## 'WHAT IS HADOOP?'

BY HADOOPWIZARD

# INTRODUCTION

## What Is Apache Hadoop?

The Apache™ Hadoop® project develops **open-source** software for reliable, **scalable, distributed computing**.

The Apache Hadoop software library is a framework that allows for the distributed processing of **large data sets** across clusters of computers using simple programming models. It is designed to scale up from single servers to thousands of machines, each offering local computation and storage. Rather than rely on hardware to deliver high-availability, the library itself is designed to detect and handle failures at the application layer, so delivering a highly-available service on top of a cluster of computers, each of which may be prone to failures.

The project includes these modules:

- **Hadoop Common:** The common utilities that support the other Hadoop modules.
- **Hadoop Distributed File System (HDFS™):** A distributed file system that provides high-throughput access to application data.
- **Hadoop YARN:** A framework for job scheduling and cluster resource management.
- **Hadoop MapReduce:** A YARN-based system for parallel processing of large data sets.

# Scale up

# Scale up

# Scale-up

# Scale-out

# Hadoop Approach

- scale-out
- share nothing
- expect failure
- smart software, dumb hardware
- move processing, not data
- build applications, not infrastructure

# What is Hadoop good for?

Don't use Hadoop - your data isn't that big

**< 100 mb - Excel**

**100 mb > 10 gb - Add memory and use Pandas**

**100 gb > 1 TB - Buy big hard drive and use Postgres**

**> 5 TB - life sucks consider Hadoop**

if your data fits in RAM  
it is not Big Data

## Quasi-Monte Carlo method

From Wikipedia, the free encyclopedia

In [numerical analysis](#), **quasi-Monte Carlo method** is a method for [numerical integration](#) and solving some other problems using [low-discrepancy sequences](#) (also called quasi-random sequences or sub-random sequences). This is in contrast to the regular [Monte Carlo method](#) or [Monte Carlo integration](#), which are based on sequences of [pseudorandom](#) numbers.

Monte Carlo and quasi-Monte Carlo methods are stated in a similar way. The problem is to approximate the integral of a function  $f$  as the average of the function evaluated at a set of points  $x_1, \dots, x_N$ :

$$\int_{[0,1]^s} f(u) du \approx \frac{1}{N} \sum_{i=1}^N f(x_i).$$

Since we are integrating over the  $s$ -dimensional unit cube, each  $x_i$  is a vector of  $s$  elements. The difference between quasi-Monte Carlo and Monte Carlo is the way the  $x_i$  are chosen. Quasi-Monte Carlo uses a low-discrepancy sequence such as the [Halton sequence](#), the [Sobol sequence](#), or the Faure sequence, whereas Monte Carlo uses a pseudorandom sequence. The advantage of using low-discrepancy sequences is a faster rate of convergence. Quasi-Monte Carlo has a rate of convergence close to  $O(1/N)$ , whereas the rate for the Monte Carlo method is  $O(N^{-0.5})$ .<sup>[1]</sup>

The Quasi-Monte Carlo method recently became popular in the area of [mathematical finance](#) or [computational finance](#).<sup>[1]</sup> In these areas, high-dimensional numerical integrals, where the integral should be evaluated within a threshold  $\epsilon$ , occur frequently. Hence, the Monte Carlo method and the quasi-Monte Carlo method are beneficial in these situations.

[Pseudorandom sequence]

[Low-discrepancy sequence (Sobol sequence)]

256 points from a pseudorandom number source, Halton sequence, and Sobol sequence (red=1,...,10, blue=11,...,100, green=101,...,256). Points from Sobol sequence are more evenly distributed.

# MOBY DICK; OR THE WHALE

By Herman Melville

## CHAPTER 1. Loomings.

Call me Ishmael. Some years ago--never mind how long precisely--having little or no money in my purse, and nothing particular to interest me on shore, I thought I would sail about a little and see the watery part of the world. It is a way I have of driving off the spleen and regulating the circulation. Whenever I find myself growing grim about the mouth; whenever it is a damp, drizzly November in my soul; whenever I find myself involuntarily pausing before coffin warehouses, and bringing up the rear of every funeral I meet; and especially whenever my hypos get such an upper hand of me, that it requires a strong moral principle to prevent me from deliberately stepping into the street, and methodically knocking people's hats off--then, I account it high time to get to sea as soon as I can. This is my substitute for pistol and ball. With a philosophical flourish Cato throws himself upon his sword; I quietly take to the ship. There is nothing surprising in this. If they but knew it, almost all men in their degree, some time or other, cherish very nearly the same feelings towards the ocean with me.

There now is your insular city of the Manhattoes, belted round by wharves as Indian isles by coral reefs--commerce surrounds it with her surf. Right and left, the streets take you waterward. Its extreme downtown is the battery, where that noble mole is washed by waves, and cooled by breezes, which a few hours previous were out of sight of land. Look at the crowds of water-gazers there.

# WEB LOG ANALYSIS

Amazon Web Services provides services and infrastructure to build reliable, fault-tolerant, and highly available web applications in the cloud. In production environments, these applications can generate huge amounts of log information.

This data can be an important source of knowledge for any company that is operating web applications. Analyzing logs can reveal information such as traffic patterns, user behavior, marketing profiles, etc.

However, as the web application grows and the number of visitors increases, storing and analyzing web logs becomes increasingly challenging.

This diagram shows how to use Amazon Web Services to build a scalable and reliable large-scale log analytics platform. The core component of this architecture is Amazon Elastic MapReduce, a web service that enables analysts to process large amounts of data easily and cost-effectively using a Hadoop hosted framework.

## System Overview

- 1 The web front-end servers are running on **Amazon Elastic Compute Cloud (Amazon EC2)** instances.
- 2 **Amazon CloudFront** is a content delivery network that uses low latency and high data transfer speeds to distribute static files to customers. This service also generates valuable log information.
- 3 Log files are periodically uploaded to **Amazon Simple Storage Service (Amazon S3)**, a highly available and reliable data store. Data is sent in parallel from multiple web servers or edge locations.

- 4 An **Amazon Elastic MapReduce** cluster processes the data set. **Amazon Elastic MapReduce** utilizes a hosted Hadoop framework, which processes the data in a parallel job flow.
- 5 When **Amazon EC2** has unused capacity, it offers EC2 instances at a reduced cost, called the **Spot Price**. This price fluctuates based on availability and demand. If your workload is flexible in terms of time of completion or required capacity, you can dynamically extend the capacity of your cluster using **Spot Instances** and significantly reduce the cost of running your job flows.

- 6 Data processing results are pushed back to a relational database using tools like **Apache Hive**. The database can be an **Amazon Relational Database Service (Amazon RDS)** instance. **Amazon RDS** makes it easy to set up, operate, and scale a relational database in the cloud.
- 7 Like many services, **Amazon RDS** instances are priced on a pay-as-you-go model. After analysis, the database can be backed-up into **Amazon S3** as a database snapshot, and then terminated. The database can then be recreated from the snapshot whenever needed.

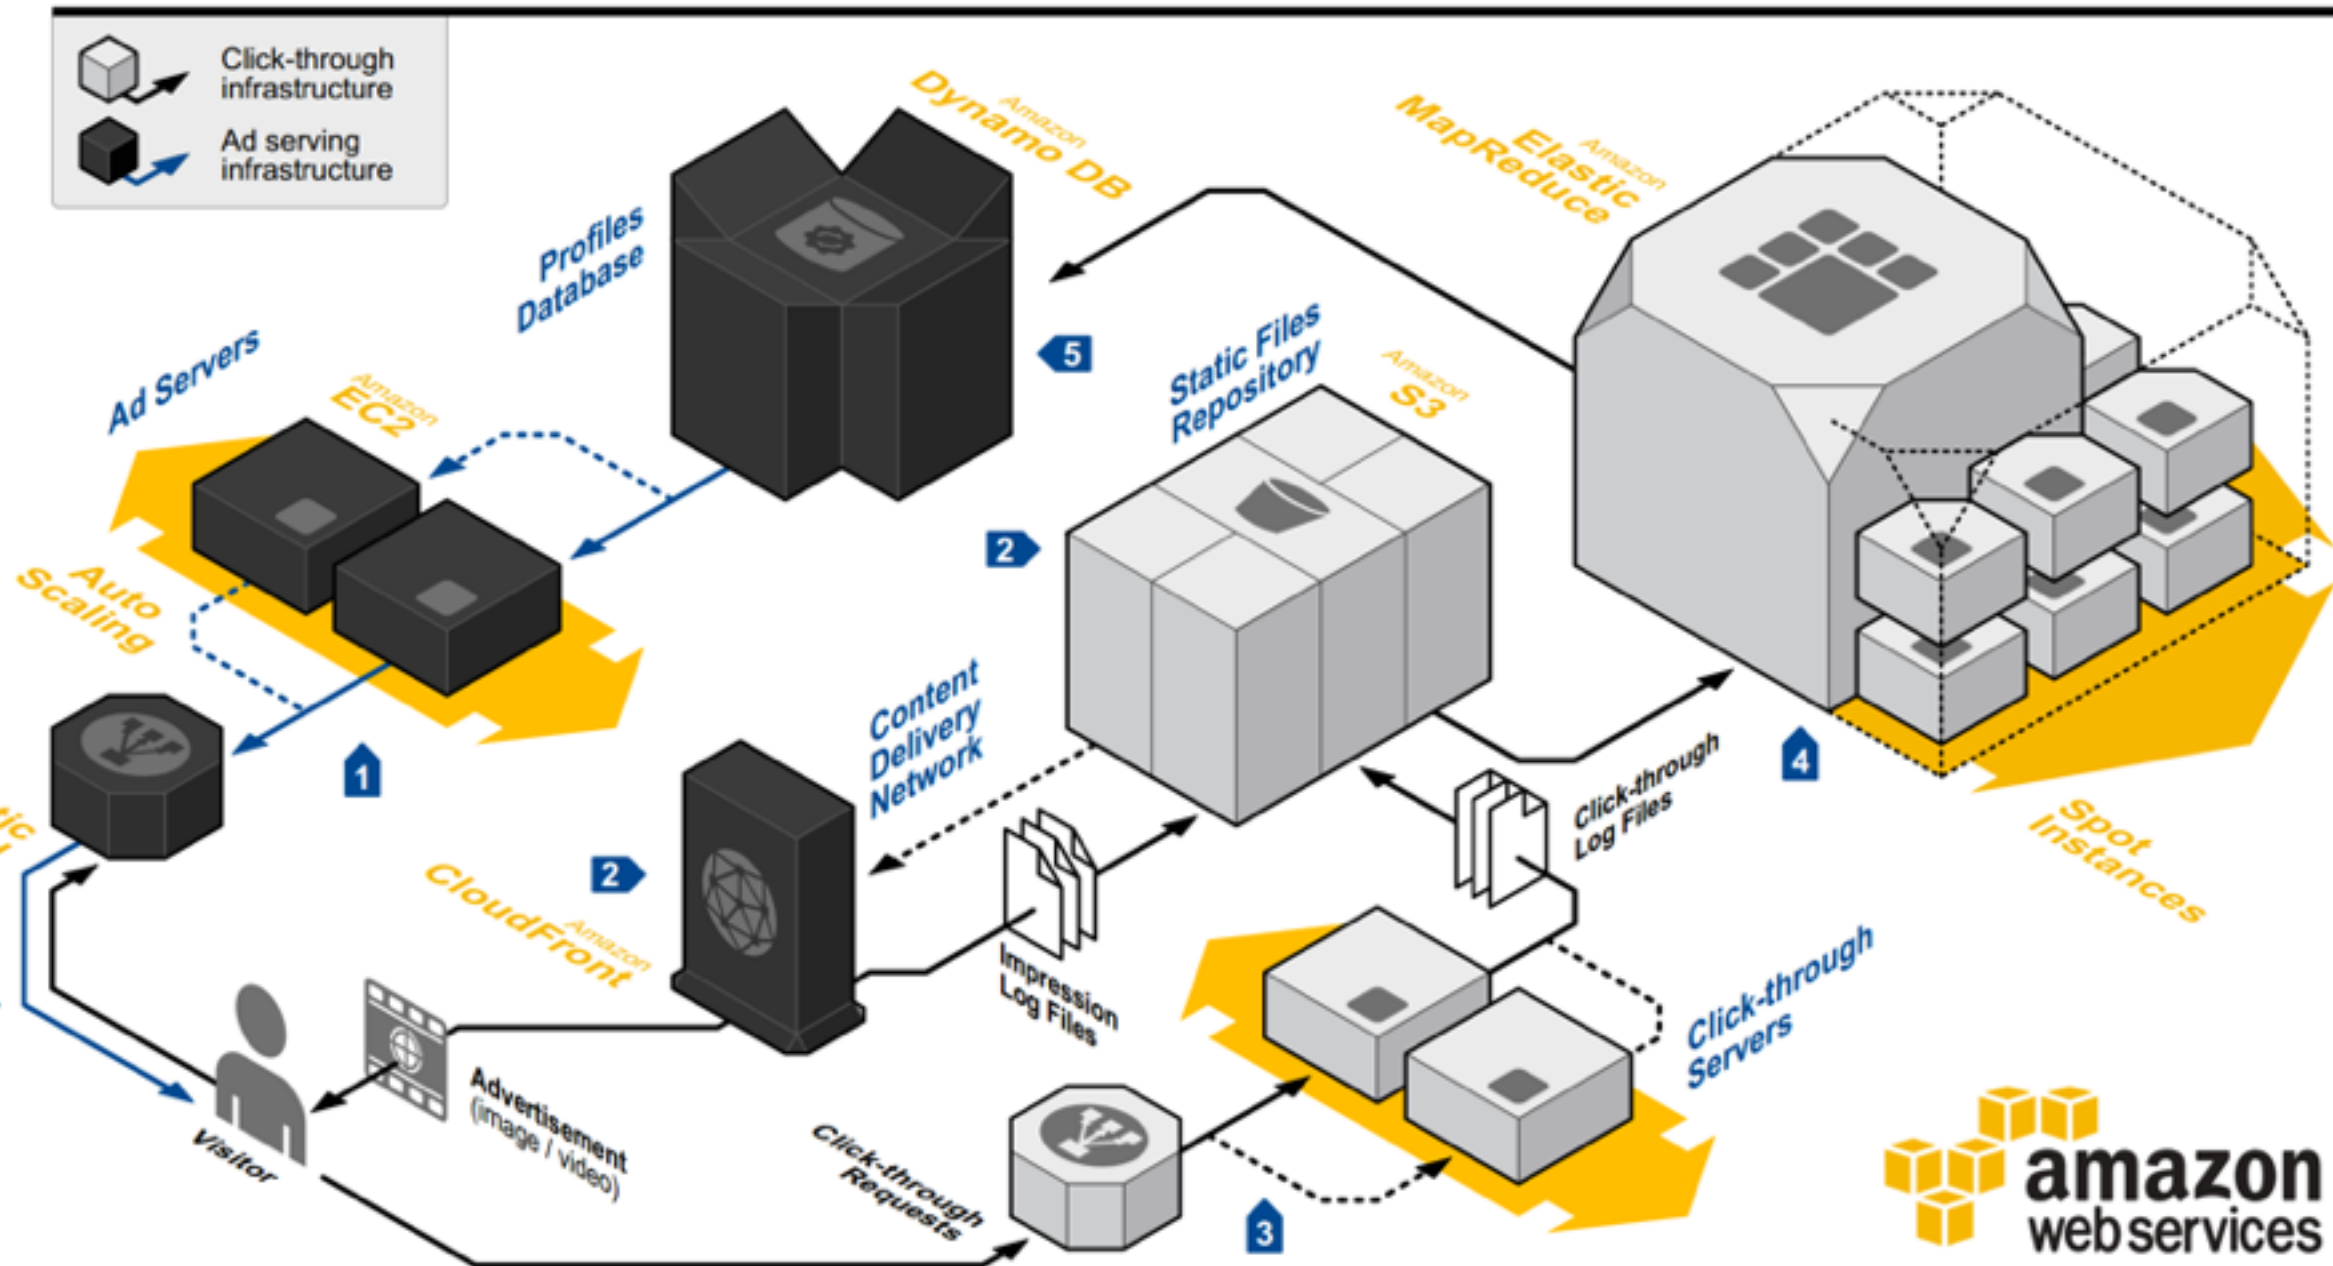

# ADVERTISEMENT SERVING

Internet advertising services need to serve targeted advertising and must do so under limited time. These are just two of multiple technical challenges they face.

Amazon Web Services provides services and infrastructure to build reliable, fault-tolerant, and highly available ad serving platforms in the cloud. In this document, we describe the two main parts of such a system: ad serving infrastructure and click-through collection featuring a data analysis cluster.

**AWS Reference Architectures**

- Amazon EC2
- Auto Scaling
- Elastic Load Balancing
- Amazon CloudFront
- Amazon EC2 Spot
- Amazon EMR
- Amazon S3
- Amazon Import/Export
- Amazon DynamoDB

## System Overview

**1** When visitors load a web page, ad servers return a pointer to the ad resource to be displayed. These servers are running on **Amazon Elastic Compute Cloud** (Amazon EC2) instances. They query a data set stored in an **Amazon DynamoDB** table to find relevant ads depending on the user's profile.

**2** Ad files are downloaded from **Amazon CloudFront**, a content delivery service with low latency, high data-transfer speeds, and no commitments. Log information from displayed ads is stored on **Amazon Simple Storage Service** (Amazon S3), a highly available data store.

**3** The click-through servers are a group of **Amazon EC2** instances dedicated to collecting click-through data. This information is contained in the log files of the click-through web servers, which are periodically uploaded to **Amazon S3**.

**4** Ad impression and click-through data are retrieved and processed by an **Amazon Elastic MapReduce** cluster using a hosted Hadoop framework to process the data in a parallel job flow. The cluster's capacity can be dynamically extended using **Spot Instances** to reduce the processing time and the cost of running the job flow.

**5** Data processing results are pushed back into **Amazon DynamoDB**, a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability. **Amazon DynamoDB** tables can store and retrieve any amount of data, and serve any level of request traffic, both of which are specific requirements for storing and quickly retrieving visitors' profile information.

The high availability and fast performance of **Amazon DynamoDB** enable ad server front-ends to serve requests with predictable response time, even with high traffic volumes or large profile's data sets.

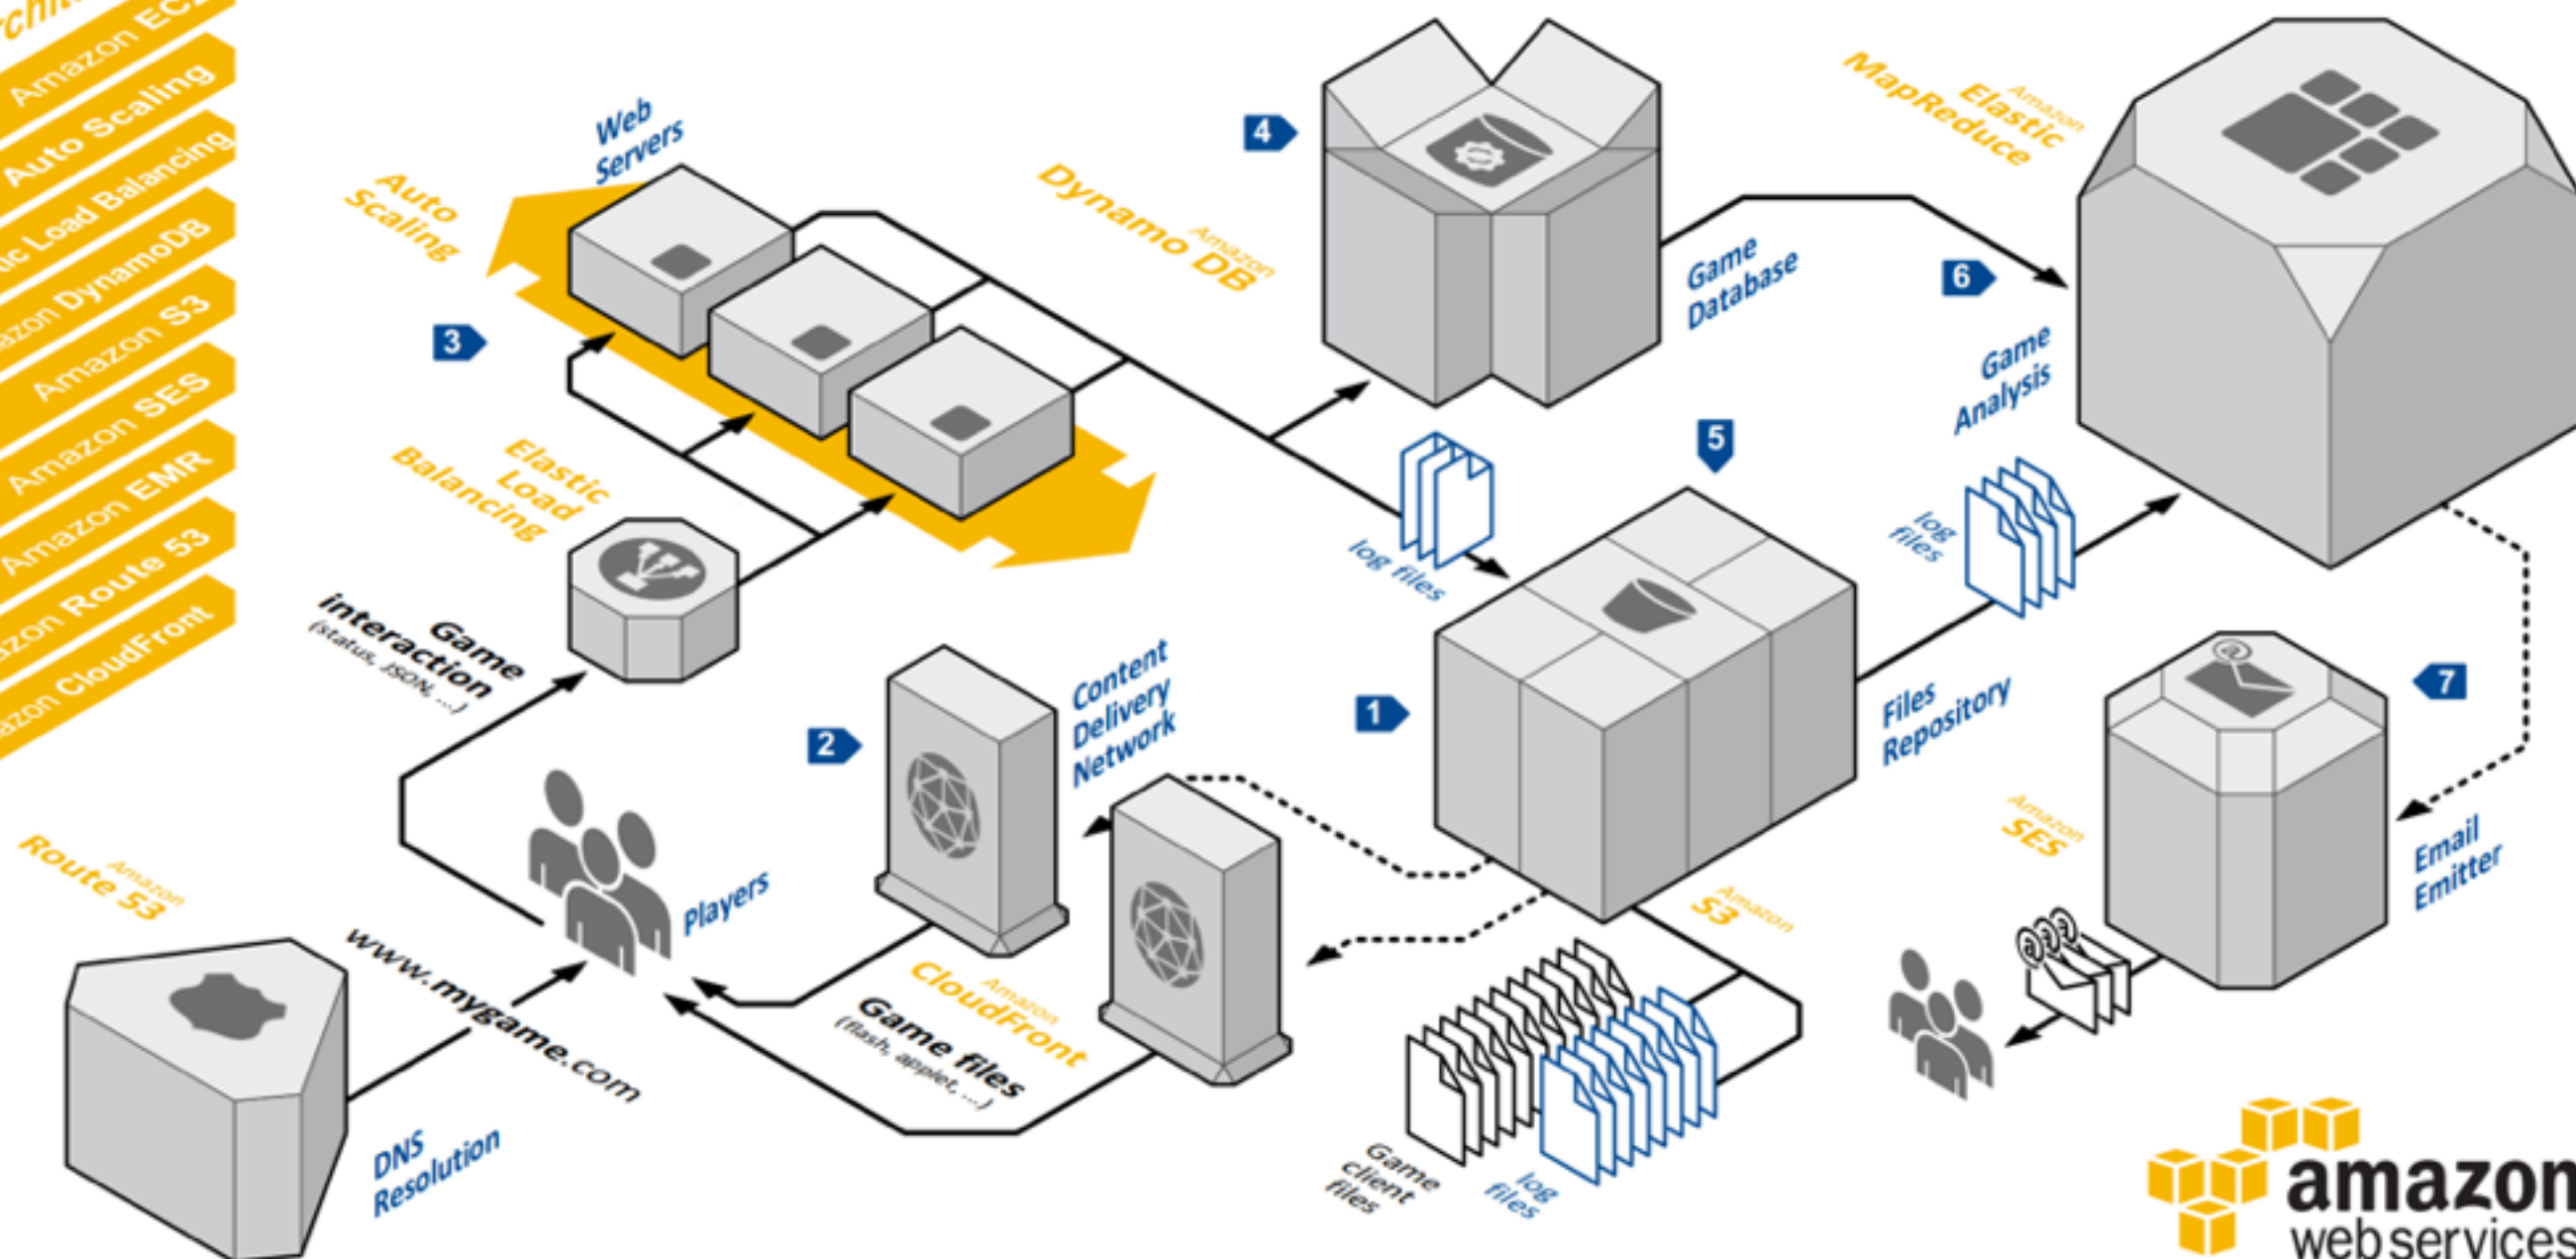

# ONLINE GAMES

Online games back-end infrastructures can be challenging to maintain and operate. Peak usage periods, multiple players, and high volumes of write operations are some of the most common problems that operations teams face.

But the most difficult challenge is ensuring flexibility in the scale of that system. A popular game might suddenly receive millions of users in a matter of hours, yet it must continue to provide a

satisfactory player experience. Amazon Web Services provides different tools and services that can be used for building online games that scale under high usage traffic patterns.

This document presents a cost-effective online game architecture featuring automatic capacity adjustment, a highly available and high-speed database, and a data processing cluster for player behavior analysis.

## System Overview

**1** Browser games can be represented as client-server applications. The client generally consists of static files, such as images, sounds, flash applications, or Java applets. Those files are hosted on **Amazon Simple Storage Service** (Amazon S3), a highly available and reliable data store.

**2** As the user base grows and becomes more geographically distributed, a high-performance cache like **Amazon CloudFront** can provide substantial improvements in latency, fault tolerance, and cost. By using **Amazon S3** as the origin server for the **Amazon CloudFront** distribution, the game infrastructure benefits from fast network data transfer rates and a simple publishing/caching workflow.

**3** Requests from the game application are distributed by **Elastic Load Balancing** to a group of web servers running on **Amazon Elastic Compute Cloud** (Amazon EC2) instances. **Auto Scaling** automatically adjusts the size of this group, depending on rules like network load, CPU usage, and so on.

**4** Player data is persisted on **Amazon DynamoDB**, a fully managed NoSQL database service. As the player population grows, **Amazon DynamoDB** provides predictable performance with seamless scalability.

**5** Log files generated by each web server are pushed back into **Amazon S3** for long-term storage.

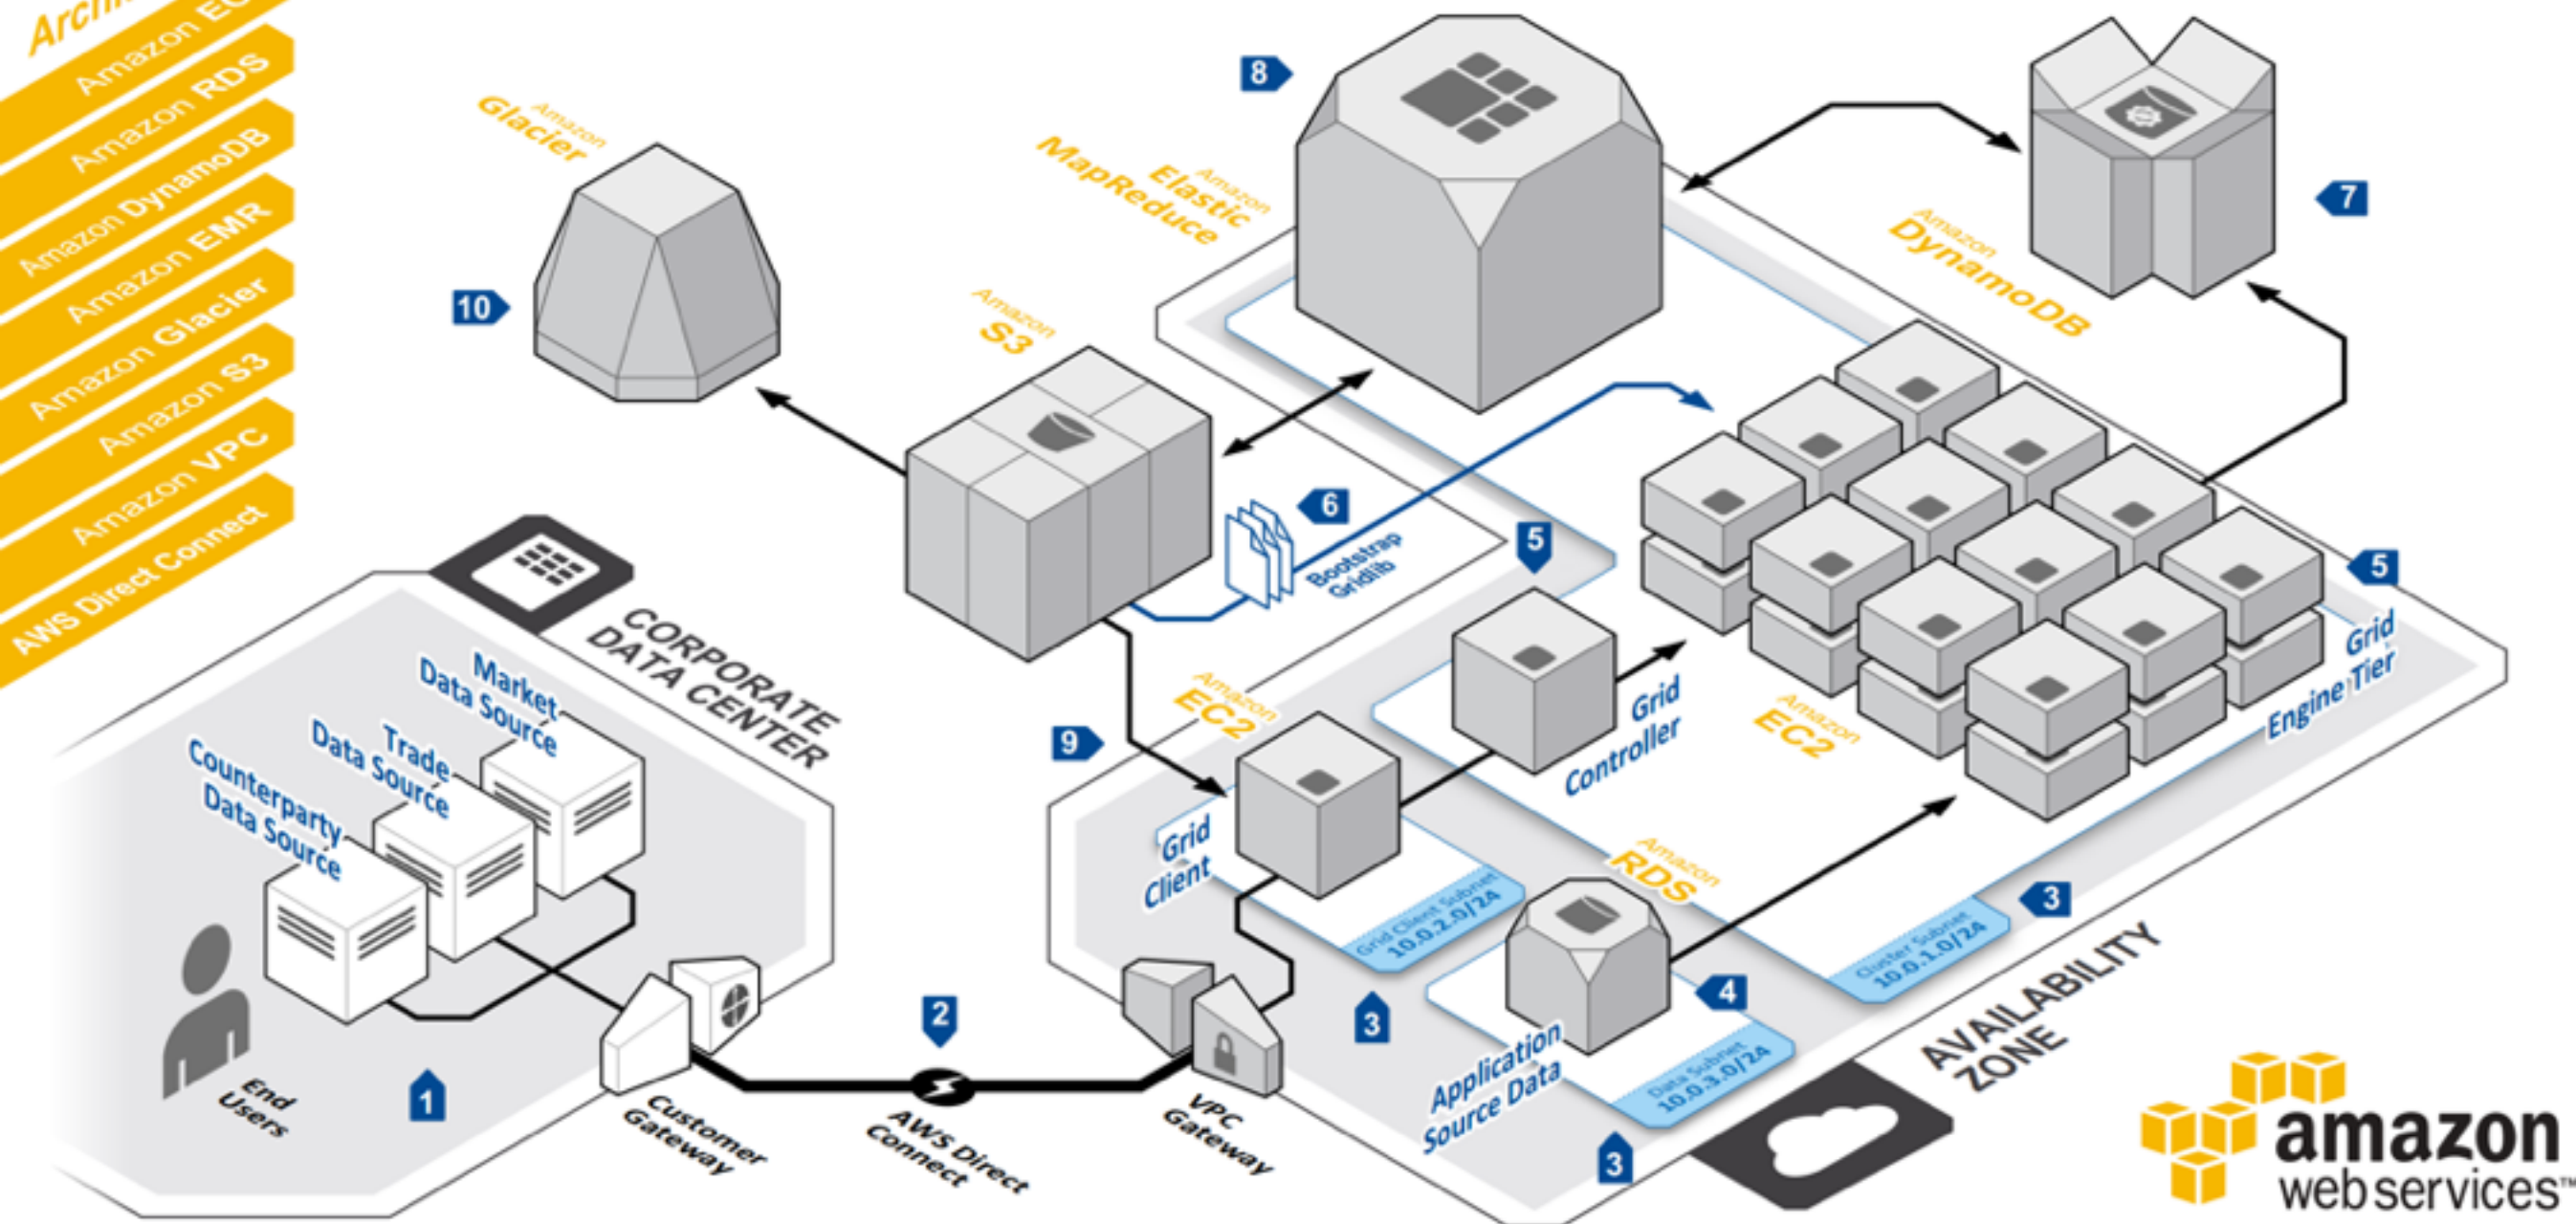

**6** Managing and analyzing high data volumes produced by online games platforms can be challenging. **Amazon Elastic MapReduce** (Amazon EMR) is a service that processes vast amounts of data easily. Input data can be retrieved from web server logs stored on **Amazon S3** or from player data stored in **Amazon DynamoDB** tables to run analytics on player behavior, usage patterns, etc. Those results can be stored again on **Amazon S3**, or inserted in a relational database for further analysis with classic business intelligence tools.

**7** Based on the needs of the game, **Amazon Simple Email Service** (Amazon SES) can be used to send email to players in a cost-effective and scalable way.

# FINANCIAL SERVICES GRID COMPUTING

Financial services grid computing on the cloud provides dynamic scalability and elasticity for operation when compute jobs are required, and utilizing services for aggregation that simplify the development of grid software. On demand provisioning of hardware, and template driven deployment, combined with low latency access to existing on-premise data sources make AWS a powerful platform for high performance grid computing systems.

## System Overview

- 1 Date sources for market, trade, and counterparties are installed on startup from on premise data sources, or from **Amazon Simple Storage Service** (Amazon S3).
- 2 **AWS DirectConnect** can be used to establish a low latency and reliable connection between the corporate data center site and AWS, in 1 to 10Gbit increments. For situations with lower bandwidth requirements, a VPN connection to the **VPC Gateway** can be established.
- 3 Private subnetworks are specifically created for customer source data, compute grid clients, and the grid controller and engines.

- 4 Application and corporate data can be securely stored in the cloud using the **Amazon Relational Database Service** (Amazon RDS).
- 5 Grid controllers and grid engines are running **Amazon Elastic Compute Cloud** (Amazon EC2) instances started on demand from **Amazon Machine Images** (AMIs) that contain the operating system and grid software.
- 6 Static data such as holiday calendars and QA libraries and additional gridlib bootstrapping data can be downloaded on startup by grid engines from **Amazon S3**.

- 7 Grid engine results can be stored in **Amazon DynamoDB**, a fully managed database providing configurable read and write throughput, allowing scalability on demand.
- 8 Results in **Amazon DynamoDB** are aggregated using a map/reduce job in **Amazon Elastic MapReduce** (Amazon EMR) and final output is stored in **Amazon S3**.
- 9 The compute grid client collects aggregate results from **Amazon S3**.
- 10 Aggregate results can be archived using **Amazon Glacier**, a low-cost, secure, and durable storage service.

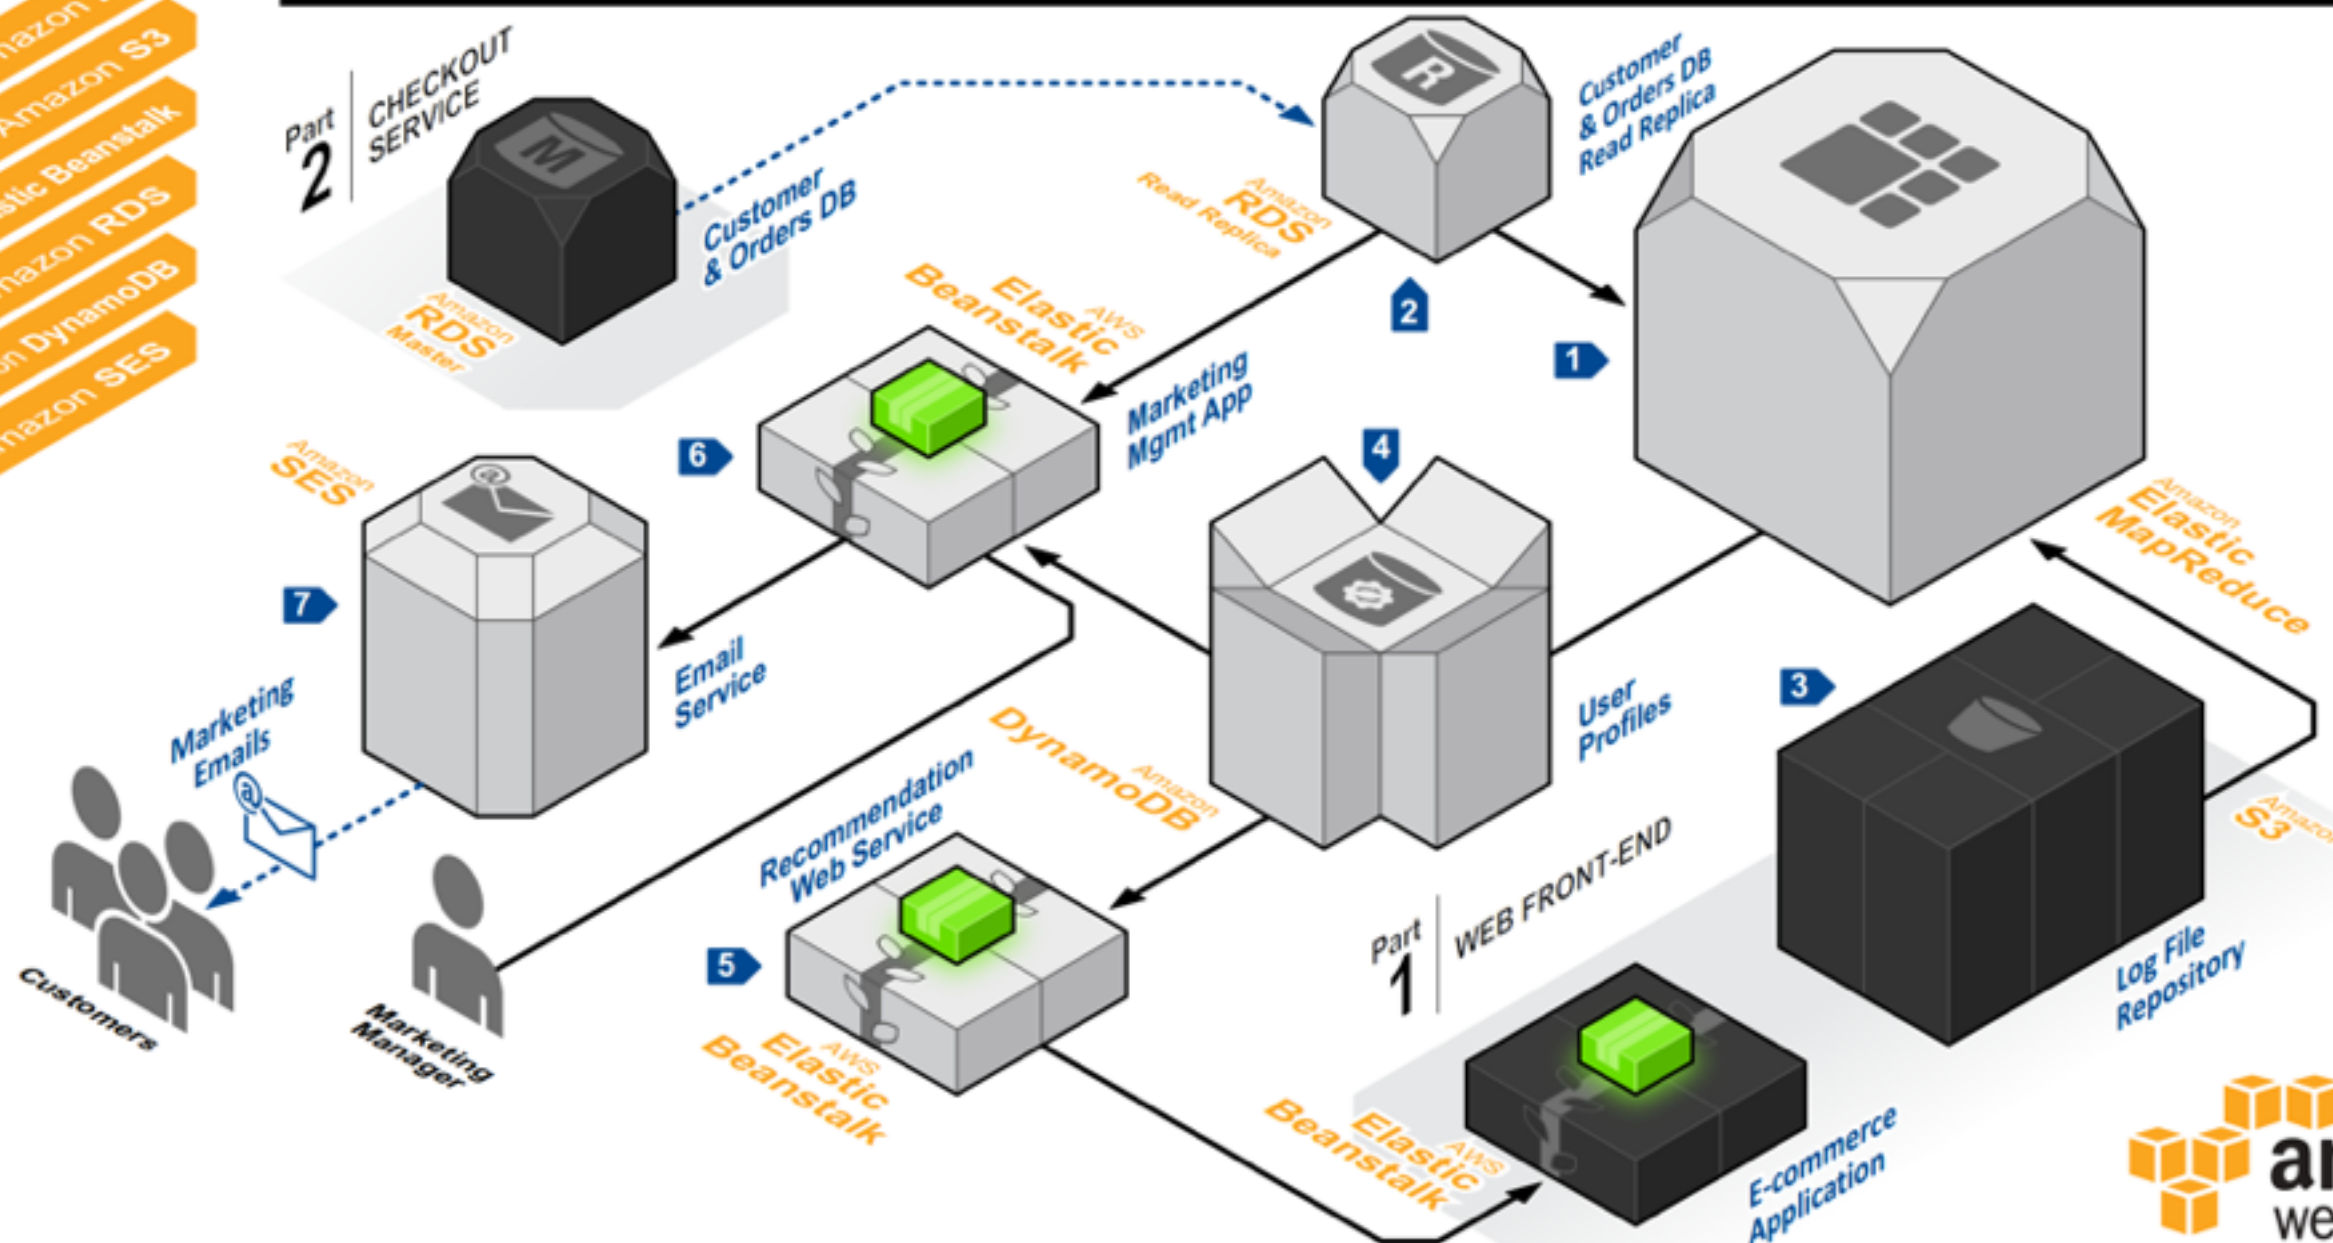

# E-COMMERCE WEBSITE

## PART 3: MARKETING & RECOMMENDATIONS

With Amazon Web Services, you can build a recommendation and marketing service to manage targeted marketing campaigns and offer personalized product recommendations to customers who are browsing your e-commerce site. In order to build such a service, you have to process very large amounts of data from multiple data sources. The resulting user profile information has to be available to deliver real-time product recommendations on your e-commerce website.

The insights that you gain about your customers can also be used to manage personalized marketing campaigns targeted at specific customer segments. With the tools that AWS provides, you can build highly scalable recommendation services that can be consumed by different channels, such as dynamic product recommendations on the e-commerce website or targeted email campaigns for your customers.

### System Overview

- 1** Amazon Elastic MapReduce (Amazon EMR) is a hosted Hadoop framework that runs on Amazon Elastic Compute Cloud (Amazon EC2) instances. It aggregates and processes user data from server log files and from the customer's purchase history.
- 2** An Amazon Relational Database Services (Amazon RDS) Read Replica of customer and order databases is used by Amazon EMR to compute user profiles and by Amazon Simple Email Service (Amazon SES) to send targeted marketing emails to customers.

- 3** Log files produced by the e-commerce web front end have been stored on Amazon Simple Storage Service (Amazon S3) and are consumed by the Amazon EMR cluster to compute user profiles.
- 4** User profile information generated by the Amazon EMR cluster is stored in Amazon DynamoDB, a scalable, high-performance managed NoSQL database that can serve recommendations with low latency.
- 5** A recommendation web service used by the web front end is deployed by AWS Elastic Beanstalk. This service uses the profile information stored on Amazon DynamoDB to provide personalized recommendations to be shown on the e-commerce web front end.

shown on the e-commerce web front end.

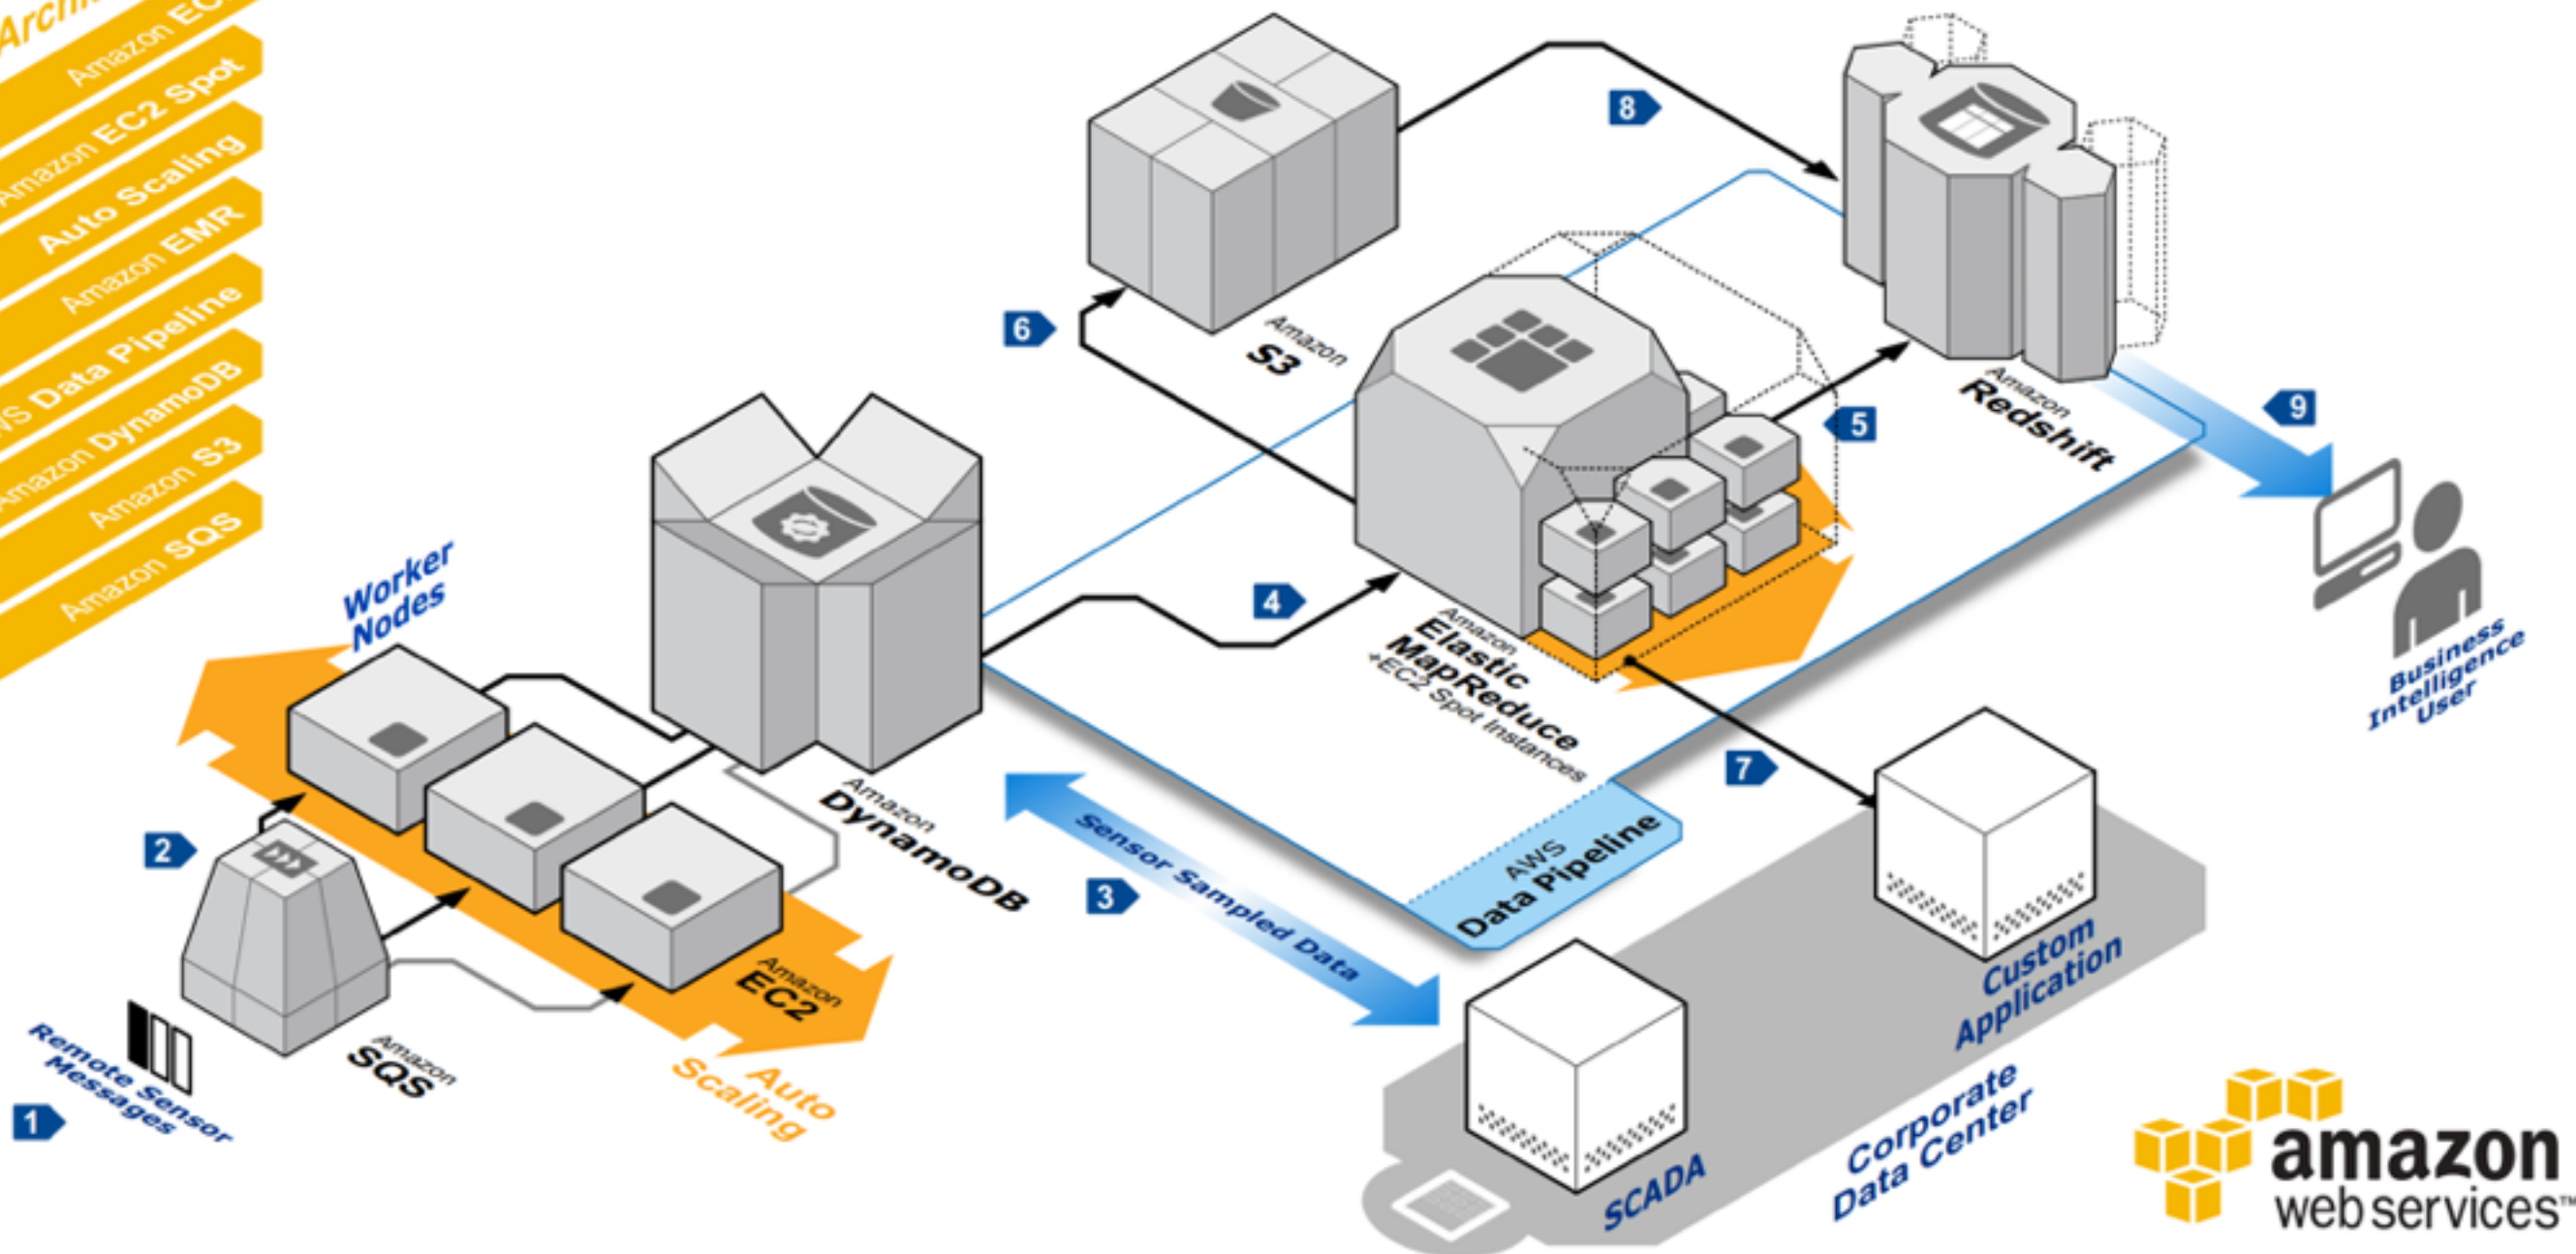

- 6** A marketing administration application deployed by AWS Elastic Beanstalk is being used by marketing managers to send targeted email campaigns to customers with specific user profiles. The application reads customer email addresses from an Amazon RDS Read Replica of the customer database.
- 7** Amazon SES is used to send marketing emails to customers. Amazon SES is based on the scalable technology used by Amazon web sites around the world to send billions of messages a year.

# TIME SERIES PROCESSING

When data arrives as a succession of regular measurements, it is known as time series information. Processing of time series information poses systems scaling challenges that the elasticity of AWS services is uniquely positioned to address.

This elasticity is achieved by using Auto Scaling groups for ingest processing, AWS Data Pipeline for scheduled Amazon Elastic MapReduce jobs, AWS Data Pipeline for intersystem data orchestration, and Amazon Redshift for potentially massive-scale analysis. Key architectural throttle points involving Amazon SQS for sensor message buffering and less frequent AWS Data Pipeline scheduling keep the overall solution costs predictable and controlled.

## System Overview

- 1 Remote devices such as power meters, mobile clients, ad-network clients, industrial meters, satellites, and environmental meters measure the world around them and send sampled sensor data as messages via HTTP(S) for processing.
- 2 Send messages to an **Amazon Simple Queue Service** queue for processing into **Amazon DynamoDB** using autoscaled **Amazon EC2** workers. Or, if the sensor source can do so, post sensor samples directly to **Amazon DynamoDB**. Try starting with a DynamoDB table that is a week-oriented, time-based table structure.

- 3 If a **Supervisory Control and Data Acquisition (SCADA)** system exists, create a flow of samples to or from **Amazon DynamoDB** to support additional cloud processing or other existing systems, respectively.
- 4 Using **AWS Data Pipeline**, create a pipeline with a regular **Amazon Elastic MapReduce** job that both calculates expensive sample processing and delivers samples and results.
- 5 The pipeline places results into **Amazon Redshift** for additional analysis.

- 6 The pipeline exports historical week-oriented sample tables, from **Amazon DynamoDB** to **Amazon Simple Storage Service (Amazon S3)**.
- 7 The pipeline also optionally exports results in a format custom applications can accept.
- 8 **Amazon Redshift** optionally imports historic samples to reside with calculated results.
- 9 Using in-house or Amazon partner business intelligence solutions, **Amazon Redshift** supports additional analysis on a potentially massive scale.

## Getting Started with Apache Hadoop

By Adam Kawa and Piotr Krevski

### INTRODUCTION

This Refcard presents Apache Hadoop, a software framework that enables distributed storage and processing of large datasets using simple high-level programming models. We cover the most important concepts of Hadoop, describe its architecture, guide how to start using it as well as write and execute various applications on Hadoop.

In the nutshell, Hadoop is an open-source project of the Apache Software Foundation that can be installed on a set of standard machines, so that these machines can communicate and work together to store and process large datasets. Hadoop has become very successful in recent years thanks to its ability to effectively crunch big data. It allows companies to store all of their data in one system and perform analysis on this data that would be otherwise impossible or very expensive to do with traditional solutions.

Many companion tools built around Hadoop offer a wide variety of processing techniques. Integration with ancillary systems and utilities is excellent, making real-world work with Hadoop easier and more productive. These tools together form the Hadoop Ecosystem.

**HOT TIP**

Many execution frameworks run on top of YARN, each tuned for a specific use case. The most important are discussed under YARN Applications below.

Let's take a closer look on their architecture and describe how they cooperate.

NOTE: YARN is the new framework that replaces the former implementation of the processing layer in Hadoop. You can find how YARN addresses shortcomings of previous version on the Yahoo! blog: <https://developer.yahoo.com/blogs/hadoop/latest-generation-apache-hadoop-mapreduce-3061.html>.

### HDFS

HDFS is a Hadoop distributed file system. It can be installed on commodity servers and run on as many servers as you need - HDFS easily scales to thousands of nodes and petabytes of data.

The larger HDFS setup is, the bigger probability that some disks, servers or network switches will fail. HDFS survives these types of failures by replicating data on multiple servers. HDFS automatically detects that a given component has failed and takes necessary recovery actions that happen transparently to the user.

HDFS is designed for storing large files of the magnitude of hundreds of megabytes or gigabytes and provides high-throughput streaming data access to them. Last but not least, HDFS supports the write-once-read-many model. For this use case HDFS works like a charm. If you need, however, to store a large number of small files with a random read-write access, then other systems like RDBMS and Apache HBase can do a better job.

NOTE: HDFS does not allow you to modify a file's content. There is only support for appending data at the end of the file. However, Hadoop was designed with HDFS to be one of many pluggable storage options - for example, with MapR-FS, a proprietary filesystem. Files are fully read-write. Other HDFS alternatives include Amazon S3 and IBM GPFS.

### DESIGN CONCEPTS

To solve the challenge of processing and storing large datasets, Hadoop was built according to the following core characteristics:

- Distribution - instead of building one big supercomputer, storage and processing are spread across a cluster of smaller machines that communicate and work together.
- Horizontal scalability - it is easy to extend a Hadoop cluster by just adding new machines. Every new machine increases total storage and processing power of the Hadoop cluster.
- Fault-tolerance - Hadoop continues to operate even when a few hardware or software components fail to work properly.
- Cost-optimization - Hadoop runs on standard hardware; it does not require expensive servers.
- Programming abstraction - Hadoop takes care of all messy details related to distributed computing. Thanks to a high-level API, users can focus on implementing business logic that solves their real-world problems.
- Data locality - don't move large datasets to where application is running, but run the application where the data already is.

### HADOOP COMPONENTS

Hadoop is divided into two core components:

- HDFS - a distributed file system
- YARN - a cluster resource management technology

## Getting Started with Apache Hadoop

By Eugene Ciurana and Masoud Kalali

### INTRODUCTION

This Refcard presents a basic blueprint for applying MapReduce to solving large-scale, unstructured data processing problems by showing how to deploy and use an Apache Hadoop computational cluster. It implements DZone Refcard #43 and #103, which provide introductions to high-performance computational scalability and high-volume data handling techniques, including MapReduce.

NOTE: YARN is the new framework that replaces the former implementation of the processing layer in Hadoop. You can find how YARN addresses shortcomings of previous version on the Yahoo! blog: <https://developer.yahoo.com/blogs/hadoop/latest-generation-apache-hadoop-mapreduce-3061.html>.

### APACHE HADOOP

Apache Hadoop is an open source, Java framework for implementing reliable and scalable computational networks. Hadoop includes several subprojects:

- MapReduce
- Pig
- ZooKeeper
- HBase
- HDFS
- Hive
- Chukwa

This Refcard presents how to deploy and use the common tools, MapReduce, and HDFS for application development after a brief overview of all of Hadoop's components.

**HOT TIP**

MapReduce frameworks produce lists of values. Users familiar with functional programming mistakenly expect a single result from the mapping operations.

### IMPLEMENTATION PATTERNS

The `Map(k1, v1) -> list(k2, v2)` function is applied to every item in the split. It produces a list of (k2, v2) pairs for each call. The framework groups all the results with the same key together in a new split.

The `Reduce(k2, list(v2)) -> list(v3)` function is applied to each intermediate results split to produce a collection of values v3 in the same domain. This collection may have zero or more values. The desired result consists of all the v3 collections, often aggregated into one result file.

**HOT TIP**

MapReduce frameworks produce lists of values. Users familiar with functional programming mistakenly expect a single result from the mapping operations.

## Apache Hadoop Deployment: A Blueprint for Reliable Distributed Computing

By Eugene Ciurana

### INTRODUCTION

This Refcard presents a basic blueprint for deploying Apache Hadoop HDFS and MapReduce in development and production environments. Check out Refcard #117, Getting Started with Apache Hadoop, for basic terminology and for an overview of the tools available in the Hadoop Project.

### WHICH HADOOP DISTRIBUTION?

There are two basic Hadoop distributions:

- Apache Hadoop is the main open-source, bleeding-edge distribution from the Apache foundation.
- The Cloudera Distribution for Apache Hadoop (CDH) is an open-source, enterprise-class distribution for production-ready environments.

The decision of using one or the other distributions depends on the organization's desired objective.

- The Apache distribution is fine for experimental learning exercises and for becoming familiar with how Hadoop is put together.
- CDH removes the guesswork and offers an almost turnkey product for robustness and stability. It also offers some tools not available in the Apache distribution.

**HOT TIP**

Cloudera offers professional services and puts out an enterprise distribution of Apache's Hadoop. Their toolset complements Apache's. Documentation about Cloudera's CDH is available from <http://docs.cloudera.com>.

### SSH Access

Every system in a Hadoop deployment must provide SSH access for data exchange between nodes. Log in to the node as the Hadoop user and run the commands in Listing 1 to validate or create the required SSH configuration.

**Listing 1 - Hadoop SSH Prerequisites**

```
keyctl=ssh-keygen -s -t rsa -p -f $KEYFILE -C $HOSTNAME
keyctl=ssh-keygen -s -t rsa -p -f $KEYFILE -C $HOSTNAME
if [ ! -e "$KEYFILE" ]; then \
  ssh-keygen -t rsa -o 2048 -p "" \
  -f "$KEYFILE" \
  fi \
  cat "$KEYFILE" >> "$SSHKEYS"; \
  chmod 644 "$SSHKEYS"; \
  echo "Hadoop SSH OK"; \
  else echo "Hadoop SSH OK"; fi
```

## Apache HBase

The NoSQL Database for Hadoop and Big Data

By Alex Baranau and Otis Gospodnetic

### ABOUT HBASE

HBase is the Hadoop database. Think of it as a distributed, scalable Big Data store.

Use HBase when you need random, real-time read/write access to your Big Data. The goal of the HBase project is to host very large tables - billions of rows multiplied by millions of columns - on clusters built with commodity hardware. HBase is an open-source, distributed, versioned, column-oriented store modeled after Google's Bigtable. Just as Bigtable leverages the distributed data storage provided by the Google File System, HBase provides Bigtable-like capabilities on top of Hadoop and HDFS.

**hbase-site.xml**

Specific customizations go into this file in the following file format:

```
<configuration>
  <property>
    <name>hbase.rootdir</name>
    <value>hdfs://myzkserver1:9000/hbase/</value>
  </property>
</configuration>
```

For the list of configurable properties, refer to <http://hbase.apache.org/doc/hbase-configuration.html> (or view the raw `conf/hbase-default.xml` source file).

These are the most important properties:

Property	Value	Description
hbase.cluster.distributed	true	Set value to true when running in distributed mode.
hbase.zookeeper.quorum	myzkserver1,myzkserver2	HBase depends on a running Zookeeper cluster. Configure using external ZK (if not configured, internal instance of ZK is started).
hbase.rootdir	hdfs://myzkserver1:9000/hbase	The directory shared by region servers and where HBase persists. The URL should be fully qualified to include the filesystem scheme.
