Background: FORE8394 is an investigational inhibitor (i) of class 1 (V600) and 2 (activating non-V600) BRAF-altered tumors. FORE8394 did not have paradoxical activation of the MAPK pathway in nonclinical studies. **Methods:** In a phase 1/2a study, patients (pts) aged ≥ 3 years with BRAF-altered, advanced solid or CNS tumors received FORE8394 (900-3600 mg/day or mg/m² dosing) with or without a pharmacokinetic booster (cobocistat 150 mg/day). CNS metastases and prior treatment with other BRAFi were allowed. Besides standard safety assessments, skin and eye exams were required. Objective response was assessed by RECIST v1.1 or RANO criteria. Efficacy was evaluated in pts with class 1/2 BRAF alterations and ≥ 1 post-baseline assessment, with mg/m² dosing (n=4) reported separately. **Results:** On 21Nov2022, 110 pts had received ≥ 1 dose of FORE8394. 85% completed ≥ 1 4-week cycle. 10 (9%) and 3 (3%) received FORE8394 ≥ 2 and ≥ 6 years, respectively; 14 (13%) are ongoing. Pts included 61 (55%) class 1 mutations, 19 (17%) class 2 mutations (excluding fusions), and 17 (15%) BRAF fusions. 64 pts (58%) had ≥ 2 prior lines of systemic therapy; 28 (25%) received prior MAPKi. Increased ALT (39%), increased AST (35%), fatigue (34%), nausea (27%), diarrhea (22%), and vomiting (20%) were the most frequently reported treatment-emergent adverse events (TEAEs); most were grade (G) 1/2. G3+ TEAEs were reported in 49% (54/110), the most common being increased ALT (9%), increased blood bilirubin (6%), and hyponatremia (5%). Transient G1 pyrexia was observed in 8 (7%) pts. All rashes were G1; none required a dose change. No TEAE of hyperkeratosis, papilloma, uveitis, retinal detachment, or LVEF reduction were reported. 1 pt discontinued due to FORE8394-related TEAE. Antitumor activity was observed in pts with MAPKi-naïve, V600 mutant tumors (excluding colorectal cancer [CRC]), 39% (9/23) having a PR (median duration of response [DoR]: 32 months). In 17 pts with V600 mutated tumors (excluding CRC) treated with prior MAPKi, 3 (18%) had PR and 5 (29%) had SD. In V600 mutated tumors, PRs occurred in 6 (55%) gliomas, 3 (100%) ovarian cancers, and 1 each in CRC (7%), small bowel (50%), papillary thyroid (13%) and anaplastic thyroid (25%) cancers. Of pts with BRAF-fusions, a pt with AGK-BRAF-fused melanoma had CR (DoR 51.8+ months); 46% (6/13) had SD. Of note, 1 child with V600E mutated Langerhans cell histiocytosis had SD with improvement in neurodegenerative changes and a progression-free survival of 55.8+ months. **Conclusions:** As single agent anticancer therapy, FORE8394 had antitumor activity in various tumors with BRAF alterations, including pts previously treated with MAPKi and pts with BRAF fusions. Durable tolerability was observed, and TEAEs indicative of paradoxical MAPK activation were not observed, consistent with the novel mechanism of action of FORE8394. These results support further evaluation of FORE8394. Clinical trial information: NCT02428712. Research Sponsor: FORE Biotherapeutics; Plexikon.

Oral Abstract Session

Tumor fraction to improve patient selection for oncology early phase clinical trials: Analysis of two precision medicine studies. *First Author: Sophie Cousin, Early Phase Clinical Trials Unit and Thoracic Unit, Institut Bergonié, Bordeaux, France*

Background: Typical entry criteria in early phase studies include expected life expectancy greater than 3 months. However, this evaluation is quite subjective and more objective and reproducible tools are needed to improve patients (pts) selection. The quantification of ctDNA shed by measuring tumor fraction (TF) has been associated with prognosis in solid tumors pts. However, prognostic implications of TF quantification have been evaluated primarily in retrospective studies and in a limited number of cancer types. We report here the first prospective evaluation of the prognostic impact of TF in 2 independent precision medicine studies enrolling pts referred to consider their eligibility to early phase trials. **Methods:** All consecutive adult pts with an advanced solid tumor included between December 2020 and December 2021 in 2 precision medicine studies: BIP (NCT02534649, sponsor: Institut Bergonié, Bordeaux, France) and STING (NCT04932525, sponsor: Institut Gustave Roussy, Villejuif, France). All pts underwent comprehensive genomic profiling with the 324-gene FoundationOne. TF was analyzed as a binary variable, indicating whether a specimen had TF $\geq 10\%$ or TF $<10\%$. Multivariate analysis included previously validated prognostic scores: the Royal Marsden Hospital (albumin, LDH, number of metastatic sites) and the GRIM (LDH, neutrophil/lymphocyte ratio (NLR), albumin) scores as well as their individual components. **Results:** 1912 pts: N=965 in BIP and N=947 in STING were included. Their characteristics are described. High TF was associated with significantly worse overall survival (OS) in both BIP and STING studies. On multivariate analysis, TF was associated with worse OS (HR:2.49 [CI95%: 2.11 - 2.95, p<0.001] and HR:2.52 [CI95%: 2.06 - 3.08, p<0.001] in BIP and STING studies respectively) independently of the RMH and GRIM scores as well as their individual components. **Conclusions:** This is the first prospective analysis confirming that TF is a strong prognostic factor in pts with advanced solid tumors and represent an helpful tool in the process of patient selection for phase I trial entry. Oral Abstract Session

A phase I study of KL590586, a next-generation selective RET inhibitor, in patients with RET-altered solid tumors. *First Author: Qing Zhou, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China*

Background: KL590586 (A400/EP0031) is a potent next-generation selective RET inhibitor (SRI) with activity against acquired resistance mutations to first-generation SRIs, and brain metastases (mets). Here we present preliminary data of the phase I part from a phase I/II study (KL400-I/II-01, NCT05265091) in patients (pts) with RET-altered advanced tumors to define safety, pharmacokinetics (PK) and efficacy. **Methods:** The phase I of KL400-I/II-01 consisted of dose-escalation (Bayesian Optimal Interval design) and dose-expansion. Primary endpoints were to determine the maximum tolerated dose (MTD) and/or Recommended Phase II Dose. Secondary endpoints included safety, PK, objective response rate (ORR), disease control rate (DCR), and duration of response (DoR) as per RECIST 1.1. **Results:** As of Dec. 30, 2022, 87 pts with RET-altered tumors were treated at 6 doses levels (10 to 120 mg QD). No DLTs were observed, and MTD was not reached. Incidence of treatment-related adverse events (TRAEs, any grade) was 93.1% (81/87), most (74.7%) were grade 1-2, reversible and included (>25%): AST increase (50.6%), ALT increase (48.3%), creatinine increase (33.3%), bilirubin increase (32.2%), constipation (32.2%) and headache (31%). 24.1% of pts had grade ≥ 3 TRAEs, the most common (occurring in >2% of pts) were ALP increase (2.3%), GGT increase (2.3%), ileus (2.3%). TRAEs led to dose reduction or treatment discontinuation in 4.6% and 6.9% of pts, respectively. Hypertension, QT interval prolongation, platelets decrease and lymphocytes decrease (leading to 1st gen SRI dose delays and modifications frequently) were rare (<5%) and low-grade. The exposure increased dose-dependently and the mean half-life was found to be 34.1-99.8h. Clinical responses were observed from 40mg onwards. 69 pts treated at the 40-120mg dose levels (57 NSCLC, 10 MTC, 1 pancreatic cancer, 1 ovarian cancer) were evaluable for efficacy analysis, ORR was 64% (NSCLC, MTC and pancreatic cancer). Most pts (58/69) remained on treatment, with the longest >11 months. The ORR in pts with systemic pretreated NSCLC (median prior treatment: 2, range 1-9, 28% pretreated with anti-PD1/PD-L1 therapy) was 63%(20/32, 1 CR), DCR 91% with median DoR not reached. 9 pts received prior 1st gen SRI, 7 with tumor shrinkage of -10% to -69%, with 3 PR and 4 SD. 11 pts with brain mets (without radiotherapy):4/5 with measurable brain disease had 100%, 100%, 80%, and 47% shrinkage. Overall CNS DCR was 100%. The ORR in treatment naïve NSCLC was 76% (19/25, 1 CR), DCR 92% and median DoR not reached. 3/4 pts with brain mets (without radiotherapy) had complete or partial disappearance of baseline brain lesions. **Conclusions:** KL590586 was well-tolerated, and associated with robust clinical activity in RET-altered tumors regardless of tumor type, including NSCLC pts with resistance to 1st gen SRIs and with CNS mets. Pivotal studies are planned. Clinical trial information: NCT05265091. Research Sponsor: Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd.

Oral Abstract Session

A phase 1 study of the protein arginine methyltransferase 5 (PRMT5) brain-penetrant inhibitor PRT811 in patients (pts) with recurrent high-grade glioma or uveal melanoma (UM). *First Author: Varun Monga, University of Iowa, Iowa City, IA*

Background: PRMT5 catalyzes symmetric arginine dimethylation of protein substrates and is involved in histone modification, transcription, and spliceosome assembly. PRT811 is a potent, selective, brain-penetrant PRMT5 inhibitor being studied in a phase 1, multicenter, open-label, dose-escalation and -expansion study in pts with advanced solid tumors, central nervous system lymphoma, and recurrent high-grade glioma (NCT04089449). Results from the dose-escalation phase have been previously presented. We report on the safety and efficacy of PRT811 in the dose-expansion phase for pts with recurrent high-grade glioma or UM, who have limited treatment (tx) options. **Methods:** Eligible pts were aged ≥ 18 years, had an ECOG performance status (PS) of 0-1, adequate organ function, biopsy-confirmed recurrent high-grade glioma or UM, and were resistant, refractory, or ineligible to receive standard tx. Pts received 15-800 mg of PRT811 orally once daily (QD; 30 days = 1 cycle). The primary objectives were to evaluate the incidence of dose-limiting toxicities and determine the maximum tolerated/recommended phase 2 dose (RP2D) of PRT811. Key secondary objectives were to evaluate the safety, tolerability, and preliminary efficacy (per RECIST v1.1/RANO criteria) of PRT811. **Results:** As of January 13, 2023, 86 pts were enrolled; of the 61 pts with recurrent high-grade glioma (n=38) or metastatic UM (MUM; n=23), 57.4% were female, 24.6% were aged ≥ 65 years, 91.4% had an ECOG PS of 0-1, and 8.2% were systemic therapy naive. Most pts (n=42) received the predicted RP2D of 600 mg QD and 19 pts received between 15 to 800 mg PRT811 QD. Overall, 13% of pts remain on tx. Most pts discontinued tx primarily due to disease progression (83.0%), adverse events (AEs; 5.7%), or pt withdrawal (5.7%). The most common tx-related AEs (mainly grade 1/2) were nausea (49.2%), vomiting (39.3%), fatigue (27.9%), constipation (14.8%), and thrombocytopenia (14.8%). The most common grade 3 tx-related AEs were thrombocytopenia (9.8%; reversible on tx interruption), anemia, fatigue, and lymphopenia (all 3.3%). No tx-related grade 4/5 serious AEs (investigator assessed) were observed; 2 pt deaths were unrelated to tx. Among the 16 *IDH1/2*-mutated (*IDH+*) pts with glioma, we observed 2 complete responses (CR; 1 ongoing, duration: 111+ weeks; 1 discontinued, duration: 33 weeks), 1 unconfirmed partial response (PR), and 8 pts with stable disease (SD). Among the 10 pts with MUM and a splicing gene mutation (*SPLC+*), 1 pt had a confirmed PR (duration: 43 weeks), 1 pt had an unconfirmed PR (ongoing), and 4 pts had SD. No CRs/PRs were observed in the 22 *IDH-* pts with glioma or 13 *SPLC-* pts with MUM. Additional follow-up data, including efficacy plots, will be presented. **Conclusions:** PRT811 demonstrated an acceptable safety profile and clinical activity in pts with glioma and MUM. Clinical trial information: NCT04089449. Research Sponsor: Prelude Therapeutics Incorporated.

Poster Discussion Session

First-in-human phase 1/2a study of a potent and novel CDK2-selective inhibitor PF-07104091 in patients (pts) with advanced solid tumors, enriched for CDK4/6 inhibitor resistant HR+/HER2- breast cancer. *First Author: Timothy A. Yap, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: PF-07104091 is a novel CDK2-selective inhibitor under investigation in pts with selected advanced or metastatic solid tumors. We present the first disclosure of data from the first-in-human, multicenter, phase 1 study of PF-07104091 monotherapy (NCT04553133). **Methods:** Pts with HR+/HER2- advanced/metastatic breast cancer (mBC) who received ≥ 2 lines of treatment for mBC including prior endocrine therapy (ET) + CDK4/6 inhibitors (CDK4/6i), and pts with other solid tumors, were included. Prior therapy with fulvestrant and chemotherapy was allowed for pts with mBC. PF-07104091 (75-500 mg) was given twice daily (BID) orally in 28-day cycles, following Bayesian design with overdose control, to determine the maximum tolerated dose (MTD)/recommended dose for expansion (RDE). Primary objective was to assess safety and tolerability. Secondary objectives included pharmacokinetics and preliminary anti-tumor activity. **Results:** At data cut off (Aug 23, 2022), 35 pts with advanced solid tumors (n = 29 mBC) with median age 62y (range 32-80y), median 4 lines of prior systemic therapy (range 1-12) and ECOG PS 0 (20% pts) or 1 were enrolled. Of 29 pts with mBC, all had prior CDK4/6i, 25 (86.2%) prior fulvestrant, and 21 (72.4%) prior chemotherapy. Treatment-emergent adverse events (TEAEs) were observed in 34 pts (97.1%; 20 [57.1%] grade [G] ≥ 3). The most frequent TEAEs (all G ≤ 3) were nausea (77.1%; 14.3% G3), diarrhea (48.6%; 8.6% G3), vomiting (48.6%; 2.9% G3), fatigue (45.7%; 20.0% G3) and anemia (45.7%; 8.6% G3). Dose-limiting toxicity occurred in 5 pts: 1 pt (G3 fatigue) at 300 mg BID; 2 pts (1 G3 nausea and G3 anorexia, 1 G3 nausea) at 375 mg BID, and 2 pts (1 G3 fatigue and 1 G3 diarrhea) at 500 mg BID. Steady-state PF-07104091 plasma exposures increased proportionally with dose. A trend of early decrease in ctDNA was observed. Further pharmacodynamic studies are ongoing. PF-07104091 300 mg BID was identified as the MTD and selected as the monotherapy RDE. Among 16 response evaluable mBC pts (all prior CDK4/6i+ET) with measurable disease at baseline, confirmed RECIST v1.1 partial responses were observed in 3 (18.8%) pts (2 pts with duration of response > 6 months and 1 ongoing at data cut off), and stable disease in 6 (37.5%) pts. Disease control rate was 61.5% in mBC pts (response evaluable set, 95% CI: 40.6, 79.8). **Conclusions:** Treatment with PF-07104091 monotherapy was generally well tolerated and showed antitumor activity in heavily pretreated HR+ HER2- mBC pts who progressed on prior CDK4/6i. Dose expansions of PF-07104091 are ongoing as monotherapy in pts with ovarian cancer and in combination with fulvestrant in pts with breast cancer. Clinical trial information: NCT04553133. Research Sponsor: Pfizer.

Poster Discussion Session

First-in-human first-in-class phase 1/2a study of the next generation CDK4-selective inhibitor PF-07220060 in patients (pts) with advanced solid tumors, enriched for HR+ HER2- mBC who progressed on prior CDK4/6 inhibitors and endocrine therapy. *First Author: Timothy A. Yap, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: PF-07220060 is a novel potent oral CDK4-selective inhibitor with significant sparing of CDK6. We report the first disclosure of the first-in-human, multicenter trial of PF-07220060 alone or with endocrine therapy (ET). **Methods:** This Phase 1/2a study in advanced solid tumors was enriched for pts with HR+ HER2- advanced/metastatic breast cancer (HR+/HER2- mBC) who had received ≥ 2 lines of treatment including ET and CDK4/6 inhibitors (CDK4/6i). Prior fulvestrant and chemotherapy were allowed. Primary objective was to assess safety and tolerability of PF-07220060 alone and in combination with ET. Secondary/exploratory objectives included anti-tumor activity, pharmacokinetics (PK) and pharmacodynamics (PD). **Results:** At data cut off (Nov 1, 2022), 34 pts with advanced solid tumors received PF-07220060 in monotherapy dose escalation (Part 1A: 100-500 mg BID), and 26 pts with HR+/HER2- mBC in combination (300mg/400mg BID) with letrozole or fulvestrant (Parts 1B + 1C). For pts with HR+/HER2- mBC, median age was 61.5y (range 41-82y), ECOG PS was 0 (38.5% pts) or 1, and median prior lines of systemic therapy (advanced setting) 4.5 (range 1-11); all had prior CDK4/6i, 19 (73.1%) prior fulvestrant and 20 (76.9%) prior chemotherapy. Most frequent all causality treatment-emergent adverse events (TEAEs) with PF-07220060 + ET were diarrhea (50.0%; 0% G3), neutropenia (50.0%; 15.4% G3) and nausea (38.5%; 3.8% G3) with no >G3 TEAEs. A similar safety profile was seen in monotherapy. Dose-limiting toxicities occurred at PF-07220060 500 mg monotherapy BID (n=2 G3 thrombocytopenia) and at 400 mg BID + fulvestrant (n=1 G3 leukopenia/neutropenia). Preliminary PK analyses showed PF-07220060 is rapidly absorbed with dose-dependent increases in exposure. PF-07220060 300 mg BID was selected as the recommended dose for expansion. PD biomarker modulation was seen in tumor (pRb, Ki67 inhibition) and blood (TK1 inhibition). In pts with HR+/HER2- mBC with measurable disease who progressed on prior CDK4/6i+ET (n=21) treated with PF-07220060 (300/400 mg BID) + ET, confirmed RECIST v1.1 responses were observed in 6 (28.6%) pts (1 complete [CR], 5 partial [PR]). Clinical benefit response (CR, PR, or ≥ 24 wks stable disease) was seen in 11 (52.4%) pts. Median progression-free survival was 24.7 wks (95% CI: 23.1, 47.4). At data cutoff, 8/26 (30.8%) pts with mBC continued PF-07220060 + ET without progression for up to 60+ wks. Updated efficacy, PK, PD, and biomarker data will be presented. **Conclusions:** PF-07220060 + ET showed efficacy in pts with HR+/HER2- mBC who progressed on prior CDK4/6i+ET. Tolerability of PF-07220060 alone and in combination with ET was encouraging. Dose expansions with PF-07220060 + ET in pts with HR+/HER2- mBC post CDK4/6i and in CDK4/6i naive pts are ongoing. Clinical trial information: NCT04557449. Research Sponsor: Pfizer.

Poster Discussion Session

FUTURE-SUPER: A randomized, subtyping-based umbrella phase II trial for first-line treatment of metastatic triple-negative breast cancer. *First Author: Shao Zhimin, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Triple-negative breast cancers (TNBCs) are heterogeneous in molecular drivers and immune traits. Our previous studies classified TNBCs into four subtypes (luminal androgen receptor, LAR; immunomodulatory, IM; basal-like immune-suppressed, BLIS; and mesenchymal-like, MES). The subtyping-based treatment strategy was proved clinically feasible, with promising efficacy (Cell Res 2021, NCT03805399) in patients with heavily pretreated metastatic TNBC (mTNBC). Here, we conducted FUTURE-SUPER, a multi-cohort, randomized trial to further evaluate the efficacy of subtyping-based therapy in the first-line treatment of mTNBC. **Methods:** Patients with untreated locally recurrent inoperable or mTNBC were enrolled. After categorization into 5 cohorts according to TNBC subtypes and genomic biomarkers, patients were randomly assigned (in a 1:1 ratio) to receive nab-paclitaxel (control group) or nab-paclitaxel plus subtyping-based treatment (subtyping-based group): pyrotinib (LAR-HER2^{mut}), everolimus (LAR-PI3K/AKT^{mut}), camrelizumab and famitinib (IM), bevacizumab (BLIS/MES-PI3K/AKT^{wt}), everolimus (MES-PI3K/AKT^{mut}). The primary endpoint was progression-free survival (PFS). Secondary endpoints included PFS in each subtyping-based cohort, objective response rate (ORR), overall survival (OS) and safety. **Results:** Between July 29, 2020, and October 17, 2022, 139 patients were enrolled and randomly assigned. With a median follow-up of 18.5 mo (range, 3.5 to 30.3), 101 (72.7%) events of disease progression or death occurred. Median PFS was significantly longer in the subtyping-based group than in the control (11.3 mo vs 5.8 mo; hazard ratio [HR], 0.38; 95% confidence interval [CI], 0.25 to 0.57; P<0.0001). Greater magnitude of PFS benefits were seen for the IM (median, 15.1 mo vs 6.5 mo; HR 0.37; 95% CI, 0.19 to 0.73), BLIS (median, 9.4 mo vs 3.9 mo; HR 0.41; 95% CI, 0.16 to 0.56) and LAR-PI3K/AKT^{mut} (median, 19.1 mo vs 8.4 mo; HR 0.42; 95% CI, 0.12 to 1.53) subtypes. The ORR (measurable-disease population) was higher in the subtyping-based group than in the control group (80.0% [48/60] vs. 44.8% [26/58]; odds ratio, 0.20; 95% CI, 0.09 to 0.46). OS data were not mature. Most adverse events were of grade 1 or 2. Grade 3 and 4 toxicities were as expected, with neutropenia more frequently reported in the subtyping-based group (56.5% vs 26.1%). No treatment-related deaths were recorded. Further high-throughput biomarker analyses are ongoing. **Conclusions:** Subtyping-based precision treatment significantly prolonged PFS versus nab-paclitaxel in the first-line treatment of advanced TNBC, with manageable toxicities. Our findings highlight the profound clinical benefits with treatment optimization according to molecular/immunological subtypes in TNBC, outlining a direction for further exploration. Clinical trial information: NCT04395989. Research Sponsor: None.

Poster Discussion Session

Debio 0123-101: A phase 1 trial of Debio 0123 in combination with carboplatin in advanced solid tumors—Safety, pharmacokinetic, and preliminary antitumor activity data. *First Author: Hans Gelderblom, Leiden University Medical Center, Leiden, Netherlands*

Background: Cell cycle faults are typical in cancer, with tumor cells depending on G2 checkpoints to avoid excess DNA damage. WEE1, a DNA damage-activated kinase, governs G2 by phosphorylating cyclin-dependent kinase 1 (CDK1) to arrest the cell cycle and permit DNA repair. Via CDK1 inhibition, WEE1 also blocks replication initiation, limiting oncogene-induced replication stress. WEE1 inhibition, with accumulating DNA damage, can induce mitotic catastrophe and apoptosis. Debio 0123, an orally available, ATP-competitive WEE1 inhibitor, is being studied as monotherapy and in combination with carboplatin (CP) in patients (pts) with solid tumors. Here, we report safety, pharmacokinetic (PK), pharmacodynamic, and antitumor activity data for the combination. **Methods:** Debio 0123-101 (NCT03968653) is a two-arm dose-escalation study in pts with advanced solid tumors that recurred or progressed after receiving platinum-containing therapy, where no standard therapy of proven benefit is available. In Arm A, Debio 0123 was given as monotherapy in cycle (C) 1 (as a single dose on day [D] -3 and once daily over D1-3) and in combination with CP from C2 until end of treatment (EOT). In Arm B, Debio 0123 was given in combination with CP on D1-3 and D8-10, from C1 to EOT. CP was given on D1 of each 21-day cycle in both arms. Skin biopsies were taken at baseline and C1D3 to assess target engagement (TE). **Results:** Arm A data (cut-off 31.12.2022) is shown. Overall, 38 pts were treated (78.9% female, mean age 58.5 years), with two pts ongoing. Using a continual reassessment method-guided dose escalation, tested Debio 0123 doses ranged from 30–520 mg. The maximum tolerated dose was declared at 520 mg. At this dose level, 2/6 pts experienced a dose-limiting toxicity. The treatment was deemed well tolerated, with a manageable safety profile in line with that expected for CP monotherapy. Most Debio 0123-related toxicities were grade 1/2. Preliminary PK data indicate that Debio 0123 plasma levels rise proportionally with dose. TE was seen from the 150 mg dose, becoming more pronounced with increasing dose levels. Confirmed partial responses (PR) occurred in 5/30 evaluable pts; 4/12 pts with platinum-resistant ovarian cancer achieved a PR (one ongoing). **Conclusions:** Debio 0123, combined with CP, has a manageable safety profile and is well tolerated up to 520 mg; this combination led to observable antitumor activity in pts with platinum-resistant cancer. Further study of Debio 0123 as a therapeutic agent is warranted. Clinical trial information: NCT03968653. Research Sponsor: Debiopharm.

Summary of treatment-emergent adverse events (TEAEs) related to Debio 0123 as per CTCAE v5.0.

TEAE	Any grade n (%)	Grade ≥3 n (%)
Thrombocytopenia/platelet count decreased	12 (31.6)	3 (7.9)
Nausea	12 (31.6)	0
Anemia	8 (21.1)	1 (2.6)
Fatigue	7 (18.4)	0
Leukopenia	5 (13.2)	1 (2.6)
Vomiting	5 (13.2)	0

Dose escalation results from a first-in-human study of ABBV-400, a novel c-Met-targeting antibody-drug conjugate, in advanced solid tumors. *First Author: Manish Sharma, START Midwest, Grand Rapids, MI*

Background: c-Met overexpression is common in non-small cell lung cancer (NSCLC), gastroesophageal adenocarcinoma (GEA), and colorectal cancer (CRC). There is a need for effective therapies that target c-Met-overexpressing tumors, as there are currently no approved options available. The antibody-drug conjugate (ADC) ABBV-400 consists of the c-Met-targeting antibody telisotuzumab conjugated to a potent topoisomerase 1 inhibitor (Top1i) payload. ABBV-400 exhibited sustained antitumor activity in patient-derived xenograft models of c-Met-expressing NSCLC, GEA, and CRC. Herein, we present data from the dose escalation of the first-in-human study of ABBV-400 monotherapy. **Methods:** A phase 1 dose escalation/expansion study of ABBV-400 has been initiated in patients with advanced solid tumors (NCT05029882). Primary objectives are to evaluate safety, tolerability, and pharmacokinetics (PK) of ABBV-400, to determine the recommended phase 2 dose, and to assess preliminary efficacy. PK will be characterized for the conjugate, total antibody, and free payload. Adults (≥18 years) with an advanced solid tumor that progressed on standard therapies were enrolled during dose escalation, without restrictions on the basis of c-Met overexpression status. **Results:** As of January 2023, 47 patients had enrolled in dose escalation with a median follow-up of 6.5 months. Median age was 58 years (range, 34–79), 25 (53%) patients were male, and the most common cancer types were CRC (n=21), NSCLC (n=5), and GEA (n=5). The median number of prior treatment lines was 4 (1–13). Most common hematologic adverse events (AEs) were anemia (66%; grade [G]≥3: 38%), neutropenia (62%; G≥3: 43%), thrombocytopenia (43%; G≥3: 26%), and leukopenia (32%; G≥3: 19%). Nausea (60%, all grade 1–2), fatigue (49%; G≥3: 4%), and vomiting (38%, all grade 1–2) were the most frequent non-hematologic AEs. One patient experienced grade 1 interstitial lung disease. Neutropenia and thrombocytopenia were the dose-limiting toxicities (DLTs) and were dose and exposure dependent. Clinical activity was observed with ABBV-400, with an objective response rate of 24.4% (11/45; 95% CI: 12.9, 39.5). All responses were confirmed partial responses (PR). In addition, 23 patients (50.0%) had stable disease (SD) and 7 (15.2%) had progressive disease. Among patients with CRC, 4/21 (19.0%) had a PR and 13/21 (61.9%) had durable SD, with a disease control rate of 81.0% (95% CI: 58.1, 94.6). Outside of CRC, PRs were observed in patients with NSCLC (EGFR wildtype and mutant), uterine cancer, and acral melanoma. **Conclusions:** On the basis of DLTs, a maximum tolerated dose of ABBV-400 was identified. At this dose, safety results appear comparable with other Top1i ADCs. Promising antitumor activity was seen with ABBV-400 across tumor types, justifying further evaluation in the ongoing dose expansion in NSCLC, GEA, and CRC. Clinical trial information: NCT05029882. Research Sponsor: AbbVie Inc.

Poster Discussion Session

Tissue-agnostic efficacy of trastuzumab deruxtecan (T-DXd) in advanced solid tumors with HER2 amplification identified by plasma cell-free DNA (cfDNA) testing: Results from a phase 2 basket trial (HERALD/EPOC1806). *First Author: Hiroya Taniguchi, Department of Clinical Oncology, Aichi Cancer Center Hospital, Nagoya, Japan*

Background: HER2 (ERBB2) gene amplification (amp) is a potential therapeutic target beyond breast and gastric cancers. HER2 amp can be detected in plasma cfDNA which may be an alternative to tissue biopsy. HERALD/EPOC1806 was a multicenter, investigator-initiated phase 2 trial of T-DXd for patients with HER2-amplified advanced solid tumors identified by cfDNA testing. **Methods:** We enrolled adults with advanced solid tumors harboring HER2 amp detected by next-generation sequencing of cfDNA (Guardant360) in the GOZILA study (UMIN000029315). We excluded breast or gastric cancer patients with HER2 overexpression (IHC 3+ or IHC 2+/ISH+). Patients received T-DXd 5.4 mg/kg every 3 weeks until disease progression or unacceptable toxicity. The primary endpoint was investigator-assessed objective response rate (ORR). **Results:** From December 2019 to January 2022, 4,734 patients were screened by cfDNA in the GOZILA study. Among 252 with HER2 amp, 62 with 16 cancer types were enrolled in HERALD. Median baseline plasma HER2 copy number (CN) was 8.55 (range, 2.4–73.9). All patients but 3 (all with salivary gland cancer) received prior anti-cancer therapy (median, 3 lines; range, 0–8). At a median follow-up of 8.9 months (data cut-off: July 17, 2022), the confirmed ORR was 56.5% (95% CI, 43.3–69.0%), statistically higher than the threshold value of 5%. Responses were observed for 13 cancer types, including KRAS-mutant colorectal (1/3), PIK3CA-mutant endometrial (5/6), and tissue HER2-negative gastric cancers (1/2). Plasma HER2 CN above vs. below the baseline median value did not impact response (ORR: 58.1% vs. 54.8%); however, the clearance vs. persistence of HER2 amp in cfDNA on Cycle 2 Day 1 corresponded to higher response (ORR: 88.0% vs. 22.7%). ORR by independent review was 58.1% (95% CI, 44.8–70.5%), and the disease control rate was 90.3% (95% CI, 80.1–96.4%). Median progression-free survival was 7.0 (95% CI, 4.9–9.7) months, and the median duration of response was 8.8 months (95% CI, 5.8–11.2). Most adverse events were mild to moderate. Interstitial lung diseases occurred in 16 patients (25.8%, G1/G2/ G3: 14/1/1). **Conclusions:** T-DXd achieved a high ORR, durable response with a manageable safety profile in patients with advanced solid tumors and HER2 amp detected in cfDNA. Clinical trial information: JapicCTI-194707. Research Sponsor: AMED.

First-in-human dose escalation and expansion study of SYSA1801, an antibody-drug conjugate targeting claudin 18.2 in patients with resistant/refractory solid tumors. *First Author: Yakun Wang, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Department of Gastrointestinal Oncology, Peking University Cancer Hospital & Institute, Beijing, China*

Background: SYSA1801 is a MMAE antibody-drug conjugate (ADC) targeting claudin 18.2 (CLDN18.2), a tight junction protein broadly expressed in gastric, pancreatic, and other solid tumors. CLDN18.2 has a highly selective cell surface expression profile that is limited to normal gastric mucosa, making it a promising ADC therapeutic target. SYSA1801 has shown significant *in vitro* and *in vivo* anti-tumor activity in multiple cell lines and patient-derived xenografts expressing CLDN18.2. **Methods:** This is an open-label, multi-center, phase I study to evaluate the safety, tolerability, pharmacokinetics and efficacy of SYSA1801 in patients (pts) with histologically confirmed resistant/refractory solid tumors that express CLDN18.2 who progressed on or were intolerant to standard treatment, or had no standard treatment. This study consists of two parts; part 1 is a modified 3+3 dose-escalation design with five dose levels of SYSA1801 (0.5, 1, 2, 2.5 and 3 mg/kg) administered intravenously (IV) every 3 weeks (Q3W), followed by dose expansion at effective doses. Part 2 is a cohort expansion at the optimal dose. Here, we present the preliminary results of SYSA1801 for part 1. **Results:** As of Nov 5, 2022, 33 pts with a median age of 59 yrs (range 22–71) were enrolled to receive up to SYSA1801 3 mg/kg in part 1. 26 pts (78.8%) had gastric cancer (GC) and 7 pts (21.2%) had pancreatic cancer. ECOG PS was 0 in 5 pts (15.2%) and 1 in 28 pts (84.8%). 11 pts (33.3%) had been heavily pretreated (≥3 prior lines). Treatment-related adverse events (TRAEs) of any grade occurred in 25 pts (75.8%), in which 8 (24.2%) were ≥ grade 3. No treatment related death was reported. The most common TRAEs (occurring in >20% of pts) were nausea (42.4%), vomiting (36.4%), dry eye syndrome (21.2%) and anemia (21.2%). Two DLTs (grade-3 nausea and vomiting) occurred at the 3 mg/kg dose. The optimal dose of SYSA1801 is being explored. Of 33 pts enrolled, 21 pts were evaluable for efficacy per RECIST v1.1. Objective response rate (ORR) was 38.1% (95% CI: 18.1–61.6%, 8 PRs) and disease control rate (DCR) was 57.1% (95% CI: 34.0–78.2%, 4 SDs). Among 17 evaluable pts with GC, ORR and DCR were 47.1% (95% CI: 23.0–72.2%, 8 PRs) and 64.7% (95% CI: 38.3–85.8%, 3 SDs). One pt with GC receiving SYSA1801 at 1 mg/kg IV Q3W tolerated treatment for 44 weeks with durable confirmed partial response ongoing at the time of analysis. Another pt with GC who failed previous anti-CLDN18.2 treatment achieved a confirmed PR on SYSA1801 2 mg/kg IV Q3W. **Conclusions:** SYSA1801 shows promising early signs of efficacy with a well-tolerated safety profile in pts with CLDN18.2-expressing resistant/refractory solid tumors, especially GC. Part 1 of the study is ongoing with part 2 to start when the optimized dose is determined in China; studies outside of Greater China including in the United States are being planned by Elevation Oncology. Clinical trial information: NCT05009966. Research Sponsor: CSPC Zhongqi Pharmaceutical Technology Co., Ltd.

ARTEMIS-001: Phase 1 study of HS-20093, a B7-H3–targeting antibody-drug conjugate, in patients with advanced solid tumor. *First Author: Jie Wang, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China*

Background: B7-H3, a member of the B7 superfamily, is highly expressed in various solid tumors, but has limited expression at low level in normal tissues. HS-20093 is a B7-H3-targeted antibody-drug conjugate. It could be an attractive therapeutic option for advanced solid tumors, especially the patients (pts) who have failed in multi-line therapy requiring novel and more effective treatment. **Methods:** This is a first-in-human, multicenter, open-label phase 1 study of HS-20093 in advanced solid tumors (NCT05276609). Dose escalation part assessed safety and tolerability of intravenous HS-20093 with doses ranging from 1.0 to 16.0 mg/kg. The dose escalation schedule utilized an accelerated titration and interval 3+3 design. Pts with advanced solid tumor were required to have received prior standard therapy. HS-20093 is administered intravenously every 3 weeks. **Results:** The study completed all planned dose cohorts (1.0 to 16.0 mg/kg) as of cutoff date (20 December 2022). In dose escalation study, 53 pts of multiple tumor types were enrolled and received ≥ 1 dose of HS-20093, which included 29 pts with non-small cell lung cancer, 11 pts with small cell lung cancer (SCLC), 9 pts with sarcoma and 4 pts with other advanced solid tumors. At baseline, 25 pts (47.2%) had received ≥ 3 prior lines therapy with a mean of 3.2 (range, 1-12) prior lines of therapy. Three pts experienced dose-limiting toxicities (1 pt at 12.0 mg/kg; 2 pts at 16.0 mg/kg). The maximum tolerated dose was determined to be 12.0 mg/kg. Treatment-emergent adverse events (TEAEs) occurred in 53 pts (100%). The most common TEAEs overall in $\geq 30\%$ of pts were leukopenia, neutropenia, anemia, pyrexia, nausea, thrombocytopenia, hyponatremia, vomiting, lymphopenia, infusion-related reaction and fatigue. No interstitial lung disease was reported. Of 40 response-evaluable pts, regardless of baseline B7-H3 expression level, 14 partial responses (PRs) were observed in pts treated with HS-20093 from 4.0 mg/kg to 12.0 mg/kg doses (response rate: 35.0%), including 9 confirmed PRs and 5 PRs awaiting confirmation. The disease control rate was 85.0% (34/40, 95% CI: 70.2-94.3). The patient with the longest treatment duration (349 days) remains on treatment. In the subset of 9 SCLC pts, 7 PRs were observed (response rate: 77.8%) with the median depth of response of 50.5%, including 3 confirmed PRs and 4 PRs awaiting confirmation. All responses of SCLC pts occurred at the first disease assessment; the median time to first response was 6 weeks. HS-20093 displayed anti-tumor activity in SCLC pts who have progressed on prior derivative of camptothecin treatment. **Conclusions:** The safety profile of HS-20093 was acceptable. HS-20093 demonstrated promising antitumor activity in several tumor types, especially in SCLC. The further dose expansion study on efficacy and safety of HS-20093 in selected tumor types is ongoing. Clinical trial information: NCT05276609. Research Sponsor: Hansoh Pharmaceutical Group Co, Ltd.

Poster Discussion Session

Preliminary safety and efficacy of tinengotinib tablets as monotherapy and combination therapy in advanced solid tumors: A phase Ib/II clinical trial. *First Author: Sarina A. Pihl-Paul, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Tinengotinib is a spectrum-selective multi-kinase inhibitor that targets cell proliferation, angiogenesis, and immune-oncology pathways by inhibiting Aurora kinases A/B, Janus kinases (JAK), and receptor tyrosine kinases (FGFRs, VEGFRs). Tinengotinib has shown preliminary efficacy in prostate cancer (PC), hormone receptor positive (HR+)/human epidermal growth factor receptor 2 negative (HER2-) breast cancer (BC), triple-negative BC (TNBC) and cholangiocarcinoma (CCA) in Phase (Ph) 1 trial. Here we present the preliminary safety, pharmacokinetics (PK), and efficacy of tinengotinib in a Ph Ib/II trial. **Methods:** Eligible patients (pts) with advanced or metastatic solid tumors were assigned to: Arm A (tinengotinib 12 mg QD), Arm B (tinengotinib 8/10/12 mg QD in combination with 100 mg/m² Abiraterone, HER2- BC); Arm C PK Run-in (tinengotinib 5/8/10/12 mg QD, or 4/6 mg BID). Objectives include safety (CTCAE v5.0) and tolerability, PK profile, efficacy (RECIST v1.1) and exploratory biomarker(s). **Results:** As of 30 Jan 2023, 157 pts with solid tumors were enrolled and treated. In monotherapy (Arm A and Arm C, N=153), median age was 62.5 years (23-83), 56% were female, 69% had ≥ 3 prior lines of therapy. In combination (Arm B, N=4), median age was 40 years (25-46), 100% were female, 100% had ≥ 3 prior lines of therapy. The treatment-related AEs (TRAE) in monotherapy arms were reported in 110 (71.9%) pts. 53 (34.6%) were Grade (G) 1-2, 55 (35.9%) were G3, 2 (1.3%) were G4, no G5 was observed; the most common TRAEs were hypertension (29.4%), stomatitis (20.9%), diarrhea (16.3%), nausea (13.7%) and palmar-plantar erythrodysesthesia syndrome (12.4%). In the combination arm, 4 treated pts at dose level 1 experienced G3 TRAEs, and the most common TRAEs were neutropenia (75%), stomatitis (50%), hyponatremia (50%), hypokalemia (50%) and hypertension (50%). In 108 efficacy-evaluable pts of monotherapy arms, the overall response rate (ORR) and disease control rate (DCR) were 16% and 60%, respectively. The ORR in PC, HR+/HER2- BC, TNBC and CCA were 50% (5/10), 40% (2/5), 50% (3/6) and 20% (3/15), respectively. Preliminary PK analysis showed a linear increase on exposure in terms of geometric mean C_{max,ss} and AUC_{0-24h,ss} from 5 mg QD to 12 mg QD. No significant difference in exposure was observed in QD vs BID. **Conclusions:** Tinengotinib monotherapy was well-tolerated. The tolerability assessment in combination with chemotherapy is underway. The PK results may support dose recommendation for subsequent trials. Encouraging anticancer activity of tinengotinib monotherapy were observed in pts with heavily pre-treated solid tumors, including PC, HR+/HER2- BC, TNBC and CCA. The ongoing Ph II study of tinengotinib continues to evaluate clinical benefit and safety in pts with PC. Clinical trial information: NCT04742959. Research Sponsor: TransThera Sciences (Nanjing), Inc.

Phase 1 trial evaluating TTI-101, a first-in-class, orally bioavailable, small molecule, inhibitor of STAT3, in patients with advanced solid tumors. *First Author: Apostolia Maria Tsimberidou, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Signal transducer and activator of transcription 3 (STAT3) is a transcription factor at the critical intersection of signaling pathways controlling gene networks integral to the survival and immune sequestration of cancer cells. Given the integral role of STAT3 in tumorigenesis and immune suppression, STAT3 signaling inhibition may have dual antitumor activity. TTI-101 is a first-in-class, orally bioavailable, selective small molecule that binds to STAT3 and prevents STAT3-mediated transcriptional activation. A first-in-human, Phase 1, dose escalation and expansion study of TTI-101 monotherapy was conducted in patients with advanced/refractory solid tumors (NCT03195699). **Methods:** Patients with advanced metastatic cancer who had failed standard therapy were treated with TTI-101 twice daily in 28-day cycles at dose levels (DL) 1-4: 3.2 (DL1), 6.4 (DL2), 12.8 (DL3), and 25.6 (DL4) mg/kg/d ("3+3" design). Three different formulations of TTI-101 were used stepwise, beginning with formulation 1 (F1). A second-generation formulation (F2) was introduced at DL3 during dose escalation and patients were stratified into two cohorts: hepatocellular carcinoma (HCC) and other solid tumors. A third-generation formulation (F3) was evaluated once the recommended phase 2 dose (RP2D) was determined. Treatment continued until disease progression, unacceptable toxicity, or study withdrawal. **Results:** Key patient characteristics included a median age of 63 years (range, 33-78), 52% male, and a median number of 3 (range, 1-9) prior systemic therapies. No dose limiting toxicities (DLTs), or fatal treatment-related adverse events (TRAEs) were observed. Diarrhea was the only TRAE observed in $\geq 30\%$ of the safety population (n=64) with events being mostly Grade 1/2. F3 was better tolerated than F1 and F2 with no events $\geq$ Grade 3. One patient experienced transient Grade 4 hyperglycemia which resolved with insulin and metformin. Five patients had serious TRAEs (all Grade 3), which resolved. TTI-101 showed linear pharmacokinetics from DL1-3 plateauing at DL3. The RP2D was determined to be 12.8mg/kg/d (DL3) for both the HCC and other solid tumor cohorts. Of the 39 patients evaluable for response, 5 (13%) patients had confirmed partial responses (cPR) and 16 (41%) stable disease (SD). Of the 15 patients with HCC, 3 (20%) had a cPR with a median duration of 10.5 months. The other two cPRs were in ovarian cancer (n=1) and gastric cancer (n=1). **Conclusions:** TTI-101 was well-tolerated and no DLTs were noted. cPRs were observed across tumor types. The antitumor activity of TTI-101 monotherapy in the relapsed/refractory setting is promising, particularly in HCC. Two Phase 2 oncology studies of TTI-101 in STAT3-driven cancers (HCC and metastatic breast cancer) are underway. Clinical trial information: NCT03195699. Research Sponsor: Tvardi Therapeutics, Inc.; V Foundation; U.S. National Institutes of Health; Cancer Prevention and Research Institute of Texas (CPRIT).

Poster Discussion Session

A first-in-human, phase 1 study of the SHP2 inhibitor PF-07284892 as monotherapy and in combination with different targeted therapies in oncogene-driven, treatment-resistant solid tumors. *First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Src homology region 2 domain-containing phosphatase-2 (SHP2) activation mediates targeted therapy resistance in various oncogene-driven cancers. In this phase 1 study (NCT04800822), the novel SHP2 inhibitor PF-07284892 (ARRY-558) was evaluated alone and in combination with different targeted therapies in patients (pts) with oncogene-driven tumors that progressed on prior targeted therapy. Unlike other phase I studies, the unique design of this trial allowed pts to receive combination therapy during dose escalation after a period of PF-07284892 monotherapy. This is critical given that monotherapy efficacy was deemed unlikely based on preclinical data. **Methods:** Eligible pts with advanced solid tumors were enrolled into escalating dose cohorts of PF-07284892 monotherapy. In the absence of dose limiting toxicity (DLT), matched targeted therapy (lorlatinib for ALK/ROS1 fusion+ cancers, encorafenib + cetuximab for BRAF^{V600E} colorectal cancers, and binimetinib for MAPK-mutant cancers) could be added after 6 weeks of monotherapy at the discretion of the investigator. Primary objectives were safety, tolerability, and recommended dose for further evaluation (RDE) determination. Secondary/exploratory objectives included analyses of pharmacokinetics (PK), circulating tumor DNA (ctDNA), and monotherapy/combination therapy objective response (RECIST v1.1). **Results:** As of 9/19/2022, 33 pts with oncogene-driven solid tumors were enrolled (20-80 mg, orally twice weekly, day 1 and 4 or day 1 and 2 schedule), of whom 18 received combination therapy (5 ALK/ROS1 fusion+ cancers, 4 BRAF^{V600E}+CRCs, 9 MAPK mutant cancers). The median age was 54.5 y (range 32-78). The most common treatment-related adverse events (TRAEs; $>15\%$) for monotherapy were anemia (21%), peripheral edema (18%), and increased AST (18%). Cycle 1 monotherapy DLTs occurred in 4 pts: G3 increased AST, ALT, and bilirubin (n=1); anemia (n=1); and increased AST and ALT, and thrombocytopenia (n=1); and G4 bilirubin (n=1). PF-07284892 PK was dose proportional. 40 mg twice weekly (day 1 and 2) was selected as the RDE. With combination therapy, confirmed RECIST v1.1 partial responses (PR) were observed in 3 treatment-refractory pts (2 lorlatinib and 1 binimetinib combination), and stable disease was observed in 6 treatment-refractory pts. $\geq 80\%$ ctDNA founder mutation reduction was observed post combination therapy initiation in 2 of the responding pts. **Conclusions:** PF-07284892 was generally well tolerated alone and in combination with rational targeted therapies. This study design enabled combination therapy rescue of disease progression on PF-07284892 monotherapy with 3 pts achieving confirmed PR. Clinical trial information: NCT04800822. Research Sponsor: Pfizer.

A phase II study of tinostamustine in patients (pts) with advanced solid tumours. *First Author: Anna Tinker, BC Cancer - Vancouver, Vancouver, BC, Canada*

Background: The novel multi-action alkylating deacetylase inhibitor tinostamustine improves drug access to DNA strands within cancer cells, breaks them and counteracts damage repair. Tinostamustine was well tolerated with signals of efficacy during dose escalation in pts with advanced solid tumours (Mita et al. Cancer Res 2019;79[13 Suppl]:CT023). **Methods:** This was an open-label Phase I/II trial of single agent tinostamustine in pts with advanced solid tumours (NCT03345485). The Phase II primary endpoint was objective response rate (ORR: complete response + partial response (PR)) and the rate of stable disease ≥ 4 mo duration following the recommended Phase II dose (RP2D; 80 mg/m² over 1 h on Day 1 & 15 of each 4-wk treatment cycle). Secondary endpoints included progression-free (PFS) and overall survival (OS), and duration of response. Eligible pts were ≥ 18 y with life expectancy ≥ 3 mo, Eastern Cooperative Oncology Group (ECOG) performance status (PS) ≤ 2 , histologically confirmed diagnosis of advanced/metastatic soft tissue sarcoma (STS), small-cell lung (SCLC), triple-negative breast (TNBC), ovarian (OvCa) or endometrial cancer, progression following ≥ 1 prior line of therapy, with no other standard therapy with proven clinical benefit available or recommended. **Results:** 36 pts were enrolled and evaluable for response; mean $\pm$ SD age 59.6 $\pm$ 11.2 y, 83.3% female, 80.6% Caucasian, all ECOG PS ≤ 1 , median of 3 (range 1–9) lines of prior therapy. At data cut-off (30 November 2022) pts had received a median of 2 (range 1–8) cycles of tinostamustine. 19 pts (52.8%) discontinued treatment due to progressive disease. One pt with synovial sarcoma (STS cohort; n=10) and one pt with OvCa (n=12) achieved a PR. Overall, 14 pts (38.9%) had stable disease ≥ 4 mo (0/4 SCLC; 3/10 STS; 3/4 TNBC; 5/12 OvCa; 3/6 endometrial cancer); Clinical Benefit Rate, 44.4% (95% CI: 27.9%, 61.9%). Median PFS and OS for all treated pts were 2.2 mo (95% CI 1.8, 3.3 mo) and 5.5 mo (95% CI 4.1, 15.0 mo), respectively. All pts experienced ≥ 1 treatment-emergent adverse event (TEAE), with 56.7% of events considered related to tinostamustine. Serious tinostamustine-related AEs were reported in 30.6% of pts (13 haematological events); 10 (27.8%) pts discontinued treatment due to TEAEs (platelet count decreased: 5 events in 3 pts, including 2 Grade 3 and 1 Grade 4; all other events n=1). Two pts experienced fatal TEAEs; n=1 each of intra-abdominal haemorrhage (considered related to study drug), hypoxia/dyspnoea (not study drug related). **Conclusions:** Tinostamustine demonstrated modest signals of efficacy, with 2 pts achieving a PR, and manageable tolerability in pts with advanced solid tumours for whom no other standard therapy with proven clinical benefit was available or recommended. Further studies are needed to fully explore the benefits of tinostamustine in solid tumours. Clinical trial information: NCT03345485. Research Sponsor: Mundipharma Research Limited and Purdue Pharmaceuticals LP.

Safety and efficacy of DB-1303 in patients with advanced/metastatic solid tumors: A multicenter, open-label, first-in-human, phase 1/2a study. *First Author: Kathleen N. Moore, Stephenson Cancer Center at the University of Oklahoma, Oklahoma City, OK*

Background: DB-1303 is an antibody-drug conjugate (ADC) consisting of a humanized anti-HER2 IgG1 monoclonal antibody, covalently linked to proprietary DNA topoisomerase I inhibitor (P1003) via a maleimide tetrapeptide-based cleavable linker, with a high drug-to-antibody ratio (~8). **Methods:** This is a global first-in-human, dose-escalation and -expansion study in patients (pts) with advanced/metastatic solid tumors. Pts (ECOG 0-1) with HER2 – (high or low) expressing or mutant cancers who failed previously systemic therapies were recruited and received DB-1303 intravenously Q3W as monotherapy. The objectives were safety, tolerability, maximum tolerated dose (MTD) or recommended phase 2 dose (RP2D), pharmacokinetics (PK), and preliminary antitumor activity. Here we report the results from dose-escalation. **Results:** As of Jan 13, 2023, 85 pts received DB-1303 at 6 dose levels (2.2, 4.4, 6.0, 7.0, 8.0, and 10.0 mg/kg) and received a median of 7 (range, 1-27) prior lines of therapy, including previous anti-HER2 ADC therapy in 32.9% of pts. The median duration of treatment was 63.0 (range, 21-211) days, and 68 pts (80.0%) remained on treatment. Treatment-emergent adverse events (TEAEs) and $\geq$ grade (G) 3 TEAEs occurred in 74 pts (87.1%) and 18 pts (21.2%), respectively; the most common TEAEs were nausea (51.8%, 3.5% $\geq$ G3), vomiting (43.5%, 1.2% $\geq$ G3), platelet count decreased (35.3%, 3.5% $\geq$ G3), and anemia (29.4%, 5.9% $\geq$ G3). Few pts experienced neutropenia (10 [11.8%]) and alopecia (3 [3.5%]). There was no DLT or TEAEs leading to death. Interstitial lung disease occurred in 2 pts (2.4%, G1), without any $\geq$ G2. The exposure parameters (C_{max} and AUC) of DB-1303 ADC increased with ascending doses from 2.2 to 10.0 mg/kg. The half-life of DB-1303 ADC is approximately 6-7 days for 6.0-8.0 mg/kg dose cohorts. The exposure of serum release payload was magnitudes lower than that of DB-1303 ADC, demonstrating stability of the ADC in systemic circulation. A total of 52 pts had undergone at least one post-baseline tumor scan. Twenty-three pts (44.2%, 23/52) had objective partial tumor response per RECIST 1.1: Thirteen HER2+ breast cancer (BC) (50.0%, 13/26, including 5 pts with brain metastases [55.6%, 5/9]), 5 HER2 low BC (38.5%, 5/13), 2 colorectal cancer (66.7%, 2/3), 1 endometrial carcinoma (33.3%, 1/3), 1 esophageal cancer (50.0%, 1/2), and 1 ovarian cancer (50.0%, 1/2). Among all the pts, the DCR was 88.5% (46/52); for pts with HER2+ BC and HER2-low BC, the DCRs were 96.2% (25/26) and 84.6% (11/13), respectively. **Conclusions:** DB-1303 was well tolerated with encouraging preliminary antitumor activity in heavily pretreated pts with advanced/metastatic solid tumors, especially in pts with HER2+ BC and brain metastasis as well as in HER2-low BC. Expansion is ongoing in selected tumor pts treated at the RP2D. Clinical trial information: NCT05150691. Research Sponsor: Duality Biologics.

Poster Session

Phase 1 study of indenoisoquinoline LMP744 in adults with relapsed solid tumors and lymphomas. *First Author: Brian Ko, Developmental Therapeutics Clinic, Division of Cancer Treatment and Diagnosis, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Indenoisoquinolines (IIQ) are non-camptothecin inhibitors of topoisomerase 1 (TOP1) that have improved characteristics over camptothecin TOP1 inhibitors. IIQs demonstrate better chemical stability, produce more persistent DNA breaks induced by trapping DNA-TOP1 cleavage complexes, induce DNA breaks at different sites than camptothecins, and are not substrates for cellular export proteins. We present data from a trial of LMP744 (NSC 706744), which was the most efficacious IIQ in a canine lymphoma trial, designed to establish the safety, efficacy, and maximum tolerated dose (MTD) of LMP744. **Methods:** We conducted a multicenter phase 1 trial in adult patients (pts) with dose escalations following design 3 of the Simon accelerated titration designs. LMP744 was administered intravenously daily on d1-5 in 28-day cycles (C), starting at dose level (DL) 1 (6 mg/m²/d). Responses and adverse events (AEs) were defined by RECIST 1.1 and CTCAE v4.0, respectively. Plasma concentrations were determined by LC-MS/MS with a validated assay over a range of 1-3,000 ng/mL. Paired biopsies (baseline and C1D2) were analyzed for DNA damage response markers (γ H2AX, pNBS1, and Rad51) by IFA. **Results:** A total of 36 pts were enrolled, median age was 61 years (range 35-81), median prior lines of systemic treatment was 5 (range 2-10) and 26 pts (72%) had received prior TOP1 inhibitor therapy. One pt on DL6 (190 mg/m²/d) experienced a dose-limiting toxicity (DLT) of grade 3 hypokalemia during C1, reverting the study to a 3+3 design. MTD was established at DL6. Of 24 patients evaluable for response, 1 pt with small cell lung cancer on DL6 achieved a partial response (PR), remaining on treatment for 7C. 17 pts had stable disease (including 1 pt with an unconfirmed PR), and 6 had progressive disease. Median duration of response among pts with SD was 4.5C (range 1-28). A total of 6 pts on DL6 with colorectal cancer (n=4, all had received prior irinotecan), mesothelioma (n=1), and low-grade appendiceal mucinous neoplasm (n=1) remained on study for >6 C. Treatment-related grade 3/4 AEs included leukopenia (n=9), anemia (n=4), dehydration (n=2), neutropenia (n=2) and nausea (n=2). Pharmacokinetic (PK) data for the first 17 patients suggests dose-linear PK, best fit to a 2-compartment model. Approximate half-life, clearance, central and peripheral volume values were 30 h, 90 L/h, 200 L, and 2500 L, respectively. Induction of γ H2AX and Rad51 was measured in the pt with PR. **Conclusions:** The MTD of LMP744 was established at 190 mg/m²/d on d1-5 in a 28d C. The single agent activity of LMP744 in this heavily pretreated population was limited; however, 4 colorectal cancer pts had prolonged stabilization of disease with prior progression on irinotecan. Analyses of secondary and exploratory correlatives are ongoing. Clinical trial information: NCT03030417. Research Sponsor: U.S. National Institutes of Health.

SGN-B6A, an integrin beta-6 (ITGB6)-targeted antibody-drug conjugate (ADC), in patients with advanced solid tumors: Updated results from a phase 1 study (SGNB6A-001). *First Author: Antoine Hollebecque, Institut Gustave Roussy, Villejuif, France*

Background: The receptor ITGB6 plays a role in tumor pathogenesis and invasiveness, and its overexpression is correlated with poor outcomes. Non-small cell lung cancer (NSCLC), head and neck (HNSCC), and esophageal cancer (EC) are among tumors with high ITGB6 expression (Lyon 2021). SGN-B6A is an ITGB6-directed vedotin ADC with a monomethyl auristatin E (MMAE) payload. SGN-B6A elicits antitumor activity via MMAE-mediated cytotoxicity, bystander effect, and immunogenic cell death. Here, we present updated results of an ongoing phase 1 study with a focus on NSCLC, HNSCC, and EC (Hollebecque SITC 2022). **Methods:** SGNB6A-001 (NCT04389632) is an open-label, multicenter, dose-escalation/expansion study evaluating the safety, pharmacokinetics, and antitumor activity of SGN-B6A (per RECIST v1.1) in patients (pts) with advanced solid tumors. Dose escalation (Part A) explored continuous weekly and intermittent dosing regimens. Dose was calculated using total body weight (TBW) or adjusted ideal body weight. Dose expansion (Part B) is enrolling pts with NSCLC, HNSCC, and EC. **Results:** As of 14 December 2022, 148 pts received SGN-B6A, 88 pts in Part A and 60 pts in Part B; enrollment for Part A is complete. In all cohorts (N=148), treatment-emergent adverse events (TEAEs) were observed in 88.5% of pts: 50.7% were Grade ≥ 3 (21.6% related), and 37.2% were serious (8.1% related); 6.1% of pts discontinued treatment due to TEAEs. 3 pts (2.0%) died due to TEAEs; none of the deaths were considered treatment-related. The most common TEAE was fatigue (35.1%); the most common Grade ≥ 3 TEAE was neutropenia (8.1%); the most common TEAEs leading to treatment discontinuation were peripheral sensory neuropathy and pneumonia (1.4% each). Prior lines of therapy and efficacy data for Part A (NSCLC, EC, and HNSCC) and Part B (HNSCC) subsets are summarized. **Conclusions:** SGN-B6A demonstrated a manageable safety profile, and showed encouraging preliminary antitumor activity and response durability in dose escalation in a heavily pretreated population. Part B dose expansion cohorts in NSCLC, esophageal squamous cell carcinoma (ESCC), and HNSCC are ongoing. Clinical trial information: NCT04389632. Research Sponsor: Seagen Inc.

Final analysis of multi-histology basket trial expansion of ado-trastuzumab emtansine in patients with *HER2* amplified cancers. *First Author: Dazhi Liu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Human epidermal growth factor receptor 2 (*HER2*, *ERBB2*) amplification occurs in 5% of non-breast non-gastric solid tumors. Ado-trastuzumab emtansine (T-DM1) showed preliminary efficacy in patients with *HER2* amplified lung, endometrial, salivary gland, biliary tract and ovarian cancers, but the extent of its differential effects across histologies is unknown. **Methods:** Patients with *HER2* amplified solid tumors were enrolled and received treatment 3.6mg/kg IV every 3 weeks. The primary endpoint was overall response rate (ORR) using RECIST v1.1 or PERCIST. A basket trial expansion used a Simon two stage optimal design applied to each of 5 histology cohorts with type I error rate under 2%, power of 90%, H0 10%, H1 40%, with family-wise error rate at 10%. After first stage, lung, salivary gland and endometrial cohorts were expanded to 23 patients. The null hypothesis was rejected for each cohort separately, if at least 6 responses were observed in each cohort. Secondary endpoints included duration of response (DOR), progression-free survival (PFS) and toxicity. *HER2* amplification was identified by fluorescence *in situ* hybridization (FISH), or next generation sequencing (NGS). Correlative studies were performed using tissue immunohistochemistry (IHC). Plasma cell-free DNA (cfDNA) was collected throughout study treatment. **Results:** 88 patients with 8 unique cancer types were treated across 5 cohorts of *HER2* amplified lung, salivary gland, colorectal, endometrial and other cancers. The median age was 66 (26-90). Median line of prior therapy was 2 (1-7). ORR was 33% (29/87 including 11 CRs, 95% CI 24-44%), including 47% (9/19) for lung cancers, 87% (13/15, 8 CRs) for salivary gland cancers, 22% (5/23, 3 CRs) for endometrial cancers, 12% (1/8) for biliary cancers, 14% (1/7) for ovarian cancers. Median DOR was 9.7 months (95% CI 4.8, 20.2), median PFS was 2.76 months (95% CI 2.53, 5.39). There were 8 (9%) G3 treatment related toxicities. *HER2* fold change corrected for purity and ploidy by FACETS algorithm correlated with response ($p=0.04$) and PFS ≥ 3 months ($p=0.0037$). *HER2* amplification by NGS correlated with *HER2*/CEP17 ≥ 2 by FISH (67/71 tested) and IHC3+ (54/68 tested). We observed persistent *HER2* amplification in plasma cfDNA during acquired resistance and progression on T-DM1 in patients with salivary gland cancers. **Conclusions:** Ado-trastuzumab emtansine showed promising efficacy in patients with *HER2* amplified lung and salivary gland cancers as identified by NGS, meeting the primary endpoint. However, its efficacy did not meet prespecified response rate in patients with *HER2* amplified endometrial, colorectal and other cancers. Histologic lineage differences in *HER2* amplified cancers affect response and translational research is critical for further drug development. Clinical trial information: NCT02675829. Mirzotamab clezutoclastax as monotherapy and in combination with taxane therapy in relapsed/refractory solid tumors: Dose expansion results. *First Author: Benedito A. Carneiro, Legorreta Cancer Center, Brown University, Providence, RI*

Background: Mirzotamab clezutoclastax (ABBV-155; Mirzo-C) is a first-in-class antibody-drug conjugate with three components: an anti-B7-H3 monoclonal antibody, a solubilizing linker, and a BCL-X_L inhibitor payload. By specific targeting of BCL-X_L, synergy with other anticancer agents was observed in preclinical models. When combined with a taxane, clinical antitumor activity was reported in relapsed and/or refractory (R/R) solid tumors during the dose escalation phase of an ongoing Phase 1, open-label study (NCT03595059). **Methods:** In the dose expansion phase of the Phase 1 study, patients were treated as follows: (i) R/R small cell lung cancer (SCLC) with Mirzo-C monotherapy, (ii) non-small cell lung cancer (NSCLC) with Mirzo-C + docetaxel, and (iii) hormone positive, Her2 negative, post-CDK4/6 inhibitor breast cancer (BrCa) with Mirzo-C + paclitaxel. Mirzo-C was administered at the recommended Phase 2 dose determined at dose escalation. Primary objectives were safety and overall response rate (ORR). **Results:** As of November 18, 2022, 78 patients were enrolled (NSCLC n=14; NSCLC n=36; BrCa n=28). The median (range) follow-up was 2.0 (0.6–9.1) months for the SCLC cohort, 4.9 (0.6–8.5) for NSCLC, and 10.4 (0.8–13.3) for BrCa. The median number of prior lines of systemic therapy was 2 in the SCLC cohort, 2 in NSCLC, and 6 in BrCa. Prior taxane therapy was received by 7% of patients in the SCLC cohort, 36% in NSCLC, and 64% in BrCa. The most common adverse events (AEs) in SCLC were fatigue, increased aspartate aminotransferase, diarrhea, and headache (21%, n=3 for each AE); fatigue was the most common AE in NSCLC (58%, n=21; Grade 3/4: 3%, n=1) and in BrCa (61%, n=17). Thrombocytopenia, a result of the systemic effects of BCL-X_L inhibitors, was not observed in the Mirzo-C monotherapy cohort. Neutropenia/decreased neutrophil count was not observed in the SCLC monotherapy cohort but was common with BrCa paclitaxel combo (64%, n=18; Grade 3/4: 29%, n=8) and NSCLC docetaxel combo (53%, n=19; Grade 3/4: 44%, n=16); 5 patients in the NSCLC cohort (14%) and 1 in BrCa (4%) had febrile neutropenia. Confirmed ORR was 0% in the SCLC cohort, 11% in NSCLC, and 18% in BrCa. **Conclusions:** Mirzo-C demonstrated a tolerable safety profile as monotherapy and with taxanes. No thrombocytopenia or neutropenia was observed with monotherapy. No single-agent activity of Mirzo-C was observed in SCLC. Combination treatments were active with high best overall response (BOR) and disease control rates in heavily pretreated NSCLC and BrCa patients, where Grade 3/4 neutropenia was observed. It is unknown if Mirzo-C exacerbated the neutropenia risk associated with taxanes. Clinical trial information: NCT03595059. Research Sponsor: AbbVie.

A phase 1 dose escalation/expansion study of FID-007, a novel nanoparticle paclitaxel formulation, in patients with solid tumors. *First Author: Jacob Stephen Thomas, University of Southern California, Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: FID-007 (FID) consists of paclitaxel encapsulated in a poly-ethyloxazoline (PEOX) polymer excipient designed to enhance PK, biodistribution, and tolerability. In addition to allowing the drug to remain in solution until it can enter a cancer cell, the PEOX nanoparticle preferentially delivers paclitaxel to the tumor through the leaky hyperpermeable vasculature. In xenograft studies, FID reduced or limited tumor growth in multiple tumor types including lung, gastric, breast, pancreatic, and ovarian cancer. Preclinically, FID was more effective at lower or comparable taxane doses, including nab-paclitaxel, with fewer side effects. We present the first-in-human trial of FID. **Methods:** The study is evaluating the safety, PK, and efficacy of FID in pts with advanced solid tumors. The primary objective is to determine the MTD and RP2D. Pts received FID in doses between 15mg/m² and 160mg/m² using a standard 3+3 dose escalation design. FID was given IV on Days 1, 8, and 15 of a 28-day cycle. Eligibility included ECOG 0-2, adequate organ function, and ≤ 3 prior lines of cytotoxic therapy for advanced disease. **Results:** Thirty-six patients were treated across 7 dose levels. Median age was 61 (39-65). ECOG PS was 2 in 1 patient, 1 in 69% of patients. Median number of prior therapies was 2 (1-5). Median number of cycles was 2.5 (1-30). There were 2 DLTs of grade 3 rash at 100 mg/m². Given the transient nature of the rash and response to topical therapy, DLT definition was modified to exclude grade 3 rash that lasts ≤ 7 days and 3 additional patients were treated at 100 mg/m² which was deemed tolerable. There was 1 DLT of grade 4 WBC decrease at 125 mg/m², and 1 DLT of G3 febrile neutropenia at 160 mg/m². There was no MTD. All grade treatment related adverse events (TRAEs) in $\geq 25\%$ of pts were rash (64%), alopecia (56%), leukopenia (47%), pruritus (44%), neutropenia (42%), anemia (42%), fatigue (39%), nausea (33%), anorexia (31%), dysgeusia (25%) and peripheral sensory neuropathy (25%). Grade 3/4 TRAEs occurring in > 1 pt were maculopapular rash (25%), anemia, neutropenia, and leukopenia (17% each). Of 36 evaluable patients, 7 (19%) had a partial response by RECIST 1.1 (pancreatic, biliary tract, and HNSCC) and 13 (36%) had stable disease. Three out of 4 HNSCC patients with PR had previously been treated with docetaxel. PK is linear and dose proportional. There is no paclitaxel accumulation after weekly dosing, and $t_{1/2}$ is between 18-26 hours. Based on overall tolerability and PK, the dose of 125mg/m² (dose level 6) has been chosen as RP2D. **Conclusions:** FID has a manageable safety profile and demonstrates preliminary evidence of anti-tumor activity in heavily pre-treated pts across different tumor types. No high-grade neuropathy has been noted to date. RP2D of FID is set at 125mg/m². PK is linear, dose proportional and comparable to that of nab-paclitaxel. Clinical trial information: NCT03537690. Research Sponsor: Fulgent Pharma.

A novel genetic marker of fluoropyrimidine-induced cardiovascular toxicity. *First Author: Claire Palles, Institute of Cancer and Genomic Sciences, University of Birmingham, Birmingham, United Kingdom*

Background: Fluoropyrimidine (FP) based adjuvant chemotherapy (5-Fluorouracil and Capecitabine) increases survival of patients with colorectal and breast cancers. However, 1-5 % of patients experience cardiovascular toxicity, which is not explained by variants in the gene encoding dihydropyrimidine dehydrogenase. **Methods:** We sought genetic determinants of FP-induced cardiovascular toxicity by performing a genome wide association study of NCI-CTCAE graded cardiovascular toxicity using samples from the QUASAR 2 trial (n=759 patients with colorectal cancer (CRC)). Validation studies (n= 5438 patients with CRC and 1478 patients with breast cancer) were performed in the SCOT, COIN and TACT2 trials. The most commonly reported symptoms were chest pain, angina and arrhythmias with 6 patients experiencing myocardial infarctions. **Results:** rs4904753, mapping to an intron of *D-glutamate cyclase (DGLUCY)* was genome wide significant in QUASAR 2 ($P=4.38 \times 10^{-16}$) and validated in SCOT, COIN and TACT2 ($P<0.0002$ in all studies. rs4904753 was associated with levels of expression of *DGLUCY* in multiple tissues including the atrial appendage. Under a recessive model, 45.3% (61/137) of patients with cardiac toxicity as compared to 10.2% (691/6786) of controls carried both minor alleles (meta-analysis: OR=7.72, 95% CI 5.31-11.22, $P=1.03 \times 10^{-26}$). **Conclusions:** The sensitivity, specificity, positive predictive value and negative predictive values of testing for two copies of the toxicity associated allele of rs4904753 were 48%, 90%, 8% and 99% respectively. Clinical implementation of testing for this variant has the potential to identify almost half of those at risk of FP-induced cardiovascular toxicity with high specificity, thereby enabling changes to their clinical management. Research Sponsor: Cancer Research UK; University of Birmingham, Cardiff University School of Medicine.

rs4904753 is a novel marker of cardiovascular toxicity and has been validated in multiple independent clinical trials.

A first-in-human, open label, multiple dose, dose escalation, and cohort expansion phase I study to investigate the safety, tolerability, pharmacokinetics and antitumor activity of BB-1701 in patients with locally advanced/metastatic HER2-expressing solid tumors. *First Author: Fei Ma, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China*

Background: BB-1701 is an antibody-drug conjugate consisting of a humanized IgG1κ monoclonal antibody and eribulin. When BB-1701 targets HER2-expressing cancer cells and is internalized, free eribulin is cleaved from the ADC by cathepsin b and causes cytotoxicity to cancer cells. The neighboring cells were affected with bystander effects, like cytotoxicity on tumor cells and non-cytotoxic effects on microenvironment by free eribulin. Here, we report preliminary results from this phase 1 study (NCT04257110). **Methods:** This dose escalation study followed an accelerated titration and traditional "3 + 3" design with 6 dose levels from 0.4 to 2.6 mg/kg Q3W. Patients with confirmed advanced/metastatic HER2 overexpressing solid tumors, who had progressed on, or were intolerant to prior standard therapies, aged ≥ 18 years, with ECOG PS ≤ 2, and measurable disease, were enrolled. HER2 expressions were determined by IHC or next generation sequencing. Tumor imaging was conducted every 9 weeks. The primary objective is the assessment of safety and tolerability, and the secondary objective is the assessment of PK and preliminary anti-tumor activity. **Results:** A total of 29 patients were enrolled in this study. Tumor types were breast cancer, gastric/gastroesophageal junction cancer, colorectal cancer, gallbladder cancer, ovarian cancer and urothelial cancer. The medium prior lines of systemic therapy were 3 (range 1 – 6). During this study, no DLT was observed and the MTD was not reached. The most commonly reported (≥20%) treatment-related adverse events (TRAEs) were peripheral neuropathy, aspartate aminotransferase increased, neutrophil count decreased, white blood cell count decreased, alanine aminotransferase increased, hypertriglyceridemia, anemia, platelet count decreased. The most commonly reported ≥ grade 3 TRAEs (≥10 %) was peripheral neuropathy. There were two grade 4 adverse events: neurological symptom and sepsis. There was no interstitial lung disease observed during the study. Nine patients discontinued the study treatment due to peripheral neuropathy. Thirteen patients out of 26 patients evaluable for antitumor activity achieved partial response (PR), and 11 patients had stable diseases (SD). The best overall response rate (BOR) was 50.0% (13/26) and the disease control rate (DCR) was 92.3% (24/26). For 17 breast cancer patients in the study, 12 patients achieved PR, and 5 patients had SD. The BOR was 70.5% (12/17) and the DCR was 100% (17/17). For 5 gastric cancer patients in the study, all patients had SD. The duration of treatment ranged from 2 weeks to 66 weeks. **Conclusions:** BB-1701 was generally well tolerated up to 2.6 mg/kg dose levels and has shown promising antitumor activity in patients with HER2-overexpression solid tumors. Clinical trial information: NCT04257110. Research Sponsor: Bliss Biopharmaceutical (Hangzhou) Co., Ltd.

Plasma lipidomic profiling of chemotherapy-induced peripheral neuropathy. *First Author: Nicole Yeung, Garvan Institute of Medical Research, Sydney, NSW, Australia*

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a dose-limiting side effect of cytotoxic cancer treatment. This may result in dose reduction (DR) or chemotherapy discontinuation (CD) and ultimately decrease the efficacy of therapy. There is a lack of studies examining the role of lipids in relation to CIPN, despite the association of obesity with worse CIPN, and hyperlipidaemia with diabetic neuropathy. The aim of this study is to determine if circulating lipids are associated with CIPN severity. **Methods:** Pre-chemotherapy plasma samples from 137 patients with CIPN from docetaxel or paclitaxel-based treatment underwent lipidomic analysis (788 lipids). CIPN severity was measured using the neurological grading scale Total Neuropathy Score-clinical version (TNSc score; John Hopkins University) and patient-reported outcome measure EORTC QLQ-CIPN20. The association of baseline lipid levels with severe CIPN, as defined by high TNSc and CIPN20 scores, was performed using linear modelling (LIMMA). Baseline lipids associated with shorter time to dose reduction (DR) or chemotherapy discontinuation (CD) due to CIPN was determined by Cox regression, with adjustment for body mass index (BMI), age and diabetes. Lipid profiles were identified using latent class analysis (LCA) of significant lipids from the Cox regression. **Results:** Higher TNSc or CIPN20 scores were associated with 107 and 43 lipid species respectively (LIMMA $p < 0.05$), of which only 3 species were in common. Triacylglycerols (TG) represented a significant proportion of lipids with elevated levels associated with higher TNSc (32.5%) or CIPN20 (9.1%) scores (Fisher's exact test $p < 0.001$). 70 lipid species were associated with shorter time to DR/CD (Cox regression $p < 0.05$), which included 15 TG with higher levels associated with shorter time to DR/CD. Unsupervised LCA identified a specific lipid profile associated with worse CIPN [Hazard ratio 2.61 (95% CI 1.40 – 4.84, $p = 0.002$)]. This lipid profile also had higher levels of TG (t-test $p < 0.05$). The high risk CIPN lipid profile was independently associated with shorter time to DR/CD when modelled with clinical factors (diabetes, age, BMI or prior numbness/tingling; Cox regression $p < 0.006$); however, these clinical factors were not associated with time to DR/CD in the multivariable models ($p > 0.08$). **Conclusions:** Higher levels of baseline plasma TG are associated with increased CIPN severity and shorter time to DR/CD in taxane-treated patients. These findings are consistent with other reports regarding the association of hyperlipidaemia with neuropathy. Further research is required to determine if TG-lowering medication can reduce the risk of CIPN development. Changes in ctDNA levels as an early indicator of outcomes in advanced NSCLC treated with TKI: Initial findings from a retrospective aggregate analysis of 8 clinical trials. *First Author: Hillary Stires, Friends of Cancer Research, Washington, DC*

Background: To determine whether changes in circulating tumor DNA (ctDNA) levels reflect treatment outcome, Friends of Cancer Research created the ctDNA to Monitor Treatment Response (ctMoniTR) Project with collaborators from industry, government, academia, and advocacy. A prior ctMoniTR effort analyzing 5 clinical trials (CT) showed an association between decreases in ctDNA levels and improved outcomes in patients with advanced non-small cell lung cancer (aNSCLC) treated with an anti-PD-(L)1. The current study expands that work and focuses on CT investigating tyrosine kinase inhibitors (TKI) treatment in oncogene-driven aNSCLC. **Methods:** We performed a retrospective analysis of patient-level clinical and ctDNA data across 8 CT representing 1,015 patients with aNSCLC treated with TKI (i.e., anti-EGFR, ALK, RET, or MET). Patients included in the analysis had a baseline ctDNA measurement (T0), an on treatment ctDNA measurement within 10 weeks of treatment initiation (for those with multiple ctDNA measurements within 10 weeks, we used the lowest measurement within 10 weeks) (T1), and overall survival (OS) data ($n = 749$). CT used different ctDNA collection timepoints and assays. We randomly divided the dataset into training (2/3 of the data) and validation (1/3 of the data) datasets stratified by CT cohort (i.e., arm), age, tumor stage, and prior lines of therapy, then ran initial analyses on the training dataset ($n = 501$; reported herein). ctDNA change was calculated as the percent change in maximum variant allele frequency (VAF) between T0 and T1 using tumor-derived variants provided by sponsors for each unique patient sample. CT used either ddPCR or an NGS assay. ctDNA limits of detection were assay specific and varied across CT. Multivariate analyses are ongoing and validation dataset analyses will be conducted. **Results:** At T0, 141 patients had non-detected (ND) ctDNA and 360 patients had detected (D) ctDNA. Of these, 27% ($n = 136$) had ND ctDNA at both T0 and T1 ("ND/ND"), 52% ($n = 260$) had changes from D at T0 to ND at T1 ("D/ND"), 12% ($n = 60$) had at least a 50% decrease from T0 to T1 ("decrease") and 9% ($n = 45$) had an increase or a less pronounced decrease in ctDNA. In a univariate analysis, patients with ND/ND and D/ND were associated with improved OS compared to the decrease group. In addition to other characteristics, patients with max VAF ≤ 0.5% or ND at T0 ($n = 214$, 43%) had improved OS (HR = 0.44, $P < 0.001$) compared to those with max VAF > 0.5% at T0 ($n = 287$, 57%). **Conclusions:** In a retrospective aggregate analysis of 8 CT, ND ctDNA at T1 was associated with improved OS in patients with aNSCLC treated with TKI. Changes in ctDNA levels, particularly from D to ND, may provide an early indication of treatment benefit and predict long-term outcomes in this population. Additional ctMoniTR analyses are ongoing to validate the potential use of ctDNA as an early endpoint. Research Sponsor: Friends of Cancer Research.

Poster Session

First report of ELUCIDATOR study: A prospective observational multicenter study on resistance mechanisms in patients with early disease progression during osimertinib. *First Author: Yasuyuki Mizumori, National Hospital Organization Himeji Medical Center, Himeji, Japan*

Background: Osimertinib (Osi) is the key standard therapy for patients (pts) with chemo-naïve advanced non-small cell lung cancer (NSCLC) harboring sensitizing epidermal growth factor receptor (EGFR) mutations. However, many of cases treated with Osi experience the disease progression (PD). Therefore, understanding first-line osimertinib resistance mechanisms is essential for future therapeutic strategies. Here, we addressed the underlying mechanisms of resistance to Osi using paired plasma DNA samples and particularly focused on early PD (PD within 6 months) cases. **Methods:** This trial is the multicenter prospective research, and we prospectively collected plasma DNA samples prior Osi treatment and at PD. Next-generation sequencing (NGS) implemented with the molecular barcoding method was performed to analyze gene mutations in 197 cancer-associated genes. Then using these ct-DNA, we analyzed the Osi resistance by ultra-sensitive NGS. In this interim analysis, we specially analyze the early PD (PD within 6 months) cases. **Results:** One hundred eighty-eight pts were enrolled between May 2019 and January 2021. Among these pts, 125 (66%) pts were female, 96 (51%) were EGFR exon 19 deletion mutation, and 109 (58%) were never smoker. Seventy-eight pts experienced PD and 36 pts experienced early PD at interim analysis. Baseline shedders, patients with plasma positivity for EGFR-activating mutation were more frequently observed in early PD pts than non-PD (86.1% vs 63.4%, $p = 0.009$). Early PD patients had significantly more co-occurring gene mutations along with EGFR mutations than non-early PD patients (2.89 ± 1.49 vs 1.97 ± 1.37 , $p = 0.002$). Most notably, 3 among 36 early PD pts and 8 among 78 PD pts had significant reduction of plasma EGFR mutant allele frequency at PD than that at baseline. Among those, 1 had germline BRCA1 mutation and 1 had BRINP3 mutation in 3 early PD pts, and 1 had germline BRCA2 mutation, and 1 had germline TP53 mutation in 5 PD pts excluding early PD pts. Co-occurring TP53 mutations were not relevant to early PD in this study cohort. **Conclusions:** Germline mutations in BRCA1/2, TP53 and BRINP3 may confer early and unprecedented resistance to Osi monotherapy. Plasma-based serial comprehensive gene profiling may help predict and identify patients unlikely to benefit from Osi treatment, though further study is warranted. Diagnostic value of hPG₈₀, as a new multi-cancer blood biomarker, in 16 different cancers: Results of the ONCOPRO prospective study. *First Author: Benoit You, Medical Oncology Department, Institut de Cancérologie des Hospices Civils de Lyon, CITOHL, Université Lyon 1, Lyon, France*

Background: hPG₈₀ (also called circulating progastrin) has been described as a promising multi-cancer blood biomarker. Indeed, hPG₈₀ is released from cancer cells to blood at the early steps of tumorigenesis due to WNT pathway activation (You et al *eBioMedicine* 2020). ONCOPRO study was designed to prospectively assess the hPG₈₀ diagnostic & clinical utility in patients with 16 types of cancers. **Methods:** ONCOPRO study (NCT03787056) was a large prospective case-control study led in Lyon University Hospital (France), designed to assess the diagnostic, and monitoring value of hPG₈₀ blood titers in 420 patients with 16 newly diagnosed cancers. hPG₈₀ was measured using kit DxPG80.Lab (Biodena care) at diagnosis, and then at each cycle/visit until recurrence for the curative cohorts, or for 3 treatment lines for the non-curative cohorts. The diagnostic value of hPG₈₀ (primary endpoint) was assessed by comparing the hPG₈₀ baseline titers measured in cancer patients to those of 330 healthy volunteers recruited in parallel (age & sex ratios matched with the cancer group), with a sample size calculated for precision of ± 0.23 for ROC AUC. **Results:** Out of 499 cancer patients enrolled between December 2018 and June 2022, 419 were assessable in 16 cancer cohorts (NSCLC & SCLC: n=70; Breast: n=50; Renal: n=50; Prostate: n=50; Liver: n=50; Head&Neck: n=49; Hepatocellular carcinoma (HCC): n=50; Colorectal: n=10; Thyroid: n=10; Pancreas: n=14; Ovarian: n=10; Glioblastoma: n=10; Endometrial: n=10; Bladder: n=10; Superficial oesophago-gastric: n=10; Lymphoma: n=10; Gastric: n=10). The median age of cancer patients was 66 [IQR: 58-73], with 60% men. hPG₈₀ concentration was significantly higher in cancer patients than in healthy subjects (median, 3.8 vs 2.0 pM, $P < 0.001$). It was not impacted by renal/liver, or CRP level, but slightly linked to age. hPG₈₀ titer was found stable on a 24h-hour period. The global diagnostic accuracy in cancer patients / control was ROC AUC, 0.63 [0.59-0.67] in the whole population. The highest diagnostic accuracy was seen in patients with lung cancer (AUC, 0.75 [0.68-0.82]; Sensitivity (Se)/Specificity (Sp) 0.49/0.90 for hPG₈₀ > 7.73 pM) and HCC (AUC, 0.75, 95% CI 0.66-0.83; Se/Sp 0.48/0.90 for hPG₈₀ > 7.73 pM). **Conclusions:** This large prospective study confirms that cancer patients have significantly higher blood concentration of hPG₈₀ than healthy subjects. The data about the different cohorts will guide the future development of hPG₈₀. Strong diagnostic accuracy was seen for lung cancers and HCC, with specificity > 90%. The screening programs of these cancers could be enriched by this simple blood hPG₈₀ ELISA assay, for complementing imaging limited specificity. Clinical trial information: NCT03787056. Early detection of lung cancer using small RNAs. *First Author: Amita Sharma, Massachusetts General Hospital, Boston, MA*

Background: Low-dose computed tomography (LDCT) screening can significantly reduce lung cancer mortality. However, annual screening is limited by low adherence in the USA and still not broadly implemented in Europe. As a result, <10% of lung cancers are detected through existing programs. Thus, there is great need for additional diagnostic modalities, such as a blood test that could be deployed in the primary care setting. **Methods:** We prospectively recruited 1,189 patients meeting the 2013 USPSTF screening criteria for lung cancer and collected stabilized whole blood. Ultra-deep small RNA sequencing was performed with a method to remove highly abundant erythroid RNAs, opening bandwidth for the detection of less abundant species originating from plasma or the immune cellular compartment. We utilized 100 random data splits to train and evaluate logistic regression classifiers using small RNA expression, discovered an 18-small RNA feature consensus signature (miLung), and validated this in an independent cohort (246 patients). Blood cell sorting and tumor tissue sequencing were performed to deconvolve small RNAs into their source of origin. **Results:** We generated diagnostic models and report a median ROC AUC of 0.86 (95% CI 0.84-0.86) in the discovery cohort, and generalized performance of 0.84 in the validation cohort. Diagnostic performance increased stage-dependently from 0.73 (95% CI 0.71-0.76) for Stage I to 0.90 (95% CI 0.89-0.90) for Stage IV. We identified a tumor-shed, plasma-bound ribosomal RNA fragment of the L1 stalk as a dominant predictor of lung cancer. The fragment is decreased following surgery with curative intent. In additional experiments, dried blood spot collection and sequencing revealed that small RNA analysis could potentially be conducted via home-sampling. **Conclusions:** These data suggest the potential of a small RNA-based blood test as a viable alternative to LDCT screening for early detection of smoking-associated lung cancer. Clinical trial information: NCT03452514. Research Sponsor: Hummingbird Diagnostics GmbH.

First report of tumor-informed circulating tumor DNA in fibrolamellar carcinoma in adolescents and young adults: 51 patients. *First Author: Elise McKenna, Columbia University, New York, NY*

Background: Fibrolamellar Carcinoma (FLC) is an extremely rare form of primary liver cancer (50-200 cases/year), unrelated to hepatocellular carcinoma. The only established standard of care is surgery. However, recurrence is at least 80%, even with R0 surgery, suggesting that FLC is best thought of as a systemic disease instead of a surgical disease. Systemic therapies in retrospective studies of more than 25 show immunotherapy and chemotherapy combinations have promise. Circulating “tumor-informed” tumor DNA (ctDNA) is a tool for tracking microscopic systemic disease, serving as a marker of systemic involvement, has shown success in management of other cancers. FLC has never been studied using this technology. Our retrospective study of 51 patients over a 2.5-year period is the first attempt to understand if ctDNA can be helpful in the management of FLC. **Methods:** All patients consented to blood draws on a 1-3 monthly basis, according to the company (Signatera) protocol. All patients had regular imaging reviewed by the FibroFighters Foundation National Tumor Board. Complete response (CR), Partial response (PR) (> 30% decrease), Progressive Disease (PD) (> 20% increase), and Stable Disease (SD) (neither PD/PR/CR) were recorded according RECIST 1.1. The imaging closest in time to the blood draw was used for correlation purposes. “Negative” is defined as a value = 0.00. “Positive” is defined as a value > 0.00. **Results:** Fifty-one FLC patients (26M, 25F, median age 23, range 10-56), 92% stage (III/IV), consented to ctDNA “blood biopsies,” (n=226 samples, mean 4.4/patient, range 1-11). Negative values correlated with no evidence of disease (NED) on imaging 78% of the time, positive values with disease 94% [PPV/NPV/sens/spec of 0.78/0.94/0.93/0.81]. NPV and sens increased to almost 100% with a ctDNA threshold of > 1.0 at the expense of a lower PPV and spec. However, consecutive negative ctDNA values correlated with radiologic NED 86% [PPV/NPV/sens/spec = 0.86/0.84/0.77/0.91] without a single PD in this cohort (n=64). A “downward trend or slope” on consecutive values predicted Objective Response (CR+PR) and Disease Control (CR+PR+SD) at 68% and 96% [PPV/NPV/sens/spec of 0.68/0.49/0.36/0.78 and 0.96/0.26/0.36/0.94, respectively], while an “upward trend” performed less well to predict relapse [PPV/NPV/sens/spec = 0.54/0.98/0.94/0.81]. **Conclusions:** In this first exploration of 51 young FLC patients, and 226 tissue-informed cell free ctDNA data points, “Positive” and “Negative” values overall performed well for predicting RECIST 1.1 “disease” or “NED” respectively, especially for consecutive values of zero, where no progressions were observed in 64 distinct FLC scenarios. A downward trend or “slope” performed better than an upward trend to predict objective response (PR+CR) versus relapse (PD). Research Sponsor: FibroFighters Foundation.

Longitudinal mutational analysis of TP53 in plasma circulating tumor DNA (ctDNA) in patients (pts) with solid tumors in a phase I study of BI 907828, an MDM2–p53 antagonist. *First Author: Alexander Peltzer, Boehringer Ingelheim Pharma GmbH & Co. KG, Department of Translational Medicine & Clinical Pharmacology, Biberach an der Riss, Germany*

Background: Inactivation of p53 can occur due to TP53 mutations or downregulation of wild-type p53 by its primary negative regulator, MDM2. Targeting the MDM2–p53 interaction may therefore restore p53 function. BI 907828, a highly potent MDM2–p53 antagonist, is being evaluated in a phase Ia/b study in pts with advanced solid tumors (NCT03449381). During dose escalation (phase Ia), BI 907828 demonstrated a manageable safety profile and early signs of efficacy. Here we present data from a longitudinal mutational analysis of TP53 using ctDNA. The objective of the analysis was to identify if mutations in TP53 can be associated with possible acquired resistance to BI 907828. **Methods:** Collection of blood samples for ctDNA analyses was optional and sampled longitudinally from pts at baseline and every cycle until end of treatment (EoT). ctDNA was purified from plasma and analyzed using tumor-specific next generation sequencing (NGS; custom-made 8-gene panel using KAPA HyperCap technology, including TP53) to identify tumor-derived somatic mutations that may be relevant to understanding resistance mechanisms to BI 907828. The limit of detection was determined to be 0.5% mutant allele frequency; common polymorphisms were filtered out. **Results:** Plasma samples for ctDNA analysis were available from 44/54 (81%) pts enrolled to phase Ia. Baseline plasma samples from 26/54 (48%) pts and EoT samples from 41/54 (76%) pts were analyzed. Mutations were found in 6/26 (23%) samples at baseline. In 2 pt samples, mutations were found in both tumor and ctDNA, but concordant results were limited to 1 pt. At EoT, no (0) mutations were found in 16/41 (39%) samples, 1 mutation in 11/41 (27%), 2 mutations in 6/41 (15%), 3 mutations in 2/41 (5%) and 4 mutations in 6/41 (15%). No sample had more than 4 mutations. The most frequent mutation at EoT (in 9/41 [22%] samples) was R175H, a known p53 loss of function (LOF) mutation, followed by R248Q/W LOF (in 6/41 [15%] samples). Mutations in non-TP53 genes were detectable independent of TP53 mutation status, suggesting ctDNA was present in all samples. No clear association of induction of mutations could be identified for any BI 907828 dose or dosing schedule, treatment duration, or tumor type. 9/20 (45%) pts with no detectable mutations at baseline maintained wild-type TP53 status at EoT. Signs of efficacy were observed in pts with acquired TP53 LOF mutations, suggesting that these mutations have no effect on efficacy. Analysis of TP53 mutational status at EoT in conjunction with correlative clinical efficacy will be presented. **Conclusions:** This mutation analysis represents one of the most comprehensive assessments of longitudinal ctDNA by NGS for TP53 from a clinical trial of an MDM2–p53 antagonist. Preliminary data suggest that BI 907828 does not systematically lead to broad acquisition of resistance by inducing alterations in TP53. Clinical trial information: NCT03449381. Research Sponsor: Boehringer Ingelheim.

Long-term clinical outcomes of cancers diagnosed following detection by a blood-based multi-cancer early detection (MCED) test. *First Author: Adam H Buchanan, Geisinger, Danville, PA*

Background: Less than 20% of cancers are diagnosed as a result of standard-of-care (SOC) screening in the US. MCED tests may expand screening to more cancers, but the long-term outcomes of MCED test-detected cancers are unknown. DETECT-A was the first large prospective interventional clinical trial to evaluate an MCED blood test. The test used was an early version of CancerSEEK and was evaluated in 9,911 women without history of cancer (*Science* 369:6499, 2020). CancerSEEK, coupled with diagnostic PET-CT, safely identified cancers including those not detected by SOC screening, the majority of which were localized or regional. This follow-up observational study evaluated longitudinal clinical outcomes of cancers diagnosed as a result of an abnormal CancerSEEK test with a median follow up of 4.4 (IQR:4.1-4.6) years from initial CancerSEEK testing. **Methods:** Nine cancer types were diagnosed in 26 participants whose cancers were first detected by CancerSEEK. Information on cancer diagnosis, treatment, treatment response, remission status, recurrence, secondary cancer diagnoses, and mortality (cancer-related and all-cause) was extracted from electronic medical records through November 2022. Data collection for living participants took place a median of 3.7 years following cancer diagnosis (IQR: 3.3-3.9) and a median of 4.3 years (IQR: 4.1-4.7) following initial CancerSEEK screen. **Results:** Fourteen (53.8%) participants underwent surgery; 5 had surgery alone, 9 had surgery with adjuvant and/or neoadjuvant chemotherapy, radiation, or hormone therapy. Twelve of 14 (85.7%) surgically treated participants were in remission as of November 2022, including 10 with localized or regional disease at diagnosis. Among patients whose treatment was non-surgical (11) or unknown (1), 1 (8.3%) was in remission (stage I at diagnosis), 9 (75.0%) were deceased (all stage III or IV at diagnosis), and 2 (16.7%) were in surveillance or ongoing treatment (stage II and stage III at diagnosis). Overall, 13 of 26 (50%) participants were in remission [ovarian (4), thyroid (1), uterus (2), breast (1), colorectal (2), and lung (3)]; 7 of these 13 (54%) had cancers without recommended SOC screening modalities. Eleven of 17 (64.7%) participants with localized or regional disease (stage I, II, or III) were in remission, whereas 2 of 9 (22.2%) with stage IV disease at diagnosis were in remission. **Conclusions:** CancerSEEK detected cancers earlier in patients who, when treated subsequently with conventional methods, achieved long-term survival. Half of all patients with a CancerSEEK-detected cancer remain cancer-free after treatment >4 years (median) after their initial CancerSEEK test. This includes 7 patients with cancer types for which no SOC screening option exists. Additional biomarkers, new analytic methods and algorithms are being incorporated in the development of the next generation of the MCED test. Research Sponsor: Exact Sciences Corporation.

Outcomes in participants with a false positive multi-cancer early detection (MCED) test: Results from >4 years follow-up from DETECT-A, the first large, prospective, interventional MCED study. *First Author: Anne Marie Lennon, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Recommended standard of care (SOC) early detection tests are solely available for four cancer types and fewer than 20% of incident cancers in the US are being diagnosed as a result of screening. Advances in detection of tumor-derived analytes in the blood are enabling the development of MCED tests that may expand early cancer detection. While MCED tests are being designed with high specificity, false positive (FP) results remain a concern for clinicians and patients alike, as no long-term outcomes of individuals with a FP MCED test have been reported. DETECT-A was the first prospective interventional clinical trial to evaluate an MCED blood test. The test used was an early version of CancerSEEK, evaluated in 9,911 women without history of cancer (*Science*, 369:6499, 2020). This prospectively planned analysis evaluates cancer incidence among DETECT-A participants with FP results, with the intention of providing key long-term data on test effectiveness. **Methods:** This analysis included 98 DETECT-A participants with FP results, where a FP was defined as a positive CancerSEEK result with subsequent PET-CT and clinical evaluation with no evidence of cancer within 1 year of the initial CancerSEEK test. Sixty-three of 98 participants had no follow-up procedure performed after imaging, and 35 subjects had noninvasive/minimally invasive follow-up procedures performed. Electronic medical records were analyzed from January 2020 through November 2022 for cancer diagnosis, treatment, remission, recurrence, and mortality. **Results:** Ninety-six of 98 participants with a FP result remained free of cancer with a median follow-up of 4.3 years (IQR: 3.9-4.9) from the initial CancerSEEK test. One stage I breast cancer and one stage III ovarian cancer were diagnosed 2.7 and 2.9 years respectively from the initial CancerSEEK test. **Conclusions:** Patients with a negative PET-CT and initial clinical evaluation after a positive CancerSEEK test had low (<1% per year) risk for cancer in the ensuing four years after the initial CancerSEEK test. If confirmed, this result should prove reassuring to clinicians and to patients who have no evidence of cancer on comprehensive imaging following a positive MCED test. Further, these results provide preliminary support for the recommendation that patients who participate in MCED testing and receive a FP result can safely return to routine care after comprehensive anatomic and functional imaging and clinical evaluation reveal no suspicion of cancer. A novel three-biomarker signature (CA-62, CEA, CYFRA 21-1) and early-stage NSC lung cancer detection. *First Author: Janneta Tcherkassova, UCM Technologies Inc., Toronto, ON, Canada*

Background: A double-blind clinical study was conducted on 304 clinically verified blood serum samples, including 141 non-small cell lung cancer (NSCLC), 133 healthy volunteers and 30 patients with chronic obstructive pulmonary disease (COPD). The objectives of the study were: The assessment of various cancer markers and their possible combinations for detection of early (I-II) stages of non-small cell lung cancer (NSCLC) and evaluation of the best cancer markers panel as a pre-screening tool for NSCLC before Low-Dose CT scan. **Methods:** Quantitative measurement of various tumor markers for serum samples was carried out using electrochemiluminescent immunoassays Elecsys CA-125, ELECSYS CA 19-9, ELECSYS CYFRA 21-1 and ELECSYS SCC (COBAS, Roche Diagnostics GmbH, Germany, EU), enzyme immunoassay CA15-3-ELISA-BEST, CEA-ELISA-BEST, NSE-ELISA-BEST (JSC "VECTOR-BEST", RF) and immunochemiluminescent analysis CLIA-CA-62 (LLC "JVS Diagnostics", RF). The results were compared to the literature data for other biomarkers and their panels. **Results:** Unlike other tumor markers, which are expressed proportionally to tumor size, the marker for epithelial carcinomas CA-62 is expressed from Stage I and demonstrated the highest diagnostic results in detecting early stages (I-II) of NSCLC. The biomarkers CYFRA 21-1 and SCC do not have sufficient sensitivity and specificity to diagnose asymptomatic lung cancer. However, the addition of cytokeratin 19 CYFRA 21-1 to glycoproteins CA-62 and CEA increases the specificity by eliminating false positive results, which significantly improves the diagnostic value of the cancer marker signature (CA-62, CEA and CYFRA 21-1): 100% Specificity, 93% Sensitivity, 100% PPV, 94% NPV and 94% test accuracy. **Conclusions:** The results of the study demonstrated that using the biomarkers signature (CA-62, CEA and CYFRA 21-1) allows increasing the specificity of CT scan for patients with suspicious abnormalities on the tomogram, improving the interpretation of visualized localized lesion, and improving the accuracy of differential diagnosis at detecting early stages of LC up to 94%. In the prospective, adding cancer markers panel signature (CA-62, CEA and CYFRA 21-1) to the current lung cancer risk assessment system as a pre-screening tool for LDCT may improve the quality of early-stage Lung cancer detection by significant increasing the sensitivity and by reducing the proportion of false positive results. Research Sponsor: UCM Technologies Inc.

Diagnostic characteristics obtained for different cancer markers and their panels.

The detection of multiple cancer types with an extended set of methylation and protein markers. *First Author: Slava E. Katerov, Exact Sciences Corporation, Madison, WI*

Background: Cancer is the 2nd leading cause of mortality in the US, with an estimated 1.96M new cases expected in 2023. With guideline recommended screening unavailable for most cancers, multicancer early detection (MCED) tests in development may extend the reach of cancer screening. As part of an ongoing program examining multiple biomarker classes in cancer early detection, we examined the feasibility of combining blood DNA methylation and cancer protein markers for the detection of multiple cancer types. **Methods:** 236 samples from subjects with cancer (13 tumor organ types) were retrospectively collected and gender/age matched with 146 unscreened non-cancer control samples. Plasma and serum were used for cfDNA methylation analysis of 36 differentially methylated regions and 8 cancer-associated protein markers in a randomized, blinded fashion. Methylated DNA markers (MDMs) were assayed using target enrichment long-probe quantitative-amplified signal assays. Protein markers were assayed with commercial kits. Normalized methylation values/protein concentrations were used to develop a logistic regression model for cancer detection. The model was built with 5 random 0.7/0.3 training/validation splits, keeping case/control, cancer types, gender, and age distributions similar to the original data set. Models for MDMs and protein markers were created, and a combined model including both MDMs and protein markers was also evaluated for performance improvement. **Results:** A reduced subset of MDM and protein markers was identified to have robust detection of several cancer types. At 99% specificity, overall sensitivity for cancer detection was 68% (95% CI: 62%-74%) for MDMs, 43% (37%-50%) for proteins, and 75% (69%-80%) for MDMs and proteins combined. **Conclusions:** Building on promising results with mutation and protein biomarker analysis (*Science* 369:6499, 2020) this pilot study demonstrates the potential of combining DNA methylation and protein biomarkers and contributes to a larger scale effort to develop a multi-biomarker class MCED test (Ann Oncol 2022 Vol. 33:S575). Research Sponsor: Exact Sciences Corporation.

Longitudinal circulating tumor DNA monitoring in patients with esophageal squamous cell carcinoma. *First Author: Shogo Takei, Department of gastroenterology and gastrointestinal oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: The clinical utility of longitudinal monitoring with circulating tumor DNA (ctDNA) as a prognostic and a predictive biomarker was recently reported in patients with resectable colorectal cancer (Kotani D, et al. Nature Medicine 2023). Here we report a prospective, observational study of longitudinal ctDNA monitoring in patients with esophageal squamous cell carcinoma (ESCC) receiving neo-adjuvant chemotherapy (NAC) followed by surgery. **Methods:** Patients with ESCC planned for NAC followed by curative surgery, were prospectively enrolled in this study. As per the protocol, plasma samples were collected at 7 timepoints: pre-NAC, post-NAC, and 4, 12, 24, 36, and 48-weeks after surgery. CT scans were conducted every 3 months. Longitudinal ctDNA testing was performed using a personalized, tumor-informed ctDNA assay (Signatera, bespoke mPCR, NGS assay). In this initial report, ctDNA results at 3 time points (pre-NAC, post-NAC, and 4 weeks post-surgery) were analyzed and their association with clinical outcomes and tumor regression grade (TRG) scores were assessed. **Results:** So far, a total of 83 blood samples from 28 patients with ESCC were collected serially at pre-NAC (N=28), post-NAC (N=27), and post-surgical (N=28) time points. Pre-NAC ctDNA was detectable in 96.4% patients (27/28), and detection rates decreased at the post-NAC (37%; 10/27) and post-surgical (11%; 3/28) timepoints. ctDNA-positivity post-NAC and post-surgery was associated with a significantly shorter recurrence free survival (RFS) with HR of 7.0 (95% CI: 1.4-35.0; $p=0.02$) and HR of 14 (95% CI 3.0-62; $p<0.001$), respectively. Notably, patients who achieved ctDNA clearance with NAC had favorable RFS as compared to the patients who did not (HR=0.15, 95% CI: 0.03 – 0.75; $p=0.02$). Post-NAC ctDNA was also associated with tumor regression grade (TRG) score. None of the patients with TRG3 score (N=3) were ctDNA positive, whereas 7.7% (1/13) patients in the TRG2 category and 81.8% (9/11) in the TRG1 category were ctDNA-positive. **Conclusions:** Our study demonstrates a strong correlation between ctDNA status and clinical outcomes in ESCC patients. Assessment of ctDNA may be useful monitoring in patients with ESCC post NAC/surgery and may be used in the future to direct post-surgical management in this patient population. Distinguishing between cancer-related mutations and clonal hematopoiesis using cell-free RNA (cfRNA) expression levels in a machine learning model. *First Author: Maher Albitar, Genomic Testing Cooperative, Irvine, CA*

Background: Liquid biopsy is currently considered an important part of the clinical practice of oncology. However, proper interpretation of somatic mutations detected in liquid biopsy remains a challenge. Distinguishing cancer-related mutations from mutations resulting from clonal hematopoiesis of indeterminate potential (CHIP) can be difficult and a source of misinterpretation of liquid biopsy findings. We explored using cell-free RNA (cfRNA) profiling as a means for distinguishing between mutations detected as CHIP vs mutations detected as cancer. **Methods:** cfDNA and cfRNA from 102 patients with confirmed solid tumors, 93 patients with hematologic neoplasms and 40 patients with CHIP abnormalities were sequenced using a panel of 1501 gene for RNA and 284 genes for DNA. The solid tumors included lung, breast, ovarian, and colorectal. The hematologic neoplasms included lymphoid and myeloid neoplasms. Using a machine learning algorithm, we first selected the relative genes that distinguish between two classes using K-fold cross-validation ($K=12$). The selected genes were used to predict one class from the other using naïve Bayesian classifier, but we applied geometric mean naïve Bayesian (GMNB) to compensate for the expected underflow. **Results:** Using machine learning with cfRNA, we were able to distinguish between cases with confirmed cancer-related mutations and CHIP mutations with area under the curve (AUC) of 0.808 (95% CI: 0.720-0.895). Precision, recall and f1-score were 0.86, 0.422 and 0.566 for CHIP and 0.359, 0.825 and 0.500 for solid tumor, respectively. The machine learning required 70 genes for this classification. Leave-one-out (LOO) validation showed AUC of 0.766 (95% CI: 0.671-0.859). Distinguishing between hematologic neoplasms and CHIP was achievable using the expression of 30 genes. The AUC for this model was 0.787 (95% CI: 0.696-0.879). Precision, recall and f1-score were 0.906, 0.516, and 0.658 for CHIP and 0.438, 0.875, and 0.583 for hematologic neoplasms, respectively. Validation using LOO showed AUC of 0.736 (95% CI : 0.638-0.835). The top 10 genes that their expression was critical for distinguishing between CHIP and solid tumors were EIF4E, HNF1A, HOOK3, HIPK2, IL1RAP, BRAF, DNAJB1, GADD45B, H2AX, and HDAC6. The top 10 genes for distinguishing hematologic cancers from CHIP were PBX1, CAMTA1, PFDN5, PCBP1, SDC4, PRKACA, NT5C2, NBR1, RPS21, and AHCYL1. **Conclusions:** Analyzing cfRNA expression levels when used with machine learning may add another level of confidence to the ability of interpreting mutations detected in liquid biopsy testing, especially when these mutations are at low levels. This is particularly important in liquid biopsy testing for minimal residual disease (MRD) when a tissue baseline sample is not tested (tumor-agnostic). A 5-hydroxymethylcytosine-based noninvasive model for ultrasensitive early detection of colorectal advanced adenoma and adenocarcinoma: The METHOD-2 study. *First Author: Jianmin Xu, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Detection of colorectal tumors at a time when there are more treatment options is associated with better outcomes. This prospective case-control study (NCT03676075) assessed the performance of 5-hydroxymethylcytosine (5hmC) biomarkers in circulating cell-free DNA (cfDNA) to detect advanced colorectal adenomas (ADA) or adenocarcinomas (CRC). **Methods:** This multi-center study enrolled 2,576 participants, including patients with newly diagnosed CRC ($n=1,074$), ADA ($n=356$), other solid tumors ($n=80$), and healthy individuals (HEA) ($n=1,066$), followed by genome-wide 5hmC profiling using the 5hmC-Seal, a highly sensitive chemical labeling approach. A weighted diagnostic model for CRC (stage I-III) and ADA was developed using the elastic net regularization in a training set of age-, sex-, region-matched samples and validated in independent samples. **Results:** Distribution of 5hmC in cfDNA reflected gene regulatory relevance and tissue of origin. In an independent validation set of 482 samples, a 96-gene model trained in stage I-III CRC, ADA, and HEA achieved an AUC (area under the curve) of 92.6% (95% CI [confidence interval], 90.7-94.5%) for distinguishing CRC from HEA, regardless of primary location or mutation. This model also showed high capacity for distinguishing ADA from HEA with an AUC of 87.9% as well as cancer-type specificity. Model performance was further confirmed in samples from multiple centers. Functionally, differential 5hmC features associated with CRC and ADA demonstrated relevance to CRC biology, including pathways such as calcium and MAPK signaling. **Conclusions:** Genome-wide mapping of 5hmC in cfDNA shows promise as a highly sensitive and specific approach to be integrated in a screening program for improving early detection of CRC and high-risk ADA. Clinical trial information: NCT03676075. Research Sponsor: the National Natural Science Foundation of China (82072653, 81602035); Clinical Research Plan of SHDC (SHDC2020CR5006);.

FS-1502 in HER2-positive advanced breast cancer: Results from an open-label, phase 1 study. *First Author: Qiao Li, Department of Medical Oncology, Cancer Hospital Chinese Academy of Medical Sciences, Beijing, Chaoyang District, China*

Background: FS-1502 is an anti-HER2 antibody-drug conjugate that was well tolerated and showed good antitumor activity in patients (pts) with advanced HER2-expressing solid tumors in the dose-escalation stage of the current Phase 1 study. The results were presented at SABCS 2022. The recommend Phase 2 dose (RP2D) was 2.3 mg/kg IV once every 3 weeks. Here, we report the efficacy and safety of HER2-positive breast cancer (BC) pts treated with FS-1502 at the RP2D. **Methods:** This open-label Phase 1 trial was conducted at 9 hospitals in China. Heavily pretreated HER2-positive (IHC 3+ or 2+/FISH+) BC pts who had failed prior anti-HER2 therapy were recruited in the dose-expansion stage. All HER2-positive BC pts treated at the RP2D were pooled for analysis. Efficacy endpoints included objective response rate (ORR) and disease control rate (DCR) per RECIST v1.1. Safety endpoints included treatment-emergent adverse events (TEAEs) and the laboratory data. **Results:** As of cutoff date, December 24, 2022, the median study follow-up duration was 5.2 months. A total of 70 female HER2-positive BC pts, with a median age of 51.8 (range: 31-76) years, were enrolled and received at least one dose of FS-1502. The median prior therapy line was 3 (range: 1-16), and 91.4% (64/70) of pts had previously received at least 2 therapy lines. The most common metastasis organs were lung 55.7% (39/70), lymph node 54.3% (38/70) and bone 50% (35/70). 81.4% (57/70) of pts had at least 3 metastatic lesions. All pts had previously received anti-HER2 therapy, among which trastuzumab ± pertuzumab ($n=67$, 96%) and pyrotinib ($n=52$, 74%) were the most common. Among 68 efficacy-evaluable pts, the best ORR of 52.9% (36/68) (95% CI, 40.45-65.17) was achieved with 2 complete responses and 34 partial responses. DCR was 88.2% (60/68), median progression-free survival was 15.5 months (95% CI, 4.57-), and median duration of response was 12.9 months (95% CI, 5.72-). FS-1502 was well tolerated. No related interstitial lung disease occurred in any grade. Eye toxicity was mostly Grade 1 or 2 of dry eye and keratitis. Grade ≥ 3 study-related TEAEs were reported in 27 (38.6%) pts, in which the most common events (≥ 5%) were hypokalemia (18.6%), platelet count decreased (7.1%), and neutrophil count decreased (5.7%). One (1.4%) patient experienced adverse events leading to drug discontinuation (hemoptysis). Adverse events leading to death were reported in 2 (2.9%) pts (bacterial pneumonia and hemoptysis, respectively). Bacterial pneumonia was not related to FS-1502, while hemoptysis was possibly related to the drug. **Conclusions:** FS-1502 demonstrated very promising antitumor activity and was well tolerated in heavily pretreated HER2-positive BC, with mild eye toxicity and no related interstitial lung disease reported. A Phase 3 clinical trial is under planning to further confirm efficacy and safety of FS-1502 in pts with advanced HER2-positive BC. Clinical trial information: NCT03944499. RAS testing of circulating cell-free DNA (cfDNA) from tissue RAS/BRAF wild-type metastatic colorectal carcinoma (mCRC) patients: Preliminary data from the Liquid Biopsy Monoclonal Antibodies in mCRC (LIBImAb) study. *First Author: Anna Maria Rachiglio, Cell Biology and Biotherapy Unit, Istituto Nazionale Tumori-IRCCS Fondazione G. Pascale, Naples, NA, Italy*

Background: In mCRC patients RAS/BRAF testing is usually performed on tissue biopsy in order to select patients for treatment with anti-EGFR monoclonal antibodies. Several studies described discordant RAS status between tissue and cfDNA testing from the same patients. In addition, up to 30% of patients with secondary resistance to anti-EGFR therapies become RAS mutant at progression. The LIBImAb study is a phase III, randomized, open-label, comparative, multi-centre trial to assess the superiority in terms of efficacy of bevacizumab versus cetuximab in combination with FOLFIRI chemotherapy in patients with mCRC, RAS/BRAF wild-type on tumor tissue and RAS mutant (RAS^{mut}) at liquid biopsy. This study is supported by the Italian Drug Agency (AIFA). We report preliminary data of liquid biopsy testing. **Methods:** Plasma samples from enrolled patients are analyzed for variants in exons 2, 3 and 4 of KRAS and NRAS genes and for codon 600 BRAF mutations using the fully automated Idylla system (Biocartis). Patients RAS^{mut} on liquid biopsy at baseline are randomized to receive FOLFIRI plus Cetuximab or FOLFIRI plus Bevacizumab. Patients RAS wild-type on cfDNA at baseline, are treated with FOLFIRI plus Cetuximab up to 8 cycles and, if not progressed, they are retested for RAS mutations on cfDNA. RAS^{mut} patients at re-screening are randomized to continue Cetuximab or to switch to Bevacizumab. **Results:** Plasma samples from 169 tissue RAS/BRAF wild-type mCRC patients at baseline and 75 patients at 8 cycles of treatment have been tested as of January 31, 2023. Analysis of baseline plasma samples detected 16 RAS mutations in 16/169 patients (9.5%). In particular, 12 KRAS variants (7.1%, 8 in exon 2 and 4 in exon 3) and 4 NRAS variants (2.3%, all in exon 2) were found. The Idylla test also detected 3 BRAF^{V600} mutations (1.8%) in 3 additional patients. The overall concordance between tissue and cfDNA testing for RAS/BRAF variants was 88.8%. RAS mutations were also detected in 6/75 (8%) plasma samples obtained at 8 cycles of FOLFIRI/cetuximab treatment. The cfDNA test revealed the presence of 5 KRAS (6.7%, 3 in exon 2 and 1 in exon 3) and 1 NRAS mutation (1.3%, exon 2). A BRAF^{V600} variant was detected in 1 additional patient (1.3%). The rate of RAS/BRAF mutant cases at 8 cycles of treatment was 9.3%. **Conclusions:** These preliminary data suggest that liquid biopsy might better recapitulate the heterogeneity of mCRC and might be useful in clinical practice to complement tissue testing. The clinical relevance of RAS variants detected in cfDNA will be determined in the LIBImAb trial. Research Sponsor: Italian Medicines Agency - AIFA.

Construction of DNA methylation-based biomarkers for diagnosis of hepatocellular carcinoma. *First Author: Ximing Xu, Renmin Hospital of Wuhan University, Wuhan, China*

Background: Hepatocellular carcinoma is the most common malignant tumor in China. Most of the patients are found in the advanced stage, which causes its low survival rate. According to the latest epidemiological data, hepatocellular carcinoma is the second leading cause of cancer mortality. DNA methylation is closely related to tumor development. In this study, differentially expressed methylated genes related to tumorigenesis and development were screened from the database and the diagnostic model was constructed for early screening. **Methods:** Limma package was used to analyze the differences between TCGA _ LIHC liver cancer and GSE113409 normal blood methylation sites and differentially expressed methylation sites (logFC>1, p<0.05) were identified. The TCGA _ LIHC methylation database was used as the training set. Lasso method, and random forest method were used for screening the differentially expressed methylation sites for the construction of the diagnostic model. After that, the characteristic coefficient of methylation sites and ROC curve of the diagnostic model were obtained from the training set. According to the cd-score, HCC patients could be diagnosed in the early stage, thus improved their survival. **Results:** Limma package was used to analyze the differences between TCGA _ LIHC liver cancer and GSE113409 normal blood methylation sites and 7109 differentially expressed methylation sites (logFC>1, p<0.05) were identified. Then the top 1000 differentially expressed methylation sites were selected. The TCGA _ LIHC methylation database was used as the training set. 30 methylation sites were screened by lasso method, and 20 methylation sites were screened by random forest. Taking the intersection, a total of 6 methylation sites were obtained for diagnostic model: cg00346208, cg00084798, cg00458878, cg00006397, cg00325910, cg00399027. The characteristic coefficient of methylation sites were displayed in the table below and the AUC of the diagnostic model was 0.9991579. High cd-score tended to have hepatocellular carcinoma, and vice versa. **Conclusions:** We have identified several DNA methylation markers for the diagnosis of hepatocellular carcinoma from GEO and TCGA databases. This model can predict hepatocellular carcinoma and the AUC is higher than that of AFP, which means it may become a more sensitive indicator for the diagnosis of liver cancer. Molecular profiling of ctDNA from NCI-MATCH patients enrolled for treatment with mTOR1/2 inhibitor sapanisertib (arm M) and the Hedgehog pathway inhibitor vismodegib (arm T). *First Author: Jennifer S. LoCoco, Illumina, Inc., San Diego, CA*

Background: The National Cancer Institute Molecular Analysis for Therapy Choice (NCI-MATCH) multi-arm phase II clinical trial tested biopsies from patients with advanced refractory cancer to assign treatment based on tumor molecular profile. Enrollment criteria for treatment with the mTOR1/2 inhibitor sapanisertib in Arm M, or the Hedgehog pathway inhibitor vismodegib in Arm T, included detection of mutations in TSC1/TSC2 or PTCH1/SMO in tissue, respectively. For a subset of patients enrolled on these two arms, matched plasma was also collected at time of enrollment or on treatment to evaluate ctDNA. **Methods:** Screening for NCI-MATCH was based on tissue sequencing that was initially performed centrally using the 143-gene OncoPrint Comprehensive Assay version 2 (OCAv2) and later referred to NCI-MATCH Designated Laboratory (DL) Network to perform sequencing for patient referral. Cell-free DNA (cfDNA) extracted from plasma collected in Streck tubes was input at 10 – 30 ng into a modified version of the Illumina TruSight Oncology 500 assay (TSO 500). Following error correction and read collapsing post-sequencing, variant calls were made and concordance between cfDNA libraries meeting prespecified QC criteria and tissue was evaluated. **Results:** Plasma, representing multiple collection timepoints, was available for 30/49 Arm M and 21/34 Arm T enrolled patients. A total of 95 cfDNA libraries, including replicates, were constructed and sequenced. Unique patient samples were tested across various timepoints (n = 35 pretreatment; n = 35 Cycle 2 Day 1; n = 8 at progression) plus replicates, with 90 (94.7%) libraries passing all prespecified QC criteria. Among Arm M patients there were 3 patients whose enrollment variant did not overlap with the TSO 500 gene panel. In total, 14 of 27 (51.8%) patients in Arm M and 18 of 21 (85.7%) patients in Arm T were concordant for enrollment mutation for at least one collection timepoint. In Arm T, 85.7% (n=38) of patient samples had at least one oncogenic or likely oncogenic (O/LO) mutation in the tumor sample at enrollment, with 73.6% (n = 28) of those also being detected by cfDNA. Interestingly, within Arm M and Arm T, a total of 7 patient samples were detected as MSI-H, with corresponding bTMB scores ranging from ~6 to > 100 Mut/Mb (median = 86.7). **Conclusions:** Detection of the enrollment mutations in treatment arms was observed in 51.8% - 85.7% of patients tested by ctDNA with overall variant concordance between tissue and ctDNA of at least 73.6%. These findings support the use of liquid biopsy as a tool for understanding genomic profiles of cancer patients both at diagnosis and progression, less invasively than standard tissue biopsies. In addition, 7 patients were identified as MSI-H, suggesting that blood-based testing could complement tissue testing for identifying patients who may benefit from targeted therapy. ctDNA-based genomic landscape analysis to evaluate molecular brake and gatekeeper mutations in FGFR2 alterations. *First Author: Paul Severson, Kinnate Biopharma, San Francisco, CA*

Background: FGFR2 and FGFR3 (FGFR2/3) gene alterations are oncogenic drivers found across various cancer types and have been successful targets of drug development. Several FGFR inhibitors (FGFRi) are approved for clinical use, and most are ATP-competitive, reversible inhibitors (1st-gen). Efficacy of the 1st-gen FGFRi can be limited by acquired resistance mutations in the FGFR kinase domain, typically molecular brake or gatekeeper mutations, which disrupt compounds binding through conformational changes or through direct steric hindrance, respectively. Irreversible (covalent) FGFRi, such as futibatinib, are in development to overcome kinase domain resistance mutations. However, preclinical evidence indicates that some of the known resistance mutations (eg. V564L) remain insensitive to futibatinib. **Methods:** To assess the landscape of FGFR-driven cancers and to better understand the prevalence of molecular brake and gatekeeper mutations, we analyzed the distribution of FGFR2/3 alterations in a large clinical genomic research database. This ctDNA-based genomic database was selected for the analysis given that liquid biopsy is a fit-for-purpose method to detect acquired resistance mutations. **Results:** We identified over 2,100 patients with FGFR2/3 alterations. Non-small cell lung cancer (NSCLC), breast, bladder, and cholangiocarcinoma (CCA) had the highest number of patients with FGFR2/3 alterations. 36% of all FGFR2 alterations across all cancer indications consisted of molecular brake or gatekeeper mutations. This finding was most enriched in CCA and breast cancer where 51% and 57%, respectively, of FGFR2 alterations were molecular brake or gatekeeper mutations. In breast cancer patients, molecular brake mutations were common and represent activating mutations in FGFRi-naïve patients. A small number of FGFR3 gene fusions were detected in CCA patients who had significantly shorter time on 1st-line treatment and trended toward shorter overall survival when compared to patients with FGFR2 fusions. We also identified CCA patients with FGFR2 fusions and one or more concurrent FGFR2 SNVs; primarily those in the kinase domain and associated with FGFRi resistance. Most of these putative cases of acquired resistance were polyclonal, with 2 or more (up to 8) FGFR2 SNVs coexisting with the fusion. Bladder cancer and NSCLC had the highest numbers of FGFR3 alterations. FGFR2/3 alterations were typically found without other driver mutations in CCA, bladder, and NSCLC patients. However, in breast there was a large overlap between FGFR2/3 alterations and other drivers. **Conclusions:** Herein, we identify a cohort of patients with FGFR2/3 molecular brake and gatekeeper mutations that may benefit from next-generation FGFR2/3-targeted therapies designed to inhibit a broad spectrum of both primary and secondary resistance mutations. Association of tumor-informed minimal residual disease (MRD) with clinical outcomes for muscle invasive bladder cancer (MIBC): A multicenter retrospective real-world analysis. *First Author: Ajitha Kommalapati, University of Alabama at Birmingham, Birmingham, AL*

Background: Muscle invasive bladder cancer is associated with a significant elevated risk of mortality and morbidity due to micro metastatic spread at the time of diagnosis. Accurate biomarkers to guide treatment determination and evaluate response are needed. Previous studies using tumor informed ct-DNA have shown that MRD assessment may be informative in these scenarios. **Methods:** We conducted a retrospective multicenter analysis of real-world data obtained from commercial testing (Signatera; Natera, Inc.). This cohort of MIBC patients included those who underwent radical cystectomy with a minimum follow up of 90 days. Data were collected on patient demographics, clinical and pathological staging, histologic type, and treatments. Correlation of ct-DNA status with clinical outcomes was analyzed using Cox-regression analysis to evaluate utility of the assay for detecting residual disease post-surgery and radiological recurrence. **Results:** A total of 109 patients with 545 plasma samples were identified that fit the inclusion criteria. The majority of the patients [79, 72.5%] were male, with a median age of 70 (range: 32-88) years. Most patients had pure urothelial carcinoma [73.4%, 80/109]. Median follow-up was 13.63 (range: 3-89.04) months. On analyzing the first time point post-surgery (median 54 days), 91.55% (65/71) of ct-DNA negative patients at the first post-surgical test remained recurrence free while 65.79% (25/38) of positive patients had recurred at data cut-off. Therefore, ct-DNA positivity at the first post-surgical timepoint was associated with shorter disease-free survival (DFS) (HR=9.9, 95% CI: 4.1-24%, $p<0.001$). ct-DNA detected imaging recurrence with a median lead time of 61 days (range: 12-381). Similarly, on analyzing ct-DNA positivity at any time post-surgery, of those who remained ct-DNA negative (N=63), 96.83% (61/63) showed no evidence of recurrent disease. On the other hand, 63.04% (29/46) of pts with ct-DNA positivity at any time after cystectomy recurred and experienced reduced DFS (HR=25, 95%CI: 5.9-103%, $p<0.001$). The assay's sensitivity for predicting radiological recurrence at any time post-surgery was 93.55%. Notably, in the multivariate analysis, anytime ct-DNA positivity after cystectomy was found to be the only significant risk factor associated with shorter DFS (HR=23.07, 95%CI: 5.1-104.4, $p<0.001$). **Conclusions:** In this initial analysis of real-world data, MRD detection via tumor-informed ct-DNA testing was highly prognostic of patient outcomes post-surgery and may guide adjuvant treatment decisions. Future studies in this setting will explore the utility of ct-DNA testing as a predictive biomarker in response to systemic therapy. Research Sponsor: None.

Development and evaluation of a multi-cancer screening (MCS) test for cancers common in Asia. *First Author: Michelle Pek, Lucence Diagnostics Pte. Ltd., Singapore, Singapore*

Background: The majority (78%) of cancer deaths in Asia arise from cancers with no existing screening recommendations. Earlier cancer detection is associated with improved outcomes. While single-cancer screening by liquid biopsy (notably plasma EBV DNA for nasopharyngeal cancer) is recognized in Asia, multi-cancer screening (MCS) liquid biopsy testing is a potential opportunity to address this key need. We developed a ctDNA mutation-based testing workflow based on targeted amplicon-based next generation sequencing testing of plasma and matched buffy coat as required to exclude clonal hematopoiesis, with a custom pipeline incorporating clinico-demographic factors for tissue-of-origin (TOO) calling. **Methods:** Primary objectives were to evaluate assay performance for detection of cancer-associated alterations, as well as TOO prediction accuracy. Validation was performed on a sample cohort of 476 untreated patients, each with 1 of 10 different cancers (lung, liver, breast, colorectal, prostate, nasopharyngeal, pancreas, bile duct, acute and chronic myeloid leukemia). 50 initial age-matched healthy controls were also used. A weighted sum model was used for TOO prediction, which was evaluated in an expanded 1478-sample cohort. Weights assigned to each cancer-associated alteration and its co-occurring combinations represent the importance or contribution of each alteration to each potential TOO. The impact of inclusion of clinico-demographic data (where available) on TOO prediction was also evaluated. **Results:** Overall sensitivity for detection of cancer-associated alterations was 72.7% (346/476). Sensitivity is higher in metastatic cases (82.5%) compared to localized cases (41.8%). Sample-level specificity for cancer-associated alterations/EBV detection was 96% (48/50), also comparable to previous series. Cancer-associated alterations/EBV were detected in approximately 50% of localized cases for 3 cancer types with no established screening recommendations in Asia (lung - 54.6%; bile duct - 50.0%; pancreas - 48.6%). In the expanded cohort, a high confidence call for TOO was obtained in 55.4% (818/1478) of samples with positive findings. Clinico-demographic data inclusion as a model variable improved overall TOO prediction accuracy in 10 cancer types to 93.8% (767/818), compared to an accuracy of 90.2% without factoring in clinico-demographic data. **Conclusions:** The MCS ctDNA assay shows reasonable sensitivity and specificity for detection of cancer-associated alterations, based on a retrospective study cohort. Tumor TOO can also be correctly classified in the majority of patients. Incorporation of clinico-demographic data to personalize TOO recommendations also improved accuracy of calls. Further prospective studies and the addition of multi-omic capabilities will continue to be helpful to determine MCS performance in an Asian multi-ethnic environment. Research Sponsor: None.

Detection of early-stage cancers using circulating orphan non-coding RNAs in blood. *First Author: Mehran Karimzadeh, Exai Bio Inc., Palo Alto, CA*

Background: Orphan non-coding RNAs (oncRNAs) are a novel category of small RNAs (smRNAs) that are present in tumors and largely absent in healthy tissue. We investigated the utility of oncRNAs extracted from serum for early cancer detection across seven cancer types. **Methods:** We collected 2,882 serum samples from individuals with known cancers of the bladder ($n=152$), breast (220), colon and rectum (141), kidney (283), lung (281), pancreas (287), and stomach (280) as well as donors with no history of cancer (1,238). We used 0.5 mL serum aliquots to generate and sequence smRNA libraries at an average depth of 20 million 50-bp single-end reads. Samples were split into age-, sex-, and smoking status-matched training (1,232 cancer; 922 control) and validation (412 cancer; 316 control) cohorts. A large catalog of oncRNAs specific to each cancer was created using tumor and adjacent normal samples from The Cancer Genome Atlas (TCGA) smRNA-seq database. Using TCGA-derived oncRNAs, we trained a machine learning model to predict cancer presence and tissue of origin (TOO) in a 5-fold cross validation setup using our training cohort. For the validation cohort, we averaged the predictions from the five training cohort models. **Results:** The model ROC-AUC for detecting cancer was 0.95 (95% CI: 0.94-0.95 for training and 0.94-0.97 for validation cohorts). Sensitivities for detecting cancer at 95% specificity were 0.74 (0.70-0.76) for early stage (I/II) and 0.80 (0.76-0.84) for late stage (III/IV) cancers in the training cohort, and 0.77 (0.71-0.81) and 0.81 (0.73-0.87) in the validation cohort. Sensitivities of detection for each cancer type are shown. For samples with cancer and TOO predictions, our top 1 and top 2 TOO accuracy was 0.76 (0.68-0.84) and 0.83 (0.76-0.90) for the validation set. **Conclusions:** These results demonstrate that oncRNAs detected in serum can be used for accurate, early detection, and localization of multiple cancers. ctDNA NGS detection of fusions acquired as mechanisms of resistance in the post-EGFR setting across multiple solid tumors. *First Author: Arielle Yablonovitch, Guardant Health, Palo Alto, CA*

Background: Oncogenic fusions are rare but have targetable, FDA-approved therapies across all solid tumor types. These fusions have been associated with resistance to EGFR-TKI (EGFRi) in advanced non-small cell lung cancer (NSCLC) and anti-EGFR antibodies in colorectal cancer (CRC), but the prevalence of acquired fusions and their associated clinical outcomes have not been well-studied. We examined fusions in >5,000 patients with advanced NSCLC or CRC who had a history of EGFR-directed therapy in the GuardantINFORM clinical-genomic database. **Methods:** Fusions in *ALK*, *FGFR1-3*, *NTRK1-3*, *ROS1* and *RET* were examined in a cohort of 2,379 patients with NSCLC and 1,072 with CRC tested with Guardant360 or Guardant360 CDx (Guardant Health, Redwood City, CA) before approved EGFR-targeting therapies, and in 3,531 patients with NSCLC and 2,132 patients with CRC tested after EGFR therapy. Fusion clonality was calculated as the fusion variant allele fraction (VAF):max somatic VAF for each patient, with subclonal fusions defined as having clonality < 0.5. Clinical outcomes were compared between patients with and without fusions in the post-EGFR population, adjusting for age, gender, regimen/line of therapy, and max VAF. Comparisons of fusion prevalence pre- and post-EGFR therapy were performed using Fisher's exact test. **Results:** Fusions were detected more frequently in patients with NSCLC and CRC after EGFR therapy relative to pretreatment (NSCLC: 3.2% vs. pre-EGFR 0.5%, $p<0.05$; CRC: 6.4% vs. pre-EGFR 1.1%, $p<0.05$). Fusions in *RET* were most enriched in the post-EGFR NSCLC population (1.0% vs. pre-EGFR 0.1%, OR=11.6, $p<0.05$), while fusions in the *FGFR* family were most enriched in the post-EGFR CRC population (3.0% vs. pre-EGFR 0.3%, OR=10.8, $p<0.05$). The majority of fusions post-EGFR were subclonal in patients with NSCLC (86%) and CRC (96%), consistent with these fusions emerging as mechanisms of resistance. In patients with NSCLC, clinical outcomes (as measured by time-to-next-treatment (TTNT)) were significantly shorter in patients who acquired fusions compared to those without fusions (median 5.9 vs. 9.5 months, log-rank $p=0.01$, adjusted HR=1.7, adjusted $p=0.02$). Patients with CRC showed no significant difference in TTNT between those with and without acquired fusions. In patients with NSCLC who acquired fusions, 45% received an EGFRi in the next line and 23% received a TKI targeted to their fusion; TTNT on these therapies was not significantly different (median 5.3 months vs. 6.4 months, respectively). **Conclusions:** Fusions in patients with NSCLC and CRC were enriched post-EGFR therapy and were associated with inferior clinical outcomes in NSCLC. Recognition of the subclonal prevalence of acquired fusions provides important context as oncologists consider the next line of therapy. This work highlights the potential utility of genomic profiling in patients over the course of treatment. Research Sponsor: Guardant Health.

Sequential monitoring of tumor macrophage fusion cells in the circulation of metastatic breast cancer and their prognostic value. *First Author: Kirby P Gardner, Creatv MicroTech, Inc., Monmouth Junction, NJ*

Background: Tumor Macrophage Fusion Cells (TMFCs) are hybrids fusions of tumor cells and macrophage/immune cells that have recently been identified in advanced solid tumors, such as metastatic Breast Cancer (mBC). Further, TMFCs are found in the blood of patients (pts) as a CD45+/CD14+ binucleated subtype of standard circulating tumor cells (CTCs), which are Cytokeratin+ (CK+) & CD45 negative, but distinct from highly hyperploidy cells known as cancer associated macrophage-like cells. However, no study has explored the clinical meaning of TMFCs in blood. To better elucidate the clinical meaning of TMFCs, we prospectively pooled 137 mBC pt samples prior to induction of new therapy, ie baseline (BL), and after therapy induction (FU). Both TMFCs or standard CTCs were identified and enumerated to analyze their prognostic value for progression-free survival (PFS) and overall survival (OS). **Methods:** In this prospective study, we collected 7.5 mL blood samples from n=137 mBC pts enrolled in prospective trials from multiple institutions before starting new treatment lines for newly progressive mBC. If possible, an optional FU sample was collected (n=73) after BL (median=4.9 weeks). TMFCs & CTCs were isolated using a CellSieve microfilter and differentiated by staining for CK, CD45, CD14, and DAPI. Cox proportional regression hazard ratios (HRs) with 95% Confidence Intervals (CI) for PFS & OS by univariate & multivariate analyses were based on RECIST v1.1, determined by local institutional pathologist over 24 months (M). **Results:** TMFCs were detected in 26.3% (n=36/137) at BL and associated with significantly worse PFS (HR=3.3, CI 1.9-5.7, p<0.001) & OS (HR=2.7, CI 1.4-5.1, p=0.005). TMFCs were also detected in 27.4% (n=20/73) at FU (n=73) and prognostic for PFS (HR=5.2, CI 2.3-11.9, p<0.001) & OS (HR=5.1, CI 1.8-14.2, p=0.004). Further, pts with increases in TMFCs between BL and FU had worse PFS (HR=4.3, CI 1.9-10.1, p=0.001) & OS (HR=4.5, CI 1.6-12.7, p=0.011). In contrast, pts with CTCs were found in 39.4% (n=54/137) at BL, which were prognostic for worse PFS (HR=2.0, CI 1.3-3.2, p=0.005) and not prognostic for OS (HR=1.7, CI 0.9-3.0, p=0.103). At FU, pts with CTCs were found in 38.4% (n=28/73), which were prognostic for worse PFS (HR=3.6, CI 1.8-7.3, p=0.001) & OS (HR=3.2, CI 1.3-8.0, p=0.021). Overall at BL, pts without CTCs or TMFCs had a 5.7 M mPFS & >24M mOS, CTCs alone had a 5.0 M mPFS & 20.3 M mOS, TMFCs had 2.0 M mPFS & 5.8 M mOS. At FU, pts without CTCs or TMFCs had a 5.8 M mPFS & 14.5 M mOS, CTCs alone had a 3.3 M mPFS & 14.6 M mOS, while TMFCs pts had a 1.7 M mPFS & 4.8 M mOS. **Conclusions:** TMFCs appear to represent a CTC subgroup with additional prognostic value to standard CTCs, that may correlate with significantly faster PFS and OS versus pts with CTCs alone, or without CTCs. Subtyping treatment regimens is ongoing to determine if the TMFC populations are responsive to specific therapy types in these mBC pts. Clonal hematopoiesis (CH) associated mutations in patients with advanced solid tumors enrolled in phase I clinical trials. *First Author: Julieta Rodriguez, Drug Development Department, Gustave Roussy Cancer Campus, Villejuif, France*

Background: An increased number of CH associated mutations has been identified in patients (pts) with solid tumors. Their impact on pts outcomes remains unclear. This study aims to integrate molecular data and clinical characteristics of CH in pts enrolled phase I clinical trials. **Methods:** Data was collected retrospectively from medical records and molecular profile reports (Foundation One Liquid CDx Assay – 309 genes) performed before first study drug administration at the Drug Development department in Gustave Roussy (Villejuif, France) within the STING trial (NCT04932525). CH prevalence was assessed according to a variant allele frequency (VAF) threshold of 1% in epigenetic modifiers (*DNMT3A*, *TET2* and *ASXL1*). **Results:** From January 2021 to December 2022, 255 pts were enrolled in a phase I clinical trial and had a liquid biopsy. In total, 55% of patients were male with a median age of 62 years [24-86]. Most common tumor locations were gastrointestinal (27%), genitourinary (21%) and thorax (18%). Patients received a median of 2 prior lines of treatment before investigational study drug and CH assessment. At the end of the data cut off, 81% of pts discontinued phase I treatment mostly due to progression disease. Overall, 104 pts (41%) had at least 1 CH mutation in liquid biopsy at baseline with 55 pts (22%) at a VAF of $\geq 1\%$. Mutation frequency was *DNMT3A* in 42% (n= 23), *ASXL1* in 38% (n=21) and *TET2* in 31% (n=17). Co-mutations were present in 26 patients, with the most frequent being *DNMT3A* + *ASXL1*. Median PFS and OS were 3.7 months (m) for CH group vs 3.5m for no-CH (p=0.3) and 24m CH vs 15m no-CH (p=0.5), respectively. **Conclusions:** CH is commonly found in pts with solid tumors treated in phase I trials, with a prevalence in our cohort of 22%. Most frequent mutated gene was *DNMT3A*. Prognostic implications of the impact of these mutations in patient's outcomes remain to be elucidated and will be presented at the meeting. Pan-cancer detection and tissue-of-origin identification by whole-genome sequencing of plasma cell-free DNA. *First Author: Wei Guo, HaploX Biotechnology, Shenzhen, China*

Background: Despite notable advances in cancer therapeutics, much of the mortality of human cancers results from late diagnosis. The early detection of cancer remains an unmet need that can benefit the effective treatments and better prognosis. Cell-free DNA (cfDNA) in the circulation provides an emerging diagnostic method for non-invasive cancer screening. The fragmentation signatures of cfDNA originating from different cell types or malignancies display distinct patterns, suggesting the potential as cancer biomarkers. This study aims to investigate the fragmentation profiles of cfDNA in several cancer types, and to develop a new approach for pan-cancer detection and tissue-of-origin identification. **Methods:** Plasma samples from 739 patients with lung (N=577), colorectal (N=98), breast (N=51) and liver (N=13) cancers, as well as 716 healthy individuals were collected in this study. Cell-free DNA was isolated and used to generate the whole-genome sequencing data. We developed an approach called PatternWGS (Pan-cancer detection and tissue-of-origin identification by whole-genome sequencing) to analyze the DNA fragmentation patterns comprehensively. Fragmentation features integrating cfDNA fragment size distribution, frequency of end motif sequence, and copy number variation were utilized to construct the optimal prediction model. We presented a multi-cancer detection model for distinguishing individuals with and without cancer using Generalized Linear Models (glmnet), and further built a cancer-origin model to predict cancer types using Random Forest algorithm. Training and testing occurred on randomly selected sampling splits of 60% and 40% of the data, respectively. Features selection and model construction were performed by only training cohort, and the test set was solely used for performance evaluation. **Results:** A larger proportion of shorter cfDNA fragments in cancers was observed. We proposed a fragment score indicating the degree of short fragmentation, and this fragment score was significantly higher in cancers (p<0.001). Several end motifs were identified to be specifically enriched in cancer patients. The multi-cancer detection model reached an area under the curve (AUC) of 0.98, with the sensitivity of 93% at 95% specificity. The sensitivity of detecting lung, colorectal, breast, and liver cancers reached 94.2%, 87%, 100% and 100% respectively, at 95% specificity. The cancer-origin model demonstrated an overall accuracy of 81.7% for the identification of tissue of origin. **Conclusions:** Our prediction model demonstrated a superior performance for multi-cancer detection and cancer origin prediction, suggesting the potential of plasma cfDNA fragmentation signatures as non-invasive biomarkers for early cancer detection in clinical. The distinct fragmentation patterns in cancer provide new insight to understand the mechanism of tumorigenesis. Research Sponsor: None.

NMR metabolomics in bladder cancer: Identification and monitoring of serum biomarkers during Pt-based treatment. *First Author: Roberta Giorgione, Clinical Oncology Unit, Careggi University Hospital, Florence, Italy. Department of Experimental and Clinical Medicine, University of Florence, Italy, Florence, Italy*

Background: To date, predictive and prognostic biomarkers for Bladder Cancer (BC) are lacking. Metabolomics, the study of small molecules involved in metabolism, aims to identify diagnostic, predictive and prognostic biomarkers. Overall, BC shows perturbations of various metabolic pathways, involved in biochemical reactions essential for energy production and for the maintenance of the REDOX balance, as well as in the metabolism of purines and pyrimidines. The main objective of this study is to characterize the serum metabolic profile of patients with BC undergoing platinum-based chemotherapy (Pt-CT), to identify the alterations induced by CT and evaluate the associated deregulated metabolic pathways, in order to identify potential biomarkers, prognostic and predictive of response to treatment. **Methods:** We enrolled patients with BC undergoing Pt-CT in different settings (neoadjuvant, adjuvant or metastatic). For each patient, a blood sample was collected before the start of each CT cycle (T0, T1, Tn). Metabolomic analysis was performed using the Bruker Avance 600 spectrometer. At baseline (T0), the metabolomic profiles of BC patients were compared with that of age- and sex-matched healthy controls. Major metabolites up- or down-regulated in patients with BC at baseline, were then monitored during CT (T1, Tn). **Results:** 14 patients were enrolled. When compared with age- and sex-matched healthy controls, patients with BC had elevated levels of acetate and acetone (ketone bodies), hypoxanthine, trimethylamine N-oxide (TMAO), glutamate, lactate, phenylalanine, and ornithine, and decreased levels of carnitine, choline, betaine, aspartate, threonine, 2-hydroxybutyrate, 2-aminobutyrate and histidine. When monitored during CT, hypoxanthine, glutamate, and aspartate levels increased; acetone, acetate and TMAO instead had a decreasing trend. **Conclusions:** The results of our pilot study confirm perturbations in several metabolic pathways: up-regulation of lactate, ketone bodies, hypoxanthine, phenylalanine, and glutamate levels in BC patients reflects altered glycolysis, fatty acid, purine, and amino acid metabolism, respectively. In addition, TMAO may play a role in the development of BC by promoting a pro-inflammatory and oxidative stress state. Furthermore, monitoring these metabolites could be a useful tool for predicting response to treatments. To our knowledge, there are no metabolomic studies that evaluated BC patients receiving CT and that included longitudinal monitoring to identify any changes in the metabolic profile induced by treatment. Diagnostic application of circulating CDH17 biomarker for screening GI malignancies. *First Author: Lui Ng, The University of Hong Kong, Pokfulam, Hong Kong*

Background: Colorectal cancer (CRC) is the most common and treatable gastrointestinal (GI) cancer, yet it remains the second leading cause of cancer associated deaths globally. Cadherin-17 (CDH17) is a biomarker for GI cancers characterized by its overexpression in stomach, liver, and colorectal cancers but controlled expression in normal tissues from healthy adults. Although an improvement in the detection strategy of CDH17 is essential to apply it for large scale CRC screening. We have developed a novel diagnostic immunoassay using a panel of highly specific antibodies (PCT/US2019/032752) that unveiled CDH17 as a potential diagnostic marker with high detection sensitivity and specificity in CRC. **Methods:** The study recruited 150 patients (Retrospective specimens - 50 colorectal adenomas and 100 colorectal cancer) and 50 asymptomatic 18-80 years old blood donors (prospective specimens). CDH17 expression levels were measured within the individual blood-plasma samples using an enzyme-linked immunoassay. **Results:** The novel CDH17 diagnostic assay showed a wide operating dynamic range extending from 90ng to a lower limit of detection at 123pg. Using the assay, we observed a progressive and a significant increase in the plasma CDH17 concentration from the asymptomatic individuals to the colorectal adenoma group, while the CRC patients showed the highest expression of the circulating protein (median: 2.5ng/mL vs 4.5ng/mL vs 8.0ng/mL, $P < 0.0001$). Within the CRC group, a higher CDH17 expression was associated with advanced tumor invasion, occurrence of nodal or distant metastases, as well as a clinical presentation of an advanced stage disease. The diagnostic power of the assay in terms of ROC AUC values was higher than 0.9 with an overall sensitivity of 82% that extended to 100% for metastatic CRC, while the specificity was at 94% for all stages combined ($P < 0.0001$). Plasma CDH17 outperformed the clinically applied CEA and CA19-9 markers in differentiating the CRC patients from the asymptomatic population. **Conclusions:** The CDH17 immunoassay is potentially a diagnostics tool aid for the detection of CDH17 within blood samples prompting the early diagnosis of CRC. **Research Sponsor:** Innovation Technology Fund: PSTS-SPC (Reference: SCT/005/21SP).

Plasma Biomarker	Cut-off	AUC	Sensitivity	Specificity
CDH17	5.5ng/mL	0.9324	82%	94%
CEA	5ng/mL	0.8501	76.09%	78.79%
CA19-9	37U/mL	0.5432	72%	18%

Preclinical circulating tumor DNA (ctDNA) shedding duration and prognostic implications of modeling 3669 participants from American Cancer Society Cancer Prevention Study-3 (CPS-3) and Circulating Cell-free Genome Atlas substudy 3 (CCGA3). *First Author: Alpa Patel, American Cancer Society, Kennesaw, GA*

Background: Early detection of cancer occurs in the preclinical phase, when development of cancers is unobservable. Shedding of ctDNA has previously been associated with aggressive cancers, suggesting these tumors may develop rapidly before diagnosis. Assays of ctDNA in blood samples from prospective cohort studies at various lead times (interval between blood draw and diagnosis) may provide insight into the timescales of preclinical cancer development, as well as prognosis. **Methods:** We used a targeted methylation assay and the associated locked classifier for cancer signal detection (CSD) on samples from two large prospective biobank studies: 1) CPS-3, where blood draw at enrollment (2006-13) occurred ≤ 3 years (Ys) before clinical diagnosis ($n=1065$); 2) CCGA3 (NCT02889978), where blood draw (2016-19) was concurrent with clinical diagnosis ($n=2604$). We constructed a model for detectability including study, inherent shedding of ctDNA at clinical diagnosis, and effect of lead time by cancer type and stage. We additionally evaluated prognosis stratified by ctDNA status (CSD positivity), compared to expected cancer-specific survival (CSS) matched by age, cancer type, and stage for ≤ 9 Ys of follow-up, noting that ctDNA status may change during lead time. **Results:** Estimated inherent ctDNA detectability did not differ between CCGA3 and CPS-3 studies (95% confidence interval [CI] for difference is [-8.2%, 4.6%] and spans zero). Median [CI] detection timescales for exponential decay of detection by time were 0.75 [0.47, 1.3] Ys for localized stage, 0.89 [0.61, 1.33] Ys for regional, and 1.2 [0.84, 1.67] Ys for distant, consistent with a published model, and ranged by type from 0.49 [0.26, 0.88] Ys for pancreas to 2.45 [1.14, 4.87] for lymphoma. For CPS-3, estimated CSS at 9 Ys from blood draw was 54% for ctDNA+ and 79.5% for ctDNA- participants. Hazard ratios (HR) [CI] for ctDNA+ vs ctDNA- alone predicting CSS were 7 [4.2, 12.2], 4.2 [2.9, 6], and 3.5 [2.5, 4.7] for those diagnosed up to 1, 2, and 3 Ys after blood draw, respectively. Compared to synthetic controls for age, cancer type, stage, and lead time in Surveillance, Epidemiology, and End Results (SEER) data, CSS was better in each group: ctDNA+ HR 0.63 (CI: 0.54, 0.74); ctDNA- HR 0.45 (CI: 0.22, 0.74). **Conclusions:** These results provide estimates for the average detection window in tumors shedding ctDNA across multiple cancer sites and stages, including cancer types with no current screening paradigm. Taking lead time into account, preclinical ctDNA status selected clinically significant cancers, limiting potential for overdiagnosis. Additionally, long-term survival remained better than in SEER data, suggesting that ctDNA+ cancers can be survivable. Results require confirmation in future prospective analyses. **Research Sponsor:** GRAIL, LLC; American Cancer Society.

Concordance of circulating and solid tumor DNA through comprehensive genomic profiling in a large integrated cancer network. *First Author: William LaFramboise, Allegheny Health Network Cancer Institute, Pittsburgh, PA*

Background: Comprehensive Genomic Profiling (CGP) of solid tumors is crucial in diagnosing and treating cancer patients. Circulating Tumor DNA (ctDNA) is a potential biomarker for detecting mutations when tissue samples are limited or unavailable. However, the sensitivity of ctDNA tests vary greatly, making concordance studies with tissue samples critical to validate clinical use. This study presents results of CGP in paired tumor tissue and plasma samples from representative cancer patients treated in a community-based, Integrated Network Cancer Program. **Methods:** Over 2000 cancer patients have provided solid tumor and/or blood samples to date including serial follow-up blood samples. To optimize ctDNA integrity, we collected blood using a membrane stabilizer (Streck), ensured courier transport in ≤ 72 hours, separated plasma via differential centrifugation $\times 3$, extracted cell free DNA with magnetic beads, and performed Next Generation Sequencing (NGS) using the ct-TSO500 assay (Illumina). In cases where patients provided both a solid tumor and concurrent blood sample, st-TSO500 NGS results from the solid tumor were compared to the ctDNA results for these matching specimens. Clinical actionability of variants was determined using the OncoKB database at levels 1, 2, and R1. **Results:** 146 matched blood and solid tumor specimens were analyzed to date. CGP studies revealed 1179 ± 102 unique variants across 20 different cancer types. Coding mutations from these specimens averaged 183 ± 25 variants. The ctDNA contained 96.5% of initial variants (1088 ± 95) and 95.1% of coding mutations (163 ± 20) found in the respective matched solid tumor. 76 patients had one or more oncogenic mutations detected only in the ctDNA and 28 (36.8%) of these included an actionable anticancer pharmacotherapy. Concordance by selective tumor type for clinical oncogenic variants was 95.8% (prostate), 95.0% (pancreas), 92.8% (lung and ovarian), 90.0% (endometrium), 84.3% (colon) and 82.4% for breast cancer. There was no difference in concordance between stage IV (91.0%) and stage I-III (86.5%) tumors ($p = 0.14$). An average of 6.2 ± 2.5 oncogenic variants were detected in both ctDNA and tissue. 99.3% of all patients contained an oncogenic biomarker in both ctDNA and tissue assays. **Conclusions:** We developed a prospective tissue and plasma repository of patients across a large integrated cancer network. These data demonstrate high concordance between circulating and solid tumor DNA using an "in-house" CGP assay. With no loss of concordance across cancer stages, ctDNA can identify actionable mutations not found in solid tumor analysis. This study is an important step toward incorporating "in-house" ctDNA CGP into routine cancer care. Future goals are to utilize these data for development of novel prognostic and predictive classifiers for use in a community-based hospital system across various disease sites. **Research Sponsor:** Highmark Health; Allegheny Health Network.

Liquid biopsy identification of ERBB2 amplified and HER2 expressing metastatic breast cancer: Comparison and combination of cell and cell-free platforms. *First Author: Giuseppe Di Caro, Epic Sciences, San Diego, CA*

Background: Liquid biopsies are a non-invasive diagnostic approach for detecting circulating tumor cells (CTCs) or circulating tumor DNA (ctDNA) that may provide clinically actionable information for treatment decisions for metastatic breast cancer (MBC) patients when a conventional biopsy is otherwise infeasible. Here we report a comprehensive liquid biopsy platform including: 1) quantitative immunofluorescent HER2 and ER protein expression in CTCs (ctcIF), 2) determination of ERBB2 amplification and the number of Large-scale State transitions (LST) by single-cells CTC genomics (ctcDNA) and 3) alterations in plasma ctDNA. **Methods:** Blood samples from 457 progressing metastatic breast cancer patients and 25 healthy donors (HDs) as controls were collected for cell & cell-free DNA analysis. After plasma isolation, nucleated cells were plated, & slides were bio-banked for Immunofluorescent staining & subsequent imaging. CTCs were identified using Epic Sciences digital imaging & machine learning algorithms, and individual CTCs were sequenced for genomic quantification of LSTs and Copy Number Variants (CNV). Bio-banked plasma was analyzed to detect ctDNA alterations with high clinical relevance (Class IA). **Results:** Within this cohort of 457 MBC patients, the presence of CTCs, ctDNA (LST*) and ctDNA alterations were detected in 98%, 58%, and 42%, respectively, while no CTCs and no ctDNA alterations were detected in the HD cohort, suggesting high specificity. ctDNA genomics was more sensitive than ctDNA in detecting $ERBB2^{amp}$ in MBC patients (16%, and 2%, respectively). A mean variant allele frequency (VAF) of $< 25\%$, which is the threshold for detecting a two-fold $ERBB2$ amplification by ctDNA, was present in 20% and 80% of $ERBB2^{amp}$ MBC detected by the ctDNA and ctDNA platform, respectively, suggesting that the ctDNA platform can identify the majority of $ERBB2^{amp}$ among patients with a low ctDNA fraction. $HER2^{exp}$ or ER^{exp} expression by ctcIF were detected in 67% and 67% of MBC patients, respectively. A liquid biopsy classification of HER2 status by combining the three platforms (ctcIF, ctDNA, and ctDNA) identified that in the tested population, 16% were $ERBB2^{amp}$, 52% were HER2 expressing ($HER2^{exp}$ and $ERBB2^{nonamp}$), and 27% were $HER2^{neg}$ ($HER2^{-}$ and $ERBB2^{nonamp}$). To identify MBC patients that may potentially change treatment as a result of the test we identified a small cohort of MBC patients ($n=46$) with HER2- disease and tissue biopsy IHC=0, 74% of these patients had $HER2^{exp}$ CTC consistent with HER2 low expression which may aid therapeutic decisions in later line MBC. **Conclusions:** Here we report a comprehensive liquid biopsy profile combining ctcIF, ctDNA, and ctDNA platforms with high sensitivity and specificity in determining clinically actionable HER2 and ER biomarker status that may impact therapeutic decision-making in MBC patients. **Research Sponsor:** Epic Sciences.

ctDNA analysis of NTRK fusion and mechanisms of acquired resistance to TRK inhibitors. *First Author: Karthigayini Sivaprakasam, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The regulatory approval of TRK tyrosine kinase inhibitors (TKIs) represented a landmark in tissue-agnostic drug development. Adult and pediatric patients harboring *NTRK* fusions derive meaningful clinical benefits from the first-generation TRK TKIs larotrectinib and entrectinib. However, characterizing *NTRK* fusions and resistance mechanisms to TRK TKIs by circulating tumor DNA (ctDNA) remains to be studied. **Methods:** Patients with *NTRK*-fusion-positive tumors who received TRK TKIs and had ctDNA analyzed using next-generation sequencing (NGS) were retrospectively identified. Samples were collected at multiple time points, including pre-TRK TKI, on-treatment, and post-progression. Mechanisms of resistance to TRK TKIs were examined when post-progression ctDNA samples were available. **Results:** Twenty-seven patients, with a median age of 57 years (range 28-81) and 11 different cancer types were identified. Twenty-two patients (81%; 22/27) had at least one ctDNA-positive sample (tumor burden greater than 0). A total of 67 ctDNA samples were analyzed by MSKCC ACCESS ctDNA pipeline, of which 10 samples (15%; 10/67) were collected before any TRK TKI. Forty-two samples (63%; 42/67) had positive ctDNA and *NTRK* fusion was detected in 16 ctDNA samples (24%; 16/67), including 9 (56%) *NTRK1* fusions and 7 (44%) *NTRK3* fusions. Among the pre-TRK TKI samples (n=10), 2 samples (20%, 2/10) had *NTRK* fusions detected. A total of 8 patients had post-progression samples with a resistance mechanism identified, of which 5 patients received larotrectinib and 3 entrectinib. The ctDNA samples revealed 7 patients (88%; 7/8) with on-target resistance and 1 patient (12%; 1/8) with off-target resistance. Among on-target mutations identified, the most common involved the solvent front residue (86%, n=6/7: n=2 *NTRK3* G623R, n=2 *NTRK1* G595R, n=1 *NTRK3* G623E, n=1 *NTRK3* G623L) followed by the xDFG motif (14%, n=1/7: n=1 *NTRK1* G667C). Regarding off-target alterations, one patient developed a *BRAF*V600E mutation. **Conclusions:** The use of plasma ctDNA can improve the identification of *NTRK* fusions through non-invasive techniques and potentially identify subsequent resistance mechanisms after the administration of the TRK TKIs. Research Sponsor: U.S. National Institutes of Health.

⁶⁸Ga-FAPI-46 PET for cancer imaging: A prospective single-arm clinical trial. *First Author: Wolfgang P. Fendler, Department of Nuclear Medicine, University of Duisburg-Essen and German Cancer Consortium (DKTK)-University Hospital Essen, Essen, Germany*

Background: Fibroblast activation protein (FAP) is expressed at high levels on tumor associated fibroblasts. FAP-directed radioligand positron-emission-tomography (FAP-PET) is a novel diagnostic tool for cancer. However, we currently do not understand the diagnostic performance of FAP-PET as compared to standard FDG-PET. Here we aim to compare tumor detection by FDG- vs. FAP-PET with independent validation of discrepant findings. **Methods:** Patients with (a) proven or suspected malignancy, (b) longest tumor diameter >1 cm, (c) intended surgery or biopsy, and (d) no prior external beam radiation or systemic tumor therapy within 3 months underwent FDG- and FAP-PET for tumor localization on subsequent days. Clinical reads were analyzed prospectively on a per-patient and per-region basis (local, locoregional nodal, distant organ or soft tissue, bone). Discrepant findings were validated as true vs. false positive by histopathology or image follow-up. Tracer uptake in tumor tissue was assessed by SUVmax. **Results:** In total n=100 patients (median 62 years, male/female n=68/32) underwent FDG- and FAP-PET. Five most frequent tumor entities and respective median FDG vs FAP uptake were RCC (n=19; SUVmax 8.4 vs. 7.1), sarcoma (n=18; 10.3 vs. 10.9), NSCLC (n=10; 12.4 vs. 13.7), lymphoma (n=9; 18.3 vs. 10.9), and PDAC (n=8; 4.1 vs. 7.3). On a per-patient basis, FDG- vs FAP-PET localized malignancy in n=93/94 patients. FDG- vs FAP-PET was concordant for the assessment of 362/400 (91%) regions. n=16/400 (4%) regions were negative on FDG- and positive on FAP-PET (88% true, 12% false positive). n=22/400 (6%) regions were negative on FAP- and positive on FDG-PET (57% true, 43% false positive). Two false positive FDG-PET findings were due to tracer uptake in reactive lymph nodes. There were no PET-related adverse events. **Conclusions:** In patients with various tumor entities, standard FDG- and novel FAP-PET localized tumor equally well. Additionally, FAP-PET was associated with a lower rate of false positive findings, especially in lymph node assessments. Clinical trial information: NCT05160051. Potential improvement in the diagnostic accuracy in detecting the estrogen receptor status in metastatic and recurrent breast cancer using 18F-FES PET/CT in the US. *First Author: Adolfo Fuentes-Alburo, GE Healthcare, Marlborough, MA*

Background: ER status helps classify BC for the most appropriate treatment pathway. Biopsy (Bx) and immunohistochemical (IHC) are established procedures to determine the ER status in metastatic BC (mBC, i.e., first occurrence of metastases) and recurrent BC (rBC, i.e., progression of mBC). In some cases, the accuracy of Bx/IHC to inform ER status may be challenged (e.g. difficult to access lesions; ER discordance within/across lesions and due to temporal heterogeneity; and when a Bx fails to obtain representative tissue). 16 α -18F-fluoro-17 β -fluoroestradiol (18F-FES) is a radiolabeled form of estrogen that binds to ER. For use with positron emission tomography /computed tomography imaging (PET/CT), it allows an assessment of whole-body ER+ status. In prospective trials and meta-analyses, 18F-FES PET/CT provided high diagnostic accuracy (DA) of ER+ disease. This study evaluated the potential increase in accuracy in determining ER+ status when 18F-FES PET/CT was added to IHC in mBC and rBC. **Methods:** An Excel based decision model was developed to estimate the impact on DA for ER+/HER2- US mBC and rBC patients over a five-year period by introducing 18F-FES PET/CT. The model assumed that 18F-FES PET/CT was added to Bx/IHC to classify ER status in three cases: (i) for mBC patients when Bx failed or was inconclusive, (ii) for mBC patients when Bx was not possible, or (iii) for all rBC patients. The DA between two scenarios was compared: scenario A, DA of Bx/IHC only and scenario B, 18F-FES PET/CT + Bx/IHC. **Results:** Scenario B, adding 18F-FES PET/CT, may lead to an increase in the initiation of appropriate endocrine- and chemotherapies, as defined by clinical practice guidelines, in all comparisons. The largest increase in DA was in rBC and, when Bx is not possible, in mBC patients. Also, results indicate that introducing 18F-FES PET/CT decreases the number of re-biopsies performed except when Bx was not possible (ii). **Conclusions:** Adding 18F-FES PET/CT to Bx/IHC is expected to improve the DA of a patients' ER status thereby increasing the information available to inform treatment, thus reducing the need for re-biopsies in mBC and rBC patients. By far the largest increase in DA of ER status using 18F-FES PET/CT was seen among patients with rBC (iii). Research Sponsor: GE Healthcare.

Modelled results in 3 cases (mBC population yr 1: n = 17,970 / yr 5: n = 72,150; rBC population yr 1: n = 8,750 / yr 5: n = 34,040).

Utility of artificial intelligence-based genomic classification of occult malignancies in clinical practice. *First Author: Sourat Darabi, Hoag Family Cancer Institute, Newport Beach, CA*

Background: Occult primary malignancies (OPM) are a significant clinical problem, representing 3 to 5% of advanced cancers. Patients with OPM have a worse prognosis and fewer treatment options than when the primary site of origin of cancer can be confidently identified. Novel artificial intelligence-based genomic classification of occult malignancies has been validated for clinical use by previous studies, but reports of clinical utility have not yet been published. We report our experience of consecutive cases where a commercial AI-based genomic classifier was used in routine practice at a high-volume community cancer center. **Methods:** Malignancies with uncertain pathological classification or site of origin were subjected to molecular profiling and AI-based genomic classification (GPSai) capable of recognizing a set of 115 distinct primary tumor sites and histology classes. Molecular profiling consisted of whole exome and whole transcriptome sequencing of FFPE tumor samples along with other predictive biomarkers assays performed by a commercial laboratory (Caris Life Sciences). The identification of targetable mutations was reported, but variants of unknown significance were excluded when reporting genomic alterations. **Results:** From 1,316 patients between October 2021-November 2022, we analyzed 70 (5.3%) patients with OPM, including 44 (62.9%) females and 26 (37.1%) males, with 34 (48.6%) being 65 or older. GPSai classification was ordered for 73 samples from 70 patients, which resulted in the classification of 33 (45.2%) tumors, inconclusive results in 36 (49.3%), and insufficient tissue quantity in 4 (5.5%). Of the 33 cases with a GPSai classification, the putative pathology diagnosis was concordant in 26 (78.8%) and discordant in 7 (21.2%) cases. We investigated discordance between the GPSai and pathological diagnoses in discordant cases. The pathological classification was favored over GPSai in all 7 discordant cases. Of the 36 cases that could not be confidently assigned a classification, 14 (38.9%) possessed potentially actionable alterations. 23 of the 36 had no presumptive site of origin. Of these, 10 of 23 (43.5%) were PD-L1 positive, 4 of 23 (17.4%) had a high TMB, and 1 of 23 (4.4%) had MMR deficiency. Additionally, based on molecular profile and examination of RNA expression levels, 2 cases were able to be classified with subsequent IHC confirmation. Based on the results from genomic testing, 55.7% of patients (39 of 70) had FDA-approved treatment options. **Conclusions:** Over a third of patients with OPM were able to be assigned a cancer diagnosis concordant with diagnoses by pathologists. Of those which could not be classified, targetable biomarkers were commonly found. AI-based genomic classification of occult primaries is useful in clinical practice to help discern the site of origin and identify treatment options. Research Sponsor: None.

Tumor mutational burden as a predictive biomarker for molecularly matched therapy in two independent pan-cancer cohorts. *First Author: Damian Tobias Rieke, Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität Zu Berlin, Charité Comprehensive Cancer Center; German Cancer Consortium (DKTK), Berlin, Germany*

Background: Personalized cancer therapy based on molecular tumor aberrations has shown efficacy in a subset of tumors. Novel biomarkers are warranted to help extend this benefit to a larger patient population. Tumor mutational burden (TMB) is an established predictive biomarker for immune checkpoint inhibition. Its role for molecularly matched therapy is unknown. **Methods:** Comprehensive molecular profiling including whole-exome and RNA-sequencing was performed in 104 patients with advanced cancer within the DKTK MASTER program. 55 patients received a systemic therapy excluding immunotherapy. TMB and survival were analyzed in patients receiving molecularly matched therapy (n=34) or non-molecularly matched therapy (n=21) as well as in an independent published cohort of patients receiving molecularly matched (n=68) or non-molecularly matched (n=40) therapy (excluding immunotherapy). TMB and co-occurring driver mutations were analyzed in the DKTK MASTER cohort. **Results:** The median TMB of 1.68 mutations per megabase (mut/Mb) in the 34 patients receiving molecularly matched therapy was used to stratify patients into TMB-high and -low groups. Median overall survival (OS) and progression-free survival (PFS) were significantly shorter in the TMB-high than in the TMB-low group (OS: 4 months [95% CI, 3.3 to 7.6] versus 19 months [95%CI, 10.0 to not reached] p < 0.001, Hazard Ratio (HR) 4.4 [95%CI, 1.9 to 10.2], p<0.001; PFS 1.8 months [95%CI, 1.1 to 3.6] versus 8.5 months [95% CI, 2.8 to 17.0] p = 0.004, HR 2.9 [95%CI, 1.4 to 6.2], p=0.005). No significant differences were observed in patients receiving non-molecularly informed systemic therapy (OS HR 0.7 [95%CI, 0.2 to 2.6], p=0.635 and PFS HR 1.2 [95% CI, 0.4 to 3.5] p=0.701). In the validation cohort, shorter progression-free survival was also identified in the TMB-high group (median TMB cut-off of 4 mut/Mb; HR 2.2 [95%CI, 1.3 to 3.7] p=0.005) treated with molecularly matched therapy but not with non-molecularly informed therapy (HR 1.1 [95%CI, 0.5 to 2.2] p=0.848). TMB was associated with co-occurring driver mutations (n=104, r = 0.78 [95%CI, 0.68 to 0.85], p<0.001). **Conclusions:** High TMB was previously established as a positive predictive biomarker associated with efficacy of immune checkpoint inhibitor treatments. Our study reveals high TMB as a negative predictive biomarker associated with low efficacy of molecularly informed systemic therapy, potentially due to co-occurring driver mutations. Thus, TMB is a candidate predictive pan-cancer biomarker for combined precision oncology and immunotherapy programs. Research Sponsor: Deutsches Konsortium für Translationale Krebsforschung (DKTK).

Deep neural networks to predict pathological invasiveness through surgical resection images: A computer vision based prospective clinical trial in pulmonary nodules. *First Author: Henian Yao, The First Clinical Medical College, Guangdong Medical University, Zhanjiang, China*

Background: Pathological subtypes associate with surgical strategies of pulmonary nodule, during which thoracic surgeons make surgical decision through intra-operative frozen resection diagnosis. However, frozen section is time-consuming, vague and maybe misleading due to the limited sample and subjective judgements from pathologists. This study developed a predictive deep neural network for pathological invasiveness of pulmonary nodules based on the surgical resection images of gross specimens. **Methods:** We prospectively collected the specimen image under standardized lighting conditions in operating theaters from patients with pulmonary nodules treated by surgery resection from June 2020 to September 2021 in Guangdong Provincial People's Hospital. Images were assigned into training cohort, validating cohort and test cohort as 8:1:1. With data augmentation, DenseNet was applied to classify the pulmonary nodules into high-risk and low-risk group. High-risk group was defined as grade 2 and grade 3 invasive pulmonary adenocarcinoma according to IASLC, while low-risk group was defined as adenocarcinoma in situ (AIS), minimally invasive adenocarcinoma (MIA) and grade 1 invasive pulmonary adenocarcinoma. Predictive efficiency was evaluated through area under the curve (AUC) of the receiver operating characteristic (ROC) curve, sensitivity, specificity, accuracy. Model performance would be compared with frozen section pathological diagnosis. **Results:** Among 1022 patients with pulmonary nodules enrolled, we have acquired 1080 images of the resected nodules in Guangdong Provincial People's Hospital, with a mean age of 56 years and 39.1% of male patients. The median age of patients were 57 years in training cohort and 56 years in validating cohort, with 38.1% male patients in training cohort and 42.5% male patients in test cohort. This study included 864 images in training cohort, 108 images in validating cohort and 108 images in test cohort. Mean diameter of the nodules were 14.6mm in training cohort and 17.2mm in test cohort. In terms of predictive performance, the AUC value of ROC curves was 96.0% in training cohort and 95.0% in test cohort. In training cohort, the sensitivity of model was 97.6%, with the accuracy of 97.5% and specificity of 97.6%. In test cohort, the sensitivity of model was 97.6%, with the specificity of 90.2% and accuracy of 95.4%. Compared with frozen resection in testing cohort, our deep neural network had higher accuracy in pathological prediction (95.4% vs 88.9%). **Conclusions:** This study developed and validated a predictive algorithm on pathological invasiveness of pulmonary nodules through computer vision technique with highly sensitivity and specificity, which could assist the rapid evaluation for pathological invasiveness and intraoperative surgical decisions. A panel of seven protein tumor markers for multi-cancer early detection by artificial intelligence. *First Author: Shichun Tu, Clinical Laboratories, Shenyao Bio, Zhengzhou, China*

Background: Early cancer detection is key to reducing cancer deaths. Unfortunately, many established cancer screening technologies are not suitable for use in low- and middle-income countries due to expenses, complexity, and dependency on extensive medical infrastructure. Therefore, a simple, affordable, efficient multi-cancer early detection test is a major unmet need. **Methods:** This study enrolled nearly 10,000 participants (1959 cancer cases and 7423 non-cancer cases) containing more than nine common cancer types. One tube of peripheral blood samples was collected from each participant and quantified a panel of seven selected protein tumor markers (PTMs) by a clinical common electrochemiluminescence immunoassay analyzer. A protein assay named OncoSeek was established using artificial intelligence to distinguish cancer from non-cancer cases by calculating the probability of cancer (POC) index based on the quantification results of 7 PTMs and clinical information including gender and age of the subjects. Then using another model to predict the possible affected tissue of origin (TOO) who has been detected with cancer signal. **Results:** In this study, we found that the conventional clinical method relied only on a single threshold for each protein tumor marker which would make a big problem that was when combining the result of those markers, the false positive rate would accumulate as the number of tests increased. Nevertheless, OncoSeek was empowered by artificial intelligence technology to significantly reduce the false positive rate, increasing the specificity from 56.9% (95% confidence interval (CI): 55.8% to 58.0%) to 92.9% (95% CI: 92.3% to 93.5%). In all cancer types sensitivity of the OncoSeek test was 51.7% (95% CI: 49.4% to 53.9%). The sensitivities ranged from 37.1% to 77.6% for the detection of the nine common cancer types (breast, colorectum, esophagus, liver, lung, lymphoma, ovary, pancreas, stomach), which account for ~59.2% of global cancer deaths annually. Furthermore, it has shown excellent sensitivity in several high-mortality cancer types for which there are a lack of routine screening tests in the clinic, such as the sensitivity of pancreatic cancer was 77.6% (95% CI: 69.3% to 84.6%). The overall accuracy of tissue of origin (TOO) prediction in true positives was 66.8%, which reduced the clinical diagnostic workup. **Conclusions:** In summary, this study supported that OncoSeek significantly outperforms the conventional clinical method, representing a novel blood-based test for multi-cancer early detection which is a non-invasive, easier, and efficient approach. Moreover, the accuracy of TOO of it which facilitates the follow-up diagnostic workup. As well as this method is affordable (the cost of the test is less than \$25) and requires nothing more than a blood draw at the screening sites, which makes it more practical in low- and middle-income countries. Systematic review and meta-analysis of the accuracy and applicability of blood-based multi-cancer early detection (MCED) in the general population. *First Author: Joo Hee Park, Northwestern University, Chicago, IL*

Background: Globally, cancer results in 10.08 million deaths per year. A single blood-based screening tool that detects multiple cancer types could significantly reduce cancer burden. We systematically reviewed and statistically examined both the accuracy and applicability of blood-based MCED tests to strategize their utilization in improving cancer detection. **Methods:** Original articles were searched from PubMed, Cochrane, and Embase for blood-based screening tests analyzing multiple cancer types and asymptomatic human subjects. We excluded studies with small sample sizes (n<30), hypothesis-generating/diagnostic tests, and non-blood-based tests. For cfDNA-based assays, measurements of diagnostic accuracy were pooled for meta-analysis. **Results:** Of 1,074 records identified and screened, 15 case-control and 4 cohort studies were analyzed, most of which utilized cfDNA-based diagnostic tests. Twelve cfDNA studies selected for meta-analysis had pooled sensitivity of 0.623 (95%CI 0.517 - 0.719) and specificity of 0.975 (0.942 - 0.990). Summary ROC curve shows variability in sensitivity and specificity between studies. However, sensitivity and specificity were not affected by study type, gender, or assay type. Sensitivity was higher for advanced staged cancers (III/IV 0.774 (0.697 - 0.837)) than early-stage cancers (I/II 0.503 (0.366 - 0.639)). Among cancer types, no significant differences were detected. Lastly, false positive and false negative rates were 0.025 (0.010 - 0.058) and 0.447 (0.438 - 0.456), respectively. **Conclusions:** Given high sensitivities and specificities, MCED tests show promise as additional screening tools. However, in the general population, misdiagnosis burden from false positive and negative rates is anticipated. Although multiple barriers exist to their application in the clinic, MCED tests may improve patient outcomes for cancers with no conventional screening tools and provide additional credibility when combined with existing tools. Future prospective studies with large and diverse populations are warranted. Research Sponsor: None.

Summarization of meta-analysis results on cfDNA-based multi cancer early detection tests.

	Sensitivity	Specificity	False Positive Rate	False Negative Rate
Events/Total	6414/11590	16093/16357	264/6678	5176/21269
Proportion (95% CI)	0.652 [0.537; 0.751]	0.978 [0.936; 0.992]	0.025 [0.010, 0.058]	0.447 [0.438; 0.456]

12 studies are included. CI = Confidence Interval.

A machine learning-based multidimensional model integrating clinical, radiomics, and cell-free DNA methylation biomarkers for the classification of pulmonary nodules. *First Author: Wenhua Liang, Department of Thoracic Surgery/Esophageal Surgery, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, Guangdong, China*

Background: Patients with pulmonary nodules undergoing excessive invasive procedures is a pressing clinical problem. We sought to develop a noninvasive, machine learning-based multidimensional tool combining clinical, radiomic, and cell-free DNA (cfDNA) methylation biomarkers for improving accuracy of pulmonary nodules classification. **Methods:** This prospectively collected and retrospective blinded evaluation trial enrolled a total of 1,276 subjects at 24 hospitals in China. All patients with a 5-30 mm pulmonary nodule at high risk of lung cancer had undergone surgical resection with definitive pathological diagnosis. Clinical information, preoperative peripheral blood, and chest CT scans were collected. The regions of interest (ROIs) containing target nodule on the CT images were automatically segmented by a deep-learning based model. 2,153 radiomics features were extracted from ROIs using PyRadiomics. Based on clinical and radiomics features, four classification models were constructed using LightGBM, Lasso, Random Forest, and Logistic Regression algorithms. Subsequently, the predicted probabilities of the above four models were averaged to obtain a final score of the combined clinical and radiomic biomarkers model (CRBM) in a training set ($n=797$). Then we integrated CRBM model with our previously established cfDNA methylation model (PulmoSeek; DOI: 10.1172/JCI145973) to create a new combined model using logistic regression ($n=201$), PulmoSeek Plus V2.0, and verified it independently ($n=278$). The ROC curves were compared to evaluate the diagnostic performance among the CRBM, PulmoSeek, and PulmoSeek Plus V2.0 model, pathologic diagnosis as the gold standard. **Results:** The CRBM model achieved AUCs of 0.81(95%CI 0.73-0.90) and 0.80 (0.74-0.86) in the two validation sets ($n_1=201$, $n_2=278$), respectively. In the training set ($n=201$) and validation set ($n=278$), the PulmoSeek Plus V2.0 obtained AUCs of 0.93 (0.90-0.97) and 0.91 (0.88-0.95), and accuracies of 0.89 (0.84-0.93) and 0.84 (0.79-0.88), respectively. In the combined set ($n=479$), when compared with CRBM and PulmoSeek, PulmoSeek Plus V2.0 yielded improved AUCs of 11% and 6%, and accuracies of 6% and 3%, respectively. PulmoSeek Plus V2.0 model for rule-out at the fixed specificity of 50%, had an overall sensitivity of 0.98 (0.96-0.99), PPV of 0.86 (0.82-0.89), and NPV of 0.998 (0.988-1.000, at 5% prevalence). It maintains good diagnostic performance in early-stage lung cancer (0-I, $n=328$) and 5-10 mm nodules ($n=92$), with sensitivities of 0.98 (0.96-0.99) and 0.98 (0.92-0.99), respectively. **Conclusions:** PulmoSeek Plus V2.0, as a novel machine learning-based multidimensional model, improves the accuracy of pulmonary nodules classification, and potentially reduces the unnecessary invasive procedures among individuals with benign nodules. Clinical trial information: NCT03181490, NCT03651986. Liquid biopsy in combination with PET/CT versus PET/CT alone in diagnosis of lung cancer in small nodules. *First Author: Rajesh Shah, VA Palo Alto Health Care System, Palo Alto, CA*

Background: In the National Lung Screening Trial, almost two-thirds of patients that underwent an invasive procedure for diagnosis had benign findings, suggesting a significant number of patients were exposed to risk that could be avoided. Currently, to help distinguish malignant from benign nodules, Positron Emission Tomography/Computed Tomography (PET/CT) is used. However, PET/CT can be limited in its use for lesions less than 2 cm in size. The detection of circulating tumor DNA (ctDNA) and cell-free DNA (cfDNA) in the blood stream via liquid biopsy has demonstrated potential as a non-invasive approach in both screening and diagnostic tests. The purpose of this study is to assess whether combining liquid biopsy with PET/CT findings can better detect malignancy in small lung nodules 6-20 mm in size compared to PET/CT alone, possibly allowing earlier cancer detection and reduction in unneeded invasive diagnostic testing. **Methods:** This was a single-center prospective observational study for which the primary objective was to compare liquid biopsy plus PET/CT to PET/CT alone for detection of lung cancer in patients with newly discovered or newly growing solid lung nodules. Patients with nodules 6-20 mm in size who were scheduled to undergo 18F-Fluorodeoxyglucose PET/CT also underwent blood collection for plasma ctDNA/cfDNA testing using an amplicon-based next-generation sequencing assay incorporating molecular barcodes for error suppression. Tumor diagnosis was based on resolution of the nodule or tissue biopsy. For liquid biopsy, a multiomic model previously built using (1) cfDNA methylation frequencies, (2) ctDNA abundance, (3) somatic ctDNA mutations, and (4) cfDNA fragment size ratio was used to predict malignancy. For imaging, lesions with a maximum standardized uptake value of 2 or greater were considered malignant. **Results:** Between December 2021 and November 2022, 24 patients were enrolled. Of these, 13 had a definitive diagnosis and were included in the analysis with the remainder still undergoing serial imaging follow-up. Of the 13 patients, 9 were biopsy or surgically proven to be malignant, and 4 were benign based on biopsy or resolution. The median (IQR) nodule size was 14 mm (8-15). The sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) for PET/CT were 0.67, 1, 1, and 0.57, respectively. For multiomic liquid biopsy alone, these values were the same. However, combining multiomic liquid biopsy and PET/CT, the sensitivity, specificity, PPV, and NPV were 0.89, 1, 1, and 0.8, respectively. **Conclusions:** Combining multiomic liquid biopsy with PET/CT results in improved sensitivity for the detection of early-stage malignant solid lung nodules by 33% compared to PET/CT alone with no reduction in specificity. This could result in improved selection of patients requiring biopsy. Further evaluation with a larger cohort is needed to confirm the findings. Research Sponsor: Lucence Health, Inc.

Large retrospective validation study of metabolomic biomarkers for resectable lung cancer detection and risk assessment. *First Author: Philippe Joubert, Quebec Heart and Lung Institute Research Center, Quebec, QC, Canada*

Background: Cancer can be regarded as a metabolic disease and many studies published aimed at identifying robust metabolites for lung cancer diagnosis using plasma samples. Regardless of the lung cancer staging, most of these studies were performed on relatively small sample sizes. The purpose of this study is to validate whether a panel of metabolomic biomarkers would improve risk assessment for lung cancer detection in 800 plasma samples from patients that underwent lung cancer resection, and to understand the potential role and intersection between lung cancer and other lung diseases. **Methods:** A blinded case-control study was performed using plasma samples from 586 patients with biopsy-confirmed lung cancer compared to 214 controls from the same institutional biorepository to evaluate the performance of a 5+ metabolites biomarker panel for lung cancer detection. The control group consists of 90 healthy individuals and 124 with other non-neoplastic lung diseases including asthma, COPD, bronchiectasis and COVID. The lung cancer subgroups include early-stage (Stage I & II) adenocarcinoma and squamous cells carcinoma, advanced stages (Stage III & IV) NSCLC and neuroendocrine tumors. In this study, plasma metabolic profiles were performed using different liquid chromatography methods coupled with a targeted and quantitative mass spectrometry approach. Metabolite concentrations, clinical data, and smoking history were used to develop logistic regression models to identify lung cancer at different stages using significant biomarkers. The area under the receiver operator characteristic curves (AUC), sensitivities and specificities at selected cut off points were calculated for each cancer stage. **Results:** Univariate and multivariate statistical analyses confirmed the performance of our 5+ metabolites panel (β -HBA, PC aa C38:0, PC ae C40:6, citric acid, tryptophan, and etc.) as being significantly different between controls and lung cancer cases. Linear regression model using metabolites alone yielded an AUC of 0.89 for lung cancer at all stages. When adding smoking status, the models achieved an AUC of 0.91 with sensitivity of 91% and specificity over 78% using a risk prediction threshold of 0.657. **Conclusions:** The blood-based metabolites panel validated on our current retrospective study exhibited robust performance for resectable lung cancer detection and risk assessment. This metabolomic panel assay demonstrates potential diagnostic applications and clinical utility for patient selection that require further follow-up and confirmation using LDCT or other lung imaging modalities. The inclusion of other lung diseases in the control group is more representative of a real clinical setting suggesting that this blood-based assay could be offered to the medical community. Further studies may also confirm its utility in the context of a lung cancer screening program. Research Sponsor: NRC-IRAP #980330; CIHR-IRSC grant # 0590008438; BioMark Diagnostics Inc.

MYC amplification segment-size mutual exclusivity analysis with other oncogenic events in a pan-cancer sequencing cohort. *First Author: Matteo Repetto, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: MYC gene alterations resulting in increased copy number are recurrent oncogenic alterations across human malignancies. Presently no clear data exists to aid in interpreting MYC amplification characteristics for identifying MYC-dependent tumors. **Methods:** Analysis was conducted on a center-wide cohort of 68,920 tumor-normal matched samples from pediatric and adult patients sequenced with an FDA-authorized targeted sequencing panel (MSK-IMPACT). To ascertain tumor content, ploidy and allelic specific gene copy number, tumor-normal samples were analyzed with FACETS. Samples with tumor purity <20% were excluded. MYC amplification was defined as total copy number (TCN) minus ploidy ≥ 4 . All samples were queried for presence of concurrent oncogenic or likely-oncogenic alterations based on OncoKb annotation. Co-occurrence (Co) and mutual-exclusivity (Me) analysis between MYC amplification according to segment size and other oncogenic alterations was performed with DISCOVER (false discovery rate threshold of 0.01) for each tumor type. **Results:** After removing low-quality samples ($n=19,010/68,920$), 49,910 samples were included in the analysis. 3,219 (6.4%) samples harbored MYC amplification, with segment size ranging from less than 100Kb to more than 100Mb, with 38% samples displaying focal amplifications shorter than 10 Mb and 62% broad amplifications longer than 10 Mb. TCN was inversely correlated with segment size ($R = -0.34$, $p=2.2e^{-16}$). Triple-negative breast cancer (13.3%), hepatocellular carcinoma (8.7%), neuroendocrine tumors of the rectum (8.3%), high-grade serous ovarian cancer (7.6%) and large cell neuroendocrine carcinomas of the lung (6.7%) had the highest prevalence of MYC amplification without concurrent potentially driver oncogene mutations, amplifications or fusions. CoMe analysis demonstrated mutual exclusivity of MYC gene amplification regardless of segment size with most major tumor-type specific oncogenic events. All MYC amplifications were mutually exclusive with MET splice variants and mutations ($q < 0.001$) and KRAS mutations ($q < 0.001$) in lung adenocarcinoma (LUAD), FGFR3 mutations ($q < 0.001$) and fusions ($q < 0.001$) in bladder cancer, PTEN mutations ($q < 0.001$) in hormone receptor-positive breast cancer, KRAS mutations ($q < 0.001$) in colorectal cancer and CDK4 amplifications ($q < 0.001$) in sarcomas. Broad MYC amplifications were mutually exclusive with RET, ROS1 and ALK fusions in LUAD, while focal ones co-occurred with RET ($q=0.007$) and ALK fusions ($q < 0.001$) or secondary mutations ($q < 0.001$). **Conclusions:** This dataset defines a subgroup of MYC amplified cancers without co-occurring drivers and further subdivided by segment size, providing information that may help better identify patients for trials of novel MYC-directed therapies. Genomic characterization of *FGFR*-altered solid tumors using a clinically annotated pan-cancer repository. *First Author: Noura J. Choudhury, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Somatic mutations, gene fusions, and amplifications in *FGFR1/2/3* are found across solid tumors. *FGFR2/3* fusions and select mutations have matched FDA-approved therapies in intrahepatic cholangiocarcinoma (ICCA) and urothelial carcinoma (UC). Identification of *FGFR*-altered tumors may inform patient selection for future drug development. **Methods:** All solid tumors that underwent MSK-IMPACT, a DNA-based NGS panel with coverage of *FGFR1-4*, were queried for *FGFR1-4* alterations. *FGFR* structural variants (SV) were manually reviewed and compared to RNA sequencing data (RNAseq, Archer FusionPlex) when available. Alteration (alt) frequencies of ICCA and UC tumors with target *FGFR* alt (level 1 OncoKB evidence), non-target *FGFR* alt (lacking level 1 evidence) and no *FGFR* alt were compared using chi-squared tests and odds ratios. Euclidean distance was calculated between cohorts based on prevalence of frequently altered genes (>5%). Consensus clustering was used to identify optimal number of clusters and compare genomic profiles between clusters. **Results:** At data lock of June 1, 2022, 5695 tumors among 48,416 patients harbored an *FGFR* alteration (11.8%). *FGFR* SV were identified in 347 tumors on MSK-IMPACT. Of these 111/140 (79.2%) with RNAseq were positive. 98% (203/207) of SV without RNAseq were considered likely activating (canonical SV, n=125; in-frame inclusive of kinase domain, n=78). The most frequent fusion was *FGFR3-TACC3* (n=124), followed by fusions unique to a single patient (n=100). Fusions were discovered in >15 tumor types, most frequently in ICCA (n=93), UC (n=50) and high-grade glioma (n=44). Among 1176 ICCA tumors, 9.9% (n = 117) had a target *FGFR2* fusion. Target *FGFR* tumors were enriched for concurrent *BAP1* alt (18%) compared to tumors without *FGFR* alt (58/969, 5.9%) and with non-target *FGFR* alt (7/90, 7.8%). Both groups without target alt were enriched in *TP53*, *ARID1A* and *IDH1* alts compared to target group. Four optimal genomic clusters were identified, with *FGFR2* fusions enriching in cluster 4 (29% vs 3%, 7% and ≤1%); 21 non-target *FGFR* alt were also in cluster 4. Among 2720 UC tumors, 24.7% (n=672) had target *FGFR* alt (select *FGFR3* mutations and *FGFR2/3* fusions). Three genomic clusters were identified, with target *FGFR* enriched in cluster 3 (42% target *FGFR* vs cluster 1: 11%, cluster 2: 18%) and non-target *FGFR* alterations enriched in cluster 1 (13% vs. cluster 2: 9.4%, cluster 3: 7.0%); 68 non-target *FGFR* alt were in cluster 3. Tumors with non-target *FGFR* alterations and no *FGFR* alterations had close genomic association (Euclidean distance: 0.18). **Conclusions:** Activating *FGFR* fusions, which occur across tumor types with marked diversity in fusion partners, present opportunities for future drug development. Non-target *FGFR* alterations in ICCA and UC, particularly those that cluster with target *FGFR* alterations, may be candidates for future *FGFR*-targeted strategies. Research Sponsor: None.

Poster Session

Aggregated analysis of 1,000 patients with cancer to assess the benefits of integrated whole exome and whole transcriptome sequencing. *First Author: Konstantin Chernyshov, BostonGene, Waltham, MA*

Background: As the field of precision medicine rapidly expands, clinical oncologists are turning to integrated whole transcriptome (WTS) and whole exome (WES) sequencing to identify the most effective treatment options. We performed a retrospective cohort analysis of WES and WTS data from 1,000 patients with 15 major cancer types to define meaningful relationships between transcriptomic-based tumor microenvironment (TME) subtypes and pan-cancer genomic biomarkers, such as tumor mutational burden (TMB) and microsatellite instability (MSI) status, that are prognostic for outcome and predictive for checkpoint inhibitor response. **Methods:** We retrospectively analyzed WES/WTS data from cancer patients for biomarkers using our internal bioinformatics workflow. Using transcriptome-based methods described by Bagaev et al., samples were classified into one of four TME subtypes prognostic of patient outcome (*Cancer Cell*, 2021). Statistical analysis consisted of Spearman's rank correlation. **Results:** Comprehensive WES and WTS analysis provided by the BostonGene Tumor Portrait Test identified biomarkers based on accepted guidelines specific to the patient's cancer type in 22.5% of cases. In addition, we revealed a correlation between WTS and IHC for cancer-relevant genes, including *CDX2* (R = 0.68), *KRT7* (R = 0.85), *KRT20* (R = 0.86), *NECTIN4* (R = 0.81), and *TACSTD2* (R = 0.81), indicating WTS may also be beneficial for estimating protein expression levels for cancer-specific biomarkers. Analysis of the TME showed that Fibrotic (F) and Immune Desert (D) were the most common subtypes. The F and D subtypes were linked to poor prognosis and were especially prevalent in liver and pancreatic cancers, respectively. TMB-high and MSI status were more prevalent in the immune-enriched subtypes, Immune-Enriched, Fibrotic (IE/F) and Immune-Enriched, Non-fibrotic (IE), over the less favorable F and D subtypes. The frequency of TMB-high and MSI status also differed in both IE subtypes associated with favorable prognosis, suggesting that TME subtyping provides additional prognostic power independent of TMB-high and MSI status. **Conclusions:** A deep interrogation of our integrated approach to genomic and transcriptomic profiling confirmed the advantages of a unified molecular analysis of tumor traits. We identified clinically significant biomarkers based on molecular features, demonstrated additional capabilities of TME analysis, and illustrated significant correlations between WTS and IHC data. These findings indicate that comprehensive WTS and WES analysis can assist clinicians in optimizing treatment plans as the landscape of personalized therapy continues to grow. Research Sponsor: None.

Frequency of pan-cancer biomarkers across conserved TME subtypes.

TME subtype	F, 34.0%	D, 30.7%	IE/F, 18.0%	IE, 17.3%	Total

Detecting early stage breast cancer using low-depth cell-free DNA fragmentomics: A multi-center cohort study. *First Author: Jiaqi Liu, Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China*

Background: Breast cancer (BC) has contributed to the most cancer-related mortalities among females in 2020. Early detection using breast imaging methods, such as mammography and ultrasound, has significantly improved patients' survival. However, these early-screening methods suffer from high false-positive rates, resulting in many unnecessary biopsies which add to patients' discomfort. Cell-free DNA (cfDNA) fragmentomics assays have recently illustrated prominent abilities for detecting various cancer. In this multi-center prospective cohort study, we aim to develop a non-invasive liquid biopsy assay utilizing cfDNA fragmentomics and machine learning for detecting early-stage BC patients. **Methods:** We recruited 402 female patients (234 with BC and 168 with benign nodules [BN]) from the Yantai Yuhuangding Hospital (training cohort, N = 193, 91 BC and 102 BN) and the Cancer Hospital of the Chinese Academy of Medical Sciences (independent validation cohort, N = 209, 143 BC and 66 BN). Surgical or core needle biopsies were performed for all 402 patients following positive breast imaging results by mammography and ultrasound. Each patient's malignant or benign status was then pathologically confirmed using the tissue specimen. Women with negative biopsy results were excluded from breast cancer through a 6-month follow-up. The fragmentomics profiles, which were generated using plasma cfDNA WGS data (~5X), were used by our machine-learning algorithm. An automated machine learning approach was deployed to optimize base models before being ensemble into the final predictive model. **Results:** Our predictive model showed excellent performance in discriminating BCs from BNs, reaching an Area Under the Curve (AUC) of 0.816 and 0.811 in the training cohort (5-fold cross-validation) and the independent validation cohort, respectively. It achieved 74.1% sensitivity (95% CI: 66.1-81.1%) at 81.8% specificity (95% CI: 70.4-90.2%) in the validation cohort. In a potential clinical setting, our model could detect 53.0% (95% CI: 40.3-65.4%) false positives from the breast imaging methods at a targeted 90% sensitivity (89.5%, 95% CI: 83.3-94.0%), which could theoretically reduce more than half of the unnecessary biopsies. Moreover, our model illustrated great predictive power (AUC = 0.830) among small nodules (≤ 1cm), which were difficult to distinguish by the traditional imaging methods (AUC = 0.690). Finally, our model maintained its predictive power during a down-sampling process, even using 2X WGS data in the independent validation cohort (mean AUC: 0.789, 0.781-0.798). **Conclusions:** Our non-invasive liquid biopsy assay, which utilized low-depth cfDNA fragmentomics profiling and machine learning, can distinguish malignant nodules from benign nodules. The highlight of our model is its ability to prevent unnecessary biopsies among patients with false positive breast imaging results. Alternative allele frequency recalibration after NGS data analysis. *First Author: Maxim Ivanov, OncoAtlas LLC, Moscow, Russian Federation*

Background: With the spread of NGS in routine clinical practice data analysis methods actively evolve to increase and refine information yield. Not much attention is given to variant allele fraction (VAF) estimation though it impacts clinical insignificance of subclonal somatic variants and identification of variant origin. **Methods:** Real-world sequencing data of 2379 samples (including 781 tumor-only and 1598 blood-only sequencing datasets) obtained via amplicon-based sequencing was used for the retrospective analysis of variant allele frequency estimation of identified genetic variants employing different methods including ITVC, SiNVICT, Mutect2 and SGA. Original method (AODvAF) utilizing alignment-free algorithm based on wild-type and alternative genome subsequence abundance estimation was developed and compared with the original output from NGS data analysis software. Anticipated VAF estimation was based on analyte type and database annotation. **Results:** Across 3447 identified potentially germline variations (PGV) VAF estimations provided by ITVC, SiNVICT and SGA were highly correlated (Pearson correlation coefficient [PCC] 1.00), while Mutect2 and AODvAF demonstrated discordant results (Mutect2/AODvAF vs ITVC PCC 0.87/0.82). VAF miscalculation defined by absolute difference between estimated and anticipated VAF of 10% and more was noted for 25%, 26%, 22%, 15% and 7% for ITVC, SiNVICT, SGA, Mutect2 and AODvAF respectively. Across 308 pathogenic BRCA1, BRCA2, PALB2 mutations identified in blood-only sequencing 25, 15, 16, 10 and 5 were characterized by VAF of 30% and lower based on ITVC, SiNVICT, SGA, Mutect2 and AODvAF estimations respectively (54, 49, 33, 51 and 9 for VAF 40% and lower), which may lead to misinterpretation of these variants as post-zygotic. Automatic in-silico annotation of variant origin (germline vs somatic) based on ISOWN was correct for 89%, 91%, 94%, 93% and 98% of these variants. Variant origin for 55 pathogenic variants of genes associated with hereditary cancer syndromes identified in tumor-only sequencing was verified by Sanger sequencing. Cohen's kappa coefficient for variant origin discrimination (Sanger vs in-silico prediction) was 0.91, 0.90, 0.91, 0.94 and 0.97 based on VAF provided by ITVC, SiNVICT, SGA, Mutect2 and AODvAF respectively. **Conclusions:** Accurate VAF calculation allows precise variant origin identification and impacts interpretation of variants. Developed method allows correction of VAF after NGS data core analysis. Research Sponsor: The research was supported by the Russian Science Foundation (project No. 22-75-10154; <https://rscf.ru/project/22-75-10154/>).

Multimodal machine learning analysis of more than 220,000 tumor profiles to diagnose molecular and morphological subtypes of cancer. *First Author: Jim Abraham, Caris Life Sciences, Phoenix, AZ*

Background: The diagnosis of a malignancy is typically informed by clinical presentation and tumor tissue features including cell morphology, immunohistochemistry, and molecular markers. Additionally, multi-omic approaches (Abraham 2021 Transl Oncol) and deep learning models using digital pathology (da Silva 2021 J Pathol) have augmented expert pathologists and led to improved diagnoses but are often not employed together on the same patient. The opportunity exists for a truly multimodal, multi-omic machine learning classifier that comprehensively assesses all aspects of a tumor from the molecular underpinnings to the morphological and histological phenotypic presentation to provide the most accurate diagnosis while at the same time providing predictive biomarker data from the same specimen. **Methods:** Whole transcriptome data from 220,246 tumor profiles, large panel and whole exome data from over 170,000 tumor profiles, and digital pathology features from over 50,000 tumors were used to construct a multi lineage classifier. The classifier was trained on 256 Oncotree classifications corresponding to established WHO diagnoses where a tumor of each class has been observed at least 30 times in our dataset. The dataset was split 50% for training and the other 50% for testing. UMAP was employed for dimensionality reduction, and ensemble models were used for making the final calls. The performance of the classifier was evaluated by comparing with traditional pathologist-directed diagnostic workup. **Results:** Tumor lineage classifiers predicted the correct classifications where the primary site was known with accuracies ranging between 97% and 100% when using the 32 highest level Oncotree categories corresponding to human tissues. Accuracy on the most granular Oncotree categories varied with many between 90 and 95%. When applied to Cancer of Unknown Primary (CUP) cases (n = 3589), an unequivocal Oncotree classification could be obtained over 90% of the time. **Conclusions:** Combining multi-omic and digital pathology information into a multimodal artificial intelligence platform can provide comprehensive information to pathologists to aid in diagnosis. This tool can be used to meet an unmet clinical need to define the lineage of CUP cases, which when coupled with biomarker data, will provide an opportunity to examine whether this information can be used to improve the outcomes of patient with CUP. Phase 1/1b study of SY-5609, a selective and potent CDK7 inhibitor, in advanced solid tumors and in 2L/3L pancreatic ductal adenocarcinoma (PDAC) in combination with gemcitabine +/- nab-paclitaxel. *First Author: Babar Bashir, Sarah Cannon Research Institute and Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA*

Background: SY-5609 is an oral, highly selective and potent noncovalent inhibitor of CDK7, a key regulator of cell cycle progression and transcription. In this Phase 1 FIH study (NCT04247126), the single agent (SA) continuous daily dosing (CDD) regimen maximum tolerated dose (MTD) was 3 mg/day. Subsequently, enhanced tolerability was demonstrated using an intermittent 7 day on/7 day off (7/7) schedule at higher dose levels (Sharma 2021). SY-5609 preclinical data and early clinical activity provided the rationale for evaluating SY-5609 + gemcitabine (gem) +/- nab-paclitaxel (np) in PDAC. Herein, we present data from the ongoing SA dose escalation and SY-5609 + gem +/- nab-paclitaxel (np) safety lead-ins (SLIs). **Methods:** The 7/7 schedule was used to further evaluate SA escalation in pts with select solid tumors. In the PDAC combination SLIs, SY-5609, starting with a dose of 4 mg, is escalated using the 7/7 schedule in combination with biweekly gem (1000 mg/m²) +/- np (125 mg/m²). Evaluations included safety, clinical activity (RECIST v1.1), PK, and induction of peripheral blood PD marker *POLR2A* (Papadopoulos 2020). **Results:** As of 13 Jan 2023, 87 pts have been enrolled (70 SA, 14 SY-5609 + gem, 3 SY-5609 + gem/np), including 30 pts across the 4, 5, 6, 7, and 10 mg SA 7/7 cohorts included in the safety summary. MTD for the 7/7 schedule has not been reached. The 15 mg SA cohort is now enrolling. Most SA 7/7 AEs were low-grade; AEs included (>20%) nausea, diarrhea, fatigue, anorexia, and thrombocytopenia. No new safety signals were observed in the SY-5609 4 mg and 5 mg + gem and SY-5609 4 mg + gem/np cohorts; 1 pt (SY-5609 5 mg + gem) had a DLT of Gr3 diarrhea. The 10 mg + gem cohort is now enrolling. Most SY-5609 + gem +/- np AEs were low grade. AEs in the SLIs were consistent with the safety profile of either SY-5609 or gem +/- np and included (>20%) fatigue, anorexia, nausea, abdominal pain, and constipation. In the SA cohorts (response-evaluable, n=29), 100% (3/3) of pts in the 10 mg 7/7 cohort had stable disease (SD) as the best response, compared to 19% (5/26) SD rate in 4 to 7 mg SA 7/7 cohorts. Disease control rate in the combination SLIs (response-evaluable, n=11) was 45% (5/11), including 1 confirmed partial response (4 mg + gem) in a patient with liver metastases who had a reduction in CA 19-9 from 60,357 U/mL to 968 U/mL, and SD in 4 pts (3 in 5 mg + gem, 1 in 4 mg + gem/np). SA and SLI PK data support an emerging exposure-activity relationship. *POLR2A* PD marker data from SA and SLI cohorts correlate with exposure. **Conclusions:** To date, intermittent dosing of SY-5609 on the 7/7 schedule has acceptable tolerability alone and in combination with gem +/- np. Encouraging preliminary clinical activity and the emerging exposure-activity relationship supports the ongoing escalation of SY-5609 in SA and combination SLI cohorts; updated results will be presented. Clinical trial information: NCT04247126. Research Sponsor: Syros Pharmaceuticals.

In silico approaches to patient selection: Credentialing elraglusib as a novel treatment in metastatic melanoma resistant to checkpoint inhibitors. *First Author: Joseph McDermott, Lantern Pharma, Dallas, TX*

Background: Elraglusib (9-ING-41), a novel inhibitor of GSK-3 β , has been evaluated in >230 patients (pts) with advanced malignancies including metastatic melanoma in the 1801 phase 1/2 trial (NCT03678883). Pts with melanoma treated with single agent elraglusib demonstrated clinical benefit including a durable complete response despite multiple prior lines of therapy including checkpoint inhibitors (CPI). **Methods:** We collected data from numerous -omic modalities in the 1801 trial to characterize markers of elraglusib response with bioinformatics and machine learning (ML). Genomic panels were collected on 105 pts. The most frequent tumor types included colorectal cancer (n=35), pancreas (n=31), lung (n=15) and metastatic melanoma (n=12). Pts were treated with elraglusib as a single agent or in combination with chemotherapy. Pathway based features were generated by quantifying the percent of each Reactome pathway that was mutated. These pathway features were iteratively evaluated for their performance in shallow neural networks predicting patient RECIST with each model using 5-15 randomly selected features at a time. Publicly available genomic data from an anti-PD-1 trial in patients with metastatic melanoma (Hugo et al., 2017) was transformed into pathway-based features and input into the final model to predict elraglusib response in this population. **Results:** Our final pathway based genomic model for elraglusib response performed with a training accuracy of 93% and a test accuracy of 88% on the 1801 patients. We then tested the model on metastatic melanoma patients who were treated with anti-PD-1 therapy. We found that patients from Hugo et al. were predicted to respond to elraglusib (22/26). In addition, most patients with tumors resistant to anti-PD-1 therapy were also predicted to respond to elraglusib (10/12). Finally, we tested the model on metastatic melanoma patients treated with elraglusib in the 1801 study that had failed CPI and for whom -omic data was available. The model correctly identified 5/5 patients that demonstrated clinical benefit (1 CR, ongoing>1400 days; 4 prolonged OS of 107, 256, 357, and 556 days). **Conclusions:** We applied robust in-silico modeling developed using 1801 trial data to develop a rationale for the development of elraglusib in the treatment of metastatic melanoma including patients that failed or were refractory to anti-PD-1 treatment. This model correctly identified metastatic melanoma patients in 1801 with good clinical outcomes that had failed prior CPI treatment. Further, we present this in silico approach as a robust way to repurpose prior clinical study genomics and ML modeling for population enrichment during the clinical development of novel drugs. Clinical trial information: NCT03678883. Research Sponsor: Actuate Therapeutics Inc.

Tolerability and preliminary activity of the potent, selective, oral CDK7 inhibitor SY-5609 in combination with fulvestrant in patients with advanced hormone receptor-positive (HR+), HER2- breast cancer (BC). *First Author: Dejan Juric, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: SY-5609 is an oral, reversible, potent, and selective inhibitor of CDK7, a key regulator of transcription and cell cycle, currently under investigation in a Phase 1 study in patients (pts) with select advanced solid tumors (NCT04247126). Single agent (SA) dose escalation is ongoing, using a 7 days on/7 days off (7/7) dosing schedule that optimized tolerability (Sharma 2021) and showed a correlation of antitumor activity with higher exposures. SY-5609 may address multiple CDK4/6 inhibitor resistance mechanisms and potentiates SERD activity in CDK4/6 inhibitor-resistant xenograft models (Johannessen 2019). In this Phase 1 study, it was combined with the SERD fulvestrant in advanced HR+, HER2- BC pts who are refractory to CDK4/6 inhibitor + hormonal therapy. **Methods:** Evaluation of SY-5609 + fulvestrant began with a SY-5609 dose that had cleared the SA dose-limiting toxicity (DLT) evaluation period. SY-5609 was dosed once daily at 3 mg or 4 mg on a 21 days on/7 days off (21/7), 5 days on/2 days off (5/2), or 7/7 schedule and was escalated using a 3+3 design, guided by safety and reports of Cycle 1 qualifying safety events (QSEs), which matched SA DLT criteria. Fulvestrant was dosed at the approved dose/schedule. Safety and tolerability of SY-5609 + fulvestrant and SY-5609 PK were secondary objectives. Exploratory objectives included preliminary antitumor activity (RECIST v1.1). **Results:** As of 12 Oct 2022, 14 pts (median age 63; range 46 - 83) received SY-5609 at 3 mg on a 21/7 schedule (n=8) or at 4 mg on a 5/2 (n=5) or 7/7 (n=1) schedule in combination with fulvestrant. Pts had advanced disease, including 79% with liver lesions, and a median of 5.5 (range 2 - 12) prior therapies; 100% had prior hormonal therapy, including 71% who received prior fulvestrant. The majority of adverse events (AEs) were low-grade and reversible. Related AEs ($\geq 10\%$) included nausea, diarrhea, fatigue, thrombocytopenia, and hot flush. Related $\geq$ Grade 3 AEs were reported in 3 pts (21%), including 1 QSE of Grade 3 thrombocytopenia at 4 mg 5/2. The highest tolerated dose in combination with fulvestrant was not reached. Stable disease (SD) was observed in 5/12 (42%) evaluable pts. SD with tumor shrinkage and/or SD >6 months was observed in 4 pts previously treated with fulvestrant and in pts with liver lesions and/or TP53 mutations. SY-5609 exposure in combination with fulvestrant appeared comparable to SA at Day 1. **Conclusions:** SY-5609 + fulvestrant has an acceptable safety profile consistent with SA SY-5609 or fulvestrant. The mechanistic rationale for CDK7 inhibition in HR+, HER2- BC and the tolerability and encouraging early activity in this heavily pretreated population support future investigation of SY-5609 in combination with SERDs, including defining the maximum tolerated combination dose using the 7/7 SY-5609 schedule. Clinical trial information: NCT04247126. Research Sponsor: Syros Pharmaceuticals.

Poster Session

Initial results of dose finding in a first-in-human phase 1 study of a novel Claudin 6 (CLDN6) targeted antibody drug conjugate (ADC) TORL-1-23 in patients with advanced solid tumors. *First Author: Gottfried E. Konecny, University of California Los Angeles Medical Center, Santa Monica, CA*

Background: CLDN6, a member of the claudin family of tight junction proteins, is expressed at high levels in multiple human malignancies and has little to no expression in normal tissues. This expression profile makes CLDN6 an ideal target for development of new therapeutics. TORL-1-23 is first-in-class ADC targeting the tumor-specific antigen CLDN6. **Methods:** TORL123-001 (NCT05103683) is an ongoing, 2-part, first in human study to characterize the safety, tolerability, dose-limiting toxicities (DLTs), maximum tolerated dose (MTD), and recommended phase 2 dose (RP2D) of TORL-1-23 monotherapy in participants with advanced solid tumors. Serum pharmacokinetics (PK), immunogenicity and clinical efficacy are also assessed. TORL-1-23 is administered as a 30-minute IV infusion once every 3 weeks in 21-day cycles. During Part 1 (Dose Escalation), cohorts of 1 to 6 participants are evaluated at each dose level according to an accelerated titration design. In Part 2 (Dose Expansion), several cohorts of patients with CLDN6-expressing cancers will be evaluated to confirm the RP2D in ovarian cancer, NSCLC, and other CLDN6-expressing cancers using a CLDN6 IHC companion diagnostic. **Results:** As of 01FEB2023, 22 patients with ovarian (n=18), testicular (n=3), and endometrial (n=1) cancers were enrolled and treated across 8 dose levels ranging from 0.2 to 2.4 mg/kg IV every 3 weeks. 95% of pts had received ≥ 3 prior lines of treatment in the metastatic setting. The most common treatment-related adverse events were Gr1/2 fatigue (n=5), Gr1 peripheral neuropathy (n=4), and Gr1 nausea (n=3). No DLTs have been reported and no dose reductions have been required. Preliminary PK data demonstrate sustained exposure of TORL-1-23 ADC over the 21 day dosing interval and low levels of serum MMAE indicating low off-target MMAE exposure outside of tumor. Partial responses (PR) were observed in 4/17 efficacy evaluable participants with CLDN6+ disease (3 ovarian, 1 testicular). Dose escalation is ongoing and updated results will be presented. **Conclusions:** TORL-1-23 has a favorable safety/tolerability profile and PK characteristics with preliminary antitumor activity in pts with heavily-pretreated CLDN6-expressing ovarian and testicular cancers. Doses above the historic MTD for MMAE containing ADCs may be explored given the safety/tolerability and PK data observed up to 2.4 mg/kg. Dose finding is ongoing to identify the MTD and optimal doses for subsequent development. Clinical trial information: NCT05103683. Research Sponsor: TORL Biotherapeutics.

First-in-human dose-escalation study of NBF-006, a novel investigational siRNA targeting GSTP, in patients with non-small cell lung, pancreatic, or colorectal cancer. *First Author: Anthony W. Tolcher, Texas Oncology-San Antonio Babcock NEXT Oncology, San Antonio, TX*

Background: Glutathione S-transferase Pi (GSTP) has an important role in detoxification and anti-oxidative damage response. Additionally, GSTP has a chaperone function which regulates key oncogenic pathways such as the KRAS and JNK pathways. Targeting multiple pathways could lead to more effective therapy than agents inhibiting single downstream kinase pathways (i.e., a MEK inhibitor), as alternative or redundant pathways could compensate for the inhibition of a single kinase. NBF-006 is a novel drug product containing a GSTP siRNA encapsulated within a lipid nanoparticle. It has been designed to deliver siRNA to tumors of the lung and common sites of metastatic spread (liver and marrow) which has been demonstrated in preclinical efficacy models. **Methods:** NBF-006-001 is a first-in-man (FIM) dose escalation study evaluating safety, tolerability, and PK of NBF-006 administered intravenously over 70 minutes, QW4 followed by a 2-week rest period in patients with advanced non-small cell lung (NSCLC), pancreatic (PANC), or colorectal cancer (CRC). **Results:** Twenty-one patients (11 NSCLC, 5 CRC, and 5 PANC) received treatment in a standard 3+3 dose escalation design (0.15 mg/kg [n=2], 0.3 mg/kg [n=3], 0.6 mg/kg [n=3], 1.2 mg/kg [n=6], and 1.6 mg/kg [n=7]). NBF-006 was well tolerated with no treatment-related grade 4-5 AEs, SAEs nor DLTs. Only one grade 3 event (WBC decrease) was assessed as possibly related. The most common NBF-006-related AEs were Grade 1 or 2 arthralgia, diarrhea, fatigue, and vomiting (11% each). There was no dose relationship in the number of AEs or any observed AEs. No meaningful complement activation, cytokine elevation nor ADA response has been observed to date (20 patients). One patient had 2 infusion related reactions (Grade 1 and 2). PK analysis indicated a terminal half-life ranging from 26 to 55 hours with no accumulation. Cmax and AUC demonstrated dose-proportionality up to 1.2 mg/kg and no additional increase in exposure at 1.6 mg/kg. NSCLC patients had an average and median number of prior lines of therapy of 4 and 3, respectively, with a range from 1-7 prior lines. One patient with NSCLC (treated at 1.6 mg/kg) experienced a durable partial response and progressed after ten months on the study. Four additional patients with NSCLC experienced stable disease, and two of these stayed on study treatment for >6 months (both treated at 1.2 mg/kg). One patient remains on treatment. CRC and PANC patients had an average/median of 4 and 3 prior lines, respectively. In CRC and PANC, stable disease for 24 weeks was the best response (n=1 each). **Conclusions:** This FIM study with NBF-006 demonstrated a favorable safety profile with early signs of antitumor activity in NSCLC. No DLTs or treatment-related SAEs were observed. Dose expansion in NSCLC is ongoing and will not be presented. Clinical trial information: NCT03819387. Poster Session

A phase 1/2, first-in-human trial of ZB131, a novel antibody targeting cancer-specific plectin (CSP) in advanced solid tumors. *First Author: David Sommerhalder, NEXT Oncology, San Antonio, TX*

Background: Cancer-Specific Plectin (CSP) is a novel pro-tumorigenic target that is selectively expressed on the surface of tumors, while absent from benign tissue. CSP is highly expressed in many solid cancers, particularly pancreatic (PC), cholangiocarcinoma (CCA), and ovarian (OC). ZB131 (Zielbio), is a humanized anti-CSP IgG1 monoclonal antibody that binds specifically to CSP on the surface of tumor cells, rapidly internalizes and modulates key proliferative and cytoskeletal remodeling signaling pathways to decrease cancer cell growth and increase the recruitment of anti-tumor immune infiltrates. **Methods:** The dose escalation (3+3 design) and expansion are enrolling adult patients (pts) with advanced treatment-refractory solid tumors. ZB131 was administered IV over 60 minutes (without pre-medication) weekly. The starting dose of ZB131 is 0.3 mg/kg followed by 1, 3, 9, 15 and 30 mg/kg. Primary objectives are safety, tolerability, and maximum tolerated dose/determination of Phase 2 dose. Secondary objectives are preliminary efficacy (RECIST v1.1), Pharmacokinetic (PK) and pharmacodynamic parameters in blood and paired tumor biopsies. **Results:** As of 31 Jan 2023, 24 pts had enrolled (9 PC, 6 CCA, 4 OC, 5 other). The median age was 59.5 yr (range, 35 – 84) with a median of 4 prior lines of therapy. The median ZB131 treatment duration is 5.3 weeks (range, 1 – 33). No dose-limiting toxicities were observed up to the dose of 30 mg/kg which is currently enrolling. Treatment-related adverse events (TRAEs) were grade 1/2: nausea (n=6), fatigue (n=5), anemia (n=3), diarrhea (n=2), flu-like symptoms (n=2), and vomiting (n=2). Mild flu-like symptoms and nausea/vomiting were observed during or following infusion at doses of 9 mg/kg and above. Except for one episode of Gr 3 neutropenia at the 30 mg/kg dose, no other drug-related grade 3/4 TRAEs were reported. Five pts had stable disease range, 12 – 33 weeks (2 PC, 1 CCA, 2 OC), with a 43% decrease in CA-125 observed in one OC pt. The PKs are linear and dose-proportional for all dose levels evaluated (estimated $T_{1/2}$ of 6-9 days). No antidrug antibodies have been detected. **Conclusions:** Interim data from dose-escalation of this first-in-class, anti CSP antibody, demonstrates good tolerability with encouraging signs of activity and target engagement in heavily pretreated pts. Results support further clinical evaluation of ZB131 in dose-expansion cohorts including OC and including combination therapy with gemcitabine. Clinical trial information: NCT 05074472. Research Sponsor: Zielbio.

Characterization of MCL-1 in patients with colorectal cancer (CRC): Expression, molecular profiles, and outcomes. *First Author: Pooja Mittal, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Myeloid cell leukemia 1 (MCL-1) is a member of the BCL-2 protein family and is anti-apoptotic/pro-survival in function. Dysregulation of MCL-1 expression has been reported in several solid tumors, including lung and breast cancer. In CRC, MCL-1 has been associated with resistance to chemotherapeutic drugs and multi-kinase inhibitor regorafenib. Our study aimed to characterize the molecular features associated with MCL-1 gene expression in CRC. **Methods:** 28,576 CRC samples were analyzed by Caris Life Sciences (Phoenix, AZ) with WTS (Illumina NovaSeq) and NextGen DNA sequencing (NextSeq, 592 Genes and NovaSeq, WES). MCL-1 expression was stratified by quartiles where top quartile transcripts per million (TPM) were considered high (Q4) and bottom quartile low (Q1). Cell infiltration (CI) in the tumor microenvironment (TME) was estimated by RNA deconvolution analysis using QuantiSeq. Interferon-gamma and T-cell inflamed signatures were also calculated from RNA data. X2 and Fisher-Exact tests were used, and statistical significance was determined as a P-value adjusted for multiple comparisons ($q < 0.05$). Real world survival was obtained from insurance claims data and Kaplan-Meier estimates were calculated for molecularly defined patients. **Results:** MCL-1 expression was significantly increased in rectal tumors compared to other primary tumor sites (median TPM [mTPM] 20.8 vs 18.9 vs 18.7, in rectal vs left-sided vs right-sided, respectively, $q < 0.0001$). MCL-1 high tumors were associated with increased rate of PD-L1 IHC levels (Q1 vs Q4: 4.2% vs 9.7% [all CRC]; 3.7% vs 8.9% [pMMR/MSS], $q < 0.0001$), while MCL-1-low showed marginally increased rates of TMB-high (8.0% vs 7.0% [all CRC]; 3.3% vs 2.6% [pMMR/MSS], $P < 0.05$). MCL-1-high expression was associated with a higher T-cell inflamed signature and IFN score ($q < 0.0001$). MCL-1 high was associated with higher mutation rates of CDKN2A, BRCA2, KRAS and GNAS, while lower mutation rates of TP53, PIK3CA, PTEN, BRAF, APC, FBXW7, AMER1, SOX9, and SMAD2 and copy number amplifications in several genes ($q < 0.05$). MCL-1 high TME had higher CI of M1 and M2 macrophages, monocytes, B cells, NK cells, and T-reg infiltration, while dendritic cells and CD4+ T-cell were lower ($q < 0.05$). Patients with high MCL-1 expressing CRC had longer survival (Q4 vs Q1: 33.5 vs 24.8 months, HR 0.72, 95% CI 0.67-0.77, $P < 0.0001$) and longer time-on-treatment with regorafenib although with limited clinical benefit (Q4 vs Q1: 2.03 vs 1.06 months, HR: 0.67, 95% CI: 0.50-0.89, $P = 0.005$). **Conclusions:** Our data show a strong correlation between distinct immune biomarkers, TME cell infiltration and MCL-1 expression in CRC. Furthermore, increased tumor MCL-1 expression improved patient prognosis and treatment outcomes. These findings suggest a key clinical role for MCL-1 as an important modulator of anti-tumor immunity and TME and a potential biomarker in CRC. Intrapatent comparative efficacy of selective RET inhibitors using growth modulation index in patients with RET aberrant cancers. *First Author: Mohamed Alaa Gouda, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Selective RET inhibitors (RETi) have changed the paradigm for treatment of RET altered cancers. Current evidence on their efficacy comes from single-arm basket trials. In this study, we performed intrapatent efficacy comparison between approved selective RETi (selpercatinib and pralsetinib) and prior and/or subsequent therapies. We used growth modulation index (GMI) as a tool to compare efficacy, where a value of >1.33 is presumed a cutoff to establish superior efficacy. **Methods:** We included patients with RET-positive tumors who were treated at our institution as part of RETi clinical trials. We excluded patients with no other systemic therapy received before or after the RETi of interest. We also excluded patients who received both drugs to avoid overlapping efficacy bias, and patients who were treated for ≤ 30 days or had non-evaluable disease. Since some patients have been treated beyond progression or discontinued RETi due to intolerance, we used ratios for both time to treatment takeoff (TTT) and time to progression (TTP) to compare efficacy of RETi (at the RETi treatment line (n)) to prior therapy (n-1) and to subsequent therapy (n+1). GMI was defined as the ratio between TTT/TTT (n±1) or TTP to TTP (n±1). **Results:** We included 66 patients who received RETi and met our inclusion criteria [39 received selpercatinib and 27 received pralsetinib]. Most patients had GMI>1.33 using either TTT or TTP (61% (n=40) and 58% (n=38), respectively). The median GMI based on pre-RETi therapy was 2.1 and 1.6 (using TTT and TTP, respectively); while the median GMI based on post-RETi therapy was 4.9 and 4.4 (using TTT and TTP, respectively). Patients with GMI>1.33 were more likely to have PR as best response compared to patients with GMI<1.33 (85% vs 53%, p=0.005 using TTT; and 87% vs 54%, p=0.003 using TTP). GMI using TTT (n/n-1) was higher in patients with RET fusions compared to patients with RET mutations (3.7 vs 1.4, p=0.048). GMI using TTT and GMI using TTP(n/n+1) were lower in patients with WBCs <8 at baseline (2.6 vs 13.8, p=0.014; 2.6 vs 11.1, p=0.014, for TTT and TTP) and GI cancer diagnosis (0.4 vs 9.3, p=0.042; 0.4 vs 10.4, p=0.042, for TTT and TTP). **Conclusions:** Intrapatent efficacy comparisons are feasible using GMI calculations and provide a proof of concept on the favorability of selective RETi compared to other systemic therapies. Research Sponsor: N/A.

Comprehensive CRISPR-enabled functional genomics profiling to identify targetable cancer genes in primary acute myeloid leukemia (AML). *First Author: Stephane Corbel, Function Oncology, San Diego, CA*

Background: Acute myeloid leukemia (AML) is a life-threatening hematopoietic malignancy affecting both older and younger patient populations. Despite the approval of multiple new therapeutics during the past decade, including new targeted agents, treatment outcomes for AML remain poor, with < 10% 5-year survival in patients over 60 years of age, and < 50% 5-year survival in younger patients. Also, comprehensive genomic profiling (CGP) for common molecular lesions (e.g., FLT3 mutation) incompletely stratifies the patient population, indicating that a more comprehensive approach to personalized medicine could be of significant clinical benefit. To this end we developed Fx Heme, an in vitro functional genomics platform using CRISPR/Cas9 technology in primary cancer patient samples. Previously, we have shown it to stratify clinical response in AML patients treated with a combination of the tyrosine kinase inhibitor sorafenib plus chemotherapy (e.g., GCLAM). Here we profile an expanded cohort to systematically characterize the AML functional genomics landscape and identify potential new targets for AML drug development. **Methods:** Unsourced primary tumor cells from patient samples were transduced with lentivirus harboring Cas9 enzyme and an sgRNA library which was designed to inhibit expression of genes encoding the targets of FDA-approved targeted oncology drugs, as well as internal negative references. Transduced cells were harvested at multiple timepoints, and sgRNA distribution was assessed by amplicon sequencing of DNA barcodes. Changes in barcode abundance were quantitated and aggregated for each gene to generate gene-level statistics, enabling identification of gene dependencies. **Results:** Comprehensive CRISPR/Cas9 functional genomics profiling was carried out retrospectively on pre-therapy samples from 59 AML patients. There were no false positives identified among negative controls. Functional dependencies on multiple genes were observed, with approximately half of patients (n=31; 52.5%) showing at least one gene dependency. We observed on average 6.7 dependencies per positive sample, with 5 of them revealing more than 10 dependencies. In addition to the targets of drugs approved to treat AML (FLT3, 10.2%; IDH1/2, 3.4%; SMO, 3.4%), a diversity of targetable genes for new therapeutic approaches to AML were identified across multiple known oncogenic signaling pathways. The prevalence of these recurrent gene dependencies ranged from 3.3% to 23.7% in our AML cohort. **Conclusions:** In summary, comprehensive functional genomic profiling using Fx Heme provides an effective platform to identify therapeutic opportunities in AML based on dependencies identified for targets of drugs not currently used to treat AML. These insights are now being utilized to develop additional treatment options and more effective personalization of treatment for AML. Research Sponsor: Function Oncology.

CBX-12-101: A first-in-human study of CBX-12, an alphalex peptide drug conjugate (PDC) in patients (pts) with advanced or metastatic solid tumors. *First Author: Ildefonso I Rodriguez Rivera, NEXT Oncology, San Antonio, TX*

Background: Tumor-targeted drug delivery technologies are urgently needed to overcome conventional chemotherapy's lack of tumor selectivity. Alphalex conjugates, which contain a pH-low insertion peptide (pHLIP), a linker and a payload, are designed to overcome this lack of selectivity. Unlike antibody drug conjugates, alphalex PDCs target tumors in an antigen-agnostic manner. At pH ≥7.0, the peptide is unstructured. In the low-pH tumor microenvironment the peptide forms an alpha helix and inserts directionally into the tumor cell membrane delivering the linker and payload intracellularly where the linker is cleaved releasing the payload in the cytosol. CBX-12 consists of the pH-sensitive peptide, a self-immolating linker, and the topoisomerase 1 (TOP1) inhibitor exatecan. **Methods:** In this Phase 1 trial, cohorts of pts were treated with escalating doses of CBX-12 in a 3 + 3 design on three dosing schedules: daily x 5 every 3 weeks, daily x 3 every 3 weeks or once weekly. The primary objectives are safety, tolerability and to determine the MTD and/or RP2D. Secondary and exploratory objectives include evaluation of plasma PK of CBX-12 and exatecan, anti-tumor activity per RECIST v1.1, and measurement of anti-drug antibodies. **Results:** As of 26 Jan 2023, 42 pts have been treated on three schedules. The most frequent treatment-related AEs (TRAEs) were anaemia (42.9%), nausea (38.1%), fatigue (33.3%), ANC and WBC decreased (33.3% each), vomiting (26.2%), diarrhoea (23.8%) and thrombocytopenia (19.0%). The most frequent Gr3/4 TRAEs were ANC decreased (28.6%), anemia (23.8%), WBC decrease (16.7%), thrombocytopenia (14.3%). Dose limiting toxicity was observed in 6 pts: myelosuppression (6 pts) febrile neutropenia (2 pts), and sepsis (2 pts). Responses were observed in 2 of 9 pts with ovarian cancer and 2 of 8 with breast cancer. The MTD on the daily x 3 schedule is 45mg/m². Dose evaluation continues on the weekly schedule. **Conclusions:** In this FIH study of a pH-targeting alphalex PDC, CBX-12 demonstrated single-agent antitumor activity including 4 responses with the dominant toxicity of myelosuppression. Phase 2 expansion cohorts are planned in pts with platinum-resistant ovarian cancer and hormone-receptor positive, HER2 negative breast cancer. Clinical trial information: NCT04902872. Sudocetaxel zendusortide (TH1902), a novel sortilin-receptor (SORT1)-targeting peptide-drug-conjugate (PDC) in patients (pts) with advanced solid tumors: Results from part 1 (dose-escalation) of a phase 1, open-label study. *First Author: Funda Meric-Bernstam, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: SORT1 is expressed in a variety of tumors when compared to most healthy tissue. TH1902 is a first-in-class PDC targeting SORT1, that consists of 2 molecules of docetaxel attached to the TH19P01 peptide via a cleavable succinyl linker. Conjugating the short peptide with various anti-cancer agents allows for targeted delivery of payloads to the tumor. Here we report results from Part 1 of a FIH, multicenter, phase 1 study, designed to explore the safety, pharmacokinetics (PK) and efficacy of TH1902 in advanced solid tumors. **Methods:** Part 1 used a modified rapid intrapatient dose escalation design. A starting dose of 30 mg/m² Q3W of TH1902 was used for the study based on the available pre-clinical data of TH1902 and the known safety profile of docetaxel. Eligibility criteria included pts with advanced solid tumors (all-comers) that have relapsed or are refractory to standard anticancer treatment. Pts had no limit on previous lines of therapy, and were required to have measurable disease by RECIST, expected survival of ≥3 months, ECOG 0-1, and adequate organ function. Pts were not required to be tested for SORT1 at entry. The primary objective of the study was to characterize the safety and tolerability of TH1902. The primary objective of Part 1 was to identify the maximum tolerated dose and the recommended dose for Part 2 (dose expansion). Additional objectives included the examination of the PK of TH1902 and free docetaxel, and outcomes as related to SORT1 expression. **Results:** As of April 2022, 18 pts were enrolled in Part 1 and included 6 ovarian, 1 endometrial, 1 cervical, 3 prostate, 3 ER+/Her2+ BC, 3 melanoma and 1 NSCLC. Pts received an average of 8 prior regimens (range: 3-20). All pts received at least 1 dose of study drug and were evaluated after the 1st cycle for a DLT. Dose levels between 30-420 mg/m² Q3W were studied. Following safety observations among the 6 patients enrolled at the 420 mg/m² dose level (Gr 3 neuropathy [n=2], Gr 4 neutropenia [n=2], Gr 3 ocular [n=1] and Gr 2 skin toxicities), the dose was reduced to 300 mg/m². At the at 300 mg/m² cohort, seven pts received a mean of 2.9 cycles. AEs (regardless of relatedness) occurred in all 7 (100%) pts, mostly Gr 1-2. One pt had Gr 3 worsening anemia (probably related) and Gr 3 abdominal pain/fistula (unrelated). AEs of interest were all Gr 1-2, and included: ocular (keratitis/dryness)=2 pts; GI (nausea/vomiting/diarrhea)=2 pts; neuropathy=2 pts; MSK (arthralgia/myalgia/extremity pain)=2 pts. In 15 evaluable pts in Part 1 clinical benefit was observed in 10 pts: 1 PR (prostate with 53% decrease in target lesion) and 9 SD. PK and SORT1 expression analyses are ongoing. **Conclusions:** Although biological activity has been observed, the optimal dosing regimen of TH1902 is currently under evaluation. Clinical trial information: NCT04706962. Research Sponsor: Theratechnologies.

Pan-cancer landscape of FOXA1 alterations: Insights and clinical implications. *First Author: Edward Christopher Dee, Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Forkhead box A1 (FOXA1) is a pioneer transcription factor that regulates organogenesis and is associated with progression in breast and prostate cancers. To explore its role more broadly in oncogenesis, we characterize FOXA1 genomic alterations and clinical correlates in a large pan-cancer cohort from the American Association for Cancer Research project Genomics, Evidence, Neoplasia, Information, Exchange (AACR-GENIE) database. **Methods:** Using AACR-GENIE, FOXA1 mutations (in frame insertions/deletions (indel-inframe), frameshift insertions/deletions (indel truncating), point mutations (missense), fusions, and amplifications) were characterized across >30 cancer types for primary and metastatic tumors with patient characteristics and clinical outcomes. FOXA1 alterations were queried in the MSK-MET cohort, a subset of GENIE cohort, allowing the definition of hazard ratios (HRs) and overall survival estimates based on Cox proportional hazard models. **Results:** Among 120,625 samples queried from the AACR GENIE data, FOXA1 was profiled in 87,706 samples: 30,268 metastases, 49,228 primary tumors, and 8,210 not specified. FOXA1 mutations were present in 1,869 samples (2.1%), mostly in the forkhead DNA-binding domain. Prostate tumors were enriched with indel-inframe alterations whereas breast cancers were enriched with missense mutations. F266, R261, and D226 mutations in the Wing2 region were common in breast and prostate cancers. In the GENIE cohort, FOXA1 copy number profiles were collected for 74,715 samples, with amplification detected in 834 (1.1%) and deletion in 96 samples (0.1%). FOXA1-amplification was most common in non-small cell lung cancer (NSCLC, 3%, n=190, in primary; 6%, n=264, in metastatic), followed by small cell lung cancer (SCLC) (4.1%, n=10, in primary; 3.5%, n=10, in metastatic), breast (2%, n=80 in primary; 1.6%, n=73, in metastatic) and prostate cancers (2.2%, n=49, in primary; 1.6%, n=27 in metastatic). In the MSK-MET cohort, FOXA1 amplifications were associated with poorer outcomes in primary breast (HR: 3.04, 95% CI: 1.89-4.89, p=4e⁻⁶), primary NSCLC (HR: 1.45, 95% CI: 1.06-1.99, p=0.02), and prostate cancer (HR: 1.94, 95% CI: 1.03-3.68, p=0.04). FOXA1 amplifications were associated with wide-spread metastases in primary breast, NSCLC, and prostate cancer. **Conclusions:** In this observational study of pan-cancer FOXA1 mutant specimens from the GENIE database, we found that FOXA1 alterations in prostate cancer (primary and metastatic tumors) were predominantly indels versus missense in other cancers. We also observe a consistent association between FOXA1 amplification and enhanced metastatic potential regardless of tissue of origin. Our findings suggest that FOXA1 amplifications could serve as a potential prognostic and therapeutic target, particularly for breast, prostate, and non-small cell lung cancer. Hypersensitivity reaction to taxanes following COVID-19 vaccination. *First Author: Bennett Osantowski, Cleveland Clinic Foundation, Cleveland, OH*

Background: In oncology, many patients receive taxanes as part of their chemotherapy regimens to treat various types of cancers. The most commonly used taxanes, paclitaxel and docetaxel, are known to cause hypersensitivity reactions (HSRs) in 5-10% of cases. Providers at our institution perceived an increase in the frequency of HSR with taxanes after patients received vaccines against COVID-19. We aimed to compare the incidence of HSRs to taxanes among our oncology patients who have or have not received one or more COVID vaccine prior to initiation of either paclitaxel or docetaxel chemotherapy. **Methods:** Under an IRB-approved protocol, adult patients, ages ≥18, who had initial treatment with one or more infusions of paclitaxel or docetaxel for any type of cancer in 2020 or 2021 at a single cancer institute, were identified. Demographic, clinical and pathologic information was reviewed from electronic medical charts. The primary objective was to compare the rate of HSR reaction to taxanes among patients who had received any vaccine against COVID-19 prior to their initial taxane infusion versus patients who did not receive a COVID vaccine prior to the first taxane infusion. We also aimed to compare the different vaccine types and to describe, if an HSR occurred, if it was at the first or subsequent taxane infusion. **Results:** In this single-center retrospective cohort study, 355 patients that met the study criteria were analyzed. 204 patients received at least one COVID-19 vaccine prior to their first taxane infusion (58.8% Pfizer-BioNTech, 27.9% Moderna, 13.2% multiple vaccine types) and 151 patients received the vaccine either after their first taxane infusion or were unvaccinated (51.7% Pfizer-BioNTech, 23.8% Moderna, 2.6% Janssen, 21.9% unvaccinated). Of the patients vaccinated for COVID-19 prior to receiving their first taxane infusion, 11.8% had an HSR while 2.6% had an HSR in the post-taxane/unvaccinated group (p 0.003). Severity of HSR reactions was categorized as mild, moderate, or severe based on symptoms. If an HSR occurred, vaccinated patients were more likely to have a worse reaction (p 0.017). Of the 24 patients that had an HSR in the vaccinated group, 14 had a mild reaction, 8 had a moderate reaction, and 2 had a severe reaction. In the post-taxane/unvaccinated group, 3 had a mild reaction and 1 was moderate. 85.7% of HSR to taxanes occurred after the first cycle (24/28 reactions, p <0.001). There was no difference among the vaccine types, though very few patients received the Janssen vaccine. **Conclusions:** Vaccination for COVID19 prior to initiation of taxane containing chemotherapy was associated with a higher risk of taxane related HSR and a higher risk for more severe reactions. Since vaccination against COVID-19 is highly encouraged, particularly among patients with cancer, it is important for clinicians to be aware of this potential association so that they can better monitor for, and promptly treat these events. Proposition of a drug score to predict the clinical usefulness of therapeutic dose monitoring of oral molecularly targeted therapies. *First Author: Arthur Geraud, Gustave Roussy Institute, Villejuif, France*

Background: Therapeutic drug monitoring (TDM) consists in measuring and interpreting drug concentrations in biological fluids to personalize drug dosage. This method is widely used for drugs with a narrow therapeutic index (e.g., immunosuppressants or neuroleptics agents). In onco-hematology, current recommendations of TDM for oral molecularly targeted therapies (oMTT) differ among molecules, making it difficult to identify good TDM candidates. This study aims to propose a quantitative approach with a score to predict the clinical usefulness of TDM of oMTT. **Methods:** We selected the four key parameters needed for an oMTT to be a good candidate for TDM (e.g. interpatient pharmacokinetic variability, feasible dose-adaptation strategy, exposure-efficacy relationship, exposure-safety relationship). We collected each drug's pharmacokinetic (PK) and pharmacodynamics variables from drug labels, Center for Drug Evaluation and Research reports and early trials data. The score was defined from oMTT's exposition variability (variability score: coefficient of variation of drug exposition, the impact of food and proton pump inhibitors), technical complexity (PK linearity, active metabolite, half-life), efficacy (Exposure-response relationship (ERR)) and safety (maximum tolerated dose, Exposure-safety relationship (ESR)). The global score ranged from 0 to 100. To assess the relevance of the score, we evaluated molecules from other therapeutic classes with known strong recommendations of TDM (clozapine, everolimus, voriconazole). **Results:** In September 2021, we collected data from sixty-seven oMTTs. Scores were normally distributed (mean 48.3, standard deviation 15.6) and varies from 15 for acalabrutinib to 80 for sunitinib. Scores of drugs with strong recommendation of TDM were 68, 68 and 64 for clozapine, everolimus as an immunosuppressant, and voriconazole, respectively. We hypothesized that a score above 60 might be associated with relevant indications of TDM. Fifteen molecules had a score above 60 (sunitinib (80), cabozantinib (76.5), nilotinib (76), abemaciclib (76), axitinib (75), sorafenib (69.5) gefitinib (69.5), trametinib (67.5), talazoparib (67), crizotinib (66), pazopanib (65), sonidegib (63.5), neratinib (62.5), panobinostat (62) and imatinib (60.5)). **Conclusions:** We defined a score to identify good candidates for TDM in onco-hematology. Usefulness of TDM in oncology should be confirmed prospectively prioritizing these molecules. Research Sponsor: None.

Bevacizumab exposure and tumor response in patients with platinum resistant epithelial ovarian cancer. *First Author: Judith Michels, Gustave Roussy, Département de Médecine Oncologique, Villejuif, France*

Background: There is a high unmet medical need for disease control in platinum resistant epithelial ovarian cancer patients (PROC). PemBOv trial (NCT03596281) showed promising results with the combination of pembrolizumab plus short-term flat dose bevacizumab with or without pegylated liposomal doxorubicin (PLD) based chemotherapy. However, overall, 20 % of pts showed trough levels for bevacizumab below the targeted threshold of plasma levels associated with efficacy. Based on the PemBOv data, the current analysis aimed to develop a pharmacometric model to characterize the tumor growth early kinetics and quantify the effect of treatment in the study cohorts. A focus was made on the association between bevacizumab exposure and tumor response. **Methods:** Tumor growth kinetic was studied to predict the clinical outcome. Population pharmacodynamic non-linear mixed-effects modeling approach was used to characterize tumor size evolution in patients. The Kkill parameter expressed as week⁻¹ was defined to best describe the shrinkage in tumor size depending on the treatments. In addition, Exposure-Response relationships was performed to evaluate whether bevacizumab plasma levels were associated with the previously determined Kkill parameter. The exposure to bevacizumab was defined by the trough level at the second treatment cycle (PreC2, µg/ml). **Results:** A strong difference in Kkill values was found between cohort A (pembrolizumab plus PLD, n=6, Kkill = 0.00091 week⁻¹) and either cohorts B (pembrolizumab + bevacizumab, n=19, Kkill = 0.002) and C (pembrolizumab + bevacizumab + PLD, n=19, Kkill = 0.02 week⁻¹) respectively, whereas little difference was observed between cohorts B and C. This difference indicates higher tumor shrinkage in cohorts B and C as compared to cohort A. No clear Exposure-Response relationship was evidenced between bevacizumab plasma levels and tumor shrinkage. Still, in patients treated with bevacizumab plus pembrolizumab (cohorts B and C), mean bevacizumab exposure was higher in patients with an ORR and Stable disease of at least 4 months as compared with patients with no clinical benefit (i.e., 69.4 VS. 48 µg/ml). Association between bevacizumab levels and clinical outcome deserves further investigations. Because Kkill can be estimated in an early fashion through *in silico* modeling, this could be evaluated as a surrogate marker to forecast clinical outcome. **Conclusions:** Bevacizumab exposure correlated with ORR and clinical benefit in PROC patients treated with bevacizumab plus pembrolizumab plus minus PLD, since higher plasma trough levels were associated with better clinical outcome. The early Kkill *in silico* modeling could pave the way for the development of prediction models for personalized treatments of PROC patients. Clinical trial information: NCT03596281. Research Sponsor: Merck; Fondation Cancer Luxembourg.

EZH2/EZH1 inhibitor tulmimetostat (CPI-0209) in patients with advanced solid tumors or hematologic malignancies: Preliminary phase II results. *First Author: Charles Drescher, Swedish Cancer Institute, Seattle, WA*

Background: Many preclinical tumor models with mutations in *ARID1A* and *BAP1* are highly sensitive to EZH2 inhibition. Tulmimetostat (CPI-0209) is an investigational oral, next-generation, dual EZH2/EZH1 inhibitor with durable target coverage. Phase I dose escalation established a recommended Phase II dose of 350 mg (Lakhani et al. ASCO 2021). We report preliminary Phase II findings from the ongoing Phase I/II study (NCT04104776). **Methods:** Phase II is evaluating tulmimetostat 350 mg once daily in 28-day cycles in 6 disease-based cohorts (Table). The Simon 2-stage study design requires 1 response (complete [CR] or partial [PR]) in stage 1 (n = 10 patients [pts]) for expansion to stage 2 (plus n = 19) (except in M4, see table). Primary endpoint is objective response rate (ORR) based on disease-specific criteria; secondary objectives include safety. **Results:** As of Nov 08, 2022, 62 pts received ≥1 dose (safety evaluable); 48 had ≥1 postbaseline tumor assessment (efficacy evaluable). Pts had median 3.2 years (0.6–19.6) since diagnosis; 77.4% had ≥2 prior lines of therapy. Cohorts M2, M5 and M6 had completed stage 1 enrollment. At cut-off, best responses among evaluable patients (Table) show 4 cohorts have at least 1 confirmed response, including 2 CR and 1 PR in 7 pts with peripheral T-cell lymphoma (PTCL). 47 pts (75.8%) experienced TEAEs leading to dose modifications, 20 (32.3%) had serious TEAEs, and 5 (8.1%) discontinued treatment due to TEAEs. The most frequent TEAEs (≥15% of pts) (any Grade/Grade ≥3) considered at least possibly related to tulmimetostat were thrombocytopenia (51.6%/27.4%), diarrhea (45.2%/12.9%), nausea (37.1%/0%), anemia (30.6%/16.1%), fatigue (29.0%/0%), alopecia (25.8%/1.6%), dysgeusia (24.2%/0%), vomiting (21.0%/0%), and neutropenia (17.7%/14.5%). **Conclusions:** Based on response criteria of ORR ≥1/10 pts, the ovarian (M2), endometrial (M3), and mesothelioma (M5) cohorts achieved eligibility for stage 2 expansion (not relevant in M4). The safety profile of tulmimetostat is consistent with EZH2 inhibition and previous data. These preliminary findings in heavily pretreated pts with multiple tumor types, including tumors with *ARID1A* alterations or *BAP1* loss, support ongoing investigation of tulmimetostat. Clinical trial information: NCT04104776. Research Sponsor: MorphoSys AG.

Phase II trial of dabrafenib and trametinib in patients with BRAFV600E/R or non-BRAFV600 mutated advanced solid tumors: Results from the BELIEVE trial (NCCH1901). *First Author: Makoto Tahara, National Cancer Center Hospital East, Japan, Kashiwa-Shi, Japan*

Background: BRAF V600 mutations are prevalent in melanoma, thyroid cancer, non-small cell lung cancer, and other malignancies to a lesser degree. The BELIEVE study, a Japanese equivalent of the NCI-MATCH trial, assessed the efficacy of the selective BRAF inhibitor dabrafenib and the MEK1/2 inhibitor trametinib in patients with solid tumors harboring *BRAFV600E/R* or non-*BRAFV600* mutations. **Methods:** The BELIEVE study was a single-arm, open-label clinical trial. Eligible patients were those with solid tumors, with the exception of those with colorectal cancer who were subsequently excluded through amendment. Participants received dabrafenib 150 mg twice daily and trametinib 2 mg/day continuously until disease progression or intolerable toxicity occurred. The primary endpoint was objective response rate (ORR; investigator assessed, RECIST criteria, CR+PR) and secondary endpoints were progression-free survival (PFS), 6-month PFS, and overall survival. The clinical hypothesis was that patients would respond to the matched drug. Bayesian analysis using a prior distribution with an expected response rate of 30% [Beta(0.6, 1.4)] was carried out. If the posterior distribution provided unexpectedly high probability (i.e. > 95%) of response rate exceeding 60% or being inferior to 20%, early termination would be considered during the trial. Otherwise, the efficacy of the drug would be concluded as promising in terms of the clinical hypothesis. **Results:** Fifty patients who had target lesions were included as primary endpoints. The median age was 56.5 years. The three most prevalent primary sites among the main cohort were the thyroid, the central nervous system and biliary tract. The confirmed ORR was 28.0% (95% CI, 16.2% to 42.5%), which met the pre-determined hypothesis, and disease control rate (DCR; CR+PR+SD) was 84.0% (95% CI, 70.9% to 92.8%); PFS was 6.5 months (95% CI, 4.2 to 7.2 months) and responses were observed across seven different types of tumors; the PFS rate at 6 months was 87.8%. Data regarding overall survival was premature, with a median of 9.7 months at the time of analysis. Furthermore, the median PFS was 4.5 months (95% CI, 0.8 to 8.6 months) for the seven patients without target lesions in the exploratory analysis. Adverse events reported among 57 safety analysis population were consistent with those previously reported for dabrafenib and trametinib. Patients who had grade ≥3 adverse events were 45.6%. The most frequent AEs were pyrexia (26.3%), anemia (12.3%), anorexia (8.8%), aspartate aminotransferase elevation (8.8%) and hypoalbuminemia (8.8%). **Conclusions:** The study met its primary endpoint with an ORR of 28.0% in this mixed histology pre-treatment cohort, furthermore, the DCR was 84.0%, which is encouraging for efficacy in *BRAFV600*-mutant tumors across solid tumors. Clinical trial information: jRCTs031190104. Research Sponsor: Health and Labour Sciences Research Grants, Japan Agency for Medical Research and Development.

BLU-222, an oral, potent, and selective CDK2 inhibitor, in patients with advanced solid tumors: Phase 1 monotherapy dose escalation. *First Author: Manish R. Patel, Florida Cancer Specialists and Sarah Cannon Research Institute, Sarasota, FL*

Background: Cell growth regulation and proliferation is dependent on cyclins and CDKs. Cyclin E1 (*CCNE1*) is a cell cycle regulator that activates CDK2. A broad range of aggressive cancers overexpress cyclin E and/or harbor *CCNE1* gene amplifications. Inhibition or loss of CDK2 impairs the growth of *CCNE1*-amplified cell lines and cyclin E overexpression represents one of several CDK4/6 inhibitor resistance mechanisms, including in hormone receptor-positive/human epidermal growth factor receptor-2-negative (HR+/HER2-) breast cancer, making CDK2 inhibition a promising novel therapeutic approach. BLU-222 is an investigational, oral, potent, and selective CDK2 inhibitor in early clinical development with best-in-class potential. **Methods:** VELA (NCT05252416) is an international, open-label, phase 1/2 study evaluating the safety, PK, pharmacodynamics, and efficacy of BLU-222. In monotherapy dose-escalation, adult patients (pts) enrolled regardless of *CCNE1* status, but *CCNE1* amplification or progression after a CDK4/6 inhibitor were of specific interest. Pts with ECOG PS 0–2 and confirmed nonresectable tumors who had progressed following standard of care for advanced relapsed/recurrent disease were enrolled. BLU-222 was administered BID in continuous 28-day cycles, with dose escalation employing a Bayesian Optimal Interval design to identify the maximum tolerated dose. Blood samples were collected for PK and circulating biomarker analysis. **Results:** By Jan 29, 2023, 27 pts were enrolled in 6 escalating BID dose cohorts and included in the safety population. Median age was 64 y (range, 29–85); 85% were female. The most frequent cancer types were breast (44%, 12/27), endometrial (15%, 4/27), ovarian (11%, 3/27), and prostate (11%, 3/27). No pts discontinued treatment due to AEs. The most common (≥15%) AEs (all-cause AE; treatment-related AE) were nausea (33%; 26%), vomiting (22%; 11%), anemia (22%; 19%), diarrhea (22%; 22%), and fatigue (18%; 15%). Transient visual AEs (including blurred vision, photophobia, vision change) were seen in 5 pts (19%). These visual symptoms were mild except in 1 pt with Grade (Gr) 3 blurred vision/photophobia; all had fully resolved by/after the data cut-off. There were 2 dose limiting toxicities reported at the 2 highest dose levels: nausea (Gr 3; n=1) and blurred vision/photophobia (Gr 3; n=1). Translational pharmacodynamic data has shown early evidence of pathway modulation. One partial response was seen in a pt with HR+/HER2- metastatic breast cancer previously treated with 5 lines of therapy, including palbociclib, abemaciclib, and capecitabine. **Conclusions:** As of the cutoff date, BLU-222 monotherapy was generally well tolerated in pts at the BID doses tested. Dose escalation is ongoing to determine the recommended phase 2 dose. Preliminary evidence of cell cycle pathway modulation and clinical activity have been observed. Clinical trial information: NCT05252416. Research Sponsor: Blueprint Medicines.

Safety, pharmacokinetics and anti-tumor activity of RP12146, a PARP1/2 inhibitor, in patients with locally advanced or metastatic solid tumors. *First Author: Piotr Jan Wysocki, Jagiellonian University Hospital, Kraków, Poland*

Background: RP12146 is an orally bioavailable, potent small-molecule inhibitor of poly (ADP-ribose) polymerase (PARP) 1 and PARP 2. Pre-clinically, RP1246 demonstrated anti-proliferative activity in both *BRCA* and non-*BRCA* mutant cancer cell lines of different tumor types as well as in xenograft models. The first-in-human of RP12146 as a single agent is underway to determine the safety, pharmacokinetics and anti-tumor activity. **Methods:** The phase I/Ib study was designed as two-part study. Phase I was a dose escalation, 3+3 design, MTD determination study and would enroll pts who have tumors which are known to harbour DNA repair deficiencies. Phase Ib is dose expansion at the MTD/ optimal dose and would enroll thirty-six pts (12 pts each of advanced/metastatic ovarian cancer (OC), breast cancer (BC), and castration-resistant Prostate cancer (mCRPC) having a confirmed deleterious HRR mutation. RP12146 was administered orally in a 28-days cycles until disease progression. Safety were the primary outcome and the investigator-assessed ORR, CBR and PFS assessed using RECIST v1.1, are the secondary outcomes. Predictive biomarker analysis included inhibition of PARP enzyme as measured by gH2AX levels in PMBCs. **Results:** As of 31-Jan-2023, 9 pts in the dose escalation at 3 dose levels (100 mg QD, 200mg BID and 400 mg BID) and 13 pts (with 5 CHEK2, 4 BRCA2, 2 ATM, 1 CDK12, and 1 RAD51C mutations) in dose expansion have been enrolled. No DLTs were reported in dose escalation. The dose of 400mg BID was considered for dose expansion. Out of 22 pts enrolled, 13 pts had PC, 3 pts had OC, and 2 pts had BC. Most of the related AEs reported were mild in severity except one event of Grade 3 anaemia which resolved, and patient continues to be on therapy. None of the pts developed related SAEs or discontinued due to an AE. Eleven patients (50%) in the expansion group continue to be on RP12146 treatment. RP12146 exhibited rapid absorption achieving maximum concentrations in 1 hr, with an elimination half-life of ~ 4 hrs. Out of the 7 efficacy evaluable PC patients, 5pts showed stable disease and 2pts showed progressive disease. Out of 3 OC pts, 2 pts showed stable disease, and one pt had progressive disease. Among two BC pts, one showed stable disease and the other had progressive disease. Overall, out of 16 efficacy evaluable patients, 8 patients (50%) showed stable disease. **Conclusions:** RP12146 showed a differentiated safety profile so far with limited hematological toxicities reported as compared to the first-generation PARP inhibitors. Updated safety and efficacy data will be provided at the time of presentation. Clinical trial information: NCT05002868. Research Sponsor: Rhizen Pharmaceuticals AG.

A phase 1, multicenter, open-label study of a new BRAF inhibitor ABM-1310 in adult patients (pts) with *BRAF*V600-mutated solid tumors. *First Author: Sarina A. Piha-Paul, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ABM-1310 is a novel small-molecule BRAF inhibitor with high water solubility, cell permeability, and blood-brain barrier penetration as demonstrated in preclinical studies. Here we report preliminary findings from a first-in-patient phase 1 study of ABM-1310. **Methods:** This US multicenter, open-label, dose-escalation with cohort expansion trial includes adult pts with advanced *BRAF*V600-mutated solid tumors, including those with active brain metastasis from solid tumors or primary malignant brain tumors. Previous BRAF/MEK inhibitor treatment is permitted. In dose escalation Part A, ABM-1310 monotherapy is given orally twice a day (25–250 mg bid). In dose escalation Part B, ABM-1310 (100 and 200 mg bid) is given in combination with the MEK inhibitor cobimetinib (60 mg QD d1–21 q4w). Primary objectives: determine maximum tolerated dose and recommended phase 2 dose of ABM-1310 ± cobimetinib. Secondary objectives: safety/tolerability; pharmacokinetics; preliminary efficacy. Dose-limiting toxicities (DLTs) are assessed during cycle 1 by a 3+3 design. **Results:** As of November 28, 2022, 20 pts (65% male; median age 57.5 years) have been treated with ABM-1310 monotherapy across six dose levels in Part A: 25 mg bid (n=3); 50 mg bid (n=3); 100 mg bid (n=4); 150 mg bid (n=4); 200 mg bid (n=4); 250 mg bid (n=2). All pts experienced adverse events (AEs), most frequently skin rash (40%) and QT prolongation (20%). Three pts had drug-related grade ≥3 AEs (nausea/vomiting, QT prolongation and rash) and two had drug-related serious AEs (SAEs) (nausea/vomiting and creatinine increase). Among 16 efficacy evaluable pts, two (pleomorphic xanthoastrocytoma and glioblastoma) had a partial response (PR) and eight had stable disease (SD) as their best response (per RECIST or RANO). In Part B, two ABM-1310 dose levels were assessed in combination with cobimetinib: 100 mg bid (n=3) and 200 mg bid (n=3). Four pts had AEs and drug-related AEs (rash and QT prolongation). There were no SAEs. Among three evaluable pts, one (melanoma) had a PR and one had SD as their best response. There were no confirmed DLTs in either dose-escalation Part A or B, although a few pts had ABM-1310 treatment interruption and subsequent dose reduction. No pts discontinued prematurely for any safety or tolerability reason and there were no drug-related deaths. Preliminary assessment of ABM-1310 drug exposure vs dosage showed a linear dose-proportional relationship. This trial is ongoing. **Conclusions:** ABM-1310 at the currently tested doses up to 200 mg bid, either alone or in combination with cobimetinib, was generally well tolerated, with no new safety signals. Preliminary efficacy data demonstrate favorable activity of ABM-1310 in pts with *BRAF*V600-mutated solid tumors, including primary CNS tumors, and pts previously refractory to other BRAF/MEK inhibitors and I/O therapies. Clinical trial information: NCT04190628. Research Sponsor: ABM Therapeutics.

First-in-human phase 1 study of pimicotinib (ABSK021), a CSF-1R inhibitor, in patients with advanced solid tumors. *First Author: Gerald Steven Falchook, Sarah Cannon Research Institute at HealthONE, Denver, CO*

Background: Colony-stimulating factor 1 (CSF-1) pathway is involved in the development of various types of cancer. Pimicotinib is an orally available, selective, potent small molecule CSF-1R inhibitor with significant pre-clinical anti-tumor activity. Here we present the results of the phase 1 trial. **Methods:** The escalation part employed a 3+3 design with a starting dose of 25 mg QD (28-day/ cycle) to determine the maximum tolerated dose (MTD) and the recommended dose for expansion (RDE). Additional pts with selected tumor types including pancreatic carcinoma, triple-negative breast cancer, lung cancer, and sarcoma were treated at RDE in the expansion part for further evaluation. Tenosynovial giant cell tumor (TGCT) cohorts were analyzed and reported separately. **Results:** As of December 31, 2022, 74 pts received at least one dose of pimicotinib at 25 mg (n=6), 50 mg (n=58), 75 mg (n=8), or 100 mg (n=2) QD, respectively. Median age was 59 y; 68.9% were female; 47.3% were white, 33.8% were Asian and 18.9% were African American. 74.3% were ECOG PS 1; 85.1% had metastasis; 67.6% had ≥3 lines of prior systemic anti-tumor therapies. Median duration of treatment was 49.5 days (range 4–377). Treatment-related adverse events (TRAEs), Grade ≥3 TRAEs, and serious TRAEs occurred in 74.3%, 21.6%, and 4.1% of pts, respectively. The most common TRAEs (≥20%) were serum enzyme elevations, including CPK, AST and LDH, which were all believed to be pimicotinib MOA related, with CPK increase (14.9%) being the only Grade ≥3 TRAE reported in ≥10% of pts. 3 pts (4.1%) reported serious TRAEs of ascites, blood bilirubin increase, and vaginal hemorrhage. After single and multiple dosing, pimicotinib plasma exposure increased slightly less than dose proportion. The rapid oral absorption (median t_{max} of 0.87–1.52 hrs) with moderate terminal $t_{1/2}$ (mean $t_{1/2}$ ranges: 43.6–63.5 hrs) suggested sustained drug exposure was achieved with a once daily dosing schedule. No dose adjustment was needed based on tested covariates including weight, age and race. Pimicotinib treatment led to a more than 85% reduction of non-classical monocytes (NCM) across all dose levels. Plasma CSF-1 levels were significantly increased from 25mg QD to 50mg QD and reached a plateau at 50mg QD, with ~40-fold maximal induction. Reduced CD163+ macrophages in skin and tumor tissues were seen at 50mg QD. All tested doses showed adequate inhibition of NCM, and CSF-1 change showed a positive correlation with plasma pimicotinib concentration. The MTD and RDE were determined as 75 mg QD and 50 mg QD. **Conclusions:** Tolerable safety profile and favorable PK/PD properties supported pimicotinib to be further evaluated in advanced solid tumors, including combinations. Clinical trial information: NCT04192344. Research Sponsor: Abbisko Therapeutics Co., Ltd.

Phase 1 results of CYT-0851, a monocarboxylate transporter (MCT) inhibitor, in combination with capecitabine (cape) or gemcitabine (gem) in advanced solid tumors. *First Author: Ryan C. Lynch, University of Washington/Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The MCT inhibitor CYT-0851 blocks lactate transport resulting in glycolytic cancer cell death. Monotherapy clinical activity has been previously reported in lymphoma and solid tumors. Preclinical studies assessing CYT-0851 with chemotherapy identified enhanced growth inhibition when combined with 5-FU or gem supporting clinical evaluation. **Methods:** Patients (pts) with solid tumors were treated with CYT-0851 + standard dosing of cape or gem in 21- and 28-day cycles, respectively, following a 3+3 design. The primary objective was to determine the MTD. Secondary objectives included: safety, PK, and anti-tumor activity by RECIST. **Results:** As of Feb 1, 2023, 14 pts (pancreatic n=9; ovarian n=5) were treated in 4 cohorts (100–400 mg QD) with cape. No DLTs occurred, and 400 mg QD was selected as the RP2D. 8 pts (57%) experienced a treatment-related adverse event (TRAE), including 2 (14%) with a G3/4 AE. The most common related AEs were primarily G1/2 and included fatigue (21%), nausea, decreased appetite, dry skin, mucosal inflammation and maculopapular rash (all 14%). 10 pts (sarcoma n=6; HNSCC n=1; ovarian n=1; pancreatic n=2) were treated in 2 cohorts (100, 200 mg QD) with gem. No DLTs occurred. Escalation is ongoing with up to 2 further cohorts. 9 pts (90%) experienced a TRAE, including 5 (50%) with a G3/4 AE which were primarily cytopenias. The most common TRAEs were fatigue (50%), anemia (50%), neutropenia (40%), thrombocytopenia (30%), nausea, pruritus, ALT/AST increased, neutrophil decreased and WBC decreased (all 20%). CYT-0851 exposure was similar between combination therapy and monotherapy. 8 pts in the cape cohorts were response-evaluable, including 3 with ovarian cancer. 1 pt with platinum-resistant ovarian cancer had a confirmed PR with treatment ongoing at 174 days. 7 pts had SD. 6 pts in the gem cohorts were response-evaluable. 1 pt with sarcoma had a confirmed PR, 4 pts had SD and 1 had PD. **Conclusions:** 400 mg QD was selected as the RP2D in combination with cape as no MTD was identified. Escalation of gem + CYT-0851 is ongoing to identify the MTD. Both combinations have demonstrated an acceptable safety and tolerability profile with no unanticipated toxicities at clinically active doses. Encouraging antitumor activity has been observed in heavily pre-treated pts with both regimens including pts with ovarian cancer in the cape combo. The cape cohort is being expanded with additional pts with ovarian cancer and will be presented. Clinical trial information: NCT03997968. Research Sponsor: Cyteir Therapeutics.

Clinical activity of palbociclib and ribociclib monotherapy in advanced cancers with cyclin D-CDK4/6 pathway alterations in the Dutch DRUP and Australian MoST trials. *First Author: Laurien Joanna Zevenin, Department of Molecular Oncology & Immunology, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: The Dutch Drug Rediscovery Protocol (DRUP, NCT02925234) and the Australian Cancer Molecular Screening and Therapeutic (MoST, ACTRN12616000931471) Program are similar non-randomized, multi-drug, pan-cancer trial platforms that aim to identify signals of clinical activity of molecularly matched targeted therapies or immunotherapies outside their approved indications. Here, we report results for advanced or metastatic pre-treated cancer patients with tumors harboring Cyclin D-CDK4/6 pathway alterations that were treated with CDK4/6 inhibitors palbociclib or ribociclib as monotherapy. **Methods:** Eligible adult patients had therapy-refractory solid malignancies with one of the following alterations: amplifications of *CDK4*, *CDK6*, *CCND1*, *CCND2* or *CCND3*, or complete loss of *CDKN2A* or *SMARCA4*. Within MoST, all patients were treated with palbociclib, whereas in DRUP, palbociclib and ribociclib were assigned to different cohorts (defined by tumor type and alteration). The primary endpoints for this combined analysis were clinical benefit, defined as confirmed objective response or stable disease (SD) ≥16 weeks, and safety. **Results:** Among 139 enrolled patients 33 tumor types were represented, with glioblastoma multiforme (18%), sarcoma (13%), non-small cell lung cancer (9%) and pancreatic cancers (9%) being most common; 116 patients received palbociclib and 23 received ribociclib. In 112 evaluable patients, the objective response rate was 0% and clinical benefit rate at 16 weeks was 15% (17 cases of SD ≥16 weeks). Median progression-free survival was 4 months (95% CI 3–5 months) and median overall survival 5 months (95% CI 4–6 months). No unexpected toxicity was observed for either drug. Additional driver alterations were identified in 98% and 77% of patients based on whole genome sequencing (WGS) and sequencing next generation sequencing (NGS) analysis at baseline, respectively (Most common in WGS: *TP53* (45%), *KRAS* (25%), *PTEN* (15%), *SMAD4* (15%). Most common in NGS: *TP53* (21%), *EGFR* (17%), *TERT* promoter (15%), *KRAS* (11%). **Conclusions:** Results show minimal clinical activity of palbociclib and ribociclib monotherapy in patients with pre-treated cancers harboring cyclin D-CDK4/6 pathway alterations. Our findings indicate that single agent use of palbociclib or ribociclib is not recommended. Furthermore, we demonstrate that merging data from similar precision oncology trials is feasible. This finding is especially relevant in the context of precision oncology, with rare molecular subsets and/or cancer histologies. Clinical trial information: NCT02925234. Research Sponsor: The Dutch Cancer Society (KWF); pfizer/novartis.

Efficacy and safety of futibatinib for refractory advanced solid malignancies with *FGFR* alterations identified in circulating tumor DNA: TiFFANY, A GOZILA-affiliated Trial. First Author: Tomoko Jogo, Department of Surgery, Munakata Medical Association Hospital, Munakata, Japan

Background: *FGFR* alterations are observed in approximately 7% of advanced solid malignancies and are associated with poor prognosis and resistance to traditional anti-cancer therapy. Despite this, optimal therapeutic strategies with *FGFR* inhibitors for most of *FGFR*-altered solid malignancies are yet to be defined. Circulating tumor DNA (ctDNA) analysis has the potential to accurately detect *FGFR* alterations by assessing spatial and temporal intratumoral heterogeneity. **Methods:** We conducted a multicenter, investigator-initiated, phase II basket-type trial, TiFFANY, to evaluate the efficacy and safety of futibatinib, a highly selective covalent pan-*FGFR* inhibitor, in patients (pts) with advanced solid malignancies with *FGFR* alterations identified by ctDNA analysis who were refractory or intolerant to standard-of-care treatment. ctDNA analysis was performed in the GOZILA study. Enrolled pts received futibatinib at a dose of 20 mg once daily in a 21 day-cycle. The primary endpoint was investigator-assessed objective response rate (ORR). We set the threshold ORR of 5% and expected one of 25%. Planned sample size was 26 with one-sided alpha of 2.5% and power of 80%. Blood and tissue samples collected before treatment (baseline), at week 3, and after disease progression were analyzed for biomarkers and resistance mechanisms. **Results:** Twenty-six pts with *FGFR* alterations (mutation, 9; amplification, 13; fusion, 4) in ctDNA were enrolled between August 2019 and March 2021. The primary endpoint was met with five (19.2%; 95% CI, 6.6–39.4%) achieving a confirmed partial response (PR) in various cancer types (biliary tract, gastric, urothelial, and urachal cancer). Median progression-free survival and overall survival were 2.6 and 8.9 months. The most common treatment-associated adverse events were hyperphosphatemia (100%), eye toxicity (46.2%) and diarrhea (42.3%), all of which were manageable. The median proportional change in ctDNA fraction from baseline to 3 weeks after treatment initiation in pts who achieved PR was significantly less than in pts with stable or progressive disease (0.11 vs. 1.0 vs. 1.6, respectively). Pts with no concurrent RTK/RAS/PI3K and cell cycle alterations in ctDNA were significantly more likely to respond to futibatinib than those with at least one of these alterations (ORR 50% vs. 0%; $P=0.0038$). Acquired gene alterations in ctDNA after progression tended to be more common in pts with *FGFR* amplification (83.3%) than in those with *FGFR* mutation or fusion (60% or 66.7%). **Conclusions:** Futibatinib demonstrated promising efficacy in refractory advanced solid malignancies with *FGFR* alterations in ctDNA with an acceptable toxicity profile. Oncogenic co-alterations detected by ctDNA genotyping may predict primary resistance. Clinical trial information: JapicCTI-194624. A phase 2 study of the WEE1 inhibitor AZD1775 in *SETD2*-deficient advanced solid tumor malignancies. First Author: Edward Maldonado, University of California San Francisco, San Francisco, CA

Background: AZD1775 is an inhibitor of the WEE1 kinase, leading to loss of genome integrity. Pathogenic *SETD2* mutations lead to genome-wide loss of histone H3K36 trimethylation (H3K36me3) and hypersensitivity to WEE1 inhibition with a synthetic lethal effect. AZD1775 was studied in 2 cohorts of patients: A) Patients (pts) with locally advanced/metastatic solid tumor malignancy other than clear cell renal cell carcinoma (ccRCC) and B) pts with locally advanced/metastatic ccRCC. **Methods:** Eligible pts had a locally advanced/metastatic cancer with progression on ≥ 1 prior systemic therapy (including prior tyrosine kinase inhibitor or checkpoint inhibitor for cohort B), and a pathogenic *SETD2* mutation by CLIA-certified next generation sequencing panel. Pts received AZD1775 at a starting dose of 300 mg PO daily on days 1-5, 8-12 of each 21-day cycle. The primary objective was to determine the objective response rate (ORR) by RECIST 1.1 criteria in each cohort. Planned sample size was 9 pts in each cohort in stage 1 of a Simon two-stage design. Secondary objectives were to determine the clinical benefit rate (CBR) (defined as partial response or stable disease [SD] > 4 months), duration of response (DOR), and safety. Correlative assays include the evaluation of H3K36me3 mark by immunohistochemistry (IHC) in archival tumor tissue. **Results:** Between 05/2019 and 10/2021, 18 pts whose tumor harbored a pathogenic mutation in *SETD2* were enrolled (9/ cohort). The median age was 60 years (range 45–74), ECOG PS 0 in 8 (44.4%). One patient remains on treatment; 17 have discontinued (disease progression, $n = 9$; adverse event, $n = 4$; patient withdrawal, $n = 2$; patient death, $n = 1$). The median duration of treatment was 1.89 months (range 0.75–13.5). There were no confirmed objective responses and therefore enrollment was halted following accrual to stage 1. Tumor regression of any magnitude was observed in 5/17 (29%) evaluable pts. Stable disease was the best overall response in 10/17 (59%) evaluable pts, including 3 pts with SD for > 4 months. One patient with RCC remains on treatment with SD for 14+ months duration. The most common adverse events of any grade were nausea (59%), anemia (41%), diarrhea (41%), and neutropenia (41%). Twelve pts (67%) experienced a Grade ≥ 3 adverse event. Evaluation of H3K36me3 using IHC as an exploratory biomarker is underway. **Conclusions:** AZD1775 given as monotherapy failed to achieve an objective response in *SETD2*-altered RCC and other solid tumor malignancies. However, a subset of pts derived clinical benefit as manifested by tumor regressions and/or durable stable disease. Evaluation of AZD1775 in combination with other DNA damage-inducing agents that cause replication stress may be warranted, potentially with the integration of the H3K36me3 mark as a biomarker for patient selection. Clinical trial information: NCT03284385. Research Sponsor: U.S. National Institutes of Health.

A multicenter, open-label, single-arm, phase 1 dose-escalation and phase 2 dose-expansion study to evaluate the safety, tolerability, and anti-tumor activity of FCN-159 in adults with neurofibromatosis type 1. First Author: Xiaojie Hu, Department of Plastic and Reconstructive Surgery, Shanghai Ninth People's Hospital, Shanghai Jiao Tong University, School of Medicine, Shanghai, China

Background: Neurofibromatosis type 1 (NF1) is a common autosomal dominant genetic disease characterized by elevated RAS-mitogen activated protein kinase (MAPK) signaling that causes tumors to grow along the nerves. There is currently no medical cure for adult patients (pts). Plexiform neurofibromas (PN) is present in 20–50% of NF1 pts and may cause serious complications. FCN-159 is a highly potent anti-tumorigenic agent that functions via selective inhibition of MEK1/2. This study assessed the safety and efficacy of FCN-159 in adult NF1 pts with PN. **Methods:** This was a multi-center, open-label, single-arm phase 1 dose-escalation (data have been published in ASCO 2022, abstract no. 3011) and phase 2 dose-expansion study. Participants with NF1-related PN that was not completely resectable or not suitable for surgery were enrolled in the study to receive FCN-159 monotherapy continuously on a 28-day cycles. Herein, we report the safety and clinical efficacy of adult participants in both phase 1 and phase 2. **Results:** As of November 21, 2022, 82 pts were enrolled, including 19 pts in phase 1 and 63 pts in phase 2. The median follow-up was 10.2 months (range 9.4–11.0 months) at the data cut-off. All pts received more than one dose of FCN-159 and 78 had at least one tumor assessment based on REINS criteria. A total of 26 (33%) pts had achieved partial response (PR) as best response, 51 (65%) pts had stable disease (SD), and only one pt was not evaluable for not meeting the minimum SD requirement of at least 16 weeks. The overall response rate (ORR) was 31.7% (95% CI: 21.9–42.9%). After 6–8 cycles of treatment, 68.2% (15/22) of pts with definite tumor pain (NRS-11 score ≥ 2 points) at baseline had a decrease in pain intensity of at least 2 points at C7/C9 assessment. Pain scores decreased by an average of 2.7 points across all 22 pts. A total of 82 (100%) pts experienced treatment emergent adverse events (TEAEs). The most common TEAEs ($\geq 20\%$) included folliculitis (69.5%), mouth ulcer (47.6%), diarrhea (41.5%), paronychia (41.5%), alopecia (32.9%), elevated lactate dehydrogenase (30.5%), elevated alkaline phosphatase (29.3%), tricuspid insufficiency (26.8%), and mitral insufficiency (26.8%). The most common grade ≥ 3 TEAEs were folliculitis (25.6%), paronychia (4.9%). There were no grade ≥ 4 treatment-related adverse events. One pt (1.2%) experienced a serious adverse event (duodenal ulcer) considered related to the study drug. 9.8% reported TEAEs leading to dose reductions, and 12.2% reported TEAEs leading to discontinuation. No death occurred during the study. **Conclusions:** Overall, FCN-159 has a manageable safety profile and demonstrated evidence of anti-tumor activity in the adult population with NF1-related PN. These promising findings warrant further investigation with long-time follow-up. Clinical trial information: NCT04954001. Research Sponsor: Shanghai Fosun Pharmaceutical Industrial Development Co., Ltd.

RAF-inhibitor rechallenge therapy in BRAF aberrated pan-cancers: RE-RAFFLE study. First Author: Blessie Elizabeth Nelson, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Prior studies have demonstrated clinical benefit with rechallenging the RAF pathway in melanoma with prior exposure to BRAF inhibitors. Purpose of this study was to explore antitumor activity and outcomes of BRAF aberrated solid tumors retreated with RAF inhibitors (RAFI). **Methods:** Between January 2010 and November 2022, 44 pts with BRAF alterations [V600E (42); V600K (1); K601Q (1)] who received RAFI as monotherapy or in combination were rechallenged with a second RAFI with or without other therapies at a single tertiary cancer center. All received therapy as part of standard of care or investigational (INV) regimens. Primary objectives: objective response rate (ORR), overall survival (OS) and progression-free survival (PFS) on rechallenge. **Results:** Median age: 54.5 (25–76) with predominantly Caucasian pts (36; 82%) and males (26; 59%). Tumor types: melanoma (16; 36%), colon (10; 23%), thyroid (4; 9%), brain (4; 9%) and others (10; 23%). Median treatment duration was 7 months (m) for first RAFI (RAF1i) and 2.8m with second RAFI (RAF2i) while median time to RAF2i was 3.3m. Best ORR to rechallenge with RAF2i was partial response (PR) (8; 18.1%), stable disease (SD) (16; 36%) and progressive disease (PD) (20; 45.4%) with 5 PR + 6 SD > 6 m. PRs were seen in thyroid (1 anaplastic; 2 papillary), 1 ovarian, 2 melanoma, 1 cholangiocarcinoma and 1 anaplastic astrocytoma with median duration of response for 2.5m. Of the 36 pts who discontinued RAF1i due to PD, 14% responded (6 PR) to RAF2i. Among 16 pts who had CR or PR on RAF1i, 5 pts had PR with RAF2i. In RAF2i group, of all pts achieving PR ($n = 8$), 5 pts had other intervening therapies prior to RAF2i (immunotherapy [IO]; kinase inhibitors; chemotherapy; INV) while 3 had no interim therapies and both factors did not have significant impact on survival for RAF2i ($p=0.2$). 5 responders received combination with MEKi, while 1 had MEKi + IO and 2 had monotherapy. ORR did not significantly differ between combination and monotherapy group in RAF2i ($p=0.056$). At median follow up of 20m, median OS and PFS from rechallenge was 15.5m and 2.7m. 9 pts had genomic testing post RAF1i (3 tumor; 7 blood) with no new acquired aberrations and persistence of BRAF V600E mutation. Independent prognostic factors for survival at rechallenge compared to RAF1i included inferior outcomes with male gender (HR: 3.05; $p=0.0089$), presence of metastatic sites (HR: 3.12; $p=0.036$), ECOG (1 vs. 0 or 2; HR: 3.50; $p<0.001$) while rechallenge with combination RAF2i had a worse survival impact compared to RAF2i monotherapy (PFS: 11.6m vs 2.7m; HR: 3.6; $p=0.00145$). These findings need to be cautiously inferred due to small sample size. **Conclusions:** Rechallenge with RAFI(s) resulted in a clinically meaningful benefit in $> 50\%$ pts on efficacy (> 6 m in 25%) and survival outcomes. Further prospective studies are warranted to validate these findings and expand re-challenging targeted therapy options in tumor-agnostic BRAF-aberrated cancers. Research Sponsor: None.

Dose optimization of novel BRAF inhibitor FORE8394 based on PK and efficacy results. *First Author: Eric Jeffrey Sherman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: FORE8394 is a selective inhibitor of class 1 (V600) and 2 (activating non-V600) BRAF alterations that avoids paradoxical MAPK pathway activation. Consistent with the paradigm shift to optimal dosing vs identifying the maximal tolerated dose, integrated pharmacokinetic (PK), genomics, safety, and efficacy data, and exposure-response modeling were used to identify the recommended dose (RD). **Methods:** In a single arm phase 1/2a study, patients (pts) age ≥ 3 years with advanced solid or CNS tumors with BRAF alterations received FORE8394 900-3600 mg/day with or without the PK enhancer cobicistat (cobi) until progression. Efficacy pts had class 1 or 2 BRAF alterations & ≥ 1 post-baseline assessment (mITT); the BRAF V600 MAPKi naïve, non CRC subset provided a homogenous subset to also inform dose selection. PK was evaluated after single and repeated dosing. **Results:** To date, 110 pts (age range 4-86 years) received ≥ 1 dose of FORE8394; 58% had ≥ 2 prior lines of therapy, 25% had prior MAPKi. PK was independent of age or weight. Cobi increased FORE8394 exposure 2-3-fold. Exposure increased with dose, with less than proportional increase at doses > 900 mg BID. Higher Cmax and trough levels were achieved with QD vs BID/TID. Objective (confirmed) responses were observed at all doses; however, objective response rate (ORR) was greatest (50%) at 900mg QD + cobi, with no further increases in ORR at higher doses. Dose-limiting toxicities were only observed at doses ≥ 1500 mg/day + cobi: 1500-1800 mg/day (4) and 2700-3600 mg/day (1). Similarly, treatment-emergent adverse events (TEAEs) $\geq$ Grade 3 (G3) increased at the higher doses. Only 1 pt discontinued FORE8394 due to treatment-related AE (G3 bilirubin; 3600 mg/day). **Conclusions:** Based on the entirety of safety, PK, and efficacy data, the optimal RD of FORE8394 in Phase 2 is 900 mg QD + cobi in pts ≥ 10 years old. This achieved targeted efficacious exposures with robust antitumor activity and favorable safety. This dose optimization is consistent with current guidelines, avoids higher exposure that may lead to higher toxicity and compromise dose intensity. QD dosing also allows for a convenient dosing regimen. A Phase 2 study at the RD is ongoing in pts with recurrent V600E BRAF-mutated primary CNS tumors and advanced solid or CNS tumors with BRAF fusions. Clinical trial information: NCT02428712. Research Sponsor: FORE Biotherapeutics and Plexikon.

Assigned Regimen	Safety	Efficacy (mITT)	Efficacy MAPKi naïve V600, except CRC
Total daily dose FORE8394 (mg) QD to TID ¹	$\geq$ G3 TEAE	ORR	ORR
900-1800	8/18 (44%)	1/13 (8%)	1/3 (33%)
900 + cobi	9/30 (30%)	7/25 (28%)	5/9 (56%)
450 mg BID	4/11 (36%)	4/10 (40%)	2/4 (50%)
900 mg QD	3/8 (38%)	3/6 (50%)	3/3 (100%)
Titration ²	2/11 (18%)	0/9 (0%)	0/2 (0%)
1200-1800 + cobi	28/49 (57%)	4/36 (11%)	2/8 (25%)
2700-3600 + cobi	6/9 (67%)	2/8 (25%)	1/3 (33%)

BID, twice daily; CRC, colorectal cancer; N, total number of pts; QD, once daily; TID, thrice daily. ¹ Does not include 4 pts ≤ 17 years with mg/m² dosing. ² FORE8394 was gradually increased from 450 mg BID based on individual tolerability.

Phase II study of crizotinib in patients with MET amplification and MET exon 14 deletion: Results from NCI-MATCH ECOG-ACRIN trial (EAY131) sub-protocols C1 and C2. *First Author: Niamh Coleman, St. James's Hospital, Dublin, Ireland*

Background: The NCI-Molecular Analysis for Therapy Choice (MATCH) platform trial enrolled patients with solid tumors, lymphomas, or multiple myeloma to trials of targeted therapies based on matching genomic alterations. Subprotocols C1 and C2 evaluated MET tyrosine kinase inhibitor crizotinib in pts with MET amplification (METamp; C1) or MET exon 14 mutation/deletion (METex14; C2). **Methods:** Pts whose tumors had METamp or METex14 were eligible for C1 and C2, respectively. Results were confirmed by MATCH Oncomine assay if possible; C2 explored METex14 quantification at DNA level retrospectively using cases with sufficient tissue for analysis of DNA mutations surrounding MET exon 14 and control samples with a variable amount of MET exon 14 counts using Anchored Multiplex PCR. Pts in C1 and C2 received crizotinib orally BD daily in 28-day cycles until progression or unacceptable toxicity. Tumor assessment occurred every 2 cycles. Primary endpoint was ORR; PFS; secondary endpoints: 6-month PFS, OS, and predictive biomarkers. **Results:** C1 enrolled 44 pts, of which 28, representing a variety of histologies, were eligible, received treatment, and included in the primary efficacy analysis as prespecified by protocol; GI (n=17) and lung (n=7) were most common. Median age: 67 (range 28-82), 9 pts were women. Median MET copy number was 16.8 (min 7.1, max 78.0). Of 28 pts, 4 had PR; 10 had SD, 13 had PD as best response; disease control rate (DCR) 50% (14/28); one pt was unevaluable. ORR was 14% (4/28, 90% CI: 5.0%-29.8%). Median PFS was 3.4 mo (90% CI: 1.8-3.7); median OS 7.1 mo (90% CI: 5.0-11.5). 4 pts with confirmed PR were lung (n=2), GI (n=1), melanoma (n=1); 1 pt had SD > 6 mo (NSCLC). Most pts had ≥ 1 co-occurring gene alteration (n=27; 96%), TP53 co-mutation most frequently (n=23, 82%); 21 pts had ≥ 3 co-occurring mutations. C2 enrolled 20 pts, 14 evaluable received treatment: GI (n=5); lung (n=6); other (n=3). Median age for the 14 pts was 68 (range 57-78); 6 pts were women, 9 (64%) had ≥ 3 lines of prior therapy. Most pts had ≥ 1 co-occurring gene alteration (n=13; 93%, range 1-4); TP53 co-mutations were frequent (n=7, 50%). Of 14 pts, 2 had PR (both NSCLC); 4 had SD, 4 had PD as best response, and DCR was 43% (6/14). 2 pts had SD > 6 mo (1 lung, 1 bladder). ORR was 14% (2/14, 90% CI: 2.6%-38.5%). Median PFS 2.0 mo (90% CI: 1.4-4.1). On quantification by Met count $\geq 50,000$ mPFS 8.8 months (90% CI: 2.1-NA), MET count $< 50,000$ mPFS 1.7 mo (90% CI: 1.1-3.7). All lung cancer pts with confirmed PR/SD > 6 mo had documented MET count $> 50,000$. Most common reason for permanent treatment discontinuation was disease progression. No new toxicity signals were identified. **Conclusions:** We demonstrate clinical activity using crizotinib across tumors in patients with METamp and METex14. In METex14, differentiating true pathogenic variants from low-level splice variant transcripts may be clinically meaningful. Clinical trial information: NCT02465060. Poster Session

A phase 1 study of TPST-1495 as a single agent and in combination with pembrolizumab in patients with advanced solid tumors. *First Author: Susanna Varkey Ulahannan, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: TPST-1495 is a novel oral therapy designed to be a selective dual antagonist of the prostanoid receptors, EP2 and EP4. Through these receptors, PGE2 stimulates tumor growth, suppresses immunity, and supports adaptive resistance to checkpoint inhibitors. In preclinical models, dual EP2/EP4 inhibition with TPST-1495 increased anti-tumor efficacy, reduced immune suppression, and activated immune effector response significantly better than single EP2 or EP4 antagonists and the COX-2 inhibitor celecoxib. **Methods:** In this Phase 1 study, subjects with advanced solid tumors received TPST-1495 in a modified 3+3 design optimizing dose and schedule as monotherapy and in combination with standard dose pembrolizumab. Study objectives included safety, PK/PD, recommended phase 2 dose (RP2D), anti-tumor activity and exploratory biomarkers. AEs were assessed per CTCAE v5 and efficacy per RECIST v1.1. **Results:** TPST-1495 monotherapy was dosed BID (n=11), QD (n=22) or QD days 1-5 every 7 days (n=17) and in combination was dosed QD only with pembrolizumab 200 mg IV q3 weeks (n=24). TPST-1495 doses ranged from 15 mg QD to 100 mg BID. Most subjects had CRC (61%) followed by endometrial (5.4%) and pancreatic (5.4%) cancer. Median prior lines of systemic therapy were 4 (2-10) in monotherapy; 3 (1-8) in combination. The most common treatment related AEs (TRAEs) were diarrhea (22%), abdominal pain (20%), fatigue, and nausea (18% each) for monotherapy and nausea (29%), fatigue (21%) and diarrhea (17%) for combination therapy. The most common Gr 3 TRAEs were anemia (6.0%) in monotherapy, and ALT/AST increased and fatigue (4.2% each) in combination. No Gr 4/5 TRAEs were reported. For mono vs combo cohorts, the median time on study was 1.9 mo (0.2-10.2) vs 2.7 mo (0.5-10.4) and the disease control rate was 43% (19/44) vs 43% (9/21) with 1 PR in a combination subject with MSS CRC. Pharmacodynamic activities included on-treatment increases in urine PGE2 metabolites and drug-dependent TNF- α rescue in an ex-vivo whole blood PGE2 challenge assay. The RP2D is 50 mg QD for mono and in evaluation for combo therapy. In a subject with endometrial cancer with 22% tumor shrinkage and 222+ days on combination therapy paired biopsies showed high COX-2 expression in the TME at baseline and increased CD8+ and CD8+GrB T cell infiltration on treatment. **Conclusions:** PGE2 is an important target for cancer and immunotherapy but remains ineffectively drugged. TPST-1495 is a novel oral therapy that inhibits signaling only at the tumor promoting EP2/EP4 receptors. In patients with heavily treated solid tumors, primarily MSS CRC, TPST-1495 had pharmacodynamic activity, a manageable safety profile, and a potential signal of activity consistent with the preclinical data and IO combination mechanism. A combination therapy cohort in endometrial cancer is underway. Updated results and biomarker work will be presented. Clinical trial information: NCT04344795. Research Sponsor: Tempest Therapeutics.

First-in-human phase 1 trial of the safety, tolerability, pharmacokinetics, and preliminary anti-tumor activity of WSD0922-Fu: Initial report from dose escalation cohort. *First Author: Sani Haider Kizilbash, Mayo Clinic, Rochester, MN*

Background: WSD0922-Fu is an oral, central nervous system (CNS)-penetrant, small molecule, ATP non-competitive, reversible EGFR inhibitor which potently inhibits EGFR aberrations specific to non-small cell lung cancer (NSCLC) and high-grade astrocytoma (HGA). We report initial results of a first-in-human phase 1 dose-escalation trial (NCT04197934) in patients with EGFR aberrant recurrent HGA and NSCLC. **Methods:** Adult patients with either recurrent EGFR mutant NSCLC with CNS metastases or recurrent EGFR mutant and/or EGFR amplified HGA were enrolled. WSD0922-Fu was orally administered, and dose escalated in cohorts based on a standard 3+3 design to determine the maximum tolerated dose (MTD). Toxicities were graded per CTCAE v5.0 and preliminary efficacy was based on modified RANO criteria or RECIST 1.1 as appropriate. **Results:** 25 patients (17 HGA, 8 NSCLC) were enrolled and treated in six cohorts (40 mg once daily to 320 mg twice daily, 28-day cycles). The median age was 57 years (range 39-75 years). 24% were female and 36% were ECOG 0. For patients with HGA, all patients were previously treated with radiation and temozolomide; the median number of prior lines of systemic therapy was 1 (range 1-4). For patients with NSCLC, all patients were previously treated with an EGFR inhibitor (prior osimertinib 88%); the median number of prior lines of systemic therapy was 1.5 (range 1-6). The median duration of exposure to WSD0922-Fu among all patients was 54 days (range 2-258 days). The most common ($\geq 25\%$) treatment-related adverse events included fatigue (68%), acneiform rash (68%), diarrhea (52%), nausea (48%) and pruritis (28%). The frequency of severe AEs was dose dependent. The most common Grade 3+ AEs ($\geq 10\%$) included lymphopenia (16%), acneiform rash (12%), headache (12%) and diarrhea (12%). The MTD was defined as 160 mg twice daily. At Cycle 1 Day 15 for patients treated at this dose level, the mean terminal elimination half-life (%CV) in the plasma was 31.6 h (102%) (median 14.5 h; range 6.2-78.7 h). The mean Cmax, Tmax, oral clearance at steady state, and AUC (0-12 h) (%CV) were 4513 ng/mL (50%), 2.0 hr (69%), 6.9 L/hr/m² (42%), and 28084 h*ng/mL (52%), respectively. Oral clearance at steady state was inversely related with dose, suggesting either inhibition or saturation of clearance processes. Among patients treated at MTD or higher dose levels and with available response data, 100% (5/5) of patients with NSCLC demonstrated clinical benefit (SD + PR) while 60% of patients had partial responses (intracranial and extracranial). Furthermore, prolonged stable disease (9 cycles) was observed in a patient with EGFRvIII mutant GBM. **Conclusions:** The MTD for WSD0922-Fu monotherapy is 160 mg BID. Preliminary efficacy was observed in patients with osimertinib-resistant NSCLC and EGFRvIII mutant HGA. Enrollment to expansion cohorts is ongoing. Clinical trial information: NCT04197934. Research Sponsor: Wayshine Biopharma; R01 FD-R-07288 (U.S. Food & Drug Administration (FDA) Office of Orphan Products Development (OOPD)).

First-in-human (FIH) phase I dose escalation study (part A) of the first oral allosteric modulator of phosphoinositide 3-kinase inhibitor delta (PI3Kδ) rognolisib in patients with advanced cancer and dose confirmation in uveal melanoma (part B). *First Author: Anna Maria Di Giacomo, Center for Immuno-Oncology, University Hospital of Siena, Siena, Italy*

Background: The highly selective oral allosteric modulator of PI3Kδ, rognolisib (IOA-244), blocks the activity of PI3Kδ -dependent signalling, in both tumour cells and Tregs. **Methods:** Part A explored the continuous daily dosing of rognolisib at 10, 20, 40 and 80 mg in patients (pts) with solid tumours and Follicular Lymphoma (FL). Part B consists of dose confirmation cohorts, including uveal melanoma (UM) pts. Primary objective: safety of the anticipated biologically effective dose (BED), or the recommended phase 2 dose (RP2D). Secondary objectives: PK; PD (e.g., inhibition of CD63 expression on basophils, changes in immune cell subsets in peripheral blood); RECIST 1.1. or Lugano-based responses; PFS and OS. Exploratory studies: phenotypic changes in circulating immune cells by Cytometry by Time of Flight (CyTOF); response assessments by radiomics; analysis of circulating protein signatures via Olink proteomic. **Results:** Part A Solid Tumour (completed): Sixteen pts were treated in 4 cohorts, each with 4 pts. Pts characteristics: uveal melanoma (9/16; 56%), cutaneous melanoma (5/16; 31%) and pleural mesothelioma (2/16; 13%). Only Grade 1 and 2 AEs by CTCAE v5 were observed, including 2 cases of transient (lasting < 24 hrs) diarrhoea and 2 of AST/ALT elevation. Part A FL Cohort (completed): 8 pts were treated at 20 mg (n=4) and 80 mg (n=4). Grade 3 toxicities were transient and observed in 2/8 (25%) pts. 2/4 pts (50%) at the 80 mg had PR as per Lugano criteria. Neither in the solid tumour nor in the haematology pts treatment-emergent adverse events (TEAE) led to study drug discontinuation, immune related toxicity, or a Dose Limiting Toxicity. Subgroup evaluation: UM pts (Part A and Part B): 24 pts (Part A: 9 pts; Part B ongoing: 15 pts), of which 18 pts treated at 80 mg QD (RP2D). Mean time on treatment: 8.6 mo (range: 1.0-27.9 mo). ORR (RECIST 1.1): PR: 1/20 (5%); SD: 16/20 (80%). Median OS for Part A: 20.8 mo (5/9 with 4 pts alive); Part B: not determined; 1-year OS rate: Part A 66.7%; Part B: ongoing. Exploratory Investigations: Radiomics-based evaluation of CT images in pts with solid tumors assessed each metastatic organ, detecting mixed responses; peripheral proteomic evaluation detected changes in several cytokines and chemokines; CyTOF detected reduction in circulating Tregs associated with increased activated effector CD8⁺ T cells. **Conclusions:** Rognolisib is well tolerated at the 80 mg dose, shows signs of efficacy and induces phenotypic changes in the circulating immune cells. As best response at the RP2D, the most robust anti-tumour activity was observed in FL (50% PR) and UM pts (5% PR; 80% SD). Clinical trial information: NCT04328844. Research Sponsor: iOncura SA.

Discovery of gene fusions in driver-negative NCI-MATCH screening samples. *First Author: Stefan T Kaluziak, Massachusetts General Hospital/Harvard Medical School, Boston, MA*

Background: NCI-MATCH aimed to determine the treatment efficacy of identifying actionable genetic alterations, irrespective of cancer histology, and to tailor treatment to the putative molecular drivers of tumors. Leveraging next-generation sequencing (NGS) and ThermoFisher's OncoPrint assay, this phase II trial genotyped 5,540 patient samples during active screening. Reviewing the genotyping statistics, we noted that NCI-MATCH identified fusions in 164 tumors, only 2.96%. This result is substantially lower than expected, given that clinical assays used at MGH's and Yale's diagnostic laboratories identified fusions in 8.5% of the 7,500 sequenced cases, 2.5% of which were novel. Notably, the OncoPrint assay, based on multiplexed PCR, is unable to detect driver fusion events when either of the gene partners are unknown, or a novel breakpoint is involved. Cross-referencing identified fusions from MGH's cohort with OncoPrint's primers, 5-30% of these fusions were potentially missed, suggesting that we could detect up to 30% more fusions than originally identified. Developed at MGH's Molecular Diagnostics Laboratory, Anchored Multiplex PCR (AMP) interrogates 138 known fusion partners, enabling unbiased fusion detection when only one partner is known. With a high likelihood of identifying novel fusion drivers using AMP technology, we sequenced 663 cases that had no identified mutations of interest (MOI) from the NCI-MATCH cohort. **Methods:** A total of 200ng of RNA per sample was shipped from ECOG-ACRIN's repository at MD Anderson Cancer Center to MGH (n = 319) and Yale (n = 349). Samples were processed with ArcherDX's FusionPlex Pan Solid Tumor v2 kit and sequenced on the NextSeq500 with 150 base pair (bp) Paired-End (PE) kits. Data analysis was completed with ArcherDX's analytics platform in conjunction with custom Python and R code. Reported fusions were manually verified on a case-by-case basis. All statistical tests were conducted in R. **Results:** Of the cases sequenced, most (663/693, 95.7%) were successfully processed with AMP. We identified 142 cases with at least one gene fusion out of 663 MOI-Negative cases (21%; 95% CI [18%, 25%]), with 90 as unique fusions, significantly more than the 8.5% observed at MGH (P < .001). Of the 142 fusion-positive cases, 36 have potentially actionable driver events, 27 contain novel fusions not previously described, and in 63 cases no drugs are available to target either component of the fusion. Additionally, we identified fusions in (12/34, 35%) Cholangiocarcinoma and (38/101, 37.6%) Sarcoma cases, 9 and 3 of which were potentially actionable respectively. **Conclusions:** As hypothesized, we identified fusions that the NCI-MATCH screening had missed, detailing sequencing technology improvement that could be broadly applicable to many clinical laboratories sequencing tumors. Clinical trial information: NCT02465060. Research Sponsor: U.S. National Institutes of Health.

Comprehensive genomic profiling before the first-line setting versus after the completion of standard of care in patients with previously untreated advanced solid tumors: The prospective FIRST-Dx study. *First Author: Junichi Matsubara, Department of Therapeutic Oncology, Graduate School of Medicine, Kyoto University, Kyoto, Japan*

Background: Precision oncology using the comprehensive genomic profiling (CGP) test by next-generation sequencing has been introduced into clinical practice. In Japan, only 6.8% of patients accessed the precision treatment because it is only indicated after standard of care (SoC). FoundationOne CDx (F1CDx) is the software as a medical device for the detection of actionable and druggable genomic alterations in 324 genes. F1CDx has the function of both CGP test and companion diagnostics (CDx). Therefore, F1CDx could be ideally used in the early stages of treatments. In this study, we investigated the clinical utility of F1CDx in previously untreated patients with metastatic or recurrent solid tumors. **Methods:** We conducted a multi-institutional, prospective study in six hospitals in Japan (FIRST-Dx study). Chemotherapy-naïve adult patients with advanced solid tumor (GI, Lung, Breast, GYN, Melanoma) and ECOG performance status of 0-1 were enrolled. Primary endpoint was the ratio of patients with actionable mutation. Secondary endpoints were the ratio of patients with druggable mutation, molecular-based recommended therapy (MBRT), gene alteration with CDx, CGP success rate, and patients who actually received MBRT. **Results:** 183 patients were enrolled between May 2021 and February 2022, 180 patients with median (range) age 64 (23-88) years underwent F1CDx test (92 men, lung [n=28], colon/small intestine [n=27], pancreas [n=27], breast [n=25], biliary tract [n=20], gastric [n=19], uterus [n=12], esophagus [n=10], ovary [n=6], and skin melanoma [n=6]). 175 tests were successful (CGP success rate: 97%), and 172 patients were evaluable for endpoint analyses with follow-up through July 2022. Actionable and druggable cancer genomic alterations were found in 172 patients (100.0% [95% CI: 97.9-100.0%]) and 109 patients (63.4% [95% CI: 55.7-70.6%]), respectively. MBRT determined by molecular tumor board was found in 105 patients (61.0% [95% CI: 53.3-68.4%]). Genomic alterations included in the CDx list of F1CDx were found in 49 patients (28.5% [95%CI: 21.9-35.9%]) in the tumor-agnostic setting. After a median follow-up of 7.9 months, 34 patients (19.8% [95% CI: 14.1-26.5%]) actually received MBRTs. Twenty-six patients received evidence level A MBRT, two received evidence level B MBRT, and six received evidence level C MBRT. **Conclusions:** We showed that 61% of the patients with previously untreated advanced cancer had MBRTs found by F1CDx and 20% of them actually received MBRTs early in their disease course. CGP test before SoC for advanced solid tumors could provide better opportunities for receiving MBRTs than after completion of SoC. Our data would recommend expanded approval with respect to the timing of CGP test for patients with previously untreated advanced solid tumors. Clinical trial information: UMIN000042408. Impact of patient travel time on disparities in precision oncology clinical trials. *First Author: Yuji Uehara, Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan*

Background: Precision oncology revolutionizes cancer care, allowing personalized treatments to improve outcomes. Precision oncology often entails participation in genotype-matched clinical trials, resulting in referrals from institutions providing comprehensive genomic profiling (CGP) testing to those conducting these trials. It is still being determined whether there are regional disparities in precision oncology. **Methods:** We conducted a retrospective review of 1127 patients (pts) referred to National Cancer Center Hospital (NCCCH) for participation in genotype-matched clinical trials following CGP testing performed between June 2020 and June 2022. Travel distance and time were calculated utilizing Google Maps from the patient's residence to the NCCCH. A total of 23 covariates were preselected and dichotomized per previous research or expert consensus as follows: age, sex, performance status, body mass index, tumor type, number of lines of prior therapies, number of metastatic sites, liver metastases, brain metastases, pleural or peritoneal effusions, biopsiality, neutrophil, hemoglobin, platelet, albumin, creatinine, total bilirubin, LDH, AST, CRP, place of residence (urban vs. rural), referring hospitals, and household income. All independent variables associated with participation in genotype-matched trials (P < 0.20) were included in a multivariable model, and variable importance was calculated using a machine learning (ML) model (gradient-boosted decision tree). **Results:** A total of 127 (11%) of 1127 pts were enrolled in the genotype-matched trials. Of 127 pts, 82 (65%) and 45 (35%) participated in phase 1 trials and phase 2/3 trials, respectively. The overall median travel distance and time were 38 km (interquartile range [IQR] 21-107) and 55 minutes (IQR 35-110), respectively. In multivariable regression, travel distance (≥100km vs. <100km) was not associated with the proportion of genotype-matched trial participation (9% vs. 12%; odds ratio [OR], 0.68; 95% confidence interval [CI], 0.42-1.07; P = 0.11); however, in pts with travel time ≥120 minutes, the proportion of genotype-matched trial participation was significantly lower than those with travel time < 120 minutes (7% vs. 13%; OR, 0.54; 95% CI, 0.32-0.89; P = 0.019). The proportion of genotype-matched trial participation decreased as travel time increased from <40 minutes to 40-120 minutes to ≥120 minutes (13% vs. 12% vs. 7%, respectively; OR, 0.67; 95% CI, 0.50-0.88; P = 0.006). Travel time was also identified as an important factor in the ML model, whereas low-income and residence in rural areas were of minor importance. **Conclusions:** Patients with travel time ≥120 minutes were less likely to participate in genotype-matched clinical trials than those with travel time <120 minutes. Regional disparities may be creating inequities in precision oncology, which warrant immediate action, including decentralization of clinical trials. Research Sponsor: None.

Poster Session

The relationship between the change with neoadjuvant chemotherapy in the tumor-infiltrating lymphocyte (TIL) expressions and pathological response in breast cancer patients. *First Author: Ahmet Bilici, Istanbul Medipol University, Medical Faculty, Department of Medical Oncology, Istanbul, Turkey*

Background: Many prognostic biomarkers for survival have been studied in the neoadjuvant setting for locally advanced breast cancer (LABC). Our study assessed the correlation between the change in tumour-infiltrating lymphocytes (TIL) before and after neoadjuvant chemotherapy (NAC) in breast tissue and its impact on survival in patients with LABC. **Methods:** Eighty-four LABC patients were retrospectively analysed in this study. TIL was assessed by means of immunohistochemistry (Eclipse Ni, Nikon, Japan) in paraffin-embedded blocks obtained by core-needle biopsy or surgical specimen with respect to the 'TIL working group' criteria. **Results:** TIL scores were grouped as 0%, <10%, 10-50%, and >50%, the median TIL percentage was 17.5% before NAC and 5% after NAC, and the difference was statistically significant ($p<0.001$). Postop-Ki-67 ($p=0.005$), molecular subtype ($p=0.027$), pre-NAC TIL score ($p=0.006$), post-NAC TIL score ($p<0.001$), postop-Ki-67 ($p=0.005$) and preoperative residual cancer burden tumour-infiltrating lymphocyte (RCB-TIL) ($p<0.001$) were significantly correlated with pCR. Higher TIL scores were significantly associated with higher PCR rates. Univariate analysis for disease-free survival (DFS) and overall survival (OS) revealed that postop-Ki-67 level and presence of pCR and postoperative Ki-67 score ($p=0.031$) were significant prognostic factors, respectively. The independent prognostic factor for DFS were postop-Ki-67 score ($p=0.012$, RR: 6.16, 95% CI: 1.48-9.12), post-NAC TIL score ($p=0.041$, RR: 0.42, 95% CI: 0.16-1.06) and the presence of pCR ($p=0.038$, RR: 0.10, 95% CI: 0.01-0.87). Logistic regression analysis showed that a preoperative Ki-67 score greater than 14% ($p=0.001$, OR: 4.55; 95% CI: 0.11-1.49), a postoperative Ki-67 score equal to or lower than 14% ($p=0.011$, OR: 1.10; 95% CI: 0.42-2.29), preop-grade 3 ($p=0.01$, OR: 2.65; 95% CI: 0.85-3.14), low postop-TIL score ($p<0.001$, OR: 3.14; 95% CI: 0.79-4.11) were significant predictive factors for pCR. **Conclusions:** Our study confirms the hypothesis that TIL expressions may be therapeutic targets, especially in specific molecular breast cancer subtypes. Molecular classification of cancer site of origin and lineage. *First Author: Nicholas Robert Rydzewski, National Institutes of Health, National Cancer Institute, Bethesda, MD*

Background: Histopathologic assessment has been the primary modality for the diagnosis of human cancers since the 19th century, and to this day remains the mainstay of diagnosis, risk stratification and staging. While the field has made significant advances, the "art of pathology" relies heavily on subjective visual inspection, with significant levels of inter-observer variability and sometimes uncertainty in diagnosis. Advances in next-generation sequencing have ushered in new molecular diagnostic frameworks that can improve accuracy, critical in deciding treatment. **Methods:** We utilized machine learning (XGBoost) and developed comprehensive molecular classifiers for cancer site of origin (22 classes i.e. breast, prostate, lung, etc.) and cancer lineage (8 classes i.e. adenocarcinoma, squamous cell carcinoma, etc.) to augment traditional histopathologic assessment. These models were trained on a total of 8,249 tumor samples. We then evaluated performance using a large independent validation cohort consisting of 10,376 samples. While 8,886 of these were primary tumors from 97 different datasets, uniquely we also assessed performance in 1,490 metastatic tumors from 17 datasets. Pathologic diagnosis of metastatic tumors can be more difficult due to de-differentiation, but metastatic samples for molecular profiling are difficult to obtain and were only rarely included in previous efforts. **Results:** After model training, we locked the site of origin and lineage expression-based models and next evaluated performance on our independent validation cohort. Overall accuracy was 92.5% for cancer site of origin and 97.2% for cancer lineage on validation. Accuracy among primary site samples was higher than for metastatic samples (93.4%, and 86.8% for cancer site of origin, respectively; 97.5% and 95.7% for cancer lineage, respectively). However, accuracy jumped to an astounding 98-99% for both site of origin and lineage in both primary and metastatic samples where the signatures were highly confident, encompassing the majority of cases. Our unique approach in evaluating site of origin and lineage separately allowed us to identify a lineage differentiation score that was associated with small cell lung and neuroendocrine prostate tumors (AUC 0.955 and 0.833, respectively), as well as worse survival across most evaluable tumor types. **Conclusions:** To our knowledge, this is the largest and most comprehensive validation of platform-independent site of origin/lineage classifiers to date. Our approach can be applied to any existing research or commercial RNA-seq assay, and provides an objective and quantifiable confidence measurement that is correlated with accuracy. This allows for nuanced interpretation of high vs. low confidence predictions, which can complement and potentially even help guide traditional histopathologic assessment in cancer research, clinical trial design, and ultimately clinical practice. Talazoparib (Tala) in patients (pts) with solid tumors with BRCA1/2 mutation (mut): Results from the Targeted Agent and Profiling Utilization Registry (TAPUR) study. *First Author: Gordan Srkalovic, Herbert-Herman Cancer Center, Michigan Cancer Research Consortium, Lansing, MI*

Background: TAPUR is a phase II basket study evaluating antitumor activity of commercially available targeted agents in pts with advanced cancers with specific genomic alterations. Results in a cohort of pts with solid tumors with *BRCA1/2* mut treated with Tala are reported. **Methods:** Eligible pts had measurable disease, ECOG performance status (PS) 0-2, adequate organ function, and no standard treatment (tx) options. Genomic testing was performed in CLIA-certified, CAP-accredited site selected labs. Pts received 1 mg of Tala orally daily until disease progression. Primary endpoint was disease control (DC) per investigator defined as complete (CR) or partial (PR) response or stable disease (SD) of at least 16+ weeks (wks) duration (SD16+) per RECIST v1.1. The hypothesized null DC rate of 15% was evaluated by a 1-sided exact binomial test (alpha 0.10; 82% power). Secondary endpoints were progression-free survival (PFS), overall survival (OS), duration of response (DOR) and SD, and safety. DOR is defined as time from pt's first documented objective response (OR) to progressive disease (PD). Duration of SD is defined as time from tx start to PD. **Results:** 28 pts with 16 solid tumors (6/28 pts had lung cancer) with *BRCA1* (n=9), *BRCA2* (n=16), or *BRCA1/2* (n=3) mut were enrolled from Dec 2019 to Sept 2021. All pts were included in efficacy analyses. Demographics and outcomes are shown. 1 CR, 9 PR and 6 SD16+ were observed for a DC rate of 57% (1-sided 90% CI: 43% to 100%) and an OR rate of 36% (95% CI: 19% to 56%); the null hypothesis of a 15% DC rate was rejected ($p<0.001$). 11/16 pts with OR or SD16+ had a *BRCA2* mut, 4 had *BRCA1* mut, and 1 had both. The pt with a CR (duration of 93 wks) had non-melanoma skin cancer, with *BRCA2* and *ATM* muts, and was microsatellite instability high with 41 muts per megabase. Pts with PR had various solid tumors; 6/9 pts had *BRCA2* mut, 2 had *BRCA1* mut, 1 had both. Of pts with DC, 11 had tumor types for which PARP inhibitors are not yet FDA approved. Median duration of PR was 20 wks (range, 11-80). 10/16 pts with DC had a co-alteration in the 24 homologous recombination-related genes examined, mainly *ATM* (3) or *ARID1A* (2). 13 pts had ≥ 1 grade 3 tx-related adverse or serious adverse events including: anemia, AST or bilirubin increase, hyponatremia, nausea, vomiting, neutrophil, platelet, or white blood cell decrease. **Conclusions:** Tala demonstrated antitumor activity in heavily pretreated pts with advanced solid tumors with *BRCA1/2* mut. Additional study is warranted to confirm the efficacy of Tala in non-breast, non-ovarian cancer pts with *BRCA1/2* mut. Clinical trial information: NCT02693535. Research Sponsor: Pfizer; AstraZeneca, Bayer, Boehringer Ingelheim, Bristol Myers Squibb, Eli Lilly and Company, Genentech, Merck, Seagen.

Temsirolimus (T) in patients (pts) with solid tumors with PIK3CA mutation (mut): Results from the Targeted Agent and Profiling Utilization Registry (TAPUR) study. *First Author: Carmen Julia Calfa, Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL*

Background: TAPUR is a phase II basket study evaluating antitumor activity of commercially available targeted agents in pts with advanced cancers with genomic alterations. Results in cohorts of pts with breast cancer (BC) and other solid tumors with *PIK3CA* mut treated with T are reported. **Methods:** Eligible pts had BC or other solid tumors, measurable disease, ECOG performance status (PS) 0-2, adequate organ function, and no standard treatment (tx) options. Genomic testing was performed in CLIA-certified, CAP-accredited site selected labs. After antihistamine pre-tx, 25 mg of T was infused over 30-60 minutes once weekly until disease progression. Primary endpoint was disease control (DC), defined as complete or partial (PR) response, or stable disease of at least 16+ weeks (wks) duration (SD16+) per RECIST v1.1. For the BC cohort, Simon's optimal 2-stage design with null DC rate of 15% vs. 35% (power=0.85, $\alpha=0.10$) was used with stage 1 (n=10) stopping for futility if $< 2/10$ pts had DC. Low accruing histology-specific cohorts with *PIK3CA* and T tx were collapsed into 1 histology-pooled (HP) cohort. For the HP cohort, the hypothesized null DC rate of 15% was evaluated by a 1-sided exact binomial test with $\alpha=0.10$. Secondary endpoints were progression-free survival (PFS), overall survival (OS), and safety. **Results:** 12 pts with *PIK3CA* mut with BC and 29 pts with *PIK3CA* mut in other solid tumors (across 9 tumor types) were enrolled. 2 pts (1 in each cohort) were found to be ineligible after enrolling and were not included in efficacy analyses. Demographics and outcomes for each cohort are shown. At the end of stage 1 in the BC cohort, 1 PR was observed for DC and OR rates of 9%; the cohort was closed for futility ($p=0.83$). For the HP cohort, 3 PR and 5 SD16+ were observed for DC rate of 29% ($p=0.049$) and OR rate of 11%; the null hypothesis was rejected. Cancer types in pts with OR or SD16+ included cervical, ovarian and head/neck; most common muts were H1047R/L (3), E545K (2) and E542K (2). 1 pt with ovarian and H1047R has ongoing PR at 86 wks. 11/41 pts had ≥ 1 tx-related grade 3-4 adverse or serious adverse event, including anemia, headache, hyperglycemia, hypertension, hypertriglyceridemia, mucositis oral, lymphocyte, neutrophil or platelet count decrease, pneumonitis, and sepsis. **Conclusions:** Although T does not appear to have antitumor activity in pts with BC with *PIK3CA* mut, it does show antitumor activity in pts with other solid tumors with *PIK3CA* mut and warrants further study. Clinical trial information: NCT02693535. Research Sponsor: Pfizer; AstraZeneca, Bayer, Boehringer Ingelheim, Bristol Myers Squibb, Eli Lilly and Company, Genentech, Merck, Seagen.

The genomic, transcriptomic, and immunological landscape of TROP2 in solid tumors. *First Author: Asaad Trabolsi, Jackson Memorial Hospital/ University of Miami, Miami, FL*

Background: TROP2 expression is associated with decreased overall survival in colorectal and pancreatic cancers. The antibody drug conjugate sacituzumab delivers a SN38 toxic payload to TROP2-expressing cells and is approved for the treatment of breast cancer and urothelial carcinoma. We aimed to explore the genomic and immunological landscape of *TACSTD2* (TROP2-encoding gene) in different solid tumors. **Methods:** Tumors from breast cancer (BC, N=11,246), colorectal carcinoma (CRC, N= 15,425), liver cancer (LC, N=433), pancreatic cancer (PC, N=5,488) and urothelial carcinoma (UC, N=5,488) were assessed at Caris Life Sciences (Phoenix, AZ) with NextGen Sequencing of DNA (592-gene or whole exome) and RNA (whole transcriptome). PD-L1 (SP142; Positive (+): $\geq 2+$, $\geq 5\%$) expression was assessed by IHC. When investigating the genomic landscape, mutation prevalence was calculated for pathogenic SNVs/indels. *TACSTD2*-High (H) and -Low (L) expression was defined as top and bottom quartile of *TACSTD2* transcripts per million, respectively. A transcriptomic signature predictive of response to immunotherapy was applied (T cell-inflamed score [Bao, 2020]). tests were applied as appropriate, with P-values adjusted for multiple comparisons ($p < .05$). Real-world overall survival data was obtained from insurance claims and Kaplan-Meier estimates were calculated for molecularly defined subpopulations of patients. **Results:** Compared to *TACSTD2*-L, *TACSTD2*-H tumors had a higher prevalence of *TP53* mutations in BC (*TACSTD2*-H 59% vs -L 48%), CRC (77% vs 71%), LC (43% vs 23%) and PC (83% vs 69%), whereas UC *TACSTD2*-H had a lower prevalence (54% vs 67%, $p < .05$ for all). *TACSTD2*-H tumors had a higher rate of *KRAS* mutations in CRC (55% vs 38%, $p < .05$) and PC (96% vs 78%, $p < .05$). In CRC, the percentage of *KRAS* mutations that were G12C was higher in *TACSTD2*-H (7.3% vs 6.4%, $p < .05$). *TACSTD2*-H tumors had a higher rate of *ARID1A* mutations in CRC (6.7% vs 10%, $p < .05$) and UC (29 vs 20%, $p < .05$). A higher prevalence of PD-L1+ tumors was observed in CRC *TACSTD2*-H (6.4 vs 3.9%, $p < .05$) and the opposite pattern was observed in UC (16% vs 37%, $p < .05$). *TACSTD2*-H tumors were more frequently T cell-inflamed across investigated cancers (BC: *TACSTD2*-H 36% vs -L 19%, CRC: 29% vs 14%, LC: 54% vs 10%, PC: 42% vs 20%, UC: 32% vs 28%, all $p < .05$). *TACSTD2*-H was associated with worse overall survival in PC (HR 1.31 [1.19-1.44], $p < .001$), BC (HR 1.13 [1.03-1.23], $p < .007$) and CRC (HR 1.33 [1.24-1.42], $p < .001$), while this association was not observed in UC (HR .98 [.86-1.12], $p = .75$) or LC (HR 1.14 [.82-1.57], $p = .44$). **Conclusions:** The association of *TACSTD2* expression with *KRAS*, *TP53* and *ARID1A* mutations and T cell-inflamed tumors (ICI responsive) should be considered as possible combination therapies with TROP2 targeting antibody drug conjugates are investigated. Pan-cancer diagnostic proteomic signature of tissue-of-origin (TOO) using data-independent acquisition mass spectrometry (DIA-MS) from 1289 human tissue samples. *First Author: Emma Boys, ProCan, Children's Medical Research Institute, Faculty of Medicine and Health, The University of Sydney, Westmead, Australia*

Background: Accurate tumour classification based upon tissue of origin (TOO) remains important to guide treatment selection and prognosis but can be challenging in patients with poorly differentiated malignancy, cancer of unknown primary (CUP) or those with prior malignancy. Data-independent acquisition mass spectrometry (DIA-MS)-based proteomics is emerging as a potential clinical diagnostic and prognostic tool. We aimed to develop a protein-based signature to identify histological subtype and adenocarcinoma TOO using DIA-MS data obtained from a pan-cancer study of human tissue samples as an adjunct to histopathological assessment in challenging clinical scenarios. **Methods:** We performed DIA-MS-based proteomic profiling of 795 fresh frozen tumour and 494 tumour-adjacent normal samples from the Victorian Cancer Biobank in a clinically orientated workflow. We filtered the cohort to include tumour types relevant to CUP. Protein quantification was derived from raw peptide intensity data. Random forest classifiers to identify histological subtype and adenocarcinoma TOO were subsequently trained and tested using 70% and 30% of the data respectively. Evaluation metrics included top-k accuracy (predicting how often the correct class is among the top k predicted classes) and area under the receiver operating curve (AUROC) (one-versus-rest) $\pm$ 95% confidence interval. **Results:** The final tumour cohort consisted of 427 tumour samples representing eight histological subtypes (adenocarcinoma, germ cell tumour, lymphoma, melanoma, renal cell carcinoma, sarcoma, squamous cell carcinoma, thyroid carcinoma) and seven adenocarcinoma TOO (breast, colorectal, liver, lung, ovary, pancreas, prostate). From 9,051 quantified proteins, 83 were identified with potential utility at identifying histological subtype and adenocarcinoma TOO for use in machine learning models. The histological subtype model identified cancer subtype in the test set with top-1 and top-2 accuracy of 0.95 $\pm$ 0.03 and 0.98 $\pm$ 0.02 respectively. Average test AUROC over all cancer types (n=8) was 0.98 $\pm$ 0.02. The adenocarcinoma TOO model identified tumour TOO in the test set with top-1 and top-2 accuracy of 0.88 $\pm$ 0.07 and 0.95 $\pm$ 0.04 respectively. Average test AUROC over all adenocarcinoma TOO (n=7) was 0.97 $\pm$ 0.02. **Conclusions:** Our clinically orientated DIA-MS-based proteomic workflow and supervised machine learning can identify protein signatures that classify histological subtype and TOO in tumour samples with high accuracy. This technology may assist diagnostic classification of cancer in challenging clinical scenarios, such as CUP. Novel deep learning-based prognostic prediction model for colorectal cancer using hematoxylin and eosin-stained whole slide images. *First Author: Teppei Konishi, Biomy Inc., Tokyo, Japan*

Background: Previous studies have shown that the presence or absence of genetic mutations is critical for colorectal cancer prognosis. However, genomic testing can be expensive and difficult to perform on all samples. In contrast, hematoxylin and eosin (H&E) staining is relatively inexpensive and can be performed on all tissue specimens. In this study, we designed a novel prognostic method using spatial image features extracted from H&E-stained whole slide images (WSIs) and genetic mutation prediction neural networks. **Methods:** We obtained H&E-stained WSIs and data on Microsatellite Instability (*MSI*), *BRAF*, *TTN* and *APC* gene mutations from a clinical cohort of 548 patients with The Cancer Genome Atlas (TCGA) Colon adenocarcinoma and rectum adenocarcinoma. We divided them into training (n=361), validation (n=90), and test (n=115) groups. Classification models were trained to predict the presence or absence of *MSI*, *BRAF*, *TTN*, and *APC* mutations. The model input comprised features of the H&E-stained WSIs, as obtained via a deep learning-based feature extractor. All resultant models were incorporated into a prognostic model (overall survival: > 60 months (low risk)/ < 60 months (high risk)). Our prognostic model's performance was evaluated against TCGA colorectal dataset, and a survival analysis was performed on the model using the Kaplan-Meier method. Finally, we compared our model's performance with the end-to-end prognostic prediction of a convolutional neural network (CNN) that also used H&E-stained WSIs as input and provided prognostic prediction as output. **Results:** Our deep learning-based prognostic prediction model achieved an AUC score of 0.834 with a 95% confidence interval (CI) of 0.734–1.000 alongside TCGA dataset; the survival analysis compared the survival distributions of low-risk and high-risk groups, as predicted by our model; a p -value < 0.01 was obtained. The model could classify low- and high-risk patients and accurately predict patient status as alive (low risk) or deceased (high risk) at 60 months. In contrast, the CNN-based model achieved an AUC score of only 0.502 (95% CI: 0.315–0.690) on the same TCGA dataset, and the p -value obtained for it under the Kaplan-Meier log-rank test was greater than 0.5. The CNN-based method was unable to distinguish between low- and high-risk patients, confirming that our method using spatial imaging features extracted from WSIs was a more effective approach. **Conclusions:** We developed a novel prognostic prediction method using spatial image features extracted from WSIs and genetic mutation prediction neural networks. Our results demonstrated the advantage of using image features over gene mutation data for prognostic prediction in colorectal cancer patients. Research Sponsor: Biomy Inc.

Tumor agnostic efficacy and safety of erdafitinib (erda) in patients (pts) with advanced solid tumors with prespecified *FGFR* alterations (*FGFRalt*): RAG-NAR primary analysis. *First Author: Shubham Pant, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: *FGFRalt* are present across malignancies at various frequencies and may act as oncogenic drivers across tissue histology. Erda is an oral selective pan-*FGFR* tyrosine kinase inhibitor with activity and safety in pts with prespecified *FGFR*-altered locally advanced or metastatic urothelial carcinoma (UC) and cholangiocarcinoma. RAGNAR (NCT04083976) is an ongoing phase 2 open-label, single-arm tumor agnostic trial of erda in pretreated adult and pediatric pts with *FGFRalt* advanced solid tumors. Interim results showed erda clinical benefit, with an objective response rate (ORR) of 29.2%. Here we report results of the primary analysis. **Methods:** Pts aged ≥ 12 y with advanced or metastatic (non-UC) tumors of any histology with predefined *FGFR1-4alt* (mutations/fusions per local/central test), disease progression on ≥ 1 prior line of systemic therapy (tx), and no alternative standard tx received oral erda until disease progression or intolerable toxicity. The primary end point was ORR by independent review committee (IRC). Secondary end points included duration of response (DOR), disease control rate (DCR [CR + PR + SD]), clinical benefit rate (CBR [CR + PR + SD > 4 mo]), progression-free survival (PFS), overall survival (OS), and treatment-emergent adverse events (TEAEs). **Results:** At data cutoff, 217 pts were treated, median age was 57.0 y (range, 12-79), median prior systemic tx was 2 (46%; ≥ 3 lines of tx) with an ORR to last line prior to study entry of 10.1%. ORR to erda tx by IRC was 29.5% (95% CI, 23.5-36.0) with 6 CRs (2.8%) and 58 PRs (26.7%) in 16 distinct tumor types, including advanced CNS, thoracic, gastrointestinal, gynecologic, and rare tumors. ORR was comparable across *FGFR1-3* mutations (25.3% [95% CI, 16.0-36.7]) and fusions (32.6% [95% CI, 25.1-40.9]). Median DOR, PFS, and OS were 6.9 mo (95% CI, 4.4-7.1), 4.2 mo (95% CI, 4.1-5.5), and 10.7 mo (95% CI, 8.7-12.1), respectively; DCR was 73.7% and CBR was 45.6%. 99.5% of pts experienced TEAEs, including 70.0% with grade ≥ 3 . Treatment-related serious AEs occurred in 8.3% of pts with no treatment-related deaths. **Conclusions:** Primary analysis results from RAGNAR, the largest tumor agnostic trial of targeted tx to date, confirm efficacy of erda in heavily pretreated pts with *FGFRalt* advanced solid tumors. Erda activity was observed in adults and adolescents across tumor types, and across *FGFR1-3* gene mutations and fusions. Erda tolerability was consistent with its known safety profile. Clinical trial information: NCT04083976. Research Sponsor: Janssen Research & Development.

Characterizing telomerase reverse transcriptase (*TERT*) promoter mutations (mut) across sex, race, and cancer types. *First Author: Talal El Zarif, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA*

Background: *TERT* promoter mut. have been evaluated as a predictive biomarker for patients (pts) receiving immune checkpoint inhibitors. Understanding the prevalence of *TERT* promoter mut. by sex, race, and cancer type is essential for optimizing its use. **Methods:** Pts who underwent next-generation sequencing at Dana-Farber Cancer Institute and Memorial Sloan Kettering Cancer Center were identified from the AACR Genomics Evidence Neoplasia Information Exchange (GENIE) registry v11.0. Self-reported race and sex data were extracted for ten cancer types with the highest prevalence of *TERT* promoter mut. The strength of associations with *TERT* promoter mut. was quantified by Odds ratios (ORs) and two-sided Fisher's exact tests, along with FDR-adjusted q-values using the Benjamini-Hochberg method. **Results:** We identified 31,925 pts – 87.6% (27,970) self-identified as White, 7.1% (2,273) Asian, and 5.3% (1,682) Black. *TERT* promoter mut. were present in 17% (5,470) tumors, including 56% (1,346/2,411) bladder cancers, 43% (966/2,243) melanomas, 41% (395/959) thyroid cancers, and 23% (183/782) head and neck cancers (HNC). *TERT* promoter mut. were significantly higher in males vs. females in melanoma, cancer of unknown primary (CUP), hepatobiliary (HPB), and thyroid cancers. In contrast, males harbored fewer mut. vs. females with HNC. Interestingly, *TERT* promoter mut. varied by race. Mut. frequency was significantly higher in White pts with melanoma (44%, n=964/2176) compared to Asian and Black pts (2.9%, n=2/67) (OR=25.8; 95% CI=6.9–217, p<0.0001). Asian males with HNC (37%, n=22/60) were enriched for *TERT* promoter mut. vs. White males (19%, n=93/489) (OR=2.5; 95% CI=1.4–4.4; q=0.03). Within HNC tumors, oral cavity (OC) tumors (44.3%, n=85/192) were associated with higher *TERT* promoter mut. vs. other HNC subtypes (16.6%, n=98/590) (OR=4.4; 95% CI=3.03–6.26; p<0.0001). Asian pts with OC (70%, n=14/20) harbored more mut. vs. White pts with OC (41.4%, n=70/169) (OR=3.3; 95% CI=1.2–9; p<0.05). **Conclusions:** Our study demonstrates differences in the distribution of *TERT* promoter mut. by sex, race, and cancer type. Considering these variations is crucial for future clinical trial design and biomarker studies. Research Sponsor: None.

Caveat emptor: A descriptive analysis of guideline-recommended biomarker inclusion in targeted NGS panels for metastatic non-small cell lung cancer (mNSCLC). *First Author: John Leonard Fox, Illumina, San Diego, CA*

Background: Next generation sequencing (NGS)-based panels are routinely used in the diagnosis of mNSCLC, guidelines recommending assessing 12 genes for small variants (SV), (EGFR, BRAF, KRAS, MET, ERBB2); fusions (F), (ALK, ROS1, RET, NTRK1, NTRK2, NTRK3); and copy number variants (CNV), (MET) to assess eligibility for targeted drug therapies. Reimbursement is often limited to targeted panels; yet, a comprehensive review of targeted panels' ability to capture all recommended biomarkers has not been reported. **Methods:** Targeted panels were classified as ≤50 and 51-100 genes. We searched the DEX Diagnostics Exchange Registry for NGS-based lung cancer and solid tumor targeted panels. Each panel was compared against the 12 recommended genetic variants. If the type of genetic analysis (SV/F/CNV) was unclear, labs were contacted for clarification. Fusion assays by PCR or FISH with reflex testing to NGS were included. **Results:** 30 targeted NGS panels from 21 commercial labs were identified; 13 (43%) were specific to lung cancer. Six of 13 panels assessing fusions used FISH or PCR not NGS alone. 12 panels reported only SV, 8 small SV/F, 5 SV/CNS, and 5 all three variant types. Only 1 of the 30 panels (51-100 genes) captured all 12 biomarkers with correct variant types. Of 20 panels reporting ALK, RET, and ROS1, only 11 (55%) reported fusions. Of the 5 reporting all three variant types, NTRK fusions were most commonly absent. On average, solid tumor panels sequenced twice as many genes (51 vs. 24) but were no more likely to capture all recommended biomarkers ((1/17 (6%) vs. 0/13 (0%), (p>0.05)). The average biomarkers captured in lung vs. solid tumor panels were 7.9 and 6.6, respectively (p>0.05), while in ≤50 gene panels vs. 51-100 gene panels, 7.0 and 7.6, respectively (p>0.05). **Conclusions:** Of 30 commercially available NGS panels with <100 genes, only one captured all recommended gene variant types for mNSCLC. Failure to capture all biomarkers was independent of panel size or specificity to lung cancer. NGS panels including small variants, fusions, and copy number variants assessed more biomarkers. Medical oncologists and clinical pathologists ordering targeted NGS panels for the management of patients with mNSCLC must ensure they assess all biomarkers relevant to targeted therapies. Insurers reimbursing targeted panels should acknowledge the inadequacy of <100 gene panels alone to provide guideline-concordant molecular diagnostic testing. Research Sponsor: Illumina.

Guideline-recommended biomarker capture count by panel type and gene variant class.				
≤50 genes	SV	1	9	
	SV/CNV		2	1

Homologous recombination deficiency (HRD) in non-small cell lung cancer: Genomic analysis using an RNA-based HRD algorithm. *First Author: Stephanie Thiede, Tempus Labs, Inc., Chicago, IL*

Background: Recent evidence has suggested that some patients with non-small cell lung cancer (NSCLC) harbor a HRD signature that represents a distinct genomic subtype that could be targeted by PARP inhibitors (PARPi). However, there is little data on HRD prevalence in NSCLC or its genomic associations. Here, we evaluated the co-occurrence of driver mutations and established immune biomarkers with an RNA-based HRD signature in a large, real-world NSCLC cohort. **Methods:** We analyzed data from 5119 NSCLC patients that underwent sequencing via the Tempus xT test (DNA-seq of 648 genes; RNA-seq with whole exome capture). HRD status was predicted by the Tempus HRD-RNA test, a pan-cancer logistic regression classifier that uses an RNA gene expression signature optimized to distinguish between BRCA-biallelic loss and homologous recombination repair (HRR)-WT samples (Leibowitz et al, 2022). Cohort samples were excluded from model training. All comparisons were tested via chi-squared or Fisher's exact tests. **Results:** An RNA-derived signature of HRD (HRD-RNA+) was observed in 3.53% (n=181/5119) of patients. HRD-RNA+ prevalence was higher in squamous cell carcinoma (84/1331, 6.3%) relative to adenocarcinoma (68/3015, 2.3%; p<0.001). The prevalence of select alterations by HRD-RNA status are shown in Table. Alterations in *BRCA1/2* and HRR genes (inclusive of *BRCA1/2*) were enriched in HRD-RNA+ vs. HRD-RNA- cases (8.8% vs. 2.5%; p<0.001; 22% vs. 15%, p=0.008 respectively). Notably, 141 (78%) HRD-RNA+ patients had no alterations in HRR genes. Of all NCCN targetable driver mutations assessed, *KRAS* G12C and *ALK* fusions were the only targetable drivers with significantly different prevalence in HRD-RNA+ vs. HRD-RNA- patients. Across the entire cohort, NCCN driver mutations were depleted in HRD RNA+ patients (18% in HRD-RNA+ vs. 30% in HRD-RNA-, p<0.001). Immune biomarkers (TMB, PD-L1) did not vary by HRD-RNA status. **Conclusions:** Compared to HRD-RNA- NSCLC, HRD-RNA+ NSCLC represents a unique, molecularly defined subset that has a decreased prevalence of NCCN-driver mutations and is not enriched for TMB-H or PD-L1 expression. Further, this signature increases the number of patients classified as HRD-RNA+ compared to HRR gene alterations alone. Functional characterization (e.g. RAD51 foci immunofluorescence assay) and clinical benefit of targeted HRD therapies such as PARPi should be explored in this HRD-RNA+ population. Research Sponsor: Tempus Labs.

Clinical activity of mitogen-activated protein kinase (MAPK) inhibitors in patients with MAP2K1 (MEK1)-mutated metastatic cancers: A systematic review and meta-analysis. *First Author: Matthew Dankner, McGill University, Montréal, QC, Canada*

Background: MAP2K1 (MEK1) mutations are potentially actionable driver mutations in cancer. MAP2K1 mutations can be classified into 3 classes according to molecular characteristics. The efficacy of MAPK inhibitors (MAPKi) for the treatment of MAP2K1 mutant tumors is not well understood. We sought to characterize the genomic and clinical landscape of MAP2K1 mutant tumors, and to evaluate the relationship between MAP2K1 mutation class and clinical activity of MAPKi in patients with MAP2K1 mutant metastatic solid tumors. **Methods:** We interrogated AACR GENIE (v13) to identify all tumors with Class 1/2/3 MAP2K1 mutant solid tumors. We performed a systematic review and meta-analysis of individual patient data from patients with MAP2K1 mutant cancer published between 2010-22. Key inclusion criteria were: MAP2K1 mutation, solid tumor, metastatic disease, treatment with MAPKi and available treatment response data. The primary endpoint was progression-free survival (PFS) and the secondary endpoints were overall response rate (RR) and duration of response (DOR). Chi-squared and Log-Rank tests were used to evaluate statistical significance of differences between groups. **Results:** MAP2K1 driver mutations were present in 917/167,423 (0.5%) tumors in the AACR GENIE dataset. MAP2K1 mutants were most commonly identified in melanoma, colorectal (CRC) and non-small cell lung cancer (NSCLC). In solid tumors, Class 2 mutations were the most prevalent (n=310, 63%) followed by Class 1 (n=119, 24%) and Class 3 (n=66, 13%). Co-occurring MAPK pathway activating mutations (*KRAS*, *NRAS*, *HRAS*, *NF1*, *BRAF*, *RAF1*, or *EGFR*) were significantly more likely (P<0.0001) to occur in Class 1 (82.3%), versus Class 2 (30.9%) or Class 3 (10.6%) MAP2K1 mutant tumors. We identified 55 patients with MAP2K1 mutant tumors who received MAPKi (n=16/30/6/3 for Class 1/2/3/unclassified, respectively). Of these, (n=22, 18, 12, 3) had melanoma, CRC, NSCLC, or other cancers, respectively. Patients were treated with BRAFi (n=12), MEKi (n=24), BRAF+MEKi (n=2), ERKi (n=1) or EGFRi (n=16). Co-occurring MAPK pathway mutations were present in 51% of tumors. In the entire cohort, the RR was 24% and median PFS was 3.3 months. The RR did not differ according to mutation class, cancer type or MAPKi regimen. However, patients with Class 2 mutations experienced longer PFS (4.0 months) and DOR (23.8 months) compared to patients with Class 1, 3 or unclassified MAP2K1 mutations (PFS 3.0 months, P=0.035; DOR 4.2 months, P=0.04). **Conclusions:** Class 2 MAP2K1 mutations are RAF-regulated oncogenic mutations with a relatively low incidence of co-occurring MAPK pathway activating mutations. Some patients with Class 2 MAP2K1 mutations may derive durable therapeutic benefit from MAPKi. Prospective clinical studies with MAPK inhibitors are warranted in patients with MAP2K1-mutated metastatic cancer. Research Sponsor: None.

Genetic heterogeneity between paired primary and metastatic solid tumors and implications for neoantigen-based personalized cancer vaccines. *First Author: Timothy I Shaw, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Neoantigen-based personalized cancer vaccines carry significant promise in treating solid malignancies. For the purpose of neoantigen prediction, questions remain on the suitability of the primary versus the metastatic tumor of an individual patient (pt). Here we performed an in-depth analysis of somatic variants of 45 pts with paired primary and metastatic solid tumors. **Methods:** Pts were enrolled in the Total Cancer Care protocol across the Oncology Research Information Exchange Network (ORIEN). Whole-exome sequencing (WES) of primary and metastatic tumor pairs was performed for 45 pts. These included head and neck (n = 8), renal cell carcinoma (n = 7), non-small cell lung cancer (n = 6), melanoma (n = 5), bladder (n = 3), sarcoma (n = 3), ovary (n = 3), esophageal (n = 2), colorectal (n = 2) and other singletons (n = 5). The data was analyzed through the ORIEN AVATAR Molecular Analysis Pipeline, which consisted of adapter trimming, single sample variant detection, somatic mutation detection and filtering, variant annotation, and filtering of variants from a panel of normal samples. In this analysis, we focused on somatic events that result in an in-frame alteration (such as missense, in-frame insertion/deletion) and out-of-frame protein-altering mutations (such as frameshifts, de novo start and nonstop gain). To assign the clones based on the variant allele frequency, we performed complete linkage clustering. Each cluster was then assigned based on the identified oncogenic driver variant. **Results:** For in-frame events, we noticed that bladder cancer, melanoma, and gynecological cancers shared close to 75% of the mutations between paired primary and metastatic cases. In contrast, esophageal, brain, and endometrial cancers had a low overlap (< 25%) of variants. For out-of-frame events, we found that these events tend to have a lower proportion of shared somatic variants between primary and metastasis than in-frame variants. Through a closer evaluation of the variant allele frequency in variants shared between primary and metastatic disease, we were able to track several cancer drivers, such as oncogenic drivers of BRAF V600E, RB1 R358*, NRAS G13R, KRAS G12A, and TP53 loss-of-function that were consistently present in paired primary and metastatic tumors. Here, we were able to assign the putative clone based on the driver event in 39 out of 45 pts. **Conclusions:** Our analysis demonstrates genetic variations that exist when comparing paired primary and metastatic tumors that appear to vary by histology. Variants are potentially undergoing negative selection supported by the preferential loss of out-of-frame events in metastatic tumors. Understanding the clonal structure will be key to neoantigen prediction for effective neoantigen-based vaccines. Additional steps in variant prioritization are ongoing and will be reported at the meeting. Research Sponsor: M2GEN ORIEN NOVA Grant; American Cancer Society.

Multi-omic characterization of RCC1 expression and its association with molecular alterations, immune phenotypes, and cancer outcomes. *First Author: Brian Warnecke, University of California Irvine School of Medicine, Orange, CA*

Background: Regulator of Chromosome Condensation 1 (RCC1) is the only identified guanine nucleotide exchange factor for the Ras-related nuclear protein Ran and it functions in nuclear transport, cell cycle and DNA damage response. Overexpressed in several cancer types, RCC1 is associated with poor outcomes. We aim to investigate the role of aberrant RCC1 co-alterations and association with immune phenotypes and cancer outcomes. **Methods:** DNA (592-gene or whole exome)/RNA (whole transcriptome) sequencing was performed at Caris Life Sciences (Phoenix, AZ). Samples were stratified by RCC1 expression quartile thresholds (Q1:low, Q4:high) for small cell lung (SCLC, n=876), non-small cell lung (NSCLC, n=21603), gastric (GC, n=1908), pancreatic (PC, n=5071) and colorectal (CRC, n=14892) cancers. PD-L1+ expression was tested by IHC (22c3: 31%; SP142: 32+5%). TMB-High was defined as ≥ 10 mutations/MB. Overall survival (OS) was calculated using Kaplan-Meier estimate. Statistical significance was determined using chi-square and Wilcoxon rank sum test and adjusted for multiple comparisons (* $P < 0.05$). **Results:** Median RCC1 expression was highest in SCLC (14.3 transcript per million [TPM]), followed by GC (9.9), NSCLC (9.9), CRC (9.8), and PC (6.9). TMB-high rates increased progressively with RCC1 expression in NSCLC (Q1-Q4 range: 31-41%*), GC (7-22%*) and CRC (3-13%*), consistent with dMMR/MSI-high rates in GC (5-18%*) and CRC (3-13%*). Similar trends were observed for PD-L1+ rates in PC (Q1-Q4 range: 13-20%*), CRC (2-5%*) and NSCLC (55-58%*). In NSCLC, TP53 (Q1-Q4 range: 57-77%*), RB1 (7-13%*), and EGFR (10-15%*) mutations were seen more with higher RCC1 expression, while STK11 (15-10%*) and KRAS (33-21%*) mutations were seen less. In PC, TP53 mutations (Q1-Q4 range: 70-85%*) and MYC amplifications (1-4%*) were seen more with RCC1 expression, whereas ATM mutations were seen less (6-3%). In CRC, TP53 (Q1-Q4 range: 70-81%*) and APC (72-81%*) mutations were seen more with RCC1 expression, while GNAS mutations were seen less (4-2%*). In both SCLC and NSCLC, high RCC1 expression was associated with increased dendritic cell (5-6%* and 8-1.3%*, respectively) and NK cell fractions (5-6%* and 2.5-3.2%*) and decreased Treg fractions (1.8-1.3%* and 3.0-2.6%*). In pMMR/MSS CRC, high RCC1 expression was associated with increased dendritic cell (6-9%*), NK cell (3-4%*), neutrophil (6-8%*) and CD4 T cell fractions (1.1-1.2%*) and decreased CD8 T cell (5-4%*) and Treg fractions (1.9-1.7%*). High RCC1 expression was associated with worse OS in NSCLC (HR 1.3*), PC (HR 1.5*) and CRC (HR 1.3*), with a similar but not significant effect in SCLC (HR 1.2) and GC (HR 1.2). **Conclusions:** RCC1 expression is a negative prognostic marker in NSCLC, PC, and CRC. Further studies to investigate this at the molecular level may be a potential opportunity for novel targeted drug development. Research Sponsor: None.

Trastuzumab emtansine (T-DM1) in advanced cancers with HER2 mutations or amplification: Results from the Molecular Screening and Therapeutics (MoST) Program substudy. *First Author: Subotheni Thavaneswaran, NHMRC Clinical Trials Centre, The University of Sydney, Sydney, NSW, Australia*

Background: The antibody-drug conjugate T-DM1 is widely used for the treatment of HER2-positive metastatic breast cancer. Its activity in other advanced solid tumors harboring HER2 alterations identified by comprehensive genomic profiling (CGP) needs further characterization. **Methods:** The MoST program provides a precision oncology framework for screening patients (pts) by CGP to identify genomic alterations with potential to match to biomarker-directed clinical trials. This multi-center, single-arm phase 2 trial (ACTRN12619001265167) enrolled adult pts with refractory solid tumors (excluding breast and gastroesophageal cancers) with HER2 alterations. This trial recruited 2 groups of 16 pts (group 1: mutations, group 2: genomic amplification, defined as copy number ≥ 6 copies). The primary composite endpoint was objective tumor response (OTR) assessed by RECIST 1.1 and time-to-progression (TTP) ratio (defined as TTP on T-DM1: TTP1 on prior line of systemic therapy). Anti-tumor activity of T-DM1 was confirmed if ≥ 3 of each 16 pt group achieved an OTR. Key secondary endpoints were progression-free and overall survival (PFS and OS) and safety as assessed by CTCAE 5.0. **Results:** 32 pts had a median age of 64 years (interquartile range [IQR] 53 to 69); 94% an ECOG PS ≤ 1 ; 53% female; and median 2 (IQR 1 to 3.5) prior lines of systemic therapy. The cohort included non-small cell lung cancer (NSCLC, n=12), colorectal (CRC, n=5), salivary gland (SGC, n=5), ovarian (n=3), uterine (n=2), gallbladder (n=2), and 1 each of bladder, pancreas and cervix cancers. After a median follow-up of 17 months (mo), the primary endpoint was met with 7 pts (22%) achieving an OTR, including 3 pts (19%) in group 1 (2 NSCLC and 1 SGC) and 4 pts (25%) in group 2 (3 SGC, and 1 uterine serous carcinoma [USC]). Fourteen of 29 TTP-evaluable pts (48%) achieved a TTP ratio ≥ 1.3 , including 10 pts without an OTR: equating to 53% (n=17) deriving clinical benefit. The median PFS and OS were 4.5 (95% CI 2.1 to 7.0) and 18.23 mo (95% CI 8.11 to not reached) respectively and 6 mo PFS rate 44% (95% CI 26 to 60%). The (NSCLC) responders in group 1 harbored exon 20 insertions (Y772_A775dup and G778_P780dup) and the SGC, a L755S mutation. None of the S310Y/F mutations (n=5, including 2 NSCLCs) had an OTR. The USC was ERBB2 amplified (18 copies) on CGP, discordant with in situ hybridisation (ISH) testing results. Overall, 4 pts had CGP-amplified, ISH negative tumors, of whom 2 achieved an OTR. No responses were seen in CRC pts (all RAS/BRAF-wildtype and IHC 2-3+). No new safety concerns for T-DM1 were reported. **Conclusions:** T-DM1 has anti-tumor activity across a heavily treated, diverse range of cancer types with HER2 alterations identified by CGP, including several unidentified by standard ISH testing. We await results from our partner trial in the first line advanced NSCLC setting to corroborate the group 1 findings. Clinical trial information: ACTRN12619001265167. A 19-protein signature to predict outcomes in a cohort of stage II and III CRC. *First Author: Rosemary Habib, The Westmead Institute for Medical Research, Faculty of Medicine, The University of Sydney, Westmead, NSW, Australia*

Background: Colorectal cancer (CRC) is the second leading cause of cancer-related deaths worldwide and remains an area of unmet clinical need. Despite advances in treating stage II and III disease, 30-50% of patients relapse. Additionally, variable survival outcomes are seen in patients with similar disease stages, making it difficult to predict relapses. Here we outline some of the proteomic pathways of early-stage CRC along with the identification of a proteomic-based prognostic signature that predicts relapse in stage II/III CRC. **Methods:** Archival formalin fixed paraffin embedded tumour (TUM) specimens and matched normal adjacent tissues (NAT) from a cohort of 495 CRC patients (with upfront resected stage II and III CRC) were prepared for proteomic analyses using data-independent acquisition mass spectrometry (DIA-MS). TUM samples with $< 20\%$ tumour were excluded from the analysis. Differential expression analyses were performed to identify the top differentially expressed proteins (DEP) within TUM. DEP were subjected to crosstalk and pathway enrichment analysis (PEA). Survival analysis based on initial univariate and subsequent 100 runs of multivariate Cox regression with Least Absolute Shrinkage and Selection Operator (LASSO) was performed to obtain a reduced list of candidate proteins associated with recurrence-free survival (RFS). The proteins that appeared in greater than 95% of the LASSO runs were used in a multivariate Cox model with recursive feature selection to yield the final list of 19 proteins. A risk score was calculated as the sum of the intensities of each of the 19 proteins multiplied by the corresponding regression coefficients. The median of the risk scores was used as the threshold to dichotomise patients into either a low- or a high-risk group. **Results:** 399 TUM and 381 NAT were analysed, showing 799 DEP, with 529 upregulated and 270 downregulated in TUM vs NAT, respectively. PEA of the upregulated proteins showed enrichment of pathways related to extracellular matrix organisation, tRNA processing and collagen formation. PEA of the downregulated DEPs revealed pathways related to smooth muscle contraction, focal adhesion and oxidation. The 19-protein signature dichotomised patients into low- and high-risk groups with a C-index of 0.829. The signature was prognostic for RFS (hazard ratio (HR) 2.7, 95% confidence interval (CI): [2.24 – 3.18]) and for overall survival (OS) (HR 1.6, 95% CI [1.40, 1.76]). The prognostic significance of the signature was maintained after adjusting for other clinical variables for both RFS and OS (both $p < 0.001$) using multivariate Cox regression. **Conclusions:** Our findings show that CRC disrupts the extracellular matrix and upregulates collagen formation, making these potential targets for novel therapies. We have also identified a 19-protein signature that is associated with survival in our cohort independent of other clinical variables. Research Sponsor: Sydney West Translational Research Centre.

Predictive biomarker for cisplatin in prospective phase 2 of liposomal cisplatin in metastatic breast cancer. *First Author: Dorte Nielsen, Herlev, Copenhagen, Denmark*

Background: Heavily pretreated late-stage breast cancer patients of any subtype represent a huge treatment challenge. Cisplatin may work in selected patients but is often disqualified because of toxicity. LiPlaCis is a liposomal formulation of cisplatin in development utilizing the sPLA₂-triggered targeted release of cisplatin. The prediction of cisplatin efficacy with a 205 mRNA profile has previously been demonstrated in a retrospective study in two NSCLC cancer patient cohorts receiving adjuvant cisplatin¹.

Methods: The dose-escalation part of a phase 1/2 study, of 20 patients with a variety of locally advanced or metastatic solid tumors, suggested a phase 2 dose of LiPlaCis to be 75mg on day 1 and 8 q 3 wks. In this phase 2 part, the cisplatin drug response predictor (DRP) was used to select metastatic breast cancer (mBC) patients with response likelihood scores from FFPE diagnostic or later biopsies. Patients were treated until progression or unacceptable toxicity. Halfway through phase 2 part, the dosing was changed to a per body surface schedule (40 mg/m²) after a fatal event with the flat dosing (in effect 51 mg/m² for this patient). Among the 52 patients included in the phase 2 part, we here report data from the 37 patients with mBC platinum naïve, with DRP scores 34-100%, and with RECIST-defined response outcomes. Within this subgroup, we conducted a post hoc analysis of possible DRP cut-off values that could identify patients with a clinically meaningful response to treatment. **Results:** mBC patients had received a median of 7 previous treatment lines. A DRP score ≥80% (DRP80+) discriminated well between responders and non-responders to liposomal cisplatin. All 4 partial remissions in the study were in the DRP80+ group, and other key efficacy endpoints were in favor of the DRP80+ vs the lower scores (DRP80-). LiPlaCis was generally well tolerated, with a mean of 4.4 treatment cycles administered per patient. Only 1 SAE (pyelonephritis) was reported and considered related to treatment. One patient died whilst on treatment, but due to disease progression. From a total of 164 treatment cycles, 18 of the patients reported 1 grade 4 and 41 grade 3 AEs considered possibly related to treatment. **Conclusions:** LiPlaCis shows efficacy in heavily pretreated mBC patients, especially when using the DRP method as a companion diagnostic. Further, this is the first clinical study to prospectively validate DRP as a method to identify responders to chemotherapy cisplatin. 1) Buhl et al PLOS One doi: 10.1371/journal.pone.0194609. Clinical trial information: NCT01861496. Research Sponsor: CHOSA Oncology; EUROSARS.

NRG1 fusions in solid tumors. *First Author: Brinda Gupta, Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC*

Background: *NRG1* fusions are rare but actionable genomic drivers that occur across a growing number of tumor types. *NRG1* has an EGF-like domain that serves as a ligand for ErbB (HER3) receptors, thereby inducing heterodimerization, usually with HER2, and subsequent activation of relevant downstream signaling pathways. Agents targeting the HER2/HER3 pathway have shown early clinical promise in *NRG1* fusion-positive cancers: currently zenocutuzumab has FDA Fast Track Designation for tumors harboring *NRG1*-fusions. Here, we update the incidence and characterization of *NRG1* fusions across tumor types. **Methods:** Samples were submitted for clinical molecular profiling at Caris Life Sciences via Caris MI Tumor Seek (Phoenix, AZ). Gene fusion detection was performed on mRNA isolated from a formalin-fixed paraffin-embedded tumor sample using the Illumina NovaSeq platform (Illumina, Inc., San Diego, CA) and Agilent SureSelect Human All Exon V7 bait panel (Agilent Technologies, Santa Clara, CA). All *NRG1* fusions with ≥ 3 junction reads were identified for manual review and for characterization of fusion class, intact functional domains, domain prediction, breakpoints, frame retention and co-occurring alterations by next-generation sequencing. **Results:** In an analysis of 169,273 tumor specimens, 261 unique tumors with an *NRG1* fusion were identified for an overall incidence of 0.154% across tumors. *NRG1* fusions were most frequently detected in NSCLC, breast cancer, ovarian cancer, pancreatic ductal adenocarcinoma, colorectal cancer, cholangiocarcinoma, prostate cancer, bladder and urothelial cancers, esophagogastric cancers and less commonly, prostate cancer, soft tissue sarcoma, anal cancer, salivary gland cancers, head and neck cancer, small intestine cancer, small cell lung cancer, endometrial cancer, thyroid cancer, neuroendocrine cancer, high grade glioma, and melanoma. The highest incidence was in breast cancer (0.301%), followed by cholangiocarcinoma (0.263%), NSCLC (0.232%), carcinoma of unknown primary (0.215%), pancreatic ductal adenocarcinoma (0.190%), ovarian cancer (0.174%), bladder cancer (0.148%), esophageal cancer (0.145%) and vulvar cancers (0.145%). There were 153 unique *NRG1* fusion partners. The most common fusion partner was CD74 (12.37%), followed by SLC3A2 (8.13%), ATP1B1 (4.59%), and RBPMS (4.24%). **Conclusions:** *NRG1* fusions are rare but actionable genomic events with significant heterogeneity of tumor type and fusion partner. Patient access to precision medicine: Identifying barriers to biomarker testing in non-small cell lung cancer. *First Author: Ayse Levent, Ipsos, New York, NY*

Background: The growing number of targeted therapies approved to treat non-small cell lung cancer (NSCLC) has anchored biomarker testing in clinical practice. Despite general concordance across international guidelines recommending advanced NSCLC patients be tested for oncogenic alterations and immune biomarkers, this is not always the case. This study uses real-world data to explore the barriers to testing across US, Japan, Germany and China. **Methods:** Ipsos' Biomarker Testing Rate Monitor is a multi-stakeholder, physician-reported syndicated patient record database. 206 cancer-treating physicians (US=69, Japan=37, Germany=41, China=59) were screened for seniority and caseload and submitted data on 990 NSCLC patients (aggregate) in which biomarker testing had not taken place. Data were collected online January – December 2022. **Results:** Analyzing physician cited barriers why patients were not tested, choosing not to test at patient's current stage was highest in the reported US patient cohort, guidelines not calling for testing at this point was more frequently cited in the Japan (27%) and Germany (25%) patient cohort and patient's co-pay was more frequently cited in the China cohort (34%). The Japan cohort had higher mentions of tissue not being available. Country disparities in the reported metastatic (IIIB-IV) cohort included lack of tissue in Japan (48%) and Germany (25%), deferring testing to a later point in the US (21%) and high co-pay in China (50%). The top cited reasons are shown. **Conclusions:** Results from this study indicate that, despite guidelines, not all oncology patients receive biomarker testing. While reimbursement structures are difficult to overcome, a concerted effort is needed to raise awareness of the clinical utility of biomarker testing and of the importance of collecting sufficient tissue during the biopsy to allow patients the chance of benefiting from precision medicines. Similarly, calls for earlier testing would support efforts that ensure the best available treatment options are available to patients throughout their journey. Further investigation using comparator cohort is warranted. Research Sponsor: Ipsos-Insight, LLC.

The genomic, transcriptomic, and immunologic landscape in solid tumors expressing leukocyte immunoglobulin-like receptor B2 (LILRB2). *First Author: Sandra Jones, University of Miami Miller School of Medicine/ Jackson Memorial Hospital, Miami, FL*

Background: *LILRB2* is primarily expressed on myeloid cells and provides negative feedback during inflammatory response. A blocking antibody targeting *LILRB2* in myeloid cells is in clinical trials. Various solid tumors are also enriched with these receptors. Here we investigate differences between *LILRB2* expression in the local versus metastatic setting, influences on the tumor microenvironment, and effects on clinical outcomes for a group of solid tumors. **Methods:** Liver cancer (LC, N=532), urothelial carcinoma (UC, N=4125), pancreatic cancer (PC, N=5488), prostate adenocarcinoma (PA, N=5500) and non-small cell lung cancer (NSCLC, N=21604) tumors were tested at Caris Life Sciences (Phoenix, AZ) with NextGen sequencing of DNA (592-gene or whole exome) and RNA (whole transcriptome). Primary and metastatic sites were defined based on the biopsy site relative to known primary site. *LILRB2*-High (H) and -Low (L) expression was defined as top and bottom quartile of *LILRB2* transcripts/million, respectively. PD-L1 (SP142; Positive (+): ≥2, ≥5%) expression was tested by IHC. Gene expression profiles were analyzed for transcriptomic signatures predictive of response to immunotherapy (T-cell inflamed score). Immune cell fractions were estimated with RNA deconvolution using quanTIseq. Mann-Whitney U and χ^2 tests were applied as appropriate with P-values adjusted for multiple comparisons. Overall survival data was obtained from insurance claims, and Kaplan-Meier estimates were calculated for molecularly defined subpopulations of patients. **Results:** Median expression of *LILRB2* was increased in metastatic versus primary UC (1.23-fold, $p<0.001$), while similar expression was observed in PC (1.1, $p=0.02$), LC (0.87, $p=0.68$), PA (1.0, $p=0.69$), and NSCLC (0.96, $p=0.003$). Compared to *LILRB2*^L, *LILRB2*^H tumors had an increased prevalence of TP53 mutations in LC (*LILRB2*^H 53 vs 22%, $p<0.05$) and UC (64 vs 53, $p<0.05$). *LILRB2*^H tumors had an increased rate of PD-L1+ in PC (20 vs 11%), NSCLC (32 vs 11%), and UC (40 vs 11, all $p<0.05$). Across all tumors, *LILRB2*^H have an increased amount of M1 (UC: 6.34-fold, PC: 1.50, LC: 3.30, PA: -H 0.5% vs -L 0.0, NSCLC: 2.08) and M2 macrophages (UC: 1.40, PC: 1.78, LC: 1.61, PA: 1.07, NSCLC: 1.47) as compared to *LILRB2*^L ($p<0.05$, all). *LILRB2*^H tumors were more frequently T cell-inflamed across investigated cancers (NSCLC: 66.4 vs 2.8%, PC: 60 vs 4.3, LC: 61 vs 3.0, PA: 69 vs 4.8, UC: 70 vs 2.6, all $p<0.05$). *LILRB2*^H PC tumors had decreased overall survival (HR 1.21 [1.0-1.2]). In NSCLC, *LILRB2*^H tumors had longer time on pembrolizumab (HR 0.87 [0.78-0.97]). **Conclusions:** *LILRB2* expression was associated with biomarkers of response to immunotherapy such as PD-L1+ and an increased proportion of T cell-inflamed tumors. These data suggest that PC, NSCLC and UC tumors could benefit from a combination of ICI and *LILRB2*-blocking antibodies. Research Sponsor: Caris Life Sciences.

Characterizing the landscape of RING-type E3 ubiquitin transferase-altered (RNF43 alt) colorectal cancer (CRC) and defining unique subsets with potential therapeutic vulnerabilities in microsatellite instability-high (MSI-H) CRC. *First Author: Abdul Rafeh Naqash, Stephenson Cancer Center, University of Oklahoma Health Sciences, Oklahoma City, OK*

Background: RNF43 is a tumor suppressor gene that represses the WNT/ β -catenin pathway. Emerging data show that RNF43 alt are commonly present in MSI-H CRC with improved outcomes to immune checkpoint inhibitors (ICI). We evaluated whether genomic and transcriptomic analysis of MSI-H RNF43 alt CRC defines distinct subsets with potential therapeutic vulnerabilities. **Methods:** We analyzed CRC tumors (any stage/ subtype) sequenced with Tempus xT assay (DNA-seq of 648 genes at 500x coverage, full transcriptome RNA-seq). RNF43 alt were defined as pathogenic/likely pathogenic per OncoKB, or copy number aberrations (CNA); deep deletions, or amplifications ($>8x$). RNF43 alt vs. wildtype (wt) were compared using Chi-squared/Fisher's Exact tests or Wilcoxon rank-sum tests to evaluate differences in biomarkers. Gene Set Variation Analysis (GSVA) was applied to gene expression data to derive single-sample pathway enrichment scores. ICI-treated MSI-H CRC from the MSKCC cohort (n = 74), publicly available in AACR GENIE v13, was used to assess the overall survival (OS) using the Kaplan-Meier method. **Results:** RNF43 alt was identified in 5.2% (635 of 12,243) CRC tumors. CNA accounted for 6% of RNF43 alt CRC. RNF43 alt vs. RNF43 wt CRC was associated with older age (median 69 vs. 59 years, $p < 0.001$), more prevalent in females (56% vs 43%; $p < 0.001$). A detailed comparison of RNF43 alt vs. RNF43 wt CRC with $p < 0.001$ are shown (Table). Of MSI-H CRC (n = 714), 51% were RNF43 alt, with 80% being RNF43 p.GLY659fs. Among MSI-H RNF43 alt CRC, BRAF alt was co-mutated in 59%, with BRAF^{V600E} constituting 99%. Median TMB was higher for MSI-H RNF43 alt vs. MSI-H RNF43 wt (40 vs. 31 mut/MB, $p < 0.001$). Among MSI-H CRC, GSVA identified significant downregulation of Cetuximab benefit pathway and upregulation of IGF1R and PI3K/AKT pathways in RNF43 alt vs RNF43 wt. Among ICI-treated MSI-H CRC (n = 74) from the MSKCC cohort, no significant OS difference (HR 0.81 [95%CI: 0.34 – 1.97]; $p = 0.65$) was noted for RNF43 alt (n = 42) vs. wt (n = 32). **Conclusions:** RNF43 alt are common in MSI-H CRC and associated with potentially actionable genomic and transcriptomic signatures. Functional characterization of interplay between the WNT signaling and therapeutically relevant pathways (PI3K/AKT, BRAF, IGF1R, Cetuximab benefit) to better define optimal ICI combination approaches in MSI-H RNF43 alt CRC is ongoing. Use of a systems-biology informed machine learning model to predict drug response using clinically available NGS data. *First Author: Maayan Baron, Zephyr AI, Mclean, VA*

Background: Tremendous progress towards understanding the molecular underpinnings of cancer has ushered in an era of precision medicine, where actionable biomarkers inform rational design of novel drugs, repurposing of existing medications or new combination therapies, agnostic of tumor type. However less than 20% of cancer patients match to therapies using existing predictive biomarkers. There is therefore an acute need for new methods to expand the population of patients who could benefit from existing drugs and improve patient selection and design of clinical trials evaluating new or repurposed drugs. **Methods:** We developed systems biology-informed AI methods trained on vast multi-omics and multi-modal datasets from DepMap, TCGA and other publicly available sources, to uncover latent vulnerabilities existing in tumors. These vulnerabilities map to pharmacological sensitivities and can be assigned to individual patients using clinically available molecular data. To evaluate our model, we focused on predicting sensitivities to a third-generation tyrosine kinase inhibitor (TKI), which we assessed in non-small cell lung cancer (NSCLC) cell lines, patient derived xenografts (PDXs) and a clinicogenomics cohort from AACR Project GENIE (n=2004 patients, n=273 patients treated with TKI of interest). Where applicable, whole exome data used as input for validation model predictions were filtered to ~300 genes included on commercial NGS panels to reflect data available in RWD cohorts. **Results:** Our model accurately predicts response to the TKI across diverse cancer cell lines with high accuracy ($r^2 = 0.768$; $\rho = 0.83$; mean absolute error = 0.065). Using NSCLC cancer cell lines and PDX model systems heterogeneous for this TKI's current FDA molecular label (but within the scope of the drug's current cancer indication), we were able to further validate our model's predictions, show they were not dependent on obvious molecular confounders, and demonstrate a potential label expansion opportunity for this drug beyond the current narrow molecular label. While all NSCLC patients from AACR Project GENIE treated with this TKI were "on label", NSCLC patients our model predicted to be sensitive to the TKI had a 4-month increased median PFS compared to patients predicted to be less sensitive (Log-rank test p -value < 0.05 ; HR = 1.64; 1.23-2.22, 95% CI). The PFS partition was not due to obvious clinical confounders such as stage ($p = 0.91$), age ($p = 0.86$), sex ($p = 0.63$), smoking status ($p = 0.57$) or on-target mutations ($p = 0.70$). Biological networks associated with each prediction provide rich context and highlight a putative rational drug combination strategy for this drug. **Conclusions:** We have developed an ML model that uses clinically obtainable NGS data to accurately predict increased sensitivity to a third-generation TKI validated in NSCLC cell lines, PDX models and a RWD patient cohort. Exploring expression levels of HER2, HER3, MET, Claudin18.2, and MUC16 across 16 cancer types using an artificial intelligence-powered immunohistochemistry analyzer. *First Author: Seunghwan Shin, Oncology, Lunit, Seoul, Korea, Republic of (South)*

Background: Quantifying tumor-associated antigen (TAA) expression levels on tumor cells (TC) from immunohistochemistry (IHC) stained slides has been widely used to predict response to novel anti-tumor agents. However, obtaining the precise quantification of TAA expression levels from various cancer types is still challenging. To quantify five targets of interest, we applied an artificial intelligence (AI)-powered analyzer to 16 cancer types. **Methods:** AI-powered whole slide image (WSI) analyzers were developed using IHC positive or negative tumor cells (TC) from PD-L1 22C3 pharmDx and HER2 4B5 datasets, annotated by pathologists. The universal model was trained by IHC-positive or negative TCs from all datasets, while the second model was trained by the intensity of positive (from 1+ to 3+) or negative TCs from the HER2 dataset. Both AI models were applied to the pan-cancer tissue microarray dataset (n = 1,370) with MUC16, CLDN18.2, MET, HER3, and HER2 IHC staining, respectively. The expression levels of those TAAs were calculated with tumor proportion score (TPS) or ASCO/CAP scoring criteria for HER2 in 16 cancer types including biliary tract, breast, colorectum, esophagus, head and neck, kidney, liver, lung, ovary, bladder, pancreas, prostate, stomach, thyroid, cervical, and endometrial cancer. **Results:** Based on the TPS of 1% or more, the positivity of MUC16 and CLDN18.2 were most frequently observed in ovary (51.6%) and kidney (24.2%), respectively, and MET and HER3 in colorectum (63.8%; 40.5%). The five most highly expressed tumors and their frequency of TPS $\geq 1\%$ are shown. HER2 3+ tumor cells were most highly expressed in the breast, followed by the bladder. **Conclusions:** This study describes the TAA expression levels in various tumors using an AI-powered IHC analyzer. This method could be useful for exploring target cancer types and predicting response to novel TAA targeted agents. Research Sponsor: None.

Order of expression levels	Positivity in all types (%)				
	First (%)	Second (%)	Third (%)	Fourth (%)	Fifth (%)
MUC16	Ovary (52.8)	Biliary tract (33.3)	Endometrium (25.0)	Cervical (18.6)	Breast (17.1)
CLDN18.2	Kidney (24.2)	Prostate (26.1)	Stomach (22.8)	Pancreas (20.0)	Bladder (16.7)
MET	Colorectum (63.8)	Thyroid (59.7)	Pancreas (40.0)	Kidney (38.2)	Lung (35.4)

Impact of HER2 assay sensitivity on the ability to detect tumors with low to ultra-low HER2 expression: A TMA study on more than 10,000 tumors from more than 100 tumor entities. *First Author: Maximilian Lennartz, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Detection of low level HER2 expression (HER2 low) is a prerequisite for therapy with new HER2 inhibitors in advanced breast cancer. Currently, tumors with immunohistochemical 1+ expression, and possibly also those with lower expression, are considered HER2 low. Therefore, the question of optimal sensitivity of HER2 assays is of increasing importance for clinical HER2 testing. In addition, there is hope that tumor types other than those with typical 3+ positivity may also benefit from these therapies. The aim of this study was to systematically investigate the influence of HER2 immunohistochemistry assay parameters on the detection rate of tumors with HER2 low expression in different tumor types. **Methods:** A tissue microarray containing $>10,000$ tissue samples from more than 100 different tumor types and subtypes was analyzed for immunohistochemical expression of HER2 using different immunohistochemistry protocols and anti-HER2 antibodies, including the HercepTest and laboratory developed tests designed for high sensitivity. HER2 IHC evaluation included the recording of HER2 low (1+), ultralow (any staining, less than 1+), and 0 (completely negative). **Results:** Irrespective of the assay sensitivity all assays showed the expected/tolerable association with HER2 fluorescence in situ data in a cohort of 356 breast cancers. For the HercepTest, HER2 amplification was seen in 93% of 28 3+ cases, 55% of 11 2+ cases and in 1.5% of 274 0 and 1+ cases. For the most sensitive assay, amplification was seen in 90% of 30 3+ cases, 19% of 37 2+ cases and in 0.8% of 249 0 and 1+ cases. In non-breast cancers, the use of different assays resulted in highly variable results regarding the range of tumors with low or ultra-low HER2 expression in different tumor entities. For example, low (1+) and ultra-low (+) expression was observed in 7-24% (1+) and 11-28% (+) of serous ovarian cancers, 6.2-24% (1+) and 3.4-19% (+) of endometrioid endometrial cancers, 5.5-14% (1+) and 7.7-13% (+) of intestinal gastric cancers, 1.8-9.2% (1+) and 4.5-11% (+) of ductal adenocarcinomas of the pancreas, 1.9-33% (1+) and 5.5-11% (+) of muscle invasive urinary bladder cancers, 2.9-16% (1+) and 4.3-12% (+) of adenocarcinomas of the colon, 0-7.7% (1+) and 2.4-4.6% (+) of clear cell renal cell carcinomas, 4.8-6.5% (1+) and 6.0-8.6% (+) squamous cell carcinomas (SQCC) of the larynx, 6.3-7.1% (1+) and 2.4-6.3% (+) SQCC of the esophagus, 0.8-26% (1+) and 2.4-12% (+) SQCC of the cervix, as well as 1.5-5.1% (1+) and 1.5-2.2% (+) SQCC of the vulva. **Conclusions:** Low level HER2 expression occurs commonly in many cancer types. The rate of identifiable tumors with HER2 low or HER2 ultra-low expression greatly varies depending on assay parameters that can easily be modified. Clinical trials are needed to identify the HER2 expression thresholds to identify patients who may benefit from anti-HER2-low therapies. Research Sponsor: None.

Pathway enrichment analysis in tumors with high mutation burdens and interferon- γ signature expression: A pancancer analysis. *First Author: Xuanyi Li, Vanderbilt University Medical Center, Nashville, TN*

Background: Tumor mutation burden (TMB) correlates with immunotherapy response, but outcomes still vary in high TMB cancers, and many high TMB tumors lack T cell infiltration. Here, we assessed gene expression signatures of high TMB, including both inflamed and non-inflamed tumors (defined by interferon- γ [IFN- γ] gene signatures). **Methods:** Gene set enrichment analysis (GSEA) was assessed from RNA-sequencing data in tumors in TCGA. TMB and IFN- γ signature score were assessed by previously published methods. We performed GSEA on high vs low TMB tumors, and further stratified by high vs low IFN- γ signature expression within high TMB tumors. We validated results in Tempus RNA-sequencing data from 264 patients at Vanderbilt. **Results:** 4020 TCGA cases in non-small cell lung, melanoma, bladder, head and neck, kidney, and colorectal cancer were included. Major signatures upregulated in the high TMB group included cell cycle signaling, nuclear protein/mRNA export, cholesterol biosynthetics, and ubiquitin signaling. High TMB/high IFN- γ signature tumors were enriched in immune-related pathways (neutrophil and monocyte chemotaxis, T cell activation and proliferation, and interleukin-1 secretion), and non-immune pathways including cAMP metabolic process and phosphatidylinositol signaling. High TMB/low IFN- γ signature tumors had enriched pathways in nonsense mediated decay, electron transport chain/oxidative phosphorylation, and mitochondrial translational disassembly. 264 tumors from Vanderbilt were used for validation; pathways including cholesterol biosynthetics also correlated with immunotherapy response. **Conclusions:** High TMB tumors were enriched in pathways such as ubiquitin signaling, which could regulate immune cell function in antitumor immunity. Within high TMB cancers, tumors with higher IFN- γ signatures have enriched immune-related, and metabolic pathways, which could suggest novel therapeutic targets to make high TMB/ low IFN- γ tumors more immunogenic. Evolution of HER2 scores after neoadjuvant systemic therapy in breast cancer. *First Author: Esther G Chong, Loma Linda University Medical Center, Loma Linda, CA*

Background: Breast cancer (BC) is a malignancy with a wide array of histopathological characteristics and tumor heterogeneity leading to major clinical implications for management. With the recent approval of antibody-drug conjugates (ADCs) for human epidermal growth factor receptor 2 (HER2)-low advanced BC, there is increased significance for characterizing the spectrum of HER2 expression in the curative setting. **Methods:** We conducted a single institution retrospective review of patients with BC who received neoadjuvant systemic therapy (NAST) followed by definitive surgical resection from 2008 to 2022. The initial tumor biopsies were tested for estrogen receptor (ER), progesterone receptor (PR), and HER2 status per ASCO/CAP guidelines and repeated on the residual tumor tissue after NAST. HER2 status was categorized into HER2-negative (IHC 0), HER2-low (IHC 1 or IHC 2/ Fluorescence in situ hybridization [FISH] negative), and HER2-positive (IHC 2/ FISH positive or IHC 3). Concordance and discordance with HER2 status in the pre and post NAST tumor samples were analyzed using descriptive statistics. **Results:** Of 340 patients with BC who received NAST, 55 patients with residual disease had pre and post treatment biomarker data available for analysis. Prevalence of HER2-low was 70.9% (39/55) in the pretreatment tumors while it was 58.2% (32/55) in the post treatment tumors. 40% of tumors (22/55) had HER2 discordance while 60% (33/55) demonstrated concordance with HER2 expression after NAST. Among the changes in HER2 status, a shift from HER2-low to HER2-negative status occurred most frequently in 18.2% of tumors (10/55). In tumors with HER2 discordance, 36.4% (8/22) were also noted to have changes in ER or PR status while this was seen in 48.5% (16/33) of tumors with HER2 concordance. For rates of recurrence, 22.7% (5/22) of patients in the HER2 discordant group had relapsed compared to 18.2% (6/33) patients in the HER2 concordant group. **Conclusions:** Dynamics of HER2 expression is increasingly important in the rapidly changing therapeutic landscape of BC. Our study shows high prevalence of HER2-low expression in tumors with residual disease after NAST and frequent conversion of HER2-low to HER2-negative status with NAST. Further studies are warranted to determine the clinical and therapeutic relevance of biomarker evolution and tumor heterogeneity in the curative setting. Research Sponsor: None.

A four-tier classification system for studying homologous recombination repair gene reversion mutations as a mechanism of resistance to PARP inhibitors and platinum chemotherapy. *First Author: Qiuxiang Ou, Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing, China*

Background: Pathogenic mutations in homologous recombination repair (HRR) genes are highly associated with the oncogenesis of multiple cancers and represent favorable biomarkers for platinum (Pt)-based chemotherapy and poly ADP ribose polymerase inhibitors (PARPi). While the development of drug resistance by restoring protein function via secondary mutation is commonly observed, a thorough analysis of the landscape of HRR gene reversion mutation is lacking. **Methods:** A real-world database with ~13,000 pan-cancer patients who underwent targeted next-generation sequencing and contained a primary germline or somatic pathogenic mutation of 25 pre-defined HRR genes, including *ATM*, *ATR*, *BARD1*, *BLM*, *BRCA1*, *BRCA2*, *BRIP1*, *CDK12*, *CHEK1*, *CHEK2*, *ERCC3*, *FANCA*, *FANCC*, *FANCD2*, *FANCI*, *FANCL*, *MRE11A*, *NBN*, *PALB2*, *RAD51*, *RAD51C*, *RAD51B*, *RAD51D*, *RAD54L*, and *WRN*, was used to identify HRR secondary mutations, which were further classified into four tiers by mutation type and intended reversion mechanism. Patient's clinical data and treatment history were retrospectively reviewed. **Results:** The potential mechanism of HRR gene reversion was categorized into four tiers, including Tier 1 (single nucleotide variation, SNV), Tier 2 (frameshift), Tier 3 (deletion), and Tier 4 of other mutation types that were not further discussed in this study. A total of 42 patients were identified with Tier 1/2/3 secondary HRR gene mutations in the presence of a primary pathogenic germline (N = 32) or somatic (N = 10) mutation. *BRCA1* (15/42, 35.7%) and *BRCA2* (23/42, 54.8%) were most frequently observed in this cohort with significant enrichment of exon 11 aberrations of both genes. The other HRR genes identified of Tier 1/2/3 reversion mutations included *PALB2* (N = 3, Tier 3) and *RAD51D* (N = 1, Tier 1). More specifically, a majority of *BRCA1* reversion mutations (8/15) were Tier 1 SNV, while the most prevalent reversion mechanism for *BRCA2* was Tier 3 deletion, which accounted for 60.9% (14/23) of all *BRCA2* cases with a median deleted length of 1164 bp (range: 153–6745 bp). Furthermore, we reported the treatment history data of three cancer patients (pancreatic, prostate, and lung, respectively) demonstrated the acquisition of *BRCA2* reversion mutations (Tier 2 and Tier 3) at post-Pt/Olaparib in the presence of a primary germline *BRCA2* pathogenic mutation, strongly suggestive of the role of reversion mutations in driving resistance to Olaparib or Pt-chemotherapy. **Conclusions:** Owing to a large-scale real-world dataset, we retrospectively investigated the landscape of the reversion mechanism of HRR genes and established a four-tier classification system for secondary HRR mutations in the presence of primary germline/somatic pathogenic HRR mutations. This study is of great clinical value in studying mechanisms of drug resistance to Pt-chemotherapy and PARPi. Research Sponsor: None.

Larotrectinib long-term efficacy and safety in adult patients (pts) with tropomyosin receptor kinase (TRK) fusion cancer. *First Author: David S. Hong, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Neurotrophic tyrosine receptor kinase (*NTRK*) gene fusions are oncogenic drivers in a broad array of tumor types. Larotrectinib is a first-in-class, highly selective, central nervous system (CNS)-active TRK inhibitor approved for tumor-agnostic use in pts with TRK fusion cancer based on a rapid, robust, and durable objective response rate (ORR) in both adult and pediatric pts with various non-primary CNS cancers. Here, we report data on an expanded cohort of adult pts with TRK fusion cancer treated with larotrectinib. **Methods:** Adults with non-primary CNS TRK fusion cancer treated in three larotrectinib clinical trials (NCT02576431, NCT02122913, and NCT02637687) were included. Larotrectinib was administered at 100 mg twice daily in most pts. Responses were assessed per Independent Review Committee (IRC) using RECIST v1.1. Data cut-off: July 2022. **Results:** As of July 2022, there were 194 adult pts enrolled, with 180 eligible for efficacy analyses by IRC; 22 pts had known brain metastases at baseline. There were 24 different tumor types; the most common were lung (n=30; 15%), soft tissue sarcoma (n=30; 15%), thyroid (n=28; 14%), salivary gland (n=25; 13%), and colon (n=23; 12%). Median age was 57 years (range 19–90). The gene fusions involved *NTRK1* (n=90; 46%), *NTRK2* (n=7; 4%), or *NTRK3* (n=97; 50%). Pts had previously received a median of one systemic therapy (range 0–10). ORR was 57% (95% CI 50–65): 29 (16%) complete response (including one pathological complete response), 74 (41%) partial response, 39 (22%) stable disease, 23 (13%) progressive disease, and 15 (8%) not evaluable. ORR in 22 evaluable pts with baseline CNS metastases was 68% (95% CI 45–86). Median time to response was 1.8 months, and median duration of response was 43.3 months (95% CI 29.2–not estimable [NE]) at a median follow-up of 32.3 months. Median progression-free survival was 24.6 months (95% CI 11.3–34.5) at a median follow-up of 28.5 months. Median overall survival was 48.7 months (95% CI 38.5–NE) at a median follow-up of 33.8 months. At data cut-off, 39 of the 73 pts who had disease progression continued treatment post-progression for ≥ 4 weeks. Treatment-related adverse events (TRAEs) were predominantly Grade 1/2. Grade 3/4 TRAEs occurred in 27 (14%) pts. Treatment discontinuation due to TRAEs was reported in one pt (increased alanine aminotransferase and aspartate aminotransferase). **Conclusions:** In this expanded dataset with extended follow-up, larotrectinib continues to demonstrate rapid and durable responses, extended survival, and a favorable safety profile in adults with TRK fusion cancer, including those with CNS metastases. These results support the wider adoption of next-generation sequencing panels that include *NTRK* gene fusions when testing pts with solid tumors; this ensures that pts are offered the right medicine for their disease as soon as possible. Clinical trial information: NCT02576431, NCT02122913, NCT02637687. Research Sponsor: These studies were funded by Bayer HealthCare Pharmaceuticals, Inc.

Treatment of chronic hepatitis C virus infection to increase access to cancer clinical trials in patients with hematologic malignancies: A prospective observational study. *First Author: Khalis Mustafayev, Departments of Infectious Diseases, Infection Control and Employee Health. The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Most cancer patients with chronic hepatitis C virus (HCV) infection are excluded from cancer clinical trials (CCTs). The use of direct-acting antivirals (DAAs) to eradicate HCV and allow access to CCTs in HCV-infected cancer patients has not been studied. We aimed to evaluate the efficacy and safety of DAA treatment to increase access to CCTs in patients with chronic HCV infection and hematologic malignancies (HM). **Methods:** HCV-infected patients with HM seen at MD Anderson Cancer Center between 01/01/2016 and 01/31/2023 were enrolled in a prospective observational study. Those initially excluded from CCTs and then treated with DAAs to allow that cancer treatment were further analyzed (cases). HCV-infected cancer patients treated with DAAs but never enrolled in CCTs were used as controls. The 1:1 matching between cases and controls was based on the cancer type and stage, history of > 3 types of chemotherapy, and presence of cirrhosis. The primary outcomes were the efficacy and safety of DAAs. The secondary outcomes were overall survival (OS) and progression-free survival (PFS). **Results:** Twenty-four patients with HM initially excluded from CCTs because of HCV were enrolled. Twelve of them (50%) received DAAs to have access to CCTs and they were matched to 12 controls. Most of the cases were men (10; 83%), white (6; 50%), non-cirrhotic (10; 83%), and with HCV genotype 1 (9; 75%). Most patients in the control group were men (7; 58%), white (9; 75%), non-cirrhotic (8; 67%), and with HCV genotype 1 (9; 75%). Among the entire study group, adverse events occurred in 6 of the 24 patients (25%), and all were grade 1-2. No HCV-associated liver failure or death occurred. The overall sustained virologic response (microbiologic cure) after completion of antiviral therapy was 92%. Median OS was 74 months in the cases vs 52 months in the controls, median PFS was 30 months in the cases vs 33 months in the controls. When compared to controls in multivariate analysis, cases had significantly better OS (hazard ratio = 0.23, 95% CI = 0.06 to 0.85, $p = 0.027$). No significant differences were noted in PFS ($p = 0.13$). Death due to progressive HM occurred in all 12 controls (100%) but only in 4 cases (33%) ($p = 0.001$). **Conclusions:** DAA treatment increases access to CCTs and improves OS in patients with chronic HCV infection and HM. HCV infection should not be considered a contraindication to investigational cancer treatment. The use of DAAs to facilitate access CCTs could become one of the most common indications for DAAs in HCV-infected cancer patients. Novel LTK fusions based on NGS sequencing data in Chinese patients with solid tumors. *First Author: Hui Chen, Shanghai Origimed Co., Ltd, Shanghai, China*

Background: Leukocyte receptor tyrosine kinase (*LTK*) gene has the same kinase domain (PTKc-ALK-*LTK*) as *ALK*, and could functionally respond to *ALK* inhibitors such as lorlatinib. Previous study reported that *CLIP1-LTK* fusion was a novel oncogenic driver mutation in lung cancer (occur in 0.4% of non-small cell lung cancer), which was sensitive to the *ALK* tyrosine kinase inhibitor lorlatinib. So far, *LTK* fusion has been rarely reported. **Methods:** A total of 11 Chinese solid tumor patients were reviewed, including 6 cases of *LTK* positive rearrangements in DNA and 5 cases of *LTK* positive fusion in RNA. FFPE samples were collected for NGS-based 450 cancer gene panel detection in both DNA and RNA level, and matched blood samples were used as normal control to filter out germline mutations. *LTK* fusions were analyzed by Origifus algorithm. **Results:** We found 6 patients with *LTK* rearrangements by DNA-based NGS detection, including lung adenocarcinoma, colorectal cancer, stomach cancer, spindle cell sarcoma of small intestine, adenocarcinoma of the pancreas, and cancer of unknown primary, and 5 soft tissue sarcoma patients with *RPAP1 E25-LTK E2* fusions by RNA-based NGS detection. We analyzed the patterns of partner genes and breakpoints of the 6 *LTK* rearrangements. The partner genes included *NUSAP1* ($n=2$), *NDUFAF1* ($n=1$), *LOC105370802* ($n=1$), *EHD4* ($n=1$), and *AGBL1* ($n=1$). All these partner genes were located on the same chromosome as *LTK*, rather than *CLIP1*, which was identified as a translocation. The breakpoints on *LTK* included exon20 ($n=2$), intron1 ($n=2$), exon6 ($n=1$), and exon10 ($n=1$). Five of the 6 fusions consisted of a complete PTKc-ALK-*LTK* domain. Among the 6 *LTK* rearrangements, *LTK E20-NUSAP1 E2* was predicted as a fusion. Interestingly, this clinical real-world sample also harbored a classic *NTRK1* fusion, *LMNA E2-NTRK1 E11*. The other *NUSAP1-LTK* was predicted to have a transcript of 3'-3', but one of the breakpoints was observed at *LTK* exon6, which could be located at the kinase domain, so the possibility of eventual fusion cannot be excluded. The two *NUSAP1-LTK* fusions were found in a stomach tumor and a soft tissue sarcoma, respectively. One non-small-cell lung cancer (NSCLC) patient had a breakpoint detected on *LTK* exon10, which is the same as the exon of *CLIP1-LTK* reported. **Conclusions:** This study revealed novel *LTK* fusions/rearrangements and their cancer distribution in Chinese patients with solid tumors. We gave the details of these fusions/rearrangements which enrich our understanding of the *LTK* fusion. Although the small number of cases, our analysis promoted the attention on *LTK* and its potential value of drug research and clinical treatment in pan-cancer. Research Sponsor: None.

Poster Session

Dupilumab for the treatment of dermatologic adverse events associated with MEK and EGFR inhibitors. *First Author: Stephanie Gu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Mitogen activated protein kinase kinase inhibitors (MEKi) and epidermal growth factor receptor inhibitors (EGFRi) are targeted therapies used in the treatment of various cancers. Dermatologic adverse events (dAEs) are common with these medications. Dupilumab, a human monoclonal antibody that targets IL-4, is an FDA approved therapy for the treatment of atopic dermatitis. It has also shown utility in the treatment of many other skin disorders, including toxicities associated with anticancer therapies. In our study, we aim to evaluate the efficacy and safety of dupilumab for the treatment of MEKi/EGFRi associated dAEs. **Methods:** Patients who received dupilumab for the treatment of a dAE attributed to MEKi or EGFRi from 3/1/2017 to 10/1/2022 were identified at Memorial Sloan Kettering Cancer Center. Severity of dAEs was graded at baseline and follow up using Common Terminology Criteria for Adverse Events (CTCAE) v5.0. Patient response to dupilumab was categorized into complete response (CR) (reduction to grade 0), partial response (PR) (reduction to grade 1), or no response (NR) (including change from grade 3/2 to grade ≥ 2). **Results:** A total of 17 patients (median age 62 years [5 – 87], 58.8% female) who received dupilumab for MEKi (70.6%) or EGFRi (29.4%) related dAEs were identified. Two patients on MEKi were also on concomitant BRAF inhibitors. Patients were white (88.2%), black (5.9%), and Asian (5.9%) and were all undergoing treatment for solid tumors. All dAEs had an eczematous phenotype; 16 were grade 2 (88.2%) and one (5.9%) was grade 3. The median time from dAE development to initiation of dupilumab was 121 days (5 – 1330). Following treatment, 15 patients (88.2%) experienced improvement, with 46.7% and 53.3% achieving CR and PR, respectively. Patients were on dupilumab for a median of 89 days (0-2556), with CR and PR patients exhibiting initial documented response after a median of 30 days (6 – 173). The median CTCAE grade decreased from 2 to 1, and the number of patients on topical and systemic steroids following addition of dupilumab decreased from 17 (100%) to 7 (41.2%) and 5 (29.4%) to 1 (5.9%), respectively. As a result of intolerable anti-cancer therapy-associated dAEs, 4 patients (all on MEKi) initially discontinued their antineoplastic. Three patients (75%) were successfully rechallenged with their original MEKi, while 1 (25%) was switched to another MEKi without subsequent dAE recurrence. No patients reported adverse events to dupilumab treatment. **Conclusions:** Patients may experience eczematous eruptions while undergoing treatment with MEKi or EGFRi. Dupilumab may be a safe and effective steroid sparing therapeutic option for the management of these dAEs. Research Sponsor: None.

Immune modulation and the oral live biotherapeutic product, MRx0518, in treatment-naïve patients with cancer: Updated safety data. *First Author: Mark Lythgoe, Imperial College, London, London, United Kingdom*

Background: Live biotherapeutic products (LBPs) are emerging novel anti-cancer therapies. MRx0518 is a gut microbiome-derived oral LBP, consisting of a single strain of *Enterococcus gallinarum*, which has demonstrated potent anti-tumorigenic efficacy pre-clinically. We have previously shown MRx0518 monotherapy is associated with significant genomic, immune, microbiome, and metabolomic changes, consistent with anti-cancer efficacy in treatment-naïve patients. Here, we report long-term subject follow-up, and further signals of immune modulatory changes from flow cytometry analysis. **Methods:** NCT03934827 is a Phase 1B single-centre study in treatment-naïve patients with confirmed cancer, planned for surgical resection. 17 patients (8 breast, 4 prostate, 3 uterine, 1 bladder & 1 melanoma) received MRx0518 (1×10^{10} – 1×10^{11} CFU) BID monotherapy for 7-28 days from inclusion until surgery. Safety data was collected from dosing until 1-year following cessation. Exploratory analysis included evaluation of pre- and post-treatment peripheral blood mononuclear cells (PBMCs) by multiparametric flow cytometry for leucocyte activation, indicative of anti-cancer efficacy. **Results:** A total of 29 adverse events (AEs), all CTCAE grade 1 (96%) and grade 2 (4%), were reported. Only 8 (28%) were deemed related to MRx0518. No grade 3/4 toxicities or serious AEs were recorded. At 30-days, and 1-year follow-up no further serious AEs occurred. At a median follow-up of 41 months, 13 (76%) patients remain cancer-free, with 2 (11%) reoccurrences and 2 (11%) lost to follow-up. Analysis of pre- and post-treatment PBMCs identified statistically significant increases in CD3⁺CD56⁺ ($p < 0.0005$), natural killer cells ($p < 0.005$), natural killer T-cells ($p < 0.01$), CD8⁺CD62L⁺ ($p < 0.001$), and CD4⁺CD62L⁺ ($p < 0.0001$) subsets following MRx0518 therapy. A positive trend was also seen in CD3⁺CD8⁺ cells. Furthermore, we observed a significant increase in both subsets of T-regulatory lymphocytes (nTreg ($p < 0.05$) and eTreg ($p < 0.05$)) and a decrease in both CD4⁺ ($p < 0.05$) and CD8⁺ ($p < 0.005$) central memory cells. Sub-analysis of the breast cancer patient group showed a significantly higher increase in CD3⁺CD56⁺ cells ($p < 0.0001$) and intermediate monocytes ($p < 0.01$). **Conclusions:** This study demonstrates the long-term safety profile of MRx0518 therapy in treatment-naïve cancer patients. Analysis of PBMCs reveals clear evidence of immune modulation, consistent with significant anti-cancer efficacy. This is concordant with prior findings from this study. Notably, significant changes in CD3⁺CD56⁺ have also been demonstrated in other studies of microbiome modulation (e.g., NCT03341143), and may be important determinant of anti-cancer efficacy. Despite the limitations of a small sample size, this effect is particularly prominent in the breast cancer subgroup, warranting further evaluation. Clinical trial information: NCT03934827. Tumor-agnostic genomic and clinical analysis of solid tumors with *BRAF* fusions. *First Author: Monica F Chen, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Approximately 15% of cancers harbor *BRAF* alterations, of which ~5% are *BRAF* fusions. *BRAF* fusions are class II alterations that have worse outcomes than class I V600E alterations. While prior investigational therapies for *BRAF* fusions had disappointing outcomes, novel therapies are in clinical trials, underscoring the need to better characterize these tumors. **Methods:** Data from adult and pediatric patients with *BRAF* fusion+ cancers identified between January 2014 and November 2022 utilizing a center-wide next generation sequencing (NGS) program of >99,000 sequenced samples were analyzed. DNA-based hybrid capture tumor NGS (MSK-IMPACT), ctDNA targeted NGS (MSK-ACCESS), and/or RNA anchored multiplex PCR tumor NGS (MSK-Fusion) were used. Fusions were manually reviewed and considered to have oncogenic potential if they had an in-frame protein fusion involving a non-*BRAF* partner gene and an intact *BRAF* kinase domain (exons 11-18). Fusions not previously reported in OncoKB, COSMIC, TCGA, NIH gene, Fusion GDB2, and PubMed were classified as novel. All cases underwent clinical data curation including baseline demographic, tumor characteristics, and treatment histories. **Results:** 212 patients (0.2%) with *BRAF*-fusion positive solid tumors were identified. 194 were identified by DNA-based tumor NGS (96 had sufficient tissue for confirmatory RNA-based NGS, all of which were positive). Six were identified by ctDNA NGS and 12 by RNA-based tumor NGS only (5 had insufficient tissue for DNA-based tumor NGS). 83 unique 5' fusion partners were found, of which 42 were novel. The most frequent tumor types were pilocytic astrocytoma (n=30, 14%), prostate CA (n=28, 13%), melanoma (n=24, 11%), lung CA (n=21, 10%), and colon CA (n=15, 7%). 44% of patients with pilocytic astrocytoma had *BRAF* fusions, of which 90% were *BRAF-KIAA1549*. Concomitant alterations ($\geq 10\%$ frequency) included *TP53* (24%), *TERT* (18%), *CDKN2A* deletions (13%), and *CDKN2B* deletions (12%). 20% (n=43) were treated with MAPK-pathway directed therapies spanning multiple histologies and lines of therapies. Of the 212 patients, 17 had acquired *BRAF* fusions after targeted therapy for another oncogene (*EGFR* mutation (n=11), *BRAF*V600E (n=4), *FGFR* fusion (n=1), *NTRK* fusion (n=1)). The majority of patients with acquired *BRAF* fusions had *EGFR*-mutant lung adenocarcinoma (n=11, 76%); the median time from *EGFR* targeted therapy initiation to *BRAF* fusion detection was 25 months (range 16-38 months). **Conclusions:** A wide variety of adult and pediatric solid tumors harbored de novo *BRAF* fusions. Complementary RNA sequencing optimized fusion identification in many cases. Multiple novel fusion partners were found. Acquired *BRAF* fusions were identified after targeted therapy for a variety of distinct oncogenes, the majority of which were *EGFR* mutations. Research Sponsor: T32.

Reporting and impact of subsequent cycle toxicities in oncology phase I clinical trials. *First Author: Avina Rami, Harvard Medical School, Boston, MA*

Background: In recent years, the landscape of clinical trial development has evolved to include immunotherapy and targeted therapies, which have different lengths of administration and toxicity profiles compared to standard chemotherapy. As treatments have evolved, the classic assumptions of toxicity associated with cytotoxic agents may be less relevant, requiring new strategies for design of trials intended to inform dosing strategies for agents that may be administered beyond a set number of defined cycles. We aimed to describe the overall incidence of dose-limiting toxicities (DLTs) during and after cycle 1, the frequency of reporting subsequent cycle toxicities, and the impact of post-cycle 1 DLTs on conclusions drawn from oncology phase I clinical trials. **Methods:** We conducted a systematic review of subsequent cycle toxicities in oncology phase I clinical trials published in the *Journal of Clinical Oncology* from 2000 to 2020. Only trials that included more than one cycle of therapy were included. Data elements captured included: year of publication, study design, trial sponsor type, intervention type, number of anti-cancer therapies involved, primary diagnosis, incidence and type of cycle 1 DLT, incidence of dose modification in cycle 1, incidence and type of post-cycle 1 DLTs, incidence of dose modification in post-cycle 1, presence of a recommended phase 2 dose (RP2D) and impact of subsequent cycle toxicity on RP2D. **Results:** From 2000 to 2020, we identified 489 full-text articles reporting on therapeutic phase I clinical trials. Of these, 421 (86%) reported data regarding cycle 1 DLTs and 170 (35%) reported cycle 1 dose modifications. The overall median cycle 1 DLT rate was 8.89%. Only 47 (9.6%) publications reported whether or not there were post-cycle 1 DLTs and only 92 (19%) reported whether or not there were dose modifications beyond cycle 1. The overall median post-cycle 1 DLT rate among trials that reported post-cycle 1 data was 14.8%. A RP2D was reported in 76% (371 of 489) trials. Among these 371 studies, 89% did not report whether post-cycle 1 toxicities impacted the RP2D. Independent predictors of reporting toxicity data beyond cycle 1 included year of publication, investigational agent type, novelty, disease type, trial size, and sponsor. **Conclusions:** Reporting of subsequent cycle DLTs and dose modification is uncommon in oncology phase I clinical trial publications. As newer oncology treatments trend towards longer duration of treatment, there will be an increased need to understand toxicities occurring post-cycle 1. Guidelines for reporting of phase I clinical trials should expand to include toxicity data beyond the first cycle. Research Sponsor: Alex's Lemonade Stand Foundation.

Phase 1 studies of D07001-F4 and D07001-softgel capsule: Oral metronomic gemcitabine in subjects with advanced solid tumors. *First Author: Chia-Chi Lin, National Taiwan University Hospital, Taipei, Taiwan*

Background: Metronomic chemotherapy with frequent, low dose administration may not only retain the anticancer feature of conventional, periodic maximum tolerated dose (MTD)-based, parenteral chemotherapy, but also possess other novel properties such as immune enhancement and angiogenesis suppression. D07001 is an absorption, enhanced oral gemcitabine originally developed as liquid form (D07001-F4), then further refined into D07001-softgel capsule to enhance therapeutical applicability. Herein, we report the results of two phase I studies that evaluated the dose-limiting toxicity (DLT), pharmacokinetics (PK), bioavailability (BA) and maximum tolerated dose (MTD) of D07001-F4 and D07001-softgel capsules in subjects with refractory, advanced solid tumors. **Methods:** Both studies applied 3+3 dose escalation design. Referring to a similar trial by Eli Lilly, in the first Phase I study (NCT01800630), eligible subjects received a bolus intravenous injection of 5 mg gemcitabine in run-in period then D07001-F4 thrice per week for 2 weeks followed by 1 week rest with escalating doses from 2 to 80 mg. Since no dose-limiting toxicity (DLT) was observed even at maximum 80mg dose-level (DL) in this study, another Ib study (NCT03531320) with the uses of refined D07001-softgel capsule and a modified regimen without the resting period was conducted in subjects with refractory gastrointestinal malignancies to investigating the DLT, maximum tolerated dose (MTD) and PK. The test dose of this Ib study was from 40 to 120 mg (40, 60, 80, 120), in which the bridging dose of 40 mg was employed based on its equivalence to the dose of 80 mg in the first Phase I study. **Results:** A total of 53 eligible patients were enrolled, 34 (10 DL) and 19 (5+1 DL) in the Phase I and Ib studies, respectively. Comparing to parenteral gemcitabine, the mean oral bioavailability of D07001-F4 was about 39%. No DLT was observed in all planned DL, until the 120 mg DL of D07001-softgel capsules, in which 2/6 patients had DLTs (grade 3 hepatotoxicity and grade 3 anorexia, respectively). An addition 100 mg DL was tested (without DLT in a 3 patient cohort) and determined as MTD. Cmax and AUC_(0-48h) of gemcitabine metabolite (dFdU) on C1D1 were largely dose-dependent and comparable for two formulations at bridging dose levels. Despite similar trend for dFdC, more inter-individual variation was observed. The mean dFdC Cmax at MTD of D07001-softgel capsules was 24 ng/mL (0.09 mM) and half-life of 5 hours. Grade >3 anorexia (10.5%) and diarrhea (10.5%) were observed in Phase Ib extension study. **Conclusions:** The results suggest the feasibility of oral gemcitabine treatment with D07001-softgel capsules, which is well-tolerated for continuous dosing and deserves further clinical investigation. Clinical trial information: NCT01800630, NCT03531320. Research Sponsor: Innopharm Inc.

The characteristics of metabolic related pathways under different anoikis activities revealed by pan-cancer analyses. *First Author: Shanshan Xiao, Hangzhou Repugene Technology Co., Ltd., Hangzhou, China*

Background: Anoikis is usually activated to eliminate extracellular matrix-detached cells. Cancers develop several mechanisms to escape from this cellular death signaling pathway which was associated with metabolic reprogramming in tumor development and progression. Comprehensively understanding the characteristics of anoikis activities in pan cancers facilitating better clinical treatment strategies. **Methods:** RNA-Seq data and related patient information were collected from 33 cancer types in TCGA database. We also obtained anoikis related genes (ARGs) from Harmonizome database. The related pathways of epithelial-mesenchymal transition (EMT) and reactive oxygen species (ROS) genes were collected from MSigDB. Autophagy genes were from HADB and metabolic intermediates were from published literatures. Firstly, pathway scores of anoikis and the related pathways were computed through single sample gene set enrichment analysis (ssGSEA). Then, survival analyses based on the anoikis scores were performed to achieve the threshold between the high anoikis (HA) or low anoikis (LA) sample groups. To study the drug efficacy, cell line transcriptome and IC50 data were obtained from GDSC database. Pearson correlations were computed between anoikis and other related pathways or immune cell infiltrations in each sample group. **Results:** Most ARGs were up-regulated in tumors, the same as the HA sample group. Differentially expressed genes between HA and LA were mostly involved in metabolic super-pathways, including metabolic intermediates (TCA cycle, carbohydrate, lipid, nucleotide, vitamin cofactor, and amino acid, etc.) and promoting anoikis-resistance pathways including EMT, inflammation and autophagy. Higher scores of anoikis related pathways were identified in HA across various cancers. Kaplan-Meier survival analysis revealed that HA in KIRC, KIRP, LAML, LGG, LUAD, PAAD, STAD, THYM, and UVM cancers had significantly worse clinical outcomes ($p < 0.05$). Functional enrichment analysis of ARGs through GSEA suggested that anoikis resistance was promoted, whereas anoikis was retarded in those cancers. However, patients in HA of several cancers had longer survives than LA, which may owe to the higher infiltrating levels of anti-tumor immune cells including CD8+ T, CD4+ memory activated T cells, particularly in BRCA, MESO, SARC, and UCEC cancers. Drug efficacy analysis revealed that *BCL2* gene was significantly associated with sensitive drug response on Venetoclax, ABT737, and Tozasertib. And *TLE1* and *CAV1* were associated with Tozasertib resistance and AZD5991 resistance, respectively. **Conclusions:** The characteristics of anoikis activities and metabolic related pathways during tumor progression were comprehensively studied and the prognosis value of anoikis was further assessed by drug efficacy. Development of bifunctional CRBN-SOS1 degraders for treatment of mutant KRAS cancers. *First Author: Kyle Begovich, Biotheryx, Inc, San Diego, CA*

Background: KRAS, a GTPase that regulates cellular growth, is the most frequently mutated oncogene in non-small cell lung, pancreatic and colorectal cancers. Hyperactivation of KRAS in mutant alleles result in upregulated signaling within the MAPK pathway leading to aberrant cell proliferation. In addition to the pan- and mutant-specific KRAS inhibitors, its upstream GEF activator, SOS1, has emerged as an attractive therapeutic target given its ability to regulate the active, GTP-loaded state of KRAS and mitigate MAPK pathway feedback. **Methods:** Utilizing our PRODEGY platform, we developed bifunctional CRBN-SOS1 degraders for the treatment of patients with KRAS-mutated cancers, independent of mutation type. **Results:** Our degraders display CRBN- and proteasome-mediated SOS1 degradation with $DC_{50s} < 15nM$ in high-throughput (HiBit) and traditional Western Blot assays in multiple mutant KRAS cell lines. SOS1 degradation resulted in the reduction of active KRAS, HRAS and MRAS levels when assayed by RAF-RBD pull-downs in MIA PaCa-2 (KRAS G12C) cells. Other downstream signaling markers (pERK and pS6) were also decreased upon SOS1 degradation in KRAS G12C, G12V, G12S and G13D cell lines in 3D Western Blot assays. Notably, the observed pERK and pS6 inhibition was driven by SOS1 degradation and not inhibition as decreases in signaling was no longer observed when SOS1 degraders were outcompeted with CRBN competitors. To assess the antiproliferative effects of our SOS1 degraders, we developed 3D proliferation assays in various KRAS mutant (G12A, G12C, G12D, G12V, G12S, G13C and G13D) as well as KRAS amplified cell lines and observed IC_{50s} ranging from 0.5 - 70nM. Treatment of CRBN KO and SOS1 KO H358 and MIA PaCa-2 cell lines with our SOS1 degraders resulted in 100- to 400-fold IC_{50} values, validating that the functional activity observed is dependent on its targets. Consistent with our *in vitro* data, treatment of SOS1 degraders in MIA PaCa-2 xenografts resulted in > 90% degradation and led to significant tumor growth inhibition. Given the diversity of mutations and tumors as well as acquired drug resistance to allele-specific KRAS inhibitors, we sought to determine if coupling SOS1 degradation with other EGFR-RAS-MAPK inhibitors could produce more potent responses to maximize patient benefit. Strong synergistic antiproliferative effects were observed when SOS1 degraders were co-treated with KRAS inhibitors AMG510 (G12C) and MRTX1133 (G12D) in respective KRAS-mutant cell lines as well as with MEK inhibition and EGFR inhibition. Lastly, combination of AMG510 or Trametinib with SOS1 degraders yielded strong synergy and a greater anti-tumor response in MIA PaCa-2 xenografts relative to the individual agents themselves. **Conclusions:** Together, these results highlight the potential of SOS1 degraders alone and in combination as therapeutic options for a variety of KRAS-driven cancers. Research Sponsor: Biotheryx.

TROPION-PanTumor03: Phase 2, multicenter study of datopotamab deruxtecan (Dato-DXd) as monotherapy and in combination with anticancer agents in patients (pts) with advanced/metastatic solid tumors. *First Author: Yelena Y. Janjigian, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pts with metastatic epithelial tumors who progress after initial therapy have a poor prognosis; new therapeutic agents could potentially improve outcomes. Trophoblast cell surface protein 2 (TROP2) is a transmembrane glycoprotein that is over-expressed on the cell surface of many epithelial cancers representing a promising target for surface-directed therapeutic modalities. Dato-DXd is an antibody-drug conjugate consisting of a humanized anti-TROP2 IgG1 monoclonal antibody covalently linked to a highly potent topoisomerase I inhibitor payload via a stable, tumor-selective, tetrapeptide-based cleavable linker. Dato-DXd monotherapy demonstrated encouraging efficacy and safety in pts with lung and breast cancer (TROPION-PanTumor01 study; NCT03401385). **Methods:** The phase 2, multicenter, open-label TROPION-PanTumor03 study (NCT05489211) is exploring safety and efficacy of Dato-DXd as monotherapy and in combination with various anticancer agents (e.g. durvalumab, AZD5305, nivolumab, bevacizumab, chemotherapies) that may be active in the tumor types being evaluated. TROPION-PanTumor03 is a master trial comprising independent substudies to enable simultaneous evaluation of the recommended phase 2 dose (RP2D), safety, and preliminary efficacy of Dato-DXd across several tumor types and treatment combinations. Pts with endometrial, gastric, metastatic castration-resistant prostate (mCRPC), ovarian, and colorectal (CRC) cancer are being enrolled. Eligible pts: age ≥ 18 years, histologically/cytologically documented advanced or metastatic disease, ≥ 1 measurable target lesion (RECIST 1.1) not previously irradiated (mCRPC substudy: non-measurable bone metastatic disease permitted), and adequate bone marrow and organ function. An FFPE tumor sample must be available for all pts. Prospective selection for TROP2 expression is required in pts with CRC; in all other cohorts, TROP2 expression will be analyzed retrospectively. In all monotherapy cohorts, pts will receive Dato-DXd 6 mg/kg IV infusion Q3W; in the combination cohorts, Dato-DXd 4 or 6 mg/kg Q3W, as appropriate for each combination. Pts will receive treatment until disease progression, unacceptable toxicity, or withdrawal. Primary endpoints: objective response rate, PSA50 response (mCRPC substudy only), and safety/tolerability. Secondary endpoints: progression-free survival, duration of response, disease control rate, best % change in tumor size, pharmacokinetics, and immunogenicity (anti-drug antibodies). Exploratory endpoints incl. overall survival, pt-reported outcomes, and biomarker analysis (incl. TROP2 and PD-L1 expression, tumor mutational profiling, proteomics and ctDNA profiling). Recruitment is ongoing as of Feb 2023. ©2023 American Association for Cancer Research. Reused with permission. Clinical trial information: NCT05489211. Research Sponsor: AstraZeneca in collaboration with Daichi-Sankyo.

A powerful drug combination strategy targeting BRAF-mutant melanoma. *First Author: Luke Daniel Rothermel, University Hospitals, Seidman Cancer Center and Department of Surgery, Cleveland, OH*

Background: BRAF inhibitors, such as vemurafenib and dabrafenib, are effective in treating patients with melanoma harboring (V600E) BRAF mutations. These drugs block the activity of the mutated BRAF protein, which impacts the development and progression of melanoma. Despite initial efficacy, drug resistance reliably occurs leading to disease relapse. Here we show how BRAF inhibitors cause metabolic reprogramming in melanoma cells to achieve drug resistance and promote cell survival. Previously we demonstrated that wild-type isocitrate dehydrogenase 1 (wtIDH1) supports mitochondrial function and maintains redox homeostasis in melanoma, and that an FDA-approved mutant IDH1 inhibitor, ivosidenib (AG-120), is actually a potent wtIDH1 inhibitor. Thus, we hypothesized that wtIDH1 inhibition would synergize with BRAF inhibition. **Methods:** Metabolomic profiling using LC-MS determined the impact of BRAF inhibition on cellular metabolism. Cell viability was assessed by PicoGreen in drug combination assays. Synergism was calculated using the Bliss-Independence dose-response model for drug interaction. *In vivo* modeling of AG-120 in combination with BRAF inhibition used melanoma cell xenografts in athymic nude mice for tumor volume analyses, and survival studies were performed in both immunocompetent C57BL/6J mice (murine YUMM1.7 cells) and immunocompromised athymic nude mice (human A375 cells). **Results:** Metabolomics data suggest that BRAF-mutated melanoma cells treated with BRAF inhibitors increased oxidative metabolism and mitochondrial dependence (i.e., survival adaptations). These alterations suggest an opportunity for mitochondrial inhibitors to improve drug efficacy. Targeting wtIDH1 with AG-120 in combination with dabrafenib significantly reduced melanoma cell viability. A positive synergy score and Bliss score greater than 1 indicate that the combined treatment was more effective in reducing cell viability than either treatment alone. Further, the combination of AG-120 and dabrafenib was the most effective *in vivo*, reducing tumor growth in the BRAF-mutated melanoma xenograft model, and improving mouse survival compared to monotherapy controls. Mice tolerated combination therapy with no reduction in body weight observed. **Conclusions:** Our findings indicate that dual inhibition of mutated BRAF and wild-type IDH1 represents a novel treatment strategy for BRAF-mutated melanomas, with potential for application to other BRAF-mutated cancers (e.g., colon, hepatobiliary, thyroid, etc.). XMT-1660: A phase 1b trial of a B7-H4 targeted antibody drug conjugate (ADC) in breast, endometrial, and ovarian cancers. *First Author: Erika P. Hamilton, Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN*

Background: Breast cancer (BC) is the most commonly diagnosed cancer and one of the leading causes of cancer death in women. Despite significant therapeutic advances, the majority of patients with unresectable or recurrent/metastatic disease eventually develop resistance to available standard of care (SOC) therapies. High B7-H4 expression has been observed in several cancers including breast, endometrial, and ovarian, with limited expression in normal tissue. As a member of the CD28/B7 family of cell surface proteins, it promotes tumorigenesis by suppressing anti-tumor immunity. XMT-1660 is a B7-H4-directed Dolasynthen antibody drug conjugate designed with a precise, optimized drug-to-antibody ratio and a DolaLock microtubule inhibitor payload with controlled bystander effect. In the preclinical setting, XMT-1660 has demonstrated anti-tumor activity in TNBC and ER+/HER2- patient-derived xenograft mouse models, which included tumors from heavily pre-treated patients (Collins et al, AACR 2022). Increased anti-tumor activity tended to be more frequent in preclinical models with higher B7-H4 expression, providing rationale for a Ph1 clinical trial. **Methods:** The Ph1 trial includes a first-in-human open-label dose escalation (DES) portion followed by dose expansion (EXP) evaluating XMT-1660 in patients with BC, EC, and OC following progression on SOC as applicable (i.e., CDK4/6i + ET; platinum-based chemotherapy). In the DES, Bayesian Optimal Interval (BOIN) design will be used to determine the MTD. Patients will receive XMT-1660 IV Q3 weeks. Primary endpoints in DES are to assess safety and determine a recommended phase 2 dose (RP2D) and assessment of preliminary efficacy as a secondary endpoint. In parallel with DES, optional backfill cohorts will enroll patients into tumor-type specific cohorts (TNBC, HR+/HER2- BC, EC, or OC) at a selected dose level from DES and can be initiated at multiple dose levels simultaneously. In the EXP portion, cohorts enrolling TNBC, ER+/HER2- BC, EC/OC are planned and additional patients may be enrolled based on emerging data. The primary endpoint of EXP is to assess safety and tolerability, overall response rate, disease control rate, and duration of response. Secondary endpoints include pharmacokinetic analysis and assessment of antidrug antibodies. Patients are not selected by B7-H4 status, but baseline tumors samples are collected for retrospective tumor tissue evaluation. The trial is currently enrolling patients. NCT05377996. Clinical trial information: NCT05377996. Research Sponsor: Mersana Therapeutics.

Poster Session

EGRET: A first-in-human study of the novel antibody-drug conjugate (ADC) AZD9592 as monotherapy or combined with other anticancer agents in patients (pts) with advanced solid tumors. *First Author: Charu Aggarwal, Perelman Center for Advanced Medicine, Philadelphia, PA*

Background: The epidermal growth factor receptor (EGFR) and mesenchymal-epidermal transition tyrosine kinase receptor (c-MET) are expressed in diverse solid tumors, and function as driver genes in some types. Clinical benefit of bispecific monoclonal antibodies (Ab) targeting these receptors was demonstrated in pts with EGFR mutated (EGFRm) non-small-cell lung cancer (NSCLC), but an ADC targeting these receptors has not been developed. AZD9592 is an ADC with a bispecific Ab targeting EGFR and c-MET. When internalized, AZD9592 releases a topoisomerase 1 inhibitor (TOP1i) warhead that traps TOP1 on DNA, causing double-strand breaks and induction of apoptotic cell death. Preclinical data have demonstrated promising efficacy and safety of AZD9592 in tumors expressing EGFR and c-MET, including but not limited to adenocarcinoma and squamous NSCLC and head and neck squamous cell carcinoma (HNSCC). **Methods:** EGRET is a phase 1, open-label, multicenter, modular study in pts with advanced solid tumors (NCT05647122). Module 1 will evaluate AZD9592 monotherapy in pts with metastatic NSCLC (mNSCLC) with EGFRm (sensitizing L858R mutation or exon 19 deletions) or EGFR wild-type, or recurrent or metastatic HNSCC. Module 2 will evaluate AZD9592 in combination with osimertinib in pts with EGFRm mNSCLC. Each module will include dose escalation (Part A) and dose expansion (Part B) cohorts. Key inclusion criteria are age ≥ 18 years, ECOG performance status 0–1, life expectancy ≥ 12 weeks, measurable disease per RECIST v1.1, and adequate organ and bone marrow function. Key exclusion criteria for both modules include unresolved toxicities of Grade ≥ 2 (NCI CTCAE v5.0) from prior therapy, uncontrolled intercurrent illness, cardiovascular disorders, history of drug-induced interstitial lung disease or pneumonitis, and previous treatment with a TOP1i ADC or an EGFR- or MET-targeted ADC. Treatment continues until disease progression, initiation of alternative anticancer therapy or unacceptable toxicity. The primary objectives of Part A are to assess safety and tolerability, and to determine the maximum tolerated dose and/or the recommended phase 2 dose of AZD9592 as monotherapy or in combination with osimertinib. The primary objectives for Part B are to evaluate safety and tolerability, and antitumor activity by investigator-assessed objective response rate (ORR) according to RECIST v1.1. Secondary objectives for both Part A and B include assessing AZD9592, as monotherapy and in combination with osimertinib, for efficacy (by ORR, disease control rate, duration of response, and progression-free and overall survival), pharmacokinetics, and immunogenicity. Descriptive statistics will be used for all variables. The study will include sites across the EU, USA, and Asia Pacific; sites in USA and Australia are currently open for enrollment. Clinical trial information: NCT05647122. Research Sponsor: AstraZeneca.

TROPION-Lung04: Phase 1b, multicenter study of datopotamab deruxatecan (Dato-DXd) in combination with immunotherapy $\pm$ carboplatin in advanced/metastatic non-small cell lung cancer (mNSCLC). *First Author: Hossein Borghaei, Fox Chase Cancer Center, Philadelphia, PA*

Background: Datopotamab deruxatecan (Dato-DXd) is a TROP2-directed antibody drug conjugate that has shown encouraging preliminary activity and safety in patients (pts) with lung or breast cancers. The TROPION-Lung04 study was designed to assess the safety, tolerability, and antitumor activity of Dato-DXd in combination with immunotherapy $\pm$ carboplatin in pts with advanced or metastatic NSCLC. **Methods:** TROPION-Lung04 (NCT04612751) is a Phase 1b, multicenter, open-label, 2-part, dose escalation/confirmation and expansion study in ≈ 232 pts without actionable genomic alterations. In Part 1 (dose escalation/confirmation), pts will be enrolled to 1 of up to 11 cohorts. Details of cohorts 1–4 (Dato-DXd [4 or 6 mg/kg] + durvalumab [1120 mg Q3W] $\pm$ up to 4 cycles of carboplatin [AUC 5] Q3W) were previously described (Borghaei H, *et al.* JTO 2021;16(10):S1098-S1099). Cohorts 5–11 were recently added to evaluate Dato-DXd in combination with bispecific immunotherapies AZD2936 (anti-PD-1/TIGIT) and MEDI5752 (anti-PD-1/CTLA-4) in treatment-naïve pts. Pts in cohorts 5–8 will receive Dato-DXd (4 or 6 mg/kg) + AZD2936 $\pm$ carboplatin; pts in cohorts 9–11 will receive Dato-DXd + MEDI5752 $\pm$ carboplatin. Cohorts 5 and 6 will recruit pts with PD-L1 tumor proportion score (TPS) $\geq 50\%$ in Parts 1 and 2A, and PD-L1 TPS 1–49% in Part 2B. Cohorts 7–11 will recruit pts with PD-L1 TPS $< 50\%$ only. Dose confirmation in Cohorts 5–11 will be guided by an mTP1-2 design where a minimum of 6 and a maximum of 9 pts will be assessed for dose-limiting toxicities (DLTs) during Cycle 1; if the DLT incidence meets pre-specified toxicity criteria, Part 2 dose expansions may be opened. Pts may continue Dato-DXd or immunotherapy treatment until disease progression (per RECIST v1.1) or unacceptable toxicity. Study endpoints are shown in the table. Enrollment across all combination cohorts is ongoing. Clinical trial information: NCT04612751. Research Sponsor: AstraZeneca in collaboration with Daiichi-Sankyo.

Study endpoints.

Primary endpoint	Assessment of safety and tolerability through the incidence of DLTs, treatment-emergent adverse events (AEs), serious AEs, AEs of special interest, ECOG performance status, vital signs and standard clinical/laboratory parameters
Secondary efficacy endpoints	Objective response rate Duration of response Disease control rate Progression-free survival Time to treatment response Best percentage change in the sum of diameters of measurable tumors Overall survival
Additional secondary endpoints	Pharmacokinetics Immunogenicity (anti-drug antibodies)

Poster Session

Phase 1/2 study of PRO1184, a novel folate receptor alpha-directed antibody-drug conjugate, in patients with locally advanced and/or metastatic solid tumors. *First Author: Justin A Call, START Mountain Region, West Valley City, UT*

Background: PRO1184 is an antibody-drug conjugate (ADC) directed to folate receptor alpha (FR α), a cell surface antigen overexpressed in multiple cancers including ovarian, endometrial, lung, mesothelioma, and breast cancer. PRO1184 consists of a human monoclonal antibody that selectively binds FR α , a novel cleavable hydrophilic linker, and a topoisomerase 1 inhibitor payload, exatecan. Previous studies demonstrated that the hydrophilic linker confers excellent physicochemical properties and pharmacokinetic (PK) profiles across a range of payload mechanisms and is superior to conventional linkers on these critical parameters for ADCs. In addition, exatecan is broadly active in many tumor types, is membrane permeable, and is not a substrate of multidrug resistance efflux pumps. It may thus lend a robust bystander effect and induce deeper or more durable responses in refractory tumors. Preclinical studies further established that PRO1184 exerts potent antitumor activity in mouse xenograft models with high, moderate, and low FR α expression, consistent with the inherent potency and expected bystander activity of the exatecan payload. PRO1184 is stable in plasma and retains the excellent PK properties and bioactivity of the unconjugated parent antibody. The preliminary safety profile of PRO1184 was more favorable than a benchmarking deruxatecan-based ADC in cynomolgus monkeys. PRO1184 is thus a promising development candidate with a potentially large therapeutic index to benefit a broad population of patients with FR α -expressing solid tumors. **Methods:** PRO1184-001 is an ongoing, phase 1/2, open-label dose escalation and expansion study. Eligible patients are adults with metastatic or unresectable solid tumors, including ovarian, endometrial, non-small cell lung, breast cancer, or mesothelioma. Patients must have measurable disease per the Response Evaluation Criteria in Solid Tumors (RECIST) 1.1, or mRECIST 1.1 for pleural mesothelioma. Patients must also have previously received therapies known to confer clinical benefit unless considered ineligible, refused by the patient, or not available in the region. PRO1184 is given by intravenous infusion on Day 1 of a 21-day cycle and treatment may continue until disease progression, unacceptable toxicity, or other reason for discontinuation. The primary objectives are to evaluate the safety and tolerability of PRO1184 and to identify the maximum tolerated dose, if reached, and recommended phase 2 dose (RP2D). Part A of the study consists of a dose escalation phase and Part B consists of 4 FR α -expressing tumor specific expansion cohorts treated at the RP2D. PK, immunogenicity, and antitumor activity will also be evaluated. The study is currently enrolling at sites in the US, with future enrollment in China planned (NCT05579366). Clinical trial information: NCT05579366. Research Sponsor: Profound Bio US Co.

Phase 1 trial of a novel C'Dot drug conjugate (CDC), ELU001, in patients with solid tumors known to overexpress folate receptor alpha (FR α). *First Author: Wen Wee Ma, Division of Medical Oncology, Mayo Clinic, Rochester, MN*

Background: ELU001 is a novel first-in-class nanoparticle drug conjugate that consists of ~ 13 folic acid targeting moieties and a payload of ~ 22 molecules of the topoisomerase-1 inhibitor, exatecan. Folic acid and exatecan are covalently bound by non-cleavable and cathepsin-B cleavable linkers, respectively, to short polyethylene glycol chains which surround the C'Dot's silica core. CDCs are very small (~ 6 nm), allowing for more efficient penetration into solid tumors compared to ADCs and a rapid elimination by the kidneys, which is expected to lead to less toxicity than ADCs that have a longer half-life in circulation. ELU001's high avidity is designed to promote binding to FR α on the surface of cancer cells that express any level of antigen (low to high). ELU001 then internalizes into the tumor cell and traffics to the lysosome where enzymatic cleavage releases the exatecan payload. ELU001 has demonstrated efficacy in preclinical models with low, moderate and high levels of FR α . The first-in-human trial, ELU-FR α -1, is currently recruiting patients with ovarian, endometrial, colorectal, gastric, gastroesophageal junction, triple negative breast, or non-small cell lung cancers, or cholangiocarcinoma cancers, and, in the opinion of the Investigator, have no meaningful life-prolonging therapy option available. **Methods:** This is a Phase 1/2 multicenter, open label clinical trial with two parts: Part 1 Dose Escalation and Part 2 Tumor Group Expansion Cohort(s). In Part 1, patients with cancer types with a high likelihood of having FR α overexpressing tumors, (ovarian, endometrial, colorectal, gastric, gastroesophageal junction, triple negative breast, or non-small cell lung cancers, or cholangiocarcinoma) will be enrolled. FR α expression is determined retrospectively. ELU001 is administered either weekly (QW) (once a week for 3 weeks, 1 week rest), every other week (Q2W, with no rest between cycles), or every three weeks (Q3W). Initial Part 2 expansion cohorts are planned in ovarian cancer with high FR α expression, ovarian cancer with moderate or low FR α expression, and endometrial cancer with any positive FR α expression. Here, FR α will be prospectively determined. Other cancer types may be assessed in the future. The primary objective for Part 1 is to identify the MTD/RP2D. The primary objective for Part 2 is to determine the ORR. Secondary objectives include DOR, PFS, TFST, PFS2, OS, frequency, severity and tolerability of adverse events, PK, ADA, and FR α expression assessments. Part 1 Dose Escalation will recruit about 2-5 patients at each dose for each regimen (QW; Q2W; Q3W). Part 2 Stage 1 will recruit about 15 patients per tumor group expansion cohort and is expected to begin recruitment in the second half of 2023. The study is enrolling in Part 1 Q2W Cohort 301 and Q3W Cohort A in the US. Clinical trial information: NCT05001282. Research Sponsor: Elucida Oncology.

First-in-human clinical trial design of a first-in-class theranostic approach with a peptide-based radioligand targeting CA IX-expressing tumors. *First Author: Darren R. Feldman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Expression of carbonic anhydrase IX (CA IX), a cell surface glycoprotein, can be induced by a state of hypoxia or by mutation of the Von Hippel-Lindau tumor suppressor gene. CAIX expression in tumors is often associated with progressive disease and overall poor outcomes in various solid cancers. Notably, high CA IX expression has been observed in 83%, 40%, and 29% of clear cell renal cell carcinoma (ccRCC), pancreatic ductal adenocarcinoma (PDAC), and colorectal cancer (CRC) specimens, respectively¹. CA IX may therefore represent a valuable therapeutic target. DPI-4452 is a first-in-class cyclic peptide that binds with high affinity to CA IX. Radiolabeling DPI-4452 with gallium-68 (⁶⁸Ga)[Ga-DPI-4452] or lutetium-177 (¹⁷⁷Lu)[Lu-DPI-4452] is an innovative theranostic approach for identifying and treating patients (pts) with CA IX-expressing tumors. Pre-clinical data has shown that [¹⁷⁷Lu]Lu-DPI-4452 is taken up by tumors and induces dose-dependent growth inhibition in ccRCC and CRC xenograft mouse models^{1,2}. **Methods:** We present the design of a Phase I/II study (NCT05706129) of [⁶⁸Ga]Ga-DPI-4452 and [¹⁷⁷Lu]Lu-DPI-4452 in pts with unresectable locally advanced or metastatic ccRCC, CRC or PDAC. The study is comprised of three phases: imaging (Part A), dose-escalation (Part B), and expansion (Part C). In Part A, pts will receive a single intravenous (IV) 185 MBq dose of [⁶⁸Ga]Ga-DPI-4452. Safety, tolerability, pharmacokinetics (PK), dosimetry and imaging characteristics of [⁶⁸Ga]Ga-DPI-4452 will be evaluated using positron emission tomography/computed tomography (CT) at four timepoints on Day 1. All pts will be followed for seven days post-injection for safety observations. In Part B, based on [⁶⁸Ga]Ga-DPI-4452 uptake, pts will receive sequential, escalating doses of IV [¹⁷⁷Lu]Lu-DPI-4452 on Day 1 of each 28-day cycle for up to eight cycles. During Cycle 1, each pt will undergo up to four whole-body planar imaging and single photon emission CT/CT analyses for dosimetry over seven days. In Part B, the recommended Phase 2 dose of [¹⁷⁷Lu]Lu-DPI-4452 will be determined, guided by a Bayesian Logistic Regression model. Safety, PK, and dosimetry will be assessed to minimize any radiation-induced toxicity and to optimize absorbed radiation dose in the tumor. Upon completion of Part B, Part C will enroll up to three cohorts of pts with CA IX-positive ccRCC, CRC or PDAC to assess preliminary efficacy of [¹⁷⁷Lu]Lu-DPI-4452, with a primary endpoint of objective response rate, as measured by RECIST v1.1. Phase 1 trial of GD2-SADA: ¹⁷⁷Lu-DOTA drug complex in patients with recurrent or refractory metastatic solid tumors known to express GD2 including small cell lung cancer (SCLC), sarcoma, and malignant melanoma. *First Author: Taofeek K. Owonikoko, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: GD2 is a disialoganglioside with high expression in small cell lung cancers (SCLC), sarcomas and melanomas and limited expression in normal tissues. The SADA platform represents a 2-step pretargeted radioimmunotherapy approach developed to optimize tumor targeting and reduce normal tissue irradiation. The GD2-SADA molecule is composed of a non-radioactive, bispecific antibody (anti-GD2 x anti-DOTA) linked to a tetramerization sequence from the p53 protein. In the first step, the GD2-SADA molecule is administered in a tetrameric form with a high affinity to the GD2 tumor target. In preclinical research, any unbound GD2-SADA molecule will disassemble to monomers and has shown to clear via the kidneys. In the second step, the radioactive payload ¹⁷⁷Lu-DOTA is administered, which binds to the anti-DOTA part of the GD2-SADA and leads to radiation-induced damage at the target and has shown limited exposure to non-target tissues in preclinical research. This pre-targeting approach supports the concept of highly focused irradiation of the tumor target with the potential of administering higher radioactivity doses. **Methods:** Trial 1001 (NCT05130255) is a first-in-human, dose-escalation, single-arm, open-label, non-randomized, multicenter phase 1 trial with the purpose of evaluating safety and tolerability of GD2-SADA: ¹⁷⁷Lu-DOTA. The trial is composed of 3 parts: Part A is dose escalation of the GD2-SADA dose and testing of different intervals between GD2-SADA and ¹⁷⁷Lu-DOTA. Part B is dose escalation of the ¹⁷⁷Lu-DOTA radioactivity dose to establish its maximum tolerated dose (MTD). Part C involves repeated dosing to assess the safety profile and determine the Recommended Phase 2 Dose (RP2D). Parts B and C may only begin upon completion of dose-limiting toxicity (DLT) observation period of Parts A and B, respectively. Escalation is based on classical 3+3 design. Parts A, B, and C will include 18, 12, and 32 patients, respectively. Patients can only be assigned to one part of the trial. The trial will include adult/adolescent patients with either SCLC, sarcoma, or melanoma with radiographical relapse/progression on standard therapies. The patients must be in ECOG performance status 0-1 and have adequate hematological, renal, and liver function. The patients must have measurable disease according to RECIST 1.1. Patients with active CNS metastases are ineligible. Safety endpoints (DLTs and adverse events) will be summarized by trial part and cohort. Objective response according to RECIST 1.1 and disease control rates at 6, 12 and 24 months will be presented with exact 95% CI. PFS, OS, and duration of response will be estimated using Kaplan-Meier methods. Additional objectives include dosimetry, PK, and immunogenicity data. The study is actively enrolling at US sites. Clinical trial information: NCT05130255. Research Sponsor: Y-mAbs Therapeutics, Inc.

FRONTIER: FAPi radioligand open-label, phase 1 study to evaluate safety, tolerability and dosimetry of [Lu-177]-PNT6555—A dose escalation study for treatment of patients with select solid tumors. *First Author: Lisa Bodei, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Fibroblast activation protein alpha (FAP) is a 170 kDa transmembrane glycoprotein expressed during development, active tissue remodeling, and cancer. Overexpression on cancer-associated fibroblasts in the tumor microenvironment, and on some cancer cells of mesenchymal origin, leads to the presence of FAP in > 90% of epithelial tumors, making FAP a compelling anti-cancer target. PNT6555, a potent FAP-targeting compound with rapid clearance from normal tissues and prolonged tumor retention in preclinical models¹, is a radioligand consisting of a DOTA chelator (1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid) and a FAP-targeting moiety (Bz-D-Ala-boroPro) connected via an aminomethyl linker. The corresponding gallium-68 and lutetium-177 chelates constitute the imaging and therapeutic theranostic pair of PNT6555 under evaluation in this phase I study. **Methods:** FRONTIER (NCT05432193) is a multicenter, open-label, multi-dose phase I study of PNT6555 in participants with pancreatic ductal adenocarcinoma, esophageal cancer, colorectal cancer, melanoma skin cancer, cholangiocarcinoma, or soft tissue sarcoma solid tumors with FAP over-expression. The primary aim is to evaluate the safety and tolerability of [Lu-177]-PNT6555 in order to determine a recommended phase II dose (RP2D). Dosimetry, pharmacokinetics, and tumor and immune responses will also be assessed for [Lu-177]-PNT6555, as well as safety, tolerability, and diagnostic performance of [Ga-68]-PNT6555 PET/CT. Key eligibility criteria include being refractory to prior treatment with no alternative available therapeutic options, having adequate organ function, and being FAP-positive on [Ga-68]-PNT6555 PET/CT scan, defined as ≥50% of lesions with an SUV_{max} of ≥1.5x the liver SUV_{mean}. [Ga-68]-PNT6555 will be dosed at 120–220 MBq (3.2–5.9 mCi), with PET/CT initiated 90 (±30) min later. FAP-positive participants will receive [Lu-177]-PNT6555 once every 6 weeks for up to 6 cycles. Starting at 4 GBq (108 mCi) ± 10%, [Lu-177]-PNT6555 may be escalated by 4 GBq, with a maximum planned dose of 12 GBq. De-escalation by 2 GBq may also occur. Dose finding will be guided by the modified toxicity probability interval (mTPI-2) statistical design with a targeted toxicity rate of 30%. The planned total sample size is 30, with targets of 3–12 DLT evaluable patients per dose level. Cohort 1 has been completed without a DLT. Enrollment to cohort 2 began in January 2023. 1. Hallet R, et al. *Pre-clinical characterization of the novel fibroblast activation protein (FAP) targeting ligand PNT6555 for the imaging and therapy of cancer. A phase 1/2 study of CFT1946, a novel, bifunctional degradation activating compound (BIDAC) degrader, of mutant BRAF V600 as monotherapy and in combination with trametinib, in mutant BRAF V600 solid tumors. *First Author: Meredith McKean, Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN*

Background: BRAF is a protein kinase that acts as a signal transducer in the MAPK pathway. Mutant BRAF V600 is capable of uncontrolled signaling and is constitutively active and signals as a monomer, leading to hyperactivation of MEK, ERK, and dysregulation of cellular proliferation. Mutant BRAF V600 is a clinically-validated target in a variety of cancers including melanoma, colorectal cancer (CRC), non-small cell lung cancer (NSCLC), and anaplastic thyroid carcinoma (ATC). Currently approved BRAF inhibitors (BRAFi) result in paradoxical RAF activation as the mutant BRAF protein is still able to dimerize with WT BRAF, resulting in a dimeric signaling complex. CFT1946 is a novel, orally bioavailable BIDAC degrader that inhibits and degrades mutant BRAF V600 protein. Distinct from approved BRAFi, CFT1946 avoids paradoxical RAF activation as the degraded BRAF V600 mutant protein can no longer incorporate into a dimeric signaling complex. CFT1946 is selective for the mutant protein and spares WT BRAF V600. CFT1946 has demonstrated preclinical activity in BRAF V600 mutant in vitro and in vivo models, including models resistant to BRAFi. These preclinical data provide rationale for a first-in-human (FIH) study to evaluate CFT1946 in BRAF V600 mutant solid tumors. **Methods:** This is a FIH, open-label, multicenter, Phase 1/2 clinical trial to characterize the initial safety, tolerability, and preliminary efficacy of CFT1946 and CFT1946+trametinib in BRAF V600 mutant melanoma, NSCLC, CRC, ATC, and other non-CNS BRAF V600 mutant solid tumors. This study includes 2 phases: dose escalation Phase 1 comprising CFT1946 (Arm A) with a starting oral dose of 20 mg twice daily and CFT1946+trametinib (Arm B) as well as dose expansion Phase 2 comprising CFT1946 (Arm A1) and CFT1946+trametinib (Arms B1 and B2). Arm A1 and B1 will include BRAF V600 mutant melanoma and NSCLC with prior BRAFi therapy while Arm B2 will enroll BRAF V600 mutant NSCLC who are BRAFi-naïve. Phase 2 will be initiated once the RP2D has been identified. Eligible subjects are ≥18yo with documented BRAF V600 mutant cancers who have received ≥1 prior therapy. CFT1946 will be administered orally in 28-day cycles until disease progression or intolerable toxicity. Primary objectives include safety, tolerability, RP2D and preliminary antitumor activity of CFT1946 monotherapy and in combination with trametinib. Secondary objectives include assessment of pharmacokinetics and pharmacodynamics. Key inclusion criteria include documented evidence of a BRAF V600 mutation obtained from tumor tissue or liquid biopsy; at least 1 prior line of standard-of-care therapy for locally advanced or metastatic disease. The study is anticipated to enroll 101–122 patients across 11 participating US and European sites and is currently open to enrollment (NCT05668585). Clinical trial information: NCT05668585. Research Sponsor: C4 Therapeutics.

A phase 1, open-label, dose escalation and dose expansion study to evaluate the safety, tolerability, pharmacokinetics, and antitumor activity of PF-07799933 (ARRY-440) as a single agent and in combination therapy in participants 16 years and older with advanced solid tumors with BRAF alterations. *First Author: J. Thaddeus Thaddeus Beck, Highlands Oncology Group, Springdale, AR*

Background: Approved BRAF inhibitors (BRAFi) are inactive against RAF dimers. Accordingly, the acquisition of BRAF dimers (e.g., through drug-acquired splice variants or BRAF amplification) may lead to therapy resistance. Non-V600 (class II and III) BRAF alterations that occur *de novo* in diverse tumor types also signal as dimers and therefore have no approved targeted therapeutic options. Additional liabilities of approved BRAFi include toxicity from paradoxical activation of wild-type (WT) RAF and limited brain penetration, a common primary and metastatic site for BRAF-altered cancers. In contrast to approved agents, investigational BRAFi inhibit WT and mutant RAF proteins (A, B, and C-RAF, monomers, dimers), and therefore may be limited by on-target toxicity from “pan-RAF” inhibition. PF-07799933 is an oral selective ATP-competitive small-molecule RAF kinase inhibitor that suppresses BRAF signaling in BRAF V600-mutant and non-V600-BRAF mutant tumors. It displays significantly less paradoxical activation than approved BRAFi and is not “pan RAF” as it spares non-BRAF-containing RAF dimers. We describe here the Phase 1 study of PF-07799933 as monotherapy or in combination with binimetinib or cetuximab in participants with BRAF-altered advanced solid tumors.

Methods: The purpose of this first-in-human study is to investigate the safety, tolerability, pharmacokinetics (PK), pharmacodynamics, and potential clinical benefits of PF-07799933 administered as a single agent and in combination in participants with BRAF Class I, II and III mutated solid tumors with or without brain involvement. Part 1 (monotherapy dose escalation) and Part 2 (combination dose escalation) will enroll participants with BRAF V600 mutation who have progressed on a approved BRAFi or with *de novo* Class II or III alterations who have progressed on standard of care therapy. The primary objective of Part 1 is to determine monotherapy MTD/RDE of PF-07799933. Participants in Part 1 will be allowed to add on rational combination with either binimetinib or cetuximab at the time of disease progression. Once PK measurements indicate the potential for significant BRAF inhibition in the brain, participants with untreated and symptomatic brain metastases will be allowed to enroll. The primary objective of Part 2 is combination MTD/RDE of PF-07799933 with binimetinib or cetuximab. The primary objective of Part 3 is efficacy in defined cohorts (total ~120 participants): Cohort 1-2: BRAF V600 mutant melanoma; Cohort 3: BRAF Class II altered melanoma; Cohorts 4-5: BRAF V600 and Class II altered CRC; Cohort 6: other BRAF V600, Class I/III altered solid tumor not qualifying for Cohorts 1-5. Clinical trial information: NCT05355701. Research Sponsor: Pfizer.

SPARK, studying pathways of resistance in KRAS-driven cancers: A remote plasma ctDNA participation study to identify mechanisms of resistance to KRAS inhibitors. *First Author: Biagio Ricciuti, Dana-Farber Cancer Institute, Lowe Center for Thoracic Oncology, Boston, MA*

Background: KRAS mutations account for a significant proportion of oncogenic mutations in cancers of the lung, colon, pancreas, and other organs. Cancers with KRAS^{G12C} mutations are now targetable with direct KRAS^{G12C} inhibitors, and other allele-specific and pan-KRAS inhibitors are in clinical development. Recent work has shown that complex resistance mechanisms can arise after treatment with KRAS^{G12C} inhibitors, including polyclonal KRAS alterations, acquired bypass mechanisms, and acquired fusions. The SPARK protocol is a remote participation ctDNA collection study that will evaluate mechanisms of resistance to RAS inhibitors and combination therapies. **Methods:** SPARK (NCT05272423) is a non-interventional, single coordinating center, decentralized biospecimen collection study, with a planned accrual of up to 250 patients with a diagnosis of KRAS-mutant cancer who are experiencing disease progression on a specific KRAS inhibitor or combination of inhibitors. The study will enable a web-based remote consent (<https://alcmi.net/research/spark/>) and subjects will be sent blood collection kits with the necessary materials for local phlebotomy for the FoundationOne Liquid CDx (F1LCDx) Biopsy Assay. Plasma NGS results will be returned to the treating physician and the study team. Patients will initially be enrolled into two cohorts: Cohort 1A will be restricted to KRAS G12C mutant cancers who progressed after being treated with KRAS G12C inhibitors. Cohort 1B will enroll patients with KRAS mutant cancers whose tumors progressed on any KRAS inhibitor (other than a direct KRAS G12C inhibitor). Cohort 2 will enroll KRAS mutant patients that have progressed on KRAS inhibitors and who have already had a sequencing assay performed to determine the resistance mechanism to KRAS inhibitors. These patients will be invited to share their data and medical history with the study team. Plasma for F1LCDx analysis will be optional for Cohort 2. Mechanisms of acquired resistance will be summarized with descriptive statistics, and compared across drugs (e.g., sotorasib vs adagrasib), between tumor types (e.g., NSCLC vs CRC), and by regimen (e.g. monotherapy vs combination therapy) to determine if different resistance mutations arise in these settings. Progression-free survival (PFS), and overall survival (OS) with KRAS inhibitors will be analyzed depending on the resistance mechanism (e.g. on-target vs off-target). Kaplan-Meier method will be used estimate median survival, and log-rank test will be used to compare groups of interests. Cox-regression model will be used to estimate univariable and multivariable hazard ratios. Outcomes from subsequent treatment after the development of acquired resistance will also be explored with descriptive statistics. No interim analysis is planned. The study activated on November 1st 2022. Clinical trial information: NCT05272423. Research Sponsor: AMGEN.

Poster Session

A phase 1, open-label, first-in-human study of TAS2940 in patients with advanced solid tumors. *First Author: Jordi Rodon Ahnert, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Aberrant expression and signaling of the ERBB family of receptor tyrosine kinases, including epidermal growth factor receptor (EGFR) and human epidermal growth factor receptor 2 (HER2), has a role in the pathogenesis of solid tumors such as breast cancer (BC), non-small cell lung cancer (NSCLC), and glioblastoma (GBM). Although therapies that target HER2 are effective in early and advanced HER2-overexpressing BC, many patients develop resistance despite tumor dependence on HER2 at the time of progression. Approximately 4% of patients with NSCLC have HER2 mutations, mostly presenting as exon 20 insertions (ex20ins); however, approved HER2/EGFR tyrosine kinase inhibitors (TKIs) have limited efficacy in patients with NSCLC and HER2 ex20ins. Many patients with NSCLC or BC develop brain metastases, and EGFR alterations, including EGFRvIII mutations, are common in GBM. There is therefore a need for a brain-penetrable TKI with activity against tumors harboring HER2/EGFR alterations. TAS2940 is a potent, selective, and orally bioavailable pan-ERBB inhibitor that has shown promising preclinical efficacy against cancers with a variety of HER2/EGFR mutations and amplifications. Further, TAS2940 inhibited tumor growth and induced tumor regression in a dose-dependent manner in nude mice intracranially implanted with NCI-N87, a HER2-overexpressing human gastric cancer cell line. **Methods:** TAS2940-101 (NCT04982926) is an open-label, phase 1, first-in-human trial to evaluate the safety, tolerability, pharmacokinetics (PK), and preliminary antitumor activity of TAS2940 in patients with advanced solid tumors and HER2/EGFR aberrations. Eligible patients are aged ≥18 years, have non-measurable (Part 1) or measurable (Part 1 and 2) disease per RECIST 1.1 or RANO criteria, ECOG performance status 0/1, and adequate organ function. Patients with non-stable brain metastases are excluded. Part 1 (dose escalation) will use a Bayesian optimal interval design with a starting dose of 15 mg/kg orally QD (planned dose levels: 15, 30, 60, 120, 240 and 480 mg). Once the recommended phase 2 dose is determined, Part 2 (dose expansion) will enroll patients with NSCLC (Cohort A), HER2+ BC (Cohort B), recurrent/refractory GBM (Cohort C), or other solid tumors with EGFR/HER2 aberrations (Cohort D). The primary objectives are the maximum tolerated dose of TAS2940 in Part 1 and antitumor activity in Part 2. Secondary objectives include antitumor activity in Part 1. The safety and PK profile of TAS2940 will be assessed in both parts. Approximately 142 patients will be enrolled, comprising ~42 in Part 1 and ~100 in Part 2. As of January 24, 2023, 15 patients have been enrolled. No dose-limiting toxicities have been reported with dose escalation up to 240 mg QD. Recruitment is ongoing. Clinical trial information: NCT04982926. Research Sponsor: Taiho Oncology, Inc.

Poster Session

BRUOG 387: Phase Ib investigator-initiated trial of a heat shock protein 90 inhibitor (HSP90i) combined with a CDK4/6i in advanced breast cancer progressing on CDK4/6i and in solid tumors with retinoblastoma (Rb)-deficiency (IND163592). *First Author: Wafik S. El-Deiry, Legorreta Cancer Center at Brown University, Providence, RI*

Background: Cyclin-dependent kinases 4/6 (CDK4/6) promote cell-cycle progression and cancer growth. CDK4/6 inhibitors (CDK4/6i), in combination with hormonal therapy, increase progression-free and overall survival (PFS and OS) in breast cancer but resistance to CDK4/6i is associated with genomic abnormalities including Rb-deficiency. Combined CDK4/6i/HSP90i has been shown to inhibit HIF1- α including in tumor cells with Rb-deficiency. Synergy between multiple CDK4/6i's and HSP90i's has suggested a drug class effect for combination. In CDK4/6i-treated cells, E3-ubiquitin ligase Smurf2 associates with and targets degradation of HIF1- α independent of VHL or hypoxia. BRUOG 387 investigates whether dual targeting of CDK4/6 and HSP90, through HIF1- α in patients with ER/PR+ Her2-advanced breast cancer progressing on CDK4/6i and patients with refractory Rb-deficient tumors is safe and reasonably tolerated. **Methods:** A phase Ib open-label single-arm dose de-escalation study is evaluating safety, tolerability as primary outcomes, recommended doses for cohort expansion and preliminary efficacy of CDK4/6i and HSP90i (IND163592; NCT05655598; the only HSP90i combination study in US). Patients with ER/PR+ Her2- advanced breast cancer progressing on CDK4/6i, and in cohort expansion, patients with Rb-deficient solid tumors (SCLC, soft tissue sarcoma, endometrial and bladder cancer) are included. CDK4/6i (palbociclib at dose previously tolerated up to 125 mg daily PO D1-21 of 28 day cycle) in combination with HSP90i (TAS-116/pimipitesib starting at 120 mg 5 days on 2 days off, for D1-28 of cycle) is used in 3+3 dose-de-escalation design. The study includes PK analysis, and PD analysis will include HIF1/2, Smurf2, Rb, HIF targets VEGF, erythropoietin, Glut1, proliferation, cell death, cancer stem cells, NK, T-cells, RNA-seq and angiogenesis in pre- and post-treatment biopsies. Biostatistical design and analysis includes 3 dose levels of TAS-116 + palbociclib (level 0: TAS-116 120 mg, palbociclib 125 mg; level -1: TAS-116 80 mg, palbociclib 125 mg); level -2: TAS-116 40 mg, palbociclib 125 mg). Limiting Toxicities will include grade 4 neutropenia lasting > 7 days, neutropenic fever, grade 4 thrombocytopenia or Grade 3 non-hematologic toxicity not controlled with medical management. The study will enroll a total of approximately 15-27 patients (6-18 patients in dose de-escalation portion of the study and 9 additional patients in the cohort expansion phase). Secondary outcome analyses include response rate (CR, PR) measured by RECIST v.1.1 with exact two-sided 95% confidence intervals. OS, PFS, TTP, and DOR will be summarized using methods of Kaplan and Meier. Clinical trial information: NCT05655598. Research Sponsor: Brown University Oncology Research Group; Legorreta Cancer Center at Brown University.

Poster Session

Phase 2, multicenter, open-label basket trial of *nab*-sirolimus for patients with malignant solid tumors harboring pathogenic inactivating alterations in *TSC1* or *TSC2* genes (PRECISION I). *First Author: Gopa Iyer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *nab*-Sirolimus is a novel albumin-bound mTOR inhibitor (mTORi) approved in the US for adult patients with malignant PEComa. In an exploratory analysis of the pivotal AMPECT trial of *nab*-sirolimus in advanced malignant PEComa (NCT02494570), 8/9 (89%) and 1/5 (20%) patients with inactivating alterations in *TSC2* and *TSC1*, respectively, had confirmed response (Wagner, *J Clin Oncol*, 2021). *TSC1* and *TSC2* alterations have been observed in patients with a broad variety of cancers. Most treatment-related adverse events in AMPECT were grade 1/2 (none were grade ≥ 4) and were consistent with mTORi class adverse events. **Methods:** PRECISION I (NCT05103358) will evaluate efficacy and safety of *nab*-sirolimus in patients with *TSC1* (Arm A) and *TSC2* (Arm B) alterations. Eligible patients are ≥ 12 y old and mTORi-naïve, possess malignant solid tumors with *TSC1/TSC2* inactivating alterations (confirmed by central review of sequencing reports), and have received appropriate standard treatments, per investigator. *nab*-Sirolimus 100 mg/m² will be given weekly intravenously over 30 min on Days 1 and 8 of each 21-d cycle. The primary endpoint is overall response rate per independent radiographic review (IRR) using RECIST v1.1. Other endpoints include duration of response, time to response, progression-free survival by IRR, overall survival, patient-reported quality of life, and safety. Enrollment began March 2022. Collaboration with leading next-generation sequencing vendors will expedite the identification of patients with qualifying *TSC1/TSC2* mutations; study access will be facilitated through a just-in-time approach to trial location activation. Based on the prevalence of *TSC1/TSC2* inactivating alterations, the most frequent tumor types expected are bladder, hepatobiliary, endometrial, soft tissue sarcoma, ovarian, and esophagogastric (Table). Clinical trial information: NCT05103358. Research Sponsor: Aadi Bioscience, Inc.

Estimated frequency of definite impact *TSC1* or *TSC2* alterations.

Tumor type	TSC1 Mutations, % ^a	TSC2 Mutations, % ^a	TSC1/TSC2 Combined, %
Bladder	6.33	1.70	8.03
Hepatobiliary	1.27	3.31	4.58
Endometrial	2.10	1.22	3.32
Soft tissue sarcoma	1.28	1.71	2.99
Ovarian	1.85	0.92	2.77
Esophagogastric	0.65	1.46	2.11
Colorectal carcinoma	0.99	0.39	1.38
Pancreatic	0.57	-	0.57

^aThe proportion of patients with definite impact mutations (ie, mutations known to have a biological impact, including frameshift, nonsense, and splice-site mutations and deep deletions) derived from analysis of TCGA and cBioPortal by Gulati et al. Data on file.

Oral Abstract Session

FOLFFOXIRI plus bevacizumab and atezolizumab as upfront treatment of unresectable metastatic colorectal cancer (mCRC): Updated and overall survival results of the phase II randomized AtezoTRIBE study. *First Author:* Carlotta Antoniotti, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa & Unit of Medical Oncology 2, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy

Background: AtezotRIE (NCT03721653) is a phase II randomized trial in which unresectable mCRC pts were randomized 1:2 to 1st-line FOLFOXIRI/bev [arm A] or FOLFOXIRI/bev/atezo [arm B]. Adding atezo to FOLFOXIRI/bev was safe and improved PFS (primary endpoint), with a modest benefit also among pts with pMMR tumors. Subgroup analyses suggest that TMB and Immunoscore IC (IS) IC - an IHC biomarker measuring CD8 and PD-L1 cell densities and their proximity - may identify pts with pMMR tumors deriving benefit from adding atezo to FOLFOXIRI/bev. **Methods:** The study had 85% power to detect a HR for PFS (time from randomization to 1st PD or death [PD1]) of .66 in favor of arm B with 1-sided α error of .10. Secondary endpoints included PFS2 (time from randomization to PD on any treatment given after PD1 or death [PD2]), 2nd PFS (time from PD1 to PD2), and OS. MMR, TMB, IS IC were correlated to clinical outcome. **Results:** 218 pts (arm A/B:73/145) were enrolled. Main pts' characteristics were right-sided 44%/45%, RAS mut 71%/74%, BRAF mut 14%/8%, dMMR 7%/6%, high TMB 10%/12%, high IS IC 32%/32%. At a median follow-up of 37.0 mos, 175 80% OS A/B: 64/111 PD1, 150 (69%, arm A/B: 53/97) PD2, and 118 (54%, arm A/B: 43/75) OS events were collected. Out of 175 pts with a PD1 event, 135 (77%, arm A/B:50/85) received a subsequent treatment; among them, 121 pts (arm A/B: 43/78) had a PD2 event. PFS, PFS2, 2nd PFS and OS results in the intention-to-treat (ITT) population and the pMMR group are listed in the Table. In the ITT population, significant interactions between treatment and MMR status (P_{int} .011), TMB (P_{int} .008), and IS IC (P_{int} .037) were reported in terms of PFS. Only IS IC was associated with a differential OS benefit (P_{int} .065), with pts bearing IS IC-high tumors deriving benefit from adding atezo (HR 0.43, 95%CI 0.19-1.00), differently than those with IS IC-low tumors (HR 1.09, 95%CI 0.65-1.83). In the pMMR group, significant interactions between treatment and TMB and IS IC were reported in terms of PFS (P_{int} .016 and .051, respectively) and OS (P_{int} .043 and .063, respectively). Pts bearing IS IC-high tumors derived higher OS benefit from adding atezo (HR 0.44, 95%CI 0.19-1.03), than those with IS IC-low tumors (HR 1.15, 95% CI 0.67-1.97).

Conclusions: Pts with IS IC-high and/or TMB high pMMR mCRC seem to derive a survival benefit from adding atezo to FOLFOXIRI/bev as upfront treatment. These findings deserve confirmation in a properly designed phase III trial. Clinical trial information: NCT03721653.

Oral Abstract Session

Trastuzumab deruxtecan (T-DXd) in patients (pts) with HER2-overexpressing/amplified (HER2+) metastatic colorectal cancer (mCRC): Primary results from the multicenter, randomized, phase 2 DESTINY-CRC02 study. *First Author: Kanwal Pratap Singh Raghav, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: T-DXd (6.4 mg/kg, every 3 weeks [Q3W]) demonstrated antitumor activity in pts with HER2+ mCRC in DESTINY-CRC01 (Siena et al. *Lancet Oncol.* 2021). We present primary results of DESTINY-CRC02 (NCT04744831), which assessed the efficacy and safety of T-DXd (5.4 and 6.4 mg/kg) in pts with HER2+ mCRC. **Methods:** This was a multicenter phase 2 study. Eligible pts had centrally confirmed HER2+ (immunohistochemistry [IHC] 3+ or IHC 2+ in situ hybridization [ISH]+) mCRC. Pts with RAS wild-type (wt) or mutant (m) mCRC were eligible. Pts had received prior standard therapy, unless contraindicated; prior anti-HER2 therapy was allowed. In stage 1, 80 pts were randomized 1:1 to 5.4 (n = 40) or 6.4 (n = 40) mg/kg T-DXd Q3W. In stage 2, an additional 42 pts received 5.4 mg/kg T-DXd. Primary endpoint was confirmed objective response rate (cORR) by blinded independent central review (BICR). Secondary endpoints included duration of response (DoR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** At data cutoff (Nov 1, 2022), most pts in the 5.4 and 6.4 mg/kg T-DXd arms had HER2 IHC 3+ (78.0% and 85.0%), RAS wt tumors (82.9% and 85.0%), and a median of 3 and 4 prior lines of therapy, respectively. cORR was 37.8% (95% CI, 27.3-49.2%) in the 5.4 mg/kg arm and 27.5% (95% CI, 14.6-43.9%) in the 6.4 mg/kg arm (all partial responses in both arms). Key efficacy data are shown in the Table: Grade ≥3 treatment-emergent adverse events (AEs) were observed in 41/83 pts (49.4%) and 23/39 pts (59.0%) in the 5.4 and 6.4 mg/kg T-DXd arms, respectively. Serious AEs were observed in 20/83 pts (24.1%) and 12/39 pts (30.8%) in the 5.4 and 6.4 mg/kg arms, respectively. Independently adjudicated drug-related interstitial lung disease occurred in 7/83 pts (8.4%) with 5.4 mg/kg T-DXd and 5/39 pts (12.8%) with 6.4 mg/kg T-DXd, and most events were grade 1/2 (1 grade 5 in the 6.4 mg/kg arm). **Conclusions:** T-DXd showed promising antitumor activity in pts with HER2+ mCRC at both 5.4 and 6.4 mg/kg doses. Antitumor efficacy was observed irrespective of RAS mutation status at 5.4 mg/kg T-DXd, and in those with prior anti-HER2 therapy. Overall, safety was consistent with the known safety profile of T-DXd and favored the 5.4 mg/kg dose. Clinical trial information: NCT04744831. Research Sponsor: Daiichi Sankyo, Inc and AstraZeneca.

Efficacy summary.		5.4 mg/kg T-DXd n = 82	6.4 mg/kg T-DXd n = 40
Median follow-up, mo (range)		8.9 (0.5-17.1)	10.3 (0.7-16.4)
Median DoR by BICR		5.5 (4.2-8.1)	5.5 (3.7-non-evaluable)
Mo (95% CI)			
Median PFS, mo (95% CI)		5.8 (4.6-7.0)	5.5 (4.2-7.0)
Best overall response by BICR in subgroups, n/N (%) [95% CI]			
Prior anti-HER2 therapy		7/17 (41.2)	4/10 (40.0)
		(18.4-67.1)	(12.2-73.8)
HER2 IHC 3+		30/54 (46.9)	10/34 (29.4)
		(34.3-59.8)	(15.1-47.5)
HER2 IHC 2+/tISH+		1/18 (5.6)	1/6 (16.7)
		(0.1-27.3)	
RAS wt		27/68 (39.7)	11/34 (32.4)

Long-term outcome of neoadjuvant mFOLFOX6 with or without radiation versus fluorouracil plus radiation for locally advanced rectal cancer: A multicenter, randomized phase III trial. *First Author: Jianwei Zhang, Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: Previous results of phase III FOWARC trial demonstrated that mFOLFOX6, with or without radiation, did not significantly improve survival versus fluorouracil with radiation in patients with locally advanced rectal cancer at 3 years. Here, we presented the data of long-term disease free survival (DFS) and overall survival (OS). **Methods:** In this multicenter, phase III trial, patients with stage II/III rectal cancer were randomly assigned (1:1:1) to receive 5 cycles of infusional fluorouracil (leucovorin 400 mg/m², fluorouracil 400 mg/m², and fluorouracil 2.4 g/m² over 48 hours) plus radiotherapy (46.0 to 50.4 Gy delivered in 23 to 25 fractions during cycles 2 to 4) followed by surgery and seven cycles of infusional fluorouracil adjuvant treatment, mFOLFOX6 plus radiotherapy, or four to six cycles of mFOLFOX6 followed by surgery and six to eight cycles of mFOLFOX6. **Results:** Totally, 495 patients were enrolled, 165 patients in each group. 445 patients underwent surgery. After a median follow-up of 9.5 years, DFS events were observed in 56, 54, and 55 patients in fluorouracil plus radiotherapy, mFOLFOX6 plus radiotherapy, and mFOLFOX6 groups. The 10-year DFS rate were 55.5%, 63.0% and 62.8% (P = 0.934 by the log-rank test). OS events were reported in 39, 38, and 40 patients in the 3 groups. The 10-year OS rate was 66.2%, 73.2% and 73.0% (P = 0.919 by the log-rank test), respectively. **Conclusions:** With long-term follow up, no significant difference in was found in survival outcome between mFOLFOX6, with and without radiation. Comparing with fluorouracil plus radiation, mFOLFOX6 plus radiation also failed to improve long-term survival. Clinical trial information: NCT01211210. Phase III FIRE-4 study (AIO KRK-0114): Influence of baseline liquid biopsy results in first-line treatment efficacy of FOLFIRI/cetuximab in patients with tissue RAS-WT mCRC. *First Author: Sebastian Stintzing, Medical Department, Division of Hematology, Oncology, and Cancer Immunology (CCM), Charité Universitätsmedizin Berlin, Berlin, Germany*

Background: FIRE-4 (AIO KRK-0114) is performed in RAS wild-type (wt) mCRC patients. This randomized study tests the efficacy of early switch maintenance during 1st-line therapy (part 1) and re-challenge with cetuximab (part 2) in later-line treatment. In part 1, arm A patients continued FOLFIRI/Cet until progression or intolerable toxicity. In arm B, patients received FOLFIRI/Cet for 8-12 cycles, after which maintenance therapy with 5-FU/FA plus bevacizumab (5-FU/Bev) was applied. The first randomization evaluates the question if an early switch from cetuximab to bevacizumab may prolong PFS. Within the translational protocol, serial baseline liquid biopsy were taken to analyze RAS and BRAF mutations. **Methods:** Within this randomized, controlled, open-label phase-III study, patients received FOLFIRI (irinotecan plus 5-FU/FA) plus cetuximab at the standard dosing schedule. In arm A, FOLFIRI plus cetuximab was continued until progression or intolerable toxicity. In arm B, patients received 8 cycles of FOLFIRI plus cetuximab (in case of tumor response) or 12 cycles (in case of stable disease) followed by maintenance with 5-FU/FA plus bevacizumab (5mg/kg) until disease progression or intolerable toxicity. Overall survival after second randomization (part 2) is evaluated as a primary endpoint. Liquid Biopsies were analyzed by RAS BEAming and BRAF ddPCR technology. **Results:** From August 2015 to January 2021, 673 patients were randomized, and liquid biopsies of 540 patients were evaluable at baseline. Of those, 70 (13%) were RAS mutant and 38 (7%) BRAFV600E mutant at baseline. Patients with a detectable RASmut had a significant shorter PFS and OS when compared to RASwt patients (PFS: 9.0mo vs. 11.5mo; p < 0.001; OS: 22.1mo vs 33.6mo; p < 0.001). Whereas, for RASwt patients no difference for both arms with respect to PFS and OS could be observed, RASmut patients (n = 70) had a clear trend towards shorter survival in the standard FOLFIRI cetuximab arm (PFS: 6.4mo vs. 10.1mo, p = 0.54; OS: 24.9mo vs. 16.3mo, p = 0.10). Patients with a BRAF mutation in liquid biopsy had median survival times as expected for BRAF mutant patients (PFS = 5.5mo; OS = 12.0mo). In the standard arm, with a continuous administration of cetuximab, the conversion rate from RASwt to RASmut was significantly higher at progression than in the switch maintenance arm. **Conclusions:** Liquid biopsy detected RAS mutation in 13% of patients deemed RASwt based on tissue analyses. These patients show outcome characteristics expected for RAS mutant patients (median PFS of 9.0 months and median OS of 22 months). The study thus shows the clinical relevance of liquid biopsy in the verification of RAS mutational status. Clinical trial information: NCT02934529. Research Sponsor: Merck.

Oral Abstract Session

NeoRAS wild-type metastatic colorectal cancer in the SCRUM-Japan GOZILA study. *First Author: Hiroki Osumi, Department of Gastroenterological Chemotherapy, Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: The "NeoRAS" phenomenon refers to RAS mutant (MT) metastatic colorectal cancer (mCRC) that becomes RAS wild-type (WT) following treatment. This NeoRAS WT population might represent a novel indication for EGFR inhibitors, which are less effective in RAS MT mCRC. The incidence and clinicopathological characteristics of NeoRAS WT mCRC using plasma cell-free DNA (cfDNA) next generation sequencing has not been defined. **Methods:** As part of a large-scale nationwide screening platform (SCRUM-Japan GOZILA), 478 patients with an initial diagnosis of RAS MT mCRC by tissue analysis (MEBGEN RASKET-B) who received systemic therapy underwent cfDNA testing (Guardant 360) prior to later lines of treatment. Based on the cfDNA results, we evaluated the clinicopathological characteristics of those with NeoRAS WT and RAS MT. NeoRAS WT was defined as no RAS MT (KRAS or NRAS) detected in plasma and was assessed in the overall cohort (Cohort A) and in the subgroup with at least one somatic alteration detected in plasma (Cohort B) to exclude those with insufficient tumor DNA shedding. **Results:** Median age at the time of blood sampling was 62.0 years old, and 257 (51.9%) were men. 160 (32.3%) and 319 (64.4%) had right-sided tumors and multi-organ metastases. The lungs were the most frequent site of metastasis (60.2%), followed by liver (57.4%), lymph nodes (28.9%), and peritoneum (28.5%). The prevalence of NeoRAS WT was 19.0% (91/478) in Cohort A and 9.8% (41/429) in Cohort B. The frequency of NeoRAS WT in tumors originally with KRAS exon 2 MT tended to be lower than in those with other RAS MT (18.1% vs 25.4%, P = 0.21 in Cohort A, 9.0% vs 15.4%, P = 0.14 in Cohort B). There were significant differences in the prevalence of NeoRAS WT between patients with single organ vs multi-organ metastases (P < 0.001 in Cohort A, P = 0.004 in Cohort B), absence vs presence of liver metastasis (P < 0.001 in both Cohort A and B), lymph node metastasis (P = 0.006 in Cohort A), peritoneal metastasis (P = 0.002 in group A), and bone metastasis (P = 0.029 in Cohort A), testing immediately prior to 2nd through to 4th line treatment vs later lines (P = 0.007 in Cohort A), immediate prior use of regorafenib (P = 0.027 in Cohort A) and any history of vascular endothelial growth factor inhibitors (P = 0.003 in Cohort A, P = 0.035 in Cohort B). In the logistic regression multivariate analysis, absence of liver metastasis (odds ratio [OR], 5.83; P < 0.001 in Cohort A, OR, 2.84; P = 0.005 in Cohort B), absence of lymph node metastasis (OR, 2.18; P = 0.034 in Cohort A) and tissue RASMT other than KRAS exon 2 (OR, 2.35; P = 0.049 in Cohort B) were significantly related to the emergence of NeoRAS WT. Among 6 NeoRAS WT patients treated with EGFR inhibitors, one had partial response and another one had stable disease for at least 6 months. **Conclusions:** Liver and lymph node metastasis and RASMT other than those in KRAS exon 2 are factors associated with the development of NeoRAS WT mCRC. EGFR inhibitors might be effective treatment. Research Sponsor: SCRUM-Japan Funds.

Oral Abstract Session

Efficacy of panitumumab in patients with left-sided disease, MSS/MSI-L, and RAS/BRAF WT: A biomarker study of the phase III PARADIGM trial. *First Author: Kentaro Yamazaki, Division of Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan*

Background: The PARADIGM trial (NCT02394795) showed longer median overall survival (OS) with first-line mFOLFOX6 plus panitumumab (PAN) vs bevacizumab (BEV) in patients (pts) with RAS wild type (WT) and left-sided metastatic colorectal cancer (mCRC; 37.9 vs 34.3 months, respectively; hazard ratio [HR], 0.82; P=0.031) and similar OS in right-sided pts (HR 1.09; Yoshino T, et al. ASCO 2022 LBA1). Based on current guideline recommendations regarding clinically relevant biomarkers, here we report clinical outcomes in left-sided mCRC pts with microsatellite stable or microsatellite instability low (MSS/MSI-L) and RAS (KRAS/NRAS)/BRAF (V600E) WT from PARADIGM. **Methods:** Baseline plasma circulating tumor DNA (ctDNA; >10 ng/mL and >10 nM DNA) from pts enrolled in the biomarker study (NCT02394834) was assessed using a custom panel (PlasmaSELECT-R 91, PGdx). The efficacy (OS, progression-free survival [PFS], response rate [RR], and curative resection rate [RO]) of PAN plus mFOLFOX6 compared with BEV plus mFOLFOX6 according to RAS, BRAF (V600E), and MSI status and primary tumor location was evaluated. **Results:** Among 802 pts in the full analysis set, 733 (91%) had evaluable pre-treatment samples for ctDNA analysis. Of these pts, 53 (7.2%) and 78 (10.6%) pts had RAS and BRAF (V600E) mutations, respectively, and 20 (2.7%) pts had MSI high (MSI-H) status. In left-sided mCRC pts with MSS/MSI-L and RAS/BRAF WT, OS tended to be longer with PAN vs BEV (40.6 [95% CI, 36.3-44.4] vs 34.8 [95% CI, 31.3-41.2] months, respectively; HR, 0.79 [95% CI, 0.64-0.97]). Although PFS was comparable between PAN (13.6 months [95% CI, 12.6-15.3]) and BEV (12.6 months [95% CI, 11.3-14.1]; HR, 0.95 [95% CI, 0.77-1.17]), RR and RO resection rates were higher with PAN (RR: 83.2% [95% CI, 78.0-87.6]; RO: 18.8% [95% CI: 14.2-24.1]) compared with BEV (RR: 66.4% [95% CI, 60.0-72.3]; RO: 10.0% [95% CI: 6.5-14.5]). OS was similar or inferior to PAN vs BEV regardless of the primary sidedness in pts with MSI-H or RAS/BRAF mutations (Table). **Conclusions:** These results support PAN + mFOLFOX6 as a first-line therapy for left-sided pts with MSS/MSI-L and RAS/BRAF WT. Clinical trial information: NCT02394795. Research Sponsor: Takeda Pharmaceutical Company Limited, Tokyo, Japan.

Transcriptional metabolic profiling young onset colorectal cancer (CRC) patients. *First Author: Deepak Vadehra, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Patients diagnosed with colorectal cancer (CRC) at age < 50 years typically present with more advanced disease, resulting in poor therapeutic response and clinical outcomes. Therefore, there is an unmet need to understand the differences in transcriptional profiles between younger (<50) and older (> 50) CRC patients. **Methods:** Using TCGA (n = 397; > 50 = 349; < 50 = 48) and Oncology Research Information Exchange network (ORIEN) CRC datasets (n = 460; > 50 = 364; < 50 = 96), patients were separated into younger and older populations. Baseline characteristics of the patients in this analysis are provided in the accompanying table. Subsequently, their transcriptional profiles were compared and assessed via differential gene expression analysis (DESeq2), gene set enrichment analysis (GSEA), immune deconvolution (TIMER2.0), and metabolic pathway analysis (MetaPhOR). These pathways were then mapped to assess transcriptional dysregulation, and patterns of predicted metabolic flux. **Results:** Comparisons of older and younger groups revealed a large number of significantly differentially expressed transcripts (n = 2629), enrichment in younger groups of metabolic pathways (amino acids and lipids), oncogenes (MYC targets and NRAS targets), and cellular processes. In the older group we found enrichment of methylation and histone modification, immune response, and other metabolic pathways, like androgens. Metabolic pathway analysis revealed consistent alterations in steroid hormone metabolism and kynurenine metabolism, which were largely upregulated in the over 50 group. Additionally, pathways associated with response to both CTLA4 and PDL1 treatment were largely upregulated in the over 50 group. This transcriptional signature may be associated with a pre-disposition to different clinical outcomes and therapeutic response for agents targeting these pathways. **Conclusions:** Overall, this study has revealed differences in transcriptional metabolic profiles and other drivers of disease, as well as immune profiles, between younger and older CRC populations. This biology should be explored in the future, as new avenues for treatment in younger CRC populations. Research Sponsor: None.

Clinical Science Symposium

Evaluation of genomic alterations in early-onset versus late-onset colorectal cancer. *First Author: Eric Michael Lander, Division of Hematology/Oncology, Vanderbilt University Medical Center, Nashville, TN*

Background: The etiology of the rising incidence of early-onset colorectal cancer (EOCRC), defined as CRC in patients aged < 50, remains unknown. In this study, we evaluated tumor genomic differences in patients with EOCRC versus average-onset CRC (AOCRC, age > 60). **Methods:** The cohort included 13,262 patients diagnosed with stages I-III colon or rectal cancer who had whole exome sequencing as part of their ctDNA testing (Signatera, bespoke mPCR NGS assay). Tumor mutational burden (TMB) and microsatellite instability (MSI) status were derived from tumor whole exome sequencing analysis. The prevalence of somatic variants and mutations in known oncogenic pathways was compared between EOCRC and AOCRC groups, stratified by TMB and MSI status. Fisher's exact test was used to test significance between the groups and p-values were adjusted using the FDR method for multiple test correction. **Results:** A total of 3,093 patients with EOCRC (70.8% colon, 27.4% rectal, 1.9% unknown) and 10,169 patients with AOCRC (79.9% colon, 18.3% rectal, 1.7% unknown) were included, where 9.0%/37.3%/53.7% were AJCC stages I, II, and III, respectively. Early-onset patients compared to average-onset patients had fewer cases of stage II CRC (30.7% vs. 39.3%, $p < 0.01$) and more cases of stage III CRC (60.9% vs. 51.6%, $p < 0.01$). Patients with EOCRC were less commonly MSI-H compared to patients with AOCRC (10% vs. 17%, $p < 0.01$), or have high tumor mutational burden (15% vs. 19%, $p < 0.01$). The BRAFV600E mutation and truncated RNF43 mutations were less prevalent in EOCRC (3% vs. 15% and 2% vs. 9%, $p < 0.01$), regardless of TMB and MSI status. Molecular alterations of the RTK-RAS pathway were less prevalent in the EOCRC cohort ($p < 0.01$), while TP53 pathway alterations were more frequent in the EOCRC cohort ($p < 0.01$). In the TMB-low/MSS group, TP53 mutations were more common in EOCRC (8% vs. 5%, $p < 0.01$), but APC gene mutations were less common in EOCRC (56% vs. 66%, $p < 0.01$). In the TMB-H/MSI-H group, BRAFV600E (4% vs. 60%), RNF43G659V (16% vs. 45%), and WNT1 G619A (6% vs. 20%) mutations were less prevalent in EOCRC ($p < 0.01$ for all mutations); however, patients with EOCRC had more PIK3CA H1047R (22% vs. 9%), APC R1468* (11% vs. 3%), and KRAS A146T (7% vs. 2%) variants ($p < 0.01$ for all mutations). In the TMB-H/MSS group, EOCRC patients were more likely to have driver mutations in the PI3K pathway (74% vs. 56%, $p < 0.01$). The POLE P286R mutation was more common in TMB-H/MSS patients with EOCRC (38% vs. 13%, $p < 0.01$), whereas ACVR2A K437R was less common (11% vs. 30%, $p < 0.01$). Prevalence of somatic variants and mutated oncogenic pathways did not vary significantly by tumor stage. **Conclusions:** Patients with AOCRC harbored more somatic variants and mutations in established pathways of CRC carcinogenesis. Tumors in EOCRC cases carried unique genomic alterations that varied across the TMB and microsatellite subpopulations. BRAFV600E and RNF43 truncating mutations were more frequent in AOCRC. Clinical Science Symposium

Metabolomic differences in young-onset versus average-onset colorectal adenocarcinoma. *First Author: Thejus Jayakrishnan, Taussig Cancer Institute, Cleveland, OH*

Background: Novel deleterious effects of environmental exposures may play a role in the rising incidence of young-onset colorectal cancer (yoCRC). We used metabolomics to assess differences between yoCRC and average-onset CRC (aoCRC), in comparison to healthy controls, which may provide insight into the pathogenesis and suggest any exposure risks. **Methods:** Patients with stage I-IV CRC and healthy controls were identified from prospective biobanks and categorized based on age < 50 years (yoCRC or young controls) or age > 60 years (aoCRC or older controls). Plasma metabolites were profiled using GC-TOF mass spectrometry. Differential abundance of metabolites was investigated using unadjusted and adjusted logistic regression. Metabolic pathway analysis was performed using Metaboanalyst 5.0. All p-values were adjusted for multiple testing (false-discovery rate, FDR $p < 0.20$ considered significant). **Results:** The study population comprised 170 CRC patients (66 yoCRC and 104 aoCRC) and 49 healthy controls (34 young and 15 old). Association analyses revealed four differentially abundant metabolites: citrate (FDR $p = 0.04$), cholesterol (0.14), and two unidentified metabolites (UM). Metabolic pathways significantly altered in yoCRC vs. aoCRC included: carbohydrate metabolism (citrate cycle, FDR $p = 0.04$), carbohydrate biosynthesis (glyoxylate and dicarboxylate metabolism, FDR $p = 0.004$), amino-acid metabolism (alanine, aspartate, and glutamate metabolism, FDR $p = 0.01$, arginine biosynthesis, FDR $p = 0.02$, and amino-acid t-RNA biosynthesis, FDR $p = 0.03$). There were no significant metabolomic differences between young and old controls. Significant associations on survival analysis included: adipic acid with aoCRC (HR = 3.1, 95% CI = 1.7-5.6, FDR $p = 0.13$, unadjusted analysis) suggesting worse survival with higher levels and 4-hydroxyhippuric acid with the whole cohort (HR = 0.4, 95% CI = 0.3-0.7, FDR $p = 0.05$, adjusted analyses) indicating better survival with higher levels. **Conclusions:** We identified significant differences in the citrate cycle - a core pathway of cellular metabolism associated with colorectal cancer. Metabolomic differences in pathways of carcinogenic significance (aspartate) and environmental exposures (arginine and dietary red meat) were also noted, suggesting potential relationships with younger age of CRC onset. Research Sponsor: Sondra and Stephen Hardis Chair in Oncology Research.

Differentially Abundant Metabolite	OR (95% CI)	FDR p
Citrate	14.54 (4.26-56.35)	0.04
Cholesterol	0.01 (0.001-0.10)	0.14
Altered Pathway	Pathway Impact Factor	FDR p
Glyoxylate and dicarboxylate metabolism	0.23	0.005
Citrate (TCA) cycle	0.14	0.04
Alanine, aspartate and glutamate metabolism	0.28	0.01
Glycine, serine and threonine metabolism	0.28	0.14
Aminoacyl-tRNA biosynthesis	0.17	0.01
Arginine biosynthesis	0.13	0.02

*Results for unknown metabolites are not included. Odds Ratio (OR) > 1 indicates higher abundance of metabolites in aoCRC vs. yoCRC.

Poster Discussion Session

Overall survival results for trifluridine/tipiracil plus bevacizumab vs capecitabine plus bevacizumab: Results from the phase 3 SOLSTICE study. *First Author: Thierry Andre, Hôpital Saint-Antoine, Paris, France*

Background: SOLSTICE, a phase 3 study, tested trifluridine/tipiracil+bevacizumab (FTD/TPI+bev) vs capecitabine+bevacizumab (cape+bev) in first-line for patients with unresectable metastatic CRC who were eligible for intensive chemotherapy (full-dose doublet/triplet). As previously reported, the study did not meet the primary endpoint (progression-free survival (PFS): 9.4 months [95% CI, 9.1-10.9] for FTD/TPI+bev vs 9.3 months [95% CI: 8.9-9.8] for cape+bev, HR 0.87 [95% CI: 0.75-1.02]). Here we report on the key secondary endpoint – overall survival (OS) and an update of the safety data. **Methods:** From 21 Mar 2019 to 14 Sep 2020, 856 patients were randomized (1:1) to either FTD/TPI+bev or cape+bev. Stratification factors were: ECOG performance status (0 vs 1 vs 2), reason for non-eligibility for intensive therapy (clinical condition vs non-clinical condition) and tumor localization (right vs left). The primary endpoint was PFS based on investigator assessment according to RECIST 1.1 criteria. The key secondary endpoint was OS, defined as the time from randomization to death from any cause. Other secondary endpoints included overall response rate, disease control rate, quality of life, and safety. OS was analyzed after 578 events to detect a hazard ratio of 0.79 with 80.0% power at one-sided 2.5% level of significance. **Results:** 426 patients were randomly assigned to FTD/TPI+bev and 430 to cape+bev. The median OS was 19.74 months with FTD/TPI+bev and 18.59 months with cape+bev (HR, 1.06; 95% CI, 0.90, 1.25) with survival probabilities for FTD/TPI+bev vs cape+bev comparable at different time-points. In the multivariate analysis, factors significantly associated with higher OS in the whole population were age < 70 years, left location of the primary disease, surgical resection of the primary tumor, number of metastatic sites (1-2 vs ≥ 3 sites), absence of liver metastasis, neutrophils lymphocyte ratio < 3, Charlson score 0 vs 1-2, and ECOG PS 1 vs 2. No significant treatment effect was observed after adjustment for the prognosis factors (HR, 1.08; 95% CI, 0.92, 1.28), which is consistent with the main OS analysis. The updated safety data was consistent with those communicated at the time of the primary PFS analysis. No new safety signal was identified. As previously reported, the most common severe emergent adverse events were neutropenia 54% vs 1%, neutrophil count decreased 19% vs 1%, anemia 16% vs 4%, hand-foot syndrome 0% vs 15%, and hypertension 9% vs 11% in FTD/TPI+bev vs cape+bev, respectively. **Conclusions:** This was the largest phase 3 study that explored two treatment regimens in a population ineligible for intensive therapy. FTD/TPI+bev was not superior to cape+bev in terms of PFS and OS. The risk of death was similar in both treatment arms. With a different and manageable safety profile, FTD/TPI+bev represents a feasible alternative to cape+bev in this population. Clinical trial information: NCT03869892. Research Sponsor: Institut de Recherches Internationales Servier.

Poster Discussion Session

Sotorasib (Soto) plus panitumumab (Pmab) and FOLFIRI for previously treated KRAS G12C-mutated metastatic colorectal cancer (mCRC): Code-Break 101 phase 1b safety and efficacy. *First Author: David S. Hong, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Soto, a KRAS^{G12C} inhibitor, had a 9.7% objective response rate (ORR) as monotherapy for chemorefractory patients (pts) with KRAS G12C-mutated mCRC. When combined with Pmab, a monoclonal anti-EGFR antibody, ORR increased to 30%, supporting the model that the doublet mitigates Soto-related feedback reactivation of the RAS-MAPK pathway and accumulation of activated EGFR. We hypothesize that Soto plus Pmab and FOLFIRI will further enhance Soto efficacy while maintaining a manageable safety profile. We report the first results for a KRAS^{G12C} inhibitor combined with an EGFR inhibitor and chemotherapy in pts with prior mCRC treatment. **Methods:** Pts included dose exploration and expansion cohorts from CodeBreak 101 subprotocol H (NCT04185883) who received Soto (960 mg PO daily) plus Pmab (6 mg/kg IV Q2W) and standard-dose FOLFIRI (IV Q2W). Key eligibility criteria were KRAS G12C-mutated mCRC and ≥ 1 prior treatment for metastatic disease. Pts in dose expansion were KRAS^{G12C} inhibitor-naïve. The primary endpoint was safety. Secondary endpoints included efficacy and pharmacokinetics (PK). **Results:** As of November 30, 2022, 33 pts (median age: 53 years; 48% female) were treated (6 in dose exploration, 27 in dose expansion). Median prior lines of systemic therapy was 2 (range: 1-6), with 33% and 67% of pts receiving 1 or ≥ 2 prior lines, respectively; 97% had prior fluoropyrimidine and 73% had prior irinotecan. Two pts in dose exploration received prior Soto. None of the 6 pts in dose level 1 of dose exploration had dose limiting toxicities (DLTs) during DLT evaluation (first 28 days), and Soto (960 mg PO daily) plus Pmab (6 mg/kg IV Q2W) and FOLFIRI (IV Q2W) was the recommended phase 2 dose. Treatment-related adverse events (TRAEs) of any grade occurred in 32 (97.0%) pts; 1 pt discontinued the full regimen due to grade 3 ALT increase. Fifteen (45.5%) had grade ≥ 3 TRAEs (most commonly dermatologic; n = 5). There were no fatal TRAEs. Safety findings were consistent with known profiles of Soto, Pmab, and FOLFIRI. No clinically meaningful PK interaction was observed between Soto and irinotecan. Of 31 pts evaluable for response, confirmed ORR (all partial responses) was 58.1% (95% CI: 39.1, 75.5). The 2 pts with prior Soto achieved partial response (n = 1) and stable disease (n = 1). Disease control rate was 93.5% (95% CI: 78.6, 99.2). With median follow-up of 5.7 and 7.4 months, respectively, progression-free and overall survival data are not yet mature. Fully enrolled data will be presented. **Conclusions:** In the first ever data set for this novel combination, Soto plus Pmab and FOLFIRI showed promising safety and efficacy in pre-treated KRAS G12C-mutated mCRC, with a confirmed ORR of 58.1%. Adverse events were manageable and consistent with the expected safety profile of the drugs used, and there was no clinically meaningful Soto and irinotecan PK interaction. Clinical trial information: NCT04185883. Research Sponsor: Amgen, Inc.

Poster Discussion Session

Postoperative hepatic arterial chemotherapy after resection of colorectal liver metastases in patients at high risk of hepatic recurrence: A multicenter randomized phase II trial (PRODIGE 43 - PACHA-01). *First Author: Maximiliano Gelli, Gustave Roussy, Villejuif, France*

Background: Hepatic arterial infusion (HAI) of chemotherapy (CTx) has been proposed as a potential treatment to decrease the risk of hepatic recurrence after resection of colorectal liver metastases (CRLM). Randomized controlled trials (RCTs) led to controversial results and meta-analyses are inconclusive. We conducted a comparative phase II RCT to assess the efficacy of adjuvant HAI oxaliplatin with concomitant intravenous (IV) CTx in pts at high risk of hepatic recurrence (≥ 4 resected CRLM). **Methods:** Pts who underwent curative-intent surgery of at least 4 CRLM after preoperative IV CTx were randomly assigned (1:1) to receive adjuvant IV fluorouracil/leucovorin (LV5FU2) combined with oxaliplatin (85mg/m²) by HAI (HAI-IV arm) or IV route (IV arm) every 2 weeks, for at least 3 months to achieve a minimal duration of perioperative CTx of 6 months. The primary endpoint was the hepatic recurrence free survival (h-RFS). Secondary endpoints included the feasibility of delivering at least 4 CTx cycles, toxicity (NCI-CTCAE 4.0) including HAI catheter-related complications, RFS, overall survival (OS) and recurrence pattern. 108 randomized pts were required to detect a gain in 18-month h-RFS from 30% to 50% with a one-sided α risk of 10% and 95% power. The primary endpoint was analyzed with a Cox regression model, with adjustment for stratification factors (tumor response to preoperative CTx and number of resected CRLM). The study was prematurely stopped after randomization of 99 pts due to recruitment issues and HAI catheters market withdrawal. **Results:** Between Jun 2015 and Dec 2020, 99 pts (median age, 62; median number of CRLM, 5) were randomly assigned in HAI-IV arm (50 pts) or IV arm (49 pts). After a median follow-up of 56 months, the intent-to-treat analysis showed a significantly longer h-RFS in the HAI-IV arm compared to the IV arm (median 25 [16-37] vs 12 months [8-21]; HR 0.598 [95%CI 0.379-0.944], p = 0.027). 5-year h-RFS was 32% [19-45] in the HAI-IV arm vs 13% [4-27] in the IV arm, respectively. Median and 5-year OS were 74 months [51-74] and 60% [43-74] in the HAI-IV arm vs 54 months [37-69] and 46% [29-61] in the IV arm (HR 0.551 [0.299-1.015], p = 0.056). The median number of postoperative CTx cycles was 6 in both groups with 86% and 78% of patients having received at least 4 cycles in HAI-IV and IV arms (p = 0.7), respectively. Grade 3-4 toxicity rate was 58% in the HAI-IV arm vs 31% in the IV arm (p = 0.01). Overall, nine pts (18%) experienced HAI-related complications. No toxic death occurred in both arms. **Conclusions:** Despite a higher but acceptable toxicity, combination of HAI oxaliplatin with IV LV5FU2 significantly improved h-RFS after curative resection of CRLM in high-risk patients. This combined treatment should be considered as a valid option for these patients. Clinical trial information: NCT02494973. Research Sponsor: Institut National du Cancer, Programme Hospitalier de Recherche Clinique du Cancer, Ligue Contre le Cancer.

Poster Discussion Session

Phase 1 study of WNT pathway Porcupine inhibitor CGX1321 and phase 1b study of CGX1321 + pembrolizumab (pembro) in patients (pts) with advanced gastrointestinal (GI) tumors. *First Author: Marios Giannakis, Dana-Farber Cancer Institute, Boston, MA*

Background: Despite the fundamental role of WNT signaling in GI cancers, especially colorectal cancer (CRC), no drug targeting WNT signaling has been successfully developed. CGX1321, a highly-potent and selective inhibitor of O-acyltransferase Porcupine, blocks WNT ligand secretion. Preclinical studies show that CGX1321 inhibits WNT signaling and growth of tumors with *RSP0* fusions or inactivating *RNF43* mutations. Activation of WNT signaling has been associated with cancer immune-suppression and resistance to immunotherapy. **Methods:** The first-in-human trials (NCT02675946 in U.S., NCT03507998 in China) include phase 1 CGX1321 dose escalation (3 – 18 mg, once daily) and dose expansion (18 mg), and phase 1b CGX1321 + pembro combination (Keynote 596). The primary objectives were safety, tolerability and identification of recommended doses and schedules for further evaluation. Secondary objectives were characterization of the PK profile and PD response and anti-tumor activity. CGX1321 was dosed once daily, orally, for 21 days out of 28-day cycles as single-agent, or for 14 days out of 21-day cycles in combination with pembro. **Results:** As of January 1, 2023, 77 pts were enrolled, including 38 pts with solid tumors in the CGX1321 dose escalation, 17 pts with CRC or small bowel cancer (SBC) carrying *RSP0* or *RNF43* alterations in the CGX1321 expansion, 17 pts with microsatellite stable (MSS) CRC in the CGX1321 + pembro dose escalation and 5 pts with MSS CRC in the CGX1321 + pembro expansion. Six of the 17 pts with MSS CRC or SBC from the CGX1321 single-agent expansion were rolled over to CGX1321 + pembro upon disease progression. Across all cohorts, treatment was well tolerated with the majority of AEs being Grade 1/2 and not related to CGX1321, while Grade > 3 AEs related to CGX1321 were infrequent ($\sim 6\%$). Dysgeusia, a common AE observed with other WNT inhibitors, was mild (mostly Grade 1). Bone resorption, the main on-target AE, was manageable and preventable by prophylactic administration of denosumab or zoledronic acid. PK and PD analyses showed adequate drug exposure and significant inhibition of WNT signaling as measured by reduced hair follicle axin2 expression from 12 mg dose. Twelve of 17 pts (71%) with confirmed tumor genetic alterations in *RSP0* or *RNF43* had SD with median time to progression of 112 days (range: 56 – 392). Of the 6 pts in the roll-over cohort, 3 pts with *RSP03* fusion tumors achieved PR during CGX1321 + pembro combination therapy. **Conclusions:** CGX1321 has demonstrated potent inhibition of the WNT pathway with manageable side effects. Promising efficacy signals have been observed in pts whose tumors harbor *RSP0* fusion, supporting further development of CGX1321 monotherapy and CGX1321 + anti-PD-1/L1 in a defined patient population that is historically known to be refractory to standard therapies and immune checkpoint inhibitors. Adjuvant systemic chemotherapy with or without hepatic arterial infusion of floxuridine in patients following colorectal cancer liver metastases resection (HARVEST): A prospective, randomized controlled trial. *First Author: Yu-hong Li, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University, Guangzhou, China*

Background: Several retrospective studies have previously demonstrated that a combination of adjuvant systemic chemotherapy and hepatic arterial infusion (HAI) could benefit patients following colorectal cancer liver metastases (CRLM) resection. This prospective clinical study aimed to determine whether adding HAI to adjuvant systemic chemotherapy could reduce the risk of recurrence following CRLM resection. **Methods:** The HARVEST study is an investigator-initiated, prospective, randomized controlled trial investigating the efficacy and safety of adjuvant intravenous chemotherapy with or without HAI floxuridine (FUDR) in CRLM patients that underwent liver metastasectomy. Patients in the systemic chemotherapy plus HAIC arm (HAI group) received systemic FOLFOX (q2w) plus HAI (FUDR, d1-14, q4w) for up to 6 months, while the systemic chemotherapy group without HAI (non-HAI group) received intravenous FOLFOX only. The primary study endpoint is the relapse-free survival in the modified intention-to-treat (mITT) population. Blood samples at different time points were also collected and circulating tumor DNA (ctDNA) was tested for NPY and SEPT9 methylation. **Results:** The study was prematurely terminated due to FUDR production halt in China. Ninety-two patients were randomized and seventy-seven patients (38 in the HAI group and 39 in the non-HAI group) were eventually included in our mITT analysis. After a median follow-up of 35.8 months, there were 22 (57.9%) and 25 (64.1%) recurrences in the HAI and non-HAI groups, respectively. The median relapse-free survival was 20.0 months in the HAI group and 11.7 months in the non-HAI group (p = 0.14; HR 0.65; 95% confidence interval [CI] 0.37 to 1.16). No significant difference was found in terms of overall survival between the two groups (p = 0.461). Our subgroup analysis revealed that patients with multiple liver metastases (p < 0.01) and RAS/BRAF mutation (p < 0.01) could benefit from adjuvant HAI treatment. Based on ctDNA status, patients with positive postoperative ctDNA methylation benefited from adjuvant HAI treatment (p < 0.01), while those with negative postoperative ctDNA methylation status (p = 0.95) did not. Chemotherapy-related adverse events were comparable between the two groups. **Conclusions:** Adjuvant chemotherapy intensification using HAI did not significantly reduce recurrence following CRLM resection. However, patients with multiple liver metastases, RAS/BRAF mutation and those with positive postoperative ctDNA might benefit from adjuvant HAI treatment. Clinical trial information: NCT03500874. Upfront palliative resection of primary tumor versus no resection in patients with synchronous metastatic colorectal cancer: The randomized phase 3 CAIRO4 study of the Dutch Colorectal Cancer Group (DCCG). *First Author: Miriam Koopman, Department of Medical Oncology, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands*

Background: Primary tumor resection (PTR) in patients with synchronous metastatic colorectal cancer (CRC) has been associated with a survival benefit in comparative cohort studies. In the CAIRO4 phase III randomized trial, the potential benefit of upfront PTR followed by systemic therapy versus systemic therapy alone was investigated. **Methods:** Main eligibility criteria included histologically confirmed CRC, unresectable metastases, resectable primary tumor in situ without related severe symptoms, and WHO performance status (PS) 0-2. Eligible patients were randomized to first-line fluoropyrimidine-based chemotherapy plus bevacizumab with or without upfront PTR strategy. Randomization was stratified for number of metastatic sites (1 versus more), institution, WHO PS (0-1 versus 2), serum LDH (normal versus > ULN), and location of the primary tumor (left versus right-sided). The primary endpoint was overall survival (OS), which was analyzed by intention-to-treat (ITT) using the Max-Combo test. The original sample size of 306 patients was amended to 206 participants due to slow accrual. With final primary analysis based on 181 events, the study had 71% power to detect the OS difference of 19 versus 13 months deemed clinically relevant in the original sample size calculation. The trial is registered as NCT01606098. **Results:** Between August 2012 and February 2021, 206 patients were randomized: 103 patients to each arm. Two patients in the upfront PTR arm were excluded due to ineligibility. A total of 204 patients (57% male, median age 65 [IQR 59-71] years, 50% right-sided CRC and 98% WHO PS 0-1) were included with a median follow-up of 63.6 months. In the upfront PTR arm 5% of patients did not undergo PTR and 13% did not receive subsequent systemic therapy. In the arm without upfront PTR, 1% of patients did not receive systemic therapy. The median number of cycles was 9 [IQR 4-15] in the upfront PTR arm versus 11 [6-16] in the arm without upfront PTR. Median OS was 22.2 (95% CI 17.5-25.7) months in the upfront PTR arm and 19.5 (95% CI 16.1-22.7) months in the arm without upfront PTR ($p = 0.269$). Median PFS was 10.1 (95% CI 8.7-11.7) months in the upfront PTR arm and 10.1 (95% CI 8.6-11.8) months in the arm without upfront PTR ($p = 0.805$). At a later point in their disease course, 1.9% of patients in the arm without upfront PTR underwent a colectomy and 16.5% required PTR for symptom palliation. **Conclusions:** In patients with synchronous metastatic CRC amenable to palliative systemic therapy without severe symptoms related to the primary tumor, upfront PTR did not result in a significant median OS difference compared to immediate start with systemic treatment. Neoadjuvant chemotherapy (NAC) followed by total mesorectal excision (TME) and adjuvant chemotherapy versus TME followed by adjuvant chemotherapy in very low-lying clinical (c) T3 rectal cancer (NAIR): A multi-center, randomized, open-label, phase 2/3 trial. *First Author: Yuichiro Tsukada, Department of Colorectal Surgery, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Chemoradiotherapy and total neoadjuvant therapy are the standard treatments for locally advanced rectal cancer (LARC). Although radiotherapy (RT) is an integral part of treatment, it negatively impacts anal function after TME for cases of very low-lying LARCs. This trial examined the efficacy, safety, and influence on postoperative anal function of NAC without RT in patients (pts) with very low-lying cT3 LARCs. **Methods:** Pts with cT3NO-2M0 adenocarcinomas located within 5 cm from the anal verge, whose anuses were expected to be preserved, were randomly assigned (1:1) to either the NAC group (preoperative chemotherapy with six cycles of mFOLFOX6 or four cycles of CAPOX followed by TME; then, postoperative identical regimen) or the TME group (upfront TME followed by postoperative chemotherapy with 12 cycles of mFOLFOX6 or 8 cycles of CAPOX), stratified by cN stage, center, and sex. The primary endpoint was the 3-year recurrence-free survival (RFS), which was compared between groups using a stratified log-rank test at a one-sided alpha level of 20%. **Results:** Between February 2013 and March 2019, 130 pts were enrolled and randomly assigned to a treatment group. A total of 127 pts were evaluable (65 in the NAC group and 62 in the TME group). All but one patient with early progression completed preoperative chemotherapy in the NAC group, and all pts in both groups underwent TME. After a median follow-up of 37.4 months (IQR 36.5-40.5), the 3-year RFS was 75.5% (95% CI 62.5-84.5) in the NAC group vs. 70.9% (95% CI 57.2-80.9) in the TME group (hazard ratio 0.67, 95% CI 0.34-1.32; $P = 0.098$), and the primary endpoint was met. There were no differences in the occurrence of grade 3 or higher postoperative complications (20% in the NAC group vs. 21% in the TME group [$P = 1.000$]), chemo-associated grade 3 or higher adverse events (28% in the NAC group vs. 23% in the TME group [$P = 0.551$]), or any grade of peripheral sensory neuropathy lasting for 3 years (22.7% in the NAC group vs. 38.5% in the TME group in pts treated with mFOLFOX6 [$P = 0.3163$], 7.1% in the NAC group vs. 33.3% in the TME group in pts treated with CAPOX [$P = 0.1038$]), between the groups. No treatment-related deaths occurred in either of the groups. At 3 years after randomization, 61 pts in the NAC group (93.8%) and 52 pts in the TME group (83.9%) could defecate via their anuses ($P = 0.092$). The median Wexner incontinence score was 11.0 in the NAC group and 10.0 in the TME group ($P = 0.3405$). **Conclusions:** For pts with very low-lying cT3 LARC, NAC followed by TME and adjuvant chemotherapy achieved significantly better RFS and anus-preserving rates compared to upfront TME followed by adjuvant chemotherapy, without deteriorating postoperative complications or postoperative anal function. Clinical trial information: UMIN000009510. Research Sponsor: National Cancer Center Research and Development Fund (23-A-26).

15-month safety and efficacy data after intraperitoneal treatment with ²²⁴Radium-labelled microparticles after CRS-HIPEC for peritoneal metastasis from colorectal cancer. *First Author: Stein G Larsen, Norwegian Radium Hospital, Oslo, Norway*

Background: Peritoneal metastasis (PM) from colorectal cancer carries a dismal prognosis. Improved survival can be achieved by extensive cytoreductive surgery (CRS), frequently used together with hyperthermic intraperitoneal chemotherapy (HIPEC), with median time to recurrence around 12 months. Radspherin is a novel treatment principle based on the delivery of short range and cytotoxic alpha particles emitted during the decay of ²²⁴Ra. Alpha particles have high linear energy transfer and a radiation range less than 100 μ m (3-10 cell diameters), generating highly localized and effective radiation with non-repairable double-strand DNA breaks in affected cells. Our hypothesis is that Radspherin produces an alpha-particle radiation field exclusively to the surfaces and liquid volumes of the peritoneum, delivering lethal doses to remaining micrometastasis in the peritoneal linings and eradicate free-floating tumor cells after surgical resection, thus assumingly prolonging time to recurrence and potentially overall survival. **Methods:** A phase 1/2a study (EudraCT 2018-002803-33) is ongoing to evaluate safety, tolerability and signal of efficacy of Radspherin injected intraperitoneally two days after CRS-HIPEC. After completion of dose escalation (1-2-4-7 MBq), an activity-dose of 7 MBq was recommended. Assessment of safety and efficacy (diagnostic imaging) was performed every three months. Safety data and progression-free survival (PFS) at 15 months are presented. **Results:** Twenty-three patients (pts) were enrolled across cohorts (safety population), of these 12 pts received the recommended dose of 7MBq, 9 pts single dose and 3 pts split dose (3,5 MBq x2). Twelve pts had synchronous PM and 11 metachronous PM. Median age was 64 years (28-78), 70 % were female and median peritoneal cancer index was 7 (3-19). To date, 271 adverse events (AE) were reported, whereof only 7 (all grade 1-2) were deemed related to Radspherin. Fourteen serious adverse events (SAEs) in 8 pts have been reported, none considered related to Radspherin. At 15 months, 9 out of 23 pts (39 %) had recurred, whereof 4 pts recurred in the peritoneum. In the expansion cohort (7MBq), 3 out of 12 pts (25 %) had recurred and none of these pts had peritoneal recurrences. Median PFS was not reached in the two populations. **Conclusions:** Radspherin was well tolerated with no related SAEs reported. At 15 months median PFS has not been reached and none of the patients at recommended dose had peritoneal recurrences. The results are encouraging and warrant further exploration of Radspherin as a novel treatment principle in clinical trials. Clinical trial information: NCT03732781. Sustained organ preservation in patients with rectal cancer treated with total neoadjuvant therapy: Long-term results of the OPRA trial. *First Author: Floris S Verheij, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The preliminary results of the OPRA trial demonstrated that a substantial number of patients with locally advanced rectal cancer treated with total neoadjuvant therapy (TNT) could achieve organ preservation. Although most tumor regrowths seem to occur within the first 3 years, longer follow-up is needed to assess the ongoing risk of regrowth. Here, we report the long-term organ preservation rate and oncologic outcomes of the OPRA trial. **Methods:** A prospective, multi-institutional phase II trial, in which patients with stage II or III rectal cancer were randomized to receive either induction chemotherapy followed by chemoradiation (INCT-CRT) or chemoradiation followed by consolidation chemotherapy (CRT-CNCT). Patients underwent reassessment for treatment response 8-12 weeks after TNT. Patients who achieved a complete or near-complete response after finishing TNT were offered a watch and wait approach (WW). Those with incomplete response were recommended total mesorectal excision (TME). We report 5-year disease-free survival (DFS), organ preservation (defined as TME-free survival), local recurrence-free survival (LRFS), distant metastasis-free survival (DMFS) and overall survival (OS) for each treatment group. We also compared DFS between patients who underwent upfront TME after restaging and patients who underwent TME after tumor regrowth. All analyses followed the intention-to-treat principle and groups were compared using the log-rank test. **Results:** Of the 324 patients randomized, 158 were assigned to the INCT-CRT group and 166 to the CRT-CNCT group. Median follow-up was 56 months; 85 DFS events were observed. The rates of 3- and 5-year DFS, TME-free survival, LRFS, DMFS and OS are listed in the Table. In total, 80 of the 225 (36%) patients who started WW developed a regrowth; 94% occurred within 2 years and 99% occurred within 3 years. The rate of TME-free survival at 5 years was significantly higher for CRT-CNCT (54%) than in INCT-CRT (39%). 5-year DFS was similar for patients who underwent TME after restaging (61%) compared to patients who underwent TME after regrowth (62%, $p = 0.86$). **Conclusions:** In patients with rectal cancer treated with TNT and WW, the majority of tumor regrowths occur in the first 2 years, and regrowth after 3 years is vanishingly rare. Salvage TME for tumor regrowth during WW appears to offer similar outcome to immediate TME after incomplete response to TNT. Distant metastases remain the most frequent cause of treatment failure, with similar rates in the two treatment groups. Clinical trial information: NCT02008656. Research Sponsor: U.S. National Institutes of Health.

Circulating tumor DNA dynamics as an early predictor of recurrence in patients with radically resected colorectal cancer: Updated results from GALAXY study in the CIRCULATE-Japan. *First Author: Eiji Oki, Kyushu University, Fukuoka-Shi Higashi-Ku, Japan*

Background: Postoperative circulating tumor DNA (ctDNA)-based molecular residual disease (MRD) is reported to be associated with a high risk of recurrence. Here, we present an updated analysis and the lead time interval (LTI) of ctDNA positivity to radiographic recurrence in patients (pts) with radically resected colorectal cancer (CRC), stage II-IV in the observational GALAXY study. **Methods:** Serial ctDNA was analyzed using personalized tumor-informed assay (Signatera bespoke multiplex-PCR NGS assay) at 1 (4-week MRD time point), 3, 6, 9, 12, 18, and 24 months after surgery until recurrence, and CT scans were conducted every 6 months. The primary endpoint was disease-free survival (DFS), defined as the time between the date of surgery and date of diagnosis with relapse or death due to any cause. The LTI was defined from the first ctDNA positive date at post-surgery to radiographic recurrence. **Results:** Among 3,615 CRC pts who were enrolled between May 2020 and April 2022 in GALAXY study, 2,083 pts that met the inclusion criteria were analyzed in this report. The median follow-up period was 16.3 months. Of 2,083 pts analyzed, 286 (14%) were ctDNA-positive at 4-weeks MRD time point and 1,797 (86%) were ctDNA-negative. Pts with ctDNA-positivity at 4-weeks MRD timepoint demonstrated an inferior DFS and were 12 times more likely to recur, compared to ctDNA-negative pts (HR:12, 95CI: 9.1-15%; $p < 0.0001$). We further combined ctDNA status with BRAF V600E status at 4-week MRD time point and observed that pts with ctDNA-positivity and BRAF V600E mutation showed significantly shorter DFS compared to ctDNA-positive pts with BRAF wild-type ($p < 0.001$). Whereas, in pts with ctDNA-negativity no significant difference in DFS was observed ($p = 0.306$). On performing ctDNA dynamics analysis between 4-weeks to 12 weeks, compared to pts who remained ctDNA-negative ($N = 1529$), a significantly shorter DFS was observed for pts who converted from ctDNA-negative to positive ($N = 112$, HR: 14.5, 95%CI: 8.8-23.8%, $p < 0.0001$) or who remained positive ($N = 124$, HR: 25.4, 95%CI: 18.3-35.3; $p < 0.0001$). Radiographic recurrence was observed in 186 pts (46%). Of these, 121 pts (65%) had CT imaging performed every 6 months, as per the protocol. The median LTI was 142 days (IQR, 43-189 days). **Conclusions:** Our study builds on the existing evidence from the recently published, prospective GALAXY study. ctDNA status at MRD time point post-surgery is prognostic of patient outcomes and is the most significant risk factor regardless of BRAF V600E status. ctDNA positivity predicted radiologic recurrence several months ahead of clinical recurrence. Pts with positive postoperative ctDNA should be examined carefully due to a high risk of recurrence. ctDNA-guided adjuvant strategy will further be established by ongoing randomized VEGA and ALTAIR studies in the CIRCULATE-Japan. Clinical trial information: UMIN000039205. Research Sponsor: Japan Agency for Medical Research and Development (AMED).

Predictive models of recurrence from transcriptomic signatures of the tumor microenvironment and cell cycle in stage III colon cancer from PETACC-8 and IDEA France trials. *First Author: Claire Gallois, Institut du Cancer Paris CARPEM, APHP, Digestive Oncology Department, APHP.Centre - Université Paris Cité, Hôpital Européen G. Pompidou, Paris, France*

Background: The objective of this work was to establish predictive models of the risk of recurrence in stage III colon cancer (CC) based on transcriptomic signatures of the tumor microenvironment (TME) and cell cycle from the PETACC-8 (training set) and IDEA-France (validation set) trials. **Methods:** 3'RNAseq was performed in 1733 patients from the PETACC-8 trial (85%) and 1263 patients from the IDEA-France trial (63%). 4 transcriptomic signatures were analyzed: a signature reflecting T-cells infiltration named "Immunoscore-Like", a signature reflecting M2 macrophage infiltration named "M2-like", the expression of CXCL13 (reflecting B cells infiltration) and a score based on the Oncotype DX® Colon Cancer RS using the same formula from the stromal score and the cell cycle score, named "Oncotype DX Like". In the 1st multivariate model, we analyzed the 4 signatures separately with a dichotomization into "high" and "low" with the best cut point value for the prediction of time to recurrence (TTR) in PETACC-8 trial. In the 2nd multivariate model, we defined a score named "IPS" (Immune Proliferative Stromal), corresponding to the number of deleterious signatures ("high" or "low" depending on the signatures), ranging from 0 to 4. **Results:** The 1st multivariate model, built from PETACC-8 trial, showed that these 4 signatures were significantly associated with TTR with a protective effect of Immunoscore Like and CXCL13 "high" (HR: 0.66, $p = 0.003$ and 0.60, $p < 0.001$ respectively) and a deleterious effect of M2 Like and Oncotype Like "high" (HR: 1.28, $p = 0.05$ and HR: 1.37, $p = 0.01$, respectively), independently of known prognostic factors, with a C-index of 0.73. This model was applied to the IDEA-France cohort by calculating a predictive score for each patient, with TTR significantly different depending on the quartile of this score with a 3-year TTR ranging from 55% for the lowest quartile to 90% for the highest quartile ($p < 0.001$). In the 2nd model, in the 2 cohorts, IPS score was independently associated with TTR with a HR increasing with the IPS score, independently of T and N stage and intra-tumoral CMS heterogeneity (Table). **Conclusions:** Using transcriptomic data of patients with stage III CC from 2 large-scale adjuvant trials, two predictive models based on signatures of the TME and the cell cycle, provide important information in addition to known prognostic factors for patient stratification on risk of recurrence. Beyond T and N stage, for the decision of adjuvant chemotherapy in stage III CC, the combination of these different variables could be exploited in the future for personalized care (de-escalation, intensification). Research Sponsor: ARCAD.

Poster Discussion Session

Association of positive ctDNA-based minimal residual disease assays during surveillance and undiagnosed concomitant radiographic recurrences in colorectal cancer (CRC): Results from the MD Anderson INTERCEPT program. *First Author: Arvind Dasari, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Observational cohorts have shown that detection of circulating tumor DNA (ctDNA)-defined minimal residual disease (MRD) following curative intent therapy has very high specificity and positive predictive value for future radiographic recurrence with a lead time of over 9 months. However, such data have not incorporated rigorous clinical evaluation for concomitant recurrence, nor have they established the clinical utility of MRD monitoring after completion of curative intent therapy. **Methods:** Pts with stages II-IV CRC (6/1/19 - 12/31/22, data cutoff) treated with curative intent at MD Anderson Cancer Center were evaluated with a tumor-informed MRD assay (Signatera, Natera), as part of the institutional INTERCEPT program that aims to integrate MRD-based testing into CRC clinical care. Surveillance visits including scans and tumor markers were performed per established guidelines. ctDNA was recommended post-operatively and q3m with each surveillance visit. Pts and providers were informed of the results and subsequent clinical courses including additional radiologic testing for ctDNA+ MRD tests were tracked. **Results:** 1259 pts were included in the INTERCEPT program (median 57y, [21-93]; 55% male; stage% I-III/IV 69/31; colon/rectum% 61/39), with 1049 pts tested after curative intent surgery. Of these, 159/1049 pts (15%) had ctDNA+; distribution of pts, % (+ve/total) from time of such surgery in m was: 0-3 (54.6/43.8); 3-6 (21.3/30); 6-12 (24/33.2). Of the pts with ctDNA+ after surgery, 49 pts (32%) were ctDNA+ prior to or during adjuvant therapy and 86 (57%) during surveillance. Of the 86 pts who were ctDNA+ during surveillance, imaging revealed concomitant new metastases in 46 (53%); i.e. only 40 (47%) were true MRD+. A total of 191 imaging studies were done (range 1-4) within 90d of the initial ctDNA+ including 99 as routine surveillance concurrent with ctDNA testing and 92 as additional follow up based on results. Of 40 pts with true MRD, majority (27 pts, 67.5%) were enrolled onto ongoing MRD trials (<https://crcmrmd.com/>). **Conclusions:** Our experience provides support for the feasibility of incorporation of MRD testing as part of routine surveillance. ctDNA+ results trigger a high rate of reflex imaging and, as a result, 53% of ctDNA+ patients have concomitant new radiographic findings. While clinical trials are feasible in true MRD+ pts, eligibility criteria for these trials need to be carefully specified about adequate radiographic evaluation. Research Sponsor: None.

Circulating tumor DNA (ctDNA) to assess response in patients with anal cancer treated with definitive chemoradiation. *First Author: Janet Alvarez, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: We hypothesize that circulating tumor DNA (ctDNA) dynamics can provide an early response indicator in patients with anal squamous cell carcinoma (ASCC) undergoing definitive chemoradiotherapy (CRT). **Methods:** Since 2021, patients with ASCC undergoing CRT at 2 institutions were offered ctDNA monitoring with the Natera Signatera assay, a commercial tumor-bespoke, multiplex PCR assay. All patients provided written informed consent for ctDNA testing. Patients were clinically restaged 3-4 months after CRT by clinical exam, endoscopy, and/or MRI, as well as annually with a chest, abdomen, and pelvis CT. Complete clinical response (cCR) was defined as having no tumor observed by digital exam, endoscopy, and/or MRI. Molecular ctDNA response was described according to cCR, tumor recurrence, and survival. **Results:** From January 2021 to October 2022, 41 patients with ASCC treated with CRT underwent ctDNA response assessment. Most patients (66%) had stage III disease. Patients were treated to a median radiation dose of 54 Gy in 27 fractions — with combinatorial mitomycin and fluoropyrimidine-based chemotherapy in 88% of patients, and fluoropyrimidine-based chemotherapy alone in 12%. The median follow-up was 22 weeks (range 0-89 weeks). ctDNA testing was performed in 36 patients at baseline, 31 patients during CRT, 27 patients within 40 days after CRT, 23 patients 3-6 months post-CRT, 23 patients 6-12 months post CRT, and 10 patients > 12 months post CRT. At baseline, 89% of patients had detectable ctDNA. Patients with stage III, as compared to stage I-II, disease had numerically higher baseline ctDNA levels (29 vs. 2.9 mean tumor molecules per milliliter (MTM/mL), $p = 0.04$). ctDNA levels decreased with treatment (24 vs. 2.1 MTM/mL, $p = 0.005$) among the 24 patients with detectable baseline ctDNA and ctDNA tested during CRT. Fifty eight percent of patients converted from ctDNA positive to ctDNA negative during CRT. Similarly, post-CRT ctDNA levels decreased (23 vs. 0.01 MTM/mL, $p = 0.01$), with 95% of patients converting from ctDNA positive to ctDNA negative. The time to ctDNA clearance was significantly shorter than the time to cCR (median 31 vs. 131 days, $p < 0.0001$). In follow up 2 patients reverted from ctDNA negative to ctDNA positive at 113 -155 days post-CRT. Currently all patients are clinically and radiographically without evidence of disease. **Conclusions:** Surveillance ctDNA monitoring provides an earlier response assessment for patients with ASCC undergoing CRT. However, longer term follow-up is required to determine if ctDNA response correlates with long-term recurrence free survival. Prospective trials are needed to assess the clinical utility of integrating molecular ctDNA response into therapeutic response surveillance. Research Sponsor: U.S. National Institutes of Health.

HPV integration as a prognostic biomarker for metastatic anal cancer: A next-generation sequencing ctDNA-based approach. *First Author: Benny Johnson, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Anal cancer is an HPV-associated malignancy with increasing prevalence in the United States. Immune checkpoint blockade demonstrates limited efficacy in patients with metastatic squamous cell cancer of the anal canal (mSCCA), and no prognostic or predictive biomarkers have demonstrated clinical utility in this population. Available circulating tumor DNA (ctDNA) assays have utilized ddPCR methodologies to report only the most common HPV types (HPV-16 and HPV-18) and HPV copy numbers. To extend the utility of an HPV ctDNA assay, we created a novel next-generation sequencing HPV ctDNA assay to analyze HPV integration as a prognostic biomarker for patients with mSCCA. **Methods:** Using an IRB-approved protocol, ctDNA isolated from the plasma of patients with mSCCA was sequenced using a 1.4Mb hybrid-capture target-enrichment panel covering the whole genome sequences of all 193 HPV types. HPV type, HPV copy number, and HPV integration status/locus were determined using a bioinformatic pipeline developed in-house. A Fisher's exact test was used to compare radiographic and ctDNA changes in response to systemic treatment. Unpaired t-tests were used to compare demographics between patients with HPV integration (I) or no integration (NI) status in the ctDNA. Median survival was estimated (Kaplan Meier) and compared according to integration status using a log-rank test. **Results:** 68 plasma samples from 27 patients with mSCCA were analyzed. While HPV-16 was detected in ctDNA of all 27 patients, five patients had additional oncogenic HPV types [HPV-18 (2), HPV-45 (2), HPV-73 (1)]. Radiographic changes in metastatic disease volume were concordant with HPV copy number changes in the ctDNA (odds ratio 12.2, 95% confidence interval (CI) 2.0-75; $p = .007$). HPV integration events were detected in the ctDNA for 16 (59%) patients (median 2, range 1-7 unique events per patient). For the 23 patients with mSCCA who received anti-PD1 immunotherapy (15 I, 8 NI), there were no differences in age (60 vs 59 years, $p = .88$) or prior lines of treatment (3.0 vs 3.5, $p = .72$). There was a trend towards improved median progression-free survival for NI ctDNA status (5.8 vs 3.2 months, hazard ratio (HR) 1.8, 95% CI .71-4.5). Relative to NI status, I status was associated with worse overall survival rates (OS) (22.5 vs 44.9 months, HR 5.0, 95% CI 1.5-17, $p = .005$). **Conclusions:** Detection of HPV integration status for all HPV types is feasible using a ctDNA-based approach for patients with SCCA. HPV integration was prognostic for worse OS in patients with mSCCA. Identification of HPV integration as a novel prognostic biomarker for survival outcomes in mSCCA warrants further evaluation in larger clinical trials. Pathological analysis of tumor microenvironmental features using deep learning to predict survival of colon carcinomas. *First Author: Frank A. Sinicrope, Mayo Clinic College of Medicine, Rochester, MN*

Background: Advances in deep learning may improve the ability to evaluate and quantify pathological features in solid tumors to improve prediction of patient disease-free survival (DFS). We used an artificial intelligence (AI) algorithm to quantify morphological features in the tumor microenvironment of stage III colon cancers. **Methods:** We analyzed digitized stage III colon carcinomas (N = 402; 382 met QC) from participants in a phase III trial of FOLFOX-based adjuvant chemotherapy that included all available tumors with dMMR and a randomly selected cohort of pMMR tumors (median follow-up 60 months) [NCCTG N0147; Alliance for Clinical Trials in Oncology]. Fifteen morphological features were extracted using the QuantCRC algorithm that segments images into carcinoma (low-grade, high-grade, signet ring cell), stroma (immature, mature, and inflammatory), mucin, tumor/stroma ratio, tumor budding/poorly differentiated clusters (TB/PDC), necrosis, smooth muscle, fat, and tumor-infiltrating lymphocytes (TILs) and tumor area (mucin, epithelium and TB/PDC). Analysis of AI-derived features with clinical variables, molecular alterations (BRAF/KRAS), and DFS were examined using Kaplan-Meier methodology and multivariable Cox regression. **Results:** Among the 15 AI-derived morphological features, the following differed significantly between dMMR (n = 191) and pMMR (n = 189) whereby dMMR tumors had lower mature stroma, but higher inflammatory stroma and tumor, higher tumor grade and increased mucin, TB/PDCs, signet ring cells, and TILs (all $p < 0.05$). Among dMMR tumors, multivariable analysis revealed that tumor area [mucin, epithelium and TB/PDC] (HR_{adj} 0.45, 95%CI (0.24, 0.84), $p < 0.01$, [Q2/3 vs Q1]) and N stage were the only significant and independent prognostic variables. Among pMMR tumors, multivariable analysis identified that tumor budding/poorly differentiated clusters (TB/PDCs) (HR_{adj} 0.20, 95%CI (0.06, 0.61), $p < 0.01$, [Q1 vs Q4]) was the strongest prognostic variable and the only morphological feature that was significantly associated with DFS along with age, N stage and T stage. **Conclusions:** Using AI, we can extract and quantify distinct morphological features in tumor sections that differ between dMMR and pMMR and multivariately, can significantly and robustly enhance prognostication within each MMR group. Among pMMR tumors, tumor budding/poorly differentiated clusters was the strongest predictor of DFS. Support: NIH U10CA180821, U10CA180882, U24CA196171, R01 CA210509 (to FAS). Variation in FOLFOX, FOLFIRI, and FOLFOXIRI effects on CD8+ T cell and PDL1 levels in MSS CRC patients. *First Author: Lindsey Carlsen, Brown University, Providence, RI*

Background: Colorectal cancer (CRC) is a heterogeneous disease treated with FOLFOX, FOLFIRI, and FOLFOXIRI chemotherapy regimens. About 85% of CRC patients have microsatellite stable (MSS) tumors that resist immune checkpoint blockade (ICB). Some studies suggest that chemotherapy modulates the MSS CRC tumor microenvironment (TME) to enhance CD8+ T cell infiltration, but ICB remains ineffective. We evaluated the TME of MSS CRC patients to investigate chemotherapy impact on immune markers. **Methods:** CRC patient samples (n = 16,827) underwent DNA (592-gene or whole exome)/RNA (whole transcriptome) sequencing at Caris Life Sciences. Immune cell fractions within TMEs were estimated from RNA deconvolution (quanTseq; Finotello, 2019; n = 11,109). PDL1 expression was assessed by IHC (SP142; $\geq 2+$ /5%). Patients who received FOLFOX (n = 425), FOLFIRI (n = 88), or FOLFOXIRI (n = 19) < 1 year prior to tumor collection or who didn't receive these treatments > 4000 days before tumor collection (untreated, n = 6,608) were analyzed. Statistical significance was determined using chi-square, Fisher's exact, and Mann-Whitney U tests, where appropriate. **Results:** FOLFOX-treated CRC (n = 213) had a higher CD8+ T cell fraction vs untreated (n = 3,449, FC = 1.9, $p < 0.01$) CRC and there was no difference among FOLFIRI-treated (n = 37, FC = 1.1, $p = 0.13$) or FOLFOXIRI-treated (n = 9, FC = 2.2, $p = 0.49$) CRC. Survival outcomes were similar in FOLFOX-treated CD8+ T cell-high (n = 82) vs low (n = 161, HR = 1.3, $p = 0.12$) and in FOLFOX-treated PDL1+ (n = 13) vs PDL1- (n = 338) CRC (HR = 1.6, $p = 0.14$). The CD8+ T cell fraction was similar in untreated KRAS wild-type (WT, n = 1714) vs untreated KRAS-mutated (mut, n = 1718) CRC (FC = 1.3, $p < 0.01$). FOLFOX-treated KRAS-mut CRC had a higher CD8+ T cell fraction (n = 1718 untreated, 96 treated, FC = 2.3, $p < 0.01$) and CD69 expression (n = 1724 untreated, 97 treated, FC = 1.7, $p < 0.01$) vs untreated KRAS-mut CRC. This FOLFOX-dependent effect on CD8+ T cells was lower in WT KRAS CRC (n = 114 FOLFOX-treated, n = 1714 untreated, FC = 1.6, $p < 0.01$) but survival outcomes were similar in FOLFOX-treated WT (n = 210) vs KRAS-mut CRC (n = 210) CRC (HR = 1.0, $p = 0.82$). The CD8+ T cell fraction was similar in untreated right- (R; n = 803) vs left-sided CRC (L; n = 927, FC = 1.3, $p < 0.01$) but PDL1+ IHC rates were significantly higher in R-CRC (n = 1340 L, 1124 R, FC = 2.2, $p < 0.01$). The CD8+ T cell fraction was similar in untreated WT (n = 3144) vs BRAF-mut CRC (n = 248, FC = 0.8, $p < 0.01$), but BRAF-mut were more frequently PDL1+ (n = 4622 WT, 340 mut, FC = 4.2, $p < 0.01$). PDL1+ rates were similar in untreated (n = 1124) vs FOLFIRI-treated R-CRC (n = 12, FC = 2.0, $p = 0.46$) but were higher in FOLFIRI-treated (n = 9) vs untreated (n = 1340) L-CRC (n = 9, FC = 6.0, $p = 0.04$). **Conclusions:** We describe an association between FOLFOX and subsequent infiltration by CD8+ T-cells and high PDL1+ rates in R-CRC, BRAF-mut CRC, and FOLFIRI-treated L-CRC. The findings provide insights for future therapeutic strategies. Research Sponsor: U.S. National Institutes of Health.

HER2 testing in the MOUNTAINEER trial: Analysis of treatment response based on central HER2 assessment using IHC/ISH and NGS. *First Author: John H Strickler, Duke University Medical Center, Durham, NC*

Background: Tucatinib (TUC) is a highly selective HER2-directed TKI approved by the FDA in combination w/trastuzumab (Tras) for treatment (tx) of pts w/ RAS wild-type HER2+ unresectable or metastatic colorectal cancer (mCRC) that has progressed following tx w/ fluoropyrimidine, oxaliplatin-, and irinotecan-based chemotherapy. There are currently no established best practices for HER2 testing/interpretation in mCRC. Here we present results of central HER2 testing across multiple platforms and response to tx for MOUNTAINEER pts treated w/ TUC + Tras based on central HER2 status. **Methods:** MOUNTAINEER (NCT03043313) enrolled pts w/ local HER2+ mCRC using ≥ 1 method: IHC, ISH, and/or NGS testing; retrospective central assessment of HER2 status was performed on multiple platforms. Pts in cohorts A+B were treated w/ TUC + Tras; pts in cohort C were treated w/ TUC monotherapy. Confirmed objective response rates (cORRs) using RECIST v1.1 per BICR, DOR, and PFS were calculated for pts treated w/ TUC + Tras based on each central testing method. **Results:** 114 pts were enrolled in cohorts A (n = 45), B (n = 39), and C (n = 30) w/ HER2+ tumors per ≥ 1 local testing method. Of samples submitted for central testing for Cohorts A and B, 70 per IHC/FISH, 50 per tissue NGS, and 71 per blood NGS had evaluable results. In all cohorts, there was 81.0% (95% CI, 68.6-90.1) agreement between blood and tissue NGS, 92.6% (95% CI, 83.7-97.6) between IHC/FISH and tissue NGS, and 79.5% (95% CI, 69.2-87.6) between IHC/FISH and blood NGS. In cohorts A and B, pts w/ HER2+ tumors by central IHC/ISH had a mDOR of 16.4 months (95% CI: 10.6-25.5) and mPFS of 10.1 months (95% CI: 4.2-15.2). cORR was 41.1% to 47.7% for the 3 assays. Detailed HER2 results are presented in the Table. **Conclusions:** Percent agreement of HER2 status was highest w/ tissue-based platforms. Detection of HER2 amplification by ctDNA NGS is useful; however, pts w/o HER2 amplification should be confirmed w/ a tissue-based assay. HER2 status by all 3 platforms predicted tx response to TUC + Tras. cORR in IHC2+/ISH+ was numerically lower but remained clinically relevant. These data support use of the above methods to identify HER2+ mCRC patients that may benefit from TUC + Tras. Clinical trial information: NCT03043313. Research Sponsor: Seagen Inc.

A prospective, cross-sectional, multicentre study to evaluate the clinical performance of the ColoSTAT in vitro diagnostic for the detection of biomarkers associated with colorectal cancer. *First Author: Emily He, Concord Repatriation General Hospital, Camperdown, Australia*

Background: Colorectal cancer (CRC) survival rates could be improved if more cancers were detected early. The ColoSTAT blood test and algorithm combines concentrations of 5 protein biomarkers with age and sex to provide an alternative to current CRC screening methods like the faecal immunochemical test (FIT). We compared the performance of ColoSTAT to colonoscopy in detecting CRC. **Methods:** Patients in this Australian study were either recently diagnosed with CRC using colonoscopy and progressing to surgery or neoadjuvant treatment (Cohort 1) or had no CRC history and were scheduled for colonoscopy (Cohort 2). Due to COVID-19 pandemic-related recruitment delays, the samples from Cohort 1 were supplemented with bio-banked blood samples (BBS) from patients with clinically confirmed CRC. Patients provided a 17 mL blood sample and were followed until start of cancer treatment or colonoscopy. All blood samples were de-identified prior to testing by an independent laboratory. The primary endpoints were ColoSTAT sensitivity of $\geq 73\%$ (lower 95% confidence limit [LCL] $> 60\%$), and specificity $\geq 90\%$ (LCL $> 80\%$). Sensitivity by TNM stage was an exploratory endpoint (ACTRN12619000301167). **Results:** Cohort 1 enrolled 29 patients, Cohort 2 enrolled 768 patients and 192 BBS were included. Patient demographic characteristics were similar in Cohorts 1, 2 and BBS. Overall, the median age of the patients ($n = 989$) was 64 years (range 40 to 88) and 53.4% were female. Definitive ColoSTAT results were obtained for 22 patients in Cohort 1, 554 in Cohort 2 and 81 in BBS. Overall, the estimated sensitivity of ColoSTAT for detection of CRC compared with colonoscopy was 81.3% (95%CL 73.0%-87.4%) and estimated specificity 91.0% (95%CL 87.7%-93.5%) (Table). **Conclusions:** The ColoSTAT test met the primary endpoints of performance based on sensitivity and specificity in detecting CRC compared to colonoscopy. ColoSTAT sensitivity and specificity for CRC were comparable with published performance parameters for FIT which range from 74-93% (sensitivity) and 85-96% (specificity).¹ Clinical trial information: ACTRN12619000301167. Research Sponsor: This study was solely funded by Vision Tech Bio Pty Ltd (subsidiary of Rhythm Biosciences Limited). S. Gibb, WriteSource Medical Pty Ltd provided medical writing services funded by Rhythm Biosciences.

Sensitivity and specificity of ColoSTAT vs colonoscopy.	
All participants/BBS (N = 989)	
Definitive ColoSTAT result (indeterminant, invalid, no test)	657 (97, 208, 27)
Colonoscopy result available (no colonoscopy)	911 (78)
Definitive ColoSTAT and colonoscopy	603
ColoSTAT True +ve (A), False +ve (B), False -ve (C), True -ve (D)	91, 35*, 21, 354*,
Sensitivity (95%CI) (A/(A+C))	81.3% (73.0%-87.4%)
Specificity (95%CI) (D/(B+D))	91.0% (87.7%-93.5%)
ColoSTAT sensitivity by CRC stage (I, II, III, IV)*	I: 87.5% (64.0%-96.5%), II: 91.3% (73.2%-97.6%), III: 92.3% (66.7%-98.6%), IV: 100% (87.9%-100%)

Chemotherapeutic sensitivity in colorectal cancer expressing low RNA of wild type homologous recombination genes. *First Author: Daniel Walden, Mayo Clinic Arizona, Phoenix, AZ*

Background: Homologous recombination deficient (HRD) colorectal cancer (CRC) has improved overall survival (OS) when exposed to DNA damaging agents (DDA) oxaliplatin (OX) and irinotecan (IR). However, this OS benefit is only observed in HRD mutated CRC. Low expression of wild type (WT) *BRCA1* RNA displays prolonged OS in ovarian cancer; this finding has not been investigated in CRC or outside *BRCA*. We investigate if low expression of WT HR genes is associated with prolonged OS in response to DDA. **Methods:** A total of 12,860 CRC patients tumor biopsies were analyzed by next-generation sequencing (592, NextSeq; WES, WTS NovaSeq). Patients with HRD mutations and MSI-H were excluded ($N = 935$). 11,925 patients were included in the analysis. A total of 11 core (*BARD1*, *BLM*, *BRCA1*, *BRCA2*, *BRIP1*, *MRE11*, *NBN*, *PALB2*, *RAD50*, *RAD51*, *RAD51B*) and 7 related (*BAP1*, *WRN*, *DNMT3A*, *ERCC1*, *FANCA*, *FANCF*, *RECQL4*) HR genes were analyzed. Samples were classified by RNA expression percentiles within the studied cohort. Real world OS was extracted from insurance claims and calculated using Kaplan-Meier estimates for molecularly defined cohorts from first of OX or IR to last contact. **Results:** OS benefit is seen in low RNA expression (bottom 10%) compared to high expression (top 10%) of all core WT HR genes except *RAD51B*, *BARD1* and *BRCA2* in response to IR. We observe a progressively longer OS with lower associated RNA expression in response to DDA. OS of nearly 7 years was observed in low expressing *BRCA1* and *RAD51* following IR exposure and 4.5-year OS benefit when compared to high expression of these genes. OS benefit in response to OX was less robust but significantly prolonged in *BRCA1* and *BRIP1* (Table). Patients harboring HRD mutations had similar OS to WT HR RNA low (bottom 10%) in response to OX (HR = 0.75; $p = 0.1$) and IR (HR = 0.82; $p = 0.36$). **Conclusions:** Here we report a novel subclass of CRC defined as patients with low RNA expressing WT HR genes that exhibit differential sensitivity to DDA. Significantly longer survival is noted in CRC with low expression *BRCA1*, *RAD51* and *BLM*, while post-OX survival was significantly prolonged with low expression of *BRCA1*, *BRIP1* and *FANCA*. Further characterization of sensitive HR genes will better predict DDA sensitivity and impact treatment sequencing. Research Sponsor: None.

Comprehensive study of the intratumoral microbiome in early- vs. late-onset colorectal cancer: Final analysis of COSMO CRC. *First Author: Benjamin Adam Weinberg, Ruesch Center for the Cure of Gastrointestinal Cancers, Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC*

Background: Although colorectal cancer (CRC) incidence has declined overall, CRC in individuals under age 45 (early-onset CRC, EOCRC) has risen dramatically. Obesity and diabetes may partially explain this epidemiologic shift; however, many patients (pts) with EOCRC are neither obese nor diabetic. Certain bacteria disrupt colonic luminal integrity and promote inflammation, leading to oncogenic mutations in colonic epithelial cells. *Fusobacterium nucleatum* (*F. nuc*) promotes CRC by suppressing immune response within the tumor microenvironment, activating the β -catenin pathway, and causing chemoresistance due to autophagy. The intratumoral microbiome (MB) in pts with EOCRC may differ from pts with late-onset CRC (LOCRC). **Methods:** We compared the intratumoral MB in pts with CRC diagnosed before age 45 (EOCRC) and after age 65 (LOCRC) in a prospective/retrospective study between 2017 and 2022. Primary and metastatic tumors were included. DNA was extracted from tumors and analyzed using 16S ribosomal gene sequencing. We compared the frequency of *F. nuc* and other bacterial and fungal DNA in tumors EOCRC vs. LOCRC pts. Next-generation tumor sequencing and diet questionnaire data were available for some pts. **Results:** Tumors from 36 EOCRC pts (median age 38 years) and 27 LOCRC pts (median age 72 years) were analyzed. In total, 917 unique bacterial and fungal species were detected. *F. nuc* was found in 30.6% of EOCRC and 29.6% of LOCRC ($p = 0.94$). *Cladosporium* sp. was seen more commonly in EOCRC (30.6% vs. 11%, $p = 0.04$), whereas *Pseudomonas luteola* (2.8% vs. 22.2%), *Ralstonia* sp. (22.2% vs. 48.1%), and *Moraxella osloensis* (19.4% vs. 44.4%) were seen more commonly in LOCRC ($p < 0.05$). *Clostridium perfringens* (11.1%), *Escherichia coli* (11.1%), *Leptotrichia hofstadii* (11.1%), *Mycosphaerella* sp. (11.1%), *Neodevriesia modesta* (11.1%), *Penicillium* sp. (11.1%), and *Leptosphaeria* sp. (11.1%) were seen exclusively in LOCRC ($p < 0.05$). There was no significant difference in median MB diversity in EOCRC vs. LOCRC (43 vs. 45 organisms per pt). Median follow up from time of diagnosis was 39.6 months (mo). Twenty-three EOCRC pts (64%) and 19 LOCRC pts (70%) are alive. Median overall survival (mOS) was 75.5 mo (95% CI: 40 - NA) in EOCRC and 60 mo (95% CI: 50.5 - NA) in LOCRC. There was no significant difference in OS in LOCRC vs. EOCRC (Log-rank test $p = 0.85$). Pts with *F. nuc* positive tumors ($N = 17$) had a mOS of 75.5 mo (95% CI: 23 - NA), whereas pts with *F. nuc* negative tumors ($N = 46$) had a mOS of 60 mo (95% CI: 50.5 - NA). There was no significant difference in OS in *F. nuc* positive vs. *F. nuc* negative groups (Log-rank test $p = 0.87$). **Conclusions:** There are significant differences in the intratumoral microbiome in EOCRC and LOCRC. These findings warrant larger, prospective studies to elucidate the role the intratumoral microbiome plays in the carcinogenesis, the tumor immune microenvironment, and responsiveness to specific therapies. Circulating tumor DNA in plasma as an early predictor for pathological lymph node involvement and (neo-)adjuvant chemotherapy in patients with colon cancer. *First Author: Louise Raunkilde, Department of Oncology, Danish Colorectal Cancer Center South, Vejle Hospital, University Hospital of Southern Denmark, Institute of Regional Health Research, University of Southern Denmark, Vejle, Denmark*

Background: Postoperative chemotherapy is standard for colon cancer patients with pathological lymph node involvement (pN+). If the presence of pN+ could be accurately predicted prior to surgery, the initiation of neoadjuvant chemotherapy could potentially reduce the presence of micrometastasis and enhance survival. The objective of this study was to assess the utility of preoperative methylated circulating tumor DNA (meth-ctDNA) as a predictive marker for pN+ and its clinical value as a marker for the initiation of neoadjuvant chemotherapy. **Methods:** The clinical data of 203 colon cancer patients (stage I-III) was collected from the Colorectal Cancer Database established at Danish Colorectal Cancer Center South, Vejle Hospital, Denmark. Patients were randomized into a discovery and a validation cohort. Plasma collected preoperatively was analyzed for three different meth-ctDNAs (Neuropeptide Y, Galactose-3-O-Sulfotransferase 3, and KN Motif and Ankyrin Repeat Domains 1) by droplet digital PCR (ddPCR). **Results:** Based on analysis of the discovery cohort, samples were considered positive if two or more of the three methylation markers had at least three positive droplets in the ddPCR analysis. 40% of patients in the discovery cohort and 46% of patients in the validation cohort were considered positive. When using meth-ctDNA as a diagnostic tool to predict pN+, the sensitivity and specificity in the discovery cohort were 42% and 61% respectively. In the validation cohort the values were 54% and 59%, respectively. AUC was $< 60\%$ in both cohorts. Meth-ctDNA was associated to clinical tumor (T-) and node (N-) category in both cohorts ($p \leq 0.01$). Four-year disease free survival (DFS) in patients with and without detectable meth-ctDNA was 60% and 90% in the discovery cohort ($p = 0.01$), and 62% and 78% in the validation cohort ($p = 0.04$). Meth-ctDNA remained the strongest prognostic factor of DFS in the multivariate analysis compared to clinical T- or N-category, gender and age ($p = 0.065$, HR 2.46, 95% CI 1.03-5.88), however not statistically significant. Four-year overall survival (OS) in patients with and without detectable meth-ctDNA was 75% and 95% in the discovery cohort ($p = 0.006$), and 78% and 91% in the validation cohort ($p = 0.02$). In the multivariate analysis, meth-ctDNA was the strongest prognostic factor of OS compared to clinical T- or N-category, gender and age ($p = 0.016$, HR 4.54, 95% CI 1.32-15.6). **Conclusions:** The preoperative measurement of meth-ctDNA was not found to be a clinically significant predictor of pN+ or a reliable indicator for the initiation of neoadjuvant chemotherapy. Nonetheless, the results showed that preoperative ctDNA is a powerful prognostic indicator, suggesting that randomized controlled trials should be conducted to determine the efficacy of neoadjuvant chemotherapy in colon cancer patients with preoperative detectable ctDNA. Correlation of single-cell cytokine secretion with clinical outcome in patients (pts) with metastatic colorectal cancer (mCRC) treated with capecitabine (C), bevacizumab (B), ± atezolizumab (A). *First Author: Niharika B. Mettu, Duke University Medical Center, Durham, NC*

Background: The BACCI trial (NCT02873195) randomized 133 mCRC pts to C+B+A (investigational) or C+B+placebo. Longer progression free survival (PFS) was observed in the investigational vs placebo arm. To investigate T-cell functional heterogeneity, we performed single-cell proteomic analyses on pts with either long or short PFS and evaluated T-cell function as a prognostic and predictive biomarker. **Methods:** Isolated CD8+ and CD4+ cells were analyzed at baseline and first restaging from pts with long (> 6 mo, N = 14) or short (< 2 mo, N = 13) PFS. Single-cell, functional proteomic analyses were conducted using the IsoLight system (Isoplexis), which assessed secretion of 32 cytokines from an average of 786 cells per sample. The cumulative readout was poly-functional strength index (PSI), a composite score of frequency and magnitude of secreted cytokines. Cytokines are organized into effector (E), stimulatory, chemoattractive (CA), regulatory, and inflammatory (I) clusters. Differential expression analyses were done using Wilcoxon rank-sum tests. Potential predictive effects were assessed using logistic regressions with interaction between treatment and biomarkers. No multiple comparison control was done due to the exploratory nature of analyses. **Results:** Baseline CD8+ and CD4+ cells were stimulated *ex vivo* and single-cell cytokine analyses performed. Prognostic analyses indicated that CD8+ cells from pts with long PFS had ~3-fold higher PSI compared to pts with short PFS (p = 0.005). Further analysis identified that the E (p = 0.005) and CA clusters (p = 0.005) most impacted PSI, significant individual cytokines are listed in the table. Baseline CD8+ cell function was not predictive of outcome. Baseline CD4+ cell function was not prognostic or predictive of outcome. Analysis of CD8+ cells after treatment identified that changes in CA cluster was prognostic of long PFS (p = 0.024). Cytokine changes from CD4+ cells were not prognostic; however, early changes in the CD4+ CA cluster were predictive of outcome (p-int = 0.055). Similarly, early changes in the CD8+ I cluster were predictive of outcome (p-int = 0.073). **Conclusions:** These results reveal pts with long PFS had more functional CD8+ T-cells with a higher PSI than pts with short PFS. Predictive analyses suggested that early changes in the CD4+ CA and CD8+ I clusters were associated with benefit from immunotherapy. These preliminary results highlight the importance of single-cell functional proteomic analyses. Research Sponsor: Mario Family Foundation.

Consensus molecular subtyping of colorectal cancer to demonstrate cetuximab benefit in right-sided CMS2 tumors, and pembrolizumab benefit in MSS CMS1 tumors. *First Author: John Paul Y.C. Shen, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Consensus Molecular Subtypes (CMS) of colorectal cancer (CRC) were first developed in 2015 using microarray-based assays but are not widely used clinically. We developed a Caris CMS classifier on whole transcriptome sequencing data (WTS) with high concordance with the previously established CMS pipeline (Guinney et al 2015), and applied to a large clinic-genomic database of CRC to investigate the utility of CMS classification in identifying patients that may respond well to therapies commonly used in CRC. **Methods:** Next-generation sequencing (NGS) of DNA (592-gene or whole exome) and WTS was tested on CRC patient samples (n = 12,788) at a CLIA-certified lab (Caris Life Sciences, Phoenix, AZ). Caris CMS classifier was trained against the original CMS datasets using a classic SVM model and cross-validated for optimization of the SVM parameters. Possible over-training was evaluated by predicting CMS from an independent blinded dataset (TCGA, N = 512) with an accuracy of 88.3%. Real-world overall survival was obtained from insurance claims and calculated from tissue collection to last contact (OS); time on treatment (TOT) was from first to last of treatment time. Kaplan-Meier estimates were calculated for molecularly defined cohorts. Significance was determined as p of < 0.05. **Results:** Among all patients, CMS1 was seen in 16%, CMS2 in 32%, CMS3 in 17% and CMS4 in 35%. MSI-H/MMRd (31%) and BRAF mut (33%) were most prevalent in CMS1 with KRAS mt the highest in CMS3 (66%). CMS2 was associated with the longest mOS (33m; 95% CI: 31m-35m), followed by CMS4 (29m; 28-31m), CMS3 (27m; 25-29m) and CMS1 (22m; 20-23m). In the microsatellite stable (MSS) tumors treated with pembrolizumab, CMS1 (N = 22, mTOT: 4.2m; 2.8-9.1m) had longer TOT than CMS2 (N = 45, mTOT: 2.1m; 1.4-3.1m), CMS3 (N = 21, 2.1m; 1.4m-3.0m) and CMS4 (N = 40; 2.1m; 1.4m-2.8m); CMS1 vs. CMS2-4 in MSS (HR: 0.58; CI: 0.34-0.97, p = 0.035). When investigating cetuximab, CMS2 had the longest mTOT (N = 189, mTOT: 6.3m; 5.4m-7.7m) among the four groups. Interestingly, although among all Ras WT tumors left-sided CRC showed longer mTOT on cetuximab (n = 457, mTOT: 5.4m; 4.7m-6.3m) than right-sided (n = 151, mTOT: 3.8m; 3.3m-4.5m), CMS2 showed similar mTOT from the left (n = 128) and the right (n = 16, mTOT: 6.3m vs. 5.6m, HR = 0.896, 95% CI: 0.501-1.604, p = 0.722). Notably, CMS2 comprises 49% of left- and 15% of right-sided tumors, potentially underlying the TOT difference seen between left and right. **Conclusions:** A WTS based CMS classifier allows for investigation in a large real-world clinic-genomic database. We found that MSS CMS1 CRC's may derive benefit from immunotherapy. Additionally, CMS2 subgroup of right-sided tumors may derive benefit from cetuximab. Routine CMS subgrouping of CRC provides important treatment associations that should be further investigated. Research Sponsor: None.

Gut microbiome composition as predictor of the efficacy of adding atezolizumab to first-line FOLFOXIRI plus bevacizumab in metastatic colorectal cancer: A translational analysis of the AtezoTRIBE study. *First Author: Federica Marmorino, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa & Unit of Medical Oncology 2, Azienda Ospedaliera Universitaria Pisana, Pisa, Italy*

Background: Gut microbiome has emerged as a biomarker of clinical benefit to immune-checkpoint inhibitors (ICI) but no data are available in metastatic colorectal cancer (mCRC). The AtezoTRIBE study demonstrated that the addition of atezolizumab (atezo) to FOLFOXIRI plus bevacizumab (bev) prolongs progression-free survival (PFS), but this benefit is limited for patients with proficient mismatch repair (pMMR) tumors. Here, we aimed at investigating the potential predictive role of microbiome in identifying mCRC patients able to achieve benefit from ICI. **Methods:** AtezoTRIBE was a phase II trial in which 218 mCRC patients, unselected for MMR status, were randomized 1:2 to receive first-line FOLFOXIRI/bev (arm A) or FOLFOXIRI/bev/atezo (arm B). Stools were prospectively collected. Metagenomic (MG) data from whole genome sequencing (WGS) at level of species genome bins (SGBs) were analysed by linear models corrected for clinical and tumor-related parameters and fold-ratios. We defined as responders (R) those patients who experienced a PFS ≥ 12 months. **Results:** Stool samples were collected at baseline for 171 (78%) patients (55 in arm A and 116 in arm B) but only 163 were available for MG. Patients with deficient MMR (dMMR) tumors (N = 10) showed significantly lower MG diversity than pMMR ones (N = 148) harboring oral bacteria and pathobionts whose intrinsic immunogenicity has not been demonstrated. Regarding pMMR mCRC patients, baseline microbiome composition was not significantly different according to the treatment arm. The microbiome diversity was not significantly different between R and not-R in both arms, but specific immunogenic SGBs (Lachnospiraceae family members) were over-represented in R treated in arm B. Veillonellaceae and pathobionts were associated with poor prognosis and/or differential benefit from the addition of atezo. Fusobacterium nucleatum was associated with a poor prognosis, also in arm B. **Conclusions:** This is the largest prospective analysis showing that SGBs may be useful as a biomarker of potential benefit or detrimental effect from atezo in pMMR mCRC patients. Our results prompt the design of microbiota-centered diagnostic tests to identify pMMR mCRC patients more likely to benefit from ICI-based therapeutic strategies. Clinical trial information: NCT03721653. Research Sponsor: GONO Foundation.

Genomic landscapes of early-onset versus average-onset colorectal cancer populations. *First Author: Michael H. Storandt, Mayo Clinic, Rochester, MN*

Background: Early-onset colorectal cancer (eoCRC, initial CRC diagnosis at age < 50 years) has been increasing in the past two decades especially in Western countries. This study evaluates somatic and germline profiles in eoCRC compared to average-onset CRC (aoCRC, initial CRC diagnosis at age ≥ 50 years). **Methods:** This is a retrospective, cross-sectional study utilizing data from de-identified records of colorectal cancer patients tested with the Tempus xT assay from 2017 to 2022. Briefly, the assay is a targeted panel that detects single nucleotide variants, insertions and/or deletions, and copy number variants in 598-648 genes, as well as chromosomal rearrangements in 22 genes with high sensitivity and specificity. Baseline characteristics and immunologic markers were compared between eoCRC and aoCRC by Wilcoxon Rank Sum or Chi-squared test (reporting p-values). Somatic and germline mutations were compared between two age groups with false discovery rate adjustments (reporting q-values). **Results:** In this study, 2,379 eoCRC and 8,627 aoCRC patients were included, with the majority diagnosed with stage IV disease. Additionally, germline alterations were assessed on a subset of 6,311 patients with tumor/normal match testing (eoCRC = 1,413 and aoCRC = 4,898). Left-sided primaries were more common in eoCRC (85% left/rectum in eoCRC vs. 75% left/rectum in aoCRC (p < 0.001), and rates of microsatellite instability-high (MSI-H) or deficient mismatch repair (dMMR) were lower compared to aoCRC (4.2% vs. 6.8%, p < 0.001). eoCRC has a unique somatic mutation profile compared to aoCRC. A higher prevalence of germline mutations was observed in eoCRC overall (6.9% vs. 5%, p = 0.006); however, no statistically significant differences were observed in individual germline genes compared to aoCRC, likely due to relatively small numbers. **Conclusions:** eoCRC has a unique mutational profile and presence of germline mutations in 6.9% of eoCRC, indicating a potential role for universal germline testing in CRC. Research Sponsor: TEMPUS Labs.

Deep learning tumor heterogeneity metric from histopathology images vs next generation sequencing-derived scores for colon cancer prognostication.
First Author: Hatim Amiji, Frank H. Netter MD School of Medicine at Quinnipiac University, North Haven, CT

Background: Tumor heterogeneity is as an important determinant of clinical behavior in many cancer types, with increased heterogeneity thought to confer inferior clinical outcome. Sequencing based assessment of colon cancer has been used to quantify tumor heterogeneity and correlate it with survival, but is sensitive to the mutation calling algorithm utilized. Digitization of histopathology slides allows application of deep learning methods for image analysis. Automated slide annotation and feature extraction provides numeric representations of underlying phenotype from which tumor heterogeneity can be estimated. Here we compare the ability of a deep-learning tumor heterogeneity score (THS) to estimate overall survival in colon cancer patients to estimates produced by bulk sequencing derived mutant-allele tumor heterogeneity (MATH) and copy number variation (CNV) event scores. **Methods:** Digitized whole slide images (WSIs) from The Cancer Genome Atlas (TCGA) colon adenocarcinoma dataset are processed in a computational pipeline for tissue detection, numerical feature extraction, and cell type classification. WSIs are tiled and local THS calculated from imaging features. Corresponding MATH and CNV derived heterogeneity metrics are calculated from published sequencing data. Kaplan Meier curves are used to compare patient survival stratified by tumor heterogeneity as calculated by the three independent methods. Automated regional annotation identifies intra-tumoral and tumor-stromal boundary tiles and tumor THS is correlated to distance from the boundary. **Results:** Images from 379 patients (209 right-sided, 152 left-sided tumors) yielded 575,762 tiles. Automated annotation resulted in 272,791 intra-tumoral and 11,340 tumor-stromal boundary tiles. Stratification by imaging derived THS provided significant separation of overall survival curves ($p < .01$) in contrast to MATH and CNV methods ($p > .05$ for both). THS significantly separated the curves in right- but not left-sided cancers ($p = .03$ and $.44$, respectively). Evaluating THS as a function of distance from the tumor-stromal boundary, right-sided tumors showed significant decrease in THS with increasing distance from tumor edge. **Conclusions:** Our novel pipeline produced spatially resolved imaging data informed by underlying tumor phenotype without need for pathologist annotation. The resultant THS correlated with outcome and outperformed sequencing-based prognostication methods. The spatial information identified higher heterogeneity at the tumor edge than interior regions of right-sided, but not left-sided tumors, capturing known but poorly understood differences in colon tumors by location. Deep learning image analysis provided reproducible and cost-effective data with great potential both in clinical biomarker discovery and as a research tool. Prognostic and predictive significance of pre- and post-operative plasma tumor markers in patients with appendiceal adenocarcinoma undergoing cytoreductive surgery: Insights from a single-center study.
First Author: Abdelrahman M.G. Yousef, University of Texas MD Anderson Cancer Center, Houston, TX

Background: Appendiceal adenocarcinomas (AA) are both rare and heterogeneous diseases. Cytoreductive (CRS) surgery followed by heated intraperitoneal chemotherapy (HIPEC) remains the best treatment for AA patients with peritoneal metastasis. This study seeks to investigate the clinical utility of pre- and post-operative plasma tumor markers (TM, CEA, CA19-9, CA-125) by association with survival outcomes. **Methods:** Under an approved IRB protocol the Palantir Foundry software system was used to query MD Anderson internal database to identify patients with AA who underwent CRS between 2016 to 2022. Elevation of TM was defined as above the laboratory upper limit of normal (CEA > 3 ng/mL, CA 19-9 > 37 U/mL, and CA-125 > 37 U/mL). Relationship between normal and elevated serum TM and progression-free survival (PFS) and overall survival (OS) was evaluated using univariate and multivariate Cox-proportional hazards regression analysis, considering multiple clinicopathologic variables. **Results:** 296 patients were identified; preoperative CEA, CA19-9 and CA125 was elevated in 60%, 29% and 28% of patients, respectively. Preoperative elevation of any TM was associated with higher PFS (22 vs. 15, $p < 0.0001$). Moreover, elevated preoperative TM was associated with incompleteness of cytoreduction (OR = 6.5, $p < 0.0001$). Compared to preoperative measurements, all TM levels dropped after surgery (Mean score 31 vs 11 for CEA, 136 vs 32 for CA19-9 and 36 vs 17 for CA125). Preoperative elevation of any TM (HR = 1.5, $p = 0.0288$) and post-op elevation of any TM were with poor PFS on univariate analysis, however only post-op elevated TM levels (HR = 2.3, $p = 0.0001$) were associated with poor PFS on multivariate analysis. Interestingly, elevated TM was not associated with OS. Post-op TM levels were analyzed to evaluate the positive and negative predictive value in prediction of relapse in 6 months from surgery, PPV was 45% and NPV was 84%. **Conclusions:** Preoperative elevation of TM can identify patients at higher risk for incomplete cytoreduction and relapse after surgery. Postoperative elevation of TM is a risk factor for relapse. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology; CCSI; Col. Daniel Connelly Memorial Fund; U.S. National Institutes of Health; Cancer Prevention & Research Institute of Texas.

Evaluation of microsatellite instability status, a definitive predictive biomarker for immune checkpoint inhibitors (ICI), in underrepresented minorities (URM) with gastrointestinal (GI) cancers.
First Author: Fiyinfolu Balogun, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Mismatch repair deficiency (dMMR) results in MSI-H state and is the first tumor type-agnostic biomarker predictive of ICI response. Among GI cancers, MSI-H is most frequent in colorectal cancer (CRC 15%), gastroesophageal (GEC, 5%) and other (small bowel, hepatopancreatobiliary; 1%). For CRC, MSI-H can be attributed to germline mutation (Lynch syndrome, 3%) or somatic inactivation (sporadic, 12%) of foundational MMR genes. Studies evaluating ICI efficacy in dMMR cancers focus primarily on non-Hispanic White (NHW) patients (pts). We present prevalence, tumor genomic features, and outcomes in pts from a large cohort at Memorial Sloan Kettering (MSK). **Methods:** Retrospective analysis of MSI-H GI cancers from MSK-IMPACT database. Pts were grouped by self-reported race and ethnicity into 4 study arms: NHW, Asian, non-Hispanic Black (NHB), and Hispanic. Age, tumor type, tumor mutation burden (TMB), and MMR genes were analyzed. Overall survival (OS) estimated with Kaplan-Meier. **Results:** Of 776 pts with MSI-H GI cancers: 623 (80.3%) NHW, 60 (7.7%) Hispanic, 50 Asian (6.5%), and 43 (5.5%) NHB. CRC (76%), GEC (14%), other cancers (10%). We present initial evaluation of CRC and GEC: Median age, TMB, and most frequently altered MMR genes (MMR gene FA) are in table. Median OS (mOS) in NHW/URM by receipt of ICI in MSI-H CRC were 38.5m/25.3m ($p < 0.07$) in no-ICI group, 34.2m/28.7m ($p < 0.64$) in +ICI group; MSI-H GEC 43.4m/30m ($p < 0.44$) in no-ICI group, 28.8m/26.7m in +ICI group. **Conclusions:** Number of URM MSI-H CRC/GEC pts is 7 to 15-fold less than NHW, with no such difference in % MSI-H/mSS between groups; reflecting significant underestimating in URM pts. In MSI-H CRC, median age (m-Age) at sequencing was younger in URM compared to NHW; pronounced in Asian and Hispanic patients, who were 10+ years younger than NHW. No such age difference seen in GEC. No difference in mOS detected between NHW and URM, however a non-significant trend towards worse mOS in URM was observed in the no-ICI group. Next steps include validation of clinico-genomics of MSI-H GI cancers in other large cohorts, including TEMPUS (N = 768) which is ongoing. Research Sponsor: None.

Does serial circulating tumor DNA (ctDNA) monitoring identify additional acquired actionable alterations in metastatic colorectal cancer (mCRC)?
First Author: Jonathan M. Loree, BC Cancer Agency, Vancouver, BC, Canada

Background: Traditionally, biomarker ascertainment occurred once for patients (pts) with mCRC. An advantage of ctDNA is the ease of repeated assessments. However, real-world evidence about the value of serial ctDNA in revealing actionable alterations is needed. **Methods:** We retrospectively evaluated 3350 pts with mCRC and a Guardant360 ctDNA assay (Guardant Health) revealing ≥ 1 somatic alteration who underwent ≥ 1 subsequent Guardant360 test to compare detection of mutations (mut: single nucleotide variants (SNVs) and indels), amplifications (amps), fusions, microsatellite instability (MSI), and blood tumor mutational burden (bTMB). Variants were filtered to pt-specific levels of detection by limiting variants across assays to those above a 0.1% mutant allele frequency (MAF) threshold on the serial test with the lowest somatic MAF for that pt. Clonal muts were defined as those at $\geq 10\%$ of max MAF per sample. **Results:** A total of 9130 assays (mean of 2.7 assays/pt) occurring a median of 165 days apart were evaluated. Among 1476 pts initially with no alteration in MAPK pathway genes (*RAS* and *EGFR* SNV or indel, *BRAF* V600E SNV, or *ERBB2/MET* amplifications), 382 (25.8%) acquired a MAPK alteration on their second test. More gains were clonal than subclonal (231:151, 60.5%:39.5%). In pts with a subsequent assay after an acquisition (N = 80), 12 (15.0%) clonal and 15 (18.8%) subclonal acquisitions disappeared in the third assay, a median of 150 days later. Among alterations with a therapy, *KRAS* G12C/D, *BRAF* V600E, and *ERBB2* amps acquisitions occurred at any later assay in 84/1476 (5.7%), 29/1476 (2%), and 21/1476 (1.4%) pts without an initial MAPK alteration, respectively. Of these, 84/134 (62.6%) emerged without another concurrent MAPK alteration, 61/84 (72.6%) of which are subclonal. Of 92 fusions noted in 86 pts, 87/92 (94.5%) were subclonal and only 28/92 (30.4%) were initially present. The majority of fusions were acquired de-novo subclonal fusions (58/64, 90.6%) but 2 pre-existing subclonal fusions subsequently became clonal. Among pts evaluable for MSI, 56/3030 (1.8%) were initially MSI-H and 30 (1%) subsequently had MSI detected on a future assay. New MSI detection was more common in pts with DNA repair muts (*BRCA1/BRCA2/ATM/CHEK2/MLH1/RAD51D*) on an initial assay (OR 7.52, 95% CI 3.39-16.69, $p < 0.0001$). Among pts evaluable for bTMB, 60/1387 (4.3%) initially had bTMB ≥ 20 muts/Mb, and 256/1327 (19.3%) subsequently rose above 20 muts/Mb on a future assay, a median of 417 days after initial assay. Rising bTMB associated with rising max somatic MAF (Spearman rho = 0.50, $p < 0.0001$). Pts with DNA repair muts on an initial assay were more likely to have bTMB rise to ≥ 20 muts/Mb (OR 2.58, 95% CI 1.81-3.68, $p < 0.001$). **Conclusions:** In this large mCRC cohort, serial ctDNA appears to be a feasible approach to identify acquired alterations with therapeutic implications. Racial and genetic ancestry associations with gene expression patterns in a real-world cohort of colorectal cancer patients. *First Author: David Hein, UT Southwestern Medical Center, Dallas, TX*

Background: There is a growing incidence of colorectal cancer (CRC) among young adults and persistent disparities in outcomes by race/ethnicity across all ages. Gene expression signatures, as well as consensus molecular subtypes (CMS) derived from these, have been proposed to predict prognosis and therapy response in CRC. However, it is unclear whether gene expression or CMS are associated with racial disparities observed in CRC. We assessed whether race or genetic ancestry are associated with CMS or gene expression patterns in a deidentified cohort of 1,768 CRC patients. **Methods:** Patients tumors underwent tumor profiling with the Tempus xT NGS 648-gene assay as well as full-transcriptome RNA sequencing. We used a set of 654 ancestry-informative markers to infer genetic ancestry likelihoods for Africa (AFR), America (AMR), East Asia (EAS), Europe (EUR), and South Asia (SAS). Race/ethnicity labels, often missing in real-world data, were imputed using ancestry proportions from the literature and adjusted based on observed metadata. Gene expression data was used to assign CMS to all patients (CMS1, 2, 3, 4 and indeterminate) using CMScaller, and multinomial logistic regression was used to assess associations with race/ethnicity imputed labels and ancestry proportions. We then assessed differential expression (DE) in the MSigDB hallmark and C2 BioCarta gene sets using four separate workflows. The first two workflows used limma-voom followed by ROAST to assess DE among the imputed labels and then among the ancestry proportions (isometric log ratio transformed). The second two workflows used GSVA followed by limma. **Results:** Among 1,768 patients, 240 were imputed non-Hispanic (NH) Black, 94 NH Asian, 261 Hispanic/Latino/Native American (HLN), and 1,173 NH White. NH Black patients had higher odds of CMS3 vs CMS1 (OR = 2.66, $p < 0.001$) and HLN patients had higher odds of indeterminate CMS vs CMS1 (OR = 1.90, $p = 0.020$), compared to NH White. AFR ancestry was significantly associated with CMS3 (OR = 1.05 per doubling in AFR proportion, $p = 0.047$) and indeterminate CMS (OR = 1.07, $p = 0.023$). In the gene set analysis, NH Black race/ethnicity was associated with over-expression of the BioCarta *WNT* pathway gene set. Both AFR ancestry and NH Black race/ethnicity were associated with under-expression of the MSigDB hallmark coagulation and BioCarta alternative complement gene sets and over-expression of the *PTX2* pathway gene set (all significant with both ROAST and GSVA). **Conclusions:** We found that NH Black patients and AFR ancestry were associated with higher rates of CMS3, which is associated with *KRAS* mutation and was previously reported to be more common among Black patients. Indeterminate CMS associations with AFR ancestry and HLN highlights the need to use diverse patient cohorts when training unsupervised learning models to improve prognosis prediction in non-White patients. A deep learning model for the prediction of microsatellite instability and pathogenic POLE mutations in colorectal cancer using histopathologic images. *First Author: Ting Xu, Department of GI Oncology, Department of Gastrointestinal Oncology, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Immunotherapy has brought about a landmark change in anti-tumor treatment in the past years. High microsatellite instability (MSI-H) is now the only clinically approved biomarker predicting response to immunotherapy in CRC. Increasing evidence suggests that POLE mutations in the exonuclease domain could drive an ultra-mutational phenotype and improve the treatment outcomes of ICI in solid tumors. In this study, we set out to apply a deep learning model using H&E-stained, formalin-fixed, paraffin-embedded (FFPE) whole slide images (WSIs) of CRC primary tumors. **Methods:** The deep learning model is developed and validated through five-fold cross-validation using WSI of primary tumors from 506 CRC patients and externally validated using 52 WSIs from a prospective cohort. The microsatellite status, tumor mutation burden (TMB) and POLE genotype were determined by next-generation sequencing (NGS). Patients with MSS status and a low TMB (< 20 Mutations/Mb) were admitted to the MSS group, and CRCs with a POLE mutation which was defined as an oncogenic mutation referring to the POLE functional mutation list at OncoKB (POLE (oncoKB.org)) were admitted to the POLE mutant group. Clustering-constrained-attention multiple-instance learning (CLAM) model is employed as the base model, and we conduct the model ensemble by performing a large-scale hyper-parameter search, selecting five models with the highest value in one of the performance metrics, including the AUROC, accuracy, precision, recall, and f1 score, and finally averaging the predictions of the five models. **Results:** The internal dataset included 237 MSS, 142 MSI-H, and 127 POLE mutant CRC. The three groups had significant differences in primary location ($p < 0.0001$), histology ($p < 0.0001$), tumor differentiation ($p = 0.002$), tumor stage ($p < 0.0001$), Crohn's-like reaction ($p < 0.0001$) and tumor growth pattern ($p = 0.001$). The cross-validation performance of the ensemble model (M_e) in the internal dataset achieves an AUROC of 0.944 for three-way classification task (POLE vs. MSI-H vs. MSS) and 0.940 for two-way classification task (POLE & MSI-H vs. MSS) which were superior to the performance of each single CLAM model. To demonstrate the generalizability of the deep learning model, a domestic perspective cohort consisting of 20 MSS, 17 MSI-H, and 15 POLE mutant CRC H&E images were used to validate the external performance. And the M_e retained robust performance on the external dataset, with an AUROC of 0.904 for three-way classification task and 0.836 for two-way classification task. **Conclusions:** A CLAM-based deep learning model could directly predict the MSI-H and POLE mutation from histological images that could be used to stratify CRC patients for immunotherapy with faster turnaround time and lower costs compared with traditional sequencing methods. Artificial intelligence-derived immune phenotypes for prediction of prognosis in patients with stage III colon cancer (NCCTG N0147; Alliance). *First Author: Bahar Saberzadeh Ardestani, Mayo Clinic, Rochester, MN*

Background: Solid tumors can be characterized by distinct immune phenotypes based on the level of T cell infiltration in the tumor microenvironment (TME) which may provide prognostic information and also inform strategies to restore the anti-tumor immune response. Immune phenotypes were determined using an artificial intelligence (AI) algorithm in digitized whole-slide images (WSI) of tumors with deficient (d) mismatch repair (MMR) vs proficient (p) MMR. **Methods:** Stage III colon carcinomas (N = 401; 393 met QC) from participants in a phase III trial of FOLFOX-based adjuvant chemotherapy were analyzed including all available tumors with dMMR (n = 196) and a randomly selected cohort of pMMR tumors (n = 195). Using an AI algorithm (Lunit SCOPE) previously trained on solid tumors, digitized tumors were categorized into three immune phenotypes based on epithelial and stromal TIL data-driven cutpoints in dMMR and pMMR (inflamed: TIL high in epithelium ($> 25\%$); excluded: TIL high in stroma ($> 25\%$), low in epithelium; and desert: TIL low in epithelium and stroma). Phenotypes were then examined in relationship to disease-free survival (DFS) using Kaplan-Meier methodology. **Results:** Of the 3 immune phenotypes in dMMR tumors, 25% were inflamed, 50% were immune-excluded, and 25% were immune-desert. Based on univariate results, multivariable modeling was performed incorporating immune phenotype in addition to age, histological grade, N stage, T stage, performance status, treatment arm, *BRAF* and *KRAS* status and identified immune phenotypes and N stage to be significantly associated with DFS. Among dMMR tumors, immune desert phenotype was associated with the poorest DFS (Desert: HR_{adj} 1.95, 95%CI (1.01, 3.80); Excluded: HR_{adj} 0.89, 95%CI (0.47, 1.69); Inflamed: ref; $p < 0.01$). When compared to immune desert tumors, immune-excluded tumors had significantly better DFS (HR_{adj} 0.49, 95%CI (0.27, 0.88), $p < 0.01$). At a median follow-up of 60 months, 3-year DFS of patients with dMMR was 71.2% with Immune inflamed, 78.5% with Excluded, and 54.5% with Desert phenotypes. In contrast to dMMR, univariate analyses of data-driven cutpoints in pMMR tumors was not prognostic. Using a different data-driven cutpoint (15%), the revised immune phenotypes remained non-significant for DFS within pMMR tumors. **Conclusions:** Distinct AI-derived immune phenotypes in the TME were identified that were significantly prognostic in patients with dMMR, but not pMMR colon cancers. A data-driven immune-desert phenotype was identified in dMMR tumors that was associated with significantly poorer survival. Further investigation of the potential predictive utility of these phenotypes for immunotherapy are planned. Support: <https://acknowledgments.alliancefound.org>. Prognostic role of TP53 variants in the phase III study of FOLFIRI/cetuximab versus FOLFIRI/cetuximab followed by cetuximab (Cet) alone in first-line therapy of patients with RAS and BRAF wild-type (wt) metastatic colorectal cancer (mCRC) (ERMES study). *First Author: Nicola Normanno, Cell Biology and Biopharmacy Unit, Istituto Nazionale Tumori-IRCCS Fondazione Pascale, Napoli, Italy*

Background: The ERMES study explored the optimal intensity of anti-EGFR-based first line therapy for RAS/BRAF wt mCRC once achieved disease control. Although the study did not demonstrate non-inferiority of maintenance with Cet alone versus standard treatment, preliminary results suggested that a strategy of de-escalation treatment with only Cet might be effective in selected patients. Conflicting results have been previously reported for the predictive and prognostic role of TP53 variants in mCRC patients receiving anti-EGFR monoclonal antibody therapy. Here we describe the role of TP53 mutations within the ERMES study. **Methods:** Patients with untreated RAS/BRAF wt mCRC were randomly assigned (1:1) to receive either FOLFIRI/Cet until PD/toxicity (arm A) or FOLFIRI/Cet for 8 cycles followed by Cet alone (arm B). Tumor tissue samples were tested using the OncoPrint Solid Tumor DNA kit covering hot spot mutations in 22 genes, including *KRAS*, *NRAS*, *BRAF* and *TP53*. Variant calling was performed using the Variant Caller Ion Torrent suite 5.16 software. The prognostic value of TP53 variants was assessed in the intention-to-treat (ITT) patients' population with available sequencing data. **Results:** Tumor tissue specimens were available for 418/593 (70.5%) patients of the ITT population. Testing failed in 29 cases, whereas *KRAS*/*NRAS*/*BRAF* V600E variants were found in 36/389 (9.2%) patients, who were enrolled on the basis of local testing. Progression free survival (PFS) data were not available for 4 cases. Therefore, the final population in analysis was 349 cases. TP53 variants were detected in 165/349 (47.3%) patients, of which 86/165 (52.1%) in arm A and 79/165 (47.9%) in arm B. The median PFS (mPFS) of TP53 wild type patients in the overall population was 9.4 months versus 10.4 months in the TP53 mutant subgroup (HR 0.8439; 95%CI, 0.673-1.058; $p = 0.142$). In arm A, the mPFS of TP53 wild type patients was 10.8 months versus 10.7 months in TP53 mutant patients, with an HR 1.053 (95%CI, 0.7582-1.462; $p = 0.76$). The mPFS of TP53 wild type patients in arm B was 8.3 months versus 10.2 months in the TP53 mutant cohort, with an HR 0.7 (95%CI, 0.5087-0.9657; $p = 0.0298$). No significant difference was observed for the overall response rate (ORR) in both arms between TP53 mutant and wild type patients. **Conclusions:** These preliminary data suggest a possible prognostic role of TP53 variants in RAS/BRAF wild type mCRC patients receiving first line FOLFIRI/cetuximab followed by Cet alone. Comprehensive genomic profiling is ongoing to identify genomic signatures associated with sensitivity to Cet. Plasma arginine as a candidate predictive biomarker for response to immune checkpoint inhibition (ICI) in metastatic colorectal cancer (mCRC): Analysis of the CCTG CO.26 trial. *First Author: Lucy Xiaolu Ma, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Nutritional stress is one of the mechanisms used by tumour cells to evade the immune system. Arginine (ARG), an amino acid involved in several cellular functions including immunomodulation, is important in regulating T-lymphocyte cell activity and the anti-tumour response. ARG deficiency in the tumour microenvironment has been shown to impair T-cell response while ARG supplementation may promote anti-tumour immune activity. In this exploratory post-hoc analysis of the Phase II CO.26 trial (NCT02870920), we investigated the role of plasma ARG in predicting response to ICI in patients (pts) with refractory mCRC. **Methods:** CO.26 was a phase II trial which randomized pts with refractory mCRC to durvalumab plus tremelimumab (D+T) versus best supportive care (BSC). Plasma ARG concentrations were determined from blood samples pre-treatment using HPLC-tandem mass spectrometry. The median plasma ARG value was used as a cut-off stratifying pts into ARG-high (≥ 10650 ng/ml) versus ARG-low (< 10650 ng/ml) groups. Progression-free (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method and compared between groups using the log-rank test. Cox proportional hazard models were used to analyze prognostic and predictive impacts of ARG on PFS and OS. **Results:** Of 180 pts enrolled in CO.26, 162 pts (N = 115 treated with D+T and 47 BSC) had pre-treatment blood samples for baseline ARG analysis. There were no significant differences in baseline characteristics between pts included in this analysis and the total study pts, or between ARG-high and ARG-low pts. In pts treated with D+T, ARG-high was associated with more favourable prognosis (ARG-high median OS 7.62 months vs. ARG-low 5.49 months, multivariable hazard ratio [HR] 0.60, 95% confidence interval [CI] 0.40-0.91, $p = 0.016$). In ARG-high pts, D+T significantly improved OS (median OS 7.62 months with D+T vs 3.61 months BSC; HR 0.61, 95% CI 0.37-0.99, $p = 0.04$). In ARG-low pts there was no OS benefit with D+T (median OS 5.49 months D+T vs 4.27 months BSC; HR 0.84, 95% CI 0.50-1.41, $p = 0.51$). Interaction $p = 0.037$. Baseline ARG values had no association with PFS or disease control rate. **Conclusions:** Baseline plasma ARG was prognostic in pts with mCRC treated with D+T, and high ARG was predictive of improved OS with ICI. Prospective studies should be done to validate ARG as a biomarker identifying mCRC pts likely to derive benefit from ICI. Therapeutic approaches targeting the ARG pathway should be investigated in future studies. Research Sponsor: The Canadian Cancer Trials Group (CCTG) is funded by the Canadian Cancer Society.; AstraZeneca provided durvalumab and tremelimumab and contributed partial funding for the CO.26 trial.

A prospective study of FOLFIRI plus aflibercept as second-line treatment after failure of FOLFOXIRI plus bevacizumab in patients with unresectable/metastatic colorectal cancer (CRC): EFFORT study. *First Author: Hironaga Satake, Department of Medical Oncology, Kochi Medical School, Nankoku-City, Japan*

Background: FOLFOXIRI plus bevacizumab (BEV) is a first-line treatment option for patients with unresectable or metastatic CRC. However, there are no clear recommendations for second-line therapy after failure of FOLFOXIRI plus BEV. The EFFORT study investigated whether FOLFIRI plus aflibercept is active following FOLFOXIRI plus BEV in unresectable/metastatic CRC. **Methods:** EFFORT was an open-label, multicenter, single arm phase II study. Patients with unresectable/metastatic CRC who failed FOLFOXIRI plus BEV as a first-line therapy received aflibercept plus FOLFIRI (aflibercept 4 mg/kg, irinotecan 150 mg/m² IV over 90 min, with leucovorin 200 mg/m² IV over 2 hours, followed by fluorouracil 400 mg/m² bolus and fluorouracil 2400 mg/m² continuous infusion over 46 hours) every 2 weeks on day 1 of each cycle. The primary endpoint was progression-free survival (PFS) in the full analysis set (FAS). To achieve 80% power to show a significant benefit with a one-sided alpha level of 0.10, assuming a threshold PFS of 3 months and an expected value of at least 5.4 months, 32 patients needed to be enrolled. Major secondary endpoints included overall survival (OS), overall response rate (ORR) and safety. **Results:** From April 2019 to May 2021, 35 patients were enrolled and FAS included 34 patients (one patient who did not meet eligibility criteria was excluded). Of them, 18 were males, median age was 63 years (range: 32-78) and ECOG Performance Status was either 0 (n = 28) or 1 (n = 6). The primary tumor was left-sided in most patients (23/34) and 27 patients had liver metastases. And 23 patients had RAS mutation. The primary endpoint was met with a median PFS of 4.3 months [80% CI: 3.7-5.1]. The median OS was 15.2 months [95% CI: 8.9-22.7]. Objective tumor responses were CR (n = 1), PR (n = 4), SD (n = 21) or PD (n = 8). ORR was 14.7% (5/34) [95% CI: 5.0-31.1], and disease control rate was 76.5% (26/34) [95% CI: 58.8-89.3]. Main grade 3 or 4 adverse events were neutropenia (7/35, 20.0%), thrombocytopenia (3/35, 8.6%), leucopenia (2/35, 5.7%), and hypertension (3/35, 8.6%). No severe proteinuria and no treatment-related death were reported. **Conclusions:** Aflibercept plus FOLFIRI given after failure of FOLFOXIRI plus BEV is active and shows a manageable safety profile. This regimen maybe a useful as second-line treatment option in such patients. Clinical trial information: jRCTs071190003. Research Sponsor: Sanofi Pharmaceutical Co., Ltd.

A phase 1 dose escalation study of GCC19CART: A novel coupled CAR therapy for patients with metastatic colorectal cancer. *First Author: Lei Xiao, Innovative Cellular Therapeutics Co., Ltd., Rockville, MD*

Background: GCC19CART, the first clinical candidate from the CoupledCAR solid tumor platform, is designed to overcome the limitations of conventional CAR T-cells in solid tumor malignancies by pairing solid tumor CAR T-cells with CD19 targeting CAR T-cells to amplify the proliferation and activation of the solid tumor CAR T component. GCC19CART targets guanylate cyclase-C (GCC), which is expressed in the metastatic lesions of 70%-80% of subjects with colorectal cancers and largely restricted to the intestinal tract. A Phase 1 investigator-initiated clinical trial is underway in China for patients with relapsed or refractory metastatic colorectal cancer who have received at least 2 prior lines of therapy. As of a data cutoff on Jan 28, 2023 21 subjects have been enrolled in 2 dose escalation groups at 5 hospitals in China. **Methods:** Subjects are screened for GCC expression by immunohistochemistry. Eligible subjects undergo leukapheresis, a single dose of lymphodepleting chemotherapy (fludarabine 30mg/m² and cyclophosphamide 300mg/m²) 3 days prior to infusion, and then administration of a single infusion of GCC19CART at one of two preassigned doses: 1×10^6 or 2×10^6 CAR T-cells/kg. All responses were confirmed by an independent third-party imaging contract research organization. **Results:** 13 subjects have been enrolled to dose level 1 (1×10^6 cells/kg) and 8 subjects have been enrolled to dose level 2 (2×10^6 cells/kg). The most common adverse events were cytokine release syndrome (CRS) in 21/21 subjects (Grade 1 19/21 (90.48%) or Grade 2 2/21 (9.52%)) and diarrhea in 21/21 subjects (Grade 1 6/21 (28.57%) Grade 2 5/21 (23.81%) Grade 3 9/21 (42.86%) or Grade 4 1/21 (4.76%)). All patients with grade 3 and higher side effects were well managed. Immune effector cell-associated neurotoxicity syndrome (ICANS) was observed in 2/21 (9.52%) subjects at Grade 3 or 4 and resolved with corticosteroids. The combined overall response rate (ORR) for both dose levels was 28.6% (6/21). For dose level 1, overall response rate (ORR) was 15.4% (2/13). Two subjects demonstrated a partial response (PR) while 3 additional subjects had partial metabolic response (PMR) on PET/CT with stable disease (SD) or progressive disease (PD) per RECIST 1.1. For dose level 2, The ORR was 50% (4/8). 4 subjects demonstrated a PR and 2 additional subjects had PMR on PET/CT with SD per RECIST 1.1. The median PFS was 1.9 months in the dose 1 group and 6.3 months in the dose 2 group. The median overall survival was 13.3 months in the dose 1 group and 18.3 months in the dose 2 group. **Conclusions:** Preliminary results demonstrate that GCC19CART has meaningful dose-dependent clinical activity and an acceptable safety profile in relapsed or refractory metastatic colorectal cancer. This trial is ongoing and updated data will be presented. A Phase 1 trial of GCC19CART in the US has opened for accrual and is expected to enroll patients in mid-2022. Clinical trial information: ChiCTR2000040645. Research Sponsor: Innovative Cellular Therapeutics.

First-line (1L) nivolumab (NIVO) + ipilimumab (IPI) in patients (pts) with microsatellite instability-high/mismatch repair deficient (MSI-H/dMMR) metastatic colorectal cancer (mCRC): 64-month (mo) follow-up from CheckMate 142. *First Author: Heinz-Josef Lenz, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: NIVO + IPI demonstrated robust, durable clinical benefit, and was well tolerated as a 1L therapy in pts with MSI-H/dMMR mCRC in the phase 2 CheckMate 142 study (NCT02060188), leading to the inclusion of NIVO + IPI in the NCCN guidelines as an initial therapy option for these pts. At 52-mo median follow-up, 1L NIVO + IPI continued to demonstrate durable clinical benefit, and no new safety signals were identified. Here we report longer follow-up results. **Methods:** Pts with MSI-H/dMMR mCRC and no prior treatment for metastatic disease received NIVO 3 mg/kg Q2W + IPI 1 mg/kg Q6W until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) by investigator assessment (INV) per RECIST v1.1. Other key endpoints were disease control rate (DCR), duration of response (DOR), progression-free survival (PFS), all by INV; overall survival (OS); and safety. **Results:** In total, 45 pts received 1L NIVO + IPI. With median follow-up of 64.2 mo (range, 59.4-68.9 mo), ORR by INV was 71% (95% CI, 56-84%). The proportion of pts with a best overall response of complete response (CR) was 20%, partial response (PR) was 51%, stable disease (SD) was 13%, and progressive disease was 16%. Median DOR (mDOR) was not reached, and the 60-mo DOR rate was 72%. Median PFS (mPFS) by INV and median OS (mOS) were not reached, with 60-mo PFS and OS rates of 55% and 67%, respectively (Table). Among pts alive at the data cutoff (n = 31), 30 remained treatment-free after initial study treatment without receiving any subsequent systemic therapy, with a median treatment-free interval of 34.7 mo (range, 1.6-61.4 mo). Exploratory analysis by tumor mutational burden status will be presented. Safety data are shown in the Table. **Conclusions:** At 64-mo follow-up, NIVO + IPI continued to demonstrate clinically meaningful survival and durable responses, with mPFS, mOS, and mDOR still not reached, suggesting the potential for long-term clinical benefit. Safety remained consistent with previous data. These findings further support current recommendations for NIVO + IPI as a 1L treatment for pts with MSI-H/dMMR mCRC. Clinical trial information: NCT02060188. Research Sponsor: Bristol Myers Squibb.

Impact of number and size of colorectal metastases (CRM) on survival in patients with RAS wild-type metastatic colorectal cancer treated within the PanaMa trial (AIO KRK 0212). *First Author: Greta Sommerhäuser, Department of Hematology, Oncology and Tumorimmunology, Charité-Universitätsmedizin Berlin, Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin, Germany*

Background: In this exploratory analysis, we aim to evaluate surrogates of metastatic burden, namely number of CRMs and size of largest CRM, for their prognostic and predictive value on efficacy of maintenance therapy with 5-fluorouracil/leucovorin (FU/FA) plus panitumumab (pmab) or FU/FA alone in RAS wildtype mCRC patients treated within the PanaMa trial. **Methods:** Number of CRMs and size of largest CRM at baseline were determined taking into account target and non-target lesions measured by central radiological review. Median number of metastases was set as threshold ($n \leq / > 10$) to assess the prognostic and predictive value of CRM count on PFS and OS of maintenance therapy. A threshold of $\leq / > 50$ mm was set to evaluate the impact of the largest CRM on the above time-to-event endpoints. PFS and OS were expressed by Kaplan-Meier method and compared by log-rank testing. Hazard ratios (HR) with 95% CIs were estimated using Cox regression models. **Results:** Out of 248 patients receiving maintenance therapy, CT and MRI scans of 211 patients were centrally evaluable (FU/FA+Pmab, $n=106$; FU/FA alone, $n=105$). At baseline, 50.1% of the patients were diagnosed with > 10 CRM. Median size of the largest CRM was 45 mm. Number of CRMs $n \leq 10$ was associated with favorable PFS, while both, number $n \leq 10$, and size of largest CRM ≤ 50 mm correlated with favorable OS compared to $n > 10$ and size of largest CRM > 50 mm, respectively. In patients with > 10 CRMs, and those with largest CRM sized > 50 mm, PFS of maintenance therapy was significantly superior with FU/FA+Pmab compared to FU/FA alone (Table). **Conclusions:** Metastatic burden was found to be prognostic for PFS and OS of maintenance therapy. Additionally, number and largest size of CRMs proved predictive of PFS of maintenance therapy with Pmab, the primary endpoint of the trial. Patients with high metastatic burden at baseline appear to benefit particularly from Pmab-containing maintenance therapy. Clinical trial information: NCT01991873. Research Sponsor: Amgen Inc.

Metastatic burden according to number and size of colorectal metastases (CRM) and treatment arms.

Size-related heterogeneity of colorectal liver metastases (CRLM) in patients with advanced RAS wild-type metastatic colorectal cancer (mCRC) treated in the PanaMa trial: Implication for treatment decisions. *First Author: Greta Sommerhäuser, Department of Hematology, Oncology and Tumorimmunology, Charité-Universitätsmedizin Berlin, Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin, Germany*

Background: In patients with mCRC, the liver represents the primary site of metastasis. In patients with primarily unresectable metastatic disease, primary tumor location and molecular subtypes mainly determine the therapeutic approach. In addition, image-based characterization of hepatic metastatic pattern may provide additional information concerning prognosis and treatment efficacy. Therefore, CRLM were characterized according to size-based heterogeneity in the PanaMa trial (maintenance therapy with 5-fluorouracil/leucovorin (FU/FA) plus panitumumab (Pmab) vs. FU/FA alone following induction therapy with six cycles of FU/FA, oxaliplatin and Pmab). **Methods:** Assessments were performed in patients with at least two lesions, considering target and non-target lesions, within a central radiological review of the trial. Variance in size expressed as ratio between the smallest and largest lesion measured ($\leq / >$ threefold difference in size) was evaluated for its prognostic and predictive impact on progression-free (PFS) and overall (OS) survival of maintenance therapy. Time-to-event endpoints were expressed by Kaplan-Meier method and compared by log-rank tests. Cox regressions were used to indicate Hazard ratios (HR) with 95% CIs. **Results:** Imaging data of 211/248 (85.1%) patients receiving maintenance therapy were evaluable for central radiological review (FU/FA+Pmab, $n=106$; FU/FA, $n=105$). Of those, 165/211 patients (78.2%) had at least two CRLM. Size of CRLM ranged between 5–180mm, with the smallest metastasis in the individual assessments measuring a median of 12mm and the largest a median of 53mm. Large heterogeneity with more than a threefold difference in size between the smallest and largest CRLM was observed in 49.7% of patients, particularly pronounced in patients with polymetastatic disease (> 5 lesions). Homogeneous metastasis in terms of lesion size ($\leq$ threefold difference) was associated with favorable OS (HR 0.63; 95% CI, 0.42–0.95; $P=0.027$) - irrespective of study arm compared to heterogeneous lesion disease. Maintenance therapy with FU/FA+Pmab compared with FU/FA alone seemed favourably active in both patients with heterogeneous metastases (HR 0.53; 95% CI, 0.34–0.85; $P=0.008$) as well as to a numerically lesser extent in patients with homogeneous metastases (HR 0.68; 95% CI, 0.43–1.10; $P=0.116$). **Conclusions:** Imaging-based characterization of CRLM focusing on size-related heterogeneity was associated with favorable prognosis potentially indicating more aggressive underlying tumor dynamics in case of heterogeneous lesion size. In addition, the efficacy of Pmab during maintenance was evident in both patient groups (homogeneous and heterogeneous disease lesions) with a numerically greater effect in patients with heterogeneous lesions. Clinical trial information: NCT01991873. Research Sponsor: Amgen Inc.

Alternating short-course oxaliplatin-based chemotherapy and nivolumab as first-line treatment of patients with abdominal metastases from microsatellite-stable (MSS) colorectal cancer (CRC): A randomized phase 2 trial. *First Author: Anne Hansen Ree, Akershus University Hospital, Lørenskog, Norway*

Background: The CRC incidence increases sharply from the age of 60. Most patients harbor primarily non-immunogenic MSS disease and abdominal metastases are in particular considered unresponsive to immune checkpoint blockade (ICB). The METIMMOX trial explored if MSS-CRC can be transformed into an immunogenic malignancy by short-course oxaliplatin-based therapy and if followed by ICB (without concomitant chemotherapy that might compromise an invoked tumor-defeating immunity) may result in durable clinical response for patients with abdominal metastases. **Methods:** Patients had MSS-CRC with infradiaphragmatic metastases deemed unresectable, ECOG performance status 0-1, and were eligible for first-line oxaliplatin-based therapy. They were randomly assigned to FLOX (oxaliplatin 85 mg/m² day 1, bolus 5-fluorouracil 500 mg/m² and folic acid 100 mg days 1-2) Q2W (control arm) or alternating cycles of 2 FLOX Q2W and 2 nivolumab (240 mg) Q2W (experimental (exp) arm) with break periods at prespecified intervals. Response assessment per i/RECIST by blinded central review was done every 8 weeks with progression-free survival (PFS) as primary endpoint. Sample size of 40 in each arm with 1:1 randomization would detect exp arm doubling of median PFS. Associations between PFS and relevant patient and disease variables were estimated by Cox proportional-hazards regression models. Prespecified correlative analyses included circulating tumor DNA (ctDNA) by droplet digital PCR and circulating immune cell composition by high-dimensional single-cell mass cytometry. **Results:** Of 80 enrolled subjects (05/2018-10/2021), 76 intention-to-treat (ITT) cases were equally allocated to the study arms and followed to censoring at 10/2022 with identical median PFS of 9.3 months (95% CI, 6.4-12.9 (control arm) and 4.6-15.2 (exp arm)). The adjusted Cox model revealed interaction between age and study arm, as patients ≥ 60 years had significantly lowered risk of progression when receiving exp therapy (median PFS 13.6 months (95% CI, 8.5-18.8); $p=0.022$). No unexpected adverse events were recorded; specifically, no grade ≥ 4 immune-mediated adverse event occurred. Of note, 17% of exp arm patients had durable complete response, among whom all BRAF-mutant cases ($n=3$) with PFS 21-35 months and rapid clearance of baseline BRAF-mutant ctDNA (control arm BRAF-mutant cases ($n=10$), median PFS 3.6 months). Responding exp arm patients showed distinct subsets of circulating immune cells with more homogenous profiles than ICB-unresponsive subjects. **Conclusions:** With equal primary endpoint for the ITT cases, alternating short-course oxaliplatin-based therapy and nivolumab significantly improved PFS compared to standard first-line chemotherapy in MSS-CRC patients ≥ 60 years with abdominal metastases. Clinical trial information: NCT03388190. Research Sponsor: Norwegian Cancer Society, including its Umbrella Foundation for Cancer Research, Grants 182496 and 215613; Bristol-Myers Squibb.

Prognostic value of liver metastases in colorectal cancer treated by systemic therapy: An ARCAD pooled analysis. *First Author: Romain Cohen, Sorbonne University, Department of Medical Oncology, Saint-Antoine Hospital, AP-HP, Paris, France*

Background: Approximately 30% of patients (pts) diagnosed with colorectal cancer (CRC) develop liver metastases (LM). Liver is the most common organ of metastasis of CRC. The ARCAD database contains individual patient data of randomized trials that included CRC pts with initially unresectable metastases treated with systemic therapy. The aim of this study was to assess the response and survival outcomes in non-LM (NLM) vs LM across different lines of treatment. **Methods:** We analyzed survival outcomes of mCRC pts with either single site (SS) or multiple sites (MS) according to LM status in the following treatment groups: A: chemotherapy (CT) alone, B: CT + VEGF-antibodies, C: CT + EGFR-antibodies in KRAS wild-type tumors, within first-line (1L) and second-line (2L) of therapy and D: pts enrolled on third line (≥ 3 L) trials treated with trifluridine/tipiracil or regorafenib and placebo. The primary and secondary endpoints were overall survival (OS) and progression-free survival (PFS) which were assessed using Kaplan-Meier estimates and adjusted Cox models on ECOG PS, age, and gender. **Results:** We included 26 trials with 17924 pts. 14066 pts had LM. Pts with LM had a higher rate of colon vs rectum as primary tumor (72 vs 62%; $P<.001$) and less SS (31 vs 47%; $P<.001$) than those with NLM. OS and PFS results in subgroups are reported in the table. In groups A and B, we found better OS and PFS outcomes in NLM pts as either SS or MS in 1L and 2L. In group C from 1L, we found better survival outcomes in pts with SS LM. In pts with MS, NLM superiority was observed in OS but not in PFS. However, these results were influenced by primary tumor sidedness. In group D, better OS and PFS was observed in pts without LM than those with LM whether in pts with SS or MS. Response rates were higher in LM than in NLM in most 1L and 2L subgroups. **Conclusions:** LM is a poor prognostic factor for mCRC increasing from the 1L to ≥ 3 L. Survival with CT alone and CT + anti-VEGF according to LM and NLM differs significantly in 1L and 2L but not with CT + anti-EGFR. This data justifies using LM as a stratification factor at least in ≥ 3 L trials. Research Sponsor: ARCAD Foundation.

A phase Ib/II study to evaluate surufatinib combined with camrelizumab and chemotherapy in the second-line treatment of advanced colorectal cancer: Phase Ib results. *First Author: Sheng Li, Department of Oncology, Jiangsu Cancer Hospital, Nanjing, China*

Background: Surufatinib is a novel small-molecule kinase inhibitor targeting VEGFR1-3, FGFR and CSF-1R with confirmed efficacy in epNET and pNET. Pre-clinical studies have demonstrated that surufatinib combined with immune checkpoint inhibitors (ICIs) have synergistic antitumor effects by modulating tumor immune microenvironment. Additionally, surufatinib plus toripalimab (anti-PD-1) has showed preliminary anti-tumor activity in multiple solid tumors, including colorectal cancer (CRC). This study aimed to evaluate the efficacy and safety of surufatinib plus camrelizumab (anti-PD-1), irinotecan and GM-CSF as second-line treatment in advanced CRC. Here we reported the results of the phase Ib study. **Methods:** This ongoing phase Ib/II, open-label trial (NCT04929652) enrolled patients (pts) aged 18-75 years old with pathologically confirmed locally advanced or metastatic CRC who have progressed on/been intolerant to the standard first-line therapy. In the Ib dose escalation/de-escalation phase, pts received surufatinib at 250mg once daily (QD) as starting dose, in combination with fixed dose of camrelizumab (200 mg, d1), irinotecan (200 mg/m², d1) and GM-CSF (5ug/kg, d2-d7), every 3 weeks (Q3W). Based on DLTs, the dose of surufatinib should escalate to 300 mg or de-escalate to 200 mg. The primary objective of the phase Ib study was to determine the safety and DLT in first treatment cycle defining the recommended phase 2 dose (RP2D). Additional 36 pts were enrolled in the phase II dose expansion stage using RP2D. Primary endpoint of phase II was ORR as per RECIST 1.1. Secondary endpoints included PFS, DCR, OS and safety. **Results:** Enrollment opened in Nov 2021 and data cutoff in Dec 2022. 12 pts (median age 54) were treated in Phase Ib study (surufatinib 250 mg: N = 6; surufatinib 300 mg: N = 6). 75% were male and 17% had ECOG PS 1. 11/12 (92%) pts were positive for KRAS, NRAS or BRAF mutations. No DLT was observed in the starting dose cohort (surufatinib 250 mg), and one patient in the surufatinib 300 mg cohort experienced DLT (Grade [G] 3 vomiting). Surufatinib 300 mg QD was defined as the RP2D. Other G3 treatment related adverse events (TRAEs) were hypertension (1/12; 8.3%) and diarrhea (1/12; 8.3%). All other TRAEs were grade 1-2, and the most common (≥40%) were diarrhea (75%), fatigue (58%), vomiting (58%), nausea (50%), hypertension (42%), proteinuria (42%) and alopecia (42%). Of the 12 pts evaluable for tumor response, 3 pts achieved PR, 9 pts achieved SD. The ORR was 25% (3/12), the DCR was 100% (12/12) and median PFS was 7.2 months (95%CI 3.7-10.7). **Conclusions:** Surufatinib plus camrelizumab, irinotecan and GM-CSF was well tolerated, with a manageable safety profile, and showed preliminary anti-tumor activity in patients with advanced CRC. The dose-expansion phase is ongoing. Clinical trial information: NCT04929652. Research Sponsor: None.

Preliminary results from ERAS-007 plus encorafenib and cetuximab (EC) in patients (pts) with metastatic BRAF V600E mutated colorectal cancer (CRC) in HERKULES-3 study: A phase 1b/2 study of agents targeting the mitogen-activated protein kinase (MAPK) pathway in pts with advanced gastrointestinal malignancies (GI cancers). *First Author: Michael Sangmin Lee, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The RAS/MAPK pathway (including BRAF) is dysregulated in a broad range of cancers including CRC, resulting in downstream activation of ERK1/2. Metastatic CRC with BRAF V600E mutation (BRAF V600E mCRC) has dramatically worse survival than non-BRAF V600E mutated CRCs, and novel therapies are needed. ERAS-007 is a novel, potent, and orally bioavailable inhibitor of ERK. The combination of a BRAF plus EGFR inhibitor (EC) is approved for the treatment of pts with BRAF V600E mCRC; however, only 20% of pts experience an objective response. ERAS-007 alone or in combination with EC showed promising in vitro and in vivo activity in BRAF V600E CRC models to support the combinatorial clinical benefit of ERAS-007+EC in BRAF V600E mCRC. **Methods:** HERKULES-3 is a Phase 1b/2 study to assess the safety, tolerability, PK, and preliminary clinical activity of ERAS-007 combinations targeting the MAPK pathway in pts with advanced GI cancers. Within this study, we are currently evaluating the safety and tolerability of escalating doses of ERAS-007 + EC in pts with BRAF V600E CRC. Prior BRAF inhibitor and EGFR inhibitor treatment is neither required nor excluded to be enrolled in this study. **Results:** As of 30 November 2022, 12 patients were dosed with ERAS-007 twice daily-once a week (BID-QW) (75 and 100 mg; n = 10) or once daily once a week (QW) (150 mg; n = 2) in combination with EC (300 mg oral daily + 500 mg/m² intravenous infusion once every 2 weeks). The treatment-emergent AEs (TEAEs) occurring in ≥20% of pts were fatigue (50%), headache (42%), constipation, diarrhea, nausea, dermatitis acneiform (33% each), and vomiting (25%). No TEAEs led to ERAS-007 discontinuation or death. Grade ≥3 TEAEs were reported in 3 pts (25%). Grade ≥3 treatment-related AEs reported in ≥ 2 patients (17%) include hypertension, headache, confusional state, and skin toxicity. Three pts (25%) died due to disease progression. No DLTs were reported. Out of 4 efficacy evaluable EC naive pts, one confirmed partial response (PR) and one unconfirmed PR were observed. Evaluation of PK is ongoing and preliminary data will be presented. **Conclusions:** ERAS-007+EC in pts with BRAF V600E CRC shows acceptable preliminary safety/tolerability and evidence of clinical activity. The highest dose of ERAS-007 evaluated and cleared by the safety review committee to date is 100 mg BID-QW when combined with EC. Observed PK, toxicity, and preliminary activity support continued evaluation of this combination in pts with BRAF V600E CRC. Clinical trial information: NCT05039177. Research Sponsor: Erasca; Lilly and Pfizer.

Trifluridine/tipiracil (FTD/TPI) in extensively pre-treated metastatic colorectal cancer (mCRC) patients: Evaluation of prognostic subgroups of the TALLISUR study. *First Author: Meinolf Karthaus, Department of Hematology and Oncology, Munich Hospital Neuperlach, Munich, Germany*

Background: Compared to placebo, FTD/TPI significantly improved overall survival (OS) in patients (pts) with pre-treated mCRC in the pivotal phase III RECURSE trial. Subgroup analyses indicated that all subgroups benefitted from FTD/TPI. Of note, FTD/TPI prolonged survival even more in pts ≥ 65 years old. To evaluate these observations with data from daily clinical practice, we performed a subgroup analysis of the TALLISUR study. **Methods:** In this prospective, multi-center, German, open-label, phase IV study, pts with extensively pre-treated mCRC chose between best supportive care (BSC) or oral FTD/TPI (35 mg/m² bid on days 1–5 and 8–12 of each 28-day cycle). Duration of treatment and OS were analyzed for various subgroups. Based on a post-hoc analysis of the RECURSE trial, 3 subgroups were defined according to: best, good and poor prognostic characteristics (BPC, GPC, PPC). Pts with < 3 metastatic sites at inclusion and ≥ 18 months from diagnosis to inclusion were considered to have GPC. GPC pts without liver metastasis at inclusion were considered to have BPC. All remaining pts were considered to have PPC. **Results:** Of 195 eligible pts, 186 pts chose treatment with FTD/TPI, while 9 pts decided to receive BSC only. Median OS was 6.9 (95% CI 6.1–8.3) months. Mean duration of treatment with FTD/TPI was 14.6 (range 0.1–102.7) weeks. Results of the subgroup analysis are summarized in the table. Pts ≥ 65 years old presented a longer median OS (7.2 vs 6.2 months). **Conclusions:** When given the choice between treatment and BSC in late-stage CRC, the vast majority of pts opted for treatment. Low metastatic burden and indolent disease were factors of good prognosis for FTD/TPI therapy regarding OS. Independent of baseline characteristics such as age, sidedness, and time of onset of metastases, virtually all pts benefitted from therapy with FTD/TPI. Albeit not statistically significant, elderly pts tend to have improved survival with FTD/TPI, consistent with results from RECURSE. Clinical trial registration number: EudraCT No 2017-000292-83. Research Sponsor: Servier.

Subgroup analysis – survival and duration of treatment with FTD/TPI.

Subgroup	Median OS (95% CI) [months]	Mean duration of treatment (range) [weeks]
BPC (n = 20)	12.2 (6.0 – 18.2)	16.3 (0.4 – 83.7)
GPC (n = 65)	7.9 (6.2 – 13.3)	15.1 (0.4 – 102.7)
PPC (n = 121)	6.8 (5.4 – 8.1)	14.3 (0.1 – 102.7)
Age < 65 years (n = 74)	6.2 (4.8 – 8.6)	13.7 (0.1 – 102.7)
Age ≥ 65 years (n = 112)	7.2 (6.3 – 11.1)	15.2 (0.7 – 102.7)
Synchronous metastases (n = 102)	6.9 (6.2 – 10.1)	12.4 (0.1 – 72.7)
Metachronous metastases (n = 63)	7.3 (5.3 – 12.4)	16.8 (1.3 – 102.7)
Left sided tumor (n = 138)	6.8 (6.0 – 8.3)	13.9 (0.1 – 102.7)
Right sided tumor (n = 42)	8.1 (5.9 – 12.8)	16.9 (0.4 – 72.7)

Preliminary results from ERAS-007 plus palbociclib (palbo) in patients (pts) with KRAS/NRAS mutant (m) colorectal cancer (CRC) or KRASm pancreatic ductal adenocarcinoma (PDAC) in HERKULES-3 study: A phase 1b/2 study of agents targeting the mitogen-activated protein kinase (MAPK) pathway in pts with advanced gastrointestinal malignancies (GI cancers). *First Author: Susanna Varkey Ulahannan, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: The RAS/MAPK pathway is dysregulated in a broad range of cancers including CRC and PDAC, resulting in downstream activation of ERK1/2. ERAS-007 is a novel, orally bioavailable inhibitor of ERK. Palbo is an oral CDK4/6 inhibitor that inhibits cellular proliferation, an essential feature of tumor growth. Both in vitro & in vivo data exploring the combination of ERAS-007 and palbo in a panel of CRC and pancreatic CDX and/or PDX models have shown promising activity to support the potential combinatorial clinical benefit in RASm CRC and PDAC pts. **Methods:** HERKULES-3 is a Phase 1b/2 study to assess safety, tolerability, PK, and preliminary clinical activity of ERAS-007 combinations targeting the MAPK pathway in pts with advanced GI cancers. Within this study, we are currently evaluating the safety, tolerability, and PK of escalating doses of ERAS-007 twice daily-once a week (BID-QW) (75, 100 mg) in combination with palbo once daily (QD) (75, 100, 125 mg) in pts with KRASm/NRASm CRC or KRASm PDAC. **Results:** As of 30 November 2022, 30 pts were dosed with the combination of palbo and ERAS-007. Treatment emergent AEs (TEAEs) occurring in ≥20% of pts were diarrhea (40%), nausea (40%), anemia (33%), vision blurred (27%), fatigue (23%), and neutrophil count decreased (20%). ERAS-007 treatment related AEs (TRAEs) were reported in 19 pts (63%), with the most frequently reported as diarrhea (40%), nausea (33%), and vision blurred (27%). Grade (Gr) ≥3 TEAEs were reported in 12 pts (40%), including 3 related to ERAS-007 (neutrophil count decreased, diarrhea and dermatitis acneiform). Neutrophil count decreased and anemia were the only Gr 3 events reported in ≥ 2 pts. No Gr 4 events were reported. Two Gr 5 events unrelated to any drugs (hemorrhage intracranial and malignant pleural effusion) and one Gr 5 event (anemia) related to palbo were reported. Two pts discontinued ERAS-007 due to TEAEs (Gr 5 malignant pleural effusion and Gr 2 neutrophil count decreased). Three pts reported 4 DLTs: 1 pt at 75mg ERAS-007 + 125mg palbo (Gr 3 maculopapular rash & Gr 4 sepsis), 1 pt at 100mg ERAS-007 + 100mg palbo (Gr 3 dermatitis acneiform), and 1 pt at 100mg ERAS-007 + 125mg palbo (Gr 3 thrombocytopenia). Based on preliminary PK, no clinically relevant PK interactions were identified between ERAS-007 and palbo. The evaluation of clinical activity is ongoing. **Conclusions:** ERAS-007 in combination with palbo in pts with KRASm/NRASm CRC or KRASm PDAC shows expected preliminary safety with reversible and manageable AEs. The highest dose evaluated and cleared by the safety review committee to date is ERAS-007 100 mg BID-QW in combination with the approved monotherapy dose of palbo 125 mg QD. Clinical trial information: NCT05039177. Research Sponsor: Erasca (Sponsor); Pfizer (collaborator).

Novel GUCY2C targeting CAR-T therapy: Efficacy in advanced colorectal cancer. *First Author: Qianyu Zhang, Anhui Provincial Cancer Hospital, Hefei, China*

Background: Chimeric antigen receptor (CAR) T cells have shown remarkable success in treating patients with hematologic malignancies. However, the majority of CAR-T cell clinical trials in solid tumors have limited success which is partially attributed to the detrimental tumor microenvironment and the lack of ideal target. Recently, GUCY2C emerges as an ideal therapeutic target which is highly expressed in colorectal cancer (CRC). Here, a novel nanobody-based GUCY2C targeting CAR-T cell developed by us is applied to treat advanced colorectal cancer patients who failed third-line therapy. **Methods:** In this open-label, single-arm, investigator-initiated exploratory trial (ChiCTR2100044831), we primarily explore the safety and the low-dose efficacy of the autologous anti-GUCY2C CAR-T cells. All patients screened by IHC met our criteria for GUCY2C positivity. All enrolled patients had received at least 3 prior lines of therapy and had multiple metastases at baseline. Totally, 13 advanced CRC patients aged 18 to 65 years were infused with the anti-GUCY2C CAR-T cells at a dose range of 0.5-3 x10⁶/kg after standard Cy-Flu lymphodepletion. Adverse events (AE) were graded according to CTCAE 5.0, and objective tumor responses were assessed per RECIST 1.1 criteria. **Results:** Between November 2021 and December 2022, 13 subjects with refractory metastatic CRC (mCRC) were treated with the anti-GUCY2C-CAR-T cells infusions at a dose range of 0.5-3 x10⁶/kg. There were no dose-limiting toxicities, treatment-related death or any form of neurotoxicity occurred in this study. The most common TEAEs were diarrhea in 9/13 (69%) subjects (Grade 1: 2/13 (15.38%) Grade 2: 3/13 (23.07%) Grade 3: 4/13 (30.77%)). 8/13 (62%) mCRC subjects experienced grade 1 or grade 2 mouth ulcer generally appear as a single lesion lasting for a few days. All cytokine release syndromes (CRS) observed were grade 1. Totally 9 pts (69%) experienced grade 1 CRS and all resolved by supportive care without the need of tocilizumab. No grade 4 AEs except for decreased lymphocytes in 12/13 pts (92%), decreased white blood cells in 1/13 pts (7.7%) and decreased platelet in 1/13 pts (7.7%). Among 10 evaluable patients, 6 partial responses, 2 stable disease and 2 progressive disease were achieved. At all dose levels ORR and DCR were 60% and 80% respectively. Notably, all 3 patients infused at the dose level above 2x10⁶/kg reached partial responses. Among the 3 non-evaluable patients, 1 patient lost follow-up, 1 patient died of bone marrow failure and 1 patient died of COVID-19 related complications before the first efficacy evaluation. Additional data will be presented at the meeting. **Conclusions:** This clinical study indicated that the anti-GUCY2C CAR-T cell therapy was well tolerated and had promising efficacy in heavily pretreated mCRC patients. Clinical trial information: ChiCTR2100044831. Research Sponsor: None.

Matching-adjusted indirect treatment comparisons (MAIC) of sotorasib vs trifluridine/tipiracil (T/T) and regorafenib as monotherapy in chemorefractory KRAS G12C-mutated metastatic colorectal cancer (mCRC). *First Author: Timothy Jay Price, Queen Elizabeth Hospital, University of Adelaide, Adelaide, Australia*

Background: In the single-arm phase 1/2 CodeBreak 100 study (NCT03600883) evaluating sotorasib monotherapy in KRAS G12C-mutated mCRC patients whose disease progressed on or after fluoropyrimidine, oxaliplatin, and irinotecan treatment, the overall response rate was 12%, and the median progression-free survival (PFS) and overall survival (OS) was 4.2 and 13.4 months, respectively (data cutoff March 2021, n = 91). To compare the efficacy and safety of sotorasib with standard of care (SOC) T/T and regorafenib as monotherapy treatments, MAICs were performed. **Methods:** Clinical outcomes and adverse events (AEs) were compared from representative studies in mCRC patients who received sotorasib 960 mg once daily in CodeBreak 100, T/T in the phase 3 RECURSE study (NCT01607957, n = 534), and regorafenib in the phase 3 CORRECT study (NCT01103323, n = 505). By weighting individual patient-level data from CodeBreak 100, differences in available baseline characteristics considered to be prognostic factors, including age, race, sex, type of cancer (colon vs. rectum), ECOG performance status, time from diagnosis of metastatic disease, number of metastatic sites, number of prior lines of therapy, and prior bevacizumab treatment, were adjusted with the MAIC. MAICs compared sotorasib with T/T and regorafenib separately. Odds ratios (ORs) were estimated for objective response rates, hazard ratios (HRs) were used for PFS and OS. AEs were compared descriptively. **Results:** The effective sample size of sotorasib with matched characteristics consisted of 29 and 56 patients in the T/T and regorafenib comparison, respectively. The MAIC results showed that treatment with sotorasib increases the likelihood of response to treatment, with an adjusted OR of 8.5 vs T/T and 16.1 vs regorafenib. Sotorasib decreased the risk of progression or death by 41% vs T/T and 45% vs regorafenib (Table). Grade 3+ treatment-emergent AEs occurred in 37%, 69%, and 78% of sotorasib-, T/T-, and regorafenib-treated patients, respectively. **Conclusions:** The analyses suggest that sotorasib monotherapy is associated with a statistically significant and clinically meaningful improvement in response rates, PFS and OS vs. T/T and regorafenib in heavily pretreated chemorefractory KRAS G12C-mutated mCRC patients. The analyses are limited by the decreased sample size for sotorasib, the lack of KRAS G12C-specific data in SOC studies, and the impact of differences in post-progression treatments on OS across studies. Research Sponsor: Amgen.

	Sotorasib vs T/T	Sotorasib vs regorafenib
Objective response, OR (95% CI)*	8.5 (3.2-22.1)	16.1 (5.5-46.6)
PFS, HR (95% CI)	0.59 (0.40-0.88)	0.55 (0.39-0.78)
OS, HR (95% CI)	0.32 (0.18-0.57)	0.42 (0.28-0.62)

Determinants of permanent liver limited disease (pLLD) in metastatic colorectal cancer (mCRC). *First Author: Francesc Salva, Vall d'Hebron Institute of Oncology (VHIO), Medical Oncology, Vall d'Hebron University Hospital (HUVH), Barcelona, Spain*

Background: CRC is a complex and heterogeneous disease, with the liver being the most frequent site of metastasis. Around 20% of patients will always progress exclusively in the liver. These patients may be candidates for more aggressive therapeutic procedures that will impact in their outcome. LIVERMET SURVEY Database (LMSD) is a prospective international database, focused on patients operated for CRC liver metastasis, whether resected or not, which purpose is to evaluate patient outcomes and prognostic factors for these resected patients. We propose to analyse all patients enrolled in the (LMSD) to better characterised those determinants that are associated with pLLD. **Methods:** We analyzed all patients included in the LMSD. Patients with relapse of their disease after the first liver surgery were selected. In order to test associations between hepatic only and extrahepatic metastasis, a univariate and multivariate logistic model was performed with the variables considered clinically more relevant. Imputation of missing data using the mice method (Multivariate Imputation via Chained Equations) was performed. All analyses were performed with R 4.1.1 software. **Results:** A total of 8715 patients out of 33581 (26%) included in the LMSD presented disease recurrence after a first liver surgery. During their oncological history, pLLD occurred in 1392 patients (16%), and extrahepatic relapse was presented in 7323 patients (84%). The characteristics of patients with pLLD were as follows: 58.4% patients presented synchronous disease, 20.2% had right sided primary tumor, 58.6% presented unilateral disease at time of first hepatic surgery and 20.4% of patients presented R1 surgery. In multivariate analysis, right sided and rectum (HR 0.82, p = 0.001), unilateral liver involvement (HR 0.74, p < 0.001) and > 3cm of diameter in greatest lesion with maximum of 3 lesions (HR 0.85, p = 0.02) were predictive determinants of extrahepatic disease. Only synchronous metastases (HR 1.29, p < 0.001) and male sex (HR 1.15, p = 0.028) were associated with pLLD. Molecular information according to RAS, BRAF and MSI status was not evaluable in a majority of patients since this item has been recently implemented in the questionnaire. **Conclusions:** This study confirms that about 16% of patients with LLD mCRC will be pLLD mCRC. Despite clinical determinants like synchronous metastatic disease, which is associated with pLLD, further analyses including molecular determinants are needed. Identifying those determinants of pLLD in a scenario where more extreme surgeries and liver transplantations are being considered is a great challenge that needs to be addressed. Poster Session

A phase II study of regorafenib plus sintilimab as salvage-line treatments in non-MSI-H metastatic colorectal cancer (mCRC). *First Author: Rui Liu, Department of Gastrointestinal Medical Oncology, Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, Tianjin, China*

Background: PD-1 blockade is particularly ineffective in patients with microsatellite stable (MSS) or mismatch repair (MMR)-proficient colorectal cancer (CRC). Regorafenib (R) has been shown to modulate anti-tumor immunity by different mechanisms including reduction of tumor-associated macrophages (TAMs) and the immunosuppressive cells. Synergy between Regorafenib and anti-PD-1/PD-L1 antibodies has been shown in pre-clinical models, as well as in several clinical studies, compared with either treatment alone. The purpose of this study was to evaluate the activity of regorafenib in combination with immune checkpoint inhibitors. **Methods:** This is a single-arm, open-label, phase II trial assessing the efficacy and safety of Regorafenib (80mg QD 3weeks/4) + Sintilimab (S) (200mg every 3 weeks) combination in non MSI-H mCRC patients (pts). The primary endpoint was the overall survival (OS). Secondary endpoints included progression free survival (PFS), objective response rate (ORR), disease control rate (DCR) and Safety. **Results:** As of February 1, 2023, a total of 103 patients with mCRC were enrolled and received R+S. Median age was 57 (range, 28-75). Male 59.2%, ECOG PS 0/1/2 20.4%/66.0%/13.6%, left-sided colon/right-sided colon/rectum 39.8%/15.5%/44.7%, RAS mutant 42.7%. The ORR was 21.4% and DCR was 63.1%, with complete response (cCR) in 1 (1.0%), partial response (PR) in 21 (20.4%) and stable disease (SD) in 43 (41.7%) patients. With a median follow up of 19.9 months (range, 0.1-41.4), the median PFS was 4.0 months (95% CI, 3.1-4.4 months) and median OS was 13.0 months (95% CI, 12.0-16.5 months). The patients who achieved ORR have significantly longer PFS (20.8 vs. 3.2 months, p < 0.001) and OS (not reach vs. 12.0 months, p < 0.001) than the non-ORR patients. The median PFS were similar regardless the KRAS mutation status, primary sidedness, or liver metastases. Multivariate analysis revealed that male, ECOG PS2, the number of metastatic sites ≥ 2, and RAS mutant were significantly associated with worse OS. The most common grade 3/4 adverse events were hand-foot syndrome (1.9%), stomatitis (1.9%), rash (1.0%), hypertension (1.0%), allergic reaction (1.0%), fatigue (1.0%) and fever (1.0%). 8(7.8%) patients experienced at least 1 dose modification or treatment interruption. No death was related to the treatment. **Conclusions:** In this study the R+S combination as salvage-line treatments in non-MSI-H mCRC achieved a promising clinical benefit, with a manageable safety profile. Female, ECOG PS0/1, single metastases, RAS wild type mCRC were associated with better OS. Clinical trial information: NCT04745130. Research Sponsor: None.

Safety and efficacy of D-1553 in KRAS G12C-mutated colorectal cancer: Results from a phase I/II study. *First Author: Dan-yun Ruan, Department of Medical Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University, Guangzhou, China*

Background: KRAS G12C mutation is an oncogenic driver that occurs in 3-4% of colorectal cancer (CRC). D-1553 is a novel oral and potent KRAS^{G12C} inhibitor. This phase I/II open-label study (NCT04585035) is an international multicohort study evaluating the safety, tolerability, pharmacokinetics (PK) and efficacy of D-1553 in patients (pts) with KRAS G12C mutated locally advanced or metastatic solid tumors. The Phase I part was conducted to determine the recommended phase 2 dose (RP2D) of D-1553. The Phase II part enrolled multiple expansion cohorts of different cancer types. The endpoints of the study include clinical activity, safety and PK. Here we report preliminary data from pts with locally advanced unresectable or metastatic CRC receiving $\geq$ RP2D of D-1553 monotherapy. **Methods:** Pts with locally advanced unresectable or metastatic CRC with progression after standard treatment were enrolled in the Phase I and Phase II parts of the study. Pts were required to have KRAS G12C mutations in tumor or ctDNA samples and no prior KRAS G12C directed therapy. The current analysis includes CRC patients who were treated with D-1553 at RP2D (600 mg BID in Phase I and II) and above (800 mg BID in Phase I) as monotherapy. **Results:** As of 30 December 2022, 24 pts with previously heavily treated locally advanced or metastatic CRC (54.2% male; median age, 61.5 years [range 44, 74]; ECOG PS 0/1: 45.8%/54.2%) were enrolled and received D-1553 600 mg (n = 23) or 800 mg (n = 1) BID monotherapy. 95.8% of pts had stage IV disease. 66.7% had $\geq$ 2 prior lines of therapy (median: 2 [range, 1, 6]). Median treatment duration was 5.75 (range 1.51, 11.83) months (mo) with a median follow-up of 6.64 (range 2.46, 13.11) mo. Confirmed ORR was 20.8% (5/24) (95% CI: 7.1%-42.2%), and DCR was 95.8% (23/24). Median PFS was 7.62 mo (95% CI, 2.89 to 9.53 mo). At the data cutoff date, 37.5% (9/24) of pts remain on study treatment. Treatment-related adverse events (TRAEs) of any grade occurred in 50% (12/24), most were grade 1 or 2 in severity. Two pts had grade 3/4 TRAEs (alanine aminotransferase increased, diarrhea, hypertension and hypokalaemia). No TRAEs were fatal or resulted in D-1553 discontinuation. The most common ($\geq$ 5%) TRAEs (any grade) were increased alanine aminotransferase or aspartate aminotransferase, increased total bilirubin or conjugated bilirubin, diarrhea, hypothyroidism and nausea. **Conclusions:** D-1553 demonstrated a tolerable safety profile and promising monotherapy activity in pts with heavily pretreated locally advanced or metastatic CRC and KRAS G12C mutations. This study is ongoing to further evaluate the safety and efficacy of D-1553 as monotherapy and in combination with cetuximab or chemotherapy in pts with locally advanced or metastatic CRC. Clinical trial information: NCT04585035. Research Sponsor: InventisBio Co., Ltd.

A multicenter randomized phase II trial comparing CAPOXIRI + bevacizumab with FOLFOXIRI + bevacizumab as first-line treatment in patients with metastatic colorectal cancer: Primary results of the QUATTRO-II study. *First Author: Hideaki Bando, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: FOLFOXIRI plus bevacizumab (Bev) is highly effective for treating patients (pts) with metastatic colorectal cancer (mCRC); however, high incidences of hematologic adverse events (AEs) and pump infusion of 5-FU q2wk can complicate treatment continuation. According to the safety lead-in (Step 1), CAPOXIRI plus Bev with 1600-mg/m² capecitabine (Cap), 130-mg/m² oxaliplatin (Ox), 200-mg/m² irinotecan (Iri), and 7.5-mg/kg Bev q3wk was the recommended phase 2 dose (Kotani D, et al., Invest New Drugs, 2021). Here, we report the results of the randomized phase II part (Step 2) of the QUATTRO-II study, which examined the efficacy and safety of CAPOXIRI + Bev versus FOLFOXIRI + Bev. **Methods:** Enrolled pts were ECOG PS 0 or 1, and had chemotherapy-naïve mCRC with wild-type or single heterozygous UGT1A1 *6/*28 genetic polymorphism. Pts were randomly allocated to FOLFOXIRI + Bev (Arm A) or CAPOXIRI + Bev (Arm B) in a 1:1 ratio. The induction treatment in Arm A/B was continued for 8/6 cycles (12/8 cycles at maximum if feasible), and the maintenance treatment was either 5-FU + leucovorin + Bev or Cap + Bev at the discretion of the investigators. The primary endpoint was progression-free survival (PFS), with the two groups deemed equivalent if the hazard ratio (HR) of the point estimate was 0.8 < HR < 1.25. Secondary endpoints were overall survival (OS), overall response rate (ORR), early tumor shrinkage (ETS), depth of response (DpR), and safety. **Results:** From June 2020 to June 2021, 103 pts (Arm A/B, 51/52 pts) were randomly assigned. Baseline characteristics, including age (median 60 years in both arms) and ECOG PS 0 (90%/94%), were well balanced between arms. At a median follow-up of 23.7 months, the median PFS (Arm A/B) was 10.6 months (95% CI 7.7–13.3)/10.9 months (95% CI 9.3–14.3; HR 1.119, P = 0.639), and the primary endpoint was met (HR: 0.8 < 1.119 < 1.25). The 2-year OS rate (Arm A/B) was 65.5% (95% CI 49.5–77.6)/74.3% (95% CI 59.8–84.2), with the median OS not reached. Moreover, the ORR was 76.5% (95% CI 62.5–87.2)/84.6% (95% CI 71.9–93.1). ETS was achieved in 71.4%/82.0% of pts, and the median DpR was 43.0%/54.2%. Incidences of major grade $\geq$ 3 AEs (Arm A/B) were as follows: neutropenia (68.6%/40.4%), febrile neutropenia (6.8%/11.5%), diarrhea (7.8%/17.3%), and appetite loss (7.8%/17.3%). No treatment-related deaths occurred. **Conclusions:** The efficacy of CAPOXIRI + Bev was comparable to that of FOLFOXIRI + Bev. Although CAPOXIRI + Bev was associated with increased incidences of certain nonhematologic AEs, it was well tolerated, with a decreased incidence of neutropenia and no unexpected safety signal. Good survival and response results suggest that CAPOXIRI + Bev could become a new first-line treatment option in pts with mCRC. Clinical trial information: NCT04097444. Research Sponsor: Chugai Pharmaceutical.

Impact of sex on the efficacy of first-line mFOLFOX6 (plus or minus bevacizumab) versus mFOLFOX6 (plus or minus bevacizumab) plus Y90-radioembolization in patients with metastatic colorectal cancer: An exploratory, retrospective analysis of the phase III SIRFLOX trial. *First Author: Kathrin Heinrich, Department of Medicine III and Comprehensive Cancer Center (CCC Munich LMU), University Hospital, LMU Munich, Munich, Germany*

Background: Clinical trials in metastatic colorectal cancer (mCRC) investigating systemic and local treatment options are usually conducted irrespective of sex. However, sex-associated differences relating to safety and efficacy in the treatment of mCRC are of gaining interest. **Methods:** The SIRFLOX trial investigated the efficacy and safety of adding radioembolization using yttrium-90 resin microspheres (SIRT) to standard fluorouracil, leucovorin, and oxaliplatin (FOLFOX)-based chemotherapy in patients with previously untreated mCRC comparing it to standard treatment with FOLFOX-based chemotherapy. In this post-hoc analysis, the study population was stratified for sex (male versus female) using Propensity Score Matching (PSM) with baseline variables with difference (p-value < 0.20) in a gender specific comparison serving as matching covariates (age, BSA, sidedness, bilirubin). Groups were matched in a 1:1 ratio, with the nearest calculated propensity logit, with a caliper width of $\leq$ 0.20 of the SD of the propensity score logit. Evaluated efficacy endpoints were progression-free survival (PFS, primary endpoint of the trial) and overall survival (OS). **Results:** 356 (67.2%) male and 173 (32.6%) female patients were randomized and treated in the SIRFLOX trial. In the overall study population, there was no difference regarding PFS or OS between male and female patients. No difference in PFS and OS between male (n = 101) and female (n = 101) patients could be observed independently of treatment arm. After PSM, female patients showed significant benefit regarding PFS from SIRT + chemotherapy compared to chemotherapy alone (12.2 [9.9-17] vs. 9.9 [7.5-12.7], p = 0.047) that translated into a trend to longer OS (27.3 [25.6-36.5] vs. 23.7 [17.8-28.8] months, p = 0.094, HR 0.68 [0.43-1.10]) while male patients did not show a difference regarding PFS and OS between treatment arms (p = 0.170, HR 1.41 [0.87-2.10]). In the experimental arm, female patients had significantly longer OS compared to male patients (27.3 [25.6-36.5] vs. 21.0 [17.9-26.7] months, p = 0.031, HR 0.64 [0.42-0.96]). Sex did not impact on OS in the chemotherapy arm (p = 0.410, HR 1.22 [0.76-2.02]). **Conclusions:** In the SIRFLOX trial, female patients seem to benefit from the addition of SIRT to chemotherapy regarding PFS and OS. This was not observed in male patients. To our knowledge, this is the first analysis to show sex-differences in the application of SIRT in patients with mCRC. Our results support the development of specific protocols according to sex. Clinical trial information: NCT00724503. Research Sponsor: None.

Poster Session

Associations between early tumor shrinkage (ETS)/depth of response (DpR) and overall and post-progression survivals (OS/PPS) from the Analysis and Research in Cancers of the Digestive System (ARCAD) database. *First Author: Hideaki Bando, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: According to the various types of clinical trials for metastatic colorectal cancer (mCRC), ETS and DpR are suggested as the surrogates of OS. Whereas associations between ETS/DpR and OS/PPS in the era of chemotherapy (chemo) +anti-EGFR antibody (ab)/bevacizumab (bev) in 1st line therapy have not been elucidated. **Methods:** From 40,889 Individual patient data (IPD) from 59 studies in ARCAD mCRC database, 2,138 treatment-naïve pts with RAS wild-type (wt) mCRC were selected from 7 randomized studies (PRIME, CAIRO2, CRYSTAL, OPUS, CALGB80495, WJOG4407G, ATOM) of chemo with/without anti-EGFR ab or bev. The ETS was defined as 20% $\geq$ tumor shrinkage at 8 $\pm$ 2wks (ETS+ $\geq$ 20%, ETS- < 20%). Multivariate Cox regression models for OS/PPS were performed to investigate associations between ETS+ and ETS- by primary tumor location (overall/left-sided/right-sided), adjusting for potential confounders. DpR was defined as tumor shrinkage at nadir. OS/PPS were evaluated across quartile limits of DpR by multivariate Cox regression models. **Results:** In pts with overall or left-sided RAS wt mCRC, adjusted hazard ratios (HRs) of OS/PPS between ETS- and ETS+ for chemo +anti-EGFR ab, chemo +bev, and chemo alone showed great improvement, respectively (Table). In pts with overall or left-sided RAS wt mCRC, HRs of ETS for OS/PPS are higher in pts treated with chemo +anti-EGFR ab compared to those treated with chemo +bev or chemo alone. Compared to the pts with highest quartile (defined as $\geq$ 75th percentile (Q3)) of DpR, HRs of OS/PPS for lower quartile groups showed upward trends in pts with RAS wt & overall (Table). **Conclusions:** ETS/DpR in pts with RAS wt mCRC might be a potential prognostic marker of OS/PPS regardless of targeted therapy and primary tumor location. Superior prognostic values of ETS+ are expected in pts treated with anti-EGFR ab. Research Sponsor: ARCAD foundation and ARCAD-Asia.

Reversion of *RAS* mutations in metastatic colorectal cancer in the CCTG CO.26 clinical trial. First Author: Florence T.H. Wu, University of British Columbia & BC Cancer, Vancouver, BC, Canada

Background: *RAS* mutations in metastatic colorectal cancer (mCRC) drive resistance to anti-EGFR antibodies. It is unclear if *RAS* mutations are ever clonally lost, potentially uncovering a new therapeutic option for patients over time. **Methods:** We examined the temporal evolution of *RAS* mutation status among patients enrolled in CO.26 [NCT02870920] – a phase II clinical trial that assessed durvalumab + tremelimumab in patients with heavily pretreated mCRC – using whole exome sequencing (WES) of archival primary tumor tissue and circulating tumor DNA (ctDNA) sequencing of serial plasma samples that were taken at baseline, week 8 and on progression. **Results:** Six out of 95 (6.3%) patients diagnosed with *KRAS*/*NRAS*-mutated mCRC showed 'neo-*RAS*-wildtype' reversions at the time of baseline or week-8 ctDNA collection for the CO.26 trial. The majority (4/6) had falling tumor mutation burden (TMB) but stable or rising maximum mutation allele frequency (MAF) when reversions occurred. These were unlikely false negatives from non-secreting cancers as there were continued strong presence of other somatic clonal mutations (e.g., *TP53*, *ATM*). The majority (4/6) of reversions were transient, with mutations reappearing with progressive disease. 'Neo-*RAS*-wildtype' reverts had numerically longer median overall survival (OS) from date of cancer diagnosis to death compared to those with persistent *RAS* mutations (7.7 vs. 4.2 yrs, HR = 0.65, 95% CI 0.31 to 1.36, log-rank $P=0.26$). However, 'neo-*RAS*-wildtype' reverts were earlier-stage at diagnosis compared to those with persistent *RAS* mutations (33% vs. 63% had synchronous metastases, $\chi^2 P=0.15$), and had lower disease burden upon enrollment (50% vs. 68.5% had liver metastases, $P=0.17$; 33% vs. 75% had > 4 lesions, $P=0.03^*$). Survival from stage IV diagnosis to death did not differ between those with reverted vs. persistent *RAS* mutations (median 3.8 vs. 3.2 yrs, HR = 0.77, 95% CI 0.35 to 1.72, $P=0.52$). 'Neo-*RAS*-wildtype' reversions were not associated with side of primary tumors ($P=0.41$), archival *BRAF*/*MEK*/*ERK*-mutant status ($P=0.16$, 1.00, 0.09), baseline *HER2* amplifications ($P=1.00$), or baseline TMB ($P=0.21$). **Conclusions:** We identified a 6.3% prevalence of 'neo-*RAS*-wildtype' reversions in the CO.26 trial, however only 2.1% of patients had persistent loss when serial time points were considered. Further research is needed to understand if 'neo-*RAS*-wildtype' reverts may benefit from anti-EGFR therapy. Clinical trial information: NCT02870920. Research Sponsor: The Canadian Clinical Trials Group is funded by the Canadian Cancer Society.

Predictive impact of *RNF43* mutation (mut) in patients (pts) with pMMR/MSS *BRAF V600E* mutated metastatic colorectal cancer (mCRC) treated with target therapy (TT) or chemotherapy (CT). First Author: Marco Maria Germani, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa & Unit of Medical Oncology 2, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy

Background: Encorafenib plus cetuximab is a standard option in the treatment of *BRAF V600E* mut mCRC pts pre-treated with at least one systemic therapy. *RNF43* is a negative regulator of WNT pathway. A recent study showed that *RNF43* mutation is associated with better outcome among pMMR/MSS *BRAF V600E* mut mCRC patients treated with TT but not in an independent cohort of pts not treated with TT (Elez et al. Nat Med 2022). However, no comparison is available between TT vs CT as second-line (2L) treatment for pMMR/MSS *BRAF V600E* mut mCRC according to *RNF43* mutational status. **Methods:** The predictive impact of *RNF43* mut was evaluated in a real-life dataset of 126 pMMR/MSS *BRAF V600E* mut mCRC pts treated with TT (consisting of *BRAF* inhibitor + anti-EGFR antibody $\pm$ MEK inhibitor) vs CT $\pm$ target agent as 2L treatment. A cohort of 36 pts receiving TT after 2L was also analyzed. **Results:** Thirty-one (25%) and 95 (75%) out of 126 pMMR/MSS *BRAF V600E* mut tumours were *RNF43* mut and *RNF43* wt, respectively. In the *RNF43* mut group 14 (45%) received CT and 17 (55%) TT; in the *RNF43* wt group, 56 (59%) and 39 (42%) received CT and TT, respectively. Among *RNF43* mut pts, those treated with TT reported longer PFS (7.1 vs 3.0 months, HR: 0.35 95%CI: 0.16-0.76, $p=0.006$) and higher ORR (42% vs 0%, $p=0.009$) than those receiving CT. On the other hand, no significant difference was observed among *RNF43* wt patients in terms of PFS (4.3 vs 3.7 months, HR: 0.69 95% CI: 0.45-1.05, $p=0.080$) and ORR (28% vs 16%, $p=0.24$). However, no significant interaction between treatment effect and *RNF43* mutational status was reported in terms of PFS ($p_{\text{interaction}}=0.17$) and ORR ($p_{\text{interaction}}=0.96$). After excluding 36 pts in the CT group that received TT after 2L, no interaction effect was observed also in terms of OS ($p_{\text{interaction}}=0.53$). However, among *RNF43* mut pts, those treated with TT reported longer OS (16.5 vs 10.1 months; HR: 0.34 95% CI: 0.11-1.00, $p=0.049$), while no significant difference was observed among *RNF43* wt pts (10.6 vs 6.6 months; HR: 0.66 95% CI: 0.39-1.11; $p=0.12$). In the group receiving TT after 2L, 9 (25%) out of 36 cases were *RNF43* mut and achieved higher ORR (78% vs 26%, $p=0.014$) and longer PFS (10.1 vs 4 months; HR: 0.35 95%CI: 0.14-0.88; $p=0.020$) and OS (11.7 vs 7 months; HR: 0.35 95%CI: 0.15-0.82; $p=0.012$) than *RNF43* wt (N = 27). **Conclusions:** pMMR/MSS *BRAF V600E* mut mCRC patients achieve benefit from TT vs CT independently of *RNF43* mutational status, but a higher magnitude of benefit from TT is observed among those with *RNF43* mut tumors. These findings deserve confirmation in past and current randomized trials (i.e. BEACON and BREAKWATER). Research Sponsor: None.

Prognostic impact of depth of response (DpR) and early tumour shrinkage (ETS) in patients (pts) with *BRAF V600E* mutated (mut) metastatic colorectal cancer (mCRC) receiving targeted therapy (TT) as second-line treatment. First Author: Guglielmo Vetere, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa & Unit of Medical Oncology 2, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy

Background: Encorafenib and cetuximab (EC) is the standard of care for pre-treated patients (pts) with *BRAF V600E* mut mCRC. DpR and ETS previously showed a strong correlation with survival outcomes in mCRC pts receiving 1st-line therapy. We assessed these tumour dynamic response parameters and their association with clinical outcome in pts with *BRAF V600E* mut mCRC treated with TT in second-line. **Methods:** Patients treated in a real-life setting with EC or EC plus binitinib (ECB) in 20 Italian centres were included. Pts with measurable disease and at least one available disease reassessment by CT scan were eligible. Pts experiencing disease progression as best response (i.e. primary resistant) were not evaluable for DpR and ETS. Associations between DpR and ETS and progression free survival (PFS) and overall survival (OS) were tested by univariate and multivariate models. **Results:** 105 pts were included: 89 (85%) and 16 (15%) pts were treated with EC and ECB, respectively. Median PFS and OS were 5.2 and 10.3 mos, respectively. Twenty-nine pts (28%) were primary resistant, while 76 (72%) pts achieved disease control (51 [48%] and 25 [24%] pts had SD or CR/PR, respectively). Among baseline characteristics, the presence of peritoneal metastases was a predictor of primary resistance ($p=0.04$). Among pts evaluable for response parameters ($n=76$), median DpR was 15% and ETS occurred in 28 pts (37%). Mucinous histology was associated with a significantly lower magnitude of DpR ($p=0.005$) and a lower rate of ETS ($p=0.002$). A significant association between DpR and PFS was observed, both as a dichotomous (ie, $\geq$ or < median value) and continuous variable in univariate and multivariate analyses. Also RECIST response correlated with PFS in the two models (table). DpR was associated with OS in the univariate analyses, but this was not confirmed in the multivariate models (table). No correlation between ETS and survival, either as a dichotomous (ie, $\geq$ or < 20%) or a continuous variable, was observed. **Conclusions:** Having a DpR of at least 15% predicts longer PFS and OS in patients with *BRAF V600E* mut mCRC receiving TT as second-line treatment. An independent cohort of pts treated with second-line chemotherapy +/- antiangiogenic is under investigation as control group. Research Sponsor: None.

Transcriptomic signatures of MSI-high metastatic colorectal cancer to predict efficacy of immune checkpoint inhibitors. First Author: Claire Gallois, Institut du Cancer Paris CARPEM, APHP, Digestive Oncology Department, APHP.Centre - Université Paris Cité, Hôpital Européen G. Pompidou, Paris, France

Background: Microsatellite instability (MSI) is currently the only predictive biomarker of efficacy of immune checkpoint inhibitors (ICI) in metastatic colorectal cancers (mCRC). However, 10-40% of patients with MSI mCRC will experience a primary resistance to ICI. **Methods:** In a cohort of 103 patients with MSI mCRC treated with ICI, 3'RNAseq was performed from primary tumors resected before the beginning of ICI. Previously described single-cell transcriptomic signatures of tumor microenvironment (TME) were analysed. **Results:** The unsupervised clustering of this cohort allowed the identification of three clusters of tumors with distinct transcriptional profiles: cluster A ("stromal^{HIGH}-proliferation^{LOW}"), cluster B ("stromal^{HIGH}-proliferation^{MED}"), and cluster C ("stromal^{LOW}-proliferation^{HIGH}"), with an enrichment of patients progressing at first disease assessment under ICI in the cluster A (30% vs 12% in cluster B and 8.1% in cluster C, $p=0.074$). Progression-free survival (PFS) was also significantly shorter in patients belonging to cluster A, compared to clusters B or C ($p<0.001$) with 2-year PFS rates of 33.5%, 80.5% and 78.3%, respectively. Similar results were observed for overall survival (OS). In multivariate analysis, PFS was still significantly longer in patients belonging to cluster B (HR: 0.26 95%CI 0.11-0.58, $p=0.001$) and cluster C (HR: 0.35 95%CI 0.16-0.78, $p=0.01$), compared to patients belonging to cluster A (Table). No association of identified clusters with PFS during non-ICI-based regimens was identified. **Conclusions:** This unsupervised transcriptomic classification identified three groups of MSI mCRCs with different compositions of TME cells and proliferative capacities of TME/tumor cells. The "stromal^{HIGH}-proliferation^{LOW}" cluster is associated with a lower efficacy of ICI. Research Sponsor: None.

Intermittent or continuous panitumumab plus FOLFIRI (FOLFIRI/PANI) for first-line treatment of patients (pts) with RAS/BRAF wild-type (wt) metastatic colorectal cancer (mCRC): An update of survival/toxicity and preliminary results of genomic alterations from IMPROVE study. *First Author: Antonio Avallone, Istituto Nazionale Tumori-IRCCS Fondazione G. Pascale, Napoli, Italy*

Background: IMPROVE is a randomized, non-comparative multicenter, phase 2 study which evaluated continuous, until progressive disease (PD), or intermittent FOLFIRI/PANI, in pts with unresectable and previously untreated RAS/BRAF wt mCRC. In the intermittent schedule 8 cycles were followed by a treatment free interval lasting until PD when another 8 cycles were restarted, continuing this strategy until PD occurred on treatment. Primary endpoints was progression-free survival on treatment (PFSOT) at 1 year. In a previous analysis the primary endpoint of the study was met and a reduced skin toxicity was observed in the intermittent arm. Here we report an updated analysis. **Methods:** Updated analysis includes PFSOT and toxicity with 9 months (mo) of additional follow-up. Moreover we report overall survival (OS), skin toxicity burden (STB) score and preliminary data on genomic alterations (GAs) in 46 pts with PD. STB score, incorporating both the frequency and the severity of skin toxicity, was obtained by summing all grades that the pts experienced across all treatment cycles. GAs were performed by NGS on circulating tumor DNA (ctDNA) from paired plasma samples (baseline and progression), focusing specifically on RAS, BRAF and PI3K mutations. **Results:** Pts received FOLFIRI/PANI continuously (arm A, 69 pts) or intermittently (arm B, 67 pts). Median number of FOLFIRI/PANI cycles administered per pt were (arm A/B) 13/16. In arm B, after induction treatment, 24/53 pts (45%) without PD had $\geq$ 2 rounds of 8 FOLFIRI/PANI cycles. ORR (arm A/B) was 63/57%. At a median follow-up of 28 mo (IQR: 21-37), median PFSOT (77% of events) was 11.4 mo (95% CI: 9.1-13.7) in arm A, and 18.1 mo (95% CI: 6.8-29.3) in arm B. Median PFSOT in left sided tumors was 11.7 mo (95% CI: 9.1-14.3) in arm A and 23.9 mo (95% CI: 15.0-32.9) in arm B, compared with 10.7 mo (95% CI: 7.3-14.1) and 7.9 mo (95% CI: 5.7-10.1) in right sided pts, respectively. OS (46% of events) was 31.0 mo (95% CI: 24.7-37.2) in arm A and 32.2 mo (95% CI: 23.6-40.8) in arm B. Main grade $\geq$ 3 toxicities were (arm A/B): skin 30/18%, neutropenia 25/24%; diarrhea 13/15%. Median STB score was 0.77/cycle (IQR: 0.20-1.06) in arm A and 0.36/cycle (IQR: 0.0-0.77) in arm B. GAs in baseline ctDNA were evidenced in 12/46 (26%) pts, persisting to PD in all but one pt. Among the 34 pts without baseline GAs, only 8 (23%) developed $\geq$ 1 acquired GAs (Acq-GAs) to PD. **Conclusions:** Updated analyses confirmed that intermittent FOLFIRI/PANI strategy produces a long PFSOT and a reduced skin severe and skin burden toxicity without any detrimental effect on OS. Preliminary data on Acq-GAs suggest that classical mutations associated with anti-EGFR resistance are infrequent with up-front use of anti-EGFR/chemotherapy. Clinical trial information: NCT04425239. Real-world comparison of triplet- versus doublet-chemotherapy with bevacizumab in patients with newly diagnosed metastatic colorectal cancer (mCRC). *First Author: William Joseph Chapin, Abramson Cancer Center at the University of Pennsylvania, Philadelphia, PA*

Background: Meta-analysis of five randomized intensification trials in mCRC demonstrated an overall survival (OS) benefit of triplet chemotherapy (5FU/leucovorin, oxaliplatin, irinotecan) plus bevacizumab (Triplet/Bev) compared to doublet chemotherapy plus bevacizumab (Doublet/Bev) (HR 0.81). Guidelines recommend first-line Triplet/Bev for patients with excellent performance status and normal organ function who can withstand increased toxicity, but such patients are less represented in the real world. In this retrospective cohort study, we examine the real-world effectiveness of Triplet/Bev compared to Doublet/Bev in the U.S. **Methods:** We used the nationwide Flatiron Health electronic health record-derived database, comprising de-identified patient-level structured and unstructured data curated via technology-enabled abstraction from ~ 280 cancer clinics. Included were mCRC patients treated with first-line Triplet/Bev or Doublet/Bev between 10/23/14 and 10/31/22. OS by treatment was assessed using the Kaplan Meier method and adjustment for confounding variables was performed using Cox proportional hazards modeling with stabilized inverse probability of treatment weighting (IPTW). Pre-specified confounding variables included age, gender, race/ethnicity, year of metastatic diagnosis, health insurance, practice setting, KRAS/NRAS/BRAF mutation status, MMR/MSI status, synchronous/metachronous metastases, primary tumor sidedness, CEA, renal dysfunction, hepatic dysfunction, and ECOG performance status. Missing data were imputed using multiple imputation with chained equations. **Results:** Among 10,016 patients, 391 (3.9%) received Triplet/Bev and 9,625 (96.1%) received Doublet/Bev. Patients who received Triplet/Bev were younger (median age 52 vs 63 years) and were more likely to be treated at academic practices (27% vs 8%), to have synchronous metastatic disease (83% vs 65%), and to have KRAS/NRAS/BRAF wild-type disease (30% vs 17%). In the univariate analysis, median OS was 30.0 months (95% CI 24.7 – 34.7) in the Triplet/Bev cohort versus 23.4 months (95% CI 22.8 – 24.1) in the Doublet/Bev cohort (HR 0.73; 95% CI 0.62 – 0.85; $p < 0.001$). In Cox proportional hazards modeling with IPTW, there was no significant difference in hazard of death between Triplet/Bev and Doublet/Bev (HR 0.92; 95% CI 0.75 – 1.12; $p = 0.4$). **Conclusions:** In this large, national, real-world population of patients with mCRC, first-line treatment with Triplet/Bev was not associated with improved survival compared to Doublet/Bev after accounting for differences in baseline patient characteristics. The benefit to Triplet/Bev observed in randomized trials does not translate well to a more heterogeneous, real-world population. Sub-group analyses including by age, tumor sidedness, KRAS/NRAS/BRAF status, and baseline CEA level will be performed. Research Sponsor: None.

Impact of WNT/B-catenin alterations and metastasis location among patients with metastatic colorectal cancer (mCRC) treated with immune checkpoint inhibitors (ICI) combinations. *First Author: Javier Ros Montaña, Vall d'Hebron Institute of Oncology (VHIO), Vall d'Hebron University Hospital, Barcelona, Spain*

Background: Emerging evidence suggests that WNT mutations and liver/peritoneal metastases in mCRC may have an immunosuppressive role that could affect ICI activity. **Aim:** To evaluate the impact of WNT alterations and liver/peritoneal metastasis among patients with mCRC treated with ICI. **Methods:** Patients from Vall d'Hebron Hospital, with mCRC treated with ICI from 2017-2022 were included. WNT alterations (APC, AXIN1/2, CTNNB1, FBXW7, EPHB2, RNF43 and SOX9) were evaluated using NGS (tissue). Clinical outcomes were calculated using survival Kaplan-Meier curves. Patients' characteristics were collected retrospectively. **Results:** Overall, 104 patients were included (66 MSI patients and 38 MSS patients). Among MSI patients, median age was 63 years (22-95), with 53% female, and 64% of patients received immunotherapy in 1st or 2nd line. Regarding tumor characteristics, 72% were right-sided and 82% harbored WNT alterations. 75% of patients presented with liver/peritoneal metastases. Patients with WNT mutations and peritoneal/liver metastases exhibit lower ORR (46% vs 57% $p < 0.5$ and 45% vs 75%, $p < 0.03$ respectively). Peritoneal/liver metastases were associated with lower PFS (HR 3.6 CI95% 1.27-10.24 $p < 0.02$ respectively). Overall, tumors with WNT pathway alterations tend to have shorter PFS and OS. Liver metastases were associated with lower OS (NR vs 34 months HR 2.49 CI95% 1.01-6.17 $p < 0.05$). Table summarizes outcomes. Among MSS patients, median age was 57 years (41-75), with 25% female and 92% of patients receiving immunotherapy $\geq$ 3rd line. Regarding tumor characteristics, 78% were left-sided and 90% harbored WNT alterations. 79%, of patients presented with liver or peritoneal metastases. WNT mutations were not associated with ORR, patients without liver/peritoneal metastases tend to have higher ORR (12.5% vs 3.3% $p < 0.335$). Patients with WNT alterations had worse PFS (9.23 vs 1.87 months, $p < 0.12$), and liver metastases were associated with lower PFS (6.98 vs 1.79 months HR 2.87 CI95% 1.17-7.09 $p < 0.02$). Regarding OS, tumors harboring WNT alterations have shorter OS (8.4 vs 12 months $p < 0.63$). The presence of liver or peritoneal metastases was associated with lower OS (NR vs 7.85 months HR 3.69 CI95% 1.09-12.55 $p < 0.04$). **Conclusions:** In our cohort, WNT pathway mutations, and liver metastases were associated with worse ORR, PFS, and OS regardless of MSI status. These findings need further validation in a prospective cohort. Research Sponsor: This research has been partially funded by CaixaResearch Advanced Oncology Research Program supported by Fundació La Caixa (LCF/PR/CE07/50610001).

Modified FOLFOXIRI plus cetuximab and avelumab as initial therapy in RAS wild-type unresectable metastatic colorectal cancer: Results of the phase II AVETRIC trial by GONO. *First Author: Veronica Conca, Unit of Medical Oncology 2, Azienda Ospedaliera Universitaria Pisana, Pisa, Italy and Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy, Pisa, Italy, Italy*

Background: The modified schedule of FOLFOXIRI (mFOLFOXIRI) in combination with an anti-EGFR agent showed a manageable safety profile and remarkable activity in RAS wild-type (wt) metastatic colorectal cancer (mCRC). The association of an active cytotoxic regimen with cetuximab (cet) may increase the exposure of tumour-associated neoantigens and induce immunogenic cell death and antibody-dependent cell-mediated cytotoxicity thus enabling the effect of immune checkpoint inhibitors. The AVETRIC study aimed at exploring the efficacy and safety of first-line mFOLFOXIRI plus cet and avelumab (ave) in RAS wt mCRC patients (pts). **Methods:** AVETRIC is a prospective, open label, multicenter, phase II, single arm trial in which initially unresectable and previously untreated RAS wt mCRC pts received mFOLFOXIRI (irinotecan 150 mg/sqm, oxaliplatin 85 mg/sqm, folinate 200 mg/sqm leucovorin [LV], and 5-fluorouracil [5FU] 2400 mg/sqm) plus cet (500 mg/sqm) and ave (800 mg) every 2 weeks up to 12 cycles followed by maintenance with 5FU/LV plus cet and ave until disease progression. A safety run-in phase including the first 6 enrolled pts was planned. Due to the occurrence of grade 3-4 diarrhoea in 2 (33%) pts, the protocol study was amended to reduce the irinotecan dose to 130 mg/sqm. Primary endpoint was Progression Free Survival (PFS). Fifty-eight pts were needed to detect an increase in median PFS (mPFS) from 10.0 to 19.4 months (mos), setting one-sided α and β errors at 0.05 and 0.10, respectively. The trial is registered at Clinicaltrial.gov, NCT04513951. **Results:** Between Jun 2020 and Dec 2021, 62 pts were enrolled in 16 Italian centres. Main pts' characteristics were: median age 56 yrs, ECOG PS 0 87%, synchronous metastases 94%, liver-only disease 42%, left-sided primary tumour 89%; all pts had BRAF wt and proficient MMR (pMMR) tumours. The primary endpoint was met. At a median follow-up of 16.0 months, 39 (63%) events were recorded and mPFS was 14.1 months (90% CI 12.0-16.7, Brookmeyer-Crowley test $p < 0.001$). Response rate and disease control rate were 82% and 98%, respectively, and R0 resection rate was 21% (27% in liver-only subgroup). Early tumour shrinkage was achieved in 74% pts and median deepness of response was 56%. In pts treated after study amendment ($n = 56$), main grade 3-4 adverse events were neutropenia (27%), diarrhoea (27%), skin rash (14%), asthenia (14%), nausea (11%), stomatitis (7%), febrile neutropenia (2%). Grade 3-4 immune-related adverse events occurred in 6% of pts. Overall survival results are still immature. **Conclusions:** AVETRIC study met its primary endpoint, showing that combining mFOLFOXIRI plus cet and ave achieves promising results in terms of PFS as well as response rate, in pts with pMMR RAS and BRAF wt mCRC. Translational analyses to evaluate the impact of immune-related biomarkers are ongoing. Clinical trial information: NCT04513951. Exploring the prognostic and predictive impact of genomic loss of heterozygosity (LOH) in patients with metastatic colorectal cancer (mCRC). *First Author: Martina Carullo, Unit of Medical Oncology 2, Azienda Ospedaliera Universitaria Pisana and Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Italy, Pisa, Italy*

Background: Genomic LOH consists in the loss of chromosomal regions and is associated with the homologous recombination repair (HRR) system deficiency (dHRR). In ovarian cancer, LOH-high predicts benefit from platinum-based chemotherapy and PARP inhibitors. In mCRC, the role of LOH has been poorly investigated. **Methods:** An NGS-based assay (FoundationOne CDx; Foundation Medicine, Inc. Cambridge, MA) was used to determine the percentage of genomic LOH and the presence of pathogenic mutations in HRR-related genes in archival chemo-naïve tumor tissues of mCRC patients included in a real-world registry and in the AtezoTRIBE (NCT03721653) and AVETRIC (NCT04513951) studies. Both these trials assessed the combination of an anti-PDL1 (atezolizumab or avelumab) with the triplet FOLFOXIRI plus bevacizumab or cetuximab. The prespecified cut-off of ≥ 14.08 for LOH-high described for mCRC (Sokol et al., JCO Precis Oncol 2020) was adopted. Tumors with at least one biallelic alteration in any of the 27 genes involved in the HRR pathway (Riaz et al., Nat Commun 2017) included in the FoundationOne CDx panel (BARD1, BRCA1, BRCA2, BRIP1, MRE11A, NBN, PALB2, RAD51, RAD51B, RAD51C, RAD51D, RAD52, RAD54L, RBBP8, XRCC2, ABL1, ATM, ATR, BAP1, CDK12, DNMT3A, ERCC4, FANCA, FANCC, FANCG, FANCL, PARP1) were defined dHRR. **Results:** Overall, 196 samples were analysed. None of 7 MSI-H tumors were classified as LOH-high. Fourteen (7%) and 6 (3%) of 189 MSS tumors were classified as LOH-high and dHRR, respectively. In particular, in LOH-high subgroup, 3 (21%) tumors were defined dHRR, while 3 (50%) tumors were classified LOH-high among dHRR tumors. LOH-high tumors were more frequently BRAF mutated ($p = 0.019$) and dHRR ($p = 0.006$) compared to LOH-low. Among patients receiving triplet chemotherapy +/- biologic agent alone ($N = 55$) or with an anti-PDL1 ($N = 58$), an interaction effect was shown between the effect of the addition of the checkpoint inhibitor and LOH with higher benefit in the LOH-high subgroup ($N = 10$) in terms of both PFS ($p_{\text{interaction}} = 0.002$) and OS ($p_{\text{interaction}} < 0.001$). In the cohort of patients not receiving the anti-PDL1, longer PFS was observed in patients with LOH-low ($N = 125$) respect to LOH-high ($N = 6$) tumors (12.1 vs 5.1 months, HR: 0.11, 95%CI: 0.04-0.26, $p < 0.001$). No differences in PFS or OS were reported between patients treated with first-line oxaliplatin- ($N = 40$) vs irinotecan-based doublets ($N = 25$) or with the triplet FOLFOXIRI ($N = 55$) vs doublets ($N = 65$) according to LOH status. No prognostic or predictive impact of HRR deficiency was shown. **Conclusions:** In MSS mCRC, LOH-high was associated with biallelic alterations in the HRR system, worse prognosis and higher benefit from the addition of anti-PDL1 agents to chemotherapy. Considering the low number of LOH-high tumors in our study, these results deserve confirmation in larger cohorts. Research Sponsor: None.

Single nucleotide polymorphisms (SNPs) in MHC class I and II genes to predict outcome in patients (pts) with metastatic colorectal cancer (mCRC): Data from FIRE-3, MAVERICC, and TRIBE trials. *First Author: Pooja Mittal, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: The immune system is alerted for virally infected cells in the body by the antigen presentation pathway, which is in turn mediated by the major histocompatibility complex (MHC) class I and II molecules. Cancer cells overcome immune evasion as a major hallmark by downregulation of antigen presentation pathway molecules. Therefore, the present study aimed to explore the effect of genetic variants in MHC class I and II pathways on first-line treatment outcome in mCRC pts. **Methods:** Genomic DNA from blood samples of 775 pts enrolled in three independent, randomized, first-line trials: TRIBE (FOLFIRI-bevacizumab [bev], $N = 215$), FIRE-3 (FOLFIRI-bev, $N = 107$; FOLFIRI-cetuximab [cet], $N = 129$) and MAVERICC (FOLFIRI-bev, $N = 163$; FOLFOX-bev, $N = 161$) was genotyped through OncoArray, a custom array manufactured by Illumina including approximately 530K SNP markers. The impact on outcome of 40 selected SNPs in 22 genes of MHC class I and II pathways (ERAP1, ERAP2, TAP1, TAP2, TAPBP, B2M, HLA-A, HLA-B, HLA-C, HLA-E, HLA-F, HLA-G, CIITA, HLA-DMA, HLA-DMB, HLA-DOA, HLA-DOB, HLA-DPA1, HLA-DPB1, HLA-DQA1, HLA-DQB1 and HLA-DRA) was analyzed. **Results:** We identified several SNPs in multiple genes associated with targeted treatment benefit across different treatment arms in our study population ($P < .05$). Germline variants in ERAP1 rs2287987 were associated with worse PFS in pts receiving FOLFIRI-bev in TRIBE (10.4 vs 8.8 months, HR 1.48, 95%CI 1.04-2.12, $P = .035$) and FIRE-3 trials (11.1 vs 9.9 months, HR 3.46, 95%CI 1.18-10.12, $P = .049$), while rs26653 SNP in the same gene was associated with better PFS in MAVERICC (10.1 vs 14.5 months, HR 0.54, 95%CI 0.35-0.84, $P = .0062$). TAP1 rs1135216, TAP2 rs1800454 and rs1044043, HLA-B rs2770, HLA-G rs1610696, CIITA rs4774, HLA-DRA rs7192 were associated with longer OS and/or PFS in cet-treated pts in FIRE-3; whereas TAP2 rs241447, TAPBP rs3106191, HLA-DNB rs10751, HLA-DOB rs11244, HLA-DPB1 rs3097671 showed worse PFS and/or OS. SNPs in TAP2 (rs1800454), HLA-C (rs1049281), HLA-G (rs1063320), CIITA (rs1139564), HLA-DMB (rs1042337), HLA-DOA (rs375256, rs129303), HLA-DPA1 (rs1042190) and HLA-DRA (rs7192) were specifically associated with clinical outcomes in the FOLFOX-bev arm of MAVERICC but not in control cohorts of pts treated with FOLFIRI-bev. Treatment-SNP interaction analyses with targeted agents (bev vs cet) and chemotherapy backbone (FOLFIRI vs FOLFOX) confirmed a significant treatment interaction for HLA-G, TAP2, CIITA, and HLA-DMB SNPs ($P < .05$). **Conclusions:** Our results highlight an important role for MHC SNPs as prognostic and predictive biomarkers for first-line treatment in mCRC, with differential effects based on biologic agent and chemotherapy backbone. These biomarkers, when further validated, may contribute to personalized treatment strategies for mCRC patients. Analysis of primary and acquired resistance to cetuximab from multiomic data in the New EPOC trial. *First Author: Sian Alexandra Pugh, Department of Oncology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom*

Background: The use of cetuximab (cetux) with chemotherapy (chemo) in patients with operable liver metastases from colorectal cancer (CRC) conferred a survival disadvantage in New EPOC. Whilst genetic alterations such as emergent sub-clonal mutations in RAS/BRAF, ERBB2 and MET are recognized as mechanisms of resistance to EGFR inhibition (EGFRi), divergent mechanisms such as transcriptomic changes may also be responsible. Of the CRC intrinsic subtypes (CRIS), CRIS-C has elevated EGFR signalling and is thought to have greater sensitivity to EGFRi. **Methods:** Resected primary tumors ($n = 205$; pre neoadjuvant treatment) and/or liver metastases ($n = 144$; post neoadjuvant treatment) from 223 patients, wild type for KRAS (codons 12/13/61) at trial entry, randomized to chemo +/- cetux underwent targeted NGS and/or transcriptome profiling. Primary clinical endpoints were progression free (PFS) and overall survival (OS). **Results:** Repeat NGS identified additional RAS/BRAF mutations in primary tumors from 49 patients (25 KRAS, 15 NRAS, 9 BRAF V600E). Of the 148 patients with confirmed RAS/BRAF wild type primary tumors, 46% were classified as CRIS-C with the remainder being CRIS-A (9.5%), CRIS-B (11%), CRIS-D (8.8%) or CRIS-E (8.1%). CRIS-C patients had a similar PFS with ChemoCetux vs Chemo (HR 0.84 95% CI 0.47-1.5 $p = 0.55$) whereas non-CRIS-C had a shorter PFS (HR 2.12 95%CI 1.24-3.63 $p = 0.006$; p interaction 0.021). OS results were similar (p interaction 0.067). In liver metastases, genetic changes were comparable (Chemo vs ChemoCetux): KRAS (4.1% v 2.1%), NRAS (4.1% v 0%), BRAF V600E (0% v 0%), ERBB2 gain/amplification (20% v 21%) and MET gain/amplification (25% v 18%). However, gain/amplification of MET resulted in shorter OS with ChemoCetux vs Chemo (HR 5.13 95%CI 1.38-19.15 $p = 0.015$) whereas those without MET gain/amplification had a similar OS (HR 1.32 95%CI 0.76-2.28 $p = 0.32$; p interaction 0.029). The same association was found after excluding liver metastases with RAS/BRAF mutations ($n = 101$, p interaction 0.030). Differential expression/mutation analyses did not identify other stratifiers after false discovery correction. **Conclusions:** The shorter survival with ChemoCetux was restricted to patients with a non CRIS-C subtype before treatment supporting the use of this transcriptomic classifier to stratify for EGFRi. After neoadjuvant treatment, gain/amplification of MET was associated with a shorter survival with ChemoCetux. By contrast MAPK pathway mutations were largely unchanged supporting earlier findings that alternative resistance mechanisms predominate when EGFRi is combined with chemotherapy. In summary these results highlight the heterogeneity and differential responses to EGFRi that exist within RAS/RAF wild type CRC and provide insights into the substantial survival detriment observed in the New EPOC trial. Nipavect: Phase II study of niraparib and panitumumab in advanced RAS WT colorectal cancer. *First Author: Olatunji B. Alese, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Panitumumab (Pmab) is a recombinant monoclonal antibody that binds specifically to the human epidermal growth factor receptor (EGFR) and it is indicated for the treatment of metastatic colorectal carcinoma (mCRC). However, the objective response rates (ORR) for the single agent are historically about 8-11%. EGFR inhibition induces synthetic lethality with poly ADP ribose polymerase inhibitors (PARPi) such as Niraparib, by attenuating DNA repair pathways. Combining PARP and EGFR inhibition has the potential to confer synergistic benefit, while also ameliorating resistance mechanism to EGFRi. We conducted this study to define the safety and efficacy of the combination of Niraparib and Pmab in RAS wildtype (WT) mCRC. **Methods:** Patients (pts) with RAS WT mCRC who have progressed on at least one line of systemic chemotherapy were eligible for the trial. Other selected inclusion criteria were ≥ 18 years of age, ECOG PS 0-1 and measurable disease per RECIST 1.1. Pmab was administered at 6 mg/kg IV on days 1 & 15 of each 28-day cycle, while Niraparib was taken orally at 200mg or 300mg (based on body weight and platelet count) daily throughout the cycle. The primary endpoint was clinical benefit rate (CBR) defined as complete (CR) + partial (PR) response + stable disease (SD) per RECIST v1.1. Multiple secondary endpoints included safety/tolerability, ORR, progression-free survival (PFS), overall survival (OS), and duration of response (DoR). **Results:** A safety run-in cohort of 6 pts was initially enrolled. Following a preplanned safety analysis showing an acceptable toxicity profile, an additional 19 pts were enrolled. Of the total 25 enrolled pts, 24 were evaluable for response. Male - 50%; Whites/African Americans/Asians - 65.2%/21.7%/13%; median age - 58.5yrs. The majority had left sided tumor (92%) and the median line of prior therapy was 2 (range 1-4). CBR was 83.3% (0 CR, 6 PR, 14 SD) and ORR was 25%. mPFS - 5.6mos (95% CI: 3.7, 6.9); mOS - 20.9mos (95% CI: 9.2, NR). Six-month PFS and OS rates were 48.4% and 100% respectively. At a median follow up time of 7.5mos (95% CI: 4.2, 10.4), 3 patients remained on treatment and DoR was yet to be determined. Muco-cutaneous adverse events (AEs) of any grade included rash (58.4%), oral mucositis (20.8%), dry skin (16.7%) and paronychia (4.2%). Most common (grade > 2) treatment related AEs (TRAEs) were anemia (G3; 12.5%), dermatitis, oral mucositis, hypertension and neutropenia (G3; 4.2% each). There were no grade 4-5 TRAEs. **Conclusions:** The combination of Pmab and Niraparib had an acceptable safety profile, and showed considerable antitumor activity in pts with advanced RAS WT mCRC compared to historical rates. Additional biomarker analyses such as survival correlation with immune cell infiltration in paired skin biopsies and HER2/BRAF mutational status are ongoing. Funding and product (Niraparib) for the study were provided by GSK (NCT03983993). Clinical trial information: NCT03983993. Research Sponsor: GSK.

OniLon: Phase II trial of trifluridine/tipiracil (TAS-102) and nanoliposomal irinotecan (nal-IRI) in advanced colorectal cancer. *First Author: Olatunji B. Alese, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: TAS-102 (FTD/TPI) is a combination of a nucleoside analogue and a thymidine phosphorylase inhibitor, and has showed activity in 5FU-resistant CRC. Nal-IRI achieves higher intra-tumor concentrations than irinotecan (Iri; 142-fold) and its major metabolite, SN-38 (9-fold). This resulted in superior anti-tumor activity compared to free Iri in multiple tumor xenografts. Furthermore, multiple clinical trials have established the activity of nal-IRI in combination with 5FU in pancreaticobiliary cancers. The combination of nal-IRI with the more potent nucleoside analogue TAS-102 may thus result in a more effective systemic therapy. We conducted this study to define the safety and efficacy of the combination of TAS-102 and nal-IRI in advanced CRC. **Methods:** Eligible patients (pts) on this investigator-initiated phase II study had advanced CRC and must have had disease progression on at least one prior therapy. Additional inclusion criteria - measurable disease, ECOG PS 0-1 & adequate organ function. Based on previously published dose escalation phase I data, the pts were treated at the recommended phase II dose of TAS-102 (given orally at 35mg/m² bid on days 1-5) and nal-IRI (60mg/m² IV on day 1) in 14-day cycles. The primary endpoint was objective response rate (ORR) = complete (CR) + partial (PR) response per RECIST v1.1. Multiple secondary endpoints included safety/tolerability, progression-free survival (PFS), overall survival (OS), disease control rate (DCR) and duration of response (DoR). **Results:** Twenty-two pts were enrolled, of whom 20 were evaluable for response. Male - 50%; ECOG PS 1 - 75%; African Americans - 38%; median age - 58yrs (interquartile range [IQR] 49-67). Median line of prior therapy was 1 (IQR 1-2) and 13.6% (3 pts enrolled during the dose escalation phase) had received prior Iri. 47.6% received concurrent Bevacizumab. ORR was 15% (3 PR, 0 CR). 60% had stable disease (SD) as best response; DCR of 75%. mPFS - 9.7 mos (95% CI: 5.6, 14.2); mOS - 10.1 mos (95% CI: 7.3, 15.9). 12-month PFS and OS rates were 34.6% and 39.5% respectively. At a median follow up of 11.9 mos, DoR was yet to be determined and 50% of the pts had maintained response for 12 mos. Median duration of progression free among pts with SD was 7.6 mos (95% CI: 4.6, 13.2), with a 12-month survival rate of 47.7% (95% CI: 15.5%, 74.5%). Median time to response (TTR) was 4.8mos. Most common treatment related toxicities included fatigue and neutropenia (G3; 27.3% each); anemia and leucopenia (G3; 18.2% each). Other G3 AEs included febrile neutropenia, diarrhea, hypokalemia, lymphopenia and nausea (4.5% each). **Conclusions:** We demonstrated that the combination of TAS-102 and nal-IRI had an acceptable safety profile, and showed antitumor activity in patients with advanced CRC. Additional biomarker analyses such as survival correlation with UGT1A1 phenotype and RAS mutational status are ongoing. (NCT03368963). Clinical trial information: NCT03368963. Efficacy and safety of fruquintinib plus investigator's choice of chemotherapy as second-line therapy in metastatic colorectal cancer: A multicenter, single-arm phase 2 trial. *First Author: Wensi Zhao, Renmin Hospital of Wuhan University, Wuhan, China*

Background: Emerging evidence suggested that chemotherapy in combination with anti-angiogenic targeted agents can achieve higher response in multiple solid tumors. Fruquintinib is a highly selective small-molecule VEGFR inhibitor that has been approved for the third-line treatment in metastatic colorectal cancer (mCRC) patients in China. Here, we assessed the efficacy and safety of fruquintinib plus investigator's choice of chemotherapy as second-line therapy in pretreated advanced mCRC patients. **Methods:** In this prospective, open-label, multicenter, single-arm phase 2 trial (ChiCTR2200059280), patients with mCRC progressed after first-line prior systemic treatment were administered fruquintinib (5-3mg, D1-21, Q4w) and investigator's choice of chemotherapy (fluorouracil ± irinotecan ± oxaliplatin, Q3w) for up to 8 cycles. Patients without disease progression (PD) were followed by fruquintinib maintenance until PD or intolerable toxicity. The primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), disease control rate (DCR), duration of response (DOR), overall survival (OS), and safety. **Results:** As the data cutoff on February 10, 2023, 37 patients have been enrolled and treated, with 31 evaluable for efficacy. Median age was 63 years (range, 44-76) and 22 (59.5%) were male. The left colon cancer involved in 28 patients (75.7%). All patients were microsatellite-stable phenotype and 11 (29.7%) had mutations in KRAS gene. 16 (43.2%) patients received prior anti-VEGF therapy. 20 (54.1%) and 11 (29.7%) patients had liver and lung metastases respectively. At a median follow-up of 8.4 months, 28 patients are still on treatment. The ORR is 48.4%, with 15 partial response. The DCR is 90.3%. At data cutoff, median PFS has not yet reached. 23 patients (74.2%) remained progression free at 6 months. In terms of safety, the regimen was well tolerated, mainly grade 1/2 adverse events (AEs). Grade 3/4 AEs were neutropenia (21.6%), leukopenia (10.8%), thrombocytopenia (5.4%), proteinuria, diarrhea, hand-foot syndrome and hypertension accounted for 2.7% respectively. 5 pts received reduced doses of fruquintinib. No treatment-related deaths occurred. **Conclusions:** Fruquintinib combined with chemotherapy followed by fruquintinib maintenance shows promising efficacy and manageable safety profile for mCRC patients in second-line setting. Updated follow up data will be presented in the future. Clinical trial information: ChiCTR2200059280. Research Sponsor: National Natural Science Foundation of China (grant no.82102954).

Deep learning-derived spatial organization features on histopathology images to predict prognosis in patients with colorectal liver metastasis, after hepatectomy. *First Author: Xin Wang, Department of Surgery, The Chinese University of Hong Kong, Hong Kong SAR, China*

Background: Histopathological images of colorectal liver metastasis (CRLM) contain rich morphometric information that may predict patient outcomes, but current indicators depend on labor-intensive and subjective visual estimation. Herein, we aimed to develop an automated framework for tissue classification of routine H&E stained whole-slide images and establish a risk-scoring model for better prognosis prediction in patients with CRLM. **Methods:** Using 161,371 hand-delineated image patches, we trained a robust deep convolutional neural network-CRLM-SPA for accurate classification of CRLM into seven tissue types. With the tissue classification results on two independent in-house cohorts (SYSUCC: $n = 433$, BJCH: $n = 404$), we systematically quantified spatial organization features (SOFs), involving whole-slide, tumor-infiltrating and tumor-distal SOFs for different tissue types as well as the interactions between tumor and non-tumor tissues. Subsequently, univariate Cox proportional hazards regression analysis was performed to investigate the association between various SOFs and patient outcomes. Nonredundant SOFs that are clinically relevant were selected to build a risk-scoring model for prognosis using multivariate Cox regression analysis in the SYSUCC cohort, followed by validation in the BJCH cohort. **Results:** CRLM-SPA achieved an overall classification accuracy of $> 93\%$ in an independent set of 17,653 image patches. With the classification result, we calculated various SOFs and built a four-SOF risk-scoring model that significantly predicted overall survival (OS) in the discovery cohort, SYSUCC ($P = 1.40 \times 10^{-5}$; HR = 2.26; 95%CI: 1.55 - 3.29) and the independent validation cohort, BJCH ($P = 4.59 \times 10^{-4}$; HR = 2.00; 95%CI: 1.35 - 2.97). The prognostic performance of our SOF risk-scoring model is independent of the clinical risk score (CRS) system. Further stratification analyses in patients without preoperative chemotherapy (CTX) indicated that adjuvant CTX consistently improved OS in the SOF high-risk subgroups in both cohorts ($P = 0.018$ and 0.049), but not in the SOF low-risk subgroups. Furthermore, a combined scoring system incorporating SOF and CRS considerably improved the prognostic performance in both cohorts over the individual SOF and CRS systems. **Conclusions:** CRLM-SPA showed a high accuracy in tissue classification and robustness in extracting prognostic information from H&E images. The SOF risk-scoring system demonstrated a strong and robust prognostic value that is independent of CRS, and could therefore provide a time- and cost-efficient tool to assist clinical decision making for patients with CRLM. The impact of sodium-glucose cotransporter-2 inhibitors on the outcome of patients with colorectal adenocarcinoma. *First Author: Cho Han Chiang, Mount Auburn Hospital, Harvard Medical School, Cambridge, MA*

Background: The mortality of colorectal cancer remains high despite the development of novel anti-neoplastic agents. Preclinical studies have shown that colorectal cancer upregulates the expression of sodium-glucose cotransporter 2 (SGLT2) channels and inhibition of these channels by SGLT2 inhibitors (SGLT2i) reduces tumor proliferation. We aimed to investigate the impact of SGLT2i on the outcome of patients with colorectal cancer. **Methods:** We conducted a retrospective cohort study by including all adult patients with colorectal adenocarcinoma and type 2 diabetes mellitus in two tertiary centers in Taiwan. SGLT2i and non-SGLT2i patients were matched 1:1 based on age, sex, and cancer stage. The primary outcome was overall survival (OS) and progression-free survival (PFS), and the secondary outcomes were previously reported serious adverse events associated with the use of SGLT2i. **Results:** We identified 1347 patients with colorectal cancer and type 2 diabetes mellitus, from which 92 patients in the SGLT2i cohort were matched to the non-SGLT2i cohort. Compared to non-SGLT2i recipients, SGLT2i recipients had a higher rate of OS (5-year OS: 86.2% [95% CI: 72.0-93.5] vs. 62.3% [95% CI: 50.9-71.8], $p = 0.013$) and PFS (5-year PFS: 76.6% [95% CI: 60.7-86.7] vs. 57.0% [95% CI: 46.2-66.4], $p = 0.021$). In Cox proportional hazard analyses, the use of SGLT2i was associated with a 50-70% reduction in the risk of all-cause mortality and disease progression. The rate of cancer-associated mortality was lower in the SGLT2i group (7% vs. 21%, $p = 0.005$). SGLT2i were not associated with an increased risk of sepsis, hypoglycemia, or acute kidney injury. We did not detect any cases of urosepsis or diabetic ketoacidosis in the SGLT2i group. **Conclusions:** The use of SGLT2i was associated with a higher rate of survival in colorectal cancer patients with diabetes mellitus. Research Sponsor: None.

A phase II study of nivolumab and ipilimumab with radiation therapy in patients with metastatic, microsatellite stable colorectal cancer. *First Author: Julie L. Koenig, Harvard Radiation Oncology Program, Boston, MA*

Background: Immune checkpoint inhibitors (ICIs) have limited efficacy in patients with microsatellite stable (MSS) colorectal cancer (CRC). Radiation therapy (RT) may increase the response rate to ICIs through multiple mechanisms. In our phase 2 trial (NCT03104439), 40 patients with metastatic MSS CRC were enrolled to receive ipilimumab and nivolumab with RT (24 Gy/3 fractions) starting on C2D1. Among the 27 patients who received RT (33% dropout rate), the disease control rate (DCR) was 37% and objective response rate (ORR) was 15%. To confirm this signal and address dropout prior to RT, we conducted a phase 2 study of nivolumab and ipilimumab with RT moved to C1D1. **Methods:** In this open-label, single-arm, phase 2 study (NCT04361162), eligible patients had histologically confirmed metastatic MSS CRC, ECOG PS 0-1, and progressed on at least one line of chemotherapy. Treatment consisted of ipilimumab 1 mg/kg every 6 weeks for the first 4 cycles, nivolumab 240 mg every 2 weeks on a 6-week cycle, and RT with 24 Gy/3 fractions to one site starting on C1D1. Treatment continued until disease progression, discontinuation, or withdrawal. The primary endpoint was ORR outside of the RT field by RECIST 1.1 with radiological evaluations every 3 months. The treatment regimen was considered to have promising activity if at least 3 of 30 patients achieved an objective response in unirradiated lesions. Secondary endpoints included DCR, PFS, OS, and safety. A single-stage design was used to enroll 30 patients for intention-to-treat analysis of patients receiving at least one dose of study treatment. The per protocol analysis included patients who completed C1D1. The treatment regimen was considered to have promising activity if at least 3 of 30 patients achieved an objective response in unirradiated lesions, providing 85% power to reject 4% ORR in favor of 15% ORR at a significance level of 15%. **Results:** We enrolled and treated 30 patients (median age 56 years [range 28-85], 60% male, 83% white) from 10/2020 to 05/2022. Patients received a median of 2 (range, 1-7) prior lines of chemotherapy. All patients in the intention-to-treat population also met criteria for inclusion in the per protocol analysis. The ORR was 13% (4/30; 95% CI, 4-31%), DCR was 33% (10/30; 95% CI, 17-53%), median PFS was 2.4 months (95% CI, 1.8-2.9 months), and median OS was 10.6 months (95% CI, 6.8-17.8 months). 16 patients had grade 3+ treatment-related serious adverse events, including lymphopenia (3 patients with grade 4), anemia, diarrhea, colitis, vomiting, alkaline phosphatase increase, hypothyroidism, fatigue, and myositis. **Conclusions:** Treatment with ipilimumab, nivolumab, and RT starting on C1D1 showed promising activity in patients with traditionally immunoresistant metastatic MSS CRC. Further analyses are ongoing to evaluate optimal patient selection and radiation strategies. Clinical trial information: NCT04361162. Research Sponsor: Bristol Myers Squibb.

Efficacy and safety of IBI351 (GFH925) monotherapy in metastatic colorectal cancer harboring KRAS^{G12C} mutation: Preliminary results from a pooled analysis of two phase I studies. *First Author: Ying Yuan, Department of Medical Oncology, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: IBI351 (GFH925) is an irreversibly covalent inhibitor of KRAS^{G12C} and has demonstrated promising anti-tumor activity with acceptable safety in advanced solid tumors. Here, we report a pooled analysis of two phase I studies (NCT05005234, NCT05497336) evaluating the efficacy and safety of IBI351 (GFH925) monotherapy for metastatic colorectal cancer (CRC) harboring KRAS^{G12C} mutation. **Methods:** Eligible metastatic CRC patients (pts) with KRAS^{G12C} mutation were included. Pts received IBI351 (GFH925) orally at dose levels of 700mg once daily (QD), or 450/600/750mg twice daily (BID). The primary endpoint was objective response rate (ORR) assessed by investigator per RECIST v1.1. Data cutoff for the analyses was November 30, 2022 unless otherwise specified. **Results:** A total of 45 pts were enrolled (median age: 58.0 years; male: 57.8%; ECOG PS 1: 71.1%; pts with ≥2 prior lines of treatment: 66.7%), including 3, 4, 37, and 1 pts in 700mg QD, 450mg BID, 600mg BID, and 750mg BID cohorts, respectively. The median exposure to therapy was 84 days (range, 7-286), and 36 pts (80.0%) were still on treatment including one patient at 450mg BID with treatment exposure for 286 days. As of December 15, 2022, ORR was 47.5% (19/40, 95% CI: 31.5%-63.9%) and disease control rate (DCR) was 85.0% (95% CI: 70.2%-94.3%) for the efficacy-evaluable pts across all dose levels. The median duration of response (DOR) was not reached. For 32 efficacy-evaluable patients at 600mg BID, ORR and DCR were 43.8% (14/32) and 87.5%, respectively. Treatment-related adverse events (TRAEs) occurred in 40 (88.9%) pts, with the most common being anaemia, white blood cell count decreased, alanine aminotransferase increased, and pruritus. Grade ≥ 3 TRAEs occurred in 9 (20.0%) pts. No drug-related adverse events leading to treatment discontinuation or death occurred. **Conclusions:** IBI351 (GFH925) monotherapy demonstrated promising anti-tumor activity with manageable safety profile in metastatic CRC patients harboring KRAS^{G12C} mutation. These two studies are still ongoing and longer follow-up will provide more solid evidence. Updated data will be presented at the meeting. Clinical trial information: NCT05005234, NCT05497336. Research Sponsor: Innovent Biologics (Suzhou) Co., Ltd.

Efficacy and safety of irinotecan-eluting HepaSphere transarterial chemoembolization combined with hepatic arterial infusion chemotherapy for unresectable colorectal liver metastases. *First Author: Aiwei Feng, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Interventional Therapy, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Both drug-eluting bead transarterial chemoembolization (DEB-TACE) and hepatic arterial infusion chemotherapy (HAIC) are recommended for unresectable colorectal liver metastases (CRLM) treatment. However, the combined application of DEB-TACE and HAIC is not widely accepted. The aim of this single-center retrospective study was to evaluate the efficacy and safety of Irinotecan-eluting HepaSphere chemoembolization combined with HAIC for unresectable CRLM. **Methods:** Patients with age older than 18 years, histologically confirmed CRLM and treated with Irinotecan-eluting HepaSphere chemoembolization plus HAIC from Oct 2020 to Jan 2022 were enrolled. Patients who had synchronously received other local treatments were excluded. Hepatic progression-free survival (hPFS) and PFS were calculated using Kaplan-Meier method. Adverse events (AE) were evaluated with CTCAE 5.0. **Results:** The eligible population was 101, composed of 66 males and 35 females. Among them, 54% patients had one of KRAS or NRAS or BRAF gene mutation and ECOG of 62% patients was 1. In addition, 59% patients were refractory to second standard line or above systemic therapy and mean interventional treatment cycles were 3.3. As the follow-up cutoff date was Dec 31, 2022, median duration of follow-up was 17.9 months (95% CI, 16.185-19.615). Median hPFS was 8.7 months (95% CI, 6.744-10.658) while median PFS was 6.2 months (95% CI, 5.048-7.352). For the patients who were refractory to second line or above systemic therapy, hPFS and PFS was 6.2 months (95% CI, 4.899-7.501) and 5.2 months (95% CI, 3.682-6.718) respectively. Overall survival has not been reached yet. There were 7 patients achieved clinical complete response. Overall response rate was 41.6% and disease control rate was 82.2%. There was no treatment-related death. 28 patients (27.7%) experienced grade 3 or higher toxicities. The most common treatment related AE were aspartate transaminase/alanine transaminase elevation (41.6%) and bilirubin elevation (40.6%). The hematologic AE included anemia (27.7%), leukopenia (27.7%), neutropenia (14.9%) and thrombocytopenia (28.7%). **Conclusions:** The combination of Irinotecan-eluting HepaSphere chemoembolization and HAIC is effective and safe for unresectable CRLM, even for patients who are refractory to second or above systemic therapy, indicating it is a promising regional treatment with improved outcome. Understanding resistance in V600E BRAF advanced colon cancer treated with BRAF inhibitors plus anti-EGFR antibodies +/- MEK inhibitors: The URBAN study. *First Author: Francesca Bergamo, Medical Oncology 1, Department of Oncology, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy*

Background: The combination of BRAF inhibitors (BRAFi) plus anti-EGFR antibodies is a new standard of care in V600E BRAF mutated (mut) metastatic colorectal cancer (mCRC). Nevertheless, resistance develops during the target therapy (TT). We designed the URBAN study, a translational prospective project, in order to identify possible primary and acquired resistance mechanisms. **Methods:** Patients (pts) with V600E BRAF mut mCRC treated with BRAFi + anti-EGFR +/- MEK inhibitors at Veneto Institute of Oncology were enrolled. Clinical data and liquid biopsy at baseline and progression were collected. The ctDNA derived from plasma was analyzed by the AVENIO expanded kit, a hybridization capture sequencing-based 77 genes pan-cancer assay contained in NCCN Guidelines. Survival outcomes were calculated using Kaplan-Meier curves, log-rank tests and univariate Cox regression models were also performed. The study is exploratory and no formal hypothesis has been postulated. **Results:** Forty consecutive V600E BRAF mut mCRC pts were enrolled. Median age was 63 years (42-77), 47.5% of pts were males. Right CRC were 65% and 20% were MSI-H. Only 5% of pts received TT after second line; doublet regimen was administered in 60% of pts while triplet in 40%. According to the mPFS of doublet arm in the BEACON trial (4.2 months, mo), our population was divided in responder (R), 24 (60%), and non-responder (NR), 16 (40%). In R vs NR group, mPFS was 9 vs 3.2 mo while mOS was 21.6 vs 10.7 mo, respectively. The V600E BRAF mut was detected in 85% of the pre-treatment plasma samples without statistically significant differences in the genomic alterations between R and NR groups, but there was a higher frequency of MET and EGFR amplification in NR group. At progression, the mutation of BRAF was lost in 2 cases in R group. After receiving TT, the most common acquired mutations involved RAS genes: 16 pts (40%) acquired at least one activating mutation in KRAS and/or NRAS. Among these, 9 pts showed multiple mutations of the same RAS gene probably due to both intra- and inter-lesional heterogeneities; none of these pts had MSI-H mCRC. We found a higher number of RAS and MAP2K1 acquired mutations in NR and a trend to acquire EGFR amplification in R group. Inactivating mutations in RNF43 gene was observed in 2 cases in R group. These data did not reach statistical significance, probably due to the low number of cases. Interestingly, 37% of NR pts acquired three or more molecular alterations vs 13% in R group. Furthermore, a higher number of genetic alterations was acquired in pts treated with doublet vs triplet regimen. **Conclusions:** This prospective, observational molecular profiling study provided further evidences to support the use of ctDNA in capturing the dynamic somatic mutational spectrum in V600E BRAF mut mCRC and to identify potential mechanisms of resistance to TT. An expansion of study population is ongoing. Research Sponsor: Partially funded by the Italian Ministry of Health grant "Ricerca Finalizzata Giovani Ricercatori" [grant number GR2019-12368903].

Optimal molecular-targeted therapies as first-line treatment for *RAS* wild-type, right-sided metastatic colorectal cancer from the Analysis and Research in Cancers of the Digestive System (ARCAD) database. *First Author: Kentaro Yamazaki, Division of Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan*

Background: Although anti-EGFR antibody plus doublet chemotherapy has become the standard of first-line treatment for *RAS* wild-type (wt), left sided metastatic colorectal cancer (mCRC), the optimal molecular-targeted therapy for *RAS* wt, right-sided mCRC is not clear. **Methods:** To evaluate the efficacy between anti-EGFR antibody vs. bevacizumab combination therapy, from 40,889 Individual patient (pt) data from 59 studies in ARCAD mCRC database, 723 pts with *RAS* wt, right-sided mCRC who received a first-line molecular-targeted therapy with backbone chemotherapy (FOLFOX/FOLFIRI when anti-EGFR antibody combination, and FOLFOX/FOLFIRI/CAPOX/FOLFOXIRI when bevacizumab combination) were selected from 10 randomized studies (FIRE-3, CALGB80495, CRYSTAL, PRIME, CAIRO2, OPUS, TRIIBE, TRIIBE2, ATOM, and CCOG1201). Primary objective was overall survival (OS), and secondary objectives were progression-free survival (PFS) and overall response rate (ORR); Hazard ratio (HR) and Odds ratio (OR) were adjusted for ECOG-PS, age, and gender. Propensity score matching (PSM) and inverse probability treatment weighting (IPTW) as sensitivity analysis were also performed. Secondary analyses were limited to *BRAF* wt pts. **Results:** Anti-EGFR antibody and bevacizumab were administered in 329 and 394 pts, respectively, of whom 162 and 151 pts were *BRAF* wt, respectively. Baseline characteristics were as follows (anti-EGFR antibody/bevacizumab): median age, 63.0 years both; female, 47.1/46.4%; and ECOG-PS 0, 53.2/65.2%. The OS and PFS were significantly prolonged in pts receiving bevacizumab combination therapy compared to those receiving anti-EGFR antibody combination therapy (Table). These trends were more pronounced when limited to *BRAF* wt pts (Table). There were no significant differences in ORR for both overall and *BRAF* wt pts. These results were similar in the sensitivity analysis (Table). **Conclusions:** For patients with *RAS* wt or *RAS/BRAF* wt, right-sided mCRC, bevacizumab combination therapy is preferred first-line treatment. Research Sponsor: ARCAD, ARCAD Asia.

Phase II study of biweekly TAS-102, irinotecan and bevacizumab in pre-treated metastatic colorectal cancer (TABASCO). *First Author: Patrick M Boland, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: The efficacy of 2nd line FOLFIRI plus VEGF inhibition (VEGFi) is limited for metastatic colorectal cancer (mCRC). TAS-102 is a novel oral anti-metabolite approved for pts with mCRC following standard treatment with FP, oxaliplatin and irinotecan. TAS-102 has a distinct mechanism of action from 5-FU and overcomes 5-FU resistance in preclinical models, and in the clinic. We hypothesized that the combination of TAS-102 with irinotecan (TAS-IRI) and bevacizumab (BEV) would prove superior to FOLFIRI/VEGFi. **Methods:** Phase II, single-arm study of TAS-IRI and BEV in 2nd-line mCRC. Eligible patients had received prior treatment with a fluoropyrimidine and oxaliplatin in the advanced setting or experienced recurrence within 12 mos of this regimen in the adjuvant setting. Adequate organ function, ECOG PS 0-1, measurable disease (RECIST 1.1), no prior irinotecan or TAS-102 exposure and candidacy for BEV were required. Pts were treated with BEV 5 mg/kg IV, irinotecan 180 mg/m² IV (day 1 and 15), and TAS-102 25 mg/m² orally bid (days 2-6 and 16-20) in 4-week cycles (PMID: 31924737). Treatment continued until disease progression or unacceptable toxicity. The primary endpoint was median progression-free survival (PFS). Assuming a median PFS for historic control (FOLFIRI/VEGFi) of 6 mos vs. 9 mos for TAS-IRI plus BEV (HR: 0.67), treatment of 36 evaluable pts would achieve 80.5% power (at $\alpha = 0.1$) to detect such an effect. **Results:** Forty-nine patients were enrolled; 42 were eligible and 38 had at least one disease assessment (median age 59 yr, 47% male, 74% colon primary, tumor KRAS/ NRAS mutated in 55%/21%). The median PFS was 8.7 mos (range: 6.7-11.8 mos, $p = 0.009$), meeting the primary endpoint. The most common reason for study treatment discontinuation was progressive disease (53%). The objective response rate was 16% (90% CI: 8.0-27.3%); the median OS was 16.5 mo (range: 11.8-25.3). Twenty-eight pts (67%) had a treatment-related adverse event (TRAE) G3 or higher (Table). The most common TRAEs were gastrointestinal and hematologic. Grade 3/4 neutropenia occurred in 34%, with only 1 episode of febrile neutropenia, though G-CSF use was frequently needed to maintain dose density/intensity. **Conclusions:** TAS-IRI plus BEV is an effective 2nd line therapy for patients with mCRC. The median PFS appears higher compared to historical controls (FOLFIRI/VEGFi). Neutropenia is common and can affect dose density/intensity mandating use of G-CSF. A randomized study versus standard of care therapy is warranted. (Clinical trial registration ClinicalTrials.gov NCT04109924). Clinical trial information: NCT04109924. Overall survival of patients with BRAF-mutant metastatic colorectal cancer treated with encorafenib-cetuximab in a real-world nationwide study in the Netherlands. *First Author: Sietske C.M.W. van Nassau, Department of Medical Oncology, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands*

Background: Approximately 10-15% of patients with metastatic colorectal cancer (mCRC) have BRAF^{V600E} mutated tumors. Encorafenib plus cetuximab (EC) combination treatment was approved following the results of the randomized phase III BEACON trial and is currently recommended for all pretreated patients with BRAF^{V600E}-mutant mCRC. Selection of patients in randomized controlled trials is based on restrictive eligibility criteria and often not representative of the patient population in daily clinical practice. Complementary real-world effectiveness studies can improve knowledge on the generalizability of trial results, and support decision making in clinical practice. **Methods:** This population-based study included all mCRC patients in the Netherlands treated with EC since approval in October 2020 until June 2022. Individual patient data and original pathology reports were collected. Primary endpoint was overall survival (OS), defined as time from EC initiation until death by any cause, analyzed by Kaplan-Meier curves. WebPlotDigitizer was used to reconstruct the Kaplan-Meier survival curve of the BEACON trial. Uni- and multivariable analyses were performed. Subgroup analyses were conducted for patients who would have been eligible for the BEACON trial based on key eligibility criteria: BRAF^{V600E} mutation, 1-2 prior regimens, world health organization performance status (WHO PS) of 0-1, normal neutrophil count, absence of brain metastases, no prior RAS/RAF/MEK treatment, and no concurrent malignancies. **Results:** 155 patients were included with a median follow-up time of 11.1 months. Patient characteristics differed from BEACON in mean age (64 *versus* 60 years), primary tumor sidedness (69% *versus* 50% right-sided) and WHO PS (23% *versus* 51% WHO 0). Median OS of the total real-world cohort was 6.6 months (95% CI: 6.0-8.3) and differed significantly from BEACON (9.3 months; 95% CI: 8.0-11.3; $p = 0.003$). 35% of real-world patients treated with EC would not have been eligible for the BEACON trial, showing an inferior median OS of 6.0 months (95% CI: 4.6-9.2) compared to 7.0 months (95% CI: 6.4-9.8) in trial eligible real-world patients. WHO PS was independently associated with poor survival in multivariable analysis. Patients with WHO PS ≥ 2 had a median OS of 3.9 months (95% CI: 2.4-NA) with a hazard rate of 2.5 (95% CI: 1.1-5.5; $p = 0.003$). **Conclusions:** This largest to date - unselected - population-based cohort of mCRC patients treated with EC showed an efficacy-effectiveness gap for OS. These outcomes should be considered in clinical practice for treatment decision making. Omitting EC for subgroups demonstrating very short OS, such as patients with WHO PS ≥ 2 , needs to be considered. Further research is warranted to adapt treatment guidelines towards a more personalized approach for patients with BRAF^{V600E}-mutated mCRC. Research Sponsor: Zorginstituut.

Real-world treatment trends and outcomes in elderly patients with metastatic colorectal cancer in the United States. *First Author: Andrew Trunk, Cleveland Clinic (Cleveland, OH), Cleveland, OH*

Background: Prospective data to guide management of elderly patients with metastatic colorectal cancer (mCRC) is limited. Whether elderly patients derive the same degree of benefit from doublet chemotherapy as younger patients is not well understood. In this study we utilized real-world data from patients in the United States (US) to evaluate treatment trends and compare overall survival (OS) in younger versus older patients with mCRC who receive first-line (1L) chemotherapy. **Methods:** The nationwide Flatiron Health electronic health record-derived de-identified database was used to select patients ≥ 50 years old (yo) with mCRC treated with 1L fluoropyrimidine-based chemotherapy with or without the addition of targeted therapy. Overall survival from the initiation of 1L therapy, stratified by receipt of a doublet or single agent cytotoxic chemotherapy regimen was assessed independently within three age cohorts (50-69; 70-74, ≥ 75) using both a cox proportional hazard model and a propensity score weighted analysis to control for potential confounding variables. A subgroup analysis was performed in patients receiving bevacizumab as part of 1L therapy. **Results:** Of 14,440 patients who received 1L chemotherapy, 5,874 (40.7%) were ≥ 70 yo, including 3,656 (25.4%) who were 75 or older. Doublet chemotherapy was received by 7,505 (87.6%) patients age 50-64 yo, 1892 (85.3%) patients age 70-74 yo, and 2297 (62.2%) patients age 75 and above. In all three groups, multivariate analysis of single agent chemotherapy vs doublet chemotherapy showed a benefit to doublet chemotherapy with a hazard ratio of 1.14, (95% CI 1.04-1.24, $p = 0.006$), 1.22 (95% CI 1.05-1.42, $p = 0.011$) and 1.19 (95% CI 1.10-1.29, $p < 0.001$), respectively. Similar results were noted when comparing doublet to single agent chemotherapy in the age 70-74 and ≥ 75 groups using a propensity score weighted analysis. In the subgroup of patients age ≥ 70 who received 1L bevacizumab, 2,604 received doublet chemotherapy and 441 received single agent chemotherapy. Median OS was 19 mos (95% CI: 18-20) vs 13 (95% CI: 11-15) vs with a propensity score weighted HR of 1.35 (95% CI 1.12-1.63, $p = 0.001$). **Conclusions:** A smaller percentage of patients over age 75 receive 1L doublet chemotherapy for mCRC in the US compared to patients age 50-69 or 70-74. Regardless of age, patients who receive doublet fluoropyrimidine-based chemotherapy appear to have improved overall survival compared to single agent chemotherapy. This retrospective US data is in contrast with recently presented data from a prospective phase III trial in Japan (JCOG1018). Elderly patients in the US should not be excluded from receiving doublet chemotherapy for mCRC without further prospective data. Research Sponsor: None.

MicroOrganoSpheres as a clinically applicable precision oncology platform for the discovery of novel therapies in colorectal cancer. *First Author: Divya Lakshmi Dayanidhi, Duke University, Durham, NC*

Background: Patient-derived models of cancer, such as cell lines, patient-derived organoids, and patient-derived xenografts, are useful models of patient response in the clinic. However, these models are often not clinically applicable within the time periods necessary to inform clinical decision making, as they can take weeks to months to develop. An ideal platform using patient-derived models would be generated from a core biopsy with a subsequent drug screen within 10-14 days to minimize delay in therapy. We recently reported the development of MicroOrganoSpheres (MOS) that can be used in drug screens within 14 days of obtaining a biopsy. In the current study, we use this MOS system as precision oncology platform in colorectal cancer (CRC) to identify new therapies and predict response to therapy. **Methods:** CRC patient tissue samples were collected under a Duke Institutional Review Board approved protocol (Pro00089222). Resections or biopsies were mechanically and enzymatically digested to obtain a single cell suspension. Cells were then plated in Matrigel at a ratio of 20,000 cells:5 μ L Matrigel to establish "mini-bulk" organoid cultures. After establishment for 5-7 days, cultures were harvested with subsequent generation of MOS at a ratio of 50 cells per MOS. After growing for 3-4 days, MOS were used for dose-response curves using oxaliplatin, SN38, and 5-Fluorouracil (5-FU) as well as high-throughput drug screens with the NCI Approved Oncology Drugs Set VI library. **Results:** We developed and optimized a MOS pipeline on over 50 CRC specimens, including 9 primary rectal, 35 primary CRC, 12 CRC liver metastasis, and 1 CRC lung metastasis lines with a success rate of 80% and an average of 10-21 days from biopsy to MOS generation. The high success of generating CRC MOS in a clinically applicable time frame led to the next phase of the project where a total of 10 CRC MOS were tested against standard of care chemotherapy agents used in CRC (oxaliplatin, irinotecan and 5-FU) as well as the NCI Approved Oncology Drugs Set VI within 14-21 days of establishment. We noted a range of sensitivity of approximately 100-fold for standard of care agents. The most sensitive drugs found in the high-throughput screen were Bortezomib, Carfilzomib, and Panobinostat and the most resistant were Gefitinib, Chlorambucil, and Procarbazine hydrochloride. **Conclusions:** These results demonstrate that our MOS pipeline can be used as a precision oncology platform within a clinically applicable time frame to potentially guide therapy. We are now in the process of correlating drug response in MOS to patient outcome data and these findings will be presented at the annual meeting. Research Sponsor: Discretionary funds.

Effect of trifluridine/tipiracil in combination with bevacizumab on ECOG-PS in refractory metastatic colorectal cancer: An analysis of the phase 3 SUNLIGHT trial. *First Author: Julien Taieb, Paris Cité University, Paris, France*

Background: SUNLIGHT, an international, open-label, randomized, phase 3 study comparing trifluridine/tipiracil (FTD/TPI) in combination with bevacizumab versus FTD/TPI monotherapy in patients with metastatic colorectal cancer (mCRC) met its primary endpoint (overall survival [OS]) and key secondary endpoint (progression free survival [PFS]). Primary and key secondary outcomes in patients with maintained ECOG-PS are reported. **Methods:** SUNLIGHT enrolled patients with ECOG-PS 0/1. ECOG-PS was evaluated at baseline, at each treatment cycle, and at withdrawal visit. Worst ECOG values and time to ECOG worsening of more than 2 were reported. Here we report a post-hoc analysis assessing OS and PFS in patients who remained at ECOG-PS 0 or 1. **Results:** Of the 492 randomized patients, 491 had ECOG-PS 0 or 1 at baseline. The median OS was improved by 3.3 months with FTD/TPI plus bevacizumab (10.8 months with FTD/TPI plus bevacizumab vs 7.5 months with FTD/TPI), hazard ratio of 0.61 (95% CI, 0.49 to 0.77; $P < 0.001$), and median PFS was of 5.6 months vs 2.4 months favoring the FTD/TPI plus bevacizumab group (hazard ratio, 0.44; 95% CI, 0.36 to 0.54; $P < 0.001$). The results showed that FTD/TPI plus bevacizumab significantly improved time to ECOG-PS worsening from 0 or 1 to ≥ 2 when compared with FTD/TPI monotherapy (9.3 months with FTD/TPI plus bevacizumab vs 6.3 months with FTD/TPI (hazard ratio, 0.54; 95% CI, 0.43 to 0.67). Highest ECOG-PS distribution showed comparable proportions over cycles with no clinically meaningful difference ($> 10\%$) in both treatment arms. Considering patients who had discontinued study treatment as of the clinical cut-off date of July 5, 2022, 189/208 (91%) patients in the FTD/TPI plus bevacizumab and 200/235 (85%) patients in the FTD/TPI remained at ECOG-PS 0 or 1 at treatment discontinuation. In patients with maintained ECOG-PS, median OS demonstrated a prolonged survival in the FTD/TPI plus bevacizumab group vs the FTD/TPI group and a decreased death risk (10.58 months [range, 9.03 to 11.24] vs 8.71 months [range, 7.39 to 10.18]; hazard ratio, 0.78; 95% CI, 0.61 to 0.99). PFS consistently showed benefit in patients with maintained ECOG 0 or 1 favoring FTD/TPI plus bevacizumab (5.22 months [range, 4.17 to 5.75] vs 2.55 months [range, 2.1 to 3.58]; hazard ratio, 0.49; 95% CI, 0.4 to 0.61). **Conclusions:** Consistent with the results of the overall study population, FTD/TPI in combination with bevacizumab prolonged overall survival and PFS in patients with maintained ECOG-PS. Maintenance of performance status may allow patients to receive further therapeutic options during the continuum of care. Clinical trial information: NCT04737187. Management of Early-onset Metastatic Colorectal Cancer (ERMIONE): A single institution analysis. *First Author: Giustina Valente, Oncologia Medica, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli-IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy*

Background: Despite rising incidence and mortality reported worldwide for CRC diagnosed in pts aged < 50 yrs, currently early onset metastatic CRC (EOMCRC) are treated as their older counterparts. We aimed to investigate how this specific subgroup is treated in real world. **Methods:** This an observational, retrospective, monocentric study aiming to describe features, management and prognosis of EOMCRC. Pts with EOMCRC treated at our Institution between Apr2002 and Dec2022 were included. Applying a descriptive method, counts and percentages were reported for categorical variables, while median and range for continuous variables. PFS and OS were estimated with the Kaplan-Meier method. A multivariate Cox regression analysis was performed. **Results:** 172 pts were included, of those 60.5% were female and 66% had an ECOG PS of 0. Median age at diagnosis was 43 yrs (range 12-49 yrs). Metastatic disease was mainly synchronous (72.1%), while only 12.2% and 15.7% were stage II and III at diagnosis and developed metachronous metastases. Primary tumor was left-sided in 70.1%. Metastatic site was most frequently liver (67.4%), followed by peritoneum (41.3%), lungs (33.7%), ovary (23.2%) and bones (9.9%). Disease was mostly widespread, while only 30.2% had a single metastatic site. MMR status was available for 87.2% of pts, being proficient in 90% and deficient in 10%. RAS/BRAF status was available for 95.3% of cases, of those 47.5% was RAS/BRAF wt, 48.2% was RAS mt and 4.3% was BRAF mt. 42.4% of cases had a family history positive for cancer. Germline pathogenic or likely pathogenic variants were identified in 6.4% of cases, of those 63.6% involved MMR genes and 18.2% involved HRD genes. Median number of lines of treatment received was 2 (range 1-6). Most frequent first line regimen was a doublet CT (69.8%), followed by a triplet CT (23.8%) and immunotherapy (4.1%). CT regimens were associated to bevacizumab in 45.3% of cases and to antiEGFRs in 29.1% of cases. Throughout the whole continuum of care 8.7% of pts received immunotherapy and 21.5% received treatment within a clinical trial. 70.3% of pts received surgery and/or local ablative treatments (LATs) with radical intent (52.9% surgery, 12.2% both, 4.6% LATs). At a median FU of 38.6 m, mPFS for first line was 13.5 m (95%CI 12.1-15.0 m) and mOS was 41.5 m (95%CI 33.9 - 44.1 m). Median OS was significantly longer for pts who received surgery and/or LATs compared to those who did not (43.4 vs 23.6 m, $p < .0001$). At multivariate analysis, besides surgery and/or LATs ($p = .0007$), BRAF status ($p = .0165$) and ECOG PS ($p = .0209$) independently correlated with OS. **Conclusions:** We confirmed that EOMCRC is more frequently diagnosed as synchronous disease, due to delayed diagnosis. Despite the small population and the retrospective nature, we showed that combining surgery and/or LATs to systemic therapy is associated with increased OS in EOMCRC. These evidence warrant further validation in prospective setting. Research Sponsor: None.

PolyPEP1018 vaccine in combination with TAS-102 in participants with late-stage microsatellite-stable metastatic colorectal cancer (MSS mCRC): A phase Ib study to evaluate safety, tolerability, immunogenicity and efficacy (OBERTO-201). *First Author: Joleen M. Hubbard, Department of Medical Oncology, Mayo Clinic, Rochester, MN*

Background: PolyPEP1018 is an off-the-shelf, multi-peptide vaccine containing 12 immunogenic epitopes derived from 7 tumor-specific antigens frequently expressed in patients with mCRC. Following early evidence of clinical activity of PolyPEP1018 in first-line MSS mCRC, here we report the results of a phase Ib study of PolyPEP1018 vaccine plus trifluridine/tipiracil (TAS-102) in late-stage mCRC patients. **Methods:** Patients with MSS mCRC who have progressed on ≤ 2 lines of prior chemotherapy regimen for mCRC received PolyPEP1018 subcutaneously on days 1 and 15 and TAS-102 orally twice daily on days 1-5 and 8-15 of a 28-day cycle. Treatment continued for up to 7 cycles, until disease progression or unacceptable toxicity. Immunomonitoring was performed at both blood and tumor levels prior to and on study treatment. The primary endpoint of the study was safety and tolerability. Data on objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS) and correlation studies will be presented. **Results:** 15 patients started treatment. Median age was 55 years (range 31-71), 73% had liver metastases (mets), 73% had KRAS mutant tumors. The most common side effect related to PolyPEP1018 was Grade (Gr) 1-2 local skin reactions in 93% of patients. Gr 3 events ($n = 15$) at least possibly related to treatment were fatigue, decreased white blood cell, lymphocyte and neutrophil counts, nausea, diarrhea, myalgia, and maculo-papular rash. There were no Gr 4 or 5 events. The ORR was 0%. The DCR was 53.3% in the overall population and 36% and 100% for the patients with liver mets and without liver mets, respectively. The mPFS was 4 months (95%CI 2.2-6.1) in the overall population and 2.3 months (95%CI 2.1-NE) and 7.6 months (95%CI 4.4-NE) for the patients with liver mets and without liver mets, respectively (HR = 5.73 (95%CI 1.21, 27.06); $p = 0.015$). At the data cut-off date (Feb 10, 2023), the mOS was 8.7 months (95%CI 6.9-NE; not mature) in the overall population and it was not reached in patients without liver mets. Patients with increased PFS (≥ 24 weeks) had more robust vaccine-specific humoral and T cell responses induced by higher number of vaccine peptides than patients with PFS < 24 weeks. **Conclusions:** To our knowledge, this is the first study investigating combination of a cancer vaccine with TAS-102 chemotherapy in advanced MSS mCRC. Our results show that PolyPEP1018 plus TAS-102 was well-tolerated with few grade 3 AEs beyond what is expected with TAS-102 monotherapy. Despite no objective tumor responses could be detected, correlative data suggest contribution of PolyPEP1018-induced immunological responses to the improved clinical benefit and the combination warrants further testing. Clinical trial information: NCT05130060. Research Sponsor: US Department of Defense.

VIC regimen (vemurafenib/irinotecan/cetuximab) versus bevacizumab plus chemotherapy as first-line treatment for *BRAF* V600E-mutated advanced colorectal cancer. *First Author: Yijiao Chen, Colorectal Cancer Center; Department of General Surgery; Zhongshan Hospital, Fudan University, Shanghai, China, Shanghai, China*

Background: The need for safe and effective therapies for untreated, *BRAF* V600E-mutated, unresectable locally advanced or metastatic colorectal cancer remains unmet. The purpose of this study was to compare the efficacy and safety of the VIC (Vemurafenib/Irinotecan/Cetuximab) regimen versus bevacizumab plus chemotherapy as first-line setting in Asian patients. **Methods:** In the single-center prospective cohort study, 78 untreated, *BRAF* V600E-mutant, locally advanced or metastatic CRC patients were enrolled. Every two weeks, the VIC regimen and bevacizumab plus doublet or triplet chemotherapy are administered. We evaluated the objective response rate (ORR), the disease control rate (DCR), and the conversion resection rate. In progression-free survival (PFS) and overall survival, the Kaplan-Meier method was utilized (OS). **Results:** In the evaluable population, 32 patients received VIC regimen and 35 patients received bevacizumab plus chemotherapy. The ORR and DCR in the VIC group were significantly higher than in the bevacizumab-therapy group (ORR: 68.8% versus 40.0%, $P = 0.018$; DCR: 100.0% versus 80.0%, $P = 0.023$). The VIC regimen was significantly superior to bevacizumab plus chemotherapy for PFS (median, 11.9 vs 7.9 months; hazard ratio [HR] = 0.48, 95% CI, 0.27-0.87; $P = 0.012$) and OS (median, 24.5 vs 14.4 months; HR = 0.36, 95% CI, 0.16-0.78; $P = 0.007$). In the VIC group, the conversion resection rate for liver metastases was 42.1% (8 of 19 patients), and for local CRC it was 66.7% (6 of 9 patients with initially unresectable local CRC). Rates of treatment-related adverse events of Grade 3 to 4 were 32.4% and 31.1% for the VIC regimen and bevacizumab plus chemotherapy, respectively. **Conclusions:** Among Asian patients with *BRAF* V600E-mutated advanced CRC, the VIC regimen was superior to bevacizumab plus chemotherapy in terms of tumor response and oncological survival, with a tolerable and manageable toxicity profile in the first-line setting. Clinical trial information: NCT05540951. Research Sponsor: None.

Preoperative assessment in lung-limited metastatic patients with colorectal cancer: The Meta-Lung Score. *First Author: Pina Ziranu, Medical Oncology Unit, University Hospital and University of Cagliari, Cagliari, Italy*

Background: Due to the inconsistent data on curative resection of isolated lung metastases (LM) from colorectal cancer (CRC) and the lack of specific recommendations, the therapeutic approaches for metastatic liver disease are mostly applied to LM treatment, despite differences in their biological behavior. Like Fong's criteria in CRC liver metastases, our study proposed a score associated with clinical outcomes in patients (pts) undergoing CRC lung metastasectomy, aiming to better pts' selection for surgery and the most appropriate therapeutic strategy. **Methods:** We retrospectively collected data from 260 pts (aged 18-85) who underwent CRC lung metastasectomy with curative intent from December 2002 to January 2022 at four Italian Centers: the Division of Thoracic Surgery at "A. Businco Cancer Center" in Cagliari, the Division of Thoracic Surgery at "Città della Salute e della Scienza" in Turin, the Department of Thoracic Surgery at "IRCCS Azienda Ospedaliero-Universitaria" in Bologna, and the Medical Oncology Unit of the University Hospital of Cagliari. Statistical analysis was performed with MedCalc (survival distribution: Kaplan-Meier; survival comparison: log-rank test; association between categorical variables: Fisher's exact test). **Results:** We analyzed the impact of different clinicopathological features on overall survival (OS). At the univariate analysis: higher baseline CEA levels ($p = 0.0001$), disease-free survival less than or equal to 12 months (m) ($p = 0.0043$), LM size larger than 2 cm ($p = 0.0187$), multiple resectable nodules ($p = 0.0083$), and positive nodal status of the primary tumor ($p = 0.0011$) were associated with poorer prognosis. In a Cox regression model, these five characteristics retained their independent role for OS ($p < 0.0001$) and were chosen as criteria to be assigned one point each for clinical risk score. The 5-year survival rate in pts with 0 points was 88%, while no pts with a 5-points score survived at 2 years. Based on the 0-2 versus 3-5 score range, we obtained a significant difference in median OS: 101.7 m (95%CI 64.6 - 101.7) vs. 39.5 m (95%CI 27.3 - 87.5) respectively ($p < 0.0001$) stratifying pts into good and poor prognosis. **Conclusions:** The Meta-Lung Score appeared to be an exciting prognostic tool in selecting CRC pts' candidates for radical surgical treatment when LM were diagnosed. Whether early surgery should be considered in pts with a score 0-2, the same choice should be taken with caution in pts with a score 3-5, for whom early chemotherapy would allow better assessment of tumor biology and appropriate selection for surgery. Research Sponsor: None.

Score	Survival (%)					Median OS (m)
	1-yr	2-yr	3-yr	4-yr	5-yr	
0	97%	91%	88%	88%	88%	NR
1	97%	90%	78%	71%	60%	NR
2	97%	80%	65%	54%	46%	45.9 (95%CI 36.1 to 75.5)
3	90%	74%	58%	45%	34%	41.7 (95%CI 29 to 87.5)
4	73%	72%	41%	27%	27%	29.3 (89%CI 8.8 to 62.2)
5	34%	0	0	0	0	12.3 (95%CI 4.6 to 19.5)
Total	95%	83%	70%	60%	55%	75.6 (95%CI 57.6 to 101.7)

Upfront vs deferred monoclonal antibodies in metastatic colorectal cancer: A target trial emulation using the GEMCAD 14-01 prospective cohort. *First Author: Joan Maurel, Hospital Clínic Barcelona, Barcelona, Spain*

Background: There are no randomized trials comparing the addition monoclonal antibodies (MAB: bevacizumab, cetuximab, panitumumab) to first line chemotherapy (upfront use) versus deferring their addition to the second-line chemotherapy (deferred use) in pts with metastatic colorectal cancer (mCRC). We emulated a target trial comparing upfront vs deferred use of MAB using the GEMCAD 14-01 observational registry. **Methods:** We first specified the (hypothetical) target trial to fully articulate the research question and then emulated it using real-world data. The eligibility criteria of the target trial were a diagnosis of mCRC, being treatment naïve, and a ECOG PS ≤ 2 . The target trial would randomize pts to the following strategies: (1) initiation of MAB within 2 months of starting first line chemotherapy ("upfront MAB") and (2) initiation of MAB within 2 months of starting second line chemotherapy ("deferred MAB"). The primary outcome of the target trial would be overall survival and the causal contrast (or estimand) would be the effect under complete adherence. We emulated this target trial using data from the GEMCAD 1401 registry (ClinicalTrials.gov identifier: NCT02254941), which collected data prospectively from 47 Spanish centers from June 2014 to June 2018. The emulation used the same definitions of eligibility criteria and treatment strategies, and classified individuals according to their baseline data using clones. The effect under complete adherence was estimated by censoring pts when they deviated from the assigned treatment strategy and by using time-varying weights to adjust for baseline and post-baseline confounding. **Results:** A total of 627 pts were eligible in the "upfront MAB" and 397 pts in the "deferred MAB". Median age was in the "upfront vs deferred" 64.6 (interquartile range: 56-71) vs 67.8 (61-75) years, 96% vs 87% had an ECOG 0-1, 80% vs 79% had a Charlson score ≤ 3 , 46% vs 60% had a *RAS* mutation, 6% vs 4% had a *BRAF* mutation, 72% vs 69% had left side primary location, 74% in both strategies had liver metastasis and 42% vs 50% had LDH levels above the normal threshold. Pts in the "upfront MAB" group contributed a total 16,057 months of follow-up and 502 if they died. Pts in the "deferred MAB" contributed a total of 7,774 months of follow-up, and 222 of them died. The 48-month overall survival was 26.7% (95% CI 21.4-38.2%) in the "upfront MAB" group and 21.6% (14.2-41.7%) in the "deferred MAB" group, corresponding to a 48-month survival difference ("upfront MAB" is the reference) of -5.0% (95% CI -17.9 to 17.95) and a hazard ratio of 1.15 (0.88-1.40). **Conclusions:** Our study suggests little or no survival detrimental effect of deferring the use of MAB to the second line of treatment compared with the use of MAB as part of the first line of treatment among pts with mCRC. Clinical trial information: NCT02254941. Research Sponsor: Supported by Instituto Carlos III PI13-01728 and an unrestricted support grant from Grupo Español Multidisciplinar en Cancer Digestivo (GEMCAD).

Targeting EZH2 to overcome the resistance to immunotherapy in micro-satellite stable colorectal cancer: Results from the CAIRE study. *First Author: Lola Jade Palmieri, Medical Oncology Department, Institut Bergonié, Bordeaux, France*

Background: Profound epigenetic and transcriptomic changes induced by EZH2 in tumor cells and immune cells mobilize the elements of the TME, leading to immune-suppressive activity of solid tumors. Targeting EZH2 can enhance anti-tumor immunity by reshaping the tumor microenvironment (TME). The CAIRE study is first study investigating the impact of EZH2 inhibition in combination with immune checkpoint inhibitor in solid tumors. **Methods:** This is a single-arm open-label multicentric phase II trial assessing the efficacy and safety of tazemetostat (800 mg BID) combined with durvalumab (1120 mg every 3 weeks) in patients with advanced microsatellite stable colorectal cancer. The primary endpoint was the disease control rate within 24 weeks after treatment onset defined as the proportion of patients with at least a tumor assessment showing confirmed or unconfirmed complete response, confirmed or unconfirmed partial response or stable disease based on central review according to RECIST 1.1. Secondary endpoints included: 1-year progression free survival (PFS), 1-year overall survival (OS), and safety using NCI-CTCAE v5.0. All patients underwent sequential blood and tissue sampling for translational studies. **Results:** Between July 2021, and June 2022, 47 pts were enrolled at Institut Bergonié (Bordeaux, Centre). Median age was 67.7 (range 39.6 – 84.0). Median number of previous treatment lines was 4: (range 1 – 6). The most common treatment related adverse events were grade 1/2 asthenia, nausea. No death was related to the treatment. Among the 34 pts for whom blinded central review of imaging was available for at least one imaging tumor assessment, best tumor response was confirmed partial response, stable disease and progressive disease in 1 (2.9%), 11 (32.3%) and 22 (64.7%) patients respectively. The disease control rate was 35.3% (95%CI 19.7 – 53.5). **Conclusions:** The CAIRE study met its first endpoint for disease control rate in patients with advanced colorectal cancer. Efficacy data on the whole cohort of patients and full biomarkers analyses will be presented at the meeting. Clinical trial information: NCT04705818. Research Sponsor: Astrazeneca; Epizyme, Inc.

Molecular landscape and survival outcomes on early phase clinical trials in sporadic young onset colorectal cancer. *First Author: Benny Johnson, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Sporadic young onset colorectal cancer (YOCRC, ages 30-49) is a public health crisis with a persistent rise in incidence globally. While a proportion of patients (pts) develop YOCRC due to hereditary predisposition, the majority develop sporadic microsatellite stable (MSS) colorectal cancer with limited options beyond standard of care in advanced settings. We report the early phase clinical trial experience at a large academic cancer center to elucidate clues regarding molecular landscape and impact of clinical trials in refractory MSS YOCRC. **Methods:** Patient and clinical characteristics were summarized using descriptive statistics. Kaplan-Meier method was used to estimate the probabilities of overall survival (OS) and progression free survival (PFS). Log-rank tests were used to assess the differences in OS and PFS between subgroups. Cox proportional hazards regression models were fit to assess the association between OS or PFS and patient characteristics. Statistical analyses were performed using SAS and Splus. **Results:** 240 MSS YOCRC pts were analyzed. Median age 42.8 (20.5-49), > 80% were white and only 10% black. 21% received at least 3 lines of therapy. The top five mutations were *TP53*, *KRAS*, *APC*, *PI3CKA* and *BRAF*^{V600E}. Median OS was 39.2 months (95% CI: 34.8 – 42.5 months). *CTNNB1* mutation was associated with a lower risk of death (HR = 0.28, 95% CI: 0.09 – 0.87, p-value = 0.03) while *BRAF*^{V600E} mutation was associated with an increased risk (HR = 3.28, 95% CI: 2.00 – 5.38, p-value < 0.001). Multivariable Cox model for OS revealed both *CTNNB1* and *BRAF*^{V600E} mutations are significant prognostic factors for OS, unlike *KRAS*. There was no difference in OS or PFS among pts who entered a mutation specific clinical trial vs. those enrolled on an unmatched clinical trial (p = 0.35, p = 0.68, respectively, log-rank test). Median PFS was 1.9 months (95% CI: 1.8 – 2.1 months). *CTNNB1* mutation was associated with a lower risk of progression/death (HR = 0.29, 95% CI: 0.09 – 0.92, p-value = 0.04) while *NRAS* mutation was associated with an increased risk (HR = 2.13, 95% CI: 1.19– 3.80, p-value = 0.01). Among 145 pts who have data on response, 9 had partial response, 41 had stable disease and 95 had progressive disease. *BRAF*^{V600E} mutation is associated with a higher probability of response (OR = 6.89, 95% CI: 1.64 – 28.94, p-value = 0.01) and pts enrolled on matched clinical trials had a higher probability of response (OR = 6.23; 95% CI: 1.24 – 31.09, p-value = 0.03). However, increased response did not translate to improved OS. No survival differences were appreciated based on pts race or BMI. **Conclusions:** *CTNNB1*, *BRAF*^{V600E} & *NRAS* mutations may have prognostic implications in YOCRC. Pts enrolled on mutation specific clinical trials did not achieve improved outcomes compared to unselected trials, highlighting aggressive biology, current lack of therapeutic targets and need for novel drug development in sporadic YOCRC. Research Sponsor: None.

Poster Session

Real-world rates of FDA-approved targeted therapy and immunotherapy prescriptions for patients with metastatic colorectal cancer in the VA's National Precision Oncology Program (NPOP). *First Author: Alice Nono Djotsa, Center for Innovations in Quality Effectiveness and Safety, Houston, TX*

Background: Colorectal cancer is the fourth most common cancer among Veterans and the third leading cause of cancer-related death in the USA. Use of comprehensive genomic profiling (CGP) to guide administration of FDA-approved biomarker directed therapies can improve outcomes among metastatic CRC (mCRC) patients. We sought to compute the rates of actionable biomarkers and prescriptions of associated FDA-approved therapies among Veterans in NPOP. **Methods:** The NPOP database was queried to identify mCRC patients who had undergone CGP via tissue or liquid biopsy between February 2019 and July 2022 and had one of the following 5 actionable biomarker profiles: *NRAS/KRAS/BRAF* wildtype, *BRAF* V600E, MSI-H, TMB-H, or *NTRK* fusion or rearrangement. The VA's Corporate Data Warehouse (CDW) was queried to extract prescription data for seven FDA-approved biomarker-directed therapies (targeted agents and immune checkpoint inhibitors (ICIs)). Rates of CGP-directed therapy prescriptions were assessed based upon biomarker and patient characteristics (sex, race, ethnicity, and rurality). **Results:** A total of 908 mCRC patients underwent CGP, with 81.4% bearing colon adenocarcinoma (COAD) and 18.6% rectal adenocarcinoma (READ). Rates of actionable biomarkers associated with FDA-approved therapies were as follows: *NRAS/KRAS/BRAF* wildtype (34.4%), TMB-H (9.6%), *BRAF*V600E (7.7%), MSI-H (5.6%), TMB-H and MSI-H (5.6%), and *NTRK* Fusion or rearrangement (0.3%). The combined rates of any actionable variant were 47.4% for COAD and 44.4% for READ patients. Relative to patients without actionable biomarkers, patients with *BRAF* V600E mutations were more likely to be older and white; patients with *NRAS/KRAS/BRAF* wildtype were more likely to be younger (all p < 0.001). Among the 424 eligible patients, the frequencies of FDA-approved CGP-directed therapy prescriptions were as follows: MSI-H (70.7%), TMB-H (47.4%), *NRAS/KRAS/BRAF* wildtype (38.5%), and *BRAF*V600E (17.1%). Across all included biomarkers, African Americans (53.4%) were more likely to receive these therapies than whites (36.8%); and patients with prescriptions were more likely to be younger than those without (all p < 0.01). **Conclusions:** Nearly 30% of patients with MSI-H mCRC did not receive efficacious ICIs, and though disease laterality data was not readily available, a substantial number of eligible patients also did not receive EGFR inhibitors. This underuse of EGFR inhibitors has been reported previously [1]. There were racial and age differences in prescription rates. Further studies should evaluate the barriers to prescribing CGP-directed therapies in the care of mCRC patients. Keywords: molecular testing, metastatic colorectal cancer, comprehensive genomic profiling, actionable biomarkers, FDA approved therapies, veterans. [1] Becker et al. 2021 PMID 34250412. Analysis of fruquintinib adverse events of special interest from phase 3 of the FRESKO-2 study. *First Author: Cathy Eng, Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: Fruquintinib (F) is a highly selective and potent inhibitor of VEGFRs-1, -2 & -3 designed with improved kinase selectivity to minimize potential off-target toxicities. In the phase 3 FRESKO-2 study (NCT04322539), F demonstrated a statistically significant improvement vs placebo (P) in overall survival (hazard ratio, HR = 0.66) and progression-free survival (HR = 0.32), with a manageable toxicity profile and without deterioration in quality of life in heavily pre-treated patients (pts) with metastatic colorectal cancer (mCRC). Here we report the treatment-emergent adverse events of special interest (AESI). **Methods:** FRESKO-2 was a double-blind, P-controlled multiregional study with 2:1 randomization to F + best supportive care (BSC) or P + BSC. F or P was given 5 mg PO, QD, 3 weeks (w) on, 1 w off, in a 28-day (d) cycle. AEs were coded using MedDRA v25.0 and graded (G) by NCI-CTCAE v5.0. Clinically relevant class toxicities were grouped into respective AESI categories. **Results:** The safety population had 686 pts (F: 456 vs P: 230); 47% were ≥ 65 yrs, 56.9%/43.1% with ECOG 1/0, 71.6% with hepatic metastases, and 50.5% with medical history of hypertension (HTN) at baseline. The median number of prior lines of anti-cancer treatment for metastatic disease F vs P was 4 (2, 16) vs 4 (2, 12); 96.4% with prior anti-VEGF agent; 91.6% with prior TAS-102; and 47.8% with prior regorafenib. Median duration of exposure was longer with F 3.06 months (m) (range, 1.84-5.5) vs P 1.84 m (range, 0.95-2.27). 368 pts (80.7%) on F and 122 pts (53.0%) on P had an AESI. The most frequent AESIs (all G) in ≥ 25% of pts (F vs P) were HTN (38.4% vs 8.7%), dermatological toxicity (34.4% vs 11.7%), and thyroid dysfunction (27.0% vs 1.7%). G ≥ 3 AESIs in ≥ 5% of pts in the F vs P, were HTN (14.0% vs 0.9%), hepatic function abnormal (8.3% vs 9.1%), dermatological toxicity (6.8% vs 0.4%), and infections (6.6% vs 5.7%). AESIs (F vs P) that led to dose reductions (DR) occurred in 13.6% vs 0.9% of pts, drug discontinuation (DD) in 8.3% vs 6.1% of pts. AESIs leading to death were 1.8% vs 1.3% of pts, with infections (1.1% vs 0.4%) being most common. The median time to first occurrence of HTN AESI was in cycle (C) 1, with hypertension (96%) being the most common AE reported. In pts with HTN AESI, 9.7% vs 0.6% had dose reduction (DR) and 1.7% vs 0% had DD. The median time to first occurrence of dermatological toxicity was C1, with palmar plantar erythrodysesthesia (PPE) being most common AE reported (56.1%); 27.3% vs 0% had DR and 3.4% vs 0% had DD. The median time to first occurrence of thyroid dysfunction was C2, with hypothyroidism (76.4%) being most common and none with DR or DD. **Conclusions:** F was well tolerated in heavily pretreated pts and despite underlying medical conditions. AESIs including HTN, PPE and thyroid dysfunction were manageable with low rates of dose reductions and dose discontinuation, which further supports F as a potential safe and new treatment option for refractory mCRC. Clinical trial information: NCT04322539. Research Sponsor: HUTCHMED LTD.

Early tumor shrinkage (ETS) as clinical factor to select maintenance with cetuximab (cet) monotherapy in patients (pts) with RAS/BRAF wild-type (wt) metastatic colorectal cancer (mCRC): A secondary endpoint analysis of the ERMES study. *First Author: Armando Orlandi, Fondazione Policlinico Universitario A. Gemelli-IRCCS-UOC Oncologia Medica, Rome, Italy*

Background: ERMES study aimed to demonstrate non-inferior PFS of maintenance with cetuximab (cet) monotherapy (arm B) compared to FOLFIRI+cet until progression (arm A) in *RAS* and *BRAF* wt mCRC pts. Although study did not meet its primary endpoint it showed better toxicity profile and OS for cet alone and comparable ORR between arms. Here we present results of ETS, a secondary endpoint. **Methods:** ETS was defined as ≥20% reduction of the sum of target lesions at 8 weeks from the start of treatment, and was assessed by blinded independent central review. PFS and OS were compared between ETS+ and ETS- pts according to treatment arm in the modified Per-Protocol (mPP) population. **Results:** 327 of 337 (97%) pts were evaluable for ETS. In arm A, no statistically significant differences were observed between ETS+ and ETS- cohort for PFS (11.9 m, 95%CI 11.28-13.19, vs 12.2 m, 95%CI 10.82-14.93; HR 1.05, 95%CI 0.73-1.50; p 0.77) and OS (30.75 m, 95%CI 25.09-37.73, vs 25.46 m, 95%CI 19.96-34.63; HR: 0.79, 95%CI 0.50-1.24; p 0.29). In arm B, a statistically significant difference was observed between ETS+ and ETS- cohort for PFS (10.62 m, 95%CI 9.86-13.09, vs 8.52 m, 95%CI 7.89-9.37; HR 0.70, 95%CI 0.49-1.00; p 0.036) and for OS (38.88 m, 95%CI 34.53-43.25, vs 27.43 m, 95%CI 20.59-36.64; HR 0.60, 95%CI 0.38-0.93; p 0.019). ETS+ pts reported no statistically significant difference between arm B and arm A in terms of PFS (HR 1.12, 95%CI 0.83-1.49; p 0.43) while experiencing a better OS for arm B compared to arm A (HR 0.72, 95%CI 0.50-1.05; p 0.08). **Conclusions:** In pts achieving ETS, induction treatment with FOLFIRI+cet may be de-escalated to cet alone without detrimental effect on PFS, resulting in less toxicity and better OS. These data support the hypothesis that ETS might be a clinical dynamic predictor of efficacy of a less intensive maintenance strategy, allowing to plan de-escalation to cet alone after 4 months of FOLFIRI+cet induction. Clinical trial information: NCT02484833. Research Sponsor: This research was financially supported by Merck Serono S.p.A., Italy, an affiliate of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

Subgroup analyses of safety and efficacy by number and types of prior lines of treatment in FRESCO-2, a global phase III study of fruquintinib in patients with refractory metastatic colorectal cancer. *First Author: Arvind Dasari, Department of Gastrointestinal Medical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Effective treatment options are limited for patients (pts) with refractory metastatic colorectal cancer (mCRC). Fruquintinib (F), a highly selective, potent, oral tyrosine kinase inhibitor of VEGFR-1, -2, and -3, was evaluated in the global phase III FRESCO-2 study (NCT04322539) and demonstrated a clinically meaningful and statistically significant improvement in OS and PFS with a favorable safety profile. Here we report subgroup analyses of efficacy and safety by prior lines (PL) and types of anti-cancer treatment (Tx) for metastatic disease (MD). **Methods:** FRESCO-2 was conducted in the US, Europe, Japan & Australia, comparing F + best supportive care (BSC) with Placebo (P) + BSC. Pts were given 5 mg PO, QD, 3 wks on, 1 wk off, in a 28-day cycle. Eligible pts received prior chemotherapy, anti-VEGF, and if RAS wild type, anti-EGFR therapies; if BRAFV600E mutant or MSI-H, and appropriate targeted regimen; and had progressed on, or were intolerant to, trifluridine/tipiracil (TAS-102) and/or regorafenib (R). Subgroup (sbgprs) analyses for efficacy and safety were performed according to number of prior lines of tx (LOT) and by types of therapy. **Results:** A total of 691 pts were randomized; F:461 vs P:230. The median number of prior lines of anti-cancer tx for metastatic disease F vs P was 4 (2, 16) vs 4 (2, 12). F improved OS and PFS compared to P for all sbgprs and prior tx for MD, consistent with those of the ITT population (pop). (Table: OS reported by sbgprs and prior tx for MD). Occurrence of adverse events (AEs) and serious adverse events were generally balanced between F vs P and consistent across all subgroups. The most common $\geq$ G3 AEs in $\geq$ 5% of pts on F within majority of sbgprs were hypertension, asthenia and palmar plantar erythrodysesthesia and were consistent with the overall safety population. Additional analyses based on duration of prior anti-VEGF and last therapy prior to F will be presented at the conference. **Conclusions:** F demonstrated clinically meaningful improvement in OS, PFS with an acceptable safety profile across all sbgprs. These results were consistent with the effect observed in the overall population; irrespective of previous tx with anti-VEGF, anti-EGFR, TAS-102 and R further supporting F as a potential new tx option for pts with refractory mCRC. Clinical trial information: NCT04322539. Research Sponsor: HUTCHMED LTD.

Cancer of unknown primary with gastrointestinal profiles: A distinct CUP subset. *First Author: Aakash Tushar Shah, Baylor College of Medicine, Houston, TX*

Background: Cancer of unknown primary (CUP) with a “gastrointestinal (GI) profile” appears to be a clinically distinct subset, based on immunophenotyping, specifically staining with cytokeratins 20 (CK20) and 7 (CK7), a type I and II keratin, respectively and caudal type homeobox 2 (CDX2) protein, a transcription factor expressed in nuclei of intestinal epithelial cells. However, only a limited clinicomolecular account of this entity exists. Comprehensive profiling is needed to substantially impact personalized therapeutics and improve prognosis. **Methods:** We identified 401 pts evaluated at MD Anderson Cancer Center. Pts were classified into 3 cohorts based on immunohistochemistry: lower GI profile CUP (LGI-CUP), other-GI profile CUP (OGI-CUP), or non-GI CUP (NGI-CUP). A control group of known lower GI primary cancers was derived from MSK-IMPACT data (cBioPortal, 1075 patients, LGI-KP). Clinical and pathological data including molecular profiling, therapy and survival were logged. Fisher-exact test was used. Kaplan-Meier method was used to estimate overall survival (OS) and compared with log-rank test. **Results:** Among 748 pts, 401 (53.6%) had adequate immunostaining for analysis. Of these, 72 (18.0%), 226 (56.4%) and 103 (25.7%) were classified as LGI-CUP, OGI-CUP, and NGI-CUP, respectively. LGI-CUP were enriched for adenocarcinoma (88% v 86% v 35%, $P < 0.0001$) and good risk Culine score (59% v 51% v 37%, $P = 0.02$), compared to OGI-CUP and NGI-CUP, respectively. While NGI-CUP had greater proportions of poorly differentiated histology (91% v 55% v 66%, $P < 0.0001$) and bone metastases (30% vs 7% v 24%, $P = 0.0001$) compared to LGI-CUP and OGI-CUP, respectively. Comparison of key mutations is shown in table. Median OS of LGI-CUP (14.6 months [95%CI: 12.0 – 17.2]) was similar to OGI-CUP (14.3 months [95% CI: 10.7 – 18.0]) and NGI-CUP (16.2 months [95%CI: 12.4 – 20.0]), $P = 0.75$, but significantly lower than LGI-KP cohort (28.6 months, [95%CI 24.4 – 32.7], $p < 0.001$). LGI-CUP was treated preferentially with fluoropyrimidine-based GI regimen [5-FU/capecitabine +/- oxaliplatin or irinotecan] (77% vs 43% v 5%) compared to OGI-CUP and NGI-CUP, respectively. However, median OS for LGI-CUP treated with 5-FU-based regimens was higher (16.0, 95%CI 13.0 – 19.0) than those treated with non-5-FU-based treatments (10.9, 95%CI 5.6 – 16.2), $P = 0.002$. **Conclusions:** LGI-CUP appears to be a molecularly distinct entity from and NGI-CUP, as well as lower GI CUP from known entities. LGI-CUP patients treated with 5-FU-based regimens appear to have improved survival. Research Sponsor: None.

Cost-effectiveness analysis of later-line therapies for metastatic colorectal cancer (mCRC) based on a novel methodology of network meta-analysis (NMA) of survival curves. *First Author: Mavis Obeng-Kusi, The University of Arizona, Tucson, AZ*

Background: With advances in the management of mCRC, survival outcomes of patients have improved. While some patients still progress after first and second lines of treatment, there remain options for third or later-line treatment. This study aimed to determine the cost-effectiveness of later-line (>3) treatments for patients with mCRC in the US, based on a NMA of survival curves. Unlike conventional NMA using constant hazard ratios, this method is not constrained by the proportional hazard assumption and uses parametric fitting that incorporates the shape and scale parameters to provide time-varying treatment effects. **Methods:** The NMA compared the efficacy of 6 treatments, atezolizumab+/-cobimetinib (ATE+/-COB), fruquintinib (FRU), regorafenib (REG), TAS-102+/-bevacizumab (TAS+/-BEV), including biosimilar, to placebo (PBO). The study used a 3-state partitioned survival model over a 5-year time horizon incorporating drug acquisition, administration, adverse events, monitoring, and end of life costs, and utilities sourced from literature. Total costs, life-years (LY) and quality-adjusted LYs (QALY) for each treatment were determined. Incremental cost-effectiveness (ICER) and incremental cost-utility ratios (ICUR) were estimated using PBO as a common comparator. **Results:** Over the 5-year period and across the 6 therapies, survival ranged from 0.62 LYs for PBO to 1.15 LYs for TAS+BEV, translating to QALYs ranging from 0.44 for PBO to 0.85 for TAS+BEV. Total costs of treatment ranged from 278,877 for PBO to 417,495 for TAS+BEV (405,002 with biosimilar). TAS+BEV yielded the lowest ICER of an additional 261,421 (237,860 with biosimilar)/LY gained (g) and ICUR of an additional 343,458 (312,504 with biosimilar)/QALYg; while ATE presented the least favorable ICER and ICUR of an additional \$522,602/LYg and \$701,381/QALYg, respectively (Table). **Conclusions:** Among the 6 treatments evaluated, TAS+BEV emerged as the most cost-effective later-line treatment for mCRC while atezolizumab was the least cost-effective. Additionally, replacing BEV with a biosimilar reduces costs and enhances cost-effectiveness, improving access for patients. Research Sponsor: None.

Impact of vitamin D on the colon tumor immune microenvironment: Results of a randomized clinical trial of preoperative vitamin D supplementation in patients with stage I-III colon cancer. *First Author: Andressa Dias Costa, Dana-Farber Cancer Institute, Boston, MA*

Background: Although the anti-tumor properties of vitamin D in colorectal cancer (CRC) have been broadly reported, its potential role as a tumor microenvironment (TME) immunomodulator has not been well established. Vitamin D receptor (VDR) and CYP27B1 (1- α -hydroxylase; required to convert vitamin D to its active form) are critical factors in the vitamin D signaling pathway and harbor prognostic significance for CRC. Pre-clinical studies suggest that higher stromal VDR expression enhances chemotherapy efficacy. To characterize the effects of vitamin D on the TME in humans, we conducted a randomized placebo-controlled trial of preoperative high-dose vitamin D supplementation in stage I-III colon cancer patients. **Methods:** Forty-two patients were randomized to receive vitamin D3 50,000 IU/day x 7 days followed by 10,000 IU/day versus placebo prior to resection. Paired pre-treatment biopsy specimens and post-treatment surgical resection specimens from 19 patients who completed the assigned treatment and had sufficient tissue for analysis were collected for spatially-resolved immune cell profiling and evaluation of VDR and CYP27B1 expression using custom multiplex immunofluorescence. Blood samples were collected pre- and post-treatment to assess plasma 25-hydroxyvitamin D [25(OH)D] levels. Linear mixed effects models were used to compare tissue parameters; plasma 25(OH)D level changes were assessed using the Wilcoxon rank-sum test. **Results:** Patients randomized to high-dose vitamin D had increased post-treatment plasma 25(OH)D (median 18.0 to 63.6 (ng/ml)) whereas placebo-randomized patients did not (median 19.1 to 18.6 (ng/ml)) ($p < 0.001$). Analysis of both biopsy and resection tissue revealed highly heterogeneous VDR and CYP27B1 expression. VDR expression was highest in tumor cells, followed by immune and then stromal cells. Although resection tissue from vitamin D-treated patients showed lower VDR expression than specimens from placebo-treated patients in all cells ($p = 0.03$), VDR was preferentially expressed by tumor cells at the tumor invasive front compared to tumor center in the vitamin D arm, while the opposite was observed in the placebo arm. Vitamin D supplementation did not alter CYP27B1 expression. While treatment did not change total immune cell density, resection tissue from vitamin D-treated patients had higher overall CD3⁺CD8⁺ T cell density ($p = 0.04$), particularly CD3⁺CD8⁺ memory T cell density ($p = 0.02$). Additionally, vitamin D supplementation led to greater co-localization between CD3⁺CD8⁺ T cells and tumor cells ($p < 0.001$) compared to placebo. **Conclusions:** In patients with stage I-III CRC, vitamin D supplementation led to changes in vitamin D pathway signaling and evidence of an anti-tumor effect in the TME. Further investigation into the underlying mechanism of action is warranted. Clinical trial information: NCT02172651. Research Sponsor: U.S. National Institutes of Health.

Predictive value of tumor-infiltrating lymphocyte (TIL) dynamics in the tumor microenvironment (TME) during preoperative chemoradiotherapy (CRT) on pathologic complete response (pCR) in microsatellite-stable (MSS) locally advanced rectal cancer (LARC). *First Author: Mitsuho Imai, TR supporting office, National Cancer Center Hospital East, Kashiwa-Shi, Japan*

Background: Preoperative CRT followed by consolidation nivolumab before surgery showed a promising pCR rate in MSS LARC; both high PD-L1 expression and an elevated CD8⁺ T cell/effector regulatory T cell ratio analyzed by pre-CRT samples were independently related to high pCR rate (Bando H, Clin Cancer Res. 2022). Here, we applied AI-powered spatial TIL analysis to the VOLTAGE study to investigate whether dynamic change of TIL in TME may predict pCR in MSS LARC. **Methods:** The VOLTAGE study is a multi-center phase I/II study to evaluate the efficacy of CRT followed by 5 cycles of nivolumab and surgery in patients (pts) with LARC. In this study, tumor samples were obtained at multiple time points; pre-CRT (B1), post-CRT/pre-nivolumab (B2), post-3 cycles of nivolumab (B3), and surgery. In this analysis, a total of 86 H&E whole-slide images (WSI) harvested at B1 and B2 time points from all the pts enrolled in the VOLTAGE study were included in the analysis. Lunit SCOPE IO (Lunit, Republic of Korea), AI-powered H&E-WSI analyzer developed based on 16,443 WSI with pathologists' annotations, was applied to quantify TIL density in TME. **Results:** In a total of 43 pts, pCR rate of MSS and microsatellite instability-high (MSI-H) were 28.9% (11/38) and 60% (3/5), respectively. In MSS subgroup (n = 38), which has a higher unmet need for pCR prediction, tumor samples with pCR (n = 11) had increased TIL density in TME (tTIL) in post-CRT (B2, median [IQR] 726 [249-1607] /mm²) compared to pre-CRT (B1, 598 [366-905] /mm²), whereas those without pCR (n = 27) had decreased tTIL in post-CRT (405 [148-748] /mm²), compared to pre-CRT (B1, 748 [460-1153] /mm²). Intratumoral TIL density changes were more prominent than stromal TIL density changes in MSS tumor samples with pCR (mean fold change x17.7 vs. x1.5). MSS Pts with tTIL change from B1 to B2 (during CRT) more than x1.8 times achieved 75% (6/8) pCR rate, whereas those with tTIL change less than x1.8 had 16.7% (5/30) pCR rate (p = 0.0035). **Conclusions:** Change of TIL density in TME during CRT was significantly correlated with favorable clinical outcome of preoperative CRT and consolidation nivolumab, resulting in high pCR rate in MSS LARC. Combined associations of a healthy lifestyle and body mass index on colorectal cancer recurrence and survival: A cohort study. *First Author: Shabane Barot, Department of Clinical Science and Education, Karolinska Institutet, Södersjukhuset, Stockholm, Sweden*

Background: Colorectal cancer (CRC) risk is associated with modifiable lifestyle factors including smoking, physical inactivity, Western diet, and excess body weight. The impact of lifestyle factors on survival is less known. A cohort study was conducted to investigate the combined effects of a pre-diagnostic healthy lifestyle and body mass index (BMI) on prognosis following CRC diagnosis. **Methods:** Treatment and follow-up data were collected from the patient files of 1098 participants from the Swedish Colorectal cancer low-risk study cohort including stage I-III CRC patients. A healthy lifestyle and BMI (HL) score was computed using self-reported data on smoking status, physical activity, adherence to a Mediterranean diet pattern, and BMI five years before diagnosis, and divided into four categories ranging from least to most healthy. Survival analyses were performed to assess recurrence-free survival and overall survival across categories of exposure, using the Kaplan-Meier method and Cox proportional hazards model, the latter adjusted for age, sex, and educational level. **Results:** Among 1098 participants with stage I-III CRC, 233 (21.2%) had an HL score of 0-1 (least healthy), 354 (32.2%) HL score of 2, 357 (32.5%) HL score of 3 and 154 (14.0) HL score of 4 (most healthy). Participants missing follow-up data (n = 29) or relapsing ≤ 6 months (n = 29) were excluded from the recurrence-free survival analysis. 221 events of cancer recurrence were observed among 1040 participants during a median follow-up time of 4.3 years, and 542 deaths among 1098 participants during a median follow-up time of 6.3 years. Patients with the healthiest lifestyle had an improved recurrence-free survival (HL 4 vs HL 0-1, HRadj 0.51 (95% CI 0.31-0.83) and overall survival (HL 4 vs HL 0-1, HRadj 0.52 (95% CI 0.38-0.70)). Stratifying these results for cancer stage (I-III) and tumor site (colon/rectum) did not alter estimated HRs or 95% CI: s. Avoidance of smoking and being physically active were independently associated with improved recurrence-free survival and overall survival: non-smoking vs smoking HRadj 0.62 (95% CI 0.43-0.90), high vs low levels of physical activity HRadj 0.71 (95% CI 0.54-0.94). **Conclusions:** Our study indicates that pre-diagnostic adherence to a healthy lifestyle may increase the recurrence-free and overall survival of patients with stage I-III CRC. Avoidance of smoking and being physically active were the strongest risk-reducing factors for these outcomes. Research Sponsor: Stockholm County Council (ALF project).

Immunotherapy for localized MSI-H colorectal cancer: Characterizing endoscopic and imaging response. *First Author: Daniel Aaron Fox, Baylor College of Medicine, Houston, TX*

Background: Early data suggests that immunotherapy (IO) for localized colorectal cancer (CRC) is associated with high rates of pathologic complete response (pCR) and durable remission. This study aims to characterize endoscopic, imaging, and pathological outcomes among patients who received IO for localized CRC. **Methods:** This was a single-institution retrospective analysis of patients with MSI-H CRC who received at least one cycle of anti-PD-1 therapy for localized (stage I-III) MSI-H CRC. Patient and tumor characteristics were obtained from the clinical record. Endoscopy reports were assessed using standardized criteria to determine response and imaging was assessed using RECIST v1.1 where applicable. Endoscopic complete response (endoCR) was characterized by flat, white scar and/or telangiectasia without residual ulcer or nodularity. Categorical variables were compared using Fisher's exact test. **Results:** 37 patients who received a median of 8 cycles of pembrolizumab (n = 36) or nivolumab (n = 1) for localized CRC were identified, of which 16 (43%) had a rectal primary. 10 patients (27%) had mucinous features on pathology. The best endoscopic response was complete response (CR) in 13 of 30 (43%) patients, which was achieved after a median of 6 cycles. The rate of endoCR after ≤ 4 cycles of IO was similar to the rate of endoCR after > 4 cycles (29% vs 50%, p = 0.284). The best imaging response was CR in 6 of 32 (19%) of patients. The rate of CR on imaging after ≤ 4 cycles and > 4 cycles of IO was 6% and 36% respectively (p = 0.064). In cases where imaging and endoscopy were available (n = 24), discrepancy in best response was noted in 14 (58%) cases. The most common discrepancy was partial response on imaging when endoCR was noted (n = 6 cases). 16 patients proceeded to surgical resection (after a median of 8 cycles) of which 11 (69%) had pCR despite non-CR on either endoscopy (n = 7) or imaging (n = 9). The endoscopic reports indicating residual disease prior to surgery included findings such as ulceration, scarring, strictures, and an obstructing mass. Of 15 patients who did not proceed to surgery and had follow-up more than 6 months after completion of IO, 13 (87%) had no evidence of progression at a median follow-up of 19.3 months from IO start. **Conclusions:** Discrepancies between endoscopic, imaging, and pathological outcomes were frequent, indicating a need for improved clinical response criteria. Nevertheless, immunotherapy was associated with deep and durable responses in most patients with localized MSI-H CRC. Research Sponsor: None.

The role of image-guided volume-adapted high-dose-rate endorectal brachytherapy boost in total neoadjuvant treatment of distal locally advanced rectal cancer. *First Author: Huangang Jiang, Department of Radiation and Medical Oncology, Zhongnan Hospital, Wuhan University, Wuhan, China*

Background: Endorectal brachytherapy has been used as palliative or preoperative treatment for advanced or locally advanced rectal cancer, with moderate radiation induced toxicity. This study aimed to explore the efficacy of high-dose-rate ¹⁹²Ir brachytherapy combined with external beam radiotherapy (EBRT) in total neoadjuvant treatment (TNT) of distal rectal cancer. **Methods:** From January 2017 to December 2022, eligible rectal adenocarcinoma patients were assessed as clinical stage II -III, with primary tumor located in distal rectum (≤ 5 cm from anal verge). The local staging was determined using endorectal ultrasound and magnetic resonance imaging (MRI). In addition, cases included in this study underwent preoperative semineck endorectal brachytherapy of 8-12Gy/2-3F/1-1.5w, followed by EBRT of 45-50.4Gy/25-28F, fluorouracil-based concurrent and consolidation chemotherapy. The brachytherapy was image-guided volume-adapted, and delivered by multi-channel ¹⁹²Ir source applicators with different diameters. Radiation proctitis was graded from 0 to 4 using Radiation Therapy Oncology Group (RTOG) criteria. **Results:** A total of 40 cases were enrolled in this retrospective study, biopsy-proven and diagnosed as clinical stage II (n = 8), stage III (n = 32). The rates of T4 and positive circumferential resection margin (CRM) were 35% and 87.5% respectively. The median value of the interval from completion of radiotherapy to operation was 86 days (interquartile range: 75-98 days). After neoadjuvant treatment, 2 cases were undergoing the watch-and-wait strategy with sustained clinical complete response (cCR), 38 patients received operation and R0 resection rate was 97.4%. The pathological complete response (pCR) rate was 28.9%, and major pathological regression rate was 67.5%. The theoretical rate of anus preservation was 62.5%, including 6 of 21 cases underwent abdominoperineal resection but achieved pCR, 17 cases underwent low anterior resection or intersphincteric resection, and 2 cases with sustained cCR. After a median follow-up of 37 months (range 12-68 months), the 3-year disease-free survival, local-regional recurrence-free survival and overall survival was 81.1% (95%CI: 64.3%-91.2%), 94.9% (95%CI: 80.6%-98.5%) and 96.9% (95%CI: 82.1%-99.4%), respectively. No patients experienced Grade ≥ 3 radiation proctitis. The median Wexner fecal incontinence score of anus-preserving cases was 1 (range 0-8). Subgroup analysis showed that the complete response rate (pCR or sustained cCR) was lower in cases received 2 fractions brachytherapy than those received 3 fractions (27.8% vs 36.4%). **Conclusions:** The addition of image-guided volume-adapted high-dose-rate ¹⁹²Ir endorectal brachytherapy boost to TNT could improve the pathological tumor response and anus preservation rate in distal locally advanced rectal cancer. The number of lymph nodes examined as a poor prognosis factor in stage II and stage III colon cancer patients undergoing curative surgery. *First Author: JEONGSEOK JEON, Yonsei University College of Medicine, Seoul, South Korea*

Background: The number of lymph nodes (LN) examined is a key factor in determining the stage of colorectal cancer. Over the past 20 years, the examination of fewer than 12 LN has been regarded as a poor prognosis. However, surgical procedures and pathologic examination improvements have increased the number of LN examined. This raised the question of reassessing the best cutoff point for staging colon cancer patients undergoing curative surgery. **Methods:** We reviewed a total of 3,126 eligible patients with stage II-III colon cancer collected from the Yonsei Cancer Center Registry (YCC) database between 2005 and 2015. As a validation cohort, we used clinicodemographic data from 9,604 patients with stage II-III colon cancer identified by the Netherlands Cancer Registry (NCR) between 2006 and 2015. The hazard ratio (HR) obtained from Cox-proportional regression was used to investigate the effect of LN's yield on 6-year overall survival (OS). The optimal LN yield was evaluated by analyzing every cutoff from 3 to 165. We used the Kaplan-Meier method to compare the effect of higher vs. lower optimal LN yield on a 6-year OS. Univariate and multivariate Cox regressions were conducted. **Results:** The proportion of patients with fewer than 12 LN examined dramatically decreased between 2005 and 2015 (17.4% in 2005 vs. 0.6% in 2015, $P < 0.001$). Based on the 12 LN examined as the conventional cutoff number, there was no significant association between 6-year OS and LN yield in all stages II-III patients (HR = 1.21, $P = 0.116$; $n = 3,126$), stage II (HR = 1.39, $P = 0.068$; $n = 1,570$), and stage III (HR = 1.18, $P = 0.297$; $n = 1,557$) colon cancer. Interestingly, a higher cutoff of 20 LN examined was associated with a significant increase in 6-year OS in all patients (HR = 1.51, $P < 0.001$ in patients with LN examined less than 20). Multivariate Cox-proportional hazard regression showed a significant decrease in 6-year OS in stage II (HR = 1.39, $P = 0.026$) and stage III (HR = 1.54, $P < 0.001$) with less than 20 LN yield. Consistent with the result in the YCC database, less than 20 of LN yield was associated with poorer 6-year OS in stage II-III patients (HR = 1.25, $P < 0.001$; $n = 9,604$), stage II (HR = 1.43, $P < 0.001$; $n = 4,689$), and stage III (HR = 1.13, $P = 0.007$; $n = 4,915$) in the NCR, respectively. **Conclusions:** Less than 20 LN examined is associated with a poorer prognosis in patients with surgically treated colon cancer, compared to the current cutoff value of 12. Further validation of re-evaluating criteria on the inadequacy of LN retrieval in high-risk stage II colon cancer is warranted. **Research Sponsor:** A grant of the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (grant number : HI22C0353); The National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) (No. 2022R1A2C4001879).

The significance of mucin on rectal MRI in patients with locally advanced rectal cancer being considered for watch-and-wait after neoadjuvant therapy. *First Author: Sean Judge, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Neoadjuvant therapy (NAT) leads to a clinical complete response (cCR) in a significant proportion of patients with locally advanced rectal cancer (LARC) allowing for possible non-operative management. Along with physical exam and proctoscopy, magnetic resonance imaging (MRI) is used to evaluate for residual tumor following NAT. The presence of mucin on MRI leads to uncertainty about residual disease and appropriateness of watch-and-wait strategy (WW) in patients with no evidence of disease on proctoscopy (endoscopic cCR). We set out to determine the impact of radiographic mucin in patients with LARC after NAT. **Methods:** MRI reports between July 2016 to January 2020 at Memorial Sloan Kettering Cancer Center were queried for the presence of mucin in the tumor bed on post-treatment rectal MRI in patients with LARC following NAT. The clinicodemographic, pathologic, and outcomes data from these patients were compiled and analyzed. **Results:** Seventy-one patients were included in the final analysis who fit the pre-specified inclusion criteria (Table). Of the 71 patients with mucin present on post-treatment MRI, 19 patients (27%) entered a watch-and-wait (WW) strategy and 52 patients (73%) were planned for surgery (non-WW). Comparing the WW and non-WW cohorts, there was no difference in age, sex, clinical nodal status, or neoadjuvant regimen. Patients entering a WW protocol had a higher proportion of cT1-T2 tumors (32%) compared to non-WW (4%) ($P < 0.01$). All WW patients had endoscopic cCR, while only one non-WW patient achieved endoscopic cCR. Of 52 non-WW patients, 49 underwent resection and 3 did not have surgery due to disease progression. The pathologic complete response (pCR) rate in the non-WW patients who underwent surgery was 10%. Of 19 WW patients, 4 experienced regrowth (21%), while 15 (79%) have no local regrowth, with a median follow up of 4.2 years (range 2.4-6.3 yrs). Two patients (11%) experienced distant failure. **Conclusions:** The presence of mucin after NAT for LARC should not necessarily preclude a WW strategy in otherwise appropriate candidates who achieve an endoscopic cCR. **Research Sponsor:** U.S. National Institutes of Health.

Efficacy and safety of mFOLFOX6 with apatinib as postoperative adjuvant chemotherapy in stage IIIB or IIIC colorectal cancer. *First Author: Xiaodong Gu, Department of General Surgery, Huashan Hospital, Fudan University, Shanghai, China*

Background: Antiangiogenic therapy has shown benefit in metastatic colorectal cancer. However, the role of apatinib in adjuvant treatment of stage IIIB and IIIC colorectal cancer remains unclear. **Methods:** Patients received modified FOLFOX6 once every 2 weeks for a 6-month period (control group) or modified FOLFOX6 for 6 months plus apatinib (500mg) once a day for a 12-month period (experimental group). Progression free survival (PFS), overall survival (OS) and treatment-related adverse events were evaluated in two groups. **Results:** 63 patients have been enrolled in this study. This trial reported a 3-year PFS of 74.2% for modified FOLFOX6 plus apatinib vs. 61.5% for modified FOLFOX6 ($P < 0.05$). 5-year OS was significantly improved in the experimental group compared with the control group (86.3% vs. 72.5%; $P < 0.05$). The most common grade 3 adverse events were hypertension and hand-foot syndrome. No treatment-related grade 4 adverse events or treatment-related deaths were observed. **Conclusions:** Apatinib can prolong PFS and OS when added to adjuvant chemotherapy in resected stage IIIB and IIIC colorectal cancer. The toxicities associated with apatinib were generally acceptable. Clinical trial information: NCT03365765. **Research Sponsor:** Jiangsu Hengrui Medicine Co., Ltd.

Mismatch Repair system protein deficiency as a factor of resistance to chemo-radiotherapy treatment in patients with locally advanced rectal adenocarcinoma and its influence on disease-free survival. *First Author: Andrea Pretta, Medical Oncology Unit, University Hospital and University of Cagliari, Cagliari, Italy*

Background: Available data on Mismatch Repair system deficit and microsatellite instability are conflicting and are generally derived from a small number of patients due to the rarity of this condition in rectal cancer. Our study aimed to evaluate the frequency and therapeutic implications of Mismatch Repair proteins (MMR) status in patients with locally advanced rectal cancer (LARC). **Methods:** We retrospectively collected data from 318 patients affected by LARC adenocarcinoma (cT3-4 +/- N1-2) treated at the Medical Oncology Unit of the University Hospital of Cagliari, Italy, the Medical Oncology Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy and at the Medical Oncology Unit, AOU Ospedali Riuniti, Ancona, Italy. All patients included in the study underwent neoadjuvant concurrent capecitabine and long-course radiotherapy (RT) (total dose of Gy 50.4), afterwards a total mesorectal excision (TME) was performed. MMR expression was evaluated through immunohistochemistry. The primary objective was major TRG (0-1 Ryan's score) while secondary objectives were pathological complete response, disease-free survival (DFS) and overall survival (OS). **Results:** 160 patients (148 pMMR and 12 dMMR) were included in exploratory cohort and 158 (146 pMMR and 12 dMMR) were included in validation cohort. A major TRG has been shown in 64/148 (42,6%) and 63/146 (43,1%) patients with pMMR in exploratory cohort and validation cohort, respectively; while no major TRG have been shown in dMMR patients in exploratory cohort nor in validation cohort. Both exploratory and validation cohorts showed a statistically significant higher median DFS in pMMR patients compared to dMMR ones: NR vs 14 months in exploratory cohort ($p = 0,003$) and NR vs 17 months in validation cohort ($p = 0,02$). **Conclusions:** Our retrospective study indicated an association between dMMR and poor or no response to preoperative chemoradiotherapy. These results are consistent with the role of MMR as a predictor of poor-response to chemoradiotherapy and represent a hypothesis-generating study for the selection of these patients for immunotherapy in the neoadjuvant setting, in which the available data are immature. **Research Sponsor:** None.

The Ave-Rec trial: Phase II trial of PD-L1/PD-1 blockade with avelumab plus chemoradiotherapy for locally advanced resectable T3b-4/N1-2 rectal cancer—Toxicity and interim efficacy data. *First Author: Michael Michael, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Neoadjuvant long course chemoradiotherapy (LCRT) for locally advanced rectal cancer (LARC) results in a complete pathological response rate in 10-30% of patients (pts), but with 20-40% non-responders and 10-15% have local recurrence. Radiotherapy (RT) is immuno-stimulatory by enhancing local/distant tumour cell death, but also immunosuppressive as it stimulates PDL1 production and myeloid-derived suppressor cell activity. Hence PDL1 inhibition may be required to enhance the immuno-stimulatory effects of RT. **Hypothesis:** In pts with resectable LARC, the anti-PDL1 antibody Avelumab given post LCRT may enhance the pathological/imaging response rates whilst reducing local/distant relapse rates. **Methods:** Phase II single arm trial. All pts had standard LCRT (50.4Gy RT plus 5FU [225mg/m²/day/CI] or Capecitabine [825mg/m² BID on days of RT] over 5.5 weeks). Post LCRT (prior to surgery), pts received 4 cycles Avelumab (AV) (10mg/kg, q2 weeks), then surgical resection at 10-12 weeks post LCRT. Fresh tumour biopsy and ctDNA sampling taken pre LCRT, pre Cycle 1 AV and at surgery. Response by FDG PET/CT and pelvic MRI at 8 weeks post LCRT, pre surgery. **Inclusion Criteria:** pts with LARC (MRI stage T3b-4/N1-2/M0), planned for LCRT followed by curative resection, tumoural lower border within 12cm from anal verge, measurable disease (RECIST1.1), ECOG 0-1, adequate organ function and no contraindications to AV therapy. **Endpoints:** (a) *Primary:* Complete pathological response rate post-LCRT (Target ≥ 35%), documented by central pathologist, (b) *Secondary:* MRI and FDG PET/CT imaging responses by RECIST1.1 and PERCIST, respectively. Toxicity. (c) *Exploratory:* Tumoural immune cell subsets/checkpoint expression (by multiplex immunohistochemistry and in-vitro functional assays) and ctDNA analysis. Distant relapse-free survival and the sites of relapse. ANZCTR: NCT03299660. **Results:** 37 pts across 6 sites, with 33 patients (89%) received allocated interventions: LCRT, AV and surgery (where possible). Age median 55 years (31-76). M:F 23:10. Baseline tumoural stage: T3b-d 75%, T4a-b 25%. No pts with dMMR/MSI-H tumour. Overall 33 pts completed LCRT, 31 pts (83%) completed all 4 cycles of AV and 32 pts (86%) had planned surgery (22, ULAR, 2 APR, 2 AR, 6 Other). ORR Pelvic MRI presurgery (N = 33): 2 CR, 14 PR, and 31 DCR. FDG PET/CT (N = 31): 10 CMR, 18 PMR and 3 SMD. Overall 10 pts Grade 3/4 AEs, with 15 G3/4 events. Only 3 pts with treatment-related G3 and no G4 AEs. No specific immune-related G3 AEs observed. Post-operative complications were not unexpected. **Conclusions:** Consolidation Avelumab post LCRT for pts with LARC, was well tolerated with promising activity. Pathological response, biological substudies (immunological and ctDNA) and survival endpoints to be reported. Clinical trial information: NCT03299660. Research Sponsor: Merck Australia.

A prospective evaluation of pelvic radiation vs. no radiation among patients with young-onset rectal cancer: Impact on patient-reported outcomes. *First Author: Kelsey L Corrigan, Department of Radiation Oncology, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The rise in young-onset rectal cancer (YORC) calls for better understanding of the long-term impact of radiation therapy (RT) on gastrointestinal (GI) toxicity and pelvic organ function. We aimed to prospectively capture the longitudinal trajectories of patient-reported outcomes (PROs) in YORC patients who received RT vs. no RT and to identify factors associated with unfavorable PROs. **Methods:** We prospectively enrolled 120 YORC patients undergoing curative-intent treatment. The validated EORTC QLQ-CR29 was self-administered at time intervals grouped as: 0-11 months, 12-23 months, and 24+ months post-resection. Responses were stratified by receipt of neoadjuvant RT (yes vs. no). The longitudinal change in PROs was described by a linear mixed effects model. Multivariate linear regression was used to determine the impact of treatment factors on long-term PROs. **Results:** The median age at diagnosis was 44. The majority (N = 92, 77%) presented with cT3,4/N+ disease. Preoperative therapy included: no RT (N = 38, 32%; 8 [7%] who received chemotherapy alone, and 30 [25%] who received no neoadjuvant therapy), vs. RT (N = 82, 68%; where 59 [72%] also received concurrent capecitabine). More patients in the RT group had advanced T stage (3 or 4; 94% vs. 56%, $P < 0.001$), distal tumor (median 7 vs. 12.5 cm from the anal verge, $P < 0.01$), and underwent abdominal perineal resection (19 vs. 0%, $P < 0.001$). After a median follow-up of 70 months, all were alive: 103 (86%) were disease-free, 9 (8%) had recurrence with successful salvage, and 8 (7%) had disease progression. In the RT group, sore skin improved at 12-23 and 24+ months (Estimate [B]: -16.5, $P = 0.03$ and $B: -14.4$, $P = 0.03$), dyspareunia improved at 12-23 months ($B: -31.8$, $P < 0.01$), and blood/mucus in stool improved at 24+ months ($B: -8.01$, $P < 0.01$) vs. 0-11 months. At 24+ months, RT receipt was associated with worse stool frequency ($B: 26.4$, $P < 0.01$), urinary frequency ($B: 18.4$, $P = 0.04$), and flatulence ($B: 23.0$, $P = 0.02$). **Conclusions:** YORC often require multimodality therapy including RT. Sore skin, dyspareunia, and blood/mucus in stool improved, but flatulence and frequency can persist beyond 2 years post RT. Proactive counseling and supportive measures are needed to inform treatment choices and mitigate long-term impact. Research Sponsor: University of Texas MD Anderson G.S.Hogan Gastrointestinal Research Fund.

EORTC QLQ-CR29 scores stratified by receipt of neoadjuvant RT at each timepoint post-resection (range from 0-100).

	Mean (SD) 0-11 months		Mean (SD) 12-23 months		Mean (SD) 24+ months	
	No RT	RT	No RT	RT	No RT	RT
Urinary frequency	43 (28)	28 (23)	32 (23)	27 (24)	18 (20)	27 (25)
Blood/mucus in stool	10 (22)	10 (13)	3 (7)	6 (11)	4 (13)	4 (8)
Stool frequency	37 (32)	30 (20)	35 (23)	31 (25)	21 (23)	35 (25)
Flatulence	27 (43)	33 (32)	36 (10)	31 (27)	21 (22)	36 (28)
Sore skin	27 (15)	43 (30)	21 (31)	25 (26)	13 (19)	26 (26)
Dyspareunia	67 (47)	67 (30)	33 (0)	42 (36)	24 (36)	46 (34)

Higher score indicates greater symptom burden.

Organ preservation and total neoadjuvant therapy for rectal cancer: Investigating long course chemoradiation versus short course radiation therapy. *First Author: Paul Bernard Romesser, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The efficacy of long course chemoradiation (LCRT) vs. short course radiation therapy (SCRT) relative to organ preservation (OP) in rectal cancer (RC) is unknown. We compared OP rates between SCRT and LCRT total neoadjuvant therapy (TNT) strategies. **Methods:** During the COVID-19 pandemic we established an institutional SCRT mandate with no exceptions. For comparison, we identified RC patients treated with LCRT immediately before and after the mandate period. After completion of TNT, patients were restaged by clinical exam, endoscopy, and MRI. A watch and wait (WW) approach was recommended for patients with a clinical complete response (cCR), defined by the MSK regression schema. Total mesorectal excision (TME) was recommended for non-cCR patients. OP was defined as remaining TME-free with no evidence of disease in the pelvis. We performed survival analysis for: local regrowth rate, OP, disease-free survival (DFS), and overall survival (OS). The validated low anterior resection syndrome (LARS) questionnaire (LARS-Q) was used to determine percentage of patients with major LARS. **Results:** We identified 332 consecutive patients with non-metastatic rectal adenocarcinoma treated with TNT (Jan. 2018-Jan. 2021). Patient and tumor characteristics were similar in the LCRT (n = 256) and SCRT (n = 76) cohorts. No significant differences in high-risk features were noted. Most patients had clinical stage III disease (82% in LCRT vs. 83% in SCRT). Induction chemotherapy followed by consolidative radiation was the most common treatment order (78% (LCRT) vs. 70% (SCRT)). The median interval from end of TNT to clinical restaging was 8 weeks (LCRT) and 9 weeks (SCRT). The cCR rate was 46% in both cohorts. Among patients with a cCR, the likelihood of WW management was similar (98% (LCRT) vs. 94% (SCRT)). From start of TNT, the median follow-up was 32 and 28 months respectively for LCRT and SCRT. The 2-year OS (95% vs. 92%), DFS (78% vs 70%), and distant recurrence (20% vs. 21%) rates were similar. Among all patients, the 2-year OP rate was 40% (95% CI 35-47%) for LCRT and 29% (95% CI 20-42%) with SCRT. In those patients managed by WW, the 2-year local regrowth rate was 20% (95% CI 12-27%) with LCRT vs. 36% (95% CI 16-52%) with SCRT. Percentage of patients reporting major LARS symptoms were similar among WW patients post TNT: baseline (23% (LCRT) vs. 18% (SCRT)), 6-months (41% (LCRT) vs. 42% (SCRT)), and 12-months (25% (LCRT) vs. 15% (SCRT)). **Conclusions:** In this nonrandomized comparison, while cCR rates were similar, we observed a numerically higher local regrowth rate with SCRT-TNT than with LCRT-TNT. Rate of major-LARS symptoms were similar with LCRT-TNT than with SCRT-TNT. The ongoing ACO/ARO/AIO-18.1 trial, hypothesizing that LCRT-TNT will increase OP rates relative to SCRT-TNT, will definitively address this question. Prophylactic hyperthermic intraperitoneal chemotherapy in T4 colorectal cancer: Can it improve the oncologic prognosis? *First Author: Lifeng Sun, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: Previous studies have shown that T4 stage was one of the risk factors for peritoneal metastasis (PM) of colorectal cancer (CRC). However, there is paradoxical data to prove that prophylactic hyperthermic intraperitoneal chemotherapy (HIPEC) treatment is beneficial for CRC patients. **Methods:** In this cohort study, 220 consecutive CRC patients with T4N0-2M0 were enrolled and recorded from November 2014 to November 2018 with a 3-year follow-up following surgery. A propensity score matching (PSM) approach was applied to balance the clinicopathological characteristics. Finally, 180 patients were matched successfully to further analyze. The 3-year disease-free survival (DFS) was set as the primary outcome, and the PM rate between the two groups after PSM was analyzed. **Results:** Before PSM, of 220 CRC patients enrolled, the 3-year DFS was 83.9% in the HIPEC group, which was better than 67.2% in the control group. The cumulative PM incidence was 2.2% in the HIPEC group and 12.6% in the control group ($p = 0.047$). After PSM, 180 matched patients were formed for further analysis. The DFS and the cumulative PM rate of the patients in the HIPEC group were also better than that in the control group ($p = 0.034$ and 0.047 , respectively). For laparoscopic surgery subgroup analyses, PM rate of the patients with laparoscopic surgery was 13.8% in the No HIPEC group, and 2.6% in the HIPEC group ($p = 0.070$). Through multivariable analysis, it was found that prophylactic HIPEC correlated to better DFS [hazard ratio (HR) 0.43, 95% confidence interval (CI) 0.19-0.95; $p = 0.037$], and N2 stage correlated to worse DFS [HR 1.97, 95% CI 1.09-3.56; $p = 0.025$]. Besides, no post-operative death occurred, the anastomotic leakage rate was 2.2% in the HIPEC group and 0.7% in the control group ($p = 0.439$). **Conclusions:** Prophylactic HIPEC may improve the prognosis in the patients with T4N0-1M0 CRC, but not in the T4N2M0 CRC, and it does not significantly increase the surgery-related complications. Laparoscopic surgery followed by HIPEC for T4 stage CRC is relatively safe, which does not increase the risk of PM. Treatments and clinical outcomes in stage II colon cancer (CC) patients (pts) with 12-gene Oncotype DX Colon Recurrence Score assay-guided therapy: Real-world data. *First Author: Baruch Brenner, Rabin Medical Center, Petah Tikva, Israel*

Background: The role of adjuvant chemotherapy (CT) in stage II CC is debated. The validated 12-gene Oncotype DX Colon Recurrence Score test provides a Recurrence Score (RS) result (range, 0-100) which estimates recurrence risk (RR) in stage II/III pts. We studied treatment and clinical outcomes in CC pts in whom treatment decisions incorporated the RS result. **Methods:** This prospectively designed cohort study included all stage II, MMR-P, CC pts who underwent the 12-gene Oncotype DX testing through Clalit between 1/2011 and 12/2016 and had available data with minimum 3-yr follow-up. Kaplan-Meier (KM) estimates and log-rank tests were used to compare RR and CC specific mortality (CCSM) between RS categories. Multivariable analysis (MVA) identified variables associated with RR/CCSM. **Results:** The analysis included 938 pts. Median age, 68 (IQR, 60-76) yrs; 96% had T3 tumors, and 89% had ≥ 12 nodes examined. Median RS was 26 (IQR, 19-33). The 3 RS categories (0-29, 30-40, and 41-100) included 65%, 24%, and 11% of pts, respectively. The overall CT use rate was 24%, with a significant difference between the 3 categories (14%, 36%, and 60%, respectively, $P < .0001$). Pts with very low RS (0-15) comprised 14% of the cohort (CT use rate, 11%). Younger pts, and those with invasion/perforation/obstruction were more likely to receive CT. Clinical outcomes with a median follow up of 6.9 (IQR, 5.5-8.6) yrs are presented (Table). Among untreated pts, KM estimates for RR and CCSM differed significantly between the 3 RS categories ($P < .0001$). Outcome of untreated RS 0-15 pts was excellent. In an MVA model, male sex, presence of invasion/perforation/obstruction and higher RS category (RR 41-100 vs 0-29 and vs 30-40, but not RS 30-40 vs 0-29) were associated with increased RR. For CCSM, the results were similar, but this time age ≥ 70 yrs replaced sex as a significant prognostic variable. Clinical outcomes within each RS group did not differ significantly between treated and untreated pts, but were numerically better with CT in the RS 41-100 group. **Conclusions:** This real-world analysis showed that the RS results provide independent prognostic information in stage II CC. Further studies are needed to investigate the potential role of the RS result as a predictor of CT benefit, but the data suggest that this benefit may be limited to pts with high RS results. Research Sponsor: Exact Sciences.

RS group	N (%)	N untreated	N CT-treated	5-yr recurrence risk (95% CI)		5-yr CCSM (95% CI)

Molecular profiling and characterization of the tumor immune microenvironment (TME) in appendiceal carcinoma (AC). *First Author: Muneeb Rehman, Ruesch Center for the Cure of Gastrointestinal Cancers, Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC*

Background: The rarity of AC presents challenges in understanding disease pathogenesis. We previously showed that AC has higher rates of mutations in *KRAS* and *GNAS* and lower rates of *TP53*, *APC*, and *PIK3CA* than CRC. The appendix also has many lymphoid clusters and regulates IgA production in the large bowel, suggesting that AC may be subject to more lymphocytic regulation than CRC. We sought to characterize the molecular profile and TME across AC histopathological types. **Methods:** AC samples were analyzed by DNA sequencing (592 genes, NextSeq, or whole exome sequencing, NovaSeq), whole transcriptome sequencing (WTS, NovaSeq), and immunohistochemistry (IHC) for molecular profiling, including microsatellite instability (MSI), mismatch repair (MMR), PD-L1 (SP142), and tumor mutational burden (TMB). Microenvironment Cell Population-counter Quantiseq was used to quantify tumor immune contexture using WTS. AC histopathology was derived from pathology reports. Mann-Whitney U and ChiSquare tests were applied as appropriate, with P-values adjusted for multiple comparisons using Benjamin-Hochberg. **Results:** AC (N = 731) were grouped by histology: 5% goblet cell (GC), 6% high-grade adenocarcinoma (HGA), 14% low grade mucinous (LGM), 33% mucinous adenocarcinoma (MA), 1% pseudomyxoma peritonei (PMP), 6% signet ring cell carcinoma (SRC), and 35% adenocarcinoma not otherwise specified (NOS) (see Table). Age at collection and PD-L1+ (0-5.2%) did not differ by histopathology. Seven patients had dMMR (4 NOS and 3 MA). Median TMB was significantly higher in NOS vs. GC (4 mutations/megabase vs 2, $q < 0.001$), NOS vs. LGM (4 vs 3, $q = 0.048$), MA vs. GC (4 vs 2, $q < 0.001$), and MA vs. LGM (4 vs 3, $q = 0.037$). Distinct TME patterns were observed in NOS vs. MA (median cell fraction: dendritic cells 0.07 vs 0, $q < 0.01$; M2 macrophages 0.055 vs 0.042, $q = 0.030$; natural killer cells 0.034 vs 0.031, $q = 0.011$; CD4 T cells 0.006 vs 0, $q = 0.044$) and GC vs. MA (M1 macrophages 0.039 vs 0.057, $q = 0.021$; dendritic cells 0.012 vs 0, $q < 0.01$; B cells 0.061 vs 0.050, $q = 0.013$; M2 macrophages 0.074 vs 0.042, $q < 0.01$; natural killer cells 0.041 vs 0.031, $q = 0.01$; and neutrophils 0.017 vs 0.038 $q = 0.045$). T cell inflamed signature (TIS) and immune-oncology (IO) marker gene expression were higher in HGA and lower in LGM and MA. Somatic mutation rates differed by histopathology (see Table). **Conclusions:** There is significant heterogeneity in TMB, TME, and mutational profiles across AC histologies. MA has a particularly immune-cold TME shown by lower infiltration of lymphocytes, TIS, and IO gene expression. These findings are critical to identify novel biomarkers and develop new therapeutic strategies for AC. Research Sponsor: None.

Efficacy and safety of KNO26 in combination with KNO46 in patients with locally advanced unresectable or metastatic HER2-positive other solid tumors. *First Author: Jifang Gong, Beijing Cancer Hospital, Beijing, China*

Background: Besides breast cancer (BC) and gastric cancer, HER2 is also widely expressed in other solid tumors, such as colorectal cancer (CRC), NSCLC, gall-bladder cancer (GBC), renal pelvis cancer (RPC), pancreatic ductal adenocarcinoma (PDAC), etc. The reports of immunotherapy combined with HER2-targeted therapy are limited. KNO26 is a novel bispecific antibody that simultaneously binds to two distinct HER2 epitopes. KNO46 is a novel bispecific antibody that blocks both PD-L1 interaction with PD-1 and CTLA-4 interaction with CD80/CD86. **Methods:** KNO26-203 study (NCT04521179) is an open-label, phase II, multicenter study to evaluate the efficacy and safety of KNO26 (30mg/kg, Q3W, C1D1 and C1D8 loading) combined with KNO46 (5mg/kg, Q3W) in patients (pts) with HER2-positive (defined as HER2 IHC 3+ or HER2 gene amplification) solid tumors. The study consisted of 3 cohorts, including HER2 positive gastric or gastroesophageal cancer (GC/GEJ), BC and other solid tumors. Pts received treatment until disease progression or unacceptable toxicity. Tumor assessments were scheduled every 6 weeks. The primary endpoints were ORR and DOR. The efficacy and safety of KNO26 combined with KNO46 were reported. **Results:** As of 10 November 2022, 26 pts with HER2 positive tumor other than BC and GC/GEJ were enrolled, including 15 CRC, 5 NSCLC, 4 GBC, 1 RPC and 1 PDAC pts. All those pts had previous systemic treatment. The median age was 56 (range 37 ~ 67) years. 15 (57.7%) pts had liver metastasis. 92.3% of pts and all CRC pts had received ≥ 2 lines prior treatment. 5 (19.2%) and 6 (23.1%) pts had received prior anti-HER2 and anti-PD-(L)1 therapy, respectively. All 26 pts were assessed according to RECIST v1.1. The confirmed ORR was 53.8% (95% CI: 33.4, 73.4) with mDOR 6.8 months (95% CI: 2.9, 15.3). The mPFS was 5.6 months (95% CI: 2.9, 16.5) and 12-month OS rate was 80.4% (95% CI: 59.1, 91.4) with median follow-up time 16.6 months. For 15 CRC pts, the ORR was 53.3% (95% CI: 26.6, 78.7) with mDOR 11.7 months (95% CI: 3.2, NE). The mPFS was 12.2 months (95% CI: 2.7, NE). 12-month OS rate was 80.0% (95% CI: 50.0, 93.1) with median follow-up time 16.0 months. Common TRAEs were infusion related reaction (38.5%), AST increased (34.6%), ALT increased (26.9%), conjugated bilirubin increased (26.9%), rash (26.9%), anemia (26.9%) and blood bilirubin increased (26.9%). Most of them were Grade 1 or 2. The most common $\geq$ Gr3 TRAEs were conjugated bilirubin increased (7.7%) and AST increased (7.7%). There was no treatment related death. **Conclusions:** KNO26 combined with KNO46 treatment had demonstrated favorable efficacy and safety profile in HER2 positive other solid tumors (non-GC/GEJ and non-BC). Especially very promising efficacy were observed in ≥ 3 lines HER2 positive CRC. Based on these results, a pivotal study was planned to verify the efficacy and safety of KNO26 and KNO46 combo. Clinical trial information: NCT04521179. Research Sponsor: Alpmab.

Comparison of synchronous neoplasms at colonoscopic diagnosis of early-onset versus average-onset colorectal cancer. *First Author: Oluwadunni Eunice Emiloju, Mayo Clinic, Rochester, MN*

Background: Colorectal cancer (CRC) incidence has steadily increased in adults younger than 50 years (EO-CRC) since the 1990s, with a predominance in the left colon and rectum. Precursor lesions of CRCs are adenomas, including advanced adenomas, and sessile serrated polyps. Given that neoplastic development is age-related, we hypothesized that patients with early-onset CRC (EO-CRC) may have fewer adenomas compared to patients with average-onset CRC (AO-CRC) at diagnosis. **Methods:** We performed a retrospective review of electronic health records at Mayo Clinic or Mayo Health System [2012 to 2021] and randomly selected 150 patients with EO-CRC who met eligibility criteria and matched them with 150 AO-CRC patients based on gender and colonoscopy indication. Known hereditary syndromes or inflammatory bowel disease were excluded. At colonoscopy where CRC was diagnosed, we recorded findings of adenomas, advanced adenomas (> 1 cm, villous histology, or high-grade dysplasia), and sessile serrated polyps (SSP). **Results:** Median age at diagnosis was 43 years for EO-CRC and 67 years for AO-CRC. No significant differences in BMI, family history of CRC, MMR, *BRAF*^{V600E} *KRAS* status or SSPs were found between groups (all $p > 0.05$). Among patients with colon cancer, no difference was found for adenoma number yet patients with EO-colon cancer (EO-CC) had larger polyps [median of 10 mm vs 5 mm, $p = 0.001$] (Table) compared with AO-colon cancer (AO-CC). At least 1 adenoma was found in 56% and 47% of patients with EO-CC and AO-CC, respectively. Moreover, advanced adenomas were significantly more common in the EO-CC group compared with the AO-CC group (42% and 14%, $p < 0.001$) [Table]. Among patients with rectal cancer, non-advanced adenomas were less frequent and although advanced adenoma were similar in frequency, they were more commonly located in the rectum in EO-rectal compared to AO-rectal cancers (Table). **Conclusions:** Patients with EO-colon cancer had a significantly higher likelihood of a synchronous advanced adenoma in the colon compared to those with AO-CRC. Together, these data suggest accelerated carcinogenesis throughout the colorectum in early onset patients, with increased risk for development of synchronous and metachronous CRC. Research Sponsor: None.

Atezolizumab plus tiragolumab in combination with chemoradiotherapy in localized squamous cell carcinoma of the anal canal: TIRANUS (GEMCAD-2103) trial. *First Author: Jaume Capdevila, Vall d'Hebron University Hospital and Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Radical chemoradiotherapy (CRT) is the standard of care in patients with localized anal squamous cell carcinoma; however, around 30% of patients do not achieve a complete clinical response (CCR) and require salvage surgery. Approximately 84% of anal carcinoma is associated with high risk types of human papilloma virus (HPV), primarily HPV 16 that generates high frequencies of tumor-infiltrating lymphocytes and inflammatory responses that have been linked with upregulation of PD-L1 (up to 74% of patients with squamous cell anal cancer). Additionally, poliovirus receptor (PVR) expression has been described in several squamous cell carcinomas, and has been correlated with PD-L1 expression and poorer prognosis, suggesting dual inhibition of PVR and PD-L1 as a potential mechanism to overcome the resistance to immune checkpoint monotherapy. Moreover, CRT induces the generation of tumor-neoantigens and could act in synergy with immunotherapy in this setting. The trial hypothesizes that the addition of atezolizumab (anti-PD-L1) and tiragolumab (anti-TIGIT) to chemoradiotherapy may lead to enhanced and more durable responses. **Methods:** TIRANUS is a Phase II, single-arm, open-label, non-randomized, multicenter clinical trial of atezolizumab and tiragolumab in concomitance with standard CRT as definitive therapy in treatment-naïve, localized squamous cell carcinoma of the anal canal. Patients receive atezolizumab (1200mg) plus tiragolumab (600 mg) for 2 cycles (Q3W) in concomitance with the 6 weeks of CRT (cisplatin: 60 mg/m² on days 1 and 29; 5-FU: 1000 mg/m² per day on days 1-4 and 29-32; radiotherapy: 1.8 Gy per day / total dose 54 Gy). After the concomitant phase, patients receive atezolizumab (1200mg) and tiragolumab (600 mg) Q3W for 6 additional cycles (consolidation phase). The primary endpoint is CCR rate, defined as the percentage of patients who achieve radiological complete response (CR), disappearance of all lesions according to RECIST 1.1 criteria (locally assessed) and no presence of residual disease assessed by biopsy at the end of consolidation phase (week 26). Secondary endpoints include Locoregional failure rate (LFR), Disease-free survival (DFS), Colostomy-free survival (CFS), Overall survival (OS), quality of life, safety and the determination of immune biomarkers potentially predictors of response in blood and tumor samples. Using a precision analysis by Clopper-Pearson method (asymptotic 95% confidence interval) and an expected CCR rate of 85%, a total of 45 evaluable patients are needed to obtain a precision estimation of $\pm 10.4\%$. Accrual started in February 2023. EudraCT: 2021-005887-24 Clinical Trial identifier: NCT05201612. Clinical trial information: NCT05661188. Research Sponsor: GEMCAD through industry partner Roche.

The Ohio State University Guardant Shield Colorectal Cancer Screening Project. *First Author: Peter Stanich, The Ohio State University Wexner Medical Center, Columbus, OH*

Background: Asymptomatic screening is an effective method for detecting early cancers when prognosis strongly depends on stage at time of diagnosis. Unscreened individuals often have a basic understanding of the importance and availability of colorectal cancer (CRC) screening but have concerns regarding the collection method of the currently available stool-based options or the invasiveness of direct visualization options that deter test completion. We hypothesize that offering a blood-based CRC screening test during a routine healthcare visit can increase screening adherence, especially within hard-to-reach populations and those hesitant about completing CRC screening. **Methods:** The Ohio State University Guardant Shield Colorectal Cancer Screening Project (NCT05716477) is a prospective study in the United States designed to recruit individuals who are currently engaging with mobile health clinics and are not up to date with CRC screening, with the aim of improving health in hard-to-reach populations. The study's primary objective is to evaluate the acceptance of a commercially available blood-based CRC screening test (Shield, Guardant Health, USA) in individuals aged 45-84, who have existing appointments with a mobile health clinic, and are not up to date with guideline recommended CRC screening. The study team screens for eligibility criteria before the appointment and reaches out to the individual to begin the informed consent process. Positive blood-based test results will be triaged to colonoscopy for further evaluation. A post-study survey will be administered to consented individuals aimed to collect data on CRC screening knowledge which will be correlated to patient demographics and uptake. Acceptance will be defined as those approached and with completed specimen collection. Progress: The study initiated on October 25, 2022, with the first patient enrolled on December 20, 2022. Enrollment is expected to continue with a target enrollment of 300 individuals. Clinical trial information: NCT05716477. Research Sponsor: Guardant Health.

Phase II/III study of circulating tumor DNA as a predictive biomarker in adjuvant chemotherapy in patients with stage II colon cancer: NRG-GI005 (COBRA). *First Author: Van K. Morris, Department of Gastrointestinal Medical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Detection of circulating tumor DNA (ctDNA) shed into the bloodstream represents a highly specific and sensitive approach for identifying microscopic or residual tumor cells after surgical resection. For patients (pts) with colon cancer (CC), the detection of ctDNA is associated with persistent disease after resection and outperforms traditional clinical and pathological features in prognosticating risk for recurrence. However, for pts with stage II CC, there are currently no validated biomarkers predicting benefit in identifying pts whose residual disease cancer be cleared by adjuvant chemotherapy. We hypothesize that for pts whose stage II colon cancer has been resected and who have no traditional high-risk features, a positive ctDNA status may identify those who will benefit from adjuvant chemotherapy. **Methods:** In this prospective phase II/III clinical trial, pts (N = 1,408) with resected stage II CC without traditional high-risk features and whom the evaluating oncologist deems suitable for active surveillance (i.e., not needing adjuvant chemotherapy) will be randomized 1:1 into 2 arms: standard-of-care/observation (Arm A), or prospective testing for ctDNA (Arm B). Postoperative blood will be analyzed for ctDNA with the Guardant Reveal assay, covering CC-relevant mutations and CC-specific methylation profiling. Pts in Arm B with ctDNA detected will be treated with 6 months of adjuvant (FOLFOX) chemotherapy. For all pts in Arm A, ctDNA status will be analyzed retrospectively at the time of endpoint analysis. The primary endpoints are clearance of ctDNA with adjuvant chemotherapy (phase II) and recurrence-free survival (RFS) for "ctDNA-detected" pts treated with or without adjuvant chemotherapy (phase III). Secondary endpoints will include time-to-event outcomes (OS, RFS, TTR) by ctDNA marker status and treatment, prevalence of detectable ctDNA in stage II CC, and rates of compliance with assigned intervention. Archived normal and matched tumor and blood samples will be collected for exploratory correlative research. Enrollment continues across North America to the 1408-patient phase III endpoint. NCT#: 04068103. Support: U10CA180868, -180822; UG1CA189867; GuardantHealth. Clinical trial information: NCT04068103. Research Sponsor: U.S. National Institutes of Health; GuardantHealth.

BREAKWATER: An open-label, multicenter, randomized, phase 3 study, with a safety lead-in (SLI), of first-line (1L) encorafenib (E) + cetuximab (C) ± chemotherapy (CT) vs standard-of-care (SOC) CT for BRAF V600E-mutant metastatic colorectal cancer (mCRC). *First Author: Scott Kopetz, MD Anderson Cancer Center, Houston, TX*

Background: Globally, 8-12% of patients (pts) with mCRC have BRAFV600E mutations, which confer poor prognosis. Based on BEACON (NCT02928224), EC was approved for the treatment (tx) of previously treated pts with BRAF V600E-mutant mCRC. BREAKWATER (NCT04607421) is evaluating EC ± CT vs SOC CT in pts with BRAF V600E-mutant mCRC. In the BREAKWATER SLI (N = 57), EC + CT showed encouraging antitumor activity. Confirmed ORR by BICR (95% CI) with EC + mFOLFOX6 and EC + FOLFIRI, respectively, was 68.4% (46.0, 84.6) and 75.0% (46.8, 91.1) in 1L, and 37.5% (13.7, 69.4) and 44.4% (24.6, 66.3) in 2L. mPFS by BICR (95% CI) with EC + mFOLFOX6 and EC + FOLFIRI, respectively, was 11.1 months [mo] (8.5, NE) and NE (13.8, NE) in 1L, and 10.8 mo (4.3, NE) and 12.6 mo (6.9, NE) in 2L. These results support the continued evaluation of EC + CT. Based on the SLI, EC + mFOLFOX6 was selected for the phase 3 portion. Here we present the updated study design. **Methods:** BREAKWATER is an ongoing, open-label, multicenter, randomized, phase 3 study evaluating 1L EC ± CT vs SOC CT alone in pts with BRAF V600E-mutant mCRC. Approximately 620 pts will be enrolled in the phase 3 portion and an additional 135 in cohort 3 (Table). Phase 3 and cohort 3 inclusion criteria are age ≥ 16 (or ≥ 18 based on country); no prior systemic tx for metastatic disease; measurable disease (RECIST 1.1); BRAF V600E-mutant mCRC (blood or tumor tissue); ECOG PS 0 or 1; and adequate bone marrow, hepatic, and renal function. Pts who received prior BRAF or EGFR inhibitors, those with symptomatic brain metastases (unless stable for ≥ 4 weeks prior to randomization), or with MSI-H/dMMR tumors (unless ineligible to receive immune checkpoint inhibitors due to a pre-existing medical condition) are excluded. Study treatments and endpoints are shown in the Table. Phase 3 enrollment began in November 2021. Clinical trial information: NCT04607421. Research Sponsor: Pfizer Inc.

An open-label clinical trial of RP2 and RP3 oncolytic immunotherapy in combination with atezolizumab and bevacizumab for the treatment of patients with advanced colorectal carcinoma. *First Author: Dale Randall Shepard, Cleveland Clinic, Cleveland, OH*

Background: Colorectal cancer (CRC) is the third most frequently diagnosed cancer and the second leading cause of cancer-related mortality worldwide. PD-1/PD-L1 inhibition, in combination with other modalities, has demonstrated significant benefit in patients (pts) with microsatellite instability-high or mismatch repair deficient CRC. However, these agents have limited, if any, clinical benefit in pts with microsatellite stable (MSS) or mismatch repair proficient (pMMR) CRC. RP2 is an enhanced potency oncolytic herpes simplex virus type 1 which expresses the fusogenic gibbon ape leukemia virus glycoprotein with the R sequence deleted (GALV-GP-R-), granulocyte-macrophage colony-stimulating factor (GM-CSF), and an anti-CTLA-4 antibody-like molecule; RP3 additionally expresses 4-1BB and CD40 activating ligands, but does not express GM-CSF. Both agents have demonstrated preliminary safety and efficacy in pts with solid tumors. This study will evaluate the safety and efficacy of RP2 and RP3 in combination with atezolizumab (Atezo) and bevacizumab (Bev) in pts with advanced MSS and pMMR CRC. **Methods:** Pts with a histologic diagnosis of unresectable and/or metastatic CRC, with documented MSS or pMMR status, and previously treated with up to 3 standard-of-care systemic regimens will be enrolled in the RP2 + Atezo + Bev or RP3 + Atezo + Bev treatment groups (30 pts per group). Further key inclusion criteria include Eastern Cooperative Oncology Group performance status 0–1 and adequate hepatic, renal, and hematologic function. RP2/RP3 will be injected into tumors by direct (including via colonoscopy) or image-guided injection. Pts will receive 8 total doses of up to 10 mL of RP2 or RP3, with a first dose concentration of 1×10^6 plaque-forming units (PFU)/mL, followed by 3 doses of 1×10^7 PFU/mL every 2 weeks, and then 4 doses of 1×10^7 PFU/mL every 3 weeks. Pts may receive a second course of up to 8 injections of RP2/RP3 if study criteria are met. Bev will be administered starting on day 1 (with first dose of RP2/RP3); Atezo will be administered starting week 7 on the same days as RP2/RP3. The primary endpoint is objective response rate; secondary endpoints are safety, overall survival, progression-free survival, duration of response, and complete response rate. Antitumor activity will be evaluated using Response Evaluation Criteria in Solid Tumors version 1.1 as modified for this study. Safety will be assessed by physical examination, clinical laboratory evaluations, vital signs, and monitoring for adverse events (AEs; including serious AEs). Clinical trial information: NCT05733611. Research Sponsor: Replimune Inc.

STELLAR-303: A phase 3 study of XL092 in combination with atezolizumab versus regorafenib in patients with previously treated metastatic colorectal cancer. *First Author: J. Randolph Hecht, David Geffen School of Medicine at UCLA, Jonsson Comprehensive Cancer Center, Santa Monica, CA*

Background: Metastatic colorectal cancer (mCRC) is associated with poor prognosis and limited treatment options for patients who have progressed on first- and second-line chemotherapy. Regorafenib and trifluridine-tipiracil are approved in third- or later-line setting, but survival benefit is limited. Immune checkpoint inhibitor (ICI) therapy with nivolumab ± ipilimumab or single-agent pembrolizumab is approved in microsatellite instability-high (MSI-H) or mismatch repair deficient (dMMR) mCRC; however, MSI-H mCRC is present in only ~5% patients. Phase 1/2 studies have evaluated the tyrosine kinase inhibitor (TKI) cabozantinib in combination with the ICIs atezolizumab and durvalumab and have demonstrated encouraging clinical activity, with data suggesting greater benefit in RAS wild-type (wt) versus RAS mutant (mut) mCRC (Abrams TA, et al. ASCO GI 2022: Abs 121; Saeed A, et al. ASCO GI 2022: Abs 135). XL092 is a TKI that targets MET, VEGFR2, and the TAM kinases AXL and MER, which are implicated in tumor growth, metastasis, angiogenesis, and immunosuppression of the tumor microenvironment. XL092 displays immunomodulatory properties that may promote an immunopерmissive tumor microenvironment and its half-life of 16–22 hours is supportive of once daily (QD) dosing. The phase 3 STELLAR-303 study (NCT05425940) is evaluating the efficacy and safety of XL092 in combination with atezolizumab versus regorafenib in patients with microsatellite stable or microsatellite instability-low mCRC who have progressed after or are intolerant to standard of care (SOC) therapy. **Methods:** STELLAR-303 is a global, randomized, open-label, phase 3 study. Eligible patients are aged ≥18 years with non-MSI-H/dMMR mCRC (determined by tissue-based analysis) that is measurable per RECIST v1.1 and have an ECOG performance status of 0–1 and adequate organ function. Patients must have progressed during/after or be intolerant to SOC therapies for mCRC; prior regorafenib, trifluridine-tipiracil, or anti-PD-L1/PD-1 ICIs are not allowed. Patients are randomized 1:1 to XL092 100 mg PO QD + atezolizumab 1200 mg IV Q3W or to regorafenib 160 mg PO QD (21 days/28-day cycle); randomization is stratified by geographic region (Asia, other), RAS status (wt, mut), and liver metastases (yes, no). Enrollment of 600 patients is planned (400 RASwt, 200 RASmut). The primary endpoint is duration of overall survival (OS) in the RASwt population, with other efficacy endpoints (progression-free survival, objective response rate, and duration of response per RECIST v1.1 by investigator and change in tumor markers) assessed in the RASwt population and, with OS, in the RASmut populations and in all randomized patients. Additional endpoints will assess safety, quality of life, changes in biomarkers, pharmacokinetics, immunogenicity, and healthcare utilization. Enrollment is ongoing. Clinical trial information: NCT05425940. Research Sponsor: Exelixis, Inc.

Alliance A022101: A pragmatic, randomized phase III trial evaluating total ablative therapy for patients with limited metastatic colorectal cancer: Evaluating Radiation, Ablation, and Surgery (ERASur). *First Author: Kathryn Hitchcock, University of Florida, Gainesville, FL*

Background: For patients with oligometastatic colorectal cancer (CRC), aggressive local therapy of isolated metastases, particularly in the liver, has been associated with long-term progression-free survival and overall survival (OS) primarily based on retrospective evidence. However, in patients with limited metastatic CRC that is deemed inoperable or those with additional disease outside of the liver or lungs, the role of local ablative therapies, including microwave ablation (MWA) and stereotactic body radiation therapy (SBRT), to render patients disease free is less clear. Further, despite the long history of treating oligometastatic CRC with local therapy, which is provider biased and not evidence based, questions remain regarding the benefit of extending the paradigm of metastatic directed therapy to patients with more extensive disease. This trial seeks to use a pragmatic multimodality approach that mirrors the current clinical dilemma. This study is designed to evaluate the safety and efficacy of adding total ablative therapy (TAT) of all sites of disease to standard of care systemic treatment in those with limited metastatic CRC. **Methods:** A022101 is a National Clinical Trials Network randomized phase III study planned to enroll 364 patients with newly diagnosed metastatic CRC (BRAF wild-type, microsatellite stable) with ≤4 sites of metastatic disease on baseline imaging. Liver-only metastatic disease is not permitted, and lesions must be amenable to any combination of surgical resection, MWA, and/or SBRT with SBRT required for at least one lesion. Patients receive first-line systemic therapy for 4–6 months and are then randomized 1:1, stratified by number of metastatic organ sites (1–2 vs. 3–4), timing of metastatic disease diagnosis (de novo vs. secondary), and presence of metastatic disease outside the liver and lungs in at least one site. Patients in Arm 1 will receive TAT which consists of treatment of all metastatic sites with SBRT ± MWA ± surgical resection followed by standard of care systemic therapy. Patients in Arm 2 will continue with standard of care systemic therapy alone. The primary endpoint is OS. Secondary endpoints include event-free survival, treatment-related toxicities, and local recurrence with exploratory biomarker analyses. The study needs 346 evaluable patients combined in the 2 arms to demonstrate an improvement in OS with a hazard ratio of 0.7 to provide 80% power with a one-sided alpha of 5%. The trial utilizes a group sequential design with two interim analyses (25% and 50% of events) for futility. The trial activated in January 2023 and recruitment is ongoing. MOUNTAINEER-03: Phase 3 study of tucatinib, trastuzumab, and modified FOLFOX6 as first line treatment in HER2+ metastatic colorectal cancer. *First Author: Tanios S. Bekaii-Saab, Mayo Clinic, Scottsdale, AZ*

Background: The current standard of care (SOC) for the treatment of metastatic colorectal cancer (mCRC) is multi-agent chemotherapy, with or without a VEGF or EGFR inhibitor. Human epidermal growth factor receptor-2 (HER2) is a validated clinical target in breast and gastric cancers. HER2 amplification occurs in 3%–5% of patients with mCRC; the rate of HER2 amplification can increase to approximately 10% in patients with RAS/BRAF wild-type mCRC tumors. Tucatinib (TUC)—a highly selective, HER2-directed tyrosine kinase inhibitor—is approved in multiple regions for HER2-positive (HER2+) metastatic breast cancer, approved in the US for HER2+ metastatic colorectal cancer, and under investigation in gastrointestinal cancers. MOUNTAINEER (NCT03043313) evaluated the safety and efficacy of TUC and trastuzumab (Tras) in patients with treatment-refractory RAS wild-type, HER2+ mCRC. Results from the primary endpoint analysis showed clinically meaningful activity, with a confirmed objective response rate (ORR) per blinded independent central review (BICR) of 38.1% (95% confidence interval [CI] 27.7, 49.3) and median duration of response per BICR of 12.4 months (95% CI 8.5, 20.5). Results also demonstrated TUC + Tras was well tolerated, with a low discontinuation rate (5.8%) and no deaths due to adverse events. MOUNTAINEER-03 will further investigate TUC in combination with modified FOLFOX (mFOLFOX) and Tras in patients with RAS wild-type HER2+ mCRC. **Methods:** MOUNTAINEER-03 (NCT05253651) is a global, open-label, randomized, phase III study for first-line treatment of HER2+ and RAS wild-type mCRC. Approximately 400 patients will be randomized 1:1 to the TUC experimental arm (TUC [300 mg orally twice daily] + Tras + mFOLFOX) or the SOC arm (mFOLFOX alone or in combination with either bevacizumab or cetuximab). HER2 status is determined centrally with tissue-based HER2 immunohistochemistry and in situ hybridization assays. Eligible patients must not have received prior treatment in the metastatic setting but may have received adjuvant treatment if completed > 6 months prior to enrollment. Patients must be ≥18 years old with an Eastern Cooperative Oncology Group Performance Status of ≤1 and RAS wild-type mCRC. Patients with treated stable central nervous system metastases are eligible. Randomization is stratified by primary tumor location (left-sided vs other) and liver metastases (presence/absence). The primary endpoint is progression-free survival per RECIST v1.1 assessed by BICR. Key secondary endpoints are overall survival and confirmed ORR per RECIST v1.1 assessed by BICR. Enrollment is ongoing in North America, Asia, Australia, and Europe. Clinical trial information: NCT05253651. Research Sponsor: Seagen, Inc.

Poster Session

A phase 1/2a, multicenter, open-label study of CNA3103 (LGR5-targeted, autologous CAR-T cells) in patients with metastatic colorectal cancer (mCRC). *First Author: Jayesh Desai, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*

Background: Leucine-rich repeat-containing G protein-coupled receptor 5 (LGR5) is a cancer stem cell (CSC) marker that is abundant in solid tumors, highly expressed in colorectal cancer and involved in tumor initiation, growth, and metastasis. Its expression is linked to poor survival and poor patient response to therapy in mCRC, and presents an attractive opportunity for selectively targeting a highly specific, functional CSC receptor in this disease. CNA3103 is a first-in-class cell product consisting of autologous T cells transduced to express a CAR to target LGR5. It contains the antigen-binding domain of BNC101, a humanized monoclonal LGR5 antibody previously tested in Phase 1 in mCRC subjects and demonstrated to be safe and well tolerated with no off-target binding activity. **Methods:** This is a first in human, multicenter, open label, Phase 1/2a dose escalation and expansion study to determine the safety of and overall best response to CNA3103 in subjects with mCRC. Up to 44 subjects (24 in Phase 1 and 20 in Phase 2a) will be enrolled. The trial follows a BOIN design with a minimum of 3 consecutively enrolled subjects per cohort, and a 28-day DLT evaluation period. Four cell dose levels (5×10^7 , 1.5×10^8 , 4.5×10^8 , 1.5×10^9) of CNA3103 will be evaluated. A Safety Monitoring Committee (SMC) will oversee the conduct of the study. The pharmacokinetic (PK) profile of CNA3103 in blood will be assessed. Exploratory objectives include evaluation of LGR5+ cells and CNA3103 in tumor biopsies, immune cellular profile, cytokine levels and circulating tumor DNA in blood, and immunogenicity of CNA3103. Main inclusion criteria: mCRC subjects positive for LGR5 expression and failing prior treatment with 5-FU, oxaliplatin and irinotecan-based regimens for metastatic disease; >1 radiologically measurable lesion per RECISTv1.1; >1 biopsiable lesion at baseline; ECOG 0 or 1; serum albumin >3 g/dL; and normal organ and marrow function. Main exclusion criteria: BRAF-mutated disease, clinical ascites/pleural effusions; active autoimmune/ connective tissue disease; history of inflammatory bowel disease or active peptic ulcer disease. The trial is sponsored by Carina Biotech. Phase 1 enrolment is limited to Australian sites. Phase 2a enrolment will take place in Australia and the US. For information, contact Lina Jablonskis lina@carinabiotech.com or +61 437 891 563. Research Sponsor: Carina Biotech.

Colon adjuvant chemotherapy based on evaluation of residual disease (CIRCULATE-US): NRG-GI008. *First Author: Arvind Dasari, Department of Gastrointestinal Medical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Currently, there are no biomarkers validated prospectively in randomized studies for resected colon cancer (CC) to determine need for adjuvant chemotherapy (AC). However, circulating tumor DNA (ctDNA) represents a highly specific and sensitive approach (especially with serial monitoring) for identifying minimal/molecular residual disease (MRD) post-surgery in CC patients (pts), and may outperform traditional clinical and pathological features in prognosticating risk for recurrence. CC pts who do not have detectable ctDNA (ctDNA-) are at a much lower risk of recurrence and may be spared the toxicities associated with AC. Furthermore, for CC pts with detectable ctDNA (ctDNA+) who are at a very high risk of recurrence, the optimal AC regimen has not been established. We hypothesize that for pts whose CC has been resected, ctDNA status may be used to risk-stratify for making decisions about AC. **Methods:** In this prospective phase II/III trial, up to 1,912 pts with resected stage III A, B (all pts) and stage II, IIIC (ctDNA+ only) CC will be enrolled. Based on the post-operative ctDNA status using personalized and tumor-informed assay (SignateraTM, bespoke assay), those who are ctDNA- (Cohort A) will be randomized to immediate AC with fluoropyrimidine (FP) + oxaliplatin (Ox) for 3-6 mos per established guidelines vs. serial ctDNA monitoring. Patients who are ctDNA+ post-operatively or with serial monitoring (Cohort B) will be randomized to FP+Ox vs. more intensive AC with addition of irinotecan (I) for 6 mos. The primary endpoints for Cohort A are time to ctDNA+ status (phase II) and disease-free survival (DFS) (phase III) in the immediate vs. delayed AC arms. The primary endpoint for Cohort B is DFS in the FP+Ox vs FP+Ox+I arms for both phase II and phase III portions of the trial. Secondary endpoints include prevalence of detectable ctDNA post-operatively, time-to-event outcomes (overall survival and time to recurrence) by ctDNA status, and the assessment of compliance to adjuvant therapy. Biospecimens including archival tumor tissue, as well as post-operative plus serial matched/normal blood samples, will be collected for exploratory correlative research. Active enrollment across the NCTN started in June 2022. NCT#: NCT05174169. Support: U10-CA-180868, -180822; UG1CA-189867; Natera, Inc. Clinical trial information: NCT05174169. Research Sponsor: U.S. National Institutes of Health; Natera, Inc.

Total neoadjuvant treatment without surgery for locally advanced rectal cancer: Prospective study to assess tumor response, circulating genetic, and epigenetic biomarkers, and stromal transcriptome to interpret clinical outcome (NO-CUT trial). *First Author: Salvatore Siena, Niguarda Cancer Center, Grande Ospedale Metropolitano Niguarda, University of Milano, Milan, Italy*

Background: Total neoadjuvant therapy (TNT) has recently become a standard therapy for locally advanced rectal cancer (LARC). All nonsurgical interventions, including chemotherapy and concurrent chemoradiotherapy (CRT), are administered before either surgical resection of the rectum or non-operative management (NOM), depending on response to TNT. In the case of NOM, the impact of distant relapse on survival remains to be elucidated and circulating tumor DNA (ctDNA) monitoring has been proposed as a tool for early detection of relapse. Furthermore, predictive biomarkers of response to TNT are warranted for the early identification of patient candidates for NOM. In this regard, stromal contribution to sensitivity to pre-operative CRT is investigated by a transcriptomic signature on baseline tumor samples, as previously proposed by Isella C et al., Nature Genet, 2015. **Methods:** NO-CUT is a multicenter one-stage phase II trial aimed at assessing if a TNT approach with CAPOX followed by CRT can safely spare demolitive surgery in patients with LARC achieving a clinical complete response without increasing the risk of distant metastatic relapse. A Brookmeyer and Crowley approach was chosen to test the null hypothesis that the true distant relapse-free survival at 2.5 years rate is $\leq 75\%$ against a one-sided alternative. The NOM cohort of the trial needs to accrue 44 evaluable patients and to be followed for at least 2.5 years. Such design yields a type I error rate of 10% and power of 80% when the true 2.5 years distant RFS proportion is 87%. Since it is assumed that the proportion of patients entering in the NOM cohort of the trial is at least 25%, a total of 180 patients are to be enrolled in NO-CUT study. Patients with medium-low LARC undergo TNT (4 cycles of CAPOX: capecitabine 1000 mg/m² bid days 1-14 q 3 weeks; oxaliplatin 130 mg/m² day 1 q 3 weeks) and 5 weeks of standard pelvic CT-RT, then restaging with imaging (MRI, CT-scan, and ultrasound endoscopy), and tumor biopsy. According to an algorithm defined for assessing tumor response, patients enter either NOM or surgery cohorts. During the follow-up phase of the trial, the NOM cohort is followed with intensive pelvic imaging and periodic blood samplings for 5 years. Tumor samples and ctDNA are studied at baseline, after TNT, and during follow-up. As of January 2023, 161 of planned 180 patients in 4 centers have been enrolled. Supported by grants from Associazione Italiana Ricerca Cancro (AIRC IG 2017-20685) and Fondazione Oncologia Niguarda. Clinical trial information: EudraCT 2017-003671-60. Research Sponsor: AIRC IG; FON (Fondazione Oncologia Niguarda).

The CIRCULATE Spain study: Circulating tumor DNA based decision for adjuvant treatment in localized colon cancer. *First Author: Noelia Tarazona, Department of Medical Oncology, INCLIVA Biomedical Research Institute, University of Valencia, Instituto Carlos III, CIBERONC, Valencia, Spain*

Background: A substantial proportion of colon cancer (CC) patients do not benefit from adjuvant chemotherapy, and almost 40% of them will develop metastases despite initial optimal treatment. We have designed the phase 2 CIRCULATE-SPAIN trial (EudraCT Number: 2021-000507-2) to prove the feasibility of using liquid biopsy detection of minimal residual disease to guide the post-surgical clinical management of localized CC patients. Moreover, it is important to define if conventional versus intensive adjuvant chemotherapy could convert plasma circulating tumor DNA (ctDNA) positive into a ctDNA negative status. **Methods:** CIRCULATE-SPAIN is a trial to prove the feasibility of using liquid biopsy detection of MRD to guide the post-surgical clinical management of early colon cancer patients. It is a multicenter, randomized, open-label phase II "Single-To-double ARm Transition (START)" study in which patients are firstly enrolled into a single arm (Phase IIa) study expandable to a randomized double arm (Phase IIb). The CIRCULATE-SPAIN trial involves two primary endpoints, one for the Phase IIa and a second one for the Phase IIb. The primary objective for Phase IIa is to analyze the potential effect of FOLFOXIRI as an intensive adjuvant treatment for ctDNA clearance as a surrogate biomarker of treatment efficacy. Only if the pre-fixed result of 14 out of 40 patients achieves ctDNA clearance, the trial will be expanded to a phase IIb in which patients will be enrolled to randomly receive intensive adjuvant treatment (FOLFOXIRI) versus conventional adjuvant therapy (CAPOX). The primary objective in this phase is to study differences on the conversion rate between both groups. An academic assay based on tumor informed approach is used for ctDNA determination. Tumor and germline samples analysis are carried out by an in-house-developed bioinformatics pipeline specialized in variant-calling analysis using a custom 29-gene panel. Somatic variants are identified by the germline mutations extraction. Different annotation databases and an internal pathological mutation database are used to rule out potential benign somatic variants. Those candidate somatic mutations with the highest allelic frequency are selected and a specific panel of amplicons is designed to monitor their presence in ctDNA using NGS. Plasma samples analysis is carried out by an in-house pipeline specialized in reducing potential background noise. To assess panel performance in both sample types, the bioinformatics pipelines include a set of methods to calculate and filter according to different quality control metrics. Recruitment for the Phase IIa is ongoing with a total of 67 pre-screened out of which two patients were eligible. Clinical trial information: 2021-000. 507-20. Research Sponsor: Instituto de Salud Carlos III.

The FOxTROT platform: Clinical trials and exploratory research for personalization of neoadjuvant (NA) therapy in locally advanced colon cancer (LACC)—ISRCTN83842641. *First Author: Christopher Williams, University of Leeds, Leeds, United Kingdom*

Background: The FOxTROT1 trial demonstrated a significant reduction in 2-year (yr) recurrence with 6 weeks (wks) of oxaliplatin and fluoropyrimidine (OxPp) NA chemotherapy (NAC) in patients (pts) with LACC, establishing NAC as a new therapeutic option. The ongoing FOxTROT platform will refine and personalize NA therapy in LACC. FOxTROT2 is testing NAC in older pts and those with frailty, who are poorly represented in clinical trials. FOxTROT3 is assessing intensified NAC with modified FOLFOLFOXIRI (mFOLFOLFOXIRI; 5-fluorouracil, oxaliplatin, irinotecan) in fit pts. The FOxTROT platform will also test targeted treatments with established safety and efficacy in defined molecular subgroups. FOxTROT4 is investigating the efficacy and safety of NA encorafenib and cetuximab in BRAF-mutant pMMR LACC. Other arms in setup are shown in Table. **Methods:** FOxTROT platform trials are international, multicenter, open-label, phase I/II/III RCTs. Pts with resectable, cT3-4 N0-2 MO, biopsy-proven colon adenocarcinoma are eligible for recruitment. Pts whose age or frailty precludes mFOLFOLFOXIRI can be considered for FOxTROT2. Pts suitable for mFOLFOLFOXIRI can be considered for FOxTROT3. BRAF-mutant pMMR pts can be considered for FOxTROT4. Pts are randomized 2:1 between intervention and control arms. FOxTROT2 randomizes between 6 wks OxPp NAC (choice of 100% or 80% dose) vs proceeding straight to surgery. Adjuvant chemotherapy (AC) is per physician choice. Primary outcome is 3-yr DFS. 759 pts will be recruited over 5 yrs. FOxTROT3: 6 wks mFOLFOLFOXIRI NAC vs 6 wks OxPp NAC. All pts receive AC but physicians may de-escalate mFOLFOLFOXIRI to OxPp. Hierarchical co-primary endpoints: tumor regression grade (TRG) (blinded central assessment) and 3-yr DFS. 873 pts over 5 yrs. FOxTROT4: 6 wks NA encorafenib and cetuximab vs 6 wks OxPp NAC. AC is per physician choice. Primary outcome: TRG. 45 pts over 3 yrs. Secondary outcomes include: histopathological endpoints, downstaging, minimal residual disease by ctDNA, safety, toxicity, OS, surgical outcomes and patient-reported outcomes; and DFS in FOxTROT4. The FOxTROT platform opened 7th Feb 2022, funded by Yorkshire Cancer Research. At submission, 50 pts had been randomized at 23 centers. Trial design and management is conducted in partnership with patient representatives. A program of translational and radiomics research is running in parallel. International recruitment in France and India will commence in 2023 with additional international partners joining from 2024. Clinical trial information: ISRCTN83842641. Research Sponsor: Yorkshire Cancer Research.

Neoadjuvant short-course radiotherapy followed by chemotherapy plus camrelizumab versus long-course chemoradiotherapy followed by chemotherapy for patients with locally advanced rectal cancer: A randomized, multicenter, open-label phase 3 trial (Union). *First Author: Zhenyu Lin, Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, Hubei, China*

Background: Short-course preoperative radiotherapy (SCPRT) and long-course chemoradiotherapy (LCCRT) are standard neoadjuvant treatments for locally advanced rectal cancer (LARC). Further, the RAPIDO trial found that SCPRT combined with consolidation chemotherapy produced better short- and long-term outcomes than SCPRT alone for patients with high-risk LARC. A phase 2, single-arm trial of neoadjuvant SCPRT followed by camrelizumab (an anti-PD-1 antibody) plus chemotherapy demonstrated promising short-term outcomes in patients with LARC. The Union trial is evaluating the efficacy and safety of neoadjuvant SCPRT followed by camrelizumab plus chemotherapy versus LCCRT followed by chemotherapy in patients with LARC. **Methods:** The Union trial is enrolling patients aged 18-75 with histologically confirmed clinical stage T3-4/N+ adenocarcinoma of the rectum, Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1, and a tumor inferior margin less than 10 cm above the anal verge. Eligible patients are randomized in a 1:1 ratio to either arm A or arm B. Patients in arm A receive neoadjuvant treatment with SCPRT (a total of 25 Gy in 5 days) followed by camrelizumab (200 mg/m² intravenous drip on day 1, every 3 weeks for 2 cycles) plus CAPOX (oxaliplatin 130 mg/m² intravenous infusion over 2 hours on day 1, capecitabine 1000 mg/m² oral twice daily, days 1-14, every 3 weeks for 2 cycles), surgery, and adjuvant treatment with camrelizumab plus CAPOX (6 cycles) followed by camrelizumab until the medication duration of camrelizumab reaches one year. Patients in arm B receive neoadjuvant treatment with LCCRT (capecitabine 825 mg/m² twice daily, 5 days a week, combined with a total dose of 50.4 Gy in 28 days) followed by CAPOX (2 cycles), surgery, and adjuvant treatment with CAPOX (6 cycles). Randomization is stratified by clinical T stage (≤T3 vs T4) and clinical N stage (N0 vs N+). The primary endpoint is pathologic complete response (pCR). The secondary endpoints are 3-year event-free survival rate, overall survival, RO resection rate, completion rate of neoadjuvant treatment, 3-year disease-free survival rate, tumor regression grading, safety, and quality of life. pCR is evaluated per the AJCC 8th Edition TRG scoring system as assessed by the blinded independent central review. Adverse events are graded by the National Cancer Institute Common Terminology Criteria for Adverse Events version 5.0. Quality of life is assessed by the European Organization for the Research and Treatment of Cancer Quality of Life Questionnaire Core 30. This study began enrollment in July 2021 with a planned enrollment of 230 patients. Clinical trial information: NCT04928807. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co, Ltd, Shanghai, China.

PACE: A phase III trial of CAPOX versus anti-PD-1 inhibitor as adjuvant therapy for patients with dMMR/MSI-H stage III colon cancer. *First Author: Zhenlin Hou, Department of Colorectal Surgery, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Approximately 12% of stage III colon cancer are deficient mismatch repair (dMMR), leading to high levels of microsatellite instability (MSI-H). In the KEYNOTE-177 study, the anti-PD-1 inhibitor Pembrolizumab alone significantly improved progression free survival (PFS) versus chemotherapy as first-line therapy for metastatic colorectal cancer (mCRC) patients with MSI-H/dMMR. We are conducting a phase III randomised trial to determine whether anti-PD-1 inhibitor Sintilimab monotherapy can improve disease free survival (DFS) compared with standard adjuvant chemotherapy in stage III colon cancer patients with dMMR. **Methods:** This is an open-label, multicentre, randomised phase III study. Patients aged ≥ 18 years with completely resected, stage III colon cancer confirmed to have dMMR/MSI-H and ECOG performance status 0-1 are eligible. Approximately 323 patients will be randomly assigned 1:1 to either Sintilimab monotherapy (200 mg IV every 3 weeks for 8 cycles) or CAPOX regimen (capecitabine, oxaliplatin for 4 or 8 cycles according to current standard practice). Adverse events (AEs) will be assessed throughout treatment and for 30 days thereafter (90 days for serious AEs) and graded per NCI CTCAE v4.0. Primary endpoint is 3-year DFS. The study was estimated to provide approximately 80% power to detect a hazard ratio of 0.56 for DFS at a two-sided alpha of 0.05. Secondary endpoints include OS, safety profile, toxicity, and quality of life. Archived tumor tissue and blood samples will be collected for correlative studies. Study enrollment is ongoing. Clinical trial information: NCT05236972. Research Sponsor: None.

Poster Session

Phase II, single-arm, open-label study of dostarlimab monotherapy in previously untreated patients with stage II/III dMMR/MSI-H locally advanced rectal cancer. *First Author: Andrea Cercek, Division of Solid Tumor Oncology, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: For patients (pts) with locally advanced rectal cancer (RC), organ-sparing non-operative management (NOM) following a clinical complete response (cCR) to treatment avoids the potential complications and quality of life impact associated with surgery/chemoradiotherapy. Although neoadjuvant chemotherapy is standard treatment, pts with mismatch repair deficient (dMMR) tumors respond poorly. Efficacy of the programmed death (PD)-1 inhibitor dostarlimab in previously untreated pts with locally advanced dMMR RC was evaluated in a Phase II study. All 12 pts who completed 6 months of treatment had clinical complete response (cCR) and received NOM, with no Grade ≥3 adverse events reported. Further research with a larger multicenter population/longer follow-up is needed to confirm these findings. AZUR-1 will evaluate the efficacy and safety of dostarlimab in pts with previously untreated locally advanced dMMR/microsatellite instability-high (MSI-H) RC. **Methods:** AZUR-1 (NCT05723562) is a global, multicenter, single-arm, open-label, Phase II study. ~100 pts will be enrolled across 10 countries. Key eligibility criteria include age ≥18 years, no prior radiation/systemic therapy or surgery for RC, Eastern Cooperative Oncology Group performance status 0-1 and no tumor-caused symptomatic bowel obstruction. Pts must have a tumor with dMMR status or MSI-H phenotype, determined locally or by the central reference laboratory. Prescreening is available at sites without local dMMR/MSI-H testing; prescreening is not required if dMMR/MSI-H status has been previously determined. Dostarlimab (500 mg) will be administered intravenously every 3 weeks for ≤9 cycles. The primary endpoint is cCR by independent central review (ICR) at 12 months, defined as achieving and maintaining cCR for 12 months (the 12-month period starts from the first disease assessment after last dose of study intervention that demonstrates cCR by ICR). Secondary endpoints include cCR by ICR at 36 months, 3-year event-free survival (EFS3) by investigator assessment, 5-year disease-specific survival, and 5-year overall survival. Pts with cCR by end of treatment will be assessed (CT/MRI, rectal MRI, endoscopy, rectal primary biopsy) every 4-6 months for recurrent disease for 5 years (NOM). Efficacy and safety will be assessed in all pts who received ≥1 dose of dostarlimab. For a range of plausible observed cCR12 rates (60-95%) in the primary analyses, the planned sample size of 100 pts will provide a Clopper-Pearson exact binomial two-sided 95% confidence interval with lower confidence limit within ~10% of the observed cCR12 rate. No interim analyses are planned. References: [1] Cercek, A *et al.* *NEJM* 2022;386: 2363-76. Funding: GSK (219369). Editorial support provided by Fishawack Health, funded by GSK. Alliance A022104/NRG-GI010: A randomized phase II trial testing the efficacy of triplet versus doublet chemotherapy to achieve clinical complete response in patients with locally advanced rectal cancer—The Janus Rectal Cancer trial. *First Author: Jesse Joshua Smith, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Recent data have demonstrated that in locally advanced rectal cancer (LARC), a total neoadjuvant therapy (TNT) approach improves compliance with chemotherapy and increases rates of tumor response compared to neoadjuvant chemoradiation (CRT) alone. They further indicate that the optimal sequencing of TNT involves consolidation (rather than induction) chemotherapy to optimize complete response rates. Data, largely from retrospective studies, have also shown that patients (pts) with clinical complete response (cCR) after neoadjuvant therapy may be managed safely with the watch and wait approach (WW) instead of pre-emptive total mesorectal resection (TME). However, the optimal consolidation chemotherapy regimen to achieve cCR has not been established, and a randomized clinical trial has not robustly evaluated it as a primary endpoint. Collaborating with a multidisciplinary oncology team and pt groups, we designed this NCI-sponsored study of chemotherapy intensification to address these issues and to drive up cCR rates, to provide opportunity for organ preservation and improve quality of life for pts.

Methods: In this Alliance for Clinical Trials in Oncology randomized phase II trial (1:1), up to 312 pts with microsatellite stable LARC, clinical stage T4N0, any T, N+ or T3N0 requiring abdominoperineal resection or coloanal anastomosis and distal margin within 12 cm of anal verge will be enrolled. Stratification factors include tumor stage (T4 vs T1-3), nodal stage (N+ vs N0) and distance from anal verge (0-4; 4-8; 8-12 cm). Pts will be randomized to receive neoadjuvant long course CRT (LCRT) followed by consolidation doublet (mFOLFOX6 or CAPOX) or triplet chemotherapy (mFOLFIRINOX) for 4 months. LCRT in both arms involves 4500 cGy in 25 fractions over 5 weeks (w) + 900 cGy boost in 5 fractions with a fluoropyrimidine (capecitabine preferred). Pts will undergo assessment 8-12 w post-TNT completion for the primary endpoint of cCR per previously validated criteria and recommended WW and surveillance if cCR is achieved or TME if an incomplete response is noted. Secondary objectives include time-to event outcomes (disease-free and overall survival, organ preservation time and time to distant metastasis) and adverse effects. Statistical power, based on cCR, incorporates a one-sided alpha = 0.048 and power = 90% yielding 312 patients (156 per arm). Biospecimens including archival tumor tissue, matched / normal blood samples and serial rectal MRI will be collected for exploratory correlative research. This study, activated in late 2022, is open across the NCTN and is actively recruiting. Support: U10CA180821, U10CA180882, U24 CA196171; <https://acknowledgments.alliancefound.org>. U10CA180868 (NRG); U10CA180888 (SWOG); Clinicaltrials.gov ID: NCT05610163 Clinical trial information: NCT05610163. Research Sponsor: U.S. National Institutes of Health.

A randomized trial of consolidation-targeted adjuvant therapy with encorafenib and cetuximab versus usual care for patients with stage II/III BRAF V600E colon cancer: Alliance for Clinical Trials in Oncology A022004. *First Author: Rona Yaeger, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients with mismatch repair proficient (pMMR) BRAF V600E mutant high-risk stage II (T4) or stage III colon cancer have a substantial risk of recurrence despite standard adjuvant therapy. In patients with metastatic BRAF V600E mutant colorectal cancer, the combination of the RAF inhibitor encorafenib and the EGFR inhibitor cetuximab has been shown to improve overall and progression-free survival compared to standard therapy after at least one prior line of therapy. This study will evaluate if this combination improves disease-free survival (DFS) in patients with resected BRAF V600E mutant pMMR/microsatellite stable (MSS) high-risk stage II (T4) or stage III colon cancer after standard adjuvant therapy. **Methods:** The study has a seamless phase II/III design, enrolling a maximum of 394 patients. BRAF mutation status can be determined locally or submitted for central testing in trial pre-screening. Eligible patients will be randomized 1:1 to usual surveillance versus 6 months of treatment with encorafenib (300mg oral daily) plus cetuximab (500mg/m² intravenous every 14 days). Stratification factors are adjuvant chemotherapy regimen (FOLFOX versus CAPOX), duration of adjuvant therapy (3 months versus > 3 months), tumor stage (T4N0 versus T1-3N1 versus T4N1/TanyN2), and ctDNA marker status (detectable versus undetectable) at randomization. Adjuvant therapy must be completed at most 8 weeks prior to registration. For the phase II component, in the ctDNA detectable cohort, the primary endpoint will be ctDNA clearance rate at 6 months, and, in the ctDNA undetectable cohort, the primary endpoint will be 6-month ctDNA recurrence-free survival, where events consist of death, recurrence, or ctDNA positivity. The primary endpoint of the phase III component is DFS, and secondary endpoints are overall survival, adverse events, and alternative DFS calculated from the date of primary resection, rather than date of study randomization. Patient reported symptoms (PRO-CTCAE) will be collected and analyzed as an exploratory endpoint, and serial blood banking will support future correlative studies. The trial will proceed to the phase III portion if either of the two endpoints in the phase II cohorts is statistically superior in patients receiving encorafenib plus cetuximab. The phase III study sample size will provide 80% power at a one-sided α of 0.05 to detect an approximately 10% improvement in the three-year DFS rate, assuming 68% in the control arm. Two interim analyses will be performed for DFS endpoint. Support: U10CA180821, U10CA180882; <https://acknowledgments.alliancefound.org>. Oral Abstract Session

ATTRACTION-5: A phase 3 study of nivolumab plus chemotherapy as postoperative adjuvant treatment for pathological stage III (pStage III) gastric or gastroesophageal junction (G/GEJ) cancer. *First Author: Masanori Terashima, Shizuoka Cancer Center, Division of Gastric Surgery, Nagaizumi, Japan*

Background: Nivolumab plus chemotherapy (N+C) in the first-line treatment and nivolumab monotherapy in the third- or later-line have shown survival benefit in patients with unresectable advanced or recurrent G/GEJ cancer. Adjuvant chemotherapy after D2 or more extended gastrectomy is a widely used standard of care for pStage III G/GEJ cancer in Asia. However, standard adjuvant chemotherapy has shown limited efficacy for pStage III G/GEJ cancer. ATTRACTION-5 is the first phase 3 study to evaluate an immune checkpoint inhibitor in combination with adjuvant chemotherapy for pStage III G/GEJ cancer. Here, we report the first confirmatory results of N+C as postoperative adjuvant treatment. **Methods:** The ATTRACTION-5 study is a multicenter, double-blind, randomized study conducted in Japan, Korea, Taiwan, and China. We enrolled patients with pStage III G/GEJ cancer who had undergone D2 or more extended gastrectomy. Investigators selected an appropriate adjuvant chemotherapy (tegafur/gimeracil/oteracil [S-1] therapy or capecitabine plus oxaliplatin [CapeOX] therapy) for each patient, and thereafter patients were randomly assigned (1:1) to the N+C or placebo plus chemotherapy (P+C) arm, using the allocation factors of country and disease stage. The primary endpoint was centrally-assessed relapse-free survival (RFS). The sample size was calculated, based on the results of the ACTS-GC study and the CLASSIC study (The assumed hazard ratio [HR], 0.67; the assumed 3-year RFS, 71% vs 60%). Secondary endpoints were investigator-assessed RFS, overall survival (OS), and 3-year RFS and OS rates. **Results:** A total of 755 patients underwent randomization from February 2017 to August 2019: 377 were assigned to the N+C arm and 378 to the P+C arm. The final analysis of RFS was performed based on the clinical data cutoff of August 2022, with the minimum follow-up of 36 months after the last patient was randomized. The primary efficacy endpoint of centrally-assessed RFS was not met (HR, 0.90; 95.72% CI, 0.69–1.18; $P=0.4363$), with the 3-year RFS rates of 68.4% (95% CI, 63.0–73.2) in the N+C arm and 65.3% (95% CI, 59.9–70.2) in the P+C arm. The completion rate of the planned postoperative adjuvant treatment was 61.5% in the N+C arm and 71.4% in the P+C arm. Incidences of grade $\geq$ 3 TRAEs, serious TRAEs, and TRAEs leading to discontinuation were 54.4%, 25.3%, and 9.2%, respectively, in the N+C arm and 46.8%, 10.7%, and 3.5% in the P+C arm. **Conclusions:** The ATTRACTION-5 study of N+C vs P+C in patients with pStage III G/GEJ cancer after D2 or more extended gastrectomy did not meet the primary endpoint of RFS. The safety profile in the ATTRACTION-5 study was consistent with its known safety profile. Clinical trial information: NCT03006705. Research Sponsor: ONO Pharmaceutical; Bristol Myers Squibb.

Oral Abstract Session

Efficacy, safety and patient reported outcomes (PROs) from the phase III IMbrave050 trial of adjuvant atezolizumab (atezo) + bevacizumab (bev) vs active surveillance in patients with hepatocellular carcinoma (HCC) at high risk of disease recurrence following resection or ablation. *First Author: Masatoshi Kudo, Kindai University Hospital, Osaka, Japan*

Background: In IMbrave050, adjuvant atezo + bev demonstrated a statistically significant and clinically meaningful improvement in recurrence-free survival (RFS) vs active surveillance in patients (pts) at high risk of HCC recurrence following resection or ablation with curative intent. Further, the safety of atezo + bev was generally manageable. Here, we additionally report PRO data from IMbrave050. **Methods:** IMbrave050 (NCT04102098) enrolled HCC pts at high risk of recurrence following resection or ablation. Pts were randomized to Arm A (atezo + bev) or Arm B (active surveillance). Pts in Arm A received atezo 1200 mg + bev 15 mg/kg IV q3w for a period of one year (17 cycles). Pts in Arm B underwent active surveillance for one year and were eligible to crossover to atezo + bev following independent review facility (IRF) confirmation of recurrence. The primary endpoint was IRF-assessed RFS. Pre-specified exploratory analyses included change from baseline in global health status (GHS)/quality of life (QoL), physical functioning, role functioning, emotional functioning, and social functioning. Clinically meaningful deterioration was defined as a $\geq$ 10-point decrease. Pts completed the IL42–EORTC QLQ-C30 (reduced) questionnaire at baseline and then at every odd treatment/surveillance visit through Cycle 17. **Results:** The ITT population included 334 pts in both Arms A and B. With a median follow-up time of 17.4 mo (clinical cutoff date: 21 Oct 2022), IRF-RFS HR was 0.72 (95% CI: 0.56, 0.93; $P=0.0120$). In the safety population, Grade 3 or 4 adverse events occurred in 41% of 332 Arm A pts and 13% of 330 Arm B pts. In ITT pts, IL42 completion rates remained $\geq$ 93% in both arms from baseline through treatment/surveillance Cycle 17. Mean scores at baseline in both arms were high and similar, as measured by the GHS/QoL and physical, role, emotional and social functioning scales. Mean changes from baseline were not considerable through Cycle 17 and were similar between arms as evidenced by overlapping 95% CIs. Pts' GHS/QoL and functioning was maintained through Cycle 17, with no clinically meaningful deterioration observed at any time. **Conclusions:** Statistically significant and clinically meaningful improvement in RFS was seen in pts receiving atezo + bev vs active surveillance. Atezo + bev safety was generally manageable, and consistent with the established safety profiles of each therapeutic agent and with the underlying disease. PRO outcome analyses revealed similar overall health-related QoL (HRQoL) and functioning between atezo + bev and active surveillance, and that treating high-risk pts with HCC with adjuvant atezo + bev following procedures with curative intent did not result in a clinically meaningful deterioration in HRQoL or function. Clinical trial information: NCT04102098. Research Sponsor: Roche.

Oral Abstract Session

Perioperative PD-1 antibody toripalimab plus SOX or XELOX chemotherapy versus SOX or XELOX alone for locally advanced gastric or gastro-oesophageal junction cancer: Results from a prospective, randomized, open-label, phase II trial. *First Author: Shuqiang Yuan, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Sun Yat-sen University, Guangzhou, Guangdong, China*

Background: The combination of PD-1 antibody and chemotherapy was shown to be effective in advanced gastric or gastro-oesophageal junction (GEJ) cancer, but has not yet been investigated in the context of locally advanced patients. In this study, we conducted a prospective, randomized, open-label phase II trial to evaluate the effectiveness of adding PD-1 antibody to perioperative chemotherapy in patients with locally advanced resectable gastric or GEJ cancer. **Methods:** In this randomized, open-label, phase II study, patients with resectable gastric or GEJ cancer clinically staged as cT3-4a N+M0 were randomized (1:1) to three preoperative and five postoperative 3-week cycles of SOX/XELOX (C arm) or PD-1 antibody toripalimab plus SOX/XELOX, followed by toripalimab monotherapy for 6 months (C+T arm). The primary endpoint was pathological complete regression/moderate regression rate (TRG 0/1). The secondary endpoints were pathological complete response (pCR), R0 resection rate, recurrence-free survival, event-free survival, objective response rate, disease control rate, overall survival and treatment safety. The study had been completed enrollment, and here, we analyzed the primary endpoint. Mantel-Haenszel test was used to test the difference of pathological regression between the two arms. The trial was registered at ClinicalTrials.gov, identifier: NCT04250948. **Results:** Between Oct 2019 and June 2022, 108 patients (C+T arm, n=54; C arm, n=54) were enrolled and assessed using intention-to-treat analysis. Patients in the toripalimab plus chemotherapy arm achieved higher proportion of TRG 0/1 than those in the chemotherapy arm (44.4% [24/54, 95% CI: 30.9%-58.6%] vs 20.4% [11/54, 95% CI: 10.6%-33.5%]; $P=0.009$). A higher pCR rate was observed in the C+T arm (24.1% [13/54, 95% CI: 13.5%-37.6%] vs 9.3% [5/54, 95% CI: 3.1%-20.3%]; $P=0.039$). Preoperative therapies (3 cycles) were completed in 96.3% of patients and postoperative cycles (>3 cycles) in 81.5%, with no significant differences observed between these two arms. A higher proportion of downstaging was observed in the C+T arm (ypT0-2: 46.3% vs 22.2% [$P=0.002$]; ypstage 0-1: 38.9% vs 16.7% [$P=0.024$]). Surgical morbidity (11.8% in the C+T arm vs 13.5% in the C arm) and mortality (1.9% vs 0%) and treatment-related grade 3-4 adverse events (27.8% vs 25.9%) were comparable between the arms. **Conclusions:** Perioperative PD-1 antibody toripalimab plus chemotherapy demonstrated a significantly improved pathological regression and might be a promising option for patients with locally advanced resectable gastric or GEJ cancer. Clinical trial information: NCT04250948. Research Sponsor: Shanghai Junshi Biosciences Co., Ltd.

Oral Abstract Session

Health-related quality of life (HRQoL) in the phase 3 KEYNOTE-966 study of pembrolizumab (pembro) plus gemcitabine and cisplatin (gem/cis) versus placebo plus gem/cis for advanced biliary tract cancer (BTC). *First Author: Changhoun Yoo, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: In the randomized, double-blind, phase 3 KEYNOTE-966 trial (N = 1069; NCT04003636), pembro + gem/cis significantly improved OS versus placebo + gem/cis (HR 0.83; 95% CI 0.72-0.95; $P=0.0034$) and had an expected and manageable safety profile as first-line therapy for unresectable locally advanced or metastatic BTC. We present the protocol-specified exploratory patient-reported outcomes (PROs) from KEYNOTE-966. **Methods:** PROs were assessed using the EORTC QLQ-C30, EORTC QLQ-BIL21, and EQ-5D-5L questionnaires. The analysis population included all treated patients (pts) who completed $\geq$ 1 HRQoL assessment for the specific endpoint. A constrained longitudinal analysis model (covariates: treatment, time, treatment by time interaction, and stratification factors) was used to compare least squares mean (LSM) score changes from baseline (BL) to wk 18 (ie, latest timepoint that completion was $\geq$ 60% and compliance was $\geq$ 80%) in QLQ-C30 global health status (GHS)/QoL, physical functioning (PF), and role functioning (RF), QLQ-BIL21 jaundice and pain, and EQ-5D-5L visual analogue scale (VAS). A stratified Cox proportional hazards model was used to assess the magnitude of the between-arm difference in time to deterioration (TTD) in GHS/QoL, PF, RF, jaundice, and pain (ie, time to first onset of $\geq$ 10-point deterioration from BL in each scale/subscale confirmed by $\geq$ 10-point deterioration from BL at the next visit; established as clinically relevant). **Results:** Questionnaire compliance was $>87\%$ from BL to wk 18 in both arms. LSM changes from BL to wk 18 in QLQ-C30 GHS/QoL, PF, and RF, QLQ-BIL21 jaundice and pain, and EQ-5D-5L VAS were similar between arms. Time to deterioration was also similar between arms: median not reached (NR) vs 21.2 mo for GHS/QoL (HR 0.86, 95% CI 0.70-1.07), NR vs 12.0 mo for PF (HR 0.95, 95% CI 0.78-1.17), 6.5 mo vs 5.8 mo for RF (HR 0.98, 95% CI 0.81-1.18), NR vs NR for jaundice (HR 1.20, 95% CI 0.94-1.54), and NR vs NR for pain (HR 0.79, 95% CI 0.59-1.05). **Conclusions:** HRQoL was maintained when pembro was added to gem/cis. Together with the efficacy and safety data, these results support pembro + gem/cis as a new first-line treatment option for advanced BTC. Clinical trial information: NCT04003636. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

	Pembro + Gem/Cis, LSM (95% CI) Change from BL to wk 18	Placebo + Gem/Cis LSM (95% CI) Change from BL to wk 18	Difference in LS Means (95% CI)
QLQ-C30	n = 518	n = 517

Oral Abstract Session

Outcomes by occurrence of immune-mediated adverse events (imAEs) with tremelimumab (T) plus durvalumab (D) in the phase 3 HIMALAYA study in unresectable hepatocellular carcinoma (uHCC). *First Author: George Lau, Humanity and Health Clinical Trial Center, Humanity and Health Medical Group, Hong Kong Special Administrative Region, China*

Background: Immune checkpoint inhibitor (ICI) studies have shown an association between the occurrence of imAEs and outcomes. In the Phase 3 HIMALAYA study (NCT03298451) in uHCC, STRIDE (Single T Regular Interval D) significantly improved overall survival (OS) vs sorafenib (S), and D monotherapy was noninferior to S. STRIDE and D had manageable safety (Abou-Alfa et al. *NEJM Evid* 2022). STRIDE is approved for uHCC in the United States and Japan and recommended for approval by the European Medicines Agency; D is approved in Japan. This exploratory analysis assessed the association between imAEs and outcomes in HIMALAYA. **Methods:** Safety was assessed in participants (pts) who received ≥ 1 dose of STRIDE (T 300 mg [one dose] plus D 1500 mg once every 4 weeks [Q4W]) or D (1500 mg Q4W). imAEs were AEs of special interest associated with drug exposure and consistent with an immune-mediated mechanism of action with no found alternate etiology. Median OS (mOS) and OS rates were estimated using the Kaplan–Meier method. OS hazard ratios (HRs) and 95% CIs were calculated using Cox modeling, with imAEs as a time-varying covariate and stratified by etiology (HBV/HCV/others), ECOG (0/1), and macro-vascular invasion (yes/no) for pts with vs without imAEs of any grade. Pts with > 1 imAE were counted once. **Results:** In total, 388 pts (STRIDE) and 388 pts (D) were included in the analysis. Any grade imAEs, Grade 3 or 4 imAEs, and imAEs leading to discontinuation occurred in 139 (35.8%), 49 (12.6%), and 22 (5.7%) pts, respectively for STRIDE and 64 (16.5%), 25 (6.4%), and 10 (2.6%) pts, respectively for D. imAEs requiring high-dose steroids (≥ 40 mg prednisone or equivalent daily) occurred in 78 (20.1%) pts for STRIDE and 37 (9.5%) pts for D. An improvement in OS was seen with STRIDE in pts with imAEs vs pts without (HR, 0.73; 95% CI, 0.56–0.95). OS rates at 6, 12, and 24 months (mo) were higher for STRIDE in pts with imAEs vs pts without. The association between imAEs and OS was less clear for D and may be limited by small pt number. In a landmark analysis of pts with vs without imAEs within 6 mo of STRIDE (n=307) or D (n=287), OS HRs (95% CIs) were 0.65 (0.47–0.90) and 1.39 (0.95–2.04), respectively. **Conclusions:** In HIMALAYA, imAEs with STRIDE or D were manageable and generally low grade. In this exploratory analysis, the occurrence of imAEs was associated with improved OS for STRIDE, generally consistent with findings for other ICIs. Clinical trial information: NCT03298451. Research Sponsor: AstraZeneca.

Oral Abstract Session

Liposomal irinotecan + 5-fluorouracil/leucovorin + oxaliplatin (NALIRIFOX) versus nab-paclitaxel + gemcitabine in treatment-naïve patients with metastatic pancreatic ductal adenocarcinoma (mPDAC): 12- and 18-month survival rates from the phase 3 NAPOLI 3 trial. *First Author: Eileen Mary O'Reilly, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Liposomal irinotecan + 5-fluorouracil/leucovorin (5-FU/LV) is approved in the USA and Europe for mPDAC following progression with gemcitabine-based therapy. A phase 1/2 study (NCT02551991) demonstrated promising anti-tumor activity in patients with mPDAC who received first-line liposomal irinotecan 50 mg/m² + 5-FU 2400 mg/m² + LV 400 mg/m² + oxaliplatin 60 mg/m² (NALIRIFOX). Here, we present results from NAPOLI 3 (NCT04083235), a randomized, open-label, phase 3 study investigating the efficacy and safety of NALIRIFOX compared with nab-paclitaxel 125 mg/m² + gemcitabine 1000 mg/m² (Gem+NabP) as first-line therapy in patients with mPDAC. **Methods:** Eligible patients with histopathologically/cytologically confirmed untreated mPDAC were randomized (1:1; stratified by Eastern Cooperative Oncology Group [ECOG] performance status, geographic region and presence/absence of liver metastases) to receive NALIRIFOX on days 1 and 15 of a 28-day cycle or Gem+NabP on days 1, 8 and 15 of a 28-day cycle. The primary endpoint was overall survival (OS); secondary endpoints were progression-free survival (PFS), overall response rate (ORR) and safety. OS was evaluated when at least 543 events were observed using a stratified log-rank test with an overall one-sided significance level of 0.025. **Results:** Overall, 770 patients (NALIRIFOX, n = 383; Gem+NabP, n = 387) were included. Baseline characteristics were balanced between arms. At a median follow-up of 16.1 months, 544 events had occurred. Median OS was 11.1 months in the NALIRIFOX group versus 9.2 months in the Gem+NabP group; median PFS was 7.4 months versus 5.6 months. Median (95% CI) duration of response was 7.3 (5.8–7.6) and 5.0 (3.8–5.6) months in patients who received NALIRIFOX and Gem+NabP, respectively. Grade 3/4 treatment-emergent adverse events occurring in at least 10% of patients receiving NALIRIFOX versus Gem+NabP included diarrhea (20.3% vs 4.5%), nausea (11.9% vs 2.6%), hypokalemia (15.1% vs 4.0%), anemia (10.5% vs 17.4%) and neutropenia (14.1% vs 24.5%). **Conclusions:** First-line NALIRIFOX demonstrated clinically meaningful and statistically significant improvement in OS and PFS compared with Gem+NabP in patients with mPDAC. The NALIRIFOX safety profile was consistent with the profiles of the regimen components and generally manageable. Clinical trial information: NCT04083235. Research Sponsor: Ipsen.

Oral Abstract Session

Tucatinib and trastuzumab for previously treated HER2-positive metastatic biliary tract cancer (SGNTUC-019): A phase 2 basket study. *First Author: Yoshiaki Nakamura, National Cancer Center Hospital Japan East, Kashiwa, Japan*

Background: Biliary tract cancer (BTC) is an aggressive malignancy with a poor prognosis, and current treatment options for advanced BTC are limited, with second-line therapy, FOLFOX and S-1 offering an objective response rate (ORR) of 5.0% and 7.5%, respectively. Up to 20% of BTCs overexpress human epidermal growth factor receptor 2 (HER2). Tucatinib (TUC) is a highly selective HER2-directed TKI approved for HER2-positive (HER2+) metastatic breast and colorectal cancer. Discussed here are the efficacy and safety results of TUC combined with Trastuzumab (Tras) in pts with previously treated HER2+ metastatic BTC. **Methods:** SGNTUC-019 (NCT04579380) is an open-label phase 2 basket study evaluating efficacy, safety, and tolerability of TUC and Tras in pts with HER2-altered solid tumors. Pts in the BTC cohort had been previously treated with and progressed after ≥ 1 line of systemic therapy for metastatic disease. Eligible pts had locally determined HER2+ (defined as HER2 overexpression determined by immunohistochemistry [IHC] 3+ or HER2 amplification determined by in situ hybridization assay or next-generation sequencing) metastatic BTC. Pts were treated on a 21-day cycle with TUC (300 mg orally twice a day) and Tras (8 mg/kg IV followed by 6 mg/kg every 3 wks). Disease status was determined based on RECIST v1.1 with assessments performed every 6 wks for 24 wks and every 12 wks thereafter. The primary endpoint is confirmed objective response rate (cORR) per investigator assessment. Secondary endpoints include overall survival (OS), disease control rate (DCR), duration of response (DOR), progression-free survival (PFS), and safety. **Results:** Thirty pts were enrolled in the BTC cohort as of data cutoff date of 30 Nov 2022. The median duration of follow-up was 8.3 months. cORR was 46.7% (90% CI, 30.8, 63.0), with 14 responses including 1 complete and 13 partial responses. Median DOR was 6.0 months (90% CI, 5.5, not estimable). DCR was 76.7% (n=23; 90% CI, 60.6, 88.5), and median PFS was 5.5 months (90% CI, 3.9, 8.1). At data cutoff, 13 (43.3%) patients had died, and the 12-months OS rate was 53.8% (90% CI, 35.2, 69.1%). Overall, the most common treatment-emergent adverse events (TEAEs) reported were pyrexia (43.3%) and diarrhea (40.0%). Grade ≥ 3 TEAEs were reported in 18 (60.0%) of 30 pts; however, only 6 (20.0%) and 2 (6.7%) of these pts had Grade ≥ 3 TEAEs related to TUC and Tras, respectively. Two (6.7%) pts discontinued TUC due to TEAEs, cholangitis and liver disorder. No deaths were due to TEAEs. **Conclusions:** The combination of TUC and Tras was well tolerated in pts with previously treated HER2+ metastatic BTC. The observed antitumor activity supports the combination of TUC and Tras as a future chemotherapy-free treatment option for this population with historically poor outcomes. Clinical trial information: NCT04579380. Research Sponsor: Seagen Inc.

Oral Abstract Session

Results from the pivotal phase (Ph) 2b HERIZON-BTC-01 study: Zanidatamab in previously-treated HER2-amplified biliary tract cancer (BTC). *First Author: Shubham Pant, MD Anderson Cancer Center, Houston, TX*

Background: For patients (pts) with locally advanced/metastatic BTC who progress after first-line treatment (tx), standard tx offers limited clinical benefit with modest improvement in survival. HER2-targeted therapies have improved survival in breast and gastric cancer, but there is no approved HER2-targeted therapy for BTC. Zanidatamab (zani), a HER2-targeted bispecific antibody, has shown durable responses in a subset of pts with BTC in a Ph 1 trial. **Methods:** HERIZON-BTC-01, an open-label, global Ph 2b study (NCT04466891), evaluated zani (20 mg/kg IV every 2 wks) in pts with HER2-amplified, locally advanced unresectable or metastatic BTC (gallbladder cancer [GBC], intra-/extra-hepatic cholangiocarcinoma [ICC/ECC]) who had received prior gemcitabine-containing therapy; pts with prior HER2-targeted therapies were excluded. Pt cohort assignment was based on tumor immunohistochemistry (IHC) status: Cohort 1 for IHC 2+/3+ (HER2 positive), or Cohort 2 for IHC 0/1+. Tumors were assessed every 8 wks per RECIST 1.1. The primary endpoint was confirmed objective response rate (cORR) by independent central review (ICR) in Cohort 1. Secondary endpoints included other efficacy and safety outcomes. **Results:** Enrollment is complete with 87 pts (Cohort 1, n=80; Cohort 2, n=7) treated. Median age was 64 yrs (range, 32-79); 54% were female; 66% were Asian; 52% had GBC, 30% ICC, and 18% ECC. Pts had a median of 1 line (range, 1-7) of prior therapy in the locally advanced/metastatic setting. In Cohort 1, cORR was 41% with median duration of response (DOR) of 12.9 months (m; 95% CI: 5.95, not estimable); median study follow-up time was 12.4 m. Among the 33 responders at the data cut (10OCT2022), 49% had ongoing responses and 82% had a DOR of ≥16 wks. Median time to first response was 1.8 m (range, 1.6-5.5). Progression-free survival and overall survival are being evaluated. No responses were observed in Cohort 2. In both cohorts (N=87), tx-related adverse events (TRAEs) occurred in 72% of pts; TRAEs in ≥10% of pts were diarrhea (37%) and infusion-related reaction (33%). Gr 3 TRAEs occurred in 18% of pts, with diarrhea (4.6%) and ejection fraction (EF) decreased (3.4%) in >3% of pts. Two pts (2.3%) discontinued zani due to an AE (EF decreased and non-infectious pneumonitis). Seven pts had serious TRAEs; no AE preferred term occurred in >1 pt. No zani-related Gr 4 AEs or deaths were reported. **Conclusions:** Results of the pivotal HERIZON-BTC-01 study indicate that the HER2 bispecific antibody zani demonstrates rapid, durable responses with a manageable safety profile in pts with tx-refractory HER2-positive BTC. Given these data, zani continues to be developed as a tx option in HER2-positive BTC. Clinical trial information: NCT04466891. Research Sponsor: Zymeworks BC Inc.

Clinical Science Symposium

Results from the MORPHEUS-liver study: Phase Ib/II randomized evaluation of tiragolumab (tira) in combination with atezolizumab (atezo) and bevacizumab (bev) in patients with unresectable, locally advanced or metastatic hepatocellular carcinoma (uHCC). *First Author: Richard S. Finn, University of California Los Angeles, Los Angeles, CA*

Background: Atezo + bev is the current first-line standard of care for uHCC based on the IMbrave150 study, which demonstrated superior overall survival, progression-free survival (PFS), and objective response rate (ORR) vs sorafenib (Finn, et al. New Engl J Med 2020; Cheng, et al. J Hepatol 2022). TIGIT is a novel inhibitory immune checkpoint present on activated T cells and NK cells. Tira (anti-TIGIT) may synergize with other immunotherapies, such as PD-L1/PD-1 inhibitors. The MORPHEUS platform comprises multiple phase Ib/II trials to identify early efficacy signals and safety of treatment combinations across cancers. Here we report data from a cohort of the MORPHEUS-liver study (NCT04524871) evaluating the combination of tira + atezo + bev vs a control arm (atezo + bev) in patients with uHCC. **Methods:** Patients with previously untreated uHCC were randomized to receive atezo (1200mg IV) + bev (15mg/kg IV) with or without tira (600mg IV) every three weeks. The primary endpoint was investigator-assessed ORR by RECIST V1.1. Secondary endpoints included PFS and safety. **Results:** A total of 58 patients were randomized (tira + atezo + bev, n=40; atezo + bev, n=18). As of 28 November 2022, median follow up was 14.0 months in the tira + atezo + bev arm and 11.8 months in the control arm. Confirmed ORR was higher in the tira + atezo + bev arm (42.5%) vs the control arm (11.1%). Median PFS was longer with tira + atezo + bev (11.1 months; 95% CI: 8.2–NE) vs control (4.2 months; 95% CI: 1.6–7.4), corresponding to a PFS hazard ratio (HR) of 0.42 (95% CI: 0.22–0.82). A similar pattern of increased ORR and PFS was observed for the treatment arms in both PD-L1+ (n=23) and PD-L1– (n=27) subgroups. For tira + atezo + bev vs control arm, grade 3/4 treatment-related AEs were 27.5% vs 33.3% and AEs leading to any treatment discontinuation were 22.5% vs 22.2%, respectively. **Conclusions:** The addition of tira to atezo + bev resulted in higher ORR and longer PFS compared with atezo + bev, and no new safety signals were identified. These data suggest that tira + atezo + bev may be a promising novel first-line treatment option for patients with uHCC, and support further study in this setting. Clinical trial information: NCT04524871. Research Sponsor: F. Hoffmann-La Roche Ltd.

Updated dose escalation results for ReFocus, a first-in-human study of highly selective FGFR2 inhibitor RLY-4008 in cholangiocarcinoma and other solid tumors. *First Author: Mitesh J. Borad, Mayo Clinic Arizona, Scottsdale, AZ*

Background: Oncogenic FGFR2 alterations (fusions/rearrangements (f/r), amplifications, mutations) represent a broad therapeutic opportunity as they drive multiple solid tumors, particularly cholangiocarcinoma (CCA). However, off-isomeric toxicity and on-target resistance limit the benefit of approved pan-FGFR inhibitors (FGFRI). RLY-4008 is the first potent, highly selective, oral FGFR2 inhibitor designed to overcome these limitations by targeting FGFR2 driver alterations and resistance mutations. Here, we present updated dose escalation results from ReFocus (NCT04526106), a seamless Phase I/II, open label study evaluating the safety and preliminary efficacy of RLY-4008 in patients (pts) with advanced, FGFR2-altered solid tumors. **Methods:** Adult pts received RLY-4008 BID, QD, QD discontinuous on a 4-week (wk) cycle following a Bayesian Optimal Interval design. Treatment-related adverse events (TRAEs), PK, ctDNA and anti-tumor activity (RECIST v1.1) were assessed. **Results:** As of 30 Jan 23, 116 pts (82 f/r, 27 mutation, 6 amplification) received RLY-4008 at doses of 20-200 mg/day, including 91 with CCA. 50% had prior FGFRI, and median lines of prior therapies was 3 (1-15). 28/46 ct-DNA-evaluable pts with CCA with prior FGFRI had ≥1 baseline resistance mutation, most commonly at FGFR2 N549X (23/46) or V564X (17/46). RLY-4008 had favorable PK with doses ≥40 mg QD providing FGFR2 occupancy ≥90%. 70 mg QD was the RP2D based on PK, safety, anti-tumor activity and exposure-dependent tumor regressions in FGFRI-naïve CCA f/r pts. Anti-tumor activity was observed in CCA and solid tumors across doses and FGFR2 alterations with radiographic tumor reductions in 74 (64%), SD/PR in 83 (72%), including 4/4 (100%) FGFRI-naïve CCA f/r pts at RP2D achieving confirmed PR. Clinically meaningful disease control and durable responses were observed in pts with FGFR2 f/r CCA. Overall, median treatment duration was 24 wks (range <1-108 wks). 105 pts discontinued (PD (81%), AE (3%), other (7%). Across doses, most common TRAEs were low-grade PPE (57%), stomatitis (56%), dry mouth (38%), alopecia (28%), and dry eye (22%). No grade 4/5 TRAEs were observed. **Conclusions:** These encouraging dose escalation data confirm the broad therapeutic potential of highly selective FGFR2 targeting with RLY-4008 by demonstrating encouraging initial efficacy across FGFR2-altered solid tumors and genomic alterations, with a differentiated safety profile that avoids FGFRI- and FGFR4-related toxicity. Phase 2 of ReFocus continues across solid tumors and with registrational intent in FGFRI-naïve, FGFR2 f/r CCA. Clinical trial information: NCT04526106. Research Sponsor: Relay Therapeutics.

Clinical Science Symposium

Subgroup analysis of double-blind, placebo-controlled Ph. 2 study of nanvuranlat in treatment of pre-treated, advanced, refractory biliary tract cancer (BTC): Patients with high LAT1 expression and response to nanvuranlat. *First Author: Masafumi Ikeda, Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: L-type amino acid transporter 1 (LAT1, *SLC7A5*) is overexpressed in cancer cells leading to aggressive proliferation and lymphatic metastases. LAT1 sustains energy resources by supplying essential amino acids to the TCA cycle in chemotherapy-resistant cancer cells. LAT1 is a documented marker of poor prognosis. In a placebo-controlled, randomized trial involving patients with pre-treated, advanced, refractory biliary tract cancer (BTC), monotherapy with nanvuranlat (JPH203), a selective LAT1 inhibitor, demonstrated a significant improvement in progression free survival (PFS) compared to placebo. Subgroup analysis was conducted to determine whether the level of expression of LAT1 affects nanvuranlat efficacy. **Methods:** Patients with four different subtypes of advanced BTC were enrolled: intrahepatic and extrahepatic cholangiocarcinoma, and gallbladder and ampulla of Vater cancers. All were refractory to or intolerant of standard chemotherapy and other investigational medicines. Our analysis compared efficacy and safety in the subgroup with high LAT1 expression and all patients group. LAT1 expression was immunohistochemically evaluated in tumor specimens of BTC patients at baseline, as defined by Yanagisawa N, et al. (Cancer Med 2014). **Results:** At data cut-off (Feb 28, 2022), 211 BTC patients consented at 14 centers in Japan, and 104 patients were randomized (2:1) to nanvuranlat (n = 69) or placebo (n = 35) as the full analysis set (FAS) population. Among the samples immunohistochemically evaluable for LAT1, 62.5% had high LAT1 expression. There was no significant difference in background demography between all patient group and the high-LAT1 subgroup. Nanvuranlat met its primary endpoint (FAS by the blinded independent central review (BICR)), demonstrating a statistically significant improvement in PFS by BICR in comparison with the placebo group. The hazard ratios were further improved with nanvuranlat versus placebo, on analysis of the high-LAT1 subgroup of patients in both PFS and OS. Safety was comparable between nanvuranlat and placebo, on analysis of the high-LAT1 subgroup. **Conclusions:** This subgroup analysis indicates that the efficacy of nanvuranlat in PFS and OS is enhanced in BTC patients with high LAT1 expression, when compared with placebo. Safety profiles were similar for nanvuranlat and placebo-treated patients in this subgroup analysis. Clinical trial information: UMIN000034080. Research Sponsor: J-Pharma Co., Ltd.

Poster Discussion Session

KEYNOTE-859 study of pembrolizumab plus chemotherapy for advanced HER2-negative gastric or gastroesophageal junction (G/GJEJ) cancer: Outcomes in the protocol-specified PD-L1-selected populations. *First Author: Sun Young Rha, Yonsei Cancer Center, Yonsei University Health System, Seoul, Korea, Republic of (South)*

Background: In the ITT population of the KEYNOTE-859 study of HER2-negative, advanced G/GJEJ cancer (NCT03675737), pembrolizumab (pembro) + chemotherapy (chemo) significantly improved OS (HR 0.78, 95% CI 0.70-0.87; $P < 0.0001$), PFS (HR 0.76, 95% CI 0.67-0.85; $P < 0.0001$), and ORR (51.3% vs 42.0%; $P = 0.00009$) vs placebo + chemo at the protocol-specified interim analysis. The safety profile of pembro + chemo was as expected. We present efficacy outcomes of the protocol-specified PD-L1 combined positive score (CPS) ≥ 1 and CPS ≥ 10 populations. **Methods:** Eligible pts aged ≥ 18 y with HER2-negative, previously untreated locally advanced or metastatic G/GJEJ adenocarcinoma, ECOG PS 0-1, and known PD-L1 CPS were randomized 1:1 to pembro 200 mg or placebo IV Q3W for ≤ 35 cycles, both given with investigator's choice of 5-FU + cisplatin (FP) or capecitabine + oxaliplatin (CAPOX). Randomization was stratified by region (Europe/Israel/North America/Australia vs Asia vs rest of world), PD-L1 CPS (< 1 vs ≥ 1), and chemo (FP vs CAPOX). Per protocol, the primary endpoint of OS and the secondary endpoints of PFS and ORR per RECIST v1.1 by blinded independent central review were tested in the PD-L1 CPS ≥ 1 and ≥ 10 populations. Data are from the interim analysis (median study follow-up, 31.0 mo). **Results:** At baseline, 618 (78.2%) of 790 pts randomized to pembro + chemo and 617 (78.2%) of 789 pts randomized to placebo + chemo had PD-L1 CPS ≥ 1 ; 279 (35.3%) and 272 (34.5%), respectively, had CPS ≥ 10 . Baseline characteristics were generally consistent between treatment arms and populations. In the PD-L1 CPS ≥ 1 population, median OS was 13.0 mo (95% CI 11.6-14.2) for pembro + chemo vs 11.4 mo (95% CI 10.5-12.0) for placebo + chemo (HR 0.74, 95% CI 0.65-0.84; $P < 0.0001$), median PFS was 6.9 mo (95% CI 6.0-7.2) vs 5.6 mo (95% CI 5.4-5.7) (HR 0.72, 95% CI 0.63-0.82; $P < 0.0001$), ORR was 52.1% vs 42.6% ($P = 0.00041$), and median DOR was 8.3 mo (range 1.2+ to 41.5+) vs 5.6 mo (1.3+ to 34.2+). In the PD-L1 CPS ≥ 10 population, median OS was 15.7 mo (95% CI 13.8-19.3) with pembro + chemo vs 11.8 mo (95% CI 10.3-12.7) with placebo + chemo (HR 0.65, 95% CI 0.53-0.79; $P < 0.0001$), median PFS was 8.1 mo (95% CI 6.8-8.5) vs 5.6 mo (95% CI 5.4-6.7) (HR 0.62, 95% CI 0.51-0.76; $P < 0.0001$), ORR was 60.6% vs 43.0% ($P = 0.00002$), and median DOR was 10.9 mo (range 1.2+ to 41.5+) vs 5.8 mo (1.4+ to 31.2+). Among all treated pts in the pembro + chemo ($n = 785$) and placebo + chemo ($n = 787$) arms, immune-mediated AE incidence was 27.1% vs 9.3%. **Conclusions:** The addition of pembro to FP or CAPOX significantly improved OS, PFS, and ORR in the PD-L1 CPS ≥ 1 and ≥ 10 populations. Together with the efficacy and safety results from the ITT population, these data support pembro + chemo as a new first-line treatment option for pts with locally advanced or metastatic HER2-negative G/GJEJ adenocarcinoma, regardless of PD-L1 expression. Clinical trial information: NCT03675737. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Poster Discussion Session

A randomized study of consolidation chemoradiation (CTRT) vs observation after first-line chemotherapy (CT) in advanced gall bladder cancers (GBC): RACE-GB Study. *First Author: Sushma Agrawal, SGPGI, Lucknow, India*

Background: CT (gemcitabine plus cisplatin) is the standard of care for patients presenting with unresectable advanced GBC but their prognosis remains poor. The value of CT after CT is uncertain. We therefore conducted a randomised trial evaluating consolidation CTRT versus Observation after four cycles of CT in those patients whose disease did not progress during CT (NCT05493956). **Methods:** Responders (partial response and stable disease) to 4 cycles of CT were randomised to CTRT vs observation ($n=135$). CTRT was delivered by 3D-Conformal Radiation Therapy along with concurrent capecitabine @1250 mg/m². The dose of RT was 45 Gy in 25 fractions to GBC and lymphatics followed by a boost of 9 Gy in 5 fractions to the GBC. The primary endpoint was overall survival which was calculated from the date of randomisation. The trial is designed to detect an improvement in 2-year OS from 8% in the control arm to 25% in study arm with 80.0% power at a 0.05 significance level. The required sample size was 130 (65 in each arm) over a duration of 4-5 years. CTRT was delivered by 3DCRT along with concurrent capecitabine @1250 mg/m². The dose of RT was 45Gy in 25 fractions to GBC and lymphatics followed by a boost of 9 Gy in 5 fractions to the GBC. Toxicities documented during CT and CTRT were recorded using the CTCAE version 3.0. and RTOG criteria respectively. Chi square test and Survival analysis was performed for the data analysis. Demographic data and CTRT Dose volume data were correlated with side effects and survival. Statistical analysis was performed with SPSS version-23. **Results:** 67 patients were randomized to observation and 68 to CTRT. Their demographic characteristics were well balanced. 63% were women, 58% had T4 tumours, 42% had N2, 27% needed stenting for obstructive jaundice. The median overall survival in the CTRT arm was 10 months versus 4 months in the observation arm (HR 0.47 [95% CI 0.33-0.68] $p=0.001$). Adverse events (grade 3 or higher) due to CTRT included the following: Nausea 3%, Anemia 9%, GI bleed 6%, hepatotoxicity 13%. Updated survival data and prognostic factors affecting overall survival will be presented in the meeting. **Conclusions:** CTRT after 4 cycles of CT significantly prolonged overall survival but was also associated with adverse events. Clinical trial information: NCT05493956. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Poster Discussion Session

A phase 2 randomized, open-label, multicentre study of sintilimab and anlotinib in combination with gemcitabine plus cisplatin (GemCis) as first-line therapy in patients (pts) with advanced biliary tract cancer (BTC): SAGC. *First Author: Li Jingjing, Department of Hepato-Pancreato-Biliary & Gastric Medical Oncology, Cancer Hospital of the University of Chinese Academy of Sciences (Zhejiang Cancer Hospital), Institute of Cancer and Basic Medicine (IBMC), Chinese Academy of Sciences, Hanzhou, China*

Background: BTC has a higher incidence in China rather than worldwide, with extremely poor prognosis, and the efficacy of standard first-line therapy is rather limited. TOPAZ-1 study suggested the immune check-point inhibitor plus chemotherapy as first line in advanced BTC significantly improved OS and PFS with manageable safety, but the median OS was just 12.8 months. SAGC is the first randomized controlled phase 2 trial to evaluate immune check-point inhibitor plus antiangiogenic targeted drug plus chemotherapy in advanced BTC as first-line treatment. **Methods:** Overall 80 advanced BTC were randomized 1:1 to receive sintilimab (200mg every 3 weeks [Q3W]) and anlotinib (10mg po qd, Days 1-14 Q3W) in combination with GemCis (Gem 1000 mg/m² and Cis 25 mg/m² on Days 1 and 8 Q3W) for up to 8 cycles, followed by sintilimab (200mg every 3 weeks [Q3W]) and anlotinib (10mg po qd, Days 1-14 Q3W) (SAGC group) or GemCis (Gem 1000 mg/m² and Cis 25 mg/m² on Days 1 and 8 Q3W) for up to 8 cycles until disease progression or unacceptable toxicity (GC group). The primary objective was to assess the progression-free survival (PFS). Secondary endpoints included, objective response rate (ORR), overall survival (OS) and safety. Next generation sequencing (NGS) was performed on pre-treatment available tumor tissue in 58 patients to screen dominant patients of the therapy. **Results:** At the time of the final data cutoff (Sep. 22, 2022), median follow-up was 13.4 mo, and 65/80 pts (81.3%) had discontinued tx. The confirmed median PFS was 8.6 months for SAGC group vs. 6.2 months for GC group (HR 0.37, $p < 0.01$) and ORR was 52.8% for SAGC group vs. 29.4% for GC group. Grade 3/4 treatment-related adverse events (TRAEs) occurred in 77.5% of pts receiving sintilimab plus anlotinib plus GemCis and 40% of pts receiving GemCis. The results from NGS suggested that patients with TMB-H and ARID1A-WT may benefit more from combination therapy. **Conclusions:** In pts with advanced BTC, sintilimab plus anlotinib plus GemCis significantly improved PFS and ORR vs GemCis with manageable safety, indicating sintilimab plus anlotinib plus GemCis may be a new first-line standard of care regimen. Clinical trial information: NCT04300959. Research Sponsor: None.

Poster Discussion Session

A multicenter, open-label, randomized phase II study evaluating adjuvant gemcitabine plus cisplatin (GC) and capecitabine with concurrent capecitabine radiotherapy (CAPE-RT) in patients with operated gallbladder adenocarcinoma (GBC): The GECCOR-GB trial. *First Author: Anant Ramaswamy, Tata Memorial Hospital (HBN), Mumbai, India*

Background: Adjuvant gemcitabine plus cisplatin (GC) and concurrent chemo-radiotherapy are commonly used treatment options for resected GBC. **Methods:** GB-GECCOR is a multicentre, open-label randomized non-comparative phase II study in patients of Gallbladder cancer (GBC), with R0 or R1 resection within 3 months of randomization. Patients were randomized 1: 1 to GC arm (Gem 1000 mg/m² and Cisplatin 25mg/m² on day 1 and 8, q 3 weeks) for 6 cycles or CAPE-RT arm (Capecitabine 1000mg/m² BD on days 1-14, q 3 weeks for 2-4 cycles followed by chemoradiation (RT: 45 Gy over 25 fractions concurrent with capecitabine: 825mg/m² twice) followed by 2-4 cycles of capecitabine for a total of 6 cycles). The primary end point was 1-year disease-free survival (DFS). With 80% power to detect the difference between a 59% (minimum sufficient activity of the regimen) and a 77% (sufficient activity for future larger studies with the regimen) 1-year DFS rate assuming an attrition of 10%, a total of 90 patients were required for the study. **Results:** Between May 2019 and February 2022, 90 patients (45 in each arm), were included. Stage II and stage III GBC were seen in 50 (56%) and 40 patients (44%) respectively, with R0 resection observed in 86 patients (96%). Patient characteristics were well balanced between the 2 arms except for R1 resections which were greater in the CAPE-RT arm ($p=0.041$). With a median follow-up duration of 23 months, the 1-year DFS rate was 88.9% (95% CI: 79.5-98.3) in the GC group and 77.8% (95% CI: 65.4 – 90.2) in the CAPE-RT group, respectively. The most common AEs were grade 3/4 neutropenia in 6 patients (13.3%) in the GC group and grade 2/3 HFS in 14 patients (31.1%) in the CAPE-RT group. The distant metastases were seen in 12 patients (26.6%) in each arm and loco-regional metastases in 3 patients (6.6%) in the GC arm. **Conclusions:** In this study of operated GBC, GC and CAPE-RT successfully achieved the minimum pre-specified DFS rates. Within the confines of a non-comparative randomised study, GC had narrowed the gap in survivals of stage III vs. stage II GBCs, which was not noted in the CAPE-RT arm. This study results give credence to the use of both regimens as reasonable standards of care till evaluation in larger phase 3 studies. Clinical trial information: CTRI/2019/05/019323. Research Sponsor: Educational grants to the institute from redxy's lab pvt for this study.

Clinical and genomic characterization of early-onset pancreatic cancer. *First Author: Florian Castet, Gastrointestinal and Endocrine Tumor Unit, Vall d'Hebron Institute of Oncology (VHIO), Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain*

Background: Pancreatic cancer is a leading cause of cancer-related death worldwide. Early-onset tumours (≤ 50 years) have risen alarmingly in recent years. However, the clinical and genomic particularities of early-onset pancreatic cancer (EOPC) remain poorly defined. We aimed to characterize EOPC and study its implications for treatment and prognosis. **Methods:** We performed a retrospective analysis of EOPC patients and a control group of patients ≥ 70 years (defined as average-onset pancreatic cancer, AOPC) followed at a tertiary cancer centre from 2010 to 2022. We collected baseline patient characteristics, tumor molecular profiling, germline genetic alterations, survival and treatment outcomes. We used a targeted gene panel to identify somatic genomic events and classified them according to the ESMO scale for clinical actionability of molecular targets (ESCAT). Key molecular findings were validated in an external cohort. We used a propensity score weighting method and multivariate Cox regression analysis to adjust for covariates. **Results:** We reviewed 824 patients, 336 of whom met all inclusion criteria (EOPC N = 139, AOPC N = 197). EOPC was associated with smoking status (current, 15.9 vs 7.9%, $p = 0.03$), lower prevalence of diabetes (3.7 vs 39.6%, $p < 0.01$), better performance status (ECOG 0, 42.9 vs 19.3%, $p < 0.01$), higher CA19.9 levels (median 574 vs 207.6 U/L, $p = 0.07$) and higher albumin levels (median 4.2 vs 3.9 g/L, $p < 0.01$). EOPC showed a non-significant higher prevalence of germline alterations (22.4 vs 14.5%, $p = 0.18$). After adjustment for baseline covariates, we observed no differences in survival (HR 0.94, 95% CI 0.63-1.4). We found a lower prevalence of *KRAS*^{MUT} tumors in EOPC when compared with AOPC (83.1 vs 91.1%, $p = 0.12$) and validated this finding in an independent cohort of 803 patients (82.9 vs 94.5%, $p < 0.01$). Notably, EOPC were enriched in potentially actionable alterations when compared with AOPC, both in our cohort (19.1 vs 14.4%) and the validation cohort (14.4 vs 7.9%, $p < 0.01$). Moreover, 294 patients in our cohort (EOPC N = 130; AOPC N = 164) were diagnosed with or eventually presented metastasis. EOPC more frequently received first-line 5FU-based chemotherapy (44.1 vs 14.7%, $p < 0.01$) and received a greater number of treatment lines (median 2 vs 1, $p < 0.01$). EOPC had a longer progression-free survival on first-line chemotherapy when compared with AOPC (HR 0.61, 95% CI 0.43-0.87, $p < 0.01$) although there were no differences in response rate. Six EOPC patients received matched targeted therapies and 5 patients with AOPC. After adjusting for the number of treatment lines received, EOPC treated with targeted therapies exhibited longer OS compared with EOPC who did not (HR 0.34 95% CI 0.12-0.93, $p = 0.04$), whereas this trend was not observed in AOPC (HR 0.82 95% CI 0.32-2.11, $p = 0.68$). **Conclusions:** EOPC patients harbor unique clinical and molecular features and may particularly benefit from precision-based oncology approaches. Research Sponsor: None.

Poster Discussion Session

Not all treated *KRAS*-mutant pancreatic adenocarcinomas are equal: *KRAS* G12D and survival outcome. *First Author: Bach Ardalan, Sylvester Comprehensive Cancer Center, Miami, FL*

Background: *KRAS* is an oncogenic driver in pancreatic ductal adenocarcinoma (PDAC) with mutations identified in $> 90\%$ of cases. G12D is the most frequent variant, followed by G12V and G12R. We recently reported on the prognostic impact of distinct *KRAS* mutations. The current study utilized a large clinical and genomic database, to further explore and characterize the prognostic and molecular differences between *KRAS* variants, focusing on *KRAS* G12D and G12R. **Methods:** PDAC samples were tested using whole transcriptome sequencing (WTS; Illumina NovaSeq) and NextGen DNA sequencing (NextSeq, 592 Genes and NovaSeq, WES) at Caris Life Sciences (Phoenix, AZ). Transcriptomic signatures including MPAS (MAPK activation score), T-cell inflamed score and tumor micro environment (TME) characterization were calculated on WTS data. Significance was determined by χ^2 and Fisher-Exact and p-value was adjusted for multiple comparisons (q). Real-world overall survival (rwOS) obtained from insurance claims data was calculated from tissue collection to last contact (comparison done by Kaplan-Meier test). **Results:** 5,555 PDAC patients harboring either *KRAS* G12D (n = 2,671), G12V (n = 1,871) G12R (n = 904) or G12C (n = 109) variants were identified. Patients with *KRAS* G12R mutant tumors had significantly longer OS compared to G12D (396 vs 311 days, HR 0.81, CI 0.74-0.88, $p < 0.0001$). There was no difference among *KRAS* variants in the rate of *TP53*, *CDKN2A* and *SMAD4* mutations. *ARID1A* and *KMT2D* were more frequently mutated in *KRAS* G12D vs. G12R. The MPAS gene signature reflecting MAPK pathway activation trended lower in G12R vs. G12D. Expression of multiple genes in this pathway was statistically lower in the G12R cohort. Immune profiling suggested that: *PDL1* expression is significantly lower in G12R vs G12D (13% vs 19%), TMB-H and dMMR were comparable in G12D vs G12R and several glucose and glutamine metabolism genes were significantly lower in expression when comparing G12R vs G12D - table. OS was improved within the G12R cohort for those patients on metformin (n=273 patients) (416 vs 388 days, HR 0.84, CI 0.72-0.99, $p = 0.037$) while no difference was seen in those with *KRAS* G12D based on metformin use. **Conclusions:** Patients with G12D mutations have significantly lower survival compared to G12R. Significant molecular differences were seen in MAPK pathway gene expression, markers of immune activation, and genes involved in glucose and glutamine metabolism. Intriguingly, metformin use appeared to impact survival in the *KRAS* G12R subgroup. We aim to further explore distinct vulnerabilities based on MAPK pathway activation and dysregulated metabolism. Based on this data, future studies should address the *KRAS* mutation status and explore distinct therapeutic vulnerabilities. Research Sponsor: None.

Poster Discussion Session

Investigating alterations in cancer driver genes and other potentially targetable mutations in patients with intrahepatic cholangiocarcinoma (iCCA) treated on the randomised phase III multicentre BILCAP clinical trial. *First Author: Valerie Elizabeth Crolley, UCL-University College London (United Kingdom), London, United Kingdom*

Background: The BILCAP clinical trial established adjuvant capecitabine as the standard of care treatment in patients with resected biliary tract cancer. Translational work to investigate the role of cancer driver genes and other potentially targetable mutations in patients enrolled on BILCAP was performed, with this analysis focusing on patients with intrahepatic cholangiocarcinoma (iCCA). **Methods:** Archived fixed formalin (FFPE) tissue samples were collected from consented BILCAP patients. These samples underwent DNA and RNA extraction followed by low-pass whole genome sequencing (lp-WGS), targeted gene sequencing (TGS) and RNA sequencing (RNAseq) for copy number (CN) analysis, mutation analysis and gene fusion analysis. **Results:** 84 of the 447 BILCAP patients had iCCA; 45 successfully underwent lp-WGS and RNAseq, of whom 36 also underwent TGS. The median age was 61 years (95% CI 57.8 – 64.2), 55.6% were female and 23 received capecitabine (51.1%). FGFR2 gene fusions were present in 9 patients (20.0%), as were fusions in NTRK1 (n = 3, 6.7%), FGFR1 (n = 3, 6.7%), FGFR3 (n = 2, 4.4%) and FGFR4 (n = 2, 4.4%). Commonly mutated driver genes included ROS1 (n = 12, 33.3%), MET (n = 10, 27.8%) and ALK (n = 7, 19.4%) with known pathogenic variants seen in IDH1 (n = 4, 11.1%; total number of mutations = 7, 19.4%), BRAF (n = 2, 5.6%; total n = 6, 16.7%), FGFR2 (n = 1, 2.7%; total n = 8, 22.2%), FGFR3 (n = 1, 2.7%, total n = 6, 16.7%), IDH2 (n = 1, 2.7%; total n = 6, 16.7%) and EGFR (n = 1, 2.7%; total n = 4, 11.1%). Commonly amplified (CN ≥ 4 , ploidy < 3) genes included NTRK1 (n = 9, 20.0%), ERBB2 (n = 8, 17.8%), and MET (n = 3, 6.7%). Most of the alterations investigated in this cohort did not significantly affect recurrence risk or overall survival (OS), including FGFR2 fusions (OS HR 1.23, $p = 0.695$; recurrence HR 1.32 $p = 0.555$). However, the presence of a FGFR3 fusion gene significantly reduced OS (OS HR 0.57, $p = 0.0091$; recurrence HR 3.71, $p = 0.0734$), and having ≥ 4 copies of either NTRK1 (OS HR 3.55, $p = 0.0027$; recurrence HR 3.48, $p = 0.0019$) or MET (OS HR 6.06, $p < 0.001$; recurrence HR 6.05 $p < 0.001$) significantly reduced OS and increased the risk of recurrence. **Conclusions:** The BILCAP cohort shows a wide variety of driver and potentially targetable mutations in unselected iCCA patients, comparable to previous early-stage biliary tract cancer datasets. Of note, patients with FGFR3 fusions, MET amplification or NTRK1 amplification had significantly shorter OS, and patients with MET or NTRK1 amplification had significantly reduced OS and significantly increased risk of disease recurrence. MET amplification, NTRK1 amplification and FGFR3 fusions may be important indicators in determining prognosis, and could provide attractive targets for future targeted anti-cancer therapy in iCCA. Clinical trial information: EUCTR2005-003318-13. Research Sponsor: Incyte.

FOOTPATH: A randomized, open-label phase-2 study of liposomal irinotecan + 5-FU and folinic acid (NAPOLI) versus sequential NAPOLI and mFOLFOX6 versus gemcitabine/nab-paclitaxel in treatment-naïve metastatic pancreatic cancer (mPDAC). *First Author: Benedikt Westphalen, Department of Medicine III and Comprehensive Cancer Center (CCC Munich LMU), University Hospital, LMU Munich, Munich, Germany, Munich, Germany*

Background: The optimal first-line regimen in the treatment of mPDAC remains unknown. Recent data demonstrated superiority of 5-FU/liposomal irinotecan/oxaliplatin (NALIR-IFOX) over gemcitabine/nab-paclitaxel. However, the question remains open if both irinotecan and oxaliplatin are required in first-line treatment and whether these agents can be given sequentially. **Methods:** Eligible patients with histologically confirmed diagnosis of mPDAC were randomized 1:1:1 to receive in Arm A standard treatment (gemcitabine 1000 mg/m² + nab-paclitaxel 125 mg/m²) or investigational therapy applying in Arm B the NAPOLI regimen (liposomal irinotecan 80 mg/m² + folinic acid 400 mg/m² + 5-FU 2400 mg/m²) or in Arm C a sequence of NAPOLI and mFOLFOX6 (oxaliplatin 85mg/m² + folinic acid 400mg/m² + 5-FU 2400 mg/m²). Overall, 274 patients were enrolled at 48 sites in Germany. The primary endpoint was progression-free survival (PFS). Secondary endpoints were overall survival (OS), objective response rate, disease control rate, duration of study treatment and safety. **Results:** In the full analysis set (n=265), neither treatment with NAPOLI (3.1 months, HR 1.224, $p = 0.2123$) nor the sequence of NAPOLI and mFOLFOX6 (6.0 months, HR 0.864 $p = 0.0720$) lead to a statistically significant improvement of PFS over gemcitabine/nab-paclitaxel (4.3 months). Median duration of treatment was 3.5 months in Arm A, 2.0 months in Arm B and 3.7 months in Arm C, respectively. In a first analysis of overall survival, OS in Arm A was 8.7 months (95% CI, 7.1-11.9 months) versus 7.9 months in Arm B (95% CI, 6.6-12.3 months; HR 1.178, $P = 0.348$) and 11.0 months in Arm C (95% CI, 8.4-13.6 months; HR 0.879, $P = 0.154$). Overall, safety was comparable with published data, with higher rates of neutropenia and peripheral neuropathy in Arm A, while diarrhea was more frequent in Arms B and C. **Conclusions:** The study did not show superiority of either NAPOLI or the sequence of NAPOLI/mFOLFOX6 over standard therapy with gemcitabine/nab-paclitaxel. In view of the published evidence, the present data supports the hypothesis that sequential NAPOLI/mFOLFOX6 may be equally effective with regard to OS, but less toxic, compared to mFOLFIRINOX. Clinical trial information: NCT03487016. Research Sponsor: Servier.

Prospective evaluation of the utility of concurrent 18F-FDG PET/CT and 68Ga-DOTA-TOC imaging in gastroenteropancreatic neuroendocrine neoplasms (GEPNENs): The PETNET study. *First Author: Joao Paulo Salar Vasconcelos, BC Cancer, Vancouver Cancer Centre, Vancouver, BC, Canada*

Background: Somatostatin receptor imaging (SRI) is a standard of care for patients with GEPNENs. The additional value of concurrent 18F-FDG PET/CT (FDG PET) remains unclear. We reviewed a prospective functional imaging study to determine the utility of FDG PET in GEPNENs. **Methods:** PETNET is a prospective study in British Columbia, Canada, which provides all 68Ga-DOTA-TOC (DOTA PET) imaging in the province. Every patient receives a DOTA PET scan and an FDG PET within 30 days. PETNET enrolls all patients with an indication for SRI. Scans are ordered per treating physician discretion at any point in the disease course. This abstract focuses on the WD-GEPNEN population. Only the first dual functional imaging scans were analyzed and FDG was interpreted qualitatively (positive/negative). **Results:** From 04/2017-01/2023, 375 patients with NEN were enrolled, 165 (44%) with metastatic GEPNENs. Baseline characteristics are described. Median time between scans was 4 days (IQR 1-11). The proportion of patients with positive FDG PET at baseline increased with WHO grade. For patients with well differentiated G1 to G3 GEPNENs (N=161), overall survival was significantly lower with a positive FDG PET (HR: 4.22; 95%CI 1.61-11.02 p=0.001). FDG remained prognostic when G3 tumors were excluded (N=148) (HR 3.52; 95%CI 1.32-9.42 p=0.007). When analyzing dual tracer PET imaging, patients with DOTA+/FDG- had reduced risk of dying in comparison with DOTA+/FDG+ (HR:0.26; 95%CI 0.09-0.67 p=0.01). After multivariate analysis, FDG positivity remained independently associated with reduced survival (HR 2.87; 95%CI 1.06-7.75 p=0.04) when controlling for grade of tumor and age. **Conclusions:** In this prospective cohort of metastatic GEPNENs, a positive FDG PET was significantly associated with reduced overall survival. These results provide additional evidence to support dual tracer functional imaging use in metastatic well differentiated GEPNENs. Research Sponsor: BC Cancer foundation.

Preliminary translational immune and stromal correlates in a randomized phase II trial of pembrolizumab with or without defactinib for resectable pancreatic ductal adenocarcinoma (PDAC). *First Author: Anser Ali Abbas, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: PDAC is an aggressive cancer and refractory to immunotherapy due to its immunosuppressive tumor microenvironment (TME). Focal adhesion kinase (FAK) is a master regulator of the TME and associated with TME immune suppression. Our current randomized phase II trial evaluates the use of pembrolizumab, a programmed cell death 1 (PD-1) immune checkpoint inhibitor, with or without defactinib, a FAK inhibitor (FAKi), as sequential neoadjuvant and adjuvant therapy in patients with high risk resectable PDAC. We hypothesize that the patients receiving pembrolizumab and defactinib treatment will exhibit a decrease in immunosuppressive fibroblasts and myeloid subtype populations, leading to increased CD8+ T-cell infiltration into the TME compared to patients receiving pembrolizumab alone. **Methods:** We performed quantitative analysis of multiplex immunohistochemistry (mIHC) using 40 biomarkers, evaluating immune and stromal cell types on 14 pre-treatment biopsies and post-treatment resections of PDAC patients enrolled in our platform neoadjuvant clinical trial (NCT03727880). All patients received 2 cycles of gemcitabine+ nab-paclitaxel neoadjuvant chemotherapy and underwent a biopsy after completion of chemotherapy. Patients randomized to Arm A received 2 cycles of pembrolizumab 200 mg IV every 3 weeks and defactinib 400 mg PO BID, and those randomized to Arm B received pembrolizumab alone, followed by surgical resection. Image cytometry was used to quantify immune cell populations and colocalize biomarker expression in distinct cell types. Cell populations were compared using unpaired T-tests. **Results:** Lower FAP+ fibroblast density was significantly associated with higher CD8+ T-cell infiltration in Arm A (p=0.002), but not in Arm B. Patients in Arm A demonstrated a 5.44-fold average increase in CD8+ T-cell percentage between pre-immunotherapy treatment and post-immunotherapy treatment specimens compared to a 2.01-fold increase in patients in Arm B (p=0.02, p=0.09, respectively). Only patients in Arm A showed a significant increase in M1 macrophage cell density (p=0.02) after treatment. Both arms increased in CXCR4+ cell percentage (p=0.011, p=0.06) following neoadjuvant immunotherapy; however, the increase in Arm A was less than in Arm B (0.72 and 0.84-fold, respectively). **Conclusions:** In this analysis, pembrolizumab combined with defactinib was associated with lower fibroblast infiltration, higher anti-tumor M1 macrophage expression and increased CD8+ T-cell infiltration into the TME, versus pembrolizumab alone. The increased expression of CXCR4 across both treatment arms may represent a resistance mechanism and supports CXCR4 as an additional TME target. These preliminary findings warrant continued research into FAK inhibition and immune checkpoint combinatorial strategies. Clinical trial information: NCT03727880. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology; U.S. National Institutes of Health.

4023 Poster Discussion Session

Neoadjuvant hepatic arterial infusion chemotherapy with FOLFOX could improve outcomes of resectable BCLC stage A/B hepatocellular carcinoma patients beyond Milan criteria: A multi-center, phase 3, randomized, controlled clinical trial. *First Author: Wei Wei, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: The efficacy of operation, as the only radical option for resectable BCLC stage A/B hepatocellular carcinoma (HCC) patients beyond Milan criteria, is still unsatisfactory. This study aimed to investigate to efficacy and safety of preoperative neoadjuvant hepatic arterial infusion chemotherapy (HAIC) with FOLFOX regimen for these patients. **Methods:** In this multi-center, prospective, phase 3, randomized, open-labeled, controlled clinical trial, resectable BCLC stage A/B HCC patients beyond Milan criteria were randomly assigned (1:1) before hepatectomy to receive either neoadjuvant HAIC (treatment group) or operation directly without any neoadjuvant treatment (control group). The primary endpoint was overall survival (OS), the secondary endpoints are progression-free survival (PFS) and safety. **Results:** Between March 2016 and August 2022, a total of 487 patients were screened from seven Chinese hospitals, and 392 patients were randomly assigned to receive neoadjuvant FOLFOX-HAIC before hepatectomy (treatment group, n = 195), or operation directly without any neoadjuvant treatment (control group, n = 197) and were included in the ITT population. Among them, 14 patients from the treatment group and 13 patients from the control group were excluded from the PP population. In the ITT population, the OS rates at 1-, 2-, and 3-year were 97.7%, 86.3%, and 77.1%, respectively, for the treatment group and were 90.0%, 80.9%, and 70.6%, respectively, for the control group. The median PFS of the treatment and control groups was 17.4 months (95% CI, 9.0-25.8) and 9.8 months (8.2-11.4), respectively, in the ITT population. The OS and PFS were significantly better in treatment group than in control group (p = 0.032 and < 0.001, respectively) in ITT population. In the PP population, the OS rates at 1-, 2-, and 3-year were 98.7%, 91.1%, and 79.7%, respectively, for the treatment group and were 89.2%, 79.3%, and 67.7%, respectively, for the control group. The median PFS of the treatment and control groups was 22.7 months (95% CI, 10.9-34.5) and 10.2 months (8.4-12.1), respectively, in the PP population. The OS and PFS were significantly better in treatment group than in control group (p = 0.001 and < 0.001, respectively) in PP population. In treatment group of ITT population, the complete regression (CR) rate, object response rate (ORR), disease control rate (DCR) was 11.3%, 61.5%, and 97.4%, respectively. Safety analysis showed HAIC was quite safe, 191 (97.9%) patients had mild HAIC related adverse events (HRAEs) (grade 0-2). The operation related adverse events (ORAEs) were similar between two groups (p = 0.265). **Conclusions:** Neoadjuvant HAIC with FOLFOX regimen before hepatectomy may bring survival benefits for resectable BCLC stage A/B HCC patients beyond Milan criteria. Clinical trial information: NCT03851913. Research Sponsor: None.

4025 Poster Session

Nivolumab (NIVO) plus chemotherapy (chemo) vs chemo as first-line (1L) treatment for advanced gastric cancer/gastroesophageal junction cancer/esophageal adenocarcinoma (GC/GEJC/EAC): 3-year follow-up from CheckMate 649. *First Author: Yelena Y. Janjigian, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: NIVO + chemo demonstrated superior overall survival (OS) and clinically meaningful progression-free survival (PFS) benefit vs chemo and acceptable safety in previously untreated patients (pts) with advanced GC/GEJC/EAC, leading to approvals in multiple countries including the US. NIVO + chemo continued to demonstrate clinically meaningful improvement in efficacy after 2 years of follow-up. We present efficacy and safety analyses from NIVO + chemo vs chemo from the 3-year follow-up of CheckMate 649. **Methods:** Adults with previously untreated, unresectable advanced, or metastatic GC/GEJC/EAC were enrolled, regardless of programmed death ligand 1 (PD-L1) expression, excluding pts with known HER2-positive status. Pts were randomized to NIVO (360 mg Q3W or 240 mg Q2W) + chemo (XELOX Q3W or FOLFOX Q2W), NIVO + ipilimumab, or chemo. Primary endpoints for NIVO + chemo vs chemo were OS and PFS by blinded independent central review (BICR) in pts with PD-L1 combined positive score (CPS) ≥ 5. **Results:** 1581 pts were concurrently randomized to NIVO + chemo or chemo. With 36-month (mo) minimum follow-up, NIVO + chemo continued to demonstrate OS and PFS benefit vs chemo in pts with PD-L1 CPS ≥ 5 and all randomized pts. The objective response rate (ORR) per BICR in pts with PD-L1 CPS ≥ 5 who had measurable lesions at baseline was 60% (95% CI 55–65) with NIVO + chemo vs 45% (95% CI 40–50) with chemo; in all randomized pts, ORR per BICR was 58% (95% CI 54–62) with NIVO + chemo vs 46% (95% CI 42–50) with chemo. Responses were more durable with NIVO + chemo vs chemo in pts with PD-L1 CPS ≥ 5 (median [m] duration of response [mDOR] 9.6 mo [95% CI 8.2–12.4] vs 7.0 mo [95% CI 5.6–7.9], respectively) and in all randomized pts (mDOR 8.5 mo [95% CI 7.7–9.9] vs 6.9 mo [95% CI 5.8–7.2], respectively). OS benefit with NIVO + chemo was observed across most prespecified subgroups. No new safety signals were identified. A summary of treatment-related adverse events (TRAEs) is shown in the Table. Additional analyses will be presented. **Conclusions:** After 3 years of follow-up, NIVO + chemo continued to demonstrate clinically meaningful long-term survival benefit with acceptable safety, further supporting its use as a standard 1L treatment in previously untreated pts with advanced GC/GEJC/EAC. Clinical trial information: NCT02872116. Research Sponsor: Bristol Myers Squibb.

Final survival results of ipilimumab or FOLFOX in combination with nivolumab and trastuzumab in previously untreated HER2 positive esophago gastric adenocarcinoma: The randomized AIO INTEGA trial. *First Author: Joseph Tintelnot, University Cancer Center Hamburg (UCC), University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: In metastatic esophagogastric adenocarcinoma (EGA), the addition of PD-1 inhibitors (i) to chemotherapy has improved the outcome in selected patient populations. The randomized INTEGA trial investigated trastuzumab and PD-1 with FOLFOX or CTLA-4i in 1st line treatment of advanced HER2+ EGA. **Methods:** Patients with previously untreated, metastatic HER2+ (local IHC3+ or 2+/ISH+) EGA, and adequate organ function were randomized to trastuzumab and nivolumab (1mg/kg Q3W x4/240mg Q2W for up to 12 months) in combination with ipilimumab (3mg/kg x4 Q3W; Ipi arm) or mFOLFOX6 (FOLFOX arm) accompanied by a large translational program. The primary endpoint was the 12month overall survival (OS) rate. The trial was registered at ClinicalTrials.gov, NCT03409848. **Results:** Between March 2018 and May 2020, 97 patients were enrolled and 88 randomized across 21 German sites with the following baseline characteristics: female/male 18/70, median age 60.5 (range 41-80), ECOG 0/1 54/34, GEJ/stomach 66/22. Central post hoc biomarker analysis on 82 evaluable patients showed PD-L1 CPS $\geq$ 1/ $\geq$ 5 in 59/46 patients and confirmed HER2 (central IHC3+ or 2+/ISH+) positivity in 77 patients. The observed OS rate at 12 months was 70% (95% confidence interval (CI) 54-81%) in the FOLFOX arm, and 57% (95% CI 41-71%) in the Ipi arm. The progression free survival was 10.7 and 3.2 months, and the overall response rate was 53.5% and 34% in the FOLFOX and the Ipi arm, respectively. Although these data are in favor of the FOLFOX arm, the overall survival curves crossed with increased follow-up (median follow-up of 18.8 months) and thus the final median OS was 22.1 and 23.3 months, numerically favoring the Ipi arm. According to the centrally assessed CPS the OS was: 22.1 and 32.2 months in the CPS $\leq$ 5 group, and 22.7 and 12.6 months in the CPS $\geq$ 5 group for the FOLFOX and the Ipi arm, respectively. Notably, the median tumor burden calculated as the sum of target lesions was numerically lowest in the Ipi arm with higher than median OS. **Conclusions:** In contrast to limited short term efficacy of the Ipi arm as reflected by the lower PFS, the Ipi arm showed favorable OS, that was inversely correlated to the CPS status. Further analysis of baseline clinical and molecular data to better identify the subgroup of patients benefiting the most of trastuzumab/nivolumab/ipilimumab will be presented at the meeting. Clinical trial information: NCT03409848. Research Sponsor: BMS.

AdvanTIG-105: A phase 1b dose-expansion study of ociperlimab (OCI) + tislelizumab (TIS) with chemotherapy (chemo) in patients (pts) with stage IV gastric/gastroesophageal adenocarcinoma (GC/GEJC). *First Author: Se Hyun Kim, Seoul National University Bundang Hospital, Seongnam, South Korea*

Background: T-cell immunoreceptor with immunoglobulin and immunoreceptor tyrosine-based inhibitory motif domains (TIGIT) inhibitor in combination with an anti-programmed cell death protein 1 (PD-1) antibody has shown antitumor activity in solid tumors. AdvanTIG-105 (NCT04047862) is a phase 1/1b open-label study designed to assess the safety and preliminary antitumor activity of OCI, an anti-TIGIT monoclonal antibody (mAb), + TIS, an anti-PD-1 mAb, in pts with unresectable, locally advanced or metastatic solid tumors. In the dose-escalation part, OCI + TIS was well tolerated with preliminary antitumor activity observed, and the recommended phase 2 dose (RP2D) of OCI 900 mg intravenously (IV) every three weeks (Q3W) + TIS 200 mg IV Q3W was established. We report results from the dose-expansion part (GC/GEJC Cohort 9) of the AdvanTIG-105 study. **Methods:** Eligible pts had histologically/cytologically confirmed stage IV GC/GEJC. Pts were excluded if they had squamous cell, undifferentiated or other histological types of GC, had GC/GEJC with positive HER2 expression, or if they had received any prior therapy for metastatic disease. Pts received either the RP2D of OCI + TIS with oxaliplatin + capecitabine Q3W for 6 cycles (C), followed by maintenance therapy with the RP2D of OCI + TIS, + capecitabine Q3W, or the RP2D of OCI + TIS with cisplatin + 5-fluorouracil Q3W for 6 C. Treatment continued until disease progression, intolerable toxicity, or withdrawal of consent. The primary endpoint was investigator-assessed overall response rate (ORR) per RECIST v1.1. Secondary endpoints included progression-free survival (PFS), duration of response (DoR), disease control rate (DCR) per RECIST v1.1, and safety. **Results:** As of September 29, 2022, 60 pts with a median age of 61.5 years (range 35-82) were enrolled; 59 were efficacy evaluable. Median study follow-up was 31.1 weeks (range 1.4-78.4). ORR was 50.8% (95% CI: 37.5, 64.1); DCR was 84.7% (95% CI: 73.0, 92.8) with a median DoR of 4.6 months (95% CI: 3.9, 7.1). Median PFS was 8.2 months (95% CI: 5.8, not evaluable). In a subgroup analysis, ORR in pts with PD-L1 tumor area positivity (TAP) score $\geq$ 5% (n = 27) was 59.3% (95% CI: 38.8, 77.6), and 50.0% (95% CI: 30.7, 69.4) in pts with PD-L1 TAP < 5% (n = 28). All 60 pts reported $\geq$ 1 treatment-emergent adverse event (TEAE), the most common being anemia (43.3%) and platelet count decreased (41.7%). In total, 43 pts (71.7%) had $\geq$ grade 3 TEAEs and 28 (46.7%) had serious adverse events. TEAEs leading to discontinuation of TIS and OCI occurred in 5 (8.3%) pts. TEAEs led to death in 2 (3.3%) pts; one event (neutropenic sepsis) was related to chemo, while the other (pulmonary embolism) was not treatment related. **Conclusions:** OCI 900 mg + TIS 200 mg + chemo was generally well tolerated and showed encouraging antitumor activity in pts with stage IV GC/GEJC. Clinical trial information: NCT04047862. Research Sponsor: BeiGene, Ltd.; This study was sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Emma Ashman, BSc, of Ashfield MedComms, an Inizio company, and was funded by BeiGene, Ltd.

Poster Discussion Session

A phase 2 study (DisTinGuish) of DKN-01 in combination with tislelizumab + chemotherapy as first-line (1L) therapy in patients with advanced gastric or GEJ adenocarcinoma (GEA). *First Author: Samuel J Klempner, Mass General Cancer Center, Boston, MA*

Background: DKN-01 is an anti-DKK1 mAb which has demonstrated anti-tumor activity in patients with advanced GEA with low tumor PD-L1 expression, a subset with very limited therapeutic options. DKN-01 has immunomodulatory activity, stimulates a pro-inflammatory tumor microenvironment, and upregulates PD-L1 levels. Here we present 2-year survival data for 1L advanced GEA patients who received combination treatment with DKN-01, the Fc-optimized anti-PD-1 tislelizumab, and CAPOX chemotherapy. The ORR was previously reported (68% in ITT and 79% in PD-L1-low populations). **Methods:** This Phase 2, multi-center, single arm Part A of the DisTinGuish (NCT04363801) study investigated DKN-01 + tislelizumab + CAPOX as 1L therapy in advanced HER2(-) GEA, regardless of DKK1 and PD-L1 expression levels. Tumor DKK1 and PD-L1 were assessed by central laboratories. The primary endpoint was ORR in a modified intent to treat population (>1 dose DKN-01); secondary endpoints included PFS and OS in the ITT population. **Results:** Twenty-five patients were enrolled from September 2020 to April 2021. As of 23 January 2023: Median age was 61 years (22, 80); 17 patients had GEJ adenocarcinoma; 8 had gastric cancer. Twenty-one patients had tumors with evaluable DKK1 expression. Twenty-two patients had tumors with evaluable PD-L1 expression; the majority (73%) were low expressors (vCPS <5%). Median (m) duration on treatment is 11.3 months (mo). Seven patients remain on study, with 4 on-treatment beyond 2 years. The mPFS is 11.3 mo in the overall ITT population and 10.7 mo in patients with low tumor PD-L1 expression. The mOS is 19.5 mo in the overall ITT population and 18.7 mo in the patients with low tumor PD-L1 expression. Treatment related adverse events (TRAEs) were mild with most G1/2. The most common AEs related to the study drug regimen were nausea (72%), diarrhea (64%) and fatigue (60%). Five patients experienced G3 DKN-01-TRAEs including decreased neutrophil count (1), diarrhea (1), vomiting (1), hypophosphatemia (2), and pulmonary embolism (1). **Conclusions:** At 2-years of follow-up, 1L treatment of advanced GEA patients with DKN-01 in combination with tislelizumab and CAPOX resulted in a prolongation of PFS and OS compared with the modern SOC regimen of nivolumab plus chemotherapy, both in the overall population (mPFS 11.3 vs 7.7 mo; mOS 19.5 vs 13.8 mo) and in the PD-L1 low subgroup (mPFS 10.7 vs 7.5 mo; mOS 18.7 vs 12.4 mo), alongside a manageable safety profile. The prolonged PFS and OS observed in the current study are notable, especially in our trial population dominated by patients with tumors of low PD-L1 expression, where the known benefit of anti-PD-1 therapy is limited. The ongoing Part C of this study is evaluating mFOLFOX6/CAPOX plus tislelizumab with or without DKN-01 in the same 1L GEA patient population. Further evaluation of biomarkers is also ongoing. Clinical trial information: NCT04363801. Research Sponsor: Leap Therapeutics.

Poster Session

A phase 2 study of HLX07 as monotherapy or combination therapy in patients with locally advanced, unresectable, or metastatic esophageal squamous cell carcinoma. *First Author: Jing Huang, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Esophageal cancer is one of the most common cancers worldwide with esophageal squamous cell carcinoma (ESCC) being the predominant histological subtype. Most patients are diagnosed at the advanced stage, and the prognosis remains poor. About 40–84% of ESCC cases showed overexpression of EGFR which was related to shorter overall survival and disease-free survival, indicating that treatment targeting EGFR could be a new strategy. This study aimed to evaluate the efficacy and safety of HLX07, a novel recombinant humanized anti-EGFR monoclonal antibody (mAb), as monotherapy or combination therapy in patients with locally advanced, unresectable/metastatic ESCC. **Methods:** In this open-label, multicenter phase 2 study, patients aged 18–75 years with histologically or cytologically confirmed locally advanced, unresectable/metastatic ESCC or esophageal adenosquamous carcinoma were enrolled. Patients with no prior systemic antitumor therapy were assigned to group A and given HLX07 1000 mg plus serplulimab 200 mg (anti-PD-1 mAb) and chemotherapy (5-FU 2400 mg/m² + cisplatin 50 mg/m²), Q2W IV. Patients who had failed first-line immuno-chemotherapy combination or at least two lines of other systemic antitumor therapy were assigned to group B and given HLX07 monotherapy (1000 mg Q2W IV). The primary endpoints were objective response rate (ORR) and progression-free survival (PFS) assessed by an independent radiological review committee and investigators per RECIST v1.1. Secondary endpoints included other efficacy measures, safety, pharmacokinetics, immunogenicity, and biomarker explorations. **Results:** As of February 4, 2023, 49 patients were enrolled in group A (n=30) and group B (n=19), with a median age of 64.5 and 59.0 years, respectively. 26 (86.7%) patients in group A and all patients in group B were male. The median follow-up duration was 2.9 months, and the preliminary efficacy was presented. Among the 42 efficacy evaluable patients (29 in group A and 13 in group B), investigator-assessed ORRs were 55.2% (95% CI 35.7–73.6%) and 23.1% (95% CI 5.0–53.8%) in the respective groups. Investigator-assessed median PFSs were not reached in group A and 1.5 months (95% CI 1.2–not evaluable) in group B. 15 (50.0%) patients in group A and 5 (26.3%) in group B had grade $\geq$ 3 treatment-emergent adverse events (AEs). AEs of special interest were observed in 16 (53.3%) and 11 (57.9%) patients, respectively, most commonly rash (43.3% vs 47.4%) and hypomagnesemia (33.3% vs 36.8%). No drug-related death was reported. **Conclusions:** The encouraging antitumor activity and manageable safety profile support further development of HLX07 as a new treatment option for patients with advanced ESCC, both in first-line and late-line settings. Clinical trial information: NCT05221658. Research Sponsor: Shanghai Henlius Biotech, Inc.

Expression molecular subtype as a predictor of outcomes of chemoradiotherapy for esophageal cancer. *First Author: Manabu Muto, Department of Therapeutic Oncology, Graduate School of Medicine, Kyoto University, Kyoto, Japan*

Background: The standard treatment for advanced esophageal cancer is preoperative chemoradiotherapy (CRT) followed by surgery or definitive CRT (NCCN Guideline 2022 ver5). CRT has the advantage of preserving organs and functions and the prognosis for patients achieved complete response by CRT is good. However, it is currently impossible to predict the outcomes of CRT before treatment. We have performed RNA expression analysis of pre-treatment biopsy specimens of esophageal cancer and identified several intrinsic molecular subtypes, as well as E-type (high expression of squamous markers) with good prognosis for CRT and M2-type (high expression of stromal markers) with poor prognosis for CRT (US patent No 10,969,390 B2). Herein, we performed an integrated analysis to confirm the relationship between intrinsic expression molecular subtype classification and prognosis in the pooled population from two prospective cohort studies (UMIN000043637). **Methods:** Two cohort studies were as follows; 1) single institute prospective cohort study conducted at National Cancer Center Hospital East (n=157, UMIN-C000000459), 2) multicenter prospective cohort study conducted at 10 institutions (n=226, UMIN000016141). A total 383 cases met inclusion criteria and the Affymetrix U331Plus 2 panel (47,104 transcripts, 38,572 genes) was used to identify E-type and M2-type. The clinical course and outcome were blinded for subtype classification. Treatment was performed as usual at each institution, and treatment details and outcomes were examined by subtype. **Results:** Among 383 patients, 181 and 164 patients were treated by CRT and surgery, respectively. Ninety-nine percent (n=342) were squamous cell carcinoma. Stage I/II/III/IV were 13/61/86/21 and 17/63/81/3 in CRT group and surgery group, respectively. Among them, 76 (22%), 100 (29%), 169 (49%) patients were classified as E, M2 and others, respectively. Among the patients treated by CRT, CR rate of E-type and M2-type were 62.8% (95% CI, 47.8-75.7) and 33.3% (95% CI, 21.9-47.1) (p=0.006). The 5-year progression free survival (PFS) and overall survival (OS) rates of CRT group was 50.5% (95% CI, 34.7-64.4) and 59.8% (95% CI, 42.6-73.3) for E-type vs. 23.0% (95% CI, 12.0-36.2) and 29.0% (95% CI, 16.8-42.4) for M2-type, with statistically significant difference (p=0.011, p=0.003). Cox regression analysis showed that crude HR for PFS and OS of E vs M2 were 0.50 (95% CI, 0.296-0.859, p=0.012) and 0.41 (95% CI, 0.226-0.750, p=0.004), respectively. In contrast, E and M2-type did not show the survival difference in surgery group. **Conclusions:** For the first time in the world, we confirmed that expression molecular subtype of esophageal cancer has the potential to predict the outcomes of CRT. The results may provide precision medicine in the selection of treatment for esophageal cancer. Research Sponsor: AMED Foundation in Japan.

Poster Session

Ramucirumab, avelumab and paclitaxel (RAP) as second line treatment in esophagogastric adenocarcinoma: Final results of the phase 2 RAP trial (AIO-STO-0218). *First Author: Peter C. Thuss-Patience, Charité University Medicine Berlin, Department of Haematology, Oncology and Cancer Immunology, Campus Virchow-Klinikum, Berlin, Germany*

Background: The addition of immune checkpoint inhibitors to chemotherapy has improved outcomes in patients (pts) with metastatic esophagogastric adenocarcinoma (EGA), but treatment combinations and optimal pt selection need to be established. Objective: To investigate efficacy and tolerability of the programmed death-ligand 1 (PD-L1) inhibitor avelumab with ramucirumab and paclitaxel in the second line treatment of pts with metastatic EGA (NCT03966118). **Methods:** In this phase 2 multicenter single-arm clinical trial the reported results are based on a median follow-up of 27.4 months. Patients with previously treated metastatic EGA, adequate organ function, and eligibility for immunotherapy were included. Interventions: Pts with metastatic EGA after progression on platinum/ fluoropyrimidine based palliative first line treatment, checkpoint-inhibitor naïve, received ramucirumab 8 mg/kg (d1,15), avelumab 10 mg/kg (d1,15) and paclitaxel 80 mg/m² (d1,8,15) q4w. **Results:** The pre-specified primary end point was overall survival rate at 6 months (mo) (H0≤50%, H1≥65%). A total of 60 patients (pts) were enrolled, 59 were evaluable (intention to treat, ITT). Participants had a median age of 64.0 yrs (range 18-81) and 80% were men. Baseline Eastern Cooperative Oncology Group performance status was 0 in 23 pts (39.0%) and 1 in 36 pts (61.0%); 29 pts (48.2%) had EGA localized in the esophagogastric junction and 30 in the stomach (51.8%). all pts had received prior platin/ 5-FU based chemotherapy, 40pts (67.8%) had prior taxanes. Central post-hoc biomarker analysis (56 pts) showed PD-L1 ligand 1 (PD-L1) combined positive score of 5 or greater in 24 pts (42.9%). The observed overall survival (OS) rate at 6 mo was 71% (95% CI 61-84%) and at 12 mo 43% (95% CI 32-58%). The median OS (ITT) was 10.6 mo (95% CI 8.4-12.8); 9.4 mo (95% CI 7.2-11.7) in pts with PD-L1 CPS < 5 and 14.0 mo (95% CI 6.0-22.1; p = 0.25) in those with PD-L1 CPS ≥ 5. Treatment was generally well tolerated without unexpected toxicities. Translational research identified subgroups with a longer survival possibly due to a higher treatment benefit. Pts with higher than median T cell repertoire (TRB) richness showed an elevated median OS of 20.4 mo compared to pts with lower than median TRB richness (med OS 8.3 mo; HR 0.43, 95% CI 0.23-0.81; p = 0.0079). Pts with lower than median cfDNA burden had a median OS of 19.2 mo compared to pts with higher than median cfDNA (med OS 7.3 mo; HR 0.30, 95% CI 0.16-0.59; p = 0.00022). **Conclusions:** In this multicenter clinical trial, ramucirumab and paclitaxel combined with avelumab showed favorable efficacy and tolerability in the second line treatment of pts with metastatic EGA. PD-L1 CPS ≥ 5, cfDNA below the median or T cell richness above the median seem to predict for even better outcomes with median OS hardly seen before in the second line setting. Clinical trial information: NCT03966118. A phase Ib/II, multicenter, open-label study of AK104, a PD-1/CTLA-4 bispecific antibody, combined with chemotherapy (chemo) as first-line therapy for advanced gastric (G) or gastroesophageal junction (GEJ) cancer: 2-Year update data. *First Author: Jiafu Ji, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Anti-PD-1 monoclonal antibodies plus chemo as first-line therapy for advanced G/GEJ cancer yields OS and PFS benefits compared to chemo alone while the survival benefits are limited, especially in patients with low PD-L1 expression (CPS<5). Simultaneous blockade of the PD-1 and CTLA-4 pathways has shown synergistic anti-tumor activity and has been proven effective across multiple cancer types. This phase Ib/II dose-escalation study evaluated the safety and efficacy of AK104, a PD-1/CTLA-4 bispecific antibody, combined with XELOX or modified XELOX (mXELOX) in the first-line treatment of G/GEJ cancer cohorts (NCT03852251). **Methods:** Pts with unresectable advanced G/GEJ adenocarcinoma and no prior systemic therapy, regardless of PD-L1 status, were enrolled, excluding known HER2-positive pts. Enrolled patients received AK104 (4 mg/kg, 6 mg/kg or 10 mg/kg Q2W, 10 mg/kg or 15mg/kg Q3W) + chemo (mXELOX Q2W or XELOX Q3W). The primary endpoint was safety and the objective response rate (ORR) based on Response Evaluation Criteria in Solid Tumors version 1.1 (RECIST v1.1). **Results:** As of 31 Oct. 2022, 98 pts were enrolled with only 4 pts in 10 mg/kg Q3W, the safety and efficacy of the regimen of 10mg/kg Q3W will be reported in the phase III study and not be reported here. 94 pts were enrolled with median age of 62.7 years (range: 29-75), 70.2% male, 62.8% ECOG PS 1, and 45.7% liver metastasis. The median follow-up was 24.0 months (range: 0.5-33.3). 88 patients (94%) had at least one post-baseline tumor evaluation. The ORR was 68.2% (60/88), with 5 (5.7%) complete responses and 55 (62.5%) partial responses. The disease control rate (DCR) was 92.0% (81/88). The median duration of response (DoR) was 9.69 months (95%CI, 5.82 to 14.00). The median PFS was 9.20 months (95%CI, 6.67 to 10.48). The median OS was 17.41 months (95%CI, 12.35 to 29.77). In pts with PD-L1 CPS ≥ 5 and CPS < 5, the median OS was 20.24 months and 17.28 months, respectively. Treatment-related adverse events (TRAEs) occurred in 97.9% of pts. The most frequent were platelet count decreased (62.8%), white blood cell count decreased (61.7%), neutrophil count decreased (59.6%), anemia (51.1%), aspartate aminotransferase increased (33.0%), nausea (30.9%), and vomiting (30.9%). Grade ≥ 3 TRAEs occurred in 69.4% of pts. No new safety signals were identified. **Conclusions:** AK104, combined with mXELOX/XELOX, showed promising activity and manageable safety in previously untreated patients with advanced G/GEJ adenocarcinoma. AK104 + chemo represents a potential new first-line treatment option for these pts. A phase III study of AK104 combined with chemo as first-line therapy for G/GEJ cancer is underway (NCT05008783). Clinical trial information: NCT03852251. Research Sponsor: Akeso Biopharma, Inc.

EPCAM CAR T (IMC001) for the treatment of advanced GI cancers. *First Author: Tianhang Luo, Shanghai Changhai Hospital, Shanghai, Shanghai, China*

Background: EpCAM is highly expressed in various cancer types of the GI system and at metastatic sites. It serves as a promising prognostic/predictive marker (CTC) and therapeutic target. IMC001 is an EpCAM-targeted CAR-T cell that showed promising anti-tumor activities in preclinical studies. Here, we report the results of the low and middle dosage groups in advanced gastric cancers (CT03) and GI cancers (CT04). **Methods:** This first-in-human, open-label trial involved two separate single-site trials. Both followed a classic 3+3 design with dose escalation of 0.3, 1 or 3 million CAR-T cells/kg after lymphodepletion chemotherapy. CT03 was an IMC001 monotherapy trial (Stage 1) for gastric cancer, while CT04 had Stage 1 and the combination with RFA or microwave ablation (Stage 2) for GI cancers. Eligible patients were those with EpCAM-positive (more than 10%) cancers who had no further standard treatment options and were ECOG 0 or 1. The objective was to assess the safety, PK/PD profile and preliminary efficacy of IMC001. **Results:** As of January 30, 2023, 12 patients with 6 colorectal and 6 gastric cancers had enrolled, with half receiving 0.3 million and the other half receiving 1 million cells/kg IMC001 infusion. No patient experienced DLT within the 4-week follow-up visits after infusion. All patients experienced ≥ Grade 3 hematologic toxicity. One patient in the low-dose group had a SAE of immune hepatitis (Grade 3), which might have been related to cell therapy, and occurred around 11 days after the CAR-T infusion, prolonging the patient's hospitalization. Manageable CRS (Grade 1 to 3) and no ICANS were observed. Other adverse events related to cell therapy were CTCAE Stage 1-2 nausea, vomiting, asthenia, or pruritus, and these recovered quickly. Analyses of the CAR-T cells in peripheral blood revealed robust engraftment in all patients, with the peak number of CAR+ cells reaching on day 5-7 after infusion. CTC remained under the detection limit for more than 40 weeks after cell infusion. Significant elevations of serum levels of IL-6, IP-10, IFN-γ, IL-15, and MCP-1 were observed in most patients. Preliminary efficacy data showed that 2 out of 6 advanced gastric cancer patients were evaluated as PR and 3 remained SD by RECIST 1.1 at the low and middle dosages (CT03). The first PR patient received a second IMC001 infusion on week 50 and had survived for more than 60 weeks. The second PR patient underwent successful surgical removal of the stomach 28 weeks after IMC001 infusion. The CT04 trial is ongoing. **Conclusions:** This is the first CAR-T therapy ever tested in humans targeting the EpCAM. IMC001 showed a favorable safety profile and reasonable anti-tumor activities at the low and middle dosage levels in patients with advanced EpCAM+ GI cancers, especially in gastric cancer. In addition, our trial has successfully provided a surgical treatment opportunity after CAR-T therapy downstaging of unresectable gastric cancers. Updated data from open cohorts will be presented. Clinical trial information: NCT05028933. Research Sponsor: Suzhou Immunofoco Biotechnology Co., Ltd.

Global prevalence of CLDN18.2 in patients with locally advanced (LA) unresectable or metastatic gastric or gastroesophageal junction (mG/GEJ) adenocarcinoma: Biomarker analysis of two zolbetuximab phase 3 studies (SPOTLIGHT and GLOW). *First Author: Kohei Shitara, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: There is an unmet need for additional therapies to treat patients (pts) with locally advanced (LA) unresectable or metastatic gastric or gastroesophageal junction (mG/GEJ) adenocarcinoma. Claudin-18.2 (CLDN18.2), a new validated target in these pts, is expressed in normal gastric mucosa cells and often retained in G/GEJ tumor cells. There are limited data on the global prevalence of CLDN18.2 in tumors of pts with LA unresectable or mG/GEJ adenocarcinoma. The SPOTLIGHT (NCT03504397) and GLOW (NCT03653507) phase 3 studies demonstrated clinically meaningful and statistically significant improvement in PFS and OS with the CLDN18.2-targeted antibody zolbetuximab + chemotherapy (mFOLFOX6 or CAPOX, respectively) vs placebo + chemotherapy as 1L therapy in pts with CLDN18.2+/HER2- disease. We report the biomarker analysis of these studies. **Methods:** Pts with LA unresectable or mG/GEJ adenocarcinoma were screened for CLDN18.2 status by IHC before enrollment. Tumors were defined as CLDN18.2+ if they had ≥75% of tumor cells with moderate-to-strong membranous CLDN18 staining per the investigational VENTANA CLDN18 (43-14A) RxDx Assay. HER2 status was evaluated per central or local assessment. Ad hoc PD-L1 IHC was performed via the Dako PD-L1 IHC 28-8 pharmDx assay for a subgroup of enrolled pts. Results exclude pts from mainland China and pts missing data for disease type, Lauren classification, or tumor collection site. **Results:** Across SPOTLIGHT and GLOW, 3576 pts had valid CLDN18 IHC results; 1399 (39.1%) had CLDN18.2+ tumors. CLDN18.2 prevalence was 43.7% (513/1175) in female pts and 36.9% (886/2401) in male pts. CLDN18.2 prevalence was 44.0% (671/1524) in pts in Europe/Middle East, 37.7% (183/485) in pts in N. America, and 36.5% (479/1314) in pts in Asia Pacific. CLDN18.2 prevalence was 41.0% (1056/2576) in pts with gastric adenocarcinoma and 37.3% (302/809) in pts with GEJ adenocarcinoma. CLDN18.2 prevalence trended higher in pts with diffuse (48.9%, 479/980) vs intestinal (38.9%, 265/682) disease. CLDN18.2 prevalence was 41.1% (175/426) in tumors collected from metastatic sites and 38.6% (1195/3094) in tumors collected from primary sites. CLDN18.2 prevalence was similar across other clinical and histopathological characteristics. Of 2908 HER2- pts with valid CLDN18 IHC results, 1264 (43.5%) had CLDN18.2+ tumors. Of 599 enrolled pts tested for PD-L1 expression, 104 (17.4%) had a PD-L1 CPS ≥5. **Conclusions:** The SPOTLIGHT and GLOW phase 3 studies are the largest data sources to date for determining global CLDN18.2 prevalence. CLDN18.2 is a high prevalence biomarker, with high tumor expression in ~35–40% of pts with LA unresectable or mG/GEJ adenocarcinoma, for whom zolbetuximab + chemotherapy represents a potential 1L therapy. Clinical trial information: NCT03504397, NCT03653507. Research Sponsor: Astellas Pharma Global Development, Inc.

Effect of autologous lymphocytes combined with chemotherapy as the first-line treatment of advanced gastric cancer. *First Author: Xiaoting Ma, Na-National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking/Union Medical College, Beijing, China*

Background: To evaluate the safety and initial efficacy of adoptive cell therapy (ACT) combined with SOX in first-line treatment of locally advanced unresectable or metastatic gastric adenocarcinoma/gastroesophageal adenocarcinoma. **Methods:** In this single-arm, single-center exploratory trial, patients with histologically confirmed locally advanced unresectable or metastatic gastric adenocarcinoma/gastroesophageal adenocarcinoma were randomly assigned (1:1) to receive ACT in combination with S-1 and oxaliplatin (SOX) or SOX alone. The primary endpoint was the incidence of adverse events (AEs). Secondary endpoints were progression-free survival (PFS), overall survival (OS), objective response rate (ORR), and disease control rate (DCR). **Results:** Fifty-nine patients were enrolled in the study between November 20, 2014 and September 6, 2017. 31 patients received ACT combined with SOX (ACT-SOX) and 28 patients received SOX. The most common AEs in both groups were gastrointestinal reaction, leucopenia, neutropenia, anemia, thrombocytopenia, hyperbilirubinemia and elevated aspartate transaminase concentration, with a higher incidence in the SOX group. The median PFS for ACT-SOX and SOX were 6.9 and 4.9 months respectively (HR 0.80, p=0.45), and the median OS were 17.8 and 9.75 months (HR 0.76, p=0.34). Patients who received more than three injections of specific lymphocyte subsets benefited the most from combination therapy. Cox univariate and multivariate analysis showed that tumor metastasis to more than two organs was the main risk factor for PFS and OS. 29 patients in the ACT-SOX group and 25 in the SOX group had measurable lesions. The ORR of ACT-SOX group and SOX group was 55.2% and 32.0%, and DCR of two groups was 93.1% and 88.0%. **Conclusions:** The safety of ACT-SOX in first-line treatment of patients with locally advanced unresectable or metastatic gastric adenocarcinoma/gastroesophageal adenocarcinoma is good. Compared with SOX alone, although the PFS and OS of ACT-SOX did not reach statistical difference, it could further extend the time of PFS and OS, and the absolute improvement time of OS was about 8.05 months. Continuous benefit of ACT-SOX was observed through long-term follow-up. Clinical trial information: NCT02504229. Research Sponsor: None.

Cell free DNA (cfDNA) assessment of esophagogastric (EG) cancer using MSK-ACCESS. *First Author: Samuel Louis Cytryn, Memorial Sloan Kettering Cancer Center - Fellowship (GME Office), New York, NY*

Background: The incidence of EG cancer is rising, the treatment paradigm is increasingly complex, and the role of predictive biomarkers is critical in selecting optimal therapies. Therefore, longitudinal, non-invasive methods to characterize dynamic tumor molecular profiles, such as cfDNA, are needed. **Methods:** Patients with EG cancer receiving care at Memorial Sloan Kettering (MSK) had cfDNA analysis with an ultrasensitive capture based liquid biopsy for detection of somatic alterations in 129 cancer associated genes (MSK ACCESS). Tumor samples were analyzed with MSK-IMPACT, a capture based next generation sequencing (NGS) platform. **Results:** 100 patients with EG adenocarcinoma underwent cfDNA analysis to evaluate for molecular residual disease with MSK ACCESS. 85 (85%) had tissue NGS with MSK IMPACT. Median TMB was 5.3 mut/Mb (IQR 2.6-7.4) and median number of alterations per sample was 11 (IQR 7-17). 71% had TP53 mutations and 22% had an ERBB2 amplification (amp). 79 (79%) patients had cfDNA obtained prior to treatment (50 [63%] metastatic disease; 29 [37%] localized disease) and 21 (21%) at the time of progression. Alterations were detectable on cfDNA more frequently in patients with later stage disease (p=0.031) and fewer alterations per sample were detected compared to tissue NGS (mean difference 14, 95% CI 10-18, p<0.001). The most common were TP53 (62%), CDKN2A (12%), PIK3CA (10%), ARID1A (10%), and ATM (10%). TP53 was detected with increasing frequency in patients with later stage disease (p=0.004). However, amplifications, which included ERBB2, MYC, EGFR, and FGFR2, were detected exclusively in those with stage IV disease (p=0.005) and cfDNA was less sensitive in detecting amplifications compared to tissue NGS (p<0.001). This is notable as HER2 positivity is determined in part by ERBB2amp. 25 of 30 HER2+ patients had both tissue NGS and cfDNA. 19 (76%) had ERBB2amp on tissue NGS and only 8 (32%) had ERBB2amp on cfDNA (p=0.004). Additionally, copy number was lower on cfDNA compared to tissue NGS (mean difference 13, 95% CI 1.3-24.9, p=0.02) and IHC 3+ tumors were more likely to have ERBB2amp detected than IHC 2+ tumors (p=0.049). However, alterations along the MAPK, PI3K, WNT, and TGF-β pathways, which are associated with trastuzumab resistance and poor survival, were detected with similar frequency on both platforms (40 v 32%, p=0.77). **Conclusions:** Our findings in this large prospective analysis highlight the utility of cfDNA with MSK ACCESS as a complimentary tool for molecular characterization in patients with EG cancer. cfDNA in EG cancer. Research Sponsor: Memorial Sloan Kettering Cancer Center.

Health-related quality of life (HRQOL) in patients (pts) with advanced gastric cancer/gastroesophageal junction cancer (GC/GEJC) or esophageal adenocarcinoma (EAC): 36-month results of nivolumab plus chemotherapy (N+C) versus (C) from CheckMate 649. *First Author: Elena Elimova, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: CheckMate 649 (NCT02872116) is a randomized, open-label, phase 3 study in first-line treatment of pts with advanced GC/GEJC/EAC. Primary results showed statistically significant improvement in overall survival (OS) for N+C versus C in all randomized pts. Prior analyses conducted for 24-month follow-up (FUP) showed pts receiving N+C maintained HRQOL and experienced delayed deterioration in HRQOL compared with pts receiving C. Here we report additional analyses of HRQOL with 36-month FUP data. **Methods:** Functional Assessment of Cancer Therapy–Gastric Cancer (FACT-Ga) and EQ-5D-3L results were collected at baseline (BL) and every 6 weeks while on treatment. Change from BL in FACT-Ga, EQ-5D Visual Analog Scale (VAS), and Utility Index (UI) scores were analyzed using mixed models. Time to first symptom deterioration (TTSD), time until definitive deterioration (TuDD), and time to improvement (TTI) were estimated with Kaplan-Meier estimators and stratified Cox models; deterioration/improvement events were based on prespecified meaningful thresholds for change scores. **Results:** A total of 1,581 pts were randomized to N+C (n = 789) and C (n = 792); of those, 1,360 pts had BL and post-BL PROs and were included in the PRO population (N+C [n = 694] and C [n = 666]). With additional follow-up, least-squares mean differences from BL remained comparable between groups across visits for HRQOL measurements with exceptions. FACT-Ga total score, GaCS, physical well-being (WB), and emotional WB tended to favor N+C; social WB tended to favor C. For all randomized pts, most time-to-event endpoints favored N+C; like the 24-month analysis, statistically significant delays in deterioration were maintained for TuDD (except FACT-G Social WB) and TTSD (only FACT-GaCS and FACT-Ga total). **Conclusions:** These results confirm the earlier 24-month FUP findings. Compared with C alone, N+C maintained HRQOL with decreased risk of deterioration in pts with previously untreated advanced or metastatic GC/GEJC/EAC. Together with improved OS, data continue to support N+C as a first-line standard treatment for GC/GEJC/EAC. Clinical trial information: NCT02872116. Research Sponsor: Bristol Myers Squibb.

Survival analysis by tumor response of nivolumab treatment in previously treated advanced gastric cancer from the DELIVER trial (JACCRO GC-08). First Author: Yu Sunakawa, Department of Clinical Oncology, St. Marianna University School of Medicine, Kawasaki, Japan

Background: We conducted a prospective observational study, DELIVER trial (UMIN000030850), to evaluate the real-world effectiveness of nivolumab monotherapy in previously treated advanced gastric cancer (GC) and have reported comparable efficacy and safety data (Takahashi, et al. *Gastric Cancer* 2021). There are few evidence regarding the association between tumor response and survival time in later-line treatment with nivolumab alone for advanced GC. We therefore report results from post-hoc exploratory analyses of survival time by tumor response from the DELIVER trial. **Methods:** The DELIVER trial enrolled 501 patients (pts) with advanced gastric or GEJ adenocarcinoma treated with nivolumab alone. Primary endpoint was overall survival (OS), secondary endpoints were response rate (RR), disease control rate, progression-free survival (PFS), tumor regression rate / tumor progression rate at 1st evaluation, tumor growth rate, and safety. The exploratory analyses were performed for survival according to tumor response and depth of response (DpR) in pts with measurable lesions who were receiving nivolumab as 3rd or later-line treatment. The survival data was fixed at the timepoint of 2 years after the last enrollment. **Results:** 234 pts were evaluable (median age 70y [26-90], 79% male, ECOG PS0/1/2 46/43/11%, 32% pts with ascites). Median OS was 6.5 months (95%CI 5.3-8.2) and median PFS was 1.8 months (95%CI 1.6-2.0). The RR was 15.0% (95%CI 10.4-19.5) with 5 complete response (CR) and 30 partial response (PR). The median PFS and OS were not reached for pts with CR, 11.7 and 29.8 months for pts with PR, 3.8 and 11.4 months for pts with stable disease, and 1.5 and 4.2 months for pts with progressive disease, respectively. In addition, the median DpR was -14.1% and was associated with PFS and OS in the Spearman analysis ($r=0.55$ and $r=0.44$, respectively). When the DpR was divided into 5 groups according to tumor shrinkage, there was difference in PFS and OS. **Conclusions:** This exploratory analysis indicated the association between DpR and survival time in pts with advanced GC treated with nivolumab alone in later-line. Increasing DpR was associated with longer median PFS and OS. Clinical trial information: UMIN000030850. Research Sponsor: Ono Pharmaceutical and Bristol-Myers Squibb.

	Median PFS(months)	HR, p-value	median OS (months)	HR, p-value

Updated results of anlotinib combined with TQB2450 (PD-L1 blockade) as first-line treatment for advanced esophageal squamous cell carcinoma (ESCC): A single-arm, multicenter, open-label phase II clinical trial. First Author: Zhiye Zhang, The First Affiliated Hospital of Henan University of Science and Technology, Luoyang, China

Background: PD-1 blockades combined with chemotherapy in first-line setting exhibited encouraging efficacy for patients with ESCC recently. However, the safety profile of conventional chemotherapy was still disappointing. Therefore, the chemotherapy-free regimen might be a promising strategy. As a novel multitarget TKI mainly targeting VEGFR1-3, anlotinib was a potential first-line combination therapy and second-line monotherapy for patients with ESCC in China. TQB2450 was a novel PD-L1 blockade developed by Chia Tai Tianqing Pharmaceutical Group Co., Ltd. (Nanjing, China). Therefore, this study was designed to explore the efficacy and safety of anlotinib combined with TQB2450 as first-line therapy in advanced ESCC. The preliminary results were reported in 2023 ASCO-GI Symposium (Abs 377) and the update results were reported here. **Methods:** Patients with previously untreated metastatic or locally advanced ESCC, whose age was between 18 and 75 years, with ECOG PS of 0 or 1 and life expectancy of > 3 months were eligible as the inclusion criteria. Eligible patients were administered with anlotinib (12mg, po, d1-14, q3w) plus TQB2450 (1200mg, iv, d1, q3w) until disease progression or unacceptable toxicity. The tumor response was assessed according to RECIST 1.1 and IRECIST using CT scans every 2 cycles for the first 6 cycles, and every 3 cycles thereafter. Adverse events were recorded by severity in accordance with the NCI CTC AE Version 5.0. The predefined sample size was 46. The primary endpoint was ORR. Secondary endpoints included safety, PFS, DCR, DoR and OS. **Results:** From Mar 2022 to Sep 2022, a total of 46 patients were enrolled. At the data cut-off date (Dec, 2022), there were 1 CR (2.2%), 27 PR (58.7%), 14 SD (30.4%) and 4 NE (8.7%). Therefore, the preliminary ORR was 60.9% (95%CI: 45.4%~74.9%), DCR was 91.3% (95%CI: 79.2%~97.6%). The median PFS of the 46 pts was not yet available. Additionally, safety profile exhibited that the regimen was tolerable. The most common treatment-related adverse events in 46 patients with the incidence > 10% were hypertension (28%), hypothyroidism (20%), leukocytosis (20%), hyperthyroidism (17%), anemia (15%), fatigue (15%), neutrophil count decreased (11%), constipation (11%), sinus bradycardia (11%) and hand-foot syndrome (11%). The common grade ≥3 treatment-related adverse events were hypertension (4%), hand-foot syndrome (2%), hyponatremia (2%), platelet count decreased (2%) and lymphocyte count decreased (2%). **Conclusions:** Preliminary results suggested that anlotinib combined with TQB2450 as first-line therapy in advanced ESCC exhibited encouraging efficacy and manageable adverse events. And the conclusions needed to be confirmed in trials continued subsequently. Clinical trial information: NCT05038813. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

Ultra-sensitive, tumor-informed ctDNA profiling in patients with gastroesophageal cancer and treated with pembrolizumab and longitudinal ctDNA kinetics. First Author: Andrew B. Nixon, Duke University Medical Center, Durham, NC

Background: Metastatic esophagogastric cancer (mEGC) is a lethal disease with poor long-term survival. Recent studies have established anti-PD-1 therapy in combination with chemotherapy as the standard of care for first-line therapy for mEGC. KeyLargo (NCT03342937) was a single arm phase II study of pembrolizumab in combination with oxaliplatin and capecitabine in the first line treatment of patients (pts) with HER2 negative mEGC. While high response rates were noted, not all pts received benefit, emphasizing the need for better biomarkers. Paired tumor biopsies and plasma were collected for optimal biomarker testing. In this retrospective study, we employed a novel, tumor-informed ctDNA approach as a tool for longitudinal disease monitoring and dynamic tumor evolution. **Methods:** Thirty-six pts were enrolled between January 2018 and January 2020. Of 34 evaluable pts, 25 pts achieved a response (ORR = 74%), including 6 pts with a complete response (CR) and 19 pts with a partial response (PR). Our initial analysis includes baseline tumor samples collected from 16 pts with over 59 corresponding on-treatment (OT; up to cycle 35) plasma samples. NeXT Personal, a tumor-informed ctDNA assay, generated personalized liquid biopsy panels derived from somatic variants (SV) from tumor whole genome sequencing. Each personalized assay includes up to 1,800 SVs for sensitive minimal residual disease (MRD) detection and a constant set of 2,100 clinically actionable variants (CAV). **Results:** Of the 36 pts who enrolled on KeyLargo, 32 pts had baseline tumor and longitudinal plasma samples collected and stored for testing. In this initial cohort of 16 pts, MRD events dynamically varied from 5.3 to 302,000 parts per million (PPM). 16/16 (100%) pts were MRD-positive at baseline, with a limit of detection between 1.5 and 4.6 PPM. OT samples were collected every 3 cycles (9 weeks). The ratio of PPM (rPPM) between baseline and the first available OT sample (typically Cycle 4 to 7) correlated with progression free survival (PFS; $p=0.0004$, logrank). rPPM was significantly reduced in pts having a best overall response of PR/CR (98% mean rPPM) versus progressive disease (25% mean rPPM, $p<0.037$, U-test). Two pts demonstrated CR, each with 11/11 (100%) MRD-negative plasma samples over approximately two years. CAVs were identified in longitudinal samples with TP53 repeatedly detected in 5 patients and a PIK3CA mutation emerging in the final 3 (of 9) timepoints from one patient. **Conclusions:** ctDNA was present in all pts at baseline; OT PPM reductions correlated with PFS and best overall response. CAV profiling suggested a de novo PIK3CA variant arising during therapy in one patient. These findings suggest that tumor-informed plasma-based ctDNA profiling in mEGC may detect known CAVs arising during therapy, and with subsequent investigations, may inform therapeutic decisions. Phase II study of lenvatinib plus pembrolizumab for patients with immunotherapy-naïve advanced gastric cancer following first line therapy. First Author: Deirdre Jill Cohen, Division of Hematology and Medical Oncology, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Immune checkpoint inhibitor (ICI) therapy has demonstrated efficacy in some patients (pts) with advanced gastric cancer (AGC) and is now approved in 1st line combination with chemotherapy. Preclinical studies suggest interplay between angiogenesis and the immune system, with VEGF exerting effects on the anti-tumor immune response including antigen presentation, effector mechanisms and immune cell trafficking. We hypothesized that the combination of VEGF inhibition and ICI may be more beneficial than either agent alone. We designed an open-label prospective phase II trial to evaluate the efficacy of lenvatinib (Len) plus pembrolizumab (Pem) beyond first line therapy in ICI-naïve AGC. **Methods:** Eligible pts included advanced gastric or gastroesophageal junction adenocarcinoma regardless of PD-L1 status, with measurable disease per RECIST 1.1, ECOG ≤1, and progressive disease on ≥1 prior regimen, no prior ICI. Pts received an initial lead-in week of Len 20mg PO daily which was then continued in combination with Pem 200mg IV every 3 weeks from day 8. Therapy was continued until progression or intolerance. Imaging was performed every 6 wks for the first 12 wks and then every 9 wks. Primary end point was objective response rate (ORR). Using the Simon optimal 2 stage design, planned sample size was 29 patients (pts) with 80% power and one-sided alpha of 5%. The study would be considered positive if ≥6 pts achieved an objective response. Secondary endpoints included safety and tolerability, PFS and OS. **Results:** During the course of this study, ICI was approved in the 1st line setting and as a result of changing practice patterns, enrollment was prematurely suspended in 7/2022 with 24 of 29 planned pts. All enrolled pts were included for the safety analysis. All subjects were mismatch repair proficient, 15 pts (62.5%) were CPS positive (≥1), data was missing for 1 pt. 19 pts who completed at least 2 cycles were evaluable for response; 15 were treated in 2nd line and 4 in 3rd line. Five pts (21%) had a partial response, including 1 with CPS=0 and 1 with CPS=1. Median PFS and OS was 12.9 and 21.4 weeks for the entire cohort. The combination was generally tolerable without new safety signals. Dose reductions were required in 3 (13%) pts, overall compliance with Len was 79% of planned doses across the study. Eleven (46%) pts experienced at least one G3 toxicity and one (4%) pt experienced G4 toxicity. Most common G3 toxicities included fatigue (27%), anorexia (18%), lymphopenia (18%), and hyperbilirubinemia (18%). **Conclusions:** Lenvatinib combined with pembrolizumab was well tolerated, responses were seen, but the study did not meet the primary endpoint in ICI naïve AGC. Given the changing landscape of care, ICI is now more broadly used in first line therapy, additional studies are warranted to determine the role of this combination in ICI exposed pts. Clinical trial information: NCT03321630. Research Sponsor: Eisai; Merck; U.S. National Institutes of Health.

Efficacy of ramucirumab combination chemotherapy as second-line treatment in patients with advanced adenocarcinoma of the stomach or gastro-esophageal junction after exposure to checkpoint inhibitors and chemotherapy as first-line therapy within the prospective phase II IKF-S628/AIO-STO-0417 (MOONLIGHT) trial. *First Author: Michael Masetti, Klinikum rechts der Isar, Technische Universität München, Klinik für Innere Medizin III, München, Germany*

Background: FOLFOX plus nivolumab has become standard of care for first-line therapy of patients (pts) with advanced gastroesophageal cancer (aGEC). The efficacy of 2nd line VEGF-2 inhibition with ramucirumab (Ram) plus chemotherapy after progression to immunochemotherapy remains unclear. **Methods:** Medical records of consecutive pts with aGEC enrolled in the multi-centre randomized phase II AIO-STO-0417 trial who had tumor progression after 1st line FOLFOX plus nivolumab and ipilimumab were retrospectively analysed. Pts were divided into two groups based on the subsequent 2nd line therapy: Ram plus chemotherapy (ramucirumab group) or chemotherapy alone (control group). Outcomes were compared between both groups in the overall population and in subgroup analysis according to best response (CR/PR) under 1st line therapy and tumor PD-L1 expression. **Results:** In total, 83 pts (38 Ram group, 45 control group) were included. The most frequent 2nd line therapy in the Ram group was Ram plus paclitaxel (85%). In the overall population, median progression-free survival (PFS) in the Ram group was longer than in the control group (4.5 vs. 2.9 months). Responders (CR/PR) to 1st line immunochemotherapy who received Ram containing 2nd line therapy (n = 15) showed a clearly prolonged median OS counted from start of 1st line therapy (28.9 vs. 16.5 months), as well as 2nd line OS (9.6 vs. 7.5 months), PFS (5.6 vs. 2.9 months) and DCR (53% vs. 29%) compared to the control group (n = 24). PD-L1 CPS $\geq$ 1 (status known for 77% of pts) was 42% and 44% for the Ram and the control group, respectively. Patients with CPS $\geq$ 1 in the Ram group (n = 16) showed a trend towards better tumor control (ORR 25% vs. 10%, DCR 44% vs. 30%) and improved survival (total OS 11.5 vs. 8.0 months; 2nd line OS 6.5 vs. 3.9 months; PFS 4.5 vs. 1.6 months) compared to the control group (n = 20). **Conclusions:** Ramucirumab is effective as 2nd line treatment after progression on 1st line FOLFOX plus dual checkpoint inhibition, especially in patients with initial response and positive PD-L1 expression. Sequential angiogenesis inhibition with anti-VEGFR-2 targeting therapy following immunochemotherapy might be a promising option to overcome resistance to immunotherapy, which warrants further investigations in a larger cohort. Clinical trial information: NCT03647969. Research Sponsor: Bristol-Myers Squibb; Lilly.

FLOT plus nivolumab in patients with previously untreated advanced or metastatic adenocarcinoma of the stomach or gastroesophageal junction: Results from the randomized phase 2 IKF-S628/AIO-STO-0417 (Moonlight) trial of the AIO. *First Author: Sylvie Lorenzen, Klinikum rechts der Isar, Technische Universität München, Klinik für Innere Medizin III, München, Germany*

Background: FOLFOX plus nivolumab (nivo) has become standard of care for first-line therapy of patients (pts) with esophagogastric adenocarcinomas. FLOT is a well-established standard of care triplet regime. Some physicians may consider a triplet in patients with aggressive disease. The aim of this Arm C part of the Moonlight trial was to evaluate the safety and efficacy of the combination of FLOT plus nivo. **Methods:** Moonlight is a multi-cohort phase-II trial. The results for Arm C evaluating FLOT + nivo (240 mg) q2w as first-line therapy in all-comers are presented here. Primary endpoint was progression-free survival at 6 months (PFS@6), main secondary endpoints were safety, OS, and overall response rate (ORR). **Results:** Fifty-two patients were enrolled. Baseline characteristics were: median age 61y, GEJ 65%. Sixty-five percent had centrally assessed PD-L1 CPS $\geq$ 1 (available in 96% of pts). Pts. received a median number of 8 cycles of FLOT and nivo and 42% received further line treatment. FLOT plus nivo was well tolerated and feasible with the most frequent adverse events of $\geq$ grade 3 being decreased neutrophils (40.4%), anemia (5.8%) and thromboembolic events (7.7%). After a median follow-up of 9.4 months, 3- and 6-month progression-free survival rates were 85% and 42%, respectively. Median PFS was 6.6 months and median OS 10.8 months. ORR and disease control rate (DCR) were 54% and 87%, respectively. Compared to the pooled study cohorts A and A1 (n = 90 pts) utilizing mFOLFOX plus nivo and ipilimumab (non-randomized comparison), FLOT plus nivo was associated with greater DCR (87% vs. 78%) and 3-months PFS (85% vs. 72%). **Conclusions:** FLOT and nivo is feasible and seems to be associated with improved disease control in the early course of therapy. FLOT plus nivo may represent an option for select patients with aggressive, rapidly progressive disease. Clinical trial information: NCT03647969. Research Sponsor: Bristol-Myers Squibb.

A phase 2 single-arm study of berzosertib in combination with irinotecan in patients with progressive TP53 mutant gastric and gastro-esophageal junction cancer. *First Author: Shannon Stockton, Vanderbilt University Medical Center, Nashville, TN*

Background: TP53 mutations are reported in 30-70% of patients with metastatic/unresectable gastric (G) and gastro-esophageal junction (GEJ) adenocarcinoma and are associated with a poor prognosis. Novel therapeutics are needed. Gastrointestinal cancer cell lines with TP53 mutations demonstrate reliance on the ataxia telangiectasia and Rad3-related protein kinase (ATR) axis for DNA damage repair (DDR) in vitro. The ATR axis is triggered by single-strand DNA breaks and thus combining ATR inhibitors with topoisomerase I (TopI) inhibitors may have a synergistic effect, particularly in patients with TP53 mutant tumors. Irinotecan, a TopI inhibitor, is an established cytotoxic therapy for gastric and GEJ adenocarcinoma. We evaluated irinotecan in combination with the ATR inhibitor berzosertib (formerly M6620) in patients with TP53-mutated gastric and GEJ adenocarcinoma. **Methods:** This was a single-arm phase II study in third-line patients with G/GEJ cancers possessing TP53 mutations (exon 2 and exons 4-11). Patients received irinotecan 180 mg/m² IV and berzosertib 270 mg/m² IV on days 1 and 15 every 28 days. The primary endpoint was overall response rate (ORR) (Ha: 35% and Ho: 15%). A subset of patients underwent biopsies on C1D1 post-irinotecan and C2D2 to evaluate the expression of DDR biomarkers Y-H2AX, KAP1 p-Ser 824, and p-ATR. **Results:** A total of 17 patients were enrolled. Of 16 efficacy-evaluable patients, one experienced a partial response. The ORR was 6.2% thus the primary endpoint was not met. The disease control rate was 56.2%. Median progression-free survival was 4.01 months [95% CI 2.07-Not Reached]. Median overall survival was 6.21 months [95% CI 4.83-8.61]. No new safety signals were observed with the experimental treatment combination and the most common $\geq$ grade 3/4 treatment-related adverse events were neutropenia (4/17, 23.5% patients), anemia (3/17, 17.6%), febrile neutropenia (2/17, 11.8%), and diarrhea (2/17, 11.8%). No grade 5 events occurred. **Conclusions:** Although the primary endpoint of ORR was not met, the combination of irinotecan and berzosertib in patients with TP53-mutated G/GEJ adenocarcinoma was well-tolerated and demonstrated anti-tumor activity comparable to other agents with published later-line data (e.g. ramucirumab-paclitaxel, TAS-102). Analyses of pharmacodynamic biomarkers of DNA damage repair are in process. While further clinical development of berzosertib is not planned, other ATR inhibitors are being explored in combination with irinotecan in gastrointestinal malignancies, including G/GEJ cancer. Clinical trial information: NCT03641313. Research Sponsor: U.S. National Institutes of Health.

Osemitamab in combination with capecitabine and oxaliplatin (CAPOX) as a first line treatment of advanced G/GEJ cancer: Updated data of cohort C from a phase I/IIa, multi-center study (TranStar102/TST001-1002). *First Author: Lin Shen, Department of Gastrointestinal Oncology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital & Institute, Beijing, Haidian District, China*

Background: Adding a claudin18.2 antibody to a chemotherapy is a clinically validated approach for patients with high CLDN18.2 expressing tumors. TST001 is a best in class differentiated antibody whose improved CLDN18.2 affinity and enhanced antibody-dependent cellular cytotoxicity, leads to anti-tumor activity in low to medium CLDN18.2 expressors gastric cancer cells. Pre-clinical studies also showed that TST001 has stronger tumor regression effects than the IMAB362-analog at the same dose. **Methods:** The efficacy and safety of osemitamab with CAPOX as 1st line treatment with G/GEJ cancer was explored in a dose escalation and expansion phase 1/2 study in China (Cohort C, NCT04495296). Positive claudin18.2 expression (membranous staining $\geq$ 1+ intensity in $\geq$ 10% of tumor cells) as assessed centrally using the LDT assay was required in the expansion phase only. **Results:** As of Dec 31, 2022, 64 patients were dosed with osemitamab in combination with CAPOX, 15 patients received osemitamab at doses ranging from 1 to 8 mg/kg Q3W in the dose escalation and 49 patients at 6 mg/kg in the dose expansion. The median follow up was 151 days. Patient characteristics were typical of 1st line G/GEJ cancer, with relatively higher percentage of peritoneal disease (48.4%). Nausea (65.4%), vomiting (46.2%) and hypoalbuminemia (65.4%) were the most common adverse events related to TST001 at dose of 6mg/kg in 52 patients (3 patients in dose escalation and 49 patients in dose expansion), most of them were grade 1 or 2 (only one patient experienced grade 3 nausea and vomiting, and one experienced grade 3 hypoalbuminemia). In the expansion cohort, 40 of the 45 patients with measurable lesions had at least one post-treatment tumor assessment. 27 achieved partial response (PR) of which 21 were confirmed. There was no obvious trend in improved efficacy with higher level of CLDN18.2 expression based on overall response rate (ORR). Progression free survival (PFS) and duration of response (DOR) were still immature. **Conclusions:** TST001 in combination with CAPOX as first-line treatment for the patients with G/GEJ cancer is safe and encouraging anti-tumor activities have been observed regardless of the CLDN18.2 expression levels above 1+ intensity in $\geq$ 10% tumor cells per central LDT assay. Updated ORR, mPFS and mDOR will be presented at the time of the congress. Clinical trial information: NCT04495296. Research Sponsor: Suzhou Transcenta Therapeutics Co., Ltd.

Heterogeneous baseline immune cell infiltration landscape as a predictor of pathological complete response in locally advanced esophageal squamous cell carcinoma (ESCC) following neoadjuvant chemotherapy and immunotherapy: Results from a single-arm, phase II clinical trial (SEEK-01). *First Author: Guangyu Yao, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Neoadjuvant immunotherapy and chemotherapy have shown promise in improving outcomes for patients with locally advanced ESCC, but the response to treatment can vary among patients. Therefore, there is a need to identify predictive biomarkers that can guide treatment decisions and improve patient outcomes. The infiltration of immune cells within the tumor microenvironment has been shown to be an important factor in cancer progression and response to treatment. In this study, we sought to explore the immune microenvironment prospectively related to treatment response of Neoadjuvant immunotherapy by scRNAseq. **Methods:** This was a single-arm phase II clinical trial, planned to enroll 20 locally advanced ESCC patients (cT2-4N0-1M0). After neoadjuvant chemotherapy (paclitaxel-albumin + carboplatin) combined with tislelizumab, patients received minimal invasive esophagectomy (MIE). Prior to neoadjuvant therapy, fresh tumor tissues were obtained via endoscopy and used for scRNAseq analysis, to evaluate the predictive capacity of the immune microenvironment. Pathological outcomes were assessed and divided into pCR, MPR defined as <10% residual tumor excluding pCR, and non-MPR defined as >10%. **Results:** Out of 18 enrolled patients, 15 completed neoadjuvant therapy and MIE surgery since March 2022. Of these 15 patients, 3 achieved pCR, 2 got MPR, and 10 were non-MPR, with a total of 51,208 single cells sequenced. Both groups showed similarly low expression of PD-L1 (5.7% vs. 2.3%). Comparing pCR to non-MPR patients, the former showed a significant increase in T lymphocytes (CD8+ (17.1% vs. 1.1%), Regulatory T (20.2% vs. 4.0%)), plasma cell (22.0% vs. 8.3%), and mature dendritic cell (1.5% vs. 0.5%); a significant decrease in B cells (0.9% vs. 1.9%), neutrophils (1.7% vs. 11.0%), and tumor cell, as well as a similar expression of macrophage (5.6% vs. 6.6%) and monocyte, indicating a clear difference in the immune cell infiltration landscape between two groups. Furthermore, we identified a new subtype of plasma cell which was highly enriched in the non-MPR group, even though the pCR group showed a great increase in plasma cells in total. **Conclusions:** This study demonstrates the heterogeneity of baseline immune cell infiltration landscape in Locally Advanced ESCC, in which pCR and non-MPR patients exhibited entirely different profiles, and provide a potential predictor of response to neoadjuvant immunotherapy. Our findings suggest that baseline immune cell infiltration status, rather than pd-L1 expression, could accurately predict pCR or non-MPR before treatment, which could guide personalizing and minimize the need for trial-and-error approaches. Effectiveness and safety of camrelizumab in advanced esophageal cancer: A prospective multicenter observational cohort studies (ESCORT-RWS). *First Author: Zhihao Lu, Peking University Cancer Hospital, Beijing, China*

Background: Camrelizumab, an anti-programmed death 1 (PD-1) monoclonal antibody, has demonstrated survival benefits in patients with advanced or metastatic esophageal squamous cell carcinoma. However, the real-world effectiveness and safety of camrelizumab in patients with advanced esophageal cancer are largely unknown. **Methods:** In this prospective multicenter observational cohort study (NCT04616040), patients with advanced esophageal cancer who were scheduled to receive camrelizumab at the discretion of the physicians in charge were screened for inclusion. Clinical outcomes were treatment emergent adverse events (TEAEs), objective response rate (ORR), disease control rate (DCR), time to treatment discontinuation (TTD), progression free survival (PFS), and overall survival (OS). **Results:** Between Dec. 24, 2020 and Dec. 30, 2022, data were available for 624 patients (median age: 64.5 years; 74 [11.9%] aged ≥ 75 years; 515 [82.5%] men; 20 [3.2%] ECOG PS ≥ 2 ; 602 [96.5%] esophageal squamous cell carcinoma) from 42 institutions in China. All patients received at least one dose of camrelizumab-containing therapy, including 305 (48.9%) in the first-line, 238 (38.1%) in the second-line, and 81 (13.0%) in the third or later line settings. Most patients were treated with camrelizumab plus chemotherapy (487 [78.0%], primarily taxane and platinum-based chemotherapy in 284 [45.5%] patients), followed by camrelizumab plus antiangiogenic therapy (64 [10.3%]), camrelizumab monotherapy (46 [7.4%]), and camrelizumab plus antiangiogenic therapy and chemotherapy (27 [4.3%]). TEAEs occurred in 541 (86.7%) patients, most commonly anemia (41.2%), decreased white blood cell (38.5%), and decreased neutrophil count (28.5%). No new safety signals were noted. At the data cutoff (Dec. 30, 2022), 152 (24.4%) patients were still on treatment. The median follow-up estimated by the reverse Kaplan-Meier method and effectiveness outcomes are summarized in the Table. **Conclusions:** The real-world effectiveness and safety profiles of camrelizumab in advanced esophageal cancer patients are generally consistent with those observed in pivotal clinical trials. Research Sponsor: None.

Camrelizumab and chemotherapy as neoadjuvant treatment for locally advanced esophageal squamous cell carcinoma (ESCC): A single-arm, phase II trial. *First Author: Lei Gong, Tianjin Medical University Cancer Hospital & Institute, Tianjin, China*

Background: This study (NCT05476380) aimed to evaluate the safety and efficacy of neoadjuvant camrelizumab plus chemotherapy in patients with locally advanced ESCC, and to explore the potential risk factors of tumor immune microenvironment (TIM) which affect the efficiency of immunotherapy. **Methods:** Patients with resectable locally advanced thoracic ESCC, staged as T1b-4a, N2-3 (≥ 3 stations), and M0 or M1 lymph node metastasis (confined to supraclavicular lymph nodes) were enrolled. Eligible patients received intravenous camrelizumab (200 mg, day 2) plus paclitaxel (175 mg/m², day 1) and cisplatin (75 mg/m², day 1) for three 21-day cycles before surgery. The primary endpoint was major pathological response (MPR), defined as $\leq 10\%$ residual viable tumor cells in resected tissue. In order to screen out the potential biomarkers, the dissected lymph nodes were collected in the pathological complete response (pCR) and non-pCR groups. The infiltrated immune cells and the status of PD-L1 was evaluated by flow cytometry. **Results:** From February 20, 2021 to July 7, 2022, 38 patients were enrolled. 34 (89.5%) patients completed the full three-cycle treatment successfully. 34 patients underwent surgery and all received R0 resection. The MPR and pCR rates were 67.6% (23/34) and 17.6% (6/34), respectively. There were 2 (5.9%) patients having complete response of the primary tumor but residual disease in lymph nodes alone (ypT0N+). 32 (94.1%) patients had any-grade treatment-related adverse events, with the most common being leukocytopenia (73.5%). 18 (52.9%) patients had adverse events of grade 3 or worse. No treatment-related deaths occurred. Based on our findings, positive lymph nodes were one of the important reasons that the patients could not achieved pCR. TIM of the lymph nodes were then tested. Compared with MPR group, the infiltrated lymphocyte cells in the non-MPR group decreased from 93% to 52.4% ($p = 0.02$), the infiltrated CD8⁺ T cells also decreased from 11.8% to 5.9% ($p = 0.02$). However, the CD4⁺ T cells showed no significant difference between the MPR and non-MPR groups (46.2% vs 55%, $p = 0.27$). The expression of PD-L1 in the immune cells is one of the biomarkers for checkpoint inhibitors. In this trial, the expression of PD-L1 in the CD8⁺ T cells showed significant difference between the MPR and non-MPR groups (14.5% vs 6.7%, $p = 0.02$). Myeloid-derived suppressor cells (MDSCs) are a group of vastly heterogeneous immunosuppressive cells derived from immature myeloid progenitors that have been linked to poor patient prognosis and immunosuppression. We found more infiltrations of MDSCs in the non-MPR group compared with the MPR group (9.7% vs 4.7%, $p = 0.04$). **Conclusions:** Neoadjuvant camrelizumab combined with chemotherapy shows promising efficacy and good safety in ESCC patients. Poor response to immunotherapy was related to lymph node metastasis in the TIM. Clinical trial information: NCT05476380. Research Sponsor: Hengrui Medicine.

Modified FOLFOX plus/minus nivolumab and ipilimumab vs FLOT plus nivolumab in patients with previously untreated advanced or metastatic adenocarcinoma of the stomach or gastroesophageal junction: The randomized phase 2 IKF-S628 Moonlight trial of the Arbeitsgemeinschaft Internistische Onkologie (AIO). *First Author: Sylvie Lorenzen, Klinikum rechts der Isar, Technische Universität München, Klinik für Innere Medizin III, München, Germany*

Background: FOLFOX plus nivolumab has become standard of care for first-line therapy of patients (pts) with esophagogastric adenocarcinomas (EGA). The AIO-STO-0417 trial (Moonlight) is a multi-cohort treatment optimization trial that evaluates the combination of FOLFOX alone (Arm B) vs FOLFOX plus nivolumab (nivo) and ipilimumab (ipi) administered in parallel (Arm A/A1) or sequentially (Arm A2) and FLOT plus nivolumab administered in parallel (Arm C) for 1L-treatment of metastatic or advanced inoperable Her-2 negative EGA. The aim is to generate signals whether a. dual checkpoint inhibition or b. a triplet chemotherapy is beneficial in the context of nivolumab therapy for this disease. **Methods:** Pts were randomized 1:1 to Arm A (mFOLFOX q2w plus nivo 240 mg q2w + ipi 1 mg/kg q6w administered in parallel) or B (mFOLFOX alone). In a subsequent phase pts were randomized 1:2 to Arm A1 (identical to Arm A) or A2 (three cycles of mFOLFOX followed by nivo q2w + ipi q6w, with optional repetition). In a final phase, all pts were allocated to single Arm C (FLOT q2w + nivo q2w). The primary endpoint was progression-free survival (PFS) based on the ITT population for Arm A vs Arm B and PFS rate at 6 months (PFS@6) for Arms A2 and C. Main secondary endpoints were PFS and ORR. Here, we present results for Arms A/A1, A2 and B. **Results:** A total of 262 pts were enrolled, Arm A (n=60), Arm B (n=60), Arm A1 (n=30), Arm A2 (n=60) and Arm C (n=52, results presented elsewhere). Baseline characteristics were comparable in all arms. Overall PD-L1 expression (CPS ≥ 1) was low with 41% and balanced between Arms A/A1, A2 and B. Analysis of pooled Arms A/A1 (n=90) showed an increase in toxicity (pts with AEs grade ≥ 3 88% vs 65% in Arm B and 75% in Arm A2, treatment related SAEs grade ≥ 3 A/A1 41% vs B 18% vs A2 17%) but not in activity. Arm A/A1 compared with Arm A2 was more effective in terms of PFS@6 (48% vs 30%), median PFS 5.8 vs 4.0 months and objective response rate (ORR) 46% vs 30%. **Conclusions:** Albeit the small number of pts in each cohort we conclude that in the first-line setting of metastatic EGA. a) Chemo plus dual checkpoint inhibition administered in parallel is associated with an increase in toxicity but not activity. b) Although associated with lower toxicity the use of sequential chemo followed by IO monotherapy is insufficient. The relatively low numbers of patients with PD-L1 CPS ≥ 1 may have impacted these results. Clinical trial information: NCT03647969. Research Sponsor: Bristol-Myers Squibb.

Advancing individualized care in advanced gastroesophageal cancers (GEC): A quality improvement initiative. *First Author: Matthew Strickland, Massachusetts General Hospital, Boston, MA*

Background: Biomarkers have become increasingly important in the treatment of metastatic gastroesophageal cancers (mGEC) with new targeted and immune-based therapies relying on biomarkers to identify patients who may benefit from these therapies. Here, we aimed to identify real-world challenges mGEC care teams face in implementing biomarker testing and evidence-based treatment choices. **Methods:** In July–September 2022, 74 health care professionals (HCPs) who treat mGEC at 3 US community oncology clinics completed surveys assessing practice patterns, challenges, and confidence related to treating mGEC. HCPs (N = 24) participated in interdisciplinary audit and feedback (AF) sessions to examine clinical evidence and develop clinic-specific action plans to address identified gaps. **Results:** Participating practices reported that ~22% of their practice is dedicated to GEC care. Participants represented the interprofessional GEC care team: medical oncologists (27%), radiation oncologists (1%), surgeons (1%), advanced practice professionals (32%), nurse/nurse navigators (32%), and other HCPs (5%). Providers reported testing for HER2, *EGFR*, *FGFR*, *NTRK*, microsatellite instability, tumor mutational burden, and PD-L1 in ~55-65% of advanced GEC patients. Most providers reported HER2 testing at time of diagnosis (91%) with 18% reporting testing at time of clinical or radiologic progression and 24% when new metastases are detected. Top reported barriers to use of predictive biomarker testing were long turnaround times for tests (32%) and keeping up to-date with current testing recommendations (23%). Top reported challenges in selecting therapies for GEC were keeping up with clinical evidence (35%) and delayed, pending, or unavailable biomarkers at the time of treatment selection (20%). Clinic action plans focused on specific gaps including (1) improved HCP education on guideline-concordant biomarker use (2) improving testing turnaround times, and (3) improving referrals to clinical trials based on biomarker results. The educational intervention increased correct identification of guideline concordant treatment for stage IV esophageal cancer (48% pre- and 72% post-AF) and confidence in use of biomarkers for treatment decision-making for patients with GEC (high/very high in 46% pre- and 72% post-AF). **Conclusions:** While molecular testing is becoming increasingly critical for mGEC care, HCPs report challenges with testing workflows and difficulty keeping up with developments in clinical data and guidelines. Clinic-specific interventions to improve biomarker workflows and ongoing educational initiatives to keep HCPs informed of the latest evidence-based best practices in biomarkers and associated therapies can address these gaps to improve outcomes for patients with GEC. Circulating tumor DNA and association with CAR-T cell therapy response in gastric and pancreatic cancer patients. *First Author: Sindhu Kubendran, Department of Medicine, University of California San Diego, La Jolla, CA*

Background: Circulating tumor DNA (ctDNA) is a form of cell free DNA that can be used to detect and measure cancer molecular residual disease (MRD) before and after systemic therapy. There are no data pertaining to the assessment of MRD in patients with solid tumors treated with chimeric antigen receptor T-cell (CAR-T) therapy. Here, we evaluated a tumor-informed ctDNA assay in the setting of gastric and pancreatic malignancies treated with claudin18.2 (CTO41)-targeted CAR-T cell therapy (NCT04404595). **Methods:** A single-center review between 7/1/2021 – 1/1/2023 identified 10 patients with pancreatic or gastric carcinoma who received CAR-T CTO41 cell therapy. Eight patients were ctDNA positive prior to treatment and had blood samples serially drawn before and after CAR-T cell therapy. Plasma was analyzed for ctDNA using a tumor-informed Signatera, mPCR-NGS ctDNA assay (Natera, Inc.). The correlative prognostic value of ctDNA to predict response after CAR-T cell therapy was analyzed by RECIST 1.1 criteria. **Results:** Pre- and post-treatment serial ctDNA was available for 8 of 10 (3/5 gastric and 5/5 pancreatic cancer) patients and all 8 were ctDNA positive prior to CAR-T CTO41 cell therapy. The median nadir of ctDNA was on day 14 after CTO41 infusion. Of the 8 patients with detectable ctDNA, 5 (62.5%) became undetectable at some time after CTO41 therapy, while 3 (37.5%) remained ctDNA positive throughout treatment. The disease control rate (DCR) was 80% for anytime negative ctDNA patients (4/5). Of patients with responsive disease after CTO41 CAR-T, 2/3 (67%) achieved undetectable ctDNA and 1/3 (33%) had a ctDNA reduction by 95%. Both patients with stable disease developed undetectable ctDNA. In those patients with progressive disease, 1/3 (33%) had a negative anytime ctDNA. One patient with a complete response had undetectable ctDNA and target lesion response, then later developed progressive disease detectable by ctDNA 3 months prior to radiography. Overall survival was higher (9.1 months vs. 3.7 months) in those who achieved anytime undetectable ctDNA. **Conclusions:** Tumor-informed ctDNA correlates with response to CAR-T cell therapy in gastrointestinal malignancies. Ongoing clinical trials of CTO41 CAR-T cell therapy will continue ctDNA analysis prospectively. Characteristics of initially ctDNA positive patients receiving CAR-T therapy. Clinical trial information: NCT04404595. Research Sponsor: Carsgen Inc.; Natera Inc.

Phase II study of telomelysin (OBP-301) in combination with pembrolizumab in gastroesophageal (GEA) adenocarcinoma. *First Author: Manish A. Shah, NYP, Weill Cornell, New York, NY*

Background: OBP-301 is a novel, replication-selective adenoviral construct that incorporates the human telomerase reverse transcriptase gene (hTERT) promoter, which is highly expressed in tumors but not in normal, differentiated adult cells, to regulate expression of the early adenoviral genes, E1A and E1B. OBP-301 has been evaluated as a single agent, and demonstrated immune responses and clinical activity in phase I studies. We examined OBP-301 in combination with pembrolizumab in a multicenter phase II study as a novel mechanism to improve immunotherapy in advanced gastric cancer. **Methods:** Eligible patients had advanced GEA that had progressed on at least 2 lines of prior therapy for incurable, advanced disease. Patients were required to have adequate end-organ function, measurable disease by RECIST 1.1, and a PD-L1 CPS > 1. Patients received OBP-301 at 2x10¹² viral particles via direct tumor injection every two weeks x 4 injections as well as pembrolizumab 200 mg IV every 3 weeks. The primary endpoint was objective response rate (ORR). The null hypothesis that the ORR is < 15% was tested against the Ha ORR > 30%. We used a Simon two-stage design, requiring 3 or more responses in 18 patients in the first stage to proceed to stage two. The study was closed after successfully completing stage one of the Simon's two stage design to formally examine OBP-301 + pembrolizumab in an immunotherapy (IO) refractory GEA population. Tissue was collected for single cell RNA Sequencing to examine the tumor immune microenvironment pre- and post-OBP-301 injections. **Results:** From May 2019 to Oct 2022, we enrolled 16 patients, median age 65 (range 43-81), male n = 13. OBP-301 direct tumor injection was well tolerated, median OBP-301 injections 3 (range 1-5). Toxicity attributed to OBP-301 included grade 2 fatigue/weakness (25%), grade 2 fever (18.7%), and a single incidence each of grade 2 nausea, anemia, grade 3 melena, and grade 4 diabetes mellitus (6.25%). We observed 3 patients (19%) with a partial response (PR), thereby meeting the Simon two-stage threshold. The responses were durable; two patients with PR are currently without evidence of disease (one completed 2 years of pembrolizumab, one underwent resection of primary tumor after 15 months), and the 3rd patient is now in month 12 of treatment. Further, one patient with brain metastases demonstrated regression of metastatic disease following progression on immunotherapy alone. All patients were mismatch repair proficient. **Conclusions:** OBP-301 viral particle injection into the tumor is feasible and safe. OBP-301 with pembrolizumab has encouraging activity in GEA, with durable responses and demonstration of activity in immunotherapy refractory disease. Single Cell RNA Sequencing data of the pre- and post-injection immune effects of OBP-301 will be presented. A formal phase II study of OBP-301 + pembrolizumab in IO refractory GEA patients is underway. Clinical trial information: NCT03921021. Research Sponsor: Oncolytics Biopharma.

Adjuvant nab-paclitaxel plus S-1 versus capecitabine plus oxaliplatin for patients with stage III gastric adenocarcinoma after D2 dissection: A multicenter, open-label, randomized phase 3 study. *First Author: Yu Pengfei, Zhejiang Cancer Hospital (University of Chinese Academy of Sciences Cancer Hospital), Hangzhou, China*

Background: Multiple clinical studies have shown that adjuvant chemotherapy could prolong the survival of patients after radical resection, it is necessary to explore better treatment options for patients with stage III gastric adenocarcinoma (GAC). We designed this study to evaluate the efficacy and safety of adjuvant nab-paclitaxel combined with S-1 (AS) versus capecitabine combined with oxaliplatin (CAPOX) in GAC. **Methods:** Patients with stage III GAC after D2 radical resection and achieved R0 resection were randomized 1:1 to receive adjuvant AS (nab-paclitaxel: 100 mg/m², d1 and 8, q3w; S-1: 40-60 mg, bid, d1-14, q3w) or CAPOX (oxaliplatin: 130 mg/m², d1, q3w; capecitabine: 1000 mg/m², bid, d1-14, q3w) for 8 cycles. Stratification analysis was performed according to histological type (differentiated vs undifferentiated GAC) and AJCC 8th pathological staging (IIIA vs IIIB and IIIC). The primary endpoint was 3-year disease-free survival (DFS) rate, secondary endpoints were overall survival (OS) and safety. **Results:** Between March 20, 2020 and January 17, 2023, 313 patients were randomized to receive AS (n = 156) or CAPOX (n = 157). Baseline characteristics were generally balanced between the two groups. Median follow-up time was 5.16 months. The 1-year DFS rates were 87.14% and 70.16%, in the AS and CAPOX groups, respectively. The median DFS and 3-year DFS rates were not reached. The 1-year OS rate was 88.47% in AS group, and 63.89% in CAPOX group. At date cutoff, 12 patients (peritoneal recurrence, 1 patient; locoregional recurrence, 3 patients; distant recurrence, 8 patients) relapsed in the AS group and 16 patients (peritoneal recurrence, 4 patients; locoregional recurrence, 5 patients; distant recurrence, 8 patients; tumor marker recurrence, 1 patient) relapsed in the CAPOX group; some patients had multiple recurrence sites. 2 patients (1 patient for GAC; 1 patient for other diseases) died in the AS group and 11 patients (9 patients for GAC; 2 patients for other diseases) died in the CAPOX group. The median relative dose intensity of nab-paclitaxel was 90.32%, of S-1 was 80.77%, of oxaliplatin was 77.44% and of capecitabine was 78.55%. The incidence of adverse events (AEs) of any grade and grade 3/4 were 79.49% and 39.74% in the AS group, 72.61% and 22.93% in the CAPOX group. In the AS and CAPOX groups, neutropenia (31.63% vs 20.13%), leukopenia (29.71% vs 17.25%), anemia (27.80% vs 23.00%) and thrombocytopenia (4.15% vs 17.25%) were the most common AEs. **Conclusions:** Compared with CAPOX regimen, AS regimen has better survival rates and acceptable tolerability. AS provided new potential adjuvant regimen for stage III gastric cancer after D2 resection. Clinical trial information: NCT04135781. Research Sponsor: CSPC ouyi Pharmaceutical Group Co., Ltd.

Perioperative immunochemotherapy (mDCF + avelumab) in locally advanced gastro-esophageal adenocarcinoma: A phase II trial. *First Author: Thierry Alcindor, McGill University Health Center, Montréal, QC, Canada*

Background: Perioperative chemotherapy improves cure rate in locally advanced gastroesophageal adenocarcinoma (GEA). Immune checkpoint inhibitors have activity in GEA. This trial is testing the hypothesis that the addition of avelumab, an anti-PD-L1 antibody, to perioperative mDCF chemotherapy, will increase the pathologic complete response (pCR) rate, a potential surrogate for overall survival, in comparison with a historical pCR rate of 7%. **Methods:** Single-arm phase II study (NCT03288350) of avelumab + chemotherapy (modified docetaxel/cisplatin/5-FU or mDCF) given every 2 weeks x 4 cycles before and after surgery. Planned sample size of 50 operated patients. The hypothesis cannot be refuted if ≥ 6 patients show pCR, the primary endpoint. Inclusion criteria: histologically proven GEA, locally advanced disease (cT3-4 and/or N+), adequate organ function, WHO performance status 0-1. Exclusion criteria: other histology, metastatic stage, use of immunosuppressants, serious autoimmune disease, intake >10 mg prednisone/d. Adverse effects prospectively recorded per NCI CTCAE guidelines. Pathological response and tumor regression grade (TRG) determined by CAP criteria: 0=complete; 1=near complete; 2=moderate; 3 = poor/no response. Data presented as median (range), KM determined survival. **Results:** Study accrual completed August 2022: 51 patients enrolled, 45 M/6 F, age 64 (18-79), ECOG 0 (35) and 1 (16). One patient withdrew consent after 2 treatment cycles and is excluded from efficacy analysis. Tumor anatomic site: Esophagus =19(38%)/gastroesophageal junction 21(42%)/subcardia stomach 10(20%). Staging: cT3 (88%), cT4 (6%), N+ (62%). Histology: all adenocarcinoma; dMMR 9/50 in 18%; CPS <1 , 1-5, 6-10, >10 in 0%/33%/27%/40% of tumors tested. All 4 pre-operative cycles administered to 48/50 (96%); 36/50 received ≥ 2 adjuvant treatment cycles and 23/50 (46%) received all 8 cycles. Grade 3-4 toxicity events from neoadjuvant therapy affected: GI tract (diarrhea 4%); respiratory system (pneumonia 4%); endocrine system (adrenal insufficiency 2%). Other common side effects (grades 1-2, incidence $>15\%$) were: fatigue, diarrhea, skin rash/pruritus. Post-operative mortality at 30 and 90 days was 0/50 (0%) and 1/50 (2%). R0 resection was achieved in 48/50 (96%); a median of 36 (13-78) lymph nodes were resected. Pathological response was TRG 0/1/2/3 in 7/21/16/25 with pCR seen in 7 (14%), meeting the primary endpoint. Major pathologic response (TRG 0 and 1) was seen in 9 (18%), but without correlation with CPS or dMMR biomarker status. At 37.5 (9-71) months follow up, overall survival at 1, 2, and 3 years is 93.6%, 75.7%, and 69.2%. MPR showed a trend to improved survival ($p = 0.06$). **Conclusions:** The neoadjuvant combination of avelumab with chemotherapy (mDCF) shows promising safety and efficacy in gastroesophageal adenocarcinoma, without obvious correlation to known biomarkers. Clinical trial information: NCT03288350. Research Sponsor: EMD Serono as part of an alliance between the healthcare business of Merck KGaA, Darmstadt, Germany and Pfizer.; MUHC Foundation.

Integration of trastuzumab (T), with or without pertuzumab (P), into perioperative chemotherapy (CT) of HER-2 positive gastric (GC) and esophago-gastric junction cancer (EGJC): First results of the EORTC 1203 INNOVATION study, in collaboration with the Korean Cancer Study Group, and the Dutch Upper GI Cancer group. *First Author: Anna Dorothea Wagner, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland*

Background: 10-20% of GC are HER-2 positive. The role of perioperative anti-HER2-directed treatment is yet undefined. **Methods:** This randomized, open-label phase II-trial investigates the benefit of combining T alone or with P and perioperative CT for GC and EGJC. Between 2015 and 2021, 172 of a planned 215 patients (pts) with centrally confirmed, positive HER-2 status and resectable GC or EGJC (UICC TNM stages Ib-III) were included. Recruitment was prematurely terminated due to slow accrual. Pts were randomized in a 1:2:2 ratio to: Arm A (CT alone) (35 pts); Arm B (CT+T [8mg/kg, followed by 6mg every 3 weeks]) (67 pts); Arm C (CT+T+P [840mg every 3 weeks]) (70 pts). CT was initially cisplatin (80 mg/m² d1) and capecitabine (2 x 1000 mg/m²/d d1) for 3 cycles before and after surgery. After publication of the FLOT-4 study, the protocol was amended. CT changed to four cycles FLOT (AI-Batran Lancet 2019) with FOLFOX or CAPOX as alternative for pts ineligible for FLOT. In the experimental arms, T and P were continued beyond CT at the same dose for a total of 17 cycles. Major pathological response rate (mpRR) determined by central pathology review was the primary endpoint. The study was designed to have 80% power to detect an increase in mpRR from 25% with CT to 45% with CT+T+P or CT+T with a one-sided alpha of 10%. CT+T+P was first tested versus CT and if positive, CT+T would be tested versus CT. **Results:** Out of 172 pts randomized, 161 fulfilled all important eligibility criteria and started their allocated treatment (per protocol population). 62.1% of pts had EGJC and 72.0% an intestinal subtype. Main CT regimens were cisplatin-capecitabine (42.2%) and FLOT (46.6%). In Arm A:B:C, 90.9%, 92.2% and 81.3% completed neoadjuvant treatment. Major reason for treatment discontinuation was toxicity (70%). Surgery was performed in 84.8%, 98.4%, 92.2% pts in Arm A:B:C. R0 resection rates were 83.9%, 90.3% and 85.9%. At present, results of central pathology review of mpRR are available for 126 out of 150 operated pts (84.0%). Pts not operated (n=11) were considered as failures for mpRR. MpRR was 23.3%, 37.0%, 26.4% in Arm A:B:C. The increase of 3.1% (80% CI: [-9.5%, 15.7%]), one-sided $p=0.378$ in Arm C vs. A was not statistically significant. The increase in Arm B vs. A was 13.7% (80% CI: [0.7%, 26.7%]), one-sided $p=0.099$. MpRR was 33.3%, 53.3% and 37.9% in Arm A:B:C after amending the protocol while, in contrast, it was 8.3%, 16.7% and 12.5% before. **Conclusions:** The primary endpoint analysis did not meet the pre-specified criteria of efficacy for the combination of CT+T+P. However, CT+T showed interesting response rates, especially with FLOT as CT backbone. Follow-up data including survival is necessary to define the clinical value of this regimen. Clinical trial information: NCT02205047. Research Sponsor: This study was funded by an unrestricted educational grant from Roche to EORTC.

Predicting role of circulating tumor DNA and blood-based tumor mutational burden in esophageal squamous cell carcinoma receiving chemoradiotherapy combined with toripalimab: Exploratory analyses from a phase II trial (EC-CRT-001). *First Author: BaoQing Chen, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: EC-CRT-001 is a phase II trial investigating the efficacy of toripalimab (an anti-PD1 antibody) combined with definitive chemoradiotherapy (CRT) in locally advanced esophageal squamous cell carcinoma (ESCC) and the results demonstrated encouraging antitumor activity and acceptable toxicity. This exploratory analysis was performed to evaluate the role of circulating tumor DNA (ctDNA) and blood-based tumor mutational burden (tMB) for efficacy prediction. **Methods:** Forty-two patients from the phase II trial (NCT04005170) who received toripalimab (240 mg every 3 weeks for up to 1 year, or disease progression, or unacceptable toxicity) combined with definitive CRT (irradiation with 50.4 Gy in 28 fractions concurrent with 5 cycles of weekly paclitaxel in 50 mg/m² and cisplatin in 25 mg/m²) were enrolled. Plasma samples were collected before, during, and after CRT. Targeted next-generation sequencing was performed on a total of 118 plasma samples and 35 matched tumor samples using a panel covering 474 cancer-associated genes. **Results:** Twenty-six (62%) of 42 patients achieved clinical complete response (cCR) at three months after CRT. ctDNA was detected in 29 (72.5%) of 40 patients at baseline. The positive rate of ctDNA decreased to 43.9% (20/41) during CRT and continued to descend to 27.0% (10/37) at the completion of CRT. A higher cCR rate was observed in patients with negative during-CRT ctDNA compared to those with detectable ctDNA (82.6% vs. 38.9%, $P = 0.008$). Patients with post-CRT detectable ctDNA also had poorer cCR rate (30.0% vs. 77.8%, $P = 0.017$). Within a median follow-up of 24.0 months (IQR 13.7-27.9), the median progression-free survival (PFS) was 12.2 months (95%CI: 8.4-16.0) and median overall survival (OS) was not reached for the whole cohort. Patients with during-CRT detectable ctDNA had shorter PFS compared to ctDNA-negative patients (HR = 2.57, 95%CI: 1.18-5.60, $P = 0.014$). Similarly, patients with post-CRT detectable ctDNA also had a significantly increased risk of disease progression (HR = 2.88, 95%CI: 1.21-6.83, $P = 0.012$) and death (HR = 3.67, 95%CI: 1.41-9.55, $P = 0.004$). Moreover, patients with higher tMB (>1) detected during CRT were associated with a favorable OS (HR = 0.33, 95%CI: 0.13-0.88, $P = 0.027$). Improved PFS was also observed in those patients with higher post-CRT tMB (>3) (HR = 0.28, 95%CI: 0.08-0.96, $P = 0.042$). **Conclusions:** Negative ctDNA status and higher tMB during or after CRT were associated with better tumor response and favorable survival in ESCC patients who underwent definitive CRT combined with toripalimab. Dynamic ctDNA has great potential in predicting efficacy and risk of disease progression in ESCC. Clinical trial information: NCT04005170. Research Sponsor: Guangdong Esophageal Cancer Institute (Q202109).

Concordance among the three commercially available PD-L1 assays for esophageal squamous cell carcinoma. *First Author: Lizhen Wang, Roche (China) Holding Ltd., Shanghai, China*

Background: Immune checkpoint inhibitors are now standard-of-care for patients with esophageal squamous cell carcinoma (ESCC). The predictive significance of PD-L1 expression in ESCC has been investigated by different antibodies, scoring algorithms and cutoff values in several phase III trials. However, it remains controversial whether PD-L1 is a predictive biomarker for response to PD-1/PD-L1 blockade. Evaluating the concordance of the commercially available PD-L1 assays is essential to understand the discrepancy in the ESCC clinical trials, and helpful to further investigate the predictive value of PD-L1 expression. **Methods:** 145 archival tumor samples were obtained from 131 patients with ESCC (stage I-IV) at National Taiwan University Hospital. Formalin-fixed, paraffin-embedded archival tumor samples were assessed by three commercially available PD-L1 assays: VENTANA SP263, Dako 22C3 and Dako 28-8 assays. Assays were performed in a College of American Pathologists accredited central laboratory and scored for PD-L1 staining by using multiple metrics including tumor cell score (TC), immune cell score (IC) and combined positive score (CPS) or tumor area percentage (TAP). Analytical concordance was calculated pairwise between assays using the Spearman (ρ) rank correlation coefficient. Classification concordance, including agreement between clinically relevant scoring algorithms, was investigated using positive percent agreement (PPA), negative percent agreement (NPA), and overall percent agreement (OPA) at multiple cutoff values to assess the overlap between populations by using different assays. **Results:** SP263, 22C3 and 28-8 assays showed good analytical correlation for TC staining (Spearman's rank correlation coefficient 0.8-0.9). Correlation was lower for IC (Spearman's rank correlation coefficient 0.59-0.61). There was moderate overlap between populations identified by SP263 and 28-8 or 22C3 based on CPS or TAP algorithm at multiple cutoff values. OPAs for these 3 assays ranged from 68%-88% at various matched algorithms. The SP263 and 22C3 PD-L1 assays appeared relatively more sensitive, assigning a higher proportion of patients as PD-L1 positive or high, compared to 28-8 assay. When using assay-specific clinically relevant algorithm, moderate classification agreement was seen for SP263 versus 22C3 or 28-8. Differences were observed between patient populations with tumor classified as PD-L1 high versus PD-L1 low/negative using CPS ≥ 10 , TAP $\geq 10\%$ and TC $\geq 1\%$. The PPA between 22C3 CPS ≥ 10 and SP263 TAP ≥ 10 or 28-8 CPS ≥ 10 or 28-8 TC $\geq 1\%$ were 75%, 57% and 68% respectively. **Conclusions:** This study is the first dataset to compare various PD-L1 assays in ESCC. Differences in classification of patients with PD-L1 high versus low/negative using clinically relevant algorithms suggest that caution should be taken when comparing data across the trials. Multi-dimensional cell-free DNA-based liquid biopsy and early detection of gastric cancer. *First Author: Yu Pengfei, Department of Gastric Surgery, Zhejiang Cancer Hospital, Institute of Basic Medicine and Cancer (IBMC), Chinese Academy of Sciences, Hangzhou, Zhejiang, China*

Background: Gastric cancer is one of the most common cancer types. Most patients were diagnosed at advanced stages and experienced poor prognosis. A non-invasive assay for the detection of early-stage gastric cancer is highly desirable for reducing the gastric cancer-associated mortality. **Methods:** We prospectively collected a study cohort of 249 participants including 110 pathologically confirmed with stage I-II gastric cancer and 139 with non-cancerous conditions. A plasma sample was collected from each patient before conventional screening modalities for gastric cancer. We performed whole-genome sequencing with plasma samples and profiled four types of cell-free DNA (cfDNA) characteristics, fragment size pattern, copy number variation, nucleosome coverage pattern, and single nucleotide substitution. We used these differential profiles to develop an ensemble model to identify gastric cancer patients from non-cancer individuals. We further collected a validation cohort consisting of 73 gastric cancer patients and 94 non-cancer individuals to validate the cfDNA-based assay. Additionally, we compared the performance of our assay and conventional gastroscopy in a hypothetical 100,000 screening population by Monte Carlo simulation. **Results:** The liquid biopsy assay that incorporated four types of cfDNA characteristics was able to identify early-stage gastric cancer patients from non-cancer individuals at an AUROC of 0.962 in the study cohort and 0.972 in the validation cohort. At a specificity of 92.1% (128/139), it achieved a sensitivity of 88.2% (97/110) in the study cohort. With this threshold, in the validation cohort, 91.5% (86/94) of healthy individuals and 91.8% (67/73) of gastric cancer patients were correctly identified. In both study and validation cohorts, the inferred probabilities of cancer showed consistent trends to increase with pathological stages in the cancer group and disease statuses in the non-cancer group. Of note, our approach detected all gastric tumors located in the cardia and fundus (100.0%, 19/19), which could be challenging for gastroscopic examination. Additionally, through in-silico simulations, we showed that our cfDNA-based non-invasive assay may detect 96.3% more gastric cancer cases than conventional gastroscopy owing to higher sensitivity and anticipated better participant compliance in a large hypothetical screening population. **Conclusions:** We introduced a liquid biopsy assay using multiple dimensions of cfDNA characteristics that could accurately identify early-stage gastric cancer from non-cancerous conditions. As a cost-effective non-invasive approach, it may provide population-wide benefits for the early detection of gastric cancer. Research Sponsor: None.

Pembrolizumab, radiotherapy, and chemotherapy in neoadjuvant treatment of malignant esophago-gastric diseases (PROCEED): Assessment of pathologic response and toxicity in a prospective, phase II single-arm trial. *First Author: Pooja Karukonda, Duke Cancer Institute, Durham, NC*

Background: A standard treatment paradigm for locally advanced, resectable, non-metastatic esophageal or gastric adenocarcinomas (EGA) is neoadjuvant chemoradiation (CRT) followed by surgery. Historical pathologic complete response (pCR) rates after CRT with carboplatin/paclitaxel in the CROSS trial are low at 23%. Efficacy of adjuvant immunotherapy has since been shown in this patient population. The main objectives of this trial were to investigate whether neoadjuvant CRT + pembrolizumab improves pCR compared to the historical control of CRT alone, and also determine the associated acute and post-surgical toxicity of this approach. **Methods:** Single-institution, prospective phase II trial (NCT03064490) evaluating the efficacy and safety of neoadjuvant pembrolizumab + CRT followed by adjuvant pembrolizumab in patients with locally advanced operable EGA. CRT (45 Gy/25 fractions with concurrent weekly carboplatin [AUC 2] and paclitaxel [50 mg/m² of BSA]) with 3 cycles of pembrolizumab was administered as neoadjuvant therapy. Patients also received 3 cycles of adjuvant pembrolizumab after surgical resection if they did not experience ≥Grade 3 (G3) toxicity during neoadjuvant treatment. Baseline characteristics were collected. Pathologic response was scored from 0-3 per tumor regression grading. The percentage of patients with pCR (score of 0) are described. Acute toxicities are defined per CTCAE v4 and include relevant events occurring within 90 days after treatment. **Results:** Accrual is complete, with 35 patients with cT2-3N0-2M0 EGA enrolled from 10/10/2017-10/07/2022. 28/32 patients have completed neoadjuvant therapy and surgical resection. 89% of enrolled patients are male, and 94% are white. 97% have an esophageal primary, and 97% underwent R0 resection. 10/28 (35.7%; 95% CI: 17%, 53%) patients achieved a pCR. 22/32 patients have experienced treatment-related ≥G3 non-hematologic toxicity to date (94.2% G3, 5.8% G4). 18 patients experienced ≥G3 toxicity related to neoadjuvant therapy, with 53 events overall, the majority being GI (24.5%) or metabolic/nutritional disorders (24.5%). 10 patients experienced ≥G3 toxicity related to surgery, with 16 events overall, the majority being procedural complications (31.3%) and infectious disorders (31.3%). **Conclusions:** Patients undergoing neoadjuvant CRT + pembrolizumab for EGA experienced higher rates of pCR and acceptable rates of treatment-related toxicity compared to historical controls. This phase II trial demonstrates the safety and efficacy of this treatment paradigm, which warrants assessment in future prospective studies. Clinical trial information: NCT03064490. Research Sponsor: Merck.

Induction chemotherapy plus definitive chemoradiotherapy versus chemoradiotherapy alone in esophageal squamous cell carcinoma: Long-term results and exploratory analyses of a randomized controlled trial. *First Author: Mian Xi, Department of Radiation Oncology, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: The previous results of our trial demonstrated that the addition of induction chemotherapy (IC) prior to definitive chemoradiotherapy (CRT) failed to significantly improve response rate or 3-year survival in patients with locally advanced esophageal squamous cell carcinoma (ESCC). Here, we report the long-term results and exploratory analyses to further evaluate the therapeutic value of IC in ESCC. **Methods:** This was a single-institution, open-label, randomized, phase II trial. Patients with previously untreated, unresectable, stage II–IVA ESCC were randomly assigned in a 1:1 ratio to receive induction docetaxel (75 mg/m² on day 1) and cisplatin (75 mg/m² on day 1) every 3 weeks for two cycles, followed by concurrent CRT, or CRT alone. The primary endpoint was overall response rate at 3 months after CRT. Second endpoints were overall survival (OS) and progression-free survival (PFS). The relationship between tumor response to IC and long-term survival was analyzed as an exploratory, post-hoc analysis. Moreover, baseline tumor biopsies were evaluated by RNA-seq to identify patients who are more likely to benefit from IC. **Results:** Between May 2015 and September 2017, 110 eligible patients were randomly assigned to the IC+CRT group (n=55) or the CRT group (n=55). The overall response rate was 74.5% in the IC+CRT group versus 61.8% in the CRT group (P=0.15). At a median follow-up of 74.9 months, the 5-year OS rate was 31.8% in the IC+CRT group and 29.1% in the CRT group (P=0.68; HR, 0.91; 95% CI, 0.58–1.43). Similarly, no significant differences were identified in 5-year PFS between groups (30.5% vs. 25.5%, P=0.51; HR, 0.86; 95% CI, 0.56 to 1.34). Patients who responded to IC had significantly better survival than nonresponders. Six key genes were identified based on RNA-seq and gene expression comparison between responders and nonresponders after IC. Risk-score model was constructed by these key genes and then validated. **Conclusions:** Addition of induction docetaxel plus cisplatin before definitive CRT still failed to provide an obvious survival benefit in ESCC based on long-term follow-up. However, this strategy did result in a significantly improved survival in IC responders. Our results also revealed potential molecular biomarkers to predict who may benefit from IC. Clinical trial information: NCT02403531. Research Sponsor: None.

Development of an artificial intelligence algorithm for adjuvant chemotherapy based on a nationwide registry of patients with gastric cancer by the Japanese Gastric Cancer Association (JGCA). *First Author: Yasuhide Yamada, National Center for Global Health and Medicine, Tokyo, Japan*

Background: Recent marked advances in machine learning have led to expectations of the clinical application of artificial intelligence (AI) to support medical care. **Methods:** A survival analysis model which consisted of 31 covariates was adopted for AI algorithms using machine learning and these were constructed using clinical data sets for training. The performance of AI algorithms was evaluated in order to determine the optimal chemotherapy including surgery alone without any adjuvant chemotherapy with the highest survival rate for each patient. This involved using clinical data for verification to compare survival of an AI-recommended treatment group, for which therapy recommended by AI was actually administered, with an AI-deprecated group, for which therapy recommended by AI was not administered. **Results:** The clinical characteristics of 23653 patients and treatment are described in the Table from 2011 to 2018 in a nationwide registry of gastric cancer patients in Japan by the Japanese Gastric Cancer Association and were made available for this study. S-1 monotherapy was used the most frequently of all adjuvant chemotherapy in this study. We used the 'restricted mean overall survival time' (RMST) of all the patients as metrics. The RMST in the AI-recommended and the AI-deprecated groups were 51.4 and 47.5 months, respectively. Patient data for the verification were matched baseline characteristics by the propensity score. This model predicted effectively overall survival after gastrectomy. The RMST of over 80 years old patients were 43.9 in the AI-recommended and 38.3 months in the AI-deprecated, respectively. This AI algorithm recommended adjuvant S-1 more frequently for patients with higher age, male, American Society of Anesthesiologists – physical status 2, Eastern Cooperative Oncology Group performance status 1, pT3/pT4, pN2/pN3, more than the upper normal limit of preoperative blood urea nitrogen, macroscopic types 2/3, differentiated adenocarcinoma, Roux-en-Y reconstruction, and Clavien-Dindo classification grade II/III. The RMST for pStage IIA/IIIB/IIIC were 55.7/53.9/50.3/45.7/42.2 months in the AI-recommended and 55.1/50.7/43.9/36.9/32.0 months in the deprecated. This AI algorithm showed a higher survival rate in pStage III patients particularly. **Conclusions:** The AI algorithm could readily be integrated into clinical practice to choose adequate adjuvant chemotherapy for each patient based on each patient's baseline data because it trained and verified the nationwide registry has good predictive performance. Research Sponsor: Cross-ministerial Strategic Innovation Promotion Program, Cabinet Office, Japan.

Efficacy and safety of camrelizumab combined with chemotherapy versus chemotherapy alone as preoperative neoadjuvant therapy for resectable locally advanced esophageal squamous cell carcinoma: Preliminary results from a multicenter, prospective, randomized controlled study. *First Author: Renquan Zhang, The First Affiliated Hospital of Anhui Medical University, Hefei, China*

Background: Camrelizumab combined with chemotherapy has a very ideal therapeutic effect and low toxicity in the treatment of solid tumors. camrelizumab plays an important role in the treatment of locally advanced esophageal squamous cell carcinoma. **Methods:** This study is a prospective, multicenter, randomized controlled study. Inclusion criteria were patients aged 18-75 years with an ECOG score of 0-1 who had not received other treatments previously and had histologically confirmed resectable locally advanced esophageal squamous cell carcinoma (clinical stages cT1-4N1-3M0 and cT3-4N0M0). Patients received camrelizumab combined with chemotherapy (albumin paclitaxel + cisplatin in chemotherapy regimen) or chemotherapy alone (albumin paclitaxel + cisplatin in chemotherapy regimen). The primary endpoints are pathological complete remission (pCR) rate and 5-year overall survival (OS). Secondary endpoints including disease-free survival rate, duration of drug treatment and adverse events and we attempt to explore the correlation between drug efficacy and PD-L1 expression. The target sample size was 400 and patients were divided into two groups according to a 1:1 ratio who were received camrelizumab plus chemotherapy and chemotherapy alone. **Results:** From January 2021 to October 2022, 243 patients with resectable locally advanced esophageal squamous cell carcinoma from four centers were enrolled. Of these, 205 (85.2%) were male and 38 (15.6%) were female. Median age was 65 years. Most patients (182, 74.9%) were in clinical stage III and had an ECOG score of 1 (185, 76.1%). 150 patients had completed all clinical trial cycles and the result showed that among 90 patients who received camrelizumab plus chemotherapy, 25 patients achieved pathological complete remission (pCR), 39 achieved major partial remission (MPR), 11 had stable disease and 1 had progressive disease, with a pCR rate of 27.8% and MPR rate of 43.3%. Among 60 patients who received chemotherapy alone, 6 patients achieved pCR, 13 patients achieved MPR, 19 patients had stable disease and 2 patients had progressive disease, with a pCR rate of 10.0% and MPR rate of 26.7%. The most common adverse events were reactive cutaneous capillary endothelial proliferation (72.1%), nausea (42%), and leukopenia (15.5%), all of which were in grade 1-2 with manageable safety. **Conclusions:** Preliminary results of this study showed that the overall efficacy of camrelizumab plus chemotherapy was better than that of chemotherapy alone and the drug was safe and reliable. In future work, we will continue to analyze the survival outcomes, drug safety and the relationship between drug efficacy and PD-L1 expression and other biomarkers. Circulating tumor DNA as a marker of recurrence risk in locoregional esophagogastric cancers with pathologic complete response. *First Author: Eric Michael Lander, Division of Hematology/Oncology, Vanderbilt University Medical Center, Nashville, TN*

Background: Following neoadjuvant therapy and definitive surgery, up to one-third of patients (pts) with gastroesophageal adenocarcinoma with a pathologic complete response (pCR; tumor regression grade 0 [TRG0]) will recur, while up to one-half of pts with a near-pCR (TRG1) experience recurrence. Our study aims to evaluate postoperative circulating tumor DNA (ctDNA) as a prognosticator of recurrence in pts with pCR or near-pCR after curative-intent neoadjuvant chemotherapy (NAC) or chemoradiation (CRT) and surgery. **Methods:** We retrospectively identified pts from 11 institutions with stages I-III esophagogastric cancers who completed neoadjuvant therapy and had TRG0 or TRG1 scores at the time of curative-intent surgery. Postoperative plasma samples were collected for ctDNA analysis within a 16-week molecular residual disease (MRD) window after definitive surgery and serially during follow-up from 9/19/19 to 2/21/22. MRD by ctDNA was assessed using a personalized, tumor-informed ctDNA assay (Signatera mPCR-NGS assay). The primary outcome was recurrence-free survival (RFS), measured from the date of surgery to the first documented sign of radiographic recurrence. Survival analysis was performed using the maximum likelihood bias reduction method for Cox regression. **Results:** We obtained 250 blood samples from 45 pts with esophageal (N=18), gastroesophageal junction (N=17), and gastric (N=10) adenocarcinomas who received either NAC or CRT. The median follow-up for this cohort was 22.8 months (range: 0.3-81.7 months). Despite pts achieving pCR (N=12) or near-pCR (N=33), ctDNA-positivity in the 16-week MRD window (N=21) correlated with higher rates of recurrence (66.7%; 2/3) compared to the absence of ctDNA (11.1%; 2/18). Detectable ctDNA was associated with a significantly shorter RFS (HR 23.0, 95% CI 2.0-268.1; p=0.012). 35 pts had ctDNA analyzed at any post-surgical time point, where the recurrence rate was 87.5% (7/8) in ctDNA-positive pts compared to 7.4% (2/27) in ctDNA-negative pts, exhibiting a further reduction in RFS (HR 44.8; 95% CI 5.4-369.7; p<0.0001). Out of 8 ctDNA-positive pts, two (25%) converted from ctDNA-positive to ctDNA-negative with subsequent treatment. **Conclusions:** Within the subgroup of pts with esophagogastric adenocarcinoma and favorable pathologic responses (TRG 0-1) following neoadjuvant treatment, the presence of post-operative ctDNA identified pts with elevated recurrence risk. If validated in larger cohort studies, testing for ctDNA may be a useful biomarker to select pts at risk for recurrence with potential to inform prospective clinical trials for direction of adjuvant therapy. Five-year overall survival with S-1 plus docetaxel as adjuvant treatment in curatively resected pStage III gastric cancer in JACCRO GC-07. *First Author: Wataru Ichikawa, Division of Medical Oncology, Showa University Fujigaoka Hospital, Yokohama, Japan*

Background: JACCRO GC-07 is a randomized controlled trial to explore postoperative S-1/docetaxel compared to S-1 alone after D2 gastrectomy for pStage III gastric cancer (GC) patients. The second interim analysis demonstrated that the significant improvement of RFS was obtained by S-1/docetaxel compared to S-1 alone. The study was terminated by the recommendation of independent data and safety monitoring committee (Yoshida K et al. J Clin Oncol 2019; 37:1296-1304). Preplanned analysis to evaluate RFS at 3 years, the primary endpoint, was also published (Kakeji Y et al. Gastric Cancer 2022; 25:186-196). We report the 5-years follow-up data from the trial. **Methods:** Patients with pStage III GC were randomly assigned to receive either S-1/docetaxel (S-1 80-120mg/body on days 1-14 with a 7-day rest followed by docetaxel 40mg/m² on day 1 and S-1 80-120mg/body on days 1-14 every 21 days for 6 cycles followed by S-1 80-120mg/body on days 1-28 every 42 days for 4 cycles) or S-1 (80-120mg/body on days 1-28 every 42 days for 8 cycles) after D2 gastrectomy. Blocked randomisation was performed and stratified by the stage (IIIA, IIIB, IIIC) and histological type (differentiated or undifferentiated). The primary endpoint was 3y RFS and the secondary endpoints were OS, TTF and safety. This analysis presents the final preplanned assessment of outcomes after 5 years. **Results:** Of 915 randomly assigned patients, 912 patients were included in the intention-to-treat (ITT) analysis. In the final analysis, 426 recurrences and 373 deaths were confirmed among the ITT population during the median follow-up period of 63.72 months (3.52-111.87). The 5y RFS of 59.8% in the S-1/docetaxel group was significantly superior to 50.6% in the S-1 group (HR 0.726, 95% CI: 0.599-0.879, p = 0.0010) and the 5y OS was 67.9% in the S-1/docetaxel group and that of S-1 group was 60.3%, respectively (HR 0.752, 95% CI: 0.613-0.922, p = 0.0059), confirming the significant improving effect on the survival of the patient. **Conclusions:** Adjuvant treatment with S-1 plus docetaxel should be considered for patients with pStage III gastric cancer who underwent D2 gastrectomy without neoadjuvant chemotherapy. Neoadjuvant docetaxel, oxaliplatin, and s-1 plus surgery and adjuvant s-1 for resectable advanced gastric cancer: Final survival outcomes of the randomized phase 3 PRODIGY trial. *First Author: Yoon-Koo Kang, Asan Medical Center, Seoul, Korea, Republic of (South)*

Background: The phase 3 PRODIGY study compared neoadjuvant docetaxel, oxaliplatin and S-1 (DOS) chemotherapy followed by surgery followed by adjuvant S-1 with surgery followed by adjuvant S-1 for Korean patients with resectable locally advanced gastric cancer (LAGC) (Kang et al. J Clin Oncol. 2021). The planned analysis of the primary endpoint of PRODIGY showed that the addition of neoadjuvant DOS to surgery and adjuvant S-1 improved progression-free survival (PFS). We herein report the long-term follow-up outcomes, including overall survival (OS), from this trial. **Methods:** Patients with histologically confirmed primary gastric or gastroesophageal junction adenocarcinoma with clinical T2-3N+ or T4Nany disease were enrolled from 18 Korean study sites. Patients were randomly assigned to D2 surgery followed by adjuvant S-1 (40-60 mg orally twice a day, days 1-28 q6w for eight cycles; SC group) or neoadjuvant DOS (docetaxel 50 mg/m², oxaliplatin 100 mg/m² intravenously day 1, S-1 40 mg/m² orally twice a day, days 1-14 q3w for three cycles) before D2 surgery, followed by adjuvant S-1 (CSC group). The primary endpoint was PFS. OS was the secondary endpoint. This analysis presents the final assessment of the outcomes after 5 years. **Results:** A total of 266 and 264 patients were randomly assigned to the CSC and SC arms, respectively, among which 238 and 246 patients were treated and included in the full analysis set. As of the data cut-off date (SEP-2022), the median follow-up duration of the surviving patients was 99.5 months (range, 68.6-127.7 months). As compared to SC, CSC significantly increased the OS (adjusted hazard ratio, 0.72; 95% CI, 0.54 to 0.97; stratified log-rank P=0.028) with a 5-year OS rate of 66.8% and 63.0% for the CSC and SC arms, respectively. CSC also significantly improved the PFS (adjusted hazard ratio, 0.71; 95% CI, 0.53 to 0.94; stratified log-rank P=0.019) with a 5-year PFS rate of 60.6% and 56.9% for the CSC and SC arms, respectively. **Conclusions:** The addition of neoadjuvant docetaxel, oxaliplatin and S-1 (DOS) chemotherapy, as part of perioperative chemotherapy, to surgery and adjuvant S-1 prolonged the OS and PFS of Asian patients with LAGC relative to patients treated with surgery and adjuvant S-1 alone. Neoadjuvant DOS chemotherapy should be considered one of the standard treatment options for patients with LAGC in Asia. Clinical trial information: NCT01515748. Research Sponsor: None.

Neoadjuvant tislelizumab combined with chemoradiotherapy for resectable locally advanced esophageal squamous cell carcinoma (ESCC): Single arm phase II study. *First Author: Peng Jin, Department of Radiation Oncology, Shandong Cancer Hospital and Institute, Jinan, China*

Background: This study aimed to evaluate the safety and efficacy of neoadjuvant tislelizumab combined with chemoradiotherapy in patients with resectable esophageal squamous cell cancer. **Methods:** This is a prospective single-arm clinical trial. A total of 20 patients with newly diagnosed resectable esophageal cancer (cT1-2N+ / cT3-4aN0-3 MO) received 2 cycles of tislelizumab (200mg every 3 weeks for 2 cycles) concurrent with chemoradiotherapy (radiotherapy: 41.4Gy in 23 fractions; chemotherapy: Paclitaxel (Albumin bound) 100mg/m², and Cisplatin 75 mg/m² once every 3 weeks for 2 cycles.) Radical esophagectomy was performed within 4-6 weeks after neoadjuvant therapy. PET/CT was performed at baseline and before surgery. Primary endpoints included pathological response rate (pCR) and major pathological response rate (MPR), the secondary endpoints were disease free survival and safety. Exploratory endpoints include molecular imaging research and immune biomarker to further explore the factors affecting the efficacy of neoadjuvant therapy for esophageal cancer. **Results:** Twenty patients enrolled, all of whom received neoadjuvant tislelizumab combined with chemoradiotherapy. Eighteen patients underwent radical esophagectomy. One patient underwent radical chemoradiotherapy due to lymph node metastases after neoadjuvant therapy. One patient died of pneumonia before surgery. Among 18 patients who underwent surgery, RO was 100% (18/18), 9 patients achieved pCR (50.0%), and 13 patients achieved MPR (72.2%). Most of treatment-related adverse event (TRAE) were grade 1-2, and the most common TRAE was anemia (15, 75.0%). The grade 3 TRAE included 1 leukopenia (5.0%), 1 neutropenia (5.0%), 1 liver damage (5.0%), and 1 elevated cardiac troponin T (5.0%). A significant decrease in SUVmax was observed in both pCR and no-pCR patients after treatment. Baseline SUVmax in no-pCR patients tended to be higher than pCR patients(p=0.0642). Furthermore, a significant increase in circulating CD4⁺ T cells, CD4⁺ effector memory T cells (T_{EM}), and M1 were found after treatment. Among the patients with pCR, the CD4⁺ T_{EM} and cDCs after treatment were higher than those in the no-pCR patients, while Tregs and M2 were lower. **Conclusions:** Neoadjuvant tislelizumab combined with chemoradiotherapy for locally advanced ESCC has promising efficacy and good safety. Clinical trial information: NCT05323890. Research Sponsor: National Natural Science Foundation of China (82172720).

Long-term quality of life and nutritional results of stomach-preserving surgery after sentinel node evaluation in patients with early gastric cancer: A multicenter, randomized phase 3 trial (SENORITA). *First Author: Bang Wool Eom, National Cancer Center, Goyang-Si, Gyeonggi-do, South Korea*

Background: In the SENORITA trial, laparoscopic sentinel node navigation surgery (LSNNS) showed no significant difference in overall and disease specific survivals compared with laparoscopic standard gastrectomy (LSG). Here, we present the effect of stomach preservation surgery on QoL and nutritional outcomes, and identify risk factors affecting QoL in stomach preservation surgery. **Methods:** SENORITA was a prospective multicenter randomized trial. Patients diagnosed with early gastric cancer of 3 cm or less were randomly allocated (1:1) to LSNNS or LSG. The primary endpoint was 3-year disease-free survival. This analysis focuses on long-term quality of life and nutritional outcomes of patients who finally underwent stomach-preservation surgery in the LSNNS group. QoL was assessed using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30) and stomach module (STO22) at 3, 12, 24, and 36 months after surgery. Linear mixed model analyses were used to evaluate differences between treatment groups. This trial is registered with ClinicalTrials.gov, NCT01804998. **Results:** From March 2013 to March 2017, a total of 580 patients were randomly assigned in the SENROTA trial. Among them, 258 patients underwent sentinel node navigation surgery and 198 finally underwent stomach preservation surgery. QoL data was available in 194 patients and compared with those of 257 patients who underwent standard gastrectomy. The stomach-preservation group had better QoL in physical function, dyspnea, and appetite loss of C30 and dysphagia, pain, reflux symptoms, eating restriction, anxiety, taste change, body image, and total score of STO22. Regarding nutritional outcomes, body mass index, hemoglobin, protein, and albumin levels were significantly higher in the stomach-preservation group than in the gastrectomy group. In multivariate analyses, tumor location (greater curvature) was an independent favorable factor affecting global health status, reflux symptoms, eating restriction, and total score of STO22 at 3 months in the stomach-preservation group. Segmental resection was a risk factor for diarrhea and eating restriction at postoperative 3 year. **Conclusions:** The stomach-preservation surgery had better long-term QoL and nutritional outcomes compared with standard gastrectomy. These findings can help decision making about treatment for patients with early gastric cancer, especially or elderly or nutritionally high risk patients. Clinical trial information: NCT01804998. Research Sponsor: This research was supported by the National Cancer Center, Republic of Korea (Grant 1110550, 1410140, 1710160, 2010150).

GaEsSeer: Early detection of gastric and esophageal cancer by integrating methylation and fragmentomics signatures in cfDNA. *First Author: Yunshi Zhong, Endoscopy Center and Endoscopy Research Institute, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Esophageal and gastric cancer (EC and GC) are two common cancer types that severely impact patients' health. The 5-year survival rate for EC and GC is as low as 19% and 31%, respectively. However, early detection will significantly increase the survival rate: stage-1 EC has a 5-year survival rate of 51%, while for stage-1 GC it's 69%. Invasive screening methods, such as endoscopy and biopsy, caused low compliance. Computational tomography and carcinoembryonic antigen were limited by low sensitivity. To address this problem, we developed GaEsSeer, a non-invasive targeted-sequencing-based assay that utilizes multiple methylation and fragmentomics features of cell-free DNA (cfDNA) to accurately detect EC and GC signals in blood. **Methods:** cfDNA was tested using the GaEsSeer panel, which was developed using in-house genome-wide sequencing data on EC and GC samples, and public datasets from databases and literature. Methylation features, which was quantified as methylation haplotypes or methylation encoding score, and fragmentomics features including copy number and end motif ratio were taken for modeling. Separate sub-models were trained utilizing each type of feature, which were eventually combined via logistic regression to establish the final predicting model. **Results:** A total of 1770 participants were recruited from multiple centers. This included 787 healthy individuals, 448 cancers (209 EC, 239 GC; stage I:156, -II:120, -III:78, and -IV:58), 174 benign esophageal diseases, and 361 benign gastric diseases. For cancer detection, the methylation-only model had an AUC of 0.909 and 0.897 in training (618 total) and test sets (617 total), respectively; while the AUC of the fragmentomics-based model was 0.885 and 0.911, respectively. The combinatorial model further improved performances, which achieves an AUC of 0.940 and 0.931 in the training and test cohorts, respectively. While the specificity remained at 96.7%, GaEsSeer detected 81.1% EC and 70.3% GC cases in the test cohort. It had a sensitivity of 74.2% and 48.9% for stage-I EC and GC, respectively. GaEsSeer also has high specificities of 87.9% and 89.8% for benign esophageal and gastric diseases, respectively. Additionally, the performance of GaEsSeer was compared with known serum cancer markers such as CEA, CA19-9, and CA72-4; and the results show that it had significantly higher sensitivity than any of these serum markers (54.8% vs 6.4% when against CEA; 53.5% vs 7.1% when against CA19-9; 50% and 16.7% when against CA72-4). **Conclusions:** In this pilot study, we developed the blood-based GaEsSeer assay and a model for EC and GC detection with high accuracy by stacking multiple methylation- and fragmentomics-based submodules together. Further optimization and validation of GaEsSeer using larger prospective cohorts are needed to validate its potentials for clinical application. Response to programmed cell death protein 1 antibody in patients with Epstein-Barr virus-associated biliary tract cancer. *First Author: Wen-Zhuo He, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Epstein-Barr virus-associated biliary tract cancer (EBVaBTC) has a distinct genomic landscape and increased infiltration of CD3⁺ and CD8⁺ T cells. However, the efficacy of immunotherapy in EBVaBTC remains largely unknown. The aim of this study is to assess the efficacy of programmed cell death protein 1 (PD-1) antibody in EBVaBTC. **Methods:** Consecutive patients with metastatic biliary tract cancer diagnosed at our institution from January 2017 to December 2021 were identified. In situ hybridization was performed to detect EBV. The objective response to PD-1 antibody was assessed. We also analyzed the immune microenvironment of EBVaBTC by multiplex immunofluorescence staining, and performed the proteomic characterization of EBVaBTC. **Results:** A total of 131 patients with BTC who received PD-1 antibody were identified, of which 9 (6.9%) had EBVaBTC. All EBVaBTC cases were intrahepatic cholangiocarcinoma. EBVaBTC was not associated with deficient mismatch repair but with lymphoepithelioma-like carcinoma and hepatitis B virus infection. Four (44.4%) patients achieved a partial response, and the remaining five (55.6%) patients had stable disease. The response lasted for at least 12 months in 8 (88.9%) patients with EBVaBTC, including 4 patients received PD-1 antibody monotherapy. Blood EBV-DNA was detectable in all 9 patients (100%) with EBVaBTC. Multiplex immunofluorescence staining revealed more abundant CD3⁺ and CD8⁺ T cells infiltration in EBVaBTC than that of mismatch repair deficient BTC. A total of 8,379 proteins were identified by proteomics. Comparison of EBVaBTC and paired normal tissue revealed 547 differentially expressed proteins. Enrichment analysis demonstrated that differentially expressed proteins in the EBVaBTC were associated with EBV infection and T cell activation. We also observed the expression of immune checkpoint other than PD-1, including LAG-3 and TIM-3. **Conclusions:** Identification of EBVaBTC may represent a subset of patients with promising response to immunotherapy. Research Sponsor: Natural Science Foundation of Guangdong, China.

Transarterial chemoembolization combined with lenvatinib and camrelizumab for unresectable hepatocellular carcinoma: A prospective, single-arm, multicenter study. *First Author: Zhibo Zhang, The First Affiliated Hospital of Fujian Medical University, Fuzhou, China*

Background: Conversion therapy for unresectable hepatocellular carcinoma (uHCC) has attracted increasing interest in recent years. In 2020 ASCO annual meeting, one abstract reported that the combination therapy of tyrosine kinase inhibitor and anti-PD-1 antibody could be a promising conversion therapy for patients with initially uHCC. This study aims to evaluate the efficacy and safety of transarterial chemoembolization (TACE) combined with lenvatinib and camrelizumab (TACE+LEN+CAM) as a conversion therapy for uHCC. **Methods:** This single-arm, prospective, multicenter study was conducted on patients diagnosed with HCC (with an Eastern Cooperative Oncology Group performance score (ECOG PS) of 0-1 and Child-Pugh class A) who were ineligible for surgery. Enrolled patients received camrelizumab (200 mg every 3 weeks) and lenvatinib (bodyweight $\geq$ 60 kg: 12 mg/day; < 60 kg: 8 mg/day) after TACE treatment. Surgery was performed after treatment response was assessed to meet the criteria of resection. Patients who did not meet the criteria for surgery continued to receive triple treatment until disease progression or intolerable toxicity. Primary endpoints were objective response rate (ORR) and safety. Secondary endpoints included percentage of patients amenable to surgery, the rate of radical (R0) resection, disease control rate (DCR). This study is registered with Chinese Clinical Trial Registry (ChiCTR2100050410). **Results:** Between Oct 25, 2021, and Jul 20, 2022, 55 patients were enrolled and received triple therapy (TACE+LEN+CAM). Of these, 37 (67.3%) patients had portal vein tumor thrombosis. Mean tumor diameter for all patients was 112 ± 83 mm. 52 (94.6%) patients with ≤ 2 target lesions, and 3 (5.4%) patients with > 2 target lesions. As of data cutoff on Dec 20, 2022, the median follow-up was 6.7 months (IQR 5.0-9.89). According to modified RECIST criteria, tumor response in patients included complete response to treatment in 9 patients (18.0%), partial response in 27 (54.0%), stable disease in 6 (12.0%), and progressive disease in 7 (14.0%). The ORR was 72.0%, and the DCR was 84.0%. 26 patients underwent surgery after successful conversion therapy. The MPR and pCR rates in the surgery population were 69.2% and 23.1%, respectively. The conversion rate was 55.3% and the R0 resection rate was 100%. 23 (41.8%) of 55 patients had treatment-related adverse event (TRAEs) that were grade 3-5. No grade 3-5 TRAEs occurred after surgery. **Conclusions:** The triple therapy (TACE+LEN+CAM) significantly improved ORR and the surgical conversion rate of uHCC patients with a manageable safety. Future large-scale randomised trials are warranted. Clinical trial information: ChiCTR2100050410. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Landmark analysis of OS by response status in previously treated patients (pts) with advanced hepatocellular carcinoma (aHCC): Post hoc analysis of the KEYNOTE-394 study. *First Author: Zhenggang Ren, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: KEYNOTE-224 and KEYNOTE-240 landmark analyses showed that objective response (OR) in pembrolizumab (pembro)-treated pts was prognostic of longer OS after the landmark. Landmark analysis was performed using the KEYNOTE-394 study to determine whether response assessment before landmark is prognostic of longer OS after landmark time in pembro-treated pts. **Methods:** Adults with confirmed HCC, radiographic progression during or after treatment with or intolerance to sorafenib or oxaliplatin-based chemotherapy were eligible for KEYNOTE-394. Landmark analyses of OS for responders, pts with SD, and pts with other status in these analyses at 6, 12, 18, and 24 wk after randomization were performed on the pembro arm. Tumor imaging was performed every 6 wk after randomization. Responders (R) at each landmark were defined as pts with any response assessment of CR or PR before the landmark date; all other pts were defined as nonresponders (NR). SD at each landmark was defined as pts with a response assessment of SD and no better response before the landmark date. Other was defined as pts with responses of PD or a missing/not evaluable status. Response was assessed per RECIST v1.1 by blinded independent central review. HR and 95% CI for survival after the landmark are based on the Cox regression model with the Efron method for handling ties, with response status by the landmark time as a single covariate. **Results:** Median time from randomization to data cutoff date (June 30, 2021) was 33.8 mo (range, 18.7-48.8) for pembro. OS after landmark time was numerically longer for R vs NR, R vs pts with SD, and pts with SD vs pts with Other status. **Conclusions:** KEYNOTE-394 landmark analysis supports the prognostic association between OR with pembro before the landmark and OS after the landmark observed in KEYNOTE-224 and KEYNOTE-240 in previously treated pts with aHCC. Landmark analysis also suggested longer OS after the landmark for pts who achieved a better response to pembro before the landmark. Clinical trial information: NCT03062358. Research Sponsor: Merck Sharp & Dohme LLC., a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Temporal patterns of immune-mediated adverse events (imAEs) with tremelimumab (T) plus durvalumab (D) in the phase 3 HIMALAYA study in unresectable hepatocellular carcinoma (uHCC). *First Author: George Lau, Humanity and Health Clinical Trial Center, Humanity and Health Medical Group, Hong Kong Special Administrative Region, China*

Background: In the Phase 3 HIMALAYA study (NCT03298451) in uHCC, STRIDE (Single T Regular Interval D) significantly improved overall survival versus sorafenib (S) and had manageable safety (Abou-Alfa et al. *NEJM Evid* 2022). STRIDE is approved for uHCC in the United States and Japan and is recommended for approval by the European Medicines Agency. In this exploratory post hoc analysis, we assessed temporal patterns of imAEs for the STRIDE regimen in HIMALAYA. **Methods:** Safety was assessed in participants (pts) who received ≥ 1 dose of STRIDE (T 300 mg [one dose] plus D 1500 mg once every 4 weeks) or S (400 mg twice daily). Treatment causality was investigator-assessed. imAEs were defined as AEs of special interest associated with drug exposure and consistent with an immune-mediated mechanism of action for which no alternate etiology was clear. Safety was summarized descriptively overall and at specific time points after the start of treatment. **Results:** In total, 388 (STRIDE) and 374 (S) pts were included in the safety analysis. Median (range) duration of exposure was 5.5 (0.4-41.9) months for STRIDE (D exposure in STRIDE) and 4.1 (0.1-38.6) months for S. Any grade treatment-related AEs (TRAEs) and Grade 3 or 4 TRAEs were less frequent for STRIDE (75.8% and 25.8%, respectively) versus S (84.8% and 36.9%, respectively). Any grade imAEs and max Grade 3 or 4 imAEs occurred in 35.8% and 12.6% of pts, respectively for STRIDE. Any grade imAEs and max Grade 3 or 4 imAEs with STRIDE occurred at all time points assessed and were most likely to occur within the first three months after treatment. For STRIDE, any grade imAEs of gastrointestinal disorders and skin and subcutaneous tissue disorders were most common within the first month after treatment (3.9% and 3.1%, respectively), whereas any grade imAEs of endocrine disorders were most common between > 1 and ≤ 2 months (6.7%). **Conclusions:** In HIMALAYA, AEs with STRIDE were manageable and generally low grade. Any grade TRAEs and Grade 3 or 4 TRAEs were less frequent for STRIDE versus S. Although imAEs with STRIDE could occur at any time, most were observed within the first three months after treatment. These findings continue to support STRIDE for the treatment of uHCC. Clinical trial information: NCT03298451. Research Sponsor: AstraZeneca.

Pts with event – n (%)	STRIDE (n=388)	STRIDE (n=388)
	Any grade	Max Grade 3 or 4
Time from first dose to imAE, months		
≤ 1	69 (17.8)	34 (8.8)
> 1 to ≤ 2	43 (11.1)	6 (1.5)
> 2 to ≤ 3	23 (5.9)	2 (0.5)
> 3 to ≤ 6	23 (5.9)	2 (0.5)
> 6	23 (5.9)	7 (1.8)

A phase 1b study of E7386, a CREB-binding protein (CBP)/ β -catenin interaction inhibitor, in combination with lenvatinib in patients with advanced hepatocellular carcinoma. *First Author: Masafumi Ikeda, National Cancer Center Hospital East, Kashiwa, Japan*

Background: E7386, a novel oral anticancer agent, inhibits β -catenin binding to its transcriptional co-activator, CBP, thus modulating Wnt/ β -catenin signaling. The objectives of the dose-escalation part in this phase 1b study were to assess safety, tolerability, pharmacokinetics (PK), biomarkers, and preliminary efficacy of E7386 combined with lenvatinib in patients with advanced hepatocellular carcinoma (HCC) or other solid tumors. Here, we present the results from the HCC subpart. **Methods:** In cycle 0, E7386 was administered orally in escalating doses once daily (QD) or twice daily (BID) for 5 or 6 consecutive days. From cycle 1 day 1, E7386 QD or BID, combined with daily oral lenvatinib (8 mg in patients with body weight of < 60 kg or 12 mg in patients with body weight ≥ 60 kg), were administered on a continuous schedule in 28-day cycles in the HCC subpart. Adverse events (AEs) were graded using CTCAE v5.0. Prophylactic antiemetics were not allowed during the dose-limiting toxicities (DLT) evaluation period but were permitted after the occurrence of nausea and vomiting. Tumor response was assessed by investigators using mRECIST (Lencioni and Llovet, 2010). PK and biomarker analyses were conducted using samples collected at defined time points. **Results:** As of the cutoff date (9 December 2022), 25 patients had been treated in the HCC subpart with E7386 dose ranges from 10 to 80 mg QD and from 60 to 120 mg BID. Among 3 patients in the E7386 120 mg BID cohort, grade 3 maculopapular rash (in 1 patient) and grade 5 acute kidney injury (in 1 patient) DLTs were observed. No DLTs were observed in other cohorts. The most common treatment-emergent AEs (TEAEs; any grade) across all cohorts were nausea (n=19; 76.0%), vomiting (n=15; 60.0%), constipation (n=13; 52.0%), palmar-plantar erythrodysesthesia syndrome (n=12; 48.0%), diarrhea (n=11; 44.0%), and proteinuria (n=10; 40.0%). The most common grade ≥ 3 TEAEs ($\geq 5\%$ of patients) were proteinuria (n=5; 20.0%) and aspartate aminotransferase level increased (n=2; 8.0%). Nausea and vomiting were well controlled by a 5HT3 antagonist. Among the 25 treated patients, 9 (36.0%) partial responses (PRs) were observed, including 3 PRs in 10 patients who had received lenvatinib as a prior regimen. C_{max} and AUC for E7386 increased with increasing E7386 dose. **Conclusions:** E7386 100 mg BID, in combination with lenvatinib (8 or 12 mg based on bodyweight) QD, was determined as the recommended phase 2 dose, and was deemed tolerable and manageable with antiemetic administration. The combination showed promising activity in patients with HCC, including those pretreated with lenvatinib. Clinical trial information: NCT04008797. Early experience with nivolumab, gemcitabine, and lenvatinib for fibrolamellar hepatocellular carcinoma. *First Author: Paul Kent, FibroFighters Foundation, River Forest, IL*

Background: Fibrolamellar Carcinoma (FLC) is a rare deadly form of liver cancer affecting adolescents and young adults (AYA), presenting at an advanced stage, with up to 80% relapse, and no proven systemic therapies. Effective systemic therapies could convert patients to resectable or prolong progression free survival (PFS) and overall survival. Because of reported successes with nivolumab + lenvatinib (LEN) and of Gemcitabine (GEM) + LEN, and the potential synergy of GEM with NIV through elimination of myeloid suppressor cells in the tumor microenvironment, we offered NIV+LEN+GEM (NLG) to relapsed/refractory FLC patients ineligible for clinical trials. Our objective is to describe our initial experience using NLG in high risk AYA FLC patients. **Methods:** We reviewed the records of all FLC patients discussed at the FibroFighters National Tumor Board who received NLG. **Results:** Twenty-five patients (10F,15M), median age 20 (7-56), all stage IV, received a total of 322 cycles of NLG (median 11 cycles/patient, 19 neoadjuvant, 1 adjuvant, 4 both). The median number of relapses, prior systemic therapies, and surgeries were 2(0-6), 3(0-6), and 2(0-7) respectively. Most patients had failed NIV+LEN (n = 8) or GEM+LEN (n = 7) prior to starting NLG. The 17 patients with at least one evaluation had a mean follow up of 10 months (3-23) and 18 cycles (6-38) of NLG with the best response by RECIST 1.1 of CR(1), PR(6), SD(10), and PD(0), for an objective response rate (PR+CR) of 41% and disease control rate (CR+PR+SD) of 100%, and estimated best volume response median of -20% (-89%,+10%). There have not yet been any progressions. Three of the 7 who were too soon for imaging, have had resolution of ascites. The PFS and Overall Survival at 6, 9, and 12 months are: 1.0/1.0, 0.82/0.82, 0.67/0.67. Two of 17 with carcinomatosis have no evidence of disease on PET and MRI after 10 cycles. Twenty-two of 24 are continuing NLG. Nine of 16 unresectable patients became surgical candidates, of these 4 showed > 50% necrosis histologically at surgery. 13 of 17 showed necrosis on imaging. Eleven of 16 are currently in their longest PFS since diagnosis. Sixteen patients had serial tumor-informed circulating DNA (Signatera) during therapy: Five became negative (0.0 mean tumor molecules/ml plasma), and overall mean drop was -27% (-93%, +111%). No patients have stopped therapy. The most common toxicities were hypertension and fatigue in 25% and 20% respectively, grade 1 or 2. There have been no grade 3 or 4 toxicities to date. **Conclusions:** Our retrospective experience with NLG for FLC offers another potential systemic option for patients who are not surgical candidates or with multiple relapses. NLG was well tolerated and provided excellent disease control to patients with few options. Prospective trials are needed. Research Sponsor: None.

Efficacy of lenvatinib (LEN) vs sorafenib (SOR) in the first-line (1L) treatment of patients (pts) with unresectable hepatocellular carcinoma (uHCC): A post hoc analysis of patients with nonviral etiology from REFLECT. *First Author: Ari David Baron, Sutter/California Pacific Medical Center, San Francisco, CA*

Background: The randomized phase 3 REFLECT trial demonstrated that LEN was non-inferior to SOR in overall survival (OS; primary endpoint) in 1L uHCC (median: 13.6 months [95% CI, 12.1–14.9] vs 12.3 months [95% CI, 10.4–13.9]) (HR, 0.92; 95% CI, 0.79–1.06). Median progression-free survival (PFS) by independent imaging review (IIR) per mRECIST was 7.3 months (95% CI, 5.6–7.5) for pts in the LEN arm and 3.6 months (95% CI, 3.6–3.7) for pts in the SOR arm (HR, 0.64; 95% CI, 0.55–0.75; $p < 0.0001$). Objective response rate (ORR) by IIR per mRECIST was 40.6% for pts in the LEN arm and 12.4% for pts in the SOR arm (odds ratio, 5.01; 95% CI, 3.59–7.01; $p < 0.0001$) [Kudo 2018, *Lancet*]. Since REFLECT, combination therapies with immunotherapy have become part of the therapeutic arsenal for the treatment of uHCC, and many studies are ongoing. Recent data suggest that viral/nonviral etiology may impact treatment outcomes [Pfister 2021, *Nature*; Rimini 2022, *ESMO Open*]. To add to the current body of evidence, this post hoc analysis evaluated efficacy in pts with nonviral etiology in REFLECT. **Methods:** In REFLECT, pts with uHCC who had not received treatment for advanced disease were randomized to LEN (12 mg/day for bodyweight ≥ 60 kg; 8 mg/day for bodyweight < 60 kg) or SOR (400 mg twice-daily) in 28-day cycles. This post hoc analysis included pts without hepatitis B or C (based on medical history) who were randomized to receive LEN or SOR. PFS, ORR (by IIR per mRECIST), and OS were analyzed. OS and PFS were estimated with the Kaplan-Meier method. **Results:** Of 478 pts randomized to LEN and 476 pts randomized to SOR, 127 and 108 pts, respectively, had nonviral etiology. Among randomized pts with nonviral etiology, median OS was 13.8 mos (95% CI, 10.5–18.7) in the LEN arm and 13.9 months (95% CI, 11.7–17.5) in the SOR arm (HR, 1.03; 95% CI, 0.75–1.43). Median PFS was 7.4 months (95% CI, 5.5–8.7) in pts randomized to LEN with nonviral etiology and 4.0 months (95% CI, 3.6–5.5) in pts randomized to SOR with nonviral etiology (HR, 0.60; 95% CI, 0.42–0.87). ORR was 39.4% (95% CI 30.9–47.9) in pts randomized to LEN with nonviral etiology and 20.4% (95% CI 12.8–28.0) in pts randomized to SOR with nonviral etiology. Fewer (n=34 [26.8%]) pts with nonviral etiology randomized to LEN received anticancer medication during survival follow-up than those randomized to SOR (n=46 [42.6%]). **Conclusions:** In this post hoc analysis, OS, PFS, and ORR in pts randomized to LEN with nonviral etiology were consistent with the overall population of pts randomized to LEN. This post hoc analysis, along with the results of the primary analysis of REFLECT [Kudo 2018, *Lancet*], demonstrates the efficacy of LEN regardless of etiology in uHCC, and supports LEN as a standard of care option for pts with 1L uHCC. Treatment efficacy by etiology should be assessed prospectively in future uHCC trials. Clinical trial information: NCT01761266. Research Sponsor: Eisai Inc., Nutley, NJ, USA, and Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

An open-label, multicenter, adaptive, phase Ib/II study of QL1706 or QL1604 plus bevacizumab as first-line treatment in patients with advanced hepatocellular carcinoma. *First Author: Feng Bi, Department of Abdominal Oncology, West China Hospital of Sichuan University, Chengdu, China*

Background: Cancer immunotherapy has expanded the treatment options for advanced HCC (aHCC). Atezolizumab plus bevacizumab is approved as the standard of care for patients (pts) with aHCC. QL1706 is a novel dual immune checkpoint blockade containing a mixture of anti-PD-1 IgG4 and anti-CTLA4 IgG1 antibodies (Abs). QL1604 is a humanized mAb against PD-1. The anti-PD-1 Ab of QL1706 has the same protein sequence and was produced by using the same single clone selection method with QL1604. Here we report the safety and efficacy results from a Ph Ib/II study of QL1706 or QL1604 plus bevacizumab (beva) as first-line treatment in pts with aHCC. **Methods:** Eligible pts had histologically or clinically confirmed HCC; had BCLC stage B/C disease and Child-Pugh class A and B liver function; were systemic therapy naive; and were not suitable for radical surgery and/or locoregional therapy, or progressed after surgery and/or locoregional therapy. This study included 3 parts. Part 1 included a safety run-in phase and an expansion phase. Patients were enrolled to receive QL1706 5 mg/kg plus beva 15 mg/kg Q3W. In part 2, pts were randomized to receive QL1604 200 mg or QL1706 5 mg/kg plus beva 15 mg/kg Q3W. In part 3, pts were enrolled to receive QL1706 7.5 mg/kg plus beva 15 mg/kg Q3W. Initiation of part 3 was to be determined based on factorial analysis on the results from parts 1 and 2. Each treatment cycle lasted for 21 days. Treatment continued until disease progression or other discontinuation events. The primary endpoint was safety. Secondary endpoints included efficacy etc. **Results:** As of data cutoff (18 Nov 2022), 76 pts were enrolled in parts 1 and 2 (QL1706: 50; QL1604: 26). The baseline characteristics were balanced between the 2 groups. A total of 43 (86%) pts and 23 (88.5%) pts in QL1706 and QL1604 groups experienced TRAEs. For both groups (QL1706 vs QL1604), the most common TRAEs were platelet count decreased (26% vs 23.1%); followed by AST increased (22% vs 19.2%). A total of 17 (34%) pts and 10 (38.5%) pts in QL1706 and QL1604 groups experienced Gr $\geq$ 3 TRAEs. A total of 25 (50%) pts and 5 (19.2%) pts in QL1706 and QL1604 groups experienced irAEs. The most common irAE in the QL1706 group was rash (16%) (vs 3.8% for QL1604). A total of 8 (16%) pts and 6 (23.1%) pts in QL1706 and QL1604 groups experienced TRSAEs. In the efficacy evaluable population, the ORR was 38.3% (18/47) and 15.4% (4/26) in QL1706 and QL1604 groups. The DCR was 74.5% and 69.2% in QL1706 and QL1604 groups. The mPFS was 6.7 months (95% CI: 3.0–11.4) and 5.4 months (95% CI: 2.4–8.5) in QL1706 and QL1604 groups. The mOS was not reached. **Conclusions:** QL1706 5 mg/kg showed comparable safety profile and numerically higher ORR and longer mPFS vs QL1604 when combined with beva as first-line treatment in pts with aHCC. Ph III head-to-head clinical trial to compare QL1706 or anti-PD-1/PD-L1 Ab plus beva in this population has been planned. Clinical trial information: NCT05603039. Safety and efficacy of transarterial chemoembolization combined with tyrosine kinase inhibitors and camrelizumab in the treatment of patients with advanced unresectable hepatocellular carcinoma. *First Author: Jinpeng Li, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China*

Background: Combined systemic and local therapy is a promising treatment strategy for patients with advanced hepatocellular carcinoma (HCC). Transarterial chemoembolization (TACE), tyrosine kinase inhibitors (TKI) and PD-1 antibodies are all recommended for patients with unresectable HCC (uHCC). This study was aimed to evaluate the efficacy and safety of TACE combined with TKIs and camrelizumab in the treatment of uHCC. **Methods:** In this multicenter, single-arm phase II trial (ChiCTR2000039508), patients with intermediate-stage uHCC who had a Child-Pugh score ≤ 7 and had not received prior systemic anti-cancer treatment would receive treatment with TACE followed by immunotherapy with camrelizumab 200 mg every 3 weeks plus a TKI agent selected from lenvatinib (12 mg/day for bodyweight ≥ 60 kg or 8 mg/day for bodyweight < 60 kg), sorafenib 400 mg bid or donafenib 200 mg bid until intolerable toxicity or disease progression. During the study treatment, patients assessed as eligible for resection would undergo surgery. The primary endpoint was objective response rate (ORR) per modified RECIST. Secondary endpoints included progression-free survival (PFS), disease control rate (DCR), duration of response (DOR) and overall survival (OS). **Results:** From September 2020 to November 2021, 87 patients (81 men and 6 women; median age, 56 years) were enrolled. Among them, 43 (49.4%) patients had extrahepatic metastases, and 65 (74.7%) patients had HBV infection. As of September 28, 2022, the median duration of follow-up was 13.6 (0.83–24.9) months. A total of 34 patients (39.1%) died, and the median OS was not reached. The median PFS was 10.5 months (95% CI: 7.8–13.1). The ORR rate was 71.3% (62/87), and the DCR rate was 89.7% (78/87) per mRECIST. According to RECIST version 1.1, the ORR rate was 35.6% (31/87), and the DCR rate was 87.4% (76/87). The ORR and PFS showed consistent benefits in subgroups based on ECOG score, HBV infection, baseline alpha-fetoprotein level, combined TKI, and the number of TACE treatments. Ten patients (11.5%) successfully underwent conversion therapy and all achieved R0 resection. Two patients achieved a complete pathological response (pCR) and four achieved a major pathological response (MPR). The most common AEs were hypoproteinemia (92%), elevated lactate dehydrogenase (80.5%), elevated glutamic oxaloacetic transaminase (79.3%), elevated bilirubin (78.2%), abdominal pain (62.1%), nausea (33.3%), and RCEP (26.4%). The incidence of grade 3–4 adverse reactions was 67.8%, and no treatment-related deaths occurred. **Conclusions:** TACE combined with TKI and camrelizumab showed promising clinical benefits. It can effectively control tumor progression and provide opportunities for resection with acceptable safety, which will bring great benefits to uHCC. Clinical trial information: ChiCTR2000039508. Research Sponsor: Jiangsu Hengrui Medicine.

Safety and efficacy of allogeneic natural killer cells in combination with pembrolizumab in patients with chemotherapy-refractory biliary tract cancer: A multicenter open-label phase 1/2a trial. *First Author: Galam Leem, Yonsei University College of Medicine, Severance Hospital, Seoul, South Korea*

Background: This study investigated the administration of combination therapy, allogeneic natural killer (NK) cells and pembrolizumab, in the treatment of advanced biliary tract cancer to determine the safety and tolerability (phase 1), and the efficacy and safety (phase 2a). **Methods:** Forty patients (phase 1, n=6; phase 2a, n=34) were enrolled between December 2019 and June 2021. The patients were inoperable and no further conventional chemotherapy was anticipated after finishing at least one chemotherapy. The patients received 3x10⁶ NK cells/kg of highly activated allogeneic NK cells (“SMT-NK”) on weeks 1 and 2 and 200 mg of pembrolizumab (Keytruda) on week 1. No treatment was given in week 3. This 3-week schedule (1 cycle) was repeated until confirmed disease progression, intolerable adverse events (AEs), patient withdrawal of consent, or finishing the maximum treatment schedule. The tumor response was evaluated after every three cycles. **Results:** In phase 1, 4 patients (66.7%) experienced 7 AEs, but no severe AEs directly related to the combination of the two drugs was observed. In phase 2a, 126 AEs occurred in 29 patients (85.3%). Severe AEs (≥ grade 3) were reported in 16 patients (47.1%). No dose limiting toxicity was reported. The overall response rate (ORR) was 17.4% in the full-analysis set and 50.0% in the per-protocol set. **Conclusions:** SMT-NKs plus pembrolizumab resulted in no severe AEs directly related to the drug combination. The combination therapy also exerted antitumor activity with improved efficacy compared to recent monotherapy with pembrolizumab in patients with advanced biliary tract cancer. A multi-center, randomized, placebo-controlled, open-label, phase 2b clinical trials to evaluate the antitumor activity of combination therapy of SMT-NKs and pembrolizumab versus pembrolizumab monotherapy in patients with advanced biliary tract cancer is now ongoing with the aim of enrolling 128 patients (ClinicalTrials.gov identifier: NCT05429697). To date, 38 patients have been enrolled and randomly assigned to each group. Within the median follow up period of 5.3 months, the disease control rate (DCR, complete response + partial response) was 27.2% in the combination therapy of SMT-NKs and pembrolizumab group, and 7.1% in the pembrolizumab monotherapy group. The ORR was 54.5% in the combination therapy group and 42.9% in the monotherapy group. So far, no severe drug-related AEs was reported. Clinical trial information: NCT03937895. Research Sponsor: SMT Bio Co.

Tislelizumab (TIS) versus sorafenib (SOR) in first-line (1L) treatment of unresectable hepatocellular carcinoma (HCC): The RATIONALE-301 European/North American (EU/NA) subgroup. *First Author: Arndt Vogel, Hannover Medical School, Hannover, Germany*

Background: HCC is one of the most commonly diagnosed cancers globally. Most cases occur in Asia, although a number of patients (pts) are affected in Europe and North America. In the phase 3, open-label RATIONALE-301 trial (NCT03412773), TIS, a PD-1 inhibitor, showed non-inferior overall survival (OS) versus SOR (hazard ratio 0.85, 95% CI: 0.71, 1.02), and a favorable safety profile, in 1L treatment of pts with unresectable HCC. Here, efficacy and safety of TIS versus SOR in the RATIONALE-301 EU/NA subgroup were compared with the overall population (OP). **Methods:** Systemic therapy-naïve adults with histologically confirmed HCC were randomized (1:1) to receive TIS (200 mg IV Q3W) or SOR (400 mg orally BID) until disease progression, intolerable toxicity, or withdrawal. The primary endpoint was OS; secondary endpoints included objective response rate (ORR), progression-free survival (PFS), and duration of response (DoR) by blinded independent review committee per RECIST v1.1, and safety. **Results:** In the EU/NA subgroup (172/674 pts randomized), at data cutoff (July 11, 2022), median (m) OS follow-up was 37.9 months (mo) (TIS) vs 38.5 mo (SOR). At baseline, fewer pts in the EU/NA subgroup had Barcelona Clinic Liver Cancer (BCLC) Stage C disease (70% vs 78%) and extrahepatic spread (51% vs 62%), and more had a non-viral etiology (60% vs 24%) or underlying HCV infection (28% vs 13%) than in the OP, respectively. Distribution of other baseline characteristics was generally similar between the EU/NA subgroup and the OP. Efficacy data in the EU/NA subgroup were consistent with the OP. Numerically longer mOS and mDoR, higher ORR, and similar mPFS were observed with TIS versus SOR in the EU/NA subgroup. In the EU/NA safety population, incidence of ≥grade 3 treatment-emergent adverse events (TEAEs; 46% vs 66%), ≥grade 3 treatment-related TEAEs (TRAES; 17% vs 50%), and TRAES leading to discontinuation (9% vs 15%) was lower with TIS versus SOR, respectively, similar to the OP. **Conclusions:** In the RATIONALE-301 EU/NA subgroup, mOS of TIS was non-inferior versus SOR, consistent with the findings from the OP. Numerically longer mOS and mDoR, and a higher ORR was seen with TIS versus SOR in the EU/NA subgroup, which had a higher rate of pts with non-viral etiology and a slightly lower number of pts with advanced-stage disease (BCLC Stage C) compared with the OP. Clinical trial information: NCT03412773. Research Sponsor: BeiGene, Ltd.; This study was sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Adeline Lum Nde, PhD, of Ashfield MedComms, an Inizio company, and was funded by BeiGene, Ltd.

Economic evaluation for the US of durvalumab plus gemcitabine and cisplatin (DGC) in advanced biliary tract cancer (BTC). *First Author: Osama Aqel, Center for Health Outcomes and Pharmacoeconomic Research, University of Arizona, Tucson, AZ*

Background: BTCs are a group of relatively rare malignancies comprised of intrahepatic cholangiocarcinoma (CCA), extrahepatic CCA, and gallbladder cancer. The first-line standard of care of gemcitabine and cisplatin (GC) has remained unchanged for the past decade, highlighting the need for novel therapies. The TOPAZ-3 trial demonstrated improved progression-free (PFS) and overall survival (OS) with durvalumab added to GC. This trial-based economic evaluation estimated the cost-effectiveness/utility of DGC versus GC from a US payer perspective. **Methods:** A three state partitioned survival model (Progression-free, Progressed, Death) was developed to compare costs and overall survival outcomes associated with both treatments. PFS and OS curves were digitized, and parametric functions fitted. A 5-year time horizon with a 3% discount rate/year was considered. Costs of treatment (average sales price), administration, and monitoring parameters were sourced from Centers for Medicare & Medicaid Services databases; costs of adverse event management (grade 3/4 with rate ≥ 5%) were sourced from prior BTC economic evaluations. Life years (LY), quality adjusted life years (QALY), incremental cost-effectiveness and utility ratios (ICER/ICUR) were estimated in a base case (BCA) and probabilistic sensitivity analyses (PSA). A cost-effectiveness acceptability curve (CEAC) was plotted to determine the probability of either treatment being cost-effective over the other at different willingness to pay (WTP) thresholds. **Results:** Exponential regression was used to extrapolate DGC and GC survival curves. As shown in the table, the BCA (PSA) shows an incremental cost of DGC over GC of \$131,350 (\$131,212), incremental LY of 0.38 (0.38), and incremental QALY of 0.26 (0.28). The BCA and (PSA) ICERs reveal an additional 345,658 (345,295) per LY gained (g) and an additional 505,192 (468,614) per QALY. The CEAC curve shows that DGC treatment has a 50% probability of being cost-effective at a WTP threshold value of \$25,000 and 100% probability at a threshold of 1,375,000 or above. **Conclusions:** This economic evaluation demonstrates that, in the setting of advanced BTC, DGC is associated with a slight improvement in LY and QALY, yet at a marked incremental cost, requiring a very high WTP threshold. Research Sponsor: None.

BCA (PSA).			
Cost	GC \$15,716 (\$15,812)	DGC \$147,066 (\$147,024)	Difference \$131,350 (\$131,212)
LY	1.07 (1.07)	1.45 (1.45)	0.38 (0.38)
QALY	0.74 (0.77)	1.00 (1.05)	0.26 (0.28)
ICER	\$345,658/LYg (\$345,295/LYg)		
ICUR	\$505,192/QALYg (\$468,614/QALYg)		

Interpretation of ICER and ICUR: incremental cost to gain resp. 1 LY or 1 QALY.

Poster Session

Impact of risk factors on overall survival (OS) in patients (pts) with unresectable hepatocellular carcinoma (HCC) treated with first-line (1L) tislelizumab (TIS). *First Author: Masatoshi Kudo, Kindai University Faculty of Medicine, Osaka, Osaka, Japan*

Background: TIS is a monoclonal antibody with high affinity and specificity for programmed cell death protein 1. In the phase 3 RATIONALE-301 trial (NCT03412773), TIS demonstrated non-inferior OS versus sorafenib (SOR) as 1L monotherapy for unresectable HCC (median [m] OS 15.9 [TIS] vs 14.1 [SOR] months [mo]; hazard ratio [HR] 0.85), with a favorable safety profile. Certain biomarkers are potential prognostic factors and may impact OS in 1L treatment of unresectable HCC; this exploratory analysis examined the effect of albumin-bilirubin (ALBI) grade, platelet count, platelet-lymphocyte ratio (PLR), and neutrophil-lymphocyte ratio (NLR) as predictors of OS in RATIONALE-301. **Methods:** Systemic therapy-naïve adults with histologically confirmed HCC (Barcelona Clinic Liver Cancer Stage C or Stage B that was not amenable to or progressed after loco-regional therapy; Child-Pugh A), with ≥1 measurable lesion per RECIST v1.1, and an ECOG performance status ≤1 were randomized 1:1 to receive TIS (200 mg IV Q3W) or SOR (400 mg orally BID) until disease progression, intolerable toxicity, or withdrawal. The primary endpoint was OS. **Results:** Overall, 674 pts were randomized (TIS n=342; SOR n=332). At data cutoff (July 11, 2022), minimum study follow-up was 33 mo. Demographic and baseline characteristics for biomarkers were generally balanced across arms. Numerically longer (≥2 mo) mOS was observed in biomarker subgroups ALBI grade 1 vs 2 and NLR ≤3 vs >3 with TIS or SOR, and PLR ≤141 vs >141 with TIS. Both platelet count threshold subgroups were accompanied by a smaller difference (<2 mo) in mOS between biomarker cutoffs, which may indicate limited prognostic value for this biomarker. TIS also demonstrated numerically longer OS versus SOR in the same subgroup categories: ALBI grade 1, PLR ≤141, and NLR ≤3. **Conclusions:** This analysis suggests that ALBI grade, PLR, and NLR could have prognostic value for OS, irrespective of treatment. TIS demonstrated numerically improved mOS compared with SOR for PLR ≤141 and NLR ≤3, suggesting higher benefit for pts with a more favorable balance between systemic inflammation and immunity. Clinical trial information: NCT03412773. Research Sponsor: BeiGene, Ltd.; This study was sponsored by BeiGene, Ltd. A novel patient-centric longitudinal data registry platform to generate insights into real-world cholangiocarcinoma (CCA) clinical practice. *First Author: Amanda Nottke, Invitae, San Francisco, CA*

Background: Treatment of advanced CCA has changed dramatically over the past five years with the advent of molecularly targeted therapy, now approved in the 2nd line and beyond. However, real world utilization of molecular profiling and targeted therapy is still unknown and these data are critical to empower treatment decision-making. **Methods:** In 2019, the Cholangiocarcinoma Foundation (CCF) and Ciitizen (a wholly owned subsidiary of Invitae Corporation) collaboratively launched a registry platform that directly consents patients and collects comprehensive medical records. De-identified data including clinical characteristics, molecular testing, interventions, and outcomes are extracted and standardized for research use. The data is longitudinal with regularly planned updates; registry participants can be re-engaged to obtain additional data and communicate tailored insights. **Results:** We quantified the rate of molecular testing, the presence of targetable biomarkers, and the utilization and outcomes on matched targeted therapies for 372 individuals with CCA. 328 (88.2%) individuals had molecular testing, with the identified targetable mutations and matched therapies reported. Of 328 individuals who had molecular testing, 111 (33.8%) individuals had one or more targetable mutations (116 mutations total). Only 46% (51) of individuals with targetable mutations received targeted therapy. Of the 54% (60) individuals with targetable mutations that did not receive any matched therapy, the majority (61.7%, 37) were in early disease or first line of treatment and therefore not yet eligible for targeted therapy. These individuals will be informed that based on their molecular profile, a targeted therapy may be an option, and suggest they discuss with their treating physician. **Conclusions:** A novel prospectively-maintained database registry for CCA has been formed in collaboration between a patient advocacy organization (CCF) and industry (Invitae). Prevalence of actionable biomarkers was higher than historically expected and may reflect patient utilization bias of the registry platform. Molecular profiling and access to targeted therapeutics remains suboptimal at this time in CCA. Future directions for the registry include identifying and targeting disparities in care and supporting biopharmaceutical development and regulatory decisions. Research Sponsor: Invitae Corporation.

Sintilimab plus gemcitabine and cisplatin as a first-line treatment for patients with advanced biliary tract cancer: A biomolecular exploratory, phase II clinical trial. *First Author: Zhen-gang Yuan, Department of Oncology, Eastern Hepatobiliary Surgery Hospital, Shanghai, China*

Background: The prognosis of biliary tract cancer (BTC) remains unsatisfactory. Thus, this study aimed to determine the efficacy, safety, and predictive biomarkers of the immune checkpoint inhibitor sintilimab in combination with gemcitabine and cisplatin (GemCis) in advanced BTCs. **Methods:** In this single-arm, phase II study (Trial registration number: ChiCTR2000036652), gemcitabine (1000 mg/m²) plus cisplatin (25 mg/m²) were administered on days 1 and 8, respectively, while 200 mg sintilimab was administered on day 1 of each 21-day cycle for 6–8 weeks, followed by sintilimab alone up to 2 years. The primary endpoint was overall survival (OS). The second endpoints were objective response rate (ORR), progression-free survival (PFS), and disease control rate, assessed using RECIST V.1.1. Multiomics biomarkers associated with clinical response were assessed as exploratory objectives. **Results:** Thirty patients were enrolled between August 2020 and May 2022. The median follow-up duration, OS, and PFS were 12.3 months (95% confidence interval [CI]: 9.1–16.0), 15.9 months (95% CI: 8.6–not reached), and 5.1 months (95% CI: 4.3–8.7), respectively. Here, 36.7% of patients were found to achieve an objective response. The most common grade 3 or 4 treatment-related adverse events were thrombocytopenia (33.3%), with no reported deaths nor unexpected safety events. Biomarker analysis indicated that patients with homologous recombination repair pathway gene alterations (median, PFS: 9.8 vs. 4.5 months, $p = 0.023$; OS: NR vs. 9.0 months, $p = 0.014$; ORR: 77.8% vs. 19%, $p = 0.004$) or loss-of-function mutations in chromatin remodeling genes (median, PFS: 8.7 vs. 4.2 months, $p = 0.021$; ORR: 63.6% vs. 21.1%, $p = 0.046$) presented better tumor response and survival outcomes. Furthermore, transcriptome analysis of the tumor immune microenvironment revealed a markedly longer PFS, and tumor response were associated with higher expression of 3-gene effector T cell signature (median, PFS: 7.8 vs. 4.3 months, $p = 0.02$; ORR: 64.2% vs. 7.1%, $p = 0.004$) and 18-gene inflamed T cell signature (median, PFS: 8.6 vs. 4.3 months, $p = 0.01$; ORR: 64.2% vs. 7.1%, $p = 0.004$). Moreover, our findings highlighted the adverse predictive value of mast cells in immuno-chemotherapy for BTCs for the first time. **Conclusions:** Sintilimab plus GemCis displayed a promising antitumor activity and acceptable safety profile as a first-line treatment in patients with advanced BTC. Multiomics potential predictive biomarkers are identified and warrant further verification. Clinical trial information: ChiCTR2000036652. Research Sponsor: None.

Liquid-biopsy detection of FGFR2 and other actionable rearrangements in GI malignancies. *First Author: Pashtoon Murtaza Kasi, Weill Cornell Medicine, Englander Institute of Precision Medicine, New York Presbyterian Hospital, New York, NY*

Background: Actionable rearrangements (RE) represent an emerging therapeutic target for GI malignancies. However, there remains uncertainty whether liquid biopsy (LBx) assays testing circulating tumor DNA (ctDNA) can detect RE with the same fidelity as tissue biopsy. Here we report the performance of ctDNA-based comprehensive genomic profiling (CGP) for the detection of RE leveraging an FDA-approved >300-gene platform, with a focus on data from patients with GI malignancies. **Methods:** An institutional research database of clinical CGP results for tissue biopsy (TBx, FoundationOneCDx) and LBx (FoundationOneLiquid CDx) from patients with cancers of the GI tract was reviewed. Sensitivity for FGFR2 RE was studied in patients with cholangiocarcinoma (CCA) or carcinoma of unknown primary (CUP) and both TBx and LBx CGP available. **Results:** Across 7870 GI LBx, 1094 predicted pathogenic RE were detected in 826 cases (10%) including 283 oncogenic kinase RE, 686 inactivating RE, and 125 other gain-of-function RE. FGFR2 RE was the most frequently rearranged gene, enriched in CCA (4.4%, 37/833) and stomach (3.0%, 11/368). EGFR RE (38) occurred across 6 cancer types and included 8 fusions, 15 c-terminal truncations, 4 intragenic deletions/inversions, and 3 kinase domain duplications. BRAF RE (31) were detected among in colorectal (22) and pancreas (9) cases. LBx detected 44 exon 3 skipping (protein stabilizing) RE in CTNNB1 (beta-catenin) across all samples. Other frequent activating RE were detected in MYC (36), FGFR3, RET, ROS1 (21 each), and ALK (13). Potentially targetable inactivating RE were detected in BRCA1 (28), ARID1A (24), STK11 (22), PTEN (17), TSC2 (14), and BRCA2 (8). Focusing on CCA, FGFR2 RE were more prevalent in cases with elevated ($\geq 1\%$) ctDNA tumor fraction (TF, 26/342, 7.6%), matching the prevalence in TBx (7.8%, 505/6,492) with a similar spectrum of fusion partners seen for both TBx and LBx (30% BICC1, 70% rare for both). In 13 CCA/CUP patients positive for FGFR2 RE by TBx, LBx detected 12 (92%) including 8 different fusion partners; the false negative case had TF <1%. In 11 CCA LBx samples with FGFR2 resistance mutations detected, LBx CGP successfully detected a driver FGFR2 RE in 10 and driver C382R mutation in 1. **Conclusions:** Rearrangements are represented across GI malignancies, including many that result in known oncogenic drivers that may be targetable with available therapies. We observe reliable detection of FGFR2 fusions in ctDNA, in contrast to some prior publications. ctDNA represents a pragmatic analyte for detection of rearrangements and other actionable alterations, offering timely result return when tissue is inadequate or unavailable. Phase II clinical trial of olaparib plus pembrolizumab in the treatment of patients with advanced biliary tract cancer. *First Author: James O'Bryan, MedStar Georgetown University Hospital, Washington, DC*

Background: Over 20% of biliary tract cancers (BTCs) carry mutations in homologous recombination DNA damage repair (HR-DDR) pathways. The PARP inhibitor olaparib (O) blocks tumor DNA repair and may induce response in BTCs with such mutations. Furthermore, HR-DDR mutations may engender neoantigens that improve response to immune checkpoint inhibitors. We propose that treatment with O and the anti-PD-1 monoclonal antibody pembrolizumab (P) will produce a durable anti-tumor response to BTC, especially in patients with HR-DDR mutations. **Methods:** Consent for participation was obtained. Eligibility criteria included age > 18 years with an ECOG score of ≤ 1 and a histologic diagnosis of advanced or metastatic BTC with progression of disease (PD) on prior first-line therapy. Treatment featured oral O (300 mg twice daily) plus intravenous P (200 mg every 3 weeks). Response was measured radiographically using RECIST 1.1 guidelines. The primary endpoint was overall response rate (ORR), with the alternative hypothesis that O + P would improve ORR compared to historical controls (versus the null hypothesis of no improvement). Type I and II error rates were set at 5% and 15%, respectively. Simon's optimal two-stage design was used. Planned sample size was 13 patients in the first stage. Continuation to the second stage would only occur if ≥ 3 patients demonstrated response. The second stage was planned to include 20 additional patients (N = 33 total), which was based on the number needed to demonstrate an improvement in ORR from 17.5% in historical controls to at least 35.0%. **Results:** Of 21 eligible patients, 14 were accrued between June 2020 and March 2022, and 13 were evaluable for efficacy. Patients had a median age of 63 years, were primarily female (71%), Caucasian (50%), and with metastatic disease (93%). Patients received a mean of 6.5 cycles of therapy. Best treatment response included partial response (N = 2), stable disease (N = 5), and PD (N = 6). The ORR was 15.3% (95% CI = 0.02–0.45). Of the partial responders, 1 patient achieved a duration of response of 8 months (mos), and 1 has ongoing response at 24 mos. Median (med) time to progression was 7.7 mos (95% CI = 1.2–9.3), med progression free survival was 5.5 mos (95% CI = 1.2–7.7), and med overall survival was 11.9 mos (95% CI = 5.5–15.4). Most patients (64%) developed at least one treatment-related adverse event (trAE). Grade 3 trAEs were experienced in 5 patients (36%) and included anemia (N = 3), diarrhea (N = 1), and transaminitis (N = 1). **Conclusions:** While O + P has acceptable safety and toxicity, the study did not achieve significant improvement in the primary endpoint. However, the two patients who demonstrated durable treatment response were found to have HR-DDR tumor mutations (including *RAD51*, *ATM*, and *BRCA2*), necessitating further research into the efficacy of O + P for patients with similar tumor genomes. Clinical trial information: NCT04306367. Research Sponsor: Merck & Co.

Characterizing *KRAS* allele variants within biliary tract cancers. *First Author: Gordon Taylor Moffat, Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: Biliary tract cancers (BTC) are aggressive malignancies with a poor 5-year survival rate and growing incidence globally. *KRAS* mutations (mut) in BTC are associated with a poor prognosis; however, PD-L1 inhibition with Durvalumab may lead to an improved survival with *KRAS* mut (TOPAZ-1 trial). It is important to understand the genomic landscape and immunophenotype of *KRAS* mut in BTC given the advent of immunotherapeutics and small molecular inhibitors targeting *KRAS* mut. **Methods:** A retrospective pooled analysis was performed from the following patient databases: Princess Margaret Cancer Centre, MD Anderson Cancer Center, Foundation Medicine, along with the publicly accessible cBioPortal for Cancer Genomics that includes the American Association for Cancer Research Project Genie cancer registry of real-world data assembled between 19 leading international cancer centers. Any overlapping cases were excluded. Patients included had a diagnosis of a BTC and completed molecular testing from January 2017 to December 2022. Cohort demographics, *KRAS* allelic variants, concurrent genetic aberrations, and immune biomarkers (PD-L1, TMB, MSI and gLOH) were summarized. Log-rank, Wilcoxon, and Kaplan-Meier tests were conducted for survival analysis. **Results:** 5,813 BTC patients were included, and 1000 patients (17.2%) had a *KRAS* mutation. The prevalence of *KRAS* mut was higher in extra-hepatic cholangiocarcinoma (EH-CCA) (36.1%) and perihilar (PH)-CCA (28.6%) than in intra-hepatic (IH)-CCA (11.82%) and gallbladder cancer (GBC) (7.6%). The most common *KRAS* allelic variant was G12D, and the most common co-mutation was TP53, except in PH-CCA, which was G12V and SMAD4, respectively. In this cohort, race was primarily White (73%). The most prevalent variant in North America was G12D, while G12V and Q61H were more prevalent with genomic African American and genomic East Asian descent, respectively. For patients with *KRAS* mut, GBC had the most PD-L1 high positivity (17%) compared to IH-CCA (7%) and EH-CCA (3%), along with the most MSI-H phenotypes and the highest mean and median TMB compared to other sites, especially in G12V and Q61H variant patients. Genomic loss of heterozygosity was low among all groups. In the survival analysis, patients with the G12V allele subtype had the lowest OS at 17.8 months, followed by Q61H (22.8 months) and G12D (25.1 months) ($p = 0.022$). Survival analysis with *KRAS* co-mut (TP53, SMAD4, CDK2NA, or additional *KRAS* mut) was not significant ($p = 0.7$). In a co-variance analysis of *KRAS* variants and tumour site, there was no difference in IH-CCA and GBC but lower OS in Q61H variants in PH-CCA and G12V variants in EH-CCA ($p = 0.0081$). **Conclusions:** This large series adds to the growing body of comprehensive genomic and immune landscape data of *KRAS* mut in BTC and will be of value in planning specific therapies in this heterogeneous group. Immune profiling studies are ongoing to further describe the immunophenotype of this subset. Research Sponsor: None.

Trastuzumab (T) plus gemcitabine-cisplatin (GC) for treatment naïve HER2 positive biliary tract adenocarcinomas (BTC): A multicentre open-label, phase II study (TAB). *First Author: Vikas S. Ostwal, Tata Memorial Hospital (HBNI), Mumbai, India*

Background: HER2 over-expression or amplification is seen in 4%-16% of BTCs and is a therapeutic target of interest. Gemcitabine-cisplatin (GC) is one of the standard regimens of choice in advanced BTCs. We aimed to evaluate the clinical activity of GC plus anti-HER2 antibody trastuzumab as initial treatment in HER2-positive BTC. **Methods:** This study was an investigator-initiated, open-label, single-arm, multi institutional, phase II trial in patients (pts) aged 18 years or older with HER2-positive (defined as IHC 3+ or IHC 2+ and FISH positive), treatment naïve BTCs. Patients received GC (Gem 1000 mg/m² IV and Cisplatin 25mg/m² IV on day 1 and 8, q 3 weeks) combined with Trastuzumab at 8mg/kg as initial dose followed by 6mg/kg q 3-weekly till disease progression (PD) or unacceptable toxicities. The primary end-point of the study was an improvement in 6-month progression free survival (PFS) from 40% (historical cohort) to 60% in the study arm. Next generation sequencing to evaluate HER2 and other mutations was conducted on the tissue samples of the patients screened for this study. **Results:** From March 2020 to August 2022, of the 876 patients were screened for HER2 status, 118 (13.4%) were found to have HER2 positive status and 90 of them were enrolled into the study. A majority of patients had GBC (95.6%) and at-least 2 sites of metastatic disease beyond primary (77.8%). With a median follow up of 8.5 months, 72 patients had PD and the median PFS was 7.95 months (95% CI: 6.84 - 9.06; median overall survival (OS) was 9.95 months (95% CI: 9.25 - 10.66). Partial responses (PR) were seen in 8 patients (8.9%) and 61 had stable disease (67.7%) for a disease control rate of 76.6%. Common chemotherapy-related grade 3 or 4 adverse events were anemia [26 (28.9%)], neutropenia [18(20%)] and thrombocytopenia [8(8.9%)] while one patient has Trastuzumab related asymptomatic fall in cardiac ejection fraction ($>=10\%$). The presence of isolated TP53 mutations predicted for inferior PFS compared to patients with other mutations (TERT promoter, HER2, PIK3CA etc) or no detected mutations (6.51 months vs. 12.02 months vs. 10.58 months; $p<0.001$). **Conclusions:** The combination of GC and trastuzumab shows near doubling of survival in treatment naïve HER2 positive BTC in a prospective manner for the first time and sets the stage for a larger phase III trial with the combination. Evaluating mutations like TP53, HER2, TERT promoter and PIK3CA along with HER2 testing could be considered as a preferred modality to select these patients for anti HER2 therapy. Clinical trial information: CTR1/2019/11/021955. Research Sponsor: Educational grants to the institute from redxy's lab pvt ltd for this study.

Individual patient-level data validation of surrogate and modified endpoints for immunotherapy in advanced hepatocellular carcinoma: Post-hoc analysis of IMbrave150 and real-world observations. *First Author: Mir Lim, UT Southwestern Medical Center, Dallas, TX*

Background: Immune checkpoint inhibitors (ICIs) have become the preferred treatment for advanced hepatocellular carcinoma (HCC). Surrogate endpoints including overall response rate (ORR) and progression-free survival (PFS) are preferred outcome measures in early-phase trials. However, ICIs can induce atypical patterns of response and progression, calling into question the validity of surrogate endpoints as predictive of overall survival (OS) benefit. We performed a post-hoc analysis of a large, randomized phase 3 clinical trial (IMbrave150) and cross-sectional analysis of a multi-institution real-world environment (RWE) to assess the OS surrogacy of ORR and PFS using Response Evaluation Criteria in Solid Tumors (RECIST), modified RECIST (mRECIST), or immune-modified RECIST (imRECIST) in patients treated with ICIs. **Methods:** The IMbrave150 cohort in our analysis included 279 out of 336 patients treated with atezolizumab and bevacizumab in the intent-to-treat population. The RWE cohort included 328 patients with Child-Pugh A or B disease treated in the first or subsequent-line setting with anti-PD-1/L1 therapies. RECIST, mRECIST, and imRECIST ORR and PFS data for the IMbrave150 cohort was determined by investigators and central review, while RECIST ORR and PFS data for the RWE cohort was determined by treating providers or retrospective review. **Results:** In the IMbrave150 and RWE cohorts, Child-Pugh A patients treated in the first-line setting with CR/PR showed greater OS versus patients with SD/PD (IMbrave150: HR 0.16, 95% CI 0.10-0.26; RWE: HR 0.25, 95% CI 0.15-0.43). CR was associated with the greatest OS benefit, followed by PR, SD, and PD. Patients treated in the second-line setting or with Child-Pugh B disease showed that ORR was able to discriminate OS benefit but hazard ratios were closer to the null. In both cohorts, there was a positive rank correlation between RECIST PFS and OS (IMbrave150: Kendall's $\tau = 0.44$, $p < 0.001$); RWE: Kendall's $\tau = 0.52$, $p < 0.001$). However, only 31-46% of the variance in OS rankings was explained by PFS rankings. mRECIST PFS and imRECIST PFS showed a positive rank correlation with OS, with an explained variance of 30% and 38% for mRECIST and imRECIST, respectively. **Conclusions:** Our results suggest that RECIST ORR is a robust surrogate endpoint in HCC treated with ICIs. In contrast, the explained variance between RECIST PFS and OS in both the IMbrave and RWE cohorts was limited. This may reflect the impact of ICIs on response to subsequent therapies which may extend OS benefit. Although prior studies have proposed that modifications to RECIST may lead to more accurate surrogate markers, mRECIST and imRECIST ORR or PFS in HCC treated with ICIs were not associated with greater predictive performance compared to RECIST. Salvage ipilimumab plus nivolumab in advanced hepatocellular carcinoma after prior anti-PD-(L)1 blockade. *First Author: Stephanie Leigh Alden, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins Hospital, Baltimore, MD*

Background: Combination PD-(L)1/CTLA-4 blockade is approved in patients with advanced hepatocellular carcinoma (HCC) in the first line or after treatment with sorafenib, but it is unclear if combination therapy has efficacy after treatment with anti-PD-(L)1 alone or in combination with a multitargeted inhibitor. We evaluated responses to ipilimumab plus nivolumab in patients with advanced HCC who previously received anti-PD-(L)1 to assess the efficacy and safety of this regimen. **Methods:** We performed a multi-center retrospective review of patients 18 years of age or older with a diagnosis of HCC based on histology or imaging who had received at least one dose of anti-PD-(L)1 therapy prior to receiving ipilimumab plus nivolumab as a subsequent line of therapy. All patients had imaging and/or laboratory monitoring to monitor for disease progression. **Results:** Our cohort contained 32 patients, with a majority being male (88%, $n = 28$) and a median age of 67 years. All patients were Child Pugh A (66%, $n = 21$) or B (34%, $n = 11$) at the start of treatment, with most having an ECOG performance status of 0-1 (84%, $n = 27$). The median number of prior lines of therapy was 2 (range 1-8). Prior anti-PD-(L)1 containing regimens included atezolizumab plus bevacizumab (50%, $n = 16$), other VEGF plus anti-PD-(L)1 combination (31%, $n = 10$), and anti-PD-(L)1 monotherapy (19%, $n = 6$). The objective response rate (ORR) was 22% (1 CR, (3%), 6 PR (19%)), with remaining responses including 8 SD (25%), 16 PD (50%), and 1 NE (3%). Among patients who had an objective response to ipilimumab plus nivolumab, none had an objective response to prior anti-PD-(L)1 treatments. Response rates were similar across major clinical (obese vs. non-obese) and etiological (viral vs. non-viral) subsets of HCC. Response to ipilimumab plus nivolumab was associated with improved PFS and OS: median PFS for PD/SD/NE 2.4 months (95% CI: 2.1-NR) vs. PR/CR not reached (NR) (95% CI: 7.5-NR), $p = 0.004$, and OS for PD/SD/NE 5.9 months (95% CI: 3.1-NR) vs. PR/CR NR (95% CI: NR-NR), $p = 0.02$. Immune related adverse events (irAEs) were reported in 13 patients (41%), and 6 patients experienced grade 3-4 irAEs (19%). One patient in our cohort experienced a fatal irAE (autoimmune hepatitis), and 5 patients discontinued therapy due to irAEs. **Conclusions:** This study demonstrates that ipilimumab plus nivolumab has clinical activity in patients with advanced HCC who previously received anti-PD-(L)1 therapy with an acceptable safety profile, supporting this regimen as second line immune checkpoint inhibitor therapy in advanced HCC. Further studies are required to determine the optimal sequence of therapies in advanced HCC. Research Sponsor: None.

Poster Session

The metabolic activity assessed by ^{18}F -FDG PET and its correlation with tumor immune status and prognosis in advanced biliary tract cancer patients treated with 1L GemCis plus durvalumab +/-tremelimumab. *First Author: Jeesun Yoon, Medical Oncology, Seoul National University Hospital, Seoul, South Korea*

Background: Gemcitabine/Cisplatin (GemCis) in combination with durvalumab have been established as a global new standard of care in first-line (1L) advanced biliary tract cancer (BTC) in the TOPAZ-1 trial (Oh et al. NEJM Evid, 2022). In our phase 2 study (NCT03046862, Oh et al. Lancet Gastroenterol Hepatol, 2022) exploring GemCis/durvalumab +/- tremelimumab, dynamics of PD-L1 expression after one cycle of treatment has been suggested as a predictor for clinical outcomes. Tumor metabolic activity assessed with ^{18}F -FDG PET is usually associated with prognosis in solid tumors. However, the role of metabolic activity in patients treated with the combination of chemotherapy and immunotherapy has not yet been much studied, in terms of correlation with tumor immune landscape and prognosis. **Methods:** This study recruited 1L, advanced BTC patients in 3 different cohorts. ^{18}F -FDG PET was conducted at baseline (pre-treatment) and at the time of first tumor response evaluation (post-treatment). Metabolic indices of the main tumor lesion were measured, including maximum standardized uptake values (SUVmax), metabolic tumor volume (MTV), and total lesion glycolysis (TLG). Metabolic response evaluation was assessed according to EORTC criteria. Tumor biopsies were done at baseline and after 1 cycle of treatment. **Results:** Among total 124 enrolled patients, 118 patients were included in this PET analysis. The early metabolic response rate was 54.3% (mCR 10.2%, mPR 44.1%, mSD 36.4%, mPD 9.3%). Pre-treatment metabolic parameters (SUVmax, MTV, TLG) were associated with disease status, previous operation history, and CRP level. High pre-treatment SUVmax was associated with poor progression-free survival (PFS) and overall survival (OS). Low post-treatment metabolism and large reduction in metabolism between pre- and post-treatment were associated with responder (vs non-responder), long PFS and long OS. In terms of PD-L1 expression and tumor metabolism, Tumor cell (TC) PD-L1 at pre-treatment was not associated with metabolic parameters; however, high immune cell (IC) PD-L1 expression showed significant association with lower MTV and TLG. In terms of dynamics of PD-L1 and tumor metabolism, post-treatment SUVmax was higher in patients with TC PD-L1 decrease. In patients with decrease of PD-L1 on both TC and IC (worst prognostic group), smaller reduction in metabolism between pre- and post-treatment was observed than the other patients. **Conclusions:** In BTC patients treated with 1L GemCis plus durvalumab +/- tremelimumab, tumor metabolic activity and its dynamics conferred prognostic impact. Furthermore, tumor metabolic activity has a potential to be associated with tumor immune landscape. Clinical trial information: NCT03046862. Efficacy and safety of first-line treatments for patients with advanced hepatocellular carcinoma: A systematic review and network meta-analysis. *First Author: Danni Li, The first hospital of China Medical University, Shen Yang, China*

Background: In recent years, the first-line treatment options for advanced HCC has been increasingly abundant, including transarterial therapies, combination of the immune checkpoint inhibitors (ICIs) and the anti-vascular endothelial growth factor (VEGF) inhibitor, ICIs combined with ICIs, and tyrosine kinase inhibitors. However, it remains to be confusing which treatment pattern would benefit people most, especially for different subgroups. **Methods:** A systematic literature search was conducted on PubMed, Embase, Cochrane Central Register of Controlled Trials, and American Society of Clinical Oncology and European Society of Medical Oncology meeting proceedings for III phase randomized clinical trials (RCTs) investigating first-line treatments for HCC compared with sorafenib. The survival outcomes and toxic effects of RCTs should be reported, including overall survival (OS), progression-free survival (PFS), objective response rate (ORR), and adverse events (AEs) of grade 3 or higher. This systematic review was performed in line with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) Guidelines. The random-effects model was used to calculate the summary hazard ratios (HRs) of OS and PFS. The likelihood of ORR, and AEs of grade 3 or higher was performed by odds ratios (ORs) using a random-effects model. **Results:** A total of 13 phase III RCTs involving 8505 patients were included in this study. Hepatic arterial infusion of oxaliplatin combined with fluorouracil (FOHAIC-1) showed OS, PFS, and ORR benefit over all other first-line therapies, except for the regimen of sorafenib plus HAIC or FOLFOX (OS: HR, 0.88; 95% CI, 0.37-2.09; ORR: OR, 1.53; 95% CI, 0.29-8.13). More importantly, we found that sorafenib combined with FOLFOX was superior to other regimens in patients with HBV infection regarding OS except FOHAIC-1 (HR, 0.57; 95% CI, 0.21-1.52) and tremelimumab-durvalumab (HR, 0.42; 95% CI, 0.16-1.11). While in HCV-infected subgroup, ICIs combined with anti-VEGF inhibitor improved OS benefit compared with tremelimumab-durvalumab (HR, 0.31; 95% CI, 0.11-0.84) and sorafenib (HR, 0.38; 95% CI, 0.16-0.88). HAIC-FO also showed significant OS benefits to other therapies in patients with portal invasion or extrahepatic metastasis. The probability of adverse events of grade 3 or higher was significantly lower with HAIC-FO than with others except for nivolumab (RR, 0.96; 95% CI, 0.51-1.82) and tislelizumab (RR, 0.57; 95% CI, 0.30-1.08). **Conclusions:** This network meta-analysis supports arterial infusion as the first-line treatment for patients with HCC. In portal invasion and extrahepatic metastasis subgroups, HAIC-FO may be a preferred option, with sorafenib combined with FOLFOX as an additional option in those with HBV infection. Besides, novel combination therapy should be focused on in patients with certain subgroups. Research Sponsor: National Natural Science Foundation of China.

Genomic targetability and survival outcomes of biliary tract cancers (BTC): A retrospective cohort study of the Australian Molecular Screening and Therapeutics (MoST) program. *First Author: Subotheni Thavaneswaran, Garvan Institute of Medical Research and The Kinghorn Cancer Centre, Sydney, NSW, Australia*

Background: Despite advances in therapeutic strategies, advanced BTC continue to have poor outcomes. We examined the genomic composition of these cancers and differences in clinical outcomes based on therapies (tx) received. **Methods:** This study included all BTC patients (pts) undergoing comprehensive genomic profiling (CGP) through an Australia-wide precision oncology program, MoST (ACTRN12616000908437). The primary outcome was overall survival (OS) measured from start of first line (1L) systemic tx. The TOPOGRAPH knowledge base was used to determine genomic actionability of alterations identified, tiered by the strength of supportive clinical evidence. Tier 1/2 are regulatory body (TGA or FDA/EMA) approved therapies in BTC; tier 3A is supported by BTC-specific clinical evidence; 3B by clinical evidence inferred from another cancer type; tier 4, pre-clinical evidence. As targeted therapies are only approved in the subsequent-line setting, a further OS analysis was performed from start of second line tx (2L). **Results:** Between December 2016 and August 2022, 223 pts had CGP results available: 170 cholangiocarcinoma (99 intrahepatic, 46 extrahepatic, 25 unspecified primary site) and 53 gallbladder carcinomas. Of 211 (95%) pts who received any systemic tx, median OS (mOS) was 14.6 (95% CI: 12.2–15.4) months (mo) from the start of 1L tx. Pts having received immunotherapy had a mOS of 20.7 vs 13.9 mo (HR 0.67, 0.44–1.04; p=0.07). For 198 pts with actionable findings across TOPOGRAPH tiers, receipt of matched tx (n=37) was associated with a significantly longer mOS of 21.4 (15.0–31.8) compared with receipt of unmatched tx (n=161), mOS 12.6 mo (11.5C15.2, hazard ratio for death, HR 0.46, p<0.001). Pts with tier 1-3 actionable alterations who received matched tx had a median OS of 30.5 mo (95% CI: 18.8 - not reached, NR) compared with 12.1 mo (9.8–16.1, HR 0.39, p=0.02) if only unmatched tx received. Receipt of tier 3B/4 matched tx (n=13) only showed a trend towards longer survival, 15.6 mo vs unmatched 14.0 mo (HR 0.60, p=0.16). For 149 pts who received >1 line of systemic tx: 35 matched and 103 unmatched alone, mOS (measured from 2L tx) was 11.3 (5.7-28.4) compared with 8.3 mo (6.1-10.6) respectively (HR 0.67, p=0.10). A significantly longer OS was seen for matched vs unmatched, in pts receiving tier 1-3 tx: mOS 19.0 mo vs 8.3 mo (HR 0.43, p=0.04), but not for tier 3B/4, mOS 5.6 vs 6.7 mo HR 1.31, p=0.48. The most common genomic alterations were in *TP53* (86, 39%), *KRAS* (59, 26%), *CDKN2A* (43, 19%), and *ARID1A* (29, 13%), while actionable findings commonly involved *IDH1* (26, 12%), *FGFR2* (20, 9%), *ERBB2* (14, 6%), and *BRAF* (11, 5%). **Conclusions:** Receipt of genomically matched tx, particularly those supported by TOPOGRAPH tiers 1-3 evidence was associated with longer OS for pts with advanced BTC. Our results support the greater use of CGP in the management of these pts. Research Sponsor: Australian Government - Medical Research Future Fund; Omico acknowledges support from Servier and Astra Zeneca.

Phase I trial of chimeric anti-GPC3 scFv-CD3 ϵ engineered T cells (CT0180) in patients with advanced hepatocellular carcinoma. *First Author: Yi Zheng, Department of Medical Oncology, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: Hepatocellular carcinoma (HCC) is associated with poor prognosis and high mortality. Glypican-3 (GPC3) is a heparan sulfate proteoglycan overexpressed in 70-80% of HCC and is considered a potential therapeutic target for HCC. We modified T cells with a fusion protein of anti-GPC3 single-chain fragment variable (scFv) linked to CD3 ϵ , which incorporates into the native T cell receptor/CD3 complex forming chimeric anti-GPC3 scFv-CD3 ϵ engineered T cells (CT0180). Preclinically, CT0180 showed competitive antitumor activity but lower cytokine release compared to 28 ζ or BB ζ chimeric antigen receptor T cells. **Methods:** This is an open-label, dose-escalation/exploration phase I study to investigate CT0180 in patients with GPC3-positive advanced HCC (NCT04756648). The study objectives are to evaluate the safety, preliminary efficacy, and cellular pharmacokinetics of CT0180. Eligible patients underwent sequential apheresis, lymphodepletion, and cell infusion. Anti-angiogenic drug monotherapy was allowed after apheresis as bridging therapy. Lymphodepletion regimen comprised fludarabine 25 mg/m² and cyclophosphamide 300 mg/m² daily for 3 days. Five dose levels (DLs, range 1 $\times$ 10⁶-600 $\times$ 10⁶ cells) with up to 3 cycles were explored using i3 + 3 design, and intra-patient dose-escalation was allowed. Data are reported as of 01-Feb-2023. **Results:** From Feb-2021 to Jul-2022, 7 patients with hepatitis B virus-related HCC were treated with CT0180 (one patient each at 1 $\times$ 10⁶ and 30 $\times$ 10⁶ DLs, 3 at 100 $\times$ 10⁶ DL, and 2 at 300 $\times$ 10⁶ DL). The median age was 46 (28-74) years. Patients had prior 2 lines or more systemic therapy, with at least one antiangiogenic tyrosine kinase inhibitor and/or anti-PD-1/PD-L1 immunotherapy. Most common grade 3-4 adverse events were hematologic toxicities, ie lymphopenia and neutropenia, which were considered to be related to lymphodepletion. No dose-limiting toxicities, immune effector cell-associated neurotoxicity syndrome, or treatment-related deaths occurred. Grade 1 cytokine release syndrome was observed in 6 patients; tocilizumab was given in one patient and no glucocorticoids were used. All 7 patients were evaluable for efficacy, in which 2 achieved partial response (PR) (30 $\times$ 10⁶ and 300 $\times$ 10⁶ DL) and 3 achieved stable disease (SD) (10 $\times$ 10⁶, 100 $\times$ 10⁶ and 300 $\times$ 10⁶ DL). One patient sustained PR for 6.7 months, and one patient sustained SD for 6.1 months with follow-up ongoing. Median follow-up time was 15.9 months, and median overall survival was 11.6 months with 3 patients alive at last follow-up. CT0180 transgene copy number ranged 47-4487 copies/ μ g genomic DNA and peaked on either D3 or D7. Interleukin-6 increased and peaked on D1 after CT0180 infusion in most patients. **Conclusions:** CT0180 demonstrated manageable safety profile and promising antitumor potential. Further exploration of CT0180 in HCC is needed. Clinical trial information: NCT04756648. Research Sponsor: CARsgen Therapeutics Ltd.

A prospective, open-label, randomized, controlled trial of radiofrequency ablation versus stereotactic body radiation therapy for recurrent small hepatocellular carcinoma. *First Author: Yaojun Zhang, Department of Hepatobiliary Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Effective treatments are urgently needed to improve the prognosis of patients with recurrent hepatocellular carcinoma (HCC). Previous studies demonstrated that both radiofrequency ablation (RFA) and stereotactic body radiation therapy (SBRT) were promising therapies for recurrent small HCC. This trial was designed to compare the efficacy and safety of RFA versus SBRT in patients with recurrent small HCC. **Methods:** This is a prospective, open label, randomized controlled trial, in which patients aged between 18 and 75 years with recurrent small HCC (occurred more than 3 months after hepatectomy or RFA, a solitary HCC ≤ 5.0 cm in diameter without vascular invasion or extrahepatic metastasis), KPS score ≥ 90 , Child-Pugh score ≤ 6 , adequate organ function, and estimated life expectancy ≥ 6 months were considered eligible. All patients were assigned 1:1 to RFA or SBRT group, and stratification was performed according to tumor size (≤ 2.0 cm or 2.1-5.0 cm). The primary endpoint was 2-year local progression-free survival. Secondary endpoints were progression-free survival, locoregional control, overall survival, and safety. **Results:** A total of 170 patients were recruited during August 2019 to May 2022 (83 in RFA arm and 87 in SBRT arm). In the ITT population, median age was 56 (range, 33-75) and 15 were female. Baseline characteristics were well balanced between treatment arms. Adverse events occurred in RFA and SBRT were mainly grade 1 or grade 2 in severity, and were gastrointestinal and constitutional symptoms, or abnormal laboratory investigations. The most common adverse events were bilirubin increase (14.6%) and AST increase (13.3%) in RFA group vs ALT increase (20.0%) and AST increase (15.3%) in SBRT group. No Grade 3-4 adverse events or mortality were noted. Late adverse events were hardly observed after 3 months. The follow-up of survival data is ongoing. **Conclusions:** Both RFA and SBRT are tolerable and safe for patients with recurrent small HCC. This randomized controlled trial will report the survival outcomes in 2024, which will make an important contribution in clinical decision-making for recurrent small HCC. Clinical trial information: NCT04047173. Research Sponsor: None.

BOLD-100-001 (TRIO039): A phase 1b/2a study of BOLD-100 in combination with FOLFOX chemotherapy in patients with pre-treated advanced gastric and biliary tract cancer: Efficacy and safety analysis. *First Author: Grainne M. O'Kane, Trinity St. James's Cancer Institute, Dublin, Ireland*

Background: BOLD-100 is a first-in-class ruthenium-based anticancer agent in Phase 1b/2a clinical development for the treatment of advanced gastrointestinal (GI) cancers in combination with FOLFOX. BOLD-100 demonstrated synergy in established preclinical models in combination with various anticancer therapies, particularly in resistant cell lines. **Methods:** This is a prospective, Phase 1b/2a study of BOLD-100 in combination with FOLFOX for the treatment of gastrointestinal cancers including biliary tract (BTC) and gastric (GC) cancers. Patients are administered BOLD-100+FOLFOX on day 1 of each 14-day cycle. Four cohorts are treated at the BOLD-100 RP2D of 625 mg/m² with FOLFOX until progressive disease or unacceptable toxicity. BTC and GC pt cohort data are presented. The primary objective is to evaluate the efficacy of BOLD-100 in three clinical endpoints (PFS, OS, and ORR). Disease Control Rates (DCR) for each cohort are also determined. Bayesian modelling is used to continually reassess these endpoints, the posterior probability of superiority to an historical landmark for each endpoint. **Results:** As of 31Dec22, 22 pts with advanced metastatic BTC and 13 pts with advanced GC median age 61 in each cohort were treated. The BTC pts received a median of 2 prior systemic therapies while the GC patients had a median of 3. All patients presented with stage IV disease. 21/22 BTC patients received prior GEM/Cis and while on study a median of 4 cycles BOLD-100+FOLFOX [range 1-19]. Median PFS was 5.0 [3.1, 8.9] months, median OS 7.3 [4.2, 14] months, ORR 6% [1, 23] and DCR 83% [62, 95] in 18 evaluable patients. Four pts remain on treatment and 3 in follow-up. 10/13 GC pts were previously treated with a platinum; currently there are 9 evaluable patients. To the data cut-off, patients received a median of 6 cycles BOLD-100+FOLFOX [1-16]. Median PFS was 5.5 [2.8, 13] months and median OS 15 [5.4, 63] months. Two pts achieved a partial response and 6 pts had stable disease for an overall DCR of 89% (8/9 [59%, 99%]). Five pts remain on treatment with an additional 6 in follow-up. Study treatment was well tolerated. For the 35 treated patients, 33 reported 1 or more treatment-emergent adverse events (AEs), most commonly neutrophil count decreased (n = 15, 43%), nausea (n = 12, 34%), fatigue (n = 10, 29%), and anemia (n = 10, 29%). Most of the AEs were grade (G) 1-2. 14 patients (40%) reported G3/4 neutrophil count decreased. **Conclusions:** BOLD-100 plus FOLFOX is an active and well-tolerated treatment regimen in the heavily pre-treated Stage IV biliary tract and gastric cancer study populations. There were no new safety signals. The preliminary mPFS, mOS, ORR and DCR data in this interim analysis demonstrate significant improvement over the currently available therapies for these difficult to treat advanced GI cancers. Clinical trial information: NCT04421820. Research Sponsor: Bold Therapeutics Inc.

Circulating tumor DNA (ctDNA) analyses in patients with HER2-positive biliary tract cancer (BTC) treated with trastuzumab deruxtecan (T-DXd): Exploratory results from the HERB trial. *First Author: Akihiro Ohba, National Cancer Center Hospital, Tokyo, Japan*

Background: In the phase 2 HERB trial (NCC1805; JMA-IA00423), T-DXd exhibited promising activity among patients with HER2-positive BTC (ASCO 2022 ab 4006). HER2 positivity was defined as tumor tissue immunohistochemistry (IHC) 3+ or IHC 2+ with in situ hybridization (ISH) positivity. HER2 gene amplification (HER2-amp) can also be detected in ctDNA, which may be an alternative when tumor tissue is not available. ctDNA may also detect tumor molecular changes during treatment and at disease progression. **Methods:** In this ancillary study, we collected plasma samples for ctDNA analysis (Guardant360) at baseline (BL), day 1 of cycle 2 (C2D1; ie, day 22 of treatment), and end of treatment (EOT). The relationships between clinical outcomes and ctDNA genomic profiles were evaluated. **Results:** Among the 30 patients in the full analysis set of HERB (22 with HER2-positive and 8 with HER2-low BTC), plasma samples for ctDNA were obtained from 30, 29, and 24 at BL, C2D1, and EOT, respectively. HER2-amp was found in ctDNA of 8 BL samples, all of which were from tissue HER2-positive patients. This included 50% (5 of 10) of the IHC 3+ tumors and 25% (3 of 12) of the IHC 2+/ISH+ tumors. Comparing clinical outcomes for patients with HER2-amp in ctDNA (n=8) to those with HER2-positive in tissue (n=22), the confirmed objective response rate (cORR) was 50.0% (95% CI, 15.7–84.3), including all 2 CR cases, vs 36.4% (95% CI, 17.2–59.3); median duration of response was 7.9 (95% CI, 2.8–11.5) vs 7.4 months (95% CI, 2.8–NA), median progression-free survival (PFS) was 6.1 (95% CI, 2.8–20.3) vs 5.1 months (95% CI, 3.0–7.3), and median overall survival was 10.8 (95% CI, 4.7–NA) vs 7.1 months (95% CI, 4.7–14.6). Plasma copy number (median 5.1, range 2.3–9.9) was not associated with response or survival, even after adjusting for maximum variant allele frequency (MAF). Common BL genomic mutations found in ctDNA were in *TP53* (n=19, 63%), *PIK3CA* (n=8, 27%), and *TERT* (n=7, 23%). No mutation was associated with treatment efficacy. Median MAF decreased from 7.3% at BL to 1.6% at C2D1. Decreased MAF was associated with better response (CR, PR, and SD) and longer PFS. Among 24 EOT samples, including 7 from patients with BL HER2-amp in ctDNA, 10 (42%) acquired potential resistance alterations, most related to receptor tyrosine kinase, MAPK, and PI3K pathways. HER2-amp was lost at EOT in 4 of the 7 patients with HER2-amp detected in BL ctDNA. **Conclusions:** Using a ctDNA assay, HER2-amp was detected in 36% of patients with tissue HER2-positive BTC. Those with HER2-amp in ctDNA than HER2-positive in tissue had potentially higher cORR and longer survival with TDXd. Clinical trial information: JMA-IA00423. Research Sponsor: Japan Agency for Medical Research and Development; Daiichi Sankyo.

A phase II study of olaparib and durvalumab in patients with IDH-mutated cholangiocarcinoma. *First Author: Erica S. Tsang, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: IDH1/2 mutations (m) occur in approximately 25% of cholangiocarcinomas (CCAs) (20% intrahepatic, < 5% extrahepatic) and result in the accumulation of R-2-hydroxyglutarate (R2HG). R2HG, suppresses homologous recombination repair and as a result IDH1/2m are hypothesized to predict PARP inhibitor sensitivity. PARP inhibition upregulates PD-L1 and the combination is thought to be synergistic. We conducted a phase II trial of olaparib with durvalumab for patients with IDH-mutated cholangiocarcinoma. **Methods:** Patients with advanced IDHm CCA were enrolled in this phase II open-label study (NCT03991832). Patients received olaparib 300 mg twice daily continuously and durvalumab 1500 mg IV every 4 weeks. Simon's optimal two-stage design was used, with an interim analysis planned for efficacy. 10 patients were accrued in the first stage, with a plan for expansion if ≥ 2 responses were observed. The primary objective was to determine the overall response rate (RECIST 1.1) and disease control rate (DCR). Secondary objectives included progression-free survival, overall survival, and safety of the olaparib and durvalumab combination. **Results:** 10 patients with IDH1m were enrolled in this study between January 2020-August 2021. Median age was 63.5 years (range 49-78), and 50% were female. All patients had a baseline ECOG PS of 0-1. 40% of patients had prior surgical resections and subsequently developed recurrent disease. 20% of patients had ≥ 2 lines of prior chemotherapy, with 90% receiving prior platinum. Median duration of treatment was 1.95 months (range 1.8-13.5). There were no treatment-related grade 3-4 toxicities. Any grade toxicities included fatigue (100%), nausea (60%), anemia (20%), hypothyroidism (20%), elevated liver enzymes (20%). We did not observe any complete or partial responses. The DCR was 30% with 3 patients demonstrating stable disease. One patient remained on treatment for 13.5 months, and was eventually taken off study due to clinical progression. The median PFS was 1.97 months (95% CI 1.73-3.93). Given that no responses were seen in the initial 10 patients, the study did not proceed to Stage 2. **Conclusions:** While the combination of olaparib and durvalumab was well-tolerated, this study was discontinued after Stage I due to lack of efficacy. IDH1/2m may not induce a BRCAness phenotype and further correlative studies are planned to evaluate this. Clinical trial information: NCT03991832. Research Sponsor: AstraZeneca.

Racial and socioeconomic disparities in time to chemotherapy and survival in patients with pancreatic cancer. *First Author: Shivani Shah, Allegheny General Hospital, Pittsburgh, PA*

Background: Pancreatic cancer is traditionally known to be an aggressive malignancy, requiring timely diagnosis and treatment, including chemotherapy and/or surgery. Prior studies have evaluated variances in overall survival (OS) based on race or income; however, research regarding time to treatment based on racial and socioeconomic disparities is underwhelmingly studied. Our project sought to evaluate the impact of race and income on time to chemotherapy and OS in pancreatic cancer patients receiving neoadjuvant or adjuvant chemotherapy. **Methods:** The National Cancer Database (NCDB) from 2004-2020 was reviewed for patients with a diagnosis of pancreatic cancer, including all types and stages. Exclusion criteria included: no documented income level, time to first treatment surgery, or time to chemotherapy. Our patient population was then separated into two cohorts: neoadjuvant and adjuvant. Income level was stratified into the following: < \$30,000, \$30,000-34,999, \$35,000-\$45,999, and > \$46,000. Race was also noted. We utilized a logistic regression to identify factors associated with longer time to chemotherapy (using median time to chemotherapy as a benchmark for early or later initiation of chemotherapy). A Cox proportional hazards model was used to identify factors associated with worse survival. A p-value < 0.05 was deemed significant. **Results:** Our final sample size included 64,640 patients. 6,887 (10.6%) of patients had an income less than \$30,000. 55,340 (85.6%) of patients were Caucasian, 6,379 (9.9%) patients were African American, and 172 (0.002%) were American Indian. 18,679 (28.9%) received neoadjuvant chemotherapy, and 45,961 (71.1%) received adjuvant chemotherapy. Median time to chemotherapy was 27 [0-2048] days and 71 [0-1895] days in the neoadjuvant and adjuvant cohorts, respectively. Within both cohorts, income > \$46,000 was noted to have significantly earlier time to chemotherapy compared to lower income levels. Those privately insured had significantly earlier time to chemotherapy compared to uninsured. The African American population was associated with a later time to first chemotherapy in comparison to Caucasians in both subgroups. A significantly less OS in the African American population was appreciated in the neoadjuvant cohort (HR 0.92, p-value 0.02), but not the adjuvant cohort. **Conclusions:** Our retrospective analysis emphasizes that minorities and/or those with a poor socioeconomic status have significant delay in time to chemotherapy in the neoadjuvant and adjuvant setting. Within the African American neoadjuvant cohort, a significantly worse OS was highlighted. This study emphasizes racial and socioeconomic disparities in our healthcare system. Limitations of our study include its retrospective nature and no information regarding the type of surgery the patients received, which could further account for differences in time to chemotherapy. Ex-vivo analysis of programmed cell death on fibrolamellar carcinoma. *First Author: Olutani-Grace Ajay, Rush University Medical School, Chicago, IL*

Background: Fibrolamellar carcinoma (FLC) is a rare liver cancer with surgery as the only established treatment. Relapse is common (>80%) and with 40% unresectable, there is a need for rationale systemic therapy. Empiric combinations, especially with lenvatinib (LEN) and gemcitabine (GEM), show promise, but are lacking a CLIA licensed laboratory rationale. Ex-Vivo Analysis of Programmed Cell Death (EVA-PCD), from Nagourney Cancer Institute, is an attempt to meet this need. **Methods:** Nagourney Institute analyzed FLC tissue (as previously described), with a panel of 34 single/26 combinations of available/promising agents from 18 drug classes. Drug concentration with 50% cell death (LC50), below, within, or above 1-standard deviation of the mean (n ≥ 15), define Highly-Sensitive/Intermediate/Resistant, respectively. Active/Moderate/Inactive are similarly defined but with n < 15. Actionable defines clinically available drug(s), not resistant/inactive and ≥ 6 assays. **Results:** Forty-four samples from 40 patients (17M,23F, age 6-56, 23 states/4 countries) were analyzed: 80% were viable and 69% of high quality for a total of 378 assays (avg 12/ patient). However, all patients had actionable agents, and 78% of the assays showed activity in at least some patients. All the universally resistant/inactive assays (22%) were single agent. 76% of assays were actionable in at least one patient (100% for combinations compared to 62% for single agents). EVA-PCD replicate FLC studies and experience, such as the failure of monotherapy and the importance of LEN. Of 11 patients who had treatment that matched testing, 72% responded as predicted, including 6 with 100% response to LEN and/or QUE as predicted. Overall LEN/QUE, LEN/EVE, TRE, REG, QUE, 5FU/INF performed the best, while single agent ALP, CAB, LAR, VOR, GEM, DAS and IBR all showed 0% activity when tested > 5 times. The largest challenge is the need for an adequate amount of viable tissue to arrive within 24 hours. However our experience demonstrates that it is feasible from other countries and across the US. **Conclusions:** This is the first demonstration of CLIA approved human FLC tumor testing. Data are in line with literature and correlates clinically. Prospective data are needed to fully incorporate EVA-PCD testing into the clinic. Research Sponsor: None.

Progression-free survival as a surrogate endpoint of overall survival in advanced biliary tract cancer: A meta-analysis of randomized trials and individual-patient level correlation. *First Author: Carles Fabregat Franco, Gastrointestinal and Endocrine Tumor Unit, Vall d'Hebron Institute of Oncology (VHIO), Hospital Universitari Vall d'Hebron, Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain*

Background: Biliary tract cancer (BTC) is a heterogeneous group of diseases commonly diagnosed at advanced stages. Overall survival (OS) is the gold-standard primary endpoint in randomized controlled trials (RCT). However, the increasing use of subsequent lines of therapies and cross-over designs may confound the treatment effect. We therefore explored the use of progression free survival (PFS) as a surrogate endpoint of OS both at the trial-level and at the patient-level. **Methods:** For the trial-level correlation, we conducted a systematic review of RCTs in advanced BTC following the PRISMA guidelines. We searched PubMed, the Cochrane Central Register of Controlled Trials and ClinicalTrials.gov from database inception to June 2022 and identified all randomized phase I/II trials testing systemic therapies for advanced BTC. We used a weighted linear regression to measure the correlation of log-transformed hazard ratios (HR) of OS and PFS based on trial size and calculated the surrogate threshold effect (STE). We used the IQWiG framework to define the strength of evidence. For the individual-level analysis, we included patients with advanced BTC treated with first and second line chemotherapy in the real-world RETUD registry. We estimated the correlation via the iterative multiple imputation method. **Results:** From a total of 1992 studies, we identified 32 RCTs including 70 treatment arms and 5140 patients that fulfilled the inclusion criteria. Twenty-three trials were performed in the first line setting and most were phase II RCTs (N = 23). We found a moderate correlation between OS and PFS (R= 0.79, 95% CI 0.61-0.89). The slope of the regression line was 0.62±0.08, indicating that a 10% risk reduction in PFS will result in a 6.2%±0.8% improvement in OS. The STE was 0.69, suggesting that in a hypothetical trial of 400 patients, a PFS HR of 0.69 will likely result in a significant improvement on OS. Regarding the individual-level correlation, a total of 593 patients with advanced BTC were included. The median age of patients was 68y (IQR 59-74), most were males (54%) and received platinum-based chemotherapy (73.1%). In the first line setting, the median OS was 9.7 months (95% CI 8.7-10.5) and median PFS was 5 months (95% CI 4.5-5.5). We observed a strong correlation between PFS and OS (r= 0.84, 95% CI 0.81-0.86). In the second line setting (N = 259), a similar correlation was observed to the first-line setting (r= 0.76, 95% CI 0.72-0.8). **Conclusions:** At the trial-level, in this analysis treatment effects on PFS were moderately correlated with OS. A HR < 0.69 in PFS suggested that it would likely lead to a significant OS benefit in a hypothetical trial including 400 patients. At the individual-level, PFS and OS were strongly correlated in a real-world cohort. Future validation in patients treated in the context of randomized trials is warranted. Research Sponsor: None.

Alteration of gut microbiota composition in patients with cholangiocarcinoma with non-responsiveness to first-line chemotherapy: A pilot study. *First Author: Thanika Ketpueak, Faculty of Medicine, Chiang Mai University, Muang, Thailand*

Background: Gut microbiota established crucial roles in host metabolism and several diseases, particularly cancers. Distinct bacterial profiles from intestine are found to be a potential factor in carcinogenesis, while some of those are associated with detrimental treatment to the responsiveness in various types of cancer. Association of gut microbiota and treatment outcome has been thoroughly investigated in intrahepatic cholangiocarcinoma (ICCA). The present study aimed to compare gut microbiota profiles between chemotherapy responder and non-responder in ICCA patients. **Methods:** Unresectable or metastatic ICCA patients were recruited in the study. The criteria of all patients were naive to chemotherapy. All patients received first line combination of cisplatin 25 mg/m² and gemcitabine 1000 mg/m² at day1 and day 8 in every 21-day cycle and were given up to 8 cycles. The primary endpoint was to evaluate the association between gut microbiota and the objective response rate. Bacterial genomic DNA samples were extracted from the stool using a commercial genomic DNA isolation kit (Qiagen, Hilden, Germany) and then underwent next-generation sequencing. Data analyses were conducted by using QIIME2 and Analysis of Compositions of Microbiomes with Bias Correction (ANCOM-BC). **Results:** Seventeen ICCA patients were recruited. The objective response rate was 23.5% comparable to historical study. Chemotherapy responder group was defined as partial response patients (N = 4) and chemotherapy non-responder group included stable of disease and progressive disease (N = 13). Baseline characteristics were similar including age, sex, ECOG performance status, numbers of metastatic organ and CA 19-9 in two groups. Median Age were 63 years old (60-70) and 61 (45-73), respectively. Alpha-diversity and beta-diversity were not different between two groups. In chemotherapy non-responder group, some taxa were dominantly observed including Ruminococcaceae, Oribacterium, Oxalobacter, Peptostreptococcus, Aggregatibacter, which had been previously reported increasing in ICCA patients. Interestingly, Ruminococcaceae, which was previously documented to be correlated with vascular invasion, was significantly increased abundance in non-responder group. Moreover, the median progression-free survival (PFS) was improved in chemotherapy responder group compared to non-responder group 11.8 and 6.6 month, respectively. Large sample sizes study to confirm this study result should be developed. **Conclusions:** Distinct bacteria from gut microbiota such as Ruminococcaceae has inversely associated with chemotherapy response in ICCA patients receiving first line cisplatin and gemcitabine combination, suggesting the possibility of the poorer PFS. Research Sponsor: Faculty of Medicine, Chiang Mai University.

Real-world multicentre analysis of patients with hepatocellular carcinoma (HCC) treated with atezolizumab and bevacizumab (A+B): Efficacy, esophago-gastro-duodenoscopy (EGD) uptake and bleeding complications. *First Author: Cha Len LEE, Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: The IMbrave150 trial established A+B as a standard of care for HCC and an EGD within 6 months (mos) of starting treatment to detect esophagogastric varices and prevent bleeding complications was advised. However, the value of performing EGD in all patients (pts) is unknown. **Methods:** We conducted a retrospective analysis of all HCC pts treated with A+B between July 2020 to August 2022 at 5 cancer centres from the Canadian provinces of Ontario, Alberta and Manitoba (members of the HCC-CHORD Consortium). Pts characteristics and treatment history including efficacy, EGD details and bleeding events were collected. Overall survival (OS), progression-free survival (PFS) and response rate (RR) were calculated. A comparative analysis was conducted to compare the correlation between the EGD uptake and bleeding events. **Results:** A total of 112 pts were identified (median age 66 years, 87% male, 24% East Asian, 67% liver cirrhosis, 33% HCV, 25% HBV, 15% NASH, 23% BCLC B, 71% BCLC C, 91% Child-Pugh A, 29% main portal vein invasion, 45% ALBI grade 1 and 54% ALBI grade 2). Prior to systemic, 61% had locoregional therapies. 90% received A+B as first-line therapy, while 9% received it as second-line and 1% as third-line. Outcomes of pts treated with A+B are shown. Before starting A+B, 78 pts (70%) had completed an EGD within 6 mos. Of these, 32 pts (41%) had evidence of varices on EGD, and 15 (20%) required treatment with either banding or beta-blockers. All bleeding events in this population was 15% (n=17). Bleeding rates in the EGD and non-EGD groups were 18% (n=14) and 9% (n=3), respectively. Bleeding adverse events were 5% (n=6) gastrointestinal vs 10% (n=11) non-gastrointestinal (6 epistaxis, 1 ecchymosis, 1 periodontal and 3 unspecified). The GI bleeding rates in the EGD and non-EGD groups were 6% (n=5) and 3% (n=1). **Conclusions:** Outcomes of HCC pts treated with A+B in Canada are comparable to those observed in the IMbrave150 trial. Our study detected and treated varices at twice the rate of the IMbrave150 trial among the EGD group, reflecting real-world treatment of a high-risk population. Yet, pts who had no EGD before starting A+B, presumably due to a low risk of portal hypertension based on physicians' judgement, did not experience more bleeding/GI bleeding than those who had an EGD. This supports the approach of selective EGD prior to A+B, and more guidelines are needed in this area. Outcomes and response rate of patients(pts) treated with Atezolizumab with Bevacizumab in this study. Research Sponsor: None.

Characteristics	All patients (n=112)
Median OS (95% CI), mos	20.3 (16.5-NR)
Pts with bleeding	20.3 (13.0-NR)
Pts without bleeding	19.7 (16.5-NR) (p=0.78)
Median PFS (95% CI), mos	9.6 (6.1-11.9)
Median follow-up time, mos	10.4 (0.4-47.6)
Complete response	1%
Partial response	35%
Stable disease	41%
Progressive Disease	23%

Application of the albumin-bilirubin (ALBI) grade as predictive marker of atezolizumab plus bevacizumab (A+B) treatment outcomes for patients with advanced hepatocellular carcinoma (HCC): Real-world retrospective analysis at Veterans Health Administration (VHA). *First Author: Munaf Alkadimi, University of Texas Health Science Center at San Antonio, San Antonio, TX*

Background: Most clinical trials use Child-Pugh (CP) for patient selection; this subjective scale was originally developed to assess liver function in cirrhosis, thus cannot be applied to HCC patients with non-cirrhotic background. Alternatively, ALBI grade is an objective and validated prognostic system that has demonstrated improved accuracy to predict survival and liver function decline in HCC patients. Our real-world study aims to assess the ALBI grade as a predictive marker of treatment response in patients with advanced HCC who received (A+B) within the VHA. **Methods:** VHA patients with HCC receiving 1st line therapy with A+B were identified through EMR using ICD-9 or ICD-10 codes between 1 Jan 2007 and 31 Dec 2021. Patients were followed from their A+B initiation date through the earliest of the last VHA visit, loss to follow up, death, or end of study on Jan 31, 2023. Structured electronic health record and chart review data were retrospectively collected to determine patient baseline characteristics, treatment response, overall survival (OS), and progression-free survival. Survival rates were based on patients with at least 6 months or 1 year of time (as indicated) from A+B initiation until the chart was reviewed; patients without a scan or known date of scan were excluded from PFS calculations. The Chi-Squared test was used to compare rates. **Results:** 332 patients were included in the study. The median age was 67 yrs, 99% were males, 63% non-Hispanic White, 26% Black, 86% with ECOG < 1, 84% had CPS class A, 16% had CPS class B and C, 56% had viral hepatitis-caused HCC, 20% had no cirrhosis present, and 60% had prior local therapies. There was a statistically significant difference in progression free survival (PFS) and over survival (OS) amongst different ALBI grades as shown. **Conclusions:** In our retrospective cohort, it was clear that patients with ALBI grade 1 had improved PFS and OS compared to ALBI score grade 3. Patients with ALBI score grade 2 also had a moderate response to treatment with modest OS and PFS compared to patients with ALBI score grade 3. Utilizing stratification ability ALBI grade in future clinical trials may improve prognostic power facilitating ideal patient selection. Research Sponsor: None.

End points for VA HCC patients given AB as 1st line, with break out by ALBI grade at staging.

Characteristic of Interest	ALBI grade	1	2	3	p-value
N		97 (29.2%)	207 (62.3%)	28 (8.4%)	–
OS: 6 mo		84 (86.6%)	150 (72.5%)	9 (32.1%)	<0.001
OS: 1 yr		61 (70.9%)	93 (48.2%)	4 (16.0%)	<0.001
Objective Response Rate (CR + PR)		29 (30.8%)	62 (30.7%)	5 (20.9%)	0.59
Disease Control Rate (CR + PR +SD)		61 (64.8%)	123 (60.9%)	12 (50.0%)	0.40
PFS: 6 mo		62 (66.0%)	118 (59.0%)	7 (29.2%)	0.005
PFS: 1 yr		41 (48.8%)	61 (33.2%)	3 (14.3%)	0.004

Association of a high E2F targets score with survival in hepatocellular carcinoma patients. *First Author: Kohei Chida, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Hepatocellular carcinoma (HCC) is one of the leading causes of cancer-related mortality. Multiple staging systems have all been proposed to date; however, the optimal tool for stratification of prognosis is still not universally accepted. E2F targets are the essential component of cell proliferation, thus we hypothesized that a score to quantify E2F activity is expected to reflect the aggressiveness and prognosis of HCC. **Methods:** Total of 655 HCC patients from TCGA (The Cancer Genome Atlas) -HCC (n=358), GSE6764 (n=75), GSE76427 (n=115), and GSE89377 (n=107) cohorts were analyzed. The score was generated using MSigDb Hallmark E2F Targets gene set using Gene Set Variation Analysis. **Results:** The E2F targets scores of TCGA-HCC patients showed a bimodal distribution, thus high vs. low score groups were divided by median. As expected, high E2F targets enriched all of the Hallmark cell proliferation-related gene sets; E2F targets, G2M checkpoint, MYC targets v1 and v2, and Mitotic spindle. It also enriched gene sets known to aggravate cancer, such as Glycolysis, mTORC1 signaling, DNA repair, and Unfolded protein response. E2F targets were significantly associated with histological grade, tumor size, and stage, as well as proliferation score and MKI67 expression. Furthermore, a higher E2F targets score was significantly associated with higher intra-tumoral genomic heterogeneity and homologous recombination deficiency, suggesting greater tumor aggressiveness. In agreement, E2F targets score correlated with the pathological progression from normal liver, cirrhosis, dysplasia, to early and advanced HCC consistently in two cohorts (GSE6764 and GSE89377). Further, the abundance of hepatocytes, fibroblasts, adipocytes, and lymphatic endothelial cells were all significantly less in high E2F HCC, which reflects proliferative cancer. On the other hand, there was no relationship between E2F and mutation rates or neoantigens. High E2F was associated with high infiltration of anti-cancerous immune cells; CD8, CD4 memory, and Th1 cells, however, there was no difference in cytolytic activity, and it did not enrich any of immune response-related gene sets. High E2F HCC was associated with worse disease-free (DFS), disease-specific (DSS), and overall survival (OS), and this was the case in both early (I and II) and late (III and IV) stages. A multivariate analysis revealed that the E2F targets score was an independent prognostic factor for OS (HR=1.68, 95%CI= 1.15–2.46, p=0.007) as well as DSS (HR=1.81, 95%CI=1.27–2.59, p=0.001) in patients with HCC. **Conclusions:** We found that the E2F targets score not only indicates cell proliferation, but also is associated with cancer aggressiveness and worse survival. Our findings suggest a possible future use of the E2F targets score as a prognostic biomarker in patients with HCC. Comprehensive profiling of clock genes expression in hepatocellular carcinoma (HCC). *First Author: Francesca Battaglin, Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA*

Background: The circadian clock mechanism controls the physiological homeostasis of the liver and plays a key role in hepatocarcinogenesis. Recent evidence unveiled core clock proteins as novel therapeutic targets in cancer. Our group showed that clock regulators BMAL1 and CLOCK can promote proliferation of liver cancer cells by modulating the cell cycle checkpoint kinase Wee1. Here we further evaluated the molecular landscape of clock pathway alterations in HCC leveraging multi-platform profiling of patient tumor samples. **Methods:** 780 HCC tested at Caris Life Sciences (Phoenix, AZ) with WTS (Illumina NovaSeq) and NextGen DNA sequencing (NextSeq, 592 Genes and NovaSeq, WES) were analyzed. Clock gene Score (CS) was determined using expression of core clock genes Z scores (positives of *CLOCK*, *ARNTL*, *RORA/B/C* and negatives of repressors *CRY1/2*, *PER1/2/3*, *REVERBA/B*) stratified by quartiles. xCell was used to quantify cell infiltration in the tumor microenvironment (TME). Significance was determined as P-values and adjusted for multiple testing (q) of < .05. Gene expression profiles were analyzed for transcriptional signatures predictive of response to immunotherapy including the T cell inflamed score (TIS) and IFG score. Real world survival was obtained from insurance claims data and Kaplan-Meier estimates were calculated for comparison. **Results:** CS was higher in metastatic sites than primary tumors (median transcripts per million [TPM]: 0.81 vs 0.37, P< .05). No significant differences in patient age and sex were observed between CS Q1 (lowest) and Q4 (highest) cohorts, although a trend towards a higher frequency of males was observed in Q4 (76% vs 68%, Q4 vs Q1, P= .07). CS was positively associated with telomerase subunit TERT mutations (64% vs 52%, Q4 vs Q1, P= .04) and negatively correlated with *FGF3* copy number amplification (2% vs 6%, P= .04) and *WEE1* gene expression (median TPM: 15 vs 28, q< .05). No dMMR/MSI-H tumors were observed in our series and there were no significant associations with tumor mutational burden and PD-L1 protein expression. Expression of immune related genes was lower in tumors with high CS, including *IDO1*, *CD80*, *PD-L1*, *LAG3*, *CD86*, *TIM3*, *PD-1* and *PD-L2* (fold change: 0.57-0.67 q< .05). NK cell infiltration in the TME and the TIS score were also significantly lower in CS-high HCC (q< .05). Individually, lower *CLOCK* and *CRY1* tumor mRNA expression were associated with longer OS (Q1 vs Q4: *CLOCK* HR 0.71, 95%CI [0.51-0.98], P= .04 and *CRY1* HR 0.70 [0.51-0.95], P= .02, respectively). **Conclusions:** This is the most extensive profiling study to investigate the expression of clock genes in HCC. Our data show that clock genes expression impacts patient survival and is associated with alterations in immune-related gene expression and TIS score which suggest a role in the modulation of anti-tumor immunity. These results support the clock pathway role as an oncogenic driver and its potential as a therapeutic target in HCC. Evaluating racial disparities for patients with advanced hepatocellular carcinoma (HCC) receiving first line immunotherapy within an equal access system. *First Author: Lauren Diaz Boyle, The University of Texas Health Science Center-San Antonio, San Antonio, TX*

Background: The incidence and mortality of HCC are increasing in the USA. HCC disparities have been reported across the entirety of the cancer timeline, from screening to local and systemic treatment and liver transplant. We aim to analyze the clinical characteristics, outcomes, and racial disparities in patients with advanced HCC receiving first-line Atezolizumab plus Bevacizumab (A+B) in the Veterans Health Administration (VHA) – the only health care system in the USA that provides equal access to all patients. **Methods:** Patients were followed from their A+B initiation date through the earliest of the last VHA visit, loss to follow-up, death, or end of study on Jan 31, 2023. Structured electronic health record and chart review data were retrospectively collected to determine patient baseline characteristics, including self-reported race, number of A+B doses, treatment response, subsequent line of treatment, length of follow-up, and overall survival (OS). The Chi-Squared test was used to compare rates, and Mann-Whitney test was used to compare medians. **Results:** Three hundred twenty-five patients were included. 64% were non-Hispanic White (NHW), and 36% were all other (AO) ethnicities or races combined (26% Black, 8% Hispanic, 2% Asian or Indigenous). The median age for each cohort was similar (66 years for AO vs. 68 for NHW), and ECOG performance was <1 in nearly 90% of each cohort. Viral hepatitis accounted for 70% and 48% of AO and NHW, respectively (p=0.0001). Despite clinical differences in OS and progression free survival (PFS), they were not statistically significant. **Conclusions:** Our VHA real-world data shows that despite having statistically significant etiologies, there was no statistically significant difference in the PFS and OS of patients with advanced HCC receiving first-line A+B in an equal access care system. This study supports our group's findings in other malignant cohorts within VHA where equal healthcare access can mitigate other socio-demographic and biological factors. Research Sponsor: None.

Survival and response rates by race/ethnicity.

Lenvatinib (LEN) combined with tislelizumab (TIS) plus transcatheter arterial chemoembolization (TACE) for unresectable hepatocellular carcinoma (uHCC): A single-arm, phase II clinical trial. *First Author: Xiang Nong, Guangxi Medical University Cancer Hospital, Nanning, China*

Background: uHCC still lacks effective treatments, combination of antiangiogenic targeted drugs and immune checkpoint inhibitors showed promising efficacy. TACE induces tumor necrosis and tumor antigen release, may synergize with immunotherapy. This study was to evaluate the efficacy and safety of TACE in combination with TIS and LEN in patients with uHCC. **Methods:** This study was a single-center, single-arm, open-label phase II exploratory clinical study (NCT05131698). Eligible patients were BCLC C stage and not candidates for surgical resection or liver transplantation, at least one target lesion evaluable, ECOG performance status of ≤ 1, and Child-pugh grade A or B. Enrolled patients received TACE treatment (Ioplatin + raltitrexed + iodine oil) followed by TIS (200 mg, IV, on Day 1 of a 21-day cycle) and LEN (body weight ≥ 60 kg: 12 mg/day; < 60 kg: 8 mg/day) daily. The primary endpoint was overall response rate (ORR) by mRECIST. The secondary endpoints included disease control rate (DCR), overall survival (OS), and progression-free survival (PFS) and safety. **Results:** As of December 28, 2022, 31 enrolled patients with uHCC were treated. Median follow-up time is 11.3 months. Among all patients with BCLC C, 28 patients (90.3%) had microvascular invasion and 17 (54.8%) had portal vein tumor thrombus. As assessed by mRECIST, the ORR and DCR were 71.1% and 87.1%, respectively (2 CR, 6.6%; 20 PR, 64.5%; 5 SD, 16.1%), 4 patients developed tumor progression (12.9%). As assessed by RECIST 1.1, the ORR and DCR were 67.7% and 87.1%, respectively (1 CR, 3.2%; 20 PR, 64.5%; 6 SD, 19.4%), 4 patients developed tumor progression (12.9%). The median PFS was 10.2 months (95% CI: 4.5-NA) , and the median OS was not reached. Any grade treatment-emergent adverse events (TEAEs) occurred in 64.5% (20/31) patients. The most common TEAEs were Increased γ-glutamyl transpeptidase (35%), Increased aspartate aminotransferase (32%), thrombopenia (25%). Only 2 patients experienced grade 3 TEAE (pneumonia). No serious adverse events (SAEs) were reported. **Conclusions:** In this study, TACE combined with TIS and LEN showed preliminary antitumor efficacy and tolerable safety profile in uHCC. Clinical trial information: NCT05131698. Research Sponsor: BeiGene biopharma incorporation.

Variable	All patients (n=31)	
	mRECIST	RECIST 1.1
Confirmed objective response, n (%) [95% CI]	22 (71.1% [52.0- 85.8])	21 (67.7% [48.6- 83.3])

The clinical feasibility of circulating tumor DNA alterations in patients with advanced hepatocellular carcinoma. *First Author: Gwangil Kim, Department of Pathology, CHA Bundang Medical Center, CHA University School of Medicine, Seongnam, South Korea*

Background: Need for individualized treatment based on tumor attributes is being reinforced with the rapid development of targeted therapies and immune checkpoint inhibitors for hepatocellular carcinoma (HCC). Lack of mandatory tissue biopsy for the diagnosis of HCC, continues to be a challenge for development of precision medicine for HCC compared to other solid tumors. Liquid biopsy enables comprehensive genomic profiling of circulating tumor DNA (ctDNA) shed from tumors into the circulation. This could compensate for the lack of tissue-based analysis in HCC providing a non-invasive and safer option for genomic profiling. This study aims to address the concordance between commercially available ctDNA and tissue genomic profiling in patients with advanced HCC and to assess the feasibility of liquid biopsy in the treatment of patients with HCC. **Methods:** Patients subjected to tissue-based next-generation sequencing (NGS) before systemic therapy for advanced HCC at CHA Bundang Medical Center from June 2020 to October 2022 and also had sufficient plasma samples available for ctDNA analysis were included. Oncomine Comprehensive Assay (OCA) ThermoFisher was used for tissue-based NGS and Guardant360 for ctDNA based NGS. For the concordance assessment for the same patient, paired samples of ctDNA and tumor tissue, we investigated the common targeted regions across both the panels. **Results:** Out of hundred thirty patients included in this study, 98% percent of ctDNA samples for these patients were successfully sequenced; ctDNA were detected in 88% of the samples. For the assessment of concordance between intra-patient ctDNA and tumor tissues, we investigated only clinically important (AMP/ASCO/CAP guidelines tier 1 or 2) variants. When we considered the variants detected in tissues as true positive, the concordance between the mutations detected from ctDNA and tissue samples indicated 68.9% sensitivity and 63.1% positive predictive value (PPV). In ctDNA, targetable alterations were detected in 16.9% of samples, such as *ARID1A* mutations (7.7%), *PTEN* mutations (6.9%), *PIK3CA* hotspot mutations (1.5%), *RAS* mutations (1.5%), and one *RET* fusion (0.8%). Regarding the concordance between ctDNA and tumor tissue, the sensitivity for mutation was high for *RAS* mutation (100.0%), *PTEN* mutations (100.0%), and *ARID1A* mutations (75.0%) but low for *PIK3CA* hotspot mutations (0.0%). One *RET* fusion was identified only in ctDNA. **Conclusions:** ctDNA-based genotyping demonstrated clinically acceptable concordance with tissue genomic profiling in patients with advanced HCC. Thus, liquid biopsy using ctDNA help address any challenges associated with the limited use of tissue-based genomic profiling in HCC. Investigation of time between blood and tissue collection and the impact it has on concordance is ongoing. Molecular subtypes from comprehensive clustering from multi-omics dataset to predict the therapeutic efficacy of immunotherapeutic agent-based treatments in advanced hepatocellular carcinoma. *First Author: Hong Jae Chon, Department of Medical Oncology, CHA Bundang Medical Center, CHA University School of Medicine, Seongnam, South Korea*

Background: In advanced hepatocellular carcinoma (HCC), combined treatment using anti-PD-L1 and anti-VEGF antibodies is a major therapeutic strategy in addition to using anti-PD-1 and anti-CTLA4 target agents. To identify clinically relevant molecular biomarkers for immunotherapeutic agents-based treatment in advanced HCC by comprehensive molecular profiling using genomics alterations and transcriptomic data. **Methods:** Multi-omics data from clinical tumor samples of patients treated with atezolizumab + bevacizumab (94 patients), nivolumab (40 patients), and ipilimumab + nivolumab (32 patients) were obtained from tumor biopsies or surgical resections in a single institution. The targeted panel sequencing was conducted via the Oncomine comprehensive assay (ThermoFisher, USA). QuantSeq mRNA sequencing (Lexogen, USA) was used to generate datasets for the genomic alterations and gene expression profiles. **Results:** A total of 166 target sequences for genomic alterations and 136 transcriptomic sequences were performed in patients with advanced HCC treated with immunotherapeutic agent-based treatment options. High tumor mutation burden was significantly associated with favorable therapeutic efficacy (disease control rate, P=0.036) and progression-free survival (P=0.037) in patients who had atezolizumab with bevacizumab treatment. The genomic alteration of CTNNB1 mutation correlated with the favorable therapeutic efficacy of nivolumab monotherapy (PFS, P=0.022), contrary to TP53 mutation (PFS, P=0.063) which demonstrated unfavorable outcomes. CD274(PD-L1) mRNA expression was significantly associated with a high drug response following nivolumab monotherapy (objective response rate, P=0.047) and oncologic outcomes (PFS, P=0.021). Interestingly, PLA2G4A, known as a downstream molecule of the VEGF signaling pathway, was highly correlated with unfavorable therapeutic efficacy of the combined atezolizumab with bevacizumab treatment (disease control rate, P=0.002) and related oncologic outcomes (PFS, P=0.003). We also identified the clinically relevant molecular subtypes from unbiased clustering using the ontologic pathway collection. We also used gene expression profiles to predict the therapeutic response and oncologic outcomes from immunotherapeutic agent-based treatment options. **Conclusions:** We identified clinically relevant molecular biomarkers from comprehensive clustering of a multi-omics dataset to predict the therapeutic efficacy and oncologic outcomes. Further prospective studies with clinical validation are warranted to confirm clinical implications. Research Sponsor: This work was supported by the National Research Foundation of Korea [NRF] grant funded by the Korea government [MSIT] [NRF-2020R1C1C1010722 to HJC, NRF- 2020R1A2C2004530 to CK].

Phase 2 multicenter trial of rucaparib and nivolumab as maintenance therapy following first-line platinum-based chemotherapy in patients with advanced biliary tract cancer (BTC): BIIT-02. First Author: Vaibhav Sahai, University of Michigan, Ann Arbor, MI

Background: Gemcitabine, cisplatin and durvalumab followed by maintenance durvalumab is standard of care first-line (1L) therapy for patients (pts) with advanced BTC. In this trial, we investigated the combination of a PARP inhibitor with anti-PD1 antibody in absence of progression after at least 4 months of standard 1L platinum-based chemotherapy. **Methods:** Pts with advanced BTC, ECOG PS 0-1 and absence of progression on 1L platinum-based therapy were enrolled on a phase 2 trial to receive rucaparib 600 mg PO BID in combination with nivolumab 240 mg IV Q2 weeks every 28 days for up to 2 years. The primary endpoint was 4-month progression-free survival (PFS) rate from the date of first study treatment with an alternative hypothesis of 85%. Secondary endpoints included median PFS and overall survival (OS) from first study treatment (PFS1, OS1) as well as from start date of first-line chemotherapy (PFS2, OS2), best overall response, and safety. **Results:** 31 pts were enrolled of which 14 (45%) were women, 25 (80.6%) Caucasian and 24 (77.6%) with ECOG 1. Primary disease site was intrahepatic, extrahepatic hilar and distal, and gallbladder cancer in 21 (67.7%), 4 (12.9%), 1 (3.2%) and 4 (12.9%), respectively. 1L platinum-based treatment included gemcitabine/cisplatin based in 26 (83.9%), FOLFOX in 3 (9.7%) and carboplatin/paclitaxel in 1 (3.2%) pts. Mean (range) cycles of rucaparib and nivolumab were 6.75 (1-24) and 5.9 (1-24). The median follow-up time is 28.7 months using reverse censoring methodology. PFS rate at 4 months was 54.8% (95% CI, 36-70.3), comparable to the 63% null estimate based on ABC-02 trial. Median PFS1 and OS1 are estimated to be 4.6 months (95% CI, 3.7-6.2) and 15.9 months (95% CI, 9.8-24.1). Median PFS2 and OS2 calculated from date of 1L chemotherapy are estimated as 9.9 months (95% CI, 8.3-11.3) and 21.4 months (95% CI, 14.8-26.7). Two (6.4%) pts had partial response (with IDH R132G and KRAS G12D) as best response with stable disease in an additional 22 (71%) pts. Grade 3-5 treatment-related adverse events (TRAEs) occurred in 15 (48.4%) pts, including 1 patient who died on therapy due to possibly-related immune-related myocarditis. The most common grade 2 or greater TRAEs included fatigue (9, 29.0%), anemia (7, 22.6%), neutropenia (6, 19.3%), elevated AST (5, 16.1%) and elevated ALT (4, 12.9%). Reasons for treatment discontinuation included death (2), progression (27), adverse event (1) while 1 patient completed 2 years of study treatment. **Conclusions:** The primary endpoint of PFS rate at 4 months was not met but the preliminary measures of PFS1 and OS1 are much longer than expected, and hypothesis generating for rational combination of PARP inhibitor with maintenance immunotherapy in this rare cancer. Exploratory endpoint of association of genomic analysis with efficacy is ongoing and will be discussed. Clinical trial information: NCT03639935. Geographical and baseline clinical characteristics of participants enrolled in hepatocellular carcinoma (HCC) trials: Analysis of US FDA approvals. First Author: M. Naomi Horiba, FDA, Silver Spring, MD

Background: Globalization of drug development is increasing, with reliance on data from patients accrued to large, randomized studies across continents. In addition to appropriate racial/ethnic representation, trials submitted to support FDA approvals should reflect the etiology and treatment patterns of HCC in the US. We conducted a pooled analysis of patient-level data from the HCC trials supporting approved marketing applications in the US to characterize geographical and baseline variables in clinical trials. **Methods:** Datasets from applications which received FDA approval for HCC between 2010-2022 were identified. The following data was abstracted: country, baseline disease characteristics (median age, HCC etiology, extent of tumor, and Child-Pugh score), and prior treatments received. Geographical region was recoded using categories observed by the United Nations M49 standard, based on country of enrollment reported in the datasets. **Results:** Variables that were defined differently across studies included region of enrollment, some categories of etiology, and prior therapy. Overall, the rate of HBV etiology was higher than that observed among patients with HCC in the US (20%), while the rate of HCV etiology was lower than in the US (50%). **Conclusions:** Variability in patient populations exist across trials submitted to FDA based on the regions that were targeted for enrollment and eligibility criteria. Global trials may be appropriate to support drug approvals for HCC; however, to ensure results are applicable to US patients, sponsors should select sites that represent a similar population with respect to racial/ethnic representation, disease etiology, and treatment patterns. Tracking the evolving ecosystem of recurrent hepatocellular carcinoma after liver transplantation. First Author: Zijie Zhang, Renji Hospital, affiliated to Shanghai Jiao Tong University, School of Medicine, Shanghai, China

Background: Liver transplant (LT) contributes to the cure of hepatocellular carcinoma (HCC) by extending the conventional surgical margin, while removing the concurrent tumor-favoring conditions of the diseased liver. Over the past two decades, HCC has emerged as a preferable indication for LT, accounting for 22-45% of the cases globally. However, despite the stringent selection criteria, recurrence still occurs in a substantial proportion of patients, leaving 10-13 months of median survival after tumor relapse. To address this challenge, a thorough exploration of molecular mechanism behind HCC recurrence after LT is required. Here, for the first time, we performed a comprehensive analysis to depict the evolving and unique ecosystem of HCC in the context of LT and immunosuppressant (IS) administration. **Methods:** We retrospectively reviewed our biobank and collected 91 paired (primary tumors (PT) from the explant after LT and relapsed tumors (RT) from hepatectomy) FFPE tumor samples from 15 patients for whole exome sequencing (WES). Also, from Jan 2021, we prospectively collected surgical tumor specimens and their adjacent non-tumor tissues from 15 primary and 6 post-LT intrahepatic recurrence patients for single-cell RNA sequencing. Moreover, 6 paired samples from 3 patients were used for spatial transcriptomic analysis. **Results:** By analysing WES data, we confirmed that RT samples represent recurrent, instead of *de novo* tumors. Also, the phylogenetic analysis demonstrated strong clonal relationship between PT and RT based on shared SNVs. As to mutation landscape differences of PT and RT, we identified a significantly enriched mutation panel from RT, including *MUC16*, *FAT3*, *APOB*, *COL6A3* and *POTEC*. And the accuracy of this panel for post-LT HCC recurrence surveillance using plasma derived cfDNA sequencing has been preliminarily validated in a prospective cohort of 17 patients. From the single-cell profiling, distinct immune microenvironment between PT and RT is identified. As predicted, proliferating T cells are decreased in RT due to IS. Pseudotime analysis of T cells revealed that T cells from PT mainly distribute at the terminal end of cytotoxic stage whereas T cells from RT mostly represent a naive state, further confirming the T cell blocking effect of IS. In terms of myeloid cells, we surprisingly found that FOLR2+ tumor associated macrophages, which is conventionally considered as a favorable prognosis factor, is increased in RT. Spatial transcriptomics and IHC also confirmed their active interplay with tumor cells at invasive margin. We postulate that such increase might be a result of the healthy nature of liver graft. **Conclusions:** Our comprehensive dissection of the HCC ecosystem provides deeper insights into the tumor relapse after LT. Targeting novel mutations and strengthen the antigen presenting process between increased TAM and disabled T cells can be the future direction in this field. Clinical trial information: NCT04506398. Research Sponsor: None.

Effect of MYC-targeting programmable epigenetic mRNA therapeutics on TME and immunotherapy responses. First Author: Yan Moore, Omega Therapeutics, Cambridge, MA

Background: c-MYC is a master transcription factor (TF) critical for multiple cell physiologies. As a pleiotropic TF, MYC regulates the tumor microenvironment (TME) and impacts cancer cell initiation, growth, and survival. Although MYC expression is normally tightly controlled in normal cells, its activity is frequently dysregulated in cancer (e.g., HCC, NSCLC, Burkitt's lymphoma). A direct MYC targeting anti-cancer agent has remained elusive, largely due the absence of a drug binding pocket and tight autoregulation. The MYC gene and its regulatory elements reside alone within an insulated genomic domain and represents a potential target for gene regulation via an epigenetic approach. **Methods:** We are developing programmable epigenetic mRNA medicines designed to controllably tune gene expression pre-transcriptionally with high specificity and durability. We have rationally designed MYC-targeted Omega Epigenomic (MYC-OEC: clinical candidate OTX-2002; MYC Lung OEC; mouse surrogate muMYC-OEC) to downregulate MYC expression, thereby selectively killing cancer cells while sparing normal cells. We investigated the role of MYC-OECs in the modulation of the TME and demonstrated in human and mouse tumor models that MYC-OECs enhanced the host immune response. **Results:** In HCC and NSCLC cell lines (Hep 3B, SKHEP1, H2009 and H460), treatment with MYC-OECs in vitro significantly inhibited PD-L1 surface expression. Using the muMYC-OEC in vivo, we demonstrated tumor growth inhibition (TGI) in Hepa1-6 liver cancer syngeneic tumor models with 70% of the mice exhibiting complete tumor response with good tolerability. Cancer cells used to rechallenge the cured mice failed to grow, demonstrating that muMYC-OEC monotherapy induced immune memory. In addition to inhibiting tumor growth with either muMYC-OEC or checkpoint blockade immunotherapy (CBI; anti-PD-1 or anti-PD-L1) treatment, combination therapy further enhanced TGI. Tumor-infiltrating lymphocyte profiling demonstrated an increase in activated T cells and a reduction in Tregs following combination treatment, resulting in an increased effector T cell to Treg ratio over monotherapy. Depletion of CD4⁺, CD8⁺ and NK cells in vivo prior to single agent or combination treatment demonstrated a requirement for both CD4⁺ and CD8⁺ T cell activity for TGI. NK cells were dispensable. Taken together, these data demonstrate that the improved CBI/MYC-OEC combination activity is mediated through the recruitment of activated T cells and reduction of immune suppressive Tregs. **Conclusions:** These efficacy and tolerability data support the combination of MYC-OEC and CBI treatment in patients with solid tumors. OTX-2002 is currently being evaluated in a Phase 1/2 clinical trial as a monotherapy and in combination with SoC (i.e., TKI and CBIs) for patients with HCC and other solid tumor types known for an association with MYC. Research Sponsor: Omega Therapeutics.

FDA analysis of treatment efficacy based on etiology of hepatocellular carcinoma. *First Author: May Tun Saung, US Food and Drug Administration, Silver Spring, MD*

Background: Retrospective analyses of trial-level data report that etiology of hepatocellular carcinoma (HCC) (e.g., viral versus [vs.] non-viral) may influence efficacy of systemic therapies used in advanced HCC. FDA conducted an analysis of 9 randomized controlled trials (RCTs; n=5,417) to assess treatment effects based on drug class, treatment line, and HCC etiology. **Methods:** FDA conducted a retrospective, exploratory analysis of 3 RCTs comparing first line (1L) treatment with anti-programmed cell death (ligand)-1-containing regimens (αPD-[L]1) to single-agent anti-vascular endothelial growth factor therapy (αVEGF), and 6 RCTs comparing second line (2L) treatment consisting of αPD-[L]1 or αVEGF to placebo. For each line of treatment (1L or 2L), meta-analyses of overall survival (OS) were performed for the overall treatment effect and by disease etiology, viral (hepatitis B [HBV], or hepatitis C [HCV]) vs. non-viral. Subgroup analyses were performed to investigate the confounding effect of subsequent therapy (yes vs. no) and region (Asian vs. non-Asian) on etiology. Trial-level hazard ratios (HRs) and 95% confidence intervals (CI) were mostly calculated using patient-level data submitted to FDA. Pooled HRs and CIs were calculated using a random-effects model. **Results:** While 1L αPD-[L]1 improved OS compared to 1L αVEGF in the overall population (HR [95% CI]: 0.8 [0.73, 0.88]), treatment effects were comparable for viral (HR [95% CI]: 0.75 [0.6, 0.92]; n=1,435) and non-viral (HR [95% CI]: 0.83 [0.72, 0.95]; n=979) subgroup analyses, and not influenced by subsequent therapy or region. Analyses based on specific viral infection (i.e., HBV or HCV), showed that improvement in OS for αPD-[L]1 vs. αVEGF appeared larger for HBV (HR [95% CI]: 0.7 [0.59, 0.82]; n=833) compared to HCV (HR [95% CI]: 0.83 [0.6, 1.16]; n=602). Treatment effects were also comparable in 2L for different etiologies for both αPD-[L]1 (HR [95% CI] for viral: 0.76 [0.62, 0.93]; n=529 and non-viral: 0.85 [0.65, 1.11]; n=337) and αVEGF (HR [95% CI] for viral: 0.79 [0.69, 0.9]; n=1,288 and non-viral: 0.74 [0.63, 0.88]; n=849), and not influenced by subsequent therapy. Nonetheless, compared to placebo, αPD-[L]1 had a larger treatment effect with HBV (HR [95% CI]: 0.69 [0.5, 0.94]; n=459) compared to non-viral etiologies. **Conclusions:** The results did not demonstrate that etiology of HCC was predictive of OS for both treatment classes based on retrospective, exploratory meta-analyses of 9 RCTs; however, the treatment effects may be more pronounced in patients with HBV who received αPD-[L]1 as 1L or 2L. Uncertainty remains regarding subgroup treatment effects given limited number of trials in the analyses (mostly leading to approvals), overlapping CIs, number of patients in some subgroups, retrospective nature, and exclusion of trials with inadequate data regarding etiology of HCC. Research Sponsor: None.

Adjuvant immune checkpoint inhibitors and association with recurrence-free survival in postoperative hepatocellular carcinoma (PREVENT): A prospective cohort study. *First Author: Le Li, Guangxi Medical University Cancer Hospital, Nanning, China*

Background: Adjuvant therapy may improve survival of patients with hepatocellular carcinoma (HCC) after curative resection, yet no such therapy is universally recommended. This study compared safety and efficacy outcomes between patients at high risk of recurrence who received different types of adjuvant therapy or no such therapy after hepatic resection for HCC. **Methods:** Recurrence-free survival (RFS), overall survival, and adverse events were compared among patients who received adjuvant immune checkpoint inhibitors (ICIs) alone, ICIs with tyrosine kinase inhibitors (TKIs), or no adjuvant therapy at our medical center between 13 March 2019 and 19 March 2022. In some analyses, patients who received adjuvant therapy were matched based on propensity scores to patients who did not, in order to reduce confounding due to baseline differences. This study was registered on ClinicalTrials.gov (NCT05221398). **Results:** Of the 492 patients in our final analysis, 410 (83.3%) received no adjuvant therapy, 50 (10.2%) received ICIs alone, and 32 (6.5%) received adjuvant ICIs and TKIs. During median follow-up of 23.3 months (IQR 15.6 to 31.1 months), HCC recurred in 221 (53.9%) of patients who received no adjuvant therapy, compared to 22 (44.0%) of patients who received ICIs and 18 (56.3%) of patients who received ICIs and TKIs. RFS was significantly longer among patients who received either type of adjuvant therapy (23.9 months, 95%CI 14.0-33.7) than among those who received none (16.8 months, 95%CI 13.2-20.3), and this difference remained significant after propensity score matching (HR 0.61, 95%CI 0.39-0.94, $P = 0.033$). However, overall survival was unaffected by either type of adjuvant therapy, even after propensity score matching. The rate of grade 3 or 4 adverse events was similar between the two types of adjuvant therapy. **Conclusions:** ICIs alone or with TKIs may improve RFS of patients at high risk of recurrence after curative resection. Clinical trial information: NCT05221398. Research Sponsor: None.

Characteristics and outcomes of patients with young-onset versus average-onset cholangiocarcinoma in the United States. *First Author: Udhayvir Singh Grewal, University of Iowa Hospitals and Clinics, Iowa City, IA*

Background: Cholangiocarcinoma (CCA) is a lethal malignancy originating from the epithelium lining the biliary tree, with a rising incidence in the Western world. CCA is commonly diagnosed after the age of 50 years, referred to as average-onset CCA (AOCCA), which has known risk factors and predictors of overall outcomes. However, robust data regarding the characteristics and outcomes of patients with young-onset (diagnosed <50 years of age) CCA (YOCCA) are lacking. **Methods:** Data on patient characteristics, tumor characteristics, incidence, and mortality were retrieved from the SEER database spanning a period from the year 2000 to 2017 (representing 48% of the US population). Intrahepatic CCA (iCCA) was identified with a topography code of C22.0 (liver) and a histology code of 8140, 8160, 8161, 8480, 8481, or 8500 or with a topography code of C22.1 (intrahepatic bile ducts) and a histology code of 8000, 8010, 8020, 8140, 8160, 8161, 8260, 8480, 8481, 8490, or 8500. Extrahepatic CCA (eCCA) was identified with a topography code of C24.1 (extrahepatic biliary ducts) and a histology code of 8000, 8010, 8020, 8140, 8160, 8161, 8260, 8480, 8481, 8490, or 8500, or for any case with a topography code of C22.0, C22.1, or C24.0 and a histology code of 8162 (Klatskin tumor). A comparison was made between the patients with YOCCA and AOCCA. Trends in incidence were analyzed using the Joinpoint regression model. Overall survival distributions were estimated using the Kaplan-Meier method. **Results:** A total of 28,367 patients were included in the analysis, which included 2,082 (7.34%) patients with YOCCA. We noted an increase in the incidence of YOCCA over the study period (annual percentage change=+2.53, $p=0.003$). The majority of the patients in the YOCCA group were males (54.66%), White (50%), and had iCCA (71.9%). When compared to AOCCA, these patients were more likely to be males (54.7% vs 52.4%, $p=0.048$), non-White (39.8% vs 35.5%, $p=0.007$), and have a diagnosis of iCCA (71.9% vs 65.7%, $p<0.0001$). Patients in the YOCCA group were more likely to present with regional spread (31.6% vs 28.4%, $p<0.0001$) and metastatic disease (31.9% vs 25.6%, $p<0.0001$). YOCCA patients were also more likely to receive surgery (33.3% vs 22.7%, $p<0.0001$) and chemotherapy (62.6% vs 37.3%, $p<0.0001$) compared to patients in the AOCCA group. Patients with YOCCA had a significantly better median overall survival (13 months vs. 7 months, $p<0.001$) than patients with AOCCA. **Conclusions:** The current analysis showed a significant increase in the incidence of YOCCA over the 17 years of the study period. Patients with YOCCA were more likely to be non-White, males and present with iCCA. Despite presentation with advanced-stage disease (with regional spread or metastatic disease), patients with YOCCA were more likely to receive cancer-directed therapy and had better overall survival than patients with AOCCA. Camrelizumab in combination with apatinib as a perioperative treatment for patients with hepatocellular carcinoma at high risk of recurrence: A prospective, single-arm, phase 2 study. *First Author: Yunlong Cui, Tianjin Medical University Cancer Hospital & Institute, Tianjin, China*

Background: Hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide, and a rising cause of cancer-related mortality. To date, the optimal perioperative treatment strategy for HCC patients remains unclear. It is urgent to develop novel and reliable therapeutic interventions to reduce the risk of recurrence and improve survival in patients with locally advanced HCC. **Methods:** This prospective, exploratory, single-arm, phase 2 study enrolled patients with primary resectable HCC who had not received prior systemic therapy. Before surgery, patients received combination treatment with four cycles of camrelizumab (200 mg, Q2W) plus apatinib (250 mg, QD). Each cycle was two weeks. The feasibility of hepatic resection was assessed by radiographic imaging. After 4-8 weeks of surgery, patients continued combination therapy (camrelizumab [200 mg, Q2W] and apatinib [250 mg, QD]) for one year. Primary endpoint was major pathological response (MPR). Secondary endpoints were pathologic complete response rate (pCR), objective response rate (ORR), disease-free survival (DFS), and safety. Exploratory endpoint was microvascular invasion (MVI). This study is registered on ClinicalTrials.gov, number NCT04701060. **Results:** Between Jan 12, 2021, and Aug 17, 2022, 31 patients with a median age of 54 years were enrolled. Among these, 21 patients (67.7%) had hepatitis B virus infection. Before surgical incision, two patients withdrew informed consent. Therefore, ORR based on RECIST 1.1 and mRECIST were 13.8% (4/29) and 48.3% (14/29), respectively. 26 patients underwent hepatic resection, R0 resection rate was 100%, 10 (38.5%) patients achieved MPR, and pCR rate was 7.7%. The reasons for patients not undergoing surgery were disease progression and serious adverse events (AEs). Among patients with MVI, M0 was found in 57.7% (15/26) patients, M1 was found in 34.6% (9/26) patients, and M2 was found in 7.7% (2/26) patients. 1-year DFS rate was 77.4%, and median DFS was not reached. The most common AEs included increased aspartate aminotransferase (74.2%), increased alanine aminotransferase (70.1%), decreased platelet count (61.3%), anemia (58.1%), and decreased lymphocyte count (51.6%). Grade 4 AEs occurred in 7 of 31 patients, and there were no treatment-related deaths. **Conclusions:** Camrelizumab plus apatinib as a perioperative treatment is effective and tolerable in patients with HCC at high risk of recurrence. Preoperative neoadjuvant therapy has reduced the rate of MVI. Because of the short follow-up period, whether perioperative treatment can effectively reduce recurrence rates and improve long-term survival still needs further investigation. Machine learning-based multimodal prediction of prognosis in patients with resected intrahepatic cholangiocarcinoma. *First Author: Benoit Schmauch, OWKIN, Paris, France*

Background: Intrahepatic cholangiocarcinoma (ICCA) is an aggressive malignancy and the second most common primary liver cancer. About a third of patients may benefit from surgery but recurrence is common and the overall survival is low. Accurate prognosis modeling that can predict response to treatment and outcome remains an unmet clinical need. Deep learning methods provide a new opportunity to better predict prognosis by extracting distinguishing characteristics interrogating multiple data sources, which appears to be superior to unimodal modeling. This study aimed to construct a predictive model of patient outcome and identify predictive biomarkers based on a combination of clinical, genomic, histological and radiological data. **Methods:** We analyzed 83 patients with ICCA that underwent surgery and designed a multi-modal model to predict overall survival (OS) and progression-free survival (PFS). Among these patients, each had one to three hematoxylin/eosin histology slides. As a pre-processing step, each histology slide was decomposed into patches, each patch was fed into a ResNet feature extractor to extract a feature representation of the patch, and the features across patches were aggregated with maximum pooling to yield a 2048-dimensional vector representation for each slide. Among these 83 patients, 76 patients had their tumors profiled for somatic genomic alterations using MSK-IMPACT, a deep targeted-sequencing assay. A binary matrix across altered genes and samples was created as an input to the prediction model. Cox proportional hazard models specific to each modality (clinical data, histological slides, and altered genes) were then designed and their predictions were averaged to produce the final log-risk score. The models were validated using a 5-fold, 5-repeat cross-validation with patient-level splits. **Results:** A model using only clinical and routine histological data achieved a concordance index of 0.74 (95% confidence interval, 0.64-0.82) for OS and 0.73 (0.64-0.78) for PFS. Adding information about genetic alterations improved performance for OS (0.80, 0.70-0.88) and similar performance for PFS (0.72, 0.64-0.79). Both models outperform a staging-based patient stratification. **Conclusions:** This study demonstrates that machine learning models can improve survival prediction using multimodal data after resection of intrahepatic cholangiocarcinoma. Such models have the potential to improve risk stratification and treatment recommendations. Research Sponsor: OWKIN.

Input data	OS	PFS
Cancer stage (AJCC/UICC 8th edition)	0.66 (0.55-0.75)	0.59 (0.49-0.66)
Clinical + Histological	0.74 (0.64-0.82)	0.73 (0.64-0.78)
Clinical + Histological + Altered genes	0.80 (0.70-0.88)	0.72 (0.64-0.79)

Utility of circulating tumor DNA (ctDNA) as a predictive biomarker for disease monitoring in patients (pts) with cholangiocarcinoma (CCA) before and during adjuvant chemotherapy (ACT): Sub-analysis of the randomized phase 2 STAMP trial. *First Author: Changhoon Yoo, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Detection of circulating tumor DNA (ctDNA) in blood is a powerful predictive biomarker for identifying molecular residual disease (MRD) post-surgery. Not much is known about the utility of identifying MRD using ctDNA in pts with resected CCA, despite its associated poor prognosis. The STAMP trial (NCT03079427), a randomized phase 2 study comparing adjuvant capecitabine (CAP) to gemcitabine plus cisplatin (GemCis) showed no difference in recurrence-free survival (RFS) and overall survival (OS) between the 2 arms. The goal of this analysis was to evaluate the feasibility of monitoring ctDNA to predict the risk of recurrence in pts with resected CCA. **Methods:** A total of 254 plasma samples were collected from a cohort of 89 CCA (hilar, N = 43; distal, N = 46) pts post-surgery at 3 separate time points; pre-ACT (baseline, N = 89), on-ACT C5D1 (after 5 cycles of treatment) (N = 88), and on-ACT C8D1 (after 8 cycles of treatment) (N = 77). Longitudinal ctDNA testing was performed using a personalized, tumor-informed ctDNA assay (Signatera, bespoke mPCR-NGS assay). ctDNA results were analyzed and evaluated for its correlation with RFS and OS. **Results:** At the MRD timepoint (baseline, pre-ACT), 24.7% (22/89) pts were ctDNA-positive, 90.9% (20/22) of whom recurred demonstrating a trend for shorter RFS (HR = 1.7, 95%CI 0.98-2.8, p = 0.069) compared to ctDNA-negative pts. All pts who remained ctDNA-positive on-ACT at C5D1 (N = 17) and C8D1 (N = 15), recurred clinically with a significantly shorter RFS (HR = 8.1, 95%CI 4.3-15, p < 0.0001 and HR = 5.0, 95%CI 2.7-9.4, p < 0.0001, respectively). The primary cancer site (hilar vs distal) or type of ACT (CAP vs GemCis) had no impact on RFS irrespective of ct-DNA result. Pts who remained ctDNA-negative on ACT (N = 56) showed significantly better RFS compared to pts who remained positive (N = 10, HR = 6.6, 95%CI 3.1-14, p < 0.001), or who turned positive (N = 11, HR = 5.2, 95%CI 2.54-10.5, p < 0.001). In multivariate analysis including primary tumor site, sex, pathological grade and ACT regimen, positive ctDNA status at baseline (pre-ACT) remained significant for poor RFS (HR = 1.82, 95%CI 1.04-3.18, p = 0.035). **Conclusions:** Personalized monitoring of ctDNA both pre and on-ACT is feasible and predictive for recurrence in pts with resected CCA. To our best knowledge, this is one of the first reports presenting the clinical implication of ctDNA monitoring on ACT, in pts with CCA. Our findings suggest ctDNA monitoring may help optimize clinical decision-making in pts with resected CCA. Larger prospective studies would be needed to validate the findings of this study. Clinical trial information: NCT03079427. Research Sponsor: Natera; Asan Institution for Life Science.

Efficacy and safety of HepaSphere drug-eluting bead transarterial chemoembolization combined with hepatic arterial infusion chemotherapy in advanced hepatocellular carcinoma. *First Author: Baojiang Liu, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Interventional Therapy, Peking University Cancer Hospital & Institute, Beijing, China, China*

Background: Transarterial chemoembolization (TACE) is widely applied and shows good efficacy in advanced hepatocellular carcinoma (HCC). Recently, hepatic arterial infusion chemotherapy (HAIC) has also gained popularity in the treatment of HCC. Several studies have described the comparison between HAIC and TACE or TACE combined with HAIC. However, the evaluation between TACE plus HAIC and HAIC is rarely reported. Here, we observed the performance of HepaSphere DEB-TACE combined with HAIC (Hepa-HAIC) comparing to HAIC in patients with advanced HCC. **Methods:** 167 patients diagnosed as advanced HCC and treated in Peking University Cancer Hospital from May 2018 to May 2022 were enrolled in this retrospective study, composed of 74 patients received HepaSphere DEB-TACE combined with HAIC-FOLFOX (Hepa-HAIC) and 93 patients received HAIC-FOLFOX. More than 60% patients experienced other treatments before the enrollment. To avoid the selection bias, propensity score matching (PSM) was conducted and applied for the efficacy and safety analysis between these two cohorts. The primary endpoints are progression-free survival (PFS) and overall survival (OS); the secondary endpoint includes objective response rate (ORR), disease control rate (DCR) and safety. **Results:** Propensity-matching yielded 48 pairs and the baselines were almost equal in Hepa-HAIC and HAIC cohorts after matching. Median PFS and median OS were both higher in matched Hepa-HAIC cohort (median PFS:8.9 vs. 5.8 months, P=0.035; median OS:22.4 vs. 9.5 months, P=0.027), which were consistent with pre-matching analysis. The ORR in Hepa-HAIC and HAIC cohorts was 75.0% and 37.5%, respectively; DCR was 93.8% after Hepa-HAIC and 81.3% after HAIC. There was no treatment-related death. Serious adverse events were similar in these two groups, except alanine aminotransferase (ALT) and vomiting. There was more frequency of Grade 3-4 ALT elevation in Hepa-HAIC (33.3% vs. 8.3%, P=0.003) while more incidence of vomiting in HAIC group (29.2% vs. 12.5%, P=0.044). **Conclusions:** All of the observed PFS, OS, ORR and DCR in Hepa-HAIC group are superior to HAIC group, which indicates the combination of HepaSphere DEB-TACE and HAIC may lead to improved outcomes with comparable safety profile in advanced HCC. Research Sponsor: None.

	Hepa-HAIC (N=48)	HAIC (N=48)	P value
ORR	75%	37.5%	P<0.001

Preliminary results of sequential transarterial chemoembolization and stereotactic body radiotherapy followed by immunotherapy using single tremelimumab regular interval durvalumab in locally advanced, unresectable hepatocellular carcinoma (START-FIT using STRIDE): A single-arm, phase II study. *First Author: Chi Leung Chiang, The University of Hong Kong, Hong Kong, NA, Hong Kong*

Background: Sequential transarterial chemoembolization and stereotactic body radiotherapy followed by immunotherapy (IO) (START-FIT) using anti-PD-L1 has demonstrated promising efficacy in locally advanced HCC (laHCC). We aimed to evaluate START-FIT activity using anti-PD-L1 and anti-CTLA-4 IO backbone. **Methods:** Adult patients with laHCC not suitable for curative resections were recruited. Each with tumor at least 5cm, maximum three tumors, and child-Pugh A5-B7 liver function. Patients had single TACE, 5-SBRT 28 days after, then single Tremelimumab (300mg) and regular 4-week interval Durvalumab (1500mg) at 7 days upon SBRT completion. Primary endpoint was overall response rate (ORR) per modified Response Evaluation Criteria in Solid Tumors (mRECIST); secondary endpoints included progression-free survival (PFS), overall survival (OS), and treatment-related (TR) adverse event (AE) [NCT04988945]. **Results:** During 11 Dec, 20 and 3 Oct, 22, 16 patients were enrolled with median age 66 (range (r): 51-84 years), 14 (87.5%) were male, the lesion(s) diameter median sum was 11.2 cm (r: 5.8-15cm), and 11 (68.8%) had macrovascular invasion (n=6, hepatic vein, n=4, branched portal vein, n=1 both). With median 11.3 months (r: 3.7-24.5 months) follow-up time, the best ORR was 81.3% (95% CI: 54.4-96.0%) (Complete response CR: n=7, 43.8%; partial response PR: n=6, 37.5%; stable disease SD + progressive disease PD: n=3, 18.7%). The 6 and 12-month PFS rates were 86.7% (95% CI: 69.3-100%) and 58.7% (95% CI: 33.6-84.4%), while 6 and 12-month OS rates were 100% (95% CI: 91.7-100%) and 83.3% (95% CI: 62.2-100%) respectively. The 12-month OS with CR vs. PR vs. SD+PD was 100%, 75%, and 50% respectively. Four (25%) and one patient (6.3%) experienced TRAEs and immune-related AE of grade 3 or worse respectively. **Conclusions:** START-FIT using STRIDE is safe and effective in unresectable laHCC resulted in 43.8% CR rate and promising survival. Clinical trial information: NCT04988945. Research Sponsor: Astra.

Primary analysis of a phase II study of atezolizumab plus bevacizumab for TACE-unsuitable patients with tumor burden beyond up-to-seven criteria in intermediate-stage hepatocellular carcinoma: REPLACEMENT study. *First Author: Kazuomi Ueshima, Kindai University Faculty of Medicine, Osaka-Sayama, Osaka, Japan*

Background: Intermediate-stage hepatocellular carcinoma (HCC) is a heterogeneous disease; therefore, the efficacy of transarterial chemoembolization (TACE) is affected by tumor burden, resulting in a wide range of survival outcomes. Multiple recent guidelines suggest that systemic therapy is preferable for patients with intermediate-stage HCC who are TACE unsuitable because of high tumor burden, such as beyond up-to-seven criteria. The Phase III IMbrave150 study established atezolizumab plus bevacizumab (atezo+bev) as the standard of care in patients with unresectable HCC. Here, we investigated whether atezo+bev is potentially superior to TACE in efficacy and safety in TACE-naïve patients with unresectable intermediate-stage HCC beyond up-to-seven criteria. **Methods:** In this multicenter, phase II study, atezo 1200 mg + bev 15 mg/kg q3w were administered to eligible patients (as defined above plus having Child-Pugh A liver function) enrolled from Dec 2020 to Sep 2021 until discontinuation due to disease progression, adverse events (AEs), or other reasons. Overall survival (OS) follow-up continued for 2.5 years after enrollment. The primary endpoint was progression-free survival (PFS) assessed by mRECIST by investigator; secondary endpoints were objective response rate (ORR), PFS by RECIST v1.1, OS, and safety. In an exploratory analysis, we conducted propensity score matching (PSM) analysis to compare the efficacy between atezo+bev and TACE, the data of which were retrospectively collected in patients treated with TACE in each participating center from Jan 2017 to Dec 2017. **Results:** In total, 74 patients were enrolled (male, 87.8%; mean age, 73.7 years; median [range] maximum tumor diameter by pre-treatment CT, 4.8 [1.0,13.0] cm). Median (min, max) follow-up was 15.0 (1.6, 21.6) months. Median PFS was 9.1 (95%CI: 7.1, 10.2) months (by mRECIST; primary endpoint). ORR was 45.9 (95%CI: 34.3, 57.9) % by mRECIST. Median OS was not reached (NR) (95%CI: NR, NR). 12-month OS rate was 84.6 [95%CI: 74.0, 91.2]%. The most frequent AEs (any grade ≥10% of patients) were hypertension, proteinuria, malaise, anorexia, edema, pruritis, and diarrhea. **Conclusions:** Atezo+bev provides clinical benefits to TACE-unsuitable patients with intermediate-stage HCC beyond up-to-seven criteria. Results of the exploratory PSM analysis will be presented. Clinical trial information: jrcs071200051. Research Sponsor: Chugai Pharmaceutical Co., Ltd.

Robotic and laparoscopic surgery versus open surgery for perihilar cholangiocarcinoma: A meta-analysis. *First Author: Laynara Vitória Da Silva Vieira, Federal University of Piauí, Teresina, Brazil*

Background: Robotic and laparoscopic surgeries provide a new approach for patients with perihilar cholangiocarcinoma (pCCA). However, whether it can achieve similar outcomes to traditional open surgery (OS) remains controversial. Therefore, to compare the outcomes of laparoscopic/robotic surgery with open surgery and investigate the efficiency for Klatskin tumors further, we systematically summarized the currently available data and performed a meta-analysis. **Methods:** A systematic review and meta-analysis were conducted to examine the most recent studies on the topic. The search was updated to January 15, 2023, and was performed on PubMed, LILACS, and Embase. The inclusion criteria were case cohort comparing two arms: robotic or laparoscopic and open surgery for pCCA, based in PICOS principle, while the exclusion criteria were review, letter, and articles with incomplete data. All the included literature was evaluated for quality and risk of bias using the Joanna Briggs Institute's critical appraisal tool and the data were extracted and entered into an Excel spreadsheet by two authors. The data was then analyzed using Review Manager 5.4 applying Odds Ratio and Mean Difference. The study protocol was registered in PROSPERO (CRD42023388478) and was conducted following the PRISMA 2020 checklist. **Results:** A total of 1133 patients were included in the study (411 laparoscopic/robotic, 722 open surgeries), 15 retrospective cohort were used in the meta-analysis. The meta-analysis revealed that laparoscopic surgery resulted in less blood loss (Mean difference -77.87; 95% CI = -89.97, -67.78; $p < 0.00001$, $I^2 = 84\%$), shorter hospital stay (Mean difference -3.25; 95% CI = -4.83, -1.67; $p < 0.0001$, $I^2 = 79\%$) but longer operation time (Mean difference 53.95; 95% CI = 48.09, 59.81; $p < 0.00001$, $I^2 = 86\%$). The mortality rate was not significantly different between the two groups (odds ratio = 0.82; 95% CI = 0.47 a 1.42; $p = 0.48$; $I^2 = 0\%$). Both surgeries showed similar results for age (Mean difference 1.71; 95% CI = -0.62, 4.03; $p = 0.15$, $I^2 = 53\%$), bilirubin (Mean difference -43.45; 95% CI = -77.11, -9.79; $p < 0.01$, $I^2 = 0\%$), BMI (Mean difference 0.25; 95% CI = -0.24, 0.74; $p = 0.31$, $I^2 = 0\%$), and tumor diameter (mean difference -0.06; 95% CI = -0.52, 0.40; $p = 0.80$, $I^2 = 0\%$). **Conclusions:** The limitations of the study evidence are due to the small number of patients included in each article. Concerning blood loss and hospital stay, minimally invasive surgery offers better results. However, open surgery still has a shorter operating time. Both surgeries had similar results in mortality. Minimally invasive surgery is as safe as open surgery for pCCA resection. Research Sponsor: None.

A phase II/III study of camrelizumab plus apatinib as perioperative treatment of resectable hepatocellular carcinoma at intermediate-high risk of recurrence: Primary results of major pathologic response from phase II stage. *First Author: Jian Zhou, Liver Cancer Institute, Zhongshan Hospital, and Key Laboratory of Carcinogenesis and Cancer Invasion (Ministry of Education), Fudan University, Shanghai, China*

Background: Surgical resection remains an important treatment strategy for patients (pts) with liver cancer. However, the 5-year recurrence rate is still 50-70% in surgically resectable pts. Intermediate-high risk factors of recurrence in HCC include single tumor size > 5 cm, multiple tumors, and microvascular invasion. The standardized perioperative regimen for resectable HCC has not been established. This study aimed to assess the efficacy and safety of camrelizumab plus apatinib (C+A) as a perioperative regimen in resectable HCC at intermediate-high risk of recurrence (Clinical trial: NCT04521153). **Methods:** In this multicentre, randomised, phase II/III study, eligible HCC pts (CNLC Ib-IIIa) were randomly assigned in a 1:1 ratio to treatment group and control group. Pts in treatment group received 2 cycles of C (200mg Q2W) plus A (250mg QD) followed by surgery and a post-surgical TACE. At least 6 cycles of sequential treatment of C (200mg Q3W) plus A (250mg QD) were performed after TACE. Pts in control group received surgical resection and a post-surgical TACE. Primary endpoint of phase III stage was 3-year EFS, of phase II stage was MPR (defined as less than 50% residual tumor) rate. In the phase II stage, futility analysis on a phase II outcome was performed after pts in treatment group completed surgical resection and pathological evaluation. If $< 15\%$ of pts achieved an MPR, or $> 20\%$ of pts had progression that precluded surgery, the study would not proceed to phase III stage. **Results:** In phase II stage, 60 pts were randomly assigned to treatment group, and 59 to control group. As of Nov 4, 2022, the last randomised pt underwent curatively surgical resection and pathological evaluation. The median age was 58 years (range, 21-75). 101 (84.9%) were male, and 96 (80.7%) had HBV infection. In treatment group, 58 pts received neo-adjuvant therapy, 52 completed 2 cycles of preoperative therapy and proceeded with planned resection. Surgery was aborted for 6 pts: 3 refused surgery, 2 deaths (1 for tumor rupture of HCC, 1 for immune related hepatitis), and 1 had protocol deviation. The MPR rates in the ITT population were 40% (24/60). Among them, 10% pts (6/60) had $\leq 5\%$ surviving tumor cells in tumor bed. The MPR rate in pts who had surgical resection were 46.2% (24/52). 19.3% pts experienced ≥ 3 grade TRAEs, the most common of which were AST increased (5.3%), hypertension (5.3%), and ALT increased (3.5%). **Conclusions:** The phase II stage of the study did not meet the stopping criteria. Neo-adjuvant camrelizumab plus apatinib therapy exhibits promising pathological response in HCC pts at intermediate-high risk of recurrence, with a tolerable safety profile. The phase III stage of the study is currently ongoing. Clinical trial information: NCT04521153. Research Sponsor: Shanghai shenkang hospital development center; Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Development and validation of a non-invasive cfDNA targeted sequencing assay for early-stage hepatocellular carcinoma detection using cfDNA methylation and fragmentomics. *First Author: Rui Liu, Singlera Genomics Ltd., Shanghai, China*

Background: Hepatocellular carcinoma (HCC) is one of the most common cancers in China, and one of the leading causes of cancer-related deaths in the country. With a 5-year survival rate of only 15-20%, early detection is crucial to improve the treatment and survival of HCC patients. Currently, alpha-fetoprotein (AFP) is commonly used as a serum marker for HCC, but it is not a sufficiently specific and can cause false positive readings due to elevated levels caused by other liver conditions. An alternative method is to use circulating free DNA (cfDNA) released by tumor cells as cancer-screening targets, which has been shown to be a more sensitive and specific biomarkers for HCC detection. This study aims to develop a non-invasive screening assay based on cfDNA features to improve the detection of early-stage HCC. **Methods:** Candidate methylation markers for HCC detection were collected and evaluated using GEO, TCGA and in-house datasets, 1601 of which were incorporated into a targeted sequencing panel named HcSeer. Multiple types of cfDNA features were constructed from the sequencing data, which included methylation-related features such as methylation haplotype blocks (MHBs) and methylated haplotype fraction (MHF), and fragmentomics features such as end motif and CNV. For model building, Cancer and healthy plasma samples were randomly divided into a training and a testing set at a 2:1 ratio. A two-step deep neural network model was built to classify HCC using selected features of both types. **Results:** We previously enrolled a total of 401 plasma samples (200 healthy, 201 HCC) for model construction and the performance of the HcSeer model have been documented. An independent validation cohort of 421 plasma samples (280 healthy, 141 HCC) was currently collected from different centers. In this independent validation, the HcSeer model achieved an AUC of 0.98 with a sensitivity of 96.5% at a specificity of 96.4%. Importantly, HcSeer maintained a high sensitivity for HCC across all stages: 94.3%, 96%, 100% and 100% for stage I – IV cases, respectively. When compared to AFP, HcSeer achieved a significantly higher sensitivity of 94% than AFP's 55% in 137 HCC cases having AFP level tested. When AFP level was combined with the HcSeer model, the sensitivity for HCC further increased to 96%. **Conclusions:** This study demonstrated that the DNA methylation and fragmentomics patterns of cfDNA can accurately distinguish HCC and healthy plasma samples, particularly in the early stages of HCC. The combination of the HcSeer and AFP further improved the accuracy of the prediction. Although this study was limited in sample size, it clearly showed the potential of the HcSeer assay for accurate HCC detection in blood. Neoadjuvant immunotherapy with ipilimumab plus nivolumab and radiologically and pathologically quantifiable responses through modulation of the tumour microenvironment in resectable hepatocellular carcinoma. *First Author: Antonio D'Alessio, Imperial College, London, United Kingdom*

Background: Liver resection (LR) is a potentially curative option for early-stage hepatocellular carcinoma (HCC), and immune checkpoint inhibitors (ICI) are being investigated in the perioperative setting to improve long-term relapse rates and survival outcomes. **Methods:** PRIME-HCC is a phase Ib study testing nivolumab (3 mg/kg, day 1 and day 22) plus ipilimumab (1mg/kg, day 1 only) (N+I) prior to LR in resectable HCC. Primary endpoint was safety, while secondary endpoints included radiological response (per RECIST v1.1) and pathological response on resection specimens (ReS). Translational endpoints encompassed analysis of tissue samples with multiplex immunohistochemistry (MIHC) and gut microbiota profiling with high-throughput sequencing and their correlation with response. **Results:** As of 7th of February 2023, 25 patients (pts) were enrolled, all Child-Pugh A, mostly male (n=18, 72%), with cirrhosis (n=13, 52%), and viral hepatitis (44%, 4 HBV and 7 HCV). Any-grade adverse events (AEs) occurred in 88% pts (n=22), of which 24% (n=6) grade (G) 3. No G4-5 AEs were recorded. Any-grade treatment-related (tr)AEs were reported by 72% pts (n=18), including 8% G3 trAEs (n=1 ALT/AST elevation and n=1 dyspnea). After a median follow-up of 14.5 months (95% CI 7.0-22.0), 21 pts were assessed for radiological response and underwent surgery. Median time from treatment start to LR was 2.4 months (interquartile range 2.2-2.7). LR was delayed in 1 pt (4.8%) because of G2 tr-hypothyroidism but occurred uneventfully. Objective response rate was 29% (n=5 partial responses, n=1 complete response [CR]); disease control rate was 95% (n=20), with 1 progressor having a mixed HCC/cholangiocarcinoma. Major pathological response (MPR), defined as $\geq 70\%$ tumour regression, was observed in 56% (n=9) of the pathologically evaluable ReS (n=16), with 38% pathological CR (n=6). In the MIHC analyses, pre-treatment biopsies of MPR pts were significantly enriched in peritumoral CD4+ and CD8+ cells, with no intratumoral difference. When comparing baseline biopsies and ReS, MPR pts had a significant decrease of intratumoral FOXP3+/CD4+ regulatory T cells (Tregs), while peritumoral Tregs increased significantly in non-MPR ReS. In baseline stool samples, α and β diversity did not differ across responders (R) and non-responders (NR), nor it changed after ICI. However, pre-treatment stool samples of NR pts were significantly enriched in *Alistipes* and *Collinsella* genera. **Conclusions:** Neoadjuvant N+I is feasible and tolerable for early-stage HCC, with promising radiological and pathological response rates. Study of tissue and gut microbiota highlights tumor and host-related changes. Immune infiltrate and gut microbiota composition lend themselves as predictors of anti-tumour efficacy of N+I combination. Clinical trial information: NCT03682276. Racial disparities in the outcomes of liver transplantation in the treatment of hepatocellular carcinoma. *First Author: Syeda Ashna Fatima Kamal, Springfield Memorial Hospital/Southern University of Illinois, Springfield, IL*

Background: According to the National Comprehensive Cancer Network (NCCN), liver transplantation (LT) is currently the treatment of choice for patients with early hepatocellular carcinoma (HCC). A retrospective study in 2016 showed a difference in mortality among races in patients undergoing treatment for HCC. Our study is the first to compare the outcomes of mortality, morbidity and hospital utilization of HCC patients undergoing LT among races in the US. **Methods:** This is a retrospective longitudinal study of patients with a primary diagnosis of HCC. We retrieved data from the Nationwide Inpatient Sample (NIS) databases from the years 2016 to 2020 using ICD-10 codes. Multivariate regression analysis was applied to compare the outcomes in races, adjusted for patient and hospital confounders. A T-Test and Chi Square test were performed to compare baseline characteristics. We used STATA Version 17.0 Software for analysis. The p-value was set at $p < 0.05$ for statistical significance. **Results:** Among a total of 112,110 adults with HCC, 2.8% (n=3,150) underwent LT. Blacks had lower rates of LT. Blacks and Hispanics were found to have a lower income ($p=0.000$). No difference in the Charlson Comorbidity index was noted among races ($p=0.5519$), however, Blacks had more smokers ($p=0.0149$). Hispanics had a significant increase in THC compared to Whites (coefficient: 102,058 US Dollars, $p=0.033$, CI95%: -109,404 - 119,787), with no difference in the length of stay among races. Blacks had higher rates of mortality ($p=0.004$), acute kidney injury (AKI) ($p=0.001$), and similar rates of transplant complications. **Conclusions:** Our study showed that while Blacks have lower rates of LT, they have a higher rate of mortality and morbidity following LT. Large scale studies are necessary to help determine factors associated with these findings. Research Sponsor: None.

The efficacy of radical hepatectomy versus stereotactic body radiotherapy for primary hepatocellular carcinoma: A propensity score matching analysis. *First Author: Yulin Hu, shenzhen university, Shenzhen, guangdong, China*

Background: Recent international guidelines have included stereotactic body radiotherapy (SBRT) which outstanding tumor control as a treatment option for hepatocellular carcinoma (HCC) in several settings. However, data evaluating surgery and SBRT are limited, and results published were controversial. The retrospective study aims to compare the efficacy of hepatectomy and SBRT for HCC. **Methods:** The study population started with patients in databases of primary HCC, treated with curative hepatectomy or SBRT, regardless of tumor number, tumor size, cirrhosis and portal vein thrombosis. Patients with prior cancer treatment other than transarterial chemoembolization were excluded. In order to reduce the potential confounding effect of treatment and selection bias, 3-to-1 propensity score models were constructed based on each patient's estimated propensity score. The variables significant for overall survival were considered for the match, including age, sex, Child-Pugh score, ECOG performance status score, maximum diameter, BCLC stage, prothrombin time, total bilirubin, albumin, and white blood cell. Overall survival and progression-free survival were compared. **Results:** A total of 174 patients, 154 in hepatectomy group and 20 in SBRT group, were analyzed. 125 men and 29 women, mean 56.2 years of age, in hepatectomy group. 12 men and 8 women, mean 70.5 years of age, in SBRT group. ECOG was a significant favorable factor for overall survival. Maximum diameter, portal vein embolization, aspartate transferase and albumin was significant favorable factors for disease-free survival of patients with primary hepatocellular carcinomas. Before PSM, patients in the hepatectomy group tended to be younger, had better performance status, less cirrhosis, less tumor number and had better hepatic function than those in the SBRT group ($P < .05$). The 3-year overall survival rate and median progression-free survival time for the surgical resection and SBRT groups were 77.9% vs 35.4 ($P = .003$) and 30 vs 20 month ($P = .486$), respectively. After PSM, 80 patients, 60 in hepatectomy group and 20 in SBRT group, were analyzed. The 3-year overall survival rate and median progression-free survival time for the surgical resection and SBRT groups were 71.9% vs 56.6 ($P = .92$) and 17 vs 26 month ($P = .656$), respectively. The patients of hepatectomy group had less cirrhosis, better liver function and less tumor number than those in 20 with SBRT. **Conclusions:** For primary HCC, regardless of tumor size and tumor number, stereotactic body radiotherapy can provide similar result on overall survival and tumor control compared to hepatectomy. Stereotactic body radiotherapy can also be less invasive and provide less inpatient time. So stereotactic body radiotherapy can be a effective treatment for patients with primary HCC. ACTION-1 phase Ib/3 trial of RYZ101 in somatostatin receptor subtype 2-expressing (SSTR2+) gastroenteropancreatic neuroendocrine tumors (GEP-NET) progressing after ¹⁷⁷Lu somatostatin analogue (SSA) therapy: Initial safety analysis. *First Author: Michael Morris, Advanced Molecular Imaging and Therapy, Glen Burnie, MD*

Background: RYZ101 (²²⁵Ac-DOTATATE) is a first-in-class, highly potent alpha-emitting radiopharmaceutical in development for treating SSTR2+ solid tumors. Alpha-particles (as emitted by ²²⁵Ac) have a shorter path length (40–100 μ m) and higher linear energy transfer (80–100 keV/ μ m) than beta-particles, causing more frequent double-strand DNA breaks and potentially higher cancer cell kill rates and less damage to healthy tissues. ACTION-1 (NCT05477576) is a 2-part, global, randomized, controlled, open-label, phase 1b/3 trial of RYZ101 in patients (pts) with advanced well-differentiated SSTR+ GEP-NETs progressing after ¹⁷⁷Lu-SSA therapy. Part 1 (phase 1b) aims to determine safety, pharmacokinetics, and recommended phase 3 dose (RP3D) of RYZ101. **Methods:** Part 1 is an uncontrolled dose de-escalation study with a Bayesian optimal interval design. Escalation (0.197) and de-escalation (0.298) boundaries based on a target dose-limiting toxicity (DLT) rate of 25% were applied. Pts received RYZ101 IV every 8w for up to 4 cycles. Planned dose levels (n=6/level): Level 0 (starting dose), 120 kBq/kg (3.2 μ Ci/kg); if necessary, Level -1, 90 kBq/kg (2.4 μ Ci/kg); Level -2, 60 kBq/kg (1.6 μ Ci/kg). No dose escalation above starting dose was permitted. DLT was assessed for 56d after the first RYZ101 treatment. Treatment-emergent adverse events (TEAEs) were graded by NCI-CTCAE v5.0. Dose de-escalation decisions and safety data review were overseen by a Data Review Committee. Data cut-off: 26 Oct 2022. **Results:** At data cut-off, 9 pts had received RYZ101 at 120 kBq/kg (median dose 8.9 MBq); 7 pts were DLT-evaluable. No DLTs occurred and no dose de-escalation steps were implemented. Baseline characteristics: median age 70y; male (n=6)/female (n=3); ECOG PS 0 (n=4)/1 (n=5); median disease duration 6.9y; primary tumor site GI (n=6)/pancreas (n=3). A safety summary is shown. No treatment-related serious AEs were observed. TEAE requiring dose reductions occurred in 2 pts (Grade 2 platelet count decreased, n=1; Grade 2 thrombocytopenia, n=1). Grade 3 or 4 TEAEs occurred in 3 pts (lymphocyte count decreased, n=2; skin infection, n=1; weight decreased, n=1). One serious adverse event (skin infection) was unrelated to treatment. **Conclusions:** RYZ101 was well tolerated at 120 kBq/kg, which was declared the RP3D. Part 2 (Phase 3) will commence after Part 1 and will compare RYZ101 at the RP3D with standard of care in pts with advanced SSTR2+ GEP-NETs with disease progression following prior ¹⁷⁷Lu-labeled SSAs. Clinical trial information: NCT05477576. Research Sponsor: RayzeBio.

Patients (%)	RYZ101 120 kBq/kg (n=9)
Any TEAE	6 (66.7)
Serious AE	1 (11.1)
Treatment-related TEAE	4 (44.4)
Treatment-related serious AE	0

Novel use of alternate (Alt) response (Rp) criteria (Cr) for early prediction of outcomes in pancreatic (P) neuroendocrine tumors (NETs): Utilizing banked imaging data from the ECOG-ACRIN E2211 study. *First Author: Namrata Vijayvergia, Fox Chase Cancer Center, Temple University Health System, Philadelphia, PA*

Background: The evaluation of treatment (Tx) Rp in NETs using CT/MRI scans can be difficult. Previous studies, including the E2211, have shown improved progression-free survival (PFS) but no significant difference in Rp as measured by RECIST 1.1 (R1.1) Cr. Thus, making it difficult to determine Tx effectiveness with short-term imaging, further complicated by differences in imaging protocols and inter-reader variability. Incorporating tumor density, using smaller threshold changes in tumor size, and novel quantitative features may be more sensitive and precise than R1.1 (e.g. CHOI in GIST) but they have not been studied for NETs. **Methods:** Banked CT images from the E2211 trial were repurposed to study novel Cr. Three radiologists provided a R1.1 assessment. Density and radiomic features were calculated from a 2D region of interest in the portal venous phase (as per CHOI Cr). Patients were classified as responders (PR), stable disease (SD), or progressive disease (PD) based on R1.1 and CHOI and compared with PFS to determine the best predictor. Radiomic features were analyzed using pyradiomics. Wilcoxon tests were used to compare scan quality by center type, agreement was measured using Cohen's Kappa, and predictive value was quantified using the c-statistic and AUC for time-varying outcomes. **Results:** 67 patients had their scans repurposed for the study. Inter-reader agreement for overall imaging studies was fair, with only 5 of 9 PD cases noted by reviewer 1 being agreed upon by reviewer 2 (proportional agreement for PD = 0.56) and a Kappa of 0.6 (95% CI 0.41 – 0.79). The CHOI Cr showed improved prediction of PFS compared to R1.1 (12-month AUC 0.75 for CHOI vs 0.69 for R1.1, c-statistic 0.66 vs 0.64, p=0.22), and was able to predict improved PFS for PR versus SD at the first interval scan. This was not seen with R1.1 (table). Radiomics and texture analysis as a potential adjunct to CHOI is being studied and results will be presented. **Conclusions:** This study using repurposed banked imaging from an NCTN trial, found that there was significant variability in the interpretation of images, and that the R1.1 Cr had a poor correlation with Rp in pNETs. The CHOI Cr emerged as a better alternative as it may have a better correlation with PFS and the ability to predict outcomes at the point of first disease assessment. Importantly, CHOI Cr can be easily applied in clinical practice to inform treatment decisions. Further research is needed to confirm these findings and define the therapeutic importance. Research Sponsor: U.S. National Institutes of Health.

	PFS	AIC	AUC 12m	c-statistic
CR/PR				
RT1.1	SD 19.2m (95% CI 15.1-NA)	23 m (95% CI 12.9- 30.1)	331.240	0.692
CHOI	23m (95% CI 17.5 – 34.2)	11.7 m (95% CI 8 – 35.4 m)	334.528	0.751
			0.658	

*Higher c-statistic, higher AUC, and lower Akaike Information Criterion (AIC) are indicators of better predictive ability and fit.

Safety and clinical activity of oleclumab (O) ± durvalumab (D) + chemotherapy (CT) in patients (pts) with metastatic pancreatic ductal adenocarcinoma (mPDAC): A phase 1b/2 randomized study. *First Author: Andrew L. Covelev, Fred Hutchinson Cancer Center, Seattle, WA*

Background: In a phase 1 study, the anti-CD73 monoclonal antibody (mAb) O plus the anti-PD-L1 mAb D showed antitumor activity and manageable safety in previously treated pts with advanced PDAC (Overman et al, J Clin Oncol 2018;36[suppl 15]:abs 4123). Here we report a multicenter, open-label study of O ± D + CT in pts with mPDAC. **Methods:** Pts were ≥ 18 years old with ECOG PS 0–1. Part 1 was a dose escalation phase: in Cohort A, previously untreated (1L) pts received O 1500 or 3000 mg IV Q2W for 4 doses then Q4W + D 1500 mg IV Q4W, with Q4W gemcitabine and nab-paclitaxel (GnP). In Cohort B, pts with previous G-based CT (2L) received O 1500 or 3000 mg Q2W for 4 doses then Q4W + D 1500 mg Q4W, with Q4W mFOLFOX. The primary objective for Part 1 was safety and tolerability; secondary objectives included antitumor activity and pharmacokinetics (PK). Part 2 was an expansion phase in which pts were stratified by high/low tumor CD73 expression by IHC. In Cohort A, 1L pts were randomized 1:1:1 to GnP alone (Arm A1), O + GnP (Arm A2) or O + D + GnP (Arm A3). O was given at the recommended phase 2 dose, 3000 mg. Cohort B did not proceed to dose expansion due to emerging therapies in 2L PDAC pts. The primary endpoint for Part 2 was investigator-assessed objective response rate (ORR) by RECIST v1.1; secondary included PFS, OS, safety, PK and antidrug antibody data. **Results:** As of November 11, 2022, 25 pts were treated in Part 1 (Cohort A, n=14; Cohort B, n=11), and 170 pts were treated in Part 2 (Arm A1, n=62; Arm A2, n=38; Arm A3, n=70). In Part 1, dose-limiting toxicities occurred in 1 pt (Cohort B, O 3000 mg: Gr 3 nausea and Gr 3 localized edema). Safety was generally similar in Parts 1 and 2. In Part 2, Gr ≥ 3 treatment-emergent adverse events (TEAEs) occurred in 85.5%, 89.5% and 90.0% of pts in Arms A1, A2 and A3 respectively, most commonly neutropenia (22.6%, 34.2% and 17.1%). In Part 2, TEAEs led to discontinuation in 11.3%, 23.7% and 24.3% of pts respectively. In Part 2, ORR was similar across Arms with a trend toward longer PFS and OS in Arm 3 vs Arm 1. There was a trend toward greater clinical benefit in pts with high CD73 expression when comparing Arm A3 vs Arm A1. **Conclusions:** O + D + GnP had similar safety and a trend toward improved outcomes compared to GnP. Clinical trial information: NCT03611556. Research Sponsor: AstraZeneca.

Part 2 efficacy summary.

	GnP (Arm A1, n=62)	O + GnP (Arm A2, n=38)	O + D + GnP (Arm A3, n=70)

Prevalence of germline variants in patients with pancreatic neuroendocrine tumors. *First Author: Chirayu Mohindroo, Department of Oncology, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: About 10% of pancreatic neuroendocrine tumors (pNETs) are thought to be related to inherited syndromes, including multiple endocrine neoplasia type 1 (MEN1), multiple endocrine neoplasia type 4 (MEN4), von Hippel-Lindau disease (VHL), neurofibromatosis type 1 (NF1), and tuberous sclerosis complex (TSC). Here, we report the prevalence of pathological/likely pathological germline variants (PV/LPV) in 2 cohorts: 1) High-risk and 2) Unselected. **Methods:** We retrospectively collected clinical data of patients with biopsy proven pNETs seen at MD Anderson Cancer Center (MDACC) and Johns Hopkins Hospital (JHH). Cohort 1 (high risk cohort) included 132 patients seen at MDACC, who underwent germline testing based on high-risk criteria such as early onset, personal or family history of cancer and syndromic features between 2013–2019. Cohort 2 (unselected cohort) included 106 patients seen at JHH, who underwent germline testing following their diagnosis of pNETs between 2020 to 2022. **Results:** In the high-risk cohort (n = 132), 33% (n = 44) had PV/LPV, and 17 % (n = 22) had a variant of unknown significance (VUS). Amongst the 132 patients, 35% underwent multigene panel testing, 53% had targeted germline testing and 12% had a physician documented outside test diagnosis. The demographics consisted of 52%(n = 69) females, 67% (n = 88) white, 54%(n = 71) had metastatic disease, 58%(n = 76) underwent surgical resection. WHO grading (n = 77) is as follows G1 (39%), G2 (59%), G3 (2%). In the unselected cohort (n = 106), 21% (n = 22) had PV/LPV, 28 % (n = 30) had a VUS. Of these, 93% of the patients underwent multigene panel testing. The demographics consisted of 42% (n = 44) females, 67% (n = 88) white, 48% (n = 51) had metastatic disease, 60% (n = 64) underwent surgical resection, WHO grading (n = 93) is as follows G1 (37%), G2 (49%), G3 (14%). **Conclusions:** PV/LPV are prevalent in patients with sporadic pNET irrespective of high-risk features or family history. While in the high-risk patients there is a higher prevalence, we also identified a 21% prevalence of PV/LPV with universal germline testing in the unselected cohort. In both cohorts, we identified a high number of mutations in the DNA repair pathway not previously described, which could affect subsequent therapies and surveillance for patients and their family members. The findings support upfront universal germline testing in all patients with diagnosis of pNETs. Research Sponsor: None.

	MDACC (High Risk Cohort) 33% (n = 44/132)	JHH (Unselected Cohort) 21% (n = 22/106)
PV/LPV		
MEN1	56% (n = 25)	36% (n = 8)

Retrospective evaluation of the value of DNA damage repair gene signature in response to platinum-based chemotherapy in advanced pancreatic ductal adenocarcinoma. *First Author: Tian Tian, Preclinical and Translational Research Program, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Barcelona, Spain*

Background: Mutations affecting DNA Damage Repair (DDR) genes have been associated with clinical benefits from platinum-based chemotherapy (PBC) in ovarian and breast cancer. Mutations of DDR genes, including BRCA1/2, PALB2, ATM, ATR, CHK1, or RAD51, are found in around 15% of pancreatic ductal adenocarcinoma (PDAC). Nevertheless, whether advanced PDAC patients harboring DDR gene mutations could benefit more from PBC has not been well established. In this study, we aimed to compare the prevalence of DDR gene mutations between advanced PDAC patients who benefited from PBC and those who did not. **Methods:** We retrospectively analyzed samples from patients with advanced PDAC who received PBC at our institution from 2008 to 2022. Patients with partial response or progression-free survival (PFS) > 6 months were considered responders, and those with progression disease as the best response were considered non-responders. Tumor molecular profiling was performed on tumor samples by Next Generation Sequencing (NGS) of DNA. Fisher's exact test was used to compare DDR genomic alterations in responders vs. non-responders. Overall survival (OS) was defined as the time from the start of PBC to the date of death. PFS was defined as the time between the start of PBC and the first date of documented progression or death, whichever occurs first. Survival outcomes were estimated using Kaplan-Meier curves, and differences were tested using the long-rank test. **Results:** A total of 132 patients with advanced PDAC treated with PBC were included in this study. The median age at diagnosis was 55 years (range 27-79 years), and 71 (53.79%) patients were male. In this cohort, 88 (66.67%) patients were identified as responders. Tumor molecular profiling showed that among responders, 42 patients (47.7%) had genomic alterations in BRCA1/2 or PALB2, and 10 patients (11.3%) had alterations in other DDR genes. In contrast, only 17 patients (38.64%) showed DDR gene alterations among non-responders. Importantly, mutations in DDR genes are significantly associated with the responder group (OR=2.28; 95% CI 1.03-5.17, p=0.04). In line with these findings, patients with DDR gene mutations showed significantly longer PFS (median PFS 9.95 months) compared with patients without DDR gene mutations (median PFS 6.51 months) (HR=0.57; 95%CI 0.39-0.85; p=0.005). Moreover, significantly longer OS was found in patients with DDR gene mutations (median OS 20.5 months) compared with those without DDR gene mutations (median OS 16.8 months) (HR=0.67; 95%CI 0.45-1; p=0.05). **Conclusions:** Genomic alterations in DDR genes are significantly associated with the benefit of PBC treatment in advanced PDAC patients. Our results argue in favor of using DDR genes as a decision-making tool for advanced PDAC patient stratification even before the stand-of-care chemotherapies. Research Sponsor: ISCIII.

Genomic characterization of somatic mutations by race and ethnicity in pancreatic cancer defined through AACR project GENIE. *First Author: J. Alberto Maldonado, Laboratory of Molecular Biology, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: *KRAS*, *TP53*, *SMAD4*, and *CDKN2A* are widely recognized as the most common somatic mutations amongst patients with pancreatic ductal adenocarcinoma (PDAC); however, previous genomic studies have disproportionately included non-Hispanic White (NHW) patients with little to no inclusion of racial and ethnic minorities, particularly non-Hispanic Black (NHB) and Hispanic patients. Additionally, little is known about the distribution of *KRAS* point mutations in PDAC in specific racial and ethnic groups. Here, we describe somatic mutation differences in a larger and more racially and ethnically representative PDAC cohort than previously characterized. **Methods:** PDAC mutational data was downloaded from AACR Project GENIE (Genomics Evidence Neoplasia Information Exchange) v13.0, an international data registry of sequenced tumor samples from nearly 150,000 patients, on cBioPortal. PDAC cancer type was identified using OncoTree code. NHW, NHB, Hispanic (of any race), and Asian patients were then selected. Mutational frequency was calculated for all mutations. The primary objective was to compare the mutation frequencies between NHW and other races with respect to the most common mutations. To maximize power, we included any mutation with a frequency $\geq 5.0\%$ where testing for mutation of that gene had been performed in at least 150 patients. Specific point mutations in *KRAS* were also extracted with stratification for racial and ethnic group. Fisher's Exact Test was used to calculate the statistical significance of the differences in mutation frequency between NHW and minority groups. **Results:** Patients in the PDAC cohort included 5,292 individuals (NHW N = 4296, 80.7%; NHB N = 264, 5.0%; Hispanic N = 460, 8.7%; Asian N = 299, 5.7%). As compared to the NHW group, NHB patients had higher rates of *TP53* (78.7% vs 69.0%, $P = 0.0006$) and *PTPR* (5.3% vs 1.8%, $P = 0.0095$) mutations but fewer *GNAS* (0.4% vs 2.8%, $P = 0.0097$) mutations while Asian patients had higher frequency of *ARID1A* mutations (13.0% vs 8.8%, $P = 0.024$). *KRAS* G12D mutation was more prevalent in Hispanic patients (47.0% Hispanic vs 41.1% NHW, $P = 0.0238$), although rate of *KRAS* mutation overall was the same. Prevalence of *KRAS* G12C mutation was equivalent amongst all groups with an overall 1.6% frequency. **Conclusions:** Understanding the genomic landscape of PDAC is critical as we move towards increased use of targeted therapies to treat this disease. In this study, *TP53*, *PTPR*, *GNAS*, and *ARID1A* mutations were shown to occur at different frequencies in specific racial and ethnic groups. G12D mutation of *KRAS* was disproportionately increased in Hispanics. These differences in molecular landscape amongst racial and ethnic groups could contribute to precision medicine strategies used to address this deadly disease. Phase 2 trial of pembrolizumab and olaparib (POLAR) maintenance for patients (pts) with metastatic pancreatic cancer (mPDAC): Two cohorts B non-core homologous recombination deficiency (HRD) and C exceptional response to platinum-therapy. *First Author: Wungki Park, Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY*

Background: Maintenance olaparib improves PFS in gBRCA1/2m (core HRD) in mPDAC (Golan, NEJM 2019). Whether other HRD indicators, such as gene mutations other than gBRCA1/2m (non-core HRD, Cohort B) and exceptional platinum responders (Cohort C, response ≥ 6 months) may benefit from PARPi in mPDAC remains unanswered. We hypothesized that pembrolizumab and olaparib (POLAR) combination may improve outcome by immunogenic cell death. **Methods:** We conducted an open-label, non-randomized, phase 2 trial of POLAR as maintenance therapy for pts with mPDAC whose disease had not progressed for 4 months (m) in Cohort B or 6 m in C. Herein, we report on Cohorts B & C. Eligibility: ECOG 0-1, mPDAC meeting eligibility of B or C. POLAR (Pembrolizumab 200mg IV Q3W+ Olaparib 300mg BID) until disease progression or limiting toxicity. Objective response rate (ORR), median PFS (mPFS), median overall survival (mOS), disease control rate (DCR), CA 19-9, cfDNA and baseline HRD mutational signature were analyzed. **Results:** Cohorts B and C enrolled N=15 each. N=25 pts evaluable by RECIST 1.1. Median follow-up 9.9 (1.3-22.8) and 11.3 (5.8-23) m, respectively. Efficacy details are shown. G3-5 AEs related to treatment: 5/14 (36%): 1 diarrhea (7%), 1 hyperglycemia (7%), 2 anemia (14%), 1 lipase increased (7%). Cohort B: 9/15 (60%) ATM, 3 CHEK2, 2 MUTHY, 1 BLM, 1 FANCC. Canonical gene mutations for mPDAC were less common for pts in Cohort B, especially in ATM PA group (n=9) vs C. Median genomic instability score (GIS) was computed and higher 28 (0-38) vs 9 (0-24) in Cohort B vs C, $p=0.052$. Median tumor mutation burden (TMB) was not different between B and C (3.3 and 4.1). **Conclusions:** Clinical activity of POLAR maintenance observed in select pts in B and C. Although PFS was modest (mPFS of 4m [2.1-5.4] in B + C), an intriguing survival signal (mOS at 14m [10-NR] from first POLAR dose) was seen in select patients without chemotherapy. Extensive correlative analyses underway to evaluate response and resistance (SPOR: 1P50CA257881-01A1). Cohort A (core HRD) actively accruing. Clinical trial information: NCT04666740. Research Sponsor: Merck Sharp & Dohme LLC; Parker Institute for Cancer Immunotherapy; U.S. National Institutes of Health.

Efficacy and safety of mitazalimab in combination with mFOLFIRINOX in patients with metastatic pancreatic ductal adenocarcinoma (mPDAC): An interim analysis of the optimize-1 phase 1b/2 study. *First Author: Hans Prenen, Center for Oncological Research (CORE), Integrated Personalized and Precision Oncology Network (IPPON), University of Antwerp, Wilrijk, Belgium*

Background: Mitazalimab is a human CD40 agonistic IgG1 antibody. Targeting CD40 kickstarts the cancer immunity cycle by licensing dendritic cells leading to tumor specific T cell priming and activation. Furthermore, in PDAC CD40 agonists on myeloid cells promote degradation of the desmoplastic tumor stroma, improving influx of T cells and chemotherapeutic agents into the tumor. OPTIMIZE-1 (NCT04888312) is a Phase 1b/2, open label, multicenter study designed to evaluate safety, tolerability, and efficacy of mitazalimab in combination with mFOLFIRINOX (Oxaliplatin 85 mg/m², leucovorin 400 mg/m², irinotecan 150 mg/m², 5-FU 2.4 g/m²) in patients (pts) with previously untreated mPDAC. In the first part of the study (phase 1b), 900 µg/kg mitazalimab was selected as the recommended phase 2 dose (RP2D). **Methods:** In the first 21 day treatment cycle, mitazalimab was administered IV at RP2D on day 1 and 10 and mFOLFIRINOX infusion started on day 8. In subsequent cycles, treatment followed a 14 day cycle where mitazalimab was always administered 2 days after mFOLFIRINOX. The primary endpoint of this ongoing study is overall response rate (ORR) per RECIST v1.1. Secondary and exploratory endpoints include progression free and overall survival, safety, PK and PD biomarker assessments. Futility was prespecified as ORR $\leq 30\%$ in pts treated at RP2D, based on historical data with FOLFIRINOX (Conroy, 2011). **Results:** As of December 8, 2022, 43 pts with untreated mPDAC were treated with mFOLFIRINOX and 450 µg/kg (N = 5) or 900 µg/kg (N = 38) mitazalimab and evaluated for safety. The most common grade (Gr) ≥ 3 TEAEs were neutropenia (16%), fatigue (12%) and hypokalemia (12%). Mitazalimab related Gr > 3 AEs were fatigue in 3 (7.9%) pts, hypokalemia in 2 (5.3%) pts, diarrhea in 1 (2.6%) pt, pneumonia in 1 (2.6%) pt, increased ALT in 1 (2.6%) pt, headache in 1 (2.6%) pt, acute kidney injury in 1 (2.6%) pt. 10 pts (23%) experienced infusion reactions (all Gr 1-2) and 5 (12%) pts discontinued treatment due to TEAEs (pneumonia, gastric obstruction, neuropathy, bacteremia). At cutoff, 23 pts were evaluable for futility. Median follow up was 170 days and median exposure was 163 days. 18 pts (78%) remain on treatment, 6 (26%) beyond the 6 month treatment period. ORR was 52.2% (12 partial responses), an additional 8 pts achieved stable disease, resulting in a 91.3% disease control rate. Combination with mFOLFIRINOX had no impact on mitazalimab PK. The PD biomarker profile was consistent with the mode of action of mitazalimab, including upregulation of MCP-1 and IFN- γ . **Conclusions:** Mitazalimab + mFOLFIRINOX is a feasible regimen with a manageable safety profile. Mitazalimab administered at 900 µg/kg in combination with mFOLFIRINOX shows encouraging antitumor activity in mPDAC, meriting continued development. The study passes futility and continues to full accrual. Clinical trial information: NCT04888312. Research Sponsor: Alligator Bioscience AB.

Development and evaluation of 5FUCore, OxaliCore, and IrinoCore transcriptomic signatures for predicting response to individual drugs in the FOLFIRINOX regimen: Towards toxicity reduction and personalized chemotherapy in PDAC. *First Author: Nicolas Fraunhofer, Cancer Research Center of Marseille (CRCM), INSERM, CNRS, Institut Paoli-Calmettes, Aix-Marseille University, Marseille, France., Marseille, France*

Background: Recently, we have successfully developed a transcriptomic signature that predicts the response to gemcitabine treatment in patients with localized pancreatic ductal adenocarcinoma (PDAC) (PMID: 36178036) and also in those with metastatic PDAC (PMID: 36496056). This was achieved by using an approach that combined several preclinical PDAC models. The FOLFIRINOX regimen (FFX) consisting of 5-Fluorouracil (5FU), Oxaliplatin, and Irinotecan is the more effective treatment option, but the high toxicity limits its use. In this study, we developed and analyzed three different transcriptomic signatures for the drugs composing FFX separately and evaluated their clinical utility. **Methods:** We combined the transcriptomic profile of 14 patients derived xenograft (PDX) and 31 patients derived cell cultures (PDC) with their corresponding chemotherapy response profiles. We developed predictive signatures for 5FU (5FUCore), Oxaliplatin (OxaliCore), and Irinotecan (IrinoCore), as previously reported for the GemCore signature (PMID: 36178036). They were then validated in three independent cohorts of patients: COMPASS (n = 94), Linehan (n = 28), and a new cohort of 87 advanced PDAC patients. **Results:** Three ICA components that reflect the chemotherapy response profiles for 5FU, oxaliplatin, and irinotecan were evaluated in the COMPASS cohort to determine their ability to identify sensitive patients in the FFX arm. Patients predicted as sensitive to each drug separately had a median overall survival (OS) of 77.6 (95% CI, 67.9-NR, $P = 0.02$), 78.7 (95% CI, 57.6-NR, $P = 0.002$), and 70.4 (95% CI, 57.6-NR, $P = 0.02$) months for 5FU, oxaliplatin, and irinotecan, respectively. Notably, the model that integrated the group of sensitive patients to two or three drugs had the highest median OS in the COMPASS and Linehan cohorts with a HR of 0.25 (95% CI, 0.11-0.57; $P < 0.001$) and 0.11 (95% CI, 0.02-0.70; $P = 0.019$), respectively. Importantly, they also show a better objective response than the other groups ($P = 0.009$). In the advanced PDAC group, the signatures showed a strong ability to discriminate sensitive patients in the FFX arm with a median OS of 20.1 (95% CI, 2.3-NR, $P = 0.006$), 13.64 (95% CI, 9.57-NR, $P = 0.003$), and 15.87 (95% CI, 2.9-NR, $P = 0.002$) months for 5FU, oxaliplatin, and irinotecan, respectively. Finally, we evaluated the best combination of two drugs in the pooled group. Patients sensitive to both 5FU and oxaliplatin showed the best response with 60% of patients achieving partial response. **Conclusions:** The signatures developed provide a tool for predicting responsiveness to the individual therapeutic drugs of the FFX regimen. They may ultimately lead to the development of a personalized strategy for combined chemotherapy regimens, increasing efficacy and reducing toxicity in PDAC. Research Sponsor: Institut Nationale du Cancer, Inca.

Poster Session

A phase 1b/2 study of surufatinib plus camrelizumab, nab-paclitaxel, and S-1 (NASCA) as first-line therapy for metastatic pancreatic adenocarcinoma (mPDAC). *First Author: Guang-Hai Dai, Senior Department of Oncology, the 5th Medical Center of the PLA General Hospital, Beijing, China*

Background: PD-1 blockade combined with anti-angiogenesis such as surufatinib (targeting VEGFR 1-3, FGFR1 and CSF1-R) might change tumor environment thus improve the efficacy in several solid tumors. A phase 1b/2 clinical study was conducted to explore the efficacy and safety of surufatinib combined with camrelizumab (PD-1 antibody), nab-paclitaxel and S-1 (NASCA) as first-line treatment compared with nab-paclitaxel and gemcitabine (AG) in mPDAC. **Methods:** In phase 1b, patients (pts) with mPDAC received surufatinib (200mg to 300mg, orally daily), camrelizumab (200mg, I.V., D1, Q3W), nab-paclitaxel (125mg/m², I.V., D1, D8, Q3W) and S-1 (40mg bid, D1-14, Q3W). Phase 2 is a prospective, open-label, randomized (1:1) trial comparing NASCA with AG in the first-line setting. The primary objective was recommended phase 2 dose (RP2D) and overall response rate (ORR) per RECIST v1.1. Tumor tissue samples were collected at diagnosis for mIHC to evaluate tumor microenvironment. **Results:** Six pts were enrolled in phase 1b and RP2D was determined as surufatinib 200mg. By Jan 10, 2023, 28 pts were enrolled in phase 2 and 27 pts were evaluable for efficacy (14 in NASCA and 13 in AG). The ORR was 55.0% (11/20) (95% CI: 34.2-74.2) in NASCA and 23.1% (3/13) (95% CI: 8.2-50.3) in AG group. Pts receiving NASCA with liver metastases exhibited significant higher ORR than those without liver metastases (90.0% vs 20.0%, $p=0.0017$). Median progression-free survival was 8.8 months (95% CI: 5.5-12.0) in NASCA and 5.8 months (95% CI: 1.5-10.1) in AG group at the median follow-up of 8.9 months. The most frequent adverse events (AEs) of all grades in pts treated with NASCA were neutropenia (55.0%), hepatotoxicity (45.0%), neuropathy (35.0%) and diarrhea (15.0%). Immune-related AEs were observed in 4 pts (20.0%) with grade 3 hepatotoxicity. Safety was comparable in two groups except for hepatotoxicity and diarrhea. The tissue of 13 pts receiving NASCA were stained for multiple markers of immune cells. CD3⁺T cells infiltrated most in the tumor core, followed by CD68⁺CD163⁺ (M1) macrophages, and FOXP3⁺ T cells. Majority of immune cells and therapeutic biomarkers were expressed at higher levels in the stroma than tumor core. Pts with liver metastases displayed elevated infiltration of tumoral FOXP3⁺ T cells ($p=0.031$), PD-L1⁺CD68⁺ macrophages ($p=0.014$), and decreased density of stromal CD8⁺ T cells ($p=0.064$) than pts without liver metastases. In pts with liver metastases, responders displayed a higher proportion of stromal PD-1⁺ cells than non-responders ($p=0.036$). **Conclusions:** Preliminary results showed that NASCA regimen presented higher clinical activity than the standard AG treatment, especially in pts with liver metastases, with a manageable safety profile. This trial is ongoing and NASCA regimen deserves further exploration in mPDAC. Clinical trial information: NCT05218889. Research Sponsor: HUTCHISON CHINA MEDITECH LTD.

Correlation of comprehensive molecular mapping of pancreatic ductal adenocarcinoma with XPO1 mRNA expression levels to potential clinical targets. *First Author: Andreas Seeber, Department of Internal Medicine V (Hematology and Oncology), Comprehensive Cancer Center Innsbruck, Medical University of Innsbruck, Innsbruck, Austria*

Background: Encouraging pre-clinical efficacy targeting Exportin-1 (XPO1) - a master regulator of tumor suppressor protein export - has been reported in pancreatic ductal adenocarcinoma (PDAC) and clinical trials are currently ongoing. However, limited data is available regarding expression and function of XPO1 in PDAC. Thus, we investigated XPO1 mRNA expression and its clinical and immune correlates in PDAC. **Methods:** 5,488 PDACs were tested at Caris Life Sciences (Phoenix, AZ) with NGS of DNA (WES) and RNA (WTS). TMB-H was defined as ≥ 10 mutations/MB. The cohort was stratified in quartiles according to XPO1 mRNA expression status, and XPO1-high (XPO1^H) and XPO1-low (XPO1^L) expression were defined as $\geq$ top and $<$ bottom quartile of transcripts per million (TPM). Immune cell fraction was calculated by QuantiSeq method. Gene expression profiles were analyzed for transcriptomic signatures predictive of response to immune checkpoint inhibitors (T cell-inflamed score) and MAPK pathway activation (MPA). The Mann-Whitney U and X2 tests were applied as appropriate, with p-values adjusted for multiple comparisons. Real-world overall survival (OS) data was obtained from insurance claims. TCGA data were used to validate molecular, biological and immunological findings. Single-cell RNA analyses on a publicly available dataset were performed to elaborate cellular localization of XPO1. **Results:** Increased XPO1 mRNA expression was observed in metastatic lesions compared to primary tumors ($p<0.001$). Copy number amplification and mutation prevalence was comparable between XPO1^H and XPO1^L samples ($p>0.05$), along with similar rates of MSI-H/dMMR (1.3 vs 0.9%) and TMB-H (2.0 vs 1.3%; $p>0.05$). XPO1^H PDACs were associated with a significant higher prevalence of T cell-inflamed tumors compared to XPO1^L cases (58 vs 5%; $p<0.05$), consistent with higher immune cell infiltration in the XPO1^H quartile as compared to XPO1^L ($p<0.05$), except for immunosuppressive regulatory T cells and monocytes ($p>0.05$). XPO1^H was associated with a higher MPA score as compared to XPO1^L (2.4 vs -2.1 Arbitrary Units; $p<0.05$). XPO1^H was associated with shorter OS (HR 1.09 [1.1-1.4], $p=0.048$). Validation studies using TCGA datasets corroborate our findings and confirmed increased immune cell infiltration as a function of XPO1. Moreover, single cell data revealed predominant and high expression of XPO1 in the tumor cell compartment. **Conclusions:** This is the first study comprehensively mapping XPO1 mRNA expression and immune-correlates in PDAC. We found that high XPO1 is linked to increased immune cell infiltration with a T cell-inflamed pattern. Our data provided a potential rationale to combine immune checkpoint therapy (+/- XPO1 inhibitors) in XPO1^H PDACs. A phase II study of nivolumab and ipilimumab with radiation therapy in patients with metastatic, microsatellite stable pancreatic adenocarcinoma. *First Author: Julie L. Koenig, Harvard Radiation Oncology Program, Boston, MA*

Background: Metastatic pancreatic ductal adenocarcinoma (PDAC) is incurable for most patients. While immune checkpoint inhibitors (ICIs) have limited efficacy in microsatellite stable (MSS) tumors, radiation therapy (RT) may promote responsiveness to ICIs. In our phase 2 trial (NCT03104439), 25 patients with metastatic MSS PDAC were enrolled to receive ipilimumab and nivolumab with RT (24 Gy/3 fractions) starting on C2D1. The disease control rate (DCR) was 20% (5/25) and overall response rate (ORR) was 12% (3/25). In 17 patients who received RT (32% dropout rate), DCR was 29% (5/17) and ORR was 18% (3/17). To confirm this signal and address dropout prior to RT, we conducted a phase 2 study of nivolumab and ipilimumab with RT moved to C1D1. **Methods:** In this open-label, single-arm, phase 2 study (NCT04361162), eligible patients had histologically confirmed metastatic MSS PDAC, ECOG PS 0-2, and progressed on at least one line of chemotherapy. Treatment consisted of ipilimumab 1 mg/kg q6weeks for the first 4 cycles, nivolumab 240 mg q2weeks on a 6-week cycle, and RT (24 Gy/3 fractions) to a single site starting on C1D1. Treatment continued until disease progression, discontinuation, or withdrawal. The primary endpoint was RECIST 1.1 ORR by centrally reviewed imaging q3months. Secondary endpoints included DCR, PFS, OS, and safety. 30 patients were enrolled in a single-stage design for intention-to-treat (ITT) analysis of patients receiving at least one dose of study treatment. The per protocol analysis included patients who completed C1D1. The treatment regimen was considered to have promising activity if at least 3 of 30 patients had an objective response, providing 85% power to reject 5% ORR in favor of 15% ORR at a significance level of 20%. **Results:** We enrolled 30 patients (median age 68 years [range 52-80], 60% male, 90% white, 97% ECOG PS 0-1, median 3 [range 2-6] prior lines of chemotherapy) from 05/2020 to 11/2021. ITT ORR was 3% (1/30; 95% CI, 0-17%), DCR was 10% (3/30; 95% CI, 2-27%), median PFS was 2.2 months (95% CI, 1.5-2.6), and median OS was 2.8 months (95% CI, 2.1-5.2). In the per protocol analysis, ORR was 4% (1/28; 95% CI, 0-18%), DCR was 11% (3/28; 95% CI, 2-28%), PFS was 2.3 months (range, 1.6-2.7), and OS was 2.9 months (range, 2.2-5.5). One patient enrolled in hospice after 1 month, had a complete response at 13 months, and is alive at 21 months. 7 patients had grade 3-4 treatment-related serious adverse events, including lymphopenia (grade 4 in 1 patient), neutropenia, fatigue, muscle weakness, ALT/AST increase, hepatobiliary dysfunction, acute kidney injury, hyperglycemia, and hypokalemia. **Conclusions:** The treatment regimen of ipilimumab and nivolumab with RT did not meet the pre-specified criteria for promising activity in metastatic MSS PDAC. Further correlative analyses of the patient with a complete response and evaluation of in-field responses are ongoing. Clinical trial information: NCT04361162. Research Sponsor: Bristol Myers Squibb.

Clinical genomic implications of transcriptional subtypes in pancreatic cancer. *First Author: Harshabad Singh, Dana-Farber Cancer Institute, Brookline, MA*

Background: Transcriptional profiling of pancreatic cancers (PC) has defined classical and basal subtypes; basal tumors have worse outcomes. Mesenchymal (MES) and neural-like progenitor (NRP) subtypes are increasingly recognized and enriched post-therapy. Initial data suggests worse outcomes to FOLFIRINOX (FFX) compared with gemcitabine nab-Paclitaxel (GnP) in basal tumors. Several clinical trials are ongoing to investigate this. Here, we examined the clinical implications of transcriptional subtypes in a large, real-world dataset. **Methods:** Retrospective IRB exempt, deidentified data was examined from NextGen DNA and RNA sequencing performed on PCs at Caris Life Sciences (Phoenix, AZ). Classical and basal cell states were identified using RNA-seq and the PurlST algorithm in a genomic cohort or GATA6 and KR75 expression levels in a clinical cohort. Tumor microenvironment immune cell composition on RNA seq was performed using QuantiSeq. Survival was obtained from insurance claims data and calculated from first treatment date to last known contact. Kaplan-Meier estimates were calculated for patient cohorts. P values were adjusted using Benjamini-Hochberg correction. **Results:** A total of 7,250 PCs were profiled in the genomic cohort. 3,063 tumors (42.2%) were strongly classical (SC), 2,015 tumors (27.8%) were strongly basal (SB) and the remaining had mixed phenotypes. MES and NRP marker genes were significantly co-expressed with each other, with basal genes, and anti-correlated with classical genes. When compared to SC, SB had significantly higher mutation rates in KRAS (93% vs. 88%), TP53 (83% vs. 72%) and ARID1A (12% vs. 8%), whereas SMAD4 (23% vs. 17%) mutations were more common in SC (all $q < 0.05$). There were no differences in mutation rates in homologous recombination or mismatch repair genes. SB had a significantly higher fraction of M1 macrophages (fold change [FC]: 1.14) and neutrophils (FC 1.16), whereas SC tumors had higher M2 macrophages (FC 1.18), NK (FC 1.2), and dendritic cells. Overall proportions of CD4/8 T cells were low and not different. Interestingly, SB had higher levels of PD-L1 by IHC (4.8% vs. 35%) and higher expression of immune exhaustion genes including CTLA4 (FC 1.19), TIM3 (FC 1.22) and PD-1 (FC 1.43) (all $q < 0.05$). The clinical cohort had 1,623 patients. Basal tumors had an inferior survival (median survival: 8.2 months (mo) vs 13.3 mo (Hazard Ratio (HR) 0.67, $p < 0.00001$)) and showed a significant improvement in outcomes when treated with upfront FFX vs GnP ($n = 80$ vs 90, Median: 15.8 vs 7.4 mos., HR 0.68, $p = 0.021$). This difference between FFX vs GnP was less pronounced in classical tumors ($n = 70$ vs 89, Median: 17.3 vs 15.4 mos, HR 0.70, $p = 0.049$). **Conclusions:** Our work represents the largest known real world molecular comparison of transcriptional subtypes of PC. Differential outcomes for patients with basal tumors treated with FFX versus GnP warrants further investigation in prospective studies. Research Sponsor: None.

Tumor mutational burden (TMB) in real-world patients with pancreatic ductal adenocarcinoma (PDAC): Differences in genomic alterations (GA) and predictive value for immune checkpoint inhibitor (ICI) effectiveness. *First Author: Amit Mahipal, UH Seidman Cancer Center, Case Western Reserve University, Cleveland, OH*

Background: Currently, ICI therapy is recommended for patients with metastatic PDAC whose tumors exhibit dMMR, MSI-H, or high TMB (≥ 10 mutations/Mb). However, due to the low prevalence of high TMB in PDAC (~1%), few studies have evaluated the role of ICI therapy in this subpopulation. This study aimed to compare GA between PDAC patients with high TMB and low TMB (< 10 mutations/Mb) and to evaluate the effectiveness of ICIs in real-world PDAC patients by TMB status. **Methods:** This study included PDAC patients who underwent genomic testing using Foundation Medicine tissue comprehensive genomic profiling (CGP) assays. GA were compared between tissue specimens with high and low TMB by chi-squared, adjusted for multiple comparisons. Patient clinical data was obtained by the US-wide de-identified Flatiron Health and Foundation Medicine real-world clinicogenomic pancreatic database (CGDB), originated from ~280 US cancer clinics between 01/2011 and 09/2022. Real-world overall survival (OS) and time to treatment discontinuation (TTD) were compared between patients receiving an ICI (high TMB versus low TMB) and between patients with high TMB (ICI versus other therapies) by Cox models. **Results:** We included 21,932 patients with PDAC with tissue CGP data available; 98.7% with low TMB and 1.3% with high TMB. Among actionable alterations, patients with high TMB had higher prevalence of mutations in *BRCA2* ($p < 0.0001$), *BRAF* ($p < 0.0001$), *PALB2* ($p < 0.0001$), and genes of the mismatch repair pathway (*MSH2*, *MSH6*, *MLH1*, and *PMS2*, $p < 0.0001$), but lower prevalence of *KRAS* mutations ($p < 0.0001$). The most common *KRAS* mutation in both groups of patients was G12D. In CGDB, 51 patients received an ICI (10 with high TMB and 41 with low TMB) and 17 patients with high TMB received other therapies. Among patients receiving an ICI, those with high TMB had more favorable median OS compared to those with low TMB (25.7 versus 5.2 months, hazard ratio (HR) 0.27, 95% confidence interval (CI) 0.09 - 0.76, $p = 0.01$) and median TTD (20.7 versus 3.0 months, HR 0.33, 95% CI 0.13 - 0.82, $p = 0.02$). Among patients with high TMB, those receiving an ICI had more favorable OS compared to those receiving other therapies (25.7 versus 6.6 months, HR 0.31, 95% CI 0.10-0.96, $p = 0.043$), nominally favoring ICI use in this small cohort ($n = 10$ versus 17). **Conclusions:** There is no randomized clinical trial evaluating ICI versus other therapies in PDAC. To our knowledge, this is the largest cohort to date comparing ICI effectiveness in PDAC. We observed more favorable OS among PDAC patients with high TMB receiving ICI versus those with low TMB who received an ICI and more favorable to those with high TMB receiving other therapies. This study supports the FDA-approved use of ICIs in patients with PDAC and high TMB and demonstrates the importance of TMB assessment for patients with PDAC. Efficacy of immune checkpoint inhibitors in microsatellite unstable/mismatch repair-deficient advanced pancreatic adenocarcinoma: An AGEO European Cohort. *First Author: Lorenzo Pilla, Department of Gastroenterology and Gastrointestinal Oncology, Hôpital Européen Georges-Pompidou, AP-HP, Université de Paris, Paris, France*

Background: Immune checkpoint inhibitors (ICI) have been approved for the use in solid tumors with MSI/dMMR. Nevertheless, the outcome of patients (pts) with MSI/dMMR pancreatic ductal adenocarcinoma (PDAC) seems poorer when compared to other malignancies. This multi-institutional analysis aimed to assess the efficacy and tolerability of ICIs in a large real-world cohort of pts with MSI/dMMR PDAC. **Methods:** Retrospective data were collected for pts with MSI/dMMR PDAC treated with ICIs from February 2016 to May 2022 in 16 different centers across Europe and Israel. Progression-free survival (PFS) and overall survival (OS) were calculated from the start of treatment, and objective response (OR) and disease control rate (DCR) were measured according to RECIST V1.1. **Results:** We identified 31 pts with metastatic MSI/dMMR PDAC. The mean age was 62.1 years (range: 37-82), 45.1% were female and ECOG PS status was predominantly 0 or 1 (83.9%). At the time of ICI treatment 1 pt had locally advanced and 30 had metastatic disease. MSH2/MSH6 deficiency (def) was found in 9 cases, MLH1/PMS2 def in 7, MSH 6 def in 4, MSH 2 def in 3, PMS2 def in 3 and MLH1/MSH6/PMS2 def and, a CpG highland methylator phenotype in 1 pt. MMR status was not available in 4 pts. Germline mutation testing was performed in 20/31 pts (64.5%) and Lynch syndrome was diagnosed in 8 pts (45%). Nineteen pts received pembrolizumab, 8 received nivolumab, 1 received lodapolimab and 3 received ipilimumab/nivolumab (ipi/nivo). The mean number of prior lines of chemotherapy was 1.5 (range 0-4). Among the 31 pts in this analysis, 15 (48.4%) had an OR (3: complete response and 12 partial response) and 6 (19.3%) had stable disease, resulting in a DCR of 67.7%. Ten pts had disease progression (PD) (32.3%). Median PFS was 26.7 months and median OS was not reached with median follow-up (FU) of 18 months. Median duration of response was not reached (95%CI:24.1-NR). Analysis of all responders, with a follow up of 12 months or more ($n=14$), showed that 100% of them maintained their response. In addition 71% of the pts of this cohort are still alive with a median time of follow up since the diagnosis of metastatic disease of 39.9 months. After ICIs discontinuation, 6 pts received chemotherapy. One pt who had PD after 15 months of pembrolizumab switched to ipi/nivo and achieved a CR. Immunotherapy was generally well tolerated; No Grade 3-5 adverse events (AEs) were reported and no therapy discontinuation due an adverse event was observed. **Conclusions:** This retrospective analysis suggests that ICIs are effective and well tolerated in pts with MSI/dMMR advanced PDAC. Hence, our work supports the use of PD-1 inhibition in this group of pts with high unmet medical need. Research Sponsor: None.

Randomized phase 2 study of nab-paclitaxel and gemcitabine with or without tocilizumab as first-line treatment in patients with advanced pancreatic cancer (PACTO). *First Author: Inna Markovna Chen, Copenhagen University Hospital - Herlev and Gentofte, Herlev, Denmark*

Background: Pancreatic cancer (PC) presents one of the most aggressive malignancies for which currently available treatments are modestly effective. We report the findings of a randomized phase 2 trial (NCT02767557) to test the efficacy of gemcitabine/nab-paclitaxel (gem/nab) with or without tocilizumab (toc), as first-line treatment in patients with locally advanced or metastatic PC. **Methods:** Prior to randomization, a safety cohort of 6 participants received gem 1000 mg/m², nab 125 mg/m² (days 1, 8, and 15 of each 28-day cycle) and toc 8 mg/kg (day 1 of each cycle). Participants were then randomized 1:1 to receive gem/nab or gem/nab/toc. Patients had modified Glasgow Prognostic Score of 1 or 2 and were stratified by performance status (PS) and stage. The primary endpoint was the overall survival (OS) rate at 6 months (OS6). Secondary end points included median progression-free survival (PFS), median OS, overall response rate (ORR), and safety. **Results:** A total of 147 patients were treated; 141 were randomized to receive gem/nab/toc ($n = 70$), or gem/nab ($n = 71$). As of January 9, 2023, the median follow-up was 8.1 months (IQR 4.2-13.9). OS6 was 68.6% (95% CI, 56.3-78.1) in gem/nab/toc group and 62.0% (95% CI, 49.6-72.1) in gem/nab group ($p = 0.41$). No significant differences in the median OS or PFS were observed between the gem/nab/toc group and the gem/nab group (OS, 8.4 versus 8.0 months; HR, 0.75; 95% CI, 0.54-1.05; $p = 0.10$), and (PFS, 5.6 versus 5.5 months; HR, 0.85; 95% CI, 0.61-1.20; $p = 0.36$). The 12, 18 and 24-month OS rates were 37.1% (95% CI, 26.0%-48.3%), 27.1% (17.4%-37.8%), 10% (4.4%-18.3%) for gem/nab/toc and 28.2% (18.3%-38.9%), 7.0% (2.6%-14.5%), 2.8% (0.5%-8.8%) for gem/nab, respectively. The ORR was 37.1% (95% CI, 25.9%-49.5%) in gem/nab/toc group and 35.2% (24.2%-47.5%) in gem/nab group. The incidence of grade 3 or higher treatment-related adverse events was 88.2% in gem/nab/toc and 63.4% in gem/nab group ($p < 0.001$). Of those, neutropenia (55.3% versus 16.9%), and thrombocytopenia (40.8% versus 11.3%) were most common. Two and one treatment-related deaths, respectively, in gem/nab/toc and gem/nab group, occurred during the study. **Conclusions:** In patients with advanced PC, the addition of tocilizumab to gem/nab did not result in improved OS rate at 6 months. Although more patients were alive at 18 months in the gem/nab/toc, long-term survival rates exceeding 24 months were not different between groups. The biomarkers for selection of patients who might benefit from gem/nab combined with tocilizumab are to be identified. Clinical trial information: NCT02767557. Research Sponsor: Celgene; Copenhagen University Hospital - Herlev and Gentofte, Herlev, Denmark.

Validation of the PDACai signature in predicting relative benefit from front-line FOLFIRINOX (FFX) and gemcitabine/nab-paclitaxel (GA) for patients (pts) with metastatic pancreatic cancer (mPDAC). *First Author: Michael J. Pishvaian, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Washington, DC*

Background: Nearly 50% of pts with mPDAC never receive a 2nd line of therapy for metastatic disease following frontline FFX or GA. Genomic alterations in the DDR pathway (e.g. *BRCA1/2*) are associated with increased progression-free survival (PFS) on platinum-containing regimens (e.g. FFX), but other biomarker-treatment associations that predict benefit from GA and/or FFX in mPDAC remain unexplored. In this retrospective real-world evidence (RWE) study, we use a data-driven machine learning approach to gain new insights from the mutational landscape in mPDAC and validate the PDACai signature in predicting personalized benefit from both FFX and GA. **Methods:** We analyzed real-world outcomes from 711 pts with mPDAC who underwent genomic profiling via the Know Your Tumor program or were referred to Perthera by treating oncologists. Chart-abstracted PFS data on either 1st line FFX or GA were split (60:40) into independent training and validation cohorts for each regimen. All models integrate a shared set of clinical (age < 63 , sex) and lab-agnostic molecular features derived from clinical NGS testing reports (DDR pathway alterations, specific *KRAS* variants, frequently mutated genes). Relative benefit scores predicted by FFX or GA models were evenly binned into three PDACai signature categories representing lower, middle, and upper tertiles for each independent cohort. Statistical differences in median PFS were evaluated using ordinal Cox regression. **Results:** Median PFS followed predicted trends as generated by PDACai for each therapy in training and validation cohorts. The predictive utility of PDACai was confirmed in the independent validation cohorts when comparing PFS on FFX ($p = 0.03744$; HR = 0.75 [95% CI: 0.58-0.98]) and GA ($p = 0.00006861$; HR = 0.65 [95% CI: 0.53-0.8]) across tertiles. **Conclusions:** Response to chemotherapy is heterogeneous and difficult to predict in pts with mPDAC. Using RWE, the PDACai signature successfully predicted relative differences in PFS on both FFX and GA in mPDAC. With prospective validation, personalized insights generated by PDACai from pts with similar biomarker profiles could be used to tailor treatment sequencing in pts with NGS testing results, particularly those without actionable genomic findings. Research Sponsor: Pancreatic Cancer Action Network; Perthera.

Summary of actual PFS in months on 1st line therapies in pts assigned to lower, middle, and upper thirds based on relative PDACai predictions.

Independent Cohort (# Pts)	Lower Tertile mPFS [95% CI]	Middle Tertile mPFS [95% CI]	Upper Tertile mPFS [95% CI]
1st line FFX Training (212)	6.4 [5.6-7.5]	8.0 [6.1-10.6]	15.8 [10.3-NR]
1st line FFX Validation (145)	9.1 [7.0-12.2]	11.1 [7.6-13.7]	13.2 [10.1-28.0]
1st line GA Training (209)	5.5 [4.4-6.5]	7.3 [5.8-8.4]	10.1 [8.1-12.1]
1st line GA Validation (145)	5.6 [4.7-8.6]	8.2 [6.5-15.6]	8.8 [7.7-13.9]

KRAS G12C-mutated pancreatic cancer: Clinical outcomes based on chemotherapeutic regimen. *First Author: Aaron Ciner, University of Maryland, Baltimore, MD*

Background: Frontline treatment for advanced pancreatic ductal adenocarcinoma (PDAC) has been either 5-fluorouracil, oxaliplatin and irinotecan (FOLFIRINOX) or gemcitabine and nab-paclitaxel (GP) for the past decade. While the NAPOLI-3 trial, utilizing liposomal irinotecan, highlighted the superiority of a triplet regimen over GP, the question remains whether certain subgroups may derive particular benefit from GP. Pre-clinical data in lung cancer suggest that KRAS G12C may facilitate enhanced DNA adduct removal after platinum chemotherapy and confer resistance to this drug class. While multiple KRAS G12C inhibitors have shown early promise in PDAC, multi-agent chemotherapy remains the frontline standard and will likely remain an important therapeutic tool. This study aimed to investigate clinical outcomes after platinum and non-platinum-based chemotherapy in patients with advanced KRAS G12C-mutated PDAC. **Methods:** PDAC samples were tested using whole transcriptome sequencing (WTS; Illumina NovaSeq) and NextGen DNA sequencing (NextSeq, 592 Genes and NovaSeq, WES) at Caris Life Sciences (Phoenix, AZ). Significance was determined by χ^2 and Fisher-Exact and p adjusted for multiple comparisons (q). Real-world overall survival (rWOS) was obtained from insurance claims data and calculated from first of treatment to last contact with comparison done by Kaplan-Meier test. **Results:** A total of 5,555 PDAC patients harboring KRAS pathogenic variants were identified, including 109 with a G12C mutation. For KRAS G12C mutants, median overall survival was 470 days for those who received GP (n=22) compared to 240 days for patients who received FOLFIRINOX (n=9) with a median difference of 230 days (HR 0.32, CI 0.12-0.82, p=0.013). In contrast, median overall survival was higher for patients harboring G12D (392 vs 297 days, p=0.003), G12V (500 vs 356 days, p=0.012) or G12R (469 vs 391 days, p=0.095) mutations who received FOLFIRINOX compared to GP. KRAS G12C mutated PDAC showed the highest rate of PDL1+ staining (27%) compared to other variants (G12R 13% and G12D 19%, q<0.01). TMB-H and MSI-H prevalence were highest in G12C compared to other variants (no statistical significance observed). **Conclusions:** In patients with advanced PDAC and a G12C mutation, median overall survival appears significantly longer in those treated with GP compared to FOLFIRINOX. The opposite trend was seen in patients with other KRAS variants including G12D, G12V, and G12R, consistent with the recently presented NAPOLI-3 trial. PDL1 staining was also highest in the KRAS G12C cohort. While this is the largest reported analysis of outcomes to frontline chemotherapy in KRAS G12C-mutated PDAC, the sample size is small and needs validation in additional datasets. Next steps include evaluating DNA mutational status and RNA expression of genes involved in DNA repair in G12C vs other KRAS variants to better understand the outcome data presented here. Nationwide implementation of best practices in pancreatic cancer care (PACAP-1): Stepped-wedge cluster randomized trial. *First Author: Tara Mackay, Amsterdam UMC, Location University of Amsterdam, Department of Surgery, Amsterdam, Netherlands*

Background: Implementation of new treatment strategies in cancer care is often inadequate and slow. We aimed to implement best practices in pancreatic cancer care using a nationwide stepped wedge design and assess the impact on overall survival. **Methods:** Nationwide multicenter stepped-wedge cluster randomized controlled trial comparing implementation of best practices with usual care (May 22, 2018 – May 29, 2020). Best practices included adequate use of perioperative and palliative chemotherapy, pancreatic enzyme replacement therapy (PERT), and metal biliary stents. The 6-week implementation period in all 17 Dutch pancreatic centers and their regional referral networks included monitoring, return visits, and provider feedback in combination with education and reminders. Primary outcome was one-year overall survival for all disease stages and secondary outcomes included guideline compliance and quality of life. **Results:** Overall, 5580 patients diagnosed with pancreatic cancer were included; 2939 after implementation of best practices versus 2641 before. One-year survival did not differ among the groups (HR 0.98, 95 CI 0.88-1.08). Overall use of perioperative chemotherapy (neoadjuvant and adjuvant) did not significantly differ, but use of palliative chemotherapy significantly increased (23.9% to 30.3%, OR 1.38, 95 CI 1.10-1.74). Also the use of PERT (34.2% to 45.2%, OR 1.64, 95 CI 1.28-2.11); and metal biliary stents (74.1% to 83.3%, OR 1.78, 95 CI 1.13-2.08) significantly increased. The Global Health Score did not differ (AUC 43.8 to 42.7, median difference -1.12, 95 CI -3.13-0.80, n=655). **Conclusions:** This nationwide population-based trial to enhance implementation of best practices in pancreatic cancer care showed successful implementation of most best practices, but no increase in one-year survival and quality of life. Clinical trial information: NCT03513705. Research Sponsor: This research was funded by a grant from the Dutch Cancer Society (grant number UVA2013-5842).

Molecular and clinical correlates of DSCR1 expression in pancreatic cancer (PDAC). *First Author: Francesca Battaglin, Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA*

Background: Individuals with Down syndrome (DS) have a lower risk for solid tumors and angiogenesis related diseases. DSCR1 is highly upregulated in DS patients and its product, calcipressin-1, was shown to suppress angiogenesis and reduce cancer risk. High DSCR1 expression has been reported to decrease PDAC growth and metastasis in animal models. Here, we analyzed the molecular features and clinical outcomes associated with DSCR1 gene expression in PDAC. **Methods:** 8352 tumor samples tested at Caris Life Sciences (Phoenix, AZ) with WTS (Illumina NovaSeq) and NextGen DNA sequencing (NextSeq, 592 Genes and NovaSeq, WES) were analyzed. Top quartile transcripts per million for DSCR1 expression were considered high (Q4) while bottom quartile low (Q1). Cell infiltration in the tumor microenvironment (TME) was estimated using QuantiSeq. Interferon-gamma (IFG) and T-cell inflamed (TIS) signatures were calculated from RNA data. Statistical significance was determined as P-value adjusted for multiple comparisons (q < .05). Real world survival was obtained from insurance claims data (N = 4223) and Kaplan-Meier estimates were calculated. **Results:** DSCR1 expression was higher in primary tumors than metastases (q < .05). No significant differences were observed between high vs low DSCR1 PDAC in immune-related biomarkers (TMB, dMMR/MSI-H and PD-L1 protein), gene mutations and copy number alterations except for KRAS mutations which were more frequent in DSCR1 Q4 (93 vs 86%, Q4 vs Q1, q < .0001). Gene set enrichment analysis showed that DSCR1 high tumors were enriched in alterations of several pathways including NOTCH signaling, DNA repair, IFG response, myogenesis and adipogenesis (P < .05, false discovery rate < .25). B cells, M1 and M2 macrophages, neutrophils, NK cells, and Tregs were more abundant in the TME of tumors with high DSCR1 while dendritic cells, CD4+ T cells and monocytes were lower (q < .05). DSCR1 Q4 was associated with higher TIS score (50% inflamed vs 3.6%, q < .05) and positively associated with immune-related gene expression including CTLA4, IDO1, CD80, PD-L1, LAG3, CD86, TIM3, IFG, PD-1, and PD-L2 (fold change: 2-4, q < .0001). Overall, DSCR1 expression above median was associated with longer median OS (17 vs 11 months, HR 0.89 [0.83-0.95], P < .0001). When stratified by quartiles, DSCR1 Q4 was associated with longer time on treatment [ToT] with gemcitabine/nab-paclitaxel (HR 0.75 [0.63-0.89], P = .001), and marginal benefit on ToT (HR 0.81 [0.65-1.0]) but longer survival in FOLFIRINOX treated patients (HR 0.73 [0.58-0.92], P = .008). **Conclusions:** This is the first and most extensive profiling study to investigate DSCR1 expression in PDAC. Our data show a strong association between tumor DSCR1 gene expression, several pathway alterations, immune-related gene expression, TME cell infiltration and patient survival. These findings suggest DSCR1 as a candidate prognostic biomarker and as a potential treatment target in PDAC. First in class TLR7/8 agonist BDB001 combined with atezolizumab and stereotactic body radiation therapy in patients with advanced pancreatic adenocarcinoma: Results from the AGADIR study. *First Author: Simon Pernot, Department of Medical Oncology, Institute Bergonié Cancer Center, Bordeaux, France*

Background: Pancreatic adenocarcinoma is refractory to immune checkpoint inhibitors such as PD1/PDL1 antagonists. Investigating alternative immunotherapeutic approaches is a crucial need for this devastating disease. The potent immunostimulatory effects of Toll-like receptor (TLRs) have spurred efforts aimed at the development of TLR agonists as new immune-oncology agents. Radiation therapy combined with TLRs agonists has been shown to enhance antitumor immunity in the preclinical setting. **Methods:** AGADIR is a multi-cohort, phase 2, multicenter, open-label study investigating the novel TLR 7/8 agonist BDB001 combined with atezolizumab and stereotactic body radiotherapy (SBRT) in patients with advanced cancers. Cohort A enrolled patients with advanced pancreatic adenocarcinoma. BDB001 was administered IV at the dose of 0.75 mg/m² on days 1, 8, and 15 of cycles 1, 2, and 3. Then from cycle 4 on day 1 every 3 weeks. Atezolizumab was given at the dose of 1200 mg every 3 weeks. SBRT of at least one metastatic lesion was started at least one week after the first administration of atezolizumab and at the latest before the Cycle 2 Day 1. The primary endpoint is disease control rate defined as the proportion of participants with complete response, partial response or stable disease, as per adapted RECIST v1.1, observed within 24 weeks of treatment onset. Secondary endpoints include objective response, progression-free survival, overall survival and safety. All patients underwent sequential blood and tissue sampling for translational studies. **Results:** Between July 2021, and June 2022, 32 pts were enrolled in 3 centers (14 male, 18 female). Median age was 64 years (range 38 – 78). Median number of previous treatment lines was 1 (range 1 – 5). The most common treatment related adverse events were grade 1/2 asthenia, chills and fever. No death was related to the treatment. Among the 21 patients for whom central review was performed at the time of this writing, best tumor response was confirmed partial response, stable disease and progressive disease in 2 (9.5%), 6 (28.5%) and 13 (62.0%) patients respectively. The disease control rate was 38.0% (95%CI 18.1-61.5). **Conclusions:** The AGADIR study met its first endpoint for disease control rate in patients with advanced pancreatic cancer. Efficacy data on the whole cohort of patients and full biomarkers analyses will be presented at the meeting. Clinical trial information: NCT03915678. Research Sponsor: Institut National du Cancer; Roche Parma AG, Seven and Eight Biopharmaceuticals Inc.

Clinical utility of next generation sequencing (NGS) on circulating tumor DNA (ctDNA) in patients (pts) with pancreatic cancer (PC). *First Author: Fergus Keane, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: ctDNA provides opportunities for identifying targeted therapies, a source to conduct NGS when tissue acquisition is infeasible, detection of minimal residual disease (MRD), and identification of resistance mutations. There are limited large data sets to inform clinical utility and limited correlation of NGS of ctDNA and tumor in PC. Herein, we evaluate the ctDNA detection rate in multiple cohorts of PC and report the ctDNA-tissue genotype concordance in PC at Memorial Sloan Kettering (MSK). **Methods:** Pts with PC at MSK who had ctDNA prospectively collected using the MSK-ACCESS 129 gene ctDNA NGS assay, were identified. ctDNA detection was defined as the identification of a mutation, copy number (no.) alteration or structural variant. Tissue-based NGS using MSK-IMPACT gene assay was performed for pts with adequate tissue, and matched with ctDNA by date. Clinical, pathologic and outcome data were abstracted. Data are summarized with descriptive statistics. Overall survival (OS) estimated by Kaplan-Meier method from date of ctDNA draw to death/last follow up. **Results:** From 08/2019 to 07/2022, N= 414 pts with PC and ≥ 1 ctDNA sample included. Median age 69 years (range 29-92), female N=206 (50%). Stage at ctDNA collection: Stage I-III N= 203 (49%); Stage IV N= 211 (51%). ctDNA detection rate by no. of involved organs; 0 organs (MRD), N=7/30 (23%); 1-2 organs, N=158/270 (58.5%); 3-4 organs, N=82/102 (80.4%); >5 organs, 12/12 (100%). CtDNA detection rate by site of metastasis: Liver only, 75/99 (76%); peritoneum only, 15/25 (60%); lung only, 10/22 (45%). In pts with detected ctDNA median CA 19-9 was 494 U/mL (range 0, 247674) vs 100 U/mL (range 1, 22360) in pts with undetected ctDNA. In pts with detected ctDNA median CEA was 7 ng/mL (range 1, 2020) vs 4 ng/mL (range 1, 99) in pts with undetected ctDNA. In stage IV untreated pts, median OS 13 months(m) (95% CI: 7.3, 16) and 10 m (95% CI: 5.6, -) for ctDNA detected vs undetected, respectively. ctDNA detection rates by stage, and concordance between ctDNA and tissue-based NGS for common driver mutations *KRAS*, *TP53*, *CDKN2A* and *SMAD4* in N=131 matched pairs are summarized in the table. **Conclusions:** ctDNA detection rates are high (89%) in pts with untreated stage IV PC, with high concordance between ctDNA and tissue-based NGS (87% - 95%). In untreated stage I-III PC, detection and concordance rates are lower (<50%). Detection rates are associated with disease burden, site of metastasis, CA 19-9/CEA levels. ctDNA is a promising tool in detection of somatic alterations in PC, particularly in stage IV disease, and is a complementary adjunct to tumor-based NGS. Research Sponsor: None.

Stage	N	ctDNA Detected N (%)	ctDNA Undetected N (%)
Stage IV Untreated	119	106 (89%)	13 (11%)
Stage I – III Untreated	61	26 (43%)	35 (57%)
MRD	30	7 (23%)	23 (77%)
Concordance Per Gene	Untreated All Stages	Stage IV Untreated	Stage I – III Untreated
<i>KRAS</i>	76%	92%	43%
<i>TP53</i>	76%	89%	50%
<i>CDKN2A</i>	92%	95%	96%

Targeting germline or somatic DNA repair defects (beyond BRCA) in pancreatic cancer with niraparib: A phase II study (NIRA-PANC). *First Author: Anup Kasi, University of Kansas Cancer Center, Westwood, KS*

Background: Targeting a molecular subset of pancreatic cancer (PC) may identify alternatives to percutaneous chemotherapy and chemo-resistance/toxicity. Poly (ADP ribose) polymerase inhibitors (PARPi) have shown efficacy in germline BRCA mutation via synthetic lethality. Preclinical evidence suggests PARPi may target DNA repair defects beyond BRCA. We conducted a Niraparib phase II study in PC patients with germline/somatic DNA repair defects. **Methods:** This is an open-label, phase 2 trial in pts with locally advanced or metastatic PC with germline or somatic mutations, known or tested after consent to pre-screening tumor tissue analysis in DNA repair genes (BRCA1/2, PALB2, ATM, NBN, ATR, BRIP1, IDH1/2, RAD51, RAD51B/C/D, RAD54L, CDK12, BARD1, FAM175A, BAP1, CHEK1/2, GEN1, MRE11A, XRCC2, SHFM1, FANCD2, FANCA, FANCC, FANCG, RPA1, ARID1A), who have progressed on or intolerant of at least one line of therapy, no prior PARPi, with evaluable disease, and ECOG PS 0-1. Eligible pts were treated with Niraparib 300mg or 200mg PO daily for 28 days (1 cycle = 28 days) (200mg dose for baseline weight is < 77 kg or baseline platelet count is < 150,000 μ L) until disease progression, unacceptable toxicity, investigator decision, withdrawal of consent, or death. The primary objective was 6-month PFS rate. The secondary objectives were OS, DCR and safety. Pts were evaluable for safety if they had received > 1 dose of Niraparib and for efficacy if they had also received > 1 follow-up imaging study. **Results:** As of Feb 2023, 36 (13 female, 23 male) pts were enrolled, with a mean age of 62.9 (median 64, IQR 51-73, min 41, max 83, SD 11.25), of whom 27 (8 female, 19 male) were evaluable for efficacy. After a median follow-up of 9.0 months (IQR 6.0-15.1 m), the 6-month PFS rate was 40.7% (11/27 pts; 95% CI 4.7%- 100 %). The median PFS is 4.4 m (CI 2.3 - 6.5 m), and median OS is 9.1 m (7.5 -15.1 m). The disease control rate at 8 weeks was 70.4% (19 of 27 pts; 95% CI 49.8%-86.3%). Of the 27 evaluable pts- BRCA2 mutation was seen in 10 pts, ATM (5), CHEK2 (5), BRCA1 (2), NBN (2), ARID1A (1), FANCA (1), FAM175A (1), RAD51B (1), IDH1 (1), IDH2 (1). Among 36 pts evaluable for safety, treatment-related adverse events occurred in 75% (27/36), and Grade 3 and grade 4 treatment-related adverse events occurred in 31% (11/36). The most common treatment-related AEs were anemia (25%, 9/36), nausea (22%, 8/36), thrombocytopenia (19%, 7/36), vomiting (19%, 7/36), and fatigue (17%, 6/36). Serious treatment-emergent adverse events were reported in 11% (4/36). There were no treatment-related deaths. **Conclusions:** In previously treated pts with locally advanced and metastatic PC harboring DNA repair defects, niraparib monotherapy yielded a 6-month PFS rate of 40%, median PFS of 4.4 months, and median OS of 9.1 months. Clinical trial information: NCT03553004. Research Sponsor: GSK (TESARO); IIT Steering Committee funds at KU Cancer Center.

Outcome	Pts (n =27)	95% CI
6m-PFS	40.7% (11/27)	4.7%- 100%
mPFS	4.4 months	2.3 - 6.5 m
mOS	9.1 months	7.5 -15.1 m
DCR	70.4% (19/27)	49.8%-86.3%

Impact of novel pan-RAS inhibitors on efficacy and resistance to AMG-510 and MRTX-1133 in pancreatic cancer cell lines. *First Author: Tariq Arshad, Qualigen Therapeutics, San Ramon, CA*

Background: Mutant-activated RAS genes are the most frequently mutated gene family associated with cancer (almost 30% of all cancers contain a mutant RAS gene). KRAS is the predominant isoform mutated in cancer and is the isoform exclusively mutated in pancreatic ductal carcinoma (PDAC). Since almost all PDAC cases harbor a mutant RAS, it is arguably the most RAS-addicted tumor type. There is now considerable evidence implicating mutant KRAS as a driver of PDAC. Recently, several mutant KRAS-targeted therapies (sotorasib and adagrasib) have been developed and show promise in PDAC patients. We have developed a direct inhibitor of RAS with a predicted unique interaction region capable of directly binding to wild-type H- and K-RAS, but which shows preferential binding for KRAS G12D and G12C mutants. This novel inhibitor disrupts the RAS effector domain and blocks the ability of RAS to signal through its effectors. **Methods:** We used *in silico* virtual library screening to identify an initial candidate inhibitor which was effective at inhibiting the 3D growth of PDAC cells without affecting their growth in 2D. Subsequent iterative rounds of medicinal chemistry was then performed to identify a series of derivatives with enhanced activity, as determined by 3D growth inhibition assays and effects on Ras signaling, as determined by Western blot analysis of phosphor-ERK, phosphor-Akt and activation of Ral A. **Results:** Our series of RAS inhibitors effectively block PDAC cell growth in 3D without impacting their 2D proliferation and suppress the interaction of KRAS with its effector cRAF. The inhibitors also effectively inhibit RAS signaling in mutant RAS containing PDAC cells. Since our novel compounds are predicted to bind to RAS at a different site to either AMG-510 (G12C specific inhibitor) and MRTX-1133 (G12D specific inhibitor), we tested the co-operativity of our compounds with these existing agents. Our compounds enhanced the anti-proliferative effects of both MRTX-113 and AMG-510 in mutant KRAS G12D and G12C PDAC cells, respectively. **Conclusions:** We have developed a series of novel RAS inhibitors that directly bind preferentially to mutant KRAS that may serve as new mutant KRAS-targeted therapeutics, and that may also have the potential to enhance the efficacy or suppress the resistance of AMG-510 and MRTX-1133. Chemotherapy dose density and effect on prognosis for patients with resectable pancreas cancer: A secondary analysis of SWOG S1505. *First Author: Sameer H. Patel, University of Cincinnati Medical Center, Cincinnati, OH*

Background: Chemotherapy is an integral part of multimodality treatment for resectable pancreatic ductal adenocarcinoma (PDAC). Assessing the impact of chemotherapy dose reductions or missed cycles on survival is difficult as few trials prospectively address the prognostic value of this important metric. **Methods:** SWOG S1505 (NCT02562716) was a randomized, phase II study of perioperative (12 weeks neoadjuvant and 12 weeks adjuvant) chemotherapy with mFOLFIRINOX or gemcitabine/nab-paclitaxel for resectable PDAC. Dose density (DD) was defined as the estimated percent of chemotherapy dose received of the total planned per protocol. Thresholds were based on published analyses and balance in sample size across treatment arms. Cox regression analysis of overall survival (OS) according to DD was performed in patients alive at two landmark time points: after surgery (among those who completed surgery) and at 40 weeks (when protocol therapy was to be completed). **Results:** Of the 103 eligible patients enrolled, median age was 64 years, 81% underwent pancreaticoduodenectomy, 15% distal pancreatectomy, and 3% a total pancreatectomy. In the 73 patients who underwent surgery, median neoadjuvant chemotherapy DD was 89%. Patients with ≥ 85% DD had higher median OS from surgery (38.1 v. 17.2 months, p = 0.039) compared to patients with < 85% DD. Of the 82 patients who survived to 40 weeks post randomization, 67 underwent surgery and 58 started adjuvant chemotherapy. The median DD for all perioperative chemotherapy was 67%; DD was significantly higher for neoadjuvant compared to adjuvant therapy (83% vs. 58%, p < 0.001). In this cohort, DD ≥ 70% was associated with better median OS from 40 weeks post randomization (32.2 v. 14.0 months, p = 0.017). DD was not significantly associated with pathologic response, margin status, or lymph node negativity. There were no significant differences in DD between the mFOLFIRINOX and gemcitabine/nab-paclitaxel arms. **Conclusions:** This is the first study to identify a prognostic role for chemotherapy DD in patients undergoing perioperative chemotherapy for resectable PDAC. Patients who received ≥ 85% DD preoperatively and/or ≥ 70% DD perioperatively had significantly higher mOS than those receiving a smaller proportion of protocol therapy. With greater survival benefit in patients who received higher chemotherapy DD, and higher DD being likelier in preoperative vs. postoperative treatment, these data support use of neoadjuvant chemotherapy for resectable PDAC. Moreover, these findings suggest that DD should be considered in prospective studies for localized PDAC to optimize therapy to be received. Research Sponsor: None.

PD-1 blockade plus chemotherapy followed by concurrent SBRT with SIB as preoperative therapy for patients with borderline resectable and locally advanced pancreatic cancer: A biomolecular exploratory, single-arm phase II clinical trial. *First Author: Juan Du, The Comprehensive Cancer Center of Drum Tower Hospital, Medical School of Nanjing University, Nanjing, China*

Background: Pancreatic cancer is fatal malignant tumor with low resection rate and poor prognosis. We aimed to assess the safety and efficacy of a new mode of preoperative therapy for patients with locally advanced (LAPC) or borderline resectable pancreatic cancer (BRPC). **Methods:** This is a single arm, exploratory phase II clinical trial (ChiCTR2000032955). Gemcitabine (1000 mg/m²) and nab-paclitaxel (125 mg/m²; AG) were administered to patients with LAPC or BRPC on days 1 and 8, along with tislelizumab (200 mg) on day 1 intravenously (IV) every three weeks. Concurrently, the patients underwent stereotactic body radiotherapy (SBRT) with simultaneous integrated boost (SIB) during the third cycle of treatment. Surgical intervention was reassessed after four cycles of treatment. Objective response rate (ORR), R0 resection rate, median overall survival (mOS), median progression-free survival (mPFS) and safety were analyzed. Multiomics potential predictive biomarkers were investigated as exploratory objectives. **Results:** Between May 2020 and October 2021, 29 patients were enrolled in the study, 25 of them included in the intention-to-treat analysis. At the end of the last follow-up (November 30, 2022), 15 patients had a best response of partial response, the ORR was 60%. Ten patients underwent resection, and the R0 resection rate was 90% (9/10). The disease control rate (DCR) was 100%. Two of the ten resected patients achieved pathologic complete response and one patient achieved major pathological response. The mPFS, 12-months PFS rate, and 12-months OS rate were 13.7 months (95% CI: 11.7–NR), 64% (95% CI: 47.6–85.8%), and 72% (95% CI: 56.3–91.9%), respectively. Grade 3 or higher adverse events are anemia (8%), thrombocytopenia (8%) and jaundice (8%). Biomarker analysis indicated that patients with continuous carbohydrate antigen 19-9 decline and elevated peripheral blood eosinophil counts during treatment exhibited better survival outcomes. Furthermore, circulating tumor DNA analysis reveals that patients with a >50% decline in maximal somatic variant allelic frequency (maxVAF) between the first clinical evaluation and baseline have a longer survival outcome and higher response rate than those who are not (PFS: 20.03 vs. 10.32 months, $p = 0.024$; OS: not reached vs. 13.47 months, $p = 0.024$; ORR: 90% vs. 35.7%, $p = 0.013$). Moreover, maxVAF decline (> 50%) is significantly associated with the surgical rate after preoperative therapy (70.0% vs. 21.4%; $p = 0.035$). **Conclusions:** Anti-PD-1 inhibitor tislelizumab plus AG chemotherapy followed by concurrent SBRT with SIB displayed promising antitumor activity and acceptable safety profile for patients with LAPC or BRPC. Multiomics potential predictive biomarkers are identified and warrant further verification. Clinical trial information: ChiCTR2000032955. Tandem duplicator phenotype: A novel targetable subgroup in pancreatic cancer? *First Author: Abdul Rehman Farooq, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Validated biomarkers are urgently needed to provide a more precise approach in pancreatic cancer (PDAC). Homologous recombination deficiency (HRD) is a heterogeneous cohort in PDAC and predicts platinum and PARP inhibitor sensitivity. The BRCA-1 genotype associates with distinct tandem duplications (TDs), however non-BRCA-1 TD phenotypes (TDP) have been observed across tumour types and may be associated with perturbations in CDK12, FBXW17, and CCNE1. Here, we characterize the prevalence and outcomes of TDP in a large series of prospectively sequenced PDAC. **Methods:** Whole-genome sequencing was performed in 191 early stage resected and 275 advanced PDAC cases in the PanCuRx initiative and the COMPASS trial at the Ontario Institute for Cancer Research and Princess Margaret Cancer Centre. Tumors underwent laser capture enrichment prior to sequencing. TD scores were calculated as previously described by Menghi et al, and HRDetect scores assigned. Samples were classified as classical or basal-like by Moffitt. Outcomes of patients with TDP tumors were evaluated. Tumors that are nonHRD and nonTDP are referred to as typical. **Results:** Of 466 cases, 46 were identified as TDP (9.9%; 17 resected, 29 advanced). Subgroups of TDP by etiology included BRCA1 (n=8; 6 germline, 2 somatic), somatic CCNE1 (n=1), and unknown (n=37; no identified alterations in TDP-related genes). Pathogenic germline variants were not found in unique genes other than BRCA1. HRD TDP was associated with a significantly smaller TD size compared to nonHRD TDP (median 12 kb vs. 125 kb, $p < 0.0001$) and median TD load of 114. NonHRD TDP genomes exhibited elevated TD load (median 70 vs. 13, $p < 0.0001$) and HRDetect scores ($p < 0.0001$) compared with typical. NonHRD TDP was not prognostic in resected PDAC disease ($p = 0.6361$) compared with typical. We observed a trend towards improved response to 1st-line platinum therapy in nonHRD TDP vs. typical ($p = 0.066$) for patients with advanced disease. When stratified for only 'classical' RNA subtype cases as per Moffitt classification (HRD TDP: 2 basal-like, 8 classical, 1 unknown; nonHRD TDP: 9 basal-like, 25 classical, 1 unknown), platinum therapy was correlated with better response in nonHRD TDP vs. typical (n = 10, 70% ORR, $p = 0.0108$) highlighting the chemoresistance of the basal-like subgroup. Superior survival was not observed in this small cohort. **Conclusions:** In PDAC, the etiology of nonHRD TDP is unclear but may represent a potential marker for platinum and DNA damage response agents. Further investigation is warranted with a larger sample size. Research Sponsor: None.

Impact of positive resection margins on recurrence and survival following resection and adjuvant chemotherapy in pancreatic cancer: Results of the PRODIGE 24-CCTG PA-6 trial. *First Author: Aurélien Lambert, Medical Oncology Department, Lorraine Cancer Institute, Nancy, France*

Background: Pancreatic adenocarcinoma (PDAC) has a poor prognosis. Only 10-15% of patients present with resectable tumors upfront, and most patients develop recurrence and die prematurely. The data are incongruous when considering R1 status, direct invasion is not consistently a significant prognostic factor. It is recommended that 7 margins be identified for surgery: the bile duct, pancreatic neck, proximal and distal duodenum, superior mesenteric vein (SMV), superior mesenteric artery (SMA), and posterior pancreas. By analyzing data from the PRODIGE 24-CCTG PA-6 trial that validated the mFOLFIRINOX regimen in adjuvant setting, our main objective was to analyze the prognostic value of margin involvement on disease-free survival (DFS). **Methods:** The protocol recommended that the surgeon inked the resection margins. R1 was defined as direct tumor margin infiltration within 1 mm of one or more resection margins. All patient data were re-evaluated centrally by an external review committee including pathologists, surgeons, and medical oncologists to verify key prognostic factors, including inking and filling of resection margins. **Results:** Among the 400 patients included in the study, the median number of documented margins was 6, IQR (5-7). In 214 patients (53.5%), fewer than 7 margins were reported. The most common margin involvement was on the SMV groove (28.3%), posterior margin (21%), SMA (14.5%), and pancreatic neck transection (5.3%). Margin inking was performed in 64.9% of cases. Misclassification of the R1 status concerned 24.1% of the files after centralized review. When positive, only 3 margins (SMV groove, median and posterior) were significant prognostic factors in univariate analysis (all $p < 0.01$). When combined, one R1 margin among these three had independent prognostic value in multivariate analysis. In multivariate analysis, DFS was significantly different by quality of resection margins in the gemcitabine arm (HR 95% CI 1.97 [1.23;3.16]; $p = .005$) but not in the mFOLFIRINOX arm (HR 95% CI 1.46 [0.91;2.35]; $p = .114$). **Conclusions:** Few studies have examined the prognostic implications of each margin. We consider that every effort should be made to evaluate the 3 best prognostic margins. One finding of this work is the likely effect of mFOLFIRINOX on local invasion in operated patients. It seems that this chemotherapy regimen (unlike gemcitabine) corrects the alteration related to margin involvement, probably explaining all or part of the improved survival. Therefore, the value of additional therapies, such as clouture radiotherapy, should be evaluated in patients with unknown marginal status or in those who did not benefit from mFOLFIRINOX chemotherapy. A patient who received mFOLFIRINOX as adjuvant therapy is more likely to recur with distant metastasis (80%) and with a better survival of 28 months. Clinical trial information: NCT01526135. Artificial intelligence (AI) –powered spatial analysis of tumor-infiltrating lymphocytes (TILs) for prediction of prognosis in resectable pancreatic adenocarcinoma (PDAC). *First Author: Yoojoo Lim, Oncology, Lunit, Seoul, South Korea*

Background: The degree of TIL infiltration in the tumor microenvironment has been suggested as a prognostic factor in multiple cancer types, but the significance in PDAC is not well known. The aim of this study is to assess the prognostic role of AI-based spatial TIL density assessment and immune phenotype (IP) classification in resectable PDAC. **Methods:** We collected hematoxylin and eosin (H&E)-stained whole slide images (WSI) of tumor tissues and clinical data from stage I – III PDAC patients who received curative surgery at Samsung Medical Center, in Seoul, Korea, between Jan 2017 and Dec 2018. For spatial TIL analysis, we used Lunit SCOPE IO, an AI-powered pathology slide analyzer that can identify TIL and segment tumor epithelium and stroma from H&E-stained WSI. It then estimates intratumoral (iTIL) and stromal TIL (sTIL) densities, as well as IP classification of each case. IPs were defined as follows: inflamed IP (IIP) as high iTIL and sTIL; immune-excluded as low iTIL and high sTIL; immune-desert as low TIL overall. Predetermined cutoffs prior to this study were used for the determination of IPs. **Results:** A total of 209 patients were identified, 182 treated with upfront surgery and 27 with preoperative chemo(radio)therapies followed by surgery. The median recurrence-free survival (RFS) and overall survival (OS) of all patients was 16.8 months (95% CI 12.1 - 21.4), and 36.8 months (95% CI 31.2 - 42.4), respectively. In the 182 patients treated with upfront surgery, the median iTIL and sTIL densities were 85.3/mm² (IQR 56.9 – 133.0) and 672.2/mm² (IQR 445.9 – 912.9). 85.7% of the cases were immune-excluded, while 11.5% were IIP. The patients having iTIL higher than the median exhibited longer RFS (HR 0.62, 95% CI 0.42 - 0.92, $p = 0.017$). Also, the patients having IIP exhibited longer OS ($p = 0.045$, HR 2.05, 95% CI 1.00 – 4.22) and a marginally longer RFS ($p = 0.051$, HR 2.03, 95% CI 0.98 – 4.18) compared to those with non-IIP. In the 27 patients who were treated with preoperative therapies, the iTIL densities in the surgical specimens were significantly higher compared to the 182 untreated samples (mean iTIL 168.8/mm² after chemo(radio)therapies vs. 112.6/mm² in upfront surgery, $p = 0.012$), although the increase in the proportion of IIP was not significant. Using the iTIL median of the 182 upfront surgery cases, 17/27 (63.0%) patients had high iTIL in WSIs obtained after preoperative therapies, and these patients were observed to have a significantly better RFS (HR 0.26, 95% CI 0.09 - 0.73, $p = 0.006$). **Conclusions:** While most cases of resectable PDAC were found to have TIL infiltration mainly in stroma, relatively higher iTIL infiltration was associated with better prognosis. An increase in iTIL after chemo(radio)therapies may be associated with better outcomes. Research Sponsor: None.

Minimally invasive versus open distal pancreatectomy for resectable pancreatic cancer (DIPLOMA): An international randomised trial. *First Author: Mohammed Abu Hilal, Istituto Ospedaliero Fondazione Poliambulanza, Brescia, Italy*

Background: In the absence of randomised trials, the oncological safety of minimally invasive distal pancreatectomy (MIDP) in patients with pancreatic cancer continues to be a matter of debate. **Methods:** An international randomised non-inferiority trial including patients with resectable pancreatic cancer from 35 centres in 12 countries. Patients were randomly assigned to either MIDP (laparoscopic or robotic) or open distal pancreatectomy (ODP). Both patients and pathologists were blinded to the assigned approach. Primary endpoint was radical resection (R0, <1mm free margin) in patients who had ultimately undergone resection. Analyses for the primary endpoint were by modified intention-to-treat, excluding patients who did not undergo a resection. The pre-defined non-inferiority margin was set at -7%. **Results:** Between May 8, 2018 and May 7, 2021, 258 patients were randomly assigned to MIDP (131 patients) or ODP (127 patients). The modified intention-to-treat population included 117 patients in the MIDP group and 114 patients in the ODP group. An R0 resection occurred in 83 (73%) patients in the MIDP group and in 76 (69%) patients in the ODP group (difference 4%, 90% CI -6 to 14%; p=0.039). Median lymph node yield was comparable (22.0 [16.0-30.0] vs 23.0 [14.0-32.0] nodes, p=0.86), as was the rate of intraperitoneal recurrence (41% vs 38%, p=0.45). Other post-operative outcomes were comparable. **Conclusions:** In this trial, the rate of radical resection following MIDP was non-inferior compared to ODP. This confirms the oncological validity of the minimally invasive approach in patients with resectable pancreatic cancer. Clinical trial information: ISRCTN44897265. Research Sponsor: Medtronic and Ethicon.

A phase I/II study of durvalumab and stereotactic ablative body radiotherapy (SABR) in locally advanced (LA) and borderline resectable (BR) pancreatic cancer. *First Author: Richard Tuli, USF Health Morsani College of Medicine, Tampa, FL*

Background: Pancreatic cancer (PC) is largely refractory to immune checkpoint blockade (ICB) in genomically unselected patients (pts). Synergistic effects of combined ICB and radiotherapy have been suggested in varied solid tumors. Few studies have evaluated this approach in pts with PC. We sought to evaluate the safety and efficacy of PD-L1 inhibitor durvalumab (D) and SABR after induction chemotherapy, in LA and BR PC. Herein, we present phase II data from two cohorts. **Methods:** A multi-institutional, non-randomized phase 1/2 trial of SABR and D was conducted at Cedars-Sinai Medical Center (CS) and Memorial Sloan Kettering (MSK). Key eligibility: ECOG 0-1; unresectable PC, with stable/responding disease following 2-3 cycles gemcitabine and nab-paclitaxel (GnP) or 4-6 months (m) FOLFIRINOX (FFX). CS enrolled pts with BR and LA PC; MSK enrolled pts with LA PC only. All pts received SABR between dose 1 and 2 of D, with slight variation in ablative radiation techniques (CS: 33Gy/5#; MSK: MRI adaptive ablative radiation, 50Gy/5#). D dosed on day 1: 750mg x 4 doses Q14 days, and subsequently Q2 or Q4 weeks x 1 year total, or until resection, progression of disease (POD), or limiting toxicity. Primary endpoint: 6-month progression free survival (6 m PFS). Secondary endpoints: rate of downstaging to resectability, objective response by RECIST v1.1, duration of response, PFS, Overall Survival (OS). PFS and OS estimated from consent date using Kaplan-Meier method. Association between surgery and outcomes was analyzed as a time dependent covariate in univariate Cox regression models for OS and PFS. To assess immunogenomic biomarkers of response, pre- and on-treatment tissue, blood and microbiome samples were gathered. **Results:** Between 08/2017 and 05/2022, N= 36 enrolled. Median age 67.5 years (range 48-79), 39% (14/36) female. Performance Status: N=12 (33%) ECOG 0; N= 24 (67%) ECOG 1. Median duration chemotherapy: 3.5 m (range 1.4, 5.8). Staging: N=31 (86%) LA; N=5 (14%) BR. N = 9 (25%) underwent resection; all R0. Conversion to resection was not associated with PFS (HR 0.45; 95% CI 0.17, 1.17, p=0.1) or OS (HR 0.69; 95% CI 0.26, 1.84, p=0.5). Survival and response data summarized in table. Toxicities of special interest: Grade 3 treatment-related: N= 7; diarrhea N= 2; elevated AST/ALT N= 2; lipase/amylase elevation, N=1; nausea N=1. Grade 4: amylase elevation N=1. **Conclusions:** D and SABR after induction chemotherapy in LA and BR PC is safe, had an encouraging 6-m PFS of 69% and favorable R0 resection rate, warranting further evaluation. Immuno-genomic biospecimen analyses underway. Clinical trial information: NCT03245541. Research Sponsor: AstraZeneca.

Median Follow-Up (95% CI)	23 m (18, -)

Meta-analyses of factors associated with long-term survival after resection of pancreatic ductal adenocarcinoma. *First Author: Asad Saulat Fatimi, Aga Khan University, Karachi, Pakistan*

Background: Pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal malignancies. Long-term survival (>5 years, LTS) is rarely seen even after 'curative-intent' resection. With improved systemic control via effective systemic therapies, LTS is now being reported more frequently. However, our understanding of LTS in PDAC remains limited. The aim of the current study was to perform a systematic review and meta-analysis to quantify the associations between various clinicopathological factors and LTS following resection of PDAC. **Methods:** The PubMed, Embase, Scopus, and Cochrane CENTRAL databases were systematically searched for articles reporting actual patient survival data. Two reviewers independently screened and reviewed articles, extracted relevant data, and assessed the risk of bias in included studies using the Newcastle-Ottawa scale (NOS). Data that compared patients who achieved LTS after resection with those who did not were extracted from the included studies. Meta-analyses using a random effects model were conducted to identify associations between LTS and various patient, tumor, and treatment related factors. **Results:** Overall, 33 studies with 46,981 patients after resection of PDAC were included. Most articles received a 'good' NOS assessment, indicating acceptable risk of bias. The median rate of LTS was 15.27% (IQR: 9.47-20.72). Multiple clinicopathological factors were found to be associated with LTS, including tumor grade (OR: 0.40, 95%CI: 0.31-0.52), tumor stage (OR: 0.36, 95%CI: 0.31-0.41), and margin status (OR: 0.43, 95%CI: 0.36-0.50). Factors that were not associated with LTS included patient age, tumor size, tumor location, or genetic mutations. Notably, adjuvant therapy (OR: 1.68, 95%CI: 1.24-2.28) but not neoadjuvant therapy (OR: 1.08, 95%CI: 0.62-1.87) were associated with LTS. **Conclusions:** This meta-analysis revealed that 15% of patients achieved LTS after resection of PDAC. Multiple clinicopathological factors are associated with LTS whereas presence of 'traditional' negative prognostic factors does not rule out LTS. Further studies are required to identify robust predictors of LTS in resected PDAC. Research Sponsor: None.

Clinicopathological characteristics associated with LTS in resected PDAC.

Parameter		Odds Ratio (95%CI)
Patient Factors	Sex	1.29 (1.01, 1.64)
	Pathologic T-stage	0.40 (0.31, 0.52)
	Pathologic M-stage	0.16 (0.06, 0.38)
	Nodal Disease	0.40 (0.35, 0.45)
	Vascular Invasion	0.50 (0.39, 0.64)

Mutation-site localized non-B DNA burden and survival heterogeneity in early-stage pancreatic cancer. *First Author: Qi Xu, Livestrong Cancer Institutes, University of Texas at Austin, Austin, TX*

Background: Pancreatic cancer is a highly aggressive disease with a poor prognosis, and one in which most measure of genomic instability (e.g., tumor mutation burden (TMB), fraction of genome altered (FGA)) have thus far, not proven informative in differentiating survival. Non-B DNA are alternative DNA forms that deviate from the canonical B-DNA structure with potential to increase susceptibility to mutations, leading to the development of cancer. The role of non-B in pancreatic cancer has not been fully explored. Herein, we investigate the relationship between gene mutation sites co-localized with non-B DNA motifs in terms of survival and B-DNA features. **Methods:** Using TCGA data, we derived a genome-wide mutation signature on 104 early-stage pancreatic patients. We introduced a metric, mutation-localized non-B burden (MLNB) by the number of non-b motifs containing mutation sites, normalized to the number of mutations and motif library size. We applied MLNB to patient-specific mutation signatures to derive an MLNB burden for non-B DNA structure motifs: G-quadruplexes (G4), Z-DNA, inverted repeats (IR), mirror repeats (MR), direct repeats (DR), and short tandem repeats (STR). We performed a cluster analysis on MLNB and compared groups based on overall survival (OS) in months (mos) using a log-rank test. Comparisons of B-DNA-derived molecular features among clusters were performed using a Kruskal-Wallis and Fisher Exact test. **Results:** Among the 104 early-stage pancreatic patients with a mutation signature, MLNB clustering resulted in six patient clusters that differentiated by non-B DNA structure, with DR burden the longest OS cluster (n=23, median OS=30mos), significantly (p < 0.05) differing as compared to IR (n=23, median OS=15 mos), STR (n=20, median OS=16mos), MR with lack of IR (n=14, median OS=13mos) and MR with IR (n=16, median OS=8mos). A mix of Z-DNA and G4 burden defined a cluster with shorter OS (n=22, median OS=14mos) as compared to DR, though not significant. Patients with the longest OS, MLNB-DR burden cluster had mutation signatures enriched in MAPK and Notch signaling pathways, as compared to the other clusters enriched with double-stranded break and mismatch repair (IR), hedgehog and WNT signaling (STR), and interleukin-4 signaling (MR) pathways. Among all clusters, CDKN2A deletion was most prevalent except for MLNB-DR burden cluster. No Significant differences were found between the MLNB clusters with age, race gender, KRAS and TP53 mutations, FGA, TMB, tumor purity, Bailey and Moffit subtypes. **Conclusions:** Our results point towards the potential use of MLNB as an emerging marker of site-structure genomic instability. Considering that triplex DNA is emerging as a marker genomic instability, and that we distinguish between two MR groups based on IR burden, our results may provide insights into various instability mechanisms associated with poor survival in pancreatic cancer. The five periampullary cancers: Not just different siblings but different families—An international multicenter cohort study. *First Author: Bas Uijterwijk, Fondazione Poliambulanza Istituto Ospedaliero 57, Brescia, Italy*

Background: Cancer arising in the periampullary region can be anatomically classified in pancreatic ductal adenocarcinoma (PDAC), distal cholangiocarcinoma (dCCA), duodenal adenocarcinoma (DAC) and ampullary adenocarcinoma (AAC). Based on histopathology, the AAC is currently subdivided in the intestinal (AmpIT) and pancreatobiliary (AmpPB) subtype. Despite close anatomical resemblance, it is unclear how the ampullary subtypes relate to the remaining periampullary cancers in tumor characteristics and behavior. **Methods:** This is an international multicenter cohort study, including patients after curative intent resection for periampullary cancer retrieved from 45 centers (from Europe, USA, Asia and Canada) between 2010 and 2021. Pre-operative CA19-9, differences in pathology and postoperative pancreatic fistula (POPF, grade B/C), 8-year overall survival (OS) and disease-free interval (DFI) were compared between DAC, AmpIT, AmpPB, dCCA and PDAC. **Results:** Overall, 3809 patients were included of which 348 DAC, 774 AmpIT, 848 AmpPB, 1036 dCCA and 803 PDAC. The best 8-years overall survival was found in patients with AmpIT and DAC (49.8% and 47.9%), followed by AmpPB (34.9%, $p<0.001$), dCCA (26.4%, $p=0.020$) and last, PDAC (12.9%, $P<0.001$). The best 8-years DFI was measured for AmpIT (62.7%) and the worst for both dCCA and PDAC (24.9% and 21.8%). This pattern correlated with the height of the pre-operative CA19-9 but not with the pathology, in which the largest and most progressed tumors were found in DAC. The incidence of POPF was lower in the pancreas-related tumor types (AmpPB 18.5%, PDAC 8.3%) compared to the non-pancreas related types (DAC 27.3%, AmpIT 25.5%, dCCA 27.6%). **Conclusions:** Despite the close anatomic relation of the five periampullary cancers, this study shows that there are prognostic and clinically relevant differences in terms of preoperative blood markers, pathology, complications, long-term survival, and recurrence. More characteristics are shared between DAC and AmpIT and between AmpPB and dCCA than between the two ampullary subtypes. Instead of using collective definitions for “peri-ampullary cancers”, this study emphasizes the need for individual evaluation of each histopathological periampullary subtype with the ampullary subtypes as individual entities in future studies. Detection and localization of gastrointestinal cancers based on multi-dimensional signatures from a single cfDNA targeted sequencing assay. *First Author: Xin-Rong Yang, Department of Liver Surgery and Transplantation, Liver Cancer Institute, Zhongshan Hospital, Fudan University; Key Laboratory of Carcinogenesis and Cancer Invasion (Fudan University), Ministry of Education, Shanghai, China*

Background: Five major gastrointestinal (GI) cancers - colorectal (CRC), gastric (GC), liver (LC), esophageal (EC), and pancreatic cancer (PC) - are responsible for hundreds of thousands of mortalities annually worldwide. Unfortunately, there is a lack of cost-effective, blood-based screening method for their early detection. To address this issue, we aimed to develop GutSeer, a noninvasive, targeted methylation sequencing-based test by leveraging methylation and fragmentomic signatures carried by cell-free DNA (cfDNA). **Methods:** The panel of GutSeer consists of 1656 target regions which were either differentially methylated between healthy and cancer samples, or distinctively methylated in a specific GI cancer. Cancer and healthy participants were recruited and randomly divided into a training and a validation cohort. Their plasma DNA samples were analyzed to generate DNA methylation and fragmentomic features. These multi-dimensional features were integrated to build ensemble stacked machine learning models to differentiate cancer against healthy, and to determine the tissue-of-origin (TOO) of the cancer. **Results:** A total of 1844 cases (787 healthy, 342 LC, 239 GC, 209 EC, 180 CRC, and 87 PC cases) were recruited for this study. A cancer-vs-healthy model achieved an AUC of 0.94 and 0.95 (sensitivity of 77.7% and 77.1% under the specificity around 96%) using either methylation or fragmentomic features only, respectively. Combining both methylation and fragmentomic features further improved performances, achieving an AUC of 0.96 (sensitivity = 86.2% at a specificity of 96.7%). For individual type of cancer, GutSeer has a sensitivity of 93.3% for CRC, 81.1% for EC, 70.3% for GC, 96.5% for LC, and 86.4% for PC. An independent test using 629 benign cases as controls achieved a specificity of 87.1%. A separate TOO model was built using all features and achieved an overall accuracy of 82% for all cancer cases (66.7% for CRC, 87.0% for GC and EC combined, 89.0% for LC, and 63.2% for PC). Same as the cancer detection model, using multi-dimensional features in TOO prediction yielded higher accuracy than when models using only methylation or fragmentomics features (accuracy = 75.6% or 75.4%, respectively). When compared with whole-genome sequencing (WGS) based approaches, GutSeer showed a comparable performance in cancer detection but a higher accuracy in TOO identification, further confirming its effectiveness for detection of GI cancers. **Conclusions:** GutSeer, a non-invasive test integrating multi-dimensional features, was demonstrated to detect and localize the 5 main types of GI cancer with high accuracy. Our results further showed that a reasonably sized panel can perform comparably or even better than WGS-based methods in cancer detection and TOO localization, indicating GutSeer may be a low-cost solution for blood-based early screening for GI cancers. Incidence, epidemiological characteristics, and cause-specific survival analysis of ampullary carcinoma using the SEER database. *First Author: Rajvi Gor, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY*

Background: Ampullary carcinomas (AC) are rare and comprise only 0.2% of gastrointestinal malignancies, and there is a paucity of studies analyzing them. We studied the incidence, demographics, tumor characteristics, and survival variables of patients with AC using the Survival, Epidemiology, and End Results [SEER] November 2021 database. **Methods:** We identified 3650 patients aged >18 with microscopically confirmed adenocarcinoma of the ampulla using ICD-O-3 site code C241 and histology codes (8140-8147, 8480, 8490, 8500). The epidemiological characteristics and the survival variables included were age, gender, ethnicity, and American Joint Committee on Cancer [AJCC] Staging. The overall 5-year survival (OS), cause-specific 5-year survival (CSS), and CSS plots across different strata were plotted using the Kaplan-Meier Method. The analysis was done using the Cox proportional hazard regression model ($p<0.05$). **Results:** The overall age-adjusted incidence of AC was 0.3 per 100,000 cases. The median age at diagnosis was 69 (Interquartile range - 59, 78). It was more common in males (56.03%) and Non-Hispanic White (58.96 %), with the most common stages at a presentation being stage 2B IIB (22.08%) and stage III (22.11%). The observed overall 5-year survival was 31%, and the cause-specific 5-year survival was 37.5%. The CSS was not significantly associated with gender ($p=0.06$). The estimated hazards of death attributed to AC increase by 13% ($p<0.0001$) for every 10-year increase in age at diagnosis above 67 years. The CSS was also associated with race, with African Americans and Hispanics being associated with higher hazards of death attributed to AC when compared to Non-Hispanic Whites with HR of 1.5 ($p<0.0001$) and 1.12 ($p=0.01$), respectively. **Conclusions:** Ampullary carcinoma is more commonly seen in males and non-Hispanic Whites with a median age of 69 years. Patients are typically diagnosed in stages IIB and III. Lower CSS rates were associated with advancing age, African American, and Hispanic populations. We need further studies to determine whether these disparities between different races are due to socioeconomic, genetic, or biological factors. Additional studies investigating how different treatment options affect AC survival, especially in this population subset, can be explored. Research Sponsor: None.

Multi-institutional study evaluating the role of circulating tumor DNA (ctDNA) in management of appendiceal cancers (AC). *First Author: Erika Belmont, University of Chicago Medical Center, Chicago, IL*

Background: AC frequently present with peritoneal metastases (PM) which are difficult to accurately measure with imaging techniques or serum tumor markers. ctDNA is a novel, promising biomarker to assess minimal residual disease (MRD) and therapy response. Its utility in AC with PM is poorly studied due to the rarity of this disease condition. This is a report on the role of ctDNA in AC management. **Methods:** Patients with AC managed at two high volume centers between 01/01/2019 to 12/15/2022 were included in this study. CtDNA measurements were prospectively collected using Signatera tumor informed ctDNA assay during clinical care and these data were abstracted retrospectively. Cox-proportional hazards were utilized for survival analysis. **Results:** 97 patients with AC were included with a median age of 57 (IQR 53-66) years, majority being non-Hispanic white (85%) and female (63%). 68 (70%) patients had ctDNA assay drawn at the time of confirmed clinical disease (radiographic or laparoscopic). The sensitivity of ctDNA was 56% (CI 44% - 67%) for all grades, and 66% (CI 49% - 80%) for grade 3 tumors. 65 (67%) patients underwent cytoreductive surgery (CRS), of which 16 (24.6%) had preoperative ctDNA assays. Sensitivity in this cohort of surgical patients was 25% and positive ctDNA showed poor correlation with PCI score at time of surgery ($n=4$, $r=0.38$, $p=0.14$). Any positive value for post-operative ctDNA was associated with lower disease free survival (DFS) (9 months (CI 5-13) in low grade AC and 10 months (CI 7-14) in high grade AC, compared to not reached for those persistently negative ($p<0.001$) over a median follow-up duration of 17 months. This difference persisted despite adjusting for adjuvant chemotherapy for high-grade disease (aHR = 11.2 (1.4-88.6), $p=0.023$). **Conclusions:** This is the largest study reported to date of tumor informed ctDNA testing in patients with AC. These data show that ctDNA has low sensitivity in both the metastatic unresectable and in pre-operative settings. However, ctDNA positivity after CRS in AC has prognostic value and could be used to guide systemic therapy decisions. Research Sponsor: None.

A phase 2 trial of chemotherapy, pembrolizumab, and propranolol in patients with advanced esophageal/gastroesophageal junction adenocarcinoma (EGAC). *First Author: Sarbajit Mukherjee, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Chronic stress suppresses the immune system and promotes cancer cell growth. In animal studies, we reported that this is mediated by the beta-adrenergic (BA) pathway. We further showed that concurrently blocking the BA pathway with β -blockers (BB) can improve immune checkpoint inhibitor (ICI) efficacy. Our retrospective data analysis revealed that esophageal cancer (EC) patients taking BB for other non-cancer reasons while receiving chemoradiation had significantly better survival and distant control than those not taking BB. We hypothesized that blocking the effects of adrenergic stress with a commonly used BB, propranolol, will improve response to therapies in EC patients. **Methods:** This is an open-label, non-randomized, phase 2 study of propranolol combined with pembrolizumab and standard chemotherapy in frontline unresectable/metastatic EGAC. Eligible patients must be treatment-naïve, have adequate organ function, have an ECOG performance status of 0–1, and be able to swallow and retain oral medication. Patients with Her-2 positive cancer, active autoimmune disease, active HIV, Hepatitis B or C, or a history of non-infectious pneumonitis/interstitial lung disease that requires treatment, are ineligible. Patients who are on BB for various indications are also ineligible. Eligible patients will receive mFOLFOX6 every two weeks in combination with pembrolizumab 400 mg intravenously every six weeks and propranolol 30 mg orally twice daily. The mFOLFOX6 dosing regimen will consist of *d*-LV 400 mg/m² and oxaliplatin 85 mg/m² followed by bolus 5-FU 400 mg/m² and a 48-hour infusion of 5-FU 2400 mg/m². The study will include an initial safety lead-in cohort of six patients. The primary endpoint is the overall response rate (ORR) determined by RECIST 1.1. Secondary endpoints include safety, progression-free survival (PFS), overall survival (OS), and ORR as determined by iRECIST. Correlative studies will assess baseline levels or changes in the levels of biomarkers, like, peripheral T-cell subsets/myeloid-derived suppressor cells (MDSC)/cytokines/ and perceived stress scale PSS/chronotropic effects of exercise with efficacy (ORR, PFS, OS). Assuming a historic ORR of 50% with standard treatment, 37 evaluable pts are needed to show a 20% increase in ORR with our proposed treatment with 80% power at a one-sided significance level of $\alpha = 0.1$. In stage 1, n1=23 evaluable pts will be enrolled. If there are 13 or more ORRs, an additional n2=14 pts will be enrolled in stage 2. If 24 or more ORRs are observed in the total n=37 evaluable pts, the proposed treatment regimen will be considered promising for further study. The study is currently open to enrollment. Clinical trial information: NCT05651594. Research Sponsor: Department of Defense CA210898P1; Roswell Park Comprehensive Cancer Center internal funding.

Phase 2 trial of zolbetuximab in combination with mFOLFOX6 and nivolumab in patients with advanced or metastatic claudin 18.2-positive, HER2-negative gastric or gastroesophageal junction adenocarcinomas. *First Author: Kohei Shitara, Department of gastroenterology and gastrointestinal oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Zolbetuximab, a chimeric immunoglobulin G1 monoclonal antibody, binds to claudin 18.2 (CLDN18.2) and mediates tumor cell death through antibody-dependent cellular cytotoxicity and complement-dependent cytotoxicity. In the pivotal phase 3 SPOTLIGHT study, zolbetuximab with modified FOLFOX6 (mFOLFOX6; leucovorin [folinic acid], fluorouracil [5-FU], and oxaliplatin) significantly prolonged progression-free survival (PFS) and overall survival (OS) in patients with CLDN18.2-positive, HER2-negative gastric and gastroesophageal junction (G/GJ) adenocarcinomas. The phase 2 ILUSTRO trial is investigating the efficacy and safety of zolbetuximab, alone and in multiple combinations, in patients with CLDN18.2-positive, HER2-negative advanced/metastatic G/GJ adenocarcinomas. **Methods:** The ILUSTRO trial is enrolling two new cohorts, 4A (safety cohort) and 4B, with approximately 12 and 50 patients planned, respectively, to assess safety and efficacy of the first-line combination of zolbetuximab, mFOLFOX6, and nivolumab in G/GJ adenocarcinomas. Both cohorts are enrolling patients whose tumors are HER2-negative with high or intermediate CLDN18.2 positivity (moderate to strong immunohistochemistry staining intensity in $\geq 75\%$ of tumor cells [high] or $\geq 50\%$ but $< 75\%$ of tumor cells [intermediate]). In Cohort 4A, patients will receive a loading dose of 800 mg/m² of zolbetuximab with 240 mg of nivolumab and mFOLFOX6 on cycle 1 day 1, followed by 400 mg/m² of zolbetuximab with 240 mg of nivolumab and mFOLFOX6 every 2 weeks (on days 15 and 29 of each 42-day cycle). Up to 12 mFOLFOX6 treatments (4 cycles) will be administered; patients may continue to receive folinic acid and 5-FU alongside zolbetuximab and nivolumab. Tolerability and safety of the combination of zolbetuximab, mFOLFOX6, and nivolumab will be evaluated during a 2-week dose-limiting toxicity assessment period. If the 800 mg/m² loading dose of zolbetuximab was assessed as not tolerable, patients were to be de-escalated to 600 mg/m² as their loading dose but received the same subsequent 400 mg/m² doses of zolbetuximab every 2 weeks. Cohort 4B will receive this combination at the dose level determined in Cohort 4A. Efficacy endpoints include objective response rate, disease control rate, duration of response, PFS, and OS. Safety and tolerability, pharmacokinetics, immunogenicity, and health-related quality of life will also be evaluated. Currently, 20+ sites are recruiting in 6 countries (France, Italy, Japan, Korea, Taiwan, United States); more US sites are planned. Clinical trial information: NCT03505320. Research Sponsor: Astellas Pharma, Inc.

Chemoradiotherapy with concurrent durvalumab for the palliative treatment of oligometastatic esophageal and gastroesophageal carcinoma with dysphagia: A single arm phase 2 clinical trial, PALEO. *First Author: Fiona Day, Department of Medical Oncology, Calvary Mater Newcastle, Waratah, Australia*

Background: Many patients diagnosed with esophageal cancer have dysphagia from their primary tumor and *de novo* metastatic disease. While multiple therapies are available, there is no accepted standard or sequence of therapies to both relieve dysphagia and control distant disease. Our preceding Phase I clinical trial showed that a 2 week hypofractionated chemoradiotherapy (CRT) protocol (30Gy/10# with concurrent weekly carboplatin and paclitaxel) is well tolerated and provides rapid dysphagia relief. Immune checkpoint inhibition has activity in esophageal and gastroesophageal (GEJ) cancer and concurrent radiotherapy may improve T cell priming through tumor antigen release. In PALEO, patients begin durvalumab concurrent with primary tumor CRT, and receive stereotactic body radiotherapy (SBRT) (24Gy/3#) to a single metastasis to maximize the breadth of tumor antigen exposure. Tissue and blood-based studies are planned to identify biomarkers for response, including immunosequencing to test for post-radiotherapy expansion in T cell receptor diversity. **Methods:** Eligible patients have biopsy-proven esophageal or GEJ cancer, either squamous cell or adenocarcinoma histology, with oligometastatic (1-5 metastases on FDG-PET scan outside the primary tumor radiotherapy field) or locoregionally advanced disease unsuitable for surgery, dysphagia (Mellow score > 0), and ECOG PS 0-2. Key exclusion criteria are prior treatment, tumor HER2 positivity, prior thoracic radiotherapy, tracheo-esophageal fistula, esophageal stent in situ and contraindications to immunotherapy. Patients begin durvalumab 1500mg q4w with CRT to the primary tumour (30Gy/10# with weekly carboplatin AUC2 and paclitaxel 50mg/m²), and continuing to disease progression, unacceptable toxicity or 2 years. SBRT to one metastasis (24Gy/3#) is delivered in week 7. Trial primary endpoint is progression free survival rate at 6 months (PFS6) with the aim to rule out a PFS6 rate of 50% in favor of 67.5%, with 80% power and a one-sided 0.05 significance level. Secondary endpoints include dysphagia relief, nutritional status change (patient weight, removal of enteral feeding tubes, PG-SGA score), quality of life, response rate, toxicity, overall survival and exploratory translational endpoints. PALEO is sponsored by the Australasian Gastro-Intestinal Trials Group (AGITG) for conduct at 8 sites in Australia and New Zealand. 6 of planned 54 patients have been enrolled. Clinical trial information: ACTRN12619001371189. Research Sponsor: Australasian Gastro-Intestinal Trials Group (AGITG) Philanthropic Major Donor funding; Hunter Medical Research Institute; This research was conducted with Study Drug support from AstraZeneca PtyLtd; Varian Medical Systems.

A phase 2 basket trial of ulixertinib (BVD-523) in combination with hydroxychloroquine in patients with advanced gastrointestinal malignancies harboring MAPK pathway mutations (BVD-523-HCQ). *First Author: Andrew H. Ko, University of California San Francisco, San Francisco, CA*

Background: RAS-induced signaling through the mitogen-activated protein kinase/extracellular signal-regulated kinase (MAPK/ERK) pathway plays an important role in the pathogenesis of many solid tumors. Ulixertinib (BVD-523) is a first-in-class and best-in-class small molecule inhibitor of ERK 1/2 that is currently being investigated in multiple cancer clinical trials, both as a single agent and as part of combination therapy. Preclinical studies have demonstrated that inhibition of the RAS/MAPK/ERK signaling cascade leads to upregulation of autophagy, a catabolic pathway that includes the lysosomal degradation of proteins to support cellular metabolism during times of cellular stress. Given cancer cells' increased reliance on autophagy to enhance their survival in this context, this study seeks to evaluate the combination of ulixertinib with hydroxychloroquine, an antimalarial drug known to suppress autophagy, in patients with advanced gastrointestinal malignancies harboring mutations in genes involved in MAPK signaling. **Methods:** This is an open-label, multicenter, phase II basket study of ulixertinib in combination with hydroxychloroquine in patients with advanced GI malignancies harboring mutations in one of the following MAPK signaling-associated genes: KRAS, NRAS, HRAS, BRAF (non-V600), MEK1/2, or ERK1/2. The completed Phase 1 dose-escalation trial (NCT04145297) established the recommended Phase 2 dose which will be the doses used in this study; ulixertinib 450mg PO BID combined with hydroxychloroquine 600mg PO BID, both drugs administered daily in 28-day cycles, with tumor assessments after every 2 cycles. The trial has five baskets based on primary disease: cholangiocarcinoma, pancreatic adenocarcinoma, colorectal adenocarcinoma, esophageal adenocarcinoma, and gastric adenocarcinoma. A Simon two-stage design will be employed within each of the 5 disease-specific baskets noted above, with the first stage of enrollment consisting of n=13 patients/ basket. To be considered evaluable, a patient must complete at least one cycle of therapy and receive at least 75% of the prescribed dose during that first cycle. If ≥ 4 patients in a specific basket achieve a response (complete or partial), that basket will then open to Stage 2 with enrollment of an additional 30 patients. Primary study endpoints will include safety/toxicity as well as ORR by RECIST 1.1. The secondary endpoint for efficacy is progression-free survival. Exploratory endpoints include pharmacokinetics of both ulixertinib and hydroxychloroquine, as well as predictive biomarkers from blood and tumor tissue-based samples. At the time of abstract submission, 26 of the planned 65 patients in Stage 1 had been enrolled. Clinical trial information: NCT05221320. Research Sponsor: BioMed Valley Discoveries, Inc.

Alliance A022102: Randomized phase III trial of mFOLFIRINOX +/- nivolumab vs. FOLFOX +/- nivolumab for first-line treatment of metastatic HER2-negative gastroesophageal adenocarcinoma (GEA). *First Author: Haeseong Park, Dana-Farber Cancer Institute, Boston, MA*

Background: Platinum/fluoropyrimidine (FP) with PD-1 inhibitor is now established as the standard first-line therapy for most patients with advanced HER2 negative gastric, esophageal, and gastroesophageal junction (GEJ) adenocarcinoma. The FP doublet chemotherapy backbone, most commonly FOLFOX, is recommended based on marginal survival benefits of taxane-containing triplet therapy at the cost of increased toxicity. Although several agents are approved as standard treatment options in later lines, only about 10% of patients in the US receive a third line of therapy, and very few have the opportunity to benefit from all approved agents in this disease. This challenge will only increase as more agents and targeted therapies are approved. FOLFIRINOX is a triplet regimen commonly used in gastrointestinal malignancies with established safety and often with superior efficacy. Two single arm phase II trials of FOLFIRINOX have reported promising activity in GEA with manageable toxicities. Reported median overall survival (OS) from these trials is around 15 months, which is superior to what is expected from FP doublet first-line chemotherapy (about 11 months). We hypothesize that using upfront triplet therapy with a more effective and less toxic triplet combination will result in improved patient outcomes by optimization of available therapies in GEA. **Methods:** This study is a randomized phase III, open-label, multicenter clinical trial with the primary objective to determine whether modified FOLFIRINOX (FU 2400 mg/m², leucovorin 400 mg/m², oxaliplatin 85 mg/m², irinotecan 150 mg/m² every 2 weeks) as first-line treatment improves OS compared to mFOLFOX in patients with advanced HER2 negative GEA. Eligible patients will have unresectable or metastatic adenocarcinoma of esophagus, GEJ, or stomach with no prior systemic treatment. Patients must have adequate organ function, and measurable or evaluable disease as defined by RECIST 1.1. Prior neoadjuvant or adjuvant therapy is allowed if completed at least 1 year prior to registration. Patients who will receive nivolumab (mandatory for PD-L1 combined positive score > 5) in addition to chemotherapy must not have any contraindications to immune checkpoint inhibitors. Patients with treated, asymptomatic and stable brain metastases are eligible. The total sample size is 382 evaluable patients for this study (191 patients per arm). The study accrual began January 2023. Clinical trial information: NCT05677490. Research Sponsor: U.S. National Institutes of Health.

A randomized, open-label, phase II/III efficacy and safety study of atezolizumab in combination with FLOT versus FLOT alone in patients with gastric cancer and adenocarcinoma of the oesophagogastric junction and high immune responsiveness: The IKF-S633/DANTE trial, a trial of AIO in collaboration with SAKK. *First Author: Salah-Eddin Al-Batran, Institut für Klinische Krebsforschung IKF am Krankenhaus Nordwest, and Krankenhaus Nordwest, University Cancer Center Frankfurt, Frankfurt, Germany*

Background: Perioperative FLOT chemotherapy has become a standard of care for locally advanced, resectable esophagogastric adenocarcinoma (EGA). However, patient outcomes are still unsatisfactory. Immune checkpoint inhibitors combined with chemotherapy have proven activity in advanced Her2 negative EGA with PD-L1 expression (KEYNOTE-590, Checkmate-649). Atezolizumab is a PD-L1 inhibitor with established efficacy and tolerability profiles and will be evaluated in this study in the perioperative treatment of potentially resectable EGA in combination with FLOT. As shown at ASCO 2022 for the phase II part of DANTE, adding atezolizumab to FLOT led to improved tumor downsizing and pCR (24% vs 15%). Of note, regression rates further improved with higher PD-L1 expression (33% vs 12% in tumors with CPS ≥ 10) or in MSI-high tumors (63% vs 27%). Prompted by these results, we decided to transition this trial from the initial phase II to a phase III design. **Methods:** This is a multinational, prospective, randomized, investigator-initiated, open label phase II/III trial. Patients (pts) with locally advanced, potentially resectable EGA (≥ cT2 and/or N-positive) without distant metastases are enrolled. Based on the subgroup analyses of the phase II trial, we decided to limit the future enrollment to pts with high immune responsiveness, i.e. either of the following: MSI-high, PD-L1 CPS ≥ 1, TMB ≥ 10/MB or EBV+. Eligibility status is centrally evaluated. Pts are randomized 1:1 to 4 pre-operative 2-week cycles (8 weeks) of FLOT (Docetaxel 50 mg/m²; Oxaliplatin 85 mg/m²; Leucovorin 200 mg/m²; 5-FU 2600 mg/m²) plus 840 mg atezolizumab q2w followed by surgery and 4 additional cycles of FLOT/atezolizumab, followed by a total of 8 additional cycles of atezolizumab at 1200 mg every 3 weeks as monotherapy (arm A) or FLOT alone (arm B). Primary endpoint is event-free survival (EFS) as assessed by the Kaplan-Meier-Method. An estimated HR of 0.72 would correspond to a median EFS of 41.67 months for the experimental Arm A. This difference is considered clinically relevant. A total of 556 pts (318 events) will be randomized. As 177/295 pts with PD-L1 positive or MSI status were already enrolled into the phase II portion, additional 379 pts will be enrolled into phase III. Main secondary endpoints are rates of locally assessed pathological regression (complete and nearly complete pathological regression), OS, OS and EFS in the subgroup of pts with PD-L1 CPS ≥ 5 and ≥ 10 and pts with MSI, R0 resection, and safety. In addition, a prospective biomarker study including serial circulating tumor DNA analysis before and during treatment will be performed. Recruitment started 2018 and continues for phase III in 2023. Clinical trial information: NCT03421288. Research Sponsor: Roche; Hector Stiftung.

Poster Session

A multi-cohort phase I/IIa clinical trial to evaluate the safety, tolerability, and pharmacokinetics of TST001 administered as a monotherapy, with nivolumab or standard of care in patients with locally advanced or metastatic solid tumors: TransStar101. *First Author: Yelena Y. Janjigian, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Gastric cancer (GC) remains the 4th leading cause of cancer death worldwide, accounting for about 7.7% of all cancer related mortality. Despite recent approval of nivolumab in combination with chemotherapy, the median survival of treatment naïve Gastric Cancer/gastroesophageal junction cancer (G/GEJ) cancer is only approximately 14 months, even in patients with high CPS PD-L1. Targeting claudin 18.2 (CLDN18.2) in combination with chemotherapy is a clinically validated approach for patients with CLDN18.2 expressing advanced G/GEJ cancer. TST001 is a humanized monoclonal antibody with improved affinity to human CLDN18.2 and enhanced antibody-dependent cellular cytotoxicity (ADCC). In pre-clinical studies, TST001 treatment upregulates PD-L1 expression on CLDN18.2-positive tumor cells. The in vivo analysis showed anti-tumor efficacy of TST001 combined with anti-PD-1 antibody and chemotherapy was superior to combination of anti-PD-1 antibody with chemotherapy or combination of TST001 with chemotherapy. Promising anti-tumor activities have been observed in patients with advanced G/GEJ cancer who have been treated with TST001 alone or in combination with chemotherapy, making the combination of TST001, nivolumab and chemotherapy attractive. **Methods:** This is a multi-cohort, open-label, multi-center phase I/II first in human (FIH) study of TST001 administered as single agent, in combination with nivolumab or standard of care in the treatment of patients with locally advanced or metastatic solid tumors. Primary endpoints include characterization of TST001 safety profile and the maximum tolerated dose / recommended phase 2 dose. Secondary endpoints include pharmacokinetics, immunogenicity, pharmacodynamics, and efficacy. The study includes two parts. Part A (completed) is a dose escalation of TST001 as a monotherapy. Part B (ongoing) consists of three independent cohorts: cohort A includes combination TST001 + nivolumab+ leucovorin calcium (folinic acid), fluorouracil, and oxaliplatin (mFOLFOX6) as 1st line treatment for G/GEJ cancer; cohort B includes TST001 in combination with nivolumab in advanced pre-treated G/GEJ cancer; cohort C includes combination therapy of TST001, gemcitabine, and nanoparticle albumin-bound paclitaxel as 1st line treatment for advanced/metastatic pancreatic cancer. Multiple doses and schedules will be assessed during Part B. **Conclusions:** Combination of TST001 with nivolumab and chemotherapy has the potential to improve the outcomes of patients with advanced or metastatic CLDN18.2 expressing G/GEJ cancer. Data from this trial will support the selection of the optimal dose and dose regimen of TST001 in these combinations. Enrollment in the trial is ongoing. Clinical trial information: NCT04396821. Research Sponsor: Transcenta Therapeutics Inc.

Poster Session

An open-label, multicenter study investigating RP3 oncolytic immunotherapy in combination with first- or second-line systemic atezolizumab and bevacizumab therapy in patients with locally advanced unresectable or metastatic hepatocellular carcinoma. *First Author: Tanios S. Bekaii-Saab, Mayo Clinic, Scottsdale, AZ*

Background: Despite advances in treatment for unresectable hepatocellular carcinoma (HCC), long-term survival rates remain poor. The combination of bevacizumab (Bev) and atezolizumab (Atezo) is the preferred frontline therapy for advanced HCC, but a minority of patients (pts) respond, and secondary resistance usually occurs within months. HCC has an immune-suppressed tumor microenvironment, mediated by activated immune checkpoint signaling and angiogenesis pathways, which may contribute to therapeutic resistance. RP3 is a genetically modified herpes simplex virus type 1 (HSV-1) that expresses the fusogenic gibbon ape leukemia virus glycoprotein with the R sequence deleted (GALV-GP-R-), an anti-CTLA-4 antibody-like molecule, CD40 ligand, and 4-1BB ligand. The direct oncolytic effect coupled with immune stimulation by RP3 in the tumor microenvironment is intended to provide systemic antitumor activity and enhance therapeutic response to anti-PD-1/PD-L1 agents, such as Atezo. Preclinical data have demonstrated improved distribution of oncolytic HSV within tumors in combination with Bev, supporting the clinical combination of RP3 with Bev. This study will evaluate the safety and efficacy of RP3 combined with Atezo and Bev as first- (1L) and second-line (2L) systemic therapies for unresectable and advanced HCC. **Methods:** The 1L and 2L cohorts will each enroll up to 30 pts. Pts in the 1L cohort may not have received prior systemic treatment; pts in the 2L cohort must have progressed on or following one prior line of systemic therapy, which must have included a PD-1/PD-L1-directed agent. Key inclusion criteria include advanced, unresectable HCC with ≥ 1 measurable tumor of ≥ 1 cm in longest diameter, Child-Pugh Class A, and Eastern Cooperative Oncology Group performance status of 0–1. Key exclusion criteria include untreated esophageal and/or gastric varices with bleeding or at high risk for bleeding and macroscopic invasion of tumor into any major blood vessel(s) and/or main bile ducts. Pts with a history of medically refractory hepatic encephalopathy and/or hepato-renal syndrome are also excluded. Pts in the 1L cohort will receive 1200 mg Atezo and 15 mg/kg Bev every 3 weeks (Q3W) together with RP3 intratumorally Q3W for a total of up to 8 doses. Pts in the 2L cohort will receive RP3 every 2 weeks for 4 doses with Bev Q3W starting on cycle (C) 1 day (D) 1, then RP3 and Bev Q3W for up to 4 more doses with Atezo Q3W being added on C4D1. The primary endpoint is overall response rate (ORR) by Response Evaluation Criteria in Solid Tumors (RECIST) v1.1. Secondary endpoints are safety, ORR using HCC modified RECIST, duration of response, complete response rate, and progression-free survival. Clinical trial information: NCT05733598. Research Sponsor: Replimune Inc.

Poster Session

A phase IIa/IIb, open-label trial of BI 907828, an MDM2–p53 antagonist, in patients with locally advanced/metastatic biliary tract carcinoma or pancreatic ductal adenocarcinoma: Brightline-2. *First Author: Lipika Goyal, Department of Medicine, Stanford Cancer Center, Palo Alto, CA*

Background: Biliary tract cancer (BTC) and pancreatic ductal adenocarcinoma (PDAC) carry a median survival of one year in the advanced stages, and effective therapies are urgently needed. Mouse double minute 2 (MDM2) is amplified in ~5–6% of cases of BTC and ~1% of PDAC. MDM2, an E3 ubiquitin ligase, is an endogenous negative regulator of p53. Aberrations affecting MDM2 may drive oncogenesis, and indeed, preclinical as well as emerging clinical data suggest blocking MDM2 in *TP53* wild-type tumors may be a potential therapeutic strategy. BI 907828 is an MDM2–p53 antagonist that binds to MDM2 and blocks its interaction with p53, thereby restoring p53 function, leading to cell-cycle arrest and apoptosis in *TP53* wild-type tumor cells. In ongoing Phase I studies, BI 907828 has demonstrated initial signs of activity in selected advanced/metastatic solid tumors, including BTC and PDAC. **Methods:** Brightline-2 is a Phase IIa/IIb, open-label, single-arm, multicenter study (~60 sites) that aims to assess the efficacy, safety, and tolerability of BI 907828 monotherapy in patients with locally advanced, unresectable, or metastatic *MDM2*-amplified, *TP53* wild-type BTC (adenocarcinoma histology; Cohort 1; n=90) or PDAC (Cohort 2; n=10) [NCT05512377]. Cohorts for other solid tumors may be added via protocol amendment. All patients will receive BI 907828 45mg orally once every 3 weeks. Key inclusion criteria include: ≥18 years of age; locally advanced/metastatic, histologically confirmed unresectable BTC/PDAC; progression or intolerance to standard therapies; local test indicating *MDM2* amplification or *MDM2* copy number ≥8 and *TP53* wild-type (liquid biopsy not permitted); ≥1 measurable target lesion (RECIST v1.1); and ECOG PS 0/1. A key exclusion criterion is prior treatment with an MDM2–p53 antagonist. Treatment will continue until disease progression, unacceptable toxicity, or withdrawal of consent. The primary endpoint is objective response rate (ORR; based on blinded central independent review). Secondary endpoints are duration of response, progression-free survival, overall survival, disease control, occurrence of adverse events, and patient-reported health-related quality of life. In Phase IIa, an interim futility analysis will be performed after the initial 30 patients in Cohort 1 have either been followed for ≥12 weeks or have discontinued. If the cohort passes the non-binding interim futility boundary (ORR = 20%), the study will enter Phase IIb, and 60 additional patients will be enrolled onto Cohort 1, totaling 100 patients planned across Cohorts 1 and 2. The final primary analysis will be performed after all treated patients have been followed for ≥12 weeks or until study discontinuation. As of 13 December 2022, 1 patient has been enrolled. Clinical trial information: NCT05512377. Research Sponsor: Boehringer Ingelheim.

Autologous cytotoxic T-cell receptor T cell therapy (SCG101) against hepatitis B surface antigen phase I/II trial for patients with advanced hepatitis B-related hepatocellular carcinoma. *First Author: Ghassan K. Abou-Alfa, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, Cornell University, New York, NY*

Background: The overall prognosis of patients with advanced Hepatitis B-related hepatocellular carcinoma (HCC) remains poor, and treatment options are limited. In an IIT study conducted in China (NCT05339321), SCG101 following lymphodepletion (cy-flu) as second-line setting or beyond in patients with Hep B-related HCC has shown acceptable safety profile, reduction in HBsAg levels (>1 log) and tumor control. A phase I/II trial has been initiated to evaluate safety and RP2D of autologous SCG101 T cell therapy in Hepatitis B virus-related HCC (NCT05417932). **Methods:** This multicenter, open-label, 3+3 dose-escalation phase I trial is ongoing across 7 sites in the United States, Singapore and Hong Kong SAR, and a parallel study is done in mainland China across 8 sites. Eligible patients have a histologically confirmed HCC, not amenable to curative intent (surgery or locoregional therapy) and failed ≥2 standard line of therapies, match any of HLA-A*02:01, *02:02, *02:03, *02:04, *02:07, *02:09, *02:16, have positive serum (or tumor) HBsAg, HBV-DNA <2000 IU/ml, BCLC B or C, CP≤7, with measurable disease at screening (mRECIST and RECIST v1.1), ECOG PS<1. Patients with CNS metastasis, prior liver transplant, autoimmune disease or prior cell therapy are excluded. SCG101 T cells are manufactured in Singapore under cGMP and ship to all study sites across the U.S., Singapore and Hong Kong SAR, while SCG101 T cells for the China sites are manufactured in SCG Cell Therapy's China facility. Patients will receive a single dose of SCG101 T cell therapy following lymphodepletion (cy-flu). Endpoints include safety, MTD and RP2D. Secondary endpoints include ORR, DOR, PFS, OS, changes in serum HBsAg. Safety is monitored together with Data Review Committee. The study is actively enrolling, and the phase II portion of the trial is expected to be initiated by H2 2023. Autologous SCG101 T cell therapy may provide a new treatment option for patients with advanced Hepatitis B virus-related HCC. Clinical trial information: NCT05417932. Research Sponsor: SCG Cell Therapy Pte Ltd.

Randomized phase 2 study of maintenance olaparib vs olaparib plus durvalumab for DNA damage repair (DDR) gene mutated unresectable or metastatic biliary tract cancer (BTC) with durable response to first-line platinum-based chemotherapy: OPTIMUM trial. *First Author: YunJung Kim, Clinical Trial Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: BTC is rare and aggressive disease with heterogeneous genetic profiles. Gemcitabine plus cisplatin (GemCis) with or without durvalumab is the standard first-line therapy but further improvement in survival outcomes is needed. In a prior study (Chae HJ et al, Eur J Cancer 2019), germline or somatic mutations in DDR genes including BRCA are detected more than half of BTC patients and associated with better survival outcomes with platinum-based chemotherapy. As the potential efficacy of Olaparib in DDR-mutated cancers and synergism between PARP inhibitors and immune checkpoint inhibitors, we designed randomized phase 2 trial investigating the efficacy and safety of olaparib monotherapy vs olaparib plus durvalumab in BTC patients as maintenance therapy for BTC patients who showed durable response to first-line platinum-based chemotherapy. **Methods:** This is a randomized, open-label phase 2 study conducted in a single center (Asan Medical Center, Seoul, Korea). Key eligibility criteria include histologically documented locally advanced unresectable or metastatic BTC, no progression at least 16 weeks with first-line platinum-based chemotherapy, DDR mutations on targeted sequencing of tumor tissues and ctDNA, ECOG performance status 0–1, and adequate organ function. Eligible patients will be randomized 1:1 into olaparib monotherapy arm (300 mg twice daily, every 4 weeks) or olaparib plus durvalumab (1,500 mg intravenous, every 4 weeks) arm. Study treatment is continued until disease progression, unacceptable toxicity, withdrawal of consent, or death. Response evaluation is performed every 8 weeks (fixed). Stratification factors are tumor location (intrahepatic vs extrahepatic/gallbladder) and best response to platinum-based chemotherapy (CR/PR vs SD). The six-month progression-free survival rates are the primary endpoint and overall survival, progression-free survival, response rates, and safety profiles are secondary endpoints. A total of 62 patients (31 for each arm) are planned, and 23 (37%) patients (ATM [n=6], BRCA2 [n=7], CHEK2 [n=2], BRCA1 [n=1], RAD51C [n=1], and PBRM1 [n=1]) are enrolled as of Jan 2023. Clinical trial information: NCT05222971. Research Sponsor: AstraZeneca Korea Ltd.

ABC-12: Exploring the microbiome in patients (pts) with advanced biliary tract cancer (BTC) in a first-line study of durvalumab in combination with cisplatin/gemcitabine (cis/gem). *First Author: Mairead Geraldine McNamara, University of Manchester/The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: Durvalumab/cis/gem improved overall survival (OS) in pts with advanced BTC versus placebo/cis/gem (Oh et al. NEJM Evid 2022). Disruption of the microbiota may impair tumour response to immunotherapy and chemotherapy and a better understanding of its role in the efficacy of these therapeutics in advanced BTC is required. **Methods:** This is a multi-centre, single arm trial exploring the microbiome in pts receiving durvalumab 1500 mg intravenously (IV) Q3w, in combination with cis 25 mg/m², gem 1000 mg/m² (Days 1 and 8, Q3w) up to 8 cycles, followed by durvalumab 1500 mg as monotherapy Q4w, until progression or intolerable toxicity. Pts with an ECOG performance status of ≤1 and histologically-proven BTC, including cholangiocarcinoma and gallbladder carcinoma, who have had no prior systemic chemotherapy for locally advanced or metastatic disease are eligible. Pts must provide a saliva and stool sample prior to commencement of durvalumab/cis/gem and at 18 weeks, or at progression (if earlier than 18 weeks). Taxonomic profiling via 16S Ribosomal ribonucleic acid gene sequencing will examine the differences in the diversity and composition of the pt gut microbiome. Pts must also have availability of a tumour biopsy. This study plans to recruit 70 pts from 10 UK centres (over 12 months). The primary objective is to determine the difference in baseline alpha diversity between “responders” (partial or complete response) and “non-responders” at 18 weeks (RECIST 1.1) in patients treated with durvalumab/cis/gem. Secondary objectives include investigation of the association between microbiome parameters and objective response rate, tumour control (partial + complete response + stable disease), progression-free and OS, and to investigate the interaction between treatment effect and microbiome parameters on clinical outcomes. The tumour biopsy will be used for research into the tumour microbiome and/or factors that may influence response to chemotherapy/immunotherapy, including, but not limited to tumour mutation burden, programmed cell death 1/programmed death-ligand 1 status, and microsatellite instability status. Clinical trial information: ISRCTN11210442. Research Sponsor: Astra Zeneca.

Phase II trial of XmAb20717 (vudalimab) in patients with advanced biliary tract cancers. *First Author: William Joseph Chapin, Abramson Cancer Center at the University of Pennsylvania, Philadelphia, PA*

Background: For patients with advanced biliary tract cancers (BTCs), gemcitabine and cisplatin has been the standard-of-care first-line therapy, with a median overall survival (OS) of 11.7 months. More recently, TOPAZ-1 demonstrated a modest, but significant overall survival benefit (HR 0.80; 95% CI 0.66 – 0.97) to the addition of durvalumab to gemcitabine and cisplatin with a median OS of 12.8 months. However, for patients without targetable molecular variants, second-line and beyond options are limited, with FOLFOX demonstrating an overall response rate (ORR) of 5% and increase in median overall survival by 0.9 months compared to active symptom control. In patients with advanced BTCs, combination immunotherapy approaches with PD-1 or PD-L1 plus CTLA-4 inhibitors have been associated with improved ORRs of 10.8% - 23% compared to ORRs of 3 – 7% observed with single agent PD-1 or PD-L1 inhibitors. XmAb20717 (vudalimab) is a novel, bispecific antibody targeting PD-1 and CTLA-4 which demonstrated an ORR of 14.1% in a phase I dose expansion cohort of patients with advanced malignancies, including patients that had experienced disease progression on prior immune checkpoint inhibitors. **Methods:** We initiated a single-arm, phase II clinical trial with a Simon two-stage mini-max design to evaluate the efficacy of XmAb20717, in terms of ORR, in patients with advanced biliary tract cancers previously treated with gemcitabine-based chemotherapy. In the first stage, 13 patients evaluable for efficacy will be accrued. If no responses are observed in these 13 patients, the study will be stopped for futility. Otherwise, 14 additional patients evaluable for efficacy will be accrued to total 27 evaluable patients. If 4 or more responses are observed in these 27 patients, then the null hypothesis will be rejected. XmAb20717 (10 mg/kg) is administered intravenously on days 1 and 15 of a 28-day cycle. Important inclusion criteria include that patients with FGFR2 fusions, NTRK fusions, or IDH1 mutations must have received molecularly targeted therapy unless contraindicated or refused. Patients are not eligible if they have received prior immune checkpoint inhibitor therapy. Correlative studies will include longitudinal peripheral blood collection for circulating immune cell profiling. As of January, 2023, 8 patients have been enrolled with enrollment ongoing. Clinical trial information: NCT05297903. Research Sponsor: Xencor.

NeoTACE: A multicenter, randomized study evaluating the efficacy and safety of neoadjuvant HAIC for TACE plus donafenib in BCLC B stage hepatocellular carcinoma outside of up-to-seven. *First Author: Xiaodong Wang, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Interventional Therapy, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Transarterial chemoembolization (TACE) is standard treatment for hepatocellular carcinoma (HCC) patients in BCLC B stage, while a number of studies demonstrated compromised effect of TACE for patients with large HCC or tumor burden outside of up-to-7. Recently, two phase 3 studies showed the survival benefit of Hepatic arterial infusion chemotherapy (HAIC) for large HCC and as neoadjuvant treatment for HCC outside of Milan criteria. A Phase 3 study also showed the survival benefit of donafenib for unresectable HCC compared with sorafenib. Here, we propose a prospective randomized study to investigate the benefit of HAIC as a neoadjuvant therapy for TACE plus donafenib in unresectable BCLC B stage HCC outside of up-to-seven. **Methods:** This is a multicenter, open-label, randomized study designed to evaluate the efficacy and safety of neoadjuvant HAIC for TACE plus donafenib compared with TACE plus donafenib in BCLC B stage unresectable HCC outside of up-to-seven. Participants are randomized in 1:1 ratio to either Arm A, receiving 2-4 cycles neoadjuvant HAIC treatment plus donafenib initially, then TACE plus donafenib sequentially, or Arm B, just receiving TACE treatment plus donafenib. HAIC consisted of infusions of oxaliplatin (35 mg/m² for 2 hours), followed by 5-fluorouracil (600 mg/m² for 22 hours) on day1-3 every 4 weeks. The primary endpoint is PFS, and the secondary endpoints are OS, ORR, DCR, and adverse events. We hypothesize that neoadjuvant HAIC for TACE plus donafenib will improve PFS from 6 months to 11 months, with the hazard ratio of 0.55. With one-sided significance level of 0.05 and power of 0.8, the sample size for randomization will be 156. The study, registered with clinical trial ID of NCT05171166, started enrolment in Feb 2022. As of Oct 2022, 65 patients have been enrolled and 11 patients have been randomized. Clinical trial information: NCT05171166. Research Sponsor: Beijing Hospitals Authority Clinical Medicine Development of Special Funding Support (No. ZYLX202117).

Phase II study on safety and efficacy of NMS-01940153E, an MPS1 inhibitor with first-in-class potential, in adult patients with unresectable hepatocellular carcinoma (HCC) previously treated with systemic therapy. *First Author: Lorenza Rimassa, Humanitas University, Department of Biomedical Sciences; IRCCS Humanitas Research Hospital, Medical Oncology and Hematology Unit, Rozzano, Italy*

Background: Monopolar Spindle 1 (MPS1) kinase regulates the spindle assembly checkpoint (SAC) which ensures proper division of chromosomes during mitosis. MPS1 is overexpressed in several tumors, including hepatocellular carcinoma (HCC), where it correlates with tumor features and poor overall and disease-free survival. NMS-01940153E is a novel, highly potent and selective small molecule inhibitor of MPS1 kinase with long residence time and strong preclinical anti-tumor activity in different tumor types. In HCC lines, specifically, NMS-01940153E showed ~2-Log higher anti-proliferative activity compared to sorafenib, lenvatinib, and regorafenib. In a previous open-label first-in-human (FIH) study, CL1-81694-001 (EudraCT 2014-002023-10), signs of activity in HCC were detected. Recently, the treatment paradigm for advanced HCC has changed, with immunotherapy combinations in first line and TKIs shifted in later lines. However, the overall prognosis of patients with advanced HCC remains poor, and there is a strong need of new drugs in this setting. NMS-01940153E novel mechanism of action, inhibiting the SAC and interfering with genomic stability in HCC, may offer a new therapeutic option in HCC. Based on the promising FIH results, a Phase I/II study, MPSA-153-001 (EudraCT 2020-001002-26), was initiated in patients with HCC previously treated with more than one systemic therapy. **Methods:** The Phase II part of the MPSA-293-001 trial is designed as a two-stage study with an interim analysis for futility and safety rules for unacceptable toxicity. The primary objective is to assess the antitumor activity of NMS-01940153E in adult patients with unresectable HCC previously treated with systemic therapy measured as objective response rate (ORR) by investigator-assessed RECIST 1.1. Secondary endpoints are safety, PK, ORR as measured by investigator-assessed mRECIST, DoR, PFS and OS. Exploratory endpoints include biomarkers. NMS-01940153E is administered IV, on days 1, 8 and 15 every 4 weeks at the RP2D of 100 mg/m²/wk, which showed PK in a predicted active range. Key eligibility criteria are 1) diagnosis of HCC; 2) disease progression on standard-of-care treatment including an immune checkpoint inhibitor as first line and at least one TKI; 3) no more than 3 prior systemic treatment lines. Interim evaluation for futility will be undertaken as soon as the first 10 evaluable patients will be enrolled. If at least 1 responder is observed with no safety issues, enrollment will proceed up to 38 evaluable patients. Otherwise, the study will be terminated for futility. An independent DSMB will review the interim results and provide recommendation on the study progress. Recruitment is currently ongoing in Italy and Spain and an FDA "Study May Proceed Notification" was received in January 2023. Clinical trial information: NCT05630937. Research Sponsor: Nerviano Medical Sciences S.r.l.

ADJUBIL: A phase II study of immunotherapy with durvalumab and tremelimumab in combination with capecitabine or without capecitabine in adjuvant situation for biliary tract cancer. *First Author: Thorsten Oliver Goetze, Krankenhaus Nordwest, University Cancer Center Frankfurt, Frankfurt am Main, Germany*

Background: Despite improvements in multidisciplinary management, patients with biliary tract cancer (BTC) have a poor outcome. Only 20% of patients are eligible for surgical resection with curative intent, with 5-year overall survival of less than 10% for all patients. Data regarding pure adjuvant chemotherapy in BTC's are conflicting and the SOC of the western world is currently capecitabine according to the British BILCAP- trial, even though BILCAP was formally negative. Based on the positive data for durvalumab in the TOPAZ- 1 – trial in BTC and for STRIDE- regimen in HCC according to the Himalaya- data, evaluation of IO-combination in the adjuvant setting seems to be promising. Preclinical studies indicate that the antibody combination results in stronger and more durable anti-tumor effects than single therapies by synergistically modulating the immunosuppressive tumor microenvironment which is particularly rich in cholangiocarcinoma. The aim of this study is the assessment of the clinical activity of the anti-PD-L1 (programmed- death 1-ligand) antibody durvalumab and the anti-CTLA-4 (cytotoxic T- lymphocyte-associated antigen 4) antibody tremelimumab in combination with or without capecitabine in patients with resectable BTC in the adjuvant situation. This is a randomized phase II study as a proof-of-concept for a potentially larger research program. **Methods:** The ADJUBIL trial is an open-label, multicenter phase II study, including patients with BTC after curative surgery with no previous systemic treatment. Patients are randomly assigned to receive tremelimumab (300mg, one dose) plus durvalumab (1500mg every 4 weeks; STRIDE, for a maximum of 12 months), with or without capecitabine (for 8 cycles). Forty evaluable patients will be enrolled in the study (1:1) to receive anticancer treatment until disease recurrence or intolerable toxicities. Primary objective is to assess the anti-tumor activity of the treatment in both arms by the recurrence-free survival rate after 12 months (RFS@12). Secondary endpoints are recurrence-free survival, overall survival, toxicity, and quality of life. Exploratory endpoints: Explore predictive biomarkers for recurrence-free survival and overall survival. Study start of the ADJUBIL trial was in June 2021. By January 2023, 12 centers across Germany have been initiated and a total of 8 out of 40 planned patients (1:1) have been enrolled. The study is currently ongoing. Clinical trial information: EUCTR2021-002389-41. Research Sponsor: AstraZeneca.

Durvalumab and tremelimumab for hepatocellular carcinoma in patients listed for a liver transplant. *First Author: Davendra Sohal, University of Cincinnati, Cincinnati, OH*

Background: Hepatocellular carcinoma (HCC) is an aggressive malignancy, developing most often in the setting of liver cirrhosis (Sohal et al Current Oncol Rep 2011; Gordan et al JCO 2020). For advanced disease, immunotherapy has now become standard of care – a combination of atezolizumab and bevacizumab has shown the best overall survival outcome so far (Finn et al NEJM 2020). For earlier stage disease, however, there is no systemic therapy standard. The best treatment for HCC in the setting of cirrhosis is a liver transplant allowing potential cure for both the cancer and cirrhosis. Nonetheless, 25-35% of patients fail to reach liver transplant because of disease progression while waiting for a transplant (Sinha et al, Hepatology 2019) and approximately 15% experience HCC recurrence after transplant (Mehta et al, Transplantation 2020). Taken together, this constitutes a large subset of this patient population who cannot achieve a cure. Given the success of immunotherapy in the advanced setting, it is imperative to study this in the pre-transplant setting, to improve the outcomes cited above. However, there is a theoretical risk of graft rejection with immunostimulatory treatment. **Methods:** This is a single-arm, open-label, Phase II, multicenter study designed to evaluate the safety and efficacy of durvalumab and tremelimumab for the treatment of HCC patients who have cirrhosis or portal hypertension and are eligible for listing for a liver transplant. Eligibility requirements include adult patients with HCC within UCSF criteria, a Child-Pugh score of up to 7, and ECOG PS of 0 or 1. Treatment includes an immunotherapy combination of 1 dose of tremelimumab and 5 doses of durvalumab for up to 4 months. After a minimum 28-day gap following the final durvalumab dose, patients undergo locoregional therapy per institutional standards. After a minimum 72-day gap from the end of immunotherapy, patients undergo liver transplant. Primary outcome is a binary endpoint, and it will be assessed in patients undergoing liver transplant. Historically, 10-20% of patients are expected to experience acute cellular rejection within 30 days of transplant. We propose that an observed proportion of 20% treatment failure will be a clear indicator of safety in this pilot study, whereas an observed proportion of 50% failure will be a clear indicator of failure. Using these guardrails, with at least 20 patients going to transplant, we will have 80.6% power to demonstrate a failure proportion of 20% (4 patients experiencing failure) versus a null of 50% (10 patients experiencing failure), with a one-sided alpha of 0.05. With 25 patients going to transplant, the power will increase to 86% (other parameters being the same). Clinical trial information: NCT05027425. Research Sponsor: AstraZeneca.

A phase II, open-label pilot study evaluating the safety and activity of liposomal irinotecan (Nal-IRI) in combination with 5-FU and oxaliplatin (NALIRIFOX) in preoperative treatment of pancreatic adenocarcinoma: NEO-Nal-IRI study. *First Author: Sherie C. Rogers, University of Florida/UF Health Cancer Center, Gainesville, FL*

Background: Neoadjuvant treatment for potentially curable pancreatic cancer (PDAC) is increasing in acceptability, but a standard regimen has yet to be established. Multiple studies have demonstrated feasibility and effectiveness of the FOLFIRINOX (5-fluorouracil, leucovorin, oxaliplatin and irinotecan) regimen in the perioperative setting. However, FOLFIRINOX often requires dose modifications, delays and growth factor support due to excessive toxicity which can complicate care delivery when given neoadjuvantly. Liposomal irinotecan injection (Nal-IRI) is FDA approved with a well-tolerated safety profile in relapsed, refractory metastatic PDAC. The current study aims to substitute Nal-IRI for traditional irinotecan in the standard FOLFIRINOX regimen (NALIRIFOX) and to demonstrate safe and effective neoadjuvant delivery. **Methods:** This phase 2, open-label, multicenter single-arm study focuses on patients (pts) with operable PDAC without metastatic disease. Other key eligibility criteria include age ≥ 18 years, resectability confirmed by multidisciplinary GI tumor board (resectable vs. borderline), adequate cardiac, renal, hepatic function and ECOG performance status of 0 to 1. Pts receive NEO-N-IRI regimen as per Table every 2 weeks for four months followed by disease reassessment. Pts who remain surgical candidates will undergo surgical resection within 4 to 8 weeks following last dose of therapy. The primary endpoint is to assess safety and feasibility of regimen in perioperative setting. Secondary endpoints include R0 resection rate, clinical, biochemical and radiological response rate and patient-reported quality of life during treatment as measured by the NCI validated FACT-G scale. Enrollment continues to a maximum of 28 evaluable pts to demonstrate a reduction in historical 30-day postoperative complication rate. Microbiota specimens will be collected for exploratory analysis. Clinical trial information: NCT03483038. Research Sponsor: Ipsen; UF Health Cancer Center.

Agent	Dose	Route/Duration
Nal-IRI	50 mg/m ²	IV over 90 minutes
Oxaliplatin	60 mg/m ²	IV over 120 minutes
Leucovorin	400 mg/m ²	IV over 120 minutes
5-fluorouracil infusion	2400 mg/m ²	IV continuous infusion for 46 hours

An open-label window of opportunity trial to evaluate the activity of durvalumab and tremelimumab with platinum-based chemotherapy (gemcitabine and cisplatin) in intrahepatic cholangiocarcinoma. *First Author: Olumide B. Gbolahan, Emory University School of Medicine, Atlanta, GA*

Background: Following surgical resection, the rate of recurrence of intrahepatic cholangiocarcinoma (ICC) is high. Expert groups recommend preoperative systemic therapy, particularly for resectable ICC with features that portend a high risk of recurrence. Based on data from ABC-02 the combination of gemcitabine and cisplatin (GC) is often used. This provides an objective response rate (ORR) of only 20% in ICC. The addition of durvalumab, an anti-PDL1 inhibitor to GC improves overall survival (OS) in the metastatic setting and is associated with an ORR of about 30%. On the other hand, while the addition of nab-Paclitaxel to GC provides an ORR of 34%, it was not associated with an improvement in OS in biliary tract cancer. It is therefore rationale to continue to explore and optimize immune checkpoint inhibitor development in ICC. We designed this study to determine the activity of durvalumab (D) and tremelimumab (T) (anti-CTLA4 ICPI) in combination with GC in resectable ICC with high-risk features. We plan to explore tumor intrinsic and tumor microenvironment related factors that will be associated with response (or lack thereof) to ICPI. **Methods:** This is a multicenter open-label, window of opportunity trial of the combination durvalumab and tremelimumab in combination with GC in resectable ICC with high-risk features. Inclusion criteria includes patients ≥ 18 years with radiologically measurable and biopsy proven ICC that is surgically resectable but with high risk features (based on multidisciplinary tumor board discussion). Prespecified high-risk features include tumor size >5 cm, T1b-T4 lesion, multifocal tumors/tumor with satellite lesions, suspicious or involved lymph nodes (N1) and vascular involvement all thought to be technically resectable. Patients with extrahepatic metastasis will be excluded. D will be administered at 1500mg IV on Day 1 every 3 weeks for up to a maximum of 4 cycles. T, 300mg will be administered on Day 1 of cycle 1 only. G (1000mg/m²) and C (25mg/m²) will be administered by IV infusion on Days 1 and 8 every 3 weeks for a maximum of 4 cycles. The primary outcome measure is to demonstrate an ORR of 52%. Secondary objectives are to assess the feasibility and safety of the combination in ICC. Given the historical objective response rate of 25% and using one-sided exact test for single proportion, we will have 80% power to reject 25% ORR at $\alpha=0.05$ when we observe ORR of 52% (Ho: Po=0.25 vs. Ha: Pa=0.52) from the study sample. The study is open at the O'Neal Comprehensive Cancer Center at the University of Alabama and will be open at other centers in the next few months. Clinical trial information: NCT04989218. Research Sponsor: AstraZeneca.

Alliance A021804: A prospective, multi-institutional phase II trial evaluating temozolomide versus temozolomide and olaparib for advanced pheochromocytoma and paraganglioma. *First Author: Jaydara Del Rivero, National Cancer Institute/National Institutes of Health, Bethesda, MD*

Background: Pheochromocytomas (PHEOs) and paragangliomas (PGLs) are rare neuroendocrine tumors (NETs) that arise from chromaffin cells. Few antitumor therapies have been developed for patients (pts) with advanced PHEO/PGLs (APP). Potent poly (ADP-ribose) polymerase (PARP) is activated after DNA damage and regulates base excision repair, homologous recombination and non-homologous end joining. Inhibition of PARP enzymatic activity blocks PARP-mediated DNA repair, therefore PARP inhibitors can be directly cytotoxic to tumor cells which then permits synergy with agents that increase prevalence of single-strand breaks in tumor models. Temozolomide (TMZ) is an alkylating agent that induces single-strand DNA breaks and therefore is an optimal therapeutic pair with a PARP inhibitor. We are conducting a phase II multi-institutional study to evaluate the antitumor activity of TMZ and olaparib [OLA (a PARP inhibitor)] in patients with APP. **Methods:** Patients with APP with radiographic evidence of disease progression by RECIST v1.1 in the 12 months prior to registration can be enrolled in this phase II randomized study. Patients will be randomized in a 2:1 allocation with more patients to Arm 1. Arm 1 will receive TMZ 75 mg/m² daily and OLA 200 mg twice daily on days 1-7 of a 21-day cycle. Arm 2 will receive TMZ 200 mg/m² daily on days 1-5 of a 28-day cycle. Treatment on Arm 1 will continue for 13 cycles, followed by OLA maintenance until disease progression. Treatment on Arm 2 will continue for 13 cycles or until disease progression. The primary objective is to compare the progression-free survival between the two arms with a planned interim analysis for futility. Secondary endpoints include safety, response rate, and overall survival. Correlative endpoints include biochemical response and biomolecular markers (germline succinyl dehydrogenase mutations and tumor status of the repair enzyme methylguanine-DNA methyltransferase). We anticipate a null PFS median of approximately 5.4 months. We plan to accrue a total of 76 patients (randomized at a rate of 2:1 with more patients enrolled to the TMZ+OLA arm) in 38 months with a minimum follow-up of 2.5 months to achieve 56 PFS events. This design includes one interim analysis for futility using Rho Family spending functions (Rho = 2.5) and will yield 89% power to detect a hazard ratio (HR) of 0.5 (median PFS of 5.4 vs. 10.8 months) assuming exponential survival and using a one-sided log-rank test with type I error rate of 0.11. Clinical trial information: NCT04394858. Research Sponsor: U.S. National Institutes of Health.

Poster Session

LANTana trial protocol: An open label, single arm, phase Ib study to evaluate the effect of pre-treatment with ASTX727 (a demethylating agent) followed by lutetium Lu 177 dotatate in patients with progressive, metastatic neuroendocrine neoplasias (NENs). *First Author: Rohini Sharma, Imperial College London, London, United Kingdom*

Background: Neuroendocrine neoplasias (NENs) are characterised by the presence of somatostatin receptors (SSTR) on cell surface, in particular SSTR2. Somatostatin and its stable analogue (SSA) bind with high affinity to SSTR2. SSA can be radiolabelled, to both stage NENs using positron emission tomography (PET), and to deliver selective radiotherapy; peptide receptor radionuclide therapy (PRRT). PRRT consists of SSA linked to the long acting radionuclide. Radiolabelled SSA binds to SSTR2 and the complex is internalised delivering high dose radiation directly to the cancer. PRRT has been significantly improve survival outcomes and maintain quality of life in metastatic disease. Suitability for PRRT depends on presence of SSTR2 as determined by PET imaging, commonly with [⁶⁸Ga]-dotatate-PET. 20% of patients will have low or no uptake on [⁶⁸Ga]-dotatate-PET precluding PRRT. The upstream promoter region of SSRT2 is methylated, with percentage of methylation correlating with SSTR2 expression. We have shown that the use of the demethylating agent, guadecitabine, increases uptake on PET imaging in such that tumours previously negative on PET imaging, become positive, correlating with a dose dependent increase in tumoural SSTR2 expression. Combination guadecitabine and PRRT was well tolerated in vivo models of NETs. Overall aim was to utilise [⁶⁸Ga]-dotatate-PET as a biomarker of SSTR2 re-expression following treatment with the demethylating agent, ASTX727, such that patients previously unsuitable for PRRT can receive therapy, improving clinical outcome. 1) Utilise [⁶⁸Ga]-dotatate-PET to image epigenetic regulation of SSTR2 in response to ASTX727. 2) Evaluate clinical efficacy and safety of ASTX727 pre-treatment in combination with PRRT. 3) Explore impact on quality of life of combination therapy. **Methods:** 27 patients with no or equivocal uptake on [⁶⁸Ga]-dotatate-PET will be enrolled. [⁶⁸Ga]-dotatate-PET will be performed at baseline and after 8days of ASTX727 (oral, fixed dose 100mg cedazuridine + 35mg decitabine). If there is a significant increase in PET uptake, patients will receive combination ASTX727 and PRRT (Lutathera). Treatment will be repeated every 2months for 4 cycles. Response assessment (RECIST 1.1), tolerability and QoL will be assessed at start of each cycle. Tumour biopsies will be taken at baseline, and after cycle1 of ASTX727 (n=5), for SSTR2 methylation. Methylation will be correlated with PET uptake and outcome. LINE-1 methylation in peripheral blood monocytes will be assessed throughout. Current enrolment: 4. Clinical trial information: NCT05178693. Research Sponsor: AAA.

Phase II trial of BXCL701 and pembrolizumab in patients with metastatic pancreatic ductal adenocarcinoma (EXPEL-PANC). *First Author: Benjamin Adam Weinberg, Ruesch Center for the Cure of Gastrointestinal Cancers, Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC*

Background: Pancreatic ductal adenocarcinoma (PDAC) has limited therapeutic options and is thought to be a “cold” tumor that does not respond to immunotherapy, due to a tumor microenvironment (TME) consisting of a desmoplastic stroma and poor T cell infiltrate. BXCL701 is an oral synthetic dipeptide that competitively inhibits dipeptidyl peptidases DPP4, DPP8, DPP9 and fibroblast activation protein (FAP). BXCL701 exerts antitumor activity via inhibition of DPP8/9, which is associated with induction of proinflammatory cytokines, as well as inhibition of FAP, which disrupts tumor-stromal interactions. Preclinical xenograft models demonstrate synergy between BXCL701 and an anti-PD-1 monoclonal antibody, reducing tumor growth and promoting an increase in intratumoral CD4+ and CD8+ T cells and NK cells. The combination of BXCL701 and pembrolizumab is already being studied in a phase II trial in patients with prostate cancer (NCT03910660) and a multi-cohort basket study (NCT04171219). **Methods:** This is a phase II trial of BXCL701 administered at 0.2 mg PO BID days 1-7 and 0.3 mg BID days 8-14 during cycle 1 (21 days) followed by 0.3 mg BID days 1-14 every 21 days in all subsequent cycles, given with pembrolizumab 200 mg IV every 21 days (all cycles). The primary objective is to determine the 18-week progression-free survival rate (PFS18weeks) in patients with metastatic PDAC treated in the second-line setting. We estimate that historical 2nd-line PFS18weeks is 30% or less; using a Simon's two-stage (minimax) design, a type I error rate of 0.05 and power of 80% when the true response rate of 50%, we will need 19 patients in stage 1 and 20 in stage 2 (a total of 39). We plan to enroll 43 patients to account for a predicted 10% drop out of unevaluable patients. Eligible patients must have metastatic PDAC and disease progression or intolerance to only 1 line of therapy for metastatic disease, without exposure to prior immunotherapy. Patients must have measurable disease amenable to serial biopsies. Correlative pharmacodynamic studies include imaging mass cytometry to examine 34 markers of the PDAC TME in tissue biopsies, as well as blood-based analyses of KRAS circulating tumor DNA, circulating markers of fibrosis, and IL-6. Enrollment began in Q1 2023. Clinical trial information: NCT05558982. Research Sponsor: BioXcel; Merck.

Open-label, single arm phase II trial investigating the efficacy, safety and quality of life of neoadjuvant chemotherapy with liposomal irinotecan combined with oxaliplatin and 5-fluorouracil/folinic acid followed by curative surgical resection in patients with hepatic oligometastatic adenocarcinoma of the pancreas (HOLIPANC). *First Author: Florian Gebauer, University Cologne, Cologne, Germany*

Background: As of today, the recommendation for patients with adenocarcinoma of the pancreas and hepatic metastases is systemic chemotherapy alone regardless of the number and location of metastases. In the past, case reports have repeatedly reported survival data of patients who received metastatic and primary tumor resection outside the guidelines. However, there are currently no controlled clinical data from prospective studies that have evaluated the effectiveness of systemic chemotherapy in combination with tumor and metastasis resection in the context of hepatic oligometastasis in pancreatic cancer. **Methods:** In this single arm, phase-2 trial, survival data from patients receiving neoadjuvant chemotherapy followed by RO/R1 resection will be compared to historic data from patients with oligometastatic adenocarcinoma of the pancreas. Inclusion criteria are patients with a maximum of 5 liver metastases and histology proven PDAC. The combination of liposomal irinotecan (nal-IRI), oxaliplatin (OX) and 5-fluorouracil (5-FU)/folinic acid (FA) (Nal-IRIFOX) was chosen as neoadjuvant chemotherapy since recent data suggested superior efficacy and less toxicity compared to mFOLFIRINOX. The primary endpoint is overall survival (OS) after RO/R1 resection. Secondary efficacy endpoints are RO/R1 resection rate and progression-free survival (PFS). Secondary safety endpoints are type, frequency and severity of adverse events with severity according to NCI CTCAE version 5.0 and perioperative morbidity and mortality. Eligible patients with hepatic oligometastatic adenocarcinoma of the pancreas will receive neoadjuvant combination chemotherapy in cycles of 14 days for a duration of 16 weeks in total. In patients with progressive disease during or after the first 4 cycles, neoadjuvant chemotherapy will be permanently discontinued. Patients with tumor response or stable disease after the first 4 cycles according to RECIST v1.1 but a non-resectable primary tumor will receive 4 more cycles. Patients with tumor response or stable disease and a resectable primary tumor after the first 4 cycles will undergo explorative laparotomy and synchronous resection of the tumor and hepatic metastases, if feasible. In total 150 patients will be enrolled for this trial with an aim of 55 patients receiving a complete macroscopic synchronous tumor and metastatic resection. The study is currently ongoing on 11 high-volume centers for pancreatic surgery within Germany. This is the first clinical study to prospectively evaluate the value of multimodality therapy concepts in oligometastatic pancreatic cancer. Clinical trial information: NCT04617457. Research Sponsor: Servier.

Phase 1b/2 trial of pepinemab plus avelumab as second line combination immunotherapy for patients with metastatic pancreatic adenocarcinoma. *First Author: Luis I. Ruffolo, University of Rochester Cancer Center & Wilmot Cancer Institute, Rochester, NY*

Background: Monotherapy with immune checkpoint inhibitors (ICIs) is not effective in metastatic pancreatic adenocarcinoma (PDAC), likely due to the unique immunosuppressive tumor microenvironment (TME) of PDAC, thus safe and novel strategies to overcome resistance and facilitate adaptive immune responses are a major unmet need. Preclinical and clinical studies demonstrated that antibody blockade of semaphorin 4D (SEMA4D) promotes tumoral infiltration and activation of DCs and CD8+ T cells and reverses immunosuppression, including attenuation of MDSC recruitment and function, leading to enhanced efficacy of ICIs without increasing toxicity. Pepinemab, a SEMA4D blocking antibody, in combination (combo) with avelumab provided clinical benefit in some patients with ICI-resistant and PD-L1-low NSCLC (NCT03268057). Pepinemab is also being evaluated in combo with pembrolizumab in patients with metastatic squamous cell carcinoma of the head and neck (NCT04815720). The principal goals of this proof-of-concept study are to investigate the safety, efficacy, and TME biomarker changes of treatment with the combo of pepinemab plus avelumab in patients with metastatic PDAC. **Methods:** This single-arm, open-label study (NCT05102721) is evaluating the safety, tolerability, and efficacy of pepinemab in combo with avelumab in patients diagnosed with metastatic PDAC who have either progressed on or are otherwise intolerant to first line chemotherapy. Patients must have received 5FU or gemcitabine-based first line therapy with evidence of intolerance or treatment failure, including progression both during or after completing first-line treatment. Accrual for the Phase 1b portion follows a Bayesian Optimal Interval Design (BOIN), beginning at the highest dose combo; 20 mg/kg pepinemab and 800 mg avelumab Q2W. Phase 2 begins after 16 subjects are enrolled at MTD, permitting a Simon's two stage assessment of futility prior to closing the Phase 1b period. The primary objective for Phase 1b is tolerability, and the primary objective for Phase 2 is therapeutic efficacy compared to historical second-line systemic chemotherapy. The trial anticipates a total evaluable cohort of 40 subjects and is powered to detect a response rate of 23% or greater, with alpha set at 0.1 and 80% power. Exploratory objectives include robust correlative analysis of immune, stromal, and genomic profiling of baseline and on-treatment tumor biopsies to ascertain mechanisms of treatment response and failure. Patient reported outcomes are incorporated throughout the trial to assess disease specific symptoms associated with pancreatic cancer and cancer cachexia. One patient has been enrolled as of Feb 14, 2023. Clinical trial information: NCT05102721. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology; Vaccinex, Inc.; U.S. National Institutes of Health.

A phase 1 study to evaluate the safety, tolerability, pharmacokinetics, pharmacodynamics and immunogenicity of LB4330, a peptide fused to CLDN18.2 antibody targeting the tumor antigen associated CD8+ T CELLS in patients with advanced solid tumors. *First Author: Jiajian Liu, Shanghai, China*

Background: PD-1/PD-L1-targeted immunotherapies have become critical roles in the treatment for many tumors. However, there is limited progress in pancreatic ductal adenocarcinoma (PDAC). PDAC is low immunogenicity. PDAC microenvironment is immunosuppressive. More than 70% PDACs have few or no CD8+ T cells around the tumor cell or in the tumor microenvironment (TME). Therefore, immunotherapy like PD-1/PD-L1 antibody alone is rarely effective for PDACs. Some cytokine or analogs may activate CD8+ T cells. An analog specifically activating tumor antigen associated (TAA) CD8+ T cells was designed and fused to anti-CLDN18.2 antibody. This specific bi-functional molecule LB4330 has high affinity to human anti-CLDN18.2 (14pM) and CD8+ T cells. LB4330, as a novel, first-in-class molecule, may activate TAA CD8+ T cells in TME and has potential in alone or in combination with PD-1/PD-L1 mAb, for the treatment of advanced solid tumors, especially for Claudin 18.2 positive PDAC. **Methods:** This is a FIH, phase 1 study to evaluate the safety, tolerability, pharmacokinetics and immunogenicity of LB4330 in patients with advanced solid tumors (MEETCD8-001). The planned sample size is approximately 66 patients in two parts: part 1 dose escalation, will evaluate safety, tolerability, pharmacokinetics (PK), pharmacodynamics, and determine the maximum tolerated dose (MTD) and/or the recommended phase 2 dose (RP2D). Part 2 dose expansion will further characterize the safety profile and preliminary tumor response in advanced gastric and gastroesophageal junction adenocarcinoma and PDAC with Claudin 18.2 expression. In dose escalation stage, patients will be recruited with advanced solid tumors who have failed standard treatment, or for whom standard treatment is not available or applicable at this stage. Exclusion criteria include a greater risk for gastric bleeding, irritable bowel syndrome with symptoms, active virus infections. The primary endpoints are incidence of dose limiting toxicities and adverse events, MTD, and recommended phase 2 dose. Secondary objectives will evaluate PK parameters, preliminary antitumor activity, and immunogenicity of LB4330. Tumor response will be assessed per RECIST and iRECIST every 2 cycles. The Phase I study in advanced solid tumors is ongoing. Enrollment in cohort 1 began in Nov 2022. Clinical trial information: NCT05707676. Research Sponsor: L&L Biopharma Co., LTD., Shanghai, China.

Randomized phase II trial of olaparib + pembrolizumab vs olaparib alone as maintenance therapy in metastatic pancreatic cancer patients with germline BRCA1 or BRCA2 (gBRCA1/2+) pathogenic variants: SWOG S2001. *First Author: Vincent Chung, City of Hope, Duarte, CA*

Background: Olaparib was approved in 2019 as maintenance therapy for gBRCA1/2+ metastatic pancreatic cancer (mPDA) patients (pts). The POLO trial showed an improvement in median progression free survival (mPFS) with olaparib compared to placebo (7.4 vs 3.8 months) for platinum sensitive gBRCA1/2+ mPDA pts. Preclinical studies have demonstrated that PARP inhibitors modulate the immune microenvironment by increasing genomic instability, PD-L1 expression and activating the immune inflammatory stimulator of interferon genes (STING) pathway. Several clinical studies in solid tumors have shown preliminary efficacy with the combination of PARP plus immune checkpoint inhibitors. Based upon these data, SWOG S2001 aims to further improve the PFS of gBRCA1/2+ mPDA pts. **Methods:** S2001 was developed in collaboration with the Alliance and was activated in SWOG in December 2020. Key eligibility criteria include: mPDA pts with gBRCA1/2 pathogenic variants identified with standard of care germline genetic testing and progression-free after receiving at least 16 weeks of platinum-based chemotherapy (FOLFIRINOX, FOLFOX or gemcitabine/cisplatin +/- nab-paclitaxel). One cycle of gemcitabine and nab-paclitaxel is allowed while waiting for germline testing. Zubrod performance status (PS) 0 or 1 pts are eligible. Pts are stratified according to first line chemotherapy, PS 0 vs 1, and disease status after 1st line treatment. The primary objective of this study is to compare PFS in mPDA pts treated with olaparib + pembrolizumab versus olaparib alone as maintenance therapy. Based upon the POLO trial, we expect a mPFS of 7 months in the control arm. Targeting a mPFS of 11.7 months in the experimental arm (hazard ratio 0.6) and assuming 15 months follow-up, 80% power and a 1-sided alpha=0.10, this design requires enrolling 88 pts for a total of 78 eligible and evaluable pts. As of February 2023, 26 participants have been accrued. Prospective serial blood samples will be collected to bank DNA and RNA for future correlative studies. Clinical trial information: NCT04548752. Research Sponsor: U.S. National Institutes of Health.

ASCEND: A randomised, double-blinded, phase II study of gemcitabine and nab-paclitaxel with CEND-1/LSTA1 or placebo in patients with untreated metastatic pancreatic ductal adenocarcinoma. *First Author: Andrew Peter Dean, St. John of God Hospital Subiaco, Subiaco, Australia*

Background: LSTA1 is a novel cyclic peptide with high tumor vascular endothelium specificity that activates an endocytotic/exocytotic transport pathway on stroma and tumor. LSTA1 potentiates greater intratumoral access for co-administered or tethered anti-cancer agents, including small molecules, antibodies, and nanoparticles, leading to increased anti-neoplastic activity. Preclinical studies in solid tumor models have shown co-administrating LSTA1 is effective in augmenting the delivery and activity of multiple anti-cancer agents. LSTA1 has been evaluated in 31 patients in a Phase I study in metastatic pancreatic ductal adenocarcinoma (mPDAC) demonstrating an objective response in 59% of patients, a 79% disease control rate at 16 weeks with a median progression free survival (PFS) of ~9.9 months. No dose limiting toxicities were observed. The ASCEND study will determine whether LSTA1 when added to SOC chemotherapy is active and safe as first-line treatment of mPDAC, and whether an additional dose of LSTA1 administered approximately 4 hours after chemotherapy further improves anti-cancer activity. **Methods:** ASCEND is a randomized, double-blind, placebo-controlled phase II trial evaluating the safety and efficacy of LSTA1 3.2 mg/kg in combination with standard of care chemotherapy (nab-paclitaxel 125mg/m² and gemcitabine 1000mg/m² on days 1, 8, and 15, every 28 days) in patients with histologically proven, previously untreated mPDAC. A total of 155 subjects will be randomized 2:1 in favor of study intervention in two cohorts and stratified by age, ECOG status, presence of liver metastasis, and study site. Patients in cohort A receive single doses of LSTA1 or placebo, and for cohort B, two doses of LSTA1 or placebo spaced 4 hours apart. Tumour assessment occurs every 8-weeks from randomization until disease progression or commencement of a new anti-cancer therapy. The primary endpoint is PFS. Secondary endpoints include objective tumour response safety, overall survival, and patient reported outcomes. At 14 Feb 2023, 70 participants have been enrolled from Australian sites. Sites in Ireland and New Zealand are anticipated to open this year. Clinical trial information: NCT05042128. Research Sponsor: Lisata Therapeutics, Inc.

Phase 3 PANOVA-3 study: Tumor treating fields (TTFields) therapy concomitant with gemcitabine and nab-paclitaxel (GnP) for front-line treatment of locally advanced pancreatic cancer. *First Author: Hani M. Babiker, Mayo Clinic Florida, Jacksonville, FL*

Background: Tumor Treating Fields (TTFields) therapy is a locoregional antimitotic treatment approved for newly diagnosed and recurrent glioblastoma GBM and pleural mesothelioma. TTFields (150 kHz) therapy, with/without chemotherapy, had anti-proliferative and anticlonogenic activity in pancreatic cancer cell lines, and reduced tumor volume and weight more than chemotherapy alone in *in vivo* models. TTFields therapy with gemcitabine and nab-paclitaxel (GnP) was well-tolerated, with promising efficacy in metastatic and locally advanced pancreatic adenocarcinoma (LAPC) in the phase 2 PANOVA study (NCT01971281). LAPC prognosis remains poor despite available therapies, which can negatively impact quality of life (QoL). As such, there remains a need for effective and tolerable treatments. **Methods:** PANOVA-3 (EF-27, NCT03377491) is a prospective, randomized, phase 3 study investigating the efficacy and safety of TTFields therapy with GnP in patients with LAPC, with a planned enrollment of 556 patients. Key inclusion criteria are: a diagnosis of unresectable LAPC (per NCCN guidelines), ECOG PS of 0–2, and no prior treatment. Patients will be stratified by performance status and geographical region and assigned 1:1 to treatment groups to receive TTFields therapy + GnP or GnP alone. GnP will be administered at a standard dose per standard of care. TTFields therapy (150 kHz, 18h/day) will be delivered by the NovoTTF-200T System until local disease progression per RECIST v1.1. Usage will be tracked by the device. Follow-up will be performed every 4 weeks and computed tomography scans of the chest and abdomen will be taken every 8 weeks until disease progression. Patients will be followed every month until death. The primary endpoint is overall survival and key secondary endpoints include QoL, pain-free survival, and puncture-free survival, which will be compared between treatment groups. Other secondary endpoints include progression-free survival (PFS), local PFS, objective response rate, 1-year survival rate, rate of resectability, and safety. Guidance around usage, lifestyle integration and prevention and management of skin adverse events will be provided by Device Support Specialists and field personnel. Usage information will be provided to patients and physicians to facilitate discussions to optimize outcomes by maximizing time on therapy. Together, these novel support approaches aim to optimize patient usage and outcomes. The trial is currently recruiting at 149 sites, globally. The DMC last reviewed the trial in August 2022, and suggested that the trial continue as planned. Clinical trial information: NCT03377491. Research Sponsor: Novocure.

CheMo4METPANC: A phase 2 study with combination chemotherapy (gemcitabine and nab-paclitaxel), chemokine (C-X-C) Motif receptor 4 inhibitor (motixafortide), and immune checkpoint blockade (cemiplimab) in metastatic treatment-naïve pancreas adenocarcinoma. *First Author: Gulam Abbas Manji, Columbia University Medical Center/New York-Presbyterian Hospital, New York, NY*

Background: Metastatic pancreatic ductal adenocarcinoma (mPDAC) is a uniformly fatal disease for which treatments result in limited benefit. Failure of immune checkpoint blockade is attributed to multiple immunosuppressive pathways within the tumor microenvironment. The C-X-C motif chemokine receptor 4 (CXCR4)/C-X-C motif chemokine ligand 12 (CXCL12) axis results in exclusion of anti-tumor immune cells. Preclinical studies demonstrated that simultaneous CXCR4 inhibition (CXCR4i) and anti-programmed cell death 1 (aPD1) resulted in tumor stabilization. We extended these findings by testing multiple combinations of CXCR4i, aPD1, and gemcitabine in the KPC mouse model of PDAC. Mice treated with gemcitabine, CXCR4i, and aPD1 (triple therapy) experienced a survival benefit compared to mice treated with either gemcitabine alone, or with CXCR4i/aPD1. Tumors from mice treated with triple therapy demonstrated increased apoptosis and a favorable tumor immune microenvironment (TIME). Motixafortide with pembrolizumab, fluorouracil, and nanoliposomal irinotecan has shown encouraging results in the second-line setting in mPDAC with a confirmed ORR of 13.2% and progression free survival (PFS) of 3.8 months (m). The goal of this first-in-man trial is to test preliminary safety and efficacy of Motixafortide (CXCR4i), Cemiplimab (aPD1), Gemcitabine, and Nab-paclitaxel (MCGN) in treatment naïve mPDAC. **Methods:** This is an open label, multicenter, investigator-initiated Simon-2-stage phase 2 clinical trial in mPDAC testing MCGN. The study includes a six-patient safety run-in cohort and an additional 4 patients comprising a pilot efficacy signal seeking study (N=10). If ≥ 3 of the 10 patients within the pilot stage were to experience a partial response (PR) by RECIST criteria within 16 weeks, the combination would be considered promising and an expansion cohort of an additional 30 patients was planned. On 09/21/22, we amended the study to forego the planned open-label expansion cohort (N=30) and transition directly to a randomized phase 2 trial testing MCGN compared to Gemcitabine and Nab-paclitaxel (GN) alone (N=102), after completion of the pilot phase of the study. The primary endpoint is PFS. The study has 80% power to detect an improvement in PFS from 6 to 9.2 m (HR 0.65) with a one-sided alpha of 0.20. One interim analysis for futility is planned when 50% of the PFS events are observed. Secondary objectives include ORR, disease control rate, duration of clinical benefit and OS. Required (pilot portion) and optional (randomized portion) paired tumor biopsies will undergo exploratory analysis including interrogation of the TIME. This trial was started in September 2020 and has enrolled 10 patients to the pilot stage as of 02/2023. Clinical trial information: NCT04543071. Research Sponsor: Regeneron Pharmaceuticals; BioLineRx.

Apollo: A randomized phase II double-blind study of olaparib versus placebo following curative intent therapy in patients with resected pancreatic cancer and a pathogenic BRCA1, BRCA2, or PALB2 mutation—ECOG-ACRIN EA2192. *First Author: Kim Anna Reiss, University of Pennsylvania, Philadelphia, PA*

Background: A meaningful subset of PDAC is characterized by a homologous recombination deficiency (HRD). The most well-defined patients within this group are those with pathogenic variants in *BRCA1*, *BRCA2* and *PALB2*. In the metastatic setting, PARP inhibitor maintenance provides a progression-free survival benefit after a period of platinum based chemotherapy^{1,2}, but the role of PARP inhibitors in the curative intent setting is undefined. The OlympiA study established one year of olaparib as the standard of care for patients with *BRCA*-related, early stage breast cancer who completed all other curative-intent treatment³. Therefore, we have designed a randomized, phase II double-blind study of one year of olaparib vs placebo in patients with pancreatic cancer and a germline or somatic variant in *BRCA* or *PALB2* who have completed all curative intent therapy. **Methods:** We have enrolled and treated 29 of 152 planned patients on study NCT 04858334/EA2192. Eligibility criteria include: a pathogenic germline or somatic variant in *BRCA1*, *BRCA2* or *PALB2* as determined by local laboratory (central review required); completion of curative-intent resection and $\geq$ three months of multi-agent chemotherapy; no evidence of recurrent disease. At enrollment, patients must be within 12 weeks of their last anti-cancer intervention. Patients are randomized 2:1 to receive oral olaparib 300 mg twice daily or placebo for 12 28-day cycles. The primary endpoint is relapse-free survival. Overall survival is a secondary endpoint. Tumor tissue, fecal material (for microbiome analysis) and serial ctDNA samples are being collected. 1) Golan T, Locker GY, Kindler HL: Maintenance Olaparib for Metastatic Pancreatic Cancer. *Reply. A phase 1b, open-label, two-part safety, tolerability, and efficacy study of a soluble beta-glucan (odetiglucon) in combination with a CD40 agonistic monoclonal antibody (CDX-1140) in patients with metastatic pancreatic adenocarcinoma whose disease did not progress during first-line (1L) chemotherapy. *First Author: Mark H. O'Hara, Hospital of the University of Pennsylvania, Philadelphia, PA*

Background: Metastatic pancreatic ductal adenocarcinoma (PDAC) is an aggressive and lethal disease with a 5-year overall survival (OS) rate of 3%. Standard of care treatment is continuous cytotoxic chemotherapy which produces modest improvements in OS but is also associated with significant toxicity raising the need for novel treatment paradigms. Although immunotherapy has yet to produce clinical benefit for most patients with PDAC, preclinical modeling demonstrates its potential and show that combinations of myeloid agonists can trigger robust synergistic anti-tumor activity against PDAC tumors that are otherwise resistant to immunotherapy including immune checkpoint blockade (anti-CTLA4, anti-PD1). In this study, odetiglucon (OD), a novel beta glucan pathogen associated molecular pattern (PAMP), will be combined for the first time with CDX-1140, a fully human Ig2K agonistic monoclonal CD40 antibody in the maintenance setting after an induction phase of cytotoxic chemotherapy. OD and a CD40 agonist directly promote the activation and maturation of antigen presenting cells and shift the suppressive TME to enhance T-cell responses through non-redundant myeloid signaling pathways. We hypothesize that the combination of OD and CD40 agonist therapy has the potential to trigger anti-tumor immunity in PDAC and thus, extend and deepen responses to 1L cytotoxic chemotherapy. **Methods:** A two-part Phase 1b study of metastatic PDAC pts who have evidence of response or stable disease following 16-24 wks of chemotherapy is being conducted. Part A uses a 3+3 design; pts will receive OD 4 mg/kg QW + CDX-1140 1.5 mg/kg Q3W. Following a dose-limiting toxicity observation period, the dose will be held at 1.5 mg/kg or decreased to 0.72 mg/kg Q3W. Once preliminary safety is established, the cohort will be expanded to 15 pts. Part B pts will receive OD 4mg/kg + CDX-1140 at the dose identified in Part A Q3W. The study will enroll 30 pts. Main eligibility criteria: Metastatic PDAC having durable stable disease or response to 1L chemotherapy; serum ABA ≥ 20 μ g/mL, and no prior anti-CD40 mAb or immunomodulatory treatment exposure. Primary endpoints are MTD, RP2D, and safety. Secondary endpoints include DOR, PFS, ORR, and OS and exploratory endpoints include evaluating immune pharmacodynamic responses in peripheral blood and tumor. Safety parameters will be listed and summarized using descriptive statistics. ORR will be tabulated by overall frequency; DOR, TTF, PFS and OS will be summarized and presented using Kaplan-Meier and waterfall plots. 5 US sites will participate. Clinical trial information: NCT04834778. Research Sponsor: HiberCell.

ExoLuminate: An observational registry study for detection of pancreatic adenocarcinoma (PDAC) in high-risk or clinically suspicious patients. *First Author: Harmeet Dhani, Biological Dynamics, Inc., San Diego, CA*

Background: The detection of pancreatic ductal adenocarcinoma (PDAC) at early-stages is critical to improving patient survival. However, the lack of a clinically useful biomarker assay poses a challenge for earlier detection. A liquid biopsy test (ExoVita Pancreas) which uses extracellular vesicles (EV) protein biomarkers has been developed for detection of PDAC. In a previous case-control study of n=715 (75 cases of PDAC Stage I and II, 640 controls), the EV-protein biomarker assay yielded a sensitivity of 96.0% and specificity of 91.1%. By optimizing the assay for high sensitivity, we aim to generate evidence for earlier detection of PDAC in high-risk and clinically suspicious patients in the hope of impacting PDAC patient diagnostic journeys. **Methods:** ExoLuminate is a prospective, multi-center, observational registry study to demonstrate that early detection of PDAC using ExoVita is non-inferior to current standard of care methods of surveillance. The study duration will be 36 months (24-month accrual, 12-month follow-up), with a minimum of 1000 subjects to be enrolled between two cohorts as described below. The first cohort enriches for "high-risk" individuals without a cancer suspicion or diagnosis including those with intraductal papillary mucinous neoplasms (IPMNs), personal or family history of pancreatitis, family member(s) who have at least one first-degree relative affected by pancreatic cancer, patients over 50 years of age with new-onset diabetes (NOD), and germline mutations known to be associated with PDAC. The second cohort includes patients with clinical findings suspicious for early-stage PDAC or those with biopsy-proven PDAC. Patients enrolled in the study will have their blood obtained at six-month intervals. The performance of ExoVita liquid biopsy will be compared to standard-of-care imaging and biomarkers such as CA19-9. Through this registry, which began enrollment in December 2022 and is open for accrual (NCT0562552), we aim to demonstrate the clinical utility of a novel liquid biopsy based on detection of EV-derived biomarkers for early diagnosis of PDAC which can provide credence to a new paradigm in early detection to improve patient outcomes. Clinical trial information: NCT0562552. Research Sponsor: Biological Dynamics, Inc.

Alliance A021806: A phase III trial evaluating perioperative versus adjuvant therapy for resectable pancreatic cancer. *First Author: Akhil Chawla, Northwestern University Robert H. Lurie Comprehensive Cancer Center, Chicago, IL*

Background: The role of neoadjuvant chemotherapy in resectable pancreatic cancer has yet to be defined. Recent phase II trial results demonstrate a median overall survival time (mOS) of only 22.4 months after treatment with perioperative modified FOLFIRINOX (mFOLFIRINOX) with 36% not reaching surgery due to disease progression during neoadjuvant therapy. While potential benefits and shortcomings of neoadjuvant chemotherapy have been well documented, to date, no phase III trial has directly compared a perioperative versus an adjuvant chemotherapy strategy in resectable pancreatic cancer. Alliance for Clinical Trials in Oncology A021806 is an actively accruing randomized controlled phase III trial evaluating the efficacy of perioperative chemotherapy with mFOLFIRINOX in patients with resectable pancreatic cancer. **Methods:** To qualify for enrollment, patients must have biopsy-proven localized resectable pancreatic adenocarcinoma as defined by the National Comprehensive Cancer Network. Patients must have good performance status (ECOG 0 or 1) and be candidates to receive mFOLFIRINOX treatment. All patients enrolled undergo central radiologic eligibility review for quality control and are then randomized to either Arm 1 which consists of 8 cycles of neoadjuvant mFOLFIRINOX followed by 4 cycles of adjuvant mFOLFIRINOX or Arm 2 which includes upfront surgery followed by 12 cycles of adjuvant mFOLFIRINOX. The primary endpoint of the trial is overall survival with secondary endpoints evaluating disease-free survival, margin-negative resection rate, surgical complications, and chemotherapeutic adverse events. Additional correlative endpoints include quality of life and radiomic imaging assessments. A total enrollment of 352 patients is planned from the US and Canada; current enrollment for this trial is at 145 patients. An OS interim analysis will be performed when 50% of the events (124) are observed combining the two arms. If the trial continues after interim analysis, the final OS analysis will be performed with a total of 248 events (combined arms). If the Cox model (stratified by tumor location and ECOG PS) comparing OS between arms produces a one-sided p-value < 0.05, then we will conclude that the OS of the perioperative therapy arm is superior to adjuvant therapy. The Alliance A021806 phase III trial aims to define a new standard of care for patients with resectable pancreatic cancer. Clinical trial information: NCT04340141. Research Sponsor: U.S. National Institutes of Health; U10CA180821, U10CA180882; U10CA180820 (ECOG-ACRIN); U10CA180868 (NRG); U10CA180888 (SWOG).

Targeting minimal residual disease (MRD) in resected RAS mutated pancreatic cancer with vaccine TG01/QS-21 +/- PD-1 inhibitor, balstilimab: A randomized phase II study (TESLA). *First Author: Anup Kasi, University of Kansas Cancer Center, Westwood, KS*

Background: MRD detected by presence of circulating tumor DNA (ctDNA) after intended curative treatment is associated with high risk of relapse in pancreatic cancer. Early treatment of patients with presence of ctDNA after completion of surgery +/- adjuvant therapy may offer an opportunity to clear ctDNA and improve outcomes. TG01 is a RAS-neoantigen peptide vaccine adjuvanted by QS-21 (Stimulon) targeting the seven most frequent codon 12-13 RAS mutations. TG01 has previously demonstrated ability to activate mutant RAS specific CD4+ and CD8+ T-cell responses in vaccinated patients and repeated TG01 dosing in resected pancreatic cancer was found to be well tolerated and associated with a median OS of 33.4 months (95% CI 24.0, 45.8)^{1,2}. Checkpoint inhibitors as single agents have not shown anti-tumor activity in pancreatic cancer, suggesting that a priming agent inducing tumor-specific T-cells may be required to support efficacy. Balstilimab is a human monoclonal antibody targeting programmed cell death protein 1 (PD-1) which is intended to reverse the immunosuppressive effects of this signaling pathway in the context of tumor immuno-surveillance by T-cells. **Methods:** Design: A two-arm, open-label, phase II randomized trial of TG01/QS-21 vaccine or TG01/QS-21 vaccine plus balstilimab (n=12 per arm, N=24) with surgically resected Stage 1-3 RAS mutant PDAC who are MRD+ following completion of standard adjuvant chemotherapy. Assay: MRD is detected by a commercially available ctDNA assay (Signatera, Natera). Somatic variants are identified by whole-exome sequencing of the primary tumor and the matched normal (whole blood) sample and a bespoke assay of up to 16 clonal, somatic variants are generated for each patient. This "tumor signature" will be monitored in plasma throughout the study. Treatment schedule: A priming phase of six vaccine administrations once every two weeks followed by a maintenance phase of administrations once every 8 weeks for up to 51 weeks. Balstilimab will be administered every 2 weeks for up to 51 weeks beginning at week 3. Imaging assessment will be done every 12 weeks. Eligibility: Surgically resected pancreatic adenocarcinoma with pathogenic RAS mutation, and no evidence of recurrent disease on baseline imaging. Inclusion criteria also include ECOG PS 0-1, and positive Signatera ctDNA MRD. Objectives: The primary objective is to assess the 6-month molecular disease control rate as defined by ctDNA stable, decreased or cleared. Secondary objectives include safety of TG01/QS-21 with or without balstilimab, 6 and 12-month DFS rate in each cohort, as well as correlation between the depth of molecular response and DFS. Exploratory: changes in clonality of RAS mutations and assess immune response. Enrollment is ongoing. 1) Gjertsen MK et al. *Int J Cancer* 1997, 72(5) 784-90. 2) Palmer DH et al. *Br J Cancer* 2020 122:971-77. Clinical trial information: NCT05638698. STAR-221: A randomized, open-label, multicenter, phase 3 trial of domvanalimab, zimberelimumab, and chemotherapy versus nivolumab and chemotherapy in previously untreated, locally advanced, unresectable or metastatic gastric, gastroesophageal junction, and esophageal adenocarcinoma. *First Author: Samuel J Klempner, Mass General Cancer Center, Boston, MA*

Background: The addition of programmed cell death/ligand protein 1 (PD-L1) inhibitors to standard chemotherapy has improved outcomes in patients with HER2-negative unresectable or metastatic esophago-gastric adenocarcinomas. Current first-line (1L) treatment for these patients comprises FOLFOX (oxaliplatin, leucovorin, and fluorouracil) and CAPOX (capecitabine and oxaliplatin) chemotherapy, with or without the addition of a PD-1 inhibitor. Domvanalimab (dom) is an Fc-silent humanized IgG1 monoclonal antibody (mAb) that blocks T cell Immunoglobulin and ITIM domains (TIGIT), reducing immunosuppression of T/natural killer (NK) cells and promoting antitumor activity. Zimberelimumab (zim) and nivolumab are mAbs that bind to PD-1 on T/NK cells, preventing the immunosuppressive effects of PD-L1 and leading to enhanced immune-mediated tumor cell death. Prior studies (including ARC-7) have demonstrated that the combination of dom + zim is safe, tolerable, and has promising activity in patients with lung cancer and esophago-gastric cancers. This study will investigate whether adding anti-TIGIT therapy to the standard combination of anti-PD-1 therapy and chemotherapy in patients with locally advanced unresectable or metastatic gastric, GEJ, and esophageal adenocarcinoma provides additional clinical benefit. **Methods:** STAR-221 (NCT05568095) is a global, phase 3, randomized, open-label study. Eligible patients are adults with locally advanced unresectable or metastatic gastric, GEJ, or esophageal adenocarcinoma treated in the 1L setting with ≥1 measurable lesion(s) per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 and an Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1. Patients with known HER2-positive tumors are not eligible. Approximately 970 patients will be randomized 1:1 into 1 of 2 treatment arms. Patients randomized to Arm A will receive either dom 1600 mg + zim 480 mg every 4 weeks (Q4W) in addition to FOLFOX chemotherapy once every 2 weeks (Q2W) or dom 1200 mg + zim 360 mg once every 3 weeks (Q3W) in addition to CAPOX chemotherapy Q3W. Patients randomized to Arm B will receive either nivolumab 240 mg Q2W + FOLFOX Q2W or nivolumab 360 mg Q3W + CAPOX Q3W. Randomization will be stratified by PD-L1 expression (tumor area positivity [TAP] ≥ 5% vs TAP < 5%), ECOG performance status (0 vs 1), and region (USA, Canada, and EU5 countries vs Asia vs rest of world). The dual primary endpoints are overall survival (OS) in the intent-to-treat population and OS in patients with high PD-L1 expression (TAP ≥ 5%). Secondary endpoints include progression-free survival, objective response rate, duration of response, and safety and tolerability. STAR-221 is currently enrolling globally. Clinical trial information: NCT05568095. Research Sponsor: Arcus Biotech.

Oral Abstract Session

Final prespecified overall survival (OS) analysis of CLEAR: 4-year follow-up of lenvatinib plus pembrolizumab (L+P) vs sunitinib (S) in patients (pts) with advanced renal cell carcinoma (aRCC). *First Author: Robert J. Motzer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In the phase 3 CLEAR trial, L+P showed clinically meaningful and statistically significant benefits in PFS (primary endpoint) and OS, and improved ORR compared with S in 1L aRCC (Motzer NEJM 2021). Here, we report 4-yr follow-up results from the final prespecified OS analysis of CLEAR (data cutoff: 31 Jul 2022). **Methods:** Treatment-naïve pts (n=1069) who had aRCC with a clear-cell component were randomized (1:1:1) to receive: L 20 mg PO QD + P 200 mg IV Q3W; or L 18 mg + everolimus 5 mg PO QD; or S 50 mg PO QD (4 wks on/2 wks off). Stratification factors were geographic region and MSKCC prognostic risk group. This final prespecified OS analysis was triggered by ~304 death events in 2 arms. OS, PFS, ORR, duration of response (DOR), and PFS on next-line therapy (PFS2) were assessed for L+P and S. PFS, ORR and DOR were assessed per independent review using RECIST v1.1. Nominal P-values are shown. **Results:** At a median follow-up (IQR) of 49.8 mos (41.4–53.1) for L+P and 49.4 mos (41.6–52.8) for S, 149 and 159 deaths had occurred, respectively. OS benefit with L+P vs S was maintained (HR, 95% CI; 0.79, 0.63–0.99). OS favored L+P vs S across MSKCC risk groups (HR, 95% CI; favorable [fav]: 0.89, 0.53–1.50; intermediate [int]: 0.81, 0.62–1.06; poor: 0.59, 0.31–1.12). PFS benefit of L+P vs S was maintained (HR, 95% CI; 0.47, 0.38–0.57). PFS favored L+P vs S across MSKCC risk groups (HR, 95% CI; fav: 0.46, 0.32–0.67; int: 0.51, 0.40–0.65; poor: 0.18, 0.08–0.42). ORR was greater with L+P (71.3%; complete response [CR], 18.3%) vs S (36.7%; CR, 4.8%) (relative risk, 95% CI; 1.94, 1.67–2.26). Less pts in the L+P arm (181/355, 51.0%) received subsequent anticancer therapies compared with the S arm (246/357, 68.9%); 56 (15.8%) and 195 (54.6%) received PD-1/PD-L1 checkpoint inhibitors, respectively. Analysis of OS adjusted for subsequent therapies will be presented. PFS2 was longer with L+P vs S (43.3 vs 25.9 mos; HR, 95% CI; 0.63, 0.51–0.77). Grade ≥3 treatment-related adverse events occurred in 74.1% and 60.3% pts in the L+P and S arms, respectively. **Conclusions:** L+P continues to demonstrate clinically meaningful benefit vs S in OS, PFS, ORR, and CR in the 1L treatment of pts with aRCC at 4-yr follow-up, thus supporting the robustness of the primary analysis data from CLEAR. Clinical trial information: NCT02811861. Research Sponsor: This study was sponsored by Eisai Inc., Nutley, NJ, USA, and Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Oral Abstract Session

Overall survival (OS) by response to first-line (1L) induction treatment with atezolizumab (atezo) + platinum/gemcitabine (plt/gem) vs placebo + plt/gem in patients (pts) with metastatic urothelial carcinoma (mUC): Updated data from the IMvigor130 OS final analysis. *First Author: Enrique Grande, MD Anderson Cancer Center, Madrid, Spain*

Background: For pts without disease progression during 1L plt-based chemotherapy (chemo), maintenance immunotherapy is a new mUC treatment option. IMvigor130 was a global, randomized Phase III study evaluating 1L atezo + plt/gem (Arm A) vs atezo monotherapy (Arm B) and placebo + plt/gem (Arm C) in patients with mUC (Galsky Lancet 2020). The final analysis showed that improved OS in Arm A vs Arm C of the intention-to-treat (ITT) population did not reach statistical significance (Galsky ASCO 2023). Here we report a post hoc analysis examining OS outcomes by response during atezo/placebo + chemo “induction” based on the final OS analysis. **Methods:** For Arms A and C, per protocol, investigators pre-specified the type of chemo pts received (gem + either cisplatin [cis] or carboplatin [carbo]), which was also a randomization stratification factor. Pts without progressive disease (PD) were allowed to continue atezo or placebo after 4 to 6 cycles of plt/gem. This post hoc analysis evaluated post-induction (Wk 18) OS in pts who completed 4 to 6 cycles of chemo followed by ≥1 dose of atezo or placebo and who had a best response of at least stable disease (SD) without PD at any time (up to and including Wk 18 tumor assessment). Post-progression OS was evaluated in pts who had PD at any time (up to and including Wk 18 tumor assessment). OS analyses by type of chemo were also performed. Multivariable Cox proportional hazards models were used, with HRs adjusted for known prognostic factors (and response for non-PD pts) and stratified by enrollment stage. **Results:** The time from last pt randomized to the data cutoff (Aug 31, 2022) was 49 mo (overall ITT population). OS improvements favoring Arm A vs C appeared greater for pts treated with cis than with carbo. In the cis subgroup, OS rates at 36 mo were 47% (Arm A) and 34% (Arm C) for pts who achieved at least SD during induction. Additional efficacy data are shown. **Conclusions:** In this post hoc analysis, the initial response to induction therapy did not seem to impact OS outcomes. Consistent with prior analyses, these data suggest that cis-treated pts may derive a greater benefit from the addition of atezo than carbo-treated pts. Clinical trial information: NCT02807636. Research Sponsor: F. Hoffman La-Roche.

Oral Abstract Session

Erdafitinib (ERDA) vs ERDA plus cetrelimab (ERDA+CET) for patients (pts) with metastatic urothelial carcinoma (mUC) and fibroblast growth factor receptor alterations (FGFRa): Final results from the phase 2 Norse study. *First Author: Arlene O. Siefker-Radtke, Department of Genitourinary Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: First-line (1L) therapy for cisplatin (cis)-ineligible pts with mUC remains an unmet need and includes alternative chemotherapy or anti-PD-(L)1 monotherapy for PD-L1 positive tumors. FGFRa tumors are enriched for the luminal 1 subtype with lower immune cell infiltrate and potential lower benefit from anti-PD-(L)1 monotherapy. We studied ERDA+CET in 1L, FGFRa, mUC to determine the potential impact in this setting (NCT03473743). **Methods:** Pts aged ≥ 18 y with mUC, susceptible FGFRa and measurable disease (no prior systemic therapy for mUC, cis-ineligible) were randomized 1:1 to once-daily ERDA 8 mg (with pharmacodynamically guided upitration (UpT) to 9 mg) or ERDA 8 mg (no UpT) + IV CET 240 mg every 2 weeks (wks) at cycles 1–4 and 480 mg every 4 wks thereafter. Primary endpoints were investigator-assessed overall response rate (ORR) per RECIST 1.1 and safety; secondary included duration of response (DOR), time to response (TTR), progression free survival (PFS) and overall survival (OS). There were no pre-planned statistical comparisons between treatment arms. **Results:** As of the data cutoff, 87 pts were randomized and treated; 44 to ERDA+CET and 43 to ERDA: median age was 69 vs 72 y; visceral metastases were present in 60.0 vs 63.6%. Median follow-up time was 14.2 months (mo). ORR for ERDA+CET was 54.5% with 6 (13.6%) CRs and 12 mo OS 68%. 11/24 responders were ongoing. ORR for ERDA was 44.2% with 1 CR and 12 mo OS 56%. 9/19 responders were ongoing. 4 pts in each arm were PD-L1 positive. 3/4 (75%) PD-L1 positive pts responded to ERDA+CET vs 0 for ERDA. The most frequent treatment-emergent AEs (any grade) were hyperphosphatemia (68.9 vs 83.7%), stomatitis (59.1 vs 72.1%) and diarrhea (45.5 vs 48.8%) for ERDA+CET and ERDA respectively. Grade ≥ 3 treatment-related AEs occurred in 45.5 (ERDA+CET) and 46.5% (ERDA) of pts. There was one CET-related death in ERDA+CET secondary to pulmonary failure. **Conclusions:** Combination ERDA+CET demonstrated clinically meaningful activity and was well tolerated. These results, in 1L cis-ineligible pts, support previously described activity of ERDA monotherapy in FGFRa mUC. The safety profile was consistent with the known profile for ERDA and CET with no additive toxicity for the combination. Clinical trial information: NCT03473743. Research Sponsor: Janssen Research & Development.

Oral Abstract Session

Adjuvant nivolumab plus ipilimumab vs placebo for patients with localized renal cell carcinoma at high risk of relapse after nephrectomy: Subgroup analyses from the phase 3 CheckMate 914 (part A) trial. *First Author: Robert J. Motzer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In part A of the CheckMate 914 trial, adjuvant nivolumab plus ipilimumab (NIVO+IPI) did not improve disease-free survival (DFS) vs placebo (PBO) in patients (pts) with localized renal cell carcinoma (RCC) at high risk of post-nephrectomy relapse (Motzer RJ, et al. *Lancet* 2023). Exploratory analyses were conducted to better understand outcomes in key pt subsets and with early NIVO+IPI discontinuation. **Methods:** Key study inclusion criteria were radical/partial nephrectomy with negative margins > 4 and ≤ 12 weeks before randomization; predominant clear cell histology; pathological TNM stage T2a (grade [G] 3/4) NOMO, T2b-T4 (any G) NOMO, or any pT (any G) N1M0; and no evidence of residual disease/metastases. Pts in part A were randomized 1:1 to NIVO 240 mg Q2W ($\times 12$) + IPI 1 mg/kg Q6W ($\times 4$) or equivalent PBO for 24 weeks or until recurrence/unacceptable toxicity. Primary endpoint is DFS per blinded independent central review. Exploratory analyses assessed DFS by key subsets including Fuhrman grade, sarcomatoid features (yes/no), PD-L1 expression, and NIVO+IPI exposure (≤ 6 cycles [1–2 IPI doses] vs > 6 cycles [3–4 IPI doses]). Safety was assessed by exposure. **Results:** 816 pts were randomized to adjuvant NIVO+IPI (N = 405) or PBO (N = 411). At 37.0 months median follow-up (min, 15.4 months), subset analyses suggested a DFS benefit for NIVO+IPI vs PBO in pts with Fuhrman grade 4 or sarcomatoid features. DFS by PD-L1 expression will be reported in the presentation. Pts who received > 6 NIVO+IPI cycles trended toward improved DFS vs pts receiving ≤ 6 NIVO+IPI cycles. Of the 102 pts who received ≤ 6 NIVO+IPI cycles, 3% had sarcomatoid features, and 20% had Fuhrman grade 4; treatment discontinuation in these pts was due to study drug toxicity (75%), unrelated adverse events (AEs; 6%), pt request (5%), recurrence (4%), consent withdrawal/non-compliance (4%), or other (6%), and most pts receiving ≤ 6 NIVO+IPI cycles were discontinued without initial dose delay (NIVO, 84%; IPI, 89%). In the group of patients who received ≤ 6 NIVO+IPI cycles, grade 1–2 all-cause AEs were reported in 35% of pts (grade ≥ 3 , 63%) and 31% of pts discontinued treatment due to grade 1–2 all-cause AEs (grade ≥ 3 , 44%). **Conclusions:** Exploratory analyses suggest that tumor grade and sarcomatoid features influence outcomes with adjuvant NIVO+IPI. Limited NIVO+IPI exposure (≤ 6 cycles) and discontinuation for low-grade AEs may have contributed to the lack of DFS benefit observed in CheckMate 914 part A. Clinical trial information: NCT03138512. Research Sponsor: Bristol Myers Squibb.

Oral Abstract Session

Study EV-103 dose escalation/cohort A: Long-term outcome of enfortumab vedotin + pembrolizumab in first-line (1L) cisplatin-ineligible locally advanced or metastatic urothelial carcinoma (la/mUC) with nearly 4 years of follow-up. *First Author: Shilpa Gupta, Cleveland Clinic, Cleveland, OH*

Background: Despite available therapeutic options, which include carboplatin-based chemotherapy, PD-1/PD-L1 inhibitor monotherapies, and avelumab maintenance, there is an urgent unmet need for effective and durable 1L therapies for cisplatin-ineligible patients (pts) with la/mUC. Both enfortumab vedotin (EV) and pembrolizumab (P) show survival benefits as monotherapies for pts with previously treated la/mUC. The combination of EV+P previously showed a manageable safety profile and promising antitumor activity in Study EV-103 Dose Escalation/Cohort A (DE/A) and Cohort K. Here, we report updated safety, efficacy per RECIST v1.1 by BICR, survival data, and subsequent therapies for DE/A after nearly 4 years of follow-up. **Methods:** In DE/A of this ongoing phase 1b/2 study, 1L cisplatin-ineligible pts with la/mUC received 3-week cycles of EV 1.25 mg/kg (Days 1, 8) in combination with P (Day 1). The primary endpoint was safety/tolerability. Key secondary endpoints included confirmed ORR (cORR), DOR, PFS (all per RECIST v1.1 by BICR and investigator), and OS. Safety and subsequent therapy results are also presented. **Results:** As of 16 Sep 2022, 45 pts with 1L la/mUC (median age 69 yrs [51-90]) received treatment. All pts discontinued treatment and 18 pts remain on study (median follow-up of 47 months). The cORR by BICR after a median of 9 cycles was 73.3% (95% CI: 58.1, 85.4), with a DCR of 84.4% (95% CI: 70.5, 93.5) and CR rate of 15.6%. The median DOR was 22.1 months (95% CI: 8.38, -), with a 12-month DOR of 63.9% (95% CI: 44.19, 78.17). The median PFS was 12.7 months (95% CI: 6.11, -), with a 12-month PFS of 55.0% (95% CI: 38.84, 68.58). The median OS was 26.1 months (95% CI: 15.51, -), with a 12-month OS rate of 83.4% (95% CI: 68.25, 91.72). The most common treatment-related adverse events of special interest for EV were skin reactions (66.7%), peripheral neuropathy (62.2%), and ocular disorders (40.0%). The most common treatment-emergent adverse events of special interest for P were severe skin reactions (24.4%), pneumonitis (8.9%), colitis (6.7%), and hypothyroidism (6.7%). Sixty percent of pts received subsequent cancer-related therapies, including systemic therapy (48.9%), surgery (8.9%), and palliative radiotherapy (8.9%). The most common 2L systemic anti-cancer therapies were P (17.8%), carboplatin-based therapy (11.1%), and EV (6.7%). **Conclusions:** EV+P, continues to demonstrate promising survival trends with rapid and durable responses in 1L cisplatin-ineligible pts with la/mUC. The safety profile of the combination is manageable and stable with a longer follow-up, and no new safety concerns have emerged. These results are concordant with previously reported DE/A data by investigator assessment and support the evaluation of EV+P in ongoing phase 3 studies in UC. Clinical trial information: NCT03288545. Oral Abstract Session

SWOG S1011: A phase III surgical trial to evaluate the benefit of a standard versus an extended lymphadenectomy performed at time of radical cystectomy for muscle invasive urothelial cancer. *First Author: Seth P. Lerner, Baylor College of Medicine, Houston, TX*

Background: S1011 tested the hypothesis that an extended lymphadenectomy (ELND) is associated with improved disease-free and overall survival (DFS, OS) compared to standard (S) LND in patients with localized muscle invasive bladder cancer (MIBC) undergoing radical cystectomy (RC)(NCT01224665). **Methods:** Eligible patients with cT2-4a N0-2 were stratified by receipt and type of neoadjuvant chemotherapy (NAC), T2 vs T3-4a and PS 0-1 vs 2. Patients were randomized 1:1 after intraoperative exploration determined they did not have disease outside the pelvis. All patients then underwent a standard bilateral pelvic LND including external and internal iliac and obturator LNs. If randomized to the experimental arm additional ELND up to at least the aortic bifurcation including common iliac (CI), pre-sciatic, and pre-sacral nodes was performed. We hypothesized that patients in the ELND arm would have a 10% improvement in 3-year DFS compared to an estimated 55% for patients in the SLND arm (HR = 0.72). Assuming a 1-sided $\alpha=0.025$ and 85% power, 564 eligible randomized patients were required. Final analysis was to occur at 184 DFS events in the SLND arm or after max follow-up (6 yrs) using a stratified logrank(LR) test with $\alpha=0.022$ to account for interim testing. Hazard ratios from Cox model are adjusted for strat factors. Secondary endpoints included OS and safety. **Results:** 36 surgeons at 27 sites in US and Canada were credentialed prior to enrolling patients, 658 were registered from 8/11-2/17, and 618 eligible patients were randomized to ELND (n=292) or SLND (n=300). Median f/up was 6.1 years in both arms. Median age was 69, 21% female, and 9% non-White. Clinical stage was balanced in both arms: T2 (71%) and T3-4a (29%). NAC was given to 57% in both. Pathologic T stage was <T2 in 39% in S and 37% in E and ³ T2 in 61% and 63%, respectively. Median lymph nodes removed was higher in ELND compared to SLND (41 vs 25), but there was no difference in node metastasis with 26% vs 24%, respectively. More ELND patients had N2 or N3 disease. ELND was associated with increased G3-4 AEs compared to SLND: 16% vs 8%. Deaths within 90 days of RC occurred in 26 (4.4%) patients, including 16 in ELND vs 9 in SLND. There was no difference in DFS between E vs S arms (HR 1.10; 95% CI 0.87, 1.42), 1-sided LR p=0.82. OS results were similar (HR 1.15 95% CI 0.89, 1.48), 1-sided LR p=0.87. **Conclusions:** Patients with MIBC undergoing RC and ELND had increased node yield and higher pathologic N stage, but no significant DFS or OS benefit compared to patients undergoing SLND. ELND was also associated with greater morbidity and higher peri-operative mortality. Clinical trial information: NCT01224665. Research Sponsor: U.S. National Institutes of Health.

Poster Discussion Session

Tumour factors and the variation in non-muscle invasive bladder cancer recurrence after transurethral resection surgery between sites: Results from the RESECT study. *First Author: Fortis Gaba, Department of Health Policy and Management, Harvard School of Public Health, Boston, MA*

Background: To determine if there is significant variation in early recurrence after transurethral resection (TURBT) surgery between sites taking part in the RESECT study (NCT05154084) after accounting for tumour characteristics. **Methods:** An international, multi-centre, observational study. A mixed effects logistic regression model with tumour size, tumour number, tumour grade, tumour stage as fixed effects and site as a random effect was fitted. Cases with first, presumed non-muscle invasive bladder cancer (NMIBC) undergoing TURBT were included. Cases were excluded if first check follow up had not been completed. Sites were excluded if they did not have at least 10 cases with first check follow up. Local and/or national approvals or ethical exemptions were obtained prior to commencing the study at participating sites. **Results:** After exclusions, 186 sites (UK: 80; Europe: 59; North America: 18; Asia: 17; Africa 7; South America: 3; Oceania: 2), contributing a total 4597 cases (average 25 cases) were included. Median recurrence rate per site was 12% (IQR 0-22) for low grade tumours and 27% (IQR 13-42) for high grade tumours. After controlling for tumour size, number, stage and grade (all significantly and independently associated with early recurrence) there was significant residual variation attributable to site ($p<0.0001$, intra-class correlation, 0.1). Adjustment for sites improved the regression model from an area under the receiver operating characteristic curve of 0.66 to 0.74. Initial analysis of surgical and peri-operative practice showed wide variation, mean 75% (IQR 66-92) cases per site had detrusor muscle resection and 42% (IQR 17-58) had use of single instillation of intravesical chemotherapy. Other differences in operative and perioperative practice were identified through surveys. **Conclusions:** There is significant variation in the early recurrence rate of NMIBC after TURBT surgery between sites that could not be explained by currently understood tumour features. We have identified differences in surgical technique and perioperative practice that may impact this and further investigation is warranted to understand how these factors impact recurrence rates. Clinical trial information: NCT05154084. Research Sponsor: The Rosetrees Trust, The Urology Foundation Action Bladder Cancer UK, Karl Storz, Photocure, The British Journal of Urology International Charity.

Long-term outcomes of pembrolizumab (pembro) in combination with gemcitabine (gem) and concurrent hypofractionated radiation therapy (RT) as bladder sparing treatment for muscle-invasive urothelial cancer of the bladder (MIUC): A multicenter phase 2 trial. *First Author: Minas P. Economides, New York University, New York, NY*

Background: Trimodality therapy (TMT) is a standard treatment option for MIUC. We previously reported an early analysis of a phase II study of pembro added to standard TMT with maximal transurethral resection of bladder tumor (TURBT), hypofractionated RT and twice weekly gem (ASCO 2021). Herein we present updated follow up safety and efficacy results. **Methods:** In this multicenter phase 2 trial, patients (pts) with clinical T2-T4aNOMO MIUC who were ineligible for or declined radical cystectomy, had ECOG PS 0/1 and eGFR $\geq$ 30 cc/min were enrolled. Pts received pembro 200 mg IV x 1 followed by maximal TURBT and then whole bladder RT (52 Gy/20 fx) with twice weekly gem 27 mg/m² and pembro Q3 wks x 3 treatments. Response was assessed every 12 weeks post-RT with CT/MRI, tumor bed biopsy and cytology. The primary endpoint was 2-yr bladder-intact disease-free survival (BIDFS); first of MIUC, regional or distant metastases, cystectomy or death). Our study had 85% power to detect a 20% absolute improvement in 2-yr BIDFS rate over 60% historical rate (Mak JCO 2014). Key secondary endpoints included safety, 12-week pathologic complete response (CR) rate, metastases-free survival (MFS) and overall survival (OS). **Results:** Between 5/2016 and 6/2022, 54 pts (median age 74 years, 72% male, 83% Caucasian; clinical stage: 74% T2, 22% T3 and 4% T4) were enrolled at 5 institutions. PD-L1 status was available in 43 pts, and 21 pts (49%) had modified proportion score $\geq$ 10. Forty-six (88%) pts completed all therapy. 1/54 (2%), 3/54 (6%), and 4/54 (7%) discontinued RT/ Gem, Gem or Pembro, respectively, most commonly due to toxicity. 6 pts (11%) underwent salvage cystectomies. As of 6/2022, with a median FU of 23 months (1.6- 62.7) there were 12 (22%) tumor recurrences (3 MIUC, 5 locoregional, 4 distant). 4 pts (7%) had non-muscle invasive only recurrences. The efficacy outcomes are shown. 10 pts died during the study period (18%; 3 from disease progression, 1 from treatment toxicity and 6 from unrelated/ unknown causes). There were no new safety signals in our updated analysis: 13 pts (24%) experienced 17 AEs that were Grade 3 or greater (cytopenias [n=7], colitis [n=5], cystitis [n=2], polyneuropathy, fatigue, hypokalemia [n=1, each]). Grade 3 or greater immune-related AEs included 2 pts with colitis, 1 pt with polyneuropathy and 1 pt with Grade 5 colonic perforation. **Conclusions:** TMT combined with pembro was well tolerated and continues to show promising early outcomes data. A large phase 3 trial is underway to further explore this treatment. Clinical trial information: NCT02621151. Research Sponsor: Merck; pembrolizumab.

Poster Discussion Session

Fibroblast growth factor receptor 3 (FGFR3) alterations in PROOF 302: A phase III trial of infigratinib (BGJ398) as adjuvant therapy in patients (pts) with invasive urothelial carcinoma (UC). *First Author: Petros Grivas, Division of Oncology, Department of Medicine, University of Washington, Fred Hutchinson Cancer Research Center, Seattle Cancer Care Alliance, Seattle, WA*

Background: Radical surgery with or without (neo)adjuvant cisplatin-based chemotherapy [(N)AC] is standard in fit pts with muscle invasive UC of bladder (UBC) or upper tract (UTUC). However, recurrence rates are high, underscoring the need for novel therapies. Since up to 70% of UTUC and 20% of UBC tumors were reported to harbor *FGFR3* alterations, targeting this pathway is a rational approach. Infigratinib is a selective *FGFR1-3* inhibitor with efficacy in advanced UC with *FGFR3* alterations [Pal et al. 2018]. PROOF 302 investigated the efficacy and safety of adjuvant infigratinib vs placebo in pts with high-risk invasive UC. **Methods:** PROOF 302 was a global, randomized, double-blind, placebo-controlled, phase III trial for pts with high-risk invasive UTUC or UBC ($\leq$ 15%) with *FGFR3* alteration (i.e. mutation, gene fusion / translocation) with residual ($\geq$ ypT2 and/or ypN+) tumor after NAC, or pts ineligible for, or refusing, cisplatin-based AC, $\leq$ 120 days post-surgery. Pts were randomized 1:1 to infigratinib 125 mg or placebo daily on days 1–21 every 28 days for up to 52 weeks or until recurrence, unacceptable toxicity, or death. Primary endpoint: centrally reviewed disease-free survival (DFS). Secondary endpoints: investigator-assessed DFS, metastasis-free survival, overall survival, safety/tolerability. Exploratory endpoints: QOL, pharmacokinetics, genomic analysis of tumor and cfDNA. Assessment of genomic alterations was pursued using descriptive statistics. **Results:** We present the results of the genomic analysis of radical surgery tissues from pts screened for the trial using the FoundationOne platform. Out of 617 pts screened, 188 (30.5%) had alterations in *FGFR 1-4* genes: 102/237 (43%) in UTUC, 85/369 (23%) in MIBC and 1/11 (9%) with unknown tumor origin. Of these 188 pts, median age 74 (32-90 years), 76% were male, 55% had UTUC, 44% had UBC. Genomic alterations are shown. In UTUC, *FGFR3* had 56% single-nucleotide variations (SNV) and insertions/deletions (INDELS), 40% amplifications and 70% structural variants (SV). In UBC, *FGFR3* had 44% SNV and INDELS, 60% amplifications and 30% SV. **Conclusions:** *FGFR3* alterations were seen in only 19% of all pts screened for PROOF-302, a trial that was enriched for UTUC: 71/237 (30%) of UTUC and 48/369 (13%) of UBC. The trial was stopped early by the sponsor, but the genomic analysis provides insights into the prevalence of *FGFR3* alterations; assessment of correlations with the primary/secondary endpoints is ongoing. The nature and frequency of co-occurring alterations in tissue samples is being investigated to help inform combination therapy strategies and putative resistance mechanisms. Clinical trial information: NCT04197986. Research Sponsor: QED therapeutics.

Known tumor origin	FGFR 1-4 (%)	FGFR1(%)	FGFR2(%)	FGFR3(%)	FGFR4(%)

Poster Discussion Session

Impact of histology on the efficacy and safety of pembrolizumab (pembro) monotherapy for advanced urothelial carcinoma (UC) in the phase 3 KEYNOTE-045 and KEYNOTE-361 trials. *First Author: Patrizia Giannatempo, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: For patients (pts) with advanced UC, pembro monotherapy has shown antitumor activity as first-line (1L) therapy in the phase 3 KEYNOTE-361 (NCT02853305) study of pembro ± platinum-based chemotherapy (chemo) vs platinum-based chemo and as second-line therapy in the phase 3 KEYNOTE-045 (NCT02256436) study of pembro vs investigator's choice chemo. This exploratory analysis evaluated efficacy and safety of pembro monotherapy by UC histology in KEYNOTE-361 and KEYNOTE-045. **Methods:** KEYNOTE-361 enrolled pts with advanced UC and no prior systemic therapy; KEYNOTE-045 enrolled pts with advanced UC whose disease progressed or relapsed after 1L platinum-based chemo. Pure transitional cell (TC) and mixed predominant TC histology, as assessed by investigator, were allowed. Pembro monotherapy was given at a dose of 200 mg IV Q3W for up to 2 y or until disease progression, unacceptable toxicity, or withdrawal of consent in both studies. End points for this exploratory analysis were ORR, DOR, and PFS per RECIST v1.1 by central radiology assessment, and OS and safety in pts with pure TC or mixed predominant TC allocated to receive pembro monotherapy. **Results:** A total of 307 randomly assigned pts (280 [91.2%] pure TC histology; 27 [8.8%] mixed predominant TC histology) from KEYNOTE-361 and 268 pts (186 [69.4%] pure TC histology; 82 [30.6%] mixed predominant TC histology) from KEYNOTE-045 were included. Median follow-up for both studies was ≥32 mo. PFS, ORR, DOR, and OS for pembro were generally similar in pts with mixed predominant TC histology and pts with pure TC histology. In treated pts, grade 3-5 treatment-related AEs occurred at similar rates in KEYNOTE-361 (17.3% [48/277] pure TC; 18.5% [5/27] mixed predominant TC) and KEYNOTE-045 (16.9% [31/183] pure TC; 17.3% [14/81] mixed predominant TC). **Conclusions:** The observed clinical activity and safety profile of pembro monotherapy was generally consistent irrespective of histology in pts with UC in the KEYNOTE-361 and KEYNOTE-045 studies. Small sample size in some subgroups and limited data available to classify histology subgroups were limitations of this exploratory analysis. Clinical trial information: NCT02256436; NCT02853305. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Outcomes by complete response to first-line pembrolizumab or platinum-based chemotherapy in advanced urothelial carcinoma (UC) in KEYNOTE-361. *First Author: Ozgur Ozyilkan, Adana Baskent Üniversitesi, Adana, Turkey*

Background: In the randomized, open-label, phase 3 KEYNOTE-361 (NCT02853305) study, superior efficacy was not demonstrated with first-line pembrolizumab ± chemotherapy versus chemotherapy in patients with advanced UC. Although not formally tested, survival outcomes appeared similar with pembrolizumab monotherapy versus chemotherapy (hazard ratio [HR] 0.92; 95% CI, 0.77-1.11). This post hoc exploratory analysis examined efficacy outcomes in patients with complete response (CR) to pembrolizumab or chemotherapy in KEYNOTE-361. **Methods:** Patients with advanced UC were randomly assigned 1:1:1 to receive first-line pembrolizumab (200 mg IV every 3 weeks for up to 2 years) ± chemotherapy (1000 mg/m² gemcitabine on day 1 and day 8 + cisplatin [70 mg/m²] or carboplatin [area under the concentration curve of 5 mg/ml/min] on day 1 of each 3-week cycle) or chemotherapy alone. Patients were stratified by PD-L1 combined positive score (≥10 vs <10) and investigator's choice of platinum (cisplatin vs carboplatin). End points of this post hoc exploratory analysis were duration of response (DOR) and progression-free survival (PFS) by RECIST v1.1 by blinded independent central review and overall survival (OS) in patients who achieved a CR in the pembrolizumab monotherapy or chemotherapy arms. **Results:** Overall, 34 of 307 patients (11.1%) in the pembrolizumab arm and 43 of 352 patients (12.2%) in the chemotherapy arm had a CR. Median follow-up (time from randomization to the data cutoff date) for patients with CR was 30.7 months (range, 22.6-42.3). Median DOR was not reached (NR; range, 4.4+ to 36.1+ months) in the pembrolizumab arm and 12.8 months (range, 2.1+ to 36.3+) in the chemotherapy arm; 75.5% and 37.1% of patients, respectively, remained in CR for ≥24 months. Median PFS was NR (95% CI, 30.3-NR) with pembrolizumab and 15.1 months (95% CI, 8.8-NR) with chemotherapy (HR, 0.32 [95% CI, 0.15-0.70]). The estimated 24-month PFS rates were 75.5% and 42.2% in the pembrolizumab and chemotherapy arms, respectively. Median OS was NR (95% CI, NR-NR) with pembrolizumab and NR (95% CI, 25.1-NR) with chemotherapy (HR, 0.20 [95% CI, 0.06-0.70]). The estimated 24-month OS rates were 94.1% and 69.5% in the pembrolizumab and chemotherapy arms, respectively. Overall, 9 patients (26.5%) in the pembrolizumab arm and 21 patients (48.8%) in the chemotherapy arm experienced disease progression after an initial CR. Among patients who achieved CR, 2 patients (5.9%) in the pembrolizumab arm and 22 patients (51.2%) in the chemotherapy arm received subsequent therapy. **Conclusions:** This post hoc exploratory analysis suggests CRs with pembrolizumab were more durable than CRs with chemotherapy in patients with advanced UC, with corresponding longer PFS and OS. Further investigation into patient selection is needed to determine which patients could benefit most from first-line pembrolizumab. Clinical trial information: NCT02853305. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Safety analysis by UGT1A1 status of TROPHY-U-01 cohort 1, a phase 2 study of sacituzumab govitecan (SG) in patients (pts) with metastatic urothelial cancer (mUC) who progressed after platinum (PT)-based chemotherapy and a checkpoint inhibitor (CPI). *First Author: Yohann Lloriot, Institut de Cancérologie Gustave Roussy, Université Paris-Saclay, Villejuif, France*

Background: SG, a Trop-2-directed antibody-drug conjugate, was granted FDA accelerated approval for pts with mUC previously treated with PT-based chemotherapy and a CPI. Approval was based on the pivotal TROPHY-U-01 Cohort 1 study of 113 pts, where SG demonstrated an objective response rate (ORR) of 27%, a median overall survival (OS) of 10.9 mo, and a manageable safety profile (median follow up 9.1 mo [range, 0-19.9], Tagawa et al. JCO 2021). A phase 3 confirmatory study TROPIC-04 (NCT04527991) is ongoing. Here, we report updated safety outcomes by UGT1A1 status. **Methods:** Cohort 1 pts were ≥18 y, had progression of UC following PT and a CPI, and ECOG PS 0-1. Pts received SG 10 mg/kg on D1 and D8 of 21-D cycles (growth factor was allowed per investigator discretion). The primary endpoint was ORR per central review by RECIST 1.1. Post hoc safety analyses were exploratory with descriptive statistics reported. **Results:** As of July 26, 2022, the median follow-up was 10.5 mo (range, 0.3-40.9) for treated pts (N=113). As previously reported, pts were heavily pretreated with a median of 3 prior therapies (78% male; median age 66 y; 66% with visceral metastases). Known baseline comorbidities included chronic kidney disease (12%), coronary artery disease (10%), myocardial infarction (8%), and diabetes mellitus II (8%). Grade (Gr) ≥3 treatment-related adverse events (TRAEs) occurrence and treatment-related discontinuation were consistent with prior reports. In total, 94% of treated pts (n=106) had evaluable UGT1A1 status (wild-type [*1]*11, n=45 [42%]; heterozygous [*1]*28, n=47 [44%]; and homozygous [*28]*28, n=14 [13%]). Gr ≥3 TRAEs occurred in 62% of wild-type, 60% of heterozygous, and 79% of homozygous pts. The incidence of treatment-related any Gr diarrhea was 53%, 72%, and 71%, respectively; any Gr neutropenia was 38%, 55%, and 50%, respectively; and any Gr anemia was 38%, 32%, and 29%, respectively. The incidence of treatment-emergent Gr ≥3 diarrhea was 4%, 15%, and 7%, respectively; Gr ≥3 neutropenia was 31%, 36%, and 50%, respectively; and Gr ≥3 anemia was 13%, 19%, and 29%, respectively. TRAEs led to SG discontinuation in 7%, 6%, and 14% of pts with wild-type, heterozygous, and homozygous status, respectively; incidence of SG interruption was 42%, 43%, and 71%, respectively and incidence of SG dose reduction was 38%, 34%, and 43%, respectively. **Conclusions:** With longer follow-up, SG safety profile was consistent with prior reports. The incidence of adverse events varied across UGT1A1 subgroups, with dose interruptions being more frequently observed in homozygous pts. This was an exploratory analysis with relatively low numbers in each subgroup. Additional studies are needed to confirm the impact of UGT1A1 status on safety outcomes with SG in UC. Clinical trial information: NCT03547973. Research Sponsor: Gilead Sciences, Inc.

Poster Discussion Session

Estimated net benefit of avelumab (AVE) + best supportive care (BSC) vs BSC alone for patients (pts) with advanced urothelial carcinoma (aUC) using a quality-adjusted time without cancer symptoms or toxicity (Q-TWiST) analysis. *First Author: Thomas Powles, Barts Cancer Institute, Experimental Cancer Medicine Centre, Queen Mary University of London, St. Bartholomew's Hospital, London, United Kingdom*

Background: The JAVELIN Bladder 100 (JB-100) trial (NCT02603432) showed that treatment with AVE first-line maintenance (1LM) + BSC significantly prolonged overall survival (OS) and progression-free survival (PFS) vs BSC alone in pts with aUC that had not progressed after 1L platinum-based chemotherapy. Safety and patient-reported outcomes (PROs) were previously reported. This post hoc analysis used JB-100 data to assess between-treatment differences using a Q-TWiST analysis, an integrated measure that incorporates efficacy, safety, and PROs into a single value. **Methods:** Mean OS was partitioned into 3 health states: time with all-cause grade ≥3 toxicity (TOX) prior to progression, time without all-cause grade ≥3 toxicity or symptoms of disease progression (TwIST), and time after progression or relapse (REL). To ensure equal observation time for each arm, analysis time was restricted to a period of 47.7 months from randomization, which was the shorter follow-up time between arms. A range of utility values were explored and weighted by the time in each health state then summed to estimate Q-TWiST to account for differences in quality of life. Mean between-treatment differences for each health state were also calculated. Bootstrap methods were used to estimate CIs for means and difference between means. **Results:** Time in TOX was slightly longer with AVE + BSC vs BSC alone; however, time spent in TwIST was much longer with AVE + BSC. Time in REL with AVE + BSC appears shorter vs BSC alone because pts experienced more time in the progression-free state, which led to less time in REL. Regardless of the range of utility values explored for each health state, the Q-TWiST estimate was always longer with AVE + BSC, with mean differences ranging from 3.7 to 7.1 months (95% CI not including 1). **Conclusions:** Pts receiving AVE + BSC demonstrated a consistently longer Q-TWiST (vs BSC alone), indicating a net benefit. Pts receiving AVE + BSC achieved greater quality-adjusted time by progressing more slowly (shorter REL) and living longer (greater OS). The Q-TWiST advantage reflects the safety profile of AVE in the context of a survival benefit. Restricted health state durations in months (mean, 95% CI). Clinical trial information: NCT02603432. Research Sponsor: This study was sponsored by Pfizer, as part of an alliance between Pfizer and the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

	AVE + BSC n=350	BSC alone n=350	AVE + BSC - BSC alone
TOX	1.81 (1.346, 2.196)	1.19 (0.761, 1.602)	0.61 (-0.013, 1.204)
TwIST	11.98 (10.722, 13.202)	5.52 (4.516, 6.530)	6.46 (4.824, 8.114)
REL	12.99 (11.821, 14.087)	16.72 (14.495, 16.993)	-2.74 (-4.593, -1.195)
PFS	13.79 (12.446, 15.102)	6.71 (5.771, 7.631)	7.07 (5.367, 8.802)

Poster Discussion Session

Long-term safety of avelumab first-line (1L) maintenance for advanced urothelial carcinoma (aUC) in the JAVELIN Bladder 100 trial. *First Author: Joaquim Bellmunt, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: In the phase 3 JAVELIN Bladder 100 trial (NCT02603432), patients (pts) with aUC without progression after 1L platinum-based chemotherapy had significantly prolonged overall survival and progression-free survival with avelumab 1L maintenance + best supportive care (BSC) vs BSC alone. The safety profile of avelumab 1L maintenance was consistent with prior avelumab monotherapy studies, with no new safety signals identified and no detrimental impact on quality of life. Results led to the adoption of avelumab 1L maintenance into international guidelines as standard of care. We report post hoc safety analyses after a minimum 2 years of follow-up. **Methods:** Eligible pts had unresectable locally advanced or metastatic UC without progression after 1L platinum-based chemotherapy. Here, pts who received treatment in the avelumab + BSC arm were analyzed. Trial treatment continued until confirmed progression, unacceptable toxicity, or withdrawal of consent. **Results:** At data cutoff (June 4, 2021), median follow-up in the avelumab arm was 38.0 months. In 344 pts who received ≥ 1 dose of avelumab, median treatment duration was 5.8 months (range, 0.5-49.7) and median number of infusions was 11.5 (range, 1.0-106.0). Treatment-related adverse events (TRAEs) of any grade occurred in 269 pts (78.2%). Grade ≥ 3 TRAEs occurred in 67 pts (19.5%); the most common ($>2\%$) were lipase increased (n=12; 3.5%) and amylase increased (n=8; 2.3%). 40 pts (11.6%) had a TRAE that led to avelumab discontinuation. Immune-related AEs (irAEs) occurred at any grade in 111 pts (32.3%) and at grade ≥ 3 in 26 (7.6%). The most common categories of irAEs (any grade in $>5\%$) were thyroid disorders (n=44; 12.8%) and immune-related rash (n=37; 10.8%); the most common categories of grade ≥ 3 irAEs ($>1\%$) were immune-related rash and hepatitis (each n=5; 1.5%). Serious irAEs occurred in 18 pts (5.2%), of which immune-related nephritis/renal dysfunction (n=4; 1.2%) was the most common category. 21 pts (6.1%) had an irAE that led to avelumab discontinuation; the most common categories ($>1\%$) were immune-related hepatitis and nephritis/renal dysfunction (each n=4; 1.2%). Among 118 pts treated with avelumab for ≥ 12 months, irAEs occurred after 12 months in 27 pts (22.9%), including grade ≥ 3 irAEs in 5 (4.2%). The most common category of irAEs occurring after 12 months (any grade in $>5\%$) was immune-related rash (n=12; 10.2%). No category of grade ≥ 3 irAEs occurred after 12 months in >1 pt. **Conclusions:** Post hoc analyses from JAVELIN Bladder 100 confirm the acceptable long-term safety profile of avelumab 1L maintenance. Grade ≥ 3 TRAEs or irAEs occurred in relatively low proportions of pts, and no new safety signals were identified with longer treatment. These results further support the use of avelumab 1L maintenance until progression as standard of care for pts with aUC without progression after 1L platinum-based chemotherapy. Clinical trial information: NCT02603432. Research Sponsor: This study was sponsored by Pfizer, as part of an alliance between Pfizer and the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009945).

First-line lenvatinib + pembrolizumab treatment across non-clear cell renal cell carcinomas: Results of the phase 2 KEYNOTE-B61 study. *First Author: Chung-Han Lee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Lenvatinib (lenva) + pembrolizumab (pembro) is a first-line treatment for advanced clear cell renal cell carcinoma (RCC). Initial results of the single-arm, phase 2 KEYNOTE-B61 (NCT04704219) study showed antitumor activity of lenva + pembro in patients (pts) with advanced non-clear cell RCC who had opportunity for ≥ 24 wk of follow-up (n=82). We report results from the complete cohort of pts enrolled in KEYNOTE-B61 (N=158) with extended follow-up. **Methods:** Adults with previously untreated advanced non-clear cell RCC and measurable disease per RECIST v1.1 received lenva 20 mg PO QD + pembro 400 mg IV Q6W for up to 18 cycles (~2 y). The primary end point was ORR per RECIST v1.1 by blinded independent central review (BICR). Secondary end points included DOR, DCR, and PFS per RECIST v1.1 by BICR; OS; and safety. Histology was assessed by investigator (assessment by central review is planned). **Results:** Of 158 treated pts, 93 (59%), 29 (18%), and 21 (13%) had papillary, chromophobe, and unclassified histology, respectively. Additionally, 6 pts (4%) had translocation and 9 (6%) had other histology. 70 pts (44%) had IMDC favorable risk and 88 (56%) had intermediate/poor risk. Median follow-up was 14.9 mo (range 8.7-19.7). ORR was 49% (95% CI, 41-57; 9 CRs [6%]; 69 PRs [44%]). DCR was 82% (95% CI, 75-88). Median DOR was not reached (NR; range, 1.5+ to 15.3+ mo). By Kaplan-Meier estimate, 75% of responders had a response for ≥ 12 mo. ORR and DCR by histology are shown in the table. For the IMDC favorable risk group, ORR was 51% (95% CI, 39-64) and DCR was 87% (95% CI, 77-94). For the IMDC intermediate/poor risk group, ORR was 48% (95% CI, 37-59) and DCR was 78% (95% CI, 68-86). In all pts, median PFS and OS were 17.9 mo (95% CI, 13.5-NR) and NR (95% CI, NR-NR), respectively; 12-mo rates were 63% and 82%. Treatment-related AEs (TRAEs) occurred in 149 pts (94%) and were consistent with results from other studies. The most common ($\geq 30\%$) TRAEs were hypertension (n=90; 57%), diarrhea (n=69; 44%), and hypothyroidism (n=58; 37%). Grade 3-4 TRAEs occurred in 81 pts (51%). Overall, 17 pts (11%) discontinued pembro, 14 (9%) discontinued lenva, and 5 (3%) discontinued both drugs because of TRAEs. No deaths occurred because of TRAEs. **Conclusions:** In pts with advanced non-clear cell RCC enrolled in KEYNOTE-B61, lenva + pembro showed antitumor activity with no new safety signals. These data support the use of lenva + pembro as first-line treatment for pts with non-clear cell RCC, regardless of histology. Clinical trial information: NCT04704219. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA and Eisai Inc., Nutley, NJ, USA.

The impact of surgery on patients with VHL-associated tumors: An international patient survey. *First Author: Murali Sundaram, Merck & Co., Inc., Rahway, NJ*

Background: Von Hippel-Lindau syndrome (VHL) is a rare hereditary neoplastic disorder caused by mutations in the *VHL* gene. Treatment (tx) options for patients are limited to multiple surgeries dispersed between regular scans, watchful waiting and txs that preserve organ function. **Methods:** An international, cross-sectional survey comprising patients in the United States (US), Canada (CA), the United Kingdom (UK), France (FR), and Germany (DE) was conducted. Patients were recruited via the VHL Alliance; data were collected between Dec 2021 and May 2022. For inclusion, patients must have renal cell carcinoma (RCC), pancreatic neuroendocrine tumors (pNET), and/or central nervous system hemangioblastoma (CNS-Hb). Data collected included demographics, impact of most recent surgery on aspects of condition (1-7 scale 1 being greatly worsened and 7 being greatly improved), tx goals (top 3 goals from a list of 11), and patient preference in treatment. Patients were presented two scenarios "watch and wait" and potentially need surgery, or "take a once-daily pill" to delay a potential surgery. **Results:** 220 patients (68.2% female, median age 40.0, median disease duration 15.8 years) in the US (n=108), CA (n=37), the UK (n=21), FR (n=3), and DE (n=51) completed the study. 146 patients reported RCC (66.4%), n=122 reported pNET (55.5%), and n=190 reported CNS-Hb (86.4%). Among the top 4 symptoms experienced by patients were kidney cysts (n=82, 37.3%), numbness (n=59, 26.8%), dizziness (n=56, 25.5%), and fatigue/low energy (n=54, 24.5%). 205 (93.2%) patients had experienced surgery; n=171 (77.7%) had experienced multiple surgeries (median number of surgeries, 4.0). 166 patients recorded data on their most recent surgery. Of these, patients reported that their most recent surgery worsened (scored 1-3) their fatigue (51.8%), mental health (51.2%), and ability to go about daily life (45.2%). 47.3% of patients selected reduce the number of surgeries as a top tx goal, 46.4% selected being able to go about life as usual, 36.8% delay the need for surgery, and 33.2% improved quality of life. 73% of patients indicated they would prefer to take a pill which would possibly delay the time until surgery, rather than watch and wait to see if the tumor would grow. **Conclusions:** Surgery negatively impacts the lives of patients, leading to a worsening in their fatigue, mental health, and ability to go about daily life. Almost half of patients would like a treatment that reduces the number of surgeries, and over a third would like a treatment that delays the need for surgery. Nearly three quarters of patients would prefer to take a pill that might delay the need for surgery. Tx options that reduce the need for surgery would benefit this patient group. Poster Discussion Session

Efficacy of first-line (1L) immunotherapy (IO)-based regimens in patients with sarcomatoid and/or rhabdoid (S/R) metastatic non-clear cell renal cell carcinoma (nccRCC): Results from the International Metastatic Renal Cell Carcinoma Database Consortium (IMDC). *First Author: Chris Labaki, The Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute and Brigham and Women's Hospital, Boston, MA*

Background: Patients with advanced RCC with S/R components exhibit poor clinical outcomes. IO-based combination therapies demonstrated substantial efficacy among patients with metastatic S/R ccRCC, compared to VEGF targeted therapy (VEGF-TT). Recent trials showed promising activity of IO-based regimens in patients with advanced nccRCC. We sought to assess the efficacy of IO regimens among patients with S/R nccRCC. **Methods:** Patients with advanced nccRCC treated with 1L IO regimens (IO/IO or IO/VEGF-TT) or 1L VEGF-TT monotherapy (sunitinib or pazopanib) were included. Cases were categorized as S/R or non-S/R. The primary outcomes were overall survival (OS) and time to treatment failure (TTF) in patients with S/R nccRCC receiving 1L IO or VEGF-TT. Overall response rate (ORR) was a secondary outcome. OS and TTF were compared between groups (IO vs. VEGF-TT) using Cox regression models adjusted for age, IMDC risk groups, and nccRCC subtype. ORR was compared between groups (IO vs. VEGF-TT) using a logistic regression adjusted for the same confounders. **Results:** Overall, 103 patients with S/R nccRCC were included, of whom 33 (32%) received 1L IO regimens. Median follow-up was 31 months. After adjustment for confounding factors, patients with S/R nccRCC treated with IO regimens presented with significantly improved survival outcomes as compared to those receiving VEGF-TT (median OS [mOS]: NR vs. 7.1 and mTTF: 9.4 vs. 2.9 mos for IO regimens and VEGF-TT, respectively). Similarly, a higher ORR was seen in patients with S/R nccRCC receiving IO regimens versus VEGF-TT (34.1 vs. 10.9%, respectively). Among 430 patients with non-S/R nccRCC (IO regimens: n=44), no significant differences in survival outcomes between regimen classes were seen (mOS: 24.4 vs. 14.8 and mTTF: 4.2 vs. 5.0 mos for IO regimens and VEGF-TT, respectively). **Conclusions:** To our knowledge, this represents the largest effort to characterize the outcomes of patients with S/R nccRCC treated with IO regimens. Patients with S/R nccRCC appear to derive a substantial and selective benefit from IO regimens (vs. VEGF-TT). These data support the use of IO-based regimens in patients with S/R nccRCC. Research Sponsor: None.

Phase II study of cabozantinib (Cabo) with nivolumab (Nivo) and ipilimumab (Ipi) in advanced renal cell carcinoma with variant histologies (RCCvh). First Author: Bradley Alexander McGregor, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: New therapeutic approaches in RCCvh are needed. Herein, we report on treatment intensification with the combination of Cabo/Nivo/Ipi in patients with metastatic RCCvh in a multi-institutional prospective single arm phase II trial. (NCT04413123). **Methods:** Eligible patients (pts) had metastatic RCCvh with ECOG performance status of 0-1 and may have received one line of prior therapy excluding immunotherapy or Cabo. Pts underwent a baseline biopsy and received treatment with Nivo 3 mg/kg and Ipi 1 mg/kg intravenously Q3 weeks (W) for 4 cycles followed by Nivo 480 mg IV Q4W. Cabo was given continuously at dose of 40 mg daily; reductions to 20 mg daily and 20 mg every other day were allowed. The primary endpoint was objective response rate (ORR) by RECIST 1.1. Safety was a secondary endpoint. **Results:** 40 pts have been enrolled. At the time of data cut-off (Dec 9, 2022), 38 pts received at least 1 study drug. 11% (n=4) pts received prior systemic therapy. 45% (n=17) received all 4 doses of Nivo and Ipi; 18% (n=7) received 3 and 37% (n=14) received ≤ 2 doses. 61% (n=23) (15 of whom received 4 cycles Nivo/Ipi) received Nivo maintenance (median number of cycles, 5 (range, 1-21)). 71% (n=27) and 13% (n=5) required Cabo dose reduction to 20 mg and 20 mg every other day, respectively. Median follow-up was 8.4 (range, 2.1-23) months. Objective response was achieved in 8 pts (ORR 21%, two-sided 80% CI, 13%-32%). Median duration of response was not reached with 5 pts maintaining response > 6 months. Median progression-free survival was 8.9 (95% CI, 4.2-12.7) months. 74% (n=28) developed treatment-related grade 3 or higher toxicities; 37% (n=14) developed $\geq$ grade 3 elevation in AST or ALT. 29% (n=11) required high dose steroids (prednisone ≥ 40 mg daily or equivalent). 13% (n=5) discontinued all study drugs due to toxicity. No grade 5 toxicity has been reported. **Conclusions:** The study suggests activity for this combination in patients with RCCvh particularly among those without chromophobe histology. An additional cohort of 20 pts is enrolling with Cabo starting dose of 20 mg daily. Clinical trial information: NCT04413123. Research Sponsor: Exelixis, BMS.

Effect of KDR mutations on efficacy of immune checkpoint inhibitors in patients with bladder cancer. First Author: Honghai Dai, Shandong Provincial Hospital, Jinan, Shandong, China

Background: KDR (kinase insert domain receptor) is the most important VEGF (vascular endothelial growth factor) receptor that mediates the signaling transduction initiated by the VEGF ligands. VEGF signaling can activate angiogenesis which plays a crucial role in tumor growth, metastasis, and treatment response. Here we explore the relationship between KDR mutation and its efficacy of immune checkpoint inhibitors (ICIs) in patients with bladder cancer. **Methods:** To explore the association between KDR mutations and the efficacy of ICIs in bladder cancer patients, we collected clinical and mutation data of 215 patients who received ICIs (PD-(L)1 and/or CTLA-4 inhibitors) from MSKCC cohort. Gene expression data and WES mutation data of 413 samples in the TCGA database were obtained from the UCSC Xena for analysis of the differences of potential biological mechanisms between KDR-mutant and KDR-wildtype tumors. TMB was calculated as the total number of somatic non-synonymous mutations per megabase. CIBERSORT was applied to infer 22 immune cell type proportions in TCGA advanced bladder cancers. **Results:** In MSKCC cohort, we observed 5.6% (12/215) samples had KDR mutation. Survival analysis showed that KDR-mutant patients had longer overall survival (OS) than that of wildtype patients (hazard ratio (HR) = 0.27, 95% CI: 0.07-1.09, logrank test P = 0.048); median OS (not reached versus 15 months). Then we compared the TMB between KDR-mutant and KDR-wildtype tumors, the results showed that KDR-mutant group had higher TMB in MSKCC cohort (median [IQR]: 17.58 [11.64-47.81] versus 7.90 [4.92-14.76], P=0.002) and TCGA cohort (median [IQR]: 10.69 [5.87-19.85] versus 4.60 [2.52-8.08], P=0.001). Analysis of 22 immune cell subsets in the TCGA advanced bladder cancers, B cells naive, plasma cells and macrophages M1 were significantly abundant in KDR-mutant tumors (all P < 0.05). **Conclusions:** In ICI-treated bladder cancers, KDR mutation is associated with prolonged OS, higher TMB and activated antitumor immunity, which suggests that KDR mutation may serve as a potential biomarker to guide ICI therapy in bladder cancer. Age-, sex-, and race-related differences in outcomes of patients with muscle-invasive bladder cancer treated with radical cystectomy: The role of biology versus access to standard medical care. First Author: Akshay Sood, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: It remains unclear whether the poor outcomes associated with older age, female sex, and African-American (AA) race in patients with muscle-invasive bladder cancer (MIBC) treated with surgery are due to differential access to standard medical care or intrinsic differences in tumor biology. **Methods:** We designed an integrative study using two complementary datasets to answer our question. We used the SEER-Medicare MIBC dataset (n=2,327) to evaluate the real-world differences in survival outcomes among patients of female v male sex, AA v Caucasian race, and older v younger age before and after adjusting for demographic, tumor, treatment, and access-to-care factors. Next, we used The Cancer Genome Atlas (TCGA) project's MIBC dataset (n=410) to evaluate the biological differences in molecular profiles of bladder tumors in these patient groups. Biological endpoints examined included DNA-level genomic alterations, mRNA expression subtypes, and RPPA-derived proteomic profiles, and clinical endpoints assessed included unadjusted and adjusted cancer-specific mortality (CSM) outcomes. Multivariable GLM, multivariate MMLR, and Fine-Gray competing-risk models were used. **Results:** Population-level analysis demonstrated that patients of female sex (10-y CSM: 51.3% v 43.8%, Gray's p<0.001), AA race (10-y CSM: 56.2% v 46.1%, Gray's p=0.022) and older age (10-y CSM: 47.8% $\geq$ 81 y v 44.1% $\leq$ 70 y, Gray's p=0.032) had worse CSM at presentation. In adjusted analyses, however, only female sex remained associated with worse CSM (HR=1.17, p=0.028). The TCGA analysis revealed that advanced age was associated with increased total mutational burden and neoantigen load, both of which have been associated with improved survival. No other age-related differences were seen in other DNA alterations, mRNA expression subtype distribution, or RPPA proteomic cluster profiles. Similarly, no racial differences were observed in molecular alterations either at the DNA-, RNA-, or protein-level. However, females were noted to have adverse molecular profiles across all levels of molecular expression i.e. DNA-, RNA-, and proteomic-level. Specifically, females were noted to have lower total mutational burden (in stage 3-4 cancers, median 170 v 240, p=0.01), lower neoantigen load (in stage 3-4 cancers, median 382 v 551, p<0.01), higher Msi2 DNA mutational signature (in stage 3-4 cancers, 65.3% v 50.5%, p=0.04), higher basal/sq mRNA subtype (in stage 3-4 cancers, 52% v 34.2%, p=0.02), and lower RPPA cluster1 subtype (in stage 2 cancers, 15.2% v 36%, p<0.01). **Conclusions:** Our findings suggest that the poor outcomes seen among patients of AA race and older age in the real-world are likely driven by multilevel biases in healthcare delivery, while in women they may be a result of a combination of biological and access-to-care factors. Prognostic significance of pretreatment immune cell infiltration in muscle-invasive bladder cancer treated with definitive chemoradiation: Analysis of NRG RTOG 0524 and 0712. First Author: Matthew Pierre Deek, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ

Background: Chemoradiation therapy (CRT) is an organ conserving approach in the treatment of locally advanced bladder cancer. Chemoradiation is thought to potentially result in immunogenic stimulation, and bladder cancer is often a tumor with high immune cell infiltration. Thus, we aimed to profile the tumor immune microenvironment of bladder cancer and identify prognostic immune biomarkers for CRT response by profiling tumor samples from NRG/RTOG 0524 and 0712, two prospective trials of CRT in muscle-invasive bladder cancer (MIBC). **Methods:** Pretreatment tissue samples from both trials were profiled using Cofactor Genomics ImmunoPrism, an RNA sequencing assay that uses gene expression profiles to quantify immune cell populations in the tumor microenvironment (TME). Differential gene expression was estimated for different immune cell type proportions across samples. Kaplan-Meier survival analysis and log rank tests were performed to evaluate differences in overall survival (OS) stratified by genes influenced by immune cell proportions or genes associated with immune response signatures. **Results:** A total of 70 samples (43 from RTOG 0524 and 27 from RTOG 0712) underwent analysis using the ImmunoPrism assay. Immune cell proportions were as follows: CD8 T cells: median 1.2%, CD4 T cells: median 0.8%, Treg cells: median 9.2%, CD19 B cells: median 5.1%, M2 macrophages: median 0.8%, M1 macrophages: median 0%. Unbiased clustering based on gene expression profiles driven by immune cell proportions demonstrated two groups: cluster 1 with a low percentage of immune cells and shorter OS (median 31 months) and cluster 2 with a high percentage of immune cells and longer OS (median 101 months, p = 0.036). Higher expression of genes associated with T cell infiltration (CD8A and ICOS) was associated with improved OS (104 vs 35 months, p = 0.028, HR = 0.48 (0.25 - 0.94), p = 0.031) as was higher expression of IDO1, which is associated with the interferon gamma pathway (104 vs 35 months, p = 0.042, HR = 0.49 (0.24 - 0.99), p = 0.046). **Conclusions:** Bladder tumors have a wide range of immune cell infiltration in the TME. Increased immune cell proportions are prognostic for OS following CRT, as well as a higher expression of genes associated with T cell infiltration interferon gamma signaling. These findings have implications for the integration of immunotherapy in the definitive management of MIBC; and can be explored further in the ongoing NRG/SWOG 1806 trial. Research Sponsor: NRG.

Determinants of resistance to nivolumab (nivo) monotherapy investigated through genomic and transcriptomic analysis of renal cell carcinoma (RCC) tumors from the HCRN GU16-260 study. *First Author: David A. Braun, School of Medicine, Yale University, New Haven, CT*

Background: Nivo monotherapy demonstrated anti-tumor activity in treatment-naïve RCC in Part A of HCRN GU16-260 across all IMDC groups and in multiple histologies. Patient tumor samples were collected to characterize the tumor-immune microenvironmental determinants of effective anti-tumor immunity with nivo. **Methods:** Whole exome sequencing (WES) was performed on formalin-fixed, paraffin-embedded tissue collected within one year prior to nivo. For single-cell RNA-sequencing (scRNA-seq), eligible patients (pts) with any RCC histology underwent tumor biopsy prior to and/or at resistance to nivo monotherapy. Gene expression signatures discovered through scRNA-seq were used to interrogate previously published bulk transcriptomic data of nivo in the treatment-refractory setting. **Results:** WES analysis (n = 96 tumors) identified recurrent focal amplifications within chromosome 11q13 (amp11q13), which was observed in 6 of 18 (33.3%) of tumors from pts with progressive disease (PD) compared to 0 of 20 (0%) of tumors from pts with complete or partial response (CR/PR; p = 0.005). amp11q13 was associated with worse progression free survival (PFS; p = 0.008) and overall survival (OS; p = 0.010). ScRNA-seq was performed on tumors from 17 pts (8 with baseline only, 7 with progression only, and 2 with paired baseline and progression samples) across 7 trial sites. Trajectory inference analysis of tumor-infiltrating T cells revealed a bifurcating structure, starting with naïve T cells and ending either in terminally exhausted CD8+ T cells or *SLAMF7*+ CD8+ T cells. Surprisingly, the *SLAMF7*+ T cell population expressed high levels of cytotoxic genes (including *GZMA*, *GZMB*, *GNLY*) and markers of tissue residency (*ZNF683*/HOBIT and *ITGAE*/CD103). Of the 14 pts with at least 100 sequenced tumor-infiltrating T cells, the presence of a higher percentage of *SLAMF7*+ CD8+ T cells (relative to total T cells) was associated with primary resistance to nivo (mean percentage in PD [n = 4] pts 32.7%; stable disease [n = 4] pts, 9.1%; CR/PR [n = 6] pts, 2.2%; p = 0.019 for CR/PR vs PD). Of 172 pre-treatment tumors from the nivo arms of the CheckMate-009/010/025 trials that we analyzed by bulk RNA-seq, a signature score derived using genes expressed in the *SLAMF7*+ CD8+ T cell trajectory branch was enriched in pts with PD compared to CR/PR as best response (p = 0.032). **Conclusions:** Bulk genomic and single-cell transcriptomic analyses uncovered somatic alterations (amp11q13) and infiltrating T cell populations (*SLAMF7*+ CD8+) associated with resistance to frontline nivo monotherapy in a phase II study in RCC. Additional independent and functional validation studies are in progress. Research Sponsor: Department of Defense CDMRP KCRP.

A phase I/II study to evaluate the safety, pharmacodynamics, and efficacy of entinostat in combination with atezolizumab and bevacizumab in patients with renal cell carcinoma. *First Author: Roberto Pili, University at Buffalo, Buffalo, NY*

Background: Immunosuppressive factors such as regulatory T cells (Tregs) and myeloid-derived suppressor cells (MDSCs) limit the efficacy of immunotherapies. We have previously reported that histone deacetylase (HDAC) inhibitors have antitumor effects in combination with PD-1 inhibition by inhibiting the function of Tregs and MDSCs in preclinical models. We hypothesized that HDAC inhibition may enhance or resensitize patients (pts) with renal cell carcinoma (RCC) to immunotherapy. Thus, we conducted a Phase I/II clinical study with the HDAC inhibitor entinostat in combination with the immune checkpoint inhibitor atezolizumab and the VEGF inhibitor bevacizumab in RCC pts, either treatment naïve or previously treated with immune checkpoint inhibitors. **Methods:** The primary objective was to evaluate the safety, tolerability, and efficacy of this combination strategy in a Phase I/II clinical trial. This clinical study was composed of a Dose Finding Phase (Phase I) and a two-stage Phase (Phase II) portion. Due to unforeseen circumstances, enrollment was halted during Stage I of the Phase II portion. In the Phase I dose finding cohorts, according to the 3+3 standard design, pts received oral entinostat at 1 mg (dose level or dl1), 3 mg (dl 2), or 5 mg (dl 3) every 7 days, continuously, with atezolizumab at a dose of 1,200 mg/kg IV every three weeks in combination with bevacizumab at a dose of 15 mg/kg IV every 3 weeks. Phase II patients were split into two distinct cohorts: Cohort A (no prior treatments with PD-1 or PD-L1 inhibitors) and Cohort B (at least one prior treatment with a PD-1 or PD-L1 inhibitor for metastatic disease). Pts treated at dl3 were included in the Phase II efficacy analyses. **Results:** 31 pts (18 and 13 pts during Phase I and II, respectively) were enrolled. Phase I was completed with the following DLTs: hypertension (3) in dl1, encephalopathy and hyponatremia (dl2), pneumonitis and pruritis (dl3). Dl3 was established as the recommended phase II dose. The most common treatment-related toxicities were thrombocytopenia, hypophosphatemia, proteinuria, diarrhea, fatigue, and neutropenia. A total of 21 grade ≥3 events were observed. Nine pts achieved a partial response in Cohort A and one patient in Cohort B with an ORR 60% (CI 32.3-83.7) and 33.3% (28.2-56.4), respectively. According to Simon's optimal two-stage design, the ORR met the Stage I primary objective. The median PFS was 13.7 months (CI 8.7-21.3) in Cohort A and 9.8 months (CI 1.3-NE) in Cohort B. We have collected blood samples to conduct several correlative studies on peripheral blood mononuclear cells. **Conclusions:** The preliminary results from this study suggest that the combination of entinostat and atezolizumab plus bevacizumab is relatively well tolerated and may be active in pts with ccRCC. Clinical trial information: NCT03024437. Research Sponsor: Genentech, Syndax.

Biomarker-driven prospective clinical trial in renal cell carcinoma: Developing machine learning models to allocate patients to treatment arms using RNA sequencing. *First Author: Anupama Reddy, Vindhya Data Science, Durham, NC*

Background: RNA sequencing has shown promise in defining the biology of individual renal cell carcinoma (RCC) tumors. However, these biomarkers have not yet been translated to the clinic for prospectively assigning optimal treatments to patients. Challenges for RNA-seq biomarker development include translating classifiers across different assays/platforms, normalization of data collected from single patients in the clinic and establishing robust thresholds for assigning prediction groups. We have designed the prospective phase II OPTIC RCC clinical trial (clinicaltrials.gov NCT05361720) to test the utility of an RNA-seq based biomarker in predicting treatment based on biologic drivers relevant to angiogenesis (anti-angiogenesis; TKI) and immune microenvironment (immunotherapy; IO). Here, we will describe the development and optimization of a machine learning model for assigning individual patients to biologically driven clusters in real time to facilitate RNA-seq based biomarker trials. **Methods:** We have utilized RNA-seq data from the IMmotion 151 trial (ref) to develop a machine learning model. Clusters were grouped into three based on their association to tumor biology and treatment: (1) Cluster 1+2 (angiogenic signature → TKI+IO therapy), (2) Cluster 4+5 (immune/proliferative signature → dual IO therapy), (3) Cluster 3+6 (neither signature → exclude). Random forest classifier was used to train a multi-class model to predict the three groups. The model is evaluated using bootstrapped cross-validation. **Results:** Our machine learning classifier was built using 188 genes and has a cross-validation accuracy of 85% and sensitivity of >90% in predicting patients into one of the three biological clusters from our training data. Predictions of the classifier are significantly associated with progression-free survival across different treatments within each of the predicted groups. We also observed significant odds ratios when comparing responders (CR/PR/SD) to non-responders (PD) across the treatment groups. The model was then validated in two independent test sets treated with Angio and IO inhibitors: (1) 61 patient renal cell carcinoma cohort (2) 12 patient clear cell renal cell carcinoma cohort. We observed a significant enrichment of responders to Angio+IO treatment for the predicted Cluster_Angio patients compared to IO treatment (p=0.05), highlighting the importance of matching patients to their optimal treatment. **Conclusions:** We have developed an accurate machine learning model to assign individual patients to RNA-seq clusters in real time. This classifier will facilitate the prospective OPTIC RCC trial. If successful, our biomarker strategy will serve as a proof of concept for selecting optimal treatments for RCC patients. Health-related quality of life (HRQoL) of risk-based patient subgroups with advanced renal cell cancer (aRCC) treated with nivolumab plus cabozantinib (NIVO+CABO) vs sunitinib (SUN) in the CheckMate 9ER trial. *First Author: David Cella, Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL*

Background: In CheckMate 9ER, NIVO+CABO improved or maintained HRQoL vs SUN in previously untreated aRCC. We report an exploratory analysis of HRQoL in International Metastatic Renal Cell Carcinoma Database Consortium (IMDC) risk-based subgroups treated with NIVO+CABO vs SUN in CheckMate 9ER (minimum follow-up, 36.5 mo). **Methods:** Subgroups were stratified by IMDC categories of favorable (F) risk (score = 0) or intermediate/poor (I/P) risk (score = 1–6) at randomization. HRQoL was evaluated using Functional Assessment of Cancer Therapy–Kidney Symptom Index (FKSI-19). Changes from baseline (BL) through wk 151 were analyzed using mixed-model repeated measures (MMRM). Bother due to treatment side effects (FKSI-19 item GP5) was assessed using a generalized estimating equations model (response dichotomized as minimal [“not at all” or “a little bit”] vs notable [“somewhat,” “quite a bit,” or “very much”]). Cox proportional hazards (CPH) modeling was used to evaluate time to confirmed deterioration (TTCD). **Results:** Differences in least square means (LSM) for FKSI-19 scores through wk 151 indicated HRQoL benefit in the NIVO+CABO arm over the SUN arm for I/P-risk patients (n = 505) but not for F-risk patients (n = 146). In the I/P-risk subgroup, longitudinal analysis of FKSI-19 total scores indicated that HRQoL improved through wk 151 in the NIVO+CABO arm but decreased from BL in the SUN arm. HRQoL declined from BL through wk 151 in F-risk patients in the NIVO+CABO and SUN arms. Patients were less likely to be bothered by side effects of NIVO+CABO vs SUN regardless of risk (I/P-risk odds ratio [OR], 0.50; 95% CI, 0.34–0.75; F-risk OR, 0.51; 95% CI, 0.28–0.91). TTCD analysis of FKSI-19 scores of the I/P-risk subgroup indicated that the NIVO+CABO arm had lower deterioration risk than the SUN arm. For the F-risk subgroup, risk based on FKSI-19 total scores was similar for both treatment arms. **Conclusions:** Compared with SUN, NIVO+CABO improved or maintained HRQoL in I/P-risk patients and had less side effect bother in all subgroups. There were no significant differences between treatment arms for F-risk patients. Clinical trial information: NCT03141177. Research Sponsor: Bristol Myers Squibb.

MMRM and CPH analyses of FKSI-19 scores: NIVO+CABO vs SUN ^a				
IMDC risk subgroup	FKSI-19 total or subscale	LSM difference ^b (95% CI)	Hazard ratio for TTCD (95% CI)	
I/P-risk (n = 505)	Total	3.33 (1.96-4.70)	0.58 (0.44-0.76)	
	Disease-related symptoms (DRS)	1.59 (1.01-2.18)	0.55 (0.40-0.76)	
	DRS-physical (DRS-P)	2.12 (1.27-2.96)	0.51 (0.37-0.70)	
	Functional well-being (FWB)	0.54 (0.09-0.98)	0.58 (0.41-0.81)	
F-risk (n = 146)	Total	-0.44 (-2.63 to 1.75)	0.99 (0.64-1.54)	
	DRS	0.15 (-0.67 to 0.97)	1.09 (0.66-1.82)	
	DRS-P	0.04 (-1.21 to 1.30)	0.78 (0.47-1.27)	
	FWB	-0.52 (-1.30 to 0.26)	1.03 (0.61-1.73)	

^aThrough wk 151. ^bPositive value favors NIVO+CABO over SUN; negative value indicates deterioration.

Effect on outcomes of toxicity-related dose reduction in TKI monotherapy or TKI-IO combination therapy for advanced renal cell carcinoma. *First Author: Giacomo Nuvoletta, Department of Experimental, Diagnostic, and Specialty Medicine, S.Orsola-Malpighi University Hospital, Alma Mater Studiorum University of Bologna, Bologna, Italy*

Background: Tyrosine kinase inhibitors (TKI) in monotherapy or TKI in combination with immunotherapeutic agents (IO) are standard of care first-line treatment for advanced or metastatic renal cell carcinoma (RCC). Dose reduction due to toxicity is extremely frequently and represents an important clinical management issue, with frequent dose reduction, treatment suspension and change of schedule. We examined the outcomes of patient treated with TKI in monotherapy and in combination with immunotherapy (TKI-IO). **Methods:** We performed a retrospective analysis of clinical outcomes in patients with RCC treated with TKI (cohort 1) or TKI-IO (cohort 2) in Italian and Spanish institutions. A descriptive analysis was performed. Univariate logistic regression models were carried out to estimate the association between best response (CR or PR vs SD or PD) and type of TKI (monotherapy or combination therapy). Survival curves were estimated using the Kaplan-Meier method and were compared by the log-rank test. Cox proportional-hazard models were used to obtain hazard ratios (HRs) with 95% Median follow-up was calculated using the reverse Kaplan-Meier method. **Results:** A total of 401 patients were divided in cohort 1 (329 patients) and cohort 2 (72 patients). Median Follow-up was 81.22 months in cohort 1 and 19.02 months in cohort 2. Most frequent toxicities that lead to dose reduction were mucositis (20.13%), Asthenia (16.88%) and Hand-foot syndrome (15.58%). Overall Response Rate was higher in patients that reduced dose, both in cohort 1 (48% vs 29%, $p < 0.01$) and cohort 2 (81% vs 40%, $p < 0.01$). In cohort 1 Progression Free Survival (PFS) was longer in patients with dose reduction (27.14 months vs 16.59 months) (HR 0.77 [0.6; 0.98]; $p = 0.04$). Overall Survival (OS) was also improved (55 months vs 34.17) (HR 0.71 [0.53; 0.93]; $p = 0.01$). In cohort 2, both PFS (39.13 months vs 41.3 months) (HR 0.63 [0.27; 1.48]; $p = 0.29$) and OS (39.13 months vs 55.85 months) (HR 0.65 [0.26; 1.63]; $p = 0.29$) did not statistically differ between patients that reduced dose and patients that did not reduce dose. **Conclusions:** TKI dose reduction due to toxicity seems to be related to improved outcomes, both in ORR and PFS/OS. ORR was statistically improved in both cohort 1 and cohort 2. PFS and OS in cohort 1 favoured patients that experienced dose reduction. PFS and OS in cohort 2 did not show a statistically significant difference, probably due to the short follow-up and small number of patients. However, outcomes seem to show a trend toward favouring patients that reduce dose. Research Sponsor: None.

Real-world outcomes among patients with advanced/metastatic renal cell carcinoma (mRCC) treated with cabozantinib or other tyrosine kinase inhibitors (TKIs) after checkpoint inhibitor (CPI) therapy. *First Author: Daniel Yick Chin Heng, University of Calgary, Calgary, AB, Canada*

Background: CPI-based therapy is the first-line standard of care for patients with mRCC, but effectiveness data for subsequent targeted therapies are limited. Cabozantinib, a multi-targeted TKI, is indicated for patients with mRCC in the USA and may be prescribed after doublet CPI therapy. **Methods:** Retrospective study of cabozantinib vs other TKI treatment after CPI therapy for mRCC using the US Oncology Network electronic health record database and chart review. Patients initiated TKI therapy between May 1, 2016 and Nov 30, 2021, immediately after CPI therapy. The primary endpoint was real-world response rate over the first 6 months of treatment (wRRR_{6months}) based on physician assessment (complete response (CR): documented CR/indication of remission/disappearance of all lesions/no evidence of disease, or partial response (PR): documented PR/improved disease/responding disease). Covariates were adjusted by inverse probability of treatment weighting. Noninferiority was assessed using a 90% confidence interval (CI) and 10% noninferiority margin; if noninferiority was met, superiority was evaluated using a 95% CI and chi-square test. **Results:** In total, 485 patients were included. Baseline characteristics were similar for the cabozantinib and other TKIs subgroups, including proportions of patients with ≥ 2 metastatic sites (74.7% vs 68.2%) and metastases in bone (45.0% vs 43.5%), brain (8.8% vs 7.1%), liver (18.1% vs 19.5%), lung (35.0% vs 44.2%) and lymph nodes (38.7% vs 31.8%). At 6 months, tumor assessment data were available for 75.5% of patients (cabozantinib, 79.8% of cabozantinib and 66.2% of other TKIs, 66.2%) patients. Adjusted wRRR_{6months} was 62.5% for cabozantinib and 46.0% for other TKIs (rate difference: noninferiority, 16.5% [90% CI, 9.3–23.7], $p < 0.0001$; superiority, 16.5% [95% CI, 7.8–25.1], $p = 0.0002$). **Conclusions:** In patients with mRCC receiving standard of care treatment in the USA, cabozantinib was effective post-CPI therapy, including in patients without prior TKI therapy. Difference in adjusted wRRR_{6months} significantly favored cabozantinib vs other TKIs. These data may inform global jurisdictions that restrict cabozantinib to the post TKI setting. Research Sponsor: Ipsen.

CASSIOPE: A prospective noninterventional study of cabozantinib treatment following prior vascular endothelial growth factor (VEGF)-targeted therapy in patients with advanced renal cell carcinoma (aRCC). *First Author: Michael D. Staehler, University of Munich, Muenchen, Germany*

Background: Cabozantinib is a tyrosine kinase inhibitor approved as monotherapy for aRCC in the USA, and as first-line therapy for patients with intermediate or poor risk aRCC, or after previous VEGF-targeted therapy in Europe. In the METEOR trial, a substantial proportion of patients required cabozantinib dose modifications. We report a real-world study of cabozantinib use for aRCC. **Methods:** CASSIOPE was a non-interventional prospective cohort study (conducted Apr 2018–May 2022; NCT03419572). Enrollment spanned 11 European countries (91 sites) where cabozantinib is marketed for aRCC. Patients had aRCC and had received ≥ 1 prior VEGF-targeted therapy (excluding cabozantinib). Decision to initiate cabozantinib was made prior to enrolment. The primary endpoint was cabozantinib usage (dose interruptions, reductions or discontinuations due to AEs) in the second- (2L) or later- (≥ 3 L) line settings. Secondary endpoints included objective response rate (ORR), progression-free survival (PFS), overall survival (OS) and tolerability. Data were analyzed descriptively for patients with safety follow-up after ≥ 1 cabozantinib dose. **Results:** In total, 679 patients were included (73.0% male; median [range] age 67.0 [29–93] yrs; 85.7% clear-cell aRCC; 80.3% prior nephrectomy). Median (range) observation period was similar for 2L (n = 335; 8.51 [0.2–15.4] mo) and ≥ 3 L cabozantinib (n = 343; 9.26 [0.0–15.0] mo). Usage data are shown. For the overall population, ORR (95% CI) and median (95% CI) PFS according to local assessment were 21.9% (17.5%–26.9%) and 7.8 (6.3–8.7) mo for 2L cabozantinib, and 38.0% (32.7%–43.5%) and 8.7 (7.6–9.6) mo for ≥ 3 L cabozantinib. Median OS (95% CI) was 13.0 (12.6–not calculated [NC]) mo for 2L, and 17.1 (13.8–NC) mo for ≥ 3 L cabozantinib. Most patients (90.4%) reported treatment-related AEs (Grade 1, 71.1%; Grade 2, 70.3% of patients), most commonly any grade diarrhea (52.4%), palmar-plantar erythrodysesthesia syndrome (27.2%), decreased appetite (25.5%), hypertension (21.9%), asthenia (21.6%), fatigue (20.5%) and nausea (20.3%). **Conclusions:** In this real-world study, tolerability of ≥ 2 L cabozantinib was consistent with the METEOR trial safety profile: cabozantinib dose modifications due to AEs were common, but discontinuation rates due to AEs were substantially less frequent. Cabozantinib activity was maintained across lines. Clinical trial information: NCT03419572. Research Sponsor: Ipsen.

Use of real-world evidence to benchmark clinical trial results: A case study in von Hippel-Lindau (VHL) disease. *First Author: W. Marston Linehan, National Cancer Institute, Bethesda, MD*

Background: Data from a natural history study can be used to benchmark results from single arm trials with comparable ascertainment of exposures and outcomes. Despite limitations of externally controlled trials, natural history study data can provide important information, especially when clinical trial results provide compelling evidence of change in the established progression of disease. Such results could include partial or complete response for patients receiving drug in a disease where spontaneous regression is not observed. The aim was to conduct a natural history study to benchmark results of a Phase 2 single-arm trial (LITESPARK [LS]-004) for a new HIF-2a inhibitor (belzutifan) using comparable RECIST-based study endpoints. After a median follow-up of 37.8 months, the objective response rate (ORR) for patients with renal cell carcinoma (RCC) in LS-004 was 64.0% (95% CI: 50.6 to 75.8). **Methods:** A study of existing electronic medical records was conducted for VHL patients with disease-associated RCC undergoing active surveillance at the US National Cancer Institute. VHL patients with ≥ 1 cm solid RCC, confirmed by independent review, were followed until death or last encounter. Additional LS-004 exclusion criteria were applied to define the natural history study cohort: ≥ 3.0 cm tumor and procedure performed within 60 days, prior systemic oncologic therapy, and metastasis prior the index date. The index date was the date of the earliest radiology report with measurable disease during the study window (July 2004 - June 2020). An analysis of radiographic outcomes was performed according to RECIST V1.1 for patients with ≥ 3 scans prior to last encounter, death, or renal therapy using an imaging charter similar to LS-004. Adjudication of best overall response (BOR) was performed if there was discordance between assessments by the two independent radiologists. **Results:** The natural history study population included 244 VHL patients (100% genetic confirmation; 55% male; median age: 41 years, median follow-up: 10 years). The median size of largest RCC tumor diameter at baseline was 2.5 cm (IQR: 1.9, 3.1), and 76% of patients had ≥ 1 surgery after the index date. Among patients with ≥ 3 scans (n=178/244), the confirmed real-world ORR within 5 years of follow-up was 1.8% (95% CI: 0.4%, 5.2%), all with partial response. The real-world BOR was progressive disease and stable disease for 22% and 74% of patients, respectively. Within 5 years, 80% of patients had disease progression. **Conclusions:** Using similar trial endpoints, this natural history study demonstrates that spontaneous regression of RCC solid tumors is unlikely for patients with VHL undergoing active surveillance in the absence of therapy, and most patients experience disease progression. These findings help contextualize the antitumor activity and efficacy of belzutifan in the treatment of patients with VHL disease-associated RCC. Research Sponsor: Merck Sharp & Dohme LLC.

Head-to-head effectiveness and safety of pembrolizumab plus axitinib vs. nivolumab plus ipilimumab in metastatic renal cell carcinoma in the United States. *First Author: Dvir Aran, Faculty of Biology, Technion-Israel Institute of Technology, Haifa, Israel*

Background: Two main first-line combination therapies for metastatic renal cell carcinoma (mRCC) are pembrolizumab plus axitinib (P+A) and nivolumab plus ipilimumab (N+I). No head-to-head clinical trial comparing these treatments has been performed, and the available real-world data (RWD) on their effectiveness is limited. Here, we used RWD to compare the overall survival and posttreatment hospitalization rates of mRCC patients receiving P+A vs. N+I. **Methods:** We included mRCC patients treated with N+I or P+A between 6/2018 and 3/2022, utilizing data from Elevance Health administrative claims and clinical data from AIM Cancer Care Quality Program. Inverse probability of treatment weighting (IPTW) was used to adjust for age, sex, socioeconomic deprivation index (SDI), ECOG performance status (PS), Charlson Comorbidity Index (CCI), and metastatic sites. Real-world overall survival (rwOS) was defined from first treatment until death or last claim and was estimated using weighted Kaplan-Meier method. Favorable risk was defined based on PS (<2) and with a treatment initiated less than 1 year from diagnosis. **Results:** We identified 764 mRCC patients, of them 483 were treated with N+I (63%). The P+A group was slightly older (p=0.08), while other features were similar in both groups. Survival analysis using IPTW showed a borderline significant advantage of P+A vs. N+I (p-value=0.07). Inspection of the Kaplan-Meier curves suggested that P+A provides short-term survival benefit: 12-month rwOS was 86% for P+A vs. 77.8% for N+I (p<0.001), while at 24-months, where power was lower, the curves almost converged (rwOS: 68% in P+A vs. 65% in N+I; p=0.52). In a subset of patients with favorable risk (N=69 P+A, N=68 N+I), the P+A survival improvement extended to at least 24-months (p=0.06). Finally, the N+I group had significantly higher rates of posttreatment hospitalizations (3-months after treatment initiation) compared to the P+A group (31.9% vs. 19.6%; p-value<0.001). **Conclusions:** Our retrospective cohort study suggests that P+A may provide short-term survival benefits over N+I, and this benefit is extended in patients with favorable risk. P+A is also associated with fewer post-treatment hospitalizations. We argue that the higher toxicity of N+I may explain its lower short-term effectiveness and may also explain its lower effectiveness in patients with favorable risk. Research Sponsor: Carlon Digital Platforms.

Phase 2 study of batiraxcept (AVB-S6-500, an AXL inhibitor) as monotherapy, in combination with cabozantinib (cabo), and in combination with cabo and nivolumab (nivo) in patients with advanced clear cell renal cell carcinoma (ccRCC). *First Author: Katy Beckermann, Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: AXL is up-regulated by hypoxia-inducible factor-1 signaling in VHL-deficient tumor cells, playing a critical role in metastasis and resistance to VEGF-targeted therapies. Batiraxcept is a recombinant fusion protein containing an extracellular region of AXL combined with the human immunoglobulin G1 heavy chain (Fc), demonstrating potent and specific AXL inhibition through competitive binding of its ligand GAS6. A prior Phase 1b study showed promising outcomes for batiraxcept + cabo combination in patients who had failed first line (1L) therapy. **Methods:** This trial tested batiraxcept 15 mg/kg every 2 weeks (q2w) in 3 cohorts of ccRCC patients: 1) batiraxcept monotherapy (n=10) in patients with relapsing disease and no curative options; 2) batiraxcept + cabo 60 mg daily (QD) in patients with at least 1 prior therapy (n=25); and 3) batiraxcept + cabo 40 mg QD and nivo 240 q2w or 480 mg q4w in 1L (n=11). Primary endpoint was investigator assessed objective response rate (ORR) by RECIST v1.1, and key secondary endpoints were safety, progression free survival (PFS), and overall survival. **Results:** Enrollment has completed as of 17-January-2023. In the 3 cohorts, IMDC intermediate + poor risk was 80%, 76%, and 27%, and median prior lines of therapy were 4, 2, 0. Prior immunotherapy (IO) was received by 100%, 88%, and 0% patients. One hundred percent of patients receiving monotherapy and 40% of 2L patients receiving batiraxcept + cabo had received prior VEGF-TKIs. We describe efficacy and safety across the 3 cohorts. **Conclusions:** Batiraxcept monotherapy was well tolerated but had limited clinical activity. Batiraxcept-based combinations demonstrated efficacy and tolerability. Given encouraging safety and efficacy signals, batiraxcept + cabo will be further studied in a phase 3 trial of 2L+ccRCC patients whose disease has progressed on prior IO and VEGF-TKI treatment. Exploratory analysis for a baseline serum soluble AXL/GAS6 ratio biomarker was found to have predictability for clinical activity in the phase 1b study evaluating batiraxcept + cabo in patients who had failed 1L therapies; a similar analysis using the biomarker is ongoing for this patient population. Clinical trial information: NCT04300140. Research Sponsor: Aravive, Inc.

Preliminary results from a phase II study comparing sunitinib alone or with stereotactic body radiotherapy (SBRT) for newly diagnosed oligometastatic renal cell carcinoma. *First Author: Yang Liu, Department of Radiation Oncology, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Although SBRT has become an option for oligometastatic renal cell carcinoma (oligoRCC), current trials supporting SBRT haven't been adequately persuasive given their single-arm, non-first-line design. Our study aimed to explore if SBRT improves oncologic outcomes compared with standard first-line systemic therapy in oligoRCC. **Methods:** This an open-label, double-arm phase II controlled trial enrolling treatment naïve oligoRCC patients (pts), defined as ≤ 5 metastatic lesions (ChiCTR1800017136). No liver or brain metastasis was allowed. Nephrectomy was mandatory before enrollment. Pts were allocated 1:1 to receive either sunitinib alone (control arm) or sunitinib plus SBRT (SBRT arm). Sunitinib was started as 50 mg daily for 4 weeks, followed by 2 weeks off treatment. SBRT was delivered to all metastatic sites within 2 months after sunitinib initiation, with 35-50Gy in 5 fractions. Primary endpoint was objective response rate (ORR); secondary endpoints were disease control rate (DCR), progression-free survival (PFS), overall survival (OS) and safety. Data from pts with ≥ 1 year of follow-up were reported this time. **Results:** Starting in 2018, the trial has currently completed its accrual, with 48 pts enrolled. Forty-two pts had ≥ 1 year of follow-up and were evaluable for the present analysis. PT characteristics for SBRT and control arms: median age 51 vs 59 years (p=0.094); synchronous metastasis 31.8% vs 10.0% (p=0.179); clear cell carcinoma 77.3% vs 80.0% (p=1.000); IMDC low or intermediate risk 86.4% vs 80.0% (p=1.000); solitary metastasis 45.5% vs 25.0% (p=0.167). Thirty-four sites received SBRT, most frequently to bone (61.8%) and soft tissue (17.6%) metastasis. The 1-year local control rate after SBRT was 93.8%. ORR (81.8% vs. 25.0%, p=0.000) and DCR (90.9% vs. 60.0%, p=0.047) were significantly higher in SBRT arm than those in control arm. The 1y-PFS was 72.7% for SBRT arm and 35.0% for control arm (HR 0.33, 95% CI 0.16-0.69, p=0.003). And the 1y-OS was 95.5% for SBRT arm and 80.0% for control arm (HR 1.06, 95% CI 0.31-3.67, p=0.923). Grade 3-4 treatment-related AEs occurred in 66.7% and 62.5% pts in SBRT arm and control arm (p=0.763), respectively. SBRT-related Grade 3-4 toxicity included radiation enteritis (n=1, grade 3) and radiation pneumonitis (n=1, grade 3). **Conclusions:** Our results showed promising efficacy and acceptable toxicity of SBRT plus sunitinib when compared with sunitinib alone for oligoRCC. Complete results are awaited in 2023 after follow-up completion of the entire cohort. Clinical trial information: ChiCTR1800017136. Research Sponsor: None.

Immune landscape of patients with metastatic non-clear cell renal cell carcinoma (nccRCC) treated with atezolizumab plus bevacizumab. *First Author: Renee Maria Saliby, Dana-Farber Cancer Institute, Boston, MA*

Background: The treatment of metastatic nccRCC remains an area of unmet clinical need. A multicenter phase II trial of atezolizumab/bevacizumab in patients with advanced nccRCC or any RCC type with ≥ 20% sarcomatoid differentiation (NCT02724878) demonstrated clinical activity of these agents, with objective response rates of 50% in patients with sarcomatoid clear-cell RCC (sccRCC) and 26% in patients with nccRCC. We aim to understand the intratumoral and circulating factors that impact immunotherapy response in this population. **Methods:** We collected blood samples prior to therapy and on-treatment (following 2 cycles of therapy) and quantified levels of plasma soluble factors (cytokines and growth factors) using a fluorescent bead array platform. We used high dimensional flow cytometry on peripheral blood mononuclear cells to analyze the composition and phenotype of peripheral immune cells. Immunohistochemistry and immunofluorescence were performed on available formalin-fixed, paraffin-embedded tumor tissue samples (archival or on-study biopsy) collected prior to the start of therapy. We assessed relationships between biomarkers and outcomes using pairwise Wilcoxon rank-sum test and log-rank tests, and univariate Cox regression models. **Results:** We collected blood samples from 60 patients with paired tumor samples from 38 patients. Baseline circulating inflammatory cytokines MIP-1b, IL-1, MCP-1, IL-6, and IL-13 were highly correlated with one another, forming an "inflammatory module" that was increased in IMDC-poor risk patients and associated with worse progression-free survival (PFS) (p = 0.028). At baseline, elevated circulating VEGF-A was associated with a lack of response (p=0.03) and worse PFS (p=0.021). Whereas a larger increase in on-treatment levels of circulating VEGF-A was associated with clinical benefit as defined by Braun et al. (Nat Med. 2020) (p=0.01) and improved overall survival (p=0.006). Among peripheral immune cell populations, an on-treatment decrease in circulating PD-L1+ T cells was associated with improved outcomes: reductions in CD4+ PD-L1+ (HR:0.62[0.49-0.91], p=0.016) and CD8+ PD-L1+ T cells (HR:0.59[0.39-0.87], p=0.009) correlated with improved PFS. Within the tumor, a higher percentage of terminally exhausted (PD-1+, TIM-3+ and/or LAG-3+) CD8+ T cells at baseline was associated with worse PFS (p=0.028). **Conclusions:** Among patients with advanced nccRCC or sccRCC, a baseline high systemic inflammatory state and high circulating VEGF-A are associated with worse outcomes after treatment with atezolizumab and bevacizumab. High levels of intratumor terminally exhausted CD8+ T cells were associated with worse PFS. These results highlight the importance of an integrative approach to explore biomarkers of response in advanced variant histology RCC which may inform future therapeutic approaches. Unique molecular underpinnings by genetic ancestry in localized clear cell renal cell carcinoma. *First Author: Roy Elias, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: Clinical studies evaluating the impact of race on outcomes in renal cell carcinoma (RCC) are inconsistent and conceivably influenced by both biological and socioeconomic factors. Self-reported African Americans (AA) are also largely under-represented in clinical trials and molecular studies of clear cell (cc) RCC compared to their White (W) counterparts. Herein, we sought to comprehensively characterize molecular differences by genetic ancestry in localized ccRCC. **Methods:** We performed whole exome (WES) and transcriptome (RNAseq) sequencing on a case-matched cohort of AA and W patients (pts) who underwent nephrectomy for localized ccRCC at our institution. Germline single nucleotide polymorphisms were combined with reference panels from the 1000 Genomes Project, and ancestry was estimated using ADMIXTURE. Molecular subtypes were defined according to the IMmotion151 (IMm151) subtypes, and a random forest model was trained to predict subgroups. **Results:** From an initial selected cohort of 84 pts, WES and RNAseq data of adequate quality were available for 61 pts including 28 of African (AFR) and 33 of European (EUR) descent. We augmented our institutional cohort with a 3:1 EUR:AFR matched subset of the TCGA KIRC by stage, nuclear grade (NG), and gender. The final analytic cohort contained 75 pts of AFR and 177 pts of EUR descent. There were no significant differences in stage, NG, or gender between AFR and EUR groups. We observed that *VHL* [OR 0.22, CI [0.11-0.43], $p < 0.001$] and *PBRM1* [OR 0.4, CI [0.19-0.79], $p = 0.005$] mutations are enriched in pts with EUR ancestry and identified a unique association of *KMT2C* somatic mutations [OR 3.7, CI [1.1-13.5], $p = 0.027$] with AFR ancestry. Consistent with a lower frequency of *VHL* mutations, gene-set variation analysis revealed lower enrichment for angiogenesis (-0.23 vs 0.045; $p < 0.001$) in AFR vs EUR ancestry, respectively. AFR ancestry was associated with an increased proportion of the "Proliferative" IMm151 subtype (14.9% [n = 11/74] vs 3.4% [n = 6/177], $p = 0.002$). There was no association between overall survival (OS) and ancestry; however, IMm151 subtypes stratified OS with longest survival in the "Angiogenic/Stromal" group (median OS NR) and shortest OS in the T-Effector/Proliferative subtype (5.5yrs CI [2.3 - NR], $p = 0.01$). **Conclusions:** Our findings indicate that genetic ancestry is associated with distinct molecular subtypes of ccRCC. Biological drivers of ccRCC pathogenesis and therapeutic response may vary by ancestry, underscoring the need for racially diverse representation in future studies. Characterizing progression to subsequent lines of therapy in metastatic renal cell carcinoma (mRCC) after nivolumab plus ipilimumab (Nivo+Ipi): Results from the International mRCC Database Consortium (IMDC). *First Author: Audreyllie Lemelin, Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada*

Background: Treatment patterns and number of lines of therapy for patients with mRCC are not well characterized in the era of immunoncology-based combinations. We aimed to quantify the attrition rates by line of therapy and to examine predictors of receiving second-line (2L) treatment. **Methods:** Using the IMDC, patients with mRCC who received first-line (1L) Nivo+Ipi were included. Clinical and pathologic characteristics and outcomes were extracted. Chi-square tests were used to compare categorical variables between patients who received 2L and those who did not. A logistic regression model was used to assess predictors of 2L therapy initiation in eligible patients. **Results:** 995 patients treated with 1L Nivo+Ipi were identified, of whom 704 stopped 1L and were thus eligible for 2L therapy. Reasons for stopping 1L included progressive disease (PD) in 39.5%, toxicity in 25.0%, death in 4.3%, complete response in 1.6% and other in 29.7%. Among 2L eligible patients, 410 (58.2%) received 2L whereas 294 (41.8%) did not. Patients who stopped 1L for PD were more likely to initiate 2L than those who stopped for other reasons (81.7% vs 43.0%, $p < 0.001$). Patients who received 2L were more likely to have clear-cell histology (75.1 vs 62.9%, $p = 0.02$), bone metastases (39.8 vs 29.6%, $p = 0.01$), and only one site of metastases (18.3 vs 10.5%, $p = 0.01$) and less likely to be poor risk by IMDC criteria (27.1 vs 34.4%, $p = 0.03$). After adjusting for IMDC criteria, no predictors of receiving 2L therapy remained significant. The overall response rate to 1L therapy was lower in patients who received 2L than in those who did not: 18.5% (76/366) and 33.7% (99/245), respectively ($p < 0.001$). Among 258 patients who stopped 2L, 145 (56.2%, overall 20.6%) started third-line (3L) therapy. Of the 98 patients who stopped 3L, 52 (53.1%, overall 7.4%) started fourth-line therapy. **Conclusions:** In our study, we found that over half of eligible patients received the subsequent line of therapy. We were unable to identify predictors of 2L therapy initiation. Attrition rates between lines of therapy have important implications for patient counseling, cost analyses, and clinical trial design. Research Sponsor: None.

Nivolumab plus cabozantinib in patients with non-clear cell renal cell carcinoma: Updated results from a phase 2 trial. *First Author: Chung-Han Lee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Identification of effective systemic therapy for non-clear cell renal cell carcinoma (RCC) remains a unmet need. We reported a two arm, phase 2 trial of cabozantinib plus nivolumab (CaboNivo) that showed promising efficacy in the treatment arm comprised primarily of papillary and unclassified histology. (Lee, JCO, 40: 2022). Herein, we report updated results with extended follow up. **Methods:** Patients had advanced non-clear cell RCC, 0 or 1 prior systemic therapies excluding prior immune checkpoint inhibitors, and measurable disease by RECIST. Cabo 40 mg/day plus Nivo 240 mg every 2 weeks or 480 mg every 4 weeks was given for both arms. Arm 1 was comprised of papillary, unclassified, or translocation associated RCC; and Arm 2 had chromophobe RCC (closed early for lack of efficacy). The primary endpoint was objective response rate (ORR) by RECIST; secondary endpoints included progression-free survival (PFS), overall survival (OS), duration of response (DOR) and safety. Arm 1 was a single stage design that met its primary endpoint and was expanded to produce more precise estimates of ORR. Correlative analyses by next generation sequencing were performed and will be presented. **Results:** A total of 40 patients were treated in Arm 1 (data cutoff: Dec 13, 2022). Median follow up time was 34 months (range 20, 51). Twenty-six patients (65%) were previously untreated, and 14 (35%) had 1 prior treatment line: 10 (25%) received prior VEGF-targeted therapy and 8 (20%) received prior mTOR-targeted therapy. ORR is 48% (95% CI 31.5–63.9). Median PFS is 13 months (95% CI: 7, 16). Progression-free survival is 51% (95% CI: 34, 65) at 12 months and 23% (95% CI: 11, 37) at 24 months. Median OS is 28 months (95% CI: 23, 43). Overall survival is 70% (95% CI: 53, 82) at 18 months and 44% (95% CI: 28, 60) at 36 months. PFS and OS were similar for previously treated and untreated patients. For responders, median DOR was 17 months (95% CI: 10, 36). Adverse effects of any grade were experienced by 35 patients (88%); grade 3/4 adverse events were experienced by 22 patients (55%). Grade 3/4 AST and ALT elevations were 18% and 23% respectively. Other common grade 3/4 adverse events were hypertension (5, 13%) and pain (4, 10%). Study therapy was discontinued in 9 patients (28%) for toxicity. **Conclusions:** Updated results with extended follow-up highlight efficacy and safety for CaboNivo in metastatic non-clear cell RCC pts with papillary, unclassified, or translocation associated histologies. Clinical trial information: NCT03635892. Research Sponsor: BMS, Exelixis.

	1 st line (any histology)	2 nd line (any histology)	Unclassified w/o papillary features (6)	Translocation-associated (2)

Disease-free survival in operated patients with nmRCC using machine learning. *First Author: Gaëlle Margue, Department of Urology, Bordeaux University Hospital, Bordeaux, France*

Background: In patients operated for a non-metastatic renal cell carcinoma (nmRCC), risk evaluation of disease recurrence enables the therapeutic strategy to be adapted after surgery. Usual risk group stratification does not fully exploit the power of machine learning (ML) applied to multimodal data. We developed a ML model capable of calculating the risk of recurrence after surgery for nmRCC patients. **Methods:** A multicentric cohort of patients undergoing surgery between May 2000 and January 2020 for a nmRCC (pT any, N any, MO) was analyzed from data collected prospectively in the French research network on kidney cancer UroCCR (ClinicalTrials.gov: NCT03293563). Using clinical, biological, histological and radiological features, we developed a signature of patient-specific DFS. Participating medical centers were randomly assigned to training or validation cohorts with a 2:1 ratio of patients. The ML signature managed missing data using multiple imputation based on gradient-boosted trees and chained equations. Several ML models were trained in a repeated 5x10-fold cross-validation procedure to optimize the integrated Area Under the ROC Curve (iAUC) between 0.5- and 5-years following surgery. The performance of the selected ML signature was then evaluated on the validation cohort and compared with usual risk scores. **Results:** 3354 patients were randomly assigned to a training cohort (n=2239 from 10 centers) and a validation cohort (n=1115 from 13 centers). Our risk score achieved an iAUC of 0.81 (0.76, 0.85) on the validation cohort and significantly outperformed the GRANT ($p < 0.001$), SSIGN ($p = 0.03$), and UISS ($p < 0.001$) risk scores. The Leibovich-2018 score was only defined in 51% of the patients, due to incomplete data. Permutation-based feature importance and Shapley values were used to estimate the contribution of each feature. The stratification of patients into four risk groups achieved an iAUC of 0.78 (0.74, 0.83) on the validation cohort. 190 (17%) patients were stratified in the low-risk group, with an actual 5-year DFS higher than 98% and no death observed within this horizon window. 188 (17%) patients were stratified in the high-risk group, with an actual 5-year DFS of 48%. **Conclusions:** The machine learning model estimating individual disease recurrence risk outperformed the predictive performances of usual risk scores while handling incomplete data in predictors. This could help in identifying patients for whom surveillance could be reduced and those who could be candidates for adjuvant therapies. Research Sponsor: INCA, France.

Health-related quality of life (HR-QOL) measures in renal cell carcinoma (RCC): Patient-reported relevance of items of the FKSI-19, EORTC QLQ-C30, and EQ-5D. *First Author: Cristiane Decat Bergerot, Oncoclinicas, Brasília, Brazil*

Background: Given the need to balance both quantity and quality of life among patients with advanced cancer, developing a robust, relevant, and consensus-driven patient-focused measurement strategy is a necessity. Our study expands upon previous findings (Bergerot *et al.*, The Oncologist 2023) in evaluating the perceived relevance of questions on the FKSI-19, EORTC QLQ-C30, and EQ-5D among patients with RCC. **Methods:** Eligible patients were diagnosed with RCC and asked to evaluate the relevance of each question of the FKSI-19, EORTC QLQ-C30, and EQ-5D (items rated as relevant vs non-relevant). Patients also responded to 2 open-ended questions regarding topics not covered by these measures and their perception of wearable technologies. Questions identified as meaningful required $\geq 66\%$ "relevant" ratings. Descriptive statistics were collated, and open-ended questions were analyzed by 2 independent reviewers (CB, PB). **Results:** 116 patients were recruited from Brazil and the US. Most (69%) were male with a median age of 64 (32-88) years. 83% were diagnosed with advanced disease, and 75% received immunotherapy and/or targeted therapy as primary treatment. Few items across surveys were identified as meaningful including 8/19 FKSI-19 questions (lack of energy, fatigue, appetite, sleeping, worry, able to work, enjoyment and quality of life), 3/30 EORTC QLQ-C30 questions (tired, overall health and quality of life), and 0/5 EQ-5D questions. Patients suggested items pertaining to treatment side effects, emotional symptoms, physical function, social/family support, and financial distress should be included. Notably, 58% of patients were open to using wearable devices to assess HRQOL. **Conclusions:** Our multi-institutional international study confirms findings from our single-institution pilot data suggesting that HRQOL measures for RCC require substantial refinement. These data will inform development of a novel-RCC specific HRQOL tool in a joint effort between experts and patients. T cell receptor-engineered T cells targeting a human endogenous retrovirus in kidney cancer. *First Author: Stefan Barisic, Laboratory of Transplantation Immunotherapy, Cellular and Molecular Therapeutics Branch, NHLBI, NIH, Bethesda, MD*

Background: Previously, our group described a novel human endogenous retrovirus type E (CT-RCC HERV-E) that is selectively expressed in most clear cell renal cell carcinomas (ccRCC). Here, we report the characterization and preclinical testing of a T cell receptor (HERV-E TCR) that targets an HLA-A11-restricted 10-mer peptide antigen (CT-RCC-1) that is derived from CT-RCC HERV-E. **Methods:** From a patient with ccRCC who had prolonged immune-mediated tumor regression following an allogeneic hematopoietic stem cell transplant, we identified a CD8⁺ T cell clone with HLA-A11-restricted specificity for the CT-RCC-1 peptide. The TCR of this clone was encoded into a retroviral vector containing a truncated CD34 cassette as a selection marker. Gene-engineered T cells expressing the HERV-E TCR (HERV-E T cells) were characterized for tumor recognition, lysis, and cross-reactivity. In vivo anti-tumor activity was assessed in a xeno-murine model using a human subcutaneous ccRCC tumor graft. A good manufacturing practice (GMP)-compliant method to produce HERV-E T cells was implemented for a subsequent clinical trial in humans with metastatic ccRCC. **Results:** When transduced into human T cells, the HERV-E TCR showed CD8-dependent specific recognition and lysis of HERV-E-expressing ccRCC cells that were HLA-A11+. The extent of tumor cytotoxicity correlated with CT-RCC HERV-E mRNA expression levels and HLA-A11 surface density ($r=0.82$). Cross-reactivity assessment established that there were no naturally occurring peptides with substantial sequence identity to CT-RCC-1 that could serve as alternative targets for HERV-E T cells. Further, immunopeptidomics and in silico analyses provided strong evidence that presentation of the CT-RCC-1 epitope depends exclusively on the transcription of the CT-RCC HERV-E genomic region. In a murine model, human HERV-E T cells mediated regression of established human ccRCC tumor grafts, significantly prolonging animal survival compared to controls that either received non-transduced T cells or no T cells (median survival 50 days vs. 20 and 20 days, respectively; $p<0.001$). Finally, the GMP-compliant production of HERV-E T cells yielded pure populations (i.e., $>90\%$ TCR-transduced) of HERV-E T cells that were highly cytotoxic to ccRCC tumor cells. The expansion numbers of GMP-produced cells were sufficient for testing the safety of the adoptively infused T cells in a phase I clinical trial. **Conclusions:** Here, we provide the first data showing T cells armed with a HERV-E TCR acquire specific anti-tumor activity in vitro and in vivo against ccRCC cells. These preclinical data provide the foundation for an ongoing first-in-human phase I clinical trial evaluating the safety of HERV-E T cell infusions in patients with advanced ccRCC. Core biopsy (bx) accuracy and safety of biopsy and preoperative immunotherapy in predicting histological subtype and nuclear grade in ECOG-ACRIN EA8143 perioperative nivolumab (nivo) versus observation in patients (pts) with renal cell carcinoma (RCC) undergoing nephrectomy. *First Author: Naomi B. Haas, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: PROSPER is a phase 3 National Clinical Trials Network study that accrued pts with clinical stage $\geq T2$ or $T_{any}N+$ RCC of any histology planned for radical/partial nephrectomy. Pts were randomized to perioperative nivo followed by primary tumor resection and 9 cycles of nivo postoperatively or standard surgery followed by observation. To address concerns that core kidney bx might 1) not provide accurate diagnosis and 2) delay surgery due to adverse events (AEs) or scheduling, the study was amended from requiring all patients to undergo core bx prior to treatment for confirmation of RCC, to only require bx in patients randomized to the nivo arm. Herein, we report the accuracy and safety of primary tumor core bxs in predicting final histology and nuclear grade by both site and central pathology review as well as time from enrollment to surgery. We also report AEs of preoperative nivo. **Methods:** Concordance of both core bx and primary tumor by site and central pathology review of histology and grade (1-2 vs 3-4) are reported, along with the Cohen's Kappa value, which measures the agreement and concordance (kappa=0 is no concordance and 1 is highest). AEs relating to core bxs and preoperative nivo, as well as time from enrollment to surgery for each arm, comparing pre- and post-amendment (dropping bx requirement in surgery alone arm) are also reported. **Results:** 387/404 pts in the nivo arm and 171/415 pts in the surgery alone arm had core bxs. 632 patients had both central pathology and site review available. 41 of all randomized patients (819) were considered as non-RCC and 26/41 were identified via bx. The median times from enrollment to surgery for nivo and control arms pre-amendment were 32d vs 19 d, and post-amendment were 21 d vs 14 d, respectively. The median (25th-75th percentile) number of days from last preoperative nivo to surgery was 14 d (9-20). AEs related to core bx, generally from bleeding, were reported in 13/558 (2.3%) pts. 2/13 bxs resulted in life-threatening complications. 21/353 (6%) of pts receiving nivo pre-surgery had $\geq$ grade 3-5 AE attributed to nivo. 181/353 (51%) pts had any grade AE attributed to nivo. Concordance between bxs and primary tumor pathologies for determining histological subtype was Kappa = 0.62. Agreement between central pathology and originating site review of primary tumor for determining nuclear grade was Kappa = 0.56, and concordance of histology was Kappa = 0.78. **Conclusions:** The PROSPER trial use of core bxs in advance of neoadjuvant therapy was generally safe, largely consistent with primary tumor histology and grade, and did not delay resection of the primary tumor. AEs of preoperative nivo were consistent with nivo AEs in metastatic disease. This approach is valid for future neoadjuvant trials. Clinical trial information: NCT03055013. Immunoglobulin as a predictive biomarker for the efficacy of immune checkpoint inhibitor combined with VEGF-TKI in metastatic renal cell carcinoma. *First Author: Honglei Cui, Department of Urology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, Beijing, China*

Background: The combination of immune checkpoint inhibitor (ICI) and vascular endothelial growth factor tyrosine kinase inhibitor (VEGF-TKI) is recommended as the first-line treatment in patients with metastatic clear cell renal cell carcinoma (ccRCC). However, no effective serum biomarker has been used to predict the therapy response and potential benefits. Abnormal content and changes of immunoglobulin (IG) in serum or cancer tissue may indicate cancer progression and impact the prognosis. We examined the content of serum IG and analyzed the alteration after treatment to assess the efficacy of ICI and VEGF-TKI. **Methods:** Eighty-four patients with metastatic ccRCC were enrolled in this study. The total serum IG level was determined as the sum of IgA, IgG, and IgM. The data of baseline level and alteration of IG after 3-mo treatment was complete in 72 ccRCC patients. These patients were then divided into two groups based on alteration in their IG levels: the IG-increased group and the IG-decreased group. This study aimed to investigate the correlation between the baseline level of immunoglobulin (IG), changes in its content after 3-mo of treatment, and clinical outcomes. **Results:** Eighty-four patients were retrospectively enrolled with a median follow-up of 17.3 months (2.5-45.1). The objective response rate (ORR) was 41.67%, and the median overall survival (OS) was 31 months in our cohort. The baseline level of IG was not associated with ORR or OS. However, dynamic alteration in IG level after 3-mo treatment had a significant impact on ORR and OS in ccRCC patients. The ORR was 2.7% in the IG-increased group and 80.0% in the IG-decreased group. The OS was 21.0 months (95% CI 14.0-NA) in the IG-increased group and 48.0 months (28.0-NA) in the IG decreased-group (Hazard ratio [HR] 4.59, $p=0.003$). **Conclusions:** The change of serum IG level after 3-mo treatment served as an effective predictor of drug response and the prognosis for metastatic ccRCC patients. Value of serum IG needs to be validated in multi-centers and the mechanism of it should be further investigated. Research Sponsor: None.

Global circulating free DNA methylation and fragmentome deconvolution in patients with metastatic renal cell carcinoma treated with immunotherapy (GOLDEN). First Author: Pavlina Spiliopoulou, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada

Background: Metastatic renal cell carcinoma (mRCC) lacks molecular biomarkers. Cell-free methylated DNA immunoprecipitation sequencing (cfMeDIP-seq) is a new, non-invasive approach to the detection of RCC-derived DNA in the circulation. In the GOLDEN study (NCT03702309), we explored the role of cfMeDIP-seq and fragmentomic dynamics as a biomarker, during immune checkpoint inhibition (ICI)-based treatment in mRCC patients (pts). **Methods:** Blood samples from mRCC pts were collected before and during treatment. Response to treatment was defined by the treating oncologist as: response, any degree of radiological tumor regression; stable disease (SD), no radiological change; or progressive disease (PD), radiological/clinical progression. More than 10ng of plasma cfDNA was subject to cfMeDIP-seq. A prognostic pan-cancer methylation signature previously generated using TCGA tissue methylation arrays was applied to cfMeDIP-seq output and cancer-signal methylation (CSM) score was calculated. An RCC-specific methylation signature, previously generated by identifying differentially methylated regions between RCC pts and controls, was applied (Nuzzo *et al*, *Nat Med* 2020). Genome-wide fragmentation profiles were generated using DELFI. Using medians as cut off, log-rank test was performed to assess overall survival (OS) and progression-free survival (PFS). **Results:** Thirty-five patients were enrolled and n=33 received systemic treatment. 31/35 pts (89%) had clear cell and 4/35 (11%) non-clear cell histology. Median age was 61 (30-81) years and the M:F ratio was 6:1. Patients' IMDC prognostic risk score was favorable n=6/35 (17%), intermediate n=23/35 (65%) and poor n=6/35 (17%). 20/33 (61%) patients received ipilimumab/nivolumab, 10/33 (30%) nivolumab and n=3/33 (9%) pembrolizumab/axitinib. There were n=14/33 (42%) responders, n=4/33 (12%) pts with SD and 15/33 (45%) pts with PD. Patients with high pan-cancer CSM score at baseline trended towards worse OS (HR 3.86, p = 0.079). Fragmentomics signature, consisting of increased proportion of short cfDNA fragments, showed a trend for worse PFS (HR = 3.04, p = 0.075) in on-treatment samples. Using the RCC-specific methylation signature, we found that those with an increase in signature score from baseline to on-treatment had better PFS (HR=2.4x10⁻¹⁰, p=0.002, n=10) and a trend towards better OS (HR=0.17, p=0.074, n=10). We hypothesize that RCC tissue-specific cell death early during ICI treatment could underpin this increase in the methylation score. **Conclusions:** This small study is the first report on the role of cfMeDIP-seq-derived methylation and fragmentomic signatures in patients with mRCC undergoing ICI-based treatment. We found several trends and one significant association between these signatures and pt outcomes, which support further validation in larger cohorts. Clinical trial information: NCT03702309. Research Sponsor: KCRNC-KCC-CUASF Research Grant.

Adjuvant everolimus in patients (Pts) with localized non-clear cell renal cell carcinoma (RCC): Subgroup analysis from the Everest trial (SWOG S0931). First Author: Shuchi Gulati, University of California Davis Comprehensive Cancer Center, Sacramento, CA

Background: In S0931, adjuvant treatment with the mTOR inhibitor everolimus respectively yielded disease-free survival (DFS) and overall survival (OS) hazard ratios (HR) of 0.85 (95% CI 0.71-1.00) and 0.90 (95% CI 0.71-1.13) in pts with resected, localized RCC. Previously, everolimus had been shown to be active in chromophobe RCC (chRCC; Tannir *et al* Eur Urol 2016) and papillary RCC (papRCC; Escudier *et al* Eur J Cancer 2016). We sought to evaluate the efficacy of everolimus within these non-clear cell subsets of EVEREST. **Methods:** 1545 adult pts with treatment-naïve, non-metastatic, fully-resected RCC at intermediate high-(pT1 G3-4 N0 to pT3a G1-2 NO) or very high-risk (pT3a G3-4 to pT4 G-any or N+) for recurrence were randomized 1:1 to 54 weeks of everolimus 10 mg PO daily or placebo within 12 weeks of radical or partial nephrectomy. Exploratory analyses of RFS and OS chromophobe and papillary subgroups were performed. **Results:** A total of 99 eligible pts had chRCC; 109 had papRCC (16 type I; 37 type II; 56 NOS). Median follow-up is 6.3 years. Pt characteristics were balanced between the 2 arms in each histological group. Thirty-four (34%) pts in the chRCC subgroup and 50 (46%) pts in the papRCC subgroup had very high-risk disease. Fewer pts completed all 54 weeks of everolimus in each subgroup compared to placebo (49% vs. 74% in the chRCC subgroup and 46% vs. 71% in the papillary subgroup). DFS and OS for each subgroup are shown. **Conclusions:** Non-clear cell histology accounted for a considerable proportion (~13%) of S0931 pts. The estimated everolimus HRs for DFS and OS in the chRCC subset are consistent with the overall trial result, but those same modest HRs were not seen in papRCC, in contrast to prior reports of mTOR inhibitor activity in this subtype. Although inferences are limited by sample size and wide CIs, this is the largest experience in chRCC or papRCC among any adjuvant trials presented to date. Clinical trial information: NCT01120249. Research Sponsor: U.S. National Institutes of Health; Novartis.

Genomic determinants of progression-free survival after second line of therapy (PFS-2) for patients on immunotherapy-based combination therapies for advanced clear cell renal cell carcinoma. First Author: Kelly N. Fitzgerald, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The role of somatic genomic mutations in predicting outcomes in clear cell renal cell carcinoma (ccRCC) is poorly defined. Both ipilimumab/nivolumab (IO/IO) and several combinations of VEGFR-targeted tyrosine kinase inhibitor (TKI/IO) are preferred first-line treatment options for metastatic ccRCC. The impact of somatic mutations on PFS-2 for IO combination therapies was evaluated in this retrospective analysis. **Methods:** One-hundred forty-one patients with ccRCC had sequencing with MSK-IMPACT and initiated 1st line combination IO at Memorial Sloan Kettering (MSK) Cancer Center between 1/1/2014 and 12/30/2020. Treatment groups are defined as IO/IO (n=76) and TKI/IO (n=65). PFS-2 is defined as time from start of 1st line to progression on next therapy, or death, and is estimated using Kaplan-Meier method. PFS-2 association with each mutation was assessed via log-rank test and a model-based approach. Restricted mean survival time (RMST) up to 48 months was calculated for PFS-2 and modeled using a generalized linear model adjusted for IMDC risk. To test for heterogeneity of effect among treatment groups, an interaction test between somatic mutation and treatment group is performed in the model. **Results:** *VHL*, *PBRM1*, *SETD2*, mTOR pathway, *BAP1*, and *TP53* were the most common somatic mutations. Only *BAP1* was significantly associated with PFS-2: median PFS-2 was 44 months for patients without *BAP1* mutation and 17 months for patients with *BAP1* mutation (log-rank p=0.006). After adjusting for IMDC risk group, 48 month RMST for PFS-2 was 13 months lower in patients with *BAP1* mutation. An interaction test performed in the RMST model showed no significant variation in the treatment effect of IO/IO or TKI/IO based on the presence or absence of *BAP1* mutation (p=0.97), although sample size limits power to detect differences. Results for other somatic mutations are shown. **Conclusions:** PFS-2 was significantly inferior for ccRCC patients with somatic *BAP1* mutation treated with IO-based therapy. Interaction test did not suggest a significant advantage for IO/IO or TKI/IO for mutation-present or -absent groups. Clinical stratification remains key for selecting TKI/IO or IO/IO for patients. Research Sponsor: Memorial Sloan Kettering Cancer Center Support Grant/Core Grant P30 CA008748.

Response to immune checkpoint inhibitor (ICI) rechallenge in patients with metastatic renal cell carcinoma who progressed on prior ICI: A systematic review and meta-analysis. First Author: Garima Gupta, University of Kentucky, Lexington, KY

Background: Several immune checkpoint inhibitor (ICI)-based combination regimens are standard-of-care for first-line treatment of metastatic renal cell carcinoma (mRCC). These include dual ICI and ICI-tyrosine kinase inhibitor (TKI) combinations. While single-agent ICI is recommended as subsequent-line therapy for ICI-naïve patients, there is limited knowledge regarding efficacy of rechallenging with a different ICI or using different ICI combinations in patients who have progressed on prior ICI therapy. This is a clinically critical question as most mRCC patients would have already received ICI therapy at progression. The aim of this study is to address the above by performing a systematic review and meta-analysis. **Methods:** PubMed, Cochrane Library and Web of Science were systematically searched to identify studies of later-line ICI rechallenge after progression on any previous ICI in mRCC patients from database inception to December 31st, 2022. Patients who had progressed on prior ICI and rechallenged with ICI as single agent/dual/TKI combination as any subsequent line of therapy in both retrospective and prospective studies were included. Exclusion criteria were phase I or any phase studies combining ICI with unapproved drugs, case reports and case series. We calculated the pooled objective response rate (ORR) and disease control rate (DCR) using mixed effects model treating individual studies as a random effect. We further stratified studies into prospective and retrospective and performed subgroup analyses. **Results:** A total of 11 studies, 6 prospective and 5 retrospective with a total of 603 patients were initially identified. Out of the 6 prospective studies, 3 had an adaptive design of using salvage ipilimumab/nivolumab in patients who had either progressed or had stable disease as the best overall response on nivolumab monotherapy. These studies were excluded as they did not meet our inclusion criteria. A total of 8 studies with 400 patients were included in the final analysis. The ORR was 28% (95% CI, 0.27-0.36) and the DCR was 70% (95% CI, 0.47-0.85) with no significant differences between prospective and retrospective studies. Our ORR is higher than an earlier meta-analysis reporting an ORR of 14% with salvage ipilimumab/nivolumab after previous treatment with ICI. **Conclusions:** This meta-analysis demonstrates a modest ORR and an impressive DCR. Therefore, it provides strong clinical rationale to consider rechallenging with ICI-based therapy for later-line treatment of mRCC patients who have progressed on prior ICI. Research Sponsor: None.

Serum soluble MAdCAM-1: A new biomarker for cancer immunotherapy.
First Author: Carolina Alves Costa Silva, Gustave Roussy Cancer Campus, Villejuif, Ile-de-France, France

Background: Antibiotics (ATB) deviate the gut taxonomic microbiota composition and have a deleterious impact on survival in ICI-treated pts. ATB downregulate the ileal mucosal addressin cell adhesion molecule-1 (MAdCAM-1), leading to the recirculation of immunosuppressive enterotrophic T cells into the tumor and ICI resistance. Here, we aimed to assess the prognostic impact of MAdCAM-1 in ICI-treated mRCC pts. **Methods:** The GETUG-AFU 26 NIVOREN phase II trial (NCT 0301335) is a multicentric study that assessed the activity and safety of Nivolumab in pts with clear cell mRCC after anti-angiogenic therapy. We measured serum soluble MAdCAM-1 (sMAdCAM-1) levels (correlating ileal MAdCAM-1 transcripts) using Human Luminex Discovery Assay in the available plasma. Progression-free survival (PFS), overall survival (OS) and clinical benefit rate (CBR) were assessed using sMAdCAM-1 median as a cut off value (high if >median and low if <median). Multivariate Cox analysis adjusted for established risk factors: ATB, gender, age, international Metastatic RCC Database Consortium (IMDC) score, number of previous lines, hypoalbuminemia, and brain, bone and liver metastasis. Two independent cohorts of metastatic lung and bladder cancer patients validated the data. **Results:** Overall, 212 pts were included. Median age was 64 years (22-87), and pts were mostly male (82%). ATB users had lower levels of sMAdCAM-1. Low sMAdCAM-1 pts had diminished OS compared to high sMAdCAM-1 pts [HR 2.97 (95%CI 1.99-4.44), $p<.0001$]: 13.3 (95%CI 9.8-14.9; 72/106) versus 25.3 (95%CI 24.1-NR; 36/106) months. Also, low sMAdCAM-1 pts had diminished PFS [HR 1.92 (1.43-2.57), $p<.0001$]: 2.6 (95%CI 2.4-2.8; 99/106) versus 5.2 (95%CI 4.6-5.7; 86/106) months. Interestingly, sMAdCAM-1 was independently associated with OS [HR 2.40 (1.52-3.80), $p=0.0002$] and PFS [HR 1.55 (1.13-2.13), $p=0.0071$] in multivariate analysis. Low sMAdCAM-1 pts had lower CBR (37% versus 63%, $p=0.0004$). Serum sMAdCAM-1 also predicted OS in 381 ICI-treated patients with lung and bladder cancer. **Conclusions:** Low sMAdCAM-1 is associated with ATB intake, ATB-independent gut dysbiosis and worse outcomes, in ICI-treated pts with metastatic lung, bladder and RCC cancer. ELISA determination of sMAdCAM-1 might guide the selection of patients amenable to microbiota-centered interventions, such as *Akkermansia sp.*, and fecal microbiota transplantation. Clinical trial information: NCT0301335. Research Sponsor: Institut National du Cancer, Direction Générale de l'Offre de Soins; Bristol-Myers-Squibb.

Association of host immune signatures with response to immunotherapy-based regimens in patients with metastatic renal cell carcinoma (mRCC).
First Author: Eddy Saad, Dana-Farber Cancer Institute, Boston, MA

Background: Treatment options for mRCC have evolved to include VEGF targeted therapies (VEGF-TT), immune checkpoint inhibitors (ICIs), or combinations of both. The interaction between the tumor and its immune microenvironment has been shown to influence clinical outcomes in patients treated with immunotherapy-based regimens. The aim of this study was to characterize the T-cell and B-cell immune repertoires in patients with mRCC treated with VEGF-TT, ICI or a combination of both, and evaluate their associations with clinical outcomes. **Methods:** We identified patients with mRCC at Dana-Farber Cancer Institute treated with VEGF-TT, ICI or both, and for whom tumor and/or blood samples were available. Bulk RNA-sequencing (RNA-seq) and T-cell receptor sequencing (TCR-seq) were performed on peripheral blood mononuclear cells (PBMCs), collected before and during therapy. Bulk RNA-seq was additionally performed on available pre-treatment primary tumor samples. Immunoglobulin heavy chain (IgH) isotypes were inferred from bulk RNA-seq data using TRUST4. Parameters of the T-cell and B-cell repertoires were evaluated in responders vs. non-responders to systemic therapies, and between pre- and on-treatment samples within patient subgroups. **Results:** In total, blood (PBMC) samples from 386 patients were available across all treatment cohorts. Following quality-control, TCR-seq and RNA-seq data were available for 367 and 134 patient samples, respectively. Responders to ICI-based regimens (ICI or VEGF-TT+ICI) presented a trend towards an increased baseline (pre-treatment) TCR clonality as compared to non-responders ($p=0.06$), corresponding to a less polyclonal T cell repertoire in responders at baseline. No significant changes in clonality were seen between pre- and on-treatment samples among responders to ICI regimens ($p=0.14$), as opposed to non-responders where a significant increase was identified ($p=0.001$). The analysis of IgH isotypes in baseline blood samples showed higher fraction of IgG1 in responders (vs. non-responders) to ICI regimens ($p=0.01$). This was further confirmed in the analysis of IgH isotypes inferred from tumor samples ($p=0.04$). No significant differences in IgH isotype fractions were identified between responders and non-responders to VEGF-TT. **Conclusions:** We were successfully able to characterize T-cell receptor and IgH repertoires in a large cohort of patients with mRCC and evaluate their associations with ICI response. Our results show that baseline TCR clonality and IgG1 antibody fraction are associated with the response to ICI regimens, suggesting a potential role for immune biomarker development. Biomarkers of response to first-line nivolumab therapy in patients with advanced renal cell carcinoma (RCC) enrolled in the HCRN GU16-260 trial.
First Author: Nourhan El Ahmar, Brigham and Women's Hospital, Boston, MA

Background: The HCRN GU16-260 study showed that nivolumab (nivo) monotherapy is active in treatment-naïve patients (pts) with RCC. Although efficacy correlated with tumor cell (TC) PD-L1 expression, more clinically relevant biomarkers are needed. We previously showed that levels of CD8+ tumor-infiltrating lymphocytes (TIL) expressing PD-1 but not TIM-3 and LAG-3 (CD8+ PD1+ TIM3- LAG3-) were associated with response to nivo in previously treated clear cell RCC (ccRCC) pts (Pignon, 2019; Ficial, 2021). Here, we sought to validate these findings in the first-line setting. **Methods:** Primary tumor tissues from pts with ccRCC ($n=67$) and non-ccRCC ($n=13$) were analyzed by multiparametric immunofluorescence (IF), and the density of CD8+PD1+TIM3-LAG3- TIL was quantified by image analysis. The correlation of the log-transformed biomarkers with objective response rate (ORR) and progression-free survival (PFS) was assessed in the ccRCC cohort and the combined (ccRCC + non-ccRCC) cohort ($n=80$) using Cox or logistic regression analysis, or Chi-square/Fisher's exact test (as appropriate) for statistical inference – alpha level was set at 5% (1-sided). **Results:** In both the ccRCC and the combined cohort, density of CD8+PD1+TIM3-LAG3- TIL (IF biomarker) measured as continuous variable was associated with ORR (ccRCC: OR = 1.54, $p=0.017$; combined: OR = 1.35, $p=0.040$) and PFS (ccRCC: HR = 0.79, $p=0.015$; combined: HR = 0.85, $p=0.016$). At a cutoff optimized for maximum sensitivity for ORR, ccRCC patients with a high (61/67) vs low (6/67) IF biomarker had higher ORR (44.3% vs. 0% $p=0.039$) and longer median PFS (10.9 months vs. 4.2 months, $p=0.016$). Of note, when combined with the IF biomarker, TC PD-L1 expression ($\geq 1\%$) further separated the clinical outcomes of ccRCC pts. **Conclusions:** High levels of CD8+ PD1+ TIM3-LAG3- TILs were associated with response to first-line nivo in pts with advanced RCC and the combination with TC PD-L1 status further separated the outcomes of pts with ccRCC, validating our previous findings. Further investigations into the role of myeloid inflammation as determinant of clinical outcome to nivo therapy are ongoing. Clinical trial information: NCT03117309. Research Sponsor: Department of defense.

	Biomarker levels	N of pts	ORR		median PFS

CD8 cell PET imaging with 89-Zr-crefmirlimab berdoxam (crefmirlimab) in patients with metastatic renal cell carcinoma (mRCC) receiving checkpoint inhibitors (CPIs): Association with response and tissue CD8 expression.
First Author: Sumanta Kumar Pal, City of Hope, Duarte, CA

Background: Novel imaging modalities using frequently expressed RCC antigens, such as CAIX, have shown promise in early-stage disease (Shuch B *et al* ASCO GU 2023). In advanced RCC, no tissue-based biomarkers have been well established to predict outcome with contemporary regimens, e.g., checkpoint inhibitors (CPIs) or targeted therapy (TT). We hypothesize that functional imaging of CD8 T-cells (CD8s) with crefmirlimab (a ~80 kDa ⁸⁹Zr-labelled minibody with high affinity for CD8) may predict response given the essential role of CD8 T-cells (CD8s) in mediating CPI response. **Methods:** Eligible pts had pathologically verified RCC, metastatic disease and an intent to initiate standard of care CPI therapy. Patients received crefmirlimab PET/CT within 1 wk of CPI infusion and 4-6 weeks after initiating therapy. Baseline biopsy was mandated, along with repeat biopsy 0-2 weeks following the second PET/CT scan. PET signal was characterized as SUV_{max}, SUV_{peak} and SUV_{mean} of the biopsied lesions, up to 5 index lesions and representative CD8 avid lymph nodes. Mean SUV_{max} in responders and non-responders were compared using students t-test (1-sided). CD8 expression in tissue was characterized as the number of positive cells per mm²; PET avidity and CD8 expression were compared using the Spearman correlation coefficient. **Results:** 17 pts (9 M: 8 F) were enrolled; most pts had clear cell histology (12; 71%) followed by unclassified (3; 17%) and papillary (2; 12%). The most commonly rendered CPI-based regimens were nivolumab alone (6 pts; 35%) and cabozantinib/ nivolumab (3 pts; 17%). Follow-up data was available in 15 of the patients. By RECIST v1.1, 3 of 15 patients were classified as responders (best overall response [BOR] of complete response or partial response) and 12 patients were classified as non-responders (BOR of stable disease or progressive disease). Average SUV_{max}, SUV_{peak} and SUV_{mean} per patient among all quantified index lesions and representative lymph nodes were 10.02, 6.95 and 6.11 for baseline and 8.82, 6.23 and 5.39 during treatment, respectively. Average SUV_{max} at baseline was 14.68 in responders to CPI and 8.28 in non-responders ($P=0.006$). On treatment SUV_{max} was 10.93 in responders to CPI and 8.22 in non-responders ($P=0.19$). A strong correlation between CD8 expression in baseline tissue and normalized SUV_{mean} was observed ($r=0.77$; 95%CI 0.53-0.91). **Conclusions:** To our knowledge, this is the first series in RCC to demonstrate that functional imaging of immune cells (here, CD8s) may segregate response to CPIs, with responders having a higher baseline SUV and a larger decrement in SUV with therapy. Our results are bolstered by a significant correlation between tissue and imaging CD8 expression. Larger studies are underway to validate this noninvasive strategy. Clinical trial information: NCT03802123. Research Sponsor: ImaginAb.

Role of cytoreductive nephrectomy (CN) in metastatic clear cell renal cell carcinoma (mccRCC) in the era of immunotherapy (IO): An analysis of the National Cancer Database (NCDB). *First Author: Maroun Bou Zerdan, SUNY Upstate Medical University, Syracuse, NY*

Background: The role of CN remains questionable after the well intentioned two large prospective trials, SURTIME AND CARMENA, failed to show the benefit of CN for mcrRCC, with Sunitinib as standard of care. **Methods:** We identified stage IV mcrRCC only patients (pts) who received IO with or without surgery in the NCDB 2004-2018. Overall survival (OS) was calculated among three groups of IO alone (group (gr)1), IO followed by CN (gr2), CN followed by IO (gr3). Cox models compared OS by treatment group after adjusting for sociodemographic, health, and facility variables. **Results:** From 615,519 renal cancer cases, 2,903 met our criteria. 6.96% of ccRCC had sarcomatoid histology. Pts in the gr 2 and gr 3 had 63%, 95% CI [0.265-0.510] and 46%, 95% CI [0.487- 0.594], $P = 0.001$, risk reduction in mortality compared to IO alone. Black race compared to white race, education attainment quartile < 6.3% compared to > 17.6%, uninsured pts compared to privately insured, and pts treated at community cancer center compared to academic center had an increased mortality risk by 16%, 95% CI [0.980-1.387] ($P = 0.083$), 26%, 95% CI [1.054-1.511] ($P = 0.011$), 30%, 95% CI [1.003-1.683] ($P = 0.047$), 44%, 95% CI [1.161-1.779] ($P = 0.001$) respectively. Median income quartiles ranging > 63k, had 25% reduction in mortality over income quartiles < 40k, 95% CI [0.630-0.902] ($P = 0.002$). Regardless of the sequence of CN, partial nephrectomy was minimally used. Pts with brain and liver metastasis had a 48% ($P = 0.063$) and a 79% ($P = 0.001$) chance of increased risk of mortality. **Conclusions:** Pts receiving CN regardless of sequence with IO did better than IO alone in this national registry-based adjusted analysis for mcrRCC. International Metastatic Renal Cell Carcinoma Database Consortium risk stratification of pts was not done however Charlson-Deyo Comorbidity Index, visceral/brain metastasis were accounted for in OS analysis. Limitations inherited in the retrospective nature of this study are lack of randomization and pts' and physicians' choice. We believe the role of CN does warrant prospective validation in the era of IO for stage IV ccRCC. OS at 2 and 5 yrs for all three groups, with respective 95% CI. Research Sponsor: None.

⁸⁹Zr-DFO-girentuximab for PET/CT imaging of clear cell renal cell carcinoma: Results from phase 3 ZIRCON study. *First Author: Brian M. Shuch, Institute of Urologic Oncology, David Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: Conventional tools (eg, CT, MRI, biopsy) have limitations for characterizing renal mass histology; approx. 25% of patients with an indeterminate renal masses (IDRM) <4cm undergo surgery for benign disease. Accurate noninvasive techniques to risk stratify the IDRM remains an unmet need. Girentuximab is a monoclonal antibody that targets carbonic anhydrase IX (CAIX), an enzyme highly expressed in clear cell renal carcinoma (ccRCC). Radiolabeled ⁸⁹Zr-DFO-girentuximab is highly specific for CAIX and can aid differentiation between ccRCCs and other renal lesions. ZIRCON evaluated the performance of ⁸⁹Zr-DFO-girentuximab PET/CT for detection of ccRCC. **Methods:** In this open label, multicenter trial, patients with an IDRM (≤ 7 cm; cT1) who were scheduled for partial nephrectomy within 90 days from planned ⁸⁹Zr-DFO-girentuximab administration were eligible. Enrolled patients received a single dose IV (37 MBq $\pm 10\%$; 10mg girentuximab) on Day 0 and underwent PET/CT imaging on Day 5 (± 2 d). Blinded central histology review determined ccRCC status. The co-primary objectives were to evaluate both the sensitivity and specificity of ⁸⁹Zr-DFO-girentuximab PET/CT imaging in detecting ccRCC in patients with IDRM, using histology as the standard of truth. Key secondary objectives included sensitivity and specificity of TLX250-CDx PET/CT imaging in the subgroup of patients with IDRM ≤ 4 cm (cT1a). Other secondary objectives included positive and negative predictive values, and evaluation of safety and tolerability. The Wilson 95% confidence intervals (CI) lower bound for sensitivity and specificity had to be >70% and 68% respectively for ≥ 2 independent readers to declare the study successful. **Results:** 300 patients received ⁸⁹Zr-DFO-girentuximab (mean age, 62 ± 12 y; 71% Male). Of 288 patients with central histopathology of surgical samples, 193 (67%) had ccRCC, and 179 (62%) had cT1a. Of 284 evaluable patients, the average across all 3 readers for sensitivity and specificity was 86% [80%, 90%] and 87% [79%, 92%] resp. for coprimary, and 85% [77%, 91%] and 90% [79%, 95%] resp. for key secondary endpoints. For all evaluable patients, positive and negative predictive values were $\geq 91.7\%$ and $\geq 73.7\%$, resp. PET+ ccRCC had higher mean CAIX expression compared with PET- ccRCC patients ($p < 0.05$). Sensitivity and specificity were consistent with masses ≤ 2 cm ($n=46$) of which, 26 were ccRCC+, 13 ccRCC-, and 3 unevaluable at central histopathology. Of 263 adverse events (AEs) in 124 patients, 2 AEs of mild intensity were treatment related. **Conclusions:** ZIRCON study confirms ⁸⁹Zr-DFO-girentuximab PET/CT is a well-tolerated and accurate modality for noninvasive identification of ccRCC in IDRM. This tool could be included in the diagnosis/management of patients with IDRM, limiting unnecessary treatment of benign lesions. Clinical trial information: NCT03849118. Research Sponsor: Telix Pharmaceuticals.

Belzutifan plus lenvatinib for patients (pts) with advanced clear cell renal cell carcinoma (ccRCC) after progression on a PD-1/L1 and VEGF inhibitor: Preliminary results of arm B5 of the phase 1/2 KEYMAKER-U03B study. *First Author: Laurence Albiges, Gustave Roussy, Villejuif, France*

Background: The oral HIF-2 α inhibitor belzutifan demonstrated antitumor activity with manageable safety as monotherapy in pts with heavily pretreated ccRCC and in combination with a VEGF-TKI in pts who previously received a PD-1/L1 inhibitor. KEYMAKER-U03B (NCT04626518) is phase 1/2, multicenter, multi-arm, open-label, adaptive umbrella study. We present preliminary results from arm B5 for belzutifan + lenvatinib. **Methods:** In all arms, adults with histologically confirmed ccRCC, KPS $\geq 70\%$, and disease progression on or after PD-1/L1 inhibitor and VEGF-TKI treatment (in sequence or in combination) were enrolled. In arm B5, pts received belzutifan 120 mg PO QD + lenvatinib 20 mg PO QD. The study comprised a safety lead-in phase to establish the recommended phase 2 dose (RP2D), followed by an efficacy phase. Primary end point for the safety lead-in phase was safety and tolerability to establish RP2D; co-primary end points of the efficacy phase were safety and ORR per RECIST v1.1 by blinded independent central review (BICR). Secondary end points include clinical benefit rate (CBR; CR + PR + SD ≥ 6 mo), DOR and PFS per RECIST v1.1 by BICR. Response will be presented in pts who had an opportunity to receive ≥ 2 postbaseline scans due to ongoing enrollment. PFS was evaluated in all enrolled pts and safety in all treated pts. End points will be evaluated in each arm separately; no comparisons will be made across arms. **Results:** As of September 29, 2022, 32 pts were enrolled and 30 received treatment. Median age was 60.5 y, 78% were male and 78% had intermediate/poor IMDC risk. 23 pts were on treatment at data cutoff date. Median follow up was 6.9 mo (range: 0.1-18.2). Safety of belzutifan 120 mg + lenvatinib 20 mg was manageable. Of 10 evaluable pts in the safety lead-in phase, only 1 experienced a dose-limiting toxicity (grade 1 dyspnea). Among pts who had opportunity for ≥ 2 postbaseline scans ($n=24$), ORR was 50% (95% CI, 29-71; all PRs); CBR was 54% (95% CI, 33-74). Median DOR was not reached (NR; range: 1.4-+14.0+ mo); 74% of responders remained in response for ≥ 12 mo by KM estimation. For all enrolled pts, median PFS was 11.2 mo (95% CI, 4-NR); 6-mo rate was 55%. In the safety analysis, 28 pts (93%) experienced a treatment-related AE (TRAE), most commonly ($\geq 40\%$) anemia (43%), fatigue (43%), and hypertension (43%). Grade 3-4 TRAEs occurred in 15 pts (50%); most commonly hypertension (27%) and anemia (17%). 1 pt experienced grade 2 hypoxia. No pt died due to a TRAE. **Conclusions:** Preliminary data from the belzutifan + lenvatinib combination exhibited promising antitumor activity in pts with ccRCC that progressed on PD-1/L1 inhibitors and VEGF-TKIs. Safety findings were consistent with individual profiles of each agent. The combination is being further evaluated in the phase 3 LITESPARK-011 study. Clinical trial information: NCT04626518. Research Sponsor: Merck Sharp & Dohme LLC., a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

Impact of smoking status (SS) on the clinical outcomes of patients with metastatic renal cell carcinoma (mRCC) treated with first line (1L) immunotherapy (IO)-combination regimens: Results from the International Metastatic Renal Cell Carcinoma Database Consortium (IMDC). *First Author: Georges Gebrael, Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: Active smoking is associated with decreased overall survival (OS) in patients (pts) with mRCC treated with VEGF targeted therapy (VEGF-TT) (Kroeger N. et al. 2019, IMDC investigators). Conversely, smoking history has been linked to improved OS in pts with advanced non-small cell lung carcinoma (NSCLC) receiving 1L pembrolizumab monotherapy (Popat S. et al., 2022). Herein, we assess the association between SS and outcomes in pts with mRCC treated with 1L standard of care (SOC) IO-based regimens. **Methods:** Real-world data from the IMDC were collected retrospectively. We included mRCC pts who received either dual IO therapy or IO + VEGF-TT in the 1L setting and known SS at disease diagnosis. Pts were categorized as current, former and non-smokers. The primary outcomes were OS, time to treatment failure (TTF) and objective response rate (ORR) on 1L IO-based regimens. OS and TTF were evaluated using Cox regression, adjusting for age at 1L treatment, IMDC risk groups, BMI, histological type and time from diagnosis to 1L treatment initiation. ORR was compared between the SS groups using a logistic regression, adjusting for the same confounders. **Results:** 989 pts were eligible and included. 438 (44.3%), 415 (42%), and 136 (13.7%) pts were non-smokers, former, and current smokers at diagnosis, respectively. Median time from diagnosis to initiation of 1L IO-based treatment was 0.47 years (IQR 0.13-2.15). At baseline, there were no significant differences in age at 1L, IMDC risk groups, KPS status, BMI, and presence of sarcomatoid features across the 3 groups ($p > 0.05$). Median follow up was 21.2 months from 1L IO-based treatment initiation. On multivariable analysis, no significant differences in OS, TTF or ORR were seen between the SS groups ($p > 0.05$). **Conclusions:** To our knowledge, this represents the first and largest effort to evaluate the impact of smoking on clinical outcomes in pts with mRCC treated with IO-based regimens. There was no association between SS at diagnosis and the clinical outcomes of patients with mRCC receiving current 1L SOC IO-based regimens. As opposed to other cancer types (i.e., NSCLC), current or past smoking history did not appear to be predictive of benefit from IO-based therapy. Research Sponsor: None.

Assessment of short-chain fatty acid (SCFA) and circulating cytokine trends in a clinical trial of nivolumab/ipilimumab and CBM588 in metastatic renal cell carcinoma (mRCC). *First Author: Nazli Dizman, Yale University School of Medicine, New Haven, CT*

Background: Recent evidence suggests that blood and stool SCFA levels (including acetic acid and butyric acid) are associated with clinical outcomes with immune checkpoint blockade in melanoma (Nomura *et al.* JAMA Network Open 2020). Herein, we report trends in plasma SCFA and cytokine levels in a randomized phase I clinical trial of CBM588, a live bacterial product containing a butyric acid-producing bacterium, *C. butyricum*, in patients with mRCC treated with immune checkpoint blockade. **Methods:** Treatment naive patients with clear cell and/or sarcomatoid mRCC and intermediate- or high-risk IMDC disease were randomized to nivolumab/ipilimumab or nivolumab/ipilimumab and CBM588 in a 1:2 fashion. Blood samples were collected at baseline and on treatment (week 12 +/- 5 weeks). Quantitative assessment of plasma SCFAs and cytokines was performed by liquid chromatography-mass spectrometry and a Human Cytokine 30-plex protein assay, respectively. Changes in SCFAs and cytokine levels were assessed using paired sample T-tests. **Results:** A total of 29 patients were randomized to the nivolumab/ipilimumab (n=19) and nivolumab/ipilimumab with CBM588 (n=10) arms. Objective response rates (ORR) with nivolumab/ipilimumab with and without CBM588 were 58% and 20%, respectively. No statistically significant change in SCFA levels was observed between baseline and on-treatment samples in either arm. Notably, however, a numerical increase in levels of acetic acid (414.3 vs 814.0 nmol/g) and isobutyric acid (7.9 vs 9.0 nmol/g) was seen in the nivolumab/ipilimumab and CBM588 arm. In contrast, both factors decreased in the nivolumab/ipilimumab arm (563.1 vs 401.1 nmol/g and 10.0 vs 8.8 nmol/g, respectively). In patients with an uptrend in isobutyric acid levels with nivolumab/ipilimumab and CBM588, ORR was 64% compared to 50% in those without an uptrend in such levels). Similarly, patients with increases in butyric acid with nivolumab/ipilimumab and CBM588 had an ORR of 66%, compared to 43% among those without an increase in butyric acid levels. Correlations between acetic acid and chemokines, including CCL2 and CCL4, were observed with correlation coefficients of 0.83 and 0.82, respectively (p<0.001 for both). **Conclusions:** A substantial increase in isobutyrate levels in CBM588 responders is indicative of altered amino acid metabolism (specifically, valine and leucine) by modified gut flora in these patients. These observations, combined with alterations in serum cytokines, provide biologic rationale for the clinical activity seen with CBM588 in combination with nivolumab/ipilimumab in this trial. Clinical trial information: NCT03829111. Research Sponsor: Kidney Cancer Association Trailblazer award; Gateway Foundation.

Characterization of the immunophenotype and tumor specificity of CD8+ T-cells in chromophobe renal cell carcinoma (ChRCC) and renal oncocytic neoplasms. *First Author: Chris Labaki, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: ChRCC is an uncommon kidney cancer variant that has a poor prognosis in the metastatic setting, with limited response to current standard-of-care immune checkpoint inhibitors (ICIs) used for other RCC histologies. We evaluated the tumor-immune microenvironment of ChRCC and other related oncocytic neoplasms to better understand the immunophenotype of these tumors. **Methods:** We performed paired single-cell RNA sequencing (scRNA-seq), single-cell T-cell receptor sequencing (scTCR-seq), and CD45 immunohistochemistry (IHC) of ChRCC, renal oncocytoma (RO) and low-grade oncocytic tumor (LOT) tumor and matched normal samples. Bulk RNA-sequencing (RNA-seq) data of clear cell RCC (ccRCC), papillary RCC (pRCC) and ChRCC were additionally analyzed using The Cancer Genome Atlas (TCGA) kidney cancer cohorts. T cell antigenic specificities from scTCR-seq were inferred using a comprehensive database of annotated T-cell receptor sequences (VDJdb). Single-cell transcriptomic signatures were used to infer the tumor specificity (Oliveira G, Nature, 2021 and Lowery FJ, Science, 2022) and viral specificity (Oliveira G, Nature, 2021) of CD8+ T-cells from ChRCC, as compared to those from ccRCC (Braun DA, Cancer Cell, 2021). **Results:** ChRCC and other oncocytic tumors had a lower infiltration of CD45+ immune cells as compared to ccRCC (p<0.01). Single-cell analysis was performed on 46,817 cells from 5 tumors (ChRCC: n=3, RO: n=1 and LOT: n=1) and 4 normal samples. Across all tumors, CD8+ T cell clusters displayed a lower expression of immune checkpoints (i.e. *PDCD1* [PD-1], *CTLA4*, *LAG3*, *HAVCR2* [TIM-3], and *TIGIT*) as compared to ccRCC. This was further validated in a bulk RNA-seq analysis using TCGA data, with a significantly lower expression of all immune checkpoints in ChRCC compared to both ccRCC (p<0.01) and papillary RCC (pRCC; p<0.01). Analysis of the T cell receptor repertoire (scTCR-seq) of ChRCC, RO and LOT samples did not show any pattern of clonal expansion, and a higher proportion of T cells in ChRCC were inferred to have a viral specificity, as compared to ccRCC (0.79 vs. 0.1%, respectively). CD8+ T cells from ChRCC (vs. ccRCC) displayed a significantly lower expression of two signatures of tumor specificity (p<0.01), and a higher expression of the viral-specific signature (p<0.01). **Conclusions:** In ChRCC, there is low infiltration by CD45+ immune cells. Although infiltrating CD8+ T cells have a predominantly non-exhausted immune phenotype, they likely lack anti-tumor specificity (i.e. are “bystander” T cells). These findings may help to understand the molecular basis for the lack of response to immunotherapy recently identified among patients with advanced ChRCC, and support future therapeutic strategies to increase infiltration of tumor-specific T cells into the tumor microenvironment. Association of neutrophil to eosinophil ratio (NER) with clinical outcomes in patients with metastatic renal cell carcinoma (mRCC) treated with first-line (1L) immune checkpoint inhibitors (ICI)-based regimens. *First Author: Marc Eid, Dana-Farber Cancer Institute, Boston, MA*

Background: ICI-based regimens (ICI + ICI or ICI + VEGF targeted therapy [VEGF-TT]) represent current standard of care systemic therapies for the management of patients with mRCC. Robust biomarkers capable of predicting the therapeutic efficacy and safety of such regimens are still lacking. Eosinophils have been shown to play an important role in the response to immunotherapy. While recent investigations in RCC evaluated NER as a biomarker of poor response to immunotherapy, they did not fully account for the impact of different lines of therapy and the therapeutic classes of ICI-based regimens. We aimed to comprehensively evaluate the association of NER with clinical outcomes in patients with mRCC treated with 1L ICI regimens. **Methods:** We retrospectively reviewed data from patients with mRCC treated with first line ICI-based regimens (dual ICI or ICI + VEGF-TT) at Dana-Farber Cancer Institute. Clinicodemographic information was collected, including tumor histology, ECOG performance status, IMDC risk score. We examined NER at baseline and at 6, 12, and 24 weeks while patients were still receiving treatment. The primary endpoint was overall survival (OS). Time to treatment failure (TTF) was a secondary endpoint. The association of NER with OS and TTF was evaluated using Cox regression models, adjusted for age, gender, BMI, histology, IMDC risk score and autoimmune disease. **Results:** Overall, 156 patients were included in the current analysis, with a median age of 61 years (IQR: 54-67). 60 patients received dual ICI therapy, while 96 were treated with ICI + VEGF-TT combinations. In the ICI+ICI group, a higher NER at baseline, 6 and 12 weeks was associated with worse OS. In the ICI + VEGF group, a higher NER only at 6 weeks appeared to be associated with worse OS. No association between NER and TTF was found. **Conclusions:** To our knowledge, this is the first study to investigate, across therapeutic classes, the association of NER with clinical outcomes in patients with mRCC treated with 1L ICI-based regimens. Higher NER was linked to poor survival outcomes, especially in patients receiving dual ICI therapy. Future translational studies are needed to clarify these findings. Research Sponsor: None.

Association of NER with OS in the ICI+ICI and ICI+VEGF-TT groups.				
	0 Weeks	6 Weeks	12 Weeks	24 Weeks
Median NER – ICI+ICI (IQR)	21 (11.2-32.9)	12 (7.5-19)	9 (7 -22)	10 (6.9-15)
HR for OS (95% CI)	4.8 (1.2-19.1)	1.2 (1.1-1.3)	1.04 (1.02-1.08)	1.04 (0.9-1.2)
Median NER – ICI+VEGF-TT (IQR)	16.4 (13.2-23.7)	13 (9.5-17.6)	12.5 (8.8-20.9)	13.7 (7.7-20.9)
HR for OS (95%CI)	1.0 (0.98-1.02)	1.03 (1.01-1.06)	0.96 (0.91-1.01)	0.95 (0.9-1.02)

Germline mutations in hereditary renal cell carcinoma (RCC) genes among 32,240 patients with all cancer types. *First Author: Maria Isabel Carlo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Germline pathogenic variants (PVs) in *VHL*, *FH*, *BAP1* and others cause hereditary syndromes with increased risk of renal cell carcinoma (RCC). Defining the clinical spectrum of these syndromes has been limited by ascertainment bias and their relative rarity. Using a large population of cancer patients who underwent germline and somatic tumor testing, we analyzed the landscape of germline PVs in RCC genes in individuals with all cancer types. **Methods:** We identified patients with germline PVs in RCC genes (*VHL*, *FH*, *SDHB*, *MET*, *FLCN*, *BAP1*) in the MSK-IMPACT cohort, an institutional protocol of patients who had somatic and germline sequencing. The *MITF* E318K variant was analyzed separately given its uncertain role in RCC risk. Objectives were to determine whether patients met clinical criteria for their respective hereditary syndromes, analyze biallelic inactivation in all tumor types, and explore under-recognized cancer associations. Fisher test was used to compare frequency of variants to population. **Results:** Of 32,240 patients who consented to germline results, 55% were female; most common cancer types were breast (n=3600), pancreas (n=3554), prostate (n=3427), with 1166 (3.6%) with RCC. 110 (0.34%) had a germline variant in a RCC syndrome gene (*BAP1*=26, *SDHB*=24, *FH*=24, *FLCN*=19, *VHL*=16, *MET*=1). Of 110 germline positive, 56% met clinical criteria for their hereditary syndrome, and 40% had RCC. For *VHL*, *FH*, *SDHB* and *MET*, a high proportion of patients met criteria for their hereditary syndromes, but this was much less for *FLCN* (Birt-Hogg-Dubé) and *BAP1*. Biallelic inactivation in the tumor, supporting causality, was very high except in *FLCN*. Possible novel cancer associations were liver cancer in *BAP1* (n=5;19%) and colon cancer in *FLCN* (n=4;17%). Additionally, 114 patients had the *MITF* E318K variant; which was not enriched in RCC cases (only 1 RCC) compared to other cancers or population control (odds ratio 0.45; p-value = 0.16, 95% confidence interval: 0.1 - 1.2). **Conclusions:** Germline analysis in a large pan-cancer cohort identifies a high prevalence of patients with hereditary RCC syndromes, variability in clinical phenotype and suggestion of novel cancer associations. The low number of *MITF* E318K variant carriers in RCC cases calls into question its role in RCC risk and warrants further study. Research Sponsor: Robert Wood Johnson Foundation; U.S. National Institutes of Health.

Germline Gene	Met clinical criteria for hereditary syndrome	Number of cancers/individual (median)	History of RCC	Tumor biallelic inactivation
BAP1	10/26 (38%)	1.5	8 (31%)	8/9
SDHB	18/24 (75%)	1	6 (25%)	16/20
FH	17/24 (71%)	1	20 (83%)	13/15
FLCN	5/19 (26%)	1	4 (21%)	5/14
VHL	11/16 (69%)	≥3	5 (31%)	NA
MET	1/1 (100%)	1	1 (100%)	NA

Patient priorities and expectations of systemic therapy in metastatic renal cell carcinoma. *First Author: Dena Battle, KCCure, Alexandria, VA*

Background: As treatment options for metastatic Renal Cell Carcinoma (RCC) have increased in number, selecting therapy has become more complicated. When prioritizing agents today, guidelines recommend selection based primarily on risk classification, as well as consideration of efficacy data, patient characteristics, quality of life, cost, and patient preference. Understanding how patients prioritize treatment selection and define treatment success is crucial to improving patient/provider communication and to improving future drug development. **Methods:** The survey was developed by the Kidney Cancer Research Alliance (KCCure) and was broadcast between 07/2022 and 09/2022 to patients via website, mailing lists and social media platforms. Those who agreed to participate were surveyed for demographics (age, gender, race, income, country) and clinical characteristics (date of the diagnosis, disease stage, treatment history). Descriptive statistics summarized the survey data. **Results:** 399 out of 1,062 patients surveyed had metastatic disease. 80% of patients were receiving or had received systemic therapy, 20% of patients had not yet received systemic therapy. 52% were female and 48% were male, with a median age of 57 years (range 28-86). Patients identified as white (89%) and living in the United States (86%). 69% of patients reported that they did not know their IMDC or risk status, 10% were favorable risk, 11% were intermediate risk and 10% were poor risk. When asked to select the most important outcome for treatment selection on a rank-choice scale from 1 to 8, the chance to eliminate all evidence of disease (complete response) scored highest (6.6), followed by durability of response (5.1), improved quality of life (5.0), rapid reduction of tumors (4.9), ability to go off therapy (4.2), low risk of toxicity (4.0) and reduction of tumor symptoms (4.0). Patients ranked low cost as the least important factor in selecting treatment (2.3). 70% of patients defined "long-term" response to therapy as five years or longer, and over a quarter of patients (26%) defined long-term response as 10 years or longer. When asked to define treatment success, patients rank radiological reduction in tumor size (83%) as the most important factor, followed by stable disease (67%), improved quality of life (48%) and the ability to return back to work (22%). The lowest ranked choice was "I just trust my doctor" (17%). **Conclusions:** Most patients are not familiar with their risk classification and may not realize the significance of this factor in treatment selection. Patients rank complete response as the most important outcome/desire when considering treatment options. Cost is the least important factor for patients in selecting treatment. Patient perceptions of long-term response to therapy may differ from provider perceptions. More research is needed to improve patient/provider communication in the therapy selection process. Pathologic concordance rate and outcomes by histologic subtype in advanced papillary renal cell (pRCC) carcinoma: An analysis from the SWOG S1500 (PAPMET) trial. *First Author: Abhishek Tripathi, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: The PAPMET trial demonstrated significantly improved progression-free survival (PFS) with cabozantinib vs. sunitinib in advanced pRCC (median: 9.0 vs. 5.6 mos; hazard ratio (HR): 0.60; 95% CI 0.37–0.97). Until recently, pRCC was subclassified as type 1 vs. 2 based on histologic features. During conception of the PAPMET study, we hypothesized that patients with type 1 pRCC will derive more benefit from cabozantinib compared to those with type 2 disease, given enrichment of MET alterations in the former. In this secondary analysis, we report the outcomes stratified by histologic subtype per central review. **Methods:** Patients with advanced pRCC who had received up to 1 line of therapy were randomized to receive either sunitinib, or cabozantinib, crizotinib or savolitinib stratified by pRCC subtype (type 1, type 2 or not otherwise specified [NOS]). Pathologic data from local pathology review was catalogued. Central pathology review was conducted by 3 expert genitourinary pathologists who independently reviewed tumor specimens. Discordant opinions among these pathologists were individually arbitrated and a unified diagnosis was assigned. Central pathology review results were considered the true positive and the sensitivity, and the positive predictive value (PPV) of local review was estimated for histologic subtypes. Clinical outcomes (objective response rate (ORR) and PFS) were compared between histologic subtypes (by central review) in the cabozantinib and sunitinib arms. **Results:** Amongst the 147 patients with available local and central pathology review, 17.7% (n=26), 53% (n=78) and 29.3% (n=43) were characterized as having type 1, 2 or NOS/mixed pRCC by local review compared to 29.3% (n=43), 45.6% (n=67) and 25.2% (n=37) respectively by central review. Individual cases were frequently reclassified and local pathology review demonstrated low sensitivity (type 1: 49%, type 2: 67% and NOS: 43%) and PPV (type 1: 80%, type 2: 57% and NOS/mixed: 37%) across subtypes. During central review, complete agreement amongst the 3 pathologists was seen in only 33.3% (n=49) of cases and was highest in type 2 tumors (40%; n=27). Compared to sunitinib, cabozantinib demonstrated numerically higher ORR and PFS in both type 1 and type 2 pRCC subgroups. **Conclusions:** Designation of pRCC subtype by central review did not identify a subset of patients with greater clinical benefit from cabozantinib. Further, classification of subtype was challenged by discordance in both local and central review. Supporting the removal of type 1 and 2 designations from the 2022 WHO guidelines, these findings highlight the limited clinical value and significant challenges associated with subtyping of pRCC. Clinical trial information: NCT02761057. Research Sponsor: AstraZeneca plc, Exelixis, Inc., and Pfizer, Inc.; U.S. National Institutes of Health.

	Type 1		Type 2	
	ORR (%)	PFS (mos, 95% CI)	ORR (%)	PFS (mos, 95%CI)
Sunitinib	0	8 (7.3,21.8)	9.5	3.1 (2.6, 6.1)
Cabozantinib	13.3	9.8 (5.14, 15.4)	26.6	6.1 (3.2, 9.8)

Association between intra-tumoral microbiome and clinical benefit (CB) from immunotherapy (IO) in patients with metastatic renal cell carcinoma (mRCC). *First Author: Luis A Meza, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Specific bacteria and microbial diversity in the gut may drive response to IO in patients (pts) with mRCC (Routy et al Science 2018; Salgia et al Eur Urol 2020). Despite the evidence of bacterial proliferation in RCC tumors (Heidler et al Urol Int 2020), the impact of the intra-tumoral microbiome in RCC has been poorly delineated. Here, we explored its association to CB in mRCC pts receiving IO-based regimens. **Methods:** We identified pts with mRCC and available RNA sequencing (RNA-seq) data from tumor tissue collected prior to start of IO. Intra-tumoral microbiome analysis was performed on formalin-fixed paraffin-embedded samples. Following quality and adapter trimming, RNA-seq reads were mapped to a human genome to filter host reads using the STAR alignment tool. Taxonomic classification was performed using Kraken2 and Bracken. Following removal of common contaminants, the relative abundances among all non-human species were calculated. Microbial diversity was assessed using the Shannon index and statistical analysis performed using a t-test. Relative microbial abundance was compared between tumors from pts with or without CB from 1st line IO treatment using the Kruskal-Wallis test. P-values less than 0.05 were considered significant. **Results:** A total of 96 pts (71:25, M:F) with mRCC were included in this analysis. Of these, 85 (89%) had clear cell histology and 68 (71%) were IMDC intermediate/poor risk. The median age at the time of tissue sampling was 62.7 yrs old and most of the samples analyzed (57%) were collected from the primary site. IO, alone or in combination, was received as 1st line treatment in 57 pts (59%), with the most common regimen being nivolumab/ipilimumab (47%). CB from 1st line IO was observed in 39 (68%) pts. Tumors from pts achieving CB from 1st line IO had elevated microbial diversity compared to tumors from pts without CB (p=0.01). Tumor samples from these pts also had a significantly higher relative abundance of several bacterial genera compared to tumors from pts without CB. These included *Pasteurella*, *Escherichia*, and *Cloacibacterium* (p<0.05). No significant differences in bacterial diversity were observed between CB and no-CB pts receiving IO as 2nd line or beyond. **Conclusions:** This is the largest study exploring the association between the intra-tumoral microbiome of mRCC and CB from IO. In line with gut microbiome studies, an increased intra-tumoral Shannon diversity index was also associated with CB to IO in our 1st line cohort, further suggesting that bacterial diversity could be a driver of response. Additionally, several genera associated with CB are particularly relevant. For instance, members of the *Pasteurella* genus have been implicated in the activation of c-myc, a proto-oncogene that has been shown to induce PD-L1 expression. Research Sponsor: None.

Kidney cancer mortality in the United States between 1999 and 2020: An observational analysis of outcomes by gender, race, and ethnicity. *First Author: Nour Abdallah, Cleveland Clinic, Cleveland, OH*

Background: Kidney cancer (KC) is one of the leading causes of cancer mortality, with recent data showing an increase in incidence and mortality worldwide. Gender, racial, and ethnic disparities can impact KC outcomes. Studies investigating the outcomes of diverse patient populations spanning the cytokine, targeted therapy and immunotherapy eras have been limited. This study aims to investigate trends in age-adjusted mortality rates (ASMR) by gender, race, and ethnicity in the US at national and state levels. **Methods:** We utilized the Center for Disease Control Wonder database to extract national and state-wide KC mortality data (ICD-10 C64) from 1999-2020. ASMR and 95% confidence intervals (CI) were extracted based on gender, race and ethnicity reported per 100,000 population. To evaluate the difference between metro and non-metro regions, we divided the national trends based on 2013 Urban NCHS Urban-Rural scheme. Jointpoint regression analysis was performed to evaluate trends. **Results:** In total, 284,224 KC deaths were reported over twenty years, with an overall decrease in ASMR in recent years. Males had significantly higher ASMR throughout the study period, with a lower decrease than females. Amongst racial groups, American Indians (AI) had the highest mortality in 1999 (5.7). However, due to the smaller decrease of ASMR in Whites compared to Non-Whites, Whites showed the highest ASMR (3.9) in 2020. According to ethnicity, Non-Hispanic Whites (NHW) had significantly higher ASMR than Hispanics in 1999 (4.0 vs. 3.5) and 2020 (3.5 vs. 3.0) with a similar rate of decline (-11.4% vs. -12.5%). State-wise, ASMR decreased in all states except Utah (+45.8%), Arkansas (+18.4%), Hawaii (+15.4%), Montana (+5.3), Kansas (+2.7) and Nevada (+2.6). Interestingly, non-metro regions showed higher ASMR throughout the study period. Also, while there was a steep decline in ASMR (15%) in metro regions, only a minimal decline (-4.7%) was observed in non-metro regions. **Conclusions:** Over the last two decades, there has been a decrease in the ASMRs across all genders, races and ethnicities and in most states in the USA. The decrease in ASMR is likely multifactorial, related to earlier detection and improved treatments. However, differences in outcomes by gender, race, and ethnicity persist, highlighting the need for strategies to better understand the etiology of differences and mitigate disparities across social determinants of health across gender, racial, and ethnic groups. Research Sponsor: None.

Microbial metabolism of tryptophan is associated with resistance to immune checkpoint (ICB) therapy in renal cell cancer (RCC). *First Author: Shahla Bari, Duke University School of Medicine, Durham, NC*

Background: Metastatic RCC has a poor prognosis. Despite improvement in treatment outcomes with ICB and targeted therapy, many patients fail to respond to first line therapy and deep and durable responses remain elusive. The tryptophan metabolite kynurenine, an agonist of the immunosuppressive aryl hydrocarbon receptor (AhR), is associated with resistance to ICB. However, IDO (Indole 2,3 dioxigenase) blockers which inhibit tryptophan metabolism to kynurenine failed to show benefit in clinical trials, suggesting the presence of alternate AhR activation. We hypothesize that microbial metabolism of tryptophan to indole metabolites may be associated with AhR activation and ICB resistance. **Methods:** We prospectively collected stool and plasma of 79 treatment naïve metastatic RCC patients, treated with ICB +/- Tyrosine kinase inhibitors (TKI). Samples were collected at treatment initiation and at time of first response assessment (12+/-3 weeks). We evaluated stool metagenomics and untargeted stool and plasma metabolomics among responders (R) and non-responders (NR). We focused on kynurenine/tryptophan and indoles/tryptophan ratio to evaluate differential host and microbial metabolism of tryptophan. A responder was classified as progression free survival (PFS) greater than six months. We also performed global metabolomics on tumors of germ-free (GF) & specific pathogen free (SPF) mice to identify microbial & host metabolites. **Results:** Among 79 patients, 28 were treated with combination ICB, while 51 patients were treated with ICB + TKI. Median follow up for entire cohort was 9.5 months. 65% of patients had PFS > six months, while 27% of all patients had continued response at one year. Using unpaired t test comparing baseline relative abundance of metabolites between R vs NR - plasma Kynurenine/tryptophan ratio was significantly higher in NR vs R, at baseline (0.04 vs 0.02, p=0.017) and further increased in NR at 3 months (0.05 vs 0.02, p=0.02). Microbial metabolites of Tryptophan -Indole pyruvic acid (IPA), Indole carboxylic acid (IpA) and Indole acetaldehyde (IAA) were differentially associated with ICB resistance and was significantly higher in NR (IcA: 8.0 vs 4.96, p=0.03; IPA: 76.8 vs 64.9, p=0.02; IAA: 76.8 vs 64.6, p=0.026). We also noted differential enrichment of microbial KEGG enzymes associated with IPA, IAA and IcA production in the stool of NR patients compared to R. Microbial origin of IpA, IAA and IcA was confirmed by its absence in tumor of GF mice. **Conclusions:** This is first study in metastatic RCC which shows the association of indoles (microbial metabolites of tryptophan) with resistance to ICB. These indoles are known to be potent AhR agonists and are associated with immunosuppression suggesting that microbial metabolism of tryptophan may represent a novel pathway for ICB resistance in RCC patients. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Disitamab vedotin, a novel humanized anti-HER2 antibody-drug conjugate (ADC), combined with toripalimab in patients with locally advanced or metastatic urothelial carcinoma: An open-label phase 1b/2 study. *First Author: Xinan Sheng, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Genitourinary Oncology, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Disitamab vedotin has shown promising data across a spectrum of HER2 expression in patients with locally advanced or metastatic urothelial carcinoma (la/mUC) who progressed on chemotherapy. This study was conducted to evaluate the safety and efficacy of disitamab vedotin plus anti-PD-1 antibody in advanced urothelial carcinoma. **Methods:** This is an open-label, multicenter, phase 1b/2 trial to evaluate the safety and activity of RC48-ADC combined with toripalimab, a humanized immunoglobulin G₄ monoclonal antibody against PD-1 in mUC. Patients received RC48-ADC at 1.5 or 2 mg/kg, in combination with 3mg/kg toripalimab every two weeks in a dose-escalation and expansion cohort until confirmed disease progression assessed by the investigators, unacceptable toxicity, or voluntary withdrawal. The primary endpoint was safety; secondary endpoints included efficacy and tumor tissue biomarkers. **Results:** Forty-one la/mUC patients were enrolled (22 males; median age 66 y [42-76]; 61% treatment-naïve). 54% of patients had visceral metastases (mets), including 24% with liver mets. The primary site was in upper tract UC in 54%. HER2 expression IHC 2+ or 3+ was in 59% patients, and PD-L1 positive in 32%. No dose-limiting toxicity was observed and the recommended dose was RC48-ADC 2mg/kg plus toripalimab 3mg/kg every two weeks. By the cutoff date of 18 November 2022, the confirmed ORR was 73.2% (95%CI: 57.1, 85.8), including 9.8% CR. The ORR was 76.0% for treatment-naïve patients. In HER2 IHC 3+/2+, IHC 1+, and IHC 0 subgroups, the ORR was 83.3%, 64.3%, and 33.3%, respectively. The ORR was 61.5% and 78.6% in PD-L1 positive and negative subgroups. DCR was 90.2% (95% CI, 76.9–97.3), with a median progression-free survival (PFS) of 9.2 months (95%CI: 5.7-10.3) and 2-year overall survival (OS) rate of 63.2%. All patients experienced treatment-related adverse events (TRAEs). The most common TRAEs were AST/ALT increase (68.3%), peripheral sensory neuropathy (61.0%), asthenia (61.0%), γ -glutamyl transferase increase (56.1%), hypertriglyceridemia (53.7%), and appetite decrease (51.2%). Grade 3 or greater TRAEs occurred in 43.9% of patients. Twenty-three patients (56.1%) had immune-related AEs (14.6% $\geq$ G3), including immune-related skin reactions, hyperglycemia, pneumonitis, hepatitis, and myositis. **Conclusions:** RC48-ADC in combination with toripalimab demonstrated promising efficacy in patients with la/mUC and a manageable safety profile. A phase 3 study is currently ongoing to compare the safety and efficacy of this regimen with standard of care. Clinical trial information: NCT04264936. Research Sponsor: RemeGen.

Gender disparities in metastatic RCC therapies and outcomes. *First Author: Olivia French Gordon, George Washington University Hospital, Washington, DC*

Background: The incidence of metastatic renal cell carcinoma (mRCC) is rising globally in both males and females. Previous studies have shown that females with mRCC experience better overall survival (OS) when compared to males. In the era of immunotherapy (IM) as part of standard of care, gender-based outcome disparities are unclear. In this study, we identify gender-specific trends in treatment regimen and OS. **Methods:** The National Cancer Database (NCDB) was queried from 2004 to 2019 for a retrospective cohort analysis of mRCC patients. 51,596 males and 25,528 females were reviewed. The primary endpoints were OS and predictors of receipt of IM. Kaplan-Meier (KM) analysis was used to assess gender-based OS and compare OS in patients who received or did not receive CN or IM. Binomial logistic regression was performed to examine gender as a predictor of treatment received. Cox proportional hazards model assessed the impact of age, gender, sites of metastases, Charlson-Deyo comorbidity classification, insurance type, treatment facility, year of diagnosis, CN, and IM on OS. **Results:** In KM analyses, females had lower median OS compared to males (7.200 months vs 8.940 months, p<0.001). Higher median OS was found in patients who received IM (21.3 vs 7.6 months; p<0.001) and CN (22.1 vs 5.13 months; p<0.001). Logistic regression demonstrated that females were less likely to receive IM after controlling for the variables listed above (OR 0.839 (95% CI: 0.787 - 0.894), p<0.001). Cox regression demonstrated that when adjusting for clinicopathologic variables and treatment regimen, female gender independently conferred a statistically significant negative impact on OS (HR = 1.039 (95% CI: 1.015-1.063), p=0.001). **Conclusions:** While CN remains an efficacious treatment option, advances in IM have led to targeted therapies that improve OS in mRCC patients. We demonstrate that a gender-based discrepancy in mRCC survival persists. In contrast to previous literature, our analysis found worse OS as well as an underutilization of IM in female mRCC patients. Moreover, females with mRCC have increased mortality even when accounting for IM. Therefore, further investigation is needed to elucidate the causes of survival discrepancy in the modern era of mRCC treatment. Research Sponsor: None.

Real-world response rates and clinical outcomes of patients treated with first-line (1L) platinum-based chemotherapy (PBC) in advanced urothelial cancer (aUC). *First Author: Helen H Moon, Kaiser Permanente, Riverside, CA*

Background: Standard of care has been established as 1L PBC followed by avelumab 1L maintenance (1LM) in eligible pts based on the JAVELIN Bladder 100 trial (NCT02603432) which showed that avelumab 1LM significantly prolonged overall and progression-free survival (OS, PFS) in pts with aUC with no disease progression after 1L PBC. Contemporary and robust real-world (rw) data are limited in pts treated with 1L PBC; however, because response status to PBC determines avelumab 1LM eligibility, it is critical to understand rw rates. This study aimed to assess current rw rates and rw outcomes in pts treated with 1L PBC. It also sought to understand avelumab 1LM eligibility and its early utilization since FDA approval on June 30, 2020. **Methods:** A non-interventional, retrospective cohort study of pts with aUC in the US was conducted using data from Flatiron Health's electronic health record database. Pts were included if they were diagnosed with aUC between Jan 1, 2017, and Sep 30, 2021, received 1L PBC, did not have a progression event and had an observed rwR (complete response [rwCR]/partial response [rwPR]) or stable disease (rwSD) during 1L. Pt characteristics and rw outcomes were described based on response type (rwCR/PR, rwSD); rwPFS and rwOS were measured from time of 1L PBC initiation using the Kaplan-Meier method. **Results:** 1,245 pts with aUC received 1L PBC and had rwR data available during study period. Of these, 80% (n=998) may have been eligible to receive avelumab 1LM (rwCR/PR: 60%, rwSD: 20%). Key characteristics and outcomes by rwR are summarized. During the study period that occurred after FDA approval of avelumab 1LM, 435 pts discontinued 1L PBC, 78% (n=339) of these pts had observed rwCR/PR/SD during 1L PBC, and 29% (n=97) of maintenance eligible pts received avelumab 1LM. Follow-up time for avelumab 1LM treated pts was short (median 7.5 months from initiation of 1LM) and outcomes were immature at the end of the study period. **Conclusions:** In this rw study, a large proportion of pts with aUC treated with 1L PBC had rwR or rwSD (~80%) and may have been eligible for avelumab 1LM, which is the standard of care supported by international guidelines. RwR rate appears slightly higher compared to historic data, and may reflect better general patient care, as shown in recent large phase 3 trials (NCT02853305, NCT02516241, NCT02807636). Early uptake of avelumab 1LM was observed, and future studies with longer follow-up may demonstrate increased utilization and allow assessment of potential impact on outcomes. Enfortumab vedotin (EV) with or without pembrolizumab (P) in patients (pts) who are cisplatin-ineligible with previously untreated locally advanced or metastatic urothelial cancer (la/mUC): Additional 3-month follow-up on cohort K data. *First Author: Terence W. Friedlander, University of California, San Francisco Medical Center, San Francisco, CA*

Background: There is a high unmet need for effective and durable first-line (1L) treatment options in cisplatin-ineligible la/mUC. EV and P have shown survival benefit as monotherapies in 2L+ la/mUC, and preclinical studies demonstrate that EV induces hallmarks of immunogenic cell death, which may be further augmented by PD-1 inhibitors (e.g., P). Promising results from EV-103 dose escalation/Cohort A (DE/A) provided rationale for this randomized Cohort K for which we are disclosing additional follow-up to previous reports (Rosenberg, ESMO 2022) on efficacy and safety. **Methods:** Untreated cisplatin-ineligible pts with la/mUC were randomized 1:1 to EV (1.25 mg/kg, day 1, day 8) as monotherapy (EV mono) or in combination with P (200 mg, day 1) using 3-week cycles. The primary endpoint was confirmed objective response rate (cORR) per RECIST v1.1 by blinded independent central review (BICR). Secondary endpoints included duration of response (DOR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety. No formal statistical comparisons were planned between treatment arms. **Results:** 149 pts were treated; EV+P, n=76; EV, n=73. Median follow-up (95% CI) for EV+P, 17.6 (16.03, 20.37) months; EV+P cORR (95% CI), 64.5% (52.7, 75.1); median DOR not reached; DCR, 86.6% (77.1, 93.5); median PFS, and OS not reached. PFS rate at 6 and 12 months (95% CI), 73.8% (62.01, 82.42) and 54.5% (41.74, 65.61); OS rate at 6 and 12 months (95% CI), 88.2% (78.48, 93.65) and 81.5% (70.78, 88.61). Median follow-up (95% CI) for EV mono, 18.2 (15.90, 20.07) months; cORR (95% CI), 45.2% (33.5, 57.3); median DOR, 13.2 months (6.14, -); DCR, 79.5% (68.4, 88.0); median PFS and OS, 8.2 (6.05, 15.28) and 21.7 (15.47, -) months; PFS rate at 6 and 12 months, 64.2% (51.09, 74.69) and 40.3% (26.62, 53.60); OS rate at 6 and 12 months, 83.6% (72.87, 90.31) and 69.7% (57.68, 78.87). EV treatment-related adverse events of special interest (AESIs) include skin reactions (EV+P, 67.1%; EV mono, 45.2%), peripheral neuropathy (EV+P, 63.2%; EV mono, 54.8%), and hyperglycemia (EV+P, 14.5%; EV mono, 11.0%). In EV+P, the most frequent (any grade) P treatment-emergent adverse events of special interest were severe skin reactions (27.6%), hypothyroidism (13.2%), and pneumonitis (9.2%). **Conclusions:** With an additional 3 months of follow-up, EV+P continues to show a high cORR with rapid and durable responses as 1L treatment in cisplatin-ineligible pts with la/mUC, including a manageable safety profile with no new safety concerns after extended treatment exposure. DOR, PFS and OS will evolve with further follow-up and continue to trend similarly to those of DE/A; EV monotherapy was consistent with prior results. Clinical trial information: NCT03288545. Final results from SAUL, a single-arm international real-world study of atezolizumab (atezo) in 1004 patients (pts) with pretreated locally advanced/metastatic urinary tract carcinoma (UTC). *First Author: Cora N. Sternberg, Englander Institute for Precision Medicine, Weill Cornell Medicine, New York, NY*

Background: In the SAUL study (NCT02928406), clinical outcomes in a broad population were similar to findings from phase 3 trials of anti-PD-(L)1 in highly selected pts. We report the final analysis 4 y after enrolling the last pt. **Methods:** Eligible pts had locally advanced/metastatic urothelial or non-urothelial UTC that had progressed during or after 1–3 prior lines of therapy for advanced UTC (or within 12 months of [neo]adjuvant therapy). Unlike most phase 3 immunotherapy trials, pts with autoimmune disease (AID), ECOG PS 2, creatinine clearance (CrCl) ≥ 15 –30 mL/min, and/or stable CNS metastases were eligible. Pts took atezo 1200 mg q3w until disease progression or unacceptable toxicity. The primary endpoint was safety. Secondary endpoints included overall survival (OS) and duration of response (DoR). **Results:** Among 997 treated pts, 10% had ECOG PS 2, 5% had CrCl < 30 mL/min, 4% had a history of AID, and 7% had 2–3 prior lines of therapy. At data cutoff (Dec 20, 2022; median follow-up 55 mo), 78% of pts had died. Median treatment duration was 2.8 mo (range 0–62 mo; mean 9.5 mo), 96 pts (10%) took atezo for > 3 y, and 68 (7%) for > 4 y. Grade ≥ 3 adverse events (AEs) occurred in 51%; AEs led to atezo discontinuation in 8%. We show outcomes overall and in key subgroups. OS was > 4 y in 136 pts (14%); 132 responders had OS > 2 y. **Conclusions:** After 55 mo median follow-up, median OS was 8.6 mo and 3-y OS was 21% in a real-world population including important understudied subgroups. Long-term safety data continue to support the tolerability of atezo in pts with complex comorbidities. AESIs were not increased in pts typically considered to be at increased risk of immune-related AEs. OS was similar to trials in highly selected pts. Ongoing analyses are characterizing pts with exceptional long-term outcomes. Clinical trial information: NCT02928406. Research Sponsor: F. Hoffmann-La Roche Ltd.

Mismatch repair deficiency and microsatellite instability-high in urothelial carcinoma: A systematic review and meta-analysis. *First Author: Elias Chandran, National Cancer Institute, Bethesda, MD*

Background: Mismatch repair deficiency (dMMR) and microsatellite instability-high (MSI-H) occur in a small subset of urothelial carcinoma (UC) and confer a sensitivity to immunotherapy in multiple solid tumors. Due to the rarity of this patient subset in UC, there is a lack of prospective data on their prevalence or of clinical outcomes with immunotherapy and other treatment modalities. **Methods:** We performed a systematic review with the objectives of estimating the prevalence of dMMR and MSI-H in urothelial bladder cancer (BC) and upper tract urothelial carcinoma (UTUC) apart from estimating survival and clinical outcomes of treatment. We searched for published prospective and retrospective studies, review articles, case reports, case series, conference proceedings, letters, commentaries, and editorials on dMMR and MSI-H in BC and UTUC published up to 10/26/2022 in PubMed, Cochrane CENTRAL, Embase and Web of Science: Core Collection databases. The study protocol is registered on the PROSPERO database (CRD42022365690). Prevalence data were analyzed using meta-analysis with random-effects models and are reported here. **Results:** A total of 1,750 studies were screened, of which 125 were included. Thirty-six studies (including 5,113 patients) reported frequencies of dMMR, and 42 studies (including 21,291 patients) reported on MSI-H. Of the total included patients, sex was reported in 11,225, with 72.6% being male and 27.4% female. Age ranged from 17–97 years. Reported primary site was BC in 64.4%, UTUC in 16.3% and not stated in 19.3%. Disease stage reported in 5,341 patients was M0 in 75.0% and M1 in 25.0%. Of the M0 patients, tumor stage data were available in 3,149 patients: T1 in 33.6% and T2–T4 in 66.4%. The pooled weighted prevalence of dMMR in UC patients was 6% (95% CI 5–8%). The breakdown for BC and UTUC were 2% (95% CI 1–3%) and 9% (95% CI 7–12%), respectively. The three most frequent MMR protein loss patterns in UC, BC and UTUC are shown in the table. Out of 42 studies reporting MSI status, 21 used polymerase chain reaction (PCR) and 21 used next-generation sequencing (NGS). Pooled weighted prevalence of MSI-H in UC was 3% (95% CI 2–3%). In BC, the prevalence was 1% (95% CI 1–1%) and in UTUC, it was 11% (95% CI 8–13%). **Conclusions:** dMMR and MSI-H were observed more frequently in UTUC than BC. Further analysis on survival and clinical outcomes of dMMR/MSI-H UC with different treatment modalities is ongoing. Additionally, clinical trials in dMMR and/or MSI-H UC are in development to study immunotherapeutic strategies to improve outcomes in both early and advanced stages for this small but important subset of patients. A phase I study of bintrafusp alfa and NHS-IL12 (M9241) alone and in combination with stereotactic body radiation therapy (SBRT) in patients with metastatic genitourinary (GU) malignancies. *First Author: Nicholas I. Simon, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: Bintrafusp alfa is a novel bifunctional fusion protein targeting PD-L1 and TGF- β which has demonstrated clinical efficacy in some tumor types and a manageable safety profile. M9241 is an immunocytokine that allows targeting of the pro-inflammatory IL-12 cytokine to exposed DNA in necrotic portions of tumors. SBRT can help promote anti-tumor responses and may potentially synergize with immunotherapy by inducing DNA damage. **Methods:** This is an open label, non-randomized, three arm phase I trial of bintrafusp alfa and M9241 combination therapy administered alone (Arm 1), or with either sequential (Arm 2), or concurrent (Arm 3) SBRT. Eligible patients must have metastatic non-prostate GU cancers with measurable disease. Bintrafusp alfa was used at a flat dose of 1200mg (q2w) for arms 1–3 and a fixed dose of SBRT (24Gy in 3 fractions) was used for arms 2–3. M9241 was administered at 16.8mcg/kg (q4w) for Arm 1 and decreased if side effects occur. Arm 1 used bintrafusp alfa and M9241 alone, with the maximum tolerated dose (MTD) of M9241 being dose level 1 (DL1) for Arm 2. Arm 2 used SBRT followed by bintrafusp alfa and M9241, with the MTD of M9241 being DL1 for Arm 3. Arm 3 used concurrent SBRT with bintrafusp alfa and M9241. The primary objective was to determine the safety and highest tolerable doses of each arm. Secondary objectives include objective response rate (ORR), progression free survival (PFS), and overall survival (OS). **Results:** Study enrollment began in 12/2019, with interim safety analyses performed quarterly. A total of 16 patients have enrolled, 12 in Arm 1, three in Arm 2, and one in Arm 3 at data cutoff 1/2/23. The first six patients enrolled in Arm 1 had no DLTs allowing Arm 2 to open. Arm 2 had no DLTs after 3 patients enrolled allowing Arm 3 to open. At data cut off four of 16 patients remained on treatment. The median age was 63 and 19% were female. The most frequent TRAEs were fatigue (grade 2, 38%), lipase increase (grade 2+3, 31%), and anemia (grade 2+3, 31%). Grade 3 hematuria occurred in 2 patients (13%); a grade 4 creatinine increase occurred in one (8%). There were no grade 5 TRAEs. Two (13%) patients had treatment discontinued and 5 (31%) had dose reductions due to AEs. Of the 16 patients enrolled on study, 11 were evaluable at data cutoff. Currently three patients (38%) on Arm 1 and one patient (50%) in Arm 2 had objective responses, corresponding to an ORR of 36.4% (4/11). All responses have been partial responses. On Arm 1 the responding patients included one with small cell carcinoma of the renal pelvis, one with Leydig cell tumor, and one with urothelial carcinoma. On Arm 2 the responding patient had a Sertoli cell tumor. **Conclusions:** The use of bintrafusp alfa and M9241 either alone or in combination with sequential or concurrent SBRT has shown clinical activity in pts with GU tumors and has not been associated with any DLTs. Clinical trial information: NCT04235777. Research Sponsor: U.S. National Institutes of Health.

Biomarkers of response to sacituzumab govitecan (SG) and efficacy after treatment with enfortumab vedotin (EV) in advanced urothelial carcinoma (aUC): Analysis of the UNITE study. *First Author: Tanya Jindal, University of California San Francisco, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: SG is an antibody-drug conjugate (ADC) with accelerated FDA approval for aUC refractory to platinum-based chemotherapy and immune checkpoint inhibitor (ICI). SG activity following treatment with EV, the most commonly used ADC in the post-platinum/ICI setting, and biomarkers of response to SG are not well described. We hypothesized that SG would be active after EV in aUC. **Methods:** Patients (pts) treated with SG monotherapy who had next-generation sequencing (NGS), were identified in the retrospective UNITE study. Observed response rate (ORR) was determined for evaluable pts with scans after ≥1 SG cycle. All pts were assessed for baseline clinical characteristics, as well as molecular biomarkers including tumor mutational burden, somatic gene alterations (alt) in ≥ 10% of pts and presence of ≥1 DNA damage response (DDR) mutations. ORRs were compared with Chi-squared test. Kaplan Meier method and cox proportional hazard (cph) models were used to assess progression-free survival (PFS) and overall survival (OS) from SG start. Pt characteristics and molecular biomarkers were evaluated in univariate analyses (UVA), followed by evaluation of biomarkers in separate multivariate cph analyses (MVA), while accounting for clinical features. **Results:** Among 90 pts treated with SG at 9 US sites, 78 had NGS data. Median age at SG start was 68, 65 (72%) men, 73 (81%) Caucasian, 56 (62%) with pure urothelial histology, 60 (67%) primary bladder tumor and 67 (74%) ECOG PS 0/1. Most (n=84, 93%) received SG after EV, and 33 (37%) had ≥4 prior therapies for aUC. ORR with SG was 23% (15/66); 24% in pts with prior CR/PR/SD on EV and 14% after primary PD on EV. Median follow-up from SG start was 8.7 mos, PFS and OS were 3.5 mos and 7.1 mos. In pts with NGS, ORRs to SG were higher in *MTAP* altered pts (50% vs 19%; p = 0.05). In UVA, low neutrophil to lymphocyte ratio (NLR), high Hgb, no prior smoking history, < 3 prior therapies, as well as *BRCA2* and DDR alts were associated with longer OS (p<0.05 for all). In MVA, pts with alt in either *TP53* or *MDM2* had longer OS. **Conclusions:** SG has notable activity after EV in heavily pretreated pts with aUC, with ORR consistent with SG phase 2 trial data in post-platinum/ICI only pts. We identified several clinical and genomic biomarkers, including *TP53/MDM2* alt, that are potentially associated with improved outcomes with SG treatment. Research Sponsor: None.

Outcomes with immune checkpoint inhibitors (ICI) in patients (pts) with *MTAP* alterations (alt) in advanced urothelial carcinoma (aUC). *First Author: Rafee Talukder, University of Washington, Seattle, WA*

Background: *MTAP* loss of function alt in aUC has been associated with poor prognosis. *MTAP* is an enzyme involved in the adenine salvage pathway and deficiency of the protein leads to susceptibility to antifolate agents, e.g., pemetrexed. *MTAP* loss has also been correlated with immunosuppressive tumor microenvironment, inducing a “cold tumor” that may be less responsive to ICI. Response and outcomes to ICI in pts with *MTAP* altered aUC need further assessment. We hypothesized that pts with *MTAP* altered aUC would have lower response and shorter survival on ICI. **Methods:** We used our database from 26 centers (US/Europe) of pts with aUC treated with ICI. We included pts with available NGS data who received ICI for aUC. We excluded pts with pure non-UC, treated with adjuvant ICI, ICI combinations, or on clinical trials. Outcomes (observed response rate [ORR], progression free survival [PFS] and overall survival [OS]) were compared in pts who received either 1st line [1L] or 2nd line and beyond [2+L] ICI with and without *MTAP* alt. We compared ORR using logistic regression; PFS and OS were compared using Kaplan-Meier and Cox proportional hazards. We separately describe outcomes in pts with *MTAP* alt who received avelumab switch maintenance. **Results:** 211 pts from 8 centers met inclusion criteria with available *MTAP* alt status; 174 received ICI as distinct aUC treatment line (16% had *MTAP* alt; n=28) either in 1L or 2+L setting; 37 pts received avelumab switch maintenance (19% had *MTAP* alt; n=7). Pts with known *MTAP* status were 72% men, 91% White, 72% pure UC, 25% upper tract UC, 64% ECOG PS 0-1, 56% visceral mets, 18% bone mets, 15% liver mets. Median follow up from starting ICI was 44 months [mo] (IQR 29-51). ORR to ICI (1L + 2+L) in pts with *MTAP* alt was 25% (95%CI 10-47) vs 47% (95%CI 39-55%) in pts without *MTAP* alt [OR 3.11 (95%CI 1.15-7.82)]. PFS for pts with *MTAP* alt was not significantly different vs pts without *MTAP* alt (median 3 vs 6 mo, respectively: HR 1.46 [95%CI 0.91-2.35]). OS was similar between groups (median 14 vs 15 mo, respectively: HR 0.93 [95%CI 0.53-1.63]). Table describes outcomes by ICI treatment line (1L, 2+L, maintenance) in pts with and without *MTAP* alt. **Conclusions:** In pts with aUC receiving ICI, the presence of *MTAP* alt was significantly associated with lower ORR and a trend towards shorter PFS compared to absence of *MTAP* alt. Limitations include retrospective nature, small sample size, selection/confounding biases, lack of randomization and central scan review. Findings need external validation and might inform discussion on the optimal therapy sequence in aUC. Research Sponsor: None.

Independent biomarkers predictive of outcomes with enfortumab vedotin (EV) in patients (pts) with advanced urothelial carcinoma (aUC): Analysis of the UNITE study. *First Author: Tanya Jindal, University of California San Francisco, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: EV is used for treatment-refractory aUC with activity also noted in a frontline trial. Independent biomarkers associated with EV treatment outcomes are lacking. **Methods:** UNITE is a multi-site retrospective study of pts treated with EV and other agents. In this analysis we included pts treated with EV monotherapy and available next generation sequencing (NGS) data. Assessed biomarkers included genomic alterations (alts) in ≥5% of pts, tumor mutation burden (TMB) and PD-L1 expression. Pts were evaluable for observed response rate (ORR) if they had scans after ≥1 EV cycle. Biomarkers were evaluated individually in univariate analyses (UVA) and in separate multivariate analyses (MVA) which accounted for clinical variables. Progression-free survival (PFS) and overall survival (OS) from EV start were assessed using Kaplan Meier method and cox proportional hazard (cph) modeling. ORR was assessed using logistic regression. **Results:** Among 303 pts with NGS treated with EV monotherapy at 16 US sites, 207 had TMB and 146 had PD-L1 data. Median age was 70; 218 (72%) men, 262 (87%) White, 196 (66%) with pure urothelial histology, 212 (71%) with lower tract primary tumor, 204 (67%) had ≥2 prior therapies. ORR was 53% (140/264); mPFS was 6.0 mos, mOS was 13.1 mos. In UVA, longer OS was associated with higher Hgb, albumin and GFR (>30cc/min), lower neutrophil to lymphocyte ratio, older age, and absence of liver mets. MVA included these variables along with histology as covariates. In multivariate cph models, better outcomes were associated with alts in *ERBB2*, *KDM6A* and *PIK3CA*, while inferior outcomes with low TMB (<10 Mut/Mb) and high PD-L1 (CPS ≥ 10). **Conclusions:** MVA of this large, multi-site, retrospective cohort of aUC pts, identified several putative biomarkers independently associated with EV treatment outcomes. Longer OS was associated with *ERBB2* and *KDM6A* alts, low PD-L1 and high TMB. Limitations include lack of central scan review, pt selection and confounding biases. These findings require external validation, while their underlying mechanisms merit translational study. Research Sponsor: None.

EphrinB2 (B2) expression predicts poor response to PD1/L1 antibodies (Ab) in metastatic urothelial carcinoma (mUC). *First Author: Sarmad Sadeghi, University of Southern California, Los Angeles, CA*

Background: B2 is a ligand for EphB4 which enhances tumor invasion, proliferation, survival and promotes angiogenesis. A prior analysis of TCGA data from 409 muscle invasive bladder cancer (MIBC) patients (pts) demonstrated that high (34%) B2 gene expression had poor survival vs. low (66%) expression (Hazard Ratio 0.7 p = 0.02). Our phase II trial of sEphB4-HSA (JCO PMID 35984996) which targets B2, in combination with pembrolizumab in previously treated mUC (N=70) demonstrated an objective response rate (ORR) of 37%. Among pts with high expression of B2, ORR was 52% with 24% complete response (CR). This retrospective study examined the ORR to PD1/L1 Ab in pts with mUC and its correlation with B2 mRNA expression. **Methods:** Pts with mUC who had received anti PD1/L1 Ab were eligible if they had radiographic response data and tumor tissue for B2 testing. Pts' demographics and disease characteristics were abstracted. Radiographic images were reviewed using RECIST 1.1. Tumor specimens were analyzed for intensity of B2 expression using in-situ hybridization (ISH). Scores of 2-4 were considered High (Hi) and 0-1 were considered Low (Lo) expression. Standard descriptive statistics were used to summarize study results. Fisher's exact test was used to test the association of ORR with B2 expression using SAS 9.4. **Results:** 120 (N) pts from University of Southern California (USC, n=49), Dana Farber (DFCI, n=55), and University of Colorado (UC, n=16) met were included. 88 pts were male (73%). Median age was 72. PD1/L1 Ab were administered in the post-platinum progressive disease (n=95, 79%) and first-line setting (n=25, 21%) and included pembrolizumab (n=88, 73%), atezolizumab (n=26, 22%) and nivolumab, avelumab, and durvalumab, 3%, 1%, and 1%, respectively. Objective response rate (ORR) defined as radiographic CR plus partial response (PR) were calculated and summarized. Among all pts (N=120), ORR was 20% (95% CI 13-28). 62% had B2 Hi expression with a response rate of 12%, and 38% had B2 Lo expression with a response rate of 33%, p=0.009. These proportions were similar for each institution. **Conclusions:** In addition to conferring poor prognosis in MIBC, B2 expression is associated with poor ORR to PD1/L1 Ab monotherapy in mUC. Given that the combination of B2 inhibition & pembrolizumab was more active in B2 expressing mUC, these data provide further rationale for investigating B2 as a mechanism of resistance to PD1/L1 ab, biomarker of response and a therapeutic target. Research Sponsor: None.

Clinical utility of plasma ctDNA sequencing in metastatic urothelial carcinoma. *First Author: Clara Helal, Institut Gustave Roussy, Villejuif, France*

Background: Genomic stratification may help to improve the management of patients with metastatic urothelial cancer (mUC) given the recent identification of targetable molecular alterations in this disease. However, collecting tissue samples in mUC remains challenging. We assessed the clinical utility of plasma circulating tumor DNA (ctDNA) sequencing in mUC. **Methods:** mUC patients were prospectively enrolled in the STING trial (NCT04932525) whereby ctDNA was profiled using the FoundationOne Liquid CDx Assay (324 genes, tumor mutational burden [TMB], microsatellite instability status). Each individual genomic report was reviewed and discussed weekly by a multidisciplinary tumor board (MTB). Actionable targets were classified by ESCAT tier leading to molecular-based treatment suggestions whenever it was possible. **Results:** Between January 2021 and June 2022, 140 mUC patients underwent molecular profiling. Median time to assay results was 20 days. ctDNA abundance was correlated with number of prior lines and number of metastatic sites. ctDNA analysis reproduces the somatic genomic landscape reported by previous tissue-based cohorts. Concordance for serial tumor tissue was moderate ($r=0.545$ CI95: [0.121-0.801], $p=0.016$). At least one actionable target was detected in 63 patients (45 %) with a total of 35 actionable alterations including TMB high (≥ 12 mutations/Mb) (N= 39, 21.1%), FGFR3 (N= 20, 10.8%) and HRD alterations (N= 14, 7.6%). The MTB recommended a matched therapy for 63 patients (45.0%). In total, 8 patients (5.7 %) were treated with an overall response rate of 50% (95%: 15.70-84.30) and a median PFS of 5.2 months (CI95%: 4.1 - NR). FGFR3 alterations were associated with lower progression-free survival in patients treated with immunotherapy. **Conclusions:** Overall, our analysis demonstrates that genomic profiling with a large panel of ctDNA in mUC is a reliable and feasible approach to timely initiate genotype-matched therapies. Clinical trial information: NCT04932525. Research Sponsor: Gustave Roussy, Cancer Campus, Grand Paris.

Evaluating the use of circulating tumor DNA (ctDNA) in patients with urothelial cancer in the context of FGFR-targeted therapy. *First Author: Elena Schönlaue, Department of Medical Oncology, BC Cancer-Vancouver Centre, Vancouver, BC, Canada*

Background: Fibroblast growth factor receptor (FGFR) inhibitors (e.g., erdafitinib) are increasingly important in the management of FGFR-mutated urothelial carcinoma. FDA-approved archival tissue testing for specific FGFR alterations was implemented as a companion diagnostic for erdafitinib. However, longitudinal sequencing studies indicate variable tumor FGFR status over time, and erdafitinib resistance mechanisms in metastatic urothelial carcinoma (mUC) are underreported. This ongoing study aims to evaluate the accuracy of cell-free DNA (cfDNA) compared to archival tissue testing in mUC for FGFR alterations detection, and to evaluate genomic mechanisms of erdafitinib resistance in cfDNA at progression. **Methods:** Patients with progressing mUC who were undergoing archival tissue testing for FGFR1-3 mutations and/or fusions and who had blood samples drawn during the management of their metastatic disease were eligible. Plasma cfDNA and matched leukocyte DNA were subjected to deep targeted sequencing with a custom panel including UC-specific gene loci and all clinically approved hotspots in FGFR1+2 and all exons and introns of FGFR3. **Results:** As of January 2023, 109 patients from 6 sites were enrolled. Median age at diagnosis was 71, 33% had upper urinary tract primaries, and 76% were male. Tissue and cfDNA results for comparison were available for 69 patients to date. Actionable somatic FGFR alterations were found in the tissue of 15 patients (31%); the most common alteration was the FGFR3 p.S249C mutation (67%). 50 of the analyzed cfDNA samples had detectable somatic circulating tumor DNA (ctDNA) variant allele fraction of 0.5% (72%). Of those, 49 had an evaluable tissue test result. Analysis of this subset revealed high concordance (92%) between the two test methods. With the assumption that archival tissue testing is considered the 'gold standard', sensitivity is 93% and specificity is 91%. The four discordant results comprised one cfDNA test with undetectable *FGFR3-TACC3* fusion, which was detected in tissue and three positive ctDNA test results in patients with *FGFR* wild-type tissue tests. In one case at erdafitinib progression, ctDNA revealed multiple subclonal populations with distinct FGFR3 gatekeeper mutations suggesting polyclonal resistance. **Conclusions:** This ongoing study suggests cfDNA is a valuable minimally invasive adjunct to tissue-based assays for the detection of FGFR alterations to identify patients for FGFR inhibitor therapy and to monitor for mechanisms of resistance. Activity of cabozantinib (CABO) plus durvalumab (DURVA) in patients (pts) with advanced urothelial carcinoma (UC) or non-UC variant histologies (VH) after platinum chemotherapy: Interim results from the phase 2 ARCADIA trial. *First Author: Patrizia Giannatempo, IRCCS Foundation National Cancer Institute, Milan, Italy*

Background: Combining multitargeted receptor tyrosine kinase inhibitor (TKI) with checkpoint inhibitors has shown synergistic effect in pts with UC due to the immunomodulatory propriety of VEGFR inhibitors. We investigated if the combination of CABO and DURVA in pts with advanced UC and non-UC histology (VHs) in a phase II study (NCT03824691). Herein the preliminary results of the interim analysis. **Methods:** Patients affected by UC and VHs recurred or progressed after failure of at least one line of platinum-based chemotherapy for metastatic disease have been treated with CABO 40 mg daily, orally, and are administered DURVA 1500 mg IV, q28 days, until disease progression (PD, by RECIST 1.1) or onset of unacceptable toxicity. Key inclusion criteria were ECOG-PS 0-1 and adequate organ function. Response was evaluated by RECIST criteria v.1.1 every 8 wks. The primary endpoint of the study was OS. Secondary endpoints included safety (CTCAE v.4.03), objective response-rate (ORR), duration of response (DoR), progression-free survival (PFS). The assumption was to detect an improvement in the median OS from ≤ 6 months (H0) to ≥ 9 months (H1). **Results:** Between September 2019 and February 10, 2023, the ARCADIA study enrolled 63 pts: this interim analysis was performed after obtaining at least one post-baseline tumor assessment data from 58 pts. The median follow-up was 23.5 mos (interquartile [IQ] range: 7.7-27.7 mos); 27% were female, the median age was 64 yrs (range: 42-81), 20 pts (34%) had a pure/predominant non-UC VH: 9 (45%) a squamous differentiation/sarcomatoid tumor, 5 (25%) an adenocarcinoma, 4 (20%) a small-cell neuroendocrine tumor, 1 (5%) a clear-cell tumor, and 1 a nested VH (5%). Eleven pts (19%) had received ≥ 2 prior systemic anticancer therapies. In 58 response-evaluable pts, 12 (20%) complete responses (CR) and 11 partial responses (PR) were obtained, the ORR being 39.7% (95%CI: 27.1-53.4) and disease control rate was 69% (95%CI: 55.5-80.5). In the cohort of pts with VH, the ORR was 45% (95%CI: 23.1-68.5). Median PFS was 7.6 mos (95%CI: 4.6-13.6 mos) and median OS was 11.6 (95% CI 6.8-20.3 months). Median exposure of treatment was 4.8 mos; 35 pts (55.5%) of 63 pts had all-grade treatment-related adverse events (AE) and 4 pts (6.3%) reported grade 3 (treatment related) AE with no grade 3-5 events. Dose-reductions of CABO were needed in 25 pts (39%). No treatment-related deaths were reported. **Conclusions:** CABO in combination with DURVA showed promising preliminary activity with a manageable safety profile in pts with advanced UC and in non-UC VH after previous chemotherapy exposure, deserving further evaluation of the combination that is ongoing with ARCADIA and other clinical trials. More mature results with longer follow-up will be presented. Clinical trial information: NCT03824691. Research Sponsor: Ipsen, Astra Zeneca.

Efficacy of sacituzumab govitecan (SG) in locally advanced (LA) or metastatic urothelial cancer (mUC) by trophoblast cell surface antigen 2 (Trop-2) expression. *First Author: Yohann Lorient, Institut de Cancérologie Gustave Roussy, Villejuif, France*

Background: Patients (pts) with mUC have an estimated 5-year overall survival (OS) rate of 14%. Trop-2 is a transmembrane glycoprotein with elevated expression in many cancers, including UC. SG is a Trop-2-directed antibody-drug conjugate with accelerated FDA approval for pts with LA unresectable or mUC who previously received platinum (PT) and a checkpoint inhibitor (CPI). SG has demonstrated activity in 3 phase 2 TROPHY-U-01 mUC cohorts: Cohort 1 (C1), 28% objective response rate (ORR); Cohort 2 (C2), 32% ORR; and Cohort 3 (C3), 41% ORR. Here, we assess efficacy outcomes in C1-3 by Trop-2 archival tumor expression. **Methods:** Pts (≥ 18 years) with previously treated (PT [C3], CPI [C2], or both [C1]) LA or mUC received SG (10 mg/kg IV) on D1 and D8 of 21-D cycles; C3 pts also received pembrolizumab (200 mg) on D1 of 21-D cycles. The primary endpoint was ORR by independent review. Archival tumor samples collected at enrollment were assessed for Trop-2 protein expression using SP295 anti-Trop-2 antibody by IHC with assessment by histological scores (H-scores; scale, 0-300) and % of membrane-positive tumor cells (Roche Tissue Services). Trop-2 association with clinical endpoints was evaluated using unstratified Cox proportional hazards models for survival data and logistic regression for ORR. **Results:** At data cutoff, 192 pts were enrolled in C1-3; 144 pts (75%) had samples evaluable for Trop-2 prevalence and 139 pts (72%) were evaluable for efficacy analysis by Trop-2 expression (5 pts not assigned to any cohort were excluded). Baseline characteristics for pts with evaluable samples were consistent with the overall population. Median (IQR) Trop-2 H-score and % of membrane-positive tumor cells for evaluable pt samples were 215 (180-247) and 92% (75-98), respectively; these readouts were highly correlated ($p=0.82$, $P<0.001$). ORRs for C1 samples with below (n=42) and above (n=45) median Trop-2 H-scores were 24% and 29% ($P=0.59$), respectively; median progression-free survival (PFS) was 3.4 and 6.7 months (HR=0.765, $P=0.262$), respectively; and median OS was 9.9 and 10.9 months (HR=0.978, $P=0.927$), respectively. Median PFS for C1 samples with below and above median Trop-2 membrane positivity were 3.9 and 6.2 months (HR=0.835, $P=0.443$), respectively. Analyses of efficacy endpoints for C2 and C3 pt samples by Trop-2 expression were consistent with C1 results. **Conclusions:** In this analysis of archival tumor samples from pts with pretreated LA or mUC, Trop-2 protein was highly expressed across cohorts, supporting prior Trop-2 expression analyses in UC. Similar outcomes were observed between C1 pts with samples that were below and above median Trop-2 H-score with most pronounced numerical differences observed for PFS. These results suggest that SG activity may be independent of Trop-2 expression in UC, but additional studies are needed to confirm these results. Clinical trial information: NCT03547973. Research Sponsor: Gilead Sciences Inc.

The effect of antibiotic (Abx) use on immune checkpoint inhibitor (ICI) efficacy in patients (pts) with metastatic urothelial carcinoma (mUC) in a real-world setting. First Author: Ubenthira Patgunarajah, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH

Background: Use of Abx may negatively affect outcomes with ICI, possibly due to negative impact on gut microbiota. We previously showed that in our real world cohort of 138 mUC pts, Abx use within 30 or 60 days (d) of ICI initiation did not impact overall survival (OS). We now report updated follow-up (fu) and results from our expanded cohort of 310 mUC pts who received ICI. **Methods:** We performed a retrospective analysis of adult pts with mUC treated at the Cleveland Clinic between 2015 and 2022 who received 2 or more cycles of ICI with pembrolizumab (P), atezolizumab (A) or avelumab (Av). Effect of Abx use within 30 and 60 (d) of ICI initiation was correlated with progression free survival (PFS) and OS. OS and PFS were estimated using Kaplan-Meier method and compared using log rank test. **Results:** Median age of pts was 71 years (41-90) and 75% pts were males. 224 pts (72.3%) received P, 82 (26.4%) A and 4 (1.3%) Av. Fluoroquinolones (31.1%), penicillins (29.6%) and cephalosporins (19.7%) were most commonly used Abx. With a median fu of 47 weeks (3.86- 325.3), median OS in pts who received Abx within 60 (d) prior to ICI was 11.79 months (mos) vs 14.55 mos in those who did not receive Abx (p=0.007) and median PFS was 3.68 mos vs 5.29 mos respectively (p=0.038). Median OS in pts who received Abx within 30 days prior ICI was 10.41 mos vs 14.46 mos in those who did not receive Abx (p=0.037). There was a non-significant trend for worse PFS in pts who received Abx within 30 (d) prior to ICI (3.06 mos vs 5.03 mos, p=0.238). There was no effect on OS or PFS with Abx use 30 or 60 (d) after ICI initiation. **Conclusions:** In our real-world cohort of mUC pts receiving ICI, Abx use 60 and 30 (d) prior to ICI initiation was associated with significant worse OS and worse PFS for the former group but Abx use after ICI initiation did not have an effect on OS or PFS. These findings have the potential to influence clinical practice, including a higher threshold for giving Abx to mUC pts starting ICI. Further prospective studies are warranted. Research Sponsor: None.

Assessing tumor-infiltrating immune cells and outcomes with cisplatin-versus carboplatin-based treatment in advanced urothelial cancer (UC): Survival analysis of three platinum-treated UC cohorts. First Author: Konrad Stawiski, Medical University of Lodz, Lodz, Poland

Background: The association between tumor-infiltrating immune cells and the response to platinum-based chemotherapy (cisplatin vs carboplatin) in advanced urothelial cancer is not well characterized. We dissected the immune microenvironment of 3 large UC cohorts to define populations of immune cells associated with survival following carboplatin- or cisplatin-based chemotherapy. **Methods:** Two advanced UC cohorts – Hospital del Mar (HM; n = 55) and GREEK (n = 62) – treated with platinum-based chemotherapy were profiled using bulk RNA sequencing (RNA-seq) with tumor-infiltrating immune cells inferred using CIBERSORTx. Our findings were validated in a publicly available platinum-treated UC cohort (n = 93; Taber et al. Nat Comm 2020). Additionally, we assessed the impact of tumor-infiltrating immune cells in IMWigor210, an anti-PD-L1 treated cohort. Analysis was adjusted by tumor stage, and treatment regimen (cisplatin, carboplatin, atezolizumab) to determine associations between tumor-immune cell populations and overall survival (OS). **Results:** In platinum-treated patients, increased lymphoid cell infiltration was associated with improved OS. Specifically, the presence of naive and memory B-cells and CD4+ T cells was associated with prolonged OS (Table). Interestingly, infiltration of memory B-cells was associated with a better prognosis in patients treated with cisplatin (HR = 0.14) and detrimental in patients treated with carboplatin (HR = 249.53; difference p = 0.006). Additionally, macrophages (HR = 3.44; p = 0.027) and resting dendritic cell (HR = 41.47; p = 0.009) infiltration was associated with worse OS in patients treated with platinum therapy alone, but enrichment of pro-inflammatory M1 macrophages was associated with prolonged OS in patients treated with immunotherapy (p < 0.001). **Conclusions:** Immune cell infiltration is associated with differential outcomes to cisplatin- and carboplatin-based chemotherapy in advanced UC. Our findings suggest better OS in advanced UC treated with cisplatin in tumors enriched with memory B-cells compared to carboplatin treatment. Research Sponsor: None.

Cohort description with initial TNM- and treatment-adjusted hazard ratios (with 95%CI) of selected cell fractions.

Presence of CD8+ cytotoxic T-cells in proximity to tumor cells, TIM3, CTLA-4 and prognostic implications for muscle-invasive urothelial cancer. First Author: Nicolaus F. Debatin, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Although it is well known that the quantity of specific immune cell types can provide prognostic information in bladder cancer, only little is known about the prognostic relevance of the localization of immune cells within the tumor microenvironment. **Methods:** To study the spatial interplay of different immune cell subpopulations and its prognostic role in bladder cancer, 2463 urothelial bladder carcinomas were immunostained with 21 antibodies (i.e., TIM-3, PD-L1, PD-1, CTLA4, CD3, CD8, CD4, FOXP3, CD20, CD68, CD163, CD11c, panCK, Ki67, CD31, Vimentin, HLA-DRa, Myosin-11, Desmoglein 3, PAX-8, and CDH16) using BLEACH&STAIN multiplex fluorescence immunohistochemistry in a tissue microarray format and analyzed using a framework of neuronal networks for image analysis. Thus, Spatial immune parameters were compared with histopathological parameters and overall survival data. **Results:** The identification of more than 300 different immune cell subpopulations and the characterization of their spatial relationship resulted in numerous spatial interaction patterns. 32 immune parameters showed prognostic significance in univariate analyses of which 16 were independent from pT, pN, and histologic grade in muscle-invasive bladder cancer. The strongest association to clinical outcome was identified for intraepithelial CD8+ cytotoxic T-cells (AUC: 0.70) while stromal CD8+ cells were less relevant (AUC: 0.64, p=0.016). A favorable prognosis of inflamed cancers with high levels of “exhaustion markers” suggests that TIM3, PD-L1, PD-1, and CTLA-4 on inflammatory cells do not hinder anti-tumoral immune response in tumors rich of tumor infiltrating tumor cells. **Conclusions:** The density of intraepithelial CD8+ T-cells was the strongest prognostic feature in muscle-invasive bladder cancer. Given that tumor cell killing by CD8+ cytotoxic T-lymphocytes through direct cell-to-cell-contacts represents the “terminal end route” of anti-tumor immunity, the quantity of “tumor-cell adjacent CD8+ T-cells” may constitute a surrogate for the efficiency of cancer recognition by the immune system that can be measured straightaway using conventional brightfield IHC in routine pathology as the CD8 labelling index. Genome-wide aneuploidy detected in circulating cell-free DNA of patients with metastatic urothelial cancer as a predictive biomarker of response to pembrolizumab. First Author: Youssra Salhi, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: Pembrolizumab is the standard of care second-line treatment of metastatic urothelial cancer patients. However, success rates are low and there is risk for significant toxicity. Therefore, reliable biomarkers to select patients who will or will not benefit from pembrolizumab are urgently needed. An earlier study showed that a high aneuploidy score (i.e. Z-score ≥ 5) at baseline in cell free DNA (cfDNA), based on the modified fast aneuploidy screening test-sequencing system (mFast-SeqS), associated with poor response to pembrolizumab. However, a low aneuploidy score (Z-score < 5) at baseline was not discriminative. The aim of this study was to evaluate early during treatment (after the first cycle pembrolizumab), whether the cfDNA based mFast-SeqS aneuploidy scores can discriminate patients with expected benefit from therapy from those who will not benefit. **Methods:** The mFast-SeqS to assess aneuploidy was performed on blood samples collected from 74 patients with metastatic urothelial cancer (mUC) at baseline and after cycle 1 of pembrolizumab. Responders were defined as patients with stable disease (SD) or partial/complete response (PR, CR) according to RECIST v1.1. and continued treatment beyond 6 months from initiation of pembrolizumab. Non-responders did not fulfil these criteria. **Results:** Paired samples were available in 60 out of 74 patients. At baseline 25% (n=15) of patients had a high aneuploidy score and 75% (n=45) had a low aneuploidy score. Two patients (13%) with a high baseline score were responders and 13 (87%) were non-responders. In all responders, there was a marked decrease in aneuploidy score after one cycle of pembrolizumab (p=0.005), irrespective of their baseline score. About half of patients (47%) with a low baseline score were non-responders and in those patients there was a significant increase of the aneuploidy score post cycle 1, when compared to the responders (p=0.039). **Conclusions:** The aneuploidy score based on mFast-SeqS may stratify mUC patients for expected lack of benefit early during treatment (after 1 cycle) with second line pembrolizumab, providing an opportunity to switch treatment and to spare patients from potential unnecessary toxicity. Clinical trial information: NCT03263039. Research Sponsor: Merck Sharp & Dohme LLC.

Final analysis results from a multicenter clinical study of tislelizumab combined with gemcitabine and cisplatin as neoadjuvant therapy in patients with cT2-T4aN0M0 MIBC. *First Author: Tianxin Lin, Department of Urology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China*

Background: To evaluate the efficacy and safety of tislelizumab combined with gemcitabine and cisplatin as neoadjuvant therapy for patients (pts) with clinical T2-T4aN0M0 (cT2-T4aN0M0) muscle-invasive bladder urothelial cancer (MIBC). At predefined interim analysis, the study has met the first stage aim. Here reported the results of the predefined final analysis. **Methods:** This phase II study enrolled pts tolerated with the cisplatin therapy. Eligible pts received tislelizumab 200 mg in day 1 (D1), cisplatin 70 mg/m² D2, and gemcitabine 1000 mg/m² D1 and D8 every 21 days for four cycles. Radical cystectomy (RC) was performed within 6 weeks after last dose treatment. The primary end point was pathologic complete response (pCR, pT0N0M0). Secondary end points were pathologic downstaging ($\leq$ pT1N0M0) (pDS), EFS, OS and safety. Simon two-stage design was used. If >5 pts achieved pCR in the first stage (n=22), study would proceed to the second stage and enroll 33 additional pts. If >18 of 55 pts achieved pCR, we would deem the study to have met the primary endpoint. **Results:** At the data cut off time of 14th Dec 2022, 63 pts (38 cT2, 19 cT3, and 6 cT4a) have completed neoadjuvant therapy, with median age of 64 (48-75) years. The median relative dose intensity of tislelizumab, cisplatin and gemcitabine were 92.3%, 85.7% and 85.6%, respectively. At this time, 55 pts underwent RC and completed 30 days post-surgery follow-up. The median time from last dose to RC was 4.4 (range: 0.6-13.3) weeks. Eight pts refused RC. Among 55 efficacy evaluable pts, 27 (49.1% [90% CI, 37.4-60.9]) pts achieved pCR, while 41 (74.5% [95% CI, 61.0-85.3]) pDS. Pts with cT2 achieved 55.6% (20/36) pCR and 86.1% (31/36) pDS. Among 14 non-responders, 3 of them (1 cT2, 2 cT3) achieved pT0, but with pathologic N1. Clavien-Dindo grade $\geq$ 3 postoperative complications occurred in 7.9% pts. Most common neoadjuvant therapy related AEs of any grade were hematologic toxicities (88.9%), nausea (77.8%), and vomiting (50.8%). Grade $\geq$ 3 neoadjuvant therapy related AEs occurred in 60.3% pts, which were hematologic toxicities (58.7%) in most. The frequently occurring immune-related AEs (irAEs) (>5%) included dizziness (14.3%), fatigue (12.7%), ASL/ALT increased (7.9%), rash (7.9%), pruritus (7.9%), and GGT increased (6.3%). Grade $\geq$ 3 irAEs occurred in 2 pts (pneumonia, n=1; cardiomyopathy, n=1). **Conclusions:** The study met its primary endpoint. Neoadjuvant tislelizumab combined with gemcitabine and cisplatin showed promising anti-tumor activity with high pCR and well tolerance in MIBC pts. Clinical trial information: ChiCTR2000037670. CDH1-mutated clinically advanced urothelial bladder cancer (UBC): A genomic landscape and real-world clinical outcome study (RWCOS). *First Author: Kyle M Rose, H. Lee Moffitt Cancer Center, Tampa, FL*

Background: CDH1 mutated bladder cancers are characterized by plasmacytoid histology and are associated with an aggressive clinical course. **Methods:** Cohort 1: 6,676 clinically advanced UBC patients underwent hybrid capture based comprehensive genomic profiling (CGP) to evaluate all classes of genomic alterations (GA) as well as microsatellite instability (MSI), tumor mutational burden (TMB), and genomic loss of heterozygosity (gLOH, high $\geq$ 16%). Tumor cell PD-L1 expression was determined by immunohistochemistry (Dako 22C3). GAs were compared between CDH1 mutated and wild-type (WT) patients using Chi-square. Cohort 2: 586 UBC patients underwent a RWCOS using the de-identified Flatiron Health-Foundation Medicine urothelial clinicogenomic database. The de-identified data originated from approximately 280 US cancer clinics (~800 sites of care) between January 2011 and April 2022. Differences in real-world progression-free survival (rwPFS) and overall survival (rWOS) were evaluated by Cox proportional hazard models. **Results:** Cohort 1: 217 UBC patients featured a CDH1 short variant mutation with 65.2% featuring plasmacytoid histology (PLC). The PLC cohort was slightly younger, with a higher proportion of male patients, and MSI-High status. Cell-Cycle regulatory GAs were significantly higher in the non-PLC cohort, specifically CDKN2A (25.5% vs 9.7%, p=0.01) and CDKN2B (23.6% vs 5.8%, p<0.01). CDH1-mutated UBCs featured a higher MSI high frequency (2.7% vs 0.8%; p=.002), mean TMB (14.8 vs 9.9mut/Mb p<.0001), RB1 GA (52.5% vs 20.3%; p<.0001), PTEN GA (9.2% vs 4.3%; p=.006) and PIK3CA GA (29.5% vs 21.8%; p=.02), but lower gLOH (6.8% vs 15.9%; p=.009), CDKN2A loss (12.4% vs 38.3%; p<.0001), MTAP loss (10.1% vs 25.1%; p<.0001), and FGFR3 GA (9.7% vs 18.1%; p=.002). TP53 GAs and PD-L1 expression levels were similar between groups. From cohort 2: 22 (3.7%) patients featured CDH1 mutations. When compared with the CDH1 WT patients, the age, gender, ethnicity and ECOG status were similar. CDH1 mutation was associated with less favorable outcomes for 270 UBC patients treated with immune checkpoint inhibitors (ICPI) including rwPFS (2.8 vs 3.5 months; p=.096) and rWOS (3.3 vs 9.5 months; p=.03). Similar comparisons for 316 UBC patients treated with chemotherapy showed no significant adverse impact of CDH1 mutation status on either rwPFS (7.9 vs 6.2 months; p=.11) and rWOS (13.4 vs 13.4 months; p=0.83). **Conclusions:** In addition to its classic association with PLC histology, CDH1-mutated UBC features an unique genomic landscape including higher MSI and TMB, activating GAs in the MTOR pathway, but lower frequency of FGFR3 GAs. RWCOS further supports that CDH1 mutation predicts resistance to ICPI-based treatment, but does not systemic chemotherapy. These findings support CGP to guide therapeutic approaches based on the personalized genomic signature of UBC. Research Sponsor: None.

Survival outcomes in patients with muscle-invasive bladder cancer receiving neoadjuvant chemotherapy stratified by number of cycles. *First Author: Anumita Chakraborty, Temple University Health System, Philadelphia, PA*

Background: Neoadjuvant cisplatin-based chemotherapy (NAC) prior to radical cystectomy is the standard of care for patients with muscle invasive bladder cancer (MIBC). Three or more cycles of NAC are commonly administered based on outcomes in prior prospective trials, however many patients are intolerant of 3 cycles of NAC due to toxicity. The prognosis of patients receiving fewer than 3 cycles of NAC has yet to be elucidated. **Methods:** This is a retrospective single-center study to quantify pathologic response, recurrence-free survival (RFS), and overall survival (OS) from time of first NAC in patients treated with < 3 cycles of NAC compared to patients treated with $\geq$ 3 cycles of NAC. Inclusion criteria include: diagnosis of MIBC between 2004-2017, $\geq$ 5 years of follow up, deceased or had recurrence prior to 5 years follow up but with adequate follow-up data. Patients were excluded from the study if they were found to have metastatic disease prior to initiation of NAC, lost to follow up prior to 5 years with no evidence of recurrence or death, or had progression of disease during NAC. The primary objective of this study was to determine RFS and OS in patients stratified by cycles of NAC. Patient characteristics were compared using chi-square tests, Fisher's exact tests, and Wilcoxon rank sum tests. Kaplan Meier curves and log-rank tests were used to compare RFS between subgroups, and Cox proportional hazards models were used to compare RFS adjusting for ECOG performance status, baseline GFR, stage, type of NAC regimen, and patient age at first dose of NAC. 5-year OS was calculated as a percentage of patients surviving at 5 years. **Results:** A total sample of 195 patients were treated with NAC for MIBC, of which 30 (15.3%) patients received < 3 cycles and 165 (84.6%) patients received $\geq$ 3 cycles of NAC. 53 patients received gemcitabine and cisplatin (GC) and 142 patients received methotrexate, vinblastine, doxorubicin, and cisplatin (MVAC). Complete pathologic response (ypT0N0) was observed in 7.4% of patients receiving < 3 cycles and in 26.8% of patient receiving $\geq$ 3 cycles of NAC (p = 0.024). Significant pathologic response (< ypT2) was obtained in 22.2% of patients receiving < 3 cycles of NAC and in 41.8% of patients receiving $\geq$ 3 cycles (p > 0.05). Median RFS in patients with < 3 cycles of NAC was 8.8 months (95% CI 6.51, 13.4) and 54.5 months with $\geq$ 3 cycles of NAC (95% CI 29.8, 111.9). Based on a log-rank test there is a statistically significant difference in unadjusted RFS between the two groups (p < 0.001). The 5-year OS in patients receiving < 3 cycles of NAC was 13.3%, and the 5-year OS in those receiving $\geq$ 3 cycles was 53.3%. **Conclusions:** Early cessation of chemotherapy due to intolerance had significant implications on pathologic response, RFS and OS. Clinicians should prioritize administering at least 3 cycles of cisplatin-based chemotherapy when feasible to optimize outcomes. Research Sponsor: None.

Survival outcomes of sarcomatoid versus classic urothelial carcinoma of bladder. *First Author: Rohan Garje, Miami Cancer Institute, Baptist Health South Florida, Miami, FL*

Background: Sarcomatoid urothelial carcinoma (SUC), a rare bladder cancer variant, has both epithelial and mesenchymal differentiation along with frequent TERTC228T promoter mutations and has poorer prognosis. In this study, we compared survival outcomes of SUC with classic urothelial carcinoma (CUC) in patients with T2-T4, N0-N1 bladder cancer after definitive therapy. **Methods:** All cases meeting our inclusion criteria for SUC and CUC during 2004-2019 were identified from National Cancer Database. Sociodemographic and clinicopathological characteristics were analyzed via descriptive and comparative statistics. Propensity-score matching was performed to adjust for baseline differences between SUC and CUC. Overall survival (OS) was compared using Cox proportional-hazards modelling and visualized through Kaplan-Meier curves. **Results:** 30072 cases of CUC and 480 of SUC were identified. Propensity-score matching resulted in N = 478 patients in both groups. Matched cohorts had no baseline differences in age, sex, race, comorbidities, insurance status, income, distance to hospital, hospital location, rural versus urban residence, histological grade, and proportion getting regional lymph node surgery. Overall, there were 675 males and 281 females, 435 underwent surgery (Sx), and 521 surgery plus chemotherapy (Sx+Cx). For SUC, median survival with Sx vs Sx+Cx was 29.5 months (95%CI 20.0-50.6) vs 43.1 months (95%CI 25.3-64.4) respectively. For CUC, median survival was 56.1 (95%CI 53.7-58.6) vs 78.0 (95%CI 75.1-81.1) months with Sx vs Sx+Cx respectively. **Conclusions:** SUC has poorer prognosis than CUC. Perioperative chemotherapy along with surgery was associated with improved survival outcomes compared to surgery alone in patients with SUC. Further studies investigating novel immunotherapy agents are warranted to improve oncologic outcomes. Research Sponsor: None.

Accuracy of genome-wide mutational analysis for tumor-informed ctDNA-guided MRD monitoring in bladder cancer. *First Author: Iver Nordentoft, Aarhus University Hospital, Aarhus, Denmark*

Background: Neoadjuvant chemotherapy (NAC) followed by radical cystectomy (RC) is the standard management of localized muscle-invasive bladder cancer (MIBC). However, about 45% of patients develop metastases within 2 years after RC. Biomarkers for treatment efficacy evaluation and early detection of minimal residual disease (MRD) are needed for earlier treatment initiation and monitoring of treatment response. Tumor-informed detection of mutations in cell-free DNA (cfDNA) has shown promising results to monitor MRD. However, the low tumor fraction after surgery and limited input material obtained from a typical plasma sample limits the probability of detecting low metastatic burden scenarios. Here we implemented and applied a whole-genome sequencing (WGS) approach to monitor circulating tumor DNA (ctDNA) for sensitive ctDNA detection. **Methods:** 110 MIBC patients undergoing NAC and RC were enrolled. cfDNA was extracted from ~1mL plasma (n=978) and procured from longitudinal plasma sampling during NAC and pre-RC and post-RC. WGS of tumor/germline pairs (30x/20x) and plasma cfDNA (>20x) was performed, facilitating detection of genome-wide genomic alterations and quantification of ctDNA using the C2inform method. **Results:** For each patient we developed a tumor-informed WGS model by integrating genome-wide mutation and copy number variation data coupled with advanced signal processing and AI-based error suppression. Patient-specific somatic variant patterns were used for detection and measuring ctDNA levels in low-input blood samples by WGS. Post-RC ctDNA analysis identified patients with recurrence with 78% sensitivity and 95% specificity and with a median lead time over radiographic imaging of 118 days (full follow-up included). When restricting follow-up time to 12 months following the latest ctDNA test, a sensitivity of 86% and specificity of 94% was achieved. ctDNA status was associated with recurrence-free (p<0.0001) and overall survival (p<0.0001). Furthermore, ctDNA clearance during NAC was also associated with recurrence-free survival (p=0.0051). The APOBEC associated signatures SBS2 and SBS13 were identified as the primary contributors to the mutational landscape of the primary tumors and *TP53*, *KMT2D*, *PIK3CA*, *RB1* and *KDM6A* were the main affected driver genes. Half of the tumors displayed whole genome doubling. Moreover, our analysis of plasma samples after treatment showed the presence of chemotherapy-induced mutational signatures not present in the primary tumor, along with increases in copy numbers on chromosomes 19q and 20, and a focal amplification of the *FGFR3* gene on chromosome 4. **Conclusions:** Our results highlight the clinical potential of personalized genome-wide mutation integration as an ultra-sensitive, non-invasive method for MRD detection and treatment response monitoring. Biology and performance of pre- and post-pembrolizumab (pembro) vesical imaging-reporting and data system (VI-RADS) to predict the pathological response in muscle-invasive urothelial bladder cancer (MIBC): Full data analysis from a clinical trials pipeline. *First Author: Andrea Necchi, Vita-Salute San Raffaele University, Milan, Italy*

Background: The VI-RADS is a standardized reporting system that uses multi-parametric magnetic resonance imaging (mpMRI) parameters to predict the probability of MIBC. It has been also used in studies using standard neoadjuvant chemotherapy. No studies have analyzed the performance of VI-RADS to predict the pT0 or pT≤1 response post-immunotherapy (IO) in MIBC. **Methods:** In PURE-01 study patients (pts) were staged with mpMRI before and after treatment (3 cycles of pembro) prior to radical cystectomy (RC). All mpMRI scans were centrally reviewed. Logistic regression models analyzed pre- and post-pembro VI-RADS against pT≤1 (primary endpoint) and pT0 (secondary endpoint). VI-RADS scores were dichotomized between 0-3 (0=no evidence of disease) and 4-5. Covariates included cT-stage, age, gender, PD-L1 combined positive score (CPS) and tumor mutational burden (TMB). Model performance was also tested in the ongoing NureCombo (nivolumab+nab-paclitaxel; NCT04876313) and SURE-01 (sacituzumab govitecan; NCT05226117) studies. Transcriptome-wide expression profiling was matched with VI-RADS scores. **Results:** In PURE-01, 115 pts had centrally-reviewed MRI scans (N=230 mpMRI), treated between 02/17 and 08/18. In total, 32 (27.8%) had pure/predominant non-urothelial carcinoma (UC) histology, 54 (47%) had a cT3-4N0 MIBC. Pre-pembro: 21 pts (18.3%) had no measurable disease (VI-RADS=0), 37 (32.2%) a VI-RADS 1-3 score, and 57 (49.5%) had a VI-RADS 4-5 score. 20 pts (17.4%) had a downstage from VI-RADS 4-5 to VIRADS 0-3 post-pembro. Pre-pembro VIRADS 4-5 were associated with higher angiogenesis and epithelial-mesenchymal transition (EMT) activity vs VI-RADS 0-3 (p=0.011 and 0.033). Both pre-pembro and post-pembro VI-RADS 0-3 scores were the only significant covariates against pT≤1 endpoint on multivariable analyses (MVA): the strongest effect was seen with post-pembro VI-RADS 0-3 against pT≤1 response (OR: 23.4, 95%CI: 7-95.3, p<0.0001). The AUC of this model was 0.90. Model-based decisions were supported in the range of threshold probabilities of 10-80%. Post-pembro VI-RADS 4-5 were characterized by higher stromal signature scores vs VI-RADS 0-3. When post-therapy VI-RADS were tested in evaluable pts from the combined NureCombo+SURE-01 cohort (N=17pts, 34 mpMRI): 90% of post-VI-RADS 0-3 revealed a pT≤1 stage at radical cystectomy. **Conclusions:** VI-RADS scores mirrored distinct biological features in MIBC, recapitulating tissue biomarkers of IO response. VI-RADS scores post-IO revealed a strong association with pathological downstaging and represented a robust feature based on which selecting pts for bladder-sparing strategies. Results seemed to be also applicable to other novel neoadjuvant therapies beyond IO monotherapy. Clinical trial information: NCT02736266. Phase I/II randomized clinical trial of in-clinic acupuncture prior to BCG in patients with high-risk non-muscle invasive bladder cancer. *First Author: Sarah P. Psutka, University of Washington, Fred Hutchinson Cancer Center, Seattle, WA*

Background: Acupuncture can reduce pain and urinary urgency and frequency. Treatment-related dose-limiting dysuria and irritative bladder symptoms are common in patients receiving intravesical Bacillus Calmette-Guerin (BCG) for the treatment of non muscle-invasive bladder cancer (NMIBC). We evaluated the feasibility, safety, and tolerability of weekly in-clinic pre-procedure acupuncture among patients receiving induction BCG. **Methods:** Patients with high-risk NMIBC undergoing induction BCG were randomized 2:1 to a standardized acupuncture protocol (Acu) or an attention waitlist control. Acu patients received acupuncture prior to each of 6 weekly BCG instillations. Feasibility was assessed via recruitment, retention, and intervention adherence. Acupuncture safety and tolerability were assessed via physician-reported CTCAE v5.0 and adverse events (AEs). Secondary endpoints included BCG treatment adherence, patient-reported BCG-related toxicity, and bladder cancer-specific and generic quality of life (QOL), assessed with the EORTC-QLQ-NMIBC-24 and -C30 surveys. Subjective assessments of acupuncture acceptability were assessed through patient exit surveys. **Results:** Between 1/21 and 7/22, 43 patients were randomized to Acu (n=28) vs. Control (n=15). Median age was 70.3 years and 76% were male. Week 7 follow-up surveys were completed by 93% of patients; 6 patients withdrew early due to disease progression, refractory gross hematuria, or for patient preference. Acupuncture was successfully delivered prior to each BCG treatment in Acu patients with no acupuncture-related AEs or interruptions to induction BCG. BCG-attributed AEs were reported by 91% Acu and 100% Control patients, including pain (28% vs. 43%, respectively, p=0.34) and urinary symptoms (62% vs. 79%, respectively, p=0.31). Comparing Acu with Controls, change in QOL over the study period demonstrated greater improvements in median urinary symptoms (9.5, IQR 0.0-19.0 vs. 0.0, IQR -14.3-7.1, p=0.02) and a trend towards improvement in median pain scores (16.7, IQR 0.0-16.7 vs. 8.3, IQR 0.0-33.3 p=0.68) among patients in the Acu arm. 96% of Acu patients reported that acupuncture was “very/extremely helpful” and 91% would recommend acupuncture to other patients. **Conclusions:** Acupuncture prior to induction BCG treatments is feasible and safe. In this Phase I/II trial, we observed reductions in pain and a trend towards improved urinary function scores over successive treatments among patients undergoing in-clinic pre-BCG instillation acupuncture. Patients receiving acupuncture reported high degrees of satisfaction with treatments. Future larger randomized controlled trials are needed to further characterize the efficacy of acupuncture with respect to pain, urinary symptoms and impact on QOL, and continuation of maintenance therapy during BCG treatment. Clinical trial information: NCT04496219. Research Sponsor: Early Phase Clinical Research Support Application, Cancer Center Support Grant Award ID# P30 CA015704-44.

Survival outcomes of micropapillary versus classic variant, loco-regional bladder cancer: A 2004-2019 National Cancer Database analysis. *First Author: Rohan Garje, Miami Cancer Institute, Baptist Health South Florida, Miami, FL*

Background: Micropapillary (MP) is a rare histologic variant of urothelial cancer (UC) with luminal-type characteristics and p53-like gene expression, leading to chemotherapy resistance and poor prognosis. However, contemporary outcomes of MP variant T2-T4, NO-N1 loco-regional bladder UC after definitive therapy are underreported, which this work sought to determine. **Methods:** A retrospective review was performed of all eligible cases of MP and classic UC (CUC) available during 2004-2019 from National Cancer Database. Socio-demographic, pathological, and clinical attributes were analyzed via descriptive and comparative statistics. Propensity-score matching was performed to adjust for baseline differences between MP and CUC. Overall survival, being the primary outcome, was compared using multivariable Cox proportional-hazards modeling and visualized through Kaplan-Meier curves. **Results:** 30072 cases of CUC and 397 of MP were identified. After propensity-score matching, 395 patients remained in both groups, with matched cohorts having no baseline differences in age, sex, race, Charlson-Deyo comorbidity index (CCI), insurance status, income, distance to hospital, hospital location, rural versus urban residence, tumor pathological grade, proportion receiving radiotherapy, and proportion getting regional lymph node surgery. In both matched cohorts there were 313 males (79%) and 82 females (21%). Both cohorts had 334 (85%) T2 cases, 41 (10%) T3 cases, and 20 (5%) T4 cases. Both cohorts had 375 (95%) N0 cases and 20 (5%) N1 cases. MP variant was associated with inferior survival compared to CUC (HR 1.26, 95%CI 1.03-1.54, P=0.024). Older age (≥65 years) and higher CCI were also associated with inferior survival. Irrespective of histology, patients undergoing surgery (S) plus chemotherapy (C) had better survival compared to S alone (HR 0.77, 95%CI 0.62-0.94, P=0.012). Regional lymph node surgery resulted in improved survival (HR 0.59, 95% CI 0.42-0.83, P=0.002). Sex, race, insurance, income, and hospital type did not impact survival. Median and two-year OS are summarized. **Conclusions:** Survival outcomes of MP are poorer than CUC of bladder. Surgery combined with perioperative chemotherapy was associated with better survival compared to surgery alone in patients with MP and CUC. Studies evaluating novel immunotherapies and antibody drug conjugates in perioperative setting are needed to improve outcomes. Research Sponsor: None.

Cohort	Median OS (months)	Two year OS (%)
MP with S + C	47.4 (34.8, 61.9)	70.2 (64.7, 75.7)
MP with S only	24.9 (20.2, 31.2)	52.2 (43.5, 61.0)
CUC with S + C	78.0 (75.1, 81.1)	72.0 (71.4, 72.7)
CUC with S only	56.2 (53.7, 58.6)	65.9 (65.1, 66.7)

Open versus robotic-assisted radical cystectomies: A risk analysis. *First Author: Rishabh Simhal, Department of Urology, Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA*

Background: Radical cystectomy (RC) is standard of care for muscle-invasive bladder cancer, but it comes with significant perioperative risk with half of patients experiencing major postoperative complications. Robot-assisted radical cystectomies (RARC) have aimed to decrease patient morbidity and have become increasingly adopted in North America. Currently, both open radical cystectomies (ORC) and RARC are frequently performed. To contribute to the existing literature using newly available data from the American College of Surgeons National Surgical Quality Improvement Project (NSQIP), representing one of the most recent, largest multi-institutional studies, while uniquely accounting for a variety of factors including type of urinary diversion, cancer staging, and neoadjuvant chemotherapy. **Methods:** RC procedures performed between 2019-2020 were identified in NSQIP and the corresponding Cystectomy Targeted database. Cases in the ORC group were planned open procedures, and cases in the RARC group were robotic with intra- or extracorporeal diversions, including unplanned conversion to open cases for intention-to-treat. Chi-square and t-tests were performed to compare baseline demographics and operative parameters. Multivariate analysis was performed for outcomes including major complications, minor complications, and 30-day mortality, while adjusting for operative approach, medical comorbidities, functional status, age, race, sex, BMI, ASA-classification, preoperative labs, type of urinary diversion, pathological staging, prior pelvic surgery or radiation, need for preoperative transfusion, preoperative sepsis, emergent or elective surgery, and recent chemotherapy. **Results:** 4,022 RC cases were identified. Of these, 3,146 (78.2%) received planned ORC while 876 (21.8%) received RARC. Baseline demographics of the patients who received ORC versus RARC were largely similar, with no significant difference in age or medical comorbidities. RARC was associated with longer operative times and shorter hospital length of stay compared to ORC. On multivariate analysis, ORC was associated with a higher rate of 30-day mortality [OR 3.1; 95% CI 1.3-7.2; p=0.009], reintubation, cardiac arrest, superficial wound infection, bleeding requiring transfusion [OR 4.7; 95%CI 3.6 - 6.1; p<0.001], prolonged postoperative nasogastric tube use, rectal injury, and urethral fistula or urine leak compared to RARC. **Conclusions:** In the NSQIP database, ORC is associated with higher rates of 30-day mortality and operative complications, most notably bleeding, compared to RARC. This study is unique in the size of the cohorts compared, the timeliness of the data (2019-2020), and the ability to control for factors, such as type of urinary diversion, pathological bladder cancer staging, and use of neoadjuvant chemotherapy. Study EV-103: Neoadjuvant treatment with enfortumab vedotin monotherapy in cisplatin-ineligible patients (pts) with muscle invasive bladder cancer (MIBC): Updated results for Cohort H. *First Author: Thomas W. Flaig, University of Colorado Cancer Center Anschutz Medical Campus, Aurora, CO*

Background: Cisplatin-ineligible pts with MIBC have no established neoadjuvant treatment options known to prolong survival before undergoing radical cystectomy and pelvic lymph node dissection (RC+PLND). Enfortumab vedotin (EV) is an antibody-drug conjugate directed to Nectin-4, which is highly expressed in urothelial cancer. In a phase 3 study, EV showed improved overall survival vs standard chemotherapy and a tolerable safety profile in pts with advanced urothelial cancer previously treated with a platinum agent and a PD-1/L1 inhibitor (Powles NEJM 2021). In Cohort H of the EV-103 phase 1b/2 study, preliminary results, including pathological complete response (pCR) and pathological downstaging (pDS) rates, showed antitumor activity in cisplatin-ineligible pts with MIBC who received neoadjuvant EV treatment (Petrylak ASCO GU 2022). Here we report updated results, including event-free survival (EFS) and subsequent cancer-related therapy. **Methods:** Cohort H of the EV-103 phase 1b/2 study (NCT03288545) enrolled cisplatin-ineligible pts with MIBC (T2-T4aNOMO) and ECOG PS ≤2 who were eligible for RC+PLND. Pts received neoadjuvant EV (1.25 mg/kg) on Days 1 and 8 every 21 days for 3 cycles before undergoing RC+PLND. The primary endpoint was pCR rate (ypT0 and NO) by central pathology review. Key secondary endpoints included pDS rate (ypT0, ypTis, ypTa, ypT1, and NO), EFS based on investigator assessment, and safety. **Results:** 22 pts (median age 74.5 yr, range 56-81) were enrolled and treated; 17 pts (77.3%) remain on study. Pts had stage cT2 (68.2%), cT3 (27.3%), or cT4 (4.5%) disease. 68.2% of pts had transitional cell carcinoma only; 31.8% had a mixed histology. 86.4% of pts completed all 3 cycles of EV treatment; the median duration of EV treatment was 2.1 months (range 0.7-2.3). The pCR rate was 36.4% (95% CI, 17.2, 59.3) and the pDS rate was 50.0% (95% CI, 28.2, 71.8). Median EFS has not been reached. The EFS rate at 12 months was 76.4% (95% CI, 52.2, 89.4). All pts underwent surgery with no delays due to EV-related TAEs. The most common EV-related TAEs were fatigue (45.5%), dysgeusia (36.4%), and alopecia (31.8%); 18.2% of pts had grade ≥3 EV-related TAEs. 68.2% of pts had surgery-related TAEs and 31.8% pts had grade ≥3 surgery-related TAEs. The most common surgery-related TAEs were procedural pain (18.2%), anaemia (13.6%), and constipation (13.6%). 3 pts died due to AEs unrelated to EV treatment; in 2 pts the AEs occurred >30 days after RC+PLND. 36.4% of pts received subsequent cancer-related therapy. **Conclusions:** Neoadjuvant EV monotherapy treatment showed promising results for antitumor activity and EFS with a manageable safety profile in cisplatin-ineligible pts with MIBC. These results support ongoing phase 2 and 3 programs in MIBC evaluating EV alone or combined with pembrolizumab (EV-103 Cohort L, KN-905, KN-B15). Clinical trial information: NCT03288545. The impact of neoadjuvant chemotherapy on 30-day radical cystectomy outcomes. *First Author: Kerith Ruoyao Wang, Department of Urology, Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA*

Background: Neoadjuvant chemotherapy (NAC), often a cisplatin-based regimen, is recommended before radical cystectomy (RC), as studies have shown a modest survival benefit. However, NAC may confer toxicity and augment preoperative frailty, affecting perioperative outcomes. We investigated the relationship between NAC and 30-day RC outcomes using the National Surgical Quality Improvement Program (NSQIP). **Methods:** RCs performed between 2019-2020 were identified in NSQIP and the corresponding cystectomy-targeted database. Baseline demographics, comorbidities, and operative parameters were compared via Pearson's chi-square and t-tests between patients who received NAC before RC and RC alone (RCA) groups. Patient frailty was compared using the NSQIP frailty index (mFI-5), a validated 5-item score including points for diabetes, functional status, chronic obstructive pulmonary disease, heart failure, and hypertension. Multivariable logistic regression was used to compare outcomes, adjusting for age, race, robotic or open approach, urinary diversion type, comorbidities, ASA classification, and functional status. Minor complications included superficial SSI, pneumonia, UTI, bleeding requiring transfusion, AKI, or C. diff infection. Major 30-day complications included sepsis, DVT, stroke, reintubation, renal failure, MI, PE, septic shock, wound dehiscence, deep wound infection, cardiac arrest, readmission, reoperation, or mortality. All statistical tests were two tailed, p<0.05 considered significant. **Results:** 4,482 RCs were identified. Of these, 1889 (42%) patients received NAC. Compared to RCA, NAC patients were younger (66.9 years vs 70.4 years, p<0.001), had higher rates of white race, being functionally independent, preoperative weight loss, and cigarette use. NAC also had lower ASA class, fewer comorbidities, and lower frailty (mFI-5 0.8 vs 0.9, p<0.001). Compared to RCA, NAC patients had more robotic cystectomies (23% vs 19%, p=0.0003), received more continent diversions, had a shorter length of stay (7.1 vs 7.8 days, p<0.001), and more commonly had pT0 tumors compared to RCA (18.4% vs 5.9%, p<0.001). On MVA, NAC patients had higher rates of minor complications, most notably increased bleeding requiring transfusion [OR 1.8; 95%CI 1.6-2.1; p<0.001]. There was no difference in major complications between NAC and RCA, except NAC was associated with higher rates of sepsis [OR 1.4; 95%CI 1.1-1.8; p=0.003]. There was no difference in 30-day need for reoperation, readmission, or mortality. **Conclusions:** In the largest study to date on this topic, we found that NAC for RC is often given to younger, healthier patients, and is not associated with higher rates of major complications or mortality. NAC is associated with higher rates of bleeding and sepsis, which may be related to the immunosuppressive effects of chemotherapeutics. Providers should discuss with patients the benefits and risks of NAC before RC. Research Sponsor: None.

A first-in-human trial of intravesical enfortumab vedotin (EV), an antibody-drug conjugate (ADC), in patients with non-muscle invasive bladder cancer (NMIBC): Interim results of a phase 1 study (EV-104). *First Author: Ashish M. Kamat, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: A majority of patients (pts) with bladder cancer present with non-muscle invasive disease; for pts with high-risk tumors, standard of care (SOC) is resection of tumor followed by intravesical Bacillus Calmette-Guerin (BCG). Once pts experience recurrence and develop BCG-unresponsive disease, SOC is radical cystectomy (RC), which many pts are unfit for or refuse. EV is an ADC directed to Nectin-4, which is highly expressed in bladder tumors. Intravenous EV has demonstrated survival benefit in pts with previously treated la/mUC. In preclinical models with intravesical administration, EV was well tolerated and showed antitumor activity. Here we present the first clinical data for intravesical administration of EV in pts with NMIBC. **Methods:** EV-104 (NCT05014139) is an ongoing phase 1, open-label, multicenter, dose-escalation and expansion study of intravesical EV evaluating the safety, tolerability, PK, and antitumor activity of intravesical EV in pts with high-risk BCG-unresponsive NMIBC with carcinoma in situ (CIS) with or without papillary disease who are ineligible for or refuse RC. Dose escalation phase aims to identify the MTD or recommended dose of intravesical EV at the following dose levels: 125mg, 250mg, 500mg, and 750mg. Pts receive intravesical EV weekly for 6 weeks in the induction phase, followed by 9 monthly maintenance doses. Preliminary safety, PK, and efficacy data for 125mg and 250mg doses are presented in this abstract. **Results:** As of data cutoff (1 Dec 2022), 6 pts received intravesical EV across 2 dose levels: 4 pts at 125mg completed 6 induction cycles and proceeded to maintenance; 2 pts at 250mg had received at least 3 doses of intravesical EV. Of 6 pts across doses, there were no Grade ≥3 TRAEs, treatment-related SAEs, TRAEs leading to dose reduction or discontinuation. 4 of 6 pts (3 at 125mg and 1 at 250mg) experienced ≥1 treatment-related adverse event (TRAE) of Grade 1 or 2. Most common TRAEs were fatigue (3 of 6) and micturition urgency (2 of 6). As of data cutoff, no DLTs were observed for 125mg; the DLT evaluation period for 250mg was not complete. All blood PK analyses (ADC and unconjugated MMAE) for pts at 125mg were undetectable; no PK data was available for 250mg. Of 4 pts receiving 125mg of intravesical EV, 3 achieved CR and continue in response. The fourth pt discontinued tx due to persistent disease but remains on study. Pts at 250mg had not been evaluated for response at data cutoff. Detailed safety and additional efficacy data will be presented. **Conclusions:** Preliminary data from EV-104 show intravesical EV is well tolerated with no evidence of systemic exposure at 125mg. Preliminary antitumor activity was observed at 125mg with 3 of 4 pts achieving a CR. Dose escalation is ongoing to identify the MTD or recommended dose for dose expansion. Clinical trial information: NCT05014139. Research Sponsor: Seagen Inc. and Astellas Pharma Inc.

CABOSUN II: Results from a phase 2, open-label, multi-center randomized study of cabozantinib (CABO) vs. sunitinib (SUN) for non-clear cell renal cell carcinoma (NCCRC). *First Author: Andrew Johns, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: NCCRC are a diverse group of rare diseases with limited data to guide treatment. CABO is highly effective in clear cell RCC, but it is unknown whether it is superior to SUN, the historic standard of care for metastatic NCCRC. **Methods:** CABOSUN II (NCT03541902) was a randomized phase II study at 3 centers for patients (pts) with metastatic NCCRC. Sixty pts were planned to detect CABO as better than SUN with a 1-sided test. Pts were randomized 1:1 to CABO 60mg daily or SUN 50mg daily (4 weeks on, 2 weeks off). SUN dose modification to 2 weeks on, 1 week off was allowed for toxicity. Stratification was by papillary RCC (PRCC) vs. non-PRCC (NPRCC), good/intermediate vs. poor risk disease by IMDC criteria, and prior TKI use. The primary outcome was progression-free survival (PFS) by RECIST v1.1 compared between the 2 arms using the log-rank test. Secondary outcomes were objective response rate (ORR), overall survival (OS), and adverse event (AE) rates (2-sided tests). **Results:** 32 pts were randomized to CABO (N=15) or SUN (N=17) between 9/2018 and 6/2021. The trial stopped early due to a change in standard therapy for PRCC not based on these pts' outcomes. Age range was 22-88 years with medians 57 and 61 for CABO and SUN. Pts were primarily white (84%) and male (72%), with good/intermediate risk (88%), and these were balanced between arms. More pts on the CABO arm had bone metastases (62% vs. 24%). NPRCC were chromophobe (N=6; 5 randomized to SUN), unclassified (N=5), and MIT family translocation (N=3; all randomized to CABO). With median follow-up of 33.3 months and 20 PFS events, median PFS for CABO vs. SUN was 8.2 vs. 13.8 months (1-sided p=0.96). There were no statistically significant differences in ORR or OS between the arms. AEs were in line with previous studies. **Conclusions:** CABO was not superior to SUN for metastatic NCCRC in this study. Both arms had high rates of stable disease or better. Despite stratification by PRCC or NPRCC, there were major differences in NPRCC subtypes between the arms that may have impacted the results. More pts with chromophobe histology, an often indolent subtype, received SUN while all pts with MIT family translocation, a relatively aggressive subtype, received CABO. Permitted SUN dose modifications may have also influenced outcomes. While the PAPMET study showed CABO to be superior to SUN for PRCC, optimal treatments for rare, NPRCC remain a pressing need. Clinical trial information: NCT03541902. Research Sponsor: Exelixis.

Gender and postoperative surgical margin status in MIBC: An analysis of the National Cancer Database. *First Author: Olivia French Gordon, George Washington University Hospital, Washington, DC*

Background: Women with muscle-invasive bladder cancer (MIBC) continue to experience persistent disparities in health outcomes despite accounting for less than 1/3 of newly diagnosed bladder cancer cases. Multiple studies have acknowledged the aggressive profile of female bladder cancer. This study aims to identify tangible areas to intervene and improve the delivery of oncologic care. **Methods:** The National Cancer Database (NCDB) was queried from 2004-2017 to conduct a retrospective cohort analysis of men and women with MIBC (cT2a-T4). N=41,037 patients with MIBC were reviewed, (30,313 male; 10,724 female). The primary endpoints were OS and surgical margin status. Logistic regression was performed to determine whether female sex conferred differential impact on surgical margin status when controlling for baseline clinical stage, age, receipt of neoadjuvant chemotherapy (NAC), Charlson-Deyo Comorbidity Classification (CDDC), and facility type. Cox proportional hazards assessed the impact of age, gender, margin status, CDDC and NAC on OS. **Results:** Logistic regression showed that sex, age, baseline clinical stage, CDDC, facility type and NAC were significant predictors of surgical margin status (p<.001). Female sex was found to have a 14.4% higher probability of having positive residual margins (HR 1.144 (95% CI: 1.07-1.23), p<.001). When adjusting for age, margin status, CDDC and NAC, Female gender (OS HR 1.063 (95% CI: 1.03-1.09), p<.001), positive microscopic margins (OS HR 2.0 (95% CI: 1.90-2.10), p<.001) and positive macroscopic margins (OS HR 2.62 (95% CI: 2.40-2.90), p<.001) independently portended poorer OS and necessitated increased adjuvant XRT (p<.001). Unexpected demographic findings included a significantly greater number of females than expected with a median household income <\$38,000 (p= 0.047) and a greater number of females in the upper quartile of patients without a HS diploma (p<.001). The median days from diagnosis to definitive surgical treatment was significantly lower compared to males (58 vs 67 days; p<.001). **Conclusions:** Women with MIBC faced obstacles to getting treatment (less education and lower median income). Despite these hurdles they may be more proactive with their health as seen by a shorter time from diagnosis to the surgical table. However, this proactivity has yet to pay off as women undergoing surgical treatment for MIBC were significantly less likely to have clear margins post-operatively. The urologic community must mirror female patient's proactivity and further investigate the gender disparity in surgical treatment of MIBC. Research Sponsor: None.

Associations of diet with survival of patients (pts) with metastatic cancer of the urothelium (mUC) and renal cell carcinoma (mRCC) on immune checkpoint blockade (ICB). *First Author: Brendan John Guercio, James P. Willmot Cancer Center/URMC - JPWCC, Rochester, NY*

Background: The gut microbiome is an emerging modifiable predictor of ICB efficacy. Diet impacts the gut microbiome and fiber intake is associated with longer progression-free survival (PFS) in advanced melanoma treated with ICB. Whether diet impacts ICB benefit in mUC or mRCC remains unknown. **Methods:** Using a prospective cohort design, baseline dietary data were collected from pts with mUC or mRCC initiating ICB at Memorial Sloan Kettering Cancer Center using the extensively validated Harvard Willett Food Frequency Questionnaire. Tumor mutational burden (TMB) was estimated by next generation sequencing (MSK-IMPACT). The primary endpoint was radiologist assessed PFS, with secondary endpoint of overall survival (OS). Fiber intake was stratified as high or low using the median intake in our cohort. Associations between fiber intake and clinical outcomes were assessed using Kaplan-Meier curves plus univariable (UV) and multivariable (MV) Cox proportional hazards regression. Models were adjusted for prior ICB exposure. Models for mUC controlled for TMB and Bellmunt risk factors. Models for mRCC controlled for histology (clear vs non-clear cell) and IMDC risk score. **Results:** From 2/2021-6/2022, 88 pts eligible for analysis were enrolled with median follow-up of 10.1 months (mo) (mUC n = 40; mRCC n = 48). Median fiber intake was 17.5 g/day (interquartile range 12.5-24.5). Among pts with mUC, high fiber intake (≥ 17.5 g/day) was associated with longer PFS (UV hazard ratio [HR] 0.56, 95% CI 0.26-1.19, p = .13; MV HR 0.39, 95% CI 0.16-0.93, p = .03). Similar trends were observed for mRCC. In subgroup analyses, PFS was numerically longer with high fiber intake among mUC pts on maintenance avelumab (median PFS 6.1 vs 3.0 mo, n = 14) and in pts with mRCC treated with first-line (1L) ipilimumab + nivolumab (median PFS 18.0 vs 5.7 mo, n = 14) and 1L ICB + tyrosine kinase inhibitor (median PFS not reached vs 5.1 mo, n = 21). Among pts with mUC on non-maintenance ICB, pts with high fiber intake had numerically higher PFS at 6 mo (38% vs 14%, n = 26). **Conclusions:** This pilot study indicates that high fiber intake is associated with longer PFS among pts with mUC on ICB. Trends towards longer PFS and OS with high fiber intake were observed among pts with mRCC. Analyses of the gut microbiome are underway to investigate mechanisms of action. Research Sponsor: Bladder Cancer Advocacy Network; U.S. National Institutes of Health.

Association of ¹⁸F-FDG PET characteristics and survival outcomes using whole body tumor analysis in patients (pts) with metastatic genitourinary (GU) malignancies. *First Author: Nicholas I. Simon, National Cancer Institute, Bethesda, MD*

Background: ¹⁸F-FDG PET scans are widely used for staging and monitoring pts with metastatic GU malignancies. In addition to identifying lesions, ¹⁸F-FDG PET scans provide semi-quantitative parameters (SUV_{max}, SUV_{mean}, total lesion glycolysis (TLG)) that can be used to characterize disease burden and treatment response. These parameters can demonstrate how treatment response varies across different patients as well as across different lesions within the same patient. This study was done to determine which parameter provides the best prognostic information for pts with metastatic GU malignancies. **Methods:** 101 patients with metastatic GU malignancies from two separate, prospective trials with at least two ¹⁸F-FDG PET scans were analyzed. All regions of interest were contoured for both the baseline and follow-up ¹⁸F-FDG PET scans. Regions of interest (ROI) were quantified and matched between timepoints using TRAQinform IQ technology (AIQ Solutions) to identify which were new, increasing, stable, decreasing, or disappeared. Imaging features were extracted from each patient, including basic features (SUV_{max}, SUV_{mean}, TLG, and changes in these features) and heterogeneity (intrapatient heterogeneity of disease and response) features. Cox regression was used to determine univariate predictive power of each measure. The TRAQinform Profile was calculated to predict either progression-free (PFS) or overall survival (OS) using 5-fold cross-validation of a random survival forest. The performance of individual features and the TRAQinform Profile was evaluated using the c-index. **Results:** 54pts were treated with single agent cabozantinib (cabo) on a phase II trial and 47 pts were treated with cabozantinib and nivolumab, with or without ipilimumab (cabonivo +/- ipi), on a phase I trial. Most pts had urothelial carcinoma (N = 65). Other histologies included prostate (4), penile (1), renal cell carcinoma (RCC) (6), renal medullary carcinoma (4), testicular (4), adenocarcinoma of the bladder (8), squamous cell carcinoma of the bladder (2), sarcomatoid bladder (1), sarcomatoid RCC (1), and small cell carcinoma (4 bladder, 1 prostate). 2389 ROIs were analyzed, with a range of 1 to 151 per patient. The TLG at the follow-up image was the strongest predictor of both PFS (c-index = 0.62) and OS (0.69), followed by number of increasing ROI (0.61, 0.64), and percentage of all ROIs classified as new or increasing (0.57, 0.63). SUV_{max} (0.49, 0.47) and SUV_{mean} (0.47, 0.56) at follow-up were found to be weaker predictors of PFS and OS. TRAQinform Profile was able to predict the responder's vs suboptimal responders to study treatment (c-index = 0.73, 0.75). **Conclusions:** The TRAQinform Profile analysis of ¹⁸F-FDG PET scans provided both prognostic and predictive information for patients with metastatic GU malignancies treated with either cabo or cabonivo +/- ipi. KEYNOTE-905/EV-303: A phase 3 study to evaluate the efficacy and safety of perioperative pembrolizumab or pembrolizumab plus enfortumab vedotin (EV) for muscle-invasive bladder cancer (MIBC). *First Author: Andrea Necchi, Vita-Salute San Raffaele University; IRCCS San Raffaele Hospital and Scientific Institute, Milan, Italy*

Background: Standard of care for MIBC is neoadjuvant cisplatin-based chemotherapy followed by radical cystectomy + pelvic lymph node dissection (RC + PLND), but many patients with MIBC are ineligible for cisplatin-based chemotherapy. In the phase 1b/2 KEYNOTE-869/EV-103 study, combination therapy with the PD-1 inhibitor pembrolizumab and the Nectin-4-directed antibody-drug conjugate EV showed promising antitumor activity in cisplatin-ineligible patients with locally advanced or metastatic urothelial carcinoma. KEYNOTE-905/EV-303 (NCT03924895) is a multicenter, randomized, open-label, phase 3 study to evaluate efficacy and safety of perioperative pembrolizumab alone or combined with EV versus RC + PLND alone in patients with MIBC who are ineligible for or decline cisplatin-based treatment. **Methods:** Patients with treatment-naïve MIBC (T2-T4aN0M0 or T1-T4aN1M0) and predominantly ($\geq 50\%$) urothelial histology who are cisplatin ineligible or decline cisplatin-based treatment and have an ECOG PS score of 0-2 are eligible. Cisplatin ineligibility will be defined as meeting ≥ 1 of the following criteria: impaired renal function with calculated creatinine clearance 30-59 mL/min; ECOG PS 2; grade ≥ 2 audiometric hearing loss per CTCAE v4.0; or NYHA class III heart failure. Patients will receive neoadjuvant pembrolizumab 200 mg intravenously (IV) every 3 weeks (Q3W) for ≤ 3 cycles followed by RC + PLND and adjuvant pembrolizumab 200 mg IV Q3W for ≤ 14 cycles (arm A); RC + PLND followed by observation (adjuvant nivolumab permitted based on clinical indication and regulatory approval [arm B]); or neoadjuvant EV 1.25 mg/kg + pembrolizumab 200 mg IV Q3W for ≤ 3 cycles followed by RC + PLND and adjuvant EV + pembrolizumab for ≤ 6 cycles and adjuvant pembrolizumab 200 mg IV Q3W for ≤ 8 cycles (arm C). In the neoadjuvant and adjuvant phases of arm C, pembrolizumab will be administered on day 1 and EV will be administered on days 1 and 8 of each cycle. Enrollment is complete for arm A; patients will continue to be randomly assigned 1:1 to arm B or arm C. Stratification factors are tumor stage (T2N0 vs T3/T4aN0 vs T1-T4aN1), geographic region (United States vs Europe vs rest of world), and cisplatin eligibility (cisplatin ineligible or cisplatin eligible but declines treatment). The primary end point is event-free survival between arm B and arm C. Secondary end points are event-free survival (arm A vs arm B) pathologic complete response, overall survival, disease-free survival, pathologic downstaging rates, and safety. Enrollment is planned for 308 patients, and recruitment is ongoing in Africa, Asia, Australia, Europe, North America, and South America. © 2023 American Society of Clinical Oncology, Inc. LITESPARK-024: Randomized phase 1/2 study of belzutifan with or without palbociclib for treatment of advanced renal cell carcinoma (RCC). *First Author: David F. McDermott, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Immunotherapy is a standard-of-care first-line treatment for advanced clear cell RCC (ccRCC). However, many patients (pts) will develop resistance to first-line therapy, and effective second- and later-line treatment options are therefore needed. The von Hippel-Lindau (*VHL*) gene is inactivated in approximately 90% of ccRCC cases and results in the constitutive activation of hypoxia-inducible factor 2 α (HIF-2 α), a key oncogenic driver in RCC. Belzutifan, a first-in-class HIF-2 α inhibitor, has demonstrated antitumor activity with manageable safety in previously treated pts with advanced ccRCC. The cyclin-dependent kinase (CDK) pathway is also associated with poor clinical outcomes in ccRCC. In RCC cell lines, the CDK 4/6 inhibitor palbociclib inhibited cell growth. CDK 4/6 inhibition has shown synergistic antiproliferative effects with HIF-2 α inhibition in HIF-2 α -dependent *VHL* $-/-$ RCC cell lines. Palbociclib could therefore potentially enhance the efficacy of belzutifan as combination therapy for previously treated pts with advanced RCC. **Methods:** LITESPARK-024 is a 2-part, open-label, multicenter, phase 1/2 randomized study (NCT05468697). Part 1 is intended to establish the recommended phase 2 dose (RP2D) of belzutifan + palbociclib using a modified toxicity probability interval design. After the RP2D is established, part 2 will directly compare the safety and efficacy of belzutifan monotherapy with belzutifan + palbociclib in pts with advanced ccRCC. In both parts, pts with measurable disease per RECIST v1.1, a KPS score of $\geq 70\%$, and histologically confirmed unresectable stage IV RCC with a clear cell component with disease progressing on or after receiving at least 2 systemic treatments (both an anti-PD-1/L1 monoclonal antibody and a VEGF receptor-targeted tyrosine kinase inhibitor, in sequence or in combination) will be enrolled. Up to 30 pts will be enrolled into 3 dose groups in part 1 and will receive belzutifan 120 mg once daily + palbociclib (75, 100, or 125 mg) daily for 21 consecutive days followed by 7 days off. In part 2, approximately 150 pts will be randomly assigned 2:1 to receive belzutifan 120 mg once daily + palbociclib RP2D (21 consecutive days/7 days off) or belzutifan 120 mg once daily. Pts will be stratified by IMDC risk (0 vs 1-2 vs 3-6) and sarcomatoid histology (yes vs no) at randomization in part 2. The primary end point for part 1 is to assess dose-limiting toxicities and adverse events and to determine the RP2D of belzutifan + palbociclib. The primary end point for part 2 is ORR per RECIST v1.1 by investigator assessment. Secondary end points for part 2 are CBR, DOR, and PFS per RECIST v1.1 by investigator assessment, OS, and safety and tolerability. Enrollment began in July 2022. Clinical trial information: NCT05468697. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA.

ARC-20: A phase 1 dose-escalation and dose-expansion study to investigate the safety, tolerability, and pharmacology of HIF-2 α inhibitor AB521 monotherapy in patients with clear cell renal cell carcinoma and other solid tumors. *First Author: Toni K. Choueiri, Dana Farber Cancer Institute and Harvard Medical School, Boston, MA*

Background: Renal cell carcinoma (RCC) is one of the 10 most common neoplasms in the United States. Patients with clear cell RCC (ccRCC) commonly have inactivation of the von Hippel-Lindau tumor suppressor protein, resulting in accumulation of hypoxia-inducible factor alpha (HIF α) subunits (especially HIF-2 α) and leading to tumor growth. AB521, an orally bioavailable small molecule inhibitor of HIF-2 α , potentially inhibits transcription of HIF-2 α -dependent genes in cell lines and preclinical species. Single doses of AB521 (3 mg, 10 mg, 30 mg, and 100 mg) and multiple ascending doses of AB521 (15 mg, 30 mg, and 50 mg) have been previously studied in healthy volunteers. ARC-20 is a first-in-patient study to investigate the safety, tolerability, and pharmacology of AB521 monotherapy in patients with solid tumors and evaluate the clinical activity of AB521 in previously treated patients with ccRCC. **Methods:** ARC-20 (NCT05536141) is a phase 1, multicenter, open-label study. Eligible patients are adults with solid tumors with ≥ 1 measurable lesion(s) per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 and an Eastern Cooperative Oncology Group performance status of 0 or 1. ARC-20 has 2 stages, dose escalation and dose expansion. The dose escalation stage uses a standard 3+3 design and includes patients with pathologically confirmed solid tumors and no other available treatment options. Patients will be sequentially assigned to 1 of 4 cohorts evaluating doses of AB521 ranging from 20 to 200 mg/day. Intermediate dose cohorts may be evaluated based on emergent safety or pharmacologic data. The dose expansion stage will evaluate approximately 30 patients with histologically confirmed ccRCC who have received previous treatment for metastasis with an anti-programmed cell death protein 1 (anti-PD-1) therapy and a vascular endothelial growth factor (VEGF)-targeting tyrosine kinase inhibitor (TKI). Patients previously treated with a HIF-2 α -targeting therapy are not eligible for dose expansion. Results from the dose-escalation stage will inform the dose and schedule used during dose expansion. Primary endpoints are the incidence of dose-limiting toxicity and adverse events. Secondary endpoints include objective response rate, AB521 plasma concentration, and AB521 pharmacokinetics. Exploratory endpoints include changes in expression of erythropoietin and other HIF-2 α driven biomarkers in blood and tumor tissues, along with progression-free survival for ccRCC patients during dose expansion. Clinical trial information: NCT05536141. Research Sponsor: Arcus Biosciences.

NRG-GU012: Randomized phase II stereotactic ablative radiation therapy (SABR) for patients with metastatic unresected renal cell carcinoma (RCC) receiving immunotherapy (SAMURAI). *First Author: William A. Hall, Medical College of Wisconsin, Milwaukee, WI*

Background: The treatment for patients with metastatic RCC is evolving. The current standard of care for patients presenting with de novo metastatic disease is combination immunotherapy (IO)-based treatment. At the time of this shift in the systemic treatment strategy, the role of immediate cytoreductive nephrectomy has also been in flux. For patients with de novo disease, there has been a shift towards initiation of upfront systemic rather than immediate cytoreductive nephrectomy. SABR is a highly focused radiation technique that delivers a high dose of radiation over a limited number of fractions. The SAMURAI trial seeks to evaluate SABR as an alternative approach to treat the primary tumor in patients with metastatic RCC receiving IO, who are not recommended for surgery, or who decline surgery. **Methods:** This is a randomized phase II trial for patients with metastatic RCC with an intact primary tumor. Eligible patients include those with any histology RCC who are candidates to receive standard IO combination treatment and are those not recommended for upfront surgery or decline surgery. Patients will be randomized to SABR + IO combination versus IO combination alone. The primary objective of the study is to determine whether the addition of SABR to the primary tumor in combination with IO improves outcomes compared to IO alone in patients with metastatic, unresected, RCC. The primary endpoint is nephrectomy and radiographic progression-free survival (nrPFS) with progression determined as per iRECIST criteria. Patients are eligible if they are not recommended for upfront surgery, have a primary tumor treatable with SABR, and are candidates for IO. Choice of IO combination regimen will be at the discretion of the treating physician and will include either IO-IO or regimens of IO in combination with a VEGF inhibitor (IO-VEGF). 240 patients will be randomized in a 2:1 ratio favoring SABR plus IO combination (n=160) as compared to standard of care IO combination alone (n=80). The sample size will provide 90% power at a one-sided alpha level of 0.05 to detect a hazard ratio for nrPFS of 0.62, i.e., an approximate 40% reduction in the rate of events. Secondary endpoints include objective response rate by iRECIST and RECIST, radiographic progression free survival by RECIST and iRECIST, time to second line therapy, rate of cytoreductive nephrectomy, treatment free survival, and overall survival. Exploratory analyses will assess potential prognostic and predictive biomarkers. The trial is currently open and accruing through the NRG oncology cooperative group (NCT05327686) and study information can be found through the Cancer Trials Support Unit website www.ctsu.org. Clinical trial information: NCT05327686. Research Sponsor: U.S. National Institutes of Health.

Phase 1b/2 study of combination ^{177}Lu girentuximab plus cabozantinib and nivolumab in treatment naive patients with advanced clear cell RCC. *First Author: Elshad Hasanov, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Complete response (CR) is still a rare event in patients with advanced clear cell renal cell carcinoma (ccRCC). The combination of nivolumab plus cabozantinib was recently approved for the first-line treatment of ccRCC based on the CheckMate 9ER phase III study demonstrating improved progression-free survival (PFS) and objective response rate (ORR) in comparison to sunitinib. However, the CR rate was only 9%. Since the anti-tumor effects of immune checkpoint inhibitors are dependent on the presence of activated tumor-infiltrating T cells, drugs that could synergize with T cells' anti-tumor activity can allow us to improve CR rates. Activation of the cGAS-STING pathway, the master regulator of anti-tumor immunity which is induced by radiation-induced DNA damage, is one promising mechanism that has been investigated. Many studies have shown that radiation treatment augments immune checkpoint inhibition. However, it is not always possible to radiate all metastatic lesions. Therefore, targeted peptide receptor radionuclide therapies (PRRT), have been developed by conjugating radioisotopes to receptor binding analogs targeting specific cancer cell surface proteins, thereby delivering targeted radiation to cancer cells in the body with minimal damage to surrounding healthy cells. ^{177}Lu girentuximab is the first antibody-radioisotope designed for ccRCC, targeting carbonic anhydrase IX-expressing cells, which includes > 90% of ccRCC. It has been tested in metastatic ccRCC as a single agent and shown to be safe and effective in stabilizing disease in 57% of pts. In this study, we hypothesize that ^{177}Lu girentuximab-induced DNA damage will potentiate the STING pathway, and this activation will synergize with nivolumab and cabozantinib to promote trafficking and infiltration of activated T cells to tumors and achieve higher CR rates. **Methods:** Up to 100 patients with treatment naive, biopsy-proven ccRCC with adequate organ/marrow function with ≥ 1 evaluable lesion by RECIST 1.1 will be enrolled. A 5-patient safety lead-in will evaluate myelosuppression. Ongoing safety, and fertility monitoring will employ a Bayesian approach. The sample size was chosen for reasonable operating characteristics to distinguish a CR rate of 18% as better than 9% using a beta(0.09, 0.91) prior. Secondary endpoints are objective response, PFS by RECIST 1.1, and overall survival. ^{177}Lu -girentuximab 1480 MBq/m² (61% of single agent MTD) will be administered every 12 weeks for up to 3 treatment cycles. After the first cycle, nivolumab and cabozantinib will be added starting with the second cycle at standard dose. To explore the effects of the combination therapy on inducing activated T cell infiltration, patients will undergo pre/post-treatment PET scan with [^{18}F]F-AraG radiotracer as well as biopsies for single cell, spatial transcriptomics and proteomics studies. A phase II study of olaparib (AZD2281) in patients (Pts) with metastatic/advanced urothelial carcinoma and other genitourinary (GU) tumors with DNA-repair defects. *First Author: Elias Chandran, National Cancer Institute, Bethesda, MD*

Background: Olaparib is a poly-ADP-ribose polymerase (PARP) inhibitor that induces synthetic lethality in tumor cells with dysfunctional DNA damage repair (DDR) from loss of function of *BRCA* or other DDR genes. It improves survival in advanced ovarian, pancreatic, prostate and breast carcinoma with DDR gene alterations and is FDA approved for these indications. PARP inhibitors still have an undefined role in non-prostate GU tumors. We hypothesize that PARP inhibitors will have activity in DDR deficient tumors, regardless of histology. We are conducting a phase 2 trial of olaparib in non-prostate GU cancers with DDR gene defects. **Methods:** Eligible pts must have metastatic/advanced urothelial carcinoma or other non-prostate GU cancers and have measurable disease by RECIST 1.1. Pts in Cohorts 1 and 2 must harbor tumor or liquid pathologic DDR alterations identified by FoundationOne CDx (F1CDx) panel and reviewed by a molecular genetics review panel: Cohort 1 includes *BRCA1*, *BRCA2*, *ATM*, *BAP1*, *MSH2*, *PALB2*, and *BRIPI1* alterations, and pts with high tumor mutational burden (TMB) (>15 mutations/megabase); Cohort 2 (exploratory cohort) includes *ABL1*, *ATR*, *ATRX*, *BARD1*, *BRD4*, *CCND1*, *CHEK1*, *CHEK2*, *DOT1L*, *FANCC*, *FANCE*, *FANCG*, *FANCL*, *IKBKE*, *MEN1*, *MLH1*, *MSH2*, *MSH6*, *MUTYH*, *NPM1*, *PMS2*, *POLD1*, *POLE*, *RAD51*, *SMARCB1*, *STEK11*, and *TP53* alterations. Cohort 3 (natural history) will include pts without pathologic alterations in any Cohort 1 or 2 genes. Pts with eligible gene alterations (Cohorts 1 and 2) will be given olaparib 300mg twice daily until progressive disease, unacceptable adverse events, withdrawal of consent or death. They will have circulating tumor cells (CTCs) collected at baseline and every 4 weeks, and CT restaging every 8 weeks. Pts in Cohort 3 will receive standard of care treatment and have baseline CTC collection and be followed for survival. The primary objective is to evaluate the objective response rates (ORR) in Cohorts 1 and 2. Secondary objectives include progression-free survival (PFS), overall survival (OS) and safety. In these cohorts, the trial will have a Simon optimal two-stage design. In Cohort 1, 25 evaluable pts will be required to provide 90% power with $\alpha = 0.1$ to differentiate between a promising ORR of 30% versus an unacceptably low ORR of 10%. In Cohort 2, 35 evaluable pts will be required to provide 90% power with $\alpha = 0.05$ to differentiate between a promising ORR of 30% versus an unacceptably low ORR of 10%. Exploratory objectives include estimating the distribution of DDR alterations in non-prostate GU malignancies, assessing the effectiveness of NGS in detecting DDR alterations in circulating tumor DNA (ctDNA), assessing levels of baseline CTCs and changes in CTC level with olaparib, and correlating with clinical outcomes. This is an ECTCN network clinical trial and is open to enrollment. Clinical trial information: NCT03375307. Research Sponsor: U.S. National Institutes of Health.

SOGUG-vexillum: Phase II non-randomized clinical trial of nivolumab/ipilimumab maintenance following first-line chemotherapy in unresectable locally advanced or metastatic urothelial cancer. *First Author: Guillermo de Velasco, Medical Oncology Department, Hospital Universitario 12 de Octubre, Madrid, Spain*

Background: The current standard of care in non-progressors to first-line platinum-based chemotherapy for unresectable locally advanced or metastatic urothelial carcinoma (UC) is maintenance treatment with avelumab plus best supportive care (BSC). The Checkmate 032 trial showed that the highest ORR (42.4%) was achieved by the combination of Nivolumab 1 mg/kg and Ipilimumab 3 mg/kg in refractory mUC (1), with a manageable safety profile and better outcomes compared to other treatment arms. The trial aims to consolidate the clinical benefit achieved from first-line chemotherapy with the combination of nivolumab 1mg/kg plus ipilimumab 3mg/kg followed by nivolumab. **Methods:** This single arm, open-label, multicenter study evaluates the effectiveness of Ipilimumab and nivolumab followed by nivolumab maintenance therapy in delaying disease progression in patients with unresectable urothelial cancer that did not progress after first-line chemotherapy. Main eligibility criteria include: Male or female subjects ≥ 18 yrs old with written informed consent, ECOG performance status 0 or 1, unresectable locally advanced or metastatic transitional cell carcinoma of the urothelium (UCC), patient inclusion within 3-12 weeks after the last chemo dose, no progressive disease per RECIST v1.1, available tumor tissue at baseline, adequate normal organ and marrow function (Haemoglobin ≥ 9.0 g/dL, ANC > 1500 per mm³, platelets $\geq 100,000$ per mm³, bilirubin $\leq 1.5 \times$ ULN, transaminases $\leq 2.5 \times$ ULN, creatinine clearance > 30 mL/min). The primary endpoint is Progression Free Survival (PFS). Secondary objectives include: objective response rate (ORR), duration of response (DoR), overall survival (OS), chemotherapy overall survival (cOS), and chemotherapy progression-free survival (cPFS). Additionally, the study also has safety secondary objectives. Dynamic biomarker analysis will be performed. As of January 2023, 5 out of the planned 66 patients have been enrolled in the study. 1) Sharma P et al. J Clin Oncol. 2019. Clinical trial information: EudraCT 2021-005364-22. A phase III randomized trial of eribulin (E) with or without gemcitabine vs standard of care (SOC) for metastatic urothelial carcinoma (UC) refractory to or ineligible for PD/PDL1 antibody (Ab): SWOG S1937. *First Author: Sarmad Sadeghi, University of Southern California, Los Angeles, CA*

Background: UC is 2nd most common genitourinary cancer. Current SOC offers platinum-based (PB) first line chemotherapy (chemo) with ddMVAC or gemcitabine-cisplatin (GC) regimens. For cisplatin ineligible patients (pts), SOC includes gemcitabine-carboplatin (GCa), and in select pts pembrolizumab. Eribulin is approved for pts with FGFR alterations and Enfortumab vedotin (EV) is approved for previously treated pts. A phase I/II CTEP study of eribulin (E) for metastatic UC (mUC) established the activity of E in UC with objective response rate (ORR) of 37.5% and a median progression free survival (PFS) of 4.1 months (mo) and median overall survival (OS) of 9.5 mo (N=150). A phase II CTEP study of gemcitabine-eribulin (GE) in cisplatin ineligible mUC showed an ORR of 50%, median OS of 11.9 mo and median PFS of 5.3 mo (N=24). The most common Grade 3-4 toxicities included: neutropenia 63%, anemia and fatigue 29%. Pts with liver metastases benefited from therapy with 5 responders in 7 pts for GE vs 12 out of 49 E. **Methods:** This is a phase III, randomized 3 arm study comparing E vs. GE vs. SOC (docetaxel, paclitaxel, or gemcitabine). E is given at 1.4mg/m² on day (D) 1 and 8 of a 21 D cycle. In the GE arm, gemcitabine is added to E at 1000 mg/m² dose to D1 and D8. SOC follows standard dosing of the agents. There is no limit to the number/sequence of prior regimens. A simplified summary of eligibility criteria is presented here. All pts must have: received frontline systemic treatment such as PB chemo or a non-platinum regimen; received PD1/PDL1 Ab or be deemed ineligible for PD1/PDL1 Ab; received EV. Assuming a median OS for the SOC arm of 7 mo the study seeks to find at least a 50% increase in median OS to 10.5 mo (Hazard Ratio (HR) = 0.667). One-sided 0.0125 type I error to account for testing of two primary hypotheses (Each arm vs. SOC). 87% power to detect a 3.5 mo improvement in OS. We require 140 eligible (155 total) pts in each arm for a total of 465. The study was activated in Feb 2021 and accrual is ongoing. Clinical trial information: NCT04579224. Research Sponsor: U.S. National Institutes of Health.

MAIN-CAV: Phase III randomized trial of maintenance cabozantinib and avelumab versus avelumab after first-line platinum-based chemotherapy in patients (pts) with metastatic urothelial cancer (mUC; Alliance A032001). *First Author: Shilpa Gupta, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH*

Background: First-line platinum-based chemotherapy followed by maintenance avelumab (Av) is the current preferred standard of care in patients (pts) with mUC who do not progress after platinum-based chemotherapy. There is an unmet need to further improve outcomes by combining Av with an effective, non-cross resistant therapy with non-overlapping toxicity. CABO is an oral inhibitor of MET, VEGFR and TAM family receptors involved in tumor growth, angiogenesis and immune cell regulation and has shown efficacy in UC in combination with PD-1/PD-L1 inhibitors. We hypothesize that CABO-Av combination will be synergistic in pts with mUC with an acceptable safety profile and will improve upon the benefit seen with Av maintenance in mUC. **Methods:** MAIN-CAV is a phase III randomized, multicenter, international trial for locally advanced/mUC pts (including N3 only disease) who do not progress after 4-6 cycles of any platinum-based chemotherapy (gem-cis, gem-carbo, MVAC or ddMVAC). 654 adult pts will be randomized 1:1 within 3-10 weeks (wk) after last dose of chemotherapy to receive Av 800 mg IV every 2 wk or combination of Av and CABO 40 mg orally daily for up to 2 yrs. Key eligibility criteria include ECOG PS 0-1, no prior use of immunotherapy (exception of BCG), no central nervous system metastases, no major surgery within 4 wk, no uncontrolled hypertension or cardiovascular disorders. Pts will be stratified based on 1) best response to 1L therapy: complete response vs partial response vs stable disease and 2) presence or absence of visceral metastases. The primary endpoint is overall survival (OS) with assumptions of one-sided alpha of 0.025, power of 80%, median OS of 21 months (mo) on Av arm and hazard ratio (HR) of 0.75, thus hypothesizing a median OS of 28 mo on CABO-Av combination arm. Key secondary endpoints include progression-free survival, safety, tolerability, and activity of CABO-Av compared to Av alone based on RECIST 1.1 and iRECIST criteria and PD-L1 status of pts' tumors. Quality of life (QOL) will be assessed using EQ-5D-5L, PROMIS-Fatigue 4a, EORTC QLQ-C30, EORTC QLQ-BLM30 between pts on CABO-avelumab vs avelumab alone. Biomarkers of response and resistance to Av will be assessed using baseline archival tissues, baseline and serial blood, ctDNA, stool and urine. Imaging studies will test correlation of established and new radiomic signatures with OS, adverse events and QOL and incorporate both radiologic and biologic features to predict outcomes. This trial would be the first to systematically address whether adding a multitargeted TKI, CABO to Av leads to improved clinical outcomes compared to Av alone. Clinical trial information: NCT05092958. Research Sponsor: U.S. National Institutes of Health; Exelixis, EMD Serono.

TROPHY-U-01 Cohort 4 (C4): Sacituzumab govitecan (SG) in combination with cisplatin (cis) as first-line (1L) therapy, followed by maintenance avelumab plus (+) SG or zimberelimab (zim) + SG in patients (pts) with treatment (Tx)-naïve metastatic urothelial cancer (mUC). *First Author: Chethan Ramamurthy, Mays Cancer Center, Philadelphia, PA*

Background: SG is a Trop-2-directed antibody-drug conjugate. In the TROPHY-U-01 study, SG monotherapy showed a 27% objective response rate (ORR) and 10.9 months median overall survival (OS) with an overall manageable safety profile in pts with mUC who received platinum (PT)-containing chemotherapy and a checkpoint inhibitor (CPI), resulting in accelerated FDA approval in this population. PT-based chemotherapy followed by avelumab maintenance is standard 1L therapy in pts with Tx-naïve mUC. Zim (anti-PD-1) is a CPI under clinical investigation for antitumor activity. C4 of TROPHY-U-01 will evaluate safety, tolerability, and clinical activity of SG+cis followed by maintenance avelumab+SG or zim+SG in cis-eligible pts with Tx-naïve mUC. **Methods:** TROPHY-U-01 (NCT03547973) is a multicohort, open-label, global, phase 2 study. C4 will evaluate 1L SG in combination with cis in pts with cis-eligible mUC or unresectable locally advanced disease. Eligibility requirements include ECOG PS 0-1; no prior anticancer monoclonal antibody within 4 weeks of study drug initiation; no history of active interstitial lung disease or noninfectious pneumonitis; adequate hematologic and hepatic function. Pts will be treated with cis at 70 mg/m² on D1 of 21-D cycles (if creatinine clearance [CrCl] ≥60 mL/min) or at an optional split dose of 35 mg/m² on D1 and D8 of 21-D cycles (if CrCl 50-59 mL/min), followed by SG (5, 7.5, or 10 mg/kg, based on 10-pt safety lead-in of a 3+3 design) on D1 and D8 of 21-D cycles. Granulocyte colony-stimulating factor support is not allowed in the safety lead-in but was permitted during escalation and expansion. SG+cis will continue for up to 6 cycles, followed by maintenance (4 to 8 wk after last induction dose of SG+cis and when RP2D is determined) in the absence of progression. Dose escalation maintenance consists of avelumab 800 mg q2w, then SG 10 mg/kg on D1 and D8 of 21-D cycles. Dose expansion maintenance consists of zim 360 mg (D1 of a 21-D cycle) and SG 10 mg/kg (D1 and D8 of 21-D cycles) and will begin once safety lead-in of 6-8 pts receiving zim+SG of a 21-D cycle in Cohort 5 is deemed safe and completed. Pts will continue Tx until progression, unacceptable toxicity, or loss of clinical benefit. Primary endpoint is ORR per RECIST v1.1 by central review. Secondary endpoints include progression-free survival, duration of response, and clinical benefit rate per central review and investigator assessment. OS and safety will also be evaluated. All statistical analyses will be performed using a two-sided hypothesis test approach at the overall 5% level of significance. Time to event endpoints will be assessed via the Kaplan-Meier method. Enrollment is ongoing; up to 57 pts expected across ~120 sites in North America and Europe. Clinical trial information: NCT03547973. Research Sponsor: Gilead Sciences, Inc.

Poster Session

A phase II trial with copanlisib plus avelumab as maintenance therapy for metastatic bladder cancer after platinum-based chemotherapy. *First Author: Hizra Farrukh, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA*

Background: Bladder cancer is the tenth most common malignancy and the fourteenth most common cause of cancer death worldwide. Currently, platinum-based chemotherapy followed by avelumab maintenance immunotherapy is the first-line standard of care for advanced bladder cancer (aBC). Even though maintenance avelumab therapy has improved overall survival, its efficacy is still disappointing with a response rate of less than 10% and progression-free survival benefit of 1.7 months. The phosphoinositide 3-kinase (PI3K) pathway harbors more activating alterations than any other growth signaling pathway in aBC. Furthermore, PI3K δ and γ are expressed by immune cells and regulate their function. Activation alterations along the PI3K pathway are putative molecular drivers and can possibly be targeted for the treatment of aBC. In preclinical studies, we found that a pan-PI3K class I inhibitor, copanlisib, potentiates anti-programmed cell death 1 (PD1) antibody in syngeneic bladder cancer mouse models with or without activation alterations along the PI3K pathway (Zhu S, J Immunother Cancer. 2021). We hypothesize that copanlisib potentiates avelumab as maintenance therapy for aBC. **Methods:** This is a multi-center, single-arm, open-label Phase II trial with a lead-in safety phase to determine the efficacy and toxicity of combination copanlisib and avelumab maintenance therapy in aBC. The major inclusion criteria are patients with aBC without disease progression after platinum-based chemotherapy and no contraindication for avelumab and copanlisib. With a type I error of 5% and power of 80% with a log-rank test, we will need 26 patients for this study. With an attrition rate of 10%, we will enroll 29 patients from four US Department of Veterans Affairs Medical Centers. Copanlisib will be administered through intravenous infusion (IV) at 60 mg on Day 1, 8 and 15, and avelumab will be administered 800 mg IV on Day 1 and 15 of each 4-week treatment cycle for up to 26 cycles. Imaging will be repeated every two cycles during first year of therapy and thereafter every 3 cycles or clinically indicated. The primary endpoint is progression-free survival (PFS). The secondary endpoints include CT or MRI determined radiographic overall response rate, toxicity, overall survival, and molecular correlative studies. Kaplan-Meier estimates will be presented together with median PFS with 2-sided 95% confidence intervals (CI). In particular, the PFS rates at 3, 6, 9, 12 and 15 months will be estimated with corresponding 2-sided 95% CIs. Adverse events will be assessed according to CTCAE v5. Tumor response is determined according to Response Evaluation Criteria in Solid Tumors version (RECIST) 1.1 criteria. This study is currently open for enrollment. Clinical trial information: NCT05687721. Research Sponsor: VA Office of Research and Development; Bayer.

ALTER-UC-007: A prospective phase 2 study of anlotinib with gemcitabine and cisplatin or anlotinib with penpulimab as perioperative treatment for patients with muscle-invasive urothelial carcinoma (MIUC). *First Author: Hailiang Zhang, Department of Urology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Radical surgery involving cystectomy and nephroureterectomy is the standard of care for patients with localized muscle-invasive urothelial carcinoma (MIUC). In recent years, neoadjuvant- and adjuvant-containing multimodality therapies have gradually been adopted in attempt to eradicate micrometastatic disease and improve the outcomes achieved with radical surgery alone. This study aims to evaluate the efficacy and safety of anlotinib (a multi-target tyrosine kinase inhibitor of angiogenesis) with gemcitabine and cisplatin or anlotinib with penpulimab (a humanized anti-PD-1 IgG1 monoclonal antibody) as neoadjuvant and adjuvant therapy in patients with MIUC. **Methods:** In this open-label, prospective, phase 2 study, eligible patients include those with histologically confirmed clinical stage T1-T4N1-3M0, T3-4N0M0 MIUC (tumors of the bladder, renal pelvis, ureter and urethra) fit and planned for radical cystectomy, nephroureterectomy or ureterectomy. Main exclusion criteria are distant metastatic disease; prior chemotherapy, anti-angiogenic therapy, radiation therapy or immunotherapies; active autoimmune disease; uncontrolled hypertension or patients at high bleeding risk. Patients will be enrolled and receive treatment based on PD-L1 status in tumor tissue. The PD-L1 status of eligible patients will be centralized and assessed using an anti-PD-L1 antibody and an immunohistochemical (IHC) assay. PD-L1 positivity was defined as combined positive score (CPS) ≥1 (previously reported as and equivalent to CPS ≥1%). The study treatment is stratified into two cohorts based on PD-L1 expression levels. In cohort 1, the PD-L1 negative patients with MIUC will receive neoadjuvant anlotinib (12 mg orally QD D1-14 every 3 weeks) + gemcitabine (1000 mg/m², intravenously [IV] on days 1 and 8) + cisplatin (35 mg/m² IV on days 1 and 8) for a maximum of 4 cycles followed by radical surgery and 2 cycles of adjuvant treatment post-surgery. In cohort 2, PD-L1 positive patients will receive anlotinib (12 mg orally QD D1-14 every 3 weeks) + penpulimab (200 mg IV every 3 weeks) for a maximum of 4 cycles followed by radical surgery and 2 cycles of adjuvant treatment post-surgery. After the completion or discontinuation of the study treatment, safety follow-up and survival follow-up will be performed. Tumor imaging was performed by computed tomography (preferred) or magnetic resonance imaging at baseline, and every 6 weeks during treatment, then every 6 months through year 2. Objective response rate (ORR) is the primary endpoint. Secondary endpoints included pathological complete response rate (pCR), disease-free survival (DFS), overall survival (OS) and safety. Recruitment have begun in October 2022. Currently, the study is active with 1 participant has been enrolled. Clinical trial information: ChiCTR2200063085. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

A phase 3 multicenter study to evaluate the safety and efficacy of padeliporfin vascular targeted photodynamic therapy (VTP) in treatment of low-grade (LG) upper tract urothelial cancer (UTUC). *First Author: Jonathan Coleman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Padeliporfin VTP is a combination product: drug, padeliporfin is administered IV and a device, a laser light delivery system, includes a source of light (the laser) that emits near-infrared (NIR) light at 753 nm, and optic fiber that delivers the light to the target lesion(s) in the upper tract urothelium. In Phase 1 NCT03617003 study 19 patients(pts) received up to 2 endoscopic VTP treatments with 6 mos follow-up(FU). Pts with residual or recurrent UTUC (high grade(HG)or LG) who failed prior endoscopic treatment/unable/unwilling to undergo surgery were included. Primary endpoint, Maximum tolerated dose (MTD) of laser light fluence, was identified using dose escalation model with a modified continual reassessment method with increasing light fluence (100-200 mW/cm). Secondary endpoint was efficacy, defined by absence of visible tumor and negative urine cytology 30 days post-treatment. 14(74%) pts received the MTD of 200mW/cm, 2 (11%) of whom experienced DLTs (flank pain grade 2 and 3). Response rate at 30 days was 94% (50% CR, 44% partial). 8 pts received 2nd VTP, with a final observed 68% complete response (CR) rate. Most frequent adverse events: transient flank pain (79%) and hematuria (84%). No treatment-associated ureteral strictures were reported. All patients had preserved kidney at the 6-mos FU(Wesley Yip,2022). **Methods:** Padeliporfin VTP is being evaluated in a phase 3 study in patients with UTUC LG,100 patients are planned to be enrolled. Enrollment started in Mar 2021 and is ongoing in USA, EU&Israel,3 pts are enrolled. Pts are being treated with padeliporfin VTP in two phases: Induction and Maintenance treatment Phases (ITP and MTP). ITP consists of 1-3 VTPs every 28 days. If CR is not achieved after 1st VTP, up to 2 additional VTPs are allowed. If CR is achieved in the ITP, pts are allowed into the MTP (12 mos). In the MTP VTPs can be provided every 3 mos for pts with recurrent tumor that is deemed treatable, defined as LG with the largest tumor (index) 5-15 mm, in up to 2 locations in the kidney or one ureter location ≤20 mm. Long Term FU Phase: Pts completing the MTP, will be followed for safety for 48 mos with no VTPs. Primary objective is to demonstrate efficacy and durability of effect of padeliporfin VTP treatment. Secondary objective-evaluation of padeliporfin VTP-related safety and tolerability. **Key inclusion criteria:** Up to 2 biopsy-proven LG UTUC tumors with the largest tumor (index) 5-15 mm, located in the calyces, renal pelvis or in the ureter, with no HG cells. Ureter involvement in one location ≤ 20 mm. **Key exclusion criteria:** Current HG or muscle invasive urothelial bladder cancer. CIS current or previous in the upper urinary tract. History of ≥ T2 urothelial cancer in the past 2 years. DSMB last reviewed the trial in Sep 2022 and suggested the trial continue as planned. Clinical trial information: NCT04620239. Research Sponsor: Steba biotech.

A phase I dose-escalation clinical trial with PLZ4-coated paclitaxel-loaded micelles (PPM) in patients with recurrent or refractory non-myo-invasive bladder cancer. *First Author: Hizra Farrukh, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA*

Background: Bladder carcinoma is one of the top ten cancers in the US with approximately 75% of patients initially presenting with non-myo-invasive bladder cancer (NMIBC). The current standard of care for NMIBC is transurethral resection (TUR) followed by intravesical instillation, usually with Bacille Calmette-Guérin (BCG). Despite combination treatment, 20-80% of patients' disease recurs and 25% progress to invasive stages. The study drug, PLZ4-coated paclitaxel-loaded micelle (PPM), is a solvent-free injectable nanoscale micelle formulation of paclitaxel (PTX). Preclinical data on bladder cancer-specific targeting ligand named PLZ4 has shown potential to specifically deliver chemotherapeutic micelle into bladder cancer cells, both in vitro and in vivo (Zhang, Urol Oncol 2012). In a toxicokinetic study, female Sprague Dawley rats were given intravesicular injections of PPM once weekly for 6 consecutive weeks. No drug related mortality was reported, and no systematic exposure of PPM was observed in toxicokinetic analysis. The purpose of this phase I trial with PPM is to determine the toxicity and recommended Phase II dose. **Methods:** This is a single arm, open label, Phase I dose-escalation first-in-human trial with an expansion cohort for the treatment of recurrent or refractory NMIBC with PPM. Eligibility includes BCG unresponsive carcinoma in situ or Ta/T1 urothelial carcinoma. Treatment with pembrolizumab is not an inclusion or exclusion criteria as intravesical taxane has comparable efficacy as intravenous pembrolizumab. Up to 29 patients will be recruited at VA Boston Healthcare system. PPM will be given once weekly for six weeks, 50 ml of solution regardless of patient's size or weight will be administered as intravesical instillation. A 3 + 3 design is adopted for this Phase I trial. There are three dose levels at the dose escalation stage: Dose level I: PTX 25 mg or 0.5 mg/ml; Dose Level II: PTX 50 mg or 1.0 mg/ml; Dose Level III: PTX 75 mg or 1.5 mg/ml. At the expansion cohort, up to 12 patients will be treated with PPM at PTX dose of 50 mg or 1.0 mg/ml to determine the efficacy. The primary objective is to evaluate the safety and tolerability of PPM administered through intravesical instillation and determine the recommended Phase II dose of PPM. The secondary objectives are to evaluate the tumor response at 6 weeks after last treatment, determine systemic absorption within 6 hours after intravesical instillation of PPM and assess progression free survival. The efficacy will be determined by urine cytology and cystoscopy after finishing treatment. Molecular correlative studies will be performed. The toxicity will be assessed by Common Terminology Criteria for Adverse Events v5.0. Patients will be followed at 3 month intervals for 2 years or until disease recurrence or progression. This study is currently open for enrollment. NCT05519241. Clinical trial information: NCT05519241. Research Sponsor: VA Office of Research and Development.

An in-progress phase 2 window of opportunity (WOO) trial of targeted therapy with erdafitinib for patients with recurrent FGFR3-altered non-muscle-invasive bladder cancer (NMIBC). *First Author: Neeta DSouza, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Alterations to FGFR3 are the most common somatic mutations in non-muscle invasive bladder cancer (NMIBC), present in 40-60% of high-grade Ta and > 80% of recurrent low grade Ta tumors. FGFR3 mutations are also known to be associated with a "cold" tumor microenvironment (TME) that may mediate BCG resistance. Erdafitinib, a targeted inhibitor of FGFR 1-4, is the first FDA approved targeted therapy for locally advanced/metastatic bladder cancer. As FGFR3 mutations are present 3-5x more commonly in NMIBC than metastatic disease, erdafitinib is a logical therapeutic candidate for FGFR3-altered NMIBC. Through this ongoing phase II trial, we seek to determine the safety and efficacy of erdafitinib for the treatment of intermediate and high risk FGFR3-altered NMIBC after prior intravesical therapy. **Methods:** To address the need for expanded targeted therapeutics for NMIBC, we launched an investigator-initiated phase II window of opportunity (WOO) trial of erdafitinib (NCT04917809, PI Pietzak). We are currently enrolling patients with intermediate or high risk NMIBC with history of ≥1 or more induction courses of BCG and/or intravesical chemotherapy who present with a clinically staged Ta papillary recurrence on office cystoscopy. Patients are also required to have an oncogenic FGFR3 mutation or fusion, as confirmed by OncoKB on MSK-IMPACT, to be included in the trial. Trial patients are treated with 6 mg oral erdafitinib daily for 28 days during the "window of opportunity" time period between office cystoscopy and transurethral resection of the recurrent bladder tumor (TURBT). The primary outcome is the rate of objective response, defined as complete (no visible tumor) or partial (> 50% reduction of measured diameter by Response Evaluation Criteria for Tumors of the Bladder [RECIT-Bladder]) as compared to cystoscopy at TURBT. We are employing an optimal Simon two-stage binomial design, assuming an objective response of > 15% would and < 2% would not be worthy of further study. We plan to enroll 16 patients in the first stage and 9 in the second (87% power). Secondary outcomes include safety (CTAE 5.0), patient reported outcomes, and recurrence-free survival. Correlative studies will be conducted with urine, blood, and tumor tissue samples. Urine and blood are collected before (day 1), during (day 14) and after treatment (day 28) and will undergo immune and molecular studies to understand shifts in the microenvironment in the setting of response and resistance. This trial is being conducted in parallel with a co-clinical trial of patient derived organoid/xenograft models (MSK 19-015, PI Pietzak) to further refine the understanding of FGFR3 mutational resistance to standard treatment and the effects of targeted immunotherapy on tumor clinicogenomics. Clinical trial information: NCT04917809. Research Sponsor: U.S. National Institutes of Health; Bladder Cancer Advocacy Network, Wofchuck Family Young Investigator Award; Janssen Pharmaceuticals, Merck & Co. Inc., QED Therapeutics, Chugai Pharmaceuticals, UroGen Pharma, and Steba Biotech; UpToDate.

Phase 2 trial of intravesical cabazitaxel, gemcitabine, and cisplatin (CGC) for the treatment of non-muscle invasive BCG unresponsive urothelial carcinoma of the bladder. *First Author: Guarionex Joel DeCastro, Columbia University Irving Medical Center, New York, NY*

Background: For patients with non-muscle invasive bladder cancer (NMIBC) unresponsive to Bacille Calmette-Guerin (BCG), multi-agent intravesical trials have been limited. The goal of this Phase 2 study is to investigate the efficacy of intravesical chemotherapy consisting of sequential cabazitaxel, gemcitabine, and cisplatin (CGC) in the salvage setting. Phase 1 results reporting on 18 subjects demonstrated adverse events limited to local Grade 1 and 2 toxicities. Partial funding support for the trial was provided by a pharmaceutical company. **Methods:** This is a Phase 2 trial (NCT02202772) presently enrolling patients with BCG unresponsive NMIBC as defined by the FDA who refuse or are ineligible for radical cystectomy. All patients undergo pre-treatment transurethral resection of bladder tumor (TURBT) and a 6-week regimen of intravesical cisplatin (100mg), gemcitabine (2gm), and cabazitaxel (5mg). Each drug is instilled weekly except for cisplatin, which is given every other week. Complete response is defined as having no evidence of cancer on post-induction biopsy and negative urine cytology at 3 months. Complete responders proceed with monthly and bimonthly maintenance therapy without cisplatin in the first and second years, respectively, for a total of 24 months. **Results:** To date thirty-one patients have been enrolled (with target accrual of 33), of whom seven are female. One patient withdrew consent before first evaluation cystoscopy. Mean age thus far is 72 years. All patients have previously received at least two prior induction cycles of BCG, and meet FDA criteria for BCG unresponsive disease. All patients have biopsy proven high grade disease at enrollment; 8 (27%) have high grade T1 disease; and 20 (67%) patients have CIS. **Conclusions:** Salvage options for BCG unresponsive NMIBC are limited. The CGC protocol has been demonstrated to be safe in a previous Phase 1 study, and accrual for this Phase 2 is near completion. Clinical trial information: NCT02202772. Research Sponsor: funding from Columbia University Medical Center/Cancer Center; Sanofi.

Adding mitomycin (MM) to bacillus Calmette-Guérin (BCG) as adjuvant intravesical therapy for high-risk, non-muscle-invasive urothelial bladder cancer (NMIBC): BCGMM; ANZUP 1301. *First Author: Dickon Hayne, UWA Medical School, University of Western Australia, Perth, Australia*

Background: Adjuvant intravesical BCG decreases disease recurrence and progression in high-risk, NMIBC, however recurrence occurs in 30% of those affected, despite optimal therapy. Meta-analyses evaluating addition of intravesical MM to BCG showed lower rates of recurrence and cancer-specific mortality in people with NMIBC who received combination regimens. Phase 3 randomized trials to definitively test this combination are lacking. The BCGMM trial (NCT02948543) will determine the effects of adding MM to the standard BCG after resection of high-risk NMIBC. This is the largest study evaluating this approach in high-risk NMIBC, is of particular relevance given the current BCG shortage, and has the potential to change global practice. **Methods:** This open-label phase 3 trial is randomizing 500 participants stratified by stage, site of disease, and presence of carcinoma in-situ, in a 1:1 ratio to Arm A (BCG induction weekly x6 then monthly x10) or Arm B (BCG weeks 1, 2, 4, 5, 7, 8; months 4, 5, 7, 8 + MM weeks 3, 6, 9; months 3, 6, 9, see figure below). This provides 85% power to detect an absolute improvement of 10% in 2-year disease free survival (DFS) at 2p = 0.05. Stage 1 (n = 130) was to determine rates of treatment completion, activity reflected by cystoscopic findings at 3 months, adverse events, resource use, and health related quality of life, established feasibility. Stage 2, including an additional 370 participants, will provide information on DFS, time to recurrence and progression, overall survival, and identification of potential predictive biomarkers, is estimated to complete accrual by Q2 2023. Progress As of Jan 2023, 484 of 500 planned participants have been recruited from 16 Australian and 1 UK site. In stage 1, successful treatment completion, defined as 75% or more of planned treatment doses, was achieved by 76% in the experimental group (BCGMM) versus 60% in the control group (BCG alone). Clinical trial information: NCT02948543. Research Sponsor: Cancer Australia (Stage 1); ANZUP and ANZUP's 'Below the Belt' Research Fund & National Health and Medical Research Council (NHMRC) (Stage 2).

Phase 1b/2 dose expansion, open-label study to evaluate safety and anti-tumor activity of intravesical instillation of TARA-002 in adults with high-grade non-muscle invasive bladder cancer. *First Author: Wei Sun, Protara Therapeutics, New York, NY*

Background: Bladder cancer is the most common malignancy involving the urinary system, with over 700,000 individuals living with bladder cancer in the US in 2019. In the US, approximately 80,000 new cases and 18,000 deaths occur each year due to bladder cancer. Approximately 70% of new urothelial bladder cancer cases are classified as non-muscle invasive bladder cancer (NMIBC). With the current Bacillus Calmette-Guérin (BCG) shortage and limited effective alternate therapies, there continues to be a significant unmet need for treatment options for patients with NMIBC. TARA-002 is being developed for intravesical instillation for the treatment of high-grade (HG) NMIBC. TARA-002 is a lyophilized biological preparation for instillation containing cells of *Streptococcus pyogenes* (Group A, type 3) Su strain treated with benzylpenicillin. The chemical characteristics of TARA-002 are intended to be comparable to OK-432. Therefore, nonclinical and clinical evidence with OK-432 and TARA-002 support the ADVANCED-1 study (dose escalation Phase 1a [NCT05085977] and dose expansion Phase 1b/2 [NCT05085990]). The dose for the planned Phase 1b/2 study (ADVANCED-1-Ph1b/2) will be based on the recommended Phase 2 dose (RP2D) established in the Phase 1a study. **Methods:** ADVANCED-1-Ph1b/2 is a Phase 1b/2, dose expansion, open-label study of intravesical instillation of TARA-002 in adults with HG carcinoma in situ (CIS) NMIBC. The purpose of this study is to evaluate the safety and anti-tumor activity of TARA-002 administered intravesically for the treatment of subjects with CIS NMIBC ($\pm$ Ta/T1) with active disease. The study includes approximately 102 eligible male and female subjects $\geq$ 18 years of age enrolled in 2 cohorts based on their prior BCG experience. Cohort A includes subjects unable to obtain BCG or subjects who have not received BCG in the last 24 months prior to CIS diagnosis, and Cohort B includes subjects with CIS who are BCG unresponsive after completion of adequate BCG therapy (at least 5 of 6 doses of an initial induction course plus either at least 2 of 3 doses of maintenance therapy or at least 2 of 6 doses of a second induction course). Those with current or a history of penicillin allergy or current evidence of any condition, therapy, or laboratory abnormality that might confound the results are excluded. The overall study duration is 6 months/24 weeks per subject for Ph1b/2-Cohort A (includes induction, reinduction [if applicable]), and 24 months/96 weeks per subject for Ph1b/2-Cohort B (includes induction, reinduction [if applicable], maintenance until 18 months). The ADVANCED-1 study started in March 2022. Phase 1a is open for enrollment. Phase 1b/2 is expected to begin enrollment in May 2023. Clinical trial information: NCT05085977; NCT05085990. Research Sponsor: Protara Therapeutics, Inc.

Prognostic impact of PSA nadir (n) ≥0.1 ng/mL within 6 months (m) after completion of radiotherapy (RT) for localized prostate cancer (PCa): An individual patient-data (IPD) analysis of randomized trials from the ICECAP collaborative. First Author: Praful Ravi, Dana-Farber Cancer Institute, Boston, MA

Background: RT + androgen deprivation therapy (ADT) is a standard of care in treatment of intermediate- and high-risk localized PCa. Identification of early surrogate measures for long-term outcome measures such as PCa-specific survival (PCSS), metastasis-free survival (MFS) and overall survival (OS) could expedite development of new systemic therapies added to RT/ADT while potentially identifying patients (pts) for therapy (de)escalation. **Methods:** IPD from the RT+ADT trials in the ICECAP repository with evaluable PSA follow-up were eligible for inclusion. Pts were grouped based on their trial-allocated treatment: RT alone, RT+stADT (short-term ADT: 3-6m), RT+ltADT (long-term ADT: 18-36m). PSAn was defined as the lowest PSA recorded within 6m after RT completion. A 12m landmark analysis for PCSS, MFS and OS was performed to account for guarantee-time bias. Multivariable Cox proportional hazards regression was used to estimate associations of PSAn < or ≥0.1ng/mL with MFS and OS, and a multivariable Fine and Gray distribution used for PCSS to account for competing risk of non-PCa deaths. Models were adjusted for age, ECOG performance status, clinical T stage, Gleason score and PSA at randomization. **Results:** 10,415 pts from 16 RCTs were included: 2629 (25%) allocated to RT, 6033 (58%) to RT+stADT, and 1753 (17%) to RT+ltADT. Median follow-up was 10.1years (yrs). 2339 (98%), 4756 (84%) and 1258 (77%) of patients allocated to RT, RT+stADT and RT+ltADT respectively achieved a PSAn ≥0.1ng/mL within 6m after RT completion. After adjustment, PSAn ≥0.1ng/mL was associated with poorer PCSS, MFS and OS in pts allocated to RT+stADT (PCSS hazard ratio [HR] = 1.97 [95% CI 1.52-2.92], MFS HR = 1.27 [1.12-1.44], OS HR = 1.26 [1.11-1.44]) and RT+ltADT (PCSS HR = 1.97 [1.11-3.49], MFS HR = 1.58 [1.27-1.96], OS HR = 1.59 [1.27-1.99]). A weaker association was noted in pts allocated to RT (PCSS HR = 1.82 [0.51-6.49], MFS HR = 2.23 [1.20-4.14], OS HR = 1.72 [0.97-3.05]). Table shows 5-yr MFS, 10-yr PCSS and 10-yr OS based on PSAn within 6m after RT completion. **Conclusions:** PSAn ≥0.1ng/mL within 6 mths after RT completion was strongly prognostic for PCSS, MFS and OS in pts receiving RT+ADT for localized PCa in this IPD analysis of > 10,000 patients. This could be used as an early signal-seeking endpoint in trials evaluating novel systemic therapies with RT + ADT and to help identify pts for therapy (de)escalation trials. Research Sponsor: None.

Development and validation of an AI-derived digital pathology-based biomarker to predict benefit of long-term androgen deprivation therapy with radiotherapy in men with localized high-risk prostate cancer across multiple phase III NRG/RTOG trials. First Author: Andrew J. Armstrong, Duke Cancer Institute Center for Prostate & Urologic Cancers, Durham, NC

Background: Androgen deprivation therapy (ADT) improves survival and reduces risk of metastasis in men with high-risk localized prostate cancer (PC) receiving radiotherapy (RT). Predictive biomarkers are needed to guide ADT duration to maximize benefits and minimize risks. We sought to train and validate the first predictive biomarker for long-term (LT) vs short-term (ST) ADT using multiple phase III NRG Oncology randomized trials. **Methods:** Pre-treatment prostate biopsy slides were digitized from six phase III NRG/RTOG randomized trials of men receiving RT +/- ADT. The artificial intelligence (AI)-derived clinical and histopathological predictive biomarker was trained on RTOG 9408, 9413, 9902, 9910, and 0521 to predict differential benefit of LTADT on distant metastasis (DM). After the AI biomarker was locked, it was validated on RTOG 9202, which randomized men to RT + STADT (4 mo) vs LTADT (28 mo). The predictive utility of the AI biomarker was evaluated for the primary and secondary endpoints of DM and PC-specific mortality (PCSM), respectively, for ADT duration with Fine-Gray interaction models. Event rates were estimated by the cumulative incidence method. Deaths from other causes were treated as competing risks. **Results:** The AI-derived biomarker was trained on 2,641 men (median follow-up of 9.8 years, IQR [8.2, 11.5]) and validated on 1,192 men from RTOG 9202 (median follow-up of 17.2 years, IQR [9.1, 19.6]), where 80% had at least one high/very high (H/VH) risk feature (ct3-4, Gleason 8-10, PSA > 20, or primary Gleason pattern 5). Consistent with published results, LTADT significantly improved DM (subdistribution HR [sHR] 0.64, 95% CI 0.50-0.82, p < 0.001) in the validation cohort. The AI biomarker was prognostic for DM (sHR 2.35, 95% CI 1.72-3.19, p < 0.001). A significant biomarker-treatment interaction was observed (p = 0.04), in which AI-biomarker (+) men (n = 785, 66%) had reduced DM with LTADT (sHR 0.55, 95% CI 0.41-0.73, p < 0.001), but no benefit was observed (sHR 1.06, 95% CI 0.61-1.84, p = 0.84) for AI-biomarker (-) men (n = 407, 34%). The 10-year DM rate difference between RT + LTADT vs RT + STADT was 13% in AI-biomarker (+) men vs 2% in AI-biomarker (-) men. Similar trends were observed for PCSM outcomes. Risk classification (NCCN intermediate [n = 221, 43% (+)] vs other H/VH risk [n = 954, 71% (+)]) was prognostic but not predictive of LTADT benefit. **Conclusions:** We have successfully validated the first predictive biomarker of LTADT benefit with RT in localized high-risk PC using an AI-derived digital pathology-based platform in the phase III NRG/RTOG 9202 trial. The predictive AI biomarker identified 34% of men that could derive similar benefit with STADT, avoiding the side effects of prolonged ADT, and 43% of intermediate risk men who would benefit from LTADT. Oral Abstract Session

Presence of somatic/germline homologous recombination repair (HRR) mutations and outcomes in metastatic castration-resistant prostate cancer (mCRPC) patients (pts) receiving first-line (1L) treatment stratified by BRCA status. First Author: David Olmos, Hospital Universitario 12 de Octubre. Instituto de Investigación Sanitaria Hospital 12 de Octubre, Madrid, Spain

Background: Understanding of the association between HRR mutations and outcomes in mCRPC pts is limited. This analysis investigated the prevalence and outcomes of pts with/without HRR mutations (somatic and/or germline), stratified as BRCA, non-BRCA, or HRR non-BRCA, who initiated 1L mCRPC treatment with novel hormonal therapy (NHT) or taxane. **Methods:** Eligible pts from PROREPAIR-B (NCT03075735), PROSENZA (NCT02922218), PROSTAC (NCT02362620), and PROSAB (NCT02787837) studies underwent paired somatic/germline DNA analyses using a custom NGS panel that included *ATM*, *BRCA1*, *BRCA2*, *BRIP1*, *CDK12*, *CHEK2*, *FANCA*, *HDAC2*, *PALB2*, *RAD51B*, and *RAD54L*. Those with pathogenic (likely) mutations in ≥ 1 allele of ≥ 1 gene were considered deficient (HRR). rPFS, PFS2, and OS were reported for BRCA, non-BRCA, and HRR non-BRCA subgroups; associations between mutations and outcomes were assessed using inverse probability weighted Cox models, which balanced the baseline (BL) characteristics between subgroups. Hazard ratios (HRs) with 95% confidence intervals (CIs) and p values are presented. **Results:** Of 729 pts, 223 (30.6%) were HRR, including 96 (13.2%) BRCA. 60.4% of pts were treated with NHT and 39.6% with taxane in 1L; 80.7% received at least second-line treatment. Median age at BL was 72.2 years, 63.5% had Gleason > 7, 53.1% had ECOG ≥ 1, and 13.3% presented with visceral metastases. BL characteristics after adjustment were similar (standard mean difference: <0.1 in HRR and maximum 0.11 for all pts). BRCA pts had significantly worse rPFS, PFS2, and OS than non-BRCA pts; BRCA pts also had significantly worse PFS2 and OS than HRR non-BRCA pts. There were no significant differences between the outcomes of somatic and germline BRCA pts. **Conclusions:** BRCA pts, regardless of somatic/germline origin, had significantly worse rPFS, PFS2, and OS than the total non-BRCA population and significantly worse PFS2 and OS than non-BRCA pts in the HRR subgroup. It is crucial to screen early for HRR mutations, particularly in *BRCA1/2*, to begin timely, targeted mCRPC treatment and improve prognosis. Research Sponsor: Janssen Pharmaceuticals.

Median rPFS, PFS2, and OS (months) comparison of BRCA, non-BRCA, and HRR non-BRCA subgroups.

	BRCA (n=96) vs. non-BRCA (n=633)		BRCA (n=96) vs. HRR non-BRCA (n=127)	
rPFS	Median (95% CI) [‡]	BRCA: 7.0 (6.1-8.4)	BRCA: 7.0 (6.1-8.4)

Oral Abstract Session

TALAPRO-2: Phase 3 study of talazoparib (TALA) + enzalutamide (ENZA) versus placebo (PBO) + ENZA as first-line (1L) treatment for patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) harboring homologous recombination repair (HRR) gene alterations. *First Author: Karim Fizazi, Institut Gustave Roussy, University of Paris-Saclay, Villejuif, France*

Background: TALAPRO-2 is the first phase 3 study to combine the poly(ADP-ribose) polymerase inhibitor TALA with the androgen receptor inhibitor ENZA in pts with 1L mCRPC unselected (Cohort 1—previously reported) or selected (Cohort 2) for HRR gene alterations. Here, we report results of the prespecified, independently powered analysis of pts with mCRPC with HRR gene alterations from Cohorts 1 and 2. **Methods:** From February 2019 to January 2022, 399 pts (169 from Cohort 1) were randomized 1:1 to receive TALA 0.5 mg or PBO (all received ENZA 160 mg) once daily. Randomization was stratified by prior abiraterone or docetaxel for castration-sensitive PC (yes vs no). Key eligibility criteria: mildly or asymptomatic mCRPC with disease progression at study entry, HRR-deficient status prospectively confirmed by tumor tissue and/or ctDNA testing (genes tested: *ATM, ATR, BRCA1, BRCA2, CDK12, CHEK2, FANCA, MLH1, MRE11A, NBN, PALB2, RAD51C*), ECOG PS ≤ 1 , ongoing androgen deprivation therapy, no prior life-prolonging therapy for CRPC. Primary endpoint: radiographic progression-free survival (rPFS) by BICR per RECIST 1.1 and PCWG3. **Results:** 200 pts received TALA + ENZA and 199 PBO + ENZA. TALA + ENZA significantly improved rPFS by BICR (HR 0.45; 95% CI, 0.33–0.61; 2-sided $P < 0.001$; median PFS not reached vs 13.8 months). The HR for rPFS by BICR was 0.20 (95% CI, 0.11–0.36; $P < 0.001$) for the *BRCA1/2* subgroup ($n=155$) and 0.68 (95% CI, 0.46–1.02; $P = 0.06$) in those without a *BRCA1/2* alteration ($n=240$). The first interim analysis of OS was immature: 21.5% (TALA + ENZA) and 26.6% (PBO + ENZA) pts had died; HR 0.69 (95% CI, 0.46–1.03; $P = 0.07$). TALA + ENZA delayed time to PSA progression, cytotoxic chemotherapy, and antineoplastic therapy, and improved ORR, PSA response, and investigator-assessed PFS2. Grade (G) 3–4 treatment-emergent adverse events (TEAEs) were reported for 66.2% (TALA + ENZA) vs 37.2% (PBO + ENZA). There were more $G \geq 3$ hematologic TEAEs (anemia, neutropenia, thrombocytopenia, and leukopenia) with TALA + ENZA vs PBO + ENZA. TEAEs led to discontinuation of TALA in 10.1% vs PBO in 7.0%; discontinuation rates of ENZA were 7.6% (TALA + ENZA) vs 7.0% (PBO + ENZA). Time to definitive clinically meaningful deterioration in global health status/quality of life (GHS/QoL) was significantly longer with TALA + ENZA vs PBO + ENZA (HR 0.69; 95% CI, 0.49–0.97; $P = 0.03$; median 27.1 vs 19.3 months). **Conclusions:** TALA + ENZA demonstrated a statistically significant and clinically meaningful improvement in rPFS over standard of care ENZA as 1L treatment for pts with mCRPC and HRR gene alterations, while delaying time to definitive clinically meaningful deterioration in GHS/QoL. Toxicity was generally manageable and consistent with known safety profiles of TALA and ENZA. Clinical trial information: NCT03395197. Oral Abstract Session

Long term follow-up analysis of plasma miR371 expression to detect early relapse in patients with clinical stage I testicular germ cell tumors on surveillance. *First Author: Lucia Nappi, Vancouver Prostate Centre, Department of Urologic Sciences, University of British Columbia, Vancouver, BC, Canada*

Background: Clinical Stage I (CSI) is the most common presentation of germ cell testicular tumors (GCT) and patients are usually managed with active surveillance, in absence of reliable biomarkers of relapse. Circulating plasma miR371a-3p (miR371) has demonstrated high sensitivity and specificity in advanced non teratoma GCT. However, its operating characteristics and power to detect early relapse are still undefined. **Methods:** CSI GCT patients enrolled in the British Columbia provincial biobank with available plasma samples after radical orchiectomy were included in this study. Plasma miR371 was qualitatively assessed by RT-PCR. Sensitivity, specificity, negative and positive predictive values (NPV, PPV) and AUC in predicting tumor recurrence were evaluated in the post-orchietomy blood samples and/or during the follow-up prior to or at the time of the clinically evident relapse. Relapse free survival (RFS) was correlated to post-orchietomy miR371 status. **Results:** One-hundred-one patients were analyzed, 35 (34.6%) experienced a disease relapse with a median follow-up of 41 months. miR371 was positive in 22/35 of the relapsed patients. The specificity and PPV were 100% (95% CI: 94.5 - 100 for both), sensitivity 62.8% (95% CI: 44.9 - 78.5), NPV 83.5% (95%CI: 76.7 - 88.6) and AUC 0.81 (95% CI: 0.71 - 0.91). No false positive results were observed. The RFS of the patients with positive post-orchietomy miR37 was significantly shorter (median: 3.5 months vs. not reached; $p < 0.0001$) compared to the patients with a negative post-orchietomy miR371 (HR: 16.9; 95% CI: 2.1 - 135.7; $p < 0.0001$). miR371 sensitivity correlated with tumor burden, time between tumor relapse and miRNA testing and histology (nonseminoma > seminoma). **Conclusions:** miR371 has high specificity and PPV in detecting GCT at an early stage and could be used to predict GCT relapse during surveillance and to guide treatment selection after orchiectomy. Further studies have been planned for validation of miR371 clinical utility. Research Sponsor: Michael Smith Health Research BC, US Department of Defense.

Oral Abstract Session

LuPARP: Phase 1 trial of ^{177}Lu -PSMA-617 and olaparib in patients with metastatic castration resistant prostate cancer (mCRPC). *First Author: Shahneen Sandhu, Department of Medical Oncology, Peter MacCallum Cancer Centre; and Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, VIC, Australia*

Background: ^{177}Lu -PSMA-617, a PSMA-directed, radionuclide therapy improves progression free survival (PFS) and overall survival (OS) in patients (pts) with mCRPC. Although many pts benefit from treatment, approximately a third have primary resistance, median PFS is 5.1 months and all pts inevitably relapse. Poly (ADP-ribose) polymerase (PARP) is implicated in repairing radiation-induced DNA single-strand breaks (SSBs). The potent PARP inhibitor (PARPi) olaparib results in the conversion of DNA SSBs to lethal double-strand breaks. Multiple preclinical studies have shown enhanced anti-tumor activity from combined PARPi and radiotherapy. LuPARP aims to evaluate the safety and efficacy of the combination of ^{177}Lu -PSMA-617 and olaparib. **Methods:** 48 pts with mCRPC and high PSMA expression (SUVmax ≥ 15 at a site of disease, and SUVmax ≥ 10 at other measurable sites) without discordant FDG positive/PSMA negative disease will be enrolled in two stages: dose-escalation (standard 3+3 design) and dose-expansion at the recommended phase 2 dose (RP2D). ^{177}Lu -PSMA-617 is administered at 7.4 GBq IV on day 1, every 6 weeks for up to 6 cycles in conjunction with 9 prespecified dose schedules of olaparib. The dose-limiting toxicity (DLT) period is 6 weeks. The primary objectives are establishing the DLTs and RP2D. Secondary objectives are toxicity, radiological PFS (rPFS), PSA response rate (PSA50-RR), PSA-PFS, objective response rate (ORR) and OS. Responses are assessed by 3-weekly PSA and conventional and PSMA PET/CT imaging every 12 weeks. **Results:** 29 pts (median age 70 years: range: 52–84; prior docetaxel: 97%; prior androgen receptor pathway inhibitor: 100%) received ^{177}Lu -PSMA-617 on day 1 with escalating doses of olaparib (cohorts 1–6: 50mg - 300 mg BD days 2–15) or alternate olaparib schedules (cohort 7: 200 BD days - 4 to 14; cohort 8: 300 BD days - 4 to 14; cohort 9: 300 mg BD days -4 to 18) for up to 6 cycles. No DLTs were reported. Common treatment related adverse events (TRAE) ($\geq 10\%$) were Grade (G) 1–2 and included xerostomia (83%), nausea (62%), fatigue (34%), constipation (31%), anorexia (17%), vomiting (14%) and diarrhea (10%). Hematologic TRAE included anemia (G1: 14%; G2: 7%; G3: 7%), thrombocytopenia (G1: 14%; G2: 7%; G3: 3%) and neutropenia (G1: 3%; G3: 7%) that were transient and without clinical sequelae. Across cohorts 1–9, the PSA50-RR was 62% (18/29) and PSA90-RR was 48% (14/29). Five of the 7 pts (71%) with RECIST measurable disease had a partial response. **Conclusions:** The combination of ^{177}Lu -PSMA-617 and olaparib is well tolerated and has promising activity. Three further patients are being enrolled to cohort 9 to confirm the RP2D ahead of dose-expansion. Clinical trial information: NCT03874884. Research Sponsor: Prostate Cancer Foundation; AstraZeneca and Advanced Accelerators Application (AAA), a Novartis Company.

Oral Abstract Session

The genomic and transcriptomic landscapes of chemotherapy naïve vs post-chemotherapy germ cell tumors. *First Author: Aditya Bagrodia, University of California San Diego Health, La Jolla, CA*

Background: Cisplatin resistance occurs in up to 30% of patients with advanced germ cell tumors (GCTs). Despite effective salvage treatment regimen, there is a 50% risk of cancer-specific death. Previously, we identified molecular features, including *TP53* mutations and *MDM2* amplification, associated with cisplatin resistance (Bagrodia, 2016). Herein, we evaluate the genomic and transcriptomic landscapes of chemotherapy naïve vs post-chemotherapy GCT's to uncover genetic factors that might drive cisplatin resistance. **Methods:** GCTs ($N = 138$) were tested at Caris Life Sciences (Phoenix, AZ) with next-generation sequencing of DNA (592-gene or whole exome) and RNA (whole transcriptome). Prevalence was calculated for pathogenic SNVs/indels and copy number amplifications (CNA ≥ 6 copies). Primary ($N = 65$) and metastatic ($N = 73$) sites were defined based on the biopsy site. A specialized genitourinary pathologist blindly reviewed selected H&E-stained slides and designated tumors as chemotherapy naïve ($N = 66$) or post-chemotherapy ($N = 17$) based on treatment related changes. Differentially regulated pathways were assessed by gene set enrichment analysis (GSEA). Transcriptomic signatures predictive of response to immunotherapy (T cell-inflamed) and platinum sensitivity (PSS, high score suggests increased platinum sensitivity) were applied. Mann-Whitney U and χ^2 tests were applied, with P-values adjusted for multiple comparisons. **Results:** Primary and metastatic GCT had slight differences between putative drivers of platinum therapy resistance: *KIT* (15% vs 1), *TP53* (10% vs 17), *KRAS* (13% vs 9) mutations and *MDM2* CNA (4% vs 3), all $p > 0.05$. When comparing post-chemo vs chemo naïve GCTs, no significant differences in the genomic landscape were observed ($p > 0.05$). Chemo naïve tumors were shown to be enriched for gene sets associated with *KRAS* signaling and epithelial-to-mesenchymal transition. Additionally, they trended towards a higher proportion of T cell-inflamed tumors as compared to post-chemo samples (32% vs 18, $p = 0.36$). The average PSS for chemo naïve was slightly higher than post-chemo (CN: 0.07 Arbitrary Units (AU), $N = 62$ vs PC: -1.82, $N = 16$, $p = .52$). Chemo naïve tumors with *TP53*, *KRAS*, or *KIT* mutation or *MDM2* CNA had a lower PSS (-4.16 AU, $N = 18$) than tumors with none of those alterations (2.17, $N = 38$), $p = 0.05$. Finally, chemo naïve tumors with *MDM2* CNA ($N = 2$, -16.26 AU) had the lowest PSS followed by tumors with mutations in *TP53* ($N = 6$, -2.04), *KIT* ($N = 2$, -1.77) and *KRAS* ($N = 9$, -1.05) (mutations were mutually exclusive except for a concurrent *KRAS* and *TP53* mutation). **Conclusions:** This study provides evidence that chemo naïve GCTs with mutations in *TP53*, *KRAS*, *KIT* or *MDM2* CNA have higher expression of genes associated with resistance to platinum-based chemotherapy. These findings contribute to a better understanding of the molecular characteristics of GCTs and may inform prognosis and treatment. Research Sponsor: None.

Oral Abstract Session

Primary retroperitoneal lymph node dissection (RPLND) in seminoma stage IIA-IIC ≤ 3 cm: Combined results of the SWENOTECA (Swedish Norwegian Testicular Cancer Group) and Cologne. *First Author: Torgrim Tandstad, St. Olav's University Hospital, Trondheim, Norway*

Background: Chemotherapy or radiotherapy have been standard treatment for stage II seminomas with excellent survival but are associated with significant long-term treatment-related toxicities. Several prospective trials have shown primary retroperitoneal lymph node dissection (RPLND) to be an effective and safe alternative. The current SWENOTECA treatment program recommends primary RPLND in seminoma stage IIA to IIB ≤ 3 cm with 1-2 metastatic nodes as the standard treatment modality. We present preliminary results combined with data from Cologne. **Methods:** Within SWENOTECA, RPLND is centralized to 5 hospitals and Cologne is a tertiary centre for patients recruited from different parts of Germany. Both patients with recurrence after initial stage I disease and patients with primary stage IIA and IIB at diagnosis were included. We collected information on operation time, bleeding, peri- and postoperative complications. We also analyzed histologic outcome and whether adjuvant chemotherapy was given. We followed the patients for any recurrence of disease. **Results:** We have included 94 patients operated from May 2018 to November 2022. The number of operations per site varied from 4 to 28. The mean age of patients at time of RPLND was 41.8 years (range 21-79). Overall, 54 patients had recurrence after initial stage I disease and 40 patients had primary stage IIA/IIB disease at diagnosis (one missing data). At time of RPLND 62 patients had IIA-disease and 31 stage IIB-disease (one missing data). The histology from RPLND showed seminoma in 83 patients, benign/necrosis in eight patients, vital non-seminomatous GCT in one patient, teratoma only in one patient and lymphoma in one patient. Mean number of resected nodes was 19, and mean number of positive nodes were 1.5. Twenty-six patients (28%) were operated with robotic laparoscopic technique. Ten patients (10.6%) had a Clavien-Dindo postoperative complication > 2 . Twenty-three of the patients were given adjuvant oncological treatment after RPLND, most of them one course of BEP. The patients have been followed for in median 18 months (range 2-59). Nine patients (9.6 %) have had recurrences, all but one in the first year after RPLND. **Conclusions:** Our early results of primary RPLND of seminomas IIA-IIB ≤ 3 cm are promising. Longer follow-up is required to ensure this as a safe treatment option. Research Sponsor: Public health care in Norway and Sweden.

Poster Discussion Session

Prostate-specific membrane antigen ligand positron emission tomography (PSMA-PET) disease extent and overall survival (OS) in patients (pts) with high-risk nonmetastatic castration-resistant prostate cancer (nmCRPC): An international multicenter retrospective study. *First Author: Boris A. Hadaschik, University of Duisburg-Essen and German Cancer Consortium (DKTK)–University Hospital Essen, Essen, Germany*

Background: PSMA-PET was positive for distant metastases (39% distant nodes, 24% bone, 6% visceral organ) in $>50\%$ of nmCRPC pts who were nonmetastatic by conventional imaging (Fendler et al. *CCRP* 2019). However, the prognostic impact of PSMA-PET disease extent and its association with oncologic outcomes is unknown. We assessed the prognostic utility of PSMA-PET disease extent in nmCRPC pts defined by conventional imaging for OS and new metastases-free survival (nMFS). **Methods:** 200 pts (6 centers) with nmCRPC by conventional imaging and prostate-specific antigen doubling time (PSADT) ≤ 10 mo and/or ISUP grade group ≥ 4 underwent PSMA-PET. Clinical course and treatment management after PSMA-PET imaging were recorded for 4-9 y. Pt characteristics and PSMA-PET disease extent were analyzed retrospectively. OS and PSMA-PET nMFS (time from primary PSMA-PET to appearance of new distant metastases by PSMA-PET or death) were analyzed for pt subgroups based on disease extent by univariate Cox regression. **Results:** Median OS was 74 mo, similar to the SPARTAN study of nmCRPC pts (74 mo; Smith et al. *Eur Urol* 2021). Polymetastatic disease (≥ 5 distant lesions by PSMA-PET) was associated with shorter OS (median 61 mo vs not reached [NR]) and shorter PSMA-PET nMFS (HR 1.8, 95% CI 1.1-2.9; median 38 vs 60 mo; $p=0.021$). Any metastatic disease by PSMA-PET and whole-body PSMA tumor volume were not prognostic for OS and PSMA-PET nMFS (all $p>0.05$). Initial pN1 status was associated with shorter OS (median 55 mo vs NR), but not with PSMA-PET nMFS ($p>0.05$). Baseline age, baseline Gleason grade ≥ 8 , prior radiotherapy (RT), and PSA and PSADT at time of primary PSMA-PET were not associated with outcomes (all $p>0.05$). Management after PSMA-PET imaging was mostly local/targeted therapy in pts with no visible/locoregional disease (40/30%) and androgen receptor signaling inhibition therapy in pts with nodal/bone distant metastases (35/43%). **Conclusions:** Polymetastases (>5) by PSMA-PET and initial pN1 status were significantly associated with worse OS. PSMA-PET disease extent provides a potential novel additional risk stratification for pts with nmCRPC without distant metastasis based on conventional imaging. Further validation is needed to prove its independent prognostic value. Clinical trial information: NCT01946204. Research Sponsor: SPARTAN was funded by Janssen Research & Development.

PSMA PET guided salvage radiotherapy among patients with prostate cancer in the post-prostatectomy setting: A single center post-hoc analysis. *First Author: Clayton P Smith, UCLA Department of Radiation Oncology, Los Angeles, CA*

Background: Prostate-specific membrane antigen (PSMA) positron emission tomography (PET) shows improved sensitivity and specificity for detection of locoregional and distant metastatic prostate cancer (Pca) compared to conventional imaging, especially at lower PSA levels as is often the case in the biochemically recurrent (BCR), post radical prostatectomy (RP) setting. Providers are now utilizing PSMA PET findings to guide their salvage radiotherapy (sRT) treatment fields and doses, although it is not well understood how PSMA PET guided sRT impacts patient outcomes. **Methods:** This was a *post-hoc* analysis of 5 prospective studies of PSMA PET conducted at UCLA from 2016 to 2021 that included patients with recurrent Pca following RP. Patients were included in this retrospective study if they initiated sRT within 3 months of PSMA PET, had at least 12 months of follow up after sRT completion, had available sRT treatment details, and did not have distant metastases (DM) by conventional imaging on upfront staging. Patients treated with palliative RT were excluded. BCR following sRT was defined as an increase in PSA of 0.2 ng/ml above the post sRT nadir. Metastasis directed therapy (MDT) was defined as sRT to all PSMA+ N1 and M1 lesions. Baseline patient demographics, PSMA PET findings, sRT & ADT treatment details, and patient outcome data were collected. **Results:** 176 patients were included in this study. Median time between RP and PSMA PET was 38 months (range 1-329). Median PSA at the time of the PSMA PET was 0.625 ng/mL (range 0.063-35). PSMA PET was positive in 128 patients (73%): 21 (12%) mIT+NOMO, 55 (31%) mITxN1M0 and 52 (30%) mITxNxM1 with 19 (11%) mITxNxM1a, 31 (18%) mITxNxM1b, and 2 (1%) mITxNxM1c. Median number of lesions seen on positive PSMA scans was 1 (range 1-8). 39 (22%) patients were subsequently treated with sRT to the prostate bed (PB) only, 59 (34%) to PB + pelvic lymph nodes (PLNs), 33 (19%) to PLNs only, 7 (4%) to PB + PLNs + DM, 7 (4%) to PLNs + DM, and 31 (18%) to DM only. 59 (34%) patients were treated with concurrent ADT at a median duration of 6 months (range 1-39). At a median follow-up of 32 months (range 12-70) after sRT, 80 patients (45%) did not develop BCR or imaging relapse (IR) following sRT, 24 patients (14%) developed BCR but not IR, 1 patient ($<1\%$) developed IR only, and 70 patients (40%) developed both BCR and IR. The median time to BCR and IR following sRT was 15 months (range 1-48) and 19 months (range 6-61), respectively. 1 year post sRT biochemical recurrence free survival was 77%. Of the 83 patients treated with MDT, 32 (39%) did not develop subsequent disease relapse. **Conclusions:** This *post-hoc* analysis assessed the outcomes of 176 patients treated with PSMA PET guided salvage RT, proving it to be an effective method for treating both pelvic and extrapelvic recurrent Pca. Further investigation is needed to assess the full extent of patient outcomes in this population. Research Sponsor: UCLA.

Poster Discussion Session

Do bone scans over-stage disease compared to PSMA PET? An international multicenter retrospective study with blinded independent readers. *First Author: Wolfgang P. Fendler, Department of Nuclear Medicine, West German Cancer Center, University Hospital Essen, University of Duisburg-Essen, Essen, Germany*

Background: PSMA positron emission tomography (PET) has a higher accuracy than computed tomography (CT) and bone scans to stage patients with prostate cancer. However, we do not understand how to apply clinical trial data based on conventional imaging to patients staged using PSMA PET. Therefore, we aim to evaluate the ability of bone scans to detect osseous metastases using PSMA PET as a reference standard. **Methods:** In this multicenter retrospective diagnostic study, 167 patients with prostate cancer, who were imaged with bone scan and PSMA PET performed within 100 days were included for analysis. Each study was interpreted by three blinded readers, and the results of the PSMA PET were used as the reference standard. Endpoints were positive predictive value (PPV), negative predictive value (NPV) and specificity for bone scans. Additionally, inter-reader reproducibility, positivity rate, uptake on PSMA PET, and number of lesions were evaluated. **Results:** 167 patients were included in the study, with 77 at initial staging, 60 in the BCR/CSPP setting and 30 in the CRPC setting. BS findings for metastatic disease validated by PSMA PET were tabulated. In all patients, the PPV, NPV and specificity for bone scans were 0.73 [0.61,0.82], 0.82 [0.74,0.88] and 0.82 [0.74,0.88]. In patients at initial staging, the PPV, NPV and specificity for bone scans were 0.43 [0.26,0.63], 0.94 [0.85,0.98], and 0.80 [0.68,0.88]. At initial staging 13/23 (57%) of positive bone scans were false positive. Inter-reader agreement for bone disease was moderate for bone scans (Fleiss k, 0.51) and substantial for the PSMA PET reference standard (Fleiss k, 0.80). **Conclusions:** In this multicenter retrospective study, the PPV of bone scans was low in patients at initial staging with majority of positive bone scans being false positives. This suggests that a large proportion of patients considered low volume metastatic by bone scan actually have localized disease. Research Sponsor: UCLA, UCSF, UKEssen.

n=167 patients	Initial staging	BCR/CSPP	CRPC	Overall

Poster Discussion Session

Health-related quality of life (HRQoL) and pain outcomes for patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) who received abiraterone (abi) and olaparib (ola) versus (vs) abi and placebo (pbo) in the phase III PROpel trial. *First Author: Antoine Thiery-Vuillemin, CHRU Besançon Hôpital J.Minjoz, Besançon, France*

Background: PROpel (NCT03732820) met its primary endpoint and showed significantly prolonged investigator-assessed rPFS with abi + ola vs abi + pbo at primary analysis (data cut-off [DCO]: 7/30/21; median 24.8 vs 16.6 months (m); hazard ratio [HR] 0.66, 95% confidence interval [CI] 0.54–0.81; $P < 0.001$). HRQoL (based on The Functional Assessment of Cancer Therapy-Prostate [FACT-P] total score) was not different when ola was combined with standard-of-care abi. We present data at the final prespecified overall survival (OS) DCO (10/12/22). **Methods:** PROpel is a randomised, double-blind trial in 1L mCRPC. Time to pain progression (TPPP) was based on the Brief Pain Inventory-Short Form (BPI-SF) Item 3 'worst pain in 24 hours' and opiate analgesic use (analgesic quantification algorithm) score. Time to first symptomatic skeletal related event (SSRE) was time to use of therapy to prevent/relieve skeletal symptoms, new bone fractures, spinal compression or surgery on bone metastases. HRQoL was assessed by change from baseline (BL) in FACT-P total and subscale scores, BPI-SF pain severity, pain interference and worst pain score between arms using a mixed model for repeated measures. **Results:** At median follow-up of 33.6 m with abi + ola and 32.1 m with abi + pbo, 17.0% pts (68/399) in the abi + ola arm and 15.1% pts (60/397) in the abi + pbo arm had pain progression (PP) events. The % of pts who had not experienced PP with abi + ola vs abi + pbo was 76.9% vs 77.2% at 24 m and 70.7% vs 71.0% at 36 m. No meaningful difference in TPPP was observed (16% maturity, HR 1.06, 95% CI 0.75–1.50, $P = 0.75$ [nominal], median not reached [NR] either arm). The % of pts who had not had a SSRE with abi + ola vs abi + pbo was 86.1% vs 82.2% at 24 m and 80.8% vs 78.5% at 36 m. No meaningful difference in time to SSRE was observed (12% maturity, HR 0.82, 95% CI 0.55–1.22, $P = 0.32$ [nominal], median NR vs NR). Least-squares mean changes from BL between arms in BPI-SF pain severity (difference, -0.06; 95% CI -0.23–0.12), pain interference (difference, -0.12; 95% CI -0.31–0.06), worst pain score (difference, -0.12; 95% CI -0.35–0.11) and FACT-P total score (difference, -0.54; 95% CI -3.00–1.92) suggest no clinically meaningful difference in HRQoL with abi + ola vs abi + pbo. Least-squares mean change from BL values for FACT-P subscale scores were consistent with FACT-P total score result. **Conclusions:** PROpel demonstrated a significant delay in rPFS for pts receiving abi + ola vs abi + pbo. Most pts in the trial did not experience a PP event. Abi + ola showed no difference in HRQoL (assessed by FACT-P total and subscale scores, BPI-SF domain and worst pain scores) vs abi + pbo, suggesting pts can derive clinical benefit from abi + ola while maintaining a similar HRQoL compared with a current standard-of-care treatment. Clinical trial information: NCT03732820. Research Sponsor: This study was supported by AstraZeneca and Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc., Rahway, NJ, USA, who are codeveloping olaparib.

Poster Discussion Session

Patient reported quality of life (QOL) and survival outcomes: Analysis of ECOG-ACRIN E3805 chemohormonal androgen ablation randomized trial (CHAARTED) in prostate cancer (PCa). *First Author: Daniel Sentana Lledo, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Chemohormonal therapy with androgen deprivation therapy and docetaxel (ADT+D) improves overall survival (OS) and quality of life (QOL) at 12 months compared to ADT alone in metastatic hormone sensitive prostate cancer (mHSPC). However, the prognostic relationship between QOL, disease characteristics, and OS has not been described in this population. **Methods:** In this post-hoc exploratory analysis of the CHAARTED trial, the QOL instrument Functional Assessment of Cancer Therapy-Prostate (FACT-P) was completed by patients treated with ADT and ADT+D. Log-rank test and Cox proportional hazards models were used to test the association between QOL and OS by clinical and disease characteristics. **Results:** 790 men were included in the study (ADT+D, $n = 397$; ADT, $n = 393$). Baseline higher QOL by FACT-P ($n = 790$) was associated with better OS in univariate regression (HR 0.70 [0.55, 0.90], $p = 0.005$), however the association was not significant in multivariate analysis (HR 0.80 [0.62–1.04], $p = 0.09$). There was a trend towards improved survival for patients with the lowest baseline QOL (lowest quartile) treated with ADT+D compared to ADT (HR 0.75 [0.53, 1.05], $p = 0.09$). In contrast, patients with the highest baseline QOL (highest quartile, 63% high volume disease) had similar survival regardless of treatment arm (HR 0.92 [0.63–1.36], $p = 0.69$). Higher 3-month QOL by FACT-P ($n = 654$) was associated with survival in the multivariate analysis independently of treatment arm (HR 0.76 [0.58, 1.0], $p = 0.05$). Patients with the highest 3-month QOL had comparable survival regardless of treatment arm (HR 1.11 [0.73, 1.67], $p = 0.63$), while patients with the lowest 3-month QOL experienced a survival benefit with ADT+D compared to ADT (HR 0.69 [0.48, 0.99], $p = 0.047$). **Conclusions:** In this analysis, 3-month QOL by FACT-P was significantly associated with survival for patients with mHSPC. Patients with the poorest QOL ("most symptomatic") appeared to experience survival benefit from ADT+D regardless of disease volume. Conversely, patients reporting the highest QOL ("least symptomatic") did not seem to benefit from ADT+D despite a predominance of patients with high volume disease in that cohort. These findings suggest that consideration of QOL may enhance decision making and patient selection when considering chemohormonal treatment for mHSPC. Research Sponsor: U.S. National Institutes of Health; Sanofi.

Poster Discussion Session

Patient-reported outcomes (PROs) among men receiving talazoparib (TALA) + enzalutamide (ENZA) vs placebo (PBO) + ENZA as first-line (1L) treatment for metastatic castration-resistant prostate cancer (mCRPC): Results from a phase 3 study (TALAPRO-2). *First Author: Neeraj Agarwal, Huntsman Cancer Institute (NCI-CCC), University of Utah, Salt Lake City, UT*

Background: TALAPRO-2 (NCT03395197) showed statistically significant improvement in radiographic progression free survival with TALA + ENZA ($n=402$) vs PBO + ENZA ($n=403$) (HR=0.63 95% CI 0.51–0.78; $P < 0.001$) in men receiving 1L treatment for mCRPC. Here we report PRO endpoints from TALAPRO-2. **Methods:** PROs were assessed at day 1 (baseline) and at scheduled visits until radiographic progression (every 4 weeks until week 53, and then every 8 weeks) using the EORTC QLQ-C30 and its prostate cancer module, QLQ-PR25. Prespecified PRO analyses included overall mean change from baseline (per longitudinal repeated measures mixed-effects model) and time to definitive clinically meaningful (≥ 10 -point change) deterioration (TTD). Between-arm comparisons of TTD were made using a stratified log-rank test and a Cox proportional hazards model. **Results:** Of the 805 men randomized and treated, 793 had a baseline score followed by at least 1 post-baseline score; TALA + ENZA ($n=395$), PBO + ENZA ($n=398$). Although the treatment effect on global health status (GHS)/quality of life (QoL) significantly favored PBO + ENZA, the predefined threshold of clinical meaningfulness was not met; moreover, no significant differences between the arms were observed in any functioning scales. A significantly longer TTD in GHS/QoL was observed for TALA + ENZA; HR=0.780 (95% CI: 0.62, 0.99), $P=0.038$; median: 30.8 months vs 25.0 months. A numerical greater delay in TTD in urinary symptoms was longer for TALA + ENZA; HR=0.759 (95% CI: 0.543, 1.061), $P=0.105$; median not reached vs 35.9 months. Additional PRO results will be presented. **Conclusions:** Compared with PBO + ENZA, in the TALA + ENZA arm there was 1) a modest deterioration disfavoring GHS/QoL (deterioration was not clinically meaningful based on the predefined threshold), and 2) a maintenance in all functioning scales. TTD in GHS/QoL was significantly longer with TALA + ENZA vs PBO + ENZA, reflecting improved disease control. These results complement the benefit-risk assessment of TALAPRO-2. Clinical trial information: NCT03395197. Research Sponsor: Pfizer Inc.

Overall change from baseline in PROs.

A prospective trial of apalutamide and abiraterone acetate plus prednisone in Black and White men with metastatic castrate-resistant prostate cancer. *First Author: Daniel J. George, Duke Cancer Institute Center for Prostate and Urologic Cancers, Durham, NC*

Background: Abi Race was the first prospective parallel cohort study of abiraterone acetate plus prednisone (AAP) in Black and White men with metastatic castrate-resistant prostate cancer (mCRPC) and demonstrated greater prostate-specific antigen (PSA) response, time to PSA progression (TTP) and toxicity rates among Black patients (pts). We designed the PANTHER trial to estimate clinical outcomes among Black and White pts with mCRPC treated with apalutamide, abiraterone, plus prednisone. **Methods:** This parallel cohort multicenter study treated androgen receptor pathway inhibitor naïve mCRPC pts with oral apalutamide (240 mg/d), abiraterone (1000 mg/d) and prednisone (10 mg/d) (AAP) continuously until disease progression, unacceptable toxicity or 2 years. The primary endpoint was radiographic progression free survival (rPFS); secondary endpoints were to estimate TTP, overall survival (OS) and best PSA response, among Black and White pts, separately. Exploratory endpoints included safety and correlative biomarkers of outcome by race and ancestry. **Results:** Between July 2017 and January 2021, we enrolled 43 Black and 50 White pts from 8 sites. Baseline prognostic characteristics were largely similar with some differences. We report an interim analysis as the pts are still followed for OS. At the time of the abstract submission, there were 18 and 36 rPFS events and 15 and 30 deaths in Black and White pts, respectively. We present the time to event endpoint rates at 12 and 24 mos and PSA declines for Black and White pts. **Conclusions:** We hypothesize that treatment with the combination of AAP may result in clinical efficacy in Black men with mCRPC. Black pts were underrepresented in the phase III ACIS trial which compared AAP to AAAP and demonstrated longer rPFS but not OS. Further studies of AAP combination therapy among Black men with advanced prostate cancer are needed to determine potential clinical benefits in this understudied population. Clinical trial information: NCT03098836. Research Sponsor: Janssen; DOD CDMRP.

Endpoint	Black men (95% CI)	White men (95% CI)

Primary analysis of STARTAR: A phase 2 salvage trial of androgen receptor (AR) inhibition with androgen deprivation therapy (ADT) and apalutamide with radiation therapy (RT) followed by docetaxel in men with PSA recurrent prostate cancer (PC) after radical prostatectomy (RP). *First Author: Tian Zhang, University of Texas Southwestern Medical Center, Dallas, TX*

Background: ADT with salvage RT improves survival for men with PSA recurrence after RP. For high risk PSA recurrence, current standard ADT duration is up to 2 years with RT; shortening but intensifying systemic therapy may improve outcomes. The STREAM trial showed 6 mo enzalutamide with ADT/RT had 3-year progression free survival (PFS) of 53% in a high risk population, including lymph node (LN) positive. Given docetaxel (doce) improves survival in mHSPC, we evaluated the combination of salvage RT, ADT/apalutamide (apa) and doce in this setting. **Methods:** STARTAR is a multicenter investigator initiated phase 2 trial for salvage treatment of PSA recurrent PC post-RP, conducted in the DOD Prostate Cancer Clinical Trials Consortium. Key inclusion criteria included Gleason 7 with T3/positive margin/N1 or Gleason 8-10 PC, PSA relapse <4 years post-RP (inclusion PSA 0.2-4 ng/mL), and <4 positive LNs, standard imaging negative. Patients (pts) received ADT with apa for 9 months, RT (66-74 Gy to the prostate bed +/- pelvic LNs over 6-8 wks) starting wk 8, and then completed 6 cycles of concurrent doce 75mg/m2 q3 wks. The primary endpoint was 36 month PFS, defined as composite of freedom from PSA>0.2 + post-RT nadir with subsequent rise, clinical progression, other therapy start, or death, among pts with testosterone (T) recovery (>100ng/dL). Kaplan-Meier estimates for PFS were used to determine landmark 24 mo and 36 mo rates and compared to PFS rates from prior trials using a binomial test. **Results:** From 3/2018 to 2/2020, 39 pts were enrolled. As of 12/2022 data cutoff, median follow up was 36 months. Baseline characteristics: Gleason 7 in 54%; Gleason 8-10 in 46%; 23% LN positive; median PSA 0.58 ng/mL (range 0.21-3.40), and median time from RP 7.6 mo (range 2-98). 37 pts (95%) and 23 pts (62%) completed at least 1 and all 6 cycles doce, respectively. All pts achieved undetectable PSA nadirs. At 24mo and 36mo, PFS rates were 84% and 72%, respectively, with 95% pts recovering T at 36 mo. Compared to 40% historical PFS and 53% STREAM PFS rates, the 72% 36-mo PFS rate was statistically significantly improved (p<0.001 and p=0.013, respectively). Common any-grade adverse events (AEs) included 98% hot flashes, 88% fatigue, 77% alopecia, 57% dysgeusia, and 53% rash (28% grade 1; 15% grade 2, 10% grade 3), with 5% febrile neutropenia. **Conclusions:** In this first phase 2 trial of ADT, apa, salvage RT, and 6 cycles of doce for high risk PSA recurrence, the primary endpoint 3-year PFS rate improved to 72%, indicating durable remissions beyond historic controls. Intensifying systemic treatments in the non-metastatic hormone sensitive but high risk salvage setting may be feasible and efficacious, with fewer pts experiencing cancer progression over time. Clinical trial information: NCT03311555. Research Sponsor: Janssen.

Poster Discussion Session

Final results from phase I study of PSCA-targeted chimeric antigen receptor (CAR) T cells in patients with metastatic castration resistant prostate cancer (mCRPC). *First Author: Tanya B. Dorff, Department of Medical Oncology & Experimental Therapeutics, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Chimeric antigen receptor (CAR)-engineered T cell therapies are being pursued for the treatment of mCRPC. Prostate Stem Cell Antigen (PSCA) is highly expressed on the surface membrane in mCRPC and with limited expression on normal tissues. We are completing a phase I study of PSCA-targeted 4-1BB-co-stimulated CAR T cell therapy in mCRPC. **Methods:** CAR T cells were manufactured at City of Hope's cGMP facility. Patients (pts) were required to have disease progression after at least 1 androgen receptor targeted therapy but there was no limit on other prior treatments. The primary objective was to define the dose limiting toxicities (DLT) as well as to describe preliminary bioactivity and activity. CAR T persistence and cytokine levels were evaluated by flow cytometry and Luminex. Circulating tumor cells (CTC) were measured by an unselected assay (Kuhn). **Results:** 14 pts were treated, median age 69, median baseline PSA 88. 12(86%) had previously been treated with chemotherapy; 9 received two taxanes and 3 docetaxel only. 79% of screened pts had PSCA expression >2+ in >80% of cancer cells. Two of 6 pts encountered DLT (grade 3 cystitis) at 100M + lymphodepletion (LD) chemotherapy. The protocol was amended to reduce the LD dose to 300 mg/m2 cyclophosphamide D1-3. No DLTs occurred in 5 pts treated in the modified LD 100M cohort. Cytokine release syndrome (CRS), best response by RECIST, CAR T cell expansion and persistence are presented by dose level in the table. CAR T expansion was greater with LD than without. PSA declines were seen, as well as radiographic improvement, though RECIST response was limited to stable disease (SD) by concurrent bone metastases. Cytokine peaks were higher in patients with anti-tumor effect noted. CTC decreases in both marrow and peripheral blood were seen, associated with PSA declines. **Conclusions:** PSCA-CAR T cells have anti-cancer activity in mCRPC with DLT of cystitis. LD was required for greater expansion and activity; lower dose LD improved toxicity without clear negative impact on expansion. Clinical trial information: NCT03873805. Research Sponsor: Prostate Cancer Foundation; DOD.

Phase I dose-escalation results of prostate-specific membrane antigen-targeted radionuclide therapy (PSMA-TRT) with alpha-radiolabeled antibody ²²⁵Ac-J591 and beta-radioligand ¹⁷⁷Lu-PSMA I&T. *First Author: Scott T. Tagawa, Weill Cornell Medicine, Division of Hematology & Medical Oncology, NewYork-Presbyterian Hospital, New York, NY*

Background: PSMA may be targeted by antibodies (mAb) or small molecules (SML), with different kinetics and biodistribution. mAb with longer circulation time and marrow exposure, but decreased access to luminal PSMA expression (e.g. salivary glands, intestine, kidney). SML diffuse to all sites of PSMA expression and then excreted. Alpha radionuclides emit more energy over shorter range vs beta. Pre-clinical data combining mAb and SML supports synergy, with enhanced uptake and retention of SML. Here, we present phase I dose-escalation results of a phase I/II trial investigating combo ²²⁵Ac-J591 with ¹⁷⁷Lu-PSMA-I&T (aka PNT2002). **Methods:** Eligibility criteria include progressive mCRPC, ≥1 prior AR pathway inhibitor (ARPI), prior chemo (or unfit/refuse), ≥1 lesion with SUVmax >liver. Doses: ¹⁷⁷Lu-PSMA-I&T (6.8 GBq); ²²⁵Ac-J591 (30, 35, or 40 KBq/kg), up to 2 doses of combo TRT 8 weeks (wks) apart with ¹⁷⁷Lu SPECT following each dose. Primary objectives: dose-limiting toxicity (DLT) and recommended phase II dose; phase II will test the proportion of patients (pts) obtaining >50% PSA decline (PSA50). DLT defined as G4 myelosuppression lasting >1 wk, Gr>2 non-hematologic adverse event (AE), any Gr attributed AE delaying therapy >3 wks. Additional endpoints include progression-free and overall survival, radiographic response rate, safety, circulating tumor cell (CTC) changes, pt reported outcomes, PSMA imaging, blood/tissue correlatives. **Results:** 18 pts treated (6 at each dose level); 3 did not receive the 2nd dose due to progressive disease or withdrawal. Median age 70 (range 54-86), PSA 54.4 (2.43-9614). 13 (72%) with bone, 9 (50%) lymph node, 2 (11%) liver, 2 (11%) lung mets. 10 (56%) pts CALGB risk category high, 7 (39%) intermediate, 1 low. Previous therapies: 11 (61%) with >1 ARPI, 12 (67%) chemo, 5 (28%) sip-T, 3 (17%) radium-223. 2 of 6 pts with DLT at 40 KBq/Kg (Gr 2 or 3 thrombocytopenia delaying cycle 2 by >3 wk); no DLT observed in other cohorts. As submission, 7 pts (39%) remain on study, including 1 without progression at 16 months and another with undetectable PSA at 10 months. With follow up ongoing, 17 (94%) with PSA decline, 9 (50%) with PSA50. Of those with paired CTC counts, 4 of 5 (80%) converted from unfavorable to favorable CTC count, 4 of 8 (50%) from detectable to undetectable, 1 of 2 (50%) remained undetectable. AEs include 3 (17%) neutropenia (all Gr <2), 12 (67%) thrombocytopenia (3 Gr 3), 10 (56%) anemia (3 Gr 3), 10 (56%) pain flare (1 Gr3 in pt with cord compression), 12 (67%) xerostomia (one Gr2), 11 (61%) nausea (all Gr 1), 9 (50%) fatigue (all Gr 1). **Conclusions:** The combination of dual-PSMA targeting with mAb + SML and alpha + beta is feasible with follow up ongoing. Efficacy will formally be tested in the upcoming phase II portion of the study with ²²⁵Ac-J591 at 35 KBq/Kg and ¹⁷⁷Lu-PSMA I&T at 6.8 GBq. Clinical trial information: NCT04886986. Clonal hematopoiesis in the phase 3 Alliance A031201 trial of metastatic castration resistant prostate cancer (mCRPC) treated with androgen receptor (AR)-targeted therapies. *First Author: Jeffrey Lee Jensen, University of North Carolina Hospital, Chapel Hill, NC*

Background: Somatic mutations in hematopoietic progenitor cells accumulate with age leading to clonal expansion in a process called clonal hematopoiesis (CH). CH increases the risk of developing myeloid neoplasms and shortens overall survival (OS), primarily linked to increased cardiovascular (CV) mortality. The impact of CH in metastatic solid cancers has been conflicting, with shorter OS in a broad cancer cohort but prolonged OS in metastatic colorectal cancer, which may be influenced by prior cytotoxic therapy that can promote emergence of CH. As AR pathway inhibitors (ARPIs) are associated with CV adverse events (AE), exploring the impact of CH in patients (pts) with mCRPC is of interest. **Methods:** A 9 gene targeted DNA sequencing panel designed to capture common CH mutations (*DNMT3A*, *TET2*, *ASXL1*, *PPM1D*, *TP53*, *CHEK2*, *SRSF2*, *SF3B1*, *JAK2*) was applied to pre-treatment peripheral blood samples of 957 pts enrolled in the Alliance A031201 phase 3 trial of enzalutamide versus enzalutamide plus abiraterone/prednisone in the first line mCRPC setting. No difference in OS was found between treatment arms. The primary endpoint was the impact of CH on OS; secondary and exploratory endpoints included progression-free survival (PFS) and associations with baseline comorbidities and AEs (hematologic and CV). Cox proportional-hazards and logit models were adjusted for treatment arm, age, and radiation therapy (RT). **Results:** CH was common with 57% of pts having low CH (VAF>0.5% in 1+ mutation, L-CH), 24% having standard CH (VAF>2%, CH), and 7% having high CH (VAF>10%, H-CH). 4% of pts had 2+ CH mutations and 1% had 3+ mutations. Patients with CH were older (73.1 vs 70.2) and had higher rates of prior RT (58.4% vs 55.7%) and prior chemotherapy (3.9% vs 2.2%). No differences in OS were detected in pts with L-CH, CH, or H-CH. Similarly, no differences in PFS or baseline CV comorbidities were seen in any CH group. Pts with H-CH and *TET2*-mutated CH had statistically higher odds of any CV event (adjusted p=0.0004 and p=0.010, respectively) There was also a difference in the occurrence of major adverse CV events (MACE) by H-CH status (5.8% vs. 1.9%, adjusted p=0.042), while there was no difference seen for CH (3.4% vs 1.8%, adjusted p=0.147). Regarding hematologic AEs, one pt with a *TP53* mutation (VAF 0.94%) developed myelodysplastic syndrome. **Conclusions:** CH did not affect OS or PFS in pts with mCRPC treated with ARPIs in the A031201 trial. However, CH with VAF>10% and *TET2*-mutated CH were associated with an increased rate of all CV AEs, suggesting an additive effect of ARPI therapy and CH on adverse CV outcomes. Confirmatory studies are warranted to assess whether CH should be considered in the risk-benefit discussion for pts receiving ARPIs. Research Sponsor: Prostate Cancer Foundation.

Poster Session

Association of adaptive immunity/inflammatory genes with survival in prostate cancer. *First Author: Austin Hopper, University of California San Diego, La Jolla, CA*

Background: Advances in immunotherapy have had little impact in prostate cancer (PCA). We have previously examined the immune microenvironment in both localized and metastatic PCA and found that primary PCA shows local inflammation/adaptive immunity whereas metastatic disease shows a shift towards immune suppression (Deichate, 2022). Herein, we examine immune remodeling in PCA by evaluating changes in gene expression between localized and metastatic disease with heterogeneous treatment patterns in both primary and metastatic samples. **Methods:** Tumors from PCA (N = 5,419) were tested at Caris Life Sciences (Phoenix, AZ) with NextGen Sequencing of DNA (592-gene or whole exome) and RNA (whole transcriptome). Samples collected from the prostate gland (N = 3,284) or metastatic sites (N = 2,135) were analyzed. The Mann-Whitney U test was applied as appropriate, with P-values adjusted for multiple comparisons ($q < .05$). Real-world overall survival (OS) data was obtained from insurance claims and Kaplan-Meier estimates were calculated for molecularly defined subpopulations. Survival for tumors with high (-H) and low (-L) expression of genes of interest, defined as top and bottom quartile of expression (transcripts per million, TPM) across all tumors, was investigated. Differentially regulated pathways were assessed by gene set enrichment analysis (GSEA). **Results:** Compared to metastatic PCA, primary samples had increased median expression of pro-inflammatory genes *IL-6* (1.2-fold), *SELE* (1.9-fold), *NRK* (6.3-fold), *CEBPD* (1.2-fold), *NFKB2* (1.4-fold) and *FOXP3* (1.4-fold) (each $q < .05$). GSEA identified enrichment of *E2F* target genes in primary samples, while metastatic samples were enriched in inflammatory response, *KRAS* signaling and *IL2/STAT5* signaling pathways. The expression of inflammatory genes affected OS differently based on site. *IL-6*, *NRK* and *SELE-H* levels in primary samples were associated with increased OS. Within metastatic samples, *CEBPD-H* was associated with decreased OS and *NFKB2-H* was associated with an increased OS. *FOSB-H* was associated with increased OS in both primary and metastatic samples. **Conclusions:** We identify significant differences in the expression of inflammatory regulators and cytokines between localized and metastatic PCA tumors, which correlate with OS. These changes in the immune microenvironment can be leveraged for rational immunotherapy development and better targeted approaches. Clinical implications of molecular alterations in intraductal carcinoma of the prostate. *First Author: Benjamin Miron, Fox Chase Cancer Center, Philadelphia, PA*

Background: Intraductal carcinoma of the prostate (IDC-P) is a recent addition to the 2016 WHO classification system and little is known about the nature of its true incidence and biology. Clinically, it has been observed to be associated with higher grade group tumors and a more aggressive disease course with a high risk of local recurrence and distant metastasis. However, the molecular underpinnings which define IDC-P are not well elucidated. Initial case series with molecular profiling have suggested an enrichment of alterations in DNA damage/repair (DDR), PI3K, WNT and MAPK pathways. We now present comprehensive molecular profiling data from the largest cohort of IDC-P reported to date in order to better characterize this relatively new histologic entity. **Methods:** Eligible patients included those with radical prostatectomy tumor tissue labeled as IDC-P on testing requisition with available tissue-based DNA and RNA sequencing utilizing a commercially available CLIA-certified assay (Caris Life Sciences). Prostatic tumor specimens were analyzed using NextGen DNA sequencing (NextSeq, 592 genes and NovaSeq, WES). Digitized H&E slides underwent central pathological review by a board certified pathologist (SW) specializing in genitourinary malignancies to confirm presence of intraductal histology according to the 2022 WHO classification. **Results:** 31 of 44 submitted cases were confirmed to be IDC-P on central review. Median age of patients was 64 yrs (range 44-79). The majority of cases (26/31 - 84%) were Grade Group 5 and all were Grade Group 3 or higher. Overall the most frequently detected alterations were in *TP53* (39%), *TMPPRSS2* fusion (39%), *FOXA1* (16%), *CDK12* (10%), *PIK3CA* (10%), *SPOP* (10%), *ATM* (7%), *AKT1* (7%) and *RB1* (5%). The most commonly altered pathways were in cell cycle regulators (50%), DDR (*BRCA1/2*, *ATM*, *CDK12*) (23%), and PI3K/AKT/MTOR (23%) and WNT (10%). The *FOXA1* mutation rate in this cohort was higher compared to the localized prostate cancer cohort from the TCGA (16% - 5/31 vs 6% - 82/1325). In the IDC-P cohort, there were no tumors which demonstrated mismatch-repair deficiency (dMMR) or microsatellite instability and none of the profiled tumors had a high tumor mutational burden (≥ 10 mutations/megabase). **Conclusions:** This data suggests that IDC-P harbors targetable molecular alterations in DDR genes (*BRCA1/2* and *CDK12*) with approved targeted agents (e.g. PARP inhibitors). These findings should underscore the importance of germline and somatic mutation testing when IDC-P is identified. We also found enrichment of oncogenic *FOXA1* mutations in IDC-P which are associated with prostate cancer progression, castrate-resistance and an unfavorable prognosis. Further efforts are ongoing to expand this cohort of IDC-P cases and compare them with a matched cohort of pure adenocarcinoma cases and will include analysis of key RNA expression signatures. Clinical analysis of optimized neural network risk models to predict clinically significant prostate cancer and avoid unnecessary prostate biopsies. *First Author: Christopher J.D. Wallis, Division of Urology and Surgical Oncology, Department of Surgery, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: Given the low specificity of the current standard of care diagnostic tests for prostate cancer (PCa), there is an unmet clinical need for higher specificity tests to counter overdiagnosis of grade group (GG) 1 PCa. The aim of the study was to create optimized neural network risk models using PSA, free PSA, and other useful clinical features, and to validate the accuracy of the risk models to predict GG ≥ 2 PCa using real-world samples and data. **Methods:** Men aged 40-75 years with PSA ≥ 3 ng/mL and a biopsy referral were recruited into cohorts from sites in Canada (Kipnes Urology Centre (KUC), Edmonton, AB, and Prostate Cancer Centre (PCC), Calgary, AB) and the United States (Johns Hopkins University (JHU), Baltimore, MD and UCLA, Los Angeles, CA). Risk models to predict all GGs or GG ≥ 2 PCa were fit using data from KUC and JHU (train cohort n = 1037) while fixed models were validated on PCC (n = 401) and UCLA (n = 945). Prediction models were created using neural networks to generate the patient's risk score. To compare the risk model test with PSA, the high-grade cancer detection sensitivity was fixed, and the number of biopsies needed to achieve that sensitivity was evaluated. Threshold values for the training cohort were determined using at least 95% sensitivity and maximum specificity. Threshold values for other clinical features and risk calculator outputs were set to match the test sensitivity when possible. **Results:** The optimized neural network risk models test had the highest area under the curve (AUC 0.81) for predicting GG ≥ 2 PCa on the validation cohorts compared to four other risk calculators; Prostate Cancer Prevention Trial Risk Calculator 2.0 (PCPTRC) with free PSA (0.78, p -value < 0.001), Prostate Biopsy Collaborative Group risk calculator (PBCG, 0.73, p -value < 0.0001), European Randomized study of Screening for Prostate Cancer risk calculator 3 (ERSPC-3, 0.72, p -value < 0.0001), and PCPTRC with no free PSA (0.71, p -value < 0.0001) and PSA (0.66, p -value < 0.0001). At a threshold of 18.6%, this test provided 94% sensitivity, 37% specificity, 49% positive predictive value, and 90% NPV for predicting GG ≥ 2 PCa. If a biopsy was performed only when the tests' risk score prediction was ≥ 17.8 for GG ≥ 2 PCa, 36-44% of unnecessary prostate biopsies could be avoided while missing 4-12% of patients with GG ≥ 2 prostate cancer. **Conclusions:** This neural network risk model is a tool that can be used to inform the physician of a patient's risk of having GG ≥ 2 PCa on prostate biopsy. Using this novel test in the clinic is expected to significantly reduce the number and burden of unnecessary prostate biopsies. Prostate cancer public health system database from Brazil: Racial disparities and heterogeneity of treatment interventions to understand evidence-based practice patterns in a large real-world database. *First Author: Daniel Herchenhorn, University of California, San Diego (UCSD), San Diego, CA*

Background: The Brazilian Public National Health System (SUS) provides an opportunity to understand epidemiologic information, treatments, discrepancies in care, and costs of men with prostate cancer (PCa) using a large real-world dataset. This analysis focuses on racial disparities and heterogeneity of specific interventions to understand evidence-based practice patterns in Brazil. Additionally, the dataset can serve as a model for other low-middle income countries (LMIC). **Methods:** Patients included in the database were those with a diagnosis of PCa receiving care in the SUS from 01/01/2008 to 08/31/2022. Data were analyzed using a proprietary Healthcare Data Science platform offered by TECHTRIALS and included information regarding stage, demographics, cancer-related information, treatment-related information, and resources utilized. **Results:** 657,609 PCa pts were diagnosed and treated at SUS during the 14.5-year study period of whom 382,263 (58%) were brown/black (non-white) and 262,820 (42%) white. Median age of the population was 72.6 years, and did not vary with race. 26.16% of the pts were diagnosed with stage IV and this was not impacted by race or localization, including state or type of city (capital or not). Rates of radical prostatectomy and radiation utilization were similar between race categories. Additionally, in patients with stage IV disease, rates of systemic therapy utilization including chemotherapy with docetaxel (7.7%), with a tendency to increase use in the last years, and androgen receptor signaling inhibitors (ARSI) with (0.6%) or enzalutamide (0.08%), were low and similar between race categories. Rates of first-generation anti-androgens and estrogens were higher (56%) The total costs of prostate cancer directed care was R\$4.31 billions (US\$820 millions) and race did not impact total cost of care and cost by procedure or therapy type options. **Conclusions:** This is one of the largest studies using public health-system databases for Prostate cancer with Real World Data ever published. Race had no impact in presenting stage, treatment received and even in the costs involved. Underutilization of chemotherapy (docetaxel) in a scenario of limiting resources and without the use of new hormonal therapies is a matter of concern, together with an overuse of agents without proven survival advantage. Our data highlights the need for increased access to life prolonging agents for patients with metastatic PCa in the SUS. Research Sponsor: None.

Longitudinal transcriptome profiling of localized hormone-sensitive tumors in treatment-naïve ENACT patients with prostate cancer with and without enzalutamide (ENZA). *First Author: Ashley Ross, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: The ENACT trial (NCT02799745) randomized men with low- or intermediate-risk prostate cancer to 12 months of ENZA monotherapy followed by active surveillance (AS) for 12 months or to AS alone. Men were followed longitudinally, including by serial genome-wide expression profiling. Of 258 genomic signatures evaluated from baseline samples, increased Decipher genomic classifier score was prognostic for progression on AS; androgen receptor activity (AR-A) and PAM50 subtypes were associated with clinical benefit from ENZA, as previously reported. Here we present transcriptomic changes over time for men undergoing AS and those treated transiently with ENZA. **Methods:** Gene-expression profiling was performed via the Decipher GRID platform (Veracyte, Inc.) on 131 ENACT patient samples (ENZA, n=57; AS, n=74) collected at prespecified time points (screening, 12 months, and 24 months). Predefined GRID signatures were assessed for correlation with biological and clinical characteristics, including immune activity, treatment sensitivity, metastatic risk, and molecular subtypes. Statistical analysis was conducted by Cox proportional hazards models and logistic/linear regression; longitudinal changes were assessed by linear mixed-effects models. **Results:** Analysis of 12-month longitudinal samples showed significant transcriptomic changes in patients treated with ENZA, including markers of AR-A downregulation, decreased regulatory T-cell suppression, and increased immune activation. Many of the transcriptomic signature changes that occurred during ENZA treatment, including immune marker changes, were transient and returned to baseline values by 24 months following ENZA treatment discontinuation at 12 months. **Conclusions:** This exploratory biomarker analysis provides valuable data on transcriptomic changes in patients undergoing AS and those exposed to ENZA followed by cessation of treatment. Longitudinal analysis data provided insights into progression of early disease in the AS arm and possible strategies for extending ENZA activity beyond progression. Immune modulation with ENZA treatment may provide further insights for exploration of immunotherapy strategies. Clinical trial information: NCT02799745. Research Sponsor: This study was funded by Astellas Pharma Inc. and Pfizer Inc., the co-developers of enzalutamide, and by Veracyte, Inc.

Building a predictive model for outcomes with ¹⁷⁷Lu-PSMA-617 in patients with metastatic castration-resistant prostate cancer using VISION data: Preliminary results. *First Author: Ken Hermann, Department of Nuclear Medicine, West German Cancer Center, University Hospital Essen, University of Duisburg-Essen, Essen, Germany*

Background: ¹⁷⁷Lu-PSMA-617 is approved in adults with PSMA+ metastatic castration-resistant prostate cancer (mCRPC). This analysis of VISION data sought to build predictive models for clinical outcomes after ¹⁷⁷Lu-PSMA-617. **Methods:** In VISION, adults with PSMA+ mCRPC received ¹⁷⁷Lu-PSMA-617 (7.4 GBq every 6 weeks, ≤6 cycles) plus protocol-permitted standard of care (SoC) or SoC alone. In this *post hoc* analysis, 29 baseline parameters were assessed for prognostic and predictive value on overall survival (OS), radiographic progression-free survival (rPFS) and PSA response (≥50% reduction; PSA50). Parameters associated with outcome regardless of treatment were prognostic, and those associated with outcome after treatment with ¹⁷⁷Lu-PSMA-617+SoC vs SoC were predictive. Cox proportional hazards (OS and rPFS) or logistic regression (PSA50) models were used in univariate analyses for parameter selection and to build statistical models. Here, univariate analyses are presented. Multiplicity was corrected by use of q values (α = 0.05). **Results:** Data from 831 adults were analyzed. In initial univariate analyses, 76%, 69% and 38% of parameters assessed were prognostic for OS, rPFS and PSA50, respectively; fewer were predictive of better outcomes after ¹⁷⁷Lu-PSMA-617+SoC vs SoC (subset shown). **Conclusions:** Baseline prognostic and predictive parameters were identified for OS, as well as for rPFS and PSA50, in adults with mCRPC in VISION receiving ¹⁷⁷Lu-PSMA-617+SoC or SoC alone. For clinical application, select parameters will be reassessed categorically, and multivariate predictive models will be developed using identified parameters and parameter shrinkage. Research Sponsor: Advanced Accelerator Applications, a Novartis company.

AI-enabled analysis of H&E-stained prostate cancer tissue images: Assessing risk for metastasis prior to apalutamide (APA) treatment of patients with non-metastatic castration-resistant prostate cancer (nmCRPC). *First Author: Pooya Mobadersany, Janssen Research & Development, Cambridge, MA*

Background: Most prostate cancer patients (pts) treated with androgen deprivation therapy (ADT) for progressive disease will experience progression to CRPC. APA has been approved for the treatment of nmCRPC and metastatic castration sensitive prostate cancer (mCSPC). AI-enabled tools developed to predict oncological outcomes from digitized whole-slide images (WSIs) of H&E-stained tissues are a practical alternative to costly genomic testing tools that require sufficient tumor material. PathomIQ has developed the AI-enabled prognostic test PRAD-DX that predicts risk of metastasis from WSIs of H&E-stained core biopsies or radical prostatectomy specimens. It has been validated as a research tool on more than 2000 tissue samples across multiple institutions. The objective of this study is to evaluate PRAD-DX on predicting risk of metastatic progression using archived primary tumor samples from a randomized, double-blind, phase 3 trial in nmCRPC pts [1]. **Methods:** WSIs were collected from 471 pts (APA+ADT (n=315); placebo+ADT (n=156)), de-identified and anonymized prior to the AI analysis. Patient outcomes were blinded to the PathomIQ team. 35 pts were excluded due to lack of tumor or poor image quality; PRAD-DX scores were generated for 436 (93%) pts. The PRAD-DX test generated a risk score for each patient between 0 and 1, with higher values representing increased risk of metastasis. A pre-determined cut-off of 0.55 was previously developed to provide the best predictive accuracy and stratification with respect to time-to-metastasis on multiple clinical cohorts and was applied to this dataset. Kaplan-Meier analysis was performed on Metastasis-free-survival (MFS). **Results:** All pts receiving APA+ADT had improved outcomes compared with pts receiving ADT alone, independent of PRAD-DX risk score category. 53% of pts had high PRAD-DX scores and significantly benefited from treatment with APA+ADT compared to placebo+ADT with regard to MFS (hazard ratio, 0.19; 95% CI, 0.1 – 0.37; P<0.005). 47% were assigned low PRAD-DX risk; also in this cohort, treatment with APA+ADT resulted in a significantly improved MFS (hazard ratio, 0.39; 95% CI, 0.17 – 0.86; P=0.02). **Conclusions:** These results indicate that PRAD-DX score derived from AI-powered image analysis could be used as a biomarker to identify pts at highest risk of metastatic progression in the nmCRPC setting. Although, there are limitations related to sample size, this may have significant impact in identifying pts for informed clinical trial patient selection based on their individual risk profile for development of novel therapies. 1) Smith MR, Saad F, Chowdhury S, et al. *N Engl J Med.* 2018;378(15):1408-1418. doi:10.1056/NEJ-Moa1715546. The performance of prostate specific antigen (PSA) testing in the population based NPCC cohort. *First Author: Jan Oldenburg, Department of Oncology, Akershus University Hospital (Ahus), Lørenskog, Norway*

Background: Prostate cancer (PCa) screening using prostate-specific antigen (PSA) is controversial. Benign prostate hyperplasia increases PSA in aging men independent of PCa such that PSA's test performance differs between younger and older men. Age-specific cut-off values might therefore be advisable. The large Norwegian Prostate Cancer Consortium (NPCC) database might be able to contribute with clinically relevant information on age-specific PSA cut-off values. **Methods:** The Norwegian Prostate Cancer Consortium (NPCC) collected 8 857 761 PSA tests from 1.291.151 men. Results were linked with the date of diagnosis and grade of PCa. Analyses were restricted to men aged 45-75 years. PSA results were grouped into two groups: PCa negative vs PCa positive. The PCa negative group comprised PSA measurements from 2005 to 2015 men being alive and without PCa diagnosis five years after PSA measurement, in total 1 775 986 PSA measurements from 533 216 men. The PCa positive group comprised PSA measurements from 2005 to 2020 of men diagnosed with PCa during this period. PCa diagnoses at autopsy, as incidental finding at cystectomy, with metastases or with PSA > 50 ng/ml were excluded, in total 242 874 PSA measurements from 48 659 men with PCa. Sensitivity, specificity, area under the curve (AUC) as well as top decile and proportion of PCa in the top decile were calculated. **Results:** For men of 50 years of age, PSA at a threshold of 3 ng/ml yielded a sensitivity and specificity of ~ 95%. In 70-74-year-old men, a 3 ng/ml PSA threshold resulted in a 95% sensitivity but declining specificity of 70%. Maintaining specificity requires increasing PSA cut-off values to 4.5, 6, 7 and 8 ng/ml for men aged 55-59, 60-64, 65-69 and 70-74 years, respectively. The increasing cut-off values for the top PSA decile as well as the decreasing proportion of PCa within the top decile are in line with a declining AUC in older men. **Conclusions:** PSA test performance declines with increasing age. PCa screening in well-informed men should take into account age adjusted PSA cut-off values. Research Sponsor: None.

Age, years	# Prostate Cancer negative	# Prostate Cancer positive	Sensitivity (95%) PSA, ng/ml	Specificity (95%) PSA, ng/ml	AUC	Top Decile PSA, ng/ml	Percent of Cancers in the Top Decile
45-49	65,870	743	2.07	2.40	0.970	>1.80	98%
50-54	98,385	2 476	2.60	3.30	0.962	>2.35	98%
55-59	106,115	6 536	3.11	4.55	0.951	>3.21	96%
60-64	107,346	11 620	3.26	5.96	0.931	>4.20	94%
65-69	95,969	15 159	3.03	7.00	0.907	>5.05	89%
70-74	59,531	17 776	2.30	7.90	0.867	>5.77	77%

Predicting absolute benefit in risk of metastasis of androgen deprivation therapy added to radiation therapy in patients with newly diagnosed prostate cancer using Prolaris. *First Author: Jonathan David Tward, Hunstman Cancer Institute at the University of Utah, Salt Lake City, UT*

Background: Most patients would defer using androgen deprivation therapy (ADT) with radiation therapy (RT) when the number-needed-to-treat (NNT) exceeds 25 persons to prevent 1 from developing metastasis, corresponding to an absolute benefit of 4%.¹ However, no tools for estimating personalized NNT or absolute benefit from ADT exist. We aimed to quantify personalized absolute benefit and NNT for persons receiving ADT added to single modality RT. **Methods:** The clinical cell-cycle risk (CCR) score combines the University of California, San Francisco's Cancer of the Prostate Risk Assessment and the cell cycle progression molecular score to accurately assess prostate cancer aggressiveness. The effect of ADT added to RT was modeled using a 10-year risk of metastasis as a function of continuous CCR score for patients treated with RT alone. The relative benefit of ADT added to RT to reduce distant metastasis was modeled using published data from The Meta-Analysis of Randomized trials in Cancer of the Prostate (MARCAP) which utilized several prospectively randomized RT±ADT trials.² The average absolute benefit was calculated for patients with CCR scores above and below a prespecified multimodality treatment threshold (MTT) using the distribution of scores in a cohort of patients commercially tested by Myriad Genetics. **Results:** The commercially tested cohort consisted of 56,485 patients spanning all National Comprehensive Cancer Network risk categories (33.7% very low/low risk, 29.8% favorable intermediate risk, 25.6% unfavorable intermediate risk, 11.0% high/very high risk), with 87.2% having CCR scores at or below the MTT and 12.7% with CCR scores above the threshold. The average absolute benefit of ADT treatment was 0.86% (NNT=116) for patients with CCR scores below the MTT and 8.2% (NNT=12) for patients with CCR scores above the MTT. Patients with CCR scores at precisely the MTT had a predicted absolute benefit of 3.7% (NNT=27). **Conclusions:** The Prolaris test can accurately predict an individual's benefit of adding ADT to RT, and the risk threshold is consistent with patient attitudes about when to use or omit ADT. 1. Sequential metastasis-directed therapy (MDT) for oligometastatic prostate cancer (Oligo PCa) assessed by PET-based imaging. *First Author: Alberto Carretero-González, Medical Oncology Department, Hospital Universitario 12 de Octubre, Madrid, Spain*

Background: Prostate specific membrane antigen (PSMA) and F-18-Fluciclovine PET imaging have high sensitivity for the detection of prostate cancer (PCa) metastases. MDT with stereotactic body radiation therapy (SBRT) to PET-detected Oligo PCa has been shown to improve progression free survival (PFS) and delay androgen deprivation therapy (ADT). However, in those patients (pts) who ultimately develop oligoprogressive disease following MDT, the utility of subsequent courses of MDT has not been well defined. **Methods:** A single institution retrospective review was undertaken to describe outcomes following ≥2 courses of PET-guided SBRT in pts with Oligo PCa. Pts included in this analysis had undergone initial SBRT for ≤5 PCa lesions detected on PSMA or Fluciclovine PET, and subsequently underwent ≥1 additional course of SBRT at progression. Baseline data collected included stage, PSA level, Gleason Score, tracer type, and concurrent systemic therapy. Endpoints collected for each SBRT course included PSA decline ≥50% (PSA50), PFS, and systemic therapy change free survival (RxFs) (initiation of ADT, or for pts already on ADT, addition of an androgen signaling inhibitor). Association of factors with PFS after SBRT2 were analyzed using multivariable Cox proportional-hazards models. **Results:** 34 pts underwent ≥2 courses of MDT (SBRT1, SBRT2). At SBRT2, progression was identified by PSMA-PET in 26 (77%) pts, and by Fluciclovine-PET in 8 (23%). With SBRT2, 18 (53%) had a concurrent systemic therapy change; 10 (29%) did not receive any systemic therapy. 12 pts subsequently underwent SBRT3. Progression was detected by PSMA PET in 9 (75%) and Fluciclovine PET in 3 (25%). Clinical outcomes are summarized in the table. In the multivariable analysis, predictors associated with PFS following SBRT2 were 1) PSA decline at SBRT1 (HR 1.10, 95% CI 1.05-1.16, P<0.001) and 2) PSA doubling time (PSADT) <12 months at the time of SBRT2 (HR 11.52, 95% CI 1.36-97.38, P=0.025). Overall, from SBRT1 to last follow-up (median 25.2 months), 23 (68%) pts remained ADT-free (14 after SBRT2; 9 after SBRT3). **Conclusions:** Serial MDT for Oligo PCa detected on PSMA or Fluciclovine PET is feasible and results in PSA declines, independent of change in systemic therapy. There is a persistent but diminishing benefit of MDT over successive courses. Overall, 2/3 of pts were able to postpone the use of ADT. PSA decline at SBRT1 and PSADT at SBRT2 may be biomarkers for SBRT2 benefit. Despite the retrospective nature of this study and cohort heterogeneity, these data provide a rationale for serial SBRT in Oligo PCa, and the need for larger, prospective studies of this strategy. Research Sponsor: None.

	% patients with CRPC at SBRT	PSA50	PFS	RxFs
SBRT1	21%	28/34 (82%)	19.9 mo	40.9 mo
SBRT2 (n = 34)	35%	22/34 (65%)	10.1 mo	9.2 mo
SBRT3 (n = 12)	42%	8/12 (67%)	6.3 mo	8.9 mo

Prevalence of mismatch repair deficiency in a large prospective prostate cancer cohort. *First Author: Ciara S. McNevin, St James Hospital, Dublin 8, Ireland*

Background: Mismatch repair (MMR) deficiency and microsatellite instability (MSI) are predictive biomarkers for immunotherapy response. The best approach to identify patients with such tumors is unclear in prostate cancer. **Methods:** This study included men diagnosed with primary prostate cancer during prospective follow-up of the Health Professionals Follow-up Study (HPFS) and Physicians' Health Study (PHS). The highest-grade/index lesions of tumor tissue from radical prostatectomy (95%) or transurethral resections of the prostate were mounted in triplicate on tissue microarrays. Immunohistochemistry for the MMR proteins MLH1, MSH2, MSH6, and PMS2 was performed, with scoring as MMR-deficient requiring a visible staining in a non-tumor internal positive control of the same case. For validation, a polymerase chain reaction-based MSI assay (Idylla MSI Test, Biocartis) was performed on tumor DNA of MMR-deficient cases and a selection of MMR-intact cases. **Results:** The study included 1016 men with prostate cancer. Tumor stage was predominantly pathologically localized (71% stage pT1/2, 18% T3a/b) with a full distribution of Gleason scores, including 20% Gleason score 6 (grade group 1), 36% 3+4 (grade group 2), 23% 4+3 (grade group 3), 8% 8 (grade group 4) and 13% 9-10 (grade group 5). MMR tumor scoring could be performed for MLH1 in 747 cases (75% of those with tumor tissue), for MSH2 in 903 cases (90%), for MSH6 in 708 cases (74%), and for PMS2 in 703 cases (72%). The remaining tumors were unevaluable due to lack of non-tumor tissue necessary as an internal positive control. Of the 903 tumors evaluable for MSH2 protein loss, 4 tumors had loss of MSH2 (prevalence 0.4%, 95% confidence interval [CI] 0.2-1.1%), and 3 of 708 evaluable tumors had concomitant loss of MSH6 (prevalence 0.4%, 95% CI 0.1-1.2%). No tumor had loss of MLH1 or PMS2. The MMR-deficient tumors had Gleason scores of 3+4, 8 (two cases), and 9-10. Tumor DNA of 1 of the 4 MMR-deficient tumors met the manufacturer's cut-off for MSI-high; two additional MMR-deficient cases had non-zero repeats, with good reproducibility between tumor cores and technical replicates. One MSH2-deficient tumor and 6 DNA samples from 3 MMR-intact cases had repeat scores of zero. **Conclusions:** In this nationwide prospective study, MMR deficiency was rare in primary, surgically treated prostate cancer. This low prevalence contrasts with hospital-based studies of MMR deficiency and MSI that may have represented tumors with certain clinical features. The low prevalence and the need for an internal positive control for reliable scoring calls into question to what extent immunohistochemistry-based screening for MMR deficiency on limited tissue specimens, such as prostate biopsies, is routinely feasible.
