Where do I see myself in 10 years with AI at my dream job?

I think in 10 years AI would've helped me be more efficient in my work in many ways, especially if I work at NVIDIA. While AI I would've been able to work past any kind of idea blocks I might've had if it was just me working alone and at the same time the AI would help me organize my time and work, helping me focus my attention to bigger tasks that might've needed my attention. This can be important because what if I'm on a time crunch on a big important project, say I'm developing the next big line of GPUs and I need to get a spread sheet of how well these cards work, how much RAM they have and other things. Rather than splitting my focus on trying to finalize the final developments on the card, worrying about how I am going to showcase the card I can just make AI do it for me and then check off on the information and the organization of it. Especially in 10 years from now with the direction that AI is taking I have confidence in AI making my work life much easier and more efficient. That's another thing about AI if I work alongside, it for the full 10 years I believe that using it to assist me will just become second nature, reaching a flow state in which I can confidently rely on the AI to do miniscule tasks for me. In addition, as I continue to use it, I might even end up improving the AI itself or developing one of my own to help me in my work rather than using Chat GPT or another on.

Another way I see myself with AI at my dream job at NVIDIA would be in making different kinds of software to make sure that the card could be compatible with other components

of a computer or sending out updates through the GeForce app to make sure that all drivers are running. In this situation AI could help me in finding little mistakes that I could've made in the programming before it's fully released or even just helping me out in making things much simpler to understand in case someone else that could be working on the same project as I needs to read my work. This would make it all much efficient and save me the headache of looking through lines of code to find a simple little kink in the programming. It will even remind me to turn in important project if I upload it my schedule to it, now on top off the ways it will help in my work and helping me be more efficient in a team setting it will send me reminders on important projects or dates that I have on my calendar that I would end up forgetting or be late on. This is most prominent if I made my own AI that I would be able to take home and not worrying about my data being stolen. I emphasize this because in 10 years AI would for sure get more intelligent and with the direction many AI companies are going with being more evasive in peoples data to make sure that they learn I would be worried about data breaches and what effect that could have if I was working on a secret project that can't be leaked. I would name my personal AI Jarvis, after the Ironman one.

Overall, in 10 years AI would be a big part of my life. Whether that's in my work setting helping me developing the next big line of GPUs and trying to present it to shareholders and the public or it would be making my own AI with the experiences from working at NVIDIA.
