

# Influences on Subtidal Salinity Variability and Change in the Delaware Estuary

Andrew Ross and Raymond Najjar  
The Pennsylvania State University

Delaware Estuary Science and Environmental Summit  
January 28, 2013

# Outline

Introduction

Statistical models

Influences on salinity

Projected change

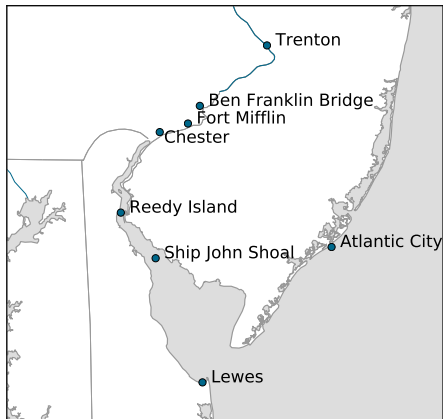

Summary

# Salinity variability makes estuaries unique

- ▶ Tidal and subtidal fluctuations in salinity are a unique feature of estuaries.
- ▶ Changes in salinity levels have a wide range of effects on the ecosystem.
  - ▶ Oyster disease (Powell et al., 1992)
  - ▶ Ammonia-oxidizing bacteria (Bernhard et al., 2005)
  - ▶ Phytoplankton blooms (Gallegos and Jordan, 2002)
- ▶ Changes caused by climate change and other influences have the potential to influence estuarine salinity.
  - ▶ Streamflow
  - ▶ Sea level
  - ▶ Wind stress
  - ▶ Oceanic salinity

# These variables have been measured throughout the Estuary

- ▶ **Streamflow:** USGS
- ▶ **Salinity:** USGS, NOAA/NOS
- ▶ **Sea level:** PSMSL (Woodworth and Player, 2003)
- ▶ **Oceanic salinity:** Gulf Stream Index (Taylor, 1995)
- ▶ **Wind stress:** North American Regional Reanalysis (Mesinger et al., 2006)

# Sea level is rising

# Streamflow is increasing

# How is salinity responding?

# Influences can be determined with statistical models

- ▶ Multiple linear regression:

$$\mathbb{E}(S_i) = \beta_0 + \beta_1 Q_i + \beta_2 H_i + \beta_{Month}$$

# Influences can be determined with statistical models

Generalized additive mixed model:

$$\mathbb{E}(S_i) = \beta_0 + f_Q(Q_i) + f_H(H_i) + f_M(Month_i)$$

- ▶  $f_Q()$ ,  $f_H()$ ,  $f_M()$ : Smooth functions that relate streamflow, sea level, and month to salinity.

$f_Q()$ ,  $f_H()$ ,  $f_M()$ : Smooth functions that relate streamflow, sea level, and month to salinity.

$$\mathbb{E}(S_i) = \beta_0 + f_Q(Q_i) + f_H(H_i) + f_M(\text{Month}_i)$$

## The model handles autocorrelated errors

- ▶ Residual lag-1 autocorrelation is roughly 0.4.
- ▶ Among other effects, autocorrelation results in decreased degrees of freedom for the smooth functions.
- ▶ We assume an AR(1) autocorrelation model.

## The model closely fits the observed salinity

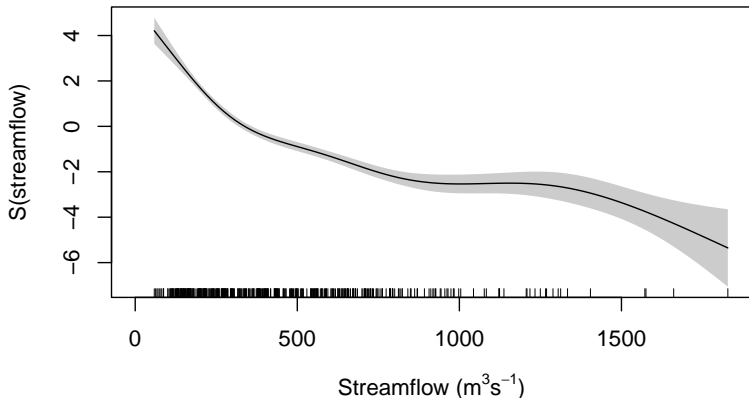

**Black:** observed Reedy Island salinity. **Green:** modeled Reedy Island salinity.

- ▶ The fits upstream in the Estuary are not as good.

# Streamflow has the largest effect

Reedy Island Jetty

- ▶ The results are similar at the other locations.

# Sea level is also important

Reedy Island Jetty

# Sea level is also important

## Other locations

### Ship John Shoal

### Chester

### Fort Mifflin

### Ben Franklin Bridge

# Alongshore wind stress may be important

## Reedy Island Jetty

- ▶ Similar result at Ship John Shoal.
- ▶ Not significant at upstream locations.

## Oceanic salinity is not important

- ▶ Oceanic salinity does not have a significant effect at any location, and the signs of the slope of the modeled effect vary.
- ▶ This makes sense, since oceanic salinity probably only has an influence over longer time scales.

## Sea level will rise significantly

- ▶ For the A2 emissions scenario, Vermeer and Rahmstorf (2009) project that mean sea level in 2100 will be 0.98-1.55 m above 1990 MSL with a model mean of 1.24 m above 1990 MSL.
- ▶ At Atlantic City, this translates to sea level rising from 7.1 m to 8.3 m (8.0-8.6 m).

# Salinity will increase as a result of sea level rise

## Streamflow changes are uncertain

- ▶ On average, models predict an increase in precipitation, leading to a  $15 \pm 20$  % change in streamflow by the end of the century for the A2 scenario (Najjar et al., 2009).
- ▶ However, a warming of  $4^{\circ}\text{C}$  results in a 15-40% decrease in streamflow due to increased evapotranspiration (Najjar et al., 2009)
- ▶ We consider three scenarios:
  1. 20% increase (to  $540 \text{ m}^3 \text{ s}^{-1}$ )
  2. 20% decrease (to  $360 \text{ m}^3 \text{ s}^{-1}$ )
  3. 45% decrease (to  $247 \text{ m}^3 \text{ s}^{-1}$ )

## Salinity responds weakly to streamflow change

# Summary

- ▶ Streamflow has the largest effect on monthly variability of salinity.
- ▶ The magnitude of the response to streamflow is relatively weak, so the long term trend in salinity may be dominated by sea level.
- ▶ Alongshore wind stress may be important, particularly downstream in the Estuary and Bay.
- ▶ Mean salinity will decrease slightly if mean streamflow increases and will increase slightly if mean streamflow decreases.
- ▶ Mean salinity will increase significantly if sea level rises as projected.
