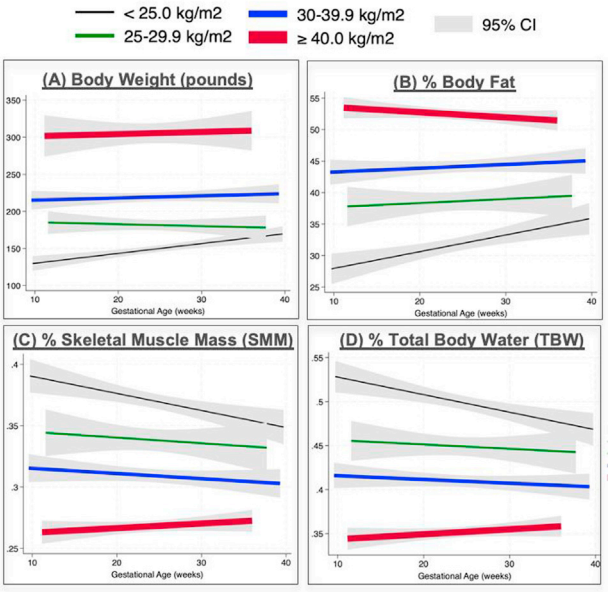
OBJECTIVE: Obesity and excessive gestational weight gain are established risk-factors for multiple adverse perinatal complications, but the pathophysiology underlying these risks is poorly understood. We sought to evaluate whether the pattern of weight gain and potential changes in body composition throughout pregnancy varies by pre-pregnancy BMI.

STUDY DESIGN: Primary analysis of a prospective cohort. Pregnant individuals at high risk for medically-indicated or spontaneous PTB were recruited from a single MFM outpatient clinic, 2021-2023. Direct segmental multi-frequency bioelectrical impedance analysis technology was used to measure each participant's body composition up to 4 times during pregnancy using the non-invasive InBody 270 scale-type device. Participants were grouped by pre-pregnancy BMI category (normal < 25, overweight 25-29.9, obese 30-39.9, morbidly obese ≥ 40 kg/m2) and body composition parameters were compared. Data were analyzed by fixed-effects linear regression accounting for varying numbers of observations per subject.

RESULTS: 284 InBody assessments were obtained from 153 subjects (24% normal weight, 22% overweight, 33% obese, and 21% morbidly obese). The population was racially (36% Black) and ethnically (20% Latinx) diverse. Initial InBody assessments occurred at a median 19.0 (IQR 15.4-24.7) weeks'; most (57%) were obtained between 14-28 weeks'. Body weight and composition varied significantly across gestation and by BMI category (Figure). Patients with normal BMIs had increased % fat as pregnancy progressed, but had reduced % skeletal muscle mass and % total body water (p< 0.001). In contrast, those with morbid obesity had increased % total body water and % skeletal mass, accompanied by reductions in % body fat as pregnancy progressed (p< 0.001).

CONCLUSION: Pregnancy is associated with distinct shifts in body composition that vary by pre-pregnancy BMI among individuals at high-risk for adverse pregnancy outcomes. An improved understanding of how pregnancy physiology differs by BMI may provide key insight into obesity-mediated disease associations and morbidities.

Figure. Body weight and body composition (fitted values) across gestation among patients at high risk for medically indicated and/or spontaneous PTB, as assessed by segmental multi-frequency bioelectrical impedance scale device (InBody 270), stratified by pre-pregnancy BMI.



357 Physical activity and pregnancy outcomes among the nuMoM2b cohort

Lauren Witchey[1], Madushka Y. De Zoysa[1], Jenny Chang[2], Argyrios Ziogas[3], Robert M. Silver[4], Judith H. Chung[5]
[1]University of California, Irvine, Orange, CA, [2]University of California Irvine School of Medicine, Irvine, CA, [3]University of California Irvine, Irvine, CA, [4]University of Utah Health, Salt Lake City, UT, [5]UC Irvine Health, Orange, CA

OBJECTIVE: To identify socioeconomic factors associated with self-reported physical activity during pregnancy and its impact on composite maternal and neonatal outcomes through a large prospective study

STUDY DESIGN: This is a secondary analysis of the Nulliparous Pregnancy Outcome Study: Monitoring Mothers-To-Be (nuMoM2b). All subjects participating in the nuMoM2b study were surveyed on whether they were physically active at three separate prenatal visits. Subjects were eligible for this analysis if they responded to this question at all three visits. Those that answered "Yes" at all visits were grouped in the "Consistent Activity" category while the remainder were grouped in the "Limited Activity" category. Delivery complications were grouped into composite maternal morbidity and composite neonatal morbidity outcomes. Statistical analysis included Chi-square, student t-tests, and multivariate logistic regression models.

RESULTS: From the 10,038 subjects enrolled in the NuMoM2b study, 9,057 (90.2%) were eligible for this analysis. Of these subjects, 4,734 (52.3%) were in the "Consistent" group while the remaining 4,323 (47.7%) were in the "Limited" group. Subjects in the "Limited" group were more likely to be from a non-white background (48.3% vs 28.8%, P< 0.0001), have government insurance (34.2% vs 17.1%, P< 0.0001), be below the poverty line (16.4% vs 9.0%, P< 0.0001), and have at most a high school level education (27.0% vs 11.2%, P< 0.0001). The "Consistent" group had a lower proportion of both composite maternal morbidity (44.3% vs 46.8%, P = 0.019) and composite neonatal morbidity (15.6% vs 17.5%, P = 0.011). In multivariate logistic modeling, consistent physical activity remained an independent predictor of composite maternal morbidity but not composite neonatal morbidity.

CONCLUSION: Subjects from socially or demographically disadvantaged groups are more likely to report limited physical activity in pregnancy. Consistent physical activity throughout pregnancy was associated with fewer adverse maternal outcomes but no difference in adverse neonatal outcomes.

Table 1 – Composite Maternal and Neonatal Morbidity Outcomes Compared Between and Predicted by Physical Activity Levels

	Physical activity throughout pregnancy		P-value
	Limited (n = 4323)	Consistent (n = 4734)

358 Is severe maternal morbidity a risk factor for postpartum mental health hospitalization?

Carrie Wolfson, Jessica Tsipe Angelson, Andreea Creanga
Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

OBJECTIVE: To examine rates of hospitalization with a mental health (MH) condition during the first year postpartum among patients with and without severe maternal morbidity (SMM) during delivery hospitalization.

STUDY DESIGN: Data are from the Maryland's State Inpatient Database and include patients with a delivery hospitalization during 2016-2019 (n=261,642). We compare rate of hospitalization with a MH diagnosis at 42 days and 42 days to 1 year postpartum by SMM status during the delivery hospitalization. We use multivariable logistic regression to examine hospitalization with a MH diagnosis (with and without substance use disorders) for patients by SMM status, adjusted for patient sociodemographic characteristics and presence of MH diagnosis during the delivery hospitalization. Analyses are also adjusted for clustering at the patient level for patients with multiple deliveries during the period of analysis. SMM and MH conditions are identified using ICD-10 diagnosis and procedure codes.

RESULTS: Overall, 7,206 patients (2.8%) experienced rehospitalization in the year following delivery. Among patients with rehospitalization, 25.5% (n=1,837) had a MH diagnosis. The rate of hospitalization with a MH diagnosis was 11.3 per 1,000 deliveries at 42 days postpartum and 23.2 at 42 days to 1 year postpartum for patients with SMM compared to 1.7 and 5.4 for patients without SMM during the delivery hospitalization. Patients with SMM had 3.7 times the odds (95% CI 2.8, 4.8) of hospitalization with a MH diagnosis during the first-year postpartum adjusting for age, race, median household income of zip code, primary insurance, urban

residence, and the presence of a MH diagnosis during the delivery hospitalization (Table 1).

CONCLUSION: Patients who experience SMM have a higher odds of hospitalization with a MH diagnosis in the postpartum period. Treatment and support resource listing should be made available to patients upon discharge after delivery, and evidence-based interventions to improve MH should prioritize women with SMM.

359 Hemoglobinopathy screening in the era of expanded carrier screening: is hemoglobin electrophoresis necessary?

Ethan P. Wood, Stephen T. Chasen
Weill Cornell Medicine, New York, NY

OBJECTIVE: ACOG recommendations for hemoglobinopathy screening involve complete blood count with MCV, with hemoglobin electrophoresis recommended for high-risk populations. Expanded carrier screening (ECS) involves testing for mutations associated with hemoglobinopathy. Our objective was to compare detection rates of hemoglobinopathy carriers through the use of electrophoresis versus expanded carrier screening (ECS).

STUDY DESIGN: This is a retrospective cohort study. Participants include patients who underwent concomitant hemoglobin electrophoresis and ECS during their initial prenatal care visit in 2022. In our multiethnic population, electrophoresis is routine. Demographics, electrophoresis, ECS results and MCV were recorded, with microcytosis defined as MCV< 80fL. Those with a known clinical diagnosis of a hemoglobinopathy were excluded. Fisher's exact test was used for statistical comparison.

RESULTS: 506 patients were included. Table 1 describes the sensitivity of screening based on testing strategy. There were 129 hemoglobinopathy carriers (25.5%), including 33 with beta-chain abnormalities, 86 alpha-thalassemia carriers, and 10 who were carriers for both. ECS identified all 129 carriers, while electrophoresis detected abnormal globin chains in 43 carriers (33.5%). Electrophoresis also identified 6 patients with globin chain variants of no clinical significance. Of 96 alpha-thalassemia carriers detected by ECS, 87 were "silent carriers" (aa/a-), and 9 had deletion of two coding genes. Microcytosis was present in all 9 patients with the two-gene deletion. While microcytosis was more common in "silent carriers" (23.0% vs 6.6%; p< .001), most "silent carriers" were normocytic.

CONCLUSION: There was no incremental benefit to hemoglobin electrophoresis in those undergoing ECS. In addition, ECS detects silent alpha thalassemia carriers, most of whom are normocytic. While we did not identify a clinical benefit in identifying "silent carriers", in those at highest risk of severe forms of alpha-thalassemia (including Hemoglobin H disease) ECS is superior to conventional screening with electrophoresis and MCV.

Table 1. Sensitivity of Hemoglobinopathy screening with Hemoglobin Electrophoresis/MCV vs DNA Carrier Screening

	Hemoglobin Electrophoresis	Hemoglobin Electrophoresis + MCV	DNA Carrier Screening
Hemoglobin S	22/22	22/22	22/22
Hemoglobin C	14/14	14/14	14/14
Hemoglobin E	4/4	4/4	4/4
Beta-Thalassemia	3/3	3/3	3/3
Alpha-Thalassemia Carrier (a-/a-)	0/9	9/9	9/9
Alpha-Thalassemia Silent Carrier (aa/a-)	0/87	20/87	87/87

360 A novel method for placental evaluation: Isolation of intact circulating trophoblast cells from maternal circulation

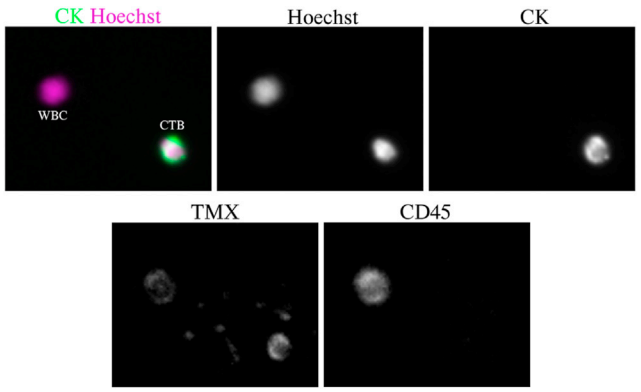
Casey Helmicki[1], Joey Wu[2], Jyoti Goad[1], Alexis Coffer[1], Matt Hart[1], Jon Ladd[1], Jeroen Vanderhoeven[2], Suzanne Peterson[2], Arturo Ramirez[1], Hilary Gammill[1], Eric Kaldjian[1]
[1]RareCyte, Inc., Seattle, WA, [2]Swedish Medical Center, Seattle, WA

OBJECTIVE: We are developing a program to test the hypothesis that gene expression profiles of placental cells in maternal circulation can be used as a biomarker to predict risk of stillbirth and other adverse pregnancy outcomes. As a foundational step in this effort, we developed a method to isolate individual, intact circulating trophoblasts (CTB) from maternal circulation.

STUDY DESIGN: After informed consent, buffy coats were isolated from third trimester pregnancy blood samples using the AccuCyte® sample preparation system. Following immunomagnetic bead enrichment, cells were spread to slides. A 4-parameter manual immunofluorescence (IF) assay was developed with the following markers: Hoechst (nucleus), pan-cytokeratin (CK, trophoblast marker), TMX (supportive trophoblast marker) and CD45 (exclusion marker). Slides were stained and then imaged on the CyteFinder® imaging system. CTBs were defined as nucleated, CK positive, TMX agnostic, and CD45 negative cells. CTBs were then isolated using the CytePicker® Retrieval Module.

RESULTS: The method was developed using the JEG-3 cell line in spike-in experiments. We then evaluated clinical samples from uncomplicated pregnancies (N=3 to date). CTBs were identified in all clinical samples and successfully retrieved from slides. A representative image of a CTB is shown (Figure 1).

CONCLUSION: Identification and isolation of intact CTB from maternal circulation was demonstrated reproducibly from third trimester samples. This methodology is a critical component of our efforts to evaluate CTB gene expression to identify risk of stillbirth and other adverse pregnancy outcomes.



361 Receipt and access to perinatal behavioral health care - experiences of birthing individuals

Brelahn Wyatt-Nash[1], Rasheda J. Vereen[2], Teri Ryals[3], Erin Blevins[3], Caitlin Drumm[4], Gayle Haischer-Rollo[4], Monica A. Lutgendorf[4]

[1]Walter Reed National Military Medical Centers, Bethesda, MD, [2]Carl R. Darnall Army Medical Center, San Antonio, TX, [3]Naval Medical Center San Diego, San Diego, CA, [4]Uniformed Services University of the Health Sciences F. Edward Hebert School of Medicine, Bethesda, MD

OBJECTIVE: Perinatal mental healthcare is critical to ensuring mental wellness and healthy outcomes for birthing individuals and their babies. We conducted a qualitative study to understand how birthing individuals experienced perinatal mental healthcare in the Military Health System (MHS).

STUDY DESIGN: This was an IRB-approved protocol which included Tricare beneficiaries who gave birth within the past five years and were recruited for semi-structured qualitative interviews from Feb 2023 to May 2023. Purposive and snowball sampling was utilized to ensure diverse participation. Interviews were recorded and transcribed with deductive coding, and themes identified until saturation was reached.

RESULTS: A total of 34 individuals completed interviews, with ten main themes identified, these included the importance of support from their obstetric provider and colleagues, the importance of mental health check-ins during pregnancy, challenges accessing care, feelings of dismissiveness regarding mental health needs, inadequate assessment of symptoms, and curtailing of symptoms and situational stress, lack of care postpartum, waiting extended periods for postpartum visits, concealing symptoms to avoid documentation in chart, and support from doulas and support groups postpartum. A common theme included the need to improve screening, "I had to be proactive about it. I don't think we have adequate screening for, at least for postpartum anxiety."

CONCLUSION: The results of our qualitative study indicate variation in mental health care experiences in the perinatal period. While some individuals had prompt and supportive care, others experienced delays and dismissals by their providers. This provides an opportunity to improve perinatal behavioral healthcare in the MHS.

362 Identifying hemolytic disease of the fetus and newborn (HDFN) in a large integrated healthcare system

Fagen Xie[1], Michael J. Fassett[2], Jiaxiao M. Shi[1], Vicki Y. Chiu[1], Theresa M. Im[1], Sunhea Kim[1], Nana Mensah[1], Daniella Park[1], Mary W. Malek[1], Carol Mao[3], Evo Alemao[3], Matthew Molaei[3], Iris Lin[4], Darios Getahun[5]

[1]Kaiser Permanente Southern California, Pasadena, CA, [2]Kaiser Permanente West Los Angeles Medical Center, Los Angeles, CA, [3]Janssen Global Services LLC, Raritan, NJ, [4]Janssen Scientific Affairs LLC, Horsham, PA, [5]Kaiser Permanente Southern California Medical Group, Pasadena, CA

OBJECTIVE: HDFN is a blood disorder caused by maternal-fetal red cell antigen incompatibility. This study aims to identify HDFN cases using electronic health records (EHR) of pregnant patients.

STUDY DESIGN: A retrospective cohort study was performed among pregnant patients receiving obstetrical care at Kaiser Permanente Southern California (01/01/2008–06/30/2022). Using structured (e.g., diagnostic/procedural codes and laboratory results) and unstructured (clinical notes analyzed via Natural Language Processing) data abstracted from EHRs, we extracted HDFN-specific "indicators" (including antibody test, antibody titer, HDFN diagnosis, blood transfusion/intravenous immunoglobulin treatment [IVIG], and jaundice/phototherapy) to identify potential HDFN patients. Chart reviews and adjudication by a clinical investigator were performed on select combinations of indicators for case ascertainment. HDFN due to ABO isoimmunization was excluded. The HDFN frequency and proportion of each combination were calculated.

RESULTS: Among 572,328 pregnancies, indicators for maternal positive antibody test (2.72%), maternal abnormal titer (0.08%), maternal/infant HDFN diagnosis (0.45%), maternal/infant transfusion/IVIG treatment (0.64%), and infant jaundice/phototherapy (35.40%) were extracted. Pregnancies with 8 different indicator combinations (out of 24 total combinations) plus 91 pregnancies from other combinations were chart reviewed. 105 (30.97%) HDFN pregnancies were confirmed (Table). A majority of HDFN pregnancies (n=87) had at least the following indicators: maternal positive antibody test, maternal abnormal titer, and maternal/infant HDFN diagnosis. Those with all 5 indicators had a confirmed HDFN rate of 89%.

CONCLUSION: We successfully identified HDFN patients using a combination of medical indicators extracted from structured and unstructured data that may be used in future pharmacoepidemiologic studies. Traditional indicators (positive antibody test results, high titers, and clinical codes) alone did not identify HDFN pregnancies, highlighting an unmet need for improved practices in HDFN coding.

Table: Accuracy of ascertaining HDFN cases

Indicators*	Total Pregnancies	Total Confirmed HDFN Pregnancies	HDFN Rate (%)
A, B, C, D, E	54	48	88.89
A, B, C, D	5	3	60.00
A, B, C, E	78	36	46.15
A, B, D, E	16	7	43.75
A, C, D, E	26	9	34.62
A, B, D	14	2	14.29
A, B, C	46	0	0.00
A, C, D	9	0	0.00
All other combinations**	91	0	0.00
Overall	339	105	30.97

HDFN: Hemolytic Disease of the Fetus and Newborn (ABO Isoimmunization was excluded)
*A: maternal positive antibody test; B: maternal abnormal titer; C: maternal/infant HDFN diagnosis; D: maternal/infant transfusion/IVIG treatment; E: infant jaundice/phototherapy
**Random sample of chart reviews was selected

363 Characteristics of cesarean deliveries among women with and without COVID-19 infection

Noa Leybovitz-Haleluya[1], Alla Saban[2], Lior Yahav[3], Yael Geva[4], Neta Geva[5], Adi Y. Weintraub[3], Tamar Eshkoli[2], Reli Hershkovitz[6]

[1]Soroka University Medical Center, Meitar, HaDarom, [2]Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Beer Sheva, HaDarom, Israel, [3]Soroka Medical Center, Beer-Sheva, HaDarom, [4]Ben Gurion University, Beer-Sheva,

HaDarom, [5]Soroka University Medical Center, Beer-Sheva, HaDarom, [6]Soroka Medical Center, Omer, HaDarom

OBJECTIVE: Pregnant women infected with the COVID-19 virus have higher risk of developing severe outcomes of the disease compared to nonpregnant women. Furthermore, pregnant women with COVID-19 infection may also be at an increased susceptibility for adverse obstetrical outcomes. Limited data exists regarding how the virus specifically affects the characteristics of cesarean deliveries (CD) among infected women. Therefore, our study aimed to examine the correlation between COVID-19 infection and CD characteristics in a cohort of women who underwent cesarean section.

STUDY DESIGN: We conducted a population-based retrospective cohort study at a tertiary medical center, including all women with singleton pregnancies who underwent cesarean section delivery (CD) between 2020 and 2022. Exclusion criteria consisted of incomplete medical records, multiple gestations, and fetal malformations. The study group included women diagnosed with COVID-19 infection during their hospitalization, while the comparison group comprised women without COVID-19 infection. We examined the differences in CD characteristics between both groups using a multivariable logistic regression analysis to adjust for potential confounders, including emergent CD, parity, ethnicity and gestational age at delivery.

RESULTS: The study population consisted of a total of 4398 women who underwent cesarean delivery and met the inclusion criteria. Among them, 98 women were infected with COVID-19. COVID-19 infection was significant associated with an increased risk of emergent surgery (Table 1, 75.5% vs. 55.1%; p< 0.001). Furthermore , COVID-19 was associated with a prolonged duration of anesthesia and higher proportion of regional anesthesia. Using a multivariable logistic regression analysis, after adjusting for parity, ethnicity and gestational age at delivery, the association between COVID -19 infection and an elevated risk of emergent CD remained significant (adjusted OR 2.45, 95% CI 1.50-3.99; p< 0.001).

CONCLUSION: Among women who underwent cesarean section, COVID-19 infection was found to be predictive of an increased risk of emergent surgery.

364 Aspartate aminotransferase to platelet ratio: predictor of early preterm delivery in women with preeclampsia toxemia

Lior Yahav[1], Noa Leybovitz-Haleluya[2], Alla Saban[3], Adi Y. Weintraub[1], Reli Hershkovitz[4], Tamar Eshkoli[3]

[1]Soroka Medical Center, Beer-Sheva, HaDarom, [2]Soroka University Medical Center, Meitar, HaDarom, [3]Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Beer Sheva, HaDarom, Israel, [4]Soroka Medical Center, Omer, HaDarom

OBJECTIVE: Preeclampsia toxemia (PET) is one of the leading causes of maternal morbidity and mortality worldwide. Inflammatory processes have been suggested as underlying mechanisms that eventually lead to ischemia and vasoconstriction in the affected end organs. Aspartate aminotransferase-to-platelet ratio index (APRI) can be easily calculated from routine blood tests, and is associated with early inflammatory processes. However, the association between APRI, PET and its complications is not well studied. Therefore, our study aims to explore the correlation between the APRI parameter and the risk of early preterm delivery (< 34 weeks of gestation) in women with PET.

STUDY DESIGN: We conducted a population-based cohort study at a tertiary medical center, including all women with singleton gestations who delivered between 2020 and 2022 and were diagnosed with PET. The exclusion criteria included women with an incomplete medical record, multiple gestations, and fetal malformations. The median APRI index of the cohort served as the cut-off point to compare the risk of preterm delivery between the low APRI index group and the high APRI index group. A multivariable logistic regression analysis was used to adjust for confounders, including parity and maternal age

RESULTS: The study population included 513 women with PET who met the inclusion criteria. The median APRI index value of the cohort served as the cutoff point, with 255 women having an APRI index < 0.26 and 258 with an APRI index ≥0.26. A higher APRI index was significantly associated with an increased risk of early preterm delivery (Table 1, 15.1% vs. 9.0%; p= 0.040). Using a multivariable logistic regression analysis, after adjusting for maternal age and parity, the association between early preterm delivery and an APRI index of ≥0.26 remained significant (adjusted OR 1.89, 95% CI 1.09-3.29; p=0.024, Table 2).

CONCLUSION: An APRI index ≥ 0.26 is independently associated with early preterm delivery before 34 weeks of gestation among women with PET.

365 Antepartum multidisciplinary approach improves postpartum pain scores in patients with opioid use disorder

Tiffany Yang[1], Julia Kim[2], Emily H. Stetler[2], Christy Chan[3], Oladunni Ogundipe[2], Chaitali Korgaonkar-Cherala[4], Lauren Stewart[2], Erika Zambrano Alvarez[3], Gabriella Lo Monaco[5], Kimberly Herrera[2], David Garry[3], Diana Garretto[6], Cassandra Heiselman[3]

[1]Stony Brook University, Stony Brook, NY, [2]Stony Brook University Hospital, Stony Brook, NY, [3]Stony Brook Medicine, Stony Brook, NY, [4]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel, [5]Renaissance School of Medicine at Stony Brook University, Stony Brook, NY, [6]Stony Brook University Hospital, E Northport, NY

OBJECTIVE: Pregnancies affected by maternal opioid use disorder (MOUD) face difficulties with postpartum pain control and Neonatal Opioid Withdrawal Syndrome (NOWS). This study aims to determine if prenatal anesthesia consultation for MOUD patients affects maternal and fetal outcomes.

STUDY DESIGN: This is a retrospective cohort study of pregnant patients diagnosed with MOUD who received prenatal care and delivered at an academic institution between January 2017 and July 2023. Subjects were divided into those who received prenatal anesthesia consultation and those who did not. Severe pain on a numerical rating scale was defined as score $\geq$7. Statistical analysis was performed using Mann-Whitney U test with statistical significance defined as $p < 0.05$.

RESULTS: The cohort included 324 women with MOUD. Of these, 15.7% (N=51) received anesthesia consultation and 84.3% (N=273) did not. When comparing pain scores in the first 24 hours postpartum, patients with prenatal anesthesia consultation had statistically significant lower rates of severe pain compared to those who did not (26% vs. 45.3%, p=0.01). Neonatal outcomes were assessed; though NOWS diagnoses were not associated with prenatal anesthesia consultation, NICU admissions were significantly fewer for patients who had anesthesia referral (p=0.01). Factors found to have significant association with prenatal anesthesia consultation were care with an obstetric provider with training in maternal opioid care ($p < 0.01$) and a higher number of prenatal care visits (10.3 vs. 8.9, p=0.02).

CONCLUSION: MOUD patients who received anesthesia consultation in pregnancy reported lower postpartum pain scores than those without consultation. Our data supports multidisciplinary care including prenatal anesthesia consultation for MOUD patients.

366 Investigating the impact maternity care access and social vulnerability on short-interval birth in Tennessee

Megan L. Young[1], Alicia Mastronardi[1], Jill Maples[2], Zach Shelton[2], Nikki B. Zite[1]

[1]University of Tennessee Graduate School of Medicine, Knoxville, TN, [2]University of Tennessee Medical Center, Knoxville, TN

OBJECTIVE: Maternity Care Access (MCA) and levels of community vulnerability can impact contraception access and health outcomes for pregnant-capable individuals. The relationship between maternity care access based on county of residence and short-interval birth (SIB) rates across Tennessee was analyzed.

STUDY DESIGN: Tennessee birth certificate data for 2015-2021 from the Tennessee Department of Health was obtained. Maternal county of residence was coded using the March of Dimes 2018 definitions of MCA (full-access, moderate-access, low-access, or maternity desert) and CDC/ATSDR 2020 social vulnerability index (SVI). Birth intervals of 6-23 months were coded as short-interval birth (SIB). Births were excluded if they were nulliparous or had missing birth interval information. Analysis was completed in SPSS 29.0 and Pearson chi-square tests, Kruskal-Wallis tests, and binary logistic were conducted.

RESULTS: Overall, 319,600 births were included in analysis. SIB was highest in maternity care deserts (24.5%; $p < .001$). There was a statistically significant difference in SVI between MCA levels ($p < 0.001$). Logistic regression was used to analyze the relationship between SIB and SVI. SIB was significantly higher among reported household incomes < $25,000 (27.6%; $p < .001$) and those with a high school diploma or GED (26.8%; $p < .001$). SVI was higher among groups experiencing SIB 2015-2020 ($p < .001$) and remained statistically significant after controlling for age, education, race/

ethnicity, and household income (AOR:1.048; 95%;CI:1.010-1.087, p< .001).

CONCLUSION: Measures of high vulnerability and low healthcare access are associated with higher rates of SIB. County-level data may not be the best indication of health access and outcomes in Tennessee as it is likely patient-level factors vary widely within counties. Future work should investigate MCA and community vulnerability on rates of prenatal contraceptive counseling and obtaining desired contraception.

367 Intrauterine transfusion before and after 34 weeks: procedure-related complications and gestational age at delivery

Ariane C. Youssefzadeh[1], Jinnen Masri[1], Lisa M. Korst[2], Arlyn Llanes[1], Catherine Hamzeh[1], Ramen H. Chmait[1]
[1]University of Southern California, Los Angeles, CA, [2]Childbirth Research Associates, North Hollywood, CA

OBJECTIVE: Maternal red blood cell alloimmunization may be treated with serial intrauterine transfusions (IUT). Few studies are available regarding the safety profile of IUT performed after 34 gestational weeks as a strategy to postpone delivery until term. In patients undergoing their final IUT before and after 34 weeks, the following were assessed: (1) the frequency and type of procedure-related (PR) complications; (2) gestational age (GA) at delivery.

STUDY DESIGN: This was a retrospective study of pregnancies complicated by alloimmunization with suspected fetal anemia treated with IUT at a single center. PR-complications were defined as any of the following within 48 hours of IUT: 1) rupture of membranes or preterm delivery, 2) intrauterine infection, 3) fetal death, 4) fetal compromise resulting in emergency cesarean, or 5) neonatal death. The secondary outcome was GA at delivery. Study outcomes were compared between patients with final IUT before and after 34 gestational weeks.

RESULTS: In total, 94 pregnancies with 237 IUT met inclusion criteria. Among the 94 pregnancies, 59 (62.8%) had their last IUT before and 35 (37.2%) had their last IUT after 34 gestational weeks. Maternal age, parity, GA at first IUT, and the presence of hydrops were similar between the groups. Patients with the last IUT after 34 weeks underwent more IUT per pregnancy (mean 3.2 versus 2.1, $p < 0.01$). There were 3 PR-complications identified (1.3% of procedures and 3.2% of pregnancies); 2 were in the group with their last IUT after completing 34 weeks. There was no difference in PR-complications when comparing pregnancies with their last IUT before and after 34 weeks ($p = 0.28$). Pregnancies with the last IUT after 34 weeks delivered at a later GA (mean 37.1 versus 36.0 weeks, $p < 0.01$).

CONCLUSION: IUT PR-complications were rare. IUT beyond 34 gestational weeks did not appear to pose additional risk to the pregnancy and may mitigate the risk of premature delivery. Future studies are needed to validate these findings and examine cost effectiveness and patient tolerability of additional IUT.

368 Utility of extended cervical length surveillance among asymptomatic patients with prior spontaneous preterm birth

Carolyn Chatterton[1], Alexandra Zetye[1], Tushar Shetty[1], Lina Fouad[1], Ariana Madson[1], Sara Koussa[1], Timothy Immonen[2], Alexander Juusela[1], Bernard Gonik[1]
[1]Wayne State University, Detroit, MI, [2]Detroit Medical Center, Detroit, MI

OBJECTIVE: Controversy exists regarding the benefit of extended cervical length (CL) surveillance with transvaginal ultrasound (TVUS) beyond 23 6/7 weeks among asymptomatic patients with prior spontaneous preterm birth (sPTB).

STUDY DESIGN: This retrospective cohort study evaluated extended surveillance (ES) in asymptomatic patients with prior sPTB. Patients were included if CL surveillance began prior to 23 6/7 weeks and ≥ 2 TVUS CL measurements were performed. Patients with previable

birth, multiple gestations, or major fetal anomalies were excluded. Two groups were identified: routine surveillance (RS) to 23 6/7 weeks, and ES to 32 6/7 weeks. Demographic data and pregnancy outcomes were recorded. The primary outcome was sPTB before 34 0/7 weeks. Chi squared and T-test were used for statistical analysis. A P value < 0.05 was significant.

RESULTS: Between 2017 and 2023, 8653 TVUS CLs were performed, and 333 patients met inclusion criteria. Maternal characteristics were similar. By 23w6d, 273 patients (81.9 %) had a normal CL (nCL), and 60 patients (18.0 %) had a short CL (sCL) < 25 mm. In the nCL group, 93 continued ES and 5 (5.4 %) were then diagnosed with sCL (Figure 1). There is no difference in incidence of sPTB or neonatal outcomes. The sensitivity of ES for sPTB < 34 0/7 weeks is 66%, and the positive predictive value is 40%. The number needed to detect one sCL after 23 6/7 weeks is 19 patients, and 50 patients to detect one sPTB < 34 0/7 weeks. The median time from diagnosis of sCL to delivery is 67 (interquartile range 63 - 100) days. The ES group had significantly more triage visits (mean 1.67 vs 2.11, $p = 0.02$).

CONCLUSION: While ES in asymptomatic patients with prior sPTB may effectively identify patients who will deliver before 34 0/7 weeks gestation, there is no currently accepted intervention to prevent sPTB. Because ES does not predict birth within 7 days of diagnosis, a sCL past 23 6/7 weeks should not direct medication administration for neonatal benefit. If an effective strategy is identified for his population, then surveillance past 23w6d gestation may be a reasonable policy.

369 A customized model versus ultrasound for predicting neonatal birthweight

Yaniv Zipori[1], Einat Borohovich[2], Zeev Weiner[3], Ronit Almog[4], Dana Vitner[5], Ron Beloosesky[6]

[1]Rambam Healthcare Campus, BINYAMINA, Hefa, [2]Rambam Health Care Campus, Haifa, Israel, [3]Rambam Medical Health Campus, Haifa, HaZafon, [4]Rambam Health Care Campus, Hospital, HaZafon, [5]Rambam Medical Health Campus, Toronto, ON, [6]Harbor UCLA Medical Center, Los Angeles, CA

OBJECTIVE: Adequate estimation of fetal weight (EFW) in utero is essential to a healthy pregnancy. Ultrasound-based formulas for EFW have a random error exceeding 15% in five percent of fetuses. As a result of this inaccuracy, under and over-intervention can occur. Herein, we propose a personalized AI model that leverages a linear mixed model to forecast neonatal birthweight.

STUDY DESIGN: Our 2005-2021 dataset included information on births $\geq$ 36 weeks of gestation to mothers with at least one consecutive birth. We excluded cases with anomalies or birthweights below 1,000 g, consecutive birthweights delta $\geq$ 20%, and variables with $\geq$ 30% missing values. The model incorporated key maternal-neonatal demographic and clinical fixed/random variables for each birth order (2 to $>$ 5) to capture individual variability, followed by a train-test split in a 63:37 ratio. The model was then compared to the standard ultrasound EFW performance using the Mean Absolute Error (MAE).

RESULTS: The dataset included 11,453 mothers, accounting for 28,629 births. The key variables used in the model were ethnic and religious background, maternal age, parity, birthweights of previous deliveries, mode of conception, comorbidities, tobacco use, uterine anomalies, gestational age at delivery, and gender. Figure 1a describes the distribution of mothers according to their parity. Figure 1b gives the EFW of the testing model vs. ultrasound. Considering all birthweight ranges, the MAE of our model was comparable to ultrasound performance (232.29 g vs. 234.02 g, p=0.279). In a sub-analysis, the MAE across our model's 3000-4000 g weight range, which represented $>$ 75% of the testing cohort, was significantly lower than the ultrasound performance (209.29 vs. 228.86, p$<$ 0.001). At the extremes of these birthweights, ultrasound performed better than our model.

CONCLUSION: The suggested model's accuracy surpasses the sonographic EFW within specific weight groups, but both methods present comparable predictive abilities when considering the total dataset. Currently, we validate our findings prospectively.

370 Endometriosis complicated pregnancy: site-specific evaluation of characteristics and maternal morbidity

Laurel S. Aberle[1], Caroline Violette[2], Rachel S. Mandelbaum[2], Bonnie Song[2], Shinya Matsuzaki[3], Joseph G. Ouzounian[2], Richard Paulson[2], Koji Matsuo[2]
[1]Los Angeles General Medical Center, Los Angeles, CA, [2]Los Angeles General Hospital + USC Medical Center, Los Angeles, CA, [3]Osaka International Cancer Institute, Osaka, Osaka

OBJECTIVE: To examine pregnancy characteristics and maternal morbidity at delivery among pregnant patients with a diagnosis of endometriosis.

STUDY DESIGN: This cross-section study queried the National Inpatient Sample, examining 17,796,365 deliveries from 2016-2020. Exclusion criteria included adenomyosis and uterine myoma. Endometriosis location was grouped as adnexa, pelvic peritoneum, and other. The outcome measures were clinical and pregnancy characteristics and CDC-defined severe maternal morbidity and postpartum hemorrhage, assessed with multivariable model.

RESULTS: Endometriosis was diagnosed in one in 1,012 patients (n=17,590), with 24.1% in the adnexa, 7.0% in the pelvic peritoneum, 5.5% in other locations, and 1.5% in multi-anatomical locations. In multivariable analysis, the prevalence of pregnancy complicated by endometriosis increased during the study period in both the adnexa and the pelvic peritoneum. The risk of placenta previa was increased in all endometriosis groups, especially in patients with pelvic peritoneal endometriosis (aOR 5.12, 95%CI 3.97-6.61). The risks of placenta accreta spectrum were increased with odds exceeding two-fold for locations other than adnexa and pelvic peritoneum (aOR 3.50, 95%CI 2.10-5.02) and multi-anatomical location endometriosis (aOR 2.87, 95%CI 1.10-7.50). All endometriosis-locations had increased risk for cesarean delivery, with multi-location endometriosis having the highest increase (aOR 42.62, 95% CI 24.91-72.92), followed by adnexal endometriosis (aOR 17.48, 95%CI 15.86-19.27). All endometriosis groups were associated with an increased risk of severe maternal morbidity at delivery, with pelvic peritoneal endometriosis having the highest risk (aOR 2.23, 95%CI 1.74-2.84), followed by adnexal endometriosis (aOR 1.97, 95%CI 1.72-2.25). The risk of postpartum hemorrhage was increased in multi-anatomical location endometriosis (aOR 1.97, 95%CI 1.26-3.09) and adnexal endometriosis (aOR 1.89, 95%CI 1.68-2.13).

CONCLUSION: Pregnancy complicated by endometriosis is associated with high-risk pregnancy characteristics and adverse delivery outcomes.

371 Association between preterm birth and adverse childhood experiences in a diverse population

Alexzandra Adler[1], Camille Hoffman[2], Robert Freedman[3], Sharon Hunter[3]
[1]University of Colorado, Denver, CO, [2]University of Colorado Health, Aurora, CO, [3]University of Colorado, Aurora, CO

OBJECTIVE: To determine whether a relationship exists between adverse childhood experiences, maternal race, earlier gestational age at delivery and maternal cortisol and choline levels among a diverse population.

STUDY DESIGN: This a prospective, observational cohort study of pregnant women enrolled before 16 weeks gestation. Demographics, including race and previous pregnancy outcomes were obtained. The Adverse Childhood Experiences (ACE) scale was used to quantify lifetime stressors. Hair cortisol concentration (HCC) and plasma choline levels were obtained from participants at 16 weeks gestation. Continuous and categorical statistical analyses were used.

RESULTS: Of 151 participants enrolled, 23 identified as Black and 128 as White. Black women had higher ACE scores compared with white women (3.59 ± 2.12 vs 2.31 ± 2.39, $p = 0.034$, $b = 0.457$). Gestational age at birth was earlier for Black infants than White infants (266.4 ± 21.1 days v s 274.0 ± 16.7 days, $p = 0.043$). In White women, ACE score ≥ 5 and plasma choline concentrations below the mean were associated with earlier gestational age at birth. ACE and maternal HCC were correlated for all women ($p = 0.048$, $b = 0.216$) although depression/anxiety, obesity, and Black race did not independently affect HCC. Maternal plasma choline concentration was lower for Black women compared with White women ($p = 0.008$) and HCC was negatively associated with plasma choline concentration ($p = 0.016$, $b = -0.571$) in Black, but not White participants ($p = 0.050$, $b = -0.416$).

CONCLUSION: Higher ACE scores were correlated with higher HCC and lower serum choline concentration for both Black and White women. These factors were also associated with earlier gestational age at birth. Black women reported higher ACE scores than White women and have a known higher risk of preterm birth. Addressing childhood trauma and stress, and supplementing pregnancies with choline, may contribute to a reduction in known racial disparities in preterm birth.

372 Comparison of ultrasound and magnetic resonance imaging in predicting congenital diaphragmatic hernia (CDH) outcomes

Lamia A. Alamri[1], Jason Gien[2], Zhaoxing Pan[3], Michael V. Zaretsky[1], Sarkis Derderian[4], Mariana Meyers[4], Nicholas Behrendt[1], Henry L. Galan[1]
[1]University of Colorado, School of Medicine, Aurora, CO, [2]Children's Hospital of Colorado, Aurora, CO, [3]University of Colorado, School of Medicine, School of Public Health, Aurora, CO, [4]Children's Hospital of Colorado, Colorado, CO

OBJECTIVE: Optimal imaging for CDH includes observed to expected lung-to-head ratio (O/E LHR) by ultrasound (US), and percent predicted lung volume (PPLV) by magnetic resonance imaging (MRI), but data for sensitivity of one modality over the other is lacking. Our primary objective was to determine whether MRI or US derived prognostic factors are best at predicting need for extracorporeal membrane oxygenation (ECMO) at early and late gestational age. Secondary outcomes included survival to discharge, length of neonatal intensive care unit stay (NLOS), ventilator days (VD), and inhaled nitric oxide duration (iNOD).

STUDY DESIGN: This retrospective study included CDH affected fetuses managed at a single fetal care center from 2013-2022 who had 2 sets of fetal MRI and US performed between 21w0d-27w6d and 32w0d-37w6d. Prenatal, and neonatal data were obtained from the electronic medical record. Those with right sided CDH, other major anomalies, < 34 weeks gestational age at birth, multiple gestations, and genetic syndromes were excluded. The relationship between prenatal prognostic factors and neonatal outcomes was described using spearman and pearson correlations with p value of < 0.05 taken as significant. We compared the sensitivity of MRI and US derived measures using univariate logistic regression.

RESULTS: Of 141 fetuses, 52 met inclusion criteria. 48 neonates survived to discharge (92%) and 20 required ECMO (38%). Lower PPLV and O/E LHR values were significantly correlated with need for ECMO, increased NLOS, longer VD, and longer iNOD at both time points (p values < 0.05). There were no significant differences at both time points in the AUCROC for PPLV vs O/E LHR for ECMO, predicting survival, increased NLOS, and increased VD (p values >0.05).

CONCLUSION: MRI PPLV and US O/E LHR derived prognostic factors are clinically useful in predicting CDH severity. We found no advantage of one modality over the other, even when compared at two different time points in predicting need for ECMO and other neonatal outcomes.

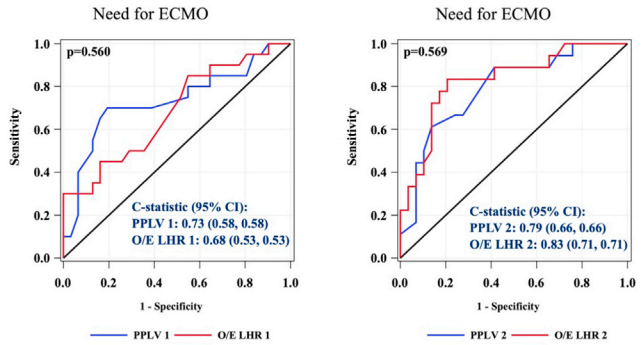

Fig 1. Comparison of MRI derived PPLV vs US derived O/E LHR at predicting the primary outcome. 1A. Second trimester imaging 1B. Third trimester imaging

373 Evaluating the Effects of the OCT on Neonatal and Maternal Outcomes in Newborns with FGR

Roie Alter[1], Hagar Herz[2], Maayan Ormianer[3], Efrat Shekel[3], Adiel Cohen[3], Yossef Ezra[4], Doron Kabiri[5]
[1]Hadassah Ein Kerem, Macabim, HaMerkaz, [2]Hadassah Hebrew University Jerusalem, Jerusalem, Yerushalayim, [3]Hadassah Medical Center, Jerusalem, Yerushalayim, [4]Hadassah-Hebrew University Medical Center, Jerusalem, Yerushalayim, [5]Hadassah, Jerusalem, Yerushalayim

OBJECTIVE: To assess the efficacy of the Oxytocin Challenge Test (OCT) prior to delivery in fetuses diagnosed with Fetal Growth Restriction (FGR) and to investigate its influence on delivery outcomes. Additionally, a comparison group of Small for Gestational Age (SGA) fetuses was included for analysis.

STUDY DESIGN: A retrospective cohort study included live singleton deliveries between January 2019 and December 2020. FGR and SGA were determined based on birthweight falling below the 3rd and 10th percentile, respectively. The cohort was stratified into three distinct groups: 1) FGR with negative OCT; 2) FGR without OCT; and 3) SGA fetuses. Primary outcome measures included the rate of emergency cesarean delivery, while secondary outcomes comprised adverse neonatal outcomes, including at least one of the following: 5-minute Apgar scores below 7, umbilical cord blood pH below 7.1, neonatal ICU admission, neonatal admission lasting longer than 4 days, neonates needing intubation, or being diagnosed with intraventricular hemorrhage.

RESULTS: A total of 1451 electronic records were included in this analysis. The FGR with OCT group comprised 42 newborns, the FGR without OCT group consisted of 277 newborns, and the SGA group included 1132 newborns. Among the 33 newborns in the FGR group with negative OCT results, 15.2% (5/33) required emergency cesarean delivery, compared to 15.5% (43/277) in the FGR group without OCT (p = .956), and more than 10.9% (109/1132) in the SGA group (p = .012). The occurrence of neonatal composite adverse outcomes was comparable between the FGR-negative group with OCT (21.2%) and the FGR group without OCT (25.6%) (p = .305), while exceeding the occurrence of adverse neonatal outcomes in the SGA group, which was 8% (p < .001).

CONCLUSION: Administration of the Oxytocin Challenge Test prior to delivery in fetuses diagnosed with Fetal Growth Restriction does not reduce adverse maternal or neonatal outcomes.

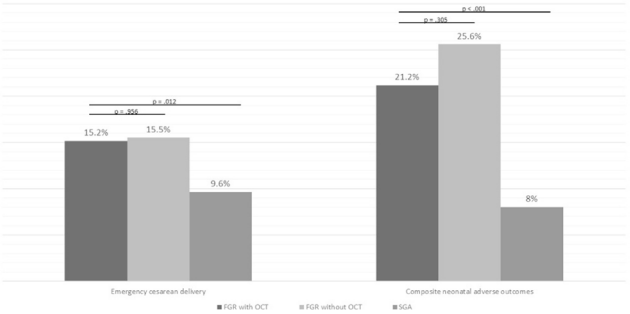

Figure 1: Comparison of Emergency Cesarean Deliveries among FGR with Negative OCT, FGR without OCT, and SGA Groups
Abbreviations: FGR – Fetal Growth Restriction; OCT – Oxytocin Challenge Test; SGA – Small for Gestational Age.

374 Elevated Middle-Cerebral-Artery Peak-Systolic-Velocity (MCA-PSV) in non-anemic fetuses: Providing a better understanding of enigmatic MCA-PSV Dopplers

Saja Anabusi[1], Tim Van Mieghem[2], Greg Ryan[2], Shiri Shinar[2]
[1]Mount Sinai Hospital, Toronto, ON, [2]Sinai Health Center, Toronto, ON

OBJECTIVE: An elevated middle cerebral artery peak systolic velocity (MCA-PSV) is a well-accepted tool for the diagnosis of fetal anemia with a progressive rise in MCA-PSV as anemia worsens . A value greater than 1.5 Multiple of Median (MoM) has a sensitivity of 100% and a false positive rate of 12% for the diagnosis of moderate to severe fetal anemia. High values of MCA-PSV may be due fetal behavioral state, fetal growth restriction, maternal diabetes, or other rare causes.

Our aim was to investigate the incidence, causes and outcome in fetuses with elevated MCA-PSV >1.5 MoM despite normal or near normal Hgb on fetal blood sampling (FBS).

STUDY DESIGN: An observational retrospective cohort study of all fetuses who underwent FBS due to MCA PSV >1.5 MoM at a tertiary fetal medicine center between 2007 and 2021. Fetuses were included if they had a no or mild anemia defined as Hgb deviation of less than 20 gr/L from a gestational age (GA) adjusted mean. Indications for Doppler assessment, causes of abnormal MCA PSV and neonatal outcomes were collected.

RESULTS: Overall, 383 fetuses had an MCA PSV >1.5 MoM and underwent subsequent FBS. Twenty-three (n=23, 6%) fetuses met inclusion criteria, and had normal Hgb or mild anemia at FBS. The reasons for Doppler assessment included abnormal fetal surveillance or genetic anomalies (n=11), maternal isoimmunization (n=5), suspected antepartum hemorrhage (n=4) and non-indicated Doppler assessment (n=3). A cause for elevated MCA PSV other than moderate to severe anemia was eventually elucidated in 12 of the 23 cases (52.2%). Favorable perinatal outcomes were observed only in truly unexplained cases with no additional anomalies (n=11, 47.8%).
CONCLUSION: Elevated MCA PSV >1.5 MoM appear in 6% of pregnancies despite normal/near normal Hgb. Pregnancies with alternative causes for this false positive measurement are at risk for poor neonatal outcomes.

375 Elevated middle cerebral artery peak systolic velocity (MCA PSV) in fetuses with unexplained anemia

Saja Anabusi[1], Tim Van Mieghem[2], Greg Ryan[2], Shiri Shinar[2]
[1]Mount Sinai Hospital, Toronto, ON, [2]Sinai Health Center, Toronto, ON
OBJECTIVE: Middle cerebral artery peak systolic velocity (MCA-PSV) Doppler measurement is a highly sensitive tool for identifying moderate to severe fetal anemia. While various factors like isoimmunization, infections, genetic conditions and less commonly, twin-twin transfusion syndrome and twin-anemia polycythemia sequence can cause fetal anemia, sometimes the cause remains unidentified before birth.

Our study aimed to determine the incidence of unexplained prenatal fetal anemia and to assess the related perinatal outcomes.
STUDY DESIGN: An observational retrospective cohort study of all fetuses who underwent Fetal Blood Sampling due to MCA PSV >1.5 MoM at a tertiary fetal medicine center between 2007 and 2021. Fetuses were included if they had a moderate or severe anemia defined as hemoglobin (Hgb) deviation of more than 20 gr/L above gestational age-adjusted mean with negative anemia workup (Parvovirus serologies, indirect coombs, maternal Hgb electrophoresis, parental molecular testing for alpha thalassemia and Kleihauer Betke test). Data collected encompassed indications for Doppler assessment, prenatal and postnatal data, neonatal outcomes, autopsy findings, placental pathology and genetic testing.
RESULTS: Overall, 383 fetuses had an MCA PSV >1.5 MoM and underwent subsequent FBS. Twelve fetuses (3.1%) had moderate to severe anemia of unknown perinatal etiology. The indications for Doppler assessment were a sonographic anomaly in all fetuses (8 with non-immune hydrops or polyhydramnios and 4 with other major structural anomalies, not typically associated with anemia). Postnatal investigations revealed rare anemia-causing factors in four cases, such as fetal Gaucher's disease, Pyruvate Kinase deficiency, KAT6A gene pathogenic variants, and Trisomy 21 with bone marrow failure. The survival was poor with 6 (50%) cases of perinatal death divided into two intrauterine death and four neonatal deaths.
CONCLUSION: Unexplained anemia in pregnancies accounts for 3.1% of cases, potentially leading to adverse neonatal outcomes. Therefore, vigilant monitoring and close surveillance are advised for such pregnancies.

376 Efficiency and Equity of Genetic Counseling Referrals: A Needs Assessment of Providers

Kathryn E. Anthony[1], Margaret Thorsen[2], Huda B. Al-Kouatly[3], Melissa L. Russo[2]
[1]Women and Infants Hospital, E Providence, RI, [2]Women and Infants Hospital, Providence, RI, [3]Thomas Jefferson University, Philadelpia, PA
OBJECTIVE: Little is known about prenatal providers' comfort and competency in counseling about genetic risks without the assistance of genetic counselors (GCs). A recent study estimates 30% of patients with indications for GC referrals are missed by their primary provider. This survey aimed to assess prenatal provider needs related to genetic counseling with a focus on referral patterns, comfort in counseling, and barriers to care.
STUDY DESIGN: We conducted an anonymous, cross-sectional survey in Qualtrics to assess clinicians' self-reported confidence in knowledge of indications for GC referrals, designated by the American College of Medical Genetics and Genomics (ACMG). The survey was reviewed by three GC experts to provide content validity and distributed electronically to physicians, midwives, advanced practice providers in our institution from Ob/Gyn, family medicine, fertility and maternal-fetal medicine. Descriptive statistics were performed.
RESULTS: The survey response rate was 44.7% (77/170). 67.5% of respondents report that the majority of their patients utilize government insurance plans. Assessing confidence, 83% percent of participants reported they could appropriately identify patients that qualify for GC. 68.8% of respondents stated they always screen family history for birth defects and congenital cardiac defects. The majority of providers did not screen for family history of audiovisual deficits (68.4%) or consanguinity (71.2%), despite ACMG recommendations. Only one third (31.2%) agreed that they were equipped to elicit family history in patients with limited health literacy or language barriers. Respondents identified multiple barriers to counseling (Figure 1). Providers were supportive of a proposed, standardized care tool to assist in the collection of family history, to improve clinic efficiency and to identify which patients may benefit from referral.
CONCLUSION: Our results demonstrate discrepancies between providers' confidence level and recognition of indications for GC. This emphasizes the need for standardized tools, designed to improve access and minimize inequities in referrals.

377 Examining the role of angiogenic imbalance via elevated sFlt-1/PLGF in the development of hypertension

Tooba Z. Anwer, David E. Cantonwine, Ellen W. Seely, Kathryn J. Gray, Thomas McElrath
Brigham and Women's Hospital, Boston, MA
OBJECTIVE: The PRAECIS study demonstrated maternal serum soluble fms-like tyrosine kinase 1 to placental growth factor (sFlt-1/PlGF) ratio provides stratification of risk of developing severe

preeclampsia (PE) and other research has established a relationship between PE and risk of later life hypertension (HTN). We sought to determine if an elevated sFlt-1/PlGF ratio in the second trimester would be associated with an increased risk of either stage 1 or stage 2 HTN later in life.

STUDY DESIGN: Blood pressure (BP) measurements greater than 2 months postpartum (PP), medications, and diagnoses were abstracted on N=1,165 singleton pregnancies that were part of a prospective birth cohort study which enrolled patients from 2006-2008. Stage 2 and Stage 1 HTN were defined using the American College of Cardiology/America Heart Association (ACC/AHA) 2017 classification criteria with at least 2 elevated BP measurements, physician diagnoses, or usage of anti-hypertensive medication. sFlt-1/PlGF ratios were collected at a median of 24.6 weeks gestation. Adjusted Cox proportional hazard models were used to estimate hazard ratios (HR) and 95%CI for the time to diagnosis for Stage 2 and Stage 1 HTN within 15 years PP in association with quartiles of sFlt/PlGF in those with either PE or gestational HTN. Potential confounders in adjusted models were identified using a directed acyclic graph.

RESULTS: Of the N=890 women with complete information, N=260 (29.2%) were diagnosed with Stage 1 and N=169 (19.0%) were diagnosed with Stage 2 HTN within 15 years of delivering. There were N=275 (23.6%) participants that were either missing electronic medical record follow up or sFlt-1/PLGF concentrations. In adjusted Cox proportional hazard models we observed no significant association between the hazard of developing either Stage 2 or Stage 1 HTN and increasing concentrations of the sFlt/PlGF ratio (Table 1).

CONCLUSION: Mechanisms other than angiogenic imbalance during pregnancy may explain the association with HDP and the heightened risk of later life HTN.

TABLE 1. Risk of hypertension within 15 years after delivery in association with quartiles of sFlt/PlGF at ~24 weeks gestation

	Unadjusted HR (95%CI)	Adjusted HR[a] (95%CI)
Stage 2 chronic hypertension

sFlt /PlGF Quartile 2	0.89 (0.63, 1.24)	0.81 (0.58, 1.14)
sFlt /PlGF Quartile 3	1.03 (0.74, 1.45)	0.96 (0.69, 1.35)
sFlt /PlGF Quartile 4	0.78 (0.55, 1.09)	0.75 (0.53, 1.05)

[a] Adjusted for maternal age at delivery, pre-pregnancy BMI, race, smoking, renal disease, and diabetes. sFlt-1=soluble fms-like tyrosine kinase; PlGF= placental growth factor.

378 Development of hypertension within 15 years postpartum by phenotype of preeclampsia

Tooba Z. Anwer, David E. Cantonwine, Ellen W. Seely, Kathryn J. Gray, Thomas McElrath
Brigham and Women's Hospital, Boston, MA

OBJECTIVE: Despite the known association between hypertensive diseases of pregnancy (HDP) and later life hypertension (HTN),less is known about how this risk is modified among those with a history of differing phenotypes of preeclampsia (PE), early onset PE diagnosed prior to 34 weeks gestational age (GA) and late-onset PE diagnosed after 34 weeks GA.

STUDY DESIGN: Postpartum blood pressure (BP) measurements greater than 2 months after delivery, medications, and diagnoses were abstracted on N=1,165 singleton pregnancies that were part of a prospective birth cohort study at a single institution from 2006-2008. Stage 2 and Stage 1 HTN were defined using the American College of Cardiology (ACC)/American Heart Association (AHA) 2017 classification criteria with at least 2 BP measurements, physician diagnoses, or usage of anti-hypertensive medication. Adjusted Cox proportional hazard models were used to estimate hazard ratios (HR) and 95%CI for the time to diagnosis for Stage1 and Stage 2 HTN within 15 years postpartum, in association with a diagnosis of PE or gestational hypertension (gHTN). Potential confounders in adjusted models were identified. Subsequent pregnancy BPs and subjects with chronic HTN were excluded.

RESULTS: Of the N=1,011 participants, N=311 (30.8%) were diagnosed with Stage 1 and N=205 (20.3%) with Stage 2 HTN within 15 years of delivering. During these pregnancies N=86 (8.5%) and N=53 (5.2%) were diagnosed with PE and gHTN, respectively. There were N=154 (13.2%) participants that were missing electronic medical record follow up. In adjusted Cox proportional hazard models, participants who had PE or gHTN had a 1.76 (95%CI: 1.16, 2.68) and 3.53 (95%CI: 2.12, 5.87) times higher hazard of developing Stage 2 HTN within 15 years post delivery (Table 1). This risk was diminished for developing Stage 1 HTN. When stratifying the hazard of developing Stage 2 HTN by phenotype of PE , late onset PE was significantly associated with an increasing hazard while there was no association with early onset PE.

CONCLUSION: The risk of later life HTN differentiates based on PE phenotype as well as HTN classification.

TABLE 1. Risk of hypertension within 15 years after delivery for participants who had hypertensive disease of pregnancy

	Unadjusted HR (95%CI)	Adjusted HR[a] (95%CI)
Stage 2 chronic hypertension		
All PE	2.36 (1.61, 3.45)	1.76 (1.16, 2.68)
Early onset PE	0.96 (0.39, 2.33)	0.69 (0.28, 1.73)
Late onset PE	2.85 (1.89, 4.30)	2.03 (1.30, 3.19)
gHTN	4.03 (2.45, 6.63)	3.53 (2.12, 5.87)
Stage 1 chronic hypertension		
All PE	0.80 (0.47, 1.34)	0.72 (0.43, 1.22)
Early onset PE	0.26 (0.06, 1.03)	0.22 (0.06, 0.90)
Late onset PE	1.12 (0.64, 1.95)	1.02 (0.59, 1.79)
gHTN	1.95 (1.22, 3.11)	1.99 (1.24, 3.18)

[a] Adjusted for maternal age at delivery, pre-pregnancy BMI, race, smoking, renal disease, and diabetes. PE=preeclampsia, gHTN= gestational hypertension.

379 Differences in Cardiovascular Disease Symptoms per Trimester Among Risk Screen Positive Pregnant Patients

Avish Arora[1], Kerly M. Guerrero[2], Ariana Banuelos[3], Kevin Flatley[4], Heike Thiel de Bocanegra[5], Afshan B. Hameed[6], Diana S. Wolfe[7]
[1]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [2]Montefiore Medical Center, New Rochelle, NY, [3]Montefiore Medical Center, Albert Einstein College of Medicine, New Rochelle, NY, [4]Montefiore Medical Center, New York, NY, [5]University of California, Irvine Medical Center, Orange, CA, [6]UCI, Orange, CA, [7]Albert Einstein College of Medicine, Bronx, NY

OBJECTIVE: Cardiovascular disease (CVD) continues to be a leading cause of maternal morbidity and mortality in the United States. The optimal time for CVD risk screening during pregnancy remains

uncertain due to symptom and vital sign variability at different gestational ages. This study sought to investigate the symptomatology of CVD in pregnant women who screened positive for CVD risk, with a focus on whether symptom presentation varied across trimesters. Furthermore, we explored the timing of screening on the likelihood of identifying true positive CVD cases.

STUDY DESIGN: This prospective cohort study included obstetrical patients who screened positive for CVD risk over a year starting June 15, 2022, at an inner-city academic medical center. Universal CVD risk screening was performed during prenatal and postpartum visits using the California Maternal Quality Care Collaborative toolkit. All positive cases underwent ECHO, EKG, and cardio-obstetric team assessment.

RESULTS: Significant differences were observed in the presentation of CVD symptoms among the study cohorts. Shortness of breath was more prevalent in the 2nd trimester, while hypertension was more common in the 1st trimester and postpartum period. Interestingly, no significant differences were found in the number of true positive cases identified across the trimesters.

CONCLUSION: Our findings highlight the potential influence of pregnancy progression on the manifestation of CVD symptoms, suggesting that the timing of screening could potentially impact disease detection. However, the consistent number of true positive cases identified across all trimesters supports the argument that screening should be conducted regardless of gestational age. This finding underscores the importance of universal screening throughout pregnancy and postpartum. Additionally, the significant increase in hypertension during the 1st trimester among this perinatal cohort of CVD risk positive patients suggests that underlying pre-existing conditions contribute to CVD, necessitating early management and treatment.

380 Cost-effectiveness of a reverse screening algorithm for syphilis in pregnancy

Megha Arora, Sarah K. Dzubay, Lily Ben-Avi, Alyssa R. Hersh, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

OBJECTIVE: Syphilis rates in the U.S. continue to rise from historic lows in 2000. In pregnancy, it is crucial to screen and diagnose infection to prevent vertical transmission. Traditionally, screening is done with a non-treponemal test such as the rapid plasma reagin (RPR) followed by confirmatory testing using a treponemal immunoassay. The greater sensitivity of the immunoassays compared to non-treponemal tests has led to the emergence of a reverse screening algorithm (immunoassay followed by RPR), however they have lower specificity. Nationally, there is heterogeneity in the algorithm used. In this study, we evaluated the cost-effectiveness of syphilis screening in pregnancy using a traditional versus reverse screening algorithm.

STUDY DESIGN: We constructed a decision-analytic model to compare outcomes between traditional and reverse screening. Our theoretical cohort included 3,408,000 individuals, the estimated annual live births among individuals without history of prior syphilis infection. Outcomes were stillbirth, preterm birth, infant death, congenital syphilis, undiagnosed syphilis cases, costs, and quality adjusted life years (QALYs). We used a willingness-to-pay for the incremental cost-effectiveness ratio of $100,000/QALY. Model inputs were derived from the literature and assessed with sensitivity analyses.

RESULTS: In our cohort, the reverse screening approach was associated with 368 fewer cases of undiagnosed maternal syphilis infections, 50 fewer stillbirths, 17 fewer preterm births, 59 fewer infant deaths, and 67 fewer cases of congenital syphilis. Despite higher costs, reverse screening was cost-effective with an ICER of $8,328/QALY. In univariate sensitivity analysis, reverse screening was cost-saving when the immunoassay cost was below $5.48.

CONCLUSION: In our study, the reverse screening approach was a cost-effective strategy to improve diagnosis of syphilis in pregnancy and reduce adverse outcomes associated with vertical transfer. Adopting reverse screening protocols for pregnant individuals could be advantageous for health systems.

Table 1. Outcomes in a theoretical cohort of 3,408,000 pregnant individuals without a history of prior syphilis infection.

	Reverse screening algorithm	Traditional screening algorithm	Difference (Reverse - Traditional)
Stillbirth	18,983	19,033	-50
Preterm birth	296,957	296,974	-17
Infant death	2,903	2,962	-59
Congenital syphilis	266	333	-67
Undiagnosed syphilis	62	430	-368
Cost (USD)	$25,221,924,047.00	$25,200,022,425.00	$21,901,622.00

381 Comprehensive Detailed Anatomic Ultrasound: Allotted Time of 30- vs 45-Minutes

Olaide Ashimi Balogun[1], Faranak Behnia[2], Anushka Chelliah[2], Jiangtao Luo[3], Suneet P. Chauhan[4], Amber Samuel[2]
[1]Obstetrix Maternal-Fetal Medicine Specialists of Houston, Missouri City, TX, [2]Obstetrix Maternal-Fetal Medicine Specialists of Houston, Houston, TX, [3]Tilman J. Fertitta Family College of Medicine, Houston, TX, [4]University of Texas-Houston Medical School, Houston, TX

OBJECTIVE: The purpose was to ascertain how often Registered Diagnostic Medical Sonographers (RDMS) complete a comprehensive detailed anatomy ultrasound (Current Procedural Terminology [CPT] code 76811) when allotted 30 vs 45 minutes to perform it.

STUDY DESIGN: We conducted a retrospective cohort study within our MFM Ultrasound Clinics. Cohorts were singletons who had a CPT 76811 performed by a RDMS at 18-24 weeks. We excluded

pregnancies with major congenital anomalies and multiples. The CPT 76811 ultrasound study was considered to be complete when all items suggested by the AIUM Detailed Second Trimester OB Checklist were visualized. Based on a baseline rate of 45% of comprehensive detailed anatomy ultrasounds that were completed in our clinics in 30 minutes, to detect a relative increase of 30% (45% to 58%; alpha error=5%; 80% power), 430 women (215 in each group) were required to demonstrate a clinically significant improvement in our primary outcome. Thus, the two cohort groups were: 215 consecutive CPT 76811 performed in July 2022, when RDMS were allocated 30 minutes, and 215 consecutive CPT 76811 performed in January 2023, when RDMS were given 45 minutes.

RESULTS: Of the 215 anatomy ultrasounds performed in each group, 117 (54%) were completed when RDMS were allocated 30 minutes compared to 173 (80%) when they were given 45 minutes ($p < 0.001$). Additionally, the number of times the patient had to return to complete the anatomy ultrasound was significantly more when RDMS were given 30 minutes compared to when they were allocated 45 minutes (p=0.005). There was no statistical difference in maternal age, race, BMI, number of prior cesarean delivery, or co-morbidities between the two groups. There was a difference in gestational age and nulliparity between the two groups. (Table 1).

CONCLUSION: RDMS were significantly more likely to complete a comprehensive detailed anatomy ultrasound using the AIUM checklist when allocated 45 minutes vs 30 minutes to perform it. Our findings provide guidance to clinicians and their practices in terms of logistics in schedule planning, billing, and allotment of resources.

Table 1. Baseline and Ultrasound Characteristics

	Anatomy Ultrasounds Performed in 30 minutes (N=215)	Anatomy Ultrasounds Performed in 45 minutes (N=215)	P Value

382 Effect of Single vs. Double Blind Peer Review: Interrupted Time Series Analysis

Rula Atwani[1], **Carole Barake**[2], **George R. Saade**[1], **Tetsuya Kawakita**[1]

[1]Eastern Virginia Medical School, Norfolk, VA, [2]University of Texas Medical Branch, Galveston, TX

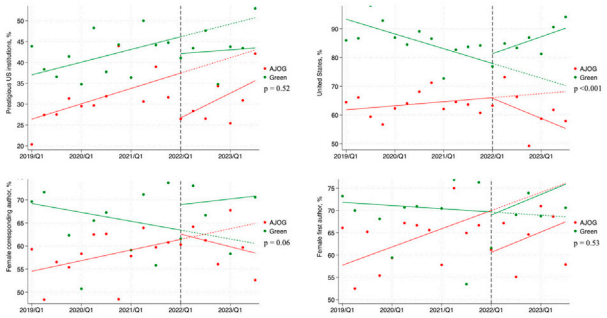
OBJECTIVE: To evaluate the impact of peer-review type (single-blind vs double-blind) on the institutional, country of origin, and female author representation in two major OBGYN journals.

STUDY DESIGN: This was a bibliometric analysis of comparing publication in Obstetrics & Gynecology (Green Journal) which implemented double-blind peer review in July 2021with the American Journal of Obstetrics and Gynecology (AJOG) which did not change from single-blind peer review. In double-blind peer review, information on authors such as name and institution was blinded. However, the country was not blinded. We retrieved all articles published from 2019 to 2023. Our primary outcome was the proportion of published articles from US institutions' in the top 50 funded OBGYN departments based on the NIH RePORTER database each year (2018-2022). Our secondary outcomes were the country of origin, female first, and last authors. The sex of the authors was determined by a Google-based webtool. Considering the review to publication period would be 3 to 4 months, we assumed that Green Journal publications in 2022 and 2023 (post-intervention) would have had double-blind peer reviews. We conducted a multiple group interrupted time series analysis using ordinary least squares regression, with AJOG being the referent journal.

RESULTS: During the analysis period, 450 of 1273 (35.4%) in AJOG and 298 of 950 (31.4%) in the Green Journal were published in the post-intervention period. Compared with AJOG, the Green Journal proportion of publications by top US research institutions, female corresponding author, and female first author did not significantly change after the intervention (p=0.52, 0.06, and 0.53 respectively), but the proportion of articles from the United States increased significantly after the intervention ($P < 0.001$).

CONCLUSION: Double-blinded review did not impact the characteristics that were blinded but did decrease the proportion of published manuscript originating outside the US. Green Journal should consider blinding the country.

Figure 1. Percentages of outcomes per quarter



383 Candidacy for Regional Anesthesia Stratified by Anticoagulation Type

Brittany Austin, Anna Eitel, Matthew M. Finneran

Medical University of South Carolina, Charleston, SC

OBJECTIVE: In women on anticoagulation in pregnancy, low molecular weight heparin (LMWH) is often preferred due to lower dosing frequency when compared to unfractionated heparin (UFH).

However, its longer half-life can theoretically increase risk of hemorrhage and inability to receive regional anesthesia. For these reasons, guidelines suggest transition from LMWH to UFH at 36 weeks' gestation. However, many patients will have a scheduled delivery or present with enough time to receive regional anesthesia. The objective of this study is to describe rates of receipt of regional anesthesia by type of anticoagulation at time of delivery.

STUDY DESIGN: This was a retrospective cohort study of all patients on anticoagulation in pregnancy delivering at a single institution between 2013-2023. Women were categorized by anticoagulation type (UFH or LMWH). The primary outcome was receipt or non-receipt of regional anesthesia. Secondary outcomes included rates of postpartum hemorrhage (PPH) and transfusion. Univariate analysis was performed using the chi-square and Wilcoxon rank sum test where appropriate.

RESULTS: 346 patients were included in the analysis with 238 (68.8%) on UFH and 108 (31.2%) on LMWH at time of delivery. There were baseline differences between groups including higher rates of Black race (55.6% vs 41.1%; p=.022) and therapeutic dosing (32.4% vs 14.7%; p< .001) among patients taking LMWH. There were no differences in rates of regional anesthesia (84.3% vs 89.1%; p=.208). There were increased rates of non-candidacy for regional anesthesia (5.6% vs 1.3%; p=.020) in the LMWH group. However, when restricting to deliveries > 36 weeks, there was no difference seen between groups (p=.417; Table 1). There were no differences in rates of PPH (p=.581) and transfusion due to blood loss (p=.097)

CONCLUSION: There was no difference in rate of receipt of regional anesthesia, but non-candidacy was higher among patients taking LMWH versus UFH at delivery. However, this finding was not significant when restricting to those delivering after 36 weeks.

Table 1 – Study outcomes

	Heparin (n=238)	Enoxaparin (n=108)	p-value
Admission to delivery, hours	8.28 (0.0-17.8)	8.38 (0.0-19.2)	.886
Delivery <24 hours	136 (60.2)	64 (60.4)	.972
Delivery <12 hours	85 (37.6)	36 (34.0)	.520

384 Digital Intervention and Hybrid Care Improves Adherence to Gestational Diabetes Surveillance - Prospective Pilot Study

Michal Axelrod[1], Ester Galler[1], Hila Lahav Ezra[1], Omer Nir[1], Galia Barkai[1], Keren Ofir[1], Eyal Sivan[2], Shali Mazaki-Tovi[3], Abraham Tsur[1]

[1]Sheba Medical Center, Ramat-Gan, HaMerkaz, [2]Sheba Medical Center, Tel-Hashomer, Ramat-Gan, Israel, [3]Chaim Sheba Medical center, Tel HaShomer, Ramat Gan, HaMerkaz

OBJECTIVE: Assessing adherence to glycemic control surveillance among women with gestational diabetes (GDM) using a digital intervention.

STUDY DESIGN: We assessed the adherence to the use of a digital intervention as part of a four-week prospective clinical study investigating hybrid remote and in-clinic visits for 19 women with GDM starting at 32-34 weeks of gestation. Virtual visits consisted of comprehensive maternal care as well as remote fetal monitoring and ultrasound assessment of amniotic fluid deepest vertical pocket. A digital intervention was used to enhance the engagement of patients with daily documentation of glucose levels (Datos Ltd. platform), from study recruitment date until birth. Our primary metric for adherence was the percent of fasting glucose measurements documented. In addition, obstetric and neonatal outcomes of the study participants were compared with a control group of 452 GDM patients followed in the same MFM clinic during the preceding year.

RESULTS: Adherence to recording fasting glucose values was 92.23% during the four-week hybrid in-clinic and remote care study and declined to 61.81% following the study period until birth (P=0.001). None of the participants required induction of labor due to glycemic imbalance. In addition, we compared the clinical outcomes of the study participants with the above-mentioned control group. In the study group there were 0/19 (0%) cases of macrosomia, high-grade perineal tears, shoulder dystocia, neonatal hypoglycemia, or respiratory distress syndrome. In comparison, in the control group, there were 47 cases of hypoglycemia and 18 cases of macrosomia. Overall, a total of 65/452 in the control group experienced complications (14.2%; P=0.059).

CONCLUSION: Digital Intervention improves adherence to glucose levels documentation. Engagement is highest when paired with hybrid care consisting of alternating in-clinic and remote visits. Additional larger studies are required to assess the potential contribution of this intervention to reduce GDM related complications.

385 Does fetoscopic laser ablation (FLA) improve perinatal outcomes in Types II and III Vasa Previa?

Sami Backley[1], Neha Das Agarwal[2], Lindsay Weitzel[3], Dejian Lai[2], Eric P. Bergh[1], Anthony Johnson[2], Jimmy Espinoza[4], Ramesha Papanna[2]

[1]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [2]McGovern Medical School at UTHealth Houston, Houston, TX, [3]McGovern Medical School at the University of Texas Health Science Center at Houston, Houston, TX, [4]McGovern Medical School at the University of Texas Health Science Center Houston, The Fetal Center- Children's Memorial Hermann Hospital, Houston, TX

OBJECTIVE: The standard management of vasa previa (VP) includes inpatient admission at 28-32 weeks gestation, followed by cesarean delivery at 34-37 weeks gestation. The objective of our study was to

compare maternal and neonatal outcomes in patients with Type II and Type III VP undergoing fetoscopic laser ablation (FLA) with those receiving standard of care.

STUDY DESIGN: This was a retrospective study of all antenatally diagnosed cases of VP identified by ultrasound between September 2016 and July 2023 at a single quaternary referral center. Data pertaining to maternal and neonatal characteristics were extracted from ultrasound antenatal scans and maternal and neonatal hospitalization records. Type I VP data were also collected, and descriptive statistics are presented. Comparative analysis was performed between standard care and FLA groups with VP type II/III, with p-value < 0.05 considered significant. Survival was analyzed via Cox Regression model.

RESULTS: A total of 144 pregnancies were identified as suspected VP upon initial ultrasound. Subsequent ultrasound confirmed 89 (61.8%) of these diagnoses of VP. There were 52 (58%) Type I, 29 (33%) Type II, and 8 (9%) Type III VP. Among patients with Type II/III VP, 11/37(30%) underwent FLA. Overall, there were no differences in baseline demographics between groups. The differences between standard and laser therapy in patients with VP type II/III are described in Table 1. Preterm premature rupture of membranes (PPROM) was significantly higher in the FLA group. However, vaginal delivery was also significantly higher in the FLA group (1/3rd of cases), and FLA patients' maternal antenatal hospital stay was 11 days shorter. Risk of earlier delivery was 44% lower in FLA than standard care (HR 0.56), prolonging pregnancies by 9 days. However, these differences were not statistically significant (p=0.06).

CONCLUSION: FLA for VP types II and III reduces maternal hospital stay and makes vaginal delivery possible. Other neonatal benefits need further study in larger prospective studies.

Table 1. Comparison of maternal and neonatal by vasa previa type and direct comparison of standard of care to laser ablation in Type II and III vasa previa.

	Vasa Previa Type I (n=52)	Vasa PreviaType II/III		
		Standard Care (n=26)	Fetoscopic Laser (n=11)	p-value

386 Breastfeeding rates among Black participants in a remote hypertension monitoring/community-based doula partnership study

Erin Bailey[1], Megan Knutson Sinaise[2], Tia Murray[1], Uchenna Jones[3], Kathleen Wannemuehler[2], Kara K. Hoppe[2]

[1]University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]University of Wisconsin Madison, Madison, WI, [3]Harambee Village, Madison, WI

OBJECTIVE: Black patients both nationwide and within our state are known to have higher rates of hypertensive disorder of pregnancy (HDP) and worse pregnancy outcomes compared to White patients. Breastfeeding has been shown to decrease long-term cardiovascular risks in patients with preeclampsia; however, pre-study and pre-COVID local data suggests lower rates of breastfeeding initiation and exclusivity at hospital discharge among the Black patients compared to White (81 vs 93%) and (70 vs 88%). The objective of this project was to adapt our preexisting remote monitoring based postpartum hypertension program to include community-based doula support with lactation counseling to increase breastfeeding rates in a Black urban community in Wisconsin.

STUDY DESIGN: This was a prospective feasibility study at a single academic center from 1/2021-12/2022. Postpartum patients were eligible if they had a diagnosis of HDP, self-identified as Black and were enrolled in remote blood pressure monitoring. Community doulas were paired with patients to offer postpartum care, lactation, social and mental support for 6 weeks postpartum.

RESULTS: Forty-nine self-identified Black postpartum patients with a HDP were enrolled. Unexpectedly, this study was conducted during the COVID epidemic and at time of discharge, 80% of patients were breastfeeding in some capacity with only 39% exclusively breastfeeding. At the conclusion of the 6 week postpartum intervention, exclusive breastfeeding rates increased to 63%, with 79% of patients continuing to breastfeed at some level. Everyone who initiated breastfeeding was still breastfeeding at 6-weeks postpartum. Furthermore, no patients were utilizing donor milk at discharge, but two patients were transitioned to donor milk from formula during the 6 week postpartum period.

CONCLUSION: These data suggest that community doula support can not only support breastfeeding efforts established in the hospital, but actually increase exclusive breastfeeding rates after hospital discharge among a patient population with historically low rates of breastfeeding.

Table 1. Breastfeeding rates at discharge and 6 weeks postpartum

Feeding method	Discharge, n (%)	6 weeks postpartum, n (%)
Breastfeeding	20 (39)	32 (63)
Breast and formula feeding	21 (41)	8 (16)
Formula feeding	7 (14)	7 (13)
Unknown	3 (6)	3 (6)
Donor milk	0 (0)	2 (4)

387 Duration of Third Stage of Labor and Maternal Hemorrhagic Adverse Outcomes

Yossi Bart[1], Rachel L. Wiley[1], Ipsita Ghose[2], Baha M. Sibai[3], Suneet P. Chauhan[4]

[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]University of Texas Medical School at Houston, Houston, TX, [3]Hermann Memorial Hospital, Houston, TX, [4]University of Texas-Houston Medical School, Houston, TX

OBJECTIVE: ACOG Practice Bulletin on postpartum hemorrhage (#183) notes, that the third stage of labor (TSL) is associated with morbidity, although this threshold is not well established. Our objective was to identify the association between the duration of the TSL and composite maternal hemorrhagic adverse outcomes (CMHAO).

STUDY DESIGN: A retrospective cohort study of all singleton vaginal deliveries (VD) between March 2020 and Feb 2022 at a single Level IV center. Individuals with an unrecorded length of the TSL were excluded. We divided the cohort into 5-minute intervals after delivery of the newborn. Each 5-minute interval group was compared to all cases with a shorter TSL. Using Poisson regression, we evaluated whether TSL was associated with CMHAO, which consisted of blood loss $\geq$ 1000 mL, use of uterotonics, mechanical tamponade, surgical techniques for atony, transfusion, venous

thromboembolism, intensive care unit admission, hysterectomy, or death. We did a sensitivity analysis of TSL among term (≥ 37 wks) and preterm VD.

RESULTS: Of the 4,599 consecutive VD in the study period 4,513 (98%) met inclusion criteria, and of those, 777 (17%) had CMHAO. After 20 min, each addition of 5 min to TSL was associated with a significant increase in the CMHAO rate. Compared to TSL < 20 min, individuals with an interval of 20-24 min had higher rates of CMHAO (aRR 2.85, 95% CI 1.64-4.94). Likewise, CMHAO differed significantly when comparing 24-29 min and < 24, and ≥ vs. < 30 min (Fig). A sensitivity analysis of term VD noted a similar pattern: compared to less than 20 minutes, the 20-24 min interval was associated with a higher rate of CMHAO (aRR 2.63, 95% CI 1.31-5.30), as were the longer intervals. Due to infrequent outcomes, we were unable to perform a separate sensitivity analysis for preterm births.

CONCLUSION: Among singleton vaginal deliveries, third stage duration of ≥ 20 min, compared to < 20 min, was associated with significantly higher likelihood of hemorrhagic adverse outcomes. If confirmed in other population, guidelines on the duration of third stage of labor and associated morbidity may need revision.

Figure 1 – Third stage duration in 5-minute intervals and composite maternal hemorrhagic outcome.

	0-4 min	5-9 min	10-14 min	15-19 min	20-24 min	25-29 min	≥ 30 min
CMHAO [a]	15.9 (469/2,944)	17.3 (218/1,260)	16.5 (27/164)	14.3 (8/56)	50.0 (7/14)	50.0 (7/14)	68.9 (42/61)
Unadjusted RR (95% CI) [b]	--	1.09 (0.94-1.26)	1.01 (0.71-1.43)	0.87 (0.46-1.67)	**3.06 (1.81-5.19)**	**3.04 (1.80-5.16)**	**4.16 (3.47-4.99)**
Adjusted RR (95% CI) [c]	--	1.06 (0.92-1.23)	1.01 (0.71-1.43)	0.86 (0.45-1.62)	**2.85 (1.64-4.94)**	**3.09 (1.86-5.13)**	**4.06 (3.36-4.89)**

388 Eye towards Artificial Intelligence: Retinal Vascular Tortuosity vs. Vasoconstriction to Differentiate Preeclamptic and Normotensive Subjects

Srilaxmi Bearelly[1], Andrea Perez Moscoso[2], Lyam Ciccone[3], Hannah R. Coleman[2], Cande V. Ananth[4], Ronald J. Wapner[5]

[1]Columbia University, Stony Brook, NY, [2]Columbia University, New York, NY, [3]Metropolitan, Woodhull Hospital, New York, NY, [4]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [5]Columbia University Irving Medical Center, New York, NY

OBJECTIVE: Previous publications have suggested a decrease in retinal vascular caliber in preeclampsia (PE) compared with controls. We sought to determine the better measure (retinal vessel caliber or tortuosity) to differentiate between severe PE (sPE) and normotensive controls in the immediate post partum period (≤72 hours).

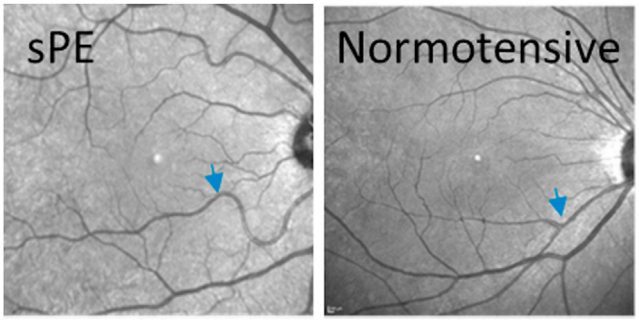
STUDY DESIGN: This cross-sectional study assessed 1) retinal vessel caliber and 2) retinal vascular tortuosity, in the artery and vein, in the superior and inferior temporal vascular arcades respectively. Controls were matched to cases by age, parity and race/ethnicity.

All measurements were made masked to diagnosis, using infrared (IR) images, on the Spectralis camera (Heidelberg Engineering, Germany). Vessel caliber (μm) was measured with the caliper function. Assessments of tortuosity were made using a standardized grading scale that spans from 1 (normal curvature) to 5 (most tortuosity) and were made by a retina specialist (HRC).

RESULTS: Mean (standard deviation) of gestational age at the time of delivery was 33 (4) weeks in 31 sPE cases and 38 (2) weeks in 35 controls. Retinal arteries measured 96.9 (13.8)μm in PE and 98.9 (14.3)μm in controls (P=0.42). Retinal veins measured 123.7 (16.8) μm in PE and 126.0 (16.1)μm in controls (P=0.62). Artery-to-vein (A:V) ratios did not differ between PE and controls.

The median (range) tortuosity level in the*infero-temporal*retinal artery was 2 (1-3.5) among sPE cases compared to 1 (1-4) in controls (P=0.04). None of the other vessels differed between cases and controls.

CONCLUSION: There was no difference in retinal vessel caliber, or A:V ratios, between subjects with sPE and normotensive controls in the immediate post-partum period. Patients with sPE had more tortuous*infero-temporal retinal arteries*than normotensive patients (Figure). This may reflect the effect of PE in arteries, compounded by gravitational changes, although the lack of effect in the*supero-temporal artery*may suggest a small sample size. Thissupportsthe use of retinal vascular tortuosity as a potential imaging marker of PE.



389 Congenital uterine anomalies and placenta accreta spectrum

Brett D. Einerson[1], Matthew B. Givens[2], Robert M. Silver[1], Michelle P. Debbink[2], Krista Childress[2], Joseph M. Letourneau[2], Savvy Benipal[2]

[1]University of Utah Health, Salt Lake City, UT, [2]University of Utah, Salt Lake City, UT

OBJECTIVE: Case reports and small studies suggests that congenital uterine anomalies (CUA) are associated with an increased risk of placenta accreta spectrum (PAS). We aimed to evaluate the association between PAS and CUA in a large, population-based study.

STUDY DESIGN: We performed a retrospective cohort study using the U.S National Inpatient Sample from 2017-2020. ICD-10 codes of delivery admissions greater than 20 weeks' gestation were used to determine patient exposures and outcomes. A logistic regression model was constructed to adjust for potentially confounding variables including history of a caesarean delivery, age, and placenta previa. A sensitivity analysis was performed including only patients with a code for PAS who also underwent hysterectomy. Data were weighted according to NIS reported sampling weights

RESULTS: The study cohort included 14,165,045 (2,833,010 unweighted) individuals. Congenital uterine anomalies were present in 60,335 (0.43%) individuals. PAS was more frequent in patients with CUAs compared to those without (0.42% vs 0.12%) with an odds ratio of 3.43 (95% confidence interval 2.60-4.54; p< 0.001). When controlling for age, prior caesarean, and placenta previa, the odds of having PAS is higher in those with a CUA (aOR 2.50; 95% CI 1.86-3.37; p< 0.001). In the sensitivity analysis including only individuals with PAS who underwent a hysterectomy, CUAs continued to be associated with PAS (aOR 2.11; 95% CI 1.33-3.34; p=0.001).

CONCLUSION: In this large population-based cohort, congenital uterine anomalies were associated with an increased risk of placenta accreta spectrum. Placental implantation is a complex process, which may be modified by CUAs.

Table 1:

	Congenital Uterine Anomaly	
	Yes n=60,334 (unweighted n= 12,067)	No n=14,104,709 (unweighted n=2,820,943)
Age	29.48 (29.37 – 29.60)	29.03 (28.98 – 29.07)

390 Does pregnancy impact bladder function in people with spinal cord injury?

Claire J. Mazzia[1], Anne Berndl[2], Sarah Daisy Kosa[3], Anne Harris[4]
[1]Temerty Faculty of Medicine, University of Toronto, Toronto, ON, [2]Sunnybrook Research Institute, Toronto, ON, [3]McMaster University, Hamilton, ON, [4]Toronto Metropolitan University, Toronto, ON

OBJECTIVE: This study aims to assess if people who had a pregnancy over 20 weeks'gestation after spinal cord injury (SCI) have worse bladder function than those with SCI who have never been pregnant using a validated survey.

STUDY DESIGN: An international online survey containing the Neurogenic Bladder Symptom Score (NBSS), (a validated bladder survey) and detailed demographic and pregnancy information was distributed. Participants were at least 18 years old and assigned female at birth. Those who had only ever had a pregnancy >20 weeks following SCI were compared to those who had never had a pregnancy >20 weeks. Mean and standard deviations (SD) were used to describe overall and bladder component scores; multivariate analyses assessed differences in NBSS between groups, controlling for relevant confounders including SCI level and severity, mobility device, bladder management methods, BMI, and age.

RESULTS: The recruitment rate was 85.4% (1056/1237) and the completion rate was 73.8% (780/1056). 288 people had never had a pregnancy >20 weeks, and 152 had only ever had a pregnancy >20 weeks after SCI. There was no difference in overall NBSS score between the groups (p=0.82), which held in multivariate analysis (p=0.69). When assessing specific components of the score, a significant difference between groups in storage and voiding was observed (P=0.003), however this is unlikely a clinicaldifference (non-pregnancy score 7.32 SD 4.45 vs pregnancy 8.27 SD 4.34).

CONCLUSION: This multivariate analysis demonstrates that people with SCI who had pregnancies have similar bladder function as those with SCI who have not had a pregnancy while considering clinically important confounders. The most important aspect of quality of life during SCI recovery is bladder function, and therefore it needs to be considered when contemplating pregnancy. This study describes key clinical information that will assist in evidence-based, preconception counselling for people with SCI and the physicians who care for them.

391 Correlation between social determinants of health and early initiation of breastfeeding after cesarean birth

Alexandra L. Berra
on behalf of Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD.

OBJECTIVE: While it is a goal to aid in early breastfeeding (BF) of postpartum persons, no study has investigated if there are racial, ethnic, or other disparities in achieving this after cesarean delivery. Our objective was to identify demographic and clinical characteristics associated with BF initiation in the first hour of life as recommended by the World Health Organization. We hypothesized that those who are non-White, Hispanic, and with public insurance would be less likely to initiate early BF.

STUDY DESIGN: In this secondary analysis of participants in a randomized trial of tranexamic acid during cesarean delivery, patients who breastfed were included.Those who experienced maternal or neonatal death prior to 24 hours after birth, delivery < 34 weeks, or had a multifetal gestation were excluded. Demographic and obstetric factors were analyzed in relation to BF initiation within the first hour. Adjusted ORs (95% CIs) were calculated using characteristics that may be associated with BF.

RESULTS: A total of 10,993 participants were enrolled in the study of whom 5,514 (50.2%) breastfed and had data regarding timing of BF initiation. Of these, 889 (16.1%) initiated BF in the first hour. Patients with private insurance (aOR 1.57, 95% CI 1.30-1.91) were more likely to achieve this outcome whereas Hispanic patients were less likely (aOR 0.74, 95% CI 0.60-0.92). There were no significant differences with regard to race or obesity. Those undergoing scheduled cesarean (versus unscheduled) were more likely to initiate BF within the first hour (aOR 1.53, 95% CI 1.28-1.83) and those who delivered prematurely were less likely to do so (aOR 0.45, 95% CI 0.31-0.64).

CONCLUSION: Public insurance and Hispanic ethnicity, which have both been associated with adverse health outcomes, were associated with delayed BF initiation. Initiation of BF is a modifiable outcome with appropriate operating room staff training. Inequities with breastfeeding in the first hour of life demonstrate the need for further evaluation and action to mitigate these disparities.

Table 1: Clinical and demographic characteristics associated with breastfeeding initiation within the first hour among patients who initiated breastfeeding after cesarean (n=5,514)

	Adjusted OR[1] (95% CI)
Black (vs. White)	0.92 (0.73, 1.16)
Hispanic (vs. non-Hispanic)	**0.74 (0.60, 0.92)**
Private insurance (vs. not private)	**1.57 (1.30, 1.91)**
Body mass index	
Overweight (vs. normal)	1.13 (0.79, 1.62)
Obese (vs. normal)	0.89 (0.63, 1.27)
Scheduled (vs. unscheduled cesarean)	**1.53 (1.28, 1.82)**
Gestational age <37 weeks (vs. ≥37 weeks)	**0.45 (0.31, 0.64)**

OR, odds ratio; CI, confidence interval

1. Multivariable models were adjusted for maternal age, body mass index, race, ethnicity, nulliparous status, marital status, use of private insurance, tobacco use during pregnancy, scheduled vs. unscheduled cesarean status, hypertensive disorders of pregnancy, diabetes, gestational age at delivery, anesthesia, TXA administration, and delivery during the SARS-Cov-2 pandemic.

392 Association of Diet Quality with Third Trimester Anemia

Courtney M. Bisson[1], Alexa A. Freedman[2], Sunitha C. Suresh[3]

[1]University of Chicago and NorthShore University Health System, Chicago, IL, [2]NorthShore University HealthSystem, Evanston, IL, [3]NorthShore University Health System, Evanston, IL

OBJECTIVE: Anemia in pregnancy is a significant contributor to maternal morbidity including risk for cesarean delivery and need for transfusion. The relationship between antepartum diet and anemia is not yet well established. A more thorough understanding of this relationship represents a potentially modifiable risk factor for adverse outcomes.

STUDY DESIGN: This was a secondary analysis of a previously collected dataset from the nuMoms2B study that included 9,289 low risk primiparous patients from September 2010 through June 2014. The American Healthy Eating Index (AHEI-2010) was completed by participants in the first trimester to assess quality of diet in the 3 months prior to conception. AHEI scores were categorized by quartile, with the lowest quartile representing the lowest quality diet. Sociodemographic information was compared by quartile using chi square test and ANOVA for categorical and continuous variables, respectively. Antenatal anemia was defined as a third trimester hemoglobin of less than 11 g/dL measured after 24 weeks. Logistic regression was used to assess the association between AHEI-2010 quartile and anemia, adjusted for confounders.

RESULTS: A total of 6,071 patients were included in our analysis. Patients with the lowest AHEI-2010 scores (22.6 − 46) differed in demographic characteristics including a lower education level (39%), higher likelihood to identify as Black race (22.3%), and higher BMI. Adjusting for confounders, only those in the lowest AHEI2010 quartile had a significant independent association with the presence of third trimester anemia (aOR 1.40 95% CI 1.09 to 1.78, p = 0.007).

CONCLUSION: Pregnant patients with the lowest pre-conception diet quality are more likely to have anemia in the third trimester. Screening for diet quality preconception or earlier in pregnancy may represent an important way of identifying patients at risk of third trimester anemia, and allow for early intervention.

Association of Diet Quality with Third Trimester Anemia

Table. Association of Diet Quality with Third Trimester Anemia

Diet Quality by AHEI-2010	Unadjusted OR (95% CI)	P value	Adjusted OR (95% CI)*	P value
Fourth Quartile	1 (Reference)	N/A		
Third Quartile	1.01 (0.85 – 1.21)	0.13	0.94 (0.76- 1.16)	0.55
Second Quartile	**1.45 (1.22 - 1.72)**	**< 0.005**	1.04 (0.84- 1.30)	0.71
First Quartile	**1.89 (1.60 – 2.24)**	**< 0.005**	**1.40 (1.09- 1.78)**	**0.007**

*Adjusted for education, chronic hypertension, public insurance, race, age, marital status, seizure history, smoking status, percentage of federal poverty level***, BMI, bleeding disorders, asthma

**Third trimester anemia defined as hemoglobin < 11 g/dL after 24 weeks

***Percentage of federal poverty level (FPL) defined as <200% FPL

393 Cervical dilation after cervical ripening balloon as a predictor of cesarean delivery during induction

Clarissa Bluemm[1], Claire H. Packer[2], Alexandria Williams[3], Sarah E. Little[1]

[1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]Brigham and Women's Hospital, Brookline, MA

OBJECTIVE: Understanding predictors of cesarean delivery (CD) during induction of labor (IOL) is important to reduce CD rates and morbidity. We aimed to understand predictors of CD among patients who had an IOL with cervical ripening balloon.

STUDY DESIGN: Retrospective cohort study of 500 patients who had an IOL with cervical ripening. Labor events were extracted from the medical record and all cervical exams after balloon removal were recorded. STATA was used for statistical analysis with t-test for continuous variables and chi-square analysis and logistic regression for categorical variables, a p-value of < 0.05 was used to indicate statistical significance.

RESULTS: Of the 500 patients with a cervical balloon, 353 had a dual agent (89% Pitocin, 11% misoprostol). The overall risk of CD was 27%. Those who had a CD were more likely to be nulliparous with a higher BMI than those who did not have a CD (Table). The average cervical dilation of first exam was significantly different between groups with a mean of 3.5 cm vs 4.2 cm for those who did and did not have a CD, respectively ($P< 0.01$). Dual agent ripening vs cervical balloon alone was not significantly associated with CD. In a logistic regression model adjusting for age, race, BMI, and birthweight, a first cervical exam $<$ or $=$ 3 cm after removal of balloon was a significant predictor of CD with an adjusted OR of 1.77 (95% CI 1.15-2.70) A first exam $<$ or $=$ 3cm after balloon removal was also a predictor of CD prior to active labor (6cm) with an adjusted OR of 2.52 (95%CI 1.44-4.41). Cervical dilation at first, second and third exam after balloon removal were also independent predictors of CD in adjusted logistic regression models.

CONCLUSION: For those undergoing induction of labor, those with a cervical dilation of $<$ or $=$ 3cm after cervical ripening balloon have a higher risk of cesarean delivery (aOR 1.77) and specifically a higher risk of CD for a failed induction (aOR 2.52). Cervical exam after balloon ripening could potentially be used as an intrapartum risk stratification tool for cesarean delivery risk.

	No Cesarean N=365	Cesarean N=135	P- value

394 Azithromycin Dose and PPROM Treatment (ADAPT): a randomized controlled Phase I trial

Rupsa C. Boelig[1], Gagan Kaushal[2], Ankit Rochani[3], Walter Kraft[4]

[1]Thomas Jefferson University Hospital, Philadelphia, PA, [2]Thomas Jefferson University, Philadelphia, PA, [3]St. John Fisher University, Rochester, NY, [4]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA

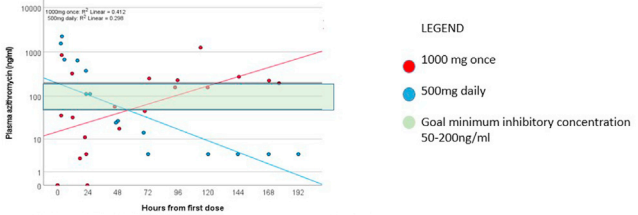
OBJECTIVE: Azithromycin clears from plasma quickly and concentrates in local tissue which is why daily dosing is not always needed. However, 1g one time dose of azithromycin may not maintain local (amniotic fluid) drug concentrations above minimum inhibitory concentrations (MIC50) for common genitourinary pathogens (50-200ng/ml). We aim to compare the pharmacokinetics of one time vs daily dosing of azithromycin in the setting of preterm prelabor rupture of membranes (PPROM).

STUDY DESIGN: This is a trial of singletons with PPROM randomized to 1gram oral azithromycin once or 500mg oral azithromycin daily x7 days. Primary outcome was amniotic fluid azithromycin concentrations over 8 days. Secondary outcomes included plasma azithromycin trough concentrations. Plasma was collected 1-4hrs, 12-24hrs after first dose, and then every 24hrs through 8 days. Amniotic fluid was collected throughout the day noninvasively with Always Flex-foam pads. We aimed to enroll 20 participants to achieve N=5 still pregnant through 8 days in each group. Continuous variables compared with Mann Whitney U test and relationship between azithromycin concentration and time assessed with linear regression.

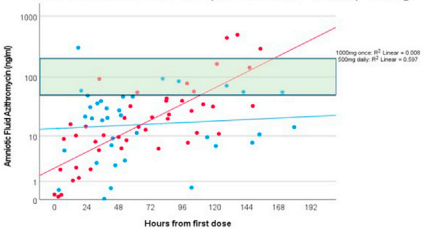
RESULTS: The study was halted after N=6 enrolled due to lagging enrollment, with 3 in each group. Mean gestational age of enrollment was 27.1 +/- 1.7wks in the 1g group and 31.0 +/- 1.4 in the 500mg daily group. One participant in each group had latency to delivery >7days. Mean amniotic fluid azithromycin concentration >96 hours from first dose was lower in the 1g once vs 500mg daily groups (25 +/-27 vs 131+/-163 ng/ml, MD -104 (-200 to -9, p=0.03). Plasma azithromycin concentration decreased over time in one time dosing (p=0.03) but not daily dosing (p=0.39) (Figure A). In contrast, amniotic fluid concentration remained relatively stable in the 1g group (p=0.71), but increased in the 500mg daily group (p< 0.001) (Figure B).

CONCLUSION: 500mg daily dosing of azithromycin maintains higher amniotic fluid concentrations, and more consistently greater than common MICs, over eight days compared to 1g once in the setting of PPROM.

A. Maternal plasma azithromycin with once vs daily dosing



B. Amniotic fluid azithromycin with once vs daily dosing



395 Factors Associated with Achieving Smoking Cessation for Pregnant Individuals with Substance Use Disorder

Ashley Boerrigter[1], Pranaya Chilukuri[2], Cynthia Cockerham[1], Adrianne Caudill[1], Gregory Hawk[1], Kaitlyn Nunnelly[3], Barbara V. Parilla[4]

[1]University of Kentucky, Lexington, KY, [2]University of Kentucky Albert B. Chandler Hospital, Lexington, KY, [3]University of Louisville, Louisville, KY, [4]UK Albert B. Chandler, Lexington, KY

OBJECTIVE: Maternal tobacco use, especially when comorbid with substance use disorder (SUD), leads to multiple adverse neonatal outcomes. Therefore, giving women the best chance for smoking cessation is important. This study evaluates interventions associated with a decrease in smoking among women with SUD receiving perinatal care within a multidisciplinary treatment program.

STUDY DESIGN: This was a longitudinal cohort study of obstetric patients with SUD enrolled in a multispecialty treatment program from 2015 to 2023. Patients were divided into two groups based on self-reported number of cigarettes smoked. Patients ≥ 36 weeks who still smoked >50% of the number of cigarettes reported at enrollment were compared to those who decreased tobacco intake by at

least 50% or quit entirely. Fisher's exact and two-sample t-tests were used for analysis.

RESULTS: Of 194 patients reviewed at 36 weeks, 137 patients reported still smoking > 50% of their tobacco use at program enrollment and 57 achieved > 50% decrease in use or quit entirely. Age, parity, race, BMI, and history of overdose did not differ significantly between groups. Nicotine replacement therapy (NRT) was used by 6.5% of patients persisting in their tobacco use compared to 10.4% of patients who decreased tobacco amount ($p = 0.52$). There was no significant difference between groups regarding participation in a group education session on tobacco cessation, adjunct anxiolytic use, or antidepressant therapy. Fetal growth restriction was diagnosed in 13.1% of patients that continued to smoke compared to 5.3% ($p = 0.13$) of patients in the cessation group.

CONCLUSION: No variables investigated differed significantly between patients who were able to decrease or completely stop smoking during pregnancy, albeit a limited sample size. Patients who successfully cut down or achieved cessation were more likely to have used nicotine replacement therapy. Surprisingly, participation in group education focused on smoking cessation did not differ.

396 Efforts to reduce NTSV cesareans by achieving ACOG/SMFM recommendations in a statewide quality improvement initiative

Patricia Lee King[1], Eileen Suse[1], Kristine kuchta[2], Dan Weiss[2], Alana Rivera[2], Ann Borders[3]

[1]Northwestern University, Chicago, IL, [2]NorthShore University HealthSystem, Evanston, IL, [3]NorthShore University HealthSystem, Evanston Hospital, Evanston, IL

OBJECTIVE: The Promoting Vaginal Birth (PVB) quality improvement (QI) initiative aims to reduce nulliparous, singleton, term and vertex (NSTV) cesarean section deliveries (C/S) and increase the percent of C/S meeting ACOG/SMFM OB care consensus recommendations for C/S indication. We aim to identify progress towards meeting initiative goals from baseline (Oct-Dec 2019) to 27-months into initiative Q1 (Jan-Mar) 2023.

STUDY DESIGN: ILPQC facilitated collaborative learning, rapid-response data and QI support for hospitals. Hospitals reported a random sample of 20 NTSV C/S per month and monthly progress on implementation of systems changes. McNemar's Test was used to evaluate progress on systems changes, proportion of deliveries that met ACOG/SMFM recommendations and % of hospitals achieving initiative goal of ≤23.6% NTSV C/S between baseline and Q1 2023. A Chi-Square Test was used to evaluate change in statewide NTSV C/S rate between baseline and Q1 2023 and change in disparities between NTSV C/S rate between white and Black patients.

RESULTS: 69 participating hospitals were included in the analysis. Hospitals improved between baseline and Q1 2023 on implementation of all systems changes ($p < .0001$) and meeting ACOG/SMFM recommendations overall from 50.1% to 65.3% ($p < .0001$) and for all C/S indications (Table 1). In Q1 2023, 47.8% of hospitals were at NTSV C/S rate goal of ≤23.6%. The statewide overall NTSV C/S rate was 25.1% at baseline and reduced to 23.4% by Q1 2023 ($p=.0118$). At baseline, the rate of NTSV C/S was higher in Black patients than white (30.5% vs. 26.3%, $p=0.02$) but by Q1 2023, the rate was similar between groups (24.3% vs. 23.1%. $p=0.37$).

CONCLUSION: Decreasing the rate of non-indicated NTSV C/S can improve maternal outcomes. Our results indicate that a statewide PVB QI initiative is associated with equitable implementation of systems changes, meeting ACOG/SMFM recommendations, an overall reduction in NTSV C/S births and reduction in the disparities gap 27 months into the initiative. Ongoing work will focus on safe reduction of NTSV C/S rates to goal for all Illinois hospitals.

Table 1. Change in percent of patients meeting ACOG/SMFM recommendations for C/S indications (N=3,840 baseline and 3,113 Q1 (Jan-Mar) 2023 patients included from 69 hospitals)

ACOG/SMFM recommendations	Baseline (2019) N (%)	Q1 (Jan-Mar) 2023 N (%)	p-value
Overall (Failed induction, arrest disorders 1st and 2nd stage)	474 (50.1)	512 (65.3)	<.0001
Failed induction	94 (33.0)	105 (48.8)	0.0003
Arrest disorder 1st stage	271 (74.9)	243 (81.5)	0.0396
Arrest disorder 2nd stage	109 (36.5)	164 (60.5)	<.0001

397 Effectiveness of a cervical pessary to prolong pregnancy after an episode of preterm labor

Sofie H. Breuking[1], Annemijn de Ruigh[1], Carme Merced[2], Laia Pratcorona[2], Madelon van Wely[3], Rik van Eekelen[3], Elena Carreras[2], Gabriele Saccone[4], Ben Willem W. Mol[5], Maria Goya[2], Eva Pajkrt[1], Frederik J. R. Hermans[1]

[1]Amsterdam UMC, location AMC, Amsterdam, Noord-Holland, [2]Hospital Universitari Vall d'Hebron, Barcelona, Spain, [3]Amsterdam Reproduction and Development Research Institute, Amsterdam UMC, Amsterdam, Noord-Holland, [4]Università degli studi di Napoli Federico II, Philadelphia, PA, [5]Monash University, Clayton, Victoria

OBJECTIVE: Randomized controlled trials (RCTs) on using a cervical pessary after an episode of preterm labor (PTL) show contradictive results. This study aims to perform an Individual Participant Data Meta-Analysis (IPD-MA) to assess the effectiveness of a cervical pessary to prolong pregnancy after an episode of PTL.

STUDY DESIGN: For this IPD-MA, RCTs were included that randomized pregnant women with a singleton pregnancy between 24-34 weeks with an ceased episode of PTL between cervical pessary or control (no intervention). This IPD-MA followed the PRISMA-IPD guidelines. Co-primary outcomes were: interval between randomization and delivery, delivery < 7 days and a composite of neonatal outcomes (mortality and severe morbidity). Secondary outcomes were maternal and neonatal outcomes according to the core outcomes set for preterm birth(PTB) studies. For all outcomes, a one-step meta-analysis approach was employed.

RESULTS: Five RCTs were eligible for inclusion of which three were included(n=273 pessary group, n=268 control group). Two trials were excluded since no data was provided. Mean prolongation of pregnancy was 59.3±27.7 days for pessary compared to 54.9±27.1 days for controls with a mean difference of 4.5 days (95% CI -0.08 - 9.0; P-value 0.054). Cervical pessary did not reduce risk of delivery < 7 days (RR 0.87; 95% CI 0.40 - 1.9; P-value 0.31). Moreover, there was no reduction in composite neonatal outcome (7.7% versus 8.2%, RR 0.95; 95% CI 0.53 - 1.7). Readmissions for PTL were lower in the pessary group (45 vs. 77, RR 0.50; 95% CI 0.32-0.77). No differences were found for other secondary maternal or perinatal outcomes (Table 1).

CONCLUSION: In women who went through an episode of PTL, we found no statistical significant beneficial effect for pessary placement in terms of delivery < 7 days, prolongation of pregnancy, PTB, or neonatal outcomes between both groups. Pessary reduced the probability of readmissions for PTL.

Table 1: primary and secondary outcomes

398 Does Timing of Diagnosis of Hypertensive Disorders of Pregnancy Impact perinatal Outcomes?

Eric K. Broni[1], Joana Lopes Perdigao[2], Nathanael C. Koelper[1], Jennifer Lewey[1], Lisa D. Levine[1]
[1]University of Pennsylvania, Philadelphia, PA, [2]University of Chicago, Chicago, IL

OBJECTIVE: Hypertensive disorders of pregnancy (HDP) can be diagnosed prior to labor starting, during the labor course or postpartum (pp). We sought to evaluate whether the timing of when HDP is diagnosed impacts pp blood pressure (BP) outcomes.

STUDY DESIGN: This was a secondary analysis of a randomized trial evaluating the efficacy of furosemide on BP outcomes. 384 patients with HDP (including gestational hypertension and preeclampsia with/without severe features) were enrolled at an urban tertiary care hospital between June 2018 to October 2019 with BPs followed for 10 days pp through a text-messaging program. Timing of HDP diagnosis was dichotomized based on distribution of outcomes: Time 1: diagnosed prior to labor or during latent labor; Time 2: diagnosed in active labor or pp. Primary outcome was time to resolution of hypertension (number of days to BP < 140/90 x 2). Secondary outcomes included persistent hypertension 7 days pp and need for antihypertensives pp. Multivariable logistic and Cox regression models were used to estimate associations between timing of HDP and outcomes.

RESULTS: Of 384 subjects, 338 (88%) were diagnosed with HDP at Time 1 and 46 (12%) at Time 2. Compared to those in Time 1, those diagnosed in Time 2 were less likely to have severe preeclampsia (11% vs. 35% p=0.001), were later in gestation (39 vs. 38 wks, p=0.004) and more likely to have a vaginal delivery (98% vs. 73%, p< 0.001), Table. Patients diagnosed at Time 2 had significantly shorter/faster median time to pp BP resolution even after controlling for severity of HDP, mode of delivery and furosemide use (5.5 vs. 6 days, aHR 1.17, 95% CI [1.07 − 1.28]). There was no difference in rate of persistent pp hypertension or need for antihypertensives, Table.

CONCLUSION: Timing of diagnosis of HDP impacts pp BP resolution. Patients diagnosed with HDP in active labor or postpartum experience a faster time to BP resolution. Our results may have implications for postpartum blood pressure monitoring. Further research targeting the pathways driving these findings should therefore be explored.

Table. Characteristics of Study participants by timing of HDP diagnosis.

Characteristics	Antepartum/Latent Intrapartum Time 1 (n=338)	Active Intrapartum/Postpartum Time 2 (n= 46)	*P* value
Maternal age, yrs, median (IQR)	27 (23 – 32)	27 (22 – 31)	0.790

399 Development of a risk scoring system for prediction of blood transfusion during admission for delivery

Ann M. Bruno
University of Utah Health, Salt Lake City, UT; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: The most widely used tool for prediction of blood transfusion during admission for delivery is informed by expert

opinion rather than data. We aimed to develop and internally validate a practical and data-driven risk scoring system to predict blood transfusion during delivery admission in a contemporary U.S. cohort.

STUDY DESIGN: This was a secondary analysis of a multicenter cohort of patients delivering on randomly selected days at 17 U.S. hospitals (2019-20). Patients with placenta accreta spectrum were excluded (given known high risk for transfusion). The primary outcome was any blood transfusion during delivery admission. Candidate risk factors for transfusion were selected based on relevant literature. A multivariable logistic regression model was developed and internally validated using stratified k-fold (k=5) cross validation with stepwise backward elimination using significance level of 0.05. Each risk factor included in the final model was assigned a point value by dividing the log of the odds ratio by the log of the odds ratio of the factor with the lowest value. The summed points for an individual generate a numeric risk score predictive of transfusion. Performance of the risk score to predict transfusion was assessed using the area under the receiver operating curve (AUC).

RESULTS: Of 21,780 included individuals, 2.5% (N=545) received a blood transfusion. Factors associated with the highest risk for transfusion in the adjusted model included thrombocytopenia and placental abruption or significant antepartum bleeding (Table). Risk score outputs among patients in the cohort ranged from 0 to 18 (maximum possible 26) with a corresponding predicted risk for transfusion from 1.0% to 87.8%. The AUC for prediction of transfusion in the validation sub-sample was 0.81. Using the full cohort, the AUC was 0.76 (95% CI 0.74-0.78).

CONCLUSION: We developed a clinically applicable numeric risk score to predict blood transfusion during delivery admission. Future work should externally validate this risk scoring system.

Table. Adjusted odds ratio, risk difference per 1000 and derived risk score for factors associated with transfusion during delivery admission

Risk Factor Description	aOR (95% CI)	Adjusted risk difference per 1000 (95% CI)*	Score†
Thrombocytopenia (platelets <100,000/μL)	6.0 (4.1 – 8.9)	152 (97 – 207)	5
Abruption or significant antepartum bleeding	4.0 (2.9 – 5.4)	56 (34 – 78)	4
Unscheduled cesarean	3.1 (2.4 – 3.9)	44 (30 – 59)	3
Multifetal gestation	2.9 (2.0 – 4.3)	45 (17 – 73)	3
Preeclampsia with severe features or HELLP‡	2.8 (2.1 – 3.6)	39 (26 – 53)	3
Assisted reproductive technology	2.4 (1.7 – 3.4)	27 (10 – 44)	2
Chorioamnionitis‖	2.2 (1.6 – 3.0)	24 (11 – 37)	2
Prior cesarean delivery or uterine surgery¶	1.8 (1.4 – 2.3)	13 (6 – 21)	2
Prolonged labor (>24 hours)	1.6 (1.3 – 2.0)	9 (3 – 15)	1
Anemia**	1.4 (1.2 – 1.8)	5 (1 – 10)	1

Adjusted odds ratio (aOR); confidence interval (CI); Hemolysis, elevated liver enzymes, low platelet count (HELLP)
*The adjusted risk difference is the attributable risk for transfusion resulting from exposure to the specified risk factor in a theoretic population of 1000.
†The risk score is calculated by dividing the log of the odds ratio for the risk factor by the log of the odds ratio of the factor with the lowest value in the model. For example, the risk score for multifetal gestation is calculated by dividing the log of the odds ratio for multifetal gestation (2.9) by the log of the odds ratio of the factor with the lowest value (anemia: 1.4) to produce a risk score of 3.
‡Preeclampsia with severe features and HELLP as defined by ACOG
‖Chorioamnionitis defined clinically with a body temperature ≥37.8°C and no other known infection
¶Includes any prior uterine surgery (e.g., myomectomy)
**Anemia defined by treatment (i.e., iron supplementation)

400 Association of Trimester-Specific Smoking Cessation and Risk of Stillbirth

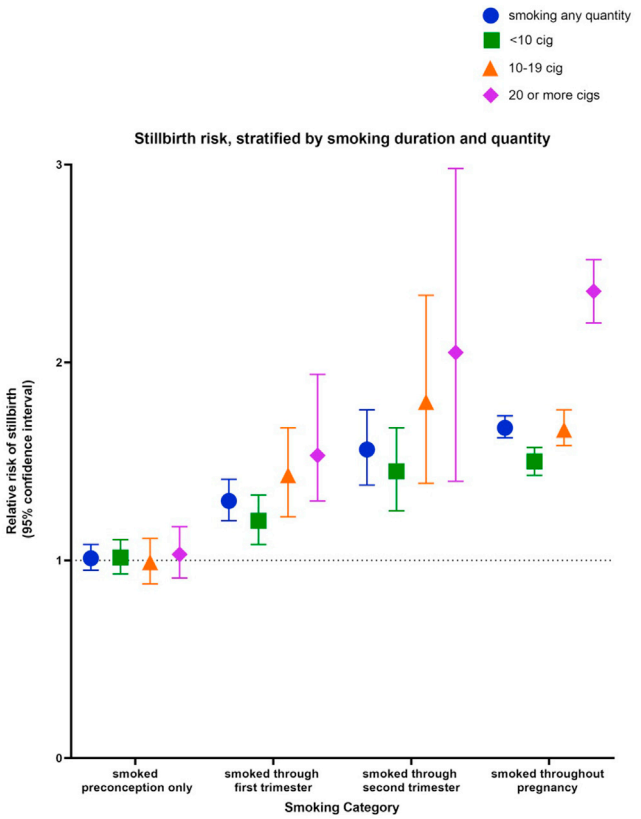
Morgan Buckley, Robert M. Rossi, Emily A. DeFranco
University of Cincinnati College of Medicine, Cincinnati, OH

OBJECTIVE: Tobacco use in pregnancy is associated with stillbirth and other adverse pregnancy outcomes. This study aims to quantify the relative influence of smoking cessation at various timepoints in pregnancy on stillbirth risk.

STUDY DESIGN: Population-based retrospective cohort study of all US live births and stillbirths using vital statistics birth records, 2014-2019. Outcomes of women who reported smoking only in the 3 months prior to conception, through first trimester then quit, through second trimester then quit, and smoked throughout pregnancy were compared to a referent group of nonsmokers. Generalized linear modeling estimated the relative risk of smoking duration during pregnancy on stillbirth risk and was also stratified by categories of number of cigarettes smoked per day. Outcomes were limited to births at 32-42 weeks.

RESULTS: Of 23,500,558 births, 10.0% smoked either preconception only or anytime during the pregnancy. The overall stillbirth rate during the study period was 0.26%, 0.20% in non-smokers, and 0.29% in smokers. Stillbirth rate was 0.20% among preconception only smokers, 0.26% and 0.31% when smoking cessation occurred after the first or second trimester, respectively, and the highest among those who smoked throughout pregnancy 0.34%, $p < 0.0001$. Smoking limited to preconception only had no significant association with stillbirth, however stillbirth risk demonstrated a sequential increase with longer durations of smoking during pregnancy, with highest risk among those who smoked throughout pregnancy. Stillbirth risk was also higher among those who smoked higher number of cigarettes per day (figure).

CONCLUSION: Smoking during pregnancy is associated with increased risk of stillbirth, with sequential increased risk with longer durations of smoking during pregnancy and smoking a higher number of cigarettes per day. These data demonstrate that quitting earlier in pregnancy is optimal, and for those who do not quit, smoking fewer number of cigarettes per day may help to minimize the risk of stillbirth.



401 Digital exams in patients with PPROM: Outcomes based on number of exams

Julia Burd[1], Evaline Xie[2], Jeannie C. Kelly[3], Ebony B. Carter[3], Anthony O. Odibo[1], Amanda C. Zofkie[3], Antonina I. Frolova[1], Nandini Raghuraman[1]

[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

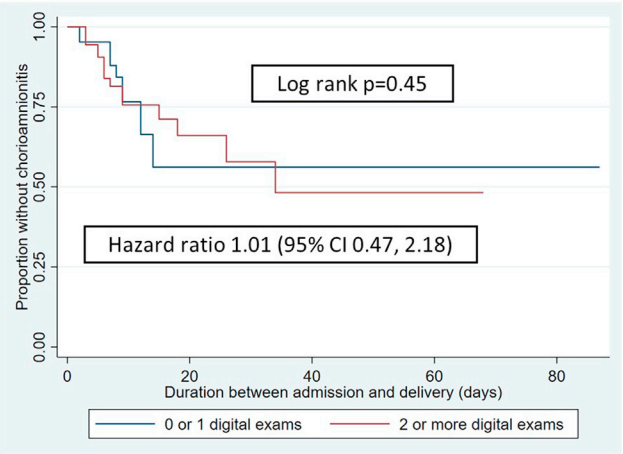
OBJECTIVE: ACOG recommends minimizing digital exams in patients with preterm prelabor rupture of membranes (PPROM). However, many patients with PPROM ultimately receive digital exams when speculum exams are limiting or not feasible. We examined the association between number of digital exams and outcomes in patients with PPROM in a modern population.

STUDY DESIGN: This was a retrospective cohort study of patients with PPROM at a single center between January 2019 and March 2021. Inclusion criteria were singleton gestations between 24w0d and 33w6d gestation with confirmed rupture of membranes who delivered > 24 hours after PPROM diagnosis. The primary outcome was chorioamnionitis. Secondary outcomes were composite maternal and neonatal infectious morbidity. These outcomes were compared between patients who had ≤1 and >1 digital exams prior to the diagnosis of labor or start of induction. A Cox proportional hazards regression model was performed to account for latency (duration between admission and delivery).

RESULTS: 125 patients with PPROM were included in this analysis. The median number of digital exams performed were 2 (interquartile range 1, 3). Patient with >1 digital exams were more likely to go into spontaneous labor (24% vs. 51%, p=0.003). However, there was no significant difference in pregnancy latency between patients with ≤1 and >1 digital exams (9 vs. 6 days, p=0.19). There was no difference in the rate of chorioamnionitis between patients with ≤1 and >1 digital exams (23.9% vs. 20.3%, hazard ratio (HR) 1.01, 95% confidence interval (CI) 0.47, 2.18). Composite maternal infectious morbidity (30.4% vs 24.1%, HR 0.92, 95% CI 0.46, 1.85) and neonatal infectious morbidity (2.2% vs 3.8%, HR 2.01, 95% CI 0.21, 19.59) were similar between groups.

CONCLUSION: Although >1 digital exam was associated with an increase in spontaneous labor, this is likely confounded by indication (symptomatic patients are more likely to get digital exams than speculum exams). Importantly, there is no association between number of digital exams and latency or infectious morbidity in patients with PPROM.

Figure 1: Kaplan-Meier survival estimates for chorioamnionitis based on number of digital exams



402 Chorion-Derived Extracellular Vesicles Cargo Transporter protein BCRP: Paracrine drug transportation at the feto-maternal interface

Benjamin A. Bush[1], Ananth Kumar Kammala[2], Mohamed Bettayeb[3], Tilu Jain[3], RamKumar Menon[4]

[1]UTMB-Galveston, Friendswood, TX, [2]University of Texas Medical Branch, Galveston, TX, [3]University of Texas - Medical Branch, Galveston, TX, [4]University of Texas Medical Branch, League City, TX

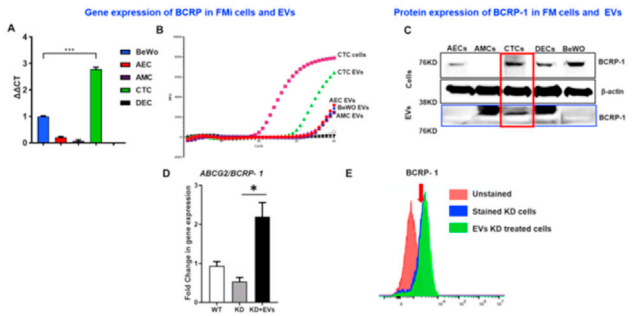
OBJECTIVE: The transport of drugs across the placenta during pregnancy impacts maternal well-being and fetal development. Transporter proteins like Breast Cancer Resistance Protein-1 (BCRP-1) participate in drug efflux mechanisms and influence the pharmacokinetics of diverse substances. BCRP-1 can be propagated in extracellular vesicles (EVs) to transition BCRP-1 lacking cells to perform drug transport functions. This study explored the paracrine signaling abilities of chorion trophoblast cell (CTC)-derived EVs in restoring BCRP-1 expression loss.

STUDY DESIGN: BCRP-1 gene (qRT-PCR) and protein (western blot) expressions were determined in fetal membrane cells (amnion, chorion) and decidua. EVs from CTCs were isolated and the presence of BCRP-1 was confirmed in EVs (western blot). We employed the CRISPR/Cas9 approach to achieve BCRP-1 knockdown in maternal decidual cells. These cells were subsequently exposed to CTC-derived EVs containing BCRP-1, and the restoration of BCRP-1 expression was assessed by PCR and surface expression by flow cytometry.

RESULTS: Gene expression levels of ABCG2/BCRP-1 were significantly higher in CTCs compared to BeWo cells (+ve control)) (Fig 1A, ***p< 0.001). EVs derived from CTCs had higher BCRP-1gene (Fig 1B) compared to AEC and DEC. BCRP-1 protein in EVs was similar to those derived from amnion and decidual cells (Fig 1C). Upon treatment with chorion-derived EVs, maternal decidual cells with BCRP-1 knockdown displayed effective restoration of BCRP-1 protein, as demonstrated by gene levels (Fig 1D) and surface protein expression levels (Fig 1E).

CONCLUSION: This study provides pioneering evidence that the delivery of BCRP-1 through EVs can trigger drug efflux activity in cells via paracrine signaling. The modulation of BCRP-1 by EVs underscores the intricate interplay between EVs and placental drug transport mechanisms, offering valuable insights into their potential involvement in modulating drug responses during pregnancy.

Figure 1. Expression and functional paracrine signaling of BCRP-1 in chorion-derived extracellular vesicles



403 Associations between diabetic keto acidosis and adverse neonatal outcomes in those with pre-gestational diabetes

Kimberly Ryan, Alyssa R. Hersh, Rachel Madding, Bharti Garg, Amy M. Valent, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

OBJECTIVE: Type 1 diabetes (T1D) and type 2 diabetes (T2D) have been associated with increased neonatal morbidity in pregnancy. Specifically, diabetic ketoacidosis (DKA) during pregnancy can cause significant adverse perinatal outcomes, however, the impact of a DKA diagnosis in pregnancy on neonatal outcomes unknown.

STUDY DESIGN: This is a retrospective cohort study of California linked hospital discharge-vital statistics data from 2008-2019. We included singleton, live-born infants with gestational age of 23-42 weeks in those with pre-gestational diabetes. We compared neonatal outcomes in pregnancies of individuals with T1D and T2D who received a diagnosis of DKA during pregnancy to those who did not. Chi-squared and multivariable logistic regression were utilized for statistical analyses.

RESULTS: A total of 7,401 pregnancies with T1D and 38,062 pregnancies with T2D were included, of which 786 (10.6%) and 703 (1.9%) had DKA during the pregnancy, respectively. Although not significant between the groups, those with T1D had high rates of NICU admission both with or without a diagnosis of DKA in pregnancy (33.4 vs 22.5%). Among those with Type 2D, a diagnosis of DKA in pregnancy was associated with NICU admission (aOR: 1.62; 95% CI: 1.35, 1.95), respiratory distress syndrome (aOR: 1.33; 95% CI: 1.01, 1.75) and large for gestational age infants (aOR: 1.32; 95% 1.27, 1.80) as compared to those without DKA.

CONCLUSION: Our study suggests that in those with T2D, DKA in pregnancy significantly increases the risk of adverse neonatal outcomes. Although the findings were not significant for T1D, there are still high rates of NICU admission. This may suggest that the effect of DKA on placental function may vary for T1D and T2D.

Table 1. Multivariable logistic regression models showing adjusted odds ratios for neonatal outcomes

	DKA in Pregnancy	No DKA in Pregnancy	aOR (95% CI)[a]
T1D (n= 7,401)			
NICU admission	263 (33.4%)	1,491 (22.5%)	1.09 (0.90, 1.32)
Respiratory distress syndrome	107 (13.6%)	502 (7.5%)	1.25 (0.95, 1.63)
Large for gestational age	285 (36.2%)	2,440 (36.8%)	1.04 (0.88, 1.24)
Neonatal Death	5 (0.6%)	15 (0.2%)	1.42 (0.42, 4.76)
T2D (n= 38,062)			
NICU admission	255 (36.2%)	7,320 (19.5%)	1.62 (1.35, 1.95)*
Respiratory distress syndrome	74 (10.5%)	2,182 (5.8%)	1.33 (1.01, 1.75)*
Large for gestational age	228 (32.4%)	10,141 (27.5%)	1.52 (1.27, 1.80)*
Neonatal Death	1 (0.1%)	75 (0.2%)	0.46 (0.05, 3.68)

404 Frequently Asked Questions in Prenatal Testing: Comparing Readability Between AI (ChatGPT) and ACOG

Angelo Cadiente[1], Jamie Chen[1], Andrew Haddad[2], Manuel Alvarez[2], Antonia F. Oladipo[2]
[1]Hackensack Meridian School of Medicine, Nutley, NJ, [2]Hackensack University Medical Center, Hackensack, NJ

OBJECTIVE: Gravid patients often seek answers to their pregnancy-related questions online, requiring simple and accurate responses to ensure adequate understanding. We aim to compare the readability between a natural language processing tool (ChatGPT) and the American College of Obstetricians and Gynecologists (ACOG) when responding to frequently asked questions (FAQs) about prenatal testing.

STUDY DESIGN: ACOG FAQ sheets were pooled under the topic "Prenatal Testing". Each question was queried in ChatGPT-3.5 (July 20 Version) - with some questions requiring contextualization, prompting "In the context of [topic], [question]?" Readability scores and grade level scores were calculated for each response. With the exception of the Flesch Kincaid Reading Ease score, each measure describes the amount of formal education required to understand a given response. Statistical analysis utilized a two-tailed t-test to compare ACOG and ChatGPT-3.5 responses.

RESULTS: Within the 11 FAQ sheets under "Prenatal Testing", 182 questions were assessed. In all readability indices, ACOG responses scored significantly better than ChatGPT-generated responses and were statistically significant. These readability indices include: Flesch Kincaid Reading Ease 57.23 (SD 19.49) vs 35.97 (9.07), Flesch Kincaid Grade Level 9.45 (3.88) vs 12.70 (1.60), Gunning Fog Score 12.31 (4.31) vs 16.33 (2.03), Smog Index 9.01 (3.07) vs 12.07 (1.34), Coleman Liau Index 11.72 (3.36) vs 15.11 (1.70), and Automated Readability Index 9.00 (4.64) vs 12.30 (1.84; all $p < 0.0001$).

CONCLUSION: ACOG FAQ responses are clearer and more readable when compared to ChatGPT-generated responses. This suggests that fewer years of formal education is required to comprehend the content. Patients can reliably use ACOG verified responses as a source of high-quality, "easy to read" and understandable information. ChatGPT is an accessible resource but caution should be taken when asking pregnancy-related questions. Further studies are needed to assess the quality of natural language processors and its impact on patient's knowledge.

405 Expectant management of Early Onset Preeclampsia with Severe Features Before 24 weeks

Kristen Cagino[1], Rylee Trotter[1], Katherine Lambert[2], Saloni Kumar[2], Baha M. Sibai[3]
[1]University of Texas-Houston Medical School, Houston, TX, [2]McGovern Medical School at UTHealth Houston, Houston, TX, [3]Hermann Memorial Hospital, Houston, TX

OBJECTIVE: The recent ACOG practice bulletin offers no guidance on management of early onset severe preeclampsia (PreE) before 24 weeks (wks). Historically, delivery was recommended due to poor perinatal outcomes and risk of maternal morbidity. An increase in maternal age, medical co-morbidities, and advances in neonatal resuscitation have led to more cases of early onset severe PreE with the possibility of expectant management at gestational ages below the limit of viability. We aimed to report perinatal and maternal outcomes after expectant management of severe PreE < 24 wks to assist in counseling and shared decision making.

STUDY DESIGN: A retrospective case series of individuals with severe PreE at < 24 wks gestation managed at a Level IV center between 2017-2022. Individuals requiring delivery within 24 hours of diagnosis were excluded. Perinatal and maternal outcomes were abstracted from electronic medical records.

RESULTS: Of 27,626 births during the study period, 51 (0.2%) had severe PreE < 24 wks and 9 (18%) were excluded due to delivery < 24 hours. Among 42 undergoing expectant management, the median gestational age of diagnosis was 23 wks. 55% had chronic

hypertension, 33% had PreE in a prior pregnancy, and 71% had a BMI >30 kg/m^2. There was one surviving neonate when PreE developed at < 22 wks. Neonatal survival was highest at 22-23 wks (43%; 95%CI 21-67% and 58%; 95%CI 36-77%, respectively). Median latency at 22 and 23 wks was 6 (range 1-38) and 4 days (range 1-46), respectively. Median NICU stay at 22 and 23 wks was 124 (range 15-271) and 88 days (range 2-151), respectively. The most common indication for delivery was uncontrolled hypertension (49%). Adverse maternal outcomes were rare, the most common being transient renal insufficiency (7%; 95%CI 2-19%) and pulmonary edema (7%; 95% CI 2-19%) (Table 1).

CONCLUSION: Our findings suggest that perinatal survival is markedly improved during expectant management of severe PreE at 22-23 weeks with minimal increase in maternal morbidity. This information should be available when counseling individuals on expectant management of severe PreE < 24 weeks.

406 Cost-effectiveness of virtual Mindfulness Based Cognitive Therapy on pregnancies at high risk of perinatal depression

Lindsay Quinn[1], **Riane Bradbury-Huang**[2], **Ellen L. Tilden**[3], **Olivia J. Curl**[1], **Uma Doshi**[1], **Taylor Shank**[1], **Aaron B. Caughey**[1]
[1]Oregon Health & Science University, Portland, OR, [2]Barnard College, New York, NY, [3]Oregon Health & Science University, School of Nursing, Portland, OR

OBJECTIVE: Previous research has shown preventive counseling for women at high risk of perinatal depression to be cost-effective. Barriers of cost, transit, time, and staffing limit accessibility of these services. We examined whether a theoretical virtual, group, social worker (SW)-administered Mindfulness Based Cognitive Therapy (MBCT) program for patients at high risk of perinatal depression would be cost-effective.

STUDY DESIGN: We used TreeAge to create a cost-effectiveness model of outcomes in pregnant patients at high risk of perinatal depression who received antenatal virtual group MBCT curriculum versus standard of care. We used a theoretical cohort of 480,390 patients, representing pregnancies at high risk of postpartum depression annually. Outcomes included perinatal depression, maternal suicide, postpartum psychosis, infanticide, preterm birth, neonatal death, and cerebral palsy in addition to cost and quality-adjusted life years (QALYs). The willingness-to-pay threshold was set to $100,000/QALY. Literature searches found model inputs, and sensitivity analysis assessed model strength.

RESULTS: Within the theoretical cohort, the virtual, group, SW-led MBCT curriculum prevented 26,821 cases of perinatal depression, 2 cases of maternal suicide, 3 cases of postpartum psychosis, 4,142 cases of preterm delivery, 40 cases of neonatal death, and 48 cases of neurodevelopmental delay. There was no significant reduction in infanticide. The MBCT strategy was cost-saving. Sensitivity analyses demonstrated that MBCT remained cost-effective until treatment costs reached $4,015, significantly higher than expected cost. The incremental cost-effectiveness ratio (ICER) was -$10,141/QALY, indicating cost savings per QALY gained. SW-administered MBCT is superior to standard of care, yielding higher QALYs at lower cost.

CONCLUSION: We found it cost-saving to offer virtual, group SW-administered MBCT to pregnant patients at high risk of depression. Clinicians should pursue implementing similar programs.

Table 1. Outcomes prevented in a theoretical cohort of 480,390 pregnancies at high risk of perinatal depression assigned to either MBCT treatment or standard of care.

Outcome	Standard of Care	MBCT Treatment	Difference
Perinatal depression	68,193	41,372	-26,821
Maternal suicide	35	33	-2
Postpartum psychosis	618	615	-3
Infanticide	26	26	0
Preterm delivery	50,393	46,251	-4142
Neonatal death	927	887	-402
Neurodevelopmental delay	1,115	1066	-48
Cost (USD)	$10,034,315,243	$9,877,955,055	-$1,563,601,188
Effectiveness (QALYs)	12,751,827	12,767,245	15,418
Incremental Cost-Effectiveness Ratio (ICER)	-$10,141		

407 Development and validation of an early-pregnancy score predictive of stillbirths: an Italian population-based study

Anna Cantarutti[1], **Giovanni Corrao**[1], **Vera Rigamonti**[1], **Patrizia Vergani**[1], **Stefania Dell'Oro**[2], **Anna Carli**[2], **Anna Locatelli**[3]
[1]University of Milano-Bicocca, Milano, Lombardia, [2]Fondazione IRCCS San Gerardo dei Tintori, Lombardia, [3]University of Milano-Bicocca, Monza, Lombardia

OBJECTIVE: Although stillbirth rates in high-income countries have decreased significantly, ending preventable stillbirth is still a major global public health challenge. We developed a score to determine the risk of stillbirth at an early stage of pregnancy to guarantee the appropriate antenatal identification and prevent intrauterine fetal demise using an Italian population-based cohort.

STUDY DESIGN: We conducted a population-based cohort study including 316,149 deliveries with gestational age between 22 and 42 weeks of women aged 15-55 years from January 2017 to December 2021 in the Lombardy region of Italy using the administrative database. A StillBirth score (SB score) was built considering the independent variables able to explain the stillbirth at the 22 gestational weeks selected through a logistic regression model. A weight proportional to the coefficient estimated by the model was assigned to each of the selected variables contributing to the SB score. Discrimination and calibration of the SB score were assessed using an internal validation set. Moreover, we evaluated the risk of stillbirth among the risk classes based on the SB score (i.e., low $\leq$5 points, intermediate 6-8 points, high $\geq$9 points).

RESULTS: We identified 869 cases of stillbirth with an incidence rate of 2.7 x1000 person-year. The AUC of the SB score was 65% in the training set and 60% in the validation set. Analysis showed a 1.4-fold (95% IC: 1.1-1.7) greater risk of experiencing the outcome of

interest among deliveries with intermediate SB score and a 2.4-fold (95% IC: 2.0-2.8) greater risk among deliveries with high SB score, respectively to deliveries with a low SB score.

CONCLUSION: Despite the limited discriminatory power, the SB score can stratify women according to their risk of stillbirth, allowing the early identification of mothers who are more likely to have a stillbirth and facilitating appropriate monitoring and timely intervention based on individual risk factors.

408 Blood pressure control in patients with pregestational diabetes and perinatal outcomes

Macie L. Champion[1], Yuanfan Ye[2], Anna Lively[1], Ayodeji Sanusi[3], Alan T. Tita[1], Ashley N. Battarbee[1]

[1]University of Alabama at Birmingham, Birmingham, AL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [3]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

OBJECTIVE: ACOG/SMFM recommends BP < 140/90mmHg for cHTN in pregnancy. A secondary analysis of CHAP suggested BP < 130/80 reduced adverse outcomes for individuals with DM. Data on diabetes type or glycemic control was not presented. We aimed to determine optimal BP goals for patients with pregestational DM and evaluate for differences by diabetes type or glycemic control.

STUDY DESIGN: Retrospective cohort study of patients with DM and cHTN who entered care < 20wga and had ^{3} 3 prenatal visits at a single center from 2012-2023. Fetal anomalies, multiple gestations, pregnancy loss < 20wga, and average BP ^{3} 160/110 were excluded. Individuals were characterized by average BP at visits: < 130/80, 130-139/80-89, and 140-159/90-109. The primary outcome was preeclampsia. Secondary outcomes were PTB, composite neonatal morbidity, and NICU admission. Outcomes were compared between groups and multivariable logistic regression estimated the association between BP and outcomes. ROC curves were constructed for the prediction of preeclampsia by BP. Optimal cutpoints were determined using the Liu method.

RESULTS: Of 486 patients with DM and cHTN, 184 (38%) had average BP < 130/80, 201 (41%) < 130-139/80-89, and 101 (21%) 140/90-159/109. Those with higher BP were more likely to use antihypertensives and aspirin. Diabetes type, prepregnancy A1c, and last A1c did not differ. Patients with BP < 130/80 or 130-139/80-89 were less likely to have preeclampsia regardless of diabetes type and prepregnancy A1c (interaction p 0.92 and 0.22). Patients with lower BP were less likely to have PTB, composite neonatal morbidity and NICU admission. When analyzed as continuous measures, SBP and DBP were good predictors of preeclampsia (AUC 0.76 and 0.71) with optimal cutpoints of 129 mmHg and 78 mmHg.

CONCLUSION: For pregnant individuals with pregestational DM and cHTN, antepartum BP control to < 130/80 may be associated with lower odds of preeclampsia, PTB, and neonatal morbidity. Statistically optimal BP cutoffs support the BP goal < 130/80 mmHg for all individuals with pregestational DM regardless of diabetes type and glycemic control.

	<130/80 aOR (95% CI)*	130-139/80-89 aOR (95% CI)*	140-159/90-109 aOR (95% CI)*

409 Evaluating mean gestational age at delivery following early identification of short cervical length

Katherine L. Chen[1], Maggie Wong[2], Nabila Azeem[1], Oxana M. Zarudskaya[3], Kirsten Russell[1], Nauman Khurshid[1], Victora Starnes[1]

[1]University of Toledo, Toledo, OH, [2]Promedica Toledo Hospital, Toledo, OH, [3]University of Texas Health Science Center at San Antonio, San Antonio, TX

OBJECTIVE: To compare mean gestational ages at delivery between different interventions after early identification of short cervical length.

STUDY DESIGN: Retrospective cohort analysis of pregnant women who were identified with a short cervix at an initial 16 week to 22 week ultrasound at a teaching community hospital were performed from January 2016 to December 2021. All patients with a short cervix defined as 25mm or less were offered treatment with vaginal progesterone, cerclage, 17-hydroxyprogesterone (17-OHP), or with a combination of the therapies.

RESULTS: A total of 293 pregnant patients were identified and evaluated for having a short cervix as defined by less than 25mm. They received either vaginal progesterone, cerclage, vaginal progesterone and cerclage, 17 OHP, or cerclage with 17 OHP for prevention of preterm birth in their pregnancies. In the less than 15mm cervical length group, there was no statistically significant difference in the gestational age of delivery (F value 1.49, p value: 0.19). In the less than 15-20mm, cervical length group, there was no statistically significant difference in the means of all treatment groups (F value 0.85, p value: 0.53). And in the 20-25mm cervical length group, there was no statistically significant difference in the means of all treatment groups (F value 0.56, p value: 0.76).

CONCLUSION: Our results show there is no significant difference in mean gestational age at delivery for women who received a cerclage, vaginal progesterone, 17-OHP, or a combination of the treatments after short cervix identification at 16-18 weeks.

		Cerclage	Vaginal Progesterone	17 OHP	Cerclage & VP	Cerclage & 17OHP	None	F Value	P Value

410 Clinical Implications of Group Residential Treatment on Pregnant Individuals with Substance Use Disorder

Pranaya Chilukuri[1], Ashley Boerrigter[2], Cynthia Cockerham[2], Adrianne Caudill[2], Gregory Hawk[2], Alexandra Mitchell[3], Barbara V. Parilla[4]

[1]University of Kentucky Albert B. Chandler Hospital, Lexington, KY, [2]University of Kentucky, Lexington, KY, [3]University of Kentucky College of Medicine, Covington, KY, [4]UK Albert B. Chandler, Lexington, KY

OBJECTIVE: Unstable housing has been associated with obstetric (OB) outcomes of increased risk of preterm birth and longer hospital stays. As clinical care for substance use disorder (SUD) may involve recovery housing, this study evaluates group residential living effects on maternal and neonatal outcomes for women with SUD.

STUDY DESIGN: This was a longitudinal cohort study of OB patients with SUD within a multi-specialty treatment program from 2015 to 2023. The intervention group included patients in group housing (i.e., residential treatment, recovery housing, or sober living facilities) at time of initial prenatal visit. Outcomes including maternal trauma, medications for opioid use (MOUD), infant birth weight, APGARs, and neonatal hospital stay length were observed. Fisher's exact and two-sample t-tests were used for analysis.

RESULTS: Overall, 87 patients resided in group housing and 380 resided in alternative housing (controls). Age, parity, race, and BMI did not differ significantly between groups. Patients in group housing had significantly greater history of past overdose (63% vs. 42%, p=0.01), violence or trauma experience (82% vs. 69%, $p < 0.05$), less likelihood of private insurance (0 vs. 5%, $p < 0.05$), higher anxiolytic use (17% vs. 9%, $p < 0.05$), and less satisfaction with living condition (56% vs. 66%, $p < 0.05$). Women in group housing reported different MOUD from those in alternative housing ($p < 0.05$), as they used more methadone (4.7% vs. 0.5%) or no MOUD at all (16% vs. 12%). Women in alternative housing reported more buprenorphine use (87% vs. 79%). Mean infant birth weight differed for those in group housing (3049 vs. 2926 grams, p=0.05). There were no significant differences in delivery mode or gestational age, APGARS, or neonatal length of hospital stay.

CONCLUSION: Despite a higher allostatic load, patients in group housing had differing infant birth weights and similar pregnancy and neonatal outcomes albeit small numbers. Further review may be valued to maximize OB outcomes and SUD treatment in this population.

411 Effect of aspirin on mechanical properties of mesenteric arteries in a mouse model of preeclampsia

Danielle Chirumbole, Ancizar Betancourt, Moises Tacam, Manu Banadakoppa, Chandra Yallampalli

Baylor College of Medicine, Houston, TX

OBJECTIVE: Prior ex vivo animal studies have shown that acetylsalicylic acid (ASA) causes direct vasodilation of resistance vessels. The objective of this study is to understand the effect of ASA on the mechanical properties of mesenteric arteries in a murine model of preeclampsia (PE) and to further characterize ASA's mechanism of PE risk reduction.

STUDY DESIGN: Mesenteric arteries from a mouse model of PE and healthy gravid mice at 17.5 days gestation were dissected into rings and mounted to a Multi-Wire Myograph System. Arterial rings were precontracted with norepinephrine. Cumulative dose-response curves were calculated for ASA (0.001-0.006 μM), Calcitonin Gene-Related Peptide/CGRP ($10^{-10} - 10^{-7}$ M), a known endothelium-independent vasodilator, and acetylcholine ($10^{-10} - 10^{-5}$ M), a known endothelium-dependent vasodilator. The relaxation response was calculated as percent inhibition of the initially induced contraction, and the maximum possible effect for the reagent (E_{max}) was calculated accordingly. The concentration of each reagent required to

reduce tension by 50% (ED_{50}) was calculated when able. Student's t-test was used for statistical analysis.

RESULTS: Sixteen arterial rings from the PE model (n=4 mice) and 14 from healthy gravid mice (n=4) were included after excluding non-functioning channels and rings that did not demonstrate sustained contraction. E_{max} values (mean ± standard error of the mean) in PE and healthy mice respectively were 34.70±3.97 and 71.63±5.25% for ASA, 90.09±1.67 and 94.53±1.43% for CGRP, and 86.43±2.5 and 95.08±1.57% for acetylcholine. Mean E_{max} was significantly different between the PE and healthy groups for all reagents. ED50 could not be calculated for ASA. ED50 was significantly different between the PE and healthy groups for acetylcholine but not for CGRP, demonstrating altered endothelium in PE.

CONCLUSION: ASA does not have a direct vasodilatory effect on mesenteric arteries in a mouse model of PE. Thus, the ability of ASA to reduce preeclampsia risk may be due to its effects in early pregnancy at sites outside of the vasculature which alter the endothelium.

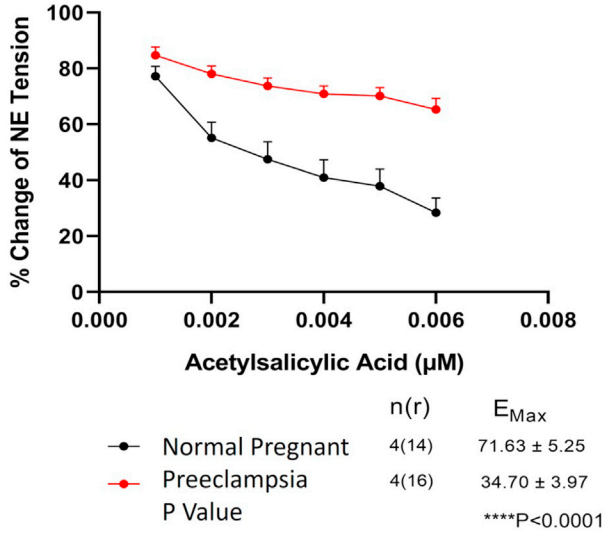

Figure 1: Percent inhibition of initial contraction induced by norepinephrine (NE) versus concentration acetylsalicylic acid (micromolar). N = number of mice, r = number of replicates, E_{max} = maximum possible effect (percent inhibition) ± standard error of the mean.

412 Flow mediated dilatation of brachial artery to evaluate endothelial dysfunction in gestational diabetes mellitus

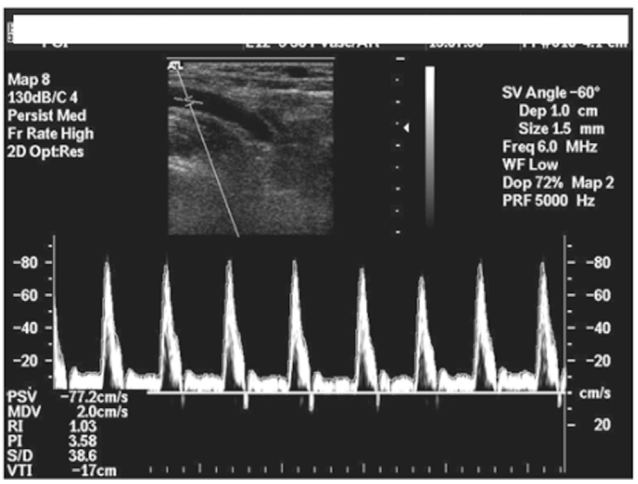
Seema Chopra[1], Purnima Singh[2], Vanita D. Jain[2], Ajay Bahl[2]
[1]Post Graduate Institute of Medical Education & Research, Chandigarh, [2]Post Graduate Institute of Medical Education & Research, Chandigarh, Chandigarh

OBJECTIVE: To evaluate flow mediated dilatation in pregnant women with GDM as a measure of endothelial dysfunction.

STUDY DESIGN: Prospective case control study conducted in OBG department PGIMER, Chandigarh, India. We included 40 women with GDM, and 40 normoglycemic age and parity matched women. FMD was measured in brachial artery in antecubital fossa with clear anterior and posterior intimal interfaces between the lumen and vessel wall as continuous 2-D gray scale imaging at a frequency 10 MHz (figure 1). Baseline vessel diameter (D1), and after flow stimulus by inflation of sphygmomanometer cuff for five minutes above the systolic blood pressure and subsequent release of pressure (D2) were measured. FMD(%)was expressed as (D2-D1/D1) x 100. Continuous variables were analyzed using Student's T test and categorical data were analyzed using Chi square test.

RESULTS: Difference in mean FMD (15.93±11.21%) in GDM group and 18.10±7.62% in normoglycemic group was not significant (p = 0.32), it was statistically significant(p = 0.01)when compared with GDM sub group on MNT(medical nutritional therapy) and insulin(FMD 10.56 ± 11.2%). Within GDM group itself, mean FMD showed a trend towards significance(p = 0.056)in women with fasting blood sugar < 126 mg% versus FBS >126mg%.It was statistically significant(p= 0.042) between MNT plus insulin compared to MNT alone. Gestation at and mode of delivery, perinatal outcome were comparable in cases and controls. 6/40 (2.25%) GDM women had persistent hyperglycemia at 6 weeks post partum.

CONCLUSION: We conclude that women with GDM who require MNT and insulin have endothelial dysfunction. This can be explored further as cause of concurrent hypertension in GDM and cardiovascular morbidity in later life.



413 Differential exposure to antenatal steroids by sociodemographic factors among late preterm births

Mark A. Clapp[1], Cynthia Gyamfi-Bannerman[2], Anjali J. Kaimal[3], Jessica Cohen[4], Scott Lorch[5], Jason D. Wright[6], Alexander Melamed[1]
[1]Massachusetts General Hospital, Boston, MA, [2]UC San Diego Health, La Jolla, CA, [3]University of South Florida Morsani College of Medicine, Tampa, FL, [4]Harvard TH Chan School of Public Health, Boston, MA, [5]Children's Hospital of Philadelphia, Philadelphia, PA, [6]Columbia University Medical Center, New York, NY

OBJECTIVE: To determine if antenatal steroid exposure among late preterm births varies based on a patient's sociodemographic characteristics.

STUDY DESIGN: This is a cross-sectional analysis using the 2021 US natality data. The primary outcome was receipt of steroids among singleton late preterm births (34-36 weeks of gestation). The rates of steroid exposure were compared among the following sociodemographic factors: age, race, ethnicity, primary payer, and education. A multivariable logistic regression model was constructed with all the sociodemographic factors and clinical factors that were hypothesized to potentially influence clinical decision-making around steroid use, including gestational age, parity, fetal sex, chronic and pregnancy-related hypertension, and pre-existing and diabetes. Models used cluster robust standard errors based on county of birth.

RESULTS: In 2021, there were 279,305 singleton late preterm births, of which 17.5% were exposed to antenatal steroids. The rates of steroid exposure varied by all examined sociodemographic factors, with the largest range observed for payer (12.5% for self-pay to 20.1% for private insurance) (Table). In the multivariable model that accounted for clinical factors, there were no differences by maternal age; however, other sociodemographic factors were associated with steroid exposure (adjusted odds ratios shown in Table). Compared with White, Non-Hispanic, and privately individuals, odds of steroid exposure were lower in most other racial groups, in Hispanic individuals, and in non-commercially insurance patients. Higher levels of education were associated with higher odds of steroid exposure.

CONCLUSION: Despite no recommendations to consider sociodemographic factors when offering the intervention, steroid exposure among late preterm infants varied significantly by these observed factors. Additional work to understand the drivers of these differences, such as physician, hospital, or regional factors, can inform policy solutions to eliminate potential disparities.

Sociodemographic Factor	Steroid Exposure (%)	p-value for comparison	Adjusted Odds (95% CI)
Maternal Age			
<18	15.1%	<0.001	0.96 (0.86, 1.07)

414 County-level antenatal steroid exposure among late preterm births, 2016-2021

Mark A. Clapp[1], Jessica Cohen[2], Cynthia Gyamfi-Bannerman[3], Anjali J. Kaimal[4], Scott Lorch[5], Jason D. Wright[6], Alexander Melamed[1]

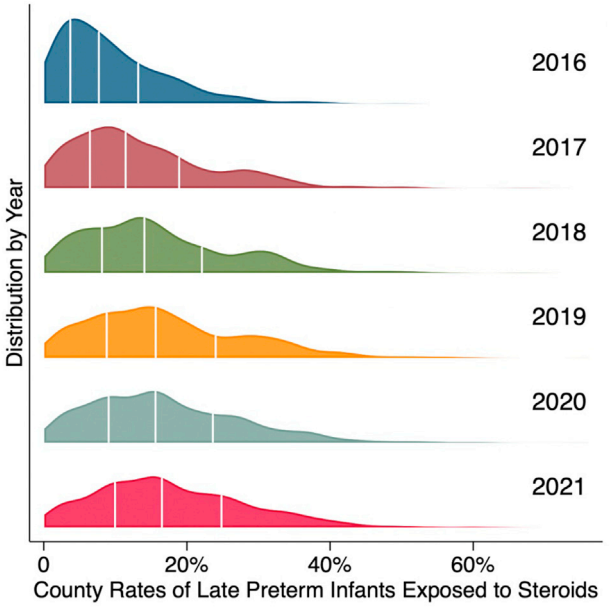
[1]Massachusetts General Hospital, Boston, MA, [2]Harvard TH Chan School of Public Health, Boston, MA, [3]UC San Diego Health, La Jolla, CA, [4]University of South Florida Morsani College of Medicine, Tampa, FL, [5]Children's Hospital of Philadelphia, Philadelphia, PA, [6]Columbia University Medical Center, New York, NY

OBJECTIVE: To examine the pace of adoption of new evidence demonstrating the benefits of antenatal steroids among late preterm births throughout the United States.

STUDY DESIGN: This is a cross-sectional analysis using the late preterm births between 2016 and 2021 using US natality data. County-level proportions of late preterm births exposed to antenatal steroids were calculated by year for counties and reported at least one steroid exposed infant per year. Ridgeline plots, weighted by a county's annual late preterm birth delivery volume, were constructed to demonstrate if and how the county-level proportions changed by year. Yearly county proportions of late preterm births exposed to steroids were compared using nonparametric K-sample test on the equality of medians.

RESULTS: There were 995 counties, and 1,338,973 late preterm births were included in this analysis. Figure 1 shows the proportion of late preterm births exposed to steroids increased significantly in US counties between 2016 and 2021 and the interquartile range widened: median (IQR) 7.1% (3.7-12.5%) to 15.4% (7.7-24.4%), $p< 0.001$. There was no significant difference in the medians between 2020 and 2021.

CONCLUSION: The proportion of late preterm births exposed to steroids increased significantly among US counties after the publication of the ALPS Trial, though practice variation widened over time. The observed increase in county-level proportions of steroid-exposed late preterm births plateaued in 2020, suggesting the practice change observed after the ALPS Trial may have reached a steady state. Studies examining the drivers of the wide variation in steroid exposure, including hospital, clinician, and patient factors, should be conducted to identify both barriers and facilitators to the adoption of this evidence-based recommendation.



The white lines in the ridgeline plots reflect the median (center line) and interquartile range (outside lines).

415 Fetoscopic laser outcomes for twin-twin transfusion syndrome with or without concomitant selective fetal growth restriction

Elisabeth Codsi[1], Francois Audibert[2], Sandrine Wavrant[1], Greg Ryan[3], Anthony Johnson[4], William Goodnight[5]

[1]Centre Hospitalier Universitaire Sainte-Justine, University of Montreal, Montréal, QC, [2]CHU Ste Justine, University of Montreal, Montreal, QC, [3]Sinai Health Center, Toronto, ON, [4]McGovern Medical School at UTHealth Houston, Houston, TX, [5]UNC Hospitals, Chapel Hill, NC; on behalf of the NAFTNet

OBJECTIVE: Fetal growth discordance (FGD) and selective fetal growth restriction (sFGR), which often accompany twin-twin transfusion syndrome (TTTS), are caused by discordant placental territories. The objective of this study was to determine the impact of FGD and sFGR on survival following fetoscopic laser surgery for the primary diagnosis of TTTS.

STUDY DESIGN: This was a retrospective cohort study of cases of fetoscopic laser performed for TTTS in monochorionic diamniotic twin pregnancies in the North American Fetal Therapy Network (NAFTNet) Complicated MC Twin Registry. FGD was defined as a ≥25% weight discordance and sFGR as FGD with one fetus >10th percentile for gestational age (GA). Exclusion criteria were loss to follow-up, selective termination, monoamniotic pregnancies and triplet or higher order multiples. Primary outcome was fetal survival and secondary outcomes were GA at delivery and fetal complications.

RESULTS: 2880 pregnancies were identified in the registry, of which 1194 were excluded. Of the 1686 pregnancies who were included for analysis, 688 had FGD and 377 qualified as sFGR. The table shows the pre-laser ultrasound evaluation. Dual survival was 75.15% in TTTS only, 62.50% in the TTTS+FGD and 61.01% in TTTS+sFGR (p< 0.001). Donor survival was 86.24%, 69.72% and 67.90% respectively (p< 0.001). Compared to TTTS alone, odds ratios for dual survival were 0.546 (0.442-0.675) in TTTS+FGD and 0.540 (0.421-0.692) in TTTS+sFGR. Odds ratios for donor survival were 0.367 (0.288-0.468) and 0.384 (0.292-0.506) respectively. Results remained statistically significant after adjusting for TTTS stage, Doppler anomalies and GA at laser. GA at delivery did not differ between groups. Fetal complications occurred in 2.56% of the TTTS-only group, 3.05% of the TTTS+FGD and 4.51% of the TTTS+sFGR.

CONCLUSION: Fetal dual survival is affected by the presence of FGD, even without sFGR, at the expense of the smaller twin.

Table: Prelaser ultrasound evaluation

	TTTS only	TTTS + FGD	TTTS + sFGR
GA at laser	20.69 (2.71)	20.92 (2.70)	21.04 (2.56)
TTTS stage at treatment n(%)			
1	150 (15.42%)	65 (9.64%)	41 (11.05%)
2	357 (36.69%)	163 (24.18%)	78 (21.02%)
3	424 (43.58%)	391 (58.01%)	223 (60.11%)
4	42 (4.32%)	55 (8.16%)	29 (7.82%)
Abnormal UA Donor Recipient	 174 (20.21%) 85 (9,86%)	 295 (45.88%) 29 (4.55%)	 181 (51.71%) 16 (4.58%)
Abnormal DV Donor Recipient	 53 (6,90%) 240 (41.38%)	 91 (15.69%) 166 (37.05%)	 53 (17.38%) 72 (34.29%)

416 Critical congenital heart disease: Contemporary prenatal screening performance in an Irish perinatology center

Fiona Cody[1], Orla Franklin[2], Nicola Mc Cay[3], Zara Molphy[1], Patrick Dicker[1], Fionnuala M. Breathnach[1]

[1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]CHI at Crumlin Children's Hospital, Trinity College Dublin, Dublin, Ireland, [3]CHI at Crumlin Children's Hospital, Dublin, Ireland

OBJECTIVE: Prenatal detection of critical congenital heart disease (CCHD) optimises neonatal outcome. The objective of this study was to determine the prenatal screening performance of a program instituted in a tertiary-referral perinatology center with a prescribed screening protocol, multi-dimensional training support, senior in-person review of all suspected CCHD cases and extended support for secondary referral services.

STUDY DESIGN: A 4-year retrospective cohort study examined all cases of CCHD requiring intervention in the first 4 weeks of life among infants delivered in a perinatology center and its affiliated regional sites. All cases of CCHD that underwent pregnancy termination, died in-utero or in the early neonatal period were also ascertained. The protocolised prenatal screening service included a scan at 18-22 weeks, repeat screening for cases of non-acquisition of defined 4-chamber or outflow tract views and Fetal Medicine review in the event of non-acquisition on 2nd attempt. CCHD was defined as duct-dependency or cardiac abnormality requiring urgent intervention in the first 4 weeks of life. All cases were referred to a single national pediatric cardiac centre. Data sources included dedicated prenatal ultrasound and pediatric cardiology databases, perinatal, neonatal and pediatric chart review.

RESULTS: From 01/2019 to 12/2022, among a consecutive cohort of 49,950 pregnancies who underwent prenatal screening for congenital heart disease, 104 cases (0.2%) were significant for CCHD, of whom 91% (95/104) were detected in the prenatal period. Aortic coarctation represented 78% (7/9) of CCHD cases first identified in the neonatal period, with 2 additional cases of postnatally-identified pulmonary stenosis. No case of single-ventricle pathology nor of transposition of the great arteries was missed by the prenatal screening program.

CONCLUSION: Prenatal detection of CCHD in a tertiary care unit and its affiliated sites exceeds 91%, with undetected cases limited to outflow tract obstructive lesions that may not be amenable to prenatal detection.

Table 1: Critical Congenital Heart Disease identified in screened cohort*

CCHD 2019-2022 N =104	Cases detected prenatally N = 95/104 (91%)	Cases 1st identified in Postnatal period N = 9/104 (9%)
Duct-dependent Left: Aortic arch/valve stenosis/ Hypoplastic left heart disease	39/46 (85%)	7/46 (15%)
Duct-dependent right: Pulmonary atresia/stenosis/ Hypoplastic right heart disease	38/40 (95%)	2/40 (5%)
Transposition of great arteries (TGA)	15/15 (100%)	0/15 (0%)
Congenital heart block (CHB)	3/3 (100%)	0/3 (0%)

*N = 49,950 pregnancies screened between Jan 2019 and December 2022

CCHD = Critical congenital heart disease (duct-dependency or requirement for urgent cardiac intervention in 1st 4 weeks of life)

417 Does the allowable blood loss calculator predict postpartum blood transfusion?

Alexa Cohen[1], Osaro Obanor[2], Marlena Plagianos[3], Samantha Goulding[4], Carly Pickett[4], Beatrice Lynch[4], Pe'er Dar[2], Georgios Doulaveris[1], Melissa Peskin-Stolze[5]

[1]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [2]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY, [3]Population Council's Center for Biomedical Research, New York, NY, [4]Albert Einstein College of Medicine, New York, NY, [5]New York University Grossman Long Island School of Medicine, New York, NY

OBJECTIVE: The allowable blood loss (ABL) calculator is a patient specific computation used in surgery, trauma and pediatrics that determines at what surgical blood loss transfusion should be considered. This calculator has not yet been studied in the obstetric population. The aim of this study was to investigate if the ABL calculator accurately predicted postpartum blood transfusion in obstetric patients with postpartum hemorrhage (PPH).

STUDY DESIGN: This retrospective cohort study included all gravidas with PPH at our regional perinatal referral center between January 2020−December 2022. Patients with BMI > 40kg/m2 were excluded. PPH was defined as quantitative blood loss (QBL) > 1L within 24 hours of delivery. ABL calculation is based on patient's weight, hemoglobin and average blood volume, with a threshold hemoglobin of 7.0g/dl. The primary outcome was the performance of ABL to predict the need for blood transfusion. We used actual QBL greater than ABL (QBL > ABL) as the threshold for prediction. Sensitivity, specificity, and positive and negative predictive values of QBL > ABL were determined using actual transfusion as the gold standard. Chi-square test and unpaired student t-test were used to compare categorical and continuous variables, respectively. Multivariable logistic regression analysis was also performed.

RESULTS: Overall, 1387 patients met inclusion criteria. Of them, 504 (36.3%) received a blood transfusion. The predictive performance of the QBL > ABL calculation for requiring blood transfusion in gravidas with PPH is presented inTable 1.The positive predictive value for transfusion requirement was 91% (table 1). Gravidas with a QBL > ABL were 21.66 times more likely to be transfused compared to those with a QBL less than ABL, after adjusting for potential confounders (95% CI 9.731−48.2, p < 0.01).

CONCLUSION: ABL calculation can assist in predicting the need for blood transfusion requirement in gravidas with PPH.

Table 1. Predictive performance of QBL > ABL calculation for requiring blood transfusion in gravidas with postpartum hemorrhage

	Sensitivity	Specificity	Positive Predictive Value	Negative Predictive Value	Odds Ratio* (95% CI)
Transfusion	16%	99%	91%	74%	21.66 (9.731 – 48.2)

*Adjusted for age, BMI, race/ethnicity, pre-eclampsia, pre-delivery anemia, infection, abruption
QBL, quantitative blood loss; ABL, allowable blood loss;

418 Effectiveness of music therapy in reducing anxiety levels among women undergoing induction of labor

Gal Cohen[1], Sivan Farladansky Gershnabel[2], Sophie Larson[2], Yuval Kuchuk[2], Rimon Moran[2], Chen Key Segal[2], Shmuel Arnon[2], Tal Biron-Shental[3], Michal Kovo[4]

[1]Meir Medical Centerartment of Obstetrics and Gynecology, Meir Medical Center, Kfar Saba, Israel, [2]Meir Medical Center, Kfar Saba, HaMerkaz, [3]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz, [4]Meir Medical Center, Macabim, HaMerkaz

OBJECTIVE: Induction of labor (IOL) can trigger anxiety and fear due to its prolonged process and uncertainty. Music therapy, an evidence-based intervention, has demonstrated potential in reducing anxiety during medical procedures. This study aimed to assess the effectiveness of music therapy in alleviating anxiety among women undergoing IOL.

STUDY DESIGN: This prospective study (2021-2023) included term pregnant women undergoing IOL using PGE_2 vaginal pessary, between 12:00PM-3:00PM. Participants were assigned to either the music group, having a 45 minutes music therapy session by a certified therapist starting one hour after IOL began, or the control group, without music therapy. Anxiety levels were measured using the State(S)-Trait(T) Anxiety Inventory (STAI) questionnaire (scale 20-80), anxiety and visual analogue stress (VAS) scores (scale 0-10) and salivary cortisol levels (in a subgroup of patients), before and immediately after the music therapy session.

RESULTS: A total of 89 women participated, with 49 in the music group and 40 controls. Maternal characteristics as marital status, education, religion, income and obstetric history were similar between the groups, as well as STAI-T scores representing general trait anxiety. Before intervention, STAI-S scores representing situational anxiety, were higher in the music group (46±11 vs. 39±10.4, p=0.004). Cortisol levels, anxiety scale scores, and VAS scores were comparable between groups. After the music therapy, there was a significant reduction in salivary cortisol levels, STAI-S, anxiety and VAS scores, in the music group compared to control: mean delta -0.08±0.07 μg/dL vs +0.04±0.18 μg/dL, p=0.032; mean delta -13.6±8.4 points vs -2.8±6.7 points, p< 0.001; mean delta -2.6±2.2 points vs -1.2±2.1 points, p=0.004, mean delta -0.9±2.1 points vs +0.7±1.2 points, p< 0.001, respectively. These results remained significant after adjusting for confounders (p≤0.02).

CONCLUSION: Music therapy effectively reduces anxiety levels among women undergoing IOL. Implementing music therapy during IOL may serve as a non-invasive approach to improve birthing experience.

Table 1. Anxiety levels in the music therapy group compared to control

Variable		Music Therapy (n=49) (n=14)*	Control (n=40) (n=20)*	P-value
Salivary cortisol levels (μg/dL)	Before intervention	0.43 ± 0.11	0.39 ± 0.12	0.305
	After intervention	0.36 ± 0.09	0.42 ± 0.27	0.408
	Delta	**-0.08 ± 0.07**	**+ 0.04 ± 0.18**	**0.032**
STAI Trait score (points)		34.6 ± 7.7	33.0 ± 6.1	0.324
STAI State score (points)	**Before intervention**	**46.0 ± 11.0**	**39.0 ± 10.4**	**0.004**
	After intervention	**32.4 ± 6.8**	**36.1 ± 9.1**	**0.032**
	Delta	**- 13.6 ± 8.4**	**- 2.8 ± 6.7**	**<0.001**
Anxiety Scale Score (points)	Before intervention	5.0 ± 2.8	4.1 ± 2.7	0.118
	After intervention	2.4 ± 2.5	2.8 ± 2.3	0.395
	Delta	**-2.6 ± 2.2**	**-1.2 ± 2.1**	**0.004**
VAS Score (points)	Before intervention	3.1 ± 2.8	2.2 ± 2.0	0.075
	After intervention	2.2 ± 2.4	2.8 ± 2.4	0.247
	Delta	**- 0.9 ± 2.1**	**+ 0.7 ± 1.2**	**<0.001**

419 Can postpartum HbA1C replace oral glucose tolerance test among gestational diabetes mellitus patients?

Nadav Cohen, Lelia Abu Nasra, Reuven Kedar, Ofer Lavie, Ariel Zilberlicht

Carmel Medical Center, Haifa, Hefa

OBJECTIVE: Gestational Diabetes Mellitus (GDM) raises the risk of developing Type 2 Diabetes Mellitus (T2DM). The American College of Obstetricians and Gynecologists (ACOG) recommends a postpartum 2-hour 75-gram Oral Glucose Tolerance Test (2h-OGTT) for T2DM detecting. However, global reports indicate low OGTT compliance. Nowadays, Glycated Hemoglobin (HbA1C) is a common diagnostic and follow-up exam for T2DM. Previous studies explored HbA1C as an OGTT replacement for diagnosing T2DM in patients with GDM, but different methodologies have led to

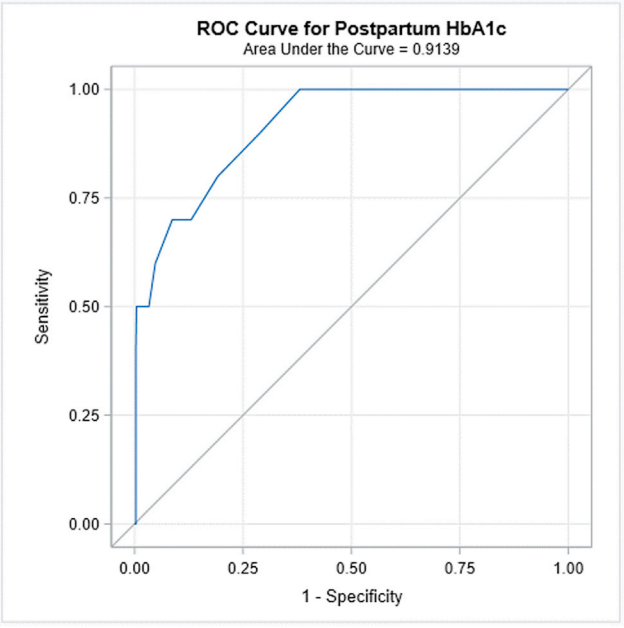
conflicting results. We aimed to assess 3-12 months postpartum HbA1C's sensitivity and specificity for T2DM detection in previous GDM cases.

STUDY DESIGN: We conducted an analysis of the largest health care organization in Israel. Inclusion criteria were pregnant individuals diagnosed with gestational diabetes mellitus (GDM) according to the Carpenter and Coustan's criteria and had records of both postpartum 2h-OGTT and HbA1C. We hypothesized that 3-12 months HbA1C postpartum, show equivalence to the OGTT gold standard.

RESULTS: Among 9,118 individuals $\geq$ 2 abnormal OGTT values, mean baseline characteristics were: age at delivery: 33.4 years, BMI before delivery: 28.6, gravidity: 3.4, parity: 2.8. Postpartum: mean HbA1C: 5.4%, fasting glucose: 92.6 mg/dL, 2-hours OGTT: 101.8 mg/dL.

677 individuals had HbA1C records at 3 to 12 months postpartum, along with records of the 2-OGTT performed up to 12 months post-delivery. The overall Pearson correlation coefficient between HbA1C and 2h-OGTT was 0.21 ($P < 0.0001$). However, when the 2h-OGTT results were stratified into values > 200 mg/dL, the ROC curve Area Under the Curve (AUC) of 91.4% [95% CI: 83.9%-98.9%], and HbA1C levels of 5.6% had 90.0% sensitivity and 71.1% specificity (95% CI: 55.5%-99.8%).

CONCLUSION: 3-12 months postpartum HbA1C can be a valid alternative to screen for Type 2 Diabetes in high-risk GDM cases.



420 CS in Single Cephalic Term Nulliparas: The Changing Size of Robson Group 1 and 2

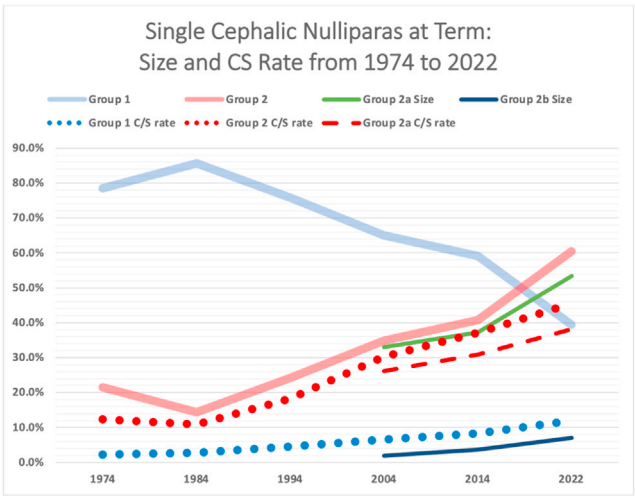
Gillian Corbett[1], Kim Ryan[2], Anne Twomey[3], Nicola O. Riordan[3], Declan Keane[3], Michael Robson[3]
[1]UCD Perinatal Research Centre, Dublin, Dublin, [2]National Maternity Hospital, Dublin, Dublin, [3]National Maternity Hospital, Dublin, Ireland

OBJECTIVE: To describe the change in sizes, pathway to delivery and and caesarean section (CS) rates in Single Cephalic Nulliparas >=37 weeks' gestation from 1974 to 2022.

STUDY DESIGN: This is a single centre longitudinal cohort study at an Irish tertiary maternity centre. The study population was singleton cephalic pregnancies at >=37 weeks' gestation with spontaneous or induced labour or prelabour caesarean section (Robson Group 1, 2a and 2b) delivered between 1974 and 2022. Regression analysis was performed to analyze trends in the size of each group as proportion of the overall population, and for CS rates within the groups.

RESULTS: From 1974 to 2022, the CS Rate in Single Cephalic Nulliparas >=37 weeks' gestation (SCNT) increased from 4.5% to 32.3% (115/2575 to 811/2515). Group 1 made up a decreasing proportion of the SCNT from 78.4% (2020/2575) to 39.5% (993/2515) and Group 2 made up an increasing proportion from 21.6% (555/2575) to 60.5% (1522/2515, R-Squared 0.951, p=0.005, Figure 1). Within Group 1, the CS Rate increased from 2.3% in 1974 to 11.9% in 2022 (R-Squared 0.9644, p=0.003). The CS Rate in Group 2 increased from 12.3% to 45.5% (R-Squared 0.994, p=0.002). Since the first recording of Group 2a and 2b in 2004, , the absolute size of Group 2a increased from 33.0% of the Singleton Cephalic Nulliparous population >=37 weeks gestation to 45.5% (R-Squared=0.829, p< 0.001). The absolute size of 2b also increased from 1.9% to 7.1% of the single cephalic nulliparous population >=37 weeks' gestation (R-Squared 0.829, p< 0.001).

CONCLUSION: Among Single Cephalic Nulliparas >=37 weeks' gestation, the primary pathway to delivery is now induced labour, where it was once spontaneous labour. Induced labour is associated with higher rates of CS than spontaneous labour, and CS within both have also increased over the last sixty years. When analysing CS rates in SCNT >=37 weeks' gestation, examination of the size of Group 1, 2a and 2b is critical as the first step to interpretation.



421 Association between placental gene expression and IL-10 levels in maternal serum

Alexa A. Freedman[1], Renee Odom[1], Steve Cole[2], Megan Choi[3], Lauren S. Keenan-Devlin[1], Janedelie Romero[1], Greg E. Miller[1], Jessica Britt[4], Britney P. Smart[1], Linda M. Ernst[5], Amy Crockett[6], Ann Borders[7]
[1]NorthShore University HealthSystem, Evanston, IL, [2]University of California, Los Angeles, Los Angeles, CA, [3]Northwestern University, Evanston, IL, [4]Prisma Health Upstate, Greenville, SC, [5]NorthShore University HealthSystem, University of Chicago Pritzker School of Medicine, Evanston, IL, [6]Prisma Health, University of South Carolina School of Medicine Greenville, Greenville, SC, [7]NorthShore University HealthSystem, Evanston Hospital, Evanston, IL

OBJECTIVE: Maternal inflammation is associated with adverse pregnancy outcomes. Interleukin 10 (IL-10), an immunoinhibitory

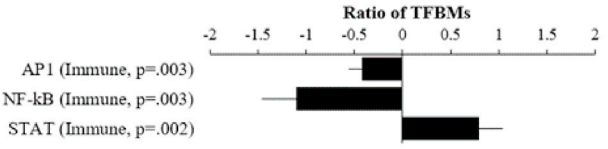
cytokine found in serum, is indicative of systemic inflammation. We utilized novel placental gene expression analysis to evaluate differently expressed placental genes and IL-10 serum levels to explore pathways that may increase risk of adverse pregnancy outcomes.

STUDY DESIGN: This is a secondary analysis of a prospective randomized controlled trial of a racially diverse, low-income sample. Serum was collected twice during gestation between 12-24 and 32-40 weeks, and fresh placental villous tissue was collected at delivery. Serum IL-10 levels were log-transformed, standardized, and averaged across time points with standard deviation marking the increase. Placental genome-wide mRNA profiles were analyzed to identify transcripts showing >2-fold differential expression over the 4-SD range of maternal IL-10 variation, adjusting for potential confounders, including age, first prenatal BMI, race and ethnicity, newborn sex, GA at delivery, and mode of delivery. TELiS analyzed transcription factor activity.

RESULTS: Maternal serum and placental biopsies were available for 428 patients. Mean gestational age at serum collections were 16.3±2.9 weeks and 34.3±1.6weeks. Higher maternal IL-10 in serum was associated with lower activity of key pro-inflammatory signaling pathways in placentas (AP1↓25%, p=.003; NF-kB↓53%, p=.003) and higher activity of the STAT family signaling pathways that mediate signaling through the IL-10 receptor (↑73%, p=.002) (Figure 1). There were no differences in pathways related to tissue hypoxia, immune response or neural signaling.

CONCLUSION: Circulating IL-10 in maternal blood in pregnancy is associated with reduced inflammatory signaling in placental tissues at delivery. Caution is needed in interpreting this correlation, but these data are consistent with the hypothesis that maternal IL-10 serum levels are related to placental inflammation, and could represent a target for clinical intervention.

Figure 1. Differential Transcription Factor Activity in Placentas with High Levels of IL-10 in Maternal Serum



X axis is the log2 ratio of transcription factor-binding motifs (TFBMs) in core promoter sequences of differentially expressed genes with >2-fold variation in expression over a 4-SD range of IL-10 levels in maternal serum. Error bars reflect standard error.

422 Differences in placental gene expression in term and preterm birth

Alexa A. Freedman[1], Renee Odom[1], Steve Cole[2], Megan Choi[3], Lauren S. Keenan-Devlin[1], Janedelie Romero[1], Greg E. Miller[1], Jessica Britt[4], Britney P. Smart[1], Linda M. Ernst[5], Amy Crockett[6], Ann Borders[7]

[1]NorthShore University HealthSystem, Evanston, IL, [2]University of California, Los Angeles, Los Angeles, CA, [3]Northwestern University, Evanston, IL, [4]Prisma Health Upstate, Greenville, SC, [5]NorthShore University HealthSystem, University of Chicago Pritzker School of Medicine, Evanston, IL, [6]Prisma Health, University of South Carolina School of Medicine Greenville, Greenville, SC, [7]NorthShore University HealthSystem, Evanston Hospital, Evanston, IL

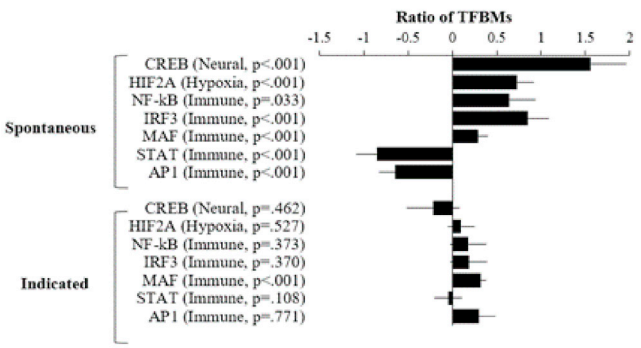
OBJECTIVE: We used novel placental gene expression analysis to compare placental gene expression of preterm birth (PTB) vs term birth (TB) participants and evaluate underlying biological mechanisms of PTB.

STUDY DESIGN: This is a secondary analysis of a prospective randomized controlled trial of a racially diverse, low-income sample. Genome-wide mRNA profiles from fresh placental villous tissues were analyzed to identify transcripts showing >2-fold differential expression in spontaneous PTB (sPTB) vs TB, controlling for potential confounders, including maternal age, first prenatal BMI, race, ethnicity, and smoking. Parallel analyses examined indicated PTB (iPTB) vs TB with a >1.5-fold differential to accommodate the more modest transcriptomic correlates.

RESULTS: Of the 700 placentas biopsied, 69 were PTB: 28 sPTB and 41 iPTB. 493 differently expressed genes between sPTB vs TB indicated increased activity of multiple gene regulation pathways (Figure 1), including hypoxia-induced pathways (HIF2A↑66%, p< .001), innate immune response pathways (NF-kB↑56%, p=.033; IRF3↑80%, p< .001; MAF↑23%, p=.004), and neural signaling (CREB↑195%, p< .001). Other inflammatory pathways were conversely down-regulated (AP1↓36%, p< .001; STAT↓45%, p< .001). Transcript origin analyses implicated myeloid dendritic cells and non-classical monocytes in mediating differential gene expression in sPTB placentas (both p< .05). Most of these patterns were not seen in iPTB placentas (no significant difference in HIF2A, NF-kB, IRF3, AP1, CREB), although iPTB showed elevated MAF activity (↑25%, p< .001) and indicated dendritic cell and monocyte activity (both p< .010).

CONCLUSION: Placental tissue from sPTB showed activation of multiple gene regulation pathways involved in hypoxia, innate immune function, and neural signaling, and indicated myeloid lineage immune cell activation. Activation of these transcription control pathways are distinct to sPTB compared to iPTB and independent of maternal characteristics. These gene regulatory alterations may illuminate novel biological pathways underlying sPTB.

Figure 1. Differential Transcription Factor Activity in Placentas that gave birth Preterm



X axis is the log2 ratio of transcription factor-binding motifs (TFBMs) in core promoter sequences of differentially expressed genes in those who gave birth to preterm newborn, shown by spontaneous preterm birth and indicated preterm birth, compared to term birth (reference). Error bars reflect standard error.

423 Cannabis use and development of hypertension in the nuMoM2b Heart Health Study

Research Institute, Pittsburgh, PA, [6]UC Irvine Health, Orange, CA, [7]Northwestern University Feinberg School of Medicine, Evanston, IL, [8]The Ohio State University, Columbus, OH, [9]Christiana Care Health Systems, Newark, DE, [10]Northwestern University Feinberg School of Medicine, Oak Park, IL, [11]University of Pennsylvania, Philadelphia, PA, [12]MetroHealth Medical Center, Cleveland, OH, [13]Cedars-Sinai Medical Center, Los Angeles, CA, [14]University of Pittsburgh, Pittsburgh, PA, [15]Columbia University, New York, NY, [16]Eastern Virginia Medical School, Norfolk, VA, [17]Indiana University School of Medicine, Indianapolis, IN, [18]Northwestern University, Chicago, IL, [19]National Institutes of Health, Bethesda, MD

OBJECTIVE: Cannabis use is increasing among reproductive age people with largely unknown health effects. Prior research demonstrates an association between cannabis use and hypertension (HTN). We aimed to quantitatively evaluate if cannabis exposure after pregnancy is associated with incident HTN 2-7 years after pregnancy.

STUDY DESIGN: Secondary analysis of the nuMoM2b Heart Health Study. Nulliparous participants were followed from the first trimester of their index pregnancy to an in-person study visit 2-7 years after their pregnancy for development of adverse cardiovascular outcomes. The primary outcome was incident stage II HTN (systolic blood pressure ≥140 or diastolic blood pressure ≥90) or use of an antihypertensive agent at the time of the 2-7 year follow up visit. The primary exposure was cannabis exposure after pregnancy defined as urine positive for THC-COOH (11-nor-9-carboxy-delta-9-tetrahydrocannabinol) metabolite (cutoff ≥15 ng/ml) at the 2-7 year study visit. A multivariable logistic regression model was fit and adjusted for covariates that were selected *a priori* including nicotine exposure assessed at the 2-7 year visit (measured via serum cotinine levels or self-report), and occurrence of any adverse pregnancy outcome (APO), race/ethnicity, area deprivation index, maternal age, and diabetes mellitus at the time of the index pregnancy.

RESULTS: Of 4079 participants, 406 (9.95%) had exposure to cannabis and 216 (5.30%) developed HTN by the 2-7 year study visit (mean (SD) time to follow up: 3.2 (0.9) years). Neither cannabis (aOR 1.05, 95% CI 0.63-1.76) nor active nicotine (aOR 1.03, 95% CI 0.66-1.63) exposure were associated with incident HTN in multivariable modeling (Table). Factors collected at the index pregnancy that were associated with incident HTN included maternal age, index pregnancy APO, Black race, Hispanic ethnicity, and pregestational and gestational diabetes (Table).

CONCLUSION: Cannabis exposure following pregnancy was not associated with incident HTN within 2-7 years after controlling for nicotine exposure and known risk factors measured during the first pregnancy.

Table. Association between participant characteristics and incident hypertension 2-7 years after index pregnancy delivery among nuMoM2b Heart Health Study participants

Participant characteristics	All participants	Incident Hypertension		aOR (95% CI)
		Absent	Present	
	N = 4079	N =3863	N =216	
Characteristics during index pregnancy				
Maternal age (y)	27.1 (5.6)	27.0 (5.5)	28.1 (6.0)	1.28 (1.12-1.47)[1]
Maternal race and ethnicity				
White Non-Hispanic	2601 (63.8)	2488 (64.4)	113 (52.3)

[1] per 5-year increase
[2] Area Deprivation Index (ADI)
[3] per 10-unit increase
[4] Includes the presence of a hypertensive disorder of pregnancy (antepartum/intrapartum/postpartum hypertension, preeclampsia, and eclampsia); small for gestational age with birth weight less than the 5th percentile; preterm birth (iatrogenic or spontaneous) and/or stillbirth.
[5] Defined as 11-nor-9-carboxy-delta-9-tetrahydrocannabinol (THC-COOH) ≥ 15 ng/ml via liquid chromatography mass spectrometry assays of banked urine specimens.
[6] Nicotine exposure was defined by serum cotinine levels (>3 ng/mL for active exposure, 1-3 ng/mL for passive exposure) or self-report.
Note: Categorical variables are represented as n(%). Continuous variables are represented by mean (SD), unless otherwise indicated.
Note: Incident hypertension defined as stage II hypertension (140/90 mm Hg) or the use of antihypertensive agents 2-7 years after index pregnancy delivery.

424 Association between resilience and depression in patients with gestational diabetes

Rosinda De La Pena[1], Amy Y. Pan[2], Sai Alekha Challa[2], Amelia Papadimitriou[2], Anna Palatnik[2]
[1]Hospital, Wauwatosa, WI, [2]Medical College of Wisconsin, Milwaukee, WI

OBJECTIVE: Research has shown higher rates of postpartum depression among patients diagnosed with gestational diabetes (GDM). Resilience could be a protective factor against depression and improve maternal adjustment to GDM diagnosis. Our objective was to examine the association between resilience and depression in patients with GDM.

STUDY DESIGN: Secondary analysis of the Nulliparous Pregnancy Outcomes study: Monitoring Mothers-to-be (nuMoM2b) dataset. Primary exposure was resilience, measured by Connor-Davidson Resilience Scale early in pregnancy and analyzed by tertiles, with the first tertile including patients with the lowest resilience score, and the third tertile with the highest resilience. The primary outcome was depression measured later in pregnancy, defined as Edinburgh Postnatal Depression (EDPS) score ≥ 10. Logistic regression was done to examine the association between maternal resilience and depression in GDM pregnancies, adjusting for marital status, insurance, maternal education, age, and BMI.

RESULTS: Of 340 participants included, 34.4% had resilience score in the lowest tertile, 32.9% had resilience in the second tertile, and 32.6% in the third tertile. EDPS score was significantly higher in the first and second tertile compared to the third tertile (7.6.2 ± 4.2, 5.6 ± 3.2, and 3.9 ± 3.6 respectively, $p < 0.001$). A total of 56 (18.2%) patients in this cohort had EDPS ≥ 10, and the rates were higher with lower resilience tertile (31.6% in the 1st tertile, 8.9% in the 2nd

tertile, and 8.1% in the 3rd tertile, p< 0.001). In unadjusted analysis, participants with higher resilience had lower odds of EDPS ≥ 10 (Table). In a multivariable analysis, higher resilience tertile remained to be independently associated with lower depression/EDPS ≥ 10 (aOR 0.22, 95% CI 0.10-0.47 for tertile 2, and aOR 0.20, 95% CI 0.09-0.46 for tertile 3), compared to the lowest tertile of resilience score (Table).

CONCLUSION: In pregnancies complicated by GDM, higher maternal resilience at the beginning of pregnancy was associated with lower odds of depression.

Table: Unadjusted and adjusted odds ratios for the association between resilience early in pregnancy and depression among patients with gestational diabetes*

Edinburg Depression Score ≥ 10	Odds Ratio (95% CI)	Adjusted Odds Ratio** (95% CI)
Resilience		
Tertile 1 (lowest resilience score)	Ref	Ref
Tertile 2	0.21 (0.10 - 0.45)	0.22 (0.10 – 0.47)
Tertile 3 (highest resilience score)	0.19 (0.09 - 0.42)	0.20 (0.09 – 0.46)

*Depression was measured with Edinburgh Postnatal Depression Scale and score ≥10 was defined as depression. Resilience was measured by Connor Davidson Resilience Scale and was reported by tertiles.
** Adjusted for age, marital status, insurance, maternal education, and BMI.

425 Effect of the COVID-19 pandemic on population-level mean arterial pressure during pregnancy and postpartum

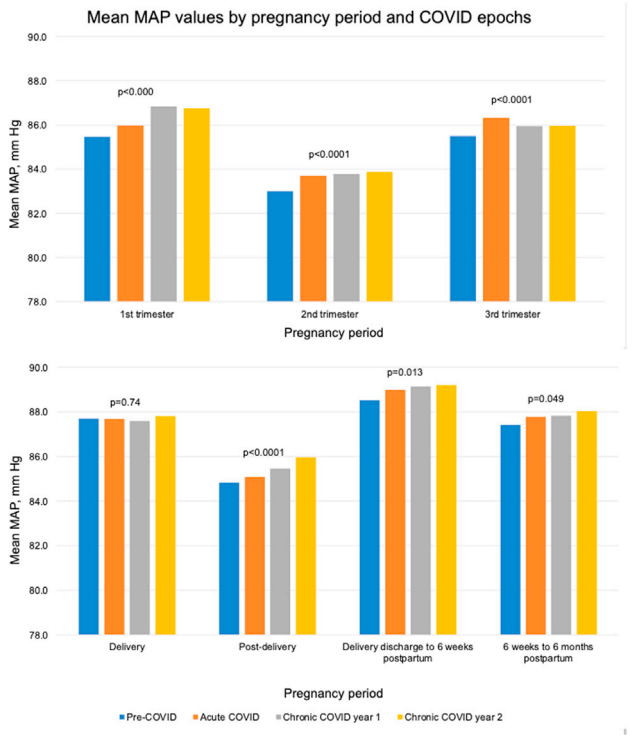
Anna Denoble[1], Suzanne Stammler[1], Caitlin Partridge[2], Lisbet S. Lundsberg[3], Jennifer F. Culhane[2]
[1]Yale University School of Medicine, New Haven, CT, [2]Yale University, New Haven, CT, [3]Yale, New Haven, CT

OBJECTIVE: We aimed to assess if population-level mean arterial pressures (MAP) in pregnancy and postpartum changed as a result of the COVID-19 pandemic and if any of these observed changes persisted.

STUDY DESIGN: This was a retrospective cohort study of pregnancies within a single healthcare system. Using EMR data, patients were assigned to one of four COVID-19 epochs (pre-, acute, and chronic years 1 and 2). Patients were assigned to acute COVID if their estimated due date was before 1/1/2021 and their gestational age was < 20 weeks by 3/10/2020. Pre-COVID and chronic 1 and 2 comprised matched months for the two years prior to, and post, acute COVID. MAP (mm Hg) was calculated for every blood pressure recorded for each patient. The mean MAP (μMAP) was computed for 7 discrete pregnancy periods (1st, 2nd, 3rd trimesters, admission for delivery-delivery [delivery], delivery-discharge [post-delivery], discharge-6 weeks postpartum, and 6 weeks-6 months postpartum). One-way ANOVA with post-hoc Tukey's honest significance test was employed to compare the μMAP across COVID epochs for each pregnancy period.

RESULTS: A total of 22,998 pregnancies occurred during the COVID epochs with the following distribution: pre-COVID n=9,174; acute COVID n=4,380; chronic 1 n=4,690; chronic 2 n=4,754. Significant elevations in μMAP were observed for the 1st, 2nd, and 3rd trimesters when comparing acute and chronic 1 and 2 to pre-COVID ($p< 0.05$; Figure). During delivery, no differences in μMAP across epochs were observed. However, we observed significant elevations post-delivery in μMAP for chronic 1 and 2 compared to pre-COVID. μMAPs were significantly higher in both postpartum periods when comparing chronic 2 to pre-COVID.

CONCLUSION: In general, μMAPs increased during acute COVID and remained elevated in the two chronic COVID epochs across pregnancy and up to 6 months postpartum. These results suggest that the COVID-19 pandemic was associated with population blood pressure elevations in pregnancy and that, at least to date, these changes have not remitted and appear to be durable.



426 Brain natriuretic peptide testing and severe maternal morbidity in pregnancies affected by heart disease

Anna Denoble[1], Jerome J. Federspiel[2], Sarah Goldstein[1], Jennifer F. Culhane[3], Kevin Dysart[4]
[1]Yale University School of Medicine, New Haven, CT, [2]Duke University Hospital, Durham, NC, [3]Yale University, New Haven, CT, [4]Nemours Children's Hospital, Wilmington, DE

OBJECTIVE: We aimed to describe patterns of brain natriuretic peptide (BNP) testing and levels prior to delivery hospitalization among pregnant patients with and without heart disease, and the association between BNP and severe maternal morbidity (SMM).

STUDY DESIGN: This retrospective cohort study included a nationwide sample of pregnant patients in EPIC Cosmos from 2018-2022 who delivered at 22-42 weeks. BNP or NT-proBNP drawn within 90 days preceding delivery were identified and categorized as normal or elevated (BNP ≥ 100 or NT-proBNP ≥ 300 pg/mL). Patients were classified as having no heart disease (no HD), congenital heart disease (CHD), acquired (AHD), or both by ICD-10 code. The primary outcomes were SMM and non-transfusion SMM per CDC definitions. Heart disease, race/ethnicity, social vulnerability index, insurance, obesity, chronic renal disease, diabetes, and gestational diabetes were included as covariates in logistic regression models exploring the association between BNP testing and SMM.

RESULTS: 1,817,361 pregnant individuals were included, of whom 1,679,306 (92.4%) had no HD, 13,648 (0.75%) CHD, 117,963 (6.49%) AHD, and 6,444 (0.35%) both. The groups differed with respect to all covariates (p< 0.001), including the proportion with a BNP within 90 days of delivery (no HD 4,685 (0.3%), CHD 131 (1.0%), AHD 2,030 (1.7%), and both 340 (5.3%); p< 0.001). Of

those who experienced SMM (N=39,331), 38,652 (98.3%) had no BNP testing, 512 (1.3%) had normal BNP, and 167 (0.4%) had elevated BNP levels. The odds of SMM and non-transfusion SMM were higher in patients who had a BNP within 90 days of delivery even if it was normal (SMM aOR 2.5, 95% CI 2.3, 2.8; non-transfusion SMM aOR 3.4, 95% CI 3.1, 3.8), and higher still if BNP was elevated (SMM aOR 8.6, 95% CI 7.1, 10.3; non-transfusion SMM aOR 12.4, 95% CI 10.0, 15.3).

CONCLUSION: Clinical judgment triggering BNP collection within 90 days of delivery likely identifies a cohort of patients at higher risk of SMM regardless of the result, but elevated results are associated with higher SMM risk.

Logistic regression of BNP testing within 90 days of delivery and severe maternal morbidity during delivery hospitalization.

	SMM			Non-transfusion SMM		
	N = 39,331			N = 17,349		
	N (%)	OR	aOR* (95% CI)	N (%)	OR (95% CI)	aOR* (95% CI)
No BNP testing	38,652 (98.3)	Ref	Ref	16,861 (97.2)	Ref	Ref
Normal BNP	512 (1.3)	3.91 (3.6-4.3)	2.5 (2.3-2.8)	360 (2.1)	6.31 (5.7-7.0)	3.4 (3.1-3.8)
Elevated BNP	167 (0.4)	16.1 (13.4-19.1)	8.6 (7.1-10.3)	128 (0.7)	28.1 (23.0-34.1)	12.4 (10.0-15.3)

aOR: adjusted odds ratio; BNP: brain natriuretic peptide or N-terminal pro-brain natriuretic peptide; CI: confidence interval; OR: odds ratio; SMM: severe maternal morbidity

427 Delivery and neonatal outcomes associated with delivery versus expectant management following term decreased fetal movement

Jia Jennifer Ding[1], Lisbet S. Lundsberg[2], Jennifer F. Culhane[3], Caitlin Partridge[3], Sarah N. Cross[1]
[1]Yale University School of Medicine, New Haven, CT, [2]Yale, New Haven, CT, [3]Yale University, New Haven, CT

OBJECTIVE: To compare delivery and neonatal outcomes among patients presenting to triage with a chief complaint of decreased fetal movement (DFM) at term who were either admitted for delivery < 24 hours, between 24-48 hours, or >48 hours.

STUDY DESIGN: This was a retrospective cohort study of patients with singleton gestations delivering at a large hospital system from 2013-2023. Using electronic medical records, patients presenting with the chief complaint of DFM at ≥37 weeks gestation were identified. Using timestamps, latency between DFM presentation and delivery admission was calculated. Patients were grouped into 3 categories: 1) < 24 hours, 2) 24-48 hours, 3) >48 hours. For patients who presented with DFM more than once beyond 37 weeks, the presentation most proximal to delivery was used. Comparisons across the categorical measure of time to admission were performed using chi-square tests or Fisher's exact tests as appropriate for categorical variables and means and standard deviations were compared using analysis of variance (ANOVA) test for continuous variable.

RESULTS: Of the 2,015 patients, 193 (9.6%) were admitted for delivery at < 24 hours, 131 (6.5%) between 24-48 hours, and 1,691 (83.9%) at >48 hours. The mean gestational ages at presentation for DFM were 39w3d +/- 7.0 days (< 24h group), 39w3d +/- 7.0 days (24-48h group), and 38w4d +/- 6.7 days (>48h group). The mean gestational ages at delivery were 39w4d +/- 7.1 days (< 24h group), 39w5d +/- 7.0 days (24-48h group), and 40w0d +/- 6 days (>48h group). There were no cases of stillbirth or neonatal demise. There were no significant differences in mode of delivery, rates of induction of labor, infectious or hemorrhagic maternal morbidities, or maternal length of stay by timing of delivery admission from DFM presentation. Neonatal outcomes were also similar such as birthweight and NICU admission (Table).

CONCLUSION: Among patients presenting with DFM to triage at term, expectant management with delivery beyond 48 hours was not associated with adverse perinatal outcomes as compared to admission for delivery within 24 hours or 24-48 hours.

Table: Delivery and neonatal outcomes among patients presenting to triage with DFM at term who were admitted for delivery within 24 hours, between 24-48 hours, or after 48 hours

	Delivery admission within 24h (n=193)	Delivery admission 24-48h (n=131)	Delivery admission >48h (n=1691)	p-value
Delivery outcomes				
Vaginal delivery	152 (78.8)	94 (71.8)	1208 (71.7)	0.11
Induction of labor	54 (28.0)	39 (29.8)	507 (30.0)	0.85
PPH	18 (9.3)	14 (10.7)	171 (10.1)	0.92
Chorioamnionitis or endometritis	7 (3.6)	9 (6.9)	86 (5.1)	0.43
ICU admission	0 (-)	0 (-)	3 (0.2)	0.75
Maternal LOS > 72h	67 (34.7)	46 (35.1)	673 (39.8)	0.25
Neonatal outcomes				
Birthweight (grams)	3410.7 +/- 454.0	3454.3 +/- 431.3	3467.2 +/- 417.3	0.21
SGA	23 (11.9)	6 (4.6)	169 (10.0)	0.08

NICU admission	18 (9.3)	11 (8.4)	190 (11.2)	0.46

Data are presented as N (%) or mean +/- standard deviation

PPH=postpartum hemorrhage (composite criteria fulfilled if estimated blood loss > 1000mL, patient received red blood cell transfusion, or had ICD-10 diagnostic code of postpartum hemorrhage), ICU=intensive care unit, LOS=length of stay, SGA=small for gestational age, LGA=large for gestational age, NICU=neonatal intensive care unit

428 Cost-effectiveness of BRCA1 testing at time of obstetrical prenatal carrier screening for cancer prevention

Shayan Dioun[1], Luiza Perez[2], Ravi Sharaf[2], June Hou[3], Jason D. Wright[1], Malavika Prabhu[4], Melissa Frey[2]
[1]Columbia University Medical Center, New York, NY, [2]Weill Cornell Medical College, New York, NY, [3]Columbia University Irving Medical Center, New York, NY, [4]Massachusetts General Hospital, Boston, MA

OBJECTIVE: Incorporation of BRCA1 mutation testing at time of obstetrical carrier screening could provide a potential avenue for identifying patients with mutations. We developed a cost-effectiveness analysis to simulate BRCA1 testing versus no BRCA1 testing at the time of obstetrical carrier screening to assess population outcomes of such an approach.

STUDY DESIGN: A decision analysis and Markov model was creating in a theoretical cohort of 1,429,074 pregnant patients who annually undergo expanded carrier screening in the U.S. The initial decision point in the model was BRCA1 testing at time of expanded carrier screening. Model probabilities, cost and utility values were derived from published literature. For BRCA1 positive patients, the model simulated breast cancer screening and risk-reducing surgical interventions. A cycle length of 1 year and a time horizon of 47 years was used to simulate the lifespan of pregnant patients. Clinical outcomes included BRCA1 mutation positivity, cancer cases, and cancer deaths. Effectiveness was calculated in terms of average quality adjusted life years (QALYs). The primary outcome was incremental cost-effectiveness ratios (ICERs), expressed in 2022 US dollars/QALYs. One-way and two-way sensitivity analyses were performed to vary the assumptions across a range of plausible values.

RESULTS: Among our cohort, BRCA1 testing resulted in 3,716 additional BRCA1 patients being identified, 1,394 breast and ovarian cancer cases prevented, and 1,084 fewer deaths (Table 1). BRCA1 testing was a cost-effective strategy compared to no BRCA1 testing with an ICER of $86,001/QALYs. Multiple one-way and two-way sensitivity analyses did not substantially impact the cost-effectiveness.

CONCLUSION: Among pregnant women, BRCA1 testing at time of obstetrical prenatal carrier screening is a cost-effective management strategy to identify at risk women at a time when cancer screening

and preventive strategies can be effective. Despite the burden of additional genetic counseling, prenatal care represents a unique opportunity to implement population based genetic testing.

Table 1. Outcome of Study Population

Strategy at time of obstetrical carrier screening	N	BRCA1 patients identified by screening	Cancer cases	Deaths	Total cost ($)*	Total QALYs	ICER ($/QALYs)
BRCA1 testing	1,429,074	3,716	2,322	1,393	75,748,177,401	33,924,267	-
No BRCA1 testing	1,429,074	0	3,716	2,477	75,015,797,037	33,915,751	86,001

Assuming a population of 1,429,074 patients undergoing obstetrical carrier screening annually
* All costs in 2022 dollars.

429 Does Vaginal Progesterone prevent preterm birth in women with shortened cervix after 24 weeks?

Omri Dominsky[1], Matan Anteby[2], Roza berkovitz shperling[1], Eli Rimon[3], Daniel Weiner Kalish[1], Neta simon[1], Eran Ashwal[4], Yariv Yogev[5], Liran Hiersch[6]

[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Tel Aviv, [2]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv, and Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [3]Tel Aviv Sourasky Medical Center, Tel Aviv, HaMerkaz, [4]McMaster University, North York, Tel Aviv, [5]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [6]Sourasky Medical Center, Tel-Aviv, Israel

OBJECTIVE: To determine the association of vaginal progesterone treatment and the risk of spontaneous preterm birth (sPTB) in women with a short cervix diagnosed at 24-34 weeks of gestation.

STUDY DESIGN: A retrospective cohort study in a single university affiliated medical center with approximately 12,500 annual deliveries (2011-2022). Women with a singleton pregnancy and a newly diagnosed short cervix (≤25mm) at 24+0-33+6 weeks who were given vaginal progesterone were compared to those that were not treated. The initiation of progesterone treatment was based on physician's preference and continued until 36 weeks. Severe short cervix was defined as cervical length (CL) ≤15 mm. Exclusion criteria were: prior progesterone or tocolysis usage, cerclage and previous PTB. The primary outcome was sPTB < 37 weeks of GA.

RESULTS: 1. Overall, 862 women were eligible for analysis, among them 471 (54.6%) women were treated with vaginal progesterone and 391 (45.4%) did not. 183 women (21.2%) were diagnosed with CL≤15mm.

2. There was no significant difference between the groups in the rate of sPTB at < 37 weeks (29.4% vs.33.5%, p=0.19), 34 weeks (8.7% vs 12.1%, p=0.11) and 32 weeks (4.9% vs 7%, p=0.19).

3. No significant differences were found in background characteristics. Women in the progesterone group were diagnosed earlier (29.5 ± 2.7 vs. 31.5 ± 2.3, weeks P< 0.001), had a shorter CL at diagnosis (17.5 ± 5.3 Vs 19.6 ± 5 mm, P< 0.001), and higher rate of CL≤15 mm (25.9% vs 15.6%, P=0.01).

4. Progesterone treatment was associated with a longer interval from diagnosis to delivery, in women with CL≤ 25mm and CL≤15mm as comparted to no treatment [Mean time of 54 ± 27 vs. 41.8 ± 23.5 days, and 52.6 ± 29.5 vs 33.2 ± 27 days, respectively. (P< 0.001)]. Hazard Ratio of 1.9, 95% CI [1.7-2.3], and 2.2, 95% CI [1.4-3.3], respectively. (Figure).

CONCLUSION: Vaginal progesterone given to women with a short cervix at 24-34 weeks of GA is associated with mean prolongation of pregnancy of 12-19 days, with not significant impact on the rate of sPTB.

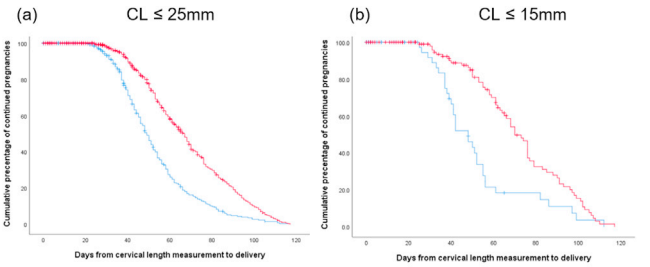

Figure:
Kaplan–Meier plot. Survival analysis shows the probability of women continuing pregnancy without spontaneous delivery (< 37 weeks) by days from the cervical length measurement to delivery for the progesterone treatment group (red line) and the no-treatment group (blue line). Progesterone showed prolongation of pregnancy for women with (a) CL ≤ 25mm, HR of 1.9, 95% CI [1.7-2.3], and (b) CL ≤ 15mm, HR 2.2, 95% CI [1.4-3.3].

430 Evidence-based stillbirth evaluation deficiencies remain following publication of national guidelines

Kaitlyn M. Dorn[1], Alexia Novara[1], Dorthea Bragg[2], F. B. Will Williams[3], Ellen Giddings[4], Haley Makuch[4], John A. Morgan[5]

[1]Ochsner Clinic, New Orleans, LA, [2]Soroka, Kibutz Lahav, HaDarom, [3]Ochsner Clinic Foundation, New Orleans, LA, [4]Ochsner Clinic Foundation, LA, [5]Ochsner Clinic, Metairie, LA

OBJECTIVE: Optimal evaluation of stillbirth has previously been limited by lack of clear evidence. Recent data from the Stillbirth Collaborative Research Network has informed new national guidelines. We sought to evaluate the impact of updated guidelines on stillbirth evaluation in a large health system.

STUDY DESIGN: This was a cohort study of patients with stillbirth delivering at 14 system hospitals from 2018 to 2022. Singleton pregnancies with antepartum stillbirth ≥ 20 weeks gestation or birthweight ≥ 350 grams were included. Multi-fetal gestations were excluded. Stillbirths from 1/2018 to 12/2019 (pre-release) were compared with those from 2/2021 to 2/2022 (post-release). The primary outcome was optimal stillbirth evaluation, defined as placental pathology, fetal autopsy/cytogenetic test counseling, and antiphospholipid testing. Secondary outcomes included evaluation of excess tests. Statistical analysis included Student's T test, chi square, and Fischer exact test when appropriate.

RESULTS: We evaluated 162 patients, with 81 pre-release and 81 post-release. Baseline characteristics were similar between groups. Prior to guideline release, 8.6% of workups were optimal compared to 18.5% post-release (OR 2.4, 0.9-6.1). Excess tests ordered were similar after release (56.8% vs 68.8%; OR 1.7, 0.9-3.2). Optimal evaluation improved at a primary teaching hospital from 14.3% to 66.7% (OR 12.0, 2.0-56.4).

CONCLUSION: In a large health system, optimal stillbirth evaluation improved at a primary teaching hospital following update of national guidelines. However, no improvement was documented system-wide, signaling obstacles to dissemination of evidence-based stillbirth evaluation.

	Pre-Guidelines (N=81)	Post-Guidelines (N=81)	Odds Ratio (95% CI)
Complete Stillbirth Evaluation	7 (8.6)	15 (18.5)	2.4 (0.9-6.1)
Placental Pathology	78 (96.3)	73 (90.1)	0.35 (0.1-1.2)
Fetal Autopsy Counseling	17 (21.0)	15 (18.5)	0.85 (0.4-1.8)
Genetic Counseling	26 (32.1)	21 (25.9)	0.87 (0.4-1.6)
Antiphospholipid Assessment	10 (12.3)	18 (22.2)	2.03 (0.9-4.7)
Excess Testing	46 (56.8)	55 (67.9)	1.61 (0.9-3.1)
Local Improvement at Ochsner Baptist	4 (14.3)	8 (66.6)	12 (2.0-56.4)

431 Examining the Cost-Effectiveness of the RSV Vaccination in Pregnancy

Uma Doshi, Sarah K. Dzubay, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

OBJECTIVE: Respiratory syncytial virus (RSV) causes severe infections in neonates at increasing rates. A new vaccine has been shown to increase health benefits for neonates if given during pregnancy. We examined the cost-effectiveness associated with vaccinating all pregnant patients against influenza.

STUDY DESIGN: We designed a cost-effectiveness model using TreeAge to compare outcomes in pregnant patients who received the RSV vaccine to those who did not. We used a theoretical cohort of 3,661,220 the number of births in the United States in 2022. While RSV is a seasonal disease, we assumed that all patients would have an equal risk of RSV in the neonate as we examined the rate of infection within the first 6 months of life. Our outcomes included RSV infections in neonates, severe RSV infections requiring hospitalization, infant death due to RSV, and asthma incurred from RSV infection in addition to cost and quality-adjusted life years (QALYs). Probabilities, costs, and utilities were derived from the literature, and QALYs generated at a discount rate of 3%. Sensitivity analyses were performed to assess the robustness of our model.

RESULTS: For a one-year theoretical cohort of 3,661,220 patients, the RSV vaccine resulted in a decrease of 63,382 RSV infections, 45,325 of which required hospitalizations. Furthermore, the RSV vaccine resulted in 4 fewer infant deaths and 3,399 fewer cases of asthma before the age of 5. Vaccination resulted in an increased cost of $52 million and increased QALYs by 20,998 leading to an incremental cost-effectiveness ratio (ICER) of $24,679/QALY. In addition, we used sensitivity analysis to vary the cost of the vaccine—currently estimated to be around $280. If the cost of the vaccine was under $140, the vaccine would additionally be cost-saving.

CONCLUSION: In our cohort, the RSV vaccine was strongly cost-effective. Our study indicates that providers should recommend that pregnant patients receive an RSV vaccine.

Table 1: Outcomes in a theoretical cohort of 3,661,220 patients

	RSV VACCINE	NO RSV VACCINE	DIFFERENCE
RSV INFECTIONS	57,911	123,093	-63,382
SEVERE RSV INFECTIONS (REQUIRING HOSPITALIZATION)	19,904	65,229	-45,325
INFANT DEATH	2	6	-4
ASTHMA (BEFORE THE AGE OF 5)	6601	3202	-3399
COST (THOUSANDS OF USD)	$25,039,444	$24,521,226	$518,218
EFFECTIVENESS (QALYS)	109,267,300	109,246,302	20,998
ICER		$24,679/QALY	

432 Examining The Cost-Effectiveness of Post-partum Medicaid Care in People with a History of SMM

Uma Doshi, Ava Mandelbaum, Oluwadamilola Sosanya, Aaron B. Caughey, Maria I. Rodriguez
Oregon Health & Science University, Portland, OR

OBJECTIVE: Emergency Medicaid is a restricted benefits program that covers immigrants who are pregnant and low-income. 5 States and the District of Columbia have extended postpartum coverage for Emergency Medicaid to 60 days postpartum. We examined the cost-effectiveness of this program among people with a delivery complicated by severe maternal morbidity (SMM).

STUDY DESIGN: We designed a cost-effectiveness model using TreeAge to compare outcomes in people with SMM who received post-partum care under extended Emergency Medicaid coverage and those who did not. We used a theoretical cohort of 5,000 as an estimate of the number of SMM cases in the 5 states and DC that have this extension in place. Patients were then stratified by use of postpartum contraception as documented under Medicaid expansion and rates of subsequent pregnancy and SMM were calculated. Our outcomes included unintended pregnancy, repeat cases of SMM, and maternal death in addition to cost and quality-adjusted life years (QALYs). Probabilities, costs, and utilities were derived from the literature, and QALYs generated at a discount rate of 3%. Sensitivity analyses were performed to assess the robustness of our model.

RESULTS: For a theoretical cohort of 5,000 patients with a history of SMM in a previous pregnancy in an emergency Medicaid eligible population, extended post-partum coverage resulted in 206 fewer unintended pregnancies with 10 fewer repeat cases of SMM. Extended Emergency Medicaid post-partum coverage also resulted in a decreased cost of $2.48 million and increased QALYs by 3 thus making it a dominant cost-effective strategy.

CONCLUSION: Extending postpartum coverage for Emergency Medicaid patients with SMM is a dominant cost-effective strategy, resulting in reduced costs and increased quality of life. These results demonstrate the benefits of such an extension and highlight the importance of expanding coverage beyond 5 states.

Table 1: Outcomes in a cohort of 5,000 Emergency Medicaid eligible patients with SMM in a previous pregnancy

	Medicaid Expansion	*No Medicaid Expansion*	*Difference*
Unintended Pregnancy	793	999	-206
Repeat case of SMM	37	47	-10
Maternal Death	<1	<1	0
Cost (thousands of $)	$23,314	$25,795	-$2,481
QALYs	134,991	134,988	3

433 Does the Timing of Resolution of Low Placentation Affect the Risk of Postpartum Hemorrhage?

Bethany Dubois[1], Henri M. Rosenberg[2], Cody Goldberger[3], Elianna Kaplowitz[4], Angela Bianco[2], Chelsea A. DeBolt[4]
[1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]Mount Sinai Medical Center, New York, NY, [3]NYU Grossman School of Medicine, New York, NY, [4]Mount Sinai Hospital, New York, NY

OBJECTIVE: Low placentation, defined as placenta previa or low-lying placenta, is associated with increased risk of postpartum hemorrhage (PPH), both if resolved antepartum or persistent until delivery. This study investigates whether the gestational age (GA) at which low placentation resolves is associated with increased odds of PPH.

STUDY DESIGN: Retrospective cohort included patients who delivered at Mount Sinai Hospital from 2015-2019 and were diagnosed with low placentation via transvaginal ultrasound at second-trimester anatomical survey. Study subjects were divided into two groups based on GA at detection of low placentation resolution: early resolution (≤28 weeks GA) and late resolution (>28 weeks GA). Primary outcome was PPH, secondary outcomes included use of uterotonics or hemostatic procedures, blood transfusion, and ICU admission. Outcomes were analyzed using multivariable logistic or linear regression, adjusting for age, body mass index, use of in vitro fertilization, original low placentation diagnosis (previa vs low-lying), placental location at time of diagnosis, and uterine surgical history.

RESULTS: 634 patients were included, 454 in the early and 180 in the late resolution group. Demographics and risk factors were similar between cohorts, except late resolution cohort had a greater percentage of placenta previa (as opposed to low-lying placenta) at diagnosis (36% vs 25%, p=0.006), and increased proportion of Black and Hispanic persons (p=0.027). There was no significant difference in odds of PPH amongst the early compared to late resolution group (aOR 1.61, 95% CI 0.90-2.82). When assessed continuously, there was no association between GA at resolution and odds of PPH (aOR 1.06, 95% CI 0.97-1.16). There was no significant difference in the secondary outcomes.

CONCLUSION: Our analysis demonstrated no significant effect of GA at observation of low placentation resolution on the risk of PPH in a large, diverse, urban cohort. Future prospective studies, with more frequent placental surveillance, will be important in determining the impact of timing of low placentation resolution on risk of PPH.

434 Evaluating the Predictive Value of Risk Factors for Fetal Acidosis at Scheduled Cesarean Deliveries

Bethany Dubois[1], Minhazur R. Sarker[2], Elianna Kaplowitz[3], Fatima A. Estrada[4], Kristina M. Feldman[5], Peter S. Bernstein[6], Lauren Ferrara[7], Lois Brustman[8], Angela Bianco[9], Chelsea A. DeBolt[3]
[1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]University of California San Diego, San Diego, CA, [3]Mount Sinai Hospital, New York, NY, [4]Montefiore Medical Center, Congers, NY, [5]Icahn School of Medicine at Mount Sinai West, New York, NY, [6]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [7]Mount Sinai School of Medicine, New York, NY, [8]St. Luke's Roosevelt Hospital Center, New York, NY, [9]Mount Sinai Medical Center, New York, NY

OBJECTIVE: This study evaluates the relative impacts of maternal and surgical risk factors, both separately and together, on the risk of fetal acidosis at scheduled cesarean delivery (CD).

STUDY DESIGN: This is a multi-center retrospective cohort study of non-labor, term, singleton, non-anomalous births via CD under neuraxial anesthesia from 2013-2019. Primary outcome was fetal acidosis defined as umbilical artery pH < 7.1. Univariable and multivariable logistic regression were used to determine the likelihood of fetal acidosis relative to maternal factors, surgical factors, and both. Receiver−operating characteristic (ROC) curves evaluated the predictive accuracy of each model, comparing the area under the curve (AUC) using the DeLong test. Best-subset selection identified the factors that best predicted the primary outcome with possible overfitting addressed via k-fold cross-validation (5 repeated 10 fold validation).

RESULTS: Fetal acidosis was present in 159 (2.5%) births included in this study. In a model of only maternal factors, predictors of fetal acidosis were body mass index (BMI), insurance type, and gestational diabetes (gDM). In a model of only surgical factors, predictors were time from anesthesia placement to delivery and hypotension (systolic blood pressure [BP] < 90 or diastolic BP < 50). In a combined model, predictors were BMI, gDM, time from anesthesia to delivery, and hypotension. Comparing the performance of all models, the combined maternal/surgical model performed better (AUC=0.77) than either the maternal (AUC=0.72) or surgical (AUC=0.70) (DeLong test p< 0.001). Using best-subset analysis, the model with the highest predictive accuracy included only obesity and hypotensive episodes (BIC=1383, AUC=0.74).

CONCLUSION: The etiology of fetal acidosis in non-labor, term, non-anomalous singleton births via CD is multifactorial, with the most predictive model including both maternal and surgical factors. Prenatal interventions to optimize metabolic health, as well as interventions to prevent hypotension or reduce time from anesthesia placement to delivery may reduce incidence of fetal acidosis.

435 Characterizing Congenital Syphilis in California Between 2008-2019

Sarah K. Dzubay, Megha Arora, Lily Ben-Avi, Uma Doshi, Bharti Garg, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

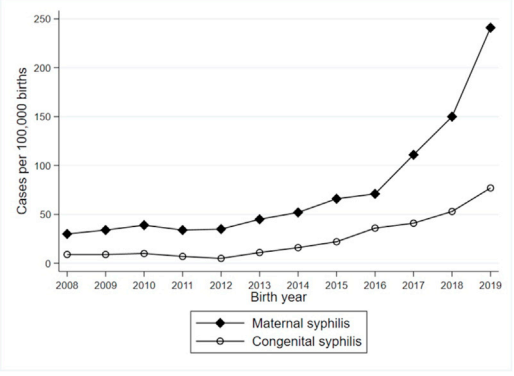
OBJECTIVE: To characterize the maternal syphilis rate, congenital syphilis rate, and maternal factors associated with congenital syphilis in California between 2008-2019.

STUDY DESIGN: We performed a retrospective cohort study among singleton, non-anomalous births delivered between 23 and 42 weeks in California between 2008 and 2019. Overall rates of maternal and congenital syphilis per 100,000 births were plotted across birth years of 2008-2019. Maternal demographic factors of interest included race/ethnicity, age, pre-pregnancy body mass index (BMI), parity, insurance type, and education level.

RESULTS: The rate of congenital syphilis in California between 2008-2019 mirrored the steep rise in the rate of maternal syphilis, but did not see as dramatic of an increase as the maternal syphilis rate between 2016-2019 (Figure 1). Relative to those unaffected by congenital syphilis, infants with congenital syphilis were more likely to have mothers who were non-Hispanic Black (11.4% vs. 4.9%) or Hispanic (61.2% vs. 50.9%); under 20 (7.4% vs. 6.6%) or between 20-34 years old (78.5% vs 73.7%); overweight (30.2% vs. 26.3%) or obese (26.1% vs. 22.5%); multiparous (72.3% vs. 60.8%); had public insurance (90.9% vs. 52.2%); and had completed high school education or less. (72.9% vs. 44.0%).

CONCLUSION: Congenital syphilis rates have increased alongside maternal syphilis rates in California between 2008-2019. Mothers of infants with congenital syphilis differ from the mothers of those who do not have congenital syphilis by numerous demographic factors, emphasizing the need to investigate the underlying structural factors leading to disparities in congenital syphilis rates.

Figure 1. Trends in maternal and congenital syphilis prevalence in California between 2008-2019.



436 Association of BMI on surgical and pregnancy outcomes in patients undergoing non-emergent vaginal cerclage

Savannah Elrod[1], John Owen[2], Gabriella D. Cozzi[1], Claire A. McIlwraith[1], Rebecca Fleenor[1], Joseph T. Edwards Jr.[3], Dhong-Jin Kim[2], Victoria C. Jauk[2], Alan T. Tita[1], Akila Subramaniam[2]
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL, [3]UAB, Birmingham, AL

OBJECTIVE: Patients with obesity (BMI $\geq$ 30 kg/m2) have more surgical and pregnancy complications than those without. We studied the association of BMI on surgical risks and perinatal outcomes in patients undergoing non-emergent vaginal cerclage.

STUDY DESIGN: Retrospective cohort study of patients with non-anomalous singleton gestations who had a non-emergent history (Hx)- or ultrasound (US)-indicated vaginal cerclage at a single tertiary center 1/2013-4/2021. Patients were defined as obese or non-obese (BMI $<$ 30). Our primary outcome was birth gestational age (GA). Secondary outcomes included preterm birth (PTB), operative morbidity, and selected perinatal outcomes. Baseline characteristics, primary, and secondary outcomes were compared in bivariate analysis. Linear regression modeled the relationship between BMI and birth GA; possible confounders were considered in these models.

RESULTS: Of 258 non-emergent vaginal cerclages analyzed, 110 (43%) were non-obese (BMI 25 $\pm$ 3.3) and 148 (57%) obese (BMI 38 $\pm$ 6.7). There were 175 Hx- and 83 US-indicated procedures. The obese group tended to be Non-Hispanic Black (n=148) and had more prior pregnancy losses (p=0.003). The obese group delivered at significantly earlier mean GAs, with greater rates of PTB across all viable GA ranges, had earlier GA at membrane rupture, and shorter cerclage durations (Table). For every BMI unit increase, there was a decrease of 0.14 weeks in birth GA (β= -0.14 wk/BMI unit, p=0.004). Obese patients also had significantly higher estimated blood loss and longer operative times, but similar operative morbidity, lengths of stay, and readmissions. Obesity was associated with different birth indications, as well as higher neonatal composite morbidity (Table). After controlling for race, cerclage indication, and obstetric history, there was still a significant effect of BMI on birth GA (β= -0.10, p=0.038).

CONCLUSION: Following non-emergent cerclage, patients with obesity delivered earlier than those without. The inverse effect of BMI on birth GA persisted after controlling for selected confounders.

Table. Operative and pregnancy outcomes among patients undergoing non-emergent vaginal cerclage 2013-2021 by maternal obesity

OUTCOMES	Non-obese patients (n=110)	Obese patients (n=148)	P-value

437 Differences in Gestational Age at Preeclampsia Diagnosis and Delivery Across BMI Categories

Merai Estafanous[1], Ruofan Yao[2], Christina Mansour[3], Elaine Hart[4]
[1]Loma Linda University School of Medicine, Loma Linda, CA, [2]Loma Linda University, Loma Linda, CA, [3]Scripps Mercy Hospital San Diego, San Diego, CA, [4]Loma Linda University, Department of Gynecology and Obstetrics, Loma Linda, CA

OBJECTIVE: Our objective was to determine if body mass index (BMI) category is associated with gestational age at time of diagnosis of preeclampsia-spectrum disorders, gestational age at time of delivery, and/or the latency period between the two. Obesity is associated with earlier onset of preeclampsia and shorter latency from diagnosis to delivery.

STUDY DESIGN: A single center, retrospective, cohort study was conducted of all deliveries that occurred at Loma Linda University Medical Center in Loma Linda, California in 2019. Patients with a diagnosis of preeclampsia were categorized into Underweight / Normal Weight (BMI $\leq$ 24.9 kg/m^2), Overweight (BMI 25-29.9 kg/m^2), Class I Obesity (BMI 30-34.9 kg/m^2), Class II Obesity (BMI 35-39.9 kg/m^2), and Class III Obesity (BMI $\geq$ 40 kg/m^2). Median number of gestational age at time of preeclampsia diagnosis, gestational age at time of delivery, and the latency period were compared across BMI categories. Completed weeks of gestation was used for gestational age.

RESULTS: For all patients with a diagnosis of preeclampsia, BMI category was significantly associated with gestational age at time of diagnosis ($p = 0.0017$) and gestational age at time of delivery ($p = 0.0038$). BMI category was not associated with the latency period between the two ($p = 0.46$).

CONCLUSION: In our population, BMI category is significantly associated with gestational age at time of preeclampsia diagnosis and gestational age at time of delivery but not associated with the length of latency period between them. Contrary to our expectation, we observed that lower BMI was associated with earlier diagnosis and delivery.

	Total N 391	Gestational Age at Diagnosis			Gestational Age at Delivery			Latency Period		
Obesity Class	N	Median	IQR	*p value*	Median	IQR	*p value*	Median	IQR	*p value*
Underweight, normal weight	16	35.5	26.5-38.5	0.0017	36	29.5-38.5	0.0038	0	0-0	0.46
Overweight	76	37	33.5-39		37	34-39		0	0-0	
Class I	91	37	36-38		37	36-39		0	0-0	
Class II	79	36	32-38		37	35-38		0	0-1

438 Complicated deliveries increase neonatal failure rates of the first Otoacoustic Emissions Hearing Test

Sivan Farladansky Gershnabel[1], Hanoch Schreiber[2], Dorit Ravid[3], Gal Cohen[2], Tal Biron-Shental[4], Shmuel Arnon[1]
[1]Meir Medical Center, Kfar Saba, HaMerkaz, [2]Meir Medical Centerartment of Obstetrics and Gynecology, Meir Medical Center, Kfar Saba, Israel, [3]Meir Hospital, Ra'anana, HaMerkaz, [4]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz

OBJECTIVE: Otoacoustic emission test (OAE) is a screening test for congenital hearing loss and it is performed usually 2 days after delivery. Newborn hearing screening may fail due to perinatal and neonatal factors. Our departmental OAE failure rate is 6.2%. We aimed to assess failure rate and associated factors among complicated pregnancies.

STUDY DESIGN: This retrospective study included all women who were admitted to our high risk unit during their pregnancy and delivered between January 2021 and June 2023. Delivery characteristics were compared between newborns with failed OAE test and those who passed the test (control group). All OAE tests were performed within 48 hours after delivery.

RESULTS: A total of 872 newborns were included, among them 136 (15.6%) were in the failed OAE group and 735 in the control group. There was no difference in maternal age, gravidity, parity or gestational age between groups. There was no difference in SGA or macrosomia rate between groups. Higher rates of vacuum extraction (8.84% vs. 1.47% p=0.001) and gestational diabetes (16.9% vs. 10.61%, p=0.02) in the study group compared to the control group. No difference in vaginal delivery and cesarean section rates.

In the multivariate analysis after adjustment for confounders, vacuum extraction (OR-6.1 ,95%CI 1.4-25.6, p= 0.012) and gestational diabetes (OR-1.7, 95% CI 1.0-2.9, p=0.03) were independently associated with failed first OAE.

CONCLUSION: Based on our cohort, infants delivered by vacuum extraction are more likely to fail in the first Otoacoustic Emissions Hearing Test. These data may be considered in setting the timing for that screening test. Infants born after complicated high risk pregnancies had significantly higher failure rates on first OAE. These higher rates were independently associated with vacuum extraction and gestational diabetes. We speculate that the timing of first OAE after high risk pregnancies with gestational diabetes and vacuum deliveries should preferably be postponed beyond the first days of infants life to improve OAE success rates and minimize parental anxiety and costs.

439 Early treatment with IV iron is associated with improved maternal hemorrhage-related outcomes

Mina Felfeli[1], Homa K. Ahmadzia[1], Emma K. Sterling[1], Nicki Mohammadi[2], Haeun Kim[1], Nisha J. Ramamurthy[1], Jaclyn M. Phillips[1]
[1]George Washington University, Washington, DC, [2]Gorge Washington University, Washington, DC

OBJECTIVE: Anemia in pregnancy is associated with hemorrhage-related morbidity and mortality. Iron deficiency anemia (IDA) is a modifiable risk factor when identified and treated antenatally. The purpose of this study is to evaluate how timing of IV iron therapy in relation to delivery impacts hemorrhage-related maternal morbidity and fetal outcomes.

STUDY DESIGN: This retrospective cohort study from a single center included patients who received antenatal IV iron therapy for a diagnosis of anemia in pregnancy from January 2017 through January 2023. Anemia was defined as admission hemoglobin < 11 g/dL. Timing of IV iron administration in relation to delivery date was analyzed. An unadjusted analysis was performed using Fisher's exact test and Student's paired t-test. Multivariate logistic regression was used to calculate odds ratios (95% confidence intervals) to compare pregnancy outcomes for IV iron therapy more than and less than 10 days prior to delivery.

RESULTS: Of 83 included pregnancies with IDA, 45 received IV iron therapy more than 10 days prior to delivery, while 38 received IV iron therapy fewer than 10 days before delivery. Pregnant patients who received their final transfusion of IV iron >10 days before delivery had significantly higher hemoglobin at delivery admission (p< 0.001). Those who received IV iron < 10 days before delivery were 6.8 times more likely to receive a blood transfusion (p=0.01, aOR=6.8, 95%CI 1.6-22) and 5.3 times more likely to have preterm birth (p=0.001, aOR =5.3). Patients who received IV iron > 10 days were significantly less likely to have ICU admission (p=0.04) or a

birth resulting in NICU admission (p=0.02). There was no significant difference in the mode of delivery, postpartum hemorrhage, or pre-existing pregnancy comorbidities between groups.

CONCLUSION: Patients who received IV iron more than 10 days prior to delivery had improved maternal and fetal outcomes, including fewer maternal blood transfusions, maternal ICU admissions, preterm births, and NICU admissions. Earlier treatment of IDA with IV iron in pregnancy may mitigate hemorrhage-related morbidity.

Table 1. Outcomes for patients treated with intravenous iron and timing of intravenous therapy with relationship to delivery

440 Association between cesarean delivery and childhood respiratory outcomes

Christine P. Field

Ohio State University / Department of OB/GYN / Division of Maternal Fetal Medicine, Columbus, OH; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: To investigate whether there is an association between cesarean delivery (CD) and childhood respiratory outcomes.

STUDY DESIGN: Secondary analysis of a prospective, follow-up study of children delivered in the NICHD Antenatal Late Preterm Steroids study. Children were included if their mothers were enrolled in the follow-up study and had data available for the primary outcome at age 6 or greater. The primary exposure was CD. The primary outcome was a composite of adverse childhood respiratory outcomes: abnormal pulmonary function testing, diagnosis of asthma or of other chronic respiratory illnesses, or inpatient admission for respiratory illness. It was planned *a priori* to assess whether results differed according to whether CD occurred after labor or rupture of membranes (ROM). Log-binomial regression was used to calculate unadjusted and adjusted relative risk (RR), with vaginal delivery as the referent group.

RESULTS: Of 1,218 children enrolled in the follow-up study, 833 (68.4%) delivered vaginally and 385 (31.6%) by cesarean. Children born by CD had lower birth weight, were more likely to be small for gestational age, have had respiratory distress syndrome and to have been admitted to the neonatal intensive care unit, and were less likely to have been breastfed. Mothers of children born by CD were older and more likely to have private insurance. The average age at follow up was 7 years in both groups. There was no difference in the primary outcome between children born vaginally and those born by CD (48.6% vs. 41.5%; aRR 1.14; 95% CI: 0.99, 1.31), although those born by CD were more likely to have had pneumonia (11.2% vs. 7.6%; aRR 1.48; 95% CI: 1.01-2.15) or wheezing or whistling in the chest (49.4% vs. 40.2%; aRR 1.17; 95% CI: 1.02-1.34). There was no evidence that the elevated risk was specific to CD after labor or ROM (Table 1).

CONCLUSION: Delivery via CD in children who were at risk for late preterm delivery was not associated with the primary outcome, although some individual adverse respiratory outcomes were more likely among those with CD.

Table 1. Association between Mode of Delivery and Primary and Secondary Outcomes

Outcome	Primary analysis	Secondary analysis	
	aRR* cesarean (N=385)	aRR* cesarean without labor or ROM (N=204)	aRR* cesarean with labor or ROM (N=181)
Primary composite outcome	1.14 (0.99,1.31)	1.14 (0.96,1.37)	1.10 (0.92,1.32)
Abnormal spirometry	1.09 (0.92,1.30)	1.09 (0.87,1.38)	1.09 (0.87,1.36)
Ever diagnosed with asthma	1.24 (0.86,1.78)	1.24 (0.78,1.97)	1.25 (0.79,1.98)
Diagnosed with other chronic respiratory illnesses	1.01 (0.56,1.81)	0.65 (0.27,1.55)	1.41 (0.72,2.78)
Ever stayed overnight in the hospital for respiratory illness	1.43 (0.98,2.08)	1.57 (1.00,2.47)	1.31 (0.79,2.20)
Ever had unscheduled doctor, ER, or urgent care visit for coughing, wheezing, or trouble breathing	1.06 (0.92,1.22)	1.05 (0.88,1.25)	1.08 (0.91,1.28)
Pneumonia	**1.48 (1.01,2.15)**	**1.83 (1.17,2.86)**	1.14 (0.67,1.94)
Ever had wheezing or whistling in the chest	**1.17 (1.02,1.34)**	1.07 (0.89,1.28)	**1.25 (1.07,1.47)**

All analyses are compared with vaginal deliveries (N=833).
Spirometry missing in 25.
Data are relative risk (95% CI).
*Adjusted by pre-specified characteristics including gestational age at delivery, maternal age, smoking during pregnancy, maternal asthma requiring medication, child age, gender, maternal education, second-hand smoke exposure, breastfeeding, small for gestational age, treatment assignment, center (and number of previous pregnancies in secondary analysis).

441 Association of nocturnal heart rate and development of gestational diabetes and hypertensive disorders of pregnancy

Stephanie A. Fisher[1], Xiaoning Huang[1], Sadiya S. Khan[2], Daniela Grimaldi[1], Phyllis Zee[1], Philip Greenland[3], Francesca Facco[4], Robert C. Basner[5], Judith H. Chung[6], William A. Grobman[7], Rebecca B. McNeil[8], Grace W. Pien[9], Uma M. Reddy[5], Susan Redline[10], Robert M. Silver[11], Lynn M. Yee[12]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Oak Park, IL, [3]Northwestern University Feinberg School of Medicine, Evanston, IL, [4]Magee-Womens Hospital, Pittsburgh, PA, [5]Columbia University, New York, NY, [6]UC Irvine Health, Orange, CA, [7]The Ohio State University, Columbus, OH, [8]RTI, Durbam, NC, [9]Johns Hopkins University School of Medicine, Baltimore, MD, [10]Harvard Medical School, Boston, MA, [11]University of Utah Health, Salt Lake City, UT, [12]Northwestern University, Chicago, IL

OBJECTIVE: Prior data suggest nocturnal heart rate (NHR) may represent a marker of cardiometabolic disease risk in non-pregnant adults, but data on NHR and pregnancy outcomes are limited. We sought to assess the association of NHR with gestational diabetes (GDM) and hypertensive disorders of pregnancy (HDP).

STUDY DESIGN: This is a secondary analysis of nulliparas enrolled in a prospective observational cohort at 8 clinical sites who completed a home sleep study using the Embletta-Gold device with bipolar electrocardiogram at baseline (6^0-13^6 weeks) and follow-up visits (22^0-29^6 weeks). We excluded those with chronic hypertension or pregestational diabetes. The primary exposure was the mean NHR at baseline and follow-up (analyzed separately). Secondary exposures were the minimum and maximum NHR at each visit. The outcomes were GDM and HDP. Independent samples t-tests compared each exposure among gravidas with and without the outcomes of interest.

Multivariable logistic regression models estimated the odds of each outcome per 5-beat increase in NHR at baseline and follow-up.

RESULTS: Among 2,952 eligible nulliparas, 4.1% (118/2911) developed GDM and 13.6% (392/2890) developed HDP. The mean (standard deviation) for the mean, minimum, and maximum NHR was 71 (8), 46 (11), and 102 (14) at baseline, and 78 (9), 51 (13), and 108 (15) at follow-up. Gravidas who developed GDM had higher mean, minimum, and maximum NHR at baseline and follow-up than unaffected gravidas ($p \leq 0.01$, Table), with each exposure associated with higher adjusted odds of GDM. Gravidas who developed HDP also had higher mean NHR (baseline and follow-up), higher minimum NHR (baseline), and higher maximum NHR (follow-up) ($p < 0.01$) than those without HDP. For each 5-beat increase in mean NHR at the baseline visit, the adjusted odds of GDM and HDP were higher by 39% and 10%, respectively, with similar increased odds at follow-up.

CONCLUSION: Higher mean, minimum, and maximum NHR in pregnancy appear to be associated with higher odds of GDM and HDP. This may reflect increased sympathetic and/or decreased parasympathetic activity in affected gravidas.

Table. Nocturnal heart rate metrics and odds of gestational diabetes and hypertensive disorders of pregnancy for each 5-beat increase in heart rate

Nocturnal Heart Rate	Average *mean (SD)*	Minimum *mean (SD)*	Maximum *mean (SD)*
Gestational Diabetes			
Baseline (6^0-13^6 weeks)			
Yes	74.9 (7.9)	49.0 (10.0)	106.0 (13.3)
No	70.9 (8.4)	45.9 (10.9)	101.7 (14.0)
aOR (95% CI)[1,2]	1.39 (1.26, 1.53)	1.17 (1.04, 1.32)	1.08 (1.04, 1.11)
Follow-up (22^0-29^6 weeks)			
Yes	81.8 (9.5)	54.0 (13.2)	113.7 (14.1)
No	77.4 (9.3)	50.5 (12.5)	108.0 (15.4)
aOR (95% CI)	1.31 (1.20, 1.42)	1.12 (1.07, 1.17)	1.09 (1.05, 1.13)
Hypertensive Disorders of Pregnancy			
Baseline (6^0-13^6 weeks)			
Yes	72.6 (8.4)	47.6 (10.7)	102.7 (14.4)
No	70.9 (8.3)	45.7 (10.9)	101.7 (14.0)
aOR (95% CI)	1.10 (1.04, 1.17)	1.07 (1.03, 1.12)	1.01 (0.97, 1.06)
Follow-up (22^0-29^6 weeks)			
Yes	79.5 (9.2)	51.8 (12.0)	110.4 (14.4)
No	77.3 (9.3)	50.5 (12.6)	107.8 (15.5)
aOR (95% CI)	1.11 (1.04, 1.18)	1.02 (0.96, 1.08)	1.04 (1.01, 1.08)

aOR—adjusted odds ratio, CI—confidence intervals, SD—standard deviation,

1. Adjusted models include maternal age, race/ethnicity (as a proxy for racism), insurance type, smoking status, average sleep hours, sleep apnea risk (high vs. low risk based on the Berlin Questionnaire), and restless leg syndrome.
2. 95% confidence intervals are based on robust standard errors clustered around clinical site.

442 Association of fatty acid intake with preterm birth in nulliparas with obesity

Stephanie A. Fisher[1], William A. Grobman[2], Gina F. Milone[3], Rebecca B. McNeil[4], Brian M. Mercer[5], Christina Scifres[6], Robert M. Silver[7], George R. Saade[8], Lynn M. Yee[9]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]The Ohio State University, Columbus, OH, [3]University of California Irvine, Irvine, CA, [4]RTI, Durbam, NC, [5]MetroHealth Medical Center, Cleveland, OH, [6]Indiana University School of Medicine, Indianapolis, IN, [7]University of Utah Health, Salt Lake City, UT, [8]Eastern Virginia Medical School, Norfolk, VA, [9]Northwestern University, Chicago, IL

OBJECTIVE: Prior data suggest the association between polyunsaturated fatty acid (PUFA) intake and preterm birth (PTB) differs by maternal body mass index (BMI), but it is unclear if the severity of obesity influences this association. We sought to assess the association between periconceptional dietary PUFA intake and PTB in gravidas with obesity.

STUDY DESIGN: This is a secondary analysis of nulliparas enrolled in a prospective observational cohort who completed a 1st-trimester food frequency questionnaire assessing PUFA intake within 3 months of conception. Primary and secondary exposures were self-reported daily intake of docosahexaenoic and eicosapentaenoic acid (DHA+EPA, in milligrams) and Alternative Healthy Eating Index-2010 PUFA scores (AHEI PUFA %, as a % of total energy intake), respectively. The primary outcome was any PTB < 37 weeks, with spontaneous and indicated PTB (iPTB) as secondary outcomes. Multivariable logistic regression was used to estimate the odds of PTB associated with each PUFA exposure categorized in quartiles (Q1, lowest; Q4, highest) in nulliparas with early-pregnancy BMI $\geq$30 kg/m^2. A test of interaction estimated effect modification of BMI $\geq$40 and, if significant, a stratified analysis was performed.

RESULTS: Among 1,874 eligible nulliparas, PTB occurred in 11% and 12% of gravidas with BMI 30-39.9 and $\geq$40, respectively. Significant interactions between BMI and EPA+DHA intake (p=0.02) and AHEI PUFA % (p=0.03) indicated that PTB rates differed by obesity strata. Specifically, in nulliparas with BMI $\geq$40, those with DHA+EPA intake in Q2 and Q3 had a 57% and 60% reduced adjusted odds of PTB, compared with those in the highest intake quartile (Q4), but no association with PTB was found for those with BMI 30-39.9 (Table). For AHEI PUFA %, Q2 intake in nulliparas with BMI $\geq$40 was associated with a 58% and 66% reduction in adjusted odds of any PTB and iPTB, respectively, but not for those with BMI 30-39.9.

CONCLUSION: Severity of obesity mediates the association between periconceptional PUFA intake and PTB, with lower PUFA intake associated with reduced PTB in nulliparas with BMI $\geq$40.

Table. Odds of preterm birth prior to 37 weeks' gestation and fatty acid intake in nulliparas with obesity

	n/N (%)	aOR (95% CI)[1]
BMI 30-39.9 kg/m²		
DHA+EPA intake (mg/day)		
Q1	41/323 (12.7)	1.43 (0.88, 2.32)
Q2	40/372 (10.8)	1.17 (0.72, 1.90)
Q3	43/381 (11.3)	1.24 (0.77, 2.01)
Q4	33/354 (9.3)	ref
AHEI PUFA %[2]		
Q1	42/388 (10.8)	0.81 (0.51, 1.27)

Q3	35/365 (9.6)	0.70 (0.44, 1.12)
Q4	45/338 (13.3)	ref
BMI ≥ 40 kg/m²		
DHA+EPA intake (mg/day)[3]		
Q1	14/127 (11.0)	0.49 (0.24, 1.02)
Q2	13/135 (9.6)	**0.43 (0.21, 0.89)**
Q3	12/131 (9.2)	**0.40 (0.19, 0.84)**
Q4	26/132 (19.7)	ref
AHEI PUFA %[4]		
Q1	13/124 (10.5)	0.54 (0.26, 1.12)
Q2	11/131 (8.4)	**0.42 (0.19, 0.90)**
Q3	16/133 (12.0)	0.64 (0.32, 1.27)
Q4	25/137 (18.3)	ref

aOR—adjusted odds ratio , AHEI—Alternative Healthy Eating Index-2010, BMI—body mass index, CI—confidence interval, DHA—docosahexanoic acid, EPA—eicosapentaenoic acid, PUFA—polyunsaturated fatty acid, PTB—preterm birth, Q1—quartile 1, lowest (DHA+EPA: 3.97-32.3mg; AHEI PUFA %: 0.0-5.14), Q2—quartile 2 (DHA+EPA: 32.4-71.5mg; AHEI PUFA %: 5.15-6.34), Q3—quartile 3 (DHA+EPA: 71.6-148mg; AHEI PUFA %: 6.35-7.73), Q4—quartile 4, highest (DHA+EPA: 149-789mg; AHEI PUFA %: 7.74-10.0),

1. Multivariable models were adjusted for race (as a proxy for racism) and tobacco use
2. AHEI PUFA %: the highest score (10) is given to individuals with ≥10% of total energy intake from PUFAs, while the lowest score (0) is given to individuals with ≤2% of total energy intake from PUFAs, excluding EPA and DHA intake.
3. Adjusted odds of indicated and spontaneous PTB, stratified by obesity status, did not differ by DHA+EPA intake quartile, although this analysis was limited by small sample size.
4. In analysis by type of PTB, the aOR in AHEI PUFA % Q2 was significant for indicated PTB (0.34, 95% CI 0.11-0.98), but not spontaneous PTB.

443 Machine Learning for the Prediction of Neonatal Neuroskeletal Injury Following Shoulder Dystocia

Itamar Futterman[1], Satjeet K. Deol Chauhan[2], Myah Griffin[3], Meghana Limaye[4], Rachel Lindfield[4], Elizabeth Cochrane[5], Chloe Getrajdman[6], Michael Silver[1], Angela Bianco[7], Shoshana Haberman[1], Fouad Atallah[1]

[1]Maimonides Medical Center, Brooklyn, NY, [2]Bronx Care, New York, NY, [3]NYU Langone Health, Atlanta, GA, [4]NYU Langone Health, New York, NY, [5]Icahn School of Medicine at Mount Sinai, New York, NY, [6]Mount Sinai Hospital, New York, NY, [7]Mount Sinai Medical Center, New York, NY; on behalf of the New York City MFM Research Consortium

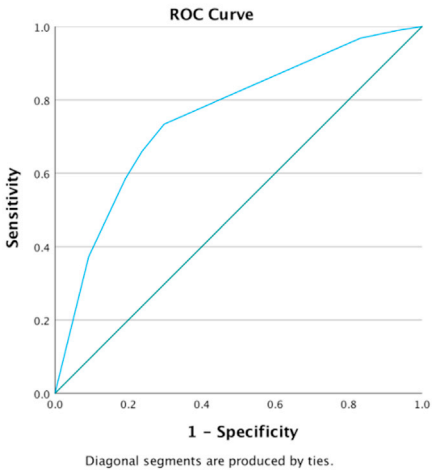
OBJECTIVE: To use machine learning (ML)-based decision tree modeling for the prediction of neuroskeletal injury in neonates following shoulder dystocia (SD).

STUDY DESIGN: A multi-center retrospective cohort study including all cases of SD across three tertiary care perinatal centers and members of the New York City Maternal Fetal Medicine research consortium, from 2015-2020. A total of 59 variables were collected including sociodemographic and obstetrical variables and outcomes. Tenfold cross-validated decision tree model (DTM) was then constructed for the prediction of neuroskeletal injury among the cases of SD. Neuroskeletal injury was defined as any of the following: Erb's palsy, Klumpke's palsy, facial nerve palsy, humeral or clavicular fractures.

RESULTS: Among the 1,155 cases of SD identified, there were 94 (8.2%) cases of neuromuscular injury. There were 56 cases of Erb's palsy (59.6%), two facial nerve palsy (2.1%), 20 humeral fractures (21.3%) and 28 clavicular fractures (29.8%) (Twelve of the cases had overlapping injuries). There were no cases of Klumpke's palsy in our cohort. ML-based, DTM encompassing five variables including head-to-body time, maternal BMI, neonatal birthweight, oxytocin use and type of delivery were able to predict neuroskeletal injury with a with 73.4% sensitivity, 70.3% specificity, 0.76 AUC (95% CI 0.70, 0.81, Figure 1) and 0.28 F1 score. Decisions were observed with head-to-body time >1.67 minutes, maternal BMI >29, type of delivery being spontaneous vaginal delivery and forceps assisted vaginal delivery, use of Oxytocin and neonatal birth weight of >3575g.

CONCLUSION: It is possible to identify a combination of factors that are associated with SD cases that maybe complicated by neonatal neuroskeletal injury with a moderate level of sensitivity and specificity by using DTM models.

Figure 1: ROC curve



444 National and International Validation of a Prenatal Machine Learning Algorithm to Forecast Cesarean Section Risk

Reetam Ganguli[1], Stephen M. Wagner[2]

[1]Warren Alpert Medical School of Brown University, Women & Infants Hospital Rhode Island, Providence, RI, [2]Beth Israel Deaconess Medical Center, Brookline, MA

OBJECTIVE: Clinical risk assessment for cesarean delivery (CD) remains subjective with poor inter-provider reliability. Our goal was to develop an objective, individualized risk prediction model for CD using machine learning (ML) models trained on routine prenatal data. Accurately identifying risk could allow more nuanced counseling on delivery mode, inform conversations around scheduling repeat cesarean, and optimize resource planning for higher risk patients.

STUDY DESIGN: We conducted a retrospective cohort study including all patients from 2018-2020 in the Center for Disease Control's Vital

Statistics System utilizing sociodemographic and clinical data prior to delivery. Deliveries with missing data for route of delivery were excluded. The primary outcome was route of delivery through cesarean section.

An extreme gradient boosting model was trained on included patients from 2018-2020, as well as CD patients from years 2014, 2016, and 2017. Weight scaling algorithms were utilized to improve model performance. The model was retrospectively tested on patients from the year 2021 of the Vital Statistics System and prospectively tested on a cohort of women enrolled across 8 hospitals in Cameroon and Nigeria.

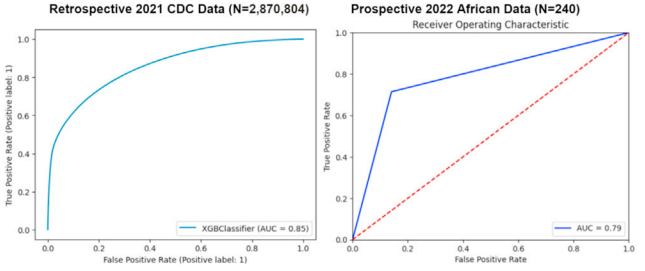
RESULTS: The model was trained on 10,541,899 patients, of which 470,2731 (44.6%) had a CD.

When retrospectively tested on 2,870,804 patients, where 1,022,481 (35.6%) had a CD, the model achieved 0.85 AUC, 78.1% accuracy, 0.72 sensitivity, and 0.78 F1 score.

When prospectively tested on 240 African patients, where 84 (35%) had a CD, the model achieved 0.79 AUC, 80.8% accuracy. 0.71 sensitivity, and 0.80 F1 score when tuned to a 0.77 threshold.

The highest weighted factors for the model were maternal body mass index/pregestational weight and maternal age.

CONCLUSION: We demonstrate that prenatal ML models can predict CD likelihood with strong discrimination ability, which can aid patient education, delivery planning, and resource optimization through data-driven clinical decision support. Our findings have the potential to reduce unplanned CD and lower correlated costs for providers and health systems.



445 Physical activity in pregnant persons with a prior preterm birth: impact of cervical insufficiency (CI)

Emily Gascoigne[1], Catherine Vladutiu[2], Abbie Smith-Ryan[1], Annie Dude[3], Tracy Manuck[1]

[1]University of North Carolina, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Rockville, MD, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

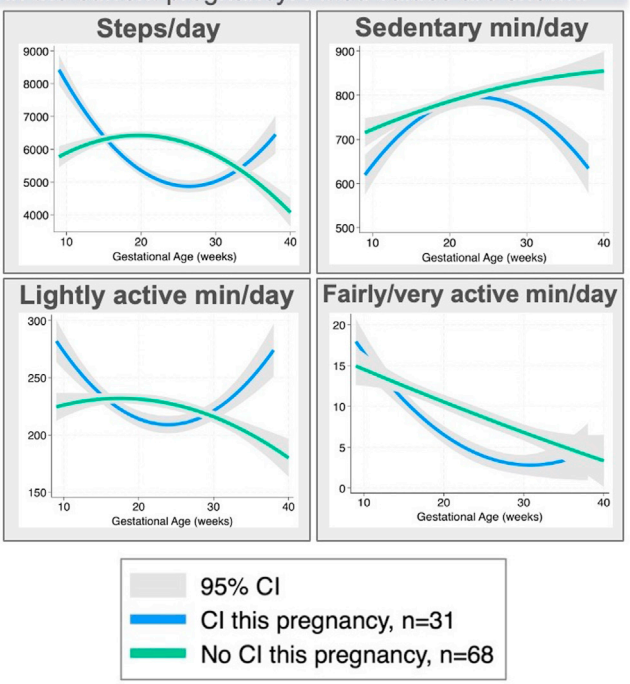
OBJECTIVE: We sought to determine the association between objectively quantified physical activity and GA at delivery among patients with a prior SPTB who did and did not develop CI in the current pregnancy.

STUDY DESIGN: Primary analysis of a prospective observational cohort designed to identify factors associated with recurrent SPTB. Patients with singleton, non-anomalous gestations and ≥1 prior SPTB < 35 wks were recruited, 9-14 wks, 2017-2022. Participants were provided FitBit activity trackers for the remainder of pregnancy and instructed to maintain their usual activity. Those with ≥7 valid monitoring days (FitBit recorded heart rate for ≥80% of the day) were included. Patients with a mid-trimester CL < 25mm & US- or exam-indicated cerclage in the current pregnancy were considered to have CI. Daily steps and intensity were compared by those with and without CI. The primary outcome was GA at delivery. Fixed-effects linear regression was used to examine whether activity parameters were associated with GA at delivery and to account for varying numbers of obs/subject.

RESULTS: 99 patients met inclusion criteria; 31 (31%) had CI. Those with CI delivered at 35.4 ± 4.1 wks vs. 36.8 ± 3.1 wks (no CI), p=0.058. The cohort was racially (40% Black) and ethnically (16% Hispanic) diverse. There were 6847 Fitbit wear days (median 60 days/person). For those with CI, daily steps, light activity min/day, and fairly/very active min/day were higher in early pregnancy and decreased mid-pregnancy; these activity patterns differed significantly from those without CI (Figure). In separate regression models including all patients and controlling for the diagnosis of CI and *a priori* for other known PTB risk factors, median steps/day (β=0.10, 95% CI 0.09, 0.12), light activity min/day (β=0.002, 95% CI 0.001, 0.002), and fairly/very active min/day (β=0.006, 95% CI 0.003, 0.009) were associated with GA at delivery (all p< 0.001).

CONCLUSION: Patients with a prior SPTB < 35 wks and CI have different physical activity patterns compared to those without CI. Physical activity amount and intensity are associated with GA at delivery.

Figure. Physical activity across gestation, measured by FitBit activity tracker. All patients had ≥1 prior SPTB <35 weeks. Data shown are findings compared based on presence of cervical insufficiency diagnosis in the current pregnancy. Fitted values are shown.



446 Exploring YouTube Sentiments on Water Births through MonkeyLearn Artificial Intelligence

Erika Fleming[1], Jamie Chen[1], Katherine Collamore[1], Antonia F. Oladipo[2]

[1]Hackensack Meridian School of Medicine, Nutley, NJ, [2]Hackensack University Medical Center, Hackensack, NJ

OBJECTIVE: YouTube is a platform for sharing accessible information about pregnancy experiences, including water births. It is imperative

healthcare professionals are aware of perceptions of water births, including those on public forums like YouTube. We employ MonkeyLearn, an Artificial Intelligence text classification tool to determine and understand sentiments expressed by pregnant individuals and their loved ones.

STUDY DESIGN: A YouTube search query on "water birth" was conducted on 3/9/2023 with a new profile and private browser. English transcripts from the top 100 "most viewed" videos were extracted and analyzed using MonkeyLearn, which categorized sentiments as positive, negative, or neutral. Video views ranged from 457,296 to 78,035,874. Chi-square goodness-of-fit and independence tests were performed to assess significance of differences between groups.

RESULTS: 63 YouTube videos were identified. 82% were uploaded from North America (NA), 5% from Australia, 1% from Africa, 5% from Asia, 6% from Europe, and 1% from South America. 36.5% (n=23) of videos had positive sentiment, 47.6% (n=30) negative, and 15.9% (n =10) neutral ($p = 0.0006$). 33% of NA videos had a positive sentiment vs 27.2% from other continents ($p = 0.1765$). 37% of NA videos had a negative sentiment vs 27.2% from other continents ($p = 0.0243$). 19.6% of NA videos had a neutral sentiment vs 45% from other continents ($p < 0.0001$).

CONCLUSION: Popular YouTube water birth videos were more likely to have a negative sentiment. North American videos were more likely to be polarizing with negative or neutral sentiments. This may reflect the negative and/or apathetic views that NA region views water birth. Future research should target education and awareness surrounding water births and subsequent impact on patient sentiments.

447 Factors associated with persistent severe hypertension in patients with preeclampsia

Kari Flicker, Maya Vishnia, Madeleine Wright, Danielle Long, Matilda Francis, Kenyone King, Lauren Gilgannon, Aref Rastegar, Rohini Siva Srinivas, Lea Nehme, Neha Gupta, Tetsuya Kawakita

Eastern Virginia Medical School, Norfolk, VA

OBJECTIVE: Hypertensive disorders of pregnancy are a leading cause of maternal morbidity and adverse pregnancy outcomes. We sought to examine factors that were associated with persistent severe hypertension.

STUDY DESIGN: This was a retrospective study of patients with preeclampsia who delivered at 23 weeks' gestation or greater from January 1, 2010, to December 31, 2020 at a single academic institution. Analyses were limited to patients with preeclampsia who developed acute severe hypertension (systolic pressure 160 mmHg or diastolic pressure 110 mmHg) and received anti-hypertensive medications during the hospital stay. Our primary outcome was persistent severe hypertension, defined as persistent severe hypertension even after the first dose of anti-hypertensive medication. Variables with p-value < 0.1 were included in multivariable logistic regression to calculate adjusted odds ratios (aORs) and 95% confidence intervals (95%CI).

RESULTS: Of 822 patients with preeclampsia, 376 (45.7%) had persistent severe hypertension after the first dose of anti-hypertensive medication and 446 (54.3%) had resolution of severe hypertension. AORs of variables with P-values less than 0.1 are presented in Table 2. Patients with chronic hypertension compared to those without had increased odds of persistent severe hypertension (aOR 1.43; 95%CI 1.07-1.92). For every 10 mmHg increase in the systolic pressure, there were increased odds of persistent severe hypertension (aOR 1.35; 95%CI 1.20-1.51). BMI 40 or greater compared with BMI< 40 was associated with increased odds of persistent severe hypertension (aOR 1.61; 95%CI 1.19-2.19). Gestational age < 34 weeks compared with gestational age 34 weeks or greater was associated with increased odds of persistent severe hypertension (aOR 1.40; 95%CI 1.04-1.88). Smoking was not associated with increased odds of persistent severe hypertension.

CONCLUSION: We found that chronic hypertension, BMI of at least 40, the degree of severe hypertension, and gestational age < 34 weeks were associated with difficult acute blood pressure control.

Table 1. Adjusted odds ratios.

Variables	Adjusted Odds Ratio (95% CI)
Chronic Hypertension	1.43 (1.07-1.92)
Systolic Pressure (Each 10 mmHg)	1.35 (1.20-1.51)
Smoking	1.64 (0.91-2.86)
BMI 40 or Greater	1.61 (1.19-2.19)
Gestational age <34 weeks	1.40 (1.04-1.88)

All variables were adjusted for each other.

448 Comparing Generalized Anxiety Disorder-7 to Edinburgh Postnatal Depression anxiety- 3 scale in antepartum anxiety screening

Yevgenia Y. Fomina[1], Kristen Warncke[1], Aldeboran N. Rodriguez[2], Anne M. Ambia[1], Tina Wolfson[1], Meitra Doty[1], Rebecca Corona[1], Mark Peters[1], Donald D. McIntire[3], David B. Nelson[1]

[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]University of Texas Southwestern, Dallas, TX, [3]University of Texas Southwestern Medical Center, Richardson, TX

OBJECTIVE: Presently, there is no singular universally recommended screening tool for peripartum anxiety disorders. Our aim was to compare the Generalized Anxiety Disorder − 7 questionnaire (GAD-7) and the Edinburgh Postnatal Depression Scale (EPDS-3) in antepartum anxiety screening among underserved patients living in an urban region. We hypothesized these standardized instruments would be equivalent.

STUDY DESIGN: This was a secondary analysis of a prospective observational study that screened for anxiety symptomatology at a prenatal care clinic in a large, inner-city healthcare system. Enrolled patients completed the GAD-7 and EPDS-3 questionnaires at the first prenatal visit. Those with a positive GAD-7 score (≥ 10) were then referred to a behavioral health counselor for further evaluation and treatment. Patients with multiple gestations, congenital anomalies, or those who established care after 34 weeks were excluded from this analysis. Study outcomes of GAD-7 and EPDS-3 scores were compared using the Pearson correlation.

RESULTS: Between Sept 2020 and December 2022, a total of 1794 patients completed the GAD-7 and the EPDS-3 surveys. Of these, 267 (15%) patients had a positive GAD-7 score (≥ 10) and 315 (17%) had a positive EPDS-3 score (≥ 5). The Pearson correlation of 4337 paired observations was 0.338 (CI 0.311, 0.364). The mean score of the GAD-7 overlaps with the confidence interval for EPDS-3 and vice versa; therefore, the two screens are equivalent in their likelihood of positivity (Figure).

CONCLUSION: This study validates the use of the EPDS-3 screen as an equivalent screening tool to GAD-7 in detecting anxiety symptomatology in pregnancy. Given the simple nature of limited screening questions, this information may facilitate deployment of universal screening among resource limited settings.

449 Early term induction of labor after the ARRIVE trial dissemination

Taylor S. Freret[1], Anjali J. Kaimal[2], Alexander Melamed[1], Mark A. Clapp[1]
[1]Massachusetts General Hospital, Boston, MA, [2]University of South Florida Morsani College of Medicine, Tampa, FL

OBJECTIVE: The ARRIVE trial showed that induction of labor at 39 weeks among low-risk nulliparous patients led to decreased cesarean delivery rates. We sought to determine if the trial's dissemination was associated with an increase in induction of labor among infants delivered at early term (37-38 completed weeks of gestation).

STUDY DESIGN: This repeated cross-sectional analysis used US natality data of 1,071,351 patients without hypertension or diabetes who gave birth to cephalic, non-SGA infants from January 2017-August 2019. A patient-level difference-in-differences (DID) analysis was performed using linear regression to determine if the ARRIVE trial was associated with changes in induction of labor among patients with early term deliveries compared to patients delivering at 36 weeks' gestation, a cohort not expected to be influenced by the ARRIVE trial. A control group was used as inductions among "low-risk" patients before 39 weeks may be for medical indications that are not tracked on natality data. As a positive control, patients delivering at 39 weeks of gestation were also compared against the 36-week cohort.

RESULTS: Induction rates were increasing in each gestational age cohort before and after the trial's publication (Figure). However, the trial did not increase inductions among infants born at 37 weeks of gestation (pre-period induction rate: 23.4%, post-period induction rate: 25.7%, adjusted DID estimate 0.2 percentage points (95% CI -0.6 to 1.0 pp, p=0.62) or 38 weeks of gestation (pre-period rate: 20.0%, post-period rate: 22.0%, adjusted DID estimate -0.2 pp (95% CI -0.9 to 0.6 pp, p=0.62) relative to the 36-week control group (pre-period rate: 22.0%, post-period rate 24.0%). As expected, the induction rate in the 39-week group did increase (pre-period rate: 26.6%, post-period rate: 31.0%, adjusted DID estimate 2.2 pp, 95% CI 1.4 to 2.9 pp, p< 0.001) compared to the control group (Table).

CONCLUSION: Appropriately, publication of the ARRIVE trial and associated guidance did not result in an increase in early term induction of labor among patients without hypertension, diabetes, or SGA infants.

450 Changes in low-dose aspirin use after updated USPSTF and ACOG guidance on race

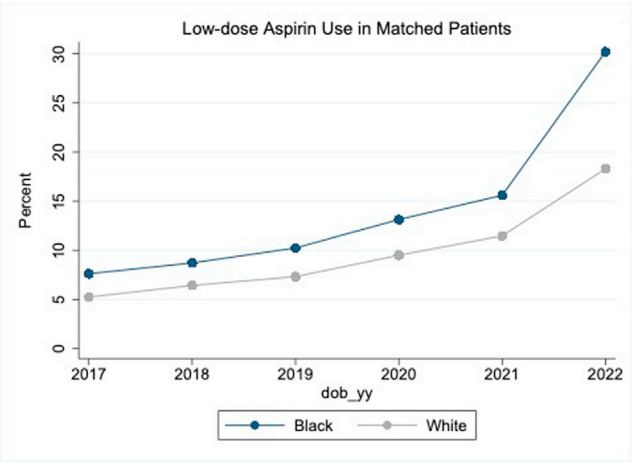
Taylor S. Freret[1], Allison Bryant Mantha[1], Kaitlyn E. James[1], Anjali J. Kaimal[2], Alexander Melamed[1], Mark A. Clapp[1]
[1]Massachusetts General Hospital, Boston, MA, [2]University of South Florida Morsani College of Medicine, Tampa, FL

OBJECTIVE: In 2021, updated USPSTF guidelines emphasized that Black race is associated with higher incidence of and morbidity from preeclampsia; ACOG also updated guidelines noting that Black race as a risk factor is a proxy for racism. It is unclear whether the change in framing of these recommendations was associated with changes in LDA use in this population.

STUDY DESIGN: Repeated cross-sectional analysis of nulliparous patients delivering at ≥24 weeks gestation from 2017-2022 in one healthcare system with an indication for LDA regardless of race (any high-risk factor or 2+ moderate-risk factors excluding Black race). USPSTF risk factors and aspirin use were obtained from the medical record. The primary outcome was LDA documented on the medication list. The primary exposure was Black race (vs white race). Exact matching was performed on risk factors, year of delivery, and site, stratified by race. A patient-level difference-in-difference (DID) analysis using linear regression was performed among matched patients. The pre-period included patients delivering before 2022; the post-period during 2022.

RESULTS: The cohort included 13,221 patients, of whom 9,822 self-identified as white or Black race. After exact matching, 2,614 patients remained (26.6%). The overall rate of LDA use was 12.2%; 27.3% among patients for whom LDA was recommended and 5.0% among those for whom it should be considered. LDA use increased over time in both cohorts (Figure). In the pre-period, LDA use was 3.1 percentage points higher among Black patients (p=0.02). The rate of LDA use among white patients increased from 8.0 to 18.3 percent; among Black patients from 11.1 to 30.2 percent. This represents a difference-in-difference of 8.8 percentage points (95% CI 7.6-16.9 pp, p=0.03). All Black patients delivering in 2022 had a USPSTF recommendation for LDA; the LDA rate in this group was 30.2%.

CONCLUSION: New wording from the USPSTF and ACOG in 2021 that emphasized the racial inequities of preeclampsia was associated with an increase in the rate of LDA use in Black patients. However, overall rates of LDA use remain well below recommended.



451 Urinary calcium to creatinine ratio for the prediction of preeclampsia: a systematic review and meta-analysis

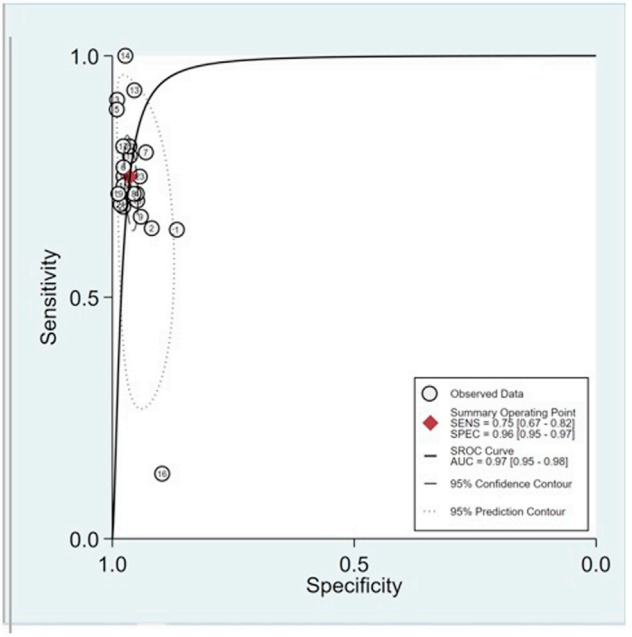
Autumn Prieto[1], Jordan A. McKinney[1], Alexander Dye[1], Patti McCall[2], Lifeng Lin[3], Luis Sanchez Ramos[1]
[1]University of Florida College of Medicine, Jacksonville, FL, [2]University of Florida, Gainesville, FL, [3]University of Arizona, Tucson, AZ

OBJECTIVE: To assess the diagnostic accuracy of the urinary calcium-to-creatinine ratio as an early predictor of preeclampsia in pregnant patients without pre-existing hypertensive disorders.

STUDY DESIGN: We conducted a systematic search of several electronic databases from inception to March 31, 2023, to identify pertinent studies assessing the diagnostic accuracy of the urinary calcium-to-creatinine ratio. These studies involved pregnant patients who were at risk for preeclampsia but were not diagnosed with the condition at the time of their participation in the study. We compiled combined measures of diagnostic accuracy, including diagnostic odds ratios, sensitivity, specificity, likelihood ratios, and hierarchical summary receiver-operating characteristic plots, to compare the performance of the calcium-to-creatinine ratio.

RESULTS: The meta-analysis included 33 studies, totaling 6,454 patients. The urinary calcium-to-creatinine ratio demonstrated a combined sensitivity of 69% (95% CI: 0.60-0.76) and a specificity of 94% (95% CI: 0.92-0.96) for the prediction of preeclampsia. The positive likelihood ratio was 12.3, and the negative likelihood ratio was 0.33, resulting in a diagnostic odds ratio of 37. Subgroup analysis of 23 studies using a common cut-off value of < 0.04 showed enhanced sensitivity (75%, 95% CI: 0.67-0.82) and specificity (96%, 95% CI: 0.95-0.97). The hierarchical summary receiver-operating characteristic curve indicated superior overall test accuracy, with an area under the curve of 0.91 (95% CI: 0.88-0.93) for all studies and 0.97 (95% CI: 0.95-0.98) for studies that employed a urinary calcium-to-creatinine cut-off value of < 0.04.

CONCLUSION: The urinary calcium-to-creatinine ratio is a useful screening tool for the early prediction of preeclampsia in pregnant patients without any underlying hypertensive disorders. It displays high sensitivity and specificity, offering the potential to improve clinical decision-making and fast-track the management of preeclampsia, leading to enhanced maternal and neonatal outcomes.



452 Evaluating updated guidelines for delivery management of severe fetal growth restriction

Taylor S. Freret[1], Anjali J. Kaimal[2], Alexander Melamed[1], Mark A. Clapp[1]
[1]Massachusetts General Hospital, Boston, MA, [2]University of South Florida Morsani College of Medicine, Tampa, FL

OBJECTIVE: In 2020, SMFM recommended 37-week delivery for severe fetal growth restriction (FGR). We sought to determine if this recommendation resulted in national practice changes.

STUDY DESIGN: This repeated cross-sectional analysis used US natality data of singletons at $\geq$37 weeks completed gestation in the US between May 2019 and Oct 2021. Exclusion criteria included hypertension, diabetes, or fetal anomalies. The FGR cohort included birthweight $<$ 3rd percentile by gestational age (a proxy for severe FGR); a control cohort included birthweight $>$10th percentile. A population-level linear regression difference-in-differences (DID) analysis was performed. The primary outcome was 37-week delivery rate. Other secondary outcomes included 37-week induction, cesarean delivery, NICU admission, respiratory support, and perinatal death. The time between online and in print publication (May-Oct 2020) was excluded. The pre-period was from May 2019-Apr 2020; the post-period from Nov 2020-Oct 2021.

RESULTS: The study included 5,975,195 patients; 2,464,143 in the pre-period and 2,308,719 in the post-period. After the guidelines were disseminated, the rate of 37-week delivery increased in the FGR group relative to the non-FGR group (DID estimate: 1.59 percentage points, 95% CI 1.06-2.13, p$<$ 0.001), an increase from 11.3% (expected delivery rate in the FGR cohort) to 12.8% (observed). Induction of labor at 37 weeks also increased (DID estimate: 1.10 pp, 95% CI 0.73-1.47, p$<$ 0.001). There was a slight increase in the need for respiratory support (DID estimate: 0.25 pp, 95% CI 0.005-0.49, p=0.046), but no change in cesarean delivery, neonatal respiratory support, or perinatal death (Table).

CONCLUSION: SMFM recommendations for severe FGR led to increased 37-week delivery, although absolute rates remained low,

suggesting many fetuses may not be diagnosed antenatally. There was a slight increase in need for respiratory support but no change in the rate of cesarean delivery or NICU admission. It is hard to assess changes in perinatal death given limited sample size and inability to know which fetuses were diagnosed antenatally.

	Control Group (BW >10%ile)		Comparison Group (BW <3%ile)			
	Pre	Post	Pre	Post	DID Estimate (95% CI)	p

453 Association of Insomnia in Pregnancy with Maternal and Neonatal Outcomes

Rachel Friedlander[1], Xiaoning Huang[1], Phyllis Zee[1], Sadiya S. Khan[2], Philip Greenland[3], Francesca Facco[4], Judith H. Chung[5], William A. Grobman[6], David M. Haas[7], Rebecca B. McNeil[8], Brian M. Mercer[9], Uma M. Reddy[10], George R. Saade[11], Robert M. Silver[12], Beth Wiener[13], Lynn M. Yee[14]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Oak Park, IL, [3]Northwestern University Feinberg School of Medicine, Evanston, IL, [4]Magee-Womens Hospital, Pittsburgh, PA, [5]UC Irvine Health, Orange, CA, [6]The Ohio State University, Columbus, OH, [7]Indiana University, Carmel, IN, [8]RTI, Durham, NC, [9]MetroHealth Medical Center, Cleveland, OH, [10]Columbia University, New York, NY, [11]Eastern Virginia Medical School, Norfolk, VA, [12]University of Utah Health, Salt Lake City, UT, [13]RTI, Chapel Hill, NC, [14]Northwestern University, Chicago, IL

OBJECTIVE: In the non-pregnant population, insomnia is the most prevalent sleep disorder and is associated with an increased risk of cardiovascular and metabolic disease. Despite the frequency of insomnia during pregnancy, little is known about its association with adverse perinatal outcomes.

STUDY DESIGN: In this secondary analysis of data from a large, diverse observational cohort of nulliparous individuals conducted at eight US medical centers, those with self-reported sleep data were included. Insomnia symptoms were evaluated via a sleep questionnaire adapted from the 'Women's Health Initiative Insomnia Rating Scale' in early (6-13 weeks') and mid pregnancy (22-29 weeks'). Having clinically significant insomnia symptoms was defined as a score of 9 or greater. The outcomes of interest included hypertensive disorders of pregnancy (HDP), gestational diabetes (GDM), preterm birth (PTB), and small-for-gestational-age birth < 10%ile (SGA). For each time point, separate multivariable logistic regression analysis was performed adjusting for maternal age, race/ethnicity as a social construct, insurance, high risk for sleep-disordered breathing, body mass index, and smoking.

RESULTS: Of 7,676 and 8,310 participants who completed sleep questionnaires in early and mid pregnancy, the prevalence of insomnia symptoms was 42.1% and 46.5% respectively. Individuals with insomnia symptoms in early pregnancy were more likely to be non-Hispanic White, publicly insured, older, a current smoker, living with obesity, and at high risk for sleep-disordered breathing. Insomnia symptoms in early pregnancy were associated with HDP (aOR 1.10, 95% CI 1.01-1.21), and insomnia symptoms in early and mid pregnancy were associated with PTB (aOR 1.17, 95% CI 1.01-1.36; aOR 1.28, 95% CI 1.10-1.49, respectively). Insomnia symptoms were not associated with GDM or SGA.

CONCLUSION: Insomnia symptoms are common in pregnancy. Even after controlling for sleep-disordered breathing, insomnia symptoms in early pregnancy are associated with an increased risk of HDP and symptoms in early and mid pregnancy are associated with an increased risk of PTB.

Table. Association of insomnia symptoms during pregnancy with adverse perinatal outcomes

	Total	No Insomnia	Insomnia[1]	p-value	aOR (95% CI)[2]
		Early pregnancy (6-13 weeks')			
	N=7,676	N=4,445	N=3,231

GDM	4.1%	3.7%	4.7%	0.05	1.04 (0.87, 1.26)
PTB	8.7%	7.9%	9.7%	0.009	**1.17 (1.01, 1.36)**
SGA	10.7%	11.0%	10.3%	0.32	0.97 (0.88, 1.07)
		Mid pregnancy (22-29 weeks')			
	N=8,310	N=4,448	N=3,862		
HDP	13.7%	12.8%	14.9%	0.006	1.11 (1.00, 1.24)
GDM	4.2%	3.6%	4.8%	0.004	1.18 (1.00, 1.40)
PTB	7.5%	6.7%	8.5%	0.003	**1.28 (1.10, 1.49)**
SGA	10.4%	10.6%	10.2%	0.59	1.05 (0.90, 1.22)

Data presented as % and adjusted odds ratio (95% confidence interval)

HDP- Hypertensive disorders of pregnancy, GDM- Gestational diabetes, PTB- preterm birth (<37w), SGA- Small for gestational age status (<10%ile), aOR- adjusted odds ratio, CI- confidence interval

1. Insomnia symptoms were defined as a score of 9 or greater (scale 0-20) on the 'Women's Health Initiative Insomnia Rating Scale.'
2. Multivariable models were adjusted for early pregnancy maternal age, race/ethnicity as a social construct, insurance, high risk for sleep-disordered breathing as measured from questions adapted from the Berlin Questionnaire for Sleep Apnea, body mass index, and current smoking within the prior 3 months.

454 Association of Restless Legs Syndrome with Adverse Perinatal Outcomes

Rachel Friedlander[1], Xiaoning Huang[1], Minjee Kim[1], Phyllis Zee[1], Sadiya S. Khan[2], Philip Greenland[3], Francesca Facco[4], Judith H. Chung[5], William A. Grobman[6], David M. Haas[7], Rebecca B. McNeil[8], Brian M. Mercer[9], Uma M. Reddy[10], George R. Saade[11], Robert M. Silver[12], Beth Wiener[13], Lynn M. Yee[14]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Oak Park, IL, [3]Northwestern University Feinberg School of Medicine, Evanston, IL, [4]Magee-Womens Hospital, Pittsburgh, PA, [5]UC Irvine Health, Orange, CA, [6]The Ohio State University, Columbus, OH, [7]Indiana University, Carmel, IN, [8]RTI, Durham, NC, [9]MetroHealth Medical Center, Cleveland, OH, [10]Columbia University, New York, NY, [11]Eastern Virginia Medical School, Norfolk, VA, [12]University of Utah Health, Salt Lake City, UT, [13]RTI, Chapel Hill, NC, [14]Northwestern University, Chicago, IL

OBJECTIVE: Restless legs syndrome (RLS) is categorized as an urge to move the legs, usually accompanied by an uncomfortable and unpleasant sensation. Pregnant individuals are two to three times more likely to experience RLS than non-pregnant individuals, but its association with perinatal outcomes is not well known. We aimed to assess the association of RLS with maternal and neonatal outcomes in a large, diverse cohort of nulliparous individuals.

STUDY DESIGN: In this secondary analysis of data from an observational cohort of nulliparous individuals conducted at eight US medical centers from 2010-2013, those with self-reported sleep data were included. RLS symptoms were evaluated in early (6-13 weeks') and

mid pregnancy (22-29 weeks') via a questionnaire adapted from the International Restless Legs Syndrome Study Group. The outcomes of interest included hypertensive disorders of pregnancy (HDP), gestational diabetes (GDM), preterm birth (PTB), and small-for-gestational-age birth < 10%ile (SGA). For each time point, multivariable logistic regression analysis was performed adjusting for maternal age, race/ethnicity as a social construct, insurance status, high risk for sleep disordered breathing, body mass index, and smoking.

RESULTS: Of 7,294 and 8,061 participants who completed sleep questionnaires in early and mid pregnancy, 15.7% and 25.9% had RLS symptoms respectively. Individuals with early pregnancy RLS were more likely to be non-Hispanic White, a current smoker, and at high risk for sleep-disordered breathing. RLS in early pregnancy was associated with HDP after adjustment for key confounders (aOR 1.17, 95% CI 1.01-1.36), but was not associated with GDM, PTB, or SGA (Table). RLS in mid pregnancy was not associated with any outcomes of interest.

CONCLUSION: In this cohort of nulliparous individuals, RLS symptoms in early pregnancy were associated with a modestly increased risk for HDP, indicating a potential area for future research regarding the prediction and prevention of HDP.

Table. Association of restless legs syndrome (RLS) during pregnancy with adverse perinatal outcomes

2. Multivariable models were adjusted for early pregnacy maternal age, race/ethnicity as a social construct, insurance, high risk for sleep-disordered breathing as measured from questions adapted from the Berlin Questionnaire for Sleep Apnea, body mass index, and current smoking within the prior 3 months.

455 Association of Insomnia in Pregnancy with Cardiovascular Health 2-7 years after first birth

Rachel Friedlander[1], Xiaoning Huang[1], Sadiya S. Khan[2], Phyllis Zee[1], Philip Greenland[3], Natalie Bello[4], Janet M. Catov[5], Bethany Gibbs[6], William A. Grobman[7], David M. Haas[8], Lisa D. Levine[9], Rebecca B. McNeil[10], Brian M. Mercer[11], Noel Bairey Merz[4], Eliza C. Miller[12], Uma M. Reddy[13], George R. Saade[14], Robert M. Silver[15], Lynn M. Yee[16]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Oak Park, IL, [3]Northwestern University Feinberg School of Medicine, Evanston, IL, [4]Cedars-Sinai Medical Center, Los Angeles, CA, [5]Magee-Womens Research Institute, Pittsburgh, PA, [6]West Virginia University, Morgantown, WV, [7]The Ohio State University, Columbus, OH, [8]Indiana University, Carmel, IN, [9]University of Pennsylvania, Philadelphia, PA, [10]RTI, Durbam, NC, [11]MetroHealth Medical Center, Cleveland, OH, [12]Columbia University Irving Medical Center, New York, NY, [13]Columbia University, New York, NY, [14]Eastern Virginia Medical School, Norfolk, VA, [15]University of Utah Health, Salt Lake City, UT, [16]Northwestern University, Chicago, IL

OBJECTIVE: In the non-pregnant population, insomnia is associated with increased risk of cardiovascular disease. This study examined the association of insomnia during pregnancy and cardiovascular health (CVH) scores 2-7 years after first birth.

STUDY DESIGN: In this secondary analysis of longitudinal data from a large, diverse cohort of nulliparas conducted at 8 US medical centers, individuals were followed 2-7 years after their first birth. Insomnia symptoms were evaluated via a sleep questionnaire adapted from the 'Women's Health Initiative Insomnia Rating Scale' in early (6-13 weeks') and mid (22-29 weeks') pregnancy. A score ≥ 9 indicated clinically significant insomnia. The primary outcome was CVH quantified by the American Heart Association's Life's Essential 8 (LE8) score, a validated surrogate of cardiovascular disease risk with lower scores associated with worse CVH. The LE8 score includes diet, physical activity, nicotine exposure, sleep, body mass index, blood pressure, blood glucose, and lipids, and ranges from 0 (worst) to 100 (best). For early and mid pregnancy, a multivariable linear regression analysis was performed adjusting for baseline maternal age, race and ethnicity as a social construct, insurance status, and being at high risk for sleep disordered breathing.

RESULTS: Of 3,453 and 4,123 individuals in early pregnancy and mid pregnancy, insomnia was reported in nearly half of participants (42.3% and 46.6%, respectively). Early and mid pregnancy insomnia symptoms were associated with lower mean LE8 score 2-7 years after first birth. These associations remained significant after covariate adjustment linear regression (Early: 82.8 [SD 11.6] vs. 79.7 [SD 12.9], $p < 0.001$; β [95% CI] -1.22 [-2.34, -0.10]); Mid: 82.2 [SD 11.9] vs. 79.9 [SD 13.0], $p < 0.001$; β [95% CI] -1.24 [-2.41, -0.07]).

CONCLUSION: Insomnia symptoms, which are common in pregnancy, were associated with worse LE8 scores 2-7 years after first birth, indicating a need for future research understanding how sleep disorders in pregnancy can affect future CVH.

Table. Association of insomnia symptoms during pregnancy with cardiovascular health 2-7 years after birth

CVH[1]	Total	No Insomnia	Insomnia[2]	p-value	β (95% CI)[3]
		Early Pregnancy (6-13 weeks')			
	N=3,453	N=1,994	N=1,459		
LE-8*	81.5 (12.3)	82.8 (11.6)	79.7 (12.9)	<0.001	**-1.22 (-2.34, -0.10)**
		Mid pregnancy (22-29 weeks')			
	N=4,123	N=2,192	N=1,931

Haas[8], Lisa D. Levine[9], Rebecca B. McNeil[10], Brian M. Mercer[11], Noel Bairey Merz[4], Eliza C. Miller[12], Uma M. Reddy[13], George R. Saade[14], Robert M. Silver[15], Lynn M. Yee[16]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Oak Park, IL, [3]Northwestern University Feinberg School of Medicine, Evanston, IL, [4]Cedars-Sinai Medical Center, Los Angeles, CA, [5]Magee-Womens Research Institute, Pittsburgh, PA, [6]West Virginia University, Morgantown, WV, [7]The Ohio State University, Columbus, OH, [8]Indiana University, Carmel, IN, [9]University of Pennsylvania, Philadelphia, PA, [10]RTI, Durbam, NC, [11]MetroHealth Medical Center, Cleveland, OH, [12]Columbia University Irving Medical Center, New York, NY, [13]Columbia University, New York, NY, [14]Eastern Virginia Medical School, Norfolk, VA, [15]University of Utah Health, Salt Lake City, UT, [16]Northwestern University, Chicago, IL

OBJECTIVE: Restless Legs Syndrome (RLS) is associated with cardiovascular disease in the non-pregnant population. Prevalence of RLS is high during pregnancy, but data are limited regarding associations with cardiovascular health (CVH) after delivery. This study assessed the association of RLS in pregnancy with CVH 2-7 years after first birth.

STUDY DESIGN: In this secondary analysis of longitudinal data from a large, diverse cohort of nulliparas conducted at 8 US medical centers, individuals were followed 2-7 years after first birth. RLS was evaluated in early (6-20 weeks') and mid pregnancy (22-29 weeks') via the International Restless Legs Syndrome Question Set. The primary outcome was CVH, quantified by the American Heart Association's Life's Essential 8 (LE8) score, a validated surrogate of cardiovascular disease risk with lower scores associated with worse CVH. The LE8 score includes diet, physical activity, nicotine exposure, sleep, body mass index, blood pressure, blood glucose, and lipids, and ranges from 0 (worst) to 100 (best). For early and mid pregnancy, a multivariable linear regression analysis was performed adjusting for baseline maternal age, race and ethnicity as a social construct, insurance status, and being at high risk for sleep disordered breathing.

RESULTS: Of 3,289 individuals with data in early pregnancy and 4,009 with data in mid pregnancy who were eligible for inclusion in this analysis, 16.2% and 28.7% reported RLS symptoms respectively. RLS in early pregnancy was associated with lower mean LE8 score 2-7 years after birth; this association remained significant after adjusting for covariates in multivariable models (82.0 [SD 11.9] without RLS vs. 79.4 [SD 13.4] with RLS, p=0.008; β [95% CI] -1.62 [95% CI -2.48, -0.77]). However, RLS in mid-pregnancy was not associated with LE8 scores 2-7 years after birth (Table).

CONCLUSION: RLS in early pregnancy was associated with worse LE8 scores 2-7 years after birth. These findings indicate a need for future research to understand how antenatal sleep disorders may relate to CVH.

Table. Association of restless legs syndrome (RLS) during pregnancy with cardiovascular health 2-7 years after birth

CVH[1]	Total	No RLS	RLS[2]	p-value	β (95% CI)[3]
		Early pregnancy (6-13 weeks')			
	N=3,289	N=2,757	N=532		
LE-8*	81.6 (12.2)	82.0 (11.9)	79.4 (13.4)	0.008	**-1.62 (-2.48, -0.77)**
		Mid pregnancy (22-29 weeks')			
	N=4,009	N=2,904	N=1,105		
LE-8*	81.2 (12.5)	81.2 (12.5)	81.1 (12.6)	0.92	-0.27 (-1.63, 1.09)

Data presented as mean and standard deviation, adjusted regression coefficient (95% confidence interval)

β – linear regression beta coefficient, C I- confidence interval, * American Heart Association Life's Essential 8 score

1. Mean and standard deviation American Heart Association Total Life's Essential 8 score for cardiovascular health, which includes diet, physical activity, nicotine exposure, sleep, body mass index, blood pressure, blood glucose, and lipids.
2. Restless legs syndrome was defined as a score of 3 out of 3 on the 'International Resltess Legs Syndrome Study Group' diagnostic criteria questionnaire.
3. Multivariable linear regression models were adjusted for maternal age, race and ethnicity as a social construct, insurance status, and high risk of sleep-disordered breathing as measured from questions adapted from the Berlin Questionnaire for Sleep Apnea.

457 Etiology of abnormal labor progress among patients with obesity: is it contraction strength?

Antonina I. Frolova[1], Candice Woolfolk[1], Nicole McCandless[1], Jeannie C. Kelly[2], Ebony B. Carter[2], Anthony O. Odibo[1], Nandini Raghuraman[1]

[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

OBJECTIVE: Over 35% of reproductive-age women in the US are obese and at risk for obstetric complications due to abnormal labor and cesarean delivery. However, there is a limited understanding of why and how obesity leads to abnormal labor. The objective of this prospective study was to compare uterine contractility characteristics, collected via universal intrauterine pressure catheters (IUPC), between patients with and without obesity.

STUDY DESIGN: This was a prospective cohort study of women with a singleton gestation admitted for labor at ≥37 weeks gestation. Upon amniotomy, all participants had an IUPC placed. The primary outcomes were four parameters of uterine contractility: frequency, peak pressure, duration, and force (Montevideo units, MVU). Secondary outcomes were intrauterine resting tone and presence of tachysystole. Outcomes were compared between patients with and without obesity (BMI ≥ 30 kg/m^2) at four time points: upon amniotomy and IUPC placement, at active labor (defined as first cervical exam ≥6 cm), at maximum oxytocin dose, and in the 1 hour prior to full cervical dilation. Sub-group analyses were performed among women with vaginal delivery and women receiving oxytocin.

RESULTS: Of the 224 participants in this study, 118 (52.7%) had obesity. Women with obesity were more likely to be induced (97.5 vs 81.1%, p< 0.01). Majority of the cohort, 88.0%, had a vaginal delivery and this did not statistically differ between patients with or without obesity. There were no differences in contraction peak pressure, frequency, duration or force between patients with and without obesity at any of the four time points evaluated. Patients with obesity had higher average resting tone (22.3 vs 19.6 mmHg,

P< 0.01). There were no differences in occurrence of tachysystole between the groups.

CONCLUSION: Women with obesity were able to achieve similar contraction characteristics associated with frequency and strength as patients without obesity. Differences in uterine contraction pressure and frequency may not explain the disparate rates of labor dystocia and cesarean rates among women with obesity.

Contraction Variable	Time point: 1 hour after active labor			Time point: 1 hour prior to complete cervical dilation (10cm)		
	Obese (n=104)	Non-obese (n=94)	p	Obese (n=103)	Non-obese (n=97)	p
Peak pressure *mean±STD*	39.7 ± 12.4	41.7 ± 10.8	0.23	39.8 ± 12.4	39.7 ± 12.4	0.93
Contraction Frequency *median (IQR) per hour*	23 (17,26)	23 (20,26)	0.87	24 (19,27)	23 (20,26)	0.97
Contraction duration *mean± STD*	84.8 ± 16.0	81.8 ± 9.0	0.10	84.8 ± 13.6	82.2 ±9.0	0.10
Median MVU *(5th, 95th percentile)*	157 (63, 253)	164 (90, 250)	0.28	163 (63, 255)	160 (63, 263)	0.98
Average resting tone *mean±STD*	22.5 ± 9.5	19.7 ± 9.0	0.04	22.7 ± 8.6	20.0 ± 9.4	0.04

458 Exploring the Association Between Provider-Patient Communication and Maternal Antenatal Anxiety

Rafaela Germano Toledo, Nadiha Noor Chelsea, Tina Yi-Jin Hsieh, Daniela A. Febres-Cordero, Elysia Larson, Laura E. Dodge
Beth Israel Deaconess Medical Center, Boston, MA

OBJECTIVE: Maternal anxiety is associated with adverse outcomes such as gestational hypertension and may be compounded by perceived higher risk of birth complications. Provider communication may impact patient's anxiety, either directly by providing information and support, or indirectly by connecting them with mental health providers. This study aims to explore whether quality provider-patient communication is associated with reduced antenatal anxiety.

STUDY DESIGN: A cross-sectional study was conducted using patient-reported data from "The Pandemic Impacts and Supports: COVID-19 Experience Study (PISCES)", a cohort of obstetric patients at a large academic center. Provider-patient communication was assessed using the Kim Alliance Scale Communication Subscale (KAS-CM). Patients were considered to have received recent mental health support if they reported seeing a mental health provider in the past month. Anxiety was assessed using the 7-item Pregnancy-Related Anxiety Scale (PRAS). Both scales were standardized. Associations were calculated using linear or negative binomial regression, as appropriate.

RESULTS: A total of 775 survey responses were collected. Respondents were on average 33 weeks gestational age (Standard Deviation (SD): 10.6), majority White (35%) and 31% had an advanced degree (Table 1). Pregnant women who had better communication with their prenatal provider exhibited lower levels of anxiety (coefficient = -0.22, p=0.001). While patients with higher anxiety were slightly more likely to have received recent mental health support (risk ratio (RR): 1.1, p=0.067), there was no association between provider communication style and receipt of therapy (p=0.984).

CONCLUSION: The association between quality provider communication and reduced antenatal anxiety emphasizes the importance of clear, non-judgmental interactions. Effective communication directly impacts anxiety, bypassing the need for improved therapy access as an intermediary. Future research should assess the association among more diverse populations.

459 Common vaginal microbes modify Group B Streptococcus growth at epithelial barriers: potential mechanisms governing colonization

Briana Ferguson[1], Dylan Curry[1], Elliot Friedman[1], Jennifer A. McCoy[2], Paul J. Planet[3], Dustin Flannery[3], Karen Puopolo[3], Lauren Anton[1], Kristin D. Gerson[4]
[1]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [3]Children's Hospital of Philadelphia, Philadelphia, PA, [4]Hospital of the University of Pennsylvania, Philadelphia, PA

OBJECTIVE: Group B Streptococcus (GBS) disease, the leading cause of early-onset neonatal sepsis, is predicated upon vaginal colonization. Given limitations of existing screening and prophylaxis strategies, primary prevention of GBS disease necessitates interventions targeting vaginal colonization. Features of vaginal ecosystems may modify GBS colonization though mechanisms are incompletely understood. We sought to investigate how common vaginal microbes modify GBS growth at epithelial barriers.

STUDY DESIGN: Ectocervical, endocervical, and vaginal (VK2) epithelial cells were treated with *Gardnerella vaginalis* (*G. vaginalis*) or *Lactobacillus crispatus* (*L. crispatus*) for 24h. Cell culture (conditioned) media was sterile filtered. Clinical isolates of GBS serotypes Ia, III, and IV were grown in varying concentrations (50%, 75%, 100%) of conditioned media. Optical density was measured across time points to create GBS growth curves. Growth at 8h was

compared across groups by one-way ANOVA with Dunnett's tests for multiple comparisons. Fold change comparing GBS growth in *G. vaginalis*-conditioned epithelial cell media to *L. crispatus*-conditioned epithelial cell media was calculated to generate heat maps.

RESULTS: GBS growth was higher in media from *G. vaginalis*-conditioned epithelia compared to *L. crispatus*-conditioned epithelia for all GBS serotypes (Fig. 1, $p < 0.05$ for all). Effects of conditioned media from ectocervical, endocervical, and vaginal epithelial cells on GBS growth were similar. GBS serotypes responded similarly to conditioned media.

CONCLUSION: Exposure of the cervicovaginal epithelium to *G. vaginalis*, an anaerobe implicated in adverse reproductive outcomes, promotes growth of clinical GBS isolates involved in invasive disease. *L. crispatus* exerts a relative protective effect. Microbial-conditioning of the cervicovaginal epithelium likely plays a mechanistic role in the complex microbial ecology governing GBS colonization — interventions aimed at optimizing host responses to components of vaginal ecosystems may offer novel approaches to GBS eradication in pregnancy.

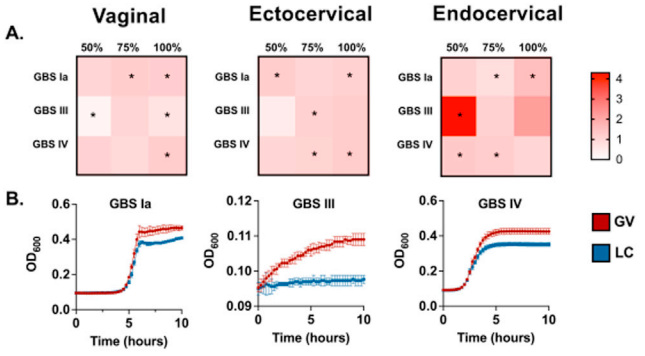

Figure 1. GBS growth in microbe-conditioned cervicovaginal epithelial cell media. **A.** Heat map depicting fold change in GBS growth in *G. vaginalis*-conditioned epithelial cell media (GV) compared to *L. crispatus*-conditioned epithelial cell media (LC) at 8h. **B.** Representative growth curves for different GBS serotypes grown in 75% microbe-conditioned cervicovaginal epithelial cell media. Graphs corresponds to the cell line listed above heat map. *p<0.05

460 Enhancing neonatal acidosis prediction: A Machine Learning approach using CTG features and clinical characteristics

Aude Girault[1], Maximino Linares[2], Xavier Tannier[3]
[1]APHP, Paris, Ile-de-France, [2]Sorbonne Université, Ile-de-France, [3]Inserm, Inserm, Ile-de-France

OBJECTIVE: Neonatal acidosis can lead to severe consequences such as hypoxic-ischemic encephalopathy, and mortality. Timely prediction during labor is essential for effective interventions and improved outcomes. We aimed to investigate the performance of machine learning techniques to predict neonatal acidemia at birth based on cardiotocography (CTG) features and maternal, pregnancy and labor characteristics.

STUDY DESIGN: A predictive modeling study was conducted on term singleton vaginal deliveries at a tertiary maternity hospital between January 2018 and July 2021. Patients with missing information or >30% signal loss were excluded. Neonates with cord pH< 7.10 were matched randomly with those with pH >7.10 to create a balanced dataset. After preprocessing of CTG tracings, features were extracted from each 10-minute interval of the 2h before delivery (baseline, short- and long-term variability, number of accelerations, decelerations, and contractions, deceleration area and reperfusion time). Maternal, pregnancy and labor characteristics were also extracted. A logistic regression model and a random forest model including all characteristics associated with neonatal acidosis with an area under the curve (AUC) >0.6 in the univariate analysis were developed. The dataset was split into training and test subsets, and a 10-fold cross-validation was performed to obtain the final AUC and accuracy of the models.

RESULTS: Among the 10561 included women, 395(3.7%) had a cord pH< 7.10 (mean pH 7.05±0.05) and were matched randomly with 395 women with a cord pH >7.10 (mean pH 7.26±0.07). Parity, oxytocin during labor and all CTG features but short time variation were associated with acidosis in univariate analysis. The logistic regression model on the test set achieved an AUC of 0.90 and an accuracy of 0.84. For the random forest model, the AUC and accuracy were 0.90 and 0.82, respectively.

CONCLUSION: The findings from this study hold the potential to facilitate timely clinical interventions, enabling healthcare providers to make informed decisions and improve perinatal outcomes.

461 Does the number of abnormal values in the oral glucose tolerance test impact pregnancy outcomes?

Hadar Gluska[1], Yael Yagur[1], Shiri Margalit[2], Karolin Sokolik[3], Ella Pardo[4], Gil Shechter Maor[1], Tal Biron-Shental[5], Michal Kovo[6], Omer Weitzner[7]
[1]Meir Medical Center, Kfar Saba, HaMerkaz, [2]Tel Aviv University, Tel Aviv, Israel, [3]Rabin Medical Center, Beilinson Hospital, Petach-Tikva, HaMerkaz, [4]Meir, Tel Aviv, HaMerkaz, [5]Meir, Tel-Aviv University, Sdeh Warburg, HaMerkaz, [6]Meir Medical Center, Macabim, HaMerkaz, [7]Meir, Kfar Saba, HaMerkaz

OBJECTIVE: The objective of this study was to assess the association between the number of abnormal values (AVs) in oral glucose tolerance test (OGTT) and adverse maternal and neonatal outcomes, among women diagnosed with gestational diabetes mellitus (GDM), considering its impact on the course of pregnancy, delivery, maternal health, and neonatal outcomes.

STUDY DESIGN: This retrospective cohort study included all pregnant women who underwent OGTT between the years 2015 and 2022, and diagnosed with GDM, at our department. The study cohort was divided into four groups based on the number of AVs in the OGTT: one AV, two AVs, three AVs and four AVs group. Maternal characteristics and pregnancy outcomes were compared between these groups.

RESULTS: A total of 1893 women diagnosed with GDM, through OGTT were included in the study. Among them 781 had one AV, 787 had two AVs, 267 had three AVs and 58 had four AVs. The rate of GDMA2 was higher among women with higher AVs in OGTT: 28.4% vs. 25.5% vs. 38.6%, vs. 65.5% among the one AV, two AVs, three AVs and four AVs groups, respectively (p< 0.001). The higher AVs groups were associated with increased maternal BMI (p=0.004), gravidity (p=0.002), and parity (p=0.001). Additionally, there was an increased rate of labor induction (p=0.002), episiotomy (p< 0.001), neonatal Apgar score < 7 (p=0.006), and NICU admission (p=0.008) in the higher AVs groups. There were no between groups differences in mode of labor, rate of macrosomia, shoulder dystocia, and composite adverse neonatal outcomes.

CONCLUSION: The study findings suggest that a higher the number of AVs in OGTT, indicates difficulty in regulating blood sugar with diet alone, which may require medical treatment and intervention. The OGTT not only aids in diagnosing GDM but also allows clinicians to be more aware about potential adverse maternal and neonatal outcomes by closely examining the number of abnormal values.

Table: ANOVA of OGTT pathological values number, comparing maternal characteristics, obstetric data and birth outcomes (maternal and neonatal).

Characteristics	Number of OGTT Pathological values				P value

462 Biophysical Profile in very premature fetuses

Luis M. Gomez[1], Laura Willingham[2], Annettee B. Hickerson[3], Jenny Q. Wang[4], Sebastian Nasrallah[4], Michael VanDillen[3], Giancarlo Mari[5]
[1]Inova Health System, FairFax, VA, [2]Regional Obstetrical Consultants Pc, Chattannoga, TN, [3]The University of Tennessee Health Science Center, Memphis, TN, [4]Inova Health System, Falls Church, VA, [5]University Hospitals Cleveland Medical Center, Case Western Reserve University, Cleveland, OH

OBJECTIVE: The applicability and interpretation of biophysical profile (BPP) in very premature fetuses have not been studied extensively. However, monitoring fetuses at < 24 wk is important because of the delivery option provided to patients at this very early gestational age. Hence, we sought to investigate if BPP score and interpretation differ according to gestational age in pregnancies between 20.0 and < 32.0 wk.

STUDY DESIGN: Prospective evaluation of BPP in uncomplicated pregnancies undergoing ultrasound for anatomic survey or fetal growth at < 32 wk was performed in 165 appropriate for gestational age fetuses that underwent 366 BPPs. Pregnancies were grouped according to gestational age: I (20.0-23.6 wk), II (24.0-27.6 wk) and III (28.0-31.6 wk). BPP was performed until a score of 8/8 was obtained. Pregnancies with obstetric/medical indication for fetal testing and/or with fetal anomalies were excluded. Duration of the study was compared to a control group (32.0-35.6 wk) undergoing indicated BPP. If patients had > 1 BPP performed during pregnancy, each BPP was analyzed individually. ANOVA and post hoc Tukey tests were used for comparisons.

RESULTS: At 30 minutes, 72% of the BPPs performed in group I and 97% in group II had a score of 8/8, whereas in group III and controls 100% of the fetuses had a BPP 8/8 within 30 minutes (P< 0.001). The mean ± SD time (minutes) for a BPP 8/8 was 23 ± 10 for group I, 17 ± 8 for group II, 13 ± 7 for group III, and 9 ± 6 for controls (P< 0.001). If extending the study to 2SD (43 minutes) in group I, 97% would have achieved a score of 8/8. None of the pregnancies in groups I-III developed adverse outcomes during the study period.

CONCLUSION: A score of BPP 8/8 can be obtained in a shorter time with advancing gestation, probably as consequence of fetal neurologic development and maturation. Our data indicate that a BPP can be performed reliably as early as 20.0 wk; however, in normal pregnancies, BPP of 8/8 is obtained within 43 minutes at a gestational age < 24 wk. This is important to consider when monitoring pregnancies and interpreting BPPs at these gestational ages.

GROUP	Total BPP readings (N)	Gestational age (weeks)	N (%) with BPP 8/8 at 30 minutes*	Mean ± SD time (minutes) to obtain a BPP 8/8*	N (%) with BPP 8/8 if study extended to 2SD mean (minutes)
I	79	20-0 to 23-6	57 (72%)	23 ± 10	77 (97%)
II	75	24-0 to 27-6	73 (97%)	17 ± 8	74 (98%)
III	72	28-0 to 31-6	72 (100%)	13 ± 7	NA
Controls	140	32-0 to 35-6	140 (100%)	9 ± 6	NA

463 Fetal fraction of cfDNA from noninvasive prenatal testing as a predictor for Placenta Accreta Spectrum

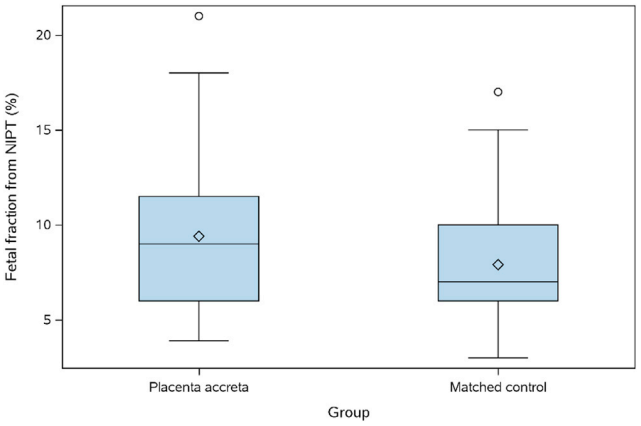
Sarah C. Graves[1], Ahmed Ahmed[2], Maeve Hopkins[3], Katherine Singh[1], Meng Yao[2], Amol Malshe[2]
[1]Cleveland Clinic Foundation, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic, Rocky River, OH

OBJECTIVE: Unanticipated placenta accreta spectrum (PAS) disorders pose significant risks to maternal health, and current sensitivity of prenatal ultrasound for PAS ranges from 50% to 80-90% depending on clinical expertise. We aim to examine the clinical significance of fetal fraction (FF) from noninvasive prenatal screening in PAS disorder.

STUDY DESIGN: We conducted a matched case-control study comparing FF from cfDNA testing in patients who had histologically confirmed PAS to normal controls. Cases were identified based on ICD codes and chart review for histologically confirmed PAS and cfDNA testing with reported FF. Controls were matched to cases 2:1 by gestational age at cfDNA testing, maternal BMI, maternal age, and self-reported race. Multiple gestations and pregnancies with chromosomal abnormalities were excluded.

RESULTS: There were 102 patients with PAS from our institution from 2013-2023. Of these, 44 patients had undergone cfDNA testing but no fetal fraction reported for 12 of them. 32 singleton pregnancies who had undergone cfDNA testing with reported FF were included in the analysis. The FF of cfDNA in PAS was significantly higher than patients with normal placentation, 9.4% vs 7.9%, p=0.038. However, in a subgroup analysis of PAS with previa (n=13) and PAS without previa (n=19), there was no significant difference in FF compared to controls. Of all patients who underwent hysterectomy at time of CD, 36% were unplanned due to uncertainty regarding PAS diagnosis from prenatal imaging.

CONCLUSION: FF was higher in patients with PAS compared to matched controls. The lack of significance in the subgroup analysis may be explained by small group numbers due to the frequency of PAS and limited reporting of fetal fraction until more recent years. More research is needed to assess the potential role for FF in cases of suspected PAS.



464 Fetal fraction from cfDNA among placenta accreta spectrum, placenta previa, and normal placentation

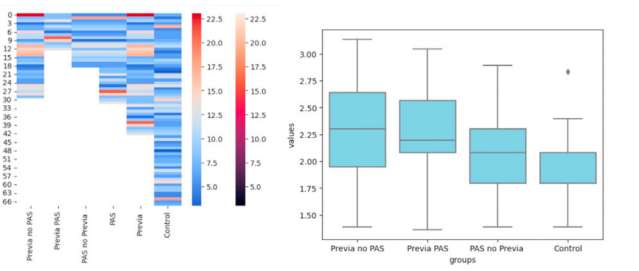
Sarah C. Graves[1], Ahmed Ahmed[2], Maeve Hopkins[3], Katherine Singh[1], Amol Malshe[2]
[1]Cleveland Clinic Foundation, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic, Rocky River, OH

OBJECTIVE: Disorders of placental morphogenesis have been associated with differences in the amount of trophoblastic DNA shed into the maternal circulation, thereby impacting the reported fetal fraction percentages from cfDNA testing. We aimed to determine the difference in FF from cfDNA in PAS, previa, and normal placentation.

STUDY DESIGN: We conducted a retrospective matched cohort study comparing FF from cfDNA testing in patients who had histologically confirmed PAS with and without PP, PP without PAS, and normal controls. Patients were identified based on diagnosis codes, ultrasound confirmation of PP, histology confirming presence of absence of PAS and cfDNA testing with reported FF. Controls were matched to cases 2:1 by gestational age at cfDNA testing and maternal BMI. Multiple gestations and pregnancies with chromosomal abnormalities were excluded.

RESULTS: There were no significant differences in mean FF from cfDNA between PAS without PP (n=19) and controls, and PAS with PP (n=13) and controls. There was a significant difference in FF between Previa without PAS and controls (10.1% vs 7.9%, p=0.014) and all cases with Previa including PAS+PP and controls (10.1% vs 7.9%, p=0.013). There was no difference in FF between PAS with PP and Previa without PAS. There was also no significant difference between PAS with PP and PAS without PP.

CONCLUSION: While all cases with placenta previa including those with PAS showed higher mean FF than controls, this is suspected to be driven by the previa component and not the presence of PAS given the significantly higher mean FF demonstrated in previa without PAS. Given the relatively recent use of routine cfDNA for prenatal genetic screening, a larger study of patients with PAS and cfDNA testing is needed to make conclusions about the clinical significance of fetal fraction in differentiating placenta previa with PAS from isolated placenta previa.



465 Fetal growth restriction: What is worse too small (EFW) or too skinny (AC)?

Olivia Grubman[1], Thomas Owens[2], Mia A. Heiligenstein[3], Kelly Wang[4], Hailey Mcinerney[1], Lily Ardente[4], Christina Cary[1], David Cole[5], Zainab Al-Ibraheemi[6], Lois Brustman[7]
[1]Mount Sinai West, New York, NY, [2]Mount Sinai West, New York, NY, [3]Stony Brook University Hospital, Amityville, NY, [4]Icahn School of Medicine at Mount Sinai, New York, NY, [5]Mt. Sinai West, New York, NY, [6]Mount Sinai West, N Caldwell, NJ, [7]St. Luke's Roosevelt Hospital Center, New York, NY

OBJECTIVE: SMFM defines fetal growth restriction(FGR) by estimated fetal weight(EFW) or abdominal circumference(AC) < 10%. There is limited data on neonatal outcomes based on FGR diagnosed by EFW vs isolated AC. The SMFM algorithm for the diagnosis and management of FGR does not address managing patients with FGR based on AC. Our objective was to assess whether FGR based on EFW had worse outcomes and perinatal morbidity than those diagnosed solely on AC.

STUDY DESIGN: This was a retrospective cohort study performed on singleton gestations from 03/2018-12/2022. All patients included, were admitted for induction of labor at term and had a pregnancy with a fetus defined as FGR at the last ultrasound prior to delivery. Group EFW was defined as FGR with overall EFW< 10%; Group AC was defined as FGR with an isolated AC< 10th% and overall EFW≥10%. The primary outcome was a neonatal composite outcome which was defined as: NICU Admission, APGAR < 5 at 5 minutes, neonatal hypoglycemia, and small for gestational age (SGA).

RESULTS: Of the 529 patients eligible, 237(45%) were in the EFW Group and 292(55%) were in the AC Group. The demographic data was similar between the groups. There was a significant difference between the two groups in respect to: gestational age at delivery, neonatal birth percentile, weight & 5 minutes APGARS. The proportion of individuals who had abnormal Dopplers, chronic hypertension, SGA at birth, and NICU admission was significantly higher in EFW vs AC Group (p< 0.0001, See Table 1). Composite neonatal outcomes were significantly worse in the EFW group compared to AC Group (p< 0.0001). The odds of having an adverse outcome among individuals diagnosed as FGR via EFW is 3.88 times higher among neonates diagnosed as FGR via AC (95% CI:2.6−5.8).

CONCLUSION: Our data suggests that neonates who were diagnosed with FGR based on EFW had worse neonatal outcomes when compared to FGR diagnosed by AC alone. These findings could be used to consult and reassure the patient that while an isolated AC< 10% gives a fetus the diagnosis of FGR, the outcomes appear to be better for these infants.

Table 1. Patient Demographics, Clinical Characteristics, and Perinatal Outcomes

Variable		ALL (n=529)	AC <10th%, EFW≥10th % (n=292)	EFW <10th % (n=237)	P value[§]
GA at time of admission for induction (weeks) – median (interquartile range)		38.4 (37.1, 39.1)	39.0 (38.1, 39.4)	37.6 (37.0, 38.6)	**<.0001**
Neonatal %ile at birth		8.0 (0.0, 59.0)	11.0 (0.0, 59.0)	5.0 (0.0, 34.0)	**<.0001**

Composite Primary Outcome

Variable	ALL (n=529)	Group AC (n=292)	Group EFW (n=237)	Odds Ratio (95% CI)	p-value
Composite Fetal/Neonatal Outcome –no. (%)	354 (66.9)	159 (54.5)	195 (82.3)	0.26 (0.17, 0.39)	<.0001

[§] The Chi-square or Fisher's exact test and the T-test or Wilcoxon Rank Sum test were used as appropriate

466 EKG/ECHO findings among Black patients with positive cardiovascular risk assessment during pregnancy and postpartum

Kerly M. Guerrero[1], Ariana Banuelos[2], Avish Arora[3], Kevin Flatley[4], Heike Thiel de Bocanegra[5], Afshan B. Hameed[6], Diana S. Wolfe[7]

[1]Montefiore Medical Center, New Rochelle, NY, [2]Montefiore Medical Center, Albert Einstein College of Medicine, New Rochelle, NY, [3]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [4]Montefiore Medical Center, New York, NY, [5]University of California, Irvine Medical Center, Orange, CA, [6]UCI, Orange, CA, [7]Albert Einstein College of Medicine, Bronx, NY

OBJECTIVE: Racial disparities exist in obstetrical care with an increased cardiovascular disease (CVD) related morbidity and mortality in non-Hispanic Black patients. Pregnancy related physiological changes in hemodynamics may cause symptoms that mimic CVD. We used a CVD risk assessment tool to identify obstetrical patients at-risk for CVD. We sought to determine if there are differences in abnormal echocardiogram (ECHO)/electrocardiogram (EKG) findings among Black and non-Black patients who screened positive.

STUDY DESIGN: This was a prospective cohort of obstetrical patients who screened positive for CVD risk during pregnancy or postpartum from 6/15/2022 to 7/1/2023 at an inner-city academic hospital. Patients who screened positive were referred for ECHO, EKG, and Cardio-Obstetric consultation. Our primary outcome was the rate of CVD diagnosis based on ECHO/EKG diagnostic criteria. Secondary outcomes included rates of symptomatology, valvular abnormality on ECHO, and abnormal EKG.

RESULTS: Of the 131 patients that screened positive for CVD risk, 71 (53.4%) self-identified as Black. Non-Black patients were more likely to report symptoms of shortness of breath (70.5% vs 48.6%, p= 0.013), orthopnea (44.3% vs 25.7%, p= 0.028), and rapid heart rate (57.4% vs 34.3%, p= 0.008) during pregnancy compared to Black patients. There were no significant differences in our primary outcome, 25 (50%) patients who completed the CVD workup were identified to have CVD in the Black group, CVD was identified in 20 (40.8%) of patients in the non-Black group. No significant differences in other diagnostic results were seen.

CONCLUSION: We found a significantly lower number of Black patients reporting symptoms that mimic CVD, yet race did not alter the rate of true CVD diagnosis in pregnancy. Increased prevalence of comorbidities in the Black race leading to CVD risk is a potential explanation, a multivariate analysis could further evaluate this finding. Cultural influences may be related to the discrepancies in symptomology among races, however more studies are warranted to further understand the drivers.

467 Effects of Economic Insecurity, a Social Determinants of Health Domain, on Adverse Maternal/Neonatal Outcomes

Kerly M. Guerrero[1], David Harary[2], Natasha Chaudhari[2], Maureen Charron[2], Mamta Fluoria[3]

[1]Montefiore Medical Center, New Rochelle, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Children's Hospital at Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY

OBJECTIVE: Adverse social determinants of health (SDoH) can impact maternal and mental health during pregnancy. Economic insecurity (EI) is one of the domains used in various frameworks of SDoH. We sought to determine the relationship between SDoH relating to EI and perinatal outcomes in a racially and ethnically diverse inner-city cohort.

STUDY DESIGN: This is a prospective cross-sectional cohort of obstetrical patients delivering at an academic institution from 05/2022 to 07/2023. Structured surveys regarding various SDoH were administered in English or Spanish. The primary study exposure was defined as exposure to any adverse SDoH relating to EI including housing, income, or food insecurity during pregnancy. Sociodemographic and obstetrical characteristics were abstracted from electronic medical records.

RESULTS: 119 patients were consented, and 85.7% (102) completed all questionnaires. Of those that completed the questionnaires, 87.2% reported EI during pregnancy. Maternal age, race/ethnicity, GA at delivery and comorbidities were similar in participants who reported EI when compared to those who did not report EI. Exposure to EI was associated with increased maternal BMI at delivery (p =0.037). Job insecurity was more common in participants with younger maternal age (p=0.024). Not surprisingly, participants who reported EI were more likely to report food insecurity (p=0.002). Infants of participants who reported EI were more likely to require NICU admission (23.2% vs 16.7%, p=0.04), information for neonatal admission was not found for seven patients. Participants who reported EI did not report more anxiety; however, those who reported anxiety were less likely to be discharged with a contraception plan (38.5% vs 43.7%, p=0.032).

CONCLUSION: A large proportion of our study participants reported EI during pregnancy. Our findings suggest the need for identifying and responding to the support needs of this patient population. Further studies are needed to evaluate the role of mental health conditions on postpartum contraception, especially given the escalating risks to reproductive justice across the US.

468 Disparities in sociodemographic factors associated with hepatitis C in pregnancy

Moti Gulersen[1], Erez Lenchner[2], Amos Grunebaum[3], Frank A. Chervenak[3], Eran Bornstein[4]
[1]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA, [2]New York University Rory Meyers College of Nursing, New York, NY, [3]Zucker School of Medicine at Hofstra of Northwell, New York, NY, [4]Lenox Hill Hospital, New York, NY

OBJECTIVE: To assess the impact of maternal sociodemographic parameters on the prevalence of hepatitis C virus (HCV) infection in pregnancy in a recent United States (US) cohort.

STUDY DESIGN: Retrospective analysis of the US Centers for Disease Control and Prevention Natality Live Birth database (2016-2021). All births were eligible for inclusion. Deliveries with missing data on HCV were excluded. We compared multiple maternal sociodemographic factors between pregnancies complicated by maternal infection with HCV and those without infection. Multivariable logistic regression was performed to evaluate the association of these factors with HCV in pregnancy. Data were presented as adjusted odds ratios (aOR) with 95% confidence intervals (95% CI) and statistical significance set at $P < 0.05$.

RESULTS: Of the 22,604,938 included, 107,761 (0.48%) were from patients who had HCV infection in pregnancy. Maternal factors associated with an increase in prevalence of HCV are presented in the Table. Concurrent infection with HBV was associated with the highest risk of HCV in pregnancy, followed by maternal factors such as older maternal age, Medicaid insurance, tobacco use, and concurrent infection with gonorrhea, chlamydia, and syphilis. Higher educational attainment, non-Hispanic black, Hispanic, and Asian race and ethnicity were associated with a decreased risk of HCV in pregnancy.

CONCLUSION: Several sociodemographic factors are associated with an increased prevalence of HCV infection in contemporary US. Specifically, concurrent infection with HBV or sexually transmitted infections, low educational attainment, non-Hispanic white race and ethnicity, Medicaid insurance, and tobacco use were associated with an increased risk of HCV in pregnancy. These data are an important step in the attempt to identify at-risk groups and better care for them.

Table. Multivariable analysis evaluating maternal factors associated with HCV in pregnancy.

	Adjusted Odds Ratio	95% Confidence Interval
Maternal age (years)		
< 20	1	Reference

469 Custody outcomes of women with opioid use disorder

Allison Gurney-McMaster[1], Emily J. Gregory[2], Christine Wilder[2]
[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]University of Cincinnati Medical Center, Cincinnati, OH

OBJECTIVE: The primary outcome was to assess the differences in custody outcomes between patients compliant with medication-assisted therapy and those with illicit substance use at delivery at an urban safety net hospital.

STUDY DESIGN: This was a retrospective cohort study at a single center of all patients admitted for delivery between 1/1/2016 to 6/1/2021. De-identified data was collected from the medical record of these patients and linked to the delivered infants. All patients admitted for delivery had urine toxicology collected with voluntary opt-out. Patients were grouped based on confirmatory opioid toxicology with sub-groups of patients on medication-assisted therapy versus illicit use. Categorical data were compared using chi-squared or Fisher's exact tests and numerical data compared using Wilcoxon rank-sum or Student's t-tests. A logistic regression analysis was conducted based on the pre-defined outcome of custody.

RESULTS: Although urine toxicology testing is voluntary, no patients were identified without results. Of the 16,827 births, 790 had positive urine toxicology screens for opioids (4.7%). A total of 202 patients had a prescription for buprenorphine and 159 for methadone. Of these, 149 were positive for buprenorphine only and 78 for methadone only, 14 were negative for all opioids. The logistic regression showed that non-Hispanic white patients had significantly

higher odds than individuals of all other races to receive full custody (OR= 3.5 [2.20-5.88]). Unemployed individuals had significantly lower odds of receiving full custody (OR=0.28 [0.16-0.50]). There was no statistical difference between the odds of receiving custody based on age, use of medication-assisted therapy, or being in the delivery hospital's perinatal addiction clinic.

CONCLUSION: This study showcases ongoing ethnic/racial disparities regarding custody outcomes and the possible negative effects of universal toxicology testing. The data suggests a lack of improved custody outcomes despite compliance with treatment. This indicates the need for further awareness and interventions to help decrease these inequities.

Logistic Regression Covariates and their Impact on Custody

Characteristic	*OR (95% CI)*	*P-value*
On Medication-Assisted Therapy	1.15 (0.80-1.66)	NS
Unemployed	0.28 (0.16-0.50)	<0.0001
Non-Hispanic White	3.52 (2.20-5.58)	<0.0001
Age	0.98 (0.95-1.01)	NS
Prenatal care at delivery hospital clinic	2.08 (1.48-2.94)	<0.001
Treated at delivery hospital perinatal addiction clinic	0.74 (0.47-1.16)	NS

A logistic regression analysis was performed regressing custody against covariates as depicted above.
OR, odds ratio; CI, confidence interval

470 Double-balloon cervical ripening in women with scarred uterus presenting with PROM: A randomized controlled trial

Gil Gutvirtz[1], Hagar Brami[2], Eyal Sheiner[3], Tamar Wainstock[4], Omri Zamstein[3], Asnat Walfisch[5], Gali Pariente[6]

[1]Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Metar, HaDarom, [2]Soroka University Medical Center, Beer-Sheva, [3]Soroka University Medical Center, Beer-Sheva, HaDarom, [4]Ben Gurion University, Beer-Sheva, HaDarom, [5]Hadassah Mount Scopus, Petach-Tikva, Israel, [6]Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel, Klahim, HaDarom

OBJECTIVE: Women with a scarred uterus who present with pre-labor rupture of membranes (PROM) pose a clinical challenge for labor induction. Using Oxytocin in this setting is associated with an increased risk for uterine rupture. Nevertheless, the insertion of a foreign body following PROM may potentially lead to intra-uterine infection. In this randomized controlled trial, we examine the safety of cervical ripening using a double-balloon catheter in women with a single previous cesarean delivery (CD) who present with PROM and an unfavorable cervix and who opt for trial of labor.

STUDY DESIGN: In this, NIH registered, prospective randomized controlled trial, women with a previous CD, who presented with PROM and an unfavorable cervix were randomly allocated following maternal consent to either cervical ripening with a double-balloon catheter or to expectant management. The double-balloon catheter was placed for 12 hours or until spontaneously expelled. After balloon expulsion or removal, an identical expectant management protocol was followed in both groups. The primary outcome was maternal or neonatal infection rates. Secondary outcomes included successful vaginal birth after cesarean (VBAC) rates and time-to-delivery interval. Multivariable analyses were used to control for confounders.

RESULTS: A total of 60 women were included in the study, 32 were allocated to the intervention group and 28 to expectant management. Rates of maternal infections and VBAC were comparable between the groups (Table). No cases of uterine rupture or neonatal infections were noted in either group. Time-to-delivery was significantly shorter in the intervention group (Table). A multivariable linear regression model, controlled for parity, proved cervical ripening with a double-balloon catheter to significantly reduce PROM-to-delivery interval (Table).

CONCLUSION: Cervical ripening with a double-balloon catheter appears to be safe in the setting of ruptured membranes. For women with a scarred uterus, PROM, and an unfavorable cervix, such intervention reduces time-to-delivery interval with no apparent increase in adverse outcomes.

Selected delivery outcomes in the double-balloon catheter group vs. expectant management: Univariable and multivariable analyses

	Double-balloon catheter (n=32)	Expectant management (n=28)	Odds ratio (95%CI)	P value
Maternal age (years, ±SD)	30.7 ± 4.8	31.8 ± 5.0		0.392
Gestational age (weeks, ±SD)	38.6 ± 1.3	38.3 ± 1.3		0.521
Maternal infection	1 (3.1%)	1 (3.6%)	0.87 (0.05 - 14.60)	0.923
VBAC	23 (71.9%)	23 (82.1%)	0.55 (0.16 - 1.92)	0.348
Time to delivery (hours, ±SD)	31.2 ± 14.3	44.3 ± 31.3		0.038
Birthweight (grams, ±SD)	3141 ± 475	3109 ± 380		0.779
Multivariable analyses: Double-balloon catheter vs. expected				
	Adjusted OR*	**B****	**95% CI**	**P value**
VBAC	0.58		0.16 to 2.03	0.301
Time to delivery		-13.3	-26.1 to -0.6	0.040

471 Association of neighborhood socioeconomic disadvantage and stillbirth

Seema Hajmurad[1], William A. Grobman[1], Robert M. Silver[2], Jiqiang Wu[3], Rebecca B. McNeil[4], David M. Haas[5], Lynn M. Yee[6], Brian M. Mercer[7], Hyagriv Simhan[8], Uma M. Reddy[9], Samuel Parry[10], George R. Saade[11], Ronald J. Wapner[12], Courtney Denning-Johnson Lynch[1], Kartik Venkatesh[3]

[1]The Ohio State University, Columbus, OH, [2]University of Utah Health, Salt Lake City, UT, [3]Ohio State University, Columbus, OH, [4]RTI, Durbam, NC, [5]Indiana University, Carmel, IN, [6]Northwestern University, Chicago, IL, [7]MetroHealth Medical Center, Cleveland, OH, [8]University of Pittsburgh, Pittsburgh, PA, [9]Columbia University, New York, NY, [10]University of Pennsylvania, Philadelphia, PA, [11]Eastern Virginia Medical School, Norfolk, VA, [12]Columbia University Irving Medical Center, New York, NY

OBJECTIVE: Individual measures of adverse social determinants of health (SDOH) are associated with an increased risk of stillbirth, but whether community-level measures are associated with this risk is uncertain. We examined whether neighborhood socioeconomic disadvantage, as measured by the Area Deprivation Index (ADI), is associated with risk of stillbirth.

STUDY DESIGN: In this secondary analysis from the prospective cohort Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-To-Be study, participant home addresses at enrollment were geocoded at the census tract level and linked to the 2015 ADI. The ADI score incorporates the domains of income, education, employment, and housing quality into a composite national US ranking of neighborhood socioeconomic disadvantage, and was analyzed in tertiles from the lowest (tertile 1 [T1], least disadvantaged, reference) to the highest (T3, most disadvantaged) score. The outcome was stillbirth,

defined as intrauterine fetal demise ≥20 weeks. Poisson regression with robust error variance was used to estimate an adjusted relative risk (aRR) and incorporated individual-level covariates including age at delivery, pre-pregnancy body mass index, chronic hypertension, and diabetes.

RESULTS: Of 9,588 enrolled pregnant individuals with available ADI data, 47 had stillbirths (38 antepartum; 9 intrapartum). The frequency of stillbirth increased with neighborhood deprivation, from 4 per 1,000 individuals in T1 (i.e., least disadvantaged) to 9 per 1,000 individuals in T3 (i.e., most disadvantaged) (p< 0.01). Pregnant individuals living in the most disadvantaged neighborhoods (T3) were more likely to experience a stillbirth compared to those living in the least disadvantaged neighborhoods (T1) (aRR: 2.15; 95% CI: 1.03 to 4.48). Those in an intermediate tertile (T2) of neighborhood disadvantage were not more likely to experience a stillbirth.

CONCLUSION: Nulliparous pregnant individuals who lived in the most disadvantaged U.S. neighborhoods were at increased risk of stillbirth.

Table. Association between Area Deprivation Index (ADI) and stillbirth

	Frequency n (%)	Unadjusted and adjusted analysis	
		Risk ratio (RR); 95% CI[1]	Adjusted risk ratio (ARR); 95% CI[1,2]
Area Deprivation Index			
Tertile 1 (least deprivation)	16/4,283 (0.4)	1.00	1.00
Tertile 2	8/2,626 (0.3)	0.82 (0.35 to 1.90)	0.72 (0.29 to 1.83)
Tertile 3 (most deprivation)	23/2,679 (0.9)	2.30 (1.22 to 4.34)	2.15 (1.03 to 4.48)

[1]Poisson regression with robust error variance was used to estimate an adjusted relative risk (aRR).
[2]Adjusted model included individual-level covariates: age, pre-pregnancy body mass index, chronic hypertension, and diabetes in pregnancy.

472 Association between adverse pregnancy outcomes and insulin resistance 2-7 years later

Katy Hallman[1], Amanda A. Allshouse[2], Robert M. Silver[2], Sadiya S. Khan[3], Hyagriv Simhan[4], Philip Greenland[5], Beth Wiener[6], George R. Saade[7], Natalie Bello[8], Eliza C. Miller[9], Bethany Gibbs[10], Victoria Pemberton[11], Lynn M. Yee[12], William A. Grobman[13], Janet M. Catov[14], Brian M. Mercer[15], Judith H. Chung[16], Uma M. Reddy[17], Abbi Lane-Cordova[18], Lauren H. Theilen[2]

[1]University of Utah, Salt Lake City, UT, [2]University of Utah Health, Salt Lake City, UT, [3]Northwestern University Feinberg School of Medicine, Oak Park, IL, [4]University of Pittsburgh, Pittsburgh, PA, [5]Northwestern University Feinberg School of Medicine, Evanston, IL, [6]RTI, Chapel Hill, NC, [7]Eastern Virginia Medical School, Norfolk, VA, [8]Cedars-Sinai Medical Center, Los Angeles, CA, [9]Columbia University Irving Medical Center, New York, NY, [10]West Virginia University, Morgantown, WV, [11]National Institutes of Health, Bethesda, MD, [12]Northwestern University, Chicago, IL, [13]The Ohio State University, Columbus, OH, [14]Magee-Womens Research Institute, Pittsburgh, PA, [15]MetroHealth Medical Center, Cleveland, OH, [16]UC Irvine Health, Orange, CA, [17]Columbia University, New York, NY, [18]University of South Carolina, Columbia, SC

OBJECTIVE: To evaluate associations between non-GDM adverse pregnancy outcomes (APOs) and insulin resistance in the years following delivery.

STUDY DESIGN: Secondary analysis of a prospective cohort of nulliparous participants enrolled during the first trimester and followed 2-7 years postpartum. We included all participants who completed a study visit at 2-7 years postpartum and excluded those with diabetes (pre-gestational or GDM) in the index pregnancy, a subsequent pregnancy during the study period, or who were not fasting at the study visit. The exposure was APO (hypertensive disorder of pregnancy, SGA, PTB, stillbirth) in the index pregnancy. The primary outcome was insulin resistance (continuous variable) measured via fasting homeostasis model assessment of insulin resistance (HOMA-IR) at follow-up. HOMA-IR is a pre-clinical measure of insulin resistance calculated from fasting insulin and glucose. Secondary categorical outcomes were highest tertile of HOMA-IR, prediabetes, and incident diabetes. Multivariable logistic regression estimated associations between APOs and outcomes of interest, adjusting for confounders.

RESULTS: Among 4,484 study participants, 3,047 were eligible for this analysis; 763 (25%) experienced APOs in index pregnancy. History of APO was associated with higher HOMA-IR at mean 2.7±0.9 years follow-up [adjusted Geometric Mean (95% CI): 1.4 (1.3, 1.5) vs 1.3 (1.3, 1.4), p = 0.01]. History of APO was also associated with HOMA-IR in the highest tertile and prediabetes (**Table**). The association between APOs and incident diabetes was not significant. Results were robust to adjustment.

CONCLUSION: In primiparas without GDM, APO history was associated with higher insulin resistance 2-7 years after first pregnancy.

Table. Associations between exposure to non-GDM adverse pregnancy outcomes and insulin resistance outcomes 2-7 years later.

Outcome 2-7 years postpartum	Adverse Pregnancy Outcome in index pregnancy[1]			Odds Ratio, 95% CI	
	yes	no	*p*	Unadjusted	Adjusted[2]
High HOMA-IR tertile	277 (36.3%)	636 (27.8%)	<0.001	1.48 (1.24, 1.76)	1.24 (1.00, 1.54)[3]
Prediabetes	148 (19.4%)	303 (13.3%)	<0.001	1.57 (1.27, 1.95)	1.32 (1.05, 1.66)
Incident diabetes	16 (2.1%)	37 (1.6%)	0.383	1.30 (0.72, 2.35)	0.96 (0.51, 1.83)

473 Deliver First or Transfer Mom? Neonatal Outcomes after Antenatal versus Postnatal Transfer ≥ 34 Weeks

Drew M. Hensel[1], Janet Chandarlis[2], Josh Hernandez[2], Megan L. Lawlor[1], Nandini Raghuraman[1], Ebony B. Carter[3], Anthony O. Odibo[1], Barbara Warner[2], Jeannie C. Kelly[3]

[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO

OBJECTIVE: Compared to neonatal transfers, maternal transfers to a Level IV Perinatal Care Center (PCC) have been associated with lower neonatal morbidity. Little is known regarding transfer outcomes for neonates born in the late preterm and term periods. We sought to compare neonatal outcomes between maternal and neonatal transfers to a Level IV PCC that delivered at ≥ 34 weeks.

STUDY DESIGN: This is a retrospective cohort study of maternal and neonatal transfers to a Level IV PCC from January – December 2021 who delivered at ≥ 34 weeks' gestation. Maternal transfers delivered during the admission and neonatal transfers within 24 hours of delivery were included. Neonates were excluded if resuscitation was declined. The primary outcome was composite neonatal morbidity which included: respiratory distress syndrome (RDS), mechanical ventilation, sepsis, grade 3-4 intraventricular hemorrhage (IVH), chronic lung disease, necrotizing enterocolitis, patent ductus arteriosus, and stage 3-4 retinopathy of prematurity. Secondary outcomes included mode of delivery, APGARs < 7 at 5 minutes, length of neonatal stay, and each component of the composite score. Chi square, fisher exact, Mann Whitney U tests, and multivariate logistic regression were used as appropriate.

RESULTS: 182 neonatal and 97 maternal transfers were included. Maternal transfers delivered at earlier gestational ages, were less likely to have congenital anomalies, and were more likely to receive antenatal steroids or be diagnosed with hypertensive disorders of pregnancy. Maternal transfers were significantly associated with

lower odds of composite neonatal morbidity (aOR 0.71 [0.61-0.82]), specifically RDS (aOR 0.69 [0.60-0.79]) and mechanical ventilation (aOR 0.84 [0.75-0.95]). Length of neonatal stay did not differ.

CONCLUSION: Compared to neonatal transports, maternal transports to a Level IV PCC have significantly lower odds of neonatal morbidity for deliveries $\geq$ 34 weeks. Our results underscore the importance of and continued need for robust maternal transport programs, even in the late preterm and term periods.

474 Association of diabetic ketoacidosis with adverse maternal outcomes for pregnant patients with pre-existing diabetes

Alyssa R. Hersh, Kimberly Ryan, Rachel Madding, Bharti Garg, Amy M. Valent, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

OBJECTIVE: Patients with pre-existing diabetes have high-risk pregnancies; however, the impact of diabetic ketoacidosis (DKA) during pregnancy on maternal outcomes is not well elucidated. We sought to assess maternal outcomes among patients with type 1 diabetes (T1D) or type 2 diabetes (T2D) who had DKA during pregnancy compared to those who did not.

STUDY DESIGN: We conducted a retrospective cohort study of singleton, non-anomalous live births in California between 2008-2019. We included patients with T1D and T2D who delivered between 23-42 weeks' gestation and compared maternal outcomes among pregnancies complicated by DKA during pregnancy to those who did not have DKA. Chi squared and multivariable logistic regression were used for statistical comparisons with a p-value of 0.05.

RESULTS: Of the 5,305,447 births in California assessed, there were 7,401 and 38,062 patients with T1D and T2D that met our inclusion criteria, of which 786 (10.6% T1D) and 703 (1.9% T2D) had DKA during pregnancy, respectively. Among patients with T1D, DKA during pregnancy was associated with hypertensive disorders of pregnancy (HDP) (adjusted odds ratio (aOR) 1.21; 95% confidence interval (CI) 1.01-1.45), ICU admission (aOR 4.03; 95% CI 1.94-8.36), severe maternal morbidity (SMM) (aOR 2.01; 95% CI 1.44-2.79), and non-transfusion SMM (aOR 3.04; 95% CI 1.99-4.66). Among patients with T2D, having DKA during pregnancy was associated with HDP (aOR 1.32; 95% CI 1.10-1.58), ICU admission (aOR 4.07; 95% CI 2.02-8.21), SMM (aOR 1.67; 95% CI 1.16-2.40), non-transfusion SMM (aOR 2.45; 95% CI 1.56-3.86), and cesarean delivery (CD) among nulliparous (aOR 1.61; 95% CI 1.21-2.13) and multiparous patients without a history of CD (aOR 1.80; 95% CI 1.31-2.46).

CONCLUSION: In this relatively large cohort of patients with DKA, we found that DKA during pregnancy was associated with significantly worse maternal outcomes.

Table 1. Maternal and neonatal outcomes among patients with type 1 diabetes and type 2 diabetes by DKA status during pregnancy

	DKA in pregnancy	No DKA in pregnancy	aOR (95% CI)
Type 1 diabetes			
Hypertensive disorder of pregnancy	30.4%	24.9%	1.21 (1.01-1.45)
Postpartum hemorrhage	5.0%	4.6%	1.23 (0.85-1.77)

*** SMM excluding blood transfusion

475 Delivery hospitalization costs associated with diabetic ketoacidosis among pregnant patients with pre-existing diabetes

Alyssa R. Hersh, Kimberly Ryan, Rachel Madding, Bharti Garg, Amy M. Valent, Aaron B. Caughey
Oregon Health & Science University, Portland, OR

OBJECTIVE: Prior data have demonstrated that patients with diabetes in pregnancy accrue higher health care costs, particularly those with antepartum admissions for diabetes-related complications, such as diabetic ketoacidosis (DKA). We sought to assess hospitalization costs for delivery among patients with pre-existing diabetes who had DKA during pregnancy compared to those who did not.

STUDY DESIGN: We conducted a retrospective cohort study of singleton, non-anomalous live births in California between 2008-2019. We included patients with type 1 and type 2 diabetes who delivered between 23-42 weeks' gestation and stratified by DKA status. We assessed median and mean hospitalization costs for delivery for the patient and infant separately, and also assessed length of stay. Kruskal-Wallis equality of populations rank test was used for statistical comparisons with a p-value of 0.05. We also performed generalized linear models to assess the adjusted mean difference between costs.

RESULTS: There were 481,749 pregnant persons with diabetes included in this analysis, of which 1,503 (0.3%) had DKA during pregnancy. Delivery hospitalization costs were significantly higher among pregnant persons who had DKA during pregnancy ($27,764 versus $22,070, $P< 0.001$) and their hospital stays were longer (4 versus 3 days, $P< 0.001$). This was also true for infants of patients with DKA during pregnancy, who had significantly higher delivery hospitalization costs ($6,435 versus $4,571, $P< 0.001$) and longer hospital length of stay (3 versus 2 days, $P< 0.001$).

CONCLUSION: In this study, we found that delivery hospitalization costs and length of stay were increased among pregnant persons with pre-existing diabetes who had DKA during pregnancy. These results allow greater understanding of health care costs associated with DKA during pregnancy and suggest that there is increased resource utilization during the hospitalization for delivery for patients with DKA in pregnancy.

Table 1. Delivery hospitalization costs and length of stay among patients with pre-existing diabetes stratified by DKA status in pregnancy.

	DKA in pregnancy	No DKA in pregnancy	*P*
Maternal costs

476 Expression and distribution of Src kinase LYN in placenta of patients with preeclampsia (PE)

Taryn Heyman[1], William E. Ackerman IV[2], Guomao Zhao[1], Bani Medegan Fagla[1], Catalin S. Buhimschi[1], Irina A. Buhimschi[1]

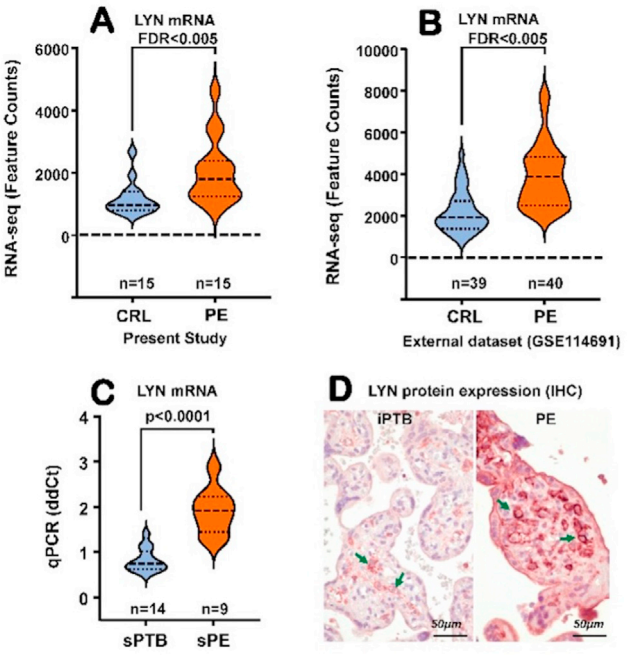
[1]University of Illinois at Chicago, Chicago, IL, [2]University of Illinois at Chicago College of Medicine, Chicago, IL

OBJECTIVE: The Src family of tyrosine kinases (SFK) plays key roles in cell migration, growth, and division. Among the 8 SFK members, some are ubiquitous (SRC, YES, FYN), while others are considered tissue specific (BLK, FGR, HCK, LCK, LYN). Cancer biology and immunology have been the primary focus of SFK research thus far. As SFK-regulated processes are also important for pregnancy, we set out to determine the relative expression of SFK members in placenta to explore their potential role in PE.

STUDY DESIGN: RNAseq was performed on placental villous samples in two groups: PE (n=15, GA 30±1w) and normotensive controls (n=15, GA 33±1w). An external RNAseq dataset (GSE114691) (n=79), and RNA from villous placenta tissues from preterm PE with severe features (n=9, GA 29±1w) or spontaneous preterm birth (sPTB, n=14, GA 29±1w) were used for database and qPCR validation, respectively. Placental immunohistochemistry (IHC) was performed using an anti-LYN monoclonal antibody. Protein-Protein Interaction networks (PPI) curated using STRING and PINOT databases provided insight into processes correlated with placental LYN expression. Non-parametric statistics and linear regression were used.

RESULTS: LYN was the only SFK elevated in PE placenta compared to controls, both in our RNAseq data (1.8-fold, FDR< 0.005, **Fig. A**) and the external dataset (FDR< 0.005, **Fig. B**). LYN mRNA correlated positively with maternal systolic blood pressure (r=0.63, p< 0.001). LYN upregulation in PE placenta was confirmed by qPCR (p< 0.0001, **Fig. C**) independent of GA, birthweight, fetal sex or delivery mode. Placental LYN expression was more conspicuous in PE, localizing primarily to syncytiotrophoblast outer basal membrane and Hofbauer cells (**Fig. D**, arrows). PPI data mining identified the hypoxia-regulated endoplasmic reticulum oxido-reductase ERO-1A as the top LYN correlated transcript (r=0.85, p< 10^{-7}).

CONCLUSION: We demonstrate for the first time that LYN mRNA and protein expression are upregulated in PE. Correlation to LYN mRNA and maternal blood pressure further support a role for this Src kinase in the pathophysiology in PE.



477 Comorbidity Burden and Social Vulnerability Among Non-Pregnant Reproductive-Age Patients: Opportunities for Preconception Counseling

Carly I. Hirschberg[1], Alejandro D. Alvarez[2], Vincent Chua[3], Fernando Suarez[3], Jonathan Hy[3], Sarah Pachtman Shetty[3], Matthew J. Blitz[2]

[1]Zucker School of Medicine at Hofstra of Northwell, New York, NY, [2]Zucker School of Medicine at Hofstra of Northwell, Bay Shore, NY, [3]Zucker School of Medicine at Hofstra of Northwell, Manhasset, NY

OBJECTIVE: To determine the proportion of non-pregnant reproductive age patients with high comorbidity burden and less effective contraception that may benefit from preconception counseling.

STUDY DESIGN: Retrospective cohort of patients 15-49 years of age presenting for annual gynecological examinations throughout a large health system in New York between January 2019 and December 2022. Clinical and sociodemographic data was obtained from the electronic medical record. Patients were classified into 3 groups based on risk to conceive: 1) no risk—menopause or prior hysterectomy, 2) low risk—intrauterine device, implant, female sterilization, 3) high risk—pill, patch, ring, shot, or no contraception documented. Obstetrical comorbidity index (OB-CMI) score was calculated (pregnancy-specific components excluded) based on ICD-10 codes and clinical documentation. High comorbidity burden was defined as OBCMI >=4. Social vulnerability index (SVI) score was determined based on the census tract of each patient's home address, and patients were grouped by SVI quartile.

RESULTS: Of the 30,722 patients, most (79%; n=24,228) had less effective or no contraception documented. The rates of highly reliable contraception did not vary when stratified by SVI quartile or OBCMI score. Non-Hispanic Black patients were more likely to have highly reliable contraception compared to non-Hispanic White patients (20.4% vs. 17.2%; OR 1.23, 95% CI 1.12-1.36). High comorbidity burden was seen in 15% of patients with less effective contraception (n=3,443/24,228). Among patients with less effective

contraception, non-Hispanic Black patients were more likely to have a high comorbidity burden compared to non-Hispanic White patients (20.9% vs. 14.3%; OR 1.58, 95% CI 1.42-1.75).

CONCLUSION: Racial and ethnic differences in contraceptive method and comorbidity burden were seen in this cohort of reproductive age patients. By identifying non-pregnant patients with high comorbidity burden and less effective contraception, we have an opportunity to direct targeted interventions such as referral for high-risk preconception counseling or family planning.

Table 1: Baseline demographics by risk to conceive.

Characteristic	High Risk	Low Risk	No Risk
Maternal age	31.5 ± 8.9	31.2 ± 8.9	44.9 ± 4.0
BMI	27.8 ± 6.8	28.4 ± 6.7	28.0 ± 5.9

478 Bictegravir Use During Pregnancy: A Multi-Center Retrospective Analysis Evaluating HIV Viral Suppression and Perinatal Outcomes

Lauren Holt[1], William Short[2], Florence Momplaisir[2], Eleanor Hyun[2], Jennifer R. McKinney[3], Andrea Lugo Morales[3], Alejandra Duque[3], brian druyan[4], Chima Ndubizu[5], Lunthita Duthely[4], Naima T. Joseph[6], Anandi Sheth[7], Martina Badell[8]

[1]Emory University School of Medicine, Department of Gynecology and Obstetrics, Atlanta, GA, [2]University of Pennsylvania School of Medicine, Philadelphia, PA, [3]Baylor College of Medicine, Houston, TX, [4]University of Miami School of Medicine, Miami, FL, [5]University of Miami, Jackson Memorial Hospital, Miami, FL, [6]Boston Medical Center, Watertown, MA, [7]Emory University School of Medicine, Department of Internal Medicine, Division of Infectious Diseases, Atlanta, GA, [8]Emory University School of Medicine, Atlanta, GA

OBJECTIVE: Integrase strand-transfer inhibitors (INSTI) are recommended as part of antiretroviral therapy for most people with HIV. Bictegravir (BIC) is a first line INSTI in non pregnant adults living with HIV, however there is a paucity of data on its use in pregnancy. The objective of this study was to describe maternal viral suppression and perinatal outcomes among people with HIV who used BIC during pregnancy.

STUDY DESIGN: We performed a multi center retrospective cohort study of pregnant people with HIV who used a BIC containing antiretroviral regimen between January 2019- June 2023 at 4 different centers in the United States. Demographics, HIV, perinatal, and infant outcomes were abstracted from the medical record and summarized by timing of BIC use in pregnancy. Viral suppression was defined as HIV-1 RNA (viral load) < 50 copies/mL.

RESULTS: 147 pregnancies with BIC use were included in the analysis (Site 1 [n=41], Site 2 [n=18], Site 3 [n=75], Site 4 [n=13]). The median age was 29 (range 16-43) years, and the median gestational age of delivery was 39 (range 26-41) weeks. Of these pregnancies, 83 (56.4%) received BIC preconception and continued in pregnancy, 59 (40.1%), started BIC during pregnancy and 5 (3.4%) received BIC preconception and discontinued during pregnancy. Viral suppression closest to delivery was highest in those receiving BIC preconception and continued in pregnancy (96.2%), and no cesarean deliveries for elevated HIV viral load occurred in this group. For those who started BIC prior to conception and continued on it through pregnancy, a birth defect was noted in 2.4%. One perinatal HIV transmission occurred after a third trimester HIV diagnosis with BIC started at 31 weeks' gestation.

CONCLUSION: In this analysis, the use of BIC in pregnancy was associated with high levels of viral suppression and similar perinatal outcomes to published literature in this patient population. These findings highlight the potential efficacy and safety of BIC in pregnancy and support its consideration in the management of HIV during pregnancy.

Table 1: Perinatal outcomes and HIV viral suppression with use of bictegravir (BIC) in pregnancy

	BIC use preconception and continued in pregnancy (n=83)	BIC started in pregnancy (n=59)	BIC use preconception then stopped in pregnancy (n=5)	Any BIC use in pregnancy (n=147)

479 Differences in time of birth between spontaneous and operative vaginal births: a nationwide population-based analysis

Christopher X. Hong[1], Mariana Masteling[1], Clarice Zhou[2], Jourdan E. Triebwasser[3], Matthew Janssen[2]

[1]University of Michigan, Ann Arbor, MI, [2]Pennsylvania Hospital, Philadelphia, PA, [3]University of Michigan, Ann Arbor, MI

OBJECTIVE: Previous studies have identified a correlation between obstetric interventions and the time of day. However, they do not account for the granular variation in temporality of such interventions, which may be influenced by healthcare provider and resource availability. Our objective was to assess differences in time of birth among spontaneous versus operative (forceps- and vacuum-assisted) vaginal births using a population-based dataset.

STUDY DESIGN: We performed a retrospective population-based study using birth certificate data from the National Vital Statistics System from 2016 to 2021, which includes the time of birth and method of delivery for all recorded births in the United States. The number of spontaneous and operative vaginal births at each minute was determined over a 24-hour time frame. To facilitate balanced comparisons between groups, birth numbers were normalized relative to

the total births within each group. Trend lines were established based on 60-minute moving averages and the distributions were compared using the Kolmogorov-Smirnov test.

RESULTS: A total of 15,413,957 vaginal births were analyzed, among which 690,912 (4.5%) were operative births. The normalized proportion of spontaneous and operative births over a 24-hour period is presented in Figure 1. There was a statistically significant difference in the time of birth between spontaneous and operative births ($p<$ 0.01). Compared to births at other time intervals, those between 4:30-7:30 p.m. were more likely to be operative births (OR 1.11, 95% CI 1.11-1.12). Conversely, births between 3:00-6:00 a.m. were less likely to be operative births (OR 0.89, 95% CI 0.88-0.89).

CONCLUSION: In this population-based study, we identified temporal differences between spontaneous and operative vaginal births with increased use of instrumentation during late afternoon and reduced use in the early morning. These results prompt further investigation into the indications for operative vaginal birth and the root causes of these temporal variations, which are likely multifactorial and involve provider and resource availability.

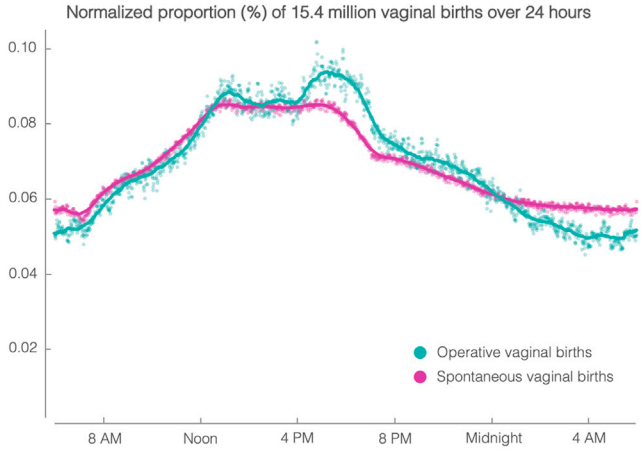

Figure 1. Normalized proportion of spontaneous and operative vaginal births over a 24 hours. Each dot represents the normalized proportion of births that occurred within 5-minute intervals. Trendlines are generated using 60-minute moving averages.

480 Cost-effectiveness of 2022 American Academy of Allergy, Asthma & Immunology Practice Parameter for cesarean prophylaxis

Maeve Hopkins[1], Margaret Kuder[2], Belinda Udeh[3]
[1]Cleveland Clinic, Rocky River, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic Foundation, Cleveland, OH

OBJECTIVE: The updated 2022 American Academy of Allergy, Asthma and Immunology (AAAAI) Practice Parameter suggests de-emphasis of skin allergy testing compared to drug challenge for majority of patients with penicillin allergy. We sought to evaluate cost-effectiveness of incorporating 2022 AAAAI practice parameter for cefazolin (Ancef) cesarean prophylaxis (AP) versus referral for penicillin allergy testing (PAT).

STUDY DESIGN: A decision analytic model was constructed to compare the costs and outcomes of 2 strategies for cesarean prophylaxis with penicillin allergy:

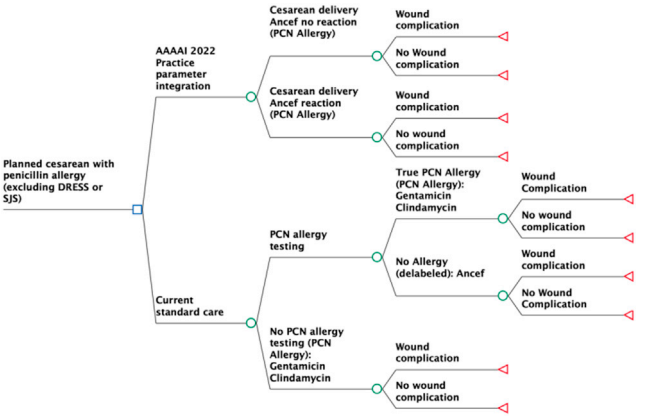
AAAAI 2022 guidelines for AP (excluding history of severe cutaneous reaction).

Current practice of referral for PAT prior to surgery.

Data was sourced from published literature, drug pricing databases, and expert opinion. Costs included allergy testing, antibiotics, and complications. Effects included testing compliance, Ancef reactions and de-labeling penicillin allergy. Comparing the costs and effects of each strategy determined the incremental cost-effectiveness ratio of cost per wound infection averted. Sensitivity analysis tested the robustness of the results to variability in the data and model structure.

RESULTS: In the base-case, incorporation of the AAAAI practice parameter was the choice strategy, with the mean cost of $283 compared to $588. Referral for penicillin allergy testing costs $43,916 per case of wound infection avoided. However, when incorporating the estimated lifelong cost of penicillin allergy into the decision model, referral for penicillin allergy testing becomes the dominant, cost saving strategy, with mean cost of $1,367 compared to $4,755. When considering the lifelong cost of penicillin allergy, incorporation of AAAAI practice parameter costs $487,934 per wound infection avoided.

CONCLUSION: Incorporation of AAAAI practice parameter for cesarean prophylaxis is cost saving compared to referral for penicillin allergy testing. However, when considering the lifelong cost of penicillin allergy and potential to de-label penicillin allergies during pregnancy, referral for allergy testing becomes the cost-saving strategy.



481 Engaging community doulas with a remote postpartum hypertension program for Black persons: A qualitative study

Elizabeth Albert[1], Megan Knutson Sinaise[1], Tia Murray[2], Nicole Thomas[1], Kathleen Wannemuehler[1], Susan Passmore[1], Kara K. Hoppe[1]
[1]University of Wisconsin Madison, Madison, WI, [2]University of Wisconsin School of Medicine and Public Health, Madison, WI

OBJECTIVE: Perform a qualitative assessment of the postpartum (PP) person's experiences with addition of a community-based doula in an existing remote patient monitoring (RPM) program for PP hypertension (HTN).

STUDY DESIGN: Qualitative study to explore Black PP person's experience with addition of a community-based doula in an existing PP RPM program for patients with Hypertensive Disorders of Pregnancy (HDP) to improve program participation with BP submission as well as an improvement in overall postpartum care. We prespecified the plan to conduct up to 20 semi-structured interviews to achieve thematic saturation in understanding participant experiences and any barriers or facilitators regarding the intervention. The interviews were coded and thematically analyzed using a modified grounded theory approach using NVivo 12.

RESULTS: Interviews were conducted with 19/49 individuals who participated in the study. Then mean (SD) maternal age was 27.3 (6.04), 74.5% were single, 96.1% had a prior pregnancy, and 33.3% delivered pre-term. Five themes emerged; three regarding facilitators/benefits 1) communicative, responsive and supportive care, 2) ability for participants to better care for their health and wellbeing, and 3) emotional support provided by doulas. The two themes regarding barriers were 4) challenges with technology and 5) difficulty remembering to submit vitals. Participants shared overwhelming positive support for the program. Any challenges or criticisms of the program were with technological difficulties.

CONCLUSION: Overall participants reported positive experiences with the addition of community-based doulas in our RPM program for patients with HDP. Specifically, they felt their physical and emotional health were better supported. Barriers were rare and limited to technology difficulties. This study highlights the ability to improve participation with clinical care measures by utilizing alternative strategies such as involving community stakeholders to assist in supporting non-clinical needs.

Table 1: Thematic analysis themes and examples

Theme	Patient example
1) Supportive communication	"It wasn't like somebody was just watching over me. It was just actually just, it felt like support, genuine support. Like we care, and we just want to make sure that you are taken care of in the best way possible and that you know what is going on and what's available for you to help you." "And then, yeah, it [their blood pressure] did, went up just once. And I was contacted by one of the nurses. And she prescribed me another blood pressure medication. But overall, like my blood pressure just got back to normal, then they got me off of it. It's just the back-and-forth communication. So that's what made the experience go really well for me."
2) Ability for participants to better care for their health and well being	"I was able to just manage it and be at home and be comfortable. Like I don't know how it really works because, like I said, this is my first being diagnosed with preeclampsia. So I didn't have to go to the clinic out there for myself. Or, you know, I didn't have to stay in the hospital longer. I was able to come home and manage my health situation." "So I felt like this program honestly saved my life because I really wouldn't have been getting my blood pressures checked or anything after having the baby until my six-week checkup. So the six weeks I was at home, you know, going through the postpartum healing from the C-section, I felt like this program really was very good for my health and my wellbeing because I wouldn't have been knowing which medicines to switch or add on or take off."
3) Emotional support by doulas	"I needed, she helped me get to my doctor's appointments for the baby. She, I needed breast pads and bras and stuff, nursing bras that would help me better to nurse. She connected me to my social worker, to the hospital, to get me bras and stuff. So she's been a huge help in just reassuring that I'm doing it right." "Well, really, she was a great listener. I'll say that. We went to the mall and stuff, you know. She helped out with the children. Or if I told her I needed something, of course she would have brought it. I didn't really need too much besides a little bit of support and a listening ear. And, you know, she was there." "Yeah, so like breastfeeding for one. I was struggling with breastfeeding. And then I was also re-hospitalized. And she was able to come and stay with me and the baby, so the baby didn't have to be separated from me. And then she also helped me with the baby weight gain, so like finding something to help with the baby gaining weight because she wasn't gaining weight at a point."
4 & 5) Challenges	"At first it was a little hard to remember to take it every day. That's the only struggle that I had, was, yeah, just like trying to basically maintain a newborn and just basically maintain taking a blood pressure on a daily basis, not forgetting, stuff like that." Several participants noted the ease of working with technology but a few saw it as a challenge, "Only the tablet had a malfunction, and I had to just manually give them to, give them my blood pressure on the phone."

482 Associations between antepartum anemia and uterine fibroids in pregnancy by race and ethnicity

Irogue Igbinosa[1], Jonathan A. Mayo[1], Stephanie A. Leonard[1], Ijeoma Iwekaogwu[1], Suzan L. Carmichael[1], Deirdre J. Lyell[2]
[1]Stanford University, Palo Alto, CA, [2]Stanford University Medical Center, Palo Alto, CA; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: Uterine fibroids cause anemia and create a significant burden of disease among Black women. Yet the degree to which fibroids contribute to racial disparities in antepartum anemia, a cause of severe maternal morbidity, is unclear. Our objectives were 1) to estimate the associations of uterine fibroids with antepartum anemia and 2) to evaluate associations across seven racial/ethnic groups.

STUDY DESIGN: We conducted a retrospective cohort study of pregnant people in California from 2007 to 2018 who delivered at 20-42 weeks. Data were abstracted from a statewide database of vital records linked to delivery hospitalization discharge data. The primary exposure, uterine fibroids, and outcome, antepartum anemia, were identified using ICD codes. We used multivariable logistic regression modeling, stratified by self-reported race and ethnicity, to estimate odds ratios of antepartum anemia and to adjust for maternal characteristics (age, insurance, BMI, parity, timing of prenatal care) and clinical factors (vaginal bleeding and placental abruption).

RESULTS: Among 5,196,914 deliveries, the frequency of fibroids was 1.6%. Patients with fibroids were more likely to be older than 30 years (85.1% vs 46.3%), pregnant by assisted reproductive technology (0.8% vs. 0.1%), and have a cesarean birth (69.9% vs 31.9%). Black pregnant patients, with and without fibroids, had the highest frequency of anemia; of Black pregnant patients, with fibroids, 26% had anemia, and 16.1% of those without fibroids had anemia, respectively (Table 1). In the total study population, fibroids were associated with increased odds of antepartum anemia (aOR 1.78, 95% confidence interval 1.74-1.82). Fibroids increased the odds of antepartum anemia by at least 70% in every racial/ethnic group except American Indian/Alaska native.

CONCLUSION: Independent of confounders, fibroids were significantly associated with 78% increased odds of antepartum anemia across nearly all racial/ethnic groups. Screening for anemia in patients with uterine fibroids may identify individuals at risk for severe maternal morbidity.

Table 1. Associations between uterine fibroids and antepartum anemia by race and ethnicity

	Anemia without fibroids n (%)	Anemia with fibroids n (%)	Crude odds ratio (95% confidence interval)	Adjusted odds ratio (95% confidence interval)*
Total Population	406,609 (8.0)	11,476 (14.2)	1.92 (1.88-1.96)	1.78 (1.74-1.82)
Stratified by racial/ethnic group†				
American Indian/ Alaska Native	1,862 (8.3)	18 (11.1)	1.39 (0.85-2.27)	1.36 (0.82-2.24)
Asian	55,011 (7.7)	2,343 (12.5)	1.72 (1.65-1.80)	1.70 (1.63-1.78)
Non-Hispanic Black	44,537 (16.0)	2,869 (26.1)	1.86 (1.78-1.94)	1.76 (1.69-1.85)
Hispanic	210,598 (8.1)	3,946 (13.8)	1.83 (1.77-1.89)	1.82 (1.75-1.88)
Pacific Islander	2,562 (10.0)	44 (16.9)	1.83 (1.32 -2.54)	1.91 (1.37-2.67)
Non-Hispanic White	91,623 (6.3)	2,230 (10.2)	1.69 (1.62-1.77)	1.71 (1.63 -1.78)
Another race specified#	416 (10.6)	26 (20.6)	2.18 (1.40-3.40)	2.31 (1.45-3.66)

*Covariates: age, insurance, education, prenatal care timing, pre-pregnancy BMI, parity, race and ethnicity, placental abruption, and vaginal bleeding during pregnancy.
†Covariates: all covariates listed above except for race and ethnicity.
#Another race as specified by the individual

483 Black and Hispanic patient-centered voices of antepartum anemia: a community engaged approach

Irogue Igbinosa[1], Susan Perez[2], Kata Nemeth[3], Shantay Davies-Balch[4], Deirdre J. Lyell[5]
[1]Stanford University, Palo Alto, CA, [2]University of California Davis, Sacramento, CA, [3]BLACK Prosperity and Wellness Center, Fresno, CA, [4]BLACK Wellness and Prosperity Center, Fresno, CA, [5]Stanford University Medical Center, Palo Alto, CA

OBJECTIVE: Black pregnant people have the highest rates of anemia, contributing to disparities in severe maternal morbidity in the United States. Our objective was to conduct community-centered

research to identify barriers to and opportunities to care for antepartum anemia among historically underserved communities.

STUDY DESIGN: We applied Howell's conceptual framework on reduction of peripartum racial and ethnic disparities (Obstet Gynecol 2018) and the Public Health Critical Race Praxis to identify community stakeholders and distill research objectives. In collaboration with our community partners, we created a semi-structured interview guide. People with a history of antepartum anemia were eligible and participated in focus groups and interviews aimed at providing insight into patient perceptions of diagnosis, management, and treatment of anemia offered and received during pregnancy. Cultural congruency between the interview facilitators and interviewees was maintained by race and ethnicity when possible. We analyzed the interviews using the grounded-based theory approach.

RESULTS: We conducted one-one interviews and virtual focus group sessions with 15 people with a history of antepartum anemia, facilitated by our community partner and academic research team. 11 focus group participants were Black, 3 were Hispanic/Latinx, and 1 was Multiracial, and all resided in California. Our analysis identified five major themes around barriers to care: 1) lack of information/education from the provider regarding anemia; 2) dismissal of patient's reported experiences with anemia symptoms; 3) treatment challenges with nutrition, oral, and intravenous iron; 4) perception of race and culture as a contributing factor to maternal care; and 5) role of patient support system.

CONCLUSION: Our qualitative community-engaged approach identified specific challenges and opportunities for patient-informed solutions to improve antepartum anemia care among Black and Hispanic pregnant patients. Community-informed interventions are needed to achieve equitable, evidence-based treatment and care of anemia in pregnancy.

Table 1. Thematic based quotes from Pregnant Patients Experiences with Antepartum Anemia

Themes		
Lack of information on anemia	"They didn't explain any of that. They just told me to take the pills." ID 4	"She gave me a sheet with a diet that I should follow, and that was pretty much it. She's just like, 'Here's the paper.'" ID 11
Dismissal of patient's reported experiences with anemia symptoms	"I was always feeling very tired, but every time I would tell the doctor, it was always being diagnosed as, 'You're pregnant.'" ID 10	"When I told her I was really tired, really dizzy, it was kind of just kind of ignored just because it's kind of like, "Oh, well, it's normal.'" ID 11
Treatment challenges	"And so from there, it was about trying to advocate and find the right words to kind of say, 'Look, I can't take this iron supplement anymore. I do need to be on infusions now.'" ID 9	"I was just like, 'Hey, these pills are making me sicker than what it was.' ...but I was so severe...I was like a 6 or 5, and they would give me infusions." ID 15
Influence of race and culture	"I do feel like what you end up doing has repercussions on your care, and so sometimes it feels like I don't want to say stuff because I don't want it to have repercussions on my care." ID 9	"And the first barrier I had going to the doctor was being as a woman of color, already being assessed without any medical test being run." ID 10
Role of Support person	"My family was a really strong support for me, especially my cousin... And she educated me a lot on it." ID 6	"I was telling them...[family] on the way that they could help out in order for me to now solve this issue I got." ID7 and ID 8

484 Donor gamete status and hypertensive disorders of pregnancy in pregnancies conceived with assisted reproductive technologies

Kaitlyn E. James[1], Sarah Hsu[1], Irene Souter[2], Charles Bormann[2], Camille E. Powe[1]

[1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Department of Obstetrics and Gynecology, Boston, MA

OBJECTIVE: It is hypothesized that abnormal maternal immune tolerance may lead to a higher risk of HDP in pregnancies conceived with ART, which accounts for an increasing percentage of live births in the United States.We sought to determine if pregnancies resulting from in vitro fertilization (IVF) of double donor gametes have a higher risk of HDP compared to other ART procedures in a cohort of deliveries in a healthcare center between 1998-2016.

STUDY DESIGN: Pregnancies conceived via ART at the healthcare center's infertility clinic were linked to delivery records. The overall cohort consisted of 48,749 deliveries; 1,949 of those deliveries were conceived with ART at the fertility clinic (13% used intrauterine insemination [IUI], 87% used IVF). HDP were ascertained using an electronic health record-based definition that incorporated quantitative blood pressure and laboratory data, as well as complications in labor and delivery. Gamete donation status was classified into four categories: no donor gamete, donor sperm, donor oocyte, double gamete donation. Adjusted generalized estimating equations accounting for multiple pregnancies per patient were used to determine differences in the risk of HDP by gamete donation categories.

RESULTS: The overall rate of HDP in the non-ART population was 7.2%; in the ART population, the rate of HDP was 12.9%. After adjustment, the risk of HDP in donor oocyte and double gamete donation categories was significantly higher than the no donor gamete category (Table 1). There was no difference in the risk of HDP between donor sperm and no donor gametes. Results did not change after adjustment for IUI versus IVF and the use of intracytoplasmic injection of sperm (ICSI) in the IVF cohort.

CONCLUSION: Donor oocyte was associated with an increased risk of HDP compared to pregnancies conceived with autologous oocytes and partner sperm in this ART cohort. While a known risk factor in spontaneously conceived pregnancies is new partner sperm, donor sperm had a similar rate of HDP compared to no donor gametes.

Table 1. Gamete donation status and HDP rate of N=1,949 ART-conceived pregnancies

Gamete Donation Status	*N (%) of ART pregnancies (N=1,949)*	*Rate of HDP*	*aOR* (95% CI); p-value for HDP*
No donor gametes	1,768 (90%)	12.2%	*Reference*
Donor sperm	63 (3.2%)	7.9%	0.61 (0.21, 1.72); 0.35
Donor oocyte	110 (5.6%)	26.4%	3.34 (1.93, 5.78); <0.001
Double gamete donation	8 (0.41%)	37.5%	8.73 (1.45, 52.6); 0.02

*Generalized estimating equations adjusted for maternal age, first trimester maternal BMI, gestational diabetes (defined using Carpenter-Coustan criteria), multiple gestation, and year of delivery

485 Association between perinatal phthalate metabolite concentrations and postpartum glucose levels: a prospective observational study

Marta Ponzano[1], Emma V. Preston[1], Marlee R. Quinn[1], David E. Cantonwine[2], Paige L. Williams[1], Ellen W. Seely[2], Blair Wylie[3], Michele R. Hacker[4], Florence M. Brown[5], Karen O'Brien[4], Russ Hauser[6], Andrea Bellavia[2], Camille E. Powe[7], Thomas McElrath[2], Tamarra James-Todd[1]

[1]Harvard TH Chan School of Public Health, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Columbia University, New York, NY, [4]Beth Israel Deaconess Medical Center, Boston, MA, [5]Joslin Diabetes Center, Boston, MA, [6]Harvard T.H. Chan School of Public Health, Boston, MA, [7]Massachusetts General Hospital, Boston, MA

OBJECTIVE: To study the associations of pregnancy and postpartum exposure to phthalates, a class of endocrine disrupting chemicals, with postpartum glucose tolerance.

STUDY DESIGN: Pregnant participants in the Environmental Reproductive and Glucose Outcomes Study with data on urinary phthalate metabolite concentrations at $\leq$ 4 study visits (median 11 [Visit 1, V1], 19 [Visit 2, V2], and 26 [Visit 3, V3] weeks' gestation and median 7 weeks postpartum [PP]) and available PP fasting and 2-hour glucose levels after a 75-gram oral glucose tolerance test were included. Phthalate metabolite concentrations (e.g. MCOCH, MHiNCH, MBP, etc.) were specific-gravity adjusted and modeled

individually and as mixtures at each timepoint. Analyses were adjusted for age, pre-pregnancy BMI, education, and parity.

RESULTS: 201 participants were included [mean(SD) age: 33 (5) years; fasting glucose: 82 (8) mg/dL; 2-hour glucose: 88 (22) mg/dL] with phthalate data measures available for 90%, 81%, 86% and 92% at V1, V2, V3 and PP, respectively. V1 MCOCH and MHiNCH; V2 MBP; and PP MEHHP, MEHP, MHBP were associated with higher fasting glucose levels, while V2 MCNP was associated with higher 2-hour postprandial glucose levels. MEHHTP at V2 and MCOP at V3 were associated with lower fasting glucose levels. V1 MECPTP and MEHHTP; V2 MBP, MBzP, MEHHP, MEOHP; V3 MEHHP and MHiNCH; and PP MCPP and MHiBP were associated with lower 2-hour postprandial glucose levels. Weighted quantile sum regression identified pregnancy MCOCH (positive direction) and MEP (negative direction) in the phthalate mixture as important contributors to the mixture's associations with PP fasting and 2-hour glucose levels.

CONCLUSION: In our cohort, pregnancy and postpartum urinary phthalate metabolite concentrations were associated with altered glucose metabolism in the postpartum period, although findings varied by timing of phthalate measurement. Given the ubiquitous nature of phthalates in consumer products, it is important to further explore the influence of phthalate metabolites concentrations on PP glucose metabolism.

486 Compliance with national guidelines for aspirin prophylaxis for preeclampsia prevention

Bhavana Janga[1], Hannah Hill[2], Gabriel Labbad[3], Angela Ranzini[1]

[1]MetroHealth Medical Center, Case Western Reserve University, Cleveland, OH, [2]MetroHealth Medical Center, Population Health and Equity Research Institute, Cleveland, OH, [3]Cedars-Sinai Health System, Los Angeles, CA

OBJECTIVE: Since 2014, the American College of Obstetricians and Gynecologists (ACOG) has recommended aspirin prophylaxis, beginning at 12 weeks gestational age, to prevent preterm preeclampsia in high-risk patients. Despite the known benefits of aspirin prophylaxis, the frequency of provider adherence to this recommendation is poorly understood. Hence, we assessed the frequency of guideline adherence over time and the risk factors for non-adherence.

STUDY DESIGN: From 2012-2023, 29,595 patients received prenatal care at our tertiary care center. Patients that met the criteria for aspirin prophylaxis were identified, and longitudinal adherence to guidelines was assessed. We then evaluated patient factors contributing to guideline non-adherence.

RESULTS: A total of 10,171 (34%) patients met the criteria for aspirin prophylaxis. Of those eligible, 1,463 (14%) were prescribed aspirin prophylaxis overall. Guideline adherence improved with time, increasing from 2.7% of eligible patients in 2014 to 26% in 2022 (Figure 1). Since the inclusion of moderate risk factors in the guidelines, eligible patients most often overlooked were a combination of Black race and low income, comprising 47% of eligible patients that did not receive a prescription.

CONCLUSION: Despite the ACOG recommendation for aspirin prophylaxis for the prevention of preterm preeclampsia, only 26% of eligible present-day patients received a prescription. Low-income Black patients were most frequently overlooked, suggesting that populations already at increased risk are being left out. Alternate methods to encourage guideline adherence, such as a provider alert, are needed to facilitate the benefit of evidence-based recommendations.

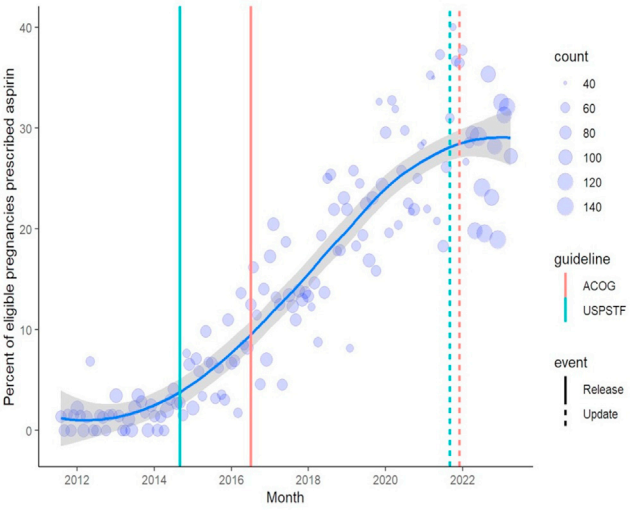


Figure 1: Longitudinal adherence to recommended aspirin prophylaxis guidelines for preeclampsia prevention. Timing of guideline implementation and updates are noted by vertical lines. The shaded area represents the 95% confidence interval.
ACOG, American College of Obstetricians and Gynecologists; USPSTF, United States Preventative Services Task Force

488 Development of umbilical vessels as vascular grafts

Young Mi Jung, Ye Seon Seok, So Young Lee, Su Jung Hong, Min-Jeong Oh

Korea University College of Medicine, Seoul, Republic of Korea, Seoul, Seoul-t'ukpyolsi

OBJECTIVE: Small-diameter arterial cardiovascular disease often requires the replacement of damaged or disease blood vessels with autologous graft such as saphenous vein or thoracic artery or synthetic graft. However, the supply of suitable vessels is often limited, and there are potential limitations such as thrombogenic risk and lack of integration associated with natural grafts. To overcome these challenges, researchers have explored decellularized tissue engineering as a promising alternative. This study aimed to create a decellularized umbilical vessel and evaluate its potential as a small-diameter vascular graft.

STUDY DESIGN: We created decellularized blood vessels using umbilical cords obtained from full-term deliveries. After separating them into artery and vein, the vessels underwent freezing, thawing, and chemical treatments to remove cellular components. Confirmation of successful decellularization was achieved through H&E staining. Subsequently, we performed interposition of these decellularized vessels into the abdominal aorta of rabbits with a similar diameter.

RESULTS: After one week following the transposition into the rabbit's abdominal aorta, we observed that the decellularized vessels maintained their structural integrity and demonstrated appropriate patency. Upon conducting a postmortem examination of the rabbit, even then, we confirmed the absence of thrombus formation, indicating that blood clots did not occur.

CONCLUSION: This study confirmed the potential of umbilical cord blood vessels as a novel artificial blood vessel. However, further research is required for practical implementation.

489 Do fetal biometry parameters> 90th percentile increase the risk of Primary Cesarean Delivery?

Lior Kashani Ligumsky[1], Ronnie Cohen[2], Ariel Many[3], Elad Miron[4], Ioana Olteanu[5], Ariel Lasry[5], Miriam Lopian[6]
[1]Mayanei Hayeshua Medical Center, Tel-Aviv, Israel, [2]Maaynei Hayeshua medical center Bnei Brak, Petach-Tikva, HaMerkaz, [3]Ma'ayne Hayeshua Medical Center Tel Aviv University, Bnei Brak, Tel Aviv, [4]Mayanei Hayeshua Medical Center, Bnei Brak, Tel Aviv, [5]Mayanei Hayeshua Medical Center, Bnei Brak, HaMerkaz, [6]Mayanei Hayeshua Medical Center, Ra'anana, HaMerkaz

OBJECTIVE: To determine whether sonographic fetal biometry parameters > 90% increase the risk of primary cesarean delivery (PCD) in Appropriate for Gestational Age (AGA) neonates across different parity groups.

STUDY DESIGN: A retrospective analysis was conducted to assess the rate of PCD for AGA neonates with Fetal Biometry above 90% in various parity groups. Singleton pregnancies at term underwent sonographic estimation using the Hadlock scale within one week of delivery between 2020 and 2023. Pregnancies with known anomalies were excluded.

RESULTS: The study included 10,515 women, divided into primiparous (n=2,183), multiparous (parity 1-4) (n=5,587), and grand multiparous (parity ≥5) (n=2,745) groups. The overall rate of PCD was higher among primiparous women, 13.4%, compared to 3.6% in multiparas and 4.8% in grand multiparas (p< 0.01). For AC >90%, the rate was 24.6% in primiparas, 6.7% in multiparas, and 8.1% in grand multiparas (p< 0.01). For HC >90%, the rates were 25.2% in primiparas, 6.4% in multiparas, and 4.8% in grand multiparas (p< 0.01). For FL >90%, the rates were 14.2% in primiparas, 2.9% in multiparas, and 5.2% in grand multiparas (p< 0.01).

When comparing the rate of CD between biometric parameters >90% and Large for Gestational Age (LGA) neonates, a higher rate of CD was observed in women with AC or HC >90% compared to LGA in primiparas (24.6% and 25.2% vs 17.2%, p< 0.01) and multiparas (6.7% and 6.4% vs 6.03, p< 0.01). However, this difference was not significant in grand multiparas (8.1% and 4.8% vs 8.6%, p=0.1).

CONCLUSION: AC and HC >90th centile confer an increased risk of PCD in primiparous and Multiparous patients but not in Grandmultiparous patients. These findings underscore the importance of considering fetal biometry, especially AC and HC, as key factors in decision-making regarding the mode of delivery, which may lead to better management and improved outcomes for pregnant women and their neonates.

490 Changes in postpartum uterine artery Doppler velocimetry in subjects undergoing conservative management of placenta accreta

Elias Kassir[1], Jennie Coselli[2], Ramesha Papanna[1], Baha M. Sibai[3], Edgar Hernandez Andrade[1]
[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [3]Hermann Memorial Hospital, Houston, TX

OBJECTIVE: In patients undergoing an uncomplicated birth, blood flow to the uterus decreases in the ensuing weeks with an increase in resistance to flow in the uterine arteries (UtA). In patients who undergo conservative management of placenta accreta spectrum (PAS), the placenta remains *in situ*, providing a plausible physiologic basis for alterations in the expected blood flow pattern to the uterus postpartum. In this study, we describe UtA Doppler findings in individuals who underwent conservative management of PAS.

STUDY DESIGN: We studied a prospective cohort of subjects with PAS. Subjects who choose conservative management undergo serial postpartum ultrasound evaluations. UtA Doppler recordings were reviewed and peak systolic velocity (PSV), end-diastolic velocity (EDV), and pulsatility index (PI) registered, and mean values calculated. Postpartum outcomes and operative reports were reviewed. UtA Doppler measurements were plotted and linear regression analyses were performed to quantify changes over time.

RESULTS: 18 subjects were identified; 7/18 had 3 or more postpartum Doppler evaluations. The remaining 11 subjects had fewer than 3 postpartum ultrasounds with UtA Doppler values. When the 7 subjects with 3 or more evaluations were analyzed, 5/7 (71.4%) had an increase in mean UtA PI over time, 4/7 (57.1%) had a decrease in UtA PSV, while 5/7 (71.4%) had a decrease in UtA EDV over time. Of these seven subjects, two (28.6%) were readmitted for heavy bleeding, one (14.3%) developed a coagulopathy, two (28.6%) underwent dilation and curettage, and four (57.1%) underwent interval hysterectomy.

When data were pooled for all 18 subjects, there was a statistically significant decrease in UtA EDV (p = 0.005) and increase in PI (p = 0.0004), with a non-significant trend towards decrease in PSV.

CONCLUSION: In subjects undergoing conservative management of PAS with the placenta remaining *in situ* after delivery, blood flow to the uterus decreases over time with a concomitant increase in resistance to flow in the UtA. When aberrations in this trend are observed, patients may be at higher risk for complications.

Table 1: Changes in mean uterine artery (UtA) PSV, EDV, and PI over time for the 7 subjects with at least 3 postpartum ultrasounds with UtA Doppler measurements. Outcomes for each corresponding individual are also demonstrated.

	Mean UtA PSV over time	Mean UtA EDV over time	Mean UtA PI over time	Readmitted for bleeding	Coagulopathy	Infection	Dilation and curettage	Interval hysterectomy (EBL in cc)

491 Can pre-cesarean angle of progression predict maternal complications in second-stage labor arrest?

Tamar Katzir, Tom Kishinevski, Miri Sacagiu Barak, Omri Kempler Zarka, Shira Leybovitch, Tovit Weinberg, Roni Levy, Edi Vaisbuch
Kaplan Medical Center, Rehovot, HaMerkaz

OBJECTIVE: An emergency cesarean delivery (CD) performed during the second stage of labor can be associated with increased maternal complications, as a low fetal head in the maternal pelvis can be associated with a challenging fetal extraction. The angle of progression (AOP) is an objective sonographic tool to monitor fetal head descent, and an AOP of 116° was described as equivalent to fetal head at station "0". This study aimed to assess the association between the AOP at rest

as measured before the decision of an emergency CD due to arrest of descent during the second stage of labor and the rates of intraoperative and postoperative maternal complications.

STUDY DESIGN: This retrospective study included all primiparous women who underwent an emergency CD due to arrest of descent during the second stage of labor and had an AOP recorded in the electronic medical charts between January 2017 and May 2023. The cohort was divided into two groups based on the AOP measurement at rest before the decision on a CD: 1. AOP≤116° and 2. AOP >116°. The maternal intraoperative and postoperative complication rates were compared between the two groups.

RESULTS: The demographic characteristics were comparable between women with an AOP≤116° (n=41) and those with an AOP >116° (n=127) (Table 1). Women with an AOP >116° had a significantly higher composite intraoperative complications rate than those with an AOP≤116° (47% vs. 29%, p=0.04), mostly attributed to increased rates of uterine extensions and difficult extractions. No significant differences were noted in the total maternal postoperative complications rate (29% vs. 29%, p=0.93) and short-term neonatal outcomes (Table 1).

CONCLUSION: Among primiparous women who underwent an emergency cesarean delivery due to arrest of descent during the second stage of labor, those with an AOP greater than 116° as assessed by trans-perineal ultrasound had a higher rate of a composite of intraoperative complications. This finding highlights the importance of adequately preparing for emergency cesarean sections (e.g., fetal head pushing from the vagina or breach extraction) in these women.

Table 1- Demographic, clinical characteristics, maternal and neonatal outcomes by study groups

	Study group		p-value
	AOP≤ 116 (n=41)	AOP > 116 (n=127)	
Demographic characteristics			
Age (years)	29.7 ± 4.8	29.3 ± 4.8	0.64

492 Can the angle of progression during a prolonged second stage increase the vaginal delivery rate?

Tamar Katzir, Omri Kempler Zarka, Miri Sacagiu Barak, Oren Barak, Calanithe Hershkovich Shporen, Roni Levy, Edi Vaisbuch

Kaplan Medical Center, Rehovot, HaMerkaz

OBJECTIVE: The revised 2014 definition by the American College of Obstetricians and Gynecologists allows women to push during the second stage of labor as long as there is observable labor progress. Studies proposed using intrapartum ultrasound during the second stage, particularly the angle of progression (AOP) at rest, as an objective tool to monitor fetal head descent. This study aimed to assess the impact of AOP measurement to monitor fetal head descent on the delivery mode and maternal and neonatal morbidity in women with a second stage of labor of at least 4 hours.

STUDY DESIGN: This retrospective study included primiparous women with a prolonged second stage of labor of ≥4 hours who delivered in our labor ward. The study group that included women who delivered between 2017 and 2020 and had a documented AOP measurement at 3:30-4:30 hours from complete dilatation was compared to a control group comprised of women delivering between 2010 and 2014 (before AOP was routinely used in our labor ward). The delivery mode and the maternal and neonatal outcomes were compared between the two groups.

RESULTS: The demographic characteristics were comparable between the study (n=126) and the control (n=134) groups (**Table 1**). The second stage was longer, and the spontaneous vaginal delivery (VD) rate was higher in the study compared to the control group (268±21 vs. 249±21 min., p< 0.001 and 14% vs. 3%, p=0.001, respectively). Although not statistically significant, there was a trend towards lower rates of cesarean delivery and failed vacuum extraction (VE) in the study group (24% vs. 33%, p=0.08, 1.5% vs. 5%, p=0.1, respectively). No other significant differences were noted in maternal and neonatal outcomes. One case of neonatal death occurred in the control group.

CONCLUSION: In primiparous women with a second stage of labor of ≥4 hours, measurement of the AOP was associated with a longer second stage, a higher rate of spontaneous VD, and a trend toward a lower rate of failed VE attempts without compromising maternal or neonatal outcomes. Further prospective randomized trials are needed to validate our findings.

Table 1- Demographic, clinical characteristics, maternal and neonatal outcomes by study groups

	Study group (n=126)	Control group (n=134)	p-value
Delivery mode			
Normal vaginal delivery	14.3% (18)	3.0% (4)	**<0.01**
Vacuum extraction	61.1% (77)	63.4% (85)	0.80
Failed Vacuum extraction	1.6% (2)	5.2% (7)	0.10
Cesarean delivery	24.6% (31)	33.6% (45)	0.08

493 Effects of chemotherapy agents on placental cells: implications for treating breast cancer during pregnancy

Nathan A. Keller[1], **Xiangying Xue**[2], **Christine Metz**[2]
[1]Zucker School of Medicine at Hofstra of Northwell, Lindenhurst, NY, [2]Zucker School of Medicine at Hofstra of Northwell, The Feinstein Institutes for Medical Research, Hempstead, NY

OBJECTIVE: To examine anti-proliferative and cytotoxic effects of three breast cancer chemotherapeutics (5-fluorouracil (5-FU), doxorubicin (DXR), and cyclophosphamide (CP)) on human placental cell lines JAR and JEG-3. Tamoxifen (TAM) a hormone therapy contraindicated in pregnancy was also examined.

STUDY DESIGN: JAR and JEG-3 cell lines (ATTC) were used as human placental cell models.

Cell Proliferation: JAR and JEG-3 cells were plated at 5x10^3/well in media containing 10% FBS in 96 well plates. Cells were treated with chemotherapeutic agents (using a range of doses, n=4 wells/condition, n≥3 experiments). After 48 hours at 37°C/5% CO_2, cells were processed for proliferation using the CyQUANT assay kit (Invitrogen) to determine relative cell numbers.

Cytotoxicity: JAR and JEG-3 cells were plated at 3x10^4 cells per well and 6x10^4 cells per well, respectively, in 96 well plates in media containing 10% FBS. Cells were treated with chemotherapeutic agents (using a range of doses, n=6 wells/condition, n≥3 experiments). After 48 hours at 37°C/5% CO_2, cytotoxicity was determined by neutral red staining.

A 3-parameter nonlinear regression model (GraphPad Prism Version 10.0.0) was used to calculate half maximal inhibitory concentrations (IC_{50}) for cell proliferation and cytotoxicity for each agent. Extra sum of squares F-test was used to compare IC_{50} values between cell lines for each chemotherapeutic agent.

RESULTS: Chemotherapeutic IC_{50} values are shown in Table 1. DXR was the most and CP was the least anti-proliferative and cytotoxic. 5-FU and TAM had significantly higher anti-proliferative effects on JEG-3 than JAR cells. The cytotoxic effects of DXR were significantly higher for JEG-3 than JAR while the inverse was true for TAM. Overall, chemotherapeutic dosages that induced cytotoxicity were similar to those that inhibited proliferation, except CP, which showed more potent cytotoxic than anti-proliferative effects.

CONCLUSION: DXR exerted the most potent anti-proliferative and cytotoxic effects. Further studies comparing the effects of these agents on breast cancer and placental cell lines are warranted.

Table 1 – Chemotherapeutic IC_{50} values for placental cell lines with 95% confidence intervals

	Placental Cell Proliferation IC_{50}			Placental Cell Cytotoxicity IC_{50}		
Chemotherapy Agents	*JAR*	*JEG-3*	*Cell Line Comparison (p-value)*	*JAR*	*JEG-3*	*Cell Line Comparison (p-value)*

494 Developing a Novel Patient-Centered Definition of Severe Maternal Morbidity

Adina R. Kern Goldberger[1], **Rebecca F. Hamm**[2], **Lauren Callans**[3], **Lisa D. Levine**[3]
[1]Cleveland Clinic Lerner College of Medicine, Cleveland, OH, [2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA

OBJECTIVE: Existing frameworks for severe maternal morbidity (SMM) do not account for how patients perceive and experience SMM. This study evaluated patient values and perceptions related to maternal complications with the goal of devising a patient-centered SMM composite.

STUDY DESIGN: This 2-part sequential qualitative to quantitative mixed-methods study first involved structured interviews of postpartum patients recruited from an urban, academic hospital with purposive sampling by race and mode of delivery. Qualitative data around patient-perceived adverse maternal events were analyzed thematically. Second, potential adverse maternal events derived from this interview data as well as established SMM criteria were evaluated in a survey which prompted ranking on a scale from 1 ["no big deal"]-5 ["worst thing imaginable"]. All postpartum patients were eligible to participate and completed the survey prior to discharge (from 6/2022-11/2022).

RESULTS: 18 patient interviews identified 9 themes distinct from established SMM criteria. 501 patients then participated in the survey study (60.7% Black, 6.5% Hispanic, median maternal age 31 [IQR 26-34], 40.6% had cesarean delivery, 6% had hemorrhage, and 1.6% had SMM without transfusion [CDC definition]). Patient rankings of potential SMM components are displayed in the Table. The 3 highest ranked outcomes were stroke/seizure, hysterectomy, and heart failure. 66.3% of patients ranked severe postpartum depression as a 4 or 5, higher than hemorrhage, transfusion, and

long-term physical disability, and > 25% ranked readmission (32.5%) and unplanned cesarean (25.7%) as 5/5.

CONCLUSION: Adverse maternal outcomes important to patients do not correlate directly with established SMM composites. Incorporating expanded maternal morbidity criteria —such as unplanned cesarean and postpartum depression —into research and intervention frameworks is important in order to take a patient-centered approach to evaluating and mitigating SMM.

Table. Patient Rankings of Potential Forms of Severe Maternal Morbidity

	Score = 5* N (%)	Score = 4* N (%)	Score of 4 or 5 N (%)	Mean Score [1-5] (SD)
Stroke, seizure, or other neurologic (brain-related) complications	343 (68.5%)	47 (9.4%)	390 (77.8%)	4.4 (1.3)
Hysterectomy (surgical removal of the uterus)	329 (65.7%)	49 (9.8%)	378 (75.4%)	4.3 (1.3)
Heart failure or other new heart problem	322 (64.3%)	70 (14.0%)	392 (78.2%)	4.3 (1.3)
Needing to be on a ventilator (breathing machine)	317 (63.3%)	60 (12.0%)	377 (75.2%)	4.3 (1.3)
Surgical complications from a c-section (like injury to the intestines or bladder)	269 (53.7%)	101 (20.2%)	370 (73.9%)	4.2 (1.3)
Needing an additional surgery after delivery because of bleeding or infection in the uterus	268 (53.5%)	114 (22.8%)	382 (76.2%)	4.2 (1.3)
Lung or breathing complication	268 (53.5%)	111 (22.2%)	379 (75.6%)	4.2 (1.3)
Being admitted to the intensive care unit (ICU)	252 (50.3%)	113 (22.6%)	365 (72.9%)	4.1 (1.3)
A new blood clot in the leg (deep vein thrombosis) or lungs (pulmonary embolism)	230 (45.9%)	133 (26.5%)	363 (72.5%)	4.1 (1.3)
Anesthesia complications (like having a complication from an epidural or needing to be unexpectedly put to sleep during a c-section)	217 (43.3%)	126 (25.1%)	343 (68.5%)	4.0 (1.3)
Another serious infection	214 (42.7%)	138 (27.5%)	352 (70.3%)	4.0 (1.3)
Having severe postpartum depression	207 (41.3%)	125 (25.0%)	332 (66.3%)	3.9 (1.3)
Uterine (womb) infection after delivery	201 (40.1%)	133 (26.5%)	334 (66.7%)	3.9 (1.3)
Wound infection at the area of a vaginal laceration (tear) or c-section scar	198 (39.5%)	127 (25.3%)	325 (64.9%)	3.9 (1.3)
Extra bleeding or hemorrhage	190 (37.9%)	128 (25.5%)	318 (63.5%)	3.8 (1.3)
Needing to be transferred to a different hospital	189 (37.7%)	129 (25.7%)	318 (63.5%)	3.8 (1.3)
Having an emergency c-section	171 (34.1%)	129 (25.7%)	300 (59.9%)	3.7 (1.4)
Being re-admitted to the hospital after being discharged	163 (32.5%)	136 (27.1%)	299 (59.7%)	3.7 (1.3)
Blood transfusion	159 (31.7%)	102 (20.4%)	261 (52.1%)	3.5 (1.4)
Having a major vaginal laceration (tear)	147 (29.3%)	118 (23.6%)	265 (52.9%)	3.5 (1.4)
Having an unplanned or unexpected c-section	129 (25.7%)	122 (24.4%)	251 (50.1%)	3.4 (1.4)
Preeclampsia or high blood pressure in pregnancy	128 (25.5%)	155 (30.9%)	283 (56.5%)	3.6 (1.3)
Having longer-term physical changes or disabilities from pregnancy like back pain, weight gain, or change in bladder control	126 (25.1%)	128 (25.5%)	254 (50.7%)	3.5 (1.3)
Staying in the hospital longer than I wanted or planned	51 (10.2%)	74 (14.8%)	125 (25.0%)	2.6 (1.4)
Needing to be delivered earlier than I wanted or planned	33 (6.6%)	66 (13.2%)	99 (19.8%)	2.4 (1.3)

*Patients were presented with a scale from 1 – 5 with 1 described as "no big deal" and 5 as "worst thing imaginable"

495 Evaluating Concordance Between Patient Perceptions of Risk for Maternal Morbidity and Established Risk Factors

Adina R. Kern Goldberger[1], Rebecca F. Hamm[2], Lauren Callans[3], Lisa D. Levine[3]

[1]Cleveland Clinic Lerner College of Medicine, Cleveland, OH, [2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA

OBJECTIVE: Perception of risk is an important driver of health behaviors and engagement in care. It is unknown whether pregnant patients accurately recognize risk level for severe maternal morbidity (SMM). This study investigates patient evaluations of SMM risk compared to established criteria for assessing maternal risk.

STUDY DESIGN: This mixed methods study was designed to evaluate postpartum patients' experiences and perceptions related to SMM. Qualitative data from structured patient interviews were used to develop a survey assessing patient understanding of their own risk in pregnancy (domains in Table). Responses were collected on Likert scales and as rankings of pregnancy co-morbidities in terms of perceived risk level (scale of 0="no increased risk"-5="high risk"). Perceptions of personal risk and risk ratings of each condition were compared by patient obstetric co-morbidity index (OB-CMI) [low = < 6 vs high = ≥ 6] derived from chart review.

RESULTS: **501** patients participated in the study 6-11/2022 (60.7% Black, 6.5% Hispanic). Median OB-CMI score was 1 (IQR 0-3) [11.6% with high OB-CMI ≥ 6]. Patients with high OB-CMI perceived increased personal risk in all domains but reported similar ability to control risk as patients with low OB-CMI (Table). When ranking antenatal conditions by risk level, patients with high OB-CMI ranked preeclampsia and hypertension higher than those with low OB-CMI (mean 4.2 [SD 1.6] vs 3.5 [2.0]; p =0.01; 3.8 [1.9] vs 3.2 [2.1], p=0.03), with no other significant differences. Of all OB-CMI components, both groups rated preeclampsia highest and asthma lowest.

CONCLUSION: Patients with established risk factors for SMM accurately perceived themselves at higher risk. They also better appreciated risks associated with hypertension/preeclampsia. These data suggest that current frameworks for conveying risk to obstetric patients are effective, but may be enhanced by increased focus on strategies to increase patient agency to modify risk.

Table. Survey Responses Regarding Personal Risk for Maternal Morbidity in Pregnancy by Patient OB-CMI Score

Survey Responses "Top Box" (agree/strongly agree)	Patients with Low OB-CMI <6* N = 443 (N, %)	Patients with High OB-CMI ≥6* N = 58 (N, %)	P-Value
"I feel like I had a high-risk pregnancy."	118 (26.6%)	39 (67.2%)	<0.01
"I was told by others that I had a high-risk pregnancy."	136 (30.7%)	42 (72.4%)	<0.01
"I had control over my risk of complications in pregnancy."	223 (50.3%)	23 (39.7%)	0.13
"My pregnancy experience puts me at risk for complications in a future pregnancy."	76 (17.2%)	23 (39.7%)	<0.01
"My pregnancy experience puts me at risk for long-term health complications."	28 (6.3%)	13 (22.4%)	<0.01
"I had a typical pregnancy experience."	296 (66.8%)	30 (51.7%)	0.02
"I experienced pregnancy complications."	145 (32.7%)	39 (67.2%)	<0.01
"I experienced more pregnancy complications than most people that I know."	61 (13.8%)	22 (37.9%)	<0.01
"My pregnancy involved complications that I did not expect."	153 (34.5%)	36 (62.1%)	<0.01
"I delivered earlier than I expected."	182 (41.1%)	38 (65.5%)	<0.01
"I did not feel prepared to deliver when I did."	86 (19.4%)	18 (31.0%)	0.04
"I stayed in the hospital longer than I expected when I delivered my baby."	64 (14.4%)	16 (27.6%)	0.01
"I needed to communicate with my doctors or go to the ER during pregnancy or postpartum more than I expected."	76 (17.2%)	18 (31.0%)	0.01
"My birth experience was negatively impacted by the complications I experienced."	39 (8.8%)	17 (29.3%)	<0.01
"The complications I experienced in my pregnancy would impact my decision about having another pregnancy."	72 (16.3%)	21 (36.2%)	<0.01

*Low OB-CMI: Score < 6; High OB-CMI ≥ 6 (Easter SR, Bateman BT, Sweeney VH, Manganaro K, Lassey SC, Gagne JJ, Robinson JN. A comorbidity-based screening tool to predict severe maternal morbidity at the time of delivery. Am J Obstet Gynecol. 2019 Sep;221(3):271.e1-271.e10. doi: 10.1016/j.ajog.2019.06.025. OBJECTIVE: Acute kidney injury (AKI) is one of 21 severe maternal morbidity (SMM) diagnoses. Aiming to address maternal morbidity, appropriate recognition and response to AKI are essential. ACOG/SMFM have released conservative guidelines for AKI diagnosis. We reviewed our institution's obstetric AKI cases to establish characteristics and outcomes for AKI severity in the context of these staging systems.

STUDY DESIGN: This study was a retrospective cohort study of AKI cases (ICD 10 code N17.0-17.9) between 01/2018 - 12/2022 at a single academic institution with ~6,000 births annually. Information was extracted via chart review. Cases were stratified by Acute Kidney Injury Network (AKIN) staging and ACOG/SMFM severe renal injury criteria. Those with unknown baseline creatinine (Cr) were assigned 0.7 (the 95th% Cr value at 39-40 weeks). Groups were compared based on demographics, comorbidities, and outcomes (Table 1).

RESULTS: 230 cases were reviewed for AKI severity: 8.3% (19 cases) met criteria by ACOG/SMFM criteria. There were no significant differences in baseline demographics, medication dependent diabetes, chronic kidney disease (CKD), or use of gentamicin. Cesarean delivery and hypertension rates were high among all groups. Higher AKIN stage was associated with higher rates of infection (p=0.019) and use of ketorolac (p=0.020); which was not seen in ACOG/SMFM comparison groups. PPH rates were similar among groups; however, more severe AKI was associated with higher EBL (p=0.019 and p< 0.001, respectively). Worse AKI severity was associated with longer time for Cr resolution and higher co-incidence of other SMM in both groups, and longer maternal length of stay in the ACOG/SMFM group.

CONCLUSION: Peripartum AKI often occurred in the presence of multiple risk factors, including cesarean delivery, hypertension, infection, and hemorrhage. AKI meeting Stage 3 AKIN or ACOG/SMFM were associated with increased morbidity. Caution may be warranted in using AKIN Stage 1 or 2 AKI criteria as it may falsely elevate institutional reporting of SMM, and conservative AKI criteria may better reflect true maternal morbidity.

Table 1: Comparison of groups and outcomes as stratified by AKI staging criteria. Results are reported in mean (standard deviation) or N (%). Univariate analysis was performed using Chi-squared test, Fisher's exact test, independent samples t-test, or ANOVA as appropriate.

497 Fetal Heart Tracing Changes at Peak Methadone or Buprenorphine Dose Appear Unrelated to NOWS Severity

Kathleen J. Koenigs[1], Kaitlyn E. James[1], Molly R. Siegel[1], Haylie Butler[2], Davida M. Schiff[3], Mark A. Clapp[1], Sarah N. Bernstein[1]

[1]Massachusetts General Hospital, Boston, MA, [2]Harvard Medical School, Boston, MA, [3]Massachusetts General Hospital for Children, Boston, MA

OBJECTIVE: Medications for opioid use disorder (MOUD) are recommended, however prenatal predictors of Neonatal Opioid Withdrawal Syndrome (NOWS) remain poorly understood, creating distress for patients and providers. Studies suggest buprenorphine and methadone reduce fetal heart tracing (FHT) variability and accelerations, although not all fetuses exhibit this effect. We sought to determine if the presence of this effect is associated with NOWS.

STUDY DESIGN: We evaluated a retrospective cohort of term singleton pregnancies with MOUD administration at the time of labor and delivery at an academic urban hospital from 2016-2023. MOUD dose, dosing time, psychotropic medications, and non-prescribed substance exposures were obtained via chart review. Clinically documented FHT variability and accelerations were collected at pharmacological trough and peak levels. FHTs with greater than 45 minutes of minimal variability during the peak period were characterized as minimal, and those without accelerations for more than 1 hour were characterized as absent. Differences in NOWS treatment were compared between the group with minimal variability and absent accelerations and the group without these features.

RESULTS: Seventy-seven dyads met inclusion criteria, and 38 neonates (49%) received pharmacotherapy for NOWS. Fifteen (19%) had FHTs with minimal variability and 43 (56%) had absent accelerations. While methadone was associated with minimal variability in FHT, there was no significant difference in the need for NOWS pharmacotherapy, use of a second agent, higher level of treatment, length of stay, or need for discharge home with medications for NOWS between groups.

CONCLUSION: FHT changes at peak methadone or buprenorphine dose appear to have limited clinical utility in predicting the severity of NOWS. Larger studies are needed to better elucidate prenatal risk factors to improve the counseling of birthing persons receiving treatment for OUD.

498 Association of shift complexity and volume with cesarean delivery among nulliparous, term, singleton, vertex patients

Insaf Kouba, Alejandro D. Alvarez, Matthew J. Blitz

Zucker School of Medicine at Hofstra of Northwell, Bay Shore, NY

OBJECTIVE: : Studies have demonstrated high variability in obstetric outcomes between hospitals, but less is known about the effect of individual shift characteristics within a given hospital. We evaluated the association between obstetric unit shift characteristics (including volume and patient complexity) and cesarean delivery rate among nulliparous, term, singleton, vertex (NTSV) patients.

STUDY DESIGN: This retrospective cohort study evaluated all NTSV pregnancies delivering at 7 hospitals within a large academic health system in New York from 2019-2022. Individual 12-hour nursing shifts were characterized based on delivery volume, patient complexity, night/day, and weekday/weekend. Individual patient clinical and sociodemographic factors were also evaluated. Maternal comorbidity burden was assessed by the Obstetric Comorbidity Index (OB-CMI) score. Shift volume for each obstetric unit was classified into three categories based on delivery volume quartile: low (1st quartile), medium (2nd and 3rd quartile), and high (4th quartile). Shift complexity for each obstetric unit was classified as low complexity (1st, 2nd, or 3rd quartile) or high complexity (4th quartile) based on median OB-CMI score of the patients delivering during the shift. The primary outcome was CD. Multivariable logistic regression was used to evaluate the association between shift characteristics and CD, adjusting for potential confounders.

RESULTS: 38,114 subjects were included in the study. The overall rate of CD was 29.3% (n=11,159). Patients that delivered on a weekend or overnight shift were more likely to deliver vaginally (Table). There was no difference in the rate of CD based on shift complexity or volume. Patients with higher OB-CMI scores, and those who self-identified as Asian or Pacific Islander, Hispanic, non-Hispanic Black, and multiracial/other were more likely to deliver via CD.

CONCLUSION: NTSV patients are more likely to deliver vaginally on weekend and overnight shifts. Shift volume or complexity are not associated with this outcome.

Table: Multivariable logistic regression model.

Characteristic	aOR (95% CI)
Weekend shift	0.84 (0.80-0.89)

499 Effect of exogenous oxytocin on placental oxidative stress in mice before onset of labor

Insaf Kouba[1], Matthew J. Blitz[1], Xiangying Xue[2], Prodyot Chatterjee[3], Christine Metz[2]

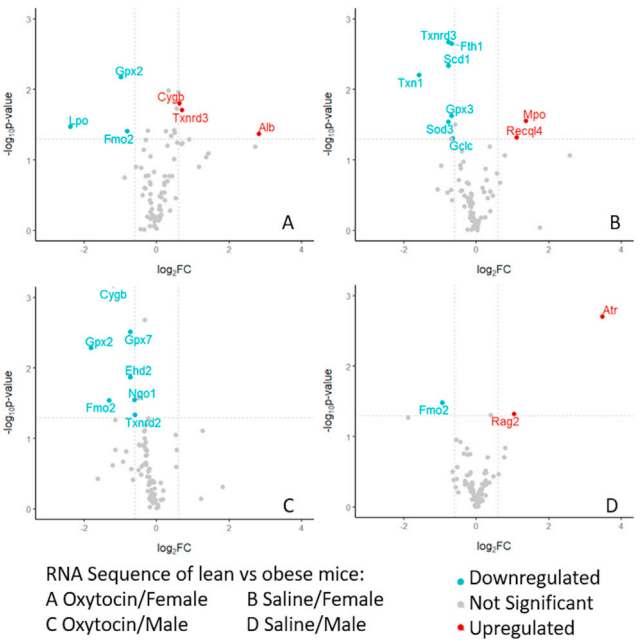
[1]Zucker School of Medicine at Hofstra of Northwell, Bay Shore, NY, [2]Zucker School of Medicine at Hofstra of Northwell, The Feinstein Institutes for Medical Research, Hempstead, NY, [3]Zucker School of Medicine at Hofstra of Northwell, Manhassat, NY

OBJECTIVE: Oxidative stress (OS) in the placenta encompasses both negative and positive regulatory effects. The aim of this study was to determine how placental oxidative stress before the onset of labor is affected by exogenous oxytocin (OXT).

STUDY DESIGN: Lean and obese C57BL/6 mice were obtained from Charles River Laboratories. On gestational age (GA) 18 day, both groups were administered either saline (100 μL) or OXT, 1 U/mouse every 30 min for 2 hours (cumulative dose 5U/mouse). Pups and placentas were delivered by cesarean section and pups and dams were euthanized. Placentas were collected, immediately flash frozen in liquid nitrogen, and stored at -80°C. High quality RNA was extracted from placentas. RNA quantity and quality were analyzed using the NanoDrop spectrophotometer. Gene expression was analyzed with the RT^2 Profiler PCR Array for mouse oxidative stress and antioxidant defense (Qiagen) using the Roche LightCycler 480. The p values were calculated based on Student's t-test of the replicate $2^{(-\text{ Delta CT})}$ values for each gene in the control group and treatment groups. P-values< 0.05 were considered statistically significant.

RESULTS: Placentas of lean and obese mice at gestational age were harvested on (GA) 21 days were selected for this study. There were 84 genes analyzed. In the saline group, there was an 11-fold increase of the *Atr* gene expression as compared vs. 6-fold increase in the OXT group. *Atr* is activated by DNA damage. There was a 2-fold increase in *Rag2* gene expression in the saline group vs. $<$ 1.0-fold increase in the OXT group. The *Rag2* gene has been implicated in increased OS. In the OXT group, there was an increase in *Nqo1*, encoding NAD(P)H dehydrogenase, which functions as an oxido-reductase, leading to a decrease in OS.

CONCLUSION: Exogenous OXT upregulated antioxidant genes in the placenta of obese mice vs. lean mice. Further studies involving human placental cells are needed to confirm this effect.



500 Combined Vaginal-Cesarean Delivery of Twins: National Risk Factors and Trends

Nicole Krenitsky[1], Anna Farooqi[2], Hooman Azad[3], Russell S. Miller[3], Lynn Simpson[3], Mary D'Alton[4], Alexander M. Friedman[5], Timothy Wen[6]

[1]Columbia University Irving Medical Center, NewYork-Presbyterian, New York, NY, [2]Texas Tech University Health Sciences Center, Amarillo, TX, [3]Columbia University Irving Medical Center, New York, NY, [4]Columbia Presbyterian Medical Center, New York, NY, [5]Columbia University, New York, NY, [6]University of California, San Francisco (UCSF), San Francisco, CA

OBJECTIVE: Combined vaginal-cesarean delivery is a known and concerning outcome of trial of labor in twin gestations. We sought to analyze trends in and risk factors for combined vaginal-cesarean twin births during delivery hospitalizations in the United States.

STUDY DESIGN: This cross-sectional study utilized 2016 to 2020 delivery data from the Nationwide Readmissions Database of women aged 15 to 54 years with monochorionic diamniotic (MCDA) or dichorionic diamniotic (DCDA) twin gestations who had vaginal or combined vaginal-cesarean births. Combined deliveries were ascertained via diagnosis codes for both vaginal and cesarean birth in the same delivery hospitalization. Trends analyses were conducted using

joinpoint regression to estimate the average annual percent change (AAPC) with 95% confidence intervals (CI). Adjusted logistic regression models were performed to evaluate the relationship between clinical, hospital, and demographic risk factors and the primary outcome of combined delivery with odds ratios (aOR) expressed as measures of association.

RESULTS: Of 75,591 hospitalizations, 66,952 (88.6%) resulted in vaginal birth of both twins and 8,639 (11.4%) in combined delivery. From 2016 to 2020, the rate of combined deliveries decreased from 12.2% to 10.8% (AAPC -3.0%, 95% CI -4.2, -2.0%), while vaginal twin births increased and cesarean births decreased. Factors associated with elevated odds of combined delivery include advanced maternal age, Medicaid payer, obesity, history of cesarean birth, and placental abruption. Compared to term twins, preterm gestational age at delivery was associated with combined delivery (Table). MCDA gestations were less likely to have a combined delivery compared to DCDA gestations (aOR 0.58, 95% CI 0.52, 0.64).

CONCLUSION: Combined deliveries decreased over the study period but were the ultimate mode of delivery in over 1 in 10 twin pregnancies. Clinical risk factors associated with combined twin delivery include advanced maternal age, obesity, prior cesarean birth, and preterm gestational age at delivery.

501 Comparing the effectiveness of postpartum transition strategies for patients with impaired glucose tolerance (IGT)

Natasha R. Kumar[1], Whitney Bender[2], Celeste Durnwald[3]
[1]Hospital of University of Pennsylvania, Philadelphia, PA, [2]Thomas Jefferson University Hospital, Haddonfield, NJ, [3]University of Pennsylvania, Philadelphia, PA

OBJECTIVE: Patients with IGT receive less antenatal support compared to patients with gestational or pregestational diabetes but carry long-term metabolic risk. At our institution, 15% repeat glucose testing postpartum and 29% follow up with primary care (PCP). We compared the effectiveness of text messaging support (BRIDGE) to text message support and IGT-focused postpartum visit (BRIDGE+) for care transitions.

STUDY DESIGN: Patients with IGT (A1C 5.7-6.4% < 20 weeks gestation) who delivered at a single tertiary care center October 2021-April 2023 were enrolled in BRIDGE, text messaging support with IGT education and follow-up reminders. From July 2022 to April 2023, BRIDGE participants were offered an additional postpartum visit for standardized IGT education (iPPV). Patients were excluded if they were non-English speaking, had gestational or pregestational diabetes, or did not complete third trimester glucose testing.

Our dual primary outcomes were A1C completion and scheduled PCP visit by 12 weeks postpartum. Bivariate comparisons assessed demographic and clinical differences. Multivariable regression models with stepwise backward elimination using $p > 0.20$ compared outcomes.

RESULTS: Characteristics of BRIDGE (n=84) and BRIDGE+ (n=80) participants were similar. 27.4% of patients completed A1C and 45.7% of patients scheduled PCP visit by 12 weeks postpartum. Controlling for scant prenatal care (< 5 visits) and history of IGT prior to pregnancy, BRIDGE+ did not increase A1C completion or PCP visit scheduling rates compared to BRIDGE (Table 1). iPPV attendance was higher than PCP visit attendance (48.9% vs 32.5%, p=0.02). Only 34% of PCP visits included documented IGT education.

CONCLUSION: Text message support improved A1C completion and PCP follow-up for patients with IGT relative to our institution's historic baseline. iPPV did not improve transitions of care compared to text message support alone. iPPV had higher rates of IGT education and visit attendance compared to PCP visits.

Table 1: Comparing the effectiveness of text messaging support (BRIDGE) vs text messaging support + wraparound postpartum visit (BRIDGE+) in completing postpartum transitions of care for patients with IGT

502 Does obstructive sleep apnea in obese patients affect neonatal outcomes?

Priyanka Kundur[1], Emily Fronk[1], Amrita Ladwa[1], Henna Ragoowansi[2], Sarah V. Sebastian[1], Martina Knechel[1], Christopher Ennen[1], Priyanka Kumar[1]
[1]University of Virginia, Charlottesville, VA, [2]UVA Health, Charlottesville, VA

OBJECTIVE: Rates of obesity continue to rise within the United States and with it, the rates of obstructive sleep apnea (OSA). This study aims to determine if there is an association between the presence of OSA in obese pregnant patients and neonatal outcomes compared to obese pregnant patients without OSA.

STUDY DESIGN: This was a retrospective cohort study of all pregnant patients with BMI over 40 kg/m^2 who delivered between Jan. 1, 2011 and Dec. 31, 2020 at a single-center institution. Maternal medical history, neonatal outcomes including APGAR scores at 1 and 5 minute, need for neonatal continuous positive airway pressure (CPAP), neonatal intensive care unit (NICU) admission, mechanical ventilation (MV) requirement, development of transient tachypnea of the newborn (TTN) and respiratory distress syndrome (RDS) were collected. Descriptive and comparative analysis with chi-square and T-test was performed.

RESULTS: 870 cases were analyzed and 70 (8%) of patients were diagnosed with OSA prior to delivery. Average BMI at delivery for patients with OSA was 55.9 kg/m^2 and those without was 50.8 kg/m^2. The presence of OSA in obese pregnant patients was significantly associated with neonatal CPAP ($p < 0.01$), NICU admission ($p < 0.01$), and development of RDS ($p < 0.01$) in comparison to those born to mothers without OSA. There was no significant association between presence of OSA and neonatal MV ($p= 0.581$) and development of TTN ($p= 0.095$). APGAR scores at 1 minute were significantly lower in neonates born to obese mothers with OSA in comparison to those without OSA (7 vs. 8, $p= 0.02$). APGAR scores at 5 minutes did not differ significantly between groups (8 vs. 8, $p= 0.075$).

CONCLUSION: This study shows that OSA in an obese pregnant patient prior to delivery is associated with increased neonatal oxygen support and escalated care in the NICU, compared to those without OSA. This highlights the importance of appropriate OSA diagnosis and treatment in order to decrease likelihood of neonatal respiratory complications. Additionally, counseling obese pregnant patients of increased risks of OSA is critical.

Table 1. Neonatal outcomes born to obese mothers with and without OSA.

	Maternal OSA (n=70)	No maternal OSA (n=800)	Chi-squared (χ^2)	p-value
NICU Admission	28 (40%)	163 (20.3%)	14.47	0.00014
Neonatal CPAP requirement	25 (35.7%)	135 (16.9%)	15.22	9.60E-05
Development of TTN	8 (11.4%)	50 (6.5%)	2.774	0.0958
Development of RDS	15 (21.4%)	88 (11%)	6.7069	0.0096
Mechanical ventilation requirement	3 (4.3%)	47 (5.8%)	0.3001	0.5838

503 Fetal and neonatal drug exposure following nipocalimab treatment in pregnant women at risk of EOS-HDFN

Edwin Lam[1], Jocelyn H. Leu[1], Jie Zhou[1], Yuan Xiong[1], Leona Ling[2], Korin Cofsky[1], Umair Amin[1], Waheeda Sirah[1], Shumyla Saeed-Khawaja[2], Arpana Mirza[1], Yosuke Komatsu[1], Jannine Williams[1], Kattayoun Kordy[1], Ricardo Rojo Cella[1], Mahesh N. Samtani[1], An Vermeulen[3]
[1]Janssen Research & Development, LLC, Spring House, PA, [2]Janssen Research & Development, LLC, Cambridge, MA, [3]Janssen Research & Development, a division of Janssen Pharmaceutica NV, Beerse, Antwerpen

OBJECTIVE: Nipocalimab is a fully human, anti-neonatal Fc receptor (FcRn) blocking antibody that is under evaluation for the treatment of early-onset severe hemolytic disease of the fetus and newborn (EOS-HDFN) based on its potential to block placental transfer of FcRn-mediated maternal to fetal IgG alloantibodies, with insignificant placental transfer of nipocalimab itself. To evaluate the placental transfer of nipocalimab in pregnancy, serum nipocalimab concentrations were evaluated in fetal and neonatal participants whose mothers received nipocalimab in the Ph2 UNITY study.

STUDY DESIGN: UNITY is a Ph2, multicenter, open-label, single-arm study evaluating the safety, efficacy, PD, and PK of nipocalimab in 14 pregnancies at high risk of EOS-HDFN who were treated with 30 or 45 mg/kg weekly intravenous nipocalimab from 14 weeks and up to 35 weeks gestational age (GA) with planned deliveries at 37 weeks GA. To evaluate serum nipocalimab concentrations, one blood sample was collected from fetuses during a clinically indicated cordocentesis as well as from neonates in cord blood at birth and venous blood at Week 4 postpartum.

RESULTS: Of the 14 pregnancies, 13 were included in the PK analysis; 1 participant enrolled twice, and only latter was included. Of the 13 pregnancies, 12 resulted in live births, 1 resulted in fetal loss due to IUT, and 6 required cordocentesis. Nipocalimab was detected in 1/5 available fetal samples (0.04 μg/mL) and 1/11 available neonatal

samples at birth (0.7 μg/mL) but was undetectable in all neonates at Week 4 postpartum. The detectable nipocalimab concentrations were observed in a single fetus and in a different single neonate during the study. Neonatal serum IgG was low at birth especially when maternal treatment ended approximately 2 weeks before delivery.

CONCLUSION: These observations imply minimal fetal and neonatal drug exposure upon maternal nipocalimab dosing and that low neonatal IgG may be the result of nipocalimab inhibition of placental IgG transfer. The potential for nipocalimab exposure in the fetus and newborn will be further evaluated in a Ph3 study.

504 Determinants of fetal growth and birth weight: the role of the mother's birth weight

Anne-Laurence Landry[1], Louise Ghesquiere[2], Paul Guerby[3], Emmanuel Bujold[2]

[1]CHU de Québec, Université Laval, Quebec City, QC, [2]Centre de recherche du CHU de Québec-Université Laval, Quebec, QC, [3]Hopital Paule de Viguier, CHU Toulouse, Toulouse III University, Toulouse, Midi-Pyrenees

OBJECTIVE: It is regularly difficult to determine whether the estimated low weight of a fetus is of constitutional origin or secondary to placental dysfunction or other pregnancy problems. A better understanding of the factors associated with limited growth of constitutional origin could help improve the interpretation and management of small for gestational age (SGA) fetuses.

STUDY DESIGN: We carried out a secondary analysis of a prospective study that recruited nulliparous pregnant women in the 1st trimester of pregnancy and followed them through to birth. We assessed the statistical correlation between newborn weight and several factors that may contribute to fetal growth, including maternal and paternal weight and BMI, maternal age, their respective birth weights, blood biomarkers (PAPP-A, PlGF) measured in the 1st trimester, and uterine Doppler. Multiple linear regression analysis was performed to determine significant variables after adjustments.

RESULTS: Among 1766 women recruited, we obtained complete data for 1703 participants. We found a positive and significant correlation between birth weight and the following variables: mother's weight and height, father's weight and height, mother's birth weight, father's birth weight, PlGF and PAPP-A. We found a significant negative correlation with the following variables: maternal age and 1st trimester uterine artery pulsatility index. After adjustment for confounding variables, 4 variables emerged as determinants of birth weight prediction: mother's birth weight ($p< 0.001$), mother's height ($p< 0.001$), PlGF level in the 1st trimester of pregnancy ($p< 0.001$), and maternal age ($p=0.03$).

CONCLUSION: The mother's birth weight and maternal height have an important influence on the birth weight of a newborn, while PlGF in the 1st trimester seems to be the early placental marker with the greatest impact. These factors should be considered when interpreting fetal weight estimates, particularly in cases of SGA.

505 Evaluating the Detection of Ferning with Previable Rupture of Membranes

Michelle Lende, Paul Feustel, Derek Lee, Johanna Bringley, Tara A. Lynch

Albany Medical Center, Albany, NY

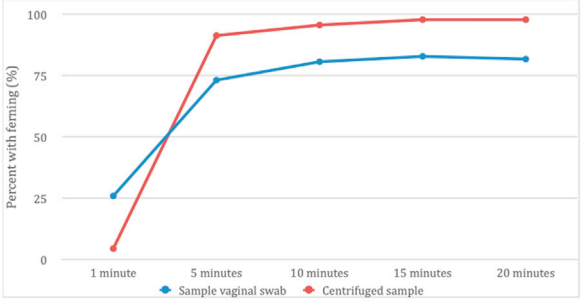
OBJECTIVE: To evaluate the impact of gestational age and drying time on the detection of ferning in vaginal amniotic fluid samples from second trimester pregnancies with rupture of membranes (ROM). Additionally, to evaluate if the use of a centrifuge for removal of red blood cells would improve the detection of ferning.

STUDY DESIGN: A prospective study evaluating vaginal amniotic fluid in individuals undergoing pregnancy termination between 15-24 weeks from 8/1/2021 to 6/9/2023 at a single institution. A control vaginal swab was collected prior to ROM and a sample vaginal swab was collected after ROM at the time of the termination procedure. A 10-ml sample of amniotic fluid was also collected and centrifuged for removal of red blood cells. All samples were analyzed and images captured under a microscope using 10x magnification at 1, 5, 10, 15 and 20 minutes after ROM. Images were assessed for ferning by two blinded investigators with a third reviewer in the case of any discrepancies. Statistical analysis was performed using descriptive statistics and regression analyses.

RESULTS: A total of 99 individuals consented and 93 were included. The mean gestational age was 19.5 weeks (2.6 STDEV). Ferning was not seen during any time point in a total of 14 cases (15.1%). None of the control samples had ferning detected. The detection of ferning increased with longer drying time in a regression analysis (OR 1.2; 95% CI 1.17-1.25). The largest difference was observed between 1 and 5 minutes (25.8% at 1 minute versus 73.1% at 5 minutes). Gestational age did not impact the detection of ferning (OR 1.06; 95%CI 0.98-1.15, $p=0.099$). Overall, ferning was detected more frequently on centrifuged samples than vaginal at all time points (Figure 1).

CONCLUSION: Both drying time and blood impacted the detection of ferning with previable ROM. Optimal detection was seen after allowing drying for 5 minutes and with centrifuge for the removal of red blood cells. These findings may improve the detection of ferning in suspected cases of previable ROM.

Figure 1. The Presence of Ferning in Vaginal Swabs versus Centrifuged Samples in Cases of Known Previable Rupture of Membranes



Statistically significant difference in the detection of ferning at all time points.

506 Association between maternal depression and opioid use following cesarean delivery

Taylor L. Lendrum

University of Utah, Salt Lake City, UT; on behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network, Bethesda, MD

OBJECTIVE: To evaluate whether there is an association between treated or untreated maternal depression and opioid use after cesarean delivery (CD).

STUDY DESIGN: Secondary analysis of a multicenter randomized trial of individuals who underwent CD at 31 U.S. hospitals (2020-22).

We evaluated two primary exposures: self-reported treated depression (pharmacologic or non-pharmacologic therapy during pregnancy) or self-reported untreated depression. The primary outcome was inpatient oral opioid use in morphine milligram equivalents (MME) per day between 12 hours after surgery through hospital discharge. Secondary outcomes included outpatient opioid

use (MME of opioid prescriptions through 6 weeks postpartum) and moderate-severe perceived pain (≥4) and interference in daily activities (≥4) on the Brief Pain Inventory (BPI, 1-10) at 1-week postpartum. Multivariable modeling evaluated the association between untreated or treated depression compared with no depression and the selected outcomes.

RESULTS: Of 5,478 study participants, 1,508 (28%) had depression of whom 663 (44%) were treated. Those with depression were more likely to have a chronic pain condition, use tobacco, and experience disordered sleep. In adjusted modeling, neither treated nor untreated depression was associated with inpatient postpartum MME (Table). Untreated depression, but not treated, was associated with higher MME use through 6 weeks postpartum (adjusted median difference 19.2, 95% CI 11.5-26.8) and higher patient perceived pain severity (Table). Both treated and untreated depression were associated with higher patient perceived pain interference in daily activities.

CONCLUSION: Inpatient postpartum opioid use did not differ by depression (treated or not). However, untreated (but not treated) depression was associated with increased outpatient opioid use and worse perceived pain. This information can inform clinicians when counseling patients. Further, it is notable that only 44% of gravidae in this cohort who reported depression received treatment for it.

Table. Association between untreated or treated depression and opioid use and pain following cesarean delivery

	Untreated depression (N=845)	Treated depression (N=663)	No depression (N=3971)		Untreated depression vs. no depression	Treated depression vs. no depression
		Median [IQR]			MME median difference [95% CI]	
Inpatient MME/day[a]	20.9 [4.9-40]	19.2 [4.5-42.4]	11.8 [0-28.8]	Un	9.1 [6.8,11.4]	7.4 [4.9,10]
				Adj	2.0 [-0.7, 4.7]	-0.1 [-3.2,3]
Outpatient total MME[b]	60.0 [7.5-120]	45.0 [0-112.5]	22.5 [0-90]	Un	37.5 [29.3, 45.7]	22.5 [11.8, 33.2]
				Adj	19.2 [11.5, 26.8]	7.9 [-1.2, 17]
		N (%)			Odds ratio (95% CI)	
BPI pain score ≥ 4[c]	528 (67.7)	407 (66.0)	2080 (57.1)	Un	1.6 [1.3, 1.9]	1.5 [1.2, 1.7]
				Adj	1.4 [1.1, 1.7]	1.2 [0.9, 1.5]
BPI pain interference[d]	418 (53.7)	344 (56)	1602 (44.1)	Un	1.5 [1.3, 1.7]	1.6 [1.4, 1.9]
				Adj	1.4 [1.1, 1.7]	1.4 [1.2, 1.8]

MME, morphine milliequivalent; BPI, brief pain inventory; Un, unadjusted comparisons; Adj, adjusted comparisons
[a]MME per day from 12 hours after surgery to discharge
[b]Total MME used from discharge to 6 weeks post-discharge
[c]BPI worst pain score in prior 24 hours ≥4 at 1 week from discharge
[d]BPI pain interference score ≥4 at 1 week from discharge
The pairwise analysis is presented in unadjusted and adjusted format for median differences for MME/day and total MME and odds ratios for BPI pain and inference. Adjusted for maternal age, chronic pain conditions, delivery body mass index, neuraxial morphine administration, postpartum hemorrhage, disordered sleep, and tobacco and/or substance use.

507 Association of patient health literacy with the decision to pursue trial of labor after cesarean

Daisy Leon-Martinez[1], Anjali J. Kaimal[2], William A. Grobman[3], Miriam Kuppermann[1]
[1]University of California, San Francisco (UCSF), San Francisco, CA, [2]University of South Florida Morsani College of Medicine, Tampa, FL, [3]The Ohio State University, Columbus, OH

OBJECTIVE: To analyze the association of health literacy with electing a trial of labor (TOLAC) and having a vaginal birth after cesarean (VBAC).

STUDY DESIGN: Secondary analysis of a multicenter randomized trial of pregnant people with one prior cesarean and no prior VBAC conducted from 2016-19. Participants were randomized before 25 weeks' gestation to have usual care or use a tablet-based decision support tool focused on TOLAC choice. Baseline health literacy was evaluated using the Newest Vital Sign (NVS) tool. Delivery approach and mode were ascertained via medical record review. Logistic regression (adjusting for primary language, age, recruitment site, and prior vaginal delivery) was performed to estimate the association of limited health literacy (defined as NVS score < =4/6) with TOLAC and VBAC. For TOLAC and VBAC, we elected *a priori* to perform interaction analyses to examine if there was effect modification of health literacy with treatment group or recruitment site.

RESULTS: Among 1455 participants (n=396 limited- and n=1059 adequate-health literacy), 44.6% had a TOLAC, and 71.0% of those who had TOLAC had a VBAC. Compared to participants with adequate health literacy, those with limited health literacy had a similar probability (45.0% vs. 43.7%, p=0.646) of opting for TOLAC. However, participants with limited health literacy who underwent TOLAC had a lower chance of VBAC than those with adequate health literacy (65.1% vs. 73.2%, p = 0.047). After adjusting for covariates, limited health literacy was associated with both TOLAC and VBAC (TOLAC: aOR 0.69, 95% CI [0.51, 0.94], p=0.020; VBAC: aOR 0.54, 95% CI [0.33, 0.88], p=0.013). Pre-specified interaction analyses showed no significant effect modification (p>= 0.10 for all).

CONCLUSION: In this study of pregnant people with a prior cesarean and no prior VBAC, those with limited health literacy had lower odds of TOLAC and VBAC. Given persistently low rates of VBAC in the US and the greater morbidity of cesarean delivery compared to vaginal birth, research is needed to learn if patient- or provider-oriented interventions can mitigate these disparities.

508 Association of health literacy on patient decision quality regarding mode of delivery after cesarean

Daisy Leon-Martinez[1], Cinthia Blat[1], Anjali J. Kaimal[2], William A. Grobman[3], Miriam Kuppermann[1]
[1]University of California, San Francisco (UCSF), San Francisco, CA, [2]University of South Florida Morsani College of Medicine, Tampa, FL, [3]The Ohio State University, Columbus, OH

OBJECTIVE: To assess the association of health literacy with patient decision quality regarding mode of delivery after cesarean.

STUDY DESIGN: Secondary analysis of a multicenter randomized trial of pregnant people with one prior cesarean and no prior vaginal birth after cesarean conducted 2016-19. Participants were randomized before 25 weeks' gestation to use a tablet-based decision support tool focused on the choice between trial of labor after cesarean (TOLAC) and elective repeat cesarean delivery (ERCD) or to having usual care (no tablet) before deciding on a mode of delivery. Health literacy was assessed at enrollment using the Newest Vital Sign (NVS) tool. Validated scales measuring decision quality (knowledge, decisional conflict, shared decision-making, decision self-efficacy, decision satisfaction) were administered by phone at 34-37 weeks' gestation. To assess the association of limited health literacy (defined as NVS score < =4/6) with decision quality, we calculated mean scores for each scale by level of health literacy (limited vs adequate) and estimated adjusted mean differences (aMD) using linear regression. Model covariates were selected by backwards stepwise regression.

RESULTS: Compared to participants with adequate health literacy (n=1059), those with limited health literacy (n=396) had significantly lower knowledge scores (3.9 vs 5.4; aMD -0.8, 95% CI [-1.0, -0.5], p< 0.001). Scores were similar for decisional conflict (17.7 vs 17.2; aMD 0.0, 95% CI [-1.9, 2.0], p=0.971), shared decision-making (76.9 vs 73.9; aMD 1.5, 95% CI [-0.8, 3.8], p=0.196), decision self-efficacy (91.1 vs 90.4; aMD 0.4, 95% CI [-1.4, 2.2], p=0.685) and decision satisfaction (4.7 vs 4.6; aMD 0.4, 95% CI [0.0, 0.1], p=0.328).

CONCLUSION: Individuals with limited health literacy reported similar levels of decision quality compared to those with adequate health literacy but had lower knowledge scores. Future efforts should be

directed towards understanding how best to support informed and values concordant decision making for individuals with limited health literacy.

509 Association of non-English primary language with patient decision quality regarding mode of delivery after cesarean

Daisy Leon-Martinez[1], Cinthia Blat[1], Anjali J. Kaimal[2], William A. Grobman[3], Miriam Kuppermann[1]
[1]University of California, San Francisco (UCSF), San Francisco, CA, [2]University of South Florida Morsani College of Medicine, Tampa, FL, [3]The Ohio State University, Columbus, OH

OBJECTIVE: To analyze the association of non-English primary language (NEPL) with patient decision quality regarding mode of delivery after cesarean.

STUDY DESIGN: Secondary analysis of a multicenter randomized trial of pregnant people with one prior cesarean and no prior vaginal birth after cesarean conducted 2016-19. Participants were randomized before 25 weeks' gestation to use a tablet-based decision support tool focused on trial of labor after cesarean (TOLAC) choice or to have usual care before electing a mode of delivery. Primary language was self-reported at enrollment. Validated scales measuring decision quality (decisional conflict, decision self-efficacy, decision satisfaction, knowledge, and shared decision-making) were administered by phone at 34-37 weeks' gestation. To assess the association of NEPL (defined as use of non-English for primary language communication) with decision quality, we calculated mean scores for each scale by NEPL status and estimated adjusted mean differences (aMD) by using linear regression. Model covariates were selected by backwards stepwise regression.

RESULTS: Compared to those who used English as their primary language (n = 1037), those with NEPL (n = 248) had significantly higher scores for decisional conflict (20.9 vs 16.7; aMD 4.1, 95% CI [1.9, 6.4], $p< 0.001$). Decision self-efficacy (88.6 vs 90.9; aMD -3.9, 95% CI [-5.9, -1.8], $p< 0.001$) and decision satisfaction (4.6 vs 4.7; aMD -0.1, 95% CI [-0.2, 0.0], $p=0.013$) were both worse (as indicated by lower scores) for NEPL participants. The aMD for knowledge scores (0.0, 95%CI [-0.3, 0.3), $p=0.956$) and shared decision-making scores (-1.1, 95%CI [-3.7, 1.6], $p=0.426$) were similar between the two groups.

CONCLUSION: In the context of decision making regarding TOLAC, NEPL participants had lower decision quality scores compared to those who used English as their primary language. Given the association of NEPL with decreased participation in shared decision-making and poorer healthcare outcomes, further research is needed to understand the experience of NEPL individuals and improve counseling strategies to mitigate disparities.

510 Congenital pulmonary airway malformations and bronchopulmonary sequestrations: features of prenatal evaluation that predict postnatal surgery

Hannah Light-Olson[1], Harold Lovvorn[2], Heidi Chen[2], Jan Niec[1], Lisa C. Zuckerwise[2]
[1]Vanderbilt University School of Medicine, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN

OBJECTIVE: Congenital pulmonary airway malformations (CPAM) and bronchopulmonary sequestrations (BPS) are residual masses of embryonic lung bud anomalies that can be detected on prenatal ultrasound. When indicated, postnatal resection is performed to alleviate respiratory symptoms or prevent recurrent pneumonias. Beyond increased CPAM-volume ratio (CVR), prenatal sonographic features of CPAM/BPS that herald postnatal symptoms remain elusive. This study sought to identify prenatal characteristics that predict need for postnatal surgery for fetuses with CPAM/BPS.

STUDY DESIGN: The maternal-fetal medicine database of a quaternary medical center was queried for pregnancies diagnosed with CPAM or BPS from January 2004 to November 2022. Patient and disease characteristics were collected from the paired medical records of pregnant patient and child. Initial and final prenatal ultrasounds were reviewed. Appropriate statistical methods were applied to categorical and continuous variables.

RESULTS: From 9,699 records at a single high-volume fetal center, we identified 122 pregnancies with a diagnosis of CPAM or BPS on prenatal ultrasound. Outcomes for 19 cases were unknown or pending and were excluded. Of 103 fetuses with known outcomes, 60 (58%) underwent postnatal surgery and 43 (42%) did not. A higher CVR predicted likelihood of surgery ($p=0.05$). Presence of cardiac displacement on last ultrasound before birth associated with surgery ($p=0.027$), while cardiac displacement on initial ultrasound did not ($p=0.18$). CPAM/BPS type, sonographic appearance of the mass, and indicators of non-immune hydrops were not associated with surgical management. Steroid administration prenatally trended towards greater CVR reduction for pathology-proven CPAM than BPS, but this did not reach statistical significance. Median follow up time of the cohort was 4.5 [1.8-9.2] years.

CONCLUSION: Late gestation cardiac displacement may predict increased risk of surgical intervention — an association not previously described. This study adds to existing literature demonstrating a positive association between CVR and postnatal surgery.

511 Comparing the yield of meaningful findings in targeted versus genome-wide cell free DNA screening

Gabriella Lobitz[1], Emily B. Rosenfeld[2], Shama Khan[2], Todd J. Rosen[2], Elena Ashkinadze[2]
[1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [2]Robert Wood Johnson Medical School, Rutgers University, New Brunswick, NJ

OBJECTIVE: Over 2 million cell free DNA (cfDNA) screens have been performed since the technology was introduced to clinical practice in 2011. Currently, three unique cfDNA screening modalities are available and range from targeted screens to genome wide. The objective of this study was to determine if genome wide cfDNA screening reveals clinically meaningful results at a higher rate than targeted cfDNA screening.

STUDY DESIGN: We conducted a retrospective cohort study that included all subjects who underwent cfDNA screening at a single academic center between 5/1/2016 and 4/1/2023. A retrospective chart review was performed to identify all screens that yielded abnormal results. Outcomes were compared between three cfDNA screening modalities: 5-cfDNA screens that detect abnormalities in chromosome 13, 18, 21 X and Y, 5-cfDNA plus selected microdeletions, and genome wide cfDNA screens.

RESULTS: 9,062 patients underwent cfDNA screening at a single institution. 1,502 were 5-cfDNA screens, 4,257 5-cfDNA and microdeletion screens and 3,303 were genome wide screens. 146 (1.6%) screens were abnormal. Of the 146 abnormal results, 118 (80.8%) would have been detected by the 5-cfDNA screen. An additional yield of 19.2% was noted when screening beyond the five most common aneuploidies. The 5-cfDNA and common microdeletion screens had an incremental yield of 8.2% (12/146) and 387 patients need to be screened for one clinically meaningful finding. There is a further 11.0% (16/146) additional yield when genome-

wide cfDNA screening was performed. Compared to 5-cfDNA screen, 254 patients needed to be screened with whole genome cfDNA to find had an additional yield of 11.0% (16/146). Most abnormal results in this category ended in first trimester loss, one ended in termination and two had live births. (Table 1).

CONCLUSION: There is an addition 21.9% yield in screening beyond the common five chromosomes. More than half of that additional yield comes from genome-wide cfDNA screens. The number needed to screen may be considered when selecting a cfDNA screen.

Table 1: Abnormal results and outcomes by screen category

Test category	cfDNA result	Invasive testing	Outcome
5-cfDNA with microdeletions	microdeletion 15q11.2	Normal	Unknown
	microdeletion 22q11.2	Normal	First trimester loss
	microdeletion 1p36	Normal	Live birth
	Duplication 22q11.21	Not done	Maternal in nature
	Deletion 22q11	Not done	Live birth
	Nonspecific multichromosomal CNVs	Normal	Live birth, maternal cancer diagnosis
	Trisomy 22	Not done	First trimester loss
	Trisomy 22	Unknown	Unknown
	Trisomy 22	Not done	First trimester loss
	Trisomy 22	Not done	First trimester loss
	Trisomy 22	Unknown	First trimester loss
	Trisomy 16	Not done	First trimester loss
Genome-Wide	Trisomy 4	Not done	First trimester loss
	Duplication of 5p	Not done	Unknown
	Chromosome 8 duplication	Not done	Live birth, maternal origin
	Trisomy 8 mosaic	Not done	Live birth
	Trisomy 8	Unknown	Unknown
	Loss of chromosome 10	Unknown	Unknown
	Trisomy 10	Normal	Live birth
	Trisomy 11	Not done	Unknown
	Trisomy 14	Not done	First trimester loss
	Trisomy 15	Not done	First trimester loss
	Trisomy 15	Not done	First trimester loss
	Trisomy 15	Not done	Termination
	Trisomy 15	Not done	First trimester loss
	Trisomy 13/Trisomy 20	Normal	Unknown
	Mosaic Trisomy 20	Normal	Unknown
	Trisomy 20	Not done	First trimester loss

512 Differences in Evidence-Based Induction of Labor Practices by Race

LeAnn A. Louis[1], Anita M. Malone[2], Rebecca F. Hamm[3], Jourdan E. Triebwasser[4]

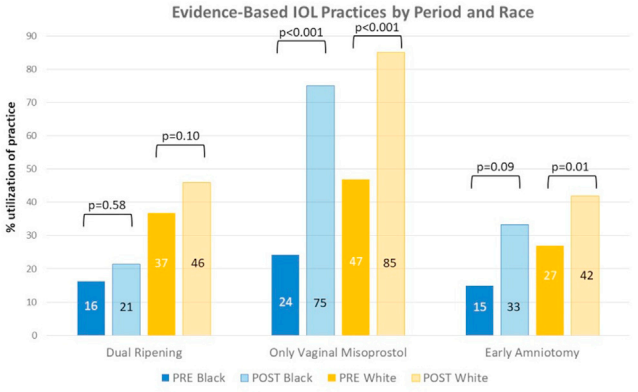
[1]University of Michigan Hospital System, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [4]University of Michigan, Ann Arbor, MI

OBJECTIVE: Limited data suggests standardized induction of labor (IOL) improves outcomes for Black birthing people. To assess the impact and uptake of a standardized protocol for IOL by self-reported race.

STUDY DESIGN: We conducted a single center quality improvement project to examine the impact of standardizing IOL with use of 3 evidence-based practices: 1) dual agent cervical ripening with foley; 2) vaginal misoprostol instead of buccal; and 3) early amniotomy ($\leq$ 4 cm). We compared IOL length and cesarean before-implementation (PRE, 11/1/21-1/31/22) and after (POST, 3/1/22-4/30/22). Singleton IOL with intact membranes, initial cervical dilation $\leq$ 2 cm, and self-reported non-Hispanic (NH) Black or NH White race/ethnicity were included. Prior cesarean and stillbirth were excluded. Chi-squared and rank sum tests were used for bivariate comparisons. Time to delivery was compared PRE to POST with Cox proportional hazard models, stratified by race, adjusting for nulliparity, age, and body mass index (BMI).

RESULTS: Of 407 included, 18.9% (N=77) were NH Black and 81.1% where NH White (N=330). NH Black patients were younger (29.5 vs. 31.6 years, p< 0.01), had higher BMI (35.5 vs. 31.3 kg/m^2, p< 0.01), and were less likely to be nulliparous (42.9% vs. 59.6%, p< 0.01). There was a significant increase in use of only vaginal misoprostol for both groups (p< 0.01) and early amniotomy among NH White (p=0.01, **Figure**). IOL length decreased among NH White (21.3 [IQR 13.2-31.0] vs. 18.3 h [IQR 12.3-25.3], p=0.02); the difference was not significant for NH Black (22.9 [IQR 14.2-29.2] vs. 20.0 h [IQR 13.4-29.8], p=0.53). After adjustment, time to delivery was shorter for NH White (HR 1.52, 95% CI 1.21-1.91) but not NH Black (HR 1.30, 95% CI 0.79-2.12). This may be due to limited sample size. Cesarean birth was no different PRE vs. POST for NH Black (22.5 vs. 28.6%, p=0.55) or NH White (28.6 vs. 26.3%, p=0.64).

CONCLUSION: Standardizing IOL has the potential to improve IOL and limit biases in care; however, barriers to implementation of evidence-based practices need to be addressed to optimize outcomes for Black pregnant people.



513 Association between maternal anemia and postpartum depression in women with vaginal delivery

Lola Loussert[1], Loïc SENTILHES[2], Alizée Froeliger[3], Marie-Pierre Bonnet[4], Aurélien Seco[4], Sarah Tebeka[5], Catherine Deneux-Tharaux[4]

[1]Toulouse University Hospital, France, Toulouse, Midi-Pyrenees, [2]CHU Bordeaux, Bordeaux University Hospital, Aquitaine, France, [3]CHU Bordeaux, Bordeaux University Hospital, Bordeaux, Aquitaine, [4]Université Paris Cité, Perinatal Obstetrical and Pediatric Epidemiology Research Team (EPOPé), Center for Research on Epidemiology and Statistics (CRESS), INSERM, Paris, Ile-de-France, [5]Department of Psychiatry, AP-HP, Louis Mourier Hospital, Colombes, Ile-de-France

OBJECTIVE: Prevention of postpartum depression(PPD) requires an understanding of its risk factors, particularly those that can be modified. Our objective was to assess the association between maternal anemia in the immediate postpartum and PPD 8 weeks after vaginal delivery.

STUDY DESIGN: Ancillary cohort study of the TRAAP trial, a French multicentric trial conducted in 2015-2016, which included women with a singleton pregnancy and vaginal delivery $\geq$ 35 weeks. The primary outcome was PPD at 8 weeks postpartum, defined as an Edinburgh Postpartum Depression Scale(EPDS) score $\geq$ 11. The exposure was the latest maternal hemoglobinemia measured in the postpartum before discharge(available per TRAAP trial's protocol). We assessed the association between hemoglobin and PPD with multivariable logistic regression. A sensitivity analysis differentiated 2 levels of PPD severity: moderate(11$\leq$ EPDS< 13) and severe(-EPDS$\geq$ 13) depressive symptoms.

RESULTS: Among the 2672 women included, 1115(43.6%) had postpartum anemia(hemoglobin< 11g/dL) and 369(13.8%) had PPD at 8 weeks. The relation between hemoglobinemia and PPD was linear. In multivariable analysis, the risk of PPD increased by 10% for each 1g/dL decrease in hemoglobinemia (aOR=0.90[0.81-0.998]). Sensitivity analysis showed that postpartum hemoglobinemia was associated with the risk of moderate depressive symptoms(18% increase for each 1g/dL reduction in hemoglobinemia) but not with severe depressive symptoms. We found a significant interaction with maternal place of birth: associations were found in European-born women but not in non-European-born women, in whom the prevalence of PPD was much higher.

CONCLUSION: This study shows an association between hemoglobin level in the immediate postpartum period and PPD at 8 weeks, with a 10% increase in the risk of PPD for each 1g/dL reduction in hemoglobin. This association specifically concerns moderate depressive symptoms and European-born women. These results emphasize the importance of precise characterization of PPD risk factors to improve its prevention. This study highlights the importance of correcting postpartum anemia.

514 Etiology of Severe Early-Onset Fetal Growth Restriction: Implications for Prenatal Diagnosis (The Multicenter PERIMETER Study)

Rocco Cuzzilla[1], David Mackin[1], Roisin McConnell[2], Karen O'Neill[3], Ronan Daly[4], Laura Ryan[2], Zara Molphy[1], Denisa Ramona Asandei[5], Elizabeth Murphy[3], Rebecca Hunter[3], Genevieve Leon[4], Anne Doolan[3], Stephen Carroll[2], Michael Boyle[4], Carmen Regan[3], Anne Twomey[2], Fergal D. Malone[4]
[1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]National Maternity Hospital, Dublin, Ireland, [3]Coombe Womens and Infants University Hospital, Dublin, Ireland, [4]Rotunda Hospital, Dublin, Ireland, [5]RCSI Rotunda, Dublin, Ireland

OBJECTIVE: Severe early onset fetal growth restriction (EO-FGR) represents a particularly challenging obstetric cohort. The PERIMETER Study collated prenatal diagnostic, obstetric and neonatal outcome data on all EO-FGR cases, with the objective being to analyze the etiology of these most severe cases.

STUDY DESIGN: The PERIMETER Study collected all singleton cases of EO-FGR confirmed by ultrasound between 18^0 and 27^6wks, at the three largest tertiary referral obstetric hospitals in one city from July 2016 to June 2020. FGR diagnosis was confirmed using electronically-stored ultrasound data, with international Delphi consensus criteria used for diagnosis, including biometry and Doppler data. Data relate to ultrasound parameters determined at the time of initial FGR diagnosis.

RESULTS: The PERIMETER Study included 445 cases of severe EO-FGR. Causes of EO-FGR included: uteroplacental (319, 72%), major structural fetal anomalies (71, 16%), genetic abnormalities (54, 12%) and congenital infection (parvovirus) in 1 (< 1%) case. Aneuploidy (42/54; 78%) was the most common genetic abnormality. FGR diagnosis was made later in pregnancy in uteroplacental cases compared with all other causes (mean 24.5 (SD 2.4) v 22.9 (SD 2.5) weeks' gestation; p< 0.001). Abdominal circumference (AC) or estimated fetal weight (EFW) < 3rd centile identified the majority of cases from any cause, including uteroplacental (235/319; 74%) and other causes combined (117/126; 93%). Umbilical artery Doppler abnormalities at sentinel scan were less common in cases of structural fetal anomaly or genetic abnormality (20/125, 16%) compared with uteroplacental cause (129/319, 40%) (p< 0.001).

CONCLUSION: Non-uteroplacental causes account for nearly one-third of all cases of severe EO-FGR, and should therefore be considered in the diagnostic work-up of all such cases. AC or EFW < 3rd centile at initial FGR diagnosis, in particular when combined with reassuring umbilical artery Doppler assessment, should prompt consideration for invasive genetic testing.

Table: Causes and ultrasound diagnostic criteria for early-onset FGR

Cause	Ultrasound criteria for early-onset FGR diagnosis				
	AC <3rd centile	EFW <3rd centile	UA EDF abnormality	AC <10th centile and UA PI >95th centile	EFW <10th centile and UA PI >95th centile
Uteroplacental, n=319	129 (40%)	197 (62%)	38 (12%)	72 (23%)	91 (29%)
Structural fetal anomaly[a], n=71	33 (46%)	58 (82%)	1 (1%)	9 (13%)	10 (14%)
Genetic abnormality[*], n=54	34 (63%)	49 (91%)	2 (4%)	5 (9%)	6 (11%)
Congenital infection (parvovirus), n=1	1 (100%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)

[a]Structural malformations: neurological, n=16; cardiovascular, n=11; multisystem, n=10; gastrointestinal, n=9; lung, n=4; genitourinary, n=3; skeletal dysplasia, n=15 (non-lethal, n=8; lethal, n=3; unspecified, n=4) and other musculoskeletal, n=3.
[*]Genetic abnormality: aneuploidy, n=42 (T21, n=10; T18, n=20; T13, n=4; 45,X, n=2; triploidy, n=6); other genetic, n=12.

515 Association of unintended pregnancy with pre-pregnancy and pregnancy-related healthcare utilization

Nigel Madden[1], Madeline F. Perry[2], Timothy Wen[3], Lynn M. Yee[4], Ashish Premkumar[5]
[1]McGaw Medical Center of Northwestern University, Chicago, IL, [2]Northwestern University, CHICAGO, IL, [3]University of California, San Francisco (UCSF), San Francisco, CA, [4]Northwestern University, Chicago, IL, [5]University of Chicago, Chicago, IL

OBJECTIVE: Unintended pregnancy is associated with adverse pregnancy outcomes. Decreased access to or engagement in pre-pregnancy or pregnancy care may underlie this relationship. We aimed to evaluate the association between unintended pregnancy and healthcare utilization before and during pregnancy.

STUDY DESIGN: This was a cross-sectional analysis of the Pregnancy Risk Assessment Monitoring System (2016-2020) respondents with singleton live births. The primary exposure was unintended pregnancy including respondents who reported ambivalence, had mistimed, or had undesired pregnancies. Outcomes included key metrics of pre-pregnancy and pregnancy-related health care utilization. Multivariable models controlled for significant (p< 0.05) sociodemographic and comorbidity differences. A subgroup analysis

examined these relationships in respondents with undesired pregnancy compared to intended pregnancy. All analyses were population weighted.

RESULTS: The weighted population included 9 million respondents, of whom 40.5% reported unintended pregnancy and 6.2% reported undesired pregnancy. In the 12 months prior to pregnancy, respondents with unintended pregnancy were less likely to have seen an Obstetrician/Gynecologist or to have had a discussion with a health care worker about their desire to become pregnant or the need to optimize medical comorbidities prior to pregnancy when compared to those with intended pregnancy (Table). During/after pregnancy, they were less likely to initiate prenatal care in the first trimester, receive adequate prenatal care, receive the flu vaccine, and attend a postpartum visit (Table). On secondary analysis, these findings were even more pronounced in respondents with undesired pregnancy. In contrast, postpartum contraception use was higher among individuals with unintended or undesired pregnancy.

CONCLUSION: Unintended pregnancy is associated with less optimal obstetric healthcare utilization. These data can be used to develop public health measures targeting barriers to care in this population, particularly as unintended pregnancy is likely to rise in the current political landscape.

516 Association of unintended pregnancy and maternal and neonatal outcomes: Evaluation in a contemporary cohort

Nigel Madden[1], Madeline F. Perry[2], Ashish Premkumar[3], Lynn M. Yee[4], Timothy Wen[5]

[1]McGaw Medical Center of Northwestern University, Chicago, IL, [2]Northwestern University, CHICAGO, IL, [3]University of Chicago, Chicago, IL, [4]Northwestern University, Chicago, IL, [5]University of California, San Francisco (UCSF), San Francisco, CA

OBJECTIVE: Nearly half of births in the United States are unintended, a metric that may rise with increasing abortion restrictions. Prior data demonstrated an association between unintended pregnancy and adverse birth outcomes among individuals who have live births. Our objective was to evaluate this relationship in a contemporary cohort of birthing individuals.

STUDY DESIGN: This was a cross-sectional analysis of the Pregnancy Risk Assessment Monitoring System (2016-2020) respondents with singleton live births. The primary exposure was unintended pregnancy including respondents who reported ambivalence, had mistimed, or had undesired pregnancies. Outcomes included adverse maternal and neonatal outcomes. Multivariable models controlled for significant ($P< 0.05$) sociodemographic and comorbidity differences. A subgroup analysis examined these relationships in respondents with undesired pregnancy compared to intended pregnancy. All analyses were population weighted.

RESULTS: The weighted population included 9 million respondents, of whom 40.5% reported unintended pregnancy and 6.2% reported undesired pregnancy. On adjusted analyses, unintended pregnancy, was significantly associated with adverse maternal outcomes (Table). Respondents with unintended pregnancy had greater odds of depression, both during pregnancy (aOR 1.51, 95% CI 1.42-1.60) and postpartum (aOR 1.28, 95% CI 1.21-1.35), intimate partner violence during pregnancy (aOR 1.18, 95% CI 1.04-1.35), and lower odds of breastfeeding for more than three months (aOR 0.89, 95% CI 0.85-0.92) compared to those with intended pregnancy. Neonatal outcomes did not differ by pregnancy intendedness. On subgroup analysis of respondents with undesired pregnancy, these findings were more pronounced, and they had 18% higher odds of developing a hypertensive disorder of pregnancy.

CONCLUSION: Unintended pregnancy, particularly when undesired, is associated with adverse maternal outcomes in this contemporary cohort. This risk factor for maternal morbidity is particularly relevant in the current political landscape and highlights the importance of preserving abortion access.

Table: Multivariate models for relationship of unintended pregnancy with maternal and neonatal outcomes[1,2]

517 Factors associated with unintended pregnancy: A cross-sectional evaluation in a contemporary cohort

Nigel Madden[1], Madeline F. Perry[2], Lynn M. Yee[3]
[1]McGaw Medical Center of Northwestern University, Chicago, IL, [2]Northwestern University, CHICAGO, IL, [3]Northwestern University, Chicago, IL

OBJECTIVE: Unintended pregnancy is associated with adverse birth outcomes. Recent restrictions on access to abortion make understanding factors associated with experiencing an unintended pregnancy especially important. Our objective was to understand the association between maternal demographic and socioeconomic factors and unintended pregnancy.

STUDY DESIGN: This was a cross-sectional analysis of Pregnancy Risk Assessment Monitoring System (2016-2020) respondents with singleton live births. The primary outcome was unintended pregnancy (including respondents who reported they were ambivalent, had mistimed, or had undesired pregnancies). Multivariable models estimated the independent association between demographic and socioeconomic variables and unintended pregnancy. A conceptual framework based on the US Department of Health and Human Services Healthy People 2030 domains of social determinants of health was used to select variables. Secondary analyses examined these relationships in respondents with undesired pregnancy. All analyses were population weighted.

RESULTS: The weighted population included 8.6 million respondents, of whom 40% reported unintended pregnancy including 6.2% with undesired pregnancy. Among demographic factors, young maternal age and non-Hispanic Black race had the highest association with unintended pregnancy (Table). Social/community and economic factors, including being unmarried, greater number of prior live births, greater number of dependents, Medicaid or lack of insurance, and lower income, were also significantly associated. Education of less than 12 years was associated with lower odds of unintended pregnancy. Similar associations were seen with undesired pregnancy with the addition of advancing maternal age.

CONCLUSION: Multiple demographic and socioeconomic factors that are markers for inequity and lower access to resources are associated with unintended pregnancy. Findings highlight populations that are vulnerable to the adverse consequences of unintended pregnancy, which is of particular importance in the era of restricted reproductive freedom.

518 Association between neighborhood poverty and adverse birth outcomes

Nigel Madden[1], Samanvi Kanugula[2], Lynn M. Yee[2], Joe M. Feinglass[2]
[1]McGaw Medical Center of Northwestern University, Chicago, IL, [2]Northwestern University, Chicago, IL

OBJECTIVE: Community-level factors, including neighborhood deprivation, have been associated with adverse birth outcomes. Our objective was to evaluate the association between area poverty and birth outcomes in a large cohort of diverse birthing persons residing in a metropolitan area in the Midwest.

STUDY DESIGN: This was a retrospective study of birthing persons delivering at one large metropolitan health system, including a large academic medical center and eight community hospitals, from 1/

2018-7/2023. The primary exposure was area poverty rate which was identified by matching patient zip codes at delivery hospitalization to the American Community Survey Zip Code Tabulation Area (ZCTA) data. The ZCTA data were coded for percentage of households living at or below the federal poverty level and categorized as < 5%, 5-9.9%, 10-19.9%, or ≥20%. Outcomes included adverse maternal and neonatal outcomes. Multivariable models controlled for socio-demographic and comorbidity differences.

RESULTS: Our cohort included 84,512 deliveries with 48.5% who lived in areas with < 5% poverty, 30.3% who lived in areas with 5-9.9% poverty, 16.4% who lived in areas with 10-19.9% poverty, and 4.7% who lived in areas with ≥20% poverty. Of birthing persons living in areas with the highest poverty rates, 98% delivered at the academic hospital. On adjusted analyses, living in an area with poverty rates ≥20% was significantly associated with increased risk of hypertensive disorders of pregnancy (aIRR 1.33, 95% CI 1.17-1.51), complication after vaginal birth (aOR 1.15, 95% CI 1.03-1.28) and cesarean birth (aIRR 1.16, 95% CI 1.01-1.34), preterm birth (aIRR 1.14, 95% CI 1.01-1.27), low birth weight (aIRR 1.20, 95% CI 1.06-1.36), and admission to the neonatal intensive care unit (aIRR 1.44, 95% CI 1.30-1.60, Table).

CONCLUSION: Neighborhood poverty was independently associated with adverse maternal and neonatal outcomes, even after accounting for other adverse social determinants of health. Findings are relevant as health systems seek to develop quality initiatives and community interventions to improve outcomes for vulnerable populations.

[7]Severe maternal morbidity, as defined by the CDC, includes hysterectomy, transfusion, sepsis, shock, eclampsia, disseminated intravascular coagulation, severe anesthesia complication, acute renal failure, amniotic fluid embolism, acute myocardial infarction, cardiac arrest, pulmonary edema, heart failure, adult respiratory distress syndrome, and cerebrovascular accident

519 Cost-effectiveness of first trimester ultrasound for identifying congenital anomalies in states with 16-20-week abortion bans

Ava Mandelbaum, Amelia H. Gagliuso, Isabel Katlaps, Uma Doshi, Aaron B. Caughey

Oregon Health & Science University, Portland, OR

OBJECTIVE: Fetal anomalies contribute significantly to infant morbidity in the United States. In states with 16-20-week abortion bans, the standard practice of identifying fetal anomalies in the second trimester limits an individual's pregnancy decision-making. This study aimed to evaluate the cost-effectiveness of a universal first-trimester ultrasound among pregnant individuals in the setting of abortion restrictions.

STUDY DESIGN: A decision-analytic model was built using TreeAge software to evaluate the cost-effectiveness of first-trimester ultrasound in states with 16-20-week abortion bans. Our theoretical cohort included 1,500,000 individuals to represent the annual number of pregnancies in 19 states with bans to date. Fetal anomalies were categorized as lethal or major. Outcomes included abortion, stillbirth, maternal death, preeclampsia, and neonatal death. The cost-effectiveness threshold was set at $100,000/QALYs. Model inputs were derived from the literature, and sensitivity analyses were used to assess the robustness of the results.

RESULTS: In our theoretical model, 3,960 lethal and 7,875 major anomalies were identified in the first trimester (Table 1). Relative to the standard second-trimester scan, the first-trimester ultrasound strategy was associated with 8,318 more first-trimester abortions, 1,970 fewer out-of-state second-trimester abortions, 266 fewer cases of preeclampsia, 831 fewer stillbirths, and 1,952 fewer neonatal deaths. First-trimester ultrasound led to 1,555 and 3,160 fewer live births with lethal and major anomalies, respectively. First-trimester ultrasound was the dominant strategy, with a 2.2 billion reduction in costs and an increase in 25,830 QALYs. The results were robust over a wide range of assumptions on sensitivity analyses.

CONCLUSION: Universal first-trimester ultrasound in states with abortion bans is cost-saving, resulting in improved neonatal outcomes, decreased healthcare costs, and improved quality of life. These findings may inform clinical practice and policies to improve individual and societal outcomes in the context of restricted healthcare access.

Table 1: Outcomes for first versus second trimester ultrasound for all pregnant individuals in states with a 16-20-week abortion ban among a theoretical cohort of 1,500,000 people

	First-Trimester Ultrasound	Second-Trimester Ultrasound	Difference
First-trimester diagnosis of lethal anomaly	3,960	0	↑ 3,960
First-trimester diagnosis of major anomaly	7,875	0	↑7,875
Abortion first-trimester	8,318	0	↑ 8,318
Abortion second-trimester, out-of-state	4.367	6,337	↓1,970
Maternal death	107	107	0
Stillbirth	7,523	8,355	↓ 831
Preeclampsia	56,427	56,694	↓ 266
Neonatal death	4,581	6,533	↓ 1,952
Live birth with lethal anomaly	830	2,384	↓ 1,555
Live birth with major anomaly	15,444	18,604	↓ 3,160
Cost	$9,933,145,877	$12,123,260,828	↓ $2,190,114,951
Effectiveness	40,407,105	40,381,275	↑ 25,830

520 Could Environmental Heat Exposure Contribute to Fetal Growth Dysregulation?

Madhumitha Manivannan[1], Melanie Mitta[2], Howard H. Chang[3], Noah Scovronic[3], Saria hassan[1], Carolynn Dude[4], Suchitra Chandrasekaran[5]

[1]Emory University School of Medicine, Atlanta, GA, [2]Nemours Foundation, Atlanta, GA, [3]Emory Rollins School of Public Health, Atlanta, GA, [4]Emory University, Atlanta, GA, [5]Emory University School of Medicine, Decatur, GA

OBJECTIVE: Evidence suggests increased heat exposure is associated with adverse fetal outcomes such as preterm birth & stillbirth. Less is known about the impacts of heat exposure on fetal growth restriction (FGR). We investigated if 1st trimester (Tri1) or 2nd trimester (Tri2) maximum (Tmax), minimum (Tmin), average (Tavg), or ambient (AT) temperatures experienced during pregnancy were associated with a diagnosis of FGR.

STUDY DESIGN: We performed a retrospective cohort study of pregnant subjects who received prenatal care & delivered at an urban hospital between 1/2016-3/2022. Those diagnosed with FGR were identified with ICD-10 codes from an institutional database. Zip-code level Tri1 & Tri2 Tmax, Tmin, Tavg, & AT were derived from 1 km gridded Daymet products & reported in degrees Celsius. After testing for normality, median temperature values were compared among those with & without FGR using the Wilcoxon Rank Sum Test. Categorical variables were compared using Chi Square Test.

RESULTS: Of N=14336 subjects, 10.5% (n=1499) had FGR (Table 1a). Those with FGR had a higher Tri2 Tmax & Tavg vs without FGR (Table 1b). No significant differences in Tri1 Tmax, Tri1/Tri2 Tmin or AT were noted among those with & without FGR (Table 1b). We also investigated whether low birth weight (LBW) defined as birth weight (BW) < 2500 kg or very low birth weight (VLBW) defined as BW < 1500kg associated with heat exposure. Those with VLBW vs without had a higher Tri2 AT *(20.27[IQR 12.55-26.18] vs 18.87[IQR 11.89-25.54], p=.05)* & Tavg *(19.56 [IQR 12.48-24.5] vs 18.34 [IQR 11.97-24.05], p=.05)*.

CONCLUSION: Our data innovatively suggests higher heat exposure in the 2nd trimester may mechanistically impact placental function & fetal growth dysregulation. Our data utilized ICD-10 coding for FGR diagnosis; hence, FGR could have been under-coded & therefore the association may even be stronger, a possibility highlighted by the stronger relationship between VLBW & heat exposure. These hypothesis generating data demonstrate significant need for future studies to investigate the role of heat exposure in fetal growth and development.

521 Association of obstetric comorbidity index with postpartum hemorrhage in a large health system

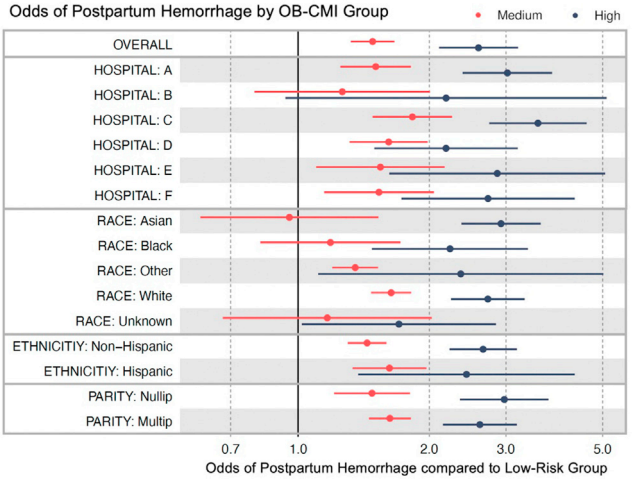
Logan Mauney, Kaitlyn E. James, Damilola M. Shobiye, Christina M. Duzyj Buniak, Sarah Rae Easter, Mark A. Clapp
Massachusetts General Hospital, Boston, MA

OBJECTIVE: Postpartum hemorrhage (PPH) is the leading cause of severe maternal morbidity in the United States and of maternal mortality worldwide, but existing risk-prediction tools have low sensitivity and specificity. We sought to examine whether the Obstetric Comorbidity Index (OB-CMI), which has been validated to predict severe maternal morbidity, was associated with PPH in a large health system.

STUDY DESIGN: This retrospective cohort study included all patients admitted for delivery at ≥24 weeks gestational age between 3/2021 and 11/2022 at 8 hospitals in an integrated healthcare system with an OB-CMI score recorded on admission. Patients were categorized into low- (OB-CMI ≤2), medium- (OB-CMI 3-5), and high-risk (OB-CMI ≥6) categories. Logistic regressions were used to assess the odds of PPH (estimated blood loss, EBL ≥1000 mL) by OB-CMI category with standard errors clustered at the level of the hospital. The odds of PPH by OB-CMI category were also compared among the following subgroups to evaluate if the associations varied: hospital, self-reported race, self-reported ethnicity, parity.

RESULTS: 24,877 patients were included: 18,639 (74.9%) were low-risk, 4,831 (19.4%) were medium-risk, and 1,407 (5.7%) were high-risk. The rates of PPH were 8.9%, 12.6%, and 20.3% in the low-, medium-, and high-risk groups. The odds ratio of PPH for medium- and high-risk groups were 1.47 (95% CI 1.31-1.65) and 2.60 (95% CI 2.10-3.22). Similar magnitudes of effect were seen when the logistic models were stratified by hospital, race, ethnicity, and parity (Figure 1), though sample size limited the ability to fully evaluate all hospital and race subgroups.

CONCLUSION: In a large healthcare system, OB-CMI was reliably associated with PPH. Future work should compare this tool to other hemorrhage risk stratification tools to determine how these tools can be accurately and effectively used to prevent PPH and associated morbidity.



522 Femur Length Correlates With Growth Restriction, Low Birthweight In Smokers: Secondary Analysis Of STOP RCT

Brendan McDonnell[1], Patrick Dicker[2], Carmen Regan[3]
[1]Coombe Womens and Infants University Hospital, Dublin, Dublin, [2]Royal College of Surgeons in Ireland, Dublin, Ireland, [3]Coombe Womens and Infants University Hospital, Dublin, Ireland

OBJECTIVE: Cigarette smoking is associated with a 3.5 fold increased risk of low birthweight. Smoking induces a late-onset pattern of fetal growth restriction (FGR). This study compares fetal biometry at two timepoints in the 3rd trimester with birthweight in pregnancies complicated by smoking.

STUDY DESIGN: This is a secondary analysis of Smoking Cessation Through Optimization of clinical care in Pregnancy (STOP) RCT, which tested a novel antenatal clinic for pregnant smokers. Singleton pregnancies smoking ≥1 cigarette daily were recruited prior to 20 weeks gestation at an urban maternity hospital. Ultrasound screening for FGR was performed at 32 and 36 weeks.

RESULTS: **436** women participated in the STOP RCT, with 285 women undergoing ultrasound screening for FGR. 261 and 228 scans were performed at 32 weeks and 36 weeks, respectively. For normally grown infants the estimated fetal weight (EFW) at 32 weeks correlated poorly with birthweight. However, when biometry of < 10th centile was analyzed, each parameter significantly correlated with low birthweight.

To further characterize the relationship between FL and FGR in smokers, a correlation matrix was generated between biometry at 32 and 36 weeks. The mean FL Z-score at 32 weeks was poorly correlated with EFW at 36 weeks. However, FL < 10th centile at 32 weeks was predictive of EFW < 10th centile at 36 weeks (p=0.003), and birthweight < 10th centile (p=0.001).

A logistic regression analysis provided an odds ratio for birthweight < 10th centile, dependent on a FL < 10th centile at 32 weeks, of 0.98 (95%CI: 0.97 - 0.99; p< 0.001). The odds ratio for EFW < 10th centile at 36 weeks, dependent on a FL < 10th centile at 32 weeks, was 4.9 (95% CI: 1.6 - 15.7; p=0.007).

CONCLUSION: FL is easy to obtain, with high accuracy and reproducibility. Short fetal FL is a common abnormal finding in smokers. Although there were strong associations between short FL and birthweight < 10^{th} centile, the positive predictive values were not strong. However, the negative predictive values were > 90%, implying that a FL > 10^{th} centile is a reassuring indicator of later normal fetal growth.

523 Fetal and Neonatal Outcomes after "Atypical Finding for Sex Chromosomes" on Cell-Free Fetal DNA Screening

Jenny Y. Mei[1], Aparna Murali[2], Alexa Nitka[2], Sung-Hae Kang[2], Sulagna Saitta[2], Christina S. Han[3]
[1]University of California, Los Angeles, Los Angeles, CA, [2]David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, [3]David Geffen School of Medicine at UCLA, Los Angeles, CA

OBJECTIVE: Prenatal cell-free fetal DNA (cfDNA) screening is primarily used to identify pregnancies at risk for common autosomal trisomies (CAT). Common cfDNA results include low risk (LR) or high risk (HR) for CAT or sex chromosomal aneuploidies (SCA), and low fetal fraction (FF). In 2020, a new report output was noted on a common cfDNA platform, labeled "atypical finding for sex chromosomes" (AFSC), stratified as "no result for all" (AFSC-NR), "LR for other conditions, no fetal sex" (AFSC-LR), or "LR for other conditions, XX sex" (AFSC-LR-XX). We aim to identify the outcomes of AFSC results on cfDNA.

STUDY DESIGN: We performed a retrospective cohort study of AFSC results at a single referral center from 01/2020-12/2022. Exclusion criteria included HR for CAT/SCA, low FF, & AFSC of suspected maternal origin. All AFSC patients were offered diagnostic testing, or if declined, neonatal phenotyping. Maternal demographic and outcome data were abstracted from medical records. Independent sample t-test, ANOVA, Chi-square, and multinomial logistic regression were used to compare outcomes between groups as indicated.

RESULTS: Of 5050 cfDNA samples (4931 singletons; 118 twins), 38 (0.008%) patients with 43 fetuses (5 twins) yielded AFSC outputs: 17 (39.5%) AFSC-NR, 11 (25.6%) AFSC-LR, and 15 (34.9%) AFSC-LR-XX. Genetic testing overview and results are listed in Figure 1. Compared to AFSC-NR, AFSC-LR were more likely to have higher rate of genetic testing (p=0.008), abnormal diagnostic testing (p=0.033), lower gestational age at lab draw (p=0.035), lower rate of twins (p=0.021), and higher likelihood of a female fetus (p=0.034). AFSC-NR had higher likelihood of preterm birth (p=0.013) and NICU admission (p=0.03). After controlling for twins, these findings lost significance.

CONCLUSION: Incidence of AFSC on cfDNA screening is low. Majority of cases result in normal genetic testing or neonatal phenotype. AFSC-LR is associated with abnormal results on karyotype or microarray. In this limited cohort, maternal & neonatal outcomes are overall reassuring.

Figure 1A: Flow Diagram of Testing after cell-free fetal DNA (cfDNA) samples with "Atypical Findings for Sex Chromosome" (AFSC) Results

524 Factors Affecting Success of Vaginal Delivery in Nulliparous Patients Receiving Magnesium Sulfate During Labor Induction

Jenny Y. Mei[1], Daniel Lee[2], Masaru Negi[3]
[1]University of California, Los Angeles, Los Angeles, CA, [2]UCLA Medical Center, Los Angeles, CA, [3]UCLA David Geffen School of Medicine, N Hollywood, CA

OBJECTIVE: Magnesium sulfate administration for preeclampsia with severe features during labor induction has been associated with increased risk of cesarean delivery (CD). We aim to evaluate associations with successful vaginal delivery (VD) in nulliparous patients undergoing labor induction while receiving magnesium sulfate.

STUDY DESIGN: This was a secondary analysis from the Consortium on Safe Labor, a multicenter cohort study of 228,438 deliveries in 19 U.S. hospitals. The analysis included nulliparous women ≥ 18 years

old with singleton gestation undergoing induction of labor for preeclampsia with severe features and receiving magnesium sulfate. Primary outcome was characteristics associated with successful VD. Secondary outcomes were maternal and neonatal outcomes. Chi-square and independent samples t-test were used to compare groups. The study was deemed IRB exempt #20-000360.

RESULTS: Total 4,122 women met inclusion criteria, of whom 2256 (54.7%) had a successful VD. Patients who had a VD were more likely to have lower maternal age ($p< 0.001$) and BMI ($p< 0.001$), higher gestational age ($p< 0.001$), higher rate of public insurance ($p=0.001$), lower rate of anti-hypertensive medication usage ($p< 0.001$), and lower admission systolic blood pressure ($p=0.049$). Other factors associated with VD included having more than 3 contractions in 10 minutes on admission ($p=0.002$), higher Bishop's score on admission ($p< 0.001$), cervical dilation greater than 0 or 1cm ($p< 0.001$), effacement greater than 50% ($p< 0.001$), and undergoing AROM ($p=0.003$) or Pitocin administration ($p< 0.001$). Successful VD was associated with shorter induction time ($p< 0.001$), higher 1-minute APGAR($p< 0.001$), and lower rates of NICU admission ($p< 0.001$) and composite neonatal morbidity ($p< 0.001$).

CONCLUSION: Rates of cesarean delivery are high in patients undergoing induction of labor for severe preeclampsia and receiving magnesium sulfate. Various characteristics are associated with increased rate of successful VD. Appropriate care should be taken in expeditiously managing labor for this high risk patient cohort.

Table 1. Characteristics between Vaginal and Cesarean Delivery

525 Effects of Dutch tocolysis protocol adjustment for threatened preterm birth after 30 weeks of gestation

J. A. L. Meliezer[1], L. I. Van der Windt[1], Anita C. Ravelli[2], W. Onland[1], Martijn A. Oudijk[1]

[1]Amsterdam UMC, location AMC, Amsterdam, Noord-Holland, [2]Amsterdam University Medical Center, Amsterdam, the Netherlands and Amsterdam Reproduction & Development, Amsterdam, Amsterdam, Noord-Brabant

OBJECTIVE: In 2019, the Dutch protocol was adjusted to not administer tocolysis for threatened preterm birth (PTB) between 30 and 34 weeks of gestation, since its effect on improving perinatal outcome is unclear. Administration of corticosteroids for fetal lung maturation was unchanged. The aim of this study is to evaluate the adjustment by investigating neonatal outcomes between 30 and 32 weeks of gestation before and after the protocol change.

STUDY DESIGN: We performed a nationwide cohort study comparing outcomes of births in the years 2018 (before protocol change) and 2020 (after protocol change). Data was extracted from the national Perinatal Registry (PERINED). Women with a spontaneous PTB from 30^{+0} to 31^{+6} weeks of gestation were included. The primary outcome was a composite of mortality, severe intraventricular hemorrhage, severe necrotizing enterocolitis, cystic periventricular leukomalacia, and retinopathy of prematurity needing therapy. Secondary outcomes included additional neonatal outcomes.

RESULTS: We included 521 women with PTB. There was no significant difference in composite neonatal outcome of births in 2018 compared to 2020 (8.4% (18/215) vs 8.2% (25/306) respectively, Odds Ratio (OR) 0.97 (95% Confidence Interval (CI) 0.52-1.83)). No difference was found when analyzing the groups as singletons (7.1% (12/170) vs 9.3% (19/204), OR 1.35 (95% CI 0.64-2.9)), and multiples (13.3% (6/45) vs 5.9% (6/102), OR 0.41 (95% CI 0.12-1.3)).

CONCLUSION: We found no significant difference in composite neonatal outcome in pregnancies resulting in spontaneous PTB between 30 and 32 weeks of gestation in 2018 (with tocolysis) compared to 2020 (no tocolysis). These results support the adjustment to not administer tocolytic treatment in women with threatened PTB between 30 and 32 weeks of gestation.

Table: Primary composite neonatal outcome in all births.

	2018 (n=215) % (n)	2020 (n=306) % (n)	P-value	OR (CI 95%)
Composite neonatal outcome	8.4 (18)	8.2 (25)	0.93	0.97 (0.52-1.83)
Neonatal mortality	3.7 (8)	1.3 (4)	0.07	
Mortality during birth	0 (0)	0 (0)	N.A.	
Neonatal death < 7 days	2.8 (6)	0.7 (2)	0.05	
IVH > grade II	1.9 (4)	1.3 (4)	0.61	
PVL > grade I	0.9 (2)	2.6 (8)	0.17	
NEC ≥ stage II	2.8 (6)	3.9 (12)	0.49	
ROP needing therapy	0.5 (1)	0 (0)	0.23	

OR: odds ratio. CI: confidence interval. IVH: intraventricular hemorrhage. PVL: periventricular leukomalacia. NEC: necrotizing enterocolitis. ROP: retinopathy of prematurity. N.A.: Not available.

526 Bedside nurses' perspectives on the role of language barriers on postpartum pain management

Tazim Merchant[1], Elizabeth Soyemi[2], Maya V. Roytman[3], Lynn M. Yee[1], Charlotte M. Niznik[1], Nevert Badreldin[3]

[1]Northwestern University, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Northwestern University, CHICAGO, IL

OBJECTIVE: Language barriers can adversely affect medical outcomes. However, knowledge of the role of language barriers on postpartum pain management is limited. Bedside nurses (RNs) spend significant time communicating with patients regarding pain treatment

preferences. We therefore evaluated RNs' perspectives on the role of language barriers on postpartum pain management.

STUDY DESIGN: We performed a qualitative study of postpartum bedside RNs at a tertiary academic medical center (9-12/2022). We used a semi-structured guide to facilitate in-depth interviews regarding postpartum pain management, including the role of language barriers. Purposive sampling was used to ensure inclusion of multilingual participants. Data were analyzed using the constant comparative method.

RESULTS: Of 21 participants, 33% were multilingual, with nine languages represented. Data yielded several themes related to the role of language barriers on postpartum pain assessment and management (Table). Nurses reported the significant time intensity associated with language barriers, leading some providers to forego the use of translator services, which hinders education and reduces the quality of pain management decisions. Participants also noted increased reliance on non-verbal cues in evaluating pain for non-English speaking patients. Even use of translator-mediated conversations were felt to be more limited in their ability to convey empathy and facilitate a connection with patients. Participants perceived non-English speaking patients to be more hesitant to fully express their pain or to ask for pain medications due to guilt regarding inconvenience and time intensity of translator services. Adverse effects of language barriers were particularly noted by multilingual RNs, who shared how communicating in a patient's preferred language helped bridge gaps.

CONCLUSION: Language barriers can hinder accurate pain assessment and may contribute to disparities in postpartum pain management. Increased accessibility to and enhanced quality of interpreter services may improve pain control in this population and promote equitable pain management.

Table. Nurses' perspectives on the role of language barriers on postpartum pain assessment and management

Theme	Exemplary quotation
Time intensity for providers	Yeah. Let's say we have five moms and five babies we don't necessarily have time to go into a room for 30 minutes and speak with an interpreter…then you can't really properly assess the patient's pain by asking a Spanish-speaking patient dolor, uno, dos, tres [pain, one, two, three]. And sometimes that's what ends up happening.
Inadequate patient education	A young girl, Spanish speaking…probably had poor discharge and poor follow-up because she didn't speak English and the nurse I'm sure was probably just like here's your medication, here's your discharge papers, good luck, congratulations…so on our end maybe there just wasn't a lot of follow-up on teaching or what to do.
Language barriers affect pain management decisions	I can't connect to an interpreter right now, I'm just gonna continue bringing them their oxy every four hours to keep their pain under control so they're not sitting there in pain and then I think the other side of it is it's night shift…they're not calling out telling me they're in pain, so I'm just not gonna ask them.
Reliance on nonverbal cues	So you usually can just go to the room and know by their face that she has more pain than what she's saying…does she have an idea of what 0 to 10 is? Does she want to tell you how much pain she's going through?…So such a person you need to round on that person more just to kind of catch the pain level at the right time because it's always facial to me. It's all mostly facial.
Translator-mediated conversations are more limited	Having to use a translator it's a lot harder to show your empathy to a patient if they're in pain through a translator…You have to stop every chunk of words…it's a little bit harder to understand what they're feeling.
Guilt regarding perceived inconvenience of translator use	It's just such a process and I know the patients they always feel bad when they feel like we need to use an interpreter because it takes so much more time. I think a lot of times those patients withhold some of their pain, like telling us, because they feel bad.

527 Differences in LDASA initiation for preeclampsia prevention in at-risk pregnancies between White and non-White patients

Omar Mesina[1], Colton Applegarth[2], Erin Buckner[3], Ayelet Ruppin[1], Kelsey Pinson[4], Maryam Tarsa[5]

[1]UCSD Department of OBGYN & Reproductive Sciences, La Jolla, CA, [2]UCSD School of Medicine, San Diego, CA, [3]University of California, San Diego, La Jolla, CA, [4]UC San Diego, La Jolla, CA, [5]UC San Diego Medical Center, San Diego, CA

OBJECTIVE: The Society for Maternal Fetal Medicine (SMFM) and the US Preventive Services Task Force recommend low-dose aspirin (LDASA) for preeclampsia (PEC) risk reduction in at-risk pregnancies. Current evidence suggests inconsistent prescribing practices for at risk patients. SMFM developed a checklist to make these practices more uniform. We sought to understand if LDASA prescribing practices for at risk patients differed between White and non-White patients at our institution.

STUDY DESIGN: We launched a PEC risk screen and LDASA eligibility smart-phrase modeled after SMFM checklist within the electronic medical record for use by all prenatal care providers. A retrospective chart review was performed to identify all patients who would be candidates for LDASA during their pregnancy between December 2022 and May 2023 to assess differences in prescribing practices by patient self-identified race.

RESULTS: 714 LDASA eligible patients with documented self-identified race were identified. Overall, 57.8% (413/714) were prescribed LDASA. 12.9% (92/714) self-identified as Asian, with 58.7% (54/92) prescribed LDASA. 21.6% (154/714) as Black, with 41.6% (64/154) prescribed LDASA. 28.6% (204/714) as Hispanic, with 68.1% (139/204) prescribed LDASA. 2.1% (21/714) identified as Multiracial, with 57.1% (12/21) prescribed LDASA. 34% (243/714) identified as White, with 59.3% (144/243) prescribed LDASA. Logistic regression was used to analyze the relationship between patient race and LDASA use. Black patients were 52% ($P < .001$) less likely than White patients to be given LDASA (OR 0.489, 95% CI [.32 - .73]). Though not statistically significant, Hispanic patients were 47% ($P=0.53$) more likely than White patients to be given LDASA (OR 1.47, 95% CI [.995 - 2.17]). No statistical difference in LDASA use was found between White patients, Asian and Multiracial patients.

CONCLUSION: Over 40% of patients with known risk factors for PEC were not prescribed LDASA during pregnancy. Black patients were less likely to be prescribed LDASA than White patients. Further work is needed to improve disparities in LDASA prescribing practices.

LDASA Prescription by Self-Identified Race

			LDASA Prescription		
			No	Yes	Total

528 Association of antenatal anxiety, short sleep duration, and blood pressure parameters: a pilot study

Hayley E. Miller[1], Samantha L. Simpson[2], Janet Hurtado[3], Chi-Hung Shu[3], Jane Chueh[4], Fiona Barwick[3], Stephanie A. Leonard[5], Brendan Carvalho[3], Pervez Sultan[3], Nima Aghaeepour[3], Maurice L. Druzin[6], Danielle M. Panelli[5]

[1]Stanford University Hospital, San Francisco, CA, [2]Stanford, Mountain View, CA, [3]Stanford University, Stanford, CA, [4]Stanford, Menlo Park, CA, [5]Stanford University, Palo Alto, CA, [6]Stanford University Medical Center, Palo Alto, CA

OBJECTIVE: Anxiety and short sleep are individually associated with hypertensive disorders of pregnancy, yet their interactive effect on specific blood pressure (BP) parameters are unknown. We evaluated the association between anxiety and BP, and the moderating effect of short sleep duration.

STUDY DESIGN: We conducted a prospective pilot study of pregnant people between 16 to 36 weeks' gestation between 2021-22. Anxiety was defined as State Trait Anxiety Inventory-State (STAI-S) score $\geq$ 40, and short sleep duration was defined as average sleep duration of $<$ 5 hours per day obtained over 3 to 7 days from a wrist-worn actigraphy device. Primary outcomes were systolic (SBP), diastolic (DBP), and mean (MAP) non-invasive BP measurements from enrollment. Generalized estimating equations (GEE) were used to first assess anxiety (independent variable) and each BP parameter (dependent variables), accounting for age, body mass index, and antihypertensive medications (Model 1). These models were then repeated including short sleep and an interaction term for short sleep and anxiety as covariates (Model 2).

RESULTS: Of 60 participants, 15 (25%) screened positive for anxiety and 36 (61%) had short sleep duration. In Model 1, anxiety was not significantly associated with any BP parameters. When short sleep was included in Model 2, all BP parameters were significantly associated with anxiety (SBP: beta 9.6, p=0.01, DBP: beta 8.1, p $<$ 0.001, and MAP: beta 8.8, p $<$ 0.001). No further significant statistical interaction was detected between short sleep duration and anxiety on BP (p-interaction SBP 0.12, DBP 0.24, and MAP 0.13) (Table 1).

CONCLUSION: Pregnant people with anxiety had 9.6 mmHg higher systolic, 8.1 mmHg higher diastolic, and 8.8 mmHg higher mean BPs than people without anxiety accounting for short sleep duration. Short sleep duration strengthened the association between anxiety and BP in this prospective cohort.

Table 1. Generalized estimating equations (GEE) assessing effect of anxiety on blood pressure parameters.

	Model 1 Beta coefficient (95% CI) for effect of anxiety on blood pressure parameter	P-value	Model 2 Beta coefficient (95% CI) for effect of anxiety on blood pressure parameter	P-value
Systolic blood pressure	2.0 (-4.2, 8.2)	0.52	9.6 (1.9, 17.4)	0.01
Diastolic blood pressure	4.9 (-0.3, 10.1)	0.07	8.1 (4.2, 12.0)	<0.001
Mean arterial pressure	3.9 (-1.2, 9.1)	0.13	8.8 (4.3, 13.4)	<0.001

*Model 1 includes anxiety, age, body mass index, antihypertensives
** Model 2 includes anxiety, short sleep, age, body mass index, antihypertensives

529 Association between method of conception of DCDA twin pregnancies and hypertensive disorders of pregnancy

Alexandra N. Mills[1], Manasa G. Rao[2], Sonia Khurana[3], Isabelle C. Band[1], Elianna Kaplowitz[4], Chelsea A. DeBolt[4]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]Columbia University, Icahn School of Medicine at Mount Sinai, New York, NY, [3]Icahn School of Medicine at Mount Sinai Hospital, New York, NY, [4]Mount Sinai Hospital, New York, NY

OBJECTIVE: Twin pregnancy is a known risk factor for hypertensive disease of pregnancy (HDP). Conception via In vitro fertilization (IVF) has been associated with HDP. However, current data on risk of HDP development in twin pregnancies conceived via IVF is limited and conflicting. We aim to investigate whether conception of dichorionic diamniotic (DCDA) twins via IVF is associated with increased odds of HDP compared to DCDA pregnancies conceived spontaneously, via intrauterine insemination (IUI) or ovulation induction (OI).

STUDY DESIGN: Retrospective cohort of DCDA twins delivered at Mount Sinai Hospital from 2008-2022. Primary outcome was HDP (gestational hypertension and preeclampsia [PEC]) defined by ACOG criteria. Secondary outcomes included mode of delivery, birthweight, gestational age at delivery, and NICU admission. Outcomes were compared between DCDA pregnancies conceived via IVF and those conceived spontaneously/IUI/OI. Univariable and multivariable regression analyses were performed.

RESULTS: Of 657 DCDA pregnancies included in this study, 265 (40.3%) were conceived via IVF and 392 (59.7%) were conceived spontaneously/IUI/OI. There was no significant difference in HDP among DCDA pregnancies conceived via IVF compared to spontaneous/IUI/OI conception (p=0.56). Patients who conceived via IVF were more likely to be nulliparous, older, have lower BMI, and commercial insurance, compared to patients who conceived spontaneously/IUI/OI (all p$<$ 0.0001). Adjusting for known risk factors of HDP, IVF DCDA pregnancies were at 2.03 increased odds of PEC without severe features compared to spontaneous/IUI/OI DCDA pregnancies (Table 1). Secondary outcomes showed IVF DCDA pregnancies were more likely to be delivered by Cesarean delivery

(p=0.0001) and were more likely to have lower birth weight (p=0.03) compared to spontaneous/IUI/OI pregnancies.

CONCLUSION: Conception of DCDA twins via IVF does not appear to be associated with an increase in HDP compared to DCDA twins conceived spontaneously/IUI/OI. While IVF DCDA twins may be at increased odds of developing PEC without severe features, larger studies are needed.

Table 1: Univariable and Multivariable Logistic Regression Analyses on Hypertensive Diseases of Pregnancy

Outcome variable	Factor	Crude*		Adjusted**	
		Odds Ratio (95% CI)	P value	Odds Ratio (95% CI)	P value
All hypertensive diseases of pregnancy (PIH)	IVF vs. Spontaneous/IUI/Clomid	1.11 (0.79-1.55)	0.56	1.11 (0.58-2.14)	0.75
Gestational hypertension	IVF vs. Spontaneous/IUI/Clomid	1.06 (0.70-1.62)	0.78	1.34 (0.59-3.02)	0.49
Preeclampsia w/o severe features	IVF vs. Spontaneous/IUI/Clomid	2.03 (1.04-3.96)	0.04	2.65 (1.28-5.50)	0.009
Preeclampsia w/ severe features	IVF vs. Spontaneous/IUI/Clomid	1.14 (0.76-1.72)	0.52	0.78 (0.35-1.74)	0.54

*Non-adjusted odds ratio estimated with the use of a simple logistic regression model.
** The outcomes of all hypertensive diseases of pregnancy, gestational hypertension, and preeclampsia w/ severe features were adjusted for age, BMI at admission, insurance, nulliparity, history of chronic hypertension or pre-gestational diabetes, and preeclampsia/gHTN in prior pregnancy. The outcome of preeclampsia w/o severe features was adjusted for BMI at admission and nulliparity.

530 Comparison of the normal mid-trimester cervical length between singleton and twin gestations

Gina F. Milone[1], Gabrielle Rieser[2], Shannen Guarina[2], Jonathan Steller[2]
[1]University of California Irvine, Irvine, CA, [2]University of California, Irvine, Orange, CA

OBJECTIVE: Limited information exists in the literature establishing a normal cervical length (CL) among asymptomatic twin pregnancies in the mid-trimester. It is unclear if the same standard normal values should be used in twins as is used for singletons. We aim to compare these two populations.

STUDY DESIGN: This is a retrospective cohort study at an academic medical center reviewing all pregnancies over a 5-year period where mid-trimester transvaginal CL data between 15-28 weeks were available among asymptomatic twin gestations. All CLs were performed by Registered Diagnostic Medical Sonographers at a single site. Previous literature has described the mean mid-trimester CL among singleton gestations to be 39.2±6.0mm, with the 10th percentile between 16-22 weeks and 22-24 weeks in singleton gestations described as less than 30mm and 25mm, respectively. In our twin cohort, the mean CL between 19 weeks through 20 weeks and 6 days, as well as the 10th percentile at 16-22 weeks and 22-24 weeks was calculated. Following a D'Agostino-Pearson normality test, these values were compared to the corresponding values in singletons using paired t-tests. Subgroup analyses were performed for those who delivered preterm and term and compared to all-comers above using ANOVA.

RESULTS: 179 twin gestations with at least one documented mid-trimester CL were analyzed. The mean CL among asymptomatic twin gestations between 19 weeks through 20 weeks and 6 days was 40.1±0.8mm, compared to the mean of 39.2±6.0mm among singletons (p< 0.001). There was no difference among those who delivered term and preterm, with values of 40.2±0.8mm and 40.1±0.8mm, respectively (p=0.999). The 10th percentile CL at 16 weeks through 21 weeks and 6 days and 22 weeks through 23 weeks and 6 days among asymptomatic twins was 32mm (n=275) and 25mm (n=193), respectively.

CONCLUSION: The thresholds for a normal mid-trimester CL among asymptomatic patients is similar between singleton and twin gestations.

531 Establishing risk thresholds for asymptomatic cervical lengths in twin pregnancies

Gina F. Milone[1], Gabrielle Rieser[2], Shannen Guarina[2], Jonathan Steller[2]
[1]University of California Irvine, Irvine, CA, [2]University of California, Irvine, Orange, CA

OBJECTIVE: In singleton gestations, a mid-trimester cervical length (CL) < 25mm (< 10th percentile) is a risk factor for spontaneous preterm birth (sPTB). This threshold unlocks interventions to reduce this risk. Currently, the same threshold is used to trigger interventions for twin gestations, however there is a paucity of data to guide whether the same CL thresholds should be used in twin gestations. We aim to determine a CL threshold of concern for sPTB among twins, as well as the optimal time for transvaginal assessment.

STUDY DESIGN: This is a retrospective cohort study at an academic medical center reviewing all twin pregnancies over a 5-year period where an asymptomatic mid-trimester transvaginal CL was available. All CL were performed by Registered Diagnostic Medical Sonographers at a single site. The mean CL was calculated at various points between 15-28 weeks' gestation among patients who had a sPTB (defined as preterm labor or PPROM leading to sPTB before 37 weeks) and patients who did not have a sPTB. T-tests compared the means at each time point to determine if there was a gestational age among patients with sPTB where there was a deviation in mean CL.

RESULTS: 179 twin gestations with at least one documented asymptomatic mid-trimester CL were available. Table 1 shows the mean CL at various gestational ages for all patients, those with a sPTB, and those without a sPTB. Differences in CL are noted beginning at 23 weeks and are most pronounced between 26 and 28 weeks with the mean CL in the sPTB group being 29.7±11.6mm compared to 36.8±10.3mm in those without sPTB (p=0.004). Importantly, the mean CL among twin gestations with a sPTB remained above the 25mm risk threshold, and often above 30mm prior to 26 weeks.

CONCLUSION: In twin pregnancies, a higher CL threshold may be considered when determining those at higher risk of sPTB. Larger studies are needed to validate these findings, which may lead to consideration of interventions to prevent sPTB in twin pregnancies at a longer CL. Additionally, there may be limited value for CL as a risk assessment before 21 weeks in twins.

Table 1. Cervical Lengths at Various Gestational Ages Among Twin Pregnancies.

Gestational Age Range (weeks)	CL Among Patients with SPTB (millimeters)	CL Among Patients without SPTB (millimeters)	p-value	CL Among All Patients (millimeters)
15w0d – 16w6d	42.6 ± 7.26 (n=22)	40.9 ± 6.50 (n=49)	0.352	41.4 ± 6.74 (n=71)
17w0d – 18w6d	40.1 ± 7.50 (n=28)	40.5 ± 8.86 (n=64)	0.825	40.4 ± 8.43 (n=92)
19w0d – 20w6d	40.1 ± 7.75 (n=38)	40.2 ± 7.80 (n=74)	0.949	40.1 ± 7.75 (n=112)
21w0d – 22w6d	38.4 ± 9.38 (n=39)	39.2 ± 8.30 (n=80)	0.652	39.0 ± 8.63 (n=119)

532 Effect of Low-Dose Aspirin on Preterm Prelabor Rupture of Membranes in Low-Risk Nulliparous Women

Joseph R. Mims Jr.[1], Lauryn C. Gabby[2], Emma Roberts[3], Gladys A. Ramos[4], Cynthia Gyamfi-Bannerman[5]
[1]University of Utah, Salt Lake City, UT, [2]UCSD Department of OBGYN & Reproductive Sciences, San Diego, CA, [3]University of California San Diego, La Jolla, CA, [4]University of California, San Diego, San Diego, CA, [5]UC San Diego Health, La Jolla, CA

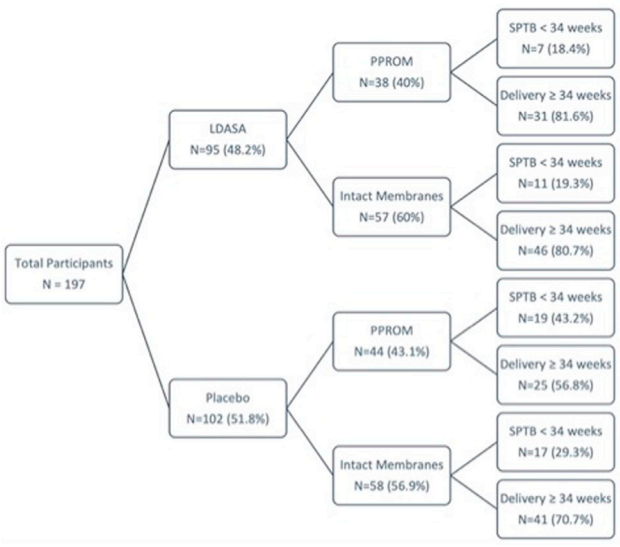
OBJECTIVE: We previously showed that low-dose aspirin (LDASA) is associated with a reduction in spontaneous preterm birth < 34 weeks (SPTB34) (Andrikopoulou, Gyamfi-Bannerman, et al. AJOG 2018), likely by an anti-inflammatory mechanism. Inflammation likely plays a role in preterm prelabor rupture of membranes (PPROM). Our objective was to determine whether a reduction in PPROM drove the decrease in SPTB.

STUDY DESIGN: This was a secondary analysis of a randomized controlled trial of LDASA for the prevention of preeclampsia in low-risk, nulliparous women. Low risk was defined by the absence of medical complications, including hypertension, renal disease, and diabetes. We included non-anomalous singleton gestations that delivered preterm, and rates of PPROM vs. preterm labor (PTL) with intact membranes were compared by LDASA exposure. Logistic regression was performed to control for clinically relevant confounders. We then performed sensitivity analyses to evaluate the rates of SPTB34 in PPROM vs. PTL with intact membranes by LDASA exposure.

RESULTS: 197 subjects were included (Figure 1). Of those, 95 (48.2%) received LDASA and 102 (51.8%) received placebo. There were no significant differences in baseline characteristics between the two groups. The rate of PPROM was similar in the LDASA and placebo groups (40.0% vs. 43.1%, respectively; p=0.66). This finding held true when adjusting for confounders (aOR 0.87; p=0.65). Limiting the analysis to those with PPROM, the median gestational age at delivery was similar in both groups, 35 weeks (IQR 34, 36) in the LDASA group and 34 weeks (IQR 32, 36) in the placebo group (p=0.62). The rate of SPTB34 was significantly lower in the LDASA group (18.4% vs. 43.2%; p=0.02). When assessing only those with PTL/intact membranes, the difference in SPTB34 was not significant (19.3% vs. 29.3%, p=0.21).

CONCLUSION: Administration of LDASA does not reduce the rate of PPROM overall, but SPTB34 by PPROM was less frequent in the LDASA group compared to placebo. A larger sample is needed to confirm these findings.

Figure 1: PPROM and SPTB<34 weeks by treatment group



533 Elevated 1st Trimester Environmental Temperatures May Underlie Development of Preeclampsia

Melanie Mitta[1], Madhumitha Manivannan[2], Howard H. Chang[3], Noah Scovronic[3], Saria hassan[2], Carolynn Dude[4], Suchitra Chandrasekaran[5]

[1]Nemours Foundation, Atlanta, GA, [2]Emory University School of Medicine, Atlanta, GA, [3]Emory Rollins School of Public Health, Atlanta, GA, [4]Emory University, Atlanta, GA, [5]Emory University School of Medicine, Decatur, GA

OBJECTIVE: Elevated environmental temperatures correlate with hypertension & diabetes in the nonpregnant state. Whether elevated temperature values may underlie metabolic disease development during pregnancy is unclear. We investigated if elevated 1st trimester (Tri1) or 2nd trimester (Tri2) maximum (Tmax), minimum (Tmin), average (Tavg) or ambient (AT) temperatures were associated with the development of preeclampsia(PRE).

STUDY DESIGN: We conducted a retrospective cohort study of subjects receiving prenatal care at an urban tertiary care center from 1/2016-3/2022. Individuals diagnosed with PRE were identified with ICD-10 codes from an institutional database. Zip-code level Tri1 & Tri2 Tmax, Tmin, Tavg, & AT were derived from 1 km gridded Daymet products & reported in degrees Celsius. After testing for normality, median temperature values were compared among those with & without PRE using Wilcoxon Rank Sum tests. Categorical variables were compared using Chi Square tests. Generalized linear regression models (GLM) estimated associations between the individual exposures (Tmax/Tmin/ Tavg/AT) and outcome (PRE) while controlling for confounders.

RESULTS: Of N=14,336 subjects, 12.48% (n=1,806) were diagnosed with PRE (Table 1a). Those with PRE had a higher Tri1 Tmax*(p=0.01)*, Tmin (*p=0.01*), Tavg*(p=0.01)*, & AT*(p=0.01)* compared to those without PRE (Table 1b). Even when performing GLM models controlling for maternal age, race, parity and obesity, the associations remained: Tmax (*β=0.001,95% CI 0.00026-0.0019, P=0.01*); Tmin (*β=0.001, CI 0.0003-0.0019, P=0.006);* Tavg (*β=0.001, CI 0.0003-0.0019, P=0.008*); AT (*β=0.001, CI 0.0028-0.0017, P=0.007*). No significant differences were noted in Tri2 temperature values.

CONCLUSION: This hypothesis generating line of inquiry noted higher environmental temperatures in early pregnancy associated with the development of PRE. It is imperative for future studies to investigate the mechanistic underpinnings connecting environmental temperature & gestational metabolic disease development, especially as climate change looms in our future.

534 Comparison of Obstetrical Randomized Controlled Trials During and Peri-Pregnancy

Rachel Moody[1], Anna Whelan[2], Indira Ranaweera[3], Uma Deshmukh[3], Suneet P. Chauhan[4], Stephen M. Wagner[5], Megha Gupta[3]

[1]Warren Alpert Medical School of Brown University, West Warwick, RI, [2]Grafton, MA, [3]Beth Israel Deaconess Medical Center, Boston, MA, [4]University of Texas-Houston Medical School, Houston, TX, [5]Beth Israel Deaconess Medical Center, Brookline, MA

OBJECTIVE: Recent attention has focused on the preconception and postpartum periods as important areas for improving perinatal outcomes. This study aimed to examine characteristics of obstetrical randomized controlled trials (RCTs) based on timing of intervention.

STUDY DESIGN: All obstetrical RCTs published in seven journals (NEJM/JAMA/Lancet, AJOG/Obstetrics & Gynecology/BJOG/AJOG MFM) from 2017-22 were collected and analyzed. Studies were categorized based on the time period (antepartum/intrapartum or preconception/postpartum) that the primary intervention was applied. Data was analyzed using Fisher's exact and Wilcoxon rank-sum test. P-value of < 0.05 was considered to be statistically significant.

RESULTS: Of the 247 RCTs, only 35 (14.2%) focused on preconception or postpartum time period. While the preconception and postpartum RCTs were mostly single-center studies (84.9%) in the US (70.6%), antepartum and intrapartum RCTs were more often multicenter studies (52.4%) performed in the US *and* other countries (56.7%$p< 0.003$). Preconception or postpartum studies were more likely to involve a drug intervention compared with studies performed in the ante/intrapartum period (44.1% vs 35.1%, $P < 0.01$). Preconception or postpartum studies were far more likely than antenatal studies to benefit the mother alone vs benefiting the fetus/newborn or both (91.2% vs 44.6%, $p< 0.001$).

CONCLUSION: The majority of obstetrical RCTs published in the 7 journals from 2017-22 were focused on interventions in the antepartum/intrapartum period versus the preconception/postpartum period. RCTs focusing on the preconception/postpartum period are lacking, and of the published studies the majority had small sample sizes and were performed at a single institution. There is a need for more large, multi-center obstetrical RCTs with interventions in the preconception or postpartum period.

535 Comparison of Obstetrical Randomized Controlled Trials That Target Maternal or Fetal/Neonatal Benefit

Rachel Moody[1], Anna Whelan[2], Indira Ranaweera[3], Uma Deshmukh[3], Suneet P. Chauhan[4], Yinka Oyelese[3], Stephen M. Wagner[5], Megha Gupta[3]

[1]Warren Alpert Medical School of Brown University, West Warwick, RI, [2]Grafton, MA, [3]Beth Israel Deaconess Medical Center, Boston, MA, [4]University of Texas-Houston Medical School, Houston, TX, [5]Beth Israel Deaconess Medical Center, Brookline, MA

OBJECTIVE: Obstetrical research is often both physiologically and ethically complex. Maternal and fetal interests may diverge, particularly in the research setting. This study aimed to evaluate the characteristics of randomized controlled trials (RCTs) focused on maternal versus fetal / neonatal outcomes.

STUDY DESIGN: Obstetrical articles published in seven journals (NEJM/JAMA/Lancet, AJOG/Obstetrics & Gynecology/BJOG/AJOG MFM) from 2017-22 were analyzed. Studies were classified as investigating either maternal or fetal/neonatal benefit based on the documented primary study objective. Data was analyzed using Fisher's test and Wilcoxon rank-sum test. P-value of < 0.05 was considered to be statistically significant.

RESULTS: Of 248 RCTs, 191 examined solely maternal (125, 65%) or solely neonatal/fetal (66, 34.6%) outcomes in the primary objective. Interventions for fetal/neonatal benefit were more often international (80.3% vs 47.1%, $p< 0.001$), multi-center (68.2% vs 40.0%, $p< 0.001$), and published in non-obstetrical journals (39.4% vs 12.8%, $p< 0.001$). Fetal/Neonatal benefit trials examined preventative measures more often than treatment (75.8% vs 56.0%, $p< 0.001$) and occurred most commonly in the antepartum (versus intrapartum) setting (71.2% v 28.8%, $p< 0.001$). Studies with maternal benefit as the primary outcome were smaller (200 [90-504] vs 476 (200-1600), $p< 0.001$) and carried out over a shorter time period (22.3 (11.2-36.0)mo vs 36.0 (21.4-47.7)mo, $p< 0.001$). There was no difference between the cohorts in the type of intervention or whether the trials demonstrated a positive result.

CONCLUSION: While the majority of obstetrical RCTs focused on maternal benefit as the primary outcome, fetal/neonatal oriented trials were larger and more likely to focus on prevention of disease in the antepartum period. Our results may inform investigators, and policy makers regarding trends and gaps in the obstetrical research completed over the past 5 years.

536 Betamethasone Exposure Among Term Newborns Following Recommendation for Late Preterm Antenatal Corticosteroids

John A. Morgan[1], Joseph R. Biggio Jr.[2], Meenakshi Mishra[3], Shannon McCloskey[4], James D. Toppin[5], Frank Williams[3]

[1]Ochsner Clinic, Metairie, LA, [2]Ochsner Health System, New Orleans, LA, [3]Ochsner Clinic, New Orleans, LA, [4]Ochsner Clinic Foundation, New Orleans, LA, [5]Ochsner Health, New Orleans, LA

OBJECTIVE: Since the Antenatal Betamethasone for Women at Risk for Late Preterm Delivery (ALPS) Trial, antenatal corticosteroids (ACS) have become standard of care for patients at risk of late preterm delivery. Emerging data suggest term newborns exposed to preterm ACS are at increased risk of adverse outcomes. We aim to compare betamethasone exposure among term newborns before and after implementation of late preterm ACS.

STUDY DESIGN: We conducted a cohort study of singleton live born term deliveries within a regional hospital system between 1/2013-3/2019. Deliveries were classified as pre- and post-ALPS, matched 1:2 in sequential fashion. Pre-ALPS deliveries occurred between 1/2013-4/2016; post-ALPS deliveries occurred between 4/2017-3/2019 with a 1-year post-publication washout. Exclusions were dexamethasone recipients and missing delivery data. The primary outcome was

betamethasone exposure among term newborns. Secondary outcomes included neonatal intensive care unit (NICU) admission and small for gestational age (SGA). Analyses were performed with student's T test and chi-square test.

RESULTS: Among 20,460 term deliveries, 6,820 were pre-ALPS and 13,640 were post-ALPS. Baseline characteristics were similar. Post-ALPS term neonates had increased exposure to betamethasone compared to pre-ALPS infants (3.1% versus 1.2%, OR 2.6, 95% CI 2.0-3.3). The percentage of pregnancies exposed to betamethasone that subsequently delivered at term increased with advancing gestational age at administration (figure). Among term-born neonates, 315 received ACS before 34 weeks, 190 after 34 weeks and 19,938 were ACS unexposed. SGA was most common in the ACS < 34 week group (11.4%) followed by the ≥ 34 week group (11.0%) and then unexposed neonates (6.1%, p< 0.001). Similarly, NICU admission was highest among < 34 week infants followed by late preterm ACS and unexposed, respectively (6.0% vs 4.7% vs 2.6%, p< 0.01).

CONCLUSION: Implementation of late preterm ACS correlated with substantially increased risk for betamethasone exposure among term-born neonates, potentially increasing both short- and long-term morbidity.

537 Fetal growth restriction diagnosed at anatomy ultrasound is associated with an increased risk of stillbirth

Matthew H. Mossayebi[1], Tracy Gao[2], Sascha Wodoslawsky[2], Lucy Qi[2], Amanda Roman[2], Rodney A. McLaren Jr.[2], Uma M. Reddy[3], Huda B. Al-Kouatly[4]

[1]Brigham and Women's Hospital, Boston, MA, [2]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA, [3]Columbia University, New York, NY, [4]Thomas Jefferson University, Philadelphia, PA

OBJECTIVE: Although fetal growth restriction (FGR) is associated with an increased risk of stillbirth, the data are limited regarding the stillbirth risk for FGR diagnosed in early second trimester. We aimed to determine the association between FGR diagnosed at anatomy ultrasound and risk of stillbirth.

STUDY DESIGN: We conducted a retrospective cohort study of singleton pregnancies delivered between 2017 to 2022 who had both a first trimester dating ultrasound and an anatomy ultrasound between 18 0/7 and 23 6/7 weeks. Cases with known major structural or genetic abnormality or congenital infection were excluded. FGR was defined as estimated fetal weight (EFW) or abdominal circumference (AC) below the 10th percentile for gestational age. Primary outcome was occurrence of stillbirth. Patient characteristics were compared, and logistic regression models were performed to estimate adjusted odds ratios (aORs) for stillbirth accounting for demographic factors and maternal medical conditions.

RESULTS: Of the 6871 patients that met the inclusion criteria, 197 (2.9%) were diagnosed with FGR at the anatomy ultrasound. Patients in the FGR group were more likely to be Black or Asian, younger, and delivered at an earlier gestational age when compared to those without FGR. Fewer male fetuses were reported in the FGR group (38.1% vs 50.6%, p=0.001). There were no significant differences in rates of chronic hypertension, hypertensive diseases of pregnancy, diabetes, obesity, autoimmune disease, or COVID-19 during pregnancy between the two groups (Table 1). The rate of stillbirth was higher in the FGR at anatomy ultrasound group (3.6% vs 0.7%, aOR 5.18 (95%Cl 2.31-11.64)) with stillbirth diagnosed at an earlier gestational age (22.4 weeks vs 29.2 weeks, OR 0.88, 95% CI 0.75-1.03) compared with the no FGR group.

CONCLUSION: Diagnosis of FGR in fetuses without known structural or genetic abnormality at anatomy ultrasound was independently associated with an increased risk of stillbirth.

Table 1. Patient characteristics

538 Cardiac structural and functional assessment of monochorionic twin pregnancies complicated by selective fetal growth restriction

Jessian L. Munoz[1], Betul Yilmaz Furtun[2], Cara Buskmiller[1], roopali V. donepudi[1], Magdalena Sanz Cortes[3], Michael A. Belfort[4], Ahmed A. Nassr[1]

[1]Baylor College of Medicine, Houston, TX, [2]Texas Children's Hospital, Baylor College of Medicine, Houston, TX, [3]Baylor College of Medicine and Texas Children's Hospital, Houston, TX, [4]Texas Children's Hospital, Houston, TX

OBJECTIVE: Selective fetal growth restriction (sFGR) complicates 10-15% of monochorionic twin gestations. Prior studies reported neonatal cardiac hypertrophy present in 25% of twins impacted by sFGR, most commonly the larger twin (AGA, 80%). Our primary objective was to characterize fetal cardiac structural and functional echocardiogram findings in these complex twins pairs.

STUDY DESIGN: A retrospective cohort analysis was performed of monochorionic twin pregnancies complicated by sFGR managed and delivered at a single tertiary center from 2015-2023. Patients undergoing laser treatment were excluded. All twin pairs underwent fetal echocardiogram by board-certified pediatric cardiologists at our center. Clinically relevant data was obtained from electronic medical records. Right and left myocardial performance index (MPI) were calculated incorporating ejection, isovolumetric contraction and isovolumetric relations times.

RESULTS: During the study period, 34 pairs of monochorionic twins were managed by our team. 2 patients were excluded as they did not undergo fetal echocardiograms as planned. The remaining 32 twin pairs underwent echocardiogram analysis at 20 weeks ± 6 days on average. Compared to the sFGR fetuses, AGA fetuses were more likely to have tricuspid regurgitation (TR, 38 vs 9%, p=0.02), right ventricular hypertrophy (RVH, 44 vs 9%, p=0.003), left ventricular hypertrophy (31 vs 3%, p=0.006), elevated right MPI (0.36 [0.26, 0.49] vs 0.29 [0.24, 0.35], p=0.03) and elevated left MPI (0.32 [0.29, 0.47] vs 0.29 [0.25, 0.35], p=0.02). No difference was noted in cardiac output (534 [483, 596] vs 522mL/min [447, 596], p=0.41). At birth, 40% (6/15) of AGA fetuses with abnormal fetal echocardiograms, had RVH and TR compared to 25% (1/4) of sFGR fetuses.

CONCLUSION: In this cohort of expectantly managed monochorionic twins complicated by sFGR, AGA twins were noted to have findings consistent with hemodynamic changes which could reflect cardiac overload in the perinatal period. Further assessment of neonatal and pediatric outcomes is needed to determine the long-term implications of these sonographic findings.

539 Clinical characteristics and outcomes of intrauterine blood transfusion (IUT) for infectious etiologies

Jessian L. Munoz[1], roopali V. donepudi[1], Cara Buskmiller[1], Ahmed A. Nassr[1], Michael A. Belfort[2], Magdalena Sanz Cortes[3]
[1]Baylor College of Medicine, Houston, TX, [2]Texas Children's Hospital, Houston, TX, [3]Baylor College of Medicine and Texas Children's Hospital, Houston, TX

OBJECTIVE: Congenital viral infectious may result in fetal anemia and thrombocytopenia. While intrauterine blood transfusions (IUTs) are more commonly performed for Rh disease, studies have reported the utilization of IUT for this indication with varying success. Our primary objective was to characterize outcomes of patients undergoing IUT for infectious etiologies at our center compared to Rh disease.

STUDY DESIGN: This was a retrospective cohort analysis of patients who underwent IUT at our fetal center from 2012-2023. Infectious etiologies were identified by maternal serologies and confirmed by amniotic fluid PCR. Clinically relevant outcomes were obtained from electronic medical records. Statistical analysis was performed using GraphPad Prism 9.

RESULTS: During the 12-year study period, 70 patients underwent IUT at our center, 34% (24/70) for Rh disease and 17% (12/70) for infectious etiologies. The remaining causes varied and were excluded from this study. Within the infectious etiology cohort, 7/12 (58%) were for parvovirus and 5/12 (42%) for CMV. Compared to Rh disease, those with infectious etiologies were more likely to be diagnosed at earlier gestational ages (22 [20, 24] vs 25 [22, 28] weeks, p=0.04), present with hydrops (75 vs 33%, p=0.03), have lower fetal platelets (27 ±33 x10^3 vs 163 ±112 x10^3, p< 0.01) and have a fewer number of procedures (2 [1, 2] vs 5 [2, 6], p< 0.01). Perinatal death was significantly greater in cases of CMV (4/5, 80%) when compared to parvovirus (1/7, 14%) or Rh disease (5/24, 21%) (p=0.02).

CONCLUSION: Fetal infectious etiologies may be an indication for IUT, but are associated with earlier gestational age at presentation, development of hydrops and, in the case of CMV, significantly greater rates of perinatal death when compared to IUT performed for Rh disease. In contrast to Rh disease, significant fetal thrombocytopenia was noted in both CMV and parvovirus infectious, yet perinatal outcomes for CMV were significantly worse. Patients should be counseled on the various outcomes and implications by indication.

Table 1. Pre-surgical and Perinatal outcomes

Factor	Rh disease (n=24)	Infectious etiology (n=12)	p-value
Maternal age (years)	29.4 ± 6.1	27.3 ± 7.5	0.38
Gravidity	3 [2, 4]	1 [1, 3]	**0.02**
Parity	2 [1, 2]	0 [0, 1]	**<0.01**
Gestational age (weeks)	25 [22, 28]	22 [20, 24]	**0.04**
Hydrops	8 (33)	9 (75)	**0.03**
Middle cerebral artery doppler			
Peak systolic velocity (MoM)	1.8 [1.6, 2.1]	2.0 [1.9, 2.1]	0.16
Pulsatility index	1.7 ± 0.2	1.6 ± 0.5	0.29
Fetal hematocrit (%)*	15.1 ± 15	18.4 ± 18	0.35

540 Exploring effects of meal supplementation on pregnancy outcomes amongst food insecure pregnant persons

Lauren M. Murphy[1], Shana Talbot[1], Lauren Schlichting[2], Swati Rajprohat[1], Janet Lefkowitz[1], Adam K. Lewkowitz[3]
[1]Women & Infants Hospital of Rhode Island, Warren Alpert Medical School of Brown University, Providence, RI, [2]Hassenfeld Child Health and Innovation Institute of Brown University, Providence, RI, [3]Warren Alpert Medical School of Brown University, Women & Infants Hospital Rhode Island, Providence, RI

OBJECTIVE: Pregnant people with food insecurity (FI) are at increased risk of adverse perinatal outcomes. A program providing free meals from Meals on Wheels (MoW) for pregnant people with FI was initiated at an urban academic clinic.

STUDY DESIGN: The Hunger Vital Sign™ was used to screen pregnant people for FI at their prenatal intake visit. All patients with FI were offered enrollment in MoW until delivery. From May 2023 to June 2023, perinatal outcomes were compared from those with FI who did versus did not enroll in the MoW and, among those who participated, those who disenrolled versus continued in MoW until delivery.

RESULTS: Among 810 screened patients, 51 (6%) had FI. Of these, 57% (n=29) enrolled in the program and, of these, 18 (62%) received meals until delivery. There were no significant differences amongst those who did or did not enroll in MoW or amongst those enrolled and continued or discontinued MoW services. FI patients who did not enroll in MoW were more likely than those who did enroll to deliver at an earlier gestational age (37.71 vs 39.43 P< 0.01), but there was no difference in GA of delivery among those enrolled who did versus did not continue MoW until delivery. Those who were obese with FI (BMI 30-35) were more likely to remain within recommended weight gain if they were ever in MoW (14lbs vs 30lbs p< 0.04). The prevalence of gestational diabetes and pre-eclampsia was lower amongst those who received MoW compared to those who declined; this was not statistically significant. The prevalence of perinatal depression differed amongst FI pregnant patients who stayed in MoW (45.5%) versus those who disenrolled (38.9%) or who never enrolled (31.8%), but this difference did not achieve statistical significance.

CONCLUSION: A free meal delivery service is feasible in urban care perinatal clinics. Trends in this small cohort suggest this survey may improve perinatal outcomes. However, mixed methods data are needed to examine why ~40% of eligible participants declined enrollment and ~40% of enrolled patients disenrolled pre-delivery.

Table 1: Outcomes and characteristics

Characteristics Total (n= 51)	Enrolled in program N (%) N=29	No enrollment N (%) N=22	p-value	Disenrolled in program N (%) N=18	Stayed in program N (%) N=11	p-value

541 Blood Pressure Threshold to Prevent Post Partum Readmission

Angela Nakahara[1], Spencer Pope[2], Natalie Oxley[3], Morgan Wallen[2], Christina Harvey[2], Jocelyn Newman[2], Patricia Goedecke[2], Jim Wan[2], Norman Meyer[1], Kerri Brackney[2]
[1]Regional Medical Center, Memphis, Memphis, TN, [2]University of Tennessee, Memphis, TN, [3]University of Tennessee Health Science Center, Memphis, TN

OBJECTIVE: Ideal postpartum blood pressure (BP) parameters are poorly defined. Improved guidance on BP parameters may help prevent maternal morbidity and mortality. We conducted an exploratory study comparing the BP values in patients readmitted for postpartum preE (PPP) with matched controls to determine BP threshold that is most associated with increased risk of readmission.

STUDY DESIGN: This is a retrospective case control study comparing women readmitted for PPP to matched controls without readmission between 01/2019 to 03/2022. Cases were matched to controls by age, gestational age and delivery year. BP values in the inpatient postpartum period (e.g., time of delivery to time of discharge) were evaluated. Primary outcome was postpartum BP threshold that would prevent PPP readmission; secondary outcome was proportion of target BP that would prevent PPP readmission. We calculated the proportion of post-partum BP readings below various thresholds and applied logistic regression, identifying area under the curve (AUC) for each threshold. Using the post-partum BP threshold with the highest AUC, we developed confusion matrices at proportions of BPs below the threshold ranging from 0.05 to 1 by 0.05. We observed which proportion had the highest Youden's Index (sensitivity + specificity − 1) to maximize predictive effectiveness.

RESULTS: There were 121 subjects readmitted for PPP and 121 controls. Patients readmitted for PPP were more likely to have HDP (OR 2.43, 95% CI 1.24-4.79), history of HDP (OR 4.02, 95% CI 1.44-11.21), and more likely to have cesarean delivery (OR 1.99, 95% CI 1.18-3.35). We found the BP threshold of 130/80 to have the greatest AUC (0.78) in the logistic prediction of non-readmission. Among proportions of post-partum readings below 130/80, we found 75% to have the highest Youden's Index (SE+SP-1) at 0.47, thus 75% of BPs needed to be below this threshold to minimize readmission risk.

CONCLUSION: Patients with greater than 25% of postpartum BPs > 130/80 have a higher risk for PPP readmission. Future studies should identify interventions to modify outcomes for patients above this threshold.

542 Association Between Maternal Hypoglycemia Using Continuous Glucose Monitoring and Adverse Pregnancy Outcomes

Sarah Nazeer[1], Rafael Santos[2], Claudia Pedroza[2], Sean C. Blackwell[3], Baha M. Sibai[4], Michal Fishel Bartal[5]
[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [3]Children's Memorial Hermann Hospital, Houston, TX, [4]Hermann Memorial Hospital, Houston, TX, [5]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX

OBJECTIVE: Several studies suggest a correlation between hypoglycemia and outcomes related to placental insufficiency or those related to elevated blood sugars. We aimed to examine the association between time below range (TBR) continuous glucose monitor (CGM) metrics and adverse perinatal outcomes among individuals using CGM during gestational diabetes (GDM) screening.

STUDY DESIGN: This was a secondary analysis of a prospective study (06/2020 to 01/2022) of individuals who underwent 2-step GDM screening at ≤ 30 weeks. Participants wore a blinded CGM (Dexcom G6 Pro) for ten days at time of 1-hour glucose challenge test (GCT). We evaluated TBR defined as the percentage of time less than 63 mg/dL. The primary outcome was a composite of adverse maternal and neonatal outcomes indicative of placental insufficiency, including preterm birth, placental abruption, hypertensive disorders of pregnancy, small for gestational age (defined as < 10th percentile on the Duryea et al nomogram), and neonatal death. Secondary outcomes

included other neonatal and maternal outcomes. TBR was expressed as a percentage of all CGM readings and mean glucose were analyzed. Pearson's Chi-squared and Fisher's exact test were calculated; p value of < 0.05 was considered as a statistically significant value.

RESULTS: Of the 92 individuals recruited, the total median time below range was 0.5% (IQR, 0.1, 1.2), with a median of 0.3% (IQR 0.0, 1.5) during daytime and 0.1% (0.0, 1.2) nocturnal TBR. CGM indicated 30 individuals (36.7%) had TBR $< 1\%$, and 63 individuals (67.4%) had TBR $>1\%$. Individuals with TBR >1 % did not have an increased risk of either adverse composite placental insufficiency outcome (p=0.59), or other neonatal adverse outcomes (Table).

CONCLUSION: In this prospective study using CGM we did not find an association between maternal TBR and adverse neonatal or maternal outcomes. Larger studies are needed to investigate whether hypoglycemia in pregnancy is associated with adverse perinatal outcomes.

Table 1: Composite Neonatal and Maternal Adverse Outcomes Associated with Time Below Range 1%.

Outcome	Time below range < 1% N = 30	Time elow range >= 1% N = 63	P-value

Data are presented as number (percentage), or median (interquartile range)
SGA, small for gestational age; NICU, neonatal intensive care unit; IV, intravenous; CPAP, continuous positive airway pressure; NC, not calculated.
*Preterm birth defined as < 37 weeks of gestation
**SGA defined as birthweight < 10th percentile using the nomogram by Duryea et al.
***Neonatal death defined as death within 28 days
^^Defined as blood glucose <40mg/dL in the first 24 hours of life or <50mg/dL after or requiring medical therapy
^^^Defined as the need for at least 4 hours of respiratory support with supplemental oxygen, CPAP, or ventilation at the first 24 hours of life)

543 Factors associated with successful elective induction of labor

Suna Njie, Fei Xu, Michael Kuzniewicz, Monique Hedderson, Mara Greenberg
Kaiser Permanente Oakland, Oakland, CA

OBJECTIVE: To determine factors associated with vaginal delivery (VD) among patients undergoing elective labor induction (eIOL).

STUDY DESIGN: Retrospective cohort study of pregnancies undergoing eIOL from 2011-2022 at Kaiser Permanente Northern California. eIOL was defined as inductions between 39w0d-40w6d with no identifiable medical indications present per criteria derived from ACOG and the ARRIVE trial including maternal age < 15 or ≥ 40 years, gestational age >39 or ≥ 41 weeks, multiple gestation, rupture of membranes prior to hospital admission, maternal medical comorbidities, obstetric pathologies, or fetal pathologies. We evaluated the association of patient characteristics with vaginal delivery using multivariable regression analysis.

RESULTS: Among the 274,039 39w0d-40w6d deliveries occurring during this time, 53,668 (19.6%) were IOL and of those, 10,709 (20%) were eIOL. Characteristics associated with vaginal delivery were induction in the 39th compared to induction in the 40th week (aOR 1.15; 95% CI 1.02-1.30), multiparity (aOR 8.07; 95% CI 6.96-9.36), and height (Table). Increasing age and BMI (Table), and Black (aOR 0.58; 95% CI 0.45-0.73) or Asian (0.68 95% CI 0.58-0.80) race categories were associated with decreased likelihood of vaginal delivery, after adjustment for maternal characteristics, induction method and prior cesarean.

CONCLUSION: Conclusion: Among those undergoing eIOL, factors associated with vaginal delivery included induction earlier in the term period, multiparity, white race, and use of oxytocin alone. Among otherwise healthy term pregnancies eligible for elective labor induction, opportunities to better understand racial inequities in vaginal delivery rates should be investigated.

Table: Adjusted odds of vaginal delivery during elective labor induction by patient characteristics

Maternal Characteristic	Adjusted Odd Ratio*
Age at delivery (yrs)	0.94 (0.93-0.95)
BMI closest to delivery (kg/m^2)	0.94 (0.93-0.95)
Height (inches)	1.12 (1.10-1.15)
Race	
Non-Hispanic White	*Reference*
Hispanic	1.03 (0.88-1.22)
Asian	0.68 (0.58-0.80)
Black	0.58 (0.45-0.73)
Other/Unknown	0.84 (0.64-1.08)
Parity	
Nulliparous	*Reference*
Multiparous	8.07 (6.96-9.36)
Gestational week at induction	
39th week	1.15 (1.02-1.30)
40th week	*Reference*
Insurance payor	
Commercial	*Reference*
Public	1.16 (0.94-1.44)
IOL mode	
PGE/mechanical dilation + Oxytocin	Reference
Oxytocin alone	1.73 (1.38-2.17)
NDI	
Quartile 1 (least deprived)	*Reference*
Quartile 2	1.06 (0.90-1.26)
Quartile 3	1.06 (0.89-1.25)
Quartile 4 (most deprived)	1.03 (0.85-1.25)

* Adjusted for maternal age at delivery, antepartum body mass index (BMI) measured most proximal to delivery, maternal height, parity, gestational week, insurance payor, induction method (oxytocin alone versus at least one of prostaglandin or mechanical ripening (cervical catheter) +/- oxytocin), neighborhood deprivation index (NDI), prior cesarean delivery

544 Association between Patient-Provider Communication and Patients' Expectations versus Childbirth Experiences

Nadiha Noor Chelsea, Tina Yi-Jin Hsieh, Rafaela Germano Toledo, Laura E. Dodge, Cassandra R. Duffy, Elysia Larson
Beth Israel Deaconess Medical Center, Boston, MA

OBJECTIVE: Patient experience in relation to childbirth expectations is a crucial component of patient-centered care. Effective patient-provider communication may shape expectations and foster high-quality care. We aimed to test whether patient-provider communication is associated with concordance between patient expectations and birth experiences.

STUDY DESIGN: English-speaking individuals, ≥ 18 years of age who were pregnant or delivered a live infant from May 2020 to July 2023 and received obstetric care at a large academic center were eligible to participate in a longitudinal online survey. Prenatally, participants indicated what they expected to experience during childbirth; they reported actual experiences in the postpartum survey. We used a scoring system (1—20) to assess alignment between expectations and experiences. Participants were categorized into "High" and "Low" alignment groups based on a median score. Patient-provider communication was measured using the Kim Alliance Scale—Communication Subscale (KAS-CM). We used a linear regression model for continuous alignment scores and negative binomial regression model for "High" alignment to calculate risk ratios (RR) and 95% confidence intervals.

RESULTS: Of 407 participants who completed both surveys, the median alignment score was 15. Most participants were white (38%), college-educated (91%), had full-time employment (74%), and had private insurance (86%). An increase of 1 point on KAS-

CM was associated with an increase in alignment score of 0.1 points (CI 0.002, 0.18). There was no statistically significant association between KAS-CM score and "High" alignment (RR 1.04, 95% CI 0.99, 1.09). Factors associated with "High" alignment included older age, prior cesarean section and multi-parity.

CONCLUSION: Quality patient-provider communication was modestly associated with a higher degree of concordance between patient expectations and birth experiences in this study population. However, future research should assess similar relationships among diverse, non-English speaking populations.

545 Complement 4a (C4a) as a potential biomarker for dystocia in labour

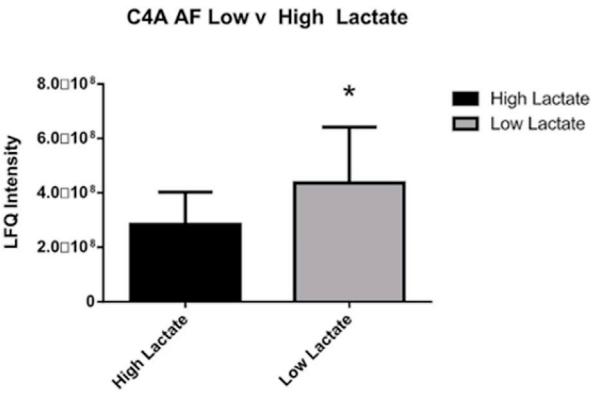
Nicola O. Riordan, Michael Robson, Declan Keane
National Maternity Hospital, Dublin, Ireland

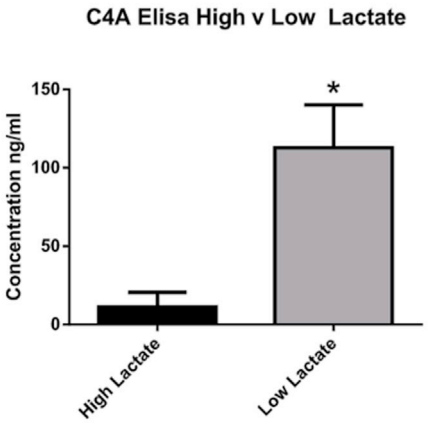
OBJECTIVE: To examine the proteome of the amniotic fluid (AF) in cases of labour dystocia. Previous research has shown high AF lactate to be associated with inefficient uterine action. We aimed to assess the proteome in those with high vs low AF lactate. The aim of this was to allow further insights into labour dystocia.

STUDY DESIGN: This was a prospective observational study. 25 patients were recruited with efficient uterine action (EUA), defined as cervical dilation ≥1cm/hour. 25 were recruited with inefficient uterine action (IUA), dilation < 1cm/hour. A sample of AF was collected at the time of caesarean delivery, and the lactate level in the AF was measured. The AF proteome was examined for those with IUA and high (n=4) lactate vs EUA and low (n=4) lactate. 28 differentially expressed proteins (DEPs) were identified using mass spectrometry, these underwent functional pathway analysis. Validation studies were completed using enzyme linked immunosorbent assay (ELISA).

RESULTS: C4a was identified as being a protein with high fold change (3.12) in low vs high lactate samples. It was also enriched in biological pathway and network analysis of DEPs using KEGG (Kyoto Encyclopaedia of Genes and Genomes). The concentration change in C4a was validated with ELISA, where a higher concentration of C4a was observed in AF with low lactate (p=.00).

CONCLUSION: C4a upregulation represents activation of the complement system and inflammation. Progress in labour is dependent on a balance between pro and anti-inflammatory factors. Upregulation of C4a has previously been linked with preterm labour onset. The decreased level of C4a in AF with IUA and high lactate may reflect an imbalance in inflammation. Our findings suggest future research into the role of C4a as a potential biomarker for labour dystocia in AF would be beneficial.





546 Examining the Impact of 1-Week Postpartum Mood Check

Jennifer Okunbor[1], Maame Amoako[1], Siera Lunn[1], Adwoa Baffoe-Bonnie[1], Ebun Olunuga[1], Matthew R. Grace[2], Sarah K. Dotters-Katz[3]
[1]Duke University School of Medicine, Durham, NC, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Duke University Medical Center, Durham, NC

OBJECTIVE: Postpartum(PP) mood disorders are prevalent and often go undetected and untreated. A 1-week mood check(MC) is a common early touchpoint to attempt to mitigate these risks. Little data exists exploring the efficacy of this visit to address postpartum mood disorders. We examined the rate of intervention at the 1-week postpartum MC among high-risk postpartum patients.

STUDY DESIGN: IRB approved retrospective cohort study of high-risk postpartum patients from a single academic health system between 4/1/2020-3/31/2022 attending a telehealth MC within 10 days of postpartum discharge. Primary outcome was the rate of intervention at MC. Intervention defined as change to care, including referrals, extra visits, medication change/start. Secondary outcomes included rate of emergent intervention, rate of mental health-related intervention, and risk factors for needing intervention at the mood check. Descriptive statistics used to analyze data; logistic regression used to identify factors associated with needing intervention at MC.

RESULTS: During the study period, 313 patients had a MC. Of those, 80(25.6%) required an intervention. Psych-related interventions occurred in 62(19.8%) patients. Nine patients(2.9%) were advised to seek urgent/emergent care, including for suicidal ideation(n=2), concern for preeclampsia(n=3), intractable headache(n=2), wound issues(n=1), and orthopnea(n=1). Other interventions in table.

Comparing patients who required intervention at MC vs those who did not, both history of anxiety(56.6%vs42.5%,p=0.03) and cocaine use(3%vs8.8%,p=0.03) were more common among those requiring intervention. Other demographics did not differ. In regression models, only cocaine remained associated with need for intervention at MC(aOR 3.56, 95%CI 1.17,10.80).

CONCLUSION: 1 in 4 patients who attended the one-week postpartum MC required intervention, with 3% requiring urgent/emergent care. These data emphasize the importance of this visit with a high-risk population. By identifying patients who require additional support, the MC may facilitate early intervention.

Interventions at Mood check	Overall n=313 (%)
Any intervention	80 (25.6)
Any psychiatric intervention	62 (19.8)
New diagnosis	4 (1.3)
Any medication adjustment[1]	42 (13.4)
Any new medication	26 (8.3)
New psychiatric medication	20 (6.4)
Medication refill or dose adjustment	16 (5.1)
Referral to lactation specialist / breastfeeding support	5 (1.6)
Referral to psychology / psychiatry	40 (12.8)
Scheduled additional follow up prior to PP visit	14 (4.5)
Patient advised to seek urgent/emergent medical care	9 (2.9)
Patient referred to another specialist*	3 (1.0)

547 Can need for intervention at 1 Week Mood Check Predict Postpartum Depression: A cohort study

Jennifer Okunbor[1], Siera Lunn[1], Maame Amoako[1], Ebun Olunuga[1], Adwoa Baffoe-Bonnie[1], Annie West-Honart[2], Sarah K. Dotters-Katz[3]

[1]Duke University School of Medicine, Durham, NC, [2]Duke University Hospital, Durham, NC, [3]Duke University Medical Center, Durham, NC

OBJECTIVE: Despite postpartum(PP) mood disorders affecting up to 20% of new mothers, these conditions are often undiagnosed and untreated. There is growing interest in determining a way to detect the emergence of these conditions earlier so intervention can be implemented to reduce the severity of these disorders. The objective of this study is to determine whether there are need for intervention at 1-wk mood check(MC) predicted the development of PP depression(PPD) by the postpartum visit.

STUDY DESIGN: Retrospective cohort study of high-risk postpartum patients at one tertiary center from 4/1/2020-3/31/2022 who had 1wk MC and attended PP visit. Patients who did not attend PP visit or who were missing EPDS at PP visit excluded. Demographic data, pregnancy characteristics, and labor/delivery information abstracted. The exposure of interest was PPD(EPDS≥13 at PP visit). Primary outcome was need for intervention at 1wk MC(defined as: new/change in medications or referrals). Secondary outcomes were need for psych intervention at MC, expression of sadness at MC and expression of anxiety at MC. Bivariate statistics used to analyze data. Regression models used to control for confounders.

RESULTS: Of the 240 patients who had mood checks, 40(16.7%) were diagnosed with PPD at PP visit. No demographic or obstetric variables other than pre-existing depression(p=0.02) and cocaine use during pregnancy(p=0.01) were significantly associated with PPD. No differences in need for intervention at MC, psych intervention, or expression of sadness or anxiety seen between those with and w/o PPD(Table). Controlling for pre-existing depression and cocaine use, expressing sadness at the mood check was associated with development of PPD(aOR 2.24, 95%CI 1.05, 4.678) while no type of intervention at MC or expression of anxiety were associated with PPD(Table 1).

CONCLUSION: The 1-week MC may be a beneficial checkpoint as an opportunity to provide interventions to address emerging postpartum depression.

	All patients N=240(%)	No PPD N=200(%)	PPD N=40(%)	p	aOR (95% CI)*
Intervention at Mood Check	65 (27.1)	50 (25.0)	15 (37.5)	0.10	1.68 (0.80,3.52)
Psych Intervention at Mood Check	51 (21.2)	39 (19.5)	12 (30.0)	0.14	1.67 (0.76, 3.67)
Urgent/Emergent Intervention at Mood Check	7 (2.9)	5 (2.5)	2 (5.0)	0.39	--
Expressed sadness at mood check	57 (23.8)	43 (21.5)	14 (35.0)	0.07	2.24 (1.05, 4.78)
Expressed anxiety at mood check	48 (20.0)	38 (19.0)	10 (25.0)	0.39	1.60 (0.70, 3.63)
Expressed stress at mood check	32 (13.3)	26 (13.0)	6 (15.0)	0.73	--
Expressed irritability at mood check	6 (2.5)	5 (2.5)	1 (2.5)	>0.99	--

548 Fetal growth trajectories in women with chronic hypertension and superimposed pregnancy-associated hypertensive disorders

Charlotte Orzolek, Victoria Ly, Tieg E. Beazer, Dongmei Li, J. Christopher Glantz

Strong Memorial Hospital University of Rochester, Rochester, NY

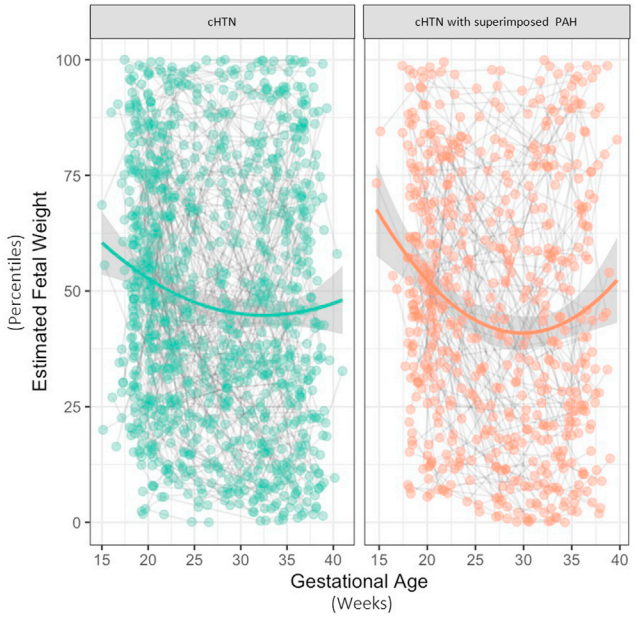
OBJECTIVE: To compare longitudinal fetal growth trajectories between those who develop superimposed pregnancy-associated hypertensive disorders (PAH) versus pregnant patients with only chronic hypertension (cHTN).

STUDY DESIGN: Retrospective cohort study from 2015-2021 comparing fetal growth patterns in cHTN vs cHTN with superimposed PAH (including preeclampsia and HELLP syndrome). Included patients were age ≥18 with singletons, had cHTN or superimposed PAH by 2020 ACOG guidelines and ≥3 ultrasounds with growth assessment. Pre-gestational diabetics and neonates with genetic disorders were excluded. Significant covariates were selected for linear mixed effects model with restricted maximum likelihood estimates for each group. EFW, BPD, HC, AC, and FL of absolute values and percentiles versus gestational age were plotted using locally estimated scatterplot smoothing (LOESS) curves. Mean and SD of biometric parameters were generated weekly from 17-39 weeks gestation with paired differences calculated. Maternal and neonatal outcomes were also compared.

RESULTS: 341 patients were analyzed: 219 (64%) had cHTN and 122 (36%) classified with cHTN with superimposed PAH. 1593 ultrasounds were used to generate growth trajectories. LOESS curves of biometry percentiles and measurements were not significantly different. There was no significant difference when comparing mean measurements in grams and millimeters of EFW, BPD, HC, AC, or FL, with week-to-week paired comparisons ranging from -178 -77 g for EFW and -10 to 6 mm for AC ($p > .05$). No difference in FGR or SGA infants ($p=0.451$). Superimposed PAH group were more likely to experience acute kidney injury, postpartum hemorrhage, have a longer hospital stay, and be on more antihypertensive at delivery and discharge, but there was no difference in delivery modality.

CONCLUSION: No significant patterns of fetal growth were observed in patients with cHTN versus those with cHTN and superimposed PAH in this cohort. This may be due to the heterogeneity in severity and diagnostic factors in types of hypertensive disorders that contribute to variability in fetal growth trajectory.

Figure 1. LOESS regression curves for EFW



549 FOX signaling mediates PLSCR1 and cytokine-induced inflammation of the lung in long-COVID

Michael Paidas[1], Rajalakshmi Ramamoorthy[1], Hussain Hussain[2], Pingping Chen[1], Karen Young[3], Shu Wu[1], Seetharam Deepa[1], Huijun Yuan[1], Andrew D. Masciarella[1], Dibe Di Gregorio[4], Natalia Ravelo[3], Arumugam Jayakumar[1]

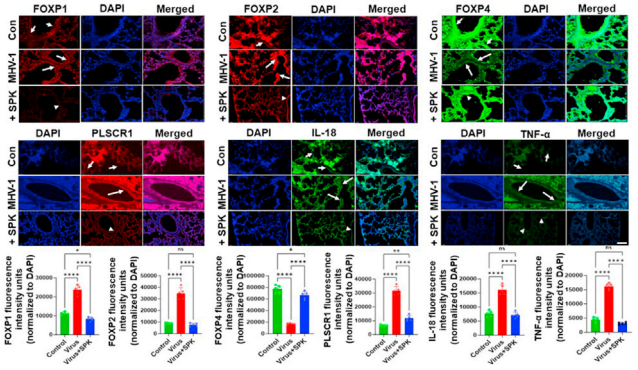
[1]University of Miami Miller School of Medicine, Miami, FL, [2]Larkin Community Hospital, Miami, FL, [3]University of Miami, Jackson Memorial Hospital, Miami, FL, [4]University of Miami College of Arts & Sciences, Miami, FL

OBJECTIVE: We reported an increase in NMDA receptors 1/2 and pathological changes in the lungs post-acute and long-term infection of mice in our established murine hepatitis virus-1 (MHV-1) model of COVID-19 (AJOG, 2023). Since glutamatergic signaling is known to influence forkhead box (FOX) transcription factors and the FOX family of proteins and phospholipid scramblase 1 (PLSCR1) are known to stimulate inflammation in other lung pathologies, we examined whether: 1) MHV-1 impacts FOX signaling, and PLSCR1, which may lead to chronic inflammation in long-term post-infection; 2) SPIKENET (SPK), our COVID therapeutic invention, reverses inflammation (Front Pharmacol, 2022).

STUDY DESIGN: Female A/J mice (Jackson Laboratory, ME, USA) equivalent to human adult age (8-week-old) were divided into 3 groups (n=3/group): 1) control (CON; no infusion); 2) MHV-1 5000 PFU inoculation; and 3) MHV-1 + SPK 5mg/kg/d s.c. on days 2,4,6. Mice were sacrificed 12 months post-inoculation. Protein levels of FOXP1,2,3,4, PLSCR1, and cytokines IL-6, IL-1β, IL-10, IL-18 and TNF-α were measured by immunofluorescence. Data were analyzed by Tukey's multiple comparisons test using GraphPad 9.5.1 software and presented as % over control.

RESULTS: Alveolar FOXP1 and FOXP2 protein levels are increased (short arrows in CON, long arrows in MHV-1) 12 months post-MHV-1 infection (109.61% and 291.78%, resp., over CON; $p< 0.0001$) (Fig. 1) (Scale bar=35 μm). FOXP4 levels are decreased (78.4% reduction, as compared to CON; $p< 0.0001$ vs. CON) (Fig. 1). In MHV-1-infected mice, PLSCR1 levels are increased (384.4% over CON; $p< 0.0001$). IL-18 and TNF-α showed the greatest increase (110.30 and 274.12%, resp., over CON; $p< 0.0001$) (Fig. 1). SPK normalized all aberrant changes (arrowheads) (Fig.1).

CONCLUSION: Increased FOXP1, FOXP2, IL-18, and TNF-α, are associated with the development of chronic lung injury, and reduced FOXP4 levels might be the major driving factor. Moreover, the protective effect of SPK strongly suggests the potential therapeutic benefit of SPK in counteracting lung dysfunction in long COVID.



550 Fetoscopic Spina Bifida (fSB) repair with Human Umbilical Cord (HUC) Compared with Open In-Utero SB Repair (oSB)

Ramesha Papanna[1], Stephen A. Fletcher[1], Lovepreet Mann[1], Jeannine Garnett[1], Neha Das Agarwal[1], Ashley Salazar[1], Sami Backley[2], Shreya Pandiri[1], Eric P. Bergh[2], Mary Austin[1], Brandon Miller[1], Jerrie Refuerzo[2], Jimmy Espinoza[3], Anthony Johnson[1], Ranu Jain[4], Kuojen Tsao[5]

[1]McGovern Medical School at UTHealth Houston, Houston, TX, [2]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX, [3]McGovern Medical School at the University of Texas Health Science Center Houston, The Fetal Center- Children's Memorial Hermann Hospital, Houston, TX, [4]Division of pediatric anesthesiology, Department of Anesthesiology, Critical Care and Pain Medicine, Houston, TX, [5]McGovern Medical School at Houston, UTHealth Houston, Houston, TX

OBJECTIVE: After successfully testing fSB repair with HUC as a meningeal patch for small myelomeningocele cases, we expanded to include all spina bifida defects, aiming to compare fSB with oSB repair.

STUDY DESIGN: Under a single-arm interventional Food and Drug Administration investigational device exemption and Institutional Review Board approved protocol, we offered fSB-HUC to patients who were candidates for oSB with a fetal spina bifida. The surgical approach was laparotomy-assisted via 3 ports (5 mm, 16 Fr and 9 Fr), with anchored fetal membranes, and it was performed under heated-humified carbon dioxide at a gestational age of 24−25 $^{6/7}$ weeks. Following placode dissection, the HUC patch was sutured circumferentially using a 4-O Stratafix suture, followed by skin closure with or without HUC patch. Three independent pediatric neurosurgeons assessed the primary outcome of successful closure by image review. Outcomes were compared to our prospective cohort of oSB repair patients from the same center.

RESULTS: Overall, 50/53 consented to participate in the study, 49 underwent procedure (1 case excluded due to hypertonic uterus). There were no conversions to open repair. The primary outcome was successful in all 49 fSB-HUC repairs. Significant difference in variables in gestational at evaluation and myeloschis was higher in fSB repair(Table). The total operative time and fetal surgical time was 90 minutes longer in the fSB-HUC repair group compared to oSB repair. There was no difference in preterm premature rupture of membranes and gestational age at delivery. Fifty-eight percent of fSB-HUC repair cases delivered vaginally. At birth, there was no leakage of cerebrospinal fluid in the fSB-HUC group compared to 5% in the oSB group, but it did not reach statistical difference.

CONCLUSION: Fetoscopic myelomeningocele repair using the HUC as a meningeal patch is feasible, having comparable neonatal short-term outcomes when compared to open in-utero repair. Vaginal delivery was possible in the majority of fetoscopically repaired patients.

Table 1. Comparing preoperative, operative and clinical outcomes between fSB repair to oSB repair

	fSB-HUC repair	oSB repair	p-value

551 Early Onset Neonatal Sepsis: Prevalence Of Bacterial Pathogens and Maternal Risk Factors

Noam Pardo[1], Abraham Tsur[2], Sharon Amit[2], Yossi Bart[3], Anat Pardo[4], Ben Peleg[2], Halit Kantor[5], Rakefet Yoeli[6], Shali Mazaki-Tovi[7], Michal Fishel Bartal[8]

[1]Sheba Medical Center, Tel Hashomer, Ramat-Gan, Tel Aviv, [2]Sheba Medical Center, Ramat-Gan, HaMerkaz, [3]McGovern Medical School at UTHealth Houston, Houston, TX, [4]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, Tel-Aviv, Israel, [5]University of Haifa, Haifa, Hefa, [6]Sheba Medical Center, Tel-Hashomer, Kiriat Ono, HaMerkaz, [7]Chaim Sheba Medical center, Tel HaShomer, Ramat Gan, HaMerkaz, [8]McGovern Medical School at UTHealth Houston, Sheba Medical Center, Tel Hashomer, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Houston, TX

OBJECTIVE: Early onset neonatal sepsis (EOS) is a rare yet life-threatening condition occurring in 1-2 neonates per 1000 live births. Diagnosis may be elusive, often leading to delay in treatment and, subsequently adverse neonatal consequences. This study aimed to describe risk factors, current pathogens, and outcomes associated with EOS.

STUDY DESIGN: This was a retrospective study of all live births (2013 to 2022) at a single tertiary center. EOS was diagnosed by a positive blood culture within 72 hours of delivery. Neonates with positive cultures of pathogens known to be contaminants were excluded (n=131). The rate of maternal, delivery risk factors, and outcomes associated with EOS, were evaluated.

RESULTS: Of 100,081 live births during the study period, EOS was diagnosed in 95 neonates (0.1%), with Escherichia Coli being the most common pathogen, followed by Viridans Streptococci and Group B Streptococci (n=29,30.5%; n=25,26.3%; n=11, 11.6%) respectively. There were no differences in maternal age, BMI, parity, induction rate between those with EOS compared to those without. Incidence of antenatal corticosteroids treatment, unknown GBS status, PPROM, prolonged rupture of membranes, intrapartum fever, and meconium-stained amniotic fluid were all more frequent in neonates with EOS. Of note 51% of individuals with neonatal EOS received antibiotics prior to delivery. As expected, neonates with EOS were more likely to be born via cesarean delivery, at an earlier gestational age and had a lower birth weight. However, 50% of EOS occurred at term, with 50% of neonates had a birthweight $\geq$ 2500g. Neonates with EOS were more prone to adverse neonatal outcome, with a median length of hospital stay of 25 days and a mortality rate of 7.4%. Mothers to neonates with EOS were more prone to postpartum hemorrhage, blood transfusion, and postpartum fever.

CONCLUSION: At a tertiary care center, EOS was uncommon but was associated with a high mortality rate. An improved understanding of modifiable risk factors and reassessment of preventative measures is warranted.

Table :Maternal Characteristics and neonatal outcomes associated with Early Neonatal Sepsis

Variable	Control N=99,986	Early Neonatal Sepsis, N=95	p-value
Maternal and Intrapartum Characteristic			
Maternal Age (years)	32.68 (5.23)	32.11 (5.89)	0.19

552 Effect of Oral Furosemide Use on Postpartum Readmissions and Blood Pressure Trends

Easha Patel[1], Courtney M. Bisson[2], Ariel Mueller[3], Luke P. Burns[3], Sanela Andelija[3], Colleen Duncan[3], Sarosh Rana[3]
[1]University of Chicago Medicine, Cleveland Clinic, Cleveland, OH, [2]University of Chicago and NorthShore University Health System, Chicago, IL, [3]University of Chicago Medicine, Chicago, IL

OBJECTIVE: A hospital-wide, quality program aimed to improve postpartum care related to hypertensive disorders of pregnancy (HDP), called STAMPP HTN, was implemented at our institution and remote patient monitoring (RPM) was added to this program. Patients with a diagnosis of preeclampsia or gestational hypertension were started on oral furosemide (PO Lasix) as a prior study demonstrated that a five-day course of Lasix can help improve the time to hypertension resolution. The purpose of the present study was to compare blood pressure (BP) trends and readmissions amongst patients who did and did not receive Lasix.

STUDY DESIGN: Prospective cohort study of postpartum patients with HDP at the University of Chicago (UCM) between October 2021 and April 2022. Patients were enrolled into RPM program for BP monitoring and started on PO Lasix as standard of care. Data was obtained from the electronic medical record (EMR) for six weeks postpartum. The primary objective was readmission up to six weeks postpartum. The secondary objective was BP trends across six weeks.

RESULTS: There were 545 total patients in the RPM program during the study period, with 306 consenting to data collection. Of these, 203 eligible patients received PO Lasix who contributed to 6081 BP recordings in 6 weeks. 18.2% of patients who received Lasix were readmitted versus 21.8% of those who did not ($p = 0.55$). There was no difference in readmissions for hypertension (15.3% vs 20.0%, $p=0.40$) or rates of hypertension (BP $\geq$ 140/90) in the first week postpartum between those who did and did not receive Lasix (43.3% vs 35.4%, $p = 0.63$). Diastolic blood pressures at the six-week visit were lower in the Lasix group compared to those without (75 [70, 81] vs 81 [76, 97]; $p=0.04$).

CONCLUSION: The addition of Lasix in an already existing postpartum hypertension program did not result in fewer hospital readmissions or better blood pressure control in first week PP although diastolic blood pressures were lower at the six-week visit in patients who received Lasix. Larger studies need to be done to validate real world impact of routine use of Lasix postpartum.

553 Evaluating AI's Prediction of Time Until Delivery Across Trimesters with Consideration of Influential Factors

Neil Bharat Patel[1], John O'Brien[1], Robert Bunn[2], John A. Bauer[1], Brandon Schanbacher[1], Garrett K. Lam[3]
[1]University of Kentucky, Lexington, KY, [2]Baiby LLC, Highlands Ranch, CO, [3]Sera Prognostics, Lexington, KY

OBJECTIVE: To examine the accuracy of artificial intelligence (AI) in predicting delivery timing as gestational age progresses with consideration of risk factors.

STUDY DESIGN: A proprietary AI software was trained and evaluated on 555,948 de-identified ultrasound images from 19,920 unique exams in 5,714 patients who delivered at the University of Kentucky from 2017-2021. Deidentified ultrasound images from 79% of this cohort (4,505 patients, 15,614 unique studies, 435,857 images) were used to train the AI. Clinical characteristics were excluded to blind the AI towards confounding demographics.

The remaining 21% (1,209 unique patients, 4,306 ultrasound studies, 120,091 total images) were used for derivation and validation of the AI's performance. Delivery outcomes were blinded from the AI analysis by independent 3rd party monitoring. The predicted number of days from exam until delivery were made for each patient after each unique ultrasound exam. R^2 values were generated to correlate the AI's predictions with the actual number of days until delivery.

The validation set was divided into subgroups based on GA at exam. The CI at each trimester were compared. The influence of potentially confounding variables on AI prediction within each trimester was examined by comparison to a reference subgroup.

RESULTS: 1,514 patient exams were evaluated to assess prediction, See Table. The Mean Absolute Error between the AI prediction vs actual time to delivery was 15.06 days (95% CI 12.13-17.98) in the 1st trimester, 14.25 days (95% CI 12.59-15.91) in the 2nd trimester, and 12.16 (95% CI 10.79-13.53) days in the third. The overlapping confidence intervals suggest the AI did not operate differently over time. Accuracy of prediction did not vary across most risk factors examined (Age, BMI, and Race) except those with a history of PTB in the mid-trimester.

CONCLUSION: AI can predict delivery timing from ultrasound images alone and the performance did not vary appreciably across trimesters nor was it influenced by most patient characteristics. Further improvement in prediction for patients with a prior preterm birth is ongoing.

Table 1. Correlation of Predicted versus Actual Gestational Age at Delivery per Trimester stratified by Factors that may impact AI performance.

554 Effect of COVID-19 variants on placental vascular pathology, with and without vaccination

Virali Patel[1], **Rupsa C. Boelig**[2]

[1]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA, [2]Thomas Jefferson University Hospital, Philadelphia, PA

OBJECTIVE: Maternal COVID-19 infection during pregnancy has been associated with higher rates of placental pathology, preterm birth, and preeclampsia, but these studies were largely done during wild-type and delta periods and prior to vaccination. This study aims to characterize the effects of COVID-19 infection during pregnancy on placental pathology through periods of recent variants of interest, with and without vaccination.

STUDY DESIGN: This was a retrospective cohort study of patients with a diagnosis of COVID-19 infection during pregnancy who delivered in 2020-2021 (wild-type/delta variant) and 2022-2023 (omicron variant), with and without vaccination. The primary outcome was placental maternal vascular malperfusion (MVM) based on Amsterdam criteria. Multivariable regression analysis was performed, controlling for race, ethnicity, and BMI.

RESULTS: **384** patients were included: 249 controls, 60 COVID+ during 2020-2021, and 75 COVID+ during 2022-2023. Of the patients who tested positive during 2020-2021, 56 (93.3%) were unvaccinated, and during 2022-2023, 47 (62.7%) were vaccinated. There was a significant increase in the rate of MVM in the COVID+ 2020-2021 cohort compared to control, and although rates of MVM were higher in the COVID+ 2022-2023 cohort, this was not statistically significant (Table). Higher rates of MVM were seen in all COVID+ patients from 2020-2021 vs 2022-2023 (48.3% vs 24.0%, aOR 2.84 (1.33-6.05) and among unvaccinated COVID+ patients from 2020-2021 vs 2022-2023 (48.2% vs 17.9%, aOR 1.50 (1.01-2.21). Rates of preterm birth and preeclampsia were similar.

CONCLUSION: There were reduced rates of placental maternal vascular pathology in patients who were COVID+ during 2022-2023 compared to 2020-2021, which may be due to a combination of different strain and pre-existing immunity in later time periods. Reduced clinical virulence of recent strains (omicron) is reflected in reduced impact on placental vascular pathology.

Table: Rates of Placental Maternal Vascular Malperfusion in Pregnancies complicated by COVID-19 delivered in 2020-2021 (wild-type/delta) and 2022-2023 (omicron)

555 Does Amniotic Fluid Index Predict Adverse Pregnancy Outcomes in Preterm Prelabor Rupture of Membranes?

Pooja Brar, Avi Hameroff

University of Pittsburgh Medical Center, Harrisburg Hospital, Harrisburg, PA

OBJECTIVE: Preterm prelabor rupture of membranes (PPROM) is associated with increased maternal and fetal morbidity. Inpatient management of PPROM after viability is recommended, however, the optimal antenatal surveillance protocol is not well defined. While some providers measure the amniotic fluid index (AFI) weekly, the clinical utility of this practice is unclear. Our objective was to determine if there was an association between AFI and adverse perinatal outcomes in pregnancies with PPROM.

STUDY DESIGN: This was a retrospective study of singleton pregnancies over a six-year period admitted with PPROM between 23 to 33-6/7 weeks gestation that had measurements of amniotic fluid at admission. Patients with multiple gestation, chorioamnionitis, nonreassuring fetal status, or advanced labor at time of admission were excluded. Patients were stratified into two groups: AFI $<$ 5 cm and AFI $>$ /= 5 cm. Demographics were collected for both groups. The primary outcomes were latency until delivery, mode of delivery, and indication for delivery. Secondary outcomes included gestational

age at delivery, postpartum length of stay (LOS), Apgar scores, birthweight, NICU admission rate, perinatal death, and NICU LOS.
RESULTS: 109 cases met inclusion criteria. Of those patients, 39% were delivered via cesarean section (42/109). AFI was < 5 in 38 patients (34.9%) and > /=5 in 71 patients (65.1%). There was no statistically significant difference in demographics, latency until delivery, or mode of delivery between the two groups. Greater AFI measurement was associated with a higher fetal birthweight (p=0.0004), higher one minute Apgar scores (p=0.0201), and shorter NICU LOS (p=0.0138).
CONCLUSION: AFI assessment at time of admission for PPROM was not a predictor of pregnancy latency or mode of delivery, although a greater measurement was associated with increased birthweight and decreased LOS in the NICU. Further research is required to identify an optimal method of evaluation of these at-risk pregnancies.

556 Fetal effects of maternal exercise on pregnancies with fetal growth restriction

Alissa Paudel[1], Jill Maples[2], Kristina Carter[3], Linda M. Szymanski[4], Nikki B. Zite[5], Rachel Tinius[6], Kimberly B. Fortner[2]
[1]University of Tennessee Medical Center Knoxville, Knoxville, TN, [2]University of Tennessee Medical Center, Knoxville, TN, [3]UTMCK, Knoxville, TN, [4]Mayo Clinic, Rochester, MN, [5]University of Tennessee Graduate School of Medicine, Knoxville, TN, [6]University of Western Kentucky, Bowling Green, KY

OBJECTIVE: Exercise has been shown to be safe for uncomplicated pregnancies. Less is known about exercise in pregnancies with fetal growth restriction (FGR). We sought to evaluate the immediate fetal response to exercise in pregnancies with FGR.
STUDY DESIGN: In this single-institution, prospective cohort, 15 individuals between 28w0d and 36w6d gestation with a diagnosis of FGR (fetal weight estimate < 10%ile) were enrolled. Participants were excluded for BMI >40, tobacco or substance use, hypertension on medications, or other contraindications to exercise. Participants exercised on a treadmill at a moderate intensity (defined by rate of perceived exertion (RPE), Borg scale) for 30 minutes. Fetal umbilical artery (UA), middle cerebral artery (MCA) and aortic dopplers were sampled immediately before and after exercise. Vital signs and RPE were monitored throughout exercise. Doppler waveforms were reviewed by blinded study personnel. Cerebro-placental ratios (CPR) were calculated after sampling. Pre and post-exercise dopplers were compared using related samples Wilcoxon Signed Rank Sum tests after testing for normality.
RESULTS: Biophysical profiles and non-stress tests were reassuring after exercise. Pre-exercise UA dopplers were not different from post-exercise. Dopplers were recorded immediately after completion of exercise with a focus on UA dopplers first [mean time 1 min (SD 0.193)]. No differences were noted between pre- and post-exercise aortic or MCA dopplers or in CPR. (Table 1). Mean maximal maternal heart rate was 141.3 (SD 11.3) bpm. A single participant had hypoglycemia (BG 52) post-exercise.
CONCLUSION: Our preliminary data suggests no changes in fetal well-being among pregnancies with FGR after a single bout of moderate intensity exercise. Continued data collection is ongoing with the aim to support safety of moderate intensity exercise in the third trimester for FGR pregnancies. Future work to determine long-term effects of exercise in this population is needed.

Doppler site	n	Pre-exercise, median [IQR]	Post exercise, median [IQR]	*P value*
Umbilical artery (systolic/diastolic ratio)	15	2.62 [2.24 - 2.92]	2.62 [2.37 - 3.05]	*0.182*
Umbilical artery (pulsatility index)	15	0.95 [0.81 - 1.07]	0.95 [0.84 - 1.04]	*0.820*
Aortic (pulsatility index)	13	1.82 [1.57 - 2.32]	1.69 [1.42 - 2.02]	*0.169*
Middle cerebral artery (pulsatility index)	15	1.41 [1.30 - 1.79]	1.66 [1.41 - 2.14]	*0.666*
Cerebroplacental ratio (CPR)	15	1.64 [1.52-1.99]	1.75 [1.56-2.13]	*0.955*

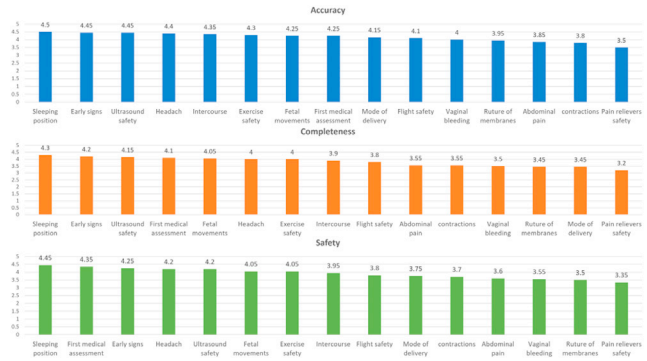
557 Evaluating the Validity of ChatGPT Responses on Common Obstetric Issues: Potential Clinical Applications and Implications

Tzuria Peled[1], Hen Sela[2], Ari Weiss[1], Sorina Grisaru-Granovsky[1], Swati Agrawal[3], Misgav Rottenstreich[4]
[1]Shaare Zedek Medical Center, Hebrew University of Jerusalem, Jerusalem, Yerushalayim, [2]Shaare Zedek Medical Center, Jerusalem, Yerushalayim, [3]Hamilton Health Sciences, Toronto, ON, [4]McMaster University, Hamilton, ON

OBJECTIVE: To evaluate the quality of ChatGPT responses to common issues in obstetrics and assess its ability to provide reliable responses to pregnant individuals. The study aimed to examine the responses based on expert opinions using predetermined criteria, including accuracy, completeness, and safety.
STUDY DESIGN: We curated 15 common and potentially clinically significant questions that pregnant women are asking. Two native English-speaking women were asked to reframe the questions in their own words, and we employed the ChatGPT language model to generate responses to the questions. To evaluate the accuracy, completeness, and safety of the ChatGPT's generated responses we developed a questionnaire with a scale of one to five. that Obstetrics and Gynecology experts from different countries were invited to rate accordingly. The ratings were analyzed to evaluate the average level of agreement and percentage of positive ratings (four or above) for each criterion.
RESULTS: Out of the 42 experts invited, 20 responded to the questionnaire. The combined score for all responses yielded a mean rating of four, with 75% of responses receiving a positive rating (four or above). While examining specific criteria, the ChatGPT responses were better for the "accuracy" criterion, with a mean rating of 4.2 and 80% of the questions received a positive rating. The responses scored less for the "completeness" criterion, with a mean rating of 3.8 and 46.7% of questions received a positive rating. For "safety", the mean rating was 3.9 and 53.3% of questions received a positive rating. There was no response with an average negative rating below three.
CONCLUSION: This study demonstrates promising results regarding potential use of ChatGPT's in providing accurate responses to obstetric clinical questions posed by pregnant women. However, it is crucial to exercise caution when addressing inquiries concerning the safety of the fetus or the mother.



558 Defining "early AROM" during induction of labor after cervical ripening and neonatal outcomes

Marta Perez[1], Emily Hall[2], Miriam Alvarez[2], George A. Macones[3], Lorie M. Harper[2], Alison G. Cahill[2]
[1]UT Dell Medical School, Austin, TX, [2]University of Texas at Austin, Dell Medical School, Austin, TX, [3]The University of Texas at Austin, Austin, TX

OBJECTIVE: Early artificial rupture of membranes (eAROM) during induction of labor (IOL) is associated with shorter time to delivery with no difference in cesarean delivery (CD) or infectious morbidity. However, definitions of eAROM vary and were developed prior to contemporary labor management. We analyzed associations of varying definitions of eAROM at specific, incremental cutoffs by either time since completion of cervical ripening or by cervical dilation with neonatal outcomes.

STUDY DESIGN: This was a retrospective cohort study of patients who had IOL and cervical ripening with intact membranes, term, singleton pregnancy at a tertiary care hospital 2015-2022. For the time-based analysis, we grouped patients by timing of ROM after completion of first dose of cervical ripening. For the dilation-based analysis, we grouped patients by the cervical dilation at the time of or preceding ROM. The outcomes were neonatal intensive care unit (NICU) admission and 5-minute APGAR < 7. Descriptive statistics were performed using chi-squared tests. Log-binomial regression was performed to estimate risk ratios adjusted for mode of delivery, gestational age, and maternal fever.

RESULTS: Of the 4,562 patients who met inclusion criteria, 353 (7.7%) infants were admitted to the NICU and 75 (1.6%) had a 5-minute APGAR < 7. Time of ROM since completion of cervical ripening was associated with higher risk of NICU admission and 5-minute APGAR < 7 in the unadjusted analysis. However, in the adjusted analysis, only ROM ≥12 hours after completion of cervical ripening had significantly higher risk of 5 min APGAR < 7 (aRR [95% CI]: 2.61 [1.14-5.98]), but not NICU admission. For the dilation-based analysis, there was no association with increased risk of either outcome in unadjusted or adjusted analysis.

CONCLUSION: In examining neonatal outcomes by varied definitions of eAROM, ROM ≥12 hours after completion of cervical ripening is associated with increased risk of 5-minute APGAR < 7. There is no association of cervical dilation at ROM with adverse neonatal outcomes. Later, rather than eAROM, by time may increase neonatal risk.

Figure

Association of eAROM with NICU admission					
Time based analysis			Dilation based analysis		
Group	aRR* (95% CI)	p-value	Group	aRR* (95% CI)	p-value
0 to 4 hours	--	--	<2cm	--	--

559 Associations between Endocannabinoids and Preoperative Pain in Patients Undergoing Cesarean Delivery: an Exploratory Study

Amelie Pham[1], Sarah S. Osmundson[1], Phillip J. Kingsley[1], Sachin Patel[2], Alex Pedowitz[3], Laura Sorabella[1], Stephen Bruehl[1]
[1]Vanderbilt University Medical Center, Nashville, TN, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]University of Miami, Leonard M. Miller School of Medicine, Miami, FL

OBJECTIVE: Endocannabinoids (EC) are endogenous cannabinoid receptor agonists involved in multiple physiological processes including nociception, cognitive function, and mood. We explored the hypothesis that EC levels in cerebral spinal fluid (CSF) and plasma are associated with patients' preoperative pain and psychosocial phenotype prior to cesarean delivery.

STUDY DESIGN: Between 2021-2022, we enrolled pregnant patients without opioid use disorder or chronic pain and collected plasma and CSF during neuraxial anesthesia placement immediately prior to scheduled cesarean delivery. Preoperative patient phenotype was determined using pain and psychosocial measures including the McGill Pain Questionnaire 2 (MPQ-2) and PROMIS-29 profile. EC levels in CSF (2-AG) and plasma (2-AG and AEA) were assayed using liquid chromatography-mass spectrometry. Hierarchical linear regressions examined associations between preoperative EC levels and preoperative phenotype measures, controlling for confounding effects of age, body mass index (BMI) at delivery, and race.

RESULTS: Complete data were available for 136 patients — mean maternal age 31.1 years (SD 5.3), BMI 34.4 kg/m^2 (SD 8.6), 27.1% publicly insured, and 77.6% non-Hispanic White. Cannabis and tobacco use were uncommon (5.9% and 2.2%, respectively). Additionally, 22.0% had a current or history of psychiatric illness (e.g., depression), with half requiring pharmacotherapy (10.6%). Mean preoperative EC levels (in pmols/mL) were: CSF 2-AG: 2.1 (SD 1.1), plasma 2-AG: 52.4 (SD 28.3), and plasma AEA: 0.9 (SD 0.5). Elevated preoperative plasma 2-AG levels were significantly associated only with lower ability to engage in social roles prior to cesarean delivery; other ECs (CSF 2-AG and plasma AEA) were not associated with any pain or psychosocial measures (Table).

CONCLUSION: EC levels in CSF and plasma are unlikely to influence cesarean patients' preoperative pain and psychosocial phenotype. Significant associations found in this exploratory study were limited to measures reflecting patients' inability to engage in social roles.

Table . Adjusted coefficients for hierarchical linear regressions between preoperative endocannabinoids levels and preoperative pain and psychosocial phenotype measures

Endocannabinoids	Preoperative Measures*	Beta	Standard Error	p-value
CSF Levels				
2-AG	PROMIS Anxiety	-0.475	0.860	0.582

	MPQ-2 Total	0.047	0.638	0.610

AEA: anandamide; 2-AG: 2-arachidonoylglyerol; EC: Endocannabinoid; MPQ-2: McGill Pain Questionnaire-2, short form; PROMIS-29: Patient Reported Outcomes Measurement Information System (PROMIS) 29 Profile v1.0

Bold: statistically significant at p<0.05

Hierarchical linear regressions controlled for the potential confounding effects of maternal age, body mass index at delivery, and race.

*Pain and psychosocial measures and definitions:

PROMIS Physical Function - ability to engage in routine physical activity

PROMIS Social Roles - ability to engage in social roles

PROMIS Pain Interference - pain-related life interference

MPQ-2 Total - assesses both neuropathic and non-neuropathic pain by rating the extent to which participants experienced each of 22 pain descriptors in the past week, using an 11-point numeric rating scale, with the total score computed by averaging participant ratings across all 22 items.

560 Differences in fetal inflammatory markers among pregnancies treated with oral or intravenous iron supplementation

Sara EK. Phillips, Aditi Bommireddy, Bharti Garg, Monica Rincon, Alyssa Hjelvik, Leonardo Pereira

Oregon Health & Science University, Portland, OR

OBJECTIVE: Little is known about the effects of iron supplementation during pregnancy on fetal markers of inflammation. The objective of this study was to assess whether there are differences in umbilical cord blood (UCB) inflammatory markers among iron-deficient pregnant individuals receiving oral or intravenous (IV) iron supplementation.

STUDY DESIGN: We performed a prospective non-randomized clinical trial comparing oral and IV iron supplementation in singleton, non-anomalous pregnancies (> 24 weeks gestation) with iron deficiency (ferritin < 30 ng/mL). Outcomes were UCB inflammatory markers: interferon (IFN) γ, interleukin (IL) 10, IL-13, IL-1β, IL-1α, IL-4, IL-6, and tumor necrosis factor (TNF) α. We compared UCB markers among oral and IV iron supplementation in the whole cohort and among pregnancies with female and male fetuses. Two-sample t-test or Wilcoxon rank sum tests were used for comparisons, when indicated.

RESULTS: Fifty-three individuals were included; 25 (47.2%) received oral iron and 28 (52.8%) received IV iron. We found no statistically significant differences in baseline demographics and UBC markers between treatment groups of oral and IV supplementation. Among pregnancies with female fetuses, IFNγ (1.63 $\pm$ 0.55 vs 1.27 $\pm$0.31; p=0.04) and TNFα (14.95 [13.84-16.82] vs 11.69 [9.60-13.84]; p=0.003) were higher in the IV iron group compared to the oral iron group. We found no statistically significant differences in UCB markers among pregnancies with male fetuses.

CONCLUSION: There are no differences in fetal inflammatory markers between pregnancies treated with oral and IV iron supplementation overall, however when stratified by fetal sex there are few differences (IFNγ and TNFα were higher in the IV iron group in pregnancies with female fetuses), suggesting that treatment modalities such as IV iron may impact male and female fetuses differently. More information is needed to better assess the long-term effects of iron supplementation on neonatal and child development and these studies should conduct sex stratified analyses.

Table 1. Comparisons of oral vs. IV iron supplementation in the entire cohort (n=53), pregnancies with female fetuses (n=30) and male fetuses (n=23)

UBC markers	Whole cohort (n=53)			Females (n=30)			Males (n=23)

561 Characterization of glucose values in labor by continuous glucose monitoring in gravidas without diabetes mellitus

Kelsey Pinson[1], Valentina Stanley[2], Jane J. Kim[2], Navyaa Sharma[1], Emily Kobayashi[1], Amit Majithia[3], Gladys A. Ramos[4]

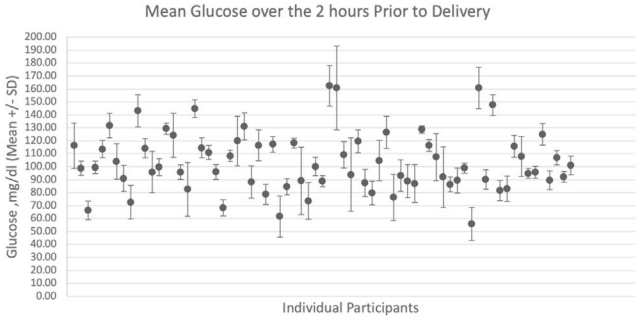
[1]UC San Diego, La Jolla, CA, [2]UC San Diego, San Diego, CA, [3]University of California, San Diego School of Medicine, San Diego, CA, [4]University of California, San Diego, San Diego, CA

OBJECTIVE: Current recommendations for glycemic control during labor in those with diabetes mellitus (DM) are based upon expert opinion. Our objective was to characterize glucose values in labor using continuous glucose monitors (CGM) in term, laboring gravidas without DM to define normoglycemia.

STUDY DESIGN: Prospective observational cohort. CGM was placed in early labor. The following metrics were obtained: glucose at delivery, mean glucose over the 2 hours(hrs) prior to delivery, mean glucose in active and 2nd stage of labor, time in range (TIR) defined as 70-120 mg/dl, time above range (TAR) defined as >120mg/dL, and time below range (TBR) as < 70mg/dL. Neonatal outcomes were assessed. Python 3.10.4 was used for analysis of CGM data and SPSS was used for univariate analysis.

RESULTS: Seventy-two participants were included. Fifty-one (71%) delivered vaginally and 21 (29%) via cesarean. The mean glucose value at delivery was 109±27 mg/dL and over the 2hrs prior to delivery was 99±23 mg/dL. 26% of patients had a glucose >120mg/dL at time of delivery. Mean glucose in active labor was 101±25 mg/dL and in the 2nd stage was 99.5± 23mg/dL. Average TIR from CGM placement to delivery was 69.8% (10-90th percentile 33.8-95.8%) and in the 2hrs prior to delivery was 68.7% (10-90th percentile 0.8-100%). Average TAR for time in labor was 19.9% (10-90th percentile 0-66.2%) and 2hrs prior to delivery was 22.8% (10-90th percentile 0-99%). Average TBR for time in labor was 10.3% (10-90th percentile 0-66%) and 2hrs prior to delivery was 8.5%(10-90th percentile 0-36%). 23 infants had glucose checked for clinical indications and 6 (26%) required treatment for neonatal hypoglycemia.

CONCLUSION: Hyperglycemia was common in patients without DM, with a TAR in labor of nearly 20% and more than 25% of gravidas exceeding glucose of 120mg/dL at delivery. To our knowledge, this is the first study characterizing glucose patterns in women without DM in labor. This data challenges contemporary definitions of normoglycemia in labor. Further study is needed to better define normoglycemia in labor and identify risk factors for adverse outcomes.



562 Factors associated with non-adherence to ACOG guidelines for labor arrest disorders

Bree A. Goodman[1], Shannon E. Beermann[1], Katherine Carbonell[1], Lucy Simpson[2], Michael Dombrowski[1], Roxane M. Rampersad[3], Ebony B. Carter[3], Jeannie C. Kelly[3], Antonina I. Frolova[4], Anthony O. Odibo[4], Nandini Raghuraman[4]

[1]Washington University in St. Louis, St. Louis, MO, [2]Mercy Hospital, St. Louis, MO, [3]Washington University School of Medicine in St. Louis, Barnes Jewish Hospital, St. Louis, MO, [4]Washington University School of Medicine in St. Louis, St. Louis, MO

OBJECTIVE: The ACOG/SMFM Safe Prevention of Primary Cesarean Delivery guidelines provide minimum time criteria at which cesarean delivery (CD) should be performed for a labor arrest disorder. Despite these guidelines, national adherence remains inadequate. We sought to evaluate clinic factors associated with non-adherence to ACOG guidelines for labor arrest diagnoses.

STUDY DESIGN: This is a case-control study of patients who underwent CD for labor arrest disorders from 2018-2021 at a single center. Charts were reviewed for adherence to the *Safe Prevention of the Primary Cesarean Delivery* criteria for failed induction of labor, arrest in the active phase, and second stage arrest. Cases were patients who underwent CD prior to meeting minimum ACOG time criteria for labor arrest. Controls were patients who met ACOG criteria for diagnosis of labor arrest. Maternal, fetal, and unit-level factors were compared between cases and controls.

RESULTS: Of 376 patients with CD for arrest disorders, 206 (55%) met minimum ACOG criteria (controls) and 170 (45.2%) did not (cases). Non-adherence was significantly more common when the obstetrician managed labor remotely compared to in-house obstetricians (54% vs 28%, P= < 0.001). Non-adherence was also more common when Category II tracing was present and was associated with certain types of labor arrest; providers were more likely to adhere to guidelines for failed induction of labor and less likely to adhere to guidelines for second-stage arrest. Providers were more likely to adhere to guidelines for patients with obesity. Factors such as time of day, parity, and co-morbidities did not influence adherence.

CONCLUSION: Maternal, fetal, intrapartum, and unit-level factors influence adherence to ACOG guidelines for labor arrest disorders. Addressing modifiable factors such as provider location may improve adherence and potentially decrease cesarean section rates.

Table: Factors associated with lack of adherence to ACOG criteria for labor arrest disorders

Clinical Factor	ACOG criteria met (n=205)	ACOG criteria not met (n=170)	p-value
Maternal/labor factors			
Advanced maternal age	31 (15.1)	29 (17.1)	0.60
Obesity	**177 (85.9)**	**124 (72.9)**	**<0.01**
Nulliparity	141 (68.4)	122 (71.8)	0.49

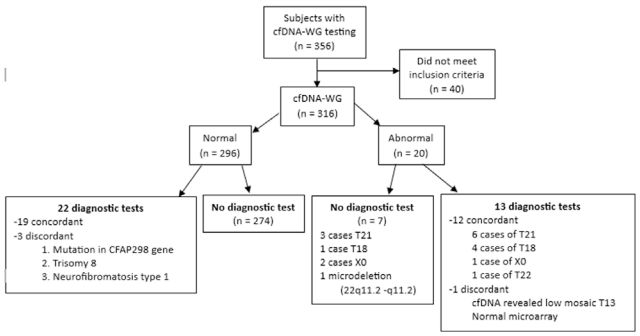
OBJECTIVE: At our institution, cell free DNA whole genome (cfDNA-WG) is offered to patients who decline diagnostic testing after genetic counseling for abnormal fetal ultrasound findings. cfDNA-WG detects > 7 MB duplications and deletions across the genome, whereas diagnostic testing considers any aberration > 1 MB abnormal. We describe cfDNA-WG test performance in our population.

STUDY DESIGN: We performed a retrospective analysis of subjects identified through our genetic counseling database. Our study group was subjects with abnormal fetal ultrasound findings in a singleton pregnancy. Descriptive data was abstracted via chart review. When diagnostic testing was also performed, this was compared to cfDNA-WG results.

RESULTS: We identified 356 subjects with cfDNA-WG results. 40 had normal sonographic exams and were excluded. In the 316 subjects remaining, ultrasound findings included multiple congenital anomalies (n = 107), isolated anomaly (n = 105), isolated soft marker (n = 48), thickened nuchal translucency (n = 46), fetal growth restriction (n = 6), and placental abnormalities (n = 3). cfDNA-WG results were abnormal in 20 cases (6.3%). Most abnormal results (90%) were whole-chromosome aneuploidies: T21 (n = 9), T18 (n = 5), T13 (n = 1), and monosomy X (n = 3). Two other abnormal results included one T22 and one microdeletion (22, q11.2-q11.2). Of the 316 subjects, 35 (11.1%) had diagnostic testing which revealed 4 discordant results where cfDNA-WG was not reflective of diagnostic results (Figure 1), including Trisomy 8 and two single gene disorders (neurofibromatosis 1, CFAP298 gene mutation). In addition, there was a case of low mosaicism for T13, not confirmed in the fetus.

CONCLUSION: In this cohort of subjects who had cfDNA-WG, 6.3% had abnormal testing, most of which could be identified on a standard cfDNA test. There were 3 cases with normal cfDNA-WG in fetuses with significant genetic disorders, giving patients false reassurance and limiting the value of normal results. Our data can aid in patient counseling on benefits and limitations of this test.

Figure 1. Flowchart of cfDNA-WG screening results and follow up.



564 Association between insulin resistance and pregnancy outcomes in obese pregnant individuals

Carmen Proctor[1], **Francesca Facco**[2], **Maisa Feghali**[3]
[1]UPMC Magee-Womens Hospital, Clinton, PA, [2]Magee-Womens Hospital, Pittsburgh, PA, [3]UPMC Magee-Womens Hospital, Pittsburgh, PA

OBJECTIVE: In gestational diabetes (GDM), predominance of insulin resistance is associated with an increased risk of adverse pregnancy outcomes. The Homeostatic Model Assessment of Insulin Resistance (HOMA-IR) is a validated tool to estimate insulin resistance. Our objective was to determine if insulin resistance in early pregnancy, estimated by HOMA-IR, is associated with adverse pregnancy outcomes in obese pregnant individuals.

STUDY DESIGN: From September 2014 to September 2019, obese pregnant individuals, defined as body mass index (BMI) $\geq$ 30 kg/m2, were enrolled in a prospective cohort study. Plasma samples were collected between 14-20 weeks gestation and fasting insulin and glucose levels were measured. Insulin resistance was estimated using HOMA-IR. We assessed the association between HOMA-IR and adverse pregnancy outcomes. Participants were grouped based on low (HOMA-IR $\leq$ 3.8) or high (HOMA-IR $>$ 3.8) insulin resistance. We performed univariate analyses as well as adjusted analyses controlling for pre-pregnancy BMI, smoking and parity.

RESULTS: We analyzed data of 238 participants with a mean HOMA-IR of 4.2 $\pm$ 4.9 (IQR 2.2-4.4). High insulin resistance occurred in n=77 (32.4%) of the cohort. Demographics and pregnancy outcomes by HOMA-IR level are presented in the table. Individuals with high HOMA-IR had a higher pre-pregnancy BMI (42.6 $\pm$ 7.9 vs 38.5 $\pm$ 5.5, $p < 0.0001$) and a higher rate of GDM (16.9% vs 4.3%, $p < 0.0001$) and hypertensive disorders of pregnancy (16.9% vs 11.2%, $p < 0.0001$). Only the rate of GDM remained statistically significant in adjusted analyses (p=0.001). There was no difference in the rate of large for gestational age (LGA), birthweight, and birthweight percentile between individuals with high and low HOMA-IR. In sex-specific analyses, high HOMA-IR was associated with lower birthweight in female infants (p=0.04). This finding was no longer significant after controlling for pre-pregnancy BMI, smoking and GDM (p=0.08).

CONCLUSION: High insulin resistance is associated with a higher risk of GDM in obese pregnant individuals, but it was not related to birthweight or rate of LGA.

Table. Demographics and pregnancy outcomes for low and high insulin resistance

Demographics and outcomes	Low insulin resistance HOMA-IR ≤ 3.8 (n=161)	High insulin resistance HOMA-IR > 3.8 (n=77)	Unadjusted p-value	Adjusted p-value*

565 Association between neonatal abstinence syndrome and access to obstetric delivery facilities

Rebecca Purvis[1], **Alissa Paudel**[1], **William L. Riley**[2], **Suzannah Parker**[3], **Kimberly B. Fortner**[4], **Megan L. Young**[5], **Tara Burnette**[3], **Keri Lattimore**[3]
[1]University of Tennessee Medical Center Knoxville, Knoxville, TN, [2]University of Tennessee Knoxville, Knoxville, TN, [3]University of Tennessee Medical Center, Nashville, TN, [4]University of Tennessee Medical Center, Knoxville, TN, [5]University of Tennessee Graduate School of Medicine, Knoxville, TN

OBJECTIVE: A growing number of counties lack access to delivery facilities offering obstetric care (OBC) due to increasing rates of hospital closures across the country. Rates of neonatal abstinence syndrome (NAS) are often higher in counties with less access to maternal and substance use services. We sought to evaluate the association between diagnosis of NAS and access to a delivering facility with OBC.

STUDY DESIGN: A retrospective chart review involving opiate-exposed maternal-infant dyads who delivered at our safety net hospital from January 2015 to December 2022 was conducted. County of residence, use of prescribed and non-prescribed substances, and neonatal outcomes were collected. March of Dimes classifications for access to delivery facilities were applied by county (delineated as full, moderate, low, or no access). The primary outcome was a diagnosis of NAS as compared to OBC access in primary county of residence.

RESULTS: A total of 1301 dyads with substance exposure were identified and stratified by access to a delivery facility with OBC (n=575 (44.2%) resided in no; n=290 (22.3%) in low; and n=436 (33.5%) in moderate). Of note, none of the dyads included had full access to delivery facilities. Of the neonates, 93% displayed NAS symptoms and 7% did not. Multivariate regression was then performed on outcome variables including LOS, need for pharmacologic therapy, and NAS symptoms using no access as the base. Moderate access was associated with decreased odds of needing pharmacologic therapy (OR 0.588, SE 0.082, $p < 0.01$) and NAS (OR 0.549, SE 0.13, $p < 0.05$) when compared to no access.

CONCLUSION: Low or no access to delivery facilities was associated with increased odds of NAS and need for neonatal pharmacologic therapy. This finding continues to demonstrate the importance of increasing access to maternal, substance use, and mental health services for improvement of both maternal and neonatal outcomes. Further studies should investigate why residing in a county with moderate access to delivery facility with OBC improved neonatal outcomes in this population.

Table 1
Neonatal Outcomes Based on Level of Access to Care

	Level of Access	Odds Ratio (SE)	β Coefficient (SE)	Difference in LOS, d (SE)

566 Co-occurring Opioid and Stimulant Use Disorders: Is there an Incremental Impact on Adverse Pregnancy Outcomes?

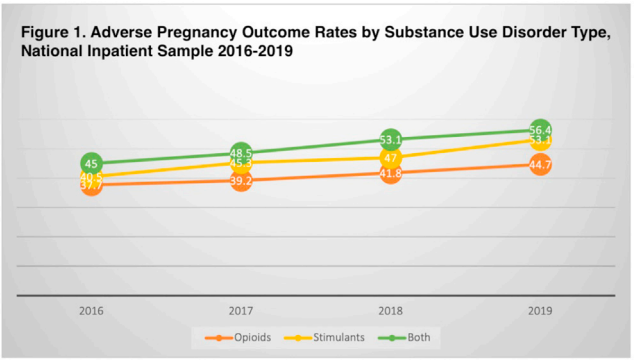
Alexandra Schroeder[1], Noor Al-Hammadi[2], Tucker Doiron[2], Niraj R. Chavan[2]
[1]St. Louis University School of Medicine, St. Louis, MO, [2]St. Louis University, St. Louis, MO

OBJECTIVE: To assess the impact of co-occurring opioid and stimulant use disorder on adverse pregnancy outcomes (APO) among inpatient delivery admissions.

STUDY DESIGN: We conducted a cross-sectional analysis of delivery admissions from the Healthcare Cost and Utilization Project (HCUP) National Inpatient Sample (NIS) from 2016 to 2019. ICD-10 codes were used to identify admissions with opioid and stimulant use disorder and APOs. Diagnosis Related Group codes were used to identify delivery admissions. APO was defined as a composite to include hypertensive disorders, antepartum hemorrhage, postpartum hemorrhage, preterm birth, and fetal growth restriction. Multivariable logistic regression analyses were undertaken to predict the likelihood of APOs among admissions with opioid use, stimulant use, or co-occurring (opioid + stimulant) use disorders while adjusting for sociodemographic characteristics including age, race and/or ethnicity, insurance payer and income level.

RESULTS: 25,243 delivery hospitalizations including 16,526 (65.5%) with opioid use disorder, 7,241 (28.7%) with stimulant use disorder and 1,476 (5.8%) with co-occurring (opioid + stimulant) use disorder were identified. The prevalence of APOs was highest among delivery hospitalizations with co-occurring use disorder (767/1,476, 52.0%, p< .001), as compared with opioid use disorder (6,772/16,526, 41.0%) or stimulant use disorder alone (3,424/7,241, 47.3%). Rates of APO increased significantly in consequent years for all cohorts (Figure 1) (p < .001). Adjusting for relevant sociodemographic covariates, co-occurring use disorder was identified as the strongest predictor of APOs [aOR 3.495 (CI 95%, 3.14-3.89)] as compared to opioid [aOR 2.34 (CI 95%, 2.17-2.31)] or stimulant use disorder [aOR 2.87 (CI 95%, 2.73-3.01)] alone.

CONCLUSION: Co-occurring opioid and stimulant use disorders represent the highest magnitude of risk for APOs, beyond the risk attributable to stimulants or opioids alone. This underscores the need for bolstering substance use recovery services in pregnancy given the recent increases in stimulant use and co-occurring use disorders.



567 Cutaneous scar characteristics and their association with abdominal adhesions during repeat CD: a prospective study

Lee Rak[1], Daniela Chen[1], Raud Qassim[2], Naama Golan[3], Eran Hadar[3]
[1]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, HaMerkaz, [2]Meir Medical Center, Technion, Hefa, [3]Rabin Medical Center, Petach-Tikva, HaMerkaz

OBJECTIVE: Cesarean delivery (CD) poses a risk of intra-abdominal adhesions, leading to various complications. We aimed to investigate the association between skin scar characteristics and subcutaneous and intra-abdominal adhesions in order to improve preoperative assessment.

STUDY DESIGN: Consecutive consenting pregnant women scheduled for elective repeat CD were prospectively recruited between February and July 2023. Detailed demographic, medical, obstetric, and gynecological information was collected, along with information of previous and current CD. Skin scar appearance was evaluated on admission using the validated Vancouver and Stony Brook Scar Scales. Intra-abdominal adhesions were assessed intraoperatively using the Modified Nair's scoring system. We analyzed the correlation between cutaneous scar scoring, subcutaneous/intra-abdominal adhesion scores and surgery length.

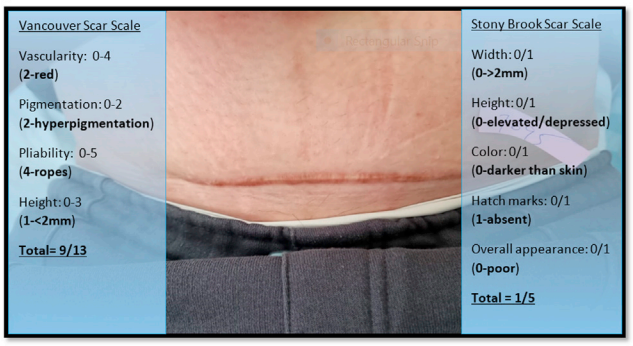
RESULTS: One hundred and eleven women were recruited. Participants had one (41.4%), two (42.3%) or 3 and more (16.2%) previous CDs. Mean maternal age was 35.6±5.1, median body mass index (BMI) was 24.5 (16.9-60.2) kg/m^2 and median gestational age at surgery was 38+3 (36+3-41+0) weeks. The average surgery length was 49.1±15.1 minutes.

The mean Vancouver Scar Scale and Stony Brook Scar Scale scores were 4.12 (±3.15) and 3.02 (±1.77), respectively. These scores showed weak but significant correlations with both intra-abdominal adhesion score (Spearman's rho = 0.24, p= 0.012 and Spearman's rho = - 0.23, p= 0.015, respectively) and subcutaneous adhesion score (Spearman's rho = 0.24, p= 0.012 and Spearman's rho = -0.22, p = 0.018, respectively). No significant correlation was found between these scar scales and surgery length.

CONCLUSION: This prospective study highlights the importance of cutaneous scar characteristics in predicting subcutaneous and intra-abdominal adhesions during repeat CDs. We found weak but significant correlation between scar characteristics and subcutaneous

and intra-abdominal adhesions. Healthcare professionals can use this knowledge to tailor surgical approaches, particularly in cases with limited surgical history.

Figure 1: Application of the Vancouver and Stony Brook scar scales



568 Association Between Maternal Care Deserts and Adverse Maternal Outcomes in Term Pregnancies Across US Counties

Sebastian Ramos[1], Isabella F. McNamara[1], Phin Has[2], Bianca Alonzo Bermudez[1], Erika F. Werner[1], Michael B. Siegel[1], Stephen M. Wagner[3]

[1]Tufts University School of Medicine, Boston, MA, [2]Lifespan Biostatistics, Epidemiology, and Research Design, Providence, RI, [3]Beth Israel Deaconess Medical Center, Brookline, MA

OBJECTIVE: Maternal care access (MCA) continues to decline in the United States (US) with maternal care deserts expanding. Lower maternal care is a known risk factor for maternal morbidity but the association between maternal care deserts and adverse maternal outcomes has been inadequately studied at the county level.

STUDY DESIGN: This was a retrospective cohort study using CDC birth certificate data from 2019-2021. Singleton, non-anomalous, live births from 37- 42 weeks were included. Using 2020 March of Dimes Maternal Care Access Report county data, MCA was classified as full, moderate, low or a desert based on county level access to hospitals providing obstetric care, number of obstetric providers per 10,000 births and percent of women without health insurance. The primary outcome was a composite maternal adverse outcome (CMAO) that included transfusion, unplanned hysterectomy, ruptured uterus and admission to the intensive care unit (ICU). Multivariable logistic regression models were used to estimate the association between MCA level and the CMAO and adjusted for both clinical risk factors and county level access to resources using the CDC's Social Vulnerability Index.

RESULTS: There were 3,137 counties and 1,099 (35%) were in maternal care deserts. Of the 9,226,640 pregnancies that met inclusion criteria 1,108,385 (12.0%) were in counties without full MCA, including 372,216 (4.0%) in maternal care deserts. The CMAO was elevated in maternal care deserts even after controlling for individual and county level factors (aRR 1.71: 95% CI 1.63-1.79) when compared to counties with full MCA. This was driven by increased rates of transfusion (aRR 2.26: 95% CI 2.14-2.39) and unplanned hysterectomy (aRR 1.32: 95%CI 1.09-1.58). There was no difference in uterine rupture (aRR 0.86: 95% CI 0.70 -1.06) or ICU admission (aRR 0.92: 95% CI 0.82-1.03).

CONCLUSION: One in 25 pregnancies are delivered in maternal care deserts and these births are associated with increased rates of maternal morbidity. This suggests that further reduction in MCA may be associated with increased risk of maternal morbidity and mortality.

569 Associations between Malaria in Pregnancy and Variation in Fetal Growth Restriction by Fetal Growth Curves

Anju Ranjit[1], Michelle Roh[1], Jimmy Kizza[2], Miriam Aguti[2], James Bwire[2], Tonny Rachkara[2], Abel Kakuru[2], Philip Rosenthal[1], Moses Kamya[2], Grant Dorsey[1], Stephanie L. Gaw[3]

[1]University of California, San Francisco (UCSF), San Francisco, CA, [2]Infectious Disease Research Collaboration, Tororo, Tororo, [3]University of California, San Francisco (UCSF), School of Medicine, San Francisco, CA

OBJECTIVE: Intergrowth-21(IG21) and World Health Organization (WHO) growth curves are designed to establish international standards for fetal growth. However, much of these data were not collected from malaria endemic countries, where malaria in pregnancy is a major risk factor for fetal growth restriction (FGR) and small-for-gestational age (SGA). We assessed the relationship between malaria and FGR using these two growth curves.

STUDY DESIGN: Data were collected from 751 women with singleton pregnancies enrolled between 12-20 weeks gestational age in a malaria chemoprevention trial. Fetal biometry data at 32 weeks was used to calculate estimated fetal weight (EFW) and percentiles according to IG21 and WHO fetal growth curves. FGR and SGA were defined as EFW and birthweight $< 10^{th}$ percentile for gestational age, respectively. Malaria status was assessed in two ways: (1) clinical malaria (fever and microscopic parasitemia) and (2) placental malaria (parasites and/or hemozoin pigment by histopathology). Multiple logistic regression was used to estimate associations between malaria and FGR and SGA risk, adjusted for gravidity and bednet use.

RESULTS: Among women with no evidence of malaria during pregnancy (n=87), the risk of FGR varied between growth standards (IG21=13.8%, WHO=22.9%). 97 women (12.9%) were diagnosed with at least 1 episode of clinical malaria and 17 (2.3%) had 2 or more episodes. 238 women (31.7%) had evidence of placental malaria, with a majority of these only having pigment detected. Neither clinical nor placental malaria were associated with increased risk of

FGR at 32 weeks by either growth curve, but was associated with increased risk of SGA, though no associations reached statistical significance (See Table).

CONCLUSION: In our study, FGR prevalence varied between IG21 and WHO standards, warranting future research to determine which metric should be used in malaria-endemic settings. Malaria was a predictor of risk of SGA, but not FGR at 32 weeks, although analyses were limited by low sample size. Our results suggest that malaria may impact fetal growth towards the end of pregnancy.

	FGR by IG21	FGR by WHO	SGA

*Women with evidence of parasitemia by microscopy or PCR after 32 weeks were excluded from analyses to ensure it was not the determinant for any past or active placental malaria. No evidence of malaria defined as negative for clinical malaria, parasitemia by microscopy and PCR and no evidence of placental malaria.
**Adjusted for maternal age, gravidity, and bed net use

570 Birth Morbidity and Readmissions in Autistic People and People With Intellectual and Developmental Disabilities

Jessica E. Rast[1], Arina Chesnokova[2], Jennifer Bromberg[1], Lindsay L. Shea[1]
[1]Drexel University, Drexel University, PA, [2]University of Pennsylvania, Philadelphia, PA

OBJECTIVE: Emerging research suggests people with intellectual and developmental disabilities (IDD) have fertility rates similar to the general population. However, studies have highlighted riskier delivery outcomes, including premature delivery and cesarean section, in this group. The objective of this study was to establish prevalence of adverse delivery outcomes, including hospital readmission, in people with autism, other IDDs, and without autism or IDD.

STUDY DESIGN: We used the National Readmission Database (NRD), an all-payer collection of inpatient hospital records, from 2019 and 2020 to examine deliveries. NRD (from the Healthcare Cost and Utilization Project) is sampled from 97% of all hospital discharges in the U.S. We compared people with autism, other IDD, and all other deliveries along antepartum (gestational diabetes), intrapartum (mode of delivery (vaginal, assisted vaginal, cesarean), hemorrhage, preeclampsia and eclampsia), and postpartum (prolonged hospital stay during delivery, readmission within 7 and 30 days of discharge) outcomes. We also examined patient characteristics including Medicaid insurance.

RESULTS: Some outcomes were more common in people with autism and IDD, including preeclampsia (12% autism, 14% IDD, 7% other), instrumental delivery (39% autism, 47% IDD, 36% other), and stays longer than 5 days (7% autism, 9% IDD, 3% other). All-cause readmission within 30 days was also more common (3% autism, 6% IDD, 1% other). There was no difference in rate of cesarean section. Medicaid coverage was common in autistic people (59%) and people with IDD (52%), compared to 41% of other deliveries.

CONCLUSION: This study highlights disparities in delivery outcomes of a demographic that is largely missing from pregnancy care and research. These disparities are likely further exacerbated by other social determinants of health, including race and ethnicity. Individual and structural factors including patient, clinician, and health system factors are all at play and need to be examined to better understand and adapt care delivery to this population.

571 Assessment of provider knowledge and recommendations for spinal muscular atrophy carrier testing

OBJECTIVE: ACOG recommends that carrier screening (CS) for spinal muscular atrophy (SMA) be offered to women who are pregnant or considering pregnancy. Despite this, SMA CS practices are varied. The increasing number of conditions and variety of available CS panels has raised concerns regarding provider knowledge and proficiency in educating patients regarding CS options and test results. We sought to determine baseline provider knowledge of SMA and SMA CS patterns in a large academic OBGYN department.

STUDY DESIGN: Cross-sectional study of obstetric care providers at an urban tertiary care health system. Providers were invited to complete an anonymous validated 20-item web-based survey to test knowledge regarding SMA screening, practice patterns, and comfort in interpretation and counseling regarding results. Data was categorized and summarized with descriptive statistics.

RESULTS: The response rate was 75% (112/150) with a survey completion rate of 64.6% (97/150). Survey participants varied in role and years of clinical experience (Table). The mean score on the knowledge portion of the survey was 3.8±1.8 out of 8 (47.5%) with 20.6% of respondents scoring ≥75% and 51.6% scoring ≥50%. Maternal fetal medicine providers had the greatest fund of knowledge. Test performance did not vary with years in practice. Although 91.3% of providers offer SMA screening at the first prenatal visit, less than 25% reported complete comfort discussing SMA screening and results. Comfort discussing screening and test results correlated with clinical role and years in practice. Providers who felt completely comfortable discussing SMA screening were more likely to score ≥75% or ≥50% on SMA knowledge ($p < 0.005$). Comfort discussing results, however, was only correlated to score ≥50% on SMA knowledge ($p = 0.007$).

CONCLUSION: Although the majority of providers offer SMA CS, provider knowledge regarding SMA is low, and most providers are not comfortable discussing SMA screening and test results. Educational measures should be undertaken to improve provider, and by proxy, patient understanding of available CS options.

572 Evaluation of implementation of an EMR-based screening tool for initiation of low-dose aspirin in pregnancy

Keely Robinson[1], Virali Patel[1], Emily Ferguson[1], Rupsa C. Boelig[2]
[1]Sidney Kimmel Medical College at Thomas Jefferson University Hospital, Philadelphia, PA, [2]Thomas Jefferson University Hospital, Philadelphia, PA

OBJECTIVE: Low-dose aspirin in pregnancy has been shown to decrease preeclampsia and history based screening has historically poor compliance. In 2021 USPSTF endorsed consideration of aspirin with even a single moderate risk factor. We aimed to assess implementation of a new EMR-based screening tool for aspirin, as well patient acceptance of aspirin in the presence of moderate or high risk factor(s) for preeclampsia.

STUDY DESIGN: We performed a retrospective cohort study of patients presenting to obstetric intake visits after implementation of an EMR-based screening tool in 2022. Patients were offered low-dose aspirin in the presence of only one moderate risk factor and recommended aspirin with more than one moderate or at least one high risk factor. The number of patients screened for aspirin at the first prenatal visit was evaluated. The relationship between moderate versus high risk factors and patient acceptance of aspirin therapy was also assessed with logistic regression. Descriptive statistics were performed.

RESULTS: Among 586 patients presenting to initial obstetric visits, 531 patients (90.6%) were screened for preeclampsia risk with the EMR-based screening tool. In our patient population, 558 (95.2%) had at least one moderate or high risk factor with 120 patients (20.5%) with a single moderate risk factor, 340 (58.0%) with more than one moderate risk factor, and 98 (16.7%) with high risk factor(s). Patient acceptance of aspirin with one moderate, more than one moderate, and high risk factor(s) was 65.2%, 77.4%, and 93.8%, respectively ($p< 0.05$, Figure).

CONCLUSION: Incorporation of an EMR-based tool during obstetric intake visits led to >90% compliance with screening for preeclampsia risk factors. Of importance, >95% of patients had at least one moderate risk factor posing further consideration of universal aspirin use. We saw increased patient acceptance of aspirin therapy with increasing risk of preeclampsia. Future directions include examining the relationship between this clinical tool and pregnancy outcomes, as well as cost effective analyses and randomized trials of universal aspirin use.

573 Does the addition of MRI in antenatal management of suspected PAS impact maternal surgical outcome?

Henri M. Rosenberg[1], Nicola F. Tavella[2], Alexandra N. Mills[3], Alexa Cohen[4], Myah Griffin[5], Itamar Futterman[6], Thomas Owens[7], Lois Brustman[8], Pe'er Dar[9], Meghana Limaye[10], Angela Bianco[1], Georgios Doulaveris[4], Rebecca H. Jessel[2]
[1]Mount Sinai Medical Center, New York, NY, [2]Icahn School of Medicine at Mount Sinai Hospital, New York, NY, [3]Icahn School of Medicine at Mount Sinai, New York, NY, [4]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, [5]NYU Langone Health, Atlanta, GA, [6]Maimonides Medical Center, Brooklyn, NY, [7]Mount Sinai West, New York, NY, [8]St. Luke's Roosevelt Hospital Center, New York, NY, [9]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY, [10]NYU Langone Health, New York, NY; on behalf of the New York City Maternal Fetal Medicine Research Consortium

OBJECTIVE: Antenatal diagnosis of placenta accreta spectrum (PAS) is difficult and sometimes uncertain. In the United States, up to 50% of patients with PAS are never diagnosed until the time of delivery. Diagnosis of PAS at the time of delivery can result in poor maternal outcomes. The objective of this study was to assess if the addition of an MRI in antenatally suspected PAS resulted in improved surgical outcomes.

STUDY DESIGN: Multicenter retrospective cohort study of histopathologically confirmed PAS cases 1/1/2013 - 6/30/2022 at four New York academic institutions. All patients with antenatal suspicion of PAS were included and subdivided into those with and without MRI. Primary outcome was composite maternal surgical morbidity (CMSM) (transfusion of >4u PRBC, >1 vasopressors, mechanical ventilation, ICU admission and injury to surrounding organs). Outcomes were analyzed using univariate and multivariate logistic regression adjusting for confounders.

RESULTS: 291 patients were included, 134 (46.0%) and 157 (54.0%) with and without MRI, respectively. MRI usage was associated with low placentation (60% vs. 40%, $p< 0.001$) and those with an interdisciplinary meeting (83% vs. 17%, $p< 0.001$). 184 (63%) patients had grade 1 PAS, 59 (20%) had grade 2 and 48 (16%) had grade 3. There was a significant difference in CMSM in patients who underwent an antenatal MRI evaluation (OR 11.5, 4.0-48.92, $p< 0.001$); however, after multivariate analysis, there was no significant

difference in CMSM with the addition of MRI even when controlling for grade of PAS (aOR 2.80, 0.54-18.35, p=0.24) (Table 1).

CONCLUSION: There was no significant difference in composite maternal surgical morbidity outcomes for patients with sonographically suspected PAS with the addition of MRI. Our data supports prior studies that reflect antenatal MRI does not appear to impact surgical outcomes which is true even when controlling for degree of invasion with PAS. Further prospective studies are needed to support the best use of MRI as an adjunct to ultrasound for antenatal diagnosis.

Table 1: Composite maternal surgical morbidity comparing MRI vs. No MRI using logistic regression

			Univariate Logistic Regression		Multivariate Logistic Regression*	
	MRI (n=134)	No MRI (n=157)	OR (95% CL)	p-Value	aOR (95% CL)	Adjusted p-value
	No. (%)	No. (%)				
Composite Maternal Morbidity	131 (52.0)	121 (48.0)	11.55 (4.00, 48.92)	< 0.001	2.80 (0.54, 18.35)	0.24
Transfusion of >4 units packed red blood cells	57 (54.3)	48 (45.7)	1.68 (1.04, 2.73)	0.03	1.66 (0.80, 3.49)	0.17

574 Cost-effectiveness of exome sequencing with major central nervous system structural anomalies

Michal Rosenberg[1], Sharon Maslovitz[2], Adi Reches[3], Yariv Yogev[4], Moshe leshno[5], Lee Reicher[6]

[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University, Tel Aviv, Israel, Tel Aviv, Israel, [2]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv University Israel, Tel aviv, Israel, [3]Lis Hospital for Women's Health, Tel Aviv, Israel, [4]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [5]Tel Aviv University, Tel Aviv, Israel, [6]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel

OBJECTIVE: The central nervous system (CNS) is affected in 9% of fetal malformations but accounts for as much as one-third of all pregnancy terminations due to fetal anomaly. When applying Chromosomal microarray (CMA) to the diagnosis of fetal CNS anomalies, the estimated diagnostic yield remains low.demonstrated that Recent study in fetuses with major CNS anomalies, Exome sequencing (ES) has an additional diagnostic yield of 44% over the 10% provided by CMA only. We aimed to determine the cost-effectiveness of ES in major CNS anomalies.

STUDY DESIGN: We modeled costs, utility and quality adjusted life years (QALYs) for CMA versus CMA+ES in prenatal testing. Two strategies were compared using Markovian process decision analysis model: (1) CMA only, abnormal result culminating in termination of pregnancy (TOP) (2) ES after a negative CMA, for positive result a TOP is conducted .The outcomes included health quality of life after TOP or having a disabled child, the cost of CMA test, ES test and the health expenses of a disabled child. The time horizon of the model was 20 years. Sensitivity analysis including probabilistic sensitivity analysis of all parameters was conducted.

RESULTS: In the base model the cost was $91,059 for CMA test and the average health expansion for disable child and $3,101 for CMA+ES. The QALY with time horizon of 20 years were 11.84 and 13.84 for CMA and CMA+ES strategies respectively, thus the strategy CMA+ES dominates the strategy CMA alone, higher QALY value and cost saving. Sensitivity analysis revealed that the results are robust and for all sensitivity analysis CMA+ES dominated the CMA with cost saving.

CONCLUSION: We suggest that Exome sequencing has the potential to be cost-effective and should be considered as a first-tier test in the prenatal diagnosis of major CNS anomalies. The substantial increase in diagnostic yield offered by ES not only provides valuable information for the current pregnancy but also holds significant relevance for future pregnancies. These findings are pivotal in facilitating timely and evidence-based decision-making.
