URL of this page: A bilirusama bin blood test measures the bilirubin level in your blood. Bilira is a yellow substance made during the normal body process of breaking red blood cells. Bilira is found in safara, a salin in your liver that helps you eat. If your liver is healthy, it will remove more and more bilirubin from your body. If your liver is damaged, you can get out of your liver and out of your blood. When too much bilirubin gets in, it can be caused by the jaundin, a condition that changes your skin and eyes yellow. Symptoms of jaundin, which is a bilirbbon blood test, can help your healthcare providers if you have liver disease. Other name: Total Serum bilira, a bilirubin bin blood test is used to check your liver health. The test is also commonly used to help diagnose the neo-neous jaundrin. Many healthy children get the jauncin because their abuse does not exist in sufficient quantities. The newborn jaundrin is usually harmful and cleans within a few weeks. But in some cases, high bilirubin levels can lead to brain damage, so children are tested as a precaution. Your health care provider can order a bilira bin blood test: if you have symptoms such as jauncial, black piss, or abdominal pain. It may indicate hepatitis, services, or other liver dapoliticalistas if there is a blockage in the structure which will monitor your lourta to diagnose problems related to an existing liver disease or disorderTo problems with red blood cell production. High bilirubin levels in the blood can be a sign of the deformity of the disease and a healthcare professional called hemolytic anaemia using a small injection, will take a blood sample from a vein in your hand. After the injection is entered, a small blood will be collected in a test tube or glass. You may feel a little bit sculptured when the injection goes in or out. It usually takes less than five minutes. You do not need any special preparation for a bilirubin blood test. If your health care provider has also ordered other blood tests, you may be fast (no food or drink) for several hours before the test. Your healthcare provider will know if you have any specific instructions to follow. There is very little risk for blood tests. You may have minor pain or rash at the place where the injection was put, but most symptoms get away faster. Normal results may be different, but high bilirubin levels mean that your liver is not working correctly. However, unusual results do not always indicate the medical condition that needs treatment. Medications above normal bilirubin levels can also be caused by certain foods, or strict exercise. To know what your results mean, talk to your healthcare provider. About laboratory tests, reference limits, and understanding results Learn more. A bilirbin blood test is the only measure Liver health. If your healthcare provider thinks you may have liver disease or red blood cell disorders, other tests may be recommended. These include liver function tests, a group of tests that measure different substances in your blood, and tests for certain proteins made in the liver. In addition, your health care provider may be recommended to get a tissue sample from your liver, a test for the liver, an al-tabernade, or a biopsy to check the symptoms of liver disease such as: skin rash. Spider Ingomeas (unusual collection of blood veins near the skin level). Palm yrethema (red dyes of palms and fingers). The analysis (urinal test) which is positive for this shows that the patient has a counjogated jaunciation. The results of the analysis should be confirmed by serum testing. Serum testing will include a complete blood count (CBC) and bilirubin levels. Your doctor will also test to determine the size and the co-mail of your liver. They or they can use the imagining (ultrasonography and computer tomographawk (CT) scan) and liver biopsy (taking a liver sample) to further diagnose.
