Background: Advancements in treatment over the last decade have greatly improved survival in B cell non-Hodgkin's lymphoma (NHL), yet not all patients (pts) benefit the same. Non-Hispanic Black (NHB), uninsured and lower socioeconomic status pts continue to suffer worse survival. However, the impact of neighborhood deprivation on disability has not been explored. We aimed to assess the association between neighborhood deprivation and disability free survival (DFS) in NHL pts. **Methods:** 258 aggressive NHL pts treated between 2005-2020 were included. Pts without documented follow up were excluded. Race/ethnicity was categorized as non-Hispanic white (NHW), Hispanic, NHB and other. Primary outcomes included progression free survival (PFS), overall survival (OS) and DFS. DFS was defined as time to needing any rehabilitative, home-health or skilled nursing services immediately following induction therapy, indicating disability and lack of functional independence. Neighborhood deprivation was assigned using the national Area Deprivation Index (ADI), a validated measure classifying neighborhood adversity. Pts were categorized into high (67-99), intermediate (34-66) or low (1-33) ADI scores, with least disadvantaged designated by lower scores. Kaplan-Meier analyses were used to compare PFS, OS and DFS. **Results:** Demographic data is shown in the table; 45% were female, 65% were NHW, 10% were NHB, 8% were Hispanic and 10% were other. Median age at diagnosis was 57 years. There was no difference in PFS or OS between racial/ethnic groups ($p=0.91$ and $p=0.23$ respectively). Payor source influenced both PFS and OS ($p<0.001$ and $p<0.001$ respectively), with self-pay associated with worse PFS and OS. Neighborhood deprivation based on ADI did not influence PFS ($p=0.33$) or OS ($p=0.76$). High ADI score was associated with worse DFS compared to lower ADI scores ($p=0.03$). ADI score differed significantly based on race/ethnicity ($p<0.0001$), with more NHB pts residing in areas of high ADI scores (40% vs 5% NHW vs 10% Hispanic). There was no association between ADI score and a pt's ECOG performance status, IPI score or albumin at diagnosis ($p=0.87$, $p=0.78$ and $p=0.59$ respectively). **Conclusions:** NHL pts with higher neighborhood adversity experience more disability after treatment despite similar survival. Further work is needed to better understand how neighborhood factors are contributing to disability before community-level strategies for improvement can be developed. Research Sponsor: None.

Final analysis of the phase IB part of the LOC-R01 trial, a non-comparative randomized phase IB/II study of escalating doses of lenalidomide and ibrutinib in association with R-MPV for patients with a newly diagnosed primary central nervous system lymphoma (PCNSL). *First Author: Marion Alcantara, Institut Curie, Saint-Cloud, France*

Background: Results of conventional induction chemotherapies in PCNSL need to be improved. Ibrutinib, a BTK inhibitor, and lenalidomide, an immunomodulatory drug, have shown promising results in the relapse setting, supporting to further assess their combination with standard high-dose methotrexate-based chemotherapy. **Methods:** Patients (pts) with newly diagnosed PCNSL, aged 18 to 60, were randomized to receive four 28-day cycles of either ibrutinib or lenalidomide in combination with R-MPV (rituximab, methotrexate, procarbazine, vincristine and prednisone) in a 3+3 design for ibrutinib 420/560/280 mg (D3 to D14 and D17 to D28) and lenalidomide 20 mg D1 to 14/20 mg D1 to 21/15 mg D1 to 21. Responder pts then received a consolidation with R-Cytarabine and an intensive chemotherapy with autologous stem cell transplantation. The objective of the phase IB study was to define the recommended phase II dose (RP2D) based on the dose-limiting toxicity (DLT) occurring during the first induction cycle. We present the results of the phase IB, including the toxicities that occurred throughout induction therapy. **Results:** 26 pts (median age 52) were randomized, 13 in each treatment group. Four DLTs (/21 evaluable pts) have been observed: grade 5 aspergillosis and pneumocystosis (N=1, ibrutinib 560 mg and concurrent high-dose corticosteroids without prophylaxis), grade 4 catheter-related infection > 7 days (N=1, lenalidomide 20 mg D1-14) and grade 3 increased alanine aminotransferase > 7 days (N=1, lenalidomide 20 mg D1-14 and N=1, lenalidomide 15 mg D1-21). RP2D of ibrutinib and lenalidomide were 560 mg (D3-14 and D17-28) and 15 mg (D1-21) respectively, in combination with R-MPV. One Yell's syndrome was reported as a serious adverse event (AE) at cycle 2 in the lenalidomide arm. Grade ≥ 3 treatment-related AEs occurring in ≥ 2 pts at any time during induction treatment are detailed in the table. After 4 induction cycles, 3/11 evaluable pts had CR/CRu and 7/11 had partial response (PR) in the ibrutinib group. In the lenalidomide arm, 6/10 evaluable pts had CR/CRu and 4/10 had PR. Survivals will be presented. **Conclusions:** Targeted induction immunotherapy with ibrutinib or lenalidomide and R-MPV is feasible for newly diagnosed PCNSL and shows promising response rates. Adverse events should be monitored carefully. The phase II part of the study is ongoing and opened to patients up to 65 years old. Clinical trial information: NCT04446962. Research Sponsor: French government funding (PHRC-K: programme hospitalier de recherche clinique national en cancérologie).

Racial and ethnic disparities in risk of second primary malignancies among diffuse large B-cell lymphoma survivors. *First Author: Pragati Gole Advani, Roswell Park Cancer Institute, Buffalo, NY*

Background: Previous studies have shown an increased risk of second primary malignancies (SPMs) among diffuse large B-cell lymphoma (DLBCL) survivors; however, this has not been comprehensively examined by race/ethnicity. We utilized a large population-based database to examine disparities in SPM risk by race/ethnicity. **Methods:** From 17 United States population-based Surveillance, Epidemiology and End Results (SEER) program cancer registry areas, we identified 57,262 $\geq$ 12-month first-primary DLBCL survivors diagnosed between 2000-2019. Standardized incidence ratios (SIRs) and accompanying 95% confidence intervals (CIs) quantified SPM risk by race/ethnicity (non-Hispanic White, Black, Asian/Pacific Islander [API] and Hispanic), compared with the general population. **Results:** Overall, we observed 4,719 SPMs after DLBCL representing a 1.2-fold significantly increased risk (95% Confidence Interval [CI] = 1.16-1.23) compared to the general population and an excess of 23 cases per 10,000 person-years. SIRs for all second cancers combined varied significantly by race/ethnicity with APIs and Hispanics presenting higher overall SPM risk [SIR_{API}: 1.42 (CI = 1.27-1.59), and SIR_{Hispanic}: 1.31 (CI = 1.19-1.43)] compared to the White or Black patients [SIR_{White}: 1.17 (CI = 1.13-1.21), SIR_{Black}: 1.16 (CI = 1.03-1.30)] (p-heterogeneity < 0.001). Heterogeneity by race/ethnicity in SIRs was even more pronounced in DLBCL survivors diagnosed at a younger age, those who were $\geq$ 5 years into their survivorship, those who had received chemotherapy, or those who had received no radiation as their initial treatment. Although SIRs for SPM was significantly higher for advanced stage DLBCL survivors (compared to those with a localized/regional disease), heterogeneity by race/ethnicity in SPM risk was significant regardless of the stage. Results from site specific analyses reported significantly higher overall SIRs for second hematological malignancies compared to solid cancers [SIR_{hemat}: 3.52 (CI = 3.22-3.85), and SIR_{solid}: 1.08 (CI = 1.04-1.11)]. Patterns by race/ethnicity also varied significantly by second cancer type, particularly for second primary anal cancer, Hodgkin's lymphoma (HL), and Acute Non-Lymphocytic Leukemia (ANLL) (p < 0.001 for each). Strikingly elevated SPM risks (SIRs > 10) were observed for second primary anal cancer, HL and ANLL among the Black patients, and HL among the APIs and Hispanic DLBCL survivors, compared to the white patients. **Conclusions:** Using a large-scale population-based data, we observed substantial disparities in SPM risk by race/ethnicity, with patients belonging to minority groups experiencing higher risks. SPMs have emerged as an important challenge for DLBCL survivors, therefore, further research to understand drivers of the observed race/ethnicity heterogeneity is warranted. Research Sponsor: None.

Preliminary data of a phase 1b/2 study of BCL-2 inhibitor lisaftoclax (APG-2575) alone or combined with ibrutinib or rituximab in patients (pts) with Waldenström macroglobulinemia (WM). *First Author: Sikander Ailawadhi, Mayo Clinic, Jacksonville, FL*

Background: B-cell lymphoma 2 inhibitors (BCL-2i) are well tolerated and effective in treating B-cell lymphoproliferative disorders such as CLL. Investigational agent lisaftoclax is a novel, oral, highly selective and potent BCL-2i. Preclinical data show a strong synergistic effect of lisaftoclax plus ibrutinib in an ibrutinib-insensitive PDXWM1 model. **Methods:** This global, open-label, multicenter study evaluates the safety and efficacy of lisaftoclax alone and combined with ibrutinib or rituximab in pts with WM. Pts were enrolled in 3 arms: Arm A (lisaftoclax), BTKi-resistant/intolerant pts; Arm B (lisaftoclax plus ibrutinib), treatment-naïve pts; and Arm C (lisaftoclax plus rituximab), BTKi-naïve relapsed/refractory pts. Lisaftoclax was escalated from 400 to 1,200 mg using a modified toxicity probability interval design. A 3-day ramp-up was used for pts at high TLS risk. Primary objectives were pharmacokinetics (PK), safety, and efficacy assessments; responses were assessed per IWWM criteria. **Results:** As of January 25, 2023, 46 pts were enrolled (Arm A [n = 14]; up to 1,000 mg; Arm B [n = 24]; up to 1,200 mg; Arm C [n = 8]; up to 800 mg). Baseline characteristics are shown in the table. Median (range) treatment duration was 6 (1-18; Arm A), 14 (1-27; B), and 8 (2-26; C) months. Overall response rates (ORRs) were: Arm A, 25% (median time to response [MTTR], 4.3 months); Arm B, 90.9% (MTTR, 1.9); Arm C, 37.5% (MTTR, 4.4). No significant difference was observed between pts with and without CXCR4-mut. At 1,200 mg, 1 DLT (grade 3 clinical TLS), due to pre-existing renal impairment, was reported. At 1,000 mg, 1 grade 3 laboratory TLS occurred in Arm B because of dehydration and active symptomatic therapies; abnormal electrolytes resolved after 1 day of drug interruption, without recurrence. Grade $\geq$ 3 lisaftoclax-related AEs included neutropenia (13%), leukocytopenia (4.3%), anemia (2.2%), weight loss (2.2%), and septic shock (2.2%). Ventricular arrhythmias were not observed. Only 1 pt required dose reduction (due to neutropenia). MTD has not been reached. A total of 14 pts discontinued study treatment because of disease progression (n = 5) and AE (n = 1). Lisaftoclax plus ibrutinib showed a PK exposure comparable to ibrutinib alone, indicating no potential DDIs. **Conclusions:** Lisaftoclax alone or combined with ibrutinib/rituximab demonstrated measurable effects in pts with naïve or BTKi-treatment-failed WM. Internal study identifier: APG2575WU101. *SA and ML are co-first authors. Clinical trial information: NCT04260217. Research Sponsor: Ascentage Pharma Group Corp Ltd.

Uncertainty and coping in patients with newly diagnosed indolent non-Hodgkin's lymphoma (iNHL). *First Author: Richard Newcomb, Massachusetts General Hospital, Boston, MA*

Background: iNHLs are a heterogeneous group of incurable diseases with prolonged illness courses requiring intermittent periods of surveillance and treatment. Due to illness uncertainty, patients with iNHL struggle with immense psychological distress. Yet, studies exploring coping, prognostic uncertainty and distress in this population are limited. **Methods:** We conducted a cross sectional study of adults (age $\geq$ 18) newly diagnosed with iNHL at a single academic center. We enrolled consecutive patients who were diagnosed $\leq$ 3 months prior to study enrollment. At baseline, we collected patient reported outcomes to assess QOL (Functional Assessment of Cancer Therapy), psychological symptoms (Hospital Anxiety and Depression Scale), prognostic understanding (Prognostic Awareness Impact Scale), and coping (Brief COPE). We categorized coping as approach-oriented (active coping, use of emotional support, positive reframing, acceptance) and avoidant (behavioral disengagement, denial, and self-blame). We used median split to differentiate between low and high utilizers of approach or avoidant coping. **Results:** We enrolled 70.6% (48/68) of eligible patients newly diagnosed with iNHL (mean age 66.8 yrs; 39.6% chronic lymphocytic leukemia/ lymphoma; 33.3% follicular lymphoma). At baseline, nearly one-third (31.2%) experience clinically significant symptoms of anxiety and depression. 45.8% of patients identified prognostic uncertainty as the "the most stressful part of being a patient," and 31.2% reported having "difficulty letting go of thoughts about their prognosis." Notably, patients had significant misperceptions about their prognosis with incurable iNHL, as 47.9% reporting that a cure was at least 'somewhat' likely. Patients with iNHL most often used acceptance (56.3%), denial (47.9%), and emotional support (47.9%) as coping strategies. Patients who were high utilizers of multiple approach-oriented coping strategies experienced fewer anxiety (B = -2.66, p = 0.01) and depression (B = -1.73, p = 0.02) symptoms and improved QOL (B = 9.43, p = 0.001). Patients who highly utilized any avoidant-oriented coping strategies experienced increased anxiety symptoms (B = 2.16, p = 0.05), but no difference in depression symptoms or QOL. **Conclusions:** Patients with iNHL report immense prognostic uncertainty and psychological distress. Use of multiple approach oriented coping strategies was associated with decreased psychological distress and improved QOL. Interventions to address prognostic uncertainty and to promote approach oriented coping in patients with iNHL are sorely needed and have the potential to ameliorate psychological distress and improve QOL in this vulnerable population. Epidemiologic characteristics, treatment patterns, and survival analysis of plasmablastic lymphoma in the US. *First Author: Alec Hansen, Department of Internal Medicine, University of Utah, Salt Lake City, UT*

Background: Plasmablastic Lymphoma (PBL) is a rare aggressive subtype of diffuse large B-cell lymphoma primarily affecting the immunocompromised, including those living with HIV. There is no established standard of care, and current survival estimates range from 8-15 months (mos). With the largest previous study of PBL limited to 590 patients (pts), we aimed to evaluate epidemiologic characteristics, treatment patterns and survival trends on a national scale. **Methods:** Pts diagnosed with PBL from 2010-2020 were identified in the National Cancer Database (NCDB) and the Surveillance, Epidemiology, and End Results (SEER) Program. Age-adjusted incidence rates (IR) were calculated using SEER. Demographic and treatment characteristics and overall survival were evaluated in the NCDB using Kaplan-Meier and multivariate Cox regression analysis. **Results:** For the 1,153 pts identified in SEER, the incidence of PBL was 0.07 per 100,000 person-years, with higher IR in males (0.12) and pts age > 75 years (0.23). IR increased on average by 4.2% per year from 2010 to 2020 (95% CI 1.51-6.96). Of the 1,822 PBL pts in NCDB, the median age at diagnosis was 57 years. PBL was more common in male (77.2%) and White pts (76.8%). Most pts presented at an advanced (III or IV) Ann Arbor stage (59.9%). Pts were HIV+ in 50.2% of cases and 51.2% had extranodal disease. The median OS (mos) was 22.4 mos (95% CI 16.2-28.6), with a 1-, 5-, and 10-yr OS of 56%, 40%, 32%, respectively. PBL pts treated with multiagent chemotherapy (N = 862, 66%) had mos of 58.6 mos (95% CI 43.0-74.3). Pts who received no systemic treatment (N = 456, 25%) had mos of 1.9 mos (95% CI 1.2-2.5). Pts with Stage I disease had a mos of 86.2 mos, Stage II of 51.1 mos, Stage III of 35.9 mos, and Stage IV of 8.8 mos. Pts with HIV had a greater mos (44.0 mos [95% CI 28.7-59.3]) than HIV- pts (21.7 mos [95% CI 12.4-30.9]). On multivariate Cox regression adjusted for age, race, and socioeconomic status, factors associated with worse OS included age (HR 1.03 [95% CI 1.02-1.04], p < 0.001), B symptoms (HR 1.35 [95% CI 1.11-1.65], p = 0.003) and advancing stage. Factors associated with improved OS included Hispanic ethnicity (HR 0.70 [95% CI 0.52-0.93], p = 0.014) and extranodal disease (HR 0.77 [95% CI 0.63-0.93], p = 0.001). HIV+ status had no significant impact on survival (HR 1.09 [95% CI 0.87-1.38], p = 0.443). **Conclusions:** We present the largest study to date describing the epidemiologic, survival, and treatment patterns of PBL. In contrast to prior studies, we found a longer mos of 58.6 mos among those treated. This may represent a large real-world population providing more accurate estimates or reflect improved outcomes from a growing number of novel therapeutic options. Notably, HIV+ status did not have a significant impact on OS. While OS remains poor, advances in treatment over the last decade are promising and highlight the need for clinical advances to improve front line therapeutic options for PBL. Outcomes among adult recipients of CD19 CAR T-cell therapy for Burkitt lymphoma. *First Author: Laura S. Samples, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Burkitt lymphoma (BL) is a rare, but highly aggressive B-cell lymphoma associated with especially poor outcomes in patients with relapsed/refractory disease. Multiple CD19 chimeric antigen receptor (CAR) T-cell products have been FDA approved to treat relapsed/refractory B-cell non-Hodgkin lymphoma in the second-line setting, however little is known about CAR T-cell responses in patients with BL. This multicenter study aims to assess real-world outcomes among patients with BL treated with CAR T-cell therapy across the United States. **Methods:** This multicenter, retrospective chart review was conducted by abstracting data from the medical charts of patients with BL who received CAR T-cell therapy. Demographic characteristics were assessed along with pre-CAR treatments, bridging therapies, infusion-related complications, CAR-T responses, and the use of post-CAR systemic therapy and/or hematopoietic stem cell transplant. **Results:** A total of 13 patients with relapsed/refractory BL received CAR T-cell therapy after a median of 3 prior therapies (range 1-6). Most patients received axi-cel (n = 8), although tisa-cel (n = 3) and liso-cel (n = 2) were also represented. The median age of these patients was 38 (range 24-68). A total of 6 (46.2%) had evidence of central nervous system involvement at diagnosis and 5 (38.5%) had a prior history of autologous stem cell transplant. The overall response rate 1 month after infusion was 69.2% with a complete response rate of 53.8%. All patients experienced grade 1-2 cytokine release syndrome (CRS). No one experienced grade ≥ 3 CRS, but 2 patients developed grade ≥ 3 immune effector cell-associated neurotoxicity syndrome (ICANS). Twenty-eight-day mortality was 23%, including one patient who died from grade 4 ICANS. Regarding long term data, only 4 (30.8%) patients sustained a complete response for more than 6 months. Median progression-free survival was 4.2 months (95% CI 28.2-257.6), and the 1-year overall survival rate was 61.5% (95% CI 0.56-0.67). Two (15.4%) patients received consolidative allogeneic stem cell transplants after CAR T-cell therapy, but both ultimately developed progressive disease. **Conclusions:** Relapsed/refractory BL is a rare and aggressive disease that remains challenging to treat despite the advent of CAR T-cell therapy. Further investigation is needed to determine the most effective management of these patients. We expect to include additional patients in this analysis over the coming months. Unveiling the prognostic significance of BCL6+/CD10+ mantle cell lymphoma: A systematic analysis. *First Author: Dan Ran Castillo, Division of Medical Oncology and Hematology, Loma Linda University School of Medicine, Loma Linda, CA*

Background: Mantle cell lymphoma (MCL) is heterogenous B-cell neoplasm that characterized by the presence of the IgH/CCND1 translocation. The significance of CD10 expression in MCL is not fully understood. The co-expression of CD10 and BCL6 in MCL is rare requiring further investigation to determine its clinical significance. This meta-analysis aims to examine the relationship between MCL variants and their cellular behaviors and clinical outcomes. **Methods:** A search of the GDC and dbGaP database was conducted using the PICOS model and PRISMA guidelines to retrieve survival data. Overall survival (OS) data was pooled from multiple studies and analyzed using the R programming package survival and a log-rank test was performed to compare OS. Mean differences between BCL6+ vs. BCL6- for individual studies were calculated and combined to minimize batch effects. Summary statistics across studies were obtained by averaging mean differences and pooling individual standard deviations. The correlation between CD10 and BCL6 was tested using Fisher's exact test, with a significance level of 0.05. **Results:** The analysis included a total of 537 patients (425 males and 112 females), with a median age at diagnosis of 69 years in CD10+ MCL and 61.5 years in CD10- MCL. Out of the 537 patients, 70 were CD10+ positive, and BCL6 positivity had an odds ratio of 5.11 [95% CI [2.49, 10.46]; p = 0.000286] for CD10 positivity compared to CD10 negativity. The subgroup analysis revealed a higher frequency of blastoid/pleomorphic/small variants in BCL6+/CD10+ MCL. BCL6 positivity was associated with worse OS, independent of CD10 expression (median OS of 14 months in BCL6+ MCL vs. 43 months in BCL6- MCL; p = 0.01). The co-expression of BCL6 and CD10 was associated with a shorter median OS (22 months in BCL6+/CD10+ vs. 55 months in BCL6-/CD10+, p = 0.01) and significantly higher mitotic index (Ki67%) compared to BCL6-/CD10+ MCL (mean Ki67% of 63.13 $\pm$ 19.45% vs. 45 $\pm$ 21.69%, p < 0.01). The forest plot analysis showed that BCL6 expression was correlated with a significantly higher Ki67% (difference of 24.29; p = 0.0094). **Conclusions:** Our meta-analysis found that BCL6 expression correlates with CD10 positivity in MCL variants and has a negative impact on prognosis, independent of CD10 expression. Higher Ki67% levels in BCL6+ MCL compared to BCL6- MCL support the prognostic value of the BCL6+ immunophenotype in MCL variants. Prognostic scoring systems adjusted for BCL6 expression should be incorporated into MCL management. Targeted therapies against BCL6 may offer potential treatment options for MCL subtypes. Investigating the impact of demographic disparities on clinical outcomes in cutaneous T-cell lymphoma (CTCL): A multicenter retrospective cohort analysis. *First Author: Tim Niyogusaba, Emory University School of Medicine, Atlanta, GA*

Background: Black patients have been shown to have a higher incidence of cutaneous T-cell lymphomas (CTCL) and display unique clinicopathologic features at diagnosis, however, drivers of these disparities and the role of social determinants of health (SDoH) remain poorly understood. **Methods:** To further characterize the prognostic relevance of racial and demographic disparities in CTCL, we performed a retrospective review of 1,198 patients seen at 8 different academic treatment centers in the United States between 2000-2020. Clinical variables included demographics, disease characteristics, and survival. Race and ethnicity were stratified into 2 groups for this analysis: non-Hispanic Black (B) and Non-Black (NB). Distance to center was stratified into short, intermediate, or long commute (< 10, 10-50, > 50 miles, respectively) based on home zip code. The primary endpoint was overall survival (OS). Univariate association and multivariable analyses were assessed using Cox proportional hazards models. **Results:** Among 1,198 total patients, 42.4% identified as B and 58.6% as NB. B patients presented younger, had a shorter commute, lower income, but no difference in insurance compared to NB patients. There was no difference in survival by race (Median OS 74 months [95% CI 65-84] compared to 65 [95% CI 58-75] for NB patients). Distance to center was strongly associated with survival and remained significant on multivariate analyses after controlling for age, race, and other SDoH. Longer commute was associated with worse OS compared to short commute for both B and NB counterparts (median 55 months [95% CI 49-66] vs. 79 [95% CI 69-90] and 75 [95% CI 63-86], respectively, p = 0.006). **Conclusions:** We characterized the impact of race and SDoH on overall survival (OS) in a diverse, multicenter cohort of patients with CTCL. We found that distance to cancer center was the most important factor contributing to disparities in OS in this study. This highlights the importance of improving access to care, particularly in rare and clinically heterogeneous diseases such as CTCL. Research Sponsor: None.

A phase 2 study of HLX208, a BRAF^{V600E} inhibitor, in adult patients with Langerhans cell histiocytosis and/or Erdheim-Chester disease harboring BRAF^{V600E} mutation. *First Author: Xin-xin Cao, Department of Hematology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China*

Background: HLX208 is a novel BRAF^{V600E} inhibitor, exhibiting excellent antitumor efficacy in preclinical studies. This phase 2 study aimed to evaluate the efficacy, safety, and pharmacokinetics of HLX208 in adult patients with Langerhans cell histiocytosis (LCH) and/or Erdheim-Chester disease (ECD) harboring BRAF^{V600E} mutation. **Methods:** This was a single-arm, open-label, multicenter, phase 2 study. Patients with histologically confirmed LCH and/or ECD were enrolled and received oral administration of HLX208 at 450 mg twice every day. HLX208 was given in 28-day cycles until disease progression, experiencing intolerable toxicity, withdrawal of consent, initiation of new antitumor therapy, or death, whichever occurred first. The primary endpoint was the objective response rate (ORR) assessed by independent review committee (IRC) per PET Response Criteria in Solid Tumors (PERCIST) 1.0. Secondary endpoints included safety, other efficacy measures, and pharmacokinetics of HLX208. **Results:** As of January 15, 2023, 22 patients with LCH and/or ECD were enrolled. All patients have received at least one dose of HLX208 and were included in the current analysis. The median age was 39 (range 18-69) years. Nine (40.9%) patients were male. 12 (54.5%) patients were diagnosed with LCH, 9 (40.9%) were diagnosed with ECD, and 1 (4.5%) had combined LCH and ECD. 6 (27.3%) patients had single system multifocal disease, while 16 (72.7%) had multisystem disease. The median follow-up duration was 4.8 months (95% CI 2.7-5.7). Among the 10 efficacy evaluable patients, ORR (unconfirmed) assessed by IRC per PERCIST 1.0 was 90.0% (95% CI 55.5-99.7%) (9/10, including 2 complete metabolic response [CMR] and 7 partial metabolic response [PMR]), while that by investigators per PERCIST 1.0 was 100.0% (95% CI 69.2-100.0%) (10/10, including 3 CMR and 7 PMR). Disease control rate was 100.0% (95% CI 69.2-100.0%) as assessed by both IRC and investigators per PERCIST 1.0. The median duration of response, median progression-free survival, and median overall survival were not reached. Of the 22 patients who received the drug, 17 (77.3%) patients experienced treatment-emergent adverse events (TEAEs); 12 (54.5%) reported treatment-related adverse events (TRAEs), most commonly alanine aminotransferase increased (36.4%), aspartate aminotransferase increased (22.7%), γ -glutamyltransferase increased (18.2%), and blood lactate dehydrogenase increased (18.2%). Most TRAEs were grade 1 (27.3%) and 2 (18.2%). Only 2 (9.1%) patients experienced grade ≥ 3 TRAEs and 1 (4.5%) experienced treatment-related serious adverse event. There were no TRAEs that led to treatment discontinuation or death. **Conclusions:** In summary, HLX208 was safe and well tolerated, and showed promising efficacy in patients with LCH and/or ECD. Clinical trial information: NCT05092815. Research Sponsor: Shanghai Henlius Biotech, Inc.

Clinical characteristics, survival outcomes, and prognostic factors in extra-nodal natural killer/T-cell lymphoma, nasal type: The National Cancer Database study (2004-2019). *First Author: Firas Baidoun, Hematology Oncology Division, Mayo Clinic-Florida, Jacksonville, FL*

Background: Extranodal natural killer/T-cell lymphoma (ENKTL), nasal type, is a rare and aggressive Epstein-Barr virus driven lymphoma, which is most prevalent in East Asia and Latin America. There have been very few large studies outside of Asia. Therapeutic and survival outcomes have not been well characterized in the US. **Methods:** The National Cancer Database was queried for patients who were diagnosed at aged ≥ 18 years between 2004 and 2019. Patients who were lost to follow-up were excluded. Kaplan-Meier and multivariate Cox regression analyses were performed. **Results:** The cohort consists of 2,036 evaluable patients with 68% males, 74% Caucasian, 22% Hispanic Caucasian and 9% African American. The median age at diagnosis was 54 (18-90) years. The median follow up was 71 months (95% CI 66.8-75.7). Early-stage disease (I and II) was reported in 64% while advanced stage disease (III and IV) constituted 36%. Treatment groups include chemotherapy alone (29%), radiation alone (10%), combined modality therapy (CMT-chemoradiation) (42%). The median overall survival (OS) for the whole cohort was 27 months (95% CI 20.6-33.7). Median OS was better in patients with early stage compared to advanced stage disease (90 vs. 6 months, $P < 0.001$). Among therapeutic groups in early-stage disease, CMT ($N = 616$) had significantly better median OS than radiation alone ($N = 152$) or chemotherapy alone ($N = 168$) (194 vs. 34 vs. 14 months, $P < 0.001$). No significant difference was seen between radiation alone and chemotherapy alone ($P = 0.617$). Among patients treated with CMT, chemotherapy-first CMT ($N = 134$) had better OS than radiation-first CMT ($N = 347$) (median OS not reached vs. 194 months, $P = 0.017$). In the advanced stage disease, chemotherapy-treated patients ($N = 418$) had better median OS compared to patients who did not receive chemotherapy ($N = 103$) (7.6 vs 1.3 months, $P < 0.001$). Among patients who received chemotherapy, patients consolidated with SCT ($N = 59$) had better median OS compared to the patients who received chemotherapy only ($N = 353$) (63 vs 6 months, $P < 0.001$). In multivariate analysis, factors associated with worse OS were age (HR 1.021 95% CI 1.015-1.026; $P < 0.001$) and B-symptoms (HR 1.463 95% CI 1.276-1.678; $P < 0.001$). Whereas factors associated with better OS were early stage (HR 0.450 95% CI 0.387-0.524, $P < 0.001$), radiation therapy (HR 0.526 95% CI 0.458-0.603, $P < 0.001$) and chemotherapy (HR 0.546 95% CI 0.473-0.630, $P < 0.001$). **Conclusions:** The study represents one of the largest studies on ENKTL in the US. Early-stage disease is highly curable with CMT with chemotherapy-first sequencing being superior to radiation-first sequencing. Advanced stage disease is associated with extremely poor prognosis overall but is associated with a significant improvement in OS with consolidative SCT with possible role of consolidative RT in advanced stage. Risk of incident melanoma among individuals with low-count monoclonal B-cell lymphocytosis (MBL). *First Author: Bryan Alexis Vallejo, Division of Computational Biology, Mayo Clinic, Rochester, MN*

Background: Prior research has consistently shown that patients with chronic lymphocytic leukemia (CLL) have an ~ 2 -fold increased risk of developing melanoma compared to controls. MBL is a common condition affecting 8-10 million adults over the age of 40 years in the United States and is a precursor to CLL. Little is known about the association between MBL and melanoma. Herein, we evaluated the risk of incident melanoma in a large cohort of individuals screened for MBL. **Methods:** Participants from the Mayo Clinic Biobank who had no prior history of hematologic malignancy, were 40 years or older, were residents of counties surrounding Mayo Clinic, and who provided blood samples between 7/2009 and 4/2022 were included in the study. Peripheral blood mononuclear cells were screened for MBL using highly sensitive eight-color flow cytometry. Individuals with MBL were classified as CLL-like MBL (CD5+, CD20dim) or atypical MBL (CD5+, CD20+) based on immunophenotypes, and also classified as low-count MBL (LCMBL) or high-count MBL (HCMBL) based on whether the percent clonal B-cell count was $< 85\%$ or $\geq 85\%$, respectively. Diagnosis of melanoma was ascertained using ICD codes and review of the electronic health records. All individuals were followed from date of sample upon which MBL screening was performed to the earliest of incident melanoma, loss to follow-up, withdrawal from the study, or September 30, 2022. We used Cox regression to estimate hazard ratios (HR) and 95% confidence intervals (CI), adjusting for age, sex, and history of melanoma in previous 5 years. **Results:** A total of 7,334 participants were screened for MBL, of which 1,151 (16%) individuals had MBL. Among those with MBL, 1,107 (96.2%) had CLL-like MBL and 1098 (95.4%) had LCMBL. The median age at entry into the MBL screening cohort was 67 years (range 40-101) and 37% were male; individuals with MBL were older (median age 72 vs 65 years) and male (49% vs 35%). After a median follow-up of 2.9 years (range 0-13.2), 121 of the 7,334 (1.6%) participants developed incident melanoma after the date of MBL screening. The 10-year cumulative incidence of melanoma among individuals with MBL was 7.8% (95% CI 4.5-13.5%) compared to 3.4% (2.7-4.4%) in those who screened negative for MBL. After adjusting for age, sex, and history of prior melanoma, we found a 1.81-fold increased risk of incident melanoma (95% CI 1.19-2.76) among individuals with MBL. The increased risk of melanoma persisted when the analysis was restricted to individuals with LCMBL (HR = 1.84; 95% CI 1.21-2.82). **Conclusions:** In the largest MBL screening cohort to date, we found that LCMBL, a common condition, was associated with an 84% elevated risk of melanoma, similar to the ~ 2 -fold increased risk observed in patients with CLL. These data, together with our prior findings of a heightened risk of serious infections and lymphoid malignancies, suggest that individuals with LCMBL are at increased risk for adverse health outcomes. Association of pharmacist interventions with adherence upon targeted anticancer oral therapy initiation. *First Author: Richard Mcshinsky, VA Salt Lake City, Salt Lake City, UT*

Background: Oncology pharmacists (OPs) increasingly play a role in managing cancer patients, with the availability of targeted oral anticancer agents (TOAs). OPs ensure appropriate indications upon initiation; screen for, anticipate, and mitigate potential drug-drug interactions; manage side effects; and promote adherence. The impact of OPs on adherence to TOAs has not been described. **Methods:** The Veterans Affairs Corporate Data Warehouse and Cancer Registry were used to: 1. identify Veterans with chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL), marginal zone lymphoma (MZL), lymphoplasmacytic lymphoma/Waldenstrom macroglobulinemia (WM), and/or mantle cell lymphoma (MCL) who received single agent TAO for the first time between 2018 and 2021; 2. retrieve patient demographics, disease characteristics, and TAO dispensation information; and 3. identify visits with OPs within a 30-day window of initial dispensation. Dispensation information was used to calculate the proportion of days covered (PDC) during the first 4, 8, and 12 week milestones after initial dispensation. Non-adherence was defined as a PDC < 0.9 . A two-sample proportion test and a Wilcoxon rank-sum test were used to compare milestone adherence between patients who visited with an OP at treatment initiation vs those who did not. **Results:** 1,944 patients were identified, with a median age of 75 years; 98% were male; 1,498 (77%) were white, 244 (13%) were black, and 53 (3%) were Hispanic, rest were other, or unknown. CLL was the most common diagnosis at 1,578 patients (81%), followed by MCL at 162 (8%), WM at 135 (7%), and MZL at 69 (4%). 1,702 patients (88%) received ibrutinib, 110 (6%) venetoclax, 91 (5%) acalabrutinib, and 32 (2%) lenalidomide. Fewer than 5 patients received either idelalisib, zanubrutinib, umbralisib, and/or duvelisib. 1,757 patients had an initial dispensation supply of either < 28 days or 28-30 days and were used to conduct the adherence analysis; of those 702 had met with an OP at therapy initiation. In the 239 patients with a dispensation day supply < 28 days, patients who met with an OP had higher 4, 8, and 12 week adherence rates (97%, 96% and 92%) compared to those who did not (82%, 75%, 72%); odds ratios (OR) 8.8, 7.7 and 4.7 respectively (all with $p < 0.01$). In the 1,518 patients with a dispensation day supply of 28-30 days, patients who met with an OP also had higher 8-, and 12-week adherence rates (96% and 91%, resp) compared to those that did not (87%, 79%); OR 3.4 and 2.6 resp, both with $p < 0.01$. **Conclusions:** Visiting with an OP upon TAO therapy initiation was associated with a clinically and statistically significant increase in adherence at 4, 8, and 12 weeks after first dispensation. To our knowledge, this is the first study to quantify the impact of an OP on non-adherence in a real-world setting. Our findings suggest a critical need to integrate OPs TAO therapy initiation workflows. Research Sponsor: AbbVie.

ZUMA-23: A global, phase 3, randomized controlled study of axicabtagene ciloleucel versus standard of care as first-line therapy in patients with high-risk large B-cell lymphoma. *First Author: Jason Westin, Department of Lymphoma/Myeloma, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The nearly 40% of patients (pts) with large B-cell lymphoma (LBCL) who are refractory to or relapse after current first-line (1L) standard-of-care (SOC) regimens, such as R-CHOP (rituximab [R] + cyclophosphamide [C], doxorubicin [H], vincristine [O], and prednisone [P]) and DA-EPOCH-R (dose-adjusted etoposide [DA-E]), have poor prognoses. High International Prognostic Index (IPI) score and the subtype of high-grade B-cell lymphoma (HGBL) are associated with shorter progression-free and overall survival (PFS and OS; Nastoupil LJ and Bartlett NL. *J Clin Oncol*. 2023). Strategies to improve outcomes in these subgroups have been largely unsuccessful; therefore, therapeutic options with a different mechanism of action are needed. Axicabtagene ciloleucel (axi-cel) is an autologous anti-CD19 chimeric antigen receptor (CAR) T-cell therapy approved to treat pts with relapsed/refractory (R/R) LBCL after demonstrating significant clinical benefit as 2L (ZUMA-7; Locke FL, et al. *N Engl J Med*. 2022) and ≥ 3 L (ZUMA-1; Neelapu SS, et al. *N Engl J Med*. 2017) therapy. Additionally, in the Phase 2 ZUMA-12 study in pts with refractory 1L LBCL, axi-cel showed a high rate of durable responses with an objective response rate of 89% (complete response rate, 78%) and an ongoing response rate of 73% (median follow-up, 15.9 mo; Neelapu SS, et al. *Nat Med*. 2022). ZUMA-23 is the first Phase 3, randomized controlled study to evaluate CAR T-cell therapy as a 1L regimen for any cancer and will assess axi-cel versus SOC in pts with high-risk LBCL, defined as IPI 4-5. **Methods:** The Phase 3 trial design will enroll ≈ 300 adult pts with high-risk, histologically confirmed LBCL based on the 2016 WHO classification, including diffuse large B-cell lymphoma (DLBCL), HGBL, and transformed follicular or marginal zone lymphoma (Swerdlow SH, et al. *Blood*. 2016). Eligible pts will receive 1 cycle of R-chemotherapy and then be randomized 1:1 to receive axi-cel or continue with SOC. Pts in the axi-cel arm will undergo leukapheresis and then receive R-CHOP or DA-EPOCH-R as bridging therapy, followed by lymphodepleting chemotherapy (fludarabine/cyclophosphamide), and a single axi-cel infusion (2×10^6 CAR T cells/kg). Prophylactic corticosteroids may be administered to reduce the incidence and severity of cytokine release syndrome at the investigator's discretion. Pts in the SOC arm will receive 5 additional cycles of R-CHOP or DA-EPOCH-R (investigator's choice). The primary endpoint is event-free survival by blinded central review. Key secondary endpoints are OS and PFS. Safety, quality of life, and pharmacokinetics will also be assessed. Pts with a history of HIV and/or hepatitis B or C and undetectable viral loads may enroll. Key exclusion criteria include LBCL of the central nervous system. ZUMA-23 is open for enrollment (NCT05605899). Clinical trial information: NCT05371093. Research Sponsor: Kite, a Gilead Company.

ZUMA-22: A phase 3, randomized controlled study of axicabtagene ciloleucel (axi-cel) versus standard-of-care therapy in patients with relapsed or refractory (R/R) follicular lymphoma (FL). *First Author: Ian W. Flinn, Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN*

Background: Patients with R/R FL experience progressively shorter remissions with each successive line of therapy, and the disease is largely considered incurable (Batlevi et al. *Blood Cancer J.* 2020). Patients who relapsed < 24 months after initiating first-line chemoimmunotherapy (POD24) have inferior overall survival compared with those who did not experience POD24 (Casulo, Barr. *Blood.* 2019). However, outcomes of R/R FL have improved with the introduction of novel options including chimeric antigen receptor (CAR) T-cell therapy, a highly effective approach with potential to change the treatment paradigm (Jacobson et al. *Lancet Oncol.* 2021; Freedman, Jacobson. *Am J Hematol.* 2020). Axi-cel, an autologous anti-CD19 CAR T-cell therapy, is approved for the treatment of R/R FL. In ZUMA-5, a single-arm, Phase 2 study of axi-cel in indolent non-Hodgkin lymphoma, patients with FL (n = 127) had a median progression-free survival of 40.2 months and median overall survival not yet reached after median follow-up of 41.7 months, with manageable long-term safety (Neelapu et al. ASH 2022. Abstract 4660). In ZUMA-5, POD24 did not adversely affect progression-free survival or overall survival. ZUMA-22 is a Phase 3, open-label, multicenter, randomized controlled trial that will evaluate the efficacy and safety of axi-cel compared with standard-of-care therapy in patients with R/R FL. **Methods:** The study will enroll approximately 230 adult patients with FL (Grades 1-3a) who have either had 1 prior line of therapy and experienced POD24 or had ≥2 prior lines of systemic therapy. Patients will be randomized 1:1 to receive axi-cel or standard-of-care therapy. Patients in the standard-of-care therapy arm will receive investigator's choice of either rituximab + lenalidomide, rituximab + CHOP, or rituximab + bendamustine. Patients in the axi-cel arm will undergo leukapheresis, followed by optional bridging therapy, lymphodepleting chemotherapy (fludarabine/cyclophosphamide), and a single axi-cel infusion (2×10^6 CAR T cells/kg). The primary endpoint is progression-free survival by blinded central assessment per Lugano classification (Cheson et al. *J Clin Oncol.* 2014). Secondary endpoints include complete and overall response rates, duration of response, overall survival, event-free survival, time to next treatment, safety, and quality-of-life assessments. Additional key inclusion criteria are ECOG 0-1, presence of ≥1 measurable lesion, and adequate bone marrow and organ function. Those with HIV or hepatitis B or C and an undetectable viral load are eligible. Key exclusion criteria are a history of large B-cell lymphoma or transformed FL, and FL Grade 3b. The study is currently open and actively accruing patients at several sites globally (NCT05371093). Clinical trial information: NCT05371093. Research Sponsor: Kite, a Gilead Company.

Phase 1b open-label study of loncastuximab tesirine in combination with other anticancer agents in patients with relapsed/refractory B-cell non-Hodgkin lymphoma (LOTIS-7). *First Author: Brian T. Hess, Division of Hematology and Medical Oncology, Department of Medicine, Medical University of South Carolina, Charleston, SC*

Background: Combining agents with different mechanisms of action may enhance treatment (Tx) efficacy in patients (pts) with relapsed/refractory (R/R) B-cell non-Hodgkin lymphoma (B-NHL). Loncastuximab tesirine (loncastuximab tesirine-lyl; Lonca), an FDA-approved, CD19-directed, antibody-drug conjugate indicated for R/R diffuse large B-cell lymphoma (DLBCL), showed significant efficacy and manageable toxicity in a phase 2 trial in pts with R/R DLBCL. In preclinical models, Lonca + polatuzumab vedotin (Pola) showed improved efficacy. CD20×CD3 T-cell engaging antibodies and Lonca target different antigens; combining these is expected to increase efficacy. The safety and activity of Lonca combined with other agents in pts with R/R B-NHL will be evaluated in LOTIS-7. **Methods:** LOTIS-7, a phase 1b, open-label, multicenter, multiarm study (NCT04970901), will enroll ~200 pts with B-NHL in part 1 (dose escalation, 60 pts) and part 2 (dose expansion, 140 pts). Part 2 may include specific subpopulation(s) of B-NHL informed by part 1. Primary endpoints are frequency and severity of adverse events (AE), serious AE, dose-limiting toxicities, and frequency of AE-related dose modifications. Secondary endpoints are overall response rate; duration of response; complete response rate; progression-free, relapse-free, and overall survival; Lonca concentrations; and antidrug antibody titers. Planned arms include Lonca + Pola (arm C), glofitamab (arm E), or mosunetuzumab (arm F). Arm C enrollment is open: pts are treated with Lonca + Pola as an outpatient infusion. In part 1, arm C pts receive Lonca at escalating doses (90-150 µg/kg) and Pola (1.8 mg/kg) on day 1 of each 3-week cycle; pts in arms E and F will receive Lonca 150 µg/kg for 2 cycles, then 75 µg/kg for subsequent cycles + glofitamab (2.5 mg on cycle [C]1 day [D]8, 10 mg on C1D15, 10 or 30 mg for C2-12 D1, arm E) or mosunetuzumab SC (5 mg on C1D1, 15 or 45 mg for C1D8, and 45 mg for C1D15 and C2-8 D1, arm F) after initial step-up dosing. Lonca Tx may continue for up to 1 year or until disease progression, unacceptable toxicity, or other discontinuation criteria. Key eligibility criteria include age ≥18 years, pathologic diagnosis of R/R B-NHL (2016 WHO classification), measurable disease (2014 Lugano classification), Tx failure/intolerance, ≥2 lines of prior therapy (LOT) for part 1 (≥1 LOT for part 2), and ECOG performance status of 0-2. Pts previously receiving a study drug could not enroll in that respective study arm. Pts who received a stem-cell transplant within 60 days (100 days for arms E/F) before study Tx; received allogeneic stem cell or solid organ transplant (arms E/F); have lymphoma with active CNS involvement, ascites, edema, or effusion; or have significant comorbidities are excluded. The study opened in December 2021; 12 pts have been enrolled and 9 treated in the Lonca + Pola arm. Clinical trial information: NCT04970901. Research Sponsor: ADC Therapeutics SA.

The ELIPSE-1 study: A phase 1, multicenter, open-label study of CNTY-101 in subjects with relapsed or refractory CD19-positive B-cell malignancies. *First Author: Krish Patel, Center for Blood Disorders and Cellular Therapy, Swedish Cancer Institute, Seattle, WA*

Background: Century Therapeutics' foundational technology is built on induced pluripotent stem cells, differentiated from allogeneic approaches that utilize non-renewable donor-derived cells. This approach allows production of a clonal cell bank of precisely edited cells that can be expanded and differentiated to supply large amounts of homogeneous allogeneic therapeutic products for off-the-shelf use. CNTY-101 is an allogeneic Chimeric Antigen Receptor NK (CAR-NK) cell product with genetic modifications designed to specifically target CD19-expressing B-cell malignancies, reduce alloreactivity in the recipient allowing for repeat dosing, increase persistence, and enable cell elimination in the event of unexpected adverse events. CNTY-101, as a CAR-NK product, has the potential for improved safety over T-cell based cellular therapies. **Methods:** This first-in-human study will determine the MTD and recommended Phase 2 regimen (RP2R) of CNTY-101 in combination with subcutaneous (SC) IL-2 in patients with R/R aggressive and indolent CD19-positive B-cell Non-Hodgkin lymphomas including diffuse large B-cell lymphoma, mantle cell lymphoma, primary mediastinal large B-cell lymphoma, follicular lymphoma and marginal zone lymphoma, who are without other treatment options. Part 1 of the study (dose escalation using the BOIN design) will start with a dose of CNTY-101 cells without IL-2 (1 to 3 subjects), followed by dose escalation up to four dose cohorts administering a single dose of CNTY-101 cells in combination with IL-2 daily for 8 days (Sched A). After the single-dose MTD (or the maximal single dose) has been reached, a fractionated schedule of 3 doses per 28-day cycle, administered on Days 1, 8, and 15 (Sched B), will also be explored, starting with approximately one-third the maximum single dose level of CNTY-101, followed by escalation/de-escalation. Subjects in whom CNTY-101 shows signs of clinical benefit (i.e. stable disease or better per Lugano 2014 criteria) may receive additional cycles of CNTY-101 if the Investigator, Sponsor, and appropriate regulatory authorities, as required, concur that the benefit-risk is positive. One overall CNTY-101 RP2R will be declared in Part 1. Part 2, expansion, will further evaluate the safety, pharmacokinetics (PK), and efficacy of the CNTY-101 regimen, treating up to an additional 12 subjects to reach a total of approximately 20 subjects treated at the RP2R. In addition to safety and efficacy endpoints, the trial will evaluate exploratory PK, immunogenicity and pharmacodynamic endpoints including evaluations of tumor cfDNA, iNK tumor trafficking and serum cytokines. Clinical trial information: NCT05336409. Research Sponsor: Century Therapeutics.

BRUIN CLL-321: A phase 3 open-label, randomized study of pirtobrutinib versus investigator's choice of idelalisib plus rituximab or bendamustine plus rituximab in BTK inhibitor pretreated chronic lymphocytic leukemia/small lymphocytic lymphoma. *First Author: George Follows, Department of Haematology, Addenbrooke's Hospital NHS Trust, Cambridge, United Kingdom*

Background: Covalent (c) Bruton tyrosine kinase inhibitors (BTKi) have transformed the management of chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL), but these agents are not curative. cBTKi share pharmacologic liabilities such as low oral bioavailability and a short half-life that may lead to suboptimal BTK target coverage, especially in rapidly proliferating tumors with high BTK protein turnover, which can manifest as acquired resistance to cBTKi. Novel therapeutic agents addressing both intolerance and resistance while also improving efficacy are needed. Pirtobrutinib, a highly selective, non-covalent (reversible) BTKi, inhibits both wildtype and C481-mutant BTK with equal low nM potency, and has favorable oral pharmacology that enables continuous BTK inhibition throughout the dosing interval, regardless of intrinsic rate of BTK turnover. In the phase 1/2 BRUIN study, pirtobrutinib demonstrated promising durable overall response rates (ORR) and was well tolerated in patients with CLL/SLL regardless of prior therapy (including cBTKi), number of prior lines of therapy, BTK C481 mutation status, or reason for prior cBTKi discontinuation. The objective of this study is to determine whether pirtobrutinib is superior to conventional therapy in patients previously treated with cBTKi. **Methods:** BRUIN CLL-321 (NCT04666038) is a randomized, open-label, global phase 3 study comparing pirtobrutinib monotherapy (200mg QD) to investigator's choice of idelalisib plus rituximab (IdelaR) or bendamustine plus rituximab (BR). Approximately 250 CLL/SLL patients previously treated with a covalent BTKi will be randomized 1:1 and stratified by both del(17p) status (yes/no) and prior venetoclax treatment (yes/no). Patients on the control arm can crossover to pirtobrutinib monotherapy if they experience progressive disease per iwCLL 2018 as confirmed by an independent review committee (IRC). Adults with CLL/SLL who require therapy per iwCLL 2018 criteria and have received prior covalent BTKi are eligible. An unlimited number of prior lines of therapy, including venetoclax, are allowed. Key exclusion criteria include CNS involvement by CLL/SLL, a major bleeding event on prior cBTKi, Richter's Transformation at any time, prior therapy with a non-covalent BTKi, or a history of either allogeneic or autologous stem cell transplant (SCT), or chimeric antigen receptor (CAR) T-cell therapy within 60 days prior to randomization. The primary end point is progression-free survival (PFS) per iwCLL 2018 criteria as assessed by IRC. Secondary endpoints include investigator assessed PFS, overall survival, ORR, duration of response, safety and tolerability, and patient reported outcomes. Enrollment for this study is ongoing. Clinical trial information: NCT04666038. Research Sponsor: Loxo/Lilly.

BRUIN CLL-322: A phase 3 open-label, randomized study of fixed duration pirtobrutinib plus venetoclax and rituximab versus venetoclax and rituximab in previously treated chronic lymphocytic leukemia/small lymphocytic lymphoma. *First Author: Toby A. Eyre, Oxford University Hospitals NHS Foundation Trust, Churchill Cancer Center, Oxford, United Kingdom*

Background: Covalent (c) Bruton tyrosine kinase inhibitors (BTKi) have reshaped the treatment landscape for chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) and are now often used as initial therapy. The MURANO study established 2-year fixed duration venetoclax plus rituximab as a standard of care regimen for patients with relapsed or refractory CLL/SLL. However, its efficacy has not been formally assessed in CLL/SLL patients treated with a cBTKi, a common setting where this regimen is used in contemporary practice. Pirtobrutinib, a highly selective, non-covalent (reversible) BTKi, inhibits both wildtype and C481-mutant BTK with equal low nM potency, and has favorable oral pharmacology that enables continuous BTK inhibition throughout the dosing interval regardless of intrinsic rate of BTK turnover. In the phase 1/2 BRUIN study, pirtobrutinib demonstrated promising durable overall response rates (ORR) and was well tolerated in patients with pre-treated CLL/SLL regardless of prior therapy (including cBTKi), number of prior lines of therapy, BTK C481 mutation status, or reason for prior cBTKi discontinuation. The study's objective is to assess the superiority of adding time-limited pirtobrutinib to the MURANO regimen, hypothesized to prolong disease control in a largely BTKi-pretreated population. **Methods:** BRUIN CLL-322 (NCT04965493) is a randomized, open-label, global, phase 3 study comparing time-limited pirtobrutinib (200mg QD) plus venetoclax and rituximab versus venetoclax and rituximab in previously treated CLL/SLL patients. Approximately 600 patients, 80% who have been previously treated with cBTKi, will be randomized 1:1 and stratified by del(17p) status (yes/no) and prior BTKi experience (discontinuation due to progressive disease vs due to other reasons vs no prior BTKi exposure). Eligible patients are adults diagnosed with CLL/SLL and require therapy per iwCLL 2018 criteria who have received prior therapy that may or may not include a cBTKi. There are no restrictions on the number of lines of prior therapy. Key exclusion criteria include CNS involvement by CLL/SLL, Richter transformation at any time, prior BCL2 inhibitor or non-covalent BTK inhibitor, or a history of either allogeneic or autologous stem cell transplant, or chimeric antigen receptor T-cell therapy within 60 days prior to randomization. The primary endpoint is progression-free survival (PFS) per iwCLL criteria assessed by an independent review committee. Secondary endpoints include investigator assessed PFS, ORR, overall survival, time to next treatment, event-free survival, safety and tolerability, and patient-reported outcomes. Enrollment is ongoing for patients previously treated with BTKi and completed for BTKi naïve patients. Clinical trial information: NCT04965493. Research Sponsor: Loxo@Lilly.

BRUIN CLL-314: A phase 3, open-label, randomized study of pirtobrutinib versus ibrutinib in patients with chronic lymphocytic leukemia/small lymphocytic lymphoma. *First Author: Jennifer Ann Woyach, Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Covalent (c) Bruton tyrosine kinase inhibitors (BTKi) have transformed the management of chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL), but these agents are not curative. cBTKi share pharmacologic liabilities such as low oral bioavailability and a short half-life that may lead to suboptimal BTK target coverage, especially in rapidly proliferating tumors with high BTK protein turnover, such as accelerating CLL/SLL, which can manifest as acquired resistance to cBTKi. Novel therapeutic agents addressing both intolerance and resistance while also improving efficacy are needed. Pirtobrutinib, a highly selective, non-covalent (reversible) BTKi, inhibits both wildtype and C481-mutant BTK with equal low nM potency and has favorable oral pharmacology that enables continuous BTK inhibition throughout the dosing interval regardless of intrinsic rate of BTK turnover. In the phase 1/2 BRUIN study, pirtobrutinib demonstrated promising durable overall response rates (ORR) and was well tolerated in patients with CLL/SLL irrespective of prior therapy (including cBTKi), number of prior lines of therapy, BTK C481 mutation status, or reason for prior cBTKi discontinuation. The objective of this study is to compare efficacy and tolerability of pirtobrutinib versus ibrutinib in patients with CLL/SLL. **Methods:** BRUIN CLL-314 (NCT05254743) is a global, phase 3, open-label, randomized study comparing pirtobrutinib with ibrutinib. Approximately 650 BTKi-naïve patients, either treatment-naïve (up to 30%) or previously treated with other non-BTKi agents, will be randomized 1:1 to receive daily 200 mg pirtobrutinib once daily or 420 mg ibrutinib as continuous monotherapy. Randomization will be stratified by del(17p) status (yes/no) and number of prior lines of therapy (0 vs 1 vs ≥2). Enrollment for this study is ongoing. Adults with CLL/SLL who require therapy per iwCLL 2018 criteria are eligible. Key exclusion criteria include prior exposure to any BTKi, use of some concomitant therapies including anticoagulants, such as warfarin and other vitamin K antagonists, significant cardiovascular disease, active infections, and other clinically significant conditions. The primary objective is to establish non-inferiority of pirtobrutinib versus ibrutinib by comparing the ORR per iwCLL guidelines assessed by an independent review committee. Superiority of pirtobrutinib versus ibrutinib in progression-free survival is a key secondary outcome. Other endpoints include duration of response, overall survival, time-to-next treatment, tolerability, and patient-reported outcomes. Trial efficacy and safety will be monitored by an independent data monitoring committee. Clinical trial information: NCT05254743. Research Sponsor: Loxo@Lilly.

KEYFORM-008: Coformulated favezelimab and pembrolizumab (MK4280A) versus chemotherapy in relapsed/refractory classical Hodgkin lymphoma. *First Author: David Lavie, Hadassah Medical Center, Jerusalem, Israel*

Background: PD-1 inhibitors are highly effective in patients (pts) with relapsed or refractory (R/R) classical Hodgkin lymphoma (cHL), but treatment options are limited for pts who have progressed after PD1 blockade. There is an unmet need for effective therapies for anti-PD1 resistant cHL. Upregulation of lymphocyte-activation gene 3 (LAG-3) expression in cHL is proposed to contribute to anti PD-1 resistance (Veldman J et al. Cancer Treat Rev. 2020; 82:101931). The anti-LAG3 antibody favezelimab plus the anti-PD-1 therapy pembrolizumab, has shown promising antitumor activity and manageable safety in pts with R/R cHL after anti-PD1 therapy (Timmerman J et al. Blood 2022; 140). In this ongoing trial, we evaluate the efficacy and safety of MK-4280A in pts with R/R cHL that are refractory to anti-PD1 therapy (ClinicalTrials.gov, NCT0508867). **Methods:** This randomized, open-label, parallel group, active-controlled phase 3 trial will enroll approximately 360 pts aged ≥ 18 years. Eligible pts will have histologically confirmed R/R cHL, which has progressed on anti-PD-1 mAb and have exhausted all available treatment options with clinical benefit including ineligibility for or failed auto-SCT. In addition, pts must have relapsed after treatment with or failed to respond to brentuximab vedotin (BV), were ineligible for BV or discontinued BV due to toxicity, have ECOG performance status (PS) 0-2, adequate organ function, and availability of archival or newly obtained tissue sample. Pts will be randomized 1:1 to receive MK-4280A (coformulated favezelimab 800 mg/pembrolizumab 200 mg; Arm A) IV Q3W or physician's choice of gemcitabine (800-1200 mg/m²) IV or bendamustine (90-120 mg/m²) IV (Arm B). Randomization will be stratified by prior auto-SCT (yes vs no), and ECOG PS (0/1 vs 2). Treatment will continue for up to 35 cycles of MK-4280A, or until unacceptable toxicity, disease progression (PD), or withdrawal from trial. Pts in Arm B with PD confirmed by blinded independent central review (BICR) per Lugano criteria may be eligible to crossover to receive up to 35 cycles of MK-4280A. Disease response assessments by PET and CT or MRI will be performed Q12W during the trial. The primary endpoint is progression free survival (PFS) by BICR per Lugano criteria. Secondary endpoints are overall survival (OS), objective response rate (ORR) and duration of response (DOR) (by BICR per Lugano criteria), and safety. Exploratory endpoints include PFS on subsequent oncologic therapy, and pt reported quality of life. Adverse events will be monitored throughout the trial and graded per NCI CTCAE v5.0. PFS, OS and DOR will be estimated using Kaplan-Meier method. ORR with 95% CI will be estimated using the Clopper-Pearson method. Efficacy will be assessed in the intention-to-treat population and safety assessed in all treated pts. Enrollment in this trial is ongoing. Clinical trial information: NCT0508867. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

SUNMO: A phase III trial evaluating the efficacy and safety of mosunetuzumab in combination with polatuzumab vedotin vs rituximab plus gemcitabine and oxaliplatin in patients with relapsed/refractory aggressive B-cell non-Hodgkin lymphoma. *First Author: Jason Westin, MD Anderson Cancer Center, Houston, TX*

Background: Aggressive non-Hodgkin lymphomas (aNHL) are a diverse group of neoplasms, of which diffuse large B-cell lymphoma (DLBCL) is the most common subtype (Thandra, 2021). Patients (pts) with relapsed/refractory (R/R) DLBCL after one prior therapy who are unable to receive, or relapse after an autologous stem cell transplant (ASCT) and/or chimeric antigen receptor T-cell therapy have a poor prognosis (Salles, 2019; Di Blasi, 2022). Mosunetuzumab (Mosun) is an off-the-shelf CD20xCD3 T-cell engaging bispecific antibody that redirects T cells to eliminate malignant B cells (Sun, 2015), with promising efficacy and safety as a single agent, as shown in a Phase I trial in pts with B-cell NHL, including aNHL (Budde, 2022). Mosun has also shown promising safety and efficacy in combination with polatuzumab vedotin (Pola), a CD79b targeted antibody-drug conjugate that delivers the microtubule-disrupting agent monomethyl auristatin E directly to B cells (Dornan, 2009), in a Phase Ib/II trial in pts with R/R aNHL (Budde, ASH 2021). **Methods:** SUNMO (NCT05171647) is a randomized, open-label, global Phase III trial evaluating the efficacy and safety of subcutaneous Mosun + intravenous (IV) Pola (M-Pola) vs IV rituximab + gemcitabine and oxaliplatin (R-GemOx) in pts with R/R aNHL. Eligible pts have CD20-positive R/R aNHL (DLBCL not otherwise specified [NOS], high-grade B-cell lymphoma double/triple hit or NOS, transformed follicular lymphoma [trFL], or Grade 3B FL), ECOG performance status 0-2, and ≥1 prior systemic therapy (if only one prior line of therapy, pts must be ineligible for ASCT). Exclusion criteria include prior treatment with CD20-directed bispecific antibodies, R-GemOx, or GemOx; prior allogeneic stem cell transplant; and any central nervous system involvement of lymphoma. Pts will be randomized 2:1, stratified by the number of prior lines of therapy (1 vs > 1) and response to last therapy (relapsed vs refractory) to receive M-Pola or R-GemOx IV for a fixed duration of up to 8 cycles (6 cycles for Pola; M-Pola, 21-day cycles; R-GemOx, 14-day cycles). The primary endpoint is progression-free survival (PFS) determined by an independent review facility (IRF). Secondary endpoints include overall survival; IRF- and investigator (INV)-assessed complete response (CR) rate, objective response rate, and duration of response/CR; INV-assessed PFS; patient-reported outcomes; and safety. Biomarker analyses include pre-specified prognostic subsets from baseline biopsies and circulating tumor DNA at baseline and during treatment. Enrollment is ongoing, and an estimated 75 sites globally will enroll approximately 222 pts (M-Pola, 148 pts; R-GemOx, 74 pts). Clinical trial information: NCT05171647. Research Sponsor: This study was sponsored by F. Hoffmann-La Roche Ltd. Third-party editorial assistance was provided by Martha Warren, MSci, and Cheryl Wright, PhD, of Ashfield MedComms, an Inizio company, and was funded by F. Hoffmann-La Roche Ltd.

BRUIN MCL-321: A phase 3, open-label, randomized study of pirtobrutinib versus investigator choice of BTK inhibitor in patients with previously treated, BTK inhibitor naïve mantle cell lymphoma. *First Author: Michael Wang, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Covalent (c) Bruton tyrosine kinase inhibitors (BTKi) have transformed the management of MCL, but these agents are not curative. cBTKi share pharmacologic liabilities (e.g., low oral bioavailability, short half-life), which collectively may lead to suboptimal BTK target coverage especially in rapidly proliferating tumors with high BTK protein turnover such as MCL, which can manifest as acquired resistance to BTKi. Pirtobrutinib, a highly selective, non-covalent (reversible) BTKi, has favorable oral pharmacology that enables continuous BTK inhibition throughout the dosing interval regardless of intrinsic rate of BTK turnover. In the phase 1/2 BRUIN study, pirtobrutinib demonstrated promising durable overall response rates and was well tolerated in patients (pts) with MCL regardless of prior therapy (including cBTKi), number of prior lines of therapy, or reason for prior cBTKi discontinuation. Pirtobrutinib was approved by the FDA in January 2023 for R/R MCL after 2 prior lines of therapy including a BTKi. The objective of this study is to establish whether pirtobrutinib is superior to investigator's choice of cBTKi in pts with previously treated, BTKi naïve MCL. **Methods:** BRUIN MCL-321 (NCT04662255) is a randomized, open-label, global phase 3 study comparing pirtobrutinib monotherapy versus investigator's choice of cBTKi monotherapy (ibrutinib, acalabrutinib, or zanubrutinib) in pts with previously treated, BTKi naïve MCL. Approximately 500 pts will be randomized 1:1 and stratified by sMIPI risk (low/intermediate vs high), comparator BTKi (ibrutinib vs acalabrutinib/zanubrutinib), and number of prior lines of therapy (1 vs ≥ 2). Enrollment for this study is ongoing. Adults with a diagnosis of MCL who have received ≥ 1 prior line of systemic therapy for MCL and are BTKi naïve are eligible. Pts must have measurable disease by imaging per Lugano criteria and have progressed on or relapsed following the most recent line of therapy. A history of current or prior CNS involvement, significant cardiovascular disease, stroke or intracranial hemorrhage within 6 months of randomization, and autologous stem cell transplant (SCT), allogeneic SCT or chimeric antigen receptor (CAR) T-cell therapy within 60 days of randomization are key exclusion criteria. Progression-free survival (PFS) per Lugano criteria assessed by an independent review committee is the primary endpoint. Overall response rate, duration of response, investigator-assessed PFS per Lugano criteria, overall survival, event-free survival, time to treatment failure, time to next treatment, PFS2 (time from randomization to disease progression on next line of treatment or death from any cause), safety and tolerability, and pt reported outcomes are secondary endpoints. Clinical trial information: NCT04662255. Research Sponsor: Loxo@Lilly.

waveLINE-007: Phase 2 study of zilovetam vedotin (ZV) in combination with cyclophosphamide, doxorubicin, and prednisone plus rituximab (R-CHP) in previously untreated diffuse large B-cell lymphoma (DLBCL). *First Author: David Lavie, Hadassah Medical Center, Jerusalem, Israel*

Background: The preferred first-line regimen for DLBCL is rituximab with cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP); but novel therapies are needed. A recent phase 3 study showed that replacing vincristine with an antibody-drug conjugate (ADC) is a viable approach (Tilly H et al. *N Engl J Med*. 2022;386:351-363). Receptor tyrosine kinase-like orphan receptor 1 (ROR1) is an oncofetal protein that is minimally expressed in adult tissues and overexpressed in DLBCL. ZV is an ADC comprising a humanized IgG1 monoclonal anti-ROR1, a proteolytically cleavable linker, and the antimicrotubule agent, monomethyl auristatin E. The single-arm, open-label, phase 2 waveLINE-007 study (NCT05406401) will investigate ZV combined with R-CHP in patients with previously untreated DLBCL. Part 1 is being conducted to determine safety and tolerability and recommended phase 2 dose (RP2D) of ZV in combination with R-CHP. Part 2 will be conducted to investigate efficacy of ZV at the RP2D with R-CHP. **Methods:** Eligible patients will be ≥ 18 years of age and have previously untreated histologically confirmed DLBCL, positron emission tomography (PET)-positive disease verified by blinded independent central review (BICR), an ECOG PS of 0 or 1, and adequate organ function. Patients diagnosed with primary mediastinal B-cell lymphoma, with a history of transformation of indolent disease to DLBCL, or active central nervous system lymphoma will be excluded. Approximately 60 patients will be enrolled (part 1, n = 45; part 2, n = 15). Part 1 will use a modified toxicity probability interval design to establish the RP2D of ZV when administered with R-CHP. The starting dose of ZV will be 1.75 mg/kg (modified to 1.5, 2.0, 2.25, or 2.5 mg/kg) administered as an intravenous infusion every 3 weeks (Q3W) in combination with R-CHP. In part 2, an additional 15 patients will receive ZV at RP2D plus R-CHP Q3W for up to 6 cycles until disease progression per Lugano 2014 criteria, unacceptable toxicity, or withdrawal. Disease response assessment, computed tomography, and PET will occur at baseline and cycles 3 and 6. Adverse events (AEs) will be monitored up to 30 days after cessation of treatment (90 days for serious AEs, or 30 days if new anticancer therapy is initiated). AEs will be graded per National Cancer Institute Common Terminology Criteria for Adverse Events, version 5.0. Primary end points are safety and tolerability and RP2D for ZV in combination with R-CHP, and complete response rate per Lugano 2014 criteria as assessed by the investigator. Secondary end points are objective response rate and duration of response per Lugano 2014 criteria by investigator review. Exploratory end points include progression-free survival per Lugano 2014 criteria by BICR and overall survival. Recruitment is currently underway. Clinical trial information: NCT05406401. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

A phase 2 trial of mosunetuzumab with lenalidomide augmentation as first-line therapy for follicular (FL) and marginal zone lymphoma (MZL). *First Author: Adam J Olszewski, Brown University, Providence, RI*

Background: First-line therapy for high-burden FL and MZL includes immunochemotherapy (most commonly rituximab with bendamustine), which is associated with toxicities, is not curative, and leads to a prolonged T-cell depletion. The alternative of rituximab with full-dose lenalidomide did not improve efficacy or toxicity [Morschhauser et al., *NEJM* 2018]. However, lower-dose, short-course lenalidomide (15mg) may enhance cytotoxic T-cell immunity and efficacy of rituximab [Zucca et al, *Blood* 2019]. Mosunetuzumab is a CD20xCD3-binding, T-cell-engaging bispecific antibody approved for relapsed/refractory FL after 2 lines of therapy. It results in a complete response (CR) rate of 60% in that setting [Budde et al., *Lancet Oncol*, 2022], despite prior exposure to immunosuppressive therapies. This trial proposes a novel therapeutic approach to first-line treatment of FL/MZL, exploring 3 hypotheses: 1) that mosunetuzumab will lead to a high rate of CR, and possibly eradication, of FL/MZL when applied before exposure to immunosuppressive modalities; 2) that low-dose lenalidomide can augment the cytotoxic T-cell response when CR is not achieved with mosunetuzumab alone, and 3) that baseline host immune environment measured in treatment-naïve state can predict CR to bispecific antibody therapy. **Methods:** The Brown University Oncology Research Group BrUOG-401/ML43251 (NCT04792502) is an investigator-initiated, multi-center, single-arm, phase 2 clinical trial for patients (pts) with FL and MZL in need of first-line systemic therapy. Pts with FL must meet the Groupe d'Etude des Lymphomes Folliculaires (GELF) criteria of high-burden disease, whereas pts with MZL must require therapy in the investigators' opinion. As of January 2023, 7 of the planned 52 pts have been enrolled. The trial uses a response-adapted design: pts start with 4 courses of subcutaneous mosunetuzumab monotherapy, using step-up dosing during Cycle 1 (5mg $\rightarrow$ 45mg $\rightarrow$ 45mg) to mitigate the risk of cytokine release syndrome (CRS). Pts attaining CR (by Lugano criteria) after Cycle 4 continue for a total of 8 cycles of mosunetuzumab monotherapy. Pts attaining partial response or stable disease receive 4 additional cycles of mosunetuzumab with low-dose lenalidomide augmentation (10mg daily), with further 4 cycles of mosunetuzumab/lenalidomide if CR after C8 is still not attained. The primary endpoints include the ORR and CR rate at final assessment, and rates of toxicities, particularly CRS, tumor flare, and immune-mediated events. PFS and rate of progression of disease at 24 months (POD24) are among secondary endpoints. The study uses Simon's two-stage design, with the null hypothesis that the CR rate is 53% (based on prior RELEVANCE trial). Correlative studies aim at determining predictive biomarkers of response, including immune signatures and dynamics of circulating tumor DNA during study therapy. Clinical trial information: NCT04792502. Research Sponsor: Genentech; Leukemia and Lymphoma Society.

MAHOGANY: A phase 3 trial of zanubrutinib plus anti-CD20 antibodies vs lenalidomide plus rituximab in patients with relapsed or refractory follicular or marginal zone lymphoma. *First Author: Loretta J. Nastoupil, MD Anderson Cancer Center, Houston, TX*

Background: Inhibition of Bruton tyrosine kinase (BTK) has emerged as a strategy for treatment of patients (pts) with B-cell malignancies including indolent non-Hodgkin lymphomas. Zanubrutinib is a second-generation, potent, and specific BTK inhibitor and has shown to be more effective and better tolerated than first-generation BTK inhibitors in several diseases including chronic lymphocytic leukemia/small lymphocytic lymphoma and Waldenström macroglobulinemia. Zanubrutinib is approved in >15 countries, including the United States and European Union, for pts with relapsed or refractory (R/R) marginal zone lymphoma (MZL) who received ≥ 1 anti-CD20-based regimen, based on the single-arm MAGNOLIA trial (Opat et al. *Clin Cancer Res* 2021). In R/R follicular lymphoma (FL), ROSEWOOD, a phase 2 randomized study of zanubrutinib plus obinutuzumab (ZO) vs obinutuzumab, met its primary endpoint of increased overall response rate (ORR) at primary analysis (Zinzani et al. *J Clin Oncol* 2022). In this trial, ZO in pts with R/R FL demonstrated deep and durable responses with a favorable safety profile. **Methods:** MAHOGANY (BGB-3111-308, NCT05100862) is a phase 3 randomized, open-label trial that compares efficacy and safety of a combination of zanubrutinib plus anti-CD20 monoclonal antibody vs lenalidomide plus rituximab in 2 independent cohorts, for pts with either R/R FL or MZL. Key eligibility criteria include histologically confirmed FL (grades 1-3A) or MZL, previously treated with ≥ 1 anti-CD20-based regimen, relapsed after or refractory to the most recent systemic therapy, in need of treatment, no prior BTK inhibitor exposure, and no prior resistance to a lenalidomide-based regimen. In the FL cohort, pts will be randomized 1:1 to ZO (N = 300) and lenalidomide plus rituximab (N = 300). Randomization is stratified by age (≥ 60 years vs < 60 years), number of prior lines of therapy (1-2 vs > 2) and rituximab-refractory status (yes vs no). The primary endpoint is progression-free survival (PFS) assessed by an independent review committee (IRC), according to Lugano 2014 criteria. Key secondary endpoints are ORR by IRC assessment and overall survival. In the MZL cohort, pts will be randomized 1:1 to zanubrutinib plus rituximab (N = 75) and lenalidomide plus rituximab (N = 75). Randomization is stratified by age (≥ 60 years vs < 60 years) and number of prior lines of therapy (1-2 vs > 2). The primary endpoint is PFS assessed by IRC according to Lugano 2014 criteria. The key secondary endpoint is ORR by IRC assessment. Zanubrutinib is given at 160 mg twice daily or 320 mg once daily according to investigator, until progression or unacceptable toxicity. Obinutuzumab or rituximab are given for up to 8 infusions. Lenalidomide is given according to approved label for up to 12 cycles. Recruitment is ongoing. Clinical trial information: NCT05100862. Research Sponsor: BeiGene.

A phase 1/2 study of STP938, a first-in-class inhibitor of CTP synthase 1, in patients with relapsed/refractory B or T cell lymphoma. *First Author: Manish R. Patel, Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, FL*

Background: The rate limiting step in *de novo* pyrimidine synthesis is catalyzed by two homologous enzymes, CTPS1 and CTPS2. CTPS1 is essential for lymphocyte proliferation, whereas CTPS2 is sufficient in non-haemopoietic cells. STP938 is a first in class oral CTPS1 inhibitor showing > 1,300-fold selectivity over CTPS2. In preclinical studies, STP938 induced death of cancer cells by apoptosis at nanomolar concentrations, and inhibited tumor growth in *in vivo* models of hematological malignancies. **Methods:** The study employs a seamless dose escalation, dose expansion design. The phase 1 dose escalation follows a standard 3+3 approach. Intra-patient dose escalation will be permitted. The recommended phase 2 dose (RP2D) will be nominated based on safety, target engagement and early signs of efficacy. An additional six patients will be treated at the RP2D with a preliminary assessment of food effect. Key phase 1 endpoints are safety and tolerability. Key phase 2 endpoints are objective response rate and duration of response. The study is open to adult patients following at least 2 prior lines of therapy who have no treatment options known to provide clinical benefit. The phase 1 study is recruiting patients with B or T cell lymphoma; the phase 2 study will be limited to cohorts of patients with specific lymphoma subtypes, which may include T cell lymphoma (peripheral or cutaneous), mantle cell lymphoma, indolent B cell lymphoma and diffuse large B cell lymphoma. Standard exclusion criteria apply; patients with ECOG performance score > 2 or known CNS involvement by lymphoma are not eligible. The phase 2 study will follow a Simon two-stage design with an interim analysis for futility based on predefined, lymphoma subtype specific response rates. In the case of STP938 showing promising efficacy, provision is included in the protocol to expand a cohort using an adaptive approach based on early efficacy signals (Mehta and Pocock, 2011). Target engagement is assessed by measuring cytokine release (TNF α , IFN γ , IL2, IL8) from *ex vivo* stimulated patient T cells. Exploratory studies include pre- and on-treatment lymphoma biopsies to assess biomarkers of response and mechanism of action. Tumor genomics will be assessed by sequencing of circulating tumor DNA prior to treatment and at disease progression using a bespoke genomic assay designed to elucidate biomarkers of response and understand mechanisms of resistance. The phase 1 study (NCT05463263) opened to enrollment in the US and UK in September 2022. No dose limiting toxicities were observed in the first cohort of 3 patients. The phase 2 study will include additional centers in France. Clinical trial information: NCT05463263. Research Sponsor: Step Pharma.

BELLWAVE-003: A phase 2 dose escalation, confirmation, and cohort expansion study of nemtabrutinib in hematologic malignancies. *First Author: Guilherme Fleury Perini, Hospital Paulistano and Instituto Américas, São Paulo, Brazil*

Background: Bruton tyrosine kinase (BTK) inhibitors (BTKi) have transformed the treatment of several hematologic malignancies. However, acquired resistance, commonly associated with *BTK* C481S mutations, can develop. Nemtabrutinib (MK-1026, formerly ARQ 531) is a noncovalent, competitive inhibitor of both wild type and C481S-mutant BTK that has shown promising antitumor activity at 65 mg once daily (QD) in relapsed/refractory (R/R) chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL). BELLWAVE-003 (NCT04728893) is an open-label, phase 2 study investigating the safety and efficacy of nemtabrutinib in patients (pts) with R/R B-cell malignancies. **Methods:** BELLWAVE-003 includes a dose escalation and confirmation phase (part 1) and a cohort expansion phase (part 2). Enrollment of 450 pts is planned. Part 1 will enroll approximately 30 pts, with a minimum of 6 and maximum of 20 per dose level. Part 2 will enroll approximately 420 pts. All pts must be ≥ 18 years and have an ECOG performance status of 0 to 2. Part 1 will enroll pts with CLL/SLL that was R/R after ≥ 2 prior therapies. Part 2 will enroll pts in 8 cohorts: CLL/SLL that is R/R to a covalent irreversible BTKi and a BCL2 inhibitor, and, for pts with CLL, R/R to or ineligible for a PI3K inhibitor (cohort A); R/R CLL/SLL that is BTKi-naïve (cohort B); del17p or *TP53*-mutant R/R CLL/SLL (cohort C); R/R Richter transformation (cohort D); R/R mantle cell lymphoma, including prior covalent BTKi (cohort E); R/R marginal zone lymphoma, including prior covalent BTKi (cohort F); R/R follicular lymphoma (cohort G); and R/R Waldenström's macroglobulinemia, including prior covalent BTKi (cohort H). Initially, pts received nemtabrutinib 80 mg QD orally at dose level 1. Data from BELLWAVE-001 and BELLWAVE-003 subsequently established nemtabrutinib 65 mg QD as the recommended phase 2 dose (RP2D) for future pt enrollment. Treatment will continue until unacceptable toxicity, disease progression, or withdrawal. Adverse events will be monitored throughout and graded using NCI CTCAE version 5.0. Hematologic toxicities in pts with CLL will be assessed using iwCLL 2018 criteria. CT/MRI and/or PET will be performed every 12 weeks, unless needed more frequently. For part 1, the primary end points are safety and tolerability and establishing the RP2D; secondary end points are pharmacokinetics (PK), ORR, and DOR. For part 2, the primary end point is ORR; secondary end points are safety and tolerability, PK, and DOR; and exploratory end points include PFS, OS, and health-related quality of life. Safety and efficacy will be assessed in all pts who receive ≥ 1 dose of study drug. Pts receiving nemtabrutinib 80 mg and 65 mg QD will be analyzed separately. Safety will be summarized descriptively. ORR and 95% CI will be estimated using an exact binomial method. DOR, PFS, and OS will be estimated using the Kaplan-Meier method. Enrollment for this study is ongoing. Clinical trial information: NCT04728893. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Poster Session

Phase 3 trial of subcutaneous epcoritamab + R-CHOP versus R-CHOP in patients (pts) with newly diagnosed diffuse large B-cell lymphoma (DLBCL): EPCORE DLBCL-2. *First Author: Laurie Helen Sehn, BC Cancer Centre for Lymphoid Cancer and University of British Columbia, Vancouver, BC, Canada*

Background: In pts with newly diagnosed DLBCL, standard treatment with rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) has a 5-year progression-free survival (PFS) rate of 67.0%, 58.4%, and 45.8% for International Prognostic Index (IPI) 2, 3, and 4-5, respectively (Ruppert et al, *Blood* 2020). Epcoritamab is a subcutaneously administered, bispecific antibody that binds CD3 on T cells and CD20 on B cells, inducing potent and selective T-cell-mediated killing of malignant CD20+ B cells (Hutchings et al, *Lancet* 2021). Epcoritamab monotherapy demonstrated deep and durable responses (overall response rate [ORR], 63%; complete response rate, 39%) and was generally well tolerated in pts with relapsed/refractory (R/R) aggressive, large B-cell lymphoma (LBCL) (Thieblemont et al, *J Clin Oncol* 2022). Results from an ongoing phase 1/2 study in high-risk pts with newly diagnosed DLBCL (EPCORE NHL-2 arm 1; NCT04663347) show that epcoritamab + R-CHOP has promising efficacy and a manageable safety profile in high-risk pts with IPI 3-5. Among efficacy-evaluable pts (n = 31), ORR was 100% and complete metabolic response (CMR) was 77%; cytokine release syndrome (CRS) events (n = 17/33; 52%) were mostly low-grade, had predictable timing, and did not lead to treatment discontinuation (Falchi et al, ASCO 2022, abstract 7523). These encouraging data support further evaluation of epcoritamab + R-CHOP for the treatment of newly diagnosed DLBCL. **Methods:** This phase 3, global, multicenter, open-label study (NCT05578976) evaluates the efficacy and safety of epcoritamab + R-CHOP in adults newly diagnosed with one of the following CD20+ DLBCL (de novo or transformed from follicular lymphoma [FL]): 1) DLBCL, not otherwise specified (NOS); 2) high-grade B-cell lymphoma with *MYC* and *BCL-2* and/or *BCL-6* rearrangement; 3) T-cell/histiocyte-rich LBCL; 4) Epstein-Barr virus-positive DLBCL, NOS; or 5) FL grade 3b. Other key eligibility criteria include IPI ≥ 2 (pts with IPI 2 not to exceed ~30% of total pts), ECOG PS 0-2, and ≥ 1 measurable disease site. Approximately 900 pts will be randomized 2:1 to either epcoritamab + R-CHOP (6 cycles, followed by 2 cycles of epcoritamab) or R-CHOP (6 cycles, followed by 2 cycles of rituximab). The primary efficacy endpoint is PFS in pts with IPI 3-5 (based on IRC assessment per Lugano criteria). The secondary efficacy endpoints are PFS in pts with IPI 2-5, event-free survival, CMR, overall survival, and minimal residual disease negativity. Safety endpoints include incidence and severity of treatment-emergent adverse events (AEs), serious AEs, and AEs of special interest (CRS, immune cell-associated neurotoxicity syndrome, and clinical tumor lysis syndrome. Enrollment began in January 2023 globally. Clinical trial information: NCT04663347, NCT05578976. Research Sponsor: Epcoritamab is jointly developed by Genmab A/S and AbbVie Inc.; AbbVie and Genmab are sponsoring this study.

Poster Session

BELLWAVE-008: A phase 3 study of the efficacy and safety of nemtabrutinib in previously untreated patients (pts) with chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL) without TP53 aberrations. *First Author: Ömür Gökmen Sevinç, Istanbul Medipol University, International School of Medicine, Istanbul, Turkey*

Background: Targeting the Bruton's tyrosine kinase (BTK) pathway has been a revolutionary treatment option for first-line treatment of CLL/SLL. Nemtabrutinib is a non-covalent, reversible, potent BTK inhibitor that targets both wild-type and C481S-mutant BTK. Results of an ongoing phase 1/2 dose-escalation study (BELLWAVE-001) have demonstrated manageable safety and preliminary antitumor activity of nemtabrutinib in pts with CLL/SLL. BELLWAVE-008 is a randomized, open-label, phase 3 study (NCT05624554) designed to evaluate efficacy and safety of nemtabrutinib compared with investigator's choice of chemoimmunotherapy (FCR or BR) in pts with previously untreated CLL/SLL without TP53 aberrations. **Methods:** Eligible pts are ≥ 18 years old with previously untreated CLL/SLL with active disease and without TP53 aberrations (17p deletion and/or *TP53* mutation), with ECOG PS of 0-2 and adequate organ function. Pts with Richter transformation or active central nervous system involvement are excluded. Approximately 300 pts will be enrolled and randomly assigned 1:1 to receive nemtabrutinib (65 mg orally once daily until progressive disease, unacceptable toxicity, or discontinuation) or intravenous infusion of the investigator's choice of chemoimmunotherapy for 6 cycles lasting 28 days each (FCR: fludarabine 25 mg/m² and cyclophosphamide 250 mg/m² on days 1, 2, and 3 of each cycle, plus rituximab 375 mg/m² initially, followed by 500 mg/m² on day 1 of each cycle; or BR: bendamustine 70-90 mg/m² on days 1 and 2 of each cycle plus rituximab 375 mg/m² initially, followed by 500 mg/m² on day 1 of each cycle). Randomization will be stratified by risk (high risk: 11q deletion and/or IGHV unmutated vs low risk: absence of high-risk factors) and age (< 65 years vs ≥ 65 years). Treatment response (imaging, physical examination, constitutional symptoms, hematologic evaluation, and bone marrow biopsy, as required) will be performed every 12 weeks up to and including cycle 25, and every 24 weeks thereafter. Adverse events (AEs) will be monitored up to 30 days after treatment cessation (90 days for serious AEs) and will be graded per National Cancer Institute Common Terminology Criteria for Adverse Events, version 5.0, and hematologic toxicities will be evaluated according to International Workshop on Chronic Lymphocytic Leukemia (iwCLL). Primary end point is progression-free survival per the iwCLL 2018 criteria as assessed by blinded independent central review. Secondary end points include overall survival, objective response rate (ORR), duration of response, and safety. Exploratory efficacy end points include resistance evaluations, ORR including partial response with lymphocytosis as a response category, pharmacokinetics/pharmacodynamics, and health-related quality of life. Enrollment is ongoing. Clinical trial information: NCT05624554. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Poster Session

waveLINE-006: A phase 2 study of the safety and efficacy of zilovetamab vedotin as monotherapy or in combination in patients (pts) with aggressive and indolent B-cell malignancies. *First Author: Pier Luigi Zinzani, IRCCS Azienda Ospedaliero-Universitaria di Bologna Istituto di Ematologia "Seràgnoli", Bologna, Italy*

Background: ROR1 is a transmembrane protein expressed in hematologic malignancies. Zilovetamab vedotin (ZV) is an antibody-drug conjugate comprising a humanized IgG1 monoclonal anti-ROR1, a proteolytically cleavable linker, and the antimicrotubule agent monomethyl auristatin E. Nemtabrutinib is a reversible inhibitor of Bruton's tyrosine kinase (BTK). The combination of ZV and a BTKi has the potential for improved responses in B-cell malignancies. The waveLINE-006 study (NCT05458297) is designed to investigate safety and efficacy of ZV as monotherapy or in combination with nemtabrutinib in pts with B-cell malignancies. **Methods:** Eligible pts are ≥ 18 years old with biopsy-proven and/or histologically confirmed mantle cell lymphoma (MCL), Richter's transformation (RT), chronic lymphocytic leukemia (CLL), or follicular lymphoma (FL), relapsed or refractory (R/R) disease, ECOG performance status of 0 to 2, and adequate organ function (table). Approximately 275 pts will be enrolled in 6 cohorts (A-F; see table). In cohorts A and B, patients will receive ZV 2.5 mg/kg IV Q3W. In cohort C, 30 patients will be enrolled in a safety run-in phase of ZV in combination with nemtabrutinib, then an additional 15 patients will receive the RP2D of the combination. Patients in cohort D (schedule optimization) will be randomized 1:1 to receive ZV 2.5 mg/kg IV Q3W (arm 1) or ZV 2.0 mg/kg IV Q2/3W (arm 2). Patients in cohorts E and F (efficacy expansion) will receive the dose and schedule of ZV determined during schedule optimization. Each recipient of ZV or nemtabrutinib will receive the assigned intervention until disease progression, unacceptable toxicity, or other discontinuation criteria are met. Tumor scans will be performed at baseline, then Q12W up to week 108, then Q24W thereafter. Adverse events (AEs) will be monitored and will be graded per NCI CTCAE version 5. The primary end points are the safety and tolerability of ZV alone (cohort D) and in combination with nemtabrutinib (cohort C), and the objective response rate of ZV alone (cohorts A, B, D, E, and F) and in combination with nemtabrutinib (cohort C). The secondary end points are the duration of response of ZV alone (cohorts A, B, D, E, and F) and in combination with nemtabrutinib (cohort C) and the safety and tolerability of ZV alone (cohorts A, B, E, and F). Clinical trial information: NCT05458297. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Cohort	Inclusion Criteria	n	Treatment
A	R/R MCL after ≥ 2 therapies including a BTKi and either received or was ineligible for CAR-T cell therapy	40	ZV 2.5 mg/kg IV Q3W
B	R/R RT after ≥ 1 prior therapy	50	
C	R/R MCL to ≥ 1 prior therapy and no prior exposure to noncovalent BTKi	45	ZV 2.0 to 2.5 mg/kg IV Q3W
D	R/R CLL or FL after ≥ 2 prior therapies	80	Nemtabrutinib 65 mg PO QD Randomized 1:1 to receive: ZV 2.5 mg/kg IV Q3W (arm 1) or ZV 2.0 mg/kg IV Q2/3W (arm 2)
E	R/R FL after ≥ 2 prior therapies	30	ZV on dose and schedule determined in cohort D
F	R/R CLL after ≥ 2 prior therapies	30

Oral Abstract Session

Carfilzomib, lenalidomide, and dexamethasone (KRd) versus elotuzumab and KRd in transplant-eligible patients with newly diagnosed multiple myeloma: Post-induction response and MRD results from an open-label randomized phase 3 study. *First Author: Stefan Knop, Wuerzburg University Medical Center, Wuerzburg, Germany*

Background: In medically fit patients with newly diagnosed (ND) multiple myeloma (MM), triplet or quadruplet induction regimens, high-dose chemotherapy (HDT) and autologous stem cell transplant (ASCT) remain a standard of care. Carfilzomib (K), lenalidomide (R) and dexamethasone (d, KRd) induction/consolidation has proven exceptionally effective. Elotuzumab (E), an anti-SLAMF-7 monoclonal antibody bears favorable tolerability in relapsed/refractory MM while its role in NDMM remains unclear. **Methods:** Transplant-eligible (TE) NDMM patients (pts) up to 70 years (yrs) were randomized 1:1 to receive six cycles (C) of KRd or E-KRd, (chemomobilisation for ASCT after C3), single (tandem, if <CR/high risk NDMM) HDT/ASCT, followed by four consolidation C (KRd/E-KRd) and R or ER maintenance. Induction (IND, 28-day C) consisted of K on D1/2, 8/9 and 15/16 (20 mg/m² IV on D 1/2 in C1 and 36 mg/m² thereafter), R (25 mg PO, D1-21) and d (36/40 mg D 1, 8, 15, 22). E was given on D 1, 8, 15, and 22 (C1/C2) and on D 1 and 15 (C3-6; 10 mg/kg IV). After IND, pts underwent restaging when bone marrow was analyzed for minimal residual disease (MRD) by next-generation flow cytometry. The first co-primary endpoint of the study was the rate of pts who were in $\geq$ VGPR and were MRD negative. The study is registered as NCT03948035. **Results:** 579 pts (574 of whom received treatment) were randomized between 08/2018 and 10/2021 at 52 sites and included in the intent-to-treat analysis. Median age was 60 (range, 31-71) yrs. 15.4% had ISS stage III disease. 108/459 evaluable pts (23.5%) had high-risk cytogenetics (del(17p); t(4;14); t(14;16); $\geq$ 3 1q21 copies). 525/574 pts (91.5%) completed 6 IND cycles. MRD negativity and $\geq$ VGPR was achieved in 145 of E-KRd (49.8%) and 102 (35.4%) of KRd patients, respectively (p=.0005). 212 (72.9%) of E-KRd versus 177 (62.5%) of KRd patients experienced treatment-emergent AEs (TEAEs) of $\geq$ grade 3. Febrile neutropenia occurred in 26 (6.4%) E-KRd versus 14 (4.9%) KRd pts. Grade 3/4 thrombocytopenia was seen in 36 (12.4%) E-KRd and 30 (10.6%) KRd pts. Pneumonia occurred in 24 E-KRd (8.2%) and 18 KRd (6.4%) pts. Grade 3/4 cardiac events occurred in 16 E-KRd (5.5%) and of grades 3 to 5 in 16 (5.7%) of KRd pts. 12 E-KRd (4%) and 9 KRd (3.2%) pts had COVID-19 infections with one grade 5 event each (0.3% and 0.4%, respectively). Three pts on E-KRd (1.0%) versus 7 on KRd (2.5%) died on induction due to infections (N=3), MM progression (2), AML (1), a cardiac event (N=1), other (N=3). **Conclusions:** In this study, the addition of elotuzumab to KRd significantly improved the rate of early, deep ($\geq$ VGPR) MRD-negative remission in TE NDMM. E-KRd pts had slightly more TEAEs. Events were mainly hematotoxicity. To the best of our knowledge, this is the first study to show a benefit for the addition of elotuzumab to a front-line regimen. Clinical trial information: NCT03948035. Research Sponsor: AMGEN, Celgene, BMS.

Oral Abstract Session

First results from the RedirecTT-1 study with teclistamab (tec) + talquetamab (tal) simultaneously targeting BCMA and GPRC5D in patients (pts) with relapsed/refractory multiple myeloma (RRMM). *First Author: Yael C Cohen, Tel-Aviv Sourasky (Ichilov) Medical Center, and Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel*

Background: Tec is the first BCMA-directed bispecific antibody approved for the treatment of triple-class exposed RRMM. Tal, a bispecific antibody targeting the novel myeloma antigen GPRC5D, has shown promising efficacy in pts with RRMM. Simultaneously targeting 2 validated myeloma target antigens, using tec + tal in combination may lead to improved outcomes by overcoming resistance mechanisms, such as antigen escape. Here, we report the first results from the phase 1b RedirecTT-1 trial (NCT04586426) in pts with RRMM. **Methods:** Enrolled pts had MM per International Myeloma Working Group 2016 criteria; were RR or intolerant to the last line of therapy (LOT); were exposed to a proteasome inhibitor, immunomodulatory drug, and anti-CD38 therapy; and had measurable disease. The primary objectives are to evaluate safety and to identify a recommended phase 2 regimen (RP2R) for the combination. Responses were investigator assessed. AEs were graded per CTCAE v5.0. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded per ASTCT criteria. **Results:** As of Dec 12, 2022, 63 pts received tec + tal. Median (range) age was 67 y (39–81); median (range) prior LOT was 5 (1–11); 33% (15/45) had high-risk cytogenetics; 78% (49/63) were triple-class refractory; 63% (40/63) were penta-drug exposed; and 43% (27/63) had extramedullary disease (EMD; all bone independent). Median (range) duration of follow-up was 14.4 mos (0.5–21.9). The most common treatment-emergent AEs were CRS (81%; grade [gr] 3, 3%, no gr 4), neutropenia (76%; gr 3/4, 75%), and anemia (60%; gr 3/4, 43%). Dose-limiting toxicities (DLTs) were reported at dose level 1 (gr 3 herpetic stomatitis) and dose level 3 (gr 3 AST/ALT elevation). One ICANS event was reported at dose level 3. No DLTs were reported at the RP2R. Across all dose levels, overall response rate (ORR) was 84% (52/62) among all evaluable pts and 73% (19/26) among evaluable pts with EMD; rate of CR or better ($\geq$ CR) was 34% (21/62) and 31% (8/26), respectively. At the RP2R, ORR was 92% (12/13) among all evaluable pts and 83% (5/6) among evaluable pts with EMD; rate of $\geq$ CR was 31% (4/13) and 33% (2/6), respectively. Median duration of response has not been reached. Updated data, with 19 additional pts at the RP2R, will be presented. **Conclusions:** In this first combination study of a BCMA- and GPRC5D-targeted bispecific antibody, tec + tal at the RP2R has a manageable safety profile consistent with each of the monotherapies. A 92% ORR was observed in pts with advanced RRMM at the RP2R, and an ORR of 83% was achieved in pts with EMD, a high-risk population with unmet need, supporting further evaluation of the combination. Clinical trial information: NCT04586426. Research Sponsor: Janssen Research & Development.

Oral Abstract Session

Maintenance therapy with carfilzomib, pomalidomide, and dexamethasone (KPD) in high-risk myeloma patients (pts): A phase 2 study with a safety run-in. *First Author: Ajay K. Nooka, Winship Cancer Center of Emory University, Atlanta, GA*

Background: High-risk pts derive survival benefit from combination maintenance (PI and IMiD) strategies. We have evaluated the safety and efficacy of the next generation PI (carfilzomib) and IMiD (pomalidomide) in combination with dexamethasone in high-risk myeloma (NCT03756896). **Methods:** Newly diagnosed high-risk myeloma pts that have achieved $\geq$ PR post-ASCT were included. High-risk myeloma was defined by the presence of t(4;14) in 27.6%, t(14;16) in 17.2%, del17p in 58.6% pts by FISH or CTG or presence of $\geq$ 20% circulating cells (pPCL) in 6.9%. Double-hit myeloma (as defined by presence of $\geq$ 2 high-risk cytogenetic abnormalities including gain of 1q) was seen in 58.6% of pts. Each cycle is 28 days. Carfilzomib 20/56 mg/m² IV was given on days 1, 8, 15 and pomalidomide 2 mg PO on days 1 to 21 and dexamethasone 40 mg PO was administered on days of carfilzomib. Statistical analysis was conducted using SAS Version 9.4. **Results:** After the safety run in the first 3 pts, 26 additional pts were enrolled. Median age was 60 years (range, 46–75); 58.6% male and 58.6% black. At diagnosis, 65.5% had RISS stage 3 disease. 54.5% of whites and 64.7% of blacks had double-hit disease. Median time from diagnosis and from transplant to study entry was 9.3 (range, 6.08-12.42) and 2.89 (range, 2.8-51) months, respectively. At study entry, $\geq$ CR and $\geq$ VGPR rates were 24.1% and 68.9%, respectively, which deepened to 79.3% and 100% while on study. The median time to best response was 2.07 months (range, 1.22-14.26). Of the 15 pts with available MRD data, MRD (10^{-5}) and (10^{-6}) were achieved in 80% and 53.3%, respectively. After a median follow-up of 25.8 months, 36 month PFS was 63.2% (95% CI 38.3-80.3%) and 36 month OS was 72.4% (44.2-88.0%). Double-hit disease was an independent predictor for progression and death. Among these high risk patients, RISS did not show any statistical significance. While there is no PFS difference by race, the 36 month OS for black pts was inferior compared to whites (61.1% [23.1-84.7%] vs 85.7% [33.4%-97.9%], log rank 0.05). At data cut-off, 37.9% of pts were still receiving treatment; most common reason for permanent treatment discontinuation was progressive disease (27.6%). Among the 6 pt deaths, the most common cause of death was progressive disease (83.3%). Most common ($\geq$ 20%) TEAEs were fever (37.9%), fatigue (34.5%), diarrhea (27.6% [G3/4, 3.4%]), nausea (24.1%), cough (20.7%), muscle cramps (20.1%), acneiform rash (20.1%). TEAEs of interest were cardiac (10.3% [G3/4, 3.4%]), cataracts (17.2% [G3/4, 17.2%]), neutropenia (6.9% [G3/4, 6.9%]) and anemia (10.3% [G3/4, 0%]). **Conclusions:** In pts with high-risk myeloma, KPD maintenance deepened responses. MRD negativity (10^{-5}) was attained in 80% of pts. Despite the encouraging results in this cohort of high-risk patients, PFS and OS among double-hit pts remains poor, warranting newer strategies aimed at remission sustenance. Clinical trial information: NCT03756896. Research Sponsor: Amgen.

Oral Abstract Session

Talquetamab (tal) + daratumumab (dara) in patients (pts) with relapsed/refractory multiple myeloma (RRMM): Updated TRIMM-2 results. *First Author: Bhagirathbhai R. Dholaria, Vanderbilt University Medical Center, Nashville, TN*

Background: Tal is a T-cell redirecting bispecific antibody (BsAb) targeting G protein-coupled receptor family C group 5 member D. Dara is an anti-CD38 mAb with direct on-tumor and immunomodulatory actions. Combining immunomodulatory effects of tal + dara may lead to synergistic efficacy. Initial TRIMM-2 (NCT04108195) results showed that SC tal RP2Ds, 0.4 mg/kg QW or 0.8 mg/kg Q2W, + SC dara had promising efficacy and increased CD38+/CD8+ T cells and proinflammatory cytokines. We report updated results with additional pts and longer follow-up. **Methods:** Pts had MM, $\geq$ 3 prior lines of therapy (LOT; including a proteasome inhibitor [PI] and immunomodulatory drug [IMiD]) or were double refractory to a PI and IMiD, and had not received anti-CD38 therapy in $\leq$ 90 d. Pts received tal RP2Ds with step-up dosing + dara 1800 mg per approved schedule. AEs were graded per CTCAE v5.0; cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded per ASTCT guidelines. Responses were assessed per IMWG criteria. **Results:** As of Dec 12, 2022 (N = 65), median follow-up was 11.5 mo (range 1.0–27.3). Median age was 63 y (range 37–81); 18% of pts had high-risk cytogenetics; 25% had extramedullary plasmacytomas. Median prior LOT was 5 (range 2–16); 63% penta-drug exposed; 58% triple-class refractory. Prior treatments included anti-CD38 (88% [77% refractory]), anti-BCMA (54% [38%]), BsAb (25% [25%]), and anti-BCMA CAR-T (17% [2%]) therapy. All pts had $\geq$ 1 AE (grade [Gr] 3/4 78%), most commonly CRS (78%; all Gr 1/2), dysgeusia (75%), dry mouth (55%), anemia (52%), fatigue (45%), and skin exfoliation (45%). CRS had a median time to onset of 1 d after the most recent dose with median duration of 2 d. 63% of pts had infections (Gr 3/4 22%; Gr 5 3% [n = 2 pneumonia, possibly related to tal + dara]). 38% of pts had neutropenia (Gr 3/4 26%). 85% had postbaseline IgG < 500 mg/dL; of these, 32% received IVIg. ICANS occurred in 3 pts (5%; all Gr 1/2 and resolved in 1–2 d). ORR was 78% (66% $\geq$ VGPR; 45% $\geq$ CR) across RP2Ds (100% in anti-CD38 naïve pts), and responses deepened over time. In pts exposed/refractory to prior therapy, ORRs were 75%/76% for anti-CD38, 74%/64% for anti-BCMA, and 75%/75% for BsAb. Median time to first response was 1 mo (range 0.9–8.3); at 12 mo, 86% of responders (89% of pts with $\geq$ CR) still had responses. At data cutoff, 84% of responders remain on therapy (83%/82% anti-CD38 exposed/refractory). mPFS was 19.4 mo; 12-mo PFS and OS rates were 76% and 93%, respectively. **Conclusions:** Steroid-sparing tal + dara showed deep and durable responses with promising mPFS in heavily pretreated pts with RRMM, including pts refractory to anti-CD38/BCMA and T-cell redirecting therapy, suggesting combined immunomodulatory actions can yield robust responses in pts with refractory disease. The safety profile was clinically manageable; no new signals were identified with longer follow-up. Research Sponsor: Janssen Research & Development, LLC.

Oral Abstract Session

Updated phase I study results of PHE885, a T-Charge manufactured BCMA-directed CAR-T cell therapy, for patients (pts) with r/r multiple myeloma (RRMM). *First Author: Adam Samuel Sperling, Dana-Farber Cancer Institute, Boston, MA*

Background: B cell maturation antigen (BCMA) targeted CAR-T cells are approved for RRMM. Long manufacturing time and high clinical demand limit access. T-Charge, an innovative platform that reduces manufacturing time to <2 days and preserves T cell stemness, results in robust expansion and prolonged CAR T cell persistence. Here we report updated results from the Phase I trial of T-Charge manufactured, fully human, BCMA CAR-T PHE885 (NCT04318327). **Methods:** Eligible pts had RRMM after ≥2 prior lines of therapy (tx). Pts received fludarabine and cyclophosphamide (or bendamustine) for lymphodepletion (LD) prior to PHE885 infusion. Primary objective was safety. Secondary objectives were clinical response and cellular kinetics. **Results:** As of December 22, 2022, 46 pts received PHE885 at the following doses: 2.5e6 (n=4), 5e6 (n=13), 10e6 (n=20), 14.3e6 (n=1), and 20e6 (n=8) CAR T cells. PHE885 was manufactured for 61% of pts at a single academic institution; these pts proceeded from apheresis to LD in a median of 16 days. Median age at enrollment was 65 y (range [R] 45-81), median prior lines of tx was 4 (R 2-10). 37% of pts had extramedullary disease; 96% were triple refractory. Despite aggressive disease, only 28% of pts required bridging chemotherapy, predominantly influenced by quick production time. 96% of pts experienced any gr cytokine release syndrome (CRS); 11% had gr 3 CRS. Median time to CRS onset was 8 (R 2-16) days and median duration was 4 (R 1-19) days. Immune effector cell-associated neurotoxicity syndrome (ICANS) occurred in 22% of pts; 7% had gr 3 ICANS. Dose limiting toxicities were experienced by 13% of pts and included gr 4 neutropenia, gr 4 lipase increase, gr 3 serum amylase increase, gr 3 neurotoxicity, gr 3 transaminitis, and gr 3 ejection fraction reduction. The most common tx-related gr ≥3 AEs included anemia (54%), neutropenia (50%), and thrombocytopenia (37%). Geo-mean peak PHE885 expansion (C_{max}) was 276,000 copies/μg by qPCR and 70.6% of CD3+ T cells by flow cytometry (n=41). The PHE885 transgene was detected in 13/14 (93%) pts at 6 mo and 5/7 (71%) at 12 mo post infusion. T cells with early memory phenotype were preserved in the final product and persisted in pts post infusion. In 43 efficacy-evaluable pts, the ORR was 98%. At 10e6 dose (n=19), ORR was 100% and CRR was 42% (median follow-up of 4.9 mo [R 1.4-11.8]); 60% of 10 evaluable pts were MRD negative at 10^{-5} by NGS. Initial efficacy data at 20e6 and longer follow-up at active doses will also be presented. **Conclusions:** T-Charge manufactured PHE885 produced high response rates with no unexpected safety findings in heavily pretreated RRMM pts with aggressive disease. PHE885 expanded rapidly and showed durable persistence in vivo. Since conversion to CR/sCR has occurred as late as 18 months after infusion in this study, longer follow-up is ongoing to identify a recommended dose for future development. Clinical trial information: NCT04318327. Research Sponsor: Novartis.

Oral Abstract Session

LINKER-MM1 study: Linvoseltamab (REGN5458) in patients with relapsed/refractory multiple myeloma. *First Author: Hans C. Lee, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Linvoseltamab is a BCMAxCD3 bispecific antibody with encouraging efficacy and a manageable safety profile in patients (pts) with relapsed/refractory multiple myeloma (RRMM) (Bumma et al. ASH 2022). Two Phase (Ph) 2 full dose cohorts (50 mg and 200 mg) in the LINKER-MM1 (NCT03761108) trial were studied to optimize dose selection. **Methods:** Ph 2 enrolled adults with MM who progressed on/after ≥3 lines of therapy (LoT) including a proteasome inhibitor (PI), an immunomodulatory drug (IMiD), and an anti-CD38 antibody (Ab), or were at least triple class (IMiD/PI/anti-CD38 Ab) refractory. A protocol amendment permitted pts who progressed during 4–12 wks on 50 mg to dose escalate to 200 mg. Primary endpoint was objective response rate (ORR). Key secondary endpoints included duration of response (DoR) and minimal residual disease status. **Results:** As of 1 Sept 2022, 252 pts have enrolled (Ph 1: 73; Ph 2: 179 [200 mg: 75; 50 mg: 104]). Median age was 66 yrs (range 37–90), 12% had extramedullary plasmacytomas, 12% high-risk cytogenetics, 37% bone marrow plasma cell percentage (BMPC) ≥50%. Median soluble BCMA concentration (sBCMA) was 0.43 mg/L (range 0–10.2), median prior LoT: 5 (range 1–16), and 81% were ≥triple class refractory. Numerically higher efficacy was observed with 200mg, including in high disease burden subgroups; ORR was 64% (200 mg cohort; n = 58, includes 12 Ph 1 pts) and 50% (50 mg cohort; n = 104). Subgroup analyses showed higher ORR in the 200 mg cohort versus 50 mg for sBCMA ≥0.4 mg/L (52% vs 37%), BMPC > 67% (64% vs 35%) and revised ISS stage III (71% vs 27%). Median DoR was not reached for both cohorts (median follow-up: 2.3 months [200 mg], 4.7 months [50 mg]). Probability of maintaining response at 6 months was 89% (200 mg) and 85% (50 mg). Eight pts dose escalated from 50 to 200 mg; 6 (75%) achieved a response. Treatment-emergent adverse events (TEAEs) occurred in 95% (Grade [Gr] ≥3: 66%) of pts in the 200 mg cohort (n = 87, includes 12 Ph 1 pts) and 100% (Gr ≥3: 80%) in the 50 mg cohort. The most common TEAEs were cytokine release syndrome (200 mg: 37% [Gr 3: 1%]; 50 mg: 53% [Gr 3: 2%]), fatigue (200 mg: 32% [Gr ≥3: 0]; 50 mg: 33% [Gr ≥3: 0]) and anemia (200 mg: 28% [Gr ≥3: 24%]; 50 mg: 40% [Gr ≥3: 36%]). Grade ≥3 ICANS occurred in 2 pts (2%) in the 200 mg cohort and 1 pt (1%) in the 50 mg cohort. TEAEs leading to treatment discontinuation occurred in 7% (200 mg cohort) and 8% (50 mg cohort) of pts. Infections occurred in 43% (Gr ≥3: 26%) in the 200 mg cohort and 59% (Gr ≥3: 31%) in the 50 mg cohort. **Conclusions:** Linvoseltamab 200 mg showed better efficacy compared with 50 mg, including in pts with high disease burden. The 200 mg dose had consistent efficacy across high-risk subgroups and induced responses in pts who progressed on 50 mg. Safety was consistent across Ph 2 doses. The recommended linvoseltamab dose for further development is 200 mg. Updated data with longer follow-up and complete enrollment of the 200 mg cohort will be presented at the meeting. Clinical trial information: NCT03761108. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Oral Abstract Session

Updated results of a phase I, open-label study of BCMA/CD19 dual-targeting fast CAR-T GC012F for patients with relapsed/refractory multiple myeloma (RRMM). *First Author: Juan Du, Shanghai Changzheng Hospital, Shanghai, Shanghai, China*

Background: GC012F is a chimeric antigen receptor (CAR)-T cell therapy with B cell maturation antigen (BCMA) and CD19 dual-target developed on the novel FasT CAR-T platform enabling 22–36 h manufacturing. Our previous results were presented at ASCO and EHA 2022 for 29 pts (NCT04236011; NCT04182581), which demonstrated GC012F treatment led to deep and durable response in RRMM pts. Furthermore, initial results showed that GC012F showed considerable efficacy and safety in high-risk transplant-eligible newly diagnosed MM pts (Blood 2022; 140 (Supplement 1): 889–890). Here we present update on RRMM study with a longer median follow-up. **Methods:** From October 2019 to January 2022, 29 heavily pretreated RRMM pts (age 27–76) with a median of 5 prior lines therapies (range 2–9) received GC012F. 26 (89.7%) pts were high risk (HR- mSMART), 8 (27.6%) pts had EM disease, 24 (82.8%) pts were refractory to last therapy. 10 (34.5%) pts had received prior anti-CD38 and 11 (37.9%) pts were treated with auto-HSCT. After lymphodepletion over 2–3 days (30 mg/m²/d, 300mg/m²/d Flu/Cy), GC012F was administered as single infusion at 3 dose levels: 1x10⁵/kg (DL1) n=2, 2x10⁵/kg (DL2) n=10 and 3x10⁵/kg (DL3) n=17. **Results:** At the time of data cut-off (January 30, 2023), 29 eligible pts had been evaluated for response with the last patient completed 12 months efficacy follow up. Overall response rate was 93.1% (27/29), stringent complete response rate was 82.8% (24/29), ≥very good partial response rate was 89.7% (26/29). All patients dosed (29/29) achieved MRD negativity by flow cytometry (sensitivity 10⁻⁴–10⁻⁶). To date 24/29 patients (82.8%) achieved MRD- sCR across all dose levels. According to the Kaplan-Meier method, the median duration of response (DOR) was 37.0 months (95%CI, 11.0–NR) and the median progression free survival (PFS) was 38.0 months (95%CI, 11.8–NR). Cytokine Release Syndrome (CRS) was reported in 25 (86.2%) pts, which was mostly ≤grade 2 (n=23, 79.3%) and 2 (6.9%) pts were grade 3. No ICANS was observed (Graded by ASBMT criteria). Median duration of CRS was 3 days (1–8 d). PK results showed no difference amongst dose levels DL1 to DL3. The median time of persistence was 41.0 days (range: 51–1183) and GC012F was still detectable in 23 (79.3%) pts at 6 months and in 16 (55.2%) pts at 12 months after infusion. sBCMA plasma levels started declining at day 4 in 80% (8/10) patients, falling sharply at day 10 in 100% (19/19), and reaching minimal levels from 30 to 60 days post infusion in 100% (29/29) patients. **Conclusions:** The updated results showed GC012F continues to provide deep and durable responses, and a very high MRD negativity rate in RRMM pts, including in pts refractory to anti-CD38, PIs and IMiDs. Based on these promising results of the study of GC012F for RRMM, further clinical studies will be conducted to confirm the efficacy of GC012F. Clinical trial information: NCT04236011; NCT04182581. Oral Abstract Session

A phase 3, open-label, randomized study to evaluate the efficacy and safety of single-agent belamaf mafodotin (belamaf) compared to pomalidomide plus low-dose dexamethasone (Pd) in patients (pts) with relapsed/refractory multiple myeloma (RRMM): DREAMM-3. *First Author: Katja Weisel, University Medical Center of Hamburg-Eppendorf, Hamburg, Germany*

Background: Belamaf, an antibody-drug conjugate targeting B-cell maturation antigen, induces cell death by direct cell kill and immune-mediated mechanisms. The DREAMM-2 trial (NCT03525678) showed rapid, deep and durable responses to belamaf monotherapy in pts with RRMM. The Phase 3, open-label, randomized, multicenter DREAMM-3 trial (NCT04162210) evaluated belamaf monotherapy vs Pd in adult pts with RRMM at second relapse (third line) or later. **Methods:** Pts were randomized (2:1) to belamaf 2.5 mg/kg Q3W or Pd (pom 4 mg PO daily on days 1–21 of 28 day cycle; dex, 40mg PO [20mg if >75 years]) Q1W. The primary endpoint was progression free survival (PFS). **Results:** 325 pts were enrolled (belamaf n=218, Pd n=107). Median (range) age was 68 (38–90) years; 57% were male. Median (range) duration of exposure for belamaf was 4.1 (0.4, 22.9) months (mo) and 5.3 (0.4, 24.0) for Pd. Median (range) duration of follow-up was 11.5 (0.6, 24.2) mo for belamaf and 10.8 (0.0, 26.4) mo for Pd. Median PFS was longer for belamaf (11.2 [6.4, 14.5] mo) vs. Pd (7.0 [4.6, 10.6] mo). There was no statistically significant difference in PFS between the 2 treatment groups, (HR 1.03 [95% CI: 0.72, 1.47]), based on the stratified Cox model (p=0.558). Belamaf induced deeper responses vs Pd (Table). Median duration of response (DoR) was more durable for belamaf than for Pd (Table). At 12 mo, the probability (95% CI) of maintaining response was 0.768 (0.641, 0.854) for belamaf and 0.484 (0.258, 0.679) for Pd. Median PFS2 was 18.7 mo (95% CI 14.5, NR) for belamaf and 12.7 mo (9.3, 21.1) for Pd. PFS2 rate at 6 mo was 73% for belamaf and 76% for Pd. Overall survival (OS) data were immature (37.5% overall maturity) at this analysis; median OS was 21.2 mo (95% CI 18.7, NR) for belamaf and 21.1 mo (15.1, NR) for Pd (HR 1.14 [95% CI 0.77, 1.68]; p=0.746). Adverse events (AEs) were reported in 97% and 93% of patients (Table). The safety profile was consistent with previous reports for belamaf and Pd. **Conclusions:** Belamaf monotherapy did not demonstrate PFS superiority when compared to a doublet (Pd). However, median PFS was longer for belamaf monotherapy and belamaf induced deeper, more durable responses than Pd. No new safety signals were observed. Subgroup analyses and PRO outcomes will be reported. Belamaf continues to be investigated in combination with established and novel agents. Research Sponsor: GSK(207495).

Oral Abstract Session

Efficacy and safety of elranatamab in patients with relapsed/refractory multiple myeloma (RRMM) and prior B-cell maturation antigen (BCMA)-directed therapies: A pooled analysis from MagnetisMM studies. *First Author: Ajay K. Nooka, Winship Cancer Institute, Emory University Hospital, Atlanta, GA*

Background: Studies in the MagnetisMM program (MM-1, NCT03269136; MM-3, NCT04649359; MM-9, NCT05014412) enrolled pts treated with prior BCMA-directed therapies. A pooled analysis from these studies evaluated the efficacy and safety of elranatamab in pts with RRMM and prior exposure to BCMA-directed therapy. **Methods:** Eligible pts received at least 1 PI, 1 IMiD, 1 anti-CD38 antibody, and 1 BCMA-directed therapy (ADC and/or CAR-T cells). Pooled analysis included pts in MM-1 (n = 13) who received SC elranatamab 215–1000 µg/kg; MM-3 (n = 64) and MM-9 (n = 9) who received the RP2D, SC 76 mg QW. Efficacy endpoints were assessed by investigator per IMWG criteria. TEAEs were graded by CTCAE (MM-1, v4.03; MM-3 & MM-9, v5.0); CRS and ICANS were graded by ASTCT criteria. Results include data up through ~10 months after last pt initial dose in all pooled studies. **Results:** In total, 86 pts were included. Median age was 66.0 y (range, 40–84); 47.7% male. At baseline, 69.8% had an ECOG PS ≥1; 24.4% had high risk cytogenetics; 54.7% had extramedullary disease. Pts received a median of 7.0 (3–19) prior lines of therapy, including BCMA-directed ADC (67.4%), CAR T-cells (41.9%), 9.3% received both. 96.5% and 54.7% of pts were triple-class and penta-drug refractory, respectively; among pts who received ADC and CAR-T cells respectively, 79.3% and 27.8% were refractory to ADC and CAR-T cells. After a median follow-up of 10.3 mo (0.3–32.3), median duration of treatment was 3.3 mo (0.03–30.4). At data cut-off, 24.4% of pts remained on treatment; most common reason for permanent treatment discontinuation was progressive disease (44.2%). ORR was 45.3% (95% CI 34.6–56.5), with ≥CR achieved in 17.4% of pts. ORR for pts with prior BCMA-directed ADC and CAR-T cells was 41.4% (95% CI 28.6–55.1) and 52.8% (95% CI 35.5–69.6), respectively. Among responders, median time to objective response was 1.9 mo (0.3–9.3). Median DOR was not reached by 10 mo; the DOR rate at 9 mo was 72.4% (95% CI 54.7–84.2). DOR rate (95% CI) for pts with prior BCMA-directed ADC and CAR-T cells were 67.3% (43.1–83.0) and 78.9% (53.2–91.5) at 9 mo, respectively. Median PFS was 4.8 mo (95% CI 1.9–7.7), and median OS was not reached by 10 mo, with a rate of 60.1% (95% CI 48.9–69.6) at 9 mo. Most common (≥25% of pts) TEAEs were CRS (65.1% [G3 1.2%]), anemia (59.3% [G3/4, 46.5%]), neutropenia (44.2% [G3/4, 40.7%]), thrombocytopenia (40.7% [G3/4, 29.1%]), diarrhea (33.7% [G3/4, 0%]), and lymphopenia (32.6% [G3/4, 30.2%]). ICANS was reported in 5.8% (G3, 2.3%) of pts. **Conclusions:** In pts with RRMM and prior exposure to BCMA-directed therapies, elranatamab was efficacious and well tolerated; no new safety signals were observed vs the BCMA-naïve population. Results support treatment with elranatamab in pts with RRMM post BCMA-directed therapy. Clinical trial information: NCT03269136, NCT04649359, NCT05014412. Research Sponsor: Pfizer.

Poster Discussion Session

Long-term remission and survival in patients with relapsed or refractory multiple myeloma after treatment of LCAR-B38M CAR-T: At least 5-year follow-up in LEGEND-2. *First Author: Jian-Qing Mi, State Key Laboratory of Medical Genomics, National Research Center for Translational Medicine, Shanghai Institute of Hematology, Ruijin Hospital Affiliated With Shanghai Jiao Tong University School of Medicine, Shanghai, China*

Background: LCAR-B38M CAR-T cells express a structurally differentiated CAR construct containing a 4-1BB costimulatory domain and 2 BCMA-targeting single-domain antibodies designed to confer avidity. LEGEND-2 was a first-in-human phase 1 study of LCAR-B38M conducted in China, which showed encouraging efficacy and manageable safety in 74 patients (pts) with RRMM. The US phase 1b/2 CARTITUDE-1 and Chinese phase 2 CARTIFAN-1 trials of ciltacabtagene autoleucl, which expresses the same CAR as LCAR-B38M, confirmed the efficacy observed in LEGEND-2. Here, we present ≥5-y FU data from LEGEND-2, the longest FU for any BCMA-targeted CAR-T cell therapy study. **Methods:** Study design was previously published. Pts underwent lymphodepletion with cyclophosphamide (cy) 300 mg/m² (n=66) or cy 250 mg/m² plus fludarabine 25 mg/m² (n=8) prior to receiving LCAR-B38M at a median dose of 0.51 × 10⁶ (range, 0.07–2.10 × 10⁶) CAR-positive T cells/kg in a single (n=9) or 3 split (n=65) infusions. **Results:** Pts were enrolled from 30 Mar 2016 to 26 Nov 2017. As of 30 Nov 2022, median FU was 65.4 mo (range, 0.4–78.8). 74 pts had received LCAR-B38M (median age, 54.5 y; 60.8% male; median [range] 3 [1–9] prior lines of therapy [LOT]; 44.6% ISS stage I; 28.4% ISS stage II; 29.7% with extramedullary disease [EMD]; 35.7% cytogenetic high risk). No new CAR-T cell-related toxicities were reported in the analysis. ORR (87.8%), CR rate (73.0%), MRD-negative CR rate (67.6%), median DOR (23 mo), and median PFS (18 mo) were mature and the same as previously reported; median OS was previously not reached. At 65.4-mo median FU, median OS was 55.8 mo, with 33 (44.6%) pts alive and 13 (17.6%) still disease-free. Compared with pts with progressive disease (PD) or who died, pts without PD were more likely to have baseline ECOG performance status (PS) 0, IgG type MM, ISS stage I MM, numerically shorter time from diagnosis, fewer prior LOT, no light chain MM, and no EMD (Table). **Conclusions:** At ≥5-y FU in LEGEND-2, median OS was 55.8 mo and 18% of pts with RRMM were disease-free, raising the possibility of a cure in this heavily pretreated pt population. Our data suggest that pts who are less heavily pretreated or have good functional status may experience greater benefit, potentially being cured, from LCAR-B38M CAR-T cell therapy. Clinical trial information: NCT03090659. Research Sponsor: Key Research and Development Plan of ShaanXi Province, Project 2018SF-002 awarded to W-H Zhao, Project 2017ZDXM-SF-25-6 (Approval No. 2018ZDXM-SF-039) awarded to A-L He; National Natural Science Foundation of China (No. 81970189) awarded to J Xu.

CARTITUDE-1 final results: Phase 1b/2 study of ciltacabtagene autoleucl in heavily pretreated patients with relapsed/refractory multiple myeloma. *First Author: Yi Lin, Mayo Clinic, Rochester, MN*

Background: Heavily pretreated patients (pts) with relapsed/refractory multiple myeloma (RRMM) treated with standard of care therapy have median overall survival (OS) of ~12 months (mo). In the single-arm, phase 1b/2 CARTITUDE-1 study (NCT03548207), pts received a single infusion of ciltacabtagene autoleucl (cilta-cel), a CAR-T cell therapy targeting BCMA. At the final protocol-specified analysis (27.7-mo median follow-up [MFU]), overall response rate (ORR) was 98%, with 83% stringent complete response (CR); 27-mo rates of progression-free survival (PFS) and OS were 55% and 70%, respectively. Here, we report study closeout results. **Methods:** Eligible pts received ≥3 prior lines of therapy (LOT) or were double refractory to a proteasome inhibitor (PI) and immunomodulatory drug (IMiD); and had received prior PI, IMiD, and anti-CD38 antibody therapy. Primary endpoint was ORR and safety; secondary endpoints included PFS, OS, and minimal residual disease (MRD) negativity at 10⁻⁵. **Results:** 97 pts received cilta-cel (median age 61 years [y]; median 6 prior LOT; 42% penta-drug refractory; 88% triple-class refractory; 99% refractory to last LOT). As of October 14, 2022, MFU was 33.4 mo (range, 1.5–45.2). Median (m) duration of response was 33.9 mo (95% CI, 25.5–not estimable [NE]). mPFS was 34.9 mo (95% CI, 25.2–NE), with an estimated 47.5% progression free and alive at 36 mo. mOS was not reached (NR), with an estimated 62.9% survival at 36 mo. Of 49 MRD-evaluable pts, 26 had MRD negativity sustained for ≥12 mo, of which 20 had sustained MRD-negative ≥CR. mPFS was NR in these subgroups (Table). 18 pts were MRD negative with ≥CR at 24 mo post infusion. No new safety signals and no new neurotoxicity events were reported since the 27.7-mo MFU. 6 new cases of second primary malignancy were reported, including 2 cases of basal cell carcinoma and 1 case each of myelodysplastic syndrome, B-cell lymphoma, melanoma, and prostate cancer. 5 additional deaths occurred (progressive disease [PD], n=3; pneumonia and sepsis, n=1 each [both unrelated to cilta-cel]), for a total of 35 (PD, n=17; unrelated to cilta-cel, n=12; related, n=6). **Conclusions:** Longer mPFS was observed after a single infusion of cilta-cel than any previously reported therapy in heavily pretreated pts with RRMM. Achieving CR and/or sustained MRD negativity was associated with prolonged PFS. Pts continue to be followed for safety and survival in the 15-y CARTINUE long-term study (NCT05201781; MMY4002). Clinical trial information: NCT03548207. Research Sponsor: Janssen Research & Development, LLC; Legend Biotech USA Inc.

PFS at ~3-y MFU.				
Subgroup	n	mPFS (95% CI), mo	30-mo PFS rate	36-mo PFS rate
All pts	97	34.9 (25.2–NE)	54.2%	47.5%
≥CR	76	38.2 (34.9–NE)	66.8%	59.8%
6-mo sustained MRD negativity ^a	34	32.2 (25.1–NE)	68.6%	45.7%
12-mo sustained MRD negativity ^a	26	NR (NE–NE)	74.9%	NE

Poster Discussion Session

Long-term follow-up from MajesTEC-1 of teclistamab, a B-cell maturation antigen (BCMA) x CD3 bispecific antibody, in patients with relapsed/refractory multiple myeloma (RRMM). *First Author: Niels W.C.J. van de Donk, Amsterdam University Medical Center, Vrije Universiteit Amsterdam, Amsterdam, Netherlands*

Background: Teclistamab is the first approved off-the-shelf BCMA×CD3 bispecific antibody for the treatment of patients (pts) with RRMM based on data from the pivotal phase 1/2 MajesTEC-1 study (NCT03145181/NCT04557098). Moreau et al (*NEJM* 2022) reported rapid, deep, and durable responses: overall response rate (ORR) was 63% (39% ≥complete response [CR] rate), with a median duration of response (mDOR) of 18.4 mo, and median progression-free survival (mPFS) of 11.3 mo after a median follow-up (mFU) of 14.1 mo. Here, we present updated results with extended follow-up of ~2 y (22 mo). **Methods:** Eligible pts were aged ≥18 y, had documented MM (per IMWG 2016 criteria), and had received ≥3 prior lines of therapy (LOT), including a proteasome inhibitor, an immunomodulatory drug, and an anti-CD38 antibody. Prior BCMA-targeted therapy was not allowed in this cohort. Pts received teclistamab 1.5 mg/kg QW (the recommended phase 2 dose [RP2D]), with the option to switch to Q2W dosing if they achieved ≥partial response after ≥4 cycles of therapy in phase 1 or ≥CR for ≥6 months in phase 2. The primary endpoint was ORR (assessed per IMWG 2016 criteria by computerized algorithm). AEs were graded per CTCAE v4.03. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded per ASTCT guidelines. **Results:** As of Dec 9, 2022, 165 pts had received teclistamab at the RP2D (median age, 64 y; 58% male; 26% high-risk cytogenetics; 12% International Staging System stage III). Pts had a median of 5 prior LOT (range, 2–14): 92% daratumumab exposed; 78% triple-class refractory; 81% daratumumab-refractory; and 90% refractory to last LOT. At 22 mo mFU, 43% of pts achieved ≥CR, mDOR was 24 mo (95% CI, 16.2–not estimable [NE]), mDOR in pts achieving ≥CR was not reached (95% CI, 24.0–NE), mPFS was 12.5 mo (95% CI, 8.8–17.2), and median overall survival was 21.9 mo (95% CI, 16.0–NE). Hematologic AEs (any grade [gr]/gr 3/4) included neutropenia (72%/65%), anemia (54%/38%), thrombocytopenia (42%/22%), and lymphopenia (35%/33%). Infections occurred in 78% of pts (52% gr 3/4); key infections included respiratory (56%), COVID-19 (27%), other viral (10%), GI (8%), fungal (5%), PJP (4%), and hepatitis B (0.6%). CRS occurred in 72% of pts (0.6% gr 3; no gr 4/5); 5 (3%) pts reported 9 ICANS events (all gr 1/2; all resolved). 1 pt in phase 1 required a teclistamab dose reduction due to neutropenia. 6 treatment-related deaths have occurred (3 due to COVID-19). Of the 49 pts who remain on study, ~90% have received Q2W dosing. **Conclusions:** After ~2 y mFU, pts receiving teclistamab demonstrated deep and durable responses regardless of refractory status, with mPFS of 12.5 mo and mDOR of 24 mo (not reached in those achieving ≥CR). These long-term follow-up data support teclistamab as a safe and effective off-the-shelf BCMA bispecific therapy for pts with RRMM. Clinical trial information: NCT03145181, NCT04557098. Research Sponsor: Janssen Research & Development.

Safety and efficacy of standard of care (SOC) ciltacabtagene autoleucel (Cilta-cel) for relapsed/refractory multiple myeloma (RRMM). *First Author: Doris K. Hansen, Department of Blood & Marrow Transplant and Cellular Immunotherapy, Moffitt Cancer Center, Tampa, FL*

Background: Cilta-cel was FDA approved in 2022 for the treatment of RRMM. We evaluated the outcomes of patients treated with intended SOC cilta-cel. **Methods:** 12 US academic medical centers contributed data to this retrospective study. As of 12/31/2022, 177 patients were leukapheresed and 139 received cilta-cel. **Results:** The table describes the study population compared to the CARTITUDE-1 trial. More patients in our study had extramedullary disease (EMD, 35%) and high-risk cytogenetics (41%). 55% of the patients would not have met eligibility criteria for CARTITUDE-1. Common reasons for ineligibility were cytopenias (19%), prior BCMA therapy (14%), organ dysfunction (12%), oligosecretory disease (13%), and plasma cell leukemia (8%). 83% of the patients received bridging chemotherapy (overall response rate, ORR: 28%). Lymphodepletion included fludarabine (Flu) + cyclophosphamide (Cy): 81%, bendamustine: 11%, Cy: 4%, and cladribine + Cy: 4%. Median CAR-T cells infused were 0.6 million/kg (range: 0.1-0.9), and 19% of patients were treated on an expanded access protocol (EAP). Median follow-up was 2.3 months (range: 0-8). Cytokine release syndrome (CRS) was seen in 81% ($\geq$ grade 3: 7%) and immune effector cell-associated neurotoxicity syndrome (ICANS) in 22% ($\geq$ grade 3: 8%) of patients. Tocilizumab, steroids, and anakinra were used in 61%, 44%, and 10% of patients, respectively. Delayed neurotoxicity (NT) was seen in 9% (cranial nerve palsy: 8, Parkinsonism: 2, others: 3). Grade $\geq$ 3 cytopenias at day $\geq$ 30 were seen in 75% of patients. Infections were seen in 32% of patients. Day 30 (N=115) and best response rates (N=118) were: $\geq$ partial response (PR), 75/80%; $\geq$ very good PR, 44/62%; and $\geq$ complete response (CR), 26/40%, respectively. In the non-EAP FluCy population (N=88), best ORR $\geq$ CR were 89/49%. 17 patients died by data cut-off, 4 due to disease progression and 13 (9%) due to non-relapse mortality (NRM) (grade 5 CRS: 3, infection: 6, CRS/infection: 1, grade 5 ICANS: 1, delayed NT: 2). **Conclusions:** Patients treated with intended SOC cilta-cel had a favorable ORR (80%) despite a larger proportion of patients having high-risk features relative to trial patients and limited follow-up. Response rates were higher in patients receiving conforming products with FluCy conditioning (89%). Delayed NT and NRM were seen in 9% of patients. Results will be updated with continued follow-up. D.K.H., K.K.P., M.J., Y.L. & S.S. contributed equally. Research Sponsor: None.

Comparison of patient characteristics and outcomes by intended SOC vs. CARTITUDE-1 trial participants.

	Intended SOC, N=139	CARTITUDE-1, N=97
Median age, yrs	64	61
ECOG PS 0 or 1	91%	96%
Extramedullary disease	35%	13%
High-risk cytogenetics	41%	24%
Median prior regimens	6 (2-18)	6 (4-8)
Penta-refractory disease	36%	42%
Grade $\geq$ 3 CRS and ICANS	7%, 8%	4%, 2%
Delayed NT/Parkinsonism	9%/1.4%	12%/6%
Best ORR $\geq$ CR	All: 80%/40%	98%/83%
	Non-EAP FluCy: 89%/49%

Plasma cell leukemia: A multicenter retrospective study of 150 patients. *First Author: Iloabueke Gabriel Chineke, The University of Arizona Cancer Center, Arizona, AZ*

Background: Despite the use of novel induction regimens, stem cell transplantation (SCT), and maintenance therapy, plasma cell leukemia (PCL) remains a challenging disease with a dismal prognosis. Currently, there is no agreed standard of care management for PCL. We conducted a multicenter retrospective analysis of the clinical presentation, treatment, and outcomes of 150 patients with PCL. **Methods:** Data of patients diagnosed with pPCL or sPCL between 01/2010 and 01/2021 were entered into a study-specific REDCap database from 7 different U.S. academic sites. PCL was defined as $\geq$ 5% circulating plasma cells. Clinical data included baseline patient characteristics, clinical presentation, treatment, therapeutic response, and survival outcomes. Overall survival (OS) curves were plotted using the Kaplan-Meier method. Cox proportional hazards regression tested associations between patient characteristics and OS, generating hazard ratios (HR) and 95% confidence intervals (CI), adjusted for PCL type (primary or secondary) and SCT. **Results:** The analytical cohort included 93 pPCL and 57 sPCL patients. Median age at diagnosis was 60 years. High-risk cytogenetics were found in 56.7% of the patients where it was documented. Of the 79 patients with a documented induction regimen, 58.2% received a proteasome inhibitor triplet, 22.8% received a VTD-Pace like conventional chemotherapy, and 3% received a daratumumab quadruplet regimen. SCT (autologous or allogeneic) was done in 56.1% of the patients. The median OS for all patients, those with pPCL, and those with sPCL was 20.3, 36.6, and 3.2 months, respectively. Secondary PCL was associated with worse survival outcomes compared with pPCL (HR, 2.46; 95% CI, 1.51-3.98; $p < 0.001$) (Table). Median OS was better in patients treated with a proteasome inhibitor triplet regimen vs VTD PACE-like combination (28.2 versus 12.6 months). OS was prolonged among patients who underwent any type of SCT compared with those who did not undergo SCT (44.0 versus 5.7 months, $p < 0.001$). **Conclusions:** This multicenter retrospective study is one of the largest PCL analyses performed to date and reveals the clinical practice patterns of treatment and survival of PCL patients across the U.S. in the novel treatment era. The survival analysis reinforces the poor prognosis in sPCL patients and the continued need for novel treatment approaches in this patient population. While limited by retrospective design, this analysis suggests prolonged survival with transplantation in both pPCL and sPCL. Research Sponsor: None.

Associations with survival (any survival, n=150).

Characteristics	Crude HR (95% CI)	Adjusted HR (95% CI)	p-value
PCL type (primary/secondary)	4.69 (3.10 - 7.10)	2.46 (1.51 - 3.98)	< 0.001
Any transplant	0.17 (0.11 - 0.28)	0.23 (0.14 - 0.38)	< 0.001
Extramedullary disease	1.57 (0.98 - 2.50)	1.09 (0.64 - 1.88)	0.749

Impact of bridging therapy (BT) on outcome of relapsed refractory multiple myeloma (RRMM) with Ide-cel CAR T-cell therapy: Real-world experience from the US myeloma CAR T consortium. *First Author: Aimaz Afrough, Simmons Comprehensive Cancer Center, UT Southwestern Medical Center, Dallas, TX*

Background: Ide-cel is an FDA-approved treatment for RRMM patients (pts). However, there is limited data on how BT for disease control during its manufacturing process affects clinical outcomes. **Methods:** Eleven US academic centers contributed data to this analysis without involvement from the manufacturer. By 5/1/2022, 235 pts had undergone leukapheresis, with 214 infused with a median follow up of 9 months (mos). BT was given between leukapheresis and CAR-T infusion. **Results:** In this analysis, 79% of pts (n = 170) received BT, which included alkylator-based in 35.5%, steroid and/or IMiD/Ab combos (IMiD combos) in 14%, PI combinations (PI combos) in 12%, and selinexor in 10%. BT recipients had higher ECOG PS 2-4, R-ISS 2-3, ferritin, and CRP before lymphodepleting (LD) chemo, however, no difference among BT subgroups. No difference in prior lines of therapy or penta-refractory between BT and No BT (NBT) groups or BT subgroups. Median cycle of the BT was 1 (1-7), with overall response rate (ORR) of 12%, with no difference among BT subgroups. Incidence and severity of CRS and ICANS were comparable in BT and NBT. However, pts who received BT had a longer median hospital stay compared to NBT, particularly in the alkylator/selinexor subgroups. There were no significant difference in cytopenias at day 90 post CAR-T between the BT and NBT or BT subgroups. For the 73% (n = 157) evaluable for day 90 response, there was no difference in the complete or ORR between the BT and NBT groups (41% vs. 52%; $p = .2$ and 84% vs. 87.5%, $p = .8$, respectively). Median PFS was worse at 8.1 mos in BT vs 11.5 mos in NBT ($p = .03$). Among BT subgroups, PFS was the longest with IMiD combos with median PFS not reached (NR), comparable to NBT, and was significantly longer than all other BT subgroups ($p = 0.01$). The median OS was 13.8 mos with BT and NR in NBT ($p = .002$). In BT subgroup analysis, alkylators had a shorter OS, although, this was not significant ($p = .06$). There was no significant difference in PFS and OS in relationship to response to BT ($p = .6$ and $p = .9$, respectively). **Conclusions:** Pts without BT had longer PFS and OS post ide-cel, likely reflective of less aggressive disease. Those who received BT with steroid/IMiD and Ab combos had similar PFS as NBT. However, BT choice is complicated by disease severity and should be evaluated per patient circumstances. Research Sponsor: None.

Poster Discussion Session

Disparities in multiple myeloma: A global perspective on drug toxicity trends. *First Author: Majid Jaberi-Douraki, DATA Consortium, Computational Comparative Medicine, Department of Mathematics, Kansas State University-Olathe, Olathe, KS*

Background: The FDA Adverse Event Reporting System (FAERS) is one of the largest pharmacovigilance databases containing information on adverse events (AEs) received from manufacturers, consumers and healthcare professionals. The purpose of this study is to evaluate the global disparities in multiple myeloma (MM) through data mining of FAERS. **Methods:** We examined AEs associated with FDA-approved MM drugs from 2003-2022 from FAERS and the Medical Dictionary for Regulatory Activities. Patient data were then stratified based on age, sex (F/M) and 6 geographical regions. We evaluated the reporting odds ratio (ROR) combined with a 95% confidence interval for the elevated incidence of AEs. **Results:** The data curation provided 381,378 patients with information from North America (NA), Europe (EU), Asia (AS), Africa (AF), Oceania (OC) and Latin America & the Caribbean (LA), merged from 129 countries and 27 phenotypic systems and organs categories when the number of AEs happened more than 0.1% of the total. Cardiotoxicities (n=23160) and vascular toxicities (n=26716) were seen more in NA (M) (ROR=1.16 $\pm$ 0.02 and EU (M) (ROR=1.11 $\pm$ 0.03) compared to the rest of the World. Nephrotoxicity (n=17486) was reported more in AF (M) (ROR=2.92 $\pm$ 0.41) compared to AS (M) (ROR $\geq$ 1.17 $\pm$ 0.12), EU (M) (ROR $\geq$ 1.34 $\pm$ 0.13) and NA (M) (ROR=1.09 $\pm$ 0.03). Peripheral neuropathies (n=14786) were frequent among EU (F) (ROR=1.09 $\pm$ 0.07) and OC (M) (ROR=1.08 $\pm$ 0.04). Mortality was higher among AS and EU (ROR $\geq$ 2.15 $\pm$ 0.93) compared to NA and OC. There were 18,222 secondary neoplasms in FAERS. Skin neoplasms (n=4650) more frequently occurred in OC and EU (ROR $\geq$ 1.70 $\pm$ 0.16). Breast neoplasms (n=694) were the highest in EU (F) (ROR=4.01 $\pm$ 0.63) and lowest in OC (F) (ROR<1). Gastrointestinal neoplasms (n=1564) were more common among AS, EU and OC (M) with (ROR $\geq$ 2.23 $\pm$ 0.47). Lymphomas (n=542) were predominant in AS(M) (ROR=2.21 $\pm$ 0.98) and OC (M) (ROR=3.35 $\pm$ 2.23). Leukemias (n=3896) cases were significantly higher in EU (M) (ROR=4.08 $\pm$ 0.40) and EU (F) (3.11 $\pm$ 0.26). Respiratory tract and mediastinal neoplasms (n=796) were more common in AS, EU and OC(M) where ROR $\geq$ 1.36 $\pm$ 0.33. More phenotypic characterization are tabulated below. **Conclusions:** FAERS can be used to assess cancer disparity from a global perspective. Our results indicates that certain AEs are influenced by gender and geographical location. These disparities in MM AEs may be the result of factors such as genetics, dosing/regimen, comorbidities, age and sex. These variables must be investigated for improved patient care, strategies for AE reduction, mortality reduction and optimal allocation of healthcare resources. Research Sponsor: None.

Phenotypic Characterization	Sex	NA (n=308177)	EU (n=40761)	AS (n=16467)	AF (n=363)	OC (n=2166)	LA (n=3919)
Age	F	70	69	71	59.5	68	67
	M	69	68	69	60	68	65
Reproductive neoplasms	F	2.1 $\pm$ 1.2	4.95 $\pm$ 2.5	4.2 $\pm$ 1.6	Data not available	1.34 $\pm$ 1.1	1.69 $\pm$ 1.2
Prostate neoplasms	M	2.11 $\pm$ 0.98	4.39 $\pm$ 0.65	1.25 $\pm$ 0.39	2.80 $\pm$ 2.40	3.53 $\pm$ 0.49	1.35 $\pm$ 0.84

Investigation into aberrant B cell repertoire in myeloma on humoral immunity and patient survival. *First Author: Lakshmi Bhavani Potluri, Wayne State Univ/DMC Sinai Grace Hospital, Detroit, MI 48235, Detroit, MI*

Background: B cells are critical to inhibiting tumor progression, as they generate tumor-reactive antibodies; promote anti-tumor killing capacity of NK cells and phagocytosis of macrophages/DCs; and enrich priming of T cells against the tumor. Multiple myeloma (MM) is a B-cell-derived malignancy, and its survival is partly driven by a deficiency in the immune response. Yet, the abnormalities of the B-cell-mediated humoral responses in MM are ill defined. **Methods:** We investigated B cell composition in bone marrow (BM) from patients with newly diagnosed MM (NDMM, N = 170), relapsed/refractory MM (RRMM, N = 140) and healthy donors (HD, N = 21) by multi-color flow cytometry. **Results:** We observed that B1b cells were significantly reduced by 45% (p = 0.004) in NDMM patients compared to HD. B1b cells are important in generating long-lasting protective antibodies, particularly against vaccines, in a T cell independent fashion. Similarly, B2 cells, which can produce all antibody types, were significantly reduced in the periphery of NDMM and RRMM patients. Within the B2 cell population, germinal center (GC) matured B cells were significantly reduced in both BM and periphery of MM patients, as shown by significantly higher expression of Fas receptor. Because of deficiencies in the GC-maturation of these B cells, their ability to switch from IgM to IgG was also significantly decreased. On the other hand, the population of regulatory B cells (Bregs) were significantly elevated by 2.3-fold (p < 0.05) in the BM and periphery of NDMM and periphery of RRMM patients. However, the ability of Breg cells to produce suppressive cytokines, like IL-10, was significantly reduced (p = 0.03), indicating impaired suppressive functional capacity. We investigated whether this dysregulated B cell homeostasis impacts myeloma patient survival following treatment. We found that a higher proportion of Bregs and a lower percent of B1a in BM and periphery prior to treatment was associated with favorable progression-free survival (PFS) in both NDMM and RRMM patients. We hypothesized that reduction of B2 cells and their inability to have GC-based maturation could impair antibody generation against acute infections and tumor neoantigens. Therefore, we evaluated MM patients' ability to produce antibodies against hepatitis B surface antigen-based vaccination. We observed that only 31% of MM patients (N = 32) respond to the vaccine compared to 90% of HD. Furthermore, MM patients' antibody titers were significantly lower (< 120 IU/L) compared to > 5000IU/L in HD. **Conclusions:** All together, these results show that in MM patients, vaccine-responsive populations of B cells are reduced, with fewer mature B cells with limited repertoires in GC to fight against acute infections, and with a high number of dysregulated regulatory B cells. These results indicate that compromised B cell functionality in MM patients could impact therapeutic outcome. Research Sponsor: U.S. National Institutes of Health.

A phase 1 study of belantamab mafodotin in combination with standard of care in newly diagnosed multiple myeloma: An interim analysis of DREAMM-9. *First Author: Saad Zafar Usmani, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Belantamab mafodotin (belamaf) is a B-cell maturation antigen-binding antibody-drug conjugate that eliminates myeloma cells via direct cell killing and anti-myeloma immune responses. DREAMM-9 (NCT04091126) is an ongoing Phase 1, randomized, dose and schedule evaluation study. It aims to evaluate belamaf plus bortezomib, lenalidomide, and dexamethasone (VRd) in adult patients (pts) with transplant-ineligible (TI) newly diagnosed MM (NDMM) and to establish the recommended dose for future development of belamaf combination therapies in the 1st-line setting. Herein, we report updated interim-analysis data. **Methods:** Belamaf dose cohorts (Co1–7) are shown in the Table. VRd was given every 3 weeks (Q3W) until cycle 8, and Rd Q4W thereafter. Following safety data from Co2–5, Co6–7 were opened in parallel (randomized 1:1) and have shorter follow-up (Table). Safety was the primary endpoint; efficacy and tolerability were secondary endpoints. Minimal residual disease (MRD) was assessed by next-generation sequencing (10⁻⁵). **Results:** As of data cutoff (Oct 20, 2022), 93 pts were treated across Co1–7. Median age (range) was 73 (51–88) years, 55% of pts were male, and 84% were white. The most commonly reported non-ocular adverse events (AEs) across all Co were thrombocytopenia (46%), constipation (36%), diarrhea (34%), and peripheral sensory neuropathy (31%). Overall, belamaf-related Grade ≥3 AEs occurred in 35% of pts and led to belamaf dose reductions in 7% and dose delays in 63% of all treated patients. Grade ≥3 ocular AEs (keratopathy and visual acuity [KVA] scale) occurred in 53% of all pts and led to dose reductions in 12% and dose delays in 52% of overall pts. Fatal AEs occurred in 7 pts, all unrelated to study treatment. Efficacy results and ocular AEs are summarized in the Table: 100% of pts responded in Co1 (1.9 mg/kg Q3/4W) and Co3 (1.9 mg/kg Q6/8W). Median time to very good partial response or better (≥VGPR) ranged from 2.1 to 3.1 months (mo) across cohorts. Highest MRD negativity (MRD-I) rates (≥VGPR) were seen in Co1 (83%) and Co3 (67%). **Conclusions:** This updated interim analysis demonstrates that belamaf plus VRd has no new safety signals and provides early and deep anti-myeloma responses in pts with TI NDMM, with high MRD-I rates. Clinical trial information: NCT04091126. Research Sponsor: GSK (209664).

Final results of pilot trial to evaluate anti-PD1 and 8 Gy in 1 fx for relapsed refractory multiple myeloma. *First Author: Mohammad Khurram Khan, Emory University, Atlanta, GA*

Background: Single agent Immune-Checkpoints, such as Anti-PD1, have not been successful. A pilot phase 1, 2 trial (NCT03267888) was conducted to see if radiotherapy (RT) and anti-PD1 (Pembrolizumab) could provide early signals of safety and response. **Methods:** Inclusion criteria included patients > 18 years of age, ECOG 0-1, able to give informed consent, have relapsed/refractory myeloma, and have ≥1 osseous and/or extra-osseous lesion that could undergo RT. Patients had to be candidates for anti-PD1 based on organ function testing, have measurable disease per International Myeloma Working Group Criteria (IMWG), and/or have progressive disease on serial staging PET/CT. IRB approval was obtained. RT (8 Gy in 1 fx) was given on day 0, cycle 1 followed by pembrolizumab (200 mg/kg iv on day 2 or 3, then every 3 weeks +/- 7 days) for 2 years or until progression. Primary endpoint was toxicity. Secondary endpoints were IMWG response, abscopal response, overall survival (OS), and immunological changes on serial blood collections. Patients were assessed at 3, 6, and 12 months for progression free survival (PFS) using IMWG and serial PET/CT scans. Patients with stable disease were continued on the trial. Patients that progressed were censored. Standard statistical analysis was performed, and included Kaplan-Meier to estimate OS and PFS. **Results:** From June, 2018 until October, 2021, 32 patients were screened and 25 were enrolled. Of the enrolled patients, 76% were Caucasian, 64% had ECOG 1, and the mean age was 60 years. Prior to enrollment, the median number of prior lines of therapy that a patient had filed was 5.0 (range: 2 – 11). There was no grade 2 or higher radiation related toxicity within the irradiated volume using CTCAE 4.0. Only one case of ≥ grade 3 (fevers) pembrolizumab-related toxicity was noted. Abscopal response, defined as improvement of a non-targeted lesion, was noted in 5 of 25 patients (20%). IMWG showed robust reduction in the paraproteins and other myeloma labs, suggesting response to radiotherapy and anti-PD1. A total of 8 patients showed response. Of those responding patients, 5 were post CarT cell patients, suggesting that the most benefit may be in post CarT cell patients. None of the post CarT cell patients were noted to have cytokine release syndrome and/or neurotoxicity. Of the responding patients, some of these were associated to have a robust CD 8 T cell activation. The 6 and 12 month PFS for the entire cohort was 31.8% and 22.7%, respectively. The 6 and 12-month OS for the entire cohort was 68% and 64%, respectively. Those that were post CarT, there was a higher 6 month PFS (50%) and OS (71.4%). **Conclusions:** Combination therapy of single-fraction, low-dose radiation therapy with pembrolizumab appears to be safe and shows early promise of efficacy in MM pts progressing following CarT therapy. Larger trials are warranted in the relapsed/refractory myeloma patients. Clinical trial information: NCT03267888. Research Sponsor: Merck Pharmaceutical.

Changing spectrum of infection with BCMA and GPRC5D targeting bispecific antibody therapy in patients with relapsed refractory multiple myeloma (RRMM). *First Author: Abhishek Janardan, Medical College of Wisconsin, Milwaukee, WI*

Background: There is a paucity of granular data on infection risk with bsAb targeting BCMA and GPRC5D in RRMM. **Methods:** We identified and followed 80 patients treated with bsAb therapy at 3 institutions in early-phase clinical trials between 2019 and 2022. Baseline demographic, disease and infection-specific variables were collected from the beginning of treatment to the last follow-up or 3 months after the study exit. **Results:** A total of 86 treatment courses were included, 56 patients received BCMA bsAb, 15 GPRC5D bsAb combination with CD38MoAb + / - IMiD (GPRC5Dc), and 15 GPRC5D bsAb monotherapy (GPRC5Dm). The median age was 70 (45-91) years and 48% (n = 41) were females. Racial/ethnic minorities accounted for 27% (n = 24) of patients included. A total of 117 infections were observed, 89 in the BCMA group, 24 in the GPRC5Dc group and 4 with GPRC5Dm. The infection rate per 100 days in recipients of BCMA bsAb and GPRC5D bsAb were 0.56 and 0.40 (p = 0.34), respectively. There was a greater incidence of high-grade infections (≥ grade 3) with BCMA bsAb treatment compared to GPRC5D bsAb (p = 0.01). Grade 5 events were observed in 8% (n = 7) of patients treated with BCMA bsAb compared to none with GPRC5D bsAb. The proportion of bacterial, viral, and fungal infection in the BCMA group were 56% (n = 50), 37% (n = 37), and 7% (n = 6) respectively and that in GPRC5D group were 46% (n = 13), 43% (n = 12), 11% and (n = 3) respectively. Of the infections during BCMA bsAb therapy, 76% (n = 67) required hospitalization compared to 54% (n = 15) with GPRC5D bsAb (p = 0.02). At 18 months, the cumulative incidence of all-grade infection in the BCMA and GPRC5D group were 72% and 47%, respectively (p = 0.05). The cumulative incidence of ≥ grade 3 infection at 18 months was higher at 60% with BCMA bsAb compared to 29% with GPRC5D bsAb (p = 0.01). The cumulative mean number of recurrent infections by 18 months with BCMA bsAb was 3.2 (95% CI 2.33-4.58) and 1.4 (95% CI 0.77-2.60) with GPRC5D bsAb (p = 0.25). In multivariate analysis, the use of BCMA bsAb, GPRC5D combination therapy and prior infections with bsAb therapy was associated with a significantly higher risk of all-grade and grade ≥3 infections. **Conclusions:** There is a significant risk of infections with bsAb therapy in RRMM with higher cumulative incidence of infection, higher grade infection and infections that require hospitalization with BCMA bsAb compared to GPRC5D bsAb. There were seven grade 5 events noted, all in patients treated with BCMA bsAb. Additionally, GPRC5D combination therapy with CD38MoAb +/- IMiDs conferred a higher risk of infections compared to GPRC5D monotherapy. Research Sponsor: None.

Poster Discussion Session

Analysis of infections and parameters of humoral immunity in patients (pts) with relapsed/refractory multiple myeloma (RRMM) treated with talquetamab (tal) monotherapy in MonumenTAL-1. *First Author: Paula Rodríguez-Otero, Clínica Universidad de Navarra, CIMA, CIBERONC, IDISNA, Pamplona, Spain*

Background: Infection, a key complication of MM, may be due to patient, disease, or treatment-related factors. Immunotherapies that impact normal immune cells may increase risk of infection. Tal, a bispecific antibody with clinical benefit in pts with RRMM, targets G protein-coupled receptor family C group 5 member D (GPCR5D), a protein of unknown function with significantly higher expression on malignant versus normal plasma cells. We report the infection profile and immune function with tal in the phase (ph) 1/2 MonumenTAL-1 study (NCT03399799/NCT04634552). **Methods:** Pts had RRMM, were intolerant to/progressed on established therapies (ph 1), or had ≥ 3 prior lines of therapy (ph 2; ≥ 1 proteasome inhibitor/immunomodulatory drug/anti-CD38 antibody). Subcutaneous tal was given at 0.4 mg/kg QW or 0.8 mg/kg Q2W. Infections (graded by CTCAE v4.03) were treated per local guidelines. B-cell subpopulations and IgG levels were assessed from whole blood and serum samples, respectively. **Results:** We evaluated 339 pts on tal QW or Q2W, of whom 51 had prior T-cell redirection therapy (pTCRT); infection rates are shown in the table (median follow-up, 15.9, 10.1, and 13.1 mo, respectively). New-onset infections were most prevalent during cycles 1–2. Grade (gr) 3/4 infections observed in >2 pts were pneumonia (3.5%) and UTI (2.1%) on tal QW; pneumonia (2.1%) and COVID-19 (2.1%) on tal Q2W; and pneumonia (5.9%) with pTCRT. Opportunistic infections were observed in 3.5%, 4.1%, and 5.9% of pts, respectively. Less than 1.5% of pts died from infections: COVID-19 pneumonia (n=2) and one each due to septic shock, fungal sepsis, and unknown etiology. Hypogammaglobulinemia rates by IgG values were 64.3% (tal QW), 65.5% (tal Q2W), and 70.6% (pTCRT); IVIg use was 14.7%, 12.4%, and 15.7%, respectively. CD19+ B-cell levels were stable, and there was a trend toward increased non-clonal IgG over time. **Conclusions:** Roughly 20% of pts had gr 3/4 infections on tal (most frequently cycles 1–2), with low rates of opportunistic infections, discontinuation, and death. Infection rates, particularly rates of fatal infections, appear lower with tal than with BCMA-targeted T-cell-based therapies. A trend toward increased non-clonal IgG suggests potential recovery of humoral immunity accompanies rapid, deep, and durable responses to tal. These results distinguish tal as an important emerging therapy for RRMM. Clinical trial information: NCT03399799, NCT04634552. Research Sponsor: Janssen Research & Development, LLC.

Treatment patterns for extramedullary multiple myeloma and outcomes with CAR-T therapy and bispecific antibodies. *First Author: Saurabh Zanwar, Mayo Clinic, Rochester, MN*

Background: Extramedullary Multiple Myeloma (EMM) is an aggressive entity with a dismal prognosis. Immune effector therapies (IETs), including chimeric antigen receptor T-cell (CAR-T) therapies and bispecific T-cell engaging antibodies (BsAb), have demonstrated excellent efficacy in relapsed/refractory MM with limited data for efficacy in EMM. Here, we report the treatment outcomes for patients with EMM. **Methods:** We identified 299 patients with EMM diagnosed between 01/01/2000 and 12/31/2021 after excluding solitary plasmacytomas, paraneoplastic MM and primary plasma cell leukemia. The IMWG criteria were used for response definition. **Results:** Of the 299 patients, 204 (68%) patients had secondary EMM (sEMM) and 95 (32%) patients had primary EMM (pEMM). For sEMM (n=204), the median progression free survival (PFS) with initial therapy was 2.9 (95% CI: 2.4-3.2) months. Initial treatment strategies for sEMM were heterogeneous and demonstrated in the table; 44% patients achieved $\geq$ partial response (PR) with initial treatment for sEMM. The median PFS in patients with $\geq$ PR was 5.8 (95%CI: 4.5-6.9) months vs 1.8 (95%CI: 1.4-2; $p < 0.0001$) months for $<$ PR. For patients with pEMM (n=95), the median PFS was 12.9 (95% CI: 6.7-18) months; the median PFS was 17.4 (95%CI: 12.9-25.4) months for patients with $\geq$ PR versus 1 month (95%CI: 0.8-2) in patients with $<$ PR. Thirty patients (all sEMM and triple class refractory) were treated with IET after development of EMM: 18 with BCMA-directed CAR-T, 10 with BsAbs, and 2 with both CAR-T and BsAbs. In patients receiving CAR-T therapy, 75% (15/20) achieved $\geq$ PR with 40% (n=8) achieving MRD negative (by flowcytometry) complete response. Fifteen (75%) patients receiving CAR-T had progressive disease (PD); 7 with systemic and EMM PD and 4 patients each with isolated EMM or systemic PD. The median PFS for patients treated with CAR-T was 4.9 months [3.1- not reached (NR)]. Among patients achieving a $\geq$ PR with CAR-T, the median PFS was 5.8 (95%CI: 4.7-NR) months vs 1.4 months [95%CI: 0.8-NR], $p < 0.001$ for $<$ PR. Among patients treated with BsAbs (10-BCMA, 1 each against FcRH5 and GPRC5D), 33% (4/12) achieved a $\geq$ PR. Ten (83%) patients had PD on BsAb; 8 with both EMM and systemic PD and 1 patient each with isolated EMM or PD. The median PFS with BsAb was 2.9 months (95%CI: 2.2-NR). **Conclusions:** Patients with EMM continue to have dismal outcomes with conventional therapies. High response rates were noted with CAR-T therapy, but these tend to be short-lived. Research Sponsor: None.

PFS with initial treatment for secondary EMM.

Groups	n	Median PFS (95%CI), months	P value
Proteasome Inhibitor (PI) plus IMiD based combination without CD38 antibody (Ab)	24	2.2 (1.9-5.2)	0.078

Busulfan, melphalan, and carfilzomib (BuMelCar) conditioning for autologous stem cell transplant (ASCT) in multiple myeloma: Phase I/II data. *First Author: Joseph Allan Norton, Loyola University Medical Center, Maywood, IL*

Background: Melphalan-200 high dose chemotherapy for ASCT has been the standard of care for multiple myeloma (MM) for over 30 years. Newer combination regimens such as Busulfan and Melphalan (BuMel) have demonstrated improved progression free survival (PFS) but with increased transplant related morbidity including mucositis and infections. Our group previously demonstrated that adding a proteasome inhibitor (bortezomib) to BuMel further increased PFS with mucositis ameliorated by Palifermin. Building on this effectiveness, we added carfilzomib to the BuMel backbone in a Phase I/II manner focused on safety and initial effectiveness of this novel regimen. **Methods:** This phase I/II open-label dose-escalation/expansion study (NCT03795597) enrolled patients with relapsed or high risk first remission MM. Patients received Busulfan over 4 days at a target total AUC of 20,000 mM-min followed by melphalan at 140mg/m². Patients received 4 total doses of IV carfilzomib, 2 before melphalan and 2 after, with the final 2 doses escalated based on toxicity. Palifermin was given on days -11, -10, 0, and +1. Once MTD was determined, 10 more patients were treated at that level. Primary objective was safety and secondary outcomes were response to treatment at day 100 including MRD, engraftment kinetics, PFS, and OS. **Results:** Patients were predominantly male (79%) with median age 60.95 years. Median KPS was 80 and median HCT-CI was 2. The carfilzomib MTD was 36 mg/m². One SAE of grade V ischemic colitis was seen at the 45 mg/m² dose level. Toxicity at 36 mg/m² yielded a similar pattern to our prior bortezomib containing regimen with grade 1 NSVT in 2 patients and hypertension in another. With a median follow up of 22 months, only 1 of the 13 MTD patients has progressed at 33mo. 2-year PFS and OS are both 100%. Analysis at D+100 showed 69% of MTD patients were MRD negative regardless of genetics. **Conclusions:** This novel BuMelCar ASCT regimen is safe and tolerable and appears to lead to a high % of MRD negative disease at D+100, which other studies correlate to a high PFS at 2 years. A comparison study with mel 200 is warranted to test whether BuMelCar can improve transplant outcomes especially in high-risk patients. Clinical trial information: NCT03795597. Research Sponsor: Amgen.

Plinabulin to shorten neutropenia and improve quality of life peri-autologous hematopoietic cell transplant. *First Author: Gunjan L. Shah, Adult Bone Marrow Transplant Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Plinabulin is a selective immunomodulating microtubule-binding agent, which prevents chemotherapy induced neutropenia (CIN) via a mechanism of action different from that of G-CSF analogues. It has been studied for CIN and anti-solid tumor activity in phase 3 trials. To decrease the period of myelosuppression and obligate neutropenia after high dose melphalan with autologous hematopoietic stem cell transplantation (AHCT) for patients with multiple myeloma, we studied the addition of plinabulin to standard growth factors. **Methods:** To achieve the primary objective of reducing the duration of absolute neutropenia post AHCT, 40mg of intravenous plinabulin was given 1-3 hours after stem cell infusion (Day 0) with pegfilgrastim on Day +1 in this pilot trial (NCT05130827). Secondary objectives include the safety, tolerability, and toxicity profile of plinabulin in combination with pegfilgrastim, neutrophil and platelet engraftment rate, disease response, progression free and overall survival, patient reported outcome (PRO) assessment of symptom burden, and plinabulin pharmacokinetic profiling. Exploratory objectives include transfusion requirements, phenotypic characterization of neutrophil population through day 30, and analysis of cytokine levels early post AHCT. **Results:** Between January 2022 and February 2023, 15 patients with median age of 64 (range 54-74) and 33% female received plinabulin after melphalan 140 (n = 4) or 200mg/m² (n = 11). Median CD34+ cells/kg infused was 4.12 x 10⁶ (range 2.18 – 7.85). Half of the patients had hypertension immediately after the plinabulin infusion, which is a known toxicity and resolved within a few hours. Median WBC on Day 0, 1, and 2 was 7.67(3.6 – 11.5), 5.2 (3.2 – 13.6), and 17.1 (5.1-59.1), respectively. Of the 14 patients who have engrafted to date, median time to ANC $> 0.5 \times 10^9$ cells/L was 11 days (range 9-16) with median days from AHCT to ANC < 0.5 of 5 days (range 5-6). The median number of days of ANC < 0.1 and < 0.5 were 2 (range 1-5) and 5 days (range 4-9), respectively. For the 7 patients who had a fever, the median time to fever was 8 days from AHCT (range 8-12), and all except one were peri-engraftment. Median length of stay was 17 days (range 15-21). Median pRBC and platelet transfusions were 0 (range 0-3) and 3 (range 0-11), respectively. **Conclusions:** Plinabulin appears well tolerated without additional major toxicities post AHCT and provided a high WBC on Day +2 and decreased rate of neutropenic fever. Plinabulin PK, quality of life data, and PROs will be presented. Adjusting the schedule of plinabulin to later post AHCT pre engraftment may further shorten the duration of neutropenia using this novel mechanism of action. Clinical trial information: NCT05130827. Prognostic value of month 1 bone marrow and PET MRD status in CAR-T therapy for myeloma. *First Author: Radhika Bansal, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Minimal residual disease (MRD) is prognostic for survival in multiple myeloma (MM). MRD is usually assessed in the bone marrow (BM) by flow cytometry or NGS. MRD by FDG PET/CT provides a global representation of the tumor burden, including response assessment of extramedullary disease. We examined MRD status in MM pts using both BM and PET/CT at Mayo Clinic. **Methods:** Medical records were reviewed retrospectively for MM pts who received CAR-T between 4/2018 and 12/2022. All PET/CT scans were assessed by radiologists. BM MRD was assessed by flow cytometry with a sensitivity of 10⁻⁵. Progression-free survival (PFS) and overall survival (OS) were analyzed by Kaplan-Meier method. **Results:** Among the 157 CAR-T pts, including 89 pts who received FDA-approved CAR-T, median age was 63 years, 59% (92/157) were males, 42% (66/157) had high risk cytogenetics with median of 5 prior lines of therapy, 36% (57/157) had plasmacytoma. Incidence of CRS was 83%, 5% grade ≥ 3 CRS. Incidence of ICANS was 19%, 4% grade ≥ 3 ICANS. CR/sCR rate was 37%. One hundred and thirty-seven pts (87%) had evaluable BM at month (mo) 1, 85% (117/137) were BM MRDneg at mo 1. Baseline demographics were comparable between the two groups except age, % BM plasma cells and use of bridging therapy. Among the MRDneg pts, CR/sCR rate was 44% (51/117) and 95% (111/117) had sFLC below normal. At median follow-up of 13.8 months, median PFS among pts with BM MRDneg at 1 mo was 12 mo (95% CI: 11, 30) vs 3 mo (95%CI: 2, 7) for BM MRDpos (p<0.001). Median OS among pts with BM MRDneg at 1 mo was 34 mo (95% CI: 24, NR) vs 22 mo (95%CI: 7, NA) for BM MRDpos (p<0.01). At month 1, 112 pts had both BM and PET/CT assessments available, 64/112(57%) were both BM MRDneg/PET MRDneg, 38/112 (34%) were MRDneg for either BM or PET and 10/112 (9%) were positive for both BM and PET (MRDpos/PET MRDpos). Baseline demographics except age were comparable between the 2 groups (Table). Rate of conversion from MRDpos to MRDneg was low. Rate of sustained BM and PET MRDneg at mo 12 was 44% (8/18). The median PFS and OS for BM MRDneg/PET MRDneg was significantly longer as compared to others (Table). **Conclusions:** Achieving FLC below normal, BM MRDneg and PET MRDneg at 1 month, regardless of IMWG response at that time, is prognostic for both PFS and OS in MM pts receiving CAR-T. Failure to achieve any of these confers poor prognosis. Research Sponsor: None.

Updated OS of patients with AL amyloidosis after CAEL-101. *First Author: Michael Sang Hughes, Columbia University Medical Center, New York, NY*

Background: Morbidity and mortality remain high in immunoglobulin light chain (AL) amyloidosis due to organ involvement despite hematologic remission. Few anti-amyloid fibril therapies for AL amyloidosis exist. We previously published the results of the phase 1a/1b study of CAEL-101 in AL amyloidosis showing significant improvement in organ response rates.¹ We report long-term outcomes. **Methods:** Patients enrolled in NCT02245867 with relapsed/refractory AL amyloidosis received in phase 1a, a one-time dose-finding CAEL-101 infusion and in phase 1b, 4 weekly CAEL-101 infusions with preplanned dose escalation. Patients were evaluated for organ response for 12 weeks after last infusion. We extracted clinical, laboratory, and pathology data regarding clinical course beyond 12 weeks after last treatment. We performed a review of all AL amyloidosis patients at our center not treated with CAEL-101 1/01/2012-12/30/19 as clinical comparisons. **Results:** 22 patients were enrolled in CAEL-101. 5 patients were treated in both phase 1a and phase 1b. With median follow-up of 81.3 months (IQR 60.4-87.7), long term follow-up data are available for 19/22 patients. 5 patients died during long term follow-up: 3 from progressive AL amyloidosis; 1 from organ transplantation complication; and 1 from venous thromboembolism sequelae. Among patients with organ data available, 10/17 had hematologic progression and received next line therapy. 5/17 patients had organ progression. All patients with organ PD had previous/concomitant hematologic PD. Median OS was not reached; median organ PFS was 93.3 months (38.9-NR). No delayed adverse events occurred. Comparison with historical control groups revealed trends toward improved OS: HR 0.42 (0.09-1.81 p=0.23) in all comers AL amyloid controls, and HR 0.20 (0.03-1.16 p=0.07) in cardiac controls. Kaplan-Meier analysis and Cox regression were performed. **Conclusions:** Patients with relapsed/refractory AL amyloidosis who received a low cumulative amount of the novel anti-amyloid CAEL-101 in a phase 1a/1b study had lengthy overall and progression-free survival compared to historical controls. Patterns of organ progression after initial response may reflect intrinsic differences in organ vulnerability. The CAEL101-301 and CAEL101-302 phase 3 clinical trials are underway to confirm these findings. Reference: 1. CT103A, a novel fully human BCMA-targeting CAR-T cells, in patients with relapsed/refractory multiple myeloma: Updated results of phase 1b/2 study (FUMANBA-1). *First Author: Chunrui Li, Department of Hematology, Tongji Hospital of Tongji Medical College, Huazhong University of Science, Wuhan, China*

Background: CT103A, which is designed with a fully human BCMA-specific CAR structure, has shown sustained efficacy and durable safety in heavily pretreated relapsed and refractory multiple myeloma patients. Here, we report updated efficacy and safety data of its phase 1b/2 study (FUMANBA-1) with longer duration of follow-up. **Methods:** FUMANBA-1 is conducted in 14 centers in China. This study enrolled RRMM patients who received ≥ 3 lines of prior therapies containing at least a proteasome inhibitor and an immunomodulatory agent and were refractory to their last line of treatment. Patients who have progressed on previous BCMA CAR-T cell therapy were also included. All patients received a single infusion of CT103A at the dose of 1.0 x 10⁶ CAR-T cells/Kg. The objective is to evaluate the efficacy, safety and PK/PD of CT103A. **Results:** As of the September 9th, 2022, 103 patients [53.4% male; median age 58.0 years (range 39-70)] with RRMM received CT103A (17 in phase 1b; 86 in phase 2) with a median follow-up of 13.8 months (range 0.4 to 27.2). The treated patients had received a median of 4 (range 3-23) lines of prior therapy. 101 patients were evaluable for efficacy assessment. The median time to first response was 16 days (range 11-179). A 96% ORR was observed, with 74.3% ≥ CR. Median DOR and median PFS have still not reached. The 12-month PFS rate was 78.8% (95% CI: 68.6–85.97). For patients without prior BCMA CAR-T therapy (N = 89), ORR was 98.9% with 78.7% ≥ CR. For patients without prior BCMA CAR-T therapy and received CT103A for more than 6 months as of the cutoff date (N = 81), ORR was 98.8% with 80.2% ≥ CR. For patients with prior BCMA CAR-T cell therapy, 4/5 (80%) of those who achieved sCR still sustained sCR over 18 months post infusion. Of the 101 patients, 95% achieved MRD-negativity with a median time to MRD-negative of 14 days (range 13-185), and all patients with CR/sCR were MRD-negative. Furthermore, 82.4% (95%CI 70.90-89.72%) achieved sustained MRD negativity over 12 months. Since the previous publication in 64th ASH meeting, no new events of CRS and ICANS occurred. The most common ≥ grade 3 treatment-related AEs were still hematologic. The expansion of CT103A reached the median peak level of 87570.6 copies/μg gDNA at a median of 12 days. CT103A was still above lower limit of qualification (100 copies/μg gDNA) in 50.0% (28/56) patients at 12 months and 40.0% (4/10) patients at 24 months after infusion. In addition, only 20 of 103 patients (19.4%) with evaluable samples were detected to be positive for the anti-drug antibody. **Conclusions:** At a longer median follow-up of 13.8 months, CT103A achieved deep and long-lasting responses in heavily pretreated patients with MM. Furthermore, patients with prior BCMA CAR-T cell therapy who achieved sCR had sustained sCR over 18 months. CT103A demonstrated a favorable safety profile with no new risk observed with longer follow-up. Clinical trial information: NCT05066646. Research Sponsor: None.

Population pharmacokinetic-pharmacodynamic model of nirogacestat effects on B-cell maturation antigen in healthy subjects. *First Author: Todd Shearer, SpringWorks Therapeutics, Inc., Stamford, CT*

Background: B-cell maturation antigen (BCMA) is expressed on the membrane of normal plasma cells (PCs) and multiple myeloma (MM) cells and is the target of several investigational agents and approved products for MM treatment. Mechanistically, BCMA is cleaved from the cell surface by the enzyme gamma secretase, resulting in reduced levels of membrane-bound BCMA (mbBCMA) and release of soluble BCMA. Gamma secretase inhibitors (GSIs) have been shown to increase BCMA receptor density and potentiate the activity of several BCMA-targeted therapies in both clinical trials and *in vitro* studies. Although the effect of GSIs on BCMA receptor density has been well characterized *in vitro*, their effect on BCMA dynamics is incompletely understood in humans. This study sought to evaluate the pharmacodynamics (PD) of the GSI nirogacestat on mbBCMA in healthy subjects. **Methods:** A total of 23 healthy subjects were administered single doses of 50, 150, or 300 mg nirogacestat or multiple doses of 100 mg every 12 hours. Density of mbBCMA on PCs isolated from whole blood and bone marrow was measured by flow cytometry at baseline and 1, 2, 4, 8, 24, and 48 hours after single doses and 24 and 48 hours after the first dose in subjects receiving multiple doses. Nirogacestat serum concentrations were also measured at multiple time points to fully characterize the pharmacokinetics (PK). A population PK-PD model of the effect of nirogacestat on BCMA dynamics in humans was developed and used to simulate various administration dose levels and schedules to find an optimal nirogacestat regimen that continually increases mbBCMA over the dosing interval. **Results:** A 2-compartment model with linear absorption and elimination described serum nirogacestat in healthy subjects. A sequential PK-PD model that included an effect compartment and drug effect on mbBCMA cleavage rate described mbBCMA values. Simulations indicated that a 100-mg dose administered twice daily sufficiently maintained elevated and clinically relevant mbBCMA levels. Exposure and efficacy benchmarks from *in vitro* experiments and published clinical studies were used to contextualize simulations and hypothesize various dose and schedule scenarios to minimize dose of the BCMA-targeting therapy while maximizing BCMA potentiation. **Conclusions:** These results suggest that nirogacestat dose and schedule may have direct implications on the potentiation of BCMA-targeting therapies. Simulations suggest that the 100-mg, twice-daily nirogacestat dose results in elevated mbBCMA levels that could even allow for use of lower doses of BCMA-targeted agents while maintaining or improving efficacy. Study results along with this PK-PD model will be used to support nirogacestat dose and schedule in ongoing and planned studies in patients with MM. Research Sponsor: SpringWorks Therapeutics.

Measurable residual disease (MRD) and clonal diversity for multiple myeloma treatment monitoring. *First Author: Joaquin Martinez-Lopez, Departamento de Hematología, Hospital 12 de Octubre, Complutense University, CNIO, Madrid, Spain*

Background: MRD assessment is a known surrogate marker for survival in multiple myeloma (MM). However, some patients with non-detectable MRD, do relapse, and some MRD-positive patients with an extensive follow-up, do not relapse. Clonal diversity is defined as the number of unique Immunoglobulin (H, K, or L) sequences in each sample. Here, we present a single institution experience assessing MRD by NGS of Ig genes and the long-term impact of depth of response as well as clonal diversity on the clinical outcome of a large population of MM patients. **Methods:** 482 MM patients at University of California, San Francisco (UCSF) diagnosed from 2008 to 2020. Of them, 304 were newly diagnosed and 178 in ≥ 2 nd line. MRD was assessed in patients achieving VGPR or better by IMWG criteria. MRD assessment was performed by NGS (Adaptive Biotechnologies, Seattle, WA). PFS curves were plotted by the Kaplan-Meier method, and the log-rank test was used to estimate statistical significance. **Results:** 1098 MRD samples were analyzed. MRD was available at 3 time points for 118 patients. Median follow-up was 26m. Overall, 181 of 482 patients (38%) achieved MRD- ($< 10^{-6}$) on one or more samples. Clonal diversity was available in 87 of those patients. In the newly diagnosed group, 84 of 120 (39%), achieved MRD- at the level of 10^{-6} at least once. These patients had a prolonged PFS versus patients who were persistently MRD+ at different levels ($p > 0.0001$). Notably, patients achieving a MRD $< 10^{-5}$ have longer OS than those with MRD $> 10^{-5}$ ($p = 0.009$). Of the 178 patients who received therapy for relapsed disease, 64 achieved MRD- at 10^{-6} (36%) and PFS was also prolonged versus patients who remained MRD+ (44 m v NR, $p = 0.03$). Then, we analyzed the effect of repeated MRD monitoring on PFS. Three categories were defined: (A) patients with ≥ 3 MRD- samples, (B) patients with continuously declining detectable clones, and (C) patients with a stable number of clones. Groups A and B had a more prolonged PFS than group C (NR vs NR vs 38m, $p < 0.0001$). Finally, we analyzed clonal diversity at the moment of maximum response: patients MRD+ who have not relapsed have higher clonal diversity than MRD+ patients who relapsed. Moreover, patients who were MRD- who have not relapsed have higher clonal diversity than patients who were MRD- who did relapse. This was also observed independently for the 3 receptors analyzed (IgH $p = 0.026$; IgK $p = 0.036$ and IgL $p = 0.036$). Patients with more than 66000 IgH unique sequences at the moment of maximum response had a prolonged PFS ($p = 0.05$). **Conclusions:** MRD assessment in a real-world setting has the same predictive power as that seen in clinical trials even on OS. MRD dynamics can accurately predict disease evolution and drive clinical decision-making. Clonal Diversity could complement MRD assessment in the prediction of the outcome in MM. Poster Session

Phase 2 study of abatacept, ixazomib, and dexamethasone in patients with relapsed/refractory multiple myeloma. *First Author: Khalid Shalaby, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Multiple myeloma (MM) usually responds to induction therapy but relapses with therapy-resistant disease. CD28 expressed on MM cells is correlated with worse outcomes. Bone marrow stromal cells expressing CD28 ligands CD80 and/or CD86 are cellular partners in the MM niche transducing a pro-survival signal to MM cells contributing to therapy resistance in relapsed disease. We have previously shown in vitro and in vivo preclinical studies that blocking the pro-survival CD28 activation on MM cells with abatacept (CTLA4 IgG binding to CD80/CD86 and blocking engagement to CD28) reverses chemotherapy resistance and re-sensitizes MM cells to drugs they previously were resistant to. **Methods:** We tested efficacy and safety of combining Abatacept with the proteasome inhibitor (PI) Ixazomib (Ixa) and Dexamethasone (Dex) in patients with MM who had relapsed (or primary refractory) disease following treatment with first line PI Bortezomib based regimen. Previous studies found that Ixa/Dex alone only had an 11% overall response rate (ORR) and 11% Clinical Benefit Rate (CBR) in patients with prior Bortezomib exposure. In our trial, patients with MM cells positive for CD28 or CD86 by flow cytometry or immunohistochemistry in any proportion were eligible. From September 11, 2018 to August 5, 2021, 15 patients received Abatacept loading dose cycle 1 day 1 followed by 125 mg subcutaneously on day 2 and then weekly. Patients received Ixa 4 mg on days 1, 8, and 15 and Dexamethasone 40 mg weekly of a 28-day cycle. The primary endpoint was ORR (partial response (PR) or better) according to International Myeloma Working Group criteria. Secondary end points were toxicity profile, progression-free (PFS), and overall survival (OS). **Results:** Median age was 62.8 years (range 50-83.9). Ten (66.6%) patients received prior autologous stem cell transplant. The ORR was 33.33% (90% CI 16.58%-54.46%) (one-sided Binomial exact test 0.4845). Complete remission (CR) was achieved in 6.7%, and 26.7% achieved PR with 53.3% of patients having stable disease (SD). Median time to best response among patients with CR and PR was 8.9 weeks (95% CI 4–21). Median time on treatment was 23 weeks (95% CI 12.143-48.143) for all patients and 52.5 weeks (95% CI 39.286-68) for patients with response. One-year PFS was 45% (90% CI 21%-66%), median PFS 12 months (90% CI 5.7-25.9) and 1-year OS 100%, median OS not reached. Two grade 3 treatment emergent adverse events (TEAE) (diarrhea and low platelets) occurred requiring hospitalization. Grade 1/2 GI TEAEs were most common. No grade 3/4 treatment related infections were observed and 2 grade 3 infections occurred. **Conclusions:** Despite prior exposure to Bortezomib, one third of patients had response to Ixa with Abatacept and Dex. Patients with response stayed on treatment for almost 1 year on average with limited AEs. Most patients on trial gained benefit with a clinical benefit rate (CR+PR+SD) of 86.66%. Clinical trial information: NCT03457142. Research Sponsor: Bristol-Myers Squibb.

Long-term outcomes with isatuximab-carfilzomib-dexamethasone (Isa-Kd) in relapsed multiple myeloma patients with 1q21+ status: Updated results from the phase 3 IKEMA study. *First Author: Thierry Facon, Department of Hematology, Lille University Hospital, Lille, France*

Background: Gain or amplification of 1q21 (1q21+, ≥ 3 copies), a chromosomal abnormality frequently observed in multiple myeloma (MM), has a negative impact on prognosis due to its potential involvement in resistance to MM therapy and disease progression. In the prespecified, long-term analysis of the Phase 3 IKEMA trial in relapsed MM patients (pts), treatment with Isa-Kd showed continued, significant improvement in progression-free survival (PFS) vs Kd (HR 0.58; 95.4% CI 0.42–0.79), with meaningful increase in depth of response (complete response or better [$\geq$ CR]) 44.1% vs 28.5%; minimal residual disease negativity [MRD-] 33.5% vs 15.4%, MRD- $\geq$ CR 26.3% vs 12.2%), and a manageable safety profile. In this subgroup analysis of IKEMA, we evaluated efficacy of Isa-Kd in pts with 1q21+ status (with or without high-risk chromosomal abnormalities [HRCAs]) and related subgroups— isolated 1q21+ (≥ 3 copies without HRCAs), gain(1q21), amp(1q21) — at long-term follow-up (44.2 months). **Methods:** Pts with 1–3 prior lines of therapy were randomized to Isa-Kd (n=179) or Kd (n=123). Assessment was prespecified (at 30% cut-off by FISH) for 1q21+ status as ≥ 3 copies, gain(1q21) as 3 copies, and amp(1q21) as ≥ 4 copies. **Results:** In the Isa-Kd and Kd arms, 41.9% and 42.3% of pts had 1q21+ status, 26.3% and 25.2% isolated 1q21+, 24.0% and 30.1% gain(1q21), 17.9% and 12.2% amp(1q21) respectively. Greater PFS benefit was achieved with Isa-Kd vs Kd in pts with 1q21+ status (HR 0.58, 95% CI 0.37–0.92) and in pts with isolated 1q21+, gain(1q21), or amp(1q21) (Table). Responses deepened by adding Isa to Kd, with increased rates of very good partial response or better ($\geq$ VGPR), $\geq$ CR, MRD-, and MRD- $\geq$ CR (Table). **Conclusions:** 1q21 abnormalities affect PFS in MM pts. Our results at long-term follow-up of pts with 1q21+ status (with or without HRCAs) in the IKEMA study continue to show greater PFS benefit and deeper responses with Isa-Kd than Kd, consistent with the overall population and earlier 1q21+ subgroup interim analyses. Thus, they support Isa-Kd as an effective treatment option also for difficult-to-treat, 1q21+ pts with relapsed MM. Clinical trial information: NCT03275285. Research Sponsor: Sanofi.

Baseline and early post-infusion biomarkers associated with optimal response to idecabtagene vicleucel (ide-cel) in the KarMMA-3 study of triple-class-exposed (TCE) relapsed and refractory multiple myeloma (RRMM). *First Author: Julia Piasecki, Bristol Myers Squibb, Princeton, NJ*

Background: Ide-cel, a B-cell maturation antigen (BCMA) chimeric antigen receptor T cell therapy, significantly improved median progression-free survival (mPFS) and overall response rate (ORR) vs standard regimens (SRs) in patients (pts) with TCE RRMM in the KarMMA-3 study (NCT03651128; Rodríguez-Otero et al. *NEJM* 2023). Previous analyses in KarMMA-3 (Munshi et al. *NEJM* 2021) of pts with later-line (4L+) TCE RRMM identified low baseline (BL) levels and complete clearance of soluble BCMA (sBCMA, a measure of tumor burden) and early minimal residual disease (MRD) negativity as correlates of durable response to ide-cel. The current analysis explored the association between biomarkers and efficacy or severity of inflammatory adverse events of ide-cel in KarMMA-3. **Methods:** sBCMA levels were measured in blood samples collected from pts in KarMMA-3 at BL and regular intervals from treatment (tx) initiation until confirmed progression. MRD status was assessed in bone marrow aspirate (clonoSeq; 10^{-5} sensitivity) at 6 and 12 mo post infusion and reported in all pts, regardless of response. Biomarker analyses were based on pts who received ide-cel or ≥ 1 dose of SR. Post hoc analyses assessed correlations between biomarkers and efficacy endpoints or cytokine release syndrome (CRS) and investigator-identified neurotoxicity (iINT); associations of interest were identified using a ranked sum test and nominal P value < 0.05 . **Results:** Lower BL sBCMA levels were associated with higher ORR ($<$ partial response [PR] vs $\geq$ PR) in both tx arms (ide-cel, $P = 0.0223$; SR, $P = 0.0395$), indicating this may be agnostic of the BCMA-directed modality. Lower BL sBCMA was also associated with higher complete response (CR) rate ($<$ CR vs $\geq$ CR) in the ide-cel arm ($P = 0.0038$). Additionally, lower BL sBCMA levels in the ide-cel arm were associated with lower grade (gr) of CRS (gr 0–1 vs 2 vs ≥ 3 ; $P = 0.0022$) and iINT (gr 0–1 vs ≥ 2 ; $P = 0.0113$); however, overlapping ranges may limit predictive utility. Further analyses will be presented. In the ide-cel arm, landmark mPFS was longer in pts with undetectable versus detectable sBCMA at 2 mo post infusion (16.3 vs 5.2 mo; HR, 0.26) or at 6 mo (16.8 vs 9.6 mo; HR, 0.62). Furthermore, landmark mPFS was also longer in pts with MRD negativity versus pts with positive/indeterminate MRD status at 6 mo (17.2 vs 5.8 mo; HR, 0.288) or at 12 mo (13.8 vs 4.6 mo; HR, 0.121). **Conclusions:** BL sBCMA levels correlated with response and CRS and iINT grade in the ide-cel arm of KarMMA-3, potentially reinforcing the importance of management of BL tumor burden for optimal response to ide-cel. Early clearance of sBCMA at 2 mo, sustained clearance of sBCMA at 6 mo, and MRD negativity at 6 or 12 mo, regardless of clinical response, may be useful biomarkers for identifying pts likely to achieve a complete and durable response to ide-cel. Clinical trial information: NCT03651128. Research Sponsor: Celgene, a Bristol-Myers Squibb Company, and 2seventy bio.

Health related quality of life (HRQoL) in patients with triple-class-exposed relapsed/refractory multiple myeloma (TCE RRMM) treated with idecabtagene vicleucl (ide-cel) versus standard regimens: Patient-reported outcomes (PROs) from KarMMA-3 phase 3 randomized controlled trial (RCT). *First Author: Michel Delforge, University of Leuven, Leuven, Belgium*

Background: Patients (pts) with TCE RRMM have few treatment (Tx) options and poor HRQoL. Ide-cel, the first in class CAR T cell Tx for pts with TCE RRMM, improved PFS versus standard (std) regimens in the KarMMA-3 trial. We report the PRO results comparing the Tx arms. PROs provide further understanding of Tx benefit of ide-cel from the pts' perspective. **Methods:** KarMMA-3 (NCT03651128) is an open-label phase 3 RCT comparing the efficacy and safety of ide-cel with std regimens in pts with TCE RRMM, who had received 2–4 prior regimens. In addition to clinical endpoints, we evaluated the impact of ide-cel compared with std regimens on the changes in HRQoL, measured by the EORTC QLQ-C30, EORTC QLQ-MY20, and the EQ-5D-5L questionnaires. PROs were collected at baseline (screening), day of infusion and monthly from 2–24 months (mo) and thereafter every 3 mo. This interim analysis reports PROs through 20 mo. Comparisons were performed on least squares mean (LSM) changes from baseline over time between arms using constrained longitudinal data analysis (cLDA). **Results:** In total, 386 pts were randomized (ide-cel, 254; std regimens, 132). PRO compliance was high over time (> 80%). At baseline, PROs were similar between arms. LSM changes from baseline to 20 mo showed significant differences ($P < 0.05$), with effect sizes of 0.3–0.7, in favor of ide-cel for most domains, including global health status/QoL, cognitive functioning, fatigue, and pain (EORTC QLQ-C30); side effects of Tx (EORTC QLQ-MY20); and the EQ-5D-5L VAS. The difference in overall LSM change reached or exceeded the pre-specified between-groups minimal importance difference (MID) for improvement in most domains in favor of ide-cel (Table). **Conclusions:** Ide-cel showed statistically significant and clinically meaningful improvements in HRQoL, including key MM symptoms and functioning, for pts with TCE RRMM compared with std regimens. The PRO data for ide-cel expands upon the clinical outcomes observed in the KarMMA-3 trial. Clinical trial information: NCT03651128. Research Sponsor: Bristol Myers Squibb.

Durability of responses with biweekly dosing of teclistamab in patients with relapsed/refractory multiple myeloma achieving a clinical response in the majesTEC-1 study. *First Author: Saad Zafar Usmani, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Teclistamab is the first B-cell maturation antigen (BCMA) bispecific antibody approved for the treatment of relapsed/refractory multiple myeloma (RRMM) at a dose of 1.5 mg/kg weekly (QW) given subcutaneously. A less frequent dosing schedule offers added convenience and flexibility to patients, physicians, and caregivers. We evaluated the ability of patients to maintain their responses after transitioning from QW to every other week (Q2W) dosing schedules in the pivotal phase 1/2 MajesTEC-1 trial (NCT03145181/NCT04557098). **Methods:** Eligible patients had RRMM and received ≥ 3 prior lines of therapy including a proteasome inhibitor, immunomodulatory drug, and anti-CD38 antibody. Prior BCMA-targeted therapy was not allowed in this cohort. Patients received the recommended phase 2 dose (RP2D) of 1.5 mg/kg teclistamab QW, with the option to switch to Q2W dosing if patients achieved a confirmed partial response or better after ≥ 4 cycles of treatment (phase 1) or a confirmed complete response (CR) or better for ≥ 6 months (phase 2). Response was assessed per IMWG 2016 criteria. **Results:** As of Dec 9, 2022, 165 patients in the pivotal cohort had received teclistamab at the RP2D. Of 104 responders, 60 patients switched to Q2W dosing; 50 met the protocol-defined criteria for switching, and 10 switched who did not meet the criteria (4 due to adverse events [AEs]; 6 due to other reasons). Patients who switched had a median age of 64 years, 58% were male, 25% had high-risk cytogenetics, 7% had extramedullary plasmacytomas, and 3% had International Staging System stage III disease at baseline. Patients received a median of 4 prior lines of therapy, and 75% were triple-class refractory. At the time of switch, 49 (82%) patients achieved $\geq$ CR, and 11 (18%) had a very good partial response. Median time to switch from QW to Q2W dosing was 11.1 months (range, 3–20). At median 11.1-month (range, 2–24) follow-up since switching, the median duration of response from the date of switch was 20.5 months (range, 1–23), with 40/60 patients still in response and ongoing treatment. Of the remaining patients, 13/60 have progressed (median time from switch to progression not estimable), 2 discontinued due to AEs, 1 discontinued for other reason, and 4 died. Additional results will be presented. **Conclusions:** Overall, patients from the MajesTEC-1 study who transitioned from QW to less frequent Q2W dosing of teclistamab had sustained remission, with a median duration of response of 20.5 months from the date of switch. Clinical trial information: NCT03145181, NCT04557098. Research Sponsor: Janssen Research & Development.

Evaluation of prophylactic tocilizumab (toci) for the reduction of cytokine release syndrome (CRS) to inform the management of patients (pts) treated with teclistamab in MajesTEC-1. *First Author: Niels W.C.J. van de Donk, Amsterdam University Medical Center, Vrije Universiteit Amsterdam, Amsterdam, Netherlands*

Background: Teclistamab is the first BCMA $\times$ CD3 bispecific antibody approved for the treatment of relapsed/refractory multiple myeloma (RRMM). In MajesTEC-1, CRS occurred in 72.1% of pts treated at the recommended phase 2 dose (RP2D) of weekly teclistamab 1.5 mg/kg (50.3% grade [gr] 1; 21.2% gr 2; 0.6% gr 3), and was successfully managed using toci in 36.4% of pts ($\pm$ other interventions) without affecting response to teclistamab. Emerging data show that prophylactic administration of toci prior to first dose of bispecific antibodies reduces CRS incidence and severity, which may facilitate outpatient initiation of therapy. The current analysis includes the first prospective study of effects of prophylactic toci on incidence and severity of CRS with teclistamab. **Methods:** Eligible pts were aged ≥ 18 y with RRMM and had previously received a PI, IMiD, and anti-CD38 antibody. Pts received subcutaneous teclistamab (following 2 step-up doses) in a prospective exploratory cohort at the RP2D or in a fixed-dose cohort. Toci (single 8 mg/kg IV dose) was given ≤ 4 hours before the first teclistamab step-up dose. CRS was graded per Lee et al 2014 and managed per institutional guidelines. **Results:** 14 pts were included: median age 64 y (range 50–82); all pts had ECOG score ≤ 1 and ISS I/II; 91% had standard cytogenetic risk; 21% had extramedullary plasmacytomas; 31% had $\geq 30\%$ BMPCs; median 4 prior lines of therapy (range 2–7); 64% triple-class refractory. Median follow-up was 1.2 mo (range 0.2–4.6). CRS occurred in 4 pts (29%; no gr ≥ 3 CRS); 1 had a subsequent CRS event (table). Median time to onset was 2 d (range 1–3); median duration was 2 d (range 2–4); all events were managed with toci and resolved without teclistamab discontinuation. 7 of 14 pts had gr 3/4 neutropenia (consistent with the overall MajesTEC-1 population). 2/14 had a gr 3/4 infection. 2/14 had a neurotoxicity AE. Of the response evaluable patients, 4/7 responded. Cytokine and PK data in additional pts with longer follow-up will be presented to further inform pt management. **Conclusions:** A single dose of toci before teclistamab treatment appeared to reduce the incidence of CRS relative to the overall MajesTEC-1 study population with no new safety signals and no evidence of impact on response to teclistamab considering the short follow-up. Prophylactic toci has the potential to reduce CRS risk in pts with disease profiles suitable for outpatient dosing, reducing the burden of hospitalization during teclistamab step-up dosing. Clinical trial information: NCT03145181, NCT04557098. Research Sponsor: Janssen Research & Development.

Pt	CRS grade	Dose after which CRS occurred	Disease characteristics in pts with CRS
1	1	Step-up dose 1	40% BMPCs (biopsy); 0 plasmacytomas
2	2	Step-up dose 2	30% BMPCs (aspirate); 2 plasmacytomas
3	1	Step-up dose 2	70% BMPCs (biopsy); 0 plasmacytomas; 11.6% circulating plasma cells at baseline
4	2	Cycle 1 Day 1	80% BMPCs (biopsy); 0 plasmacytomas
4	2	Step-up dose 1

Tumor-intrinsic features associated with progression-free survival (PFS) in patients (pts) with relapsed and refractory multiple myeloma (RRMM) treated with idecabtagene vicleucl (ide-cel). *First Author: Nicholas Stong, Bristol Myers Squibb, Princeton, NJ*

Background: Ide-cel, a B-cell maturation antigen chimeric antigen receptor T cell therapy, has demonstrated frequent, deep, and durable responses in pts with RRMM in the KarMMA (NCT03361748), KarMMA-2 (NCT03601078), and KarMMA-3 (NCT03651128) trials. A previous analysis of KarMMA showed comparable efficacy of ide-cel across molecular high-risk/resistance (HR/R) features such as biallelic p53 inactivation, 1q amplification, t(4;14), and *CRBN* dysregulation, and identified a baseline gene expression pattern (PC4) associated with PFS (Martin N, et al. *Hemasphere* 2022;6:(S6):1452). We aim to identify additional genomic features associated with ide-cel efficacy in KarMMA and KarMMA-2, and evaluate samples from KarMMA-3 pts as an independent validation cohort. **Methods:** Transcriptional and genomic profiles were assessed at baseline in CD138+ cells from bone marrow from pts in KarMMA, KarMMA-2 cohort 1, and KarMMA-3. Gene copy number aberrations were evaluated for associations with response. Analyses were post hoc and exploratory, and a P -value, or false discovery rate (FDR), of < 0.05 was used to identify associations of interest. **Results:** In evaluable pts in KarMMA ($n = 70$), single copy number loss was observed at 2 loci that associated with PFS, a broad region across 14q ($n = 16$) and deletion at 1p31.2 ($n = 6$). These were generally independent and collectively represented 30% (21/70) of pts. Both were associated with shorter median PFS (mPFS) in KarMMA (cohort mPFS, 8.8 mo, $n = 128$; Munshi et al. *N Engl J Med* 2021;384:705-16) after FDR correction (del 14q, mPFS, 4.0 mo; del 1p31.2, mPFS, 2.3 mo). No pt with 1p loss achieved a best overall response (BOR) better than partial response. Pts with loss vs non-loss of 14q had similar BOR distribution, but poorer mPFS within each BOR (10.4 vs 29.7 mo for loss vs non-loss in pts with complete response/stringent complete response). Due to small sample size in KarMMA-2 cohort 1 ($n = 18$), these data were aggregated with those from KarMMA. When combined, previously described associations with HR/R features were maintained except for biallelic p53 inactivation, which showed a stronger association with shorter PFS in the aggregate dataset ($n = 83$, $P = 0.04$) than in KarMMA ($n = 65$, $P = 0.09$). KarMMA-3 ($n = 210$) analysis is ongoing and will be used as a validation cohort for these findings. Consistent trends for the association of the PC4 gene signature with PFS were observed in KarMMA-2 but were not statistically significant and limited by sample size. **Conclusions:** Two novel genomic HR/R features associated with PFS were identified using samples from KarMMA; validation is ongoing using samples from KarMMA-3. The PC4 gene signature was consistent in 2 RRMM cohorts. A modest association between biallelic p53 disruption and PFS emerged with increased sample size and will be studied in KarMMA-3. Pivotal phase 2 MonumenTAL-1 results of talquetamab (tal), a GPRC5DxCD3 bispecific antibody (BsAb), for relapsed/refractory multiple myeloma (RRMM). *First Author: Carolina D. Schinke, Myeloma Center, University of Arkansas for Medical Sciences, Little Rock, AR*

Background: Tal is a first-in-class BsAb targeting the novel antigen G protein-coupled receptor family C group 5 member D. In MonumenTAL-1 (NCT03399799/NCT04634552), tal showed promising efficacy and clinically manageable safety in patients (pts) with RRMM. We report pivotal phase 2 results in pts with and without prior T-cell redirection therapy. **Methods:** Eligible pts were intolerant to or progressed on established therapies (phase 1) or had ≥ 3 prior lines of therapy (LOT), including ≥ 1 proteasome inhibitor, ≥ 1 immunomodulatory drug, and ≥ 1 anti-CD38 antibody (phase 2). Pts received RP2Ds of SC tal 0.4 mg/kg QW or 0.8 mg/kg Q2W with step-up doses. CRS and ICANS were graded by ASTCT criteria; all other AEs were graded by CTCAE v4.03. Response was assessed by IMWG criteria. Data cut-off was Sep 12, 2022 for efficacy and Oct 19, 2022 for safety. Data will be updated for the meeting. **Results:** From the pivotal cohorts, 288 pts received tal 0.4 mg/kg QW (n = 143) or 0.8 mg/kg Q2W (n = 145), and 51 pts with prior T-cell redirection therapy received either dose. In the QW, Q2W, and prior T-cell redirection cohorts, respectively, median prior LOT was 5–6; 74%, 69%, and 84% were triple-class refractory and 29%, 23%, and 41% were penta-drug refractory; 15%, 11%, and 12% received prior belantamab. In the prior T-cell redirection cohort, 71% received CAR-T therapy, 35% received a BsAb, and 6% received both. In the pivotal cohorts, ORR was 74% (QW, 14.9 mo median follow-up [mF/U]) and 73% (Q2W, 8.6 mo mF/U), with very good partial response or better ($\geq$ VGPR) in 59% (QW) and 57% (Q2W). ORR was consistent across subgroups, including baseline ISS stage III disease, cytogenetic risk, number of prior LOT, and belantamab exposure. In pts with baseline plasmacytomas, ORR was 49% in both pivotal cohorts. In the prior T-cell redirection cohort, ORR was 63% (53% $\geq$ VGPR) at 11.8 mo mF/U. Median PFS was 7.5, 11.9 (61% censored), and 5.1 mo in the QW, Q2W, and prior T-cell redirection cohorts, respectively. Common AEs included CRS (79%, 75%, 77%), skin-related AEs (56%, 71%, 69%), nail-related AEs (54%, 53%, 61%), and dysgeusia (50%, 48%, 61%); most were grade 1/2 and clinically manageable. ICANS occurred in 11%, 11%, and 3% of pts. Infections occurred in 58%, 65%, and 71% (grade 3/4: 22%, 16%, 26%) of pts, with low rates of opportunistic infections. AEs resulted in dose reductions in 15%, 8%, and 10% of pts and discontinuation in 5%, 8%, and 6%. There were no tal-related deaths. Responders to tal had higher T cell counts and lower frequencies of exhausted T cells and CD38+ Tregs vs non-responders. **Conclusions:** Pivotal phase 2 tal data showed $> 70\%$ ORR in heavily pretreated pts with RRMM. High response rates were also seen in pts with prior T-cell redirection therapy. The safety profile was clinically manageable with low rates of high-grade infections and tal discontinuations. Clinical trial information: NCT03399799, NCT04634552. Research Sponsor: Janssen Research & Development, LLC.

Results from a first-in-human phase I study of F182112, a B-cell maturation antigen (BCMA)-CD3 bispecific antibody, in patients with relapsed/refractory multiple myeloma. *First Author: Mingyuan Sun, State Key Laboratory of Experimental Hematology, National Clinical Research Center for Hematological Disorders, Institute of Hematology and Blood Diseases Hospital, Tianjing, China*

Background: F182112 is a BCMA x CD3 bispecific antibody that redirects CD3+ T cells to mediate T-cell activation and subsequent lysis of BCMA-expressing myeloma cells. NTP-F182112-001 is a First-in-human, Open-label, Multiple center Phase 1 Dose-Escalation Study to Evaluate Safety, Tolerability, Pharmacokinetic, Immunogenicity, and Preliminary Efficacy of F182112 in Patients with Relapsed or Refractory Multiple Myeloma. Clinical trial information: NCT04984434. **Methods:** Eligible patients aged ≥ 18 years had received at least 2 prior multiple myeloma treatment regimens (not including autologous stem cell transplant) including a proteasome inhibitor, an immunomodulatory agent. Three dose cohorts (0.01, 0.1, and 0.3 μ g/kg) were planned for accelerated titration phase and the following dose cohorts (3, 10, 20, and 30 μ g/kg) were planned for the i3+3 dose escalation phase. F182112 were administered as QW or Q2W IV infusion. The primary endpoint was safety and tolerability assessed throughout the study by monitoring AEs per the CTCAE 5.0, except CRS per ASTCT 2018. **Results:** As of Feb 2, 2023, 16 pts in the first 7 cohorts received F182112 (0.01–20 μ g/kg). Median follow-up was 3.1 mo (range 0.9–11.7; median age 64 y [range 52–74]; 68% female). 9 (56%) pts had received ≥ 4 prior lines of therapy and 12 (75%) pts were refractory to last lines of therapy. The ORR was 43.8% (95% CI 19.8–70.1) among all enrolled patients (7/16). Of the 9 pts treated with ≥ 10 μ g/kg F182112, 6 pts achieved a partial response (PR) or better (overall response rate; 66.7%), including 2 (22.2%) with a very good partial response or better. The most common treatment-related AEs were CRS (81%), lymphopenia (75%; grade 3/4: 69%), neutropenia (63%; grade 3/4: 44%), leukopenia (56%; grade 3/4: 50%), and anemia (31%). CRS and anemia events were all grade 1–2 and median duration time to CRS was 2 days (1–5). One dose-limiting toxicities (transient ALT elevation, grade 3) occurred at the dose group of 10 μ g/kg. No pts required a F182112 dose reduction due to AEs. **Conclusions:** F182112 provides a novel immunotherapy approach for the treatment of Relapsed/Refractory Multiple Myeloma that may yield improved clinical efficacy in heavily pretreated pts. Clinical trial information: NCT04984434. Research Sponsor: Shan Dong New Time Pharmaceutical Co. Ltd.

Adjusted indirect treatment comparison of progression-free survival (PFS) associated with DRd and VRd based on MAIA and SWOG S0777 individual patient-level data. *First Author: Brian G. Durie, Samuel Oschin Comprehensive Cancer Center, Los Angeles, CA*

Background: Both daratumumab in combination with lenalidomide and dexamethasone (DRd) and bortezomib in combination with lenalidomide and dexamethasone (VRd) are endorsed by NCCN guidelines as preferred regimens for the treatment of transplant-ineligible (TIE) patients with newly diagnosed multiple myeloma (NDMM). DRd and VRd have each demonstrated superior efficacy relative to lenalidomide and dexamethasone (Rd) alone in the MAIA and SWOG S0777 trials, respectively, but have not been compared directly in a head-to-head trial. Naive comparisons of efficacy across the 2 trials may be biased because MAIA enrolled only TIE patients (median age 73 years), whereas S0777 enrolled a mixed transplant-not-intended (TNI) population, which included both TIE patients and patients choosing to defer/refuse frontline stem cell transplantation (median age 63 years). **Methods:** The present study leveraged individual patient-level data (IPD) from both trials to perform an anchored indirect treatment comparison of DRd vs VRd, adjusting for differences in trial eligibility criteria and baseline patient characteristics. Harmonized inclusion criteria (NDMM, age ≥ 65 years, ECOG performance status ≤ 2) were applied to both trial populations. Age ≥ 65 years served as a proxy for TIE status since S0777 enrolled a mixed TNI population. Propensity score (PS) reweighting was used to balance the 2 trial populations on key baseline prognostic factors including age, sex, ISS stage, ECOG performance status, hemoglobin, eGFR, lactate dehydrogenase (LDH) level, and cytogenetic risk. Missing data were addressed with multiple imputation. After alignment of inclusion criteria and PS reweighting, an anchored indirect comparison was performed wherein within-trial progression-free survival (PFS) hazard ratios (HRs) for DRd vs Rd and VRd vs Rd were estimated and used to make indirect inference about PFS for DRd vs VRd. **Results:** 727 MAIA participants and 198 S0777 participants were eligible for inclusion. After PS reweighting, the trial populations were balanced on the key baseline prognostic factors identified above (standardized difference < 0.1 for each). The adjusted PFS HRs were 0.53 (95% CI: 0.41–0.68; $P < 0.0001$) for DRd vs Rd in MAIA and 0.88 (0.63–1.23; $P = 0.46$) for VRd vs Rd in S0777. In the adjusted Rd-anchored indirect comparison, the PFS HR for DRd vs VRd was 0.60 (0.39–0.90; $P = 0.02$). **Conclusions:** In this adjusted indirect treatment comparison based on IPD from the MAIA and S0777 trials, PFS was significantly longer for DRd relative to VRd. In the absence of a head-to-head trial comparing DRd and VRd, the present study may help to inform treatment selection in TIE patients with NDMM. Research Sponsor: Janssen.

Poster Session

Elranatamab, a B-cell maturation antigen (BCMA)-CD3 bispecific antibody, for patients (pts) with relapsed/refractory multiple myeloma (RRMM): Extended follow up and biweekly administration from the MagnetisMM-3 study. *First Author: Mohamad Mohty, Sorbonne University, Hôpital Saint-Antoine, and INSERM UMRs938, Paris, France*

Background: MagnetisMM-3 (NCT04649359) is an open-label, multicenter, registration phase 2 study evaluating the efficacy and safety of elranatamab monotherapy in pts with RRMM; pts naive to BCMA-directed therapies were enrolled in Cohort A. **Methods:** Eligible pts were refractory to at least 1 PI, 1 IMiD, and 1 anti-CD38 antibody. Pts received SC elranatamab in 28-d cycles with step-up doses of 12 mg on C1D1 and 32 mg on C1D4 followed by 76 mg QW beginning C1D8. Pts treated for 6 cycles and achieving partial response (PR) or better with response persisting ≥ 2 mo were switched to 76 mg Q2W, 46 and 58 pts are included in the Q2W efficacy and safety analyses, respectively. **Results:** Overall, 123 pts received elranatamab. Median pt age was 68.0 y (range, 36–89), 63.4% of pts had an ECOG PS ≥ 1 and median prior lines of therapy was 5.0 (2–22); 96.7% and 42.3% of pts were triple-class- and penta-drug refractory, respectively. At data cutoff (~12 mo after last pt initial dose), the median follow up was 12.8 mo (0.2–22.7); 34.1% of pts remained on treatment. Most common reasons for permanent treatment discontinuation were progressive disease (39.0%) and adverse events (AE; 13.8%). Objective response rate per blinded independent central review (BICR) was 61% (95% CI 51.8–69.6), with 39 (31.7%) pts with complete response (CR) or stringent CR (sCR); very good partial response (VGPR) and PR were achieved in 29 (23.6%) and 7 (5.7%) pts, respectively. MRD-negativity (threshold 10^{-5}) was achieved by 92.0% (n = 23/25) of evaluable pts. Median duration of response (mDOR) has not been reached (95% CI 12.9–NE) and DOR at 12 mo was 74.1% (95% CI 60.5–83.6). In pts with CR/sCR or VGPR, mDOR was not reached by 12 mo; in pts with PR, mDOR was 5.2 mo (95% CI 1.6–NE). There were 46 responders by BICR who switched to Q2W dosing ≥ 24 wk prior to the data cut-off; among these pts, 80.4% maintained/improved their response ≥ 24 wk after the switch. Median progression-free and overall survival have not been reached by 12 mo, and the respective rates (95% CI) at 12 mo were 57.1% (47.2–65.9) and 62.0% (52.8–70.0). Most common Grade 3/4 treatment emergent AEs were hematologic; Grade 3/4 non-hematologic events reported in $\geq 5\%$ of pts were COVID-pneumonia (10.6%), hypokalemia (9.8%), pneumonia (7.3%), sepsis (6.5%), hypertension (6.5%), ALT increased (5.7%), and SARS-CoV-2 test positive (5.7%). Among pts who switched to Q2W dosing, the incidence of Grade 3/4 AEs decreased by $> 10\%$ after the switch. **Conclusions:** Elranatamab remains efficacious and well tolerated in pts with RRMM after > 1 y of follow-up. Updated analysis with a median follow up of ~15 mo, the longest of all phase 2 BCMA-CD3 bispecific antibody studies, including the outcome of pts who switched to the Q2W dosing, will be presented. These results support continued elranatamab development for pts with MM. Clinical trial information: NCT04649359. Research Sponsor: Pfizer.

Poster Session

Efficacy and safety of elranatamab by age and frailty in patients (pts) with relapsed/refractory multiple (RRMM): A subgroup analysis from MagnetisMM-3. First Author: Noopur S. Raje, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA

Background: Multiple myeloma is predominantly a disease of elderly and frail pts, who are often ineligible for intensive therapies. Data from the ongoing Phase 2 MagnetisMM-3 (NCT04649359) study demonstrated the efficacy and safety of elranatamab in pts with RRMM and no prior BCMA-directed therapy (Cohort A). Here we report results for subgroups of pts by age and frailty. **Methods:** Eligibility criteria, dosing and administration were previously reported (Bahlis, ASH 2022). Subgroups of pts within Cohort A (n = 123) were analyzed by age: < 65 (n = 43) vs ≥65 years (n = 80), and frailty: non-frail (n = 84) vs frail (n = 39). A simplified frailty scale was used (Facon et al, Leukemia 2020). Results include data up through ~12 months after last pt initial dose. **Results:** The median treatment duration was 8.2 vs 5.5 mo in the < 65 vs ≥65 years, and 6.4 vs 5.6 mo in the non-frail and frail subgroups, respectively. Discontinuation occurred in 62.8% vs 67.5% of pts aged < 65 vs ≥65 years and in 63.1% vs 71.8% of the non-frail vs frail groups, respectively. The most common reason for discontinuation in all subgroups was progressive disease, 51.2%, 32.5%, 42.9%, and 30.8% of < 65, ≥65 years, non-frail, and frail subgroups, respectively. The objective response rate (ORR) (95% CI) was 58.1% (42.1%, 73.0%) vs 62.5% (51.0%, 73.1%) for pts aged < 65 vs ≥65 years. Median duration of response was not reached in either age subgroup. The probability of maintaining response (95% CI) at 12 mo was 74.1% (51.0%, 87.5%) vs 73.8% (55.7%, 85.4%) for pts aged < 65 vs ≥65 years. The ORR (95% CI) for non-frail pts was 63.1% (51.9%, 73.4%) vs 56.4% (39.6%, 72.2%) for frail pts. Median duration of response was not reached in either frailty subgroup. The probability of maintaining response at 12 mo (95% CI) was 76.0% (60.2%, 86.2%) vs 70.5% (41.9%, 86.9%) for non-frail vs frail pts. Any Grade treatment-emergent adverse events (TEAEs) were reported in 100% of pts in the study. Grade 3/4 TEAEs were reported in 74.4%, 68.8%, 73.8% and 64.1% of pts in < 65, ≥65, non-frail and frail subgroups, respectively. Infections (Any Grade; Grade 3/4; Grade 5) were reported in 72.1%, 32.6% and 4.7% vs 68.8%, 40.0% and 6.3% in < 65 and ≥65 pts, respectively, and in 70.2%, 38.1% and 4.8% vs 69.2%, 35.9% and 7.7% in non-frail and frail pts, respectively. The rate of cytokine release syndrome was similar in patients with respect to age (< 65, 58.1%; ≥65 years, 57.5%) and frailty groups (non-frail, 57.1%; frail, 59.0%). Immune effector cell-associated neurotoxicity syndrome was reported in 2.3%, 6.3%, 6.0% and 2.6% of pts in < 65, ≥65, non-frail and frail subgroups, respectively. **Conclusions:** Elranatamab is efficacious and has a manageable safety profile in elderly or frail pts with RRMM and may be a treatment option for those ineligible for more intensive myeloma therapies. Clinical trial information: NCT04649359. Research Sponsor: Pfizer.

Poster Session

Phase 1 study of tasquinimod, an S100A9 inhibitor, alone and in combination with IRd for relapsed and refractory multiple myeloma (RRMM). First Author: Dan T. Vogl, Abramson Cancer Center, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Background: S100A9, a protein produced by myeloid-derived suppressor cells (MDSCs) in the bone marrow microenvironment, promotes multiple myeloma (MM) progression and confers therapeutic resistance. Tasquinimod (tasq), an oral S100A9 inhibitor, has pre-clinical anti-myeloma effects alone and combined with proteasome inhibitor (PI) and immunomodulator (ImiD) therapy (Lin C, EHA 2020; EP896). Tasq previously improved PFS in prostate cancer patients (pts) (JCO 2016;34(22):2636-43). We are conducting a phase 1 trial (NCT04405167) of tasq as a single agent and in combination with ixazomib (ixa), lenalidomide (len), and dexamethasone (dex) (IRd) in pts with RRMM. **Methods:** We enrolled pts with RRMM refractory to, intolerant of, or with contraindication to len, pomalidomide (pom), bortezomib, carfilzomib (cfz), and a CD38 monoclonal antibody. Tasq was given in 28-day cycles as shown below, with a 3+3 dose escalation scheme. For combination therapy, pts received ixa (4 mg days 1/8/15), len (25 mg days 1-21, with adjustments for renal dysfunction), and dex (40 mg qwk). **Results:** Of 15 pts, median age was 70y (range 56-84); 53% were male; 27% were African American and 73% Caucasian. Pts had received a median of 8 prior lines of therapy (range 4-17), and all were refractory to ≥1 ImiD, 87% to ≥1 PI, and 100% to a CD38 mAb, with 87% triple class refractory and penta-exposed. 10 pts received single-agent tasq at dose levels 1 (3 pts), 2 (3 pts), and 3 (4 pts). The most common treatment-emergent adverse events (TEAEs) were fatigue (all grade [gr] 1/2), anemia (5 pts, gr 3 in 2), anorexia (5 pts, gr 3 in 2), pain (5 pts, all gr 1/2), nausea/vomiting (4 pts, all gr 1/2), and neuropathy (3 pts, all gr 1/2). No dose-limiting toxicities (DLTs) were observed, but at dose level 3, 2 pts stopped for intolerable toxicities, and we identified dose level 2 as the single-agent MTD. 5 pts have received tasq with IRd at dose levels 1 (3 pts) and 2 (2 pts). Gr ≥ 3 TEAEs were gr 4 thrombocytopenia in 1 pt (improved with dose reductions of ixa and len), gr 3 insomnia in 1 pt, and gr 5 COVID pneumonia in 1 pt. No tasq-related DLTs were observed. On single-agent tasq, 3 pts with progressive disease at study entry had stabilization of serum markers while on study. Of 5 pts on the IRd combination, 1 has had a partial response that is ongoing after 10 months, despite being previously refractory to ixa/pom and cfz/pom combinations. **Conclusions:** Tasquinimod, an S100A9 inhibitor, is well tolerated in pts with RRMM as a single-agent and in combination with IRd, with a single-agent MTD of 1 mg daily after a 1-week dose escalation. Tasq has anti-myeloma activity in combination with IRd, as evidenced by a partial response in a patient previously refractory to ImiD/PI combination therapy. Enrollment continues to tasq with IRd at dose level 2. Clinical trial information: NCT04405167. Research Sponsor: The Leukemia & Lymphoma Society; Active Biotech.

Dose level	Tasquinimod dose
1	0.25 mg qd x1 wk, 0.5 mg qd x1 wk, then 1 mg qd
2	0.5 mg qd x1 wk, then 1 mg qd
3	1 mg qd
4	1.25 mg qd
5	1.5 mg qd

Efficacy, safety, pharmacokinetic (PK), and pharmacodynamic (PD) support for talquetamab (tal) QW and Q2W dosing in patients (pts) with relapsed/refractory multiple myeloma (RRMM): Analyses from MonumentAL-1. First Author: Xuewen Ma, Janssen Research & Development, Spring House, PA

Background: Tal is a first-in-class bispecific antibody targeting the novel antigen G protein-coupled receptor family C group 5 member D. In MonumentAL-1 (NCT03399799/NCT04634552), tal demonstrated an overall response rate (ORR) of > 70%, with clinically manageable safety in pts with RRMM. We summarize efficacy, safety, PD, and PK results supporting the recommended phase 2 doses (RP2Ds) of tal: 0.4 mg/kg QW and 0.8 mg/kg Q2W SC. **Methods:** In MonumentAL-1, pts received IV (0.5–180 µg/kg) or SC (5–1600 µg/kg) tal doses in phase 1 and at the RP2Ds in phase 2, preceded by step-up doses. Blood samples were collected for the measurement of tal serum concentration and anti-tal antibodies (ADAs). Covariate effects on PK and efficacy were characterized. Efficacy and safety exposure-relationships (E–R) were evaluated using predicted PK metrics, ORR, and key treatment-emergent adverse events (TEAEs), including neurotoxicity, infections, cytopenia, ageusia, dysgeusia, weight loss, and cytokine release syndrome (CRS). **Results:** PK exposure was approximately dose proportional across IV and SC doses, with a SC bioavailability of 61.9%. At the RP2Ds, the mean concentration–time profiles were comparable and maintained at or above the concentration associated with the 90% maximal drug effect identified in an ex vivo cytotoxicity assay. The incidence of ADAs was 29% (QW) and 20% (Q2W). Presence of ADAs had no apparent impact on PK, safety (CRS, systemic administration-related reaction, or injection site reaction), or efficacy (ORR). At the RP2Ds, PD changes indicative of the proposed mechanism of action, such as T-cell activation, induction of cytokines, and T-cell redistribution, were comparable. Body weight, myeloma subtype, and International Staging System stage were identified as covariates for tal PK; however, there was no clinically relevant impact of age, sex, race, or mild/moderate hepatic or renal impairment on PK. Across SC doses in phase 1, ORR increased with exposure and reached a plateau at or above the RP2Ds, supporting the selected RP2Ds. Baseline myeloma subtype and extramedullary plasmacytoma status were identified as prognostic factors for ORR at the RP2Ds. There were no observed E–R for key TEAEs, including grade ≥3 infections or cytopenia, grade ≥2 weight loss, or grade 2 ageusia. No E–R for grade ≥1/≥2 CRS and peak tal exposure for any step-up doses, irrespective of tocilizumab administration, was observed. Dysgeusia rates were comparable between the 2 RP2Ds. **Conclusions:** Efficacy, safety, PK, and PD analyses support the selection of tal 0.4 mg/kg QW and 0.8 mg/kg Q2W SC regimens as RP2Ds. The RP2Ds provided comparable PK, PD, efficacy, and safety profiles. Covariates for PK exposure had no impact on E–R, and dose adjustment was not warranted. Clinical trial information: NCT03399799, NCT04634552. Research Sponsor: Janssen Research & Development, LLC.

Poster Session

Clinical characteristics, markers of adverse prognosis, and predictors of development of extramedullary multiple myeloma. First Author: Saurabh Zanwar, Mayo Clinic, Rochester, MN

Background: Extramedullary Multiple Myeloma (EMM) has an aggressive clinical course and can present at diagnosis [primary EMM, (pEMM)] or relapse [secondary EMM, (sEMM)]. Here, we report clinical characteristics and outcomes of EMM, and predictive factors for the development of sEMM. **Methods:** We identified 299 patients with biopsy-proven EMM between 01/01/2000 and 12/31/2021. Patients with solitary plasmacytoma, paraneoplastic MM and primary plasma cell leukemia were excluded. A 1:1 matched pair analysis (matched for year of diagnosis of MM for comparable follow-up and treatment eras) was performed to compare clinical characteristics and outcomes for patients with and without sEMM. **Results:** The median follow-up from the diagnosis of MM was 11.5 years (95%CI: 9.3-14.8). Of 299 patients, 204 (68%) patients had sEMM and 95 (32%) had pEMM, with largely comparable baseline characteristics (Table). The median overall survival (OS) from the diagnosis of sEMM was 0.7 (95% CI: 0.6-0.9) years compared to 3.6 (95%CI: 2.4-5.6) years for pEMM (p<0.0001). For sEMM, multivariable analysis (MVA) for OS identified visceral organ involvement (eg. liver, lung/pleura, brain, pancreas, etc.) to be associated with inferior OS [HR 1.6 (95% CI: 1.1-2.4), p=0.01]; high-risk cytogenetics (HR-CTG), ISS-3 stage, and age did not impact OS from sEMM. For pEMM, HR-CTG [HR 2.3 (95% CI 1.1 -4.8), p=0.03] and ISS-3 stage [HR 3.1 (95% CI 1.5-6.7), p=0.003] were associated with inferior OS on MVA whereas visceral EMM or age did not impact OS from pEMM. On univariate analysis, patients with sEMM were younger (median age 58.7 vs 61 years, p=0.006), had a higher proportion of 1q duplication (32% vs 17%, p=0.001), t(4;14) [16% vs 9%, p=0.047] and elevated LDH (30% vs 19%, p=0.04), compared to the matched cohort of patients without sEMM. On MVA, younger age at diagnosis, t(4;14) and 1q duplication at diagnosis of MM were independent predictors of development of sEMM. The median OS from diagnosis of MM was 5.4 years (95%CI: 4.1-6.2) for patients with sEMM versus 7.5 years (95% CI: 6.4-10.1; p<0.001) for the matched cohort. Secondary EMM was an independent poor prognostic marker for OS from the diagnosis of MM [HR 1.6 (95%CI: 1.2-2.1); p=0.004] in addition to age, ISS3 disease and HR-CTG. **Conclusions:** Outcomes of patients with EMM, especially sEMM, remain dismal. Patients with sEMM have higher rates of 1q duplication and t(4;14) at diagnosis of MM and carried an independent adverse prognosis in a matched cohort. Research Sponsor: None.

Parameter at Diagnosis of MM	Primary EMM (n=95)	Secondary EMM (n=204)	p-value
Median age, years, (range)	61 (18-83)	58.7 (35-89)	0.09

Identification of cytokines associated with response and cytokine release syndrome: Analysis of MagnetisMM-3 cohort A. *First Author: Hang Quach, St. Vincent's Hospital, University of Melbourne, Melbourne, VIC, Australia*

Background: MagnetisMM-3 (NCT04649359) is a phase 2 study of elranatamab monotherapy in patients with multiple myeloma refractory to at least 1 proteasome inhibitor, 1 immunomodulatory drug, and 1 anti-CD38 antibody. Promising efficacy and safety have been observed in patients who were naïve to B-cell maturation antigen (BCMA)-directed therapy (Cohort A) in MagnetisMM-3 (Bahlis et al., ASH 2022). **Methods:** In MagnetisMM-3, patients received subcutaneous elranatamab in 28-day cycles with step-up doses of 12 mg on C1D1 and 32 mg on C1D4 followed by 76 mg QW beginning C1D8. Serum samples were collected on C1D1 prior to first priming dose, and on C1D2, pre-dose C1D4, C1D5, pre-dose C1D8, C1D15, and C1D22. Levels of 45 peripheral cytokines were analyzed by proximity extension assay and a longitudinal mixed effects model was applied to each cytokine separately. Cytokines with a significant 2-fold differential expression (responders [defined as patients with best overall response of very good partial response or better] vs non-responders [defined as patients with best overall response of partial response or worse]; cytokine release syndrome [CRS] vs no CRS) at any timepoint are reported. Clinical data cutoff was in Oct 2022 with median follow up of 10.4 months. **Results:** Baseline levels of IL-6 (2.6-fold), IL-17C (2.0-fold), and MIP-1 α (2.1-fold) were lower in patients who achieved a response. After the first priming dose, 13 cytokines in the panel, including CCL8, IFN- γ , IL-2, and IL-27, were differentially expressed in responders vs non-responders. At baseline, no cytokines were found to predict CRS. After the first priming dose, 18 cytokines in the panel, including CCL8, IFN- γ , IL-10, IL-2, IL-27, IL-6, and IL-17A, were differentially expressed in patients with CRS vs no CRS. The maximal differential expression for 17/18 cytokines occurred at C1D2, ~24 hours post the first priming dose. **Conclusions:** Lower baseline levels of IL-6, IL-17C, and MIP-1 α correlated with a response of VGPR or better in BCMA-naïve patients from MagnetisMM-3, suggesting that lower levels of these cytokines might reflect a favorable immune environment. Many cytokines were differentially expressed at higher levels in patients who experienced CRS vs those who did not; the most prominent cytokines included CCL-8, IFN- γ , and IL-10. The timing of induction of CCL-8, IFN- γ , and IL-10 occurred by C1D2 suggesting a potential contribution of these cytokines in driving CRS. Clinical trial information: NCT04649359. Research Sponsor: Pfizer.

ISAMAR: Multicenter phase II single arm trial of isatuximab (ISA) with/without lenalidomide (LEN) in pts with high risk smoldering multiple myeloma (HRSM). *First Author: Elisabet Esteve Manasanch, Department of Lymphoma/Myeloma, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: HRSM patients (pts) have a median time to progression of < 2 years. ISA is a monoclonal antibody that binds to highly expressed CD38 on myeloma cells and is approved in RRMM. We designed a phase II study to test the efficacy of ISA +/- LEN in HRSM (NCT02960555). **Methods:** The primary endpoint of the study was the overall response rate (ORR) after 6 months of ISA 20 mg/kg IV days 1, 8, 15, 22 cycle 1; days 1, 15 cycles 2-6; day 1 cycles 7-30 monotherapy (stage 1, n = 25) or with LEN 25 mg po daily on days 1-21 every 28 days, cycles 1-6 (stage 2, n = 36). Secondary endpoints are progression free survival (PFS), overall survival (OS) while exploratory endpoints included quality of life (QoL), flow and sequencing. **Results:** 61 HRSM pts (+immunoparesis and $\geq 95\%$ abnormal plasma cells in bone marrow) (stage 1 n = 25; stage 2 n = 36) were accrued 02/2017-10/2022. The study met its primary endpoint of ORR $\geq 70\%$ after 6 cycles of therapy [Stage 2 ORR (89%) = VGPR 9 (25%), PR 23 (64%), MR 3 (8%), PD 1 (3%)]. Median time to response was 1 cycle. In stage 2, 17/36 (47%) patients had grade 3 treatment related adverse events (AEs): 1 pt related to ISA (myalgia, 3%) and 16 pts related to LEN (44%) [ANC decrease (36%), skin rash (8%), ALC decrease (11%), WBC decrease (8%), fatigue (6%)] and 1/36 pts a grade 4 (related to LEN) [ANC decrease 3%]. Most common grade 1-2 AEs: WBC decrease (53%), ANC decrease (56%), skin rash (28%), fatigue (39%), ALC decrease (42%), thrombocytopenia (28%), diarrhea (39%), constipation (28%). There were no grade 5 AEs. No patients discontinued treatment due to AEs. There were 3 deaths in stage 1 unrelated to therapy: 1 patient progressed to and died while on systemic AL amyloidosis therapy, one patient (with COPD) died of COVID19 while in sustained PR, one heavy smoker died of squamous cell cancer of the tongue. Pre- and post-treatment BM flow showed that ISA/LEN increased CD4+/CD8+ and effector memory cytotoxic T cells. QoL measures (n = 32; 15 in stage 1, 17 in stage 2 and 21 with both BL/after 6 months data) showed that ISA +/- LEN resulted in decreased cancer worry/anxiety and improved future perspective at 6 months compared to BL in both stages. QoL was favorable and conserved throughout treatment, suggesting minimal effects of treatment on patient assessment of well-being. For stage 1, median PFS was 49.3 months (95% CI: 40.8-NA months); median OS not reached at a median f/u of 49 months (range 6.3-68 months). Stage 2 median PFS/OS is not reached. **Conclusions:** ISA/LEN results in high ORR without decrease in patient well-being. ISA monotherapy also results in prolonged PFS when compared to historical data. ISA/LEN therapy remodels the BM TME with increase in memory cytotoxic T cells. The results of this study give rationale for the ongoing phase 3 ITACHA evaluating ISA +/- LEN/DEX with the potential to change the standard of care in HRSM (NCT04270409). RO and OL have equal contribution. Clinical trial information: NCT02960555. Genomic analysis to identify determinants of inherent response and resistance to elranatamab in MagnetisMM-3 cohort A. *First Author: Nizar J. Bahlis, Arnie Charbonneau Cancer Institute, University of Calgary, Calgary, AB, Canada*

Background: MagnetisMM-3 (NCT04649359) is an open-label, multicenter, non-randomized phase 2 study of elranatamab monotherapy in patients (pts) with multiple myeloma refractory to at least 1 proteasome inhibitor, 1 immunomodulatory drug and 1 anti-CD38 antibody. This analysis examined molecular correlates of elranatamab response and resistance in pts naïve to B-cell maturation antigen (BCMA)-directed therapy (Cohort A). **Methods:** Bone marrow aspirate (BMA) samples collected at screening were analyzed by whole exome and whole transcriptome sequencing. To investigate the contribution of the tumor microenvironment (TME) in elranatamab response, the abundance of cell types in the BMA samples collected at screening was estimated using single sample gene set enrichment analysis (ssGSEA) of LM22 cell type signatures. Response was defined as a best overall response of very good partial response or better (partial response was considered non-response for this analysis). **Results:** *TNFRSF17* (BCMA encoding gene) expression correlated with markers of disease burden: levels increased with disease stage (with progressively higher levels in R-ISS stages I, II, and III; $p = 0.014$), were higher in pts with high-risk cytogenetics ($p = 0.002$) and correlated with plasma cell content in BMA samples ($p = 0.80$; $p < 10^{-10}$). *TNFRSF17* expression trended higher in non-responders ($p = 0.08$), but this trend was diminished when adjusting for disease burden. These findings suggest *TNFRSF17* expression in bulk BM samples is associated with higher disease burden and likely poorer response. According to ssGSEA of LM22 cell types, plasma cells in BMA were associated with non-responders ($p = 0.03$). Further multivariable modeling (controlling for plasma cell content) revealed additional cell types associated with response, including macrophages and monocytes, which were associated with poor outcome. Pts with both low plasma and low myeloid cells were most likely to respond. Genome wide copy number analysis showed that *TNFRSF17* locus amplification was associated with non-response ($p = 0.008$). Chromosomal alterations associated with non-response were identified, including genomic loci known to define high-risk MM (eg, 1q21+) and loci not known to be associated with high-risk MM (eg, 17q21+ and 6p21+). **Conclusions:** Genomic analysis of BMA samples from MagnetisMM-3 identified an association between higher *TNFRSF17* expression in the TME and unfavorable outcomes, likely due to its surrogacy with increased tumor burden. Features of high-risk disease were also associated with lack of response to elranatamab. Adjusting for tumor cell content revealed additional aspects of the TME associated with poor response, including increased myeloid cell populations. Lastly, alterations in specific genomic loci were also associated with response, consistent with tumor intrinsic features influencing elranatamab response. Clinical trial information: NCT04649359. Research Sponsor: Pfizer.

Patient-derived MicroOrganoSpheres (MOS) and precision clinical decision-making for patients with multiple myeloma. *First Author: Rui Xi, Xilis, Inc, Durham, NC*

Background: There are many multiple myeloma (MM) treatments and nearly all patients undergo continual cycles of treatment, response, and resistance. Selecting an effective therapeutic strategy is of critical importance; but there is currently a lack of patient-derived MM models that can enable functional precision medicine to help real-time clinical decision-making to guide individual patient treatment. **Methods:** We show a method to rapidly establish MM patient-derived MicroOrganoSpheres (MOS), which are microscale, droplet-sized patient avatars that sustain the native tumor niche, including both stromal and immune compartments. We generated first-of-its-kind data showing that MM MOS predicted patient treatment outcomes and have the potential to guide clinical treatment decisions. We further developed high-throughput drug screen to demonstrate MM MOS response to FDA-approved single and combination therapies and developed MOS assays to predict patient responses to immunotherapies including bispecific and phagocytosis-inducing antibodies. **Results:** MM MOS established from patient bone marrow (BM) biopsies preserved CD138/CD38 tumor cells, stromal (e.g., osteoblast) cells, and all major immune cell populations (T, NK, B, macrophage, dendritic, and myeloid-derived suppressor cells) for 11 days in culture. We performed single and combo drug testing on MOS derived from 7 MM patients within 10 days of biopsy collection. Patients went on receiving treatments and their responses were assessed using International Myeloma Working Group response criteria. The MOS assay predicted responses of both treatment-naïve and refractory patient to standard-of-care regimens, including combinations of proteasome inhibitors (bortezomib, carfilzomib), immunomodulatory agents (lenalidomide) and DCEP. Moreover, the BM biopsy-derived MOS enabled high-throughput drug testing of single agents and combinations in 9-dose titrations, providing clinicians the ability to evaluate alternative treatment options. Furthermore, because MOS retain the immune compartments of the original tumor niche, we were able to evaluate patients' response to bispecific T cell engagers and developed a phagocytosis assay to measure anti-tumor phagocytosis activity, which showed efficacy in both single-agent and combo settings. Multi-modal profiling and an AI image analysis pipeline provided robust measurements that confirmed the unique phenotypic profile of each patient sample, highlighting the critical unmet need to guide each patient to the optimal treatment. **Conclusions:** Based on this groundbreaking feasibility study, a subsequent clinical trial of 40 patients is current under IRB review to further validate the clinical power of MM MOS to predict patient outcome and to demonstrate utility as a viable functional precision medicine approach to inform treatment decisions in the clinic. Retrospective analysis of the relationship between time to anti-resorptive therapy and incidence of skeletal related events in patients with multiple myeloma. *First Author: Adam F Binder, Sidney Kimmel Cancer Center at Thomas Jefferson University, Philadelphia, PA*

Background: Patients with multiple myeloma (MM) often have bone disease at diagnosis and are at risk of developing skeletal related events (SRE) (pathological fractures, spinal cord compression, and/or need for radiotherapy or surgery to bone). It is well established that for patients with lytic bone lesions at diagnosis, the use of anti-resorptive agents lead to a lower incidence of SREs. However, it is common for initiation of anti-resorptive therapy to be delayed. Recent studies have demonstrated that anti-resorptive therapy is underutilized in patients with MM. However, the effect of time to initiation of anti-resorptive agent after diagnosis of MM on SREs has not been well studied. Herein, we conducted a multi-center retrospective analysis to determine if time to anti-resorptive agent has an adverse impact on the risk of SREs. **Methods:** We performed a retrospective cohort study using our Electronic Health Record system to identify patients with newly diagnosed MM between July 1st, 2016 and June 30th, 2019 at two large academic centers. Patients previously treated or patients not treated with anti-resorptive therapy were excluded. The study's primary endpoint was hazard ratio of developing a SRE based on time to anti-resorptive therapy. The relationship between incidence of SREs and time to anti-resorptive therapy, gender, age, International Staging System (ISS) stage at diagnosis, and prior SRE present at diagnosis was analyzed by using a multivariable Cox proportional hazards model. The cutoff point of anti-resorptive therapy delay was based on the recursive partitioning of univariable Cox model. **Results:** 759 patients were included in the study (Thomas Jefferson University: n = 232; The Ohio State University: n = 527). Median age at diagnosis is 60.2 years (IQR: 12.4 years). 57% of patients were male. 77.9% and 20.3% of patients identified as white and black respectively. 210 patients (27.7%) were noted to have osteopenia, 45 (5.9%) had osteoporosis, 229 (30.2%) were vitamin D deficient, and 319 (42%) were obese at diagnosis. A skeletal related event was present at diagnosis in 338 (45.1%) of patients. 180 (34%) patients received anti-resorptive agents within 31 days. A delay in initiating anti-resorptive agents of greater than 31 days from diagnosis had an increased risk for SRE with a hazard ratio 1.654 (1.054–2.598; p-value: 0.029). **Conclusions:** This large multicenter retrospective study demonstrated that time to anti-resorptive therapy MM patients has a significant impact on the risk of SRE. Given many of the challenges in starting anti-resorptive therapy in a timely manner, this study emphasizes the need for inter-professional, multi-disciplinary collaborations to streamline the workflow and start therapy within the first month of diagnosis. Ongoing efforts are underway to develop quality improvement processes to achieve this goal. Research Sponsor: None.

Safety and clinical activity of belantamab mafodotin plus lenalidomide and dexamethasone in transplant ineligible patients with newly diagnosed multiple myeloma: The phase 1/2, prospective, open-label, BelARd study. *First Author: Evangelos Terpos, Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece*

Background: We present the updated safety and efficacy of upfront belantamab mafodotin (belamaf) plus lenalidomide and dexamethasone (Rd) in transplant ineligible (TI) pts with newly diagnosed multiple myeloma (NDMM). **Methods:** The ongoing, prospective, open-label, phase 1/2 BelARd study (NCT04808037) aims to enroll 66 pts with TI NDMM, with ECOG PS < 2 and adequate organ function. In Part 1, 36 pts are randomized (1:1:1) to receive belamaf 2.5, 1.9, or 1.4 mg/kg Q8W plus Rd. Eye exams include Snellen best corrected visual acuity (BCVA) and corneal exam (slit lamp examination). Ocular adverse events (OAEs) are classified by CTCAE v5.0. This descriptive analysis presents the updated safety and efficacy findings for all Part 1 pts (cutoff date 15/12/22). **Results:** The analysis included 36 pts [median age: 73 years (64–86); male: 19 (53%)], of whom 31 (86%) were still on treatment and 5 (14%) had discontinued [4 pts due to belamaf-unrelated adverse events (AEs); 1 pt withdrew consent]. At baseline, 32 (89%) pts were intermediate fit as per International Myeloma Working Group frailty score and 34 (94%) had ECOG PS ≤ 1. Median follow up was 15 months (3–23); median belamaf administrations and number of cycles reached were 6 (2–10) and 15 (3–22). Thirty-four (94%) pts experienced ≥ 1 grade (Gr) ≥ 3 treatment-emergent AEs (TEAEs). Most common (≥ 10% of pts) non ocular Gr ≥ 3 TEAEs were fatigue (21 pts, 58%), rash (6 pts, 17%), diarrhoea (5 pts, 14%) and COVID-19 infection (4 pts, 11%); no Gr ≥ 3 thrombocytopenias and any Gr infusion-related reactions were reported. Regarding pts visual acuity, out of a total of 499 BCVA assessments, 164 (33%) were Gr 2 and 54 (11%) were Gr 3. Notably, a meaningful BCVA decline (worse than 20/50 in better seeing eye) was observed in 38 (8%) assessments, with a median time to resolution of 1 month. Regarding clinically relevant Gr ≥ 2 ocular symptoms, blurred vision, dry eye and visual impairment were observed in 38 (8%), 96 (20%) and 98 (20%) assessments, with a median time to resolution of 2, 3 and 2 months. Slit lamp examinations by the ophthalmologist (N = 501) revealed a Gr 2 keratopathy in 55 (11%) assessments and Gr 4 keratopathy in 2 (< 1%) assessments, with a median time to resolution of 4 months. Overall response rate [partial response (PR) or better] was 100.0% [36 pts; stringent complete response: 14% (5 pts); complete response: 19% (7 pts); very good partial response: 47% (17 pts); PR: 19% (7 pts)]. Median time to first response was 1 month. **Conclusions:** Part 1 of the BelARd study showed that in TI pts with NDMM, the safety profile of belamaf plus Rd was manageable and a meaningful BCVA decline was noted in a minority (< 10%) of assessments which resolved quickly (1 month). The combination induced rapid and deep responses, with all pts achieving ≥ PR and first response observed at a median of 1 month. Clinical trial information: NCT04808037. Research Sponsor: GSK.

Evaluating the efficacy of commercial teclistamab in relapsed refractory multiple myeloma patients with prior exposure to anti-BCMA therapies. *First Author: Ross Firestone, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Teclistamab (Tec) is the first CD3 x BCMA bispecific antibody (BsAb) receiving accelerated FDA approval for treatment of relapsed or refractory multiple myeloma (RRMM) in patients who have received ≥ 4 prior lines of therapy, including a PI, IMiD and an anti-CD38 monoclonal antibody. The approval was based on the results of the MajesTec-1 study (Usmani S et al Lancet 2021, Moreau P et al NEJM 2022), demonstrating a 63% overall response rate in a heavily pretreated RRMM population. Patients with prior exposure to anti-BCMA therapies, such as BCMA targeted ADCs, CAR T-cell products and BsAbs were excluded from this study. Herein, we present our institutional experience with commercial Tec for RRMM including patients with prior BCMA and GPRC5D directed therapies. **Methods:** We have performed an IRB-approved, retrospective analysis of clinical outcomes of all patients who have received commercial Tec at MSKCC since its approval on 10/26/2022 using the PCD research database. Descriptive analyses were performed for baseline characteristics. The IMWG criteria (Kumar S et al, Lancet Oncol 2016) were used to assess response and define prior therapy refractoriness. Immune profile was assessed via high-dimensional flow cytometry using lineage, exhaustion, and activation markers. Serum soluble BCMA levels were assessed using an immunoassay. **Results:** As of 2/4/2023, 24 patients have received commercial Tec and 15 are response evaluable with ≥ 1 month of clinical follow-up. Median age was 66 (51–80), prior lines of therapy was 7 (4–13), time from diagnosis was 7 years (1.5–16), 53% had high-risk cytogenetics, and 40% had EMD. All patients were triple class refractory and 80% were penta-drug refractory. Ten had prior anti-BCMA therapy (7 Belamaf, 8 BCMA CART, 1 BCMA BsAb, 5 with ≥ 2 anti-BCMA therapies). With a median follow-up time of 1.3 months, the median time to response was 16 days. ORR was 60% (9/15) in all patients and 50% (5/10) in the prior anti-BCMA therapy group. Pts with ≥ 2 anti-BCMA therapies had a 40% (2/5) response rate to Tec. Clinical benefit rate (CBR) in all patients was 73% (11/15). None of the responders have progressed at this short follow-up time. Cytokine release syndrome was observed in 7/15 patients (41%) during step-up dosing (5/7 with g1 and 2/7 with g2 CRS) and CBR was 100% in patients with CRS (71% ORR). Other notable toxicities include 2 patients with grade 2 neurotoxicity that improved with therapy discontinuation. **Conclusions:** To our knowledge, this is the first report of commercial Tec in RRMM. Tec remains effective in RRMM despite prior exposure to anti-BCMA therapies, though exposure to multiple prior anti-BCMA therapies may be predictive of diminished efficacy. Clinical data on additional patients will be presented at the meeting. Ongoing translational investigations on soluble BCMA levels and patient-specific immune phenotype will also be presented at the meeting. Research Sponsor: MSKCC.

Outcomes of patients with primary refractory multiple myeloma in the era of triplet and quadruplet induction therapy. *First Author: Charalampos Charalampous, Mayo Clinic, Rochester, MN*

Background: Patients with multiple myeloma (MM) that do not respond to initial therapy have worse outcomes compared to primary responders, and effective treatments are lacking in this population. However, the outcomes of primary refractory disease in the modern treatment era have not been studied. **Methods:** From 2007–2019, we reviewed MM patients treated with triplet/quadruplet therapy in our institution to assess the incidence of primary refractory disease and the impact of salvage therapies in this population. Primary refractory disease was defined as either progressive disease or stable disease at 4–6 cycles. The Kaplan-Meier estimates were used for survival probabilities. PFS and OS were calculated from MM diagnosis to progression, escalation/change of treatment, or death, respectively. For the primary refractory group, the second PFS and second OS were measured from the start of second-line therapy. The Cox regression model was used for multivariable analysis with the following variables (age, ISS, induction therapy, FISH, and bone marrow plasma cells at diagnosis). **Results:** We identified 1127 patients, of which 1086 were evaluated for hematologic response after 4–6 cycles. Of these, 93.3% (1013) had evidence of response, while 6.7% (73) had primary refractory disease. With a median OS of 50.7 months, patients with primary refractory disease had an increased risk for shorter survival in univariable and multivariable analysis (HR: 3.6, 95% CI = 2.61 – 4.96, HR = 3.89, 95% CI = 2.68 – 5.65, respectively). In subgroup analysis of primary refractory patients, the median second PFS and second OS from the first relapse were 11.9 months (95% CI: 8.7 – 17.3 months) and 43.4 (95% CI: 31.4– 75.9 months), respectively. Patients that received 2nd line ASCT had increased second PFS (20.9 vs. 8.1 months, respectively, p < 0.01) and second OS (74.7 vs. 31.3 months, respectively, p = 0.02) compared to patients that did not. Patients that took daratumumab as the second line did not have any significant survival differences compared to those who did not, p = NS. **Conclusions:** We conclude that early progression remains a significant factor for shorter OS in the current era, and salvage ASCT could be the most beneficial option for this population. Research Sponsor: None.

Determinants of overall survival of young adults with multiple myeloma: A National Cancer Database (NCDB) analysis of years 2004-2017. *First Author: Chakra Pani Chaulagain, Cleveland Clinic Florida, Weston, FL*

Background: There is paucity of real-world data on the outcomes of younger patients with multiple myeloma (MM). In this IRB approved retrospective analysis, the NCDB was used to evaluate the determinants of overall survival (OS) of young adults ≤ 50 years with MM who were treated at commission on cancer (CoC) accredited facilities across the USA. **Methods:** Using the NCDB, we identified $N = 16,792$ patients ≤ 50 years old diagnosed and treated for MM from 2004 to 2017. Multivariable cox regression analysis with backward elimination was utilized to identify the independent survival factors, using significance level of $p < 0.05$. Kaplan-Meier survival curves were generated and SAS version 9.4 was used to analyze the data. **Results:** Overall median survival time was 119 months; while survival rates of 1, 3, and 5-year were 90.6%, 78.0%, and 67.8%, respectively. Multivariable cox regression analysis with backward elimination method revealed that there were 13 significant independent survival factors: age, sex, race, ethnicity, Charlson-Deyo score, insurance status, facility type, median income, education level, distance to facility, year of diagnosis, hematopoietic stem-cell transplantation (HSCT), and treatment-regimen. Male patients were more likely to die compared to female patients (HR = 1.22, $p < 0.0001$). Black patients were predicted to have less death events compared to White patients (HR = 0.91, $p = 0.004$). In addition to that, Hispanic patients were more likely to die compared to non-Hispanics (HR = 1.2, $p = 0.0006$). Subjects who were treated in non-academic facilities were more likely to die compared to the ones who received care in academic centers (HR = 1.2, $p < 0.0001$). Moreover, patients with Medicare (HR = 1.65, $p < 0.0001$), Medicaid (HR = 1.49, $p < 0.0001$), and no insurance (HR = 1.63, $p < 0.0001$) had higher chance of death compared to those with private insurance. Patients with lower income $< \$38,000$ were more likely to die compared to income $\geq \$63,000$ (HR = 1.19, $p = 0.0007$). Only 6.8% of patients underwent HSCT and 93.2% did not. Patients undergoing HSCT had worse OS compared to those treated without HSCT (HR = 0.36, $p < 0.0001$). Detailed analysis will be presented. **Conclusions:** In this large cohort of real-world data analysis of very young MM patients, we found that White and Hispanic patients age ≤ 50 years had significantly inferior survival compared to Black and non-Hispanic patients. Patients with lower income, lower education level, non-private insurance, and those without access to academic centers for MM care had worse survival outcomes. The findings can be useful for designing prospective studies addressing disparity and equitable access to MM care. Despite being a pivotal part of MM therapy, HSCT utilization in the real-world setting is minimal. The barriers to HSCT utilization and the reason why it is inferior to no-HSCT in real-world setting need to be identified and addressed. Lenalidomide-based monotherapy versus augmented therapy for maintenance in standard risk multiple myeloma patients with no complete response post autologous hematopoietic cell transplantation. *First Author: Hussein Awada, Department of Translational Hematology and Oncology Research, Lerner Research Institute, Cleveland Clinic, Cleveland, OH*

Background: Standard risk (SR) multiple myeloma (MM) is typically characterized by the absence of poor prognostic cytogenetic aberrations, and better outcomes. However, outcomes in SR MM remain far from homogeneous, especially in patients undergoing autologous hematopoietic cell transplant (AHCT). While many patients do well initially, relapse is inevitable. Here, we studied the role of lenalidomide (R) maintenance therapy in determining outcomes in SR MM with no complete response (non-CR) post-AHCT. **Methods:** We retrospectively reviewed all MM patients who underwent AHCT at the Cleveland Clinic between January 1, 2011 and January 15, 2021. Electronic medical charts were accessed to retrieve data on demographic characteristics, comorbidities, International Scoring System (ISS) staging, cytogenetic risk categorization, serum and bone marrow studies, as well as maintenance therapy. SR MM was considered in patients who did not have t(4;14), t(14;16), t(14;20), del(17p), or gain(1q). Remission status was determined by serum studies at 3 months post-AHCT. The primary endpoint was median time to either progression or death, reported as time to event (TTE) determined by Kaplan Meier analysis. **Results:** A total of 517 patients were reviewed, of whom 279 were determined as SR MM. Further stratification yielded 100 non-CR SR patients on lenalidomide-based maintenance, of whom 87 were on R monotherapy and 13 on R combination. Comparison between the R-monotherapy and combination groups showed similar age at AHCT (60.5 vs 56 years, $P=0.07$), time to transplant (23.5 vs 30.8, $P=0.7$), albumin levels (<3.5 g/dL 25 vs 25%, $P=1$), Hematopoietic Cell Transplantation-specific Comorbidity Index (HCT-CI) score (≥ 3 43.5 vs 30.8%, $P=0.5$), Male preponderance (58.8 vs 69.2%, $P=0.6$), ethnicity (White 82.4 vs 76.9%, $P=0.7$), ISS stages (I 41 vs 45.5%, II 41 vs 36.4%, III 17.9 vs 18.2%, $P=0.9$), pre-AHCT lines of therapy (≥ 2 31.8 vs 38.5%, $P=0.8$), and pre-AHCT bone marrow plasma cells ($\geq 10\%$: 9.5 vs 7.7%, $P=1$), respectively. The only significant difference between the two groups was in the MM immunoglobulin subtype (IgG 80 vs 50%, $P=0.02$). Kaplan-Meier analysis for median TTE revealed that the R monotherapy group had a significantly shorter median TTE at 38.1 months versus 68.6 months ($P=0.03$) for the R combination group. **Conclusions:** SR MM patients who do not achieve a CR post-AHCT have better outcomes with R-combination rather than monotherapy. Ixazomib and daratumumab without dexamethasone (I-Dara) in elderly frail patients with RRMM: Results of the multicenter phase 2 study (IFM 2018-02) of the Intergrroupe Francophone du Myélome (IFM). *First Author: Cyrille Touzeau, University Hospital of Nantes, France, Nantes, France*

Background: Frailty is associated with inferior outcome in older myeloma patients, especially in the relapse setting.^{1,2} This adverse prognosis is mainly related to a high discontinuation rate for treatment (Tx) related adverse events (AE). Dexamethasone is responsible of a high rate of infections and metabolic AE. We present here the updated results from the phase 2 study I-Dara evaluating efficacy and tolerability of Ixazomib-Daratumumab without Dexamethasone in elderly frail patients with relapsed myeloma (RRMM) (NCT03757221). **Methods:** Ixazomib-naïve RRMM patients received oral Ixazomib (4 mg: days 1, 8, 15), IV Daratumumab (16 mg/kg; days 1, 8, 15, 22, cycles 1-2; days 1, 15, cycles 3-6; days 1, cycles 7+) and IV Methylprednisolone before Daratumumab (100 mg at day 1, 8, cycle 1 and then 60 mg). They were enrolled after 1 or 2 prior therapy if their frailty score was ≥ 2 by IMWG score. The primary endpoint was $\geq$ very good partial response rate (VGPR) at one year. Secondary endpoints included ORR, PFS, OS & toxicity according to NCI-CTCAE version 5. **Results:** Sixty-three patients were screened and 55 enrolled between 03/2018 and 09/2021. Patient were at first ($n = 36$) or second relapse ($n = 19$). Thirty-five patients (64%) were previously exposed to bortezomib, 37 (67%) were previously exposed to lenalidomide (Len) and 23 (42%) were refractory to Len. Median age was 82 (72-93). All patients had a frailty score ≥ 2 and 13 (24%) had a 3 or 4 frailty score. In 41 patients ISS at diagnosis was stage I ($n = 11$), II ($n = 18$) or III ($n = 12$). Seventeen (36%) patients harbored high-risk (HR) cytogenetic, including t(4;14) ($n = 8$) or del17p ($n = 10$). The median duration of Tx (DOT) in 14 pts with ongoing Tx was 22 mos [min-max: 16-40] at data cutoff (January, 19). The median DOT in 41 pts who stopped Tx was 10 mos [min-max: 0-31]; 28 had progressive disease (PD). Fourteen patients died during the study: Daratumumab-related bronchospasm (D1C1); Ixazomib-related overdose (C2), sepsis ($n = 3$), pneumonia ($n = 2$), PD ($n = 7$). Regarding toxicity, 31 pts had $\geq$ grade 3 AE (55%). The most common grade 3-4 AE were thrombocytopenia ($n = 10$), other cytopenias ($n = 5$), anemia ($n = 3$), infection ($n = 6$), gastrointestinal disorders ($n = 5$) and hypertension ($n = 3$). The $\geq$ VGPR rate is 32% @ 1 year (34% overall) with an ORR of 70% @ 1 year (74% overall). In Len refractory patients the $\geq$ VGPR rate is 40% @ 1 y and the ORR 70%, in HR patients the $\geq$ VGPR rate is 60% and ORR 80%. With a median follow-up of 23.0 mos median PFS is 18.5 mos and median OS NR (75% OS estimated at 27.9 mos). **Conclusions:** In this elderly frail population Ixazomib-Dara is a feasible combination with favorable efficacy profile even in Len refractory and HR cytogenetic patients. Early toxicity remains a concern in this population even though more manageable with Dara SC. Late benefit is consistent with one third of patients still on treatment. Clinical trial information: NCT03757221. Research Sponsor: Takeda and Janssen.

Three-dimensional telomere profiling to predict risk of progression in smoldering multiple myeloma. *First Author: Shaji Kumar, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Multiple myeloma (MM) is preceded by monoclonal gammopathy of undetermined significance (MGUS). A transitional stage of smoldering multiple myeloma (SMM) can be identified between MGUS and MM. While MGUS carries a steady risk of progression of 1% per year, SMM is more heterogeneous with nearly 40% of patients progressing in the first 5 years, 15% in the next 5 years, reaching the same low risk as MGUS after 10 years. SMM with its high risk of progression in the initial years after diagnosis presents a viable opportunity for early intervention. For implementing early intervention, the ability to identify SMM patients at the highest risk of progression is critical. This has led to the development of several risk stratification systems. Using these systems high risk SMM patients studied in phase 3 trials demonstrated delayed progression to MM and improved overall survival with early initiation of therapy. However, these approaches showed limited specificity exposing patients at lower risk of progression to therapy. To date, identifying high risk SMM patients and confirming disease stability in low risk SMM patients remain an important clinical need. Genomic instability has been shown to be a sensitive indicator of disease progression in cancer. Telomere dysfunction is an early event in genomic instability. The 3-dimensional spatial profiling of telomeres using TeloView technology allows for quantification of telomere dysfunction, and was shown to be instrumental in risk stratification of cancer patients generally, but particularly in selected hematological malignancies. Importantly, in a previous SMM proof-of-concept study telomeric parameters measured by TeloView technology was found to be significantly different between SMM patients who progressed to active MM within 2 years and those who remained stable for over 5 years. **Methods:** We analyzed a total of 162 SMM patients using TeloView technology. 88 patients were employed as training dataset in Receiver Operating Curve (ROC) modeling to develop a scoring model that stratifies individual SMM patients based on risk of progression to full stage MM. An additional cohort of 74 SMM patients was used for blind validation of the developed scoring model. **Results:** We report area-under-the-curve (AUC) in the ROC analysis of 0.8 (accuracy 80%) achieved by the scoring model developed using the training dataset. Furthermore, the independent blind validation achieved positive predictive value of 83% and negative predictive value of 71%, with sensitivity and specificity of 80% and 76% respectively. **Conclusions:** The result of this study supports presenting TeloView as an accurate prognostic biomarker which appears able to stratify SMM patients into their respective risk groups with high sensitivity and specificity. This will potentially allow for evidence-based treatment decisions for high risk SMM patients and confident monitoring of stable patients. Research Sponsor: Telo Genomics Corp.

A phase 2 evaluation of daratumumab-based induction therapy in patients with multiple myeloma with severe renal insufficiency. *First Author: R. Donald Harvey, Emory University School of Medicine and Winship Cancer Institute, Atlanta, GA*

Background: Myeloma patients (pts) with renal insufficiency (RI) have inferior disease outcomes; up to 50% present with acute kidney injury (AKI). AKI results from light chain-induced cast nephropathy; physicochemical properties (self-association, aggregate formation) may determine severity. Daratumumab has extensive data in myeloma, reduces circulating light chains, preserves renal function in AL amyloidosis, and has non-renal clearance. We hypothesized early therapy with daratumumab and VRD normalize myeloma-induced AKI in a population rarely included in trials. **Methods:** We used a Simon's two-stage design in newly diagnosed pts with severe AKI (CrCl <30 mL/min) of 4 x 21-D cycles of daratumumab 16mg/kg IV QW x 3 (C1-3, C4D1 only), bortezomib 1.3 mg/m² SQ D1, 4, 8, and 11, and dexamethasone 40mg (reduced to 20mg at C2 for ≥75 yrs.) D1-4 (C1 only, D1 only C2-4), 8, and 15, with add-on lenalidomide at C2 (25mg if CrCl ≥30 mL/min). Standard antitumor, antiemetic, premedications were used. Eligibility criteria were broad (CrCl <30 mL/min, PS 0-2, ANC>1000/mm³, Hgb>7 g/dL, plt>75,000/mm³) with liberal dose reductions for generalizability. Primary objective: determine proportion with renal recovery (CrCl ≥50 mL/min) after 2 cycles; secondary objectives: best response (IMWG), renal function at end of treatment, dose density/tolerability, adverse events (AE), renal function change by estimates [Cockcroft-Gault (C-G), MDRD, 24-hour urine, CKD-EPI], and daratumumab PK. If ≥7 responses seen in the first 11 pts, 14 more would be accrued. These data are the planned analysis of the initial cohort. **Results:** Thirteen pts enrolled: 8 male, 7 white/6 black, median age 69 yr (46-82), 11 treated/evaluable for the primary endpoint. Median baseline CrCl 13.8 mL/min (4.9-20.2), median serum creatinine (SCr) 4.92 mg/dL (3.53-9.93). One withdrew consent, 1 was inevaluable (rapid disease progression and death). Seven achieved CrCl of ≥50 mL/min (median C3D1 CrCl 61 mL/min, 22-151) after 2 cycles, all had SCr improvement at C3D1. Lenalidomide dose was 25 mg on C2D1 in 9/11 pts. Median (range) dose density (delivered/planned): daratumumab 100% (40-100), bortezomib 100% (25-100), dexamethasone 80% (67-100), lenalidomide 100% (0-100). The overall response rate was 100%, ≥VGPR rate 82%. Best responses were CR (3), VGPR (6), PR (2). Treatment-emergent grade ≥3 hematologic AEs: anemia (90.9%), lymphopenia (81.8%), thrombocytopenia (36.4%), neutropenia (9.1%). **Conclusions:** Early, aggressive therapy with a daratumumab-based induction regimen in myeloma pts with severe AKI improves renal function, with the majority achieving CrCl ≥50 mL/min after 2 cycles; all responded. AEs seen were consistent with prior experience with the 4-drug regimen. Per protocol, 14 additional patients will be accrued in the second stage. Clinical trial information: NCT04352205. Research Sponsor: Janssen.

Curability of multiple myeloma (MM) based on relative survival rate (RSR) in patients (pts) treated on earlier total therapy (TT) protocols. *First Author: Samer Al Hadidi, University of Arkansas for Medical Sciences, Little Rock, AR*

Background: Long term overall survival (OS) follow-up data in pts with MM treated on clinical trials is limited. TT approach uses all MM-active drugs upfront to target drug-resistant subclones during initial treatment to prevent later relapse. We report the longest follow up of MM trials (TT1 (NCT00580372), TT2 (NCT00083551), TT3a (NCT00081939) and TT3b (NCT00572169)) reported to date with RSRs to assess for curability. **Methods:** Pts treated on TT1, TT2, TT3a and TT3b were followed at the University of Arkansas for Medical Sciences after completion of therapy including multi-agent chemotherapy, high dose melphalan followed by tandem autologous stem cell transplantation (ASCT) and fixed duration maintenance therapy with introduction of thalidomide (thal) (TT2+thal vs TT2-thal), bortezomib (TT3a) and lenalidomide (TT3b). Expected survival rate was defined as probability of a population surviving from yr to yr. RSR was defined as ratio between observed survival of trials to expected survival in population adjusting for age and sex based on enrollment year. Data cut-off was October 10, 2022. **Results:** 1379 pts were enrolled (TT1:231, TT2:668, TT3a:303, TT3b:177) with median follow up duration of 16.6 years (yrs) (TT1:25 yrs, TT2:18.4 yrs, TT3a:16.2 yrs, TT3b:14.2 yrs). 10-yr PFS increased from 8.8% (TT1) to 15.5% (TT2-thal) to 25.1% (TT2+thal) to 32.9% (TT3a) to 42.4% (TT3b). Median OS improved over time (TT1:5.8 yrs, TT2:10.4 yrs, TT3a:11.9 yrs, TT3b:10.1 yrs). 15-yr OS improved from 24.2% in TT1, 33% in TT2, 40% in TT3a and 37% in TT3b. 20-yr OS is 24.4% for pts treated on TT2 protocol. Outcomes were better for standard risk disease defined by low-risk gene expression profiling (GEP) with 20-yr OS of 30% in TT2 and 15-yr OS of 45% in TT3a. RSRs approach 1 at 10-15 yrs for TT1, but this occurs earlier, at 5-10 yrs, for TT2+Thal, TT3a and TT3b [Table]. No difference in RSR between TT3a and TT3b was noted. Relative excess risk (RER) showed an estimated 23%, 44% and 54% lower excess mortality when comparing TT2 (+ thal), TT2 (-thal) and TT3a with TT1, respectively. **Conclusions:** In the longest follow up duration of any MM clinical trial, a subset of MM pts are cured as evidenced by RSRs approaching 1. Approximately one third of pts treated on TT2 protocol and one-half pts treated on TT3a are alive at 20 year and 15 yrs from initial diagnosis, respectively. Incorporation of immunomodulatory drugs and proteasome inhibitors along with tandem ASCT resulted in cumulative improvement of OS as evidenced by lower RER of mortality. Clinical trial information: NCT00580372, NCT00083551, NCT00081939, NCT00572169. Research Sponsor: None.

Genomic landscape of multiple myeloma with extramedullary disease: Results from a large patient database. *First Author: Mateo Mejia Saldarriaga, Weill Cornell Medicine, New York, NY*

Background: Extramedullary disease (EMD) is associated with poor outcomes and the biological mechanisms driving this phenotype are poorly understood. We used the CoMMpass registry data to explore the genomic characteristics of EMD. **Methods:** The CoMMpass study is a prospective, international registry of newly diagnosed MM. 1143 patients had clinical data. Patients were classified as EMD if they had EMD at any point. Genomic data from bone marrow (BM) samples at diagnosis (whole genome sequencing, whole exome sequencing (WES), and RNA sequencing (RNAseq)) were compared between EMD and non-EMD. A multivariable model was constructed based on univariable results. Differential expression (DEA) and gene set enrichment analysis (GSEA) were performed after normalization using Hallmark and MM transcriptomic subgroups. The top 24 most mutated genes in MM were selected. **Results:** The median overall survival (mOS) and progression free survival (PFS) was shorter for EMD. The presence of EMD, anemia at diagnosis, age >65 years at diagnosis, ISS stage, and use of ASCT at the first line were independently associated with worse mOS and PFS. EMD was associated with worse mOS (HR 1.7, 95% CI 1.3 - 2.2 p <0.01) and PFS (HR 1.5, 95% CI 1.23 - 1.8, p <0.01) in multivariable analysis and was not abrogated by ASCT, triplet induction or maintenance. Results did not vary when landmark analysis was used. *MYC* amplification, deletion 18q and 1q amplification were enriched in EMD cases. *TP53* mutations and *TP53* bi-allelic inactivation (mutation and deletion) were enriched in EMD (Table). DEA identified 1552 genes with increased and 3344 with decreased expression (2.7%, 5.4% of total genes respectively) in EMD when compared to non-EMD. On GSEA, EMD cases were enriched for the CD-1, PR, and CTA myeloma gene expression signatures, in addition to the Hallmark pathways MYC target, E2F targets, G2M checkpoint and unfolded protein response, while the adhesion molecules pathway and MM gene signatures LB, MS, and MF were down-regulated in EMD. **Conclusions:** EMD cases were enriched for *TP53* mutations and bi-allelic *TP53* inactivation, both of which are prognostic. In addition, *MYC* amplification, 18q deletion and 1q gain were enriched in EMD which are novel CNA associated with EMD. EMD is also enriched for distinct molecular subgroup, including enrichment for CD-1, PR, and CTA signatures, the latter two are associated with poor outcomes, and the Hallmark pathways MYC, E2F and G2M checkpoints consistent with *MYC* amplification and PR molecular subgroup. WES and RNAseq of matching BM and EMD tissue samples from our institution is currently being performed. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

T cell exhaustion markers in multiple myeloma patients before and after physical activity intervention. *First Author: Janine Joseph, Department of Cancer Prevention and Control, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: There is substantial evidence that the immune system is dysfunctional in multiple myeloma (MM). Adaptive immune cells, such as CD4⁺ and CD8⁺ T cells, are ineffective at controlling MM progression, suggesting immunosuppression. Therefore, efforts to overcome immunosuppression are likely key to more effective tumor control. Recent evidence from pre-clinical models suggests that exercise represents a non-pharmaceutical means to reduce immune exhaustion, but few studies have examined the relationship between an exercise intervention and biomarkers of immune exhaustion in cancer patients, especially in MM – the objective of this study. **Methods:** In this feasibility trial, 24 MM patients participated in a six-month physical activity intervention. The strength training arm (n=12) performed twice weekly supervised resistance trainings. The walking arm (n=12) engaged in an unsupervised, home-based wearable activity tracker intervention. Subjects provided peripheral blood samples before the start and at the conclusion of the intervention. Comprehensive flow cytometry was utilized to assess the frequency of mononuclear cells of interest, including CD4⁺ and CD8⁺ T cells and subpopulations expressing the markers of exhaustion PD-1 and/or TIGIT, which are the two exhaustion markers with the highest expression in this study sample. Ratios of exhausted cells (expressing any, one, or both of those markers) to non-exhausted cells (expressing no exhaustion markers) were calculated. Changes in the median values of these ratios were compared using Wilcoxon signed-rank tests. **Results:** Results from the immune panels are shown for the combined sample (n=24). All ratios of exhausted to non-exhausted cells were lower at the end of the six-month intervention, compared to baseline. The ratio of CD4⁺ TIGIT⁺ to non-exhausted CD4⁺ cells was significantly reduced, from 0.71 to 0.57 (p=0.04). The ratio of CD8⁺ PD-1⁺ to non-exhausted CD8⁺ cells was borderline significantly reduced, from 1.81 to 1.48 (p=0.06). **Conclusions:** This pilot study suggests that physical activity induces changes in MM patients' immune systems, potentially rendering a less exhausted T cell state. Larger studies are warranted to examine how exercise alters activation vs exhaustion phenotypes within specific T cell subsets (naïve, central memory, effector memory, regulatory) and to elucidate the effects of strength-based vs aerobic exercise on T cell function. Research Sponsor: Roswell Park Comprehensive Cancer Center.

Ratio ^a	Baseline	Final	p-value
CD4 ⁺ PD-1 ⁺ or TIGIT ⁺	1.33 (1.18)	1.15 (1.04)	0.14

Utilizing a two-step frailty assessment strategy in older adults with multiple myeloma (MM): A decision curve analysis. *First Author: Andrew Gahagan, Department of Hematology and Oncology, University of Alabama at Birmingham, Birmingham, AL*

Background: The International Myeloma Working Group Frailty Index (IMWG-FI) has been shown to predict risk of toxicity and mortality in older adults with MM (Palumbo et al., *Blood* 2015). However, IMWG-FI requires a geriatric assessment (GA) that is not routinely done in clinical practice due to time constraints. A simplified frailty index (SFI; Facon et al., *Leukemia* 2020) has been proposed as an alternative using ECOG PS as a proxy to functional status. We previously reported a moderate concordance between these two frailty indices (Kappa statistic 0.50; Gahagan et al., *ASH* 2022). Here, we examined if SFI can be utilized as a screening tool to identify patients who would benefit from a formal GA and frailty assessment. We hypothesized that a two-step approach would minimize the need for unnecessary GAs, while saving time in clinical practice. **Methods:** For this analysis, we included patients ≥ 50 yo with newly diagnosed (ND) or Relapsed/Refractory (RR)-MM at a single institution initiating a new treatment regimen (1st to 6th line) who are enrolled in a prospective registry (NCT05556928). All patients underwent a GA prior to a new line of therapy. ECOG PS and comorbidities were abstracted from medical records. We calculated IMWG-FI and SFI using published methods. Sensitivity, specificity along with their 95% CI were calculated for both SFI and IMWG-FI, using published SFI cutpoints. Lastly, we used decision curve analysis (DCA) as described by Vickers et al. to calculate the benefit of frailty screening using SFI for detection of non-frail patients and avoiding unnecessary GAs. We assumed that reasonable threshold probabilities were 0.25 and 0.33 respectively indicating that missing an unfit patient was 3 and 2 times worse than exposing a fit patient to an unnecessary GA (odds of 1:3 and 1:2 respectively). We quantified the net benefit (NB) of this two-step frailty assessment versus GA-for-all in terms of net reduction in unnecessary GAs. **Results:** A total of 146 adults with MM (49 ND-MM, 51 pre-transplant, and 46 RR-MM) starting a new line of therapy between 8/2020-1/2022 were included in this study. The median age was 62 (IQR 57-70) with 53% males and 36% blacks. The distribution by IMWG-FI was 43% fit, 32% intermediate-fit, and 25% frail. Using SFI, 32% of patients were frail. Using a cutpoint of ≥ 2 , SFI as a screening tool had a sensitivity of 89.2% (95% CI 75-96%) and a specificity of 65% (95% CI 56% to 73%). DCA showed that selecting candidates for GA based on a two-step strategy (SFI followed by IMWG-FI) led to an absolute 40-45% reduction in the number of unnecessary GAs without missing any frail patients. **Conclusions:** Our results suggest that using a two-step frailty assessment strategy of SFI as a screening tool followed by confirmation with IMWG-FI reduces the need for unnecessary GAs by 40-45% and may be more suitable for integration in busy oncology practice. A first-in-human phase 1, multicenter, open-label study of CB-011, a next-generation CRISPR-genome edited allogeneic anti-BCMA immune-cloaked CAR-T cell therapy, in patients with relapsed/refractory multiple myeloma (CAMMOUFLAGE trial). *First Author: Jesus G. Berdeja, Sarah Cannon Research Institute, Nashville, TN*

Background: Autologous CAR-T cell therapies have shown significant benefit in the treatment of adults with relapsed/refractory multiple myeloma (r/r MM). However, these CAR-T cell therapies may have inherent challenges, including functional deficiencies in the patient's T cells, that could yield an inconsistent or impaired product, as well as require extended time and complexity in manufacturing, thereby limiting patient access and potentially requiring bridging therapy. CB-011 is an allogeneic, off-the-shelf anti-BCMA CAR-T cell therapy derived from healthy donor T cells. A next-generation CRISPR-Cas12a genome-editing technology using CRISPR hybrid RNA-DNA (chrDNA) guides, developed at Caribou to significantly reduce off-target editing, was implemented to generate 4 genome edits in the manufacture of CB-011: (i) the *TRAC* gene was knocked out to eliminate T cell receptor (TCR) expression and prevent graft versus host disease (GvHD), (ii) the BCMA-specific CAR was site-specifically inserted into the genome at the *TRAC* locus to eliminate random integration and serves to target the tumor antigen, (iii) the *B2M* gene was knocked out to eliminate expression of HLA class I molecules to mitigate host T cell cytotoxicity, and (iv) a B2M-HLA-E fusion transgene was site-specifically inserted into the genome at the *B2M* locus to overcome host NK cell-mediated killing following recognition of "missing self." This immune cloaking strategy has the potential to allow persistent antitumor activity of the CAR-T cells in the context of antigen engagement. Significant preclinical efficacy in vitro and in vivo supports the clinical evaluation of CB-011. **Methods:** CB-011 is being evaluated in a multicenter, Phase 1 clinical trial in patients with r/r MM. A 3+3 dose escalation design followed by expansion at the maximum tolerated dose (MTD) and/or the recommended Phase 2 dose (RP2D) is being utilized. Primary objectives are to determine the safety and tolerability of CB-011, and the recommended Phase 2 dose (RP2D). Additional key objectives include preliminary antitumor activity and pharmacokinetics (PK). After concurrently receiving lymphodepletion therapy with cyclophosphamide (300 mg/m²/d) and fludarabine (30 mg/m²/d) for 3 days, patients receive a single dose infusion of CB-011 and are followed for safety and efficacy. Antitumor activity and disease response are measured by International Myeloma Working Group criteria. The CAMMOUFLAGE Phase 1 trial is actively enrolling patients and additional information is available on clinicaltrials.gov (NCT05722418). Clinical trial information: NCT05722418. Research Sponsor: Caribou Biosciences.

Presence of hyperdiploidy and history of tobacco use in African American patients with SMM. *First Author: Rujul H Parikh, Emory University, Winship Cancer Institute, Atlanta, GA*

Background: Smoldering multiple myeloma (SMM) has a clinically variable course in progression to active myeloma (MM). Accurate risk stratification is essential in identifying which patients may benefit from early therapeutic intervention. Current models do not account for the potential impact of race on risk of progression to SMM. Here, we seek to identify independent risk factors for progression in African American (AA) versus white patients in a real-world single institutional database of SMM patients. **Methods:** We retrospectively identified 224 patients (pts) with untreated SMM from 2007 to 2021 treated at our institution. Patient demographics and disease characteristics were obtained from our IRB-approved myeloma database. TTP was defined as the time from diagnosis of SMM to diagnosis of active MM, estimated by Kaplan-Meier and compared by log-rank test. Univariate analyses were performed using Cox proportional hazard models for TTP. **Results:** A total of 224 pts (AA 35%, white 47%, other/unknown 17%) were identified with median age 62y (range 32-82). Median follow-up was 4.3y in Whites and 5y in AA pts. Notable characteristics include M/F 45%/54%, IgG/IgA/FLC 76%/17%/6%, 30% current/past smoker (median 15 pack-years), 12% alcohol use (≥ 10 drinks/wk), 45% with BMI > 30 . Multiple cytogenetic abnormalities were defined as presence of ≥ 2 of the following: t(4;14), t(14;16), gain(1q21), del(1p), del(13), or del(17p). The median TTP (mTTP) was 6.8 [95% CI (3.7, 8.2)] years in whites and 5.6 [95% CI (4.6, 11.8)] years in AA. On univariate analysis, M-spike > 1.5 , involved K/L ratio > 12 , and bone marrow PC $> 20\%$ were associated with increased risk of progression for both AA and whites (all $p < 0.05$). As expected, gain of 1q21 was associated with increased risk of progression for both groups, though more pronounced in AA (HR 2.94, $p = 0.025$) versus whites (HR 2.33, $p = 0.013$). Hyperdiploidy was associated with shorter mTTP in AA (HR 3.03, $p = 0.004$) compared to whites (HR 1.39, $p = 0.3$). Multiple cytogenetic abnormalities was associated with shorter mTTP in whites (HR 2.63, $p = 0.004$) but was not statistically significant in AA (HR 2.63, $p = 0.104$). Interestingly, tobacco use was associated with shorter mTTP in Blacks (HR 2.94, $p = 0.005$) but not in whites (HR 0.96, $p = 0.85$). **Conclusions:** Understanding the potential impact of racial background on progression from SMM to MM is critical in the appropriate management of all patients with SMM. In this database, with a large proportion of AA patients, hyperdiploidy and +1q portend high risk of progression in AA patients. Further study is needed to better classify these potential differences to ensure risk stratification models are applicable to all patients. Research Sponsor: None.

CAMMA 2: A phase I/II trial evaluating the efficacy and safety of cevostamab in patients with relapsed/refractory multiple myeloma (RRMM) who have triple-class refractory disease and have received a prior anti-B-cell maturation antigen (BCMA) agent. *First Author: Shaji Kumar, Mayo Clinic, Rochester, MN*

Background: Multiple myeloma (MM) remains an incurable disease. Combinations of established agents, including proteasome inhibitors (PIs), immunomodulatory drugs (IMiDs), and anti-CD38 antibodies, are used in all lines of therapy, but re-exposure to previously received classes of therapy is associated with decreasing response rates and duration of response (Moreau et al. 2021). BCMA-targeted agents have recently been approved for the treatment of patients with RRMM whose disease has been exposed or become refractory to PIs, IMiDs and anti-CD38 antibodies (triple-class exposed or refractory MM). Although effective, the majority of patients who respond to anti-BCMA agents eventually relapse. Proven salvage therapies for these patients are currently lacking and represent a new unmet medical need. Cevostamab is an immunoglobulin G1-based T-cell-engaging bispecific antibody that targets Fc receptor-homolog 5 (FcRH5) on myeloma cells and CD3 on T cells. Dual binding results in T-cell activation and potent killing of MM cells. In an ongoing Phase I study (G039775; NCT03275103), cevostamab monotherapy showed promising activity in heavily pre-treated patients with RRMM, including those with prior exposure to anti-BCMA agents (Trudel et al. 2021). **Methods:** CAMMA 2 (CO43476; NCT05535244) is an open-label, multicenter Phase I/II trial evaluating cevostamab monotherapy in patients with RRMM who are triple-class refractory and have previously received an anti-BCMA agent. Prior anti-BCMA antibody-drug conjugates or chimeric antigen receptor (CAR) T cells are permitted in Cohorts A1 and B1, while prior anti-BCMA bispecific antibodies are allowed in Cohorts A2 and B2. In A1 and A2, cevostamab is administered by intravenous infusion and is initiated with step dosing (0.3mg on Cycle [C] 1 Day [D] 1 and 3.3mg on C1D2, D3, or D4 depending on the emergence and resolution of cytokine release syndrome [CRS] after the initial administration), with the target dose of 160mg given on C1D8 and on D1 of each subsequent 21-day cycle. Patients are hospitalized for the C1 administrations only and treatment is continued until disease progression or unacceptable toxicity occurs. CRS is managed per protocol based on the clinical presentation and may involve corticosteroid and tocilizumab treatment. Primary objectives are evaluation of efficacy (primary endpoint: objective response rate by investigator assessment using IMWG criteria) and safety. Secondary objectives include assessment of quality of life, pharmacokinetics, pharmacodynamics, and immunogenicity. Cohorts B1 and B2 will evaluate the efficacy and safety of cevostamab at the recommended Phase II dose in this setting. As of February 2023, enrollment into Cohorts A1 and A2 is ongoing. Clinical trial information: NCT05535244. Research Sponsor: CAMMA 2 is sponsored by F. Hoffmann-La Roche Ltd. Third-party medical writing assistance, under the direction of all authors, was provided by Helen Cathro, PhD, of Ashfield MedComms, an Inizio company, and was funded by F. Hoffmann-La Roche Ltd.

MagnetisMM-6: An open-label, multicenter, randomized phase 3 study of elranatamab + daratumumab + lenalidomide (EDR) versus daratumumab + lenalidomide + dexamethasone (DRd) in transplant ineligible (TI) patients with newly diagnosed multiple myeloma (NDMM). *First Author: Sebastian Grosicki, Department of Hematology and Cancer Prevention, Medical University of Silesia, Katowice, Poland*

Background: Elranatamab, a humanized bispecific antibody targeting B cell maturation antigen (BCMA) on myeloma cells and CD3 on T cells, has shown promising efficacy and acceptable safety in clinical studies, as monotherapy (MagnetisMM-3, NCT04649359) and in combination with daratumumab (MagnetisMM-5, NCT05020236), in the treatment of patients with relapsed/refractory multiple myeloma (RRMM). Despite recent advances in the treatment of NDMM, MM remains incurable and more effective treatment options are needed. The aim of the MagnetisMM-6 study (NCT05623020) is to evaluate EDR versus DRd for TI patients with NDMM. **Methods:** MagnetisMM-6 is an ongoing, open-label, 2-arm, multicenter, randomized phase 3 study estimated to enroll ~646 patients. There are 2 parts: Part 1 evaluates the safety and recommended phase 3 dose (RP3D) of EDR; Part 2 evaluates the efficacy and safety of EDR at RP3D vs DRd in TI patients with NDMM. TI is defined as age ≥ 65 or age < 65 with comorbidities impacting the possibility of transplant. The primary endpoints of Part 2 are minimal residual disease (MRD) at 12 mo and progression-free survival. Secondary endpoints include overall and sustained MRD negativity rates, duration of MRD negativity, objective response rate, complete response (CR) rate, time to response, duration of response, duration of CR, overall survival, safety, quality of life, immunogenicity, and pharmacokinetics. Part 1 includes TI patients with NDMM as well as patients with RRMM who have received 1–2 prior lines of therapy including ≥ 1 immunomodulatory drug and ≥ 1 proteasome inhibitor. Part 2 includes only TI patients with NDMM. Key inclusion criteria are: ≥ 18 y; a diagnosis of MM (according to International Myeloma Working Group [IMWG] criteria); an ECOG performance status ≤ 2 ; and measurable disease based on IMWG criteria (serum M-protein ≥ 0.5 g/dL, urinary M-protein excretion ≥ 200 mg/24 hr, or involved serum free light chain [FLC] ≥ 100 mg/L and abnormal serum immunoglobulin $\kappa:\lambda$ FLC ratio [< 0.26 or > 1.65]). Key exclusion criteria are: smoldering MM; monoclonal gammopathy; Waldenström's macroglobulinemia; plasma cell leukemia; active, uncontrolled bacterial, fungal, or viral infections; previous systemic treatment for MM (NDMM patients only); previous treatment with a BMCA-directed therapy or anti-CD38-directed therapy ≤ 6 mo of the first dose of study treatment (RRMM patients only); or stem cell transplant ≤ 3 mo of the first dose of study treatment or active graft versus host disease (RRMM patients only). As of February 2023, the study is open and enrolling at 9 sites in 5 countries. Clinical trial information: NCT05623020. Research Sponsor: Pfizer.

MajesTEC-9: A randomized phase 3 study of teclistamab versus pomalidomide, bortezomib, and dexamethasone or carfilzomib and dexamethasone in patients with relapsed/refractory multiple myeloma. *First Author: Cyrille Touzeau, Centre Hospitalier Universitaire de Nantes, Nantes, France*

Background: Despite the advance in therapeutic options for patients with relapsed/refractory multiple myeloma (RRMM) over recent years, there remains a significant unmet medical need for new, well-tolerated therapies in earlier lines for patients who have previously received an anti-CD38 monoclonal antibody and lenalidomide. Teclistamab is the first B-cell maturation antigen (BCMA)-directed bispecific antibody approved for the treatment of triple class-exposed RRMM. Teclistamab redirects CD3+ T cells to mediate T-cell activation and subsequent lysis of BCMA-expressing myeloma cells. MajesTEC-9 (NCT05572515) is a phase 3, randomized, open-label, multicenter study comparing teclistamab with investigator's choice of pomalidomide, bortezomib, and dexamethasone (Pvd) or carfilzomib and dexamethasone (Kd) in patients with RRMM. **Methods:** Patients aged ≥ 18 years with RRMM (International Myeloma Working Group [IMWG] criteria) must have evidence of progressive disease or failure to achieve a response to last line of therapy and an Eastern Cooperative Oncology Group performance status score of 0–2. All patients must have received 1–3 prior lines of therapy, including ≥ 2 consecutive cycles of an anti-CD38 monoclonal antibody and ≥ 2 consecutive cycles of lenalidomide. Those treated with prior BCMA-directed therapy will be excluded. Approximately 590 patients will be randomized 1:1 to receive either teclistamab (28-day cycles) or Pvd (21-day cycles) or Kd (28-day cycles). Stratification factors include investigator's choice of Pvd or Kd, stage of disease, number of prior lines of therapy, and anti-CD38 monoclonal antibody refractory status. Treatment will continue until disease progression, death, intolerance, withdrawal of consent, or end of study, whichever occurs first. The primary endpoint is progression-free survival (IMWG 2016 criteria); secondary endpoints include overall response rate, duration of response, and overall survival. Adverse events (AEs) will be graded by Common Terminology Criteria for AEs v5.0; cytokine release syndrome and immune effector cell-associated neurotoxicity syndrome will be graded by American Society for Transplantation and Cellular Therapy criteria. The study opened in January 2023 and enrollment is ongoing. Clinical trial information: NCT05572515. Research Sponsor: Janssen Research & Development.

MagnetisMM-7: An open-label, multicenter, randomized phase 3 study of elranatamab versus lenalidomide in post-transplant patients with newly diagnosed multiple myeloma. *First Author: Maria Victoria Mateos Manteca, Salamanca University Hospital, Salamanca, Spain*

Background: Elranatamab is a humanized bispecific antibody targeting B cell maturation antigen (BCMA) on myeloma cells and CD3 on T cells. Elranatamab has shown promising efficacy and acceptable safety in pts with relapsed and/or refractory multiple myeloma (MM). The aim of the MagnetisMM-7 study is to evaluate elranatamab monotherapy vs lenalidomide monotherapy in pts with newly diagnosed MM (NDMM) after undergoing autologous stem cell transplant (ASCT). **Methods:** MagnetisMM-7 is an ongoing, open-label, 2-arm, multicenter, randomized phase 3 study estimated to enroll ~700 pts. ClinicalTrials.gov ID: NCT05317416. Pts are randomized to receive either subcutaneous elranatamab or oral lenalidomide once daily. After initial step-up dosing, two alternative dosing regimens of elranatamab are examined. The primary endpoint is progression-free survival (PFS) assessed by blinded independent review per International Myeloma Working Group (IMWG) criteria (up to ~5 y). Secondary endpoints include overall survival, minimal residual disease (MRD) negativity rate at 12 mo after randomization per IMWG criteria as assessed via next-generation sequencing (NGS), sustained MRD negativity rate at 24 mo after randomization as assessed via NGS, PFS by investigator, duration of MRD negativity, complete response (CR) rate, duration of CR, safety, quality of life, immunogenicity, and pharmacokinetics. Key inclusion criteria are: ≥ 18 y; a diagnosis of MM with measurable disease according to IMWG criteria; history of induction therapy for NDMM, followed by high dose therapy and ASCT with or without consolidation; partial response or better according to IMWG criteria; identification of the dominant malignant clone; and Eastern Cooperative Oncology Group performance status ≤ 1 . Randomization must occur ≤ 120 d from ASCT; for pts who receive consolidation therapy after ASCT, randomization must occur ≤ 60 d of consolidation and ≤ 7 mo of ASCT. Key exclusion criteria are: plasma cell leukemia; amyloidosis; Waldenström's macroglobulinemia; POEMS syndrome; known active CNS involvement or clinical signs of myelomatous meningeal involvement; previous MM maintenance treatment; prior treatment with BCMA-targeted therapy; any other active malignancy ≤ 3 y of enrollment; active, uncontrolled bacterial, fungal, or viral infection; and previous administration of an investigational drug or vaccine ≤ 30 d or 5 half-lives preceding the first dose of study treatment. As of February 2023, the study is open and enrolling at 29 sites in 13 countries. Clinical trial information: NCT05317416. Research Sponsor: Pfizer.

OMNIA-2: Phase I/II study of ANV419, an IL-2R- $\beta\gamma$ targeted antibody-IL-2 fusion protein, in patients with relapsed or refractory multiple myeloma. *First Author: Dagmar Hess, Kantonsspital St. Gallen, St. Gallen, Switzerland*

Background: ANV419 is a potent, selective IL-2R $\beta\gamma$ targeted antibody IL-2 fusion protein, designed to enable the delivery of high dose interleukin-2 (IL-2) to patients, in order to stimulate anti-tumour response and minimise toxicities. The ANV419-001 first-in-human study (NCT 04855929) demonstrated that ANV419 preferentially stimulates cytotoxic CD8+ T and natural killer (NK) cells over immunosuppressive regulatory T cells, with a significantly longer half-life than that of conventional IL-2. The safety and tolerability data from this study confirmed that ANV419 delivers high molar equivalents of IL-2 in a tolerable and convenient way. In patients with multiple myeloma, the critical role of NK cells has been well described. ANV419 is expected to promote antitumor response via the preferential stimulation of cytotoxic CD8+ T and NK cells. **Methods:** The OMNIA-2 study (ANV419-102; NCT 05641324) will evaluate safety and preliminary efficacy of ANV419 as monotherapy and in combination with daratumumab (dara), or lenalidomide with low dose dexamethasone (lena/dex), in patients with relapsed or refractory multiple myeloma. OMNIA-2 is a Phase I open-label, multi-center study in adult patients ($n = 52$) with symptomatic multiple myeloma who responded to previous treatment and received autologous stem cell transplant, or at least 2 lines of therapy including an immunomodulator, proteasome inhibitor, and/or dara. The study is conducted in 2 stages using a Bayesian Optimal Phase 2 approach. Stage 1 consists of a run-in phase with subsequent randomization to ANV419 243mcg/kg or ANV419 108mcg/kg for 8 weeks, followed by a second randomization to ANV419 108mcg/kg in combination with lena/dex or dara for a further 8 weeks. Stage 2 follows a similar design as stage 1 and consists of a monotherapy run-in phase with either high or low dose ANV419, with a second randomisation to ANV419 108mcg/kg in combination with either lena/dex or dara, according to the safety and efficacy observed in Stage 1. ANV419 is administered intravenously over 15 to 20 minutes every two weeks. Lena, dex and dara are administered at their respective approved dosing regimens. Tumour response is determined using IMWG (2016) response criteria. AEs are assessed according to CTCAE V5.0. OMNIA-2 is being conducted in Denmark, France, Germany, Spain, Switzerland, UK and enrolment began in January 2023 and preliminary data are expected in Q1 2024. Clinical trial information: NCT05641324. Research Sponsor: ANAGEON AG.

EXCALIBER-RRMM: A phase 3, two-stage study of iberdomide, daratumumab, and dexamethasone (IberDd) versus daratumumab, bortezomib, and dexamethasone (DvD) in patients (pts) with relapsed/refractory multiple myeloma (RRMM). *First Author: Sagar Lonial, Winship Cancer Center of Emory University, Atlanta, GA*

Background: New treatments (Tx) are needed to achieve deep and durable responses in RRMM. Iberdomide (IBER) is a novel, potent oral cereblon E3 ligase modulator (CELMoD) with enhanced tumoricidal and immune-stimulatory effects compared with immunomodulatory drugs (IMiDs). IBER has synergy with dexamethasone (DEX), daratumumab (DARA), and bortezomib (BORT) in vitro. In a phase 1/2 trial, IberDd demonstrated efficacy with a manageable safety profile in pts with RRMM (Lonial S, et al. *HemaSphere* 2021;5(S2):S187). The EXCALIBER-RRMM phase 3 trial (NCT04975997) will compare the efficacy and safety of IberDd with that of DvD in pts with early RRMM. **Methods:** This multicenter, open-label study will be conducted in 2 stages: in Stage 1, ≥ 200 pts will be randomized 1:1:1 to 1 of 3 IBER doses (1.0, 1.3, or 1.6 mg) + DARA and DEX or to the DvD arm to identify optimal IBER dose when combined with DARA + DEX; in Stage 2, ≈ 664 additional pts will be randomized 1:1 to IberDd at the selected IBER dose or to DvD, for efficacy and safety analyses (Stage 1 pts in IBER selected dose cohort and DvD arm to be also included). Pts will be stratified by number of prior Tx lines (1 vs 2), age (≤ 70 vs > 70 y), and ISS stage at study entry (I-II vs III). Primary efficacy endpoint is progression-free survival (PFS), which is defined as the time from randomization to progressive disease (PD) or death. Assuming a decrease in PFS risk by 25% (HR = 0.75) with IberDd, under exponential distribution assumption of PFS (1-sided $\alpha = 0.025$) and adjusted for 3 interim analyses, 458 PFS events will have $\approx 84\%$ power to detect an improvement in Tx effect. The 3 planned interim analyses are: for IBER dose selection at end of Stage 1; and to examine PFS futility and superiority when ≈ 138 (30%) and ≈ 344 (75%) events, respectively, have been accumulated. Secondary endpoints include overall survival, duration of response, time to progression, overall response rate, measurable residual disease negativity rate, safety, and quality of life. Tx in the IberDd arm will consist of 28-day (D) cycles (C) with IBER on D1–21; 1800 mg subcutaneous (SC) DARA on D1, 8, 15, and 22 of C1–2, D1 and 15 of C3–6, and D1 of $\geq C7$; and 40 mg oral DEX (20 mg in pts > 75 y of age) on D1, 8, 15, and 22. Tx in the DvD arm will consist of 21-D cycles for C1–8 and 28-D cycles for $\geq C9$; 1800 mg SC DARA on D1, 8, and 15 for C1–3, D1 for $\geq C4$; 1.3 mg/m² SC BORT on D1, 4, 8, and 11 for C1–8; and 20 mg oral DEX (10 mg in pts > 75 y of age) on D1, 2, 4, 5, 8, 9, 11, and 12 for C1–8. Tx will continue until confirmed PD, unacceptable toxicity, or consent withdrawal. Key eligibility criteria include age ≥ 18 y, 1–2 prior lines of anti-myeloma Tx, partial response or better to ≥ 1 prior Tx, and documented PD during or after the last regimen. Prior anti-CD38 Tx is allowed only in Stage 2 ($\leq 10\%$ of pts). Enrollment began in June 2022 and is currently ongoing. Clinical trial information: NCT04975997. Research Sponsor: Bristol Myers Squibb.

Poster Session

A phase 3, two-stage, randomized study of mezigdomide, carfilzomib, and dexamethasone (MeziKd) versus carfilzomib and dexamethasone (Kd) in relapsed/refractory multiple myeloma (RRMM): SUCCESSOR-2. *First Author: Paul G. Richardson, Dana-Farber Cancer Institute, Boston, MA*

Background: Mezigdomide (MEZI), a novel oral cereblon E3 ligase modulator (CELMoD), induces maximal degradation of Ikaros/Aiolos leading to increased MM cell apoptosis and immune-stimulatory effects. MeziKd has shown potent synergistic antiproliferative activity in MM cell lines resistant to lenalidomide (LEN), and in a phase 1/2 study showed promising preliminary efficacy and safety in RRMM. The SUCCESSOR-2 phase 3 trial (NCT05552976) will compare the efficacy and safety of MeziKd vs Kd in patients (pts) with RRMM. **Methods:** This multicenter, open-label study comprises 2 stages. In Stage 1, ≥ 128 pts will be randomized 3:3:3:2 to 1 of 3 MEZI doses (1.0, 0.6, or 0.3 mg) + Kd, or to the Kd arm to select the optimal MEZI dose in combination with Kd for Stage 2. In Stage 2, ≈ 397 additional pts will be randomized 3:2 to MeziKd at the selected MEZI dose or to Kd, for efficacy and safety analyses (Stage 1 pts in the selected MeziKd dose cohort and Kd arm will also be included in these analyses). Pts will be stratified by age (≤ 70 vs > 70 y), number of prior lines of treatment (Tx; ≤ 2 vs > 2), and ISS stage at screening (I vs II vs III). MEZI dose selection will be based on Stage 1 efficacy, safety, pharmacokinetic and pharmacodynamic data, and exposure-response analyses. Primary efficacy endpoint is progression-free survival (PFS). Assuming a decrease in PFS risk by 33.3% (HR = 0.667) with MeziKd, under exponential distribution assumption of PFS (1-sided $\alpha = 0.025$) and adjusted for 3 interim analyses, ≥ 273 PFS events will have $\approx 89\%$ power to detect improvement in Tx effect. The planned interim analyses are for: MEZI dose selection at end of Stage 1, and to examine PFS futility and superiority when ≈ 82 (30%) and ≈ 205 (75%) events, respectively, have been accumulated. Secondary endpoints include determination of the recommended MEZI dose plus Kd (Stage 1 only), and assessment of overall survival, overall response rate, time to response, duration of response, time to progression, safety, and quality of life. MeziKd arm Tx consists of 28-day (D) cycles (C) with MEZI on D1–21; 20 mg/m² intravenous (IV) carfilzomib (CFZ) on D1 of C1, then 56 mg/m² on D8 and 15 of C1, on D1, 8, and 15 of C2–12, and on D1 and 15 of $\geq C13$; and 40 mg oral/IV DEX (20 mg optional in certain pt groups) on D1, 8, 15, and 22. Tx in the Kd arm consists of 28-D cycles with 20 mg/m² IV CFZ on D1 and 2 of C1, then 56 mg/m² on D8, 9, 15, and 16 of C1, and on D1, 2, 8, 9, 15, and 16 of $\geq C2$; and 20 mg oral/IV DEX (10 mg optional in certain pt groups) on D1, 2, 8, 9, 15, 16, 22, and 23. Tx will continue until progressive disease (PD) or unacceptable toxicity. Key eligibility criteria include age ≥ 18 y, ≥ 1 prior line of anti-MM Tx including LEN and an anti-CD38 monoclonal antibody, minimal response or better to ≥ 1 prior Tx, documented PD during or after last regimen, and no prior CFZ Tx. Enrollment began in October 2022 and is ongoing. Clinical trial information: NCT05552976. Research Sponsor: Bristol Myers Squibb.

Poster Session

Enrolling patients in Cardiac Amyloid Reaching for Extended Survival (CARES) trials: Two placebo-controlled, double-blind, randomized, international phase 3 trials assessing CAEL-101 in patients with Mayo stage IIIa or stage IIb AL amyloidosis. *First Author: Michaela Liedtke, Stanford Cancer Center, Stanford, CA*

Background: Light-chain (AL) amyloidosis is a rare, progressive, systemic disorder caused by plasma cell dyscrasia (PCD). Amyloid fibrils deposit in organs leading to progressive organ damage and death. Prognosis is poor for patients with cardiac involvement. Median survival is 24 and 4 months for patients in Mayo Stages IIIa and IIb (based on the 2013 European Modification of the Mayo 2004 staging criteria), respectively. The standard of care (SoC) is anti-PCD therapy to suppress amyloid fibril generation. As yet, there are no therapies that remove deposited fibrils. CAEL-101 is a monoclonal antibody that binds to amyloid fibrils and may facilitate their systemic removal, improve organ function, and patient survival. These ongoing trials will evaluate the efficacy and safety of CAEL-101 as first-in-class treatment to reduce amyloid burden in patients with cardiac AL amyloidosis. Notably, 301 (Mayo Stage IIb) is the first randomized, placebo-controlled efficacy clinical trial to formally assess the effects of a pharmacological in this severely ill population. Because the median expected survival for Mayo Stage IIb patients is far shorter than for Mayo Stage IIIa patients, the resulting sample size required for the Mayo Stage IIb study is less than for the Mayo Stage IIIa study. The objective of these trials is to evaluate the efficacy and safety of CAEL-101 when administered concurrently with SoC anti-PCD therapy in treatment-naïve patients with cardiac AL amyloidosis in Mayo Stages IIb (NCT04504825; 301) or IIIa (NCT04512235; 302). **Methods:** These international, multicenter, double-blind, randomized, phase 3 trials, initiated in 2020, are enrolling patients at > 100 sites in > 20 countries. Newly diagnosed adults with AL amyloidosis stage IIb or IIIa measurable hematologic disease, and histopathological diagnosis of amyloidosis with cardiac involvement are eligible. Patients with other forms of amyloidosis, symptomatic orthostatic hypotension, or supine systolic blood pressure < 90 mm Hg are ineligible. Patients in Mayo Stages IIb (N = 124) and IIIa (N = 267) are being randomized 2:1 to receive once-weekly IV infusions of CAEL-101 (1000 mg/m²) or placebo for 4 weeks, followed by maintenance dosing every 2 weeks. In these event-driven studies, treatment will continue to a minimum of 101 and 79 events for 301 and 302, respectively. Patients will receive concurrent institutional SoC anti-PCD therapy at the discretion of the investigator. Overall survival (primary endpoint) will be analyzed via time-to-event log-rank statistics. Secondary endpoints include functional outcomes, quality of life, and echocardiography. Clinical trial information: NCT04504825, NCT04512235. Research Sponsor: Alexion, AstraZeneca Rare Disease.

Oral Abstract Session

Surgical outcomes of patients with resectable non-small-cell lung cancer receiving neoadjuvant immunotherapy with nivolumab plus relatlimab or nivolumab: Findings from the prospective, randomized, multicentric phase II study NEOpredict-Lung. *First Author: Clemens Aigner, West German Cancer Center, University Medicine Essen - Ruhrlandklinik, Essen, Germany*

Background: Feasibility of surgical resection for non-small-cell lung cancer (NSCLC) after preoperative immune checkpoint inhibitor therapy (PICIT) with PD-1/PD-L1 and CTLA-4 inhibitors has been established. This study reports the first data on surgery after preoperative LAG-3 inhibition in NSCLC patients. **Methods:** Patients with histologically confirmed NSCLC stage IB, II or IIIA (UICC 8th edition) were randomized to receive two preoperative doses (q14d) of nivolumab (240 mg, arm A), or nivolumab (240 mg) plus relatlimab (80 mg, arm B). Primary study endpoint was the number of patients undergoing curatively intended surgery within 43 days of initiation of PICIT. Surgery was performed following the institutional standards. Outcomes and peri-operative events were prospectively recorded. **Results:** 60 patients (29 female) were randomized 1:1 from 4/2020 to 7/2022. All patients were operated within 43 days after initiation of PICIT. Median age in arm A was 65 (43-78) years and 67 (44-81) years in arm B. Clinical UICC stages were similar between both arms. Central tumor location was present in 50% in arm A and 45% in arm B. R0 resection was achieved in 57 patients (95% ITT population, 98,3% curatively resected population). Two patients had pleural carcinosis only detected at surgery, and 1 patient had R1 resection. Resection was performed by lobectomy (n=23 and 24), bilobectomy (2 and 1), sleeve lobectomy (5 and 4) and combined lobectomy+segmentectomy (0 and 1). Surgical approach was either by videothoracoscopy (n=60% and 63,3%) or thoracotomy (n=40% and 36,6%). Conversion was required in 3 vs. 2 patients. Median operation time was 149 (77-234) and 165 (61-205) minutes. Median number of resected lymph nodes was 15 (3-52) and 10 (3-50). Intraoperative bleeding from the pulmonary artery was observed in 1 patient in each arm and was managed without sequelae. Post-operative complications occurred in 33,3% and 26,6%. Median hospital stay was 7 (2-22) and 5,5 (2-24) days. Complete or major histopathological response was observed in 27% and 30%. Overall perioperative 30-day mortality was 0%. No negative impact on adjuvant therapy was observed. The 12 months OS rate across both arms was 96% (95% CI: 83-99%), the DFS rate was 91 % (78-97%). **Conclusions:** Curative surgical resection following neoadjuvant combined PD-1/LAG-3 inhibition was equally safe and feasible as after PD-1 inhibition alone. Perioperative course, complications rate and outcome are comparable to other neoadjuvant regimens. Standard adjuvant therapies can be safely administered in this setting. Clinical trial information: NCT04205552. Research Sponsor: Bristol Myers Squibb.

Oral Abstract Session

First-in-human dose-escalation trial of BI 764532, a delta-like ligand 3 (DLL3)/CD3 IgG-like T-cell engager in patients (pts) with DLL3-positive (DLL3+) small-cell lung cancer (SCLC) and neuroendocrine carcinoma (NEC). *First Author: Martin Wermke, Technical University Dresden, NCT/ UCC Early Clinical Trial Unit, Dresden, Germany*

Background: The inhibitory Notch ligand, DLL3, is highly expressed on the cell surface of SCLC and NEC tumors and is a promising drug target. BI 764532 is a DLL3/CD3 T cell engaging bispecific antibody that has shown potent preclinical anti-tumor activity in DLL3+ cells and xenograft models. NCT04429087 is an ongoing phase I first-in-human, open-label, dose-escalation trial of BI 764532 in adults with locally advanced/metastatic DLL3+ (confirmed centrally) SCLC, NEC or small cell carcinoma of any other origin (grouped as NEC), or large cell NEC (LCNEC). **Methods:** BI 764532 was administered intravenously using three different regimens: Regimen (R) A (fixed iv dose q3w); RB1 (fixed iv dose qw); RB2 (step-in doses followed by a fixed dose). Treatment (Tx) continued until progressive disease (PD), unacceptable toxicity, other withdrawal criteria, or maximum Tx duration (36 mos). The main objective was to determine the maximum tolerated dose (MTD) and/or recommended dose for expansion of BI 764532, based on dose-limiting toxicities (DLTs) during the MTD evaluation period. Further objectives were safety, tolerability, PK/PD and preliminary efficacy based on investigator review (RECIST v1.1). **Results:** As of 28th Dec 2022, 90 pts received ≥ 1 dose of BI 764532 (RA: n = 24, 8 dose levels; RB1: n = 10, 3 dose levels; RB2: n = 56, 6 dose levels; starting dose: 0.03 µg/kg). Median age: 60 years (32–78); ECOG PS 0/1: 24/74%; prior PD1/PD-L1 Tx: 40%; ≥ 2 prior lines of Tx: 69%. SCLC/NEC/LCNEC: 52/41/4%. Median Tx duration: 43 days (range 1–443); 25 pts are ongoing. DLTs were seen in 1 pt on RA (Grade 3 confusion) and 4 pts on RB2 (Grade 4 cytokine release syndrome [CRS]; Grade 3 CRS, Grade 3 nervous system disorder, Grade 2 infusion-related reaction). MTD has not been reached and dose escalation is ongoing. Overall, the most common treatment-related AEs were (any/Grade 3+): CRS (58/2%); pyrexia (19/0%); decreased lymphocytes (18/14%); asthenia (17/1%); dysgeusia (14/0%). CRS was managed with supportive care, corticosteroids, and/or anti-IL-6R antibodies. With RB2, most CRS and neurological events occurred early, and were reversible. Tumor response data were available for 70 pts (RA/RB1/RB2: n = 19/8/43). In pts with SCLC (n = 24) or NEC (n = 23) who received ≤ target dose of BI 764532, ORR was 33% and 22% across all regimens, respectively. One pt with LCNEC was also evaluable for response and achieved PR. **Conclusions:** BI 764532 showed clinically manageable tolerability and MTD has not been reached at the doses administered to date. Promising efficacy has been observed, not only in SCLC but also in difficult to treat entities such as NEC and LCNEC. The study is ongoing; updated data will be presented. Clinical trial information: NCT04429087. Research Sponsor: Boehringer Ingelheim.

Oral Abstract Session

Perioperative toripalimab + platinum-doublet chemotherapy vs chemotherapy in resectable stage II/III non-small cell lung cancer (NSCLC): Interim event-free survival (EFS) analysis of the phase III NEOTORCH study. *First Author: Shun Lu, Shanghai Chest Hospital, Jiao Tong University, Shanghai, China*

Background: Adjuvant and neoadjuvant immunotherapy have been approved by US FDA to treat early-stage NSCLC. However, the optimal neoadjuvant and adjuvant treatment, including duration of treatment, are unknown. We present the interim results of a randomized, double-blind, placebo-controlled, Phase III trial to evaluate the efficacy and safety of perioperative toripalimab plus chemotherapy followed by toripalimab maintenance vs chemotherapy in resectable stage III NSCLC. **Methods:** Patients with stage II/III resectable NSCLC, without EGFR/ALK alterations for non-squamous NSCLC, were randomized 1:1 to receive 240 mg toripalimab or placebo combined with chemotherapy Q3W for 3 cycles before surgery and one cycle after surgery, followed by toripalimab or placebo monotherapy Q3W for 13 cycles. Stratification variables for randomization included disease stage, histopathologic subtype, PD-L1 expression and surgical procedure. Primary endpoints were EFS by investigator and major pathological response (MPR) rate by a blinded independent pathologic review (BIPR) in the stage III and the ITT populations. Secondary endpoints included overall survival (OS), pathologic complete response (pCR) rate, EFS by independent review committee (IRC), and safety. A planned interim analysis was performed on the primary endpoint of EFS in the stage III subjects. **Results:** A total of 404 stage III NSCLC patients were randomized to toripalimab (n=202) or placebo (n=202). By the data cutoff date (November 30, 2022), the median follow-up was 18.3 months. Baseline characteristics were well balanced between the two arms. EFS was significantly improved in the toripalimab arm, HR=0.40, 95% CI (0.277-0.565), P<0.0001, and crossed the pre-specified efficacy boundary. The median EFS was not reached in the toripalimab arm and 15.1 months in the placebo arm. A consistent effect on EFS, favoring toripalimab, was observed in all subgroups. The MPR and pCR rates per BIPR were also higher in the toripalimab arm, 48.5% vs 8.4% and 24.8% vs 1.0%, respectively. The OS results showed a trend favoring toripalimab. The incidence of Grade ≥ 3 adverse events (AEs) (63.4% vs 54.0%), fatal AEs related to toripalimab/placebo (0.5% vs 0%) and AEs leading to discontinuation of toripalimab/placebo (9.4% vs 7.4%) were comparable between the two arms. However, the incidence of immune-related AEs (42.1% vs 22.8%) was more frequent in the toripalimab arm. **Conclusions:** The addition of toripalimab to perioperative chemotherapy showed statistically significant improvements in EFS for stage III NSCLC patients with a manageable safety profile. Patients will be followed for overall survival. Clinical trial information: NCT04158440. Research Sponsor: Shanghai Junshi Biosciences Co.,Ltd.

Oral Abstract Session

Exploratory biomarker analysis of the phase 3 KEYNOTE-604 study of pembrolizumab plus etoposide for extensive-stage SCLC. *First Author: Charles M. Rudin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In the phase 3 KEYNOTE-604 study of extensive-stage small-cell lung cancer (ES-SCLC; NCT03066778), first-line pembrolizumab (pembro) plus etoposide and platinum (EP) significantly improved PFS vs placebo (pbo) plus EP (HR, 0.75; P = 0.0023), with favorable OS (significance threshold not met; HR, 0.80; P = 0.0164). PFS/OS were similar regardless of PD-L1 CPS. In this exploratory analysis, tumor mutational burden (TMB), 18-gene T cell-inflamed gene expression profile (Tcell_{infl}GEP) and SCLC transcriptional subtypes were assessed as correlates of survival. **Methods:** Patients (pts) eligible for this analysis of KEYNOTE-604 had previously untreated ES-SCLC with evaluable pretreatment tumor samples. TMB was assessed by whole-exome sequencing (WES) of tumor and matched normal DNA. RNA-seq was used to determine Tcell_{infl}GEP and SCLC transcriptional subtypes (ASCL1, POU2F3, NEUROD1, YAP1, or inflamed). Associations of TMB, Tcell_{infl}GEP, and SCLC subtype with OS were analyzed using an adjusted Cox proportional hazards model. 1-sided (pembro + EP) and 2-sided (pbo + EP) P values were calculated for TMB and Tcell_{infl}GEP (prespecified α = 0.05); 2-sided P values were calculated for SCLC subtype (multiplicity-adjusted, α = 0.10). Clinical utility was assessed using prespecified cutoffs of ≥ 175 mut/exome for TMB and the first tertile for Tcell_{infl}GEP. Clinical data cutoff date was Dec 2, 2019. **Results:** Of 453 pts randomized in KEYNOTE-604 (ITT), 318 had WES data (pembro + EP, n = 167; pbo + EP, n = 151), and 316 had RNA-seq data (pembro + EP, n = 159; pbo + EP, n = 157). High TMB was positively associated with OS in the pbo + EP group (P = 0.005) but not the pembro + EP group (P = 0.450). There was a positive association between higher Tcell_{infl}GEP and OS in the pembro + EP (P = 0.003) and pbo + EP (P < 0.005) groups. SCLC subtypes were not associated with OS in either group (pembro + EP, P = 0.960; pbo + EP, P = 0.999). Clinical benefit of pembro + EP over pbo + EP was demonstrated for TMB < 175 mut/exome, but not for TMB ≥ 175 mut/exome. Pembro + EP benefit over pbo + EP was consistent across Tcell_{infl}GEP subgroups. **Conclusions:** In this exploratory analysis of biomarker subgroups of KEYNOTE-604, TMB and SCLC subtypes were not associated with OS in the pembro + EP group in pts with ES-SCLC. While Tcell_{infl}GEP was positively associated with OS in both treatment groups, no additional OS benefit was observed with pembro + EP. Further research is warranted to better identify predictive biomarkers to immunotherapy. Clinical trial information: NCT03066778. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

		n	Median OS (95% CI), mo	HR (95% CI)
TMB <175 mut/exome	Pembro + EP	87	10.2 (8.5–14.4)	0.60 (0.43–0.85)

Oral Abstract Session

SWOG S1929: Phase II randomized study of maintenance atezolizumab (A) versus atezolizumab + talazoparib (AT) in patients with SLFN11 positive extensive stage small cell lung cancer (ES-SCLC). *First Author: Nagla Fawzy Abdel Karim, Inova Schar Cancer Institute, University of Virginia, Fairfax, VA*

Background: In unselected patients (pts) with extensive-stage small cell lung cancer (ES-SCLC), the addition of immune checkpoint inhibitors (ICI) to chemotherapy resulted in a modest improvement in OS. In a retrospective analysis of a study with veliparib (PARP inhibitor [PARPi]) and temozolomide in patients with SCLC, Schlafen-11 (SLFN11) predicted PFS and OS benefit for the addition of PARPi. We evaluated whether the addition of PARPi (talazoparib) to standard-of-care maintenance ICI (atezolizumab) following frontline chemoimmunotherapy improved outcomes in pts with SLFN11-positive ES-SCLC. **Methods:** Participants with ES-SCLC expressing SLFN11 (H-score ≥ 1 , evaluated centrally at MDACC) were randomized to maintenance atezolizumab (A) versus atezolizumab plus talazoparib (AT) following frontline chemotherapy and A. Randomization was stratified by Zebrod PS (0-1 vs 2) and use of consolidation thoracic radiation. The primary endpoint was PFS, and secondary endpoints included ORR, OS, and toxicity. The primary analysis was done using a 1-sided 10% level stratified log-rank test. Target sample size was 94 pts. **Results:** From June 2020 to December 2022, 309 pts were screened, of which 204 of 259 (79%) with evaluable tissue were SLFN11 positive, and 106 were randomized (52 A, 54 AT). Median follow up time is 5 months. Median age was 67 (45-84); 51 (48%) were females; 94 (89%) were white, 102 (96%) were PS 0-1, and 26 (25%) had radiation prior to randomization. With 80 PFS events reported, PFS was significantly improved with AT (hazard ratio [80% CI]: 0.70 [0.52-0.94]; $p = 0.056$). Median PFS was 2.8 months (80% CI 2.0-2.9) for A and 4.2 months (80% CI 2.8-4.7) for AT. OS was not different (hazard ratio [80% CI]: 1.17 [0.80-1.71]; $p = 0.30$). Median OS was 8.5 months (80% CI 7.4-12.7) for A and 9.4 months (80% CI 8.1-14.2) for AT. ORR was 16% (5/32, 80% CI 8-27%) for A and 12% (4/34, 80% CI 5-22%) for AT. Grade 3 or greater treatment related non-hematological adverse events (AEs) occurred in 13% pts in A and 15% in AT. Hematological AEs occurred 4% in A compared to 50% pts in AT (Expected for T) ($p < 0.001$). There were no treatment related grade 5 events. One participant on AT experienced grade 3 febrile neutropenia. The majority of grade 3 AEs were due to anemia (2% in A and 37% in AT). Only three pts discontinued treatment due to toxicity (2 in A and 1 in AT). **Conclusions:** This study met its primary endpoint demonstrating that maintenance AT improved PFS in SLFN11-selected patients with ES-SCLC. Hematologic toxicity was increased with AT as expected, with majority being grade 3 anemia. This study demonstrates the feasibility of conducting biomarker selected trials in SCLC, paving the way for future evaluation of novel therapies in selected SCLC populations. Oral Abstract Session

Efficacy, cellular and molecular determinants of PD-1 checkpoint inhibition in relapsed mesothelioma. *First Author: Dean Anthony Fennell, University of Leicester and Leicester University Hospitals, Leicester, United Kingdom*

Background: Leveraging adaptive immunity to control mesothelioma is now a standard approach, however the factors that underpin clinical response are poorly understood. Here we report the final analysis of the CONFIRM trial (NCT03063450), a double-blind phase III randomized study of the PD-1 inhibitor nivolumab (N) versus placebo (P) in patients (pts) with unresectable mesothelioma. Genomic, transcriptomic and multiplex spatial phenotypic correlates were explored in mesotheliomas exhibiting either partial response or progressive disease as their best outcome. **Methods:** Pts with relapsed pleural or peritoneal mesothelioma with ECOG performance status 0-1 were randomized 2:1 to N (3 mg/kg) or P once every 2 weeks until progression, or a maximum of 12 months. Pts were stratified by epithelioid (E) vs non-epithelioid (NE) histology. Co-primary endpoints were progression-free survival (PFS) and overall survival (OS); key secondary endpoints included best overall response, safety and tolerability. PD-L1 tumour proportion score (TPS, Dako22C3) was evaluated. To decipher correlates response to N, blinded multi-omic analysis was conducted in a subset of responders (R, n=16) versus progressors (NR, n=13). Whole exomes (WES) and transcriptomes were sequenced, with immune landscapes profiled by 19x depth 4-panel multiplex immunofluorescence. Acquired resistance was explored by WES in a biopsied responder at the time of progression. **Results:** Between April 2017-March 2020, 332 pts were randomised to N (n=221) or P (n=111). Median follow up was 37.2m. Baseline characteristics were balanced between arms. Histology: E 88.3%, 3rd line or greater 69.9%. PFS was longer for N vs P (events=324; median, 2.9 vs 1.6 months; HR 0.65; 95% CI, 0.51 – 0.82; $P < 0.001$). Crossover from P was 18.0% (due to widespread availability of N during the covid19 pandemic). OS curves crossed at 32m; 9.5 vs 6.8 months; HR, 0.81; 95% CI, 0.64 – 1.04; $P = 0.096$). Grade 3-4 treatment-related toxicity occurred in 20.4% vs 7.2% of pts; discontinuation occurred in 13.6% (N) versus 9.9%. PD-L1 TPS was not predictive of PFS or OS. The R-subgroup had longer PFS versus NR (319 versus 30 days, Hazard ratio, HR 0.02, $p < 0.001$) and OS (670 vs 122 days HR 0.19, $p < 0.001$). The R-group were enriched for BAP1 inactivation, CD8+ T-cell infiltration, T cell co-stimulation, cytolytic activity and mature tertiary lymphoid structures (TLSs). Conversely, the NR group had significantly more aneuploidy (notably uniparental disomy, UPD), and enrichment of epithelial mesenchymal transition, TGF beta signalling, and E2F transcription. Acquired resistance was associated with increased aneuploidy (UPD) and subclonal evolution including a new DNMT3A c2204A>G mutation. **Conclusions:** N met its co-primary endpoint of PFS with responding mesotheliomas harbouring a TLS enriched, inflamed tumour microenvironment and stable genome compared to non-responders. Clinical trial information: NCT03063450. Research Sponsor: Stand Up to Cancer, Cancer Research UK; BMS.

Oral Abstract Session

Association of somatic mutations and histologic subtype/grade on prognosis and PD-L1 expression in mesothelioma. *First Author: Allen Zhu, University of Chicago, Chicago, IL*

Background: Mesothelioma includes epithelioid, sarcomatoid, and biphasic histologic subtypes, and the epithelioid subtype is histologically graded based on mitotic count and nuclear atypia. Correlation between the most common somatic mutations (*BAP1*, *NF2*, *TP53*, *CDKN2A*), and overall survival is poorly understood. High PD-L1 expression is a poor prognostic factor for survival and may be a predictor of response to immunotherapy. Few studies have evaluated the relationships between these factors. **Methods:** We performed a retrospective study in 217 patients with pleural, peritoneal and bicavitary mesothelioma as part of an IRB-approved biobanking protocol. Histologic subtype, grade of epithelioid mesothelioma, tumor stage, and overall survival time were determined. Next-generation DNA sequencing (NGS) was used to identify the prevalence of somatic mutations. PD-L1 immunohistochemistry was obtained on 184 samples and quantified as percentage of tumor cells. Histologic subtype, nuclear grade, clinical stage, PD-L1 expression, survival time, and the prevalence of each mutation were compared using chi-squared, Kruskal-Wallis, or Cox proportional hazard tests. All p-values were determined in R version 4.2.0 using a two-sided alpha error of 0.05 to mark statistical significance. **Results:** The most frequent somatic mutations were found in *BAP1* (99/217, 45.6%), *CDKN2A* (47/217, 21.7%), *TP53* (37/217, 17.1%), and *NF2* (31/217, 14.3%). Patients with *CDKN2A*-mutated mesothelioma experienced shorter survival ($p = 0.032$). *TP53* mutations were associated with higher nuclear grade ($p = 0.015$), higher mitotic count ($p = 0.013$), and greater nuclear atypia ($p = 0.015$). *TP53* mutations were more prevalent in pleural than peritoneal mesothelioma ($p = 0.016$) and in tumors without lymph node metastasis ($p = 0.05$). As expected, patients with epithelioid mesothelioma had superior overall survival ($p = 0.02$) and their tumors had lower PD-L1 expression ($p = 0.007$) than either sarcomatoid or biphasic mesotheliomas. Neither PD-L1 expression nor mutations in *BAP1*, *NF2*, *CDKN2A*, or *TERT* were associated with nuclear grade, atypia, or mitotic count. No association was found between *BAP1* or *NF2* mutations and tumor stage, lymph node metastasis, or PD-L1 expression. **Conclusions:** To our knowledge, this is the first study of this scale to correlate PD-L1 expression, somatic mutation data, histologic features, and survival in mesothelioma patients. The most significant findings were that patients with *CDKN2A* mutations had shorter survival and *TP53* mutations, which were more prevalent in pleural mesotheliomas, were associated with higher nuclear grade, higher mitotic count, and greater nuclear atypia. An ongoing analysis evaluates the contribution of germline mutations, which occurred in a significant proportion (15.7%) of this mesothelioma patient cohort. Research Sponsor: Supported, in part, by John D. Cooney and the firm of Cooney and Conway through the University of Chicago Comprehensive Cancer Center.

Clinical Science Symposium

Phase II trial of neoadjuvant osimertinib for surgically resectable EGFR-mutated non-small cell lung cancer. *First Author: Jacqueline V. Aredo, University of California, San Francisco, San Francisco, CA*

Background: Osimertinib is a third-generation EGFR tyrosine kinase inhibitor (TKI) effective in treating advanced EGFR-mutated non-small cell lung cancer (NSCLC). Adjuvant osimertinib significantly decreases disease recurrence in stage IB-IIIa EGFR-mutated NSCLC. However, the benefit of neoadjuvant osimertinib prior to surgical resection remains unknown. **Methods:** This was a multi-institutional phase II trial of neoadjuvant osimertinib for patients with surgically resectable stage I-IIIa (AJCC V7) EGFR-mutated (L858R or exon 19 deletion) NSCLC (NCT03433469). Patients received osimertinib 80 mg orally daily for up to two 28-day cycles prior to surgical resection. The primary endpoint was major pathological response (mPR) rate ($\leq 10\%$ residual viable tumor). 27 evaluable patients provide 87% power to detect a mPR rate of 50% with $\alpha = 0.05$. Secondary endpoints included pathological response (PR) rate ($\leq 50\%$ residual viable tumor), pathological complete response (pCR) rate, unconfirmed objective response rate (ORR), rate of lymph node downstaging, unanticipated delays to surgery, surgical complication rate, disease-free survival (DFS), overall survival (OS), safety, and tumor mutational profile. **Results:** A total of 27 patients with early-stage (8 stage IA/B, 10 stage IIA/B, 9 stage IIIA) EGFR-mutated (11 exon 19 del, 16 L858R) NSCLC were treated with neoadjuvant osimertinib for a median 56 days prior to surgical resection. 24 (89%) patients underwent subsequent surgery; 3 (11%) patients were converted to definitive chemoradiotherapy. The mPR rate was 15% (4/27 patients) by intention-to-treat analysis. The PR rate was 48% (13/27). No pCRs were observed. Partial responses by radiography were observed in 52% (14/27) of patients and stable disease in 44% (12/27) of patients. Lymph node downstaging was achieved in 44% (4/9) of patients with positive lymph nodes. Median DFS after surgical resection was 32 months (95% CI 26-not reached) with a median follow-up of 11 months. OS data are immature. Significant adverse events occurred in 3 patients with grade 2 (G2) dyspnea, grade 3 (G3) pulmonary embolism, and G3 atrial fibrillation. One patient developed G2 treatment-related pneumonitis that resolved without steroids. Perioperative complications occurred in 38% (9/24) of patients; most involved rapidly reversible postoperative G2 atrial fibrillation (6/9) unrelated to study drug. Tumors were evaluable for genetic alterations from 16 patients. 4/6 patients who did not achieve a PR had tumors that harbored loss of function mutations in *RBM10* as compared to 0/10 patients who achieved a PR ($p < 0.01$). **Conclusions:** Neoadjuvant osimertinib in surgically resectable EGFR-mutated NSCLC achieved a 15% mPR, which did not meet the primary endpoint. Treatment was safe and may induce pathological responses and lymph node-downstaging of disease. Co-mutations in *RBM10* may limit response. Clinical trial information: NCT03433469. Research Sponsor: AstraZeneca.

Rapid Abstract Session

Preliminary results from the Female Asian Nonsmoker Screening Study (FANSS). *First Author: Elaine Shum, NYU Langone Perlmutter Cancer Center, New York, NY*

Background: Lung cancer (LC) is the leading cause of cancer death in Asian Americans and unfortunately the majority are diagnosed at advanced or late stages. In Asia, approximately 60-80% of female LC patients are never smokers. Current screening in the U.S. with low-dose CT (LDCT) Chest scans is offered only to current or former smokers based on the National Lung Screening Trial (NLST). The LC detection rate in NLST was 1.1%. The TALENT study, a LC screening study for high-risk nonsmokers in Taiwan reported a LC detection rate of 2.6% which included invasive adenocarcinoma (adeno), adeno in situ, minimally invasive adeno and adenocarcinoma. Invasive adeno detection rate was 1.52%. We are conducting the ongoing FANSS in the U.S. to screen female Asian nonsmokers with LDCT Chest scans to evaluate the feasibility of a LC screening program in this population. We report preliminary results here. **Methods:** This is an IRB-approved, prospective, multicenter study (NYU, MGH, UCI). Inclusion criteria are women, age between 40-74 years old (yo), never smoked or smoked < 100 cigarettes in one's lifetime and identify as from Asian descent (report ancestry or race from the continent of Asia). Participants (pts) with history of LC or treatment of any cancer < 5 years ago are excluded. Following informed consent, eligible pts undergo a shared-decision making discussion prior to obtaining a baseline LDCT Chest scan, read according to Lung-RADS 1.1 with plan for annual LDCT for two additional years. A plasma-based assay to analyze cell-free DNA (cfDNA) fragments for early detection of cancer by Delfi Diagnostics (Baltimore, MD) is sent at the time of each scan. A questionnaire regarding ethnicity, family history and environmental exposures is collected at baseline. **Results:** From 3/1/21 to 1/15/23, 222 pts signed consent and 201 had a baseline LDCT at NYU. Age range was 40-74 yo and median age of 56.8 yo. 83 (41%) reported a family history of LC. Of 201 pts who completed a baseline LDCT, 87 (43%) were Lung-RADS 1, 101 (50%) were Lung-RADS 2, 6 (3%) were Lung-RADS 3 and 7 (3.5%) were Lung-RADS 4. 5 pts with Lung-RADS 3 and 3 pts with Lung-RADS 4 have solid, subsolid or groundglass nodules > 6 mm that remain in close follow-up. 3 pts were diagnosed with invasive lung adeno for a LC detection rate of 1.5%; 2 are stage IIB and 1 is stage IIIC. All pts were surgically resected, EGFR mutation positive and are receiving adjuvant osimertinib. Analysis of the cfDNA fragmentation profiles is ongoing. **Conclusions:** Our data shows that LC screening in Asian female nonsmokers is feasible. Preliminary results demonstrate an invasive adeno detection rate comparable with TALENT and higher than in NLST. Early detection brings new meaning with the recent FDA approval for adjuvant targeted therapy in early stage LC. The expansion of LC screening guidelines to other high-risk populations warrants further attention. FANSS is continuing to accrue at additional U.S. sites this year. Clinical trial information: NCT05164757. Research Sponsor: NYU Lung Cancer Center; Delfi Diagnostics.

Rapid Abstract Session

Pembrolizumab and ramucirumab neoadjuvant therapy for PD-L1-positive stage IB-IIIa lung cancer (EAST ENERGY). *First Author: Keiju Aokage, Department of Thoracic surgery, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Neoadjuvant treatments for resectable non-small cell lung cancer (NSCLC) using novel combination therapies are being developed. Angiogenesis inhibitors have been reported to modify tumor immunity, and the efficacy and safety of treatments added to immune checkpoint inhibitors (ICIs) have been investigated in advanced NSCLC. In this multi-institutional phase II study, we evaluated the efficacy and feasibility of neoadjuvant therapy with pembrolizumab and ramucirumab, a direct vascular endothelial growth factor (VEGF) receptor-2 antagonist, followed by surgery, in patients with PD-L1 positive, clinical stage IB-IIIa NSCLC. **Methods:** Patients (aged ≥ 20) with pathologically proven NSCLC harboring PD-L1 expression $\geq 1\%$ (22C3), resectable clinical stage IB-IIIa NSCLC, and performance status of 0 to 1 were eligible. Patients received two cycles of pembrolizumab (200 mg/body) and ramucirumab (10 mg/kg) every three weeks. Surgery was scheduled 4-8 weeks after the last dose. The primary endpoint was to determine the major pathologic response (MPR) rate. The sample size was calculated based on the exact binomial distribution, considering a threshold MPR rate of 20%, an expected MPR rate of 45%, a one-side alpha of 5%, and a desired power of 80%. **Results:** A total of 24 eligible patients, with a median age of 75 years (range 50-78), were enrolled between July 2019 and April 2022; 18 patients were male. The histological subtype was adenocarcinoma in 12 patients, and the clinical stage was IB, IIA, IIB, and IIIA in 1, 4, 9, and 10 patients, respectively. PD-L1 was $\geq 50\%$ in nine patients (37.5%). The MPR rate by the blinded independent central review of three pathologists was 50.0% (90% confidence interval, 31.9-68.1%); therefore, the primary endpoint was met. Six of the 12 patients who achieved MPR showed pathological complete response. One patient developed pneumonia before neoadjuvant treatment and one patient showed progressed disease after neoadjuvant treatment. Grade 3 adverse events (AEs) occurred in nine of 24 patients (37.5%) during the protocol treatment. Postoperative complications of grade 3 AEs, including postoperative hematoma, pulmonary fistula, and intraoperative arterial injury, were observed in three patients. Immune-related AEs related to protocol treatment were thyroid dysfunction, acute tubulointerstitial nephritis, and hepatic dysfunction in three, two, and two patients, respectively; however, no grade 3 or high AEs were observed. Twenty-one patients achieved R0 resection and one patient underwent R1 resection. There were no wound-healing adverse events of concern due to the anti-VEGF action of ramucirumab. **Conclusions:** The results of this study demonstrated that this new neoadjuvant combination of ICI and anti-VEGF agent (pembrolizumab and ramucirumab) is feasible and showed encouraging results. Clinical trial information: NCT04040361. Research Sponsor: MSD and Eli Lilly.

Rapid Abstract Session

Bemcentinib and pembrolizumab in patients with relapsed mesothelioma: MIST3, a phase IIa trial with cellular and molecular correlates of efficacy. *First Author: Matthew G Krebs, The University of Manchester and The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: AXL receptor tyrosine kinase is a key facilitator of immune escape and drug resistance, conferring a more aggressive phenotype. Targeting the PD1-PDL1 axis has demonstrated significant efficacy in patients with relapsed malignant mesothelioma (MM), however, responses are only observed in a fraction of patients. Preclinical studies suggest that dual PD1 and AXL inhibition is synergistic. We developed a multi-centre, molecularly stratified phase IIa trial to evaluate the efficacy of AXL/PD-1 inhibition with bemcentinib (Bem)/pembrolizumab (Pem) and to uncover cellular and molecular determinants of efficacy as arm 3 of the Mesothelioma Stratified Therapy umbrella trial (NCT03654833, MIST3). **Methods:** Patients with pleural mesothelioma were enrolled. Key inclusion factors were ECOG performance status (PS) 0-1, prior platinum-based chemotherapy (maximum of 2 prior lines allowed), evidence of disease progression with measurable disease by CT (Modified RECIST 1.1), and adequate haematological/organ function. All patients received 200mg Pem IV q3W in combination with Bem, loading dose 400mg PO for the first 3 days and then 200mg od q3w. Primary endpoint was disease control rate at 12 weeks (DCR12w). Secondary endpoints: DCR at 24 weeks (DCR24w), best objective response rate (ORR) and toxicity (NCI CTCAE 4.03). Pre-treatment fresh biopsy was required to enable multiplex immunofluorescence, whole exome and RNA transcriptome sequencing. Gut microbiome 16s RNA sequencing also was undertaken at baseline (n=21). **Results:** Between September 2020 and March 2022, 26 patients with MM started treatment and received at least one dose of Pem Bem. Median age was 72.5 (range, 55-85) years, 88% were male 12% were female, Histology: 88% epithelioid, 8% Biphaseic, 4% Sarcomatoid, ECOG PS 1 77%, > 1 prior systemic therapy 35%. The median cycles of Pem Bem was 4 (IQR, 2-11). The DCR12w was 46.2% (12/26) (90% confidence limit (CI), 29.2% - 63.4 %); ORR was 15.4% (95%CI, 4.4-34.9%; all PR) with stable disease in 57.7% (36.9 - 76.6%); DCR24w was 38.5% (10/26) (95%CI, 20.2% - 59.4%). Adverse events (any cause): $\geq$ grade 3 toxicities affected 38% of pts and there were no treatment-related deaths. The most frequent adverse events recorded were fatigue in 12/26 (46%) patients and nausea in 11/26 (42%) patients. **Conclusions:** MIST3 met its primary endpoint and warrants further evaluation. Analysis of the cellular and molecular correlates of response are ongoing and will be presented. Clinical trial information: NCT03654833. Research Sponsor: Asthma and Lung UK and Victor Dahdaleh Foundation; Bergen Bio.

Poster Discussion Session

Final survival data from a randomized phase II trial comparing high-dose with standard-dose twice-daily (BID) thoracic radiotherapy (TRT) in limited stage small-cell lung cancer (LS SCLC). *First Author: Bjorn H. Henning Gronberg, Norwegian University of Science and Technology (NTNU), Trondheim, Norway*

Background: Concurrent chemotherapy and TRT is standard treatment of LS SCLC. BID TRT of 45 Gy/30 fractions is the most recommended schedule. Trials report 5-year survival rates of up to 36%, illustrating that some are cured but also need for better treatment. Many treatment failures are due to relapses within TRT fields, and it has been proposed that higher TRT doses might improve local control and consequently survival. However, high-dose once-daily (QD) TRT of 66-70 Gy do not prolong survival. We investigated whether high-dose BID TRT of 60 Gy/40 fractions was tolerable and improved survival compared with the established 45 Gy schedule (NCT02041845). **Primary analyses** presented at ASCO 2020 showed that the trial was highly positive for the primary endpoint, 2-year survival (60 Gy: 74.2%, 45 Gy: 48.1%, OR 3.09 [95% CI 1.62-5.89]; $p=0.0005$). We now present updated and final survival data. **Methods:** Patients ≥ 18 years with PS 0-2, confirmed SCLC, LS according to the IASLC definition after PET CT staging received 4 courses of platinum/etoposide and were randomized to receive 60 Gy or 45 Gy to PET CT positive lesions. TRT started concurrently with the 2nd chemotherapy course. Responders were offered QD prophylactic cranial irradiation of 25-30 Gy. All patients were followed for 5 years or until death. **Results:** 170 eligible patients were randomized at 22 Scandinavian hospitals from 2014-2018 (60 Gy: $n=89$, 45 Gy: $n=81$). Median age was 65, 31.2% were ≥ 70 years, 57.1% women, 89.4% had PS 0-1, 83.5% stage III disease, 7.6% pleural effusion and 20.0% $\geq 5\%$ weight loss last three months before enrollment. Baseline patient and disease characteristics and TRT planning target volumes were well balanced between treatment arms. Completion rates of chemotherapy (60 Gy: 92.1%, 45 Gy: 87.7%) and TRT (60 Gy: 96.6%, 45 Gy: 91.4%) were similar. Patients on the high-dose arm did not experience more grade 3-4 esophagitis (60 Gy: 21.2%, 45 Gy: 18.2%; $p=0.83$) or pneumonitis (60 Gy: 3.4%, 45 Gy: 0.0%; $p=0.39$), other grade 3-4 toxicity or treatment related deaths. The 60 Gy group had numerically longer PFS (median PFS 60 Gy: 18.6 months [95% CI 11.6-25.6], 45 Gy: 10.9 months [95% CI 8.7-13.2], HR 0.76 [95% CI 0.53-1.08]; $p=0.13$). Results for the primary endpoint remain unchanged. The higher TRT dose significantly prolonged survival (median OS 60 Gy: 43.5 months [95% CI 30.4-56.6], 45 Gy: 22.6 months [95% CI 17.2-28.0], HR 0.69 [0.48-0.99]; $p=0.043$) and provided higher 4.5 year survival rate (60 Gy: 41.6% [95% CI 30.4-56.6], 45 Gy: 28.4% [95% CI 18.9-39.5], OR: 1.79 [95% CI 0.95-3.41]). 5-year survival rates will be presented at the meeting. **Conclusions:** Compared with LS SCLC patients who received standard TRT, patients receiving high-dose BID TRT of 60 Gy did not experience more toxicity, had a substantial prolongation of survival and a much higher long term survival rate. Clinical trial information: NCT02041845. Research Sponsor: The Norwegian Cancer Society; Norwegian University of Science and Technology; The Liaison Committee for Education, Research and Innovation in Central Norway.

Poster Discussion Session

The prognostic value of patient reported outcomes (PROs) and clinical/demographic variables in the CASPIAN study. *First Author: Apar Kishor Ganti, University of Nebraska Medical Center, Omaha, NE*

Background: PROs have been shown to predict outcomes in non-small cell lung cancer and, using the FACT-G PRO instrument, in extensive stage small cell lung cancer (ES-SCLC). This study explored the relationships between EORTC QLQ-C30 domains and overall survival (OS) and progression free survival (PFS) in the phase III ES-SCLC CASPIAN trial, with and without adjustments for treatment (tx) and baseline clinical and demographic variables. **Methods:** CASPIAN had 3 treatment arms: durvalumab plus platinum-etoposide; durvalumab plus tremelimumab plus platinum-etoposide; and platinum-etoposide alone. It included the EORTC QLQ-C30, a PRO instrument consisting of 5 functioning scales (physical, role, emotional, cognitive, social), a global health status/quality of life (QoL) scale, 3 symptom scales (fatigue, nausea/vomiting, pain), 5 single item symptom assessments (dyspnea, insomnia, appetite loss, constipation, diarrhea) and a single financial difficulties item. Higher functional and QoL scores indicate better health status/function (anticipated positive OS/PFS associations) while higher symptom and financial difficulty scores represent a greater burden (anticipated negative OS/PFS associations). Baseline PRO scores were pooled across the 3 CASPIAN arms to obtain the most PRO information and used in 3 Cox proportional hazard models for OS and PFS: (A) scores only, (B) scores with a tx category for each CASPIAN arm, and (C) scores with tx categories and other baseline covariates (sex, age [< 65 , ≥ 65], ECOG performance status [0, > 1], smoker [Y/N], CNS metastasis [Y/N], race [Asian, non-Asian], stage [III, IV], region [Asia, Europe, North and South America]). Models B and C were stratified by the type of platinum received. Backwards selection found the set of variables most associated with OS and PFS. There was no correction for multiplicity and nominal P-values < 0.05 were used to assess importance. **Results:** The outcomes and models associated with more favorable baseline PRO scale/item scores were: (i) better OS and PFS across all 3 Cox models [physical, role, social, QoL, fatigue, pain]; (ii) better OS [emotional (models A,C), nausea/vomiting (model C), dyspnea (model C)], and (iii) better PFS [emotional (model C), financial difficulties (models A,B,C)]. Among the 90 estimated Cox hazard ratios, 82 had the anticipated directions for OS and PFS with 54/90 of the estimates having $P < 0.05$. In each Cox model, more favorable baseline diarrhea scores were associated with reduced OS. All 15 baseline PRO score domains for OS and 10/15 for PFS were important in the stepwise selection process. **Conclusions:** The results largely indicate that baseline PROs had prognostic value in the CASPIAN trial across different specifications, some including tx and baseline clinical and demographic values. A better understanding of the relationship between tx and PROs may aid tx decisions. Clinical trial information: NCT03043872. Research Sponsor: AstraZeneca.

Poster Discussion Session

CRES³T: A single-arm confirmatory trial of S-1 plus cisplatin with concurrent radical-dose radiotherapy followed by surgery for superior sulcus tumor. *First Author: Kazuya Takamochi, Department of General Thoracic Surgery, Juntendo University School of Medicine, Tokyo, Japan*

Background: A multicenter, single-arm, confirmatory trial (CRES³T) was conducted to investigate the efficacy and safety of S-1 plus cisplatin and concurrent radical-dose thoracic radiotherapy (TRT) followed by surgery in patients with superior sulcus tumor (SST). To date, no clinical trials on radical-dose TRT in the induction setting for SST have been conducted. **Methods:** SST was defined as a tumor that directly invades the chest wall including the first rib or more cephalad, subclavian artery, or subclavian vein according to CT or MRI scans. Eligible patients were 20 to 75 years old and had pathologically proven non-small cell lung cancer, performance status of 0-1, and no history of prior treatment. The patients received induction therapy consisting of three cycles of S-1 plus cisplatin with concurrent TRT (66 Gy in 33 fractions) followed by surgery. S-1 was administered orally at 40 mg/m² twice per day, on days 1-14 along with an intravenous infusion of cisplatin (60 mg/m²) on day 1. The treatment cycles were repeated every four weeks. The primary endpoint was the 3-year overall survival (OS) rate, and key secondary endpoints included progression-free survival (PFS) rate, objective response rate (ORR), pathological complete remission (pCR) rate, and toxicity. **Results:** Between June 2014 and March 2019, 61 patients registered and received induction therapy. Pathological diagnoses were 30 adenocarcinoma, 20 squamous cell carcinoma, and 11 others. Radiologically diagnosed tumor invasion sites were the chest wall ($n=57$), subclavian artery ($n=18$), and subclavian vein ($n=10$). One patient with distant metastasis that manifested after starting induction therapy was removed from this study. Forty-nine patients underwent lobectomy and resection of the involved sites. The complete resection rate was 98% (48/49). Median follow-up time was 54 months. The 3-year OS and PFS rates were 73% (95% CI: 60-83%) and 53% (95% CI: 40-65%), respectively. The ORR and pCR rate were 42% (25/60, 95% CI: 29-54%) and 33% (16/49, 95% CI: 20-46%), respectively. Grade (G) 3 or 4 toxicities during induction therapy included neutropenia (28%), anemia (13%), thrombocytopenia (5%), and hyponatremia (8%). Two (3%) cases of pneumonia resulted in death. G3 surgical complications such as supraventricular arrhythmia, chylothorax, pleural effusion, pneumonia, mediastinitis, wound infection, and arm neuropathy developed in one (2%) patient each. One (2%) cardiac arrest on postoperative day 3 resulted in death. **Conclusions:** CRES³T demonstrated that induction therapy using S-1 plus cisplatin and concurrent radical-dose TRT followed by surgery was safe and effective in treating SST. Therefore, this strategy is potentially a new standard treatment for SST. (UMIN: 000014386, JRCT: s031180401). Clinical trial information: UMIN000014386. Research Sponsor: None.

Poster Discussion Session

Phase II study of durvalumab plus olaparib as maintenance therapy in extensive-stage small-cell lung cancer (TRIDENT): Preliminary efficacy and safety results. *First Author: Yan Huang, State Key Laboratory of Oncology in South China, Guangzhou, China*

Background: First-line durvalumab in extensive-stage small-cell lung cancer (ES-SCLC) demonstrated significant improvement of OS in phase III CASPIAN trial. PARP inhibitors have the potential to confer antitumor activity, modify tumor immunogenicity, and sensitize tumors to anti-PD-1/PD-L1 therapy. Durvalumab in combination with Olaparib (a PARPi) had clinical activity in relapsed SCLC in a phase I/II study. This phase II study aimed to assess the efficacy and safety of durvalumab plus olaparib as maintenance therapy in patients with ES-SCLC. **Methods:** TRIDENT is a single arm, multicenter, phase II study. Treatment-naïve ES-SCLC aged ≥ 18 with ECOG PS 0-2 were eligible. Durvalumab (1500 mg) was concurrently administered with platinum-etoposide every 3 weeks for 4 cycles, followed by durvalumab 1500 mg every 4 weeks plus olaparib 300 mg twice daily until disease progression or unacceptable toxicity. The primary endpoint was the rate of progression free survival (PFS) at 12 months, the secondary endpoints included progression free survival, objective response rate (ORR) according to RECIST 1.1, duration of response (DoR), overall survival (OS) and safety profile. All patients should provide tumor sample for biomarker analysis (exploratory endpoint). **Results:** Between August 2021 and August 2022, 60 eligible patients were enrolled from 4 sites in China. At data cut-off (Jan 16th, 2023), 18 (30%) patients were still on treatment. The median age was 63 years (range 57-68). The median cycle of durvalumab was 7 (range 1-17), and durvalumab plus olaparib as maintenance therapy was 3.5 (range 1-13). The PFS rate at 6-, 9-, 12-month were 49.7% [95%CI 37.8%-65.4%], 26.3% [95%CI 13.8%-40.3%] and 18% [95%CI 9.3%-34.7%], respectively. ORR was 75% (45/60), the median DoR was 5.0 months [95%CI 3.8-6.5]. With a median follow-up of 10.5 months, the median PFS was 5.8 months [95%CI 4.9-7.7] as calculated from the first cycle of durvalumab plus chemotherapy. The median OS was not reached [95%CI 10-NA]. Of all, treatment emergent adverse event (AE) occurred in 93.3% (56/60) patients, and AEs $\geq$ grade 3 occurred in 36.7% (22/60) patients. There were no unexpected adverse events identified in this study. There were 5 patients (8.3%) discontinued treatment and 1 death (1.6%) due to AE. Biomarker analysis is still on-going and will be presented in the meeting. **Conclusions:** TRIDENT is the first study to evaluate the efficacy and safety of durvalumab plus olaparib as maintenance therapy in Chinese ES-SCLC patients to date. The preliminary result warrant further investigation of this treatment modality in ES-SCLC. Clinical trial information: NCT05245994. Research Sponsor: This study is sponsored by Sun Yat-sen University Cancer Center; This study is partly supported by AstraZeneca.

Poster Discussion Session

Associations between patient-reported nutritional status, survival, and toxicity among patients with limited stage small-cell lung cancer (LS SCLC) in a randomized trial of high-dose, twice-daily (BID) thoracic radiotherapy (TRT).
First Author: Evgenia Taranova, University of Bergen, Bergen, Norway

Background: Up to 1/3 of LS SCLC patients are cured by chemoradiotherapy (CRT), but severe toxicity is frequent and population-based studies show that many patients do not receive standard CRT. More knowledge on how to predict who experiences side-effects or achieves long term disease control is needed. Poor nutritional status is strongly associated with inferior survival in many types of cancer including non-small cell lung cancer, but little is known about whether this is the case in LS SCLC. We investigated whether nutritional status reported by patients on the Patient-Generated Subjective Global Assessment Short Form (PG-SGA SF) was associated with toxicity and survival among participants in a trial comparing high dose with standard dose twice-daily TRT in LS-SCLC (NCT02041845, n=170). **Methods:** Patients received four courses of platinum/etoposide chemotherapy and were randomized to TRT of 60 Gy/40 fractions or 45 Gy/30 fractions. Patients completed PG-SGA SF before treatment commenced and were categorized as having low (PG-SGA SF score 0–3.9), intermediate (4.0–8.9) and high (≥9) risk of malnutrition. Toxicity was graded according to CTCAE 4.0. Median follow-up for survival was 49 months. **Results:** 113/170 (66.5%) patients completed PG-SGA SF at baseline. Median age was 65 years, 46.0% were men, 88.5% had PS 0-1, 87.6% stage III disease and 22.1% weight loss of >5% the three months before inclusion. Median PG-SGA SF score was 3.0, 52.2% of patients had low, 29.2% intermediate, and 18.6% high risk of malnutrition. Numerically, there were more patients with stage III, PS 1-2 and pleural fluid among those at high risk. There was no difference in mean no. of chemotherapy courses (low: 3.85, intermediate: 3.88, high: 3.90, p=0.95) or TRT completion (low: 96.6%, intermediate: 97.0%, high: 95.2%, p=1.0). There were no statistically significant differences in proportions who experienced grade 3-4 toxicity (low: 88%, intermediate: 91%, high: 86%, p=0.86), median PFS (low: 15.1 months, intermediate: 11.8 months, high: NR, p=0.23), 2-year survival (low: 68%, intermediate: 52%, high: 67%, p=0.28) or median OS (low: 38.1 months, intermediate: 25.8 months, high: NR, p=0.15). Patients with weight loss >5% did not experience more grade 3-4 toxicity (92% vs. 87%, p=0.73), had similar median PFS (24.0 vs. 15.9 months, p=0.69), 2-year survival (64.0% vs. 66.2%, p=0.84) and median OS (30.6 vs. 35.1 months, p=0.93) as those without. **Conclusions:** Our study suggest that LS SCLC patients tolerate and should receive concurrent chemotherapy and twice-daily TRT regardless of nutritional status and weight loss. Clinical outcomes with neoadjuvant nivolumab (N) + chemotherapy (C) vs C by definitive surgery in patients (pts) with resectable NSCLC: 3-y results from the phase 3 CheckMate 816 trial. *First Author: Jonathan Spicer, McGill University Health Center, Montreal, QC, Canada*

Background: In CheckMate 816, neoadjuvant N + C demonstrated statistically significant and clinically meaningful improvements in event-free survival (EFS) and pathologic complete response (pCR) vs C in pts with resectable NSCLC. Here, we report clinical outcomes in pts with or without definitive surgery following neoadjuvant treatment (tx). **Methods:** Adults with stage IB (tumors ≥ 4 cm) to IIIA (per AJCC 7th ed) resectable NSCLC, ECOG PS ≤ 1, and no known EGFR/ALK mutations were randomized 1:1 to 3 cycles of N 360 mg + C Q3W or C Q3W, followed by definitive surgery within 6 wk of tx. Primary endpoints were EFS and pCR, both per blinded independent review. Exploratory analyses included EFS (secondary definition; no censoring for subsequent tx), time to death or distant metastasis (TTDM), and DFS2 (EFS on next-line tx) in pts with or without surgery. **Results:** Among 358 randomized pts, 149 (83%; N + C) and 135 (75%; C) had definitive surgery. Baseline characteristics were similar in pts with or without surgery (N + C, 30; C, 44) and between tx arms, except that a higher proportion of pts who did not have surgery had ECOG PS 1 (both arms) or were from Europe (N + C arm). Surgery was canceled due to progressive disease (PD) in 11 (N + C) and 17 (C) pts; PD was locoregional in 4 and 15 pts and distant in 3 and 2 pts, while 4 pts in the N + C arm had both locoregional and distant PD. At database lock (October 14, 2022; median f/u: 41.4 mo), EFS, TTDM, and DFS2 were numerically improved in pts with vs without surgery, regardless of tx arm. In pts with surgery, median TTDM was not reached (NR) vs 46.8 mo (HR, 0.55) with N + C vs C, respectively; 3-y TTDM rates were 77% vs 59%. In pts without surgery, median TTDM was 24.8 vs 15.6 mo (HR, 0.63) with N + C vs C; 3-y rates were 36% vs 13%. Among pts without surgery, 17 (57%) vs 28 (64%) pts in the N + C vs C arms, respectively, received subsequent tx: radiotherapy 37% vs 41%; surgery 3% vs 2%; systemic tx 50% vs 52%. Grade 3/4 tx-related AEs occurred in 38% (N + C) and 36% (C) in pts with surgery, and 26% and 46% in pts without surgery. **Conclusions:** In CheckMate 816, neoadjuvant N + C demonstrated long-term clinical benefit vs C in pts with resectable NSCLC who received definitive surgery. In pts who did not receive definitive surgery, these exploratory analyses showed that neoadjuvant N + C was associated with numerically improved TTDM. Clinical trial information: NCT02998528. Research Sponsor: Bristol Myers Squibb.

Pembrolizumab vs placebo for early-stage non–small-cell lung cancer after resection and adjuvant therapy: Subgroup analysis of patients who received adjuvant chemotherapy in the phase 3 PEARLS/KEYNOTE-091 study. *First Author: Kersti Oselin, North Estonia Medical Centre, Tallinn, Estonia*

Background: In the randomized, triple-blind, phase 3 PEARLS/KEYNOTE-091 study (NCT02504372), at the second interim analysis, pembrolizumab (pembro) significantly prolonged DFS vs placebo (pbo) in the overall population of patients (pts) with completely resected stage IB–IIIA NSCLC per AJCC v7 who may or may not have received adjuvant chemotherapy (chemo; up to 4 cycles) as recommended per local guidelines (n = 1177; HR, 0.76 [95% CI, 0.63–0.91]; P = 0.0014). Here we present outcomes for those pts who received 1–4 cycles of prior adjuvant chemo, per protocol. **Methods:** Eligible adults had pathologically confirmed, completely resected stage IB (T ≥ 4 cm), II, or IIIA NSCLC (AJCC v7) of any PD-L1 expression, ECOG performance status of 0 or 1, and had not received neoadjuvant radiotherapy or chemo. Pts were randomized 1:1 to pembro 200 mg or pbo Q3W for 18 doses (~1 year); receipt of adjuvant chemo (yes vs no) was one of the stratification factors. Dual primary endpoints were DFS in the ITT and PD-L1 TPS ≥50% populations. No alpha was assigned to this subgroup analysis of pts who received adjuvant chemo for 1–4 cycles per local guidelines. **Results:** Of 1177 pts in the ITT population, 1010 (85.8%) received adjuvant chemo and were included in this analysis (pembro, n = 506; pbo, n = 504). Pts received a median of 17 and 18 study doses, respectively. As of data cutoff (Sep 20, 2021), 52.6% in the pembro arm vs 64.9% in the pbo arm had completed treatment. Median time from randomization to data cutoff was 37.4 mo. Median (95% CI) DFS was 58.7 mo (39.2 mo–not reached [NR]) in the pembro arm vs 34.9 mo (28.6 mo–NR) in the pbo arm (HR, 0.73 [95% CI, 0.60–0.89]). Estimated 18-mo DFS rates were 73.8% and 63.1%, respectively. In pts with PD-L1 TPS ≥50% (pembro, n = 143; pbo, n = 141), median DFS was NR in both treatment arms (HR, 0.80 [95% CI, 0.54–1.20]). Grade 3–5 adverse events (AEs) occurred in 170 pts (34.3%) in the pembro arm and 128 (25.7%) in the pbo arm (grade 5, 2.2% vs 1.0%). Immune-mediated AEs and infusion reactions occurred in 195 pts (39.3%) in the pembro arm and 69 (13.8%) in the pbo arm. **Conclusions:** Consistent with the ITT population, pembro substantially improved DFS vs pbo in the subgroup of pts with stage IB (T2a ≥ 4 cm), II, or IIIA NSCLC who received adjuvant platinum-based chemo following complete resection. Based on these results, pembro was approved for adjuvant treatment in this pt population by the US FDA. Clinical trial information: NCT02504372. Poster Discussion Session

IMpower010: Exploratory analysis of disease-free survival by KRAS status in patients with stage II-IIIA NSCLC treated with adjuvant atezolizumab vs best supportive care. *First Author: Martin Reck, Lung Clinic Grosshansdorf, Airway Research Center North, German Center of Lung Research, Grosshansdorf, Germany*

Background: The Phase III IMpower010 trial (NCT02486718) met its primary disease-free survival (DFS) endpoint leading to approval of atezolizumab after adjuvant platinum-based chemotherapy for completely resected PD-L1 TC ≥1% or ≥50% stage II-IIIA NSCLC in the US, EU and other regions. Mutant KRAS (mKRAS) is the most prevalent oncogenic driver in metastatic NSCLC (27% mKRAS [KRAS G12C, 11%]; Osta et al, J Thorac Oncol 2019). Here, we report exploratory DFS outcomes by KRAS mutational status in patients from IMpower010. **Methods:** The study design and primary results of IMpower010 have been reported (Felip et al, Lancet 2021). After complete resection, patients received cisplatin-based doublet chemotherapy (1-4 21-day cycles) and were subsequently randomized to receive atezolizumab 1200 mg q3w (16 cycles) or best supportive care (BSC). This post hoc analysis evaluated DFS in subgroups of patients by KRAS mutational status. KRAS mutational status was assessed retrospectively using whole-exome sequencing (WES) on resected tumor tissue. Analyses were conducted in patients whose tumors harbored any mKRAS type, including G12C. A separate analysis of the KRAS G12C subgroup was not conducted due to limited patient numbers. **Results:** Of the 1005 patients in the intention-to-treat population (all randomized patients with stage IB-IIIA NSCLC), 603 comprised the WES biomarker-evaluable population (WES-BEP), and of these, 536 had stage II-IIIA NSCLC. Within the stage II-IIIA WES-BEP, the prevalence of mKRAS and KRAS G12C was 22% (n=118) and 10% (n=52), respectively. mKRAS was enriched in White, non-squamous and smoker populations. Atezolizumab showed DFS improvement vs BSC regardless of KRAS status in the stage II-IIIA WES-BEP (Table). In the mKRAS stage II-IIIA WES-BEP, atezolizumab showed DFS improvement vs BSC regardless of PD-L1 status. **Conclusions:** In IMpower010, the prevalence of mKRAS and KRAS G12C was similar to that seen in metastatic NSCLC. Despite limited patient numbers in this exploratory analysis, DFS appeared to be consistent and in favor of atezolizumab across subgroups regardless of KRAS status. Clinical trial information: NCT02486718. Research Sponsor: F. Hoffman-La Roche, Ltd.

Response to neoadjuvant immune checkpoint inhibitor (ICI)-based therapy in oncogene-driven resectable non-small cell lung cancer (NSCLC). *First Author: Samuel Rosner, Johns Hopkins University, Baltimore, MD*

Background: Neoadjuvant (NEO) chemotherapy (chemo) plus nivolumab (nivo) has received FDA approval for treatment of resectable NSCLC, demonstrating superior event-free survival compared to chemo alone. However, outcomes of NEO ICI-based therapies in patients (pts) with oncogene-driven (OD)-NSCLC remains an unanswered question. **Methods:** We conducted a retrospective secondary analysis of pts enrolled in the clinical trial NCT02259621 with clinical stage I-IIIa NSCLC, treated with NEO ICI-based therapies: nivo alone, nivo+ipilimumab (ipi), or nivo+chemo followed by surgery. Pts underwent baseline genomic profiling using NGS. Pts with *KRAS*, *EGFR*, *MET*, *BRAF*, *ALK*, *HER2*, *ROS1*, *RET* or *NTRK* alterations were identified as OD-NSCLC. *STK11* and *KEAP1* mutations (mut) were also recorded. For pts who underwent definitive resection (DR) and baseline NGS testing, association of OD-status and clinical outcomes, including major pathologic response (MPR) and recurrence-free survival (RFS) are reported. Proportions are reported with exact 95% binomial confidence intervals (CI). Binomial probabilities are compared with Chi-square or Fisher's exact tests. RFS and median follow-up (f/u) are reported using the Kaplan-Meier (KM) and reverse KM methods, respectively. **Results:** 61 pts received NEO ICI-based therapy: 60% treated with nivo alone, 15% with ipi+nivo and 25% with chemo+nivo. 92% of pts underwent DR. Pathologic complete response (pCR) and MPR rates were, 12.5% and 37.5%, respectively. Baseline NGS testing was available for 47 pts, of whom, 49% had OD-NSCLC, with the majority (78%) harboring a *KRAS* mut. Additional OD alterations included non-classical *EGFR* (9%), *MET* skipping (9%) and *ROS1* fusion (4%), of whom, 3/5 pts had a MPR after NEO-ICI. *STK11* muts were noted in 16% pts, and co-altered with *KRAS* in 9%. Median f/u for OD-NSCLC was 42.58 months. Pts with OD-NSCLC had comparable RFS after NEO-ICI compared to those with non-OD-NSCLC (HR 0.64, CI 0.19-2.13, $p=0.5$), including those with *KRAS*+ disease (HR 0.73, CI 0.2-2.73, $p=0.6$). Pts with co-mut *KRAS*+*STK11*+ trended toward shorter RFS compared to *KRAS*+*STK11*- (HR 6.36, CI 0.56-72.82, $p=0.1$). *STK11*+ also trended toward shorter RFS without reaching statistical significance (HR 2.51, CI 0.67-9.35, $p=0.17$). No significant associations between OD-status and MPR rates were seen, however *KRAS*+ (4/18) vs. *KRAS*- (13/29) trended toward lower MPR rate ($p=0.1$). Four of 5 pts with disease progression preventing DR harbored an *STK11* or *KEAP1* mut. **Conclusions:** Findings from this cohort treated with various NEO ICI-based therapies, suggests comparable RFS, regardless of OD status with the majority harboring *KRAS* muts. Lower MPR rates were observed for pts with *KRAS*+ tumors. *STK11* mut and *KRAS*+*STK11*+ co-mut status both trended toward shorter RFS, though definitive conclusions are limited by cohort size and treatment heterogeneity. Research Sponsor: BMS; Stand Up 2 Cancer (SU2C).

Safety and efficacy of QL1706 plus carboplatin/etoposide (EC) as first-line (1L) treatment for extensive-stage small-cell lung cancer (ES-SCLC): The results from a phase II single-arm study. *First Author: Yun Fan, Zhejiang Cancer Hospital, Hangzhou, China*

Background: Although the combination of PD-L1 inhibitor and platinum-etoposide chemotherapy has been the preferred 1L treatment for patients (pts) with ES-SCLC, the clinical benefit of the addition of PD-L1 inhibitor was still modest. QL1706 is a novel bifunctional antibody, containing a mixture of anti-PD-1 IgG4 and anti-CTLA-4 IgG1 antibodies produced by MabPair. In phase I trials, QL1706 monotherapy has shown promising antitumor efficacy in nasopharynx cancer and cervical cancer, as well as other advanced solid tumors including SCLC (to be published). This study aims to assess the safety and efficacy of QL1706 plus EC in treatment-naïve ES-SCLC. **Methods:** In this phase II, open-label, single-arm, multi-center study, eligible pts (18-75 years, ECOG 0-1) received 4-6 cycles of QL1706 (5mg/kg, IV, Q3W) plus EC (etoposide, 100 mg/m², D1-3, Q3W; carboplatin, AUC = 5, D1, Q3W), followed by the maintenance therapy of QL1706 until disease progression, intolerable toxicity or other discontinuation events defined in the study protocol. Tumor imaging was performed every 6 weeks for the first year and every 9 weeks thereafter. The primary endpoint is safety. **Results:** From Apr 18, 2022 to Jul 27, 2022, a total of 40 pts were enrolled with a median age of 58.5 years (range, 38–73). 87.5% pts were men, 80% were smokers and 90% had ECOG PS of 1. As of data cutoff (Jan 16, 2023), the median QL1706-treatment duration was 5.9 (range, 0.7–8.9) mo. Twenty pts remained on treatment and 20 pts discontinued due to progressive disease (16, 40.0%) or patient decision (4, 10.0%). Thirty-two (80.0%) pts had at least one TRAE (QL1706-related). Fifteen (37.5%) pts experienced grade 3-4 TRAEs, including neutropenia (8, 20%), thrombocytopenia (4, 10%), anemia (3, 7.5%), WBC count decreased (2, 5.0%), AST increased (2, 5.0%), ALT increased (1, 2.5%), gamma-GT increased (1, 2.5%), rash (1, 2.5%), and diarrhea (1, 2.5%). No grade 5 TRAE occurred. No AE led to discontinuation of any treatment. Of the 39 pts who had at least 1 post-baseline tumor assessment, 37 achieved PR (35 confirmed and 2 unconfirmed) and 1 achieved SD. Thus, the confirmed ORR was 89.7% (95% CI, 75.8%–97.1%), and the DCR was 97.4% (95% CI, 86.5%–99.9%) (per RECIST v1.1). The mDoR was 4.5 (95% CI, 4.2–not evaluable) mo, with the longest response duration more than 7.2 mo and ongoing. The mPFS was 5.7 (95% CI, 5.4–7.1) mo, together with 3 mo- and 6 mo-PFS rates of 94.8 (95% CI, 80.8–98.7%) and 44.7% (95% CI, 27.3–60.6%), respectively. With a median follow-up time for OS of 6.2 mo, the mOS has not been reached. **Conclusions:** QL1706 plus EC chemotherapy showed tolerable safety profile and promising efficacy as first-line treatment for pts with ES-SCLC. These data support further clinical development of QL1706 in ES-SCLC. Clinical trial information: NCT05309629. Research Sponsor: Qilu Pharmaceutical Co., Ltd.

Predictive value of co-existing genetic alterations and tumor mutation burden for patients with completely resected non-small cell lung cancer harboring EGFR mutation: Biomarker analysis of phase III IMPACT study. *First Author: Satoshi Ikeda, Kanagawa Cardiovascular and Respiratory Center, Yokohama, Japan*

Background: Although osimertinib has recently become an option for adjuvant therapy in many countries, biomarkers predicting the efficacy of adjuvant EGFR-TKI and the risk of postoperative recurrence in completely resected NSCLC harboring EGFR mutations have not been fully investigated. **Methods:** This IMPACT-TR study is an exploratory biomarker study for completely resected, EGFR-mutated NSCLC patients who received gefitinib or cisplatin plus vinorelbine (cis/vin) in a phase III IMPACT study (Trial registration number: UMIN000044738. Funding: AstraZeneca K.K.). Surgically resected lung cancer tissue specimens were analyzed for co-existing somatic mutations and tumor mutation burden (TMB) determined by OncoPrint Tumor Mutation Load, and these data were matched with disease free survival (DFS) and overall survival (OS) data. **Results:** Of the 234 patients in the IMPACT study, 211 patients were enrolled, and 202 patients in the Per Protocol Set were analyzed. The most frequent co-existing somatic mutation was *TP53* (58.4%), followed by *CSMD3* (11.8%), *NOTCH1* (9.9%) and *SYNE1* (9.9%). The median TMB was 6.67 mutations/Mb, and only 15.2% had ≥ 10 mutations/Mb. EGFR mutation subtypes, *TP53* co-mutation and TMB were not associated with DFS or OS in either the gefitinib or cis/vin groups. In the gefitinib group, patients with *NOTCH1* mutation had significantly shorter OS (hazard ratio [HR] 4.18, 95%CI 1.65-10.61, $p=0.003$) and tended to have shorter DFS (HR 1.44, 95%CI 0.62-3.37, $p=0.399$) than those without *NOTCH1* mutation. In the cis/vin group, patients with *CREBBP* mutation had significantly shorter DFS (HR 2.70, 95%CI 1.05-6.97, $p=0.040$) and tended to have shorter OS (HR 3.05, 95%CI 0.90-10.37, $p=0.074$) than those without *CREBBP* mutation. **Conclusions:** This study suggested that *NOTCH1* mutation may be a biomarker to predict poor response to adjuvant gefitinib and *CREBBP* mutation to predict poor response to cis/vin in patients with completely resected, EGFR-mutated NSCLC. Clinical trial information: UMIN000044738. Research Sponsor: AstraZeneca K.K.

Clinical and financial implications of ADURA trial on a real-world population. *First Author: Bharathi Muthusamy, Cleveland Clinic, Cleveland, OH*

Background: In the ADAURA trial, adjuvant (adj) osimertinib improved disease free survival (DFS) in resected, EGFR-mutant (*EGFRm*) Stage IB-IIIa NSCLC compared to placebo. Based on these results, the FDA approved osimertinib in the adj setting. In this study, we have evaluated the hypothetical clinical and financial effects of adj osimertinib on the early-stage, *EGFRm* NSCLC patients at Cleveland Clinic who were treated prior to the FDA approval. **Methods:** Starting in 2010, Cleveland Clinic has been performing targeted molecular testing in all resected NSCLCs. With this information, we created a database of patients from 01/2010 to 01/2021 with resected, non-squamous NSCLC. The standard of care (SOC) arm of this study consisted of patients with stage IB-IIIa, *EGFRm* disease from our internal database. Data for the adj osimertinib arm were obtained through a microsimulation study by first generating the per-stage DFS distribution in the SOC arm, and then applying the per-stage hazard ratios from ADAURA to obtain the parameters of the exponential DFS distribution with osimertinib treatment. Outcomes and costs, such as treatment and imaging, were directly calculated for the SOC arm based on the amount of time each patient spent in a recurrence-free or recurrent state, and whether there was CNS involvement at recurrence. Costs and outcomes were averaged across 1000 simulated datasets for the osimertinib arm. Based on ADAURA we assumed that 78.4%, 16.2%, and 5.4% of DFS events were CNS- recurrence, CNS+ recurrence, or death. **Results:** 1,487 patients were included in the database. 724 of these patients had stage IB-IIIa disease and *EGFR* testing. 82 patients were *EGFRm*+ (exon 19 deletion or the L858R mutation), and their survival outcomes were used in the SOC arm. At 5 years, 32 (39%) of the patients were alive and disease free. With the addition of adj osimertinib, an estimated average of 61 (71.4%) of patients would have been disease free and alive. This corresponds to an average improvement in 5-year DFS of 35.4%. The cost of testing all 724 patients would have been \$2,865.80 per patient eligible for osimertinib with single-gene *EGFR* testing or \$5,279.11 per eligible patient with targeted NGS testing. The total treatment and healthcare costs with adj osimertinib in the 82 patients would have been \$49,057,952.75 or \$598,267.72 per patient. With SOC (surveillance +/- adj chemotherapy + osimertinib only upon recurrence), total and per patients costs were \$12,297,374.11 and \$149,967.98 respectively. This corresponds to an average increase in total costs of \$448,299.74 per person with the use of adj osimertinib. **Conclusions:** Over a decade at Cleveland Clinic, about 5.5% (1,487) patients with early stage NSCLC would have been affected by the adj osimertinib approval. In our simulation, we estimated adj osimertinib would have improved 5-year DFS by 35.4% (29 more patients) but with a significant financial cost of about \$450,000 per eligible patient. Research Sponsor: None.

A study of tumor neoantigen burden and HLA-LOH by whole-exome sequencing to characterize immune biomarkers of lung cancer. *First Author: Wei Wang, Department of Thoracic Surgery, Renmin Hospital of Wuhan University, Wuhan, China*

Background: Lung cancer is a leading cause of cancer-related death worldwide. Precision immunotherapy, such as the use of immune checkpoint inhibitors (ICIs), has been shown to improve the survival of lung cancer patients. Cancer cells with high amount of neoantigens are more likely to be captured by immune cells and thus patients with high Tumor Mutation Burden (TMB) and high Tumor Neoantigen Burden (TNB) are estimated to be prone to ICIs treatment. HLA class I is one of the main factors affecting the prognosis of ICI in treatment. Studies have indicated that patients with highly heterozygous HLA-I are more likely to have better responses to ICI treatment. Some specific HLA-I genotypes and somatic mutations can affect the prognosis of ICIs treatment. **Methods:** In this study, we performed whole-exome sequencing (WES) of 200 pairs of tumor and gDNA samples from lung cancer patients. Tumor sample comes from tumor tissue or paraffin-embedded tissue and gDNA is extracted from white blood cells from *peripheral blood*. We analyze the WES data to obtain the TMB and HLA types of each sample. Then the peptide affinity of MHC-I genes were quantified based on IC50(nM) by netMHCpan software, and the level of neoantigen affinity were classified as strong ($IC50 \leq 50nM$), weak ($50nM < IC50 \leq 500nM$), and negative ($IC50 > 500nM$). TNB is defined as the number of high-affinity neoantigens per megabase of interrogated genomic sequence. Then we conducted linear regression analysis to study the statistical relationship between TMB and TNB. Finally, we analyzed the LOH status at the major region of HLA (HLA-A, HLA-B, and HLA-C) and classified the individuals who have LOH at all three types of HLA as HLA-LOH strong positive, samples with one or two LOH among the three HLA types as weak positive, and samples have no LOH are classified as HLA-LOH negative. **Results:** Among the 200 samples, the median value of TMB and TNB is 3.25 Muts/Mb and 1.09 Neos/Mb, respectively. 8.5% of the sample have high TMB ($TMB \geq 10$). TMB and TNB are also significantly positively correlated (p -value < 0.0001). For HLA typing, 82.0% HLA-A, 96.0% HLA-B, and 92.5% HLA-C are heterozygous. The dominant HLA types are: (A*11:01), (A*02:01), (B*46:01), (B*40:01), (C*01:02), and (C*07:02). As for LOH status among the three HLA types, 14.57% of the individuals are HLA-LOH strong positive, 31.66% are HLA-LOH weak positive, and 53.77% of the samples are HLA-LOH negative. Lastly, the average numbers of detected high-affinity neoantigens are statistically significantly related to the occurrence of HLA-LOH (Analysis of Variance p -value < 0.01). **Conclusions:** HLA-LOH occurs in nearly half of our lung cancer samples, and it is associated with TMB-High and TNB-High. The analysis of HLA-LOH refines the prediction of neoantigen and gain understanding of drug resistance and immunotherapy. Research Sponsor: None.

Differential expression analysis of circRUNX1 in patients with early resected EGFR-mutant NSCLC. *First Author: Carlos Pedraz, Pangaea Oncology, Laboratory of Molecular Biology, Barcelona, Spain*

Background: In the ADAURA study, patients with stage IB-IIIA of resected EGFR mutated lung adenocarcinoma receiving adjuvant osimertinib had a 2-year survival of 89% versus 52% in the placebo group ($p < 0.001$), however, predictive markers of response and recurrence are still needed. Circular RNA (circRNA) is a type of RNA which forms a covalently closed continuous loop. Some circRNAs have been reported as essential for tumor cell proliferation through functions distinct from the canonical linear RNA. In this project, we studied circRNA expression levels in formalin-fixed paraffin-embedded (FFPE) lung tumor samples in order to explore potential biomarkers that could predict the benefit of adjuvant EGFR TKIs in EGFR-mutant NSCLC patients. **Methods:** FFPE tumor samples from patients with EGFR-mutant, stage I-IIIB NSCLC ($n=79$) were collected. RNA was purified using the High Pure FFPE RNA Isolation Kit (Qiagen) and quantified by Nanodrop 2000 (Thermo Scientific). A total of 250 ng of RNA were subjected to overnight hybridization and downstream nCounter processing (NanoString) following manufacturer's instructions for our circRNA custom panel. Differential expression analysis was performed using Excel (Microsoft) and Prism GraphPad (Dotmatics) software. **Results:** Analysis of the 79 samples included in the study shown a cluster of 3 circRNAs significantly upregulated ($p < 0.05$ and > 2 fold-change) in EGFR mutation-positive NSCLC relapsing within the 36 months after resection, including circRUNX1, circFUT8 and circAASDH. Disease-free survival (DFS) was significantly shorter for the subgroup of patients with high versus low circRUNX1 expression. Additional multivariate analysis identified circRUNX1 expression and tumor stage as the only statically significant prognostic factors (circRUNX1 hazard ratio = 4.480, confidence interval = 2.172-9.239, $P < 0.001$; pathological stage hazard ratio = 2.237, confidence interval = 1.183- 4.231, $P = 0.008$). **Conclusions:** CircRUNX1 could be a novel biomarker to predict the benefit of adjuvant EGFR TKIs with regards to DFS in EGFR-mutant resected NSCLC patients. Dynamic ctDNA to inform the precise management of resected NSCLC: LUNGCA-2 study. *First Author: Liang Xia, Institute of Thoracic Oncology and Department of Thoracic Surgery, West China Hospital, Sichuan University, Chengdu, China*

Background: Circulating tumor DNA (ctDNA) has been reported to be valuable for minimal residual disease (MRD) detection, but there is a lack of studies comprehensively assessing whether dynamic ctDNA monitoring can inform whole-course precise postoperative cancer management. In the present study (LUNGCA-2), we analyzed data obtained from longitudinal ctDNA monitoring of stage I-III NSCLC patients in the LUNGCA cohort, and sought to assess the use of dynamic ctDNA monitoring for precise whole-course postoperative management of NSCLC patients. **Methods:** All eligible NSCLC patients underwent curative-intent surgery and subsequently received adjuvant therapies when indicated by clinical practice guidelines for NSCLC. The clinical follow-up was scheduled to be every 3-6 months mainly involving CT and/or MRI. Fresh frozen or paraffin-embedded tissues of primary tumors were collected intraoperatively for baseline somatic mutation profiling. Blood samples were collected before surgery, at 3 days and 1 month after surgery, and then every 3-6 months at clinical visits up to 3 years postoperatively. 233 patients with a total of 2123 plasma samples were ultimately included in the longitudinal ctDNA analysis in the current study. NGS assays were performed with a custom-designed panel that covered 769 cancer-related genes via the MinerVA platform (Genecast Biotechnology Co., Ltd). **Results:** Among the cohort, 166 patients harboring targetable mutations in the primary tumor tissue, 15 were preadjuvant ctDNA positive, and among them, only 25% patients treated with adjuvant TKI therapy experienced relapse during follow-up, and patients received ACT or no adjuvant therapy had a relapse rate of 100%. TKI treatment tended to improve RFS compared with no treatment ($HR 0.1$, $P = 0.025$), but ACT failed to improve RFS ($HR 1.1$, $P = 0.834$). Among all 82 patients receiving adjuvant therapy, the pre- and post-adjuvant therapy postoperative ctDNA status with a negative-negative or positive-negative pattern had similar and favorable RFS ($P = 0.545$) but that patients with a positive-positive or negative-positive pattern had significantly inferior RFS than those with a negative-negative pattern (both $P < 0.001$). For recurrence monitoring, posttreatment ctDNA MRD status had a positive predictive value of 100% and a negative predictive value of 91.8%, and the sensitivity of MRD detection was affected by the organ of relapse. Among positive ctDNA MRD patients, faster increase of ctDNA concentration correlated with more imminent clinical relapse. The median lead time from ctDNA detection to radiological relapse was 273 days. Moreover, ctDNA negativity after relapse was associated with favorable survival. **Conclusions:** These findings highlight the clinical significance of ctDNA dynamics for the precise whole-course postsurgical management of NSCLC patients. Elucidating the genomic and transcriptomic landscape of L858R vs ex19del EGFR-mutated NSCLC. *First Author: Stephanie Pei Li Saw, National Cancer Centre Singapore, Singapore, Singapore*

Background: Epidermal growth factor receptor (EGFR)-mutated non-small cell lung cancer (NSCLC) is heterogeneous and L858R derive less benefit from osimertinib than ex19del in both the metastatic and adjuvant setting, which remains poorly understood. We sought to examine the genomic and transcriptomic features of L858R vs ex19del. **Methods:** Consecutive patients with AJCC7 Stage IA-IIIA EGFR-mutated NSCLC diagnosed 1/1/2010 – 31/12/2019 who underwent surgery at National Cancer Centre Singapore were included. Patients who received neoadjuvant therapy were excluded. Fresh frozen tumour and normal samples were subject to whole exome sequencing (WES) at 400X and 100X coverage respectively, with approximately 50 million paired-end reads for RNA-seq per sample. Wilcoxon and Fisher's exact test were used for association analysis. **Results:** A total of 203 patients were included. Median age at diagnosis was 66, 66.0% (134/203) were females and 84.2% (171/203) never-smokers. Stage IA comprised 44.3% (90/203), IB 28.6% (58/203), II 15.8% (32/203) and IIIA 11.3% (23/203). Median tumour mutational burden (TMB) was 1.3 mutations/megabase (range 0.3 – 44.3). Ex19del represented 46.3% (94/203) and L858R 41.9% (85/203). Whole genome doubling (WGD) was found in 70.0% (142/203) and was more common in TP53-mutated compared to TP53-wildtype (81.1% vs. 63.6%, $p=0.01$). TP53 mutations were more common in stage II/IIIA tumours compared with stage IB and IA (50.9% vs 32.8% vs 30.0%, $p=0.035$). Comparing ex19del and L858R, there was no difference in stage distribution ($p=0.337$), proportion of TMB ≥ 10 (1.1% vs 5.9%, $p=0.103$), number of cancer co-driver mutations ($p=0.174$), TP53 mutations (39.4% vs 32.9%, $p=0.437$) and WGD (69.1% vs 76.5%, $p=0.316$). L858R had a higher incidence of smoking mutational signature (median 0.35 vs 0.28, $p=0.018$) compared to ex19del despite similar smoking history (15.3% vs 12.8%, $p=0.67$), whereas APOBEC mutational signature was higher in ex19del (median 0.06 vs 0.04, $p=0.015$). L858R tumors were associated with a higher incidence of co-mutations in *RBM10* (21.2% vs 6.38%, $p=0.004$), *RNF213* (10.6% vs 1.06%, $p=0.007$) and amplification of *NTHL1* (15.3% vs 2.13%, $p=0.001$) and *AXIN1* (17.6% vs 3.19%, $p=0.002$) compared to ex19del. Transcriptomic subtype differed significantly by EGFR mutation with a higher representation of TRU subtype among L858R than ex19del (51.0% vs 35.3%, $p=0.010$), while GEP score was similar (median 0.189 vs 0.325, $p=0.122$). **Conclusions:** L858R have distinct co-mutations and copy number alterations compared to ex19del, in addition to a higher representation of smoking mutational signature and TRU subtype. TP53 co-mutations are more frequently observed in higher stage tumours and are associated with WGD. Our findings highlight the molecular heterogeneity of resected EGFR-mutated NSCLC, which could contribute to the differential outcomes to adjuvant osimertinib between ex19del and L858R. Prevalence of *EGFR* mutations in patients with resected stage I-III non-squamous NSCLC: Results from the EARLY-EGFR study. *First Author: Ross A. Soo, National University Cancer Institute, National University Hospital, Singapore, Singapore*

Background: The prevalence of *EGFR* mutations (*EGFRm*) in resected stage I-III NSCLC remains controversial as prior research studies were retrospective in nature. EARLY-EGFR is the first prospective, international study to determine the prevalence of *EGFRm* and treatment patterns in patients (pts) with early-stage NSCLC. **Methods:** EARLY-EGFR (NCT04742192), a non-interventional real-world study, captured data on *EGFRm* status, treatment patterns, demographic, clinical and pathological characteristics in consecutively enrolled pts with surgically resected stage IA-IIIB (AJCC 8th) non-squamous NSCLC (Mar 2021 – Oct 2022). The primary endpoint was prevalence of *EGFRm* and secondary endpoints included prevalence of *EGFRm* subtypes and treatment patterns. **Results:** Of 601 pts (median [range] age: 62 [30-86] yrs) enrolled at 33 centers across Middle East and Africa (n=16), Latin America (n=80), and Asia (n=505), 317 (52.7%) were females, 354 (58.9%) were never smokers. The majority had stage IA-IB NSCLC (64.1%) involving right lung (62.9%), no nodal involvement (81.5%), T1a-T2b tumor (82.7%), adenocarcinoma histology (98.7%), and 105/420 (25.0%) tumors were poorly differentiated. About 23.3% (130/559) were diagnosed through a screening program; 60/539 (11.1%) reported family history of lung cancer. The overall prevalence of *EGFRm* was 50.7% (300/592). *Exon-19* deletions accounted for 50.3%, *L858R* mutations for 35.7%, and compound mutations for 2.3% of mutations. *EGFRm* tumors were found to be PD-L1 positive in 38.5% of cases (15/39). Women had higher *EGFRm* rate than men (63.6% vs 36.2%). Compared with *EGFR* wild type (*wt*), pts with *EGFRm* were more likely to be never smokers (39.5% vs 60.5%) and have stage I/II NSCLC (46.5% vs 53.5%) (Table). Of 216 stage I/II/III NSCLC pts, only 51.4% received systemic adjuvant therapy. Significantly higher *EGFRm* rates in stages I and II than in stage III NSCLC (p<0.001 and p=0.050) were found, while no significant difference was found between stages I and II NSCLC (p=0.158). **Conclusions:** In this first prospective, real-world study of *EGFRm* prevalence in resected NSCLC, stage III and smoking were independent predictors associated with decreased odds of *EGFRm*. The results highlight the need to adhere to ASCO adjuvant chemotherapy guidelines, as only half of stage II/III NSCLC pts received adjuvant systemic therapy. Clinical trial information: NCT04742192. Research Sponsor: AstraZeneca.

Clinical validation of an activity-based enzyme assay for early stage lung cancer. *First Author: Paul W. Dempsey, Hawkeye Bio, Inc., Torrance, CA*

Background: The USPSTF guidelines recommend annual LDCT scans for 15.5 million adults with a heavy smoking history. While LDCT can reduce deaths by 20%, screening compliance remains low. A blood test with clinically useful, cost effective performance could improve compliance and access when integrated with the standard of care. We describe here a lyophilized nanosensor system for detecting protease enzyme activity in sera with clinically useful diagnostic activity in early stage lung cancer. We evaluated the performance of the assay by examination of prospectively collected sera for detection of cancer in high risk patients. **Methods:** Sera were obtained in multiple independent studies to include pathologically confirmed, treatment naive lung cancer patients and LDCT confirmed negative individuals. Protease activity was measured on 18 different nanosensors built with protease targets mainly selective for members of the Matrix Metalloproteinase and Cathepsin families. Lyophilized plates were incubated with serum and enzyme activity was measured indirectly as a continuous variable by a fluorescent plate reader. A machine learning modeling tool (Emerge) was used to detect signal associated with a cancer "fingerprint" of protease activity. The analysis stratified allocation into training and testing sets of 250 samples each and reserved a third out of sample validation set (250 samples) for reporting. **Results:** 750 clinical samples included 30% lung cancers, 63% males, 91% smokers, and an average age of 63 years (SD=9). Cancer cases were distributed across stages I (41%), II (17%), III (20%) and IV (20%) with 5% unknown. Histological classification included 59% adenocarcinoma, 31% squamous cell and 11% other subtypes. Using an EmERGE model with only nanosensor activity and gender as inputs, we evolved a balanced algorithm. The algorithm can be further modified to favor sensitivity or specificity depending on the application by applying model weighting factors. We report the performance observed in the 250 out of sample validation set at three points on this spectrum (Table). Among Stage I cancer samples, the balanced algorithm had an accuracy of 90% (26/29). **Conclusions:** Current LDCT tools show low compliance. We demonstrate clinical validity of a cost effective tool to detect lung cancer in support of LDCT screening. Based on a simple blood sample, the current test may predict early stage lung cancer with an accuracy of 90%. The performance suggests applications in LDCT compliance, post LDCT management, and eventually screening. A clinically validated version of this technology is being evaluated as a triage tool for LDCT screening. Research Sponsor: Hawkeye Bio, Inc.

	Specificity Max	Balanced	Sensitivity Max
Sensitivity:	62%	90%	97%
(95% CI)*	(49-73%)	(80-96%)	(90-100%)
Specificity:	86%	82%	54%

Examining ultrafine particle pollution and lung cancer risk in a large, diverse cohort. *First Author: Arthur Bookstein, Keck School of Medicine of University of Southern California, Los Angeles, CA*

Background: Health effects associated with particles less than 2.5 μm in diameter ($\text{PM}_{2.5}$) have been well studied, leading to the establishment of air quality standards and routine monitoring. Additionally, there is growing experimental evidence that ultrafine particles (UFPs), defined as particles less than 0.1 μm in diameter, may adversely affect lung health, eliciting greater injury than larger particles due to deeper penetration into airways and longer retention in the lung parenchyma. Only two epidemiological studies have investigated this topic, finding no associations between ambient UFPs and respiratory mortality or overall lung cancer incidence respectively. Given the limited epidemiologic investigation of UFPs and lung cancer, we examined the association between airport-related UFPs and lung cancer incidence in a large, racially and ethnically diverse cohort. **Methods:** We estimated airport-related UFP exposure for 71,387 participants of the Multiethnic Cohort, who lived within a 53 km $\times$ 43 km grid area around the Los Angeles International Airport (LAX) from date of cohort entry (1993-1996) through December 31, 2013. Cox proportional hazards regression was used, with calendar month/year as the time variable, to examine associations between UFP exposure and lung cancer risk adjusting for demographics, lifetime smoking, neighborhood socioeconomic status, occupation and lifestyle factors. Subgroup analyses were conducted by racial and ethnic groups, lung cancer histology, and smoking status. Copollutant models were run to mutually adjust for other traffic-related air pollutants. **Results:** A per unit increase in the interquartile range (IQR) of airport-related UFP exposure was not associated with lung cancer risk overall [HR = 1.01, 95% CI: 0.97-1.05] or by race and ethnicity. UFP exposure was suggestive of a positive association with risk of lung squamous cell carcinoma (SCC) [HR per IQR = 1.08, 95% CI: 1.00-1.17]. No associations were observed for other histologies [P_{het} for histology = .05]. UFP exposure was associated with an increased SCC risk among current smokers [HR = 1.11, 95% CI: 1.01-1.22] but not among never or past smokers [P_{het} for smoking = 0.51]. **Conclusions:** This study suggests a possible association between airport-related UFP exposure and risk of SCC. These results may be explained by previous studies finding that UFPs activate genes involved in oxidative damage, TNF- α signaling via NF- κ B, and secretion of inflammatory and cardiopulmonary disease biomarkers. These findings warrant further investigation in large epidemiologic cohorts. Research Sponsor: U.S. National Institutes of Health.

Multi-genomic analysis of compound and uncommon EGFR mutations in patients with non-small cell lung cancer. *First Author: Jayoung Park, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, South Korea*

Background: There are similar and different properties between the epidermal growth factor receptor mutations (mEGFR), which are classified into common, uncommon, and compound mutation subtypes depending on their location and pattern on the EGFR gene. We investigated the RWD and RNA expression profile of uncommon and compound mutations in the mEGFR+ NSCLC patients. **Methods:** We collected the medical information for stage I-III mEGFR+ NSCLC patients receiving curative surgical resection in Seoul St. Mary's Hospital. We explored the RNA expression profile using multiplex IF and High-Plex Digital Spatial Profiling. A total of 18,676 DEG libraries were constructed, and 151 significance genes with > 2-fold changes, 4-log 2 normalized read counts, and p-value = 0.05 (up and down) were identified. **Results:** In hospital cohort, 941 mEGFR+ cases of total 6,609 cases consist of common, 860 (91.4%), uncommon, 60 (7.4%), and compound, 21 (2.2%). Median relapse-free survival in uncommon and compound mEGFRs (31.4M and 33.7M) was shorter than common mEGFRs (40.1M, p = 0.877), but median overall survival did not differ between the groups. CNS recurrence rates in the uncommon and compound mEGFRs (40.0% and 35.3%) tended to be higher than that of common mEGFRs (27.4%, p = 0.361). Spatial RNA-seq data of the ratio of deconvolution individual cells showed that genes involved in inflammatory and immune response were relatively lower in mEGFR+ groups. According to the difference in DEG library through clustering heat map, uncommon or compound mEGFR in the immune, inflammatory response category, extracellular matrix, RNA splicing gene category, JAK-STAT, p53, PI3K-AKT, and notch signaling pathway related genes were down regulated compared to common mEGFR+ group. Gene ontology string analysis revealed RNA expression of genes in compound mEGFR was functionally associated with chemokine production (23.4%), electron transfer activity (14.9%) and T cell selection (8.5%), and, in uncommon mEGFRs, was associated with regulation of oligopeptide transport (26.1%), hypermethylation of CpG island (21.7%), and CD4+ CD25+ $\alpha\beta$ regulatory T cell lineage commitment (13.0%), compared to common mEGFR+ groups. Based on the GSEA, relatively highly clustered genes in compound mEGFR were the protein modification process, G-protein coupled receptor, regulation of cytosolic calcium ion concentration, and IL-5 production pathways, and lower ES levels in oxidative phosphorylation and RNA processing pathways, when compared to common mEGFR+ groups. **Conclusions:** In conclusion, our results suggest that uncommon and compound mEGFR+ subtypes exhibiting distinguished RNA expression profile of functional signaling pathways and protein network be not same disease entity as common mEGFR+ subtype. Poster Session

Validation of recurrence prediction using circulating tumor DNA in patients with curatively treated early stage non-small cell lung cancer. *First Author: Milou Schuurbijs, Department of pulmonary diseases, Radboud university medical center, Nijmegen, Netherlands*

Background: Stage II-III non-small cell lung cancer (NSCLC) patients receive adjuvant chemotherapy after surgery as standard-of-care treatment, despite an absolute 5-year disease free survival benefit of only 5.8%. Stage I patients do not receive adjuvant treatment but may benefit. Identification of residual disease by circulating tumor DNA (ctDNA) after curative intent therapy may allow more accurate decisions. **Methods:** Tumor tissue and serial plasma samples were collected from stage I-III NSCLC patients enrolled in the LEMA trial (NCT02894853). Somatic mutations identified by tumor exome sequencing were used to design patient-specific RaDaR assays, targeting up to 48 variants per patient, to analyze ctDNA in serial plasma samples. Results were compared and combined with an independent dataset (LUCID; Gale et al, Annals Oncol 2022). **Results:** In LEMA, 129 patients (53% stage I, 18% stage II and 29% stage III) were treated with curative intent by surgery (n=117), chemotherapy (n=8) or stereotactic radiotherapy (n=4) and followed for a median of 3.4 years. The LUCID dataset included 88 patients (49%/28%/23% in stage I/II/III). Results in the two cohorts were highly concordant (Table) and were assessed in the combined dataset of 808 serial plasma samples. Before treatment, ctDNA was detected in 22%, 72% and 90% of patients with stage I, II and III disease. ctDNA was detected post-treatment (at least one positive samples $\geq$ 14 days after the end of therapy) in 41/65 (63%) of patients who developed radiographic recurrence of their primary cancer, and preceded recurrence by a median of 204 days. For recurrence prediction by ctDNA detection post-treatment, the sensitivity, specificity, positive and negative predictive value (PPV and NPV) in stage I patients were 53%, 99%, 91% and 90%. In stage II-III patients, sensitivity was higher but specificity and NPV were lower (67%, 93%, 91% and 74%, respectively). ctDNA detection after treatment was associated with shorter recurrence-free survival (hazard ratio (HR) 11.5, P=1.8x10⁻³²) and overall survival (HR 8.1, P=1.2x10⁻¹⁷). **Conclusions:** ctDNA detection by RaDaR assays predicted recurrence in two independent cohorts, confirming the potential to identify patients for adjuvant treatment. In stage I patients with positive ctDNA, adjuvant treatment could be offered with confidence due to high specificity of 99% and PPV of 91%. In stage II-III patients, the primary cancer recurred in a quarter of patients with no ctDNA detected post-treatment (NPV 74%). Our results help identify the potential role for ctDNA analysis as a decision support tool for adjuvant therapy in NSCLC. Research Sponsor: None.

Phase 1 trial of gavocabtagene autoleucel (gavo-cel, TC-210) in patients (pts) with treatment refractory mesothelioma and other mesothelin-expressing solid tumors. *First Author: Raffit Hassan, Thoracic and GI Malignancies Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background: We have conducted a Phase 1 trial of gavo-cel, an autologous genetically engineered anti-mesothelin T cell receptor fusion construct (TRuCTM) cell therapy in pts with refractory mesothelin-expressing mesothelioma (MPM), ovarian cancer (OvC), cholangiocarcinoma (CHO), or non-small cell lung cancer (NCT03907852). **Methods:** T cells were engineered with a lentiviral vector to express an anti-mesothelin single domain antibody fused to the CD3 ϵ subunit, which upon translation, integrated into and reprogrammed native T cell receptors to target mesothelin-expressing cancer cells in an HLA-independent manner. Eligibility required central laboratory confirmation of 2+ or 3+ mesothelin expression by IHC in $\geq$ 50% of tumor cells. Dose escalation followed a modified 3+3 design. **Results:** At data cut-off date (January 17th, 2023), 32 pts (23 MPM, 8 OvC, 1 CHO) received a gavo-cel infusion at one of 7 dose levels (DL): DL0 (n = 1, no lymphodepletion [LD]) and DL1 (n = 8), 5x10⁷ transduced cells/m²; DL2 (n = 1, no LD) and DL3 (n = 13), 1x10⁸ transduced cells/m²; DL3.5 (n = 5), 3x10⁸ transduced cells/m²; DL4 (n = 1, no LD) and DL5 (n = 3), 5x10⁸ transduced cells/m². Median number of prior therapies was 5 (range, 1-13), including immune checkpoint inhibitors (ICI) in 87% of MPM pts. Bridging therapy was required in 24 (75%) pts. Two DLTs were reported: grade (gr) 3 pneumonitis at DL1 and gr5 bronchoalveolar hemorrhage at DL5. At the RP2D (1x10⁸/m² after LD) 2/13 (15%) pts had reversible gr $\geq$ 3 CRS. The ORR and disease control rate was 20% and 77%, respectively. The 6-month OS rate was 70.2%. The ORR of pts with MPM or OvC receiving gavo-cel after LD was 21% and 29%, respectively. The median PFS and OS in MPM was 5.6 and 11.1 mos and in OvC was 5.8 and 9.4 mos. Responses correlated with declines in soluble mesothelin related peptides. Peak expansion and persistence correlated with dose and LD administration. At the RP2D, the median C_{max} was 14,385 copies/ug gDNA (range, 64.4–100,782) and the median peripheral blood (PB) persistence was 84 days (range: 0-170). Consistent elevation in IL-6 and IFN- γ levels but minimal IL-8 and TNF- α were observed. Gavo-cel expanded preferentially in cancerous tissues, where it was detected long after becoming undetectable in PB. Gavo-cel therapy led to increased CD3⁺CD8⁺ T cell tumor infiltration. Non-responders exhibited upregulation of immunoinhibitory ligands (CD155, PDL1), indicating potential resistance mechanisms. **Conclusions:** A single IV gavo-cel infusion at the RP2D was associated with a manageable toxicity profile and high rates of disease control, including objective responses in pts with refractory MPM and OvC. A phase 2 study is underway testing the safety and efficacy of gavo-cel in combination with checkpoint inhibitors in pts with mesothelin-expressing solid tumors. Clinical trial information: NCT03907852. Research Sponsor: TCR2 Therapeutics.

Real-life efficacy of nivolumab plus ipilimumab combination in untreated, unresectable malignant pleural mesotheliomas: Result of French early access program—MESOIMMUNE – GFPC 04-2021. *First Author: Olivier Bylicki, HIA SAINT ANNE, Toulon, France*

Background: The SOC for unresectable malignant pleural mesothelioma (MPM) has changed in 2020 with the combination nivolumab plus ipilimumab (NIVO+IPI) results of CheckMate 743 study. As CheckMate 743 was therapeutic trial in selected MPM patients (pts), additional data would be of interest to confirm the results in real-life setting. **Methods:** The present multicenter, retrospective study assessed the outcomes of NIVO+IPI, via an early access program (EAP) in France, in pts with treatment naïve unresectable MPM. The primary objective was investigator-assessed real world progression-free survival (rwPFS) from initiation of NIVO+IPI, defined as time from first dose of NIVO+IPI to first documentation of objective disease progression or death from any cause. The secondary objectives were real world OS (rwOS), objective response rate (ORR), and safety of NIVO+IPI combination. **Results:** From April 1, 2021 to Feb 15, 2022 (last day of EAP) there were 143 pts included out of 350 pts treated by EAP for unresectable MPM in 44 centers. Population characteristics are described in the table. With a median follow-up of 14.1 months, median rwPFS was 7.8 months (95%CI 6.2-9.5), rwPFS rates no differ according to histological subtypes: rwPFS for epithelioid MPM was 8.1 months (95%CI 6.0-12.6) and 7.4 months (95% CI 5.3-11.2) for other histological subtypes. The median rwOS was not reached (NR), 1-year survival rate was 65% (95% CI 57-75%). Median rwOS was NR and 13.1 (95% CI 7.8- NA) in epithelioid and non-epithelioid MPM, respectively. At 1 year, 71.2% of pts with epithelioid MPM are still alive versus 51.2% in pts with other histological subtypes. ORR was 23.9% (95% CI 16.9-32.0%) with median time to response of 3.68 months (2.33-5.09) after introduction of NIVO+IPI. Disease control rate was 80.4%. Grade 3-4 adverse events (AE) occurred in 37.8%. Severe immune-related AE occurred in 13.9% of patients. Five deaths were associated with treatment-related AEs according to investigators judgment. **Conclusions:** While pt's characteristics differed from the pivotal trial, notably with older and unselected patients, efficacy outcomes that we observed here compares favorably with CheckMate 743 results. Tolerance looks acceptable in real-life setting despite 5 toxic deaths reported. Extended follow-up of our cohort will allow consolidation of the results. Clinical trial information: NCT05308966. Research Sponsor: BMS.

Long-term outcomes of single and five fraction schedules of stereotactic body radiation therapy for early-stage central or peripheral NSCLC: Neither fractionation nor location matter? *First Author: Karen Huang, Department of Radiation Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Due to concerns with toxicity, treatment of early-stage non-small cell lung cancer (NSCLC) with stereotactic body radiation therapy (SBRT) often involves different fractionation schemes for peripheral and centrally located tumors. There is a paucity of long-term SBRT survival outcomes comparing peripheral versus central NSCLC. **Methods:** This is a single-institution observational cohort study of patients diagnosed with early-stage NSCLC (T1-2NOMO) who underwent 27 Gy in 1 fraction or 50 Gy in 5 fractions with heterogeneity correction at Roswell Park Comprehensive Cancer Center between September 2008 to December 2018. All patients treated with single-fraction SBRT had peripheral NSCLC and those treated with five-fraction SBRT had central NSCLC. Clinically relevant variables including age, gender, race, Karnofsky Performance Status (KPS), histology (adenocarcinoma, squamous cell carcinoma, NSCLC not otherwise specified), T stage, smoking status, tumor location, and the year of SBRT delivery were obtained retrospectively. Cox multivariable analysis (MVA), Kaplan-Meier plot, and log-rank test were performed to evaluate progression-free survival (PFS) and overall survival (OS). Fine-Gray competing risk MVA was performed to evaluate local failure (LF), nodal failure (NF), and distant failure (DF) with death as a competing event. To reduce selection bias, propensity score matching was performed between single- versus five-fraction SBRT cohorts. **Results:** A total of 265 patients (142 female [53.6%]; median age 77 years) met our criteria. There were 74 (27.9%) and 191 (72.1%) patients with central tumors treated with five-fraction SBRT and peripheral tumors treated with single-fraction SBRT, respectively. On Cox MVA, there was no statistically significant difference in OS (peripheral vs central tumors: adjusted hazards ratio [aHR] 1.04, 95% confidence interval [CI] 0.74-1.46, p=0.81) and PFS (peripheral vs central tumors: aHR 1.05, 95% CI 0.76-1.45, p=0.77). On Fine-Gray competing risk MVA comparing peripheral vs. central tumors, there was no statistically significant difference in LF, NF, and DF. After propensity score matching, 68 matched pairs were identified for peripheral vs. central tumors with similar results. **Conclusions:** Among patients with early-stage NSCLC treated with SBRT central versus peripheral location was associated with similar long-term survival and tumor recurrence outcomes. EGFR assessment using next generation sequencing as a reflex testing on surgically resected non-squamous non-small cell lung carcinoma. *First Author: Samantha Goffinet, Laboratory of Clinical and Experimental Pathology, Pasteur Hospital, FHU OncoAge, Université Côte d'Azur, CHU Nice, Nice, France*

Background: EGFR status assessment is mandatory in early stage (IB-IIIA) non-squamous non-small cell lung carcinoma (NS-NSCLC), but whether NGS methods should be used as reflex testing for this evaluation in daily practice is controversial. However, co-occurring mutations, notably TP53 mutations, may have an impact on tumor behavior and prognosis, and so, on future adjuvant therapeutic strategies. **Methods:** EGFR mutations were assessed prospectively using NGS (OncoPrint Precision Assay panel) in 720 NS-NSCLC surgically resected between January 2021 and September 2022 in a single institution (LPCE, Nice, France). PD-L1 expression was evaluated in all tumors. Disease free survival (DFS) analysis was available in 675/720 (94%) patients. **Results:** EGFR mutations were detected in 83/720 (11.5%) cases. A common non-compound EGFR mutation (L858R or del19) was observed in 62/83 (75%) cases. 12/83 (14%) and 9/83 (11%) tumors had a rare non-compound and compound EGFR mutations, respectively. 40/83 (48%) has a co-occurring mutation, including a TP53 (30/40; 75%) mutation, mainly in exon 5, 7 or 8. EGFR/TP53 mutated tumors were significantly associated with higher PD-L1 expression compared to EGFR mutated tumors. A significant correlation was noted between worse DFS and the detection of a mutation in EGFR exon 18 mutation, as well as the detection of a co-mutation in TP53 exon 7 and in MET exon 14. **Conclusions:** Genomic alteration should be systematically evaluated using an NGS reflex testing in surgically resected NS-NSCLC, since future adjuvant therapeutic decision making may consider the presence of compound EGFR mutations as well as co-occurring mutations in other genes, especially in TP53. The RESECT study: Factors associated with overall survival (OS) and relapse-free survival (RFS) among patients with stages I–III resected NSCLC without known EGFR mutations. *First Author: Jhanelle Elaine Gray, Moffitt Cancer Center, Tampa, FL*

Background: Approximately one-third of patients with Stages I–III resected non-small-cell lung cancer (NSCLC) do not survive 5 years from diagnosis. This retrospective observational study analyzed factors associated with OS and real-world (rw) RFS among Stage I–III NSCLC patients before the introduction of immuno-oncology (IO) treatment. **Methods:** We analyzed data from the US CancerLinQ database for adult patients with no known EGFR mutations and no other cancers, who were diagnosed with Stage I–III NSCLC from 2014–2019 and had surgical resection within 140 days after initial diagnosis. 3081 patients met the study criteria of whom 1677 were Stage I, 853 were Stage II, and 551 were Stage III; 4 Stage I patients who received neoadjuvant or perioperative treatment were excluded (too few for analysis). Most patients received surgery only (71.5%); the rest also received adjuvant (24.7%), neoadjuvant (2.4%) or perioperative (1.5%) treatment, most often chemotherapy ± radiotherapy. Key demographics, clinical characteristics, treatment patterns, and relevant 2-way interactions were considered for inclusion in the model, based on Cox regression analyses and medical insights. Multivariable Cox regression analysis (backwards selection, $p < 0.05$) was used to model OS and rwRFS. **Results:** In the multivariable analyses (in which no Stage I patients with neoadjuvant or perioperative treatment were included), factors associated with both OS and rwRFS ($p < 0.05$) were disease stage, race, ethnicity, year of diagnosis, ECOG performance status, and neoadjuvant treatment. Factors associated with OS ($p < 0.05$), but not rwRFS, were age, sex, time from diagnosis to surgery, and type of surgery. Factors associated with rwRFS ($p < 0.05$), but not OS, were geographic region, nodal status, and adjuvant treatment in Stage II and III patients but not Stage I patients. **Conclusions:** This study identified several risk factors associated with OS and rwRFS, many of which are known. Notably, in this analysis, neoadjuvant treatment was associated with both improved OS and rwRFS in Stage II–III patients and was not evaluable in Stage I patients. However, adjuvant treatment was only associated with improved rwRFS, and only in Stage II–III patients. Based on these findings, there remains an unmet need for Stage I–III NSCLC patients. The recent introduction of IO treatment in this setting may help improve patient outcomes. Research Sponsor: AstraZeneca.

Stereotactic body radiation therapy with sequential immunochemotherapy as neoadjuvant therapy in resectable non-small cell lung cancer (SACTION-01 study). *First Author: Ze-Rui Zhao, Sun Yat-Sen University Cancer Center, Guangzhou, VA, China*

Background: Neoadjuvant PD-1 inhibitor plus chemotherapy increases pathological response for resectable non-small cell lung cancer (NSCLC) compared with chemotherapy alone. Previous phase II trial indicated that stereotactic body radiation therapy (SBRT) served as an immunomodulator and enhanced the effect of preoperative immunochemotherapy. However, whether SBRT would further increase the efficacy of immunochemotherapy for NSCLC remains unknown. **Methods:** In this phase II trial, patients with resectable EGFR wild-type stage IIA to IIIB NSCLC were recruited to receive SBRT (24 Gy in 3 daily fractions) to the primary tumor followed by two cycles of PD-1 inhibitor tislelizumab (200 mg) plus platinum-based doublet chemotherapy (Q3W) before surgical resection. The primary endpoint was major pathological response (MPR) defined as no more than 10% of viable tumor cells in the specimen. Simon's optimal two-stage design was used for conducting the trial. The null hypothesis was that the MPR rate is 0.30, and the alternative hypothesis was that the true MPR rate was 0.50. More than 4 MPRs were needed in stage 1 ($n=15$) to continue, and if there were 19 or more MPRs in 46 patients by the end of stage 2, the null hypothesis can be rejected. The design controls the type I error rate at 0.05 and yields the power of 0.80. (NCT05319574). **Results:** Between May 2022 and Jan 2023, 32 patients were enrolled with 31 (96.9%) male and 19 (59.4%) having squamous cell lung cancer. Twenty-six (81.3%) patients had stage IIIA/B disease. All patients received at least one cycle of immunochemotherapy; 23 of the 25 patients (92.0%) who completed treatment had undergone R0 resections, except for one patient who had disease progression and the other one that unable to tolerate surgery because of grade 4 neutropenia. Twenty-two patients underwent minimally invasive approaches and 3 of them (13.6%) converted to thoracotomy. The median percentage of the viable tumor was 0 (interquartile range: 0–4.0%). Twenty patients achieved MPR, which surpassed the prespecified required number to reject the null hypothesis, resulting in the MPR rate of 80.0% (20/25) in the intention-to-treat population, and 87.0% (20/23) in the per-protocol population. Pathological complete response (pCR) was found in 14 patients (56.0% in the intention-to-treat population and 60.9% in the per-protocol population). Nodal clearance status (pNO) was found in 20 of 23 cN1/2 cases (87.0%). Grade 3–4 adverse events related to neoadjuvant treatment included neutropenia (13.0%), anemia (4.3%), and pneumonia (4.3%). No 30-day or 90-day mortality was observed. **Conclusions:** Neoadjuvant SBRT followed by immunochemotherapy yields unprecedentedly high MPR and pCR rates in NSCLC without EGFR mutation. The trial will continue to recruit 14 more patients to reach a final sample size of 46 participants. Clinical trial information: NCT05319574. Research Sponsor: None.

Two-year lung cancer survival between 2000 to 2020: Results from 3 French nationwide cohorts. *First Author: Didier Debieuvre, Service de Pneumologie, Groupe Hospitalier de la Région Mulhouse Sud-Alsace, hôpital Emile-Muller, Mulhouse, France*

Background: Each decade since 2000, the French College of General Hospital Pulmonologists (CPHG) conducts the KBP study, a real-life nationwide prospective multicenter study on LC in non-academic public hospital (NPH). Here, we report the two-year survival (2-y) rate among the 2020 cohort and the comparisons with the 2000 and 2010 cohorts. **Methods:** Collection of all consecutive diagnosed LC, all stage and all histology, between 01/01 and 12/31 in NPH pulmonology or oncology units in 2000, 2010 and 2020 with the same methodology. A Scientific Committee controlled inclusion exhaustivity and quality in each center. Survival rates were calculated using the Kaplan-Meier method and risk factors were assessed using Cox models. **Results:** 8,999 patients were included in 82 centers in 2020. The 2-y survival rate was 40.3%, the median overall survival was 15.3 months. Compared to 2000, mortality rates at 2 years decreased significantly (–19.1%), while early (1 month and 3 months) mortality remains similar. Survival improved in 20 years whatever histologic types (Table). Factors associated with 2-y survival were sex (36.1% vs 48.1% respectively for male and female respectively, significantly increased over 20 years: +15.3% for M and +24.5% for F), high age (>80 y-o), poor ECOG status (3 or 4) and advanced disease. As expected in 2020, TNM stage was still determining for 2-year mortality, 15.2 [12.6–17.7] stage I vs 75.6 [74.4–76.8] stage IV. In 2020 the Covid-19 infection ($n=283$) impacted the survival (HR = 4.02 95%CI [3.33–4.86]) on multivariate analysis adjusted to age, sex, tobacco consumption, histology, ECOG status, TNM stage. **Conclusions:** These results confirmed the major improvement in the last two decades for LC. 5-years survival will provide us more enlightenment. Association of nuclear shape in the tumor epithelium with response to atezolizumab in NSCLC. *First Author: Patrick Leo, Genentech, South San Francisco, CA*

Background: Anti-PD-(L)1 treatment is the standard of care for advanced non-small cell lung cancer (NSCLC). However, additional biomarkers are needed to identify patients who will benefit from these therapies. In this study, we demonstrate the atezolizumab response score (ARS), which uses digital pathology features of the shape and size of nuclei in the tumor epithelium to predict response to the anti-PD-L1 antibody atezolizumab in NSCLC. **Methods:** Patients were drawn from two trials comparing atezolizumab to docetaxel in second-line advanced NSCLC. A single digitized slide stained for the epithelial cell marker pan-cytokeratin (CK) and CD8 was selected for each patient. OAK, a phase III trial, had 819 patients with images available and was used for training the ARS model. POPLAR, the phase II trial preceding OAK, had 168 evaluable patient images for validating ARS. Color deconvolution was used to identify the CK-positive regions in each image. Nuclei were segmented using the hematoxylin channel. The area, perimeter, eccentricity, solidity, and minor/major axis lengths were extracted from each nucleus in the CK-positive compartment of the pathologist-annotated tumor lesion, excluding necrosis and artifacts. Each measure's mean, median, standard deviation, skewness, and kurtosis across the slide was calculated, for a total of 30 features. Features with an interaction $p < 0.35$ with trial arm in a Cox model were used to fit an elastic-net regularized Cox model on the atezolizumab-treated training set patients, producing ARS. The ARS threshold maximizing atezolizumab overall survival (OS) benefit in the ARS-high group was identified in OAK and applied to POPLAR (the validation set). ARS performance was assessed in the validation set by OS concordance index (c-index) and by atezolizumab benefit in the high- vs. low-ARS groups by hazard ratio (HR) [95% confidence interval]. **Results:** ARS employs five features. Lower nuclear median and standard deviation of major axis length, higher perimeter mean and standard deviation, and higher area were associated with better atezolizumab response. In the validation set, high-ARS (prevalence = 42%) patients had longer OS on atezolizumab vs. docetaxel (HR = 0.42 [0.24-0.72]) while low-ARS patients did not (HR = 0.95 [0.62-1.47]). ARS was positively associated with OS in the validation set atezolizumab arm (c-index = 0.60 [0.54-0.66]), but not the docetaxel arm (c-index = 0.47 [0.41-0.54]). **Conclusions:** We validated a nuclear morphology-based biomarker for atezolizumab response in advanced NSCLC. This demonstrates the utility of digital pathology for biomarker development and motivates study into the identified responder phenotype. Combination of ARS with additional markers, such as PD-L1 expression, might further improve stratification. Research Sponsor: Roche.

Phase I Beamion Lung 1 trial of BI 1810631, a HER2 tyrosine kinase inhibitor (TKI), as monotherapy in patients (pts) with advanced/metastatic solid tumors with HER2 aberrations: Updated data. *First Author: John Heymach, Department of Thoracic/Head and Neck Medical Oncology, Division of Cancer Medicine, MD Anderson Cancer Center, University of Texas, Houston, TX*

Background: There is an unmet need for effective TKIs against HER2 mutations in solid tumors, especially NSCLC. BI 1810631 is a highly potent and selective HER2 TKI that covalently binds to both wild-type and mutated HER2 receptors, including exon 20 insertions (ex20ins), while sparing EGFR. Beamion Lung 1 is an ongoing Phase Ia/Ib study to determine the safety, MTD, PK, PD, and preliminary efficacy of BI 1810631 in pts with HER2 aberration-positive solid tumors (NCT04886804). Preliminary results from Phase Ia are presented. **Methods:** In Phase Ia, pts with advanced/unresectable/metastatic solid tumors who were refractory or unsuitable for standard treatment (Tx) and had HER2 aberrations (e.g. overexpression, gene amplification, somatic mutation, or gene rearrangements) were enrolled. Pts received escalating doses of BI 1810631 BID starting from 15 mg or BI 1810631 QD starting from 60 mg via a Bayesian model. Phase Ib will initially include 30 pts with advanced HER2 tyrosine kinase domain mutation-positive, pre-treated NSCLC. Additional cohorts may be included. Primary endpoints: MTD based on DLTs; pts with DLTs (Phase Ia); ORR (Phase Ib). Secondary endpoints: number of pts with DLTs throughout entire Tx period and PK parameters (Phase Ia/Ib); DoR, DCR, duration of disease control, and PFS (Phase Ib). **Results:** As of 23 January 2023, 36 pts had been treated in the US, The Netherlands, Japan, and China. Pts had NSCLC (n = 22), colorectal cancer (n = 3), or other tumors (n = 11). Most pts (n = 26; ex20ins: n = 23) had a pathological HER2 mutation. Median (range) lines of prior systemic Tx: 2.5 (1–8). Prior HER2-targeted Tx: 12 (33%). Pts received BI 1810631 at 15, 30, 60, 100, 150 mg BID (n = 3/3/4/4/3) or 60, 120, 180, 240, 300 mg QD (n = 5/4/5/4/1). Median number of cycles was 4 (range 1–14). Tx is ongoing in 20 pts. To date, 3 DLTs have been observed (grade 2 edema [60 mg BID], grade 3 anemia [60 mg QD], grade 3 elevated ALT [180 mg QD]). The MTD has not been reached with either schedule. Tx-related adverse events (TRAEs) were reported in 25 pts (69%). The most common TRAEs were diarrhea (n = 10), anemia (n = 5), increased alkaline phosphatase, increased creatinine, increased ALT, hypalbuminemia (all n = 4), hypocalcemia, increased AST, dry skin, increased GGT (all n = 3). Three pts had grade 3 TRAEs (anemia/increased GGT [n = 1], increased ALT [n = 2]). Strong preliminary efficacy signals were observed across all dose levels. Of 22 evaluable NSCLC patients, 10 responded (all PRs; all ex20ins) and 11 had SD. Two patients with other tumors (esophagus; cholangiocarcinoma) also achieved PR. **Conclusions:** These preliminary data indicate that BI 1810631 is well tolerated and shows encouraging anti-tumor activity in pts with HER2 aberration-positive solid tumors. Recruitment into Phase Ia is ongoing. Updated data, including durability endpoints, will be presented. Clinical trial information: NCT04886804. Research Sponsor: Boehringer Ingelheim.

Radiation therapy (RT)-free pembrolizumab plus chemotherapy (P+C) for PD-L1 TPS $\geq 50\%$ locally advanced non-small cell lung cancer (LA-NSCLC): An early report analyzing depth of response from multicenter single arm phase II study (Evolution trial: WJOG11819L). *First Author: Akito Hata, Kobe Minimally Invasive Cancer Center, Kobe, Japan*

Background: Standard of care for unresectable LA-NSCLC is chemoradiation therapy (CRT) followed by durvalumab (D). Survival curves of P monotherapy/P+C for PD-L1 TPS $\geq 50\%$ stage IV NSCLC suggested possible comparable survival to CRT for stage III patients (pts). Moreover, some studies of neoadjuvant C+immunotherapy (I) for stage III pts have demonstrated high pCR and MPR rates, implying potentially outstanding efficacy of C+I for earlier stage. We thus hypothesized P+C without RT in PD-L1 $\geq 50\%$ LA-NSCLC pts provides a comparable efficacy to CRT followed by D while avoiding CRT-induced severe toxicities. **Methods:** This early report focuses on depth of response in a phase II study by WJOG. P with platinum plus pemetrexed (PEM) (non-squamous) or P with carboplatin plus nab-paclitaxel (squamous) was administered every 3 weeks without RT. After four cycles of induction P+C, P with PEM (non-squamous) or P alone (squamous) was continued until progression or 2 years. The primary endpoint was PFS rate at 2 years. **Results:** Between May 2020 and February 2022, 21 pts were enrolled. Median age was 74 (range, 53–89). Stage IIIA/B/C included 12 (57%)/6 (29%)/3 (14%), respectively. Histologic subtypes were 13 (62%) adenocarcinoma, 5 (24%) squamous, and 3 (14%) others. Investigator-assessed best response: 8 (38%) CR; 10 (48%) PR; 2 (10%) SD; and 1 (5%) NE were confirmed, resulting in response rate (RR) of 86% and disease control rate of 95%. RR of TPS 50–79% and 80–100% were 78% and 92%, respectively. Deep response (DR): defined as tumor shrinkage $\geq 80\%$ was obtained in 12 (57%) of 21 pts. DR was accomplished in 4 (44%) of 9 TPS 50–79% and 8 (67%) of 12 TPS 80–100%. Median time to response was 43 (range, 41–92) days. Early tumor shrinkage (ETS): PR-in at the time of first CT evaluation (6 weeks) was achieved in 16 (89%) of 18 CR+PR pts. At the time of data cut-off, median follow-up period was 18.5 (range, 0.3–29.0) months, and 14 (67%) of 21 pts were progression-free. All 12 pts achieving DR, including all 8 CR were progression-free, also in 14 (88%) of 16 ETS pts. Three pts after local progression received salvage definitive-CRT. Median number of P administrations was 20 (range, 1–35). AEs $\geq$ grade 3 were observed in 11 (52%) pts, including: 2 (10%) pneumonitis; 2 (10%) pneumonia; 1 (5%) diarrhea; 1 (5%) ALT elevation; and 1 (5%) acute heart failure, excluding hematological AEs. There was one (5%) possible grade 5 AE (pneumonia). **Conclusions:** RT-free P+C exerted a notably high RR, including some CRs. The deeper/earlier response and higher PD-L1 TPS could be associated with the higher progression-free incidence at the data cut-off. To investigate our hypothesis: RT-free P+C can be a less toxic curative option in selected LA-NSCLC pts with PD-L1 TPS $\geq 50\%$, further matured data is warranted. Clinical trial information: NCT04153734. Research Sponsor: MSD.

A systematic comparison of whole genome sequencing and targeted panel sequencing for precision oncology. *First Author: Ji-Hyung Park, Graduate School of Medical Science and Engineering, Korea Advanced Institute of Science and Technology, Daejeon, South Korea*

Background: The analysis of the cancer genome provides clinically meaningful information such as actionable cancer driver mutations. Whole genome sequencing (WGS) provides a complete mutational landscape at an affordable cost thereby having increase clinical utility compared to the usual approach of targeted panel sequencing (TPS). To understand the capabilities of WGS in oncology, we conducted a study in lung adenocarcinomas. **Methods:** We produced WGS (surgically resected tumor tissues and matched blood; mean coverage 42x) and TPS (tumor only; SNUH panel encompassing 75 cancer genes; mean coverage 904x) through the Illumina sequencing platform and conducted comprehensive bioinformatic analyses. Oncogenic driver events, including single base substitution (SBS), insertion or deletion (INDEL), complex deletion-insertion, and fusion oncogene, were investigated in both datasets. Lastly, we compared the pattern-based mutational features, such as tumor mutational burden (TMB), mutational signatures, and copy number changes which is associated with genomic instability. **Results:** In 60 lung adenocarcinomas, the TPS method identified 120 driver mutations from the 75 targeted genes. Of these, 114 mutations were also detected by the WGS method, showing 95.0% sensitivity of WGS in detection of core driver mutations. In uncovered genomic regions by TPS, WGS captured 9 additional driver mutations (such as loss-of-function mutations in PIK3R2, ARID2, and APC) and 37 copy number variations (such as amplification of LMO and SMO, deletion of PIK3R1 and APC) in the cancer genes. TMB calculation is straightforward in WGS however, sophisticated considerations were necessary in TPS for TMB, to remove false positives and germline mutations. TPS showed a good capability for identifying hypermutator tumor samples, but a quantitative estimation was not always feasible due to the substantial background fluctuation, particularly for INDELs. Mutational signatures are unique combinations of mutation types in a given sample, which can give important clues to the mechanism underlying mutations. TPS showed adequate mutational signatures (cosine similarity > 0.7), but was not constantly satisfactory in tumors with high TMB ($> 20,000$ genome wide SBS and INDELs). In TPS, approximately 30% of high TMB tumors represented marginal cosine similarity (0.5–0.7), and tobacco smoking related signature (SBS 4) found in WGS was captured only in 50% of the associated cases (9 out of 18). For DNA copy number changes and loss-of-heterozygosity analyses, WGS showed a much higher resolution. **Conclusions:** Our study demonstrates that WGS has comparable capabilities for the detection of driver mutations in core oncogenes and tumor suppressor genes. WGS was superior for pattern-based features, such as TMB, mutational signatures, and copy number changes. WGS is a medically necessary more comprehensive approach to precision oncology. SAKK 16/18: Immune-modulatory radiotherapy to enhance the effects of neoadjuvant PD-L1 blockade after neoadjuvant chemotherapy in patients with resectable stage III (N2) non-small cell lung cancer (NSCLC)—A multicenter phase II trial. *First Author: Laetitia A Mauti, Department of Oncology, Kantonsspital Winterthur, Winterthur, Switzerland*

Background: Neoadjuvant chemo-immunotherapy has become a new standard of care in locally advanced, resectable NSCLC. The SAKK 16/14 trial demonstrated a major improvement in pathological response (pCR), major pathological remission (MPR) and event-free survival (EFS) with the addition of perioperative durvalumab after standard induction chemotherapy (ChT) with cisplatin and docetaxel. Based on data suggesting a potential enhancement of immunotherapy efficacy, the ongoing SAKK 16/18 trial investigates the addition of immune-modulatory radiotherapy (RT) given concurrently with neoadjuvant durvalumab. **Methods:** In this non-comparative randomized phase II trial patients (pts) with resectable stage IIIA-B(N2) (cT1-3 or T4 due to size N2 MO) NSCLC receive 3 cycles of cisplatin 100mg/m² and docetaxel 85mg/m² followed by durvalumab (1500mg) and one of three randomized RT regimens before tumor resection and adjuvant durvalumab for 1 year. RT is delivered to the primary tumor only, using either 20x2 Gy, 5x5 Gy, or 3x8 Gy (delivered inhomogeneously). RT planning is optimized for strict organ at risk and mediastinal lymph node sparing. The primary endpoint is 1-year EFS. We report a preplanned interim analysis of the secondary endpoints safety, surgical outcomes and pathological response after surgery in 25 pts. **Results:** At data cut-off on Oct 8, 2022, 25 pts had reached post-operative day 30 and a total of 31 pts were included in the safety analysis. Thirty pts (97%) had at least one treatment related adverse events (TRAE). Eighty-eight % were attributed to neoadjuvant ChT (16% G3-4), 4% each to neoadjuvant durvalumab (1% G3) and RT (1% G4), and 8% to surgery (35% G3-4). One fatal TRAE occurred in a pt with COVID-pneumonia during neoadjuvant ChT. No difference in safety was seen between the three RT arms. There was no treatment-related cancellation or delay in surgery and 0% 30-day postoperative mortality. Eighty-one % of pts underwent tumor resection (96% RO). Non-resection was due to death (n = 1), progressive disease (n = 3), or unresectable tumor (n = 2). The pCR-rate was 28%, and MPR (≤10% viable tumor cells) was detected in 76% of all specimens. Details of pathological responses with regard to immune-modulatory RT regimen will be presented at the meeting. **Conclusions:** The preplanned interim safety analysis of the SAKK 16/18 trial did not show a relevant increase in TRAE due to immune-modulatory RT. Surgical feasibility and safety are confirmed and the trial continues enrolment to a planned total of 90 pts (30 per RT arm). Preliminary pathological responses are promising, and exploratory analyses will study potential differences between the RT regimens, in order to better understand the potential role of immune-modulatory RT in the multimodal treatment of resectable stage III(N2) NSCLC. Clinical trial information: NCT04245514. Research Sponsor: AstraZeneca.

Prospective dynamic sampling and molecular residual disease monitoring to predict clinical outcomes for patients with unresectable, locally advanced non-small cell lung cancer undergoing radical radiotherapy. *First Author: Jia-Tao Zhang, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China*

Background: The role of molecular residual disease (MRD) detection in non-small cell lung cancer (NSCLC) patients after definitive resection has been progressively elaborated. However, the dynamic patterns of circulating tumor DNA (ctDNA) during and after radical radiotherapy (RT) remain unclear but are critical for detecting MRD in this context. **Methods:** We enrolled 139 patients with locally advanced NSCLC treated with radical RT in this prospective study. And 761 blood samples were successfully detected by ctDNA-MRD assay at different preset timepoints before, during and after RT. **Results:** There was a declining trend in ctDNA concentrations of “during RT” time point (RT reached 40 Gy) relative to those after RT. Patients with negative ctDNA of “during RT” and “after RT” time points may indicate an early response to RT, and had better progression-free survival (PFS) than those with late response to RT(ctDNA clearance only at “after RT” time point, HR = 0.30, 95%CI: 0.12-0.75, p = 0.004). Moreover, patients with both negative ctDNA of “during RT” and “after RT” time points could not benefit from consolidation therapy (HR = 0.72, 95%CI: 0.29-1.78, p = 0.478), while patients with any positive ctDNA of them could (HR = 0.59, 95%CI: 0.38-0.93, p = 0.023).The sensitivity of longitudinal MRD was 97.8% and only two patients with local progression were overlooked. The 2-year cancer-specific PFS of patients with longitudinal undetectable MRD was 88.4%, which corresponds to the potentially cured population. For patients with only blood-informed MRD detection, the sensitivity and median lead time of longitudinal MRD were 97.7% and 3.9 months, respectively, which indicating the feasibility and efficacy of blood-informed MRD detection strategy. **Conclusions:** These data shed new light on the ctDNA-MRD detection for localized NSCLC patients who received radical RT. Sequential intravenous chemotherapy with drug-eluting bead bronchial arterial chemoembolization for the treatment of stages III and IV lung squamous cell carcinoma: A retrospective controlled clinical study. *First Author: Jianfei Tu, The Fifth Affiliated Hospital of Wenzhou Medical College, Lishui, China*

Background: To determine the differences in efficacy and safety between drug-eluting bead bronchial arterial chemoembolization (DEB-BACE) combined with intravenous chemotherapy and systemic chemotherapy alone for the treatment of stages III and IV lung squamous cell carcinoma (LSCC). **Methods:** 136 patients with stages III and IV LSCC were retrospectively recruited between January 2018 and August 2021 and divided into group A (chemotherapy-only, N = 95) and group B (DEB-BACE combined with intravenous chemotherapy, N = 41). The short-term efficacy, hemoptysis and dyspnea remission rates, and incidence of adverse reactions were compared between the two groups. Survival estimation was performed by Kaplan-Meier, and the Log-rank test was performed to compare survival differences between groups. **Results:** The One-month DCR (90.2% vs. 49.5%) and ORR (75.6% vs. 38.9%) were better in group B than in group A (both P < 0.05). Progression-free survival (PFS) was 8.0 months in Group B and 6.0 months in Group A, a statistically significant difference (P < 0.05). The PFS rates at 6, 12, and 24 months were 63.4%, 24.4%, 0.0%, 43.2%, 13.7%, and 0.0% in groups B and A, respectively, this difference was significant (P < 0.05). The median overall survival was better in group B than in group A (19.0 vs 14.0 months, P < 0.05). The OS rates at 6, 12, and 24 months were 100%, 85.4%, 26.8%, 78.9%, 56.8%, and 22.1% in groups B and A, respectively, with statistically significant differences (P < 0.05). The hemoptysis and dyspnea remission rates were better in group B than in group A within one month after treatment (P < 0.05), however, in terms of the incidence of adverse reactions, incidences, such as post-treatment fatigue and bone marrow suppression, were significantly lower in Group B than in Group A during the follow-up period (P < 0.05). **Conclusions:** DEB-BACE combined with intravenous chemotherapy is effective for the treatment of advanced LSCC, with lower adverse reactions, and significant improvement in patients' hemoptysis and dyspnea symptoms, which is worthy of clinical application. Association of circulating CD103⁺ T cells with major pathological response in a randomized phase 2 trial of neoadjuvant durvalumab with or without stereotactic body radiotherapy in patients with early-stage non-small cell lung cancer. *First Author: Zachary Walsh, Columbia University Medical Center, New York, NY*

Background: We previously reported results of a randomized phase 2 study, demonstrating a higher rate of major pathological response to durvalumab in combination with stereotactic body radiotherapy (SBRT) compared to durvalumab alone in patients with localized (stage I-IIIa) non-small cell lung cancer (NSCLC). Biomarkers of response in NSCLC are poorly understood. To address this, we evaluated sequentially collected peripheral blood mononuclear cells (PBMCs) from study participants to identify easily accessible biomarkers associated with major pathological responses. **Methods:** PBMCs were obtained from study participants at defined pre-treatment, peri-operative, and post-operative timepoints. We performed 25-marker spectral flow cytometric analysis of the T cell compartment in these samples and used dimensionality reduction and clustering programs to identify populations of interest. **Results:** Our analysis of these samples revealed populations of both CD4⁺ and CD8⁺ T cells with hallmarks of prior antigen exposure and tissue residency (CD103⁺, CCR7⁺, CD45RA⁺), suggesting tumor-experienced T cells circulating into the blood. Greater pre-treatment frequency of these T cell populations was associated with major pathological responses to neoadjuvant therapy. This observation was consistent when evaluating patients with major pathological responses across both treatment arms, and within the durvalumab plus SBRT group, where we had enough patients with major pathological responses. Maturation of disease-free survival data from this trial will enable us to evaluate the association of these biomarkers with long-term survival. **Conclusions:** Together, these data reveal an unexpected population of T cells in the peripheral blood with features of tissue-residency, which are associated with major pathological responses, and suggest that re-circulation of tumor-experienced T cells may represent a predictive biomarker for neoadjuvant treatment of NSCLC. Association of peripheral memory B cell population maintenance and long term survival after perioperative chemoimmunotherapy in NSCLC (NADIM trial). *First Author: Belen Sierra-Rodero, Instituto de Investigación Sanitaria Puerta de Hierro-Segovia de Arana, Hospital Universitario Puerta de Hierro-Majadahonda, Madrid, Spain*

Background: In the context of perioperative immunotherapy, it is crucial to personalize adjuvant treatment, identifying which patients should or should not receive post-surgical immunotherapy. Here we describe the changes in B cell peripheral blood immunophenotype during perioperative immunotherapy and its potential to predict disease progression in patients from NADIM I clinical trial (NCT03081689). **Methods:** Blood samples from 42 patients were obtained at pre-, post-neoadjuvant chemoimmunotherapy (pre-surgery) and at 6 and 12 months of adjuvant IO. Peripheral mononuclear cells were stained with CD19, CD20, CD38, CD24, CD27, CD25, CD10 antibody panel and analyzed by flow cytometry using FlowJo. Statistical analysis in paired samples was performed with Wilcoxon test and differences in parameters' fold changes between disease status groups (Progression-free at 34.2 months) were determined by Mann-Whitney U tests. Variables cutoffs were established using ROC curve analysis. Progression-free survival (PFS) was evaluated using Kaplan-Meier curves and long-rank test. The median follow-up was 38.0 months. **Results:** Regarding the impact of NADIM complete treatment scheme in patient's B cells, there was a reduction of memory B cells (CD19+CD20+CD38-CD24+CD27+; $p < 0.001$) and CD20 levels in total B cells (CD19+CD20+; $p = 0.001$) ($n = 17$). Importantly, this decrease occurs in all patients regardless their pathological response or disease progression. However, the magnitude of the memory B cell percentage and CD20 levels reduction was significantly more pronounced in patients whose disease progress thereafter ($p = 0.023$, $p = 0.052$ at 6 and 12 months for memory B cells; and $p = 0.002$, $p = 0.009$ at 6 and 12 months for CD20 expression). Patients with a relative drop of memory B cells greater than 90% at 6 or 12 months, showed a shorter PFS ($p = 0.028$, $p = 0.007$). Likewise, patients with a relative decrease of CD20 expression on B cells higher than 60% at 6 or 12 months had shorter PFS ($p = 0.016$, $p < 0.001$). The AUC ROCs to identify patients with disease progression, were 0.824 and 0.885 at 6 and 12 months for memory B cells; and 0.912 and 0.981 at 6 and 12 months for CD20 levels. Moreover, memory B cells percentage and CD20 levels decrease occur between surgery and the first 6 months of adjuvant therapy ($n = 21$, $p < 0.001$, $p = 0.025$). After that, these levels are maintained from 6 to 12 months of adjuvant treatment ($n = 20$, $p = 0.290$, $p = 0.682$), thus the overall reduction is also observed between surgery and 12 months samples ($n = 17$, $p < 0.001$, $p = 0.001$). **Conclusions:** Perioperative IO produces a significant reduction in memory B cells and CD20 levels. Importantly, stronger decreases might be helpful to predict progression since they are associated to shorter PFS, indicating that the maintenance of the memory B cell peripheral compartment is relevant for long-term survival of these patients. Genomic comparison of MET exon 14 skipping and MET amplified non-small cell lung cancer. *First Author: Rachel Minne, Department of Human Oncology, School of Medicine and Public Health, University of Wisconsin, Madison, WI*

Background: In non-small cell lung cancer (NSCLC), the MET tyrosine kinase receptor can be dysregulated by mutations and/or gene amplification. The most common MET mutation is in exon 14 (METex14), leading to impaired receptor degradation and increased MET-mediated signaling causing sustained tumor proliferation. MET amplification also leads to continued MET signaling and oncogenesis and can be a mechanism of resistance to targeted therapy. We sought to compare the genomic landscape of METex14 and high-level MET amplified tumors, both of which can be targeted with tyrosine kinase inhibitors. **Methods:** We analyzed 18,047 NSCLC tumors (any stage/subtype) sequenced with Tempus xT assay (DNA-seq of 648 genes at 500x coverage, full transcriptome RNA-seq). Tumors were queried for METex14 mutations, high MET amplification (METamp), defined as copy number gain (CNG) ≥ 10 , and other MET mutations (METother). Immuno-oncology (IO) biomarkers were compared across MET-altered and MET wild-type (METwt) groups. The prevalence of somatic gene alterations was compared similarly with the false-discovery rate (FDR) adjustment. **Results:** A total of 276 (1.53%) METex14, 138 (0.76%) METamp, 27 (0.15%) METother, and 17,606 (97.56%) METwt tumors were identified. Across groups, patients with METex14 were older, more likely to be female, and nonsmokers. METex14 exhibited the lowest tumor mutational burden (TMB) and lowest neoantigen tumor burden (NTB). PD-L1 positivity rates were higher in METex14 tumors compared to METamp and METwt tumors. MET log10 gene expression was highest in METamp. METamp exhibited the lowest proportion of CD4 T cells and the highest proportion of NK cells. Compared to METex14, METamp exhibited increased prevalence of TP53 (83% vs 37%), TFCE (46% vs 1.1%), CFTR (37% vs 1.4%), EGFR (31% vs. 7.6%), WNT2 (11% vs 0.4%), KEAP1 (14% vs 0.7%), and STK11 (8% vs 1.4%), and decreased prevalence of MDM2 (4.3% vs. 14%), and FRS2 (2.9% vs. 12%). **Conclusions:** In this large population-based analysis of MET-altered NSCLC, METex14 tumors exhibited differences in IO biomarkers and the somatic landscape compared to non-METex14 NSCLC tumors. Variations in immune profiles may affect immunotherapy selection in MET-altered NSCLC and require further exploration. Research Sponsor: Tempus Labs; U.S. National Institutes of Health.

Phase II trial of consolidation pembrolizumab (pembro) after proton reirradiation (re-RT) for thoracic recurrences of non-small cell lung cancer (NSCLC). *First Author: Nikhil Yegya-Raman, University of Pennsylvania, Philadelphia, PA*

Background: Isolated thoracic recurrences of NSCLC in/near previously irradiated fields present a therapeutic challenge. One treatment option is re-RT with proton beam therapy (PBT) to minimize normal tissue exposure; however, distant failure is common. Herein, we report the first prospective trial of PBT re-RT followed by pembro. **Methods:** This phase II, single-arm trial (NCT03087760) enrolled patients (pts) with isolated locoregional recurrences of NSCLC in/near previously irradiated fields. Key inclusion were definitive thoracic RT > 6 months (mo) prior, ECOG 0-1, and clinical target volume (CTV) < 250 cc. Key exclusion were extrathoracic metastases, prior grade ≥ 3 pneumonitis, and prior immunotherapy < 30 days from re-RT start. 4-12 weeks after completion of 60-70 Gy PBT re-RT, pts without progressive disease started pembro 200 mg IV q21 days for up to 12 mo. Primary endpoint was progression-free survival (PFS). Secondary endpoints were overall survival (OS) and CTCAE v5.0 toxicity. PFS and OS were measured from re-RT start and estimated using Kaplan-Meier method. **Results:** Between November 2017 and April 2021, 32 pts were consented; 10 were excluded most commonly due to CTV ≥ 250 cc ($N = 3$) or separate primary ($N = 3$). 22 were eligible and initiated PBT re-RT. Trial closed early due to slow accrual. Median age was 68 years. All recurrences were biopsy-proven; 8 (36%) were squamous. Recurrences were primary tumor ($N = 4$), nodal ($N = 8$), and both ($N = 10$). 8 pts (36%) received prior durvalumab. Median interval from prior RT end to re-RT start was 20 mo (range 10.2-74.8). Median delivered re-RT dose and dose/fraction were 60 Gy (range 18-70) and 2 Gy (range 1.8-4), respectively; 21 pts (95%) received concurrent chemotherapy. 15 pts (68%) initiated consolidation pembro on trial and received a median of 3 cycles (range 2-17). Pembro was discontinued due to completion of 1 year ($N = 3$), disease progression ($N = 4$), toxicity ($N = 5$; 2 pembro-related [grade 2 pneumonitis after cycle 3 and grade 3 mucositis after cycle 13], the former also re-RT-related), death without progression ($N = 2$; NSTEMI and unknown), and pt decision ($N = 1$). Median follow-up was 38.7 mo. Median PFS and OS were 8.8 mo (95% CI 4.2-23.7) and 22.8 mo (95% CI 6.9-not reached) for all pts, respectively, and 13.5 mo (95% CI 4.2-25.3) and 22.8 mo (95% CI 6.5-not reached) for pts who started pembro. Receipt of > 3 cycles pembro ($N = 7$) associated with better OS (median 46.7 vs 13.8 mo, log-rank $p = 0.007$). 10 pts (46%) had grade ≥ 3 toxicity; 2 were pembro-related (grade 3 lymphopenia and mucositis). 1 pt had grade 5 toxicity (aortic fistula), from re-RT. **Conclusions:** In the first prospective trial of PBT re-RT + consolidation pembro, treatment proved feasible and PFS was acceptable though the capacity to administer pembro was limited. This approach may be considered in selected patients with isolated thoracic recurrences of NSCLC. Clinical trial information: NCT03087760. Research Sponsor: Merck & Co.

Stereotactic ablative radiotherapy with nivolumab for early-stage operable non-small cell lung cancer: A phase 2 study. *First Author: Gustavo Schvartsman, Hospital Israelita Albert Einstein, São Paulo, Brazil*

Background: Surgery is standard of care for patients with stage I non-small cell lung cancer (NSCLC). However, 5-year mortality can reach up to 30%. For patients with contraindication to surgery, treatment with stereotactic ablative radiotherapy (SABR) leads to adequate local tumor control, but has a high rate of regional and distant failure. SABR as neoadjuvant therapy for stage I NSCLC produced a pathologic complete response (pCR) rate of only 60% when surgery was performed after 10 weeks of treatment, demanding improvement in the management of both operable and inoperable early-stage NSCLC. Immune checkpoint inhibitors (ICI) are routinely used in stages III-IV NSCLC, with recent approvals in the peri-operative setting, and may be synergistic with radiotherapy. We hypothesized that neoadjuvant nivolumab plus SABR may improve pCR rate and provide insight to its changes in the tumor micro-environment. **Methods:** This is a phase 2, single arm, open label study evaluating neoadjuvant treatment for patients with NSCLC of up to 4 cm, with no lymph node involvement (AJCC 8th edition: up to cT2aN0), and adequate surgical conditions. Treatment consisted of nivolumab 360 mg every 3 weeks for 3 doses or unacceptable toxicity. SABR started on D1 of nivolumab, with a duration of 2 to 3 weeks, depending on the lesion size and location (3 x 18 Gy; or 5 x 10 Gy; or 8 x 7.5 Gy). Standard-of-care surgery was performed at 10 (+/- 2) weeks after the last radiotherapy dose. The primary endpoint of the study is pCR rate at surgery. Tissue, blood, and stool samples were collected during treatment. **Results:** We included 25 patients. All but one were cared for in the Brazilian public system. Mean age was 68 years. Mean tumor size was 2.45 cm. Only 3 patients were never-smokers. Surgery was performed as scheduled in all but one patient. pCR rate was 80% (19/24) and MPR rate was 83% (20/24) of patients who underwent surgery. Twenty-nine treatment-emergent adverse events occurred in 13 patients (23 grade 1-2 events, two grade 3 and two grade 5 events, being only one grade 3 diarrhea related to experimental treatment). The single patient who was not operated died during study treatment from relapsed acute alcoholic hepatitis. The other grade 5 event was due to a respiratory infection, both unrelated to treatment. Two patients died from surgical complications 185 and 72 days after surgery, respectively (one with pulmonary artery lesion with subsequent clinical complications and other with thromboembolic events), deemed unrelated to experimental treatment. During follow-up, two additional patients died due to comorbidities, and none relapsed to date. **Conclusions:** In this trial with patients with significant comorbidities and smoking history from the public system in Brazil, we demonstrated a pCR rate of 80% with SABR + nivolumab. Further studies are warranted to evaluate this strategy versus surgery in operable patients with stage I disease. Clinical trial information: NCT04271384. Research Sponsor: Bristol-Myers Squibb.

Assessing the efficacy and safety of DEB-BACE combined with intravenous chemotherapy for the treatment of intermediate to advanced lung adenocarcinoma after progression of targeted drug resistance. *First Author: Lingqiang Lai, The Fifth Affiliated Hospital of Wenzhou Medical College, Lishui, China*

Background: To compare the efficacy and safety of drug-eluting bead bronchial arterial chemoembolization (DEB-BACE) combined with intravenous chemotherapy versus systemic intravenous chemotherapy for intermediate to advanced lung adenocarcinoma with positive driver genes after progression of targeted therapy. **Methods:** A total of 131 patients with intermediate to advanced lung adenocarcinoma were retrospectively recruited from 2018-2022 and divided into Group A (standard chemotherapy regimen, N=62) and Group B (DEB-BACE and intravenous chemotherapy, N=69). The short-term efficacy, hemoptysis remission rate, dyspnea remission rate, and incidence of adverse effects were compared between the two groups using the χ^2 test. Survival estimates were performed by Kaplan-Meier, and a Log-rank test was performed to examine survival differences between groups. **Results:** The three-month disease control rate (DCR): 82.6% vs 58.1% and objective remission rate (ORR: 60.9% vs 38.7%) were better in group B than in group A (both $P < 0.05$). Median progression-free survival (PFS, 10.0 vs 7.9 months) and median overall survival (OS, 33.0 vs 18.0 months) were better in group B than in group A (both $P < 0.05$). The PFS rates at 6, 12, and 24 months were 67.3%, 40.8%, and 0.0% and 54.1%, 23.2%, and 0.0% in groups B and A, respectively; and the OS rates at 6, 12, and 24 months were 100%, 95.7%, 72%, 88.6%, 66.1%, and 21.8% in group B and group A, respectively, with statistically significant differences ($P < 0.05$). Within one month after treatment, group B had better hemoptysis relief (83.3% vs. 20.0%) and dyspnea relief (57.5% vs. 30.0%) than group A (both $P < 0.05$). During the follow-up period, the incidence of adverse reactions was significantly lower in group B than in group A ($P < 0.05$). **Conclusions:** For patients with intermediate to advanced lung adenocarcinoma who have failed to progress on targeted therapy, DEB-BACE combined with intravenous chemotherapy has shown superior efficacy and survival benefit and lower adverse effects, while significantly improving patients' symptoms of hemoptysis and dyspnea, with important application prospects. Development of a novel blood-based RNA gene expression platform for early-stage lung cancer diagnosis. *First Author: Martin J Keiser, IV BioHoldings (IVBH), Newport Beach, CA*

Background: Blood-based methods using circulating tumor DNA (ctDNA) and cell-free DNA (cfDNA) are under development for early and less invasive detection of lung cancer, although detection of the earliest stage cancers (stages 0-II) using these modalities is suboptimal. We hypothesized that a machine learning approach using RNA gene expression may offer important information on the biology of the patient, allowing for gene expression profiles to be used as a surrogate measurement of cancer disease phenotype and as a promising direction for early detection of lung cancer. In a previous study, 23 miRNA biomarkers were successfully discovered and validated for the non-invasive diagnostic classification of lung adenocarcinoma, achieving 97.7% sensitivity, 98.7% specificity in blood obtained from 383 clinical subjects. The aim of this study was to train a machine learning algorithm, from the 23 miRNA features, to test the signature for early lung cancer detection. **Methods:** A large and diverse clinical cohort was obtained from the NIH Gene Expression Omnibus database, GEO Accession Number GSE137140 ($n=3,744$), comprised of miRNA extracted from serum samples consisting of subjects with pre-operative lung cancer ($n=1,566$) and non-cancer controls ($n=2,178$). Our analytic plan leveraged machine learning methods derived from XGBoost classification, a popular supervised-learning algorithm that uses sequentially built shallow decision trees to provide accurate results and avoidance of overfitting. The algorithm was trained using XGBoost 1.4.1.1 R library programmed with R v3.6.3. **Results:** The lung cancer cohort was heavily weighted towards early-stage lung cancer (87.7% stage I/II), including representation across prevalent histologic types (adenocarcinoma 77.8%, non-adenocarcinoma 22.2%) and those who self-reported as never smokers (37.9%). The 23-miRNA signature achieved 98% sensitivity, 89% specificity in the held-out test set (Table). When incorporating age and gender, the 23-miRNA signature achieved 95.5% sensitivity, 90.3% specificity. **Conclusions:** A machine learning approach using RNA gene expression in patient serum achieved high sensitivity and specificity in a large, predominantly early-stage, lung cancer cohort. A multi-analyte, multimodal approach that leverages machine learning algorithms with RNA gene expression profiles and available demographics and clinical risk-factors, represents the possibility to accurately detect lung cancer in the earliest stages. This approach has successfully been translated from microarray to PCR instrumentation, with further validation of this machine learning method and approach currently underway. Phase Ib study of neoadjuvant concurrent chemoradiation plus durvalumab followed by surgery and adjuvant durvalumab for resectable stage III NSCLC. *First Author: Jiyun Lee, Lung Cancer Center, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: The use of neoadjuvant and adjuvant immunotherapy in resectable non-small cell lung cancer (NSCLC) has become a standard of care. However, the integration of immunotherapy into a trimodality treatment regimen has not been widely explored. We hypothesized that adding durvalumab to neoadjuvant concurrent chemoradiation and surgery would not increase treatment-related adverse events (TRAE) during neoadjuvant period. **Methods:** This was a prospective, single center, single-arm, open-label phase Ib study. Patients with resectable, stage III N2 NSCLC received concurrent chemoradiation [weekly paclitaxel (45mg/m²)/carboplatin (AUC 2.0) for 5 weeks with radiotherapy 45Gy] and durvalumab 1,500mg Q4W for 2 cycles followed by surgical resection and adjuvant durvalumab for 1 year. The primary endpoint was the frequency of patients who experience grade 3 or more TRAE during neoadjuvant therapy based on CTCAE 4.03. **Results:** Of 30 patients (median age 65.5 years; 67% male), 56.7% had squamous histology and 60.0% had stage IIIA. Any grade AEs and TRAEs (neoadjuvant/adjuvant) were reported in 83.3%/76.7% and 70.0%/63.3% of patients, respectively. Grade 3 or more AEs and TRAEs (neoadjuvant/adjuvant) were reported in 10.0%/3.3% and 10.0%/0.0%, respectively. Grade 3 or more TRAE reported during neoadjuvant treatment were neutropenia, anemia, and nausea, one each; no Grade 5 AEs occurred. Surgical resection was not performed in three patients: two due to treatment-related adverse events (AEs) and one due to patient refusal. Among 27 patients who received complete resection, the pathologic complete response (pCR) rate and major pathologic response (MPR) rate were 40.7% (95% CI, 22.4–61.2) and 74.1% (95% CI, 53.7–88.9), respectively. Excluding four patients with EGFR, ALK, KRAS G12C, or MET ex14skipping mutations, the pCR rate was 47.8% (95% CI, 26.8–69.4) and MPR rate was 87.0% (95% CI, 66.4–97.2). Overall, pathologic downstaging was achieved in 70.4% (95% CI, 49.8–86.2). Objective response rate according to RECIST v1.1 was 50.0% (95% CI, 31.3–68.7). One patient delayed the schedule for surgical resection due to radiation pneumonitis (G2), unrelated to the drug administered. Otherwise, there were no peri-operative mortality or morbidity. All patients who underwent surgery, except one whose disease progressed immediately after resection, received at least one dose of adjuvant durvalumab; 61.5% completed 1-year treatment, 11.5% were continuing treatment, 11.5% discontinued due to AE, and 11.5% discontinued due to disease progression at the time of data cutoff. Grade 3 or more TRAE reported during adjuvant treatment were radiation pneumonitis and proteinuria, one each. **Conclusions:** This study confirms the manageable safety profile of adding durvalumab to neoadjuvant concurrent chemoradiation for treatment of resectable stage III NSCLC. Clinical trial information: NCT03694236. Research Sponsor: AstraZeneca.

Benefit of post-operative radiation therapy for incompletely resected stage I-IIIa non-small cell lung cancer: An analysis of the National Cancer Database. *First Author: Sindu Iska, Maroon Cancer Center, Cleveland Clinic Florida, Weston, FL*

Background: The presence of micro-residual (R1) or macro-residual (R2) disease in non-small cell lung cancer (NSCLC) is associated with a higher risk of recurrence. The benefits of post-operative radiation therapy (PORT) in incompletely resected NSCLC is not clear. The purpose of this study is to compare median overall survival (mOS) of treatment modalities in the post-operative setting for resected stage I-IIIa NSCLC with residual disease (R1/R2) and to determine if PORT provides benefit in this patient population using the National Cancer Database (NCDB). **Methods:** From the NCDB dataset for the years of 2006-2016, we extracted patients diagnosed with stage I-IIIa NSCLC and who had incomplete resection with residual disease (R1/R2). Kaplan-Meier analysis was performed to differentiate the effect of different post-operative treatment modalities, concurrent chemoradiotherapy (CCRT), sequential chemo-radiotherapy (SCRT) and chemotherapy (CT) alone on mOS. Subsequently, univariate Cox regression was used to identify statistically significant variables, then multivariate Cox regression was performed to establish variables that contributed to the survival. Lastly, multinomial logistic regression was utilized to establish association of the independent factors. SAS version 9.4 was used to analyze the data. **Results:** Among the 2701 patients who met inclusion criteria, the average age was 64.1, 64.8 and 65.9 year old for CCRT, SCRT and CT, respectively. Male's constituted 53.6% and white's were 88.1%, and patient's were distributed equally across clinical stages. The majority of patients received SCRT (51.7%) followed by CT alone (39%), and CCRT (9.2%). There were no statistically significant differences in mOS between the different treatment modalities ($p=0.220$). Patients with R2 were 177% more likely to receive CCRT than CT compared to R1 (OR 2.77, CI 1.86-4.13 and $p<0.001$). Male's were 28% more likely to receive SCRT than CT compared to females (OR 1.28, CI 1.08-1.52 and $p=0.0041$). Nodal involvement was associated with decreased mOS with N2/N3 having 37% lower mOS compared to N0 (HR=1.37, CI 1.19-1.57 and $p<0.0001$). Patients who had R2 disease had a 38% lower mOS compared to those R1 (HR 1.38%, CI 1.19-1.62, $p<0.0001$). **Conclusions:** Despite the risk of unfavorable outcomes for patients with residual disease after surgery for NSCLC, the addition of radiotherapy, either concurrently or sequentially, to CT did not offer statistically significant mOS benefit compared to CT alone. Given the known toxicities of radiation, and the lack of impact on survival, the benefit of post-operative radiation is questionable among patients with residual disease after resection. Large scale evaluation of pulmonary nodule workup: A real-world study of over 150,000 patients in New York State. *First Author: Vamsidhar Velcheti, NYU Langone-Laura and Isaac Perlmutter Cancer Center, New York, NY*

Background: Around 1.6 million patients in the US annually have a pulmonary nodule (PN) found on imaging. Previous studies suggest 1-12% of PNs represent an underlying malignancy at a potentially curative stage. PNs ≥ 6 mm are considered higher risk. Despite guideline availability, only about one-third of commercially insured patients with a PN receive recommended workup, which may include further investigation via imaging or surgery. In addition, patients and providers may delay workup of PNs identified during COVID-19. We aimed to describe variations in PN workup for different patient demographic and clinical characteristics at 7 healthcare institutions in New York (NY) state. **Methods:** We used a retrospective cross-sectional design in which structured demographic and unstructured clinical data were used to analyze patient documents from a NY state health information exchange from January 2018 to February 2022. Clinical features were abstracted using a clinical natural language processing platform, CLIX unlock. **Results:** 58 million documents from 5.5 million unique patients were analyzed. Of the overall 151,436 patients with PNs, workup was found in 47% (71,071). Across institutions, workup ranged between 24% and 52%; 40% (60,749) had evidence of a PN in the upper lung location. We found 52,789 patients (35%) had a maximum PN ≥ 6 mm and of those, 55% (28,958) had a workup (Table). For patients with a PN ≥ 6 mm, workup for non-English speaking patients was 9% lower than for English speaking patients (47% vs 56%), 17% lower for patients 18-44 years than patients 45-90 years (39% vs 56%), 47% lower for patients presenting with a chest injury rather than cancer screening (28% vs 75%), and 9% higher for patients with initial imaging via chest computed tomography (CT) rather than other CT (58% vs 49%). After the start of the COVID-19 pandemic (January 2020), overall workup decreased 3.8% and prevalence of symptoms such as dyspnea and chest pain increased. **Conclusions:** The descriptive findings of this analysis demonstrate gaps and variations in workup for patients with PNs across different demographics and clinical scenarios. A subsequent project is underway to explore strategies for improvement in adherence to guideline-recommended care to benefit patients by diagnosing lung cancer at an earlier, potentially curative stage. Research Sponsor: AstraZeneca LLC.

Incidence, outcomes, and risk factors of acute immune checkpoint inhibitor (ICI) pneumonitis post-chemoradiation with durvalumab for patients with locally advanced non-small cell lung cancer (LA-NSCLC): A population-based multicenter study. *First Author: Chloe Lim, University of Calgary, Calgary, AB, Canada*

Background: The PACIFIC trial has drastically changed the LA-NSCLC treatment paradigm and improved survival outcomes with consolidation durvalumab post-chemoradiotherapy. Despite these promising results, real-world practice has demonstrated that ICI pneumonitis can have significant clinical complications and terminate consolidation therapy prematurely. This study aimed to identify clinical predictors, outcomes, and healthcare utilization in ICI pneumonitis in LA-NSCLC patients who received consolidation durvalumab in real-world practice. **Methods:** Using the Alberta Immunotherapy Database, we retrospectively evaluated all NSCLC patients who received durvalumab in Alberta, Canada from January 2018 to December 2021. Pneumonitis cases were identified based on radiographic changes and oncologists' clinical assessments. We examined incidence and predictive values of severe pneumonitis ($\geq$ grade 3), with secondary outcomes of overall survival (OS) and time-to-treatment failure (TTF). Exploratory multivariate analyses were performed to identify predictive values to developing severe pneumonitis and worse OS/TTF. **Results:** Of 189 total patients, most were ECOG 0-1 (91%) and had partial response from chemoradiation (85%) prior to durvalumab. 49% received full year of therapy (n = 93). Median TTF was 11.2 months, and median OS of 19.7 months with 1-year OS 64% (n = 121). 26% (n = 49) developed any grade of pneumonitis. 9% (n = 17) had severe pneumonitis. Corticosteroids were administered to 86% of the pneumonitis patients (n = 42); 53% (n = 26) required admission. 13% (n = 9) of deaths were attributed to pneumonitis. Male gender and pre-existing autoimmune condition were associated with severe pneumonitis whereas V_{20} (percentage of irradiated lung volume ≥ 20 Gy) was associated with developing any grade pneumonitis. In multivariable analysis, male gender and V_{20} was significantly associated with worse OS whereas older age, smoking status, pneumonitis, and male gender with lower TTF. Pneumonitis development was found to be an independent risk factor for worse OS (p = 0.038) and TTF (p = 0.007). **Conclusions:** We report a pneumonitis incidence comparable to prior retrospective studies and higher rate of severe pneumonitis compared to PACIFIC trial. Our results corroborate that V_{20} , a previously established risk factor for durvalumab associated pneumonitis, is a significant predictor for developing pneumonitis and worse OS. In contrast to smaller retrospective studies, we observed male gender and pre-existing autoimmune conditions appear to predict severe durvalumab associated ICI pneumonitis. These results affirm the importance of careful patient selection for safe completion of consolidation durvalumab in real-world LA-NSCLC population. Research Sponsor: None.

Mortality benefit of a blood-based biomarker panel for lung cancer and the PLCO cohort. *First Author: Johannes Fahrman, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: A 4-protein biomarker panel (4MP) combined with the validated PLCO_{m2012} clinical risk model has been shown to improve lung cancer risk estimation over either metric alone. We investigated whether these panels in combination could also identify individuals at high risk of harboring a lethal lung cancer. **Methods:** We used data from an established logistic regression combining the 4MP and the PLCO_{m2012} risk model, which were assessed in pre-diagnostic sera from 552 lung cancer cases and 2,193 non-cases from the Prostate Lung Colorectal and Ovarian (PLCO) cohort. Of the 552 lung cancer cases, 387 (70%) died from lung cancer. Cumulative incidence of lung cancer death as well as sub-distributional and cause-specific hazard ratios were calculated based on 4MP+PLCO_{m2012} risk scores at a pre-defined 1.0% and 1.7% 6-year risk thresholds, which correspond to the 2013 and 2021 US Preventive Services Task Force lung cancer screening criteria, respectively. **Results:** When considering cases diagnosed within 1 year of blood draw and all non-cases, the AUC estimate of the 4MP+PLCO_{m2012} model for risk prediction of lung cancer death was 0.88 (95% CI: 0.86-0.90). Among cases, the cumulative incidence of lung cancer death was statistically significantly higher in individuals with 4MP+PLCO_{m2012} scores above the 1.0% 6-year risk threshold (modified χ^2 : 5.42, P: 0.02). Corresponding sub-distributional and lung cancer death-specific hazard ratios for test-positive cases were 1.69 (95% CI: 1.07-2.66) and 1.80 (95% CI: 1.15-2.82), respectively. **Conclusions:** The blood-based biomarker panel in combination with PLCO_{m2012} identifies individuals at high risk of a lethal lung cancer. Impact of SARS-COV2 infection on the clinical outcomes in patients with lung cancer compared to all other cancers. *First Author: Vaishali Deenadayalan, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL*

Background: The outbreak of 2019 Novel coronavirus disease (COVID) has led to various deleterious outcomes in cancer patients. Those with lung cancer were noted to have increased morbidity and mortality when infected with COVID. We aimed to study the outcomes of COVID infection in patients with lung cancer compared to those with all other types of cancer. **Methods:** Healthcare Cost and Utilization Project-Nationwide Inpatient Sample database-2020 was queried to identify all COVID patients with lung cancer and those with all other types of cancer excluding lung cancer. The groups were compared for socio-demographic differences, medical comorbidities, inpatient mortality, length of stay (LOS), and total hospital charges (THC). Secondary outcomes included a diagnosis of thrombocytopenia (TCP), Acute Respiratory Failure (ARF), sepsis, anemia, pancytopenia and shock. Statistics were performed using t-test, univariate and multinomial logistic regression. **Results:** A total 1,050,045 COVID-19 admissions in cancer patients were identified, of which 4,625 (8.7%) had lung cancer whereas 48,840 (91.3%) had other types of cancer other than lung cancer. Lung cancer patients were older (Mean age 72 vs 69 years, p < 0.01). There was a higher prevalence of lung cancer compared to other cancers in whites (71 vs 58%, p < 0.01), hispanics had a lesser prevalence of lung cancer (7 vs 17%, p < 0.01). Lung cancer patients has a higher Charlson Comorbidity burden (> 2) compared to other cancers (91 vs 62%, p < 0.01). Lung cancer patients were less likely to have private insurance (14 vs 22%, p < 0.01). Among the comorbidity burden, lung cancer patients had a higher rate of dyslipidemia, COPD, Coronary artery disease, Smoking, venous thromboembolism (p < 0.05). A total of 8,135 cancer patients who were admitted with COVID died, among them 970 (11.9%) had lung cancer and 7,165 (88.1%) had other types of cancer making up 21% of all lung cancer admissions that died compared to 14.7% other cancer admissions (p < 0.05). On multivariate regression analysis, after adjusting for confounders those with lung cancer had a higher odds of all-cause mortality (aOR 1.37; 95% CI: 1.13-1.67, p = 0.002). Among lung cancer patients, adjusted LOS was reduced by 0.6 days (95% CI: -1.2 to -0.1, p = 0.017) and adjusted THC was decreased by \$11,977 (95% CI: -19,010 to -4,943, p = 0.001). Among the secondary outcomes, lung cancer patients had lower rates of thrombocytopenia (6.5 vs 8.8%, p = 0.01) and anaemia (34.4 vs 38.5%, p = 0.02) compared to other cancer types. **Conclusions:** COVID-19 infection led to increased mortality in lung cancer patients compared to those with other types of cancer. The lower healthcare utilization was likely due to early mortality in the lung cancer cohort. This study calls attention to the increased vulnerability of lung cancer patients to the SARS COV2 infection than other cancer types. Research Sponsor: None.

Development and validation of a prediction model for the recurrence of stage 1 EGFR mutation positive NSCLC in patients using machine learning with WES-based gene sets. *First Author: Akiko Tateishi, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: Predicting the risk of postoperative recurrence is becoming increasingly important in EGFR mutation positive (EGFR-m) non-small cell lung cancer (NSCLC). Only a few reports conducted whole exome sequencing (WES) for genomic profiling in large scale EGFR-m NSCLC cases. **Methods:** We conducted WES and analyzed the clinical course of patients (pts) with NSCLC who underwent surgery between 1985 and 2019 in the PRISM project of our institute. We evaluated the EGFR-m patients' characteristics, recurrence-free survival (RFS), and developed a prediction model using machine learning, Overlapping Group LASSO to predict whether the EGFR-m patients will recur within 5 years or not as "high-risk" and "low-risk". To develop and validate the prediction model, we divided the data from 2006 as the training cohort data set and the data before 2006 as the validation cohort data set. After the development of the prediction model, we performed a stratified Cox proportional hazards model to compare the RFS between the predicted groups. **Results:** A total of 585/1351 (43.3%) pts were EGFR-m included in the PRISM project. Of all pts, stage I, EGFR-m were 205 pts. The median RFS of the stage I, EGFR-m 123.1 months (m). In the training cohort, the model detected 43 pts for high-risk and 88 pts for low-risk. In the validation cohort, the model predicted 29 pts for high-risk and 45 pts for low-risk. Median RFS of high-risk vs. low-risk were 52.2 m vs. 105 m (HR 2.43, $p=0.01$). The 1-year RFS rate, 2-year RFS rate, and 5-year RFS rates for high-risk and low-risk pts were 100% vs. 98.5%, 66.7% vs. 89.2%, and 41.7% vs. 66.1%, respectively. Twenty-eight gene set coefficients were non-zero in the prediction model. The gene sets with large positive coefficients that were considered important for prediction as "high risk" were the gene sets affected by KRAS gene overexpression and p53 gene knockdown. In contrast, gene sets repressed by mTOR inhibition and genes repressed by TBK1 gene knockdown and KRAS gene overexpression had large negative coefficients. **Conclusions:** We developed and validated the prediction model whether the EGFR-m patients will recur within 5 years or not. EGFR-m NSCLC recurrence appears to be high risk with pathways associated with KRAS and p53 genes, and low risk with mutations in the gene sets suppressed by the mTOR pathway and TBK1 gene. Research Sponsor: None.

Association of immune-related adverse events and efficacy outcomes in phase II trial of consolidation nivolumab plus ipilimumab or nivolumab alone after chemoradiation in patients with unresectable stage III non-small-cell lung cancer (NSCLC). *First Author: Cynthia Wei, Indiana University School of Medicine, Indianapolis, IN*

Background: Immunotherapy has been widely incorporated into the treatment of patients with non-small-cell lung cancer. Many of these patients will experience immune-related adverse events (irAEs) that may lead to early discontinuation of therapy. Previous studies have reported that patients with Stage III and metastatic NSCLC who experienced irAEs receive fewer cycles of immunotherapy without decreased efficacy. Here we report a retrospective analysis of the association between irAEs and efficacy outcomes from the BTRC LUN 16-081 randomized phase 2 trial of consolidation immunotherapy with nivolumab (N) plus ipilimumab (IPI) vs N alone following concurrent chemoradiotherapy in patients with unresectable Stage IIIA/IIIB NSCLC. **Methods:** A total of 105 eligible patients were enrolled from 9/2017 to 4/2021. Demographics, disease characteristics, and number of immunotherapy cycles received were reported in patients with and without irAEs in the two arms. Chi-square test was used for comparisons for categorical variables and Wilcoxon test for continuous variables. The Kaplan-Meier method was used to analyze progression-free survival (PFS) and overall survival (OS). A log-rank test was used to compare groups. **Results:** In treatment arm A (N alone), any grade irAEs occurred in 64.8% of patients. At a follow up of 48 months, there was no significant difference in number of N cycles started (6 vs 6, $p=0.238$), progression free survival (29.4 vs 31.9 mo, $p=0.897$), or overall survival (NE vs. 31.9 mo, $p=0.798$) in patients with and without irAEs. Patients who discontinued N because of irAEs ($n=8$ or 14.8% of patients) received significantly fewer cycles of N (2 vs 6, $p<.0001$) and had a shorter PFS (8.2 vs. 31.9 months, $p<.0001$) and OS (12.3 months vs. NE, $p<.0001$). In treatment arm B (IPI+N), any grade irAEs occurred in 84.3% of patients. At follow up of 48 months, there was no significant difference in number of IPI+N started (4 vs. 4, $p=0.260$) or overall survival (NE vs. NE, $p=0.576$), but there was a significantly longer PFS in those who experienced irAEs (30.9 months vs. 6.8 months, $p=0.0083$). Patients who discontinued IPI+N because of irAEs ($n=18$ or 35.3% of patients) received significantly fewer cycles of IPI+N (2 vs 4, $p<.0001$) without a significant difference in PFS (28.1 vs. 25.3 mo, $p=0.830$) or OS (NE vs NE, $p=0.755$). **Conclusions:** The occurrence of irAEs alone in both arms, regardless of number, was not associated with decreased efficacy outcomes in this exploratory analysis. However, if irAEs resulted in the discontinuation of therapy, these patients did have a shorter PFS and OS in the N alone arm. This difference was not observed in the IPI+N arm and those who experienced any irAEs in the IPI+N arm had an improved PFS. Research Sponsor: Bristol Myers Squibb.

Phase II trial of safety and efficacy of tislelizumab plus chemotherapy in stage II-IV non small cell lung cancer (LungMark). *First Author: Yaobin Lin, Department of Thoracic Surgery, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: The current study aimed to investigate the safety and efficacy of chemotherapy with PD-1 inhibitor, tislelizumab, for stage II-IV NSCLC. Meanwhile to explore the potential biomarkers for safety and efficacy of tislelizumab plus chemotherapy in NSCLC. **Methods:** This was an open-label, multicenter, phase 2 trial conducted at 3 hospitals in China. Patients with treatment-naïve, stage II-IV NSCLC without EGFR/ALK driver mutations were enrolled. This study consisted of two cohorts, one cohort is potentially resectable disease (PRD) and the other is unresectable disease (URD). The PRD patients received 3-4 cycles of tislelizumab (200 mg Q3w) plus carboplatin-based chemotherapy. Candidates eligible for surgery underwent surgery, followed by adjuvant tislelizumab monotherapy for 1 year. The URD patients received platinum-based doublet chemotherapy plus tislelizumab for 4-6 cycles, followed by tislelizumab for squamous and tislelizumab in combination with pemetrexed for non-squamous, until disease progression or intolerable toxicity. Primary endpoint was safety. Secondary endpoints were efficacy, such as MPR/pCR (PRD cohort), ORR, PFS and OS, etc. Multi-omics analysis of baseline and post-treatment samples were conducted to explore the safety and efficacy for chemoimmunotherapy. (NCT05244837). **Results:** Between December 2020 and November 2022, a total of 100 eligible patients were enrolled and received at least one cycle of immunotherapy. 58 patients were with PRD, of whom 40 (68.9%) were squamous cell lung cancer. 50 (86.2%) patients were stage III disease. During neoadjuvant treatment period, 52 patients (91.2%) experienced neoadjuvant TRAEs. Most of the TRAEs were grade 1 or 2. No grade 4 or 5 TRAEs was observed. The most common grade 1 or 2 TRAEs were alopecia ($n=29$; 50.9%), anemia ($n=25$; 43.9%), rash ($n=29$; 50.9%). Four patients (7.0%) experienced severe TRAE of grade 3 increased ALT/AST. 39 patients received surgical resection, R0 resection was performed for 38 (97.4%) patients. 29 (74.4%) achieved MPR (major pathological response), including 19 (48.7%) with a complete pathological response (pCR). 42 patients with URD were enrolled, 26 (61.9%) patients were stage IV disease. 37 patients (88.1%) experienced TRAEs. The most common grade 1 or 2 TRAEs were anemia ($n=27$; 64.3%), rash ($n=12$; 57.0%). Severe TRAEs occurred in 8 (2.0%) cases, including increased ALT/AST, decreased white blood cell count etc. 29 genes were identified as differentially expressed in pre-treatment tumors from patients with pCR compared to non-pCR. **Conclusions:** Neoadjuvant tislelizumab plus chemotherapy was safe and effective with high MPR and manageable TRAEs in patients with PRD. For patients with URD, tislelizumab plus chemotherapy was generally well tolerated. We have identified a differential immune landscape between pCR and non-pCR tumors. Clinical trial information: NCT05244837. Research Sponsor: None.

EGFR tyrosine kinase inhibitors (TKIs) versus durvalumab (durva) following concurrent chemoradiation (CRT) in unresectable EGFR-mutant non-small-cell lung cancer (NSCLC). *First Author: Amin Nassar, Yale Cancer Center, New Haven, CT*

Background: Adjuvant osimertinib (osi) improves disease-free survival (DFS) in patients (pts) with resected, early-stage, EGFR-mutant (EGFRmut) NSCLC, yet the benefit of osi after CRT in pts with unresectable locally advanced NSCLC is unknown. Post-hoc analysis of the PACIFIC trial showed a lack of survival benefit with consolidation durva versus placebo in pts with EGFRmut NSCLC. Comparisons between consolidation durva and EGFR TKIs in unresectable EGFRmut NSCLC following CRT are lacking. **Methods:** We conducted a multi-institutional retrospective analysis of pts with stage III unresectable EGFRmut NSCLC (exon19 deletion, exon21 L858R), who received EGFR TKI or durva after ≥ 2 cycles of platinum-based chemotherapy plus definitive radiation therapy between 2015-2022. Baseline characteristics including age, sex, smoking history, PD-L1 status, and outcomes on DFS, overall survival (OS), and safety were collected. Multivariable (MVA) cox regression analysis was used for statistical analysis. Treatment-related adverse events (trAE) were defined using CTCAE 5.0. **Results:** Seventeen pts from 12 institutions received an EGFR TKI (osi, $n=15$; erlotinib, $n=2$), and 13 pts received consolidation durva. Median follow-up was 23 months. Median age of all pts was 61 years (IQR:52-72) and 76.7% were female. Most pts in both groups had never-smoked and had adenocarcinoma. All pts received ≥ 60 Gy of radiation with concurrent chemotherapy. PD-L1 expression was $\geq 50\%$ in 1/10 (10%) pts treated with durva vs 6/13 (46.2%) treated with TKI, $p=0.09$. Median duration on treatment for EGFR TKI and durva was 12.2 months and 4.8 months, respectively. Pts treated with EGFR TKI had significantly longer 24-month DFS versus pts treated with durva after adjusting for stage (3A vs 3B vs 3C) (Table). Any grade trAE occurred in 58.8% (10/17) of pts treated with EGFR TKI vs 38.5% (5/13) with durva. Grade > 3 trAE occurred in 15.4% (1 pneumonitis and 1 AST/ALT elevation) of pts treated with durva but in none of pts treated with EGFR TKI. Three pts within each arm came off treatment due to toxicity (EGFR TKI: 1 pneumonitis and 2 dermatitis; durva: 1 of each pneumonitis, Type 1 diabetes, AST/ALT elevation). **Conclusions:** EGFR TKI therapy after definitive CRT was associated with significantly longer DFS compared to durva in this retrospective study of pts with stage III unresectable EGFRmut NSCLC, without unanticipated safety signals. Follow-up is ongoing and OS outcomes will be evaluated subsequently. Further investigation is warranted to define the optimal therapy for locally advanced EGFRmut NSCLC. Research Sponsor: None.

A combinatorial model of plasma proteins and LDCT imaging and the diagnosis of pulmonary nodules. *First Author: Meng Yang, Department of Pulmonary and Critical Care Medicine, Center of Respiratory Medicine, China-Japan Friendship Hospital, Beijing, China*

Background: Low dosage computer tomography (LDCT) has been widely adopted as a sensitive method to detect early-stage lung cancer; however, debate regarding its accuracy and overdiagnosis is still ongoing. An accurate non-invasive test is needed to identify malignant nodules and reduce unnecessary invasive procedures. Studies show that plasma proteins and LDCT imaging features may be used to discriminate malignant pulmonary nodules from benign ones. We aimed to develop a combinatorial approach integrating serum protein markers and imaging features to improve the classification of pulmonary nodules. **Methods:** This study established a prospective research cohort, which enrolled 608 patients of pulmonary nodules. Plasma samples were collected to measure protein levels using Proximity Extension Assay (PEA) technology. The imaging features of the pulmonary nodules were extracted using the python 'radiomics' package. Following feature extraction, a deep learning networks model was built using training cases. The model was then tested in the testing set to evaluate its accuracy and robustness. **Results:** From the study cohort, 184 benign (BN) and 184 malignant (MT) samples matched for sex and age were chosen to have a representative training set. The rest 240 samples (81 BN and 159 MT) were used as a testing set. Image features were extracted from 448 patients (119 BN and 153 MT in training; 57 BN and 119 MT in testing) with raw LDCT image available. In the testing set, the model trained using only protein levels had an AUC of 0.83 [0.782-0.877] (sensitivity = 71.1% [95% CI 63.6-77.6]; specificity = 82.7% [73.1-89.4]) when classifying plasma samples of lung cancers from those of benign nodules. In comparison, the imaging features-only model had an AUC of 0.874 [0.821-0.916] (sensitivity = 81.5 [73.6-87.5]; specificity = 73.7 [61.0-83.4]). The combinatorial model integrating both protein and imaging features had an AUC of 0.878 [0.830-0.921] (sensitivity = 83.2% [75.5-88.8]; specificity = 77.2% [64.8-86.2]). Notably, the combinatorial model was highly sensitive for early-stage lung cancer, achieving a sensitivity of 93.1% [78.0-98.1] when classifying stage-0 lung cancer cases (n = 29) and 94.8% [85.9-98.2] for stage-I cases (N = 58). Its sensitivity for stage II-IV (n = 7) and clinically diagnosed lung cancers cases (n = 25) were 100% [64.6-100] and 40.0% [23.4-59.3], respectively. **Conclusions:** This study aimed to construct a model to distinguish malignant pulmonary nodules from benign lung diseases using protein levels and LDCT imaging features. The resulted combinatorial model showed by utilizing both types of features, it was able to accurately differentiate benign and malignant pulmonary nodules, suggesting it may provide guidance for the clinical management of these nodules. Optimal number of lymph node stations associated with improved survival among patients with non-small cell lung cancer (NSCLC). *First Author: Meredith Ray, University of Memphis, School of Public Health, Memphis, TN*

Background: Good quality pathologic nodal evaluation is associated with improved long-term survival in NSCLC after surgical resection. However, there is no universal definition of quality. We examined the association between number of lymph node stations (NLNS) sampled and overall survival. **Methods:** We examined the population-based Mid-South Quality of Surgical Resection (MS-QSR) cohort, excluding patients with neoadjuvant therapy, positive margins, and secondary resections. We summarized demographic and clinical characteristics with appropriate statistics. We employed four Cox regression models: 1) including NLNS as the only predictor; 2) model 1, adjusting for age, sex, histology, clinical stage, extent of resection, and surgical technique; 3) examined the impact of pathologic staging (pStage in 3 groups: IA/IB [<4 cm tumor size]; IB[>4 cm]/II/IIIA[pN2-]; pN2]) by modeling interaction with pStage and NLNS; 4) model 3 plus adjustments (no clinical stage). In a cut point analysis to identify the optimal NLNS for improved survival, we dichotomized the NLNS for cut points 0 to 12. Hazard ratios (HR) were calculated (as above) and plotted for each dichotomization. **Results:** The 3916 eligible patients were 21% Black, 54% male, 15% on Medicaid and 49% Medicare; 84% and 85% had clinical and pathologic stage I/II, respectively; 84% had no invasive staging; 84% had a PET-CT scan. For every additional lymph node station sampled, the HR decreased by 0.94 (95% confidence interval: 0.92, 0.96). After adjustments, the HR remained significant (Table). Our pStage cohorts comprised of 2474 (64%) IA/IB[<4 cm]; 1080 (28%) IB[>4 cm]/II/IIIA[pN2-]; and 290 (8%) pN2+. Once stratified, HRs remained significant among those with early stage but not for pN2+ (Table). When further adjusted, only pStage IA/IB[<4 cm] patients had a significant HR, 0.94 (0.91, 0.97). The cut point analysis indicated sequential survival improvement up to ≥ 7 total stations sampled, consistently across all models/adjustments. **Conclusions:** The number of lymph node stations examined is directly associated with survival after lung cancer resection. Examination of a total of 7 intrapulmonary, hilar and mediastinal stations seems optimal. Hazard ratios (95% confidence intervals) for modeling hazards as a function of lymph node stations sampled (model 1), further adjusted for age, sex, histology, clinical stage, extent of resection, and surgical technique (model 2), including interaction with pathologic stage with no adjustments (model 3), and interaction with pathologic stage with adjustments (no clinical stage) (model 4). Research Sponsor: U.S. National Institutes of Health.

Cancer risk assessment in patients with persistent pulmonary nodules and its correlation with cancer-free survival. *First Author: Hui Li, Department of Thoracic/Head and Neck Medical Oncology, Department of Imaging Physics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: With the wide use of CT for lung cancer screening and diagnosis, detection of pulmonary nodules increases drastically. Brock malignancy risk scoring is a validated risk prediction model for distinguishing malignant nodules, but it only provides a snapshot without incorporating the dynamic changes of lung nodules. Our study tested the performance of Brock malignancy risk scoring system in patients with persistent lung nodules. **Methods:** We prospectively studied a cohort of 304 patients with persistent lung nodules (at least 2 CT scans, 3 months apart with no evidence of shrinkage) who were under management at MD Anderson Cancer Center from 11/28/2018 to 12/14/2022. These lung nodules were assessed by radiologists with Brock full model. These patients were followed up routinely and subjected to biopsy as determined by treating physicians. The area under the receiver operating characteristic curve (AUC) and the optimal cut-off of Brock model was studied. Additionally, we studied another cohort with 130 patients with histologically confirmed lung cancer. We retrospectively reviewed the CT or PET/CT scans and assessed the corresponding persistent lung nodules as defined above prior to the cancer diagnosis. We explored the correlations among nodule characteristics, demographic factors and Brock cancer risk scores. Cox proportional hazards model was built for multivariate analysis. **Results:** The median follow-up time for the prospective cohort was 337 days and 40 of the 304 patients (13.16%) were diagnosed with lung cancer with a median lung cancer-free survival of 228 days. The mean risk score was 24.20% (0.12%-62.86%) for histologically confirmed malignant vs 11.01% (0.07%-61.84%) for the remaining lung nodules (P < 0.001). Of note, 4 of 46 (8.70%) patients with persistent lung nodules of risk scores between 5%-10% and 8 of 134 (5.97%) patients with risk score < 5% were diagnosed with lung cancer. The AUC for Brock model was 0.72 and the optimal cut-off value is 10.64% (sensitivity: 0.702, specificity: 0.677). Among the retrospective cohort of 130 lung cancer patients (82.3% adenocarcinoma, 13.1% squamous cell carcinoma and 4.6% others), the predicted risk score ranged from 0.09% to 85.82%, including 33.85% of patients with risk score < 10% and 26.15% of patients with predicted risk score < 5%. The risk score was not correlated with age, sex, race, ethnicity, smoking history, family history of lung cancer, emphysema, nodule types or locations. The low-risk patients had a longer median cancer-free time (P = 0.001). **Conclusions:** Persistency is an important risk factor for malignant lung nodules. Using Brock criteria, a substantial proportion of lung nodules with true malignant potential can be overlooked because of predicted "low risk". Improved prediction models incorporating the dynamic changes of lung nodules are warranted to guide early diagnosis of lung cancer. Reevaluating the role of adjuvant chemotherapy in early-stage, resectable NSCLC with high-risk clinical and pathologic features. *First Author: Brendan Heiden, Washington University School of Medicine, St. Louis, MO*

Background: The preferred treatment for early-stage non-small cell lung cancer remains surgical resection with the consideration of adjuvant chemotherapy for tumors with certain high-risk features. It is commonly cited that such treatments confer a meager 5% 5-year survival benefit compared to observation alone. We sought to reassess the benefit of adjuvant chemotherapy using modern, real-world datasets. **Methods:** We performed a retrospective cohort study using a dataset from the National Cancer Database. All patients with early-stage stage NSCLC (3-5cm, node-negative) who would be eligible for adjuvant chemotherapy based on National Comprehensive Cancer Network guidelines were included (i.e., presence of at least 1 high-risk feature). High-risk clinical and pathologic features were defined as poor differentiation, tumor size (≥ 4 cm), non-anatomic wedge resection, inadequate lymph node evaluation, vascular invasion, and visceral pleural involvement. We employed average treatment effect on the treated (ATT) weighting to match patients with similar demographic, tumor, and treatment-related variables to compare outcomes between chemotherapy versus observation groups. The primary outcome was overall survival. These findings were further validated in an independent cohort from the US Veteran Health Administration (VHA). **Results:** The study included 10,812 patients with early-stage NSCLC who had at least 1 high-risk feature. The frequencies of high-risk features were as follows: tumor size ≥ 4 cm (n = 3,271, 30.3%), poor differentiation (n = 9,454, 87.4%), visceral-pleural invasion (n = 2,542, 23.5%), vascular invasion (n = 1,742, 16.11%), non-anatomic wedge resection (n = 781, 7.2%), and inadequate nodal sampling (n = 6,306, 58.3%). Despite the presence of high-risk features, only 1,427 (13.2%) patients received adjuvant chemotherapy. In the ATT weighted analysis, 1,261 (49.7%) patients received adjuvant chemotherapy and 1,278 (50.3%) patients received observation. The 5-year overall survival was 70.0% (95% CI 67.1-72.7) in the chemotherapy group versus 62.0% (95% CI 60.2-63.7%) in the observation group (absolute 5-year survival difference 8.0%). In the VHA cohort, 11.3% of patients received adjuvant chemotherapy. Similarly, the 5-year overall survival was 64.0% (95% CI 51.4-74.2) in the chemotherapy group versus 56.2% (95% CI 48.3-63.4) in the observation group (absolute 5-year survival difference 7.8%). **Conclusions:** These data suggest a notably larger benefit of adjuvant chemotherapy in eligible patients with high-risk clinical pathologic features compared to commonly cited statistics. With the addition of more robust treatment options in early-stage disease, adherence to adjuvant and neoadjuvant treatment guidelines may disproportionately improve early-stage NSCLC outcomes following curative-intent resection. Acute hospitalizations after proton beam therapy (PBT) versus intensity-modulated radiotherapy (IMRT) for locally advanced non-small-cell lung cancer (LA-NSCLC) in the era of immune checkpoint inhibitor (ICI) consolidation: A retrospective propensity score weighted study. *First Author: Michelle Iocolano, University of Pennsylvania, Philadelphia, PA*

Background: Prior work found that PBT is associated with fewer acute hospitalizations compared to photons for a variety of cancers. Patients (pts) with LA-NSCLC treated with concurrent chemoradiation (cCRT) and ICI consolidation are at high risk for treatment-related toxicity and acute hospitalizations. We hypothesized that PBT is associated with fewer acute unplanned hospitalizations as compared to IMRT in the era of ICI consolidation. **Methods:** This single institution, multi-site retrospective study included consecutive pts with LA-NSCLC treated with definitive cCRT with either PBT or IMRT from October 2017 to December 2021. Pts were evaluated for consolidative ICI. Primary endpoint was unplanned hospitalization within 90 days of first radiation (RT) treatment. Secondary endpoints included grade 3+ pneumonitis, grade 3+ esophagitis, PFS, and OS. Logistic regression was used to assess associations with 90-day hospitalization. Competing risk regression was used for grade 3+ pneumonitis and esophagitis and Cox regression for PFS and OS. Inverse probability treatment weighting (IPTW) was applied to adjust for differences in PBT and IMRT groups. **Results:** 316 pts were included: 117 (37%) received PBT and 199 (63%) IMRT. Median age was 68.5 yrs; median RT dose 66.6 Gy (IQR 65.9-70.0). PBT group was older (median 71.1 vs 67.2 yrs, $p < 0.005$) and had a higher Charlson comorbidity index (CCI) (median 4 vs 3, $p = 0.02$). There was no difference in receipt of ICI consolidation (66.7% vs 68.3%, $p = 0.76$). PBT group had lower mean heart dose (5.9 vs 10.8 Gy, $p < 0.001$), LAD V15 (0 vs 6%, $p = 0.001$), mean lung dose (14.7 vs 15.7 Gy, $p < 0.008$) and effective dose to immune circulating cells (median 3.7 vs 4.9 Gy, $p < 0.001$) but not mean esophagus dose. PBT was associated with fewer unplanned 90-day hospitalizations (23.9% vs 34.7%; aOR 0.52, 95% CI 0.30-0.90, $p = 0.02$). This difference persisted on IPTW analysis (OR 0.48, 95% CI 0.33-0.70, $p = 0.0002$) after adjusting for CCI, ECOG, smoking pack yrs, T stage, N stage, target volume, concurrent chemotherapy agent and histology. Reasons for hospitalization in PBT and IMRT groups included progression (1.4% vs 1.6%), definite/probable toxicity from cCRT (11.4% vs 18.2%), possible toxicity from cCRT (7.3% vs 12.8%) or unrelated to cCRT (2.5% vs 2.3%). There was no significant difference between PBT and IMRT groups in G3+ pneumonitis (1-year 6.0% vs 9.1%, $p = 0.49$), G3+ esophagitis (1-year 6.0% vs 6.5%, $p = 0.71$), PFS (median 14.4 vs 15.1 months, $p = 0.69$), or OS (median 34.2 vs 29.4 months, $p = 0.41$); results remained unchanged in IPTW analysis. **Conclusions:** Among pts with LA-NSCLC treated with cCRT in the era of ICI consolidation, PBT was associated with fewer acute unplanned hospitalizations compared to IMRT. A theranostic approach: Imaging and therapy of delta-like ligand 3-expressing small cell lung cancers. *First Author: Salomon Tendler, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Small cell lung cancer (SCLC) is a highly radiosensitive tumor, with selective cell surface expression of the inhibitory Notch ligand Delta-like ligand 3 (DLL3). This facilitates targeted radionuclide therapy accompanied by complementary imaging agents to evaluate and monitor disease progression. The project aims to identify the next generation of DLL3-targeting radioimmunoconjugates to improve the clinical outcome for SCLC patients. **Methods:** In collaboration with the Tri-Institutional Therapeutics Discovery Institute, we screened and assessed >100 humanized antibodies for their binding affinities, internalization rates, and other pharmacodynamic properties. Here, we present data on two leading candidates (mAb1 and mAb2) holding highest promise in both imaging and therapy studies conducted in DLL3-expressing SCLC tumors. For in vivo imaging, antibodies were radiolabeled with Zirconium-89 (^{89}Zr), which allows for immuno-positron emission tomography (immunoPET). Therapeutic studies were performed with the same antibodies conjugated with Lutetium-177 (^{177}Lu). Human SCLC NCI-H82 xenografts were implanted in nude athymic female mice. ImmunoPET scans were acquired during multiple time points post-injection of the imaging agent, and terminal biodistribution analysis was performed. Treatment studies included administration of 400 and 600 Ci ^{177}Lu -conjugated antibodies in cohorts of mice, with appropriate positive and negative controls. **Results:** Both lead antibodies demonstrated efficient radioconjugation with either isotope. ImmunoPET imaging utilizing ^{89}Zr showed specific high-level tumor uptake for both clones with low background in non-tumor organs. *Ex vivo* gamma counting biodistribution analysis, performed 120 hours post-injection, confirmed these findings. Dosimetry estimates suggested a similar therapeutic index between the two clones, with the bone marrow being the dose-limiting organ. Preliminary results from therapy studies demonstrate a statistically significant ($p < 0.05$) prolonged overall survival for the experimental arms compared to controls, and include durable tumor responses. As expected for radionuclide therapy, transient hematologic suppression was observed within 7-10 days after the beginning of the treatment, with normalization of blood cell counts for all groups within three weeks. **Conclusions:** This study highlights the promise held by novel DLL3-direct radioimmunoconjugates as a diagnostic tracer, prognostic biomarker, and therapeutic agent. Both lead candidates appear promising for translation as both imaging and therapeutic agents for patients with SCLC. Research Sponsor: NIH grants; Druckenmiller Lung Cancer Foundation.

Association of single-click radiomic classifier with response and prognosis in non-small cell lung cancers (NSCLC) treated with immune checkpoint inhibitors. *First Author: Amogh Hiremath, Picture Health, Cleveland, OH*

Background: Radiomics has shown promise to non-invasively phenotype disease and address the limitations of extant biomarkers (e.g. PD for immune checkpoint inhibitors (ICI) in cancers, such as NSCLC. However, considerable barriers to the clinical adoption of these tools remain, such as their dependence on precise annotation of tumor extent by experienced clinical users. Here, we demonstrate a radiomic solution that requires only a single user mouse click within one or more target lesions on a baseline CT scan, to contour tumors in 3D and generate a patient-level radiomic prediction of response and outcome in ICI treated NSCLC patients. **Methods:** 1778 CT scans from 1261 patients were used to develop and validate an interactive, semi-automated tool for predicting ICI outcomes in NSCLC patients prior to therapy. A user click based deep learning contouring model was trained and validated on 1146 patients, then used to create annotations for radiomic analysis. A least absolute shrinkage and selection operator (LASSO) Cox proportional hazards model was utilized to select features associated with post-ICI overall survival (OS) and derive a radiomic risk score within a training cohort ($n=74$) that can separate patients into high and low risk groups. The model was tested on held out pre-treatment CTs of 41 ICI recipients from 2 institutions for association with OS, progression-free survival (PFS), and objective response (OR). **Results:** A total of 77 lesions were identified and segmented within the testing set. Average volume per lesion was 54.10 mL and per patient was 101.60 mL. OR was observed in 48.70% of patients. A threshold of -0.31 defining high and low radiomic risk groups was chosen based on optimal separation within the training set (HR=2.59 [95% 1.48-4.50], $p=0.0009$). Radiomic risk groups significantly stratified patients by OS (C-index=0.64, HR=3.03 [95% 1.15-8.02], $p=0.03$) and PFS (C-index=0.59, HR=3.20 [95% 1.13-9.10], $p=0.03$). Radiomic IO risk group was independently prognostic of clinical variables (Table 1) and further predicted ICI response with AUC=0.74 [95% 0.71-0.78]. **Conclusions:** From a single click in target lesions, our model was able to predict response and prognosis of ICI recipients from a baseline radiology scan. Additional multi-site validation and prospective evaluation will assess the value of the radiomics classifier as a decision support tool in the clinic. Research Sponsor: Industrial funding.

Variables	HR [95% CI]	p

Reconsidering the cutoff between sensitive and refractory relapses in extensive-stage small cell lung cancer in the era of immunotherapy. *First Author: Masahiro Torasawa, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: The use of platinum-based doublet chemotherapy combined with immune checkpoint inhibitors (ICIs) has demonstrated promising outcomes in the first-line treatment of extensive-stage small cell lung cancer (ES-SCLC). Relapsed SCLC has been classified into "sensitive" or "refractory" relapse types according to cutoff values (60 or 90 days) of duration from the last chemotherapy administration to disease progression. However, it is unclear whether these cutoff values can be applied to ICI combination therapy. **Methods:** We retrospectively analyzed a multicenter database of ES-SCLC patients who received second-line therapy after the platinum-etoposide plus ICI (atezolizumab or durvalumab). An optimal cutoff value for the platinum-free interval (PFI) was selected, which minimized the two-sided p-value and maximized hazard ratio (HR) regarding relapse type (sensitive or refractory according to a cutoff value) calculated from a multivariable Cox regression model for overall survival (OS) including performance status (PS) and sex as covariates. The internal validity of the selected cutoff value was assessed via two-fold cross-validation (CV) manner. **Results:** A total of 101 patients (61 deaths) from 10 hospitals were included in the study. The median follow-up period was 21.1 months. The optimal cutoff value was 75 days ($p=0.0002$), and when applying this cutoff value, median OS was 15.9 and 5.0 months of sensitive- ($n=51$) and refractory- ($n=50$) relapsed patients, and the HR calculated from a two-fold CV was 3.13 (95% confidence interval [CI], 1.66 to 5.90). Additionally, traditional cutoff values of 60 and 90 days also predicted prognosis better, but cutoff values of 110 days or longer did not (Table). **Conclusions:** Even in the era of combined immunotherapy in ES-SCLC patients, the threshold days for classifying as sensitive- or refractory- relapse did not exhibit a significant change compared to the pre-immunotherapy era. Although further validation studies with a larger sample size would be needed, relapse type classification using the selected cutoff value of 75 days is worth considering as a new prognostic factor for relapsed ES-SCLC patients. Research Sponsor: None.

Analysis of tumor- and circulating-free DNA methylation to identify clinically relevant small cell lung cancer subtypes. *First Author: Simon Heeke, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Small-cell lung cancer (SCLC) is an aggressive malignancy composed of distinct transcriptional subtypes, defined by the predominant expression of one of the three transcription factors ASCL1 (SCLC-A), NEUROD1 (SCLC-N) and POU2F3 (SCLC-P) as well as an inflamed subtype (SCLC-I; see Gay et al. Cancer Cell. 2021), each with potential therapeutic vulnerabilities. Implementing subtyping in the clinic has remained challenging due to limited tissue availability, particularly for longitudinal monitoring. Given the known epigenetic regulation of critical SCLC transcriptional programs, we hypothesized that there would be subtype-specific patterns of DNA methylation that could be detected in tumor or blood from SCLC patients. **Methods:** We included 179 patients with SCLC and performed RNA sequencing and genomic-wide reduced-representation bisulfite sequencing (RRBS). We further analyzed DNA methylation in 68 plasma samples including longitudinal samples to track SCLC subtype evolution over time. **Results:** Using machine learning approaches, we developed a highly accurate DNA methylation-based classifier (SCLC-DMC) that could distinguish SCLC subtypes using clinical tumor samples with 95.8% accuracy in the testing set compared to mRNA-based profiling. We further adjusted the classifier for circulating-free DNA (cfDNA) to subtype SCLC from plasma. Using the cfDNA classifier (cfDMC), we could demonstrate that SCLC subtypes evolve frequently during disease progression, highlighting the need for longitudinal tracking of SCLC during clinical treatment. Furthermore, methylation-based subtyping predicted response to a wide variety of drugs in preclinical models like CDK and AURK inhibitors, and clinical outcomes were indistinguishable in cohorts of patients subtyped using mRNA or SCLC-DMC ($p = 0.95$). **Conclusions:** These data establish that tumor and cfDNA methylation can be used to identify SCLC subtypes and guide precision SCLC therapy. Research Sponsor: U.S. National Institutes of Health.

Phase I/II combination study of tificemalimab with toripalimab in patients with refractory extensive stage small cell lung cancer (ES-SCLC). *First Author: Ying Cheng, Department of Medical Thoracic Oncology, Jilin Cancer Hospital, Changchun, China*

Background: The B- and T-lymphocyte attenuator (BTLA) is a novel inhibitory co-signaling receptor expressed on B cell, T cells and NK cells. Co-blockade of the BTLA and PD-1 pathways improved antigen specific anti-tumor T cell response. Tificemalimab (JS004 or TAB004) is a humanized IgG4 monoclonal antibody with a hinge mutation (S228P) that binds BTLA and blocks its interaction with its ligand HVEM. In previous phase I studies, tificemalimab has shown preliminary anti-tumor activities as monotherapy or in combination with toripalimab (anti-PD-1) with a manageable safety profile in patients with advanced malignancies. **Methods:** Eligible ES-SCLC patients refractory to prior therapies were enrolled in this I/II study (NCT05000684). Patients received 200mg tificemalimab and 240mg toripalimab intravenously once every three weeks until disease progression, intolerable toxicity or 2 years of treatment. Study objectives included safety, anti-tumor activity and correlative biomarkers. **Results:** As of Jan 31, 2023, a total of 43 ES-SCLC patients refractory to prior therapy were enrolled. The median age was 60.0 (range 38-75) years. The median prior line of therapy was 1 and 14 (32.6%) patients received prior anti-PD-1/L1 treatment. By the cut-off date, the median follow-up duration was 12.1 weeks. Thirty-two (74.4%) patients experienced treatment-emergent adverse events (TEAEs); 12 (27.9%) patients experienced grade ≥ 3 TEAEs. The most common TEAEs were hyponatremia (16.3%), alanine aminotransferase increased (14%), aspartate aminotransferase increased (14%), and blood creatine phosphokinase increased (14%). Three (7.0%) patients experienced treatment-related adverse events (TRAEs) led to interruption of study drugs and no TRAEs led to discontinuation of study drugs were reported. Fifteen (34.9%) patients experienced immune related AE (irAEs), and 2 (4.7%) patients experienced grade ≥ 3 irAEs. Among 38 efficacy evaluable patients, the ORR was 26.3% and the DCR was 57.9%. The ORR was 8.3% in immunotherapy treated patients and 40.0% in immunotherapy naïve patients. By the cut-off date, 70.0% of the responses were ongoing and the median duration of response was not reached. Tumor expression of HVEM and PD-L1 was evaluated to explore the correlation with clinical response. **Conclusions:** Tificemalimab in combination with toripalimab were well tolerated in patients with refractory ES-SCLC. Further clinical evaluation of this combination treatment in SCLC is warranted. Clinical trial information: NCT05000684. Research Sponsor: Shanghai Junshi Biosciences.

Pathological images machine learning and prediction of long-term efficacy for immunotherapy in small cell lung cancer. *First Author: Yuki Sato, Kobe City Medical Center General Hospital, Kobe, Japan*

Background: In development of effective treatment such as immune checkpoint inhibitors (ICIs) among patients with small-cell lung cancer (SCLC), the absence of biomarkers is critical. Tumor-infiltrating lymphocytes are the main activator of anti-tumor immunity and could be a promising biomarker if TIL can be objectively assessed throughout the whole tumor immune microenvironment (TIME). To evaluate TIME, pathological assessment is one of the easiest ways. Recently, several studies showed that machine learning analysis can assess type of lymphocytes and their localization in pathological images. Here, we aimed to develop a novel biomarker to predict efficacy of ICI in SCLC using machine learning of pathological images. **Methods:** This study was a biomarker analysis of the APOLLO study which was 32-centered, prospective cohort study of patients with extensive-stage SCLC who received chemo-immunotherapy as the first-line treatment between September 2019 and September 2020. The patient who can provide sufficient tumor tissue sample from the primary tumor were enrolled. We trained a classifier which predicts 365-day progression-free survival (PFS) by all three types of pathological images (hematoxylin and eosin, programmed death-ligand 1, and CD8_FoxP3) and patient information, and developed the patient information model, pathological image model, and combination model. We used the area under the curves (AUC) to evaluate the machine learning models. **Results:** Of 78 patients, the median age was 78 (interquartile range, 48-87), 65 patients (83%) were male, 67 patients (86%) had a performance status of 0 or 1, and three patients (3.8%) treated with steroid therapy. Among all patients, the median PFS and the 365-day PFS rates were 145 days and 10.3%. The mean AUC of these models was 0.789 (range, 0.571-0.982) in the patient information model, 0.782 (range, 0.750-0.911) in the pathological image model, and 0.868 (range, 0.786-0.929) in the combination model, respectively. According to the median precision model, the median PFS was longer for the high efficacy group than the low efficacy group (the patient information model; hazard ratio (HR) 0.468, 95% confidence intervals (CI) 0.287-0.762. the pathological image model; HR 0.334, 95%CI 0.117-0.628. the combination model; HR 0.353, 95%CI 0.195-0.637). **Conclusions:** Using machine learning by pathological images, we could predict the efficacy of immunotherapy in SCLC. This study demonstrated the potential of machine learning to help the biomarker development in SCLC by assessing TIME. Clinical trial information: UMIN000038064. Updated safety and efficacy results of SHR-1316 combined with chemotherapy and sequential chest radiotherapy as first-line therapy for extensive-stage small cell lung cancer (ES-SCLC) from a phase II trial. *First Author: Dawei Chen, Shandong Cancer Hospital, Shandong University, Jinan, China*

Background: CAPSTONE-1 study showed that SHR-1316 (PD-L1 antibody) combined with first-line chemotherapy could prolong overall survival in patients (pts) with ES-SCLC. Previous studies have shown that radiotherapy could potentially promote tumor antigen presentation and reverse immunosuppressive microenvironment in tumor. The purpose of this study was to explore the efficacy and safety of SHR-1316 combined with chemotherapy and sequential chest radiotherapy as first-line therapy for ES-SCLC. **Methods:** Key inclusion factors were 18-75 years old, histologically or cytologically confirmed ES-SCLC, ECOG performance status 0-1, no previous systematic treatment. Pts included in this study received 4-6 cycles of SHR-1316 (20mg/kg, D1, q3w) combined with EP/EC (cisplatin, 75mg/m², D1-3, q3w or carboplatin, AUC = 5, D1, q3w and etoposide, 100mg/m², D1-5, q3w), sequentially SHR-1316 combined with chest radiotherapy ($\geq 3\text{Gy} \times 10\text{f}$ or $\geq 2\text{Gy} \times 25\text{f}$, involved-field irradiation), and then entered the maintenance treatment stage until disease progression or intolerable side effects. The main endpoints included objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS) and safety. **Results:** From October 2020 to January 2023, 63 pts with ES-SCLC were enrolled and received at least one dose of SHR-1316, 33 of them have received chest radiotherapy. The median age was 63 (range: 38-75), and most pts were male (53, 84.1%), former smokers (42, 66.7%) with an ECOG performance status 1 (60, 95.2%). At baseline, 24 (38.1%) pts were diagnosed with brain metastasis and 19 (30.2%) pts had liver metastasis. At the data cutoff date, the average number of treatment cycles was 6.9, 17 pts remained on treatment. 55 pts had at least one post-treatment tumor assessment. 41 pts achieved a confirmed partial response, and 12 pts had stable disease. The confirmed ORR and DCR were 74.5% and 96.4%, respectively. The median PFS was 7(CI: 4.3-9.7) months. Adverse events (AEs) occurred in 47 (74.6%) pts. Grade 3 or 4 AEs occurred in 35 (55.6%) pts. The most common grade 3 or 4 AEs included neutropenia (27, 42.9%), leukopenia (13, 20.6%), lymphocytopenia (5, 7.9%), pneumonia (4, 6.3%), anemia (3, 4.8%), and thrombocytopenia (2, 3.2%). **Conclusions:** SHR-1316 combined with chemotherapy and sequential chest radiotherapy as first-line therapy for ES-SCLC showed promising efficacy and acceptable safety. It is worthy of further clinical exploration. Clinical trial information: NCT04562337. Research Sponsor: None.

Characteristics and outcomes of patients with small cell lung cancer (SCLC) detected with CT screening at a single health system. *First Author: Manasi Manoj Godbole, Henry Ford Cancer Institute, Henry Ford Health, Detroit, MI*

Background: At diagnosis, the majority of SCLC patients have extensive-stage disease, and their median survival is only 13 months, even with the addition of checkpoint inhibitors. Previous CT screening trials did not reveal reduction in mortality for SCLC patients. The aim of our study was to analyze the baseline characteristics and clinical outcomes of SCLC patients diagnosed with low-dose CT scan as a part of lung cancer screening program. **Methods:** A retrospective chart review-based study of SCLC patients diagnosed clinically or by lung cancer screening between January 2018 and June 2022 at the Henry Ford Health System was conducted. Baseline characteristics, details of SCLC diagnosis and treatment, and outcome were recorded. Statistical analysis was performed using Chi-squared test, T-test and log-rank test. **Results:** Of the 258 patients who met eligibility criteria, 34 were diagnosed by lung cancer screening. Patients diagnosed with screening tended to be older (mean age- 70.5 years vs. 67.3 years, $p=0.010$). There were no differences in gender distribution, race and smoking status. Mean smoking history was 43 pack-years in both groups. Among screen-detected patients, 73.5% had limited-stage disease compared to 36.6% among clinically detected patients ($p<0.001$). No significant difference in the presence of brain metastases at diagnosis was observed. Among screen-detected patients, 97.1% received any therapy compared to 85.3% among the clinically detected patients ($p=0.105$). Overall survival (OS) was significantly better in screen-detected patients, with a 3-year survival rate of 45.5% vs. 17% ($p=0.00027$). By multivariable analysis, OS was better in screen-detected patients (HR=0.37, 95% CI 0.20-0.68; $p=0.001$) (Table). There was no significant difference in progression-free survival between the groups. **Conclusions:** Our results demonstrate that SCLC patients diagnosed through the lung cancer screening program have better overall survival rates than those diagnosed clinically. These results suggest that developing appropriate screening measures may impact SCLC-related mortality. Research Sponsor: None.

Impact on overall survival.

Variable	N (%)	Hazard Ratio (Univariable)	Hazard Ratio (Multivariable)
Screening	34 (13.2)	0.37 (0.22-0.65, $p<0.001$)	0.45 (0.25-0.79, $p=0.005$)

Tarlatamab in small cell lung cancer (SCLC): Safety and efficacy analyzed by baseline brain metastasis. *First Author: Stephane Champiat, Gustave Roussy, Département d'Innovation Thérapeutique et d'Essais Précoces (DITEP), Villejuif, France*

Background: Tarlatamab, a BiTE molecule targeting DLL3 and CD3, is being studied in patients (pts) with extensive stage small cell lung cancer (ES-SCLC).¹ Up to 25% of pts diagnosed with SCLC have brain metastases (BM) and 50% or more will develop BM during the course of the disease. Pts with ES-SCLC and BM have poor prognosis and quality of life. We analyzed the characteristics and outcomes of pts included in the tarlatamab phase 1 study (NCT03319940) who had baseline BM vs those who did not. **Methods:** Pts included in the phase 1 trial had SCLC that progressed after ≥ 1 platinum-based regimen and received tarlatamab (0.003–100 mg IV). Pts with treated BM were eligible if local therapy was delivered ≥ 2 weeks prior to first tarlatamab dose. **Results:** As of 03 January 2023, 192 pts had received tarlatamab as monotherapy. Median age was 62 (range, 32–80) y; 188 pts (98%) had ECOG PS 0–1 and median prior therapy lines was 2 (range, 1–6), with 107 pts (56%) receiving prior anti-PD1/PD-L1. 48 pts (25%) had BM at screening and 142 (74%) did not (No BM); data was missing for 2 pts (1%). Pts with BM were more likely to have received > 3 prior lines of therapy (BM, 29%; No BM, 9%) and have a record of prior brain radiation (BM, 85%; No BM, 40%); otherwise, characteristics of pts with BM were generally similar to those without. Tarlatamab delivered comparable activity in pts with BM vs. those without in terms of objective response rate (ORR; 20%, 25%) and disease control rate (DCR; 59%, 50%) (Table). Median duration of response (DoR) was 14.9 months (BM) vs. 13.0 months (No BM). Median overall survival (OS) was 13.2 months in the BM group vs 15.5 months in the no BM group. Safety outcomes were similar in terms of treatment-related AEs (TRAEs; BM, 90%; No BM, 94%) and grade (≥ 3 (BM, 38%; No BM, 39%). Groups were also comparable with respect to immune effecter cell-associated neurotoxicity syndrome (ICANS) and associated neurologic events (any-grade, 6% vs 9%; $gr \geq 3$, 4% vs 4%) and neutropenia (any-grade, 10% vs 15%; $gr \geq 3$, 8% vs 8%). AEs numerically different in the BM vs No BM group included $gr \geq 4$ TRAEs (17%, 7%) and any-grade CRS (67%, 54%). The only grade 5 TRAE (pneumonitis) occurred in the BM group. **Conclusions:** Tarlatamab continues to show promising efficacy and is generally safe in pts with ES SCLC irrespective of the presence of BM. Rates of ICANS and associated neurologic AEs were comparable between those with and without BM at baseline. Reference: 1. Paz-Ares L, et al. J Clin Oncol. DOI:10.1200/JCO.22.02823. Clinical trial information: NCT03319940. Research Sponsor: Amgen.

Long-term effectiveness and treatment sequences in patients with extensive stage small cell lung cancer receiving atezolizumab plus chemotherapy: Results of the IFCT-1905-CLINATEZO real-world study. *First Author: Lionel Falchero, Hôpitaux Nord-Ouest, Service de Pneumologie et Cancérologie Thoracique, Villefranche-Sur-Saône, France*

Background: Small cell lung cancer (SCLC) is a highly aggressive type of lung cancer with a tendency towards early recurrence and limited survival. Standard-of-care in 1st-line treatment is platinum-etoposide chemotherapy plus anti-PD-L1 immune checkpoint inhibitor atezolizumab or durvalumab, based on landmark, randomized, phase 3 clinical trials. **Methods:** IFCT 1905-CLINATEZO is a nationwide, non-interventional, retrospective chart review study of patients (pts) with extensive-stage SCLC who received atezolizumab + chemotherapy as part of the French early access program between May 2019 and January 2020 (1402 pts). Inclusions were exhaustive per participating centers (65/307). Data collection run from February to November 2021. Key objectives were to assess effectiveness and safety of atezolizumab + chemotherapy and analyze subsequent treatment sequences. **Results:** The population analyzed included 518 out of the 1402 pts. There were 66% male and mean age was 65.7 years (range: 36.7-88.0); 89% had a performance status (PS) 0/1 and 27% brain metastases. Almost all the pts (96%) were smokers, with a median number of pack-years of 40. Fifty-five pts (10.6%) received at least 1 previous treatment. Median number of atezolizumab injections was 7 (range: [1-48]) for a median duration of 4.9 months (95% CI 4.5-5.1). Twenty-seven pts (5%) were under ongoing treatment at date of last news. Atezolizumab was continued beyond disease progression in 122 pts (24%) for a median duration of 1.9 months (95% CI 1.4-2.3). Best objective response was complete and partial response in 19 (3.9%) and 378 pts (77.1%) respectively; stable disease was observed in 50 pts (10.2%). After a median follow-up of 30.8 months (95% CI: [29.9-31.5]), median overall survival (OS), 12- and 24-months OS rates were 11.3 months (95% CI: [10.1-12.4]), 46.7% (95% CI 42.3-50.9) and 21.2% (95% CI 17.7-24.8) respectively. Median real world-progression free survival (based on date of the first source evidence for progression referenced by the treating physician), 6- and 12-months rates were 5.2 months (95% CI 5.0-5.4), 37.5% (95% CI 33.3-41.7) and 15.2% (95% CI 12.2-18.6) respectively. For the pts with PS 0/1, median OS was 12.2 months (95% CI 11.0-13.5). For the 55 pts with previous treatment, median OS was 14.9 months (95% CI 10.1-21.5). A total of 326 (66.4%) pts received subsequent treatment. **Conclusions:** IFCT 1905-CLINATEZO study shows the reproducibility, in a real-life setting, of the key survival outcomes of IMpower-133, that may be attributed to the selection of pts fit for this regimen, the adoption of pragmatic approaches for the management of pts receiving atezolizumab, that includes concurrent radiotherapy and treatment beyond progression, and the high proportion of pts treated with 2nd-line therapies, mostly based on chemotherapy. IFCT-2105 lurbinectin real-world effectiveness and treatment sequences in patients (pts) with extensive-stage small cell lung cancer (ES-SCLC) who received lurbinectin as part of the French Early Access Program (EAP-ATU). *First Author: Nicolas Girard, Institut du Thorax Curie Montsouris, Institut Curie, Paris, France*

Background: Novel options are needed for pts with ES-SCLC after the failure of first-line chemotherapy. Lurbinectin demonstrated efficacy in a landmark phase II study [Trigo et al. Lancet Oncol. 2020 May;21(5):645], and was granted EAP-ATU in France in June 2020. **Methods:** Multicenter, retrospective cohort of consecutive pts with histologically or cytologically confirmed ES-SCLC, who received at least one dose of treatment with lurbinectin as part of the French EAP-ATU from June 2020 until March 2021, and gave consent for the data collection, were enrolled in 47 sites. Primary and secondary endpoints were description of clinical characteristics, and exposure to treatment, response, PFS, OS, safety. **Results:** 312 pts – 64% male, median age 65 years, 72% PS0-1, 47% with brain metastasis, 58% with previous immunotherapy – were enrolled. Lurbinectin was administered as second-line in 44% of pts; 58% were chemotherapy-refractory. Pts received a median number of 3 cycles of lurbinectin. Concurrent radiotherapy on metastases was delivered to 38% of pts. Lurbinectin was discontinued because of progression/death/toxicity/other reasons in 83%/8%/5%/4% of pts. Grade3/4 events were observed in 9%/5% of pts. Response rate was 22% [95%CI 17-27%], disease control rate was 38% [95%CI 32-44%]. After a median follow-up of 20.8 months, median PFS and OS were 1.9 [95%CI 1.8-2] and 4.7 [95%CI 4-5.4] months; 6-month PFS and OS were 7% [4-10%] and 42% [95%CI 37-48%]. PS ≤ 2 and chemotherapy-free interval ≥ 90 days were associated with significantly longer OS (HR = 0.71 [95%CI 0.53-0.95] and HR = 0.58 [95%CI 0.44-0.76] respectively). Main sites of progression were the lung (39% of pts), the brain (39% of pts), the liver (30% of pts), and the mediastinum (30% of pts). Subsequent treatment was administered to 154 pts after discontinuation of lurbinectin, mostly consisting of topotecan (26% of pts); response/disease control rates, and median PFS of first subsequent treatment were 11% [95%CI 6-17%], 35% [95%CI 27-44%], and 1.9 [95%CI 1.7-2.3] months. **Conclusions:** Lurbinectin provides an additional option from second-line for ES-SCLC, with efficacy outcomes comparable to that of historical treatments. Phase Ib/IIa study assessing the safety and efficacy of AL8326 monotherapy in patients with ≥ 3 rd line small cell lung cancer (SCLC) treatment. *First Author: Xiaochun Zhang, The Affiliated Hospital of Qingdao University, Qingdao, China*

Background: AL8326 is a novel, orally administered, small molecule tyrosine kinase inhibitor (TKI). The primary objective of this Phase Ib/IIa study is to evaluate the safety and efficacy of AL8326 monotherapy in patients with ≥ 3 rd line small cell lung cancer (SCLC) treatment. **Methods:** Patients with a diagnosis of small cell lung cancer either limited or extended stage requiring third or further line treatment were eligible for enrollment. The regimen was a 28-day cycle with oral AL8326 administered at 60 mg once per day via RECIST1.1 evaluation until disease progression (PD), or intolerable toxicity or any other reason discontinuations. **Results:** At the cut-off date Nov 30, 2022, total n = 30 patients were enrolled. The objective response rate (ORR) was 20% (6/30) (4 confirmed). The disease control rate (DCR) was 56.7% (17/30). Median progression-free survival (PFS) was 3.65 months (95% CI: 1.9 – 5.5) and median overall survival (OS) was 10.42 months (95% CI: 5.4, NE). The median duration of response (DOR) was 5.6 months. All 30 subjects had reported AE at least once. Common treatment emergent adverse events (TEAE) were similar to other TKI drug and included (incidence $\geq 20\%$): thyroid stimulating hormone (TSH) increase (46.67%), proteinuria (43.33%), weight loss (40.00%), hypertension (36.67%), thrombocytopenia (33.33%), diarrhea (33.33%), positive fecal occult blood (30.00%), hypercholesterolemia (26.67%), hypertriglyceridemia (26.67%), hand- foot syndrome (HFS) (20.00%), loss of appetite (20.00%). Most of these AEs were grade 1-2 (CTCAE V5.0). **Conclusions:** AL8326 has demonstrated acceptable tolerability and positive efficacy on small cell lung cancer treatment. A US Phase 2 (NCT05363280) study is ongoing and a phase 3 study is in preparation. Clinical trial information: NCT04890795. Research Sponsor: AL8326.

Efficacy and safety of high dose twice-daily thoracic radiotherapy versus standard dose for limited stage small-cell lung cancer: A multicentre, open-label randomised, phase 3 trial. *First Author: Jiayi Yu, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Radiation Oncology, Peking University Cancer Hospital & Institute, Beijing, China*

Background: We aimed to assess the efficacy and safety of high-dose, hyperfractionated thoracic radiotherapy of 54 Gy in 30 fractions compared with standard dose (45 Gy in 30 fractions) as a first-line treatment for LS-SCLC. **Methods:** The study was an open-label, randomised, phase 3 trial, done at 16 public hospitals in China. Key inclusion criteria were patients aged 18-70 years, with previously histologically or cytologically confirmed LS-SCLC, previously untreated or received 1-2 courses of intravenous cisplatin (75 mg/m² of body-surface area, on day 1 or divided into two days of each cycle) or carboplatin (area under the curve of 5 mg/mL per min, day 1 of each cycle) and intravenous etoposide (100 mg/m² of body-surface area, on days 1-3 of each cycle), and an Eastern Cooperative Oncology Group (ECOG) performance status of 0-1. Eligible patients were randomly assigned (1:1) to receive receive volumetric-modulated arc radiotherapy (VMAT) of 45 Gy in 30 fractions or the simultaneous integrated boost VMAT (SIB-VMAT) of 54 Gy in 30 fractions to the primary lung tumour and lymph node metastases starting 0-42 days after the first chemotherapy course. Both groups of patients received thoracic radiotherapy twice per day and 10 fractions per week. Prophylactic cranial radiation (PCI, 25Gy in 10 fractions) was implemented to patients with responsive disease. The primary endpoint was overall survival. Safety was analysed in the as-treated population. This study is complete and registered with ClinicalTrials.gov, NCT03214003. **Results:** Between June 30, 2017, and April 6, 2021, 224 eligible patients were enrolled and randomly assigned to 54 Gy (n = 108) or 45 Gy (n = 116). Median follow-up for the primary analysis was 45 months (IQR 41-48). Median overall survival was significantly improved in the 54 Gy group (62.4 months) compared with the 45 Gy group (43.1 months; p = 0.001). Median progression-free survival was significantly improved in the 54 Gy group (30.5 months) compared with the 45 Gy group (16.7 months; p = 0.044). The most common grade 3-4 adverse events were neutropenia (30 [28%] of 108 patients in the 54 Gy group vs 27 [23%] of 116 patients in the 45 Gy group), neutropenic infections (6 [6%] vs 2 [2%]), thrombocytopenia (13 [12%] vs 12 [10%]), anaemia (6 [6%] vs 4 [3%]), and oesophagitis (1 [1%] vs 3 [3%]). There were one treatment-related deaths in 54 Gy group (myocardial infarction). **Conclusions:** Compared with standard thoracic radiotherapy dose of 45 Gy, the high dose of 54 Gy improved overall survival and progression-free survival without increasing toxicities in patients with LS-SCLC, supporting twice-daily hyperfractionated thoracic radiotherapy of 54 Gy with concurrent chemotherapy is an alternative treatment option for LS-SCLC. Clinical trial information: NCT03214003. Tumor microenvironment-mediated immune profiles and efficacy of platinum doublet chemotherapy plus ICIs stratified by DLL3 expression in small cell lung cancer. *First Author: Masayuki Shirasawa, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: Delta-like ligand 3 (DLL3) frequently expressed in small cell lung cancer (SCLC) and has been emerged as a therapeutic target. However, it remains unclear how DLL3 expression status affects tumor microenvironment (TME)-mediated immune profiles and clinical outcomes of platinum doublet chemotherapy plus ICIs in SCLC patients. **Methods:** We retrospectively reviewed post-surgical limited-stage (LS)-SCLC, and extensive-stage (ES)-SCLC patients treated with platinum and etoposide (PE) plus anti-PD-L1 antibody. In LS-SCLC cohort, the transcriptome and whole-exome sequencing (WES) analysis were performed to assess the immune profiles, mutation status and neoantigen status. In ES-SCLC cohort, the association between the efficacy of immunochemotherapy and DLL3 expression by transcriptome analysis were evaluated. **Results:** Fifty-nine and 17 patients were included in the LS- and ES-SCLC cohort, respectively. In LS-SCLC cohort (n = 59), WES analysis revealed that SCLC with DLL3^{High} had a significantly higher number of neoantigens (77 [95% confidence interval (CI) 65-113] vs. 48 [95% CI 17-58], p = 0.004), and a significantly higher rate of signature SBS4 associated with smoking (43% [95% CI 28-53] vs. 28% [95% CI 15-36], p = 0.02), although TMB did not differ according to DLL expression (6.6 mut/Mb [95% CI 5.3-9.6] vs. 6.5 mut/Mb [95% CI 5.2-9.9], p = 0.26). The transcriptome analysis in LS-SCLC cohort revealed that SCLC with DLL3^{High} tumors had significantly suppressed immune-related pathways (IFN- γ response, inflammatory response, and TNF α signaling via nfkb), and dendritic cells (DC) function (DC Differentiation, DC Antigen Processing and Presentation, DC Migration). Profiling tumor infiltrating immune cells with CIBERSORT showed that SCLC with DLL3^{High} had significantly lower proportions of T-cells, macrophages, and DCs compared with those with DLL3^{Low}. These results suggested that DLL3^{High} tumors suppressed tumor immunity by inhibiting antigen-presenting function. In ES-SCLC cohort (n = 17), the PFS of PE plus anti-PD-L1 antibody in patients with DLL3^{High} was significantly worse than those in patients with DLL3^{Low} (4.1 months [95% CI, 2.0-6.3] vs. 7.4 months [95% CI, 2.5-12.3]; HR 3.78 [95% CI, 1.1-12.5], p = 0.03). **Conclusions:** SCLC with high DLL3 expression was characterized by resistance to immunochemotherapy due to suppressed tumor immunity, although those tumors had higher neoantigen loads. The effect of various social determinants of health on overall survival in the SCLC population. *First Author: Matthew M Mirsky, University Hospitals Seidman Cancer Center and Case Western Reserve University, Cleveland, OH*

Background: Small cell lung cancer (SCLC) comprises 10-15% of all lung cancers yet little is known about the impact of social determinants of health (SDOH) on outcomes in patients with SCLC. This study aims to assess the impact of various SDOH on overall survival (OS) in patients diagnosed with SCLC at a single institution. **Methods:** We have established a large clinical/pathologic/genomic database of all patients diagnosed and treated for SCLC between 1998-2022 at our institution for retrospective study. Demographic data including sex, race, age, stage, address, and smoking status were collected. Poverty index was assessed by percent of school-aged children in poverty at the school district level based off 2021 census using the SAIPE tool and stratified as low (poverty index ≤ 15.1) and high (poverty index > 15.1). Water/Air carcinogens were obtained by zip code through EPA TRI Explorer database at year of SCLC diagnosis. Food desert designation was acquired through USDA low income and low access atlas at 0.5 miles for urban residences and 10 miles for rural residences respectively. Violent crime rates were obtained from the FBI Crime Data Explorer by year of diagnosis and police department jurisdiction. OS was computed from date of diagnosis to death or last known follow up date, and univariate Cox proportional hazards (PH) regression analysis was performed. Factors that were significant at significance level of 0.25 in univariate analysis were further evaluated using multivariable Cox PH model. **Results:** A total of 982 patients with SCLC were included. Univariate PH analysis demonstrated statistically significant improvement in OS with younger age (HR = 1.03, 95% CI 1.02-1.03, p < 0.0001), female sex (HR = 0.8, 95% CI 0.7-0.92, p 0.001), low poverty index (HR = 1.12, 95% CI 0.98-1.12, p = 0.097), limited stage disease (HR = 3.12, 95% CI 2.66-3.66, p < 0.0001), and lack of air pollution exposure (HR = 1.09, 95% CI 0.95-1.24, p = 0.227). Multivariable PH analysis showed statistically significant OS improvement for those from lower poverty areas (HR = 1.22, 95% CI: 1.07- 1.4, p = 0.004) as well as in those without air pollution exposure (HR = 1.21, 95% CI: 1.05- 1.39, p = 0.008), controlling for age, sex, stage and smoking. Exposure to water pollution, violent crime rate, food desert designation and pack years smoked were not found to be independent predictors of OS. **Conclusions:** In this large detailed cohort of 982 patients with SCLC, there was a significantly lower OS for patients living in high poverty areas and for patients exposed to air pollutants. This effect was durable even after for controlling for age, sex, stage, and smoking status, demonstrating that these are independent risk factors associated with poorer OS. Our next research steps will be to examine the biologic basis for these disparities through genomic and transcriptomic analysis. Research Sponsor: None.

Poster Session

Assessing inpatient outcomes for patients with small cell lung cancer presenting with superior vena cava thrombosis. *First Author: Jay Vakil, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL*

Background: Superior Vena Cava Syndrome (SVCS) is a condition characterized by obstruction of the SVC that can commonly be caused by thrombus formation in the SVC. Small cell lung cancer (SCLC) frequently results in obstruction of the SVC. When severe enough, SVCS can present as a life-threatening oncological emergency. In this study we aim to explore baseline characteristics of SVC thrombosis (SVCT) in patients with SCLC, the prevalence of US hospitalizations, and disparities with regards to race and socioeconomic status. **Methods:** National Inpatient Sample was utilized to obtain pertinent data. Total hospitalizations with coexistent comorbidities of SCLC were extracted from the 2016 to 2019 database. Adult patients with a secondary diagnosis of SVC thrombosis were determined by using ICD-10 codes. We studied the racial and socioeconomic differences as well as length of stay (LOS), total hospital charges (THC), and all-cause mortality outcomes in cancer patients with and without SVC thrombosis. Statistical analysis was performed on STATA, with logistic regression analyses and chi-square tests. **Results:** A total of 480,750 patients were hospitalized for SCLC. 720 of these patients had SVC thrombosis (0.15% of SCLC patients). The mean age of those with thrombi was significantly lower compared to those without thrombi (64 vs. 69, $p < 0.001$). The SCLC with SVCT cohort had statistically higher proportion of black patients than the other cohort. Charlson index was significantly higher in SCLC with SVCT cohort (5.8 vs. 5, $p < 0.001$). Average income between the two cohort groups were similar. Medicaid and private insurance utilization were more common in SCLC with SVCT admissions compared to without SVCT. Patients presenting with SVC thrombosis had an increased hospital LOS (10 vs. 6 days, $p < 0.001$) and cost compared to other cohorts (\$117,320 vs. \$80,806, $p < 0.005$). All-cause mortality in patients with SCLC was 7.7% and the presence of SVC thrombosis significantly increased the odds of inpatient mortality (18.0%). Non-White races were associated with higher odds of mortality in SCLC admissions. In addition, patients with SVC thrombus also had greater odds of having a concomitant pulmonary embolism during hospitalization. **Conclusions:** In this study we found that race, insurance type, and comorbidities impacted the likelihood of developing thrombosis in the superior vena cava in patients with SCLC. Though the incidence is rare, SVC thrombosis indicates a poor prognostic factor for patients with SCLC. Further studies to evaluate these disparities in race and socioeconomic factors are warranted. The development of thrombosis and subsequent SVC syndrome is a potentially life-threatening condition; addressing potential reversible risk factors could improve mortality in a large subgroup of hospitalizations related to SCLC. Efficacy and safety of lurbinectedin in elderly patients with relapsed SCLC. *First Author: Sophie Cousin, Medical Oncology Department, Institut Bergonié, Bordeaux, France*

Background: Relapsed SCLC is a difficult-to-treat disease. A considerable number of SCLC patients are elderly with associated fragility and numerous comorbidities. Accelerated approval from the US FDA of lurbinectedin (Zepzelca) 3.2 mg/m² q3wk as second-line therapy in metastatic small cell lung cancer (SCLC) was based on results from a phase 2 basket trial (NCT02454972) showing overall response rate of 35.2% and duration of response of 5.3 months. The ATLANTIS trial (NCT02566993) assessed the combination of lurbinectedin 2mg/m²/doxorubicin (DOX) 40 mg/m² as second-line treatment for SCLC vs. a control arm of topotecan/CAV. **Methods:** This *post hoc* analysis explores the efficacy and safety of lurbinectedin in relapsed SCLC patients ≥65 years included in both phase 2 basket (26 patients treated with lurbinectedin) and ATLANTIS (121 patients treated with lurbinectedin/DOX and 118 patients treated in the control arm) trials. This analysis did not include patients from the phase 2 basket trial with chemotherapy-free interval (CTFI) < 30 days, as these patients were excluded in the ATLANTIS trial. **Results:** Median age was similar (72.5 in lurbinectedin basket vs. 69 in ATLANTIS lurbinectedin/DOX vs. 69 in ATLANTIS control arm), most were males (65.4% vs. 57.9% vs. 60.2%), with ECOG PS 1 (65.4% vs. 68.6% vs. 68.6%) and CNS involvement (7.7% vs. 10.7% vs. 15.3%). Median CTFI (days) was also similar (105.5 vs. 123 vs. 120). Median number of cycles was 4 vs. 6 vs. 4. Main efficacy and safety results are shown in the table. Treatment-related adverse events (AEs) were reported in 92.3%, 92.6% and 94.1% of patients, respectively (grade ≥3 in 50.0%, 59.5% and 81.4%). **Conclusions:** In elderly patients, lurbinectedin seems to be superior to the standard of care in terms of both efficacy (higher response rate and longer duration of response and overall survival) and safety (less associated hematological AEs), which reinforces its role as a treatment option in relapsed SCLC patients ≥65 years. Clinical trial information: NCT02454972, NCT02566993. Research Sponsor: PharmaMar.

A multicenter phase I/II trial of induction chemotherapy followed by camrelizumab, apatinib, plus chemotherapy as first-line treatment for extensive-stage small-cell lung cancer. *First Author: Chengzhi Zhou, Pulmonary and Critical Care Medicine, Guangzhou Institute of Respiratory Health, National Center for Respiratory Medicine, State Key Laboratory of Respiratory Diseases, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China*

Background: Extensive-stage small-cell lung cancer (ES-SCLC) is a highly aggressive tumor with poor prognosis and limited treatment options. It is necessary to explore new first-line therapeutic strategies to improve patients' outcomes. This study aimed to assess the safety and efficacy of induction chemotherapy followed by camrelizumab, apatinib plus chemotherapy as first-line treatment in patients with ES-SCLC. **Methods:** Patients (pts) aged 18-75 years with histopathologically confirmed ES-SCLC and ECOG performance score of 0-1 who did not receive systemic treatment were prospectively enrolled to this study. After two 21-day cycles of induction chemotherapy (etoposide 100 mg/m² on days 1-3 and carboplatin AUC 5 mg/mL/min on day 1 [ECI], pts received camrelizumab (200 mg, q3w) plus apatinib (250 mg, qd) and EC for 2-4 cycles, then followed by camrelizumab and apatinib as maintenance treatment until disease progression/unacceptable toxicity/up to two years. The primary endpoint was safety. Secondary endpoints were objective response rate (ORR), PFS and OS. Targeted sequencing and whole transcriptome sequencing (WTS) were performed for pts who had sufficient tissue samples. **Results:** From Jan 28, 2021 to Aug 20, 2022, 40 eligible pts were enrolled. At the data cut-off (Jan 21, 2023), the median follow-up time was 13.6 months. Grade 3/4 treatment-related adverse events (TRAEs) were reported in 72.5% (29/40) of pts. The most common grade 3/4 TRAEs were decreased neutrophil count (35.0%, 14/40), anemia (15.0%, 6/40), decreased platelet count (12.5%, 5/40), increased serum alanine aminotransferase (12.5%, 5/40), and hyponatremia (12.5%, 5/40). Hemoptysis was observed in 15.0% of (6/40) pts, all of whom were grade 1-2. No treatment-related deaths occurred. Efficacy was evaluated in 36 pts who received two cycles of induction therapy and had at least one post-treatment efficacy evaluation. The ORR after two cycles of induction chemotherapy was 66.7% (24/36). The overall ORR and disease control rate reached 88.9% (32/36) and 97.2% (35/36), respectively. The median PFS was 7.4 months (95% CI: 6.5-8.3). The 1-year OS rate was 63.4%. Thirty and 20 pts underwent targeted sequencing and WTS, respectively. Pts with high tumor mutational burden level (TMB ≥ 7.0, $p < 0.001$), high homologous recombination deficiency score (HRD ≥ 34.0, $p = 0.012$), and altered *RB1* ($p < 0.001$) presented a longer PFS, respectively. WTS suggested that high expression of cancer-associated fibroblast signature was associated with a shorter PFS ($p = 0.001$). **Conclusions:** Induction chemotherapy followed by camrelizumab, apatinib plus EC and then maintenance therapy showed acceptable safety and encouraging efficacy, and might be a promising regimen as first-line treatment in ES-SCLC. TMB, HRD and *RB1* might be predictive biomarkers of response to the regimen. Clinical trial information: NCT05001412. Research Sponsor: 1. Dissecting small cell lung cancer subtypes with cell-free DNA fragmentomes. *First Author: Lorenzo Rinaldi, Delfi Diagnostics, Inc., Baltimore, MD*

Background: Although small cell lung cancer (SCLC) is managed as a single cancer type, new evidence supports that subtypes (high vs low neuroendocrine) of SCLC acquire diverse transcriptional and epigenetic states. Furthermore, distinct SCLC subtypes acquire unique therapeutic vulnerabilities, such as the low-neuroendocrine highly inflamed SCLC subtype that has been linked to immunotherapy sensitivity. We have previously shown that DELFI (DNA evaluation of fragments for early interception) can be used to non-invasively distinguish SCLC from non-small cell lung cancer (NSCLC). Here, we report a preliminary analysis of using the DELFI approach for distinguishing among SCLC subtypes. **Methods:** Circulating cell-free DNA (cfDNA) was isolated from plasma samples of patients diagnosed with relapsed SCLC and treated with durvalumab plus olaparib in a phase II trial (NCT02484404). Over 200 cfDNA libraries were prepared for whole genome sequencing in batches with internal controls. To infer tumor gene expression profiles in cfDNA, we investigated genome-wide signals of tissue-specific transcription factors differentially regulated in SCLC, and applied a novel DELFI-based approach to inform SCLC molecular subtypes. Clinical information, patient-matched tissue transcriptome (RNA-seq), and chromatin accessibility data (ATAC-seq) were examined in orthogonal analyses. **Results:** The DELFI classifier detected SCLC cases ($N = 47$) with a median DELFI score of 1.0 (95% CI 0.99-1), significantly higher than previously reported scores for other lung cancer subtypes. Comparison of DELFI fragmentome signals to publicly available tumor transcriptomes shows subtype-level concordance ($r = 0.78$, $p < 0.001$, Pearson), particularly in pre-treatment SCLC cases separating high- vs low-neuroendocrine subtypes. High-neuroendocrine SCLCs exhibited a decrease in aggregate cfDNA fragment coverage at *ASCL1* transcription factor binding sites relative to low-neuroendocrine SCLCs ($r = 0.90$, $p < 0.001$, Pearson). Additionally, low-neuroendocrine SCLCs revealed a significant decrease in aggregate cfDNA fragment coverage at genomic binding sites regulated by hematopoietic transcription factors, reflecting the inflamed phenotype of this SCLC subtype. Integration of these approaches provided a cfDNA fragmentation-based machine learning model that distinguished SCLC subtypes with high performance. **Conclusions:** Genome-wide cfDNA fragmentome analyses can differentiate high- and low-neuroendocrine SCLC subtypes. Given the challenges for performing SCLC biopsies in a clinical setting, we believe this approach could be a viable method of subtyping SCLC in a non-invasive manner. Phase 2 small cell lung cancer (SCLC) cohort of a phase 1b/2 trial of a liposomal formulation of eribulin in combination with nivolumab. *First Author: Koichi Azuma, Kurume University Hospital, Kurume, Japan*

Background: E7389-LF is a liposomal formulation of the microtubule dynamics inhibitor eribulin. Combining E7389-LF with an immune checkpoint inhibitor (ICI; eg, nivolumab) may improve antitumor response via vascular remodeling. The phase 1b part of the open-label Study 120 evaluated the dosing and safety of E7389-LF in combination with nivolumab in patients (pts) with solid tumors. The phase 2 part assessed efficacy and safety in disease cohorts; herein, we report results from the SCLC cohort. **Methods:** Pts with unresectable and measurable SCLC who had progression during or after 1st-line (1L) platinum-based chemotherapy with/without an ICI were enrolled to the SCLC cohort of the phase 2 part of Study 120. Pts received E7389-LF 2.1 mg/m² in combination with nivolumab 360 mg IV Q3W. The primary objective of the phase 2 part was to assess the objective response rate (ORR). Secondary objectives included assessments of safety and progression-free survival (PFS); exploratory objectives included the disease control rate (DCR), overall survival (OS), and biomarker analysis. Tumor response was assessed by investigators per RECIST v1.1 Q6W. All adverse events (AEs) were monitored and recorded. **Results:** In the SCLC cohort, 34 pts were enrolled; the median age was 66.0 years (range 46–81). At data cutoff (May 31, 2022), 5 pts (14.7%) were undergoing treatment. Discontinuations occurred in 29 pts (85.3%)—26 (76.5%) primarily due to disease progression, 3 (8.8%) due to an AE. Efficacy analyses included 33 pts, as 1 pt had their diagnosis of SCLC changed to a different cancer type after being enrolled. Of the 33 evaluable pts, 27 (81.8%) had an ICI as part of their prior 1L therapy. The ORR of E7389-LF in combination with nivolumab was 24.2% (95% CI 11.1–42.3) in the evaluable population; the DCR was 75.8% (95% CI 57.7–88.9). Median PFS was 3.98 mos (95% CI 2.63–4.40); the 6-mo PFS rate was 27.7% (95% CI 13.0–44.6). At a median follow-up period of 10.6 mos, median OS was not reached (95% CI not estimable); the 6-mo OS rate was 90.9% (95% CI 74.4–97.0). Treatment-related, treatment-emergent (TE) AEs of any grade and of grade ≥3 severity occurred in 97.1% (n = 33) and 82.4% (n = 28) of the 34 enrolled pts, respectively; the most common treatment-related TEAE was neutropenia (any grade: 58.8% [n = 20]; grade ≥3: 52.9% [n = 18]). The neutrophil count nadir occurred around cycle 1 day 8. TEAEs led to dose reduction of E7389-LF in 19 pts (55.9%). Withdrawal of E7389-LF or nivolumab occurred in 5 pts (14.7%): acute kidney injury, cough, myocarditis, pneumonitis, and radiation pneumonitis (n = 1 each). Changes in vascular and immune-related plasma markers were observed. **Conclusions:** E7389-LF in combination with nivolumab showed notable antitumor activity as 2L therapy in pts with SCLC, as evidenced by the notable ORR of 24.2%. No new safety signals were observed for this combination. Clinical trial information: NCT04078295. Research Sponsor: This trial was sponsored by Eisai Co., Ltd., Tokyo, Japan. Nivolumab was provided by Ono Pharmaceutical Co., Ltd., Osaka, Japan.

Role of consolidative thoracic and prophylactic cranial radiation in extensive stage small cell lung cancer in chemo-immunotherapy era. *First Author: Jai Kumar Khatri, Marshall University School of Medicine, Edwards Cancer Center, Huntington, WV*

Background: The role of consolidative thoracic and prophylactic brain radiation in extensive stage small cell lung cancer patients is controversial. We investigated the factors associated with the use of any radiation therapy (RT) and whether Radiation has a benefit to overall survival (OS) in the total patient group and whether this benefit is the same if Chemotherapy (CT) only is used, or chemo-immunotherapy (CT-IO) is used. **Methods:** The NCDB database was queried from years 2017-2019. Patients receiving systemic therapy-STX (CT or CT-IO) had to have at least 6 months of follow-up and have no brain metastases at diagnosis. All RT patients had to receive upfront systemic therapy, were treated 2 to 6 months from diagnosis, and if treated to the brain received 25Gy in 10 fractions only. Multi-variate analyses (MVA) were used to determine factors associated with OS and selection for any radiation. Propensity matching for factors affecting OS were used to generate Kaplan-Meier OS curves. Log-rank tests were used to determine differences in Kaplan Meier survival curves for the effects of RT on OS. **Results:** The total number of patients receiving RT or systemic therapy alone as well as their median follow-ups(months(mn)) were (981, 33.02mn) and (8909, 30.59mn). The median time to the start of STX and RT were 22days and 135 days respectively. MVA noted that RT had a greater effect on OS (Thoracic, Brain, Both – HRs = 0.78, 0.75, and 0.68) than other interventions including IO (HR 0.87) and palliative care without RT (HR 1.07). Selection for radiation depended significantly upon factors affecting OS(HR) including liver metastases (0.59), females (1.21), age/10yr(0.78) and Charlson co-morbidity index of > 3(0.66), but did not depend upon insurance status, race, or county income/high school graduation rates. Propensity score matched OS curves noted the same effects of RT on OS whether CT or CT-IO was given. The lowest HRs were noted when both thoracic and brain RT were given (see table). **Conclusions:** The patient with extensive stage small cell lung cancer who reach candidacy and receive RT may have a significant improvement in OS compared to the patients treated only with CT or CT-IO. Combined thoracic and prophylactic brain RT seems to be better than either one alone. The impact of radiation whether given to one or two sites may be more beneficial than immunotherapy added to chemotherapy. Research Sponsor: None.

Regimen	HR	p-value	N	18Month OS-KM
CT only	REF	REF	5783	15%

Spatially resolved multi-region transcriptomic subtyping and assessment of gene expression profiles associated with long-term benefit from chemo-immunotherapy in patients with extensive-stage small cell lung cancer (ES-SCLC). *First Author: Melina Peressini, Hospital Universitario 12 de Octubre, Madrid, Spain*

Background: Transcriptomic subtyping holds promise for personalized therapy in SCLC, but intratumoral transcriptomic heterogeneity and its clinical significance remain poorly defined. In this study, we aimed to assess transcription factor defined subtypes within multiple regions of intact tissues and identify gene sets associated with long-term chemo-immunotherapy benefit. **Methods:** We assessed baseline FFPE tumors from 32 ES-SCLC patients enrolled in the IMfirst clinical trial (EudraCT: 2019-002784-10). We used GeoMx DSP to perform transcriptomic analysis from multiple intratumoral regions of interest (ROIs). We used an assay with +1800 genes (GeoMx CTA) plus custom-designed mRNA probes targeting subtype-defining transcription factors not included in the CTA assay (POU2F3, NEUROD1, and YAP1). Custom probes were quantitatively validated using FFPE cell lines. **Results:** We profiled 175 ROIs from 32 tumors. Cluster analysis based on the expression of ASCL1, NEUROD1, POU2F3, and YAP1 showed that all samples clustered within 4 groups: SCLC-A (76 ROIs [43%]), SCLC-N (31 ROIs [18%]), SCLC-P (18 ROIs [10%]), and SCLC-Y (50 ROIs [29%]). ASCL1 was the most abundantly expressed transcription factor, prevalent in the SCLC-A subtype, and showed inverse correlation with POU2F3 (r=−0.55, p<0.0001) and YAP1(r=−0.70, p<0.0001). YAP1 was expressed at low levels and was more broadly distributed across all 4 subtypes. Differential expression and gene set enrichment analysis (GSEA) using linear mixed models revealed that SCLC-A subtype was enriched in cell cycle and DNA damage repair genes, and showed repression of multiple gene sets associated with anti-tumor immune response. In contrast, SCLC-Y subtype showed the opposite pattern. The SCLC-P subtype was also enriched in genes related to cancer antigens and T-cell checkpoints. Most patients (n=18, 56%) had tumors with coexistence of more than one subtype, not evident through morphological inspection. Combined SCLC-A and SCLC-Y subtypes was the most common mixed phenotype (n=8, 25%). Four patients (13%) had tumors with coexistence of three subtypes. Transcriptional subtypes, subtype-defining transcription factors as single genes, or the presence of subtype heterogeneity, were not associated with outcomes. Gene sets involved in mitochondrial metabolism and MHC class I antigen presentation were the highest enriched pathways in tumors from patients with sustained benefit (time to progression³ 12 months). **Conclusions:** This study reveals substantial intratumoral transcriptomic subtype heterogeneity in human SCLC. In this limited sample set, we did not observe outcome association for transcriptional subtypes. Our findings related to long-term chemo-immunotherapy benefit require validation in independent cohorts. Research Sponsor: Roche Pharma SA.

Brain metastasis burden and management in small cell lung cancer: An analysis of 8705 patients. *First Author: Karolina Gaebe, University of Toronto, Toronto, ON, Canada*

Background: Patients with small cell lung cancer (SCLC) have historically been characterised by poor overall survival (OS) and high risk for intracranial metastatic disease (IMD), but large-scale real-world evidence on clinical presentation and treatment in this population is lacking. These patients traditionally receive whole brain radiation therapy (WBRT) for IMD, however, a recent systematic review has indicated that OS following stereotactic radiosurgery (SRS) may be non-inferior compared with WBRT. We aim to describe the clinical characteristics and outcomes of patients with SCLC and IMD in Ontario, Canada. **Methods:** We included all patients diagnosed with SCLC between April 2007 and March 2018 identified through a provincial health administrative database. Information on patient and treatment characteristics, incidence and time to IMD, and OS from time of SCLC diagnosis were collected and analyzed using R. **Results:** A total of 8705 patients were included. Median age was 68 years (range 18-103). Most patients presented with extensive disease (n = 5625) and were diagnosed after 2011 (n = 5768). Patients who received chemotherapy (n = 5563) had significantly longer OS than those who did not (median 10.64 vs 1.58 months (mo), hazard ratio (HR) 0.36, 95% confidence interval (CI) 0.34-0.37). 6662 patients received brain imaging at the time of primary diagnosis (CT: 5126, MRI: 1536), and 88% of patients surviving longer than 6 mo received more than one follow-up brain scan. 31% developed IMD (synchronous: 1175, asynchronous: 1511) with median intracranial progression-free survival of 5.65 mo. Median OS of patients with IMD was 9.76 mo, 29 and 1300 received SRS and WBRT as first treatment for their IMD, respectively. OS was in favour of SRS over WBRT (median 20.47 vs 8.74 mo, HR 0.57, 95% CI 0.39-0.84), which remained significant in multivariate analysis (p < 0.001). **Conclusions:** OS for patients with SCLC remains poor, and many patients present with IMD. With careful selection, patients with SCLC may benefit from SRS treatment. Research Sponsor: None.

Molecular predictors and immunomodulatory role of dual checkpoint inhibitor blockade using ipilimumab/nivolumab in patients with extensive stage small cell lung cancer. *First Author: Anne C. Chiang, Yale University School of Medicine, New Haven, CT*

Background: Small cell lung cancer (SCLC) is an aggressive neuroendocrine carcinoma with poor prognosis. In extensive stage patients, frontline treatment with chemoimmunotherapy shows modest clinical benefit. However, the biological impact of immunotherapy in SCLC is poorly understood with no clear predictive biomarkers to guide patient selection in this setting. **Methods:** We collected paired baseline (pre-treatment), on-treatment (week 4), and progression biopsies from patients with relapsed advanced-stage SCLC treated with combination nivolumab (nivo) and ipilimumab (ipi) in a single-arm, phase 2 clinical trial (NCT03670056). Nivo 1 mg/kg and ipi 3 mg/kg were administered every 3 weeks for 4 cycles, followed by nivo maintenance until progressive disease (PD) by RECIST 1.1 or treatment-limiting toxicity. Paired pre/on-treatment samples were available from 16/22 patients, as well as 3 biopsies at progression. The tumor samples were studied using whole exome DNA sequencing (including germline DNA) and RNA-sequencing coupled to Ocean Genomics TxomeAI data analysis pipeline. **Results:** 6/11 evaluable patients had PD; 5 patients showed clinical activity of treatment (3 with stable disease, 2 with partial response). The frequency of deleterious mutations in *TP53* and *RB1* was 91% and 64%, respectively. Mutations in *HLA-A* were more common in baseline samples from patients with PD than those with clinical activity. New *TP53* and *PLEC* mutations were found 4 of 6 patients with PD in week 4 samples vs baseline. The baseline tumor mutational burden was not associated with treatment sensitivity and prominently increased in week 4 biopsies of PD patients. All four molecular SCLC transcriptomic subtypes based on the expression of *ASCL1*, *NEUROD1*, and *POU2F3* were present in the trial with SCLC-A being the most common (9/16 cases). All patients with clinical activity to ipi/nivo were of SCLC-A subtype. 2/16 of cases showed a different molecular subtype after 4 weeks of treatment: one case with SCLC-N switched to SCLC-A and another case converted from SCLC-A to SCLC-N. Comparison of baseline and on-treatment samples showed upregulation of transcripts associated with T-cell activation and PD-1 signaling. In the 3 biopsies at progression, transcriptomic changes included reduction of neutrophil degranulation, type 1/2 interferon and signatures, as well as down-regulation of β -2 microglobulin, while cell cycle and mitotic prophase pathways were overexpressed. **Conclusions:** Dual checkpoint blockade using nivo/ipi has a prominent immunomodulatory role in extensive stage SCLC characterized by increased local adaptive immune responses, reduced HLA class-I antigen presentation and change in the molecular subtype in a subset of cases. We identified genomic features associated with treatment sensitivity/resistance. Clinical trial information: NCT03670056. Research Sponsor: Bristol-Myers Squibb.

Durvalumab with chemotherapy as first line treatment in advanced pleural mesothelioma: A phase 3, randomised trial (DREAM3R). *First Author: Patrick M. Forde, Bloomberg–Kimmel Institute for Cancer Immunotherapy, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD*

Background: Two phase 2 trials of durvalumab plus chemotherapy in advanced pleural mesothelioma exceeded pre-specified efficacy criteria. The recent CM 743 trial showed overall survival (OS) was longer in those assigned ipilimumab and nivolumab (ipi nivo) than standard chemotherapy, however the benefits were primarily in the subgroup with non-epithelioid histology. DREAM3R will determine the effectiveness of durvalumab plus chemotherapy as first line treatment for advanced pleural mesothelioma. The DREAM3R protocol was recently amended to allow treatment with ipi nivo as per CM 743 in the control group, and to confine further accrual to epithelioid subtype. **Methods:** Treatment-naïve patients with advanced, epithelioid pleural mesothelioma will be randomized (1:1) to either experimental group treatment: durvalumab 1500 mg every 3 weeks plus chemotherapy (pemetrexed 500 mg/m² plus either cisplatin 75 mg/m² or carboplatin AUC 5) every 3 weeks for 4-6 cycles, followed by durvalumab 1500 mg every 4 weeks until disease progression, unacceptable toxicity or patient withdrawal, or control group treatment: physician's choice of either chemotherapy or ipi nivo (up to 2 years). The target sample size of 480 recruited over 33 months, with follow up for another 18 months provides over 85% power if the true hazard ratio for OS is 0.70, with 2-sided alpha of 0.05, assuming a median OS of 18 months in the control group. Key eligibility criteria: Epithelioid pleural mesothelioma; measurable disease per RECIST 1.1 modified for mesothelioma; ECOG PS 0-1; and adequate hematologic, renal, and liver function. Exclusions: Prior systemic anticancer treatment for pleural mesothelioma, diagnosis based solely on cytology or fine needle aspiration biopsy, contraindication to immunotherapy or conditions requiring immunosuppressive agents or corticosteroids. Participants are stratified at randomization for: age (18-70 years vs. > 70), sex, planned control regimen (chemotherapy or ipi nivo), platinum (cisplatin vs. carboplatin) and geographic region (USA vs. ANZ). The primary endpoint is OS. Secondary endpoints include progression-free survival; objective tumor response; adverse events; health-related quality of life; and use of healthcare resources in ANZ. Tertiary objectives are to identify potential prognostic and/or predictive biomarkers (including those identified in prior phase 2 studies, PD-L1 expression, tumor mutation burden, genomic characteristics, and HLA subtypes), validation of radiological measures of response, and studies of possible radiomic biomarkers in mesothelioma. The study is active and enrolling in both ANZ and in the US. Clinical trial information: NCT04334759 and ACTRN12620001199909. Research Sponsor: AstraZeneca.

Utilization of circulating tumor DNA (ctDNA) analysis to detect minimal residual disease post-surgery and disease progression in metastatic thymic tumors. *First Author: Fatemeh Ardeshtir-Larijani, Indiana University, Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: Thymic epithelial tumors (TETs) are rare and tend to have an indolent disease course. Follow-up consists of physical examinations and routine imaging (CT scans) with no currently available biomarkers to complement surveillance. This study aimed to assess the utility of ctDNA in MRD detection and disease monitoring in TETs. **Methods:** From Nov 2020 till Feb 2022, ctDNA analysis using a tumor-informed mPCR-NGS (Signatera) assay was performed on 29 patients (pts) with primary (pTETs) or metastatic TETs (mTETs). For pts with early-stage disease, the baseline ctDNA was measured 4-8 w post-surgery and repeated q3m. For mTETs, ctDNA was measured at the first visit, and then q3m with interval CT scan q3-4 m. ctDNA was quantified as mean tumor molecules (MTM)/mL of plasma. All pts had at least one measurement (up to 4). GraphPad was used for statistical analysis. **Results:** Of 29 pts overall, 9 pts were excluded at the time of analysis for various reasons; a) insufficient specimen (n=5), b) presence of concurrent active cancer (n=2), and c) final report delay (n=2). Of 20 evaluable pts, 7 pts had pTETs and 13 mTETs. The median age was 50 yrs (range, 17-72), and WHO histology distribution of AB=3, B1=5, B2=9, B3=12, TC=3. History of autoimmune disease and second malignancy (not active at the time of obtaining ctDNA) was reported in 33% (n=9) and 40% (n=8) of evaluable pts, respectively. Of 13 metastatic pts, 6 had stage IVA with pleural-only metastasis, 7 pts had Stage IVB with 2 extra-thoracic (liver, adrenal), and 5 with intrathoracic (lung, chest wall, and LNs) involvement. From 7 pTETs, 6 pts had R0 resection with undetectable post-operative ctDNA, while R1 resection with detectable ctDNA was reported (0.47 MTM/mL) in one pt. In mTETs, the mean level of ctDNA in pts with the stable disease was 0.18 MTM/mL (0.1-0.2), pleural-only progression 1.26 MTM/mL (0.1-1.9), and progressive disease (primary and/or pleural) 7.67 MTM/mL (5.04-9.5). Comparing the mean level of ctDNA in clinically stable metastatic pts with those who had progression, pts with pleural-only progression did not have a significantly higher level of ctDNA (p=0.51). In contrast, pts with primary and/or pleural progression had significantly higher levels of ctDNA (p=0.02). The level of ctDNA correlated with tumor size. An increase of 4-6mm in tumor size was associated with an approximate 0.2 MTM/mL increase in ctDNA or making the undetectable status detectable. **Conclusions:** The ctDNA level correlates well with the tumor volume in mTETs. In pTETs, ctDNA was negative following R0 resection but not in the R1, supporting its potential use as a surrogate biomarker for MRD. This is a pilot study, and the expansion of these data is ongoing to validate the utility of ctDNA testing in these settings. If validated, ctDNA may augment or minimize the routine use of CT scans for disease monitoring in resected and mTETs. Research Sponsor: Alumni award hematology/oncology fellowship/ Indiana University.

Poster Session

A randomised phase II trial of niraparib versus active symptom control in patients with previously treated mesothelioma: NERO. *First Author: Gareth Owen Griffiths, Cancer Research UK Clinical Trials Unit, University of Southampton, Southampton, United Kingdom*

Background: Malignant mesothelioma is a universally lethal cancer that has been increasing over the last three decades. No treatment has been licenced for patients with relapsed mesothelioma after receipt of licenced systemic anti-cancer therapy in the UK. A previous single-arm phase IIa trial (MiST1) evaluated the efficacy of Poly (ADP-ribose) polymerase (PARP) inhibition in mesothelioma, which met its primary endpoint with 15% of patients having durable responses exceeding 1 year. Therefore, there is a need to evaluate PARP inhibitors in a randomised trial in relapsed mesothelioma patients. NERO is currently in progress in this setting. **Methods:** Co-ordinated by the CRUK Southampton Clinical Trials Unit, NERO is a multicentre, two arm, open-label UK randomised phase II trial comparing niraparib + Active Symptom Control (ASC) versus ASC alone in mesothelioma patients who have relapsed after previously receiving platinum-based systemic therapy. NERO is not restricted by line of therapy and treatment allocation ratio is 2:1 (niraparib + ASC:ASC), stratified by histology and response to prior platinum-based therapy. Participants will receive either niraparib + ASC or ASC alone for a period of 24 weeks. Participants will be treated until disease progression, withdrawal, death or development of significant treatment limiting toxicity. Participants randomised to niraparib will receive 200/300 mg every day in a 21-day cycle. The primary endpoint is progression-free survival, where progression is determined by modified RECIST or RECIST 1.1; investigator reported progression; or death from any cause, whichever comes first. Time to event data will be analysed and presented using Kaplan-Meier curves according to the intention to treat principle, with treatment-related intercurrent events handled using the treatment strategy policy, and study withdrawal following the "while on study" strategy. A Cox proportional hazards model will be used to calculate the Hazard Ratio, 95% CIs and p-value adjusted for stratification factors. Median PFS and 6 and 12 month PFS will also be reported. Secondary endpoints include overall survival, best overall response, 12 and 24 week disease control, duration of response, treatment compliance and safety/tolerability. Patients consent to provide mandatory diagnostic tissue blocks, blood samples and an optional stool sample for translational research. These will be used to interrogate homologous recombination deficiency and its association with response in NERO, translational research comprising multi-omic analysis with multiplex immune landscape phenotyping will be analysed and correlated with clinical outcome using machine learning. NERO opened in July 2022 and will be run in approximately 10 UK secondary care hospitals with the aim of recruiting 84 evaluable patients (recruitment is currently 24 on 11-Jan-2023). Clinical trial information: NCT05455424. Research Sponsor: Asthma and Lung UK; GSK.

Nivolumab with chemotherapy in pleural mesothelioma after surgery: The NICITA trial. *First Author: Rajiv Shah, Department of Thoracic Oncology/ Internal Medicine, Thoraxklinik, Heidelberg University Hospital and Translational Lung Research Center Heidelberg (TLRC), German Center for Lung Research (DZL), Heidelberg, Germany*

Background: Pleural mesothelioma (PM) is a highly aggressive cancer of the pleura, predominantly caused by prior asbestos exposure. Currently, there is no approved standard therapy for the treatment of early-stage PM. In most cases a multimodal therapy is recommended consisting of locoregional treatment by surgical cytoreduction via extended pleurectomy/decortication (eP/D), which, if feasible, can be combined with hyperthermic intrathoracic chemoperfusion (HITOC), together with inductive or adjuvant chemotherapy. Considering the immunogenic effects of chemotherapy on the tumor microenvironment, synergistic effects are expected when such a treatment is combined with immune checkpoint inhibitor therapy. In addition, interactions between immune infiltrates and mesothelioma cells play a role in the advent of PM, also implying a beneficial role for immunotherapy in this entity. This is also supported by recent clinical data that demonstrated beneficial effects of immune checkpoint inhibitors in patients with advanced PM. The NICITA trial is an investigator-initiated trial, investigating the combination of adjuvant chemotherapy with immune checkpoint inhibitor compared to chemotherapy alone in radically resected patients with early stage PM. **Methods:** The NICITA trial is a randomized, open-label, phase II clinical trial that is conducted in 14 centers across Germany. Eligible patients have been diagnosed with PM in tumor stages I-III (UICC 8th edition) and epithelioid subtype, and must have undergone cytoreductive surgery by eP/D with or without HITOC. Patients will be randomized 1:1 to receive either a combination of 4 cycles of pemetrexed/platinum-based adjuvant chemotherapy and nivolumab (480 mg q4w) followed by nivolumab maintenance therapy (12 cycles, 480 mg q4w) or 4 cycles of adjuvant chemotherapy only. Stratification will take place according to previous HITOC treatment (yes vs. no), ECOG status (0, 1 vs. 2), and achievement of macroscopic complete resection (yes vs. no). The primary endpoint of this trial is time-to-next-treatment. Secondary endpoints include additional measures of efficacy (progression-free survival, overall survival, measures of treatment-beyond-progression) and quality of life, as well as the assessment of safety. Furthermore, a comprehensive longitudinal collection of biomarker samples, including tumor tissue, blood, and stool samples, for an accompanying translational research project is implemented in this clinical trial. Sample size justification: the recruitment of 46 patients to each arm with a low drop-out rate of 13% appears feasible resulting in 40 patients to be analyzed per arm. This sample size will permit a descriptive comparison and adequately describe the tested treatment options as deduced from the precision of the median TNT confidence interval estimate. As of February 2nd 2023, 85 of planned 92 patients have been enrolled into the NICITA trial. Clinical trial information: NCT04177953. Research Sponsor: Bristol Myers Squibb GmbH & Co. KGaA (BMS).

Phase 2 randomized trial of neoadjuvant or palliative chemotherapy with or without immunotherapy for peritoneal mesothelioma (Alliance A092001). *First Author: Aaron Scott Mansfield, Mayo Clinic, Rochester, MN*

Background: Peritoneal mesothelioma is a rare and poorly studied disease with few treatment options. For patients (pts) who are not surgical candidates, treatment recommendations for systemic therapy have been extrapolated from clinical trials for pleural mesothelioma that commonly exclude pts with peritoneal mesothelioma. Recently, the combination of the PD-1 inhibitor nivolumab and the CTLA-4 inhibitor ipilimumab received FDA-approval for the frontline treatment of non-resectable pleural mesothelioma. Additionally, a prospective, non-randomized phase 2 trial demonstrated activity with combined PD-L1 (atezolizumab) and VEGF (bevacizumab) blockade in peritoneal mesothelioma. In parallel, encouraging activity with combined chemo-immunotherapy has been reported in pleural mesothelioma. Given the benefits observed with immunotherapy, and the potential to improve upon those with chemotherapy and VEGF inhibition, we seek to determine whether the addition of the PD-L1 inhibitor atezolizumab improves outcomes with chemotherapy and bevacizumab in pts with newly diagnosed peritoneal mesothelioma. **Methods:** Alliance for Clinical Trials in Oncology A092001 is a prospective, randomized phase 2 clinical trial. All pts with newly diagnosed peritoneal mesothelioma will be randomized 1:1 using a dynamic allocation Pocock-Simon procedure to receive carboplatin, pemetrexed and bevacizumab, with or without atezolizumab, every 21 days for four cycles. Patients who are eligible to proceed with surgery after four cycles of therapy will then do so. Pts who are not eligible to proceed with surgery may receive maintenance bevacizumab and atezolizumab, or second-line atezolizumab with bevacizumab until progression of disease or toxicity. The primary objective is to determine if frontline treatment with carboplatin, pemetrexed, bevacizumab and atezolizumab results in a superior best response rate (RR) to carboplatin, pemetrexed and bevacizumab as determined by RECIST. With 31 eligible pts per arm (62 eligible total), this randomized design has 80% power to detect an improvement in the RR from 20% to 45%, with a 1-sided significance level of 0.10 where an interim futility analysis will be conducted after 32 pts are enrolled. Stratification factors include eligibility for cytoreductive surgery at diagnosis and histologic subtype. Secondary endpoints include progression-free survival, overall survival and adverse events. As integrated biomarkers, we will determine if soluble mesothelin-related peptides and megakaryocyte potentiating factor correlate with responses. This trial was recently approved by the National Cancer Institute Central IRB and is activating at sites across the country. Clinical trial information: NCT05001880. Research Sponsor: U.S. National Institutes of Health; Alliance.

Neoadjuvant immunotherapy in sarcomatoid mesothelioma (Alliance A082101). *First Author: Aaron Scott Mansfield, Mayo Clinic, Rochester, MN*

Background: Sarcomatoid mesothelioma is the most aggressive form of pleural mesothelioma and is associated with the worst prognosis of the histologic variants of this disease. In the Checkmate 743 clinical trial the patients with sarcomatoid mesothelioma who received ipilimumab and nivolumab had survival outcomes that were similar to those of patients with epithelioid mesothelioma. In comparison, the patients with sarcomatoid mesothelioma who received chemotherapy had the worst outcomes in this trial, highlighting the known limited efficacy of chemotherapy against this histologic variant. Checkmate 743 demonstrated that ipilimumab and nivolumab is a new standard of care for non-epithelioid mesothelioma. Surgery typically has not been offered to this group of patients given their historically poor outcomes. With the significant survival gains seen in patients with sarcomatoid mesothelioma treated with immunotherapy, we hypothesized that surgery may extend the benefits seen with immunotherapy. **Methods:** Alliance for Clinical Trials in Oncology A082101 is a prospective, phase 2 nonrandomized clinical trial for patients with sarcomatoid mesothelioma. The co-primary objectives are to determine the percentage of patients with potentially resectable sarcomatoid mesothelioma able to proceed with surgery after neoadjuvant ipilimumab and nivolumab, and the progression-free survival (PFS) at 12 months (12-month PFS). For sample size determination, we assumed that if the true rate of surgery is 75% or greater, it would indicate that neoadjuvant immunotherapy is feasible to be given prior to surgery. On the other hand, if the true rate of surgery is 50% or less it would indicate that neoadjuvant immunotherapy is not worthy of further investigation. Twenty-six (26) eligible patients will be needed to receive neoadjuvant immunotherapy. If 16 or fewer of the 26 eligible patients proceed to surgery, it will be concluded that the experimental therapy is not worthy of further investigation. Otherwise, it will be concluded that the experimental therapy is worthy of further investigation. Safety monitoring will be done through a 6-week run-in for the first 10 patients to assess for pre-operative and post-operative toxicities and complications. Sequential boundaries will be used to monitor severe toxicity and complication rates. Accrual will be halted if excessive numbers of severe toxicity and complications in pre-operative and post-operative phases are seen. Tumor and blood-based biomarkers will be included as exploratory biomarkers. Clinical trial information: NCT05647265. Research Sponsor: U.S. National Institutes of Health; Alliance.

NeoCOAST-2: A phase 2 study of neoadjuvant durvalumab plus novel immunotherapies (IO) and chemotherapy (CT) or MEDI5752 (volrustomig) plus CT, followed by surgery and adjuvant durvalumab plus novel IO or volrustomig alone in patients with resectable non-small-cell lung cancer (NSCLC). *First Author: Florian Guisier, Department of Pneumology, Rouen University Hospital, Rouen, France*

Background: Neoadjuvant platinum-based CT plus IO prolongs event-free survival (EFS) and increases pathological complete response (pCR) rate in patients with resectable NSCLC vs CT alone (Forte et al. N Engl J Med 2022). IO+IO+CT combinations have the potential to further improve pCR and survival outcomes. The phase 2 NeoCOAST-2 study (NCT05061550) is evaluating multiple neoadjuvant IO+IO+CT combinations in patients with resectable, early stage NSCLC. Novel IO molecules being evaluated include the anti-CD73 monoclonal antibody (mAb), oleclumab; the anti-NKG2A mAb, monalizumab; and the PD-1/CTLA-4 bispecific mAb, volrustomig. The latter recently demonstrated durable responses vs a PD-1 inhibitor plus CT as first-line treatment for patients with metastatic NSCLC (ESMO 2022; LBA56). Here we describe the NeoCOAST-2 study design. **Methods:** This randomized, open-label, multicenter study will enroll approximately 210 patients with previously untreated, histologically/cytologically confirmed, resectable Stage IIA–IIIB (AJCC 8th edition) NSCLC. Patients will be stratified by PD-L1 expression (< 1% vs ≥ 1%) and receive treatment with durvalumab + oleclumab + CT, durvalumab + monalizumab + CT, or volrustomig + CT every 3 weeks for 4 cycles prior to surgery, followed by adjuvant durvalumab + oleclumab, durvalumab + monalizumab, or volrustomig for up to 1 year or until disease progression per RECIST v1.1. Surgery should occur within 40 days after the last dose of neoadjuvant therapy and adjuvant therapy should commence within 10 weeks after surgery. The primary endpoints are pCR rate (per blinded independent pathologist review) and safety and tolerability. Secondary endpoints include investigator-assessed EFS, disease-free survival and overall survival, feasibility to surgery, major pathological response rate, objective response rate following neoadjuvant therapy, pharmacokinetics, immunogenicity, and changes in circulating tumor DNA. The study is currently recruiting patients across the US, Europe, Canada, and Asia. Clinical trial information: NCT05061550. Research Sponsor: AstraZeneca.

A phase I-III platform study evaluating the safety and efficacy of multiple therapies in patients with biomarker-defined locally advanced, unresectable stage III non-small-cell lung cancer (NSCLC). *First Author: Luis G. Paz-Ares, Hospital Universitario, 12 de Octubre, Universidad Complutense de Madrid, Madrid, Spain*

Background: Durvalumab following chemoradiation (CRT) is a standard of care for unresectable stage III NSCLC, but there remains an unmet need for improved therapeutic options among patients with driver-mutated tumors that are unresponsive to immunotherapy. As targeting of specific driver mutations (e.g. *ALK*, *RET*, *ROS1*) has proven effective in the metastatic setting, it is hypothesized that outcomes could also be improved for patients with driver-mutated stage III NSCLC. **Methods:** B042777 (NCT05170204) is a phase I-III platform study evaluating the safety and efficacy of multiple targeted therapies versus durvalumab following CRT in patients with locally advanced, unresectable stage III NSCLC. Biomarker eligibility is determined via local tissue testing or central testing within the BX43361 master screening study (NCT05419375). Biomarker-eligible patients are enrolled into the relevant cohort and randomized 1:1 to receive durvalumab or targeted therapy (alectinib [*ALK*], entrectinib [*ROS1*], or pralsetinib [*RET* fusion+]). New cohorts may be added in the future. Key inclusion criteria: locally advanced, unresectable stage III NSCLC, age ≥ 18 years, ≥ 2 prior cycles of concurrent or sequential CRT (cCRT or sCRT), and ECOG PS 0–2. Patients are stratified based on staging (IIIA vs IIIB or IIIC), CRT type (cCRT vs sCRT), and PD-L1 status (tumor cell score $< 1\%$ vs $\geq 1\%$ vs unknown) and will receive investigational treatment for three years or durvalumab for one year, until progression or maximum duration of treatment, unacceptable toxicity, consent withdrawal, or death. Primary endpoint: progression-free survival (RECIST v1.1) by blinded independent central review. Key secondary endpoints: distant metastasis-free survival, time to CNS progression, objective response rate, duration of response, overall survival, and safety (adverse events). Time to confirmed deterioration and patient-reported outcomes will be assessed through questionnaires. Tumor response will be assessed by CT/MRI imaging at regular intervals. Enrollment is ongoing (target of 320 patients) across 200 sites in 11 countries. As of 7 February 2023, five patients have been randomized. This trial in progress was previously presented at ELCC, Luis Paz-Ares *et al.* (#744), and reused with permission. Clinical trial information: NCT05170204. Research Sponsor: These trials are sponsored by F. Hoffmann-La Roche Ltd.

Poster Session

Phase 3 study of durvalumab with SBRT for unresected stage I/II, lymph-node negative NSCLC (PACIFIC-4/RTOG3515). *First Author: Clifford Grant Robinson, Department of Radiation Oncology, Washington University in St. Louis/Siteman Cancer Center, St. Louis, MO*

Background: Stereotactic body radiation therapy (SBRT) is a standard treatment for patients with unresectable (UR) stage I/II, lymph-node negative NSCLC, with excellent safety and high rates of primary tumor control. Despite predominant regional and distant failure that increases with tumor size, no adjuvant therapy is approved for these patients. Durvalumab is a selective, high-affinity, human IgG1 monoclonal antibody that blocks PD-L1 binding to PD-1/CD80. In the placebo-controlled, phase 3 PACIFIC trial of patients with stage III UR-NSCLC without disease progression on/after concurrent chemoradiotherapy, durvalumab improved progression-free survival (PFS) and overall survival (OS) with manageable safety (Antonia, *et al.* 2017; 2018), leading to its approval in stage III UR-NSCLC. Osimertinib is a 3rd-generation, irreversible CNS-active EGFR tyrosine kinase inhibitor that selectively inhibits NSCLC tumors with EGFR-sensitizing mutations (EGFRm). In the recent placebo-controlled, phase 3 ADAURA trial, osimertinib demonstrated statistically significant and clinically meaningful improvement in disease-free survival (DFS) (HR, 0.20 [99.12% CI, 0.14–0.30], $P < 0.001$) in patients with resected stage IB-IIIa EGFRm NSCLC (Wu, *et al.* 2020), leading to its approval in an adjuvant setting. Based on data for durvalumab and osimertinib in the early-stage setting, PACIFIC-4 is designed to assess the efficacy and safety of durvalumab combined with SBRT in patients with stage I/II UR-NSCLC and osimertinib after SBRT in patients with stage I/II EGFRm UR-NSCLC. **Methods:** PACIFIC-4 (NCT03833154) is an international, phase 3 study with two independent cohorts. Eligible patients are ≥ 18 years of age with stage T1-T3, N0, M0 unresected NSCLC and ECOG PS 0–2. The main cohort of approximately 630 patients will be randomized (1:1) in a double-blind manner, stratified by tumor size and location, to receive durvalumab (1500 mg IV) or placebo every 4 weeks for up to 26 cycles with concurrent standard of care (SoC) SBRT. The primary endpoint in this cohort is PFS (RECIST v1.1) by blinded independent central review; other endpoints include OS, health-related quality of life, and safety. The protocol was amended (v4) to exclude patients with an identified EGFRm from the main cohort and add a separate cohort of approximately 60 patients with EGFRm (L858R or Ex19del) who will receive osimertinib 80 mg PO QD, following SoC SBRT, for up to 36 months. The primary endpoint in this cohort is 4-year PFS (RECIST v1.1) by independent central review; secondary endpoints include PFS, OS, and safety. Trial recruitment is ongoing. Previously presented at the European Lung Cancer Congress (ELCC) 2022, FPN (Final Publication Number): 122TiP, Clifford Robinson *et al.* – Reused with permission. Clinical trial information: NCT03833154. Research Sponsor: AstraZeneca.

Poster Session

A randomized, double blinded, multicenter phase 3 study of platinum-based chemotherapy with or without QL1706 as adjuvant therapy in completely resected stage II-IIIB NSCLC. *First Author: Yuming Zhu, Department of Medical Oncology, Shanghai Pulmonary Hospital, Shanghai, China*

Background: Adjuvant atezolizumab is approved for PD-L1 positive stage II-IIIA NSCLC in USA and China. To date, there are few clinical studies on dual immune checkpoint inhibitors in adjuvant settings of NSCLC. QL1706, a MabPair product, is a novel bifunctional antibody containing a mixture of anti-PD-1 IgG4 and anti-CTLA-4 IgG1 antibodies. QL1706 monotherapy has demonstrated good safety and promising antitumor activity in advanced solid tumors in a phase Ia/Ib study with 518 patients, including 146 NSCLC patients. Meanwhile, in NSCLC patients with negative oncogene drivers, QL1706 plus 2 cycles of chemotherapy as first line treatment resulted in an ORR of 58.6% (17/29) and the mPFS was 6.97 months. Furthermore, in the EGFR mutant NSCLC patients who previously were treated with EGFR-TKI, QL1706 plus platinum-based chemotherapy and bevacizumab showed promising efficacy with an ORR of 64.5% (20/31). This study is designed to investigate the efficacy and safety of QL1706 or placebo plus platinum doublet chemotherapy as adjuvant treatment in stage II-IIIB NSCLC. **Methods:** In this phase III, randomized, double-blind, placebo-controlled, multicenter study, 632 eligible pts, who is completely resected stage II-IIIB NSCLC (AJCC 8th) with negative EGFR, ALK etc, will be enrolled. Pts will be randomized 1:1 to receive QL1706 (5 mg/kg) or placebo plus chemotherapy, administered every 3 weeks (Q3W). The regimen of vinorelbine/paclitaxel plus cisplatin/carboplatin is chosen for squamous NSCLC, while pemetrexed/vinorelbine plus cisplatin/carboplatin for non-squamous NSCLC. Randomization will be stratified by PD-L1 TPS (ie, $< 1\%$, $\geq 1\%$), disease stage (stage II, III) and predominant tumor histology (ie, squamous vs non-squamous). The primary endpoint is disease-free survival (DFS) per investigators in PD-L1 TPS $\geq 1\%$ pts and in all randomized pts, which will be tested hierarchically. An interim analysis is to occur when about 70% DFS events achieved in pts with PD-L1 $\geq 1\%$. Enrollment began in Nov, 2022. ClinicalTrials.gov NCT05487391. Clinical trial information: NCT05487391. Research Sponsor: Qilu Pharmaceutical Co., Ltd.

Poster Session

A master screening study to determine biomarker status and trial eligibility for patients with malignant tumors. *First Author: Benjamin J. Solomon, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Targeting of oncogenic driver alterations has proven to be an effective clinical approach across many tumor types. As a result of the approval of targeted therapies against oncogenic driver alterations, molecular biomarker testing is commonly recommended for patients with advanced/metastatic non-small cell lung cancer (NSCLC) before initiation of first-line treatment. Although there are emerging clinical trial data using targeted therapies in patients with early-stage NSCLC, currently molecular biomarker testing is not universally performed as part of routine clinical practice in the early-stage setting. Screening platforms can be utilized to provide comprehensive, validated biomarker testing to facilitate access to clinical trials for appropriate investigational therapies, based on biomarker status. This type of approach aims to be more efficient and to streamline patient recruitment and improve patient access to clinical trials where biomarker testing is not currently performed as part of routine care, especially when the biomarkers of interest are at low prevalence. **Methods:** This global, non-Investigational Medicinal Product (non-IMP), multicenter master screening study (NCT05419375) provides centralized tissue-based testing to determine patients' biomarker eligibility for linked Roche clinical trials. Currently this study is only open to screening patients for a linked platform study in unresectable stage III NSCLC (NCT05170204). However, it is envisaged that this screening study will be expanded to support additional clinical trials and indications in the future. Eligible patients must be aged ≥ 18 years with locally advanced, unresectable stage III NSCLC (according to AJCC 8th edition), an ECOG PS of 0–2, confirmed availability of a formalin-fixed paraffin-embedded tumor specimen obtained prior to chemoradiation, and adequate hematologic and end-organ function. If a patient is found to have an oncogenic driver mutation and is considered a good candidate for a linked clinical trial, the investigator may propose that they be screened into the respective study. Tumor tissue samples will be centrally tested by validated molecular tests for the presence of specific genetic alterations: *EGFR*, *ALK*, *ROS1*, *KRAS*, *BRAF*, *HER2*, *RET*, *MET*, and *NTRK1/2/3*. Immunohistochemistry may also be performed to determine PD-L1 expression as required by the linked trial eligibility criteria. The primary objective of this screening trial is to determine the biomarker status of patients and their eligibility to participate in a linked clinical trial. Exploratory objectives include characterization of biomarker profiles and patients' subsequent treatment. No therapeutic intervention will be administered in this study. Enrollment is ongoing across 51 sites in ten countries, with a target enrolment of 15,000 patients. As of 9 February 2023, 27 patients have been enrolled. Clinical trial information: NCT05419375. Research Sponsor: This study is sponsored by F. Hoffmann-La Roche Ltd. Third-party medical writing assistance, under the direction of the authors, was provided by Vanessa Poon, BSc of Ashfield MedComms, an Inizio company, and was funded by F. Hoffmann-La Roche Ltd.

Phase 3 trial of durvalumab combined with domvanalimab following concurrent chemoradiotherapy (cCRT) in patients with unresectable stage III NSCLC (PACIFIC-8). *First Author: Mustafa Özgüroğlu, Istanbul University—Cerrahpaşa, Cerrahpaşa School of Medicine, Istanbul, Turkey*

Background: The PACIFIC trial (NCT02125461) established up to 12 months of consolidation therapy with durvalumab as standard of care (SoC) for patients with unresectable stage III non-small-cell lung cancer (NSCLC) and no disease progression after platinum-based cCRT. To improve outcomes further in this population, novel immunotherapy combinations that build on the backbone of PD-L1 inhibition with durvalumab are being explored. Domvanalimab (AB154) is a Fc-silent humanized IgG1 monoclonal antibody that blocks interaction of the T cell immunoreceptor with Ig and ITIM domains (TIGIT; upregulated by immune cells) with CD112 and CD155 (expressed by tumor and antigen-presenting cells), reducing inhibition of T cells and natural killer cells and, thereby, promoting antitumor activity. The combination of TIGIT inhibition with PD-(L)1 inhibition has shown encouraging activity in phase 1 and 2 trials in metastatic NSCLC, with enriched benefit observed among patients with PD-L1 positive tumors (Rodriguez-Abreu, et al. 2020; Niu, et al. 2020). In ARC-7 (NCT04262856), a randomized, phase 2 trial, the combination of domvanalimab and PD-1 inhibition was associated with improvement in progression-free survival (PFS) versus PD-1 inhibition alone (HR, 0.55; 95% CI, 0.31–1.0) in treatment-naïve patients with metastatic NSCLC and high PD-L1 expression (tumor proportion score $\geq 50\%$) (Johnson, et al. 2022). PACIFIC-8 (NCT05211895) is assessing the efficacy and safety of durvalumab combined with domvanalimab as consolidation therapy in patients with PD-L1 positive, unresectable stage III NSCLC and no disease progression after platinum-based cCRT. **Methods:** PACIFIC-8 is a phase 3, double-blind, placebo-controlled, randomized, global trial. Eligible patients (aged ≥ 18 years) must have PD-L1 positive, unresectable stage III NSCLC (tumor cell [TC] expression $\geq 1\%$ by central lab; VENTANA SP263 IHC assay), WHO performance status 0/1, documented EGFR/ALK wild-type tumor status, and not have progressed following definitive, platinum-based cCRT (≥ 2 cycles). Approximately 860 patients will be randomized (1:1) to receive SoC durvalumab (1500 mg IV) combined with either domvanalimab (20 mg/kg IV) or placebo, every 4 weeks for up to 12 months. The primary endpoint is PFS (RECIST v1.1) by blinded independent central review (BICR) in patients with PD-L1 TC $\geq 50\%$. Secondary endpoints include PFS (RECIST v1.1; BICR) in patients with PD-L1 TC $\geq 1\%$, overall survival, objective response rate and duration of response (RECIST v1.1; BICR), safety/tolerability, and patient-reported outcomes. Trial enrollment is ongoing. *Previously presented at the European Society for Medical Oncology (ESMO) Congress 2022, FPN (Final Publication Number): 971TiP, Mustafa Özgüroğlu et al. – Reused with permission.* Clinical trial information: NCT05211895. Randomized phase 3 study of tarlatamab, a DLL3-targeting bispecific T-cell engager (BiTE), compared to standard of care in patients with relapsed small cell lung cancer (DeLLphi-304). *First Author: Luis G. Paz-Ares, Hospital Universitario 12 de Octubre, CNIO-H120 Lung Cancer Unit, Ciberonc and Universidad Complutense, Madrid, Spain*

Background: Small cell lung cancer (SCLC) is an aggressive malignancy for which very few patients achieve long term disease control; response to most treatments is transient and second line treatment options are limited. Delta-like ligand 3 (DLL3) is a Notch ligand aberrantly expressed on the surface of up to 85% of SCLC cells and minimally expressed in normal tissues, making it an attractive therapeutic target. Tarlatamab is a bispecific T cell engager (BiTE) molecule designed to bind DLL3 on target cancer cells and CD3 on T cells, thereby driving T cell-dependent killing of tumor cells. Results from the first-in-human study in patients with relapsed/refractory SCLC (DeLLphi-300; NCT03319940) demonstrate tarlatamab efficacy in pretreated patients with confirmed responses in 23% of patients and median duration of response > 12 months.¹ Median overall survival (OS) was 13.2 months. Grade ≥ 3 treatment-related AEs (TRAEs) occurred in 31% of patients and TRAEs resulted in discontinuation in 4% of patients. This promising efficacy/safety profile is being evaluated further in a phase 2, open-label study in patients with relapsed/refractory SCLC after ≥ 2 lines of prior treatment (DeLLphi-301; NCT05060016). **Methods:** NCT05740566 is a randomized, open-label, phase 3 study of tarlatamab compared with standard of care (SOC) in ~ 700 patients with relapsed SCLC after platinum-based first-line chemotherapy. Patients will be randomized 1:1 to receive tarlatamab or SOC therapy (lurbinectedin or topotecan in US, Canada, Australia, Singapore, Korea; amrubicin in Japan; topotecan in all countries except Japan), stratified by prior anti-programmed cell death 1 (PD-1) or anti-programmed cell death ligand 1 (PD-L1) exposure, chemotherapy-free interval, presence of brain metastases, and SOC (topotecan/amrubicin vs lurbinectedin). The primary objective is to compare the efficacy of tarlatamab with SOC on prolonging OS. Key secondary endpoints include comparison of progression free survival (PFS) based on investigator assessment per Response Evaluation Criteria in Solid Tumors Version 1.1 (RECIST 1.1) and patient-reported outcomes (PRO) including disease-related symptoms, physical function, and global health status of quality of life. Key eligibility criteria include adults with histologically or cytologically confirmed relapsed SCLC who progressed following 1 platinum-based regimen. Patients must have measurable lesions as defined per RECIST 1.1 within the 21-day screening period and must have adequate organ function. Exclusions include untreated or symptomatic central nervous system metastases, history of immune checkpoint inhibitor use resulting in severe immune-mediated adverse event, and previous history of NSCLC. Enrollment is ongoing. References 1. Paz-Ares L, et al. *J Clin Oncol*. DOI:1200/JCO.22.02823. Clinical trial information: NCT05740566. Research Sponsor: Amgen.

Poster Session

Phase 3 study of durvalumab combined with oleclumab or monalizumab in patients with unresectable stage III NSCLC (PACIFIC-9). *First Author: Fabrice Barlesi, Gustave Roussy and Paris Saclay University, Faculty of Medicine, Villejuif / Kremlin-Bicêtre, France*

Background: Based on the findings of the phase 3 PACIFIC trial, durvalumab as consolidation therapy is the standard of care for patients with unresectable Stage III NSCLC and no disease progression following chemoradiotherapy (CRT; the PACIFIC regimen). However, further improvements in outcomes are needed for this population and, to build upon the backbone of PD-L1 inhibition with durvalumab, immunotherapy combinations including anti-TIGIT, anti-CD73, and anti-NKG2a monoclonal antibodies (mAbs) are now being explored. Two potential candidates, oleclumab and monalizumab, have demonstrated encouraging clinical activity in a randomized, phase 2 trial when combined with durvalumab in this setting. Oleclumab (MEDI9447) is a human IgG1 λ mAb that inhibits the function of CD73, to reduce extracellular adenosine production and thus promote antitumor immunity. Monalizumab (IPH2201) is a first-in-class, humanized, IgG4 mAb that prevents NKG2A from binding to HLA-E, which reduces inhibition of natural killer and CD8+ T cells. The combination of each of these molecules with durvalumab consolidation therapy was evaluated in the phase 2 COAST study (NCT03822351). In COAST (n = 189), patients receiving combination therapy reported numerically higher objective response rates (durvalumab plus oleclumab: 30.0%; durvalumab plus monalizumab: 35.5%; durvalumab monotherapy: 17.9%) and prolonged progression-free survival versus durvalumab alone, with no new/significant safety signals (Herbst, et al. 2022). Thus, the combination of oleclumab or monalizumab with consolidative durvalumab warrants further evaluation in a phase 3 trial. **Methods:** PACIFIC-9 (NCT05221840) is a phase 3, double-blind, placebo-controlled, randomized, international trial. Eligible patients (age ≥ 18 years) must have EGFR/ALK wild-type unresectable Stage III NSCLC, a WHO performance status of 0/1, documented PD-L1 status, and must not have progressed following ≥ 2 cycles of definitive, platinum-based concurrent CRT. Approximately 999 patients will be randomized (1:1:1) to receive up to 12 months of treatment (in 28-day cycles) with durvalumab plus either oleclumab (Arm A); monalizumab (Arm B); or placebo (Arm C). The primary endpoint is progression-free survival (RECIST v1.1) by blinded independent central review (BICR). Overall survival is a key secondary endpoint. Other secondary endpoints include objective response rate and duration of response (RECIST v1.1; BICR), patient-reported outcomes, PD-L1 expression on tumor cells relative to efficacy outcomes, and safety/tolerability (CTCAE v5.0). Trial enrollment is ongoing. *Previously presented at the World Conference on Lung Cancer (WCLC) 2022, FPN (Final Publication Number): P1.10-01, Fabrice Barlesi et al.* Clinical trial information: NCT05221840. Research Sponsor: AstraZeneca.

TPS8612

Poster Session

A phase II study to evaluate the efficacy and safety of combination therapy of durvalumab (MEDI4736) and amrubicin in patients with recurrent small cell lung cancer (SCLC): Aphrodite trial, in progress. *First Author: Yuka Kato, Department of Thoracic oncology and Medicine, National Hospital Organization Shikoku Cancer Center, Matsuyama-City, Ehime, Japan*

Background: Immunochemotherapy (ICT) is the standard first-line treatment for extensive stage (ES)-SCLC. However, progression-free survival for patients (pts) treated with ICT as first-line therapy is approximately 5 months, and half of the pts will relapse within 6 months. Several drugs have been approved for the treatment after relapse, and amrubicin has been used as a second-line treatment in Japan for 20 years. However, the efficacy of pts treated with amrubicin is unsatisfactory, the median survival was 9.2 months (pts with sensitive relapse (SR-pts)) and 2.6 months (pts with refractory relapse (RR-pts)), indicating an urgent need for new therapeutic strategies in the treatment of post-relapse SCLC pts. A retrospective study showed significant improvement in survival for patients who progress on immunochemotherapy, treated with same ICI plus chemotherapy as second-line therapy (Trans Lung Cancer Rec. 2020). Cytotoxic chemotherapy introduced immunogenic cell death and the addition of chemotherapy to ICI might have a synergistic effect. Based on these assumptions, the combination of amrubicin with ICI may provide additional benefit for post-progression pts and we are therefore initiating this study. **Methods:** This is an open-label, single-arm, multicenter, physician-initiated Phase 2 study of amrubicin plus durvalumab in Japanese pts with relapsed SCLC. The study is divided into a lead-in cohort (LIC) and a Phase 2 part; the LIC will use a 3+3 design to ensure safety and will proceed to the Phase 2 part if the first 3 pts have no dose limiting toxicity (DLT) or the first 6 pts have only 1 DLT. Eligibility criteria include pts with ES-SCLC who relapse after platinum-containing chemotherapy with durvalumab as first-line therapy, age ≥ 20 , ECOG 0-1. The primary endpoint is 1-year survival. Patients were treated with intravenous amrubicin 40 mg/m² on day 1-3 and durvalumab 1500 mg/body on day 1 every 3 weeks until PD or unacceptable toxicity. The planned number of pts was 18 each with sensitive relapse (SR-pts) and refractory relapse (RR-pts) which was calculated based on the results of a previous randomized controlled trial (J Clin Oncol. 2008). In this trial, the point estimates and two-sided 90% confidence intervals (Clopper Pearson method) for 1-year survival corresponding to the expected 1-year survival were: SR-pts (11/18 patients): 0.611 (90% CI: 0.392-0.801), RR-pts (8/18 0.444 (90% CI: 0.244-0.659). Enrollment began in October 2022, and will be completed by March 2025. Clinical trial information: jRCT2061220036. Research Sponsor: AstraZeneca.

Poster Session

A phase III study of lurbinectedin alone or in combination with irinotecan vs investigator's choice (topotecan or irinotecan) in patients with relapsed small cell lung cancer (SCLC; LAGOON trial). *First Author: Benjamin Besse, Institut Gustave Roussy, Villejuif, France*

Background: Lurbinectedin is a novel synthetic chemical entity that acts as an inhibitor of oncogenic transcription and is active in tumors addicted to transcription. A phase II Basket trial (NCT02454972) in patients with small cell lung cancer (SCLC) treated with lurbinectedin in the second-line setting showed overall response rate (ORR) of 35.2% and median duration of response (DoR) of 5.3 months, with durable responses (43.0% $\geq$ 6 months). Based on these results, lurbinectedin was granted accelerated approval by the US FDA. An ongoing phase I/II trial (NCT02611024) is evaluating the lurbinectedin/irinotecan combination. Preliminary results showed ORR of 62% and median DoR of 5.7 months (2020 World Conference on Lung Cancer) warranting expansion to 100 patients. These results have supported the conduction of a phase III trial (LAGOON - NCT05153239). **Methods:** LAGOON is a randomized phase III clinical trial evaluating two experimental arms (lurbinectedin alone, 3.2 mg/m² D1 q3wk, or lurbinectedin 2 mg/m² D1 plus irinotecan D1, D8 q3wk) versus Investigator's Choice (topotecan D1-5 q3wk or irinotecan D1 q3wk according to label) as control arm in relapsed SCLC patients. Approximately 705 patients will be enrolled. Central randomization will be implemented (1:1:1 ratio). Stratification will be done according to chemotherapy-free interval (CTFI) after first line (sensitive vs. resistant); prior anti-PD-(L)1; baseline central nervous system (CNS) involvement; lactate dehydrogenase value, and Investigator's preference for the Control Arm. Main inclusion criteria include age $\geq$ 18 years, confirmed SCLC diagnosis, one prior line of platinum-containing chemotherapy with/without anti-PD-(L)1, and CTFI $\geq$ 30 days. Patients with CNS metastases can participate if pretreated and radiologically stable for at least 4 weeks. Main exclusion criteria include platinum-naïve patients, patients pretreated with more than one prior chemotherapy regimen (including platinum re-challenge), and prior treatment with lurbinectedin, trabectedin, PM14, or topoisomerase I inhibitors. An Independent Data Monitoring Committee will oversee the conduct of the study. An Independent Review Committee will provide the patient's response at each tumor assessment endpoint to determine the best patient's response and the date of objective response or progression/censoring according to RECIST v.1.1. Clinical trial information: NCT05153239. Research Sponsor: PharmaMar.

Poster Session

Dares: A phase II trial of durvalumab and ablative radiation in extensive stage small cell lung cancer. *First Author: Aditya Juloori, University of Chicago Medical Center, Chicago, IL*

Background: Most patients diagnosed with small cell lung cancer have extensive stage disease (ES-SCLC) at presentation, portending a poor prognosis with median survival rate of 9 - 11 months and a 2-year overall survival (OS) of less than 5%. Checkpoint inhibitors have recently transformed the landscape for first-line treatment for ES-SCLC patients with the CASPIAN and IMpower133 trials demonstrating an OS benefit with the addition of Durvalumab and Atezolizumab to chemotherapy, respectively. Hypofractionated ablative radiation therapy (RT) provides effective local metastasis control. Increasing evidence suggests that apart from its direct effects, ablative RT can trigger the innate and adaptive immune system. Beyond synergistic mechanisms of modulating the immune response, direct tumor debulking by radiation may also be particularly well suited as an adjunct to immunotherapy. Such upfront cytoreduction can relieve tumor-related immunosuppression and prevent early treatment failure at sites of initial involvement. Prior studies have demonstrated OS and PFS benefits to the addition of local therapy in metastatic non-small cell lung cancer. Multi-site ablative RT has also been shown to be safe in the setting of immunotherapy in multiple published prospective trials. We hypothesize that the addition of RT to chemotherapy and Durvalumab for newly diagnosed ES-SCLC patients will improve PFS. **Methods:** 49 patients will be enrolled across four institutions in this phase II clinical trial. Treatment naïve ES-SCLC patients with PS 0-2 who have at least one RECIST measurable lesion meeting criteria for ablative radiation will be eligible for enrollment. Patients with symptomatic brain metastasis will undergo cranial radiotherapy prior to starting on trial. Patients will be treated with four cycles of platinum/etoposide and Durvalumab. During cycle 2, patients will undergo ablative radiation therapy to 1 - 4 sites of extracranial disease. Radiation dose and organ at risk (OAR) constraints are consistent with NRG BR001. During planning, OAR constraints will be prioritized over tumor coverage. Following four cycles of chemotherapy and Durvalumab, patients will continue with maintenance Durvalumab 1500 mg q28 days until progression, toxicity, or study withdrawal. The primary endpoint is PFS. Using a historic control of 5 month median PFS with chemo/immunotherapy from CASPIAN and IMpower133, we hypothesized that the addition of ablative RT would improve the PFS from 5 months to 8 months. Sample size of 49 patients was calculated for 80% power with alpha of 0.1. Secondary endpoints include overall survival, time to second line therapy, response rate, and rate of grade 3+ adverse events. Peripheral blood, stool, nasal, and buccal samples will be obtained at baseline, after RT, and at the time of progression and/or immune-related toxicity and will be used for exploratory analysis. NCT05068232. Clinical trial information: NCT05068232. Research Sponsor: AstraZeneca.

Prophylactic cerebral irradiation or active brain magnetic resonance imaging surveillance in small-cell lung cancer patients (EORTC-1901: PRIMaLung). *First Author: Antonin Levy, Gustave Roussy, Villejuif, France*

Background: PRIMaLung is an EORTC-sponsored study. Primary objective is to show that overall survival with brain MRI surveillance alone is non-inferior to brain MRI surveillance combined with PCI in patients with SCLC. PCI is currently SOC in most institutions, but can be associated with neurocognitive toxicity and impact quality of life. 600 patients will be recruited from 50 EORTC centres in 10 countries. This study is currently recruiting and will play an important role in clarifying whether MRI surveillance is a viable strategy in SCLC. Furthermore, it will answer important questions about the role of PCI in the era of immunotherapy, particularly in ES-SCLC. **Methods:** Key eligibility: ECOG performance status $\leq$ 2 patients with SCLC (Limited or Extensive-Stage, stage I-IV) who did not progress after ($\leq$ 16 weeks from day 1 of last cycle of chemotherapy to randomisation) completed standard therapy. Absence of progression, brain metastases or leptomeningeal disease after completing therapy. Trial Interventions: Patients will be randomised 1:1 to receive brain MRI surveillance with or without PCI (25Gy in 10 fractions). Primary objective - to show that overall survival with brain MRI surveillance alone is non-inferior to brain MRI surveillance combined with PCI. Secondary objectives - cognitive failure-free survival, quality of life and acute/late toxicities according to CTCAE v5.0. The trial was open to recruitment on 27/10/2022. Three countries open to date (Belgium, Switzerland, UK). Further sites in France, Poland and Austria will be open to recruitment Q1 2023. The first patient has been randomized on the 4th of January 2023. Further information: <https://clinicaltrials.gov/ct2/show/NCT04790253> contact: 1901@EORTC.org. Clinical trial information: NCT04790253. Research Sponsor: Astra Zeneca; EORTC LCG, PHRC-K (France), Ligue contre le Cancer (France), CE (Belgium), Swiss Cancer League (Switzerland).

Phase II study of hemithoracic intensity-modulated pleural radiation therapy (IMPRINT) for patients with pleural metastases from thymic malignancies. *First Author: Andreas Rimner, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pleural metastases are common sites for recurrence and progression in patients with thymic malignancies. The management of pleural metastases typically involves surgical resection with or without neoadjuvant or adjuvant systemic therapy. After surgical resection of pleural metastases, the 5-year progression-free survival (PFS) rate is about 29-45%. While radiation therapy (RT) is standardly used in the management of locally-advanced thymic malignancies, the role of RT in patients with pleural metastases is unclear. Intensity-modulated pleural radiation therapy (IMPRINT) is a RT technique currently being used to treat malignant pleural mesothelioma (MPM) patients with 2 intact lungs at centers that specialize in MPM treatment. This IMPRINT technique can potentially be extrapolated to thymic patients with pleural metastases. Because the risk of toxicity is of greater concern for thymic patients given their overall relatively favorable prognosis, the rate of toxicity, particularly radiation pneumonitis, needs to be established in the thymic patient population. **Methods:** This is a single-arm, single institution Phase II study of hemithoracic IMPRINT for patients with pleural metastases from thymic malignancies. The primary endpoint of this study is grade 3 or higher radiation pneumonitis within 4 months of completing RT. Secondary endpoints include any toxicity, progression-free survival, patterns of failure and overall survival. Patients must have a pathologically confirmed diagnosis of a thymic malignancy with radiologic or pathologic evidence of pleural metastases. Thymoma or thymic carcinoma are allowed. Patients may have de novo stage IVA disease or recurrent disease in the pleura. There must be no evidence of extra-thoracic metastatic disease or contralateral pleural/pericardial disease. Surgical resection of the pleural nodules (ex: pleurectomy/decortication, debulking/metastectomy) are allowed. Extrapleural pneumonectomy is not allowed. Patients are excluded if they have undergone prior thoracic radiation therapy preventing hemithoracic pleural IMRT, whereas prior thymic bed radiation and/or prior pleural SBRT are allowed. RT will be administered to the ipsilateral pleura to 50.4 Gy in 28 fractions. An optional dose-painting boost to gross disease up to 60 Gy while respecting normal tissue constraints is allowed. Patients can be treated with photon or proton therapy. Simulation, contouring and RT planning guidelines have been developed. Patients will be followed per protocol at regular intervals for at least 12 months following RT. The expected accrual is 36 patients over 4 years. Further information can be found on clinicaltrials.gov (NCT05354570). Clinical trial information: NCT05354570. Research Sponsor: Memorial Sloan Kettering Cancer Center.

Oral Abstract Session

Sunvazertinib for the treatment of NSCLC with EGFR Exon20 insertion mutations: The first pivotal study results. *First Author: Mengzhao Wang, Department of Respiratory and Critical Care Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China*

Background: Sunvazertinib (DZD9008) is a rationally designed selective, irreversible EGFR exon20 insertion (exon20ins) inhibitor with wild-type EGFR selectivity. Here we reported the results of WU-KONG6, the first pivotal study of sunvazertinib in previously treated NSCLC patients with EGFR exon20ins. **Methods:** WU-KONG6 (NCT05712902 and CTR20211009) is a phase II, multi-center pivotal study in NSCLC patients with EGFR exon20ins, whose diseases had progressed on or were after platinum-based chemotherapy. Tumor tissue EGFR exon20ins status was tested by local or central laboratory. The primary and key secondary endpoint were objective response rate (ORR) and duration of response (DoR), respectively, assessed by Blinded Independent Central Review (BICR). Patients received 300 mg sunvazertinib once daily until discontinuation criteria were met. **Results:** Between July 19, 2021, and May 6, 2022, a total of 104 Chinese patients were enrolled into WU-KONG6 study. The efficacy analysis set included 97 patients, whose EGFR exon20ins status was retrospectively confirmed by a central laboratory. A total of 30 different exon20ins subtypes were enrolled. The median age was 58 years; 59.8% (58/97) were female; 95.9% (93/97) were adenocarcinoma; 95.9% (93/97) had metastatic diseases at study entry; 32% (31/97) had baseline brain metastasis; the median prior lines of therapy were 2. By the data cutoff date (October 17, 2022), the BICR assessed confirmed ORR (cORR) was 60.8% (59/97). In patients with baseline brain metastasis, the cORR was 48.5% (15/31). Anti-tumor efficacy was observed irrespective of age, gender, smoking status, prior lines of therapies, prior onco-immunotherapies, mutation subtypes, and baseline brain metastasis. By the data cut-off date, median follow-up time for responders was 7.1 months, and 64.4% (38/59) of responders were still responding. The longest DoR was > 11 months, and the median DoR has not been reached. The safety analysis set included all enrolled 104 patients. The most common treatment emergent adverse events (TEAEs) were similar as what have been previously reported for sunvazertinib, and also similar as that of other EGFR inhibitors. Majority of the TEAEs were grade 1 or 2, and clinically manageable. **Conclusions:** The first pivotal study results confirmed sunvazertinib's superior anti-tumor efficacy than the current available therapy for NSCLC with EGFR exon20ins. The safety profile from WU-KONG6 study was consistent with previously reported findings. The updated data will be presented at the meeting. A multinational phase II pivotal study (WU-KONG1, NCT03974022) with the same study design is ongoing in the USA, Australia, and countries/regions in Asia, Europe and South America. Clinical trial information: NCT05712902. Research Sponsor: Dizal Pharmaceutical.

Oral Abstract Session

Randomized phase 3 study of first-line AZD3759 (zorifertinib) versus gefitinib or erlotinib in EGFR-mutant (EGFRm+) non-small-cell lung cancer (NSCLC) with central nervous system (CNS) metastasis. *First Author: Yi-Long Wu, Guangdong Lung Cancer Institute, Guangzhou, China*

Background: Patients (pts) with EGFRm+ NSCLC have high rates of CNS metastasis, few treatment options, and a poor prognosis. So far there are no solid evidence from head to head phase 3 trials in this setting. The potent EGFR TKI AZD3759 has high blood-brain barrier penetration, preliminary data has shown promising intracranial (IC) and systemic antitumor activity, and a tolerable safety profile. **Methods:** This was the first phase 3, open-label, multicenter, randomized controlled trial to compare the efficacy and safety of first-line AZD3759 with first generation EGFR TKIs specifically in pts with EGFRm+ (L858R and/or exon 19Del) NSCLC and CNS metastasis. Adult pts were randomized 1:1 to receive AZD3759 (200 mg twice daily) or first generation EGFR TKIs (the control group, gefitinib 250 mg or erlotinib 150 mg once daily). The primary endpoint was progression-free survival (PFS) by blinded independent central review (BICR) per RECIST 1.1. **Results:** Between Feb 1, 2019, and Jan 12, 2021, 439 pts were randomized: 220 to AZD3759 and 219 to the control group. As of July 12, 2022, median follow-up was 20.4 months (mo) for both. Median PFS (95% CI) was significantly superior with AZD3759 vs the control group (9.6 [8.2–9.7] vs 6.9 [6.3–8.0] mo; HR 0.719, 95% CI 0.580–0.893; p=0.0024). The objective response rate (ORR; BICR/RECIST 1.1) was 68.6% for AZD3759 vs 58.4% for the control group (p=0.027), with a trend toward longer median duration of response (DoR) with AZD3759 (8.2 vs 6.8 mo; p=0.0997). IC PFS, ORR, and DoR with AZD3759 were all superior vs the control group regardless of the assessor or evaluation criteria. The overall survival was immature. The incidence of any-grade treatment-related adverse events (TRAEs) was similar between the two groups (97.7% vs 94.0%). Grade ≥3 TRAEs occurred in 65.9% (AZD3759) and 18.3% (the control group) of pts. The main TRAEs were skin and subcutaneous tissue events, gastrointestinal system events and abnormal liver function. No new safety signals arose. **Conclusions:** First-line AZD3759 demonstrated superior systemic and IC antitumor efficacy compared with first generation EGFR TKIs in pts with EGFRm+ NSCLC and CNS metastasis. Adverse events were as expected and manageable. IC antitumor activity. Clinical trial information: NCT03653546. Research Sponsor: Alpha Biopharma (Jiangsu) Co., Ltd.

IC variable	Assessor	AZD3759	The control group	HR/OR (95% CI)	p

Oral Abstract Session

Final overall survival and biomarker analyses of CHOICE-01: A double-blind randomized phase 3 study of toripalimab versus placebo in combination chemotherapy for advanced NSCLC without EGFR/ALK mutations. *First Author: Jie Wang, State Key Laboratory of Molecular Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Toripalimab in combination with chemotherapy showed significant improvement over chemotherapy alone in progression-free survival (PFS) and overall survival (OS) as first-line treatment of advanced NSCLC at the final PFS analysis of the CHOICE-01 study (NCT03856411). Here we report the final OS analysis. **Methods:** Patients (n=465) with treatment-naïve, advanced NSCLC without EGFR/ALK mutations were randomized 2:1 to receive toripalimab 240 mg (n=309) or placebo (n=156) in combination with chemotherapy for 4–6 cycles, followed by maintenance toripalimab or placebo plus standard care until disease progression, intolerable toxicity, or completion of 2 years of treatment. Patients from the placebo arm were actively crossed-over to receive toripalimab upon disease progression. The primary endpoint was PFS. The secondary endpoints included OS and safety. **Results:** By the cutoff date of August 31, 2022, when 283 events triggered the final OS analysis, the median survival follow up was 19.4 months. A significant improvement in OS was observed for the toripalimab arm over the placebo arm: HR=0.73 (95% CI: 0.57–0.93), two-sided p=0.0108, median OS 23.8 vs 17.0 months. A consistent effect on OS, favoring the toripalimab arm, was observed all PD-L1 expression subgroups. The OS benefit is greater in non-squamous NSCLC, HR=0.50 (95% CI: 0.36–0.70), median OS 27.8 vs 15.9 months, whereas no significant difference was found in the squamous subgroup (mOS 19.6 vs 18.1 months) despite a significant PFS improvement. The squamous subgroup had a high 70% crossover rate. No new safety signal was identified since the interim report. The incidence of Grade ≥3 adverse events (AEs) (78.9% vs 82.1%) was similar between the two arms. AEs leading to discontinuation of toripalimab/placebo (14.3% vs 3.2%), fatal AEs (5.5% vs 2.6%), and immune-related (irAEs) (50.6% vs. 21.2%) were more frequent in the toripalimab arm. Whole exome sequencing results indicated patients with mutations in the FAK-PI3K-Akt pathway achieved significantly better OS from the toripalimab arm. **Conclusions:** The addition of toripalimab to chemotherapy in patients with advanced NSCLC provided significant OS benefit than chemotherapy alone with a manageable safety profile. These results support the use of toripalimab with chemotherapy as 1st line therapy for advanced NSCLC patients without EGFR/ALK mutations. Clinical trial information: NCT03856411. Research Sponsor: Shanghai Junshi Biosciences.

Oral Abstract Session

TROPION-Lung02: Datopotamab deruxitecan (Dato-DXd) plus pembrolizumab (pembro) with or without platinum chemotherapy (Pt-CT) in advanced non-small cell lung cancer (aNSCLC). *First Author: Yasushi Goto, National Cancer Center Hospital, Tokyo, Japan*

Background: Despite advances in first-line (1L) immunotherapy ± CT, most patients (pts) with aNSCLC experience disease progression, necessitating novel strategies. Dato-DXd is an antibody drug conjugate (ADC) composed of a humanized anti-TROP2 IgG1 monoclonal antibody covalently linked to a topoisomerase I inhibitor payload via a plasma-stable tetrapeptide-based cleavable linker. Dato-DXd had encouraging efficacy and manageable safety in heavily pretreated aNSCLC. Dato-DXd + immunotherapy yielded greater preclinical activity than either agent alone. **Methods:** TROPION-Lung02 (NCT04526691) is a phase 1b, global, dose-escalation and -expansion study evaluating Dato-DXd (4 or 6 mg/kg) + pembro 200 mg ± Pt-CT (cisplatin 75 mg/m² or carboplatin AUC 5) every 21 days across 6 cohorts. Pts in escalation may have received ≤2 prior lines of therapy for aNSCLC. Pts in expansion were primarily treatment (tx) naïve (pts receiving Dato-DXd + pembro may have ≤1 prior Pt-based tx). The primary objective is to assess safety and tolerability, including dose-limiting toxicities (DLTs). Secondary objectives include evaluation of efficacy, pharmacokinetics, and immunogenicity. **Results:** As of the Oct 31, 2022, data cutoff (DCO), 120 pts were treated. All cohorts met DLT criteria to move to escalation. Median age was 65 years. PD-L1 expression was <1%, 1%-49%, and ≥50% in 40%, 33%, and 26% of pts, respectively. Median tx duration was 4.6 mo, with 55% receiving tx at DCO. The most frequent any-grade (gr) tx-emergent adverse events (TEAEs) were nausea (45%) and stomatitis (45%). Gr ≥3 TEAEs occurred in 61% of pts; most frequent were neutrophil count decreased (8%) and amylase increased (8%). TEAEs that were serious, associated with discontinuation, or associated with death occurred in 31%, 24% (16% associated with Dato-DXd), and 6% of pts, respectively. Dose reductions due to TEAEs associated with Dato-DXd occurred in 17%. Drug-related interstitial lung disease occurred in 12 pts (10%; 9 gr 1/2; 3 gr 3). The objective response rate (ORR) with 1L Dato-DXd + pembro doublet and Dato-DXd + pembro + Pt-CT triplet tx was 60% (95% CI, 36%-81%; 12 [2 unconfirmed]/20) and 55% (95% CI, 39%-70%; 23 [5 unconfirmed]/42), respectively. The ORR for any line of therapy was 38% (95% CI, 25%-54%; 18 [2 unconfirmed]/47) with doublet and 47% (95% CI, 34%-60%; 28 [5 unconfirmed]/60) with triplet tx. In both subsets, the disease control rate was 85% and median duration of response was not reached. Responses were observed in all 3 PD-L1 expression level subgroups. Although immature, median progression-free survival (95% CI) was 10.8 (8.3-15.2) and 7.8 mo (5.5-NE) with doublet and triplet tx, respectively. **Conclusions:** Dato-DXd + pembro ± Pt-CT demonstrated tolerable safety with notable 1L activity in this first and largest dataset with an ADC + immunotherapy ± Pt-CT in aNSCLC pts. Clinical trial information: NCT04526691. Research Sponsor: Daiichi Sankyo, Inc.

Oral Abstract Session

The primary endpoint analysis of SCARLET study: A single-arm, phase II study of sotorasib plus carboplatin-pemetrexed in patients with advanced non-squamous, non-small cell lung cancer with KRAS G12C mutation (WJOG14821L). *First Author: Shinya Sakata, Department of Respiratory Medicine, Kumamoto University Hospital, Kumamoto, NA, Japan*

Background: Efficacy and safety of sotorasib in combination with platinum-doublet chemotherapy in KRAS G12C-mutated non-squamous, non-small cell lung cancer (non-Sq, NSCLC) has not been investigated. **Methods:** In this single-arm, phase 2 study, chemotherapy-naïve, advanced non-Sq, NSCLC patients with KRAS G12C mutation were enrolled. Participants were treated with sotorasib 960mg, QD plus carboplatin (AUC 5)/pemetrexed 500mg/m² for four cycles, followed by sotorasib plus pemetrexed until disease progression. The primary endpoint was overall response rate (ORR) by independent review. The secondary endpoints were progression-free survival (PFS), overall survival (OS) and safety. Using plasma samples, next-generation sequencing analysis was done at baseline, 3 weeks and disease progression. Regarding statistical consideration, the threshold and the expected ORR were set as 40% and 65%, respectively with one-sided $\alpha = 0.1$, and $\beta = 0.1$, the required sample size was 28 cases (Simon's two-stage design). A total of 30 cases was planned to take into account the possibility of a few dropped or ineligible cases. This study was funded by AMGEN Inc. and Trial identification no. is jRCT2051210086. **Results:** Between Oct 2021 and Jul 2022, 30 patients were enrolled. Twenty-nine and 27 were analyzed for safety and efficacy, respectively. Of those, median age was 70, male/female: 25/5, never-/smoker: 1/29, ECOG performance status: 0/1 11/19 and PD-L1 expression level: ≥50%/1-49%/<1% 15/10/5. The primary endpoint, ORR by independent review was 88.9% (80%CI 78.5-94.8%). Median PFS was not reached mainly due to shorter follow-up period (median 4.2 months) and PFS rate at 6 months was 61.2%. OS rate at 6 months was 87.0%. Subgroup analysis revealed that ORR did not differ by PD-L1 expression level (≥50%/1-49%/<1%: 76.9%/77.8%/80.0%, respectively). Common adverse events were anemia, neutrophil count decreased, nausea and platelet count decreased. Grade ≥3 AEs were mostly hematological toxicities, but one treatment-related death (pneumonia) occurred. At baseline, 70% of plasma samples were positive for KRAS G12C and most common co-occurring mutation was TP53 (50%). At 3 weeks, plasma KRAS G12C disappeared among 60% of patients. **Conclusions:** Sotorasib in combination with CBDCA/PEM demonstrated favorable ORR and tolerability in advanced non-Sq, NSCLC patients with KRAS G12C mutation. Clinical trial information: jRCT2051210086. Research Sponsor: AMGEN Inc.

Tumor treating field (TTFields) therapy with standard of care (SOC) in metastatic non-small cell lung cancer (mNSCLC) following platinum failure: Randomized, phase 3 LUNAR study. *First Author: Tician Leal, Winship Cancer Institute of Emory University, Atlanta, GA*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2023, issue of the *Journal of Clinical Oncology*.

9007

Oral Abstract Session

KontRast-01 update: Safety and efficacy of JDQ443 in KRAS G12C-mutated solid tumors including non-small cell lung cancer (NSCLC). *First Author: Philippe Alexandre Cassier, Centre Léon Bérard, Lyon, France*

Background: KRAS G12C oncogenic mutations occur in ~13% of NSCLCs and up to 4% of other solid tumors. JDQ443 is a selective, covalent, orally bioavailable KRAS^{G12C} inhibitor that irreversibly traps KRAS^{G12C} in the inactive, GDP-bound state. Clinical activity was seen in initial cohorts of patients (pts) treated with JDQ443 monotherapy, and 200 mg twice daily (BID) was selected as the recommended dose (RD) for expansion (Tan DS, *et al.* AACR 2022; Abstract CT033). **Methods:** KontRast-01 (NCT04699188) is a Phase Ib/II, open-label, multicenter, dose-escalation (DEs), and dose-expansion (DEX) trial of JDQ443 as a monotherapy or in combination with TNO155 (SHP2 inhibitor) and/or tislelizumab (anti-PD-1 monoclonal antibody). Primary objectives of DEs are to assess safety/tolerability and identify the RD and regimens for future studies. The primary objective of DEX is to assess efficacy. Key inclusion criteria: advanced, KRAS G12C-mutated solid tumors; previous standard-of-care treatment; age ≥18 years; and ECOG PS 0-1. Prior KRAS^{G12C} inhibitor treatment is not permitted for the JDQ443 monotherapy arm and is allowed for the JDQ443 + TNO155 and JDQ443 + tislelizumab DEs arms. **Results:** As of Oct 28, 2022, 84 pts were treated with JDQ443 monotherapy, orally, continuously, in DEs, DEX, and food effect (FE) cohorts at 200 mg once daily (QD; n=10), 400 mg QD (n=11), 200 mg BID (n=56), and 300 mg BID (n=7). Median age was 61 years (range 26-83); median prior lines of therapy was 3 (range 1-7); and indications included NSCLC (n=38), colorectal cancer (n=42), and others (n=4). Median duration of exposure was 14.6 weeks (range 0.1-68.4) for all pts and 15.1 weeks (0.1-68.1) for pts treated at 200 mg BID. Among pts treated at 200 mg BID, 40 (71.4%) and 4 (7.1%) experienced treatment-related adverse events (TRAEs) of any grade (Gr) and of Gr 3, respectively. There were no Gr 4-5 TRAEs at any dose level. The most common TRAEs (any Gr, occurring in ≥10% of pts) at 200 mg BID were fatigue (17.9%), edema (14.3%), diarrhea (16.1%), nausea (16.1%), vomiting (10.7%), and peripheral neuropathy (10.7%). Gr 3 TRAEs were neutropenia in 2 pts, ALT and AST increase in 1 pt, and myalgia in 1 pt. One pt receiving 200 mg BID required a dose reduction due to a TRAE of Gr 2 peripheral neuropathy. Among response evaluable pts with NSCLC treated in DEs and FE cohorts, the confirmed overall response rate was 41.7% (10/24 pts) across dose levels and 54.5% (6/11 pts) at the RD of 200 mg BID. Combination JDQ443 + TNO155 and JDQ443 + tislelizumab arms are enrolling. Additional data will be available at the time of presentation. **Conclusions:** JDQ443 demonstrates an acceptable safety and tolerability profile at 200 mg BID, with clinical activity in pts with NSCLC. Enrollment is ongoing to the JDQ443 monotherapy DEX and the JDQ443 + TNO155 and JDQ443 + tislelizumab combination arms. Clinical trial information: NCT04699188. Research Sponsor: Novartis Pharmaceuticals Corporation.

9008

Oral Abstract Session

Biomarker subgroup analyses of CodeBreak 200, a phase 3 trial of sotorasib versus (vs) docetaxel in patients (pts) with pretreated *KRAS* G12C-mutated advanced non-small cell lung cancer (NSCLC). *First Author: Ferdinando Skoulidis, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Sotorasib is a first-in-class oral, irreversible *KRAS*^{G12C} inhibitor approved for adults with pretreated *KRAS* G12C-mutated advanced NSCLC. In CodeBreak 200, the first *KRAS*^{G12C} inhibitor randomized phase 3 trial, sotorasib demonstrated superior progression-free survival (PFS) and overall response rate (ORR) vs docetaxel and a more favorable safety profile. We report prespecified exploratory biomarker analyses comparing sotorasib vs docetaxel efficacy in molecularly-defined *KRAS* G12C-mutated advanced NSCLC subsets. **Methods:** In CodeBreak 200, 345 pts with *KRAS* G12C-mutated advanced NSCLC who progressed after platinum-based chemotherapy and a checkpoint inhibitor were randomized 1:1 to oral sotorasib 960 mg daily or IV docetaxel 75 mg/m² Q3W. Primary endpoint was PFS by blinded independent central review (RECIST 1.1; key secondary endpoint: ORR). In prespecified exploratory analyses, baseline tissue and plasma samples were analyzed for key genomic alterations (eg, *STK11*, *KEAP1*, *EGFR*, *MET*, *TP53*), by central targeted next-generation sequencing (Skoulidis *N Engl J Med* 2021), and PD-L1 protein level by local standard of care testing in biomarker-evaluable cases; biomarker status was correlated with PFS and ORR. Inferred tumor mutation burden by plasma circulating tumor DNA (sum of mutant molecular variant reads) was assessed. Association of baseline genomic alterations with long-term benefit (PFS ≥ 6 m) vs early progression (PFS < 3 m; no complete/partial response) was evaluated. **Results:** Most prevalent *KRAS* G12C co-alterations in biomarker-evaluable cases with available tumor and/or plasma samples (n=317) were *TP53* (181 [57.1%]), *STK11* (119 [37.5%]), and *KEAP1* (82 [25.9%]) in CodeBreak 200, consistent with CodeBreak 100; 55 (17.4%) pts had *STK11* and *KEAP1* co-alterations. Sotorasib showed superior clinical benefit vs docetaxel independently of PD-L1 expression and across all prespecified subgroups (eg, *STK11*, *KEAP1*, *TP53*). No clinical response occurred with either treatment in 26 (8.2%) pts with additional *KRAS* alterations, including amplifications. High baseline plasma tumor burden was associated with greater odds of early progression vs long-term benefit in both arms (odds ratio, 3.54 [95%CI 1.83-6.85] per tertile increase; p<0.0001). Correlation of *KRAS* G12C co-alterations with response detected a signal toward shorter median PFS (sotorasib, 2.8 m [95%CI 1.6-3.4]; docetaxel, 7.5 m [95%CI 3.0-NE]) with sotorasib vs docetaxel in pts with *KRAS* G12C and *NOTCH1* co-altered tumors. **Conclusions:** Sotorasib demonstrated consistent clinical benefit vs docetaxel in all prespecified molecularly-defined subgroups (eg, *STK11*, *KEAP1*, *TP53*) in this exploratory analysis of CodeBreak 200. No predictive biomarkers were confirmed, but novel hypothesis-generating signals were observed. Clinical trial information: NCT04303780. Research Sponsor: Amgen Inc.

Rapid Abstract Session

BLU-945 monotherapy and in combination with osimertinib (OSI) in previously treated patients with advanced *EGFR*-mutant (*EGFRm*) NSCLC in the phase 1/2 SYMPHONY study. *First Author: Yasir Y Elamin, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Despite improved frontline OSI treatment outcomes, patients (pts) with advanced *EGFRm* NSCLC inevitably progress, with worse outcomes in the *EGFR* L858R subgroup (median PFS of 14.4 vs 21.4 mo in pts with exon 19 deletions). BLU-945 is an investigational, next-generation, oral tyrosine kinase inhibitor (TKI) that targets common *EGFR*-activating and T790M and C797X resistance mutations, while being selective against *EGFR* wild type (WT). Preclinically, BLU-945 in combination (combo) with OSI had enhanced potency on L858R and extended antitumor response durability versus OSI alone. SYMPHONY (NCT04862780) is an ongoing first-in-human phase 1/2 study of BLU-945 monotherapy (mono) or combo with OSI. **Methods:** In the phase 1 dose escalation, pts (aged ≥18 y; metastatic *EGFRm* NSCLC; ECOG PS 0-1; treated with ≥1 *EGFR* TKI) received BLU-945 mono starting at 25 mg QD. Pts progressing on OSI could receive BLU-945 with 80 mg OSI starting at 50% of the highest safe BLU-945 mono dose. Each dose escalation followed a Bayesian Optimal Interval design. Safety, including dose-limiting toxicities (DLT), PK, and circulating tumor DNA (ctDNA) mutational status were assessed. **Results:** As of Jan 6, 2023, 108 pts received BLU-945 mono (25-600 mg QD; 100-300 mg BID). Pts had a median of 3 lines of prior therapy and were genomically complex with ctDNA detectable *EGFR* on-target and/or off-target resistance alterations (46%) at baseline. DLTs included alanine transaminase (ALT) and aspartate transaminase (AST) elevation, hepatic cytolysis, fatigue, nausea, vomiting, and hyponatremia, occurring at doses of ≥400 mg/d. The maximum tolerated dose was 500 mg/d. The most common AEs were nausea (42%), headache (40%), increased ALT (38%), increased AST (37%), and vomiting (32%). Robust on-target *EGFR* activity was observed with ctDNA reduction on day 15 in 90%, 85% and 70% of *EGFR* T790M, C797S, and L858R alleles at ≥400 mg/d doses, respectively. At ≥400 mg/d, 48% had tumor shrinkage, including partial responses (PRs). Twenty-five pts received BLU-945 (200-400 mg QD; 100-200 mg BID) combo with OSI. Pts had a median of 2 lines of prior therapy. The most common combo AEs were fatigue (36%), diarrhea (32%), headache (32%), and nausea (28%). Other *EGFR* WT AEs were dry skin (20%) and rash (8%). One DLT (Grade 4 pneumonitis) was reported in the BLU-945 300 mg QD with OSI group. Tumor reductions, including PRs in 2 pts progressing on OSI, were observed at ≥300 mg/d. Dose escalation is ongoing. **Conclusions:** BLU-945 mono and combo with OSI were generally well tolerated and showed robust on-target *EGFR* ctDNA reduction, with tumor shrinkage in genomically heterogeneous, heavily pretreated pts. Combo showed responses at BLU-945 doses lower than in mono, consistent with additive benefit. The combo safety profile and on-target activity provide rationale for further development in front line. Clinical trial information: NCT04862780. Research Sponsor: Blueprint Medicines.

Rapid Abstract Session

First-line immune checkpoint inhibitors alone or in combination with chemotherapy in real-life elderly patients with advanced non-small cell lung cancer (NEJ057). *First Author: Mao Uematsu, Department of Thoracic Oncology and Respiratory Medicine, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan*

Background: Immune checkpoint inhibitor (ICI) plus chemotherapy is now a standard treatment for non-small cell lung cancer (NSCLC) without targetable oncogene alterations. However, the efficacy and safety of ICI plus chemotherapy (ICI-chemo) in 75 years or older patients have not been elucidated. The aim of this study is to reveal the real-world choice of first-line drugs in elderly patients (pts) and evaluate the efficacy and safety of ICI-chemo. **Methods:** We conducted a multicenter (58 centers in Japan), retrospective cohort study of consecutive 75 years or older pts with clinical stage IIIB, IIIC, IV, postoperative or radiotherapy recurrent NSCLC who started first-line systemic therapy between December 2018 and March 2021. Pts with epidermal growth factor receptor mutations, anaplastic lymphoma kinase rearrangements, or whose first-line systemic therapy was molecular targeted therapy were excluded. **Results:** A total of 1245 pts were enrolled: median (range) age 78 (75-95) years; 278 (22%) female; 367 (29%) ECOG PS 0, 680 (55%) PS 1 and 171 (14%) PS 2; 678 (54%) adenocarcinoma; PD-L1 tumor proportion score ≥50%: 268 (22%) <1%, 387 (31%) 1-49% and 410 (34%) ≥50%; 354 (28%) ICI-chemo, 425 (34%) ICI alone, 311 (25%) platinum-doublet chemotherapy and 155 (12%) single agent chemotherapy. The median overall survival (OS) was 20.0 months (95% CI, 17.1-23.6) in the ICI-chemo group, 19.8 months (95%CI, 16.5-23.8) in the ICI alone group, 12.8 months (95%CI, 10.7-15.6) in the platinum-doublet chemotherapy group and 9.5 months (95%CI, 7.4-13.4) in the single agent chemotherapy group, respectively. After propensity score matching, there was no difference in OS and progression-free survival (PFS) between ICI-chemo group (n=96) and ICI alone group (n=95) in PD-L1 ≥1% (OS: HR, 0.98; 95% CI, 0.67-1.42; PFS: HR, 0.92; 95% CI, 0.67-1.25). Regardless of PD-L1 subgroups (1-49% or ≥50%), no significant differences in OS and PFS were observed. Concerning safety, Grade 3 or higher immune-related adverse events (irAEs) occurred in 86 pts (24.3%) in the ICI-chemo group and 76 pts (17.9%) in the ICI alone group (p=0.03). The number of pts who required steroids for irAEs was 115 (32.5%) in the ICI-chemo group and 105 (24.7%) in the ICI alone group (p=0.02). Pneumonitis was reported in 83 pts (23.4%) in the ICI-chemo group and 66 pts (15.6%) in the ICI alone group (p=0.006). **Conclusions:** In real-world data for pts aged 75 years or older, ICI-chemo did not improve survival and increased the incidence of grade 3 or higher irAEs compared to ICI alone. Based on our results, ICI alone is recommended for elderly pts with PD-L1 positive NSCLC. Clinical trial information: UMIN000046700. Research Sponsor: None.

Clinical Science Symposium

Predictive biomarkers for treatment with amivantamab plus lazertinib among EGFR-mutated NSCLC in the post-osimertinib setting: Analysis of tissue IHC and ctDNA NGS. First Author: Benjamin Besse, Gustave Roussy, Villejuif, France

Background: Amivantamab (ami) is a bispecific antibody targeting EGFR and MET with immune cell-directing activity, and lazertinib (laz) is a brain-penetrant, third-generation EGFR tyrosine kinase inhibitor. In a previous report, the overall response rate (ORR) of ami+laz in the post-osimertinib (osi) setting was 36%, with median duration of response of 9.6 months (Bauml JCO 2021; 39:15_suppl, 9006). Exploratory analyses suggested certain immunohistochemistry (IHC) and ctDNA-based next-generation sequencing (NGS) biomarkers may enrich for response. A prospective study was conducted to further evaluate these potential biomarkers. **Methods:** CHRYSALIS-2 (NCT04077463), an ongoing phase 1/1b study, examines the efficacy (ORR per RECIST v1.1) of ami+laz in patients (pts) with EGFR-mutated NSCLC. Cohort D enrolled osi-relapsed, chemotherapy-naïve pts with EGFR exon 19 deletion or L858R mutated advanced NSCLC who had tumor tissue for IHC staining and plasma for ctDNA NGS collected after their most recent therapy. Training and validation subsets identified biomarker criteria and predictive validity, respectively. A Bayesian posterior probability (biomarker positive group ORR is $\geq 35\%$ and negative group ORR is $\leq 20\%$) was predefined to be $\geq 85\%$ for acceptance. **Results:** There were 101 response-evaluable pts enrolled in Cohort D. A total of 87 pts had detectable baseline ctDNA and 77 pts had evaluable MET IHC. The training set (n = 50) identified IHC-based MET expression of 3+ staining on $\geq 25\%$ of tumor cells (MET+) as a potential predictive biomarker, and the validation set (n = 27) confirmed these results. Of those with MET IHC data, 28/77 (36%) were MET+. The overall ORR for MET+ was 61% (95% CI, 41–78) and 12% (95% CI, 5–25) for MET-, with median PFS for MET+ not reached (95% CI, 4.3–NE) vs 4.1 months (95% CI, 2.8–5.7) for MET-. NGS evaluation of ctDNA did not identify predictive biomarkers meeting predetermined criteria. Of note, only 1 pt was identified by ctDNA as having MET amplification (the pt was also MET+ by IHC). Further details will be provided at the time of presentation. **Conclusions:** MET+ by IHC may be a predictive biomarker for response to ami+laz in the post-osi, chemotherapy-naïve setting. In contrast, molecular profiling with ctDNA failed to identify a subgroup of pts more likely to benefit. Ami+laz represents a potential chemotherapy-free option for pts with EGFR-mutated advanced NSCLC who have progressed on osi and are also MET+ by IHC. Clinical trial information: NCT04077463. Research Sponsor: Janssen.

Poster Discussion Session

FAK inhibition with novel FAK/ALK inhibitor APG-2449 could overcome resistance in NSCLC patients who are resistant to second-generation ALK inhibitors. First Author: Yuxiang Ma, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: APG-2449 is a novel, orally active FAK inhibitor and an ALK/ROS1 tyrosine kinase inhibitor (TKI) that has shown potent activity in preclinical models. It had been demonstrated that APG-2449 was well tolerated, and preliminary efficacy was observed in pts who were resistant to second-generation ALK/ROS1⁺ inhibitors (Zhao H et al. *J Clin Oncol* 2022; 40:9071). We provide updated safety and efficacy results and potential mechanisms of action(s) of this therapy. **Methods:** After the RP2D was determined as 1,200 mg daily (QD), NSCLC pts were enrolled into 2 dose expansion cohorts. Cohort 1 included pts who were resistant to second-generation ALK/ROS1⁺ TKIs. Cohort 2 included those who were ALK or ROS1⁺ TKI naïve. **Results:** As of December 9, 2022, 130 pts enrolled (median [range] age 53 [21–78] years; 53.8% female) with NSCLC, mesothelioma, or ovarian cancer were treated with APG-2449 at doses ranging from 900 to 1,500 mg. A total of 117 (90%) pts experienced treatment-related adverse events (TRAEs). The most frequent TRAEs included elevated blood creatinine (43.8%), ALT (40.8%), and AST (33.1%) levels, as well as gastrointestinal disorders: nausea (25.4%), vomiting (21.5%), and diarrhea (21.5%). A total of 17 (13.1%) TRAEs were grade ≥ 3 . In a subgroup of pts with TKI-naïve NSCLC (n = 33; 31 with efficacy evaluable), the overall response rate (ORR) and the disease control rate (DCR = CR + PR + SD) were 70.6% (12/17) and 88.2% (15/17), respectively, in ROS1⁺ treatment naïve pts; the ORR and DCR were 78.6% (11/14) and 100% (14/14) in ALK⁺ treatment naïve pts. Of 27 NSCLC pts resistant to second-generation ALK inhibitors, 7 were observed with PR (7/27; 25.9%) during APG-2449 treatment at RP2D. In this subgroup, compared to baseline, pts who experienced PR showed lower phosphorylated FAK (pFAK) levels in peripheral blood mononuclear cells (PBMCs) by Day 28 (24 hours after dosing on D28) than pts who experienced SD. Furthermore, pts with progressive disease showed an increase of PBMC pFAK levels on D28 compared to baseline, indicating that APG-2449 could inhibit FAK phosphorylation. Pts with higher pFAK expression in tumor tissues at baseline tended to achieve better clinical responses than those with lower pFAK expression post APG-2449 treatment. **Conclusions:** APG-2449 showed a favorable preliminary safety profile and antitumor efficacy in pts with NSCLC. Preliminary efficacy was observed in those whose disease was TKI naïve and resistant to second-generation ALK inhibitors. FAK inhibition could be a novel approach to overcome ALK resistance in pts with NSCLC who are resistant to second-generation ALK inhibitors. Internal study identifier: APG2449XC101. Clinical trial information: NCT03917043. Research Sponsor: Ascentage Pharma Group Corp Ltd.

Poster Discussion Session

Safety and preliminary efficacy of YK-029A, a novel EGFR TKI, in patients with advanced NSCLC harboring ex20ins, T790M or rare mutations. First Author: Jianchun Duan, State Key Laboratory of Molecular Oncology, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: This study aimed to evaluate the safety and preliminary efficacy of YK-029A, a novel third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor, in treated or untreated patients with advanced NSCLC. **Methods:** This dose-escalation and dose-expansion phase 1 trial recruited previously untreated or treated patients with EGFR ex20ins mutant locally advanced or metastatic NSCLC and previously treated patients with EGFR T790M or rare mutations. In dose-escalation phase, patients with EGFR T790M mutation were enrolled. YK-029A was given at doses of 50, 100, 150, 200 to 250 mg/day (3+3 design). In dose-expansion phase, patients with EGFR T790M, EGFR ex20ins, or rare mutations were enrolled. The primary objective was safety. Dose-limiting toxicity (DLT) and maximum tolerated dose (MTD) were explored. In the treatment-naïve cohort of EGFR ex20ins mutant NSCLC, patients were administered oral YK-029A 200 mg once daily in a 28-day cycle, and efficacy was assessed by the independent review committee. The study was registered (chinadrugtrials.org.cn, CTR20180350). **Results:** A total of 108 were included in the safety analysis set. DLT did not occur in dose-escalation phase. MTD was not reached. Treatment-emergent adverse events (TEAEs) of any grade and grade ≥ 3 occurred in 106 (98.1%) and 41 (38.0%) patients, respectively. Treatment-related adverse events (TRAEs) of any grade and grade ≥ 3 occurred in 102 (94.4%) and 30 (27.8%) patients, respectively. One patient had liver abscess related to YK-029A and died. Three patients terminated the treatment because of TEAEs. The most common TRAEs were diarrhea (46.3%), anemia (38.0%), and rash (32.4%). For the treatment-naïve EGFR ex20ins mutant cohort, 26 patients were included in the efficacy analysis set. Most patients were adenocarcinoma (96.4%) and at stage IV (85.7%). At the cut-off date on October 30, 2022, 19 patients (73.1%) had partial remission, five patients (19.2%) had stable disease, and two patients (7.7%) developed disease progression. The confirmed objective response rate achieved 73.1% (95% confidence interval [CI], 52.21% to 88.43%). The median progression-free survival was 9.3 months (95% CI, 5.85 to not evaluated). **Conclusions:** YK-029A was well tolerated and showed preliminary efficacy in treatment-naïve EGFR ex20ins mutant patients with locally advanced or metastatic NSCLC. Research Sponsor: Puhe Biopharma Co., Ltd.

	Treatment-naïve ex20ins cohort (200 mg) (N=26)
Objective response rate	73.1% (95% CI, 52.21% to 88.43%)
Disease control rate	92.3% (95% CI, 74.87% to 99.05%)
Median progression-free survival, months	9.3 (95% CI, 5.85 to NE)
Median duration of response, months	7.5 (95% CI, 3.75 to NE)
12-month overall survival rate	83.1% (95% CI, 47.17% to 95.53%)

Poster Discussion Session

Intracranial and systemic efficacy of repotrectinib in advanced *ROS1* fusion-positive (*ROS1*+) non-small cell lung cancer (NSCLC) and central nervous system metastases (CNS mets) in the phase 1/2 TRIDENT-1. *First Author: Jessica Jiyeong Lin, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Repotrectinib is a next-generation ROS1 and TRK tyrosine kinase inhibitor (TKI) that has demonstrated durable activity with a manageable safety profile in TKI-naïve and TKI-pretreated patients (pts) with advanced *ROS1*+ NSCLC. We report the first analysis of outcomes on repotrectinib in pts with *ROS1*+ NSCLC by baseline (BL) CNS met status in the global pivotal phase 1/2 TRIDENT-1 trial (NCT03093116). **Methods:** Pts with *ROS1*+ NSCLC were assigned to 4 cohorts by treatment history: ROS1 TKI-naïve, 1 ROS1 TKI and no chemotherapy (chemo), 1 ROS1 TKI and 1 platinum-based chemo, and 2 ROS1 TKIs and no chemo. Treated or untreated asymptomatic CNS mets were permitted. Brain scans were mandated for all pts in phase 2 at screening and at protocol-specified intervals until progression. Endpoints included confirmed objective response rate (cORR) and duration of response (DOR) by blinded independent central review (BICR; RECIST v1.1); intracranial ORR (icORR) in pts with measurable brain mets at BL by BICR per mRECIST v1.1; and safety. **Results:** In pts with BL measurable CNS mets who were TKI-naïve (n = 8) and in those with 1 TKI and no chemo (n = 12), icORR (95% CI) was 88% (47-100) and 42% (15-72), respectively. At data cutoff (June 20, 2022), 0 of 7 responders in the TKI-naïve cohort and 2 of 5 in the cohort with 1 prior TKI and no chemo had intracranial progression or death; intracranial DOR range was 1.9-14.8+ mo (TKI-naïve) and 3.0-11.1+ mo (1 TKI and no chemo), with 86% and 80% of pts with an intracranial response remaining on treatment, respectively. Median follow-up and systemic response by CNS met status are shown in the Table. In pts with *ROS1*+ NSCLC with (n = 118) or without (n = 178) CNS mets, most common any-grade neurologic treatment-emergent adverse events were dizziness (57% / 63%), dysgeusia (42% / 53%), paresthesia (32% / 34%), headache (27% / 12%), ataxia (17% / 22%), and memory impairment (14% / 10%). **Conclusions:** In TRIDENT-1, repotrectinib showed durable clinical activity in ROS1 TKI-naïve and -pretreated pts with or without BL CNS mets, including intracranial responses. Repotrectinib safety profile was similar in pts with *ROS1*+ NSCLC with or without CNS mets. Clinical trial information: NCT03093116. Research Sponsor: Turning Point Therapeutics Inc, a wholly owned subsidiary of Bristol Myers Squibb Company.

LIBELULE: A randomized phase III study to evaluate the clinical relevance of early liquid biopsy (LB) in patients with suspicious metastatic lung cancer. *First Author: Aurélie Swalduz, Department of Medical Oncology, Centre Léon Bérard, Lyon, France*

Background: Timeliness of molecular testing is essential to minimize the time to appropriate 1st line treatment initiation (TTI) in advanced NSCLC pts. We hypothesized that LB-based molecular testing performed at the patient's 1st visit could reduce this TTI. **Methods:** LIBELULE is a multicenter, randomized, comparative, open-label study, enrolling pts with radiological suspicion of stage IV lung cancer, no prior biopsy or cytology for advanced NSCLC diagnosis. In Arm A, a LB was performed at the 1st visit using the InVisionFirst-Lung assay, an amplicon-based NGS panel covering 37-NSCLC associated genes. When LB results were informative, treatment was initiated on the basis of: InVisionFirst-Lung alone for pts with *EGFR*, *BRAF V600E* mutation (mut), *ALK* or *ROS1* rearrangement (category 1 alterations); InVisionFirst-Lung and pathological results for pts with *ERBB2*, *MET* exon 14, *KRAS*, *BRAF* non V600 and/or *LKB1* mut, *RET* or *NTRK* rearrangement (category 2 alterations). In control Arm B, histological sampling was planned with genomic analysis when indicated (local LB allowed) and treatment was initiated according to ESMO guidelines. The primary endpoint was the time from randomization to initiation of appropriate treatment based on informative genomic and pathological results. 286 pts were needed to detect a 21% shortening in TTI ($\alpha = 0.05$, $1-\beta = 90\%$). **Results:** 319 pts were randomized between Arm A (n = 161) and B (n = 158): median age 68 y (39-97), 56.1% male, 28.5% non-smokers, PS0-1 82%, PS $\geq$ 2 18.1%; adenocarcinoma: 56.7%, squamous cell carcinoma: 11%, SCLC: 10%, other tumor types: 5%. 5.3% of pts had no cancer. In Arm A, 81% of pts had ctDNA findings; category 1 and category 2 alterations were identified on tissue and/or LB in 29.2% (*EGFR* mut: 21.7%) and 24%, respectively, whereas in Arm B, 23.2% of pts had category 1 (*EGFR* mut: 20.3%) and 20% had category 2 alterations detected. Systemic treatment was initiated in 74.5% and 65.8% of pts in Arm A and B, respectively. Main reasons for not initiating treatment were diagnosis other than cancer, local treatment and palliative care. The mean TTI was 29.0 days (d) (95%CI 25.9-32.1) in Arm A vs 33.9 d (95%CI 28.4-39.5) in Arm B in the intention-to-treat population (p = 0.28), but significantly shorter in Arm A 29.1 d vs 38.8 d in Arm B for pts receiving systemic treatment (p = 0.01). The mean TTI was significantly shorter (21 d vs 37.4 d) in pts with category 1 alterations (p = 0.004) as well as the time to contributive genomic analysis (17.9 d vs 25.6 d; p < 0.001) in Arm A and B, respectively. In Arm A, 7.4% of pts vs 13.3% in Arm B initiated a treatment without genomic analysis available. **Conclusions:** Early LB significantly reduces the time to contributive molecular analysis and the time to initiation of appropriate 1st line therapy in pts eligible for systemic treatment, especially for pts with actionable alterations indicating targeted 1st line therapy. Clinical trial information: NCT03721120. Research Sponsor: Grant from French Ministry of Health PHRC-K 2017.

Poster Discussion Session

Efficacy and safety of encorafenib (enco) plus binimetinib (bini) in patients with *BRAF* V600E-mutant (*BRAF*^{V600E}) metastatic non-small cell lung cancer (NSCLC) from the phase 2 PHAROS study. *First Author: Gregory J. Riely, Thoracic Oncology Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The combination of dabrafenib, a BRAF inhibitor, and trametinib, a MEK inhibitor, is a current standard of care for patients (pts) with *BRAF*^{V600E} NSCLC. We report efficacy and safety of enco+bini in pts with *BRAF*^{V600E} metastatic NSCLC. **Methods:** PHAROS is an ongoing, open-label, single-arm, phase 2 study that enrolled pts with *BRAF*^{V600E} metastatic NSCLC who had measurable disease by RECIST 1.1 and Eastern Cooperative Oncology Group performance status of 0 or 1, and who were either treatment-naïve or had received 1 prior therapy (chemotherapy, monotherapy, or combination immunotherapy) for metastatic disease. Exclusion criteria included prior treatment with a BRAF or MEK inhibitor. Pts received enco 450 mg QD + bini 45 mg BID administered orally in 28-day cycles. The primary endpoint was confirmed objective response rate (ORR) by independent radiology review (IRR). Secondary endpoints included duration of response (DOR), disease control rate (DCR), progression-free survival (PFS), and time to response (TTR), all by IRR, and safety. Exploratory endpoints included biomarker assessments. **Results:** At the data cutoff (Sep 22, 2022), 98 pts (59 treatment-naïve, 39 previously treated) received enco+bini. The median duration of treatment was 9.2 months with enco and 8.4 months with bini. Treatment is ongoing in 34% of the pts; 38% permanently discontinued due to disease progression and 18% due to adverse events (AEs). The ORR (95% CI) by IRR was 75% (62, 85) in treatment-naïve and 46% (30, 63) in previously treated pts. Secondary endpoints are shown in the table. The most frequent ($\geq$ 30%) treatment-related AEs (TRAEs) were nausea (50%), diarrhea (43%), and fatigue (32%). AEs led to permanent discontinuation of enco+bini in 15% of pts and dose reductions in 24% of pts. One grade 5 TRAE of intracranial hemorrhage was reported. Next-generation sequencing analysis was conducted with archival tumor biopsies from 48 treatment-naïve and 32 previously treated pts. The most frequent genomic alterations, in addition to *BRAF*^{V600E}, were *SETD2* and *TP53* (43% each), *SMAD4* (21%), *ATM*, *MLL2*, *CSF1R*, and *SMARCA4* (14% each), and *CDKN2A* (11%). **Conclusions:** The combination of enco+bini showed meaningful clinical benefit in treatment-naïve and previously treated pts with *BRAF*^{V600E} metastatic NSCLC. The safety profile of enco+bini was generally consistent with that established for pts with *BRAF*^{V600E} melanoma. ClinicalTrials.gov: NCT03915951. Clinical trial information: NCT03915951. Research Sponsor: Pfizer.

Large-scale transcriptomic profiling of the tumor immune microenvironment in *ALK*+ lung cancer. *First Author: Vincent K. Lam, The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Patients (pts) with *ALK*+ Non-Small Cell Lung Cancer (NSCLC) do not derive significant clinical benefit from immune checkpoint inhibitors. To better understand this lack of immunotherapy sensitivity, we aimed to characterize major immune components of the tumor microenvironment (TME) by comprehensive transcriptomic and immunohistochemistry (IHC) analyses. **Methods:** We analyzed NGS data from 5490 NSCLC pts that underwent DNA (592 Gene Panel, NextSeq, or WES, NovaSeq) and RNA (NovaSeq, WTS) sequencing at Caris Life Sciences (Phoenix, AZ). 374 *ALK*-rearranged cases were evaluated, along with 3169 *KRAS*-mut (*STK11/KEAP1*-wt) and 1947 *EGFR*-mut cases serving as comparators with known heterogeneous and inert immune TMEs, respectively. PD-L1 (22C3) was evaluated by IHC. Immune cell fractions were inferred using quanTiseq. Gene expression profiles were analyzed for a T cell-inflamed signature (TIS) predictive of response to immunotherapy and for other immune modulatory genes such as *IFNG*, *GZMB*, *TGFB1*, and those of the adenosine pathway (*CD73/NT5E*, *CD39/ENTPD1*, *ADORA1*, *ADORA2A/B*). A significant difference between genomic subgroups was defined as fold-change > 1.2 . In an independent cohort of 14 *ALK*+ NSCLC pts, density and spatial organization of CD4+ and CD8+ T cells, Tregs, major myeloid lineage cells, PD-L1, and CD73 were assessed by quantitative IHC. **Results:** *ALK*+ tumors were associated with high PD-L1 ($\geq$ 50%) expression (40% vs 47% for *KRAS*-mut vs 18% for *EGFR*-mut, p < 0.001) and low TMB (median 3 mut/MB vs 9 for *KRAS*-mut vs 4 for *EGFR*-mut, p < 0.001). The abundance of CD8+ T cells (fold-change -1.3, p < 0.001), Tregs (fold-change -1.2, p < 0.001), M2 macrophages (fold-change 1.2, p < 0.001), and CD4+ T cells (fold-change 1.9, p < 0.001) differed from *KRAS*-mut; notably, similar to *EGFR*-mut. In *ALK*+ tumors, *IFNG* (fold-change -1.5, p < 0.001), *GZMB* (fold-change -1.6, p < 0.001), *TGFB* (fold-change -1.3, p < 0.001), *LAG-3* (fold-change -1.4 p < 0.001), *CD73/NT53* (fold-change -1.7 p < 0.001), and *ADORA2A* (fold-change -1.4, p < 0.001) were decreased while *ADORA1* (fold-change 1.3, p < 0.001) was increased compared to *KRAS*-mut. *EML4-ALK* comprised 94.7% of the *ALK*+ tumors and distribution of *EML4-ALK* variants was consistent with prior reports (e.g. v1 35.6%, v3 35.1%). Immune cell fractions and immune-related gene expression did not vary significantly between major variant subgroups (v1 vs non-v1, and v3 vs non-v3, p > 0.05). **Conclusions:** To our knowledge this is the largest transcriptomic analysis of the *ALK*+ NSCLC TME. Despite high levels of PD-L1, *ALK*+ tumors exhibit multiple features of an inert immune TME, primarily characterized by low TMB and decreased CD8+ T cells and immune activation markers. Our findings suggest that, while immunosuppressive factors such as M2 macrophages and adenosine signaling may also be targeted, strategies to enhance immunogenicity are critical for an effective immune response in *ALK*+ NSCLC. Poster Discussion Session

Tepotinib + osimertinib for *EGFR* mutant (*EGFRm*) NSCLC with *MET* amplification (*METamp*) after first-line (1L) osimertinib. *First Author: Daniel Shao-Weng Tan, Division of Medical Oncology, National Cancer Centre, Singapore, Singapore*

Background: *METamp* is a common resistance mechanism developed in patients (pts) with *EGFRm* NSCLC treated with osimertinib. *MET* tyrosine kinase inhibitors (TKIs) such as tepotinib may be effective in treating these pts after osimertinib. Here we report interim data from the INSIGHT 2 study evaluating tepotinib + osimertinib in *EGFRm* NSCLC with *METamp* previously treated with osimertinib. **Methods:** In this open-label Phase II study (INSIGHT 2, NCT03940703), pts with advanced *EGFRm* NSCLC with *METamp* after progression on 1L osimertinib received tepotinib 500 mg (450 mg active moiety) + osimertinib 80 mg once daily. *METamp* was centrally detected in tissue biopsy (TBx) by FISH (*MET* gene copy number [GCN] ≥ 5 and/or *MET/CEP7* ≥ 2) and/or in liquid biopsy (LBx) by NGS (*MET* plasma GCN ≥ 2.3 ; Archer). The primary endpoint was objective response by Independent Review Committee in tepotinib + osimertinib treated pts with centrally detected *METamp* by FISH (FISH+). Efficacy data are reported for pts with ≥ 3 months' follow-up, and safety for all pts who received one dose of tepotinib + osimertinib by Sep 26, 2022 (data cut-off). **Results:** Among 472 pts prescreened, 451 pts had *METamp* results by either TBx FISH and/or LBx NGS, of which 175 (38.8%) were positive for *METamp*. 122 pts received tepotinib + osimertinib (median age 61 years [range 20–84], 59.8% female, 59.8% Asian, 68.0% never smoker, 72.1% ECOG PS 1). In 98 pts with FISH *METamp* (29.6% had < 12 months on 1L osimertinib; median GCN 11 [range 5.0–50.6]; mean $\pm$ SD sum of target lesion diameters [SOLD] 73.2 ± 47.1 mm), objective response rate (ORR) was 43.9% (95% CI 33.9, 54.3), median (m) DOR was 9.7 months (95% CI 5.6, ne), mPFS was 5.4 months (95% CI 4.2, 7.1), and mOS was not reached (95% CI 11.1, ne). Of the 98 pts, treatment is ongoing in 42 pts. In 31 pts with *METamp* detected by LBx NGS, of which 24 were also FISH+ (mean $\pm$ SD SOLD 93.9 ± 51.4 mm), ORR was 51.6% (95% CI 33.1, 69.8), mDOR was 5.6 months (95% CI 2.9, ne), mPFS was 4.6 months (95% CI 2.7, 6.9), and mOS was not reached (95% CI 6.8, ne). Of 122 pts treated with tepotinib + osimertinib, any grade treatment-related AEs were reported by 99 (81.1%) pts including 34 (27.9%) Grade ≥ 3 . Most common ($> 15\%$ pts) treatment-related AEs included diarrhea 46.7% (0% Grade ≥ 3), peripheral edema 34.4% (4.1% Grade ≥ 3), paronychia 20.5% (0.8% Grade ≥ 3), decreased appetite 18.0% (3.3% Grade ≥ 3), and nausea 16.4% (1.6% Grade ≥ 3). Treatment-related AEs led to a dose reduction in 21 (17.2%) pts, following either or both treatments and led to treatment discontinuation in 7 pts (5.7%). **Conclusions:** In this interim analysis of INSIGHT 2, tepotinib + osimertinib was highly active with durable responses, and was well tolerated in pts with *EGFRm* NSCLC with *METamp* after progression on 1L osimertinib. Tepotinib + osimertinib provides a potential chemotherapy-sparing oral targeted therapy option in this population with a high unmet need. Clinical trial information: NCT03940703. Poster Discussion Session

Circulating tumor DNA (ctDNA) dynamics and survival outcomes in patients (pts) with advanced non-small cell lung cancer (aNSCLC) and high ($> 50\%$) programmed cell death-ligand 1 (PD-L1) expression, randomized to cemiplimab (cemi) vs chemotherapy (chemo). *First Author: Natalie I Vokes, Thoracic Head & Neck Medical Oncology, MD Anderson Cancer Center, Houston, TX*

Background: While ctDNA has emerged as a promising tool for monitoring response on therapy, there is a paucity of data from prospective, randomised Phase 3 studies to establish clear criteria for the clinical application of ctDNA. In the EMPower-Lung 1 study, first line (1L) cemi monotherapy improved overall survival (OS) vs platinum chemo in pts with aNSCLC, PD-L1 $\geq 50\%$, and no EGFR, ALK, or ROS1 aberrations and an acceptable risk/benefit profile. We performed personalized tumor-specific analysis of ctDNA from pts treated in the EMPower-Lung 1 study to determine the optimal time point and magnitude of ctDNA variation that are associated with OS and progression-free survival (PFS). **Methods:** Tumor tissue next-generation sequencing was performed to identify tumor-specific DNA variants. ctDNA levels were monitored using personalized pt specific probe sets (Natera, Foundation Medicine) in the plasma at baseline, end of week 3 (W3) and W9. Endpoints included overall response rate (ORR) complete or partial response (CR/PR), stable disease (SD) and progressive disease (PD) per RECIST 1.1, OS and PFS. Association between ctDNA decrease and clinical endpoints was tested in 3 groups of pts defined by sensitivity analysis: no-decrease, any decrease (molecular response, MR), and complete clearance (complete MR, cMR) of ctDNA. **Results:** ctDNA analysis was performed on samples from 175 pts (chemo n = 89; cemi n = 86). Baseline characteristics, ORR, OS, and PFS were comparable to those of the intention to treat population. At W9, cMR/MR was associated with clinical response to cemi (CR/PR: 97%, SD:58%, PD:17%), but not with clinical response to chemo, as it was detected in the majority of chemo pts across all RECIST categories (CR/PR: 100%, SD:90%, PD:80%). In the cemi arm, ctDNA cMR was associated with the longest survival, with median OS (mOS) not-reached compared to pts with MR (mOS of 29 months) and pts with no-decrease (mOS of 8 months), as well as statistically significant hazard ratios (cMR vs MR: W9 HR = 8, 95% CI 1.8-35, p = 0.0056; cMR vs no-decrease: W9 HR = 25, 5.7–110, p = 0.000021 and W3 HR = 5.9, 1.4-25, p = 0.017). Delayed MR/cMR (i.e., MR/cMR at W9 but not at W3) was observed in 8/66 pts (12%), and transient MR (i.e., MR at W3 but not W9) in 9/66 pts (14%), with available ctDNA data at both timepoints. **Conclusions:** This is the largest data set to date correlating ctDNA levels with efficacy outcomes from a randomized clinical trial comparing chemo with immunotherapy in 1L aNSCLC. The results indicate that lack of treatment-induced decrease in ctDNA may identify pts with inferior OS benefit from cemi monotherapy as early as 3 weeks following initiation of therapy and can inform future use of early ctDNA response assessment in prospective interventional studies. Poster Discussion Session

Safety and clinical activity of target-preserving anti-CTLA-4 antibody ONC-392 as monotherapy in NSCLC patients who progressed on PD(L)1-targeted immunotherapy. *First Author: Kai He, James Thoracic Oncology Center, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: PD-1 or PD-L1 inhibitors have transformed clinical care of NSCLC patients. However, many patients may develop primary or secondary resistant to PD-(L)1 inhibitors. The marketed anti-CTLA-4 mAbs are ineffective as monotherapy for NSCLC. ONC-392 is a novel target-preserving anti-CTLA-4 antibodies that confers immunotherapeutic effect by selective depletion of regulatory T cells (Treg) in the tumor microenvironment. Preclinical studies show that ONC-392 is more effective and less toxic for immunotherapy than other clinically used anti-CTLA-4 antibodies. In first-in-human study in patients with advanced solid cancer, the recommended Phase 2 dose (RP2D) for ONC-392 monotherapy was established as 10 mg/kg. In this study, we tested safety and clinical activities of ONC-392 in NSCLC patients who progressed on PD(L)1-targeted therapy. **Methods:** Anti-PD-(L)1 resistant NSCLC patients were enrolled as parts of PRESERVE-001 studies (NCT04140526) expansion cohort Part C Arm I and treated with 2 cycles of 10 mg/kg, followed by 6 mg/kg, q3w, ONC-392 by IV infusion. Safety was evaluated based on treatment emergent and treatment-related adverse events, while efficacy was evaluated by investigators using RECIST1.1 criteria. **Results:** As of December 18, 2022, 33 NSCLC patients have received at least one dose of ONC-392 at 10 mg/kg. The median age is 66 yrs (range 43 – 89 yr), 61% male. 61% were non-squamous cell carcinoma and 39% were squamous cell carcinoma. 27% are ECOG score 0 and 73% were ECOG score 1. The median prior treatment was 2 cycles (range 1 to 4). The average ONC-392 treatment period was 3.5 cycles (range 1 to 13 cycles). Overall, the patients with TRAE in grade 3 or above is 33% (11/33), including diarrhea/colitis (3, 9%), AST/ALT increase or hepatitis (3, 9%), muscular weakness (2, 6%), nephritis (1, 3%), adrenal insufficiency (1, 3%). Due to pace of enrollment, efficacy data are available in 22 patients. 6 of 22 evaluable patients have partial response and 12 patients have stable disease per RECIST 1.1, resulting in a response rate of 27% and disease control rate of 82% among evaluable patients. The median follow-up period for all patients is 5.8 months and 8.6 months for 20 alive patients (range 2.9 to 14.1 months). The estimated 6- and 12-month overall survival (OS) rates were 65% and 55%. Median OS has not reached. **Conclusions:** Overall, ONC-392 monotherapy with 10 mg/kg is safe and tolerable. Onc-392 monotherapy has showed encouraging anti-tumor activity in IO-resistant NSCLC when compared with historical data. Based on these encouraging data, we have initiated a Phase 3 study testing ONC-392 monotherapy among NSCLC who progressed on PD(L)1-targeting immunotherapy (NCT05671510). Clinical trial information: NCT04140526. Research Sponsor: OncoC4, Inc.; U.S. National Institutes of Health.

SI-B001 plus chemotherapy in patients with locally advanced or metastatic EGFR/ALK wild-type non-small cell lung cancer: A phase II, multicenter, open-label study. *First Author: Yuanyuan Zhao, Department of Medical Oncology, Sun Yat-sen University Cancer Center & State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China*

Background: SI-B001 is a first-in-class novel EGFR×HER3 bispecific antibody. The objective of this phase II study was to investigate the efficacy and safety of SI-B001 in combination with chemotherapy in pts with locally advanced or metastatic EGFR/ALK wild-type NSCLC. **Methods:** This phase II study enrolled patients with locally advanced or metastatic EGFR/ALK wild-type NSCLC who had failed first-line anti-PD-1/L1 therapy, with or without platinum-based chemotherapy (PBC). This study consisted of three cohorts: In Cohort A pts received SI-B001 plus PBC as second-line treatment after failure to first-line anti-PD-1/L1 antibody monotherapy; Cohort B pts received SI-B001 plus docetaxel as second-line treatment after failure to first-line anti-PD-1/L1 therapy plus PBC; Cohort C pts received SI-B001 plus docetaxel as third-line or higher treatment after failure to first-line anti-PD-1/L1 therapy and PBC. This study evaluated SI-B001 in three distinct dosing schedules: Schedule 1 (16+9mg/kg once weekly), Schedule 2 (14mg/kg on Days 1 and 8 every 3 weeks), and Schedule 3 (21+12mg/kg once weekly). The primary endpoints of the study were to determine the objective response rate (ORR) in evaluable patients and to identify the optimal dose. The secondary endpoints included assessment of progression-free survival (PFS), disease control rate (DCR), duration of response (DOR), and safety. **Results:** As of November 11, 2022, 55 pts have been enrolled in the study, including 1 pt in Cohort A, 45 pts in Cohort B, 8 pts in Cohort C, and one pt enrolled based on the investigator's discretion. Of the 55 pts, 48 were evaluable for efficacy; ORR (n/N, [95%CI]) of 31.3% (15/48, [18.7, 46.3]), DCR of 77.1% (37/48, [62.7, 88.0]). In Cohort B, 23 pts were enrolled in schedule 1, 21 pts were enrolled in schedule 2, and 1 pt was enrolled in schedule 3. Of the 45 pts enrolled in Cohort B, 38 were evaluable for efficacy. Among 22 evaluable pts in schedule 1 the ORR was 45.5% (10/22, [24.5, 67.8]) and the DCR was 68.2% (15/22, [45.1, 86.1]). 18 out of the 22 had no actionable genomic alterations (AGA), the ORR was 50.0% (9/18, [26.0, 74.0]), the DCR was 72.2% (13/18, [46.5, 90.3]), and the mPFS has not been reached. The most common grade ≥3 treatment-related adverse events (TRAEs) were myelosuppression (17%), decreased neutrophil count (15%), and decreased white blood cell count (12%). There was no drug-related death. **Conclusions:** SI-B001 plus docetaxel demonstrated antitumor activity in locally advanced or metastatic NSCLC EGFR/ALK wild-type pts who failed on prior first-line anti-PD-1/L1 antibody plus PBC, especially without AGA. The toxicity of SI-B001 + docetaxel was manageable. These findings support the continued investigation of SI-B001 and docetaxel as a treatment option in NSCLC. Clinical trial information: NCT05020457. Research Sponsor: Sichuan Baili Pharmaceutical Co., Ltd.

The genomic, transcriptomic, and immunological landscape of SGLT2 in lung cancer. *First Author: Heng Tan, University of Miami/Jackson Memorial Hospital, Miami, FL*

Background: Retrospective data suggest that SGLT2 inhibitors, commonly used in diabetes, are associated with a lower incidence of cancer development and *in vivo* data indicate SGLT2 plays a role in the development of NSCLC. We investigated the genomic and immunological landscape of NSCLC [adenocarcinoma (AC) or squamous cell carcinoma (SCC) histology] with high and low expression of the SGLT2-coding gene *SGLT2* and the relationship with clinical outcomes. **Methods:** NSCLC tumors of AC (N = 11,725) or SCC (N = 4,158) histology were tested at Caris Life Sciences (Phoenix, AZ) with NextGen Sequencing on DNA (592 genes or whole exome) and RNA (whole transcriptome). PD-L1 expression (22C3; Positive (+): TPS ≥1%) was assessed by IHC. High tumor mutational burden (TMB-H) was defined as ≥10 mutations/MB. Mutations were defined as pathogenic SNVs/indels. *SGLT2*-H and -L expression (transcripts per million) was defined as top and bottom quartile, respectively. A transcriptomic signature predictive of response to immunotherapy was applied (T cell-inflamed). The Mann-Whitney U test was applied as appropriate, with P-values adjusted for multiple comparisons (p < .05). Real-world overall survival (OS) data was obtained from insurance claims and Kaplan-Meier estimates were calculated for molecularly defined subpopulations of patients (N = 13,505). **Results:** In AC tumors, *SGLT2*-H was associated with higher rates of *EGFR* (20.8 vs 13.5%, p < .05) and *STK11* mutations (20.1 vs 12.9%, p < .05), but lower rates of *TP53* (50.8 vs 69.5%, p < .05) and *ARID1A* (8.7 vs 4.6%, p < .05) mutations. There was no significant difference in the *KRAS* mutation rate (35.6 vs 37.1%, p = 1). AC and SCC *SGLT2*-H tumors had a lower prevalence of PD-L1+ (AC: 47 vs 68%, SCC: 50 vs 67%, p < .05). AC *SGLT2*-H tumors had a lower prevalence of TMB-H (30 vs 39%, p < .05), but not in SCC (40 vs 41%, p = .6). *SGLT2*-H tumors were associated with a higher prevalence of T cell-inflamed tumors (AC: 40 vs 19%, SCC: 33 vs 11%, p < .05). *SGLT2*-H AC had longer OS as compared to *SGLT2*-L AC tumors (HR = 0.787 [1.73-.85], p < .001) but no significant difference in time on treatment (TOT) with pembrolizumab was observed (HR .90 [1.78-1.03], p = .13). *SGLT2*-H SCC tumors had significantly longer OS (HR .88, [1.78-1.00], p = .045) and they had significantly longer TOT with pembrolizumab (HR .72 [1.56-.94], p = .01). Finally, *SGLT2*-H, *KRAS* mutant AC tumors had significantly longer OS (HR .64 [1.57-.73], p < .001) whereas *SGLT2*-H *KRAS* mutant SCC tumors (HR 1.46 [1.83-2.57], p = .19) trended towards shorter OS. **Conclusions:** *SGLT2* expression was associated with a highly altered genomic landscape in AC. In specific mutational and histological subgroups, differences in *SGLT2* expression were associated with OS and responsiveness to immunotherapy. These mutational and histological subtypes should be further investigated as research on SGLT2 inhibitors progresses. Research Sponsor: None.

Poster Session

Large-scale comparative analysis of clinico-genomic characteristics, treatment outcomes and resistant mechanisms of *ALK/ROS1/RET*-rearranged non-small cell lung cancer (NSCLC) in a nationwide genomic screening project (LC-SCRUM-Asia/TRY). *First Author: Yosuke Kagawa, National Cancer Center Hospital East, Chiba, Japan*

Background: There is limited understanding of the clinico-genomic differences among *ALK/ROS1/RET*-rearranged NSCLC due to their low frequency. We aimed to characterize these fusions using a large-scale LC-SCRUM-Asia/TRY database. **Methods:** We conducted a prospective screening of treatment-naïve and refractory lung cancer to identify genomic alterations using RT-PCR and/or targeted next-generation sequencing (NGS) assays in LC-SCRUM-Asia/TRY. We compared clinico-genomic characteristics, treatment outcomes and resistant mechanisms among *ALK/ROS1/RET*-rearranged NSCLC. **Results:** Between February 2013 and December 2022, 18,616 lung cancer patients (pts) were enrolled in LC-SCRUM-Asia/TRY and 16,583 were NSCLC pts. *ALK/ROS1/RET* fusions were identified in 430 (2.6%)/240 (1.4%)/202 (1.2%) pts in NSCLC. The patient characteristics were as follows (*ALK/ROS1/RET*): median age, 58/60/63 years; females, 53/54/54%; never-smokers, 57/55/59%; adenocarcinoma, 93/95/96%. The frequencies of brain metastasis at diagnosis were 26/20/19% (p = 0.15). Among pts tested by NGS, the frequencies of *TP53*, *TET2* and *NOTCH1* mutations were lower in *ALK* than in *ROS1* and *RET* (*TP53*; 23/34/27%, *NOTCH1*; 17/34/35%, *TET2*; 17/30/32%). Overall survival (OS) was significantly longer in *ALK* than in *ROS1* (mOS [*ALK/ROS1/RET*] 108.8 vs. 43.6 vs. not reached [NR] months, *ALK* vs. *ROS1*; p < 0.01, *ALK* vs. *RET*; p = 0.04) among stage IV pts underwent TKI therapy. *TP53* mutation was associated with shorter OS in all three fusions (mOS [*TP53* mt+/mt-] *ALK*; 35.7 vs. 108.8, p < 0.01, *ROS1*; 26.4 vs. 47.4, p = 0.06, *RET*; 28.9 vs. 76.1 months, p = 0.05), shorter PFS with first line alectinib in *ALK* (mPFS [*TP53* mt+/mt-] 11.0 vs. 38.4 months, hazard ratio [HR] 2.5 [95% CI, 1.5-4.2], p < 0.01) and shorter PFS with initial crizotinib in *ROS1* (mPFS [*TP53* mt+/mt-] 5.8 vs. 25.2 months, HR 2.6 [95% CI, 1.3-4.8], p < 0.01). There was no significant difference in PFS with first-line platinum plus pemetrexed among fusions (mPFS 12.6 vs. 10.7 vs. 9.2 months) and PFS with initial immune checkpoint inhibitors among fusions (mPFS 3.9 vs. 5.1 vs. 3.0 months). Among 60/13/10 re-biopsy samples refractory to TKI, on-target resistant mutations were identified in 14 (23%) /3 (23%) /1 (10%) samples. **Conclusions:** Pts with *ALK/ROS1/RET*-rearranged NSCLC shared similar characteristics, but the occurrence of concomitant mutations was lower in *ALK* than in *ROS1* and *RET*. *TP53* mutation was associated with worse prognosis in pts with *ALK/ROS1/RET*-rearranged NSCLC. Among those received TKI, pts with *ALK*-rearranged NSCLC had better prognosis than those with *ROS1* and *RET*-rearranged NSCLC. The development of highly effective molecular targeted therapies for *ROS1*- and *RET*-rearranged NSCLC is warranted. Research Sponsor: None.

Peripheral myeloid cells as prognostic markers in patients (pts) with non-small cell lung cancer (NSCLC) treated with cemiplimab: Pooled analysis of EMPOWER-Lung 1 and EMPOWER-Lung 3 phase 3 trials. *First Author: Joseph Christopher Murray, Johns Hopkins Kimmel Cancer Center, Baltimore, MD*

Background: Circulating innate and adaptive immune cells can modulate clinical responses to immune checkpoint inhibition in pts with cancer; however, there are no clear validated baseline clinical tests to guide clinicians, outside of programmed cell death-ligand 1 (PD-L1) IHC tests on limited biopsy specimens. High neutrophil/lymphocyte ratio (NLR) is associated with poor prognosis in NSCLC, but data are limited on the potential contribution of other immune cells such as monocytes and eosinophils in modulating systemic immune response. Further, previous correlative studies have not established clinically actionable immune cell cut-off values. **Methods:** We used multiple quantitative analytic methods including multivariable Cox regression and conditional decision trees to assess the prognostic importance of NLR and peripheral myeloid cells, including monocytes and eosinophils, in pts with NSCLC treated with cemiplimab in Phase 3 trials EMPOWER-Lung 1 (NCT03088540) and EMPOWER-Lung 3 (NCT03409614). In EMPOWER-Lung 1, pts with PD-L1 ≥50% were randomized 1:1 to cemiplimab 350 mg every 3 weeks (Q3W) or platinum-based chemotherapy (chemo). EMPOWER-Lung 3 was a 2-part study. In Part 1, pts with PD-L1 < 50% were randomized 1:1 to chemo, cemiplimab 350 mg Q3W + chemo, or cemiplimab 350 mg Q3W + ipilimumab 50 mg Q6W + chemo. In Part 2, pts were randomized 2:1 to receive cemiplimab 350 mg or placebo Q3W + chemo. **Results:** Overall, 691 pts in EMPOWER-Lung 1 and 769 pts in EMPOWER-Lung 3 were included in this analysis. The results showed significant association between multiple factors including NLR and overall survival (OS) and progression-free survival (PFS). For pts with NLR > 3.98 vs ≤3.98, median OS (95% CI) was 10 (9-13) vs 20 (17-24) months (HR: 2.04; 95% CI: 1.60-2.61; P < 0.001) and median PFS (95% CI) was 4 (4-6) vs 6 (6-7) months (HR: 1.80; 95% CI: 1.50-2.18; P < 0.001), respectively, accounting for known prognostic factors. In multivariable analyses, monocytes (OS HR: 1.72; 95% CI: 1.29-2.30; P < 0.001; PFS HR: 1.37; 95% CI: 1.08-1.75; P = 0.010) and log eosinophils (OS HR: 0.90; 95% CI: 0.85-0.97; P = 0.003; PFS HR: 0.93; 95% CI: 0.88-0.98; P = 0.004) were significantly associated with OS and PFS in both studies. (Neutrophil + monocyte)/lymphocyte ratio was the top predictor of both OS and PFS in decision tree analysis. Peripheral blood cell count correlations were not affected by tumor PD-L1 levels (p < 0.15 for all markers). **Conclusions:** This is a large and comprehensive prognostic analysis of data from two prospective Phase 3 clinical trials in advanced NSCLC. Clinically actionable peripheral blood cell count parameters, incorporating putative immunosuppressive myeloid cells (neutrophils and monocytes) and protective lymphocytes and eosinophils, may help predict response to anti-PD-1 therapy in advanced NSCLC. Clinical trial information: NCT03088540, NCT03409614. Research Sponsor: Regeneron Pharmaceuticals, Inc., and Sanofi.

Impact of *EML4-ALK* fusion variant and co-occurring *TP53* mutation on treatment duration of first-line next-generation ALK TKIs in ALK fusion+ NSCLC. *First Author: Kaushal Parikh, Mayo Clinic, Rochester, MN*

Background: Molecular biomarkers such as *EML4-ALK* fusion variant 3 (V3) and *TP53* mutation are associated with poor prognosis in patients (pts) with anaplastic lymphoma kinase fusion positive (*ALK*+) non-small cell lung cancer (NSCLC). We evaluated the effect of *EML4-ALK* fusion variants and *TP53* mutation status on time to treatment discontinuation (TTD) of first-line (1L) treatment with a next-generation ALK tyrosine kinase inhibitor (TKI) in pts with *ALK*+ NSCLC in the real-world setting. **Methods:** Pts with advanced/metastatic NSCLC who were *ALK*+ in circulating tumor DNA by Guardant360 (G360) liquid biopsy test from Jan 1, 2018, to Dec 31, 2021, and received 1L monotherapy with a next-generation ALK TKI (alectinib, brigatinib, ceritinib, lorlatinib) were identified in the Guardant INFORM clinical-genomics database. Median TTD of 1L ALK TKI treatment was determined by Kaplan-Meier (KM) methods. The impact of *EML4-ALK* fusion variant and *TP53* mutation status on TTD was evaluated. **Results:** Database search identified 495 pts with advanced/metastatic NSCLC who had *ALK* fusion by G360; of these, 214 pts received 1L treatment with a next-generation ALK TKI; 164 had G360 testing before treatment (alectinib, n=147; brigatinib, n=7; ceritinib, n=2; lorlatinib, n=8). Among these 164 pts, median age was 58.6 y, 53% were female, and 29% had baseline brain metastases. Median follow-up from start of 1L treatment was 14.8 mo. Median TTD was 19.6 mo (95% CI: 13.6–not reached [NR]). *TP53* mutations were detected in 66 pts (40%). Median (95% CI) TTD in pts with *TP53* mutation vs WT was 17.1 (9.5–28.5) vs 21.9 mo (14.3–NR; log-rank $P=0.1712$). Of 130 pts with *EML4-ALK* fusion variant type detected, 63 (48%) had V1, 54 (42%) V3, 8 (6%) V2, 4 (3%) V5, and 1 (1%) V8. In pts with *EML4-ALK* fusion V1 vs V3, median (95% CI) TTD was 19.0 (13.6–NR) vs 21.8 mo (8.7–NR; HR: 0.73; log-rank $P=0.3039$), with the KM plot showing numerically longer TTD in pts with V1 vs V3 during the first 18 mo and lines crossing at the tail end. Of 117 pts with both an *EML4-ALK* fusion variant (V1/V3) and *TP53* data, 21 (18%) had both V3 and a *TP53* mutation. Pts with co-occurring *EML4-ALK* V3 and *TP53* mutation had the shortest TTD (median TTD 8.7 [3.9–NR; HR: 2.59; $P=0.0219$]; Table). **Conclusions:** Among pts with NSCLC and *ALK* fusion, co-occurrence of *EML4-ALK* V3 and *TP53* mutation is common and associated with poor prognosis and high risk of early discontinuation of 1L treatment with a next-generation ALK TKI, most likely due to disease progression. Additional novel or combination therapies are warranted for this subpopulation. Research Sponsor: Takeda Development Center Americas, Inc., Lexington, MA, USA.

	n ^a	Median TTD (95% CI), mo	HR (95% CI)	P value
<i>EML4-ALK</i> V1 and <i>TP53</i> WT	38	19.5 (11.4–NR)	Reference	
<i>EML4-ALK</i> V1 and <i>TP53</i> +	25	19.0 (9.5–NR)	1.01 (0.42–2.44)	0.9849
<i>EML4-ALK</i> V3 and <i>TP53</i> WT	33	NE (9.4–NR)	0.89 (0.38–2.09)	0.7873
<i>EML4-ALK</i> V3 and <i>TP53</i> +	21	8.7 (3.9–NR)	2.59 (1.15–5.84)	0.0219

^a 117 pts had data for both *TP53* and *EML4-ALK* V1 or V3.

MSH3 and MSH6 gene polymorphisms: Association with lung cancer susceptibility and prognostic value in patients with NSCLC undergoing platinum-based chemotherapy. *First Author: Navneet Singh, Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India*

Background: DNA mismatch repair (MMR) pathway is responsible for recognizing and repairing errors (insertion, deletion and misincorporation of bases) occurring during DNA replication and recombination. Single nucleotide polymorphisms (SNPs) in *MSH3* and *MSH6* genes are related to development of various cancers. SNPs of particular interest include rs26279 G > A polymorphism for *MSH3* and rs3136228 557G > T polymorphism for *MSH6*. In this cohort study, we evaluated the association of *MSH3* (rs26279) and *MSH6* (rs3136228) SNPs with occurrence of lung cancer (LC), baseline demographic and clinical characteristics and with overall survival (OS) amongst LC patients undergoing platinum-based doublet chemotherapy. **Methods:** 500 LC patients and 500 healthy controls were enrolled. Genomic DNA was isolated from 4ml of peripheral blood using a phenol-chloroform extraction procedure and genotyping of patients and controls was performed using PCR-RFLP. All enrolled patients had pathologically confirmed LC. Written informed consent was obtained from all enrolled subjects and the study was approved by institutional ethics committee. Odds ratio (OR) and 95% confidence intervals (CIs) were calculated using logistic regression analysis. Kaplan-Meier method was used for OS analysis and (multivariate) Cox regression models to obtain (adjusted) hazards ratios (HRs). **Results:** Mean age (61 years) was similar for cases and controls. Compared to controls, LC cohort had higher prevalence of non-smokers (20% vs. 10%), female sex (20% vs. 9%) and smoking pack-years (mean 20.8 vs. 13.8). Majority of LC patients had metastatic disease (54%) and ECOG performance status of 0-1 (45%) or 2 (40%). Adenocarcinoma and squamous were equi-prevalent (41% each). Mutant genotype (TT) for *MSH6* polymorphism was more frequent in LC patients (OR = 1.43; 95% CI = 1.01 – 2.03; $p = 0.03$) with the association more marked in adenocarcinoma histology (OR = 1.74; 95% CI = 1.05 – 2.93; $p = 0.03$). For non-smokers, mutant genotype (TT) for *MSH6* polymorphism was associated with a 3-fold increased risk of LC (OR = 3.22; 95% CI = 1.26 – 8.18; $p = 0.01$). Amongst females, heterozygous genotype (GA) for *MSH3* polymorphism was more frequent amongst LC cases (24%) than controls (16%) (OR = 2.35, 95% CI = 0.85 – 6.52, $p = 0.04$). Patients treated with docetaxel-platinum chemotherapy and carrying heterozygous (GT) genotype for *MSH6* polymorphism had worse OS (median 4.9 vs 9.1 months; adjusted HR = 2.3; $p = 0.03$). No association was observed between *MSH3* (rs26279) and *MSH6* (rs3136228) polymorphisms and other baseline clinical/demographic characteristics. **Conclusions:** The results of this cohort study suggest that *MSH3* and *MSH6* polymorphisms are involved in modulating the risk towards LC occurrence. *MSH6* polymorphism is also associated with higher mortality amongst patients treated with docetaxel-platinum chemotherapy. Real-world testing and treatment patterns among patients with stage IV non-small cell lung cancer: A retrospective observational study. *First Author: Jeffrey A. Scott, Integra Connect PrecisionQ, West Palm Beach, FL*

Background: Guidelines (NCCN, CAP/IASLC/AMP) recommend clinical molecular testing of patients with advanced NSCLC to inform therapy decisions. We investigated the testing and treatment patterns of patients with stage 4 NSCLC treated in the real-world setting. **Methods:** This retrospective observational study included de-identified stage 4 NSCLC patients from the Integra Connect PrecisionQ database (ICD) enriched with information obtained by curation. Patients with a positive mutation for EGFR, ALK, ROS1, BRAF, MET, RET, HER2, or NTRK and who initiated treatment for stage 4 NSCLC between 01/01/2018 and 12/31/2021 were included with follow-up through 05/31/2022. Also included were demographics, ECOG score, time of ordering test, and date of death. Genomic test data were classified by method and type of test. Overall survival (OS) was calculated using Kaplan-Meier curves and data are presented using descriptive statistics. **Results:** Of 5195 patients in the ICD with stage 4 NSCLC, 3532 patients initiated first line of therapy (LOT1), and 2899 had somatic molecular testing ordered, specifically via tissue-based next-generation sequencing (NGS, 30%), plasma-based NGS (26%), or non-NGS methods (44%). A total of 934 patients tested positive for a driver mutation at any time during the study observation period, and 671 patients (72%) had test results available before initiating treatment. Of those treated after receiving biomarker results, 407 (61%) initiated treatment with a tyrosine kinase inhibitor (TKI), 43 (6%) with chemotherapy (chemo), 156 (23%) with chemo + immuno-oncology (IO), and 65 (10%) with IO. The median OS (95% confidence interval [CI]) was 24.46 (21.90–29.18) months for patients treated with TKI and 14.2 (11.6–16.5) months for patients treated without TKI (unadjusted hazard ratio [95% CI], 1.56 [1.26, 1.92]; $P < 0.001$). **Conclusions:** Among patients with stage 4 NSCLC treated in the real-world setting, patients treated with TKI after receiving test results had better overall survival than patients treated without TKI. While subject to the limitations of a retrospective observational real-world data study, this study suggests that, with regard to utilizing genomic testing and appropriate selection of targeted treatment, adherence to treatment guidelines may improve patient outcomes. As new targeted agents continue to emerge in NSCLC, these data encourage utilization of genomic testing data to guide treatment selection. We acknowledge the significant contributions of our dear friend, Dr. Robert E. Smith, whose cheerful enthusiasm and deep expertise were a driving force of this work. Research Sponsor: Thermo Fisher.

Impact of genomic alterations measured in circulating tumor DNA (ctDNA) on clinical response to telisotuzumab vedotin treatment in patients with non-small cell lung cancer (NSCLC). *First Author: D. Ross Camidge, University of Colorado Cancer Center, Aurora, CO*

Background: The antibody-drug conjugate telisotuzumab vedotin (Teliso-V) is composed of the c-Met-targeting antibody telisotuzumab (ABT-700) linked to the microtubule inhibitor monomethyl auristatin E. In the LUMINOSITY study (NCT03539536), efficacy of Teliso-V was seen in patients (pts) with *EGFR* wildtype nonsquamous NSCLC and c-Met overexpression ($\geq 25\%$ tumor cells at 4+ intensity by IHC); overall response rate: 36.5%. Data are limited on whether specific driver oncogene states affect responses. We investigated genomic alterations in relation to response to Teliso-V in this population. **Methods:** Pts received 1.9 mg/kg Teliso-V monotherapy once every 2 weeks in LUMINOSITY. ctDNA was isolated from plasma collected at different timepoints. The PGDx elio plasma complete assay was used to identify genomic alterations in ctDNA samples. This assay included 521 genes for single nucleotide variants and insertion-deletion mutations, 38 for amplifications (amp), and 21 for translocations. **Results:** In total, 52 pts were included in the study; ctDNA from 48 pts was analyzed. The overall response rate among pts with ctDNA results was 37.5% (18 pts with partial response) compared with 36.5% for the ITT population of 52 pts. Genomic alterations are listed in the Table. Three out of 4 pts with *MET* amp at baseline responded, accounting for 17% of total responses. The observed *MET* amp frequency in this *MET* IHC pre-selected cohort was 8%, which is similar to the prevalence observed in tissue analysis by FISH. Of note, 1 nonresponder harbored a *MET* ex14del mutation at baseline, and a responder had a low-frequency mutation detected at the final visit. Mutations in *KRAS* were the most common genomic alteration and were detected in 13 (27%) pts at baseline. Three pts with a *KRAS* mutation were responders; among these, 2 out of 3 had a *KRAS* G12C mutation (seen in 3 pts total). Response rates were higher in pts with *MET* amp (75%; 95% CI: 0.30, 0.95) vs those without *MET* amp (34%; 0.22, 0.49), and higher in pts without *KRAS* mutations (43%; 0.28, 0.59) vs those with *KRAS* mutations (23%; 0.08, 0.50); however, confidence intervals were wide and larger sample sizes are needed. **Conclusions:** *MET* amp occurred more frequently in responders; however, Teliso-V activity was not restricted to these pts, as most responders were not *MET* amplified. Specific genomic alterations beyond *MET* may influence clinical response. The current analysis demonstrated numeric differences between pts with identified drivers who did or did not respond to Teliso-V. Additional research on this topic is needed in larger pt cohorts and/or with tissue-based NGS analyses. Research Sponsor: AbbVie Inc.

Analytical and clinical validation of oncomine Dx target (ODxT) test and local testing for identifying patients with HER2 (*ERBB2*)-mutant (HER2m) non-small-cell lung cancer (NSCLC) for treatment with trastuzumab deruxtecan (T-DXd) in DESTINY-Lung01/02 (DL-01/02). *First Author: Bob T. Li, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Based on the international DL-01 trial, the US Food and Drug Administration (FDA) approved the ODxT Test as a companion diagnostic (CDx) to identify patients (pts) with NSCLC harboring activating HER2 mutations who may benefit from T-DXd. The ODxT Test uses next-generation sequencing (NGS) to detect genomic alterations in formalin-fixed, paraffin-embedded tumor tissue. The accuracy of the ODxT Test by central testing and its agreement with clinical trial assays (CTAs; NGS, polymerase chain reaction, etc.) by local testing was evaluated using analytical and clinical validation data from DL-01 cohort 2 and DL-02 arm 1. **Methods:** ODxT Test and Illumina TruSight Tumor170 NGS assay results were compared for analytical accuracy in NSCLC samples from DL-01 and commercial vendors. Diagnostic agreement was assessed for DL-01/02 by concordance between the ODxT Test and CTAs. Clinical accuracy per objective response rate (ORR) and duration of response (DoR) to T-DXd were evaluated in all pts with HER2m NSCLC identified by ODxT Test vs CTA. Activating HER2 mutations included single nucleotide variants and exon 20 insertions. Pts received T-DXd 6.4 mg/kg in DL-01 or 5.4 mg/kg (FDA-approved dose) in DL-02 every 3 weeks. **Results:** NSCLC samples from DL-01 (n = 91), DL-02 (n = 102), and commercial vendors (n = 129) were individually assessed. The ODxT Test met requirements for analytical accuracy (≥90% agreement when excluding unknown results), with a positive percent agreement (PPA) of 100% and negative percent agreement (NPA) of 99.1% for detecting HER2 mutations. Clinical accuracy of the ODxT Test also met FDA requirements (excluding unknowns) for NPA (≥98%) and PPA (95% CI lower bound ≥85%). DL-01 PPA (95% CI) was 98.0% (89.2%-100%) and NPA was 100.0% (96.6%-100%); for DL-02, PPA was 96.7% (88.7%-99.6%) and NPA was 100% (96.6%-100%). In DL-01, confirmed ORR (95% CI) for pts with HER2m NSCLC identified by central ODxT Test was 58.3% (43.2%-72.4%) vs 54.9% (44.2%-65.4%) of pts identified by local CTA; median DoR (95% CI) was 12.0 mo (5.5 mo-18.2 mo) per the ODxT Test vs 9.3 mo (5.7 mo-14.7 mo) per CTA. In DL-02 (prespecified interim analysis early cohort), ORR (95% CI) was 53.6% (33.9%-72.5%) per ODxT Test vs 53.8% (39.5%-67.8%) per CTA; median DoR (95% CI) was not estimable (NE [NE-NE]) per the ODxT Test and NE (4.2 mo-NE) per CTA. **Conclusions:** This study demonstrates the analytical and clinical accuracy of the ODxT Test as a CDx for detecting activating HER2 mutations in NSCLC to identify pts who may benefit from T-DXd. A high level of agreement was also shown between the ODxT Test and CTAs. Clinical trials for HER2m NSCLC may successfully use a central testing assay as a CDx while allowing adequately validated local testing assays to expedite patient enrollment. Clinical trial information: NCT03505710, NCT04644237. Research Sponsor: Daiichi Sankyo, Inc and AstraZeneca.

The effect of ctDNA tumor fraction (TF) on overall survival and concordance between tissue genomics and ctDNA in Lung-MAP. *First Author: Philip C. Mack, Mount Sinai Health System, New York, NY*

Background: Discordance in genomic profiling between tumor tissue and ctDNA can occur due to *inter-patient* variability in shed tumor DNA, and *intra-patient* variability in sources of cell-free DNA (tumor heterogeneity, metastatic variants, CHIP). TF is an aneuploidy-based estimation of tumor-specific DNA in circulation. We evaluated the impact of TF levels on overall survival (OS), mutation concordance and tumor mutation burden in tissue (tTMB) and ctDNA (bTMB) in the LUNGMAP screening study. **Methods:** Eligible advanced NSCLC pts had blood drawn ≤30 days of fresh tissue biopsy with no intervening therapies. Genomic profiling was done by FoundationOne CDx and FoundationOne Liquid CDx. ctDNA TF was quantified via aneuploidy using deviations in genome-wide SNP coverage or somatic allele frequencies if under aneuploidy LoD. High TF was defined as ≥10%. Concordance among driver genes, cancer genes of interest (CGol: *TP53*, *PIK3CA*, *STK11*, *KEAP1*, *RB1*, *PTEN*, *ATM*, *BRCA1/2*), and variant subtype were assessed by the percentage positive agreement (PPA) and positive predictive value (PPV) with 95% confidence intervals (CI). OS by TF used a Cox model and log-rank test. PPA and TF among CGols was compared with a Wilcoxon test. Correlation between tTMB and bTMB used Lin's coefficient (LC). **Results:** 167 pts met inclusion criteria; 161 had TF data with 51 (32%) ≥10% (high TF). High TF was associated with worse OS (HR: 2.06 [1.43-2.95], p<0.001). The PPA and PPV ranged from 50%-100% and 60%-100%, respectively for driver genes. The PPA was numerically larger for high versus low TF for most drivers (p=0.18) and significantly larger for all mutations and SNVs combined (Table). For CGol, the distribution of PPA differed between high and low TF (p=0.03). The median PPA for CGol (25thtile, 75thtile) was 56% (50,87) for low TF and 100% (100,100) for high TF. PPV for CGol did not differ by TF (p=0.20). High TF was associated with higher levels of TMB and bTMB (p<0.01 for both). TMB LC (CI) for low and high TF were 0.46 (0.27,0.61) and 0.69 (0.53,0.81). **Conclusions:** High TF was associated with worse OS, better PPA among CGol, and better LC for t/bTMB. TF may improve the clinical utility of mutations detected by liquid biopsies and should be reported and considered in interpreting these results. Research Sponsor: U.S. National Institutes of Health; National Institutes of Health; Friends of Cancer Research.

Molecular characterization of resistance to immune checkpoint inhibitor and chemotherapy treatment in advanced non-small cell lung cancer. *First Author: Jordan Kardos, Gilead Sciences, Inc., Foster City, CA*

Background: Non-small cell lung cancer (NSCLC) is the most common type of lung cancer and a leading cause of cancer death. Standard of care (SOC) treatment for advanced NSCLC patients include immune checkpoint inhibitors (ICI) and/or chemotherapy (CT). However, the majority of patients do not respond to SOC therapy. Mechanisms of resistance and how they differ across treatments are not fully understood. We characterized molecular markers of resistance for advanced NSCLC patients with ICI monotherapy, CT, or combination ICI-CT. **Methods:** Advanced stage III or IV NSCLC patients with adenocarcinoma histology who received at least 21 days of ICI monotherapy, CT, or combination ICI-CT were identified from a de-identified, multimodal real-world database from Tempus Labs, Inc. All patients had a tissue biopsy taken within 100 days prior to the specified therapy start and all samples underwent next generation sequencing with the Tempus xT assays (DNA-seq of 596-648 genes at 500x coverage and whole transcriptome RNA-seq). Resistance to therapy was defined as having time to next treatment < 90 days, or disease progression or death within 120 days of therapy initiation. We characterized the clinical and molecular characteristics of patients and compared differential expression of genes by resistance status for each cohort. **Results:** A total of 365 patients were included in the study (ICI = 121, CT = 122, ICI-CT = 122). Across cohorts, 30% of patients were identified as having resistance to treatment (ICI = 35%, CT = 23%, ICI-CT = 32%). 53% of patients were > 65 years (median [range] = 67 [25- 88]), and 53% were males. Most patients were white (63%) and had a history of tobacco use (85% current or former smoker). At the time of biopsy, most patients were diagnosed with metastatic NSCLC (Stage IV = 73%) and had received no previous lines of therapy (92%). The alteration frequencies of known NSCLC oncogenic driver mutations including TP53 (65%), KRAS (42%), STK11 (14%), KEAP1 (11%), and EGFR (9%) were broadly consistent with previous characterizations of NSCLC. Validated biomarkers of response to ICI treatment such as Tumor Mutation Burden, IFN-γ signaling, PD-1, and PD-L1 expression were negatively associated with resistance to ICI treatment. Across the ICI, ICI-CT, and CT cohorts, 253, 153, and 178 genes, respectively, were significantly upregulated (FDR < 0.05, LogFC > 1) in patients with resistance to treatment. Of the 550 distinct genes correlated to resistance across treatments, 95% were unique to each cohort, and only 32 genes (5%) were shared across more than one treatment cohort. **Conclusions:** Distinct molecular characteristics were associated with resistance to ICI and/or CT treatment. This suggests that mechanisms of resistance to ICI monotherapy, ICI-CT, or CT could be separate and unique. Further research can provide valuable insights for novel therapies or combinations. Efficacy and safety of polymeric micelle paclitaxel (pm-Pac) plus tislelizumab and carboplatin for first-line treatment of patients with advanced squamous non-small-cell lung cancer. *First Author: Meiqi Shi, Department of Medical Oncology, Jiangsu Cancer Hospital & Jiangsu Institute of Cancer Research & The Affiliated Cancer Hospital of Nanjing Medical University, Nanjing, Jiangsu, China*

Background: The pm-paclitaxel formulation for injection (pm-Pac), a novel drug delivery system composed of nanoparticle-encapsulated paclitaxel micelles, combined with cisplatin has been proven to improve clinical outcomes in patients with advanced non-small-cell lung cancer (NSCLC). But the efficacy and safety of pm-Pac in addition to PD-1/PD-L1 inhibitors had never been reported before. **Methods:** Treatment-naïve, stage IIIB/IV Sq-NSCLC patients with ECOG PS 0-2(≤1, 91.1%) were eligible. Participants were given intravenous Tislelizumab (200mg, d1) plus pm-Pac (230 mg/m², d1) and carboplatin (AUC 5, d1), every 3 weeks until progression or unacceptable toxicity, with local radiotherapy or surgery allowed if treatment needed. The primary endpoints were ORR and safety. The secondary endpoints include DCR, PFS, and OS. AEs were graded according to CTCAE v5.0. **Results:** From Nov 2021 to Dec 2022, 45 patients were enrolled. The median age was 68 years (range 41-84), and most were male (93%) and former/current smokers (87%). 3 patients had baseline brain metastases and 31 patients had baseline PD-L1 evaluated. Twenty-two patients (48.9%) received subsequent local treatment because of the stable efficacy, including 18 radiotherapy and 4 surgery. Among all, 2 achieved confirmed CR, 36 achieved PR, 7 achieved SD, ORR was 84.4% and DCR was 100%. PFS and OS were immature. Kaplan-Meier survival analysis indicated that the 6m-PFS rate was 94.8% (95%CI:89.8% , 97.6%), and a total of 41 (91.1%) patients are still alive on 1L treatment at the last follow-up on Feb 2023.The most common TRAE were alopecia (91.1%), leukopenia (80%), peripheral neurosensory numbness (55.6%) and extremity pain (24.4%). The most common grade 3 or higher AE was neutropenia (33.3%), which is commonly associated with chemotherapy. **Conclusions:** This is the first report about the new chemo-drug pm-Pac plus PD-1 inhibitor regimen that significantly improved ORR for advanced Sq-NSCLC with a tolerable safety profile, supporting further development of this new combination in the first-line treatment. Exploring the potential of combination immune checkpoint strategies in non-small cell lung cancer (NSCLC). *First Author: Aakash Desai, Mayo Clinic, Rochester, MN*

Background: The clinical outcomes for patients with NSCLC remain suboptimal despite recent advancements in anti-PD-1/PD-L1 immunotherapies. Thus, identification of rational combinations of novel immune checkpoint (IC) strategies is imperative. This study aimed to comprehensively characterize the expression of IC targets to inform drug development and design effective combinatorial strategies, to advance the search for optimized therapies for NSCLC. **Methods:** We analyzed the differential gene expression of IC targets in 537 primary lung adenocarcinoma (LUAD) samples and 59 normal lung tissue samples pre-immunotherapy receipt using RNA-sequencing data from The Cancer Genome Atlas. Gene expression of IC-targets including *PDCD1* (PD-1), *CD274* (PD-L1), *CTLA4*, *TIGIT*, *LAG3*, *HAVCR2* (TIM-3), *VSIR* (VISTA), *ICOS*, *CD276* (B7-H3), *BTLA*, *IDO1*, *KLRD1* (CD94/NKG2A), *NT5E* (CD39), *TNFRSF4* (OX-40), *TNFRSF18* (GITR), and *TNFRSF9* (4-1BB) were obtained. Differential gene expression was determined intra-tumorally by comparison of transcripts per million and inter-tumorally using the DESeq2 algorithm. Log2 fold change >0.5 and false discovery rate adjusted $P < 0.05$ were used as criteria for significant differential expression. Hierarchical clustering was used to identify subsets of tumors with similar profiles of IC-targetable gene expression. **Results:** Tumors showed significantly increased expression of *TNFRSF18* (GITR), *NT5E* (CD39), *TNFRSF9* (4-1BB), *LAG3*, *TIGIT*, *CTLA4*, *PD-1*, *BTLA*, *B7-H3*, and *OX-40* (Table 1). On the other hand, tumors exhibited significant downregulation of *CD274* (PD-L1), *HAVCR2* (TIM-3), *ICOS*, *KLRD1* (CD94/NKG2A), and *VSIR* (VISTA). Hierarchical clustering revealed recurrent patterns of IC gene overexpression which were characterized by: 1) *IDO1*-hi, 2) *CD276*-mid + *TNFRSF18*-mid, 3) *VSIR*-hi, 4) *CD276*-hi, 5) *NT5E*-hi, and 6) *CD276*-mid + *NT5E*-mid. Interestingly, patterns of IC gene expression distinguish tumors from controls. Of note, high *VSIR* expression was specific to normal tissue rather than tumors. **Conclusions:** Our study identified many IC targetable genes that were significantly overexpressed in tumors. However, subsets of tumors showed distinct and segregable combinations of overexpressed IC genes. These results suggest heterogeneous mechanisms of immune evasion in NSCLC, which may explain suboptimal outcomes with anti-PD-1/PD-L1 based strategies in this patient population. Our findings emphasize the importance of biomarker-guided approaches for the optimal selection of ICs and the development of rational combinatorial immunotherapies in NSCLC. Research Sponsor: None.

Effects of mutations in SWI/SNF subunits on context-specific prognosis in driver positive and driver negative NSCLC. *First Author: Benjamin Herzberg, Columbia University Irving Medical Center, New York, NY*

Background: Mutations (mt) in the Switch/Sucrose-Nonfermentable chromatin remodeling complex (SWI/SNF) are commonly found in NSCLC and have been associated with worse prognosis. However, the overall prognostic role of the individual SWI/SNF subunits in all NSCLCs and in oncogenic driver-positive (D+) and driver-negative (D-) groups remains unclear. Our study attempts to clarify the prognostic role of SWI/SNF subunit alterations in these populations. **Methods:** 42,379 NSCLC tumor specimens were tested at Caris Life Sciences (Phoenix, AZ) with NextGen Sequencing (NGS) of DNA (592-gene panel or whole-exome sequencing). Based on the observed frequency of likely pathogenic/pathogenic (LP/P) mts, the four most commonly-altered SWI/SNF subunits – ARID1A (8.29%), SMARCA4 (6.29%), ARID2 (3.05%) and PBRM1 (1.98%) – were further analyzed. We divided the cohort by driver mts. D+ tumors possessed at least one of the following alterations: LP/P mts in KRAS, EGFR, BRAF, ERBB2 or MET; METex14 skipping; ERBB2 amplification, LP/P fusions in ALK (including IHC overexpression), RET, ROS1, NTRK (1-3) & NRG1. D- tumors were devoid of mts/amplifications/fusions in all genes mentioned above. Kaplan-Meier analysis was performed on real world survival data ($n = 24685$) obtained from insurance claims. Statistical significance was determined using chi-square and Mann-Whitney U test adjusted for multiple comparisons ($q < 0.05$). **Results:** Of the SWI/SNF genes, only SMARCA4mts were associated with worse survival in the overall (HR = 1.46), D+ (HR = 1.984) and D- (HR = 1.224) cohorts (all $p < 0.01$). While SMARCA4mt was associated in the D- cohort with KEAP1 and STK11 mts, the worse prognosis persisted even in their absence (HR = 1.41, $p < 0.001$). To understand the role of SWI/SNF mts in the context of driver co-mts, we compared the survival of D+ vs D- tumors for each SWI/SNF subunit. As expected, D+ tumors were associated with better survival in SWI/SNF wild-type (wt) tumors (HRs 0.76-0.78, $p < 0.00001$). There was no survival effect of ARID1A, ARID2 or PBRM1 mts (HRs = 0.9-1, $p = ns$). In contrast, in SMARCA4mts, D+ tumors had much worse survival than D- (HR = 1.295, $p = 0.003$). This effect is driven by the KRASmt cohort, as KRASmt/SMARCA4mt tumors had significantly worse survival compared with D- tumors (HR = 1.882, $p < 0.001$). Of note, KRASmts are enriched in the D+/SMARCA4mt subgroup (78% of all oncogenic drivers). When KRASmts were removed from the D+ group, no survival difference was observed between D+ and D- SMARCA4mt tumors (HR = 0.938, $p = ns$). **Conclusions:** In this largest-ever retrospective cohort of NSCLC patients with SWI/SNF mutations, SMARCA4mt is the only SWI/SNF alteration broadly associated with worse survival. SMARCA4mt is associated with particularly short survival in KRASmt tumors. These data suggest underlying biology which may inform further investigation and therapeutic development. Co-mutational status and PD-L1 expression in KRAS mutant non-small cell lung cancer (NSCLC): Role in treatment selection and association with clinical outcomes. *First Author: Hina Khan, The Warren Alpert Medical School of Brown University, Providence, RI*

Background: In NSCLC, different *KRAS* mutations (mt) define unique subgroups and certain co-mutations (co-mt) could have prognostic and therapeutic implications. Retrospective studies associate poor prognosis with co-mts in *STK11* and *KEAP1* with *KRAS*. It is unclear if PD-L1 expression and co-mt in *KRAS* mt NSCLC impacts outcomes. **Methods:** Molecular profiles of 27748 NSCLC tumors were tested with next-generation sequencing (Caris Life Sciences, Phoenix, AZ) and classified by *KRAS* mt. PD-L1 IHC (22C3) was reported as TPS. Real-world post-immunotherapy (IO) overall survival (OS) was obtained from insurance claims and calculated from start of an immune check-point inhibitor (with or without chemotherapy) to the last day of follow-up. **Results:** In all, 7634 (28%) samples had a *KRAS* mt; most common being G12C (11%), G12V (5.3%), G12D (3.9%) and G13X (2.0%). The most frequent co-mt was *KRAS*-TP53 (KP) (46%), similar in all *KRAS* subtypes. *KRAS*-STK11 (KL) was in 23% of *KRAS* mt, enriched in G13X (33%) and lowest in G12D (16%). *KRAS*-KEAP1 (KK) was co-mt in 10% of *KRAS* mt, highest in G13X (16%) and lowest in G12D (8%). *KRAS*mt/STK11wt/KEAP1wt/TP53wt (K only) was 27% of *KRAS* mt, highest in G12D (36%) and lowest in G13X (16%). A small subgroup, 5.6% was *KRAS*-STK11-KEAP1 co-mt (KKL). The majority of pts in the KL (61%), KK (52%) and KKL (62%) cohorts had TPS <1%. In 1723 *KRAS* mt NSCLC pts treated with IO, KL, KK and KKL had significantly worse post-IO OS than KP and K only (table); KKL had the lowest OS. In the TPS ≥ 1% *KRAS* mt group, KL, KK and KKL had worse post-IO OS than KP and K-only. In TPS <1% group, KL and KK had poor post-IO OS and K-only had favorable outcomes. However, KP had worse post-IO OS compared to K-only in TPS <1%. In G12C and G12V, similar trend with worse post-IO OS in KL, KK and KKL, compared to KP and K only was noted. **Conclusions:** We report a large real-world dataset evaluating outcomes with check-point inhibitors in NSCLCs with *KRAS* and specific co-mts. KL, KK and KKL subgroups demonstrate universally poor outcomes in all *KRAS* subtypes irrespective of PD-L1. Pts with KP co-mts have adverse post-IO outcomes in TPS <1% but favorable in TPS ≥ 1%. TPS score remains a predictive marker of IO outcomes in KP, but not in KL, KK and KKL. These observations emphasize that both PD-L1 and co-mts have a clear association with clinical outcomes in *KRAS*-mt NSCLC, and must be used in predictive models for individualized therapy. Research Sponsor: None.

TROP2 expression and response to immune checkpoint inhibition in patients with advanced non-small cell lung cancer. *First Author: Antoine Italiano, Early Phase Trials Unit, Institut Bergonié and University of Bordeaux, Bordeaux, France*

Background: Despite anti-monoclonal antibodies targeting programmed cell death-1 (PD-1) or its ligand PD-L1 revolution, most patients (pts) with advanced NSCLC displayed primary resistance to PD1/PD-L1 blockade. Identifying targetable alterations involved in resistance represent a promising approach to improve immunotherapy efficacy. TROP2 expression is associated with a poor prognosis in NSCLC, and offers a promising target for treatment with the development of new antibody drug conjugate. TROP2 has been suggested to play a role in innate immunity response, but, it's unclear whether TROP2 expression by tumor cells is detrimental specifically in the context of PD1/PD-L1 blockade. The aim of our study was to investigate the role of TROP2 expression in outcome of NSCLC pts treated with ICI. **Methods:** We analyzed the largest NSCLC gene expression data set worldwide including the whole-transcriptome profile of 891 pre-treatment tumors from POP-LAR and OAK trials, two randomized studies assessing the efficacy of atezolizumab versus docetaxel in NSCLC. We complemented this transcriptional approach with multiplex IF and digital pathology analysis to confirm our findings at the protein level. We investigated whether a non-invasive approach focusing on the level of plasma levels of circulating TROP2 may be relevant to predict efficacy of ICI. **Results:** The PFS of pts with high expression of TROP2 was significantly lower than in pts with low expression 2.5 vs 4.1 months, $p < 0.001$. Strikingly, high TROP2 expression was also associated with lower clinical benefit rate 15% vs 28%, $p = 0.009$ and worse overall survival (OS) 12.6 vs 16.3 months, $p = 0.007$. When adjusting for covariates such as histological subtype, TMS signature, PD-L1 expression, TROP2 remained independently associated with PFS and OS. None of these correlations were observed in the docetaxel arm, suggesting a predictive value of TROP2 gene expression specifically for response to ICI. By using a deconvolution approach, we also observed that TROP2-high tumors were characterized by a significant lowest expression of genes specific to immune populations (T effector memory cells, Th17 cells). Multiplex IF on an independent cohort 53 NSCLC tumors confirmed the correlation between high TROP2, microenvironment features and poor response to PD1 inhibition. Analysis of circulating plasma levels of TROP2 in 97 NSCLC patients revealed a strong correlation with expression in tumor tissue. High plasma levels of circulating TROP2 was also significantly associated with worse ORR, PFS and OS on treatment with PD1/PDL1 antagonist. **Conclusions:** Our study revealed that TROP2 expression by tumor cells in NSCLC is associated with worse outcome in patients with NSCLC independently of PDL1 expression. Targeting TROP2 in combination with ICI may represent a promising strategy to improve ICI efficacy in pts with TROP2-high NSCLC. Research Sponsor: None.

Pre-treatment plasma-informed circulating tumor DNA detection as an early identification of therapeutic benefit for patients with untreated advanced lung squamous cell carcinoma. *First Author: Tao Jiang, Department of Medical Oncology, Shanghai Pulmonary Hospital and Thoracic Cancer Institute, Tongji University School of Medicine, Shanghai, China*

Background: Circulating tumor DNA (ctDNA) detection as a promising prognostic factor to assess treatment response has been widely studied with customized tumor-informed strategies, the application of which was limited by the inaccessibility for tumor biopsies in a substantial proportion of patients. To overcome this challenge, we presented a proof-of-concept study for the development of a novel personalized pre-treatment plasma-informed next generation sequencing (NGS) panel and investigated its prognostic value for first line treatment in patients with advanced lung squamous cell carcinoma (LUSC). **Methods:** Paired plasma and white blood cell (WBC) samples were collected from 227 of stage IIIB-IV LUSC patients who were treated with first line either chemotherapy or chemotherapy plus PD-1 blockade at pre- and post-treatment. Somatic mutations in pre-treatment plasma were identified with a 769-gene based NGS panel (Genecast, Wuxi, China) followed with germline or clonal hematopoietic variants filtering by referring to the WBC samples. Positive variants detected in the pre-treatment plasma served as a basis for personalized variants tracking in post-treatment plasma. ctDNA kinetics was measured by plasmaDelta ($\Delta\text{geneaf} = (\text{post-treatment geneaf} - \text{pre-treatment geneaf}) / \text{pre-treatment geneaf}$; geneaf was defined by variant allele frequency for each individual gene). Progression-free survival (PFS) as the primary endpoint and overall survival (OS) as the secondary endpoint were assessed. **Results:** ctDNA positivity was observed in 80% (182/227) of pre-treatment samples and subsequently 54% (99/182) of post-treatment samples. ctDNA positivity at post-treatment was shown to be a significant predictor for both PFS and OS in the whole group as well in the sub-treatment groups (Table). After adjusting for clinicopathologic variables, ctDNA positivity remained significantly associated with both worse PFS and OS (PFS: HR = 2.3, $P < 0.001$ and OS: HR = 2.56, $P < 0.001$). ctDNA kinetics further identified a worse treatment response group. Patients with high plasma-Delta had remarkably worse outcomes than patients with low plasma-Delta (PFS: HR = 4.8; 95%CI=2.8-8.3; $P < 0.001$ and OS: HR=2.8; 95%CI=1.7-4.6; $P < 0.001$). **Conclusions:** These results demonstrated the feasibility of pre-treatment plasma-informed ctDNA detection and kinetics for monitoring treatment response in LUSC patients whose tumor biopsies were unavailable. Research Sponsor: None.

Prognostic value of ctDNA positivity.						
Groups	No. of ctDNA positive patients	No. Of ctDNA negative patients	PFS		OS	
			HR (95% CI)	P value	HR (95% CI)	P value
All	99	83	3.2 (2.3-4.4)	<0.001	3.4 (2.3-5.0)	<0.001
Chemotherapy plus PD-1 blockade	39	49	2.7 (1.7-4.4)	<0.001	3.8 (2.1-6.8)	<0.001

Factors impacting outcomes in individuals ≥ 80 years with non-small cell lung cancer (NSCLC): A national cancer database (NCDB) analysis. *First Author: Ethan Burns, Houston Methodist Neal Cancer Center, Houston, TX*

Background: Older individuals with advanced/metastatic NSCLC have inferior outcomes compared to younger patients. Aside from baseline comorbidities and treatment-limiting toxicities, identifying factors that impact overall survival (OS) in this population is needed. The aim of this study is to assess characteristics impacting outcomes in patients ≥ 80 years with NSCLC using the NCDB. **Methods:** Adults ≥ 80 years with NSCLC, stage III/IV disease, diagnosed between 2015-2018, and available demographic data were included. Age, sex, race, insurance status, hospital subtype, Charelsion-Deyvo comorbidity (CDCC) index, cancer stage (III/IV), geographic region in the United States (US), and histologic NSCLC subtypes were compared. Kaplan-Meier methodology assessed differences in median OS, and differences were compared using hazard ratios (HR) with 95% confidence intervals (CI). Pearson Chi-Squared test assessed the significance of covariates, and a p value < 0.05 was considered statistically significant. **Results:** There were 42,356 patients included. Median age was 83 (80-90) years, 20,422 were (48.2%) female, 35,653 (84.2%) were white, 37,738 (89.1%) had medicare coverage, 11,055 (26.1%) received treatment at an academic hospital, and 14,383 (33.9%) received care in the southern United States. Treatment at an academic hospital (HR: 0.91 [95% CI: 0.87, 0.95], $p < 0.001$), females (HR: 0.82 [95% CI 0.81, 0.84], $p < 0.001$), Medicaid (HR: 0.77 [95% CI: 0.65, 0.93], $p = 0.005$) vs no insurance, and adenocarcinoma (HR: 0.79 [95% CI: 0.74, 0.84], $p < 0.001$) or squamous cell carcinoma (HR: 0.84 [95% CI: 0.80, 0.90], $p < 0.001$) had better outcomes. Patients in the Northeastern (HR: 0.90 [95% CI: 0.87, 0.93], $p < 0.001$), Southern (HR: 0.92 [95% CI: 0.89, 0.94], $p < 0.001$), and Western (HR: 0.89 [95% CI: 0.88, 0.93], $p < 0.001$) US had better OS compared to the Midwest. Compared to whites, patients who were black (HR: 0.92 [95% CI: 0.88, 0.85], $p < 0.001$), Asian (HR: 0.77 [95% CI: 0.72, 0.82], $p < 0.001$), Hispanic (HR: 0.83 [95% CI: 0.78, 0.88], $p < 0.001$), or other (HR: 0.88 [95% CI: 0.79, 0.97] had better outcomes. Per year increase in age (HR 1.009 [95% CI: 1.006, 1.013], $p < 0.001$), patients with CDCC score of 1 (HR: 1.16 [95% CI: 1.14, 1.19], $p < 0.001$), 2 (HR: 1.22 [95% CI: 1.18, 1.27], $p < 0.001$), and ≥ 3 (HR: 1.33 [95% CI: 1.284, 1.380], $p < 0.001$) vs 0, and stage IV NSCLC (HR: 1.83 [95% CI: 1.79, 1.88], $p = 0.000$) had poorer survival. **Conclusions:** White race, males, uninsured status, receipt of treatment in the Midwest, community hospital treatment, large cell histology, advancing age, stage IV disease, and increasing CDCC score all had poorer outcomes in adults ≥ 80 years with advanced NSCLC. These factors should be taken into consideration when discussing the diagnosis, management, and expectations of the disease course with patients in the geriatric age group. Research Sponsor: None.

Treatment at twilight: Is less more in the management of octogenarians with non-small cell lung cancer (NSCLC)? *First Author: Ethan Burns, Houston Methodist Cancer Center, Houston, TX*

Background: Treatment of advanced/metastatic NSCLC in older patients is hindered by performance status, comorbidities, and treatment toxicities. Moreover, whether multiagent chemotherapy in combination with immune checkpoint inhibitor (ICI) therapy outweighs a conservative approach is controversial. This study aims to assess treatment patterns and outcomes in patients ≥ 80 years with NSCLC through data provided by the national cancer database (NCDB). **Methods:** Adults ≥ 80 years with stage III/IV NSCLC, available treatment data, and diagnosis between 2015-2018 were included. Patients were stratified by therapy including none, ICI alone, chemotherapy alone, and chemotherapy+ICI; radiation and surgical management was also assessed. Median overall survival (OS) was evaluated by Kaplan-Meier survival methods, and differences were assessed by hazard ratios (HR) and 95% confidence intervals (CI). The mean difference in OS was compared between systemic therapy arms. Pearson Chi-Squared tests assessed the significance of treatment differences, with a p-value of < 0.05 considered statistically significant. **Results:** There were 42,356 patients included; 29,698 (70.1%) had stage IV disease and 26,314 (62.1%) had adenocarcinoma. A total of 3,248 (7.7%) received ICI, 11,505 (27.2%) received chemotherapy, 2,393 (5.6%) received chemotherapy+ICI, and 25,210 (59.5%) received no therapy. Median OS for no therapy, ICI, chemotherapy, and chemotherapy+ICI was 2.63 (95% CI: 2.57, 2.69), 10.68 (95% CI: 9.96, 11.39), 12.35 (95% CI: 11.98, 12.72), and 14.03 (95% CI: 13.87, 14.88) months, respectively. Compared to no therapy, ICI alone (HR: 0.377 [95% CI: 0.361, 0.393], $p = 0.000$), chemotherapy alone (HR: 0.439 [95% CI: 0.426, 0.452], $p = 0.000$), and chemotherapy+ICI (HR: 0.345 [95% CI 0.328, 0.363], $p = 0.000$) improved OS. Compared to ICI, chemotherapy and chemotherapy+ICI had a longer mean OS difference of 2.48 (95% CI 1.82, 3.13) ($p < 0.001$) and 1.9 (95% CI 1.01, 2.78 ($p < 0.001$)) months, respectively. In chemotherapy alone, the median OS was 1.12 months (95% CI: 0.55, 1.70) ($p < 0.001$) longer with multiagent vs single agent. There was no difference between chemotherapy vs chemotherapy+ICI (0.57 months [95% CI: 0.16, 1.31], $p = 0.234$), or for ICI+single agent vs ICI+multiagent (0.67 months [95% CI -1.18, 2.54], $p = 1.00$). Treatment with radiation (HR: 0.664 [95% CI: 0.649, 0.679], $p < 0.001$), primary-sit(HR: 0.495 [95% CI: 0.465, 0.527], $p < 0.001$) and non-primary surgery (HR: 0.867 [95% CI: 0.811, 0.927], $p < 0.001$), and receipt of ICI vs no ICI (HR: 0.912 [95% CI 0.873, 0.954], $p < 0.001$) improved OS. **Conclusions:** Patients ≥ 80 years with NSCLC derived most benefit from multiagent chemotherapy or chemotherapy+ICI, with no OS difference between ICI+single or ICI+multiagent therapy. ICI alone and no therapy had inferior OS. Future trials to corroborate this finding would benefit the elderly population. Research Sponsor: None.

A phase II study of afatinib in combination with pemetrexed and carboplatin in patients with EGFR mutation positive non-squamous, advanced non-small-cell lung cancer (NSCLC) refractory to first-line osimertinib treatment: NEJ025B. *First Author: Tatsuro Fukuhara, Department of Respiratory Medicine, Miyagi Cancer Center, Natori, Japan*

Background: To date, osimertinib has been commonly used as a first-line treatment for EGFR mutated advanced NSCLC. However, the issue of what constitutes effective treatment after osimertinib failure remains. We evaluated treatment with afatinib plus chemotherapy for EGFR mutated NSCLC resistant to osimertinib. **Methods:** Patients (pts) with EGFRm (Del19 or L858R) after failure of osimertinib treatment were assigned to a regimen of afatinib 20mg daily combined with carboplatin AUC5 mg/ml/min and pemetrexed 500mg/m² every 3 weeks followed by maintenance treatment with afatinib plus pemetrexed until disease progression or unacceptable toxicity was noted. The primary endpoint was rate of PFS at 6 months after initiation of treatment (6M-PFSR). The threshold was set at 35% and the expected value at 60% (two-sided P-value of 5% and power of 80%). Thirty-one patients were required, and the target number of patients was set at 35 after accounting for ineligible cases. Secondary endpoints were PFS, OS, ORR, DOR, and Safety. In this study, blood samples were collected before and after study treatment and at the time of PD to examine biomarkers using CAPP-SEQ. This biomarker study is ongoing. **Results:** Between June 7, 2020 and January 19, 2022, 36 pts were enrolled. One patient was found to meet the exclusion criteria, and the efficacy was analyzed in the other 35 patients. The mean age was 70 years, 60% were women, and 54.3% were nonsmokers. The 6M-PFSR, the primary endpoint, was 57.1%. The confidence interval of 39.3%-71.5% exceeded the threshold of 35%, and the study met its primary endpoint. Notably, 24.1% of pts had a long-term PFS of 1 year or longer. ORR was 48.6%, DCR was 88.6%, median PFS was 8.2M, median DOR was 5.6 M, and median OS was not reached. By mutation type, ORR were similar for Del19 and L858R (46.7% and 50.0%, respectively), but median PFS tended to be longer for Del19 compared to L858R (9.6M and 5.2M, respectively). Pts who responded to previous osimertinib therapy (CR and PR: n = 29) tended to have longer mPFS compared to non-responders (SD, PD, and NE: n = 6) (8.5M and 5.8M, respectively). Adverse events due to TKI and chemotherapy were observed. Diarrhea (52.8%), anorexia (44.4%), fatigue (33.3%), and paronychia (36.1%) were the most frequent adverse events, and these adverse events were predictable and manageable. Interstitial pneumonia developed in three patients (8%), one of whom was the only death in the study. **Conclusions:** The combination of afatinib and the platinum doublet showed satisfactory efficacy with manageable adverse events in tumors refractory to osimertinib, and met its primary endpoint. OS follow-up and biomarker analyses are still ongoing. This regimen is expected to be a candidate for second-line therapy after osimertinib. Clinical trial information: jRCTs021200005. Uncommon *EGFR* mutations conducted with osimertinib in patients with NSCLC (UNICORN): A phase 2 study. *First Author: Yusuke Okuma, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: Non-small cell lung cancer (NSCLC) harboring uncommon *EGFR* mutation (u-*EGFR*m), excluding exon 20 insertion, is a heterogeneous rare fraction consisting of 10% of all *EGFR* mutations. Key drugs for metastatic NSCLC (mNSCLC) u-*EGFR*m are limited, with only afatinib being FDA approved. Data on the efficacy of osimertinib for previously untreated metastatic patients (pts) harboring u-*EGFR*m NSCLC is limited. **Methods:** UNICORN study for previously untreated mNSCLC pts harboring u-*EGFR*m, excluding exon 20 insertion mutation, evaluating osimertinib with a dose of 80 mg QD orally is a multicenter, open-label, single-arm phase 2 study. The primary endpoint was the overall response rate (ORR) evaluated by central review according to the Response Evaluation Criteria in Solid Tumors (version 1.1), and key secondary endpoints were disease control rate (DCR), progression-free survival (PFS), overall survival (OS), duration of response (DoR), and safety. **Results:** Between March 2020 to May 2022, a total of 42 pts were registered. Among the eligible 40 pts, 45.0% were female; the median age was 72 years (range 39-88); 42.5% were never smokers or light smokers; 92.5% were adenocarcinomas, solitary u-*EGFR*m/compound mutation ratio was 57.5%/42.5%. The most common mutations were G719X (50.0%), followed by S768I (25.0%), L861Q (20.0%), and others, including compound mutation data. The ORR was 55.0% (90% confidence interval [CI]; 40.9-68.5), the DCR was 90.0% (95% CI; 76.3-97.2), the mPFS was 9.4 months (95% CI; 3.7-15.2) after a median follow-up of 27.0 months, the mOS was not reached (NR) (95% CI, 19.23-NR), and the mDoR 22.7 months (95% CI; 9.43-NR). In solitary and compound mutations with u-*EGFR* m NSCLC, ORR was 52.2%/58.8%, mPFS was 5.4 months/11.4 months, mOS 23.0 months/NR, and mDoR was 22.7 months/NR, respectively. Safety was similar to previous reports and Grade 3/4 AEs were reported in 8 of 36 pts (27.5%) and 12.5% of pts developed pneumonitis. All of the AEs were manageable and there were no treatment-related deaths. **Conclusions:** Osimertinib in mNSCLC pts harboring u-*EGFR*m other than exon 20 insertions showed clinical activity with manageable toxicities. These results suggest that osimertinib can be considered as a treatment option for this specific population. Clinical trial registration: jRCT071200002. The study was funded by AstraZeneca. Clinical trial information: jRCT071200002. Research Sponsor: AstraZeneca.

Poster Session

Updated efficacy and safety of entrectinib in patients (pts) with locally advanced/metastatic *NTRK* fusion-positive (fp) non-small cell lung cancer (NSCLC). *First Author: Byoung Chul Cho, Yonsei University College of Medicine, Seoul, Korea, Republic of (South)*

Background: *NTRK* fusions, encoding for constitutively active oncogenic tropomyosin receptor kinase proteins, are present in many solid tumors, including NSCLC. As central nervous system (CNS) metastases are common in pts with advanced NSCLC, treatments with intracranial efficacy are needed. Entrectinib, a potent CNS-active tyrosine kinase inhibitor, has previously demonstrated efficacy in pts with *NTRK*-fp NSCLC in an integrated analysis of three phase I/II trials (ALKA-372-001 [EudraCT, 2012-000148-88], STARTRK-1 [NCT02097810], STARTRK-2 [NCT02568267]); objective response rate (ORR) was 63.6% (14/22; data cutoff: August 31 2020). We present updated data for this cohort. **Methods:** Pts $\geq$ 18 years old with locally advanced/metastatic *NTRK*-fp tumors were enrolled and received 600 mg oral entrectinib until disease progression, toxicity, or death. At Week 4 and then every 8 weeks, tumour response was assessed by blinded independent central review (BICR) per RECIST v1.1. Co-primary endpoints were ORR and duration of response (DoR). Secondary endpoints included progression-free survival (PFS), overall survival (OS), intracranial efficacy, and safety. Enrollment cutoff: July 2 2020; data cutoff: August 2 2021. **Results:** The efficacy-evaluable population included 31 pts with *NTRK*-fp NSCLC. Median age was 60.0 years (range 22-88); 26 pts (83.9%) had adenocarcinoma; 11 pts (35.5%) had $\geq$ 2 prior lines of systemic therapy; 18 pts (58.1%) were current or former smokers; 15 pts (48.4%) had investigator-assessed baseline CNS metastases. Median survival follow up was 21.8 months (95% CI 19.5-30.2). Entrectinib treatment showed efficacy in pts with *NTRK*-fp NSCLC, including those with baseline CNS metastases by investigator (Table). In pts with BICR-assessed CNS metastases, intracranial ORR was 60.0% (6/10; 95% CI 26.2-87.8), median intracranial DoR was not estimable (NE), and median intracranial PFS was 8.9 months (95% CI 5.6-NE). In the safety-evaluable population (N=35), most treatment-related adverse events (TRAEs) were Grade 1-2 and non-serious. TRAEs led to dose reduction, interruption and discontinuation in 31.4%, 28.6%, and 5.7% of pts, respectively, and no treatment-related deaths occurred. **Conclusions:** In line with previously reported data, treatment with entrectinib was associated with deep and durable systemic and intracranial responses in pts with advanced *NTRK*-fp NSCLC. Clinical trial information: EUCR 2012-000148-88, NCT02097810, NCT02568267. Research Sponsor: This study is sponsored by F. Role of immunotherapy in stage IV non-small cell lung cancer with liver metastasis: A NCDB analysis. *First Author: Takefumi Komiya, Penn State Cancer Institute, Hershey, PA*

Background: Despite approvals of immune checkpoint inhibitors in stage IV non-small cell lung cancer (NSCLC), survival benefit of immunotherapy (IO) in those with liver metastasis is controversial. Randomized controlled trials demonstrated conflicting results. **Methods:** Using National Cancer Database (NCDB), Stage IV NSCLC cases diagnosed in 2016-2017 with at least 30-day follow up were analyzed. Clinical demographics included age (20-69 vs. 70+), sex (male vs. female), race (whites vs. others), institution (academic vs. others), Charlson-Deyo score (0-1 vs. 2-3), year of diagnosis (2016 vs. 2017), Histology (adenocarcinoma NOS vs. other), brain metastasis (Yes vs. No), bone metastasis (Yes vs. No), liver metastasis (Yes vs. No). They were divided into liver-metastasis positive (LM+) vs. negative (LM-). Information regarding cancer treatment was limited to the first course of therapy, including surgery for primary lesion (Yes vs. No), radiation (Yes vs. No), multi-agent chemotherapy (Yes vs. No), and IO (Yes vs. No). Overall Survival (OS) analysis was performed using Kaplan-Meier curves and Log-rank tests. Cox proportional hazard model was used for multivariate analyses. A two-sided p-value < 0.05 was considered as significant. **Results:** A total of 13,594 LM+ and 69,885 LM- cases met eligibility and further analyzed. 2,944 and 15,553 patients were treated with IO, respectively. No significant association between use of IO and status of liver metastasis was observed (p = 0.124). The median OS in LM+ cases was significantly shorter than that in LM- cases (5.0 vs 8.8 months, respectively, p < 0.0001). Use of IO was associated with improved OS in both LM+ and LM- cohorts with similar HRs/p-values (0.62/ < 0.0001 and 0.64/ < 0.0001, respectively). Multivariate analysis demonstrated that use of IO had a significantly improved OS in both LM+ (HR = 0.69, p < 0.0001) and LM- (HR = 0.64, p < 0.0001) cohorts. The OS benefit of IO in LM+ cohort remained with propensity score matching analysis (mOS 9.0 vs. 4.4 months, HR = 0.62, p < 0.0001). Further exploratory analysis focusing on those treated with multiagent chemotherapy showed that the addition of IO improved OS in both LM+ (HR = 0.77, p < 0.0001) and LM- (HR = 0.79, p < 0.0001) cohorts. **Conclusions:** This retrospective study using one of the largest cancer databases suggests that use of IO improves OS of NSCLC patients with LM regardless of chemotherapy status, and its magnitude of OS benefit is similar to that in LM-patients. Research Sponsor: None.

	LM+ with IO	LM+ without IO	LM- with IO	LM- without IO
Median OS (month)	9.0	4.1	15.6	7.2
12-month OS (%)	41.7	24.1	57.8	37.9
24-month OS (%)	24.8	13.1	37.6	23.7

Initial chemotherapy for locally advanced and metastatic NUT carcinoma: A report from the NUT carcinoma registry. *First Author: Jia Luo, Dana-Farber Cancer Institute, Boston, MA*

Background: NUT carcinoma (NC) is an uncommon squamous cell cancer. This disease is driven by a *NUTM1* gene fusion, most commonly encoding a BRD4-NUT fusion oncoprotein, that enhances transcription of numerous genes including *MYC*. BET bromodomain inhibitors (BBDi), which block oncoprotein binding, are being studied in clinical trials. A subset of NC is sensitive to chemotherapy, but the optimal regimen is unknown; experts have recommended platinum- (PLAT) and ifosfamide-based (IFOS) therapy based on case reports. **Methods:** Patients with NC with known chemotherapy treatment and survival outcomes who consented to participate in a worldwide registry were included. Cohorts of patients with non-metastatic and metastatic disease were of interest. Medical records were manually reviewed. Results were summarized using 95% confidence intervals (95CI) and Kaplan Meier survival estimates, when appropriate. **Results:** A total of 60 patients with NC were included and received either PLAT (83%) or IFOS (17%); 38% were female and the median age was 37 (range 10-82); 55% of tumors were thoracic primaries, 48% had squamous differentiation, and 70% were driven by BRD4-NUTM1 (n = 43 with known fusion status). Of 31 patients with non-metastatic disease, 32% had a thoracic primary; 23% received peri-operative chemotherapy and 77% received concurrent chemoradiation (cRT). The most common chemotherapies used for cRT were cisplatin (n = 12), platinum-taxane (n = 6), and platinum-etoposide (n = 5). Of 4 non-metastatic patients who received IFOS, 4 (100%) had a disease-free survival (DFS) > 3 months and 1 (25%) had a DFS > 1 year. By comparison, of the 27 patients who received PLAT, the estimated 3-month and 1-year DFS was 70% (95CI 48-84%) and 53% (95CI 30-71%) respectively. Of the 29 patients with metastatic disease, 79% had a thoracic primary; 6 received IFOS and 23 received PLAT. The most common chemotherapies were platinum-taxane (52%), platinum-etoposide (17%), and ifosfamide-etoposide (14%). ORR of IFOS vs PLAT was 50% (95CI 12-88%) vs 23% (95CI 7-44%). Compared to IFOS, PLAT had similar 3-month and 6-month PFS (3; 6mo: PLAT est: 36% [95CI 18-56%]; 9% [95CI 2-25%] vs IFOS 50%; 17%). The estimated 1-year OS and 1-year OS were 18% (95CI 6-35%) vs 33% for PLAT vs IFOS respectively. Of the 5 patients (8%) with a known OS > 3 years, all had a non-thoracic primary, non-metastatic disease, and had received PLAT. **Conclusions:** NUT carcinoma is a highly aggressive disease. There may be a numerically higher ORR for ifosfamide-based therapy as compared to platinum-based therapy, with limited durability. Development of effective combination targeted therapies, eg. combinations with BBDi, is an urgent unmet need for this patient population. Thoracic SMARCA4-deficient cancer descriptors and clinicopathologic determinants of survival: Analysis of a pooled database. *First Author: Frankie Lee Powell, Feist-Weiller Cancer Center at LSUHSC-Shreveport, Shreveport, LA*

Background: Inactivation of SMARCA4, a catalytic subunit of the SWI/SNF complex, has been linked to high-grade aggressive cancers with poor prognoses. SMARCA4-deficient thoracic tumors (SDTT) can involve any part of the chest cavity, including the lungs, mediastinum, pleura, and chest wall. SDTT's detailed clinical features and optimal treatment still need to be clarified. Therefore, we conducted this pooled database analysis to delineate key clinicopathological characteristics, prognostic indicators, and treatment modalities that affect survival in this unique group of thoracic cancers. **Methods:** To study the demographic characteristics, molecular and immunohistochemical signatures, therapeutic interventions, survival, and prognostic factors, we compiled a pooled database of 120 cases of SDTT. Kaplan-Meier survival curves were constructed. Cox proportional hazards model and Log-rank tests were used to assess the influence of demographic and clinicopathologic factors on overall survival (OS). **Results:** A total of 120 patients with confirmed SDTT were identified. The median age was 54, with a peak incidence between 56 and 68. There was a male preponderance with M:F of 3. The median duration of symptoms before diagnosis was 3.5 months. Patients presented with local disease in 11%, locally advanced in 21%, and metastases in 61%. The primary sites were the lungs (45%), mediastinum (42%), and pleura (13%). Common metastatic sites were bone (32%), adrenals (30%), liver (20%), Brain (20%), and lungs (18%). The median OS of the whole group was 6 months. Ninety percent of patients had a smoking history with a median of 26 pack-years. Histology comprised epithelioid/rhabdoid (79%) and carcinoma (adenocarcinoma, mucinous, and undifferentiated, 21%). Carcinomas had a better median OS than sarcomatous histology (11 vs. 6 months, $p=0.03$). Furthermore, early stages (NO/N1) had a superior median OS compared to advanced stages ($N\geq 2$, M+) (16 vs. 5 months, $p=0.02$). Compared to no treatment, local therapies (surgery (S) or radiation (RT)), combination chemotherapy (CT), and combined modalities (CT $\pm$ S/RT) were statistically superior with a median OS of 1, 4, 6, and 11 months, respectively ($p<0.0001$). Further analysis revealed CT+S had superior median OS to CT+RT (16 vs. 9.5 months). Moreover, those with immune checkpoint inhibitors incorporated into their therapies had the best median OS outcomes ($p<0.0001$). Age, sex, primary site, and size did not impact OS. **Conclusions:** This study presents updated clinicopathologic data from a pooled cohort of patients with SDTT cancers. It identifies the histologic type, stage, and treatment approach as critical determinants of OS. Research Sponsor: None.

Clinical outcomes among patients with advanced non-small cell lung cancer who received targeted therapy in a real-world setting. *First Author: Mo Yang, EMD Serono, Rockland, MA*

Background: In the past decade, therapies targeting *EGFR*, *KRAS*, *ALK*, *ROS1*, *BRAF*, *NTRK*, *MET*, *RET*, *HER2* and PD-L1 were approved and recommended by National Comprehensive Cancer Network (NCCN) for use in advanced non-small cell lung cancer (aNSCLC). This study compared real-world clinical outcomes in biomarker positive patients with aNSCLC who received treatments based on the NCCN NSCLC Guidelines (v5.2021) versus other therapies in the US. **Methods:** This is a retrospective cohort study of patients with aNSCLC using the TEMPUS oncology dataset. Patients were included if they were diagnosed with stage IIIB-IV NSCLC (index date) between 1/1/2012 and 12/31/2020, ≥ 18 years of age at index, were biomarker (i.e., *EGFR*, *KRAS*, *ALK*, *ROS1*, *BRAF*, *NTRK*, *MET*, *RET*, or PD-L1) positive, and received at least one line of treatment. Patients were stratified by NCCN recommended treatment (v5.2021) receipt anytime following aNSCLC diagnosis. Median overall survival (mOS), progression free survival (mPFS), and time to next treatment (mTTNT) were evaluated by treatment group using Kaplan Meier analysis. Patient demographic and clinical characteristics were evaluated as potential predictors of receipt of NCCN recommended therapy. **Results:** Of the 2,158 biomarker positive patients who met study criteria, 55.7% ($N=1,201$) received NCCN recommended treatment. PDL1 (38.0%), *EGFR* (32.2%), and/or *KRAS* (30.3%) were the most common over-expressions/mutations. Biomarker positive patients with aNSCLC treated with NCCN recommended treatment ($N=1,201$) in any line had significantly longer mOS (24.7mo, 95% CI: 22.5–27.6) than those treated with non-recommended treatment ($N=957$, 19.8mo, 95% CI: 17.5–22.6) ($p<0.001$). Biomarker positive patients with aNSCLC treated with NCCN recommended treatment also had significantly longer mPFS (8.5mo, 95% CI: 7.9–9.0) and mTTNT (20.6mo, 95% CI: 19.3–23.7) than those treated with non-recommended treatment (4.9mo, 95% CI: 4.5–5.4) and (11.0mo, 95% CI: 10.0–12.7), respectively (both $p<0.001$). Never smokers (vs current smokers), patients of unknown or other race (vs whites), and patients who received 2 or more lines of treatment (vs 1) were more likely to receive NCCN recommended treatment and those with squamous or other/unknown histology (vs non-squamous) or missing ECOG scores (vs ECOG 0) were less likely to receive NCCN recommended treatment. **Conclusions:** In this study, biomarker positive patients with aNSCLC who received NCCN recommended treatment had significantly longer mOS, mPFS, and mTTNT than those who were treated with non-recommended regimens. Following the recommendations of the NCCN NSCLC Panel improves real-world clinical outcomes among biomarker positive patients with aNSCLC. Meanwhile, some biomarker positive patients—including current smokers and those with squamous cell histology—were less likely to receive targeted treatments. Safety, pharmacokinetics (PK), pharmacodynamics (PD) and preliminary efficacy of AZD2936, a bispecific antibody targeting PD-1 and TIGIT, in checkpoint inhibitor (CPI)-experienced advanced/metastatic non-small-cell lung cancer (NSCLC): First report of ARTEMIDE-01. *First Author: Kristoffer Staal Rohrberg, University Hospital of Copenhagen, Copenhagen, Denmark*

Background: PD-1 and TIGIT are implicated in cancer-related T cell immunosuppression. AZD2936 is a bispecific, humanized IgG1 (triple-mutated to minimize Fc effector function) targeting PD-1 and TIGIT. It has demonstrated encouraging activity compared to both anti-PD-1 and anti-PD-1/TIGIT combinations in murine models. We report data from dose escalation (Part A) and an expansion cohort (Part B) of the first-in-human study ARTEMIDE-01 (NCT04995523). **Methods:** This open-label, multicenter study enrolled pts with advanced NSCLC who had prior CPI treatment and a PD-L1 tumor proportion score $\geq 1\%$. Part A evaluated doses of 70–1500 mg IV Q3W; Part B evaluated the recommended phase 2 dose (RP2D). Primary endpoints included safety, tolerability, dose-limiting toxicities (DLTs) and preliminary efficacy. Secondary endpoints included PK and PD, defined as percentage PD-1 and TIGIT receptor occupancy (RO). **Results:** As of Dec 5, 2022, 80 pts were enrolled (Part A, $n=48$; Part B, $n=32$). Pts were 62.5% male, median age 63.5 years; 72.5% had adenocarcinoma, 23.8% had squamous cell carcinoma; 96.3% had metastatic disease; and 22.5% had brain metastases. They had a median of 2 prior regimens. Median duration of therapy was 11 wks. AZD2936 was well tolerated with no DLTs. In total, 46.3% of pts had treatment-related adverse events (TRAEs), all grade 1–3; the most common were pruritus, rash and lipase increased (6.3% each). Serious TRAEs occurred in 3 pts (3.8%): immune system disorder, acute hepatitis and fatigue ($n=1$ each). AZD2936 systemic exposure increased in a near dose-proportional manner. Doses of ≥ 210 mg achieved $\sim 90\%$ PD-1 and TIGIT RO in peripheral T cells. The RP2D was determined to be 750 mg Q3W based on safety, preliminary efficacy, PK/PD and modeling analysis predicting intratumoral RO. Among 76 evaluable pts, 3 had a partial response and 30 had stable disease (Table). Time to response was 1.9–4.0 mos and duration of response was 2.1–6.4 mos. **Conclusions:** In this interim analysis, AZD2936 showed an acceptable safety profile and preliminary antitumor activity in pts with advanced/metastatic NSCLC previously treated with standard therapy including CPIs. Further exploration of AZD2936 in CPI-naïve NSCLC pts, including a randomized dose optimization cohort is ongoing. Clinical trial information: NCT04995523. Research Sponsor: AstraZeneca.

Prognostic and predictive implications of plasma ctDNA in guiding first-line targeted therapy for metastatic HER2-mutant non-small cell lung cancer (NSCLC). *First Author: Si-Yang Liu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Trastuzumab deruxtecan (T-DXd) is the first HER2-targeted drug approved for NSCLC with human epidermal growth factor receptor 2 (*HER2*, *ERBB2*) mutation in the second or later line settings. However, the optimal first-line treatment for these patients remains unclear. Access to rapid tissue sequencing is not always available, thus presenting challenges to first-line drug development. Circulating tumor DNA (ctDNA) analysis has the potential to overcome these obstacles to guide optimal first-line targeted therapy for patients with *HER2*-mutant NSCLC. **Methods:** We retrospectively analyzed patients with metastatic *HER2*-mutant NSCLC who underwent prospective clinical ctDNA sequencing at Memorial Sloan Kettering Cancer Center (MSK) from January 2016 to September 2022. *HER2* mutations were identified by next-generation sequencing through MSK-IMPACT, MSK-ACCESS or Resolution ctDx Lung. **Results:** We identified 64 patients with metastatic *HER2*-mutant NSCLC who had received at least one line of systematic therapy. The median age was 63 years (range: 23–90), and there were more women ($n = 38$, 60%), and never-smokers ($n = 38$, 60%). The activating *HER2* mutations included exon 20 insertions (73%), exon 8 (11%), 19 (11%), and 20 SNVs (5%). Plasma ctDNA was tested before initial therapy in 40 patients with a median overall survival (OS) of 28 months (95% CI 21–34), in whom 31 patients (78%) had at least one detectable ctDNA alteration by MSK-ACCESS and ctDx Lung. 55% (17/31) received chemoimmunotherapy with pembrolizumab as the first-line treatment. The median time to treatment discontinuation (TTD) was 6 months (95%CI 5.5–6.9). Additionally, 19% of patients (6/31) received a *HER2*-targeted antibody-drug conjugates (ADC) as first-line treatment with a median TTD of 6 months (95% CI 2–10), including 5 with T-DM1 and one who received first-line T-DXd treatment with a TTD of 9 months. Patients with baseline ctDNA alterations had significantly shorter OS (hazard ratio (HR), 5.25; 95% CI, 1–24; $p = 0.019$). **Conclusions:** Baseline plasma ctDNA has the potential to guide first-line targeted therapy for patients with *HER2*-mutant NSCLC. As an independent negative prognostic biomarker, detectable ctDNA at baseline would need to be taken into account for patient selection in future studies to avoid underestimating the effects of therapy. Safety and efficacy of immune checkpoint inhibitors in patients with cancer and pre-existing autoimmune disease: A systematic review and meta-analysis in non-small cell lung cancer. *First Author: Wint Yan Aung, Northwell Health, Manhasset, NY*

Background: Cancer patients with pre-existing autoimmune diseases (AID) have been traditionally excluded from clinical trials of immune checkpoint inhibitors (ICI) due to concerns for immune activation leading to toxicity. As indications for ICI expand, there is a need for robust data on safety and efficacy of ICI in cancer patients with AID. Existing studies examined a heterogeneous group of cancers and do not include a comparison to cancer patients without pre-existing AID. Therefore, data are lacking concerning how safety and efficacy of ICI in this group of patients may differ from the general population and whether the results are generalizable to non-small cell lung cancer (NSCLC). **Methods:** We searched for studies consisting of NSCLC, AID, ICI, treatment response, and adverse events using database-controlled vocabulary terms. We systematically searched Medline (PubMed), EMBASE, Scopus, CINAHL, and Web of Science. We selected studies that included NSCLC and excluded abstracts, case reports, review articles, and articles lacking outcomes or populations of interest. Three authors (WA, CL, NS) independently reviewed all abstracts to determine study eligibility and quality. Study quality was assessed using the Newcastle-Ottawa Scale. Study data were pooled using random-effects meta-analysis. **Results:** Data were extracted from 24 cohort studies, consisting of 10,924 cancer patients, of which 4353 were NSCLC patients. Studies examined a broad spectrum of AID consisting of 1157 patients, of which 291 were NSCLC patients. Pooled analysis revealed an AID flare incidence of 36% (95%CI 27%-46%) in all cancers and 23% (95%CI 9%-40%) in NSCLC. Tests of subgroup difference revealed no significant difference in AID flares by organ system in all cancers and NSCLC ($p = 0.602$ and $p = 0.19$, respectively). Pre-existing AID was associated with a higher risk of de novo iRAE in all cancer patients (RR 1.38, 95%CI 1.16-1.65) and in NSCLC patients (RR 1.51, 95%CI 1.12-2.03). There was no difference in de novo grade 3-4 iRAE and tumor response between cancer patients with and without AID. However, in NSCLC patients, pre-existing AID was associated with a 2-fold increased risk of de novo grade 3-4 iRAE (RR 1.95, 95%CI 1.01-3.75) but also better tumor response in achieving a complete or partial response (RR 1.56, 95%CI 1.19-2.04). **Conclusions:** Pre-existing AID confers an increased risk of toxicity during ICI therapy. NSCLC patients with AID are at a higher risk of de novo grade 3-4 iRAE but are also more likely to achieve treatment response than those without AID. Multidisciplinary collaboration is paramount when considering ICI therapy in this patient population with careful calculation of risk and benefit as well as close monitoring for toxicity. Assessment of sociodemographic disparities in outcomes among pts with metastatic NSCLC (mNSCLC) receiving select immuno-oncology (IO) regimens: CORRELATE. *First Author: Stephen V. Liu, Georgetown University, Washington, DC*

Background: IO treatment (tx) has transformed the care of pts with mNSCLC, persistently demonstrating significant survival benefits over chemotherapy. Prior analyses have shown OS and PFS are shorter in the real-world (rw) setting compared with randomized clinical trials (RCTs). A contributing factor may be the more diverse sociodemographic characteristics of pts in the rw. Race and socio-economic status (SES), in particular, have been associated with disparities in cancer outcomes, which may be related to inequalities in healthcare access. One aim of CORRELATE was to assess whether outcomes differ based on sociodemographic characteristics in pts receiving IO in the rw setting. **Methods:** Eligible pts from the US Flatiron Enhanced Datamart database had mNSCLC (progressed or *de novo*), started 1L IO tx between Nov 1 2016 and May 31 2021, and met eligibility criteria based on 6 RCTs (KEYNOTE [KN]-024, KN-189, KN-407, IMpower150, CheckMate [CM] 9LA and CM 227) for IO regimens approved in the US for mNSCLC. Flatiron's area-level measure of SES, available for pts treated at community oncology centers, was based on a validated composite index and has 5 levels (highest [5] to lowest [1]). Multivariate Cox regression models were used to determine the association of sociodemographic variables (age, sex, race, US region and SES) with OS and rPFS separately; smoking history, ECOG performance status (PS) and PD-L1 expression were also included in the models, as were any pairwise interactions that were statistically significant ($P < 0.05$). **Results:** 2070 pts with non-missing data on the variables of interest were included in the dataset: 60% were aged ≥ 65 y, 86% white, 55% male and 53% were from the US Southern region. SES was relatively evenly distributed (SES 1-5: 18%, 22%, 21%, 24% and 15%, respectively); 41% of pts had PD-L1 $\geq 50\%$ (17% unknown PD-L1 expression), 61% had ECOG PS 1 and 92% were former/current smokers. Median OS was 13.3 mos (95% CI 12.3-14.7); median rPFS was 5.9 mos (5.6-6.2). In the multivariate analyses, race, region and SES did not have a statistically significant association with either OS or rPFS. Older age (≥ 65 y; $P = 0.0091$) and male sex ($P < 0.0001$) were associated with a higher risk of death (HR [95% CI] 1.16 [1.04-1.29] and 1.28 [1.15-1.43], respectively). For rPFS, the interaction between sex and smoking status was statistically significant ($P = 0.0312$); specifically, female non-smokers had a higher risk of progression or death vs female smokers (HR 1.45 [95% CI 1.15-1.82]). **Conclusions:** Our results from a nationally representative dataset of pts with mNSCLC treated at non-academic facilities show that, in pts who had equivalent access to IO tx, the OS and rPFS benefits derived from IO were similar, irrespective of race, region or SES. More efforts are required to identify and address barriers of access to care to ensure that all pts receive appropriate cancer tx. Research Sponsor: AstraZeneca.

Phase II trial of lazertinib in patients with epidermal growth factor receptor (EGFR) mutation-positive (M+), metastatic non-small cell lung cancer (NSCLC) with asymptomatic or mild symptomatic brain metastases after failure of EGFR tyrosine kinase inhibitor (TKI) (KCSG LU20-15). *First Author: Min Hee Hong, Yonsei Cancer Center, Seoul, South Korea*

Background: Central nervous system (CNS) metastases occur not infrequently, ultimately devastating consequences in advanced EGFR M+ NSCLC. Lazertinib, a 3rd-generation (G) EGFR-TKI, has shown potent antitumor activity in EGFR-mutant NSCLC. We conducted a phase II single-arm study of lazertinib in EGFR M+ NSCLC patients (pts) having CNS metastases to evaluate its CNS activity. **Methods:** The patients exhibiting CNS progression upon 1st or 2nd-G EGFR-TKIs with least one measurable CNS lesion were enrolled. The primary endpoint was intracranial objective response rate (iORR) in evaluable for response set (ERS). Secondary endpoints included iORR without T790M mutation, overall ORR (oORR), disease control rate (DCR), intracranial progression-free survival (iPFS) in ERS. Overall survival (OS) and safety analyses were performed in pts who received at least one dose of lazertinib. Cerebrospinal fluid (CSF) penetration was measured as exploratory biomarker study. **Results:** Of 40 pts enrolled, 38 were evaluable for tumor response. Nineteen pts harbored exon 19 deletion and 21 pts for exon 21 L858R and 30% of pts had radiologic evidence of leptomeningeal carcinomatosis (LM) with 2 cytological confirmed cases. Forty-five percent of pts received afatinib as first line treatment, followed by 42.5% of gefitinib and 12.5% of erlotinib. Baseline plasma samples of all the 40 patients obtained for liquid-based next-generation sequencing (Guardant360) and T790M was found in 5 pts prior to lazertinib treatment. iORR was 57.9% (22/38). iORR with T790M-negative, oORR, and DCR were 54.5%, 39.5%, and 97.4%, respectively. With median follow-up of 13.6 months, median iPFS and OS were not reached. Treatment-related adverse events (TRAEs) emerged in 85.0% of pts with most common TRAEs being skin rash (50.0%) and paresthesia (42.5%). Grade 3 or 4 TRAEs were reported in 10.0%. The CSF penetration rates of lazertinib and its metabolite (YH26334) were 46.2% and 33.1%, respectively in paired CSF and plasma samples, suggesting high CNS penetration efficacy. **Conclusions:** Lazertinib has substantial CNS activity regardless of T790M status against the progression of intracranial metastases $\pm$ LM during the treatment of 1st or 2nd-G EGFR-TKIs in metastatic EGFR M+ NSCLC pts. These results suggest that using lazertinib instead of brain local treatment would be a potential strategy in EGFR M+ NSCLC, who progressed on CNS metastases after prior EGFR-TKI. Clinical trial information: NCT05326425. Research Sponsor: Yuhan.

Efficacy outcome.

Intracranial response, % (95% CI)	
iORR	57.9 (40.8 – 73.7)
iORR in T790M-negative patients	54.5 (36.4 – 71.9)
Best intracranial response, No. (%)	
Complete response	2 (5)
Partial response	20 (52.6)
Stable disease	15 (37.5)
Progressive disease	1 (2.5)
Not evaluable	2 (5)

Poster Session

Long-term efficacy and safety of larotrectinib in patients with tropomyosin receptor kinase (TRK) fusion lung cancer. *First Author: Jessica Jiyeong Lin, Department of Medicine, Massachusetts General Hospital, Boston, MA*

Background: Neurotrophic tyrosine receptor kinase (*NTRK*) gene fusions are oncogenic drivers in a variety of tumor types, including lung cancer. Larotrectinib is a highly selective, central nervous system (CNS)-active TRK inhibitor that demonstrated rapid, deep, and durable responses in patients (pts) with TRK fusion lung cancer (Drilon et al. ASCO 2022) and is considered a preferred first-line therapy option for these pts (Owen et al. J Clin Oncol 2022). We report updated data from a larger cohort with longer follow-up. **Methods:** Pts with TRK fusion lung cancer enrolled in 2 larotrectinib clinical trials (NCT02576431 and NCT02122913) were included in this analysis. Larotrectinib was administered at 100 mg twice daily, and response was assessed by independent review committee (IRC) per RECIST v1.1. **Results:** As of July 20, 2022, 30 pts with a median age of 55.5 years (range 25–81) with TRK fusion lung cancer enrolled, including 12 pts with CNS metastases at baseline. The gene fusions involved *NTRK1* ($n = 24$; 80%) or *NTRK3* ($n = 6$; 20%). Pts received a median of 2 prior lines of systemic therapies, with 20 pts (67%) receiving ≥ 2 . Among 27 pts eligible for IRC assessment, the objective response rate (ORR) was 74% (95% CI 54–89): 3 complete responses, 17 partial responses (PR), 4 stable disease (SD), 2 progressive disease (PD), and 1 not evaluable. Among the 12 pts with baseline CNS metastases, the ORR was 67% (95% CI 35–90): 8 PR, 2 SD, and 2 PD. The median time to response for all responders was 1.8 months. Median duration of response (DoR) was 33.9 months (95% CI 9.5–not estimable [NE]); median follow-up was 22.9 months. Median progression-free survival (PFS) was 33.0 months (95% CI 11.3–NE); median follow-up was 24.7 months. Median overall survival (OS) was 39.3 months (95% CI 17.2–NE); median follow-up was 23.1 months. For the 12 pts with CNS metastases, the medians for DoR, PFS, and OS were 9.5, 9.9, and 19.4 months, with median follow-ups of 17.4, 19.3, and 22.2 months, respectively. Duration of treatment for all pts evaluable per IRC ranged from 0.3+ to 75.2+ months. At data cut-off, 10 pts had progressed, with 6 continuing treatment post-progression for ≥ 4 weeks due to continued clinical benefit. Treatment-related adverse events (TRAEs) were predominantly Grade 1–2. Grade 3–4 TRAEs were reported in 5 pts (2 each increased aspartate aminotransferase, increased weight; 1 each increased alanine aminotransferase, myalgia, hypersensitivity). There were no treatment discontinuations due to TRAEs. **Conclusions:** In this larger dataset with longer follow-up, larotrectinib continued to demonstrate rapid and durable responses, extended survival, and favorable long-term safety in pts with advanced TRK fusion lung cancer, including those with CNS metastases. These results support the wider adoption of next-generation sequencing testing for *NTRK1–3* gene fusions in pts with lung cancer. Clinical trial information: NCT02576431, NCT02122913. Research Sponsor: These studies were funded by Bayer HealthCare Pharmaceuticals, Inc. and Loxo Oncology, Inc., a wholly owned subsidiary of Eli Lilly and Company.

The safety and efficacy of SNK01 (autologous natural killer cells) in combination with cytotoxic chemotherapy after failure of prior tyrosine kinase inhibitor in non-small cell lung cancer: Preclinical mouse model and phase I/IIa clinical study. *First Author: Myeong Geun Choi, Division of Pulmonary and Critical Care Medicine, Department of Internal Medicine, Mokdong Hospital, College of Medicine, Ewha Womans University, Seoul, Seoul, South Korea*

Background: It is challenging to choose subsequent treatment option in patients with Osimertinib resistance in epidermal growth factor receptor (EGFR)-mutated non-small cell lung cancer (NSCLC). Meanwhile, antitumor effect of the antibody-dependent cellular cytotoxicity of natural killer (NK) cells mediated by cetuximab –anti-EGFR monoclonal antibody– has been reported. Therefore, we aimed to evaluate the safety and efficacy of SNK01 (non-genetically modified autologous NK cell) in combination with cytotoxic chemotherapy including cetuximab in NSCLC after failure to prior tyrosine kinase inhibitor (TKI) in a preclinical humanized cell line-derived xenograft (CDX) mouse model and phase I/IIa clinical study. **Methods:** We established a humanized CDX mouse model using Osimertinib-resistant lung cancer cell line. Re- construction of the humanized mouse, CDX-related skills, and analytic data were made according to C&SR Inc. manufacturing technique & SOP protocol. The mice were divided into 4 groups based on treatment (no treatment [n = 2]; Cetuximab only [n = 3]; SNK01 only [n = 4]; SNK01 plus Cetuximab [n = 4]) and treated weekly for 5 weeks (SNK01, 1x10⁷ cells/dose; Cetuximab, 20 ug/dose). In the clinical study, 12 patients with EGFR-mutated NSCLC who failed prior TKI treatment were finally enrolled. They received weekly SNK01 in combination with Gemcitabine/Carboplatin (n = 6) or Gemcitabine/Carboplatin/Cetuximab (n = 6), and dose escalation of SNK01 following “3+3” design (4x10⁹ cells/dose or 6x10⁹ cells/dose). The primary endpoint was safety, and secondary endpoint was efficacy. **Results:** In the preclinical study, flow cytometry analysis showed that NK cells (CD45+/CD56+/CD3-) were significantly increased in the groups administrated SNK01. The volume of tumor extracted after completion of treatment was the smallest in SNK01 plus cetuximab group. In the clinical study, the median age of patients was 61 years, 33.3% were male, and all patients had adenocarcinoma. The enrolled patients received weekly infusions of SNK01 for 7 to 8 weeks (4x10⁹ cells/dose [n = 6]; 6x10⁹ cells/dose [n = 6]). Since dose limiting toxicity was not observed, maximum tolerated dose of SNK01 was determined to be 6x10⁹ cells/dose. SNK01-related adverse event ≥grade 3 was also not observed. In the efficacy analysis, objective response rate was 25%, disease control rate was 100% (partial response, n = 3/12; stable disease, n = 9/12), and median progression free survival (PFS) was 143 days. PFS will be updated as some patients are still being followed. **Conclusions:** SNK01 in combination with cytotoxic chemotherapy, including cetuximab in EGFR-mutated NSCLC with resistance to TKI was safe and showed a potential antitumor effect in this preclinical study and early phase I/IIa clinical trial. Clinical trial information: NCT04872634. Research Sponsor: NKMAX.

Phase 2 clinical trial of the proautophagic drug ABTL0812 combined with paclitaxel and carboplatin in first-line patients with advanced squamous non-small cell lung carcinoma. *First Author: Joaquim Bosch-Barrera, Catalan Institute of Oncology, Hospital Josep Trueta, IDIBGi. Medical Oncology, Girona, Spain*

Background: ABTL0812 induces the inhibition of Akt/mTOR pathway by upregulation of TRIB3 protein, an endogenous Akt inhibitor, and promotes endoplasmic reticulum (ER) stress. As a result, ABTL0812 induces cytotoxic autophagy that leads to specific death of cancer cells, without affecting non-tumor cell viability. A Phase II clinical trial was designed where ABTL0812 was evaluated in combination with paclitaxel and carboplatin in first-line patients with advanced squamous non-small cell lung cancer (NSCLC). **Methods:** ABTL0812 was administered 1300 mg TID orally with 175 mg/m² paclitaxel and AUC5 carboplatin every 3 weeks, for up to 8 cycles, followed by ABTL0812 as a maintenance until disease progression or unacceptable toxicity. The study enrolled patients with non-irradiable IIIB stage or stage IV squamous NSCLC. Primary endpoint was overall response rate (ORR) by RECIST criteria v.1.1. Secondary endpoints were progression free survival (PFS), overall survival (OS), duration of response (DOR), safety and tolerability according to CTCAE v4.03, pharmacokinetics (PK) of ABTL0812 enantiomers ((-)-ABTL and (+)-ABTL) and pharmacodynamics assessed by two surrogate blood biomarkers: TRIB3 and CHOP. **Results:** Forty patients were included; median age was 66.1 years old; 90% men/10% women; 100% ECOG 0-1; 30% current smokers/67.5% former smokers and 37.5% had received prior chemotherapy > 12 months before inclusion. 39 patients had at least 1 adverse event (AE), anemia appeared in 32.5% of the patients (5.0% grade 3), neutropenia in 27.5% (25% grades 3-4) and thrombocytopenia in 17.5% of the patients (2.5% grade 3). For non-hematological AEs, asthenia was reported in 62.5% of the patients (2.5% grade 3); diarrhea in 45% (no grade 3-4) and nausea in 37.5% (5% grades 3-4). Twenty-five patients reach the primary endpoint for efficacy evaluation. ORR was 52.0% (95% CI 34.2-65.9) and 32.0% of the patients had stable disease. Median OS was 22.5 months (10.4-NC), median progression free survival 6.2 months (4.4-8.8), and DOR 5.1 months (3.9-7.4). Area under the curve (µg·h/ml) for (-)-ABTL and (+)-ABTL were 39.0±12.3 and 17.1±6.3 respectively, maximal concentrations (µg/ml) were 6.4±2.6 and 5.1±2.2 and minimum concentrations (µg/ml) 2.2±1.5 and 0.8±1.3. TRIB3 and CHOP PD biomarkers were induced by the treatment. **Conclusions:** The combination of ABTL0812 with paclitaxel and carboplatin shows survival outcomes that compare favorably with historical controls in squamous-NSCLC with an acceptable safety profile. PK analysis is compatible with drug activity, and pharmacodynamic analysis shows drug engagement. Clinical trial information: NCT03366480. Impact of first-line immunotherapy on survival and intracranial outcomes from a real-world cohort of patients with non-small cell lung cancer with brain metastases at diagnosis. *First Author: Benoît Nigen, Nantes University Hospital, Nantes, France*

Background: Although brain metastases (BM) at diagnosis are common in non-squamous NSCLC patients (ns-NSCLC), they have been mostly excluded from randomized trials. The aim of this retrospective study was to evaluate real-world outcomes of frontline immune checkpoint inhibitor (ICI) in these patients. **Methods:** We conducted a retrospective study to assess the intracranial and overall efficacy of first-line ICI-based therapy compared to chemotherapy (CT) in ns-NSCLC patients diagnosed with BM, showing no targetable alterations. Patients were divided according to systemic therapy: CT, ICI, or CT-ICI respectively. Primary endpoint was overall survival (OS), compared using Kaplan-Meier and Cox methodology. Secondary endpoint was intracranial progression free survival (icPFS). **Results:** Between 01-2018 and 05-2021, 118 newly diagnosed ns-NSCLC patients with BM were included (52 CT, 38 ICI and 28 CT-ICI). Median follow-up was 30.0 months [95% CI: 25.9-36.0]. Intracranial radiotherapy was delivered for 75.0%, 68.4% and 67.9% of patients for CT, ICI and CT-ICI groups (p = 0.805) respectively. OS rates at 24 months were respectively 25.3% (95% CI: 15.7-40.9), 44.6% (95% CI: 30.8-64.7) and 50.5% (95% CI: 34.3-74.4) in CT, ICI and CT-ICI groups (p = 0.048). Twelve-month icPFS was respectively 17.0% (95% CI: 9-32), 47% (95% CI: 33-66) and 45% (95% CI: 30-69) in CT, ICI and CT-ICI groups. After adjustment, ICI and CT-ICI were associated with a better OS compared to CT (HR = 0.46, 95%CI: 0.23-0.89, p = 0.021 and HR = 0.52, 95%CI: 0.27-1.01, p = 0.054 respectively). ICI and CT-ICI were associated with a significant reduction in the risk of intracranial progression by 54% (HR = 0.46, 95%CI: 0.25-0.84, p = 0.0123) and 59% (HR = 0.41, 95%CI: 0.23-0.77, p = 0.0050) compared to CT. Stereotactic radiosurgery was associated with an increased icPFS compared to systemic therapy alone (HR = 0.51, 95% CI: 0.29 – 0.92, p = 0.0247), whereas whole-brain was not (p = 0.096). **Conclusions:** Real-life ns-NSCLC patients with BM at diagnosis treated frontline with ICI presented OS and icPFS benefit compared to CT alone. A prospective assessment of the ideal type and sequence of systemic and local therapy should be conducted. Research Sponsor: None.

Long-term outcomes of tepotinib in patients with MET exon 14 skipping NSCLC from the VISION study. *First Author: Paul K. Paik, Thoracic Oncology Service, Memorial Sloan-Kettering Cancer Center, New York, NY*

Background: Tepotinib is a highly selective MET inhibitor with clinical activity in patients (pts) with MET exon 14 (METex14) skipping NSCLC. We previously reported robust and durable activity of tepotinib from the Phase II VISION study (NCT02864992; data cut: Feb 20, 2022; median follow-up: 26.1 months [mos]; Thomas, et al. WCLC 2022). Here, we report long-term outcomes from VISION, fulfilling an FDA post-market requirement (data cut: Nov 20, 2022; follow-up: Cohort A [primary cohort] ≥35 mos, Cohort C [confirmatory cohort] ≥18 mos). **Methods:** Pts with advanced METex14 skipping NSCLC detected by liquid and/or tissue (T+) biopsy received tepotinib 500 mg (450 mg active moiety) once daily. The primary endpoint was objective response by independent review using RECIST v1.1. Secondary endpoints included duration of response (DOR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** Of 313 pts enrolled, median age was 72 years (range 41–94) and pts received tepotinib for a mean (standard deviation [SD]) of 11.5 mos (11.6); median follow-up was 32.6 mos (range 0.3–71.9). First line (1L) pts (n=164; median age: 74 years [range 47–94]; male: 50.6%; ECOG PS 1: 72.0%; smoking history: 53.7%) received tepotinib for a mean (SD) of 12.4 mos (12.2), with 27 pts still receiving treatment. ORR was 57.3% (95% CI: 49.4, 65.0), mDOR was 46.4 mos (13.8, not estimable [ne]), mPFS was 12.6 mos (9.7, 17.7), and mOS was 21.3 mos (14.2, 25.9). Among 111 1L T+ pts, ORR was 58.6% (48.8, 67.8), mDOR was 46.4 mos (15.2, ne), mPFS was 15.9 mos (11.0, 49.7), and mOS was 29.7 mos (18.8, ne) (Table). Second-or-later line (2L+) pts (n=149; median age: 71 years [range 41–89]; male: 47.7%; ECOG PS 1: 75.8%; smoking history: 40.9%) received tepotinib for a mean (SD) of 10.5 mos (11.0), with 10 pts still receiving treatment. ORR was 45.0% (36.8, 53.3) and mDOR was 12.6 mos (9.5, 18.5). Across all 313 pts, ORR was 51.4% (45.8, 57.1), mDOR was 18.0 mos (12.4, 46.4), mPFS was 11.2 mos (9.5, 13.8), and mOS was 19.6 mos (16.2, 22.9). No new safety concerns were observed. Grade ≥3 treatment-related adverse events (TRAEs) occurred in 34.8% of pts; 14.7% of pts discontinued treatment due to TRAEs. Any grade related peripheral edema occurred in 67.1% of pts (Grade ≥3: 11.2%). **Conclusions:** The long-term outcomes of VISION demonstrate the robust and durable clinical activity of tepotinib, particularly in 1L T+ pts, and manageable safety profile, further defining its use in clinical practice. Clinical trial information: NCT02864992. Research Sponsor: The healthcare business of Merck KGaA, Darmstadt, Germany.

Long-term follow-up of “adjuvant” pembrolizumab following locally ablative therapy for oligometastatic non-small cell lung cancer. *First Author: David John Cantor, University of Pennsylvania, Philadelphia, PA*

Background: Patients with oligometastatic (OM) non-small cell lung cancer (NSCLC) benefit from local ablative therapies (LAT); however, the role of adjuvant systemic therapies post LAT remains less clear. In a single-arm Phase II clinical trial (NCT02316002), we demonstrated that patients with OM NSCLC treated with adjuvant pembrolizumab following LAT had superior progression free survival (PFS) compared to historical controls. Here, we present long term follow-up on PFS and overall survival (OS). **Methods:** Patients with OM (≤ 4 metastatic sites) NSCLC treated with LAT to all sites received pembrolizumab every 21 days for up to 16 cycles from February 1, 2015 through September 30, 2017. Other key inclusion criteria included ECOG PS 0-1 and the absence of autoimmune diseases. Patients were eligible regardless of the number of prior therapies or PD-L1 status. Our study design was an intention to treat analysis with a null hypothesis that PFS would be equivalent to historical controls (6.6 months) compared with the alternative that PFS would be greater than 10 months. Assuming 42 patients enrolled over 2 years, we calculated 80% power to detect improvement in PFS with a 1-sided 5% significance level. Primary efficacy endpoint was PFS from the start of pembrolizumab and was defined as evidence of progressive disease (PD) via RECIST v1.1 criteria, death, or last contact. Secondary endpoints included OS, determined by date of death or last contact, and safety. Cox proportional hazard models were performed to assess associations between clinicopathologic features and PFS or OS. **Results:** 51 patients enrolled in the study; 45 patients (median age, 64 years [range, 46-82]; 21 [47%] women; 31 [69%] with solitary OM site) received pembrolizumab following LAT. Patients received a median of 11 cycles of pembrolizumab; 18 (40%) patients completed 16 cycles. At the data cutoff (December 1, 2022; median f/u, 65.8 months), 32 patients had PD, 19 patients died, and 13 patients had no evidence of relapse. Median PFS was 19.7 months (95% CI, 7.6-31.7 months); median OS was not reached (95% CI, NR-NR). OS rate at 5 years was 60.0% (SE, 7.4%). Upon PD, 94% of patients received salvage therapies. Median OS from the time of PD was 39.7 months (95% CI, 13.8-65.6 months). Metachronous OM disease was significantly associated with improved OS (HR, 3.2 [95% CI, 1.5-6.7] and PFS (HR, 2.9 [95% CI, 1.2-7.5]) via multivariate Cox proportional-hazard models. The number of OM sites, CNS disease, nodal stage at diagnosis, or tumor PD-L1 status was not significantly associated with PFS or OS. We did not observe new safety signals for pembrolizumab following LAT aside from those previously reported. **Conclusions:** Pembrolizumab following LAT for OM NSCLC results in promising PFS and OS compared to historical experience with a tolerable safety profile. Further investigation of this approach with a randomized trial is warranted. Clinical trial information: NCT02316002. Research Sponsor: Merck & Co.; U.S. National Institutes of Health.

Management of patients with ALK-positive advanced non-small cell lung cancer who received brain radiotherapy on study in the phase 3 CROWN trial. *First Author: Todd Michael Bauer, Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN*

Background: Approximately 30% of patients with ALK-positive non-small cell lung cancer (NSCLC) present with brain metastases at diagnosis. Lorlatinib is a potent brain-penetrant ALK tyrosine kinase inhibitor (TKI) that showed improved time to intracranial (IC) progression compared with crizotinib in patients with and without brain metastases at baseline. This post hoc analysis from the phase 3 CROWN study summarizes the management of patients who received brain radiotherapy (RT) during the study. **Methods:** In the CROWN study, 296 patients with previously untreated ALK-positive advanced NSCLC were randomized 1:1 to receive oral lorlatinib 100 mg once daily ($n = 149$) or crizotinib 250 mg twice daily ($n = 147$). Patients who received brain RT while on study treatment or after the initiation of subsequent systemic anticancer therapy were included in this post hoc analysis. **Results:** As of September 20, 2021, at approximately 3 years of follow-up, median time to IC progression was not reached (NR; 95% CI, NR-NR) in the lorlatinib arm and was 16.6 (95% CI, 11.1-NR) months in the crizotinib arm. At the time of this analysis, 4 of 149 patients (2.7%) in the lorlatinib arm and 20 of 147 patients (13.6%) in the crizotinib arm received brain RT; study treatment was ongoing in 2 of 4 patients (50.0%) in the lorlatinib arm and discontinued in all 20 patients in the crizotinib arm. Median time from randomization to first brain RT was 18.2 (range, 6.4-31.3) months in the lorlatinib arm and 11.1 (range, 2.5-37.5) months in the crizotinib arm. In patients who had brain RT, median duration of treatment was 20.0 (IQR, 6.3-37.1) months with lorlatinib and 7.8 (IQR, 4.0-11.1) months with crizotinib. In the lorlatinib arm, 2 of 4 patients (50.0%) received concomitant brain RT and continued lorlatinib beyond progression. In the crizotinib arm, patients received brain RT while on study treatment or on subsequent systemic anticancer therapies with ALK TKIs or chemotherapy. Follow-up analysis is ongoing. **Conclusions:** At approximately 3 years of follow-up in the CROWN study, fewer patients in the lorlatinib arm received brain RT than those in the crizotinib arm. At the time of this analysis, study treatment was ongoing in 2 of 4 patients (50.0%) in the lorlatinib arm but was discontinued in all patients in the crizotinib arm. Patients were mostly managed with other ALK TKIs and/or chemotherapy following brain RT in the crizotinib arm. ClinicalTrials.gov: NCT03052608. Clinical trial information: NCT03052608. Mechanisms of resistance to tyrosine kinase inhibitor treatments in patients with ROS1 fusion-positive non-small cell lung cancer. *First Author: Jialei Wang, Department of Thoracic Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: ROS1 rearrangement was found in about 1% non-small cell lung cancer (NSCLC), and the fusion proteins created during this process will result in the successive activation of the ROS1 kinase domain. NSCLC patients with ROS1 gene fusions were considered a unique subtype highly sensitive to related tyrosine kinase inhibitor (TKI) treatments. However, the acquired TKI resistance was the major hurdle preventing patients from getting prolonged treatment benefits. **Methods:** 107 patients diagnosed with advanced or metastatic NSCLC harboring ROS1 fusion were retrospectively recruited. All patients were treated with crizotinib as first-line treatment, and 21 patients received lorlatinib after crizotinib progression. Samples were collected at baseline, after crizotinib progression, and after lorlatinib progression, which all underwent targeted DNA sequencing. TKIs binding to mutated ROS1 fusion proteins was simulated using molecular dynamics simulations. **Results:** The most witnessed fusion partner of ROS1 was CD74 (58%), followed by SDC4 (14%), EZR (11%), and SLC34A2 (9%). The median progression-free survival was 12.9 months for crizotinib and 6.4 months for lorlatinib. Patients with CD74-ROS1 and SLC34A2-ROS1 had significantly longer PFS than those with other ROS1 fusion types when treated with crizotinib. Patients with baseline TP53 mutations showed worse PFS compared to TP53 wild-type (WT) patients ($P < 0.001$, HR: 0.19, 95%CI: 0.09-0.39) under crizotinib treatment. An accumulation of both on-target (baseline vs. post-crizotinib vs. post-lorlatinib: 0% vs. 43% vs. 62%) and off-target resistant mutations (baseline vs. post-crizotinib vs. post-lorlatinib: 22% vs. 26% vs. 43%) after multiple TKI treatments was observed. A total of ten on-target resistance mutations were detected after TKI therapies, with 4 first-reported mutations (ROS1 L2010M, G1957A, D1988N, L1982V). According to the molecular dynamics simulation results, ROS1 L2010M mutations (happening in the ROS1 kinase ATP binding cassette) maybe resistant to lorlatinib, entrectinib, cabozantinib, and crizotinib. ROS1 G1957A may lead to resistance to cabozantinib. Moreover, all four novel on-target mutations may lead to resistance to crizotinib. **Conclusions:** In summary, CD74- and SLC34A2-ROS1 patients showed better crizotinib efficacy with different resistance mutation patterns. Patients of these subtypes are potential beneficiaries of molecular testing after crizotinib progression, directing future treatment strategies. Multiple TKI treatments may lead to the accumulation of both on-target and off-target resistance mutations. In addition, 4 novel ROS1 on-target mutations identified underwent molecular dynamics simulations, unveiling potential resistance to different TKIs, which can provide vital information for future ROS1 fusion-positive NSCLC patient treatment selections. Emerging phase 1 data of BLU-451 in advanced NSCLC with EGFR exon 20 insertions. *First Author: Danny Nguyen, City of Hope- Long Beach Elm, Long Beach, CA*

Background: In patients (pts) with NSCLC harboring *EGFR* exon 20 insertions (ex20ins), treatment options are limited, with platinum-based chemotherapy with/without programmed death-ligand 1 inhibitors being the standard of care in first line, and recent accelerated approvals of mobocertinib and amivantamab in the USA for second-line treatment. These second-line therapies have overall response rates of 28% and 40%, respectively, limited CNS activity, and are associated with AEs such as severe gastrointestinal AEs and edema. BLU-451 is an investigational, CNS-penetrant, potent, selective, and wild-type sparing *EGFR* tyrosine kinase inhibitor that is under investigation in the ongoing phase 1/2 CONCERTO trial (NCT05241873), including in pts with ex20ins. **Methods:** In phase 1 dose escalation using a 3+3 design, BLU-451 monotherapy was administered orally QD or BID and given in continuous 21-day cycles. The primary objectives include maximum tolerated dose (MTD) and/or recommended phase 2 dose (RP2D) determinations and safety. Key secondary objectives include antitumor activity, PK, and pharmacodynamics. Pts with *EGFR* ex20ins-positive NSCLC after prior platinum-based chemotherapy were enrolled. Prior ex20ins-targeted therapy and asymptomatic CNS disease were permitted. Tumor response was assessed per RECIST v1.1. Serial blood samples for analysis of BLU-451 PK and circulating tumor DNA (ctDNA) were collected. **Results:** As of Jan 20, 2023, 28 pts have been enrolled and dosed in 5 cohorts (100 mg–400 mg QD and 200 mg BID), including 19 (68%) pts with exon 20 insertions. The median number of prior systemic lines of therapy was 2.5 (range, 1–10), and 19/28 (68%) pts had prior ex20ins-targeted agents. The most common AEs were diarrhea (21%), cough (18%), fatigue (14%), pruritis (14%) and rash (14%); all were Grade 1 or 2. There were no dose-limiting toxicities. Partial responses, including a disappearance of a CNS target lesion, were seen, and early evidence of on-target activity with ctDNA reductions was observed. **Conclusions:** As of the data cutoff, BLU-451 monotherapy was generally well tolerated, with early evidence of clinical activity in heavily pretreated pts with *EGFR* ex20ins-positive NSCLC. Early data at initial dose levels consisted of tumor reduction including responses, CNS activity, and ctDNA responses. The dose escalation is ongoing to determine the MTD and/or RP2D. Clinical trial information: NCT05241873. Research Sponsor: Blueprint Medicines.

First results from the RETgistry: A global consortium for the study of resistance to RET inhibition in *RET*-altered solid tumors. *First Author: Alissa Jamie Cooper, Massachusetts General Hospital, Boston, MA*

Background: Rearranged during transfection (*RET*) gene alterations are the oncogenic driver in diverse tumor types, including *RET* fusions identified in 1-2% of non-small cell lung cancers (NSCLC). While *RET*-selective tyrosine kinase inhibitors (TKIs) selpercatinib and pralsetinib are effective, acquired drug resistance remains a challenge. Here, we report the initial results from the RETgistry, an international consortium aimed at elucidating mechanisms of resistance to *RET* TKIs across *RET*-altered solid tumors. **Methods:** This was a retrospective analysis performed across 16 institutions. Patients (pts) were eligible if they had advanced solid tumor harboring an oncogenic *RET* alteration, received ≥ 1 *RET* TKI with disease progression, and underwent resistant tumor or liquid biopsy for next-generation sequencing (NGS). **Results:** A total of 103 time-distinct biopsies (62 tissue, 30 plasma, 11 paired tissue/plasma) were included in analysis, obtained from 88 pts with progression on a *RET*-selective TKI [selpercatinib (n = 70), pralsetinib (n = 14), selpercatinib and pralsetinib sequentially (n = 4)]. Pts had the following tumor types: 72 NSCLC (69% *KIF5B-RET*, 21% *CCDC6-RET*, 10% other *RET* fusion), 13 medullary thyroid cancer (TC) (54% *RET* M918T, 46% other *RET* mutation), and 2 papillary and 1 anaplastic TC (all, *RET* fusion). Median age was 58 (range, 21-86); 48% were male with 89% never/light smokers. Median duration of *RET* TKI preceding biopsies [first-line, n = 32 (31%); second-line, n = 42 (41%); third-/greater-line, n = 29 (28%)] was 16.5 months (mos) (95% CI, 14.0-19.6); median PFS was 14.1 mos (95% CI, 9.3-17.0). Resistant biopsies were obtained at median 15.0 mos from TKI initiation (range, 1.8-58.8). Acquired *RET* mutations were detected in 14 (14%), most common being G810 substitutions in 12 (12%). Potential off-target resistance gene alterations identified in 43 cases (42%) included *MET* amplification (14%), *BRAF* V600E or fusion (2%), *KRAS* gain or mutation (5%), *ERBB2* amplification (2%), *EGFR* amplification (3%), *ROS1* fusion (1%), and activating *PIK3CA* mutation or *PTEN* loss (4%). No resistant lung cancer biopsy demonstrated small cell transformation. The duration of TKI therapy (HR 0.64, p = 0.11) or PFS (HR 0.75, p = 0.33) did not differ according to the presence of on-target vs off-target resistance. NGS analyses of pre-*RET*-selective TKI tumors (n = 92) revealed frequent co-occurring alterations in *TP53* (29%) and *CDKN2A/B* (12%). **Conclusions:** On-target resistance to *RET* inhibition due to acquired *RET* mutations was less common than off-target resistance, identified in 14%. The majority of *RET* TKI resistance is mediated by off-target mechanisms such as bypass receptor tyrosine kinase activation. Further studies are warranted to enable the development of therapeutic strategies to address resistance in pts with *RET*-altered tumors. The RETgistry accrual and data analyses continue. Sex differences in prognostic utility of peripheral eosinophil count in first-line immune checkpoint therapy against metastatic NSCLC. *First Author: Hyunwoo Kwon, Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: To date, few studies have associated elevated Absolute Eosinophil Count (AEC) with improved outcome to a single agent immune checkpoint inhibitor (ICI) as first or subsequent line of therapy in patients with NSCLC. Here, we investigated prognostic utility of AEC and the sex difference in patients undergoing standard-of-care first-line ICI with or without chemotherapy for metastatic NSCLC. **Methods:** This was a retrospective cohort study of 310 patients with Stage IV NSCLC treated with first-line ICI-based therapies (alone or in combination with chemotherapy) under IRB approved protocol 2021C0069. Demographic data are summarized in the table. Peripheral AEC measured by cells/microL was collected within 1 week before the start of therapy. Eosinophil count was evaluated in males and females by both descriptive statistics and Chi-squared test as a continuous and categorical variable, respectively. High level of baseline AEC was defined as 75th percentile (270 cells/microL). Overall Survival (OS) was plotted using the Kaplan-Meier method and p-values from log-rank test were reported. PD-L1 was assessed by tumor proportion score (TPS) and classified into < 1%, 1 to 49% and $\geq 50\%$. **Results:** 14% male vs 6% female patients were found to have peripheral eosinophilia (AEC ≥ 500) at the start of immunotherapy, p = 0.02. Patients with lower AEC had a median OS of 18.6 months vs 29.3 months in those with higher AEC (p = 0.02, HR: 1.465, 95% CI: 1.073-2.001). Patients with higher baseline AEC showed a sex difference, with median OS of 23.9 months in males vs 19.4 months in females with over 60% survival at the time of last follow up (p = 0.04, HR: 1.934, 95% CI: 1.040-3.597). This difference was seen with ICI monotherapy (p = 0.02, HR: 2.630, 95% CI: 1.192-5.805), but not ICI with chemotherapy (p = 0.83, HR: 1.116, 95% CI: 0.4054-3.070). Higher AEC was associated with TPS $\geq 50\%$ in both males and females (p = 0.004 and 0.001, respectively), though no significant sex difference was observed. **Conclusions:** Our data highlight critical sex differences in interpretation of baseline AEC in patients on ICI therapy for metastatic NSCLC. While males have a higher frequency of peripheral eosinophilia, higher AEC correlates to improved OS predominantly in females. Further, this female-biased outcome is seen only with ICI monotherapy, even though higher AEC is associated with high PD-L1 expression in both sexes. Future studies are indicated to assess the longitudinal trend in eosinophil count as well as their active versus passive role in anti-tumor immunity and toxicity in the presence or absence of chemotherapy. Efficacy and safety of PD-1/PD-L1 inhibitor plus platinum-based chemotherapy vs. platinum-based chemotherapy alone in patients with previously untreated advanced large-cell neuroendocrine cancer of the lung. *First Author: Fengchun Mu, Department of Radiation Oncology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China*

Background: Large-cell neuroendocrine carcinoma (LCNEC) is a rare tumor with a poor prognosis and limited treatment options. The efficacy of first-line therapies for LCNEC has not yet been established. This study evaluated the efficacy and safety of the combination of PD-1/PD-L1 inhibitor and platinum-based chemotherapy in treatment-naïve patients with advanced LCNEC. **Methods:** We retrospectively analyzed patients with advanced LCNEC who were treated with a PD-1/PD-L1 inhibitor plus platinum-based chemotherapy (PD-1/PD-L1 inhibitor group) or with platinum-based chemotherapy alone (chemotherapy group) based on data obtained from electronic databases of three participating cancer centers from January 2015 to August 2022. Progression-free survival (PFS), overall survival (OS), objective response rate (ORR), and disease control rate (DCR) were evaluated for each group. Safety was assessed in all patients who received at least one dose of their assigned treatment. **Results:** Among the 75 enrolled patients, 25 were allocated to receive PD-1/PD-L1 inhibitor plus platinum-based chemotherapy and 50 were allocated to receive platinum-based chemotherapy alone (patients were matched 1:2 on baseline characteristics). The median PFS was 15.1 months (95% confidence interval [CI], 7.1–23.2) in the PD-1/PD-L1 inhibitor group and 5.3 months (95% CI, 4.4–6.2) in the chemotherapy group (hazard ratio [HR], 0.26; 95% CI, 0.113–0.428; p < 0.0001). The 12-month OS was 88.0% (95% CI, 67.7–96.9) in the PD-1/PD-L1 inhibitor group and 56.0% (95% CI, 41.4–69.7) in the chemotherapy group (p = 0.0056). The ORRs in the two groups were 40% and 16%, respectively (p = 0.022), and the DCRs were 96% and 70%, respectively (p = 0.010). Regarding safety, the most common incidences of grade ≥ 3 adverse events involved neutropenia, leukopenia, anemia, and fatigue. There were no significant differences between the two groups. Immune-related adverse events (irAEs) in the PD-1/PD-L1 inhibitor group included cutaneous hemangiomas, hypothyroidism, anaphylaxis, and pneumonitis. Grade 3 or 4 irAEs were not observed. No new safety signals were noted. **Conclusions:** First-line PD-1/PD-L1 inhibitor plus platinum-based chemotherapy significantly improved PFS in patients with advanced LCNEC compared with platinum-based chemotherapy alone. Research Sponsor: None.

Nivolumab (Nivo) plus ipilimumab (Ipi) 6-month treatment versus continuation in patients with advanced non-small-cell-lung cancer (aNSCLC): 3-year results of the IFCT-1701 DICIPLE phase 3 trial. *First Author: Gerard Zalcman, Université Paris Cité, Thoracic Oncology Department & CIC Inserm 1425, Hôpital Bichat Claude Bernard, AP-HP, Nord, Paris, France*

Background: 1st-line immunotherapy (io) is a standard treatment for patients (pts) with advanced NSCLC devoid of targetable mutation. Classical 2-year io duration does not rely on indubitable evidence. We aimed to assess whether 6-month nivo/ipi was equivalent to continuation until progression or unacceptable toxicity in pts with disease control (DC). **Methods:** In this multicenter non-inferiority randomized phase 3 trial, eligible treatment-naïve pts, age > 18 , PS 0-1, had stage IV NSCLC and measurable disease. They received Nivo 3 mg/kg q2w plus Ipi 1 mg/kg q6w, until progression or unacceptable toxicity for a maximum of 6-month induction treatment. At 6 months, pts with DC and no severe TRAEs were randomized (1:1) into io continuation (arm A), and observation (arm B). At progression, arm A pts received an investigator's choice 2nd line platinum-based chemo, while arm B pts resumed double io. Primary endpoint was progression-free survival (PFS). 450 pts x 2 were to be randomized, to achieve 80% power, with 0.025 one-sided α error. Observing that European filing for the io combo was not submitted, the trial's steering committee recommended to stop the accrual on Jan. 2021. **Results:** From May. 2018 to Jan. 2021, 265 pts (70.6% male, 62.7yr median age, 59% stage IVB, 22.3% SCC, 9.9% PDL1 $\geq 50\%$, 12.2% PDL1 $< 1\%$) were accrued. 138 (72.6%) pts had disease progression before 6 months, 11 died (5.8%), 30 (15.8%) experienced TRAEs contra-indicating continuation, 11 (5.8%) were deemed ineligible for randomization. 71 pts with DC were randomized. With a median follow-up from randomization of 29.9 months, median PFS was 20.5 (7.4-36.7) months in arm A, 35.2 (21.4-NR) in arm B. 12-month PFS was 55.6% (38.0-69.9) and 81.2% (62.9-91.1), respectively (p=0.08). Adj.HR (arm B vs. arm A) was 0.66, 95%CI (0.28-1.31), p=0.23. OS data, yet immature, did not show any significant difference between both arms (adj.HR arm B vs. A: 0.54 95%CI (0.20-1.49), p=0.23). From randomization, 28.6% G3-5 TRAEs in arm A were observed vs. 2.9% in arm B (p=0.005). **Conclusions:** The 6-month i.o. interruption for NSCLC patients with DC did not yield significant PFS or OS differences in this prematurely halted trial. Updated OS with a 3-year follow-up, quality of life and biomarker data, will be presented at the meeting. Clinical trial information: NCT03469960. Research Sponsor: BMS; IFCT.

Spectrum of acquired *KRAS* mutations in driver mutation-positive non-small cell lung cancer. *First Author: Joshua E. Reuss, Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC*

Background: With the emergence of effective targeted-therapies for *KRAS* G12C, and the development of promising agents for *KRAS* G12V and G12D among others, the identity of unique *KRAS* mutations in non-small cell lung cancer (NSCLC) has become increasingly relevant. Acquired *KRAS* mutations are a known mechanism of resistance observed across driver mutation-positive (DM+) NSCLC. The incidence and diversity of these acquired alterations, and whether they differ from those observed in *de novo* *KRAS*-mutated NSCLC, is unknown. **Methods:** NSCLC molecular profiles were obtained using next-generation sequencing (Caris Life Sciences) with paired whole-transcriptomic sequencing (Illumina NovaSeq) and immunohistochemistry (Caris Life Sciences). Demographic data were abstracted from medical records. *KRAS* mutation diversity was defined for *de novo* *KRAS*-mutated (*KRASmt*) NSCLC (*KRAS* as only identified driver – *KRASmt_dn*) and DM+ NSCLC with acquired *KRAS* mutations (concurrent *KRASmt* with other known driver – *KRASmt_acq*). Fisher's exact test was used to compare the distribution of unique *KRAS* mutations between the groups. Due to the unique biology of NSCLC with class II/III *BRAF* mutations, this subset was removed from the *KRASmt_acq* subgroup for the final analysis. **Results:** A total of 5932 *KRASmt* NSCLC samples were identified, among which 5879 were *KRASmt_dn* and 53 were *KRASmt_acq* (see table). The distribution of unique *KRAS* mutations was not significantly different between groups ($p = 0.14$). Within the *KRASmt_dn* group, *KRAS* G12C was most common (40%), followed by G12V (19%), G12D (14%), G12A (7%) and Q61H/G13C (4% each). In the *KRASmt_acq* group, *KRAS* G12C was most common (30%), followed by G12D (19%), G12V (17%), Q61H (11%), G12A (7%), and G13C (6%). The most common observed driver mutations in the *KRASmt_acq* group were *EGFR* (38%) and *MET* (30%). In the *EGFR* group, *KRAS* G12D (25%), Q61H/G12C (20% each), G12V/G13C (10% each), and G12F/A/R (5% each) were observed. In the *MET* group, *KRAS* G12C (25%), G12D/N/A (19% each), Q61H (12%) and G12S (6%) were seen. Among 7 patients with a documented history of smoking in the *KRASmt_acq* group, *KRAS* G12D and Q61H were most common (29% each), followed by G12V/F and G13C (14% each). **Conclusions:** While the distribution of unique *KRAS* mutations did not differ significantly between *KRASmt_dn* and *KRASmt_acq* groups, acquired *KRAS* mutations were seen across DM+ NSCLC subsets, among which the frequency of observed mutations appeared to vary. The functional and immunological significance of these mutations, and their impact on clinical outcomes, warrants further investigation. Research Sponsor: None.

Sexual dysfunction in women with lung cancer: Updates from the SHAWL study. *First Author: Narjst Florez, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: Despite its direct correlation with quality of life, sexual dysfunction is under-discussed and underreported in patients with lung cancer (LC). Sexual dysfunction is highly prevalent in patients with LC, with issues persisting over time; however, most data precede the approval of targeted therapies and immune checkpoint inhibitors. We report updated data from the SHAWL study, focusing on women's sex life satisfaction. **Methods:** This cross-sectional, international survey study was administered via the G02 Foundation Lung Cancer Registry. We utilized the Patient-Reported Outcomes Measurement Information System (PROMIS) Sexual Function and Satisfaction Measures for data collection. Participants were recruited from June 2020 to June 2021. Eligibility criteria included age > 18 years, self-identification as a woman, and an LC diagnosis within ten years. Participants were asked about sexual health pertaining to 30 days before survey completion, now referred to as "recent." **Results:** The survey was administered to 249 women (median age: 61 years). Most (67%) had stage IV LC and 47% were receiving targeted therapy; 66% were undergoing active treatment. Before LC diagnosis, 49% (117) of participants reported having no sexual health issues. Most women (54%, 128) indicated having had recent sexual activity, though 77% (183) reported moderate to severe sexual dysfunction. Indeed, only 7.5% (18) reported being quite or very interested in sexual activity, and only 6.7% (16) felt as if they always or often wanted to be involved in it. Out of the 128 women indicating recent sexual activity, the vast majority (72%, 91) also reported minimal to no satisfaction with their sex life, with 17% (22), 31% (39), and 24% (30) reporting none, a little bit, and some satisfaction, respectively. The most common reasons for lack of recent sexual activity were lack of interest (68%, 76) or vaginal dryness or pain (30%, 33). Most women (69%, 88) also reported rarely becoming sufficiently lubricated during sexual activity, with 54% (68) indicating that it was difficult to impossible to do so. Patients with stage IV diagnosis had a lower interest in and desire for sexual activity than those with non-metastatic LC. Patients not receiving active treatment reported similar rates of lack of interest and desire for sexual activity as those in active cancer therapy. Patients on targeted therapy had similar rates of sexual dysfunction as those receiving other LC treatments. **Conclusions:** The SHAWL study is the largest study evaluating sexual dysfunction and satisfaction in women with lung cancer in our current clinical environment. Sexual dysfunction, dissatisfaction, and lack of interest in sexual activity were highly prevalent in women with LC regardless of treatment status and type of therapy, suggesting that even after treatment completion, sexual issues persist. Sexual health should be integrated into thoracic oncology care for all patients with lung cancer. Research Sponsor: G02 Foundation for Lung Cancer and University of Wisconsin Carbone Cancer Center.

Patients with *EGFR* mutant (m) MET-altered NSCLC receiving tepotinib with an *EGFR* tyrosine kinase inhibitor (TKI): A case series. *First Author: Xiuning Le, Department of Thoracic Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Oncogenic activation of MET is a common mechanism of acquired resistance to *EGFR* TKIs in patients (pts) with *EGFRm* NSCLC, with *MET* amplification (amp) constituting the most frequent cause of bypass pathway activation. Currently, there are no approved targeted treatment options for these pts. Data from the Phase II INSIGHT (NCT01982955) and INSIGHT 2 (NCT03940703) studies indicate the combination of the selective MET TKI tepotinib plus an *EGFR* TKI has encouraging activity. We present a case series of pts with *EGFRm* MET-altered NSCLC receiving tepotinib plus an *EGFR* TKI outside of clinical trials. **Methods:** Access to tepotinib was provided to pts with *EGFRm* MET-altered NSCLC and resistance to *EGFR* TKIs through unsolicited compassionate use requests. All pts received tepotinib (500 mg [450 mg active moiety] once daily; first dose by Oct 2022) plus an *EGFR* TKI. Participating physicians provided case information up to January 2023. **Results:** 28 cases of pts with *EGFRm* NSCLC and MET alterations who received tepotinib plus an *EGFR* TKI were collated. 21 pts had *METamp* after *EGFR* TKI treatment, 5 had MET overexpression, and 2 had *MET* exon 14 skipping. Pts were aged 41–86 years, 15 were Asian, 13 were white, 19 were female, 8 had smoking history, and all had adenocarcinoma histology. *METamp* was detected by tissue biopsy in 17 pts, and liquid biopsy in 4 pts. Of 12 pts with *METamp* detected by FISH, gene copy number ranged from 5.3–33.4, and *MET:CEP7* ratio from 0.7–15.1. *EGFR* TKIs received in combination with tepotinib were osimertinib ($n = 21$, 19 of whom received prior osimertinib), gefitinib ($n = 6$), dacomitinib ($n = 1$), afatinib ($n = 1$), with 1 pt received gefitinib followed by osimertinib. Tepotinib plus *EGFR* TKI was received by 9 pts as second-line, 9 as third-line, and 10 as fourth-or-later line. Median treatment duration was 8.8 months (range 1.3–20.6), with treatment ongoing in 13 pts (10 with current duration ≥ 10 months). Per the physician's assessment, 25/28 pts (89%) had clinical benefit, 16 of whom (57%) were considered to have a partial response (PR). Clinical benefit was reported in 18/21 (86%) pts with *METamp* (12 PR, 57%), in 5/5 with MET overexpression (2 PR), and 2/2 with *MET* exon 14 skipping (2 PR). The most reported adverse event (AE) considered related to tepotinib was edema in 15 pts (most commonly peripheral edema). Grade 3 AEs related to tepotinib were reported in 5 pts (including Grade 3 edema in 2 pts), 1 of whom discontinued the combination due to Grade 3 pneumonitis. **Conclusions:** Tepotinib plus an *EGFR* TKI showed promising clinical activity in pts with MET-altered NSCLC who have progressed on a previous *EGFR* TKI, including those with several lines of prior treatment. Clinical benefit was observed irrespective of MET alteration type in this case series of pts treated outside of clinical trials, with a large proportion of patients continuing to benefit from ongoing treatment. Outcomes of patients with advanced *EGFR* mutant lung cancer treated with first line (1L) osimertinib (osi) who would not have met eligibility criteria for the FLAURA trial. *First Author: Connor Wells, BC Cancer Agency, Vancouver, BC, Canada*

Background: Osi is a 1L therapy for *EGFR* mutant lung cancer based on the results of the FLAURA clinical trial. Patients on clinical trial are typically highly selected and the overall effectiveness of therapies may be lower in the real-world setting. We report the real-world outcomes of patients treated with first line osi and compare the outcomes of trial eligible and ineligible patients. **Methods:** Pharmacy records from January 2020 to October 2022 were used to retrospectively identify patients who received 1L osi for advanced *EGFR* mutant (exon 19 del. or exon 21 L858R) lung cancer in British Columbia, Canada. Patients were deemed ineligible for the FLAURA trial if they met one of five criteria: ECOG ≥ 2 , unstable brain metastases (symptomatic or on steroids), hemoglobin < 90 , platelet < 100 , or creatinine clearance < 50 . Comparisons of overall survival (OS) and time to treatment discontinuation (TTD) were made between using Kaplan-Meier survival curves and log-rank testing. Hazard ratios (HR) are reported using Cox regression adjusting for baseline factors (Table). **Results:** Of 312 patients included, 133 (43%) were considered FLAURA-ineligible. Reasons for ineligibility were poor ECOG ($n = 120$ [including ECOG 2=69, ECOG 3=48, and ECOG 4=4]), unstable brain metastases ($n = 21$), anemia ($n = 7$), thrombocytopenia ($n = 5$), and low creatinine clearance ($n = 9$). Median follow up was 22.7 months. At the time of analysis, 103/133 (77%) of ineligible patients had discontinued osi and 87/133 (65%) had died. 82/179 (45%) of eligible patients had discontinued osi and 53/179 (30%) were deceased. The median TTD in the ineligible group was 11.9 months (95% CI 10.5–15.5) vs 26.9 months (95% CI 21.9–34.6) in the eligible group ($p < 0.001$), HR 2.1 (95% CI 1.5–2.9, $p < 0.001$). The median OS in the ineligible group was 15.8 months (95% CI 12.4 to 21.1) vs NR [not reached] (95% CI 28.5 to NR) in the eligible group ($p < 0.001$), HR 2.6 (95% CI 1.8–3.7, $p < 0.001$). Rates of dose reduction for toxicity were similar between ineligible (25%) and eligible (19%) patients ($p = 0.25$). Second-line therapy was received by 28/102 (27%) of trial ineligible patients and 46/82 (56%) of trial eligible patients. **Conclusions:** Over 40% of the real-world population receiving 1L osi would have been ineligible for the FLAURA clinical trial. These patients had significantly inferior outcomes. This study provides benchmark data to better inform patient prognosis using real-world data. Research Sponsor: None.

	Trial Ineligible (n= 133)	Trial Eligible (n= 179)
Age (mean, years; range)	69 (37-92)	68 (33-95)

Efficacy and safety of sunvozertinib in treatment naïve NSCLC patients with EGFR exon20 insertion mutations. *First Author: Yan Xu, Department of Respiratory and Critical Care Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China*

Background: Sunvozertinib (DZD9008) is a rationally designed, irreversible EGFR inhibitor targeting *EGFR* mutations with wild-type EGFR selectivity. Two pivotal second line studies (WU-KONG1 [NCT03974022] and WU-KONG6 [NCT05712902 and CTR20211009]) are ongoing in NSCLC patients with *EGFR* exon20 insertion mutations (exon20ins). Primary analysis of WU-KONG6 study demonstrated promising efficacy and safety of sunvozertinib in ≥ second line setting. Herein, we reported preliminary results of sunvozertinib in the first line setting. **Methods:** Two ongoing studies WU-KONG1 and WU-KONG15 (NCT05559645) enrolled treatment naïve advanced NSCLC patients with *EGFR* exon20ins. WU-KONG1 is a multinational phase I/II study, and WU-KONG15 is an investigator-initiated phase II study in China. *EGFR* mutation status was confirmed by local or central testing using tissue or cytological samples. Sunvozertinib was administered orally until disease progression or other discontinuation criteria were met. Patients who had at least one post-treatment RECIST assessment by investigators were evaluable for efficacy analysis, and all patients who received at least one dose of sunvozertinib were included in the safety analysis. **Results:** As of January 15, 2023, a total of 36 treatment naïve advanced NSCLC patients with *EGFR* exon20ins received sunvozertinib daily dosing at RP2Ds. Median age was 66.5 years, and 63.9% (23/36) were female. The baseline ECOG PS was 0 or 1. Majority of patients (33/36, 91.7%) had metastatic diseases at study entry, with 22.2% (8/36) having > 3 metastatic sites and 22.2% (8/36) having baseline brain metastasis (BM). The most frequent mutation subtypes included 769_ASV (13/36, 36.1%), 770_SVD (2/36, 5.6%) and others (21/36, 58.3%). In 26 efficacy-evaluable patients, 19 patients showed tumor response, with a best objective response rate of 73.1%, among them 14 patients had confirmed response, and another 3 patients were still on treatment and pending confirmation. In patients with BM, tumor response was also observed intracranially. Median duration of response had not been reached by the data cut-off date. Safety findings were consistent with what was observed in previous studies of sunvozertinib. The most common treatment emergent adverse events (TEAEs) included diarrhea, CPK increase, and skin rash. The majority of adverse events were CTCAE grade 1 or 2 and manageable with supportive measures. **Conclusions:** Consistent with second line results, sunvozertinib demonstrated promising efficacy and safety profile as monotherapy in the first line setting for patients with advanced *EGFR* exon20ins NSCLC. The updated data will be presented at the conference. A phase III, multinational, randomized study (WU-KONG28, NCT05668988) is ongoing to compare sunvozertinib to chemotherapy as first line treatment for *EGFR* exon20ins NSCLC. Clinical trial information: NCT03974022, NCT05559645. Research Sponsor: Dical Pharmaceutical.

Circulating tumor DNA (ctDNA) monitoring to inform maintenance outcomes in patients (pts) with advanced NSCLC treated with induction atezolizumab+carboplatin+nab-paclitaxel (A+CnP). *First Author: Bruna Pellini, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Chemoimmunotherapy (ChemoIO) is a prevalent first-line treatment for advanced NSCLC without driver mutations, with maintenance therapy recommended after induction. However, real-world data suggests variability in maintenance therapy's timing, intensity, and duration. Motivated by evidence that ctDNA monitoring can predict outcomes in pts receiving IO for advanced cancers, we hypothesized ctDNA monitoring could inform outcomes in advanced NSCLC prior to the start of maintenance therapy. **Methods:** This retrospective study included 98 pts from a completed phase III trial of A+CnP in squamous NSCLC (IMPower131; G029437). Pts were treated with 4 or 6 cycles of induction A+CnP followed by maintenance atezolizumab. ctDNA monitoring utilized FoundationOneTracker, involving 1) comprehensive genomic profiling of pretreatment tumor tissue, 2) variant selection using an algorithm to filter out non-tumor variants, and 3) multiplex PCR of up to 16 variants to detect ctDNA and quantify plasma mean tumor molecules per mL (MTM/mL). Progression free-survival (PFS) and overall survival (OS) were estimated with Kaplan-Meier analysis and hazard ratios (HR) were calculated using multivariate Cox proportional hazard models adjusting for age, smoking history, PD-L1, and performance status. PFS and OS analyses were landmarked from C4D1 unless otherwise stated; pts with progression/death before the landmark date were excluded. **Results:** TP53 (91%), CDKN2A (41%) and PIK3CA (32%) were frequently altered in baseline tissue; 51% had TMB ≥10 mut/Mb. A median of 10 variants (range 2-16) were tracked per pt. ctDNA was detected (ctDNA+) in 43% of C4D1 samples (median 15.2 MTM/mL, range 0.3-787.3). ctDNA+ at C4D1 was associated with a lower objective response rate (41%) compared to undetectable ctDNA (ctDNA-, 77%, p < 0.001). Pts with ctDNA- at C4D1 (56/96) had better PFS than their ctDNA+ counterparts (median PFS from C4D1 7.7 vs 2.8 months; HR: 3.07 [1.88-5.02]). Median OS from C4D1 was not reached for ctDNA- pts and was 8.3 months for ctDNA+ pts (HR: 4.31 [2.31-8.06]). In a C6D1 landmark analysis of 34 pts who were ctDNA+ at C4D1, prolonged induction (6 cycles vs 4 cycles) was not associated with any improvement in PFS (1.6 vs 2.2 months, HR 1.41 [0.58-3.39]) or OS (4.7 vs 9.8 months, HR 1.84 [0.71-4.76]). Additional analysis of plasma samples at baseline and on-treatment time points is ongoing. **Conclusions:** On-treatment ctDNA monitoring during induction chemoIO can inform outcome on subsequent maintenance therapy in pts with advanced NSCLC. For pts with ctDNA+, prolonged induction chemoIO was not associated with improved outcomes. ctDNA testing during induction chemoIO may offer an opportunity to identify pts at higher risk for disease progression and inform selection for novel personalized maintenance treatment strategies. Detection of MET amplification (METamp) in patients with EGFR mutant (m) NSCLC after first-line (1L) osimertinib. *First Author: Helena Alexandra Yu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: METamp is a common resistance mechanism to osimertinib in patients with EGFRm NSCLC and is associated with sensitivity to MET TKIs. Reported METamp rates vary considerably depending on the type of biopsy and assay used. Here, we report a large comprehensive analysis of METamp detected by TBx FISH (FISH+) and/or LBx NGS (L+) after 1L osimertinib. **Methods:** During prescreening of the INSIGHT 2 study (NCT03940703) of tepotinib + osimertinib in post 1L osimertinib patients (pts) with EGFRm NSCLC, METamp was centrally assessed by TBx FISH (METGCN ≥5 and/or MET/CEP7 ≥2) and/or by LBx NGS (MET plasma GCN ≥2.3; Archer). **Results:** Of 472 pre-screened pts (64% female, 57% Asian, 97% adenocarcinoma), 350 provided TBx and 443 provided LBx. After excluding 36 TBx and 7 LBx 'not analyzed/not evaluable' samples, there were 314 TBx (163 from primary tumors, 151 from metastases) and 436 LBx samples with METamp results (positive or negative). Overall, FISH+ METamp was detected in 159/314 pts (50.6%), with similar FISH+ rates in the primary tumor (77/163, 47.2%) and metastases (82/151, 54.3%). FISH+ METamp detection by region was: 43.6% (82/188) in Asia, 61.5% (72/117) in Europe, and 55.6% (5/9) in the US. When limiting analysis to sites without reported local prescreening, the overall FISH+ METamp rate was 46.5% (93/200) and by region was: 43.5% (60/138) in Asia, 52.7% (29/55) in Europe, and 57.1% (4/7) in the US. In 159 FISH+ pts, median GCN was 11.8 (range 5.0-50.6) and median MET/CEP7 ratio was 2.3 (range 0.8-12.7). Mean TBx turn-around time (TAT) from shipment to results was 6.8 days. Overall, L+ METamp was detected in 51/436 pts (11.7%). In 35 L+ pts who were also FISH+, the median GCN was 16.6 (range 5.3-45.3) and median MET/CEP7 ratio was 4.5 (range 1.0-12.7). 299 pts had both central TBx FISH and LBx NGS results (Table), of whom 152 (50.8%) were FISH+ and 38 (12.7%) were L+. LBx NGS identified METamp with high specificity (negative percentage agreement [NPA] 98.0%) but low sensitivity (positive percentage agreement [PPA] 23.0%) compared with TBx FISH: only 3/38 L+ samples were FISH+ but 117/152 FISH+ samples (77.0%) were L-. Clinical activity of tepotinib + osimertinib was comparable in FISH+ and L+ pts. **Conclusions:** In this large comprehensive analysis, FISH+ METamp was detected in ~50% of pts progressing on 1L osimertinib, while L+ METamp was detected in only 11.7% of pts. METamp, which is the most common mechanism of resistance post 1L osimertinib, can frequently be undetected by using LBx NGS only. Given high specificity but low sensitivity of LBx, L+ pts can receive a MET TKI while a negative METamp result by LBx should be confirmed by FISH. FISH allows optimal identification of METamp post 1L osimertinib, can be delivered in a clinically meaningful timeframe, and may allow more pts to benefit from an oral MET TKI. Clinical trial information: NCT03940703. Research Sponsor: the healthcare business of Merck KGaA, Darmstadt, Germany.

Utility of ctDNA tumor fraction to inform negative liquid biopsy (LBx) results and need for tissue reflex in advanced non-small cell lung cancer (aNSCLC). *First Author: Christian Diego Rolfo, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Negative LBx results can be challenging to interpret. Absence of a targetable alteration may accurately reflect the tumor genotype (true negative) or may represent a false negative due to insufficient ctDNA shed, concealing a targetable oncogenic driver. Reflex to tissue biopsy (TBx) profiling is thus advised, per FDA label, for negative LBx results. Here we investigate whether algorithmic quantification of ctDNA in a LBx sample can increase confidence in negative LBx results, reducing need for confirmatory TBx testing. **Methods:** This study used the nationwide (US-based) de-identified Flatiron Health-Foundation Medicine NSCLC clinico-genomic database (CGDB) from approximately 280 US cancer clinics (~800 sites of care), limited to patients (pts) with aNSCLC receiving any multi-gene LBx followed by TBx CGP. In parallel, we queried an institutional database of pts with both LBx (FoundationOneLiquid CDx, F1LCDx) and TBx (FoundationOneCDx, F1CDx) to calculate positive predictive agreement (PPA) and negative predictive value (NPV) of LBx compared to TBx for detection of 7 targetable NSCLC driver alterations: KRAS G12X, EGFR, MET exon 14, BRAF V600E mutations or ALK, ROS1, and RET rearrangements. Foundation Medicine's ctDNA tumor fraction (TF) on F1LCDx is a composite algorithm prioritizing aneuploidy at higher levels to avoid germline signal and prioritizing variant allele frequency of canonical alterations at lower levels to maximize dynamic range. **Results:** Of 1,734 LBx sent prior to 1st-line therapy in pts with aNSCLC, 59% (1,024) were negative for an NCCN biomarker. For 465 pts with TBx after negative LBx (median 2.4 weeks from LBx to TBx result), 179 (38%) had a driver detected on reflex to TBx. In 45 receiving matched targeted therapy, median real-world PFS was 25 months. For pts starting therapy after reflex to TBx (n = 233), median time from LBx result to start of therapy was 4.7 weeks. To understand whether reflex to tissue may be avoided in some cases, LBx (F1LCDx) sensitivity was studied across 2,138 pairs in the institutional database. PPA for the 7 driver alterations was 59% overall (679/1,157) and improved to 96% (433/453) when limited to cases with TF ≥1%. Similarly, NPV was modest overall (67%) but improved when limited to LBx specimens with TF ≥1% (96%). Studying TF in the CGDB cohort, 33 of 85 pts (39%) with reflex TBx after negative LBx had a LBx TF ≥1% and, given high NPV for driver alterations, might have avoided reflex to confirmatory TBx. **Conclusions:** Elevated TF (≥1%) on F1LCDx informs assay sensitivity and identifies a subset of LBx results with high NPV where reflex to TBx, and the associated treatment delay, may be less valuable. Conversely, for pts with a negative LBx with low TF (< 1%) on F1LCDx, reflex to TBx is an important follow-on step to identify potentially missed driver alterations with potential for durable benefit on targeted therapy. Research Sponsor: Foundation Medicine Inc.

Treatment patterns and unmet need for patients with advanced non-small cell lung cancer and poor performance status: A real-world evidence study. *First Author: Stephen V. Liu, Georgetown University, Washington, DC*

Background: Performance Status (PS) is prognostic for poorer survival in oncology. Poor PS (pPS) may lead to inferior outcomes both as an independent factor and by limiting the range of available treatment options and the ability of patients to tolerate those regimens. Despite high real-world prevalence, patients with pPS are consistently underrepresented in clinical trials. Limited information is available regarding current treatment patterns for patients with pPS and advanced or metastatic non-small cell lung cancer (mNSCLC). **Methods:** We conducted a retrospective analysis using the nationwide de-identified Flatiron Health electronic health record (EHR)-derived database, selecting patients with mNSCLC diagnosed between 2017-2022 without *EGFR* or *ALK* genomic tumor aberrations. We estimated the prevalence of pPS (ECOG 2-3) within this cohort, and described common systemic treatment patterns by year and by PD-L1 status. For the subset of patients treated with pemetrexed/pembrolizumab/carboplatin (PPC), we estimated the association between pPS versus good PS (gPS - 0/1) and early discontinuation (< 4 cycles) or dose reduction (AUC < 4) of carboplatin using logistic regression controlling for observable confounders. **Results:** One quarter (24%) of the 22,575 patients in our sample had pPS. Relative to patients with gPS, patients with pPS were more likely to be older (mean age 72 vs. 69y, $p < 0.001$), to have stage IV cancer (62% vs 56%, $p < 0.001$) and less likely to have known PD-L1 status (60% vs. 63%, $p = 0.002$). The fraction of patients with no documented treatment was substantially higher among pPS versus gPS (37% vs. 21%). In the subset of patients with PS3, 53% of patients had no documented treatment. The most common treatment regimens among pPS patients were mono-immunotherapy (mono-IO - 19%) and PPC (15%). Use of mono-IO was positively correlated with higher PD-L1 expression (44% vs. 14% vs. 5.9% in PD-L1 high/low/negative, respectively). No documented treatment was negatively correlated with PD-L1 status (26% vs. 35% vs. 42%). Among patients with PS3, higher rates of no documented treatment were observed (39% vs. 50% vs 58% for PD-L1 high/low/negative, respectively). Anti-CTLA-4 combination use was low regardless of PS. pPS was associated with greater likelihood of early carboplatin discontinuation, (adjusted odds ratio, aOR 2.06), and dose reduction (aOR 1.75), both $p < 0.001$. **Conclusions:** One quarter of patients with mNSCLC have pPS. These patients are almost twice as likely to receive no treatment as those with gPS, and within the subset treated with the most common platinum containing regimen (PPC), pPS patients are also more likely to both initiate carboplatin at a reduced dose, and to discontinue it prior to completion. This suggests a substantial unmet need for this important subset of patients with mNSCLC. Research Sponsor: Genentech, Inc.

A biomarker study of atezolizumab (atezo) + bevacizumab (bev) + carboplatin (carbo) + paclitaxel (pac) (ABCP) for patients with NSCLC harboring *EGFR* mutations (EGFRm) after failure of TKI therapy: NEJ043. *First Author: Satoshi Watanabe, Department of Respiratory Medicine and Infectious Diseases, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan*

Background: EGFRm NSCLC patients (pts) have limited treatment options after EGFR-TKI failure. We previously showed that the NEJ043 study investigating ABCP in EGFRm NSCLC pts after EGFR-TKI failure had a clinically meaningful efficacy (Furuya et al, ASCO 2022). Here we report the results of the biomarker study of NEJ043. **Methods:** NEJ043 study is a phase II study to evaluate the efficacy of ABCP in sensitizing EGFRm nonsquamous NSCLC pts after TKI failure. Pts received atezo (1200 mg), bev (15 mg/kg), carbo (AUC 6 mg/mL/min), and pac (175 mg/m²) every 3 weeks up to 4 cycles followed by atezo plus bev until loss of clinical benefit. Before treatment initiation and three cycles of ABCP, peripheral blood mononuclear cells (PBMCs) were collected, and immunophenotypic data at each time point was obtained by flow cytometry. **Results:** 60 pts were included in the NEJ043 study and PBMCs were obtained from 31 pts. Pts with a higher percentage of CD11b^{DR}CD3^{CD14}⁺ myeloid-derived suppressor cells (MDSCs) before ABCP had significantly longer PFS (median, 9.7 months (95% CI, 5.3-17.7) vs 5.6 months (95% CI, 3.9-8.1); HR 0.38; $P = 0.0313$). Further analysis of the immune cell phenotypes that changed between pre-treatment and the third cycle showed that pts with increased CD62L^{low}CD8⁺ cells (median, 12.8 months (95% CI, 5.6-20.3) vs 5.7 months (95% CI, 4.4-8.1); HR 0.25; $P = 0.003$) and PD-1⁺CCR7⁺CD45RA^{CD8}⁺ cells (median, 8.5 months (95% CI, 5.6-13.8) vs 5.7 months (95% CI, 2.6-8.1); HR 0.37; $P = 0.0324$) had significantly longer PFS. **Conclusions:** Inhibition of MDSCs by ABCP, especially bev, may be important for EGFRm pts whose antitumor immunity is suppressed by MDSCs before treatment. Better PFS may be expected in pts in whom ABCP therapy induced CD62L^{low}CD8⁺ effector T cells and PD-1⁺CCR7⁺CD45RA^{CD8}⁺ effector memory T cells. Clinical trial information: jRCTs031190066. Integrated efficacy and safety of brigatinib in patients with ALK TKI-naïve advanced *ALK*⁺ NSCLC in the ALTA-1L and J-ALTA studies. *First Author: D. Ross Camidge, University of Colorado Cancer Center, Aurora, CO*

Background: Brigatinib demonstrated efficacy and manageable safety in patients (pts) with anaplastic lymphoma kinase (ALK) tyrosine kinase inhibitor (TKI)-naïve *ALK*⁺ non-small cell lung cancer (NSCLC) in phase 3 (ALTA-1L) and phase 2 (J-ALTA) trials. We present results of integrated efficacy and safety analyses of ALTA-1L and J-ALTA. **Methods:** ALTA-1L (NCT02737501) and J-ALTA (NCT03410108; conducted in Japan) were open-label, multicenter studies in pts with advanced or metastatic *ALK*⁺ NSCLC. Pts in ALTA-1L and in part 3 of J-ALTA were *ALK* TKI-naïve. Stable or asymptomatic brain metastases were allowed in both studies. Pts received brigatinib 180 mg qd (7-day lead-in at 90 mg). Primary endpoints were blinded independent review committee (IRC)-assessed progression-free survival (PFS) in ALTA-1L and IRC-assessed 12-month PFS in the J-ALTA *ALK* TKI-naïve cohort (both per RECIST v 1.1). Secondary endpoints included IRC-assessed objective response rate (ORR), duration of response, intracranial ORR, intracranial PFS, overall survival, and safety. Pooled efficacy and safety data from both studies are presented. **Results:** The pooled analysis population included 169 pts (ALTA-1L, N = 137; J-ALTA *ALK* TKI-naïve cohort, N = 32). Median follow-up overall was 35.8 months (last pt last contact: ALTA-1L, January 2021; J-ALTA, July 2021). Most (66%) pts were aged < 65 years, 24% had baseline brain metastases, 95% had stage IV disease at study entry, and 21% had received prior chemotherapy for locally advanced or metastatic disease. With brigatinib treatment, median PFS by IRC was 29.3 months (95% CI, 23.9–44.7). The confirmed ORR was 79% (95% CI, 72–85%), with 36 complete responses and 97 partial responses. Median duration of response was 38.1 months (95% CI, 22.9–not reached). Median overall survival was not reached; the 3-year survival rate was 74% (95% CI: 66–80%; 84 pts at risk). Intracranial ORR and intracranial PFS will be presented. Grade 3/4 treatment-emergent adverse events were reported in 74% of pts; the most common were increased blood creatine phosphokinase (31%), hypertension (18%), and increased lipase (16%). Any grade interstitial lung disease/pneumonitis was reported in 12 (7%) of pts. Adverse events led to treatment discontinuation in 11% of pts. **Conclusions:** Brigatinib treatment demonstrated clinically meaningful systemic and intracranial efficacy in this integrated analysis of pts with *ALK* TKI-naïve advanced or metastatic *ALK*⁺ NSCLC in the ALTA-1L or J-ALTA trials. Safety results were consistent with the known profile for brigatinib, with no new safety findings. Clinical trial information: NCT02737501; NCT03410108. Tislelizumab plus chemotherapy in patients with advanced brain metastases of non-squamous non-small cell lung cancer: A multicenter, prospective, open-label phase 2 study. *First Author: Yan Huang, Sun Yat-Sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center of Cancer Medicine, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Sun Yat-sen University, Guangzhou, China*

Background: Patients (pts) with brain metastases (BM) were usually unrepresented in clinical trials assessing the efficacy of PD-(L) 1 inhibitors. Here, we investigated the efficacy and safety of tislelizumab (TIS) plus chemotherapy in NSCLC pts with asymptomatic untreated BM or with stable BM after local radiotherapy. **Methods:** This multicenter, prospective, open-label phase 2 study enrolled systemic treatment-naïve pts with stage IV non-squamous (nsq) NSCLC without EGFR or ALK mutations who had BM. Pts received TIS combined with pemetrexed and carboplatin for 4 cycles, followed by maintenance TIS and pemetrexed. RECIST v1.1 and RANO-BM were applied for assessment for systematic and brain disease, respectively. The primary endpoint was the investigator-assessed 1-year PFS rate per RECIST v1.1. **Results:** 36 pts were enrolled with 77.8% having stage IVB disease, 25.0% liver metastases and 41.7% bone metastases. 29 (80.6%) pts were with untreated, asymptomatic brain metastases, and the other 7 (19.4%) received radiotherapy for BM previously. As of 30 Nov 2022, the median follow-up was 12.3 months. 1-year systematic PFS rate was 36.8% (95% CI, 18.0-55.7), with median PFS of 7.5 months (95% CI, 5.1-NE). Systematic ORR was 50.0% (95% CI, 31.9-68.1%). Median OS was not reached, with 1-year OS rate of 70.5% (95% CI, 51.7-83.1). For intracranial efficacy assessment per RANO-BM, 1-year intracranial PFS (iPFS) rate was 56.6% (95% CI, 31.7-75.5), with 45.5% (95% CI, 19.4, 68.5) and 100% in pts with untreated and pretreated BM, respectively. Intracranial ORR was 56.7% (95% CI, 37.4-74.5%), with 53.8% (95% CI, 33.4-73.4%) in pts with untreated BM and 75% (95% CI, 19.4-99.4%) in pretreated BM. No grade 5 toxicities were observed. Grade 3-4 TRAEs occurred in 33.3% (12/36) of pts. 13.9% of pts experienced iRAEs; grade 3-4 iRAEs occurred in 2 (5.6%) pts. **Conclusions:** TIS plus chemotherapy yielded promising systematic and intracranial PFS, and was generally well tolerated in nsq-NSCLC pts with untreated or pretreated BM. Clinical trial information: NCT04507217. Research Sponsor: None.

	Efficacy analysis set* (EAS)	
	EAS per RECIST v1.1 (n=32)	EAS per RANO-BM (n=30)
1-year PFS rate, % (95% CI)	36.8 (18.0, 55.7)	56.7 (31.7, 75.5)
Median PFS, months (95% CI)	7.5 (5.1, NE)	NR (8.2, NE)
ORR, % (95% CI)	50.0 (31.9, 68.1)	56.7 (37.4, 74.5)
DCR, % (95% CI)	90.6 (75.0, 98.0)	96.7 (82.8, 99.9)
1-year OS rate, % (95% CI)	70.5 (51.7, 83.1)	

*Efficacy analysis set included pts receiving ≥ 1 dose of TIS or chemotherapy, and having completed ≥ 1 post-treatment tumor assessment unless treatment was discontinued before the first tumor assessment due to disease progression or death; NR, not reached; NE, not estimable.

Patient-reported outcomes of furmonertinib versus gefitinib in patients with locally advanced or metastatic, EGFR mutation-positive non-small cell lung cancer (FURLONG): A multicenter, double-blind, randomized phase 3 study. *First Author: Yuankai Shi, Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study On Anticancer Molecular Targeted Drugs, Beijing, China*

Background: Furmonertinib showed superior efficacy compared with gefitinib as first-line therapy in Chinese patients with EGFR mutation-positive non-small cell lung cancer (NSCLC), along with an acceptable safety profile without new signals in the FURLONG study. Here we present patient-reported outcomes (PROs). **Methods:** FURLONG is a multicenter, double-blind, double dummy, randomized phase 3 study done in 55 hospitals across mainland China. Eligible patients were randomly assigned (1:1) to receive either furmonertinib or gefitinib. The primary endpoint of IRC-assessed progression-free survival has been reported previously. PROs as prespecified secondary outcomes by the European Organization for Research and Treatment of Cancer (EORTC) Quality-of-Life Questionnaire Core 30 (QLQ-C30) and Quality-of-Life Questionnaire Lung Cancer 13 (QLQ-LC13), were analyzed in randomly assigned patients who had received at least one dose of study drug and completed at least one PRO assessment. Changes from baseline to randomized treatment discontinuation were analyzed with mixed model for repeated measures and time-to-event analyses. This study is ongoing for survival follow-up. **Results:** 357 patients received at least one dose of study drug, all of them completed at least one PRO assessment. Questionnaire completion rates were ≥95% at most time points. Baseline mean scores were similar in the furmonertinib and gefitinib groups. From baseline to randomized treatment discontinuation, statistically significant differences favoring furmonertinib for physical function, nausea/vomiting, appetite loss, diarrhea, alopecia, and other pain (any pain other than chest, arm, or shoulder pain) were observed. Time to deterioration in physical function, cognitive function, nausea/vomiting, appetite loss, diarrhea, cough, dyspnea, dysphagia, and alopecia were significantly longer with furmonertinib versus gefitinib (Table). **Conclusions:** Furmonertinib demonstrated favorable PROs as measured by the EORTC QLQ-C30 and QLQ-L13 versus gefitinib. These data presented the positive benefit risk profile of first-line furmonertinib and further support this novel third generation EGFR-TKI as a new standard of first line treatment in EGFR mutation-positive NSCLC. Clinical trial information: NCT03787992. Research Sponsor: Shanghai Allist Pharmaceuticals Co., Ltd.; China National Major Project for New Drug Innovation (2017ZX09304015).

Clinical and genomic predictors of response and toxicity to sotorasib in a real-world cohort of patients with advanced KRAS G12C-mutant non-small cell lung cancer. *First Author: Kathryn C. Arbour, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: With the accelerated approval of the KRAS G12C inhibitor sotorasib for patients with advanced KRAS G12C-mutant non-small cell lung cancer (NSCLC), there is a new need to explore efficacy and identify clinical and genomic factors associated with activity and toxicity among patients treated in routine clinical practice. **Methods:** Patients(pts) treated with sotorasib outside of the clinical trial setting at three institutions (MSK, Columbia, NYU) were examined to identify factors associated with real-world PFS (rwPFS), overall survival (OS), real-world (rw) response, and clinically significant toxicity (CTCAE v5.0 grade 3 or higher treatment-related adverse events [G3+ TRAE]). *TP53*, *STK11*, and *KEAP1* status were assessed by targeted NGS. Response and rwPFS were determined by investigator assessment of radiology reports. rwPFS and OS were estimated by Kaplan-Meier methods; log-rank tests were used for univariate group comparisons and Mantel-Haenszel method was used to determine hazard ratios (HRs). Fisher's exact test was used to determine associations between categorical variables. **Results:** 105 pts with advanced KRAS G12C-mutant NSCLC treated with sotorasib were identified. The response rate for patients treated was 28%, with median rwPFS of 5.3 months, and median OS of 12.6 months. *KEAP1* co-mutations were associated with shorter rwPFS and OS (rwPFS HR 3.19, *P* = 0.004; OS HR 4.10, *P* = 0.003); no significant differences in rwPFS or OS were observed among pts with or without *TP53* co-mutations (rwPFS HR 1.10, *P* = 0.731; OS HR 1.19, *P* = 0.631) or *STK11* co-mutations (rwPFS HR 1.66, *P* = 0.098; OS HR 1.73, *P* = 0.168). Dual *STK11/KEAP1* co-mutation status was associated with shorter OS compared to *STK11* wild-type (WT)/*KEAP1* mutant (MUT) status (OS HR 4.04, *P* = 0.033) and *STK11* MUT/*KEAP1* WT status (OS HR 5.41, *P* = 0.012). 16/105 (15%) pts experienced G3+ TRAEs. 15/16 (94%) patients with G3+ TRAE had previously been treated with immune checkpoint inhibitor (ICI). Among pts with prior ICI exposure (*n* = 86), last exposure within 12 weeks of sotorasib initiation was associated with G3+ sotorasib TRAEs (*P* < 0.001) and TRAE-related sotorasib discontinuation (*P* = 0.014); there was no association between prior irAE during ICI therapy and G3+ sotorasib TRAEs (*P* = 0.757). In total, 15/53 (28%) pts with last ICI exposure within 12 weeks of sotorasib initiation experienced G3+ TRAEs, most commonly hepatotoxicity. No cases of G3+ TRAEs were observed in 33 pts with last ICI exposure > 12 weeks prior to sotorasib treatment. **Conclusions:** Among patients treated with sotorasib in routine clinical practice, *KEAP1* co-mutations were associated with poor outcomes. Severe toxicity was almost exclusively associated with recent ICI exposure. These observations may help further guide sequencing of sotorasib and may help inform the next generation of KRAS G12C clinical trials. Research Sponsor: LUNGEVITY Foundation.

Mobocertinib efficacy in patients with NSCLC and EGFR exon 20 insertion mutations (ex20ins) identified by next-generation sequencing (NGS) of circulating tumor DNA (ctDNA). *First Author: Joel W. Neal, Stanford University Medical Center, Stanford, CA*

Background: EGFR ex20ins are distinct targetable driver mutations present in ~2% of all NSCLC. While most EGFR TKIs have limited effectiveness, mobocertinib is the first oral therapy approved for this unmet need. EGFR ex20ins are heterogeneous (> 60 variants), and PCR testing detects a limited number of variants, leading to undetected disease in ~50% of cases, whereas NGS can identify all such mutations. Testing plasma ctDNA is a noninvasive approach for detection of genomic variants, such as EGFR ex20ins. **Methods:** In the mobocertinib phase 1/2 study (NCT02716116), patients were enrolled based on EGFR ex20ins detected by various local tissue or liquid clinical trial assays (CTAs). Baseline plasma samples were collected and processed to extract cell-free DNA and were evaluated for EGFR ex20ins status using FoundationOne Liquid CDx (F1LCDX), an NGS-based plasma ctDNA test. Concordance between F1LCDX and the CTAs was demonstrated by testing patient samples from the phase 1/2 trial and paired tissue and plasma samples from commercially acquired and stage-matched patients with NSCLC (*N* = 305). Efficacy analyses by assay method were performed in EGFR ex20ins-positive platinum-pretreated patients (PPP; *n* = 114 [FDA approved population]; data cutoff: 1 Nov 2021) in the phase 1/2 trial. **Results:** Concordance between F1LCDX and CTAs was demonstrated with samples from the CTA-positive (*n* = 159) and CTA-negative populations (*n* = 87) tested by F1LCDX where tissue and plasma were assessable; the point estimate of positive percentage agreement (95% CI) was 68.6% (61.0–75.3), and the point estimate of negative percentage agreement was 100% (95.8–100). F1LCDX detected 34 individual EGFR ex20ins variant types. In the response evaluable population, patients who tested EGFR ex20ins positive by F1LCDX (*n* = 55) demonstrated confirmed ORR (34.5%) and disease control rate (74.5%), which was comparable to those observed among all PPP in the phase 1/2 trial (confirmed ORR: 28%; confirmed disease control rate: 78%). **Conclusions:** Mobocertinib has shown efficacy in PPP with EGFR ex20ins NSCLC. F1LCDX effectively identified patients with EGFR ex20ins who may benefit from mobocertinib, providing an additional noninvasive diagnostic option to guide treatment. Clinical trial information: NCT02716116. Research Sponsor: Takeda Development Center Americas, Inc., Lexington, MA, USA.

Survival associations and driver oncogene overlap for copy-number amplifications of ERBB2, KRAS and MET in non-small cell lung cancer. *First Author: Alexander Watson, Tom Baker Cancer Center, Calgary, AB, Canada*

Background: Next-generation sequencing (NGS) to detect targetable oncogenic driver mutations is standard of care in non-small cell lung cancer (NSCLC). However, the interpretation and clinical impact of copy number amplifications (CNA) of driver genes is less clear. *ERBB2*, *KRAS* and *MET* are oncogenic drivers with intersecting resistance mechanisms and evolving therapeutic landscapes. We examined the overlap between other oncogenic drivers and CNA of these genes, and the association of CNA with overall survival (OS), in a cohort of patients with NSCLC. **Methods:** NGS of DNA (592 genes or WES)/RNA (WTS) was performed for 5870 consecutive lung adenocarcinoma tumors submitted to Caris Life Sciences (Phoenix, AZ). The copy number of each exon was determined by calculating the average depth of the sample along with the sequencing depth of each exon. Driver oncogenes (Driver+/-) were defined as pathogenic fusions in *ALK*, *NTRK* (1.2 and 3), *RET* and *ROS1* or pathogenic SNVs/indels in *ALK*, *BRAF*, *EGFR*, *ERBB2*, *KRAS*, *MET*. Tumor mutational burden high (TMB-H) was defined as 10 mutations per MB. The χ^2 test was applied as appropriate (*p* < .05). **Results:** The cohort was 55% female; median age was 69 years (range 24-89) and similar across all cohorts. Incidence of CNA at different amplification thresholds was correlated with oncogene drivers. At CNA ≥6 for *ERBB2* and *KRAS*, but CNA ≥4 for *MET*, a significant tendency for mutual exclusivity with driver mutations was observed (log2 odds ratio *ERBB2*: -3.1, *KRAS*: -1.1, *MET*: -2.2, all *p* < .001). Tumors meeting these thresholds were designated CNA-High (Gene-H), versus CNA-Low (Gene-L). Only one tumor harboured two CNA-H genes (*KRAS* and *MET*). Independent of CNA status, the TMB-H frequency was decreased in Driver+ tumors (27% vs 52% in Driver-, *p* < .001). CNA-H tumors were associated with decreased OS (compared to CNA-L); for *ERBB2*-H, hazard ratio (HR) 1.74 (95% CI 1.44-2.10, *p* < .001), for *KRAS*-H HR 1.29 (1.16-1.65, *p* < .001), and for *MET*-H HR 1.46 (1.28-1.68, *p* < .001). Similar results were observed when stratified by driver mutation status (Table), with the exception of *KRAS*/Driver- tumors. **Conclusions:** These data suggest tumors with high CNA of *ERBB2*, *KRAS* and *MET* represent clinically distinct entities and are significantly less likely to harbour concurrent driver oncogenes. The association between increased copy number and worse OS suggests amplified tumors are an important area for therapeutic development. Overall survival (collection to last contact) for *ERBB2*, *KRAS* and *MET* CNA-High versus CNA-Low tumors, by Driver mutation status. Research Sponsor: Caris Life Sciences.

Impact on turnaround times (TAT) among non-squamous non-small cell lung cancer (NSCLC) patients across three time periods with varying biomarker testing techniques. *First Author: Zhen (Jason) Fan, University of Toronto, Toronto, ON, Canada*

Background: Biomarker testing and identification of actionable genomic alterations (AGAs) in NSCLC patients have led to targeted therapy use and improved outcomes, particularly in advanced stages. We sought to evaluate the impact of different testing paradigms on TAT, particularly with respect to treatment decision and time to initiation of treatment, across three time periods. **Methods:** A retrospective review of stage III or IV non-squamous NSCLC patients at the Princess Margaret Cancer Centre (Toronto, Canada) was conducted. Both *de novo* advanced and patients with metastatic progressions are included. Cohort 1 (C1; 01/2015 – 01/2017) underwent reflex EGFR (EntroGen) and ALK (5A4 immunohistochemistry, IHC) single gene testing. Cohort 2 (C2; 02/2017 – 09/2020) underwent reflex next generation sequencing (NGS; TruSight Tumor 15), ALK and ROS1 testing. Cohort 3 (C3; 10/2020 – 01/2022) underwent reflex comprehensive NGS (161 genes, OncoPrint OCA v3). Descriptive statistics are presented, including AGAs found and TAT from biopsy to result sign-out, and treatment related TAT. **Results:** Three cohorts of stage III and IV patients were identified, with C1 having proportionally more females (60%), never smokers (42%) with adenocarcinomas (98%). More patients with AGA were identified using NGS with larger panels (42%, 41%, 57%, respectively across C1 – C3). However, there is a longer median time from first oncology visit to treatment (14, 22, 27 days, respectively across C1-C3), and longer biopsy to treatment TAT trended towards more comprehensive testing (34, 38, 40 days, respectively across C1 – C3) in stage IV patients. **Conclusions:** As more comprehensive biomarker testing became available, more AGAs are identified with an increase in TAT from biopsy to sign-out and treatment start. Despite our institutional policy of reflex testing, future endeavours will be focus on ways to reduce TAT. Research Sponsor: Princess Margaret Cancer Center; Pfizer; PM Lung Cancer Molecular Diagnostics Program.

Cohort	C1	C2	C3
Patients with successful testing (n)	177	657	205
Median age (range)	70 years (46-93)	69 years (19-97)	70 years (33-91)
Female	106 (60%)	313 (48%)	102 (50%)
Never smoker	71 (42%)	193 (30%)	68 (34%)
Adenocarcinoma	173 (98%)	558 (85%)	184 (90%)
Stage IV patients with AGAs identified	52/123 (42%)	191/463 (41%)	*84/148 (57%)
Median time from biopsy to result sign-out	14 days (IQR: 10-19)	28 days (IQR: 22-33)	31 days (IQR: 27-38)
Median time from first oncology visit to treatment (stage IV only)	14 days (IQR: 2-28)	22 days (IQR: 14-36)	27 days (IQR: 15-38)
Median time from biopsy to treatment (stage IV only)	34 days (IQR: 22-52)	38 days (IQR: 26-52)	40 days (IQR: 22-60)

Phase II results of ivonescimab (AK112/ SMT112), a novel PD-1/VEGF bispecific, in combination with chemotherapy for first line treatment of advanced or metastatic non-small cell lung cancer (NSCLC) without actionable genomic alterations (AGA) in EGFR/ALK. *First Author: Li Zhang, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Since the initial approval of bevacizumab (bev) with chemo in NSCLC, the subsequent focus of bev use in combination with PD1 therapy for first line metastatic disease has largely focused on non-squamous (non-SCC) histology. Ivonescimab is a novel anti-PD-1/VEGF bispecific antibody. The bispecific approach to these targets has the potential to recalibrate the malignant immuno-architecture in favor of a more immune-responsive and anti-tumor microenvironment. Cooperative VEGF binding with the bispecific has been shown to elevate affinity of ivonescimab to PD-1 by more than 10-fold. Ivonescimab has a mean $T_{1/2}$ of 6-7 days while bev $T_{1/2}$ is 20 days. Therefore, we aimed to assess the efficacy and safety of ivonescimab combined with chemotherapy for first line advanced or metastatic NSCLC in patients (pts) with squamous (SCC) or non-SCC NSCLC. **Methods:** An open-label, multicenter phase II study evaluating the efficacy and safety of ivonescimab combined with chemotherapy in pts with advanced or metastatic NSCLC. Pts were enrolled into 3 cohorts based on prior therapy and presence of AGA. Data from pts with prior therapy for advanced or metastatic disease were presented in ASCO 2022 and here we report additional pts and longer-term data from pts with NSCLC without AGA receiving first line therapy for advanced/metastatic disease. Pts were treated with 10 or 20 mg/kg ivonescimab once every 3wks combined with carboplatin and pemetrexed (non-SCC) or carboplatin and paclitaxel (SCC). The primary endpoint was ORR per RECIST by investigator. **Results:** 135 pts with advanced or metastatic NSCLC received ivonescimab plus chemotherapy including 63 with SCC and 72 with non-SCC. Median age was 61 yrs (. 78% male, 3% and 97% pts had ECOG PS 0 and 1, respectively, and 20% pts had baseline brain metastasis. Median follow-up was 11.5 mo. Pts with SCC experienced a 75% ORR with median DOR 15.4 mo, 95% DCR, the 9-mo PFS and OS rate was 67% and 93%, respectively. Pts with non-SCC experienced a 55% ORR, DOR was not reached, 100% DCR, the 9-mo PFS rate and OS rate was 61% and 81%, respectively. The most common treatment related adverse events (TRAEs) $\geq 10\%$ were epistaxis, proteinuria, rash, amylase increased, anemia, ALT increased, infusion related reaction, AST increased, pruritus, decreased appetite, and WBC decreased. Grade ≥ 3 TRAEs occurred in 28.1% TRAE leading to discontinuation occurred in 6.7% of pts. **Conclusions:** Ivonescimab, plus chemotherapy has shown promising anti-tumor activity in pts with advanced/metastatic NSCLC without AGA and can be administered safely in combination with platinum doublet chemotherapy to patients with SCC and non-SCC histology. Clinical trial information: NCT04736823. Research Sponsor: Akeso Biopharma, Inc.

Immune checkpoint inhibitors use and the incidence of hepatitis B virus reactivation or immune-related hepatitis in non-small cell lung cancer patients with chronic hepatitis B. *First Author: Joohyun Hong, Yongin Severance Hospital, Gyeonggi-Do, Korea, Republic of (South)*

Background: The safety and efficacy of immune-checkpoint inhibitors (ICIs) has not been thoroughly investigated in non-small cell lung cancer (NSCLC) patients with chronic hepatitis B (CHB) or occult hepatitis B infection (OBI). We analyzed incidence of hepatitis B virus (HBV) reactivation, immune-related hepatitis and jaundice in NSCLC patients treated with ICIs according to HBV DNA and hepatitis B serologic markers in real-world setting. **Methods:** A total of 1,277, consecutive NSCLC patients treated with ICIs from January 2015 to December 2020 at the Samsung Medical Center, Seoul, Korea were analyzed. Among them, 52 patients were hepatitis B surface antigen (+) (Group A, CHB), 759 patients were HBsAg (-)/anti-HBc IgG (+) (Group B, OBI), and 466 patients were HBsAg (-)/anti-HBc IgG (-) (Group C). Among 52 patients with CHB, 38 patients (73.1%) were receiving antiviral therapy. Primary endpoint was HBV reactivation, immune-related hepatitis and jaundice. Secondary endpoints include other immune-related adverse events, objective response rate, progression free survival (PFS) and overall survival (OS). **Results:** HBV reactivation was observed in two patients (0.2%) which was exclusively observed in Group A (CHB). Among CHB patients who were not receiving antiviral therapy, HBV reactivation was observed for 14.3% (2/14 patients). Incidence of immune-related hepatitis were 21.2%, 30.3% and 30.5% for Group A, Group B and Group C ($p > 0.05$), respectively, and incidence of immune-related of jaundice was 3.8%, 4.0% and 2.8% for Group A, Group B and Group C ($p > 0.05$), respectively. Incidence of $\geq$ grade 3 other immune-related adverse events, objective response rate, PFS, and OS were comparable among three group ($p > 0.05$ for all comparison). **Conclusions:** In this large, real-world cohort study, safety and efficacy of ICIs were comparable in patients with CHB or OBI, suggesting similar outcomes can be expected with ICIs in patients with CHB or OBI. HBV reactivation was observed in patients with CHB without antiviral therapy indicating antiviral prophylaxis might be required for them. For patients with OBI, risk of HBV reactivation was null. First line (1L) durvalumab in patients with PD-L1 positive, advanced non-small cell lung cancer (NSCLC) with a performance status of 2 (PS2): Primary analysis of the multicenter, single-arm phase II trial SAKK 19/17. *First Author: Michael Thomas Mark, Division of Oncology/Hematology, Cantonal Hospital Graubünden, Chur, Switzerland*

Background: The safety and efficacy of 1L durvalumab in PS2 patients (pts) with advanced NSCLC is unknown. Important safety data leading to exclusion of pts with relevant respiratory symptoms have been published as an interim report. Here we present the primary analysis of 1L durvalumab in PS2 pts, unsuitable for combination chemotherapy and PD-L1 expression in $\geq 25\%$ of tumor cells. **Methods:** In this single-arm, multicenter, phase II trial pts with PD-L1 positive (tumor proportional score, TPS $\geq 25\%$), advanced NSCLC with PS2, unsuitable for combination chemotherapy determined by the investigators, in the absence of known contraindications for immunotherapy and sufficient organ function, received a fixed dose of 1500 mg durvalumab every four weeks. The primary endpoint was overall survival (OS) at 6 months. The statistical hypothesis was to improve OS at 6 months from $\leq 35\%$ to $\geq 53\%$. Adverse events (AEs) were assessed according to National Cancer Institute Common Terminology Criteria for AEs (NCI CTCAE) version 5.0. **Results:** Forty-eight pts were included (29 males, 19 females). Median age was 76 years (range, 37-87). OS at 6 months was 60% (95% CI: 45-74%). OS at 6 months after the exclusion of pts with initially relevant respiratory symptoms was 67% (95% CI: 46-84%, $n = 27$) compared to the subgroup of pts without this exclusion criteria who were recruited before the amendment (52%, 95% CI: 30-74%, $n = 21$). Median OS was 8.5 months (95% CI: 4.4-16.7). Objective response rate and median PFS were 17% (95% CI: 8-30%) and 2.5 months (95% CI: 1.8-7.1). Thirty-three deaths (69%) were observed to date. Ten early fatal events considered not treatment-related occurred during the first 5 weeks of treatment. Four out of the first 7 early fatal events (4/7; 57%) were respiratory failures in pts with advanced symptomatic primary lung tumors. Only 3 more early fatal events occurred after the protocol amendment excluding pts with severe respiratory symptoms. Thirty-nine patients (81%) had an AE grade ≥ 3 (G3). The most frequent AEs ≥ 3 were lung infection (19%), dyspnea (15%) and hypertension (10%), respectively. Treatment-related AEs ≥ 3 were reported in 9 pts (19%) and included colonic perforation in one patient (grade 5), colitis in 5 pts (10%), hepatitis and increased lipase in 3 pts each (6%). **Conclusions:** 1L durvalumab in PS2 pts with advanced PD-L1 positive (TPS $\geq 25\%$) NSCLC is effective and led to a promising 6-month OS of 60%. Four-weekly durvalumab can be safely offered to pts presenting without severe pulmonary symptoms who are not candidates for chemotherapy. Clinical trial information: NCT03620669. Research Sponsor: AstraZeneca.

Safety, efficacy and biomarker data in patients with non-small cell lung cancer treated with the anti-IL1RAP antibody nadunolimab in combination with platinum doublet. *First Author: Luis G. Paz-Ares, Hospital Universitario 12 de Octubre, Madrid, Spain*

Background: Interleukin-1 Receptor Accessory Protein (IL1RAP), expressed in various tumors, is essential for IL-1 α and IL-1 β signaling. IL-1 α /IL-1 β are implicated in tumor progression and therapy resistance, and chemotherapy can upregulate IL-1 α in e.g. non-small cell lung cancer (NSCLC). Nadunolimab (CAN04), a fully humanized ADCC-enhanced IgG1 antibody, targets IL1RAP and blocks IL-1 α /IL-1 β signaling. Here, data are reported from clinical phase 1/2 trials in NSCLC pts given nadunolimab and platinum doublet. **Methods:** Pts with advanced NSCLC, 1st line or progressed on pembrolizumab, received nadunolimab at 1 (n=16), 2.5 (n=3) or 5 mg/kg (n=11) with cisplatin/gemcitabine (NCG), or at 2.5 mg/kg with carboplatin/pemetrexed (NCP) (n=5). Four additional pts, 3rd line or beyond, received NCG at 1 or 1.75 mg/kg nadunolimab. Primary objective was safety; efficacy was evaluated as a secondary objective and effects on serum and tumor tissue biomarkers explored. **Results:** The 30 1st or 2nd line pts given NCG had a median PFS of 7.2 months (95% CI 5.5-8.2), ORR of 53% (34-72) and DoR of 5.8 months (3.7-7.5). A dose-response trend was observed for PFS and DoR (Table). Twenty non-progressing pts continued nadunolimab as monotherapy post chemo; 8 of these remained in disease control for a further 12-131 wks. Nadunolimab monotherapy was well tolerated with $\geq$ grade 3 adverse events reported less frequently. Two pts (non-squamous, 2nd line post pembrolizumab) showed complete responses, one observed after >40 wks of nadunolimab monotherapy. Furthermore, confirmed partial responses were observed in 3 of 5 pts given NCP, and 2 of 4 3rd line or beyond pts given NCG. NCG reduced several serum markers, e.g. CRP and tumor-promoting HGF, effects which were maintained by nadunolimab monotherapy. Additionally, a decrease of MCP-3 and 4 was observed during monotherapy. NCG also reduced IL-1- and tumor microenvironment (TME)-related markers in serum (angiopoietin 1, CXCL5, IL-8, TWEAK and VEGFA). Spatial analyses of protein and RNA markers in tumor biopsies are ongoing to verify potential effects in the TME. **Conclusions:** NCG shows promising efficacy in NSCLC with a trend for dose response, and long-term disease control by nadunolimab monotherapy post chemo with good safety. These observations are supported by changes in TME-related serum biomarkers. Preliminary data suggest similar efficacy with NCP, and in more heavily pretreated pts. Clinical trial information: NCT03267316, NCT05116891. Research Sponsor: Cantargia AB.

RET testing and treatment patterns among patients with aNSCLC in US clinical practice. *First Author: Eunice Kim, Genentech, Inc., South San Francisco, CA*

Background: Biomarker testing, including for rearrangement during transfection (RET), is recommended and important in selecting efficacious targeted therapy for patients with advanced non-small cell lung cancer (aNSCLC). This retrospective cohort study characterized RET testing and treatment patterns among aNSCLC patients in clinical practice. **Methods:** We used the nationwide Flatiron Health electronic health record-derived de-identified database to select patients diagnosed with aNSCLC (stage $\geq$ IIIB) from 2017-2022. We measured rates of RET testing (test result $\leq$ 90 days after advanced diagnosis). We used logistic regression to identify baseline characteristics predictive of timely testing. Finally, we described treatment patterns for patients with RET+ aNSCLC before and after the US approval of RET inhibitors. **Results:** Among 26,329 aNSCLC patients, rates of RET testing $\leq$ 90 days after advanced diagnosis increased from 25% (2017 Q1) to 73% (2022 Q1). Patients were less likely to receive RET testing within 90 days if they were Black (multivariate odds ratio [OR] 0.8) or Hispanic (OR 0.8) compared to White, or had Medicare (OR 0.9; all p<0.001) compared to commercial insurance. Patients were more likely to receive RET testing within 90 days if they were in the highest socioeconomic quintile (OR 1.4), had *de novo* disease (OR 2.1), or no history of smoking (OR 1.3; all p<0.001). Between 2017 and 2022, there were increases in the use of next-generation sequencing (66% to 89%) and blood samples for biomarker testing (25% to 49%) and a decrease in mean days from diagnosis to test result (33 to 28) for the first RET test among those who had testing within 90 days. Among all patients with aNSCLC tested within 90 days (n=12,275), 73 were RET+ and received 1L treatment $\leq$ 90 days after advanced diagnosis. The most common 1L treatments before (n=35) and after (n=38) RET inhibitor approval were chemotherapy (40%) and RET inhibitor (42%), respectively (Table). **Conclusions:** RET testing has increased over time, but certain patient subgroups are less likely to receive timely RET testing and therefore may not be optimally treated. Among patients with RET+ aNSCLC identified after RET inhibitor approval, only 42% were treated with a RET inhibitor in the 1L setting. These results suggest both disparities in access to RET testing and unmet medical need among patients with RET+ aNSCLC. Research Sponsor: This study is sponsored by Genentech, Inc.

Treatment patterns of RET+ patients.			
Treatment type	Patients who initiated 1L before approval of 1st RET inhibitor (n=35 of 73)		Patients who initiated 1L after approval of 1st RET inhibitor (n=38 of 73)
Chemotherapy only	14 (40%)		4 (11%)
Chemotherapy + Checkpoint inhibitor	10 (29%)		7 (18%)
Checkpoint inhibitor only	5 (14%)		4 (11%)
RET inhibitor	-		16 (42%)
Other targeted therapy	2 (6%)		3 (8%)
Clinical trial drug	4 (11%)		1 (3%)
Other	0 (0%)		3 (8%)

The impact of PD-L1 expression and co-mutations on outcome of KRAS-driven non-small-cell lung cancer. *First Author: Petros Christopoulos, Department of Thoracic Oncology, Thoraxklinik and National Center for Tumor Diseases at Heidelberg University Hospital, Heidelberg, Germany; Translational Lung Research Center Heidelberg (TLRC-H), Member of the German Center for Lung Research (DZL), Heidelberg, Germany*

Background: Interest has surged for KRAS mutated ($KRAS^{mut}$) non-small-cell lung cancer (NSCLC) after approval of the covalent $KRAS^{G12C}$ inhibitors sotorasib and adagrasib. It remains unclear, how prognosis of these tumors is influenced by co-mutations and which cases could benefit most from novel drugs alongside immunotherapy (IO) or chemo-immunotherapy (CHT-IO). **Methods:** This retrospective study included all NSCLC patients with $KRAS^{mut}$ NSCLC treated in the Thoraxklinik Heidelberg from 01/2014 until 01/2021. For molecular profiling, PCR-based next-generation sequencing (NGS) was performed with a 40-gene panel, including *TP53*, *KEAP1* and *STK11*. Date of progression was verified through reevaluation of radiologic images by the investigators according to RECIST v1.1. Stratification was performed according to the type of KRAS mutation ($G12C$ vs. other), presence of *TP53*, *STK11* and *KEAP1* co-mutations (vs. wild-type [WT] status), and the PD-L1 tumor proportion score (TPS < 1 *aka* PD-L1^{neg}, vs. TPS 1-49, vs. TPS 50+ *aka* PD-L1^{high}). **Results:** Among 370 identified patients, no differences (all p-values > 0.08) were observed between $KRAS^{G12C}$ (n = 163) and $KRAS^{non-G12C}$ (n = 207) regarding clinicopathological features, like age (median 65 years), sex, smoking status, initial ECOG performance status, PD-L1 TPS, type of treatment in any line, number of treatment lines, and overall survival (OS, 19.4 months in median; details in the poster). In contrast, there was a strong association of PD-L1 TPS with OS (20.2 vs. 9.7 months for PD-L1^{high} vs. PD-L1^{neg}, p = 0.011) and progression-free survival (PFS, 5.7 vs. 1.9 months, p = 0.004) under IO. In addition, specifically within the PD-L1^{neg} subset, OS was longer for $KRAS^{G12C}$ compared to $KRAS^{other}$ patients (22.6 months vs. 12.1 months, p = 0.032). This was driven by the longer PFS under CHT-IO (9.7 vs. 4.5 months for $KRAS^{G12C}$ vs. $KRAS^{other}$, p = 0.005), particularly in the absence of *TP53* mutations (8.5 vs. 4.0 months with p = 0.004 for $TP53^{wt}$ patients; p > 0.50 for $TP53^{mut}$) and *KEAP1* mutations (11.3 vs. 5.1 months with p = 0.01 for $KEAP1^{wt}$ patients; p > 0.70 for $KEAP1^{mut}$). Also, across all patients, *KEAP1*^{mut} cases showed a trend for shorter PFS under CHT-IO (2.7 vs. 8.0 months, p = 0.07) and IO (1.9 vs. 3.9 months, p = 0.081), as well as shorter OS (15.9 vs. 19.5 months, p = 0.068) compared to *KEAP1*^{wt}, in contrast to *STK11*^{mut} cases (p = 0.42-0.92 for the same comparisons). Overall, $KRAS^{mut}$ NSCLC after chemotherapy and immunotherapy showed poor prognosis under standard therapies with a median PFS of 3 months, and a median OS of 6.8 months. **Conclusions:** In PD-L1^{neg} NSCLC, $KRAS^{G12C}$ is associated with better outcome under CHT-IO and longer OS compared to $KRAS^{other}$, especially in the absence of *TP53* and *KEAP1* co-mutations. *KEAP1*, but not *STK11* mutations are associated with impaired benefit from (CHT-)IO in $KRAS^{mut}$ NSCLC. Treatment of $KRAS^{mut}$ NSCLC after chemo-immunotherapy represents an unmet medical need. Research Sponsor: Amgen GmbH; Thoraxklinik Heidelberg.

Explore ALK: Alectinib activity in patients with ALK+ metastatic non-small cell lung cancer—A national real world analysis (GFPC 03-2019). *First Author: Aurélie Swalduz, Department of Medical Oncology, Centre Léon Bérard, Lyon, France*

Background: Alectinib is a standard of care option in advanced ALK-rearranged (ALK+) non-small cell lung cancer (NSCLC) patients (pts), with efficacy established by phase 3 trials, in first-line and beyond. There are few efficacy data in unselected populations. **Methods:** The objective of this study was to evaluate the efficacy of alectinib in real-world setting. All ALK+ advanced NSCLC pts initiating alectinib, between December 13, 2017 (date of access in France) and June 27, 2020, whatever the line, were included in explore ALK study. Patient characteristics, alectinib duration of treatment (DOT), progression-free survival assessed locally (rwPFS), overall survival (OS) according to the prescription line of alectinib, the presence of brain metastases at alectinib initiation, response rate and tolerance were collected from the medical files. **Results:** The analysis included 223 pts: 46.2% were men, 84.7% had no smoking history or were former smokers, median age was 59 (22-101) years and 95% were adenocarcinomas. Alectinib was initiated as first-line treatment in 119 pts, with a PS of 0/1/>1 in 42%/31%/27% of cases, a median number of metastatic sites of 2 (cerebral, hepatic, bone in 33%, 24% and 32% of cases). In first-line setting, after a median follow-up of 33.7 months (95%CI, 32.2-37.5), the median of rwPFS and DOT were 28.1 (95%CI, 20.7-40.4) and 26.9 (95%CI, 20.2-31.3) months, respectively. The median OS was not reach (NR), the 3-year OS rate was 72.1%. The rwPFS was not significantly different depending on whether or not the patient has brain metastases, 28.1 (95%CI, 14.5-NR) and 30.5 (85%CI, 18.9-40.4) months, respectively. The best response was complete (CR), partial (PR) and stable (SD) in 21%, 58% and 17%. The cerebral response, evaluable in 30/39 of the pts, was CR, PR and SD in 26%, 46% and 23% respectively; 33% of pts had a grade 3 adverse event, resulting in a temporary interruption of treatment in 7.6% of cases and a permanent discontinuation in 5.9% of cases. At the time of progression, 48.1% of pts had a new biopsy (66% of tissue biopsy). Efficacy data for alectinib prescribed as second line and above are summarized in the table. **Conclusions:** In this large real-world, cohort of unselected advanced ALK+ NSCLC pts, alectinib initiated in 1st-line or beyond provides similar efficacy and safety results as obtained in phase III clinical trials. Research Sponsor: Roche.

Line of alectinib initiation	Median (95% CI)
2 nd (n = 49)	
Duration of treatment	28.9 (17.7-40.6)
rw PFS	28.5 (16.5-49)
pts with cerebral metastasis (n= 23)	30.9 (17.49)
pts without cerebral metastasis (n = 26)	16.8 (9.9-NR)
OS	NR (NR-NR)
3-year OS rate	70.1%
3 rd (n = 25)	
Duration of treatment	20.6 (17.7-31.2)

A phase I trial of sequential dosing of sonidegib and pembrolizumab in advanced solid tumors (aST) and non-small-cell lung cancer (NSCLC). *First Author: Mohamed Shanshal, Mayo Clinic, Rochester, MN*

Background: Pembrolizumab interrupts PD-1/L1 interaction and is efficacious in many cancers. However, resistance invariably emerges in the majority of patients. Potential mechanisms include activation of compensatory pathways. The inhibition of sonic hedgehog signaling (SHH) was previously shown to induce intratumoral (IT) infiltration by CD4+, CD8+ and HLA-DR class II cells. Our preclinical data showed SHH inhibitor enhanced IT penetration by monoclonal antibodies and induced PD-L1 expression. We conducted a phase I study using a novel sequential pulse dosing of sonidegib followed by pembrolizumab in aST with an expansion cohort to determine the maximum tolerated dose (MTD), tolerability and preliminary efficacy. **Methods:** The dose escalation utilized a 3+3 design to determine the MTD and proceeded to expansion cohort upon determination of the MTD. Patients enrolled to each dose level were observed for dose limiting toxicities (DLTs) during the 1st cycle. The expansion cohort consisted of NSCLC and head/neck squamous cell carcinoma (HNSCC) previously treated by anti-PD1/L1. The recommended phase 2 dose (RP2D) was determined following the review of the toxicity profile of the combination from all cycles. The study treatment consisted of sonidegib oral daily from day 1 to 8 and pembrolizumab I.V. 200 mg on day 8 on an every 3-week cycle. The sonidegib dose levels explored were 400, 600 and 800 mg. Archival tumor and blood specimens were collected for correlative studies. Adverse events (AEs) were categorized and graded per CTCAE v5.0, and tumor response by RECIST v1.1. **Results:** The study enrolled a total of 33 patients and 29 received treatment (13 in escalation and 16 in expansion), including patients with NSCLC, HNSCC, skin cancer, gastric cancer and melanoma. The enrollment to the NSCLC cohort is complete and HNSCC continues. No DLT was encountered during dose escalation and the MTD was not reached. The highest planned dose level was selected to proceed to expansion (sonidegib 800mg days 1-8 in combination with pembrolizumab I.V. 200 mg on day 8 on an every 3-week cycle). The expansion cohort proceeded to enroll 15 patients evaluable for AEs (10 NSCLC and 5 HNSCC). Grade 3 and above treatment-related AEs across all patients were hyperglycemia, fatigue, dyspepsia, abdominal pain. The mature efficacy data will be reported at the meeting. **Conclusions:** The study successfully determined the RP2D of sonidegib when dosed sequentially with pembrolizumab in advanced solid tumors. The AE profile of the combination is similar to that for respective agents given individually. The efficacy data among anti-PD1/PDL1-treated NSCLC will be reported at the meeting. Clinical trial information: NCT04007744. Research Sponsor: Sun Pharma.

Updated molecular analysis of MET exon 14 skipping mutations (METex14) in non-small cell lung cancer (NSCLC). *First Author: Jennifer Aline Marks, Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC*

Background: METex14 is a heterogeneous family of mutations (mt) in NSCLC that can be effectively treated with approved targeted agents. Unlike some other drivers in NSCLC, METex14 occurs in both squamous and adenocarcinoma histology and in both smokers and non-smokers. Here, we present updated results from analysis of a large dataset to characterize the mutational landscape within METex14 NSCLC. **Methods:** NSCLC tissue samples were analyzed with DNA-based next-generation sequencing (NGS; 592 genes, NextSeq) or whole-exome sequencing (NovaSeq). RNA-based whole transcriptome sequencing (WTS, NovaSeq), and PD-L1 immunohistochemistry (Dako 22C3) at Caris Life Sciences (Phoenix, AZ). METex14 was detected by WTS. TMB-high was defined as ≥ 10 mt/Mb. Chi-square, Fisher's exact or Mann-Whitney U tests were used to determine statistical significance and corrected for multiple hypothesis testing ($q < 0.05$). Immune cell estimates (quanTiseq) and pathway analysis (ssGSEA) were informed by WTS analysis. **Results:** A total of 711 METex14 cases were detected with 288 distinct METex14 mt. By histology, 79 (11.1%) were squamous (Sq), 478 (67.23%) were nonsquamous (nSq), and 24 (3.23%) were adenocarcinomas. The most common METex14 mt were D1028H (8.1%), D1028N (7.8%), c.3082+2T>C (5.0%), D1028Y (4.6%), and c.3082+1G>T (4.4%). Co-mutated TP53 was common (43.4%) but varied by specific METex14 mt, observed in 60.0% of MET c.3082+3A>G vs 16.7% of MET G344R. Co-amplified CDK4 was found in 9.3%, with 42.9% in MET c.2924-1G>A vs 6.7% in MET c.3082+1G>T ($p < 0.05$). High TMB was seen in 9%; median TMB ranged from 2 mt/Mb in MET c.3082+2T>A to 6.5 mt/Mb in MET c.3082+2T>G ($p < 0.05$). PD-L1 $\geq 1\%$ was seen in 80.8% compared to 56.2% in METex14-WT ($p < 0.05$), and median PD-L1 tumor proportion score (TPS) ranged from 0% in MET G344R to 75% in MET c.3082+2T>A ($p < 0.05$). Co-mutations varied by histology: in Sq-NSCLC, 18.18% had TP53 mt ($q < 0.05$), 8.97% had POT1 mt ($p < 0.05$), 6.06% had TERT mt ($p < 0.05$), 5.13% CASP8 mt ($q < 0.05$), and 2.53% RNF43 mt ($p < 0.05$), while in nSq-NSCLC, 45.51% had TP53 mt, 3.38% had POT1 mt, 0.87% had TERT mt, and 0% in CASP8 and RNF43 mt. Smoking status was available for 120 cases: 88% were smokers and 12% were nonsmokers. Wnt, Hedgehog, and Notch signaling were enriched in nSq ($q < 0.05$) while upregulation of KRAS signaling, Epithelial-Mesenchymal Transition, and angiogenesis pathways were enriched in smokers with METex14 NSCLC ($q < 0.2$). Higher estimates of neutrophils and lower estimates of M2 macrophages, NK cells, and CD8+ T-cells were observed in Sq-NSCLC. PD-L1, PD-1, HAVCR-2, IDO-1 and IFN- γ expression were higher in nSq than Sq-NSCLC ($q < 0.05$). **Conclusions:** METex14 NSCLC is highly heterogeneous, with variations in co-mutation, TMB, and PD-L1 expression. Although Sq- and nSq-NSCLC harbor METex14, the enrichment of oncogenic pathways and infiltrating immune cells differ between histology and smoking history. Research Sponsor: None.

Characterization of diverse targetable alterations in ERBB2 and ERBB3 in 93,465 non-small cell lung cancers (NSCLC). *First Author: Dazhi Liu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Recently, fam-trastuzumab deruxtecan-nxki was approved for NSCLC with selected activating ERBB2 (HER2) mutations. Patritumab deruxtecan, a novel HER3 directed antibody drug conjugate, exhibits *in vitro* activity against HER3 mutations. We present a comprehensive landscape of ERBB2/ERBB3 alterations (alt) that may predict sensitivity to HER2/HER3 targeted therapies in development. **Methods:** We queried an institutional database (Foundation Medicine) of tissue or liquid comprehensive genomic profiling (CGP) results from 93,465 patients with NSCLC (85,704 tissue and 7,761 liquid samples). ERBB2 amp was defined as $\geq$ sample ploidy +3. Activating/likely activating alts were called using annotations including presence in COSMIC, functional knowledge of the gene affected, internal insights, and characterization in the literature. ctDNA tumor fraction (TF) on FoundationOneLiquid Cdx was estimated using a composite algorithm. **Results:** Activating/likely activating alt in ERBB2 and ERBB3 were detected in 3.9% ($n = 3337$) and 0.8% ($n = 696$) of NSCLC tissue samples, respectively (ERBB2: 2.0% amp, 1.7% mutations [mut; SNVs or indels], 0.001% rearrangements [RE], and 0.2% multiple; ERBB3: 0.5% amp, 0.3% mut, and 0.004% multiple). Age at diagnosis, sex, and predicted ancestry were similar among patients with ERBB2alt and ERBB2wt tumors. ERBB2alt were more frequently observed in non-squamous NSCLC (4.3% vs 2.3% in SCC), largely driven by differential ERBB2 mut frequencies (2.0% vs 0.4%). ERBB2 mut were most common in the kinase domain (KD; 70%, 56% of which were exon 20 insertions [ex20ins]), followed by the extracellular domain (ECD; 20%) and transmembrane domain (TMD; 6%), while ERBB3 mut were most common in the ECD (88%, most commonly V104L/M and G284R). ERBB2 RE or splice mut affecting exon 16 were detected in 23 cases (0.03%). While ERBB2 alt were mutually exclusive with other oncogenic drivers (KRAS, ALK, BRAF, EGFR, MET, ROS1, RET; each $p < 0.05$), ERBB3 alt were found to co-occur with both ERBB2 (8.5% vs 3.9% ERBB2wt, $p < 0.001$) and MET (8.6% vs 5.2% ERBB2wt, $p < 0.001$) alt. A similar distribution of ERBB2 alt (1.6% amp, 2.4% mut, 0.4% multiple) was detected in liquid samples with elevated TF ($\geq 10\%$; $n = 1458$); across all liquid samples, ERBB2 mut frequency was comparable to tissue (1.5%) but frequency of amp was 0.5%. In our study, 26% of ERBB2 mut tissue samples had activating/likely activating mut not included in the DESTINY-Lung01 trial, most notably 100% of both TMD mut ($n = 99$) and exon 16 alt ($n = 25$), as well as 35% of ECD mut (117/331) and 14% of KD mut (162/1145), including 6% of ex20ins). **Conclusions:** Diverse ERBB2 and ERBB3 alt in NSCLC may predict sensitivity to anti-HER2/3 therapies, but not all classes of alts are detected/ reported by all profiling assays. Utilization of comprehensive testing to guide biomarker definitions, treatment selection, and clinical trial enrollment is imperative. Research Sponsor: Foundation Medicine, Inc.

Long-term outcome for patients with advanced non-small-cell lung cancer treated by autologous cytokine-induced killer (CIK) cell immunotherapy in combination with sintilimab plus chemotherapy: NSCLC-CCICC-002. *First Author: Liang Liu, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*

Background: Autologous cytokine-induced killer (CIK) cell immunotherapy in combination with Sintilimab demonstrated robust antitumor activity and safety in the phase Ib CCICC-002 study (NCT03987867) of Non-Small-Cell Lung Cancer. Long-term outcomes in patients are reported herein. **Methods:** Systemic therapy naïve patients received platinum-based doublet chemotherapy, Sintilimab (PD1 inhibitor), and CIK cells every 3 weeks for 4 cycles, then maintenance treatment with Sintilimab in squamous and with Sintilimab plus pemetrexed in non-squamous NSCLC until disease progression or unacceptable toxicity or two years. Kaplan-Meier estimates of overall survival (OS) and progression-free survival (PFS) were calculated. OS and PFS were based on immune-related response criteria by investigator assessment (data cut-off, January 31, 2023). **Results:** From May 2019 to Jan 2021, CCICC-002 enrolled 33 patients (19 squamous, 14 non-squamous NSCLC; 1 patient was excluded because the second biopsy revealed EGFR mutation) aged 46-73 years with median follow-up was 31.4 months (range, 7.6-44.4 months). Estimated 3-year OS was 51.8% in all patients; median OS was not reached (95% CI, 26.6 months-not reached) in all patients. In subgroups, median OS was 27.6 months (95% CI, 13.4 months-not reached) in squamous NSCLC and not reached (95% CI, 29.9 months-not reached) in non-squamous NSCLC, respectively. Median OS was not reached (95% CI, 27.6 months-not reached) in PD-L1 positive patients and 28.3 months (95% CI, 15.6 months-not reached) in PD-L1 negative patients, respectively. Estimated 3-year PFS rate was 27.5% and median PFS was 17.9 months (95% CI, 8.2-26.5 months) in all patients. Median PFS was 17.3 months (95% CI, 5.0-24.0 months) in squamous NSCLC and 22.4 months (95% CI, 5.7 months-not reached) in non-squamous NSCLC, respectively. Median response duration was 18.7 months (95% CI, 10.1-27.6 months). 30.3% of patients were ongoing at data cut-off, and the longest response was ongoing at 41.3 months. 1 of the 5 CMR (complete metabolic response by PET-CT) patients experienced disease progression during observation. Treatment-related AEs (TRAES) occurred in 94.0% of patients and resulted in study discontinuation in 7.8%, and 15.2% experienced grade 3/4 TRAE. **Conclusions:** This long-term analysis of CCICC-002 represents the longest follow-up for CIK to date and confirms the durable antitumor activity and tolerability of CIK cells therapy in combination with Sintilimab plus chemotherapy in advanced NSCLC. Further studies are warranted to confirm these preliminary results. Clinical trial information: NCT03987867. Research Sponsor: Tianjin Medical University Cancer Institute and Hospital.

A nation-wide genomic screening project for further development of targeted therapies in treatment-refractory non-small-cell lung cancer (LC-SCRUM-TRY). *First Author: Hiroki Izumi, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Targeted therapies based on oncogenic drivers demonstrate dramatic and durable response in patients with non-small cell lung cancer (NSCLC). However, acquired resistance inevitably develop by diverse genomic resistance mechanisms. Genotype-matched targeted therapies to overcome treatment-resistance have not been established, except osimertinib against *EGFR* T790M mutation. **Methods:** We established a nation-wide genomic screening project in treatment-resistant NSCLC (LC-SCRUM-TRY; UMIN000041957) in September 2020 to identify the genetic resistant alterations, and to promote clinical therapeutic development. Enrolled patients have been screened for genetic alterations using a rapid next-generation sequencing (NGS) system, OncoPrint Precision Assay (OPA) for tissue samples, and Guardant 360 (G360) or OPA for plasma samples. *MET* amplification was also evaluated by FISH for NSCLC post EGFR-TKI treatment. **Results:** As of January 2023, 129 institutions in Japan were participating, and 1252 patients had been enrolled. Sample types were tissue (84%), and plasma (16%), respectively. Turn-around-time (median [interquartile range]) of OPA and G360 was 5 (4-6), and 9 (8-10.5) days, respectively. Of these, a total of 711 (57%) were already identified to have oncogenic driver at enrollment (*EGFR*, 556 [43%]; *ALK*, 70 [6%]; *RET*, 22 [2%]; *ROS1*, 21 [2%]; *KRAS*, 15 [1%]; *ERBB2* exon 20 insertion [ex20ins], 8 [0.6%]; *MET* exon 14 skipping [ex14skip], 8 [0.6%]; *BRAF*V600E, 7 [0.6%]; *NTRK3*, 2 [0.2%]; others, 2 [0.2%]). Of 556 *EGFR*-mutated NSCLC, 537 (97%) were enrolled post EGFR-TKIs. *EGFR* mutation subtypes were exon 19 deletion (52%), L858R (41%), ex20ins (1%), others (6%), respectively. Of 537 EGFR-TKI resistant tumors, 326 (40%) had at least one genetic alteration related with drug resistance, including *EGFR* alterations (amplification [13%], C797S [4%], A750P [3%], E709X [2%], L792X [1%], L718Q [1%]), *MET* amp (16%), and other driver mutation/rearrangement (8%). Through this screening, 37 (7%) of patients resistant to EGFR-TKI were enrolled into clinical trials, with 16/102 (16%) patients with targetable alterations (*MET* amp or *EGFR* C797S). In addition, of 541 NSCLC without oncogenic drivers at enrollment, 116 (21%) were identified to have actionable oncogenic drivers with FDA-approved drug (*KRAS* G12C, 23 [4%]; *ERBB2* ex20ins, 23 [4%]; *RET*, 13 [2%]; *MET* ex14skip, 13 [2%]; *EGFR* except ex20ins, [4%]; *EGFR* ex20ins, 10 [2%]; *ALK*, 6 [1%]; *ROS1*, 5 [1%]). **Conclusions:** LC-SCRUM-TRY contributes to the clinical development of precision medicine to overcome drug resistance, especially for *EGFR*-mutated NSCLC resistant to EGFR-TKI. This screening platform also help to practice precision medicine for patients initially diagnosed as driver-negative. Clinical trial information: UMIN000041957. Poster Session

Patient-reported outcomes in patients with metastatic non-squamous non-small cell lung cancer from the PERLA trial comparing first-line chemotherapy plus dostarlimab or pembrolizumab. *First Author: Martin Reck, Lungen Clinic, Grosshansdorf, Germany*

Background: PERLA (NCT04581824) is a global, randomized, Phase II, double-blind study assessing the efficacy and safety of chemotherapy (CT) combined with programmed death 1 (PD-1) inhibitors dostarlimab (dostCT) and pembrolizumab (pembCT) as first-line (1L) treatment (tx) for patients (pts) with metastatic non-oncogene-driven, non-squamous, NSCLC. DostCT had similar efficacy and safety to pembCT [1]. Exploratory analyses of patient-reported outcomes (PROs) from PERLA have been conducted. **Methods:** In PERLA, pts with ECOG status 0-1 were randomized 1:1 to receive ≤ 35 cycles (C) of dostCT or pembCT Q3W (CT was ≤ 35 cycles [C] of 500 mg/m² pemetrexed every 3 weeks [Q3W] and ≤ 4 C of cisplatin or carboplatin). PROs were collected at baseline (BL), Q3W until C4, Q9W until C16, Q12W until end of tx and at 30-day safety follow-up. Change from BL in EORTC QLQ-C30 and QLQ-LC13 were analyzed using a longitudinal mixed model, with a ≥ 10 -point change from BL considered clinically meaningful; scores were categorized as improved, stable, or worsened. Time to deterioration (TTD) in QLQ-C30 and selected QLQ-LC13 symptoms were estimated using Kaplan-Meier methods. **Results:** Analysis populations for dostCT/pembCT included 102/99 pts for QLQ-C30 and 96/90 pts for QLQ-LC13. Completion rates for QLQ-C30 and QLQ-LC13 were $>80\%$ up to C4 in both tx arms, decreasing after C7. At C13, 55.0% [n=33/60] and 54.2% [n=32/59] of dostCT pts, and 37.1% [n=23/62] and 35.7% [n=20/56] of pembCT pts completed QLQ-C30 and QLQ-LC13, respectively. Overall, least squares (LS) mean QLQ-C30 and QLQ-LC13 scores remained stable up to C13. Relative to BL, average pt functioning (e.g., physical, role) and cancer symptoms (e.g., pain, cough, dyspnea) were stable through C13 (~ 1 yr on tx); no clinically meaningful difference in LS mean QLQ-C30 or QLQ-LC13 scores were observed between tx arms. Across most QLQ-C30 and QLQ-LC13 subscales, $>60\%$ pts in both tx arms had stable or improved responses up to C13. At C13, meaningful improvements in chest pain and dyspnea were reported in a higher % of dostCT pts (34.4% [n=11/32] and 40.6% [n=13/32], respectively) than pembCT pts (10.0% [n=2/20] and 25.0% [n=5/20], respectively). TTD for QLQ-C30 and QLQ-LC13 subscales were comparable between tx arms, except for longer median TTD in dyspnea in dostCT pts (N=96) than pembCT pts (N=90) (4.24 vs 1.54 months; HR 0.64 [95% CI: 0.44-0.93]). **Conclusions:** HRQoL was similar and stable through C13 in both tx arms. These results supplement efficacy and safety data reported in PERLA and support further investigation of dostarlimab as an appropriate PD-1 inhibitor for use in combination with standard of care and novel therapies in metastatic NSCLC. Retrospective clinical analysis of circulating tumor DNA (ctDNA)-based molecular response (MR) and baseline blood-based tumor mutational burden (bTMB) for monitoring response in phase 3 trial of bintrafusp alfa vs. pembrolizumab treatment of non-small cell lung cancer (NSCLC). *First Author: Zheng Feng, Clinical Measurements Sciences, Global Research & Development, EMD Serono, Billerica, MA USA, an affiliate of Merck KGaA, Billerica, MA*

Background: The clinical utility of ctDNA-based approaches, such as bTMB and MR, to monitor and predict response during chemo-immunotherapy was evaluated using longitudinal cohort samples from a Phase 3 study of bintrafusp alfa versus pembrolizumab as a first-line treatment in patients with PD-L1 expressing advanced NSCLC. **Methods:** ctDNA was collected at baseline and day 42 after treatment with bintrafusp alfa (Q2W, 1200mg) or pembrolizumab (Q3W, 200mg). The GuardantOMNI liquid biopsy (LBx) assay was used to detect somatic alterations in 497 genes and generate bTMB from baseline, and MR scores from baseline and day 42 (n = 424 samples). bTMB and somatic alterations influencing response were explored. MR scores were calculated using the validated Guardant Response algorithm. Associations between ctDNA metrics and PFS were assessed. **Results:** 418/424 samples passed sequencing QC; of these, somatic mutations were detected in 236/237 baseline samples and 177/181 day 42 samples. Of 212 NSCLC patients with eligible bTMB results at baseline, 104 (49.1%) patients received bintrafusp alfa and 108 (50.9%) received pembrolizumab. bTMB high (bTMB-H) is defined as >20 mut/MB. In the bintrafusp alfa arm, PFS was significantly longer in patients with bTMB-H (median 8.3 months vs 2.7 months, p = 0.00086). In the pembrolizumab arm, PFS was also longer in patients with bTMB-H (median 5.65 months vs 5.5 months, p = 0.0898). Of 132 NSCLC patients with eligible MR results, 67 (50.8%) patients received bintrafusp alfa and 65 (49.2%) patients received pembrolizumab. In the bintrafusp alfa arm, molecular responders had significantly longer PFS (median 7.9 months vs 4.2 months, p = 0.00042). In the pembrolizumab arm, molecular responders also had significantly longer PFS (median 8.95 months vs 4.1 months, p = 0.00054). **Conclusions:** ctDNA analysis from plasma samples supported MR assessment in patients treated with ICI, indicating its utility as an adjunct to RECIST in monitoring of tumor response. Blood-based TMB-high was associated with immunotherapy treatment benefit. Analysis of b-TMB and MR allowed identification of patients with improved PFS in both treatment arms. Investigation of treatment specific TMB cut off selection and potential clinical utility of defined somatic mutations is ongoing. Clinical trial information: NCT03631706. RAMP 202: A phase 2 study of avutometinib (VS-6766) $\pm$ defactinib, in patients with advanced KRAS G12V mutant non-small cell lung cancer (NSCLC). *First Author: Joshua E. Reuss, Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC*

Background: *KRAS* mutations (mt) occur in $\sim 30\%$ of lung adenocarcinomas, among which G12C is most common (40%), followed by G12V (22%) and G12D (16%). Approved treatments for advanced *KRAS* mt NSCLC (excluding G12C) are limited to chemotherapy and immune checkpoint inhibitors (ICIs). Avutometinib is a novel small molecule RAF/MEK clamp. Focal adhesion kinase (FAK) activation is a resistance mechanism to RAF/MEK inhibition. Defactinib, a small molecule FAK inhibitor, has shown synergistic antitumor activity with avutometinib in preclinical models. In prior studies, avutometinib $\pm$ defactinib has shown responses in patients (pts) with *KRAS* mt NSCLC, including *KRAS* G12V. **Methods:** RAMP 202 is a randomized, phase 2, adaptive, multicenter, open-label study evaluating the efficacy and safety of avutometinib $\pm$ defactinib in previously-treated *KRAS* mt NSCLC (NCT04620330). Key inclusion criteria include histologically confirmed NSCLC with known *KRAS* mt and ≥ 1 prior systemic therapy (platinum-based and immune checkpoint inhibitor or appropriate therapy for activating mutation). Part A evaluated the optimal regimen, either 4.0 mg avutometinib orally (PO), twice weekly, 3 weeks on, 1 week off (mono) or 3.2 mg avutometinib PO twice weekly + 200 mg defactinib PO twice per day, 3 weeks on, 1 week off (combo) in pts with *KRAS* G12V mt NSCLC. Primary endpoint was confirmed objective response rate (ORR) by blinded independent central review. The optimal regimen determined in Part A would subsequently be assessed for efficacy in Part B. Exploratory assessment of ORR is also planned in *KRAS*-other (non-G12V) NSCLC. **Results:** Of 35 pts with *KRAS* G12V enrolled to Part A, 16 pts received mono, and 19 received combo. Patients received up to 5 lines of prior systemic therapy (median 2), including prior platinum-based chemotherapy, ICIs, and bevacizumab. No confirmed responses were seen in the mono group. In the combo group, 2 pts (11%) experienced a confirmed partial response. The duration of each response was 7.9 and 8.5 months, with both ongoing at data cut. The majority of treatment-related adverse events (TRAEs, any grade) (N = 72) were mild to moderate. The most common Grade ≥ 3 TRAEs included blood CPK increase (11.1%), diarrhea (5.6%), anemia (5.6%), and rash (1.4%). Most AEs were manageable/reversible. **Conclusions:** In this heavily pretreated population of patients with *KRAS* G12V mt NSCLC, limited clinical activity was observed with combination therapy. While no new safety signals were identified, criteria to proceed to part B were not met, and further evaluation of avutometinib $\pm$ defactinib in *KRAS* G12V mt NSCLC will not be pursued. Additional trials evaluating rational avutometinib combinations (sotorasib, adagrasib, everolimus) are ongoing in patients with *KRAS* mt NSCLC. Clinical trial information: NCT04620330. Association between duration of immunotherapy and overall survival in advanced non-small-cell lung cancer. *First Author: Lova Sun, University of Pennsylvania, Philadelphia, PA*

Background: For patients (pts) with advanced non-small cell lung cancer (NSCLC) treated with front line immunotherapy-based treatment, the optimal duration of immune checkpoint inhibitor (ICI) treatment is unknown. We aimed to assess practice patterns surrounding ICI treatment discontinuation at two years, and to evaluate association of duration of therapy with overall survival by comparing pts who received fixed duration ICI therapy for 2 years vs those who continued therapy beyond two years. **Methods:** This study used the nationwide Flatiron Health electronic health record (EHR)-derived de-identified database, and included adult pts diagnosed with advanced NSCLC from 2016-2020, who received frontline immunotherapy-based treatment. Pts who were still on treatment without progression at 2 years were classified as “fixed duration” (treatment discontinuation at 2 years, between 700-760 days) vs “indefinite duration” (continued treatment beyond two years, > 760 days). Overall survival from 760 days was analyzed using Kaplan-Meier methodology. Multivariable Cox regression adjusted for patient and cancer-specific factors was used to compare survival between fixed and indefinite-duration groups. **Results:** Our analytic cohort consisted of 113 pts in the fixed duration group and 593 in the indefinite duration group; median age was 69, 49% were female, and 71% were White. Pts in the fixed duration group were more likely to have a history of smoking and be treated at an academic center. There was no significant difference in overall survival between pts in the fixed duration and indefinite duration groups, either on univariable (HR 1.26, 95% CI 0.77-2.08) or multivariable Cox regression (HR 1.33, 95% CI 0.78-2.25). **Conclusions:** In a real world cohort of advanced NSCLC pts treated with front line ICI, only about 1 in 5 stopped treatment at two years rather than continuing treatment beyond two years. The lack of significant overall survival advantage for the indefinite duration cohort on adjusted analysis provides reassurance to pts and providers who wish to stop therapy at 2 years. The final analysis of a phase I/II study of nivolumab, ipilimumab combined with nintedanib in advanced non-small cell lung cancer. *First Author: Sonam Puri, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Nintedanib (NT) is an oral triple kinase inhibitor that is active against NSCLC and inhibits the activity of the immunosuppressive cancer associated fibroblasts in the tumor microenvironment (TME). Targeting the TME with NT may represent an important synergistic approach in improving immunotherapy (IO) outcomes for NSCLC. We initiated a phase I/II trial to evaluate the combination of NT, nivolumab (N) and ipilimumab (I) in advanced (a)NSCLC. Based on the phase IB (dose escalation) results, the combination of N (3mg/kg/2w), I (1mg/kg/6w) and NT (150mg once daily) was declared as the recommended phase 2 dose (RP2D). Here we present the final analysis of the regimen in treatment naïve (TN), and IO pretreated (IP) aNSCLC. **Methods:** This is a single institution, non-randomized, parallel assignment phase I/II clinical trial of aNSCLC pts. Eligible pts were TN (Arm A) or with disease progression following IO (Arm B) with planned sample size of 40/arm. Enrollment into phase II was by the Bayesian two-stage design method with the primary objective of determining the overall response rate (ORR) in the intent to treat population. Key secondary objectives were overall survival (OS) and progression-free survival (PFS). Descriptive statistics were used to summarize demographic and safety data. The Kaplan-Meier method with log-rank test (5% level of significance, 95% CI and 2-sided test) was used for survival analysis. **Results:** 22 and 29 pts received the N+I+NT at the RP2D in Arm A and B, respectively. The median age was 67 [42;92] with 53% (27/51) females, 84% (42/51) Caucasian, ECOG 1 in 88% (45/51), and a current/prior history of tobacco use in 88% (45/51) pts. Adenocarcinoma histology was common (64%, 33/51) with PD-L1 ≥1% in 52% (22/42) pts. As of Oct 24, 2022, 18 and 26 pts were evaluable for response in Arm A and B, respectively. Clinical efficacy was observed in the TN and IP cohorts (Table). The most common treatment-related adverse events (TRAEs) were similar in both cohorts. TRAE of any grade in Arm A were nausea (8, 36%), diarrhea (8, 36%), fatigue (7, 32%), and in Arm B were nausea (10, 34%), fatigue (9, 31%), anorexia (8, 27%). **Conclusions:** The combination of nivolumab, ipilimumab and nintedanib had a manageable toxicity profile and demonstrated promising antitumor activity in both TN and IP aNSCLC patients. Clinical trial information: NCT03377023. Research Sponsor: Drug support BI, BMS, Other support: Florida Department of Health James and Esther King Grant.

Anti-tumor activity of sunvozertinib in NSCLC with EGFR sensitizing mutations after failure of EGFR TKI treatment. *First Author: James Chih-Hsin Yang, National Taiwan University Hospital, Taipei City, Taiwan*

Background: Sunvozertinib is a rationally designed, irreversible EGFR inhibitor targeting various EGFR mutations with wild-type EGFR selectivity. Clinical studies have showed its superior efficacy than current available therapies and favorable safety profile for treating NSCLC patients with EGFR exon20 mutations. Here we reported its anti-tumor activity in patients with EGFR sensitizing mutations (EGFRm) who failed from standard EGFR TKI treatment. **Methods:** This is a pooled analysis of three clinical studies in patients with EGFRm or HER2m NSCLC: WU-KONG1 (multinational phase I/II study, NCT03974022), WU-KONG2 (phase I study in China, CTR20192097), and WU-KONG15 (phase II study in China, NCT05559645). Patients were enrolled to receive sunvozertinib once daily at defined doses until discontinuation criteria were met. Patients who had EGFRm NSCLC, at least one measurable lesion at baseline, received at least one dose of sunvozertinib, and underwent at least one post-treatment RECIST assessment were evaluable for efficacy analysis. Patients with EGFRm or HER2m NSCLC who failed from standard systemic therapies and received at least one dose of sunvozertinib were included in the safety analysis. **Results:** As of October 17, 2022, a total of 32 patients who met efficacy evaluable criteria were included in the analysis. The doses of sunvozertinib ranged from 50 mg - 400 mg. Baseline characteristics: median age was 64.5 years old; 68.8% (22/32) were female; 75.0% (24/32) ECOG PS was 1; 34.4% (11/32) had more than three metastatic sites; 43.8% (14/32) had baseline brain metastases. Patients were heavily pretreated, with a median of 5 lines (range 1 - 16) of prior therapies. All patients had been treated with at least one type of EGFR TKI, including 68.8% (22/32) had been treated with a 3rd generation EGFR TKI. The majority of patients (29/32, 90.6%) had also been treated with chemotherapy. Anti-tumor activity was observed starting from 50 mg. Per investigators' assessment, the best objective response rate (BoR) was 21.9% (7/32). Anti-tumor activity was observed regardless of T790M mutation status. At the data cutoff date, the median duration of response and progression-free survival were 4.0 months and 5.9 months, respectively. Sunvozertinib was well-tolerated across all dose levels. The safety profile was similar to what has been previously reported. The longest treatment duration was more than 35 months (still ongoing). **Conclusions:** Sunvozertinib monotherapy demonstrated promising anti-tumor activity in heavily pretreated EGFRm NSCLC patients. Further clinical evaluation of sunvozertinib in this patient population is warranted. The updated data will be presented at the conference. Clinical trial information: NCT05559645 NCT03974022 and CTR20192097. Research Sponsor: Dizal Pharmaceutical.

Association of alterations in multiple tumor suppressor genes with poor outcomes in patients with EGFR-mutant lung cancer. *First Author: Paul Stockhammer, Yale School of Medicine, New Haven, CT*

Background: Co-occurring alterations in tumor suppressor genes (TSG) have been described as determinants of disease heterogeneity in EGFR-mutant non-small cell lung cancer (NSCLC), however, detailed analyses of their impact on patient outcomes are limited. **Methods:** Patients with EGFR-mutant NSCLC treated with EGFR tyrosine kinase inhibitors (TKIs) at the Yale Cancer Center who had tumor genomic profiling either before EGFR-TKI therapy (pre-TKI) or at disease progression (post-TKI) were included. Whole exome sequencing (WES) of paired pre- and post-TKI tumor specimens were performed for a subset of patients. The cohort was divided into three subgroups based on alterations in *TP53* and five additional TSGs (*RB1*, *NF1*, *ARID1A*, *BRCA1* and *PTEN*): patients with tumors harboring a *TP53* mutation plus a mutation in at least 1 additional TSG (*TP53*^{mut}/TSG^{mut}), patients with tumors harboring a *TP53* mutation without an additional TSG mutation (*TP53*^{mut}/TSG^{wt}), and patients with *TP53*^{wt} tumors. Clinical characteristics including progression-free (PFS) and overall survival (OS) were assessed. **Results:** One-hundred-one patients were included in this retrospective study. *TP53* mutations were identified in 65 (64%) tumors, of which 23 (35%) and 42 (65%) were classified as *TP53*^{mut}/TSG^{mut} and *TP53*^{mut}/TSG^{wt}, respectively. Among those cases with paired WES available (n = 34), frequencies of alterations in the six included TSGs did not significantly differ between pre- and post-TKI tumor specimens. In the full study cohort, the presence of a *TP53* mutation was associated with numerically worse PFS (HR 1.46, CI 0.97 – 2.21, p = 0.09) and OS (HR 1.68, CI 1.05 – 2.70, p = 0.04) on first-line EGFR-TKI. Strikingly, after dividing the *TP53*^{mut} cohort into *TP53*^{mut}/TSG^{mut} and *TP53*^{mut}/TSG^{wt} cases, alterations in additional TSG were found to drive the poor outcomes: *TP53*^{mut}/TSG^{mut} cases had significantly worse PFS and OS on first-line EGFR TKI than *TP53*^{mut}/TSG^{wt} (mPFS 8.0 vs 10.6 months, p = 0.006; mOS 30.0 vs 33.3 months, p = 0.12) or *TP53*^{wt} cases (mPFS 8.0 vs 12.6 months, p < 0.0001; mOS 30.0 vs 48.8 months, p = 0.001). There was no significant difference in PFS or OS between patients with *TP53*^{mut}/TSG^{wt} and *TP53*^{wt} tumors. Similar outcome differences between the three groups were found in patients who received osimertinib in the second-line setting. **Conclusions:** The inferior outcomes associated with EGFR/*TP53*-mutant NSCLC tumors may be due to additional TSG alterations rather than *TP53* mutational status alone. Alterations in the investigated TSGs did not appear to emerge under EGFR-TKI therapy, which suggests that they are truncal. Our findings may have implications for understanding the biologic underpinnings of differential outcomes to EGFR TKIs. Research Sponsor: U.S. National Institutes of Health.

Safety and efficacy of inetetamab in combination with pyrotinib in HER2 mutant patients with non-small cell lung cancer (NSCLC): An open-label, phase Ib trial. *First Author: Wenfeng Fang, Department of Medical Oncology, Sun Yat-sen University Cancer Center & State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, Guangdong, China*

Background: Currently, limited targeted therapies are available for HER2 mutant NSCLC patients. Previous studies have shown the antitumor activity of pyrotinib in advanced NSCLC patients with HER2 mutations. Inetetamab is a recombinant humanized anti-HER2 monoclonal antibody. Whether inetetamab combined with pyrotinib could show manageable safety and more active antitumor activity remains unknown. This study was designed to evaluate the safety and efficacy of inetetamab in combination with pyrotinib in HER2 mutant patients with advanced NSCLC. **Methods:** This study was an open-label, phase Ib study. The HER2 mutant patients with locally advanced or metastatic NSCLC were assigned to receive inetetamab combined with pyrotinib. The study consisted of dose-escalation part and dose-expansion part. During dose-escalation period, the parallel "3+3" dose-escalation design was used to determine the dose-limiting toxicity (DLT). Inetetamab was administered every 3 weeks (8 mg/kg loading dose for cycle 1, followed by 6 mg/kg in subsequent cycles) with pyrotinib (dose-escalation part, 240mg QD, 320mg QD; dose-expansion part, 320mg QD). Primary endpoint of the study was DLT dosage and safety. The DLT was assessed during the 21-day DLT evaluation period after the first dose. Secondary endpoints included objective response rate (ORR), disease control rate (DCR), progression free survival and overall survival. **Results:** Between August 6, 2021, and August 25, 2022, 48 patients were enrolled. No DLT occurred during pyrotinib 240mg and 320mg escalation period. Therefore, pyrotinib 320mg was chosen as expansion dose. The most common treatment-related adverse events (TRAEs) were diarrhea (66.7% [2/3] in pyrotinib 240mg group, 95.6% [43/45] in pyrotinib 320mg group), rash (66.7% [2/3] in pyrotinib 240mg group, 22.2% [10/45] in pyrotinib 320mg group) and vomiting (0 in pyrotinib 240mg group, 24.4% [11/45] in pyrotinib 320mg group). TRAEs were generally Grade (G) 1-2. Only 7 patients reported G3 TRAE (1 in pyrotinib 240mg group, 6 in pyrotinib 320mg group). The preliminary efficacy was shown in the table below. The ORR and DCR of group receiving inetetamab with pyrotinib 240mg were 0% and 66.7%, respectively. The ORR and DCR of inetetamab with pyrotinib 320mg group were 36.6% and 85.4% respectively. The relationship between different mutation subtypes or co-mutations and efficacy will be updated during the conference reports. **Conclusions:** The preliminary data of inetetamab in combination with pyrotinib showed manageable safety and compelling antitumor activity in advanced NSCLC patients harboring HER2 mutations. Clinical trial information: NCT05016544. Research Sponsor: None.

Clinical and molecular features of long-term response to anti-PD-(L)1 therapy in patients with advanced non-small cell lung cancer. *First Author: Rohit Thummalapalli, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: PD-(L)1 blockade can generate long-term responses in subsets of patients (pts) with advanced non-small cell lung cancer (NSCLC), but the clinical and molecular features of long-term responders (LTR) are not well established. Whereas features predictive of initial response have been rigorously explored, long-term follow up in large cohorts is required to identify features distinguishing LTR from short-term responders (STR). **Methods:** We analyzed pts with advanced NSCLC treated with anti-PD-(L)1 therapy at three institutions (MSK, DFCI, MDACC) between 2011 and 2022; responses were assessed by RECIST. LTR was defined as partial response (PR) or complete response (CR) $\geq$ 24 months; STR was defined as PR/CR $<$ 12 months followed by progressive disease (PD). PD-L1 IHC, tumor mutational burden (TMB), next generation sequencing (NGS), and whole exome sequencing (WES) results from subsets of pts were analyzed. High TMB was defined by harmonized TMB z-score $\geq$ 0 ($\geq$ median TMB in each cohort: $\geq$ 7.9 for MSK, $\geq$ 10.5 for DFCI). **Results:** Among 3240 pts overall (MSK = 1536, DFCI = 1238, MDACC = 466), LTR was achieved in 267 (8.2%, 95% CI 7.3 to 9.2%) and STR was achieved in 213 (6.6%, 95% CI 5.7 to 7.5%), with similar rates from each site. 5-year overall survival (OS) was 83% among LTR and 20% among STR. In univariate analyses, non-squamous histology (non-SQ: odds ratio [OR] 2.13, $p = 0.005$), peripheral blood derived neutrophil to lymphocyte ratio (dNLR) $<$ 3.0 (OR 2.15, $p < 0.001$), and high TMB (OR 2.25, $p = 0.001$) were associated with LTR compared to STR; high PD-L1 (PD-L1 $\geq$ 50%: OR 1.19, $p = 0.494$) was not. In multivariate analyses, non-SQ histology (OR 2.56, $p = 0.047$) and high TMB (OR 2.73, $p = 0.001$) remained independently associated with LTR over STR. Among LTR compared to patients with best response of PD, dNLR $<$ 3.0 (OR 1.72, $p = 0.030$), high PD-L1 (OR 5.23, $p < 0.001$), and high TMB (OR 2.55, $p = 0.001$) associated with LTR. LTR showed deeper radiographic responses compared to STR (best response of -50% or greater: OR 3.88, $p < 0.01$). Among 1798 pts with NGS, pathogenic *ARID1A* alterations were numerically higher among LTR compared to STR, but this was not significant when accounting for multiple hypothesis testing (14% vs 2%, $p = 0.022$, $q = 0.196$). Among 73 pts with available WES, both clonal ($p = 0.037$) and subclonal TMB ($p = 0.010$) were significantly higher among LTR compared to STR. **Conclusions:** We report outcomes from $>$ 10 years of advanced NSCLC pts treated with anti-PD(L)1 therapy in a large multicenter cohort, with on-going response at 2 years associated with $>$ 80% 5-year OS. High TMB was a strong independent predictor of LTR over STR. Non-squamous histology, low dNLR, and depth of response also correlate with LTR, while no individual genomic alterations clearly distinguish LTR. These features may assist in identifying pts more likely to derive durable benefit from anti-PD(L)1 therapy without treatment intensification. Research Sponsor: U.S. National Institutes of Health.

Dacomitinib for patients with non-small cell lung cancer harboring uncommon epidermal growth factor receptor mutations: Do mutation patterns matter? *First Author: Hong-Shuai Li, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Previous evidence has revealed the potential efficacy of dacomitinib in patients with advanced non-small cell lung cancer (NSCLC) carrying uncommon epidermal growth factor receptor (EGFR) mutations, but it remains unknown whether there are differences in its efficacy for different combination patterns of these uncommon mutations. **Methods:** The AFANDA cohort, an ambispective cohort including 121 NSCLC patients with uncommon EGFR mutations admitted from two tertiary hospitals in China, was employed for exploration. Meanwhile, a cohort of 63 patients with common mutations was included for comparison. Objective response rate (ORR), progression-free survival (PFS), and adverse events (AEs) were assessed between groups. **Results:** A total of 133 patients with advanced or recurrent NSCLC that received dacomitinib were eligible for analysis. Baseline characteristics were balanced between subgroups. A significant difference was observed between patients with common mutations (C group, $n = 63$), common mutation plus uncommon mutations (C+U group, $n = 24$), and uncommon mutations (U group, $n = 46$) regarding to PFS (mPFS: 7.07, 8.17, and 11.97 months; $p = 0.026$). Moreover, the highest ORR and DCR of the U group were observed among subgroups, although the differences were not statistically significant (ORR, 40.4%, 40.9%, and 61.4%; $p = 0.085$; DCR, 78.9%, 72.7%, 90.9%; $p = 0.134$). Furthermore, the multivariate analysis revealed that the mutation pattern was an independent prognostic indicator of PFS ($p = 0.049$), with the C+U group having the highest risk of progression (HR [hazard ratio]: 1.438, 95% CI [confidence interval]: 0.818-2.528) while the U group having the lowest one (HR: 0.666, 95% CI: 0.409-1.084). For toxicity analysis, no significant difference was observed regarding grade 3-4 AEs among subgroups (12.7%, 8.3%, 13.0%; $p = 0.827$). The drug resistance analysis did not reveal a significant difference concerning the secondary T790M mutation rate (26.3%, 0%, 13.3%; $p = 0.331$). **Conclusions:** Dacomitinib demonstrated different therapeutic efficacy for patients with NSCLC harboring different combination patterns of uncommon EGFR mutation, which should be considered in clinical trials' design and clinical application. Tissue and plasma-based mechanisms of resistance to first-line osimertinib in EGFR-mutant NSCLC: A multi-institutional cohort. *First Author: Zofia Piotrowska, Massachusetts General Hospital, Harvard Medical School, Boston, MA*

Background: Osimertinib (osi) is the preferred 1st line (1L) therapy for patients (pts) with EGFR+ NSCLC, but acquired resistance is universal. Identification of mechanisms of resistance (MoR) to 1L osi can inform subsequent therapies. We report a retrospective, multi-institutional cohort of pts with tissue biopsy (TBx) and/or liquid biopsy (LBx) upon 1L osi progression (PD). **Methods:** Pts with advanced EGFR+ NSCLC who had TBx and/or LBx (for ctDNA analysis) obtained at PD on 1L osi at 8 participating institutions were included. Molecular testing was performed using next-generation sequencing (NGS) and, in a subset, FISH per local standards. We retrospectively collected clinical characteristics, tissue histology, NGS/FISH results and subsequent therapies. **Results:** 193 pts (128 female; median age 64 yrs) had TBx ($n = 129$) and/or LBx ($n = 122$) upon PD on 1L osi, 58/193 had both tissue and ctDNA. Primary EGFR mutations included del19 (102), L858R (76), and other (15). Median time from osi start to first bx was 14 mos (range, 1-55). MoRs are summarized in the table. In all, 86/193 (45%) pts had a known MoR identified on TBx and/or LBx. Among 129 pts with TBx, histologic transformation (trans) and MET amplification (amp) were the most common MoR, each seen in 16% pts. Among 122 pts with LBx, secondary EGFR mutations were the most common MoR, seen in 15%. Among the 58 pts with both TBx + LBx, discordance between major MoRs was seen in 21/58 pts (36%), most commonly due to histologic trans detected on TBx only ($n = 7$) and discordant MET amp status ($n = 8$; 6 TBx+/LBx-, 2 TBx-/LBx+). No MoR was identified in 53% TBx and 75% LBx (including 14% Lbx where the original EGFR mutation was not detected in ctDNA). Results of TBx led to MoR-directed 2L therapy in 41/129 (32%) pts, while LBx results led to MoR-directed 2L therapy in 16/122 (13%). **Conclusions:** In this large, multi-institutional cohort, histologic trans (16%) and MET amp (16%) were the most common MoR to 1L osimertinib on tissue bx. In ctDNA, secondary EGFR mutations (15%) were the most frequent MoR. The results of TBx were more likely to impact second-line therapy than LBx. Our results underscore the importance of tissue biopsy (and limitations of liquid biopsy) after osimertinib PD, where tissue testing remains the gold standard. In addition, with more than half of patients having no identifiable MoR despite comprehensive testing, our results highlight the need for MoR-agnostic treatment strategies. Research Sponsor: None.

Contemporary biomarker testing rates in both early and advanced NSCLC: Results from the MYLUNG pragmatic study. *First Author: Makenzi Colleen Evangelist, US Oncology Research/New York Oncology Hematology, Albany, NY*

Background: The MYLUNG (Molecularly Informed Lung Cancer Treatment in a Community Cancer Network) consortium pragmatic study aims to identify and overcome barriers to timely and appropriate biomarker testing in patients (pts) with NSCLC. We previously reported retrospective real-world testing rates for 5 biomarkers from 2018-2020 in metastatic pts. We now report results from the prospective observational phase, including additional biomarkers in pts with both early and advanced NSCLC. **Methods:** This was a prospective, non-interventional cohort study of newly diagnosed pts with early stage (ES), locally advanced (LA), or metastatic NSCLC (mNSCLC) between 12/2020 and 9/2022 and enrolled from 12 community practices (69 sites) across The US Oncology Network. The proportion of pts with test results for 9 biomarkers at time of protocol initiation were examined: ALK, BRAF, EGFR, ROS1, PD-L1, KRAS, MET, NTRK, and RET. Timing of tests, use of single vs multigene NGS testing, clinical and socioeconomic factors, and reasons for not testing were collected in real time. **Results:** Of 1002 pts screened, 987 were enrolled and analyzed. There were 405 stage IB-IIIC pts (n = 284 stage IB-IIIA (ES cohort); n = 121 stage IIIB-IIIC (LA cohort)) and 582 stage IV pts (mNSCLC cohort). Descriptions for ES and LA vs mNSCLC pts respectively include median age 68 vs 69 yrs, 49% vs 52% female, 83% vs 77% white, 58% vs 79% adenocarcinoma histology, 71% vs 68% ECOG 0-1, and 33% vs 30% high school education level. Testing rates for ES vs mNSCLC cohorts are shown in the table below: prior to treatment initiation, 64% of ES and 83% of mNSCLC pts had at least one biomarker result; and 37% of mNSCLC pts had results for all 9 biomarkers. NGS testing occurred in 37% and 57% of the ES and mNSCLC cohorts respectively. Reasons for not testing included: barriers to ordering (42%, 25%), insufficient tissue (18%, 18%), clinical deterioration/crisis (5%, 12%), and other reasons (37%, 49%), respectively. **Conclusions:** As more genomic alterations are identified in NSCLC, we observed that many pts do not get full genotyping prior to treatment, and biomarker testing remains of utmost importance. Further analyses by distinct stages (e.g. LA), histology, social determinants, utilization of targeted therapies, and other reasons for not testing will be performed. These data will be used to evaluate future prospective interventions for MYLUNG, to help improve comprehensive biomarker testing for NSCLC. Research Sponsor: Amgen, AstraZeneca, Eli Lilly, Genentech, Mirati.

Poster Session

A first-in-human phase I, dose-escalation and dose-expansion study of SY-5007, a highly potent and selective RET inhibitor, in Chinese patients with advanced RET positive solid tumors. *First Author: Caicun Zhou, Department of Medical Oncology, Shanghai Pulmonary Hospital and Thoracic Cancer Institute, Tongji University School of Medicine, Shanghai, China*

Background: RET gene fusions have been identified as oncogenic drivers in 1-2% of non-small-cell lung cancer (NSCLC) and 10-20% of papillary thyroid carcinomas. Activating RET mutations occur in 50-60% of medullary thyroid cancer (MTC). Recently, selective RET TKIs, selpercatinib and pralsetinib, were approved for RET positive solid tumors by FDA. SY-5007 is a highly potent RET inhibitor that selectively targets RET fusions and mutations. This study is to investigate the safety, PK characteristics and preliminary efficacy of SY-5007 in Chinese patients with advanced RET-altered solid tumors. **Methods:** In this first-in-human phase I study, eligible patients previously treated and with positive RET were enrolled. In the dose escalation phase, following 3+3 design, the patients were administered orally with SY-5007 20 mg once daily, or 20, 40, 80, 120, 160, 200 mg twice daily in a 28-day cycle. The expansion doses (160 and 200 mg twice daily) were executed in a dose expansion phase to determine a recommended phase II dose (RP2D). Then three cohorts (RET fusion-positive NSCLC or thyroid cancers and RET mutant MTC) at RP2D were expanded in eligible patients. Primary endpoints included safety, tolerability, MTD, DLTs. Secondary endpoints included PK and preliminary antitumor activity of SY-5007 per RECIST v1.1. **Results:** As of Feb.06, 2023, a total of 60 patients including 55 RET fusion NSCLC and 5 RET mutant solid tumors were enrolled into dose escalation cohorts (n = 17) and dose expansion cohorts (n = 43). Totally, 55 (91.7%) patients experienced treatment-related adverse events (TRAEs) including increased aspartate aminotransferase (50.0%), increased alanine aminotransferase (41.7%), diarrhea (41.7%), etc. Grade ≥3 TRAEs were observed in 22 (36.7%) patients including hypertension (15%), diarrhea (5%), increased alanine aminotransferase (3.3%), etc. PK study showed SY-5007 was absorbed rapidly, exposure of SY-5007 increased in a dose-dependent manner at doses between 20 and 160 mg twice daily, and it was saturated at 160 mg twice daily. In 50 evaluable patients, the overall ORR and DCR was 62.0% (95% CI, 47.2-75.4) and 94.0% (95% CI, 83.5-98.8), respectively. 29 patients (24 NSCLC, 4 MTC) received SY-5007 at 160 mg twice daily, 27 of 28 (96.4%) evaluable patients showed tumor regression, ORR and DCR was 72.4% (95% CI, 52.8-87.3) and 89.7% (95% CI, 72.7-97.8), respectively. For NSCLC patients, the ORR and DCR was 75.0% (95% CI, 53.9-90.2) and 91.7% (95% CI, 73.0-99.0), respectively. **Conclusions:** SY-5007 was well tolerated in patients. Preliminary anti-tumor activity was also observed in patients with advanced RET-fusion positive NSCLC and RET mutant MTC. The pivotal Phase II clinical study of SY-5007 in NSCLC patients is ongoing. Efficacy and safety of SY-3505, a third-generation ALK TKI, in ALK-positive advanced non-small cell lung cancer: Results from a phase I/II, multi-center study. *First Author: Yuankai Shi, Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study On Anticancer Molecular Targeted Drugs, Beijing, China*

Background: SY-3505 is a potent, brain-penetrant, 3rd-generation (gen) anaplastic lymphoma kinase (ALK) tyrosine kinase inhibitor (TKI) with preclinical activity against both wild-type and most known resistance mutations of ALK occurring in 1st and 2nd-gen ALK TKI-resistant patients. Here we report the efficacy and safety results from the ongoing phase I/II study of SY-3505. **Methods:** Patients aged ≥18 years with histologically/cytologically confirmed, advanced, ALK-positive non-small cell lung cancer (NSCLC) and an Eastern Cooperative Oncology Group (ECOG) performance status (PS) of 0-2 were recruited from 13 hospitals in China. In phase I study, patients received SY-3505 from 25-800mg once daily in dose-escalation phase, followed by dose-expansion at 500/600mg. Patients received alectinib only or ≥2 prior ALK TKIs were recruited in phase II study and treated with SY-3505 at 600mg once daily. The primary endpoint was investigator (INV)-assessed objective response rate (ORR) per Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1. Secondary endpoints included disease control rate (DCR), duration of response (DoR), progression-free survival (PFS), overall survival (OS) and safety. **Results:** At data cut-off date of Feb.03, 2023, 92 ALK-positive NSCLC patients were enrolled in phase I/II, 82 were evaluable for efficacy, the ORR was 34.2% (95% confidence interval [CI] 24.0-45.5%), DCR was 74.4% (95% CI 63.6-83.4%). Herein the ORR and DCR of 59 patients in phase I for dose-escalation and dose-expansion was 32.3% (95% CI 20.6-45.6%) and 69.5% (95% CI 56.1-80.8%), respectively; median DoR and PFS was 11.1 (95% CI 5.28-not reached [NR]) and 6.20 (95% CI 3.08-10.3) months, respectively. Fifty-six patients received SY-3505 at 600mg once daily (two patients received non-alectinib 2nd-gen ALK TKI only, 22 received alectinib only and 32 received ≥2 prior ALK TKIs). Thirty-two (57.1%) patients experienced treatment-related adverse events (TRAEs) and two (3.6%) had grade ≥3 TRAEs. The most common TRAEs were diarrhea (42.9%), nausea (28.6%) and vomiting (26.8%), consistent with previous reported in phase I. Forty-seven patients were evaluable for efficacy, the ORR and DCR was 38.3% (95% CI 24.5-53.6%) and 83.0% (95% CI 69.2-92.4%), respectively. Median DoR and PFS were NR. Twenty-two patients had baseline central nervous system metastases, the ORR and DCR was 50.0% and 86.4%, respectively. **Conclusions:** SY-3505 was well-tolerated and showed significant and durable clinical activity in ALK-positive NSCLC patients who received at least one prior 2nd-gen ALK TKI, demonstrating a potential new treatment option for these patient population. Pivotal clinical study will be performed in future. Clinical trial information: NCT05257512. Research Sponsor: Shouyao Holdings (Beijing) Co., Ltd.

Phase 1 study evaluating the safety, tolerability, pharmacokinetics (PK), and efficacy of GEC255, a novel KRAS^{G12C} inhibitor, in advanced solid tumors. *First Author: Yan Zhang, Department of Thoracic Oncology, Cancer Centre, Sichuan University West China Hospital, Chengdu, China*

Background: The KRAS^{G12C} mutation occurs in 12-14% of NSCLC and in 3-5% of CRC patients and is recognized as an oncogenic driver mutation. Recently the discovery of a cryptic binding pocket within the effector region of the KRAS^{G12C} oncoprotein has led to the rapid clinical development of a new series of specific inhibitors. GEC255 is a novel small molecule which showed excellent target engagement ability and a favorable pharmacological profile. **Methods:** This is a phase 1, open-label, multicenter study (CTR20212486) to evaluate the safety, tolerability, pharmacokinetics (PK), and efficacy of GEC255 in patients (pts) with advanced solid tumors bearing KRAS^{G12C} mutation. The primary endpoint is safety and key secondary endpoints include PK and ORR. Key inclusion criteria: KRAS^{G12C} mutation identified through digital PCR, measurable or evaluable disease, ECOG PS ≤1, and life expectancy > 3 months. Key exclusion criteria: previous administration of specific KRAS^{G12C} inhibitors, uncontrollable plasma cavity effusion. Phase 1a is an accelerated titration, dose-escalating study to determine the maximum tolerated dose (MTD) or recommended phase 2 dose (RP2D). Phase 1b is a dose expansion study which will enroll pts with NSCLC, CRC, and other solid tumors harboring the KRAS^{G12C} mutation. GEC255 will be administered PO QD until disease progression, intolerance, or withdrawal of consent. **Results:** 16 NSCLC pts (15 men, 1 woman, median age 58 y) were enrolled in Phase 1 dose escalation for the first 4 dose cohorts followed with dose escalation in chosen doses. No dose-limiting toxicity was observed and MTD has not been identified yet. GEC255 showed the linear increase in AUC exposure and C_{max} with increasing doses. T_{max} was 2-4 hours in all dosing groups and C_{trough} within the 24-hour period was higher than pERK IC₅₀ even in low dose group. The half-life of GEC255 in 24h period is about 8-9h and there is no increase in AUC upon daily dosing for 28 consecutive days. Among the 16 pts, most pts (n = 13) had ≥1 prior lines of treatment (tx). A total of 15 patients had treatment-related adverse events and most AEs are G1 or G2 (93.3%); the most frequent AEs are diarrhea (56.3%), ALT increase (37.5%), rashes (25%), and anemia (25%). Tumor response was evaluated in 13 pts. 10 pts (76.9%) had objective response (complete or partial response) and 12 pts (92.3%) had disease control (objective response or stable disease). In 600mg dose group, the ORR was 83.3% and DCR was 100% (n = 6). 7 pts are continuing to receive GEC255. **Conclusions:** GEC255 has been well tolerated at the doses tested and has shown encouraging anticancer activity to advanced NSCLC patients with KRAS^{G12C} mutation pts. MTD has not been determined, and enrollment into the dose exploration is ongoing. (<http://www.chinadrug-trials.org.cn/index.html>). Clinical trial information: CTR20212486. First-in-human, multicenter phase I study of TGRX-326 in patients with advanced ALK-positive non-small cell lung cancer. *First Author: Hongyun Zhao, Department of Clinical Research, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China*

Background: TGRX-326, a deuterated derivative of lorlatinib (LOR), is a potent 3rd generation ALK and ROS1 dual TKI with high potency against multiple ALK-resistant mutations. Deuteration of the key metabolic site of the molecule allows to achieve a higher exposure than with LOR and this may result in alleviated toxicities and better efficacy. **Methods:** The study comprised 3 phases: dose escalation (D-ESCAL), dose expansion (D-EXP) and cohort expansion (C-EXP). In D-ESCAL and D-EXP, ALK+ pts prior failed on 2nd gen ALK-TKIs or ROS1+ pts resistant to crizotinib (CRZ) were enrolled; in C-EXP, ALK+ pts progression after CRZ (C-EXP-A1), progression after ≥ 1 2nd gen TKIs (C-EXP A2), ROS1+ progression after CRZ (C-EXP-B) and pts with ALK TKI naïve (C-EXP-C) were enrolled. **Results:** Up to Jan 13, 2023, 185 pts (median age 53 years, 45.9% male) were enrolled; Median treatment and follow-up was 5.5 and 6.7 months, respectively. There were no DLT observed and no MTD identified in D-ESCAL (5-125mg QD, n=19). Based on the safety, efficacy and PK exposure data of 42 pts in D-ESCAL and D-EXP, 60 mg QD was selected as the RP2D for C-EXP, the average AUC₀₋₂₄ of 60mg QD reached to 5443ng*hr/mL. Treatment-related adverse events (TRAEs) occurred in 87.5% patients (162/185), the most common TRAEs were hypercholesterolemia (74.1%), hypertriglyceridemia (68.1%), weight gain (36.2%), peripheral edema (15.7%), peripheral neuropathy (14.1%). As for R2PD, 132 of 155 (85.2%) experienced TRAEs, Grade ≥3 TRAEs occurred in 19.7%, most frequent were hypertriglyceridemia (11%) and hypercholesterolemia (8.4%). Dose interruptions and dose reductions associated with TRAEs were reported in 10 (5.4%) and 5 (2.7%) pts respectively. Confirmed response were observed in 142 ALK+ pts enrolled in C-EXP, results are shown in the Table (Efficacy of B-ROS1+ pts will be reported separately). Eleven ALK mutations were detected in 16 pts (either alone or in combination); 50.0% pts achieved PR. Out of 6 pts who were positive for G1202R, 50.0% experienced PR. **Conclusions:** TGRX-326 was well tolerated in pts with advanced ALK+ NSCLC and showed promising clinical antitumor activity irrespectively of ALK+ resistance to CRZ and 2nd gen TKIs, especially among those with brain metastases. Impressive activity was seen in ALK TKI naïve NSCLC. TGRX-326 demonstrated antitumor activity against multiple ALK mutations including G1202R. Clinical trial information: NCT05441956. Implementation strategies for monitoring adherence in real time (iSMART): A pilot randomized trial. *First Author: Katharine A. Rendle, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: Helping patients to manage symptoms and adhere to oral anticancer agents (OACAs) is a major challenge in oncology. OACAs cause side effects that can lead to suboptimal adherence if not optimally managed, contributing to decreased effectiveness. Low-cost, text messaging approaches have shown promise, but have not been robustly studied in oncology. Guided by principles from implementation and behavioral science, we developed and tested the effect of an augmented intelligence chatbot on OACA adherence and symptom burden in patients with advanced lung cancer. **Methods:** We conducted a two-arm pilot randomized trial (NCT04347161) to evaluate the effect of the chatbot on OACA adherence and symptom burden compared to usual care. The chatbot engages patients via text messaging and applies natural language processing and machine learning to learn from interactions. Core functionalities include: 1) motivational daily adherence reminders, 2) longitudinal symptom monitoring with self-management support, and 3) bidirectional communication with clinical teams. Participants included English-speaking patients with advanced lung cancer treated with any of 9 OACAs targeting EGFR, ALK, or ROS-1. The primary outcome was 12-week adherence, measured using the microelectronic monitoring system (MEMS) and defined dichotomously if the patient achieved ≥95% adherent days or not. Secondary outcomes were assessed at baseline and 12 weeks using validated survey instruments, including symptom burden using the Edmonton Symptom Assessment System Total Distress Score (range 0-90), health-related quality of life (HRQOL) using EQ-5D-3L (range 0-100), and usability using Health-ITUES (range 1-5). We used multivariable logistic regression adjusting for stratification variables to test the chatbot's effect on adherence (intent-to-treat analysis) and evaluated mean differences (by arm) in secondary outcomes using Fisher's exact test. **Results:** From February 2021 to August 2022, 75 patients across 4 sites enrolled (median age 65 years, 64% female, 88% White, 21.3% high school education or lower); 50.7% (n=38) were randomized to intervention. Compared to usual care, we observed no significant differences in adherence in the intervention arm (78.8% vs 81.8%; aOR=1.7 95% CI: 0.3-9.4). However, in contrast to those in usual care, participants in the intervention arm had significantly greater decreases in symptom burden (mean difference: -2.7 vs 2.6; p<0.05) and increases in HRQOL (mean difference: 4.1 vs -4.8; p<0.05) from baseline to 12 weeks. Overall chatbot usability was high (mean score=3.9). **Conclusions:** In this pilot randomized trial, an augmented intelligence chatbot successfully reduced symptom burden and improved HRQOL but did not significantly alter OACA adherence. Chatbots are a potentially scalable strategy for improving symptom management that warrant study in larger randomized trials. Clinical trial information: NCT04347161. SKB264 (TROP2-ADC) for the treatment of patients with advanced NSCLC: Efficacy and safety data from a phase 2 study. *First Author: Wenfeng Fang, Department of Medical Oncology, Sun Yat-sen University Cancer Center & State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, Guangdong, China*

Background: TROP2 (trophoblast cell surface antigen 2) is commonly overexpressed in non-small cell lung cancer (NSCLC) and associated with poor prognosis. SKB264 is a novel anti-TROP2 ADC developed using sulfonyl pyrimidine-CL2A-carbonate linker to conjugate its payload, a belotecan-derivative topoisomerase I inhibitor, to achieve an average Drug-to-antibody Ratio (DAR) of 7.4. The design was to achieve a more effective balance between stability in circulation and release of the ADC payload in tumor cells. Here we report clinical efficacy and safety results of SKB264 in the treatment of patients (pts) with NSCLC from a Phase 2 expansion cohort. TROP2 expression level by immunohistochemistry was assessed retrospectively. Correlation analyses between response and TROP2 level will be provided. **Methods:** This is a Phase 1/2, multicenter dose-escalation/expansion study in pts with relapsed or refractory locally advanced/metastatic NSCLC and other tumor types (NCT04152499). All NSCLC pts received SKB264 at 5 mg/kg IV Q2W. Tumor assessments based on RECIST 1.1 were performed every 8 weeks by investigators. **Results:** As of February 9th, 2023, 43 pts (63% male, 88% ECOG PS 1, median age 58 yrs [44-74]) were enrolled. Median follow-up was 11.5 months (mo; 95% CI, 10.4-12.2). Median treatment duration was 5.7 mo (range, 0.5-14.1). Among 39 response-evaluable pts, the ORR was 44% (17/39, 15 confirmed and 2 pending confirmation), median DoR was 9.3 mo (range, 1.3+ to 11.2+), 6-month DoR rate was 77%. For EGFR wild type subgroup (previously received median 2 lines of therapy including anti-PD-1/L1), the ORR was 26% (5/19), DCR was 89% (17/19), median PFS was 5.3 mo, and 9-month OS rate was 80.4%. For subgroup with TKI resistant EGFR mutant NSCLC (50% also failed at least one line of chemotherapy), the ORR was 60% (12/20), DCR was 100% (20/20), median PFS was 11.1 mo, and 9-month PFS rate was 66.7%. 67.4% (29/43) of pts had Grade ≥ 3 treatment-related adverse events (TRAEs). The most common Grade ≥3 TRAEs (occurred in ≥5% of pts) were neutrophil count decreased (32.6%), anemia (30.2%), white blood cell count (WBC) decreased (23.3%), stomatitis (9.3%), rash (7.0%), and lymphocyte count decreased (7.0%). Grade 4 TRAEs occurred only for neutropenia and WBC decreased. Most of the hematotoxicity occurred within the first two months of treatment and resolved after treatment with granulocyte colony stimulating factor or erythropoietin without blood transfusions. 23.3% (10/43) of the pts experienced dose reduction due to TRAEs. No neuropathy or drug-related ILD/pneumonitis was reported. No TRAEs led to treatment discontinuation or death. **Conclusions:** SKB264 at 5 mg/kg Q2W demonstrated encouraging anti-tumor activity and manageable safety profile in pts with relapsed or refractory locally advanced/metastatic NSCLC. TRAEs were mainly hematologic. Phase 3 studies of SKB264 in pts with advanced NSCLC have been planned. Clinical trial information: NCT04152499. Research Sponsor: Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd.

Characteristics of long-term survivors with EGFR mutant (EGFRm) metastatic non-small cell lung cancer (mNSCLC). *First Author: Melina Elpi Marmarelis, University of Pennsylvania, Philadelphia, PA*

Background: Although osimertinib has become standard first-line (1L) therapy for patients (pts) with EGFRm mNSCLC, a subset treated with earlier-generation EGFR-targeted TKIs and chemotherapy have had long-term survival. We sought to characterize clinical features of long-term survival in pts with EGFRm mNSCLC treated prior to the osimertinib era. **Methods:** Data were abstracted from electronic medical records at 12 cancer centers participating in the Academic Thoracic Oncology Medical Investigator's Consortium (ATOMIC). We included patients with mNSCLC with sensitizing mutations in EGFR who started 1L systemic therapy before 2015. Survival distributions and predictors were assessed using Kaplan-Meier estimates and a multivariable Cox proportional hazards model including time-dependent brain metastasis (met) development, age, 1L therapy (targeted vs. chemotherapy), sex, race, and smoking status. Multivariable logistic regression was used to evaluate baseline predictors associated with 5+ year survival vs. not for those with known survival status at 5 years after start of 1L. **Results:** We identified 304 patients (69% female, 56% White, 29% Asian, mean age 61.2). First-line targeted therapy was given in 70% of patients. With a median follow-up of 81.5 months, median overall survival was 63.5 months (95% CI 59.4-71.9). 135 (44%) pts survived 5+ years; among those with baseline next-generation sequencing (NGS), presence of a baseline pathogenic ERBB2 variant was higher in 5+ year survivors (4/51 [8%], 2x amplification, y772_A775dup, S310F) v others (1/65 [2%], amplification). Among 161 pts with baseline brain imaging, both baseline and on-treatment development of brain mets were associated with worse survival (HR 1.29, 95% CI 1.21-1.37; HR 1.59, 95% CI 1.47-1.72; both P < 0.001). Excluding 22 patients lost to follow-up before 5 years, a history of smoking (OR 2.99, 95% CI 1.35-6.90, P = 0.008) and baseline brain metastases (OR 3.57, 95% CI 1.64-8.13, P = 0.002) were associated with death before 5 years. **Conclusions:** Long-term survivors with EGFRm mNSCLC treated before the osimertinib era were more likely to be non-smokers and have no baseline brain metastases. This highlights a subset of EGFRm patients who had excellent outcomes with older treatment strategies and may not benefit as much from intensification approaches. Additional baseline mutational data will be presented at the conference. Research Sponsor: AstraZeneca; LUNGEVITY.

Association between real-world, upfront, next-generation sequencing and overall survival (OS) in advanced non-small-cell lung cancer (aNSCLC) in the United States. *First Author: Benjamin Philip Levy, John Hopkins Sidney Kimmel Cancer Center, Washington, DC*

Background: Multiple biomarker testing strategies exist as the treatments of aNSCLC rapidly evolve. While upfront NGS is considered optimal, this practice has not been universally adopted. Surprisingly, the impact of NGS vs non-NGS approaches on OS is unclear, with the largest study to date demonstrating lack of benefit. We aim to identify the genomic testing strategy associated with the most optimal OS in aNSCLC using data from a large, contemporary electronic health record (EHR) database. **Methods:** This retrospective study used Flatiron EHR data. Patients diagnosed with aNSCLC between 11 Apr 2019 and 31 Dec 2021 who received systemic therapy were identified and followed from the date of diagnosis to 31 May 2022 or death. Testing methods reported within the patient's chart were extracted. Methods assessed included NGS (defined as any test type with 'NGS' as test name) and non-NGS (defined as PCR, FISH, IHC, and other sequencing methods not containing 'NGS'). Upfront testing was defined as tests received on or prior to the date of initiation of first-line (1L) therapy. Kaplan-Meier analyses were used to estimate and compare real-world overall survival (rWOS) by testing strategies. Among those with actionable genetic mutations, we also explored rWOS by timing of targeted therapy (TT) initiation. **Results:** Of a total 13,139 patients, mean age was 69, 49% female, 64% white, 33% Medicare insured, and 88% treated in community setting only. Median follow up time was 9 months. The percentage of patients with upfront NGS increased from 29% in 2019 to 66% in 2022. Median OS (mOS) was longest in patients with upfront NGS compared to those with upfront non-NGS genomic tests ($p < 0.05$), those with NGS after 1L ($p < 0.05$), and those with no NGS test ever ($p < 0.05$) (see table). 19% of patients with upfront NGS vs. 15% of those with upfront non-NGS received TT in 1L; 23% of patients with NGS vs. 19% of those with upfront non-NGS received TT at any line of therapy. In patients with actionable genetic mutations, mOS decreased with later initiation of TT; mOS was not reached (NR) (34.6 – NR) in patients who initiated TT in 1L, 34.7 (29.1 – NR) months in those with 2L TT, and 24.3 (20.3 – 30.1) months in those who initiated TT in 3L. **Conclusions:** This is the first and largest study to demonstrate that upfront NGS testing leads to better OS when compared to upfront non-NGS genomic testing, later NGS, or no-NGS in aNSCLC. In line with these results, we also found an OS benefit associated with earlier TT initiation. These results highlight the significant impact of upfront NGS testing and underscore for the need for both education and wider accessibility of NGS testing. Research Sponsor: Novartis, Inc.

	Upfront NGS testing (n = 6,210)	Upfront non-NGS genomic testing (n = 2,697)	NGS testing after 1L initiation (n = 2,824)	No NGS tested ever (n = 2,152)
Median OS (CI) in months	20.9 (19.8-21.9)	17.5 (16.1-19.2)	18.2 (16.6-19.4)	16.9 (15.3-18.6)

FDA analysis of toxicity profiles of oral TKIs recently approved for non-small cell lung cancer based on receipt of prior immune checkpoint inhibitor therapy. *First Author: Yufan Liu, United States Food and Drug Administration, Silver Spring, MD*

Background: Immune checkpoint inhibitors (ICIs) targeting PD-(L)1 are standard front-line therapy for advanced non-small cell lung cancer (NSCLC). Molecularly targeted tyrosine kinase inhibitors (TKIs) are standard of care for subsets of oncogene-driven NSCLC. Published literature suggests the possibility of increased toxicity in patients who receive ICIs followed by *EGFR* or *ALK* TKI treatment. However, the toxicity profile in patients who receive ICIs followed by TKIs with other genomic targets has not been well described. **Methods:** Marketing applications for TKIs in patients with NSCLC submitted to the Office of Oncologic Diseases between Jan 2019 to Dec 2022 were reviewed. Datasets were analyzed for demographics, treatment-emergent adverse events (TEAE), and prior anti-cancer therapies for TKI-treated patients in the primary efficacy population. Drug classes for which $< 5\%$ of patients received prior ICI were excluded. Grade 3-4 TEAE, serious adverse events (SAE), discontinuation TEAE and TEAE of interest (hepatotoxicity, rash, and interstitial lung disease [ILD]) were summarized. **Results:** 9 applications were identified and 2 were excluded. The remaining applications involved TKIs targeting *EGFR* exon 20 insertion, *KRAS G12C*, *MET* exon 14 skipping, and *RET* fusion alterations. Analyses included 867 patients; 61% received prior ICI therapy. Patient characteristics and results of analyses are presented in the table. In our pooled analysis, the incidence of Grade 3-4 AEs, SAEs, and hepatotoxicity were slightly higher in the prior ICI group, while the incidence of discontinuation TEAE, ILD, and rash were similar between groups. Analysis for hepatotoxicity was limited to reported AEs (did not include analysis of laboratory data). Review of toxicity data across individual drug classes did not show major differences compared to the overall results. **Conclusions:** Our analysis of safety data for newer TKIs with varied genomic targets does not appear to show excessive toxicity in patients with NSCLC who received prior ICI compared to those who did not. In future clinical trials evaluating TKIs in this population, inclusion of patients who have received prior ICI therapy should be considered when appropriate. Research Sponsor: None.

Clinical, pathologic, and genomic hallmarks of *KRAS*-amplified non-small cell lung cancer. *First Author: Biagio Ricciuti, Dana-Farber Cancer Institute, Lowe Center for Thoracic Oncology, Boston, MA*

Background: *KRAS*-mutant non-small cell lung cancers (NSCLCs) have unique clinicopathologic and genomic features, and novel therapies are in development to target many *KRAS*-mutant tumor types. Whether *KRAS* amplification also defines a unique, potentially targetable, molecular subset of NSCLC is currently unknown. **Methods:** Clinicopathologic and genomic data were abstracted from multiple independent cohorts of pts whose cancers underwent tumor genomic profiling at the Dana-Farber Cancer Institute (Cohort 1), AACR Project GENIE v.13, The Cancer Genome Atlas (TCGA), and 212 other studies (Cohort 2). Patient (pt) outcomes were examined according to *KRAS* amplification status (*KRAS* amplified vs *KRAS* non-amplified). Whole transcriptome sequencing and quantitative proteomics data from TCGA and the Cancer Cell Line Encyclopedia (CCLE) were used to correlate *KRAS* amplification with *KRAS* RNA levels and protein expression. **Results:** Among 15,341 pts with NSCLC, *KRAS* amplification was identified in 355 (2.3%) cases (median number of copies [range]: 11 [7-87]); the prevalence was similar in adenocarcinomas and squamous cell carcinomas. Compared to *KRAS* non-amplified cases, pts with *KRAS*-amplified NSCLC were more likely to be men (52.4% vs 45.6%, $p = 0.01$), have a history of smoking (82.1% vs 64.2%, $p < 0.01$), and higher median pack-years (35 vs 23.5, $p < 0.01$). However, median age was similar between the two groups (66 vs 66, $p = 0.88$). *KRAS* amplification was also associated with higher aneuploidy (median fraction of genome altered 30.4% vs 14.3%, $p < 0.01$), tumor mutational burden ($p < 0.01$ across different platforms), and increased median PD-L1 expression (20% vs 5%, $p = 0.01$). Of the 355 NSCLC samples with *KRAS* amplification, 152 (43%) had no concurrent oncogene driver mutations. In unbiased mutation enrichment analyses, *KRAS*-amplified tumors were enriched in concurrent mutations in *KRAS*, *PALB2*, *POLE*, and *SLC34A2* ($q < 0.1$), while *KRAS* non-amplified tumors were enriched for oncogenic *EGFR* mutations ($q < 0.1$). Transcriptomic and proteomic profiling from the TCGA and CCLE cohorts demonstrated that *KRAS* amplification was associated with significantly increased *KRAS* mRNA ($p < 0.01$) and protein expression ($p < 0.01$), compared to *KRAS* non-amplified samples. In pts with available clinical outcomes data in the combined cohort ($N = 9,335$), the median overall survival (OS) from the date of diagnosis was significantly shorter in *KRAS*-amplified vs *KRAS* non-amplified cases (adjusted HR: 1.40, $p < 0.01$). *KRAS* amplification was confirmed to confer significantly worse survival outcomes in pts with both *KRAS* wild-type ($N = 6,695$, adjusted HR 1.37, $p = 0.02$) and *KRAS*-mutant ($N = 2,640$, adjusted HR 1.34, $p = 0.02$) NSCLC. These results were independently replicated in Cohort 1 and Cohort 2. **Conclusions:** *KRAS* amplification defines a novel molecular subset of NSCLC characterized by distinct clinicopathologic and genomic features and worse survival. Research Sponsor: None.

Stimulus of interferon gene (*STING*) expression as a biomarker for overall survival in PDL1-negative, TMB-low non-small cell lung cancer (NSCLC) treated with immune checkpoint inhibitors (ICIs). *First Author: Matthew James Hadfield, RI Hosp Brown Univ, Providence, RI*

Background: cGAS-STING (CGS) is an intracellular DNA sensing pathway that when activated, stimulates interferon and other immune-related signaling pathways. While increased expression of CGS-related genes has been associated with better survival in NSCLC, studies investigating this phenomenon in tumors less likely to respond to ICIs such as PDL1-negative, TMB-Low NSCLC are lacking. Here we report the role of CGS pathway in NSCLC tumors that are both PDL1-negative and TMB-Low. **Methods:** DNA (592-gene or whole exome) and RNA sequencing (whole transcriptome) was performed for NSCLC specimens ($n=7264$) submitted to Caris Life Sciences (Phoenix, AZ). PDL1 negativity was defined as $< 1\%$ TPS score (22C3) & TMB-Low as < 10 mutations/Mb. Hierarchical Agglomerative Clustering (HAC) was performed on STING pathway genes (CXCL10, CCL5 and GZB) and tumors were grouped into STING-high ($n=3070$), STING-intermediate ($n=1609$) and STING-low ($n=2585$) groups. Microenvironmental cell populations (MCP)-counter analysis was used to estimate cellular composition of immune cells. Statistical significance was determined using chi-square/Fisher's exact/Mann-Whitney U tests and adjusted for multiple comparisons ($q < 0.05$). Kaplan Meier method was used to estimate the overall survival (OS) derived from insurance claims of IO treated pts with NSCLC ($n=400$). Pts were stratified into groups above or below the median expression of the *STING* gene (*TMEM173*). **Results:** Compared to STING-low, tumors that were STING-high had enrichment in immune cell infiltrates including CD8+ T cells (4.4-fold) and B-cells (5.9-fold); Additionally, STING-high cohort had significantly higher expression of immune checkpoint (IC) genes including *CD274* (2.5-fold), *CD80* (2.7-fold, all $q < 0.05$). STING-high tumors also had a higher prevalence of *TP53* mutations (mts) and a lower prevalence of *STK11* and *KEAP1* mts (Table). Median overall survival (OS) was 21.1 months in the STING-high cohort ($n=200$) vs 11.9 months in the STING-low cohort ($n=199$) in IO treated pts (HR = 0.62, $p < 0.0001$). **Conclusions:** To our knowledge this is the largest real-world dataset indicating that enrichment of both the *STING* gene, and gene signatures associated with the STING pathway represent valuable transcriptomic biomarkers to stratify pts with PDL1-negative and TMB-Low NSCLC who benefit more from IO therapies. Conversely, novel IO combination strategies need to be employed in STING-low tumors to enhance outcomes. Research Sponsor: None.

Alterations	Overall STING- HIGH (n=3070)	Overall STING-LOW (n=2585)
<i>STK11</i> (% Prevalence)	15.4	21.3
<i>KEAP1</i> (% Prevalence)	10.6	15.8
<i>TP53</i> (% Prevalence)	56.5	50

Nivolumab and ipilimumab in advanced non small cell lung cancer previously treated with PD1 axis inhibition. *First Author: Scott N. Gettinger, Yale Cancer Center, New Haven, CT*

Background: Nivolumab combined with ipilimumab is currently one of many first line treatment options for patients with advanced non-small cell lung cancer (NSCLC). The benefit of this regimen in patients with NSCLC previously treated with a programmed death 1 (PD1) axis inhibitor is unclear. **Methods:** We conducted a phase II study (NCT03262779) of nivolumab and ipilimumab in patients with PD1L1 unselected advanced NSCLC with either primary resistance (cohort 1) or acquired resistance (cohort 2) to prior PD1 axis inhibitor therapy. Nivolumab 3 mg/kg was administered intravenously every 2 weeks, and ipilimumab 1 mg/kg every 6 weeks, and continued until disease progression or treatment limiting toxicity. If > 1 response or prolonged stability (> 24 weeks) using immune related response criteria were observed in the first 10 patients treated on cohort 1, an additional 30 patients would be accrued (simon 2-stage). A total of 10 patients would be accrued to cohort 2 (exploratory cohort). The primary endpoint was objective response rate (ORR) by RECIST v1.1 in cohort 1. Secondary endpoints included, ORR in cohort 2, progression free survival (PFS) and overall survival (OS) in both cohorts. **Results:** Among 10 patients with primary resistance to PD1 axis inhibitor therapy, no objective responses were observed (8 patients had progressive disease (PD) and 2 patients had unconfirmed stable disease (SD) as best response). Among 10 patients with acquired resistance to PD-1 axis inhibitor therapy, ORR was 10% (1 patient with confirmed complete response, 5 patients with confirmed SD including 4 patients with SD lasting more than 9 months, 3 patients with unconfirmed SD, and 1 patient with PD). Durable clinical benefit (DCB, response or SD for at least 6 months) rate was 50%. Median duration of benefit in the 5 patients with DCB was 11.9 months. Nine of the 10 patients in cohort 2 developed initial resistance to PD-1 axis inhibitor monotherapy (rather than combination chemo-immunotherapy), all received immunotherapy as part of their last line of therapy. The remaining patient developed resistance while on maintenance chemoimmunotherapy after initial response to chemoimmunotherapy; best response to trial therapy in this patient was unconfirmed SD. Median PFS/ OS in cohort 1 were 1.8 months/ 6.8 months, and in cohort 2, 6.7 months/ 31.8 months. Grade 3 treatment-related adverse events (TRAEs) occurred in 4 patients across both cohorts, including colitis (2 pts), diabetes (1 pt), pneumonia (1 pt) and elevated lipase (1 pt). There were no grade 4/5 TRAEs. Two patients discontinued trial therapy due to toxicity (colitis), both in cohort 2. **Conclusions:** Combination immunotherapy with nivolumab and ipilimumab does not overcome primary resistance to PD1 axis inhibitor therapy; however, can overcome acquired resistance to PD1 axis inhibitor therapy. Translational studies from tumor and serial peripheral blood collections are ongoing. Clinical trial information: NCT03262779. Research Sponsor: BMS; U.S. National Institutes of Health.

Amplification of wild-type *RET* and clinical response to selpercatinib for non-small-cell lung cancer (NSCLC). *First Author: Malini Marion Gandhi, Dana-Farber Cancer Institute, Lowe Center for Thoracic Oncology, Boston, MA*

Background: *RET* rearrangements and *RET* kinase domain mutations represent targetable genomic alterations in various cancer types. However, the frequency and characteristics of *RET* amplification in cancer and its potential role as a targetable oncogenic driver are not well-characterized. **Methods:** In a pan-cancer cohort of patients at the Dana-Farber Cancer Institute (DFCI) whose tumors underwent next-generation sequencing (NGS), we evaluated the frequency of wild-type (wt) *RET* amplification (defined as ≥ 6 copies) in the absence of *RET* rearrangements or activating mutations. We validated our findings using merged data from the TCGA, GENIE, and China Pan-Cancer datasets. **Results:** The frequency of wt *RET* amplification across all cancers was 0.08% (28/34,463) in the DFCI cohort and 0.16% (145/91,466) in the validation cohort. In NSCLC, the frequency of *RET* amplification was 0.10% (5/4773) in the DFCI cohort and 0.13% (15/11,622) in the validation cohort. Other cancer types with *RET* amplification included hepatobiliary cancer, prostate cancer, and breast cancer, among others. For 22 *RET*-amplified cases with available copy number data, the median *RET* gene copy number was 7 (range 6-36). Among 20 *RET*-amplified NSCLCs, 10 had no other known driver mutations, and 10 had concurrent driver mutations (including *MET* exon 14 skipping, *MET* amplification, *KRAS* G12C/S/D, *EGFR* L858R, *EGFR* exon 20 insertion, and *EGFR* exon 19 deletion). In cases with available smoking status, 5 out of 6 patients with *RET*-amplified NSCLC had a history of tobacco use. A 69-year-old man with unresectable stage III NSCLC had disease recurrence after chemoradiation and durvalumab. Both the initial and recurrent biopsy samples showed focal high-level *RET* amplification (22 and 28 copies, respectively); genomic and RNA sequencing showed no other driver mutations or *RET* rearrangements. He experienced partial response to the selective *RET* inhibitor selpercatinib with decrease of both intracranial and systemic tumor burden. **Conclusions:** Amplification of wt *RET* represents a novel, targetable, rare molecular subset of NSCLC and other cancers. A decision-making tool for first-line treatment in advanced non-small-cell lung cancer based on plasma proteomic biomarkers. *First Author: Itamar Sela, OncoHost LTD, Binyamina, Israel*

Background: Initial treatment selection for advanced NSCLC patients without driver mutations is mainly based on evaluating PD-L1 expression levels in the tumor tissue. However, PD-L1 assays are only moderately predictive. In addition, the guidelines for the PD-L1 $\geq 50\%$ subpopulation are not definitive, enabling the usage of immune checkpoint inhibitors (ICI) either as a monotherapy or combined with chemotherapy. Here we aim to provide a decision-making tool for the first-line treatment of advanced NSCLC patients based on plasma derived biomarkers obtained before treatment initiation. **Methods:** Pre-treatment plasma samples were collected from 545 NSCLC patients receiving ICI-based therapy. Clinical benefit was evaluated based on progression-free survival (PFS) at 12 months as a threshold. Deep plasma proteomic profiling was performed using aptamer technology. Based on the proteomic profiles, a computational model, termed PROphet, was developed and evaluated in a blinded manner on the validation subset ($n = 272$). The model output, clinical benefit probability, was used to stratify the patients into two groups, PROphet-positive or -negative. **Results:** The model displayed good performance with a high correlation between the predicted clinical benefit and the observed clinical benefit rate ($R^2 = 0.97$), outperforming a PD-L1-based prediction model ($R^2 = 0.35$). Patients classified as PROphet-positive achieved significantly longer overall survival (OS) than PROphet-negative patients, with a median OS of 25.9 versus 10.8 months (hazard ratio, HR = 0.51; 95% confidence interval, CI = 0.37-0.70; p -value < 0.001). Next, we examined the clinical utility of combining the PROphet output with PD-L1 levels by comparing different treatment modalities. Focusing on PD-L1 $\geq 50\%$, patients with PROphet-positive results displayed similar OS and PFS when receiving ICI monotherapy or ICI-chemotherapy (OS HR = 0.77; CI = 0.42-1.43; p -value = 0.4096), suggesting that these patients may consider monotherapy, thus avoiding chemotherapy-related toxicity. Conversely, PD-L1 $\geq 50\%$ patients with a PROphet-negative result displayed a significantly longer OS and PFS when receiving ICI-chemotherapy in comparison to ICI monotherapy, with a median OS that was not reached versus 11.10 months in the combination therapy and monotherapy groups, respectively (HR = 0.29; CI = 0.14-0.59; p -value < 0.001). These patients should consider combination therapy, avoiding a treatment that is suboptimal for them. Results for PD-L1 1-49% and < 1% provide additional clinical information for each subgroup. **Conclusions:** Plasma proteomic profiling can provide biomarkers that accurately predict the benefit of ICI-based treatment. The model output complements tissue PD-L1 expression levels as a tool to assist therapeutic decisions. Research Sponsor: OncoHost LTD.

Multi-center real-world data curation and assessment of tumor growth rate and overall survival in advanced NSCLC treated with PD-(L)1 immune checkpoint inhibitor therapy. *First Author: Chiharu Sako, Onc.AI, San Carlos, CA*

Background: While Immune Checkpoint Inhibitors (ICI) have become the standard-of-care for advanced non-small cell lung cancer (NSCLC) for certain patient populations, durable responses only occur in a small subset of patients. Therefore, there is an unmet need to identify patients that will respond before and during treatment to optimize treatment strategies. Multiple studies have shown promise that quantitative imaging biomarkers can predict response to ICI therapy. Studies have also shown that tumor growth parameters derived from time series data can provide early indications of long-term response. However, most studies to date have investigated single institution or clinical trial datasets, which are inadequate to capture the broad spectrum of real-world diversity of ICI treatments. In this study, we aimed to build a generalizable, well-validated imaging biomarker for treatment response. **Methods:** We have curated a retrospective dataset including serial imaging data of 1,215 advanced NSCLC patients who received ICIs from nine institutions across the US and Europe, capturing the diversity of the imaging data, such as CT scanner models, image acquisition parameters, reconstruction algorithms, as well as diversity in patient population, performance status, and treatment settings. Expert lesion annotations and manual volumetric segmentations were performed on all visible lesions (ranging from 1-18 lesions per subject, totaling 6,441 lesions) across the serial imaging data (ranging from 1-18 follow-up scans per subject), which enables lesion and organ-specific tumor burden assessment. We stratified overall survival based on volumetric response and tumor growth rate using a model defined by the sum of exponential growth (g) and decay (d), $vol(t) = vol(0) * (e^{gt} + e^{-dt} - 1)$. **Results:** Survival analysis showed that the 3-month volumetric response ($N = 875$) was significantly associated with overall survival (OS) for the lowest quartile (Q1; log-rank p -value, $P = 2.1 \times 10^{-4}$) and highest quartile (Q4; $P = 9.8 \times 10^{-5}$) compared to the middle quartiles (Q2+Q3). The median overall survival (OS) stratified by the volumetric response was 547.7, 450.9, and 332.0 days in the Q1, Q2+Q3, Q4 quadrants, respectively. Among patients having a minimum of 2 follow-up scans in the first 18 weeks ($N = 264$), we found that patients with the tumor growth parameter (g) in the highest quartile had significantly lower OS compared to the patients in the Q2+Q3 quadrants ($P = 7.2 \times 10^{-5}$). **Conclusions:** Our results demonstrate the potential of large multi-center real-world imaging datasets in investigating novel early response assessment methodologies, such as volumetric tumor burden quantification and tumor growth modeling. In our further work, we will investigate response patterns at individual lesion levels and correlations with overall patient-level response. Research Sponsor: Onc.AI.

Phase II randomized trial of first-line pembrolizumab and vorinostat in patients with metastatic NSCLC (mNSCLC): Final results. *First Author: Andreas Nicholas Saltos, Moffitt Cancer Center, Tampa, FL*

Background: Histone deacetylase inhibitors enhance tumor immunogenicity through various mechanisms including induced expression of MHC and T cell chemokines. A previous phase I trial demonstrated the combination of pembrolizumab (P) with vorinostat (V) in advanced/metastatic (m)NSCLC was well tolerated with signals of activity in ICI-pretreated pts. To further investigate the combination, we conducted a first-line, phase II trial. **Methods:** Pts with treatment-naïve mNSCLC and tumor PD-L1 expression $\geq 1\%$ were eligible. Pts were randomized, open-label, 1:1 to receive P 200 mg IV q3 wk as monotherapy [Arm A] vs P 200 mg IV q3 wk plus V 400 mg PO daily [Arm B]. The primary endpoint was overall response rate (ORR). Secondary endpoints included DOR, PFS and OS. Tumor biopsies were collected both pre- and on-treatment (day 15-21) for exploratory correlative analysis including gene expression and changes in the tumor microenvironment. **Results:** Between 7/2017–2/2022, 86 pts were enrolled, with 83 pts evaluable for response (40 in Arm A and 43 in Arm B). Median age was 69 (range 44–87), 47% female, and ECOG PS 0/1 in 9%/91%. PD-L1 TPS was $\geq 50\%$ in 20/40 (50%) of pts in Arm A, and in 23/46 (50%) of pts in Arm B. The most common TRAEs in Arm A included diarrhea (15%) and fatigue (10%). 3 pts in Arm A experienced grade ≥ 3 irAEs (including 1 each of grade 3 hepatitis, pneumonitis, and rash). The most common TRAEs in Arm B included fatigue (41%), nausea (44%), diarrhea (35%) and increased creatinine (33%). 3 pts in Arm B experienced grade ≥ 3 irAE (2 grade 3 pneumonitis and 1 grade 4 myopericarditis). In Arm B, 22/45 (49%) of pts had a dose-reduction in vorinostat, most commonly due to grade 2-3 fatigue or nausea. Efficacy results by intention-to-treat are summarized in the Table below. For evaluable patients only, ORR was 44% in Arm B (19/43) and 28% in Arm A (11/40) ($p=0.18$). RNA-sequencing of a subset of patients showed a significant increase in interferon- γ pathway activity in both Arms. However, between the two Arms, interferon- γ pathway activity was enhanced to greater extent in Arm B, which may have contributed the higher overall response rate. **Conclusions:** To our knowledge, this is the first randomized trial investigating the combination of HDAC inhibition and anti-PD1 therapy in NSCLC. Although the combination arm had a numerically higher ORR compared to P monotherapy, the result did not meet the primary endpoint for significance. While there were no new safety signals with the combination therapy, reduction or interruption in V dose occurred frequently, which may have contributed to lack of survival differences between arms. Clinical trial information: NCT02638090. Research Sponsor: Merck Sharp & Dohme LLC; Department of Defense.

Best response:	Arm A N= 40	Arm B N = 46	P value

Changes in PD-L1 and tumor mutational burden between paired samples and relationship to immune checkpoint inhibitor outcomes in non-small cell lung cancer. *First Author: Alessandro Di Federico, Dana-Farber Cancer Institute, Lowe Center for Thoracic Oncology, Boston, MA*

Background: Programmed cell death receptor ligand 1 (PD-L1) tumor proportion score (TPS) and tumor mutational burden (TMB) are key biomarkers of response to immune checkpoint inhibitors (ICI) in non-small cell lung cancer (NSCLC). How often PD-L1 and TMB values change across samples within individual patients (pts) and the impact of this variation on ICI outcomes are limited. **Methods:** Pts with NSCLC and multiple PD-L1 or TMB assessments at the Dana-Farber Cancer Institute were included. Clinicopathologic and genomic data were analyzed in association with PD-L1 and TMB changes. In patients with > 2 samples, each sample was paired with the subsequent and each pair was analyzed independently. Minor and major changes in PD-L1 were defined as absolute changes of 10-49% and 50-100%, respectively. **Results:** The PD-L1 cohort included 402 sample pairs (median Δ PD-L1: 0; range: -90,+95%) and the TMB cohort included 413 sample pairs (median Δ TMB: 0 mut/Mb; range: -20.6,+24.5). Concordance between pairs was high for both PD-L1 ($R=0.53$, $P < 0.01$) and TMB ($R=0.80$, $P < 0.01$). Samples taken within < 1 year had higher concordance for PD-L1 than samples taken ≥ 1 year apart ($P < 0.01$), but length of time between biopsies did not impact TMB concordance. Minor or no changes in PD-L1 were observed in 82.3% of pairs; the frequency of major increases was 9.7% and major decreases was 8%. After dividing TMB into tertiles, 72.6% sample pairs showed no tertile change, 16% increased to a higher tertile, and 11.4% decreased to a lower tertile. PD-L1, but not TMB, decreased with intervening ICI ($P = 0.02$), but PD-L1 and TMB did not change significantly with other intervening systemic therapies. Acquired copy number losses of the *CD274* gene (encoding for PD-L1) were enriched in pairs with a major PD-L1 decrease ($Q < 0.05$). Similarly, acquired loss of chromosome 9p (which contains the *CD274* locus) correlated with a reduction in PD-L1, while 9p gains correlated with an increase in PD-L1 ($P = 0.02$). A total of 142 pts had multiple PD-L1 scores assessed before ICI initiation. Among pts with at least one PD-L1-positive sample (TPS $\geq 1\%$), the presence of another sample that was PD-L1 negative ($< 1\%$) correlated with worse outcomes to ICI compared to pts with no PD-L1-negative samples: response rate was 11% vs 39% ($P < 0.01$), median progression-free survival (mPFS) 2.7 vs 8.0 months ($P < 0.01$), and median overall survival 13.6 vs 21.2 months ($P = 0.05$), respectively. Among pts with at least one PD-L1 TPS $\geq 1\%$ and one $< 1\%$, cases where the last PD-L1 TPS before ICI was $\geq 1\%$ achieved longer mPFS than if the pre-ICI sample was PD-L1 negative (3.6 vs 1.8 months, $P = 0.03$). **Conclusions:** Although PD-L1 and TMB generally had high intrapatient concordance across samples, significant changes in values occurred in some patients. Variations in PD-L1 influenced ICI outcomes, warranting an assessment proximal to ICI initiation whenever feasible. Research Sponsor: None.

Subcutaneous amivantamab (ami) in patients (pts) with advanced solid malignancies: The PALOMA study—Updated safety and identification of the recommended phase 2 dose. *First Author: Anna Rachel Minchom, Drug Development Unit at Royal Marsden Hospital/Institute of Cancer Research, Sutton, United Kingdom*

Background: Ami, an EGFR-MET bispecific antibody, is approved for pts with advanced *EGFR* exon 20 insertion non-small cell lung cancer after progression on platinum-based chemotherapy. Intravenous (IV) delivery is associated with infusion-related reactions (IRRs) in 67% of pts, requiring splitting the first dose over 2 days (Park *Ann Oncol* 2021; 32[suppl_5]:S981). PALOMA (NCT04606381) is an ongoing phase 1b dose escalation study of subcutaneous (SC) ami $\pm$ rHuPH20 (a hyaluronidase that aids SC agent absorption) in pts with advanced solid tumors who may benefit from *EGFR*- or *MET*-directed therapy. Preliminary results showed SC ami was well tolerated, improved time and ease of administration, and meaningfully reduced IRRs (Krebs *Cancer Res* 2022;82: 12_Supplement, CT198). We present updated safety results and identification of the recommended phase 2 dose (RP2D) for ami SC Q2W administration. **Methods:** PALOMA enrolled pts with various advanced solid tumors. Objectives were to evaluate administration feasibility, safety, and PK of low and high concentration formulations of ami SC (50 mg/mL ami $\pm$ rHuPH20 [Part 1; Cohorts 1a/b] and 160 mg/mL ami $\pm$ rHuPH20 [Part 2; Cohorts 2a/b, Cohort 3a, Cohort 5a]). Cohorts 1a/b and 2a/b received 1050 mg (1400 mg, ≥ 80 kg), Cohort 3a received 1600 mg (2240 mg, ≥ 80 kg), and Cohort 5a received 2560 mg (3360 mg, ≥ 80 kg). Cohorts 1-3 were dosed weekly for the first 4 weeks and Q2W thereafter. Cohort 5a was dosed weekly for the first 3 weeks and Q3W thereafter. **Results:** As of Jan 3, 2023, 81 pts were enrolled (16 pts in Part 1, 65 pts in Part 2) and majority had NSCLC (71; 88%). Median age was 64 years, 44 (54%) pts were female, and most pts were White (44; 54%) or Asian (34; 42%). Across all doses, IRRs were reported by 13 (16%) pts; all of grade 1-2. The most frequent manifestations of IRRs were chills (7%), pyrexia (7%), and asymptomatic tachycardia (4%). Treatment-emergent AEs (TEAEs) of rash were reported by 59 (73%) pts, with no grade ≥ 3 . In total, 3 (4%) pts discontinued ami SC due to toxicity (2 pneumonitis, 1 asthenia). Grade ≥ 3 related TEAEs were reported by 3 (4%) pts (hyponatremia, lymphopenia, hypertension). Full ami SC dosing on day 1 was feasible (≤ 7 min), obviating the need for split dosing. PK analysis confirmed that ami SC 1600 mg (2240 mg, ≥ 80 kg) Q2W resulted in similar exposure to the approved IV dose (1050 mg [1400 mg, ≥ 80 kg] Q2W). Compared to IV, ami SC resulted in lower C_{max} and equal or higher C_{trough} and AUC_{0-336h} at Cycles 2 and 4. Based on these data, ami SC 1600 mg (2240 mg, ≥ 80 kg) was selected as the RP2D for ami SC Q2W administration. **Conclusions:** Ami SC was well tolerated with meaningful reductions in administration time and TEAEs. Ami SC provided a quantitative and qualitative improvement in the symptoms of IRRs vs historical IV rates. The identified RP2D for ami SC on the Q2W schedule achieved similar exposure as the approved IV dose. Clinical trial information: NCT04606381. Research Sponsor: Janssen R&D, LLC.

Results from a first-in-human phase 1B study of a complement factor H inhibitor (GT103) in patients with non-small cell lung cancer (NSCLC). *First Author: Jeffrey Melson Clarke, Duke Cancer Institute, Durham, NC*

Background: GT103 is a first-in-class IgG3 monoclonal antibody that was derived from a single human B cell and inhibits complement factor H (CFH). CFH is implicated in cancer immune evasion and overexpression portends a poor prognosis in multiple malignancies. CFH regulates C3 convertase in the alternative pathway of the complement cascade, limiting downstream opsonization and membrane attack complex formation. Monoclonal antibody inhibition of CFH facilitates complement-dependent tumor cell lysis, modulates the adaptive immune response, and inhibits tumor growth. **Methods:** GT103 is being evaluated in a multi-institutional, first-in-human, phase 1b study in patients with advanced stage, refractory NSCLC. A standard '3+3' dose escalation schema was used across four dose levels, with treatment given until disease progression or unacceptable toxicity. Dose limiting toxicity (DLT) observation period included cycle 1 and radiographic disease assessment was performed every 6 weeks. We have previously reported that no DLT was seen at the highest two dose levels of 3 mg/kg or 10 mg/kg administered IV every 3 weeks. Two expansion cohorts have now been opened at 10 mg/kg IV every 2 week and 15 mg/kg every 3 weeks dose levels allowing up to 6 patients at each dose level. We herein present updated clinical outcomes and analysis of correlative biomarkers. **Results:** As of February 3, 2023, twenty-five patients have been treated, with a median follow up of 230 days. Five of the 21 patients in the dose escalation cohort demonstrated stable disease by RECIST criteria. In the 10 mg/kg dose level, one patient has experienced prolonged disease stabilization and has received 12 cycles to date with tumor reduction on CT. The DLT period is ongoing for two patients enrolled in the 10 mg/kg IV every 2 weeks and two patients in the 15 mg/kg every 3 weeks expansion cohorts. Soluble C5b-9 (sC5b-9) is a candidate pharmacodynamic biomarker for GT103 and was measured at baseline and at day 15 from patients in all four dose escalation levels (0.3, 1, 3, 10 mg/kg). An increase in sC5b-9 was found in 13 of 21 patients at day 15. A marked doubling of the baseline sC5b-9 level was demonstrated in a subset of patients by day 15 indicative of biologic activity. **Conclusions:** GT103 is well tolerated in heavily pretreated advanced NSCLC population. Early clinical activity has been demonstrated to date with stable disease seen in 24% of patients. Updated clinical results and correlative data will be presented. A separate phase 2 study of combination GT103 with pembrolizumab is planned for patients with refractory NSCLC. Trial Registration: The study was approved by Duke University IRB with approval number Pro00104564. Clinical trial information: NCT04314089. Research Sponsor: Grid Therapeutics.

Clinical and genomic landscape of EGFR-mutant lung cancers (LCs) with squamous and adenosquamous differentiation. *First Author: Arielle Elkrif, Department of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Outcomes to first-line therapy with osimertinib in patients (pts) with EGFR-mutant (EGFR+) squamous (sq) or adenosquamous (adenosq) LC have not been well described. Pts also undergo adenocarcinoma to squamous transformation (transformed) after treatment with EGFR tyrosine kinase inhibitor (TKI). The clinical and genomic characteristics of pts with EGFR+ sq and adenosq LC are largely unknown. **Methods:** We clinically and genomically characterized all pts with EGFR+ LC with baseline sq or adenosq histology and transformed histology at Memorial Sloan Kettering Cancer Center. Next-generation sequencing was performed with the MSK-IMPACT. We compared clinical outcomes (time to discontinuation (TTD), overall survival (OS), and post-progression survival after osimertinib discontinuation (PPS)) among the different cohorts. **Results:** A total of 51 pts were identified: 14 with baseline sq/adenosq treated with first-line (1L) osimertinib; 8 transformed cases post 1L osimertinib; 13 with baseline sq/adenosq treated with early generation TKI; 3 transformed cases post early generation TKI; the remainder of pts had early-stage EGFR+LC with baseline sq/adenosq. Median age was 63, and 57% were female. Eighteen (35%) were former or current smokers. Among pts with baseline sq/adenosq histology who were treated with 1L osimertinib, median TTD was 11.1 months (95%CI 7.7, not reached (NR)), and median OS was 24.3 months (95%CI 11.1 months, NR). Compared to a non-overlapping time-matched cohort with baseline adenocarcinoma treated with 1L osimertinib (N = 55), TTD was numerically shorter in the sq/adenosq cohort (11 vs. 17 months, HR 1.8, p = 0.076), and median OS was significantly shorter (24 vs. 33 months, HR 2.64, p = 0.03). PPS was shortest in baseline sq/adenosq (5 months, HR 2.94, p = 0.023), but similar in transformed (11 months, HR 0.89, p = 0.8) compared to adeno (11 months). The sq/adenosq cohort had significantly higher proportion of L858R EGFR (48% vs 31% p < 0.001) and atypical EGFR mutations at baseline (17% vs 7.3%, p < 0.001) compared to the adenocarcinoma cohort. PIK3CA mutations were enriched at baseline in the sq/adenosq cohort. In the transformed cases, RB1 alterations were present in 13% at baseline. There was a similar distribution of type of EGFR mutations in the non-overlapping pts in the AACR GENIE EGFR+ LC cohort with sq/adenosq histology (N = 4, 50% L858R, 25% atypical). **Conclusions:** Pts with EGFR+ sq/adenosq LCs exhibit inferior TTD and OS with 1L osimertinib compared to adenocarcinoma controls. Sq/adenosq LCs appear to be molecularly distinct with enrichment in EGFR L858R and atypical EGFR mutations. Transcriptomic profiling of a subset of samples will be presented. Our findings highlight the need for novel therapeutic strategies among pts in this high-risk subgroup. Research Sponsor: U.S. National Institutes of Health.

Poster Session

A phase 2a study evaluating the efficacy and safety of sunitinib in patients with advanced non-small-cell lung cancer (NSCLC) harboring uncommon EGFR mutations. *First Author: Fengying Wu, Shanghai Pulmonary Hospital, Shanghai, China*

Background: Although non-small cell lung cancer (NSCLC) patients with tumor harboring classical Epidermal Growth Factor Receptor (EGFR) mutations have numerous therapeutic choices, uncommon EGFR mutation NSCLC patients have limited treatment options. Sunitinib is a selective tyrosine kinase inhibitor (TKI) targeting uncommon EGFR mutations. **Methods:** In this multicenter, open-label phase 2a study, treatment-naïve adults with NSCLC harboring uncommon EGFR mutations (G719X, S768I, L861Q) received oral sunitinib monotherapy at 80 or 64 mg/day (Chinese trial register CTR20190681). The primary endpoint was objective response rate (ORR) per RECIST v1.1. Secondary endpoints included duration of response (DoR), overall survival (OS), safety and tolerability. Adverse events (AEs) were graded according to the CTCAE v5.0. **Results:** Sunitinib was administered to 30 NSCLC patients at 80 (n = 15) or 64 (n = 15) mg/day. Median age was 60 years old (range 47-74 years). Twenty patients (66.7%) were females, 10 patients (33.3%) had a history of smoking. Patients had an ECOG PS of 0 (10.0%) or 1 (90.0%). Tumors had a G719X (36.7%), L861Q (30.0%), or S768I (20.0%) EGFR mutation, or a combination of these uncommon EGFR mutations (13.3%). None had EGFR T790M, L858R, exon 19 deletions, or exon 20 insertions. The ORR was 71.4% (20/28), including 92.9% (13/14) and 50.0% (7/14) in the 80 and 64 mg/day cohorts, respectively. The disease control rate (DCR) was 96.4%, including 100.0% (14/14) and 92.8% (13/14) in the 80 and 64 mg/day cohorts, respectively. All responses were partial responses. The median DoR was 12.5 months (20.3 and 9.2 months in the 80 and 64 mg/day cohorts, respectively). One-year OS was 84.7% (92.9% and 75.0% in the 80 and 64 mg/day cohorts, respectively). As of 15 January 2022 (database lock), 11 (36.7%) patients were still receiving sunitinib treatment. Grade ≥3 treatment emerged AEs were similar in the 80 mg/day (80.0%, 12/15) and 64 mg/day (73.3%, 11/15) cohorts. The most frequently reported grade ≥3 treatment-related AEs (TRAEs) were diarrhea (36.7%), abnormal liver function (13.3%), and rash (10.0%). One grade 4 TRAE was observed: hypokalemia in the 64 mg/day cohort. **Conclusions:** Sunitinib demonstrated a high response rate with durable antitumor activity in patients with NSCLC harboring uncommon EGFR mutations. The toxicities are expected and comparable to other EGFR TKIs. A multi-center phase 2b study is ongoing in the United States and China to further evaluate Sunitinib in uncommon EGFR mutation NSCLC. Clinical trial information: CTR20190681. Research Sponsor: Suzhong Pharmaceutical Group Co., LTD.

Evaluating generalizability of practice-changing randomized clinical trials in non-small cell lung cancer using machine learning-based in-silico trials. *First Author: Xavier Orcutt, Chinle Comprehensive Health Care Facility, Chinle, AZ*

Background: Results of randomized clinical trials (RCTs) of anticancer agents are not generalizable to many real-world patients. Advances in machine learning (ML) and increasing availability of curated real-world data offer opportunities to assess generalizability by simulating trials "in-silico". Our objective was to assess the generalizability of survival outcomes reported in 2 practice-changing phase III trials in first-line (1L) advanced non-small cell lung cancer (aNSCLC). **Methods:** Our cohort included patients from the nationwide Flatiron Health EHR-derived de-identified database diagnosed with stage IIIB-IV or recurrent aNSCLC between 2011 and 2020. First, we trained and validated supervised ML models (gradient boosted, random forest, support vector machine and penalized Cox) to predict 1-year survival for patients with aNSCLC; the Lung Cancer Prognostic Index (LCPI), a published disease-specific prognostic index, was used as a comparator model. We used 130 demographic, vital sign, laboratory, and biomarker features at aNSCLC diagnosis to build models. Second, we used the best-performing ML model to create 4 prognostic risk groups. Third, we simulated 2 seminal trials for 1L treatment of aNSCLC, using inverse probability of treatment-weighted survival analyses, coarsely reproducing inclusion/exclusion criteria across ML-derived risk groups. We compared median overall survival (mOS) using Kaplan-Meier curves from the start of 1L treatment to death in in-silico trials (ISTs) vs. RCTs. **Results:** Our cohort included 61,339 patients with aNSCLC. The best-performing gradient boosted model outperformed the LCPI (AUC 0.784 vs 0.688). In ISTs, survival benefits of novel treatments varied across risk groups and were generally lower in ISTs compared to RCTs (Table). IST results in high- and very high-risk patients were inconsistent with RCT survival results. For example, for KEYNOTE-024, mOS in the pembrolizumab arm was 30.0 months, whereas in the IST, mOS among patients receiving pembrolizumab varied from 1.3 months in very high-risk patients to 41.5 months in low-risk patients. RCT results overestimated treatment effects for high-risk aNSCLC patients. **Conclusions:** ML-based ISTs can reveal heterogeneity in real-world survival outcomes associated with novel oncology treatments and elucidate populations for whom RCT results generalize poorly. Research Sponsor: None.

Artificial intelligence algorithm developed to predict immune checkpoint inhibitors efficacy in non-small-cell lung cancer. *First Author: Mehrdad Rakae, University Hospital of North Norway, Tromsø, Norway*

Background: Many non-small cell lung cancer (NSCLC) patients with high PD-L1 IHC expression and/or high TMB level do not respond to immune-check point inhibitors (ICIs). Discovery of novel predictive biomarkers for ICI response in NSCLC continues to be a critical unmet medical need, given the expense, potential toxicity, and therapeutic delay due to ICI treatment without benefit. **Methods:** We developed a supervised deep learning algorithm (Deep-IO) to predict therapeutic response to ICIs in NSCLC patients from standard histology whole slide hematoxylin and eosin (H&E) images, which was trained based on ICI objective response rate. We utilized a convolutional neural network (CNN) implemented in Pytorch. The efficiency of the Deep-IO was evaluated through classification performance metrics and the area under the receiver operating characteristic curve (AUROC). The algorithm was trained and tested on 85218 tiles (size: 512x512 pixels) in 446 advanced stage NSCLC patients from the Dana Farber Cancer Institute (DFCI), all treated with ICI monotherapy. **Results:** The objective response rate, comprising complete and partial response, was 26% (n = 114) in the overall cohort. The DFCI patient cohort was randomly split into a training set (N=379, 85%) and a test set (N=67, 15%). The classifier's predicted class (responder vs non-responder) probabilities at the tiles level were averaged for each patient. Quantitative evaluation of whole section test dataset shows that the developed model achieves the accuracy of 0.72, weighted average (WAVG) precision of 0.77, WAVG recall of 0.72 and WAVG F-score of 0.74 on classifying ICI non-responders from responders. Comparing with PD-L1 expression (TPS%) and TMB (mu/Mb), Deep-IO had superior predictive power for ICI response (AUROC=0.75) in the test set. The combined Deep-IO+PD-L1 scores resulted in a significantly greater AUROC value of 0.82 compared to single tests and a 32% improvement in specificity (0.88 vs. 0.56) compared to PD-L1 evaluation alone (Table). **Conclusions:** This proof-of-concept study shows that an artificial intelligence-powered H&E image classifier can predict ICI effectiveness in NSCLC. Deep-IO outperformed both established predictive biomarkers. We will assess Deep-IO in additional external NSCLC data sets for validation and confirmation. Research Sponsor: None.

Biomarker	AUROC	Specificity	Sensitivity	PPV	NPV
Deep-IO+PD-L1	0.82	0.88	0.70	0.58	0.92
Deep-IO	0.75	0.55	0.93	0.34	0.97
PD-L1	0.67	0.56	0.80	0.31	0.92
TMB	0.61	0.25	0.97	0.25	0.99

Investigating racial inequities of circulating tumor DNA (ctDNA) use in patients with non-small cell lung cancer: A real world analysis. *First Author: Angelica D'Aiello, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY*

Background: The use of ctDNA has emerged as an invaluable adjunct to tissue-based molecular testing, though it remains unclear if racial inequities associated with ctDNA implementation exist. We sought to assess disparities in frequency of actionable alterations detected and utilization of those results for treatment decisions in a diverse urban population of NSCLC patients. **Methods:** We performed a retrospective study of NSCLC patients who received Guardant ctDNA testing from 11/2015-10/2022. Kaplan Meier curves with log-rank tests were used to assess time-to-treatment initiation or treatment change from date of ctDNA collection among race/ethnicity subgroups (Hispanic, Black, White). Univariate associations between race/ethnicity subgroups, NCCN actionable mutation detection, and variant allele frequency, were assessed using Chi-Square and Kruskal-Wallis tests for categorical and continuous variables, respectively. **Results:** We identified 258 subjects. The race/ethnicity distribution in order of prevalence was Hispanic (33.0%, n = 85), Black (32.6%, n = 84), White (24.8%, n = 64), and Asian/other/unknown (9.7%, n = 25). Median turnaround time for ctDNA result was 8 days (range 2-24 days) from collection date. Median time-to-treatment initiation or change was 25 days for the combined cohort, and 24 days for patients with treatment naïve metastatic disease. Time-to-treatment initiation or change was similar among race/ethnicity subgroups in the combined cohort, as well as those specifically with metastatic disease not yet initiated on treatment at time of ctDNA testing (p = 0.52 and p = 0.43, respectively). Similar proportions of all race/ethnicity subgroups had an NCCN actionable mutation detected (p = 0.92) and similar variant allele frequencies (p = 0.68). An NCCN actionable mutation was detected in 35.3% (n = 91) of patients, the most common being EGFR (n = 53) and KRAS G12C (n = 17). CtDNA results helped avoid the need for repeat tissue biopsy in 25.6% (n = 66) of patients. Of the 68% (n = 175) of patients with paired tissue and liquid biopsies, 24.0% (n = 42) of patients had discordant results, and 8.6% (n = 15) had additional alterations detected on liquid biopsy. **Conclusions:** In our diverse cohort, we observed a similarly high detection rate of actionable mutations and early time-to-treatment based on ctDNA results across all race/ethnicity subgroups. In addition, ctDNA helped avoid need for repeat tissue biopsy in 25% of patients and yielded additional alterations not detected on tissue in nearly 10% of patients with discordant results. Our findings suggest that broad based molecular testing utilizing ctDNA is not only feasible, but also that it enables faster time-to-treatment in a racially diverse urban population. Continued efforts are necessary to ensure timely molecular testing among all patients, and to identify any racial inequities that may exist. Research Sponsor: None.

Final results from a phase II trial of CIMAvax-EGF and nivolumab as second-line (2L) therapy after platinum-based chemotherapy in advanced non-small cell lung cancer (NSCLC). *First Author: Rachel Frascati, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: CIMAvax-EGF (C-E) is a recombinant anti-human epidermal growth factor (EGF) depleting immunotherapy which has previously shown increased survival as maintenance after platinum-based chemotherapy in patients (pts) with advanced NSCLC. The primary objective of this single-arm phase II trial was to evaluate the 12-month overall survival (OS) in pts receiving C-E in combination with Nivolumab(N) as 2L therapy for advanced NSCLC. **Methods:** Pts with previously treated, immunotherapy-naïve advanced NSCLC received 2.4 mg C-E IM every 2 weeks(w) for 4 doses (loading phase) in combination with N 240mg IV every 2 w, then continued monthly maintenance C-E combined with N 240mg IV every 2 w. Enrollment to this arm was terminated before estimated sample size was met due to poor accrual as immunotherapy became incorporated into 1st line therapy. We present OS and progression-free survival (PFS) data [determined using a Kaplan-Meier test with 90% confidence intervals (CI)] of pts who were able to complete the loading phase per protocol (PP). **Results:** 21 out of 23 enrolled pts were included in the PP analysis. Among the 21 pts, 17 (81.0%) had non-squamous(nsq) histology, 12 (57.1%) were KRAS wildtype (9.5% unknown status), 13 (61.9%) had PD-L1 tumor proportion score 0%. 43% pts (n=3) with known KRAS mutation (n=7) had co-mutated STK11. Disease control rate was 47.6% (n=10) defined as pts who had stable disease or partial response as best response per RECIST v1.1. The 21 PP pts had a 29% 3-year(yr) OS rate (90% CI 14, 45; intention-to-treat [ITT] population in 23 pts with 26% 3-yr OS rate, 90% CI 13, 42). Median(m) OS for PP pts was 11.9 months, 90% CI 8.0 – 23.9 months (ITT mOS 10.4 months, 90% CI 6.8-13.6). Pts with squamous histology had a better 3-yr OS rate compared to those with nsq histology [50% (90% CI 10, 81) vs 24% (90% CI 9, 41), respectively]. Pts with PD-L1 expression $\geq 1\%$ had higher 3-yr OS [38% (90% CI 12, 63)] and 3-year PFS [38% (90% CI 12, 63)] compared to pts with no PD-L1 expression (3-yr OS 23% [90% CI 8, 44] and 3-yr PFS 8% [90% CI 1, 25]). mOS, 1-yr and 3-yr OS for EGFR/ALK/KRAS wildtype pts was higher [31.7 months (90% CI 5.9, NR), 67% (90% CI 4, 84), 50% (90% CI 24, 71), respectively] compared to KRAS mutated NSCLC [10.1 months (90% CI 6.5, 12.1), 29% (90% CI 6, 56), 0% (90% CI 1, 41), respectively]. **Conclusions:** NSCLC pts who were able to complete the PP combination of C-E plus N at the minimum had numerically better OS compared to historical study cohorts with N as 2L monotherapy. Among pts who completed PP treatment, pts with KRAS wildtype NSCLC had the longest mOS observed. C-E is currently being investigated in combination with pembrolizumab as maintenance therapy after completing 1L chemoimmunotherapy for NSCLC with PD-L1 $< 50\%$ and as 1L therapy in combination with pembrolizumab for EGFR/ALK wildtype NSCLC and PD-L1 $\geq 50\%$. Clinical trial information: NCT02955290. Research Sponsor: Roswell Park Alliance Foundation.

Amivantamab and lazertinib in treatment-naïve EGFR-mutated advanced non-small-cell lung cancer (NSCLC): Long-term follow-up and ctDNA results from CHRYSALIS. *First Author: Se-Hoon Lee, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: CHRYSALIS (NCT02609776) evaluated the combination of amivantamab (ami) and lazertinib (laz) in treatment-naïve patients (pts) with epidermal growth factor receptor (EGFR)-mutated NSCLC. As previously reported, all 20 pts achieved a partial response (overall response rate of 100%) but interpretation of long-term outcomes was limited by the length of follow up (Cho *Ann Oncol* 2020;31: suppl.4, 12580; Cho *J Thorac Oncol* 2022;17:S126, P1.16-01). Herein, we present long-term results from this treatment-naïve cohort. **Methods:** The treatment-naïve cohort enrolled pts with EGFR exon 19 deletion (ex19del) or L858R mutated advanced NSCLC. All pts received 1050 mg IV ami (1400 mg if ≥ 80 kg) and 240 mg oral laz. Response was assessed by the investigator per RECIST v1.1. Circulating tumor DNA (ctDNA) was analyzed from plasma samples prior to initiation of treatment, at Cycle 3 Day 1, and at end of treatment (EOT). **Results:** Of the 20 pts enrolled in the treatment-naïve cohort (median 62.5 years, 55% women, all Asian), 11 had EGFR ex19del and 9 had L858R NSCLC. As of Nov 15, 2022, the median follow-up and duration of treatment were 33.6 and 33.5 months, respectively. Ten (50%) pts were progression-free and remained on treatment, including 7 of 11 (64%) with ex19del and 3 of 9 (33%) with L858R. The median duration of response (DOR), median progression-free survival (PFS), and median overall survival (OS) were not estimable. The estimated landmark PFS rate was 85% at 12 months, 65% at 24 months, and 51% at 36 months. Of note, 2 (10%) pts were treated beyond progression. The longest ongoing pt has a duration of treatment of 37.2 months and DOR of 35.7 months. Treatment-related dose interruptions, reductions, and discontinuations of either ami and laz occurred in 7 (35%) pts, 8 (40%) pts, and 1 (5%) pt, respectively. The safety profile was consistent with prior reports, with predominantly on-target EGFR- or MET-related adverse events. Among the 10 pts who discontinued treatment, 4 submitted samples for ctDNA analysis at both baseline and EOT. There was 1 pt with new PIK3CA mutations, 1 with low-level HER2 amplification, 1 pt with a new CCNE1 and EGFR amplification, and 1 pt with no new mutations detected. Updated data on ctDNA at EOT may be available at the time of congress presentation. **Conclusions:** At a median duration of treatment of 33.5 months, median DOR, PFS, and OS have not been reached in treatment-naïve pts receiving ami+laz, with 50% remaining progression-free and on treatment. No new safety signals were identified. The ongoing phase 3 MARIPOSA study (NCT04487080) is further investigating ami+laz vs osimertinib vs laz in previously untreated, EGFR-mutated, advanced NSCLC. Clinical trial information: NCT02609776. Research Sponsor: Janssen R&D, LLC.

Real-world outcomes of first-line immune checkpoint inhibitors with or without chemotherapy in KRAS G12C altered NSCLC according to PD-L1 status. *First Author: Charu Aggarwal, University of Pennsylvania, Philadelphia, PA*

Background: There is a considerable debate whether treatment approaches should be tailored in advanced KRAS G12C-mutated NSCLC. Increasing evidence suggests that KRAS G12C-mutated NSCLC is associated with genomic heterogeneity that may impact clinical outcomes. Herein, we report a multimodal, real world outcomes analysis of 1L patients with advanced KRAS G12C-mutated NSCLC stratified by treatment type and PD-L1 status. **Methods:** Deidentified multimodal real-world data (RWD) of 1576 advanced, 1L NSCLC patients across the US were retrospectively analyzed from the Tempus database. Selection criteria included: Tempus xT targeted NGS, known PD-L1 status, absence of EGFR, ALK and ROS1 mutations, and treatment with chemotherapy (CT) + pembrolizumab (P), or P only. Patients were stratified by the presence or absence (wt) of KRAS G12C alterations. Median OS (mOS) was estimated using Kaplan-Meier methods. Subgroup analyses were performed using Cox model stratified by KRAS G12C status, PD-L1 status, and pathogenic alterations of STK11 and KEAP1. **Results:** In this study, two cohorts were assessed, KRAS G12C (n = 201) and KRAS G12C wt (n = 1375). Characteristics and demographics were balanced between both cohorts. Among TPS < 50 patients treated with CT + P, KRAS G12C (n = 109, 54%) had a mOS of 11.64 months (m) versus 16.81m (HR = 1.32, p = 0.06) for KRAS G12C wt (n = 864, 62.8%). Among TPS < 1 patients treated with CT + P, KRAS G12C (n = 46, 22%) had a mOS of 11.18 m versus 16.44 m (HR = 1.67, p = 0.01) for KRAS G12C wt (n = 489, 35%). Among TPS ≥ 50 patients treated with P only, KRAS G12C (n = 45, 22.3%) had a mOS of 30.03m compared to 25.03m (HR = 0.94, p = 0.83) in KRAS G12Cwt (n = 236, 17.1%). TPS < 50 subgroup was enriched for select co-mutations with KRAS G12C (STK11, 24.5%; KEAP1, 10.7%) vs. TPS ≥ 50 (STK11, 3.8%; KEAP1, 5.1%). When evaluating the impact of co-mutations in the KRAS G12C with TPS < 50 , STK11 (n = 30) mOS was 10.59m (HR = 1.01, p = 0.81) and KEAP1 (n = 13) mOS was 7.63m (HR = 2.14, p = 0.03). **Conclusions:** This largest RWD analysis to date demonstrates that 1L KRAS G12C NSCLC patients with TPS $< 1\%$ and $< 50\%$ receiving standard CT + P have the shortest survival among all evaluated sub-groups. Novel KRAS G12C targeted combination therapies in development for this patient population may offer the promise of better outcomes. Research Sponsor: Tempus Labs and Mirati Therapeutics.

Risk factors for venous thromboembolism (VTE) among patients with EGFR-mutated advanced non-small cell lung cancer (NSCLC) receiving amivantamab plus lazertinib versus either agent alone. *First Author: Nicolas Girard, Institut Curie, Institut du Thorax Curie-Montsouris, Paris, France*

Background: Amivantamab (ami), an EGFR and cMET bispecific antibody with immune cell-directing activity, and lazertinib (laz), a CNS-penetrant 3rd-generation EGFR tyrosine kinase inhibitor have shown clinical activity in biomarker-selected patients (pts) with advanced NSCLC. Antitumor activity has been suggested to be improved when the agents are given in combination (Leighl *Ann Oncol* 2021;32:suppl_5, 1192MO). We examined the incidence of VTE, a common adverse event (AE) among pts with lung cancer, for those receiving ami monotherapy, laz monotherapy, and ami+laz to investigate if there is elevated risk and understand potential predisposing risk factors. **Methods:** CHRYSLIS (NCT02609776; ami monotherapy and ami+laz), CHRYSLIS-2 (NCT04077463; ami+laz), and LASER201 (NCT04075396; laz monotherapy) are ongoing open-label studies of locally advanced/metastatic NSCLC. Two descriptive, univariate risk analyses were performed, with the primary analysis including all treatment-emergent VTE events (grouped term) and a secondary analysis that excluded VTE events occurring after progression of disease (PD) or within 30 days prior to PD. **Results:** This analysis included 560 pts who received ami monotherapy, 536 ami+laz, and 252 laz monotherapy, predominantly in the TKI-relapsed setting. The incidence of VTE events of any grade was numerically higher in pts who received ami+laz (21%) than those who received ami (11%) or laz (11%) monotherapy. The median time to onset of the first VTE event was 84.5 days for ami, 79 days for ami+laz, and 170 days for laz. The majority (64%) of ami+laz pts had VTE events in the first 4 months. The most common VTE events by preferred term were pulmonary embolism and deep vein thrombosis. The incidence of grade ≥ 3 VTE events was comparable among pts receiving ami (5%), ami+laz (6%), and laz (6%), and there were no grade 5 VTE events for ami+laz. The overall incidence of serious VTE AEs was low (ami, 3%; ami+laz, 5%; laz, 4%). There were 6 discontinuations due to VTE, 1 (0.2%) ami, 2 (0.4%) for ami+laz, and 3 (1.2%) laz. In the primary analysis, age ≥ 60 years was a significant risk factor ($P < 0.05$). In the secondary analysis, age ≥ 60 years, ECOG performance status of 1 (vs 0), and response to therapy (partial response or better) were significant risk factors ($P < 0.05$). **Conclusions:** Lung cancer diagnosis is a known risk factor for VTE. In a review across clinical trials, single-arm cohort data suggest there is a numerically higher incidence of VTE for ami+laz compared with each monotherapy. Age ≥ 60 years, ECOG performance status, and response to treatment are potential risk factors. The relationship between response and VTE is emerging and may reflect possible immune or inflammatory-mediated mechanisms. Further efforts to understand VTE-associated risk factors in randomized clinical trials are ongoing. Clinical trial information: NCT02609776, NCT04077463, NCT04075396. A phase 1a/1b study of aurora kinase A inhibitor VIC-1911 as monotherapy and in combination with sotorasib for the treatment of KRAS G12C-mutant non-small-cell lung cancer. *First Author: Sarah B. Goldberg, Yale Cancer Center, Yale School of Medicine, New Haven, CT*

Background: Activity of direct covalent KRAS^{G12C} inhibitors in NSCLC is limited by mutational and adaptive resistance. AURKA has roles in centrosome maturation and cytokinesis. AURKA amplification/overexpression is reported in multiple tumors, including NSCLC, and AURKA signaling may mediate adaptive resistance to KRAS inhibition. VIC-1911 is a highly selective, orally active small molecule inhibitor of AURKA. VIC-1911 demonstrated monotherapy activity *in vitro* in KRAS^{G12C}-mutant human NSCLC cells with intrinsic and acquired resistance to the KRAS^{G12C} inhibitor sotorasib, and combination VIC-1911 and sotorasib showed synergy in the same cell lines. Combination VIC-1911 and sotorasib delayed the emergence of adaptive resistance *in vitro*. These findings suggest that 1) AURKA activation is present in both intrinsic and acquired resistance to sotorasib in KRAS^{G12C}-mutant NSCLC and 2) the combination of VIC-1911 and sotorasib is a potential therapeutic approach for KRAS^{G12C}-mutant NSCLC with intrinsic or acquired resistance to sotorasib monotherapy. In addition, *in vivo* data suggest both sotorasib and adagrasib are synergistic in combination with VIC-1911 in human KRAS^{G12C}-mutant NSCLC cell line xenograft models. **Methods:** A non-randomized, open-label Phase 1a/1b study of VIC-1911, an aurora kinase A inhibitor, administered as monotherapy and in combination with sotorasib for the treatment of advanced KRAS^{G12C}-mutant NSCLC is in progress. Participants ≥ 18 years, with locally advanced or metastatic KRAS^{G12C}-mutant NSCLC, prior treatment with at least 1 line of PD-1/PD-L1 inhibitor therapy with or without platinum-based chemotherapy and have adequate organ function are eligible. Both KRAS^{G12C} inhibitor naïve and experienced patients are eligible. VIC-1911 monotherapy is given at oral doses of 25–90 mg twice daily in dose escalation and at the VIC-1911 maximum tolerated dose (MTD) in the expansion cohort in patients who are refractory/relapsed on prior KRAS^{G12C} inhibitor therapy. The combination regimen includes dose escalation with VIC-1911 at oral doses of 75, 150 or 200 mg twice daily on days 1-4, 8-11 and 15-18 every 28-day cycle plus sotorasib 960 mg daily in patients who are refractory/relapsed or naïve to prior KRAS^{G12C} inhibitor therapy. In dose escalation, a 3+3 schema is followed with dose limiting toxicity (DLT) criteria for toxicity and a sample size ≤ 36 . For expansion cohorts, the sample size is based on Simon 2-stage optimal design, with a sample size ≤ 104 . VIC-1911 and sotorasib dose modification criteria are provided. Supportive medications are allowed and early stopping rules for toxicity will be followed. VIC-1911 pharmacokinetics will be assessed. Pharmacodynamics will be determined from ctDNA and tumor biomarker analysis. Clinical trial information: NCT05374538. Research Sponsor: VITRAC Therapeutics, LLC.

A phase III, multicenter, double-blinded, randomized, active-controlled study on the efficacy and safety of QL1706 with chemotherapy (CT) as first-line therapy for PD-L1-negative advanced or metastatic non-small-cell lung cancer (NSCLC). *First Author: Li Zhang, Department of Medical Oncology, State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China*

Background: PD-(L)1 immunotherapy plus platinum-doublet chemotherapy has been the standard 1L treatment for EGFR/ALK wild-type advanced NSCLC pts. However, pts with PD-L1 negative achieve minimal benefit from the PD-(L)1 immunotherapy plus CT. PD-(L)1 plus CTLA-4 blockade with CT in 1L treatment of PD-L1 negative NSCLC derived an improved median overall survival (OS) versus CT alone in CheckMate-9LA study (Luis Paz-Ares *et al.*, *Lancet Oncol* 2021) and POSEIDON study (M L. Johnson *et al.*, *JCO* 2022). QL1706 is a novel bifunctional antibody, containing a mixture of anti-PD-1 IgG4 and anti-CTLA-4 IgG1 antibodies produced in a fixed ratio (2:1) from the same single cell and manufactured together as one product (MabPair). QL1706 monotherapy or plus CT showed impressive safety and efficacy in advanced NSCLC both in phase I and phase II studies (data have been submitted for publication). Of note, QL1706+CT exhibited promising antitumor activity in advanced PD-L1 negative NSCLC. The phase III study aims to compare the efficacy of QL1706+CT versus anti-PD-1 (tislelizumab) + CT (approved in China for 1L treatment of mNSCLC) as 1L treatment in advanced PD-L1 negative NSCLC. **Methods:** The phase III, multicenter, double-blinded, randomized, active-controlled study is enrolling pts aged 18-75 years with ECOG PS of 0-1, previously untreated, PD-L1 negative (TPS $< 1\%$), EGFR/ALK wild-type, and pathologically identified stage IIIB-IV NSCLC. Eligible pts will be randomized (1:1) to receive 4-cycle treatment of QL1706 (5 mg/kg, Q3W) plus CT or tislelizumab (200 mg, Q3W) plus CT followed with maintenance treatment of QL1706 or tislelizumab monotherapy (squamous), or in combination with pemetrexed (non-squamous), until disease progression, intolerable toxicity, or for up to 2 years of immunotherapy. Stratification factors include histology (squamous vs non-squamous), brain metastasis (yes vs no), and sex (male vs female). Co-primary endpoints are progression-free survival (PFS) and OS. Secondary endpoints include objective response rate (ORR), disease control rate (DCR), duration of response (DOR) assessed by investigator per RECIST v1.1, 6 mo- and 12 mo-PFS, 6 mo- and 12 mo-OS, and safety. Exploratory endpoints include PK characteristics, immunogenicity, PFS2 (defined as time from randomization to progression after first subsequent therapy or any-cause death), and efficacy (iPFS, iORR, iDCR, iDOR) by investigator per iRECIST, biomarker analysis of tumor mutation burden. The study planned to enroll 650 pts to obtain approximately 493 PFS events (HR = 0.69; Power = 94%) and 445 OS events (HR = 0.75; Power = 83%) across the QL1706+CT and tislelizumab+CT arms for the final analyses of PFS and OS, respectively. The alpha was split between PFS ($\alpha = 0.005$) and OS ($\alpha = 0.02$). Enrollment began from Feb 2023. Clinical trial information: NCT05690945. Research Sponsor: Qilu Pharmaceutical Co., Ltd.

Poster Session

STAR-121: A phase 3, randomized study of domvanalimab (DOM) and zimberelimab (ZIM) in combination with chemotherapy vs pembrolizumab (pembro) and chemotherapy in patients with untreated metastatic non-small cell lung cancer (mNSCLC) with no actionable gene alterations. *First Author: Delvys Rodriguez-Abreu, Complejo HU de Canarias, Santa Cruz De Tenerife, Spain*

Background: Although immune checkpoint inhibitors have improved clinical outcomes in mNSCLC, the majority of patients will experience progression and shorter survival. Thus, an urgent need exists for more effective treatment options in mNSCLC. DOM is an anti-TIGIT IgG1, Fc-silent monoclonal antibody designed to inhibit the interaction between TIGIT and its ligand, CD155, thereby reducing immunosuppression of T cells and natural killer cells and promoting antitumor activity. ZIM is an anti-PD-1 IgG4 monoclonal antibody with demonstrated antitumor activity *in vivo* and preliminary clinical activity in multiple tumor types. Preliminary studies have shown that dual blockade of TIGIT and PD-(L)1 increases antitumor activity relative to PD-(L)1 inhibition. In ARC-7, a randomized phase 2 study in PD-L1-high, first-line NSCLC, DOM and ZIM in combination recently demonstrated a higher objective response rate (ORR) and longer median progression-free survival (PFS) than ZIM monotherapy. We hypothesize that DOM and ZIM in combination with chemotherapy will improve clinical outcomes in patients with untreated mNSCLC without EGFR or ALK aberrations regardless of PD-L1 expression. **Methods:** STAR-121 is a phase 3, global, open-label, randomized study to evaluate the safety and efficacy of DOM and ZIM plus chemotherapy vs pembro plus chemotherapy as first-line therapy for patients with mNSCLC with no EGFR or ALK aberrations or other known actionable gene alterations. Approximately 720 patients will be randomized into 3 groups (A, B, or C) in a 4:4:1 ratio and stratified by baseline PD-L1 tumor proportion score ($< 50\%$ vs $\geq 50\%$), histology (squamous vs nonsquamous), and geographic region (East Asia vs non-East Asia). Eligible patients are aged ≥ 18 with untreated mNSCLC with no EGFR or ALK aberrations. Group A will receive DOM 1200 mg + ZIM 360 mg + platinum-doublet chemotherapy (PT), group B will receive pembro 200 mg + PT, and group C will receive ZIM 360 mg + PT. DOM, ZIM, and pembro will be administered until disease progression (PD) as assessed by blinded independent central review (BICR) per RECIST 1.1 or intolerable toxicity or for up to 35 doses. Study treatment will be administered IV every 3 weeks. PT will be chosen by investigators based on tumor histology and administered for the first 4 cycles, after which, pemetrexed can be continued for patients with nonsquamous histology until PD or intolerable toxicities. The primary endpoints are PFS by BICR and overall survival. Key secondary endpoints are ORR and duration of response by BICR, safety, and quality of life. This study is currently enrolling globally. Clinical trial information: NCT05502237. Research Sponsor: Gilead Sciences, Inc.

Poster Session

A phase 2 multi-arm study of magrolimab in combination with docetaxel in patients with locally advanced or metastatic solid tumors: ELEVATE Lung and UC. *First Author: Vivek Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Patients (pts) with solid tumors that progress on standard chemotherapy and/or immune checkpoint inhibitors experience limited efficacy with existing standard of care options. These pts have a significant unmet need, and novel agents that safely enhance treatment efficacy are needed. Magrolimab is a monoclonal antibody that blocks CD47, a "don't eat me" signal often overexpressed on solid tumor cells. Magrolimab blockade of CD47 induces macrophage-mediated phagocytosis of tumor cells and has shown preclinical activity and promising clinical efficacy in hematologic malignancies. Certain chemotherapies, including taxanes, enhance phagocytic signals on tumor cells, leading to potential synergistic anti-tumor activity when combined with magrolimab. This study is evaluating the safety, tolerability, and efficacy of magrolimab with docetaxel in metastatic non-small cell lung cancer (mNSCLC), small cell lung cancer (mSCLC), and urothelial cancer (mUC). **Methods:** This open-label study includes a safety run-in and 3 phase 2 cohorts. Pts eligible for the safety run-in must have had ≥ 1 (mNSCLC, mSCLC) or 2 and not more than 3 (mUC) prior lines of systemic anticancer therapy in a locally advanced/metastatic setting and will be treated with magrolimab + docetaxel. In phase 2, pts must have either mNSCLC treated with platinum-based chemotherapy and/or an immune checkpoint inhibitor (ICI), mUC treated with prior systemic chemotherapy and/or an ICI, or mSCLC treated with platinum-based chemotherapy with or without an ICI in a locally advanced/metastatic setting. Pts refractory to prior taxane therapy or who have received a taxane within 12 months of study start are excluded. Pts who had prior treatment with CD47/SIRP α -targeting agents were also excluded. Magrolimab is administered intravenously (IV) as a 1-mg/kg priming dose on cycle 1 day 1 (C1 D1) to mitigate on-target anemia followed by 30 mg/kg on D8 and D15. Magrolimab 30 mg/kg is administered on C2 D1, D8, and D15 and 60 mg/kg on D1 for C3+. The recommended phase 2 dose (RP2D) is determined in the safety run-in, with de-escalation if prespecified dose-limiting toxicity criteria are met. Once the RP2D is determined, the phase 2 cohorts will follow the same dose schedule. Docetaxel 75 mg/m² is administered IV on D1 of each cycle. Reasons for treatment discontinuation may include unacceptable toxicity, disease progression, or pt/investigator choice to discontinue. The primary endpoints are incidence of adverse events by CTCAE v5.0 (safety run-in, phase 2) and investigator-assessed objective response rate by RECIST 1.1 (phase 2 cohorts). Secondary endpoints are magrolimab concentration vs time and antidrug antibodies (safety run-in, phase 2), progression-free survival and duration of response by RECIST 1.1, and overall survival (phase 2 cohorts). Planned enrollment is ≈ 116 pts. Clinical trial information: NCT04827576. Research Sponsor: Gilead Sciences, Inc.

Poster Session

KontRAST-02: A phase III trial investigating the efficacy and safety of the KRAS^{G12C} inhibitor JDQ443 vs docetaxel in patients with previously treated, locally advanced or metastatic, KRAS G12C-mutated NSCLC. *First Author: Federico Cappuzzo, Hematology Department, AUSL della Romagna, Ravenna, Italy*

Background: Kirsten rat sarcoma viral oncogene homolog (KRAS) is the most frequent mutated oncogene in non-small cell lung cancer (NSCLC). KRAS G12C is the most common KRAS variant, present in $\sim 13\%$ of patients (pts) with non-squamous NSCLC. KRAS G12C mutations cause the accumulation of active, GTP-bound KRAS, which leads to activation of downstream pathways involved in cell proliferation and invasiveness. JDQ443 is a potent, structurally novel, selective KRAS^{G12C} inhibitor that irreversibly traps KRAS^{G12C} in its inactive, GDP-bound form. Data from the JDQ443 monotherapy arm of the first-in-human KontRAST-01 study demonstrated encouraging anti-tumor activity and an acceptable safety profile of JDQ443 in pts with previously treated, KRAS G12C-mutated, advanced NSCLC. For pts with advanced NSCLC who progress following first-line immunotherapy or doublet platinum-based chemotherapy, single agent docetaxel remains a standard option, although it presents modest activity and is generally poorly tolerated. In this context, alternative treatment options are needed to improve pt outcomes. **Methods:** KontRAST-02 (NCT05132075) is a global, Phase III, open-label, randomized, multicenter study evaluating JDQ443 as a monotherapy in comparison to docetaxel in pts with KRAS G12C-mutated, advanced NSCLC previously treated with PD-(L)1 inhibitors and platinum-based chemotherapy (either in combination or as sequential treatments). Approximately 360 pts stratified by ECOG performance status (0 vs 1 and 2) and prior therapy (platinum-based chemotherapy and immunotherapy combined vs sequential) will be randomized at 1:1 to receive 200 mg oral JDQ443 twice daily continuously or 75 mg/m² intravenous docetaxel once every 21 days. The primary endpoint of this study is progression-free survival (PFS) per Blinded Independent Review Committee (BIRC) according to RECIST version 1.1. The key secondary endpoint is overall survival (OS); other secondary endpoints include objective response rate, disease control rate, time to response, duration of response, PFS on subsequent therapy, safety of JDQ443 monotherapy, pt-reported outcomes, pharmacokinetics, time to deterioration of ECOG performance status, and safety in pts who crossover from docetaxel to JDQ443. Exploratory objectives include biomarker analyses aimed at investigating predictors of responsiveness to JDQ443. Pts randomized to docetaxel will be allowed to crossover to JDQ443 following confirmed disease progression per BIRC. To allow more pts to be treated with JDQ443, crossover will also be offered to all patients on docetaxel if the primary endpoint (PFS) is met. Treatment beyond progression will be allowed for pts receiving JDQ443 according to investigator judgement. The KontRAST-02 study is currently enrolling pts. Clinical trial information: NCT05132075. Research Sponsor: Novartis Pharmaceuticals Corporation.

ECOG-ACRIN LUNG-MAP S1900E substudy: A phase II study of sotorasib in participants (Pts) with previously treated stage IV or recurrent KRAS G12C mutant non-squamous (Non-sq) non-small cell lung cancer (NSCLC). *First Author: Sukhmani Kaur Padda, Samuel Oschin Cancer Center, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: KRAS mutant NSCLC is further defined molecularly by specific mutation subtypes and co-mutations in tumor suppressor genes. Two targeted therapeutics, sotorasib and adagrasib, are currently approved for the treatment of previously treated advanced KRAS G12C mutant NSCLC. Sotorasib has also demonstrated superiority to docetaxel in the randomized phase III CodeBreak 200 study (*de Langen et al Lancet. 2023 Feb 7 Epub*). The impact of co-mutations in tumor suppressors, including TP53 and STK11, on the efficacy of first generation KRAS G12C inhibitors has been inconclusive. The S1900E substudy aims to prospectively understand, using rigorous biomarker testing/definitions, the impact of co-mutations on the clinical activity of sotorasib in pts with KRAS G12C mutant NSCLC. **Methods:** S1900E is a phase 2 open-label study of sotorasib in biomarker-defined cohorts for pts who have KRAS G12C stage IV/recurrent non-sq NSCLC, received at least one line of systemic treatment, and are naive to KRAS G12C inhibitors. Pts are assigned to S1900E under the Lung-MAP screening protocol (NCT03851445) using FoundationOne F1CDx next generation sequencing assay on tissue (Foundation Medicine, Cambridge, MA). S1900E cohorts include: #1) Presence of TP53 co-mutation AND Wild Type STK11, KEAP1, NFE2L2, CUL3; #2) Presence of STK11 co-mutation AND Wild Type TP53, KEAP1, NFE2L2, CUL3; #3) All pts not eligible for Cohorts 1 and 2 (e.g. dual co-mutations in STK11 and TP53; co-mutations in KEAP1, NFE2L2, CUL3, or others; or lack of any co-mutations). Pts with treated, clinically controlled, and asymptomatic brain metastases are eligible and with amendment 3 (Mar 20 2022), eligibility expanded to pts with asymptomatic untreated brain metastases. Sotorasib is dosed 960 mg oral daily. The primary objective is to evaluate the RECIST 1.1 response rate (ORR) per cohort. For cohorts 1 and 3, the target sample size is 40 eligible pts based on a design with 92% exact power to rule out a 14% ORR at the 1-sided 5% level, if the true ORR were 34%; ≥ 10 responses would rule out a 14% ORR. Cohort 2 has a target sample size of 25 eligible pts with 93% exact power to rule out a 14% ORR at the 1-sided 5% level, if the true ORR were 40%; ≥ 7 responses would rule out a 14% ORR. Secondary endpoints include PFS, OS, duration of response, and toxicity. Circulating tumor DNA is being collected at day 1 of cycle 1, 2, and 3 and at progression. Enrollment started April 2 2021 with conservative accrual targets met, currently with 72% enrolled (84/116) as of Feb 14 2023, including 37, 16, and 31 pts, in cohorts 1, 2, and 3, respectively. Clinical trial information: NCT04625647. REFINE-Lung: A multicentre phase III study to determine the optimal frequency of pembrolizumab in non-small cell lung cancer utilising a novel multi-arm design. *First Author: Michael Seckl, Imperial College London, London, United Kingdom*

Background: Pharmacological and clinical data suggest standard regimens for anti-PD1 agents nivo and pembro result in overtreatment. These agents have high target affinity, saturate PD1 at very low concentrations and maintain receptor occupancy for up to 30 wks following discontinuation. Clinical studies suggest no dose-response relationship in the wide range tested (0.1 – 10 mg/kg) and retrospective data suggest the efficacy of lower doses or longer administration frequency. Given their high costs and important implications for pt quality of life and toxicity, new approaches to optimise treatment regimens are required. However, conventional 2-arm non-inferiority designs require large numbers of patients, explore a single alternative to the standard of care and potentially require multiple trials to establish optimal parameters such as dose or frequency. Here we present a new multi-arm trial design to tackle this problem, implemented in the UK multicentre phase III REFINE-Lung study that aims to determine the optimal treatment frequency of pembro in NSCLC. Pts who are progression free after 6 months of standard therapy are randomised to 5 pembro frequency reduced arms (q6w, q9w, q12w, q15w and q18w). By evaluation of the frequency-response relationship, we will determine the longest frequency that is equivalent to standard of care within a pre-defined margin. **Methods:** The REFINE-Lung trial (NCT05085028) is a multicentre, randomised open-label, phase III trial in advanced NSCLC. REFINE-Lung utilises a novel Multi-Arm Multi-Stage Response Over Continuous Interventions (MAMS-ROCI) design to determine the optimal dose frequency of pembro. 1750 pts aged ≥ 18 and progression free at six months into 1st line pembro and planning to continue, will be enrolled from up to UK 35 hospital groups. Pts will be randomised across 5 arms to determine the optimal dose frequency. To assess safety, pts will initially be randomised 1:1 into q6w (control) and q12w arms. Interim analysis will be conducted once 37 progression free events are observed in the control arm. If PFS in the q12w arm is not significantly reduced, the remaining q9w, q15w and q18w arms will be opened. Pts who progress on a frequency reduced arm may re-escalate to q6w therapy. The primary objective is to determine the optimal continuing dose frequency of pembro, defined as the longest dose interval non-inferior to standard therapy using 2-year survival as the primary outcome. Secondary endpoints include OS, PFS, ORR, duration of response, adverse events, quality of life and cost effectiveness. An exploratory sub-study will explore fundamental aspects of cancer immunotherapy and develop novel biomarkers of response, resistance, toxicity and patient suitability for dose frequency de-escalation. Recruitment is ongoing and the trial is open at 16 centres at time of submission. Clinical trial information: NCT05085028. Research Sponsor: National Institute for Health Research; Lung Cancer Research Charity and North West London Pathology Consortium.

PRESERVE-003: Phase 3, two-stage, randomized study of ONC-392 versus docetaxel in metastatic non-small cell lung cancers that progressed on PD-1/PD-L1 inhibitors. *First Author: Mark A. Socinski, AdventHealth Cancer Institute, Orlando, FL*

Background: For NSCLC without driver mutation, the PD-1/PD-L1 inhibitor as the first-line (monotherapy or in combination with platinum-based doublet agents) or second-line therapy after chemotherapy significantly improved overall survival. However, there remain a significant number of patients who do not have response or have an initial response followed by disease progression to PD-1/PD-L1 inhibitor therapy. CTLA-4 is a proven immunotherapy target in solid tumor, unfortunately no monotherapeutic efficacy has been shown in NSCLC by marketed anti-CTLA-4 antibodies, including ipilimumab and tremelimumab. These anti-CTLA-4 mAbs cause severe toxicity that prevents adequate dosing in cancer patients. In contrast, ONC-392 keeps high-level CTLA-4 on Treg cells through a recycling mechanism and makes Treg cells a better target for antibody-dependent cellular cytotoxicity, particularly in the tumor microenvironment where macrophages are more abundant. The selective elimination of Treg cells in the tumor microenvironment and maintenance of CTLA-4 expression in Treg cells in the peripheral tissues by ONC-392 form the cellular and molecular basis for more potent tumor rejection and low toxicity in animal studies. Our first in human studies have demonstrate safety and clinical activities of ONC-392 in patients with NSCLC and other solid tumors. **Methods:** This is a seamless 2-stage, randomized, open-label, active-controlled, Phase 3 study of ONC-392 for treatment of NSCLC patients who progressed on PD-1/PD-L1 inhibitor (NCT05671510). Approximately 600 patients will be enrolled. Stage 1, the dose-confirmation stage, will assess the efficacy and safety of two ONC-392 dosing regimens (3 mg/kg Q3W and 6 mg/kg Q3W with 2 loading doses of 10 mg/kg Q3W) in comparison to docetaxel 75 mg/m² Q3W. A total of 120 patients will be randomized 1:1 in Stage 1 into one of two ONC-392 dose cohorts or docetaxel cohort. An interim analysis will be conducted at the end of Stage 1 when 120 patients are enrolled. Stage 2 will start when ONC-392 dose is determined and approximately 480 patients will be randomized 1:1 to receive ONC-392 or docetaxel treatment. All enrolled patients who are randomized to the ONC-392 arms will receive ONC-392 at the randomized dose for up to 17 cycles in approximately 1 year or until discontinuation criteria are met. Patients who are randomized to the docetaxel arm will receive docetaxel 75 mg/m² Q3W until disease progression per RECIST 1.1. The primary endpoint is overall survival. The treatment effect will be estimated using a Cox Proportional Hazard model stratified by the randomization stratification factors to calculate the estimated hazard ratio and its 95% CIs. Kaplan-Meier (i.e., product-limit) estimates of median OS time will be presented by treatment arm with two-sided 95% CIs. The analyses will be based on the ITT Population. Clinical trial information: NCT05671510. Research Sponsor: OncoC4, Inc.

ARC-10: A phase 3 study to evaluate zimberelimab + domvanalimab versus pembrolizumab in front-line, PD-L1-high, locally advanced or metastatic non-small-cell lung cancer. *First Author: Christos Chouaid, Centre Hospitalier Intercommunal de Créteil, Créteil, France*

Background: Despite improvements in the management of locally advanced or metastatic non-small cell lung cancer (NSCLC) from programmed cell death/ligand protein 1 (PD-L1) inhibition, there remains an unmet need for improved treatment options. PD-L1 expression is a known biomarker of response to anti-PD-L1 therapies in metastatic NSCLC. The combination of PD-1 inhibition with inhibition of the immunosuppressive T cell Immunoglobulin and ITIM domain (TIGIT) pathway is associated with improved response and prolonged progression-free survival in patients with advanced NSCLC. Domvanalimab (dom) is an Fc-silent humanized IgG1 monoclonal antibody (mAb) that blocks TIGIT, thereby reducing immunosuppression of T/natural killer (NK) cells and promoting antitumor activity. Zimberelimab (zim) is an mAb that binds to PD-1 on T/NK cells, preventing PD-L1-mediated immunosuppressive effects and resulting in tumor cell death. This phase 3 study will investigate the efficacy and safety of combination therapy with dom + zim compared with pembrolizumab monotherapy in patients with PD-L1-high NSCLC. **Methods:** ARC-10 (NCT04736173) is a global, phase 3, randomized, multicenter, open-label study. Eligible patients are adults with histologically confirmed, treatment-naïve, locally advanced or metastatic, squamous or non-squamous NSCLC with ≥ 1 measurable lesion(s) per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1, high expression of PD-L1 (tumor cells [TC] $\geq 50\%$), and an Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1. Patients must not have genomic tumor aberrations for which targeted therapies are approved and available (eg, *EGFR*, *ALK*, *ROS*, *BRAF*, *NTRK*). Approximately 600 patients will be randomized 1:1 to receive combination therapy with dom + zim (dom 1200 mg intravenous [IV] once every 3 weeks [Q3W] + zim 360 mg IV Q3W) or pembrolizumab monotherapy (200 mg IV Q3W) for 21-day cycles until disease progression, intolerance, or a maximum of 35 cycles. Randomization will be stratified by ECOG performance status (0 vs 1), geographical region (Asia vs non-Asia), and histology (squamous vs non-squamous). The primary efficacy endpoint is overall survival. Secondary efficacy endpoints include blinded independent central review of progression-free survival and confirmed overall response rate according to RECIST v1.1. Safety endpoints include the presence of treatment-emergent adverse events and laboratory parameters. Health-related quality of life will be assessed by measuring the time to first symptom deterioration in the NSCLC-Symptom Assessment Questionnaire total score. Study recruitment is planned in Asia, North and South America, Africa, and Europe. Clinical trial information: NCT04736173. Research Sponsor: Arcus Biosciences.

Phase 1 multicenter dose escalation and dose expansion study of antibody-drug conjugate (ADC) MYTX-011 in subjects with non-small cell lung cancer. *First Author: Alexander I. Spira, NEXT Oncology - Virginia Cancer Specialists, Fairfax, VA*

Background: cMET is a receptor tyrosine kinase and proto-oncogene whose activity is upregulated across a wide range of cancers. In NSCLC, expression of cMET is upregulated by DNA amplification (2% to 5%), exon 14 skipping mutations (2% to 4%), and overexpression (30% to 60%). In NSCLC, cMET upregulation has also been demonstrated to be a resistance mechanism for several approved EGFR-targeted kinase inhibitors, and this may limit their effectiveness. Despite the approval of MET tyrosine kinase inhibitors, almost half of patients do not respond to these inhibitors and resistance is inevitable. MYTX-011 is an ADC incorporating the clinically validated vcMMAE linker-payload conjugated to a novel, pH-dependent anti-cMET antibody. In preclinical studies, MYTX-011, compared to a surrogate of an advanced clinical stage cMET ADC, showed markedly higher (> 3 fold) internalization and increased cytotoxicity in cMET+ tumor cells *in vitro*, which translates to greater (≥ 3 fold) efficacy in high or moderate c-Met+ xenograft models *in vivo*. PK and toxicity studies revealed that MYTX-011 exhibited favorable PK characteristics, and a toxicity profile similar to previously described MMAE-based ADCs. **Methods:** MYTX-011-01 (ClinicalTrials.gov Identifier: NCT05652868) is a first-in-human Phase 1 dose escalation and dose expansion study. MYTX-011 will be administered intravenously every 21 days for a maximum of 2 years. Part 1 (dose escalation) will assess the safety and tolerability of MYTX-011 in patients with advanced NSCLC and identify the recommended Phase 2 dose (RP2D). Part 2 (dose expansion) will include subjects with NSCLC with cMET overexpression or MET amplification/exon 14 skipping mutations. In Part 1, subjects will be enrolled to evaluate the safety of escalating doses of MYTX-011 as a single-agent and to establish the RP2D and/or MTD. The dose escalation scheme is based on a 3-subject cohort minimum Bayesian Optimal Interval (BOIN) design. The RP2D will be selected as a biologically active dose at or below the MTD (or the highest dose tested if an MTD is not identified during the study) and will be informed by safety, tolerability, pharmacokinetic data, and preliminary anti-tumor activity of MYTX-011 based on RECIST 1.1. Part 2 of the study will be initiated once the RP2D has been determined and will enroll subjects into different cohorts based on cMET IHC positivity cutoff and/or presence of MET genetic alterations (MET amplification or exon 14 skipping). All cohorts are defined to explore preliminary anti-tumor activity in populations with different thresholds of cMET positivity that were selected based on data for cMET expression and efficacy observed with MYTX-011 in preclinical models, published data for responses to cMET targeting agents, and on the prevalence of subject tumors with different expression levels. Enrollment in the MYTX-011-01 study is ongoing. Clinical trial information: NCT05652868. Research Sponsor: Mythic Therapeutics.

Phase 2 study of telisotuzumab vedotin (Teliso-V) monotherapy in patients with previously untreated MET-amplified locally advanced/metastatic non-squamous non-small cell lung cancer (NSQ NSCLC). *First Author: Hidehito Horinouchi, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: Teliso-V is a first-in-class anti-c-Met antibody-drug conjugate composed of the monoclonal antibody telisotuzumab (ABT-700), a cleavable valine-citrulline (dipeptide) linker, and cytotoxic monomethylauristatin E (MMAE; potent microtubule polymerization inhibitor). Direct MMAE payload delivery to c-Met protein over-expressing (OE) cells enables Teliso-V to work independently of c-Met signaling. In NSCLC, while c-Met OE is more common than MET gene amplification (Amp), about 90% of MET Amp tumors will also be c-Met OE. In an ongoing phase 2 trial, Teliso-V showed encouraging efficacy and acceptable safety in previously treated c-Met OE NSQ NSCLC population (Camidge et al. JCO.2022.40.16_suppl.9016). From this study, a retrospective analysis of 10 patients with MET Amp (≥ 1.8 MET gene to chromosome 7 copy number ratio by fluorescence in situ hybridization [FISH]) demonstrated an objective response rate (ORR) of 80%. Described here is an ongoing phase 2 study evaluating efficacy and safety of Teliso-V monotherapy in patients with previously untreated MET Amp locally advanced/metastatic NSQ NSCLC. **Methods:** This is a phase 2, single-arm, open-label, global study (NCT05513703). Eligible patients (≥ 18 years) have histologically documented advanced/metastatic NSQ NSCLC, measurable disease by RECIST v1.1, confirmed MET Amp determined centrally by FISH or locally by FISH, tissue next-generation sequencing (NGS), or plasma NGS using sponsor-approved assays. Additional eligibility criteria include Eastern Cooperative Oncology Group performance status 0 or 1, no alterations in *EGFR*, *ALK*, *ROS1*, or *BRAF* that predict sensitivity to targeted therapy, no prior systemic therapy for locally advanced or metastatic NSCLC, no prior c-Met-targeted antibody therapy. Teliso-V is administered intravenously at 1.9 mg/kg every 2 weeks until disease progression, intolerable toxicity, or other study drug discontinuation criteria are met. Primary endpoint is ORR assessed by independent central review (ICR). Secondary endpoints include duration of response and disease control rate, progression-free survival per ICR, overall survival, patient-reported outcomes (PROs). Tumor assessments (per RECIST v1.1) are performed at baseline and approx. every 6 (year 1), 8 (year 2), and 12 weeks (year 3 and beyond). PROs are assessed through validated questionnaires (EORTC QLQ-LC13, EORTC QLQ-C30, EQ-5D-5L). Safety and tolerability are evaluated by adverse events, physical examinations, laboratory data, and vital signs. Pharmacokinetic and biomarker evaluations may be used for exploratory analyses. The trial intends to enroll approx. 70 efficacy-evaluable patients, with interim analyses planned after 20 and 50 patients are able to be followed for ≥ 6 months. The study was open to enrollment as of Nov 2022. Clinical trial information: NCT05513703. Research Sponsor: AbbVie Inc.

Circulating tumor DNA to guide furmonertinib monotherapy or combination therapy in advanced EGFR mutant non-small cell lung cancer (NSCLC): A randomized, open-label, multicenter study (FOCUS-C). *First Author: Wen-feng Fang, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Detection of EGFR ctDNA after several weeks EGFR-TKIs treatment was an effective method to identify prognosis of advanced EGFR mutant NSCLC patients. Patients with uncleared EGFR ctDNA had shorter progression-free survival (PFS) (*Mack PC et al; CCR 2022*). However, whether they can benefit from EGFR-TKI combination therapy has not been reported. Furmonertinib (AST2818), a potent, orally bioavailable, highly brain penetrant, third generation EGFR-TKI with unique chemical structure designed to improve potency and specificity, showed superior efficacy compared with gefitinib as first-line therapy in EGFR mutant NSCLC along with an acceptable safety profile without new signals (*Shi, YK et al.; Lancet Respir Med 2022*). We hypothesized that monitoring clearance of EGFR ctDNA in blood could rationally guide subsequent monotherapy or combination therapy with furmonertinib and will improve outcomes in patients with uncleared EGFR ctDNA. **Methods:** The FOCUS-C study is a multicenter, open-label, randomized study. Patients who are aged 18 years or older and have histologically confirmed, locally advanced or metastatic, stage IIIB, IIIC, or IV unresectable NSCLC with EGFR exon 19 deletions (19Del) or exon 21 Leu858Arg mutation (L858R) on tissue biopsy and plasma will be treated with furmonertinib. Eligible patients with uncleared EGFR 19Del or L858R ctDNA after 3 weeks furmonertinib treatment will be stratified according to EGFR mutation (19Del or L858R), central nervous system metastases (with or without) and detectable accompanying gene aberrances in plasma (with or without) and randomly assigned (2: 2: 1) to receive furmonertinib or furmonertinib plus chemotherapy (pemetrexed and carboplatin for 4 cycles followed by maintenance pemetrexed) or furmonertinib plus chemotherapy plus bevacizumab (pemetrexed, carboplatin and bevacizumab for 4 cycles followed by maintenance pemetrexed and bevacizumab) in 21-day cycles until disease progression, the occurrence of intolerable toxicities, withdrawal of consent, or other discontinuation reasons judged by the investigators. The primary endpoint is PFS between furmonertinib plus chemotherapy versus furmonertinib alone. Secondary endpoints include PFS, objective response rate, duration of response, disease control rate, overall survival and safety. Several exploratory endpoints will also be evaluated based on ctDNA detection by next-generation sequencing (Genecast, Wuxi, China). The study is enrolling. 34 patients had been enrolled till 2nd Feb 2023. Clinical trial information: NCT05334277. Research Sponsor: Y-2021AST/zd-0053/Beijing Xisike Clinical Oncology Research Foundation, CSCO-Leading Oncology Research Fund.; Shanghai Allist Pharmaceuticals Co., Ltd, Shanghai, China. Genecast Biotechnology Co., Ltd, Wuxi, China. Qilu Pharmaceutical Co., Ltd, Jinan, China.

Poster Session

A phase II multi-cohort single-arm study of tiragolumab with atezolizumab plus bevacizumab in previously treated advanced non-squamous non-small-cell lung cancer. *First Author: Joshua E. Reuss, Georgetown University, Washington, DC*

Background: Checkpoint inhibitor immunotherapy (CPI) offers durable, immune-mediated, anti-tumor responses to a subset of patients (pts) with advanced non-small cell lung cancer (NSCLC), but not all derive meaningful benefit. Two clinical unmet needs where CPI has fallen short include EGFR-mutated NSCLC, where CPI is minimally effective, and NSCLC with intrinsic or acquired resistance to currently available CPI. Novel combination strategies have shown promise. Two agents that have demonstrated synergy with the anti-PD-L1 CPI atezolizumab in NSCLC are bevacizumab, a vascular endothelial growth factor (VEGF)-blocking antibody, and tiragolumab, a T-cell immunoglobulin and ITIM domain (TIGIT) immune checkpoint-blocking antibody. This multi-cohort phase II trial seeks to evaluate the efficacy of tiragolumab with atezolizumab plus bevacizumab in 2 CPI-resistant cohorts - EGFR-wild type, CPI-refractory advanced NSCLC (cohort A) and EGFR-mutated, CPI-naïve advanced NSCLC (cohort B) - incorporating novel genomic and immunologic analyses to deliver mechanistic insight into the biology of CPI-resistance in NSCLC. **Methods:** This open-label, phase II study has two cohorts. Cohort A includes pts with advanced PD-L1+ (TPS $\geq$ 1%), EGFR/ALK/ROS1 wild type NSCLC with progression on prior anti-PD(L)1-based CPI therapy. Cohort B includes pts with targeted therapy-refractory EGFR-mutated NSCLC who are CPI-naïve. Pts must have measurable disease and those with symptomatic and/or untreated brain metastases are excluded. Pts in both arms will receive tiragolumab 600mg IV with atezolizumab 1200mg IV and bevacizumab 15mg/kg IV every 3 weeks until progressive disease or unacceptable toxicity. The primary efficacy endpoint will be assessed separately in each cohort by investigator-assessed objective response rate (ORR) according to RECIST v1.1. Each cohort utilizes a Simon 2-stage design in which a null ORR of 4% is tested against a one-sided alternative of 20%. A sample size of 21 pts/cohort provides 80% power with a one-sided type 1 error rate of 5% to determine a true ORR of 20%. Secondary efficacy endpoints include: duration of response, progression-free survival (PFS), 6-month PFS, overall survival. Blood and tumor specimens will be acquired pre- and on-treatment. Correlative analyses to illuminate the biology of CPI resistance will include multiplex imaging mass cytometry of tumor tissue. In addition, whole exome sequencing, T-cell receptor sequencing, and MANAFEST neoantigen prediction will be used to identify neoantigen-specific T-cells and track these temporally (during/post treatment) and spatially (across biologic compartments). The study is activated and both cohorts are accruing simultaneously with enrollment ongoing. Clinical trial information: NCT04958811. Research Sponsor: Georgetown Lombardi Comprehensive Cancer Center; LUNGevity Foundation; MedStar Health Research Institute; Genentech/Roche.

Poster Session

LUNG-IST-127: A pilot phase II study of maintenance cabozantinib plus pembrolizumab for patients with metastatic squamous non-small cell lung cancer (sqNSCLC) with disease control following induction therapy. *First Author: Ryan Huu-Tuan Nguyen, Department of Hematology Oncology University of Illinois at Chicago College of Medicine, Chicago, IL*

Background: First-line combination chemotherapy with pembrolizumab followed by maintenance pembrolizumab is the standard of care treatment for patients with metastatic sqNSCLC. This was established by the phase III KEYNOTE-407 trial, which demonstrated a median progression-free survival (PFS) of 6.4 months in the experimental arm. Despite these advances, there remains a need to continue to improve upon survival outcomes for these patients. Cabozantinib is a small-molecule inhibitor of multiple tyrosine kinases including MET, VEGFRs, AXL, RET, and ROS, which are receptors involved in tumor cell-proliferation, angiogenesis, and immune cell regulation. Preclinical studies have demonstrated the ability of cabozantinib to modulate both adaptive and innate immune cells and to exhibit synergistic activity when used in combination with immune checkpoint inhibitors. We hypothesize that cabozantinib in combination with pembrolizumab in the maintenance phase of first-line treatment of metastatic sqNSCLC will prolong median PFS with a tolerable toxicity profile. **Methods:** LUNG-IST 127 is a pilot phase II, single-arm clinical trial of maintenance cabozantinib in combination with pembrolizumab for patients with metastatic sqNSCLC who achieved disease control following standard 1L induction therapy with chemotherapy and pembrolizumab. Thirty-six patients will be enrolled at 2 US sites to receive first-line induction therapy with carboplatin, nab-paclitaxel or paclitaxel, and pembrolizumab for four cycles. After induction therapy, those who have achieved disease control based on re-staging imaging will continue onto maintenance therapy with cabozantinib 40mg PO daily in combination with pembrolizumab 200mg IV every 3 weeks. The primary endpoint is PFS estimated by Kaplan-Meier methods with associated 95% confidence intervals. Based on an exploratory power analysis using an elevated one-sided alpha level of 0.40, we hypothesize that the proposed therapy will prolong median PFS from 6.4 to 9 months. Key secondary endpoints include overall survival (OS), overall response rate (ORR), and characterizing the safety and tolerability of cabozantinib in combination with pembrolizumab. Quality of life will also be measured with the EORTC QLQ-C30. Correlative endpoints include characterizing cfDNA from biofluids and assessing the change in circulating immune cells in different phases of treatment in association with PFS and OS. This trial would be the first to address whether there is clinical benefit in utilizing combination cabozantinib and pembrolizumab in the maintenance phase of treatment in metastatic sqNSCLC. Clinical trial information: NCT05613413. Research Sponsor: Exelixis.

Poster Session

Aumolertinib with chemotherapy or alone compared with osimertinib in patients with EGFR-mutant non-small-cell lung cancer (TREBLE). *First Author: Melissa Lynne Johnson, Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN*

Background: Aumolertinib is a novel third-generation (3G) epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI). Safety and efficacy of aumolertinib have been demonstrated in patients with EGFR-mutated locally advanced or metastatic (LA/m) NSCLC. (Lu, 2021; Lu, 2022) A phase 3 study in these patients in the first-line setting showed a significant improvement in progression-free survival (PFS) for aumolertinib vs gefitinib (median 19.3 months versus 9.9 months; $P < 0.0001$). Aumolertinib was generally well-tolerated. (Lu, 2022) Aumolertinib is approved in China for patients with LA/m NSCLC who have an EGFR T790M resistance mutation upon disease progression and for treatment naïve patients with EGFR-mutated NSCLC. Studies evaluating first-generation EGFR-TKI + chemotherapy (chemo) showed improved PFS in select patient populations. (Hosomi, 2019) It is unclear if the addition of chemo to a 3G EGFR-TKI will improve PFS in patients with EGFR-mutated LA/m NSCLC. As the addition of chemo to a 3G EGFR-TKI may prove warranted, there is a need to understand the relative efficacy and safety in the diversity of patients encountered in routine clinical practice. (Tanaka, 2021). **Methods:** This is a randomized, multi-regional, phase 3 clinical trial comparing aumolertinib + chemo or aumolertinib monotherapy with osimertinib monotherapy. Patients are eligible if they have stage IIIB, IVA, or IVB NSCLC; harbor ex19del or L858R EGFR mutations alone or with other EGFR mutations; and have an ECOG PS of $\leq$ 2. Patients are ineligible if they received prior systemic therapy for mNSCLC or are a candidate for curative intent therapy. Eligible patients will be randomized 2:2:1 and stratified by mutation status (ex19del or L858R), ECOG PS (0 vs 1/2), and race (White vs Asian vs other races combined). Anticipated enrollment is 500 patients; 200 to receive aumolertinib + chemo (110 mg PO QD aumolertinib + investigator's choice chemo), 200 to receive osimertinib (80 mg PO QD), and 100 to receive aumolertinib (110 mg PO QD). The primary endpoint is PFS, by blinded independent review committee (BICR) per RECIST 1.1, for aumolertinib + chemo vs osimertinib. Overall survival (OS) is a key secondary endpoint for aumolertinib + chemo vs osimertinib. Additional efficacy endpoints will be assessed for aumolertinib + chemo vs osimertinib and aumolertinib vs osimertinib, as well as safety and patient reported outcomes. Exploratory endpoints include characterizing mechanisms of acquired resistance across all arms, CNS efficacy, and exposure-response relationship. Enrollment began in July 2022. The study is currently recruiting and will include approximately 200 sites globally. The study design will provide a power of 80% at a 2-sided Type I error of 0.05 for the primary endpoint. If the primary endpoint is statistically significant, a sequential test method will be used to evaluate OS. Clinical trial information: NCT05493501. Research Sponsor: EQRx.

Poster Session

Phase 1b/2a safety and tolerability study of bemcentinib (BEM) with pembrolizumab/carboplatin/pemetrexed in first line (1L) advanced or metastatic non-squamous non-small cell lung cancer (NSCLC) without/with a STK11 mutation. *First Author: Rajwanth Veluswamy, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: The combination of platinum, pemetrexed, and pembrolizumab (CIT) has become the standard of care in 1L non-oncogene addicted NSCLC. Despite an initial improvement in response rate and survival, the 5-year survival of NSCLC remains approximately 20-30%, due to the emergence of primary and acquired resistance. Additionally, the presence of brain metastases occurs in ~30-50% of NSCLC patients and confers a poor prognosis. Among the currently non-actionable mutations, STK11/LKB1 mutations (STK11m) are common (~20%) in NSCLC. Recent evidence suggests that STK11m NSCLC patients have a minimal response to checkpoint inhibitors and to chemo-immunotherapy in the first line setting. STK11m tumors are characterized by an immune-suppressed phenotype which is highly associated with AXL signalling. BEM, a first-in-class, oral, selective AXL inhibitor, has demonstrated the ability to prevent chemoresistance, re-sensitize STK11m NSCLC tumors to pembrolizumab, and enhance efficacy of CIT in preclinical lung models. Moreover, following oral administration, BEM readily distributes in brain tumour tissue in recurrent glioblastoma patients, with a 25.9 mean ratio of drug concentration in brain tissue to plasma. Therefore, the addition of BEM to CIT has the potential to improve 1L treatment outcomes in NSCLC overall and particularly in STK11m tumors. **Methods:** This is an open-label, multi-center, phase 1b/2a study to assess the safety, tolerability, and preliminary anti-tumor activity of BEM + CIT as 1L treatment in patients with advanced (Stage IIb/IIc) or metastatic (Stage IV) non-squamous NSCLC without actionable mutations. Patients with stable brain metastases are eligible to participate. Phase 1b follows a 3+3 design and will explore CIT in combination with one of 3 BEM dose levels: Cohort 1 = 75mg; Cohort 2 = 100 mg; or Cohort 3 = 150 mg. BEM is administered orally once/day on Day 1 of each 21-day treatment cycle. After 4 cycles of CIT + BEM, maintenance with BEM + pemetrexed + pembrolizumab is administered for up to 2 years. An independent data safety monitoring board will assess the safety data at the end of the dose-limiting toxicity period (the first 21 days of treatment for each patient, i.e. cycle 1) of each cohort and will recommend the BEM dose for the phase 2a expansion. In the phase 2a, up to 40 patients harboring a STK11m (regardless of their co-mutational status), in the absence of driver mutations will be enrolled. The study will include extensive co-mutational analyses via next-generation sequencing to identify potential subgroups of patients deriving particular benefit. The trial is open to patient enrolment in phase 1b in the US; recruitment for phase 2a is planned to open in Q2 2023 in Europe and US. *EudraCT 2019-003806-28/NA/124645*. Clinical trial information: NCT05469178. Research Sponsor: BerGenBio ASA.

Poster Session

A phase 1 study to assess BDTX-1535, an oral EGFR inhibitor, in patients with glioblastoma or non-small-cell lung cancer. *First Author: Melissa Lynne Johnson, Lung Cancer Research, Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN*

Background: The epidermal growth factor receptor (EGFR) is a potent oncogene commonly altered in many cancers, including glioblastoma (GBM) and non-small cell lung cancer (NSCLC). EGFR tyrosine kinase activity driven by common EGFR mutations can be inhibited by small molecules, however, resistance to available agents may be driven by mutations in the EGFR active kinase site or other regions. BDTX-1535 is an orally available, highly potent, selective, irreversible inhibitor of EGFR mutations, including extracellular variants and amplifications commonly expressed in GBM and inhibits the common and uncommon EGFR mutations found in NSCLC, including the C797S mutation acquired following 3rd generation EGFR inhibitor therapy. Preclinical data demonstrated the ability of BDTX-1535 to cross the blood-brain barrier and produce sustained inhibition of EGFR signaling. Preclinical studies suggest that BDTX-1535 has the potential to be clinically active in suppressing tumor growth in patients with GBM and NSCLC with or without CNS metastases, including a potential survival benefit. **Methods:** BDTX-1535-101 (NCT05256290) is Phase 1, open-label, multicenter study to assess the safety, tolerability, PK, CNS activity, and preliminary antitumor activity of BDTX-1535 in recurrent GBM (rGBM) or locally advanced or metastatic NSCLC with or without CNS disease. The Monotherapy Dose Escalation portion will evaluate BDTX-1535 in patients with either rGBM expressing EGFR alterations or locally advanced/metastatic NSCLC harboring sensitizing EGFR mutations with or without CNS disease. Patients with rGBM must have previously received available standard therapy of surgical resection followed by chemo-radiotherapy and/or temozolomide (TMZ). Eligible NSCLC patients must have EGFR mutated NSCLC that has progressed following standard of care EGFR inhibitor therapy. Once a provisional recommended Phase 2 dose (RP2D) has been established, BDTX-1535 monotherapy will be explored in the following Dose Expansion cohorts to further evaluate safety, PK, and preliminary assessment of efficacy: 1) rGBM with confirmed EGFR alterations, 2) NSCLC with uncommon EGFR mutations following EGFR inhibitor therapy; 3) NSCLC with acquired EGFR resistance mutation following a 3rd generation EGFR inhibitor in 1L setting. NSCLC patients may enroll with or without CNS metastases and must not be known to express excluded resistance mutations such as EGFR T790M or MET. BDTX-1535 will also be studied in combination with TMZ to assess safety, tolerability, and a recommended combination dose for the treatment of patients with rGBM harboring EGFR mutations or variants. Enrollment was initiated in 2022 and dose escalation is ongoing. Dose Expansion cohorts are expected to open in 2023. For additional information, please contact BDTX_1535_101_Study@bdtx.com. Clinical trial information: NCT05256290. Research Sponsor: Black Diamond Therapeutics.

VELOCITY-Lung: A phase (Ph) 2 study evaluating safety and efficacy of domvanalimab (dom) + zimberelimab (zim) + sacituzumab govitecan (SG), or etrumadenant (etruma) + dom + zim, or etruma + zim in patients (pts) with treatment-naïve metastatic non-small cell lung cancer (mNSCLC). *First Author: Alexander I. Spira, Virginia Cancer Specialists, Fairfax, VA*

Background: Current standard of care (SOC) for pts with mNSCLC lacking an actionable mutation includes checkpoint inhibitor (CPI), platinum (PT)-based therapy, or a combination of the two, but is associated with poor outcomes. SG is a Trop-2-directed antibody-drug conjugate. SG monotherapy resulted in a 17% objective response rate (ORR), with a manageable safety profile in pts with mNSCLC who had multiple prior therapies (Heist RS, et al. *J Clin Oncol*. 2017), and a Ph 2 study is currently ongoing assessing SG+CPI±PT-based therapy (NCT05186974) in treatment-naïve mNSCLC. Etruma (dual adenosine receptor antagonist), dom (anti-TIGIT), and zim (anti-PD-1) are under clinical investigation for antitumor activity. Substudy-01 is part of the VELOCITY-Lung Ph 2 platform study evaluating novel treatment combinations in pts with treatment-naïve mNSCLC. **Methods:** VELOCITY-Lung (NCT05633667) is an open-label, multicenter, randomized, Ph 2 platform study. Key eligibility criteria for substudy-01 include age ≥18 y; pathologically documented stage IV NSCLC at time of study entry without *EGFR*, *ALK*, or other actionable genomic alterations; no prior systemic treatment for mNSCLC; ECOG PS 0-1; any PD-L1 status. Pts previously treated in the (neo)adjuvant setting may be included if therapy was completed ≥12 mo before study drug initiation. Current treatment arms in the preliminary stage are Arm A: dom+zim+SG; Arm B: etruma+dom+zim; Arm C: etruma+zim. Dosing will be as follows: etruma 150 mg po once daily, dom 1200 mg IV q3wk, zim 360 mg IV q3wk, SG 10 mg/kg IV on D1 and D8 of a 21-D cycle. Randomization will be stratified by histology and baseline PD-L1 status (central testing; ≥50% vs < 50%). Pts are randomized equally between treatment arms (arms can be added to evaluate additional novel combinations) in the preliminary stage. Once the expansion stage opens, pts will be randomized based on the number of experimental arms in the expansion stage, the comparator arm, and any newly added preliminary stage treatment arms. Pts will continue to receive treatment until progressive disease, death, unacceptable toxicity, or initiation of a subsequent anticancer therapy. The primary endpoint is ORR assessed by investigator per RECIST v1.1. Secondary endpoints include progression-free survival, duration of response, overall survival, and safety. During the preliminary stage, efficacy will be compared with historical SOC; during the expansion stage, efficacy will be compared with an active comparator arm within the study. Depending on the number of arms being tested in the expansion stage, this study plans to enroll ~69 to 289 patients globally and is open for recruitment. Clinical trial information: NCT05633667. Research Sponsor: Gilead Sciences, Inc.

A phase II trial of JDQ443 in *KRAS G12C*-mutated NSCLC with PD-L1 expression <1% or PD-L1 expression ≥1% and an *STK11* co-mutation. *First Author: Colin R Lindsay, The University of Manchester and The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: Kirsten rat sarcoma viral oncogene homolog (*KRAS*) is the most frequently mutated oncogene in non-small cell lung cancer (NSCLC). *KRAS G12C*, the most frequent *KRAS* variant, is found in ~13% of patients (pts) with NSCLC. *KRAS* is a GTPase that regulates cell signaling pathways necessary for proliferation, differentiation, and survival. *KRAS* mutation reduces the intrinsic GTPase activity of the enzyme, allowing for the accumulation of active, GTP-bound *KRAS* and hyperactivation of downstream signaling, driving tumorigenesis. JDQ443 is a potent, selective *KRAS^{G12C}* inhibitor that irreversibly traps *KRAS^{G12C}* in its inactive, GDP bound state and blocks downstream signaling. In preliminary data from the Phase Ib part of the KontRASP-01 study (NCT04699188), JDQ443 showed promising antitumor activity and an acceptable safety profile in previously treated pts with *KRAS G12C*-mutated advanced NSCLC. Pts with *KRAS G12C*-mutated NSCLC currently receive the same first-line (1L) treatment as those without driver mutations, consisting of immunotherapy alone or combined with chemotherapy; however, ~30% of pts with NSCLC present with programmed death-ligand 1 (PD-L1) expression <1%, and ~10–20% of pts harbor an *STK11* mutation, both indicators of poor response to immunotherapy. Therefore, alternative 1L treatment options are needed for these pts. Of note, PD-L1 expression and *STK11* mutation do not affect responsiveness to *KRAS^{G12C}* inhibitors, raising interest in the evaluation of these targeted therapies as 1L alternatives to immunotherapy for pts with *KRAS G12C*-mutated NSCLC. **Methods:** KontRASP-06 (NCT05445843) is an open-label, Phase II, single-arm, multicenter study evaluating JDQ443 monotherapy (200 mg JDQ443 twice daily in 21-day cycles) as a 1L treatment for 2 cohorts of adult pts with locally advanced or metastatic, *KRAS G12C*-mutated NSCLC. Cohort A (n=90) includes pts whose tumors have PD-L1 expression <1%, regardless of *STK11* mutation status, while Cohort B (n=30) includes pts whose tumors have PD-L1 expression ≥1% and an *STK11* co-mutation. Local testing for PD-L1 status and *KRAS* and *STK11* mutations is accepted; *KRAS* and *STK11* mutations may be assessed in blood samples. A tissue sample is required for retrospective biomarker status confirmation and exploratory study. The study is currently enrolling pts into both cohorts. The primary endpoint is the overall response rate (ORR) per RECIST version 1.1, assessed by a blinded independent review committee, in Cohort A. Key secondary endpoints are ORR in Cohort B and duration of response in both cohorts. Other secondary endpoints include progression-free survival, overall survival, safety, pharmacokinetics, and p-reported outcomes. A comprehensive biomarker strategy aims to investigate predictors of treatment response and resistance in the study population. © 2023 American Association for Cancer Research®. Reused with permission. Clinical trial information: NCT05445843. Research Sponsor: Novartis Pharmaceuticals Corporation.

Poster Session

Osimertinib then chemotherapy in EGFR-mutated lung cancer with osimertinib third-line rechallenge (OCELOT). *First Author: Daniel Adam Breadner, Schulich School of Medicine and Dentistry, London, ON, Canada*

Background: The results of the FLAURA study established osimertinib as the new first-line standard of care for patients with the two 'common' types of epidermal growth factor receptor mutation-positive (EGFR+) advanced non-small-cell lung cancer (aNSCLC). Second-line (2L) treatment is typically platinum pemetrexed chemotherapy and the standard third-line (3L) treatment is docetaxel throughout much of the globe, which has a modest response rate of 7 – 15%. Previously, when first generation (1G) EGFR tyrosine kinase inhibitor (TKIs) were standard of care in the first-line setting, a number of prospective and retrospective studies examined 3L rechallenge with the same 1G EGFR TKI following 2L chemotherapy, with varying levels of success. Osimertinib is a well-tolerated EGFR TKI which is active against the T790M resistance mutation, which would have limited the efficacy of rechallenge with 1G EGFR TKIs. **Methods:** This is a multicenter international phase II investigator-initiated study of osimertinib in the 3L rechallenge of patients with EGFR+ aNSCLC, following 1L treatment with osimertinib and 2L therapy with platinum pemetrexed chemotherapy. A maximum of 255 patients will be enrolled. Patients with 'common' EGFR exon 19 deletions or L858R mutations will enroll at the start of 2L chemotherapy or 3L osimertinib rechallenge. The primary objective is 3L objective response rate (ORR) in the first 100 evaluable patients, according to RECIST 1.1. Secondary objectives include disease control rate (DCR), progression free survival (PFS), time to treatment failure, overall survival and toxicity for 3L osimertinib rechallenge. Exploratory objectives include assessment of osimertinib resistance based on serial ctDNA samples collected from all participants. The OCELOT study, NCT04335292, is actively enrolling participants. Clinical trial information: NCT04335292. Research Sponsor: AstraZeneca.

A first-in-human, open-label, dose escalation and expansion study of orally administered NX-019 in patients with advanced EGFR mutant cancer. *First Author: Alexander I. Spira, NEXT Oncology - Virginia Cancer Specialists, Fairfax, VA*

Background: CNS involvement, brain metastases and/or leptomeningeal disease, is common in patients with EGFR mutant NSCLC and occurs in 25–50% of patient's journeys. Despite the activity and increased CNS penetration of later generation EGFR inhibitors, management of CNS disease remains a clinical challenge. NX-019 is a broad-spectrum EGFR inhibitor targeting both common and rare mutations including EGFR ex20ins, G719S, and L861Q. NX-019 exhibits selective activity towards mutant vs. wt. EGFR in preclinical studies. Substantial CNS exposure has been demonstrated in animal models, as well as potent anti-tumor activity toward intracranial xenografts with prolonged inhibition of EGFR signaling. Similar drug levels compared to plasma were measured in the brains of rats and mice. NX-019 was readily detectable in the CSF of cynomolgus monkeys, dogs and rats at concentrations similar to the estimated plasma free fraction. **Methods:** NT019-101 is a first-in-human, international, open-label study designed to evaluate single-agent NX-019 in patients with EGFR-mutant, locally advanced or metastatic NSCLC that has progressed following prior treatment. Patients with ECOG performance status 0–2 and EGFR mutant cancers including stable, asymptomatic brain metastases are eligible for Dose Escalation. Patients with known *EGFR C797S* mutations and secondary drivers, e.g., *MET* amplification and *RET* fusions, are excluded. Primary endpoints are to determine recommended phase 2 dose (RP2D), maximum tolerated dose (MTD), safety and tolerability (part 1), and to evaluate antitumor activity at the RP2D by RECIST v1.1 and RANO-BM (part 2). Secondary endpoints are to evaluate pharmacokinetics (PK) and antitumor activity by RECIST v1.1 (part 1) and PK, safety, tolerability, and CNS antitumor activity (part 2). Dose escalation will utilize a 3+3 design with up to 6 patients per cohort in part 1. Part 2 will enroll patients in 5 cohorts (n = 10 or 29 each), including patients with NSCLC who have (1) new or progressing CNS metastases including leptomeningeal disease after treatment with osimertinib, (2) active CNS disease and ex20ins mutations, (3) ex20ins mutations without CNS disease and (4) other rare mutations, based on a Simon 2-stage design. First patient was treated in October 2022 and enrollment is ongoing. The study is planned for approximately 35 centers in North America and Asia-Pacific region. Clinical trial information: NCT05514496. Research Sponsor: Nalo Therapeutics Inc.

LATIFY: Phase 3 study of ceralasertib + durvalumab vs docetaxel in patients with locally advanced or metastatic non-small-cell lung cancer that progressed on or after anti-PD-(L)1 and platinum-based therapy. *First Author: Benjamin Besse, Gustave Roussy, Villejuif, France*

Background: Following progression on first- or second-line immunotherapy ± platinum-based chemotherapy (CT), the prognosis for patients (pts) with metastatic non-small-cell lung cancer (NSCLC) is poor with limited alternative options to docetaxel. Ceralasertib is a selective inhibitor of Ataxia Telangiectasia and Rad3-related (ATR) protein kinase, which is activated in response to DNA damage. Clinical data suggest that ceralasertib may sensitize tumors to immunotherapy by biasing T cells to an immune-effective phenotype. Durvalumab is a selective, high-affinity human IgG1 monoclonal antibody that binds programmed cell death ligand-1 (PD-L1) and inhibits PD-L1-mediated suppression of T-cell activation. Combining ceralasertib with durvalumab may amplify the antitumor immune response, and potentially lead to durable tumor control. In the ongoing phase 2 HUDSON study in pts with locally advanced or metastatic NSCLC who progressed on anti-PD-(L)1 therapy and platinum-doublet regimen, ceralasertib + durvalumab showed promising efficacy with median progression-free survival (PFS) of 6.0 mos (80% CI, 4.6–7.5) and median overall survival (OS) of 15.9 mos (80% CI, 14.1–20.3). **Methods:** LATIFY is a phase 3, open-label, randomized, multicenter study in pts with NSCLC (NCT05450692). Key inclusion criteria are age ≥18 years; ECOG performance status 0–1; documented *EGFR* and *ALK* wild-type, and tumor cell PD-L1 status; and adequate organ and bone marrow function. Stable brain metastases are allowed. Pts should be eligible for second- or third-line therapy, and must have received an anti-PD-(L)1 therapy and a platinum-containing doublet regimen for locally advanced or metastatic NSCLC either separately or in combination, but no other prior therapies. Key exclusion criteria include mixed small-cell lung and NSCLC histology, unresolved toxicities of Grade ≥2 (NCI CTCAE v5.0) from prior therapy, active or prior autoimmune or inflammatory disorders, > 1 line of prior anti-PD-(L)1 therapy (alone or in combination), and > 1 line of platinum-based CT in a metastatic setting. Pts are randomized 1:1 to receive either oral ceralasertib 240 mg twice daily on Days (D) 1–7 with IV durvalumab 1500 mg on D8 (28-day cycle) or IV docetaxel 75 mg/m² (D1, 21-day cycle). The primary objective is to assess efficacy by OS. Secondary objectives include evaluating efficacy by PFS, objective response rate and disease control rate by RECIST v1.1; duration of, and time to, response; time to second progression or death; OS at 12 mos; time to deterioration of health-related quality of life and physical function; determining the pharmacokinetics of ceralasertib; and assessing safety. Approximately 580 pts will be recruited from around 21 countries in the Americas, Europe, and Asia Pacific. Clinical trial information: NCT05450692. Research Sponsor: AstraZeneca PLC.

Poster Session

CAN-2409 plus prodrug with standard of care immune checkpoint inhibitor for patients with stage III/IV NSCLC. *First Author: Charu Aggarwal, University of Pennsylvania, Philadelphia, PA*

Background: Immune checkpoint inhibitors (ICI) are a standard of care (SOC) treatment that have improved outcomes for patients (pts) with non-small cell lung cancer (NSCLC). However, most pts progress, signaling a need for combination approaches to further improve outcomes. CAN-2409 is a replication-defective adenoviral construct encoding the herpes simplex virus thymidine kinase (HSV-tk) gene that is injected intratumorally followed by 2 weeks of prodrug (valacyclovir or acyclovir). HSV-tk converts the prodrug in the tumor microenvironment into a toxic metabolite, resulting in immunogenic cell death, while the adenoviral proteins provide a strong pro-inflammatory signal. Together, this leads to *in situ* vaccination against the patient's own tumor. As a result, CD8+ cytotoxic T cells are educated on how to recognize and kill tumor cells in both the injected tumor and the uninjected metastases. A completed neoadjuvant phase I trial in resectable NSCLC demonstrated safety and immune stimulation (Predina et al 2021), warranting further investigation of CAN-2409 + prodrug as a therapy that can lead to improved long-term outcomes for pts with NSCLC who have a suboptimal response to ICI.

Methods: LuTK02 (NCT04495153) is an open-label, multi-arm, phase II clinical trial to evaluate CAN-2409 + prodrug added to SOC ICI (anti-PD-(L)1) therapy in pts with stage III/IV NSCLC presenting with inadequate response (as defined below) to ICI. Cohort 1 includes pts with nonresponding but stable disease ≥ 18 weeks after starting ICI; cohort 2 includes pts with progressive disease ≥ 18 weeks after starting ICI. Key eligibility criteria include RECIST-evaluable disease; an injectable lesion (via bronchoscopy or US/IR guidance); ability to continue ICI for the treatment period; no change of ICI or prior interruptions of > 4 weeks within 6 months of enrollment; and no focal therapy at > 3 sites of disease within 12 months prior to enrollment. Key exclusion criteria include a history of ICI immune-related adverse events and known alterations in *EGFR*, *ALK*, or *ROS1*. Eligible patients receive 2 injections of CAN-2409 approximately 6 weeks apart followed by prodrug for 14 days. After treatment of ~ 40 evaluable pts in cohort 2 with two injections of CAN-2409, the protocol has been amended to include a new cohort (n ~ 20) of pts treated with three injections of CAN-2409 approximately 4 weeks apart, each followed by prodrug for 14 days, to further define the optimal therapeutic regimen. Primary endpoints are overall response and/or disease control rate per RECIST 1.1 criteria and safety of CAN-2409 + prodrug. Secondary endpoints include duration of response, PFS, OS, and biomarker studies. Exploratory endpoints include evaluation of effects in non-injected lesions, changes in non-target (per RECIST) lesions, tumor growth trajectory, and viral shedding. Clinical trial information: NCT04495153. Research Sponsor: Candel Therapeutics.

Oral Abstract Session

Significant durable response with fiantlimab (anti-LAG-3) and cemiplimab (anti-PD-1) in advanced melanoma: Post adjuvant PD-1 analysis. *First Author: Omid Hamid, The Angeles Clinic & Research Institute, A Cedars-Sinai Affiliate, Los Angeles, CA*

Background: Previous reports have demonstrated that treatment (Tx) with anti-LAG-3 Ab fiantlimab + anti-PD-1 Ab cemiplimab had a 63.8% ORR across two separate cohorts of advanced PD-(L)1 naïve metastatic melanoma (Mel) patients (pts). The benefit the fiantlimab + cemiplimab combination in pts exposed to prior anti-PD-1 Tx as adjuvant (adj) Tx is unknown. Here we present phase 1 safety and clinical activity data from pts with advanced Mel including those who received prior adj systemic Tx. **Methods:** Three separate expansion cohorts of adult pts with unresectable or metastatic Mel (excluding uveal Mel) who were anti-PD-(L)1 Tx-naïve for advanced disease were enrolled. All pts received fiantlimab 1600 mg + cemiplimab 350 mg IV Q3W for 12 months (mos) (optional additional 12 mos if clinically indicated). Study enrollment closed in June 2022. Tumor measurements were performed every 6 weeks (wks) for 24 wks, then every 9 wks. **Results:** 98 pts were enrolled and treated with fiantlimab + cemiplimab as of 01 Nov 2022 data cutoff. Median age was 68.0 years, 60.2% were male, and 89.8% were White. 2.0% of pts had received prior metastatic Tx (not anti-PD-(L)1) and 23.5% had received prior systemic Tx for Mel in the adj/neo-adj setting (disease-free interval > 6 mos), including 13.3% treated with an anti-PD-1 (nivolumab or pembrolizumab). Median follow up was 12.6 mos and median treatment duration was 32.9 wks. Grade ≥3 treatment-emergent adverse events (TEAEs), serious TEAEs, and immune-related AEs (irAEs) occurred in 43.9%, 32.7%, and 65.3% of pts, respectively. 16.3% of pts discontinued Tx due to a TEAE. Rates of irAEs were similar to anticipated rates for PD-1 monotherapy with the exception of adrenal insufficiency (AI) with 12.2% (all grades) and 4.1% (grade ≥3). RECIST 1.1-based investigator-assessed overall ORR was 61.2% (12 complete responses; 48 partial responses), with median DOR (mDOR) not reached [NR] (95% CI: 22.6– not estimated [NE]). KM estimation of median PFS (mPFS) was 15.3 (95% CI: 9.4–NE) mos. In pts with any prior adj Tx, ORR, mDOR, and mPFS was 60.9% (14/23), NR, and 13.3 mos, respectively. In pts with prior anti-PD-1 adj Tx, ORR, mDOR, and mPFS was 61.5% (8/13), NR, and 11.8 mos, respectively. Data from subgroup and correlative biomarker analyses, PK and immunogenicity will be included in the presentation. **Conclusions:** Fiantlimab + cemiplimab in advanced Mel pts showed high clinical activity that compares favorably with other approved combinations of immune checkpoint inhibitors in the same clinical setting. This is the first indication that dual LAG-3 blockade can produce high level of activity with significant ORR in pts with advanced Mel post adj anti-PD-1 Tx. The safety profile of fiantlimab + cemiplimab is similar to anti-PD-1 monotherapy with the exception of AI. A phase 3 trial (NCT05352672) of fiantlimab + cemiplimab in Tx-naïve advanced Mel pts is ongoing. Clinical trial information: NCT03005782. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Oral Abstract Session

Nivolumab (NIVO) plus relatlimab (RELA) vs NIVO in previously untreated metastatic or unresectable melanoma: 2-year results from RELATIVITY-047. *First Author: Hussein A. Tawbi, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In RELATIVITY-047 (NCT03470922), NIVO + RELA demonstrated a statistically significant progression-free survival (PFS) benefit vs NIVO; there was an observed improvement in overall survival (OS) although it was not statistically significant. The combination also had a descriptively higher confirmed objective response rate (ORR) assessed by blinded independent central review (BICR) vs NIVO. Here we report updated descriptive analyses (efficacy, safety, and secondary analyses) with longer (~2 years) follow-up. **Methods:** Patients were randomized 1:1 to receive NIVO 480 mg + RELA 160 mg fixed-dose combination or NIVO 480 mg every 4 weeks, as previously described. Primary endpoint of PFS per RECIST v1.1 was assessed by BICR; secondary endpoints included OS and ORR per BICR. Exploratory analyses were performed for melanoma-specific survival (MSS; defined as death due to melanoma, with censoring of deaths due to other causes) and efficacy outcomes on subsequent systemic therapy. **Results:** Patients received NIVO + RELA (n = 355) or NIVO (n = 359). Median follow-up was 25.3 months in this updated analysis (minimum follow-up, 21.0 months). NIVO + RELA continued to show a benefit over NIVO for PFS, OS and ORR (Table). A similar improvement was also observed in MSS. NIVO + RELA was generally favored over NIVO across key subgroups (consistent with previous reports). Subsequent systemic therapy was received by 131 (36.9%) and 136 (37.9%) patients in the NIVO + RELA and NIVO arms, respectively. Treatment-related adverse events (TRAEs; any grade) leading to treatment discontinuation were observed in 61 (17.2%) and 31 (8.6%) patients on NIVO + RELA and NIVO, respectively. Grade 3–4 TRAEs were observed in 78 (22.0%) patients on NIVO + RELA and 43 (12.0%) patients on NIVO. In total, there were 6 treatment-related deaths (NIVO + RELA, n = 4; NIVO, n = 2); no new treatment-related deaths have been reported since the last analysis. **Conclusions:** With 12.3 months of additional follow-up, a consistent benefit was observed with NIVO + RELA vs NIVO for PFS, OS and ORR in the ITT population, as well as in key patient subgroups. MSS was longer with NIVO + RELA compared with NIVO. The safety profile of NIVO + RELA remained consistent with previous reports, with no new or unexpected safety signals. Efficacy outcomes on subsequent systemic therapy (by type of subsequent therapy, including PD-L1/CTLA-4) will be presented. Clinical trial information: NCT03470922. Research Sponsor: Bristol Myers Squibb.

	NIVO + RELA (n = 355)	NIVO (n = 359)

Oral Abstract Session

Association of biomarkers (BMs) with efficacy of adjuvant nivolumab (NIVO) vs placebo (PBO) in patients with resected stage IIB/C melanoma (CA209-76K). *First Author: Georgina V. Long, Melanoma Institute Australia, The University of Sydney, and Royal North Shore and Mater Hospitals, Sydney, NSW, Australia*

Background: Adjuvant NIVO significantly prolonged recurrence-free survival (RFS) over PBO in stage IIB/C melanoma in the randomized, phase III Checkmate 76K trial (HR; 95% CI: 0.42 [0.30–0.59]). For the first time, select BMs and their association with RFS were analyzed in early-stage melanoma treated with an anti-PD-1 agent. **Methods:** Baseline primary tumor and serum BMs were analyzed, including interferon gamma-related gene expression signature (IFN γ -sig), TMB, BRAF mutation, % intratumoral CD8+ T cells, tumor cell PD-L1 expression, and serum CRP levels. BMs were evaluated as continuous variables (high vs low levels) and dichotomized by median or prespecified cutoffs. HRs were estimated using a Cox proportional hazards model. **Results:** Analysis of continuous BM levels within treatment arms showed that higher IFN γ -sig, TMB, and % CD8+ T cells, and lower CRP levels were associated with prolonged RFS with NIVO but not PBO. The same trend was observed in the dichotomized analyses. No clear association between PD-L1 expression and RFS was identified in either arm. Benefit of NIVO over PBO was seen across all BM subgroups, including by BRAF^{V600} mutation status. Patients with higher IFN γ -sig, TMB, and % CD8+ T cells, and lower CRP levels showed numerically greater relative benefit with NIVO, although CIs overlapped (Table). **Conclusions:** Higher IFN γ -sig, TMB, and % CD8+ T cells, and lower CRP levels were associated with longer RFS with NIVO treatment. No BMs assessed were prognostic for RFS in the PBO arm, in contrast to previous reports in melanoma. Prolonged RFS was seen in patients treated with NIVO over PBO across levels of BMs, and irrespective of BRAF mutational status. Composite analyses of BMs with clinical and histopathologic factors will be evaluated for their potential to optimize risk:benefit stratification for NIVO in this patient population. Clinical trial information: NCT04099251. Research Sponsor: Bristol Myers Squibb.

Association between biomarker levels and RFS (unstratified HR ^a).				
	NIVO (within arm) [526]	PBO (within arm) [264]	NIVO vs PBO arms (BM high)	NIVO vs PBO arms (BM low)
IFN γ -sig ^b	0.59 (0.41, 0.86) [425]	0.91 (0.65, 1.27) [213]	0.29 (0.17, 0.48)	0.44 (0.29, 0.66)

Oral Abstract Session

Non-comparative, open-label, international, multicenter phase I/II study of nivolumab (NIVO) ± ipilimumab (IPI) in patients (pts) with recurrent/metastatic merkel cell carcinoma (MCC) (CheckMate 358). *First Author: Shailender Bhatia, Division of Medical Oncology, University of Washington and Fred Hutchinson Cancer Center, Seattle, WA*

Background: MCC is a rare and aggressive skin cancer. Programmed death-ligand 1 (PD-L1) is often upregulated in MCC and blockade of PD-L1 or its receptor, PD-1, has improved survival for patients with metastatic MCC. Anti-PD-1 combined with anti-CTLA-4 has been reported to improve outcomes over anti-PD-1 monotherapy (NCT03071406; Kim S et al., *Lancet* 2022), however further investigation is needed. CheckMate 358 (NCT02488759) assessed NIVO ± IPI in 2 non-randomized MCC cohorts. **Methods:** Eligible pts had recurrent or metastatic MCC, ≤ 2 prior therapies, ECOG performance status (PS) 0–1, and no prior immune checkpoint inhibitor (ICI) therapy. Pts were eligible regardless of PD-(L)1 status. Pts received NIVO 240 mg Q2W or NIVO 3 mg/kg Q2W + IPI 1 mg/kg Q6W for ≤ 24 months (m) or until disease progression, unacceptable toxicity, or consent withdrawal. Imaging was conducted Q8W in year 1 and Q12W thereafter. Planned sample sizes were 23 pts for NIVO and 40 pts for NIVO + IPI. The primary endpoint was investigator-assessed objective response rate (ORR). Secondary endpoints included duration of response (DOR), investigator-assessed progression-free survival (PFS), and overall survival (OS). **Results:** 68 pts received NIVO (n = 25) or NIVO + IPI (n = 43) with ≥ 24 m follow-up (median: NIVO, 62.5 m; NIVO + IPI, 24.4 m). In the NIVO arm, median age was 66 yrs (range, 27–88), 10 (40.0%) pts had ECOG PS of 1, and 15 (60.0%) were treatment-naïve. In the NIVO + IPI arm, median age was 70 yrs (range, 48–85), 27 (62.8%) pts had ECOG PS of 1, and 33 (76.7%) were treatment-naïve. Treatment duration was 15.8 m in the NIVO arm, and 7.9 m for NIVO and 6.0 m for IPI in the NIVO + IPI arm. Efficacy and safety outcomes are summarized in the table. ORR was 60.0% (95% CI, 38.7–78.9) in the NIVO arm and 58.1% (95% CI, 42.1–73.0) in the NIVO + IPI arm. The most common reasons for treatment discontinuation were disease progression (NIVO, 28.0%; NIVO + IPI, 32.6%) or study-drug toxicity (NIVO, 20.0%; NIVO + IPI, 25.6%). There was 1 study drug-related death in each arm (NIVO, pneumonitis; NIVO + IPI, gastrointestinal motility disorder). **Conclusions:** Both NIVO and NIVO + IPI show durable clinical efficacy in advanced MCC. While the non-randomized trial design limits comparisons between the arms, results do not suggest additional efficacy benefit with IPI added to NIVO. Higher incidence of grade 3/4 TRAEs observed in the combination arm could have resulted in shorter treatment duration. Clinical trial information: NCT02488759. Research Sponsor: Bristol Myers Squibb.

	NIVO (n = 25)	NIVO + IPI (n = 43)

Oral Abstract Session

Towards organ preservation and cure via 2 infusions of immunotherapy only, in patients normally undergoing extensive and mutilating curative surgery for cutaneous squamous cell carcinoma: An investigator-initiated randomized phase II trial—The MATISSE trial. *First Author: Charlotte L. Zuur, Department of Head and Neck Surgical Oncology, Netherlands Cancer Institute (NKI-AVL), Amsterdam, Netherlands*

Background: Standard of care for locally advanced cutaneous SCC (CSCC) consists of extensive and mutilating surgery often with adjuvant radiotherapy (RT). To improve clinical prospects of these patients (pts), we tested efficacy of neoadjuvant nivolumab (NIVO) and nivolumab plus ipilimumab (COMBO) in pts with CSCC with an indication for extensive surgery with or without adjuvant RT. **Methods:** 40 pts with T1-4N0-3MO or TxN1-3MO CSCC and an indication for extensive and/or mutilating surgery were needed to reach the primary objective of this trial. Pts were randomized for ARM A: NIVO (3 mg/kg, weeks 0&2, N = 26) or ARM B: NIVO (3 mg/kg, weeks 0&2) + IPI (1 mg/kg, week 0, N = 24) prior to surgery (week 4). Primary objective was pathological response at time of surgery. A major pathological response (MPR) was defined as ≤10% residual viable cancer cells in the surgical resection specimen. Secondary endpoints were tolerability (CTCAE v5.0), survival, and quality of life (QOL). Key exploratory aim for the trial was the serial collection of pre- and on-treatment tumor samples to investigate immunogenomic features correlating with immunotherapy response. **Preliminary results:** 50 pts were enrolled at median age 76, of whom 32% with TxN1-3MO disease. Grade 3-4 irAEs occurred in 6 (12%) pts and were well manageable. 40 pts underwent standard of care surgery w/o adjuvant RT, of whom 40% and 53% reached an MPR upon NIVO and COMBO, respectively. However, 10 pts withdrew consent to undergo surgery and RT, of whom nine pts declined because of self-reported substantial clinical remission upon neoadjuvant immunotherapy. These clinical responses were confirmed via FDG-PET evaluation in week 4. All these 9 pts are currently cancer free at median FU of 12 months (range 4 to 27) with superior QOL compared to MATISSE pts undergoing standard of care. Overall, we found deep clinical responses in 13/26 (50%) and 14/23 (61%) of pts upon NIVO and COMBO, respectively, being either a MPR at time of surgery or a clinical CR in patients declining surgery. **Preliminary conclusions:** The MATISSE trial shows deep responses of 50% and 61% upon neoadjuvant NIVO and COMBO, respectively, with well manageable toxicity in this elderly CSCC population. Nine MATISSE patients have proven the concept that organ preservation and durable complete remissions can be achieved after two infusions of neoadjuvant immunotherapy only, without extensive or mutilating curative surgery and/or RT. Clinical trial information: NCT04620200. Research Sponsor: The MATISSE trial is an investigator-initiated randomized phase II trial, partly funded by Bristol-Myers Squibb; Riki Foundation (private foundation).

Oral Abstract Session

Temozolomide plus cisplatin versus toripalimab (anti-PD-1) as adjuvant therapy in resected mucosal melanoma. *First Author: Bin Lian, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Melanoma and Sarcoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Chemotherapy (temozolomide plus cisplatin) has been demonstrated to be a better adjuvant regimen compared to high-dose interferon alpha-2b in resected Mucosal Melanoma (MuM) in the pre-immunotherapy era. Yet in the present immunotherapy era, PD-1 inhibitor was recommended as a standard adjuvant therapy for resected Melanoma. No adjuvant trial comparing chemotherapy with PD-1 inhibitor in resected MuM had been reported. We conducted this study to determine the efficacies of adjuvant chemotherapy versus PD-1 inhibitor in resected MuM. **Methods:** All patients (pts) with resected MuM received chemotherapy (temozolomide 200 mg/m²/day orally on days 1 to 5 plus cisplatin 75 mg/m² i.v. on days 1-3, repeated every 3 weeks for six cycles) or Toripalimab (anti-PD-1, 3 mg/kg every 2 weeks via intravenous infusion) as adjuvant therapy from 2013 to 2019 were included retrospectively. Demographic and clinical characteristics between the two groups were matched with 1:1 by propensity score matching (PSM) to reduce the bias. After PSM, the efficacies of the two groups were compared, and subgroup analysis was performed according to the baseline characteristics. The endpoints were relapse-free survival (RFS), distant metastasis-free survival (DMFS), and overall survival (OS). Kaplan-Meier methods and Cox regressions were used to estimate median RFS, DMFS, OS and HR. **Results:** A total of 247 pts were included, of which 78 were in the Toripalimab group and 169 were in the Chemo group. PSM matched 65 pts from each of the two groups. The baseline characteristics were similar. At a median follow-up of 52.6 months (95%CI, 44.6–60.6 months), patients receiving chemo had a longer median RFS (28.2 vs. 12.0 months; HR=0.64, 95% CI, 0.42 to 0.98; P=0.04), DMFS (42.0 vs. 19.0 months; HR=0.58, 95% CI, 0.36 to 0.92; P=0.02) and OS (93.4 vs. 39.3 months; HR=0.56, 95% CI, 0.33 to 0.94; P=0.03) versus the toripalimab group (Table). **Conclusions:** Adjuvant chemotherapy (temozolomide plus cisplatin) shows remarkable longer RFS, DMFS, and OS than Toripalimab (anti-PD-1). It suggested that adjuvant chemotherapy may be a better option for patients with resected mucosal melanoma even in the present immunotherapy era. Research Sponsor: None.

Poster Discussion Session

Initial efficacy and safety of RP1 + nivolumab in patients with anti-PD-1-failed melanoma from the ongoing phase 1/2 IGYTE study. *First Author: Bartosz Chmielowski, Jonsson Comprehensive Cancer Center, University of California Los Angeles, Los Angeles, CA*

Background: Patients (pts) with melanoma who progress on anti-PD-1 therapy (anti-PD-1-failed) have limited treatment options. RP1 is an HSV-1-based oncolytic immunotherapy expressing human GM-CSF and a fusogenic protein (GALV-GP-R). Here, we present data from the first 75 pts enrolled into the registration-directed (R-D) cohort in anti-PD-1-failed melanoma (target enrollment N = 125) from the phase 1/2 IGYTE study (NCT03767348). **Methods:** Pts must have locally advanced or metastatic cutaneous melanoma with ≥ 1 measurable and injectable tumor (≥ 1 cm) and confirmed progressive disease (PD) on 2 assessments ≥ 28 days apart while on ≥ 8 consecutive weeks of anti-PD-1 $\pm$ anti-CTLA-4 therapy, with anti-PD-1 being the last treatment received. Pts on prior adjuvant anti-PD-1 therapy must have had PD confirmed by biopsy while on adjuvant therapy. RP1 is initially given intratumorally at 10^6 PFU/mL and then every 2 weeks (Q2W) at 10^7 PFU/mL for ≤ 8 total cycles (≤ 10 mL/dose) combined with nivolumab (nivo; cycles 2-8, 240 mg IV); pts then receive nivo alone (240 mg Q2W or 480 mg Q4W IV) for ≤ 2 years, with the option to reinitiate RP1 if specified criteria are met. **Results:** A total of 91 pts are included in this analysis (initial melanoma cohort, 16 pts; R-D cohort, 75 pts; data cut: Dec 30, 2022). The overall objective response rate (ORR) was 37.4% (initial cohort, 37.5%; R-D cohort, 37.3%) and 18.7% of pts achieved complete response (CR; Table). The response rates seen were also encouraging when evaluated by prior anti-PD-1 therapy setting and disease stage (Table). Responses were seen in uninjected lesions in most responding patients, including in pts with bulky and visceral disease. The majority of responses were observed in pts with PD-L1-negative tumors at baseline (17 of 52 pts with PD-L1-negative tumors responded, compared to 15 of 26 pts with PD-L1-positive tumors, and 2 of 13 pts for whom PD-L1 status was unknown). 85.3% of responses were ongoing 3.7-36.6 months from initiating therapy. Most treatment-related adverse events (TRAEs) were Grade 1-2 with the most common ($>20\%$) being fatigue, chills, pyrexia, and nausea. **Conclusions:** The initial data from this expanded cohort show that RP1 + nivo provides durable and clinically meaningful antitumor activity in pts with anti-PD-1-failed melanoma. Responses were observed in both injected and uninjected lesions, including visceral lesions. The combination continues to be well tolerated, with mostly on-target TRAEs. Additional and updated data will be presented. Clinical trial information: NCT03767348. Research Sponsor: Replimune Inc.

Oral Abstract Session

Randomized phase II trial of dabrafenib and trametinib with or without navitoclax in patients (pts) with BRAF-mutant (MT) metastatic melanoma (MM) (CTEP P9466). *First Author: Zeynep Eroglu, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Standard MAPK-targeted therapy (tx) for pts with BRAF MT MM involves combined BRAF and MEK inhibition with high efficacy in advanced melanoma, but durability of response is limited by acquired resistance. One combination, dabrafenib and trametinib (DT), was shown to be less effective in the frontline setting than combined immune checkpoint inhibition (ICI) but did achieve a 48% objective response rate (ORR) after ICI. (Atkins et al., JCO 2022) Preclinical data show that targeting mediators of apoptosis improves response and survival with BRAF-targeted tx. Navitoclax (N) is a BH3-mimetic that inhibits BCL-2, BCL-xL, and BCL-W. We previously demonstrated the safety of DTN in patients with BRAF MT solid tumors in a phase I trial. This randomized phase II study compared DTN to DT. (NCT01989585). **Methods:** Pts with BRAF MT MM were randomized 1:1 to either DT (standard dosing D 150 mg BID and T 2 mg QD) or DTN (standard DT plus N 225 mg QD) and stratified by maximal tumor burden (RECIST 1.1 sum of diameter of target lesions ≥ 100 mm or < 100 mm). The target sample size was 50 evaluable pts (25 per arm). Prior ICI, but not prior BRAF targeted therapy, was permitted. The co-primary endpoints were to estimate complete response (CR) rate for DTN compared to historic controls and to assess maximal tumor shrinkage of pts treated with DTN vs DT. Secondary endpoints included ORR, progression-free survival (PFS) and overall survival (OS). **Results:** Fifty-six pts were enrolled and 50 treated (25 DTN, 25 DT) from 1/11/19 - 3/25/22 at 13 sites. Seventeen pts (68%) in each arm received prior ICI. The ORR was 84% for DTN and 80% for DT. The CR rate for DTN was 20% and 15% for DT; this met pre-specified criteria for success of the primary CR endpoint. There was no difference in the maximal tumor shrinkage in pts treated with DTN vs DT. With median follow up of 25.9 months (mo), there was a trend for improved OS with DTN vs DT (median 36 vs 25 mo, log-rank $p = 0.07$). In the stratification cohort of 37 pts (74%) with smaller baseline tumor burden, there was a statistically significant improvement in OS among pts receiving DTN (log-rank $p = 0.05$), with two-year estimates of OS of 78% (95% CI: 0.46 to 0.93) for DTN and 57% (95% CI: 0.29 to 0.77) for DT. There was no difference in PFS between the two groups. The most common treatment-related toxicities ($> 50\%$ of pts) were nausea (36), diarrhea (31), fatigue (30), fever (28), and vomiting (27), which were not different in pts treated with DTN vs DT. **Conclusions:** In pts with BRAF MT MM, DTN was associated with a CR rate of 20% and ORR of 84%. There was a trend for improved OS in pts treated with DTN compared to DT; the difference in OS was significant in pts with smaller tumor burden. The DTN regimen may be considered for further exploration in the post-ICI setting. Updated data on survival and translational studies will be presented. Clinical trial information: NCT01989585. Research Sponsor: U.S. National Institutes of Health.

Poster Discussion Session

Efficacy and safety of tunlmetinib in patients with advanced NRAS-mutant melanoma: A multicenter, open-label, single-arm, phase 2 study. *First Author: Lu Si, Key laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: NRAS-mutant melanoma is an aggressive subtype with worse prognosis. However, no targeted therapy has been approved to date worldwide. Tunlmetinib (HL-085), a novel, potent, selective, oral small-molecule MEK1/2 inhibitor, has showed a favorable pharmacokinetics profile, acceptable tolerability and encouraging antitumor activity in the phase 1 study (BMC Med. 2023 Jan 4;21(1):2). **Methods:** This is an ongoing, multicenter, open-label, single-arm, phase 2 pivotal registration study. Patients (pts) with NRAS-mutant unresectable stage III or IV melanoma were enrolled and received tunlmetinib 12 mg orally twice daily. A historical control of objective response rate (ORR) of 10% was predefined for sample size estimation (100 pts, assuming loss to follow-up rate of 5%) and efficacy evaluation. The primary endpoint was the confirmed ORR per RECIST v1.1 assessed by independent radiology review committee. **Results:** A total of 100 pts were enrolled. All pts were included in the safety analysis set and 95 pts were included in the full analysis set (FAS) for efficacy analysis. At cut-off date (August 17, 2022), median follow-up was 7.9 months (95% CI: 6.6, 9.8). In the FAS, the median age was 58.0 years (range: 24 to 84). Sixty-four pts (67.4%) had received prior immunotherapy (PD-1/PD-L1 inhibitor). Fifty-six pts (58.9%) were acral melanoma, 16 (16.8%) mucosal melanoma and 12 (12.6%) skin melanoma. Fourteen pts (14.7%) were stage III and 81 (85.3%) stage IV. The most frequent NRAS mutation types were Q61R (40.0%), Q61K (29.5%) and G12D (9.5%). Confirmed ORR was 34.7% (95% CI: 25.3%, 45.2%). Median progression-free survival was 4.2 months (95% CI: 3.5, 5.6), overall survival was immature, and 1-year survival rates was 57.2% (95% CI, 44.7%, 67.8%). Subgroup analysis showed that, in pts who had previously received immunotherapy, the confirmed ORR was 39.1% (95% CI: 27.1%, 52.1%). The most frequent treatment related adverse events (TRAEs) were increased blood creatine phosphokinase (CK), diarrhea, peripheral edema, facial edema and increased aspartate aminotransferase. Grade ≥ 3 TRAEs occurred in 68 pts (68.0%), of which 38.0% (38/100) were increased blood CK. Most of pts with CK elevation are asymptomatic and can be managed by dose interruption or reduction without permanent treatment discontinuation. No treatment-related death was reported. **Conclusions:** Tunlmetinib was well tolerated and demonstrated encouraging treatment response rate in pts with advanced NRAS-mutant melanoma. These results indicate that tunlmetinib could be a promising treatment option for NRAS-mutant melanoma, even for those immunotherapy failed pts. Clinical trial information: NCT05217303. Poster Discussion Session

Tumor infiltrating lymphocyte (TIL) harvest and ex vivo expansion from primary and metastatic (met) uveal melanoma (UM) tumors. *First Author: Sapna Pradyuman Patel, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Adoptively transferred autologous cell therapy using tumor-infiltrating lymphocytes (TIL) is an emerging treatment for met melanoma. Responses have been seen in patients (pts) with checkpoint inhibitor-naïve and -refractory cutaneous melanoma. UM represents a disease subtype that is traditionally less responsive to immune checkpoint blockade (ICB). Preliminary studies have shown clinical utility of TIL in UM pts. However, data describing the success rates of TIL harvest and ex vivo expansion of cells from primary and met UM tumors, and of the treatment of pts with met UM, is limited. **Methods:** Between 2004 and 2019, we conducted a single-center IRB-approved trial (NCT00338377) for TIL harvest in pts age 18 and older with documented met melanoma, including UM pts. The protocol was amended to allow harvest of primary UM tumors in 2015 if the pt was dispositioned for enucleation as primary treatment. **Results:** A total of 96 UM pts underwent TIL harvest; 9 underwent treatment with TIL. Median age was 54 years (range: 28 – 86); 56% of the pts were male; 78% were Caucasian, 9% Hispanic, and 13% unknown ethnicity. Overall successful ex vivo expansion of TIL occurred in 34.8% (32/92) of UM tumors in typical tumor fragment culture with IL-2 (TIL 1.0), with higher rates observed with UM mets (29/65; 44.6%) than UM primary tumors (3/27; 11.1%). Better results were observed with a culture method (TIL 3.0) that includes agonistic stimulation of CD3 and 41BB, with 96.8% (30/31 tumors). Expansion using this new method was successful in 9/10 primary UM tumors and 21/21 UM mets. Average number of days in culture for successful initial ex vivo expansion was 33.0 days for TIL 1.0 and 17.9 days for TIL 3.0 (p -value<0.0001). Overall, the average number of TIL expanded from culture and cryopreserved for clinical use was 130.4 million for TIL 1.0 (range: 34-460) and 326.2 million for TIL 3.0 (range 102-760) (p -value<0.0001). Nine met UM pts received treatment with up to 150×10^9 post-Rapid Expansion Protocol (REP) TIL (5 TIL 1.0, 4 TIL 3.0). Median age was 53, 44% were male, and all had active liver mets with a median of 3 lines of prior treatment for advanced disease. 8 of the TIL products were from UM mets (4 soft tissue, 3 liver, 1 combination of soft tissue and liver tumors), and 1 was from primary UM tumor, for which TIL could only be expanded with TIL 3.0. Best overall response rate per immune-related response criteria was 22% partial response (PR, duration of response was 22.1 months and 16.5 months), 44% stable disease (SD), and 33% progression of disease (PD) for a disease control rate of 66% (PR + SD). Both responding pts had TIL harvests from mets and had previously progressed on ICB, one was treated with TIL 3.0. **Conclusions:** TIL harvest and successful ex vivo expansion of cells is possible from both primary and met UM with TIL 3.0 culture method and can be therapeutically effective. Clinical trial information: NCT00338377. Research Sponsor: U.S. National Institutes of Health.

NeoPlus: A phase II study of neoadjuvant lenvatinib and pembrolizumab in resectable mucosal melanoma. *First Author: Lili Mao, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Melanoma and Sarcoma Oncology, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Combination therapy of anti-PD1 agent with VEGFR inhibitor is a promising therapeutic approach in unresectable or metastatic mucosal melanoma. We conducted this study evaluating neoadjuvant lenvatinib and pembrolizumab in pts with resectable mucosal melanoma. **Methods:** This was a single-arm, open-label, single-center, ongoing phase 2 study conducted from Sep 2021. Eligible pts were adults (18-75 yr) with histologically confirmed, resectable mucosal melanoma. Pts received lenvatinib 20mg qd and pembrolizumab 200mg q3w for 2 cycles, followed by surgery. Pembrolizumab (200mg q3w) continued post operatively for further 15 cycles. The primary endpoint was complete pathologic response (pCR). Secondary endpoints were Event free survival (EFS), Overall survival (OS) and safety. **Results:** As of Dec 2022, 19 pts were enrolled with a median follow-up of 49 wks (95%CI, 38 -60). Median age was 57 yrs, 14 were female. Primary sites included: 8 female genital, 6 ano-rectal, 4 head & neck (1 nasal, 3 oral), 1 esophageal. 12 pts were localized disease, 7(37%) were regional lymphatic disease. KIT or NRAS mutations were presented in 2 and 3 pts, respectively. 15 pts underwent surgery, 2 pts had a pCR (13.3 %), 1 MPR, 3 pPR, with a pathologic response rate of 40%(6/15,95%CI 16-67%). 4 pts did not proceed with planned surgery for pts preference. Median EFS has not been reached. IHC data of the resected tumor showed higher CD8+ T cells density in responders ($R=pCR+MPR+pPR$) than non-responders ($NR=pNR$) ($p=0.04$). In 6 pts (one pPR and 5pNR) with paired pre and post treatment samples, CD3+ and CD8+ T cells were significantly increased following treatment ($p=0.03$). Most common AEs were proteinuria (6, 32%), hypothyroidism (6, 32%), dysphonia (5, 26%). One pt(5%, 1/19) had grade 3 ALT elevation. No grade 4-5 toxicities were observed. **Conclusions:** The combination of pembrolizumab plus lenvatinib as neoadjuvant therapy in resectable MM is safe. The preliminary data has shown promising pathologic response with increased CD8+ T cell infiltration, supporting further investigation of neoadjuvant treatment in MM. Poster Discussion Session

Revisiting the optimal neoadjuvant immunotherapy regimen in resectable stage III melanoma based on the interferon gamma signature: A pooled analysis. *First Author: Minke W. Lucas, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Neoadjuvant anti-PD1 has been shown to be superior to adjuvant administration. Combination of neoadjuvant ipilimumab (IPI) + nivolumab (NIVO) induces even higher pathologic response rates (pRR) and event-free survival (EFS), but at the cost of higher toxicity. We previously showed that the interferon gamma (IFN- γ) signature is associated with a higher pRR after neoadjuvant IPI+NIVO. We hypothesized that IFN- γ high patients (pts) might benefit from less toxic anti-PD1 monotherapy (mono), while IFN- γ low pts might need an escalated regimen with IPI 3mg/kg + NIVO 1mg/kg. **Methods:** In this pooled analysis, pts with macroscopic nodal melanoma who received neoadjuvant NIVO 1mg/kg + IPI 3mg/kg (IPI3/NIVO1), IPI 1mg/kg + NIVO 3mg/kg (IPI1/NIVO3), sequential IPI 3mg/kg and NIVO 3mg/kg (IPI3>NIVO3), or NIVO mono (240mg; IFN- γ high pts only) from the OpACIN-neo, PRADO and DONIMI trials, were analyzed according to their baseline IFN- γ signature. RNA gene expression from baseline tumor biopsies was analyzed using the Nanostring nCounter platform. The IFN- γ scores were calculated using an algorithm and cut-off previously developed at the NKI and prospectively tested in the DONIMI trial. **Results:** Baseline tumor material was available from 151 pts (Table). Median follow-up was 42 months for the entire cohort and 19 months for NIVO mono pts. Combined IPI+NIVO in IFN- γ high pts induced similar major pathologic response (MPR) rates compared to NIVO mono in IFN- γ high pts (71% vs 80%, $p=0.715$), and significantly higher MPR rates compared to IPI+NIVO in IFN- γ low pts (71% vs 45%, $p=0.003$). At 18-months, EFS rates were 87%, 100% and 73% respectively, and overall survival (OS) rates were 98%, 100% and 96%. Notably, IPI3/NIVO1 seemed to induce a higher MPR rate than IPI1/NIVO3 in IFN- γ low pts (64% vs 41%), which was not statistically significant due to small subgroups. At 36 months, EFS was 91% vs 62% and OS was 91% vs 82%. **Conclusions:** Neoadjuvant NIVO mono seems to have equal outcomes as IPI+NIVO in IFN- γ high pts. IFN- γ low pts may benefit from IPI+NIVO with higher doses of IPI. Incorporating baseline biomarkers like the IFN- γ signature algorithm in neoadjuvant treatment decisions will optimize the risk-benefit ratio for these pts. Research Sponsor: BMS and 4SC.

IFN- γ score	Neoadjuvant regimen	No. pts	MPR (%)	EFS	EFS	OS	OS

Final clinical results and first translational correlates of a phase 2 trial of adaptively dosed nivolumab and ipilimumab based on early radiographic assessment in advanced melanoma (ADAPT-IT). *First Author: James William Smithy, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Initial results from ADAPT-IT (NCT03122522) demonstrated that adaptive dosing of nivolumab (nivo) and ipilimumab (ipi) based on early radiographic assessment was associated with comparable response rates and toxicity compared to historical data for conventional nivo + ipi. Here, we report the final clinical analysis, including median progression-free survival (PFS), and present the first correlative analyses of blood-based biomarkers of response. **Methods:** ADAPT-IT was a multicenter, phase 2 clinical trial with a planned sample size of 60 patients with unresectable melanoma. Patients received two doses of nivo (1 mg/kg) + ipi (3 mg/kg) followed by a computed tomography scan at week 6. Patients with early favorable antitumor effect (FATE; defined as the absence of new lesions and $\leq 4\%$ index lesion tumor growth), discontinued ipi and continued nivo alone. Patients without FATE at week 6 received third and fourth doses of nivo + ipi followed by nivo alone. The primary endpoint was investigator-assessed overall response rate (ORR; defined as the percent of patients with complete or partial responses by RECIST v1.1) at week 12. A Simon two-stage design was employed where a 43% 12-week ORR was considered not promising, a 60% 12-week ORR was considered promising, and the probabilities of type I and type II error were each set at 0.10. Pre- and on-treatment peripheral blood samples were assayed for 1) ten cytokines using a multiplex immunoassay (Meso Scale Diagnostics) and 2) circulating tumor DNA (ctDNA) using the MSK-ACCESS sequencing platform. The Wilcoxon rank sum test and Cox regression modeling were used to evaluate associations between biomarker levels with radiographic response and PFS, respectively. **Results:** 60 patients were enrolled. Week 12 and best ORR were 48% (95% CI, 35-61%) and 58% (95% CI, 45-71%), respectively. Median follow-up was 34 months (interquartile range: 21-36) in survivors, median PFS was 21 months (95% CI: 11-not reached) and the median overall survival was not reached. There were no new Grade 3-5 treatment-related adverse events since the initial report. Higher baseline IL-6 was observed in non-responders compared to responders ($p = 0.03$; $n = 26$) and was associated with shorter PFS (HR for progression or death 1.24; 95% CI: 1.01-1.52; $p = 0.04$). Among 20 patients with detectable ctDNA at baseline (of 25 patients with available samples), an increase in mean adjusted variant allele fraction from baseline to week 6 was associated with shorter PFS (HR 1.14; 95% CI: 1.02-1.27; $p = 0.02$). **Conclusions:** In this updated analysis, now with long-term follow-up, the efficacy of adaptively dosed nivo + ipi resembles that of historical data for standard dose nivo + ipi. Baseline IL-6 and on-treatment changes in ctDNA warrant further prospective study as biomarkers of response to ipi + nivo. Clinical trial information: NCT03122522. Research Sponsor: Bristol Myers Squibb.

Poster Discussion Session

Cemiplimab for kidney organ transplant recipients with advanced cutaneous squamous cell carcinoma: CONTRAC-1. *First Author: Glenn J. Hanna, Dana-Farber Cancer Institute, Boston, MA*

Background: Solid organ transplant recipients are often excluded from immunotherapy trials given the risk of allograft rejection and loss. We report the results of the first prospective study using the PD-1 inhibitor Cemiplimab (Cemi) for kidney transplant recipients (KTR) with advanced, incurable cutaneous squamous cell carcinoma (cSCC), adopting a standardized approach to immunosuppression (IS) with mTOR inhibition and dynamic prednisone (NCT04339062). **Methods:** This single-arm, open-label prospective clinical trial enrolled KTRs (eGFR ≥ 30 mL/min without proteinuria) with advanced cSCC, ECOG ≤ 2 , measurable disease (RECIST v1.1), with no prior immunotherapy exposure. KTRs received mTOR inhibition (target trough 4-6 ng/mL) with a prednisone taper each cycle (40 mg on day -1 to 3, 20 mg days 4-6, 10 mg days 7-20) along with Cemi 350 mg IV every 21-days. Primary endpoint: rate of rejection (futility defined as $\geq 2/3$ or $4/6$ KTRs with rejection events). Secondary endpoints: overall response rate (ORR), duration of response, progression-free survival (PFS), overall survival (OS), infection rates. Exploratory: baseline tumor PD-L1 score, molecular and immunologic predictors of response. **Results:** From 11/2020 to 1/2023, 10 KTRs (median years from transplant: 8, range: 3-31) enrolled including 8 (80%) men, median age 64 (range: 43-86), median eGFR 48 (range: 32-60) often with head and neck primaries (9, 90%) and distant metastases (7, 70%). Six (60%) had prior systemic therapy. For mTOR inhibition, 7 (70%) received sirolimus and 3 (30%) everolimus. At a median follow-up of 6.3 months (range: < 1 -24.9), no patients experienced kidney allograft rejection or loss. Of 8 evaluable patients, ORR was 50% (2 CR, 2 PRs), while 4 had PD. At data cutoff no responder had progressed, with 2/4 in response > 18 months (range: < 1 -22.7+). One patient is pending first restaging; 1 was unevaluable (died before first restaging). One KTR with initial PD experienced a subsequent durable response to cetuximab. Fatigue (40%) and limb edema (30%) were the most common treatment-related adverse events (TRAEs). Grade 3+ TRAEs occurred in 5 (50%) patients including diarrhea, infections ($n = 3$), and electrolyte derangements; there were no Cemi-related deaths. Median PFS was 7.9 mos (95%CI: 1.2-not reached [NR]); the 3-month OS estimate was 61% (95%CI: 27-83). Baseline tumor PD-L1 scores ranged from 0-5%; median TMB was 49 muts/Mb (range: 10-97). Tumor mutations in *TP53*, *CDKN2A*, and *NOTCH1* were common. Exploratory tumor/circulating multiparametric immune profiling and circulating tumor (ct)DNA findings will be presented. **Conclusions:** Using IS with mTOR inhibition and dynamic prednisone resulted in no kidney allograft rejection among KTRs treated with Cemi for advanced cSCC. Durable anti-tumor efficacy was observed. mTOR inhibition with prednisone should be the preferred IS regimen when treating KTRs with anti-PD-1 therapy. Clinical trial information: NCT04339062. Research Sponsor: Regeneron Pharmaceuticals.

Efficacy of adjuvant therapy in patients (pts) with AJCC v8 stage IIIA cutaneous melanoma. *First Author: Piyush Grover, Melanoma Institute Australia, Sydney, Australia*

Background: Pts with resected AJCC v8 stage IIIA melanoma have been under-represented in clinical trials of adjuvant drug therapy. The benefit of adjuvant targeted and immunotherapy in this population is unclear. **Methods:** In this multicenter, retrospective study, pts with stage IIIA melanoma (AJCC v8) who received adjuvant pembrolizumab or nivolumab (PD1), BRAF/MEK-targeted therapy dabrafenib + trametinib (TT), or no adjuvant treatment (OBS) were included. Recurrence free survival (RFS), distant metastasis free survival (DMFS), and toxicity rates were examined. **Results:** 613 pts from 34 centers across Australia, Europe and USA were included. The median follow-up was 2.6 yrs (IQR, 1.6-3.4 yrs). Pt characteristics and follow-up were similar across the cohorts (Table). Completion rates of 12-month PD1 and TT therapy were 57.0% and 69.2% respectively. 1-yr RFS was 93.3% (95% CI, 90.3-96.4) in PD1, 100% in TT and 91.3% (95% CI, 88.1-94.7) in OBS cohorts. 2-yr RFS was 79.3% (95% CI, 74.1-84.8) for PD1, 100% for TT and 84.3% (95% CI, 79.9-89.0) in OBS cohorts. 2-yr DMFS was 88.4% (95% CI, 84.3-92.8) in PD1, 100% in TT and 91.1% (95% CI, 87.7-94.7) in OBS cohorts. Risk of recurrence was associated with higher Breslow thickness (HR 1.73, 95% CI 1.36-2.20), higher mitotic rate (HR 1.07, 95% CI 1.02-1.12) and neck as the site of nodal metastases (HR 2.71, 95% CI 1.45-5.06) in the overall cohort ($p < 0.05$). Neck nodal metastases were associated with higher risk of recurrence in OBS cohort (HR 3.82, 95% CI 1.91-7.66; $p < 0.05$) but not in the PD1 cohort. Rates of $\geq$ Grade 3 toxicities were 10.9% with PD1 and 20.0% with TT; discontinuation due to toxicity occurred in 25.0% and 30.0%, respectively. No new safety signals were observed. Rates of unresolved toxicity at last follow-up were 26.9% in PD1 and 7.7% in TT cohorts. **Conclusions:** In this large international study, adjuvant PD1 or TT did not significantly improve RFS or DMFS compared to OBS in pts with resected stage IIIA melanoma. Prognosis in stage IIIA melanoma is favourable and outcomes after adjuvant therapy in this population needs further study in prospective randomised trials. Research Sponsor: None.

Role of nivolumab maintenance therapy in advanced melanoma patients following severe immune-related adverse events from combination nivolumab and ipilimumab. *First Author: Anna Maloney, Frank H Netter MD School of Medicine, North Haven, CT*

Background: The combination of ipilimumab (ipi), and nivolumab (nivo) has been shown to be a highly effective treatment for metastatic melanoma. However, immune-related adverse events (irAEs) are common with this treatment, leading to treatment interruption and the use of immunosuppressive agents. There are no data on the impact of resuming single agent nivo on survival outcomes following recovery from the irAE and completion of immunosuppressive treatment. Some physicians hold therapy permanently as done on clinical trials and other physicians resume nivo after steroid taper. **Methods:** In this retrospective analysis, we examined a cohort of patients treated with ipi/nivo who developed irAEs that required treatment interruption and immunosuppressive therapy. The differences in practice patterns among physicians at our institution allowed us to examine the effect of single agent nivo resumption on survival after treatment of irAEs. Multivariate analysis of clinical factors associated with improved survival was performed. **Results:** We identified 165 patients who were treated with ipi/nivo and developed irAEs requiring treatment interruption and immunosuppressive therapy. To remove any impact of immediate disease progression on the analysis patients who progressed on ipi/nivo prior to or during treatment hold were removed from analysis. Of the remaining 131 patients, 45 resumed single agent maintenance nivo following the resolution of toxicity and completion of steroid taper. When stratified by age and adjusted for sex, M-stage, LDH, duration of therapy, and type of irAE causing the treatment pause, the effect of resumption of nivo upon survival remained highly significant ($p = 0.001$). Patients who resumed nivo had an 82% reduction in the hazard of death compared with patients who had not yet or never resumed nivo (HR: 0.18, 95% CI: 0.06 to 0.52). Of the patients who resumed nivo, 12 (26%) patients had subsequent irAEs with 5 patients having grade 3 irAEs (only one of whom had a recurrence of the prior ipi/nivo associated toxicity) and no grade 4 or 5 irAEs were noted. **Conclusions:** The resumption of single agent maintenance nivolumab following a treatment hold for ipi/nivo associated irAE and completion of immunosuppressive therapy increased overall survival compared to discontinuing nivo permanently in patients with metastatic melanoma after stratification for many factors. Toxicity observed post resumption of single agent nivolumab was manageable with no severe irAEs observed. These results suggest that restarting maintenance nivo post irAEs should be studied prospectively. Research Sponsor: Dana-Farber Cancer Institute.

Real-world treatment patterns and clinical outcomes among subgroups of BRAF-positive metastatic melanoma patients treated with dabrafenib + trametinib. *First Author: Zeynep Eroglu, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Whether disease attributes such as tumor burden or central nervous system (CNS) metastases can affect outcomes for patients with BRAF+ metastatic melanoma (MM) is currently unclear. This study examined real-world patient characteristics, treatment patterns, and clinical outcomes among subgroups of patients with BRAF+ MM treated with dabrafenib + trametinib (dab/tram) in the United States. **Methods:** This retrospective cohort study used the nationwide Flatiron Health electronic health record-derived de-identified database from 1/1/2014 to 9/30/2021. Included patients were aged ≥ 18 years with a diagnosis of BRAF+ MM and received first-line (1L) dab/tram. Patients were stratified into 4 subgroups: high tumor burden (HTB; ≥ 3 sites of metastasis and lactate dehydrogenase [LDH] ≥ 333 IU/L), low tumor burden (LTB; < 3 sites of metastasis and LDH < 333 IU/L), with CNS metastases (prior to 1L dab/tram), and without CNS metastases (prior to 1L dab/tram). Patient characteristics and treatment patterns were evaluated descriptively. Given the potential patient overlap between subgroups, no comparative statistics were conducted. Real-world progression-free (rwPFS) and overall survival (OS) were explored from dab/tram initiation. **Results:** Among 460 included patients (mean age 60 years, 64% male), 66 (14%) had a HTB, 69 (15%) had a LTB, 164 (36%) had CNS metastases, and 296 (64%) did not. Patient characteristics were comparable across the subgroups. Over 60% of HTB patients had documented metastases in each of the liver, lung, bone, lymph nodes, and other sites. Only lung metastases had $> 60\%$ prevalence among patients with a LTB. Overall, 51% of the included patients went on to receive a second-line therapy; LTB patients and those without CNS metastases had a longer time to next therapy. The median rwPFS and OS were significantly shorter among patients with a HTB vs LTB, and among patients with vs without CNS metastases (Table). **Conclusions:** Both tumor burden and presence of CNS metastases appear to have a significant impact on survival among BRAF+ MM patients treated with 1L dab/tram. With growing use of 1L immunotherapy in MM, 1L BRAF/MEK inhibitors are increasingly being used in patients with a worse prognosis, which may explain the lower rwPFS and OS with dab/tram when compared with clinical trials. The validity of a machine learning algorithm in predicting response to immune checkpoint inhibitors in melanoma. *First Author: Faisal Fa'ak, Laura and Isaac Perlmutter Cancer Center, NYU School of Medicine, Mineola, NY*

Background: We previously reported the development of a machine learning algorithm to predict immunotherapy response in patients with advanced melanoma using retrospectively collected pretreatment histologic slides (Johannet et al, CCR 2021). In this study, we tested the validity of the same algorithm in two independent cohorts of melanoma patients enrolled in phase III clinical trials of immune checkpoint inhibitors (ICI), one metastatic, and one adjuvant. **Methods:** We examined 336 patients enrolled in CheckMate 067(NCT01844505) and CheckMate 238 (NCT02388906). We used deep convolutional neural networks (DCNN) to automatically segment images into three regions of interest: tumor, lymphocytes, and stroma. The algorithm was previously trained and tested to predict the complete and partial response (CR/PR) versus progression of disease (POD) and to predict the probability of progression-free survival (PFS) while on ICI. We tested the performance in the two cohorts; the first (CheckMate 067) included 164 patients with stage III/IV unresectable melanoma who received ipilimumab (n= 49), nivolumab (n = 59), or combination (n= 56) therapy as a first line, then tested whether the algorithm could perform as well in the second cohort (CheckMate 238) which included 172 patients with stage III/IV resectable melanoma who received adjuvant ipilimumab (n = 87) or nivolumab (n = 85) therapy as first line. **Results:** The segmentation classifier identified tumor within slides with an area under the curve (AUC) of 0.99. A combined model of DCCN and treatment predicted POD with an AUC of 0.72 in metastatic melanoma patients enrolled in Checkmate 067. The DCCN classified patients into high and low risk based on their likelihood of PFS (P < 0.0001). However, the same algorithm is not effective in predicting recurrence in patients treated in the adjuvant setting in Checkmate 238 (AUC 0.52). Retraining and testing using only patients treated in the adjuvant setting improved the AUC average to 0.65-0.70. **Conclusions:** Our results show the reproducibility of our previously developed algorithm in predicting response in patients with advanced metastatic melanoma. The inability of the model to predict recurrence in patients treated in the adjuvant setting might reflect the difference in the endpoint tested (response versus recurrence), which requires further training on larger datasets for this particular endpoint prediction, and/or the limited tumor volume in resected disease below a threshold that machine learning can predict a difference. Subsets of interferon signaling and response to immune checkpoint blockade. *First Author: Daniel Lee, Yale School of Medicine, New Haven, CT*

Background: Interferon (IFN) signaling in tumors is critical for both response and resistance to immune checkpoint inhibitors (ICI). While PD-L1 is an approved biomarker for ICI response in some cancers, most have no approved biomarkers for ICI response. Further, there are no clinical strategies to predict IFN sensitive vs resistant states. We hypothesized that distinct patterns of IFN signaling in melanoma, including STAT1 (precursor to IFN signaling), phosphorylated STAT1 (pSTAT1, marker of active IFN signaling), and PD-L1 (canonical inhibitory output), are associated with response or resistance to ICI. **Methods:** Samples from 2 tissue microarrays of 97 patients total with metastatic melanoma who received ICI from 2011-2017 were randomized into discovery [D] or validation [V] cohorts. Multiplexed immunofluorescent microscopy was used to assess STAT1, pSTAT1, and PD-L1. 54 tumors were assessed for CD3. Signals were quantified via AQUA (Automated Quantitative Analysis). High vs low signals were defined around the discovery cohort median AQUA scores. Treatment response was assessed using RECIST, and 3-year survival was analyzed. For *in vitro* studies, 4 human melanoma cell lines were stimulated with IFN- γ / β , and Western blots were performed for STAT1, pSTAT1, and PD-L1. **Results:** Median follow up time was 20.2 mos (range 0.9-95.4 mos). Higher overall histospot, tumor, and nuclear STAT1 were in responders (CR/PR/SD > 6 mos) compared to non-responders (SD < 6 mos/PD, histospot p = 0.029 [D] and 0.040 [V]) and were associated with improved survival (histospot HR 0.25 [95% CI 0.08-0.76] p = 0.015 [D]; HR 0.32 [95% CI 0.12-0.84] p = 0.021 [V]). PD-L1 and pSTAT1 did not validate as associated with ICI response/survival. While many tumors had concordant high/low STAT1, pSTAT1, and PD-L1, many also had a discordant STAT1 or PD-L1 predominance. To assess the basis of this discordance, we performed IFN stimulation and Western blots of melanoma cell lines. IFN β upregulated STAT1 greater than PD-L1 in both acute and chronic settings (p < 0.001 and < 0.001), while chronic IFN- γ upregulated PD-L1 compared to the acute setting (p = 0.039) but not STAT1 (p = 0.105). Therefore, we hypothesized patients with discordant STAT1 and PD-L1 expression may have differential responses to ICI. In the overall cohort, STA-T1^{high}PD-L1^{high} tumors (IFN engaged) were associated with improved survival compared to STAT1^{low}PD-L1^{low} tumors (IFN low, HR 0.28 [95% CI 0.11-0.70] p = 0.007). Interestingly, STAT1^{high}PD-L1^{low} tumors were associated with improved survival compared to STAT1^{low}PD-L1^{high} tumors (HR 0.28 [95% CI 0.08-0.94] p = 0.04). Accordingly, STAT1^{high}PD-L1^{high} and STAT1^{high}PD-L1^{low} tumors had greater CD3 AQUA scores compared to STAT1^{low}PD-L1^{low} tumors (p < 0.001 and p = 0.018 respectively). **Conclusions:** Combined STAT1 and PD-L1 expression patterns may better predict melanoma response to ICI and provide insight into IFN sensitive versus resistant states. Identification of RPTOR mutation as a novel predictor of efficacious immunotherapy in melanoma. *First Author: Yongzhao Li, Shijiazhuang People's Hospital, Shijiazhuang, China*

Background: mTOR pathway is known to influence cancer immunity by metabolism reprogramming. RPTOR (Regulatory Associated Protein of MTOR Complex 1), one of mTOR pathway genes, which is involving in control of mammalian target of mTORC1 activity for regulating cell growth and survival. Whether mutations of RPTOR are associated with clinical efficacy of immune checkpoint inhibitors (ICIs) in melanoma is still ambiguous. **Methods:** In discovery cohort, we retrospective analyzed the genomic data of 418 melanoma samples which derived from seven immunotherapy studies (<http://www.cbioportal.org/>) to evaluate the relationship between RPTOR mutation status and efficacy of immunotherapy. Then in validation cohort, the predictive value of RPTOR mutation was confirmed in 320 melanomas from MSKCC cohort (<http://www.cbioportal.org/>). TMB was calculated as the total count of nonsynonymous mutations in coding sequence. We used the CIBERSORT to evaluate the 22 types immune cell infiltration status in TCGA melanoma cohort. **Results:** The TMB level of RPTOR-mutant patients was higher than RPTOR-wildtype patients in both discovery (Median [IQR]: 43.11[23.76-140.15] vs. 6.13[2.07-13.66], P < 0.001) and validation (Median [IQR]: 37.38[20.17-84.95] vs. 8.85[3.35-21.07], P < 0.001) cohort. In discovery cohort, compared to RPTOR-wildtype patients, the RPTOR-mutant patients achieved prolonged OS (median OS: not reach, NR vs 22.7 months, HR (95%CI): 0.47(0.22-0.99), P = 0.043). This result was confirmed in validation cohort (median OS: NR vs. 42; HR (95%CI): 0.34 (0.11-1.0); P = 0.049). According to analysis of immune cell infiltration status, the mechanism of the predictive values of RPTOR mutations to ICI efficacy may be activated CD4 memory T cell more abundant in RPTOR-mutant tumors. **Conclusions:** RPTOR mutation is associated with higher TMB in ICI-treated melanoma patients. Survival analysis shows RPTOR mutation have a good link with longer OS after immunotherapy. These findings indicate that RPTOR mutation may serve as a potential predictive biomarker for ICIs in melanoma. Research Sponsor: None.

CHARLI: A phase Ib/II trial of ipilimumab-nivolumab-denosumab or nivolumab-denosumab in patients with unresectable stage III and IV melanoma. *First Author: Peter Kar Han Lau, Peter MacCallum Cancer Centre, Sir Charles Gairdner Hospital, Harry Perkins Institute for Medical Research, University of Western Australia, Melbourne, Australia*

Background: Denosumab (deno) is an antibody directed against Receptor Activator of NF Kappa-b ligand (RANKL) with established indications as a bone anti-resorptive agent in several cancers. Pre-clinical studies and several case series suggest anti-RANKL can enhance the anti-tumor effect of immune checkpoint inhibitors possibly via modulation of Treg and M2 macrophages. We did a multicentre phase Ib/II trial (NCT03161756) to investigate the safety and efficacy of deno in combination with nivolumab (nivo) or ipilimumab-nivolumab (ipi-nivo). **Methods:** Patients (pts) with unresectable stage III or IV melanoma were recruited to either Arm A (nivo-deno) or Arm B (ipi-nivo-deno) as first-line therapy. In Arm A pts received nivo 3 mg/kg IV q2 weekly for 4 doses and deno 120 mg SC on D1, D8, D15, D29 and then maintenance nivo 480 mg IV with deno 120 mg SC q 4 weekly. In Arm B pts received combined ipi 3mg/kg with nivo 1 mg/kg IV 3 weekly for 4 doses with deno 120 mg SC on D1, D8, D15, D29 followed by 4 weekly maintenance nivo 480 mg with deno 120 mg. Co-primary endpoints were median PFS and grade 3-4 treatment related adverse events (TRAE) of interest. Secondary endpoints were objective response rate (ORR) and overall survival (OS). **Results:** 27 pts (15 males, median age 67 years, 48% (13/27) stage IVM1c, 26% elevated LDH, 31% BRAF^{V600} mutant) were enrolled in Arm A and 24 of 25 evaluable pts (16 males, median age 62, 46% (11/24) stage IVM1c, 13% (3/24) stage IVM1d, 30% elevated LDH and 33% BRAF^{V600} mutant) were enrolled in Arm B. Median follow up was 30.8 months (m) for Arm A and 24.8 m for Arm B. The RECIST 1.1 ORR was 56% (n=15/27, 15% (4/27) complete responses [CR] and 41% (11/27) partial response [PR]) for Arm A and 71% (17/24, 25% (6/24) CR and 46% (11/24) PR) for Arm B. The median PFS in both arms has not been reached with 12 month PFS rates of 59% (95%CI: 43-81) and 63% (95%CI: 46-88) for Arms A & B, respectively. Grade 3-4 TRAE were 11% (3/27) in Arm A and 71% (17/24) in Arm B. Common TRAE (≥10%) in Arm A was rash (52%), pruritus (30%), fatigue (26%), nausea (19%), diarrhoea/colitis (15%), arthralgia (11%), vitiligo (11%), hyperthyroidism (11%). Common TRAE (≥10%) in Arm B included rash (63%), fatigue (54%), diarrhoea/colitis (54%), hepatitis (46%), hyperthyroidism (29%), pneumonitis (29%), pruritus (25%), increased GGT (17%), hypothyroidism (17%), hypocalcaemia (13%). Arm B G3-4 TRAE included diarrhoea/colitis (25%), pneumonitis (17%) and hepatitis (13%). **Conclusions:** Nivo-deno and ipi-nivo-deno had numerically similar G3-4 TRAE compared to nivo and ipi-nivo. The median PFS, 12 month PFS and ORR for nivo-deno and ipi-nivo-deno are encouraging compared with CHECKMATE 067. Clinical trial information: NCT03161756. Research Sponsor: Amgen and Bristol Myers Squibb.

Preliminary safety and efficacy results from an open-label, multicenter, phase 1 study of RP2 as a single agent and in combination with nivolumab in a cohort of patients with uveal melanoma. *First Author: Joseph J. Sacco, The Clatterbridge Cancer Centre and University of Liverpool, Liverpool, United Kingdom*

Background: Uveal melanoma, although rare, represents the most common primary intraocular tumor in adults and is associated with high risk of liver metastases. Effective treatments are limited as uveal melanoma is an immunologically cold tumor that does not respond well to immunotherapy. RP2 is an enhanced-potency oncolytic herpes simplex virus type 1 expressing human granulocyte-macrophage colony-stimulating factor, fusogenic gibbon ape leukemia virus glycoprotein with the R sequence deleted (GALV-GP-R-), and an anti-CTLA-4 antibody-like molecule. Here, we present updated safety and efficacy data of RP2 monotherapy and RP2 + nivolumab (nivo; anti-PD-1) in patients (pts) with uveal melanoma. **Methods:** Pts ≥18 years old with histologically or cytologically confirmed advanced or metastatic non-neurological solid tumors (including uveal melanoma) who progressed on or could not tolerate standard therapy were included; pts had ≥1 measurable and injectable tumor (≥1 cm). After determination of the recommended phase 2 dose of RP2 (concentration of 10⁶ plaque-forming units [PFU]/mL intratumorally [IT] once followed by up to 7 additional IT doses at 10⁷ PFU/mL; [≤10 mL total/treatment day with amount per lesion determined by tumor diameter]), pts received RP2 monotherapy every two weeks (Q2W) or RP2 Q2W + nivo (NCT04336241). Responses were assessed using modified Response Evaluation Criteria in Solid Tumors version 1.1. **Results:** As of December 30, 2022, 17 pts with uveal melanoma were enrolled (RP2 monotherapy, n = 3; RP2 + nivo, n = 14). The majority of pts received both anti-PD-1 and anti-CTLA-4 therapy (12/17, 70.6%) and 17.6% received ≥3 prior lines of therapy. The overall objective response rate for the 14 pts with sufficient follow up for analysis was 28.6% [4/14] (all partial responses [PRs]; RP2 monotherapy, 1/3; RP2 + nivo, 3/11). The disease control rate (complete response + PR + stable disease [SD]) was 57.1% (8/14; 4 pts with SD in RP2 + nivo cohort). The median (range) duration of response at the data cut-off was 5.8 (1.7–14.7) months. The most common overall Grade 1–2 treatment-related adverse events (TRAEs; ≥20%) were pyrexia, chills, fatigue, and hypotension. The only Grade 3 TRAE occurring in > 1 pt was hypotension (2 pts receiving RP2 + nivo); no Grade 4–5 TRAEs were observed. **Conclusions:** Preliminary RP2 monotherapy and RP2 + nivo data demonstrated a favorable safety profile and meaningful antitumor activity in pts with metastatic uveal melanoma, an immunologically cold tumor with few effective treatment options. These data continue to support the hypothesis that IT oncolytic immunotherapy expressing anti-CTLA-4 in combination with anti-PD-1 may provide clinically meaningful benefit in pts with hard-to-treat/unresponsive tumors. Clinical trial information: NCT04336241. Research Sponsor: Replimune Inc.

Leveraging longitudinal clinical annotations and panel sequencing to characterize dynamics of organotropism in metastatic melanoma. *First Author: Tyler J Aprati, Dana-Farber Cancer Institute, Boston, MA*

Background: Although metastasis plays a major role in the mortality and morbidity of melanoma, patterns of metastasis and drivers of organotropism have not been well characterized clinically. Although previous efforts have been made to examine genomic drivers of organotropism, a longitudinal examination of metastasis dynamics has not been well characterized clinically. **Methods:** To address these questions, we leveraged a clinico-genomic dataset of patients with metastatic melanoma (Kehl et al. 2021). From this dataset, we assembled a cohort consisting of 26,143 artificial intelligence-annotated imaging reports from 879 patients with metastatic melanoma with an average of 2 years of followup after initial metastatic diagnosis. Annotated metastasis sites included brain, bone, adrenal, liver, lymph node, lung, and mesentery. All patients were evaluated at the Dana-Farber Cancer Institute, and each patient has at least one tumor biopsy sequenced with OncoPanel, a next-generation sequencing panel that identifies mutations in 447 cancer-related genes. Lifetime incidence of metastatic sites was defined as whether a patient ever had a report annotated with that site. Time-to-event analyses on metastatic sites used the acquisition of a metastatic site as the event of interest. For each patient index dates were defined as the date of the first scan with cancer present. We used cumulative incidence models to examine the incidence of each site in our cohort, and both cause-specific hazard models and Fine-Gray modeling to account for competing events and determine the effect of genomic covariates. **Results:** For lifetime metastasis status, the overall incidence varied by site, with LN being the most common, occurring in ~75% of patients, and mesentery the rarest, occurring in ~12% of patients. For lifetime metastasis status, patients with adrenal metastases were positively enriched for mutations in SETD2 (P < 0.005). Among the significant genes for all sites were many genes encoding epigenetic modifiers. In the time-to-event setting, the order of the cumulative incidence functions for each site matched the lifetime frequency of sites. Through time-to-event analysis we found genes whose mutant status were significantly associated with a change in risk and/or rate of certain metastatic sites. Among other results, we found that having a mutation in SETD2 is significantly positively associated with an increase rate and risk of adrenal metastases (cause-specific HR 2.4, P < 0.005, Fine-Gray HR 2.6, P < 0.005), and NRAS mutations were significantly associated with lower rate and risk of liver metastasis (cause-specific HR 0.59 P < 0.05, Fine-Gray HR 0.58 P < 0.01). **Conclusions:** By using time-to-event analysis with longitudinal metastatic annotations, we identify potential drivers of organotropism in melanoma patients. Poster Session

Anti-PD1 plus BRAF/MEK inhibitors (triplet therapy) after failure of standard therapy in patients (pts) with advanced melanoma. *First Author: Lisa Zimmer, Department of Dermatology, University Hospital Essen, Essen, Germany*

Background: Preclinical models support the combination of immune checkpoint inhibitors (ICI) with targeted therapy (TT), suggesting a synergistic effect; however, clinical trials evaluating the efficacy of triplet combination in first-line setting showed limited advantage compared to TT only. Early data from the phase II TRIDEANT (NCT02910700) study showed promising clinical activity in anti-PD1 refractory pts. We sought to evaluate the efficacy of combined TT plus anti-PD1 after the failure of standard therapy in pts with advanced melanoma. **Methods:** This retrospective, multicenter study included pts with advanced melanoma who were treated with a BRAF inhibitor and a MEK inhibitor in combination with a PD1 inhibitor after failure of a minimum of one standard therapy in seven major melanoma centers between February 2016 and July 2022. Demographics, disease characteristics, therapy details, and outcome data were evaluated. **Results:** 59 pts were identified; med age was 48 yrs (range, 24-80), 32 pts (54.2%) were males, 20 pts (33.9%) had ECOG PS 1, 46 pts (78%) had 3 or more metastatic sites, 40 pts (67.8%) had brain metastases, and 25 (42.2%) had LDH levels above the upper limit of normal before initiation of triplet therapy. Median follow-up time was 16.2 months (IQR, 6.02-20.81). Median number of previous treatment lines was 2 (range, 1-6); 40 pts (67.8%) were pretreated with at least one line of ICI and TT in any sequence. Of 55 pts who received ICI (n = 41 CTLA4 plus PD1; n = 9 PD1 mono; n = 2 CTLA4 mono; n = 3 PD1-based therapy) prior to triplet therapy, 44 pts (80%) were primary resistant (progressive disease [PD]); stable disease (SD) for < 6 months, and 11 pts (20%) secondary resistant (complete response [CR], partial response [PR], SD for > 6 months) to the ICI therapy. Treatment with triplet therapy resulted in an overall response rate (ORR) of 44.1% (n = 26) and a disease control rate (DCR) of 55.9% (n = 33) with a median duration of response of 13.7 months (range, 5.4-33.2). Median PFS for the entire cohort was 6 months (95% CI, 3.88-8.08), with a 12-month PFS of 29.4% (95% CI, 17.8-42.1) and a 24-month PFS of 20.2% (95% CI, 11.0-32.8). Median OS was 15.7 months (95% CI, 8.1-23.3 months), with a 12-month OS of 52.7% (95% CI, 39.1-65.7) and a 24-month OS of 43.2% (95% CI, 29.6-55.9). Pts with extracerebral PD prior to triplet therapy (40.7%, n = 24) showed an ORR of 50%, pts with intracerebral PD (32.2%, n = 19) of 47.4%, and pts with global PD (27.1%, N = 16) of 31.3%. Treatment-related adverse events (TRAE) of grade ≥3 occurred in 17 of 59 pts (28.8%), of which cytokine release syndrome (n = 7) and hepatitis (n = 3) were the most common. In 16.9% (n = 10) of pts, TRAEs led to treatment discontinuation. **Conclusions:** Triplet therapy has shown promising efficacy in heavily pretreated pts with advanced melanoma and may represent a treatment option after failure of standard therapy with ICI and TT. Research Sponsor: None.

Risk of further progression or death among durable progression-free survivors with melanoma in PD-1 blockade trials: Implications for imaging surveillance. *First Author: Lei Deng, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Durable progression-free survivors (dPFSors) over 2 years have been reported among melanoma patients treated with PD-1 blockade. However, non-negligible risk of further progression still exists and the optimal imaging surveillance interval is unknown. **Methods:** Individual patient data of progression-free survival (PFS) were extracted from PD-1 blockade clinical trials with follow-up of at least 5 years of PFS events. Co-treatment with anti-CTLA4 antibody was allowed. Patients with PFS of at least 2 years were considered as dPFSors. Conditional risk of progression or death with 95% CI was estimated based on a piece-wise exponential survival model, with the assumption that within each year from the beginning of the third year, the risk of progression/death (P/D) was constant. Conditional risks of P/D every 3, 4, 6, and 12 months in each subsequent year were calculated with 95% confidence interval (CI). We pre-specified three maximal risk levels – 10%, 15%, and 20% at each imaging scanning interval. An interval is considered as acceptable if the 95% CI upper bound of the risk at each scan is lower than a pre-specified risk level. **Results:** Of 1495 melanoma patients from 3 clinical trials, 474 (31.7%) were dPFSors. Among them, the PFS probability for additional 3 years was 76.4%. During the 3 years, no more than 5.0% of patients had P/D in any quarters. The yearly risk of P/D was 15.5% (95% CI 13.7% - 17.3%), 8.8% (6.8% - 10.8%), and 6.3% (3.8% - 8.8%) during the 3rd, 4th, and 5th year, respectively. Under risk at 10%, 15%, and 20%, melanoma dPFSors can be scanned every 6, 6, and 12 months during the 3rd year, every 6, 12, and 12 months during the 4th, and every 12, 12, and 12 months during the 5th, respectively. **Conclusions:** Based on their own risk tolerance level, our findings allow clinicians and dPFSors make data-driven decisions regarding imaging surveillance schedule beyond every 3 months. Research Sponsor: U.S. National Institutes of Health.

Proposed imaging surveillance intervals according to three risk tolerance level per scan.			
	10%	15%	20%
3rd year	Every 6 months (Risk: 8.1%, 95% CI 7.2% - 8.9%)	Every 6 months (Risk: 8.1%, 95% CI 7.2% - 8.9%)	Every 12 months (Risk: 15.5%, 95% CI 13.7% - 17.3%)
4th year	Every 6 months (Risk: 4.5%, 95% CI 3.6% - 5.5%)	Every 12 months (Risk: 8.8%, 95% CI 6.8% - 10.8%)	Every 12 months (Risk: 8.8%, 95% CI 6.8% - 10.8%)
5th year	Every 12 months (Risk: 6.3%, 95% CI 3.8% - 8.8%)	Every 12 months (Risk: 6.3%, 95% CI 3.8% - 8.8%)	Every 12 months (Risk: 6.3%, 95% CI 3.8% - 8.8%)

Encorafenib (enco) + binimetinib (bini) + pembrolizumab (pembro) for unresectable locally advanced or metastatic BRAF V600-mutant melanoma: Results from STARBOARD safety lead-in (SLI). *First Author: Dirk Schandendorf, University Hospital Essen, Essen, Germany*

Background: BRAF inhibitors (BRAFi) + MEK inhibitors (MEKi) (eg, enco + bini) and immune checkpoint inhibitors (CPIs) (eg, pembro) are approved for patients (pts) with BRAF V600-mutant metastatic melanoma. Combinations of BRAFi + MEKi with CPIs further improve outcomes and may offer additional treatment strategies. STARBOARD (NCT04657991) is an ongoing randomized, double-blinded, placebo-controlled, phase 3 study of enco + bini + pembro vs pembro in pts with unresectable locally advanced or metastatic BRAF V600-mutant cutaneous melanoma. Here we present the SLI results. **Methods:** Key inclusion criteria were histologically confirmed unresectable/metastatic BRAF V600E/K-mutant cutaneous melanoma and ≤1 prior systemic therapy for unresectable/metastatic disease. Pts received enco 450 mg QD + bini 45 mg BID + pembro 200 mg IV Q3W (COMBO450+P) or enco 300 mg QD + bini 45 mg BID + pembro 200 mg IV Q3W (COMBO300+P). The primary objective was to identify the recommended phase 3 dose (RP3D). The primary endpoint was dose-limiting toxicity (DLT) incidence; secondary endpoints included safety, objective response rate (ORR), time to response (TTR), and PFS (post hoc). **Results:** 20 pts received COMBO450+P and 17 COMBO300+P (cutoff: Dec 2, 2022). See table for baseline characteristics. 1 pt had a DLT with COMBO450+P: Grade (G) 3 drug-induced liver injury with concurrent G4 ALT increase and G3 bilirubin increase that resolved. 2 pts had DLTs with COMBO300+P: 1 with G3 rheumatoid arthritis flare and 1 with inability to receive drug due to G4 arthralgia, G4 back pain, G4 pyrexia, G3 chills, G3 headache, G3 paraneesthesia, and G3 maculopapular rash. Drug-related AEs led to permanent discontinuation in 4, 5, and 6 pts for enco, bini, and pembro, respectively. 1 pt in the COMBO300+P arm died <28 days after discontinuing all study treatments due to disease progression. See table for antitumor activity data. **Conclusions:** Safety across cohorts was comparable and consistent with the known safety profile of each agent. Both regimens were generally tolerable; COMBO450+P was chosen as the RP3D based on the totality of the safety data. The phase 3 portion of STARBOARD is ongoing. Clinical trial information: NCT04657991. Research Sponsor: Pfizer Inc.

Early safety and efficacy from a phase I clinical study of TWP-101, a novel CD137 agonist antibody, in patients with advanced melanoma and urothelial carcinoma. *First Author: Jun Guo, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: CD137 plays the roles as a potent co-stimulator of both adaptive and innate immune cells, being an attractive target for cancer immunotherapy. TWP-101 is a fully humanized agonistic anti-CD137 monoclonal IgG4 antibody, targeting a novel epitope of CD137 with a unique mechanism of actions as a CD137 agonist but not CD137 ligand antagonist. The phase I study of TWP-101 in patient (pts) with advanced melanoma and urothelial carcinoma was initiated (NCT04871334). **Methods:** Enrolled pts were advanced melanoma refractory to standard therapy. Dose-escalation includes accelerated titration (0.01 and 0.03mg/kg) and conventional Fibonacci 3+3 dose levels (0.1, 0.3, 1.0 and 3.0 mg/kg). TWP-101 was administered intravenously every Q2W until confirmed progressive disease, unacceptable toxicity or withdrawal of consent. The primary objectives were to define the safety profile, to determine the maximum tolerated dose and RP2D of TWP-101. Secondary objectives were to evaluate pharmacokinetics (PK), immunogenicity and preliminary clinical efficacy. Exploratory objectives were to determine pharmacodynamics (PD) biomarkers. **Results:** From Feb 2021 to Mar 2022, 13 melanoma pts (median age 54 years, range 39-73; 6 men, 7 women; median 2 prior lines of therapy, range 1-6; 12 with prior immunotherapy) were treated. The following five dose levels had been evaluated from 0.01 to 1.0 mg/kg. 3mg/kg dose escalation is ongoing, no MTD has been reached. The median treatment time was 16 wks. (range 2-59). On cutoff date of October 31, 2022, 13 pts discontinued treatment due to progression disease (n = 12) and protocol deviation (n = 1). No DLTs were observed. 9 pts (69.2%) experienced treatment-related adverse events (TRAE). The most common TRAEs (≥10%) were neutropenia (23.1%), leukopenia (15.4%), hypertriglyceridemia (15.4%), anemia (15.4%), hyponatremia (15.4%). 1 pt experienced grade 3-4 TRAEs: hyponatremia, Asthenia and reduced appetite. In all TRAEs, one grade 1 decreased free triiodothyronine and one grade 2 pyrexia were possibly related, and all other TRAEs, including 2 treatment-related SAEs (1 grade 4 hyponatremia and 1 grade 2 subarachnoid hemorrhage), were identified as possibly unrelated. Deaths were due to progression disease (n = 3). Preliminary PK analysis showed dose-proportional kinetics. For 12 evaluable pts, 2 pts achieved PR (16.7%), 5 pts was SD. DCR was 58.3%. Median PFS was 16 wks. (range 16-60), PFS of 2 PR pts was 24 and 60 wks. **Conclusions:** TWP-101 demonstrated a good safety profile without hepatotoxicity frequently observed with other studied CD137 antibodies. Both favorable tolerability and preliminary antitumor activity warrant further evaluation in pts with advanced melanoma and urothelial carcinoma. Clinical trial information: NCT04871334. A prediction model for response to immune checkpoint inhibition in advanced melanoma. *First Author: Isabella A.J. van Duin, University Medical Center Utrecht, Utrecht, Netherlands*

Background: Immune checkpoint inhibition (ICI) has greatly improved the prognosis for advanced melanoma in the last decade. However, it is still difficult to predict who will benefit from treatment. We aimed to develop a multivariable prediction model for response to ICI, using clinical data including primary melanoma characteristics. **Methods:** We used a population-based cohort of 3525 patients with advanced cutaneous melanoma treated with anti-PD-1-based therapy, originating from the Dutch Melanoma Treatment Registry. The endpoint of the study was objective response to ICI within 6 months after treatment initiation. The model considered 15 candidate predictor variables, was developed with logistic regression using Akaike information criterion-informed backward selection, and was internally validated with bootstrap resampling. Performance evaluation included calibration and discrimination. We used multiple imputation to account for missing data. **Results:** Patients received anti-PD-1 monotherapy (n = 2366) or ipilimumab plus nivolumab (n = 1159) in any treatment line. Median follow-up time was 15 months and 1311 patients (39%) had an objective response within 6 months. The prediction model for response included sex, serum lactate dehydrogenase, World Health Organization performance score, type of systemic therapy, line of systemic therapy, stage of disease, location of primary melanoma, type of primary melanoma, satellites and/or in transit metastases at time of primary diagnosis, and time to first distant recurrence. The model was well-calibrated. The AUC was 0.664 (95% confidence interval [CI] 0.645-0.682), and the over-optimism adjusted AUC was 0.649 (95% CI 0.631-0.667). The range of predicted response probabilities was 6-78%. Based on these probabilities, patients were categorized into quartiles. The median predicted response probability was 25% (interquartile range [IQR] 21-28%) for the lowest quartile and 54% (IQR 50-59%) for the highest quartile. Compared to the lowest response quartile, patients in the highest quartile had a significant longer median PFS (19.9 versus 2.8 months; p < 0.001) and median OS (66.5 versus 8.4 months; p < 0.001). **Conclusions:** We present a model based on both clinical variables and primary melanoma characteristics capable of predicting response to ICI in patients with advanced melanoma. This model can discriminate between patients with a very good and very poor prognosis. Research Sponsor: None.

A phase I, randomized, controlled, multicentre trial of isolated hepatic perfusion in combination with ipilimumab and nivolumab in patients with uveal melanoma metastases (the SCANDIUM 2 trial). *First Author: Roger Olofsson Bagge, Department of Surgery, Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

Background: Uveal melanoma is a rare disease characterized by liver metastasis and a very poor prognosis. In patients with metastatic UM, a single treatment with isolated hepatic perfusion (IHP) with high dose melphalan has shown response rates of 40%, while immune checkpoint blockade with ipilimumab (3 mg/kg) in combination with nivolumab (1 mg/kg) every third week (IPI3/NIVO1 q3w) for four cycles followed by nivolumab monotherapy has shown response rates of 11-18%. The impact of these treatments on overall survival, especially if combined, is unclear. This phase I trial investigates the safety and tolerability of the combination of IHP and IPI3/NIVO1. **Methods:** Eligible in this multicenter open, randomized, controlled, phase I trial, were patients with liver dominant metastatic uveal melanoma who had not received previous systemic treatment. Patients were randomized to receive either (Arm A) IHP followed by combination immunotherapy (four cycles IPI3/NIVO1 q3w) or (Arm B) one neoadjuvant cycle of IPI3/NIVO1 prior to IHP followed by three cycles IPI3/NIVO1 q3w. Thereafter, both Arm A and B received monotherapy with nivolumab (480 mg q4w) for up to 1 year. IHP was performed using melphalan 1mg/kg perfused through the liver for 60 minutes under hyperthermia (40°C). The primary endpoint was incidence and severity of adverse events while, secondary endpoints included response according to RECIST v1.1 criteria reported according by the local investigator. **Results:** A total of 18 patients were included and randomized, nine to Arm A and nine to Arm B. Three patients did not undergo IHP as planned, one due to perioperative complications (Arm A), one due to extensive metastatic liver infiltration (> 50% liver volume) (Arm B) and one due to encephalitis related to neoadjuvant IPI3/NIVO1 (Arm B). A total of 20 serious adverse events (SAEs) were reported in eleven patients. There were ten SAEs in each arm, with no treatment related deaths. In total, 11 of 18 patients (six in Arm A and five in Arm B) did not complete the planned four cycles of IPI3/NIVO1, with a mean of 2.4 cycles in Arm A and 3.0 cycles in Arm B. Response was evaluable in 17 patients, with the best clinical responses reported as three complete responses (18%), four partial responses (24%), seven stable disease (41%) and three progressive disease (18%). The overall response rate was 63% in Arm A (5/8) and 22% in Arm B (2/9). **Conclusions:** For previously untreated patients with liver dominant metastatic uveal melanoma, treatment with IHP in combination with IPI3/NIVO1 had a high, yet manageable toxicity profile. The efficacy of this combination treatment is encouraging, however, one cycle of neoadjuvant IPI3/NIVO1 given before IHP did not seem beneficial, neither in regards to safety nor efficacy. Clinical trial information: NCT04463368. Updated results from an ongoing phase 1/2a study of T3011, an oncolytic HSV expressing IL-12 and PD-1 antibody, administered via IT injection as monotherapy or combined with pembrolizumab in advanced solid tumors. *First Author: Jiaxin Niu, Banner MD Anderson Cancer Center, Gilbert, AZ*

Background: T3011 is a recombinant HSV-1 oncolytic virus expressing both IL-12 and anti-human PD-1 antibody. Upon injection, locally produced IL-12 induces IFN- γ production, enhances the oncolytic activity of NK cells and cytotoxic T lymphocytes, promotes anti-angiogenesis and inhibits tumor growth. PD-1 antibodies act as immune checkpoint inhibitors to augment tumor-killing activity of T-cells. Here we report the updated results from an open-label, dose escalation and expansion study of T3011 administered via intratumoral injection as monotherapy or in combination with intravenous pembrolizumab. **Methods:** Pts with pathologically confirmed recurrent or metastatic malignancy after failure of SOC were enrolled and received T3011 monotherapy (1×10^6 - 5×10^7 PFU/mL Q2W) or in combination with pembrolizumab (Lead-in T3011 1×10^6 PFU/mL Q2W monotherapy for 2 cycles followed by combination therapy Q3W). Pts with documented progression on T3011 monotherapy may cross over to receive combination therapy at the discretion of the investigator. The primary endpoints were safety and tolerability. Key secondary endpoints included confirmed ORR, DCR, DOR, PFS by investigator per RECIST1.1; OS; PD and PK. **Results:** As of 17 Jan 2023, 29 pts received T3011 alone or in combination with pembrolizumab, the median follow-up was 14.1 (1.2-27.6) months. No DLTs were reported. Any treatment-related adverse events (TRAEs) occurred in 75.9% (22/29) of pts ($\geq$ G3 in 10.3%). Treatment-related SAEs occurred in 3.4% (1/29). Most frequent TRAEs ($\geq$ 10%) were pyrexia (27.6%), fatigue (20.7%) and chills, injection site pain, arthralgia, nausea, headache (10.3% each). No additional safety signals were observed with combination therapy. 12 advanced melanoma pts failing prior PD-1 or PD-1/CTLA-4 combination treatment received 5×10^7 PFU/mL of T3011 monotherapy. The confirmed ORR and DCR were 25.0% (3/12) and 33.3% (4/12), respectively. 12-month PFS rate was 36.4%. 6 of these pts were re-challenged with immunotherapy with T3011 (5×10^7 PFU/mL) combined with pembrolizumab after progressing on T3011 monotherapy, 1 pt achieved PR after 4 months lasting > 8 months at data cutoff. 15 pts had tumor tissues for PD analysis. Increased CD8+ cells were observed in 46.7% (7/15) of all pts and 50% (5/10) of melanoma pts. It appeared to be more pronounced in pts with PR and SD, 66.7% (6/9) in all pts and 80% (4/5) in melanoma pts, respectively. Notably, the increment of CD8+ cells in 2 melanoma pts with PR was over 15 folds. **Conclusions:** Both T3011 IT monotherapy and combination therapy with pembrolizumab were safe and tolerable. The efficacy of T3011 in immune-resistant melanoma was encouraging. Our data suggest T3011 may modify the tumor microenvironment and overcome immune resistance. Clinical trial information: NCT04370587. Research Sponsor: Immvira Pharma Co., Limited.

Phase 1b trial of IFx-Hu2.0, a novel personalized cancer vaccine, in checkpoint inhibitor resistant merkel cell carcinoma and cutaneous squamous cell carcinoma. *First Author: Andrew Scott Brohl, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Merkel cell carcinoma (MCC) and cutaneous squamous cell carcinoma (cSCC) exhibit high response rate to immune checkpoint inhibitor (ICI) therapy. However, patients with advanced disease who fail initial ICI therapy have limited treatment options. IFx-Hu2.0 (IFx) is a plasmid DNA encoding for an immunogenic bacterial protein, Emm55, formulated with a transfection agent for direct intratumoral injection. In a phase 1 study in advanced melanoma, biomarker analyses demonstrated robust immune priming effects of IFx administration. As part of an ongoing Phase 1b study, we evaluated the safety and immunologic response of different schedules of IFx intratumoral administration in patients with advanced MCC or cSCC. We report the initial results of the first stage of this study. **Methods:** In the first trial stage (n = 9), IFx was administered intratumorally in up to 3 lesions on 3 schedules; weekly x 1, 2, or 3. We report safety data for these patients. Given the proposed potential for immune priming effects of IFx, we performed an unplanned exploratory analysis of post-protocol treatment efficacy to evaluate for response to ICI rechallenge if given. **Results:** Five patients with advanced MCC and four with cSCC were enrolled. Prior to trial enrollment, all patients with MCC received ICI with pembrolizumab (4) or avelumab (1), all had progressive disease with median 3 months treatment (2.0-4.5mo). All 4 patients with cSCC previously received cemiplimab with median 6 months treatment (3.0-11.5mo). IFx was well tolerated at all dose schedules evaluated with no treatment-related G3-5 adverse events observed. Best response to trial therapy was SD in 2 patients and PD in seven. One MCC patient experienced complete clinical response in 2 injected lesions, but progression of disease overall with development of new disease areas. Following completion of protocol therapy, all 5 MCC patients and 2 of 4 cSCC patients were treated with anti-PD(L)1 therapy as the immediate post-protocol therapy: pembrolizumab (3) or avelumab (2) in MCC and cemiplimab (2) in cSCC. Four of 5 MCC patients and 1 of 2 cSCC patients, or 5 of 7 total (71%), experienced objective response to ICI rechallenge in this setting, with duration of response ongoing in 4 patients (7+, 8+, 9+, 20+ months) and one response lasting 23 months. **Conclusions:** IFx-Hu2.0 is safe and well tolerated at weekly dosing repeated up to 3 weeks. An exploratory analysis showed that five of seven patients (71%) treated with standard of care ICI agents following protocol therapy experienced a durable objective response despite prior failure of this same drug class prior to protocol enrollment. An additional 11 patients are planned for enrollment in the expansion stage of the study using the weekly x3 dosing schedule. Preliminary biomarker analyses from the first nine patients are ongoing and will be presented. Clinical trial information: NCT04160065. Research Sponsor: Morphogenesis, Inc.

Targeting AMP kinase in melanoma: A phase I trial of phenformin with dabrafenib/trametinib. *First Author: Paul B. Chapman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: AMP-activated protein kinase (AMPK) can phosphorylate BRAF and block its activation of MEK. AMPK is activated by biguanides such as metformin and phenformin (phen). Preclinical data indicated that phen can enhance the effects of BRAF inhibitors (BRAFi) in sensitive and BRAFi-resistant melanoma (mel) cell lines whereas metformin does not. Phen also can decrease myeloid-derived suppressor cells (MDSCs) enhancing immune reactivity against mel. For these reasons, we designed a phase I trial combining phen with dabrafenib/trametinib (dab/tram) in patients (pts) with metastatic BRAF V600-mutated mel. **Methods:** Bulk phen was provided by the Division of Cancer Treatment and Diagnosis of the National Cancer Institute under a materials transfer agreement. Phen was encapsulated at the Pharmaceutical Product Facility at MSKCC under cGMP procedures and used under an IND held by MSKCC. Eligible pts had metastatic BRAF V600-mutated mel. For the dose-escalation phase, prior BRAFi therapy was allowed. A 3+3 dose escalation design was used starting at a phen dose of 50 mg bid and standard dosing of dab/tram (150 mg bid/2 mg qd). Subsequent planned dose levels were 100 mg bid, 200 mg bid, and 300 mg bid with de-escalation to intermediate doses for toxicity. Plasma PK samples were collected and assayed by MRI Global Inc using a validated, GLP-compliant, HPLC-MS/MS assay. PBMC were collected to measure circulating MDSCs. At the recommended phase 2 dose (RP2D), we planned to treat 10 BRAFi-naïve pts. **Results:** We accrued 18 patients from March 2017 through December 2019. Dose-escalation to 200 mg bid was not tolerable nor was 150 mg bid. Therefore, we determined 100 mg bid to be the RP2D and accrued 2 patients on the dose expansion cohort before further accrual became impossible due to the COVID-19 pandemic. The most common toxicities were gastrointestinal – nausea, vomiting, anorexia, and transaminase and alkaline phosphatase elevation – accounting for 9 DLTs. Two patients were hospitalized due to lactic acidosis. There were also constitutional/inflammatory and skin/mucosal adverse events thought to be related to dab/tram. Weight loss was seen in most patients (median 3.7% at week 8) thought to be related to phen. There were 8 PRs and 2 CRs. Responses were observed in 2/7 pts who had received prior therapy with BRAFi. One CR lasted > 1 year. There were 8/11 (73%) responders among the BRAFi-naïve pts. At the RP2D of 100 mg bid, day 8 median phen plasma level was 73.4 ng/ml (range 32.8-253.2). At the the 50 mg bid dose level, it was 40.8 ng/ml (range 29.7-110.2). MDSC could be analyzed from the 150 mg bid and 200 mg bid dose levels (N = 7 pts). In all but 1 pt, MDSCs decreased while on phen. **Conclusions:** We observed 10/18 (55.5%) total responses with 2/7 among previously treated pts. Circulating MDSCs decreased on treatment. Phen at 100 mg bid can be combined safely with dab/tram and should be explored in future randomized phase II trials. Clinical trial information: NCT03026517. Research Sponsor: MSKCC; U.S. National Institutes of Health.

Avelumab as second-line or later (2L+) treatment in patients (pts) with metastatic Merkel cell carcinoma (mMCC): Analysis of real-world outcomes in France using the CARADERM registry and the French national healthcare database. *First Author: Astrid Blom Fily, CHU Ambroise Paré, Boulogne-Billancourt, France*

Background: Avelumab, an anti-PD-L1 antibody, has been approved in multiple countries for the treatment of mMCC based on the results of the pivotal phase 2 JAVELIN Merkel 200 trial (NCT02155647). In pts who received avelumab as 2L+ treatment in the trial (part A), median overall survival (OS) was 12.6 months and median progression-free survival (PFS) was 2.7 months. The French health technology assessment agency requested the collection of real-world data from pts with mMCC from a comprehensive registry; data are reported here. **Methods:** This retrospective, noninterventional, real-world study evaluated all pts with mMCC in France using combined data from 2 databases: CARADERM (French national database of rare dermatological cancers) and Système National des Données de Santé (SNDS; national healthcare database). For this analysis, eligible pts were diagnosed with mMCC and initiated 2L+ avelumab outside of a clinical trial between August 2016 and December 2019. Pts were followed for 24 months after initiation of avelumab. Probabilistic linkage was performed to identify pts registered in both databases. OS and PFS were analyzed using Kaplan-Meier methodology. Safety data were not collected. **Results:** A total of 180 pts who received 2L+ avelumab were identified, data were obtained for 112 pts from the CARADERM database and for 68 additional pts after SNDS linkage. Median age at diagnosis was 74.0 years, 66.7% were male, and 98.3% received chemotherapy as first-line treatment. Median follow-up was 13.1 months. 79.5% of CARADERM database pts had discontinued avelumab; the most common reasons specified were progressive disease (36.4%), complete response (17.0%), and death (13.6%). Median OS was 14.6 months (95% CI, 9.9-21.3 months) overall; in CARADERM database pts, median OS was 15.9 months (95% CI, 8.6-28.3 months) vs 13.3 months (95% CI, 6.7-19.1 months) in non-CARADERM database pts. 12- and 24-month OS rates in the overall population were 53.8% (95% CI, 46.2%-60.8%) and 40.5% (95% CI, 33.2%-47.6%), respectively. In CARADERM database pts (data not available in non-CARADERM database pts), median PFS was 3.6 months (95% CI, 2.7-7.5 months), and the objective response rate was 55.3% (95% CI, 45.3%-65.4%), including complete response in 31.9%. Median duration of response was 39.3 months (95% CI, 24.3 months-not estimable). **Conclusions:** In this real-world study of national data from France, outcomes with avelumab as 2L+ treatment for mMCC were similar to those observed in part A of the JAVELIN Merkel 200 trial. These findings confirm the effectiveness of avelumab in pts with mMCC that have progressed following first-line systemic treatment in routine clinical practice. Economic evaluation for the US of relatlimab and nivolumab (RELA+NIVO) versus nivolumab (NIVO) monotherapy in untreated advanced melanoma. *First Author: Osama Aqel, Center for Health Outcomes and Pharmacoeconomic Research, University of Arizona, Tucson, AZ*

Background: The RELATIVITY-047 trial demonstrated longer median progression-free survival (PFS) with the combination of RELA+NIVO (10.1 months, 95% CI = 6.4 to 15.7) over NIVO (4.6 months, 95%CI = 3.4 to 5.6) in patients with untreated advanced melanoma (hazard ratio for progression or death = 0.75, 95%CI = 0.62 to 0.92). This economic evaluation aimed to estimate the cost-effectiveness/utility of RELA+NIVO vs. NIVO monotherapy in this setting. **Methods:** A two state partitioned survival model (PFS, progressed/death) was developed to compare costs and PFS outcome associated with both treatments. PFS curves were digitized and parametric functions fitted. A 5-year time horizon from a US payer perspective with a 3% discount rate/year was considered. Costs of treatment (average sales price), administration and monitoring parameters were derived from Centers for Medicare & Medicaid Services databases; cost of adverse events (grade 3/4 with rate >5%) were derived from prior advanced melanoma economic evaluations. Incremental costs, PFS life years (PFSLY), and PFS quality adjusted life years (PFSQALY) gained (g) were estimated in base case (BCA) and probabilistic sensitivity analyses (PSA). A cost-effectiveness acceptability curve (CEAC) was plotted to determine the probability of either treatment to be cost-effective over the other at different willingness to pay (WTP) thresholds. **Results:** Exponential regression was used to extrapolate RELA+NIVO and NIVO survival curves. According to the result table shown below, the BCA (PSA) shows an incremental cost of RELA+NIVO over NIVO of \$405,663 (\$402,936), incremental PFSLY of 0.326 (0.325), and incremental PFSQALY of 0.260 (0.256). The BCA (PSA) ICERs indicated an additional \$1,244,365 (\$1,239,803) per PFSLY gained (g) and an additional \$1,560,242 (\$1,573,969) per PFSQALYg. The CEAC curve shows that RELA+NIVO treatment had a 50% probability of being cost-effective regimen at a WTP threshold value of \$1,525,000 and 100% probability at a threshold of \$3,050,000 or above. **Conclusions:** In the setting of advanced melanoma, this economic evaluation showed that RELA+NIVO is associated with improvement in LY and QALY, however, at a marked incremental cost, requiring a very high WTP threshold. Research Sponsor: None.

BCA (PSA).			
	RELA+NIVO	NIVO	Difference
Cost	\$682,148 (\$679,432)	\$276,485 (\$276,496)	\$405,663 (\$402,936)
PFSLY	1.673 (1.665)	1.347 (1.340)	0.326 (0.325)
PFSQALY	1.338 (1.331)	1.078 (1.075)	0.260 (0.256)
ICER			\$1,244,365/PFSLYg (\$1,239,803/PFSLYg)
ICUR			\$1,560,242/PFSQALYg (\$1,573,969/PFSQALYg)

Interpretation of ICER and ICUR: incremental cost to gain resp. 1 LY or 1 QALY.

Immune infiltrates in metastatic uveal melanoma liver metastases and associations with clinical outcomes. *First Author: Katherine Emilie Rhoades Smith, Mayo Clinic, Rochester, MN*

Background: Uveal melanoma has a poor prognosis following metastasis to the liver. Immune checkpoint inhibitors (ICIs) are often utilized in patients with metastatic uveal melanoma (MUM); however, ICIs in MUM have low response rates. We studied the association of immune infiltrates in MUM liver metastases with survival outcomes for all patients, in addition to evaluating if immune infiltrates improve survival for patients treated with ICIs. **Methods:** We included MUM patients with liver metastases who had pre-treatment liver biopsies available at Mayo Clinic Rochester. Demographics, disease characteristics, treatments, and clinical outcomes were obtained from the electronic medical record. Core biopsies of liver metastases were reviewed for the presence of lymphocytes at interface of the tumor and liver parenchyma, and for tumor-infiltrating lymphocytes (TILs). If TILs were present, then additional immunohistochemistry (IHC) staining was performed for CD3, CD4, CD8, PD1, CD25, and FoxP3. Overall survival (OS) was estimated with the Kaplan-Meier method and compared between groups with Cox proportional hazards regression. Median OS and hazard ratios (HR) were calculated and p-values (p) <0.05 were considered statistically significant. **Results:** 140 patients with MUM who had pre-treatment liver biopsies were identified. 122 biopsies were evaluable for the presence of lymphocytes, either at the tumor-liver interface, or for TILs. 80/122 (65.6%) biopsies showed presence of any lymphocyte and 27/80 had TILs. 27 biopsies had sufficient tissue for further IHC classification. CD8+ T cells were identified in 27/27 samples, T cell PD1 positivity $\geq 1\%$ in 4/27 samples, and regulatory T cell markers (CD25 and/or FoxP3) in 18/27 samples. Median OS for the entire cohort was 16 months (mo). Patients still alive at the time of data analysis had at least one year of follow-up available (range 13-124 mo). Univariate analyses (UVA) showed no significant improvement in OS based on the presence of any lymphocytes (HR 1.01, p 0.98), lymphocytes at the tumor-liver interface (HR 1.10, p 0.64), TILs (HR 0.78, p 0.27), >50% CD8+ T cells (HR 0.88, p 0.77), or absence of FoxP3+ T cells (HR 0.68, p 0.40). In the 69 patients treated with ICIs (pembrolizumab, nivolumab, or ipilimumab plus nivolumab), neither the presence of any lymphocytes (HR 1.19, p 0.56) nor TILs (HR 0.68, p 0.24) were associated with an OS benefit. **Conclusions:** We present a large cohort of patients with MUM where we characterized immune infiltrates in liver metastases and evaluated clinical outcomes. OS did not significantly improve with the presence of any lymphocytes, TILs, CD8+ T cells, or with the absence of FoxP3+ T cells. These results were consistent across all patients whether they were treated with ICIs or not. Our findings suggest that lymphocytes in MUM are functionally dormant and highlights the need for novel immune-activating treatment strategies. Research Sponsor: Mayo Clinic.

Interim results from a phase I/II study of duvelisib PI3K δ γ inhibitor and nivolumab in patients with advanced unresectable melanoma who have progressed on anti-PD1 therapy. *First Author: Jingxiao Jin, University of Pittsburgh Medical Center Cancer Center, Pittsburgh, PA*

Background: The majority of unresectable melanoma patients eventually progress on first-line checkpoint blockade therapy. Duvelisib is a potent phosphoinositide 3-kinase (PI3K) δ and γ isoform inhibitor approved for relapsed/refractory CLL. PI3K γ inhibition has been shown to restore anti-PD1 activity in preclinical tumor models through conversion of tumor associated macrophages (TAMs) from an immunosuppressive to a pro-inflammatory state. PI3K δ inactivation has been associated with impaired T regulatory cell (Treg) function and reduced intratumoral Treg numbers. We report study design and results of a phase I study to evaluate the safety and efficacy of duvelisib and nivolumab in anti-PD1 refractory patients. **Methods:** Utilizing a modified 3+3 design with escalating doses of duvelisib (15 mg daily, 25 mg daily, and 25 mg BID), patients with unresectable melanoma were treated with nivolumab and duvelisib until unacceptable toxicity or disease progression. Primary endpoints for the phase I portion were maximum tolerated dose (MTD) and recommended phase II dose (RP2D) of duvelisib. Secondary endpoints include early and late toxicities and anti-tumor activity based on RECIST v1.1. Exploratory endpoints were to evaluate dose-dependent changes in the immune cell populations of peripheral blood and tumor tissue with duvelisib and nivolumab. **Results:** Ten patients have been enrolled (7 at dose level I, 3 at dose level II) with mean age 64. Two patients had BRAF V600E mutation and were previously treated with BRAF/MEK inhibitors. No dose limiting toxicities (DLT) were observed. Grade 3 or higher adverse events (AEs) attributable to study treatment occurred in 4 patients (40%), including G3 neutropenia (10%), G3 diarrhea (10%), G3 vomiting (10%) and G4 hepatitis (20%). Both instances of hepatitis resolved rapidly with 1-2mg/kg of prednisone. In one patient, hepatitis and nausea/vomiting led to discontinuation of treatment. Out of 6 patients who had follow-up imaging, 4 exhibited progressive disease, one stable disease, and one had partial response of 11 months duration. Given the published data on the regulation of macrophages and Tregs by PI3K δ γ inhibitors, we are utilizing multispectral imaging to measure the spatial interactions of key immune cells within the tumor microenvironment (T cells, B cells, and macrophages) in all matched pre-/post-treatment paraffin-embedded tissues, for which results will be presented. **Conclusions:** The combination of duvelisib and nivolumab was well-tolerated in patients with advanced unresectable melanoma refractory to ICI without DLTs to date at 15 and 25mg daily dosages. Significant anti-tumor activity was noted in one patient. Enrollment at dose level II is ongoing. Clinical trial information: NCT04688658. Research Sponsor: Secura Bio, Inc.

Updated safety and efficacy results from the phase I study of either LBL-007 (an anti-LAG-3 antibody) in combination with toripalimab (an anti-PD-1 antibody) or LBL-007 in combination with toripalimab and axitinib in patients with advanced melanoma. *First Author: Xue Bai, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Initial safety and efficacy data of LBL-007 plus toripalimab in patients with advanced melanoma (Part A) have been reported in 2022 ASCO (Abstract 9538). Here we present the updated results of part A and the preliminary results of part B (LBL-007 plus toripalimab with axitinib). Median follow-up was 9.7 months at cut-off data (January 11, 2023). **Methods:** Patients with advanced melanoma with or without prior therapy were enrolled during Jan 2021 - Aug 2022. This trial comprised 2 parts: Part A, patients received LBL-007 (0.25 - 10 mg/kg for dose escalation; 3 or 6 mg/kg for dose expansion) plus toripalimab at 3 mg/kg (both i.v. Q2W); and Part B, patients received LBL-007 at 3 or 6 mg/kg plus toripalimab at 3 mg/kg (both i.v. Q2W) and axitinib at 5 mg BID. The primary objective was safety, the second objectives were pharmacokinetics, pharmacodynamics and efficacy (per RECIST v1.1). **Results:** In part A, 68 patients in total (57 treatment-naïve) were enrolled including 20 patients in dose escalation and 48 patients in dose expansion, and among which, 31 additional patients have been enrolled since 2022 ASCO report. Nineteen (27.9%) patients occurred grade ≥ 3 TEAEs, the common grade ≥ 3 TEAEs was anaemia (11.8%). No new safety signals were detected. Among 55 efficacy evaluable treatment-naïve patients (41 with acral, 7 mucosal, 7 others), ORR was 23.6%, DCR was 58.2%, and mPFS was 5.7 months (95% CI: 3.7, 9.5). In part B, 11 patients (10 mucosal, 1 acral) were enrolled. No DLT was observed. Five patients (45.5%) occurred grade ≥ 3 TEAEs, the common grade ≥ 3 TEAEs included blood pressure increased (18.2%) and transaminases increased (18.2%). One (9.1%) patient discontinued treatment due to TEAEs. ORR was 45.4% (including 4 mucosal and 1 acral), DCR was 72.7%, and mPFS was 5.5 months (95% CI: 1.8, 9.1). **Conclusions:** LBL-007 plus toripalimab continued to show promising antitumor activity and manageable safety profile in patients with treatment-naïve melanoma, which support further development in this indication. LBL-007/toripalimab/axitinib combination demonstrated acceptable safety profile and encouraging antitumor activity in patients with mucosal melanoma. Acknowledgements: Junshi Biosciences. The effect of LNS8801 alone and in combination with pembrolizumab in patients with metastatic uveal melanoma. *First Author: Alexander Noor Shoushtari, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: LNS8801 is an oral, selective, small molecule agonist of the G-protein coupled estrogen receptor (GPER). LNS8801 treatment results in increased melanocytic differentiation, reduced c-Myc protein levels in cancer cells, inhibition of proliferation, suppression of invasion, and enhancement of immune recognition. In preclinical models, LNS8801 has demonstrated increased activity in combination with immune checkpoint inhibitors (ICIs). In the first-in-human dose escalation study, LNS8801 was safe and tolerable alone and in combination with pembrolizumab in patients with advanced solid tumors (NCT04130516). **Methods:** Patients with measurable metastatic uveal melanoma (mUM) received LNS8801 (125 mg, QD, PO) alone or with pembrolizumab (200 mg, Q3W, IV) (NCT04130516). The primary objective was safety and tolerability assessed according to NCI CTCAE v5.0. Secondary endpoints include pharmacokinetic, pharmacodynamics, objective response rate (ORR) and disease control rate (DCR, CR+PR+SD) per RECIST v1.1. Presence of a consensus, fully-functional, germline GPER coding sequence was assessed via Sanger sequencing on DNA extracted from blood as a potential predictive biomarker. **Results:** As of 1/25/23, 15 patients with mUM were treated with LNS8801 alone (n = 8) or a combination of LNS8801 and pembrolizumab (n = 7). Patients were previously treated with a median of 2 prior lines of systemic therapy. 4 of 8 monotherapy patients had AEs potentially related to study drug (all grade 1), with no AEs occurring in more than one patient. 6 of 7 combination patients had AEs potentially related to study drugs (grades 1-2), with fatigue occurring in more than one patient. Of the 14 patients evaluable for efficacy (7 mono, 7 combo), 7 had disease control (4 mono, 3 combo) resulting in a disease control rate of 50%. 1 patient treated with combination achieved a confirmed partial response. Consensus germline GPER was present in 2 of 12 sequenced patients (1 mono, 1 combo), and both of these patients have ongoing disease control lasting longer than 24 weeks. **Conclusions:** LNS8801 alone and in combination with pembrolizumab is tolerable without unanticipated toxicities and demonstrates encouraging anti-tumor activity in patients with mUM. The hypofunctional germline GPER variant appears over-represented in this cohort compared to the normal population, suggesting a potential significant role for GPER in the development of mUM. These data support further development of LNS8801 alone and in combination with pembrolizumab as a therapeutic approach to treat mUM patients, especially for patients with consensus germline GPER. Clinical trial information: NCT04130516. Research Sponsor: Linnaeus Therapeutics.

Durable clinical outcomes in patients (pts) with advanced melanoma and progression-free survival (PFS) ≥ 3 y on nivolumab (NIVO) $\pm$ ipilimumab (IPI) or IPI in checkmate 067. *First Author: F. Stephen Hodi, Dana-Farber Cancer Institute, Boston, MA*

Background: NIVO + IPI has demonstrated durable clinical benefit at 7.5 y in pts with advanced melanoma in the phase 3 CheckMate 067 study. PFS curves plateaued at ~ 3 y in this study, suggesting that being alive and progression-free for ≥ 3 y (PFS ≥ 3 y) may be a good surrogate for long-term clinical benefit. We conducted analyses to quantify this association. **Methods:** Pts with treatment (tx)-naïve, unresectable stage III/IV melanoma (stratified by PD-L1 expression, BRAF mutation status, and metastasis stage) received NIVO 1 mg/kg + IPI 3 mg/kg for 4 doses Q3W, followed by NIVO 3 mg/kg Q2W (n = 314); NIVO 3 mg/kg Q2W + placebo (n = 316); or IPI 3 mg/kg Q3W for 4 doses + placebo (n = 315) until progression or unacceptable toxicity. Exploratory post hoc analysis was performed in pts with PFS ≥ 3 y. **Results:** In the NIVO + IPI, NIVO, and IPI arms, respectively, 99 (32%), 78 (25%), and 21 (7%) pts had PFS ≥ 3 y. Objective response rates (ORRs) in these pts were $\geq 95\%$ (table). The majority of responses were complete responses (CRs; table); in almost all pts with partial responses (PRs) on NIVO + IPI or NIVO, target-lesion size decreased by $\geq 50\%$. At 7.5 y of follow-up among pts alive and progression-free at 3 y, PFS rates were $\geq 68\%$, overall survival (OS) rates were $\geq 85\%$, and melanoma-specific survival (MSS) rates were $\geq 95\%$ in the 3 tx groups (table). Among pts in this group who died after 3 y on study, the majority of deaths were unrelated to disease (table). The majority of pts with PFS ≥ 3 y who were alive and in follow-up were tx-free at the 7.5-y data cutoff (77/84, 57/64, and 13/16). Pts who received NIVO + IPI were off tx (median) for 75.5 mo (NIVO, 55.7 mo; IPI, 59.2 mo). Among pts with PFS ≥ 3 y in the 3 tx groups, 4%, 5%, and 19% received subsequent systemic tx (table). No new safety signals were observed in pts with PFS ≥ 3 y. **Conclusions:** This exploratory post hoc analysis suggested that PFS ≥ 3 y may be a good surrogate for long-term MSS with NIVO + IPI or NIVO, with very few occurrences of progression or death due to melanoma in this population through 7.5 y. Most pts were tx-free without having received subsequent systemic tx after demonstrating PFS ≥ 3 y. Further study of pts with PFS ≥ 3 y may allow the burden of imaging and follow-up visits to be reduced in this group. Clinical trial information: NCT01844505. Research Sponsor: Bristol Myers Squibb.

Breaking primary checkpoint inhibitor resistance: Interim analysis of a multicenter phase II study by intermittent application of an alkylating agent among patients with metastatic melanoma. *First Author: Lucie Heinzerling, Department of Dermatology, Ludwig-Maximilians-Universität München, München, Germany*

Background: Patients with BRAF wildtype (wt) metastatic melanoma with primary resistance to immune checkpoint inhibitors (ICI) have a dismal prognosis. Chemotherapy has been shown to induce mutations, alter the tumor microenvironment as well as the microbiome, and modulate the immune system. This prospective phase II trial investigates whether two applications of an alkylating agent (dacarbazine/DTIC) can render ICI non-responsive patients with metastatic melanoma responsive to the same checkpoint inhibitor regime. **Methods:** The PROMIT trial (NCT04225390) targets patients with histologically confirmed BRAFwt metastatic melanoma showing primary resistance to ICI therapy. Applying an optimal two-step design, the uninteresting responder rate was set to 5% with an expected rate of 20%. Response is defined as complete or partial response by week 14 according to RECIST 1.1. Design foresaw 29 assessable patients at first step and 38 patients overall (alpha one-sided 5%, 90% power). After showing primary resistance to ICI, patients received 2 doses of DTIC (850 mg/m² i.v.) on days 1 and 21, and were subsequently re-exposed to the same ICI therapy they had previously shown resistance to. **Results:** In total, 38 patients were screened at 4 skin cancer centers. Interim analysis was performed after 29 patients who had received at least one ICI re-exposure were assessable for efficacy. Overall response rate was 24% (90%CI 12-41%) with 7 out of 29 patients showing a partial response; disease control rate was 38%. Application was well tolerated with 16% grade 3 or more adverse events and no new safety signals. **Conclusions:** Interim analyses results indicate that this approach of a short-term chemotherapy can break resistance in a subgroup of patients and allows us to continue the phase II trial to assess relevance of this treatment approach for metastatic melanoma. Enrollment is ongoing. Clinical trial information: NCT04225390. Research Sponsor: German Cancer Aid; University hospitals.

Real-world comparison between 6 weeks versus 3 weeks adjuvant pembrolizumab in high-risk stage IIB-IIID cutaneous malignant melanoma: Experience from an academic cancer center. *First Author: Manan Shah, The James Cancer Hospital and Solove Research Institute, Columbus, OH*

Background: The KEYNOTE-555 trial demonstrated similar efficacy and safety profile of 6-week (q6w) pembrolizumab (400 mg/m²) vs 3-week (q3w) in unresectable and metastatic melanoma leading to FDA's approval of this dosing schedule for adults in 2020. Limited real-world data is available on the use of 3 weeks vs 6 weeks pembrolizumab in the adjuvant setting in cutaneous melanomas. Q6w is hypothesized to cause more adverse effects due to higher drug concentration. **Methods:** We conducted a retrospective study of surgically resected Stage IIB-IIID cutaneous melanomas receiving adjuvant pembrolizumab from 2019-2022 at The James Comprehensive Cancer Center with a follow-up of ~1 year. Fifty patients [n=35 (q6w) and n=15 (q3w)] were included. The primary objectives were to compare disease free survival (DFS) and safety profile based on the NCI-CTCAE (v 5.0) criteria. Kaplan-Meier curves were generated for DFS comparisons between the two groups. Fisher's exact test was used to compare the safety profile between the two groups. Accuracy of the sample size for final analysis was planned based on log rank test. With 15 patients (q3w) and 35 patients (q6w), our study had 80% power to detect differences in clinical outcomes. A *p*-value of less < 0.05 was considered statistically significant. The secondary objective was to compare overall survival (OS) which will be reported later with a longer follow-up. **Results:** The mean age in the q6w and q3w groups was 59 years and 69 years, respectively. The median follow up was ~ 9 months with males predominating in both groups (54% and 18%). In the q6w group, 68% had ECOG status 0 (vs.30% in q3w) and most of our patients (32%) were stage IIB (vs. 6% in q3w) and 28% were stage IIIC (vs 12% in q3wk). *BRAF* mutation was present in 32% in q6w vs. 2% in q3w. Toxicity profile was noted to be similar in both groups with no significant statistical difference (*p*-value=0.4), though there were more Grade-3 immune-related toxicities in 7 patients in the q6w group (vs 3 in q3wk). The most common grade 3 toxicity noted was colitis (n=4, q6w; n=1, q3w). Notably, no significant difference was noted in the DFS between the two groups (*p*-value=0.6). At the time of analysis, 3/15 (20%) patients in q3w and 7/35 (20%) in the q6w group had disease progression with the most common site being the regional lymph-nodes. At the time of the last follow up, 96% of the patients were alive with only 2 deaths occurring due to non-cancer related causes. **Conclusions:** We demonstrate comparable efficacy of q6w and q3w adjuvant pembrolizumab for advanced stage melanoma, with a trend towards increased immune-mediated colitis events in q6w. Research Sponsor: None.

Retreatment and rechallenge with BRAF/MEK inhibitors in patients with metastatic melanoma: Results from the observational study GEM1801. *First Author: Pablo Ayala de Miguel, Medical Oncology Department, Hospital Universitario San Pedro de Alcntara, Caceres, Spain*

Background: Most patients with BRAF-mutant melanoma eventually develop resistance to therapy with BRAF/MEK inhibitors and immune-checkpoint blockade. Alternative treatment strategies are required in these patients since further therapy options lack survival benefit. Small series have shown promising activity from re-exposure to BRAF/MEK inhibitors after a treatment free interval of targeted therapy (TT), probably due to regression of resistant tumors and proliferation of clones that maintain sensitivity to BRAF/MEKi. However, prospective evidence for this approach is limited. Here we report the results of 30 patients who received a second course of TT at relapse after adjuvant therapy (retreatment) or after first progression on TT in the advanced setting (rechallenge). **Methods:** GEM1801 is a prospective observational study from the Spanish Melanoma Group (GEM) including 893 patients with melanoma treated in 37 centers. This is a descriptive analysis of basal characteristics, response rates (RR), progression free survival (PFS) and overall survival (OS) from 30 patients that received retreatment or rechallenge with BRAF/MEKi in GEM1801 study. **Results:** 4 patients received retreatment and 26 rechallenge. For retreatment, BRAF/MEKi median free interval from end of adjuvant TT to subsequent retreatment was 17.8 months (range: 12.4 - 57.7). RR with retreatment were 25%, with a median PFS and OS of 5.7 and 8.5 months. For rechallenge, RR was 38.5% and median PFS and OS 11.1 and 22.2 months respectively. Patients who were selected for rechallenge had higher complete response (CR) rates to first TT (26.9% vs 20.3%; *p*= 0.026). Patients who experienced deeper responses with 1st TT in the metastatic setting showed a correlation to longer PFS to 2nd TT with 12-m PFS rates of 66.7% versus 35.7% (HR 9.09 [95%CI: 1.42-58]; *p*= 0.02). OS showed a not statistically significant improvement in patients who reported CR to first TD (24-m OS rate of 75% versus 40.7% respectively). BRAF/MEKi free interval since first progression and retreatment or rechallenge was not associated with prognosis. Prognostic factors as LDH and number of metastatic sites did not correlate with the efficacy of retreatment. **Conclusions:** Retreatment or rechallenge with BRAF/MEKi in the metastatic setting achieved encouraging efficacy and may be a valid therapeutic strategy in a selected group of patients. Response to first treatment, retreatment and rechallenge with BRAF/MEKi. Clinical trial information: NCT03605771. Neoadjuvant T-VEC + nivolumab combination therapy for resectable early metastatic (stage IIIB/C/D-IV M1a) melanoma with injectable disease: NIVEC trial. *First Author: Lisanne P. Zijlker, Division of Surgical Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Neoadjuvant systemic treatment with checkpoint inhibitors (ICI) has shown high response rates in patients with resectable metastasized melanoma. In patients with unresectable stage IIIB-IVA melanoma; intralesional treatment with talimogene laherparepvec (T-VEC) has also shown high and durable response rates. In this trial we investigated the safety and efficacy of neoadjuvant treatment with a combination of nivolumab and T-VEC in regionally metastasized melanoma. **Methods:** In this single arm phase II open-label trial (NCT04330430), 24 patients with resectable stage IIIB-IVA melanoma were included. Inclusion criteria were a RECIST 1.1 measurable lesion of ≥10mm and no prior systemic therapy. Treatment consisted of four doses of intralesional T-VEC (dose in ml according to the size of the lesions) and three doses of nivolumab 240 mg flat dose every two weeks, followed by surgery. The primary endpoint was pathological response rate according to the International Neoadjuvant Melanoma Consortium (INMC) criteria, secondary endpoints were delay or failure to perform surgery, event free survival (EFS) from time of randomization and safety. **Results:** Baseline characteristics are presented in the table. The overall pathological response rate was 74%, with a major pathological response (MPR = pathologic complete response (pCR) + near-pCR (max 10% viable tumor cells) in 15 patients (65%), a partial response in two patients (9%), a non-response in 4 patients (17%) and progression of disease (PD) in two patients (9%). In one patient the response was not evaluable because surgery was delayed due to a vena cava thrombosis. The two patients with PD had evidence of distant metastasis on preoperative imaging and therefore did not proceed to surgery as planned. Grade 2 treatment related adverse events (trAE) occurred in 7 patients (29%) and grade 3 in 2 (8%). There were no grade 4-5 trAEs. The 1-year EFS was 75% (95%CI 0.55-1). **Conclusions:** Neoadjuvant combination therapy of nivolumab and T-VEC for patients with regionally metastasized melanoma (satellite/in-transit +/- lymph node metastases) has an acceptable toxicity profile and has shown a significant major pathological response rate of 65%. Clinical trial information: NCT04330430. Research Sponsor: AMGEN.

A phase 1 study of fianlimab (anti-LAG-3) in combination with cemiplimab (anti-PD-1) in patients with advanced melanoma: Poor-prognosis subgroup analysis. *First Author: Inderjit Mehmi, The Angeles Clinic & Research Institute, A Cedars-Sinai Affiliate, Los Angeles, CA*

Background: Co-blockade of LAG-3 improves the effectiveness of anti-PD-1 treatment (Tx) in advanced melanoma (Mel) patients (pts). We previously reported high clinical activity of the combination immunotherapy of anti-LAG-3 (fianlimab) and anti-PD-1 (cemiplimab) in pts (N = 80) with anti-PD-1/PD-ligand (L)1-naïve advanced Mel enrolled in two expansion phase 1 cohorts. The objective response rate (ORR) (N = 80) and disease control rate (DCR) was 63.8% and 80.0%, respectively with median duration of response (mDOR) not reached (NR). Factors associated with poor prognosis include elevated lactate dehydrogenase (LDH) levels and sites of metastases, including liver or other visceral organs (M1c). Here we present updated efficacy data in poor prognosis pts from three phase 1 advanced Mel expansion cohorts: cohort 6 and 15 of anti-PD-(L)1/systemic Tx-naïve pts and cohort 16 of pts previously exposed to adjuvant (adj) or neo-adj systemic Tx including anti-PD-1. **Methods:** Pts with advanced Mel (excluding uveal Mel) were treated with fianlimab 1600 mg + cemiplimab 350 mg intravenously every 3 weeks for 12 months (+ additional 12 months if clinically indicated). Tumor measurements were assessed by RECIST 1.1 every 6 weeks for 24 weeks, then every 9 weeks. **Results:** 40 pts each in cohort 6 and 15, and 18 pts in cohort 16 (total N = 98) were enrolled and treated with fianlimab + cemiplimab as of 01 Nov 2022 data cutoff. In the adj/neo-adj setting, 23.5% of pts had received prior systemic Tx for Mel including 15.3% with prior exposure to immune checkpoint inhibitors (iCPIs). Median follow up was 12.6 months and median Tx duration was 32.9 weeks. ORR among all 98 pts and in 15 pts with prior iCPIs was 61.2% and 60.0%, respectively. In pts with LDH > upper limit of normal (ULN) (N = 32, 32.7%), ORR, DCR, and mDOR were 53.1%, 71.9%, and NR (95% CI, 7.4–not estimated [NE]), respectively, and median progression-free survival (mPFS) was 11.8 months (95% CI, 3.7–NE). In pts with liver mets at baseline (BL) (N = 21, 21.4%), ORR, DCR, and mDOR were 42.9%, 57.1%, and 9.0 months (95% CI, 2.8–NE), respectively, and mPFS was 4.2 months (95% CI, 1.2–NE). In pts with any M1c disease and LDH > ULN at BL (N = 17, 17.3%), ORR, DCR, mDOR were 35.3%, 58.8%, and NR (95% CI, 5.7–NE), respectively, and mPFS was 7.1 months (95% CI, 1.2–NE). Overall, 43.9% and 32.7% of pts reported grade ≥3 Tx-emergent adverse events (TEAEs) and serious TEAEs. Correlative biomarkers analyses are in progress and will be included in the presentation. **Conclusions:** The combination of fianlimab and cemiplimab showed high activity in pts with advanced Mel and poor prognosis features at BL. The ORR and DCR observed in these subgroups compare positively with the available data for approved combinations of iCPIs in the same clinical setting. A phase 3 trial (NCT05352672) of fianlimab + cemiplimab in Tx-naïve advanced Mel pts is ongoing. Clinical trial information: NCT03005782. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Determinants of racial disparities in immune-related adverse events (irAE) with checkpoint inhibition (ICI) in melanoma. *First Author: Milad Ibrahim, New York University, New York, NY*

Background: We recently reported that a pretreatment autoantibody (AutoAb) signature predicts immune-related adverse events (irAE) with an AUC of ~0.80 in melanoma patients enrolled in two phase III clinical trials of adjuvant ICI (Johannet *et al. CCR* 2022). The vast majority of those patients were non-Hispanic whites (NHW). We hypothesized that underrepresented minority (URM) melanoma patients might have a different baseline autoAb profile compared to NHW patients, as their site-specific irAEs differ (Xue Bai *et al. Br J of Derm* 2022) and autoimmune disease is generally more common in underrepresented minorities (Roberts MH, Erdei E. *Autoimmune Review* 2020). We also explored the possibility that differences in the immuno-biology of acral melanoma (AM) and cutaneous melanoma (CM) – most commonly detected in URM and NHW patients, respectively – might inform our understanding of the racial differences in irAEs. **Methods:** We compared pre-treatment sera autoAb from URM melanoma patients (n=35) to NHW patients (n= 185) enrolled in Checkmate-238 (NCT02388906), Checkmate-915 (NCT03068455) or the NYU melanoma program database using the CDI and Sengenics proteomic platforms, and analyzed their association(s) with the development of grade 3-4 irAEs. We carried out single cell RNA-seq in AM versus CM tumor tissues to test whether expression of genes whose proteins were associated with irAE were preferentially expressed in AM tissue. We also compared RNA-seq of an immunoregulatory gene panel in AM versus CM tumors. **Results:** We identified autoAbs that were only detected in sera from URM patients with grade 3-4 irAEs (e.g. *ALDOA*, *BANK1*, *LDHB* and *RNF7*) and autoAbs that were only detected in NHW patients with grade 3-4 irAEs (e.g. *GMEB2*, *YWHA* and *ANKRD45*). A subset of these autoAb targets was preferentially expressed in AM or CM tissues, while other targets were undetected in these melanoma subtypes. Cytokine signaling pathways were enriched in sera from URM but not NHW patients, and expression of genes known to modulate irAEs and response to ICI were significantly more expressed in AM than CM tumors, e.g. *FOXP3* ($P=0.01$), *IL2* ($P=0.00547$), *IL4* ($P=0.0221$) and *IL10* ($P=0.0126$). **Conclusions:** Our data suggest that URM patients have an altered tumor immune microenvironment that defines their response to ICI and risk of developing irAE. An integrative analysis of both the tumor and systemic immune environments is needed to better understand molecular links between response to ICI and irAEs in URM and NHW melanoma patients. A multi-center study is planned to address these questions. Research Sponsor: U.S. National Institutes of Health.

Final results: Dose escalation study of a personalized peptide-based neo-antigen vaccine in patients with metastatic melanoma. *First Author: Sofie Kirial Mørk, National Center for Cancer Immune Therapy (CCIT-DK), Department of Oncology, Copenhagen University Hospital, Herlev, Denmark, Herlev, Denmark*

Background: Despite the advances made with CPIs such as aPD-1/aPD-L1, aCTLA4 and aLAG-3 there still is a significant unmet medical need for patients with metastatic cancers. As it has been shown that the effect of CPIs are mediated by tumor specific T cells, one strategy for increasing treatment success is to actively induce tumor specific T cells. Here, we report on a first-in-human clinical trial evaluating a personalized neoantigen vaccine (EVX-01) in patients with metastatic melanoma. **Methods:** Stage-IV metastatic melanoma patients were treated with standard aPD-1 in combination with a personalized tumor-specific neo-antigen vaccine. The vaccine consisted of multiple 15-27mer peptides comprising one or more patient specific neoantigens identified from tumor DNA and mRNA sequencing data by an integrated AI-platform; PIONEER and delivered together with the novel liposomal adjuvant CAF09b to potentiate immune responses. **Results:** Vaccines were designed and manufactured for each patient in less than 7 weeks. In total, 12 eligible patients received either 500ug (5 patients, reported in PMID: 35036074), 1000ug (3 patients) or 2000ug (4 patients) total peptide load keeping the peptide:CAF09b ratio constant. Four patients had stable disease on aPD-1 treatment for at least 4 months before enrolment in the study, whereas the remaining patients were treatment naïve. All patients received monotherapy with pembrolizumab (11) or nivolumab (1) during the vaccine manufacturing period. The personalized vaccine was shown to be safe and well tolerated with fatigue and injection site reactions being the most frequently reported events and only grade 1-2 events being related to the vaccine. Response was evaluated by RECIST 1.1, according to the investigator's assessment with 8 patients (67%) having objective response (CR: n = 2, PR: n = 6), of which 1 patients had response initiation before addition of the vaccine. Importantly the vaccine induced neoantigen specific T cells in all patients analyzed. Both CD4+ and CD8+ T cells were detected, with the majority of responses being CD4+ T cell mediated. Interestingly, we report a significant correlation between the PIONEER prediction score and induced immunogenicity. Furthermore, the breadth of the neoantigen recognition seemed to be important for the clinical effect of the vaccine as responders demonstrated T cell recognition of more epitopes within the vaccine compared to non-responders. We found, in our cohort, that the neo-antigen scores effectively separated responders and non-responders, as opposed to the TMB (by FDA guidelines). **Conclusions:** aPD-1 treatment combined with a peptide-based personalized neo-antigen-based vaccine was shown to be feasible and safe with promising signs of efficacy, warranting further study. Further, the neo-antigen selection method appeared crucial for designing an efficacious vaccine. Clinical trial information: NCT03715985. Research Sponsor: Innovation Fund Denmark; Evaxion Biotech.

Phase II clinical trial of camrelizumab combined with famitinib for advanced acral and mucosal melanoma. *First Author: Lili Mao, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Melanoma and Sarcoma, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Acral and mucosal melanoma were rarely seen in Caucasians but common in Asians. Previous studies revealed that acral and mucosal melanoma are more aggressive than cutaneous melanoma with a high unmet need for effective treatments. Camrelizumab plus anti-angiogenic agents have shown promising antitumor activity in previously untreated melanoma. Famitinib, a selective multiple-target tyrosine kinase inhibitor that exhibits both anti-angiogenesis and anti-proliferative effects via targeting VEGFR-2, PDGFR, c-kit, FGFR and so on, combined with camrelizumab had been proven effective in multiple cancers. This study aimed to assess the antitumor activity and safety of camrelizumab plus famitinib in both immunotherapy naïve and experienced advanced mucosal or acral melanoma. **Methods:** This single-center, open-label phase II study recruited patients (pts) with advanced acral and mucosal melanoma. Pts who were immune checkpoint inhibitors (ICI) treatment naïve were in cohort 1, while pts experienced ICI in cohort 2. In both cohorts, pts received camrelizumab (200 mg i.v. q3w) and famitinib (20 mg po qd) until disease progression or intolerable toxicity. The primary endpoint was objective response rate (ORR) per RECIST1.1. Secondary endpoints included progression free survival (PFS), disease control rate (DCR), overall survival (OS), and safety. This analysis focused on cohort 2. **Results:** As of January 12, 2023, 18 pts (9 mucosal and 9 acral histology subtypes) were enrolled in cohort 2. The median age of all pts was 58 yrs (ranged 38-71 yrs); 9 pts (50.0%) were female; prevalence of mutations: BRAF (11.1%), C-KIT or NRAS (16.7% each); 38.9% received ≥ 2 prior treatments. All pts progressed after anti-PD-1/L1 monotherapy (27.8%) or combinational therapy (66.7%), except one progressed after 4-1BB mAb monotherapy. The combination drugs included anti-LAG-3/CTLA-4 antibodies (38.9%), oncolytic viruses (11.1%), c-kit inhibitors, chemotherapy and anti-angiogenic agents (5.6% each). The median follow-up was 7.3 months (ranged 4.6-14.7 months). At the data cutoff, 5 pts remained on treatment. 17 pts were evaluable. The ORR and DCR were 17.6% and 64.7%, including two pts with confirmed PR, and one with unconfirmed PR, all of which were acral subtype. The median PFS was 6.0 months. The median OS was not reached. Of 18 pts, the incidence of treatment-related adverse events (TRAEs) was 88.9%. The most common grade 3 TRAEs was neutrophil count decreased (11.1%). No grade 4 TRAEs and no treatment-related deaths occurred. **Conclusions:** Camrelizumab plus famitinib showed promising antitumor activity in ICI-experienced advanced acral and mucosal melanoma pts, and was generally well tolerated. Clinical trial information: NCT05051865. Research Sponsor: None.

Efficacy and safety of first-line (1L) nivolumab plus relatlimab (NIVO + RELA) versus NIVO plus ipilimumab (NIVO + IPI) in advanced melanoma: An indirect treatment comparison (ITC) using patient-level data (PLD). *First Author: Dirk Schadendorf, University Hospital Essen, University Duisburg-Essen, West German Cancer Centre (WTZ), and German Cancer Consortium, Partner Site Essen, Essen, Germany*

Background: NIVO + RELA and NIVO + IPI are approved as dual checkpoint inhibitor, 1L treatment options for patients (pts) with advanced melanoma based on results from the RELATIVITY-047 (NIVO + RELA vs NIVO; enrollment, 2018–2020) and CheckMate 067 (NIVO + IPI or NIVO vs IPI; enrollment, 2013–2014) trials, respectively. However, there is no head-to-head trial comparing the combinations; therefore, this ITC was conducted using PLD. **Methods:** To adjust for cross-trial imbalances in baseline characteristics, inverse probability of treatment weighting (IPTW) was used. Database locks were selected to best align follow-ups in RELATIVITY-047 (min., 21 mo; median, 25 mo) and CheckMate 067 (min., 28 mo; median, 29 mo). Efficacy and safety outcomes were selected based on data availability, including progression-free survival (PFS) per investigator, confirmed objective response rates (ORRs) per investigator, overall survival (OS), treatment-related adverse events (TRAEs), and TRAEs leading to discontinuation (DC). Efficacy was also evaluated in key subgroups. PFS and OS were compared for NIVO + RELA vs NIVO + IPI using Kaplan–Meier curves and hazard ratios (HRs); ORRs were compared using odds ratio (OR). As an internal validation of the ITC and matched assessments, the weighted NIVO cohorts from both trials were compared. **Results:** After IPTW, key baseline characteristics were balanced for NIVO + RELA (n = 340) and NIVO + IPI (n = 298). PFS, confirmed ORR, and OS after IPTW were similar between the treatments (table). Efficacy outcomes appeared to be similar between the treatments across subgroups, although trends favoring NIVO + IPI were observed for certain subgroups, such as pts with *BRAF* mutant disease or lactate dehydrogenase more than twice the upper limit of normal. Grade 3/4 TRAEs occurred in 23% and 61% of pts receiving NIVO + RELA and NIVO + IPI, respectively; any-grade TRAEs leading to DC occurred in 17% and 40% of pts. Efficacy outcomes were similar between the NIVO cohorts (table). **Conclusions:** In the absence of head-to-head trials, this ITC suggests that 1L treatment with NIVO + RELA may have comparable efficacy to, and better tolerability than, NIVO + IPI in pts with advanced melanoma. Similar outcomes between the NIVO cohorts support the ITC methodology. Results should be interpreted with caution given differences in study design and changes in treatment landscape over time. Research Sponsor: Bristol Myers Squibb.

Melanomas lacking HLA class I expression and response to checkpoint inhibitor. *First Author: Paul B. Chapman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The current paradigm of how checkpoint inhibitors (CPIs) mediate anti-tumor effects relies on $\alpha\beta$ T cells as the effector cells. However, HLA class I allele expression loss is common in melanoma, and in some cases, both β 2-microglobulin (β 2m) alleles are silenced, which results in complete loss of HLA I expression. We reasoned that if CPI therapy requires $\alpha\beta$ T cells as the effector cells, melanoma tumors with biallelic loss of β 2m could not present antigen to $\alpha\beta$ T cells and should never respond to CPI. **Methods:** We screened the 2754 melanoma patients (pts) whose tumors had been genotypically analyzed using MSK-IMPACT, a hybridization capture-based next-generation assay for targeted deep sequencing of all exons and selected introns of up to 505 genes, including β 2m. We identified 13 pts who had been treated with CPI, were evaluable for response and progression-free survival, and whose pre-treatment melanoma was found to have biallelic loss of β 2m. In 1 pt, only a post-treatment tumor was available for genetic testing for β 2m loss but lack of β 2m expression in a pre-treatment tumor was confirmed by immunohistochemistry (IHC). Pts were assessed for clinical responses using RECIST 1.1. We recorded best overall response, duration of response, and overall survival. When available, pre-treatment tumor tissue was assessed by IHC for β 2m and HLA class I expression, and for lymphocytic infiltrates expressing CD3, CD4, CD8, and CD56. **Results:** Anti-tumor responses were observed in 3/13 patients (23%); 2 PRs, 1 metabolic CR lasting for 24, 9.4, and 6.4 months, respectively. Responses were to ipilimumab (ipi) (N=2) and ipi/nivolumab (N=1). One pt responding to ipi had progressed on pembrolizumab; the other 2 responders were treatment-naïve. One pt died 11.5 months after starting treatment; the other 2 pts remain alive 5.5 and 8.9 years after starting treatment. IHC confirmed the lack of cell surface expression of β 2m and HLA class I in all 5 tumors available for IHC staining. IHC evaluations of lymphocyte infiltrates in tumors from 1 responder and 4 non-responders showed variable degrees of CD3⁺ tumor infiltrating lymphocytes (TIL) with CD4⁺ T cell predominance. Interestingly, the 1 responder had the least dense pretreatment TIL among the 5 cases. In all 5 tumors, CD56⁺ lymphocytes, indicating NK cells, were rare-to-absent. **Conclusions:** Melanomas lacking HLA class I expression can respond to CPI therapy. Although all patients ultimately progressed, some responses were long-lived and 2 of 3 patients remain alive >5yrs. It seems unlikely that traditional CD8⁺ T cells are mediating these responses but more work needs to be done to identify the effector cells in these cases. Research Sponsor: None.

High dose ipilimumab (Ipi) plus temozolomide (TMZ) after progression on standard or low dose Ipi in advanced melanoma. *First Author: Julie Williamson, Department of Internal Medicine, University of Utah, Salt Lake City, UT*

Background: Despite advancements in checkpoint inhibitor-based immunotherapy (IO), patients (pts) with advanced melanoma who have progressed on Ipi + nivolumab (Nivo) continue to have poor prognosis. Several studies support a dose-response activity of Ipi. One promising combination for these pts is Ipi 10mg/kg (Ipi10) + TMZ. TMZ depletes regulatory T cells and suppresses their function, and it may enhance the antitumor activity of Ipi. We studied outcomes of pts with advanced melanoma treated with Ipi10+TMZ in the IO refractory/resistant setting, using a cohort of similar pts treated with Ipi3+TMZ as comparison. **Methods:** Clinical data of pts with IO refractory melanoma treated with Ipi+TMZ was collected retrospectively following IRB approval. Molecular profiling by WES and RNAseq of tumors harvested throughout one responder's treatment were analyzed: the primary skin lesion (P1), a liver metastasis (M2) 2 days after low-dose Ipi1+Nivo, and a soft tissue metastasis (M3) after Ipi10+TMZ. **Results:** Overall 12 pts met eligibility: 6 received Ipi10 and 6 received Ipi3. All pts in Ipi10 cohort had progressed on prior Ipi+Nivo. Two pts (33% ORR) with CNS involvement demonstrated extraordinary near complete responses to Ipi10+TMZ despite progressing on prior therapies, including regular or low dose Ipi+Nivo. With a median follow up of 119 days, pts treated with Ipi10+TMZ had statistically significant longer median progression free survival (PFS) of 144.5 days (range 27–219) vs 44 (26–75) for Ipi3+TMZ, $p = 0.04$. There is a trend for longer median PFS for pts who had > 1 cycle of treatment, and for those who had progressed on prior Ipi+Nivo. There is a trend for longer median overall survival (OS) of 154.5 days (27–537) with Ipi10 vs 89.5 (26–548) for Ipi3 +TMZ. In those previously exposed to Ipi3+Nivo, median OS in the Ipi10+TMZ group was 154.5 days (27–537) vs 39 (26–55) in Ipi3+TMZ group. WES of one responder's tumors revealed only 12 shared somatic mutations among P1, M2 and M3, including BRAF V600E, suggesting common lineage but significant clonal evolution. Genes involved in several important immune response pathways were mutated in M2 and M3 but not in P1. RNAseq showed enrichment of inflammatory signatures, including interferon responses in both M2 and M3 compared to P1, and downregulated negative immune regulators such as Wnt and TGF β signaling. M2 is a responding liver lesion to prior Ipi1+Nivo but disease progressed to bones and brain that subsequently responded to Ipi10+TMZ. **Conclusions:** Ipi10+TMZ demonstrated efficacy including dramatic responses in pts with advanced melanoma refractory to standard or low doses of Ipi + anti-PD1, even with CNS metastases. Molecular data suggest a potential threshold of Ipi dose for activation of sufficient anti-tumor immune response, and higher dose Ipi is required for some pts. Research Sponsor: None.

Safety and preliminary efficacy of intrathecal (IT) and intravenous (IV) nivolumab (N) for patients (pts) with leptomeningeal disease (LMD). *First Author: Isabella Claudia Glitza, MD Anderson Cancer Center, Houston, TX*

Background: Pts with LMD have a dismal prognosis, with median overall survival (OS) < 3 months, no approved therapies and extremely limited clinical trial options. We previously reported initial safety findings from the dose escalation of an open label, single arm, single center phase I/II trial (NCT03025256) for pts with metastatic melanoma (MM), in which IT/IV N were well tolerated, without any CNS-specific or unexpected toxicity. Here we report an update on safety, maximum tolerated dose (MTD), and dose expansion cohort (including 2 pts with NSCLC) and preliminary efficacy. **Methods:** Pts aged ≥ 18 with evidence of LMD by MRI and/or CSF cytology, ECOG PS ≤ 2 were treated with IT/IV N. Dexamethasone (dexa) ≤ 4 mg/daily and concurrent BRAF/MEK inhibitor(i) therapy (tx) were allowed. For cycle 1, IT N was administered via ommaya reservoir on day (D)1. For subsequent cycles (every 14 days) pts received IT N on D1, followed by IV N 240 mg on D2. IT N doses evaluated were 5, 10, 20, and 50 mg. Blood and CSF were collected at multiple time points for translational research. The primary objectives were to determine safety and/or recommended dose/MTD of IT N given with IV N in pts with LMD and the safety of the MTD in an expansion cohort. OS was a secondary objective. Bayesian mTPI methodology was used to define the MTD. **Results:** 50 pts were treated: 17 in the dose escalation (2 at 5; 3 at 10; 6 at 20; 6 at 50 mg IT N), 8 in the initial expansion of 20mg, and 25 at the MTD 50 mg IT N. 48 pts had a diagnosis of MM, 2 NSCLC. Median age at LMD was 49 (19–74); 27 pts are male. All pts had radiographic evidence of LMD; 26 pts had positive baseline CSF cytology. 46 pts received prior systemic tx including checkpoint inhibitors (n = 42) and targeted tx (n = 34). 39 pts had prior CNS radiation (RT), including whole brain RT (n = 14). 18 pts used concurrent steroid, with a median dose of 2mg (0.9–4) dexa equivalent and 27 pts used concurrent targeted tx with BRAF/MEKi. The median number of IT N doses was 6 (1–92). The combination regimen was well tolerated by all evaluable pts (n = 50), with 9 pts (18%) experiencing grade (gr) 3 AEs and no reported gr 4 or 5 toxicities. Rash (58%), nausea (44%), vomiting (34%), and dizziness (22%) were the most common AEs. Thirty pts (60%) experienced AEs after IT N administration, all gr 1/2 and 1 gr 3 (vasogenic edema). At a median follow-up of 4.6 months (mths) (0, 54.8 mths), median OS was 7.0 mths. OS was 66.6% at 3 mths, 53.1% at 6 mths and 34.8% at 12 mths. **Conclusions:** IT + IV nivo was safe and well-tolerated in MM pts with LMD, with no unexpected toxicities of the 50 mg MTD of IT N. OS rates at 6 and 12 mths are encouraging and support further evaluation of IT immunotherapy for LMD, including in other tumor types. Overall results also demonstrate the feasibility of prospective clinical trials in pts with LMD. Final presentation will also include immunological analysis of longitudinally collected CSF samples collected in the trial. Clinical trial information: NCT03025256. The impact of emotional distress on pathologic response and survival after neoadjuvant combination immune checkpoint blockade (ICB) in high-risk stage III melanoma. *First Author: Irene L.M. Reijers, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Neoadjuvant ICB has been shown to induce high pathologic response rates in high-risk stage III melanoma, outperforming adjuvant ICB with respect to survival benefit. Biomarkers that have been shown to predict ICB efficacy, including the interferon-gamma (IFN- γ) signature and tumor mutational burden (TMB), do not completely explain why some patients (pts) fail to benefit from neoadjuvant ICB. Emerging evidence in preclinical and clinical studies suggests that emotional distress (ED) negatively affects tumor progression and anti-tumor immune responses, mediated by β -adrenergic and glucocorticoid signaling. Here, we investigate the association between ED prior to neoadjuvant ICB and pathologic response and survival in pts with stage III melanoma treated in the PRADO trial. **Methods:** PRADO tested neoadjuvant ipilimumab + nivolumab followed by a response-directed surgical and adjuvant treatment regimen in stage III melanoma pts. The European Organization for Research and Treatment of Cancer (EORTC) scale for emotional functioning was used to identify pts with ED, based on established clinically relevant thresholds. Association between ED and pathologic response or survival was assessed using multivariable logistic or Cox regression analysis. Potential effects of ED on the tumor and its microenvironment were examined in baseline tumor biopsies using RNA sequencing. **Results:** Pts who completed the baseline EORTC questionnaire were included and defined as pts with ED (n = 28) or without ED (n = 60). Baseline characteristics, IFN- γ signature expression and TMB were comparable. Pts with ED showed a trend towards achieving less major pathologic responses (MPR; $\leq 10\%$ viable tumor) compared to pts without ED (46% vs 65%, $p = 0.099$). Multivariable analysis showed a significant association between ED and MPR (OR 0.20, $p = 0.043$) when adjusted for age, sex, IFN- γ signature (OR 9.36, $p = 0.002$) and TMB (OR 13.21, $p = 0.003$). Pts with ED also had a significantly lower relapse-free survival (RFS) compared to pts without ED (2-year RFS 74% vs 91%, $p = 0.011$), and ED at baseline remained associated with relapse in multivariable regression (HR 3.81, $p = 0.034$) when adjusting for IFN- γ signature (OR 0.34, $p = 0.109$) and TMB (OR 1.02, $p = 0.972$). Analyses investigating the relation between ED with β -adrenergic and glucocorticoid signaling and factors representing anti-tumor immune responses are ongoing and will be presented at ASCO. **Conclusions:** Emotional distress was identified as baseline marker associated with impaired clinical outcomes after neoadjuvant combination ICB in pts with high-risk stage III melanoma. This data warrants further investigation in independent cohorts and into the potential effect of pharmacological and psychosocial interventions, e.g. adrenergic receptor blockade, on the anti-tumor immune response and patient outcomes. Clinical trial information: NCT02977052. Research Sponsor: BMS.

A phase 2 study of alrizomadlin (APG-115) in combination with pembrolizumab in patients with unresectable or metastatic cutaneous melanoma that has failed immuno-oncologic (IO) drugs. *First Author: Montaser F. Shaheen, University of Texas Health Science Ctr, San Antonio, TX*

Background: Alrizomadlin is a novel, orally active small-molecule MDM2 inhibitor that activates p53-mediated apoptosis in tumor cells, also functions as a host immunomodulator, and may restore antitumor activity in patients with cancer that has progressed on PD-1/PD-L1 inhibitors. Alrizomadlin is currently being investigated for treatment of patients with unresectable or metastatic cutaneous melanoma that progressed on prior immunotherapy. **Methods:** This multicenter clinical trial was conducted in the United States and Australia in patients with unresectable or metastatic cutaneous melanoma that had progressed on PD-1/PD-L1 immunotherapy. Eligible patients had an ECOG performance status of 0-2. Alrizomadlin 150 mg was administered orally every other day for 2 consecutive weeks, with 1 week off, and pembrolizumab 200 mg intravenously for 30 minutes on Day 1 of a 21-day cycle. **Results:** As of December 12, 2022, preliminary and interim results are reported for 31 patients with cutaneous melanoma, of whom 21 were male and 10 female, with a median (range) age of 65 (27-84) years. Treatment-related adverse events (TRAE) of any grade (> 10%) for either alrizomadlin or pembrolizumab were reported in 30/31 (96.8%) patients. These AEs included nausea (71%), vomiting (38.7%), fatigue (35.5%), thrombocytopenia (32.3%), diarrhea (25.8%), neutropenia (19.4%), decreased appetite (16.1%), and decreased leukocyte count (12.9%). A total of 4/31 (12.9%) patients reported treatment-related serious AEs, including anemia, thrombocytopenia, deep vein thrombosis, joint effusion, pulmonary embolism, and vomiting. In 26 efficacy-evaluable patients, the confirmed overall response rate (ORR; partial response [PR] + complete response [CR]) was 23.1%, including 2 patients reporting CRs and 4 reporting PRs based on RECIST v.1.1. The initial analysis indicated that the ORR observed in patients whose disease had failed IO treatment was primarily due to alrizomadlin combined with pembrolizumab, not the delayed effect of prior immunotherapy. **Conclusions:** Alrizomadlin combined with pembrolizumab is well tolerated and demonstrates clinical efficacy in these patients with highly refractory unresectable or metastatic cutaneous melanoma that had progressed on PD-1/PD-L1 immunotherapy. Internal study identifier: APG-115-US002. Clinical trial information: NCT03611868. Research Sponsor: Ascentage Pharma Group Corp Ltd. (Hong Kong) and Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Correlation of DNA methylation signatures with response to immune checkpoint inhibitors in metastatic melanoma. *First Author: Julia Maria Ressler, Department of Dermatology, Medical University of Vienna, Vienna, Austria*

Background: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of metastatic melanoma with objective response rates of 40-58%. However, reliable biomarkers to predict treatment response are lacking. Tumor tissue methylation profiles were recently proposed to have predictive value in various solid organ tumor entities. **Methods:** Patients with metastatic melanoma, American Joint Committee on Cancer (AJCC; 8th Edition) stage IV, receiving first-line ICI-based therapy, were retrospectively identified and formalin-fixed paraffin-embedded tumor tissue samples (FFPE) prior to ICI therapy were retrieved. We analyzed DNA methylation profiles of > 850,000 CpG sites in tumor specimens by Infinium MethylationEPIC microarrays. DNA methylation profiles were then correlated with radiological response (iRECIST). **Results:** 71 patients with metastatic melanoma (44 (62.0%) male, 27 (38.0%) female) were investigated; median progression free survival (PFS) was 8.5 months (range: 0 – 104.1 months) and median overall survival (OS) was 30.6 months (range: 0 – 104.1 months), respectively. 29 (40.8%) patients achieved an objective response to ICIs. Microarray analyses revealed a methylation signature including mainly hypomethylation, corresponding to the response to ICIs. Based on the 500 mostly differentially methylated genes, a total of 3 clusters were identified with the majority of responders being in cluster 2 (12/12) and 3 (12/22). The predictive performance of the methylation signature was high with 80% sensitivity, 81% specificity, and an AUC of 0.853. **Conclusions:** Our findings suggest that tumor DNA methylation profiling may be useful to predict response to ICIs in patients with metastatic melanoma. Machine learning (ML)-based quantification of tumor-infiltrating lymphocytes (TIL) and clinical outcomes of patients with melanoma treated with immune-checkpoint inhibitors (ICI). *First Author: Elio Adib, Brigham and Women's Hospital, Boston, MA*

Background: TIL quantification has shown promising prognostic and predictive impact in various tumors treated with ICI. More recently, TIL therapy has become an emerging treatment agent for ICI-refractory melanoma. In this work, we studied the effect of intrinsic TILs on clinical outcomes of patients with melanoma treated with ICI and quantified its utility as a biomarker in combination with tumor mutational burden (TMB). **Methods:** We applied a previously developed ML model to process digital whole-slide images of hematoxylin and eosin slides to quantify TIL density (TIL/mm²) in 182 metastatic melanoma samples treated with ICI at the Dana-Farber Cancer Institute. All samples underwent next-generation targeted-panel sequencing and had available TMB data (mutations/megabase). Overall survival (OS) was calculated from the date of ICI initiation to the date of death. TTF was calculated from the date of ICI initiation to the date of next line treatment or death. Alive patients were censored at the date of last follow-up. Multivariable cox regression was used to estimate adjusted hazard ratios (adj-HR) and p-values (adj-p), with TMB, prior lines of treatment and regimen type (single vs. combination ICI) used as covariates. TMB-high (TMB-H) group was defined as samples with TMB ≥ 10. TIL-high (TIL-H) group was defined as samples with TIL density higher than the median. **Results:** Of 182 patients, 60% (110/182) were male and the median age at ICI start was 65.5 years. 63% (115/182) of patients received single-agent ICI (anti-PD1 or anti-CTLA4). Of 182 tumor specimens assessed for TILs, 47 (25.8%) were obtained from the primary site. There was no difference in TIL density (medians 583 vs. 817 TILs/mm², p=0.57; 709 TIL/mm² for full cohort) or TMB (medians 11.4 vs 12.2 mutations/megabase) between primary and metastatic samples, respectively. Moreover, there was no correlation between TIL density and TMB (pearson's correlation coefficient = 0.92, p=1) across all samples. Compared to patients in the TIL-low (TIL-L) category, patients in TIL-H had significantly longer median TTF (33.9 [15.9-NR] versus 13.0 [7.8-18.6] months, adj-HR: 0.53 (95% CI: 0.36-0.78); adj-P=0.0012), while there was no difference in OS (P=0.57). In fact, patients in the TMB-H/TIL-H group had the longest TTF, followed by TMB-H/TIL-L, TMB-L/TIL-H then TMB-L/TIL-L (table). **Conclusions:** Our results support the potential use of ML-based TIL scoring as a novel and independent biomarker to predict time to failure on ICI. There is ongoing effort to validate our findings in an external dataset. Research Sponsor: None.

Group	Median OS (months)	Median TTF (months)
TMB-H/TIL-H	74.0 [45.7 – NR] months	49.0 [26.6 – NR] months
TMB-H/TIL-L	NR [43.2 – NR] months	23.3 [14.4 – NR] months
TMB-L/TIL-H	50.5 [24.5 – NR] months	15.5 [8.1 – 33.9] months
TMB-L/TIL-L	29.0 [18.1 – NR] months	6.4 [5.0 – 12.9] months

Association of ultra-sensitive ctDNA assay to identify actionable variants and response to immune checkpoint inhibitor (ICI) therapy in metastatic melanoma. *First Author: Christoffer Gebhardt, Skin Cancer Center, University Medical Center Hamburg-Eppendorf (UKE), Hamburg, Germany*

Background: Detection of molecular residual disease (MRD) via circulating tumor DNA (ctDNA) can identify therapeutic response/resistance months in advance of imaging, and monitoring clinically actionable variant dynamics in ctDNA may be important for guiding treatment. Despite this, adoption has been slow due to the reduced sensitivity and reproducibility of current approaches. Here, we profile melanoma patients receiving ICI over several years using an ultra-sensitive, tumor-informed ctDNA platform, and correlate the findings with clinical outcome. **Methods:** Over 150 plasma samples from 23 advanced melanoma patients (stage IV) were collected during ICI treatment (up to 40 months) and profiled with NeXT Personal, a tumor-informed ctDNA assay that leverages whole-genome sequencing of tumor/normal samples to generate personalized liquid biopsy panels. Each bespoke panel consists of up to 1,800 selected variants which enable sensitive MRD detection, and a fixed set of 2,100 known clinically actionable and resistance loci for detection of variants emerging under therapeutic pressure. MRD signal and variant dynamics were then correlated with RECIST assessments and outcome. **Results:** In this cohort, ctDNA was detected across a broad dynamic range (2.3-100,000 PPM; median limit of detection = 1.97 PPM) with 37% of detections occurring below 100 PPM. Baseline ctDNA was detected in 94% (17/18) of patients, and was significantly correlated with S100B and metastatic burden (Spearman's rho, 0.73 and 0.5; p, 0.0002 and 0.025). The mutation-rate normalized count of melanoma-specific driver genes detected at baseline predicted reduced overall survival (OS) (p = 0.03). 94% (17/18) of ctDNA+ patients displayed dynamic variant allele frequency (VAF) shifts, impacting 149 loci across 37 ICI-related genes including BRAF, CDKN2A, KIT, MAP2K1, and NRAS. Delta ctDNA from baseline to the first on-treatment time point correlated with PFS (log rank p = 0.004). Treatment elicited greater than 3-fold reduction in average PPM, and the magnitude was significantly correlated with progression (p = 0.0005). VAF increases in known ICI-related genes (JAK1, ALK, etc) predicted shortened OS (p = 0.007) and fewer variants in genes conferring sensitivity to (NRAS, BRAF, etc) ICI were detected on-treatment in progressing patients (p = 0.025). **Conclusions:** We tracked both tumor-informed MRD and tumor-agnostic evolution of ICI related variants over the course of treatment using a single liquid biopsy platform. We achieved ultra-sensitive ctDNA detection down to 2.3 PPM and dynamics in ctDNA signals were predictive of clinical outcome. Furthermore, we demonstrated that ctDNA measurements and VAF dynamics of clinically actionable and resistance variants correlated with response as well as resistance to ICI. Interim analysis of a phase II study of nivolumab/ipilimumab plus cabozantinib in patients with unresectable advanced melanoma. *First Author: Geoffrey Thomas Gibney, Georgetown - Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Nivolumab/ipilimumab (Nivo/Ipi) is a standard therapy in patients with unresectable stage III/IV melanoma, demonstrating an objective response rate (ORR) of 58% and 12-month progression free survival (PFS) rate of 49% [Wolchok J, NEJM 2017]. c-MET/VEGFR2 inhibition with cabozantinib (Cabo) has modest clinical activity in melanoma and can augment antitumor immunity by increasing CD8+ T cell and macrophage tumor infiltration, decreasing intratumoral regulatory T cell levels, and increasing tumor cell MHC antigen presentation. Nivo/Ipi plus Cabo showed clinical activity and acceptable toxicity profile in GU malignancies [Apolo AB, JCO 2020]. We performed a study of Nivo/Ipi plus Cabo in advanced melanoma patients aimed at improving efficacy. **Methods:** We conducted a multicenter phase II study of induction Nivo 3mg/kg IV and Ipi 1mg/kg IV and Cabo 40mg PO daily every 3 weeks for 4 cycles, followed by Nivo 480mg IV plus Cabo 40mg PO daily every 4 weeks for up to 2 years, until disease progression or unacceptable toxicity/patient withdrawal. Patients with unresectable stage III/IV melanoma and no prior anti-PD-1 or CTLA-4 exposure (unless in adjuvant setting > 6 months since last dose) were included. Uveal melanoma excluded. Primary endpoint was 12-month PFS rate. Secondary endpoints included ORR, overall survival (OS), and adverse events (AEs). Interim analysis was preplanned after first 14 subjects were evaluated in a Simon 2 stage design (goal >8 subjects 12-month progression free). **Results:** As of 1/2023, 14 subjects were enrolled across three cancer centers within the Georgetown-Lombardi Comprehensive Cancer Center Consortium. Median age 66.5 years, all stage IV disease, 10 with cutaneous primary site, 5 with elevated LDH, and 6 with BRAF V600 mutant tumor. Median follow up was 10.6 mos. 12-month PFS rate was 30% (3/10 evaluable subjects); 3 subjects pending PFS evaluation; median PFS 10.3 mos. ORR was 46% (6/13 evaluable subjects) with 2 CR, 4 PR, and 1 SD. Responders had cutaneous (5) or unknown (1) primary sites. 9 patients were alive at last follow up. 12-month OS rate was 67% (6/9 evaluable subjects). Reasons for treatment discontinuation included AEs (4), patient withdrawal (1), and disease progression (6). 3 subjects remain on study drug(s). Treatment related AEs (TRAEs) were observed in 13 subjects; 9 experienced a grade 3-4 TRAE (most frequent were elevated AST/ALT 29% and hypokalemia 14%). Most frequent grade 2 TRAEs were diarrhea (35%) and palmar-plantar-erythrodysesthesia (29%). No treatment related deaths occurred. **Conclusions:** Clinical activity was observed with Nivo/Ipi plus Cabo in advanced melanoma but did not meet the predefined threshold to advance to the second stage of enrollment. TRAE profile was similar to prior reports. Biomarker analyses are planned to identify patient profiles associated with particular benefit from this regimen. Clinical trial information: NCT04091750. Research Sponsor: Exelixis.

Expression of lymphoid structure-associated cytokine/chemokine gene transcripts in tumor and protein in serum: Outcomes for patients with melanoma. *First Author: Lilit Karapetyan, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Proinflammatory chemokines/cytokines support development and maturation of tertiary lymphoid structures (TLS) within the tumor immune micro-environment (TIME). In the current study, we sought to investigate the prognostic value of TLS-associated chemokine/cytokine (TLS-kine) expression levels in melanoma patients (MEL PTs) by performing serum protein and tissue transcriptomic analyses, and to then correlate these data with PT tumor clinicopathological and TIME characteristics. **Methods:** Levels of TLS-kines in PT sera were quantitated using a custom Luminex Multiplex Assay. The Cancer Genomic Atlas MEL cohort (TCGA-SKCM) and a Moffitt MEL cohort were used for tissue transcriptomic analyses. Associations between target analytes and survival outcomes, clinicopathological variables, and correlations between TLS-kines were statistically analyzed. **Results:** Serum of 95 PTs with MEL were evaluated; 48 (50%) female, median age of 63, IQR 51-70 years. Serum levels of APRIL/TNFSF13 were positively correlated with levels of both CXCL10 and CXCL13. Tumors with brisk/non-brisk tumor-infiltrating lymphocytes (TIL) vs. absence of TIL exhibited significantly higher levels of APRIL/TNFSF13 ($p = 0.01$), CCL19 ($p = 0.01$) and CXCL13 ($p = 0.01$). In multivariate analyses, high levels of serum APRIL/TNFSF13 were associated with improved event-free survival after adjusting for age and stage (HR = 0.64, 95% CI 0.43-0.95; $p = 0.03$). High expression of APRIL/TNFSF13 transcripts was significantly associated with improved OS in TCGA-SKCM ($n = 448$) (HR = 0.69, 95% CI 0.52-0.93; $p = 0.01$) and in Moffitt MEL PTs ($n = 134$) (HR = 0.51, 95% CI: 0.32-0.82; $p = 0.006$). Further incorporation of CXCL10 and CXCL13 transcript levels in a 3-gene index revealed that high APRIL/CXCL10/CXCL13 expression was associated with improved OS in the TCGA SKCM cohort (HR = 0.42, 95% CI 0.19-0.94; $p = 0.035$). High coordinate expression of the TNFSF13/CXCL10/CXCL13 transcripts in MEL was correlated with an increased presence of naïve B cells, plasma B cells, CD8⁺ T cells, and M1 macrophages and decreased levels of M2 macrophages and mast cells as well as a reduced neural network gene signature. **Conclusions:** Serum protein and tumor transcript levels of APRIL/TNFSF13 are associated with improved survival outcomes. PTs exhibiting high coordinate expression of APRIL/CXCL10/CXCL13 transcripts in their tumors displayed superior OS. MEL differentially expressed genes positively associated with high coordinate APRIL/CXCL10/CXCL13 expression were linked to tumor infiltration by a diverse array of proinflammatory immune cell types. Further investigation of TLS-kine expression profiles related to clinical outcomes is warranted. Analysis of overall survival (OS) and progression-free survival (PFS) in the phase 1b clinical trial of anti-PD-1 ab (toripalimab) plus intrahepatic injection of orienX010 in stage IV melanoma with liver metastases. *First Author: Chuanliang Cui, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Melanoma and Sarcoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Advanced melanoma with liver metastasis has a lower response rate and survival even in immunotherapy era which might because of its immunosuppressive tumor microenvironment. CPI combined with TVEC had showed a remarkable in cutaneous melanoma. The initial results of the phase 1b trial, systemic toripalimab (anti-programmed cell death-1 antibody) combined with Intratumoral injection of liver with OrienX010 - a HSV-1-derived oncolytic virotherapy with expression of GM-CSF in liver metastasis patients without extra-hepatic injectable lesions had shown its efficacy. Here we present the PFS and overall survival (OS) outcomes. **Methods:** Eligible pts included those over 18 with injectable liver metastasis confirmed by biopsy with or without extra-hepatic metastasis; the ocular melanoma and brain metastasis were excluded. Pts received intravenous toripalimab Q2W combined with ultrasound guided intratumoral injection of OrienX010 Q2W (8×10^7 pfu/ml, 10ml per injection) until intolerance or disease progression per iRECIST criteria. Liver biopsy would be performed at baseline and first tumor evaluation (8-12 weeks). The primary endpoint was toxicity; secondary endpoints included ORR, disease control rate (DCR), PFS and OS. Clinical trial information: NCT04206358. **Results:** From Jul 2019 to Feb 2023, 30 pts enrolled. 60.0% pts primary from mucosal; 73.3% got extra-hepatic metastasis; median size of injected lesions: 24mm (10-94mm); median number of liver metastasis: 7 (1-10); median number of injection: 10 (3-36). Among these pts, 29 pts could be evaluated for efficacy. The median PFS was 7.0 months (95% CI: 4.7-9.3 months) and the median OS was not reached. The 3-year OS rates 51.5%. The global ORR by investigator was 20.7% (6/29), DCR 48.3% (14/29); the response rate was 31.0% (9/29) for injected lesions, 30.0% (6/20) for non-injected lesions in liver, and 27.8% (5/18) for extra-hepatic metastases. For pts (21.7% (2 PR and 3 SD)) with no melanoma cells residual by immunohistochemistry in biopsies the median PFS was 14.0 months (95% CI: 3.7-24.4 months), and it was much longer than that of other pts which was 4.1 months (95% CI: 1.4-6.8 months). The median OS of the pts with no melanoma cells was 19.7 months (95% CI: 7.5-31.9 months). Most adverse events (AE) were grade 1-2 and manageable. The grade 3-4 treatment-related AE included elevated transaminase (3 [10.0%]), nausea (1 [3.3%]), pulmonary embolism (1 [3.3%]) and vomiting (1 [3.3%]). No treatment-related deaths occurred. **Conclusions:** Systemic toripalimab combined with intrahepatic OrienX010 injection has shown remarkable long PFS, OS and ORR in melanoma pts with liver metastases with manageable toxicity. Clinical trial information: NCT04206358. Research Sponsor: None.

Exploring the clinical significance of specific immune-related adverse events (irAE) in patients with melanoma undergoing immune checkpoint inhibitor (ICI) therapy. *First Author: Nethanel Asher, Ella Lemelbaum Institute for Immuno Oncology and Melanoma, Sheba Medical Center, Ramat-Gan, Israel*

Background: Several studies have demonstrated that patients who experience irAE as a result of ICI treatment, exhibit significantly improved outcomes compared to patients without toxicity. However, data regarding the impact of specific irAE is currently lacking. **Methods:** This is a real world single-site cohort of advanced melanoma patients who were treated with ICI as first line between 2014 and 2020. This study explores the effects of specific irAE on treatment efficacy. **Results:** Three hundred and ninety-five (395) patients were treated with either monotherapy anti PD-1 (65.4%), combination ICI (24.3%), or anti CTLA-4 (10.3%). Median age was 68 years (12-99y), and 57% were male. The median follow up was 24.5m. Any-grade irAEs were seen in 72% ($n = 299$), and 26% experienced high-grade irAE ($n = 104$). The most frequent irAE were dermatologic ($n = 110$, 27.8%), vitiligo ($n = 48$, 12.1%), rheumatologic ($n = 68$, 17.2%), gastro-intestinal ($n = 66$, 16.7%), and endocrine ($n = 61$, 15.4%). The development of irAE was associated with a significantly longer median PFS (19.3m vs 4.5m; HR 0.46, $p < 0.001$) and median OS (55m vs 16.9m; HR 0.44, $p < 0.001$). Specific irAE that were significantly associated with survival benefit were rheumatologic (HR 0.34 for PFS, $p < 0.001$; HR 0.38 for OS, $p < 0.001$), dermatologic (HR 0.58 for PFS, $p < 0.001$; HR 0.54 for OS, $p = 0.001$), vitiligo (HR 0.30 for PFS, $p < 0.001$; HR 0.29 for OS, $p < 0.001$) and endocrine (HR 0.6 for PFS, $p = 0.01$; HR 0.52 for OS, $p < 0.001$). After adjustment for ECOG performance status, LDH level, type of ICI protocol and M-stage - the rheumatologic, dermatologic and vitiligo irAE remained significant on multivariate analysis for both PFS and OS. **Conclusions:** The development of rheumatologic, vitiligo and other dermatologic irAE during ICI treatment, is correlated with a noteworthy survival advantage. These irAE may reflect a hyper-activated immune response and thus can serve as meaningful clinical biomarkers. Research Sponsor: None.

Transforming growth factor-b1 and soluble co-inhibitory immune checkpoints as putative drivers of immune suppression in advanced basal cell carcinoma. *First Author: Bernardo Leon Rapoport, Department of Immunology, Faculty of Health Science, University of Pretoria, Pretoria, South Africa*

Background: BCC rarely metastasizes and the mortality rate is low; however, the disease is associated with substantial morbidity. Transforming growth factor-b1 (TGF-b1) is a key player in cell proliferation, differentiation, apoptosis, and immune regulation. TGF-b1 is associated with immunosuppression and resistance to immunotherapeutic drugs. Immune checkpoint proteins (ICMs) maintain self-tolerance and modulate the immune responses of effector cells. The current study compared the levels and possible associations between systemic soluble ICMs (sICMs) and a group of humoral modulators of immune suppressor cells in a cohort of patients with advanced basal cell carcinoma (BCC, n=40) and a group of healthy control subjects (n=20). **Methods:** We measured sICMs and immunosuppressive humoral modulators by using multiplex bead array or ELISA procedures, with plasma as the matrix. The sICMs comprised seven co-inhibitory (CTLA-4, BTLA, LAG-3, PD-1, PDL-1, PDL-2, and TIM-3) and eight co-stimulatory (CD27, CD28, CD40, CD80, CD86, GITR, GITRL, and ICOS) proteins, as well as the two dual-active sICPs, HVEM and TLR2. The seven humoral modulators of immunosuppressor cells included arginase 1, fibroblast activation protein (FAP), RANTES (Regulated upon Activation Normal T Cell Expressed and Presumably Secreted) also known as CCL5, interleukin-10 (IL-10), TGF-b1, and the M2-type macrophage biomarkers, soluble CD163 (sCD163) and sCD206. Ethics approval was granted by The Research Ethics Committee, Faculty of Health Sciences, University of Pretoria (Ethics Committee Approval Numbers 356/2020). **Results:** The plasma levels of six co-inhibitory sICPs, sCTLA-4, sLAG-3, sPD-1, sPDL-1, and sTIM-3 and sPD-L2 were significantly elevated in the cohort of BCC patients ($p < 0.001$ - $p < 0.00001$), while that of sBTLA was significantly decreased ($p < 0.006$). Of the co-stimulatory sICPs, sCD27 was significantly increased ($p < 0.0002$) in the cohort of BCC patients, with the levels of the others essentially comparable with those of the control patients; of the dual active sICPs, sHVEM, sTLR2 was significantly elevated ($p < 0.00001$) and TLR2 comparable with the control group. Although the plasma levels of the seven modulators of immune suppressor function were not significantly different between the BCC and control groups, correlation heat maps revealed selective, strong associations of TGF-b1 with seven co-stimulatory ($z = 0.618468$ - 0.768131) and 4 co-inhibitory ($z = 0.674040$ - 0.808365) sICPs, as well as with sTLR2 ($z = 0.696431$). **Conclusions:** Notwithstanding the association of BCC with selective elevations in the levels of a large group of co-inhibitory sICPs, our novel findings also imply the probable involvement of TGF-b1 in driving immunosuppression in this malignancy, possibly via activation of regulatory T cells. Overall survival after the introduction of adjuvant treatment in stage III melanoma: A nationwide registry based study. *First Author: Hildur Helgadóttir, Department of Oncology-Pathology, Stockholm, Sweden*

Background: Adjuvant treatments with PD-1 and BRAF+MEK inhibitors significantly prolong recurrence-free survival in stage III cutaneous melanoma. However, the effect on overall survival is still unclear. After the approval of adjuvant treatments with PD-1 inhibitors and BRAF+MEK inhibitors, based on recurrence-free survival data, these treatments have been widely implemented. However, there are significant side effects and costs of the treatment, and the overall survival effect remains a highly anticipated outcome. **Methods:** Clinical and histopathological parameters were obtained from the Swedish Melanoma Registry that covers nearly all (99%) primary cutaneous melanomas diagnosed. Information on deaths was received from the Cause of Death Registry, a virtually complete register of all deaths in Sweden. Patients diagnosed with stage III melanoma between 2016 and 2020 were included and divided depending on if they were diagnosed before or from July 2018, the timepoint when adjuvant treatment was introduced in Sweden (designated as pre- and post-cohorts). In Sweden, approved treatments are freely available for all residents and there is a high-adherence to national treatment guidelines. Data was retrieved for the age and sex of the patients, the site, histopathological subtype, Breslow thickness and ulceration of the primary melanoma, type of locoregional spread and numbers of affected lymph nodes. Patients were followed until the end of 2021. Melanoma-specific and overall survival were calculated using the Kaplan-Meier method and Cox regression analyses. **Results:** There were 1371 patients diagnosed with stage III melanoma in Sweden in 2016-2020. The median time of follow-up in the pre-cohort was 57 months (range 42-72 months) and in the post-cohort 27 months (range 12-42 months). The 2-year overall survival rates, comparing the 634 patients in the pre-cohort and the 737 in the post-cohort, were 84.3% (95% CI 81.4-87.3) and 86.1% (95% CI 83.4-89.0), respectively, with an adjusted HR 0.91 (95% CI 0.70-1.19, $P = 0.51$). Further, no significant overall or melanoma-specific survival differences were seen when comparing the pre- and the post-cohort in different subgroups depending on the age, sex or tumor characteristics. **Conclusions:** To our knowledge, this study is the first to assess the impact on overall survival from a national introduction of adjuvant treatment in stage III melanoma. In this nationwide, population and registry-based study, no survival benefit was detected in the cohort receiving adjuvant therapy. Considering also the significant side effects and costs, these findings encourage a careful assessment of the current recommendations on adjuvant treatment. To offer close follow-up, and only treat if relapse occurs, should be an option discussed with patients with fully resected stage III melanoma. De-correlating immune checkpoint inhibitor toxicity and response in melanoma via the microbiome. *First Author: Nyellia Williams, Division of Medical Oncology, Department of Internal Medicine, The Ohio State University, Columbus, OH*

Background: Immune-checkpoint inhibitor (ICI) immunotherapy increases survival in patients with melanoma. Yet only half of the patients respond, and 10-40% of patients experience immune-related adverse events (irAEs). Previous studies have found a correlation between the development of an irAE and treatment response. Modifying the gut microbiome could positively affect response to ICIs and reduce toxicities. We sought to determine if the microbiome at the onset of treatment, during an irAE, and at 12 weeks, can predict the response or toxicity during ICI treatment for metastatic melanoma. **Methods:** Melanoma patients (pts) > 18 yo treated with ICI enrolled in a prospective observational cohort study at The Ohio State University Comprehensive Cancer Center Skin Cancer Clinic. Excluded were patients on corticosteroids at the start of ICI cycle 1, except for adrenal physiologic replacement. Stools were collected at baseline, within 2 days of an adverse event assessed by physician chart review using CTCAE (Common Terminology Criteria for Adverse Events) v5.0, and at 12 weeks. Response (ORR) to ICIs was assessed by Response Evaluation Criteria in Solid Tumors (RECIST v1.1) q12 weeks and progression-free survival recorded. Metagenomic whole-genome shotgun sequencing was performed on an Illumina NovaSeq 6000 and classified using HUMAnN3. The effect of microbe relative abundances on irAEs was modeled by logistic regression with the R package glm. **Results:** Of the 88 patients enrolled, 48 had metastatic disease with 32 assessable for response. ORR at 12 weeks was 28% (1 CR, 8 PR, 17 SD, and 6 PD) and 24 patients showed PFS at 12 months. Grade > 2 irAEs were observed in 11/48 pts. Abundance of *Bacteroides dorei* (False Discovery Rate Corrected p-value = 9.5E-07) and *Blautia species CAG:257* (padj = 0.001) were enriched in responders, *Prevotella Stercora* (padj = 1.1E-07) and a phage with a predicted target of *Salmonella* (padj = 8.3E-09) in non-responders. Responders with an irAE had enrichment of *Bacteroides plebeius* (padj = 4.2E-13) and *Bacteroides coprophilus* (padj = 0.0002) whereas responders without irAE had enrichment of *Eubacterium siraeum* (padj = 7.2E-05). **Conclusions:** Longitudinal and event-driven biospecimen collection in patients treated with ICIs showed several bacteria and viruses but no fungi associated with response, with and without the development of an irAE. The abundance of the two high-taxonomic rank microbe groups is significantly associated with irAEs. The association with the *Bacteroides* Genus is consistent with previous studies and is associated with response to ICIs. A microbiome abundant in *Bacteroides* and lacking *Prevotella* is associated with response to ICI. An abundance of *Bacteroides* could be a biomarker for irAEs, and an abundance of *Eubacterium*, a biomarker for response without irAEs. Future analyses are necessary to assign causal roles for microbe biomarkers with specific irAEs. Clinical trial information: NCT05102773. Research Sponsor: Pelotonia.

Population-based validation of the melanoma institute australia (MIA) and the memorial sloan-kettering cancer center (MSKCC) predictive tool for sentinel node status in patients with melanoma. *First Author: Rasmus Mikiver, University of Linköping, Linköping, Sweden*

Background: Patients with primary cutaneous melanoma are selected for sentinel lymph node biopsy (SLNB) based upon their risk of a positive SLN being identified. To improve upon stage-based categorization, the Memorial Sloan Kettering Cancer Center (MSKCC) and Melanoma Institute Australia (MIA) developed predictive models. Which model is more clinically useful is currently unclear. **Methods:** Consecutive patients undergoing SLNB from 2007-2021 were identified from the Swedish Melanoma Registry (SweMR), which covers 99% of patients with invasive cutaneous melanoma in Sweden. The predicted probability of SLN positivity was calculated using the MSKCC and limited MIA models (using mitotic rate as absent/present instead of count and excluding the optional variable lymphovascular invasion) for each patient. The operating characteristics of the models were assessed and compared. The "clinical utility" of each model was assessed using decision curve analysis (DCA) and compared with a strategy of performing SLNB on all patients. **Results:** In total 10,089 patients were included; the median Breslow thickness was 1.8 mm, 33.7% were ulcerated, and 1,802 patients had a positive SLN (17.9%). Both the MSKCC and limited MIA models were well calibrated across the full range of predicted probabilities, and had similar external area under curve (AUC), MSKCC 70.8% (95% CI 69.5-72.1%) and MIA 70.3% (95% CI 68.9-71.7%). When new models were constructed to compare the incremental value of the additional parameters of either nomogram over Breslow thickness alone, the AUCs were 70.1%, 71.6% and 72.0% for Breslow alone, MIA parameters and MSKCC parameters, respectively. At a risk threshold of 5%, DCA indicated no added net benefit for either model compared to performing SLNB for all patients. At risk thresholds of 10% or higher, both models added net benefit compared to SLNB for all. The greatest benefit was observed from use of the models in patients with T2 melanomas when a threshold of 10% was used to select patients for SLNB. In that setting, use of the nomograms led to a net reduction in seven avoidable SLNBs per 100 patients for the limited MIA nomogram and eight for the MSKCC nomogram, when compared to a strategy of SLNB for all. **Conclusions:** This study confirms the statistical performance of both the MSKCC and limited MIA models in a large, nationally-representative dataset. However, clinical utility as assessed by DCA demonstrated that using the models only improved selection for SLNB when a risk threshold of at least 10% was employed, and then mainly for T2 melanomas. Either further development of the nomograms, or other strategies, are needed to improve selection at lower risk thresholds. Tumor-informed circulating tumor DNA (TI-ctDNA) based molecular residual disease (MRD) detection and relapse risk for patients with stage II-IV melanoma in surgical remission: A single center experience. *First Author: Logan Rhea, Virginia Commonwealth University Health System, Richmond, VA*

Background: Melanoma is associated with significant risk of relapse after surgery. While the odds of relapse increase with advancing stage, long term relapse free survival (RFS) is possible without adjuvant therapy in a significant subset of patients as shown by AJCC v8 staging long term survival data. TI-ctDNA (Signatera™) is a non-invasive biomarker for MRD detection and functions by sequencing the patient's own tumor for the creation of a customized panel of PCR probes based upon a tumor's unique mutational profile. Positive TI-ctDNA testing is significantly associated with relapse after surgical resection in colorectal cancer and may help inform treatment decision-making, allowing for intensification or de-intensification of patient management. This study describes the operating characteristics of TI-ctDNA in monitoring for relapse in patients with resected melanoma. **Methods:** This is a single center retrospective analysis of patients with stage IIb-IV melanoma in surgical remission. Between January 2021 and January 2023, male and female patients presenting in surgical remission were monitored with TI-ctDNA at 6- or 12-week intervals. Surveillance imaging for relapse was performed according to standard of care guidelines appropriate for tumor stage. Patients were treated with immunotherapy, targeted therapy, or melanoma specific anti-tumor vaccine. Duration of RFS from surgery to detectable TI-ctDNA was recorded, along with duration of RFS from surgery to confirmed melanoma relapse. **Results:** 45 eligible patients were included in the analysis. 10 patients had detectable TI-ctDNA during the study period. 7 patients had confirmed relapse, 6 of whom were TI-ctDNA positive and 1 who was TI-ctDNA negative. The total relapse rate in TI-ctDNA positive patients (6/10) was significantly higher than the relapse rate in TI-ctDNA negative patients (1/35) [p = 0.0002]. Time to detection of positive TI-ctDNA was variable and ranged from 0 to 664 days (median 73 days). **Conclusions:** TI-ctDNA testing demonstrated preliminary ability to differentiate melanoma patients at the highest risk of relapse. Prospective evaluation of TI-ctDNA monitoring for determination of patients at high versus low risk of relapse is warranted and may help to inform future clinical trial designs by allowing for patient stratification to low risk (undetectable TI-ctDNA) and high risk (detectable TI-ctDNA) disease states. Intralesional therapy, limb infusion/perfusion, and immune checkpoint inhibitors as first-line therapy in surgically unresectable melanoma in-transit metastases. *First Author: Danielle K DePalo, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Surgery remains the gold standard for resectable melanoma in-transit metastases (ITM). Unresectable ITM is a heterogeneous disease with multiple treatment (tx) options including systemic therapies such as immune checkpoint inhibitors (ICI), regional therapies such as isolated limb infusion or perfusion (ILI/P), and intratumoral therapies such as talimogene laherparepvec (IT). Until now, there has been no direct comparison of these first-line tx for unresectable ITM. **Methods:** A retrospective chart review of patients (pts) with ITM treated first-line with IT, ILI/P, or ICI was performed at 11 institutions. Pts with unresectable ITM, synchronous nodal or distant metastatic disease were excluded. **Results:** 560 pts (54% women) were identified, 86 received IT, 353 received ILI/P, and 121 received ICI from 1990-2022. ICI pts were youngest, IT pts were oldest (p<0.001). Limb was the most common site of ITM. There was no difference in largest ITM size, but number of lesions (burden of disease (BOD)) was highest in ILI/P pts and lowest in IT pts (p=0.003). Toxicity (tox) requiring <90 days (p<0.001) or > 90 days (p=0.034) of pharmacologic tx as well as tox requiring hospitalization (p<0.001) was greatest in ICI pts. Lymphedema was more likely in ILI/P pts (p=0.016). Median follow-up was much longer for ILI/P pts at 8.0 yrs compared to 2.5 yrs for IT pts and 3.1 yrs for ICI pts. Overall response rate (ORR) was 82.2% in ILI/P pts, significantly higher than IT (72.1%, p=0.047) or ICI pts (63.6%, p<0.001). Overall survival was similar between modalities (p=0.167); however, ILI/P pts had worse progression-free survival (PFS) (p<0.0001) and melanoma-specific survival (MSS) (p=0.003). On multivariable analysis of MSS by number of ITM present, MSS remained worst if ILI/P was used for low BOD, ≤3 ITM (p=0.005), but no difference was seen between tx modalities for higher BOD, >3 ITM (p=0.211). **Conclusions:** ICI was used more often in younger pts with less BOD, IT in older pts with less BOD, and ILI/P in older pts with high BOD. Short and long-term tox was greater in ICI. ILI/P had the best ORR, but ICI and IT resulted in greater overall MSS. Multidisciplinary consideration of risks and benefits of each modality should guide ITM tx selection. Research Sponsor: None.

Discovery and validation of AMBLor as a prognostic biomarker for non-ulcerated cutaneous AJCC stage I/II melanoma. *First Author: Penny Lovat, Newcastle University, Newcastle upon Tyne, United Kingdom*

Background: Cutaneous melanoma incidence continue to increase, with a particular increase in the number of patients diagnosed with thin, < 1mm tumours with reduced probability of recurrence-free survival. The inability of current AJCC staging criteria to identify genuinely low risk subsets of patients with AJCC stage I/II tumours thus emphasises the acute need for credible prognostic biomarkers to stratify patient follow-up based on personalised risk. The combined immunohistochemical (IHC) expression of AMBRA1 and Loricrin (AMBLor) in the epidermis overlying non-ulcerated AJCC stage I melanomas has recently been identified as a prognostic biomarker and valuable pre SLNB test. The aim of the present study was to evaluate the potential for AMBLor as a prognostic biomarker for both AJCC stage I and II non-ulcerated melanoma. **Methods:** Prospective analysis of AMBLor was performed in two independent retrospective cohorts of non-ulcerated AJCC (8th edition) stage I and II cutaneous melanomas derived from the USA and Australia (discovery cohort) and Spain and the UK (Validation cohort) following validated automated immune-histological staining and binary scoring analysis to define at risk vs low risk subgroups. Each cohort was powered to represent rates of 10% or up to 20% metastasis for stage I or stage II disease respectively. **Results:** Data revealed retention of AMBLor in the discovery cohort of 541 melanomas correlated with significantly increased recurrence-free survival (RFS) of 96% compared to 87% for patients with stage I/II melanomas in which AMBLor was lost (P = 0.06; HR 3.6, 95% CI 1.99-6.84, NPV 96%). Subsequent AMBLor analysis in the validation cohort of 303 tumours, further confirmed retention of AMBLor was associated with increased RFS of 98% compared to 81% for patients with stage I/II tumours in which AMBLor was lost (P = 0.01; HR 8.16, 95% CI 3.68-18.07). **Conclusions:** Collectively data from this multi-international study confirm AMBLor as a prognostic biomarker marker able to identify genuinely low risk subsets of AJCC stage I/II melanomas. Inclusion of AMBLor into clinical melanoma management may therefore aid stratification of patient follow up, enable significant savings on healthcare resources and improve patient anxiety. Nature and management of melanoma recurrences following adjuvant anti-PD-1 (PD1) therapy. *First Author: Rachel Woodford, Melanoma Institute Australia, Wollstonecraft, Australia*

Background: Despite improved outcomes with the use of adjuvant PD1 therapy, approximately 50% of patients (pts) develop recurrent disease by 5 years. Data to define best management of recurrences is lacking, including whether retreatment with PD1 has benefit. **Methods:** This was a multicentre, international retrospective study of pts with resected stage II-IV melanoma who commenced adjuvant PD1 therapy before January 2022 and then recurred. Demographics, disease characteristics, treatment, toxicity, recurrence patterns, management and outcomes were collected. **Results:** 711 pts from 17 sites were included. Med age was 60 [range 16-92], 64% (N=451) were male. 641 (91%) pts were stage III (A 7%, B 24%, C 54%, D 3%), 18 (2%) stage II, 51 (7%) stage IV. 80% (N=536) underwent SLNB prior to PD1, of which 44% (N=236) went onto CLND. 635 pts (90%) received PD1, 74 (10%) PD1 + other. Med time to recurrence was 6.2 months (m) (0-68.5); 63% (N=444) recurred ON PD1, while 36% (N=257) recurred OFF. 338 pts (48%) recurred within 6m of starting adjuvant, 166 (23%) between 6-12m, 140 (20%) 12-24m and 59 (8%) after 24m. Initial recurrences were locoregional (LR) alone in 315 (44%), 307 (43%) distant alone, and 78 (11%) both. Patients with LR recurrences alone underwent definitive surgery, or surgery + radiation in 98 (31%) and 42 (13%) respectively. After initial LR management, 164 (52%) had a further local and 129 (41%) distant recurrence. Those with initial distant recurrences were managed with definitive surgery (21, 7%), surgery + radiation (8, 3%) and radiation alone (14, 5%). Further 'second' adjuvant therapy was given in 27% (N=86) of LR and 6% (N=25) of distant recurrences. Definitive systemic therapy at first recurrence was given in 77% (N=296) distant and 23% (N=73) LR recurrences (Table). **Conclusions:** Patients recurring after adjuvant PD1 therapy do so early, and often while on drug. Patients with resected recurrences often receive "second adjuvant" therapy, although whether adjuvant or definitive, outcomes are poor. Novel drug therapies and clinical trials are required for those who recur despite PD1 therapy. Research Sponsor: None.

NEO-CESQ study: Neoadjuvant plus adjuvant treatment with cemiplimab in surgically resectable, high risk stage III/IV (M0) cutaneous squamous cell carcinoma. First Author: Paolo Antonio Ascierto, Melanoma, Cancer Immunotherapy and Development Therapeutics Unit, Istituto Nazionale Tumori IRCCS "Fondazione G. Pascale", Naples, Italy

Background: In the last years, the treatment of locally advanced and/or metastatic cutaneous squamous cell carcinoma (CSCC) has been revolutionized by the introduction of cemiplimab, an anti-PD-1 antibody, which showed a 50% overall response rate and long term benefit (1). Recently, a phase II trial of neoadjuvant cemiplimab in resectable CSCC patients (2), showed a major pathological response (MPR) rate of 63.3%. In the current multicenter, phase II trial we evaluated the efficacy of neoadjuvant plus adjuvant immune checkpoint inhibitor in patients with surgically resectable, high-risk stage III/IV (M0) CSCC. **Methods:** Patients with surgically resectable high-risk stage III/IV (M0) CSCC received cemiplimab at a dosage of 350 mg every 3 weeks for two cycles prior surgery and for one year after surgery. The study primary endpoint was MPR [pathological complete response (pCR) or near pCR (< 10% remaining viable tumour cells in the surgical pathology sample)] per independent central pathology review. Key secondary endpoints included recurrence-free survival (RFS), overall survival (OS), safety and the analysis of predictive biomarkers. **Results:** From May 2021 to October 2022 twenty-three patients were enrolled in 6 centers. pCR was observed in 9 (39%) patients and near pCR in 2 (8%) patients, while pathological partial response (10-50% remaining viable tumour cells) and no pathologic response was observed in 1 patient and 11 patients, respectively. At data lock of 31st January 2023, only one patient was discontinued due to clinical progression. Furthermore, it was observed n = 60 (57%) any adverse events (AE) and n = 29 (30%) treatment-related AE. No any G3/G4 AE were observed. **Conclusions:** Neoadjuvant cemiplimab induced a pathological response in 52% of stage III/IV (M0) CSCC patients with a MPR in 48%. The study is still ongoing to evaluate the impact of combined neoadjuvant and adjuvant immunotherapy on RFS and biomarkers analysis. Clinical trial information: NCT04632433. Research Sponsor: SANOFI.

Association of circulating tumor DNA kinetics with disease recurrence in patients with stage IIIB/C/IV melanoma treated with adjuvant immunotherapy in Checkmate 238. First Author: Mahrukh M. Syeda, New York University School of Medicine, New York, NY

Background: In patients (pts) with resected, stage III/IV melanoma receiving adjuvant immunotherapy, pre-treatment (pre-Tx) and on-treatment (on-Tx) circulating tumor DNA (ctDNA) combined with tumor features were evaluated to predict recurrence risk. **Methods:** We used analytically validated, mutation-specific droplet digital PCR (ddPCR) assays to measure ctDNA in pre- and on-Tx plasma samples from pts with resected stage IIIB/C/IV melanoma enrolled in CheckMate 238 (NCT02388906) receiving either adjuvant Nivolumab (NIVO) or Ipilimumab (IPI). Assay choice was based on detection of one of the 7 melanoma hot-spot mutations in pt tumors: BRAF V600E/K, NRAS Q61R/L/K, or TERT C228T/C250T. We evaluated associations between ctDNA detection, recurrence free survival (RFS), distant metastasis free survival (DMFS), and known immunotherapy tumor biomarkers including PD-L1, IFNg gene signature, CD8, and tumor mutational burden. Associations between ctDNA kinetics and RFS/DMFS were analyzed using Kaplan-Meier and Cox regression models. **Results:** Mutations were identified in 87% of tumors. ctDNA was detected in pre-Tx samples from 94/753 (12.5%) pts. Pre-Tx ctDNA was significantly associated with higher stage of disease, LDH $\geq$ ULN, PD-L1 < 5%, and tumor IFNg-RNA signature expression below the median. Detection of pre-Tx ctDNA was associated with shorter RFS and DMFS in both NIVO and IPI arms compared to undetectable ctDNA (Table). ctDNA detection on-Tx (week (w) 3, 7, 13, 25, 37, 49) was also associated with shorter RFS. Refined subgroup predictions that potentially impact therapy were achieved by incorporating pre- and on-Tx time points. Of those with baseline and w7 ctDNA results, pts in the NIVO arm with undetectable pre-Tx ctDNA (n=308) that became positive at w7 (n=22) had shorter RFS (median RFS 20.68 mos [95% CI, 2.79, NR]) than pts in whom on-Tx ctDNA remained undetectable (n=286) (median RFS, NR [95% CI, 61.1, NR]). Pts with positive pre-Tx ctDNA (n=42) that remained positive at w7 (n=23) had markedly shorter RFS (median RFS, 3.35 mos [95% CI, 2.73, 20.44]) vs pts in whom on-Tx ctDNA became undetectable (n=19) (median RFS, NR [95% CI, 14, NR]). Similar results were observed in the IPI arm. **Conclusions:** Pre- and on-Tx ctDNA measurements are associated with melanoma recurrence risk during adjuvant checkpoint inhibitor therapy. Incorporation of ctDNA with other tumor molecular features may improve prediction of RFS and DMFS in this setting. Clinical trial information: NCT02388906. Research Sponsor: U.S. National Institutes of Health; Bio-Rad; Bristol Myers Squibb.

Melanoma disparities in urban vs rural communities in the era of immunotherapy: An NCDB analysis. First Author: Rachel Akers, Rush University Medical Center, Chicago, IL

Background: Several barriers to care exist for melanoma patients including distance to specialty care, transportation, and cost. Additionally, differences in rural and urban melanoma incidence have not been fully investigated. Using a large nationwide database, we aim to investigate the relationship between urban and rural locations in stage of melanoma presentation and access to adjuvant systemic treatment. **Methods:** The National Cancer Database (NCDB) was queried for all adult patients ($\geq$ 18 years old) with diagnosis of cutaneous melanoma from 1/1/2011 – 12/31/2020. For receipt of adjuvant immunotherapy, diagnosis from only 1/1/2017 - 12/31/2020 was analyzed. Demographic, socioeconomic, tumor-related, and treatment-related factors were analyzed using SPSS Statistics, with Chi-square analysis performed for categorical variables and ANOVA performed for continuous. **Results:** Between 2011 and 2020, 558,445 patient cases were identified and included in the analyses. The average age was 63.7 years, and patients predominantly identified as White (97.6%) and non-Hispanic (96.2%). Patients in urban areas were more likely to present with melanoma of the extremities (40.8% vs 36.2%, $p < 0.001$), while patients in rural areas presented with head and neck melanoma (26.2% vs 31.0%, $p < 0.001$). Additionally, patients in urban areas were more likely to have an early-stage melanoma (0, 1, or 2) melanoma (51.4% vs 48.5%, $p < 0.001$). Patients in rural areas traveled an average of 68 miles for care, in contrast to urban patients who traveled an average of 20 miles ($p < 0.001$). There was no significant difference when comparing receipt of immunotherapy for stage 3 or stage 4 patients. **Conclusions:** In rural areas, patients with melanoma tended to present with a higher portion of head and neck melanoma and of later stage. Rural patients also had to travel farther for care. However, these differences did not result in fewer patients in rural areas receiving immunotherapy for appropriate treatment. Further studies are needed to evaluate how these presentation differences influence care outcomes. Research Sponsor: None.

A pilot study of the neoadjuvant use of vemurafenib plus cobimetinib in patients with BRAF-mutant melanoma with palpable lymph node metastases: Survival results. First Author: Teresa M. Petrella, Sunnybrook Hospital, Toronto, ON, Canada

Background: Melanoma patients with palpable nodal metastases have a very poor prognosis with the majority recurring within the first 2-3 years post-resection with survival ranging from 20-50% at 5 years. We aimed to ascertain if patients with a BRAF V600 mutation that receive vemurafenib and cobimetinib before surgery (neoadjuvantly) have a higher probability of resectability, pathologic complete response (pCR), and a lower risk of local recurrence and a longer disease free survival (DFS), distant metastatic free survival (DMFS) and overall survival (OS). **Methods:** This was a single arm, prospective, multi centre phase II study in patients with histologically confirmed, BRAF V600 mutated Stage IIIB and IIIC melanoma (AJCC 7th Edition) with palpable nodal disease. Patients received vemurafenib 960mg PO BID and cobimetinib 60mg PO OD for 4 months prior to resection followed by 8 months of adjuvant therapy post-surgery. CTscans were performed at baseline and before resection and every 6 months for the first 3 years and yearly in year 4 and 5. Biopsies for correlative studies and diagnosis were performed at baseline prior to starting therapy. The primary outcomes were the proportion of patients achieving resectability, radiologic response as per RECIST and the proportion of patients achieving a pCR. Presented here are the LRFS, DMFS, DFS and OS. **Results:** Twenty-four patients were enrolled and received neoadjuvant vemurafenib and cobimetinib and 21 underwent resection. Following resection and pathological evaluation 12 (57%; 95% CI 34.02-78.18) patients achieved a pCR, 8 (38%; 95% CI 18.11-61.56) had a partial pathologic response and 1 had no pathologic response. Of the 24 patients, 2 patients (8%) developed local recurrence, 6 patients (25%) developed distant metastasis, and 8 patients (33%) had either local or distant recurrences. 7 patients (29%) died due to metastatic disease. At 60 months, LRFS was 89.5% (76.7-100%), DMFS was 75.0% (59.5-94.5%), DFS was 85.7% (72.0-100%), and OS was 63.9% (95% CI 43.5-93.8). Among total 20 evaluable patients, 17 patients had CR/PR and 3 had PD/SD as best response. There was no significant difference between patients with CR/PR or SD/PD (log-rank p-value = 0.0548) with 48 month survival of 82.4% for CR/PR population compared to 33.3% with SD or PD. **Conclusions:** In this small phase II study, neoadjuvant vemurafenib and cobimetinib led to a higher LRFS, DMFS, DFS and OS of all resected patients with bulky nodal disease compared to historical survival rates. Clinical trial information: NCT02036086. Research Sponsor: Roche; institutional funding.

Prognostic significance of immune-related adverse events and immunosuppression in patients with melanoma receiving adjuvant anti-PD-1 therapy. *First Author: Andrew David Knight, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: Treatment with anti-Programmed Death-1 (PD-1) therapy reduces the risk of recurrence for patients (PT) with resectable Stage IIB-IV melanoma (MEL). This treatment is associated with the development of immune-related adverse events (irAEs), which may necessitate use of immunosuppressive therapy and treatment discontinuation. This project investigates the impact of irAE and immunosuppressive therapy in survival outcomes of PTs with MEL. **Methods:** PTs with stage IIB-IV resectable MEL who received adjuvant or neoadjuvant treatment with anti-PD-1 therapy were enrolled from the University of Pittsburgh Melanoma Center biospecimen repository. The association between irAEs/immunosuppressive therapy and recurrence-free survival (RFS) and overall survival (OS) were evaluated by univariate and multivariate Cox proportional hazards regression models. **Results:** A total of 6059 PT were consented to the repository: stage III = 1,328, stage IIB = 403, and stage IIC = 269 PT. Of these PT, 180 men and 93 women received adjuvant anti-PD-1 therapy. Average age at diagnosis was 61. BRAF mutation present in 94 PTs: V600E = 71 PT, V600K = 11 PT. Documented irAEs occurred in 50.9% of PTs. Cutaneous irAEs were most common (65/139, 46.8%), followed by endocrine (45/139 32.4%), and visceral organ (37/139, 26.6%). Of the 32 visceral organ irAEs, 15 were gastrointestinal, 10 pulmonary, 5 hepatic, and 1 renal. Systemic corticosteroids > 10mg of prednisone equivalent were administered during adjuvant therapy for 24.9% of PT. In the univariate model, development of irAEs was associated with improved OS (HR = 0.38; CI 0.18-0.83, p = 0.015). In a multivariate analysis after adjusting for age and sex, irAE development continued to be associated with improved OS (HR = 0.38; CI 0.17-0.82, p = 0.014). RFS did not differ for patients that developed irAEs (HR = 0.9; CI 0.59-1.4, p = 0.67). Steroid treatment was not associated with a change in OS (HR = 1.04; CI 0.46-2.4, p = 0.93) or RFS (HR = 0.96; CI 0.59-1.56, p = 0.87). **Conclusions:** Half of stage IIB-IV resectable MEL PT receiving adjuvant anti-PD1 therapy developed irAEs, of which 24% required steroid therapy. Development of irAE was associated with improved OS and corticosteroid use for irAE did not mitigate adjuvant therapy outcome benefits. Research Sponsor: None.

Longitudinal circulating tumor DNA monitoring for detection of molecular residual disease in patients with surgically resected stage II/III melanoma. *First Author: Revathi Kollipara, Rush University Medical Center, Chicago, IL*

Background: Over the past decade, advances in immunotherapy (IO) have dramatically improved overall survival (OS) for patients with metastatic melanoma. Immune checkpoint inhibitors and BRAF/MEK inhibitors also became standard of care for surgically resected stage III melanoma, and most recently pembrolizumab was approved for stage IIB/C patients. Although the phase III trials that led to their respective approvals met their primary endpoints for relapse-free survival, no benefit in OS has been observed. Given that a large proportion of early-stage melanoma patients are cured with surgery alone, the decision to proceed with adjuvant therapy should be weighed against the risk of potential life-altering toxicity. There is a high unmet need to develop biomarkers to accurately select patients who are most likely to benefit from adjuvant IO while sparing a group of low risk patients from unnecessary treatment. In this study, we evaluated the prognostic value of personalized, tumor-informed circulating tumor DNA (ctDNA) testing in patients with resectable stage II/III melanoma. **Methods:** In this real-world study, longitudinal plasma samples (n = 159) were analyzed in real-time from 45 stage IIA-IIID cutaneous melanoma patients treated at Rush University between 03/30/2021 and 01/12/2023. A personalized, tumor-informed ctDNA assay (Signatera bespoke, mPCR-NGS assay) was used for detection and quantification of ctDNA in plasma samples. **Results:** Personalized, tumor-informed ctDNA assays were successfully designed for 93% (42/45) of patients using tissue samples from either surgical resection (14/42, 33%) or biopsy (26/42, 67%; 16 shave, 10 excisional, 1 punch, 1 core). ctDNA was detectable at one or more time points in 36% (15/42) of patients. We observed a higher ctDNA-positivity rate in stage III patients (11/20, 55%) compared to stage II patients (4/22, 18%). Twelve of the 15 ctDNA-positive patients received adjuvant IO/treatment escalation after a positive ctDNA result; 6 patients had sustained ctDNA clearance, 2 had transient clearance, and 4 continue to receive adjuvant IO and follow-up ctDNA testing. Radiographic recurrence was observed in 7/42 patients, 6 of whom were ctDNA-positive. Ninety-six percent (26/27) of patients with persistent ctDNA-negativity remain clinically and radiographically progression-free. **Conclusions:** Our data suggest that molecular residual disease detection using a personalized, tumor-informed ctDNA assay is highly prognostic in melanoma patients undergoing curative resection. Sustained clearance of ctDNA was achieved with adjuvant therapy in a subset of this cohort. Prospective studies evaluating the utility of ctDNA to aid clinical decision-making regarding adjuvant treatment intensification or de-escalation are warranted. Research Sponsor: None.

Intralesional oncolytic virotherapy with talimogene laherparepvec in patients with cutaneous lymphomas and non-melanoma skin cancers. *First Author: Egle Ramelyte, Department of Dermatology, University Hospital of Zurich, Zurich, Switzerland*

Background: Cutaneous lymphomas (CL) and non-melanoma skin cancers (NMSC) present with skin lesions and can often be treated with local therapies. However, some do not respond or relapse, underlining the need for new treatment options. Intralesional oncolytic virotherapy with genetically modified Herpes simplex 1 virus called Talimogene laherparepvec (T-VEC) was approved for cutaneous melanoma. Given previous reports on oncolytic virotherapy in non-melanoma tumors, we investigated the effect of intralesional T-VEC in patients with CL and NMSC. **Methods:** Patients with CL and NMSC without extracutaneous spread were eligible (NCT03458117). They were treated according to the standard for up to 8 injections. We assessed clinical response of injected and, whenever possible, non-injected lesions using response criteria for intratumoral therapies (iTRECIST). Safety was assessed using CTCAE v5 criteria. To evaluate T-VEC induced changes, we collected tumor biopsies at baseline, after 2 and 5 injections. We performed multiplex immunohistochemistry for CD3, CD8, CD79a, CD56, CD11c and FoxP3 and evaluated the changes using Akoya Bioscience technology. **Results:** Twenty-seven patients were enrolled into the study: 19pts with cutaneous B-cell lymphoma (CBCL), 5pts with cutaneous T-cell lymphoma, 1pt with cutaneous squamous cell carcinoma and 1pt with Merkel cell carcinoma. The mean age was 61.9yrs. In total, 26pts have received at least one intralesional T-VEC, one patient has withdrawn consent before the first infusion. Patients received median of 7 injections, 11pts (44%) have received 8 planned injections. Therapy was well tolerated with treatment related fever, flu-like symptoms and ulceration of the injected tumor being the most common treatment related adverse events (AE) (34% each). Three patients (12%) had grade 3 AE. Of the injected lesions, 84% demonstrated response, with reduction of the elevation in 84% and reduction of redness of the tumor in 68%. Non-injected response was 40% and overall response was 32%. Tissue samples of 18pts were available for analysis. Following T-VEC injections, responding lesions had an increase of CD8+ and decrease of FoxP3+ cells, while all lesions had an increase of CD56+ cells and slight reduction of CD79a+ cells. Responding CBCL samples had increased CD3+ cells, whereas all samples had an initial reduction of CD79a+ and CD11c+ cells, independent of response. **Conclusions:** Oncolytic virotherapy with intralesional T-VEC induces clinical responses and is tolerated without any unexpected toxicities in patients with locally advanced cutaneous lymphomas and NMSC. T-VEC induces activation of immune response, with differences in responding and non-responding lesions. T-VEC represents a viable treatment option for patients with CL and NMSC, and should be investigated in larger controlled clinical trials. Clinical trial information: NCT03458117. Expanded cohort and extended follow-up of neoadjuvant plus adjuvant (neo + adj) dabrafenib (D) and trametinib (T) in patients (pts) with surgically resectable stage (stg) III/IV melanoma. *First Author: Tarin Hennegan, MD Anderson Cancer Center, Houston, TX*

Background: Most melanoma pts are diagnosed with earlier-stage, surgically resectable disease. Although there are approved adjuvant immunotherapy (IT) and targeted therapy (TT) options available, neoadjuvant systemic treatment (NST) has demonstrated improved outcomes based on pathologic complete response (pCR). We previously reported outcomes from a randomized trial comparing neo + adj DT vs upfront surgery followed by adj DT in pts with surgically resectable stage III/IV BRAF mutated melanoma. After enrolling 21 pts, the randomized study was closed by the Data Safety Monitoring Board due to rapid disease progression in pts randomized to upfront surgery. The trial continued as a single-arm study to evaluate neo + adj DT. With a median follow up of 35 mos (range 6-97 mos), we report the updated outcomes for the pts evaluable for the primary endpoint. **Methods:** We conducted a single-center, phase II clinical trial (NCT02231775) evaluating neo + adj DT in pts with surgically resectable, RECIST measurable clinical stg III or oligometastatic stg IV BRAF V600E/K mutated melanoma. Study objectives included determination of pCR and survival outcomes based on INMC path response. Pts received oral D 150mg BID and T 2mg daily for 8 wks prior to surgery and 44 wks of adjuvant DT starting 1wk post-surgery. Imaging was performed prior to surgery to determine the RECIST 1.1 objective response rate (ORR) and then every 12 wks to monitor for recurrence. **Results:** Of the 51 pts who received neo DT, 49 were considered evaluable for the primary endpoint unrelated to progression prior to surgery. Median age was 56 (IQR 45-66). 10 pts received prior adj IT. All but 1 pt underwent surgery on time with delay due to treatment related toxicity. The radiographic ORR was 78%, including 6 (12%) CR. 17 (35%) pts achieved a pCR, 7 (14%) near pCR, 12 (24%) partial path response, and 13 (27%) path non-response. 47 (96%) pts initiated adj treatment; 23 (47%) completed all planned adj treatment, 7 (14%) discontinued adj treatment due to recurrence and 12 (24%) due to toxicity. Median RFS for all pts was 17.6 mos (95% CI: 14.40.1) and was improved for pts with pCR versus non-pCR [median Not Reached (NR) vs 11.3 mos; p = 0.0002]. Median distant metastasis free survival (DMFS) for all pts was 48.9 mos (95% CI: 24.1, NA) and was also improved for pCR pts (median NR vs 17.5 mos; p = 0.0004). Median OS was not reached for all pts and was improved in pCR pts (p = 0.03). No new safety signals were seen. **Conclusions:** Neo + adj DT is feasible and safe in pts with surgically resectable BRAF mutated melanoma. With a median follow-up of 35 mos, median RFS, DMFS, and OS have not been reached for pts with a pCR after neo DT, and are all significantly prolonged compared to non-pCR pts. These results demonstrate durable benefit for neo + adj DT in this high-risk pt population that achieve a pCR. Clinical trial information: NCT02231775. Research Sponsor: Novartis; Melanoma Research Alliance and Rising Tide Foundation.

[¹⁸F]FDG-PET to identify pathological responses upon neoadjuvant immune checkpoint blockade in cutaneous squamous cell carcinoma. *First Author: Sabine Breukers, The Netherlands Cancer Institute (NKI), Amsterdam, Netherlands*

Background: To improve clinical prospects of patients with locally advanced cutaneous SCC (CSCC), we tested the efficacy of neoadjuvant nivolumab with or without ipilimumab prior to standard of care curative surgery ± radiotherapy; the MATISSE trial (NCT04620200). Neoadjuvant immunotherapy-response prediction via FDG-PET imaging was demonstrated feasible in the IMCISION trial (PMID 34937871), where a decrease of ≥12.5% in total-lesion glycolysis (TLG) upon immunotherapy identified deep pathological responders to immunotherapy in head and neck SCC prior to surgery with 95% accuracy. The current research investigates the predictive power of FDG-PET to identify deep pathological responses to neoadjuvant immunotherapy in MATISSE patients. **Methods:** 26 patients with primary CSCC (stage I–IVa) were treated with neoadjuvant nivolumab with (n = 14) or without (n = 12) ipilimumab (weeks 0 and 2). FDG-PET/CT scans were evaluable at baseline and shortly before surgery (week 4) in 20 patients. Images were analysed for SUV_{max}, metabolic tumor volume (MTV), and TLG. Responders to immunotherapy were defined as having a major or partial pathological response to immunotherapy (MPR and PPR, showing ≤ 10% and 11–50% remaining viable cancer cells at time of surgery, respectively). **Results:** Overall, median SUV_{max}, MTV, and TLG decreased upon immunotherapy at the primary tumor site in responders (n = 15), whereas median SUV_{max}, MTV and TLG increased in non-responders (Table). Three patients with stable or increased SUV_{max}, MTV and TLG, also showed a pathological response and were classified as pseudo-progressive. Another patient with a MPR had an increase in SUV_{max}, but a decrease in MTV and TLG. All patients with any decline in SUV_{max}, MTV or TLG at the primary tumor site showed a pathological response (PPV 100%) and none of them developed a relapse at median follow-up 9.0 months. **Conclusions:** Primary tumor response assessment using FDG-PET-based ΔSUV_{max}, ΔMTV and ΔTLG accurately identifies pathological responses early upon neoadjuvant immunotherapy in cutaneous SCC. FDG-PET could, upon validation, select CSCC patients for response-driven treatment adaptation in future trials. FDG-PET-CT upon neoadjuvant immunotherapy in CSCC, changes in PET-parameters and predictive values of any decline in SUV_{max}, MTV or TLG. Clinical trial information: NCT04620200. Research Sponsor: The MATISSE trial is an investigator-initiated phase-2 clinical trial, partly funded by Bristol-Myer-Squibb (BMS) and KIKI-foundation (private).

	Responders n=15	Non-responders n=5	p-value	PPV (%)	NPV (%)	Sens (%)	Spec (%)

Successful management of Australian patients with locally advanced keratinocyte cancer (KC) and/or extensive skin field cancerization (ESFC), using widefield volumetric arc radiation therapy (VMAT): Report with 24-month follow-up. *First Author: Andrew Potter, GenesisCare, Adelaide, SA, Australia*

Background: Keratinocyte cancer (KC) diagnoses are associated with an elevated risk of developing new skin lesions. Patients with extensive skin field cancerization (ESFC) have large areas (generally ≥50cm²) of actinic keratoses and often, frequent keratinocyte cancers, necessitating repeated interventions. Volumetric modulated arc radiation therapy (VMAT) can precisely target large, complex surfaces with modulated doses, as required, leading to its increasing application to ESFC +/- KC. This is a follow-up 24-month report on the efficacy, safety, cosmetic, and quality of life outcomes of VMAT in the management of patients with ESFC +/- KC at Australian facilities. **Methods:** Two hundred and twenty-four fields for 194 patients with ESFC +/- KC have been prescribed widefield VMAT and prospectively enrolled in the National (Australian) Dermatology Radiation Oncology Registry (NDROR). One hundred and six fields are now beyond 24-months post-treatment. Over 80% of patients had received up to 4 prior non-radiotherapy interventions. Fields included lower and upper limb, face, scalp, or trunk regions. 3-, 6-, 12-, 18-, and 24-month follow-up assessments rated the percentage of field clearance, lesion response, new lesion events, cosmesis using the Lovett's scale, toxicity based on CTCAE, and quality of life as assessed using a EQ-5D-5L visual analogue scale (VAS). **Results:** Median dose delivered to ESFC-only and ESFC + KC fields were 45 Gy (16.2–60 Gy) and 47 Gy (22–60 Gy), respectively, in 25 daily fractions (7–30) across 7 weeks (2–13). At 24-month follow-up of 106 fields, 96% and 94% of ESFC-only and ESFC + KC fields, respectively had clinical success, defined as > 90% field clearance. Cosmesis was graded excellent or good in 98% of fields. The incidence of new KC within the field out to 24-months was 11%. Grade 1–2 radiation dermatitis was induced in all fields during treatment, but resolved by 3-month follow-up. Six percent of fields exhibited grade 3 dermatitis. Twelve percent of patients discontinued treatment due to acute toxicities (Median 88% dose delivered). The most common persistent toxicity at 24-month follow-up was localized grade 1–2 xerosis (51%), alopecia (43%), and/or pruritis (8%). Quality of life was sustainably improved in patients at 24-month follow-up (3.67; p = 0.026). **Conclusions:** Widefield VMAT has a promising profile of clinical efficacy, safety, and cosmesis in patients with ESFC +/- KC for whom other therapies had failed. Treatment was also associated with significant and durable improvements in quality of life. While long-term follow-up of patients continues, these results provide further support for widefield VMAT as a suitable option for patients with increasingly unmanageable presentations of ESFC and locally-advanced KC. Clinical trial information: ACTRN12618000627257. Research Sponsor: GenesisCare.

FDG-PET/CT response and prediction of pathological response to neoadjuvant nivolumab and ipilimumab for clinical stage III melanoma. *First Author: Milton Jose De Barros E Silva, A.C. Camargo Cancer Center, São Paulo, Brazil*

Background: Neoadjuvant immunotherapy with nivolumab 3mg/kg and ipilimumab 1 mg/kg (N3+I1) for two cycles for clinical stage III melanoma have shown rates of major pathological response (MPR) of approximately 60%. The prognosis of this group seems to be excellent so far. On the other hand, patients classified as pathological non-responders have a worse outcome and early identification of this group may allow us to tailor the treatment before surgery. **Methods:** We conducted a multicenter retrospective analysis of patients with clinical stage III melanoma treated with neoadjuvant N3+I1 for two cycles who did baseline and pre-operative 18F-FDG-PET/CT. The total number of FGD avid lesions and the percentual difference between the maximum SUV per lesion was calculated. The pathological results were correlated to FGD-PET/CT findings. **Results:** Between January 2019 and January 2023, 28 patients with clinical stage III melanoma treated with N3+I1 who had baseline and preoperative 18F-FDG PET were identified. Gender: 20 (71%) males, median age (range): 55 (34–78), BRAFV600E/K mut: 15(53%), positive nodes on baseline PET/CT: 1 = 26 (92%), 2 = 1(4%), and 3 = 1(4%). All known lesions identified by CT scan were also captured by FGD-PET/CT. Site of node(s): axilla = 12 (43%), cervical = 10 (36%), and inguinal = 6(21%). All but one patient received 2 cycles of N3+IP1 (1 patient had grade 3 toxicity and received only one cycle). Pathological response: MPR = 19(68%), non-MPR: 8 (28%), and 1(4%) did not undergo surgery due to widespread progression. An increase in maximum SUV and/or appearance of new lesion(s), n = 8(28%), was correlated to non-MPR or metastatic disease in all cases, including a patient who developed sarcoidosis-like reaction with increase of SUV in the index lesion (+68%) and appearance of inflammatory mediastinal lymph-nodes. The median increase was (range): +73% (+11% to 483%). Reduction or stable maximum SUV with no appearance of new lesion, n = 20 (72%), was associated with MPR in 19 patients (95%). One patient, who had G3 colitis with the need of infliximab, had 32% of reduction in maximum SUV but 100% of viable tumor cells on pathological report. The median decrease (range) was -76% (-1.2% to -100%). **Conclusions:** FGD-PET/CT may help to predict pathological response in patients with clinical stage III melanoma who undergo to neoadjuvant nivolumab and ipilimumab. Research Sponsor: None.

Comprehensive genomic profiling (CGP) of clinically advanced and metastatic cutaneous adnexal carcinomas (CAs; MCADCA): A genomic landscape study. *First Author: Maroun Bou Zerdan, SUNY Upstate Medical University, Syracuse, NY*

Background: Cutaneous adnexal tumors are a large group of malignant neoplasms that exhibit morphologic differentiation towards one of the four primary adnexal structures present in normal skin: hair follicles, sebaceous glands, sweat-apocrine glands, and sweat-ecrine glands. **Methods:** 276 cases of MCADCA underwent hybrid capture-based CGP to evaluate all classes of genomic alterations (GA). Microsatellite instability (MSI) status, tumor mutational burden (TMB), genomic loss of heterozygosity (gLOH), genomic ancestry prediction and COSMIC genomic signature were determined from sequencing results. PD-L1 was measured by IHC (TPS; Dako 22C3). Fisher exact method was used for statistical analysis with the false discovery rate corrected using Benjamini-Hochberg adjustment. **Results:** Sequencing was performed on the primary cutaneous tumor in 131 (47.4%) and on a local recurrence or metastatic site biopsy in 145 (52.5%) MCADCA. Male preponderance (64–81%) and age distributions mean (59–63 yrs) were similar in all groups with apocrine (APO) older than eccrine (ECC) (72 vs 62 yrs; p = .001). There were 173 (62.7%) sweat gland (SWG) derived, 55 (19.9%) were sebaceous gland (SEB) derived, 14 (5.1%) were hair follicle (HRF) derived and 34 (12.3%) were unclassified (UNK). 150/173 (86.7%) of SWG were ECC and 23 (13.3%) were APO. The SWG cases included 12 (6.9%) digital papillary ca's (DPA), 11 (6.3%) mucinous ca's (MAC), 19 (11.0%) porocoma's (POR), 14 (8.1%) spiradenoma's (SPR), 10 (5.8%) syringadenoma's (SRNG) and 77 (44.5%) unclassified ca's (UNC). GA/tumor were highest in SEB vs SWG (7.9 vs 4.9; p = .004) and lowest in DPA (2.1 vs 5.0 non-DPA; p = .03). There were no ancestry distribution differences. When compared with the SWG group, the SEB group had higher frequencies of RB1 GA (38.2% vs 8.1%; p < .0001) and TP53 GA (76.4% vs 43.4%; p = .0002) indicating likely neuroendocrine differentiation. The MAC group had significantly higher PTCH1 GA than the non-MAC group (36.4% vs 1.8%; p = .044). MSI-High status was highest in the SEB group vs all other groups (SEB 15.7% vs SWG 1.2%; p = .005). gLOH > 16% was most frequent in SEB when compared with SWG (19.6% vs 7.2%; p = .081). The MMR signature was more frequent in SEB than SWG (32.0% vs 2.1%; p = .005). The mean TMB was high in all MCADCA ranging from 10.4 mut/Mb in HRF to 38.8 mut/Mb in MAC with the exceptions of APO (2.7 mut/Mb; p = .001 and DPA 1.4 mut/Mb; p = .003). PD-L1 expression was not significantly different in all the MCADCA with low positive scores SWG vs SEB (37.0% vs 33.3%; NS). **Conclusions:** As there is limited evidence on the treatment of MCADCA, we provide a repertoire of common GA found. An increased frequency of GA is observed in SEB MCADCA. Clinical trials are needed to evaluate MCADCA-based biomarkers prognostic of ICI response. Only then can we successfully incorporate novel therapeutic strategies in the evolving landscape of treatment. Research Sponsor: None.

A phase Ib study of endogenous T cell therapy using SLC45A2-specific CD8 T cells for patients with metastatic uveal melanoma. *First Author: Suzanne Phillips, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Overall survival (OS) for patients (pts) with advanced uveal melanoma (UM) is poor compared with outcomes in cutaneous melanoma. Roughly half of all pts with UM will develop distant metastatic disease despite effective treatment of the primary tumor. Antigen-specific endogenous T cells (ETC) can be expanded and infused successfully in pts with many different types of cancer. Our group has identified epitopes of SLC45A2, a melanosomal transport protein, which are highly expressed in UM and are present at low levels in normal melanocytes. *In vitro*, we showed that cytotoxic T cells against SLC45A2 were able to kill HLA-matched UM cell lines. *In vivo*, we hypothesize that infused ETC can traffic to tumor sites. **Methods:** Between 6/2017 and 12/2022, we conducted a single-center, IRB-approved, first-in-human phase Ib dose escalation study of ETC targeting SLC45A2 in pts with metastatic UM (NCT03068624). Eligible pts with metastatic UM who express HLA-A*02:01 or A*24:02 underwent apheresis to collect peripheral T cells which were then selected and expanded (Turnstile 1). For Turnstile 2, conditioning with low-dose cyclophosphamide (300 mg/m²) occurred on Day -2. For pts in the radiation cohort, radiation occurred between Day -7 and Day -1. Infusion of ETC was done via hepatic arterial or central venous catheter on Day 0 followed by low dose subcutaneous interleukin-2 (IL-2) twice daily for 14 days +/- ipilimumab. The study utilized a 3+3 design with a starting dose level of 3.3 x 10⁹ cells/m² of ETC alone. The primary objective was to evaluate the safety and tolerability of infusing ETC targeting SLC45A2. Secondary objectives were to evaluate the *in vivo* persistence and anti-tumor efficacy of this regimen. **Results:** With a median age of 58 years (30-77), 34 pts were enrolled, 16 (47%) men and 18 (53%) women. 33 (97%) pts underwent apheresis and 11 (32%) received infusion of ETC. One dose limiting toxicity (DLT) thought to be unrelated to treatment or underlying cancer (cardiac disorder Grade 5) occurred at the starting dose level with no additional DLTs. The maximum tolerated dose was established as 1 x 10¹⁰ cells/m². The most common treatment-related grade 3 and 4 toxicities were lymphocyte count decrease 9 (82%), hyponatremia 1 (9%), and hypophosphatemia 1 (9%). Per immune-related response criteria (irRC), 4 (36%) pts had stable disease (SD), 6 (55%) had progression of disease (PD), and 1 (9%) was not evaluable for best response. Median overall survival (OS) was 8.9 weeks (wks). OS was 91% at 4 wks, 55% at 8 wks and 46% at 13 wks. Median progression-free survival was 5.9 wks. In the 4 patients with stable disease, the median duration of SD was 5.7 months. **Conclusions:** ETC targeting SLC45A2 is safe and well-tolerated in pts with metastatic UM. Further analyses are underway to evaluate T cell trafficking and persistence. Clinical trial information: NCT03068624. Survival outcomes associated with liver-directed therapies in patients with metastatic uveal melanoma. *First Author: Michael M Caplan, Columbia University Irving Medical Center, New York, NY*

Background: Metastatic uveal melanoma (mUM) is characterized by a hepatotropic pattern of spread and poor outcomes. Tebentafusp, the only FDA approved therapy, is restricted to patients (pts) with the HLA-A*02:01 genotype. As a result, a variety of liver-directed therapies (LDT) are commonly used for management of hepatic metastases. **Methods:** Pts with mUM with hepatic metastases who underwent LDT, including radiofrequency ablation, microwave ablation, hepatic metastasectomy, Yttrium-90 radio-embolization (SIRT), transarterial chemoembolization (TACE), bland embolization, and immunoembolization (IE), were identified from an institutional database. Data collected included: age, gender, tumor location and size, baseline liver function tests (LFT) and lactate dehydrogenase (LDH), molecular tumor characteristics (where available), type(s) of LDT received, systemic therapies received, and vital status. Time from onset of hepatic metastasis until death (Liver-OS), as well as time from initial diagnosis of primary uveal melanoma until death (Ocular-OS) were calculated. **Results:** A total of 119 pts were identified. The median age at diagnosis was 53.8 years (range 26-83), 47% were female. At the time of LDT initiation, 33% had bilobar disease and 16% had extrahepatic metastasis. 18% pts had elevated LFTs and 55% had elevated LDH. 72% of pts had M1a disease, 24% had M1b and 4% had M1c disease. 45% of pts received more than one form of LDT. SIRT (31%) was the commonly administered initial LDT, followed closely by IE (26%) and TACE (9%). 86% of pts received systemic therapy including 42% who received immune checkpoint blockade overlapping with LDT. Molecular profiling in 26 pts revealed recurrent mutations in BAP1 (n = 18) and SF3B1 (n = 8). The median ocular-OS across all pts was 71.0 months (95% confidence intervals (CI), 62.8-99.4). The median liver-OS across all pts was 31.8 months (95% CI 25.2-35.3). In pts who received TACE, IE, or SIRT exclusively (n = 44), the median Liver-OS was 15.2 months (95% CI 12.8-NA) for TACE (n = 8), 23.3 months (95% CI 15.8-NA) for SIRT (n = 28), and 28.2 months (95% CI 22.6-NA) for IE (n = 8). **Conclusions:** Our results provide additional support for the utilization of LDT in pts with mUM, as demonstrated by improved OS compared to historical survival data. Early ctDNA reduction may identify patients with stable disease and long OS on tebentafusp. *First Author: Dan Feng, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Tebentafusp, a bispecific (gp100 × CD3) ImmTAC showed significant overall survival (OS) benefit (HR 0.51) versus investigator's choice in a Phase (Ph) 3 trial in first line (1L) HLA-A*02:01+ adult patients (pts) with metastatic uveal melanoma (mUM) (Nathan NEJM 2021). In Ph2 and Ph3 trials of tebentafusp, OS was improved regardless of RECIST best response and the degree of early reduction in ctDNA was a better predictor of OS (Cavajal Nat Med 2022; Sullivan AACR 2023). Here we explored whether early on-treatment reduction in ctDNA could distinguish pts with stable disease (SD) and long OS vs those with SD and short OS in a Ph3 trial of tebentafusp in 1L mUM pts. **Methods:** 1L HLA-A*02:01+ pts with mUM received 68 mcg tebentafusp weekly intravenously after intra-patient dose escalation (NCT03070392). Response was assessed by investigators per RECISTv1.1. Sera collected at baseline (BL) and week 9 on tebentafusp were analyzed for ctDNA using targeted mPCR-NGS assay for mutations in 15 genes including GNAQ, GNA11, SF3B1, CYSLTR2, PLCB4 and EIF1AX. Landmark OS from week 9 was analyzed in subsets with ≥0.3 log reductions in mean tumor molecules (MTM) per ml of serum on treatment. Data cutoff 11-Nov-2022. **Results:** 76/245 (36%) tebentafusp-treated pts had best response of SD, with a median OS of 29 months and were evaluable for ctDNA. Baseline tumor burden as assessed by sum of longest lesion diameters and percentage of pts with elevated BL serum LDH were greater in the subset with < 1 year (yr) OS (median 70 mm and 64%, respectively) than in subsets with OS ≥ 1 yr (median 42 mm, 11%) or OS ≥ 2 yrs (median 31 mm, 9%). Almost half (36/76; 47%) of all SD pts had detectable ctDNA mutations in one or more UM genes at baseline. Baseline ctDNA levels were similar across survival groups. By week 9 on-treatment, ctDNA reduction was observed in 34/36 (94%) evaluable SD pts, including 29/36 (81%) with ≥ 0.5 log reduction, 18/36 (50%) with ≥ 2 log reduction and 16/36 (44%) with undetectable ctDNA (clearance). Deeper reductions in ctDNA were associated with better OS (Table). **Conclusions:** In this Ph3 trial, ctDNA reduction by week 9 on tebentafusp was strongly associated with improved OS in pts with best RECIST SD. Early ctDNA reduction may predict SD patients with long OS on tebentafusp. Research Sponsor: Immunocore.

ctDNA subset	N (%)	OS hazard ratio (95% CI)*	≥ 1-year OS %	≥ 2 year OS %
All stable disease with evaluable ctDNA	76 (100%)	NA	73%	51%
ctDNA detected at baseline	36/76 (47%)	NA	78%	48%
ctDNA not detected at baseline	40/76 (53%)	NA	90%	72%
No decrease by week 9	2/36 (6%)	NA	50%	50%
Any (>0 log) decrease by week 9	34/36 (94%)	1.02 (0.14-7.67)	79%	48%
≥0.5 log	29/36 (81%)	0.61 (0.23-1.64)	83%	53%
≥2 log	18/36 (50%)	0.33 (0.14-0.78)	89%	72%
≥3 log (ctDNA clearance)	16/36 (44%)	0.28 (0.12-0.67)	94%	75%

Long-term outcomes of chronic immune-related adverse events from adjuvant anti-PD-1 therapy for high-risk resected melanoma. *First Author: Rachel S Goodman, Vanderbilt University School of Medicine, Nashville, TN*

Background: Adjuvant anti-PD1 improves relapse-free survival in high-risk, resected melanoma, but can lead to irAEs, which become chronic in up to 41% of patients (Patrinely et al, JAMA Onc 2021). Given the expanding use of anti-PD-1 in earlier settings in many tumors, it is imperative to assess their long-term effects. We aimed to determine the incidence, characteristics, and long-term outcomes, including resolution vs persistence, of chronic irAEs from adjuvant anti-PD1. **Methods:** We retrospectively analyzed patients (pts) treated with adjuvant anti-PD1 for resected stage III-IV melanoma from 2015-2022 from 6 institutions; all pts had at least 18 month follow up post-anti-PD1 discontinuation. Demographics, disease characteristics, treatment and recurrence details, and outcomes were collected. Type, grade, duration, treatment, and resolution of acute (onset during treatment) and chronic irAEs (defined as those extending 6+ months after treatment cessation) were characterized. **Results:** Among 318 pts, 226 (64%) developed acute irAEs arising during treatment, including 44 (20%) with grade 3-5 irAEs. Chronic irAEs developed in 147 (46%) pts, of which 74 (50%) were grade 2+, 6 (4%) were grade 3-5, and 100 (68%) were symptomatic. With long-term follow-up (median 35 months), 52 (35%) pts experienced resolution of chronic irAEs while 95 (30% of the full cohort) had persistent chronic irAEs at last follow-up. Among these 95 pts with persistent chronic irAEs, 43 (45%) were grade 2+, 42 (44%) were symptomatic, 24 (16%) were on steroids, and 42 (29%) were on other management. The most common persistent chronic irAEs were hypothyroid (n = 38), arthritis (n = 18), dermatitis (n = 9), and adrenal insufficiency (n = 8). Of 37 pts with chronic irAEs who received additional immunotherapy, 12 (32%) had a flare, 10 (27%) had no effect, and 20 (54%) had a distinct irAE. **Conclusions:** In this large cohort of anti-PD1 treated pts, chronic irAEs were common (46%) and frequently were persistent with long-term follow up (30%, most often hypothyroid and arthritis). Prolonged monitoring and management are needed for these long-term survivors. Research Sponsor: Burroughs Wellcome Fund; Susan and Luke Simons Directorship for Melanoma, the James C. Bradford Melanoma Fund, the Van Stephenson Melanoma Fund; U.S. National Institutes of Health.

ARTISTRY-6: Nemvaleukin alfa monotherapy in patients with advanced mucosal and cutaneous melanoma. *First Author: Jeffrey S. Weber, Laura and Isaac Perlmutter Cancer Center, NYU Langone Health, New York, NY*

Background: Despite improved outcomes in melanoma with the introduction of checkpoint inhibitors (CPIs), ~50% of patients do not respond. A subset of responders ultimately progress and have limited treatment options, underscoring a high unmet need for novel treatments with durable benefit. Patients with mucosal melanoma exhibit response rates and progression-free survival ~2 times lower than those with cutaneous melanoma. Nemvaleukin alfa (nemvaleukin, ALKS 4230) is a novel, engineered cytokine that selectively binds to the intermediate-affinity interleukin-2 receptor complex to preferentially activate CD8⁺ T and natural killer cells, with minimal expansion of regulatory T cells. Nemvaleukin has been granted Orphan Drug designation for the treatment of mucosal melanoma by the US FDA. In the ARTISTRY-1 study, the intravenous (IV) recommended phase 2 dose (RP2D) for nemvaleukin monotherapy (6 µg/kg on days 1-5 of a 21-day cycle) demonstrated durable antitumor activity in patients with advanced melanoma, including mucosal melanoma, previously treated with a CPI (N = 46, overall response rate [ORR] 13.0% [95% CI 4.9-26.3], median duration of response 8.1 weeks [range 6.1-79.0]). In the ARTISTRY-2 study, the subcutaneous (SC) RP2D was identified as 3 mg every 7 days, which demonstrated pharmacodynamic effects consistent with those of IV delivery. Data from these studies support further evaluation of nemvaleukin monotherapy among patients with advanced mucosal or cutaneous melanoma. Additionally, a less frequent IV nemvaleukin dosing schedule is being evaluated in patients with advanced solid tumors in the ARTISTRY-3 study. **Methods:** ARTISTRY-6 (NCT04830124) is an ongoing phase 2, global, multicenter, open-label study that is currently enrolling. Eligible patients will have had prior anti-PD(L)1 therapy with or without anti-CTLA-4 therapy, an Eastern Cooperative Oncology Group performance status of 0 or 1, and adequate hematologic reserve and hepatic and renal function. In Cohort 1, patients with advanced cutaneous melanoma will receive nemvaleukin at the SC RP2D of 3 mg every 7 days. In Cohort 2, patients with advanced mucosal melanoma will receive nemvaleukin at the IV RP2D of 6 µg/kg on days 1-5 of a 21-day cycle. In Cohort 3 (added as a protocol amendment), patients with advanced cutaneous melanoma will receive IV nemvaleukin in 1 of 2 less frequent dosing schedules of 1 or 2 doses per cycle. The dosing schedules for Cohort 3 will be determined when a less frequent IV RP2D has been established in ARTISTRY-3. Patients will receive nemvaleukin until progression or intolerable toxicity. The primary objective is to evaluate the antitumor activity of nemvaleukin monotherapy defined by ORR. Additional objectives include evaluation of safety, health-related quality of life, predictive biomarkers, pharmacokinetics, immunogenicity, and pharmacodynamic effects. Clinical trial information: NCT04830124. Research Sponsor: Alkermes, Inc.

Poster Session

A phase 2/3 trial in progress on tebentafusp as monotherapy and in combination with pembrolizumab in HLA-A*02:01+ patients with previously treated advanced non-veal melanoma (TEBE-AM). *First Author: Diwakar Davar, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Tebentafusp is a bispecific (gp100 x CD3) ImmTAC that can redirect T cells to target gp100+ melanoma cells. In a Phase (Ph) 3 trial, tebentafusp demonstrated an overall survival (OS) benefit (HR 0.51) compared to investigator's choice (IC) in first line HLA-A*02:01+ patients with metastatic uveal melanoma (mUM). Gp100, which has limited expression in normal cells, is overexpressed in melanoma, including skin melanoma, supporting the investigation of tebentafusp in non-veal melanoma. In a first-in-human trial, tebentafusp monotherapy demonstrated a promising 1-year OS (~74%) in anti-PD(L)1 naïve HLA-A*02:01+ patients with metastatic cutaneous melanoma (mCM). In a subsequent Ph1 trial, tebentafusp combined with anti-PDL1, with or without anti-CTLA4, demonstrated a 1-year OS of 75% in patients with mCM who progressed on prior anti-PD(L)1 therapy, which compares favorably with recent benchmarks (1-year OS 38%-57%) in similar patient populations.¹⁻³ The promising activity of tebentafusp as monotherapy and in combination with anti-PD(L)1 agents in advanced melanoma (AM) provides the rationale to conduct a Ph2/3 trial of tebentafusp (TEBE-AM; NCT05549297) in patients who have progressed on standard of care therapies. In mUM trials, RECIST response underestimated the OS benefit of tebentafusp, whereas a strong association was shown between OS and early reduction in ctDNA levels relative to baseline.⁴ As an early measure of changes in tumor burden, ctDNA reduction is included as an innovative dual primary endpoint with OS for the Ph2 part of this study. **Methods:** TEBE-AM is a multicenter, open-label, seamless Ph2/3 study in HLA-A*02:01+ patients with non-veal AM who have progressed on prior anti-PD(L)1, received prior ipilimumab, and a prior BRAF/MEK inhibitor regimen if actionable BRAF mutation is present. Patients are randomly assigned (1:1:1) to receive tebentafusp monotherapy, tebentafusp combined with pembrolizumab, or IC. In the IC arm, patients may enroll in clinical trials of investigational agents, receive local standard of care, or receive best supportive care, while being followed for key endpoints. Randomization into the Ph3 portion will commence immediately following completion of accrual into the Ph2 portion. Efficacy from the Ph2 portion may inform changes to the Ph3 design. Primary endpoints are ctDNA reduction relative to baseline and OS in Ph2 and OS in Ph3. Ph2 enrollment opened in Jan 2023 in the US and is expected to open in other countries mid-2023. Clinical trial registration: NCT05549297. 1. Zimmer L, et al. Eur J Cancer 75:47-55, 2017. 2. Silva IPD, et al. J Clin Oncol 38:10005-10005, 2020. 3. Arance AM, et al. J Clin Oncol 39: S9504, 2021. 4. Carvajal RD, et al. Nat Med 28:2364-2373, 2022. Clinical trial information: NCT05549297. Research Sponsor: Immunocore.

Camrelizumab combined with anlotinib and nab-paclitaxel in patients with untreated advanced mucosal melanoma: A single-arm, multicenter, exploratory study. *First Author: Di Wu, Cancer Centre, The First Hospital of Jilin University, Changchun, China*

Background: Anti-programmed cell death-1 (PD-1) monotherapy is a part of the standard treatment for cutaneous melanoma, but its efficacy in mucosal melanoma is not ideal. In vivo studies have demonstrated that co-inhibition of the VEGF receptor (VEGFR) and PD-1 pathways increased T cell infiltration and suppressed tumor growth synergistically. Early phase trial data confirmed that PD-1 inhibitors combined with anti-angiogenic drugs showed efficacy in the treatment of advanced mucosal melanoma, but still did not meet clinical needs. Previous studies have shown that chemotherapy combined with anti-angiogenic drugs has significantly improved median PFS and median OS compared with chemotherapy alone, and has a certain effect as a salvage treatment for progression after PD-1 inhibitor treatment. In addition, previous retrospective analysis showed that PD-1 inhibitors combined with chemotherapy drugs such as nab-paclitaxel were superior to anti-PD-1 monotherapy in the treatment of advanced mucosal melanoma. In summary, the combination of anti-PD-1, anti-angiogenic drugs and chemotherapy may bring new hope for the treatment of advanced mucosal melanoma. **Methods:** This is a single-arm, multicenter, exploratory study to evaluate the efficacy and safety of camrelizumab combined with anlotinib and nab-paclitaxel as first-line therapy in patients with advanced mucosal melanoma. The trial is expected to enrol 66 patients. Key Inclusion Criteria are pts with confirmed recurrence, unresectable or metastatic mucosal melanoma after surgery (stage III/IV) and ECOG performance status of ≤1. Pts with previous adjuvant therapy or neoadjuvant therapy (except PD-1/PDL1 monoclonal antibody and VEGFR TKI) at least 4 weeks before the first administration of the study drug are allowed. Patients received intravenous camrelizumab (200 mg) on day 1, intravenous nab-paclitaxel (260mg/m²) on day 1, and oral anlotinib (8mg) on days 1-14 every 3 weeks. The primary endpoint is objective response rate (ORR). Secondary endpoints include disease control rate (DCR), progression-free survival (PFS), and 2-year overall survival (OS). Clinical trial information: NCT04979585. Research Sponsor: Jiangsu Hengrui Medicine Co., Ltd.

Phase Ib/II study of XmAb23104 (PD1 X ICOS) and XmAb22841 (CTLA-4 X LAG3) combination in metastatic melanoma refractory to prior immune checkpoint inhibitor therapy with and without CNS disease. *First Author: Saya Jacob, UCSF Hem/Onc Fellowship, San Francisco, CA*

Background: Immune checkpoint inhibitors (ICI) have greatly improved outcomes for patients by targeting programmed cell death protein 1 (PD1), cytotoxic T-lymphocyte-associated antigen 4 (CTLA4) and Lymphocyte Activation Gene-3 (LAG-3) to increase immune-mediated anti-tumor response. Despite these advances, ~50% of patients with metastatic melanoma do not respond to standard of care ICI. We strive to address this unmet clinical need through a Phase Ib/II, first-in-human, multi-center trial of two bispecific antibodies targeting four different immune checkpoints: XmAb23104 (PD1 X ICOS) and XmAb22841 (CTLA-4 X LAG3) in patients with melanoma refractory to ICI. This is the first trial of quadruple checkpoint inhibitor therapy. Furthermore, bispecific antibodies may allow simultaneous checkpoint blockade on the same cell and have been shown to heighten T cell activation in pre-clinical models. Two ongoing phase I trials of these bispecific antibodies with PD1 therapy have observed an immune related adverse event (irAE) rate of 20-24% with efficacy analysis ongoing (NCT03752398; NCT03849469). We postulate that treatment with XmAb23104 and XmAb22841 will enhance immune activation, overcome resistance, and improve disease control for patients refractory to traditional ICI. **Methods:** Eligible patients must have advanced/metastatic melanoma and have progressed on prior PD1/PD-L1 inhibitor or PD1/CTLA4 dual inhibition. Cutaneous, acral, mucosal and melanoma of unknown origin are allowed. Patient with CNS metastasis are allowed if these are asymptomatic and stable on MRI imaging obtained within 4 weeks of enrollment. Patients with prior unresolved irAE or irAE ≥ grade 3 are not allowed. XmAb23104 and XmAb22841 will be given on D1 and D15 of a 28-day cycle for 4 cycles, after which XmAb23104 (PD1 X ICOS) will be given alone for a total of 2 years. The phase I portion will be a dose escalation using standard 3+3 design of XmAb22841 (CTLA-4 X LAG3) with three dose levels (0.3 mg/kg, 1 mg/kg and 3 mg/kg). The dose of XmAb23104 (PD1 X ICOS) will remain at 10 mg/kg. These doses were selected based on results of prior early phase trials when these agents were combined with PD1. Once the P2RD of XmAb22841 (CTLA-4 X LAG3) is established, we will move on to dose escalation using a Simon's 2-stage design. This portion will include two arms: Arm A consisting of 17 patients without CNS disease and Arm B consisting of 17 patients with CNS disease (total 34). Primary endpoints include dose limiting toxicities (DLT)/irAE and Objective Response Rate (ORR) at the time of best response by RECIST 1.1. Secondary endpoints include progression-free survival, overall survival, CNS response. At the time of this abstract submission, Cohort 1 of dose escalation has begun with the first few patients still within the DLT observation window. Clinical trial information: NCT05695898. Research Sponsor: Xencor.

Phase II study of niraparib in patients with advanced melanoma with genetic homologous recombination (HR) mutation/alteration. *First Author: Kevin B. Kim, California Pacific Medical Center, San Francisco, CA*

Background: There are a limited number of therapeutic options available for metastatic melanoma patients progressing on the checkpoint inhibitor(s) and BRAF-targeting drugs. PARP inhibitors have been approved in the setting of BRCA1/2 germline mutations, and have demonstrated activity in the setting of HR deficiency in other cancers. Documentation of PARP inhibitors in melanoma would have clear clinical impact. We have previously shown that 21-34% of metastatic melanomas harbor at least 1 molecular aberration in the HR pathway, considered pathogenic, and likely leading to HR deficiency. Previously, we demonstrated dramatic regression of tumors harboring HR mutation(s) with PARP inhibitor treatment in a PDX model. These findings provide a strong rationale to evaluate the clinical efficacy of a PARP inhibitor in patients with advanced melanoma with HR deficiency. **Methods:** This is a single arm, open-label, multi-center phase II trial. The primary objective of the study is: To evaluate the clinical efficacy of niraparib in advanced melanoma patients with HR deficiency. The secondary objectives is to evaluate PFS, OS, and safety profile of niraparib. The key eligibility criteria: Advanced melanoma patients with mutation in any of the following: ARID1A/B, ARID2, ATM, ATR, ATRX, BARD1, BRCA1/2, BAP1, BRIP1, CHEK2, FANCD2, MRN11A, RAD50, RAD51, RAD54B, PALB2 (requires a genetic analysis result performed at any CLIA-certified laboratory) disease progression on PD1-antibody therapy and if BRAF mutant, BRAF/MEK inhibitors ≥ 18 years of age; ECOG PS ≤ 1 ; prior systemic cytotoxic therapy ≤ 1 regimen; no limit on number of prior immunotherapy or targeted therapy regimens. No symptomatic brain metastasis; active brain lesions ≥ 6 mm size, or requiring steroid treatment. Patients will be treated with oral niraparib once daily (28-day cycle); the dose will be 300 mg (if weight ≥ 77 kg and platelet counts of $\geq 150,000$ μ L); otherwise 200 mg RECIST 1.1 will be used to evaluate clinical response every 8 weeks. Adverse events will be recorded according to CTCAE version 4.03. The primary study endpoint is overall response rate. Simon's optimal 2-stage design is proposed. With significance level of 5% and 80% power, our null hypothesis that the true response rate is 0.10 will be tested against a one-sided alternative: $H_0: p \leq 10\%$, a response rate of no real interest VS $H_1: p \geq 30\%$, a response rate that would be of considerable interest. 10 patients will be analyzed for a response evaluation in the first stage of the study, and 19 in the second stage, for a total of 29 patients. If the response rate is 10% (1/10) or less at the end of the first stage, further accrual will be terminated. With 2 or more responses in the first stage, accrual will continue to a total of 29 patients for this cohort. The null hypothesis will be rejected if ≥ 6 responses are observed in a cohort of 29 subjects. Clinical trial information: NCT03925350. Research Sponsor: Glaxo Smith Kline.

Poster Session

A phase 3 trial comparing fianlimab (anti-LAG-3) plus cemiplimab (anti-PD-1) to pembrolizumab in patients with completely resected high-risk melanoma. *First Author: Timothy J. Panella, University of Tennessee Medical Center at Knoxville, Knoxville, TN*

Background: Melanoma (Mel) accounts for the majority of skin cancer-related deaths. Most patients (pts) with a newly diagnosed Mel have resectable disease and are potentially cured by surgery. However, regional nodal and/or distant relapses can occur after curative-intent resection. Postoperative adjuvant therapy with immune checkpoint inhibitors improves relapse-free survival (RFS) and distant metastasis-free survival (DMFS) of pts at high risk of Mel. Fianlimab (anti-LAG-3) and cemiplimab (anti-PD-1) are both high-affinity, fully human, IgG4 monoclonal antibodies (MAbs) that combined have shown high clinical activity in pts with advanced Mel in a phase 1 study. Additionally, combination of relatlimab (anti-LAG-3) and nivolumab (anti-PD-1) have shown superiority over nivolumab for PFS in advanced Mel. These observations provide a rationale for use of fianlimab and cemiplimab combination in high-risk adjuvant Mel. **Methods:** Our study (NCT05608291) is a three-way, double-blind, phase 3 trial to compare fianlimab + cemiplimab to pembrolizumab in the adjuvant therapy (Rx) of high-risk, resected Mel. The primary objective is RFS, and the secondary objectives are overall survival, safety, pharmacology, and immunogenicity. This international trial will be conducted at 200 sites. Pt eligibilities: (1) ≥ 12 years of age; (2) Stage IIc, III or IV (all M-stages) and histologically confirmed Mel, completely resected ≤ 12 weeks prior to randomization; (3) no prior systemic anti-cancer Rx or radiation Rx for Mel in the previous 5 years; (4) no evidence of metastatic disease on staging investigations; and (5) an Eastern Cooperative Oncology Group performance status (PS) of 0 or 1 (for adult pts), Karnofsky PS > 70 (pts > 16 years) or Lansky PS > 70 (pts < 16 years). Study arms (all Rx every 3 weeks intravenously for one year): A. fianlimab (1600 mg) + cemiplimab (350 mg); B. fianlimab (400 mg) + cemiplimab (350 mg); C. pembrolizumab (200 mg) + saline/dextrose placebo. The placebo controlled trial will enroll about 1530 pts, randomized 1:1:1 to Arms A:B:C, treated for up to 1 year. The trial will stratify by disease stage (stage IIIA vs IIC-IIIB-IIIC vs IIID-IV [M1a/b] vs IV [M1c/d]), and geography (North America vs Europe vs Rest of World). The primary endpoint is investigator-assessed RFS. The secondary endpoints include efficacy (overall survival, DMFS, melanoma-specific survival), safety [treatment-emergent adverse events (TEAEs), interruption or discontinuation of drugs due to TEAEs], pharmacokinetic (concentrations of fianlimab and cemiplimab in serum over time), immunogenicity (anti-drug Abs and neutralizing Abs in serum against fianlimab or cemiplimab), and patient reported outcomes. The first analysis will be performed when 242 RFS events have been observed. Clinical trial information: NCT05608291. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Poster Session

Phase 1 study of SGN-BB228, an investigational CD228 x 4-1BB costimulatory antibody anticalin bispecific, in patients with advanced melanoma and other solid tumors (SGNBB228-001). *First Author: Jason Timothy Henry, Sarah Cannon Research Institute at HealthONE, Denver, CO*

Background: SGN-BB228 is an investigational costimulatory Antibody Anticalin bispecific (Mabcalin) molecule directed to CD228 and 4-1BB. CD228 is a tumor-associated antigen selectively expressed by multiple tumor types including melanoma, mesothelioma, pancreatic, colorectal, and lung cancers with minimal expression in normal tissue. 4-1BB is an inducible costimulatory receptor expressed on activated T cells and other immune cell populations. The clinical development of 4-1BB agonist antibodies has been hampered by limited efficacy and/or poor tolerability at active doses (Segal et al 2017, Segal et al 2018). SGN-BB228 is designed to deliver a potent costimulatory bridge between tumor-specific T cells and tumor cells, potentially localizing antitumor activity to the tumor microenvironment and expanding the therapeutic window for 4-1BB agonism. In vitro, SGN-BB228 shows potent CD228-conditional 4-1BB stimulation and cytotoxic T cell activation (Updegraff et al 2022) providing rationale for evaluating SGN-BB228 in patients (pts) with melanoma or other solid tumors. **Methods:** SGNBB228-001 (NCT05571839) is a phase 1, open label, multicenter study designed to evaluate the safety, tolerability, PK, and antitumor activity of SGN-BB228 in adults ≥ 18 years of age with advanced melanoma or other solid tumors. The study includes dose escalation (Part A), dose and schedule optimization (Part B; optional), and dose expansion in disease-specific cohorts (Part C). Parts A and B will enroll pts with histologically or cytologically confirmed metastatic or unresectable cutaneous melanoma, and Part C will enroll pts with cutaneous melanoma, mesothelioma, pancreatic, colorectal, or non-small cell lung cancer. Pts must have disease that is relapsed, refractory, or intolerant to standard of care therapies, ECOG PS 0-1, and adequate organ function. Pts with known active CNS metastases or prior use of agents targeting CD228 or 4-1BB are excluded. Pts with cutaneous melanoma must have received anti PD(L)-1 agent as monotherapy or in combination. Pts with a targetable BRAF mutation must have received, been intolerant to, or declined treatment with BRAF/MEK targeted therapy prior to study entry. Primary endpoints include rate of adverse events, laboratory abnormalities, dose-limiting toxicities, and cumulative dose-level safety. Secondary endpoints are PK, ORR, DOR, PFS, OS, and incidence of antidrug antibodies. Safety and antitumor activity endpoints will be assessed by dose, schedule, and tumor type using descriptive statistics. The ORR and its 95% CI will be estimated. DOR, PFS, and OS will be estimated using Kaplan-Meier method. Enrollment is ongoing in the US and planned in Europe. Clinical trial information: NCT05571839. Research Sponsor: Seagen Inc.

Poster Session

OMNIA-1: A phase I/II study, an IL-2R- $\beta\gamma$ targeted antibody-IL-2 fusion protein, as monotherapy or in combination with anti-PD-1 or anti-CTLA-4 antibodies, in patients with advanced melanoma. *First Author: Paolo Antonio Ascierto, Istituto Nazionale Tumori IRCCS "Fondazione G. Pascale", Naples, Italy*

Background: ANV419 is a potent and selective IL-2R $\beta\gamma$ targeted antibody IL-2 fusion protein, designed to enable the delivery of high dose interleukin-2 (IL-2) to patients in order to stimulate anti-tumour response and minimise toxicities. Recombinant IL-2 (proleukin) induces durable responses in approximately 10% of patients with melanoma. Signalling through IL-2R α expressing cells is believed to limit its therapeutic potential in cancer. By eliminating binding to IL-2R α , ANV419 could lead to increased anti-tumor effect while increasing tolerability. The ANV419-001 first-in-human study (NCT 04855929) demonstrated that ANV419 preferentially stimulates cytotoxic CD8+ T and natural killer (NK) cells over immunosuppressive regulatory T cells, with a significantly longer half-life than that of conventional IL-2. The safety and tolerability data from this study confirmed that ANV419 delivers high molar equivalents of IL-2 in a tolerable and convenient way. **Methods:** ANV419 is being evaluated in a global multicentre, open-label, randomized Phase I/II study in patients with unresectable or metastatic cutaneous melanoma to assess the safety and efficacy of intravenous ANV419 as monotherapy and in combination with anti-PD1 or anti-CTLA-4 antibodies. The OMNIA-1 study leads in with a monotherapy dose expansion part, followed by a combination dose-finding with either anti-PD-1 or anti-CTLA-4 and a combination dose expansion part. ANV419 is administered intravenously every 2 weeks as monotherapy and every 3 weeks when given in combination. Patients with advanced cutaneous melanoma, no active brain metastases and whose disease has progressed on or following at least 1 line of standard of care immunotherapy are eligible. In Part 1, a total of 30 patients will be randomised and evaluated for response to Q2W ANV419 monotherapy (108 μ g/kg or 243 μ g/kg). In Part 2, escalating doses of Q3W ANV419 are evaluated to define the maximum tolerated dose (MTD) and recommended Phase 2 dose (RP2D) in combination with pembrolizumab (200 mg) or ipilimumab (3 mg/kg). In Part 3, the efficacy and safety of ANV419 in combination with the approved doses pembrolizumab or ipilimumab will be evaluated using a Simon's 2-stage design. Up to 130 patients are planned to be enrolled. Patients will be stratified according to BRAF mutation status. AEs are assessed according to CTCAE V5.0. Tumour response is determined using RECIST 1.1 criteria. The study is conducted at sites in the US, France, Spain, Germany, Italy, and UK. The first patient was dosed in December 2022. Preliminary monotherapy efficacy data are expected by Q1/2024. Clinical trial information: NCT05578872. Research Sponsor: Anaveon.

NOTOS: A pivotal study of navtemadlin, a first-in-class mouse double minute 2 inhibitor (MDM2i), in patients (pts) with *TP53* wild-type (*TP53*^{WT}) Merkel cell carcinoma (MCC) for whom anti PD-1/L1 therapy has failed. *First Author: Michael K.K. Wong, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: There are no approved therapies for pts with MCC for whom an anti PD-1/L1 agent has failed. The high rate of non-responsive disease after anti PD-1/L1 therapy together with high mortality rate and the absence of a standard of care in this setting highlight the urgent unmet need for effective novel therapies. Approximately 80% of MCC tumors carry the oncogenic Merkel cell polyoma virus (MCPyV) and most cases are *TP53*^{WT}. Oncoproteins from MCPyV inhibit p53 tumor suppressor functions by activating MDM2. Navtemadlin, a potent, selective, orally available MDM2i, overcomes MDM2 dysregulation by restoring p53 activity and inducing apoptosis of *TP53*^{WT} MCC tumors. Navtemadlin is the first targeted therapy to show single-agent activity in pts with metastatic MCC for whom anti-PD-1/L1 has failed (Wong ASCO 2022). In the dose finding study, evaluable pts (n=8) receiving the recommended phase 2 dose of navtemadlin (180 mg QD on Day 1-5/28-day cycle) demonstrated a 25% confirmed objective response rate (ORR), 38% unconfirmed + confirmed ORR, and 63% disease control rate. The median duration of response was not reached (range, 6-16.2+ months [mos]) and median time to treatment response was 4.1 mos (range, 1.2-7). Responses to navtemadlin were highest in those pts with no prior chemotherapy (chemo; Wong ASCO oral 2022). In pts receiving navtemadlin at doses of ≥ 180 mg, an ORR of 40% was reported with no prior chemo (n=15) versus 14% in those who received prior chemo (n=14, Wong ASCO oral 2022). Navtemadlin demonstrated an acceptable safety profile with the most common treatment emergent adverse events (TEAEs) cytopenias, nausea, vomiting, diarrhea, and fatigue. Grade 3/4 TEAEs were 32% anemia, 32% lymphopenia, and 19% thrombocytopenia (Wong 2022). Based on this encouraging data, the NOTOS study (navtemadlin induces p53-driven apoptosis in Merkel cell carcinoma) will evaluate the safety and efficacy of navtemadlin in two post PD-1/L1 treated cohorts: chemo-naïve pts and chemo treated pts. **Methods:** Adults with MCC for whom anti PD-1/L1 therapy has failed, who have ≥ 1 measurable lesion per RECIST v1.1, ECOG PS 0-1 and *TP53*^{WT} MCC by central testing will receive 180 mg QD on days 1-5 of a 28-day cycle until disease progression, unacceptable toxicity, death or withdrawal of consent. The primary endpoint is ORR per RECIST v1.1 by blinded independent review. Secondary endpoints include ORR per investigator, duration of response, progression-free survival, overall survival, clinical benefit rate (including stable disease for ≥ 10 wk, partial response or complete response), and safety. The NOTOS trial is currently enrolling (NCT03787602). Clinical trial information: NCT03787602. Research Sponsor: Kartos Therapeutics.

A phase 3 trial of fiantlimab (anti-LAG-3) plus cemiplimab (anti-PD-1) versus pembrolizumab in patients with previously untreated unresectable locally advanced or metastatic melanoma. *First Author: Ana Baramidze, Todua Clinic, Tbilisi, Georgia*

Background: Fiantlimab (anti-lymphocyte activation gene 3 [LAG-3]) and cemiplimab (anti- programmed cell death-1 [PD-1]) are both high-affinity, fully human, IgG4 monoclonal antibodies (Abs). Concurrent blockade of anti-LAG-3 and anti-PD-1 has shown enhanced efficacy (increase in progression free survival [PFS]) in advanced melanoma (Mel). We previously presented data from a phase 1 study showing a 63.8% objective response rate (ORR) across two separate cohorts of advanced PD-(L)1 naïve metastatic Mel patients (pts) treated with fiantlimab plus cemiplimab with an acceptable risk-benefit profile. **Methods:** This is a randomized, double-blind, phase 3 study to evaluate fiantlimab plus cemiplimab compared to pembrolizumab in pts with previously untreated unresectable locally advanced or metastatic Mel (NCT05352672). This study will be conducted globally, at approximately 200 sites. Key inclusion criteria are: (1) ≥ 12 years of age; (2) histologically confirmed unresectable Stage III and Stage IV (metastatic) Mel (3) no prior systemic therapy for advanced unresectable disease, prior (neo) adjuvant therapies are allowed with treatment/disease-free interval of 6 months; (4) measurable disease per Response Evaluation Criteria in Solid Tumors version 1.1; (5) valid LAG-3 results; (6) Eastern Cooperative Oncology Group performance status (PS) of 0 or 1 (for adult pts), Karnofsky PS ≥ 70 (pts ≥ 16 years) or Lansky PS ≥ 70 (pts < 16 years); and (7) anticipated life expectancy of at least 3 months. There are 4 arms to the study: (1) Arm A: fiantlimab (1600 mg) + cemiplimab (350 mg) every 3 weeks (Q3W), intravenously (IV); (2) Arm A1: fiantlimab (400 mg) + cemiplimab (350 mg) Q3W, IV; (3) Arm B: pembrolizumab (200 mg Q3W, IV) + saline/dextrose placebo (placebo); (4) Arm C: cemiplimab (350 mg Q3W, IV) + placebo. The trial is expected to enroll approximately 1590 pts. The primary endpoint is progression-free survival. The key secondary endpoints are overall survival and objective response rate. The additional secondary endpoints include disease control rate, duration of response, safety, pharmacokinetics of cemiplimab and fiantlimab, and immunogenicity (incidence and titer of anti-drug Abs and neutralizing Abs). The study is currently open for enrollment. Clinical trial information: NCT05352672. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Phase III study of adjuvant encorafenib plus binimetinib versus placebo in fully resected stage IIB/C BRAFV600-mutated melanoma: COLUMBUS-AD study design. *First Author: Alexander Christopher Jonathan Van Akkooi, Melanoma Institute Australia, Wollstonecraft, Australia*

Background: Significant progress has been made in the treatment of advanced BRAFV600-mutant melanoma. Encorafenib in combination with binimetinib is a well-tolerated and effective treatment option, providing sustained progression-free and overall survival benefit in unresectable or metastatic setting. The focus has shifted to early-stage disease in order to prevent recurrence. 18% of stage IIB and 25% stage IIC patients die due to melanoma within 10 years from the diagnosis [Gershenwald and al 2017], indicating an unmet medical need. Currently only immunotherapy has been approved in first countries across the world in this setting. There is a need for more treatment options for BRAF-mutated stage II disease. We report here the rationale and design of COLUMBUS-AD (NCT05270044). **Methods:** COLUMBUS-AD study is an international randomized, placebo-controlled, triple-blind, multicenter Phase III trial evaluating adjuvant encorafenib + binimetinib against placebo in patients with fully resected stage IIB/C BRAF V600-mutant melanoma. Approximately 815 patients will be enrolled. More than 170 sites in up to 26 countries worldwide will participate in the study conducted in collaboration with the European Organisation for Research and Treatment of Cancer (EORTC). Patients will receive encorafenib + binimetinib or placebo for 12 months, or until disease recurrence and will be followed monthly during treatment period, then every 3 months up to year 3, and then at regular intervals. The participants will be followed for a total of 10 years. Patients included in the study must have undergone resection of a stage IIB/C cutaneous melanoma with a BRAFV600E/K mutation, confirmed on resected tumor sample by a central laboratory, and a negative result on sentinel node biopsy. Patients must have recovered from surgery, have an ECOG 0/1, and adequate hematologic, hepatic, cardiac, coagulation and renal functions. Eligible patients will be randomized 1:1 to receive either encorafenib 450 mg once daily plus binimetinib 45 mg twice daily or matching placebos. The primary objective of the study is to evaluate the efficacy of the combination of encorafenib+ binimetinib for prolonging recurrence-free survival (RFS). The secondary objectives are to compare distant metastasis-free survival (DMFS), overall survival (OS), health-related quality of life (QoL), and safety and tolerability between the two arms and to provide additional pharmacokinetic data. **Conclusion:** COLUMBUS-AD is the first phase 3 randomised trial to evaluate adjuvant BRAFi/MEKi in stage IIB/C melanoma. This study will evaluate whether the combination of encorafenib and binimetinib can decrease the risk for recurrence and improve distant metastasis-free survival and overall survival versus placebo in completely resected IIB/C BRAFV600E/K-mutant cutaneous melanoma. Clinical trial information: NCT05270044. Research Sponsor: Pierre Fabre Medicament.

Poster Session

A randomized phase 2 trial of encorafenib + binimetinib + nivolumab vs ipilimumab + nivolumab in BRAFV600-mutant melanoma brain metastases: SWOG S2000. *First Author: Zeynep Eroglu, Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: While anti-PD-1 and anti-CTLA4 immunotherapies are widely used in the treatment of metastatic melanoma, including melanoma brain metastases (MBM), their efficacy in patients with symptomatic MBM is very limited. In the Checkmate-204 trial of ipilimumab with nivolumab in MBM, the 6-month progression free survival (PFS) rate was 19% with a median PFS of only 1.2 months in symptomatic participants (those with neurological symptoms including steroids up to 4 mg/day of dexamethasone, n=18). (Tawbi, Lancet et al., 2021) In the COMBI-MB study of BRAF/MEK-inhibitors in BRAF-V600 mutant MBM, median PFS was 5.5 months in those with symptomatic metastases (n=17). (Davies et al., Lancet Oncol, 2017) The combination of anti-PD-1/PD-L1 therapy with BRAF/MEK inhibitors has been tested in various trials. The single-arm phase 2 TRICOTEL study explored the triplet regimen of vemurafenib + cobimetinib + atezolizumab in MBM; in the symptomatic brain met cohort, 6-month PFS was 57% (n=24). (Dummer et al., Lancet Oncol 2022). **Methods:** SWOG S2000 is a randomized phase 2 trial exploring the efficacy of a triplet regimen of BRAF/MEK inhibitors with PD-1 therapy (encorafenib 450 mg qday + binimetinib 30 mg BID + nivolumab 480 mg IV q4 weeks) versus ipilimumab 3 mg/kg + nivolumab 1 mg/kg q3 weeks in patients with symptomatic BRAF-mutant MBM. (The study was amended to exclude patients with asymptomatic MBM.) Eligible patients are ≥ 18 years old, ECOG 0-2, and prior neoadjuvant or adjuvant anti-PD-1, CTLA-4, or BRAF/MEK-inhibitors is permitted. Steroids up to 8 mg of dexamethasone/day (or equivalent), leptomeningeal spread, and prior local therapy (radiation or surgery) for brain mets are permitted, if a patient has at least one measurable, progressing brain met ≥ 0.5 cm in size. Primary objective is to compare PFS per (RECIST 1.1) between the two study arms. Secondary objectives include overall survival, toxicity profile, objective tumor response, intracranial response and duration per modified RECIST 1.1, modified RANO-BM, and iRANO criteria, and evaluation of radiographic response criteria by centralized review of banked images. This study is powered to detect an increase in estimated 6-month PFS from 20% to 52% with 80% power and type I error rate of 10%, with 24 eligible patients required. Total sample size is 28 to account for ineligible patients. Available blood, tissue, CSF and stool samples are banked for future correlative studies. The study is currently enrolling patients through SWOG, ECOG and NRG centers. Funding: NIH/NCI grants U10CA180888, U10CA180819, U10CA180820 U10CA180868; and in part by Pfizer, Inc. Clinical trial information: NCT04511013. Research Sponsor: U.S. National Institutes of Health.

A pilot, open study to assess efficacy and safety of ON-01910 (rigosertib) in patients with recessive dystrophic epidermolysis bullosa associated locally advanced/metastatic squamous cell carcinoma. *First Author: Lauren Banner, Department of Dermatology and Cutaneous Biology, Thomas Jefferson University, Philadelphia, PA*

Background: Recessive Dystrophic Epidermolysis Bullosa (RDEB) is an extremely rare, severe blistering disease driven by mutations in collagen seven (COL7A1). Besides the skin and mucosal blistering, this genodermatosis is also characterized by aggressive cutaneous squamous cell carcinomas (cSCCs) arising from patients' chronic wounds. The cumulative risk of death from these cSCCs is 70% by age 45. There are limited effective treatment options for advanced (unresectable/metastatic) RDEB-associated cSCCs. While the standard of care for any advanced cSCC is immune checkpoint inhibitors, only half of the treated patients had responses in clinical trials. Their use for RDEB-associated SCCs been limited to case reports, and our own experience has not been positive. Conventional chemotherapy in RDEB-associated cSCC is another proposed treatment strategy, however, case reports demonstrated limited response rates without lasting effects. Currently it is recommended palliatively, although there are concerns about adverse effects. Other existing options are tyrosine kinase inhibitors, resulting in mixed responses to treatment for advanced cSCCs of any type, and epidermal growth factor receptor inhibitors, demonstrating limited effectiveness in a small number of case reports on RDEB-associated cSCCs. More effective therapeutic modalities for advanced/metastatic RDEB-associated cSCCs are needed. We previously demonstrated that RDEB SCC keratinocytes are specifically affected by polo-like kinase-1 (PLK-1) siRNA. Eight PLK-1 inhibitors were screened for cytotoxicity. Of the 8 candidates, ON-01910 was superior as it demonstrated the largest therapeutic window for distinguishing between tumor versus normal cells. The ON-01910 clinical trial is in progress in patients with RDEB with advanced/metastatic cSCCs. **Methods:** ON-01910 is being evaluated in both oral and intravenous formulations in an open-label, non-randomized phase 2 study in RDEB patients with advanced, treatment resistant cSCC. The trial explores the anti-tumor activity of ON-01910 and evaluates its safety and tolerability. Secondary objectives are to assess the impact on quality of life and to perform biomarker analysis on patient tissue. This study began in August 2021 and is ongoing. One patient is currently enrolled in the oral arm at Thomas Jefferson University in the USA. Safety is assessed according to the CTCAE v5. Tumor response in lymph nodes is determined per the RECIST 1.1 and in skin via clinical examination with serial tumor measurements. Key eligibility criteria include 1) diagnosis of RDEB and associated measurable, advanced cSCC confirmed histologically 2) failure to respond to standard of care including excision for localized disease 3) no concomitant cancer therapies. Clinical trial information: NCT04177498. Research Sponsor: Dystrophic Epidermolysis Bullosa Research Association of America; Onconova Therapeutics.

A pilot trial of autologous tumor infiltrating lymphocytes (lifileucel, LN-144) for patients with asymptomatic melanoma brain metastases. *First Author: Allison Betof Warner, Stanford Cancer Institute, Stanford, CA*

Background: Melanoma brain metastases (MBM) are a leading cause of morbidity and mortality for patients with advanced melanoma. Modern systemic therapies are insufficient at controlling MBM, and median overall survival (OS) for pts with MBM is < 1 year. Adoptive T cell therapy using tumor infiltrating lymphocytes (TIL) has demonstrated efficacy in advanced melanoma. Lifileucel (LN-144), an autologous TIL product, was recently shown to be safe and effective for patient with PD-1 refractory melanoma. Patients with active MBM were excluded from lifileucel trials to date. **Methods:** This single-center pilot trial (NCT05640193) is enrolling up to 10 pts with asymptomatic MBM from non-veal melanoma to receive lifileucel. Patients must have ≥ 1 intracranial lesion measuring 5-30mm visible on MRI to be used as a target lesion for modified (m)RECIST measurement, progression on prior anti-PD-1 therapy (with or without anti-CTLA-4), progression on targeted therapy if BRAF V600E/K-mutated, ECOG PS ≤ 1 , ≥ 1 resectable lesion(s) (≥ 1.5 cm), recovered from prior surgery/anticancer treatment-related AEs (grade ≤ 1). Patients are not eligible if they have symptomatic MBM and/or require corticosteroids of ≥ 10 mg/day of prednisone or equivalent. Lifileucel is generated from resected tumor in a centralized GMP process. The regimen includes nonmyeloablative lymphodepletion, lifileucel infusion, and a short course of high-dose IL-2. The primary endpoint is feasibility, defined as $\geq 7/10$ patients who undergo tumor harvest receiving lifileucel infusion. Secondary endpoints are safety, feasibility of manufacturing lifileucel in patients with MBM, and brain metastasis response rate (BMRR) per mRECIST 1.1. Exploratory endpoints include overall objective response rate by mRECIST 1.1, best extracranial response rate, intracranial progression-free survival (PFS), overall PFS, OS. Extensive correlative analyses of peripheral blood mononuclear cells, plasma, tumors, and cerebrospinal fluid are planned to better understand MBM growth, treatment resistance, and response of the central nervous system to lifileucel. Clinical trial information: NCT05640193. Phase II study of nivolumab (nivo) in combination with relatlimab (rela) in patients (pts) with active melanoma brain metastases (MBM). *First Author: Suzanne Phillips, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: More than half of all pts diagnosed with metastatic melanoma (MM) will develop brain metastases. Despite this prevalence, pts with MBM are excluded from the majority of clinical trials, preventing them from potential benefit of novel therapies. Long-term outcomes of the CheckMate 204 study combining ipilimumab (ipi) (3mg/kg) plus nivo (1 mg/kg) for asymptomatic MBM reported an intracranial (IC) response in 54% of pts. The 36-month IC progression-free survival (PFS) was 54% and overall survival (OS) was 72%. Grade 3 or 4 treatment-related adverse events (TRAEs) occurred in 55% of pts. RELATIVITY-047, a global phase II/III randomized study, reported on the fixed-dose combination of nivo (480 mg) and rela (a LAG-3-blocking antibody, 160 mg) compared to nivo (480 mg) alone for pts with advanced unresectable and untreated melanoma. The combination demonstrated significantly improved PFS and improved OS and objective response rate (ORR) compared to monotherapy. At 19.3 months of median follow-up, only the PFS benefit was statistically significant with a hazard ratio (HR) of 0.78 (95% CI 0.64-0.94). The OS benefit was not statistically significant (HR 0.8, 95% CI 0.64-1.01), and the descriptive ORR was 43.1% compared to 32.6% for single agent nivo. Grade 3 or 4 TRAEs occurred in 21% of pts in the combination group compared to 11% in the monotherapy group with no new safety signals. The nivo/rela combination has been FDA approved for the treatment of pts with MM but has not been studied in pts with MBM. We hypothesize that nivo/rela will be safe and tolerable for pts with MBM and demonstrate favorable outcomes compared to nivo monotherapy with fewer AEs in contrast to ipi/nivo combination. **Methods:** This single arm, single center, open-label phase II trial will evaluate the safety and efficacy of nivo/rela in pts with MBM (NCT05704647). 30 MBM pts who are treatment naïve to anti-PD-1 therapy will be enrolled. At least one unirradiated parenchymal brain metastasis at least 5 mm or larger is required for inclusion. Asymptomatic pts not requiring steroids for the management of their neurological symptoms are eligible. Pts requiring urgent local therapy with radiation or surgery are not eligible. Pts will be treated with nivo (480 mg)/rela (160 mg) every 4 weeks for up to 25 cycles, disease progression, or unacceptable toxicity. The primary objective is to evaluate IC ORR (CR + PR) by MRI per modified RECIST 1.1 criteria. Monitoring for fertility will be performed using the Bayesian Optimal Phase 2 (BOP2) design. Thirty evaluable patients will provide 82% power to detect a difference between the historical IC ORR of 20% for nivo alone to a targeted ORR of 40% for nivo/rela. Longitudinal research blood, tissue, and microbiome samples will be collected along with neurocognitive assessment and quality of life surveys. Clinical trial information: NCT05704647. Research Sponsor: Bristol-Myers Squibb Company (BMS); MD Anderson Cancer Center Melanoma Moon Shots.

Poster Session

A phase 3 study (TILVANCE-301) to assess the efficacy and safety of lifileucel, an autologous tumor-infiltrating lymphocyte cell therapy, in combination with pembrolizumab compared with pembrolizumab alone in patients with untreated unresectable or metastatic melanoma. *First Author: Daniel Olson, University of Chicago, Chicago, IL*

Background: Most patients (pts) with advanced (unresectable or metastatic) melanoma receiving front-line immune checkpoint inhibitor (ICI) therapy progress within a year (Robert *Lancet Oncol* 2019; Larkin *NEJM* 2019; Tawbi *NEJM* 2022). Early-line therapies are needed to improve the rate of deep and durable responses and increase the proportion of pts with long-term benefit. Lifileucel demonstrated an ORR of 31.4% and median DOR not reached (median 36.5 mo follow-up) in pts with post-ICI advanced melanoma (Sarnaik *SITC* 2022). Earlier-line treatment with lifileucel plus pembrolizumab (pembro) in pts with ICI-naïve advanced melanoma demonstrated an ORR of 67%, including a CR rate of 25% (Iovance Press Release, April 5, 2022; O'Malley *JITC* 2021). TILVANCE-301 will evaluate the efficacy and safety of lifileucel plus pembro compared with pembro alone in pts with untreated advanced melanoma. **Methods:** TILVANCE-301 (NCT05727904) is a phase 3, multicenter, randomized, open-label, parallel group, treatment study that will randomize ~670 pts (1:1) to either Arm A: lifileucel plus pembro (study intervention includes tumor tissue resection, pembro, nonmyeloablative lymphodepletion [NMA-LD], lifileucel infusion, an abbreviated course of high-dose IL-2, and thereafter, continued pembro) or Arm B: pembro alone. Pts in Arm B who receive pembro and experience confirmed progressive disease verified by blinded independent review committee (BIRC) have the option to receive lifileucel as the immediate next line of treatment. Eligible adults have histologically confirmed advanced melanoma (Stage IIIC, IIID, or IV); ECOG PS of 0 or 1; estimated life expectancy > 6 mo; ≥ 1 resectable lesion ~1.5 cm in diameter postresection to generate lifileucel and ≥ 1 measurable lesion (RECIST v1.1); and adequate hematologic parameters and organ function. Neoadjuvant or adjuvant treatment including ICI meeting protocol-specified criteria may be allowed. Exclusion criteria include prior therapy for metastatic disease; symptomatic untreated brain metastases; organ allograft or prior cell transfer therapy; uveal/ocular melanoma; chronic systemic steroid therapy; active systemic infections; cardiovascular, respiratory, or immune system illnesses; primary/acquired immunodeficiency; or other primary malignancy in the last 3 y. The dual primary efficacy endpoints are BIRC-assessed (RECIST v1.1) ORR and PFS. Key secondary efficacy endpoint is OS. Additional secondary efficacy endpoints include BIRC-assessed CR rate, DOR, and EFS; investigator-assessed ORR, PFS, CR rate, DOR, EFS, and PFS2; and safety as characterized by severity and seriousness of TEAEs, and relationship to study drug. The study will enroll globally. Clinical trial information: NCT05727904. Research Sponsor: This study is sponsored by Iovance Biotherapeutics.

Poster Session

The DIET study: A randomized controlled trial of a high fiber diet in cancer patients (pts) receiving immune checkpoint blockade (ICB). *First Author: Rachel Farias, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Gut microbiome modulation is a promising strategy to enhance response to ICB. Fecal microbiota transplant studies have shown positive signals of improved outcomes in both ICB naïve and refractory melanoma; however, this strategy is challenging to scale. Diet is a key determinant of the gut microbiota and we have previously shown that a) habitual high dietary fiber intake is associated with improved response to ICB and b) fiber manipulation in mice impacts anti-tumor immunity. We recently demonstrated feasibility of a controlled high-fiber dietary intervention (HFDI) conducted in melanoma survivors with excellent compliance and tolerance. Building on this, we are now conducting a single center Phase II randomized trial of HFDI versus healthy control diet in cancer pts receiving ICB (NCT04645680). **Methods:** 57 pts starting standard of care (SOC) ICB will be enrolled in 4 cohorts: 3 melanoma cohorts in the adjuvant (n = 21), neoadjuvant (n = 12), and unresectable (n = 12) settings and 1 metastatic renal cell carcinoma (RCC) cohort (n = 12). Key inclusion criteria include BMI 18.5-40 kg/m², and willingness to exclusively eat the diet. Key exclusion criteria include diabetes mellitus, inflammatory bowel disease, total colectomy or bariatric surgery, recent use of prebiotic/probiotic supplements, steroids (within 14 days), antibiotics (within 21 days), current smoker or heavy drinker, and dietary fiber > 20g/day. Pts are randomized 2:1 to the HFDI (target fiber 50g/day) or control diet (fiber 15-20g/day) stratified by BMI and cohort. Both diets have same macronutrient composition but differ in fiber content. The primary objective is to establish the effects of a dietary intervention on the structure and function of the gut microbiome. Secondary endpoints include change in circulating and stool metabolites, systemic and tumor immunity, and safety and tolerability of dietary intervention. As a controlled feeding study, all meals are isocaloric and prepared by MD Anderson Bionutrition Research Core for up to 11 weeks. Meals follow American Cancer Society and American Institute for Cancer Research recommendations which include whole foods plant-forward diet, little to no processed meats or added sugars, and no alcohol consumption. Meals are shipped weekly within the contiguous United States and include breakfast, lunch, dinner, and snacks. The HFDI group start at 30g fiber/day, up titrated every 2 weeks up to 50g/day based on tolerance. Blood and stool samples are collected longitudinally. Tumor biopsies are required in the neoadjuvant cohort and optional in unresectable. A Fitbit is provided to monitor physical activity and a scale to measure daily weight. 24 of the planned 57 pts have been enrolled: n = 13 adjuvant, n = 5 neoadjuvant, n = 5 unresectable, n = 1 RCC. 14 treated with PD1 monotherapy, 9 with ipilimumab + nivolumab, and 1 with nivolumab + relatlimab. Clinical trial information: NCT04645680. Research Sponsor: Seerave Foundation; Elkins Foundation, Rising Tide Foundation, Mark Foundation.

KEYVIBE-010: Adjuvant coformulated vibostolimab with pembrolizumab versus adjuvant pembrolizumab in patients with high-risk stage II-IV melanoma. *First Author: Georgina V. Long, The University of Sydney, Sydney, NSW, Australia*

Background: Pembrolizumab is an anti-PD-1 monoclonal antibody that has been shown to significantly improve recurrence-free survival and distant metastasis-free survival when used as adjuvant therapy in patients with high-risk resected melanoma (Long GV, et al. *Lancet Oncol.* 2022;23:1378-88; Eggermont AMM, et al. *Lancet Oncol.* 2021;22:643-54). Combining pembrolizumab with other therapies may further improve outcomes in this setting. Vibostolimab is an anti-TIGIT monoclonal antibody that showed antitumor activity and manageable safety when used in combination with pembrolizumab in patients with advanced solid tumors in the phase 1 KEYVIBE-001 study (Niu J, et al. *Ann Oncol.* 2022;33:169-80). The randomized, double-blind, phase 3 KEYVIBE-010 study (NCT05665595) is designed to evaluate the efficacy and safety of adjuvant coformulated vibostolimab and pembrolizumab (MK-7684A) versus pembrolizumab alone in patients with resected high-risk stage IIB-IV melanoma. **Methods:** Eligible patients are ≥12 years of age (weighing ≥40 kg if <18 years), with surgically resected stage IIB or IIC (pathologic or clinical), III, or IV cutaneous melanoma per AJCC 8th edition guidelines, and an Eastern Cooperative Oncology Group performance status of 0 or 1 (Lansky play-performance scale ≥70 if <16 years; Karnofsky performance status ≥70 if ≥16 to <18 years). Patients must not have received any prior systemic therapy beyond complete resection and no more than 12 weeks can have elapsed between final surgical resection and randomization. Patients with ocular, mucosal, or conjunctival melanoma, and prior allogeneic tissue/solid organ transplant are excluded. Patients will be stratified by risk. Approximately 1560 patients will be randomly assigned 1:1 to receive intravenous coformulated vibostolimab 200 mg with pembrolizumab 200 mg or pembrolizumab 200 mg (2 mg/kg up to a maximum of 200 mg for adolescents) every 3 weeks. Treatment will continue for 17 cycles or until disease recurrence, unacceptable toxicity, or withdrawal. The primary end point is recurrence-free survival by investigator review. Secondary end points are distant metastasis-free survival by investigator review, overall survival, safety and tolerability, and quality of life. Hazard ratios and 95% confidence intervals will be estimated using a stratified Cox regression model with the Efron method of handling ties, with treatment as a covariate. Between-treatment differences will be evaluated using a stratified log-rank test. Enrollment is ongoing. Clinical trial information: NCT05665595. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

A phase 2 study to determine the pathological (path) response to neo-adjuvant nivolumab (nivo) and relatlimab (rela) in high-risk stage II cutaneous melanoma: NeoReNi II. *First Author: Maria Gonzalez, Melanoma Institute Australia, Sydney, Australia*

Background: Patients diagnosed with stage II melanoma account for ~50% of those who develop metastatic disease and die (Poklepovic et al., 2020). Neoadjuvant therapy (NAT) is a powerful treatment platform to rapidly assess drug activity in resectable cancers using the International Neoadjuvant Melanoma Consortium (INMC) path response criteria (Tetzlaff et al., 2018), wherein a major path response (≤10% viable tumor) correlates with low risk of recurrence in resectable stage III melanoma (Menzies et al., 2021). Other benefits include early insight into response, feedback to pts regarding their individual response and prognosis, ability to tailor subsequent management, and collection of translational specimens to explore mechanisms of response and resistance (Amaria et al., 2019). NAT for stage II melanoma is an opportunity to improve survival rates beyond the gains achieved with adjuvant therapy, as illustrated by the phase II SWOG 1801 trial (Patel et al., 2022) for pts with stage III melanoma. The NeoReNi II trial will examine whether combination PD-1 blockade plus lymphocyte-activation 3 (LAG3) checkpoint inhibition will achieve a high rate of path response with manageable toxicity. **Methods:** Pts with histologically confirmed AJCC (8th ed.) clinical stage IIA (T2b, T3A), IIB (T3b, T4a), or IIC (T4b) primary cutaneous melanoma from a partial biopsy, with residual macroscopic disease at study entry, are eligible (N = 20). Pts with IIA disease must have an estimated ≥20% risk of recurrence at 5 years, according to the Melanoma Institute Australia stage II risk calculator (melanomarisik.org.au). All pts undergo wide excision and sentinel lymph node resection (RES) at wk 6 following NAT with 2 doses of nivo (480 mg, IV) plus rela (160 mg, IV). Pts with no (> 50% viable tumor) or partial path response (> 10% - ≤50% viable tumor) receive a further 11 cycles (Q4W) of adjuvant nivo (480 mg) plus rela (160 mg), and radiological and clinical surveillance. Pts with complete (pCR; 0% viable tumor) or near-complete (≤10% viable tumor) path response will undergo radiological and clinical surveillance after RES. All pts will be followed for recurrence (6 monthly CT) and survival for 10 years. Lymphatic mapping, dermoscopy, in vivo confocal microscopy, CT, and FDG PET/CT will be performed at baseline (BL) and prior to RES to measure response to NAT. Tumour and fecal samples are collected at BL, RES, and recurrence. Blood samples are collected at BL, wk 4, RES, and recurrence. The primary endpoint is the rate of pCR at RES after 6 wks of NAT using INMC response criteria (Tetzlaff et al., 2018). Secondary endpoints include assessing the feasibility of NAT in a stage II pt population, RFS, OS, safety/tolerability, surgical outcomes, changes in confocal microscopy and dermoscopy, rate of sentinel node positivity and changes in lymphatic mapping, QOL, and biomarker analyses. Clinical trial information: NCT05418972. Research Sponsor: BMS; Melanoma Institute Australia.

NADOM trial: Neoadjuvant/adjuvant trial of darovasertib in ocular melanoma (OM). *First Author: Roderick O'day, Royal Victorian Eye and Ear Hospital, Melbourne, Australia*

Background: Darovasertib (Daro) is a novel inhibitor of PKC, that has pre-clinical activity in GNAQ/GNA11 tumours including ocular melanoma. A recently completed clinical trial of Daro monotherapy in metastatic OM with a response rate of 11%, and DCR of 78% with only mild manageable toxicity, suggesting utility in localized disease and in the adjuvant setting. **Methods:** NADOM is an investigator-initiated window-of-opportunity phase 2 clinical trial open in 3 centers across Australia. Eligible patients include patients planned for enucleation, ECOG 0-1 with adequate organ function. The primary objective is the feasibility and safety of neoadjuvant Daro in a pilot cohort of 12 patients. Secondary objectives include the effect of Daro on circulating biomarkers (including CTCs and ctDNA), imaging assessments (MRI, FDG-PET and ocular ultrasound), pharmacokinetic and pharmacodynamic correlates and radiographic PFS in the adjuvant setting. Treatment comprises a neo-adjuvant period of treatment of up to 6 months at ophthalmologist discretion with Daro (300mg bid) before definitive management. Patients who demonstrated radiological, biomarker or clinical response are then offered an adjuvant period of treatment for up to 6 months following integrated consensus at multi-disciplinary ocular oncology meetings. DSMB meetings are scheduled to ensure clinical and peri-operative safety regularly. Enrollment commenced in November 2022 and accrual is ongoing in the 6 month neo-adjuvant cohort. **Results:** To date, an initial safety cohort of 1 month of neo-adjuvant treatment has been cleared following DSMB review. **Conclusions:** Recruitment is ongoing and expected to complete in late 2023. Clinical trial information: NCT05187884. Research Sponsor: Ideaya Biosciences.

Poster Session

PLUME: A single-arm phase II trial evaluating the combination of pembrolizumab and lenvatinib in metastatic uveal melanoma (mUM) patients (pts) previously treated or not with tebentafusp. *First Author: Manuel Rodrigues, Medical Oncology Department, Institut Curie, Paris, France*

Background: Up to 50% of pts with uveal melanoma (UM) develop metastases, mainly hepatic, with poor overall survival and limited treatment options as response rate to first-line immune checkpoint inhibitors (ICI) is low in mUM pts. Tebentafusp, a bispecific T-cell engager, was recently approved in this setting but only in HLA A*02-01+ mUM patients. Lenvatinib is a tyrosine kinase inhibitor targeting multiple growth factor receptors including vascular endothelial growth factor receptors (VEGFRs), fibroblast growth factor receptors (FGFRs) and colony-stimulating factor receptor (CSF1-R), which are key pathways in UM. Lenvatinib showed an immune-modulating effect in preclinical models. The combination demonstrated synergic clinical anti-tumor activity in various tumor types including microsatellite-stable endometrial cancers, kidney cancers and ICI-resistant skin melanomas. We hypothesize that combining pembrolizumab with lenvatinib in mUM may lead to an improved immune response in mUM patients. **Methods:** Fifty-four, ICI-naïve, metastatic UM pts will be enrolled in this monocentric, single-arm phase II trial at Institut Curie, Paris, France. Because previous exposure to tebentafusp might increase the activity of subsequent ICI, the combination will be assessed in two independent cohorts: cohort 1 with HLA A*02-01^{neg}, tebentafusp-naïve patients (22 assessable patients), and cohort 2 with HLA A*02-01^{pos} pts previously treated with tebentafusp (28 assessable patients). Up to 54 patients may be included according to an 8% drop-out rate. Each participant will receive pembrolizumab (200 mg Q3W, maximum of 35 cycles) plus lenvatinib (starting at 20mg QD) until reaching a discontinuation criterion. Liver MRI and chest-abdomen-pelvis CT will be performed every 9 weeks until progressive disease. Primary objective is to evaluate the progression-free survival (PFS) after nine cycles of treatment (27 weeks) as assessed by the investigator using the RECIST v1.1. Secondary objectives include PFS according to immune RECIST (iRECIST), overall survival, overall response rate, safety and tolerability, quality of life. Inclusion period started mid-July 2022 for two years. To date, twenty-four (21 in cohort 1, 3 in cohort 2) of planned 54 pts have been enrolled in six months. Biospecimens (longitudinal blood samples and tumor tissue at inclusion) will be collected during the study to allow biomarker research. Clinical trial information: NCT05282901. Research Sponsor: INCa PHRC-K 2020; Merck Sharp & Dohme LLC.

CemiplimAb-rwlc survivorship and epidemiology (CASE): A prospective study of safety and efficacy of cemiplimab in patients with advanced basal cell carcinoma in a real-world setting. *First Author: Soo J Park, University of California San Diego, La Jolla, CA*

Background: Basal cell carcinoma (BCC) is the most common form of non-melanoma skin cancer in the United States. Surgical excision is the standard treatment, with < 1% of cases progressing to locally advanced or metastatic disease. Hedgehog pathway inhibitors (HHIs) are the first-line therapy for advanced BCC (aBCC); the US Food and Drug Administration and European Medicines Agency have approved the use of cemiplimab (a programmed cell death-1 inhibitor) in advanced BCC (aBCC) patients previously treated with (or are inappropriate for) HHI. Limited real-world data exist on the clinical characteristics, disease management and progression, and survivorship of patients with aBCC. The ongoing C.A.S.E. study aims to evaluate the efficacy, safety, disease evolution, survivorship, and patient reported outcomes (PRO) in patients treated with cemiplimab in the real-world setting. **Methods:** This trial in progress (NCT03836105) aims to describe the effectiveness and safety of cemiplimab 350 mg administered every 3 weeks for treatment of patients with aBCC in real-world clinical settings. Up to 100 adult patients with aBCC who are prescribed commercially available cemiplimab from ~65 study sites in the United States will be included. The duration of follow-up will be 24 months. Endpoints for this study relate to real-world efficacy, including overall survival; progression-free survival; objective response rate, (partial or complete response); and disease control rate, defined as the percentage who do not progress for ≥ 6 months; Time to response, duration of response, time to treatment failure, and disease-specific death will also be assessed. Real-world safety outcomes will also be captured, including immune-related adverse events, infusion-related reactions, and serious adverse events. Patient selection criteria and treatment patterns will be analyzed using descriptive statistics. This study also aims to describe the patient experience of real-world treatment with cemiplimab. PROs including global quality of life, functioning, and symptoms will be captured at baseline and follow-up visits via the EORTC QLQ-C30 and the Skin Care Index. Recruitment for this trial is ongoing. Clinical trial information: NCT03836105. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Oral Abstract Session

High risk neuroblastoma (HR-NB) with MNA and age <18 months: Results from the HR-NBL1/SIOPEN trial. *First Author: Ruth Lydia Ladenstein, St. Anna Children's Hospital and St. Anna Kinderkrebsforschung, Department of Paediatrics, Medical University Vienna, Vienna, Austria*

Background: The INES 99.4 trial (JCO 2009, 27(7):1014-9) for MYCN amplified (MNA) infants using 6 courses of CBDCA-Vp16/CADO showed early progressions or non-response in 30%. Two-year overall survival (OS) was 30% (SE, 0.08) with median survival of 12 months. Aims are to report risk factors and outcomes for patients < 18 months with MNA neuroblastoma treated on HR-NBL1/SIOPEN. **Methods:** From 2006-2022, patients < 18 months with MNA INSS stages > 1 were eligible. All infants received Rapid Cojec induction, eventually 2 TVDs, Busulfan-Melphalan as high-dose treatment and could receive Dinutuximab- beta immunotherapy. Toddlers (12-18 months) followed the HR-NBL1/SIOPEN respective eligibility criteria. **Results:** Median age at diagnosis was 1.2 years in 414 patients (median follow up 7 years): 56% were male; 18.6% had localised tumours, 6.8% stage 4S and 75% stage 4. The predominant primary tumour site was abdominal (85%). Rapid Cojec was used in 85%, BUMEL in 89% and 26% received Dinutuximab-beta. Multiple metastatic compartments were reported in 82% of stage 4. Five-year event-free (5y-EFS) and overall survival (5y-OS) was 0.46 ± 0.03 and 0.51 ± 0.03 . Stage 2,3&4S patients had a better 5y-EFS of 0.64 ± 0.03 ($p < 0.005$) (5y-OS: 0.66 ± 0.06), compared to stage 4 with 0.41 ± 0.03 (OS: 0.46 ± 0.03). Infants' 5y-EFS was superior with 0.53 ± 0.04 (5y-OS: 0.57 ± 0.04) ($p = 0.015$) over the toddlers with 5y-EFS 0.42 ± 0.03 (5y-OS: 0.46 ± 0.03). Patients with bone marrow (BM) and skeletal metastases > other sites (MS) did worse ($p < 0.005$) with a 5y-EFS of 0.31 ± 0.04 (5y-OS: 0.36 ± 0.04) whilst other metastatic combinations revealed outcomes above 0.50 ± 0.03 . LDH ($2x > \text{normal}$) predicted a worse 5y-EFS of 0.43 ± 0.03 (5y-OS: 0.46 ± 0.03) ($p < 0.001$) versus normal LDH (5y-EFS 0.71 ± 0.07 ; 5y-OS: 0.80 ± 0.06). EFS multivariable analysis at diagnosis (MVA) showed independent significance for stage 4 (p-value 0.0139; HR: 1.608) and LDH (p-value 0.0042; HR: 2.237), but not for age. In stage 4 patients MVA on EFS found LDH (p-value 0.0098; HR: 2.567) and BM/skeleton involvement (p-value 0.0024; HR: 1.693) as independent risk predictors. In maintenance Dinutuximab-beta had a major impact on 5y-EFS in stage 4 patients with 0.69 ± 0.05 (5y-OS: 0.71 ± 0.05) vs. 0.41 ± 0.07 (0.46 ± 0.07) for those treated with 13-cis retinoic acid ($p = 0.002$ & $p = 0.001$), but not on others. **Conclusions:** In HR-NBL1/SIOPEN outcomes improved with almost half of patients alive at 5 years and only few late events. Clinical trial information: NCT01704716. Research Sponsor: EC 5th Frame Work Grant SIOPEN-R-NET EC grant no. Oral Abstract Session

A multicenter cooperative group study of late effects after high-risk neuroblastoma: COG ALTE15N2—LEAHRN study. *First Author: Tara O. Henderson, The University of Chicago, Chicago, IL*

Background: Aggressive therapies for high-risk neuroblastoma (HRNBL) have resulted in increased survival, but late effects have not been well-characterized. **Methods:** Comprehensive cross-sectional evaluation of health outcomes in HRNBL survivors enrolled on the COG Neuroblastoma Biology Study after 1/1/2000 and ≥ 5 years from primary diagnosis, using medical record abstraction and in-person clinical assessments. Descriptive and multivariable analyses identified extent of and risk factors for late toxicity. **Results:** There were 375 participants from 88 COG centers, 205 (55%) male; 92 (26%) non-white; 45 (13%) Hispanic. Median age at neuroblastoma diagnosis was 2.5 years (range: 0.2-15.8), at enrollment was 12.0 years (range: 5.0-24.0). All had received chemotherapy; 94% received cisplatin (median dose: 398 mg/m²). Other exposures included: radiation (95%), isotretinoin (91%), anti-GD2 antibody therapy (64%), MIBG (7%), single (79%) or tandem autologous transplantation (ASCT; 20%). ASCT conditioning included: Busulfan/Melphalan (BuMel) (18%), Carboplatin/Etoposide/Melphalan (CEM) (73%), Thiotepa/Cytosan (19%), and total body irradiation (5%). Severe ototoxicity (requiring hearing aids) was observed in 58% of participants. Physician-reported late effects included hypothyroidism (17%), pulmonary hypertension (1%), congestive heart failure (2%), and hypertension (6%). Pulmonary Function Studies revealed restrictive lung disease [RLD - Total Lung Capacity < 70% predicted] in 8% of subjects. Laboratory study showed elevated creatinine in 7% and Hemoglobin A1c in 7%. Growth failure (height Z-score < -1.7) was observed in 34%. Subsequent malignant neoplasms (SMN) developed in 15 participants (4%; 4 sarcomas, 3 MDS/t-AML, single instance of 8 other malignancies). Adjusting for sex, follow-up time, age, and race, there were no differences in risk of SMN, severe ototoxicity, growth failure, or RLD for participants who received BuMel vs. CEM-based conditioning, or among those who received anti-GD2 antibody therapy vs. those who did not. Use of carboplatin during ASCT was not associated with increased ototoxicity risk for any category of cisplatin induction dose. Comparing subjects who received CEM as a component of tandem ASCT (vs. single CEM), there was increased risk of growth failure [OR (95%CI) = 4.2(2.1, 8.4); $p < 0.0001$], but not RLD. Exposure to isotretinoin was not associated with increased risk of growth failure. Further multivariable analyses will be presented, exploring risks for late toxicity associated with conditioning regimens, radiation therapy, surgical approaches, and acute and chronic complications of therapy. **Conclusions:** The burden of late toxicity in HRNBL survivors is substantial. Anti-GD2 immunotherapy and isotretinoin do not appear to be associated with SMN, ototoxicity, growth failure, or RLD. Research Sponsor: St. Baldrick's Foundation.

Oral Abstract Session

Irinotecan and temozolomide combined with dasatinib and rapamycin for patients with relapsed or refractory neuroblastoma: Results of the prospective randomized RIST trial. *First Author: Selim Corbacioglu, University Hospital of Regensburg, Regensburg, Germany*

Background: Relapsed or refractory neuroblastoma (r/rNB) are associated with a dismal outcome. RIST is the acronym for irinotecan and temozolomide (I/T) as backbone in combination with dasatinib (S) and rapamycin (R) aligned in a molecular targeted, metronomic design. **Methods:** RIST-rNB-2011, an open label randomised Phase II trial (NCT01467986), compared RIST (experimental arm) with I/T (control arm; CA). Patients with high-risk r/rNB (stage 4 and all MYCN amplified stages; MYCN+) were randomized with a block-wise (block length of 6) randomization stratified by MYCN. RIST treatment consists of courses of R/S (4 days/week) followed by I/T (5 days/week). Phase 1 is defined by 4 cycles with one R/S and one I/T course (8 weeks). In phase 2 each of the 4 cycles comprise 2 R/S and 1 I/T course (12 weeks). CA consisted of I/T courses only. The primary endpoint was progression-free survival (PFS), analysed by a Cox proportional hazards model adjusted for MYCN- to test the null hypothesis of a hazard ratio of 1 assuming proportional hazard rates at a two-sided 5% significance level. A point estimate and a two-sided 95% confidence interval was provided. A sample size of N = 114 patients was calculated. Primary analysis was based on the intention-to-treat principle (ITT). Toxicity was assessed in all participants who received at least one dose of protocol therapy. **Results:** Subjects (N = 124) eligible for follow-up were enrolled from 08/2012 – 09/2020. Median age was 5.37 years (y) (range 1.1 – 24.6 y). Disease characteristics were relapse in 80% (< 18 months (m) after diagnosis: 40%) and refractory disease in 20%, MYCN+ was present in 39%. Median overall follow-up was 72 m. In the ITT population median PFS was 11 m in RIST vs 5 m in CA (HR: 0.62 (95%-CI: 0.42, 0.92), $p = 0.019$), and 16 m in RIST vs 4 m in the CA (HR: 0.53 (95%-CI: 0.31, 0.90), $p = 0.018$) in the per protocol (PP) population. Subgroup analyses showed a selective effect in the MYCN+ (HR: 0.45 (95%-CI: 0.24, 0.84), $p = 0.012$) compared to MYCN- patients (HR: 0.84 (95%-CI: 0.51, 1.38), $p = 0.492$). PFS at 2 y in MYCN+ was 38% vs 8% in CA (ITT) and 50% vs 6% (PP), respectively. In MYCN+ patients with a relapse < 18 m from initial diagnosis (N = 33) PFS remained significantly better ($p = 0.048$). Median overall survival (OS) for RIST vs CA was 20 m vs 16 m in ITT (HR: 0.68 (95%-CI: 0.45, 1.04), $p = 0.073$) and 26 m vs 16 m in PP (HR: 0.55 (95%-CI: 0.32, 0.98), $p = 0.041$). OS was significantly better in MYCN+ patients: 11 m vs 6.5 m in ITT (HR: 0.51 (95%-CI: 0.27, 0.96), $p = 0.037$) and 17 m vs 5 m in PP (HR: 0.34 (95%-CI: 0.14, 0.83), $p = 0.018$). In MYCN- no differences were observed neither in PFS nor in OS. R/S did not add additional toxicity to I/T. **Conclusions:** RIST was well tolerated and led to a significantly improved PFS and OS in MYCN+ patients, allowing a targeted approach for this high-risk population. Clinical trial information: NCT01467986. Research Sponsor: Deutsche Krebshilfe.

Oral Abstract Session

Biological medicines for diffuse intrinsic pontine glioma (DIPG) eradication (BIOMEDE): Final results of an international randomized phase II platform trial comparing 3 targeted therapies in combination with radiotherapy from ITCC, SIOPE-Brain and ANZCHOG. *First Author: Jacques Grill, Gustave Roussy, Villejuif, France*

Background: DIPG is the most aggressive brain cancer in children and adolescents with a median survival of 9 months. Surgery is not possible due to the invasive nature of the disease in a critical area of the brain; only radiotherapy has shown a transient palliative effect on disease progression and no adjuvant therapy has proven to increase disease control. **Methods:** We launched a large randomized biomarker-driven platform trial to compare three targeted therapies (erlotinib, everolimus and dasatinib) in combination with 54 Gy radiotherapy, in newly diagnosed patients with DIPG (NCT02233049). A central pathological review was performed prior to study entry to confirm the diagnosis of DIPG with H3K27me3 loss (with or without H3K27M mutation) and assess biomarkers. The randomization was designed so that a drug could not be allocated if the corresponding biomarker was absent in the tumor (EGFR overexpression for erlotinib, mTOR activation for everolimus, no specific biomarker for dasatinib). Tumors underwent whole genome sequencing and RNAseq to evaluate prognostic and theranostic biomarkers. Primary endpoint was overall survival. **Results:** Among the 279 DIPG patients screened for the randomized trial between October 2014 and September 2019, 233 were enrolled in 45 centers in 7 countries; among the 46 screen failures, the diagnosis of DIPG could not be confirmed in 23 patients. No biopsy- or treatment-related death was reported. Serious adverse events ≥ 3 unrelated to disease progression were reported in 40% of patients, 34%, 36% and 46%, in the erlotinib, everolimus and dasatinib arms, respectively ($p = 0.32$). With a median follow-up of 5.3 years, median overall survival (OS) from the date of randomization was 9.0 (95% confidence interval, 7.4-14.4), 11.3 (10.3-13.4) and 9.4 (7.7-10.7) months for erlotinib, everolimus and dasatinib, respectively ($p = 0.45$). OS were not statistically different from those of a historical biopsy-proven cohort. The molecular profiling with copy number aberrations (CNA) had a strong impact on survival (log-rank test, $p = 0.0001$) as shown by the preliminary analysis of the first hundred patients identifying a group of tumors with very poor prognosis with a HR for death of 1.96 (1.07-3.64) characterized by TP53 mutations ($p = 3.05e-11$) associated with more CNA ($p < 0.0001$). **Conclusions:** This trial demonstrated the feasibility and safety of a large randomized trial for DIPG based on biomarker information from a stereotactic biopsy at diagnosis in an international multicenter setting and generated new tumor biological insights to further develop innovative therapies. Clinical trial information: NCT02233049. Research Sponsor: French National Cancer Institute; Imagine4Margo; Roche, BMS, Novartis.

Oral Abstract Session

Clinical activity of pan-RAF inhibitor tovorafenib in the registrational pediatric low-grade glioma arm of the phase 2 FIREFLY-1 (PNOC026) study.
First Author: Lindsay Baker Kilburn, Children's National Hospital, Washington, DC

Background: Pediatric low-grade gliomas (LGGs) are the most common brain tumors of childhood. Genomic alterations of *BRAF* (*KIAA1549-BRAF* fusions, 50–60% and *BRAF* V600E mutations, 5–15%) are the most frequent oncogenic drivers in pLGGs. Tovorafenib is an investigational, oral, selective, brain-penetrant, small molecule, type II pan-RAF inhibitor. Tovorafenib has demonstrated clinically meaningful responses in 24/35 patients (2 CR, 7 PR and 15 SD) in the pediatric phase 1B PNOC014 (NCT03429803) trial in patients with *RAF*-altered cancers (Wright, SNO 2022). **Methods:** FIREFLY-1 (NCT04775485) is a multicenter phase 2 study evaluating the efficacy and safety of tovorafenib monotherapy in patients with *BRAF*-altered cancers. Registrational arm 1 of FIREFLY-1 includes patients 6 months–25 years of age with recurrent or progressive LGG previously treated with ≥ 1 prior line of systemic therapy. Tovorafenib 420 mg/m² (not to exceed 600 mg) is administered weekly, in 28-day cycles, (tablet or liquid suspension formulation) until progression. The primary end-point of arm 1 is ORR, as defined by Response Assessment in Neuro-Oncology (RANO) criteria and determined by blinded independent review. **Results:** As of September 28, 2022, arm 1 had enrolled 77 patients and is fully accrued. All patients had ≥ 6 months of follow-up. Median age at enrollment was 8 years (range 2–21). Patients were pretreated with a median of 3 prior lines of systemic therapy (range: 1–9); 60% had received prior MAPK pathway-targeted agents. The most common tumor site was optic pathway (51%). Sixty-four patients harbored a *BRAF* fusion/rearrangement (83%) in their tumors, and 13 (17%) had a *BRAF* V600E mutation. Median duration of tovorafenib treatment is 8.4 months (range 0.7–16.8), with 59 patients (77%) remaining on treatment at the time of data cutoff. Per independent assessment in 69 RANO-evaluable patients, ORR was 64%, [3 CR, 41 PR (10 unconfirmed) and 19 SD] with a clinical benefit rate of 91%. Responses were achieved in tumors with *BRAF* fusions and V600E mutations, including those previously treated with MAPK inhibitors. The most common treatment-related adverse events (TRAEs) of any grade were hair color changes (75%), increased creatine phosphokinase (64%), anemia (46%), fatigue (42%) and maculopapular rash (42%). Tovorafenib dose modifications occurred in 16 (21%) and discontinuations in 2 (3%) patients due to TRAEs. Updates from a longer follow-up on the 77 patients in arm 1 will be presented at the meeting. **Conclusions:** Tovorafenib was generally well tolerated and showed encouraging evidence of antitumor activity in children and young adults with recurrent/progressive *BRAF*-altered pLGG. LOGGIC/FIREFLY-2 (NCT05566795), a global, phase 3 trial is evaluating once-weekly tovorafenib monotherapy in newly-diagnosed patients with pLGG harboring a known activating *RAF* alteration. Clinical trial information: NCT04775485. Research Sponsor: Day One Biopharmaceuticals.

Oral Abstract Session

Palbociclib in solid tumor patients with genomic alterations in the cyclin D-CDK4/6-INK4a-Rb pathway: Results from NCI-COG pediatric MATCH trial Arm I (APEC1621I).
First Author: Margaret E Macy, Department of Pediatrics, University of Colorado and Center for Cancer and Blood Disorders, Children's Hospital Colorado, Aurora, CO

Background: The NCI-Children's Oncology Group (COG) Pediatric Molecular Analysis for Therapy Choice (MATCH) trial assigns patients aged 1 to 21 years with relapsed or refractory solid tumors, lymphomas, and histiocytic disorders to phase 2 treatment arms of molecularly-targeted therapies based on genetic alterations detected in their tumor. Arm I evaluated palbociclib, a reversible, selective oral small molecule inhibitor of CDK 4 and 6 in tumors harboring specified genomic alterations in the cyclinD-cdk4/6-INK4a-Rb pathway: amplification of *CDK4*, *CDK6*, *CCND1*, *CCND2*, or *CCND3*. Positive Rb expression by IHC was required. **Methods:** Palbociclib was administered on days 1–21 at 75 mg/m² once daily in 28-day cycles for up to 2 years, until disease progression, or intolerable toxicity. Response assessment occurred every 2–3 cycles. The primary endpoint was objective response (OR) rate; secondary endpoints included safety/tolerability and progression-free survival (PFS). **Results:** Twenty-three patients (median age 15 yrs; range 9–21) were enrolled between August 2018 and May 2022. Twenty patients received protocol therapy and were evaluable for response. Of treated patients, osteosarcoma was the most common diagnosis (9/20, 45%), with amplification of *CCND3* detected in 6/9 patients, *CDK4* in 2, and *CDK6* in 1. Rhabdomyosarcoma was next most frequent (6/20, 30%), with all tumors harboring *CDK4* amplifications. Other diagnoses were high grade glioma (n = 2), soft tissue sarcoma (n = 2), and neuroblastoma (NB) (n = 1). Additional genomic alterations were detected in 9/20 tumors, most frequently *TP53* mutations (n = 4, including 2 patients with Li-Fraumeni syndrome). Palbociclib was generally well tolerated with hematologic toxicities being the most common treatment related events and no related grade 5 events. Neutropenia was the most common grade 3–4 adverse event (n = 10, 50%) followed by thrombocytopenia (n = 8, 40%), leukopenia (n = 7, 35%), and anemia (n = 5, 25%). Four patients came off study for toxicity (3 for prolonged thrombocytopenia (cycle 1 (x2) and cycle 2) and 1 for prolonged grade 4 neutropenia (cycle 3)). Non-hematologic toxicities were mild (grade 1–2). No ORs were seen. Two patients with tumors harboring *CDK4* amplifications had stable disease (SD): one with NB had SD for 5 cycles and one with sarcoma had SD for 3 cycles but came off therapy for toxicity. Six-month PFS was 10% (95% CI: 1.7%–27.2%) and six-month overall survival was 65% (95% CI: 40.3%, 81.5%). **Conclusions:** The CDK4/6 inhibitor palbociclib at 75mg/m² PO daily was well tolerated in this heavily-pretreated cohort. No objective responses were observed in these biomarker-selected patients with treatment-refractory solid tumors. Further evaluation of this agent in combination with chemotherapy in the pediatric population is ongoing. Clinical trial information: NCT03526250. Research Sponsor: U.S. National Institutes of Health.

Treatment of focal anaplastic Wilms tumor (FAWT): A report from the Children's Oncology Group (COG) AREN0321 and AREN03B2 studies.
First Author: Amy E. Armstrong, Washington University in St Louis, St. Louis, MO

Background: FAWT represents tumors with circumscribed small areas of anaplastic nuclear changes confined to the kidney within an otherwise favorable histology WT. In National Wilms Tumor Study-5, patients with stage I FAWT treated with vincristine and dactinomycin (VA) without flank radiation had 4-year event-free survival (EFS) and overall survival (OS) of 67.5% and 88.9%, respectively. Patients with stage II–IV FAWT were treated with VA plus doxorubicin and radiation (DD4A). Of the 20 patients with stage II–III FAWT, 4 had a relapse and 3 died. The 4-year EFS and OS for stage IV FAWT/upfront nephrectomy were 61.4% and 71.6%, respectively. The COG AREN0321 study evaluated whether intensifying therapy for stage I and IV FAWT would improve survival of these patients. **Methods:** Tumor histology and stage were confirmed for all patients by real-time central pathology, surgery, and radiology review on protocol AREN03B2, the COG renal tumor classification, biology, and banking study. Patients then enrolled on AREN0321 with stage I–III FAWT received DD4A and those with stage IV FAWT received vincristine, doxorubicin, cyclophosphamide, carboplatin and etoposide with radiation (UH-1). We analyzed outcomes of patients with FAWT treated on AREN0321 and those enrolled only on AREN03B2 who received the same chemotherapy regimens. **Results:** A total of 46 patients (25 AREN0321 and 21 AREN03B2) were included in the analyses. Of the 25 AREN0321 patients, 17 (68%) had upfront nephrectomy and all 25 received radiation. Of the 5 AREN0321 patients with stage IV FAWT, 4 had metastasis to lung and 1 to lung and liver. Of the 21 AREN03B2 patients, 19 (90%) had upfront nephrectomy and 17 (81%) reported receiving radiation. The 2 AREN03B2 stage IV patients had lung only metastases. The 4-year EFS and OS are displayed in the table below. No events occurred in stage I–II AREN0321 patients nor in any AREN03B2 patients. Of 10 patients with stage III FAWT on AREN0321, 3 had a relapse. None of the 7 stage IV FAWT patients who received UH-1 had a relapse, but one patient died due to toxicity. **Conclusions:** Patients with stage I and II FAWT had outstanding survival when treated with DD4A and radiation. Intensification of therapy may be warranted for stage III FAWT and appears to have improved patient survival for stage IV FAWT but with increased risk of toxicity. Strategies to alleviate toxicity of UH-1 therapy have been incorporated into the ongoing COG trial for high-risk patients. Clinical trial information: NCT00335556. Research Sponsor: Children's Oncology Group.

Oral Abstract Session

Erdafitinib in patients with FGFR-altered tumors: Results from the NCI-COG Pediatric MATCH trial arm B (APEC1621B).
First Author: Alice Lee, Children's Hospital at Montefiore, Bronx, NY

Background: The NCI-Children's Oncology Group (COG) Pediatric Molecular Analysis for Therapy Choice (MATCH) trial assigns patients aged 1–21 years with relapsed or refractory solid tumors, CNS tumors, lymphomas, and histiocytic disorders to phase 2 treatment arms of molecularly-targeted therapies based on genetic alterations in their tumor. Arm B (APEC1621B) evaluated the orally bio-available FGFR inhibitor erdafitinib in patients whose tumors harbored activating alterations in FGFR 1/2/3/4. **Methods:** Patients received oral erdafitinib 4.7 mg/m²/dose (Max dose: 8 mg) daily for 28-day cycles until disease progression or drug related dose limiting toxicity (Max 26 cycles). Disease assessments were performed every 2–3 cycles. The primary endpoint was objective response rate; secondary endpoints included progression free survival (PFS). **Results:** A total of 20 evaluable patients (median age: 15 yrs) were enrolled from June 2018 to July 2022 in this first study of erdafitinib in pediatric patients. The most common diagnosis (n = 17) was glioma or glioneuronal tumor (11 low grade and 6 high grade). Three patients had non-CNS solid tumors (1 each with neuroblastoma, osteosarcoma, and rhabdomyosarcoma). FGFR alterations detected consisted of activating hotspot mutations in *FGFR1* (n = 16), *FGFR2* (n = 1), *FGFR4* (n = 1), and *FGFR1* fusions (n = 2; *FGFR1:TACC1*, *FGFR1:TACC3*). Partial responses were confirmed by central review in 2/20 patients (10%, 90%CI: 3.4%, 26.2%), both with low grade gliomas or glioneuronal tumors (LGG, LGGNT) and *FGFR1* hotspot mutations (K687E and N577K). A best response of stable disease (SD) was observed in 6 additional patients with gliomas with a median duration of SD of 6.5 cycles. Six-month PFS was 45% (95% CI: 23.1%, 64.7%) and six-month OS was 89.7% (95%CI: 64.8%, 97.3%). Treatment related adverse events included those previously reported with FGFR inhibitors including hyperphosphatemia and nail changes or infections. Grade 1 vision changes were also reported. There was one Grade 3 spinal cord compression and one Grade 4 intracranial hemorrhage. **Conclusions:** Erdafitinib was generally well tolerated in this heavily pre-treated cohort of children with relapsed tumors harboring FGFR alterations. Partial responses or stable disease were observed in the majority (6/11, 54%) of patients with *FGFR1*-mutant low grade gliomas or glioneuronal tumors, suggesting the possible benefit of FGFR inhibitor therapy for these patients. Further studies would be necessary to more thoroughly evaluate the activity of erdafitinib for patients with other histologies and FGFR alteration types or combination approaches that include other targeted and/or cytotoxic agents. Clinical trial information: NCT03210714. Research Sponsor: U.S. National Institutes of Health.

Oral Abstract Session

Phase 2 study of larotrectinib in children with newly diagnosed infantile fibrosarcoma (IFS): Children's Oncology Group (COG) ADVL1823 cohort A. *First Author: Theodore Willis Laetsch, Division of Oncology, Children's Hospital of Philadelphia, and Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: *NRK1/2/3* gene fusions (TRK fusions) occur in a range of pediatric cancers and are the canonical molecular alterations in IFS. Larotrectinib is a highly selective TRK inhibitor that is FDA-approved for TRK fusion solid tumors in patients with no satisfactory alternative treatments or whose cancer has progressed following initial treatment. ADVL1823 (NCT03834961) evaluated larotrectinib in children with newly diagnosed TRK fusion positive solid tumors in two histology-based cohorts. Cohort A enrolled patients with IFS and is the focus of this analysis. **Methods:** Newly diagnosed patients ≤ 30 years old with unresectable or metastatic IFS and a locally identified *NRK* gene fusion were eligible for Cohort A utilizing a Simon 2-stage design. Patients received larotrectinib at a dose of 100 mg/m²/dose BID (max of 100 mg/dose) continuously in 28-day cycles until disease progression, unacceptable toxicity, the tumor becoming surgically resectable following a minimum of 6 cycles of therapy, or completion of 12 cycles (for those with CR) or 26 cycles (for those with PR) of therapy. The primary endpoint was the centrally confirmed objective response rate within 6 cycles according to RECIST 1.1; response assessment occurred every 2 cycles for the first 6 cycles. The data cutoff was December 31, 2022. **Results:** Between October 2019 and May 2022, 18 patients with IFS were enrolled from 14 centers. The median age was 2 months (range <1 month to 4.6 years). *NRK* fusions included presumed/confirmed *ETV6:NRK3*, *n*=15, *NRK3* (partner unconfirmed), *TMP3:NRK1* and *DCTN1:NRK1*, *n*=1 each, and were identified by FISH (*n*=8), NGS (*n*=7), and PCR (*n*=3). 17 of 18 patients (94%) demonstrated confirmed objective responses (16 PR and 1 CR,) resulting in closure to enrollment after meeting the pre-specified efficacy threshold. The only patient without confirmed response demonstrated 79% tumor reduction after cycle 2, but no confirmatory scan was obtained within the first 6 cycles. No patient discontinued therapy within the first 6 cycles due to disease progression or toxicity. Four (22%) patients had dose limiting toxicities: 2 neutropenia (both CTCAE V5 grade (G4) and 1 each G3 AST increase and G3 weight loss. All patients resumed therapy following a dose reduction. Treatment-related grade ≥ 3 toxicities occurred in 7 patients, most commonly neutropenia (*n*=5, 3 G3, 2 G4). **Conclusions:** Larotrectinib is highly active and well tolerated in newly diagnosed patients with IFS. Enrollment of this very rare molecularly defined patient population was feasible within the COG. Ongoing follow-up will evaluate durability of response after treatment discontinuation at protocol specified response-adapted timepoints with or without surgical resection of tumor. Clinical trial information: NCT03834961. Research Sponsor: U.S. National Institutes of Health; St. Baldrick's Foundation; Bayer.

Oral Abstract Session

Feasibility and acceptability of social determinants of health data collection in the context of a Children's Oncology Group trial. *First Author: Emily Jones, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: Children who are Black, Hispanic or of proxied low socioeconomic status experience inferior survival outcomes despite receipt of uniform treatment on Children's Oncology Group (COG) trials. Investigation of mechanisms underlying these disparities and evaluation of interventions to address them has been limited by inadequate data. Prior COG trials have collected child race, ethnicity, insurance and zip code—non-modifiable data elements that are prone to misclassification bias—as proxies for exposure to adverse social determinants of health (SDOH). Collection of parent-reported SDOH data provides key information not previously assessed in COG trials, including modifiable exposures such as household material hardship (HMH): food, housing, utility or transportation insecurity. We report the preliminary feasibility and acceptability of the first COG trial to prospectively embed SDOH data collection. **Methods:** ANBL1531 (NCT03126916), the current frontline, groupwide COG trial for patients with high-risk neuroblastoma, was amended in September 2019 to include an opt-in, correlative aim to evaluate parent-reported SDOH. Parents of patients < 18 years could opt-in during initial ANBL1531 consent to complete a brief, single-timepoint survey at their enrolling site during Induction Cycle 1. Survey domains included parent-reported demographics, HMH, household income, and social support. Paper/pencil surveys available in English, Spanish or French were self-completed or read-aloud by site personnel and could be administered in any language with an interpreter. Surveys were submitted to a central disparities study team for data cleaning and entry into an electronic database. **Results:** As of December 31, 2022, 360/413 eligible participants opted-in to the embedded SDOH aim across 101 COG sites (87.2% consent rate). Among participants, 316 surveys (87.8%) were completed a median of 11 days post-enrollment. Four (1.1%) parents declined survey completion (3 withdrew consent). Reasons for non-completed surveys included: survey still pending within protocol-specified window (*n* = 10), institutional COVID-19 restrictions (*n* = 6), site scheduling issues (*n* = 6), patient came off ANBL1531 protocol (*n* = 5) and unknown (*n* = 13). Data missingness for HMH, the primary SDOH of interest, was 0.8%. Surveys were administered in English, Spanish, French, Vietnamese, Arabic, Mandarin and Tamil. **Conclusions:** Collection of parent-reported SDOH data as an optional, embedded component of a groupwide COG trial is feasible and acceptable, as demonstrated by remarkable willingness to participate and infrequency of missing data. Incorporation of this approach in future National Clinical Trials Network trials is essential to inform impactful health equity research, including the development and evaluation of targeted interventions to address outcome disparities. Research Sponsor: Philanthropic Funds.

Oral Abstract Session

Feasibility of the Poverty-Targeted Pediatric Cancer Resource Equity (PediCARE) intervention. *First Author: Haley Newman, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Children with cancer living in poverty are more likely to relapse and die, even when treated uniformly on clinical trials. No evidence-based interventions targeting poverty as a risk factor for disparate outcomes exist in pediatric oncology. We previously developed and refined the Pediatric Cancer Resource Equity (PediCARE) intervention—a centrally-delivered, household material hardship (HMH)-targeted intervention that provides transportation and groceries to low-income pediatric oncology families. We report feasibility of administering PediCARE as a randomized intervention across 2-centers. **Methods:** We conducted a pilot randomized controlled trial (RCT) of PediCARE versus usual care at Dana-Farber Cancer Institute (DFCI) and University of Alabama Birmingham (UAB) between May 2019 and August 2021 (NCT03638453). Eligible participants included children age < 18 years with *de novo* cancer diagnosed in the prior 2-months, who were planned to receive at least 4-cycles of chemotherapy and lived in a household that screened positive for HMH (food, housing, utility or transportation insecurity). Participants were randomized 1:1 by site to receive PediCARE or usual care for 6-months. Parent/guardians completed a household survey at baseline and at completion of the 6-month intervention. The primary outcome was feasibility defined *a priori* as a recruitment and consent to randomization rate of $\geq 75\%$ and $< 20\%$ attrition per arm—endpoints intended to justify the feasibility of a subsequent efficacy RCT. Secondary outcomes included proportion of recipients who successfully received the intervention and intervention acceptability. **Results:** A total of *N* = 40/40 eligible families (*n* = 12 UAB; *n* = 28 DFCI) were approached and offered an opportunity to participate (100% consent rate). Among participants, there was 0% attrition in either arm following randomization and the 6-month intervention period; 100% of parent/guardians completed both baseline and 6-month surveys. Among those randomized to PediCARE, 100% (*n* = 20) successfully received grocery and transportation resources; 100% reported that it was "easier to buy food for my family," 85% reported it was easier to get to and from the hospital, and 95% reported they would be "very likely to recommend the intervention to other families". **Conclusions:** Stark disparities exist in pediatric oncology. Advancement in health equity science must include establishment of a robust, evidence-based portfolio of scalable health equity interventions for evaluation in the Children's Oncology Group (COG) drug trial setting. Findings from this pilot RCT support feasibility and utility of a poverty-targeted intervention from the clinical oncology setting—as evidenced by 100% of parent/guardians consenting to randomization with 0% attrition across 2-centers. Immediate next steps include randomized efficacy evaluation in a COG trial-embedded study. Clinical trial information: NCT03638453. Research Sponsor: Charles Hood Foundation and Family Reach Foundation.

Oral Abstract Session

Medicaid enrollment changes among U.S. adult survivors of childhood cancer following medicaid expansion: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Xu Ji, Emory University School of Medicine, Atlanta, GA*

Background: Little is known about whether Medicaid expansion under the Affordable Care Act (ACA) affected insurance coverage among adult survivors of childhood cancer, a population at high-risk for poor health outcome. We addressed this gap by evaluating the association between ACA Medicaid expansion and Medicaid enrollment among participants in the Childhood Cancer Survivor Study (CCSS). **Methods:** The CCSS cohort of 5-year survivors of childhood cancer was linked to administrative Medicaid insurance data in 2010-2016. We identified 13,895 adult survivors (aged 18-64 years) diagnosed with cancer under age 21 and between 1970 and 1999. Outcomes included (1) percentage with any Medicaid enrollment by year; and (2) Medicaid-covered days (number of days when a survivor was enrolled in Medicaid) during each year. Multivariable difference-in-differences (DD) models were used to examine outcome changes pre vs. post ACA Medicaid expansion, in expansion- vs. non-expansion states, adjusting for age, sex, race/ethnicity, income, education, and chronic conditions. Multivariable models were conducted overall and then stratified by cancer type, race/ethnicity, income, and education. **Results:** Medicaid enrollment rates increased more in expansion states (17.6% pre-expansion to 24.1% post-expansion) than non-expansion states (16.4% to 16.9%), leading to a net increase in enrollment of 6.6 percentage points (ppt; 95% CI = 5.5-7.7) in the multivariable DD model. Multivariable DD model showed a net increase of 18.4 days (95% CI = 13.8-23.1) in Medicaid-covered days in expansion states relative to non-expansion states. The expansion-associated increase in Medicaid enrollment rates was greatest among survivors of leukemia (multivariable DD estimate: 8.9 ppt, 95% CI = 6.9-11.0) and non-Hodgkin lymphoma (8.0 ppt, 95% CI = 5.0-10.9). Greater increases in Medicaid enrollment were seen in non-Hispanic Black (13.5 ppt, 95% CI = 8.0-19.1) and Hispanic survivors (15.8 ppt, 95% CI = 10.6-21.0) than non-Hispanic White peers (5.1 ppt; 95% CI = 4.0-6.2); in survivors with $< \$20K$ household income (11.7 ppt, 95% CI = 8.9-14.4) compared to those with $\geq \$60K$ household income (2.9 ppt, 95% CI = 1.6-4.2); and in survivors with high school or lower education (9.3 ppt, 95% CI = 6.9-11.8) compared to those with a college or higher degree (3.9 ppt, 95% CI = 2.6-5.3). Similar patterns were observed across survivor subgroups when examining Medicaid-covered days. **Conclusions:** We provide the first evidence on increased Medicaid enrollment and longer coverage duration among adult survivors of childhood cancer following Medicaid expansion, with greater increases seen among survivors of underrepresented racial/ethnic populations, those with low socioeconomic status, and high medical need survivors. Oral Abstract Session

Enhancing prediction of cancer therapy-related cardiomyopathy from surveillance echocardiograms: A Children’s Oncology Group (COG) report. *First Author: Eric Jessen Chow, Fred Hutchinson Cancer Center, Seattle, WA*

Background: Many childhood cancer patients receive cardiotoxic therapies and need surveillance for therapy-related cardiomyopathy (CM). (Echo)cardiography is used to screen for cardiac dysfunction but has relatively poor discriminatory ability to predict who will develop CM. We sought to identify combinations of echo parameters that can better predict which patients subsequently develop CM. **Methods:** Longitudinal echos (obtained per routine care) of patients diagnosed with cancer < 21y who subsequently met CM criteria (left ventricular [LV] ejection fraction $\leq 50\%$ / fractional shortening $\leq 28\%$, ≥ 2 times, with ≥ 1 time after completion of cancer therapy) plus clinical data were collated from COG sites. Echos and data from patients without CM were also collated. All echos were centrally remeasured for 42 routinely reported parameters in blinded fashion. We applied least absolute shrinkage and selection operator (LASSO) to fit logistic models to identify the most influential predictors for CM development within 2 and 5y of echo, plus age and sex. Data were randomly split into training (85%) and test (15%) sets with 10-fold cross validation. Prediction accuracy was calculated using area under the ROC curve (AUC), based on the model that provided the minimum mean cross-validated error. **Results:** Echos from 88 CM cases (248 echos predating CM) and 126 non-cases (518 echos) were available. Patients (n = 214) were diagnosed at mean age 7.7 ± 5.2 y with mean 9.5 ± 4.0 y follow-up. Mean doxorubicin equivalent doses for cases and non-cases were 350 ± 188 and 272 ± 199 mg/m², respectively. For 2y CM prediction, models achieved training AUC 0.85 (95%CI 0.78-0.92; 261 echos) and test AUC 0.74 (95% CI 0.74-0.90; 46 echos). Factors selected included age, 2-dimensional (2D) measurements of LV geometry (LV systolic and end-systolic dimensions, and posterior wall thickness), systolic function (M-mode fractional shortening), diastolic function (mitral inflow E wave, septal E', septal A'), and a measurement of combined systolic and diastolic function (myocardial performance index). For 5y CM prediction, models achieved training AUC 0.90 (95%CI 0.85-0.95; 175 echos) and test AUC 0.89 (95%CI 0.78-0.99; 30 echos). Age, LV end-systolic dimension (2D and M-mode), M-mode LV posterior wall thickness, 2D wall thickness-dimension ratio, mitral inflow E, septal E', septal A', and the myocardial performance index were selected. At both times 2D end-systolic dimension was the most influential parameter. Inclusion of anthracycline and chest radiotherapy dose did not meaningfully improve the AUCs. **Conclusions:** Prediction models that incorporate conventional echo data may be able to accurately identify childhood cancer patients at high risk of developing CM 2-5y prior to CM diagnosis. This may provide a window of opportunity to introduce interventions that may arrest or slow CM progression. Research Sponsor: Rally Foundation; U.S. National Institutes of Health.

Oral Abstract Session

Clonal hematopoiesis in survivors of childhood cancer. *First Author: Danielle Novetsky Friedman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Subsequent malignancies and cardiovascular (CV) disease are the leading cause of premature death in childhood cancer survivors, a population also at risk for premature aging. Clonal hematopoiesis (CH), the age-related clonal expansion of mutated hematopoietic stem cells, is a prominent risk factor for early-onset malignant and CV disease. Data are lacking on the prevalence of CH in childhood cancer survivors. **Methods:** We evaluated the prevalence of CH in a retrospective case-control study of childhood cancer survivors and matched controls (all ≥ 13 years of age). Cases included individuals diagnosed with a solid tumor or lymphoma at age ≤ 25 years who were ≥ 6 -months from completion of chemotherapy and/or radiotherapy. Age-matched controls (5-year age bins) with and without a history of cancer were included, given evidence of shared genomic risk factors between cancer and CH. Samples were batched and sequenced at an average depth of 19,830x using a custom, targeted amplicon-based UMI sequencing platform (ArcherDX), which included full exons of DNMT3A, TET2, ASXL1, TP53, CHEK2 and targeted regions of PPM1D, SRSF2, SF3B1, JAK2. Mutations at a variant allelic frequency (VAF) $\geq 0.02\%$ were identified with VAF $> 2\%$ considered clinically significant. Logistic regression adjusted for age, gender, and race was used to test for an association between CH and case-control status. **Results:** Samples were analyzed from 104 childhood cancer survivors (median age 19 years [y], range, 13-49y; median time since end-of-therapy: 10y, range 0.5-39y), 71 controls with untreated, newly diagnosed cancer (median age 25y, range 8-48y), and 68 healthy controls (median age 23y, range, 15-51y). The frequency of CH was higher in childhood cancer survivors compared to controls across ages with CH detected in 36.5% of survivors and 20.1% of controls (OR 3.2, 95% CI, 1.6-6.1). The enrichment of CH in survivors was observed both relative to healthy controls (OR 2.3, 95% CI 1.1-5.3) and treatment-naïve solid tumor controls (OR 5.0, 95% CI, 2.1-13.7). A trend toward a stronger association for CH mutations with VAF $> 2\%$ (OR 10.9, 95% CI, 1.9-60.7) compared to VAF $< 2\%$ (OR 2.7, 95% CI, 1.4-5.2) was observed. The most commonly mutated genes were in the DTA (*DNMT3A*, *TET2* and *ASXL1*) and DDR (*PPM1D*, *TP53* and *CHEK2*) classes. While a higher proportion of both DTA and DDR mutations was noted among survivors compared to controls, the enrichment of DDR mutations was stronger than DTA (OR 7.1, 95% CI 2.8-18.3 for DDR; OR 2.3, 95% CI 1.1-4.6 for DTA). A sub-analysis of 5 year survivors showed a higher frequency of CH in this cohort compared to controls (OR 2.8, 95% CI, 1.3-5.9). **Conclusions:** Childhood cancer survivors have higher frequencies of CH than age-matched controls, which persists for years after treatment. These data suggest that CH may, in part, drive the long-term premature multimorbidity seen in survivors. Longitudinal assessment of CH among survivors may be indicated to elucidate these associations. Carvedilol for prevention of heart failure in anthracycline-exposed survivors of childhood cancer: Results from COG ALTE1621. *First Author: Saro Armerian, City of Hope, Duarte, CA*

Background: Carvedilol improves cardiac function in patients with heart failure (HF), but remains untested as cardioprotective therapy in long-term childhood cancer survivors at risk for HF due to high-dose anthracycline exposure. We hypothesized that low-dose carvedilol would be safe and efficacious in reducing anthracycline-related heart failure risk in long-term survivors without evidence of HF. **Methods:** This was a randomized, double-blind, placebo-controlled phase 2B trial (NCT02717507) conducted at 28 sites. Eligibility included ≥ 250 mg/m² cumulative anthracycline exposure by age 21 years (y), ≥ 2 y from completion of cancer treatment, and preserved systolic function (ejection fraction [EF] $\geq 55\%$ and/or fractional shortening [FS] $\geq 28\%$) at enrollment. Patients were randomized 1:1 to take low-dose carvedilol (12.5 mg/day) or placebo for 2y; dose up-titration started at 3.125 mg/day. The primary objective was to determine the impact of carvedilol on echocardiographic indices of HF risk: standardized left ventricular (LV) wall thickness/dimension ratio (LVWT/Dz; primary endpoint), LV end-systolic wall stress (ESWS), LV chamber diameters, systolic and diastolic function. These indices were obtained every 6 months and measured centrally in a blinded fashion. Common Terminology Criteria for Adverse Events (CTCAE v4.0) was used to assess toxicity. Cardiac event was defined as relative EF/FS decline $< 20\%$ from baseline or both $< 55\%$ [EF] and $< 28\%$ [FS]. Treatment effects were analyzed using the Generalized Estimating Equation for normally distributed data, assuming linear time-trend. Group differences were evaluated by treatment*time interaction. **Results:** Of 196 participants enrolled, 182 were eligible and randomized. Characteristics (median, range): age at enrollment, 24.7y (10.4-53.9); time from cancer diagnosis, 13.4y (2.9-43.6); anthracycline dose, 374 mg/m² (250-1760); 19% had received chest-directed radiotherapy. There were no group differences in baseline participant demographics, cardiotoxic treatment exposure, or cardiac endpoints. LVWT/Dz was similar (+0.053, p = 0.15) between arms at 2y. However, treatment effects varied by time since diagnosis (p = 0.008) suggesting greater efficacy among longer-term survivors. Compared to placebo, carvedilol arm participants had significantly better LV end-diastolic diameter (-0.16 cm, p = 0.005) and LVESWS (-7.53, p = 0.027) at 2y. There were no CTCAE grade ≥ 3 events; all except 2 participants tolerated full dose escalation. Six out of eight cardiac events occurred on the placebo arm; longer-term follow-up of study participants is ongoing. **Conclusions:** In this randomized trial of long-term survivors of childhood cancer treated with high-dose anthracyclines, low-dose carvedilol was safe and effective in reducing established biomarkers of HF risk and could serve as a risk reduction strategy. Clinical trial information: NCT02717507. Oral Abstract Session

Genomic determinants of outcome in acute lymphoblastic leukemia: A Children’s Oncology Group study. *First Author: Ti-Cheng Chang, St. Jude Children’s Research Hospital, Memphis, TN*

Background: While cure rates for childhood acute lymphoblastic leukemia (ALL) exceed 90%, half of relapses arise in those originally classified with standard risk (SR) disease. **Methods:** We performed genome/transcriptome sequencing of diagnostic and germline samples of children with SR (n=1381) B-ALL or high-risk (HR) B-ALL with favorable cytogenetics (*ETV6:RUNX1* or double trisomy (DT) of chromosomes (chr) 4+10; n=115) to identify predictors of relapse. We used a case-control study to analyze 439 patients who relapsed and 1057 who remained in complete remission for > 5 years. **Results:** Genomic subtype was associated with relapse. Unbalanced *ETV6:RUNX1* translocations were more common than balanced in relapse patients (OR=2.01, CI=1.25-3.20, P=0.002). Conversely, balanced *TCF3:PBX1* translocations were more often associated with relapse than unbalanced in *TCF3:PBX1* ALL (OR=0.11, CI=0.01-0.50, P=0.003). A striking finding was the high relapse rate in PAX5 altered ALL (57 of 116 cases (49%); OR=3.29, CI=2.16-5.01, P=3.49x10⁻⁸). The nature of the heterogeneous PAX5 driver alterations in this subtype influenced relapse risk, with internal PAX5 amplifications and biallelic PAX5 alterations associated with the highest risk. Specific chr gains influenced outcome in hyperdiploid ALL, with gain of chr 10 and disomy of chr 7 associated with favorable outcome (OR=0.27, CI=0.17-0.42, P=8.02x10⁻¹⁰, St Jude Children’s Research Hospital (SJCRH) validation cohort: OR=0.22, CI=0.05-0.80, P=0.009), while disomy of chr 10 and 17 and gain of chr 6 were enriched in patients that relapsed (OR=7.16, CI=2.63-21.51, P=2.19x10⁻⁵; SJCRH cohort: OR=21.32, CI=3.62-119.30, P=0.0004). Genomic alterations were also associated with relapse in a subtype-dependent manner, including alterations of *INO80* in *ETV6:RUNX1*, *IKZF1* and *CREBBP* in hyperdiploid, and *FHIT* in Ph-like ALL. **Conclusions:** Genetic subtype, aneuploidy patterns, and secondary genomic alterations influence risk of relapse in children otherwise classified with SR ALL, or HR ALL with favorable genetics. Comprehensive genomic analysis is required for optimal risk stratification and treatment allocation, and particularly to study reduction of therapy in the lowest risk patients. Research Sponsor: U.S. National Institutes of Health; St Baldrick’s Foundation; American Lebanese Syrian Associated Charities of St. Jude Children’s Research Hospital.

Association of driver genetic alterations with relapse in the most common MP2PRT subtypes*.

Genetic Driver	Odds Ratio	Confidence Interval	N (remission)	N (relapse)	p-value

Oral Abstract Session

A phase 3 trial of inotuzumab ozogamicin for high-risk B-ALL: Second safety phase results from Children's Oncology Group AALL1732. *First Author: Maureen Megan O'Brien, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Inotuzumab ozogamicin (InO) is effective in adults and children with relapsed/refractory (R/R) CD22+ B-acute lymphoblastic leukemia (B-ALL). Children's Oncology Group AALL1732 is a phase 3 randomized trial evaluating InO for newly diagnosed patients (pts) with high-risk B-ALL. Given known hepatic, hematologic, and infectious toxicities, two safety phases were completed. **Methods:** Pts with residual marrow disease < 0.01% by end consolidation are randomized to chemotherapy (Arm A) or chemotherapy plus 2 cycles of InO (Arm B) after consolidation and interim maintenance 1 (IM1). Modifications after safety phase 1 [SP1; McNeer et al. *Blood* (2021) 138 (Suppl 1):3398] included reducing InO to 1.2mg/m²/cycle, increasing hydration during IM1 on Arm B, and enhancing supportive care in delayed intensification (DI) with antimicrobials. Safety phase 2 (SP2) assessed methotrexate (MTX) clearance, treatment delays and infectious/hepatic toxicity. Planned interim analysis is reported. **Results:** Fifty pts were randomized and evaluable (25 Arm A, 25 Arm B). There was no difference in gr ≥3 ALT or bilirubin elevations. Sinusoidal obstruction syndrome (SOS) occurred in 4 Arm B pts during DI including 3 (1 gr 3, 2 gr 4) in DI part 2 (DI2). IM1 day 1 MTX clearance was similar 65.4 (range 52.6-154) vs 70.2 hrs (range 56.5-267) on Arm A vs B, p = 0.27. Mean duration of IM1 was 74.8 (sd 11.8) vs 84 days (sd 13.3) on Arm A vs B, p = 0.013. Arm B IM1 duration in SP2 was shorter than SP1 [90 days (sd 15.3)]. DI part 1 (DI1) duration was similar between Arms. Arm B DI2 was longer than Arm A [53.8 (sd 20.2) vs 42.6 days (sd 9.5), p = 0.025]. Sepsis occurred in DI1 in 0 Arm A and 5 Arm B pts and in DI2 in 1 Arm A and 5 Arm B pts (Table). In DI2 1 pt on each Arm had gr 5 multiorgan failure (MOF) with sepsis. In DI1 50% of Arm A and 87.5% of Arm B pts had absolute neutrophil count (ANC) < 500 (p = 0.011). In DI2 all Arm A and 92.5% of Arm B pts had ANC < 500 with longer duration on Arm B [19.3 (sd 8.1) vs 7.8 days (sd 12.4), p = 0.015]. Compliance with prophylactic antibiotics was higher on Arm B (DI1 Arm A 41.7% vs Arm B 80.9%; DI2 Arm A 52.2% vs Arm B 85%). **Conclusions:** While SP2 modifications improved MTX clearance and duration of IM1, SOS and infections remain concerning on Arm B, particularly during DI. Most SOS events occurred proximal to thioguanine in DI2. Neutropenia was more pronounced in DI on Arm B but compliance with antimicrobials was high. Higher sepsis rates, primarily gr 3, were observed on Arm B with no increase in gr 5 infections. Additional modifications are planned for Arm B to further mitigate toxicity during post InO chemotherapy blocks. Clinical trial information: NCT03959085. Research Sponsor: U.S. National Institutes of Health.

Poster Discussion Session

Frequency and spectrum of clinically significant molecular alterations detected by tumor gene panel testing for pediatric cancer patients in the Texas KidsCanSeq study. *First Author: Frank Y. Lin, Texas Children's Cancer and Hematology Center, Baylor College of Medicine, Houston, TX*

Background: Tumor sequencing has the potential to inform diagnosis, prognosis, and treatment of childhood cancer patients. Prospective data are needed to evaluate the clinical utility of these tests. **Methods:** Patients less than 18 years of age with extracranial solid tumors (ST), central nervous system tumors (CNS), lymphomas and histiocytic disorders (L/H) were enrolled in the Texas KidsCanSeq clinical genomics study at six Texas institutions. Available tumor samples from a subset of patients designated as high risk (based on poor prognosis at diagnosis or tumor recurrence) were sequenced using pediatric cancer-focused targeted DNA (initially 124 genes; expanded to 169 genes) and RNA (81 genes) panels developed at Texas Children's Hospital. DNA variants (single nucleotide variants, insertion/deletions, splice site variants, copy number alterations) and fusion genes detected by RNA testing were analyzed. Tumor alterations were classified by molecular pathologists and oncologists as carrying strong (Tier 1) or potential (Tier 2) clinical significance following consensus guidelines from the Association for Molecular Pathology, American Society of Clinical Oncology, and College of American Pathologists. **Results:** A total of 626 patients were enrolled between 2018 and 2021, of whom 380 were designated as high risk. Tumor samples adequate for molecular testing were available from 342 of the 380 (90%) high risk patients (196 ST [57%], 132 CNS [39%] and 14 L/H [4%]). Clinically significant alterations were identified in 246 of 342 (72%) tumors: 165 (48%) from DNA testing only, 34 (10%) from RNA testing only, and 47 (14%) from both modalities. The frequency of clinically significant alterations was similar across tumor cohorts (74% ST, 68% CNS, 71% L/H). Alterations relevant to therapy-choice were reported in 127 of 342 (37%) tumors (35% ST, 26% CNS, 57% L/H); 87 of these 127 (69%) were not known from prior clinical testing. The most frequently altered therapeutic gene alterations (Table) involved *BRAF* (n=25), *CDKN2A/B* (n=20), *SMARCB1* (n=17), *GFR1/2/3/4* (n=14), *NF1* (n=13), *PIK3CA* (n=11), *ALK* (n=10), *CDK4* (n=9), and *RET* (n=7). One hypermutated tumor was identified: a high-grade glioma (tumor mutation burden > 190 mut/Mb) in a patient with Lynch syndrome due to a germline *MSH6* variant. **Conclusions:** Tumor alterations of clinical significance according to consensus guidelines were reported in a large proportion of children with diverse high risk or recurrent cancer diagnoses, the majority of which were not detected by other standard pathologic analysis. These data further support broader adoption of tumor molecular profiling for these patients. Research Sponsor: U.S. National Institutes of Health.

Oral Abstract Session

Preliminary results from the first-in-child phase II trial (ITCC-054/COG-AAML1921) of bosutinib in pediatric patients with newly diagnosed (ND) chronic myeloid leukemia (CML). *First Author: Edoardo Pennesi, Erasmus MC, Rotterdam, Netherlands*

Background: Bosutinib is a tyrosine kinase inhibitor (TKI), approved for adults with Philadelphia Chromosome (Ph+) CML; at the standard initial dose of 400 mg/day in ND patients, and 500 mg/day in resistant/intolerant (R/I) patients, administered orally once daily (QD) with food. Compared to the TKIs already approved in pediatrics, bosutinib has a different tolerability profile, and preclinical data suggest that longitudinal growth is potentially less impaired. Study NCT04258943 is an international, open-label, phase I/II trial, sponsored by the Erasmus Medical Center and the Children's Oncology Group, and funded by Pfizer Inc. The phase II arm enrolled ND patients, as well as R/I ones. The latter are not included in this analysis. **Methods:** ND patients aged 1-18 years with chronic phase CML, without evidence for organ toxicities, were enrolled. Main exclusion criteria included known T315I or V299L BCR-ABL1 mutations, and use of proton pump inhibitors and CYP3A inducers/inhibitors. The primary objectives of the phase II part of the study were to assess the safety and pharmacokinetics (PK) of bosutinib at the recommended phase II dose, which is body surface area adjusted, and consists of 300 mg/m² QD for ND patients (max 500 mg/day), as determined in the phase I part of the study. Based on regulatory authorities requirements, at least 35 patients have to be enrolled in phase II, with a total of 50-60 patients in phase I and II combined. This allows for pooled AE rates to be estimated with a maximum standard error of 0.071 and 0.065, respectively. **Results:** On 20/12/2022, 25 ND patients were screened, and 24 were enrolled: 15 males, median age 13 years (range: 5-17). The median follow up was 14 (range: 0.9-31) months. The most common non-hematological adverse events (AEs) were diarrhea (n = 16, Grade (Gr) ≤ 2 = 13), abdominal pain (n = 10, Gr ≤ 2 = 10), and nausea/vomiting (n = 8/8, Gr ≤ 2 = 7/8). Most common hematological AEs included platelet count decrease (n = 11, Gr ≤ 2 = 5), and anemia (n = 10, Gr ≤ 2 = 4). At 6 and 12 months, the cumulative incidence of Major Cytogenetic Response (MCyR) was 85% (95%CI 49%-96%) and 92.5% (95%CI 39%-99%), while for Complete CyR it was 77% (47%-91%) and 88.3% (95%CI 55%-98%), and for Major Molecular Response it was 23% (95%CI 7%-46%) and 30% (95%CI 10%-54%), respectively. Three patients permanently discontinued bosutinib due to intolerance, four due to unsatisfactory response per investigator's judgment, 17 were still on treatment at time of dataset lock. **Conclusions:** Bosutinib was well tolerated, despite common grade 1-2 gastrointestinal AEs. The preliminary efficacy seems comparable to published data from other second generation TKIs in children and to ND adult patients treated with bosutinib. Clinical trial information: NCT04258943. Research Sponsor: Pfizer Inc provided financial support.

Poster Discussion Session

Comprehensive nationwide study on the prescription of experimental anticancer therapies for compassionate use in children and adolescents in France. *First Author: Pablo Berlanga, Gustave Roussy Cancer Campus, Villejuif, France*

Background: Compassionate use prescriptions of innovative anticancer therapies are common in pediatric oncology, although rarely reported and activity/safety information mainly based on single/limited institutional retrospective experiences. **Methods:** In France, early drug access before marketing authorization is granted by the French National Agency for the Safety of Medicines and Health Products (ANSM) in case on unmet need, positive benefit/risk balance of preliminary data and no access within clinical trials. All anticancer prescriptions approved by the ANSM from 01/01/2020 to 31/12/2022 for patients < 18 years-old were analyzed. Patients safety and activity data were collected through the SACHA France study (NCT04477681) in the 2020-2021 period. 2022 data analysis is currently ongoing and will be included in the presentation at ASCO. **Results:** In the study period, 1022 anticancer compassionate use prescriptions were authorized by ANSM. The most frequently prescribed drug was methotrexate drinkable solution (n = 526) and 383 prescriptions were within the inclusion criteria of the SACHA study (anti-cancer innovative therapies not approved in Europe or new formulation of an already approved drug after 2007). In the 2020-2021 period, 28 different therapies were prescribed to 188 patients in a French Society of Pediatric Oncology (SFCE) center. Of them, 14 patients never received the prescribed drug, mainly due to early death. 107 of 174 (61%) eligible patients from 21 SFCE centers were included in the SACHA study (56% in 2020 and 67% in 2021). Median age at inclusion was 6.0 years (range: 0.3 -17.3). Main cancer types were central nervous system (CNS) tumors (69), followed by non-CNS tumors (24) and leukemia/lymphoma (14). Main prescribed therapies targeted MEK/BRAF (66), EZH2 (11), BCL2 (7) and ALK/ROS1/MET (5). In 40/107 patients (37%) at least a grade ≥2 clinical and/or grade ≥3 biological adverse drug reaction (ADR) was reported, leading to delayed therapy in 15 % of patients. Overall, 10 serious ADRs were reported in 10 patients. At last news, 53/107 patients had stopped their drug, mainly due to disease progression (33), followed by physician decision (11) and toxicity ± physician decision (8). 12-months PFS was 49% (95 IC: 38-60 %), with a median of 334 days of follow-up for patients on therapy. **Conclusions:** To our knowledge, this is the first comprehensive nation-wide study on compassionate use prescriptions of experimental anticancer therapies to children and adolescents with cancer with prospective safety/activity information in more than 60% of patients. This study underscores the importance, and feasibility, of the close collaboration between academia and regulatory authorities to ensure adequate real-life monitoring of these prescriptions. Prognostic factors of early mortality in children and adolescents enrolled in oncology trials with a dose-finding part in the era of targeted and immune therapies: An Innovative Therapies for Children with Cancer (ITCC) study. *First Author: Fernando Carceller, The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: Phase I/II trials play a key role for children with relapsed/refractory tumors. Life expectancy beyond 8-12 weeks is a common eligibility criterion. However, there are no objective means to determine life expectancy for trial candidates. A better understanding of the risk factors associated with early mortality on trial could maximize the efficiency of such trials, whilst ensuring the ethical aspects of recruitment. **Methods:** Patients with relapsed/refractory solid tumors or lymphomas aged < 18 years and participating in interventional clinical trials with a dose-finding part between 2000-2018 in 14 ITCC centers (across 5 European countries) were eligible. The mortality at 30 and 90 days (30-DM and 90-DM, respectively) from Cycle1-Day1 (C1D1) and its association with clinical, laboratory and efficacy data were assessed. Validated prognostic scores (RMH, MDACC) were correlated with early mortality rates. **Results:** Overall, 527 cases were included in the study; 19 subjects had participated in > 1 trial, leaving a total of 507 subjects enrolled in their first phase I/II trial. Median age at C1D1 was 11.6 years (range, 0.5-17.9); male:female ratio 1.2:1; central nervous system (CNS) tumors (40%) Vs extra-CNS tumors (60%); 75% cases were treated in trials with at least one targeted therapy. The 30-DM (24/507) and 90-DM (116/507) were 4.7% (95%CI 3.1-7.0) and 23.0% (95%CI 19.3-26.8), respectively. At baseline the clinical variables which correlated with higher 90-DM in the univariate analysis were: performance status (Lansky or Karnofsky) $\leq 80\%$, no school/work attendance, requirement of opioids, ≥ 3 metastatic sites, Hb < 100 g/dL and Total Bilirubin, LDH or AST above normal levels (up to the maximum permitted according to protocol eligibility criteria). Higher RMH and MDACC scores also correlated with higher 90-DM. **Conclusions:** To our knowledge this is the largest case series of children and adolescents participating in pediatric phase I/II trials to date, in which most of the patients were treated with targeted or immuno-oncology agents. The reported 30-DM and 90-DM will serve as a reference benchmark for future trials. Performance status $\leq 80\%$, no school/work attendance, requirement of opioids and ≥ 3 metastatic sites correlated with higher 90-DM. Adult prognostic scores (RMH, MDACC) showed good correlation with 90-DM in the pediatric population. Prognostic factors of early mortality should be given appropriate relevance at the time of study design, informing families and recruiting patients to these studies. Research Sponsor: None.

Poster Discussion Session

Identifying osteosarcoma signatures in cell free DNA using 5-hydroxymethylcytosine profiling. *First Author: Evan W Neczypor, University of Chicago Pritzker School of Medicine, Chicago, IL*

Background: Osteosarcoma is the most common primary bone tumor in children and adolescents. Prognostic biomarkers are limited, and post-treatment surveillance relies heavily on radiologic imaging. Capture and analysis of cell-free DNA (cfDNA) from the bloodstream is an emerging technique that could be used to provide additional prognostic information and track residual disease following treatment. 5-hydroxymethylcytosine (5-hmC) is an epigenetic marker of open chromatin and active gene expression, and tumor specific patterns of global 5-hmC deposition are identifiable in several cancers and vary according to disease burden. We profiled 5-hmC using plasma-derived cfDNA from osteosarcoma patients and healthy children to assess its utility as a biomarker of disease status. **Methods:** cfDNA was isolated from patients diagnosed with osteosarcoma and well child controls. Nano-hmC-Seal, a technique developed to isolate 5-hmC-modified DNA fragments, was used to generate sequencing libraries of cfDNA. Genomic DNA from osteosarcoma cell lines was serially diluted with healthy donor-derived cfDNA. DESeq2 was used to identify genes with high 5-hmC deposition in osteosarcoma cell line DNA relative to serial dilutions. In patient cfDNA samples, the relative abundance of 5-hmC deposition on these osteosarcoma genes was determined using gene set variation analysis (GSVA). GSVA returns a score ranging from -1 to 1, with positive values indicating a relative abundance of 5-hmC deposition on osteosarcoma genes. **Results:** The cohort consisted of 33 healthy children and 17 patients with osteosarcoma including 53 serially collected samples from these patients. 139 osteosarcoma genes were identified and used for GSVA analysis. Patients with osteosarcoma had significantly higher GSVA scores than well children (0.26 vs -0.38; $p < 0.001$). Hierarchical clustering identified two clusters of samples from children with osteosarcoma. Cluster 1 contained samples with scores correlating with osteosarcoma-derived DNA compared to Cluster 2 (0.14 vs -0.18; $p < 0.001$). Furthermore, Cluster 1 contained 17 of 23 samples from patients with active disease on clinical imaging (sensitivity = 74%, specificity = 57%). High 5-hmC deposition on *MYC* was readily identified in one sample obtained at diagnosis from the only patient with a *MYC* amplified tumor. Additional samples from this patient during treatment showed decreasing 5-hmC deposition on *MYC*, consistent with a treated tumor shedding less DNA into the blood. Additionally, decreased disease burden following surgical resection was identifiable in 5-hmC profiles (presurgical GSVA score 0.22 vs postsurgical -0.08; $p = 0.004$). **Conclusions:** Osteosarcoma 5-hmC signatures can identify patients with active disease. Monitoring cfDNA in osteosarcoma using 5-hmC profiling is a promising technique that warrants further investigation with larger patient cohorts. Research Sponsor: U.S. National Institutes of Health.

Intensity at the end of life in pediatric neuro-oncology patients: The case for pediatric palliative care. *First Author: Chinwe Udemgba, University of Chicago, Chicago, IL*

Background: Although pediatric cancer is rare, it is the leading cause of death by disease after infancy for children and adolescents in the United States. Children exist in the context of a family; hence, excellent care for a child must also include attention to the needs of the family. Palliative care aims to enhance quality-of-life for these children living with life threatening illnesses and their families. Among pediatric cancers, brain tumors have high disease-related mortality rates; therefore, early introduction of palliative care to these patients is critical. This study aims to evaluate the association of palliative care during the terminal admissions of pediatric neuro-oncology patients and intensity of care provided at the end of life. **Methods:** Pediatric patients with brain tumors were identified using the Pediatric Health Information System (PHIS). Inclusion criteria were age <18, diagnosis of brain tumor as defined by ICD-10 codes, discharged as deceased, and hospital admission between 1/1/2017 and 12/31/2021. Intensity of care measures included: pediatric intensive care unit (PICU) admission, mechanical ventilation, total parenteral nutrition (TPN), and extracorporeal membrane oxygenation (ECMO). **Results:** 567 patients met the inclusion criteria. 359/567 (63%) patients had an inpatient palliative care consultation during their terminal hospital stay. Patients receiving a palliative care consultation had a lower percentage of PICU admission (64.9 vs 83.2, $p < 0.001$), mechanical ventilation use (51.0 vs 76.0, $p < 0.001$), and TPN use (18.1 vs 25.5, $p = 0.027$). There were no significant differences in length of stay (22.07 vs 22.25 days, $p = 0.181$) and ECMO use (0.28% vs 1.92%, $p = 0.450$). **Conclusions:** Pediatric patients receiving palliative care consultations during their terminal admission received less intense care while having comparable lengths of stay. Palliative care should be offered to all families, even with aggressive goals, to help incorporate quality of life and comfort in the treatment plan and to ensure bereavement support is available if needed. Similar to data in the adult palliative care literature, this data demonstrates reduced resource utilization among pediatric patients receiving palliative care. Palliative care has been shown to be a supportive service that has the potential to improve the quality of life of patients. The first step toward equitable healthcare is to ensure that all children with a potentially terminal cancer diagnosis have access to full supportive services, including palliative care. A multicenter, open-label, single-arm phase 1/2 study to evaluate the safety and efficacy of FCN-159 in pediatric participants with neurofibromatosis type 1. *First Author: Xiaojie Hu, Department of Plastic and Reconstructive Surgery, Shanghai Ninth People's Hospital, Shanghai Jiao Tong University, School of Medicine, Shanghai, China*

Background: Neurofibromatosis type 1 (NF1) is an autosomal dominant genetic disease characterized by multiple progressive tumor and non-tumor manifestations, with abnormal activating MAPK pathway. Plexiform neurofibromas (PN) presents in 20-50% of NF1 patients (pts) and may cause serious complications. Selumetinib was approved for pediatric pts with NF1-related PN in US and EU, but therapeutic options remain limited in China. FCN-159 is a highly potent selective anti-tumorigenic inhibitor of MEK1/2, potentially effective in NF1-related PN. **Methods:** This multicenter, open-label phase 1/2 clinical trial is the first-in human study to assess safety and efficacy in pediatric pts with NF1-related PN. The primary objective was to determine the dose limiting toxicity (DLT) and recommended phase 2 dose (RP2D) in the dose escalation, followed by a dose expansion phase 2 to evaluate safety and efficacy. The starting dose in pediatric pts was determined according to the adults in the dose-escalation phase (previously published in ASCO 2022, abstract no. 3011). Here, we first present the safety and efficacy results in pediatric participants. **Results:** As of data cut-off (November 21, 2022), 65 pts were enrolled, 19 pts in phase 1 and 45 pts in phase 2. A dose of 4 mg/m² (10 pts) and 5 mg/m² (9 pts) were evaluated in phase 1 and no DLT was observed. Pediatric pts in the 5 mg/m² cohort achieved similar exposure to the 8 mg adult cohort. AUC simulation from population PK model at different BSA ranges were also similar to the adults of 8 mg. Therefore, the RP2D was determined to be 5 mg/m². Treatment-emergent adverse events (TEAEs) were reported in 62 pts (95.4%). Common TEAEs ($\geq 20\%$) were mouth ulcer (43.1%), sinus arrhythmia (36.9%), upper respiratory tract infection (35.4%), folliculitis (21.5%), paronychia (21.5%), and increased blood creatine phosphokinase (20%). 5 pts (7.7%) experienced grade ≥ 3 treatment-related AEs (TRAEs), including 2 pts (2/10, 10%) in the 4 mg/m² group and 3 pts (3/55, 5.5%) in the 5 mg/m² group. Grade 3 TRAEs were increased aspartate aminotransferase (1.5%), electrocardiogram QT prolongation (1.5%), folliculitis (3.1%), and dermatitis acneiform (1.5%). No grade ≥ 4 TRAEs were observed. 2 pts (3.1%) reported treatment-related serious adverse events (one case of rhabdomyolysis and dermatitis acneiform each). TEAEs led to dose interruption (26.2%), and discontinuation (1.5%). No reported TEAE led to dose reduction or death. Of the 19 pts with at least one tumor assessment data after baseline, 8 (42%) pts had partial response, 11 (57.8%) with stable disease and none with disease progression. The median DOR could not be evaluated. **Conclusions:** Overall, FCN-159 was well-tolerated and demonstrated promising anti-tumor activity in pediatric participants with NF1-related PN. Long-term efficacy and safety follow-up are ongoing. Clinical trial information: NCT04954001. Research Sponsor: Shanghai Fosun Pharmaceutical Industrial Development Co., Ltd.

A phase 2 study of sirolimus in combination with metronomic chemotherapy (CHOAnome) in children with recurrent and/or refractory solid and CNS tumors. *First Author: Thomas Cash, Aflac Cancer & Blood Disorders Center, Children's Healthcare of Atlanta, Emory University School of Medicine, Atlanta, GA*

Background: Multiple low-dose, anti-angiogenic (metronomic) chemotherapy regimens have demonstrated activity in pediatric solid and central nervous system (CNS) tumors. The mTOR pathway is activated in many human cancers and provides an attractive therapeutic target. We previously conducted a phase 1 trial establishing the dose (2 mg/m²), safety and tolerability of sirolimus in combination with metronomic chemotherapy. In the current study, we conducted a prospective, multi-institutional phase 2 trial to determine the objective response rate (ORR) in pediatric patients with recurrent and/or refractory (R/R) solid and CNS tumors treated with this regimen (NCT02574728); herein we report the results of the CNS tumor stratum. **Methods:** Patients aged 12 months to 30 years with R/R CNS tumors of all world health organization (WHO) grades were eligible. After completion of the trial's first stage, patients with diffuse intrinsic pontine glioma (DIPG) were excluded due to lack of efficacy. Patients were required to have measurable disease and no known curative therapeutic options. Treatment consisted of continuous sirolimus (2 mg/m²/dose PO daily), celecoxib (100 mg PO BID), and oral etoposide (50 mg/m²/day; max dose: 100 mg) alternating every 21 days with oral cyclophosphamide (2.5 mg/kg/day; max dose: 100 mg) in 42-day cycles. Sirolimus was dose-adjusted to maintain a serum trough concentration of 10-15 ng/ml. Response was determined using a modified Response Assessment in Neuro-Oncology (RANO) criteria. Enrollment proceeded using a Fleming's two-stage design based on best overall response (BOR), which required two objective disease status determinations. **Results:** Twenty-two CNS tumor patients were enrolled; 20/22 were evaluable for response. Median age was 11.2 years (range: 5.9 – 18.1); 6 (30%) were female. Diagnoses included DIPG (N = 5), medulloblastoma (N = 3), high-grade (HG) glioma (N = 5), HG/malignant neuroepithelial tumor (N = 3) and one each of diffuse midline glioma, atypical teratoid/rhabdoid tumor (ATRT), choroid plexus carcinoma, and pineoblastoma. Median number of cycles was 2 (range: 1-6). Best response after any cycle was partial response (PR) in 4 [medulloblastoma (N = 3); pineoblastoma (N = 1)], stable disease (SD) in 4, and progressive disease (PD) in 12 for an ORR of 20%; all patients with DIPG had PD at or before their first disease evaluation. BOR was PR in 3 (15%), SD in 2 (10%), PD in 14 (70%), and unknown in 1 (5%). Four patients had SD or response for ≥ 6 months [medulloblastoma (N = 1), pineoblastoma (N = 1), and HG glioma (N = 2)]. **Conclusions:** The combination of sirolimus with metronomic chemotherapy showed activity in pediatric patients with some R/R CNS tumors, producing objective responses in medulloblastoma and pineoblastoma. Patients with DIPG did not benefit from this regimen and should be offered alternative treatments. Clinical trial information: NCT02574728. Research Sponsor: Cannonball Kids cancer Foundation; Hyundai Hope on Wheels.

Pediatric oncologist referral practices for CAR T-cell therapy: A mixed methods study. *First Author: Anurekha Gollapudi Hall, Seattle Children's Hospital, University of Washington, Seattle, WA*

Background: Chimeric antigen receptor (CAR) T-cells are a promising therapy for children with relapsed/refractory B-acute lymphoblastic leukemia. However, few centers provide CAR T therapy, which may lead to disparate access, particularly for those from disadvantaged populations. Referral by pediatric oncologists is an essential step in this process—and one susceptible to bias—but prior literature evaluating referral practices for CAR T therapies is limited. **Methods:** We conducted a mixed methods study to better understand oncologists' perspectives on barriers and facilitators to referral for CAR T therapies and possible biases in referral practice. Oncologists who previously referred patients for CAR T at five CPCI pediatric hospitals were emailed a survey. Descriptive statistics illustrated oncologist characteristics and factors influencing the referral process. We developed multivariable models to examine the association between oncologist characteristics, familiarity with CAR T, and referral practices. We conducted semi-structured interviews with a subset of participants and used thematic analysis to code transcripts. **Results:** 68 oncologists participated in the survey; 79% practiced at institutions with > 50 new pediatric oncology diagnoses per year. Factors identified as most significantly influential in the decision to refer included goals of care (75%), family interest in CAR T (35%), support from enrolling site (25%), insurance (22%), and family resources (20%). 77% of oncologists expressed being 'very familiar' with CAR T and 'very comfortable' providing information about CAR T to patients and families. In multivariate analysis, Hispanic oncologists and those at institutions with fewer than 50 new diagnoses per year were less likely to express familiarity with CAR T (OR 0.02 (CI: 0.0001-0.91), p = 0.04 and OR 0.04 (CI: 0.003-0.30), p = 0.005). 38% considered non-clinical patient and family-level factors (compliance, social support, resources, insurance, language, education, and race or ethnicity) to be significantly influential in referral decisions. Oncologists who were Hispanic and those practicing for at least 20 years were more likely to consider these factors significantly influential (OR 14.52 (CI: 1.49-358.66), p = 0.04 and OR 6.76 (CI: 1.18-50.5), p = 0.04) in multivariate analysis. Nine oncologists completed in depth interviews; important factors in the referral process included ease of insurance approval and established partnership with CAR T center. **Conclusions:** Many oncologists consider factors in addition to medical criteria when deciding to refer patients for CAR T, raising concern for bias in the referral process. Familiarity with available CAR T therapies may also affect eligible patient referral. Future work should focus on identifying ways to improve familiarity with CAR T in order to optimize patient access, while ensuring equitable referral practices. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology; U.S. National Institutes of Health.

Poster Discussion Session

Physical and emotional quality of life in children with B-acute lymphoblastic leukemia randomized to every 4- vs. 12-week vincristine/dexamethasone during maintenance: Children's Oncology Group AALL0932. *First Author: Lyn M. Balsamo, Yale University, New Haven, CT*

Background: Children with B-acute lymphoblastic leukemia (B-ALL) undergo 2-3 years of treatment that impacts their quality of life. AALL0932 randomized reduction in vincristine and dexamethasone pulses (VCR/DEX every 4 weeks vs. every 12 weeks) during maintenance in the average-risk (AR) subset of NCI standard risk (SR) B-ALL. We longitudinally measured physical and emotional function overall and by treatment. **Methods:** SR AR B-ALL patients enrolled on AALL0932, aged ≥4 years, with English-speaking parents were evaluated at 5 timepoints (T1-T5: end consolidation, maintenance month 1, maintenance month 10, maintenance month 18 for boys/end of therapy for girls, end of therapy for boys). Parents completed the Pediatric Quality of Life Inventory Generic Core Scales 4.0 and a survey of supportive services received. Age- and sex-matched z scores and proportion impaired (> 2 SD below normative mean; 2.5% expected in normative population) on the emotional and physical function subscales were measured longitudinally and compared by treatment with the Fisher's exact test and repeated measures logistic regression. **Results:** Consent and data were obtained from 555 participants (mean/sd age = 6.0 ± 1.6 years, 46.8% female). Among randomized participants with completed evaluations, 31.3% had impaired physical function at T1 decreasing to 12.5% at T4. Emotional function was impaired in 24.5% of patients at T1 decreasing to 9.8% at T4. Overall 34.9-43.8% received special education/accommodations at T1-T5; there was low use of other services (Table). In adjusted analysis, treatment group was not associated with physical or emotional function. T2 impairment predicted increased risk of impairment at T4 for physical (OR = 4.7, 95% CI 2.3-9.7, p < 0.0001) and emotional (OR = 4.7, CI 2.3-9.5, p < 0.0001) function. **Conclusions:** Impaired physical and emotional function were prevalent early in SR AR B-ALL therapy, improved by the end of therapy, but remained higher than norms. Outcomes did not vary with VCR/DEX frequency. Patients with early emotional and physical impairment are at elevated risk of later impairment. Clinical trial information: NCT01190930. Research Sponsor: U.S. National Institutes of Health; St. Baldrick's Foundation.

Efficacy and safety of pembrolizumab (pembro) in children and young adults with newly diagnosed classical Hodgkin lymphoma (cHL) with slow early response (SER) to front-line chemotherapy (chemo) in the phase 2, open-label, KEYNOTE-667 study. *First Author: Luciana Vinti, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy*

Background: Patients (pts) with cHL with SER to initial chemo are at higher risk of relapse, and chemo dose intensification and radiotherapy (RT) can increase the burden of late organ toxicities. The open-label, phase 2 KEYNOTE-667 study (NCT03407144) is evaluating pembro plus chemo in pts with cHL and SER to front-line chemo. Results of an interim analysis in pts with high-risk cHL (group 2) and SER are presented. **Methods:** Pts were aged 3-17 (children) or 18-25 y (young adults) with newly diagnosed stage IIEB, IIIEA, IIIEB, IIIB, IVA, or IVB cHL. Pts received induction with 2 cycles of vincristine, etoposide, prednisone/prednisolone, and doxorubicin (OEPA). Response was assessed after induction (early) and consolidation (late) therapy by PET/MRI/CT. After induction, pts with rapid early response at the early response assessment (ERA) received nonstudy therapy and pts with SER at ERA received consolidation with 4 cycles cyclophosphamide, vincristine, prednisone/prednisolone, dacarbazine (COPDAC-28) plus pembro 2 mg/kg up to 200 mg IV every 3 weeks (Q3W; aged 3-17 y) or 200 mg IV Q3W (aged 18-25 y). Pts with PET positivity (Deauville score 4-5) after consolidation (late response assessment [LRA]), received involved-site RT (28.8 Gy) to late PET-positive residua; RT was omitted in pts with PET negativity. All pts with SER received maintenance pembro Q3W for a total of 17 doses. Primary end point was ORR by blinded independent central review (BICR) per Cheson 2007 International Working Group criteria in pts with SER. Secondary end points included PET negativity after consolidation and safety. **Results:** At data cutoff (Sep 02, 2022), median follow-up was 15.3 mo (range, 3.2-30.5); 49 pts with high-risk cHL with SER were included. Median age was 15 y (range, 6-22), 24 (49%) pts had bulky disease, and 31 (63%) had Ann Arbor stage IV disease. 22 (45%) pts completed treatment and 24 (49%) were ongoing on consolidation/maintenance treatment. Median time on pembrolizumab was 10.4 mo (range, 0.5-11.8). 42 (86%) of 49 pts had a LRA, of whom 27 (64%) were PET negative by BICR (30 [71%] PET negative by investigator). All-cause adverse events (AEs) occurred in 42 (86%) pts, with 30 (61%) having a treatment-related AE. Grade ≥3 AEs occurred in 13 (27%) pts, with 7 (14%) having a serious AE. Grade ≥3 treatment-related AEs occurred in 6 (12%) pts. 4 (8%) pts had immune-mediated AEs (2 grade 1 hypothyroidism; 2 grade 2 hypothyroidism). **Conclusions:** In pediatric pts with high-risk cHL and SER to standard OEPA induction, pembro plus COPDAC-28 consolidation had manageable safety and resulted in 64% of pts having a PET-negative response at end of chemo and being spared RT. These results suggest adding pembro to COPDAC-28 consolidation may augment responses in this high-risk population. Clinical trial information: NCT03407144. Accelerated brain age and associated neurocognitive impairments in adult survivors of childhood cancer. *First Author: Nicholas Steve Phillips, St. Jude Children's Research Hospital, Memphis, TN*

Background: Structural brain aging assessed from routine clinical MRI exams is associated with neurologic and neurocognitive impairments in older non-cancer populations yet is unexplored in childhood cancer survivors. **Methods:** Neurocognitive assessments and clinical 3-D T1 MRI whole brain images were obtained on 253 childhood cancer survivors (acute lymphoblastic leukemia = 118; brain tumor = 49; Hodgkin lymphoma = 86) and 43 community controls. Brain age was estimated using open-source Gaussian process regression software (BrainAgeR) on visually inspected, segmented, and normalized MRI scans. Benjamin-Hochberg adjusted T-tests were used to compare age-adjusted neurocognitive z-scores between controls and survivors. Linear regression tested associations between brain age acceleration (brain age-chronological age) and treatment (multivariable), and neurocognitive outcomes (univariable). **Results:** Survivors (mean(SD) age 31.2 [8.9]) had poorer executive function (Trails B survivors -0.72 vs controls 0.32, $p < 0.0001$), processing speed (Grooved Peg Board -0.77 vs 0.05, $p < 0.0001$), memory (visual selection -0.73 vs -0.10, $p = 0.0010$; digit backward span -0.45 vs 0.08, $p = 0.0304$), vocabulary (WASI vocabulary -0.43 vs 0.14, $p = 0.0007$), and reading (WJ letter word -0.43 vs -0.05, $p = 0.0006$) compared to controls. In survivors, mean[95%CI] brain age was 7.5 [6.4 to 8.6] years older than chronologic age; 0.65[-1.0 to 2.3] years for controls. Compared to males without cranial radiation, for females age $\geq$ 10 years at cancer diagnosis treated with $\geq$ 40Gy cranial radiation, brain age acceleration was 13.35 years ($p < 0.001$), which worsened by an additional 9.81 years ($p = 0.017$) for those diagnosed < 10 years. Greater brain age acceleration was associated with a worse performance in executive function ($\beta = -1.73$, $p < 0.001$), processing speed ($\beta = -2.18$, $p < 0.001$), memory ($\beta = -2.07$, $p < 0.001$; $\beta = -1.78$, $p < 0.029$), vocabulary ($\beta = -2.04$, $p < 0.001$), and reading ($\beta = -3.77$, $p < 0.001$). **Conclusions:** Survivors of childhood cancer experience significant brain age acceleration that is associated with impairments in neurocognitive function. In non-cancer populations, accelerated brain age has been shown to predict late morbidities and mortalities. BrainAge is a promising surrogate biomarker that could predict cognitive decline and improve early detection of dementia risk. Finally, it highlights the risk of cranial radiation in < 10 -year-old female cancer survivors. Research Sponsor: U.S. National Institutes of Health; ALSAC.

Adherence to mercaptopurine (6-MP) and habit strength in pediatric acute lymphoblastic leukemia (ALL). *First Author: Mira Yang, Department of Medical Education, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Rates of adherence to mercaptopurine (6-MP) below 90% have been associated with increased relapse in pediatric patients with acute lymphoblastic leukemia (ALL). Habit strength has been associated with medication adherence through multiple mechanisms, including self-efficacy and social norms. The goal of this study was to investigate the relationship between habit strength, adherence to 6-MP, and health-related quality of life domains. **Methods:** This was a single center, cross-sectional study. A total of 52 participants, including 11 patients (ages 12-23, mean age 16 ± 4 , 45% Female) and 41 parents/caregivers (ages 25-43, mean age 37 ± 5 , 80% Female) of patients with ALL under the age of 18. Participants completed the Visual Analogue Scale (VASdose), PROMIS Medication Adherence Scale (PMAS), Self-Regulated Habit Index (SRHI), and PROMIS quality of life measures (PROMIS-CAT). Spearman's rho correlations were used to assess relationships between variables. Eleven semi-structured interviews of patients and caregivers were conducted and analyzed using Grounded Theory coding and thematic analysis. **Results:** Overall, 81% ($n = 42/52$) of participants surveyed had high adherence to 6-MP (VASdose $\geq 95\%$); 91% ($n = 10/11$) of patients and 78% ($n = 32/41$) of parents/caregivers reported high adherence. The median VASdose and PMAS score were 100% (IQR 97-100) and 39.5 (IQR 38-40) across all participants, respectively. Participants with higher adherence, VASdose $\geq 95\%$ and PMAS ≥ 39.5 , reported less physiological stress ($p = 0.02$), and better cognitive function ($p = 0.09$) and peer relations ($p = 0.08$), compared to those with lower adherence. No significant correlation was found between medication adherence rate and habit strength. Emerging themes from qualitative coding included the influence of routine and automaticity on 6-MP as well as adherence strategies. Strategies such as reminders, care team communication, and developing personalized tools were cited by participants as potentially improving adherence in taking or administering 6-MP. Other facilitating participant characteristics included experience with medication administration, self-efficacy, and access to social support. Financial burden, scheduling conflicts, and medication access were common barriers cited by participants. **Conclusions:** Nearly one-fifth of our participants reported lower adherence to 6-MP (VASdose $< 95\%$), which increases risk of relapse. Medication adherence to 6-MP was not associated with habit strength, but our results show preliminary associations between adherence rates and quality of life outcomes, such as physiological stress. Behavioral interventions are needed to better optimize adherence to 6-MP and improve health outcomes in pediatric ALL. Research Sponsor: None.

Genetic study of type 2 diabetes risk in diverse populations of survivors of childhood cancer: A report from the St. Jude Lifetime Cohort (SJLIFE) and the Childhood Cancer Survivor Study (CCSS). *First Author: Cindy Im, University of Minnesota, Minneapolis, MN*

Background: Type 2 diabetes (T2D) is an established late effect of cancer treatment among long-term survivors of childhood cancer. Genetic factors underpinning T2D in diverse populations of survivors have not been well studied. **Methods:** We conducted a multi-ancestry genome-wide association study (GWAS) for clinically ascertained T2D among survivors of European (EUR; $N = 3,102$ with 261 cases) and African (AFR; $N = 574$ with 43 cases) ancestry from SJLIFE. Replication analyses were performed between ancestries in SJLIFE and in EUR survivors in CCSS ($N = 5,965$; 270 self-reported cases). Two published T2D polygenic risk scores (PRSs) were assessed in survivors: a 338-variant multi-ancestry PRS ($N \sim 1.4$ million; 49% non-EUR descent) and a ~ 6.9 million-variant EUR-only PRS ($N \sim 160K$; DIAGRAM Consortium and UK Biobank Study). Treatment-related T2D risk effect modification was evaluated for abdominal irradiation and alkylating agents. **Results:** In SJLIFE AFR survivors, one novel locus with suggestive significance was identified (5p15.2: OR = 10.19, $P = 5.1 \times 10^{-7}$), replicating in both SJLIFE EUR ($P = 0.011$) and CCSS EUR survivors ($P = 0.021$). A EUR-specific genome-wide significant association at 8q11.21 (*SNTG1* intronic variant; OR = 1.99; $P = 4.4 \times 10^{-8}$) was replicated in CCSS ($P = 8.1 \times 10^{-3}$). Two other loci with suggestive associations ($P < 5 \times 10^{-6}$) in SJLIFE EUR survivors replicated in SJLIFE AFR survivors ($P < 0.05$), achieving genome-wide significance in multi-ancestry meta-analysis (2p25.3: OR = 2.05, $P = 4.5 \times 10^{-8}$; 19p12: OR = 2.43 $P = 5.7 \times 10^{-9}$). Each of the three novel trans-ancestral loci overlapped putative Polycomb-repressed regions, i.e., chromatin-based gene regulation elements, in pancreatic cells and displayed treatment-related effect heterogeneity across ancestry groups. Notably, AFR survivors with risk alleles experienced disproportionately greater T2D risk if treated with alkylating agents (2p25.3: OR = 3.95; 19p12: OR = 5.74; 5p15.2: OR = 17.81). Increases in the T2D odds per multi-ancestry PRS standard deviation were consistent in survivors across ancestries (SJLIFE EUR: OR = 1.84, $P = 1.1 \times 10^{-16}$; SJLIFE AFR: OR = 1.80, $P = 2.8 \times 10^{-3}$, CCSS EUR: OR = 1.60, $P = 8.4 \times 10^{-13}$). However, T2D risk association with the EUR-only PRS was absent in AFR survivors (OR = 0.97, $P = 0.95$). **Conclusions:** Multi-ancestry genetic analyses revealed three novel T2D risk alleles associated with disproportionately greater alkylating agent-related risk among African-ancestry survivors. Furthermore, an external multi-ancestry T2D PRS was associated with increased risk in diverse ancestry survivors, whereas a EUR-only PRS was not useful for African-ancestry survivors. This study supports precision diabetes surveillance and survivorship care for all childhood cancer survivors, including those in minority ancestry groups. Real-world use of tisagenlecleucel in children and young adults with relapsed or refractory B-cell lymphomas. *First Author: Jonathan Bender, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Survival for pediatric B-cell lymphomas (BCL) exceeds 90% with modern regimens, however outcomes remain poor for patients with relapsed or refractory (R/R) disease. Tisagenlecleucel is a CD19-directed CAR T-cell therapy (CAR T) that is FDA approved for adults with R/R BCL. No data exists for use of tisagenlecleucel in R/R pediatric BCL. **Methods:** We surveyed 48 sites in the Pediatric Real-World CAR Consortium to retrospectively describe use and outcomes of tisagenlecleucel for pediatric patients with R/R BCL. This cohort included 10 patients from 7 centers aged ≤ 25 years who were infused between 2019-2022 and were ≥ 3 months from CART. We aimed to describe response rates, as determined by each institution based on positron emission tomography, bone marrow evaluation, and/or cerebrospinal fluid (CSF) studies, along with toxicity and outcomes in this population. **Results:** Ten patients received CART with a median age at infusion of 19 (range, 7-24) years. Five patients had B-lymphoblastic lymphoma (B-LyL), 2 had primary mediastinal BCL, and 1 each had Burkitt lymphoma, diffuse large B-cell lymphoma (DLBCL), and post-transplant lymphoproliferative disorder related DLBCL. Five patients had primary refractory disease, and 5 were in $\geq 2^{nd}$ relapse. Three had received prior hematopoietic stem cell transplant (HSCT). Two had CSF involvement, and 1 had central nervous system parenchymal disease at time of infusion. CART was well tolerated with 1 patient experiencing grade 3 cytokine release syndrome and 2 patients experiencing neurotoxicity (grade 2 $n = 1$, grade 3 $n = 1$), both of whom had CSF involvement at time of CART infusion. Best overall response was complete response (CR) for 6, partial response (PR) for 2, and refractory disease for 2. Two patients, both with B-LyL, underwent allogeneic HSCT while in CART-mediated CR with B-cell aplasia. Both patients with PR (1 DLBCL, 1 Burkitt) subsequently relapsed with CD19-negative disease; the patient with DLBCL subsequently achieved CR with salvage immuno-chemotherapy and HSCT. All 6 CR patients remain in remission at a median time to follow-up of 31 (range, 14-47) months. **Conclusions:** This multicenter case series of CD19-directed CART for R/R pediatric BCL suggests that tisagenlecleucel may be safe and active in this population with all CR patients currently in sustained remission. Larger studies are needed to understand how best to incorporate CART into treatment for R/R pediatric BCL. Research Sponsor: None.

Prior # Therapies, median (range)	4 (1-8)
Prior HSCT	3/10 (30%)
Best Overall Response of Complete Response	6/10 (60%)

Outcomes in pediatric relapsed/refractory anaplastic large cell lymphoma: A multi-institutional retrospective analysis. First Author: Lianna Jean Marks, Stanford University School of Medicine, Palo Alto, CA

Background: Treatment options for relapsed or refractory (R/R) anaplastic large cell lymphoma (ALCL) have increased in the era of targeted therapies such as brentuximab vedotin (BV) and Anaplastic Lymphoma Kinase (ALK)-inhibitors. However, there is no standard treatment and limited published data evaluating their use in this patient population. **Methods:** We conducted a retrospective, multi-institutional study of patients <22 yrs old at initial diagnosis with R/R ALCL treated between 2011-2021 across 18 institutions. **Results:** We identified 85 patients with R/R ALCL (median age at initial diagnosis 12 yrs, 67% male, 96% ALK+). Treatment for initial diagnosis included ALCL99 (31%), ANHL12P1 + BV (32%), ANHL12P1 + crizotinib (CZ) (11%), ANHL0131 (14%), or other (13%). Median time from diagnosis to relapse was 0.7 yrs (range 0.2-10.8 yrs) with sixteen patients (18%) relapsing on initial chemotherapy. Stage at relapse for 82 ALK+ patients: I (9%), II (15%), III (41%), IV (35%). Initial re-induction regimens shown in the table. Fifty-nine (72%) patients received a hematopoietic stem cell transplant (HSCT), 11 autologous and 49 allogeneic with one receiving both. Of 59 transplanted patients, 10 relapsed (6 allo 4 auto) and 7 died. All but one of the patients who relapsed post-HSCT responded to additional therapy and remain alive. Of 23 ALK+ patients who never had a transplant, 4 patients died and 19 are alive in remission. Eleven remain on active therapy (6 CZ, 3 BV, 1 BV+CZ, 1 vinblastine) with eight off therapy. Patients who received a transplant more likely to be off therapy and alive. Duration of treatment for patients receiving BV or the ALK-inhibitor CZ varied widely (BV 1-11 yrs; CZ 2-10 yrs) with 20 patients continuing on therapy at the time of data collection. Five-year overall survival for patients with or without transplant was 91% (CI 84-99%) and 86% (CI 73-100%) respectively. **Conclusions:** This is the largest collection of patients with R/R ALK+ ALCL treated in the era of targeted therapy. Patients achieved excellent responses to ALK-inhibitor or BV monotherapy, but questions remain about duration of therapy. Transplant may not be necessary for all R/R patients including those with high-risk disease. Research Sponsor: Stanford Maternal & Child Health Research Institute Award.

Single-agent activity of the anti-GD2 antibody dinutuximab beta given as a long-term infusion in relapsed and refractory neuroblastoma (APN311-304).

First Author: Holger N. Lode, University Medicine Greifswald, Pediatric Hematology and Oncology, Greifswald, Germany

Background: Severe pain is a common side effect associated with short-term infusions of anti-GD2 antibodies in combination with cytokines and isotretinoin and was reduced by the long-term infusion (LTI) strategy. We investigated efficacy and tolerability of a single-agent dinutuximab beta (DB)-LTI in patients with primary refractory or relapsed (R/R) stage 4 neuroblastoma (NB). **Methods:** Patients with R/R-NB were enrolled into an open label phase II trial. Previous anti-GD2 antibody therapies were allowed, if anti-DB antibody could not be detected. Patients received 5 cycles of DB-LTI (100 mg/m²/10 days). The primary endpoint was objective INRC response 24 weeks after the end of cycle 5. A sample size of 40 patients provides at least 80% power to reject the null hypothesis of an objective response in < 10% of patients if the true objective response rate observed was 25% (overall 1-sided significance level 0.05, exact binomial test). Secondary endpoints included safety, morphine use, best response and duration of response, pharmacodynamics and pharmacokinetics, 3-year progression-free (PFS) and overall survival (OS). **Results:** 40 patients were treated and 38 patients had evaluable response. The objective response rate 24 weeks after the end of cycle 5 was 26% (10/38) (CR/PR) (p = 0.0034) and 32% (12/38) (CR/PR/MR), with a higher response rate in refractory vs. relapsed patients (50% vs 25%; p = 0.0159). The best response rate was 53% (20/38). Of 14 patients with bone marrow involvement, 13 patients responded (93%) (12 CR, 1 PR). The median duration of response (CR/PR) was 238 days (95% CI [108-290d]). The 3-year probability of PFS was 31% (95% CI [0.17-0.47]) and of OS was 66% (95% CI [0.47-0.79]). Survival was higher for patients with refractory compared to relapsed disease (PFS 47% vs 19%, OS 93% vs 50%; p = 0.015). Grade 3 treatment emergent adverse events (TEAE) were pain (18%), diarrhea (5%), and hypokalemia (5%) and grade 3 hypotension, capillary leak and neurotoxicity were not observed. In patients who experienced pain, mean pain scores (scale 0-10, where 0 is no pain) were low and decreased between cycles 1 and 2: pain score at rest decreased from 1.01 to 0.30, and at stress from 1.45 to 0.28. There were no grade 4 or 5 TEAEs. The morphine usage decreased from cycle 2 to 5 (C2 95%; C3 12%; C4 0%; C5 0%). DB peak serum concentration in cycle 1 was 10.8±0.7 µg/ml and patients showed 7- and 11-fold increase of antibody-dependent cell-mediated (ADCC) and complement-dependent cytotoxicity (CDC), respectively. Anti-DB antibodies were found in 24% of patients. There was no association and no trend between exposure to DB (area under the curve, peak or trough level) and response rate or survival in this cohort. **Conclusions:** Single-agent treatment with single agent dinutuximab beta given as long LTI without cytokines and without isotretinoin is effective and highly tolerable in R/R-NB. Clinical trial information: NCT02743429. Research Sponsor: Apeiron Biologics; Hector Stiftung; University Medicine Greifswald; EUSA Pharma; Kinderkrebsstiftung.

Impact of fludarabine exposure on the depth and duration of lymphopenia and CAR T-cell outcomes. First Author: Keagan Lipak, Pediatric Oncology Branch, Center for Cancer Research (CCR), National Cancer Institute, NIH, Bethesda, MD

Background: Chimeric antigen receptor (CAR) T-cells are highly effective for patients with relapsed or refractory B-ALL. Lymphodepletion has been paramount to CAR T-cell expansion and efficacy. Recent data identified an association of fludarabine exposure with reduced relapse rates, longer leukemia free survival, and more prolonged B-cell aplasia following tisagenlecleucel. However, the relationship of fludarabine exposure to lymphopenia and the mechanism by which dosing impacts outcomes following CAR T-cells remains unknown. **Methods:** We conducted a retrospective review of children and young adults with B-ALL who received fludarabine for lymphodepletion (LD) prior to infusion of anti-CD19, anti-CD22, or anti-CD19/22 bispecific CAR T-cells. The primary objective of this study was to investigate the impact of fludarabine on the depth and duration of lymphopenia. Secondary objectives included examining the impact of fludarabine exposure on: 1) overall clinical response, and 2) CAR T-cell expansion. All patients in the analysis cohort received fludarabine 25 mg/m²/day x 3 days (= 75 mg/m² cumulative dosing). Fludarabine exposure (AUC per dose) for each patient was predicted using a validated population PK model and analyzed with various responses/endpoints using the 3-day cumulative exposure/patient. **Results:** Of 137 children and young adults, the median cumulative AUC was 8.3 mg*hr/mL (range, 3.00-13.83 mg*hr/mL). The overall complete response (CR) rate was: 67.9% (93/137). The median duration of lymphopenia (defined as an absolute lymphocyte count (ALC) ≤ 150 K/uL) was 5 days (range, 0-15); and the median ALC on Day 0 was 80 K/uL (range, 0-1250 K/uL). When stratified by the median fludarabine exposure, there was no difference in depth or duration of lymphopenia or CAR T-cell expansion collectively or per trial. The median fludarabine exposure also did not differ between responders and non-responders. However, depth and duration of lymphopenia did differ in the CD22 CAR T-cell trial. Specifically, in those achieving CR, the duration of lymphopenia was longer than in non-responders (7 days versus 4 days, p = 0.030). Similarly, CAR T-cell expansion was higher if lymphopenia duration was greater than 5 days (p = 0.019). These findings were not seen across our less persistent CD19 or CD19/22 CAR T-cell trials. **Conclusions:** Although lymphodepletion impacts CAR T-cell response, we did not find an association between CR rate, depth of lymphopenia, or duration of lymphopenia with varying fludarabine exposures. This raises additional questions regarding the impact of LD therapy on CAR T-cell outcomes—especially since a more prolonged lymphopenia was associated with high CR rates and greater peak expansion in at least one of our studies (CD22 CAR T-cells). Future analysis will evaluate the impact of fludarabine on Day 0 cytokines and other immune parameters. Clinical trial information: NCT03448393. Research Sponsor: U.S. National Institutes of Health.

Comprehensive genomic profiling and individual therapeutic planning in high-risk/refractory pediatric solid tumors: A single-center real-world study.

First Author: Ondrej Slaby, Masaryk University, Faculty of Medicine, CEITEC, Brno, Czech Republic

Background: Despite major improvements in the survival of pediatric cancer patients that were achieved through the intensification of chemotherapy and the perfection of supportive care in the past decades, treatment outcomes for high-risk, relapsed, and refractory solid cancers remain unsatisfactory. Accelerating the progress of pediatric oncology requires both therapeutic advances and attention to reducing the long-term cytotoxic treatment-related side effects. This could be achieved by targeting specific molecular changes that drive pediatric malignancies. **Methods:** From September 2016 to August 2020, a total of 192 patients with pediatric high-risk solid tumors successfully underwent comprehensive genomic profiling. Since more than thirty patients had two or more biopsies from recurrent relapses, the total number of samples examined was 295. In the cohort, there were 78 cases of central nervous system tumors, 68 sarcomas, 14 neuroblastomas, 10 lymphomas, and 22 tumors of other histology. Whole-exome sequencing was performed in all patients, fusion gene analysis in 96% of patients, whole-transcriptome profiling in 84% of patients, and CNV analysis in 63% of patients. **Results:** The diagnostic yield of therapeutically actionable findings was 40%, with single-nucleotide variants and small insertions/deletions being the most common actionable alteration types. In 23% of patients, a clinically relevant gene fusion was identified. The majority of the identified fusions were of diagnostic significance, and 18% of those were therapeutically targetable gene fusions involving BRAF, RAF1, ALK, FGFR1, or NTRK2. Four patients were eligible for immunotherapy based on high tumor mutational burden (> 10 mut/Mb). Lymphomas and CNS tumors showed the highest rate of patients with therapeutically actionable findings (60% and 56%, respectively), followed by neuroblastomas (36%), sarcomas (25%), and other solid tumors (23%). All results and individual treatment plans were discussed and approved at multidisciplinary molecular tumor boards. **Conclusions:** Precision medicine in pediatric oncology has rapidly developed over the last decade and resulted in new therapeutic options based on molecular biomarkers and increased our understanding of the complexity of pediatric malignancies. Supported by the Ministry of Health of the Czech Republic, grant nr. NU20-03-00240 and the project National Institute for Cancer Research (Programme EXCELES, ID Project No. LX22NP05102) - Funded by the European Union - Next Generation EU. A phase 1b study of crizotinib in combination with temsirolimus in pediatric ALK- or MET-aberrated relapsed or refractory neuroblastoma (ITCC-053): Results of the phase 1 part. *First Author: Kim Schellekens, Department of Pediatric Oncology, Erasmus MC-Sophia Children's Hospital and Princess Máxima Center for Pediatric Oncology, Rotterdam, Netherlands*

Background: Preclinical data in neuroblastoma (NBL) models provided evidence that the addition of an mTOR inhibitor with crizotinib may overcome the relative resistance to ALK inhibitors (Berry et al., 2012, Cancer Cell). The primary objective of this phase 1b trial was to establish the recommended phase 2 dose (RP2D) of crizotinib in combination with the mTOR inhibitor temsirolimus in pediatric NBL patients. **Methods:** Patients aged 1-21 years with relapsed/refractory ALK/MET aberrant NBL were eligible to enroll onto stratum 2 of the CRISP trial (EudraCT: 2015-005437-53, ITCC-053), sponsored by Erasmus MC. This was an open-label, non-randomized, two-stage phase 1b dose finding study. Crizotinib was dose escalated using the EWOC method in four dose levels (DL) ranging from 100 mg/m² to 280 mg/m² twice daily (BID) in 28 day cycles. Temsirolimus was administered intravenously in a fixed dose of 60 mg/m²/week. Both starting doses were reduced compared to the single agent RP2D because of an expected CYP3A4 interaction. Primary endpoint was dose limiting toxicity (DLT) during cycle 1. Radiological disease assessments and blood sampling for pharmacokinetics were scheduled per protocol. **Results:** Nine NBL patients were enrolled onto stratum 2 between 06-2018 and 12-2022. Eight patients with a median age of 4 years (range: 1-12) received trial treatment. The temsirolimus dose was reduced to 40 mg/m² after the first 3 patients based on unexpected toxicity. DLTs occurred in 2/3 patients treated with crizotinib at DL2 (200 mg/m² BID); grade 3 elevated ALT (alanine aminotransferase) and grade 3 gastritis (temsirolimus dose; see table). No DLT occurred in 5 patients treated with crizotinib DL1 (150 mg/m² BID). Dose re-escalation of crizotinib to DL2 was considered not feasible. The RP2D was established at 150 mg/m² BID crizotinib with 40 mg/m² temsirolimus. Frequent grade 3 treatment-related adverse events were anorexia, gastritis, oral mucositis (n = 2) and anemia (n = 3). Treatment, toxicity and response are summarized in table. **Conclusions:** We established a RP2D of 150 mg/m² BID crizotinib in combination with 40 mg/m² temsirolimus. The expansion cohort is currently open for enrollment. Clinical trial information: EUCR2015-005437-53. Research Sponsor: Pfizer; Go4Children.

Healthcare resource use for pediatric low-grade glioma care: A cohort of linked electronic health records and claims data. *First Author: Tab Cooney, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: Pediatric low-grade glioma (pLGG) is the most common brain tumor in children and is associated with persistent long-term tumor- and treatment-related morbidities. This study aims to characterize the costs associated with the treatment of pLGG. **Methods:** A retrospective study using the Optum de-identified Market Clarity Dataset linked claims (commercial, Medicare Advantage and Managed Medicaid beneficiaries) and electronic health records (EHRs) of cases ≤ 18 years of age, with an ICD-10 code for brain neoplasm and ≥ 1 physician notes between January 2017 and June 2018 was performed. Index date was the first claim or EHR with an ICD-10 code for brain neoplasm. Natural language processing was used to identify pLGG-relevant data from physician notes. The observation period included 3 months prior to index date and 6-month segments from index date for 36 months. Cases had either continuous insurance coverage or continuous EHR activity during this period. Results for procedures and medication use were reported as averages throughout the 36-month post-index follow-up period. **Results:** A total of 154 patients with pLGG were identified. Median age was 11 years (range 2-18). Among the cohort, 49% (n=76) were female; 75% (n=116) were non-Hispanic white, 13% (n=20) Hispanic, 5% (n=7) African American, 1% (n=1) Asian and 6% (n=10) other/unknown. Of benefits, 56% had commercial and 44% Medicaid. Brain imaging and neuropsychological evaluations were performed at least once in 85% and 57% of the cohort, respectively. Among pLGG relevant medications, 57% of the cohort used analgesics, 45% anti-emetics, 32% anxiolytics, and 29% anticonvulsants. A total of 100 patients received ≥ 1 pLGG disease control treatments: Of these, 53% underwent emergency brain surgery, 24% had planned brain surgery, 14% received chemotherapy, and 6% received targeted therapy. Of the 100 patients who received disease control treatments, 57% relapsed after first-line treatment; 37% of patients received 2 lines of therapy, and 20% of patients received ≥ 3 lines of therapy. **Conclusions:** Our findings show that patients with pLGG often require long-term medical care and high levels of healthcare resources to treat their disease and its sequelae. Additionally, a majority will relapse and face a higher burden of disease. Further studies using integrated data sources are warranted to help us understand the burden of pLGG and inform evidence-based health care planning for these patients. Stage 4N neuroblastoma before and during the era of anti-GD2 immunotherapy. *First Author: Brian H. Kushner, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients with stage 4N neuroblastoma (distant metastases limited to lymph nodes) stand out as virtually the only survivors of high-risk neuroblastoma (HR-NB) before myeloablative therapy (MAT) and immunotherapy with anti-GD2 monoclonal antibodies (mAb) became standard. No report presents results with contemporary treatment programs for 4N. The only large study to date (from the International Neuroblastoma Risk Group) analyzed patients diagnosed 1990-2002, found 4N to have significantly better event-free (EFS) and overall survival (OS) compared to other stage 4 patients, and recommended considering less intensive therapy for 4N.

Methods: We conducted a retrospective analysis of patients treated at our center from 1985-2021 to analyze our large experience to fill the gap in the literature on treatment of 4N, namely, results with contemporary multi-modality therapy including MAT and anti-GD2 mAbs. **Results:** We found and reviewed 48 pediatric 4N patients (< 18 years old) treated 1985-2021 at our center. Biological features included segmental chromosomal aberrations in 21/21 MYCN-non-amplified patients, mutations of ALK in 4/22 (18%), ATRX in 4/16 (25%), and TERT in 4/12 (33%) patients. Among 33 MYCN-non-amplified high-risk patients (> 18 months old), 19 are relapse-free 1.6+ to 36.9+ (median 12.2+) years post-diagnosis, including 13 without prior MAT and 3 with no mAb, while 14 patients (7 without prior immunotherapy) relapsed (all in soft tissue initially). Eleven of the 14 died, including 3 who developed late osteomedullary metastases after 3-5 relapses in soft tissue alone. Of 13 MYCN-amplified 4N patients, 6 are relapse-free 4.5+ to 25.8+ (median 11.7+) post-diagnosis (all received mAbs; 3 underwent MAT) and 3 are in 2nd remission 4.4+ to 21.1+ years post-relapse (all soft tissue). For all high-risk 4N patients, 5/10-year EFS was 55%/52%, and OS was 76%/64%. MAT was not prognostic. The 2 patients with intermediate-risk 4N (14 months old) are relapse-free 7+ years post-resection of primary tumors; distant disease spontaneously regressed. **Conclusions:** The natural history of 4N is marked by NB confined to soft tissue without early relapse in bones or bone marrow, sites where mAbs have proven efficacy. These findings plus the possibility of survival without MAT and/or mAb immunotherapy, as seen elsewhere and at our center, support consideration of treatment reduction for selected MYCN-non-amplified 4N patients. Recommended phase 2 dose (RP2D) for abemaciclib in combination with irinotecan (IRN) and temozolomide (TMZ) in pediatric patients with relapsed/refractory solid tumors (JPCS Part A). *First Author: Alvaro Lassaletta, Hospital Infantil Universitario Niño Jesús, Madrid, Spain*

Background: There remains an unmet need to improve outcomes for pediatric patients (pts) with relapsed/refractory solid tumors. Abemaciclib is an orally administered, selective cyclin-dependent kinase (CDK) 4 & 6 inhibitor approved for breast cancer. Based upon preclinical data and the role of CDK4 & 6 in multiple pediatric solid tumor types, we hypothesized that abemaciclib in combination with IRN and TMZ would demonstrate clinical activity to support further pediatric development. This Phase 1b study aimed to determine the RP2D of abemaciclib in combination with IRN and TMZ in this pt population. **Methods:** This dose escalation study was part A of study JPCS (NCT04238819), and enrolled pts ≤ 18 years, weighing ≥ 10 kg, with a body-surface area ≥ 0.5 m², and with relapsed/refractory solid tumors, including CNS tumors, that progressed on standard treatment or experienced disease recurrence. IRN (50 mg/m²) and TMZ (100 mg/m²) were administered on days 1-5 of 21-day cycles and remain the same for all dose levels, while abemaciclib was tested on four dose levels: 55, 70, 90, and 115 mg/m² twice daily (BID). The starting dose was 70 mg/m² BID for abemaciclib. The maximum tolerated dose was defined as the highest dose level at which < 33% of pts experienced a dose-limiting toxicity (DLT) during Cycle 1. The primary objective, determination of the abemaciclib RP2D, was defined based on the totality of safety, tolerability, and pharmacokinetic (PK) results, and confirmed in an expansion cohort. Secondary objectives included safety and response assessments. **Results:** At the data cut-off of 13 June 2022, a total of 20 pts received abemaciclib at 70 mg/m² (n = 7) or 55 mg/m² (n = 13). The most frequent diagnoses (≥ 3 pts) were medulloblastoma (n = 4), malignant glioma (n = 3), and rhabdomyosarcoma (n = 3). At the starting dose of 70 mg/m², DLTs were experienced by 3 pts (neutropenia [n = 3; 43%]; gamma glutamyltransferase increased [n = 1; 14%]). The dose was de-escalated to 55 mg/m², at which one pt (8%) experienced a DLT (thrombocytopenia). High grade adverse events (AEs) were mostly hematological. Discontinuations due to AEs occurred in 2 pts (29%) at 70 mg/m² and 0 pts at 55 mg/m². Five pts (71%) at 70 mg/m² and 4 pts (31%) at 55 mg/m² achieved a best overall response of stable disease; 1 pt (8%) at 55 mg/m² achieved a complete response (rhabdomyosarcoma). No partial responses were observed. PK concentrations of abemaciclib at 55 mg/m² achieved average plasma abemaciclib concentrations of ~ 150 ng/mL and the abemaciclib C_{trough} concentrations appeared reasonably constant over time at ~ 100 ng/mL. PK concentrations of IRN and TMZ were as expected. **Conclusions:** The RP2D of abemaciclib is 55mg/m² BID in combination with IRN and TMZ. This combination appears tolerable with plasma concentrations within the range associated with efficacy in adult studies. Clinical trial information: NCT04238819. Research Sponsor: Eli Lilly and Company.

Safety and PK (pharmacokinetic) profile of niraparib (nir) + dostarlimab (dost) in pediatric patients (pts) with recurrent or refractory (RR) solid tumors: SCOOP study. *First Author: Francois Doz, Institut Curie and University of Paris, Paris, France*

Background: Combination therapies may improve clinical outcomes in pediatric pts with tumors with single-agent resistance. Emerging preclinical and clinical data have shown a positive effect for combination PARP/immune checkpoint inhibition. The SCOOP study was designed to evaluate combination nir+dost in pediatric pts with non-central nervous system (CNS) RR solid tumors. Herein we present the safety, dose-limiting toxicities (DLTs), PK, and recommended phase 2 dose (RP2D) of nir+dost. **Methods:** SCOOP is a phase 1, multicenter, open-label, dose-escalation, and cohort-expansion study in pts aged ≥ 6 mo to < 18 y with non-CNS tumor types reported to have a *BRCA* gene signature. Part 1A comprised multiple dose-level cohorts (0, 1A, 1B, and 2; Table) of pts ≥ 20 kg able to swallow nir tablets. The primary endpoint was determination of the RP2D of nir+dost based on DLT incidence during the first 2 cycles. Plasma concentrations were compared with simulated adult concentrations using population PK models. **Results:** A total of 23 pts with non-CNS RR solid tumors were enrolled with 16 evaluated for DLTs and 23 for PK analysis (see Table for dose-level cohorts and observed DLTs). Grade (Gr) ≥ 3 drug-related (DR) treatment-emergent adverse events (TEAEs) in part 1A included hematologic toxicities, decreased appetite, and fatigue, with DR serious TEAEs of immune-mediated encephalitis, headache, nausea, vomiting, cerebral hemorrhage, and hyponatremia. Observed plasma nir concentrations at 100 and 200 mg once daily (QD) in pediatric pts were similar to simulated adult concentrations at 200 or 300 mg QD. Observed dost concentrations at 7.5 mg/kg every 3 weeks (Q3W) in pediatric pts were in the expected range for adults at 500 mg Q3W. **Conclusions:** Observed DLTs were consistent with the individual safety profile of each drug; overall no unexpected safety issues were observed. Based on these results, nir 100 mg QD + dost 7.5 mg/kg Q3W was selected as the RP2D for the SCOOP expansion cohorts in neuroblastoma and osteosarcoma. Pts in the expansion study will receive nir+dost at the RP2D until disease progression. Clinical trial information: NCT04544995. Research Sponsor: GSK.

Cohort	Dosage	DLTs observed
0 (n=11; 8 evaluable ^a)	Nir 100 mg QD + dost 3 mg/kg Q3W	n=1; Gr 3 anemia requiring blood transfusion
1A (n=7; 6 evaluable ^a) Selected as RP2D	Nir 100 mg QD + dost 7.5 mg/kg Q3W	n=1; Gr 3 vomiting, nausea, and anorexia and Gr 5 immune- mediated encephalitis
1B (n=5; 2 evaluable ^{a,b})	Nir 200 mg QD + dost 3 mg/kg Q3W	n=2; 1 Gr 4 thrombocytopenia requiring transfusion, 1 Gr 3 cerebral hemorrhage
2 Did not open for enrollment as 1B was not deemed safe	Nir 200 mg QD +dost 7.5 mg/kg Q3W	

^aDLT-evaluable population comprises pts who completed the DLT observation period or experienced a DLT. ^bTwo additional pts in cohort 1B experienced Gr 3 neutropenia leading to interruption and reduction of nir dose, resulting in inadequate dosing compliance.

Reduction in curie score in neuroblastoma patients treated with naxitamab. *First Author: Jaume Mora, Pediatric Cancer Center Barcelona, Hospital Sant Joan de Déu, Barcelona, Spain*

Background: Patients with high-risk neuroblastoma (HR-NB) most frequently present with metastases in the bone marrow (BM; 70–89%) and bone (56–65%). Approximately 15% of HR-NB patients will be refractory to induction therapy and 50% will relapse. Naxitamab is a humanized GD2-binding monoclonal antibody approved in the US with granulocyte-macrophage colony-stimulating factor (GM-CSF) for treatment of patients ≥ 1 -yr with refractory/relapsed (R/R) HR-NB in the bone or BM with partial response, minor response, or stable disease to prior therapy. Curie Score (CS) is an important tool for assessing extent of disease and treatment response. The reduction in CS by baseline disease status, i.e., refractory or relapsed, from Trial 201 pre-specified interim analysis (data cut-off 31-dec-2021) is reported. **Methods:** Ongoing Trial 201 (phase II, NCT03363373) evaluates naxitamab+GM-CSF in patients with R/R HR-NB with residual disease limited to bone/BM. Soft tissue and actively progressing disease were addressed prior to enrollment. Naxitamab was administered (intravenously) at 3mg/kg/day over 30-60 min on Days 1/3/5 with GM-CSF (subcutaneous) on Days -4 to 5 at 4-week cycles. ¹²³I-MIBG scans were used to assess CS and treatment response according to INRC criteria per independent review. **Results:** Interim analysis included 52 (efficacy group) and 74 (safety) patients. The primary endpoint achieved an overall response rate (ORR) of 50% [95% CI: 35.8–64.2] with complete response rate (CR) of 38%. A summary of changes in overall CS by disease status is reported in the table. Median change in CS from baseline to end of treatment (EOT) was -1 across refractory and relapsed subgroups and ranged from -18 to 18 . Baseline CS (≤ 2 vs. ≥ 3) did not affect the safety profile. The most common adverse events were pain, hypotension, urticaria, and bronchospasm. The frequency of Grade 3 or higher and serious related adverse events was lower for patients with refractory vs. relapsed disease, i.e. lower rates of severe hypotension (51% vs. 68%), increased ALT (0% vs. 14%), and hypoxia (3% vs. 16%). **Conclusions:** Clinically meaningful reductions in CS were seen in patients regardless of baseline disease status (relapsed or refractory HR-NB). Baseline CS did not affect the safety profile. Refractory patients had a lower frequency of severe and serious related adverse events. Clinical trial information: NCT03363373. Research Sponsor: Y-Mabs Therapeutics.

Summary of Curie Score (CS) overall and by disease status.

	Overall (n=47*)	Refractory (n=24)	Relapsed (n=23)
Median Baseline CS (range)	3 (1-20)	3 (1-20)	3 (1-19)
Mean Baseline CS	5.6	5.5	5.7
Median end of treatment (EOT) CS (range)	1 (0-24)	1 (0-6)	1 (0-24)
Mean EOT CS	2.9	1.3	4.5
Median change from baseline (range)	-1.0 (-18 to 18)	-1.0 (-18 to 1)	-1.0 (-17 to 18)
Mean change from baseline	-2.7	-4.2	-1.2

*In the efficacy group, 2 patients had BM only disease and 3 patients did not have EOT CS.

Clinical application of ctDNA detection in Chinese pediatric patients with soft tissue sarcoma (STS). *First Author: Jia Zhu, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Circulating tumor DNA (ctDNA) is an effective and noninvasive supplementary approach for assessing minimum tumor burden in a range of solid tumors; however, studies on pediatric soft tissue sarcoma (STS) are limited. The purpose of the study was to assess the utility of ctDNA detection in predicting patient response and recurrence, and to inform treatment strategies through dynamic monitoring of ctDNA during the treatment of various types of pediatric STS. **Methods:** From January 2022 to January 2023, a total of 27 tissues and 112 plasma samples were obtained at baseline and during treatment. Utilizing the next-generation sequencing approach, ctDNA profiling was performed on tissue and plasma samples from 48 pediatric STS (< 18 years old) with a panel of 481 sarcoma-specific genes (Nanjing Geneseeq Technology Inc.). **Results:** The study included thirty patients with rhabdomyosarcoma, nine Ewing sarcoma, and nine other subtypes of sarcoma, with 52.1% (n = 25) female. Seven patients were stages I-II, and 24 were stages III-IV. At baseline, ctDNA was identified in 56.25 % (18/32) of plasma before chemotherapy and 87.50 % (14/16) of plasma before surgery. Comparable mutational burdens were seen in baseline tissue and plasma samples, with an average of 3.8 and 3 mutations per sample, respectively. The concordance of detected mutations between tissue and plasma was 64.3%. The average plasma abundance (p = 0.007), maximum abundance (p = 0.0045), ctDNA concentration (hGE/ml) (p = 0.0005), and relative ctDNA abundance (p = 0.0083) of stage IV patients (n = 5) were higher than those of stage I-III patients (n = 6). Following surgical resection, four patients (25 %, 4/16) had detectable ctDNA. In the longitudinal monitoring, we found a high correlation (75.86 %, 22/29) between ctDNA trend and clinical response. Notably, ctDNA positive in Ewing sarcoma had the strongest correlation with clinical response. The inconsistency between ctDNA detection and clinical response could be attributed to the presence of bone lesions (57.1%, 4/7). One patient was observed to have positive ctDNA before any radiological findings. **Conclusions:** Our findings showed that it is feasible to use ctDNA to dynamically monitor tumor burden in pediatric soft tissue sarcoma, especially Ewing sarcoma. ctDNA may serve as a safe, non-invasive option complementary to imaging assessment of sarcoma, and further clinical benefits are being investigated. Effect of bispecific B7H3 x CD19 CAR T cells on host CD19 expression and CAR T cell engraftment. *First Author: Navin R. Pinto, University of Washington, Seattle, WA*

Background: Our experience of B7H3 chimeric antigen receptor T cells (CAR-T) revealed modest engraftment (max 4.9 cells/uL) and no objective responses on first infusion. Previous CD19 CAR T cell trials have revealed that host B cell CD19 can drive robust engraftment and persistence even in the absence of malignant CD19 expression. We therefore developed a bispecific B7H3xCD19 CAR T cell with the intent of using host CD19 expression to drive better engraftment of the B7H3-targeting CAR. **Methods:** Young patients with relapsed/refractory solid tumors (R/RST) were enrolled onto a Phase 1 trial (NCT04483778) to examine the safety of autologous T cells lentivirally transduced to express either or both scFv-IgG4hinge-CD28tm-4-1BB-zeta B7H3-specific and CD19-specific CARs. The B7H3 CAR construct contained the methotrexate resistance/selection cassette DHFR^{td} and the tracking/suicide construct EGFRt and the CD19 CAR construct containing the tracking/suicide construct HER2tg, allowing for differential CAR tracking. CAR T cells were cultured in low-dose methotrexate to select for B7H3 containing CAR T cells and limit exposure to monospecific CD19 CAR T cells. All patients received lymphodepleting fludarabine and cyclophosphamide prior to infusion of cryopreserved CAR-T at the prescribed dose level. The maximal tolerated dose or biologically effective dose (BED) was determined based upon observed toxicity through day 28 from initial CAR-T infusion and using a 3+3 statistical design. **Results:** 11 subjects (age 5-23, median 18 years) enrolled and received dose level (DL) 0B (0.5 x 10⁶ TOTAL CAR-T/kg, n = 7) or DL1B (1 x 10⁶ TOTAL CAR-T cells/kg, n = 4). One subject experienced dose limiting toxicities at DL1 of transaminitis, hyponatremia, worsening of a pericardial effusion and hypoxia. Most common toxicities were cytokine release syndrome (CRS) (n = 4, maximum CTCAE grade 2). No occurrence of ICANS was noted. Maximum total circulating CAR-T expansion on first infusion was 796.3 cells/uL and max B7H3 expansion was 374.2 cells/uL with 7/11 continuing with ongoing detection of CAR T cells in the peripheral blood at time of last follow up (21 days to 8 months). CAR engraftment was predominated by the B7H3 CAR single expressing CAR T cells in all subjects. All subjects developed B cell aplasia which is ongoing in 10/11 subjects at time of last check (range of 21 days to 8 months). Best overall response of Stable Disease was observed in 2 of the 11 subjects infused. **Conclusions:** B7H3xCD19 CAR T cells robustly engraft and expand in patients with R/RST and are safe, but despite ongoing detection of the CAR T cells, no objective responses were observed. It is likely that additional measures will be required to enhance the activity of CAR-T cells to achieve objective responses. STRIVE-02 Arm C will explore the addition of pembrolizumab post bispecific CAR infusion to evaluate the effect of PD1 blockade on anti-tumor activity. Clinical trial information: NCT04483778. Research Sponsor: Seattle Children's Therapeutics.

Neurosurgical morbidity in pediatric supratentorial midline low-grade glioma: Results from the German LGG studies. *First Author: Michèle Simon, Department of Pediatric Oncology and Hematology, Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt Universität zu Berlin, Berlin, Germany*

Background: Surgical resection is a mainstay of treatment for pediatric low-grade glioma (LGG) within all current therapy algorithms, yet associated morbidity is scarcely reported. As supratentorial midline (SML) interventions are particularly challenging, we investigated the frequency of neurosurgical complications/new impairments aiming to identify their risk factors. **Methods:** Records were retrospectively analyzed from 318 patients with SML-LGG from successive German multicenter LGG studies, undergoing surgery between May 1998 and June 2020. **Results:** 537 operations (230 resections, 167 biopsies, 140 non-tumor procedures) were performed in 318 patients (54% male, median age: 7.6 years at diagnosis, 9.5 years at operation, 11% NF1, 42.5% optic pathway glioma). Surgical mortality rate was 0.93%. Applying the Drake classification, postoperative surgical morbidity was observed in 254/537 (47.3%) and medical morbidity in 97/537 (18.1%) patients with a 40.1% 30-day persistence rate for newly developed neurological deficits (65/162). Neuroendocrine impairment affected 53/318 patients (16.7%), visual deterioration 34/318 (10.7%). Postsurgical morbidity was associated with patient age <3 years at operation, tumor volume ≥80cm³, presence of hydrocephalus, complete resection, surgery in centers with less than median reported tumor-related procedures and during the earlier study period between 1998-2006, while the neurosurgical approach, tumor location, NF1 status or previous non-surgical treatment were not. **Conclusions:** Neurosurgery-associated morbidity was frequent in pediatric patients with SML-LGG undergoing surgery in the German LGG-studies. We identified patient- and institution-associated factors that may increase the risk for complications. We advocate that local multidisciplinary teams consider the planned extent of resection and surgical skills. Research Sponsor: None.

Postsurgical morbidity according to the classification by Drake et al.* (n=537 interventions).			
	All	Surgical morbidity	Medical morbidity
Resections	260	324 incidences (170 patients)	85 incidences (69 patients)
Biopsies	167	76 incidences (57 patients)	19 incidences (15 patients)
Other interventions	140	36 incidences (27 patients)	13 incidences (13 patients)

¹⁸F-MFBG PET imaging in patients with neuroblastoma: Lesion targeting and comparison with MIBG. *First Author: Shakeel Modak, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: ¹²³I-MIBG gamma camera imaging (MIBG) is routinely used for the imaging of neuroblastoma. Limitations include need for two-day imaging schedule and lack of quantitative uptake measurements. Phase I study showed that ¹⁸F-MFBG (MFBG), a positron-emitting analog of MIBG, is safe and feasible (PMID:28705916). In the follow-up phase II trial (NCT02348749) we evaluated MFBG PET imaging, comparing neuroblastoma lesion between the two modalities. **Methods:** Patients with known neuroblastoma underwent whole-body PET CT or PET-MR imaging one hour post-injection with 8mCi/1.7m2 of MFBG. All patients had concurrent MIBG scan with planar and SPECT-CT imaging without intervening therapy. MFBG and MIBG images were independently analyzed for lesion targeting; lesion number, site and uptake was noted for each patient and compared. Discordant lesions were further investigated with correlative imaging and/or clinical follow up. MFBG score was generated, similar to the modified Curie score for MIBG, for each patient. **Results:** 25 patients (median age 8 y) underwent MFBG scans at a median of 2 (range 0-24) days after MIBG scans; in one patient MFBG scan was performed 1 day before MIBG scan. No MFBG-related adverse events were noted. 24 patients had both MIBG and MFBG positive scans while 1 patient had both MIBG and MFBG negative scans. A total of 367 lesions were visualized on MFBG as against 217 on MIBG. There were no MIBG-positive that were negative on MFBG. A median number of 11 (range 0-57) lesions per patient were detected on MFBG scan. Uptake was noted in osteomedullary only, (n=13), soft tissue only (n=1) and both soft tissue and osseous lesions (n=10). MFBG detected a median of 6 (range 1-24) additional lesions in 19 patients. In 16/19 patients where follow up was available, the discordance was related to true positive disease, including at least 116 sites. Respective median curie scores were 3 (range: 0-22) and 9 (range:0-24) with MIBG and MFBG respectively. **Conclusions:** MFBG scan detected disease in all patients with MIBG positive disease. MFBG detected similar or more lesions compared to MIBG in patients with neuroblastoma, with overall increased scores. Further analysis to evaluate impact on patient management is underway. Clinical trial information: NCT02348749. Research Sponsor: U.S. National Institutes of Health.

Quality of cancer family history taking in pediatric solid tumor patients. *First Author: Benjamin Hu, Stanford University School of Medicine, Palo Alto, CA*

Background: Approximately 10% of childhood solid tumors occur in individuals with a cancer genetic predisposition. Identifying cancer predisposition permits interventions for prevention and early detection of future cancers in the child and their affected family members and may have other important medical care implications. The American Society of Clinical Oncology (ASCO) guidelines recommend reviewing family history (FHx) to identify high-risk patients who should be offered genetic testing. To our knowledge, adherence to ASCO guidelines by pediatric oncology providers (POPs) has not been studied. **Methods:** Retrospective chart review of solid tumor patients <18 years of age referred for genetic counseling 1/1/2017-1/31/2019. POP and genetic counselor (GC) FHx documentation was assessed for adherence with the ASCO minimum quality metrics: 2 generation pedigree, patient ethnicity, cancer genetic testing results in relatives (GTRR), and cancer type, age at diagnosis, and lineage (maternal/paternal) for each relative with cancer (RWC). Comparisons of FHx quality between POPs and GCs were evaluated with 1-sided t-tests. Ethnicity was considered assessed if both maternal and paternal ethnicities were documented. GTRR was considered assessed if the results of all relatives who had undergone genetic testing were noted. Cancer type, age at diagnosis, and lineage were considered assessed if they were checked for all RWCs. Whether or not the child underwent genetic testing and their testing results were also documented. **Results:** Of 129 eligible patients, 102 underwent germline genetic testing. Twelve (12%) had pathogenic alterations in cancer predisposition genes. The POP failed to document FHx in 20 patients (16%), including 2 with pathogenic germline alterations. The POP missed first/second degree RWCs in 32 of 88 patients with RWCs (36%). GCs achieved >99% on each of the 6 ASCO quality metrics, whereas POPs performed significantly more poorly (Table). In patients with RWCs, GCs achieved all 6 metrics in more cases than POPs (99% vs. 3%, p<0.001). **Conclusions:** POPs performed significantly worse than GCs in documenting family history compliant with ASCO minimum family history guidelines, raising concern for missed genetic cancer predisposition syndrome diagnoses in those not referred to a GC. Routine referral of pediatric solid tumor patients to a GC for family history review and interventions to improve the quality of family history taking by POPs may improve germline cancer predisposition detection, improving care of both patients and their affected family members. Research Sponsor: None.

Family History Quality Metric	Proportion Achieving Metric		p-value
	POP	GC	
All Patients (n=129)			
2 generation pedigree	58%	100%	<0.001
Ethnicity	9%	99%	<0.001
Cancer genetic testing results in relatives (GTRR)	8%	100%	<0.001
Patients with ≥ 1 RWC (n=88)			
RWC cancer type	76%	100%	<0.001
RWC age at cancer diagnosis	30%	100%	<0.001
RWC lineage	76%	100%	<0.001

Adherence to surveillance guidelines in survivors of hodgkin lymphoma: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Jamie Michelle Shoag, Cleveland Clinic, Cleveland, OH*

Background: Pediatric Hodgkin lymphoma (HL) is a highly curable disease. However, survivors are at high risk for long-term complications of therapy. The impact of sociodemographic and clinical factors on adherence to late effects surveillance guidelines is unknown. **Methods:** The CCSS is a retrospective cohort with prospective follow-up of survivors diagnosed from 1970-1999. HL survivors enrolled in CCSS who responded to a 2017 questionnaire were included. We assessed adherence to the Children's Oncology Group surveillance guidelines for cardiomyopathy, breast cancer, colorectal cancer, and skin cancer. Multivariate logistic regression was used to estimate adjusted odds ratios and 95% confidence intervals (aOR [95% CI]) for sociodemographic and clinical risk factors associated with adherence. Estimates were adjusted for area deprivation index (ADI); chronic health conditions; recent (≤2 years) routine check-up, cancer center or survivorship clinic visit; and possession of a survivorship care plan (SCP). **Results:** 1,380 HL survivors (45.6% male; median age 43.6 years, range 21.6-65.9 years) responded, of whom 55.5% were at elevated risk for cardiac dysfunction, 71.0% for breast cancer, 83.5% for skin cancer, and 39.4% for colorectal cancer. Of those at elevated risk, 42.7%, 19.9%, 31.3% and 48.9% were adherent to the guidelines for cardiac, breast, skin, and colorectal screening, respectively. Predictors of adherence to cardiac dysfunction guidelines were male sex (aOR 1.7 [1.1-2.6]), having children (aOR 1.6 [1.1-2.4]), recent routine checkup (aOR 4.0 [1.3-13.1]), recent visit to a cancer center or survivorship clinic (aOR 6.2 [3.9-10.0]), and possession of a SCP (aOR 3.1 [1.9-5.0]). Adherence to breast cancer guidelines was higher in those who were unmarried (aOR 2.1 [1.0-4.1]), had a recent visit to a cancer center or survivorship clinic (aOR 3.7 [2.0-7.0]), and possessed a SCP (aOR 3.5 [1.5-8.3]). Adherence to skin cancer guidelines was higher in those > 14 years at diagnosis (aOR 1.8 [1.3-2.4]), living in a low deprivation area (ADI 1-24.9) compared to a high deprivation area (ADI 75-100) (aOR 3.4 [1.9-5.9]), employed (aOR 1.8 [1.1-2.9]), > 30 years from diagnosis (aOR 2.4 [1.6-3.6]), with a recent routine check-up (aOR 3.6 [1.1-12.5]), and recent cancer care (aOR 2.4 [1.6-3.5]). Adherence to colorectal cancer guidelines was higher in those with grade 3-4 chronic health conditions (aOR 1.9 [1.1-3.3]). **Conclusions:** Less than 50% of HL survivors are adherent to screening guidelines. Sociodemographic risk factors are significant predictors of non-adherence, particularly to skin cancer screening guidelines. This threatens to potentiate outcome disparities among HL survivors. Financial hardship among siblings of long-term survivors of childhood cancer: A Childhood Cancer Survivor Study (CCSS) report. *First Author: Timothy James Daeun Ohlsen, Cancer and Blood Disorders Center, Seattle Children's Hospital, Seattle, WA*

Background: Siblings of children with cancer may experience adverse household economic and psychosocial impacts during and after treatment. While many long-term survivors of childhood cancer experience financial hardship, financial outcomes of siblings in later adulthood are unknown. **Methods:** We surveyed randomly selected nearest age siblings of survivors (aged 18-64y) enrolled in the CCSS to estimate the prevalence of financial hardship, using 20 items adapted from validated national surveys grouped into 3 domains (material, psychological, behavioral). We calculated the prevalence of reporting any hardship within each domain. Multivariable logistic regression estimated associations between sibling sociodemographic characteristics and each domain of hardship. For individual financial hardship items with a matching item in the contemporaneous National Health Interview Survey (n = 21,271) or Behavioral Risk Factor Surveillance System (n = 259,901), we compared siblings with national survey respondents aged 18-64, calculating adjusted prevalence ratios to sample-weighted responses, adjusted for sex, race, ethnicity, household income, education, and marital status. **Results:** 1,008 siblings participated (of 1,590 approached; 63%) with median age of 46y (IQR 39–53y). Siblings were 57% female, 89% non-Hispanic White, 69% college-educated, and 74% married. The prevalence of reporting any material, psychological, and behavioral hardship among siblings was 34%, 28%, and 23%, respectively. Sibling factors associated with reporting material financial hardship included: female sex (OR 1.7, 95% CI 1.2–2.4), age (30–39y vs 21–29y: OR 2.61, 95% CI 1.1–6.5), household income (\$50,000–\$74,999 vs $\geq$ \$75,000: OR 2.3, 95% CI 1.4–3.6), lack of health insurance (OR 2.4, 95% CI 1.1–5.1), presence of severe/disabling chronic medical conditions (OR 1.7, 95% CI 1.1–2.8), out-of-pocket medical expenses $\geq$ 10% of income (vs <10%: OR 4.9, 95% CI 1.9–12.3), and increased non-medical/non-home debt (for example, \$25,000–\$49,999 vs none: OR 5.2, 95% CI 3.2–8.6). Associations with psychological and behavioral hardship were similar. Compared with national survey respondents, siblings were more likely to report financial hardship on several individual items: difficulty paying medical bills (PR 1.2, 95% CI 1.0–1.4), worries about bills (PR 1.1, 95% CI 1.1–1.2), foregoing medical care (PR 1.3, 95% CI 1.0–1.6) and dental care (PR 1.4, 95% CI 1.2–1.6) due to cost, and worries about affording nutritious foods (PR 1.7, 95% CI 1.5–2.0). **Conclusions:** Adult siblings of childhood cancer survivors are more likely to experience multiple aspects of financial hardship than US adults in the general population, suggesting that childhood cancer may have life-long impact on siblings. Increased support for families across the trajectory of cancer treatment may help prevent or reduce financial hardship. Research Sponsor: U.S. National Institutes of Health.

Demographic predictors of successful transition to adult survivorship care for survivors of pediatric cancer. *First Author: Renee Gilbert, University of Kansas Clinical Child Psychology Program, Lawrence, KS*

Background: There is a growing number of childhood cancer survivors in the U.S. (Chow et al., 2020) who are at risk for experiencing negative long-term health outcomes (Oeffinger et al., 2006). Current guidelines state the importance of receiving risk-based follow-up at adult survivorship clinics, yet available estimates suggest that less than 50% of survivors receive yearly survivorship care (Landier et al., 2004; Daly et al., 2018). The transition from pediatric to adult care is a difficult process, with various factors acting as barriers (Devine et al., 2017). The present study sought to evaluate demographic predictors of successful transition to adult survivorship care in a Midwestern clinic serving a large urban and rural catchment area. **Methods:** The study includes adult survivors of childhood cancer (n = 203) who received pediatric or adult survivorship care in a Midwestern metropolitan area from 2015 to 2022. For this study, successful transition to adult care was defined as attending at least one appointment in the adult survivorship clinic. Dates of clinic attendance, cancer diagnosis, insurance data, and zip code were abstracted from the medical record. 86.2% of survivors had commercial insurance, 13.8% had government-sponsored insurance, self-pay or other insurance. Participant zip codes were 66.7% urban, 19.5% metropolitan (low and high commuting), 9.2% micropolitan, and 4.6% rural. Survivor ages ranged from 20 to 68 years (M = 29.48, SD = 7.74) and 53.2% were female. Participant-reported race/ethnicity was 90.1% White, 5.4% Hispanic, 3.4% Black and 1% Other. **Results:** 66% of the sample attended at least 1 appointment in the adult survivorship clinic. Chi-square analyses revealed a significant relationship between insurance type and attendance at the clinic, $X^2(1) = 16.60$, $p < .001$, such that a greater proportion of survivors with commercial insurance transitioned to adult survivorship care (71%), compared to government-assisted (Medicare), self-pay or other insurance (32%). Analyses revealed a significant relationship between rurality and transition, $X^2(3) = 14.11$, $p < .01$, such that a greater proportion of survivors from urban areas transitioned (74%) compared to rural areas (22%). Race/ethnicity, gender and cancer type were not significantly associated with transition. **Conclusions:** Results suggest that a lack of commercial insurance and rurality served as risk factors for not successfully transitioning to an adult survivorship clinic, highlighting opportunities for improvement in clinic reach. Associations between psychosocial and lifestyle factors and biological age acceleration among long-term survivors of childhood cancer: A prospective study from the St. Jude Lifetime Cohort. *First Author: Brennan Streck, National Cancer Institute, Rockville, MD*

Background: Survivors of childhood cancers may be at risk for premature, or accelerated, biological age aging, which is associated with cancer treatment exposures. However, life course theory and a growing body of evidence suggest that psychosocial and lifestyle factors may also contribute. The objective of this study was to explore associations between psychosocial and lifestyle factors and biological age acceleration in the St. Jude Lifetime Cohort. **Methods:** In this cross-sectional study, we applied physiology-based methods (Klemera-Doubal method and Phenotypic Age) and DNA methylation-based epigenetic clocks (Horvath's, Hannum's, Levine's PhenoAge, GrimAge, and DunedinPACE clocks) to compare biological age acceleration, estimated as the residual from regressing biological age on chronological age, among survivors (n = 4,117) and age- and sex-frequency-matched non-cancer community controls (n = 606). We compared psychosocial and lifestyle factors between survivors and controls using t-tests/Wilcoxon rank sums, and chi-square. Multivariable linear regression was used to assess associations of self-reported smoking, alcohol use, physical activity, overweight/obesity, and depressive symptoms with biological age acceleration in survivors, adjusted for age, race/ethnicity, sex, education, and cancer treatment. **Results:** Childhood cancer survivors at a mean chronological age of 35.1 years (SD 10.2) were biologically older than controls according to KDM-BA, Phenotypic Age, Hannum's clock, Levine's PhenoAge clock, and DunedinPACE, with biological age acceleration ranging from 1.7–4.7 years ($p < 0.05$). A greater proportion of survivors reported elevated depressive symptoms (10.3% v. 8.7%), current smoking (17.8% v. 12.3%), < 150 minutes of physical activity (47.3% v. 38.2%), and were overweight/obese (66.0% v. 59.9%) compared to controls (p 's < 0.001). In survivors, < 150 minutes of physical activity (B's (difference in biological age acceleration [years]) = 1.10–2.68), current (B's = 1.18–5.96) and former smoking (B's = 2.53–4.29) were consistently associated with higher biological age acceleration across measures (p 's < 0.05). Risky drinking and higher depressive symptoms were associated with higher biological age acceleration, but only for KDM (B = 1.26, $p < 0.021$) and DunedinPACE measures (B = 0.15, $p < 0.001$), respectively. **Conclusions:** Biological aging in childhood cancer survivors is associated with psychosocial and lifestyle factors. Interventions designed to optimize healthy behaviors and mitigate poor emotional health may have potential to prevent or remediate this phenotype in childhood cancer survivors. Treatment and treatment-related toxicity following subsequent breast cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Cindy Im, University of Minnesota, Minneapolis, MN*

Background: Long-term survivors of childhood cancer are at high risk for treatment-related breast cancer and have elevated mortality risk after a breast cancer diagnosis than the general population. There is no standard of care for women with treatment-related breast cancer, and treatment patterns and risk for toxicity are not known. **Methods:** Female survivors in CCSS diagnosed and treated for childhood cancer between 1970–1999 who developed a subsequent breast cancer (N = 344) were matched with females with sporadic breast cancer (multi-institution sampling; 1:1 matching ratio) on age at breast cancer diagnosis, breast cancer treatment decade, race/ethnicity, histology, and hormone receptor status. Conditional logistic regression evaluated univariate associations with treatments, toxicities, and synchronous breast cancer (≤ 12 months from diagnosis). Hazard ratios (HR) for metachronous disease risk (> 12 months from diagnosis) were estimated using proportional hazard models with robust variance estimation. **Results:** Among survivors, the median time between the primary cancer and initial breast cancer diagnosis at median age 40 years (IQR 35–45) was 26 years (IQR 21–30). Two-thirds received chest radiation therapy (RT) and 44% were treated with anthracyclines for their childhood cancer. In the matched sample, breast cancer clinical features were similar between survivors vs. controls, but the odds of synchronous bilateral disease at diagnosis was 4.8-fold greater (95% CI 2.2–10.2) among survivors. Surgical interventions (99% vs. 98%, $P = 0.22$) and treatment with chemotherapy (46% vs. 45%, $P = 0.43$) were similar between groups. However, women with sporadic breast cancers were more likely to receive RT (OR 4.4, 95% CI 2.9–6.8) or anthracyclines (OR 2.4, 95% CI 1.5–3.8). Survivors were more likely to undergo mastectomy (OR 3.0, 95% CI 2.1–4.2) and experience surgical complications (OR 2.2, 95% CI 1.4–3.4), and had 1.4-fold greater odds (95% CI 1.01–1.98) of experiencing any treatment-related toxicity compared to controls. The 15-year cumulative incidence of developing a metachronous breast cancer was 20% (95% CI 13–25%) in survivors versus 9% (95% CI 5–13%) in controls ($P < 0.001$). Risk of metachronous disease remained higher among survivors (HR 2.4, 95% CI 1.5–4.0) after adjusting for breast cancer treatments (mastectomy, RT, and anthracyclines). **Conclusions:** Female survivors of childhood cancer who develop subsequent treatment-related breast cancer are more likely to develop synchronous and metachronous breast cancer compared to controls. Despite similar biologic characteristics, survivors are treated differently from females with sporadic breast cancer and are more likely to experience treatment-related toxicities. Further study of how treatment of subsequent breast cancers and corresponding toxicities impact prognosis and survival is needed. Research Sponsor: U.S. National Institutes of Health.

Mortality and the burden of subsequent malignant neoplasms in survivors of childhood cancer beyond age 50: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Rusha Bhandari, City of Hope, Duarte, CA*

Background: The first generation of survivors of childhood cancer is now older than 50 years (y) of age. There is a paucity of information on the risk for late mortality and the evolving burden of subsequent malignant neoplasms (SMNs) in these aging survivors. **Methods:** We assessed cause-specific mortality (National Death Index) and self-reported SMNs (excluding nonmelanoma skin cancers) among CCSS participants diagnosed between 1970-1999, conditional on having survived to 50y by 12/31/2017. There were 4,772 survivors alive at 50y eligible for mortality analyses. Of the 3,355 who completed a baseline CCSS questionnaire, 2,273 also completed a follow-up questionnaire at ≥50y and were included in the SMN analyses. Cumulative mortality, standardized mortality ratios (SMRs), and, for SMNs, cumulative burden, standardized incidence ratios (SIRs), and relative rate (RR) with 95% confidence intervals (CIs) were calculated, compared with the general US population and by survivor subgroups. Piecewise-exponential multivariable regression was used to identify risk factors associated with the development of SMNs after 50y. **Results:** Mean age at diagnosis was 14y (standard deviation 4.2y). Mortality: Among survivors who attained 50y of age, the subsequent 5y, 10y, and 15y incidences of all-cause mortality were 9%, 19%, and 35%, respectively, (overall SMR 3.7 [95% CI 3.4-4.1]). SMRs were highest for SMN (SMR 5.1 [95% CI 4.4-5.9]), pulmonary (SMR 4.7 [95% CI 3.3-6.5]) and cardiovascular (SMR 3.9 [95% CI 3.2-4.8]) causes of death. The highest SMR (SMR 9.2 [95% CI 7.7-10.8]) was seen in female survivors of Hodgkin lymphoma. SMN: By age 50y, 14% of CCSS participants reported >1 SMN. History of SMN <50y was independently associated with the rate of developing another SMN at >50y (RR 1.6 [95% CI 1.1-2.3]). The most frequent SMNs ≥50y were breast (41%) in females and prostate (21%) in males, followed by gastrointestinal cancers in both (14% [females], 19% [males]). The cumulative burden of SMNs in survivors treated with radiation therapy (RT) increased sharply with age and exceeded 50 per 100 survivors by 65y (SIR 3.3 95%CI 2.0-5.2). Survivors who did not receive RT had a SMN rate comparable to the general population (Table). **Conclusions:** This sentinel population of survivors of childhood cancer is at high risk for poor outcomes as they enter older adulthood. RT exposure and history of SMN <50y are associated with increased risk for developing SMNs after 50y. The evolving burden of late morbidity attributed to SMNs may be lower for contemporary survivors projected to have less RT exposure. Research Sponsor: U.S. National Institutes of Health.

At age (y)	Cumulative burden of SMN per 100 survivors (95%CI)		SIR for SMN (95%CI)	
	RT	No RT	RT	RT No
55	26.8 (23.7-29.8)	15.0 (11.9-18.5)	2.7 (2.1-3.4)	1.2 (0.7-2.0)
60	34.3 (30.0-38.5)	20.5 (15.8-26.0)	1.9 (1.3-2.7)	1.4 (0.7-2.5)
65	53.4 (42.5-66.0)	21.7 (16.4-27.4)	3.3 (2.0-5.2)	0.4 (0.0-2.3)

Predictors of cancer center-based follow-up among pediatric and adolescent/young adult cancer survivors. *First Author: Emily Pang, Stanford University School of Medicine, Stanford, CA*

Background: Though guidelines recommend lifelong follow-up for pediatric and adolescent/young adult (AYA) cancer survivors, this has been challenging to implement in clinical practice. We constructed an institutional cohort of pediatric/AYA cancer survivors in order to evaluate follow-up patterns and identify predictors of cancer center-based follow-up. We hypothesized that follow-up would be lower for patients with greater individual- and area-level socioeconomic disadvantage and longer time since treatment. **Methods:** This retrospective cohort study used EHR data at an academic medical center. We included all patients who completed cancer treatment between 2010-2019 and were aged 0-29 years at last treatment date. Treatment was defined by diagnosis/procedure codes and medication records for chemotherapy, radiation, stem cell transplant, and cancer surgery. The primary outcome of cancer center-based follow-up was defined by clinic visits in an oncology department through 12/31/2022. Patients who died were excluded after the date of death. Multivariate logistic regression models (overall, age 0-19, age 20-29) evaluated the association of follow-up with age, sex, race/ethnicity, treatment intensity, insurance type, primary language, distance to cancer center, and area deprivation index (ADI, a composite measure of socioeconomic disadvantage). **Results:** 2210 patients were included with an overall rate of cancer center-based follow-up that decreased from 94% 1 year after treatment to 61% at 2-3 years, 45% at 4-5 years, and 35% at 6-7 years. Follow-up was not significantly associated with race/ethnicity, insurance type, primary language, or ADI for overall or age-specific cohorts. Patients >100 miles away had lower odds of follow-up. Increasing age was associated with decreased odds of follow-up, and this trend persisted over time since treatment (Table). **Conclusions:** Patterns of decreased pediatric/AYA cancer survivor follow-up were largely predicted by age and time since treatment. Further work is ongoing to understand drivers of follow-up disparities, including transfers of care and insurance type among AYA patients and the role of community support and telemedicine in healthcare access and health promotion. Research Sponsor: Stanford University School of Medicine.

Longitudinal associations between peripheral neuropathy and neurocognitive decline in long-term survivors of pediatric cancer treated without central nervous system (CNS) directed therapy. *First Author: AnnaLynn Williams, University of Rochester School of Medicine and Dentistry, Rochester, NY*

Background: Survivors of pediatric cancer treated without CNS-directed therapy are at risk of neurocognitive impairment and peripheral neuropathies. Using the St. Jude Lifetime Cohort, we investigated longitudinal associations with neuropathy to inform contributors to long-term cancer-related neurocognitive decline. **Methods:** Survivors of pediatric cancer (N=899 mean age 32 [SD 12], 24[10] years from diagnosis) treated without CNS-directed therapy completed neurocognitive testing and medical assessments at two timepoints (T1, T2 4.4[2.3] years apart). Peripheral sensory and motor neuropathy subscales combined with functional tasks were severity graded using a modified CTCAE (no neuropathy = none or grade 1 at T1 and T2; new onset = new grade 2 or 3 at T2; persistent = grade 2 or 3 at T1 & T2). Linear regression models estimated change in neurocognitive Z-score associated with neuropathy groups, adjusted for diagnosis age, time between visits, sex, race/ethnicity, high-dose intravenous methotrexate & baseline neurocognitive Z-score. **Results:** New onset sensory (n=33, 3.6%) and motor (n=35, 3.9%) neuropathy was associated with a 0.33 standard deviation (SD) decline in visual-motor processing speed (Table). New onset motor neuropathy was associated with a 0.50 SD decline in sustained attention as well as significant declines in verbal recall, working memory, and cognitive flexibility (p's<0.05). Persistent sensory neuropathy (n=25, 2.8%) was associated with large declines in focused attention and cognitive flexibility (p's<0.05). Persistent motor neuropathy (n=18, 2.0%) was associated with a 0.50 SD decline in sustained attention, verbal recall, and working memory (p's<0.05). **Conclusions:** Peripheral neuropathies are associated with future neurocognitive decline in adult survivors of pediatric cancer. Research is needed to understand shared mechanisms (e.g. pain, inflammation) to inform targeted interventions to improve neuropathic symptoms and neurocognitive function. Research Sponsor: U.S. National Institutes of Health; ALSAC.

Outcomes of childhood, adolescent, and young adult cancer survivors (CAYACS) with solid organ transplants: A population-based study. *First Author: Sumit Gupta, Division of Haematology/Oncology, The Hospital for Sick Children, Toronto, ON, Canada*

Background: Organ toxicity requiring solid organ transplant (SOT) is a rare but serious effect of cancer treatment. Given restricted donor organ supply, teams must assess CAYACS requiring SOT in relation to potential recipients with non-malignant indications; decisions are limited by scant long-term outcome data. We compared long-term outcomes for CAYACS requiring SOT with other SOT recipients. **Methods:** All Ontario, Canada children < 18 years at cancer diagnosed 1986-2021 at pediatric centres, and AYA aged 15-21 diagnosed at adult centres for acute leukemia, lymphoma, sarcoma, or testicular cancer between 1992-2012 were identified using population-based clinical databases. Patients with SOT prior to their primary cancer diagnosis were excluded. SOT was identified through linkage to healthcare databases; patients were matched 1:2 to non-malignant SOT recipients by sex, SOT year and type, and birth year. Post-SOT outcomes including overall survival (OS) and post SOT cancers were compared between CAYACS and SOT controls. **Results:** Among 16,533 CAYA with cancer, 85 received SOT: 46 liver, 18 kidney, 11 lung, and 10 heart. Among liver recipients, 33 (71.7%) were for primary cancer treatment (e.g. hepatoblastoma) vs. 13 (28.3%) for organ toxicity. Median age at original cancer diagnosis was 4 years [interquartile range (IQR) 1-13] and at SOT was 13 (IQR 3-20). CAYACS with SOT as treatment for long-term toxicity (liver subset plus all renal, lung, heart, N = 52) had a median time from cancer diagnosis to SOT of 9 years (IQR 4-16) and experienced lower 10-year OS from time of SOT [67.7%, 95th confidence interval (95CI) 50.8-79.9] vs. SOT matched controls [86.0% (74.8-92.5); hazard ratio (HR) 3.9; 95CI 1.6-9.7; p = 0.003]. When stratified by SOT type, similar trends were seen but were only statistically significant among lung SOT recipients (Table). The 5-year cumulative incidence of primary cancer relapse from time of SOT among those who received liver SOT for primary cancer therapy was 15.9% (95CI 5.6-30.8). Among CAYACS who require SOT following organ toxicity, 10-year cumulative incidence of second cancers was 8.6%±4.2%; this was similar to the incidence of first cancer among SOT controls (6.4%±2.6%; HR 1.6, 95CI 0.6-4.0; p = 0.34). **Conclusions:** Though CAYACS requiring SOT have inferior survival compared to other SOT patients, the majority achieve long-term cancer-free survival. These data can inform discussions on the suitability of CAYACS for SOT. Research Sponsor: None.

	10-year OS		HR (95CI)	p

Outcomes among survivors of childhood cancer in low- and middle-income countries: A systematic review. *First Author: Avram Denburg, Division of Haematology/Oncology, The Hospital for Sick Children, Toronto, ON, Canada*

Background: Low- and middle-income countries (LMICs) account for most of the global childhood cancer burden. Though cure rates lag behind those in high-income countries (HICs), a substantial proportion of LMIC children do survive. Long-term side effects of cancer or cancer therapy (late effects) are well-documented among childhood cancer survivors (CCS) in HICs, but whether prevalence and risk factors of late effects are comparable in LMICs is unclear. We thus conducted a systematic review to assess LMIC CCS outcomes. **Methods:** Five major health sciences databases were searched from inception to November 2022 in all languages. We included observational studies conducted in LMICs (World Bank 2021 classification) that evaluated outcomes in CCSs diagnosed with any malignancy. Mean or median length of follow-up must have been ≥ 5 years from original cancer diagnosis. Meta-analyses were precluded by cohort and outcome heterogeneity. **Results:** Of 1,994 studies identified, 113 underwent full-text review and 21 met inclusion criteria (16 full articles and 5 conference abstracts). Studies were conducted in lower-middle income (N = 12, 57%) or upper-middle income (N = 9, 43%) countries; no low-income country data were found. Study regions were mainly South and East Asia (N = 10, 48%) and the Americas (N = 8, 38%). Almost half (N = 9, 43%) of studies were conducted in India and only one African study from Cameroon was identified. Over half (N = 12, 57%) of studies were cross-sectional in design. Only five (24%) cohorts were comprised entirely of 5-year survivors. CCS of all childhood cancer types were evaluated in 12 (57%) cohorts, and 9 (43%) were specific to one cancer type. Ten (48%) studies were conducted in a survivorship clinic. Second cancers, followed by endocrine, reproductive, and cardiovascular late effects were most frequently assessed. Second cancers were reported in 1%-11% of CCS cohorts (N = 10 studies). The prevalence of hypothyroidism and metabolic syndrome ranged from 2%-49% (N = 6 studies) and 4%-17% (N = 5 studies), respectively. Gonadal dysfunction ranged from 2%-82% (N = 6 studies). Cardiac dysfunction and hypertension ranged from 1%-16% (N = 3 studies) and 5-19% (N = 3 studies), respectively. Late effects of the musculoskeletal (N = 4 studies) and urinary (N = 4 studies) systems were least investigated. **Conclusions:** Substantial knowledge gaps exist in LMIC childhood cancer survivorship. Few LMIC-based studies were identified, with no low-income country data available. In middle-income countries, variability existed in how late effects were defined and assessed; data was also limited by selection bias and small sample sizes. Additional systematically collected data on LMIC CCS cohorts are urgently needed. Research Sponsor: None.

Poster Session

Leveraging a community-academic partnership to evaluate the needs of Latinx AYA cancer survivors. *First Author: Stephanie M Smith, Division of Hematology/Oncology, Department of Pediatrics, Stanford University School of Medicine, Stanford, CA*

Background: Adult survivors of childhood cancer have an increased risk of late death and treatment-related comorbidities, yet < 20% of survivors receive guideline concordant risk-based care. Individual-level disadvantages and population-level measures of deprivation contribute to unequal health outcomes among survivors. We aimed to explore the experiences of adolescent/young adult (AYA) cancer survivors and their parents in a region in California with low socioeconomic status and high rates of non-English language preference. **Methods:** We formed a community-academic partnership with Jacob's Heart, a nonprofit organization that provides material/psychosocial support to predominantly Hispanic/Latino (Latinx) families of children with cancer. Between Feb-July 2022, we conducted semi-structured interviews in-person or by video or phone with English- or Spanish-speaking AYA survivors of childhood cancer (age ≥ 15 years, ≥ 5 years post-diagnosis), parents, and Jacob's Heart staff members, with assistance from certified medical interpreters. Data were analyzed qualitatively using reflexive thematic analysis based on grounded theory and the constant comparative method. Themes were refined through team discussions with our community partners. **Results:** We interviewed 12 AYAs (11 Latinx and bilingual), 11 parents (8 Latinx, 7 non-English preferred), and 7 organization staff (5 Latinx and bilingual). AYAs (5 female, 7 male) were median age (min-max) 20 (16-32) and 9 (5-19) years post-diagnosis; parents (9 female, 2 male) were median age 48 (40-60) and 14 (6-23) years post-child's diagnosis. Cancer types were leukemia (6 AYAs, 9 parents), CNS tumors (1 AYA, 2 parents), other solid tumors (3 AYAs), lymphoma (2 AYAs). Key themes across interviews included gratitude and trust in the pediatric cancer care team and Jacob's Heart staff, challenges obtaining healthcare outside of the pediatric cancer setting, lasting effects of cancer on the family (e.g., parental job loss, financial strain, impact on siblings, prolonged fear of recurrence in parents, unmet mental health needs in parents and AYAs), and communication barriers between Latinx families and clinicians (e.g., hesitancy to ask questions, overwhelmed by medical information) and between AYAs and parents (e.g., avoidance of talking about cancer history, cancer-related stigma, differing language preferences of AYAs and parents). **Conclusions:** Childhood cancer has long-lasting effects on families and those with fewer socioeconomic resources face additional burdens. Communication gaps experienced by Latinx families may be a target for intervention to improve AYA survivorship care. Future steps include sharing results with participants and partnering with the community to co-design interventions to facilitate triadic communication among Latinx AYAs, parents, and clinicians. Subsequent meningiomas in survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Tab Cooney, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: Meningiomas are the most common subsequent central nervous system tumor among aging survivors of childhood cancer, yet incidence across the lifespan, occurrence of multiple meningiomas, and risk for mortality are not established. **Methods:** Meningiomas were identified by self-report and validated with pathology/medical records. Twenty-year cumulative incidence of meningioma (95% confidence interval) was estimated and multivariable models assessed demographic- and treatment-related meningioma risk factors. **Results:** Among 24,902 5-year survivors of childhood cancer diagnosed 1970-1999, we identified 472 survivors with 710 meningiomas, 145 (20.4%) of which were WHO grade 2/3. Among survivors with meningioma, 137 (28%) had ≥ 2 meningiomas, and 80 (16%) met criteria for meningiomatosis. The median latency from childhood cancer to first meningioma diagnosis was 26.2 years (range 5.6-48.2), and the median time from first to second meningioma (among those without meningiomatosis) was 1.4 years (range 0-30.2 years). The twenty-year cumulative incidence did not significantly decrease between survivors diagnosed in the 1970s (0.58, 95% CI 0.41-0.79) and the 1990s (0.42, 95% CI 0.32-0.55). In multivariable analysis, female sex (HR 1.52, 95% CI 1.21-1.91) and all cranial radiotherapy dose levels (> 0.30 Gy, HR 57.0, 95% CI 7.93-419.60; 30.1-50 Gy, HR 228.90, 95% CI 30.89-1695.99; > 50 Gy, HR 113.29, 95% CI 15.09-850.34) were associated with increased meningioma risk, while older age at diagnosis (10-14 years, HR 0.60, 95% CI 0.44-0.82; 15-20 years, HR 0.35, 95% CI 0.22-0.55) was associated with reduced meningioma risk. Among 71 deaths in survivors with meningioma, the most prevalent cause of death was meningioma (N = 25, 35.2%). The 5-year all-cause mortality from first meningioma diagnosis was 4.20% (95% CI: 2.44-5.96%). **Conclusions:** In conclusion, cranial radiation, younger diagnostic age and female sex were identified as independent meningioma risk factors in, to our knowledge, the largest study to date. The risk for meningioma-associated mortality argues for assertive meningioma surveillance and treatment in this population. Research Sponsor: None.

Influence of genetic predisposition and lifestyle on modifiable cardiovascular risk factors among survivors of childhood cancer. *First Author: Carmen L Wilson, St. Jude Children's Research Hospital, Memphis, TN*

Background: We aimed to evaluate associations between polygenic risk score (PRS), and lifestyle with cardiovascular risk factors (CVRFs) assessed as continuous phenotypes (LDL, HDL, triglycerides, fasting glucose [FG], systolic [SBP] and diastolic blood pressure [DBP]) among childhood cancer survivors. **Methods:** Participants included 2,347 White survivors (mean age=35.5 (± 9.3) years) enrolled in the St. Jude Lifetime Cohort. Phenotype-specific PRS (derived from general population) were divided into tertiles and survivors classified as being at low-, intermediate-, or high-genetic risk. Lifestyle, classified as good, intermediate, or poor, was assessed based on four factors (smoking [yes/no], physical activity [meeting CDC guidelines for physical activity], diet quality [Healthy Eating Index score > 59], and obesity [BMI ≥ 30 kg/m²]). A general linear model was created for each CVRF in which the effect of lifestyle (good, intermediate, poor) was examined within genetic risk group (low, intermediate, high), adjusting for sex, age, cancer therapies and current medication use. **Results:** The table shows worsening CVRF profiles associated with declining lifestyle and with increasing genetic risk. For example, among survivors with poor lifestyle-high genetic risk, SBP and DBP were higher on average by 14 (95% CI = 9-18) and 9 (95% CI = 6-12) mmHg respectively, compared to survivors with good lifestyle-low genetic risk. In analyses restricted to survivors with high genetic risk, mean SBP (7, 95% CI=2-12) mmHg, DBP (4, 95% CI=1-7) mmHg, triglyceride (61, 95% CI=5-117) mg/dL, and FG (7, 95% CI=4-10) mg/dL values were higher among survivors with poor versus good lifestyle, while mean HDL was lower (-13, 95% CI= -18) mg/dL. **Conclusions:** While the risk of CVRFs among cancer survivors are associated with high genetic risk and cancer therapies, healthy lifestyle choices may partially ameliorate perturbations in CVRFs even among those with high genetic risk. Our findings highlight the importance of developing interventions targeting modifiable behaviors in this high-risk population. Research Sponsor: U.S. National Institutes of Health.

Racial disparities in treatment and outcomes of pediatric hepatoblastoma. *First Author: Taylor Billion, Creighton University School of Medicine, Omaha, NE*

Background: Hepatoblastoma is the most common malignant liver tumor which affects pediatric patients. However, the incidence is rare with 100 cases reported per year.¹ Current management consists of surgery and adjuvant cisplatin chemotherapy and radiation depending on tumor histology, resectability, and metastasis.² However, due to its rarity, optimal treatment protocol remains unclear. The 5-year overall survival rate in the US is approximately 57-69%.¹ **Methods:** The National Cancer Database (NCDB) was used to identify patients diagnosed with hepatoblastoma from 2004 to 2020 using the histology codes 8970 as assigned by the Commission on Cancer Accreditation program. Kaplan-Meier, Chi-Square, and ANOVA tests were performed. Data was analyzed using SPSS version 27 and statistical significance was set at $\alpha = 0.05$. **Results:** This study identified 1215 patients with hepatoblastoma. Black patients had a significantly lower median survival rate compared to White and other race patients (126.2 months vs 165.4 months vs 166.1 months; all $p < 0.05$). Black patients were more likely to be from low-income households than White patients (29.6% vs 17.3%; $p < 0.05$). The mean age of diagnosis was higher for Black patients compared to White patients (2.42 vs 1.99; $p < 0.05$). Black patients were less likely to receive surgery (63.5% vs. 75.4%; $p < 0.05$). Black patients on average had shorter distances to travel from their residence to the hospital (30.61 vs. 59.52 miles; $p < 0.05$). Black patients had longer mean stay times compared to white patients (16.7 days vs 11.2 days; $p < 0.05$). There was no significant difference in survival across incomes. When comparing Black and White patients there was no significant difference in insurance type, surgical margins, grade, stage, size of tumor, regional lymph nodes and time of diagnosis to treatment. No significant difference was shown between adjuvant therapies including chemotherapy and radiation. **Conclusions:** This study showed Black patients experienced inferior overall survival when diagnosed and treated for hepatoblastoma compared to White patients. This population was less likely to receive surgery, older when diagnosed, and had longer hospital stays. Poorer outcomes suggest a disparity in hepatoblastoma treatment. References: 1. Expansion of the fertility preservation program to all newly diagnosed prepubertal oncology patients at a pediatric hospital. *First Author: Antonia Pryor Leavitt, Duke University School of Nursing, Durham, NC*

Background: As the majority of pediatric oncology patients survive their disease, generating a population of over 500,000 survivors in the United States, it is imperative to minimize the lifelong consequences of treatment, which includes temporary or permanent infertility caused by certain cancer treatments. Fertility preservation (FP), the opportunity to preserve one's ability to have genetically-related children prior to damaging the reproductive system, is a young but rapidly expanding field and recent scientific advances have led to an expansion of options for prepubertal patients. A fertility consultation at diagnosis can provide patients and families with the opportunity to be informed regarding likelihood of gonadal dysfunction and to consider FP. **Methods:** After our pediatric hospital started to offer tissue cryopreservation, we initiated this evidence-based interventional quality improvement project. Our primary aim was to ensure that all newly diagnosed prepubertal oncology patients who met criteria for FP were correctly identified and offered an educational consultation and preservation. Inpatient admission lists and provider schedules were reviewed daily to identify patients. Treatment plans were discussed with providers to calculate infertility risk. All procedures were to be completed at the time of another procedure to increase likelihood of insurance coverage and minimize delays. **Results:** Between 07/15/22 and 11/30/22, 54 newly diagnosed prepubertal patients' treatment plans were evaluated to determine treatment-related infertility risk using the Oncofertility Consortium Pediatric Initiative Network's Risk Assessment tool. 15 patients were at a high level of significantly increased risk and were therefore eligible for consultation. 7 patients and their families received an educational consultation and 6 elected to undergo FP (3 TTCs; 3 OTCs). FP procedures did not cause a delay in starting treatment for any of these patients. 8 patients did not receive consultations. Reasons included the provider electing to proceed with treatment without consultation (4), the patient's comorbidities (1), the inability to bundle FP with another procedure (1), and the family decision to decline consultation (1). **Conclusions:** Of the patients at high risk of infertility, only 46% received consultation with lack of referral prior to initiating treatment as the primary reason. Of the patients offered preservation methods, 86% elected to preserve their fertility, illustrating patient and family interest. Providers must acknowledge changes in practice and be informed on the impact that high-risk treatment protocols can have on fertility. An FP program with established policies processes can increase the likelihood that prepubertal patients at high risk for infertility are correctly identified, educated, and offered preservation. Clinical course and native antibody development after COVID-19 infection in 50 pediatric oncology patients. *First Author: Maeve Smart, Dana-Farber Cancer Institute, Boston, MA*

Background: Pediatric oncology patients are at higher risk for severe COVID-19 infection compared to healthy children. However, pediatric cancer patients appear to be at lower risk of severe infection compared to adults with cancer. Lower rates of native antibody development have been seen in adults with hematologic malignancies particularly those with a history of transplant or anti-CD20 therapy. Data on the clinical characteristics of COVID-19 and antibody development after infection in children with cancer are limited. This study aims to describe the clinical manifestations of COVID-19 infection in pediatric cancer patients, identify variables associated with severe infection, and evaluate native antibody development. **Methods:** REsearch on COVID-19 in Oncology to Inform Recovery and Mitigate Future Risk (RECOVER) is an IRB approved institutional cohort study at Dana-Farber Cancer Institute. Pediatric patients with cancer who had COVID-19 are eligible 1-12 months following qPCR confirmed infection. Blood samples are collected at 2 timepoints (3-12 months after COVID-19 infection and 6-9 months later) and undergo research analysis as well as clinical Anti-SARS-CoV-2 (antibody response only to native infection) testing. **Results:** We report on the first 50 patients enrolled on the RECOVER study from March 2021 to December 2022 (COVID infection between March 2020 and November 2022). In this cohort, 56% (28/50) were male, 60% (30/50) had hematologic malignancies, 28% (14/50) had solid tumors, and 12% (6/50) had CNS tumors. Median patient age was 10.4 years (range 1-22 years). Most patients (86%; 43/50) were on active cancer treatment, of which 76% (33/43) had modifications in cancer-directed therapy due to COVID-19 infection. 76% of patients with COVID-19 were symptomatic and 26% (13/50) were hospitalized for COVID-19 symptoms. COVID-19 directed treatments were administered to 44% (22/50) of patients, most commonly antivirals ($n = 12$), monoclonal antibodies ($n = 9$), steroids ($n = 3$) and IVIG ($n = 2$). Native COVID-19 antibody testing 3-12 months post infection was performed for 88% (44/50) of patients, with 64% (28/44) seropositive at a median time of 5 months post-infection. Repeat antibody testing at timepoint 2 was available for 20 patients, with 14/14 remaining seropositive, 6/7 remaining seronegative, and 1 converting from seronegative to seropositive. **Conclusions:** The clinical characteristics of COVID-19 seen in this cohort of 50 pediatric oncology patients is consistent with prior reports, highlighting a high risk of hospitalization in this population. This study is the first to evaluate COVID-19 antibody development in pediatric cancer patients and showed that 63% of patients developed antibodies. Pediatric enrollment is ongoing and additional analyses are underway to assess factors associated with severe COVID-19 infection and/or associated antibody response. Self-reported sleep difficulties and association with cognitive function in pediatric cancer survivors. *First Author: Pete Stavinocha, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Preventing and ameliorating cognitive impairment following treatment for pediatric cancer remains a persistent challenge, with recent literature examining lifestyle factors as possible targets for intervention. An association between sleep and cognitive impairment has been identified in adult cancer patients and survivors, yet information is limited for pediatrics. Thus, the primary goal of our retrospective study was to explore self-reported sleep difficulties in pediatric patients and survivors with mixed cancers. A secondary aim was to explore the impact sleep problems on specific cognitive functions. **Methods:** Children and adolescents who completed neuropsychological assessments at two large pediatric cancer centers ($N = 298$) were identified via medical record review. In addition to demographic data, clinically collected cognitive tests included Wechsler Working Memory (WM), Processing Speed (PSI), and General Ability (GAI) indices. Objective attention measures included Conners Continuous Performance Test (versions II and 3) Omissions (O), Commissions (C), and Reaction Time (RT). Sleep Disturbance (SD) and Sleep-Related Impairment (SRI) were captured using pediatric self-report PROMIS scales. PROMIS cut points were used to categorize sleep issues within the study population and PROMIS scores were compared to reference population means. Multiple linear regression was used to identify relationships between cognitive domains and sleep factors. Common cancer-related clinical and demographic characteristics were controlled as covariates. **Results:** 21.5% of patients reported severe SD, while 12.8%, 15.9% and 49.7% reported moderate, mild, and within normal limits (WNL) SD, respectively. For SRI, 13.3% reported severe SRI, while 20.0%, 15.9% and 50.8% reported moderate, mild and WNL SRI, respectively. Mean SD and SRI were higher than in the reference populations ($p = 0.000$ for both measures). Pearson correlation results suggested a moderate relationship between SD and SRI ($r = 0.489$, $p = 0.000$). After controlling for covariates, multiple linear regressions indicated significant relationships between SD and GAI ($p = 0.006$), SD and O ($p = 0.018$), and SRI and WM ($p = 0.006$). **Conclusions:** Results suggested that ~50% of our pediatric cancer patients and survivors reported SD and SRI. SD was correlated with SRI in our sample, and regression analysis indicates a significant relationship between sleep problems and O, WM, and GAI in our sample. Findings from this retrospective study suggest a relationship between sleep problems and cognitive performance in pediatric cancer survivors. As a potentially modifiable factor to improve cognitive function in pediatric cancer survivors, sleep difficulties warrant more research to potentially guide interventions to better manage and improve cognitive function in this population. Poster Session

Phase 1/2 study of tiragolumab and atezolizumab in patients with relapsed or refractory SMARCB1 or SMARCA4 deficient tumors. *First Author: Mary Frances Wedekind, Pediatric Oncology Branch, NCI, NIH, Bethesda, MD*

Background: The SMARCB1/A4 gene products are core subunits of the SWI/SNF chromatin remodeling complex. Tumors with defects in SWI/SNF are histologically distinct aggressive cancers occurring in children and young adults. SMARCB1/A4 deficient tumors, particularly rhabdoid tumors, poorly differentiated chordoma, epithelioid sarcoma, and medullary renal cell carcinoma, have immune cell infiltrates and programmed death ligand 1 (PD-L1) expression. Response to immune checkpoint inhibition (ICI) has been observed in SMARCB1/A4 deficient tumors; however, responses are not durable. T cell immunoreceptor with Ig and ITIM domains (TIGIT) is a novel inhibitory receptor expressed on multiple immune cells. TIGIT inhibits T and NK cells by binding to its ligand poliovirus receptor (PVR) and Nectin2 on tumor cells and antigen-presenting cells. Utilizing RNAseq data, SMARCB1/A4 deficient tumors demonstrate high expression of PVR and Nectin2. Tiragolumab is an antibody to the TIGIT receptor. In patients with non-small cell lung cancer, tiragolumab with atezolizumab increased survival compared to atezolizumab alone. Thus, data suggest that SMARCB1/A4 deficient tumors are susceptible to ICI; however, monotherapy is unlikely to achieve durable responses; the addition of tiragolumab may enhance response rates. **Methods:** This is a phase 1/2 trial of tiragolumab monotherapy and in combination with atezolizumab in patients ≥ 12 months of age with SMARCB1/A4 deficient tumors administered IV on Day 1 of 21-day cycles. Part A will evaluate the safety of tiragolumab monotherapy (300 mg if ≤ 15 kg; 420 mg if > 15 to ≤ 40 kg; 600 mg if > 40 kg or ≥ 18 yrs) based on cycle 1 DLTs in up to 6 evaluable patients < 18 yrs of age. Part B will estimate the antitumor activity of tiragolumab in combination with atezolizumab (15 mg/kg [max 1200 mg]) if < 18 yrs or 1200 mg if ≥ 18 yrs) in 6 histology-specific cohorts (renal medullary carcinoma, malignant rhabdoid tumor, atypical teratoid rhabdoid tumor, poorly differentiated carcinoma, epithelioid sarcoma, and other) Each cohort will be conducted using a 6+4 Simon's 2 stage design. Up to 13 patients may enroll in each cohort allowing for invaluable patients (maximum n=78). Enrollment of patients ≥ 18 yrs on Part B may occur concurrently with enrollment of patients < 18 yrs on Part A. If the pediatric dose of tiragolumab is deemed safe, patients < 18 yrs old may be enrolled on Part B. Cycle 1 toxicities of the combination therapy will be monitored in Part B using a Bayesian Optimal Interval Design in patients < 12 yrs of age. The secondary objectives are to characterize pharmacokinetics/anti-drug antibody and estimating progression free survival, overall survival, and duration of response. Enrollment is open for all Pediatric Early Phase Clinical Trial Network sites. Clinical trial information: NCT05286801. Phase 1b/2 study of abemaciclib combined with chemoimmunotherapy in pediatric and young adult patients with relapsed/refractory neuroblastoma (JPCS Part C). *First Author: Emily Gustava Greengard, University of Minnesota, Eden Prairie, MN*

Background: Survival for high-risk neuroblastoma (NBL) remains poor with over 50% of patients experiencing disease relapse. The addition of dinutuximab (DIN) and granulocyte macrophage colony-stimulating factor (GM-CSF) to irinotecan (IRN) and temozolomide (TMZ) in patients with first relapse achieved an overall response rate of 42% in the study ANBL1221¹ and is now standard of care. However, there remains a significant unmet need to improve outcomes for children with relapsed/refractory NBL. Deregulation of the Cyclin D/cyclin-dependent kinase (CDK) 4 & 6 pathway has been observed in NBL, rendering CDK4 & 6 inhibition logical to explore. Abemaciclib is an orally administered, selective CDK4 & 6 inhibitor approved to treat breast cancer. JPCS (NCT04238819) is designed to assess the pharmacokinetics, safety, and tolerability of abemaciclib added to standard treatment regimens for relapsed/refractory pediatric solid tumors. Part A defined the recommended phase 2 dose (RP2D) of abemaciclib in combination with IRN and TMZ. In Part C, the addition of DIN + GM-CSF to the JPCS Part A regimen will be evaluated. The co-primary objectives of Part C are to determine the RP2D and to estimate the anti-tumor activity of abemaciclib added to the ANBL1221 chemoimmunotherapy backbone in patients with first relapse/refractory NBL. **Methods:** JPCS Part C is a two-stage, non-randomized, open-label, Phase 1b/2 study for patients < 21 years of age with first relapse/refractory NBL. Stage 1 aims to identify the maximum tolerated dose (MTD) of abemaciclib at a starting dose of 55 mg/m² combined with DIN, GM-CSF, IRN and TMZ using a 3+3 design. One dose de-escalation (30 mg/m²) will be possible if the starting dose is not tolerated. Further tolerability and initial anti-tumor activity will be evaluated in an expansion cohort at the MTD. Up to 11 evaluable patients will enroll in Stage 1 at the MTD; the MTD will be declared the RP2D if adequate safety and tolerability are observed and ≥ 6 patients achieve minimal response or better per International Neuroblastoma Response Criteria (INRC). Following determination of the RP2D, Stage 2 will enroll 35 patients. If ≥ 26 of 46 total patients achieve an INRC minimum response or better, further investigation of this regimen could be warranted. As of 31 Jan 2023, Part C is open for enrollment at one site (US) and additional sites are being evaluated. References: Mody et al. J Clin Oncol. 2020; 38(19):2160-2169. Clinical trial information: NCT04238819. Research Sponsor: Eli Lilly and Company.

LOGGIC/FIREFLY-2: A phase 3, randomized trial of tovorafenib vs. chemotherapy in pediatric and young adult patients with newly diagnosed low-grade glioma harboring an activating RAF alteration. *First Author: Cornelis Martinus van Tilburg, Hopp Children's Cancer Center Heidelberg (KITZ), Heidelberg University Hospital and German Cancer Research Center (DKFZ), Heidelberg, Germany*

Background: Pediatric low-grade gliomas (pLGGs) are the most common CNS tumors of childhood. Genomic alterations of *BRAF* are oncogenic drivers in almost all pLGGs. Approximately 50%–60% of pLGGs harbor a *KIAA1549-BRAF* fusion and 5%–15% a *BRAF* V600E mutation. Tovorafenib is an investigational, oral, selective, CNS-penetrant, small molecule, type II pan-RAF inhibitor. The registrational, phase 2 FIREFLY-1 (NCT04775485) study of tovorafenib in pediatric patients with recurrent/progressive LGG is ongoing and interim analysis has shown encouraging anticancer activity. **Methods:** LOGGIC/FIREFLY-2 (NCT05566795) is a registrational, 2-arm, randomized, multicenter, global (~ 100 sites across Australia, Canada, Europe, New Zealand, Singapore, South Korea, and USA), phase 3 trial being conducted in collaboration with the SIOPE Brain Tumor Group LOGGIC Consortium. The study is evaluating the efficacy, safety, and tolerability of tovorafenib vs. standard of care (SoC) chemotherapy in patients < 25 years old with pLGG harboring an activating *RAF*-alteration and requiring first-line systemic therapy. Approximately 400 patients will be randomized 1:1 to receive oral tovorafenib, 420 mg/m² (≤ 600 mg) once weekly (tablet or liquid suspension), or an investigator's choice of SoC chemotherapy: COG-V/C regimen (60 weeks), SIOPE-LGG-V/C regimen (81 weeks), or single-agent vinblastine (70 weeks). Tovorafenib will be continued until the occurrence of radiographic progression (based on Response Assessment in Neuro-Oncology [RANO] criteria as determined by the investigator and confirmed by independent review) or unacceptable toxicity; patients with radiographic progression may be allowed to continue tovorafenib if, in the opinion of the treating investigator, they are deriving clinical benefit from study treatment. Patients who progress in the SoC arm during or after completion of chemotherapy are eligible to cross-over to receive tovorafenib. The primary endpoint is the objective response rate based on RANO criteria, as determined by independent review. Key secondary endpoints are progression-free survival and duration of response per RANO criteria by independent review and overall survival. Other secondary endpoints include efficacy assessments per Response Assessment in Pediatric Neuro-Oncology (RAPNO) criteria, changes in neurological and visual function, and safety and tolerability. Exploratory endpoints include efficacy assessments per investigator, tumor volume, adaptive behavior and quality of life. Prognostic and predictive molecular biomarkers, including senescence profiles for treatment outcome, response prediction, and treatment resistance, will be explored in parallel studies. Clinical trial information: NCT05566795. Research Sponsor: Day One Biopharmaceuticals.

Evaluation of palbociclib in combination with topotecan and cyclophosphamide in pediatric patients with recurrent or refractory neuroblastoma. *First Author: Theodore Willis Laetsch, Division of Oncology, Children's Hospital of Philadelphia, and Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: Palbociclib is an orally administered, highly selective, reversible, small molecule cyclin-dependent kinases 4/6 (CDK4/6) inhibitor. Inhibition of CDK4/6 reduced growth of neuroblastoma cell lines. The phase 1 portion of the study, conducted and funded by Pfizer in collaboration with the Children's Oncology Group, established the recommended phase 2 dose (RP2D) of palbociclib with topotecan and cyclophosphamide (TOPO/CTX) in children with solid tumors. Per study protocol, if 2 or more patients from the phase 1 study show a confirmed objective response (OR) in a specific tumor type, an open-label, non-randomized tumor-specific cohort (TSC) may be opened. **Methods:** A neuroblastoma TSC has been opened to evaluate the preliminary antitumor activity of palbociclib with TOPO/CTX in the treatment of patients with recurrent/refractory neuroblastoma using a modified Simon's 2-stage optimal design. Up to 21 patients will be enrolled and receive palbociclib with TOPO/CTX. The primary endpoint is OR, as assessed by investigator using International Neuroblastoma Response Criteria (INRC). Secondary efficacy endpoints include duration of response, progression-free survival, and overall survival. Key eligibility criteria include: recurrent/refractory neuroblastoma, measurable disease as defined by INRC, aged ≥ 2 and < 21 years at the time of study entry, adequate blood counts organ function, and performance status. Patients may have received prior TOPO and/or CTX, provided their disease did not progress on this regimen. Prior treatment with a CDK4/6 inhibitor is exclusionary. Patients will receive palbociclib at the RP2D of 75 mg/m² orally once daily on days 1–14 of each 21-day treatment cycle. CTX (250 mg/m²) followed by TOPO (0.75 mg/m²) will be administered intravenously once daily on days 1–5. Concurrent radiotherapy or surgery for local control will be permitted. Treatment will continue until disease progression, patient and/or legal guardian refusal, unacceptable toxicity, or up to 24 months of treatment, whichever occurs first. Enrollment in the neuroblastoma TSC was initiated in December 2022 (NCT03709680). Clinical trial information: NCT03709680. Research Sponsor: Pfizer Inc.

Phase 1/2, first-in-child study of sonodynamic therapy (SDT) using low intensity focused ultrasound and 5-aminolevulinic acid (ALA) for patients with diffuse intrinsic pontine glioma. *First Author: Hasan R Syed, Children's National Hospital, Washington, DC*

Background: Diffuse intrinsic pontine glioma (DIPG) is a devastating pediatric brain tumor with poor prognosis. Sonodynamic therapy (SDT) with ALA is a non-invasive strategy that sensitizes target tissues with a non-toxic chemical agent followed by exposure to low intensity MR-guided focused ultrasound (MRgFUS). Preclinical studies have shown that ALA is preferentially taken up by glioma cells and metabolized to protoporphyrin IX (PpIX). SDT activates protoporphyrin IX and induces tumor cell death via photodynamic effect (lipoperoxidation, apoptosis). Suheiro et al and Wu et al demonstrated that SDT killed tumors via apoptosis and lipoperoxidation in rodent glioma models with minimal damage to surrounding normal brain.^{1,2} ALA SDT was well-tolerated in an ongoing first-in-human trial in adults with recurrent high-grade gliomas and demonstrated biomarker evidence of the photodynamic effect.³ **Methods:** A Phase 1/2, multicenter, open label study (NCT05123534) is enrolling patients at Children's National Hospital. The study employs the Bayesian optimal interval (BOIN) algorithm to evaluate safety and tolerability of treatment with SDT in newly diagnosed DIPG subjects to determine the maximum tolerated dose (MTD) or recommended phase 2 dose (RP2D) of MRgFUS energy in combination with ALA. The study will evaluate 3 ALA doses and 3 acoustic energy doses. ALA is administered IV six to nine hours prior to MRgFUS with the Exablate type-2 device. The first cohort, B1C1, evaluates the lowest drug-device dose combination and if no dose-limiting toxicity (DLT) is encountered after 3 patients, ascending dose-escalation will proceed to the second cohort, B2C1, treated with lowest dose of ALA with the second level of MRgFUS energy. Again, if no DLT is experienced, the next cohort will receive a higher dose combination. The initial patient in each cohort is treated in 2 sessions 21 to 28 days apart, each covering one-half of the pons. Subsequent patients are treated in 1 session to the whole pons. The primary objective is to evaluate the safety and tolerability of SDT in DIPG subjects. Secondary outcomes include preliminary efficacy assessments, pharmacokinetics of ALA and PpIX, mechanical performance of the Exablate Type-2 device, and radiographic evidence of tumor physiological changes associated with SDT. All patients at least 5 years of age with newly diagnosed, radiographically typical DIPG between 4-24 weeks after completion of standard radiotherapy are eligible for the trial. Patients with evidence of disease progression, diagnosis of porphyria, or prior or concurrent therapy with any other anticancer or investigational intervention will be excluded. Cohort 1 has been completed without DLT. References: 1. Suheiro et al. *J Neurosurg* 2018;129:1416-1428. 2. Wu et al. *Sci Rep* 2019;9:10465. 3. Sanai et al. *NeuroOnco* 2022;24(4):vii72-vii73. Poster Session

A multicenter, phase II trial of maintenance sirolimus in combination with metronomic chemotherapy in children and adolescents with high-risk solid tumors. *First Author: Kathryn S. Sutton, Aflac Cancer and Blood Disorders Center, Children's Healthcare of Atlanta, Emory University School of Medicine, Atlanta, GA*

Background: Risk of relapse for children with high-risk solid tumors (ST) remains unacceptably high despite aggressive multimodal therapy. Maintenance therapy is an emerging option to improve outcomes. Sirolimus, an inhibitor of mammalian target of rapamycin, is a potent immunosuppressant with antiproliferative and antiangiogenic effects. Low-dose metronomic chemotherapy along with the cyclooxygenase-2 inhibitor celecoxib also decreases neovascularization in *in vitro* and *in vivo* systems. The maximum tolerated dose (MTD) of sirolimus in combination with celecoxib and etoposide alternating with cyclophosphamide was determined in a phase I study in pediatric patients with relapsed/refractory ST. The regimen was well-tolerated and showed best response of stable disease in 8/18 subjects and partial response in 1/18. The efficacy of this regimen in relapsed/refractory ST is being tested in a Phase II study (NCT02574728). We hypothesize that patients with high-risk ST administered a 12-month course of this maintenance regimen will have improved 2-year progression-free survival (PFS) when compared to matched historical patients who were observed following completion of upfront therapy. **Methods:** This is a phase II study of sirolimus in combination with celecoxib and alternating low-dose etoposide and cyclophosphamide delivered as maintenance therapy. Sirolimus will be given at the MTD of 2mg/m²/day with celecoxib 100mg twice daily and oral etoposide 50mg/m²/day (max 100mg) alternating every 21 days with oral cyclophosphamide 2.5mg/kg/day (max 100mg). This study includes: 1) a prospective cohort of patients with high-risk ST in first complete remission (CR), 2) a prospective cohort of patients with recurrent ST in second CR, and 3) a historical cohort matched 2:1 with cohort 1 on diagnosis, age, metastatic sites, and date of diagnosis treated with observation following upfront therapy. The study will enroll up to 38 patients in cohort 1. Eligible subjects are children (1-30 years) with a diagnosis of high-risk extracranial ST (metastatic sarcoma, desmoplastic small round cell tumor, malignant rhabdoid tumor) in first CR or any ST in second CR. Patients enrolled in upfront clinical trials are excluded. Primary endpoint is 2-year PFS of cohort 1 compared to the historical cohort. Secondary endpoints are median PFS of cohort 1, 2-year PFS and overall survival of cohorts 1 and 2, incidence of severe toxicities, and feasibility of completing the 12-month course following standard upfront therapy. Exploratory objectives include evaluation of circulating tumor DNA (ctDNA) in this population of patients in CR or with minimal disease burden and correlation of clinically obtained tumor molecular profiling with outcomes. As of January 2023, 12 subjects are enrolled, 9 in cohort 1 and 3 in cohort 2. Clinical trial information: NCT04469530. Research Sponsor: Peach Bowl LegAcY Fund (Children's Healthcare of Atlanta).

Update for NCI-COG Pediatric MATCH: Active trial cohorts for children, adolescents and young adults with refractory cancers. *First Author: Donald Williams Parsons, Texas Children's Cancer and Hematology Center, Baylor College of Medicine, Houston, TX*

Background: The National Cancer Institute-Children's Oncology Group Pediatric Molecular Analysis for Therapy choice (MATCH) trial seeks to facilitate evaluation of molecular-targeted therapies in biomarker-selected cohorts of childhood and young adult patients with cancer by screening tumors for actionable alterations. The Pediatric MATCH screening protocol and first seven treatment arms were activated in July 2017 for patients treated at COG sites across the United States; six additional treatment arms were activated between 2017 and 2020. In 2022 a major screening protocol amendment discontinued centralized tumor testing at MATCH laboratories and mandated use of molecular profiling reports from outside laboratories to determine treatment arm eligibility. **Methods:** The trial assigns patients aged 1 to 21 years with relapsed or refractory solid tumors, lymphomas, and histiocytic disorders to phase 2 treatment arms of molecularly-targeted therapies based on the genetic alterations detected in their tumor. Starting in January 2022, a clinical tumor molecular profiling report from a CAP/CLIA-approved laboratory has been required for patients to enroll in the screening protocol. The treating site indicates which molecular alteration in the submitted report is believed to be actionable as well as the open Pediatric MATCH study arm for which the patient is proposed to be eligible. The submitted report is then reviewed by the study Molecular Review Committee to determine if an actionable alteration is present (based upon study-defined levels of preclinical and clinical evidence); if so, the patient is assigned to the relevant MATCH treatment arm. Other treatment arm eligibility requirements are typical of phase 2 pediatric trials including adequate patient performance status and standard washout periods for prior therapy. Each treatment arm follows a one (arms A, D, F, M, N) or two (arm K) stage design with a 20 patient primary cohort and option for histology-specific expansion cohort(s) if at least 3 objective responses are seen in a tumor histology. The primary endpoint is objective response rate; secondary endpoints include safety/tolerability and progression-free survival. Therapy is discontinued if there is evidence of progressive disease or drug related dose-limiting toxicity that requires removal from therapy; therapy may otherwise continue for up to 2 years. As of January 2023, 6 of the 13 Pediatric MATCH treatment arms remain open to enrollment (Table). Clinical trial information: NCT03155620. Research Sponsor: U.S. National Institutes of Health; St. Baldrick's Foundation.

A pilot clinical study of oral irinotecan HCl (VAL-413) in patients with recurrent pediatric solid tumors. *First Author: Jeffrey A. Bacha, Edison Oncology Holding Corp., Menlo Park, CA*

Background: Intravenous irinotecan hydrochloride (IRN-IV) is approved for the treatment of adult colorectal cancer and also used off-label to treat a range of adult and pediatric tumors including recurrent Ewing sarcoma, rhabdomyosarcoma, neuroblastoma, hepatoblastoma, Wilms tumor, gynecologic cancers, lung cancer and medulloblastoma. Previously, a regimen of IRN-IV administered as a 60-min i.v. infusion daily for 5 days, bi-weekly in combination with other agents such as temozolomide has been recommended use in treating children with solid tumors (*Blaney. ClinCanRes, 2001*). Protracted administration schedule of IRN-IV is inconvenient for patients, so oral regimens utilizing IRN-IV have been developed and implemented with favorable tumor response (*Wagner. ClinSarcRes, 2015*). Unfortunately, the palatability of the IRN-IV is poor, leading to reduced compliance especially in younger pediatric patients. Development of an advanced formulation to improve tolerability and patient compliance is an important unmet need. VAL-413 is a novel formulation developed to improve palatability of oral irinotecan. This pilot trial will examine the safety and tolerability of this novel formulation and assess pharmacokinetics compared to current oral regimen. **Methods:** Eligibility: Up to 20 patients $\geq$ 1 year of age or $\leq$ 30 years of age with recurrent pediatric solid tumors and adequate bone marrow, renal and liver function, for whom irinotecan therapy is a treatment option will be enrolled. Trial Design: Two different dose levels of VAL-413, 90mg/m²/day or 110mg/m²/day will be studied in combination with fixed-dose temozolomide using a standard 3 + 3 phase I design. In the event the starting dose of 90 mg/m²/day is not tolerable due to toxicity, a lower dose of 75 mg/m²/day may be implemented. Treatment: During the first cycle of treatment, each patient will receive 4 daily doses of VAL-413 and one daily dose of the intravenous preparation of irinotecan taken orally (IRN-IVPO). During all subsequent cycles, only VAL-413 will be given with temozolomide in 5-day courses administered every 21 days, as tolerated. Outcome Measures: Toxicity is assessed by NCI CCTCAEv5; tumor response is assessed by RECIST 1.1. A palatability survey instrument will assess palatability of VAL-413 vs. IRN-IVPO; comparative intra-patient pharmacokinetics of irinotecan and its metabolites will be assessed. This trial is ongoing (CT.gov: NCT04337177), with no DLT observed to date. Clinical trial information: NCT04337177. Research Sponsor: Valent Technologies LLC; Edison Oncology Holding Corp.

Oral Abstract Session

Germline genetic testing use and results after a cancer diagnosis. *First Author: Allison W. Kurian, Stanford Cancer Institute, Stanford University School of Medicine, Stanford, CA*

Background: Germline genetic testing is increasingly essential for cancer prevention and treatment. There is a growing call for universal germline testing after a cancer diagnosis. In this evolving context, little is known about genetic testing use and results across cancer types at the population level. **Methods:** All patients aged ≥ 20 years, diagnosed with any cancer type and reported to statewide Surveillance Epidemiology and End Results (SEER) registries in Georgia and California from 2013-2019, were linked to 2013-2021 results from four laboratories providing nearly all germline testing in these regions. Testing use was evaluated in patients diagnosed with all cancer types reported by SEER. Pathogenic variant (PV) and variant of uncertain significance (VUS-only) results were evaluated across cancer types. Tested genes were grouped by major cancer associations and by clinical guidelines for testing and results management after a cancer diagnosis, as follows: breast/ovarian including *BRCA1/2*; gastrointestinal including the Lynch syndrome genes (*MLH1*, *MSH2*, *MSH6*, *PMS2*, *EPCAM*); other hereditary cancer syndromes; and preliminary evidence genes with no clinical guidelines. Genetic testing trends were analyzed with logistic regression modeling. **Results:** Among 1,369,660 patients, 6.8% linked to genetic testing results. Genetic testing use was highest among patients with male breast cancer (50.0%), followed by ovarian cancer (38.6%), female breast cancer (26%), multiple primary cancers (7.5%), endometrial cancer (6.4%), pancreatic cancer (5.6%), colorectal cancer (5.6%), prostate cancer (1.1%) and lung cancer (0.3%). Genetic testing use increased over time, notably ten-fold for pancreatic cancer (2013 diagnoses, 1.2%; 2019 diagnoses, 18.6%). Most (67.5-89.6%) of identified PVs were in genes with clinical guidelines for testing and management, and had an established association with the patient's cancer type (breast/ovarian including *BRCA1/2*: 79.5% of PVs in patients with female breast cancer, 83.8% in patients with male breast cancer, 82.0% in patients with ovarian cancer; gastrointestinal including Lynch syndrome genes: 68.3% of PVs in patients with colorectal cancer, 71.8% in patients with endometrial cancer). Preliminary evidence genes comprised 5.1%-28.1% of PVs detected across cancer types. Compared to non-Hispanic Whites (NHW), patients from other racial/ethnic groups received less testing (Black, odds ratio (OR) 0.58, 95% confidence interval (CI) 0.55-0.63; Hispanic, OR 0.62, CI 0.58-0.66; Asian OR 0.71, CI 0.58-0.66) without improvement over time, and more VUS-only results (NHW, 24.9%; Black 39.0%; Asian, 40.0%), a difference which increased over time. **Conclusions:** At the population level, germline testing use is low across cancer types, falling short of guidelines. Racial/ethnic disparities in testing use and clarity of test results persisted over time. These gaps are priorities for intervention. Research Sponsor: U.S. National Institutes of Health; Centers for Disease Control.

Oral Abstract Session

Incidence round screening performance among women with dense breasts undergoing abbreviated breast MRI and digital breast tomosynthesis (ECOG-ACRIN EA1141). *First Author: Christiane K. Kuhl, Rheinisch-Westfälische Technische Hochschule Aachen, Aachen, Germany*

Background: The sensitivity of mammography, including digital breast tomosynthesis (DBT), is limited by breast density. Abbreviated breast MRI (AB-MR) significantly increases breast cancer detection in women with dense breasts. In the prevalence (baseline) screening round of the EA1141 trial, AB-MR offered a 2.45-fold higher cancer detection rate (CDR) than DBT. Here we report the CDR and diagnostic accuracies of AB-MR and DBT during the EA1141 incidence screening round and the overall interval cancer rate. **Methods:** Informed consent was obtained from all participants. Asymptomatic average risk women aged 40-75 years with mammographically dense breasts scheduled for routine screening with DBT were enrolled. All women underwent DBT and AB-MR at baseline (prevalence) and year 1 (incidence) screens which were interpreted independently by 2 different radiologists blinded to the other modality. Women were contacted 11-13 months after the year 1 screen to assess for a subsequent breast cancer diagnosis. Pathology of biopsy was the reference standard for CDR and positive predictive value of biopsy (PPV3). Interval cancers reported during 11-13 months of follow-up until the next annual screening were included in the reference standard for sensitivity and specificity. A post hoc adjustment was made for multiple testing using the Bonferroni method; p-values are reported for comparisons which met the adjusted significance threshold (0.05/5 = 0.01). Reported 95% confidence intervals were not adjusted for multiplicity. **Results:** Of 1516 enrolled subjects, 1444 completed the baseline and 1291 also the incidence screen. During the latter, 9 women were diagnosed with breast cancer. DBT detected cancer in 5 women (3 DCIS, 2 invasive) for a CDR of 3.9/1000 (5/1291, CI 1.7, 9.0). AB-MR detected cancer in 6 women (0 DCIS, 6 invasive), 4 of which were not detected on DBT, for a CDR of 4.6/1000 (6/1291, CI 2.1, 10.1). The additional imaging (subject-level) rate for DBT was 7.9% (102/1291, CI 6.6%, 9.5%) vs 3.7% (48/1291, CI 2.8%, 4.9%) for AB-MR ($p < 0.001$). The PPV3 (lesion-level) for DBT was 29.4% (5/17, CI 13.5%, 52.6%) and 15.0% (6/40, CI 6.9%, 29.6%) for AB-MR. During the 2 years of study screening (baseline and year 1), there was 1 interval cancer (palpable lump 348 days after year 1 screen), for an overall interval cancer rate of 0.37/1000 person-years (1/2677 person-years, CI 0.05, 2.65). Sensitivity and specificity were 50.0% (5/10, CI 23.7%, 76.3%) and 98.5% (1261/1280, CI 97.7%, 99.0%) for DBT vs 60% (6/10, CI 31.3%, 83.2%) and 93.3% (1193/1278, CI 91.8%, 94.6%, $p < 0.001$) for AB-MR. **Conclusions:** On the incidence screening round, AB-MR detected additional invasive breast cancers not seen on DBT. In addition, a low overall interval cancer rate was observed with combined screening. Although the need for additional imaging was lower for AB-MR, specificity was higher for DBT. Clinical trial information: NCT02933489. Research Sponsor: U.S. National Institutes of Health; Bracco Diagnostics, Monroe/NJ.

Oral Abstract Session

Breast cancer risk associated with missense variants in *BRCA2*. *First Author: Siddhartha Yadav, Mayo Clinic, Rochester, MN*

Background: Greater than 90% of missense variants in *BRCA2* are classified as variants of uncertain significance (VUS). In addition, among the few known missense pathogenic variants (PVs) in *BRCA2*, breast cancer risk has been reported to be lower compared to pathogenic truncating variants (PTVs) (Li et al., 2022). Herein, we aim to reclassify several missense variants in *BRCA2* and investigate the associated breast cancer risk. **Methods:** A total of 450 *BRCA2* missense variants in the C-terminal DNA binding domain (DBD) were evaluated for functional effect utilizing a previously validated homology-directed DNA double-strand repair (HDR) assay. The results of the functional evaluation along with clinical, structural, and in-silico data were applied to the rules-based ACMG/AMP criteria for variant classification to identify pathogenic/likely pathogenic (P/LP) variants and benign/likely benign (B/LB) variants. A pooled case-control analysis was performed comparing the frequency of reclassified P/LP missense variants among 82,372 women with breast cancer within the Ambry Genetics database as cases and 174,167 unaffected women within gnomAD, CARRIERS, and BRIDGES datasets as controls to evaluate associated breast cancer risk. Separate case-control analysis and comparisons with *BRCA2* DBD PTVs, exon 11 PTVs, and known missense PV standards in ENIGMA were also performed. **Results:** From the 450 missense variants in the DBD, 137 (30.4%) were noted to be functionally deleterious and 313 (69.6%) were functionally neutral by the HDR assay. Incorporation of the functional and other data into an ACMG/AMP model led to the reclassification of 439 (97.6%) variants, with 131 as P/LP and 308 as B/LB variants. In a pooled case-control analysis, reclassified *BRCA2* missense P/LP variants were associated with clinically significant increased risks of breast cancer (Odds Ratio (OR): 5.6, 95%CI: 3.9-8.0), whereas B/LB missense variants were not (OR: 1.1, 95%CI: 1.1-1.2). Similarly elevated risks of breast cancer were observed for *BRCA2* PTVs in the DBD (OR: 6.8, 95%CI: 5.1-9.0) and missense PV standards in ENIGMA (OR: 7.8, 95%CI: 4.1-14.7). However, PTVs in exon 11 of *BRCA2* were associated with a lower risk of breast cancer (OR: 4.4, 95%CI: 3.8-4.9) compared to PTVs in DBD, confirming the ovarian cancer cluster region effect in *BRCA2*. **Conclusions:** The study demonstrates that the HDR functional assay in conjunction with other clinical and genomic data can be a powerful tool that can aid in the reclassification of $> 95\%$ of missense variants in *BRCA2*. In addition, missense PVs in DBD were noted to have a similarly elevated risk of breast cancer as PTVs. The reclassification of the *BRCA2* missense VUS and identification of associated breast cancer risk in this study will significantly influence breast cancer risk assessment and management strategies among carriers of these missense variants. Oral Abstract Session

Second primary breast cancer in young breast cancer survivors. *First Author: Kristen D Brantley, Harvard School of Public Health, Boston, MA*

Background: Prior data suggests that the risk of second primary breast cancer (SPBC) is higher among women diagnosed with primary breast cancer (BC) before age 40. There is evidence that risk differs by primary tumor characteristics, cancer treatments, and genetic predisposition. However, studies investigating risk of SPBC by clinical risk factors are often limited by low numbers of young women and lack of complete patient data, particularly regarding germline genetic risk. **Methods:** Using the Young Women's BC Study (YWS), a prospective cohort of 1,302 women ≤ 40 years diagnosed with BC from 2006-2016, we sought to compare clinical and treatment characteristics among women who developed an SPBC vs. those who did not. The analytic cohort included women diagnosed with Stage 0-III BC who did not undergo bilateral mastectomy ($N = 685$). Demographics, genetic testing and results, clinical events, and treatment data were collected through self-report on baseline and follow-up surveys (every 6 months for 3 years, then annually). Detailed tumor and treatment information, confirmation of genetic testing results, and new and recurrent cancer events were obtained through regular and triggered medical record review. Univariate and multivariate Cox proportional hazards models were used to examine associations of age, race, genetic testing results, hormone receptor status, stage, and grade of primary tumor, and cancer treatments with SPBC. Participants were censored at the time of local recurrence, metastasis, death, or loss of follow-up. **Results:** At a median follow-up time of 9.9 years [inter-quartile range (IQR) = 6.6-12.0 y], 17 patients developed an SPBC (2.5%), in whom 3 occurred in the ipsilateral breast after lumpectomy as primary BC surgery. Median time from primary BC diagnosis to SPBC diagnosis was 4.2 years (IQR = 3.3-5.6 y). Compared to those who did not develop an SPBC, a greater percentage of women who developed an SPBC had *in situ* disease as their primary BC (24% v. 6%) and were of Ashkenazi descent (12% v. 5%). In the 577 women who had had genetic testing, 544 (94%) were non-carriers of pathogenic variants. Risk of SPBC was 2.2% ($N = 12$) in non-carriers and 9.1% ($N = 3$) in the 33 carriers. In Cox univariate analyses, carriers had a 4.1 times higher risk of SPBC compared to non-carriers (HR = 4.14, 95% confidence interval (CI) = 1.67-14.66, $p = 0.03$), and primary diagnosis with *in situ* BC was associated with a 5-fold increased risk of SPBC (HR = 5.02, 95% CI = 1.63-15.41, $p = 0.005$). Both factors remained strongly associated with SPBC when tested together in a multivariate model. **Conclusions:** This prospective study demonstrated a low risk of SPBC in the first 10 years after diagnosis of early BC in young women who are not germline pathogenic variant carriers. The finding that risk of SPBC was higher after *in situ* primary BC at a young age warrants further investigation. These findings have important implications for the treatment and follow-up care of young women with BC. Research Sponsor: Susan G. Komen; Breast Cancer Research Foundation.

Oral Abstract Session

Ancestry-adjusted genomic analysis to identify known and novel associations with single and multiple cancer phenotypes. *First Author: Vijai Joseph, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Germline cancer risks are impacted by cancer type, stage, specific mutation, and ancestry. This study aims to determine the magnitude of genetic risks for commonly tested genes across patients with single and multiple primary cancers (MPC). **Methods:** We conducted a partially de-identified, retrospective cohort study of all patients consented to using the MSK-IMPACT, a matched tumor-normal sequencing assay, over a five-year period. Approximately 83% of IMPACT testing is derived from patients with metastatic disease. We collected data on demographics and clinical cancer features through cBioPortal and institutional databases. MPC were classified based on the IARC guidelines. Clinically actionable, pathogenic variants in cases and gnomAD non-cancer controls were identified using PathoMAN. Statistical methods incorporated ancestry adjusted, weighted generalized linear model, and ancestry specific methods to estimate risk. Biallelic losses were analyzed from paired tumors. **Results:** We analyzed 28,000 individuals across 35 cancer types, where germline variants were discovered within 100 cancer predisposition genes. 16% carried pathogenic, clinically actionable variants in known and novel cancer predisposition genes (15% in those with single primary and 21% in MPC). We discovered statistically significant novel associations of germline variants with several cancer phenotypes, including *BRCA2* and biliary cancer (OR = 4.5, CI = 2.2-8); *ATM* and *BRCA2* with mesothelioma (OR = 4.8, CI = 2.1-9.2; OR = 8, CI = 3.1-16.6, respectively); *NF1* and breast cancer (OR = 5.8, CI = 2.4-12.1); *NBN* and lung cancer (OR = 4.2, CI = 2.3-6.9), bladder with *ATR* and others. We replicated known associations and discovered pleiotropy of *BRCA1/2*, *NF1*, *ATM*, *TP53* with several cancer types. We failed to replicate reported associations such as *PALB2* and ovarian cancer and *CHEK2* and colon cancer. Amongst cancer pairs of multiple primaries, we observed mismatch repair genes *MSH2*, *MSH6* and *MLH1* to be associated with increased risks for stomach, bowel, and uterine cancer pairs, and *TP53* in breast MPC compared to breast single primaries. **Conclusions:** An ancestry adjusted, weighted analysis of a large real-world case-cohort enriched with metastatic disease did not confirm some prior genotype-phenotype correlations, while suggesting novel associations with hereditary cancer types. Oral Abstract Session

Integrating polygenic risk scores into clinical breast cancer models: Influence on prediction in diverse cohorts. *First Author: George B.J. Busby, Allelica Inc, Oxford, United Kingdom*

Background: Breast cancer (BC) is the second leading cause of cancer death in women worldwide. Periodic mammography screening has been shown to reduce breast cancer mortality by around 20% in average-risk women and several BC risk models are currently used to identify women at higher risk who can be targeted with increased or earlier screening. However, despite their broad use, these models display only moderate discrimination performance (AUC ranging between 0.51 to 0.68). Here we explore the potential of integrating PRS into a BC risk model using a testing dataset comprising over 175,000 women of diverse ancestry in the UK Biobank and Women Health's Initiative Cohorts. **Methods:** We built and validated novel ancestry-specific BC PRSs utilizing novel methodology that leverage multiple Genome Wide Association Studies (GWASs) and linkage disequilibrium maps. We assessed genetic ancestry from 5 continental level ancestry groups across all individuals and applied the PRSs to our testing dataset to assess the clinical implications of integrating genetic information to the Tyrer-Cuzick (TC) breast cancer clinical risk model. **Results:** The PRSs were well calibrated and displayed high risk stratification (Odds Ratios per Standard Deviation: 1.41 (1.28-1.62) to 1.76 (1.40-2.20; Table) which were comparable or better than benchmarking comparisons with previously published PRS panels. Across genetic ancestries, integrating PRS led to a relative increase of women identified at high lifetime BC risk (20% or higher) from between 1.7 fold (East-Asian ancestry) to around 3 fold (European ancestry). The Net Reclassification Improvement compared to the TC-only model was around 12% for East-Asian (0.001-0.254), European (0.111-0.133), and Admixed American ancestries (0.002-0.228), 17% (0.079-0.266) for South-Asians, and 5% (0.008-0.094) for African ancestry individuals (Table). **Conclusions:** Our results demonstrate that optimizing PRSs for genetic ancestries and integrating them into BC risk models can lead to a significant improvement in risk stratification. This can enable more targeted use of enhanced screening and prevention strategies improving their cost/benefit ratio. Research Sponsor: Allelica Inc.

Oral Abstract Session

Polygenic risk score calibration and association with breast cancer in diverse ancestries. *First Author: Matthew Kucera, Myriad Genetics, Inc., Salt Lake City, UT*

Background: Polygenic risk scores (PRS) have been shown to substantially improve breast cancer (BC) risk prediction when incorporated into traditional risk assessment models. However, PRS developed primarily in women of European ancestry have shown poor performance when applied to non-European populations. We previously described development and validation of a multiple-ancestry PRS (MA-PRS) that is based on individual ancestral genetic composition. MA-PRS has been incorporated into the Tyrer-Cuzick model for use in clinical practice and has been shown to provide independent value to the model. Here, we describe performance of the MA-PRS in a large cohort of women from diverse ancestral backgrounds. **Methods:** The study cohort included 203,586 patients who were referred for hereditary cancer testing and negative for pathogenic variants in genes associated with BC. MA-PRS was calculated as previously described based on 149 SNPs (93 BC and 56 ancestry-informative). Association of MA-PRS with invasive BC status (affected vs unaffected) was analyzed using logistic regression adjusted for personal and family cancer history, age, and ancestry. Calibration was assessed by examining the MA-PRS distribution within unaffected patients, and through goodness-of-fit tests. All analyses were conducted within the full cohort and within ancestral subpopulations. Odds ratios (ORs) are reported per standard deviation. **Results:** One-fifth (43,782/203,586, 21.5%) of patients were diagnosed with invasive BC, and 60,657 (29.8%) of patients reported BC in a first degree relative. The MA-PRS distribution was centered around zero among unaffected patients overall and within each subpopulation. MA-PRS significantly improved BC risk prediction over clinical factors in the full cohort (OR = 1.43, 95% CI: 1.41-1.44) and within each ancestral subpopulation (Table). The strongest associations were observed in Ashkenazi Jewish (OR = 1.56, 95% CI: 1.39-1.76) and South Asian (OR = 1.49, 95% CI: 1.23-1.81) populations. The top decile of the MA-PRS consistently identified patients with two-fold increased risk of developing BC. Goodness-of-fit tests showed that the MA-PRS was well calibrated and predicted BC risk accurately in the tails of the distribution for both European and non-European women. **Conclusions:** The breast cancer MA-PRS based on genetic ancestral composition is well-calibrated and strongly associated with BC in all tested ancestral populations. Incorporation of PRS adds independent information to risk models and supports equitable access to personalized BC risk management. Research Sponsor: Myriad Genetics, Inc.

Population	Total Patients	OR	95% CI

Oral Abstract Session

Whole exome sequencing and machine learning germline analysis of individuals presenting with phenotypes of extreme high and low risk of developing tobacco-induced lung adenocarcinoma. *First Author: Jose Luis Perez-Gracia, Department of Oncology, Clinica Universidad de Navarra, Pamplona, Spain*

Background: Tobacco is the main risk factor for developing lung cancer. Yet, while some heavy smokers develop lung cancer at young age others never develop it, even at advanced age. This suggests a remarkable variability in the individual susceptibility to the carcinogenic effects of tobacco. We characterized the germline profile of subjects presenting these extreme phenotypes with Whole Exome Sequencing (WES) and Machine Learning (ML). **Methods:** We sequenced germline DNA from heavy smokers who either developed lung adenocarcinoma at early age (*extreme cases*) or did not develop it at advanced age (*extreme controls*). The discovery and validation cohorts included respectively 50 and 66 extreme cases and 50 and 83 extreme controls, selected from databases including > 6,000 subjects. We selected individual coding variants and variant-rich genes showing a significantly different distribution between extreme cases and controls. We trained ML models (Logistic Regression, Random Forest, Support Vector machine Classifier (SVC)) on the discovery cohort to classify subjects into their respective phenotypes and tested them on the validation cohort. **Results:** Mean age for extreme cases and controls in both cohorts was 50.2 and 78.4 years. Mean tobacco consumption was 38.1 and 59.1 pack-years. We validated 16 significant individual variants. The most significant variants were in *ADAMTS7* (2 variants) in cases and *TMEM191B* (1) in controls. We validated 33 genes enriched with significant variants. The genes harboring more variants were *HLA-A* (4 variants) and *ADAMTS7* (2) in cases; and *PLIN4* (2) in controls (Table). We trained several ML models on the discovery cohort using as input the 16 significant individual variants and the number of variants in the 33 enriched genes. We tested them in the validation cohort obtaining accuracy of 72% and AUC-ROC of 87.4% with the best model (SVC), using 16 variants as input, confirming their association with the phenotypes. Functions of validated genes included oncogenes, tumor-suppressors, DNA repair, maintenance of genomic stability, HLA mediated antigen presentation and regulation of proliferation, migration, apoptosis and inflammatory pathways. **Conclusions:** Individuals presenting phenotypes of extreme high and low risk of developing tobacco-induced lung adenocarcinoma have different germline profiles. Our strategy may allow to identify high-risk subjects and to develop new therapeutic approaches. Research Sponsor: Spanish Society of Medical Oncology, Fundación SEOM and Fundación Salud 2000.

Oral Abstract Session

Lung cancer metabolomics: A pooled analysis in the cancer prevention studies. First Author: Ziyin Tang, Emory University, Atlanta, GA

Background: Lung cancer is a heterogeneous disease, often diagnosed at advanced stages, with low overall survival rate. To better understand the lung cancer etiology and discover screening and early detection biomarkers, we performed a nested case-control study to examine the metabolic perturbation related to lung cancer. **Methods:** This study included 741 case-control pairs (mean age = 67 years) from the ongoing Cancer Prevention Study (CPS) cohorts. Participants completed a comprehensive exposure and health questionnaire at enrollment. Pre-diagnosis blood samples were collected between 1998-2001 in CPS-II and 2006-2013 in CPS-3. Cases and controls were 1:1 matched on date of birth, blood draw date, gender, and race/ethnicity. All eligible controls were cancer-free at the time of case diagnosis. Odds ratios (ORs) per standard deviation and 95% confidence intervals (CIs) were estimated using conditional logistic regression, controlling for potential confounders including body mass index, fruit and vegetable consumption, smoking status, and hormone use. We further performed stratified analyses by smoking status (never/former/current) and follow-up time (i.e., within 3 years/ beyond 3 years between blood draw and diagnosis). Statistical significance was determined as false discovery rate (FDR) < 0.2. **Results:** Sphingomyelin (d18:0/22:0), a bioactive sphingolipid of cell membranes, was associated with lung cancer risk (OR:1.32, 95% CI: 1.15, 1.53), FDR = 0.12). When stratified by follow-up time, participants diagnosed within 3 years of blood draw had a 59% higher risk of lung cancer per standard deviation increase in sphingomyelin (d18:0/22:0) (OR:1.58, 95% CI: 1.16, 2.15, $p = 0.004$) and 25% higher risk for those diagnosed beyond 3 years (OR:1.27, 95% CI: 1.08, 1.50, $p = 0.005$). Metabolites associated with lung cancer at raw p -value < 0.05 indicated the perturbation mostly in lipid, amino acid, and xenobiotics metabolism. We observed variants in perturbed metabolic pathways between never-smoker lung cancer cases and current-smoker lung cancer cases. **Conclusions:** This is the largest prospective study examining lung cancer risk and metabolic response using an untargeted metabolomics platform. These findings provide preliminary support for sphingomyelin (d18:0/22:0) as a potential screening and early detection biomarker for lung cancer. Results also highlight that lipid metabolism including sphingolipid and bile acid metabolism may play an important role in lung cancer etiology. Clinical Science Symposium

Redefining early-onset cancer and risk of hereditary cancer predisposition. First Author: Zsafia Kinga Stadler, Memorial Sloan Kettering Cancer Center, New York, NY

Background: For most solid tumors, early age of onset, a marker for potential increased inherited risk, has been arbitrarily defined as a diagnosis of cancer at age < 50. However, this disregards the variation in mean age of diagnoses across solid tumors resulting in the potential misclassification of patients at increased risk of germline alterations. **Methods:** 25,305 prospectively ascertained cancer patients, representing 32 solid tumor types, underwent sequencing analysis of up to 90 cancer predisposition genes using next-generation genetic analysis with reporting of germline likely pathogenic (LP) and pathogenic variants (P). Mean age of diagnosis by cancer type, with standard deviations (STD), were calculated according to Surveillance, Epidemiology, and End Results Program (SEER) data. Early-onset (EO-CA), average-onset (AO-CA), and late-onset (LO-CA) cancers were defined as cancers diagnosed < -1 STD, -1 < STD > 1, and > 1 STD around the mean age at diagnosis for the specific cancer type, respectively. Prevalence of LP/P variants was classified according to age of onset. Statistical analyses were performed using STATA. **Results:** Among 25,305 patients with 32 solid tumor types classified as per SEER data, 31% ($n = 7,854$) of patients were categorized as having EO-CA. Overall prevalence of germline alterations varied as a function of age at diagnosis with 19.2% ($n = 1509$), 15.9% ($n = 2588/16,299$), and 12.9% (149/1152) of EO-CA, AO-CA, and LO-CA patients harboring a germline LP/P variant ($p < 0.0001$). The enrichment of variants in EO-CAs was driven by high- and moderate-penetrance genes with 13.2%, 9.2% and 5.1% of EO-CA, AO-CA, and LO-CA patients having an LP/P variant ($p < 0.0001$); low-penetrance germline alterations were static across the age groups (6%, 6.7%, 7.8%). An age cutoff of 50 for early-onset cancer was > 1 STD below the mean age at diagnosis in 20 cancer types resulting in 2,226 patients who would not have been classified as having EO-CA inclusive of 394 patients who tested positive for a germline LP/P, representing 26.1% of all germline EO-CA positives. **Conclusions:** Early-onset cancer should be defined taking into consideration the mean age at diagnosis for a specific cancer type as an arbitrary cutoff of age < 50 misses over 25% of patients with an inherited cancer predisposition syndrome. Due to the high prevalence of inherited predisposition syndromes, genetic testing of all patients with EO-CA, irrespective of tumor type, is warranted. Clinical Science Symposium

Effect of germline mutations on somatic alteration landscapes in BRCA-associated cancers. First Author: Ali Arafa, University of Minnesota, Minneapolis, MN

Background: The interaction between germline alterations in homologous recombination repair (gHRR) genes and tumoral genomic landscapes is poorly understood. We hypothesized that gHRR alterations may influence somatic mutational landscapes in BRCA-associated cancers. **Methods:** Using a large de-identified real-world dataset of patients undergoing matched tumor/normal next-generation DNA sequencing (Tempus xT), we compared somatic genomic landscapes of tumors arising in individuals with germline HRR mutations (gBRCA1, gBRCA2, gPALB2, gATM, gCHEK2) versus their sporadic counterparts, across four BRCA-associated cancers (breast, ovary, pancreas, prostate). **Results:** In breast cancer ($N = 6955$; gHRR-altered 5.9%, sporadic 94.1%), somatic TP53 muts were enriched in gBRCA1 pts, and depleted in gATM and gCHEK2 pts (all $P < 0.001$). ESR1 muts were depleted in gBRCA1 pts, and enriched in gATM and gCHEK2 pts (all $P < 0.05$). PIK3CA muts were depleted in gBRCA1/2 pts, and enriched in gATM and gCHEK2 pts (all $P < 0.05$). FGFR1 muts were depleted in gBRCA1/2 and gPALB2 pts, and enriched in gATM pts (all $P < 0.01$). HER2 and CDH1 alterations were depleted in gBRCA1 pts ($P < 0.05$). In ovarian cancer ($N = 4244$; gHRR-altered 6.2%, sporadic 93.8%), somatic TP53 muts were enriched in gBRCA1/2 pts, and depleted in gATM and gCHEK2 pts (all $P < 0.05$). ESR1 muts were enriched in gATM pts ($P < 0.001$). PIK3CA muts were depleted in gBRCA1/2 pts, and enriched in gATM pts (all $P < 0.05$). KRAS muts were depleted in gBRCA1/2 pts ($P < 0.05$). In pancreatic cancer ($N = 5386$; gHRR-altered 3.9%, sporadic 96.1%), somatic TP53 muts were enriched in gBRCA1 pts, and depleted in gATM and gPALB2 pts (all $P < 0.05$). KRAS muts were enriched in gBRCA1/2 and gATM pts ($P < 0.05$). Unexpectedly, ESR1 muts were enriched in gPALB2 and gCHEK2 pts ($P < 0.05$). In prostate cancer ($N = 4378$; gHRR-altered 4.5%, sporadic 95.5%), somatic TP53 muts trended higher in gBRCA1 pts, and lower in gATM and gPALB2 pts ($P = NS$). TMPRSS2-ERG fusions were depleted in gBRCA1 and gBRCA2 pts ($P < 0.05$). FOXA1 muts were enriched in gBRCA2 pts ($P < 0.05$), while BRAF and CDK12 muts were enriched in gCHEK2 pts ($P < 0.05$ and $P = 0.07$). Median TMB was higher in BRCA-associated cancers with gBRCA1/2 and gPALB2 muts relative to sporadic cancers (all $P < 0.05$), but not in pts with gATM or gCHEK2 muts. There were no differences in MMR mutations or MSI status. **Conclusions:** Across four BRCA-associated cancers, TP53 muts are enriched in BRCA1 pts and depleted in gATM pts. In breast/ovarian cancers, PIK3CA muts are depleted in gBRCA1/2 pts, while ESR1 muts are enriched in gATM pts. KRAS muts are enriched in gBRCA1/2-altered pancreas cancers, but are depleted in gBRCA1/2-altered ovarian cancers. gBRCA2-altered prostate cancers are enriched in FOXA1 muts, and depleted in ERG fusions. These data suggest that gHRR-mutated cancers have distinct genomic landscapes compared to their sporadic counterparts; this may influence therapeutic considerations. Research Sponsor: None.

Clinical Science Symposium

POT1 germline pathogenic variants and evolving understanding of tumor spectrum: Evidence for lung cancer predisposition. First Author: Michael Francis Walsh, Memorial Sloan Kettering Cancer Center, New York, NY

Background: As a critical component of the shelterin complex, the protection of telomeres 1 protein (POT1) plays important roles in telomere length regulation and tumorigenesis. POT1 germline pathogenic/likely pathogenic variants (PVs) have been primarily linked to the development of melanoma, chronic lymphocytic leukemia, and glioma. Recent studies report POT1 PVs also predispose to other tumors such as certain sarcomas and thyroid cancer. **Methods:** To better understand the role of POT1 in the development of solid tumors, we explored the spectrum of POT1 germline variants in 6644 patients with POT1 sequencing performed utilizing the MSK-IMPACT assay. **Results:** In total, 91 POT1 germline rare variants (population frequency < 0.01%) were identified in our cohort in 90 patients across 47 cancer types. We found 16 POT1 PVs including frameshift variants (p.Ile49fs, p.Gln358fs, p.Asp617fs), a nonsense variant (p.Arg363Ter), a missense variant (p.Asp224Asn), and splice site variants (c.10-2A > C, c.1369+1G > T). One cutaneous melanoma patient, one uveal melanoma patient, and one glioma patient were identified to have POT1 PVs. Interestingly, 8 patients with germline POT1 PVs were diagnosed with lung cancer (7 with lung adenocarcinoma and one with small cell lung cancer). Three of these 7 patients with lung adenocarcinoma had biallelic inactivation of POT1 in their tumor. The proportions of POT1 PVs in MSK lung adenocarcinoma compared to the gnomAD non-cancer control cohort were statistically significantly different (odds ratio = 16.28, 95%CI = 6.52-33.54, $P = 2.87e-06$). Moreover, of the 90 patients with rare germline POT1 variants, 22 had POT1 biallelic inactivation, and 9 of these 22 were diagnosed with lung adenocarcinoma. **Conclusions:** Taken together, our study refines the role of POT1 germline variants in solid tumors and highlights an apparent association of POT1 PVs with lung adenocarcinoma development. Clinical Science Symposium

Germline alterations in patients with lung cancer. *First Author: Ramaswamy Govindan, Washington University School of Medicine, St. Louis, MO*

Background: Despite extensive knowledge about genomic alterations in tumor cells, less is known about germline alterations in patients with lung cancer. In this study, we explore the association between germline alterations in cancer-predisposing genes across lung cancer patients with different tumor histologies and smoking status. **Methods:** To compare the alterations in cancer-predisposing genes through germline profiling, we analyzed 11,740 tumors from primary Lung patients (any stage/ subtype) sequenced with Tempus xT tumor/normal matched assay (DNA-seq of 648 genes at 500x coverage, full transcriptome RNA-seq). Prevalence of pathogenic/likely pathogenic (P/LP) germline alterations in 46 genes was compared between smokers and non-smokers, non-smoker somatic *EGFR* altered (sEGFRalt) and non-smoker somatic *EGFR* wild-type (sEGFRwt), non-small cell lung histology (NSCLC) and small cell histology (SCLC), and lastly NSCLC sEGFRalt and NSCLC sEGFRwt. Due to the low prevalence of germline, most differences were insignificant, although statistics of interest are reported. **Results:** Of 10,419 lung cancer patients with known smoking status (89%) 8845 were smokers and 1574 non-smokers. *MUTYH* germline alterations were detected in 1.3% vs. 1.1%, *ATM* 0.7% vs. 1.0%, and *EGFR* < 0.1% vs. 0.4% in smokers and non-smokers with lung cancer respectively. Among non-smokers, 549 were sEGFRalt and 1025 were sEGFRwt. *MUTYH* germline alterations were detected in 1.1% non-smoker sEGFRalt vs. 1.1% non-smoker sEGFRwt, *ATM* 0.7% vs. 1.1%, and *EGFR* 1.1% vs. 0%. Germline *EGFR* was significant after FDR adjustment ($q < 0.037$). There were 10115 patients identified with NSCLC histology and 595 with SCLC histology. *MUTYH* germline alterations were detected in 1.3% NSCLC vs. 0.3% SCLC, *ATM* 0.8% vs. 0.3%, and *BRCA2* 0.7% vs. 0%. Of note, SCLC was more likely to be smokers than NSCLC (93% vs. 85%, $p < 0.001$). Among NSCLC, 1,141 were sEGFRalt and 8,974 were sEGFRwt. *MUTYH* germline alterations were detected in 1.6% NSCLC sEGFRalt vs. 1.3% NSCLC sEGFRwt, *ATM* 0.5% vs. 0.8%, *EGFR* 1.3% vs. 0%, and *BRCA2* 0.8% vs. 0.6%. Germline *EGFR* was significant after FDR adjustment ($q < 0.001$). A separate analysis of the United Kingdom Biobank data found the prevalence of P/LP germline alterations in the same 46 genes in 4.3% of 1132 smokers with lung cancer and 5.1% in 198 never-smokers with lung cancer. The most common germline alterations involved *ATM* (0.8%), *BRCA 2* (0.79%), *MUTYH* (0.62%) among smokers and *MUTYH* (1.5%), and *CHEK2* (1.01%) among non-smokers. **Conclusions:** Currently, there are no standard guidelines for germline analysis for patients with lung cancer. The Tempus database enables the identification of pathogenic or likely pathogenic germline alterations in a variety of lung cancer subtypes along with their distribution frequency among various groups. The findings suggest that germline P/LP alterations in the select panel of 46 genes occur infrequently across subgroups of lung cancer. Research Sponsor: Tempus.

Poster Discussion Session

Lorpicutinin (JNJ-64251330) in patients with familial adenomatous polyposis (FAP): Results from a phase 1b study. *First Author: Robert Hüneburg, Department of Internal Medicine I, University Hospital Bonn, Bonn, Germany; National Center for Hereditary Tumor Syndromes, University Hospital Bonn, Bonn, Germany*

Background: FAP is the most common hereditary adenomatous polyposis syndrome and, if left untreated, will lead to colorectal cancer development in nearly all patients. Chronic inflammation, driven in part by the Janus kinase (JAK)/signal transducer and activator of transcription (STAT) pathway, may promote polyp formation. Enteric-selective inhibition of the JAK/STAT pathway may provide a treatment for FAP. Lorpicutinin is an oral, small molecule, potent pan-JAK inhibitor with favorable enteric-selective properties. Here, we report the efficacy, safety, and pharmacokinetic (PK) results from a phase 1b study of lorpicutinin in patients with FAP (NCT05014360). **Methods:** Patients aged ≥ 18 years with ≥ 6 polyps ≥ 2 mm in diameter in the rectum or colon with FAP (*APC* germline mutation or obligate carrier) received lorpicutinin 75 mg twice daily for 24 weeks. The primary objective was to evaluate the effect of lorpicutinin on colorectal polyp burden at Week 24, assessed by endoscopy at baseline and Week 24. Secondary objectives were safety, PK, and biomarker assessments of lorpicutinin activity. **Results:** Overall, 42 (23 pre-colectomy; 19 post-colectomy) patients with FAP were enrolled, with a median age of 33 (range, 19-61) years. No clear effect on polyp burden was observed at Week 24. Gut mucosal and polyp concentrations of lorpicutinin were much higher than plasma concentrations, indicating an enteric-selective distribution. Mean sigmoid colon, rectum, and polyp concentrations of lorpicutinin at Week 8 were 112-, 473-, and 108-fold higher, respectively, than the observed maximum plasma concentration at Week 8 (1 hour). At Week 8, lorpicutinin achieved JAK tyrosine kinase inhibition in mucosal biopsies as evidenced by a median 37% reduction in normalized pSTAT-3 levels. Lorpicutinin reduced serum-based inflammatory biomarkers such as C-reactive protein and serum amyloid A by Week 16 of therapy. Some patients reported an improvement of clinical symptoms such as less frequent bowel movements and less blood in the stool. The most common adverse events (AEs) were abdominal pain (16%), bilirubin increased (13%), headache (13%), lipase increased (13%), and diarrhea (13%). There were no treatment-related serious AEs, grade 3 treatment-emergent AEs, serious infections, or venous thromboembolisms. **Conclusions:** These results show that lorpicutinin had no clear effect on polyp burden. The study found that lorpicutinin is safe and exhibits an enteric-selective distribution in FAP patients. Inhibition of JAK tyrosine kinase signaling was associated with reduced STAT-3 phosphorylation in mucosal biopsies from FAP patients. While reductions observed in polyp burden were not clinically significant, lorpicutinin treatment lowered levels of several serum inflammatory biomarkers. Treatment with lorpicutinin was safe and well tolerated, and may improve clinical symptoms associated with FAP. Clinical trial information: NCT05014360. Famitinib for familial adenomatous polyposis-associated aggressive desmoid tumors: A single-center exploratory study. *First Author: Sai Ge, Department of Gastrointestinal Oncology, Key laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital & Institute, Beijing, China*

Background: Desmoid tumour (DT) is a common extra-intestinal manifestation of familial adenomatous polyposis (FAP), with high risk of recurrence and became the second leading cause of FAP patients' death. The treatment of FAP-associated DTs are limited. Famitinib is an orally bioavailable, tyrosine kinase inhibitor against VEGFR-2, PDGFR, c-kit, and FGFR, and has shown antitumor activity in these patients (pts). **Methods:** This is a prospective, single arm study of FAP pts with progressing DT per RECIST v1.1, treated with famitinib 20 mg QD since 11/2021. The primary endpoint was objective response rate (ORR), with secondary endpoints of safety, progression-free survival (PFS), and quality of life (EORTC QLQ C30). We also collected the FFPE slices of DTs to test both genetic and proteomic backgrounds of pts with different therapeutic results. **Results:** Between Nov 24, 2021 and Aug 8, 2022, 11 pts were enrolled and evaluated every 9 weeks. The median follow-up time was 9.4 m (6.6 to 14.9 m). The median age was 36 (28-53) and 45% were male. Nine pts were diagnosed with intra-abdominal (IA) tumors while two had extra-abdominal (EA) DTs. Eight had stage III-IV DTs with rapid growth and severe symptoms. 10 of them had history of intestinal resection. Two pts were treated with dacarbazine and epirubicin before enrollment, while one patient received radiotherapy before famitinib. Five pts achieved partial response (PR) and six achieved stable disease (SD), with a median time to response of 7.0 months. The ORR was 45.5% and the disease control rate (DCR) was 100%. The 6-month PFS rate was 91%. The ORR of pts with IA DTs was 55.6%. Of adverse events (AEs) with famitinib, 87% were grade 1/2, the most frequently reported being hypertension (73%), neutropenia (64%), bilirubinemia (55%) and proteinuria (36%). Mean global health status/QoL before and after 6 months' treatment was 58.3 vs 75.8 ($P = 0.09$). Of all 11 pts, germline APC mutations scattered from codon 457 to 1578, and five of them detected somatic APC mutations from codon 547 to 1896 in DTs. Correlative study analysis will be presented. **Conclusions:** Famitinib demonstrated promising efficacy and a favorable safety profile in FAP-associated aggressive DTs. Poster Discussion Session

Real-world outcomes and safety in patients with VHL associated tumors receiving belzutifan. *First Author: Anusha Chidharla, University of Kansas Cancer Center, Kansas City, KS*

Background: Belzutifan, a small molecule HIF-2 α inhibitor was FDA approved for the treatment of VHL-associated renal cell carcinoma (RCC), CNS hemangioblastomas and pancreatic NET (pNET). The approval was based on the results from the phase 2, open-label, single-group trial, enrolling 61 patients at approximately 12 study sites (Srinivasan, 2021). Objective responses were seen in 49% patients with VHL-associated RCC, 63% patients with VHL-associated CNS hemangioblastomas, and 83% of patients with VHL-associated pNET. Common adverse events included anemia, fatigue, renal dysfunction, nausea, and elevated glucose levels. There is currently very limited data on real-world outcomes using belzutifan in VHL patients. **Methods:** After obtaining IRB approval, we retrospectively evaluated the efficacy and safety of Belzutifan for patients with VHL disease and renal cell cancer and/or VHL-associated tumors who received Belzutifan between August 2021 and January 2023 at KU Cancer center. **Results:** A total of 16 patients are started on Belzutifan treatment. The baseline characteristics include median age of 45 years, including 8 (50%) females and 8 (50%) males. Patients with VHL-associated RCCs were seen in 15 patients ($n = 15$), VHL-associated pNET ($n = 13$), and CNS hemangioblastomas ($n = 13$). Patients were started on belzutifan 120mg daily. The patients underwent bloodwork and clinic follow-up every 6-8 weeks, and response assessment was done in 11/15 patients who had follow-up scans at 6-month intervals. Objective Response to Belzutifan in any of these VHL-associated tumors was seen in 9 of 11 patients (81%), and 1/11(9%) had progressive disease (PD). Objective response in patients with VHL-associated RCC was observed in 8/11 (72%) patients and 2/11 (18%) with partial response (PR), and 6/11 (54%) with stable disease (SD). Responses observed in patients with pancreatic lesions were 1/11 patients (9%) with CR, 1/11 (9%) with PR, and 5/11 (45%) with SD. Patients with CNS hemangioblastomas 4/9 (44%) had SD. Safety was assessed in all the patients. The predominant side effect was anemia 12/16 (75%) and fatigue 11/16 (68%). Other side effects reported are foggy 4/16 (25%), nausea 2/16 (12.5%), dizziness 2/16 (12.5%), and shortness of breath 2/16 (12.5%). Dose reduction to 80mg was needed in 2/16 (12.5%) patients due to moderate fatigue, hypoxia in one, and dysgeusia, respectively. **Conclusions:** Our real-world outcomes analysis of patients with VHL-associated tumors who are treated with Belzutifan shows an improved objective response when compared to the initial clinical trials, which is promising for patients. The analysis based on our real-world data shows the superior objective response in VHL-associated RCCs with Belzutifan, with a manageable safety profile. These findings reinforce Belzutifan as an effective treatment option for this patient population but warrant confirmation in a larger sample. Research Sponsor: None.

Poster Discussion Session

Neoplasia detection via colonoscopic surveillance among young patients with MSH6 and PMS2-associated Lynch syndrome. *First Author: Alicia Latham, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Lynch syndrome (LS) is the most common colorectal cancer (CRC) predisposition syndrome. While patients (pts) with *MLH1/MSH2*-associated LS are recommended to start colonoscopy between age 20-25, recent guidelines recommend delaying initiation in pts with *MSH6/PMS2*-associated LS to age 30-35. However, data on findings from colonoscopic surveillance in young *MSH6/PMS2*-LS pts are limited. **Methods:** We performed a retrospective review of a multi-institutional cohort of pts with *MSH6/PMS2*-associated LS who underwent any colonoscopic surveillance prior to age 50, and assessed corresponding pathology results. Neoplastic lesions were defined as a CRC, adenomas, or non-hyperplastic serrated lesions. Clinicopathologic variables were reported with summary statistics and compared using non-parametric tests at the patient level and among pooled procedures. **Results:** We identified 285 pts [161(56%) *MSH6*; 124(44%) *PMS2*] with history of colonoscopic surveillance prior to age 50. 190 (67%) pts were female, with similar sex distribution among the *MSH6* and *PMS2* groups. 107 (38%) pts had personal history (hx) of any cancer, 67 (42%) *MSH6* and 40 (32%) *PMS2*, including 58 (20%) with CRC [35(22%) *MSH6*; 23 (19%) *PMS2*]. Median age at CRC diagnosis (dx) was 39 and did not differ between groups (41 *MSH6* vs. 37 *PMS2*, $p = 0.47$) with 16 (5.6%) pts dx prior to age 35. 157 (57%) pts had a family hx of CRC, and there was no difference in the rate of CRC between pts with or without family hx of CRC [50% (n = 25) vs 60% (n = 31), $p = 0.33$]. Pts underwent a median of 2 colonoscopic surveillance procedures (range 1-12) with 824 total procedures, 806 (98%) colonoscopies and 18 (2%) sigmoidoscopies, with 691 (85%) occurring at an academic/tertiary center. Among the 824 pooled procedures, there were 194 (24%) procedures with neoplastic lesions identified, including 19 (2.3%) with advanced adenomas or advanced serrated lesions and 34 (4.1%) with CRC. Among 247 procedures completed at age < 35, 43 (18%) detected neoplastic lesions, including 4 (1.6%) with advanced adenomas or advanced serrated lesions and 9 (3.6%) with CRCs. Notably, in 123 procedures performed prior to LS diagnosis, 43 (35%) had a neoplastic finding with 28 (23%) showing CRC. These findings did not differ between the *MSH6* and *PMS2* groups. **Conclusions:** Among this large, multi-institutional cohort of pts with *MSH6/PMS2*-associated LS with history of colonoscopic surveillance performed prior to age 50, colonoscopic surveillance was found at similar rates in both *MSH6* and *PMS2*-associated LS. 20% of overall pts had CRC, with 48% presenting prior to LS dx. In surveillance procedures performed < age 35, the upper threshold of initiation of colonoscopic surveillance as per NCCN, 18% found a neoplastic finding with 3.6% finding CRC, highlighting the need to optimize the age of colonoscopic surveillance initiation in *MSH6/PMS2*-associated LS. High-risk constitutional *MLH1* methylation as a cause of early-onset colorectal and endometrial cancers displaying mismatch repair deficiency and *MLH1* methylation. *First Author: Megan Philippa Hitchins, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Mismatch repair deficiency (MMRd) occurs in ~15% of colorectal (CRC) and ~30% of endometrial (EC) cancers, of which ~20% are caused by Lynch syndrome (LS). Universal screening of all incident CRC and EC for MMRd uses *MLH1* methylation (in tumors with *MLH1*-loss by immunohistochemistry) to omit common sporadic cases from follow-up germline testing for LS. However, this overlooks unusual cases with constitutional *MLH1* methylation (epimutation), a poorly-recognized high-risk mechanism for LS-type cancers that are *MLH1* methylated. We aimed to determine the role and prevalence of constitutional *MLH1* methylation among CRC and EC cases with tumor *MLH1* methylation from clinical and population-based series and if age limits could be used to triage cases warranting additional germline methylation testing. **Methods:** We screened blood DNA for constitutional *MLH1* methylation by pyrosequencing and methylation-specific qPCR in patients with *MLH1*-loss, *MLH1* methylated CRC and EC ascertained from: i) cancer clinics, referred by oncologists and genetic counselors; ii) Ohio population-based "Columbus" and "OCCPI" cohorts. Bisulfite sequencing confirmed constitutional *MLH1* methylation. **Results:** In clinical cases, constitutional *MLH1* methylation was identified in 3/7 EC and 3/8 CRC cases < 60 years. In population-based cohorts, constitutional *MLH1* methylation was identified in 4/95 (4.2%) and 4/281 (1.4%) CRC cases of all ages from Columbus and OCCPI, respectively. Highest rates of detection with the majority of cases detected were at age ≤55 years, with 3/4 (75%) in Columbus and 4/17 (23.5%) in OCCPI ≤55 years. For EC, constitutional *MLH1* methylation was identified in 0/68 Columbus cases of all ages and 1/24 OCCPI cases < 60 years (age-limited testing). She was one of six (~17%) cases < 50 years in the combined cohorts. EC was the first/dual-first presenting "sentinel" cancer in three female patients with constitutional *MLH1* methylation. Of the 14 cases with constitutional *MLH1* methylation, nine had hemiallelic methylation (~50% alleles methylated, affecting a single parental allele) and five had mosaicism across various normal tissues. Somatic "second-hits" affecting the unmethylated allele were found in the tumors of mosaic cases, demonstrating causation. **Conclusions:** A correct diagnosis of constitutional *MLH1* methylation at first cancer presentation is important as it will significantly alter clinical management of these high-risk patients. Although rare overall, high rates of detection were found ≤55 years for CRC and ≤50 years for EC cases with a MMRd, *MLH1* methylated tumor, entailing minimal extra screening. Testing for constitutional *MLH1* methylation is warranted in patients with young-onset CRC or EC, or syn/metachronous cancers at any age, with MMRd and *MLH1* methylated tumor(s). Poster Discussion Session

Clinical and molecular characterization of microsatellite stable (MSS) tumors in patients with Lynch syndrome (LS). *First Author: Emily Harrold, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: LS, caused by germline pathogenic variants in DNA mismatch repair genes (*MLH1*, *MSH2*, *MSH6*, *PMS2*, *EPCAM*), is characterized by near universal microsatellite instability (MSI)/mismatch repair deficiency (dMMR) of associated tumors. Accurate MSI/dMMR assessment is critical to determine immune checkpoint blockade (ICB) eligibility but discordant MSI and immunohistochemical analysis of MMR status (IHC) is described. We sought to characterize MSS tumors in LS pts. **Methods:** Cancer-associated LS pts consented to tumor and matched normal DNA sequencing via MSK-IMPACT (NCT01775072), from 01/2014 to 10/2022 were identified with MSI status inferred via MSLens. Microsatellite stable (MSS) or indeterminate (MSI-I) tumors were further assessed using MiMSI, a multiple instance learning tool demonstrating high sensitivity for MSI even with low sample tumor purity. MSLens and MiMSI status were correlated with MMR IHC. **Results:** Of 405 LS cancer-affected pts, 120 had MSS, 59 MSI-I and 226 MSI-H tumors using MSLens. Tumor MSI status varied by LS gene with *MSH6* (MSS: 33 % (40/120), MSI-I: 42 % (25/59), MSI-H: 14%, (33/226)) and *PMS2* (MSS: 42% (50/120), MSI-I: 12% (7/59), MSI-H: 12%, (28/226)) more frequently associated with MSS/MSI-I than MSI-H tumors ($p = 0.005$) Utilizing orthogonal analysis 43% (63/147) of MSS/MSI-I tumors were re-classified as either MSI or dMMR. MiMSI was available on 106/147 MSS/MSI-I tumors resulting in the re-classification of 36 (28/38 MSI-I, 8/68 MSS tumors) as MSI. IHC was concordant with reclassified MSI status in 23/36 tumors. 5/36 reclassified cases (MSI-I on MSLens) had pMMR on IHC, in 2 of these cases MSI was driven by POLE/POLD1 somatic mutations. IHC was unavailable for 8/36 tumors reclassified by MiMSI. 18/36 (50%) tumors reclassified by MiMSI had low tumor content in profiled samples a known limitation of MSLens. Tumors reclassified as MSI on MiMSI included those considered part of the LS cancer spectrum (8 CRC, 3 gastroesophageal, 8 endometrial, 3 ovarian, 3 urothelial, 2 brain) in addition to cancers not clearly LS associated. 6 tumors classified as MSS/MSI-I on MSLens were MSI-I on MiMSI, 2/6 were dMMR on IHC. Amongst the 41 MSS/MSI-I tumors on MSLens for which only orthogonal IHC was available, 25 (11 MSS, 14 MSI-I) demonstrated protein loss consistent with the implicated LS gene. Low tumor content was noted in 44% (11/25) of tumors reclassified by IHC. Of 34 tumors found to be both MSS and MMR-proficient on orthogonal analysis, the majority (88%) were in *PMS2* or *MSH6* carriers, representing 9 tumor types of which 4 are considered part of the LS cancer spectrum. **Conclusions:** MSS tumors occur in LS pts, especially in lower-penetrance *MSH6* and *PMS2* carriers. Given increasing ICB utilization for MSI/dMMR tumors, orthogonal testing methods are critical to comprehensively identify all LS pts who may derive benefit from ICB particularly when sample tumor purity is low. Poster Discussion Session

Early real-world (RW) experience with a multi-cancer early detection (MCED) test. *First Author: Candace Westgate, Adventist Health, Saint Helena, CA*

Background: An MCED test (Galleri, GRAIL, LLC, Menlo Park, CA) intended to complement recommended screening has been in clinical use since 04/2021. Here, we report RW clinical experience across age, sex, ordering site, and use case with the initial ~53,000 tests. **Methods:** This cell-free DNA-based MCED test uses a targeted methylation assay and a machine learning classification algorithm to detect a cancer signal (CS) and predict CS origin (CSO). This report includes tests returned from 04/20/2021 to 12/31/2022 on individuals aged ≥22 years (yrs) and excludes tests from clinical studies and sites limiting external data sharing, and repeat tests. Systematic collection of outcomes for cases with a "CS detected" (CSD) result was completed for a limited subset and continues via a rigorously controlled quality assurance (QA) program. **Results:** Tests were ordered and processed from across all US states (results returned, 98.9%; mean turnaround time, 6.7 business days). Among the 53,134 tests with results returned, CSD rate (CSDR) was 1.0% (95% CI, 0.9-1.0; 51,053/53,134), generally higher in males (1.1% [1.0-1.2; 313/29201]) vs females (0.8% [0.7-0.9; 197/23933]), and comparable to expected CSDR (males 1.07%; females 0.96%) as modeled based on MCED test performance and cancer incidence from SEER. CSDR increased with age (Table), which was a significant predictor of CSDR ($p < 2e-13$). In males and females, 67.4% and 61.9% of CSOs represented cancers without (w/o) recommended population screening, respectively. Early data from the QA program from an initial limited subset of CSD cases showed that a CSD result was associated with a diagnosis of invasive cancer across multiple cancers (eg, anus, breast, esophagus, head and neck, liver/bile duct, lymphoma, ovary, pancreas, plasma cell neoplasm, prostate, sarcoma), including stage I and II cancers. **Conclusions:** RW experience with the MCED test was consistent with previous large-scale clinical studies with an average CSDR of 1.0%, which increased with age. The test detected a CS and predicted CSO across multiple cancers, including early-stage cancers and cancers w/o recommended screening. This indicates that the MCED test can reliably detect a CS, which is essential to support population screening. Follow-up of CSD cases is ongoing through the QA program and will allow for future reporting of RW outcomes. Research Sponsor: GRAIL.

CSDR (%) by sex and decade with most frequent top-one CSOs.

	<50	50-59	60-69	70-79	>80	Most Frequent First CSO (all ages; %)

Poster Discussion Session

Clinical evaluation of cancer signal origin prediction and diagnostic resolution following multi-cancer early detection testing. *First Author: Eric A. Klein, GRAIL, LLC, a subsidiary of Illumina, Inc., currently held separate from Illumina, Inc., under the terms of the Interim Measures Order of the European Commission dated 29 October 2021, Menlo Park, CA*

Background: PATHFINDER (NCT04241796) was a prospective, interventional return of results study that enrolled 6,662 participants (pts) from 7 US institutions to assess clinical implementation of a blood-based multi-cancer early detection (MCED) test. Test results for those with a cancer signal detected also included a cancer signal origin prediction designed to help guide diagnostic evaluations. We analyzed whether the diagnostic evaluations in PATHFINDER were appropriately directed by cancer signal origin predictions, assessed the residual risk of cancer after negative initial evaluation, and examined the role of whole-body imaging (WBI), defined as PET/CT or CT chest/abdomen/pelvis) in diagnostic evaluation. **Methods:** Analysis included pts with a cancer signal detected result from the two different versions of an MCED test evaluated in PATHFINDER. Prespecified criteria blinded to study results were used to define expected diagnostic evaluations by cancer signal origin prediction. These criteria were then used to judge concordance between cancer signal origin predictions and the diagnostic evaluation actually performed. Definitive cancer or no cancer diagnosis (cancer status at end of study [EOS]) was assessed at 12 months after enrollment (EOS). **Results:** 39 pts had cancer signal detected results by both test versions. Diagnostic evaluations were consistent with cancer signal origin in 30/39 (77%) cases. Diagnostic resolution was achieved in 32/39 (82%) pts after initial evaluation, while 7/39 (18%) required additional workup. 25 of the 32 (78%) pts who achieved diagnostic resolution after initial evaluation had a cancer signal origin-guided workup. Additional evaluation of the 7 pts not achieving initial diagnostic resolution was based on persistent clinical suspicion of cancer due to prior cancer history (n = 1) or abnormal/equivocal findings on initial evaluation (n = 6). Additional workup led to diagnostic resolution in all 7 cases (3 with cancer and 4 with no cancer confirmed at EOS). WBI was ordered in 27 cases, of whom 9 had a prior cancer history, 10 had non-localizing cancer signal origin (hematologic or indeterminate), and 1 had both. WBI was equivocal or had no impact on diagnostic resolution in 8/27 (30%) cases. **Conclusions:** Most cases resulted in diagnostic resolution after cancer signal origin-directed diagnostic workup. In pts with a cancer history and negative initial evaluations, and those with equivocal initial evaluations, there was still a risk of cancer, suggesting the need for additional evaluation. WBI was used mostly in those with a cancer history or non-localizing cancer signal origins, and had no impact on diagnosis in almost one-third of pts. Clinical trial information: NCT04241796. Research Sponsor: GRAIL.

Germline mutations and the presence of clonal hematopoiesis of indeterminate potential (CHIP) in 20,963 patients with BRCA-associated cancers. *First Author: Catherine Handy Marshall, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University School of Medicine, Baltimore, MD*

Background: The contribution of germline genetics on the emergence of CHIP in patients with solid tumor malignancies is not well understood. We hypothesized that those with germline (g) alterations in homologous recombination repair genes (gHRR) and BRCA-associated cancers (breast, ovarian, prostate, pancreas) would have different rates of CHIP than those without. **Methods:** We analyzed a large real-world Tempus multimodal database of paired germline and somatic DNA sequencing results. CHIP was calculated based on the presence of pathogenic or likely pathogenic alterations in any one of 16 CHIP-associated genes (ASXL1, BCOR, BCORL1, CBL, CREBBP, CUX1, DNMT3A, GNB1, JAK2, PPM1D, PRPF8, SETDB1, SF3B1, SRSF2, TET2, U2AF1) with a variant allele frequency of at least 2%. Patients with g alterations in BRCA1, BRCA2, ATM, CHEK2, and PALB2 were compared to those without gHRR alterations (sporadic). **Results:** In breast cancer, patients with gBRCA1 (n = 104) mutations were younger (med 43 yrs) at diagnosis compared to sporadic cases (n = 6,546 med 56yrs) but had similar rates of CHIP (3% vs 5%). Those with gPALB2 (n = 42 med age 55) had the highest rate of CHIP (14%). gBRCA2 (n = 148; med age 52), gATM (n = 57 med age 52), and gCHEK2 (n = 57 med age 53) and similar rates of CHIP (3%, 4%, 7%). In ovarian cancer, patients with gBRCA1 (n = 137 med age 53) were younger at diagnosis than sporadic cases (n = 3,979 med age 63) with similar rates of CHIP (4% vs 3%). Those with gBRCA2 (n = 83 med age 61) were similar (4%) and gPALB2 (n = 11 med age 68) had the highest rate of 9%. CHIP was not detected among patients with gATM (n = 23 med age 61) or gCHEK2 mutations (n = 9, med age 59). In prostate cancer, 4% of patients with sporadic cases had CHIP (n = 4, 183 med age 66) compared to 4% in gBRCA2 (n = 109 med age 63) and 5% in gATM (n = 44 med age 66). gCHEK2 had 17% prevalence of CHIP (n = 12 med age 66) followed by gPALB2 (n = 12 med age 69). There were no CHIP mutations found among those with gBRCA1 (n = 16 med age 64). In pancreatic cancer, patients with gBRCA2 (n = 89 med age 64) and PALB2 (n = 20 med age 62) were younger at diagnosis, compared to sporadic cases (n = 5,176 med age 67) with lower rates of CHIP (1% gBRCA2, 0 PALB2, 5% sporadic). The highest proportion was in gBRCA1 patients (n = 20 med age 63) with 10%, gCHEK2 (n = 16 med age 68) with 6% and gATM (n = 60 med age 66) with 5%. **Conclusions:** Despite younger age at diagnosis, patients with gBRCA1 had similar or higher rates of CHIP within breast and ovarian cancer. Women with gPALB2 alterations and breast and ovarian cancer, as well as men with gCHEK2 mutations and prostate cancer, had higher rates of CHIP. These data suggest that gHRR mutations may influence the prevalence of CHIP among patients with BRCA-associated cancers and more research is needed. Research Sponsor: Tempus Labs; Commonwealth Fund.

Poster Discussion Session

Real-world performance of a multi-cancer early detection test based on integrative analysis of cell-free DNA whole-methylome sequencing. *First Author: Yulong Li, Genecast Biotechnology Co., Ltd., Beijing, China*

Background: Early detection and diagnosis is key to reducing cancer-related mortality. We developed a blood-based multi-cancer early detection test, called THEMIS, using multimodal analysis of plasma cell-free DNA (cfDNA) methylation, fragmentation, and copy number alteration features by whole-methylome sequencing (WMS). The real-world performance of THEMIS was investigated with a prospective cohort of high-risk populations and the preliminary results were reported here. **Methods:** A total of 1,374 adults over 65 y with additional cancer risk factors for five common cancers (colorectal, esophageal, liver, lung, or stomach cancer) were recruited in the city of Wuxi, Jiangsu province, China. Additional risk factors included fecal occult blood, smoking history, H. pylori infection, HBV infection, and serum protein biomarkers. Participants had no known cancer diagnosis at the time of administration. Blood samples were collected and subject to low-pass WMS assay (~2X) and cancer probability was predicted by the THEMIS model, which was developed and locked in previous studies. Participants predicted as cancer positive by THEMIS were followed up until positive cancer diagnosis in a clinic or one year after receiving the test report, whichever was earlier. **Results:** At a fixed cutoff rendering 99% training specificity, THEMIS predicted 58 (4.15%) positive cases, among whom 19 participants consented to and completed follow-up. Ten participants received confirmed cancer diagnosis within the follow-up period, including five lung cancers, three liver cancers, one esophageal cancer, and one colorectal cancer. These results yielded a positive predictive value (PPV) of 52.6%. Those who declined follow-up upon a positive THEMIS report were predicted with digestive tract cancers, which need gastrointestinal endoscope for diagnostic confirmation. **Conclusions:** The noninvasive blood-based THEMIS test demonstrated promising performance and patient compliance for clinical utility to detect cancer early and improve patient outcome. Given that clinical follow-ups were only conducted with a subset of participants, future investigations of the precise real-world performance of THEMIS are needed with more complete patient follow-up. Prevalence of unexpected actionable germline pathogenic variants identified on broad-based multi-gene panel testing in a cohort of cancer patients. *First Author: Kara K. Landry, University of Vermont Larner College of Medicine, Burlington, VT*

Background: Broad-based germline multi-gene panel testing (MGPT) for inherited predisposition has become increasingly common for cancer patients. Both indications for germline testing and the spectrum of genes on MGPT have expanded. We sought to examine the frequency of an unexpected pathogenic/likely pathogenic variant (P/LPV) in patients with a variety of solid and hematologic malignancies undergoing MGPT. **Methods:** A retrospective review of patients with a history of cancer who underwent MGPT at a single institution from 2015 to 2021 with MGPT of > 20 cancer predisposition genes. Low penetrance genes and genes with a recessive inheritance pattern were excluded. Deidentified pedigrees were analyzed by genetic counselors for clinical diagnostic criteria and gene-specific national testing guidelines to determine whether clinical suspicion of the P/LPV was present. **Results:** 10,975 cancer patients underwent MGPT. 1,180 (10.9%) patients were found to have > 1 P/LPV in a moderate or highly penetrant cancer susceptibility gene. 357 (3.3%) of the P/LPV were unexpected based on patient's personal cancer history alone. 208 (1.9%) of the P/LPV remained unexpected after patient and family cancer histories were considered. Most common cancer subtypes with an unexpected P/LPV were breast [1.5% (83/5691)], prostate [2.1% (28/1300)], colorectal [2.2% (18/823)], ovarian/fallopian [1.7% (13/781)] and uterine [2.8% (10/352)] cancer. Most frequent unexpected P/LPV were PMS2 (n = 19), MTF (n = 18), ATM (n = 18), BRIP1 (n = 17), CHEK2 (n = 14), HOXB13 (n = 13), SDHA (n = 12), BRCA2 (n = 7), MSH6 (n = 7), SDHC (n = 7), TP53 (n = 7), and PALB2 (n = 6). No predictor of having an unexpected P/LPV was identified in multivariable logistic regression analysis. Low penetrance or recessive variants were found in 521 (4.8%) patients. Variants of uncertain significance (VUS) were found in 3,774 (35.0%) patients. **Conclusions:** This large retrospective analysis of cancer patients undergoing MGPT identified an overall rate of 1.9% of P/LPV in actionable cancer predisposition genes. Findings were more often unexpected (3.3%) when considering only the patient cancer history, endorsing the importance of family cancer history for consideration of more targeted genetic testing. Identification of moderate or highly penetrant P/LPV in cancer patients is increasingly important in guiding treatment decisions, cancer screening in survivors and testing of at-risk family members. These findings may justify consideration of broader MGPT panels especially when family cancer history is uncertain or unavailable. MGPT also detected a high rate of VUS, reinforcing the importance of physician education to ensure appropriate interpretation and management. Research Sponsor: None.

CDH1 incidental findings in patients with personal or family history of breast cancer. *First Author: Hiam Abdel-Salam, Clinical Cancer Genetics Program, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Pathogenic variants in *CDH1* (*CDH1*+) are associated with hereditary diffuse gastric cancer (HDGC), with an increased risk for DGC (~40-83%) and lobular breast cancer (BC) (~64%) [1]. The National Cancer Center Network recommends the inclusion of *CDH1* in multi-gene panel testing (MGPT) for patients with significant history of BC, given its classification as a high-risk BC gene [2]. Management includes prophylactic gastrectomy or consideration of annual endoscopic biopsies and high-risk breast screening, with consideration of prophylactic mastectomy. Several studies have identified *CDH1* patients who do not meet the International Gastric Linkage Consortium's diagnostic criteria for HDGC [3,4,5,6]. These studies have brought concerns of *CDH1* pathogenic variants in patients with low risk phenotypes, given the potential for total gastrectomy to reduce DGC risk. Our study aims to investigate our cohort of patients with a personal and/or family history of BC to determine if there is a significant number of *CDH1* patients with a non-classical presentation of HDGC. **Methods:** 17,208 families with a history of BC who underwent MGPT were seen in a Clinical Cancer Genetics (CCG) high-risk breast clinic between August 2013 and July 2022. They were identified using a prospectively maintained MD Anderson Cancer Center CCG database. Families were categorized by their history of GC and *CDH1* status. **Results:** Among the families, 10,202 (59%) had a proband with a personal history of BC, with a mean age of onset of 51 years. 49 families (0.28%) were *CDH1*+. 21 *CDH1* families (43%) had no personal and/or family history of GC. Overall, 0.12% of families within the cohort were *CDH1* and had no family history of GC. A chi-square goodness of fit test was performed comparing observed (O) versus expected frequencies (E) (O/E) of families that were: 1) *CDH1* and had a history of GC (28/28), 2) *CDH1* and no history of GC (21/21), 3) *CDH1* - (benign variant or variant of unknown significance (VUS)) and a history of GC (180/164), and 4) *CDH1* - and no history of GC (16,979/16,995). O was determined by using a general population risk of GC (0.81%) and estimated risk of DGC for *CDH1* individuals (58.2%). The χ^2 was determined to be 1.576, with a p-value of 0.66483. **Conclusions:** In comparison to the expected frequency of incidental *CDH1* families identified via MGPT, we found that there was not a significant difference in expected and observed frequencies of families based on *CDH1* status and presence of GC. These results likely reflect the incomplete penetrance and variable expressivity of HDGC, in addition to reported cases of occult signet ring cell carcinomas in biopsy samples or surgical pathology that has been reported in low risk presenting families [7]. We seek to validate these results with cohort of patients in which the diffuse gastric cancer pathology is known and to expand the analysis in patients specifically with a personal history of lobular breast cancer. Twenty-year patterns in area deprivation index and risk of metastatic prostate cancer at initial diagnosis among men in Ohio. *First Author: Jennifer Cullen, Case Western Reserve University School of Medicine, Cleveland, OH*

Background: Men diagnosed with prostate cancer (PCa) have a 5-year overall survival (OS) rate of 98%. However, this rate plummets to approximately 30% for men diagnosed with metastatic PCa. Furthermore, PCa exerts a greater burden on African American men with a higher incidence and a higher mortality rate than other races. These disparities have been contributed to a result of interactions among genes, health behaviors, and access to care. In our study, we examined Social Determinants of Health (SDoH) – social risk factors that contribute to disparities in cancer mortality. Area deprivation index (ADI) is one of the assessments used to measure these social risk factors. ADI can assess a geographic area's level of socioeconomic deprivation and is associated with health outcomes on the census block level. Variables used in ADI are grouped into 4 domains – education, income, employment, and housing quality. Most of the communities will fall between a standardized score of 40 to 160. In this study, we used a large population-based cancer database to examine the impact of ADI on risk of metastatic PCa at diagnosis in Ohio. **Methods:** The Ohio Cancer Incidence Surveillance System (OCISS) data were examined for the period 1996 to 2016 to predict the odds of distant stage at diagnosis. Generalized additive models were constructed with age and year of cancer diagnosis, area deprivation index, race, and Hispanic ethnicity as predictors. The relationship between continuous variables and odds of distant diagnosis was modeled via penalized cubic splines. Odds ratios were calculated for race and Hispanic ethnicity. To summarize the results for variables modeled via splines, predicted probabilities were calculated with other variables held at their average or reference values. **Results:** We identified 112,023 men with PCa in OCISS database. The median age was 67 (IQR 61-67) years old. Subjects were 85.3% White, 13.8% Black, and 0.9% other races. Only 0.6% of men were Hispanic. By stage, 84.6% (N=94753) had localized PCa, 10.4% (N=11640) had regional PCa, and 5.0% (N=5571) had distant PCa. The median ADI was 93.9 (IQR 83.6-106.5). Our analysis showed that Black men had 41.8% higher odds of having metastatic PCa at diagnosis than White men. Furthermore, our analysis showed similar risk of metastatic PCa at diagnosis in lower ADI values but higher risk at higher ADI values (Table). **Conclusions:** Higher ADI values were associated with higher risk of metastatic PCa at diagnosis. Interventions should target populations with socioeconomic deprivation and aim to improve patient access to prostate cancer prevention, screening, and treatment services. The impact of climate change on cancer incidence in U.S. women: Who is most affected? *First Author: Caitlin Ruth Johnson, California Pacific Medical Center Research Institute, San Francisco, CA*

Background: To determine the association between cancer incidence and regional climate change among U.S. women. **Methods:** Data on climate change-associated cancers (breast, lung, melanoma) were obtained from the United States Cancer Statistics (USCS) database from 2001-2019. Climate change data were obtained from federal reports, insurance companies, and nonprofits. States greatly impacted by, moderately affected by, and most resistant to climate change were analyzed. SEER*Stat 8.3.9.2 and Joinpoint regression program 4.9.0.0 were used to calculate cancer incidences and trends per 100,000. Average annual percentage change (AAPC) was used to describe trends. Age-adjusted incidences were adjusted by the U.S. 2000 standard population. **Results:** Prior studies suggest that breast, lung, and skin cancers are associated with climate change. States greatly impacted by climate change were FL, TX, LA, CA, SC, OK, KS, UT, AR, GA, NC, AL, and MO. States most resistant to climate change were VT, MN, ME, NH, MI, HI, RI, PA, MA, CO, AK, IL, and WY. Breast cancer incidence decreased overall by -0.12% per year from 2001-2019 (p = 0.001). Of states with significant AAPCs, those greatly impacted and moderately affected by climate change had increases of 0.34% (p = 0.008) and 1.31% (p = 0.002) while incidence among resistant states decreased at -0.31% (p = 0.03) per year. Regarding race, minority populations in greatly impacted states had higher increases at 0.83% for Blacks (p < 0.001), 2.21% for Asians (p = 0.003), and 2.38% for Hispanics (p = 0.01) and remained unchanged for Whites (p = 0.4). Melanoma incidence increased overall by 1.59% per year from 2001-2019 (p = 0.008). Of states with significant AAPCs, those greatly impacted by climate change had the largest increases at 2.82% (p = 0.002) while moderately affected and climate-resistant states had increases of 2.37% (p < 0.001) and 2.24% (p < 0.001). Incidence decreased at -1.10% for the overall Black population (p = 0.007). In climate-impacted states, incidence increased for Whites at 2.23% (p < 0.001) and remained unchanged for Asians (p = 0.9), Hispanics (p = 0.9), and Blacks (p = 0.3). Lung cancer incidence decreased overall by -0.73% per year from 2001-2019 (p < 0.001). Moderately affected and climate-resistant states had larger AAPC decreases at -1.24% (p = 0.004) and -1.34% (p < 0.001). In states greatly impacted by climate change, overall incidence only decreased by -0.94 (p < 0.001) with incidence decreasing for Blacks at -1.56% (p < 0.001), Hispanics at -6.78% (p < 0.001), and Whites at -0.41% (p = 0.02) while remaining unchanged for Asians (p = 0.1). **Conclusions:** This data suggests that women in states greatly impacted by climate change had larger increases in climate change-associated cancers. Particularly regarding breast cancer, climate change appears to negatively impact racial minorities when compared to White populations. Further studies are warranted to better understand these trends. Research Sponsor: None.

Trends in diagnosis of de novo metastatic hormone sensitive prostate cancer in US Veterans, 2002-2021. *First Author: Nada Al masalmeh, St. Louis University, St. Louis, MO*

Background: The incidence of non-localized prostate cancer in the US has been increasing since 2011. While the etiology of this increase is unknown, improved detection of metastatic disease and changes in prostate-specific antigen (PSA) screening may be contributing factors. In this retrospective study, we report the frequency and characteristics of veterans with de novo metastatic prostate cancer to understand changes in the diagnosis over time. **Methods:** The study population consisted of veterans diagnosed with de novo metastatic Hormone Sensitive Prostate Cancer (mHSPC) with a biopsy between 2002 and 2021 in the Veterans Health Affairs Prostate Cancer Data Core were included. All patients had no prior diagnosis of prostate cancer and were classified as SEER stage 'distant'. We collected the highest PSA within 3 months of diagnosis, age, race, and calculated the Charlson Comorbidity Index. Year of diagnosis was categorized into 5-year periods and differences over time were assessed by chi-square linear by linear ANOVA test for linearity as appropriate. **Results:** 15,485 patients were diagnosed with de novo mHSPC between 2002 and 2021. The mean age was 72.9 years and the median PSA was 88.0 ng/mL. There was a 39% increase of the number of patients diagnosed with mHSPC (from 3,274 between 2002-2006 to 4,560 between 2017-2021). Mean age increased from 71.6 years between 2002-2006 to 74.4 between 2017-2021 (p < 0.001). Median PSA decreased from 96.6 ng/mL in 2002-2006 to 80.3 ng/mL in 2006-2021 (p < 0.001). The percentage of patients who were identified as black decreased from 29.8% between 2002-2006 to 25.4% between 2017 and 2021 (p < 0.001). Mean comorbidity index increased from 3.2 between 2002-2006 to 4.5 between 2017-2021 (p < 0.001). BMI increased from 26.2 between 2002-2006 to 27.2 between 2017-2021 (p < 0.001). Median overall survival improved from 26.7 months in 2002-2006 to 31.7 months in 2016-2021 (p < 0.001). **Conclusions:** Over a 20-year period, the Veterans diagnosed with prostate cancer were older, with higher comorbidities and with decreased PSA at diagnosis. Additionally, overall survival improved from 26.7 to 31.7 months. The findings of this study are consistent with a reduction in screening and more sensitive imaging modalities to detect metastatic disease combined with changes in the veteran population and improvements in treatment of mHSPC. Further study is warranted to understand these trends over the same time period. Breast cancer: Global patterns of incidence, mortality, and trends. *First Author: Ephrem Tadele Sedeta, Department of Medicine, One Brooklyn Health Brookdale University Hospital, Brooklyn, NY*

Background: The global burden of cancer incidence and mortality including that of female breast cancer continues to increase largely because of the growth and aging of the population and adoption of western lifestyle behaviors that increase cancer risk. In this study, we summarize the current burden, trends, and survivorship of female breast cancer that account for nearly 12% of the cancer burden worldwide. **Methods:** Estimates of incidence and mortality in the year 2020 were obtained from Global Cancer Observatory (GLOBOCAN) database. GLOBOCAN provides country-specific estimates of cancer incidence, mortality, and prevalence for 185 countries or territories and 36 cancer types by age group and sex. For US rates, data from Surveillance, Epidemiology, and End Results (SEER) program were assessed. Rates are age-standardized (ASRs) (per 100,000 person-years) using the 1966 Segi-Doll World Standard Population. Geographic variability was assessed using 20 predefined world regions, and the 4-tier Human Development Index (HDI). Finally, we provide a prediction of the future burden of female breast cancer in 2040 based on demographic projections. **Results:** Breast cancer is the most frequently diagnosed cancer and the leading cause of cancer death in females worldwide, with an estimated 2.3 million new cancer cases (1 in 4 new cancer cases) and 685,000 cancer deaths (1 in 6 deaths) in 2020. Breast cancer incidence rates varied by nearly 4-fold across WHO areas. The highest incidence rates (per 100,000) were found in Australia/New Zealand (95.5), Western Europe (90.7), and Northern America (89.4), while the lowest rates were in South-Central Asia (26.2), Middle and Eastern Africa (33), and Central America (39.5). In contrast, the highest breast cancer mortality rates were recorded in Melanesia (37.5), Polynesia and Western Africa (22.3), and the Caribbean (18.9), while the lowest rates were found in Eastern Asia (9.8), Central America (10.4), and Australia/New Zealand (12.1), a 2.8-fold difference. In the United States, the age-standardized breast cancer incidence rate (per 100,000) increased from 106 (1975) to 142 (1999), decreased to 128 (2004), and then slowly increased to 137 (per 100,000) in 2019. Similar broad temporal trend patterns were observed in other western countries. Incidence rates are rising in South America, Africa, and Asia where rates were historically low. Worldwide, an estimated 2,964,197 new female breast cancer cases are projected to occur in 2040, a 31% increase from the corresponding 2,260,127 cases in 2020. **Conclusions:** There is significant variation in female breast cancer incidence and mortality rates worldwide. Breast cancer incidence is increasing at different rates in various regions of the world. Mortality rates in many high HDI countries have been on the decline, in contrast to increasing rates in low HDI countries. This study also shows a substantial increase in new breast cancer diagnoses over the next two decades. Research Sponsor: None.

Epidemiologic effectors on the breast tumor microenvironment: Results from the Cancer Prevention Study-II and -3 cohorts. *First Author: Maha AT Elsebaie, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL*

Background: Despite breast cancer being the leading cancer among women, we have a poor understanding of the impact of epidemiologic risk factors on its tumor microenvironment (TME). We examined risk factors for TME favorability using a novel aggregate marker: the Histomic Prognostic Score (HiPS). **Methods:** Data were from whole slide image (WSI) scans of hematoxylin & eosin slides from women in the Cancer Prevention Studies CPS-II and -3, diagnosed with nonmetastatic breast cancer. Diagnoses occurred between enrollment and the last administrative date (1992/1993 to 2011 in CPS-II and 2006–2013 to 2018 in CPS-3). Median year of diagnosis was 2004 in CPS-II and 2014 in CPS-3. Using the WSI, a deep-learning model was trained to extract features and summarize the morphology of the epithelium, stroma, and tumor-infiltrating lymphocytes within the TME. These features, along with demographic, tumor biomarkers, and survival data, were then used to generate the HiPS, a novel measurement of “prognostic favorability” of TME, ranging from 0 (favorable) to 10 (unfavorable). Multivariable linear models estimated associations between the HiPS score and epidemiologic risk factors: hormone replacement therapy use (HRT; current vs. former/never), cigarette smoking (current vs. former/never), alcohol intake (>1 drink vs. <1 drink/day), aspirin intake (daily vs. not daily) controlled for, age at diagnosis, body mass index (BMI), race, and cancer detection method (screen-vs. self-detected). **Results:** We included 1264 CPS-II and 651 CPS-3 participants in the analysis. Compared to CPS-II, CPS-3 participants were younger (mean (± sd) age 54.7 ± 7.6 vs. 72.2 ± 7, p<0.001), heavier (mean (± sd) BMI 27.1 ± 5.8 vs. 26 ± 4.8, p<0.001), and more diverse (7.4% vs. 2.1% non-White, p<0.001). Most breast cancers (69.9% of CPS-II and 64.1% of CPS-3) were screen-detected, p=0.206. Increasing age and BMI were associated with higher HiPS score in both cohorts, Table. Daily aspirin use and current HRT use were associated with lower HiPS scores in CPS-3 only. The inverse association for HRT use was lost in the following subgroups age < 50, ER-, HER2+, TNM stage-1, and screen-detected cancers. **Conclusions:** Increasing age and BMI have independent adverse effects on breast TME. Daily aspirin intake and current HRT use were only associated with a favorable TME in the younger, more contemporary cohort. Additional studies are needed to confirm these findings and better understand the role of these epidemiologic factors on the TME. Research Sponsor: U.S. National Institutes of Health.

Multivariable models*				
	CPS-II		CPS-3	
	Coeff	p-value	Coeff	p-value
Age (years)	0.04	< 0.001	0.05	< 0.001
BMI (kg/m ²)	0.05	< 0.001	0.09	< 0.001
Screen vs. self-detected	-0.69	< 0.001	-0.85	< 0.001
Daily vs. never aspirin use	-0.10	0.336	-0.55	0.005
Current vs never HRT use	-0.11	0.283	-0.68	0.004

* Each variable was controlled for a standard set of covariates: age at diagnosis, BMI, race, and detection method.

Comparison of 5- and 10-year breast cancer risk predictions. *First Author: John L. Hopper, Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, University of Melbourne, Melbourne, VIC, Australia*

Background: Breast cancer risk assessment is valuable in personalizing risk-reduction and screening approaches for the general population. Maximizing the benefits while reducing the harms associated with current breast cancer screening and risk-reduction recommendations should increase the efficacy of these paradigms. Because healthcare providers have limited time with their patients, we developed a risk prediction model, BRISK, which uses the most important clinical risk factors for breast cancer (in an easily collected format), polygenic risk and mammographic density. We previously validated BRISK 5-year risk predictions and found that it performed better than IBISv7 and BCRAT. **Methods:** The dataset comprised 241,633 women (mean age at baseline assessment = 56.6 years). We included all races/ethnicities available in the UK Biobank. There were 3726 women affected during the first five years of follow-up and 7482 women affected during the full 10 years of follow-up. We compared the performance of the 5-year and 10-year risk predictions by assessing the association with breast cancer using Cox regression to estimate the hazard ratio (HR) per SD of risk, discrimination using calculating Harrell’s C-index and calibration using logistic regression to estimate the slope and the intercept of the logit of the risk predictions. Nelson–Aalen estimates of the hazard function by quintiles of risk and standardized incidence ratios (SIRs) of the number of breast cancer cases expected were used to illustrate performance. **Results:** The predictive performance of BRISK was consistent for 5-year and 10-year risk predictions. Discrimination was similar, with a Harrell’s C-index of 0.645 (95% CI = 0.636, 0.654) for the 5-year risk and of 0.638 (95% CI = 0.632, 0.645) for the 10-year risk. We used Nelson–Aalen cumulative hazard estimates to compare breast cancer incidence by risk quintile for both 5 and 10-year risk. Both risk scores overestimated risk in the top two deciles with the 5-year expected risks of 2.8% and 5.0% corresponding to observed risks of 2.3% and 3.3%. The 10-year expected risks for the top two deciles were 5.6% and 9.8% while the corresponding observed risks were 4.6% and 6.4%. Finally, we used clinically actionable thresholds to show the standard incidence ratios (SIR) of 1.77 (95% CI = 1.69, 1.85) for women ≥3% 5-year risk and 2.05 (95% CI = 1.93, 2.18) ≥8% 10-year risk. **Conclusions:** The BRISK 5-year and 10-year risk prediction perform equally well. There is an overestimation of risk for the top decile in both models. This is important to consider in risk-management conversations between clinician and patient. While the observed risk of the top decile remained above the 3% 5-year risk threshold used in the United States, the top decile observed risk dropped below the 8% 10-year risk threshold used in the United Kingdom. Risk scores are not used in isolation, but it may be preferable to err on the side of overestimation rather than underestimation. Research Sponsor: Genetic Technologies Ltd.

Clinical characteristics of interval breast cancer within 12 months and 13-24 months in Utah. *First Author: Mei Wei, University of Utah, Salt Lake City City, UT*

Background: A breast cancer (BC) that emerges following a negative/benign screening mammogram (SMG) but before the next expected SMG is referred to as an interval breast cancer (IBC). Current guidelines vary in the recommended frequency of SMG: some guidelines support SMG every 12 months, others every 24 months, and many adapt the 12- or 24-month recommendation by age. This study compared the clinical characteristics of IBC that developed within a 3-12 month interval (12m IBC) and a 13-24 month interval (24m IBC) in a statewide population. **Methods:** This is a retrospective cohort study using demographic/medical records in the Utah Population Database linked to the Utah Cancer Registry, a Surveillance, Epidemiology, and End Results (SEER) registry. Index SMG refers to the SMG just prior to a diagnostic mammogram or other clinical encounter, which led to a BC diagnosis before the next, expected SMG. Women ages ≥38y who underwent SMG during 2005–2019 at Intermountain Healthcare and University of Utah Health, had no history of BC prior to first SMG, and had BI-RADS assessment of normal or benign finding at index SMG were included. Clinical characteristics of 12m IBC and 24m IBC were compared using multivariable logistic regression to provide odds ratio estimates with covariate adjustment for age at diagnosis, stage, tumor size, grade, histology, biomarkers, breast density, body mass index, family history of breast cancer, and age at first birth. Women who developed IBC during the 3-12 month interval were not counted in the 24m IBC group. **Results:** A total of 7776 BC were observed in this study, among which 2122 were IBC; 486 (6.3%) 12m IBC and 1636 (21.0%) 24m IBC. Women with 12m IBC and 24m IBC had similar rates of a first-degree family history of breast cancer (16% and 17%, respectively). Women 70 and older were the least likely to develop IBC in 12 months as compared to 24 months (OR 2.34, 95% CI: 1.61–3.40, p< 0.01). The odds of having axillary lymph node metastases (regional disease) at the time of BC diagnosis was higher among 12m IBC than 24m IBC (OR 1.68, 95% CI: 1.29–2.19, p< 0.01). A total of 41 women with IBC had distant metastatic disease at the time of diagnosis (5% 12m IBC, 1% 24m IBC). Among those, the odds that metastatic IBC would be a 12m IBC were significantly higher than 24m IBC (OR = 4.07, CI 2.03–8.29, p< 0.01). The 12m IBC group was more likely to be HER2 positive (OR 2.10, 95% CI: 1.36–3.22, p< 0.01) or triple negative (OR 2.08, 95% CI: 1.26–3.39, p< 0.01) than the 24m IBC group. Extremely dense breast tissue at SMG increased the odds of developing 12m IBC compared to 24m IBC (OR 2.05, 95% CI: 1.13–3.80, p< 0.01). **Conclusions:** Compared to 24m IBC, 12m IBC appeared to be more advanced and aggressive. Women with extremely dense breast tissue were more likely to develop 12m IBC than 24m IBC. These results suggest that women with extremely dense breast tissue or age < 70y may benefit from annual SMG instead of biennial SMG. Trends in mortality caused by neoplasms of the heart in the United States between 2000 and 2019: An observational analysis of disparities by gender and race. *First Author: Abhishek Shahapurkar, Department of Internal Medicine, Mount Auburn Hospital, Cambridge, MA*

Background: Neoplasms of the heart, primary and metastatic, are relatively rare diseases in the US. Metastatic neoplasms are 30 times more common than primary neoplasms and constitute more than 99.3% of the total neoplasms of the heart. Only a few studies have evaluated the mortality trends of this rare disease. Therefore, we aim to analyze the trends of mortality caused by benign and malignant neoplasms of the heart from 2000-2019 and compare them based on gender and race. **Methods:** We utilized the CDC WONDER database to extract data on Heart Benign Neoplasms (ICD 10 D15.1), Heart Malignant Neoplasms (C38.0), and overlapping lesions of Heart, Mediastinum, and pleura (C38.8) mortality in the United States between 2000 to 2019. ICD codes were applied to multiple causes of death. Age-standardized mortality rates (ASMR) per 1,000,000 with a 95% confidence interval were presented for the total population, stratified by gender and race. We assessed the mortality trends using joinpoint trend analysis. **Results:** From 2000 to 2019, 3493 deaths were reported due to neoplasms of the heart, out of which 1672 (47.86%) were due to benign neoplasms, and 1821 (52.13%) were due to malignant neoplasms. Overall, total deaths and ASMR decreased from 221 to 139 and 0.82 to 0.35, respectively, with an Average Annual Percentage change (AAPC) of -3.5. Out of 3493, the majority were females (2254, 64.5%). On evaluating ASMR based on gender, it decreased from 0.65 to 0.32 (AAPC -2.6) for males and from 0.89 to 0.35 for females (AAPC -3.9). On dividing based on racial subgroups, 2962 deaths were in whites, 413 were in African Americans (AA), and 118 were from other races (Asian, Pacific Islanders, Native Indians). On further comparison between Whites and AA, ASMR was found to be higher in AA throughout the study period. For AA, ASMR decreased from 1.18 to 0.51 (AAPC -4.9), and for Whites, from 0.76 to 0.33 (AAPC -2.5). **Conclusions:** This study has shown a decline in overall mortality trends across genders and races. This could be attributed to increased cardiac workups for cardiovascular conditions and advances in imaging modalities, cardiac oncology, and therapeutic interventions. Although the mortality trend in females is decreasing, they still have higher mortality rates than males. At the same time, although AA showed a higher rate of reduction in ASMR, they showed an overall higher ASMR throughout the study period. Further studies are needed to assess if increased screening, early detection, and management plans are causing a decrease in overall mortality in neoplasms of the heart. Research Sponsor: None.

Cardiorespiratory fitness and BMI in youth and site-specific cancer mortality in men: A population-based cohort study with register linkage. *First Author: Aron Onerup, University of Gothenburg, Gothenburg, Sweden*

Background: There is insufficient evidence on the associations between cardiorespiratory fitness (CRF), body mass index (BMI), and site-specific cancer mortality. **Methods:** We collected data on all men who underwent military conscription 1968-2005 in Sweden at ages 16-25. CRF was assessed as maximal aerobic workload on a cycle ergometer test and classified as low, moderate, or high. BMI (kg/m²) was classified as underweight (< 18.5), normal weight (18.5-24.9), overweight (25-29.9), or obesity (≥30). Data was cross-linked on individual level through the Swedish identification number with national registers with high validity for information on cancer mortality. Follow-up was from conscription until death, emigration, or end of follow-up (12/31/2019). Cox regression analyses included CRF and BMI as well as age, year, and site of conscription, parental education, and muscle strength. Primary analyses tested linear trends for CRF and BMI, with effect sizes for categorical comparisons for interpretation. **Results:** 1,083,738 men were included in the analyses and were followed for a mean of 33 years, during which 8,912 cancer-specific deaths occurred. Lower CRF and higher BMI were linearly associated with any cancer mortality as well as with several site-specific cancer mortalities (table). However, death in some major cancer sites (prostate, CNS) were not associated with CRF or BMI and higher CRF was associated with higher mortality from malignant skin cancer. **Conclusions:** Higher CRF and lower BMI was associated with lower cancer mortality for some, but not all cancer sites. These results could be used as a further incentive for working with modifiable risk factors in public health. Research Sponsor: The Swedish state under the ALF agreement; Assar Gabrielsson's Foundation.

Epidemiological and clinicopathological features of patients (pts) with early-onset (EOPC) and late-onset pancreatic cancer (LOPC): A mono-institutional retrospective analysis. *First Author: Maria Bensi, Oncologia Medica, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli-IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy*

Background: PC is mostly diagnosed in the 7th decade of life. Recent evidence suggests a rising incidence of both EOPC and LOPC. However, there are few data about their specific characteristics. The aim of our study is to determine the incidence of EOPC and LOPC and their correlation with epidemiological and clinicopathological features. **Methods:** Real world data were extracted and analyzed by the Gemelli GENERATOR within the Gemelli Science and Technology Park (G-STeP). Study population was identified from health records matching main inclusion criteria: hospitalized pts with a diagnosis of PC (International Classification of Disease 9, ICD-9 codes captured from structured data source) or pts with at least one anatomic pathology report including PC evidence (selected using clinically validated text mining techniques from unstructured data source). Two subgroups were defined: EOPC (< 50 years old) and LOPC (> 75 years old) pts. Epidemiological and clinicopathological variables (gender, age, BMI, diabetes, history of pancreatitis, histology, primary tumor site, primary tumor surgery) were extracted using SAS (SAS(R) Institute suite for ETL). Statistical analyses were conducted using R (v4.2.1). **Results:** From January 2018 to December 2020, a total of 1606 PC pts treated at our Institution were included in the analysis. The median age was 69 years, 51% were male and the median BMI was 25. Regarding comorbidities, only 4% and 3% of pts had diabetes and history of pancreatitis, respectively. Adenocarcinoma (1120/1126; 99%) was the most common histotype and pancreatic head (576/901, 64%) was the most frequent primary tumor site. Two hundred and ninety-three pts (18%) underwent primary tumor surgery. Concerning the two subgroups, 92 (6%) pts had EOPC and 510 (32%) had LOPC. The median age was 43 years in EOPC group and 81 years in LOPC group. No difference between the two groups was found in gender (p 0.83), BMI (p 1) and tumor histology (p 1). Diabetes was present in 1% and 7% of EOPC and LOPC pts (p 0.07) and pancreatitis history in 3% and 2% (p 0.79), respectively. The primary tumor site was pancreatic head in 78% and 65% (p 0.06) of LOPC and EOPC, respectively. Regarding primary tumor surgery, a significant difference was observed between the two groups (27% in EOPC pts vs 11% LOPC pts; p < 0.001). **Conclusions:** In our study, we did not observe a different epidemiology or a distinctive clinicopathological profile between EOPC and LOPC pts. Despite the retrospective nature of our analysis and single-institution evaluation, our findings showed that EOPC pts more frequently underwent primary tumor surgery, probably related to better clinical conditions. Additional analyses on survival outcomes, molecular and genetic features may help to clarify differences between the two groups. Research Sponsor: None.

Examining the potential for lead-time bias by estimating stage-specific proportions of deaths due to diagnosed cancer. *First Author: Ellen T. Chang, GRAIL, LLC, a subsidiary of Illumina, Inc., currently held separate from Illumina, Inc., under the terms of the Interim Measures Order of the European Commission dated 29 October 2021, Menlo Park, CA*

Background: Lead-time bias occurs when cancer is detected earlier in time, but with no change in lifespan. Cause of death is not susceptible to lead-time bias; therefore, stratifying cause of death by cancer stage informs the potential for lead-time bias in early detection across cancer types. **Methods:** Using recent data from 17 US Surveillance, Epidemiology, and End Results (SEER) cancer registries for 1 152 610 first incident primary cancers among patients aged 50-84 years at diagnosis in 2006-2010, we evaluated proportional causes of death by cancer type and uniformly classified stage at diagnosis (American Joint Committee on Cancer, 6th edition), following or extrapolating all patients until death. **Results:** A minority of cancer patients diagnosed at stages I-II (27%) went on to die from their index cancer, whereas most stage IV cancer patients (85%) did. For patients diagnosed with stage I cancer at all sites combined, an estimated 26% of deaths were due to the index cancer, 61% due to non-cancer causes, and 12% due to a subsequent primary (non-index) cancer. At stage II, 27% of deaths were due to the index cancer, 60% due to non-cancer causes, and 13% due to a non-index cancer. In contrast, at stage IV, 85% of deaths were attributed to the index cancer, with 13% non-cancer and 2% non-index-cancer deaths. Index cancer mortality from stages I-II cancer was proportionally lowest for thyroid, melanoma, uterus, prostate, and breast, and highest for pancreas, liver, esophagus, lung, and stomach. Leading causes of non-index cancer death (lung, pancreas, and colorectal) and non-cancer death (heart disease and COPD) at each stage were similar to those in the general US population. Non-White racial/ethnic groups, including Hispanics and non-Hispanic Blacks, Asian Americans/Pacific Islanders, and American Indians/Alaska Natives, experienced a higher percentage of deaths from stages I-II cancer than non-Hispanic Whites. **Conclusions:** Across all cancer types, the percentage of patients who went on to die from their cancer was three times greater at stage IV than at stages I-II. As mortality patterns are not influenced by lead-time bias, these data suggest that earlier stage at diagnosis is broadly, if not uniformly, associated with substantially reduced risk of cause-specific death from cancer; therefore, early detection is likely to improve outcomes across cancer types, including those currently unscreened. Research Sponsor: GRAIL, LLC, a subsidiary of Illumina, Inc., currently held separate from Illumina, Inc., under the terms of the Interim Measures Order of the European Commission dated 29 October 2021.

Causes of death (extrapolated if not observed) by stage for first incident primary cancer cases aged 50-84 years at diagnosis in 2006-2010, followed for mortality through 2019, SEER 17.

Obesity and breast cancer in women under age 40. *First Author: Rabia Cattie, Ochsner Health System, New Orleans, LA*

Background: Obesity is a well-established risk factor for postmenopausal hormone-receptor positive breast cancer (BC). The role of obesity in premenopausal BC, especially in women under the age of 40, is not well understood. Multiple studies have shown a decreased rate of premenopausal BC with increasing body mass index (BMI), notably for estrogen receptor positive tumors. Even though there is an inverse association between obesity and premenopausal BC, it has been suggested that obesity has a negative prognostic role in premenopausal BC. This may be explained if premenopausal obese women develop more aggressive tumors. Obesity is associated with triple negative and Luminal B cancers in premenopausal women. We sought to evaluate the relationship between premenopausal breast cancer and obesity in a diverse patient population. **Methods:** We assembled a 10-year database of women diagnosed with breast cancer before age 40 in a single health system. Data collected included age at diagnosis, self-identified race, breast cancer subtype, BMI, and stage at diagnosis. The control group was all women under the age of 40 presenting to our health system in the same time period. Stratification analysis was performed using Mantel-Haenszel Risk Estimation. **Results:** The risk ratio between the standardized estimates of BC patients under 40 with BMI ≤ 30 to BMI > 30 is 0.7924, 95% CI (0.683 – 0.920), P = 0.0022. This implies that young BC patients are more likely to be obese than all young women presenting to our health system. There are more obese Black patients compared to White patients. The effect of obesity on BC diagnosis was more pronounced in Black patients, with a risk ratio of 0.59 compared to 0.96. **Conclusions:** The data presented here challenge previous research which had shown that obesity seemed to be protective against breast cancer in premenopausal women. Here, we see a statistically significant increase in obesity among young women < 40 years presenting with breast cancer. The increased risk of breast cancer diagnosis was particularly pronounced in obese Black women. Previous studies have had a very low proportion of Black women represented, which may cause underestimation of risk in this patient population. These data suggest that obesity is a risk factor for breast cancer in young women, especially in Black patients. Research Sponsor: None.

Race	BMI ≤ 30	BMI > 30	Risk Ratio	95% CI

Association between excess body mass index trajectory and change in monoclonal protein level in patients diagnosed with monoclonal gammopathy of undetermined significance. *First Author: Lawrence Liu, City of Hope National Comprehensive Cancer Center, Duarte, CA*

Background: Obesity is a known risk factor for the development of multiple myeloma (MM) and for progression of its asymptomatic premalignant state, monoclonal gammopathy of undetermined significance (MGUS) to MM. Prior studies have demonstrated that monoclonal protein (M-spike) at MGUS diagnosis as well as high M-spike velocity within a year following MGUS diagnosis predict progression of MGUS to MM, making M-spike a useful, readily available, and less invasive (compared to bone marrow biopsy) marker to assess progression risk. However, no studies have evaluated to what extent exposure to high body mass index (BMI) over time influences M-spike trajectory. **Methods:** Patients diagnosed with MGUS from 1999-2021 in the Veterans Health Administration were identified. We used a natural language processing-based algorithm to confirm MGUS diagnosis and progression to smoldering MM or MM. MGUS patients without IgM or IgD subtype or Diabetes Mellitus and were black or white were included in the analysis. Other exclusion criteria were progression within 5 years of MGUS diagnosis, patients without M-spike level within a year before or after MGUS diagnosis, and patients without BMI data 3 years or more after MGUS diagnosis. The exposure was the trajectory of excess BMI (defined as BMI > 25 kg/m²), defined by an area under the curve (AUC) of excess BMI during the 5 years following MGUS diagnosis. The outcome was continuous M-spike trajectory post-MGUS diagnosis since a prior study demonstrated that this was a reliable marker for progression risk. A multivariable mixed model was used to estimate the association of excess BMI trajectory AUC with M-spike trajectory to control for correlation between M-spike values overtime. The covariates included BMI at MGUS diagnosis, M-spike level (> = 1.5g/dL) at MGUS diagnosis, age at MGUS diagnosis, sex, race, MGUS heavy chain subtype, and light-chain MGUS. **Results:** After applying the inclusion and exclusion criteria, the analytic cohort consisted of 6757 MGUS patients. Our multivariable analysis demonstrated a positive association between excess BMI trajectory and increasing M-spike trajectory (β = 0.005, p = 0.007). **Conclusions:** In patients diagnosed with MGUS, increasing BMI over time following MGUS diagnosis was associated with increasing M-spike level. This further supports the relationship between obesity and weight gain in the pathway of MGUS to MM progression. Research Sponsor: U.S. National Institutes of Health.

The impact of high body mass index on hepatocellular carcinoma in viral hepatitis and cirrhosis. *First Author: Moonho Kim, Department of Hematology and Oncology, University of Ulsan College of Medicine, Gangneung Asan Hospital, Gangneung, South Korea, Gangneung, South Korea*

Background: The impact of a high body mass index (BMI) on hepatocellular carcinoma (HCC) has been unclear in patients with viral hepatitis and liver cirrhosis (LC). Our aim is to investigate the association between BMI and HCC in patients with viral hepatitis and LC. **Methods:** We conducted a population-based cohort study. In total, 156,143 Korean adults who underwent routine health examinations during 2003-2006 were followed up until December 2019 via linkage to the national hospital discharge records. Multivariable-adjusted hazard ratios (HRs) per each 5 kg/m² increase in BMI for HCC risk were calculated using Cox proportional hazard models. **Results:** BMI was positively associated with HCC in hepatitis B virus (HBV) patients with BMI range of 27.5~29.9 kg/m² and BMI ≥30 kg/m² and LC patients with a BMI range of 27.5~29.9 kg/m². Assuming linear associations, HRs were 1.17 for HBV, 1.08 for hepatitis C virus (HCV), and 1.11 for LC. In the subgroup analysis for the LC, the HR were 1.19 in the HBV-LC, 1.38 in the HCV-LC, 1.36 in the alcoholic LC, and 1.59 in the fatty liver LC. Women showed stronger positive associations between BMI and HCC than men in the HBV (HR, 1.45 vs 1.06) and LC (1.27 vs. 1.02). The positive association seemed to be stronger in younger age (< 65 years) in HBV (1.17 vs 1.05) and HCV (1.33 vs 0.77) patients compared to older age (> 65 years). **Conclusions:** In the BMI range of ≥25 kg/m², a higher BMI was associated with an increased risk of HCC in LC and HBV. The associations between BMI and HCC risk are different according to liver disease, sex and age. County-level food insecurity to predict cancer incidence and mortality in the United States, 2015-2020. *First Author: Krista Y. Chen, Johns Hopkins School of Medicine, Baltimore, MD*

Background: Modifiable dietary patterns incorporating inexpensive, calorie-dense, processed foods and meals low in fiber and other nutrients are associated with development of cancer. Inadequate access to quality nutrition is a crucial but underappreciated social determinant of health and predictor of poor cancer outcomes. We investigated the impact of county-level food insecurity on age-adjusted incidence and mortality rates (AAIR, AAMR) for all cancers. **Methods:** We linked county-level cancer incidence and mortality rates for 2015-2020 from NCI State Cancer Profiles to food insecurity measures from Feeding America and County Business Patterns. Measures included percentage of individuals experiencing food insecurity (as defined by USDA), percentage on Supplemental Nutrition Assistance Program (SNAP) benefits, average cost per meal, and density of fast-food restaurants. AAIR and AAMRs of all cancers per 100,000 individuals were compared between 1st and 4th quartiles for each measure using robust linear regression models with log transformation and population weights. **Results:** There was an annual average of 1,728,431 cancer diagnoses with AAIR 449 and 599,666 deaths with AAMR 149. Highest AAIRs were observed in >50y (1351), men (488), non-Hispanic Whites (467), and urban counties (459). This differed from highest AAMR groups including >50y (502), men (178), non-Hispanic Blacks (175), and rural counties (168) suggesting factors of increased disease severity or decreased access to care in the latter. Both AAIRs and AAMRs increased significantly when moving from least to most insecure counties, as defined by overall food insecurity, higher proportion of population on SNAP, higher fast-food density, and lower meal cost. AAMRs and AAIRs for lung cancer and CRC, and for rural residents were most exacerbated by changes in all measures of food insecurity, even when adjusting for screening rates for CRC in low access areas. **Conclusions:** Our study highlights the most food insecure counties have higher cancer incidence and even greater mortality burden. We recognize food insecurity as a proxy for socioeconomic disadvantage prior to and during cancer treatment. These results encourage prioritization of policies that optimize food assistance programs and clinical practices that incorporate food insecurity-related screenings in care delivery models. Research Sponsor: None.

The role of metabolic perturbations in mediating the effects of ambient air pollution on lung cancer in the cancer prevention studies. *First Author: Donghai Liang, Emory University, Atlanta, GA*

Background: Exposure to ambient air pollution is an established risk factor for lung cancer. Investigation on the underlying mechanisms of air pollution carcinogenicity remains challenging due to the complex composition of air pollution and a lack of sensitive biomarkers to accurately measure exposure and corresponding response. To address the knowledge gaps, we applied high-resolution metabolomics to identify metabolic signatures of exogenous air pollution exposures and endogenous processes involved in lung carcinogenesis. **Methods:** A total of 683 matched lung cancer and control pairs within the established Cancer Prevention Study-II (CPS-II) Nutrition and CPS-3 cohorts were included in this study. The plasma metabolome was profiled with ultrahigh-performance liquid chromatography-tandem mass spectrometry. Assessment of exposure to six ambient air pollutants, including carbon monoxide (CO), nitrogen dioxide (NO₂), particulate matter (PM₁₀), fine particulate matter (PM_{2.5}), sulfur dioxide (SO₂), and ozone (O₃), was conducted using spatiotemporally-resolved models based on residential address at blood draw and calculated based on yearly average levels. We conducted metabolome-wide association studies with multiple linear regression models to assess associations of ambient air pollution and lung cancer with a meet-in-the-middle approach. Models controlled for potential confounders and covariates including age at blood draw, sex, race, body mass index, alcohol consumption, smoking status, passive smoke exposure, vegetable and fruit intake, and educational level. Metabolites significant at the FDR < 0.2 level in the air pollution model were analyzed in the lung cancer model. High-dimensional mediation analysis was used as a secondary analysis to compare results from the meet-in-the-middle analysis. **Results:** Among 1,204 metabolic features extracted from the blood samples, seven features were significantly associated with air pollution exposure and lung cancer incidence at the FDR < 0.2 level in the meet-in-the-middle analysis. Six features were significant at the p < 0.01 level through high-dimensional mediation analysis. All confirmed metabolites are enriched within peptide, lipid, and amino acid pathways. Gamma-glutamylglutamine and gamma-glutamylmethionine were statistically significantly associated with CO, NO₂, and PM₁₀ exposure and lung cancer incidence in both analyses. **Conclusions:** This is the largest prospective metabolomics study examining biological perturbations associated with air pollution exposure and lung cancer incidence. Peptide metabolism may play an important role in mediating the association between air pollution and lung cancer. Findings from this study will lay the foundation for future studies to further understand the biological mechanisms underlying the carcinogenicity of air pollution. Impact of social media messages on perceived risk and severity of adverse effects and regret of HPV vaccination: The moderating role of decision-making preference. *First Author: Jorge Villegas, University of Illinois Springfield, Springfield, IL*

Background: The HPV vaccine has proven to be a highly effective and safe public health intervention for reducing the risk of various types of cancer. Despite its efficacy and safety, misinformation and negative opinions about the vaccine on social media can lead to negative emotions such as regret among those who have received it. This study investigated the impact of different content of social media messages on perceived risk and severity of adverse effects and regret of HPV vaccination. **Methods:** An experiment was designed to expose participants to messages posted on social media that manipulated the number of Vaccine Adverse Effects and the appeal used (narrative vs. statistics). The study measured the effect of the message on decisional regret and also assessed preferred level of involvement with medical decision-making. The online study was implemented among college students enrolled in a Midwestern or a South Texas university. We used structural equation modeling (SEM) to systematically test the relationships between the variables of interest. **Results:** A total of 721 participants were exposed to the experimental materials and completed the questionnaire. The results of the SEM (with overall good fitness of RMSEA = 0.015, CMIN/df = 1.172) suggest that messages that contained more numeric information (standardized regression weights [Std Reg Wght = 0.161]) and more adverse effects of the HPV vaccine (Std Reg Wght = 0.076) led to a higher perception of the risk of vaccine adverse effects. The severity of adverse effects was significantly associated with the number of side effects in the message (Std Reg Wght = 0.147). This increase in perceived risk (Std Reg Wght = 0.182) and severity of side effects of the vaccine (Std Reg Wght = 0.163) seem to increase decisional regret. However, this relationship was moderated by individuals' preferences for making their own medical decisions. Individuals with a higher preference to make their own health decisions were less likely to experience decisional regret (Std Reg Wght = -0.238). **Conclusions:** Messages on social media can exacerbate negative emotions and lead to hesitation in following future medical advice. Encouraging individuals to play a more active role in their medical decision-making appears to reduce this negative emotion and increase their confidence in health decisions. Research Sponsor: None.

Global burden and economic impact of vaccine-preventable cancer mortality. *First Author: Goran Bencina, Center for Observational and Real-World Evidence, MSD Spain, Madrid, Spain*

Background: Cancer has a high clinical and economic burden, with ~10 million deaths globally in 2020. In Europe, the total cost of cancer was €199 billion in 2018. Infections are responsible for approximately 13% of cancer cases worldwide. Human papillomavirus (HPV) and hepatitis B (HBV) are among the most important infections associated with cancer for which vaccines are available. However, global vaccination rates for these cancer-causing infections remain low (~12% for HPV; 42% for HBV). Elimination of vaccine-preventable cancers is a public health priority, and the World Health Organization (WHO) has proposed a strategy to eliminate cervical cancer and viral hepatitis by 2030. This analysis aims to estimate the global burden and economic impact due to vaccine-preventable cancer mortality. **Methods:** The number of deaths and Years of Life Lost (YLL) in 2019 from liver cancer caused by hepatitis B (ICD-10 C22), head and neck cancers (ICD-10 C00-14 and C32), and cancer of the cervix uteri (ICD-10 C53) were sourced from the Institute for Health Metrics Evaluation (IHME) Global Burden of Disease. Deaths and YLL were applied to attributable fractions for each vaccine-preventable cancer based on published data. The Value of YLL (VYLL) was estimated by multiplying the GDP per capita (World Bank, in USD) and YLL for each cancer, in each WHO region. Sensitivity and scenario analyses were performed to test the robustness of results. **Results:** In 2019, there were 479,750 potentially vaccine-preventable cancer deaths and 14,561,049 YLL (38% in males) across WHO regions (Table). The estimated economic impact due to vaccine-preventable cancer deaths was over \$171 billion globally with the Americas and European region accounting for 63% of the total cost (\$107 billion). Cervical cancer had the highest mortality burden (52% of total deaths). Globally, 78% of non-cervical HPV-related cancer deaths were in males. **Conclusions:** In 2019, 1,314 people died per day due to vaccine-preventable cancers leading to substantial YLL and economic impact. The overall burden is likely to be higher since several other HPV-related cancers were not included in this analysis. Improved implementation of HPV and HBV vaccination programs should be prioritized to decrease this burden. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

The impact of HPV vaccination in Florida compared to New York. *First Author: Thanuja Neerukonda, HCA Florida Brandon Hospital, Brandon, FL*

Background: HPV is responsible for cancers including anus, penis, vulvovaginal, and oropharyngeal but cervical cancer is the most common cancer caused by HPV. To study the impact of HPV vaccination, we compared age-adjusted cervical cancer incidence and death rates in New York, a state with a high HPV vaccination rate, to Florida, a state with a lower vaccination rate, prior to HPV vaccination and 10 years post HPV vaccination availability. **Methods:** This is an ecologic study observing the cervical cancer incidence and death rates prior to (2005) and after (2016) the introduction of the HPV vaccination using state wide healthcare cancer registries. **Results:** The HPV vaccine became available in the United States in 2006. Historically, Florida was found to have a low HPV vaccination rate in 2009 with less than 40% compared to New York which had a high rate of 50% in 2009. By 2016, Florida's HPV vaccination rate improved to 55% but was still low compared to New York with a rate greater than 70%. New York had a decline of cervical cancer incidence of 9.7 per 100,000 in 2005 to 8.3 in 2016. New York had a decrease in death rate from 3.0 in 2005 to 2.7 in 2016. In Florida, the cervical cancer incidence rate from 2005 to 2016 increased from 9.7 to 9.9 and the mortality was 3.0 in 2005 and 2.9 in 2016. When comparing New York's cervical cancer incidence rates, there was a statistically significant drop in age-adjusted incidence before HPV-vaccination compared to 10 years post vaccination availability. When analyzing cervical cancer incidence in 2016, significant increase in cases between Florida's incidence compared to New York's. **Conclusions:** Since the introduction of the HPV vaccination, age-adjusted incidence rate of cervical cancer has declined in New York but not in Florida. This may be due to lagging HPV vaccination rates in Florida in addition to other sociodemographic or healthcare factors. There has been minimal change in cervical cancer death rates between both states, likely attributed by the low death rate associated with cervical cancer. The medical community needs to work together to address the barriers to HPV vaccination and promote programs to increase vaccination rates which will reduce the incidence and mortality of cervical, anus, penis, vagina, vulva, and oropharyngeal cancer. Research Sponsor: None.

Directly standardized cervical cancer age-adjusted incidence and death rates effects in 2005 and 2016: Florida and New York.

State/Year	Comparison	Incidence Rate Ratio (95% CI)	Mortality Rate Ratio (95% CI)
Florida/2005	New York/2005	1.0033 (0.91545-1.09947)	0.994 (0.84280-1.17233)
Florida/2016	New York/2016	1.1941 (1.09003-1.30818)	1.071 (0.90901-1.26185)
Florida/2005	Florida/2016	0.9965 (0.91151-1.08939)	1.065 (0.90771-1.24950)
New York/2005	New York/2016	1.2096 (1.10131-1.32848)	1.178 (0.99470-1.39591)

Barriers to cervical cancer screening in a developing Middle Eastern country: A nationwide survey. *First Author: Ahmed A Abdulelah, University of Jordan, Amman, Jordan*

Background: In addition to being ranked as the 4th leading malignancy worldwide, cervical cancer is associated with considerable morbidity and mortality resulting in significant burden. However, cervical cancer screening is available and has been proven to significantly minimize the associated morbidity and mortality through early detection. The identification of the barriers towards cervical cancer screening in Jordan, a developing middle eastern country, is of outstanding significance towards effective intervention and minimizing the collective health and socio-economic burden imposed. **Methods:** The first consecutive 695 females aged 25 years and above with no prior history of cervical cancer and residing in Jordan across the different regions were enrolled via random probability sampling through a self-reporting survey that comprises of extensive questions regarding the participant's demographics, medical history, awareness about cervical cancer and its screening methods. Single females were not included in the study due to culture unacceptability of performing pap smears on unmarried females. Statistical analysis was performed to identify the key barriers towards cervical cancer screening in Jordan. **Results:** The mean age of the enrolled participants was 42 ± 9 years with the majority of the participants having a higher level of education (84.5%), are medically insured (72.4%), and are non-smokers (74.7%). The majority of the participants, 77.7%, did not report a family history of cervical cancer. 472 participants (67.9%) were aware of the availability of a screening modality for cervical cancer, with the majority being informed through awareness campaigns (64.7%). Nonetheless, only 30.1% of the participants previously underwent pap smear for screening purposes. When the participants who did not undergo previous cervical cancer screening were compared with those who did, the participants who did not undergo any prior screening were more likely to identify the lack of information and knowledge towards screening (49.0% vs 9.6%) (p-value < 0.001), fear of the results (81.5% vs 7.2%) (p-value = 0.016), lack of belief in screening and its efficacy (2.1% vs 0.0%) (p-value = 0.037) as crucial and leading barriers. Additionally, the presence of a positive family history for cervical cancer was identified as a statistically significant promoter for screening uptake (p-value = 0.004). Nonetheless, there was no statistically significant difference between the two groups when evaluating the financial aspects of screening or embarrassment from the test as potential barriers, p-value = 0.159 and 0.738, respectively. **Conclusions:** Lack of knowledge towards screening and belief in its efficacy, and fear of the results were identified as driving barriers towards screening. Effective formulation of comprehensive awareness campaigns is pivotal towards successful intervention to the reported barriers. Research Sponsor: None.

Sex differences in cancer incidence rates by race and ethnicity: Results from the surveillance, epidemiology, and end results (SEER) Registry (2000-2019). *First Author: Sararat Tosakoon, National Cancer Institute, Rockville, MD*

Background: Sex differences in cancer incidence are pronounced, with men having 2-3 times the rate of most non-reproductive cancers than women. However, whether the male predominance is due to differences in biological factors or behavior remains not well understood. This study investigated sex differences in cancer incidence by race and ethnicity to provide a greater understanding of whether differences are driven by biological factors or environmental exposures. **Methods:** Cancer incidence data from the Surveillance, Epidemiology and End Result (SEER) program (2000-2019) was used to calculate male-to-female incidence rate ratios (MF IRR) for each cancer site and histological subtype, stratified by race and ethnicity (non-Hispanic White, non-Hispanic Black, non-Hispanic Asian/Pacific Islander, American Indian/Alaskan Native, and Hispanic), and age-standardized to the 2000 U.S. population for individuals ages ≥ 20 years. **Results:** Most non-reproductive cancers had a male predominance across race and ethnicity, with the largest MF IRR seen for cancers of the tonsil, hypopharynx, larynx, and Kaposi sarcoma (MF IRR > 4). Three cancers, gallbladder; peritoneum, omentum, mesenter; and thyroid, were more common among females than males across all race and ethnicity. Females had a higher incidence of anal cancer than males for all racial and ethnic groups except for non-Hispanic Black individuals where the MF IRR was >1. Cancers of the stomach, skin (excluding basal and squamous cell), melanoma skin, and other non-epithelial, and myeloma had greater MF IRR among non-Hispanic White adults than all other racial and ethnic groups. Non-Hispanic Black individuals had higher MF IRR of cancers of the liver and lung and bronchus, compared to other racial and ethnic group. Non-Hispanic White males had the highest MF IRRs for esophagus adenocarcinoma and gastric cardia adenocarcinoma and the lowest MF IRR for esophagus SCC compared to other races and ethnicity. **Conclusions:** The MF IRR for most cancers in this study did not differ by race and ethnicity, suggesting the influence of biological factors. Differences in the MF IRR across race and ethnicity may indicate carcinogenic exposure differences leading to the development of non-sex-specific cancers. Further research is needed to identify biological drivers of cancer incidence for most non-reproductive cancers. Incomplete HPV vaccination among individuals aged 27-45 years in the United States: A mixed effect analysis of individual and contextual factors. *First Author: Victor Adekanmbi, University of Texas Medical Branch, Galveston, TX*

Background: In the United States, the Human papillomavirus (HPV) vaccine is approved for use up to age 45. Incomplete HPV vaccination rates among those over age 26, however, remain high. The aim of this study was to examine the independent effects of individual- and neighborhood-level factors on incomplete HPV vaccine series in the United States (US) among those aged 27-45 years. **Methods:** This retrospective cohort study used administrative data from Optum's Clinformatics DataMart Database to identify individuals aged 27-45 years who received 1 or more doses of HPV vaccine between July 2019 and June 2022. Multilevel multivariable logistic regression models were applied to the data on 7,662 individuals aged 27-45 years who were fully vaccinated against HPV or not, nested within 3839 neighborhoods across the US. **Results:** More than half of the participants in this study (52.93%) were not completely vaccinated against HPV. About 64% of the eligible participants aged 27-30 years did not complete their HPV vaccine series. After adjusting for all other covariates in the final model, being older than 30 years old decreased the odds of incomplete HPV vaccine series. Participants living in neighborhoods of South region of the US had enhanced odds of incomplete HPV vaccine series compared to those residing in Northeast region (aOR 1.21; 95% CrI 1.03-1.42). There was significant clustering of incomplete HPV vaccine series at the neighborhood level. **Conclusions:** This study revealed that individual- and neighborhood-level factors significantly influence HPV vaccination incompleteness in the US. Interventions to improve HPV vaccination uptake and completion should take into consideration both individual- and contextual-level characteristics during design, planning and implementation of policies and programs to improve HPV vaccination coverage and completion in the US and other similar countries. Polygenic risk scores in assessing lung cancer susceptibility in non-Hispanic White and Black populations. *First Author: Matthew R Trendowski, Wayne State University School of Medicine, Detroit, MI*

Background: Polygenic risk scores (PRS) have become an increasingly popular approach to evaluate cancer susceptibility, but have not adequately represented Black patients in model development. We used previously identified single nucleotide polymorphisms (SNPs) and annotated SNPs in associated gene regions to develop PRS in non-Hispanic Whites and Blacks using the INHALE dataset. **Methods:** Using the Multi-Ethnic Genotype Array, 1,204 SNPs for non-Hispanic Whites and 1,515 SNPs for Blacks were evaluated for their association with lung cancer risk adjusting for age, sex, total pack-years, family history of lung cancer, history of COPD and the top five PCs for genetic ancestry. Gene region-specific significant SNPs (p < 0.05) were used to develop race-specific PRS. **Results:** The race-specific PRS included different sets of significant SNPs and were highly associated with lung cancer risk in both non-Hispanic Whites (OR = 1.07, 95% CI: 1.05-1.09, p = 3.44×10^{-9}) and Blacks (OR = 1.12, 95% CI: 1.08-1.17, p = 9.14×10^{-8}). These models remained significant for both Whites (OR = 1.05, 95% CI: 1.03-1.09, p = 0.0004) and Blacks (OR = 1.08, 95% CI: 1.01-1.15, p = 0.01) who currently do not meet USPSTF screening guidelines. AUC analysis demonstrated the Black-specific model (AUC = 0.68) outperformed the White-specific model (AUC = 0.57) (p = 0.03) when examined exclusively in the Black cohort. **Conclusions:** Using previously validated SNPs and gene regions, we developed race-specific PRS in non-Hispanic White and Black INHALE participants. Further validation of PRS could enable the incorporation of genetic risk modeling into lung cancer screening to identify patients who do not have traditional risk factors for lung cancer, as well as stratify patients into different levels of risk based on their genetic profile. Through the development of a reliable genetic risk factor prediction model, clinicians will have another method by which to evaluate lung cancer susceptibility, potentially leading to earlier diagnoses that portend more favorable treatment outcomes. Racial disparities in germline testing among men with pancreas, breast and metastatic prostate cancers in two health systems. *First Author: Jeffrey Shevach, University of Pennsylvania-Abramson Cancer Center, Philadelphia, PA*

Background: Germline genetic testing is a guideline-based practice for men with pancreas, breast and metastatic prostate cancers. Emerging evidence in female breast and ovarian cancers suggests that Black patients are less likely to receive germline genetic testing, but it is unclear how disparities extend to male cancers and vary by health system. We examined differences by race in germline genetic testing for men with pancreas, breast and metastatic prostate cancers in equal-access and non-equal access systems. **Methods:** We conducted a retrospective cohort study of men with newly diagnosed pancreas, breast and metastatic prostate cancers between January 1, 2019, and September 30, 2021. We studied two national cohorts: 1) Veterans receiving care in the Veterans Health Administration (VHA), an equal-access health system, and 2) commercially insured beneficiaries. Data consisted of claims and electronic health record data from the VHA Corporate Data Warehouse and claims data from Optum's De-Identified Clinformatics Data Mart Database (2007-2021). Current Procedural Terminology codes $\pm$ laboratory orders and results, and genetic services notes were used to ascertain germline testing prior to the end of the study period. Cox proportional hazards models were used to test the association of non-Hispanic White vs. Black race with the primary outcome of germline genetic testing completion, adjusted for baseline covariates (age, cancer subtype, census region, diagnosis year, Elixhauser comorbidity index and Agent Orange exposure [VHA only]). **Results:** Our cohort consisted of 7,894 men (5,142 commercially-insured; 2,752 Veterans), including 1,589 Black men (779 [15.1%] commercially-insured; 810 [24.9%] Veterans). Among commercially-insured beneficiaries, one-year germline genetic testing rates were higher in White compared with Black men (18.8% vs. 13.1%; log-rank $p < 0.001$). Among Veterans, one-year germline genetic testing rates were similar for White and Black Veterans (13.1% vs. 16.9%; log-rank $p = 0.335$). After adjusting for baseline covariates, Black race was associated with a lower hazard of testing among commercially-insured beneficiaries (adjusted hazard ratio [aHR] 0.72; 95% confidence interval [CI] 0.58 – 0.90; $p = 0.004$), but not among Veterans (aHR 0.99; 95% CI: 0.79 – 1.25; $p = 0.960$). **Conclusions:** This is the first study to examine disparities in germline genetic testing across equal-access and non-equal access healthcare systems, and the largest national study examining germline genetic testing completion in men. While overall rates of testing were similar between Veterans and commercially-insured beneficiaries, racial disparities in testing were observed in non-equal-access settings but not in equal-access settings. Access to care, cost, and other sequelae of structural racism may impact access to guideline-based germline testing. Research Sponsor: Bassett Center for BRCA; U.S. National Institutes of Health.

Characterizing medical mistrust (MM) in a socio-demographically diverse sample of patients with cancer. *First Author: Cindy Park, Temple University, Lewis Katz School of Medicine, Philadelphia, PA*

Background: Genetic and genomic testing are increasingly recognized as essential to high quality cancer care. Despite expanded eligibility for testing in recent years, barriers to genomic medicine persist. Notably, growing political and social mistrust risks negatively impacting views of medical institutions, medical professionals and complex technologies, and could undermine acceptance of genetic/genomic testing to guide treatment and identify risk in families. Prior studies have documented disparities and increased MM of genetic counseling and testing among underserved minorities which have been associated with delays or avoidance to care. We sought to identify individual characteristics associated with MM among cancer patients. **Methods:** A cross-sectional survey of cancer pts from the Fox Chase Cancer Center (FCCC) Burholme Campus (n=105, mixed urban/suburban, primarily insured) and Broad street campus (n=95, primarily urban underserved population) was conducted from 6/22-12/22, using a maximum variation (purposeful) sampling approach. Surveys queried MM using the LaVeist MM Index (MMI, range 0-10, measures healthcare/institution MM) and the Thompson Group Based MM Scale (GBMMS, range 1-5, measures race/ethnic specific MM; suspicion, discrimination, and lack of support subscales). Demographic and disease factors, as well as psychosocial measures (general/genetic health literacy, social support, self-advocacy, conspiratorial thinking, relationship with doctor, and trust in information sources) were also assessed. Medical decision making preference and health literacy were assessed with single validated items. The study was approved by the FCCC IRB #22-8003. **Results:** Participants had a median age of 62 yrs (range 25-91); 62% were female, 47% African American (AA), 15% Hispanic, 42% married, 47% high school graduate or less, 52% had household income $< \$50K/yr$. Breast (28%), colorectal (16%), and GYN/GU (12%) cancers were the most commonly reported, and 23% reported > 1 previous cancer diagnosis. Mean GBMMS was 2.11 (SD 0.80) and mean MMI was 4.63 (SD 1.54). See the table for significant associations. **Conclusions:** High levels of healthcare institution and race-based MM are associated with socio-demographic vulnerabilities, putting the most vulnerable cancer patients at high risk of making poor health decisions. Research Sponsor: U.S. National Institutes of Health; ECOG ACRIN.

Predictor	MMI Healthcare institution mistrust	GBMMS Race-based medical mistrust	Comparators
Age	NS	$p=0.04$	Younger>older
Race/ethnicity	$p=0.04$	$p<0.001$	AA>Hispanic>White
Stage (Early/Late/Unsure)	$p=0.04$	NS	"Unsure" highest
Education	$p=0.03$	NS	< high school highest
Insurance type	$p=0.04$	NS	Medicaid highest
Annual household income	NS	$p=0.05$	< \$25K highest
Site (urban/suburban)	NS	$p=0.03$	Urban higher
Health literacy	NS	NS

Disparities in germline genetic testing results from a cohort of 493,515 black and white patients. *First Author: Rachel Wyatt, UT Health San Antonio, San Antonio, TX*

Background: When undergoing germline genetic testing (GGT), Black patients (pts) are more likely than non-Hispanic White (NHW) pts to receive uncertain results and less likely to receive definitive molecular diagnoses as the Black genome is less well-characterized. As GGT is increasingly pertinent to cancer care, it is important to explore the scope of these disparities. **Methods:** A retrospective cohort of clinician-reported Black and NHW pts who underwent GGT (43-84 genes) from 2015-2022 was evaluated. Frequencies of pathogenic/likely pathogenic (P/LP) and variant of uncertain significance (VUS) results were compared between Black and NHW pts. Rate and type of VUS reclassifications were also compared. Differences in proportions were determined using Chi-square test and significance was set at 0.05. **Results:** The cohort consisted of 493,515 pts (48,684 [10%] Black and 444,831 [90%] NHW). VUS results were significantly more frequent and P/LP results significantly less frequent for Black compared to NHW pts (46% vs. 32% and 9 vs. 13%, respectively). This was also true for pts who reported a history of cancer, across all common hereditary cancer types (Table). Comparing Black to NHW pts, there were more unique instances of VUS reclassifications over time (13% of 13,629 vs. 9% of 53,195 unique VUS), including 12% vs. 8% downgraded to benign/likely benign and 0.9% vs. 1.3% upgraded to P/LP. **Conclusions:** Lower rates of actionable results limit risk-reducing interventions for Black pts and their families. However, VUS rates continue to decline, particularly in Black pts, as more individuals (of any race or ethnicity) are sequenced. Clinicians can be reassured that most (but not all) VUS that are reclassified are downgraded to benign. Research Sponsor: Invitae.

Test result yield by cancer type among black and white pts.

Training oncologists (Oncs) to conduct better informed discussions with African American (AA) cancer (CA) patients (pts) about tumor genomic profiling (TGP): Results of a randomized pilot trial of gene pilot pro (GPP). *First Author: Michael J. Hall, Fox Chase Cancer Center, Philadelphia, PA*

Background: Molecular characterization of tumors to guide therapy choices using next-generation sequencing-based TGP has become standard practice for pts w/ multiple CA types. AAs are more likely to have negative attitudes towards genetics, rooted in concerns about privacy, cost and discrimination, and higher mistrust of medical institutions. Oncs are poorly prepared for informed discussions w/CA pts about secondary hereditary risks of TGP and often fail to have these conversations despite 2015 ASCO guidelines benchmarking this standard, and further are poorly informed of the potential challenges of discussing TGP and germline risk w/their AA CA pts. **Methods:** Formative work included 1-on-1 interviews (n = 10) to assess oncs' perceptions of TGP use and discussions w/AA CA pts, and a national survey (n = 50) to assess TGP practice patterns, communication of hereditary risk, and challenges encountered in AAs. Interviews/survey data and advisory board input informed development of GPP, a 12 min online training video to improve Oncs' awareness of ASCO guidelines, confidence and preparation to have TGP discussions w/pts, and improve awareness of barriers to TGP unique to AA CA pts. The control consisted of 10 slides with information about TGP drawn from industry/academic websites and the 2015 ASCO guidelines. Participants (n = 63) completed baseline (100%), post-intervention (100%), and 1-month (95%) follow-up surveys. The study was approved by the Fox Chase Cancer Center IRB 18-8006. **Results:** Oncs were recruited by email and randomized to view GPP or control material. The majority were age 40-49 (38%), 71% male, 44% White, w/mean 15 yrs in practice; 85% reported none or only informal training to communicate TGP risks/results to pts. GPP produced a durable increase in recognition of 4 core ASCO guideline elements (20% baseline, 67% post, 63% 1 month). At 1-month follow-up, GPP significantly improved recognition of barriers specific to AA CA pts related to TGP and hereditary risk ($p = 0.001$) and promoted greater preparedness to support TGP discussions w/AA pts including preparedness to identify ($p < 0.01$) and understand ($p < 0.01$) issues that matter most to their AA pts. 1-month confidence to conduct difficult discussions related to genetic mistrust ($p = 0.004$) and TGP cost ($p = 0.003$) was better preserved after viewing GPP compared to control. Among Oncs viewing GPP, 90% agreed/strongly agreed that GPP helped them "better understand how to address concerns my AA pts may have about TGP" and 97% definitely/probably would recommend GPP to other Oncs. **Conclusions:** GPP significantly improved Oncs' awareness of barriers related to TGP communication in AA CA pts, improved preparedness to facilitate informed decision-making, and supported sustained confidence to lead difficult discussions. Integrated clinical, pathologic, and genetic data in a racially diverse hereditary breast cancer cohort. *First Author: Kenna Noel Koehler, Vanderbilt University Medical Center, Nashville, TN*

Background: Hereditary breast cancers (HBC) represent 5-10% of breast cancer, predominantly due to pathogenic/likely pathogenic (P/LP) variants in the *BRCA1* and *BRCA2* genes and other high (e.g., *PALB2*) and moderate (e.g., *ATM* and *CHEK2*) penetrance genes. There remains a paucity of data evaluating the role of germline-somatic interactions and possible confounders on breast cancer outcomes. Furthermore, current knowledge about HBC is predominantly defined in the context of European ancestry. We sought to characterize differences in clinicopathological features and somatic mutations across P/LP variants in a racially diverse HBC cohort. **Methods:** Among females with breast cancer and a confirmed P/LP variant in *BRCA1*, *BRCA2*, *PALB2*, *CHEK2*, and/or *ATM* currently enrolled through existing Vanderbilt-based studies (ICARE: Inherited Cancer Registry and BEST: Black Women: Etiology and Survival of Triple Negative Breast Cancers (TNBC)), we abstracted data from medical records and performed tumor sequencing using the Tempus xT assay (a 596-gene DNA next-generation sequencing panel and whole-transcriptome RNA sequencing). Interim differences in clinicopathological features were analyzed using Pearson's chi-square test and the frequency of somatic mutations reported by gene. **Results:** To date, we have data from 91 females with breast cancer (77% White and 23% Black) and a P/LP variant (36 *BRCA1*, 27 *BRCA2*, 13 *PALB2*, 11 *CHEK2* and 4 *ATM*). The median age at diagnosis was 44 (38-50), 85% had localized breast cancer (Stage I-II), and 69% had Grade 3 tumors. Significantly more Black participants were *BRCA1* carriers ($p = 0.008$), with no significant racial differences observed in other genes. There were significant differences in IHC subtype by gene ($p < 0.001$); with higher frequency of TNBC in *BRCA1* carriers (64%) whereas *BRCA2*, *PALB2*, *CHEK2*, and *ATM* carriers were more likely to have HR+, HER2- breast cancer (67%, 54%, 73%, 75%, respectively). Of the 85% who received chemotherapy, significantly higher rates were observed in *BRCA1* carriers ($p = 0.02$). Most participants opted to proceed with a risk-reducing mastectomy (69%) with no difference across genes ($p = 0.91$). Higher rates of somatic *TP53* mutations were observed among *BRCA1*, *BRCA2*, *PALB2* carriers (89%, 56%, 46%) but not as frequent among *ATM* (25%) and *CHEK2* (9%) carriers. **Conclusions:** These preliminary results show that among a diverse cohort of females with HBC, *BRCA1* mutations were overrepresented among Black females and those with TNBC. *BRCA1*, *BRCA2*, and *PALB2* carriers had a higher prevalence of somatic *TP53* mutations, which are typically associated with more aggressive tumor biology and worse survival outcomes. Current efforts underway include full genomic and transcriptomic analysis, through which we will be able to improve our understanding of breast cancer clinicopathological characteristics and survival outcomes among a diverse cohort of females with HBC. African American women who carry the *BRCA1/2* mutation: Clinical characteristics and prevention strategies. *First Author: Ujjwal Karki, Corewell Health William Beaumont University Hospital, Royal Oak, MI*

Background: Carriers of pathogenic variants (PV) in *BRCA1/2* have an increased risk of breast, ovarian, and other cancers. The clinical characteristics and uptake of risk-reducing interventions in African American (AA) women with *BRCA1/2* PVs are less well studied. **Methods:** After IRB approval, we performed a retrospective chart review on African American women seen at Nancy and James Grosfeld Cancer Genetics Center at Beaumont Health from January 1, 2006, to December 31, 2021, who tested positive for a *BRCA 1/2* mutation. We analyzed demographics, cancer characteristics, outcomes, and prevention strategies. **Results:** Of 238 African American (AA) women who underwent genetic testing, 69 patients (29%) were identified to be a carrier of *BRCA1/2* PVs or likely pathogenic variants (LPVs). The median age at testing was 49 years (range: 24-87). Forty-six women (67%) had a cancer diagnosis, with a median age at diagnosis of 52 years. Four women had two, and one had three cancers, for a total of 52 cancers. Breast cancer was the most common type of cancer (40; 77%), with a median age at diagnosis of 48 years (range 24-73) and a majority (26; 65%) being *BRCA2* carriers. Most were invasive ductal carcinoma (87.8%), high-grade (80%), ER-positive (52%), PR-negative (68%), HER2-negative (94%) and stage I or II disease (63%). Fifteen (38%) were triple-negative. Most patients (87%) received adjuvant systemic chemotherapy or endocrine therapy, 31% received neoadjuvant chemotherapy, and 39% received adjuvant radiation. The 3- and 5-year survival was 94% and 91%, respectively, with a median follow-up of 103 months. Three patients (all *BRCA2* carriers) developed contralateral breast cancer (median time to recurrence: 201 months); 3 (all *BRCA2*) developed local recurrence (median time to recurrence: 60 months); and 4 (2 *BRCA1*, 2 *BRCA2*) developed metastatic recurrence (median time to recurrence: 34 months). Other cancers observed were ovarian ($n = 6$; 4 *BRCA2*, 2 *BRCA1*), uterine (2), lung (2), kidney (1), and glioblastoma (1). Compared to AA carriers without cancer, those with cancer were more likely to undergo risk-reducing mastectomy (RRM; 68% vs. 23%) and risk-reducing salpingo-oophorectomy (RRSO; 72% vs. 55%). In the non-cancer group, significantly fewer patients elected RRM (23%) compared to RRSO (55%). **Conclusions:** Our study outlines the characteristics of AA women who carry *BRCA1/2* PVs, revealing that most had high-grade invasive ductal breast cancer with excellent survival. Patients without a cancer diagnosis were less likely to undergo risk-reducing surgery, highlighting the importance of effective counseling focusing on primary prevention in these high-risk patients. Further research is needed to better characterize cancer risk and address potential barriers to uptake of risk-reducing interventions in this population. Research Sponsor: None.

Racial disparities in aging-related comorbidity among breast cancer survivors. *First Author: Kirsten Nguyen, Vanderbilt University School of Medicine, Nashville, TN*

Background: Black breast cancer (BC) patients have a higher mortality rate than their white counterparts, potentially due to age acceleration caused by cancer and its treatments. However, epidemiological evidence is limited. **Methods:** Our study includes 1885 BC patients and 1224 cancer-free women (controls) recruited at Vanderbilt University Medical Center from 2004 to 2021. Patient demographics and aging-related outcomes were extracted from the tumor registry or electronic health records. Aging-related outcomes included 28 comorbidities and the Charlson Comorbidity Index (CCI) at baseline (biopsy) and follow-up (latest clinical visit). The associations of BC status with CCI and specific comorbidities were evaluated by linear and logistic regression models, respectively. The associations of race with aging-related outcomes were evaluated among cases. All analyses were adjusted for age, and follow-up outcomes were adjusted for baseline information. **Results:** The median follow-up time is 10 years. BC patients had a higher mean CCI at baseline (1.32 vs 0.59, $p < 0.01$) and follow-up (beta=1.04, 95% CI=0.94-1.14) than controls. Results from individual comorbidities showed that BC survivors had a higher risk of developing cardiovascular disease, liver disease, hypertension, hyperlipidemia, gastroesophageal reflux disease (GERD), and depression. Among BC patients, Black women were diagnosed at a younger age (52.0 vs 55.8, $p < 0.01$), but had a higher baseline and follow-up CCI than Whites. Black BC survivors were more likely to develop peptic ulcer disease, diabetes, second malignancy, hypertension, and GERD than White BC survivors, even after adjustment for baseline comorbidities. Research Sponsor: MMC, VICC, and TSU: Partners in Eliminating Cancer Disparities Grant (U54CA163072); Vanderbilt-Ingram Cancer Center SPOR in Breast Cancer (P50CA098131).

Prevalence of and racial/ethnic distribution of full-body skin examination among sexual and gender minority patients. *First Author: Jincong Q. Freeman, Department of Public Health Sciences, The University of Chicago, Chicago, IL*

Background: Skin cancer disproportionately affects sexual and gender minorities in the United States. A full-body skin examination (FBSE) can help detect early signs of skin cancer and is an important prevention method. However, there are no national guidelines of routine FBSE for skin cancer. Further, data on FBSE participation among lesbian, gay, bisexual, transgender, and/or queer (LGBTQ+) patients are lacking, and little is known about the racial/ethnic distribution of FBSE in this patient population. **Methods:** Cross-sectional survey data on FBSE participation and key characteristics were collected from patients who were recruited at clinics and community centers or via social media from August 2022 to January 2023. Eligibility criteria included being at least 18 years old and self-identifying as LGBTQ+. Receipt of an FBSE, assessed by asking patients whether they had ever received an FBSE in the past, was dichotomized as yes and no. Descriptive statistics, i.e., mean (SD) and count (%), were calculated, with distribution comparisons using Student's t, Pearson's Chi-square, or Fisher's exact tests as appropriate. **Results:** A total of 124 LGBTQ+ patients responded to the survey. The mean age was 32.4 (SD = 12.1) years. Overall, 41.5% of the patients reported ever having received an FBSE in the past. By race/ethnicity, 62.5% of Non-Hispanic Black patients reported ever having received an FBSE, followed by 52.1% of Non-Hispanic White, 28.6% of Hispanic or Latino, 28.6% of multiple races, and 10.5% of Asian ($p=0.005$). By gender identity, 61.5% of transgender male patients reported receipt of an FBSE in the past, followed by 57.1% of transgender female, 39.3% of cisgender female, 35.4% of cisgender male, and 35.0% of genderqueer, non-binary, or gender non-conforming. Comparing patients who reported ever having received an FBSE, those who did not were more likely to not be employed (47.9% vs. 26.0%, $p=0.046$), to be on Medicaid (18.5% vs. 6.1%, $p=0.074$), to not have visited a dermatologist in the past (41.7% vs. 7.8%, $p<0.001$), and to not have been told at an increased risk for skin cancer (87.3% vs. 43.2%, $p<0.001$). No significant differences in educational attainment or sexual orientation were observed between patients who reported ever having received an FBSE and those who did not. **Conclusions:** The prevalence of FBSE was higher among Non-Hispanic Black or Non-Hispanic White LGBTQ+ patients than among those who are Hispanic or Latino, multiracial, or Asian. In addition, our findings suggest that low socioeconomic status and health care utilization may influence FBSE access or participation in LGBTQ+ patients. Strategies for improving equitable access to FBSE among LGBTQ+ patients, particularly among those with ethnic minority background or low socioeconomic status and health care utilization, may be needed. Vitamin D deficiency as a risk factor for breast cancer development. *First Author: James David Mackey, Alara Medical Group, Dallas, TX*

Background: Previous studies and meta-analyses have suggested that women with low levels of vitamin D may be at increased risk of breast cancer development and recurrence. The relationship is suspected to be inverse, nonlinear, and predominantly present in postmenopausal women. The purpose of this study was to use the TriNetX platform to determine the magnitude of breast cancer risk increase for women with significant vitamin D deficiency and evaluate the significance of menopause on vitamin D-associated breast cancer risk. **Methods:** The TriNetX platform was used to generate patient cohorts via International Classification of Disease-10 (ICD-10) codes. All patients were females over 40, had no prior history of breast cancer (C50), and had been diagnosed with menopause (Z78.0). One cohort had less than 20 ng/mL of vitamin D while the other had greater than 30 ng/mL. The cohorts were balanced for age, race, and ethnicity, resulting in 73,659 patients in each arm. They were then evaluated for the future development of breast cancer (C50). Two additional cohorts were created of premenopausal patients aged 40-55 using the same vitamin D parameters and cohort balancing. **Results:** Postmenopausal women with vitamin D levels below 20 ng/mL had a 45% greater risk of developing breast cancer (risk ratio 1.45, 95% CI (1.38, 1.52), p -value <0.0001). (Table) Deficient premenopausal women were also found to be at significantly increased risk although the absolute risk difference was small (relative risk 1.18, 95% CI (1.10, 1.27), p -value <0.0001). **Conclusions:** These results confirm and also quantify the previously-suspected increased breast cancer risk for women who are deficient in vitamin D. The impact of low vitamin D levels on breast cancer risk in premenopausal patients was statistically significant but small in magnitude, while postmenopausal women were found to have approximately 45% higher risk as compared to women who were not deficient. Vitamin D supplementation for all deficient postmenopausal women should be considered. Research Sponsor: None.

New breast cancer incidence rates by vitamin D subgroup.

Melanoma literacy and predictors for skin self-examination in three western U.S. states: A population-based survey. *First Author: Jacob Nelson, Oregon Health & Science University, Portland, OR*

Background: Melanoma is a leading cause of skin cancer deaths, despite being easily treated when detected early. The objective of this study is to investigate the relationship between melanoma knowledge and beliefs, and the performance of skin self-examination (SSE) in three US states with high incidence rates of melanoma. Understanding the barriers to behaviors such as SSE can aid in the development of interventions aimed at increasing the frequency of early detection and reducing melanoma-related deaths. **Methods:** A total of 15,000 surveys were distributed to households in the states of Oregon, Washington, and Utah using a stratified two-stage sampling design. The survey responses were weighted to resemble the gender and age distributions of the US census. Rural areas were oversampled to ensure sufficient representation. The first objective of this study was to assess melanoma literacy, including knowledge about melanoma risks, attitudes, and preventive behaviors. Our second objective was to investigate the relationship between self-reported SSE and melanoma literacy, self-efficacy, and belief in the benefits of performing SSE. **Results:** Among 2,326 respondents, characteristics were similar across states (weighted by census-based population percentages), including demographics, baseline knowledge, performance of SSE, and self-efficacy in performing SSE. Rural respondents had a higher frequency of personal history of melanoma (16.2%) compared to urban respondents (9.9%). Only 21.2% of the respondents demonstrated high knowledge of melanoma. 62.8% of respondents reported having performed a SSE at some point in their lives, with only 24.6% of respondents having done so in the past 2 months. Most respondents (84.8%) believed in the effectiveness of SSE in detecting skin cancer, but only 38.3% and 7.3% reported being "fairly" or "very" confident in performing SSE, respectively. The performance of SSE was most strongly correlated with higher melanoma knowledge, higher self-efficacy, and a personal history of melanoma. **Conclusions:** The results of the survey indicate that melanoma literacy among respondents in 3 high-risk Western states is limited. A higher level of literacy was associated with a higher likelihood of reported early detection behaviors. This study provides a baseline assessment and serves as a foundation for the development of public health campaigns aimed at promoting prevention and early detection of this deadly cancer. A nationwide population based primary CNS lymphoma (PCNSL) analysis: Do Hispanics have better outcomes? *First Author: Ysaith Orellana, Ohio University Heritage College of Osteopathic Medicine, Cincinnati, OH*

Background: Over the last decade, overall survival (OS) of PCNSL patients has increased from 12.5 months to 26 months (N. Oncol, PMID 30418592). One study examined the incidence of PCNSL in the Hispanic (HI) population in Texas (Cureus, PMID: 33042676), but a national study is needed to understand ethnic disparities, as many HI face barriers to health care access (Natl Cancer Inst Monogr. PMIDL 8562207). This study aims to understand demographics, treatment patterns, and outcomes of HI and Non-Hispanic (NH) patients with PCNSL nationally. **Methods:** Data analyzed on PCNSL patients in the United States (US) was reported to the Surveillance, Epidemiology, End Results (SEER) 18 database between 2000 and 2018. Racial groups analyzed included NH whites, HI whites, Blacks, and Asian/Pacific Islanders (PI). Patient characteristics, age-adjusted incidence rate, and survival rate were compared across ethnic groups (HI vs. NH). Stratification by age, gender, and stage at diagnosis was considered. Data was stratified using Kaplan-Meier and Cox regression analyses to compare OS between HI and NH. Multivariate analysis and propensity score matching was performed with adjustment for age, stage, and B-symptoms. **Results:** Of 5819 PCNSL patients, 15% were HI, and 85% NH. 57% were male compared to 51% of NH. As compared to NH at diagnosis, HI patients were younger, 59 years vs. 66 years ($p<0.001$); the majority of HI (42%) were diagnosed in the age bracket of 60-80y ($p<0.001$). Approximately 30% of HI were diagnosed in 2015-2018, while most of NH (29%) were diagnosed in 2010-2014 ($p=0.054$). With 52% of HI being diagnosed at $<60y$, only 32% in NH. As for race, most of HI and NH were White (97% vs. 79%), followed by Black (1% vs. 8%). On survival analysis, the survival probability at 2, 5, and 10y of HI vs. NH were (0.507 vs. 0.441), (0.395 vs. 0.322), and (0.237 vs. 0.225), respectively. The median survival time was 2.1y for HI vs. 1.2y for NH. There was an OS difference favoring HI ($p=0.0009$). On multivariate analysis, when adjusted for age, patients with PCNSL between 60-80y and above have 3.4 times more likely to die from disease after diagnosis with HR 3.4 (95% CI: 2.9-4) and 1.7 (95% CI: 1.6-1.9). **Conclusions:** Our study demonstrates statistically longer median survival and OS favoring the HI population. The younger age of diagnosis in HI patients could be a factor in their survival probability for PCNSL, given that both HI and NH received similar treatment and had a similar staging. However, additional studies would be needed to validate this observation and determine other biological or socioeconomic factors that may play a role. Research Sponsor: None.

Elevated cancer risk among individuals with combinations of cancer-related risk factors: A large claims database analysis. *First Author: Ze Cong, GRAIL, LLC, a subsidiary of Illumina, Inc., currently held separate from Illumina, Inc., under the terms of the Interim Measures Order of the European Commission dated 29 October 2021, Menlo Park, CA*

Background: Besides age, many risk factors have been associated with elevated cancer risk. Understanding cancer incidence rates among patients with single or multiple risk factors can help inform cancer prevention and detection efforts. **Methods:** A retrospective observational analysis was conducted on individuals aged 50-79 in 2020 using Optum's de-identified Clinformatics Data Mart Database which includes Medicare Advantage (MA) (vast majority aged 65+) and commercially insured members (mostly below 65 and employed). Patients with no prior cancer diagnosis (continuously enrolled with no cancer claims for one year) and with cancer risk factors were identified using ICD-10-CM and CPT-4 codes, including autoimmune-related chronic inflammation (diabetes, inflammatory bowel disease, asthma, or rheumatoid arthritis) (INFLAM AUTO); non-autoimmune related chronic inflammation (fatty liver disease, obesity, or cirrhosis/chronic hepatitis B/C) (INFLAM NONAUTO); immunodeficiency (primary or secondary immunodeficiency, HIV, or status post organ transplant); and smoking. Cancer incidence rate ratios (IRR) were calculated by comparing one-year cancer incidence rate among the groups with risk factors versus the general population by insurance type (IRR>1 means elevated risk of cancer). Groups with evidence of any risk factor and combinations of risk factors were assessed. Statistical significance of IRRs was evaluated using logistic regression models adjusting for demographic characteristics. **Results:** Cancer incidence rates of 1.12% and 2.11% were observed among the approximately 1.3 and 2.4 million general population aged 50-79 in commercial and MA plans, respectively. Enrollees with any of the risk factors or combinations analyzed had statistically significantly elevated risk of cancer (IRRs>1.00, p<0.05). Commercially insured groups with highest risk included transplant (IRR=7.68, prevalence=0.02%), immunodeficient and smokers (IRR=3.66, prevalence=0.16%), cirrhosis/chronic hepatitis B/C (IRR=2.61, prevalence=0.41%), INFLAM AUTO and smokers (IRR=2.43, prevalence=3.56%), and smoker (IRR=2.33, prevalence=11.11%). Results in MA were generally consistent with the commercial plan (Table). **Conclusions:** Patients in both commercial and MA plans with any risk factor experienced significantly elevated cancer risk. Cancer prevention and screening strategies can be informed by risk levels among different patient subgroups to optimize resource allocation. Research Sponsor: GRAIL, LLC, a subsidiary of Illumina, Inc. currently held separate from Illumina, Inc. under the terms of the Interim Measures Order of the European Commission dated 29 October 2021.

Assessing disparities in lung cancer screening eligibility among high-risk individuals. *First Author: Abdi Gudina, University of Rochester Medical Center, Rochester, NY*

Background: Low-dose computerized tomography (LDCT) scanning confers a 20% reduction in lung cancer mortality by diagnosing the disease at earlier, more treatable stages. Racial/ethnic minorities have historically been less likely to be eligible for lung cancer screening. In 2021, the U.S. Preventive Services Task Force (USPSTF) updated its 2013 guideline for lung cancer screening eligibility by reducing the minimum age (55 to 50) and decreasing the cumulative number of cigarette pack-years smoked (30 to 20). The purpose of this study was to assess if the updated guideline will mitigate disparities in lung cancer screening eligibility among high-risk individuals. **Methods:** Data were obtained from the Behavioral Risk Factor Surveillance System (2017-2019), a population-based survey administered annually by the Centers for Disease Control and Prevention. Only subjects with complete information on the variables used to determine eligibility (age, smoking status, age at first start smoking, age at last smoked, average number of cigarettes smoked each day) (n = 793,537) were included in the final analysis. Logistic regression was used to model the association between predictors and 2021 vs. 2013 lung cancer screening eligibility. **Results:** Based on the 2013 guideline, Non-Hispanic Blacks (OR: 0.34; 95%CI: 0.31 - 0.38), Hispanics (OR: 0.12; 95%CI: 0.10 - 0.14), and other racial/ethnic minorities (OR: 0.59; 95%CI: 0.54 - 0.64) were less likely to be eligible for lung cancer screening than Non-Hispanic Whites. Using the 2021 guideline, Non-Hispanic Blacks (OR: 0.45; 95%CI: 0.42 - 0.49), Hispanics (OR: 0.15; 95%CI: 0.13 - 0.16), and other racial/ethnic minorities (OR: 0.63; 95%CI: 0.58 - 0.67) remain less likely to be eligible for lung cancer screening than Non-Hispanic Whites. **Conclusions:** The 2021 guideline slightly reduces racial/ethnic disparities in lung cancer screening eligibility. Further efforts should be made to develop a guideline that better addresses disparities in lung cancer screening eligibility to reduce lung cancer deaths in racial minorities. Modeling genetic testing (GT) attitudes in a socio-demographically diverse cohort of patients (pts) with cancer: The importance of race/ethnicity and medical mistrust (MM). *First Author: Michael J. Hall, Fox Chase Cancer Center, Philadelphia, PA*

Background: Germline GT and tumor genomics are relevant to the care of nearly every cancer pt. These tests inform treatment planning by NGS-based tumor genomic profiling (TGP) and hereditary risk assessment. Socioeconomic and race-based disparities in GT are well-known, but the impact of growing MM, fueled by political polarization and social unrest due to overt and institutional racism, has been less studied. In previous research of African American (AA) cancer pts, we identified a consistent association of high levels of MM with negative attitudes toward GT. To inform development of an intervention to support informed decisions about GT in cancer pts, we further characterized the relationship of MM to GT attitudes. **Methods:** Pts from two Fox Chase Cancer Center (FCCC) sites were recruited (6/2022-12/2022) to complete a cross-sectional survey (n=105, Burholme campus; n=95, Temple University Hospital). A stratified purposive sampling method was employed. Data on pt demographics and disease factors were collected. MM was queried with two validated measures: LaVeist MM Index (MMI: range 0-10, measures healthcare/institution MM) and Thompson Group Based MM Scale (GBMMS: range 1-5, measures race/ethnicity specific MM; suspicion, discrimination, and lack of support subscales). Attitudes toward GT (GTpros=6 items/GTcons=11 items) were measured w/a validated scale (Morren: range 0-10) plus 4 items developed by our team. The study was approved by the FCCC IRB 22-8003. **Results:** Median age of pts was 62 yrs (range 25-91); 62% were female, 47% AA, 15% Hispanic, 42% married, 47% ≤high school grad, 52% had household income ≤\$50K/yr. Mean GBMMS was 2.11 (SD 0.80) and mean MMI was 4.63 (SD 1.54). Mean of GTpros was 8.77 (SD 1.68); GTcons 4.16 (SD 2.32). MM was associated with race/ethnicity by GBMMS (p<0.001) and MMI (p<0.04), as were GBMMS subscales (suspicion, discrimination, lack of support, all p<0.001). Race/ethnicity was not associated w/GTpros (p=0.59) but was w/GTcons (p<0.001). In univariate models both GTpros and GTcons were associated with GBMMS (p=0.005 and p<0.001, respectively) and MMI (p=0.002 and p<0.001, respectively). In a multivariable model examining GTcons, GBMMS score remained significant (p<0.001) even when controlling for race (p<0.01) and an interaction btw race*-mistrust. A similar model showed MMI score also remained significant (p=0.04) when controlling for race and interaction effects. Only the GBMMS suspicion subscale remained significant (p<0.02) in a model with both race and an interaction term. **Conclusions:** MM is markedly more common among racial/ethnic minority cancer pts, but the relationship btw MM and GT attitudes is only partially rooted in race/ethnicity. Oncologists considering germline GT or tumor genomics for pts, and efforts to support informed decision-making, must consider the pervasiveness of MM. Patient-level factors associated with the use of active surveillance: The talking about prostate cancer cohort. *First Author: Nita Mukand, Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA*

Background: Talking About Prostate Cancer is a population-based cohort study on multilevel determinants of active surveillance (AS) and patient reported outcomes in a racially and ethnically diverse population of men with low-risk prostate cancer. The study includes qualitative one-on-one interviews with patients and physicians, and quantitative cross-sectional provider and longitudinal (baseline and 12-month follow-up) patient surveys to address gaps in the literature regarding patient-level factors associated with AS, particularly among understudied populations including Asian American and Hispanic patients, we assessed socio-demographic characteristics associated with receipt of AS. **Methods:** Men aged 40-79 diagnosed with low-risk prostate cancer from May 2018 through March 2022 were identified within 12 months of diagnosis from the population-based Greater Bay Area Cancer Registry. To expand recruitment, men were also identified from the cancer registries covering the rest of California. To ensure sufficient representation of diverse racial and ethnic groups, 20% of non-Hispanic White men were sampled, while all Asian American and Pacific Islander, Black, and Hispanic men were invited to participate. Univariable and multivariable logistic regression were used to estimate the odds ratios (OR), adjusted odds ratios (aOR), and 95% confidence intervals (CI), of receiving AS. Potential predictors included year of diagnosis, age, health insurance, usual source of care, race and ethnicity, educational attainment, employment, nativity, and language preference. **Results:** Among 500 men with low-risk prostate cancer, 27% went on AS, 30% underwent surgery, radiation, hormonal treatment, cryotherapy, and/or high-intensity focused ultrasound, and 43% had not yet made a treatment decision at baseline. Among those who had made a treatment decision at baseline (N = 287), 27% of Hispanic men received AS, which was the lowest proportion among the racial and ethnic groups (Black 28%; Asian 47%; White 59%). A higher proportion of coupled men (29%) received AS compared to single men (15%). Less than half of men with less than a high school education received AS. Compared to men with a high school education or less, men with a bachelor's degree had an aOR of 2.91 (95% CI 1.10 - 8.42) and men with a graduate degree had an aOR of 4.37 (95% CI 1.50-12.76) of receiving AS. A significantly lower odds of AS was identified among Black (aOR 0.26; 95% CI 0.11-0.64) and Hispanic men (aOR 0.35; 95% CI 0.15 - 0.81) compared to non-Hispanic White men. **Conclusions:** We identified several significant socio-demographic differences between patients who received definitive treatment versus AS in this cohort, including race and ethnicity and educational attainment. Further study of these domains in larger, diverse samples will elucidate the strength of these associations within racial and ethnic groups. Research Sponsor: U.S. National Institutes of Health.

Colorectal cancer and digital/live screening navigation: Promoting prevention through personalized recommendations and access. *First Author: Kim Newcomer, Colorectal Cancer Alliance, Washington, DC*

Background: This project evaluates the effectiveness of an advocacy organization-led digital and live navigation framework aimed at colorectal cancer (CRC) screening completion. The Colorectal Cancer Alliance's screening quiz guides patients to a clinically valid, personalized CRC screening recommendation with a handoff to live navigation for those at risk. The framework utilizes digital innovation, targeted awareness, and financial support to support populations experiencing the greatest disparities and increase screening intention, behavior, and further health equity in colorectal cancer. This simple intervention is critical due to existing research consistently indicating on-time screening for CRC leads to favorable outcomes. **Methods:** In July 2022, the Alliance launched an enhanced quiz to improve the CRC screening navigation experience and increase engagement. The new survey instrument was restructured to streamline time to completion while preserving clinically accurate risk stratification. The follow-up navigation protocol was reordered from digital-first to live-first to leverage high-touch strategies earlier in the screening journey and dynamic content was added to the recommendation page to create a more personalized resource. The Alliance also deployed social media and influencer campaigns to increase outreach to at-risk communities. **Results:** The enhanced quiz delivered over 8,300 CRC screening recommendations and improved the average monthly completion rate (33%) and contact capture rate (14.4%) compared to the previous quiz in 2022 (24%; 8%). The median age of respondents was 55, and 37.2% of the respondents were between the ages of 45 and 64. Of the respondents, 26.7% were male and 73.3% were female. The majority were White (77.1%), 7.3% identified as Black/African American, 5.5% were Hispanic or Latino, and 3% were Asian. Most respondents were symptomatic (67.8%) but 8.1% were asymptomatic high-risk. Respondents (1,078) were triaged to live Alliance patient navigation. **Conclusions:** This digital and live navigation framework may serve as a strong solution in driving colorectal cancer screening and supporting shared-decision making conversations compared to other available interventions. The framework provides users with robust access to live navigation, educational resources, and support services for CRC screening and diagnosis. The Alliance is uniquely positioned to utilize its communications channels, social media and influencer campaigns to reach at-risk communities with credibility. Data attributed to specific campaigns are still being analyzed, and the Alliance will continue to optimize its navigation protocol and awareness efforts as quality improvement processes allow for a deeper understanding of more inclusive and impactful navigation experiences to close screening gaps among at-risk populations. Navigation program for LDCT lung cancer screening implementation: A quality initiative. *First Author: Jasmine Shrestha, Mercy Clinic, Fort Smith, AR*

Background: Lung cancer remains the leading cause of cancer-related death worldwide. Despite recommendations from experts, the lung cancer screening has not been well adopted in practice. **Methods:** We started a pilot program in our cancer center in collaboration with Pulmonary medicine in November 2021 as we identified that the rates of Low Dose CT scan (LDCT) are meager in our community. Two areas that needed attention were identified. The first was the need for shared decision-making by the primary care physician (PCP) before ordering LDCT. The second was the follow-up for patients with positive lung nodules. A lung nodule patient navigator was assigned exclusively for this initiative. Reports were obtained from EPIC every month to identify patients who fit the criteria. PCPs of the respective patients were then reminded to discuss LDCT in the upcoming visit. The lung nodule navigator then followed the ordering and test results of LDCT. A dedicated lung nodule conference discussed all patients with positive lung nodules. Follow-up interventions included referrals to pulmonology, interventional radiology, or further imaging with PET scan. Per guidelines, patients who did not need acute intervention were kept on track for their follow-up CT as recommended. **Results:** We reviewed our baseline performance in LDCT from January to June 2021. The total screening included 271(32%) patients compared to 836 eligible patients who fit the criteria. From January 2022 to June 2022, out of 749 eligible patients who were expected to meet their PCP, 574(76%) patients received LDCT. Of the patients screened, 436(75%) had their baseline CT chest, with the remaining patients having follow-up CT. Fifteen patients had findings needing immediate intervention. **Conclusions:** The USPSTF has updated its annual lung cancer screening guidelines with LDCT for adults aged 50 to 80 years who have a 20-pack-year smoking history and current smoker or have quit within the past 15 years. With our approach, the screening rates have more than doubled compared to previous year. LDCT does carry certain risks, including false positive results and unnecessary biopsies; hence shared decision-making is needed before ordering the test. We identified the shared decision process as the rate limiting step across our institution. Our contact with PCP was a significant intervention that improved the screening. The second obstacle was the follow-up for positive LDCT, and we alleviated it with the multidisciplinary lung nodule conference. This process is undoubtedly difficult to achieve without a lung nodule navigator. Each hospital system is unique and has various difficulties implementing screening guidelines. We show that, with the help of a lung nodule navigator, the rates of lung cancer screening can be significantly increased. Research Sponsor: None.

The impact of extending CRC screening to the older population: Results from CRC-AIM microsimulation model. *First Author: Derek W. Ebner, Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN*

Background: Average-risk screening for colorectal cancer (CRC) is effective and recommended. The U.S. Preventive Services Task Force issued grade A and B recommendations for screening ages 50-75 and 45-49, respectively, however the recommendation for the older population (ages 76-85) is grade C (moderate certainty that the net benefit is small). With emerging blood-based CRC screening, we evaluated the benefits of screening the older population with continued multi-target stool DNA (mt-sDNA) or FIT strategies and/or with a modality shift to blood-based tests after age 75. **Methods:** Using the validated CRC-AIM microsimulation model, triennial mt-sDNA and annual FIT screening (ages 45-75) followed by four strategies for ages 76-85 (no screening, continued mt-sDNA/FIT, or a modality shift to blood-based screening using either CMS criteria [CMS] or recently reported blood test data from the ECLIPSE study¹ [BT; Guardant Health, Inc.]) were considered. For CMS criteria and BT, CRC sensitivity were set at 74% and 83%; and adenoma sensitivity was set to 20%, and 13%; and CRC specificity was set to 90% for both tests. Real-world (RWE) adherence for initial screening was set to 80% (CMS, BT), 65.6% (mt-sDNA), and 42.6% (FIT). Adherence for follow-up colonoscopy was set to 72.1% (mt-sDNA, CMS, BT) and 46.0% (FIT). **Results:** Screening among the population aged 45-85 resulted in 281 life years gained (LYG) with continued mt-sDNA as compared to 193 with continued FIT. Furthermore, mt-sDNA reduced CRC mortality by 70% as compared to 49% by FIT (Table). When screening modality was shifted to CMS (76-85 year olds), mt-sDNA/CMS resulted in 279 LYG as compared to 196 for FIT/CMS. CRC incidence was reduced by 59% (mt-sDNA/CMS) as compared to 38% (FIT/CMS), and mortality declined by 69% (mt-sDNA/CMS) as compared to 51% (FIT/CMS). Reductions in disease burden were lower when modality was switched to BT after age 75 due to reduced test performance. **Conclusions:** Extending CRC screening to the older population with continued mt-sDNA demonstrated the best health outcomes compared to other modalities. A modality shift after age 75 to blood-based testing resulted in greater LYG as compared to no screening, with performance at CMS criteria yielding better results than BT. Therefore, despite inferior performance, blood-based tests may offer a CRC screening option for older patients who are unable to complete stool testing. Research Sponsor: Exact Sciences Corporation.

Outcomes for patients by screening modality.

Modality (Ages 45-75)	Modality (Ages 76-85)	LYG*	Incidence Reduction	Mortality Reduction
mt-sDNA	No screening	270	57%	65%
mt-sDNA	mt-sDNA	281	60%	70%
mt-sDNA	CMS Blood	279	59%	69%
mt-sDNA	BT	279	58%	69%
FIT	No screening	180	35%	43%
FIT	FIT	193	37%	49%
FIT	CMS Blood	196	38%	51%
FIT	BT	195	36%	50%

LYG: life-years gained; COL: colonoscopy; CMS Blood: Center for Medicare Services recommended blood-test; BT: trial performance blood-based test. *Per 1000 individuals¹ ECLIPSE study.

The probability of lung cancer in patients with incidentally detected pulmonary nodules detected via low-dose computed tomography screening in China. *First Author: Guo Lan-Wei, The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, China*

Background: Low dose computed tomography (LDCT) screening has been proven to be effective in reducing lung cancer mortality, but the ensuing high false-positive and overdiagnosis rates shackle the effectiveness of lung cancer screening (LCS) in China. Nodule malignancy prediction models may be an applicable solution. **Methods:** We developed and internally validated the model using data from the ongoing Henan province Cancer Screening Program in Urban China (CanSPUC). From 2013 to 2021, 23031 heavy smokers underwent baseline screening with LDCT; 2553 participants were diagnosed with pulmonary nodules. Detailed questionnaire, physical assessment and follow-up were completed for all participants. We then externally validated the model using the National Lung Screening Trial (NLST) dataset consisting of 10485 lung nodules in 4660 participants. Multivariable Cox proportional risk regression models were used. Data analysis was performed from July 1, 2022, through December 31, 2022. **Results:** A total of 111 and 1089 lung cancer cases with a median follow-up duration of 3.7 years occurred in the Henan CanSPUC and NLST study, respectively. Age, gender, physical activity, consumption of pickled food, history of silicosis or pneumoconiosis, nodule type, size, calcification, and pleural retraction sign were included into the model. The AUC (95% CI) of the model for 5-year lung cancer risk was 0.857 (0.801, 0.914) and 0.847 (0.829, 0.881) in the training set and validation set, respectively. Compared with Mayo model, VA model, PKU model, and Brock model, the Henan CanSPUC model yield statistically better discriminatory performance (all *P* values < 0.05). The model calibrated well across the deciles of predicted risk in both the overall population and all subgroups. **Conclusions:** The model developed and validated in this study may be used to estimate the probability of lung cancer in nodules detected at baseline LDCT, allowing more efficient risk-adapted follow-up in population-based LCS programs. LungFlag, a machine-learning (ML) personalized tool for assessing lung cancer risk in a community setting, to evaluate performance in flagging non-small cell lung cancer (NSCLC) regardless of sex or race. *First Author: David Morgenstern, Roche Diagnostics, Indianapolis, IN*

Background: Application of ML-based risk prediction models to lung cancer screening cohorts have been shown to increase screening efficiency. However, ML-based models may be vulnerable to sexual and racial bias arising from historical bias in health care access as well as biased training data. Demonstrating fairness in the predictions of ML-based models is a prerequisite to their acceptance by clinicians and patients. We assessed the clinical performance of LungFlag based on sex and race, two key demographic subgroups at risk for disparate outcomes due to bias. **Methods:** The LungFlag machine learning model is a retrospectively validated ML model intended to identify individuals who are at elevated risk for lung cancer and should be counseled regarding lung cancer screening. LungFlag uses existing routine outpatient lab measurements, smoking history, comorbidities, and demographic data to flag high-risk individuals. We compare performance of LungFlag between sexes and between races and calculate the sensitivity at the overall positivity rate of 3%. We chose a case-control design based on a large US-based community and outpatient dataset including 39,135 case patients with NSCLC and 212,454 contemporaneous NSCLC-free controls. We included ever-smokers, ages 45-80, with available lab measurements from 3-12 months before diagnosis, and minimal follow-up of 24 months. Sub-populations with less than 1% representation from the total population were excluded. **Results:** The comparison between the sub-populations presented by sensitivity and specificity indexes is detailed in the table. No statistically significant difference was demonstrated in the sensitivity of the model to flag individuals that were diagnosed with NSCLC on multiple sub-populations. **Conclusions:** The LungFlag model demonstrated fairness with respect to sex and race based on similar clinical sensitivity in a large, community-based retrospective dataset. Further assessment in prospective studies and in additional racial sub-populations is recommended to support this conclusion. Research Sponsor: Roche Diagnostics.

Demographic Parameter	Sub-Population	N Cases	N Controls	Specificity @ 3% Positivity Rate (95% CI)	Sensitivity @ 3% Positivity Rate (95% CI)	Odds Ratio @ 3% Positivity Rate (95% CI)
Sex	Female	19,555	112,720	97.2 [97.1 - 97.3]	23.1 [22.6 - 23.7]	10.4 [9.8 - 11.2]
	Male	19,580	99,734	96.8 [96.7 - 96.9]	23.4 [22.8 - 24.0]	9.2 [8.7 - 9.9]
Race	White	33,724	179,387	96.9 [96.8 - 97.0]	23.5 [23.1 - 24.0]	9.6 [9.1 - 10.2]
	Black	4,058	19,554	97.1 [96.8 - 97.3]	23.7 [22.5 - 25.0]	10.4 [8.8 - 12.0]

Rates of routine cancer screening compared with pre-pandemic levels. *First Author: Allison H Oakes, Trilliant Health, Brentwood, TN*

Background: The COVID-19 pandemic caused significant disruptions to health-care delivery in the US due to mandatory stay-at-home orders and patient fears about visiting healthcare facilities. A logical consequence, many forms of healthcare use, including cancer screenings, sharply decreased in early 2020. Early studies suggest that cancer screening rebounded through the summer of 2020; however, > 2 years removed from the start of the pandemic, the long-term impact of missed screenings is unknown. The objective of this study was to examine trends in breast, cervical, and colorectal cancer screening from 2017-2022. **Methods:** This cross-sectional study used the Trilliant Health national all-payer claims database to analyze calendar year quarterly medical claims from Q1 2017- Q2 2022. We limited the study sample to those aged 21-85, the guideline-concordant target populations for the screening procedures. For breast and cervical cancer, we limited our sample to women. Using Current Procedural Terminology (CPT) codes, we calculated the quarterly number of individuals, per 100,000 eligible beneficiaries, who received screening for breast cancer, cervical cancer, and colorectal cancer. Percentage change in screening tests was compared. **Results:** In total, the analysis included > 300M unique individuals. For breast cancer, the median quarterly rate of pre-pandemic screening mammography was 8013 per 100k beneficiaries, which declined to 4,884 in Q2 of 2020—a 39% decrease. Screening mammography rebounded to pre-pandemic levels by Q3 and Q4 of 2020 but declined to a median rate of 7,314 per 100,000 beneficiaries in Q2 2022, with quarterly deficits ranging from 4-16%. For cervical cancer, the median quarterly rate of pre-pandemic screening was 5,469 per 100k beneficiaries. The rate of cervical cancer screening fell to 3,550 in Q2 of 2020—a 35% decline. By Q3 2020, cervical cancer screening rebounded toward the pre-pandemic median, then progressively declined to 4,557 per 100k beneficiaries by Q2 2022. Over the same time period, colorectal cancer screening decreased from a pre-pandemic median of 3,111 per 100k beneficiaries to 1,731 in Q2 of 2020—a 44% difference. From Q3 2020 to Q1 2022, the quarterly colorectal cancer screening rate remained 10-17% below pre-pandemic levels, but returned to 3,047 per 100k in Q2 2022, only 2% below the pre-pandemic median. **Conclusions:** Across the three studied cancer types, population-based screening remains below pre-pandemic levels. In agreement with other research, we find that screening quickly rebounded following the initial stages of the pandemic; however, the longer follow-up time reveals that gaps in preventive cancer screening returned and worsened. Underutilization of recommended cancer screenings will likely result in an increase in later-stage initial diagnoses and excess mortality from cancer in the future. Research Sponsor: Trilliant Health.

Assessing the risk of gastrointestinal cancers among cannabis users compared to nicotine users. *First Author: Shanawar Ali Waris, West Virginia University School of Medicine, Morgantown, WV*

Background: Exposure to nicotine is a well-studied preventable cause of numerous malignancies, while the association of cannabis use with the development of cancer is not clear. Cannabis contains both carcinogens as well as compounds with anti-tumor activity, which inhibit chronic inflammation. The aim of this study is to assess the risk of gastrointestinal malignancy in cannabis users compared to nicotine users. **Methods:** A retrospective cohort study was conducted using TriNetX, a federated database of ~100 million patient records. Adult patients (≥18 years) were queried by ICD-10 coding to find variables of interest. Two groups were created: one group with a history of only cannabis use and the other with a history of only nicotine use. Then lifetime risk of nine different gastrointestinal cancers were assessed and compared between the two groups. 1:1 propensity score matching was conducted, adjusting for comorbidities and demographics, to calculate adjusted risk ratios (aRR) with 95% Confidence Interval for the comparative analysis. **Results:** A matched cohort of 413,628 patients revealed that cannabis only patients had a significantly lower lifetime risk of developing esophageal cancer (aRR[95%CI]): (0.456 [0.364,0.572]), gastric cancer (0.492[0.41, 0.60]), pancreatic cancer (0.547 [0.47,0.64]), liver & intrahepatic bile ducts cancer: (0.728[0.70,0.75]), colon cancer (0.351[0.32,0.38]), rectosigmoid cancer (0.699[0.59,0.83]), and rectal cancer (0.563[0.46,0.68]). No significant differences were seen for small intestinal cancer (1.21[0.88,1.6]) and anal cancer (0.87[0.67,1.14]). **Conclusions:** The results of this study suggest that the lifetime risk of developing numerous gastrointestinal malignancies is lower in cannabis users when compared to nicotine users. It is not clear if this relative risk reduction is due to the beneficial effects of cannabis or a lack of nicotine consumption and its associated effect on carcinogenesis. Long-term studies following cannabis users may provide a better understanding of the association of cannabis use with the risk of developing various malignancies. Additionally, the quantity of exposure to cannabis and its association with the risk of cancer should be further investigated. Research Sponsor: None.

	Unadjusted Risk Ratio [95% CI]	Adjusted Risk Ratio [95% CI]

Incidence, landscape and survival outcome of de novo malignancy after double lung transplantation. *First Author: Liam II-Young Chung, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Organ transplant recipients are at greater risk of developing malignancies due to their immunosuppressive management. However, the incidence of post-transplant malignancy after double lung transplantation (DLT) has not been studied. This study investigated the incidence, trends, and most common types of post-transplant malignancy following DLT. **Methods:** Data extracted from the Organ Procurement Transplantation Network (OPTN) registry after DLT for non-cancerous disease. We evaluated the incidence of post-transplant malignancy, and assessed the annual and cumulative risk of each malignancy after DLT. And the overall survival (OS) of recipients with or without post-transplant malignancy was analyzed by Kaplan-Meire survival method. **Results:** A total of 23,935 cases were identified and analyzed from the OPTN database (13,768; 57.5% male, 10,167; 42.5% female). 5,629 cases (23.5%) were found to have post-transplant malignancy and 18,306 cases (76.5%) had no post-transplant malignancy. Among patients with post-transplant malignancy 3,785 (67.2%) were male and 1844 (32.8%) were female. Those with post-transplant malignancy had a longer OS compared to those without post-transplant malignancy (P < 0.001). While the median OS was 97.2 months and 5-year survival rate was 83.6% in recipients with post-transplant malignancy, the median OS was 36.7 months and 5-year survival rate was 67.3% in For those without post-transplant malignancy. The risk for post-transplant malignancy was greatest during the first 3-5 years post-transplantation. The most common types of post-transplant malignancies were squamous cell skin cancer (n = 2711, 48.2%), basal cell skin cancer (n = 965, 17.1%), lymphoma (n = 570, 10.1%), lung cancer (n = 187, 3.3%), colorectal cancer (n = 184, 3.3%). **Conclusions:** The lifetime incidence of post-transplant malignancy following DLT was identified to be 20.1% and those with post-transplant malignancy had a longer OS compared to those without post-transplant malignancy. Further studies are needed to investigate the underlying mechanism for the increased risk of malignancy following DLT and its association with OS. Research Sponsor: None.

Enhancing lung cancer screening through 'Saved by the Scan': Lessons from a multipronged public service advertising program. *First Author: Shreyas S Bellur, Miami Cancer Institute, Baptist Health South Florida, Miami, FL*

Background: Lung cancer screening rates remain low across the US in populations recommended for screening by low-dose CT (LDCT). Screening rates further declined during the COVID-19 pandemic, particularly in high-risk populations including racial and ethnic minorities. The American Lung Association (ALA) launched a nationwide public service advertising (PSA) program called 'Saved by the Scan' to enhance lung cancer screening rates, for which Baptist Health South Florida (BHSF) became the first healthcare system partner. The following work describes this major PSA effort in South Florida to enhance lung cancer screening, and the lessons learned thereof. **Methods:** A multipronged, institutionally-driven public awareness program, in collaboration with ALA, was initiated in 2021 by BHSF, the largest healthcare organization in the region, and was targeted towards South Florida residents. This innovative multimedia effort used traditional communication modalities, including newspapers, billboards, etc., along with digital modalities, including email and social media, to increase lung cancer screening awareness in both English and Spanish in a locally-adapted manner. Key performance indicators (KPIs), reach, and impact of the program were tracked. The most successful components, as per KPIs, were identified. Deidentified data of screening LDCT done at BHSF was reviewed to determine all individuals screened during 2019-2021 and descriptive statistics were calculated. **Results:** 4619 individuals from South Florida were screened at BHSF from 2019-2021, 1498 were in 2019, 1193 in 2020, and 1928 in 2021. Screening fell by 20.3% in 2020, likely due to the pandemic, and rose by 61.6% in 2021, helped by the program. Overall, a 21.9% increase from pre-COVID screening rates was seen. In 2022, the total reach of traditional media was estimated to be 4,607,273 individuals. Out of 133,554 emails sent, 36,877 (27.2%) were opened, with a click-through rate of 6.4%. Out of 1,768,438 digital impressions, 16,791 (0.9%) had links clicked. The total number of conversions from digital media was estimated to be 337 individuals with 232 (68.9%) from emails and 105 (31.1%) from social media. **Conclusions:** Lung cancer screening can be successfully boosted through large organizational efforts, particularly those targeted to needs of the local population. Digital media approaches for improving public health have seemingly low conversion rates but their large outreach provides a high impact. Efforts are warranted to enroll more healthcare systems and scale the program nationwide. Research Sponsor: None.

Patient navigation for lung cancer screening in an urban safety-net system: A pragmatic randomized clinical trial. *First Author: Sheena Bhalla, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Although low-dose computed tomography (LDCT)-based lung cancer screening (LCS) can decrease lung cancer mortality in high-risk individuals, it may be a complex and time-intensive process that poses challenges to patients, particularly those from minority, under- and uninsured populations. We conducted a pragmatic randomized controlled trial of telephone-based navigation for LCS within an integrated, urban safety-net healthcare system (Parkland Health, Dallas, Texas). **Methods:** Patients eligible for LCS based on United States Preventive Services Task Force 2013 Guidelines were randomized (1:1) to usual care with or without phone-based navigation. Following a structured protocol, navigators made systemic contact with patients to provide appointment reminders, share information and resources, assess barriers to LCS, and address smoking cessation. The primary endpoint was completion of the first three consecutive steps (eg, 3 annual LDCTs or LDCT, other imaging, biopsy) in a patient's LCS process. We also explored differences in completion of LCS steps in navigation and usual care groups according to patient characteristics using chi-square test. **Results:** Patients (n=447) were randomized to phone-based navigation (n=225) or usual care (n=222) between February 2017 and February 2019. Mean patient age was 62 years, 46% were female, and 69% were racial-ethnic minorities. There was no significant difference in completion of the first three steps of the LCS algorithm (12 vs. 9%; $P=0.3$) between arms. Completion of LCS steps was not impacted by navigation among different subgroups, including age (<65 vs. ≥65 years), gender (male vs. female), race/ethnicity (non-hispanic white vs. racial minorities), and comorbidity status (Charlson Comorbidity Index <5 vs. ≥5). A key reason for step non-completion was lack of order placement. In the navigation arm, 368 of expected 675 steps (55%) were ordered, and in the usual care arm, 344 of expected 666 steps (52%) were ordered. Despite low three-step completion rates overall, the majority (>75%) of LCS algorithm steps were completed when ordered by their clinical team (Table). In exploratory univariable analysis, completion rates for ordered steps were 86% for navigation and 79% for usual care ($P=0.03$). **Conclusions:** In this study, lack of order placement was a key reason for incomplete LCS steps. When orders were placed, navigated patients had higher rates of completion. Clinical team education and enhanced EHR processes to simplify order placement, coupled with patient navigation, may increase LCS uptake and completion in safety-net healthcare systems. Clinical trial information: NCT02758054. Research Sponsor: Cancer Prevention Research Institute of Texas.

Status of LCS steps	Steps ordered in the navigation cohort (%) n=368	Steps ordered in the usual care cohort (%) n=344	P value
Completed	315 (86)	273 (79)	0.03
Not completed	53 (14)	71 (21)

A multivariate analysis of low-dose CT lung cancer screening in a Michigan community hospital network. *First Author: Jason Law, Michigan State University, Lansing, MI*

Background: Lung cancer is the leading cause of cancer deaths in the United States. The USPSTF recommended screening for lung cancer with low-dose chest computer tomography (LDCT) in 2013. This was based on the National Lung Screening Trial (NLST) which showed a 20% relative reduction in mortality from LDCT compared with chest radiography in high-risk individuals. The major NLST eligibility criteria were age 55-74, a 30 + pack year smoking history and current smoking status or having quit in the last 15 years. The impact of other risk factors on screening results besides inclusion criteria is unknown. We sought to identify other factors for the risk of lung cancer detection in screened individuals. **Methods:** This was a retrospective cohort study employing a Michigan based McLaren Hospital Network Lung Cancer Screening Program (LCSPP) database from 2015-2022. Participant eligibility in screening was the USPSTF criteria except for an age range of 50-80. Analyses were stratified by BMI, smoking pack-years, insurance status, smoking status, sex, other CT findings, pre- vs. during COVID pandemic (before and after January 2020). Multivariate logistic regression analysis was used for odds ratios (OR) with 95% confidence intervals (CI) as estimates of the relative risk of an elevated Lung-RADS category ≥3 (high risk of detecting lung cancer). **Results:** A total of 2638 subjects, 49.91% females, 50.09% males, mean BMI 29.50 ± 7.17 (SD), pack-years 44.52 ± 18.29, Medicaid 6.66%, Medicare 32.01%, Private Insurance 57.62%, Self-pay/unknown 3.71%. Current smoker 65.49%, Former smoker 34.51%, other CT findings 51.99%, pre-COVID 46.08%, during COVID pandemic 53.92%. Lung-RADS category 0 (0.04%), 1 (35.33%), 2, (50.61%), 3 (6.56%), 4a (4.85%), 4b (1.55%), 4x (1.06%). A statistically significant association with a Lung-RADS category ≥3 was found with lower BMI, OR=0.980 (95% CI, 0.969-0.991), $p=0.0005$, and female gender, OR=1.232 (95% CI, 1.039-1.462), $p=0.0166$ (Table). **Conclusions:** In our study cohort a lower-than-average BMI and also female gender were statistically correlated with an elevated Lung-RADS category ≥3. These findings might be incorporated into a risk stratification model, however further larger studies are needed to validate our findings. Research Sponsor: None.

Multivariate logistic regression predicting Lung-RADS ≥3 among all patients (n=2,638). Odds Ratio Estimates				
Effect	Point Estimate	95% Wald Confidence Limits		P-values
BMI, below vs above mean	0.980	0.969	0.991	0.0005
Smoking pack-years	0.999	0.995	1.004	0.7867

Long-term clinical and psychosocial outcomes of surveillance in Li Fraumeni syndrome. *First Author: Milita Zaheed, Garvan Institute of Medical Research, Darlinghurst, Australia*

Background: Li Fraumeni Syndrome (LFS) is a high penetrance multi-organ cancer predisposition syndrome, associated with a significant lifetime risk of developing cancer. The Surveillance study in Multi-Organ Cancer prone syndromes (SMOC+) is investigating the utility of annual surveillance, with inclusion of whole-body magnetic resonance imaging (WBMRI), for hereditary cancer syndromes without well-established risk management strategies. Here we report the long-term clinical and psychosocial outcome of surveillance in participants with LFS. **Methods:** Multimodality surveillance in this multi-centre, prospective, longitudinal, observational study for adult participants with LFS included annual clinic review and examination, WBMRI, breast MRI (MRIB), full blood count, prostate specific antigen; 2-5 yearly gastro-intestinal endoscopy and faecal occult blood test in intervening years. Quantitative psychometric evaluations were requested at regular intervals each year using Hospital Anxiety and Depression Scale (HADS), the Impact of Events scale anchored to cancer (IES-C), and the Impact of Events scale MRI (IES-MRI). **Results:** From July 2013 to December 2021, 132 (67% female) participants were enrolled at a median age of 36 (range 18-69) years. There were 116 prior diagnoses of neoplasms among 68 (52%) participants, including 27 (20%) with multiple primaries. At a median follow up of 4 years, 46 new primary malignancies were diagnosed in 30 (23%) individuals, with median age at diagnosis of 43 (range 24-71 years). Four (3%) individuals developed recurrence of a prior malignancy. The malignancies were detected as a result of WBMRI (27), MRIB (7), gastroscopy (1), colonoscopy (1) and clinical review and examination (17). The most frequent new primaries were leiomyosarcoma and breast cancer (Table). Overall, 22 (17%) are not currently participating due to cancer related death (10), active cancer (6) or other life events (6). At 4 years after enrollment, 94, 80 and 50 participants completed at least one HADS (463 unique observations), IES-C (362 unique observations), and IES-MRI (268 unique observations) questionnaire, respectively. Controlling for demographic and cancer history variables, there was no evidence of changes in overall anxiety or depression ($p=0.2$), nor in degrees of distress associated with cancer ($p=0.06$) or WBMRI ($p=0.6$) over time. **Conclusions:** In LFS, annual surveillance with WBMRI is feasible and well tolerated, with no difference in distress experienced in the longer term. Over 80% of participants continue to engage with surveillance. The majority of cancer-affected individuals were able to resume surveillance after management of early disease. Effect of colorectal cancer screening on 1-year mortality and medical costs: Real-world evidence from the largest commercial medical claims database in the US. *First Author: Chi Mai Nguyen, Department of Biostatistics and Health Data Science, Indiana University School of Medicine, Indianapolis, IN*

Background: Colorectal cancer (CRC) is the third leading cause of cancer-related deaths in the United States with increasing trends in both mortality and incidence in individuals under age 50. Whether CRC screening reduces mortality recently becomes controversial in some observational studies due to a lack of data and a possibility of screenings confounded with social determinants of health (SDoH) and patient characteristics that were not properly addressed. **Methods:** We used the Optum's de-identified Clinformatics Data Mart Database that provides information of healthcare plan, major SDoH, the CRC diagnosis, treatments, medical service and prescription charges, and survival data since 2007 for over 75 million patients to re-examine benefits of CRC screenings. Our CRC study cohort (N=99,704) included persons first diagnosed with CRC between 2010 – 2020, with 3-year pre-diagnosis continuing insurance coverage to identify pre-diagnosis screening, and 1-year follow-up to identify death and associated costs. Primary outcomes are 1-year mortality, the post-diagnosis medical and prescription cost increments, and health plan change after CRC diagnosis. Augmented inverse probability weighting (AIPW) models were employed to estimate the benefits of CRC screening, adjusting the probabilities of pre-diagnosis screenings due to insurance cover types (commercial/employer, Medicare advantage, and dual Medicare-Medicaid or low-income subsidy (LIS) covers), and healthcare plans (pre-paid, only-in-network, pay-less in-network, and fee-for-service plans), ages, sex, race, residential states, and calendar year. **Results:** In the study cohort, 37.8% have pre-diagnosis screening records, 18% died within 1 year. Women, persons under age 45, and persons with dual covers were more present in the non-screening group than the screening one. CRC screening was associated with a significant reduction of one-year mortality after adjusting for age, sex, race, health plans, and other factors (death rates in the non-screening group vs the screening one were 23% vs 12%, adjusted OR = 0.57, 95%CI = 0.55 - 0.59). Persons with no screening records experienced higher one-year medical cost increases than those who had pre-diagnosis screenings (17.8% vs 14.8%). No significant difference in health plan changes and/or disruption among the two groups was obvious for persons having either dual- or commercial-cover beneficiaries, yet the screenings slightly induced more these plan changes in the Medicare advantage beneficiaries (OR = 1.06, 95%CI = 1.01 - 1.11). **Conclusions:** The real-world evidence from the US largest medical claims database suggested that, after adjusting for the screening probability due to healthcare plans and other confounders, CRC screening dramatically reduced one-year death risk, and slightly eased the 1-year financial burdens after CRC diagnosis. The role of molecular biomarker CDKN-2A in early diagnosis of colorectal cancer. *First Author: Yakov Ten, National Cancer Center of Uzbekistan, Tashkent, Uzbekistan*

Background: Polyps are considered as obligate precancerous disease. The percentage of malignization ranges from 20% in single polyps to 95% in diffuse polyposis. Current research examines the results of the early diagnosis of colon cancer by using the biomarker CDKN2A for development of molecular-biological methods of prognostication. The correlation with the molecular-biological indicators were studied. It is also planned to develop an effective system for development prognostication of CRC and the formation of "risk groups" for evidence-based counselling for families which are highly predisposed to colorectal cancer. **Methods:** Investigations were carried out in 30 patients during the period 2016-2022, the study included patients with single polyps, multiple polyps, polyposis of the colon, as well as patients without a history of either familial or sporadic cancer. 12 patients had multiple polyps, 9 polyposis and 9 single colon polyps. The levels of methylation of the gene CDKN2A were determined in 10 patients. The material for the isolation of DNA was a serum obtained from venous blood, and biopsy material. DNA extraction was held according to standards. After the conversion of DNA methyl-specific PCR was done. **Results:** Among 30 patients with polyps and polyposis of the colon, serum gene CDKN2A methylated DNA was detected in 10 patients. In 4 patients malignization of the polyp was determined. If patients without malignization surgical intervention was limited with resection of the intestine without lymph dissection. In 20 patients the test result was negative. We did not perform surgical intervention to these patients and they were sent to dynamic observation. Thus, the diagnostic efficacy of detecting colorectal cancer in early diagnosis of by means of methylated DNA of the gene CDKN2A was - 33.3%. **Conclusions:** If there is a positive test for methylation of the CDKN2A-gene, the risk of colorectal cancer is considered very high and these patients underwent surgical treatment. Application of the molecular biological marker CDKN2A may be an effective method in early diagnosis of malignization of polyps. Research Sponsor: None.

Colorectal cancer screening with blood-based tests: Estimated impact of a 1-, 2-, or 3-year screening interval compared with annual FIT and triennial mt-sDNA strategies. *First Author: A. Mark Fendrick, University of Michigan, Ann Arbor, MI*

Background: Blood-based tests are an emerging option for non-invasive colorectal cancer (CRC) screening for which the Centers for Medicare & Medicaid Services (CMS) has proposed coverage every 3 years for average-risk individuals. Analyses with the CRC-AIM microsimulation model demonstrated that triennial screening with blood-based tests with CMS minimum performance often yields inferior outcomes to stool-based CRC screening (fecal immunochemical test [FIT] and multi-target stool DNA [mt-sDNA]). CRC-AIM was used to explore the impact of blood-based screening intervals, using reported performance characteristics from the ECLIPSE study (Guardant Health, Inc.)¹, on estimated clinical outcomes vs FIT and mt-sDNA screening. **Methods:** Outcomes were simulated for average-risk individuals screened between ages 45-75 years. Intervals were set at 1, 2, or 3 years for blood-based, 3 years for mt-sDNA and annually for FIT screening. The blood-based test was modeled at 83% CRC sensitivity, 13% advanced adenoma sensitivity, and 90% specificity. Perfect adherence (100%) was modeled for blood-based tests and real-world adherence rates used for CRC initial screening tests (mt-sDNA=65.6%; FIT=42.6%) and follow-up colonoscopy (mt-sDNA=72.1%; FIT=46.0%). Primary outcomes were life-years gained (LYG) and colonoscopies (COL) per 1000 individuals for blood-based screening compared to mt-sDNA and FIT. As a secondary analysis, estimates were generated with perfect (100%) adherence assumed for initial screening and follow-up colonoscopy for mt-sDNA and FIT as well. **Results:** Blood-based testing at a 3-year interval with 100% adherence led to 11% fewer LYG than mt-sDNA at RWE adherence (240 vs 270, respectively), and 9% more COL (1402/1000 vs 1288/1000). Meanwhile, blood-based testing at a 1-year interval and perfect adherence (best case scenario) resulted in the lowest LYG per COL ratio across all scenarios (16% more LYG and 87% more COL compared to mt-sDNA at RWE adherence). Blood-based test results showed similar trends when compared to FIT. **Conclusions:** Outcomes for blood-based screening every 3 years based on reported test performance characteristics and unrealistic perfect adherence demonstrate fewer LYG as compared to either mt-sDNA or FIT. When compared to real-world adherence for mt-sDNA and FIT, blood-based tests with 1- and 2-year intervals and perfect adherence had higher LYG with the tradeoff of a greater number of diagnostic colonoscopies. Research Sponsor: Exact Sciences Corporation.

LYG and COL per 1,000 patients by screening modality, interval, and adherence (RWE and perfect).					
Modality	Interval	LYG (RWE)	Number of COL (RWE)	LYG (perfect)	Number of COL (perfect)
FIT	1	179	699	326	1,668
mt-sDNA	3	270	1,288	319	1,695
Blood test	1	-	-	314	2,408
Blood test	2	-	-	273	1,771
Blood test	3	-	-	240	1,402

LYG: life-years gained; RWE: real-world evidence; COL: colonoscopy. ¹ ECLIPSE study.

Does adherence to cancer prevention guidelines before diagnosis associate with improved cancer survival? *First Author: Evan W. Davis, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: The American Institute for Cancer Research and American Cancer Society regularly publish cancer prevention recommendations for decreasing cancer risk. Which lifestyles, or whether they work together to impact cancer survival is not well established. We examined associations of adherence to cancer prevention recommendations with mortality in 5,766 patients enrolled in the Data Bank and BioRepository at Roswell Park. **Methods:** Patients were newly diagnosed between 2003 and 2016 with a variety of pathologically confirmed invasive malignancies. Detailed epidemiological data including lifestyles one year prior to diagnosis were linked with Tumor Registry data. The primary analytic exposure was a composite Lifestyle Index Score (LIS) created in accordance with previously published standardization guidance; the primary analytic outcome was all-cause mortality. The LIS comprised seven lifestyles including: physical activity (PA); body mass index (BMI); fruit and vegetable (FV) intake; red and processed meat (RPM) intake; sugar sweetened beverage (SSB) consumption; alcohol consumption; and smoking status. Kaplan Meier analyses were used to compare survival experience according to LIS tertiles. Multivariable Cox proportional hazard models adjusted for age, tumor type, stage, and sex were used to estimate the associations of the LIS and each lifestyle factor with mortality in the overall study population and according to tumor stage. **Results:** During follow-up through April 2022, we observed 2,316 deaths (median follow-up 6.9 years). Patients reporting strongest adherence to prevention recommendations (highest LIS tertile) had significantly improved survival compared to patients with the lowest LIS (93.0 vs. 75.0 months, respectively; log-rank $p < 0.0001$). In multivariable analyses, the highest versus lowest LIS tertile was associated with a 17% reduction in mortality in the overall study population (HR = 0.83, 95% CI: 0.74-0.93). Significant mortality reductions were observed in patients diagnosed with both early- and late-stage disease (HR = 0.73, 95% CI: 0.59-0.90 and HR = 0.85, 95% CI: 0.73-0.99, respectively). Being a never smoker (HR = 0.54, 95% CI: 0.47-0.62), meeting the PA Guidelines (HR = 0.74, 95% CI: 0.66-0.83), and highest FV intake (HR = 0.82, 95% CI: 0.73-0.91) were the only independent factors associated with significant reductions in mortality. **Conclusions:** Strongest adherence to the cancer prevention recommendations before diagnosis was associated with significant reductions in mortality. These findings provide additional evidence that modifiable lifestyle factors can impact cancer survival, even among patients diagnosed with advanced-stage disease. Confirmatory studies examining post-diagnosis lifestyles are needed so that lifestyle assessment tools, education, and intervention can be clinically leveraged to improve patient outcomes. Genetic testing into survivorship after diagnosis of breast cancer. *First Author: Steven Katz, University of Michigan Medical School, Ann Arbor, MI*

Background: Support for universal genetic testing after diagnosis of breast cancer is growing because of concerns that targeted guidelines fail to identify all patients who could benefit from genetic risk evaluation (GRE). Little is known about use of genetic testing in survivors of breast cancer over time. **Methods:** Women who were diagnosed with breast cancer in 2014-15 and reported to the SEER registries of Georgia and Los Angeles County completed a baseline survey about 9 months after diagnosis (N=2502). We performed a follow-up survey (FUPs) about 6 years after diagnosis among survivors (N=2347), of whom 1423 responded (60% response rate). We asked women about their receipt of clinical germline genetic testing and results, communication with relatives about cancer genetic testing, and use of direct-to-consumer testing (DTCT) after diagnosis. We categorized women into indications (yes/no) for GRE based on National Comprehensive Cancer Network guidelines at time of diagnosis (GRE indication baseline) and at the time of the follow-up survey (GRE indication FUPs only). **Results:** We present results for a preliminary sample (N=1272). About half of the respondents (44.6%) had indications for GRE over the study period; 28.0% at baseline; and an additional 16.6% at time of the follow-up survey (FUPs only). The Table below shows patient-reported testing at FUPs by GRE indication category (baseline, FUPs only, no indication). About two thirds of those with a baseline indication for GRE received genetic testing over the observation period: 66.5% vs 43.9% with indication at FUPs only vs 35.0% of those with no indication (p<.001). A substantial proportion of those who reported testing received the test during the survivorship period (1 to 6 years post-diagnosis): approximately one-third of those with baseline indications vs over half of those with GRE indication at FUPs only. Testers with a pathogenic variant result (n=59) were much more likely to have talked to most or all of their first-degree adult relatives about genetic testing than those with a variant of unknown significance (n=40) or a negative finding (n=382): 64.3% vs 35.0% and 37.1%, respectively (p<.001). Overall, there was very little interest in DTCT for cancer risk: 5.0% researched DTCT online somewhat to a lot; and only 3.5% had DTCT. **Conclusions:** The proportion of patients with indications for GRE after diagnosis of breast cancer markedly increases into survivorship but many patients do not receive genetic testing. Lack of survivor interest in DTCT for cancer risk is reassuring that patients are not substituting DTCT for clinical testing. Research Sponsor: American Cancer Society.

Patient-reported receipt of germline genetic testing at FUPs by GRE indication.

Date of genetic test (reported on FUPs)	GRE Indication Category(%)		
	At baseline n=356	On FUPs only n=211	No indication n=705
Ever received	66.5	43.9	35.0

Twenty-one gene recurrence scores in individuals with breast cancer associated with CHEK2 and ATM germline pathogenic variants. *First Author: Payal Deepak Shah, University of Pennsylvania, Philadelphia, PA*

Background: The 21-gene recurrence score assay (Oncotype DX, Genomic Health Inc., CA) is prognostic, quantifies predicted benefit of adjuvant chemotherapy, and informs clinical decisions for patients with early-stage, hormone receptor-positive (HR+) breast cancer (BC). Differences in Oncotype recurrence scores (RS) in individuals with and without *BRCA1* and *BRCA2* pathogenic variants (PV) have been demonstrated, but the results of this assay in patients with BC and germline *CHEK2* or *ATM* PV have not previously been described. This is of particular relevance as *CHEK2* BC have been associated with a worse prognosis. **Methods:** Prospective Registry of MultiPlex Testing (PROMPT) is an online research registry for individuals who have had multigene panel testing for inherited cancer susceptibility. We retrospectively evaluated Oncotype DX recurrence scores from PROMPT participants (pts) with PV or likely PV in *CHEK2* or *ATM*. Mood's median tests were used to compare median RS, and Yates corrected Chi-square tests were used to compare RS distributions between carriers and a genetically unselected reference population. **Results:** Oncotype DX reports were reviewed for 75 pts with 77 BC (n = 50 pts with *CHEK2* PV with 51 BC; n = 24 with *ATM* PV; n = 1 with *CHEK2* and *ATM* PV with 2 BC). Among *CHEK2* carriers, median RS was 17 (range 2-43) overall, 17 (2-36) for pts < age 50, and 18.5 (8-43) for pts ≥ age 50 (p-value 0.47), with distributions not significantly different than reference (< 50, p = 0.70; ≥ 50, p = 0.93). Ten pts had low penetrance *CHEK2* alleles (p.S428F or p.L157T) with median RS 16 (9-28) compared to 18 (2-43) in those with other *CHEK2* alleles (p = 0.35). Among *ATM* carriers, median RS was 17 (1-35) overall, 17 (1-35) for pts < age 50, and 16 (11-32) for pts ≥ age 50 (p = 0.51), with distributions also not significantly different (< 50, p = 0.78; ≥ 50, p = 0.79). **Conclusions:** Unlike data seen in BC associated with *BRCA1* and *BRCA2*, Oncotype DX RS in individuals with *CHEK2* and *ATM*-associated BC are similar to the published genetically unselected commercial database median RS of 16, with no clear difference based on penetrance of *CHEK2* allele. Proportions of patients < 50 and ≥ 50 with *CHEK2* and *ATM* PV with RS within the range for chemoendocrine therapy consideration are also similar to the historical reference. The inferior prognosis that has been suggested in *CHEK2* BC is not reflected in Oncotype DX RS. Research Sponsor: None.

Women with pathogenic variants in moderate penetrance breast cancer genes: How frequently do they meet high penetrance genetic testing criteria? *First Author: Nicole Casasanta, Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: 5-10% of breast cancers are associated with germline pathogenic variants in breast cancer predisposition genes. 2-5% of these variants are in moderate penetrance (MP) genes, conferring a relative risk to develop breast cancer of 2-5. Various personal history (PH) and family history (FH)-based criteria for testing high penetrance genes, such as *BRCA1* and *BRCA2*, have been proposed, but it is unknown to what extent women with pathogenic variants in MP genes may meet such criteria. We evaluated PH and FH of cancer among women with pathogenic variants in MP genes in a diverse and unselected patient cohort in New York City to determine how often they met well-established genetic testing criteria from the National Comprehensive Cancer Network (NCCN). **Methods:** Exome sequence data from ~16,000 female BioMe Biobank participants were evaluated for expected pathogenic (per ClinVar, or predicted loss-of-function) variants in *ATM*, *BARD1*, *BRIP1*, *CHEK2*, *NF1*, *PALB2*, *RAD51C*, and *RAD51D*. We extracted demographic information, PH and FH of breast, ovarian, and/or pancreatic cancer, and PH and FH of genetic testing from participant questionnaires and electronic medical record review. We then determined which participants met current NCCN criteria (version 1.2023) for high penetrance breast, ovarian, and pancreatic cancer genetic testing. **Results:** We identified 252 women with expected pathogenic variants in MP genes: 105 *CHEK2*, 58 *ATM*, 35 *BRIP1*, 24 *PALB2*, 9 *BARD1*, 8 *NF1*, 8 *RAD51D*, and 5 *RAD51C*. 30% met NCCN criteria, including 30% of those with *CHEK2* variants, 36% *ATM*, 14% *BRIP1*, 33% *PALB2*, and 30% with variants in *BARD1*, *NF1*, *RAD51D*, or *RAD51C*. 36% of those who met NCCN criteria had previously undergone clinical genetic testing. 29 of 33 (88%) women with a PH of breast cancer and 52 of 81 (64%) women with a FH of breast cancer met criteria. **Conclusions:** Current genetic testing criteria focus on identifying individuals harboring pathogenic variants in high penetrance cancer genes. However, in our study, a substantial portion of women with a pathogenic variant in a MP breast cancer gene also met such criteria, particularly when PH or FH of breast cancer were present. Only a third of those who met NCCN criteria had undergone clinical genetic testing. These findings suggest that the majority of women with genetic risk for breast cancer may be missed in clinical practice. Studies have shown that most physicians would change management strategies for patients with pathogenic variants, including variants in MP genes. As our understanding of genetic risk for breast cancer continues to evolve, we must explore strategies to improve identification and management of individuals with variants in MP breast cancer genes. Analysis of ATM germline mutations in solid tumors from Chinese patients. *First Author: Tao Fu, China-Japan Friendship Hospital, Beijing, China*

Background: Ataxia-telangiectasia mutated (ATM) is a tumor suppressor genes and plays an important role in the repair of DNA double-strand breaks (DSBs). Germ-line mutations of ATM gene result in the well-characterized ataxia telangiectasia syndrome, which manifests with an increased cancer predisposition, including a 20% to 30% lifetime risk of lymphoid, gastric, breast, central nervous system, skin, and other cancers. Novel therapies are in development that may improve the response to therapy of patients with ATM-deficient cancers including targeted therapy and immunotherapy. Nevertheless, the knowledge of incidence of ATM germline mutations in solid tumor remains poorly understood. **Methods:** We identified 19248 malignant solid tumors patients without selecting age or family history in a retrospective cohort. The pathogenicity of germline mutations was categorized based on American College of Medical Genetics and Genomics (ACMG) guidelines. The patients were divided into two groups, P/ LP group (with pathogenic or likely-pathogenic mutations), and Non-P/LP group (neither pathogenic nor likely-pathogenic mutation). **Results:** In 19248 patients with pan-cancer, 76 patients were found 76 heterozygous pathogenic or likely pathogenic germline mutations in ATM gene and the mutation frequency was 0.39%. Among these 76 carriers, 71 (93.4%) carried frameshift, nonsense or splice mutations (33 for frameshift, 21 for missense and 17 for splice mutations). 4 carried missense mutations and 1 carried intron mutations. Eliminated a few types of cancers that had a smaller number (less than 50), the higher frequency of mutations contained cancers were pancreatic cancer (1.0%, 7/692), breast cancer (0.71%, 3/423), gastric cancer (0.6%, 7/1094). The median age of group P/LP and non-P/LP group was 64 and 63 in pancreatic cancer, 62 and 53 in breast cancer and 62 and 61 in gastric cancer. The three genes with the most somatic mutations were TP53, MUC16 and KRAS in P/LP group and were TP53, MUC16 and EGFR in non-P/LP group. There was no significant difference in mutation frequency of the four genes. The media TMB in P/LP group and non-P/LP group were 3.55 and 2.84 respectively and there was no statistical difference. In P/LP group, only one patients is high microsatellite instability who carried a MLH1 and a ATM pathogenic mutation. **Conclusions:** This was the first report of the incidence of ATM germline mutations in Chinese solid tumors which expanded the understanding of ATM and provided a direction for clinical trial design of novel therapies. The relationship between germline mutations and cancer susceptibility will be studied in the future. Research Sponsor: None.

Characteristics and clinical outcome of BRCA germline mutation carriers with advanced breast cancer treated with PARP (poly ADP-ribose polymerase) inhibitors: A single institution experience. *First Author: Fatma Nihan Akkoc Mustafayev, University of Texas, MD Anderson Cancer Center, Houston, TX*

Background: About 5-10% of breast cancers (BC) are related to germline BRCA 1/2 pathogenic variants (PV). Several studies have demonstrated the effectiveness of PARP inhibitors (PARPi) in this population. However, BC patients with BRCA PVs remain a challenge to treat. In this report, we aim to characterize the clinical characteristics and outcome of a single institution cohort of advanced BC patients with a BRCA PV and who received PARPi therapy. **Methods:** Patients with BRCA 1/2 germline PVs who presented to the University of Texas MD Anderson Cancer Center Breast Medical Oncology clinics and were treated with PARPi between 2008-2022 as part of their treatment for metastatic or recurrent disease were included in the analysis. Variables included in this analysis included age at diagnosis, family history of BC and ovarian cancer, treatment details, tumor characteristics including histological type, receptor status and clinical outcome. Descriptive statistics, the Kaplan-Meier method, and The Cox proportional hazards regression model were used to report patient characteristics and outcomes. Progression free survival (PFS) was defined as the time from treatment initiation of PARPi to disease progression or death. Overall survival (OS) was defined as the time from treatment initiation of PARPi to death of any cause. **Results:** One hundred and seven patients were treated with PARPi. Median age at diagnosis was 38 years (23-73). Forty-eight (44.9%) and 59 (55.1%) patients had BRCA1 and BRCA2 mutations, respectively. Ninety-seven (90.7%) had invasive ductal carcinoma and 42 (39.3%) had triple negative BC. Nineteen (17.8%) patients were de novo metastatic BC (Stage IV). Sixty-two (57.9%) patients received one or more prior lines of chemotherapy before being treated with PARPi; 24 (22.4%) patients received prior platinum. In 91 patients evaluable for clinical response, the overall response rate (ORR) was 59.4% and the duration of response (DoR) was 7 months (2.1-96.2). In platinum-naïve patients ORR was 70.4% and DoR 7.4 months (2.1-96.2). Median PFS was 8.9 months (95% CI 6.3-10.3) and median OS 25.8 mo (95% CI 18.3-30.9). In univariate analysis, first-line PARPi use (p = 0.0274) and no previous use of platinum (p = 0.0121) were statistically significant for better PFS. Hormone receptor positive BC (p = 0.0105) was statistically significant for better OS. **Conclusions:** In this real-world single institution cohort of advanced BC patients with BRCA germline PVs who were treated with PARPi, the ORR and outcome of patients is similar to those reported in the previous clinical trials. Platinum naïve and patients who received PARPi as 1st line therapy had a better ORR. Further studies of predictive markers of response and resistance as well as sequencing with platinum are needed to optimize the use of PARPi in this patient population. Investigation of cancer predisposition in Fanconi anemia heterozygotes: A DiscovEHR cohort population study. *First Author: Joseph Deng, National Cancer Institute, Rockville, MD*

Background: Fanconi anemia (FA) is a cancer predisposition syndrome caused by biallelic pathogenic variants in one of 22 genes involved in DNA intrastrand crosslink repair. 20 of these genes have an autosomal recessive inheritance pattern. Of the FA genes, 5 (*BRCA1*, *BRCA2*, *BRIP1*, *PALB2*, *RAD51C*) are known cancer predisposition genes (CPG) when inherited in monoallelic autosomal dominant manner, though the heterozygous predisposition status of the remaining 15 remains unclear. Large population-level exome sequencing projects with linked health records such as the DiscovEHR cohort serve as promising tools to establish sufficient power to investigate all FA genes. Quantifying cancer risk is important for the counseling and surveillance of FA heterozygotes, especially with the ever-increasing use of genetic testing identifying these individuals. **Methods:** 170,503 individuals enrolled in the DiscovEHR Cohort were analyzed for pathogenic/likely pathogenic variants in 22 FA genes and identified 5834 subjects, the case group. ICD10 phenotype classifications for these subjects were curated to Phecodes and ICD-O-3 Site Recodes for two control arms of analysis. The first control arm included all DiscovEHR subjects excluding the case group and those with a variant of uncertain significance in the genes of interest with a deleterious in-silico score. The second control arm included individuals from the Surveillance, Epidemiology, and End Results (SEER) database. Phecode analysis yielded odds ratios adjusted for age, sex, race, smoking status, and BMI. SEER analysis yielded Standardized Incidence Ratio scores adjusted for age, sex, and birth cohort. When both arms of the analysis were completed Phecodes and SEER analyses were matched and positive signals for cancer risk were defined by statistically significant ratios in both. **Results:** The 5 known CPGs demonstrated multiple signals for cancer predisposition as expected (p < 0.0001). Results for *FANCA* (p = 0.4231) and *FANCC* (p = 0.8142) heterozygotes validated recent results from our group showing no increased risk of cancer in relatives of FA patients with these genotypes. Ten other FA genes also showed no increased risk of cancer. 3 genes suggested a possible increased risk of specific cancers in heterozygotes and are currently being evaluated in a second large population exome cohort to validate these findings. **Conclusions:** This is the largest study to date on the cancer predisposition risk in Fanconi anemia heterozygotes. We have confirmed the known risk in 5 well-described CPGs and the lack of risk amongst *FANCA* and *FANCC* heterozygotes, the most common in population. Further analysis via an additional large population cohort is underway to validate any possible novel cancer predispositions in 3 genes. For the remaining FA genes, this population analysis supports previous literature on known CPGs and the lack of cancer predisposition in most FA genes. Comprehensive analysis of patients with cancer with a positive CHEK2 test: Are we getting closer to a genotype/phenotype correlation? *First Author: Ana Frago, Instituto Português de Oncologia de Lisboa, Francisco Gentil, Lisboa, Portugal*

Background: The *CHEK2* gene encodes a protein kinase that acts as a tumor suppressor with an important role in DNA damage repair. This gene is included in most hereditary breast, ovarian and prostate cancer panels, but the clinical actionability of *CHEK2* pathogenic/likely pathogenic variants (PVs) may be challenging. Indeed, decisions concerning clinical surveillance and/or risk reducing procedures as well as screening for multiple associated cancer risks are not consensual. Our objective was to identify a potential genotype/phenotype association regarding *CHEK2* PV identified in our population. **Methods:** Study group included all patients (pts) who tested positive for *CHEK2* PVs between July 2000 and June 2022; control group included pts without PVs after multigene panel testing (wt) between January 2020 and June 2022. PVs were categorized as: truncating (includes nonsense, frameshift, splice site variants, gross deletions and duplications) and not truncating (missense and in-frame deletions). Clinical characteristics from both groups included gender, personal and family cancer history and tumor characteristics. **Results:** From 8604 pts tested, we identified 101 *CHEK2* and 1506 wt pts. *CHEK2* pts were mainly women (95; 92%) and Portuguese (94; 93.1%). All non-Portuguese pts had Eastern Europe ancestry. *CHEK2* pts were either heterozygous (94;93%), homozygous (3; 3%) or had digenic inheritance (4; 6%: both a *CHEK2* and a *BRCA1/2* PV). Compared to wt pts, heterozygous *CHEK2* pts were younger at 1st cancer diagnosis (44.5 yrs vs 47 yrs) and had more multiple primary cancers (OR: 1.8; p: 0.02). *CHEK2* breast cancer was mostly but not exclusively estrogen receptor positive (69/78; 88,4%) and Her2 negative (54/69; 78%). Two BC cases had triple negative phenotype. The most frequent PVs detected were c.349A > G (25 pts), c.1100del (24 pts) and c.319+2T > A (20 pts). Considering heterozygous PVs, 57 were truncating and 37 non-truncating, with c. 1100del and c.349A > G being the most frequent, in each group, respectively. For truncating versus non-truncating PVs there was no difference in phenotype regarding breast (OR: 0.69; p: 0.15), CRC (OR: 0.94; p: 0.91), gastric (OR: 0.76; p: 0.65), thyroid (OR: 1.3; p: 0.69) and kidney cancer (OR: 0.36; p: 0.27). Further stratification of PVs according to cancer type revealed a correlation of CRC with c.1100del (OR: 4.57; p: 0.0025) and c.349A > G (OR: 5.49; p: 0.0003), while gastric, kidney and thyroid cancers correlated with c.349A > G (OR: 5.8; p: 0.0069), c.1100del (OR: 26.86; p: 0.02) and c.319+2T > A (OR: 3.31; p: 0.05) PVs, respectively. **Conclusions:** This analysis suggests a potential genotype-phenotype correlation regarding *CHEK2* pathogenic variants, regardless of its truncating potential. The study of clinical outcomes will further contribute to determine how this information may influence the clinical and risk management of *CHEK2* pts and their families. Research Sponsor: None.

Rates of potentially actionable germline variants in homologous recombination repair genes in a large international cohort outside of the United States. *First Author: Sarah M. Nielsen, Invitae, San Francisco, CA*

Background: Identification of pathogenic germline variants (PGVs) in homologous recombination repair (HRR) genes among patients (pts) with breast (BC), ovarian (OC), pancreatic (PaC), and prostate cancer (PrC) is critical to determine potential eligibility for targeted therapies such as PARP inhibitors (PARPi). It is important to evaluate the frequency and patterns of PGVs across different regions of the World to help inform the counseling of pts and implementation of precision medicine. **Methods:** A retrospective analysis of pts with BC, OC, PaC, and/or PrC cancer undergoing GGT through a single laboratory was conducted. The location of the ordering provider determined the assigned region, which included: Asia-Pacific (APAC), Latin America (LATAM), Middle East and African (MEA), and United Kingdom and Europe (UEKU). Analyses were limited to pts tested for PARPi-eligible (in the US) HRR genes and PGV analysis to the 10 most frequent genes for that cancer type. Descriptive statistics and Chi square with Yates correction were utilized. Significance was set at p<0.05. **Results:** The cohort consisted of 40,539 pts with an average age at testing of 51 years, the majority of whom had BC (81%) (Table). The median number of genes tested ranged from 14-85 (Table). *BRCA1* and *BRCA2* were the most frequent genes with PGVs (3,358 pts, 8%). LATAM BC pts had significantly higher rates of *BRCA1/2* PGVs (10%) than the other 3 regions (p<0.0007). OC *BRCA1/2* rates were high, and statistically similar, across regions (15-17%, p>0.08). Rates of *BRCA1/2* and *PALB2* in PaC pts did not differ between regions (4-7%, p>0.08), nor did rates of *BRCA1/2*, *CHEK2*, *ATM*, and *PALB2* in PrC pts (7-11%, p>0.16) (Table). In sum, 3,434 pts (9% of those tested for the eligible genes) had PGVs in the above PARPi-eligible HRR genes. A notable limitation is that pts were ascertained by cancer type but information on other PARPi eligibility, namely metastatic/advanced disease, was not available. **Conclusions:** 1 in 12 pts were found to carry PARPi-eligible PGVs across the 4 cancer types and regions analyzed. Knowledge of these PGVs can help inform public health policies, current and future treatment strategies, and identify at-risk family members. In some countries, GGT may represent a more cost-effective and accessible pathway to targeted therapies compared to tumor profiling due to ease of sample collection and lower cost of testing. Research Sponsor: Invitae Corporation.

Pts with PARPi-eligible PGVs by region and cancer type.

Region	Median # of genes tested				Pts tested for PARPi-eligible genes				% pts with PARPi-eligible PGVs*			
	BC	OC	PaC	PrC	BC	OC	PaC	PrC	BC	OC	PaC	PrC
APAC	48	49	50	50	7257	1622	568	533	9	15	4	7
LATAM	84	84	85	85	12202	1319	818	547	10	17	5	8
MEA	85	85	85	85	10410	1135	732	880	7	15	4	7
UEKU	14	48	30	19	2961	174	137	107	7	17	7	10

*BC and OC=BRCA1/2; PaC=BRCA1/2, PALB2; PrC=ATM, BRCA1/2, CHEK2, PALB2.

Implementation of universal pan-cancer germline genetic testing in an Arab population: The Jordanian exploratory cancer genetics (Jo-ECAG) study. *First Author: Hikmat Abdel-Razeq, King Hussein Cancer Center, Amman, Jordan*

Background: Germline genetic testing (GGT) has a significant impact on cancer care. While universal testing has been selectively implemented in the U.S., less is known about adoption of this approach in other ethnic groups. This study reports on GGT results among newly diagnosed cancer patients (pts) in Jordan. **Methods:** Jo-ECAG was a prospective study of newly diagnosed cancer pts between April 2021 and September 2022 who underwent 84 gene GGT. Patients were classified based on the 2020 National Comprehensive Cancer Network (NCCN) GGT criteria as meeting (in criteria, IC) or not meeting criteria (out of criteria, OOC). Demographics and clinical history were clinician-provided. Pts who were carriers for autosomal recessive conditions were excluded from pathogenic germline variant (PGV) count. Differences in proportions were determined using two-tailed Fisher's exact test and the significance was set at $p \leq 0.05$. **Results:** The cohort consisted of 3,313 Arabic cancer pts, predominantly female (69.8%), with a median age of 54 at testing. Breast was the most commonly diagnosed cancer (50.4%), followed by colorectal (14.9%) and prostate (14.3%). 52% of pts tested were guidelines-based (IC). 460 PGVs were identified in 426 (12.9%) pts. PGVs were most commonly identified in *APC* (predominantly 11307K variant, 144 pts, 4.4%), *BRCA2* (72, 2.2%), *BRCA1* (36, 1.1%), *CHEK2* (26, 0.8%) and *ATM* (25, 0.8%). While IC pts were more likely than OOC pts to have a PGV (15.7% vs 9.8%, $p < 0.0001$), 156 (36.6%) pts with PGVs were OOC. 232 (54.5%) pts had PGVs in DNA damage response and repair/homologous recombination repair (DDR/HRR) genes, including 61 (26.3%) OOC pts. 3,602 variants of uncertain significance (VUS) were identified in 2,199 (66.4%) pts with 1,868 of these pts having only VUS results (56.4%), but the frequency in the latter group was not different between IC and OOC pts ($p = 0.42$). **Conclusions:** Universal GGT of all new cancer pts was successfully implemented and led to actionable findings that would have been missed with guidelines-based testing. With the exception of an overrepresentation of *APC* 11307K variants, PGV rates were similar to Western ethnic groups. Over half of pts had PGVs in DDR/HRR genes that confer potential eligibility for targeted therapies and/or clinical trials. While VUS rates were high, they were similar between IC and OOC pts. Additional efforts to sequence underrepresented populations and develop variant interpretation methods agnostic to ancestry may help to mitigate these disparities. A pan-cancer statistical study of microsatellite instability and Lynch syndrome-associated mismatch repair genes germline mutations. *First Author: Huiya Cao, HaploX biotechnology Co., Ltd., Shenzhen, Guangdong, China*

Background: Lynch Syndrome (LS), known as hereditary nonpolyposis colorectal cancer (HNPCC1), is caused by germline mutations in the mismatch repair (MMR) genes (*MLH1*, *MSH2*, *PMS2*, *MSH6*), or epigenetic silencing of *MSH2* which caused by deletion of 3-prime exons of the *EPCAM* gene and intergenic regions directly upstream of the *MSH2* gene. DNA mismatches commonly occur in regions of repetitive nucleotide sequences called microsatellites, and the status of microsatellite instability (MSI) is the key feature in LS-associated cancers. Although there are sporadic reports of MSI and LS in certain cohorts, the real-world status of MSI in large pan-cancer cohort remains to be analyzed. **Methods:** We retrospectively reviewed all 18189 solid tumor patients from August 1, 2020 to February 5, 2023 from HaploX Genomic Sequencing Center and analyzed their germline mutations in MMR genes (*MLH1*, *MSH2*, *PMS2*, *MSH6* and *EPCAM*). MSI status was determined using Sanger sequencing or Next-generation sequencing, with tumor MSI status classified as microsatellite instability-high (MSI-H), or microsatellite-stable (MSS). **Results:** LS-associated germline mutations were detected in 0.313% ($n = 57$) of patients, and 75.4% ($n = 43$) of patients were identified as MSI-H, and 24.6% ($n = 14$) of patients were MSS. The patients were grouped into CRC/EC group (colorectal cancer and endometrial cancer) and non-CRC/EC (lung cancer, central nervous system tumor, gastric cancer, esophageal cancer, hepatological cancer, pancreatic adenocarcinoma, small bowel carcinoma, kidney cancer, etc.). Among MSI-H patients, the CRC/EC group accounted for 90.7% ($n = 39$) and the non-CRC/EC group accounted for 9.3% ($n = 4$). In MSS patients, the CRC/EC patients accounted for 35.7% ($n = 5$), and the non-CRC/EC patients accounted for 60% ($n = 9$). Among patients with MSI-H, the most frequently mutated gene was *MSH6* ($n = 9$): *MSH6* (NM_000179) c.3261dup (p.F1088Lfs*5) mutation was detected in 4 patients, of which 2 patients were paternal and both were diagnosed as colorectal cancer; *MSH6* c.718C > T (p.R240*) mutation was detected in 2 patients with available MMR IHC results, and one of them was *MSH6* negative in IHC staining. **Conclusions:** Traditionally, a family history of colorectal cancer or endometrial cancers was the primary clinical feature to diagnose Lynch syndrome. Once it was recognized that Lynch-associated CRCs were microsatellite unstable, tumor testing became an additional tool for identification of Lynch syndrome. Some previous studies also reported Lynch syndrome mutations, primarily *MSH6* and *PMS2*, were present in a few MSS patients. Thus, MSI status or family history as diagnostic factor alone may result in Lynch syndrome under-recognized, and additional NGS test on MMR genes should facilitate more accurate diagnosis. Real life use of biomarkers of homologous recombination deficiency (HRD) status beyond BRCA to predict the effectiveness of PARP inhibitors in ovarian cancer patients. *First Author: Lorena Inconvaia, Department of Surgical, Oncological, and Oral Sciences, Section of Medical Oncology, University of Palermo, Palermo, Italy*

Background: Testing for *BRCA* mutations (BRCAm) and genomic instability can identify epithelial ovarian cancer (OC) patients most likely to benefit from PARP-inhibitors (PARPi). However, current biomarkers of non-*BRCA* Homologous Recombination Repair (HRR) mutations are insufficient for guiding use of PARPi in the clinic. Despite non-*BRCA* HRR pathway gene mutations are rare, these patients may benefit from PARPi. Furthermore, recent preclinical findings showed that sensitivity to PARPi could be associated also with mutations in mismatch repair (MMR) genes, although sensitivity in the clinic is not proven. **Methods:** We report our real-life experience to assess the HRD status beyond *BRCAm* in newly-diagnosed OC patients, with the use of HRR gene panel and HRD genomic instability tests. After primary diagnosis, tumor and germline *BRCA* (gBRCA) status were assessed and, if *BRCA* WT, tumor HRR deficiency status were centrally determined by myChoiceCDx (Myriad) assay. NGS panel evaluating 20 MMR and HRR-genes beyond *BRCA1/2* was proposed to patients with significant personal and/or family history of cancer, resulted negative to gBRCA testing. **Results:** From January 2017 to January 2023, 540 unselected epithelial OC patients, aged 27 to 81, were tested for tumor and gBRCA status; 109 were carriers of germline pathogenic or likely pathogenic variants (PVs) in *BRCA1/2* genes (20.2%): 72 in *BRCA1* (66.1%) and 37 in *BRCA2* gene (33.9%). Additional 19 patients showed somatic PVs confined to tumor samples (3.5%). In the population of 70 *BRCA* WT patients tested by multigene panel testing, 14 germline PVs in HRR-associated (7.1%) or MMR-associated genes (12.8%) were found, including 5 in *MUTYH* (35.7%), 2 in *ATM* (14.3%), 2 in *MLH1* (14.3%), 2 in *PMS2* (14.3%), 1 in *RAD51C* (7.14%), 1 in *RAD51D* (7.14%), and 1 in *CHEK2* gene (7.14%). Out of 72 samples analyzed by HRD genomic instability test, 23 cases were identified as HRD positive (31.9%), with a median GIS score of 65.5 (44-83). Median GIS were 35 (1-72) in the 6 cases of non-*BRCA* mutated tumors (8.3%), 40 (4-82) in the 17 tumor with non-*BRCA* variant of uncertain significance (VUS) (23.6%), and 27 (2-83) in the WT samples. Median GIS were significantly higher in tumors with PVs/VUS of *RAD51* than *BRIP1* (55.5 vs 35). **Conclusions:** HRRm gene panel and HRD genomic instability tests are not interchangeable to study HRR deficiency beyond *BRCAm*. HRD genomic instability test is effective to identify patients most likely to gain benefit from PARPi, but not for predicting familial risk of cancer. In our population, NGS panel evaluating HRR genes, beyond *BRCA1/2*, improved the detection rate of HRRm by 7%, with additional finding of MMR germline mutations, and important clinical implications for family members. Prospective data are expected to evaluate the effectiveness of PARPi in these population. Research Sponsor: None.

Hereditary breast and ovarian cancer syndrome: A misnomer? *First Author: Jessica M. Weiss, New York Medical College, Valhalla, NY*

Background: Germline pathogenic gene variants (PGV) in homologous recombination deficiency (HRD) genes are traditionally associated with breast, ovarian, pancreatic, prostate and melanoma skin cancer. Recent evidence suggests other cancers may also be associated with these genes. We analyzed the prevalence of somatic HRD mutations in common, traditionally non-hereditary breast and ovarian cancer (HBOC) associated incident cancers in the US. **Methods:** Data were collected from the American Association for Cancer Research's (AACR) Project Genomics Evidence Neoplasia Information Exchange (GENIE) database version 13.0 via cBioPortal (<http://genie.cbioportal.org>). This is a publicly available, multi-institutional database of next-generation sequencing (NGS) genomic profiles of tumor samples. The database was queried for all cancers with at least 20,000 incident cases in 2022, as reported by the American Cancer Society, excluding well established HBOC associated cancers – breast, ovarian, prostate, pancreatic, melanoma. Frequencies of somatic PGVs were reported for nine HRD genes currently included in National Comprehensive Cancer Network (NCCN) management guidelines for HBOC: *ATM*, *BARD1*, *BRCA1*, *BRCA2*, *BRIP1*, *CHEK2*, *PALB2*, *RAD51C* and *RAD51D*. **Results:** A total of 78,285 tumor samples across 12 cancer types were included. At least 1 somatic HRD was found in 6.8% of all included tumors. At least 1 HRD PGV was most common in: Uterine Cancer (694/5,760, 12.1%), Non-Melanoma Skin Cancer (1271/2,09, 10.5%), Bladder Cancer (462/4,605, 10.0%), Colorectal Cancer (1306/14,625, 8.9%) Non-Hodgkin's Lymphoma (5/58, 8.6%), Esophagogastric Cancer (356/4,649, 7.7%), Hepatobiliary Cancer (219/3,325, 6.6%), Lung Cancer (1,480/23,621, 6.3%), Kidney Cancer (113/2,564, 4.4%), Brain Cancer (420/10,206, 4.1%), Thyroid Cancer (89/2,246, 4.0%) and Leukemia (80/5,417, 1.5%). The most common PGVs across all cancer types were *BRCA1/2* and *ATM* (Table). **Conclusions:** A pan-cancer analysis using NGS data demonstrates a substantial rate of somatic HRD PGVs in common, traditionally non-HBOC associated cancers in the US. These data raise the possibility that germline pathogenic variants in HRD genes could be associated with several more cancers than currently known, underscoring the need for studies evaluating risks of the aforementioned cancers in germline PGV carriers. Additionally, these findings present opportunities for trials evaluating the efficacy of HRD-targeting therapies in these cancers. Research Sponsor: None.

Cancer Type	Mutation frequency of <i>BRCA1/2</i>	Mutation frequency of <i>ATM</i>	Mutation frequency of other included HRD genes
Bladder	3.4%	4.3%	3.3%
Brain	1.3%	1.7%	1.8%
Colorectal	4.1%	4.7%	3.3%
Esophagogastric	3.3%	3.4%	2.2%
Hepatobiliary	2.5%	2.9%	1.7%
Kidney	1.0%	2.1%	1.6%
Leukemia	0.4%	0.6%	0.7%
Lung Cancer	2.1%	3.2%	2.0%
Non-Hodgkin's Lymphoma	0%	5.2%	3.6%
Non-Melanoma Skin	4.8%	3.0%	3.9%
Thyroid	1.2%	2.0%	1.1%
Uterine	5.3%	6.3%	4.1%
