Letter From the Editors

The *2023 ASCO Annual Meeting Abstracts* (a supplement to *Journal of Clinical Oncology*) is an enduring record of the more than 2,900 abstracts selected by the ASCO Scientific Program Committee for presentation as part of the ASCO Annual Meeting.

Abstracts can be accessed online through the ASCO Meeting Experience (asco.org/abstracts). Online abstracts include the full list of abstract authors and their disclosure information. To download a PDF of the full abstract supplement and/or the presented abstracts by track, visit conferences.asco.org/am/abstracts-posters.

Publication-only abstracts are included in the online supplement to the June 1 issue of *Journal of Clinical Oncology* at JCO.org and are also available online at asco.org/abstracts.

All abstracts carry *Journal of Clinical Oncology* citations, for example:

J Clin Oncol 41:16s, 2023 (suppl; abstr 500).

We are excited to promote and increase awareness of *JCO Meeting Abstracts* publication through social media,

specifically to increase awareness of less publicized, yet important research. We continue to partner with JCO to curate abstract collections for publication on JCO.org and promote collections via Twitter. For the *2023 ASCO Annual Meeting* the collections will reflect the presidential theme of partnering with patients through cancer care and research and will include de-escalation of therapy, patient reported outcomes, personalized cancer medicine, and improving patient health equity in addition to highlighting our merit awardees. Follow us on Twitter @JCO_ASCO, @ASCO, #ASCO23!

Should you have any questions or comments about this publication, we encourage you to provide feedback by contacting us at abstracts@asco.org.

Sincerely,

Pamela L. Kunz, MD
ASCO Meeting Abstracts Editor,
Journal of Clinical Oncology

Ryan D. Gentzler, MD, MS

ASCO Abstracts Policy

Public Release of Abstracts

The 2023 ASCO Annual Meeting Regular Abstracts were publicly released by ASCO at 5:00 PM EDT on Thursday, May 25, 2023. Abstracts are publicly available online at asco.org/abstracts. Late-Breaking Abstracts, which include all Plenary Abstracts, will be publicly released according to the following schedule:

- Late-Breaking Abstracts presented in a scientific presentation on Friday, June 2, will be publicly released Friday, June 2, at 8:00 AM EDT.
- Late-Breaking Abstracts presented in a scientific presentation on Saturday, June 3, will be publicly released Saturday, June 3, at 8:00 AM EDT.
- Late-Breaking Abstracts presented in a scientific presentation on Sunday, June 4, will be publicly released Sunday, June 4, at 8:00 AM EDT.
- Late-Breaking Abstracts presented in a scientific presentation on Monday, June 5, will be publicly released Monday, June 5, at 8:00 AM EDT.
- Late-Breaking Abstracts presented in a scientific presentation on Tuesday, June 6, will be publicly released Tuesday, June 6, at 8:00 AM EDT.

In the unlikely event that ASCO publicly releases an abstract in advance of the scheduled time, the release will be publicly announced on <https://conferences.asco.org/am/abstract-policies-embargoes-exceptions>.

Conflict of Interest Disclosure

All financial relationships reported by contributors to this activity are provided to learners prior to the start of the activity. During planning and development of the activity, relevant financial relationships were mitigated for all contributors. Relationships are considered self-held and compensated unless otherwise noted (I = Immediate family member; Inst = My Institution). Disclosures are submitted per the ASCO Policy for Relationships with Companies.

LBA1**Plenary Session**

INDIGO: A global, randomized, double-blinded, phase 3 study of vorasidenib versus placebo in patients with residual or recurrent grade 2 glioma with an IDH1/2 mutation. *First Author: Ingo K. Mellinghoff, Memorial Sloan Kettering Cancer Center, New York, NY*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2023, issue of the *Journal of Clinical Oncology*.

LBA2**Plenary Session**

PROSPECT: A randomized phase III trial of neoadjuvant chemoradiation versus neoadjuvant FOLFOX chemotherapy with selective use of chemoradiation, followed by total mesorectal excision (TME) for treatment of locally advanced rectal cancer (LARC) (Alliance N1048). *First Author: Deborah Schrag, Memorial Sloan Kettering Cancer Center, New York, NY*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2023, issue of the *Journal of Clinical Oncology*.

LBA3**Plenary Session**

Overall survival analysis from the ADAURA trial of adjuvant osimertinib in patients with resected EGFR-mutated (EGFRm) stage IB–IIIA non-small cell lung cancer (NSCLC). *First Author: Roy S. Herbst, Medical Oncology, Yale School of Medicine and Yale Cancer Center, New Haven, CT*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2023, issue of the *Journal of Clinical Oncology*.

LBA4**Plenary Session**

SWOG S1826, a randomized study of nivolumab(N)-AVD versus brentuximab vedotin(BV)-AVD in advanced stage (AS) classic Hodgkin lymphoma (HL). *First Author: Alex Francisco Herrera, City of Hope National Medical Center, Duarte, CA*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2023, issue of the *Journal of Clinical Oncology*.

LBA100

Clinical Science Symposium

KEYNOTE-671: Randomized, double-blind, phase 3 study of pembrolizumab or placebo plus platinum-based chemotherapy followed by resection and pembrolizumab or placebo for early stage NSCLC. *First Author: Heather A. Wakelee, Department of Medicine, Division of Oncology, Stanford University, Stanford Cancer Institute, Stanford, CA*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2023, issue of the *Journal of Clinical Oncology*.

Clinical Science Symposium

The impact of response-directed surgery and adjuvant therapy on long-term survival after neoadjuvant ipilimumab plus nivolumab in stage III melanoma: Three-year data of PRADO and OpACIN-neo. *First Author: Irene L.M. Reijers, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Neoadjuvant ipilimumab (IPI) + nivolumab (NIVO) has been shown to induce high pathologic response rates associated with an excellent relapse-free survival (RFS) in high-risk stage III melanoma. While OpACIN-neo tested different neoadjuvant IPI + NIVO regimens followed by therapeutic lymph node dissection (TLND) without adjuvant systemic therapy (ST), PRADO tested a personalized approach. In patients (pts) achieving a major pathologic response (MPR; $\leq 10\%$ viable tumor), TLND and adjuvant ST were omitted, and pts with pathologic non-response (pNR; $>50\%$ viable tumor) were treated with adjuvant ST (BRAF/MEKi or anti-PD1) $\pm$ radiotherapy after TLND. Here, we address 1) whether omitting TLND in MPR pts had an adverse effect on long-term survival and 2) whether adding adjuvant ST in pNR pts had a favorable effect on survival. **Methods:** The 3-year (3y) RFS and distant metastasis-free survival (DMFS) of pts with MPR and pNR from PRADO and OpACIN-neo were analyzed, comparing MPR pts with TLND versus without TLND and pNR pts with adjuvant ST versus without adjuvant ST. Survival rates were calculated and compared with Kaplan-Meier and log-rank methods. Associations between baseline characteristics and RFS or DMFS were examined by Cox regression analysis. **Results:** Median follow-up was 37.9 months in PRADO (cutoff Jan 8, 2023) and 46.8 months in OpACIN-neo (cutoff Feb 14, 2022). For MPR pts, TLND omission did not affect survival, with a 3y RFS of 93% versus 96% ($p=0.47$) and 3y DMFS 98% versus 98% ($p=0.92$) for pts without TLND ($n=59$) versus with TLND ($n=53$), respectively. In pNR pts, an indication for a RFS and DMFS benefit was seen favoring pts with adjuvant ST ($n=17$: $n=10$ BRAF/MEKi and $n=7$ anti-PD1) over pts without adjuvant ST ($n=23$), with 3y RFS rates being 64% versus 35% ($p=0.10$) and 3y DMFS rates 70% versus 52% ($p=0.24$). Baseline clinical characteristics did not differ between PRADO and OpACIN-neo pts or were not associated with RFS and DMFS. **Conclusions:** Omitting TLND in MPR pts after neoadjuvant IPI + NIVO seems not to affect RFS/DMFS. Given the high survival rates, adjuvant ST is unlikely to give further benefit in these pts. In pts with pNR, addition of adjuvant ST with ongoing anti-PD1 or switch to BRAF/MEKi appears to improve RFS and DMFS. Clinical trial information: NCT02977052. Research Sponsor: BMS.

3y rates	Personalized	Non-personalized	p-value
MPR pts (n=112)	No TLND (n=59)	TLND (n=53)	
RFS	93%	96%	0.47
DMFS	98%	98%	0.92
pNR pts (n=40)	Adjuvant ST (n=17)	No adjuvant ST (n=23)	
RFS	64%	35%	0.10
DMFS	70%	52%	0.24

Clinical Science Symposium

Biomarkers predicting response to 5 immunotherapy arms in the neoadjuvant I-SPY2 trial for early-stage breast cancer (BC): Evaluation of immune subtyping in the response predictive subtypes (RPS). *First Author: Denise M. Wolf, University of California San Francisco, San Francisco, CA*

Background: Previously, we showed that in our first PD1-inhibitor (PD1-inh) arm of I-SPY2, pCR associates with high STAT1/chemokine/dendritic signatures in TN and with high B-cell/low mast cell in HR+. From these results, we defined a research-grade Immune classifier incorporated into the RPS (PMID: 35623341), a schema designed to increase pCR if used to prioritize treatment. A clinical-grade version of the Immune (ImPrint) and other RPS biomarkers are now used in I-SPY2.2. Here we evaluate immune markers in 5 Immune-Oncology (IO) therapy arms (2 PD1-inh, 2 PD1-inh combinations, and 1 PDL1-inh combination). **Methods:** 343 patients with HER2-negative BC with information on pCR and mRNA in 5 IO arms ($n=60-72$ pts) plus controls (Ctr: 343) were considered. 32 continuous markers including 30 immune (7 checkpoint genes, 14 immune cell, 3 T/B-cell prognostic, 1 TGFB and 5 tumor-immune) and ESR1/PGR and proliferation signatures, were assessed for association with pCR using logistic regression. p-values were adjusted using the Benjamini-Hochberg method (BH $p<0.05$). Correlations to multiplex immunofluorescence (mIF) data from our initial arm (immune cell and spatial proximity markers) were calculated. Performance of ImPrint, developed with Agendia Inc, was characterized overall and within HR subsets. **Results:** A larger number of the research-grade immune markers predict response to IO in HR+ than in TN, with the most for HR+ in combination-IO arms (27/32 biomarkers). Tumor-immune signatures dominated by chemokines/cytokines were most consistently associated with pCR across IO arms and across receptor status. Moreover, we found that these markers correlate to mIF spatial proximity measures reflecting high spatial co-localization of PD1+ immune and PDL1+ tumor cells, in TN especially ($r=0.59$; $p=0.003$). The ImPrint classifier was evaluated in the IO arms. In HR+, 28% were ImPrint+, and pCR rates were 76% in ImPrint+ vs. 16% in ImPrint-. In TN, 46% were ImPrint+, and pCR rates were 75% in ImPrint+ and 37% in ImPrint-. Overall (HR+ and TN, in all IO arms), pCR rates were 75% in ImPrint+ and 23% in ImPrint-. Performance varied by arm, with the highest pCR rates for HR+/ImPrint+ $>90\%$; and for TN/ImPrint+ $>81\%$. In contrast, pCR rates in the control arm were 34% for ImPrint+ (HR+:33%; TN: 34%) and 13% for ImPrint- (HR+: 21%; TN:8%). **Conclusions:** Tumor-immune signaling signatures predict response for IO drug class in both TN and HR+HER2-. The ImPrint single-sample classifier predicts response to a variety of IO regimens in both subsets and may inform prioritization of IO vs other treatments and best balance likely benefit vs risk of serious immune-related adverse events. Clinical trial information: NCT01042379. Research Sponsor: QLHC.

103

Clinical Science Symposium

Friendly-user score assessing gut dysbiosis and resistance to immune checkpoint inhibitors (ICI). *First Author: Lisa Derosa, Gustave Roussy Cancer Campus, Villejuif, France*

Background: Accumulating evidence pointed to the impact of the intestinal microbiota on ICI outcomes across various cancers. Although specific gut microbial species have been associated with beneficial responses (*i.e. Akkermansia muciniphila* (Akk)), no consensus exists on a gut fingerprint predicting immunoresistance to clinical routine use. **Methods:** NCT04567446 provided whole genome sequencing (WGS) of longitudinal fecal samples from patients (pts) with advanced non-small cell lung cancer (NSCLC) during ICI (alone or with chemotherapy) in France and Canada. Topological Pearson networks clustered into species interacting groups (SIG) correlating with overall survival (OS; $OS<12=NR$; $OS>12=R$). Forty harmful (SIG1) and thirty-four beneficial (SIG2) WGS species were associated with NR and R to ICI. A monodimensional score (TOPOSCORE) based on SIG1/SIG2 ratio combined with Akk relative abundance was calculated and compared to machine-learning (ML) algorithms. Multivariate Cox analysis (MVA) adjusted for established risk factors (ATB, gender, age, ECOG, PD-L1, LIPI score). Intraindividual dynamics of the TOPOSCORE was evaluated in pts with at least two fecal samples. Three independent cohorts of NSCLC and genitourinary (GU) cancers pts validated the data. **Results:** In $n=245$ and $n=148$ NSCLC pts, we could classify pts into dysbiotic (SIG1+,33%) and eubiotic (SIG2+, 67%), using the TOPOSCORE. Pts falling within the SIG2+ exhibited a significantly prolonged OS than pts falling into SIG1+ (HR: (95% CI), 0.50 (0.36-0.71), $p<0.0001$). TOPOSCORE also predicted OS in 277 ICI-treated NSCLC and GU pts and compared to the state-of-the-art ML algorithms, held the highest percentage of correct predictions (63%). At MVA, TOPOSCORE was independently associated with OS (HR: 0.56 (0.39-0.81), $p=0.002$). Analyzing the intraindividual dynamics of the TOPOSCORE ($n=67$), we found that 74% of SIG2+ and 68% of SIG1+ individuals remained in their initial classification during ICI treatment. We finally scaled the calculation of the TOPOSCORE down to 24WGS (instead 75WGS) and set up a qPCR-based friendly-user test capable of accurately identifying the fecal presence of the bacteria of interest within 48 hrs. We confirmed ($n=323$) that OS was superior in those pts harboring a 24-bacteria-qPCR-based TOPOSCORE falling within the SIG2+ category (HR: 0.65 (0.48 to 0.87), $p=0.0005$). **Conclusions:** TOPOSCORE represents a robust biomarker predicting and following the dynamic of the immunoresistance to ICI across cancers on an individual basis. By converting the WGS TOPOSCORE to a qPCR-based test with a rapid turnaround time, it will be possible to adopt this score in routine clinical practice to improve pts stratification and ICI success rates guiding the selection of dysbiotic pts amenable to microbiota-centered interventions and eubiotic fecal microbiota transplantation donors. Clinical trial information: NCT04567446. Research Sponsor: None.

Clinical Science Symposium

Effect of CBM588 in combination with cabozantinib plus nivolumab for patients (pts) with metastatic renal cell carcinoma (mRCC): A randomized clinical trial. *First Author: Hedyeh Ebrahimi, City of Hope Comprehensive Cancer Center, Duarte, CA*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2023, issue of the *Journal of Clinical Oncology*.

105

Clinical Science Symposium

Fecal microbiota transplantation combined with anti-PD-1 inhibitor for unresectable or metastatic solid cancers refractory to anti-PD-1 inhibitor. *First Author: Sook Ryun Park, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: The gut microbiome is emerging as a key regulator of the immune system during immunotherapy. However, the effect of modulating the gut microbiome in patients (pts) with cancer refractory to immunotherapy remains largely unknown. We aimed to evaluate whether the fecal microbiota transplantation (FMT) could help overcome resistance in pts with advanced solid cancer refractory to anti-PD-(L)1 inhibitors and identify specific commensal bacteria that contribute to the efficacy of FMT (NCT04264975). **Methods:** This is a prospective, single-arm clinical trial of FMT plus anti-PD-(L)1 inhibitor in pts with advanced solid cancer refractory to anti-PD-(L)1 inhibitors. The key eligibility criteria for donors included ongoing durable complete or partial response ≥ 6 months with anti-PD-(L)1 monotherapy for advanced solid tumors. FMT was performed using colonoscopy, followed by continuation or reintroduction of anti-PD-(L)1 inhibitor until unacceptable toxicity or disease progression. Repeated FMT from the same or different donors was allowed. **Results:** From Jan. 2019 to Aug. 2020, 13 pts with metastatic gastric cancer (GC) (n=4), esophageal squamous cell carcinoma (ESCC) (n=5), and hepatocellular carcinoma (HCC) (n=4) were enrolled; male (77%), median age=60 yrs (range, 38-76), and median line of prior systemic therapy=3 (range, 2-5). All had confirmed disease progression on nivolumab monotherapy with primary (46.2%) or secondary resistance (53.8%), and underwent FMT with continued nivolumab. There were six FMT donors (HCC [n=4], GC [n=1], ESCC [n=1], who had maintained (CR; n=4) or (PR; n=2) with nivolumab or pembrolizumab monotherapy. Of the 13 recipients, five showed SD and one achieved PR after FMT with a disease control rate of 46.2% (6/13) and an objective response rate of 7.7% (1/13). Recipient #7 (R7), who had metastatic HCC with primary resistance to nivolumab, initially showed PD to the 1st FMT from donor #1, but achieved PR after the 2nd FMT from donor #5. Clinical response was accompanied by an increase in levels of cytotoxic T cells in the blood and tumor microenvironment, immune cytokines, and the relative abundance of a new species derived from donor #5 showing 97% whole genome nucleotide sequence similarity with *Prevotella* sp. Marseille-P4119. We isolated this species from feces of R7 and preclinical experiments showed that treatment with this species activated human CD4+ and CD8+ T cells with increased IFN- γ secretion, and suppressed tumor growth in a syngeneic mouse model by enhancing tumor infiltration of cytotoxic T cells. Moreover, the combination treatment with anti-PD-1 and this species reduced the tumor volume more than with anti-PD-1 alone. **Conclusions:** FMT containing the effective microbiota could overcome resistance to anti-PD-1 inhibitor by modulating the tumor microenvironment in advanced solid cancer pts. Clinical trial information: NCT04264975. Research Sponsor: grants from National Cancer Centre, Korea (NCC-1911267); a grant (2018-0608) from the Asan Institute for Life Sciences, Asan Medical Center, Korea.

Oral Abstract Session

Efficacy and safety results by age in monarchE: Adjuvant abemaciclib combined with endocrine therapy (ET) in patients with HR+, HER2-, node-positive, high-risk early breast cancer (EBC). *First Author: Erika P. Hamilton, Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN*

Background: Adjuvant abemaciclib (a CDK4 & 6 inhibitor) combined with ET demonstrated a sustained benefit in invasive disease-free survival (IDFS) and a tolerable safety profile in patients (pts) with HR+, HER2-, node-positive, high-risk EBC. Almost half of the newly diagnosed breast cancers occur in women older than 65 years. Older pts often have a higher incidence of comorbidities and increased risk for toxicities. Here, we report efficacy and safety by age subgroups in monarchE to help guide management of older pts receiving adjuvant abemaciclib. **Methods:** Pts were randomized (1:1) to receive ET for up to 10 years +/- abemaciclib for 2 years (study treatment period). Efficacy in IDFS and distant relapse-free survival (DRFS) was assessed in the intent-to-treat population by the pre-specified age groups of <65 and ≥65 years, with hazard ratios (HR) estimated using unstratified Cox proportional hazard model within each subgroup. Safety was evaluated among older pts (≥65 years) in two subgroups; 65-74 and ≥75 years. **Results:** In monarchE (NCT03155997), 4787 pts (84.9%) were aged <65 years and 850 pts (15.1%) were ≥65 years. At median follow-up of 42 months, a numerically favorable IDFS effect was observed in both the <65 (270 vs 414 events; HR = 0.646, 95% CI: 0.554, 0.753) and ≥65 (66 vs 85 events; HR = 0.767, 95% CI: 0.556, 1.059) groups for abemaciclib + ET vs ET alone. Similar findings were observed in DRFS. Older pts (≥65 years) had ~5% higher incidence of grade ≥3 adverse events (AEs) than younger pts, mainly diarrhea and fatigue. Neutropenia was not increased among older pts and similarly, venous thromboembolic events occurred at similar rates (≥65 years, 3.0%; <65 years, 2.5%). Serious AEs (SAEs) and treatment discontinuations due to AEs were more common in older pts. Older pts required more dose reductions to manage AEs. **Conclusions:** In pts with high-risk EBC, adjuvant abemaciclib + ET showed treatment benefit across age subgroups with a manageable safety profile. Older pts did have higher rates of AEs and discontinuations, especially those older than 75 years, suggesting that more frequent surveillance with early intervention may be key to the management of these pts. Clinical trial information: NCT03155997. Research Sponsor: Eli Lilly and Company.

Oral Abstract Session

Detection of circulating tumor DNA following neoadjuvant chemotherapy and surgery to anticipate early relapse in ER positive and HER2 negative breast cancer: Analysis from the PENELOPE-B trial. *First Author: Nicholas C. Turner, The Institute of Cancer Research, Royal Cancer Hospital, London, United Kingdom*

Background: The PENELOPE-B phase III trial investigated the addition of one year of palbociclib to endocrine therapy (ET), in patients with hormone receptor positive HER2 negative breast cancer with residual invasive disease after neoadjuvant chemotherapy. Prior research has demonstrated that detection of circulating tumor DNA (ctDNA) in the adjuvant setting is associated with a high risk of disease relapse. We assessed the potential of ctDNA analysis to predict future clinical relapse for patients enrolled in the PENELOPE-B trial. **Methods:** Patients who were endocrine naïve at the time of study entry were selected for ctDNA analysis. Plasma samples were collected at baseline (after completion of neoadjuvant chemotherapy and surgery), prior to cycle 7 (approximately 6 months into ET +/- palbociclib), end of treatment (EOT), and progressive disease. A tumor sample was subjected to exome sequencing, and up to 50 tumor somatic mutations were tracked in plasma using error-corrected sequencing combined with a proprietary algorithm for ctDNA detection (RaDaR assay). Detection of ctDNA was associated with invasive disease-free survival (IDFS) and distant metastasis-free survival using Cox proportional hazard models. **Results:** Of 1250 patients enrolled in PENELOPE-B, 129 were endocrine naïve at trial entry, and 78 had a baseline ctDNA sample analyzed. The ctDNA analysis group was representative of the overall endocrine naïve group, with median follow-up of 42.9 months. Seven patients had baseline ctDNA detected, with detection strongly associated with iDFS (HR 8.8, 95% CI 3.3-23.4, p < 0.0001). Detection of ctDNA at cycle 7 (4 patients) was also strongly associated with iDFS (HR 25.5, 95% CI 6.5-99.6, p < 0.0001). Of the 7 patients with baseline ctDNA detection, 2 had undetectable ctDNA at cycle 7 and remained progression free at 30 months, although one later relapsed; the 3 patients with detectable ctDNA at cycle 7 all relapsed within 25 months. Of the 12 patients with a distant relapse within 24 months, only 4 had ctDNA detected at baseline and 3 first at cycle 7/EOT. Of the 8 patients with distant relapse after 24 months, 2 had ctDNA detected at baseline and none first at cycle 7/EOT. **Conclusions:** Detection of ctDNA following neoadjuvant chemotherapy, and surgery, is associated with a very high risk of early relapse suggesting limited efficacy of adjuvant ET. Clinical imaging and studies of experimental therapy are warranted in this patient population. Testing ctDNA after recent neoadjuvant chemotherapy in luminal-A like breast cancer has relatively low 'sensitivity' for predicting future relapse, in particular for later relapses, in part suggesting that response to neoadjuvant chemotherapy may reduce ctDNA detection. Clinical trial information: NCT01864746. Research Sponsor: Pfizer.

Oral Abstract Session

Effects of ovarian ablation or suppression on breast cancer recurrence and survival: Patient-level meta-analysis of 14,993 pre-menopausal women in 25 randomized trials. *First Author: Richard G. Gray, University of Oxford, Oxford, United Kingdom*

Background: Suppressing ovarian function of women with breast cancer may improve outcome by preventing estrogenic stimulation of any residual cancer, particularly for pre-menopausal women with estrogen receptor (ER)-positive tumors. We report a collaborative meta-analysis of individual participant data from randomized trials of ovarian ablation or suppression. **Methods:** Data were sought from randomized trials that compared ovarian ablation or suppression versus not. Primary analyses included only pre-menopausal women aged < 55 with ER-positive or unknown tumors, stratified into those who received no chemotherapy, or remained premenopausal following chemotherapy, and those whose menopausal status following chemotherapy was not ascertained. Standard log-rank methods estimated ER-weighted annual event rate ratios (RR). **Results:** Individual patient data were provided for 25 of 27 relevant trials, comprising 14,993 (98.7%) of 15,195 women randomized. Overall, fewer breast cancer recurrences were seen with ovarian ablation/suppression than control (RR = 0.82, 95%CI 0.77-0.88; p < 0.0001). Recurrence reductions were significantly (p = 0.0003) larger among women (n = 7,213) known to be premenopausal prior to ovarian suppression (RR = 0.70, 0.63-0.78; p = 0.0003) than among those (n = 7,786) whose menopausal status was uncertain after chemotherapy (RR = 0.91, 0.83-0.99; p = 0.03). For known premenopausal women, 15-year risk of recurrence was improved by 12.1% (28.9% vs 41.0%; p < 0.0001). 15-year breast cancer and all-cause mortality were improved by 8.0% (20.9% vs 28.9%; RR = 0.69, 0.60-0.80; p < 0.0001) and 7.2% (26.0% vs 33.1%; RR = 0.73, 0.64-0.82; p < 0.0001), respectively, with no increase in deaths without recurrence (RR = 0.88, 0.67-1.14; p = 0.33). Recurrence reductions were significantly (p = 0.003) larger among premenopausal women aged under 45 (RR = 0.63, 0.55-0.72; p < 0.0001) than among those aged 45-54 (RR = 0.84, 0.70-1.00; p = 0.045), but did not differ significantly by other recorded patient or tumor characteristics. **Conclusions:** For pre-menopausal women aged under 45, ovarian ablation or suppression substantially reduces the 15-year risk of recurrence and death from breast cancer without increasing mortality from other causes. Oral Abstract Session

Evaluation of PAM50 intrinsic subtypes and risk of recurrence (ROR) scores in premenopausal women with early-stage HR+ breast cancer: A secondary analysis of the SOFT trial. *First Author: Lauren Claire Brown, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: The landmark Suppression of Ovarian Function Trial (SOFT) in premenopausal breast cancer patients revealed that the addition of ovarian function suppression (OFS) to adjuvant endocrine therapy with either tamoxifen (T+OFS) or exemestane (E+OFS) reduces the risk of recurrence compared with adjuvant tamoxifen alone. There are no biomarkers to aid decision-making about intensification of endocrine therapy with OFS. The purpose of this study is to assess the prognostic and predictive ability of PAM50 intrinsic subtypes and ROR scores in premenopausal women with HR+/HER2- breast cancer in the SOFT trial. **Methods:** Gene expression analyses were performed via the NanoString Breast Cancer 360 assay on RNA isolated from FFPE tumor samples from the SOFT trial that were HR+/HER2- (n=1245/3047). PAM50 subtype and ROR score were determined centrally by NanoString Technologies (Seattle, WA, USA), blinded to clinical characteristics, treatment and outcome. Median follow-up was 12 years. Primary endpoint in this study was distant recurrence-free interval (DRFI). Secondary endpoints were breast cancer-free interval (BCFI) and disease-free survival (DFS). Kaplan-Meier analysis and Cox proportional hazards regression models, stratified by prior chemotherapy and lymph node status, were used to evaluate the predictive performance of PAM50 intrinsic subtypes and ROR categories (low vs intermediate vs high), and secondarily ROR score as a continuous variable. We also investigated differences between very young (<40yrs) vs young (>40yrs) women. **Results:** Tumor samples from 1084/1245 (87%) patients successfully completed PAM50 testing and are included in this analysis. Patient characteristics in this cohort were similar to the entire SOFT trial population. Intrinsic subtype and ROR category distribution is described below. Subtype distribution significantly differed between very young vs young premenopausal women, with fewer luminal A and more luminal B and non-luminal tumors seen in the very young (p<0.001). The ROR score distribution also differed significantly: in node-negative patients there were significantly more ROR-high scores amongst very young compared to young women (36% vs 14%, p<0.001). **Conclusion:** Breast cancer diagnosed in very young women has aggressive disease biology. Prognostic and predictive analyses of both intrinsic subtypes and the ROR score are ongoing and will be presented at the meeting. Clinical trial information: NCT00066690. Research Sponsor: Breast Cancer Foundation New Zealand, National Breast Cancer Foundation of Australia, Breast Cancer Research Foundation, NHMRC and the Royal Australasian College of Physicians, Fundación SEOM.

	Very young (<40 yr)	Young (≥40 yr)	Overall
N patients	309	775	1084

Oral Abstract Session

Association of tumor-infiltrating lymphocytes (TILs) with clinicopathologic characteristics and prognosis in young women with HR+/HER2- breast cancer (BC). *First Author: Megan E Tesch, Dana-Farber Cancer Institute, Boston, MA*

Background: Increased TILs are associated with better prognosis in triple-negative BC, including in patients (pts) age < 40. However, the role of TILs remains unclear in HR+/HER2- BC and little data exist in young pts, in whom immune microenvironment could be altered by age-related host/tumor differences. We assessed the extent and composition of immune infiltration in HR+ tumors of young women and correlated with clinicopathologic features and survival outcomes. **Methods:** From a prospective cohort study of women with BC diagnosed age ≤40, we identified those with stage I-III HR+/HER2- BC and available pre-treatment (tx) tumor tissue. Multiplexed immunofluorescence was used to quantify cytotoxic T (CD8+), T helper (Th, CD3+CD8-), T regulatory (Tregs, FOXP3+CD3+) and exhausted T (PD1+CD8+) cells in stroma and tumor. Univariate analyses tested associations between clinicopathologic variables and immune markers by high or low expression, divided based on median. High vs. low TILs were evaluated in Cox regression analyses for invasive breast cancer-free survival (iBCFS), distant disease-free survival (DDFS) and overall survival (OS). **Results:** In 390 pts, median age was 37 years (21-40), most had grade 2 (51%), T1 (65%), N0 (63%) tumors and 67% received adjuvant chemotherapy. Black pts (n = 17) had higher expression of stromal CD8+ (P=.010), FOXP3+CD3+ (P=.027) and PD1+CD8+ TILs (P=.043); intratumoral TILs did not differ by race. Older age (36-40) was associated with high expression of CD8+ (P=.033) and PD1+CD8+ TILs (P=.031) within stroma and CD3+CD8- TILs within tumor (P=.046). Grade 3 tumors had higher stromal and intratumoral expression of CD3+CD8- (P=.002; P<.001) and FOXP3+CD3+ TILs (P=.020; P<.001). No differences in TILs were seen according to recency of pregnancy, BRCA1/2 status or T/N stage. Over a median follow up of 8 years, 85 iBCFS events, 64 DDFS events and 37 deaths occurred. High stromal expression of CD3+CD8- TILs was associated with better iBCFS (HR 0.49, P=.002) and DDFS (HR 0.57, P=.046), which remained significant when adjusted for T/N stage, grade and chemotherapy (iBCFS HR 0.41, P<.001; DDFS HR 0.45, P=.008). High stromal expression of CD3+CD8- and FOXP3+CD3+ TILs was associated with better OS (HR 0.47, P=.038) and iBCFS (HR 0.58, P=.018), respectively, on adjusted analyses only. High intratumoral expression of CD3+CD8- and FOXP3+CD3+ TILs was associated with better iBCFS (HR 0.59, P=.025; HR 0.63, P=.043) after adjustment only. **Conclusions:** The distribution of TIL subtypes in young women's HR+ BC varied according to race, age and grade. High stromal and intratumoral expression of Th and Tregs was associated with improved BC outcomes. Characterization of immune cell subsets could help refine the prognostic value of TILs in HR+ BC, particularly in young pts who may benefit from individualized escalated/de-escalated tx strategies. Oral Abstract Session

Differential impact of proliferation signature on efficacy of neoadjuvant chemoimmunotherapy in sTIL-high and sTIL-low triple-negative breast cancer (TNBC): Biomarker analysis of the NeoPACT trial. *First Author: Shane R Stecklein, University of Kansas Medical Center, Kansas City, KS*

Background: TNBCs with enrichment of stromal tumor-infiltrating lymphocytes (sTILs) and/or immune gene expression are more sensitive to neoadjuvant systemic therapy (NAST) and exhibit higher rates of pathologic complete response (pCR). Other biomarkers, including proliferation, are also prognostic in TNBC patients treated with NAST. We aim to investigate the impact of proliferation gene expression on efficacy of NAST in sTIL-high and sTIL-low TNBC. **Methods:** 110 TNBC patients treated with neoadjuvant chemoimmunotherapy (Carboplatin+Docetaxel+Pembrolizumab) on the phase II NeoPACT trial (NCT03639948) with available whole exome RNA sequencing were included. sTILs were scored in 5% increments by H&E. Tumors were defined as sTIL-high (≥ 20% sTILs) or sTIL-low (< 20% sTILs). The *ImmSig* Proliferation Signature score (ProlifSig) was computed from RNA sequencing data and samples were classified as ProlifSig-high (≥ median) or ProlifSig-low (< median). ProlifSig was tested for prediction of pCR in sTIL-high and sTIL-low groups. Logistic regression was used to examine the independent prognostic utility of sTILs and ProlifSig on pCR. **Results:** 63/110 (57%) patients achieved a pCR. 56/110 (51%) patients were classified as sTIL-high, and 54/110 (49%) classified as sTIL-low. sTILs and ProlifSig as continuous variables were each predictive of pCR (OR = 1.022, 95%CI = 1.009-1.035, P= 0.001 for sTILs; OR = 2.682, 95%CI = 1.23-5.85, P= 0.01 for ProlifSig). In the sTIL-high group, ProlifSig was not associated with pCR either as a continuous score (AUC = 0.56) or when assessed as high/low categories (pCR 78% vs. 67% in ProlifSig-high and ProlifSig-low groups, respectively; OR = 1.79, 95%CI = 0.54-5.89, P= 0.34). In contrast, in the sTIL-low group, ProlifSig was significantly associated with pCR both as continuous score (AUC = 0.74) and when assessed as high/low categories (pCR 57% vs. 29% in ProlifSig-high and ProlifSig-low groups, respectively; OR = 3.18, 95%CI = 1.03-9.86, P= 0.045). On multivariate analysis, sTILs and ProlifSig were independent predictors of pCR (OR = 1.02, 95%CI = 1.01-1.03, P= 0.004 for sTILs; OR = 3.13, 95%CI = 1.44-6.83, P= 0.004 for ProlifSig). **Conclusions:** In TNBC patients treated with chemoimmunotherapy sTILs and ProlifSig provide complimentary information for prediction of pCR. ProlifSig is positively associated with pCR in sTIL-low tumors but not in sTIL-high tumors. We hypothesize that the therapeutic response in sTIL-high tumors is dominated by lymphocyte-dependent cytotoxic mechanisms, while in sTIL-low tumors, the response may be dominated by proliferation-dependent responses. ProlifSig could identify a subgroup of immune low TNBCs that can achieve substantial rates of pCR with neoadjuvant chemoimmunotherapy. Oral Abstract Session

Do tumor infiltrating lymphocytes (TILs) predict benefits from trastuzumab therapy for HER2 positive breast cancer? Meta-analysis of individual patient data from 4097 women in 5 trials. *First Author: Robert Kerrin Hills, University of Oxford, Oxford, United Kingdom*

Background: High TIL counts are associated with a lower risk of breast cancer recurrence, especially in women with ER negative, HER2 negative tumors and, possibly, greater benefit from trastuzumab in women with HER2 positive cancer: the FinHER trial reported a differential effect of trastuzumab based upon TIL status. We performed a meta-analysis of randomized trials of trastuzumab in early breast cancer to attempt to validate this finding. **Methods:** TILs were quantified in 4097 women in 5 randomized controlled trials (NSABP B-31, FinHER, HERA, Intergroup N9831, PACS-04). All trials contributed to the Early Breast Cancer Trialists' Collaborative Group individual patient data meta-analysis of trastuzumab for women with HER2 positive tumors which found a significant benefit for trastuzumab therapy. TILs were assessed using established International Guidelines, with HERA using digital TIL-scores. The primary outcome was time to first recurrence. Cox regression analyses, adjusted for trial, treatment allocation, and nodal status, were used to quantify the prognostic value of TILs; and standard stratified logrank tests were used to assess the differential effect of trastuzumab therapy. **Results:** The median percentage TILs was 13% (Interquartile Range 5-30), with fewer than 10% of patients exhibiting TILs >50%. The prognostic value of TILs was confirmed, with patients with higher TILs being at lower risk for recurrence (adjusted hazard ratio per 10% increase in TILs 0.87 (95% CI 0.84-0.90), $p < .0001$) with similar effects in both treatment groups. Outcomes improved steadily with increasing TILs, and unadjusted 10-year recurrence rates fell from 30% in women with TILs <10% to 15% in those with TILs 70% or greater. Consequently, analyses of the predictive effect of TILs were stratified into 5 groups (0-9, 10-19, 20-39, 40-59, 60+). Overall, there was a highly significant benefit of trastuzumab on recurrence (HR 0.62 (0.54-0.70) $p < .0001$), but there was no evidence of any interaction between TILs and the proportional reduction in recurrence ($p = 0.8$ for heterogeneity and trend). **Conclusions:** While higher TILs are associated with lower recurrence rates, there was no indication that the proportional reduction in recurrence with trastuzumab varied by TILs, although the number of patients with high levels was limited. Owing to a lower underlying recurrence rate, absolute benefits from trastuzumab were lower, but still substantial, in women with high TIL tumors. Clinical trial information: NCT00045032, ISRCTN76560285, NCT00005970, NCT00004067, NCT00054587. Research Sponsor: Cancer Research UK.

TILs percentage	HR for trastuzumab	95% CI
0-9 (n=1224)	0.60	0.49 to 0.75

Prognosis and trends in chemotherapy use for patients with stage IA triple-negative breast cancer (TNBC): A population-based study. *First Author: Paolo Tarantino, Dana-Farber Cancer Institute, Boston, MA*

Background: Outcomes for patients with stage IA TNBC in the modern era remain poorly characterized, and the benefit and utilization of adjuvant chemotherapy (chemo) in this setting remains controversial. **Methods:** We analyzed data from women diagnosed with pathological stage IA TNBC in the Surveillance, Epidemiology, and End Results (SEER) database during 2010 to 2019. We evaluated the associations of adjuvant chemo with breast-cancer specific survival (BCSS) stratified by tumor size, using multivariate cox models adjusted for tumor size (overall cohort only), age at diagnosis, race, tumor grade, histology, radiation, marital status, income, and rurality. Frequency of chemo use over time was examined by tumor size. Multivariate logistic regression assessed variables associated with chemo administration. **Results:** In total, we examined data from 8,601 women with stage IA TNBC. Median age at diagnosis was 62 years. Most patients had high-grade tumors (70.1%), ductal histology (92.8%), and received adjuvant chemo (61.6%). Median follow up was 48 months (IQR: 20 – 83). The use of chemo significantly increased during 2010-2019 for both T1b tumors (p for trend = 0.001) and T1c tumors (p for trend < 0.001), with 52.5% and 63% of the patients with T1b and T1c TNBCs receiving chemo in 2010, respectively, compared with 60.5% and 71.1% in 2019. No significant differences were observed in the use of chemo for T1mic (p for trend = 0.567) and T1a (p for trend = 0.637) tumors, with low utilization seen in both cohorts (9.5% overall in T1mic, 22.5% overall in T1a). Variables associated with chemo use included younger age, white race, married status, higher income, more recent diagnosis, higher tumor grade, ductal histology, and larger tumor size (all $p < 0.02$). Overall, 5-year BCSS was high across T groups (> 90%; Table). Receiving chemo (vs. none/unknown) was associated with an improved 5-year BCSS (adjusted HR for BCSS = 0.70, $p = 0.006$). For T1c tumors specifically, adjuvant chemo (vs. none/unknown) was also associated with BCSS (adjusted HR 0.64, $p = 0.002$). The small number of BCSS events precluded comparisons for other tumor size subgroups. Table shows sample sizes and 5-year BCSS rate by chemo receipt for each T group. **Conclusions:** In a large population-based cohort of patients with stage IA TNBC, we observed excellent 5-year BCSS outcomes, supporting the good prognosis of this patient population. The use of adjuvant chemo increased over time for T1b and T1c TNBCs, and was associated with improved BCSS for T1c tumors, although evaluation of benefit is limited by the inherent treatment bias in registry data. Research Sponsor: None.

Assessment of risk of overall and late distant recurrence by Breast Cancer Index in postmenopausal women with early-stage, HR+ breast cancer in the TEAM trial. *First Author: John MS Bartlett, Cancer Research UK Scotland Centre, University of Edinburgh, Edinburgh, United Kingdom*

Background: Individual risk assessment of distant recurrence (DR) is particularly relevant for early-stage HR+ breast cancer patients, as they face a prolonged risk of recurrence even after adjuvant endocrine therapy. Previously, we have shown that the Breast Cancer Index (BCI) and BCIN+ risk groups are significantly prognostic for risk of overall (0-10y) and late (5-10y) distant recurrence in NO and N1 breast cancer patients, respectively, enrolled in the Tamoxifen and Exemestane Adjuvant Multinational (TEAM) trial. Here, the prognostic performance of BCI and BCIN+ as a continuous risk score for overall and late distant recurrence was evaluated in the TEAM trial. **Methods:** BCI testing was performed blinded to clinical outcome with BCI/BCIN+ risk scores calculated as previously described. Cox proportional hazard models adjusted for age, tumor size, grade and treatments were used to estimate hazard ratios (HRs) and the associated 95% confidence intervals (CIs) for BCI/BCIN+ continuous risk scores. The 10y risk of overall and late DR were estimated as a function of risk scores from the Cox models using Breslow estimates. **Results:** Continuous risk curves for overall and late DR were obtained in patients who did not receive adjuvant chemotherapy and those who remained DR-free at 5 years regardless of chemotherapy, respectively, to reflect the two key time points for breast cancer treatment decision-making. In NO patients not treated with chemotherapy (N = 1197), BCI was significantly prognostic for overall DR with a HR of 1.39 (95% CI 1.25-1.54; $p < 0.001$), while BCIN+ was significantly prognostic in N1 patients who did not receive chemotherapy (N = 1319) with a HR of 4.29 (95% CI 2.93-6.28; $p < 0.001$). Among patients who remained DR-free at 5 years, in the NO subset (N = 1285), BCI was significantly prognostic for late DR with a HR of 1.23 (95% CI 1.07-1.42; $p < 0.001$), while BCIN+ remained to be significantly prognostic in the N1 subset (N = 1762) with a HR of 2.78 (95% CI 1.75-4.43; $p < 0.001$). Similar results were observed in the HER2- subset for both overall and late DR. Continuous risk curves for BCI and BCIN+ for overall and late DR showed an increasing risk of DR with higher BCI/BCIN+ scores. **Conclusions:** Results from this largest BCI study to date further support the use of BCI to provide individualized risk estimates for both overall and late DR in women with HR+ breast cancer to aid in personalized decision-making for adjuvant therapy. Research Sponsor: Hologic.

Racial/ethnic differences in 21-gene recurrence score and survival among estrogen receptor-positive breast cancer patients. *First Author: Jasmin Gill, University at Buffalo, The State University of New York, Buffalo, NY*

Background: Despite studies on racial/ethnic disparities in breast cancer patients, there is limited literature evaluating association of racial/ethnic differences with 21-gene recurrence score (RS) and survival differences stratified by RS risk categories. We performed an observational cohort study to evaluate such disparities in context of RS. **Methods:** The National Cancer Database (NCDB) was queried for patients with ER-positive, pT1-3N0-1aM0 breast cancer who received surgery followed by adjuvant endocrine therapy with available RS from 2006 to 2018. Racial/ethnic groups were stratified by non-Hispanic White (NHW), Hispanic White (HW), Black, and Asian/Pacific Islander (API). Our primary endpoint was overall survival (OS). Logistic multivariable analysis (MVA) was built upon baseline patient and tumor characteristics to evaluate variables associated with RS > 25. Cox MVA was used to evaluate OS. Interaction term analysis was used to identify heterogeneous association of racial/ethnic groups and RS; if significant, subgroup analyses compared magnitude of racial/ethnic differences stratified by RS. To address immortal time bias, Cox MVA analyses were repeated after excluding patients with post-diagnosis survival < 6 months. P values were two-sided. Bonferroni correction was used for multiple comparisons (NHW vs HW women, NHW vs Black women, and NHW vs API women) with p values less than 0.017 being statistically significant. **Results:** A total of 140,133 women (median [interquartile range (IQR)] age, 60 [52-67] years) were included for analysis. 115,651 (82.5%), 8,213 (5.9%), 10,814 (7.7%), and 5,455 (3.9%) were NHW, Hispanic, Black, and API women respectively. Median (IQR) follow up was 66.2 mo. (48.0-89.8). Logistic MVA showed compared to NHW women, Black women were associated with higher RS (26 or higher vs < 26: adjusted odds ratio [aOR] 1.19, 95% confidence interval [CI] 1.12-1.26, $p < 0.001$), while HW (aOR 0.93, 95% CI 0.86-1.00, $p = 0.04$) and API (aOR 1.03, 95% CI 0.95-1.13, $p = 0.45$) were not. Cox MVA showed compared to NHW, Black women were associated with worse OS (adjusted hazards ratio [aHR] 1.10, 95% CI 1.02-1.19, $p = 0.012$) while HW (aHR 0.85, 95% CI 0.77-0.94, $p = 0.001$) and API (aHR 0.66, 95% CI 0.56-0.77, $p < 0.001$) were not. There was significant interaction between race/ethnicity and RS (interaction $p = 0.006$). Subgroup analysis found similarities in those with RS < 26, while only API women were associated with improved OS among those with RS ≥ 26 . After excluding those with post-diagnosis survival < 6 mo., our findings remained comparable. **Conclusions:** To our knowledge, this is the largest nationwide oncology database study to suggest that Black women are associated with higher RS, while HW and API are not. It also suggests that Black women are associated with worse OS among those with RS < 26, while API are associated with improved OS regardless of RS compared to NHW women. Research Sponsor: U.S. National Institutes of Health.

A randomized controlled trial of a mobile app and tailored messages to improve outcomes among women with breast cancer receiving adjuvant endocrine therapy. First Author: Ilana Graetz, Emory University, Rollins School of Public Health, Atlanta, GA

Background: Adjuvant endocrine therapy (AET) use among women with early-stage, hormone receptor-positive breast cancer reduces the risk of cancer recurrence, but adverse symptoms contribute to lower adherence. We evaluated the effectiveness of an app that integrates patient-reported outcomes with electronic health records and tailored messages. **Methods:** Women with early-stage breast cancer initiating AET (November 2018-June 2021) were randomized into three arms: (1) an “App” group that received instructions and access to the study app and weekly text reminders to use it; (2) an “App+Feedback (AF)” group received additional weekly tailored messages about managing symptoms, adherence, and communication; or (3) a “Usual Care (UC)” group without access to the app. The intervention lasted 6-months and participants completed surveys at enrollment, 6-, and 12-months. Increasing/severe symptoms and missed doses triggered alerts that prompted follow-ups from the oncology team. Outcomes included AET adherence, captured using an electronically monitored pillbox and self-reported adherence, symptom burden (FACT-ES), mental and physical health quality of life (SF-12), self-efficacy for managing symptoms (PROMIS 1.0), and 6-month count of emergency department visits/urgent care/hospitalizations [higher cost encounters] and office visits. **Results:** Overall, 300 women were randomized (102 UC, 96 App, and 102 AF). Median age was 60 years (range: 31–83), 34% identified as Black, 21% had incomes below 200% of the federal poverty level, and 20% had a high school degree or less education. Retention at 12-months was 88% (N=264). Mean app logins were 14.4 among intervention participants, which resulted in 4.2 mean alerts, with 58.0% having at least one alert during the 6-month intervention. AET adherence over 12-months measured using the pillbox was similar across groups: 76% for UC, 73% for App, and 71% for AF ($p=0.57$). At 12-months, AF participants had fewer higher cost care encounters over the previous 6 months (0.30, 95%CI: 0.15 to 0.45, $p=0.01$) compared to UC (0.71, 95%CI: 0.44 to 0.97) but not for App only vs. UC (0.46, 95% CI: 0.25 to 0.66, $p=0.15$). Mean mental health scores were 2.0 points better (95% CI: 0.21 to 3.84) at 6-months for AF (43.0) compared to UC (41.0). There were no statistically significant differences by group in self-reported adherence, symptom burden, physical health, self-efficacy for managing symptoms, and office visits at 6- or 12-months. **Conclusions:** While the intervention did not improve AET adherence, the app combined with tailored messages resulted in better self-reported mental health during the intervention and fewer higher cost care encounters at 12-months without increasing office visits. Symptom monitoring apps with tailored messages may be scalable and effective strategies for improving outcomes for patients with breast cancer. Clinical trial information: NCT03592771. ECOG-ACRIN E2197: Comparison of HER2 gene expression by RT-PCR across all HER2 immunohistochemistry groups with recurrence analysis. First Author: Nhu Thuy Can, Genomic Health Inc, an Exact Sciences Corporation (Redwood City, CA), Redwood City, CA

Background: Accurate assessment of HER2-low [immunohistochemical (IHC) score of 1+ or 2+ and in-situ hybridization negative] breast cancer is clinically relevant following DESTINY-Breast04. In hormone receptor positive breast cancers, Oncotype DX assay Recurrence Score results are widely used to guide adjuvant chemotherapy selection, and standardized quantitative HER2 mRNA reference-normalized expression levels by RT-PCR are included in patient reports. Previously, a high degree of concordance between central IHC and quantitative HER2 by RT-PCR was demonstrated in E2197. Here, we compare quantitative HER2 gene expression using Oncotype DX assay within all IHC subgroups and risk of recurrence in E2197. **Methods:** Data analyzed were from a case-control sample from E2197 (no adjuvant anti-HER2 therapy) of 755 patients. Central IHC for HER2 used duplicate 1.0 mm microarrays (HercepTest, Dako) and scored per 2007 ASCO/CAP guidelines. Based on quantitative reference-normalized RT-PCR measures of HER2 expression, cases were assigned: positive ≥ 11.5 units, equivocal ≥ 10.7 to < 11.5 units, and negative < 10.7 units (1 unit increase represents ~2-fold increase in RNA). Spearman's rank correlation was used to measure strength of association between the 2 methods. Cox proportional hazards regression was used to evaluate the association between quantitative HER2 expression and recurrence (defined as invasive breast cancer in local, regional, or distant sites). Analyses were weighted to account for study design. **Results:** 48% were IHC 0, 11% were IHC 1+, 23% were IHC 2+, and 18% were IHC 3+. 85% were HER2 negative, 3% equivocal, and 11% positive by RT-PCR. While there was moderately strong correlation between HER2 IHC and HER2 gene expression by RT-PCR [Spearman's rho: 0.63 (95% CI: 0.59, 0.67); $p<0.001$], there were wide and overlapping ranges of HER2 gene expression across all IHC categories with almost identical medians and inter-quartile ranges for HER2 IHC 1+ and 2+ ($n=248$; see table). An exploratory analysis showed 86% of IHC 0, 97% of IHC 1+, and 99% of IHC 2+ had HER2 > 8 units. After controlling for baseline clinicopathologic features (age, hormone receptor status, grade, size, and nodal status), continuous quantitative HER2 expression was associated with time to recurrence in HER2 IHC 0 to 2+ [HR 1.17 per 1-unit increase in HER2 (95% CI 1.01, 1.35; $p=0.036$)]. **Conclusions:** There was a wide range of quantitative HER2 gene expression using Oncotype DX assay across all IHC categories; continuous HER2 expression is independently associated with recurrence. Quantitative HER2 expression may be useful for identification of HER2-low breast cancer. Further studies are needed. Research Sponsor: None.

Correlation of HER2 low status in I-SPY2 with molecular subtype, response, and survival. First Author: Hope S. Rugo, University of California Comprehensive Cancer Center, San Francisco, CA

Background: HER2low, defined as immunohistochemical (IHC) 1+ or 2+ without HER2 gene amplification, predicted improved progression free and overall survival with trastuzumab deruxtecan (TDXd) compared to chemotherapy in patients (pts) with metastatic breast cancer in Destiny Breast04. Controversy exists regarding the correlation of HER2low with molecular subtypes and outcome. We evaluated these associations in the neoadjuvant I-SPY2 trial. **Methods:** We investigated HER2 IHC class in pts with clinically HER2-negative breast cancer (BC) enrolled in the first 10 arms of I-SPY2. To explore the biology of HER2low, we used Fisher's exact test to assess association of IHC class (0 vs 1+ or 2+) with Response Predictive Subtypes-5 (RPS-5; based on immune, DNA repair damage (DRD), HER2, and luminal markers; PMID: 35623341), SET index [endocrine responsiveness], and Mammaprint high1 (MP1) vs high2 (MP2). Association with pathologic complete response (pCR) was assessed using Fisher's exact test, and association with distant recurrence free survival (DRFS) was assessed using Cox Proportional Hazards modeling. **Results:** Of 742 HER2negative pts enrolled in the first 10 arms of I-SPY2, local HER2 IHC is available for 585; 299 hormone receptor + (HR+) and 286 triple negative (TN). 63% of pts are HER2low, with HER2low status more frequent in HR+ (71%) compared to TN BC (55%; OR = 1.97; $p = 0.00011$). There was no clear relationship between HER2low IHC and RPS-5 subtypes or endocrine sensitivity measured by the SET index. There was no significant association of HER2low with pCR overall or within treatment arms ($p > 0.05$); this was true for TN and HR+ subsets. 562 pts with HER2negative disease have distant recurrence free survival (DRFS) data with a median follow-up of 4.23 yrs. Pts with pCR had excellent outcome (5yr DRFS $> 94\%$), with no impact from HER2low vs 0 status. For pts with nonpCR, after adjusting for HR+ status, the DRFS hazard ratio for HER2low vs 0 status is not significant [0.68(0.46-1.02)]. Within HR+, HER2low is found in $> 70\%$ for both SET low and high. HR+/MP1 pts (with generally low pCR rates) are significantly more likely to be HER2low (75%; (172/219)) compared to HR+/MP2 (61%; (49/80)) (OR: 1.79; Fisher $p = 0.044$). Importantly, 70% of HER2-Immune-DRD- (78% HR+ and 56% TN), a subtype with low response to all I-SPY2-tested agents, are HER2low. **Conclusions:** In I-SPY2 which enrolls patients with MP high risk BC, HER2low by IHC was frequent and higher in HR+ than TN disease. There was no clear association with molecular markers, pCR or DRFS. The frequency of HER2low in the immune-DRD- subtype raises the potential for exploring T-DXd in this high risk, low-response setting. Clinical trial information: NCT01042379. AI-based HER2-low IHC scoring in breast cancer across multiple sites, clones, and scanners. First Author: Patrick Frey, Mindpeak GmbH, Hamburg, Germany

Background: Assessment of immunohistochemical (IHC) HER2 expression plays a pivotal role in breast cancer diagnostics. In the era of HER2-low and HER2-targeted antibody drug conjugates, accurate discrimination of defined HER2 IHC scores is essential. At the same time, HER2 IHC scoring suffers from poor interobserver concordance. Artificial intelligence (AI) may optimize this scoring in regard to standardization, accuracy and efficiency, but previous approaches fail to show the required consistency across samples from different sites, clones and scanning hardware. **Methods:** We have investigated the use of an AI-based HER2 IHC quantifier software to support pathologists in standardized HER2 IHC assessment in breast cancer. Validation specimens were derived from four institutions and five scanners. Using the “region of interest” (ROI) software version (part I), pathologists choose the ROI to be assessed within the whole slide image (WSI). In contrast, the fully automatic version (part II) analyzes the complete WSI. Part I: Three pathologists selected one ROI per slide from a cohort of $n = 150$ specimens. They scored HER2 expression in these ROIs (path-only) according to ASCO/CAP 2018 guidelines (each pathologist $n = 50$). After a 2-week washout period, the same pathologists were presented with the same ROIs and corresponding AI-suggested results (AI-only), and then decided on final HER2 scores (AI-assisted). Scoring times were recorded. Part II: Fully automatic AI accuracy without human intervention was analyzed using the WSI cohort of part I and an additional cohort of $n = 94$ WSIs. For both parts, IHC scores were compared to the clinical workflow derived ground truth defined as the manually assessed HER2 IHC score. **Results:** Part I: In discriminating HER2-neg from HER2-low/pos cases, AI-assisted and AI-only ROI scoring showed agreement rates of 91.3% and 86.7%, respectively, with path-only decisions across all institutions and scanners. In discriminating the four HER2 scores (0, 1+, 2+, 3+) individually, interrater-agreement of AI-assisted vs. path-only ROI HER2 scoring was 78.7%, exceeding literature rates of $< 70\%$, with the mean scoring time per ROI being 29 sec vs. 50 sec, respectively; interrater-agreement of AI-only vs. AI-assisted was 85.3%. Part II: In discriminating HER2-neg from HER2-low/pos cases, fully automatic AI WSI scoring showed 89.1%/86.2% agreement for both cohorts, respectively. **Conclusions:** Across challenging validation data from four institutions and five scanners, scoring with the support of an AI HER2 IHC quantifier software showed very high agreement when discriminating HER2-neg from HER2-low/pos cases and high accuracy for general HER2 scoring. When using AI-assistance, scoring time was reduced by almost 50%. Altogether, these results demonstrate the potential of AI solutions to increase consistency and efficiency of HER2 scoring and ultimately to improve patient outcome. Research Sponsor: None.

Outcomes according to treatment received for small node-negative HER2+ breast tumors in the Surveillance, Epidemiology, and End Results (SEER) database, 2010-2019. *First Author: Adrienne Gropper Waks, Dana-Farber Cancer Institute, Boston, MA*

Background: The magnitude of systemic therapy (tx) benefit for small, node-negative HER2+ breast tumors is unknown, with uncertainty about how benefit varies across stage I tumor sizes. We analyzed treatment patterns and outcomes for patients (pts) with stage IA (pT1N0) HER2+ breast cancer in the national SEER database. **Methods:** Pts with one lifetime diagnosis of pT1N0 HER2+ breast cancer between 2010-2019 were included. Receipt of chemotherapy (chemo) was categorized as yes vs no/unknown; receipt of endocrine tx is not available in SEER. All systemic tx was administered in the adjuvant setting. The primary outcome variable was breast cancer-specific survival (BCSS; recurrence events are not available in SEER), which was compared between treatment groups using a multivariate Cox model adjusted for age at diagnosis (dx), race, tumor grade/histology/size, hormone receptor (HR) status, radiation, marital status, income, rurality. Chemo use predictors were evaluated by multivariable logistic regression. **Results:** We identified 12,861 pts with pT1N0 HER2+ breast cancer; 9,513 (74%) HR-positive and 3,348 (26%) HR-. Median age at dx was 59 yrs. Median follow-up was 46 months. In the overall cohort, BCSS at 3, 5, and 7 yrs was: 99.3% (with chemo) vs 99.1% (without chemo); 98.6% (with chemo) vs 97.4% (without chemo); and 97.5% (with chemo) vs 96.4% (without chemo), respectively. Adjusted hazard ratio (HzR) for BCSS events in the chemo vs no chemo group of the overall cohort was 0.63 (p=0.004). BCSS events by tumor size and HR status are shown; p values are not shown where event rates were too low to run an adjusted model. Chemo use increased significantly between 2010-2019 within each tumor size category (all p for trend < 0.04), except for T1a HR+/HER2+ and T1mi HR-/HER2+. Pts were less likely to receive chemo if they were older, Hispanic (vs non-Hispanic White), separated/divorced/widowed (vs single), or had lower median household income (vs > \$75K). Pts were more likely to receive chemo if they had larger tumor size, HR- tumor, higher tumor grade, were married (vs single), or had later yr of dx. **Conclusions:** Receipt of chemo was associated with higher BCSS in the overall stage IA cohort and among pts with HR+/HER2+ stage IA tumors. Tumors ≤ 1cm had excellent outcomes with or without chemo. Sociodemographic factors including income, race, and marital status impacted chemo receipt. Research Sponsor: None.

Poster Discussion Session

Gene expression signatures, stromal tumor infiltrating lymphocytes (sTILs), and change in tumor cellularity to predict pathological complete response (pCR) after 12 week de-escalated neoadjuvant endocrine therapy (ET) vs paclitaxel + dual HER2 blockade in the WSG-TP-II trial. *First Author: Monika Karla Graeser, West German Study Group, Moenchengladbach, Germany*

Background: There are limited data on predictive biomarkers for de-escalated ET or chemotherapy with dual anti-HER2 blockade in HR+/HER2+ early breast cancer (BC). In this translational pre-planned project of the WSG-TP-II phase II-trial (NCT03272477), we aimed to identify associations of gene expression signatures and sTILs with pCR. **Methods:** Patients with cT1c-cT4c, cN0-3 centrally confirmed HR+/HER2+ BC were randomized to 12 weeks of standard ET (n = 100) or paclitaxel (Pac; n = 107). All patients received trastuzumab + pertuzumab (T+P) q3w as neoadjuvant and adjuvant treatment. Gene expression signatures were analyzed using NanoString BC360 panel in baseline biopsies (T+P+ET: n = 72; T+P+Pac: n = 78). sTILs were analyzed in 93 (T+P+ET) and 97 patients (T+P+Pac) at baseline and in 65 (T+P+ET) and 57 patients (T+P+Pac) at week 3. Impacts of standardized BC360 gene expression signatures and sTILs on pCR (ypT0/is ypN0; primary endpoint) expressed in odds ratios (OR) were estimated by logistic regression analysis. **Results:** pCR rate in patients with BC360 analysis was 39.3% (T+P+ET: 23.6%; T+P+Pac: 53.9%). Overall, ERBB2 (OR 2.37; 95%CI 1.55, 3.62) and cytotoxic cells signature (OR 1.42; 95%CI 1.02, 1.99) were favorable for pCR, while apoptosis (OR 0.64; 95%CI 0.44, 0.92), estrogen receptor 1 (OR 0.60; 95%CI 0.42, 0.85), estrogen receptor signaling (OR 0.64; 95%CI 0.45, 0.91), and progesterone receptor (OR 0.67; 95%CI 0.47, 0.94) signatures were unfavorable. Analyzing by treatment arm, a similar pattern was observed in the T+P+Pac arm (ERBB2: OR 2.01; apoptosis: OR 0.59; estrogen- and progesterone-related signatures: OR 0.41-0.58), but not in the T+P+ET arm where only ERBB2 was prognostic for pCR (OR 7.24; 95%CI 2.12, 24.05). Baseline ≥30% sTIL levels (vs < 30% sTILs; n = 16 vs n = 174) were associated with pCR (OR 5.16; 95%CI 1.60, 16.66); significance was not achieved in either trial arm. Compared to < 30% sTILs (n = 90), low tumor cellularity at week 3 precluding sTILs analysis (< 500 invasive tumor cells, n = 22), but not ≥30% sTILs (n = 10), was prognostic for pCR in all patients (OR 9.47; 95%CI 2.94, 30.50) and in individual trial arms (OR 6.00-11.79). **Conclusions:** This hypothesis-generating translational results suggest that gene expression signatures (particularly ERBB2), baseline sTILs, and low tumor cellularity at week 3 predict pCR after ET + double HER2 blockade. Future neoadjuvant trials are needed to prospectively test the use of baseline gene expression and sTILs analysis, and early on-treatment cellularity measurement to select patients with HR+/HER2+ tumors for de-escalated endocrine-therapy-based approaches. Clinical trial information: NCT03272477. Research Sponsor: Roche Pharma AG.

Poster Discussion Session

MammaPrint Index as a predictive biomarker for neoadjuvant chemotherapy response and outcome in patients with HR+HER2- breast cancer in NBRST. *First Author: Peter D. Beitsch, Dallas Surgical Group, Dallas, TX*

Background: Hormone receptor positive (HR+), HER2- early stage breast cancer (ESBC) is a heterogeneous disease that has shown lower response to neoadjuvant chemotherapy (NCT) compared with other clinicopathologic subtypes. Genomic profiling may help inform neoadjuvant treatment decisions for ESBC by predicting likelihood of pathological complete response (pCR) or chemosensitivity. The 70-gene MammaPrint (MP) test classifies ESBC patients as having a Low or High Risk of distant metastasis. In the I-SPY2 trial, further stratification of MP High Risk into High 1 (H1) or High 2 (H2) improved prediction of chemosensitivity, with significantly higher pCR rates in H2 vs. H1 tumors, particularly in response to immune therapy. Here we evaluate the utility of H1/H2 risk as a biomarker for chemosensitivity and 5 year distant-metastasis free survival (DMFS) in NCT treated patients from the Neoadjuvant Breast Registry Symphony Trial (NBRST). **Methods:** NBRST (NCT01479101) is an observational prospective study that included 1069 patients with ESBC who received neoadjuvant therapy. Patients with HR+HER2-, MP High Risk tumors who received NCT were included in this analysis (n = 327). Patients were further stratified into H1 (score ≤ 0, > -0.57) or H2 (score ≤ -0.57) groups. Differences in pCR between MP High Risk subcategories were assessed by two-sided proportional z-test. Differences in DMFS was evaluated by Kaplan Meier analysis and log-rank test. **Results:** MP classified 198 (61%) patients with H1 tumors and 129 (39%) patients with H2 tumors. Age, tumor stage, and lymph node status were comparable between both groups. However, there was a higher proportion of Grade 3 tumors in the H2 group. A significantly higher percentage of pCR was achieved in H2 tumors (30/129; 23%) vs. H1 tumors (12/198; 6.1%) (p < 0.001). Median follow-up was 5.3 years. The 5-year DMFS (% [95% CI]) was significantly worse for patients with H2 tumors (64.8 [55.9 – 75.1]), with most events occurring early (< 3 years), compared with H1 tumors (77.1 [70.4 – 84.3]; p = 0.012). Patients with H1 tumors that achieved pCR had improved 5-year DMFS (81.8 [61.9 – 100]) compared to H1 tumors that did not achieve pCR (76.8 [69.9 – 84.4]; p = 0.009). Patients with H2 tumors that had a pCR demonstrated significantly better 5-year DMFS (80.7 [65.3 – 99.8]) than patients with residual disease (60.2 [50.1 – 72.4]; p = 0.009). **Conclusions:** These data suggest MammaPrint predicts pCR in HR+HER2- BC patients, with H2 risk tumors exhibiting higher chemosensitivity than H1 tumors. Patients with either H1 or H2 tumors that achieved pCR had similar outcomes, which were significantly improved compared to those with residual disease. Notably, the worst outcomes were observed among patients with H2 risk and residual disease; it should be investigated whether addition of immune therapy to standard NCT would enhance the pCR rates in this patient population. Clinical trial information: NCT01479101. Research Sponsor: Agendia Inc.

Poster Discussion Session

Primary efficacy analyses of NeoRHEA, neoadjuvant biomarker research study of palbociclib combined with endocrine therapy in estrogen receptor positive/HER2 negative breast cancer. *First Author: Elisa Agostinetto, Université Libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (HUB), Institut Jules Bordet, Academic Trials Promoting Team (ATPT), Brussels, Belgium*

Background: CDK4/6 inhibitors (CDK4/6i) and endocrine therapy (ET) are standard of care in the treatment of estrogen receptor (ER) positive, HER2-negative (ER+/HER2-) advanced breast cancer (BC). We tested palbociclib + ET as neoadjuvant therapy to identify baseline biomarkers of no response. **Methods:** NeoRHEA (NCT03065621) was a phase II, single arm trial evaluating 4 months of neoadjuvant palbociclib and ET in pre- or post-menopausal women with ER+/HER2- early BC. The primary objective was to identify biomarkers of no response by locally-assessed ultrasound (US) using RNA-seq on baseline (pretreatment) tumor biopsies. No response to treatment was defined as stable or progressive disease (SD or PD) at post-treatment US based on WHO criteria. Secondary endpoints included residual cancer burden (RCB) of 3 and absence of complete cell cycle arrest (CCCA) defined as Ki67 by immunohistochemistry (IHC) $> 2.7\%$ at surgery. We evaluated baseline clinicopathological characteristics, RNA-seq derived PAM50 subtypes and mRNA expression of *ESR1*, *Ki67*, *CCNE1*, *RB1* and *CDK6* single genes according to US response and CCCA. We also performed gene set enrichment analysis (GSEA) for 50 gene sets related to cancer hallmarks according to US response and CCCA. **Results:** 73 of 100 patients enrolled had baseline frozen tumors with enough cellularity and successful RNA-sequencing performed. Among the 73 patients, 70% were post-menopausal, 84% had cT2 and 70% cN0 tumors, 75% had invasive ductal carcinoma and 66% had histological grade 2 tumors. RNA-seq derived PAM50 subtypes were Luminal A, Luminal B, and non-Luminal in 56%, 36% and 8% of patients, respectively. Among the 73 patients, 31 (42%) had absence of US response (28 and 3 patients had stable and progressive disease by US, respectively) and 23 (31%) had RCB 3 tumors. Fifty-three of 73 patients had Ki67 by IHC available at surgery out of whom, 14 (26%) had absence of CCCA. Neither baseline clinicopathological characteristics nor PAM50 subtypes nor expression of *ESR1*, *Ki67*, *CCNE1* and *RB1* were associated with absence of US response or absence of CCCA. Interestingly, we observed higher baseline mRNA expression of *CDK6* in patients with absence of US response ($p = 0.039$) or those with no CCCA ($p = 0.004$). We observed an enrichment in inflammatory / IFN- γ response and proliferation-related, G2M checkpoint gene sets in patients with US response (NES: 2.06, 2.30, 1.47; FDR: 7.04e-9, 5.48e-17, 0.0193 respectively) and an enrichment in early estrogen response gene set in patients with absence of US response (NES: -1.78, FDR: 0.0006). No signaling pathway was enriched in patients without CCCA. **Conclusions:** High pre-treatment mRNA expression of the *CDK6* gene was associated with no US response or absence of CCCA in patients treated with neoadjuvant palbociclib and ET. Independent validation is needed. Clinical trial information: NCT03065621. Research Sponsor: Pfizer; Fondation Contre le Cancer.

Poster Discussion Session

Axillary surgery efficacy for patients with breast cancer receiving neoadjuvant chemotherapy on NSABP B40 and B41. *First Author: Raymond Mailhot Vega, Department of Radiation Oncology, University of Florida College of Medicine, Jacksonville, FL*

Background: Alliance A011202 is evaluating the efficacy of axillary lymph node dissection (ALND) compared to regional nodal irradiation (RNI) for patients with cN1 breast cancer who receive neoadjuvant chemotherapy (NCTX) that becomes ycN0 but remains pN+. In the absence of its publication, level I guidance does not exist regarding the optimal axillary surgery for patients receiving NCTX. We sought to evaluate outcomes across two national contemporary clinical NCTX trials based on axillary and breast response to NCTX, particularly if more aggressive surgery was associated with more favorable outcomes. **Methods:** With IRB approval (IRB201802781), we obtained data from NCTX trials NSABP B40 and B41. B40 enrolled women with HER2- disease, and B41 enrolled those with HER2+ disease. RNI and axillary surgery were selected at physician discretion and not protocolled. Patients received sentinel lymph node biopsy (SLNB), SLNB+ALND (S+ALND), or ALND. We examined outcomes of locoregional recurrence (LRR), distant recurrence (DR), disease free survival (DFS), and overall survival (OS). Univariable and multivariable analyses of B40 and B41 data were performed to evaluate the associations of axillary surgery with the outcomes above, adjusting for age, tumor subtype, mastectomy or not, breast pathologic complete response (pCR), axillary pCR, tumor subtype, regional nodal irradiation, and grade. Kaplan-Meier estimation was used for OS and DFS, with cumulative incidence function for LRR and DR. **Results:** Median follow-up for studies B40 and B41 were 4.5 and 5.1 years, respectively, including 1154 and 504 patients for analysis. A total of 786 (47%) patients were cN+, and of those, 377 had a pCR (48%). 440 (27%), 505 (31%), and 663 (41%) patients had SLNB, S+ALND, and ALND respectively. 855 (52%) and 803 (48%) patients had mastectomy and lumpectomy, respectively. 783 (51%) received RNI. For the 518 ypN+ patients on B40, 7/25 (SLNB), 69/234 (S+ALND), and 107/259 (ALND) experienced an event. DFS at 5 years was 71%, 68%, and 56% for the SLNB, S+ALND, and ALND groups respectively with ypN+ on B40. For the 112 ypN+ patients on B41, 3/6, 15/43, and 27/63 experienced an event. DFS at 5 years was 50%, 64%, and 55% for the SLNB, S+ALND, and ALND groups, respectively, with ypN+ on B41. In multivariable analyses for the combined population of B40 and B41 for LRR, DR, DFS, and OS, SLNB was never associated with a higher chance of relapse or inferior survival ($HR > 1$) compared to S+ALND or ALND. **Conclusions:** Among women prospectively treated on national trials with NCTX and axillary surgery and RNI selected at physician discretion, receipt of SLNB alone was not associated with a higher likelihood of recurrence compared to S+ALND or ALND. Anticipated results of A011202 will provide level I guidance on axillary surgery for patients with cN1 disease converting to cN0 post-NCTX. Poster Discussion Session

A randomized controlled trial comparing primary tumor resection plus systemic therapy with systemic therapy alone in metastatic breast cancer (PRIM-BC): Japan Clinical Oncology Group study JCOG1017. *First Author: Tadahiko Shien, Okayama university hospital, Okayama-Shi, Japan*

Background: The possibility of primary tumor resection (PTR) improving the survival of de-novo Stage IV breast cancer (dn-StIV BC) patients has been evaluated by several prospective studies but remains controversial. We designed this phase 3 trial (JCOG1017) comparing with/without primary dissection after initial systemic therapy based on clinical subtype in dn-StIV BC patients. **Methods:** Dn-StIV BC patients were enrolled in the first registration. All patients received systemic therapies according to clinical subtypes. The patients not showing refractory disease were randomized to systemic therapy alone (arm A) or PTR plus systemic therapy (Arm B). The same systemic therapy was continued after randomization as additional therapy, for as long as possible. The primary endpoint was overall survival (OS). Secondary endpoints included the proportion of patients without progression at metastatic sites after initial systemic therapies for 3 months, local relapse-free survival (LRFS), primary tumor resection-free survival, and incidence of local ulcer/local bleeding and adverse events. The median overall survival time (MST) after initial systemic therapy for patients with dn-StIV BC was 20 months, on average, and a clinically relevant prolongation of the MST of Arm B was considered to be 6.0 months or longer (hazard ratio: 0.77). The required number of events was 359, to obtain a statistical power of 80% with a one-sided significance level of 0.05. Thus, the planned sample size was 410 patients for the second registration, assuming an accrual period of 7 years and a follow-up time of 4 years. **Results:** 570 patients were enrolled between 11/5/2011 and 31/5/2018 in the first registration. Of these, 407 eligible patients were randomized to either Arm A (N = 205) or Arm B (N = 202). The patient characteristics were well balanced between the two arms. The MST of randomized patients was 70 months, with 221 deaths. The difference in OS was not statistically significant (HR 0.857, 90% CI 0.686-1.072, one-sided $p = 0.1283$). MST was 69 months in Arm A and 75 in Arm B. The proportions of patients without progression at metastatic sites in Arms A and B were 81.5% and 67.3%, respectively ($p = 0.0014$). LRFS in Arm B was significantly longer than that in Arm A (median LRFS 20 vs 63 months: HR 0.415, 95% CI 0.327-0.527, $p < 0.0001$). In Arm B, patients with incomplete resection had poorer outcomes than those in whom resection was complete (94 vs. 61 months, HR 1.971 (1.161-3.347) $p = 0.0120$). In the subgroup analysis, PTR improved survival in patients with ER-positive tumors, pre-menopausal status or single-organ metastasis. **Conclusions:** PTR is not recommended for all dn-StIV BC patients but can control local disease and is acceptable in a select population of patients because of the clear improvement in local control. Clinical trial information: UMIN000005586. Research Sponsor: Japan Agency for Medical Research and Development, the National Cancer Research and Development Fund.

Poster Discussion Session

Long-term oncologic outcomes after omitting axillary surgery in older women with early stage, node-negative breast cancer: A systematic review and meta-analysis. *First Author: Mariam Rana, Harvard T.H. Chan School of Public Health, Boston, MA*

Background: In 2016, Choosing Wisely recommended the omission of routine sentinel lymph node biopsy (SLNB) in early stage, clinically node-negative, hormone receptor-positive, Her2-negative breast cancer in women ≥ 70 years old, although data supporting this was limited. Our study aimed to examine the long-term impact of omitting axillary staging in elderly women undergoing surgery for early stage, clinically node-negative breast cancer. **Methods:** A systematic review and meta-analysis was conducted. Medline (Ovid) and Embase were searched for published papers and abstracts using a systematic search strategy. Randomized and observational studies comparing women aged ≥ 70 years of age with early-stage, clinically node-negative breast cancer undergoing surgery for breast cancer with and without axillary staging, were included. Included studies reported at least one of the following outcomes: axillary recurrence (primary outcome), disease-free survival (DFS), breast cancer-specific survival (BCSS), and overall survival. Risk ratios (RR) were calculated as summary estimates for all outcomes. A weighted pooled mean difference and 95% CI was calculated using a random-effects inverse variance meta-analysis for each outcome. Heterogeneity was calculated using I^2 statistics, and explored using meta-regression. The Newcastle-Ottawa Scale was used to assess the methodological quality of eligible trials, based on the selection of patients, comparability of cohorts, and the methods of outcome assessment. **Results:** Nine studies were eligible for meta-analysis, including data for 48,523 patients. For the primary outcome of axillary recurrence, data for 3,591 patients was meta-analyzed. Axillary staging was found to reduce the risk of axillary recurrence compared to no axillary staging, although this was not statistically significant (RR 0.59, 95% CI: 0.26 to 1.35, $I^2 = 46.6\%$, $p = 0.21$). For overall mortality, data for 14,981 patients was meta-analyzed, and a statistically significant protective effect of axillary staging on overall mortality was demonstrated (RR 0.55, 95% CI: 0.33 to 0.90, $I^2 = 78.1\%$, $p = 0.003$). No significant differences were observed in DFS (RR 1.02, 95% CI: 0.51 to 2.07, $I^2 = 0.0\%$, $p = 0.37$) and BCSS (RR 0.96, 95% CI: 0.57 to 1.62, $I^2 = 0.0\%$, $p = 0.78$). **Conclusions:** Omission of axillary surgery to stage the axilla may be associated with a higher risk of overall mortality in older women with early-stage breast cancer compared to those who undergo axillary surgery. Omission of axillary surgery in this patient population should be carefully tailored to the individual patient, taking into consideration co-morbidity, life expectancy, and formal measures of frailty. Randomized trials are required to further explore the oncologic safety of omitting axillary staging in women aged 70 years or older undergoing breast cancer surgery. Research Sponsor: None.

Differences of prediction performances by multigene assays in patients with breast cancer with distinct genetic backgrounds. *First Author: Fei Xing, Department of Oncology, Shengjing Hospital of China Medical University, Shenyang, China*

Background: The 21-gene (Oncotype Dx), PAM50 (Prosigna) and Chinese-based 28-gene (RecurIndex) are validated genomic assays that provide prognostic information for distant recurrence risk in patients with hormone receptor (HR)-positive, HER2-negative early breast cancer (EBC). In this study, we aim to compare the differences in prediction performance by different multigene assays and gene expression profiles between the Eastern and the Western. **Methods:** Under the Affymetrix U133 platforms, the differences in gene expressions and risk scores from the Eastern population comprised of GSE20685 (n = 327) and part of GSE45255 (n = 95), and the Western population GSE25066 (n = 508) and the European in GSE45255 (n = 44) were analyzed respectively. Patients were stratified by 21-gene Recurrence Scores (RS) of low (0-10), intermediate (11-25) and high (26-100) and categorized by ROR-S score of PAM50 of low (0-40), intermediate (41-60) and high (61-100). For 28-gene, a recurrence index for distant recurrence (RI-DR) cutoff of 33 was used to classify patients into high- and low-risk groups. Wilcoxon rank test was used to test for continuous variables and the chi-square test was used for categorical variables. **Results:** The Western population has significantly higher RS (85.9 vs. 65.5, $p < 0.001$) and ROR-S (57.4 vs. 53.7, $p = 0.034$) scores than the Eastern population. The distribution of 28-gene risk groups was significantly different between races with a higher proportion of high-risk in the Western (10.5% vs. 6.6%, $p = 0.035$). The low-risk patients in the Eastern stratified by 28-gene assay had significantly higher distant metastasis-free survival (DMFS) rates than high-risk (80% vs. 52%, $p < 0.001$), which compared with Oncotype Dx RS (96% vs. 76%, $p < 0.001$) and PAM50 ROR-S (93% vs. 72%, $p < 0.001$). At the same time, the analysis of gene expressions revealed significantly high expressions of *YWHA*, *SF3B5*, *CKAP5*, and *DDX39A* in the Eastern than that in the Western. However, most genes from 21-gene and ROR-S were more highly expressed in the Western than that in the Eastern. **Conclusions:** 21-gene and PAM50 provide the good performance and show similar patterns in the prognosis of EBC; However, the DMFS rate of the high-risk in the Eastern population determined by 28-gene was much lower than 21-gene and PAM50, which means there are bigger chemo-benefit in the high-risk from 28-gene. In conclusion, 28-gene has better performance in the prognosis of the Eastern population and is a more suitable tool for Eastern breast cancer patients. Research Sponsor: None.

Differential benefit of capecitabine-based chemotherapy among TNBC subtypes in the context of the CBCSG010 study. *First Author: Junjie Li, Shanghai Cancer Center, Shanghai, China*

Background: Our previous study classified TNBCs into four mRNA subtypes, provided additional insights into TNBC heterogeneity and potential therapeutic options. Then we conducted a phase Ib/Ii subtyping-based and genomic biomarker-guided umbrella trial (FUTURE, NCT03805399), demonstrated the clinical benefit of subtyping-based targeted therapy for refractory metastatic TNBC. Here, we further evaluate the prognosis and predictive value of molecular classification in early TNBC in CBCSG010 trial (NCT01642771), which is a prospective, randomized phase III trial confirmed adding capecitabine to anthracycline-taxane-based adjuvant chemotherapy significantly improved survival in TNBC. **Methods:** Tumor tissues and pathological sections were retrospectively collected. Immunohistochemical (IHC) staining and hematoxylin and eosin (HE) staining were performed on paraffin-embedded sections to conduct TNBC IHC subtype staining. RNA-sequencing were performed to characterize the intrinsic molecular features of TNBC microenvironment. **Results:** 585 patients enrolled in the CBCSG010 trial, 450 patients had pathological sections, among which 207 patients achieved successfully stained sections. PDL1, CD8 and stromal tumor infiltrating lymphocytes (STILs) were chosen for identified TNBC Immune enriched phenotype. Patients with $\geq 20\%$ positive tumor cell proportion score (TPS) of PDL1, $\geq 10\%$ positive cells of CD8, and $\geq 10\%$ positive STILs were significantly associated with better 5y-DFS (disease-free survival). Among Immune enriched TNBC, kaplan-Meier curves showed that DFS rates were 96.4% and 73.7% in the capecitabine and control groups. Transcriptome data was used to picture the immune microenvironment landscape, showed that “immune-hot” patients (immune cells or immune genes enriched) were more likely to benefit from capecitabine treatment. **Conclusions:** TNBC subtypes is significantly associated with DFS, with Immune enriched phenotype achieving the best outcome, and “immune-hot” patients are more likely to benefit from adjuvant capecitabine. Designing future clinical trials adding immunotherapy in adjuvant treatment of TNBC might base on molecular features. Efficacy of ovarian function suppression of 3-monthly versus monthly GnRH agonist as endocrine therapy for premenopausal breast cancer patients. *First Author: Daniella Audi Blotta, Hospital Beneficência Portuguesa de São Paulo, São Paulo, Brazil*

Background: The combined analysis of the Suppression of Ovarian Function Trial (SOFT) and Tamoxifen and Exemestane Trial (TEXT) trials have shown significant survival benefit of adding ovarian function suppression (OFS) with GnRH agonists (GnRHa) to aromatase inhibitors (AI) versus tamoxifen in high-risk premenopausal patients (pts) with estrogen receptor (ER)-positive breast cancer (BC). In both studies, GnRHa was administered every 4 weeks. However, the efficacy of 3-monthly GnRHa plus AI has not been well studied. We conducted a retrospective study designed to assess the efficacy of OFS with 3-monthly compared with monthly goserelin, associated with AI, in premenopausal pts with ER-positive BC. **Methods:** Medical records of premenopausal pts with ER-positive BC who received OFS with 10.8mg 3-monthly goserelin plus AI or 3.6mg monthly goserelin plus AI, between June/2013 and January/2023 were reviewed. Patient characteristics, such as age, body mass index (BMI) and prior chemotherapy were analyzed. Estradiol (E2) levels were measured by gas chromatography tandem mass spectrometry. Pts with at least one E2 level above 2.72 pg/ml were considered to have ineffective OFS. Analysis of E2 measurements was divided into periods: < 3 , 3 to 6, 6 to 9, 9 to 12, 12 to 18, 18 to 24 and > 24 months. E2 levels greater than 2.72 pg/ml were evaluated at each timepoint. **Results:** A total of 88 pts were included. 27 (30.7%) received monthly goserelin and 61 (69.3%) 3-monthly goserelin. Patient characteristics were well balanced between the groups. Relevant demographic data are shown in table. For E2 analysis, 20 (22.7%) pts had at least one measurement greater than 2.72 pg/ml, 11 (40.7%) in the monthly group and 9 (14.8%) in the 3-monthly group ($p = 0.007$). The percentages of E2 measurements ≥ 2.72 pg/ml, in each time period, were 0%, 40%, 12.5%, 16.7%, 33.3%, 50% and 50% in monthly group versus 8%, 4.2%, 10%, 14.3%, 4.8%, 8.3% and 5.6%, in 3-monthly group, respectively. **Conclusions:** Our study demonstrated that more pts who underwent 3-monthly goserelin had E2 levels below the defined threshold of 2.72 pg/ml compared with monthly goserelin, when associated with AI, with statistical significance. These findings suggest that 3-monthly goserelin may result in better efficacy in OFS when comparing with monthly and provide greater convenience for pts. Research Sponsor: None.

Variable	Monthly Goserelin, n (%)	3-Monthly Goserelin, n (%)	P value
Median age at OFS start, years (IQR)	39 (35-43)	39 (35-44)	$p = 0.839$
Patients younger than 40 years	14 (51.8%)	34 (55.7%)	Not applicable
Median BMI, kg/m ² (IQR)	23 (21-25)	23 (21-26)	$p = 0.693$
High clinical risk by MINDACT criteria	7 (53.8%)	21 (72.4%)	$p = 0.298$
Metastasis at diagnosis	5 (18.5%)	7 (11.5%)	$p = 0.501$
HER2-positive status	1 (3.7%)	12 (19.7%)	$p = 0.058$
Prior chemotherapy	17 (77.3%)	50 (92.6%)	$p = 0.111$

Assessing the marginal costs of radiation therapy and antiestrogen therapy for post-lumpectomy, early-stage breast cancer across Medicaid and Medicare plans. *First Author: Victoria Wu, Case Western Reserve University School of Medicine, Cleveland, OH*

Background: With recent Level I evidence (FAST FORWARD) supporting radiation therapy (RT) duration as short as one week and Level I evidence (CALGB9343) supporting RT omission in favor of antiestrogen endocrine therapy (ET) alone in select patients, the necessity of both RT and ET, adjuvantly, in early-stage breast cancer (BC) has been questioned. Evidence providing granular details on the role of insurance in the aggregate cost of RT and ET is lacking. This project disaggregates costs by insurance plan to increase transparency of out-of-pocket (OOP) cost estimates. **Methods:** National Comprehensive Cancer Network guidelines were utilized to determine the proper treatments, with FAST FORWARD radiation dose/fractionation (26 Gy in 5 fractions) representing RT. Treatments were identified using Current Procedural Terminology and Healthcare Common Procedure Coding System codes. OOP costs, deductibles, and copay/coinsurance were calculated for Medicaid, Original Medicare, Medigap Plan G, and Medicare Part D Rx. The medicare.gov, medicaid.oh.gov, aarpmedicareplans.com, and cms.gov were used to determine pricing. Price estimates reflect actual costs per insurance plan rather than costs estimated from claims data. All procedures were considered to be performed in an Ohio hospital setting, insurance coverages were based on the zip code 44106, and total expenses were based on all treatments plus a 5-year follow-up (not adjusted for inflation). **Results:** Treatment charges for ET include medical oncology initial consultation, biannual medical oncology follow-up, baseline bone density study, and Anastrozole cost (5-years). Treatment charges for RT include initial consultation, treatment planning, dosimetry calculations, treatment device, simulation and verification, RT delivery, on-treatment visits, and medical physics consultation. Original Medicare beneficiaries face an OOP cost of 20% for Medicare Part B claims with no cost cap for approved procedures after the deductible. Medications are covered under Medicare Part D with copays. This results in a marginal OOP treatment charge (after 5-year follow-up) of \$767.54 for ET alone and \$1,416.78 for ET + RT. Medigap Plan G beneficiaries face a marginal OOP charge of \$1,225 for both ET alone and ET + RT, assuming the \$226 Medicare Plan B deductible is met by the cost of lumpectomy during the year of RT. For Medicaid beneficiaries (assuming all treatments are approved by Medicaid), all expenses are covered without limit, resulting in no OOP expense for either treatment plan. **Conclusions:** Discussions of adding RT to ET for post-lumpectomy early-stage BC often involves considerations of treatment costs. This model (based on actual cost estimates per insurance plan rather than claims data) can help to enhance cost transparency by comparing expenses between Medicare and Medicaid plans. Association between patient-reported outcomes and therapeutic outcomes in patients with breast cancer: A pooled individual-participant data analysis.*First Author: Natansh Modi, Flinders University, Adelaide, SA, Australia*

Background: Patient-reported outcomes (PROs) are captured in validated tools to provide the patients' perspective and voice on their physical, social, emotional, functional, and cognitive abilities. Pre-treatment PROs have shown prognostic importance in other cancer types, however, the prognostic value of PROs in breast cancer has been minimally explored. **Methods:** In a pooled analysis of contemporary clinical trial IPD from patients with breast cancer, cox-proportional hazard analysis and binary logistic regression was used to assess the association between potential predictors with overall survival (OS) and adverse event (grade ≥ 3) outcomes, respectively. PROs were recorded using the EORTC QLQ-C30 version 3.0 questionnaire in the pooled cohort. Statistical significance was set at a threshold of $P < 0.05$ and was determined via the likelihood ratio test. Model fit and linearity of variable associations were assessed via the Akaike information criterion (AIC). All analyses were stratified by age, performance status, treatment arm, and study. The primary assessed outcome was OS, with grade ≥ 3 adverse events assessed as a secondary outcome. A forward inclusion process (starting with the variable of lowest AIC, PRO domains were retained in the model if they decreased the AIC by 2 or more on addition, and remained statistically significant) was used to evaluate the value of multiple PRO domains on prognostic performances. **Results:** Within data available, the EORTC QLQ-C30 version 3.0 questionnaire was used in a pooled cohort of 8,544 patients across 8 clinical trials. In the pooled cohort, the association between PROs and outcomes was best described by a linear association. Patient-reported physical functioning, appetite loss, and pain were significantly associated with OS. On forward-inclusion, only physical functioning remained within the OS prognostic model. Except for patient-reported financial difficulties, all PRO domains were significantly associated with grade ≥ 3 adverse events. On forward-inclusion, physical functioning, pain, and constipation all remained statistically significant. **Conclusions:** Within large high-quality IPD, pre-treatment PROs demonstrated significant prognostic relationships with therapeutic outcomes in patients with breast cancer initiating contemporary anticancer treatments. Patient-reported physical functioning was found to be the most prognostic PRO domain for OS, while patient-reported physical functioning, pain, and constipation were retained in a multivariable model prognostic of grade ≥ 3 adverse events. A multicenter phase II study of vaccines to prevent recurrence in patients with HER-2-positive breast cancer. *First Author: Hyo S. Han, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Patients (pts) with early stage HER2-positive breast cancer are commonly treated with neoadjuvant HER2-targeted therapy. Pts who have residual invasive disease have a less favorable outcome and increased risk of recurrent disease than pts with a complete pathologic response (pCR). It also has been observed that pts who do not achieve a pCR have low or absent anti-HER-2 CD4 Th1 responses. We hypothesized that correcting anti-HER-2 CD4 Th1 response using vaccines will be safe, induce anti-tumor immunity in HER2-positive breast cancer and reduce the risk of recurrence. We conducted a multi-center, phase 2, randomized study to determine the safety, immunogenicity and recurrence free survival of two HER2 vaccines (multivalent anti-oncogene DNA vaccine (WOKVAC) or HER-2-pulsed dendritic cell vaccine (DC1)). **Methods:** Pts with HER2-positive early breast cancer were eligible if they had residual invasive disease at surgery after receiving neoadjuvant chemotherapy plus HER2-targeted therapy. Patients were randomly assigned in a 1:1 ratio, with stratification according to residual cancer burden (RCB) (1+2 vs 3) to receive adjuvant HER2 vaccination with either DC1 or WOKVAC. For the initial vaccination phase, DC1 was delivered via US guided inguinal lymph node administration, weekly x 6 weeks and WOKVAC was given intradermally on weeks 1, 4, and 7. Booster vaccines were given at months 6, 9 and 12. The primary end point is to evaluate the safety and tolerability of each vaccine and assess immune response rate as measured by ELISPOT. Each treatment arm will be assessed separately. Secondary endpoints include recurrence-free survival. Exploratory analyses include the assessment of prognostic and predictive biomarkers including circulating tumor cells, serum HER2 levels, and other immune correlative biomarkers. Here we are reporting the initial safety results. **Results:** Total of 110 eligible pts (55 WOKVAC vs 55 DC1) were enrolled from 2/2018 to 12/2022 and received at least one dose of treatment and 38 pts pending completion of the booster phase. Most pts had clinical stage I/II/III 56/35 (82%) and 50% had positive node disease at diagnosis. 82% had hormone receptor positive disease. 37/38/8 patients had RCB 1/2/3. For patients without known RCB status, ypTNM was used to randomize (yp stage I/II/III = 13/13/1 pts). The most frequently observed treatment related adverse events (TRAE) were injection site pain/reaction (38%) and chills (34%), fever (25%) and fatigue (40%) for DC1 arm. For WOKVAC, the most common toxicities included injection site reaction (68%) and fatigue (37%). All of these were grade 1 and 2. Nine patients had events including new primary cancer (1), local recurrence (2), metastatic disease recurrence (6). **Conclusions:** Both DC1 and WOKVAC HER2 vaccines were well tolerated without significant toxicities. Updated results will be presented at the meeting including correlatives. Clinical trial information: NCT03384914. Research Sponsor: Department of Defense.

The impact of the 4R Oncology model on OncotypeDx turnaround time. *First Author: Jenny Wei, Department of Medicine, The Permanente Medical Group, San Francisco, CA*

Background: The OncotypeDx genomic assay has been widely used to predict recurrence in those with early-stage ER positive breast cancer to determine whether adjuvant chemotherapy is beneficial. Receiving OncotypeDx results in a timely manner prior to medical oncology appointment is critical to inform adjuvant therapy decisions. In this quality improvement project, we implemented a care delivery optimization for patients with breast cancer receiving OncotypeDx assays in an integrated healthcare system. The optimization was conducted as part of implementing the 4R Oncology model (Right Info / Right Care / Right Patient / Right Time), a novel care model that aims to optimize patient-centric care planning, team-based delivery and patient self-management. Herein, we assess the impact of implementing this model on improving OncotypeDx turnaround time. **Methods:** We examined two patient groups with newly diagnosed early-stage ER positive breast cancer who attended a multidisciplinary clinic and underwent surgery at a single medical center. The historical control (HC) group received care pre-4R implementation, from January 2019 through June 2020, while the 4R Intervention group received care from July 2020 to December 2021. The OncotypeDx-related care optimization was a team effort of 5 medical specialties that involved establishing an OncotypeDx reflex testing practice, updating workflows, working with a testing company to streamline the process and implementing a method to align result timing with scheduling medical oncology appointments. Bivariate analyses were used to compare the HC and 4R groups on demographic characteristics and OncotypeDx turnaround time. **Results:** Within the 4R group (N = 208), 72 (34.6%) patients received OncotypeDx and 89 (32.5%) patients from the HC cohort (N = 274) received OncotypeDx. The groups were balanced by median age at time of multidisciplinary clinic visit (HC: 59 years vs 4R: 60 years), female gender (HC: 99.6% vs 4R: 99.5%), race, combined race and ethnicity, language spoken, Charlson Comorbidity Index and tumor characteristics. The average turnaround time from surgery date to delivery of OncotypeDx results was significantly reduced in the 4R cohort (19.4 days) compared to that of the HC cohort (23.1 days), a difference of 3.8 days, $p = 0.004$. The availability of OncotypeDx results by the first medical oncology visit after surgery increased from 40% in the HC cohort to 69% in the 4R cohort, $p = 0.0003$, helping optimize the transition to adjuvant therapy for the appropriate population. **Conclusions:** The implementation of the 4R Oncology model within an integrated healthcare system significantly reduced turnaround time for patients with breast cancer awaiting OncotypeDx results, improving patient-centric care and enabling informed discussions at medical oncology visits. The 4R Oncology model is an effective method to optimize delivery of time-sensitive care. Research Sponsor: Genentech (for 4R).

Does RSCLin provide additional information over classic clinico-pathologic scores (PREDICT 2.1, Influence, CTS-5)? A TEAM Pathology substudy. *First Author: Ana-Alicia Beltran-Bless, The Ottawa Hospital, Ottawa, ON, Canada*

Background: Gene-expression profiling tests (e.g. Oncotype, MammaPrint, Prosignia, Breast Cancer Index and EndoPredict) are widely used in the care of patients with early-stage hormone positive breast cancer (node negative or 1-3 lymph nodes). However, these tests are resource intensive, and few studies have compared their value with either free and widely available clinico-pathologic risk calculators (e.g. PREDICT 2.1, INFLUENCE 2.0, and CTS-5) or tools that combine genomic testing with clinico-pathologic data (e.g. RSCLin). The TEAM pathology substudy population was used to compare these different predicted model scores with outcomes. **Methods:** The TEAM pathology study consists of 3284 postmenopausal hormone positive breast cancer patients treated with either exemestane or tamoxifen followed by exemestane. Accrual was from 2001 to 2006. Genes comprising the multi-parametric Oncotype Dx were used to train signatures to create true assay results. Patient data was then used to calculate recurrence scores through various tools. This included clinico-pathologic models and their respective endpoints PREDICT 2.1 (overall survival at 5 years), INFLUENCE 2.0 (distant metastasis at 5 years), CTS-5 (distant recurrence risk at year 5-10), the purely genomic Oncotype Dx trained results (distant recurrence risk at 9 years), as well as the new clinico-pathologic RSCLin (distant recurrence risk at 10 years). We compared the level of association between these predictive model scores using Spearman correlation coefficients. The prognostic ability of each model was contrasted for each outcome using Harrell's C-statistic. **Results:** Results were available for CTS-5 (3022 patients), INFLUENCE 2.0 (3485 patients), ODX-trained (3825 patients), and RSCLin (3029 patients). Correlation coefficients showed low correlation between Influence ($r = 0.25$) and CTS-5 ($r = 0.17$) with Oncotype-Dx trained results, and high correlation between RSCLin ($r = 0.84$) and Oncotype-Dx trained results. The concordance index was similar (0.65 to 0.68) for all models with distant metastasis-free survival as the outcome. Analysis is ongoing and further results will be available at the time of presentation. **Conclusions:** Other clinico-pathologic tools such as Influence 2.0 and CTS-5 have good prognostic ability when compared to Oncotype Dx-trained results and RSCLin. Real-world impact of TAILORx on chemotherapy use and SOFT/TEXT on ovarian function suppression uptake in a population based-cohort of women 40 years and under with HR-positive, HER2-negative, axillary lymph node negative breast cancer. *First Author: Malek B. Hannouf, Schulich School of Medicine and Dentistry, Department of Internal Medicine, Western University, London, ON, Canada*

Background: Gene expression profiling (GEP) testing is prognostic for distant recurrence risk in women with hormone receptor positive (HR+), human epidermal growth factor receptor-2 negative (HER2-), axillary lymph node negative (LN-) breast cancer (BC). The TAILORx trial generated prospective evidence demonstrating the 21-gene recurrence score (RS) is also predictive of chemotherapy (CT) benefit. The literature suggests that GEP testing reduces adjuvant CT prescription and is cost-effective. In the same era, the SOFT/TEXT trials demonstrated disease-free survival benefit for the addition of ovarian function suppression (OFS) to endocrine therapy in premenopausal women. Real-world uptake and impact of these advances in the management of HR+, HER2-, LN- BC in young women may be limited due to complex reasons. This retrospective study evaluated GEP and CT use post TAILORx and OFS use post SOFT/TEXT in women 40 years old or younger diagnosed with HR+, HER2-, LN BC from 2011 to 2020 in Alberta, Canada. **Methods:** Clinical variables were retrieved from the Alberta Health Services Cancer Care Breast Data Mart and through review of the electronic medical record. GEP testing and CT use were compared between 3 cohorts of women defined by diagnosis: pre RS funding/pre TAILORx (before April 2014), post RS funding/pre TAILORx (April 2014-May 2018), post TAILORx (June 2018 and beyond). OFS use was compared between 2 cohorts of women defined by diagnosis pre- and post SOFT/TEXT (May 2015). In subgroup analyses, we compared CT use by GEP status and RS category and OFS use by CT status. **Results:** Among the 291 women identified, GEP testing increased by 37% post GEP funding (pre 2% vs. post 39%; $P < .0001$) and by additional 15% post TAILORx (pre 39% vs. post 54%; $P < .0001$) whereas overall CT use declined by 15% post GEP funding (pre 85% vs. post 70%; $P = .01$) and by additional 16% post TAILORx (pre 70% vs. post 54%; $P = .01$). Although not significant, OFS use increased by 8% post SOFT/TEXT (pre 13% vs. post 21%; $P = .08$). In subgroup analyses, post TAILORx was associated with a significant reduction in CT use of 19.5% in non-GEP tested women (pre 85% vs. post 65% $P = .01$) and non-significant increase in CT use of 6% in RS tested women (pre 40% vs. post 46%; $P = .61$) mainly driven by high mid range RS 21-25 and lower high range RS 26-30. There was no significant change in OFS use in non-CT treated women post SOFT/TEXT (Pre 5.3% vs. Post 8%, $P = .68$) whereas OFS use increased by 15% in women treated with CT post SOFT/TEXT (pre 15% vs. post 30%; $P = .01$). **Conclusions:** Public GEP funding and TAILORx led to widespread adoption of GEP and real-world decline in CT use in women 40 years of age or younger diagnosed with HR+, HER2-, LN- BC in Alberta. SOFT/TEXT led to real-world incline in OFS use in those treated with CT but adoption remained suboptimal. Research Sponsor: None.

Image-only deep learning risk model performance in patients with known germline mutations. *First Author: Faezeh Sodagari, Massachusetts General Hospital, Boston, MA*

Background: Mammograms contain highly predictive biomarkers of future breast cancer risk, which can be identified by deep learning (DL) risk stratification models. DL model performance in discerning risk in patients with known germline mutations has yet to be established. The aim of this study is to assess image-only DL model risk score performance in patients with and without a germline mutation undergoing screening breast MRI. **Methods:** This retrospective, multisite study included the first screening MRI of consecutive females ≥ 30 years from 3/1/2011 to 11/30/2021 at four facilities, with a prior bilateral screening mammogram containing a DL risk score and at least one year of follow-up. A mammography-based DL five-year model was used to assess risk, with an increased-risk threshold of ≥ 2.2 and high-risk of ≥ 5.8 . Patient demographics, germline mutation status, and traditional risk factors were extracted from electronic medical records. Standard screening performance metrics including cancer detection rate (CDR) within one year of MRI were determined. Cancer outcomes were determined via linkage to a regional tumor registry. DL model performance was compared using Pearson's chi-squared tests. **Results:** 4025 patients who underwent screening breast MRI met inclusion criteria. 381 (9.5%) had a known germline mutation. There was no significant difference in age of those with or without a germline mutation (54.9y $\pm$ 10.5 vs 54.8y $\pm$ 8.8, $p = 0.284$) or family history of breast cancer (68.5% vs 65.3%, $p = 0.205$). Patients with a germline mutation were more likely to be White (95.0 vs 91.4%, $p < 0.05$), have non-dense breasts (52.8% vs 35.3%, $p < 0.001$) and less likely to have a personal history of breast cancer (25.7% vs 36.3%, $p < 0.001$). The CDR in those with a germline mutation was higher than those without a mutation (39.4 vs 20.3, $p < 0.05$). The median DL risk score in those with a germline mutation was lower than those without a mutation: 1.9 (IQR: 1.4-2.5) vs 2.3 (IQR: 1.7-3.8), $p < 0.001$. In patients with a germline mutation, the CDR in those with elevated DL scores was higher than those with low DL scores (47.6 vs 34.2, $p = 0.512$: increased-risk threshold; 60.6 vs 37.4, $p = 0.512$: high-risk threshold). A similar trend was seen in those without a germline mutation (26.4 vs 12.8, $p < 0.01$: increased-risk threshold; 27.1 vs 19.0, $p = 0.203$: high-risk threshold). Trends were demonstrated across all comparisons, but significance was only reached in the largest group. **Conclusions:** Compared to patients without germline mutations, those with mutations had higher CDRs on MRI but lower DL risk scores. Patients with higher DL risk scores had higher CDRs in those identified as increased or high-risk by DL model, regardless of germline mutation status. Further study to elucidate mechanisms to explain differential performance of DL models in patients with germline mutations is ongoing. Research Sponsor: MGH, Ralph Schlaeger Fellowship Award.

Disease-free survival (DFS) as a surrogate for overall survival (OS) in patients (pts) with HR+/HER2- early breast cancer (EBC): A correlation analysis. *First Author: Michael Untch, Interdisciplinary Breast Cancer Center, Helios Klinikum Berlin-Buch, Berlin, Germany*

Background: DFS has been widely adopted as a clinically meaningful primary endpoint in EBC trials in place of OS, which needs extensive follow-up to observe sufficient events and fails to assess survival benefit early. However, a rigorous validation of DFS as a surrogate endpoint for OS is required for each given setting. The objective of this analysis was to evaluate DFS as surrogate for OS in the adjuvant treatment of HR+/HER2- EBC. **Methods:** A systematic literature review (SLR) was conducted using biomedical literature databases (ie, Embase, PubMed, and Medline [from database inception to January 2023]) and key conferences to identify published studies in EBC. The eligibility criteria for the SLR were RCTs that included $\geq 80\%$ of adult pts with HR+/HER2- EBC and assessing different treatment options (ie, cyclin-dependent kinase 4/6 inhibitors [CDK4/6i], endocrine therapies [ET], and chemotherapies [CT]). Studies were considered for correlation analysis if hazard ratios (HRs) were reported for both DFS and OS. The analysis excluded observational studies and trials with immature OS data. Spearman rank correlation (r_s) and weighted linear regression analyses (measured by coefficient of determination [R^2]) were performed to evaluate the correlation between HRs for OS and DFS. Considering heterogeneity, multiple scenario analyses were conducted. Surrogate threshold effect (STE) was also estimated; STE is defined as the maximum value of the HR for DFS that needs to be observed in a trial to ensure the possibility of concluding that a significant effect on OS occurred. Correlation was also assessed using pt-level data from the FACE trial (letrozole vs anastrozole in postmenopausal pts with HR+/HER2- EBC) to validate findings of the trial-level analysis. **Results:** A total of 14 RCTs ($N = 31,668$) were included (CDK4/6, 2; ET, 7; CT, 5). Trial-level analysis showed that r_s between OS and DFS was 0.81 (95% CI, 0.56-0.94), which when weighted by variance was 0.81. Regression analysis showed that 84% of the variability in OS was explained by DFS ($R^2 = 0.84$). A meta-regression model estimated an STE of 0.82 for HR of DFS, which can be leveraged to validate the surrogacy based on the DFS estimated from a future trial. Analysis of pt-level data from the FACE trial demonstrated a correlation between DFS and OS ($r_s = 0.75$). Additionally, correlation coefficients estimated by the Pearson method and iterative imputation were 0.83 and 0.89, respectively. **Conclusions:** Both trial-level and pt-level analyses demonstrate a positive correlation between DFS and OS. These results support the use of DFS as a reliable surrogate endpoint for OS in HR+/HER2- EBC trials to give an early access to innovative therapies. Effect of astragalus polysaccharides (PG2) treatment of adjuvant chemotherapy-induced fatigue in premenopausal patients with breast cancer. *First Author: Kun Ming Rau, E-Da Cancer Hospital, Kaohsiung, Taiwan*

Background: Fatigue is one of the most common symptoms of breast cancer (BC) patients who are receiving adjuvant chemotherapy. Astragalus Polysaccharides (PG2) had been proved to relieve cancer-related fatigue in advanced BC patients. The aim of this study is to evaluate the efficacy of PG2 as a complementary treatment among stage II/III BC patients with adjuvant chemotherapy of epirubicin-cyclophosphamide(EC) regimen in reduction of chemotherapy-induced toxicity and encouraging compliance with chemotherapy. **Methods:** This double blind, multicenter, phase II trial randomized stage II/III BC patients who would receive adjuvant EC at least 4 cycles to either PG2 500 mg or placebo on day1, 3, 8 every 21 days as the combination. Changes in chemotherapy-related fatigue score (CRFS) was evaluated by the Brief Fatigue Inventory-Taiwanese Form and incidence of Grade 3/4 neutropenia were the primary endpoints. **Results:** A total of 66 eligible patients were enrolled and equally randomized to PG2 and placebo groups, 30 cases in each group completed this trial. In general, there was no significant difference in the mean change of CRFS and fatigue intensity between the groups. But the CRFS and fatigue intensity in premenopausal-PG2 group were less aggravated after 4 cycles of EC than that of postmenopausal-placebo group. Persisted significance difference in CRFSs from cycle 1 day 5 (PG2: 0.6; Placebo: 1.9, $P = 0.023$) to cycle 4 day 15 (PG2: -0.3; Placebo: 0.7, $P = 0.002$). In all population, a lower proportion of patients suffered from grade 3/4 neutropenia from cycle 1 to cycle 4 were observed in the PG2 group compared to the placebo group (78.8% vs. 87.9% in intent-to-treat population). **Conclusions:** PG2 combined with adjuvant EC significantly improved adjuvant EC-induced fatigue in premenopausal BC patients. PG2 assists these patients with maintaining normal daily life and job activities, also less need of family support during chemotherapy. Furthermore, patients treated with PG2 might have better compliance to complete the whole course of adjuvant chemotherapy. Clinical trial information: NCT03314805. Prognostic impact of adjuvant endocrine therapy for estrogen receptor-positive and HER2-negative T1a/bNOMO breast cancer. *First Author: Yuko Takahashi, Department of Breast and Endocrine Surgery, Okayama University Hospital, Okayama, Japan*

Background: Adjuvant endocrine therapy (ET) is the standard of care for Estrogen Receptor (ER)-positive early-stage breast cancer. However, many patients suffer from adverse events associated with ET. The prognosis of patients with T1a/bNOMO breast cancer with ER-positive and human epidermal growth factor 2 (HER2)-negative is excellent, and it is not clear whether adjuvant ET should be recommended. Here we evaluate the effect of adjuvant ET for ER-positive and HER2-negative T1a/bNOMO breast cancer. **Methods:** This study was a multicenter, retrospective cohort study that evaluated adjuvant ET for patients with ER-positive and HER2-negative T1a/bNOMO breast cancer. Patients who underwent surgery between 2008 and 2012 in 47 institutions of the Japan Clinical Oncology Group (JCOG) breast cancer group were eligible. We analyzed the cumulative incidence of distant metastasis as primary endpoint using the Gray test model and time to event endpoints (distant disease free survival and overall survival) using log-rank test between patients treated with and without adjuvant ET. We also used Gray test model for the analysis of the cumulative incidence of ipsilateral and contralateral breast cancer. Predictive factors were assessed using the Fine-Gray model and the Cox proportional hazards model. **Results:** The median follow-up period was 9.2 years. Of 4758 eligible patients (1202 T1a [25.3%] and 3556 T1b [74.7%] diseases), 3991 (83.9%) received adjuvant ET. The 9-year cumulative incidence of distant metastasis was 1.5% with ET and 2.6% without ET (adjusted subdistribution hazard ratio [sHR], 0.54; 95% CI, 0.32-0.93). In the multivariate analysis, the independent risk factors of distant metastasis were no ET, mastectomy, high grade, and lymphatic invasion. The 9-year overall survival was 97.0% and 94.4% (HR, 0.54; 95% CI, 0.38-0.77). Adjuvant ET reduced the incidence of ipsilateral and contralateral breast cancer (9-year rates; 1.1% vs 6.9%; sHR, 0.17; 95% CI 0.11-0.28, and 1.9% vs 5.2%; sHR, 0.33; 95% CI, 0.22-0.49). **Conclusions:** Adjuvant endocrine therapy significantly reduces distant metastases, however the absolute difference is small for ER-positive and HER2-negative T1a/bNOMO breast cancer. Furthermore, it reduced ipsilateral and contralateral breast cancer as well. Shared decision making regarding the omission of adjuvant endocrine therapy is crucial, especially in patients with low risk of distant metastasis. Research Sponsor: None.

Pulsed electrical fields in combination with anti-PD1 and survival of mice with TNBC (EMT6) murine breast tumor. *First Author: Ebtesam Nafie, Galvanize Therapeutics INC, Redwood City, CA*

Background: Delivery of pulsed electric field (PEF) energy is used to destabilize cells through multiple biochemical processes. We questioned whether a specific PEF treatment type could synergize with anti-PD1 in an orthotopic Triple Negative Breast Cancer (TNBC) EMT6 mouse model. Our previous studies have demonstrated that PEF treatment induces neo-antigen presentation and triggers an innate and adaptive immune response. Anti-PD1 therapy is ineffective at blocking growth of (TNBC) EMT6 tumors that are orthotopically implanted in mice. We evaluated whether a biphasic monopolar form of PEF could synergize with anti-PD1 when it was administered intraperitoneally or intra-tumorally, and whether there was a change in immune response post treatment. **Methods:** Forty-eight female Balb/c mice were implanted with 200,000 EMT6 cells into the mammary fat pads. Once tumor diameter reached 5 mm they were randomized into 6 groups of 8 animals: 1) Sham/IgG; 2) intra-tumoral (IT) anti-PD-1; 3) intra-peritoneal (IP) anti-PD-1; 4) PEF + anti-PD-1(IP); 5) PEF + anti-PD-1(IT) 6) 2X PEF on day 0 and day 7 + anti-PD-1(IT administered weekly). Sham-PEF mimicked the same procedure but without PEF. Anti-PD1 was administered weekly, IT or IP at 200 µg/mouse and PEF was delivered once on day of randomization. Tumors were measured three times per week, and animal survival was monitored until tumor volume necessitated euthanasia ($\geq 2000\text{mm}^3$). Blood was collected on day 14 for flow cytometric analysis of systemic immune response which included quantifying CD3 positive T cells, B cells and NK cells. **Results:** Anti-PD1 treatment (IT or IP) did not reduce tumor growth, nor did it prolong survival compared to Sham/IgG treated animals. All anti-PD1 alone (IT or IP) as well as Sham treated animals had to be euthanized by day 35. In contrast, PEF combined with anti-PD1 given IT and IP significantly reduced tumor growth by 83% and 70%, respectively, on Day 14 compared to anti-PD-1 only treated animals ($p = 0.03$). Interestingly, EMT6 bearing mice treated with double PEF + IT administered anti-PD1 survived longer compared to mice treated with single PEF + IT administered anti-PD1. On day 65, 71% of double PEF + IT administered anti-PD1 were still alive compared to 12.5% of mice treated with PEF + IT administered anti-PD1 ($p = 0.002$). Flow cytometry analysis on day 14 indicated an increase in circulating adaptive (T- and B-cells) and innate (NK cells) immunocytes in the PEF + anti-PD1 treated animals compared to the control. **Conclusions:** Collectively, these results indicate that some types of PEF ablation synergize with weekly anti-PD1 in stimulating an increase of CD3+ T cells, B cells and NK cells, reducing tumor growth and prolonging survival of tumor bearing mice. These results suggest the synergistic potential of combining Immunotherapy with some forms of PEF, which warrants further study in patients. Research Sponsor: Galvanize Therapeutics.

Poster Session

HRD signature and HRD genomic landscape of tumors from 896 patients with early-stage breast cancer (BC). *First Author: June Evelyn Jeon, Yale School of Medicine, New Haven, CT*

Background: Pathologic mutations in *BRCA1*, *BRCA2* and *PALB2* lead to impaired homologous recombination repair (HRR). Cells with defects in HRR are dependent on non-homologous DNA end joining for DNA repair through the poly(ADP-ribose) polymerase (PARP) catalytic activity. PARP inhibitors (olaparib, talazoparib) are FDA-approved therapies that are toxic to tumors with HRR deficiency (HRD) and are recommended as adjuvant therapy in high-risk germline *BRCA* (gBRCA) positive BC. Despite the clinical implications of HRD, the prevalence of HRR alterations and HRD signature in early-stage primary BC and its association with hormone receptor (HR) status has not been well characterized. **Methods:** This study used the nationwide (US-based, ~280 US cancer clinics) de-identified Flatiron Health-Foundation Medicine BC clinico-genomic database and included patients (pts) who underwent tissue comprehensive genomic profiling (FoundationOne/FoundationOneCDx) between 2014 and 2022. The analysis included all pts with BC who presented with "early" stage I-III disease, had a primary tissue specimen collected within 3 months of diagnosis, and had a reportable novel scar-based HRD signature (HRDsig). **Results:** A total of 896 primary BC pts with stage I-III met our inclusion criteria. Of these early BC pts 21% (188/896) were HRDsig+ (stage I: 17% (32/188); stage II: 22% (84/376); and stage III: 22% (72/332)). For early BC pts, high rates of HRDsig+ were seen in gBRCA (87% [34/39]), somatic *BRCA* (sBRCA, 78% [14/18]), and gPALB2 (71% [5/7]) mutated tumors, with a lower rate seen with other HRR genes [16% (10/63); *ATM*, *BARD1*, *BRIP1*, *CDK12*, *CHEK1*, *CHEK2*, *FANCL*, *sPALB2*, *RAD51B*, *RAD51C*, *RAD51D* and *RAD54L*]. HRDsig+ was also detected in 16% (135/832) of BC without g/s *BRCA* or gPALB2 mutations. BC pts who presented with stage I-III disease have similar prevalence of HRDsig+ when compared to those with stage IV disease (21% [188/896] vs 23% [177/767], $p = 0.31$), with similar trends in HR+ disease (HR+/HER2+: 7% [4/57] vs 9% [4/45], $p = 0.73$; and HR+/HER2-: 17% [78/466] vs 18% [82/463], $p = 0.73$). Conversely, in HR- cohorts, decreased prevalence of HRDsig+ was observed in the stage I-III vs stage IV cohort (HR-/HER2+: 3% [1/38] vs 18% [6/33], $p = 0.04$; HR-/HER2-: 31% [99/321] vs 38% [83/216], $p = 0.08$). **Conclusions:** In this study, HR+/HER2- group was the most common early BC subtype, followed by HR-/HER2-, HR+/HER2+, and HR-/HER2+. This distribution is similar to the SEER study, and closely reflects that of the general population. We observed the expected high rates of HRDsig+ in early-stage BC pts with g/sBRCA or gPALB2 mutations where clinical trial data already support the use of PARP inhibitors for early and advanced disease. Importantly, HRDsig positivity was also seen in 16% of early BC without g/sBRCA or gPALB2, and clinical trials will be needed to determine if these pts could also benefit from HRD directed therapies. Impact of endocrine therapy adherence on racial disparities in breast cancer survival. *First Author: Kimberley T Lee, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Black women have worse breast cancer outcomes compared to their White counterparts, even for hormone receptor positive (HR+) HER2 negative (HER2-) breast cancer (BC). This tumor type is usually treated with 5-10 years of adjuvant endocrine therapy (ET) to reduce risk of BC recurrence and improve survival. We investigated the impact of adherence to ET on racial differences in survival for HR+ HER2- BC survivors. **Methods:** We conducted a population-based, retrospective cohort study using the Surveillance, Epidemiology, and End Results (SEER)-Medicare database, which links demographic and clinical data with cause of death for persons with cancer and Medicare claims for covered health services. We examined 9,039 women with HR+ HER2- stage I-III BC diagnosed between 2007 and 2016, who received primary breast surgery and initiated ET. Adherence to ET was measured using the medication possession ratio (MPR), which assesses the proportion of time a patient has medication available via filled prescriptions. As in established literature, we defined ET adherence as $\text{MPR} \geq 80\%$. Causal mediation analysis was performed to measure to impact of adherence on survival disparities between Black and White BC survivors. **Results:** Mean age at diagnosis was 72 years, 6.5% were Black, and 20.9% were dual eligible for Medicaid (a surrogate for socioeconomic hardship). Most had stage I or II breast cancer (69.3%) and mastectomy as primary surgery (69.7%). Nineteen percent received chemotherapy and 62.5% received radiation. In univariate analyses, factors associated with ET adherence were Black race (OR 0.62, 95% CI 0.54-0.75), insured by Medicaid (OR 0.72, 95% CI 0.65-0.81), being married (OR 1.14, 95% CI 1.03-1.25), and increased comorbidities (Charlson score ≥ 2) (OR 0.88, 95% CI 0.78-0.99). Age, BC stage, type of surgery, and receipt of chemotherapy or radiation were not associated with ET adherence. In multivariable models adjusting for age, race, marital status, Medicaid eligibility, and Charlson score, Black race and Medicaid eligibility remained inversely associated with ET adherence (OR 0.70, 95% CI 0.59-0.83 and OR 0.77, 95% CI 0.69-0.87 respectively). Among those who were adherent to ET, Black women had 43% higher risk of mortality compared to White women (HR 1.43, 95% CI 1.17-1.76). In mediation analysis, 4.25% of the observed survival disparity between Black and White women can be explained by differences in ET adherence. **Conclusions:** We identified racial disparities in ET adherence and overall survival among women with BC. Adherence to ET accounted for a small percentage of racial disparities in survival. Further research is needed to delineate other factors contributing to ET non-adherence among Black women and to investigate additional factors contributing to known disparities in BC survival. Real-world outcomes with adjuvant nonsteroidal aromatase inhibitors (NSAIs) vs tamoxifen (TAM) in patients with hormone receptor–positive/human epidermal growth factor receptor 2–negative (HR+/HER2–) early breast cancer (EBC): A US database analysis. *First Author: Stephanie L. Graff, Lifespan Cancer Institute, Providence, RI*

Background: Randomized controlled trial (RCT) meta-analysis data have shown a significantly greater disease-free survival (DFS) benefit with aromatase inhibitors than TAM in patients with HR+/HER2– EBC. Here we compare real-world outcomes in patients with HR+/HER2– EBC who received adjuvant endocrine therapy (ET) with NSAIs or TAM. **Methods:** This was a retrospective analysis of ConcertAI's deidentified electronic medical records data set of patients treated at US academic and community oncology clinics from January 1, 1995 to April 30, 2021. The cohort included patients with stage II–III (if IIIB or IIIC, confirmation was required on residual tumor status) HR+/HER2– EBC who underwent surgery and initiated adjuvant ET (excluding those who switched classes of ET); ovarian function suppression (OFS) was permitted. Menopausal status was determined using age (≥ 50 years) as a proxy for undocumented status. Invasive DFS (IDFS; risk of disease recurrence, death, or second primary tumor), distant DFS (DDFS; risk of distant recurrence, death, or second primary tumor), and overall survival (OS; risk of death) were assessed and defined as the time interval between start of ET and first event. Multivariate Cox regression analyses were performed, adjusting for age, stage, Charlson Comorbidity Index, and prior adjuvant or neoadjuvant chemotherapy for the ET cohort. **Results:** Of the total 3133 patients analyzed, 2507 were included in this analysis (NSAI $\pm$ OFS, $n = 1854$; TAM $\pm$ OFS, $n = 653$). Among these patients, the median (range) age was 59.5 (22.8–86.6) years, 25.4% were premenopausal, and 56.2% had tumor node involvement. The mean (SD) time to ET discontinuation was 46.2 (35.9) months overall and was similar between the NSAI and TAM cohorts. Reasons for ET discontinuation were undocumented or missing from the database for 76.8% of patients. Multivariate Cox regression analyses suggested a significant risk reduction with NSAIs vs TAM, with a 17% reduction in risk of an IDFS event (hazard ratio [HR], 0.83 [95% CI, 0.69–0.98]) and an 18% reduction in risk of a DDFS event (HR, 0.82 [95% CI, 0.69–0.98]). Although there were few events, OS analysis suggested a numerical trend favoring NSAIs over TAM, with a 12% reduction in risk of death (HR, 0.88 [95% CI, 0.69–1.13]). **Conclusions:** This real-world data analysis revealed a reduction in risk of IDFS and DDFS events with adjuvant NSAIs vs TAM in patients with HR+/HER2– EBC. Collectively, RCT and real-world data demonstrate greater benefit with adjuvant NSAIs vs TAM with respect to risk of recurrence in this patient population. Pathologic complete response after neoadjuvant systemic therapy for breast cancer in BRCA mutation carriers and noncarriers. *First Author: Sara P. Myers, Breast Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Distinct pathological characteristics and mutational signatures in *BRCA*-associated breast cancers may result in differential response to chemotherapy but understanding of treatment response after neoadjuvant chemotherapy (NAC) is limited. We describe a single-institutional experience to compare rates of pathologic complete response (pCR) after NAC in *BRCA* carriers (*gBRCA1/2*) and noncarriers. **Methods:** From 11/2013 to 01/2022, 1426 consecutive women with clinical stage I–III breast cancer were treated with NAC followed by surgery. Baseline disease characteristics were compared between *gBRCA1/2* and noncarriers using two-sample non-parametric tests. Conditional logistic regression was used to evaluate the association between *BRCA* status and pCR (i.e., ypT0/is pN0) adjusting for variables selected using backward elimination. **Results:** 92 (6.5%) and 73 (5.1%) had deleterious mutations in *BRCA1* and *BRCA2*, respectively. Compared to noncarriers, *gBRCA1/2* were younger ($p < 0.001$) with clinical T1 ($p = 0.002$) and triple negative disease (TN) (57% vs 25% noncarriers, $p < 0.001$). Almost all patients received docorubicin/cyclophosphamide/paclitaxel therapy (93%) with *gBRCA1/2* more likely to receive carboplatin ($p < 0.001$). pCR rate was 42% of *gBRCA1*, 21% of *gBRCA2*, and 26% of noncarriers ($p = 0.001$). Among clinically node positive (cN+) patients, nodal pCR was higher in *gBRCA1/2* compared to noncarriers (53/96 (55%) vs 371/856 (43%), $p = 0.012$). This difference was seen in ER+/HER2– (36% *gBRCA1/2* vs 20% noncarriers; $p = 0.027$) and TN subtypes (79% *gBRCA1/2* vs 45% noncarriers; $p < 0.001$). Poorly differentiated tumors ($p < 0.001$), cN+ ($p = 0.010$), lower cT stage ($p = 0.028$), ductal histology ($p < 0.001$), TN and HER2+ receptor status ($p < 0.001$), absence of lymphovascular invasion ($p < 0.001$), carboplatin receipt ($p = 0.041$), and *BRCA1* status ($p = 0.001$) were also associated with pCR on univariate analysis. After adjusting for differentiation and molecular subtype, *BRCA1* status remained independently associated with pCR. **Conclusions:** *gBRCA1* undergoing NAC have higher pCR rates relative to *gBRCA2* and patients with sporadic disease. Across breast cancer subtypes, *gBRCA1/2* more frequently converted to pN0. Defining biological mechanism for these findings would allow customization of treatment based on germline genetics. The worldwide impact of HER2-targeted treatments in women with breast cancer: An epidemiological modeling study. *First Author: David J. Press, Genentech Inc., South San Francisco, CA*

Background: HER2-targeted therapies (trastuzumab, pertuzumab, and T-DM1) have revolutionized the treatment and epidemiological landscape of HER2+ breast cancer, resulting in population-level increases in survival and decreases in disease recurrence. The aim of this epidemiological modeling study was to quantify the estimated global impact of HER2-targeted therapies, by estimating the number of women diagnosed with HER2+ early breast cancer (eBC) who have avoided (or will avoid) metastatic disease recurrence following treatment. **Methods:** We used data and projections from cancer registries, observational studies, clinical trials, and drug sales volumes (ie, utilization) to create annual country-level synthetic cohorts of patients diagnosed with HER2+ eBC, for the years 2004–2033 in 185 countries. The real-world uptake of HER2-targeted treatments and treatment flow was estimated in the main scenario. The impact of chemotherapy alone was estimated in the counterfactual scenario, assuming 100% chemotherapy worldwide. The occurrence of distant recurrences was modeled in both scenarios using weighted transitional probability averages based on invasive disease-free survival curves from clinical trials. **Results:** In total, during the 3-decade study period, we predicted that 11.9 million (M) women would be diagnosed with HER2+ eBC, out of which 7.5M were estimated to be treated with HER2-targeted therapies in a real-world uptake scenario. In the counterfactual scenario with only chemotherapy available, a total of 2.9M women were estimated to experience a metastatic disease recurrence, compared to only 2.1M women in the base scenario of predicted real-world uptake of HER2+ targeted therapies. This corresponds to a reduction of 26% or 768,000 women who may avoid metastatic recurrence since the introduction of HER2-targeted therapies (Table). **Conclusions:** HER2+ targeted therapies have substantially improved breast cancer outcomes and continue to contribute to the reduction in breast cancer recurrence rates. Further research may elucidate treatment-related reductions in costs to society as a result of population-level improvements in disease outcomes for breast cancer survivors. Given the expected rise in the burden of breast cancer globally, therapeutic advances and increased treatment utilization may further accelerate global patient benefit. Research Sponsor: Hoffmann-La Roche.

Estimated number of women globally diagnosed with BC and experiencing distant recurrence, by year and treatment scenario.

	Years of diagnosis/ recurrence			
	2004–2013	2014–2023	2024–2033	2004– 2033
Women diagnosed with BC (in millions)				
Total	15.3	21.0	26.9	63.2
HER2+ eBC	1.9	4.0	5.9	11.9
Treated with any HER2-targeted therapies	0.7	2.3	4.4	7.5
Women experiencing distant disease recurrence (in thousands)				
Counterfactual: Chemotherapy alone	408	886	1,610	2,904
With predicted real-world uptake of HER2+ therapies	380	723	1,033	2,136

Validation of a novel and rapid reagent free assay to predict outcomes for adjuvant therapy decision making in hormone receptor-positive breast cancer. *First Author: Charles Coombes, Imperial College, London, United Kingdom*

Background: Digistain is a mid-infrared imaging technology that assesses aneuploidy by measuring the nuclear-to-cytoplasmic chemical ratio in the cellular content of tissues to generate the Digistain Index (DI). DI correlates with tumor grade and shows promise for risk stratification. Here we investigated whether DI could predict clinical outcomes in patients with early breast cancer to guide decision making regarding subsequent adjuvant chemotherapy. **Methods:** Infrared spectrometry was performed on existing tissue microarrays to determine the DI of 801 patients with hormone receptor-positive, HER 2-negative primary breast cancer with ≤ 3 positive lymph nodes who had received systemic endocrine therapy only. Multivariate logistic modelling incorporated the DI with pathological features to generate the Digistain Prognostic Score (DPS). Receiver operator characteristics curves were used to assess the ability of DPS to predict 5- and 10-year progression-free survival (PFS), recurrence and overall survival (OS). **Results:** In a Cox-regression analysis, the hazard ratio (HR) of DI to predict OS was 4.49 (95% CI 1.08–18.67; $P = 0.039$) compared with HRs in the range of 1.04–1.81 (all $P < 0.001$) for age, tumor grade, tumor size and lymph node stage. In multivariate modelling analysis, DPS was consistently highly accurate and had negative predictive values for PFS, recurrence, and OS at 5 and 10 years that were similar, if not superior, to existing genomic-based tests. Using the DPS, the HRs for Kaplan-Meier curves for low- vs. high-risk classification were statistically significant ($P < 0.001$) for PFS, recurrence and OS (1.80, 1.83 and 2.49, respectively). **Conclusions:** In patients with early breast cancer, DPS showed high accuracy and predictive performance, and was able to stratify patients into low or high risk. Considering its low cost and ability to provide almost immediate prognostic information, DPS has the potential to offer clinical utility to reduce the use of unnecessary chemotherapy. Influence of hormone therapy timing intake on disease free survival (DFS) for patients with high-risk early breast cancer: Results of the UCBG-UNIRAD phase III randomized trial. *First Author: Sylvie Giacchetti, APHP University Hospital Saint Louis, Senopole, Paris, France*

Background: Circadian rhythms regulate the cellular and molecular processes that determine treatment effects. Scarce data suggest that daily timing could influence endocrine therapy (ET) pharmacology. We prospectively tested this hypothesis within the UNIRAD adjuvant phase III trial (NCT01805271) in patients (pts) with hormone receptors positive (HR+) and human epidermal growth factor receptor 2 negative (HER2-) breast cancer (BC). **Methods:** Between June 2013 and March 2020, 1,278 pts with high-risk HR+/HER2- primary BC were randomly assigned to adjuvant ET combined with EVE or placebo. Pts were stratified according to lymph node involvement, progesterone receptor status, ET (tamoxifen or aromatase inhibitors (AI)), prior neoadjuvant or adjuvant chemotherapy, and duration of ET before randomization. Throughout their participation in the trial, patients were asked to declare prospectively in a daily diary the timing of ET intake within four 6-h slots (06:00 to 11:59 (morning), 12:00 to 17:59 (afternoon), 18:00 to 23:59 (evening), or 24:00 to 05:59 (night)). The prognostic impact of the timing of ET and EVE/placebo on DFS was a prespecified secondary endpoint. **Results:** A total of 855 patients (67%) recorded ET intake daily timings (n = 401 in the EVE arm, n = 454 in the placebo arm). Morning intake was preferred by 465 pts (54%), whilst 344 pts (40%) chose evening intake, and minor proportions took ET in the afternoon (49 patients, 5%) or at night (5 patients, 1%). Pts choosing morning or afternoon intake were significantly older than those preferring evening or night intakes (mean age: morning: 56.4 y.o.; afternoon: 58.4 y.o.; evening: 53.1 y.o.; night: 50.8 y.o.; p < 0.001). Only 10 patients (1.1%) reported changing ET timing during the study. With a median follow-up of 72.5 months, 118 patients relapsed (locally n = 30, metastases n = 84), and 41 patients died. In the whole population, ET intake timing was not associated with DFS (HR 0.77 [95%CI, 0.53-1.12], p = 0.17). ET intake timing effects according to the stratification factors revealed a significant interaction between its prognostic impact and ET agent (tamoxifen versus AI, p for interaction = 0.01). DFS was prolonged in those pts taking tamoxifen in the evening/night rather than in the morning/afternoon (HR = 0.43 [0.22 - 0.85], p = 0.015), while no such effect was found for those on AI (HR = 1.07 [0.68 - 1.7], p = 0.761). Such interaction remained statistically significant at multivariate analysis (HR 0.38, p = 0.003). **Conclusions:** Tamoxifen intake in the evening was associated with an improved DFS in high-risk HR+/HER2- breast cancer pts and could be recommended at no cost in the adjuvant setting. Clinical trial information: NCT01805271. Research Sponsor: French Ministry of Health PHRC; La Ligue contre le Cancer; Novartis.

Additional prognostic value of the BCT score in patients with ER+HER2-breast cancer receiving 21-gene assay-guided adjuvant treatments. *First Author: Sung Gwe Ahn, Gangnam Severance Hospital, Yonsei University, Gangnam-Gu, NA, Korea, Republic of (South)*

Background: In early estrogen receptor (ER)+HER2- breast cancer, a 21-gene expression assay-guided decision-making for adjuvant treatments has been widely utilized as a standard-of-care. The GenesWell BCT is a multigene assay that is designed to predict the risk of distant recurrence (DR) in patients with ER+HER2-breast cancer. This assay consists of nine genes, which are used to generate a risk score that can help guide treatment decisions. We addressed an additional value of the GenesWell Breast Cancer Test (BCT) score using the cohort of ER+HER2-breast cancer patients receiving a 21-gene assay-guided adjuvant treatments, focusing the chemotherapy untreated subset with low 21-gene recurrence score (RS). **Methods:** This multicentre, observational follow-up study was done in 4 academic institutions in South Korea. Patients with ER+HER2- breast cancer who received RS-guided adjuvant treatments were enrolled. A total of 705 patients were included. Of these, the rate of women with node-positive disease was 21.6% (152/705), and the rate of women with younger than 50 years old was 61.4% (433/705). The BCT score was obtained using the specimens which were previously analyzed for RS. The primary endpoint was recurrence-free survival (RFS), and the secondary endpoint was distant recurrence-free survival (DRFS). **Results:** Among the 705 patients, the RS assigned 110 (15.6%) as high risk (≥ 26), whereas the BCT score assigned 239 (33.9%) as high risk (≥ 4). The agreement between two tests was noted in 494 (70.1%); concordances were made in 69 for high and in 425 for low, respectively. At a median follow up of 85 months, 80 had tumor recurrences, 38 had distant recurrences, and the 7-year RFS was 90.0% (95% CI, 87.6%-92.5%). In the 595 patients with low RS, 556 (93.4%) did not receive adjuvant chemotherapy. Within the 556 chemotherapy-untreated patients with low RS, the RFS differed significantly according to the BCT score (p = .014); the 7-year RFS was 92.9% in the BCT-low, while it was 85.7% in the BCT-high. Within the group, the BCT score was demonstrated as an independent prognostic factor for both RFS and DRFS adjustment of tumor size, nodal stage, and histologic grade. In addition, the RFS of the low-BCT score group was superior to that of the high-BCT group in either women younger than 50 years of age with an RS of 21 to 25 or all women with an RS of 21 to 25. **Conclusions:** We found that the BCT score was useful in stratifying the risk of relapse in chemotherapy-untreated patients with a low recurrence score (RS). This indicates that the BCT score could provide additional clinical value in identifying patients with a long-term risk of relapse, particularly in young women with an RS of 21 to 25. Prognostic role of HER2 expression in patients with ER-positive/HER2-negative breast cancer: Results from a population-based cancer registry study. *First Author: Antonino Musolino, Gruppo Oncologico Italiano di Ricerca Clinica (GOIRC), Parma, Italy*

Background: Estrogen Receptor (ER)-positive (+)/Human Epidermal Growth Factor Receptor 2 (HER2)-negative (-) breast cancers (BCs) express variable protein levels of both ER and HER2, which can influence prognosis. **Methods:** We evaluated all invasive ER+/HER2- BCs (n = 3633) that were diagnosed and systematically collected by the Parma Province Cancer Registry, Italy, from 2004 to 2018. Tumors were classified by HER2 (IHC score of 0, 1+ or 2+ with negative FISH) and ER status (ER-low [1-9%], ER-moderate [10-79%] or ER-high [80-100%]). Comparisons of clinicopathologic characteristics and disease outcome were performed. **Results:** BCs with late-stage diagnosis (P = 0.04), high histologic grade (P < 0.0001), or high proliferative rate (P < 0.0001) were more likely HER2 2+/FISH-. The rate of ER-high BCs did not change from 2675 of 2938 (91%) HER2 0 tumors to 508 of 560 (90.7%) HER2 1+, and 124 of 135 (91.9%) HER2 2+/FISH- tumors. Correspondingly, ER-low BCs were not enriched among HER2 0 tumors compared to the other tumors with different HER2 expression (P = 0.6). The 5-year overall survival (OS) for HER2 2+/FISH- BCs was lower than that for HER2 0 or 1+ tumors (P = 0.03). ER-low/moderate tumors were associated with poorer OS in comparison with ER-high BCs (P < 0.0001). HER2 2+/FISH- status was detrimental to OS among patients (pts) with ER-high tumors (P = 0.04), while this finding was not observed among ER-low/moderate BCs (P = 0.21). An interaction between HER2 2+/FISH-expression and ER-high status was found for poorer OS after adjusting for prognostic variables (HR = 1.7; 95% CI: 1.1-2.9). **Conclusions:** The prognostic role of HER2 expression in pts with ER-positive/HER2-negative BCs seems to be restricted to ER-high tumors, while the worse prognosis of tumors with lower ER expression is not associated with HER2 status. These findings may help identify optimal patient inclusion criteria for clinical trials with novel anti-HER2 therapies in ER-positive/HER2-negative disease. Research Sponsor: None.

An analysis of breast cancer index scores predicting benefit of extended endocrine therapy by race. *First Author: Nicholas Siu-Li, University of Hawaii John A. Burns School of Medicine, Honolulu, HI*

Background: Patients with early-stage hormone receptor-positive (HR+) breast cancer have a good prognosis. Prior studies have shown that extending endocrine therapy beyond the first 5 years reduces the risk of late distant recurrence. The Breast Cancer Index (BCI) is a gene expression assay that provides both a prognostic risk of late distant recurrence in addition to a yes/no prediction of benefit from receiving extended endocrine therapy. To date, no studies have examined the relationship between race and BCI score. This study aims to investigate the interaction between race and BCI scores in women with early-stage HR+ breast cancer. **Methods:** We analyzed BCI scores, demographics, and tumor characteristics from 89 women diagnosed with early-stage HR+ breast cancer. Univariate logistic regression analysis was run using race, BCI recurrence risk, hormone status, tumor size, or tumor grade as predictor variables. BCI prediction of benefit was used as the outcome variable. **Results:** Compared to Caucasians, Native Hawaiians had significantly greater odds of having a BCI score predicting benefit from receiving extended endocrine therapy (OR = 7.00, p = 0.04). Additionally, there were significantly greater odds of having a score predicting benefit among those who had a recurrence risk of 5-10% (OR = 3.84, p = 0.04), or $\geq 10\%$ (OR = 9.16, p < 0.001) compared to a recurrence risk < 5%. **Conclusions:** Our findings highlight the utility of characterizing differences in BCI predictive and prognostic scores by race among breast cancer patients with early-stage HR+ tumors. Notably, Native Hawaiian women had 7.0 times increased odds of having a score predicting benefit of extended endocrine therapy compared to Caucasians. This result is salient given the high incidence of breast cancer among Native Hawaiians. Though not statistically significant, our data also demonstrated Filipinos had increased odds of a score predicting benefit as well. Furthermore, our findings show a direct correlation between prognostic risk of late distant recurrence and predictive benefit of extended endocrine therapy with a higher odds ratio associated with higher recurrence risk. Our study shows notable differences in BCI findings when stratifying patients by race. However, our sample size is relatively small, and we lack sufficient data from patients representing other races such as Hispanic and Black. Future studies may expand the sample size and adjust for known breast cancer risk factors. The goal is to identify trends that may improve our usage of the BCI as a tool to effectively guide hormone therapy recommendations in patients with early-stage HR+ breast cancer. Research Sponsor: U.S. National Institutes of Health.

Cardiac safety and efficacy for patients with early-stage breast cancer treated with pegylated liposomal doxorubicin (PLD) or doxorubicin. *First Author: Lichen Tang, Department of Breast Surgery, Fudan University Shanghai Cancer Center; Cancer Institute, Fudan University Shanghai Cancer Center, Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China*

Background: Anthracyclines play an important role in the treatment of breast cancer (BC) while cardiotoxicity, a serious side effect, limits the clinical application. Pegylated liposomal doxorubicin (PLD) is a new dosage form of doxorubicin encapsulated in liposomes, which can reduce the plasma free level of doxorubicin and drug to normal tissue delivery, thereby reducing cardiotoxicity. The aim of this study was to evaluate the cardiac safety and efficacy of PLD compared with doxorubicin as adjuvant therapy in breast cancer patients. **Methods:** This is an open-label, randomized trial involving patients with operable breast cancer who were at high risk of recurrence after radical surgery (NCT03949634). Patients were randomized (1:1) to receive adjuvant PLD or doxorubicin (A) and cyclophosphamide followed by taxanes ± trastuzumab. The primary endpoint was cardiotoxicity, which was defined as congestive heart failure (CHF) with clinical symptoms, or no symptoms but with an abnormal left ventricular ejection fraction (LVEF). Secondary endpoints included 5-year disease-free survival (DFS) rate, 5-year overall survival (OS) rate and safety. **Results:** Between November 2017 and September 2019, 247 patients were randomized and received study treatment (PLD arm, 131; A arm, 116). The median age was 49 years (range, 26-67) in PLD arm and 48 years (range, 25-70) in A arm. The pathological stages were 18.3% stage I, 58.0% stage II, and 22.1% stage III in PLD arm, while those of A arm were 20.7% stage I, 59.5% stage II, and 19.8% stage III. The median follow-up time was 43.0 months. The incidence of abnormal LVEF was 0 in the PLD arm and 1.7% the A arm (P = 0.220). The incidence of CHF was 0 in the PLD arm and 0.9% the A arm (P = 0.470). Survival data analysis is immature. The exploratory analysis of cardiac-related biomarkers showed that the incidence of high-sensitivity cardiac troponin-T (hs-cTnT) was lower in PLD arm than in A arm (3.8% vs. 30.2%, P < 0.001). Grade 3/4 adverse events (AEs) occurred in 42.7% patients in PLD arm and in 61.2% patients in A arm. The most common grade 3/4 AEs in PLD arm and A arm included neutropenia (34.4% vs. 55.2%), leukopenia (30.5% vs. 39.7%), and hand-foot syndrome (4.6% vs. 0.0%). **Conclusions:** Hs-cTnT elevation may have a role in the AE prediction of anthracycline. PLD usage may present lower incidence of cardiotoxicity than doxorubicin in the adjuvant treatment of patients with early-stage breast cancer. Clinical trial information: NCT03949634. Research Sponsor: CSPC Ouyi Pharmaceutical Co., Ltd.

Beneficial effect of repeated participation in breast cancer screening upon survival. *First Author: Robert A. Smith, American Cancer Society, Atlanta, GA*

Background: The benefit of mammography screening in reducing population mortality from breast cancer is well established. However, the effect of repeated participation at scheduled screens on case survival is less well documented. **Methods:** In this retrospective analysis of breast cancer survival, we analyzed incidence and survival data on 37,079 women ages 40-69 from nine Swedish counties who had between one and five invitations to mammography screening and were diagnosed with breast cancer between 1992 and 2016. Of these, 4,564 subsequently died of breast cancer. For each breast cancer diagnosed in each county's period of observation, we obtained data on previous screening history, and subsequent death (or not) from breast cancer. Formal comparisons of survival with respect to numbers of screening exams attended prior to a diagnosis of breast cancer were carried out using Cox proportional hazards regression with time-varying covariates, ie, cumulative numbers of screens, yielding hazard ratios and 95% confidence intervals (CI). We corrected for potential self-selection using the method of Duffy et al, which gives a corrected estimate based on the proportion of participants, the uncorrected estimate, and the relative risk of breast cancer death for non-participants compared to an uninvited population. **Results:** Depending on number of invitations, 58-73% (average 65%) participated in all scheduled screens, and 73-96% (average 91%) participated in at least one examination. There was successively better survival among women with increasing numbers of screening exams. For a woman with five previous screening invitations who participated in all five screening exams, the hazard ratio was 0.28 (95% CI 0.25-0.33, p<0.0001), a 72% risk of dying from breast cancer, compared to a woman attending none. Following a conservative adjustment for potential self-selection factors, the hazard ratio was 0.34 (95% CI 0.26-0.43, p<0.0001). **Conclusions:** For those women who develop breast cancer, regular prior participation in mammography screening confers significantly better survival. Most women will not develop breast cancer in their lifetime. These results indicate that for those who do, regular participation in screening considerably improves the probability of surviving it. The distinction between the general, population benefit of mammography screening, and the benefit of regular participation in mammography screening should be clearly articulated in breast cancer screening messaging and decision aids. Research Sponsor: American Cancer Society.

Hazard ratios by number of screens in which the women participated, unadjusted and adjusted for potential self-selection factors.

Number of screens participated in	Hazard ratio (95% CI)	
	Unadjusted	Adjusted
0	1.00 (-)	1.00 (-)
1	0.71 (0.57-0.89)	0.87 (0.67-1.12)
2	0.50 (0.40-0.63)	0.61 (0.45-0.83)
3	0.37 (0.30-0.46)	0.45 (0.34-0.60)
4	0.37 (0.31-0.43)	0.45 (0.35-0.58)
5	0.28 (0.25-0.33)	0.34 (0.26-0.43)

Influence of adherence to adjuvant endocrine therapy in early breast cancer: Results from a large German real-world claims data analysis. *First Author: Dominik Dannehl, Department of Women's Health, Tuebingen University Hospital, Tuebingen, Baden-Wuerttemberg, Germany*

Background: In hormone-receptor positive (HR+) early breast cancer (EBC) adjuvant endocrine therapy (ET) significantly reduces recurrence and mortality. The most common way to estimate therapy adherence is the use of patient reported outcome measures. Yet, this method is inaccurate due to the social-desirability bias. We therefore aimed to analyze adherence to ET over the first 5 years of treatment by using claims data from a large German health insurance provider (AOK Baden-Wuerttemberg). **Methods:** Female patients diagnosed with HR+ EBC between July 1st 2010 and December 31st 2019 were included into the analysis. Adherence to ET was defined as the ratio of the summed number of pills of filled prescriptions for ET (either aromatase inhibitors or tamoxifen) and the duration of endocrine therapy in days (from the start of the first prescription after completion of surgery and chemotherapy, if applicable). ET administration was observed over 5 years. High/low adherence was defined as a ratio between 0.8 – 1 and 0 – 0.8, respectively. ET duration was divided into yearly intervals and adherence was calculated as above. Continuous high/low adherence was then defined as an adherence between 0.8 – 1 and 0 – 0.8 in each year. Distant recurrence-free survival (DRFS) was calculated from the day of the first diagnosis of EBC until onset of distant metastatic disease. Overall survival (OS) was defined as the period between first diagnosis of EBC until death. **Results:** In total, 20998 patients were included. 17006 patients (81%) were HR+. Regarding overall adherence during the first 5 years, average adherence was 0.81 ± 0.26, with 72% of all HR+ patients showing high adherence to ET. Of 17006 HR+ EBC patients, 8363 (49%) showed a continuous high adherence to ET and 1731 (10%) showed a continuous low adherence to ET over 5 consecutive years. Continuous adherence to endocrine therapy had a significant impact on DRFS (HR: 0.61; 95% CI: 0.52 - 0.71; p < 0.0001) and OS (HR: 0.52; 95% CI: 0.46 - 0.59; p < 0.0001). The 10-year OS rate was 79% / 64% for patients with continuous high / low adherence to endocrine therapy. **Conclusions:** As measured by the number of prescribed pills, adherence during the first 5 years of endocrine therapy was higher than expected by literature. Continuous adherence to ET over 5 years has a significant impact on OS and DRFS. Future research should focus on identifying factors that influence therapy adherence in HR+ EBC patients. State-of-the-art management of HER2-negative early breast cancer: Treatment patterns among healthcare professionals and concordance with expert recommendations. *First Author: Marie N. Becker, Clinical Care Options, Reston, VA*

Background: The management of high-risk HER2-negative early-stage breast cancer (EBC) has recently evolved with the addition of newer agents including abemaciclib, olaparib, and pembrolizumab as (neo)adjuvant therapy options for appropriate patients. To aid healthcare professionals (HCPs) in the recommended implementation of these agents, we developed an online treatment decision support tool providing case-specific treatment guidance from 5 breast cancer experts. Here, we report an analysis of cases entered into the tool by HCPs, comparing their planned treatment with expert recommendations. **Methods:** Expert therapy recommendations for 10 case scenarios in high-risk HER2-negative EBC based on 3 pivotal clinical trials (KEYNOTE-522, OlympiA, and monarchE) were obtained in March 2022. Patient and disease characteristics included hormone receptor (HR) status, *BRCA* mutational status, lymph node positivity, presence of residual disease after resection, and additional criteria based on the 3 practice-changing trials. HCPs entered specific patient and disease factors into the tool along with their intended treatment plan and were shown 5 individual expert treatment recommendations for the unique case scenario. **Results:** From June 2022 to January 2023, 547 HCPs entered 982 patient case scenarios into the tool. A comparison of treatment recommendations by experts and HCPs showed divergence for several case scenarios. For patients with high-risk HR-positive/HER2-negative EBC and no *BRCA* mutation, all 5 experts recommended adjuvant abemaciclib plus endocrine therapy. By contrast, 64% of HCPs' therapy choices were discordant with the experts, with 49% choosing chemotherapy followed by endocrine therapy. For patients with triple-negative breast cancer (TNBC) who received neoadjuvant chemotherapy and have no residual disease, all 5 experts recommended observation, whereas 36% of HCPs recommended additional adjuvant therapy. In the setting of *BRCA*-mutated TNBC with residual disease after neoadjuvant pembrolizumab plus chemotherapy, 4 of 5 experts recommended adjuvant pembrolizumab plus olaparib, but just 33% of HCPs chose this combination. One third of HCPs who initially selected treatment options that diverged from expert recommendations or who were uncertain about treatment choice intend to change their therapy selection to align with the experts. **Conclusions:** Analysis of data from this tool suggests differences in clinical practice between experts and HCPs for multiple case scenarios of high-risk EBC, including examples of potential overtreatment. Moreover, our data demonstrate that this decision support tool may lead to better alignment of HCP treatment choices with experts, with the potential to improve clinical management of patients. SEER analysis of 9-year breast cancer specific mortality (BCSM) in patients (pts) with invasive lobular breast cancer (ILC) assessed by the 21-gene Breast Recurrence Score assay. *First Author: Charles E. Geyer, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Linking of the results of the 21-gene Breast Recurrence Score (RS) commercial assay to SEER registries provides opportunity to assess real world prognostic performance of the assay in important subgroups of early breast cancer (BC). ILC is less common than invasive ductal carcinoma (IDC) and the performance of the RS assay in ILC is of interest. The relationship between RS results and 5-year BCSM in patients with ILC was reported based on a linkage in 2015 at this meeting in 2017. Here we present a comparison of 9-year BCSM of ILC vs IDC from a linkage update in 2019. These results will be updated further based on a new linkage of RS data to be completed in April 2023. **Methods:** Eligible pts had 0-3 axillary nodes at initial surgery, were hormone receptor positive and HER2-negative with a RS result, had no prior malignancy, and were diagnosed between January 2004 and December 2012. Pts with ICD-0-3 code 8520 were categorized as ILC and those with code 8500 as IDC. 9-year BCSM of both cohorts was estimated using actuarial methods. Multivariable Cox proportional hazards models characterized association between RS results and BCSM. **Results:** Of 89818 pts, 9835 (11.0%) had ILC and 64669 (72.0%) had IDC. Among pts with ILC, median age was 60 years; 12.5% were N1 and 28.4%, 63.7% and 7.9% were grade 1, 2 and 3. Median follow-up was 84 months. Chemotherapy (CT) use and BCSM increased with increasing RS result in both cohorts. After adjusting for age, race, tumor grade, tumor size, nodal status, and histologic subtype, the RS result was independently associated with BCSM ($p < .001$) in both ILC and IDC. **Conclusions:** In this linked SEER analysis of pts with ILC or IDC, the RS results were prognostic for 9-year BCSM, regardless of nodal status. Research Sponsor: U.S. National Institutes of Health; Exact Sciences.

Histologic subtype	RS result	Node-negative			Node-positive		
		N	% CT use	9-y BCSM (95% CI)	N	% CT use	9-y BCSM (95% CI)
IDC	0-15	24265	5.6	1.9% (1.6, 2.1)	3599	21.1	2.8% (2.2, 3.8)
	16-20	13556	17.9	2.5% (2.1, 2.8)	1912	36.8	4.9% (3.7, 6.4)
	21-25	8559	36.7	4.5% (4.0, 5.2)	1051	52.7	8.2% (6.3, 10.6)
	26-100	10544	64.9	8.4% (7.8, 9.1)	1183	73.3	16.0% (13.3, 19.2)

Detection of homologous recombination deficiency (HRD) using a novel genomic and epigenomic liquid biopsy assay in patients with breast cancer. *First Author: Catalin Barbacioru, Guardant Health, Redwood City, CA*

Background: Homologous recombination and repair (HRR) deficiency (HRD) is characterized by genomic instability associated with dysfunction in *BRCA1/2* or other HRR genes. Patients with breast cancer harboring an HRD phenotype with or without HRR mutations have derived clinical benefit from PARPi therapy. We have previously shown that GuardantINFINITY, a novel genomic and epigenomic liquid biopsy assay, can identify HRR SNVs, indels, rearrangements, copy number loss, reversions, and *BRCA1* promoter methylation for patient selection and resistance monitoring, a major challenge for PARPi treatment. Here, we present a method of predicting HRD status by cfDNA using GuardantINFINITY in patients with advanced breast cancer. **Methods:** We developed a probabilistic genomic model to predict HRD status, inferred from genome-wide somatic SNV, indel, and CNV signatures indicative of *BRCA1/2* deficiency, including large-scale state transitions (LST), whole-genome tumor loss of heterozygosity (LOH), telomeric allelic imbalance (TAI). A second probabilistic model, based on targeted measurements of genomic and epigenetic changes was learned from a subset of clinical samples to enhance the genomic model. The model was trained and tested on a cohort of over 12,000 GuardantOMNI and GuardantINFINITY clinical breast cancer samples to assess the sensitivity of accurately detecting deficiency in select HRR-genes (*BRCA1/2*, *PALB2*, *RAD51D*). The aggregated predictive model was validated on an independent cohort of breast cancer samples. **Results:** The model based on genomic and epigenetic signals identified HRR-gene deficiency in a breast cancer cohort with an estimated 95% LoD of 22.5% tumor fraction and an AUC of 0.75 across all tumor fractions, an improvement in sensitivity over when only the genomic model is used (AUC of 0.7, 95% LoD of 28%). Specificity remained high for both models (100%, $n = 83$) in cancer free samples. Application of this model in a cohort of 1,101 patients with unselected breast cancer identified 390 patients with an HRD phenotype, of whom 192 patients had a known HRR-gene mutation. Of the 201 patients with a known pathogenic mutation in an HRR gene, 49 also had co-occurring LoH in the same gene, indicating biallelic loss. **Conclusions:** In this analysis, we demonstrate that a probabilistic model of genomic and methylation predictors can detect HRD status in patients with breast cancer from cfDNA using GuardantINFINITY. Additional analytical and clinical studies to further evaluate this model are ongoing. With HRD prediction, GuardantINFINITY provides a comprehensive minimally-invasive solution for PARPi and DNA damage treatment selection, longitudinal monitoring, and an exploratory platform for investigating epigenetic signals that may underpin resistance. Impact of neoadjuvant chemo-immunotherapy on surgical outcomes and time to radiation in triple negative breast cancer. *First Author: Sara P. Myers, Breast Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The impact of preoperative chemo-immunotherapy on surgical complications and timing of adjuvant therapy is not well understood. We examined the association between neoadjuvant pembrolizumab plus chemotherapy (NAC+P) compared to neoadjuvant chemotherapy alone (NAC) and treatment delays and postoperative complications in triple negative breast cancer (TNBC). The effect of immune-related adverse events (irAEs) on these outcomes was also compared. **Methods:** 143 women with stage II-III TNBC treated with NAC+P based on the KEYNOTE 522 (KN522) regimen from 8/2021-9/2022 were compared to 287 consecutive patients who received NAC prior to 7/2021. Baseline characteristics, time to treatments, and surgical complications were compared between KN522 and non-KN522, and among KN522 with/without irAEs using two-sample non-parametric tests. Linear regression evaluated association of irAEs with time to surgery and radiation. Conditional logistic regression identified factors associated with surgical complications among KN522 patients. **Results:** Age, BMI, race, ASA class, and mastectomy rates were similar among KN522 and non-KN522 patients. Interval from end of neoadjuvant treatment until surgery was one day longer for patients receiving NAC+P (median 32 days (IQR 27, 43) vs. 31 days (26, 37) non-KN522, $p = 0.035$). Time to radiation did not differ ($p = 0.2$). Postoperative complications occurred in 26 (9%) non-KN522 vs 12 (8.4%) of KN522 patients ($p = 0.7$) (Table). 55/144 (38%) of KN522 patients experienced 74 irAE; 42 (76%) required treatment. Pembrolizumab was held in 21 (38%) and discontinued permanently in 17 (31%). One KN522 patient experienced a fatal irAE (pneumonitis). Older age (coeff. 0.38, 95% CI 0.06-0.70, $p = 0.02$) and ASA class 4 (coeff. 53, 95% CI 14-92, $p = 0.009$) were associated with delays to surgery but irAE was not ($p = 0.070$). Neither presence of irAE (coeff. 6.8, 95% CI -0.74-14, $p = 0.081$) or number of irAEs (coeff. 4.1, 95% CI -1.2-9.3, $p = 0.13$) were associated with time to radiation. IrAEs were not associated with surgical complications ($p = 0.5$). **Conclusions:** Postoperative complications or delays to surgery or adjuvant radiation were similar in patients treated with NAC+P compared to NAC. IrAEs were not associated with delays to surgery or adjuvant radiation or postoperative complications. Research Sponsor: None.

Trends and outcomes of systemic therapy in hormone receptor-positive early-stage male breast cancer: A propensity score analysis. *First Author: Liuwen Yu, Department of Breast Surgery, Fujian Medical University Union Hospital, Fuzhou, China*

Background: Male breast cancer (MBC) is a rare disease. Research on trends and survival outcomes in systemic treatment for MBC is limited. This study aims to describe trends and survival outcomes of different systemic treatments in hormone receptor-positive (HR+) early MBC and to assess the factors related to treatment selection. **Methods:** We identified stage I-III HR+ invasive MBC patients who have undergone surgery and systemic therapy diagnosed during 2004-2014 from the National Cancer Database (NCDB). Treatment groups include: endocrine therapy (ET), chemotherapy (ET), combination therapy (ET+CT), and None. Using Cochran-Armitage trend tests to describe the temporal trends of different treatments. Performing propensity score models to evaluate overall survival. Conducting a logistic regression to analyze factors associated with ET+CT. **Results:** Among 6217 patients included (median follow-up 50.1months), 1290 (20.7%) patients received no systemic therapy (None), 705 (11.3%) patients only received CT, 2358 (37.9%) patients only received ET, and 1864 (30.0%) patients received ET+CT. From 2004 to 2013, there was a significant increase in the use of ET ($P(\text{trend}) < .001$), which was accompanied by a decrease in CT and no treatment (all $P(\text{trend}) < .001$). And the use of ET+CT showed no significant change. After using overlap weighting (OW) to control confounders, multivariable cox regression analysis showed that ET+CT was associated with improved survival compared with ET (hazard ratio [HR], 0.46; $P < .001$). Sensitivity analyses (including the inverse probability of treatment weighting (IPTW) (HR, 0.49; $P < .001$), IPTW with stabilized weight (HR, 0.49; $P < .001$), propensity score matching (PSM) (HR, 0.51; $P < .001$), PS regression adjustment (HR, 0.47; $P < .001$), and PS stratification (HR 0.44; $P < .001$)) and exploratory subgroup analyses (except for well-differentiated, stage I, and breast conservation + radiotherapy subgroups) indicated similar outcome. Factors associated with receiving ET+CT include younger age, private insurance, Charlson Comorbidity Index was 0, poorer differentiation, higher stage, mastectomy and radiotherapy, estrogen receptor-positive and progesterone receptor-negative, and HER2-positive. **Conclusions:** ET+CT was associated with improved survival compared with ET in HR+ early MBC patients, except for some low-risk subgroups. Decision value of the circulating tumor DNA on the adjuvant anti-Her2 regimens in patients with Her2-positive breast cancer treated with neo-adjuvant therapy. *First Author: Po-Han Lin, National Taiwan University Hospital, Taipei City, Taiwan*

Background: A significant proportion of patients with early-stage Her2-positive breast cancer are treated with neoadjuvant therapy (NAT). Previous studies suggested the presence of circulating tumor DNA (ctDNA(+)) after NAT was a significant predictor for recurrence in early-stage Her2-positive breast cancer. However, it is unknown whether the ctDNA(+) was able to guide adjuvant anti-Her2 regimen for patients with early-stage Her2-positive breast cancer? **Methods:** We enrolled 117 patients who had Her2-positive breast cancer and received NAT. CtDNA was collected before and after NAT as well as detected by Oncomine breast cell-free DNA assay. Adjuvant anti-Her2 regimens were classified as T-DM1 and non-T-DM1. Recurrence-free survival (RFS) was estimated by Kaplan-Meier method and hazard ratio (HR) with 95% confidence interval (CI) was analyzed by Cox proportional hazards regression model. **Results:** Of the 117 patients enrolled, there were 18 patients receiving adjuvant T-DM1 and 99 receiving trastuzumab (N = 70) or trastuzumab plus pertuzumab (N = 29). CtDNA(+) was observed in 79 patients before NAT while 32 patients remained ctDNA(+) after NAT. Multivariate Cox regression model showed that ctDNA(+) after NAT (HR 3.497 95% CI 1.364-8.964, $p = 0.009$) was an independently poor factor that predicted recurrence, after adjustment with clinical and pathologic parameters. Non-pCR was associated with an inferior trend of survival but not a statistically significant factor of recurrence. Patients who received adjuvant T-DM1 had a reduced risk of recurrence (HR 0.118, 95% CI 0.015-0.931, $p = 0.043$) in the multivariate analysis. Further analysis of the prognostic value of adjuvant T-DM1 therapy in context with and without ctDNA, we divided patients into 4 subgroups: ctDNA(-)/non-T-DM1, ctDNA(-)/T-DM1, ctDNA(+)/non-T-DM1 and ctDNA(+)/T-DM1. Our data revealed that patients with ctDNA(+)/T-DM1 had a significantly better RFS than those with ctDNA(+)/non-T-DM1 ($p = 0.019$). The 5-year RFS was similar between patients with ctDNA (+)/T-DM1 and those with ctDNA(-) after NAT. **Conclusions:** The presence of ctDNA in patients with early-stage Her2-positive breast cancer after NAT was independently associated with disease recurrence; however, ctDNA(+) after NAT became inconsiderable when patients were treated with adjuvant T-DM1 therapy, which represented ctDNA(+) as an important factor determining adjuvant anti-Her2 regimen. Research Sponsor: Yonglin Foundation.

Utility of Ki67 in guiding adjuvant abemaciclib therapy for patients with hormone receptor (HR)-positive, early breast cancer (EBC). *First Author: Rima Patel, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: The monarchE trial found that the addition of adjuvant abemaciclib to endocrine therapy in pts with lymph node (LN)+, HR+ EBC improved invasive disease-free survival in two pt cohorts: (1) ≥ 4 LNs or 1-3 LNs and Grade 3 disease or tumor ≥ 5 centimeters and (2) 1-3 LNs and Ki67 $\geq 20\%$. The FDA approved adjuvant abemaciclib only in pts with HR+, HER2-negative, LN+ EBC with Ki67 $\geq 20\%$. The role of Ki67 as a predictive biomarker in this setting is unclear. ASCO guidelines recommend offering abemaciclib to pts who meet eligibility for either cohort and not restricting inclusion by Ki67. The objectives of this study were to (1) determine the association between Ki67 and the 21-gene recurrence score (RS), an established prognostic and predictive biomarker, using Ki67 cutoff $\geq 20\%$ and (2) compare eligibility for adjuvant abemaciclib by FDA versus ASCO criteria. **Methods:** Women with HR+, HER2-negative EBC with 1-3 LNs, diagnosed between 2018 and 2019, and who had available information on Ki67 and RS in the National Cancer Database were identified. Pts were categorized into Ki67 low ($< 20\%$) or high ($\geq 20\%$) based on cutoff used in the monarchE and stratified by RS of low-intermediate (0-25) or high (26-100). Stratified agreement between Ki67 and RS were assessed using the proportion of agreement and Kappa statistic. McNemar's test was used to compare proportion of pts eligible for abemaciclib by FDA versus ASCO criteria. **Results:** 50,222 eligible women were included. 63.9% ($n = 32,082$) had Ki67 $< 20\%$ and 36.1% ($n = 18,140$) Ki67 $\geq 20\%$. There was fair agreement (Kappa 0.21-0.40) between Ki67 and RS, which was statistically significant (Kappa = 0.272, $p \leq 0.001$). Overall, using the FDA criteria for abemaciclib, 36.1% ($n = 18,140$) of patients would be eligible while based on ASCO criteria, 39.9% ($n = 20,061$) could be offered adjuvant abemaciclib ($p < 0.001$). Among the 20,061 patients eligible for abemaciclib based on ASCO criteria, 57.4% ($n = 11,513$) were eligible due to Ki67 $\geq 20\%$ alone, 9.6% ($n = 1,921$) due to Grade 3 alone, while 33.0% ($n = 6,627$) satisfied both Ki67 $\geq 20\%$ and Grade 3 criteria. There were 33,789 patients who were post-menopausal with RS 0-25 and would be spared chemotherapy, yet 32.1% ($n = 10,856$) would be eligible for adjuvant abemaciclib based on FDA or ASCO criteria. **Conclusions:** There was only fair agreement between Ki67 and RS in patients with 1-3 LNs based on Ki67 cutoff of 20%. Among patients with LN+ EBC, more patients would be offered abemaciclib using ASCO criteria compared to FDA criteria. Most were eligible for abemaciclib based on Ki67 alone, suggesting that Ki67 may provide additional information beyond tumor grade. In postmenopausal women with 1-3 LNs, about 30% may be spared adjuvant chemotherapy based on the RS but still be sufficiently high risk to be considered for adjuvant abemaciclib. Influence of ovarian function suppression on quality of life in breast cancer survivors during adjuvant endocrine therapy. *First Author: Natalija Dedic Plavetic, School of Medicine University of Zagreb, Zagreb, Croatia*

Background: Adding ovarian function suppression to adjuvant endocrine therapy (AET) lowers the disease recurrence rates among premenopausal women with hormone receptor-positive (HR+) early breast cancer (EBC). However, a detrimental effect on endocrine symptoms burden (ESB) is expected. Therefore, this study aimed to investigate differences in Quality of life (QoL) and endocrine symptoms in premenopausal women prescribed AET, with/without gonadotropin-releasing hormone agonist (GnRH). **Methods:** This cross-sectional study included women, with HR+ EBC, premenopausal at diagnosis, treated with AET for more than 3 months, with and without GnRH. The research was conducted with institutional Ethics Committee approval at the University Hospital Centre Zagreb, General Hospital Šibenik, and with online survey. A validated instrument, the Functional Assessment of Cancer Therapy - Endocrine Symptoms (FACT-ES), was used. The collected data were analysed using SPSS v. 29 ($p \leq 0.05$). **Results:** Overall, 314 eligible BC survivors with a median age of 45 years (22-65) and a median duration of AET of 2 years (3 months-12 years) responded to FACT-ES and were included in the analysis. Altogether 45.2% ($n = 142$) of participants were prescribed tamoxifen (TAM), 25.8% ($n = 81$) GnRH+TAM, and 29% ($n = 91$) GnRH+aromatase inhibitor (AI); exemestane (9%), letrozole (13.6%) and anastrozole (6.4%). The total QoL (FACT-ES) score was higher in patients treated with TAM as opposed to patients treated with AI+GnRH ($p = 0.01$). Adding GnRH to TAM did not significantly change QoL when compared to TAM alone or AI+GnRH. In addition, patients on AI+GnRH had lower physical well-being (PWB) score than patients on TAM+GnRH ($p = 0.03$) or TAM alone ($p = 0.05$) and lower endocrine subscale score (ESS-19) than patients on TAM ($p = 0.01$), indicating more endocrine symptoms in premenopausal women treated with AI+GnRH. Among patients treated with AI+GnRH letrozole had lower PWB ($p = 0.03$) and ESS-19 score ($p = 0.01$) than exemestane. **Conclusions:** This study showed that GnRH+AI in premenopausal women with HR+ EBC results in greater ESB and lower QoL compared to patients treated with TAM or GnRH+TAM. Therefore, interventions helping decrease the ESB in patients treated with AI+GnRH should be explored and developed to help patients adhere to and persist in AET. Research Sponsor: None.

	Subscale score - mean (SD)

Prognosis of squamous cell carcinoma of the breast by biological subtypes and the efficacy of radiotherapy: The Japanese Breast Cancer Registry analysis. *First Author: Mami Ogita, Department of Radiology, The University of Tokyo Hospital, Tokyo, Japan*

Background: Primary squamous cell carcinoma (SCC) of the breast is a rare disease, accounting for about 0.1% of all breast cancers. We aimed to determine the clinical features and prognosis of breast SCC, and the effect of radiotherapy by biological subtypes using the Japanese Breast Cancer Registry. **Methods:** We conducted a matched-pair analysis of 350,977 breast cancer patients with SCC or invasive ductal cancer (IDC) in the Japanese Breast Cancer Registry between 2004 and 2014. Inclusion criteria were female breast cancer patients who underwent surgery with stage I-III diseases, SCC or IDC, and age ≥ 18 . Patients who received preoperative radiotherapy were excluded. We performed 1:1 SCC-IDC exact matching analysis by pre-dominant subtypes in SCC: ER(-) and PgR(-)/HER2(-) or ER(+) and/or PgR(+)/HER2(-). Overall survival (OS), breast cancer-specific survival (BCSS), recurrence-free survival (RFS), and first locoregional or distant metastasis recurrence incidence were compared between IDC and SCC by Kaplan-Meier methods and log-rank test. In-field area recurrence was compared between those who received radiotherapy and those who did not. **Results:** We included 452 SCC and 182,707 IDC patients for the analysis. SCC patients were more likely to present with advanced stage disease compared to those with IDC. Among SCC patients, 59% was ER(-)/PgR(-)/HER2(-), 19% was ER(+)/PgR(+)/HER2(-), 8% was ER(-)/PgR(-)/HER2(+), 2% was ER(+)/PgR(+)/HER2(+), and 12% was data missing. Ten-year OS, BCS, and RFS rates were 70%, 80%, and 66% in SCC, and 88%, 93%, and 81% in IDC, respectively, and SCC carried a significantly worse prognosis than IDC (all $P < 0.001$). For exact-matched analysis, 10-year BCS of ER(-)/PgR(-)/HER2(-) SCC patients was significantly worse than IDC ($P = 0.02$), whereas there were no significant differences between SCC and IDC of ER(+)/PgR(+)/HER2(-) patients in OS, BCS, and RFS. Among patients who received radiotherapy, no difference was found in in-field area recurrence between SCC and IDC in either ER(-)/PgR(-)/HER2(-) or ER(+)/PgR(+)/HER2(-) subtype. **Conclusions:** SCC of the breast was often diagnosed in an advanced stage and had a worse prognosis than IDC. More than half of them were triple-negative subtype. In the triple-negative subtype, SCC was an independent poor prognostic factor. No significant differences in in-field area recurrence after radiotherapy between SCC and IDC suggested that the effect of radiotherapy on local control for SCC was similar to IDC. Survival outcomes of young patients under 40 with breast cancer in Asian countries according to subtype: An international multicenter cohort study.

First Author: Jinyong Kim, Department of hemato-oncology, Seoul National University Hospital, Seoul, South Korea

Background: The incidence of young Asian women with breast cancer has been increasing but these patients are underrepresented in global data. We analyzed the epidemiology and outcomes of the young Asian patients with breast cancer in different subtypes with clinically unmet need. **Methods:** Female patients of age 20 years or older diagnosed with early breast cancer of stage I, II, or III from the prospective cohort of the Asian Breast Cancer Cooperative Group (ABCCG) were analyzed. For comparison, data of patients with early breast cancer from Surveillance, Epidemiology, and End Results Program (SEER) cancer registry was used. The patients were divided into three age groups: young (below 40 years), alleged premenopausal mid-age (40-49 years), and alleged postmenopausal elderly (50 years and older). Multivariable Cox proportional-hazard models for survival were adjusted with age, subtypes consisting of hormone receptor (HR) and human epithelial growth factor receptor 2 (HER2) status, histologic grade, T stage, nodal status, and countries. Patients diagnosed in 2000-2010 were censored at 6 years for comparability with SEER database. **Results:** Total 45,021 patients with breast cancer from Asian countries, 496,332 of SEER Whites and 18,279 from SEER non-Whites were included. The median age at diagnosis was younger in Asians compared to SEER Whites and non-Whites (51, 62, 58 years, respectively). Among subtypes, HR-positive and HER2-negative breast cancer was more frequent among SEER Whites and SEER non-Whites, compared to Asians (75.89%, 73.38% vs. 65.75%, respectively). In the young group, HR-positive and HER2-negative breast cancer was prevalent in Asians and SEER non-Whites, compared to SEER Whites (61.2% and 59.8% vs. 54.7%, respectively). In the elderly group, the proportion of HR-positive breast cancer increased in SEER Whites, while that of triple-negative breast cancer (TNBC) increased in Asians. Elderly group showed the worst survival in all subtypes and in all populations. In Asian population, the mid-age group of the patients with HR-positive and HER2-negative breast cancer showed significantly superior overall survival (OS) than the young group (6 year OS 96.6% vs. 94.4%; hazard ratio 0.62, 95% confidence interval 0.50-0.76; $p < 0.001$). Similarly, young patients in SEER Whites also showed early decline of survival curve compared those in mid-age group (89.1% vs. 94.0%, $p < 0.001$), while young patients of SEER non-Whites showed equivalent prognosis to those in mid-age group (92.4% vs. 95.0%, $p = 0.118$). **Conclusions:** Young Asian breast cancer patients diagnosed with HR-positive and HER2-negative subtypes, but not HER2-positive or TNBC subtypes, are more likely to have worse survival outcomes than those in mid-age. Further studies on young patients with breast cancer are needed for tailored treatments among different subtypes and ethnic groups. Research Sponsor: None.

Impact of race on Blueprint genomic subtyping in HER2+ breast cancer.

First Author: Sonya A. Reid, Vanderbilt-Ingram Cancer Center, Nashville, TN

Background: Breast cancer (BC) is the leading cause of cancer-related deaths in Black women, who are 41% more likely to die than White women. We've recently reported that Black women have a significantly greater proportion of hormone receptor-positive (HR+) tumors further classified as Basal-Type with Blueprint genomic subtyping, which may contribute to their worse outcomes. Here, we evaluated whether there were differences in tumor genomics among patients with clinically assessed HER2+ (cHER2) tumors between Black and White women. **Methods:** This study includes 204 women with stage I-III cHER2 BC who received Blueprint testing and are participants of the BEST study (SRO1CA204819) at Vanderbilt University Medical Center or FLEX study (NCT03053193). Patients were treated per NCCN guidelines based on immunohistochemistry (IHC)/FISH classification. cHER2 tumors were further classified by Blueprint, an 80-gene molecular subtyping test, as Luminal-Type (gLuminal), HER2-Type (gHER2), or Basal-Type (gBasal). White women within FLEX were matched by age, tumor and node status and included as a reference group. A two-tailed proportional z-test was used to assess Blueprint subtype differences. Limma R package was used for differential gene expression analysis (DGEA) of whole transcriptome data. Significant differentially expressed genes had an adjusted p-value < 0.05 and absolute log2 fold change > 1 . **Results:** Of 102 Black women with cHER2 tumors, 59 had gHER2, 34 had gLuminal and 9 had gBasal tumors, and of 102 White women, 63 had gHER2, 28 had gLuminal and 11 had gBasal tumors. There were no significant differences in the frequency of Blueprint subtypes or in gene expression by race among cHER2 tumors. All gHER2 tumors had upregulated HER2 signaling compared to upregulated estrogen signaling genes in gLuminal tumors, and upregulated genes characteristic of metastasis and triple negative tumors in gBasal tumors. Among patients with available neoadjuvant treatment response data, 57.1% (16/28) gHER2, 33.3% (2/6) gLuminal and 50.0% (3/6) gBasal achieved a pathologic complete response (pCR). **Conclusions:** Unlike HR+HER2- tumors, these data suggest that race may not influence the biology underlying cHER2 tumors. However, there was genomic heterogeneity among cHER2 tumors identified by Blueprint, independent of race. Overall, the rate of Blueprint classification among cHER2 tumors was comparable to NBRST and APHINITY, which demonstrated distinct treatment response and outcome based on Blueprint genomic subtype. In this study, DGEA suggests gHER2 tumors exhibit extensive HER2 signaling and may benefit most from HER2-targeted therapy. Although limited by sample size, rates of pCR to neoadjuvant therapy appear greater in gHER2 than non-HER2 tumors (gLuminal, gBasal). gBasal tumors may harbor more aggressive tumor characteristics, which has important clinical implications for optimizing treatment and improving outcomes in these patients. Poster Session

Association of human epidermal growth factor receptor 2 expression with 21-gene recurrence score and survival among patients with estrogen receptor-positive breast cancer. First Author: Sung Jun Ma, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Trastuzumab-deruxtecan was recently shown to improve survival for metastatic human epidermal growth factor receptor 2 (HER2)-low breast cancer. HER2-negative breast cancer has been redefined as a group of heterogeneous entities. However, HER2-low status is not considered as a prognostic factor among patients with nonmetastatic breast cancer, and the role of HER2 expression levels in the setting of 21-gene recurrence score (RS) remains unclear. We performed an observational cohort study using a national oncology database to evaluate the association of HER2 expression levels with RS and survival among patients with estrogen receptor (ER)-positive breast cancer. **Methods:** The National Cancer Database was queried for women diagnosed between 2006 and 2018 with ER-positive, pT1-3N0-1aM0 breast cancer who received surgery followed by adjuvant endocrine therapy with or without chemotherapy. HER2 expression levels were stratified by 3 groups: HER2-0 (immunohistochemistry [IHC] 0), HER2-1 (IHC +1), and HER2-2 (IHC +2 and in situ hybridization [ISH] negative). Logistic and Cox multivariable analysis (MVA) were used to identify factors associated with high RS (26 or higher) and overall survival (OS), respectively. Interaction term was analyzed to evaluate any heterogeneous associations in survival outcomes between HER2 levels and RS. Subgroup analysis was performed by repeating Cox MVA stratified by RS. Holm-Bonferroni correction was used to adjust for multiple comparisons, with p value less than 0.05 considered as statistically significant. **Results:** Among 108,973 women, 31,738 (29.1%), 52,839 (48.5%), and 24,396 (22.4%) patients had HER2-0, HER2-1, and HER2-2, respectively. Logistic MVA showed that, compared to HER2-0, HER2-2 was associated with higher RS (adjusted odds ratio [aOR] 1.09, 95% confidence interval 1.04-1.15, $p < 0.001$), but HER2-1 was not (aOR 0.96, 95% CI 0.91-1.00, $p = 0.05$). Cox MVA showed that both HER2-1 (adjusted hazards ratio [aHR] 1.03, 95% CI 0.97-1.10, $p = 0.34$) and HER2-2 (aHR 1.06, 95% CI 0.98-1.14, $p = 0.14$) were not associated with OS. There was an interaction between HER2 expression levels and RS (interaction $p = 0.03$). Among those with RS < 26 , compared to HER2-0, HER2-2 was associated with worse OS (aHR 1.10, 95% CI 1.01-1.20, $p = 0.02$), but HER2-1 was not (aHR 1.04, 95% CI 0.97-1.12, $p = 0.24$). Among those with RS 26 or higher, both HER2-1 (aHR 1.00, 95% CI 0.88-1.13, $p = 0.98$) and HER2-2 (aHR 0.94, 95% CI 0.82-1.09, $p = 0.41$) were not associated with OS. **Conclusions:** To our knowledge, this is the largest study using nationwide oncology database to suggest that, when compared to HER2-0, HER2-2 was associated with higher RS and poor survival among patients with RS < 26 . Further studies would be warranted to evaluate the role of HER2 expression levels for risk stratification to tailor interventions. Research Sponsor: U.S. National Institutes of Health.

Lipidomic signature from plasma to detect localised breast cancer. First Author: Gillian Lamoury, Royal North Shore Hospital, St. Leonards, NSW, Australia

Background: An effective and accurate blood test to detect localised breast cancer may increase the screening detection rate and improve patient outcomes. We have previously reported a series of lipidomic studies and derived a lipid signature from plasma enriched extracellular vesicles (EVs) that effectively distinguished people with localised breast cancer from cancer-free controls. Here we report on a significant refinement to the test methodology allowing the assessment of the lipid signature directly from plasma samples and its performance, with the aim of advancing the commercial viability of the test as we move towards clinical application. **Methods:** Lipids were extracted from enriched EVs from plasma samples donated by fasted people with localised breast cancer and control samples ($n=793$) and analysed by high resolution accurate mass liquid chromatography-mass spectrometry (LC-MS). Over 400 manually curated lipids were quantified. Following variable selection, a lipid signature capable of distinguishing breast cancer samples from controls was derived. The lipid signature was modelled on each of the cohorts using leave-one-out internal cross-validation. Next, we analysed the lipids in cancer and control ($n=256$) plasma samples corresponding to patients from Cohorts 3 and 4 previously used for EV preparations, and applied the signature derived using EVs on plasma lipidomic data. **Results:** EV samples of people with breast cancer were distinguished from controls with an area under the curve (AUC) of 0.77-0.89 across 4 cohorts. When the lipid signature was assessed directly from plasma the test achieved a comparable AUC of 0.84. Assessing the markers directly from plasma samples would make the test more scalable, higher throughput and easier to perform. **Conclusions:** Our study demonstrated the high performance of a lipid biomarker signature derived from plasma enriched EVs for early detection of localised breast cancer. Our results suggest that the lipidomic signature could potentially be assessed directly from plasma samples instead of EVs reducing the test complexity. Ongoing studies will optimise the plasma lipidomic signature and prospectively compare the test against mammographic and pathological diagnoses. Research Sponsor: BCAL Diagnostics Limited.

Correlation of gene signatures of Kaiso and LC3A/B protein expression with distinct tumor ecosystems and to predict response to breast cancer therapy. *First Author: Sandeep K. Singhal, Department of Pathology, School of Medicine and Health Sciences, University of North Dakota, Grand Forks, ND*

Background: The multifunctional transcriptional repressor, Kaiso, is a member of the BTB/POZ (Broad complex, Tramtrak, Bric à Brac/Pox zinc finger) family of zinc finger proteins. Kaiso protein levels in both the nucleus and the cytoplasm have each been shown to be highly sensitive and independent predictors of overall breast cancer survival. Through the use of gene signatures and/or gene modules developed through the analysis of RNA-seq data from breast cancer patients following biomarker stratification by either nuclear Kaiso, cytoplasmic Kaiso, or the Kaiso's functional downstream target LC3A/B, we demonstrate the utility of Kaiso and LC3A/B derived signatures as predictors of treatment outcome. **Methods:** We used a machine Learning approach to assess a cohort of racially diverse 555 BC patients who underwent surgery for their primary BC in Greenville, NC and develop proteomics-based genomics (PbG) signatures. The cross-validated logistic regression model using publicly available gene expression data compiled from neoadjuvant clinical trials (N=996, JCO:30(16):1996-2004). **Results:** Kaiso and LC3A/B derived gene modules show accuracy in predicting pathological complete response (pCR, AUC = 0.728, 95% CI: 0.689-0.764). Moreover, predictive estimates of distant metastasis-free survival utilizing Kaiso and LC3A/B derived gene modules are also significant (overall DMFS, AUC= 0.737, 95% CI: 0.665-0.819) and (DMFS of non-pCR patients AUC= 0.71, 95% CI: 0.633-0.773). We then validate these findings in an independent, racially diverse breast cancer cohort receiving neo-adjuvant treatment (N=443). Gene modules based on Kaiso and LC3A/B were also highly predictive in this independent cohort (total cohort pCR, AUC= 0.775, 95% CI: 0.687-0.838; pCR NHW (N=257), AUC= 0.762, 95% CI: 0.659-0.855; pCR Hispanic (N=125), AUC= 0.725, 95% CI: 0.493-0.873; and pCR NHB (N=42), AUC= 0.681, 95% CI:0.405-0.904). **Conclusions:** Combined analysis by multiplex immunofluorescence and deconvolution of gene expression data show that the protein expression of Kaiso and LC3A/B in tumors are associated with distinct tumor ecosystems where high levels cytoplasmic Kaiso are linked to an immune-suppressed tumor microenvironment. Comprehensive profiling of mutational signatures and machine learning and subtypes of homologous recombination deficiency. *First Author: Joonoh Lim, Genome Insight Inc., San Diego, CA*

Background: Recently, genomic features have proven effective at gene-agnostic detection of homologous recombination deficiency (HRD). However, it remains to be explored to what extent we can exploit genome analysis to assess HRD status. Here, we show that a machine learning (ML) classifier based on mutational signatures enables a robust detection and subtyping of HRD and outperforms a current state-of-the-art HRD classifier. **Methods:** We whole-genome-sequenced (WGS) ~700 breast cancers and identified pathogenic variants in HR-related genes (*BRCA1/2*, *PALB2*, *CHEK2*, *RAD51B*, *ATM*, etc.). Mutational signatures of all variant types, single-base substitution (SBS), indel (ID), structural (SV) and copy-number variant (CN), were included as features. Biallelic inactivation in *BRCA1/2* by germline pathogenic variant and somatic loss-of-heterozygosity (LOH) was regarded as true HRD. We trained four different classifiers with *n*-fold cross validation and used averaged scores for prediction. In addition, we performed cluster analysis and subgroup analysis within the predicted HRD cases to unveil the heterogeneity of HRD. **Results:** We identified a total 88 (12%) germline pathogenic variant carriers with somatic LOH, including 29 *BRCA1* (4%), 28 *BRCA2* (4%), 4 *PALB2* (0.6%), and 3 *RAD51B* (0.4%). Among them, 70 (80%) were classified as HRD positives. As expected, most *BRCA1* (28/29) and *BRCA2* (28/28) cases were HRD-positive. All the *PALB2* (4/4) and *RAD51B* (3/3) cases were also classified as HRD-positive, confirming their importance in HR. Inclusion of somatic *RAD51B* biallelic mutants (10; 1.4%) reached a statistical significance for the HRD enrichment (Fisher's; *P* = 0.045). We identified a total 171 (24%) having at least one somatic pathogenic variant with LOH, including 57 *PTEN* (33%), 40 *CDK12* (23%), 17 *RAD51B* (10%), 17 *ARID1A* (10%), and 15 *BRIP1* (9%). 72 of these (42%) were HRD-positive. Our classifier identified 12 (7%) more HRD cases than HRDetect (167 vs. 155; *F1* = 0.99 vs. 0.95) using signature ID6, SV3 (or RS3), LST, and SBS3. Further, it correctly identified *BRCA1* (33/34) and *BRCA2* (27/28) somatic and germline biallelic mutants from each other (*F1* = 0.97), based on RS3, ID6, RS1, and SBS37. Features of *RAD51B* were similar to *BRCA1*, and *PALB2* to *BRCA2*, but our classifier was able to distinguish *PALB2* from *BRCA2* using a combination of CN11, ID11, LOH, CN8, and SBS40 (*F1* = ~1). Total 112 (67%), 48 (29%), and 7 (4%) cases were identified as *BRCA1*-like, *BRCA2*-like, and *BRCA1/2*-like, among which 47 (28%) were monoallelic HR-gene mutants and 27 (16%) were wild types. Our results suggest that mutational signatures can identify ~40% (47/120) more HRD cases than using mutation profile alone. **Conclusions:** We believe that the method developed here, using ML to detect and classify HRD, will benefit from larger WGS data and identify more patients who can benefit from HRD-related therapeutics. Association of anthracyclines induced cardiotoxicity (AIC) in patients with early breast cancer (eBC) with germline BRCA1/2 (gBRCA1/2) mutation: BRCAN study. *First Author: Juan José Serrano Domingo, Medical Oncology Department, Ramón y Cajal University Hospital, Madrid, Spain*

Background: BRCA1/2 genes play a critical role in genome stability and DNA repair in human cells, including cardiomyocytes. In animal models, loss of cardiomyocyte-specific BRCA1/2 is associated with DNA damage, apoptosis, cardiac dysfunction, and cardiac mortality following anthracyclines (A) exposure. However, whether these preclinical findings translate to humans still remains unclear. We conducted the BRCAN study to assess the impact of gBRCA1/2 status on AIC in a cohort of patients with eBC. **Methods:** This is a single center retrospective/prospective study including patients diagnosed with HER2-negative eBC treated with A based chemotherapy in the neo/adjuvant setting, known gBRCA1/2 status, left ventricular ejection fraction (LVEF) ≥ 50% at baseline and no previous significant cardiovascular events. During follow-up, we performed myocardial dysfunction blood biomarkers (MDBB), cardiac ultrasound and quality of life questionnaires (QoL). Primary objective was to assess the absolute LVEF change from baseline in BRCA1/2 mutation carriers (gBRCA1/2mut) versus non-carriers (gBRCA1/2wt). Secondary objectives were comparing MDBB and QoL in these groups. **Results:** 137 patients with eBC were included in the study (103 gBRCA1/2wt and 34 gBRCA1/2mut). Patients' characteristics were similar between both groups in terms of age, baseline LVEF, radiotherapy (RT) on left side, total A accumulative dose, time from A exposure, antihypertensive or hypolipidemic agents use and smoking habit. Compared to baseline, LVEF % reduction was -4.7 [-12.0, 0.0] versus -9.5 [-18.0, -5.0] in gBRCA1/2wt and gBRCA1/2mut, respectively (*p*=0.027). To correct for confounding, we fit a regression model for the variables smoking habit, antihypertensive and hypolipidemic agents use. On average, LVEF % reduction in gBRCA1/2mut group was -4.5 [CI 95% -8.6, -0.4, *p*=0.032] compared to gBRCA1/2wt. No differences between MDBB (protein C-reactive, hsTn, NT-ProBNP, D-Dimer, ST-2 or Galectine-3) and QoL (MLHFQ and EQ5-D index) were detected between groups. **Conclusions:** Our data suggest that gBRCA1/2mut patients could represent a high risk population for AIC. A baseline comprehensive cardiovascular risk assessment and a closer follow-up should be recommended in these patients. Further research is needed on order to identify early predictive biomarkers for AIC. Research Sponsor: Instituto Ramón y Cajal de Investigación Sanitaria.

ERBB2 mRNA expression to distinguish HER2-low/neg breast cancer prognosis. *First Author: Yueping Liu, Department of Pathology, the Fourth Hospital of Hebei Medical University, Shijiazhuang, Hebei, China*

Background: Antibody-drug conjugates such as Trastuzumab deruxtecan significantly improved progression-free and overall survival for the HER2 low expression (HER2-low) breast cancer (BC) patients, pushing the research field of HER2-low to a new climax. In fact, the traditional immunohistochemistry (IHC) to identify the HER2-low or HER2-negative expression (HER2-neg) has been challenged, and it cannot predict the prognosis of HER2-low/neg patients well. **Methods:** Three pathologists evaluated the HER2 expression status of the subjects via IHC. More than two pathologists judged HER2 0-2 and FISH negative samples were included in this trial. *ERBB2* mRNA level of formalin-fixed, paraffin-embedded BC post-surgery specimens were detected by MammaTyper quantitative real-time polymerase chain reaction (qRT-PCR) kit. The consistency of HER2 immunohistochemistry (IHC) and MammaTyper results were analyzed by interclass correlation coefficients (ICC). Differences in disease-free survival (DFS) were assessed by Kaplan Meier analysis. **Results:** 793 cases were included. The ICC value between IHC and MammaTyper, assessed for HER2-neg vs HER2-low is 0.28. With a median follow up of 2.5 years, there were 36 events in the whole subjects. In the whole subjects, MammaTyper successfully showed that the prognosis of HER2-low was significantly better than HER2-neg (*P* < 0.001, HR = 3.497, 95%CI, 1.807-6.77), but IHC could not distinguished them (*P* = 0.1071, HR = 1.776, 95%CI, 0.9194-3.43). Although the follow-up time is short, HER2-low subjects also showed better prognosis than HER2-neg in TNBC subjects distinguished by MammaTyper (*P* = 0.0271, HR = 2.912, 95%CI, 1.129-7.511), not by IHC (*P* = 0.1032, HR = 2.213, 95%CI, 0.8512-5.756). However, in 291 cases of IHC and MammaTyper detection discordancy group, IHC results showed that the prognosis of HER2-low was worse, which was contrary to the MammaTyper results and the results of the above overall test results, suggesting that IHC could not verily reflect the amount of HER2 expression in some samples, and the prognosis of HER2-low population might be more related to the mRNA expression of HER2. **Conclusions:** Compared with IHC/FISH, MammaTyper qRT-PCR assay may actually reflect the prognosis of HER2-neg/low, which is expected to become a diagnostic beacon for HER2-low target drugs. Research Sponsor: None.

Do HER2 low tumors have a distinct clinicopathologic phenotype? *First Author: Natália Polidoro, Breast Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Clinicopathologic features of breast cancer subtypes defined by hormone receptor (HR) and HER2 status differ. These analyses classified HER2 IHC <3+ with negative FISH as HER2-. With the recognition of the clinical relevance of HER2 low, there is debate as to whether this is a distinct subtype. We sought to determine if features of HER2 low tumors differ from HER2- and HER2+ after controlling for HR status. **Methods:** Patients undergoing upfront surgery from 1998 to 2010 were identified from a prospectively maintained institutional database. HER2 status was classified by IHC/FISH analysis as HER2-, HER2 low (IHC 1+ or 2+ with negative FISH), and HER2+ (IHC 3+ or FISH +) and stratified by HR status. Univariable (UVA) and multivariable multinomial logistic regression analysis (MVA) were performed to determine associations among variables and subtypes. **Results:** 11,323 tumors from 11,072 patients were included. 5,104 (45%) were HER2 low, 41.2% were HER2- and 13.6% were HER2+. On MVA stratified by HER2 status only, compared to HER2- tumors, HER2 low was associated with LVI (OR 1.2 [95% CI 1.06-1.36]; $p=.003$), multifocality (OR 1.26 [95% CI, 1.12-1.42]; $p<.001$), nodal micrometastasis (OR 1.15 [95% CI, 1.02-1.31]; $p=.024$), and lower rates of <3 positive nodes (OR 0.77 [95% CI, 0.66-0.90], $p=.001$). HER2+ was associated with younger age, high grade, multifocality, extensive intraductal component (EIC), and pN2/3 nodal stage. Clinicopathologic features stratified by HR and HER2 status are shown in the table. On UVA, in both HR+ and HR- tumors, age and multifocality were associated with HER2 low, and LVI, multifocality, and EIC with HER2+ compared to HER2- tumors. On MVA, no variables were independently associated with both HR+ and HR-/HER2 low tumors compared to HER2-. In contrast, HER2+ tumors regardless of HR status were significantly associated with multifocality and EIC. **Conclusions:** HER2 low breast cancer features seem to be driven by HR status and HER2 overexpression. We do not have enough evidence to support the interpretation of HER2 low as a distinct subtype. Research Sponsor: Memorial Sloan Kettering Cancer Center.

Clinical meaning of stromal tumor infiltrating lymphocytes (sTIL) in luminal early breast cancer. *First Author: Esmeralda García-Torralba, Department of Hematology and Medical Oncology, Hospital Universitario Morales Meseguer, Murcia, Spain*

Background: Luminal breast cancer (BC) is associated with lower immune activation. Although stromal tumor infiltrating lymphocytes (sTIL) are a marker of better prognosis and response in hormone receptor (HR) negative tumors, sTIL predictive and prognostic implications are less clear in luminal BC. Further insights on the clinical correlations of immune microenvironment in luminal disease may facilitate therapeutic improvement and prognostic stratification in these patients. **Methods:** Observational and single-center cohort of 345 women with early luminal (HR positive, HER2 negative) BC (2012-2020) treated with chemotherapy. Pre-treatment sTIL were determined in the diagnostic biopsy following validated standard methods. The correlation between sTIL and other tumor characteristics were analyzed (Spearman's Rho and Chi-squared tests). Association of sTIL with pathologic complete response (pCR) in patients treated with neoadjuvant chemotherapy (nCT) was evaluated with logistic regression models. Prognostic value of sTIL for overall (OS) or relapse free interval (RFI) was analyzed by Cox regression models. **Results:** Median age: 50 (range: 24-89); 48.1% premenopausal; 91.3% infiltrating ductal carcinoma; 30.1% grade 3; 87.2% progesterone receptor (PgR)+; 67.5% treated with nCT and 32.8% with adjuvant CT (aCT); 47.6% N0, 32.8% N1, 19.6% N2-3; median ki67: 30% (82.7% >10%). A 29% of patients showed sTIL=0%. Median sTIL infiltration was 5 (Q1-Q3 range [IQR], 0-10), with higher values in premenopausal ($p<0.001$), grade 3 ($p<0.001$), N+ ($p<0.001$) and luminal B tumors (defined as PgR- and/or grade 3 and/or Ki67>15%) ($p<0.001$). Ki67 was significantly correlated with sTIL ($p<0.39$; $p<0.001$). The percentage of sTIL was associated with pCR after nCT (OR: 1.045, 95%CI 1.02-1.07, $p=0.001$). No prognostic impact of sTIL for OS or RFI was found in luminal A tumors. In luminal B cases ($n=286$), any grade of lymphocytic infiltration (defined as sTIL > 0%) was associated with a shorter RFI both in univariate ($p=0.01$) and multivariate Cox models (HR: 4.83, 95%CI 1.28-18.21, $p=0.02$), with a non-significant trend for poorer OS ($p=0.06$). **Conclusions:** In luminal BC, an increased level of sTIL is associated with luminal B subtype characteristics such as higher proliferation, higher tumor grade and nodal involvement. Lymphocytic infiltration has been found to be a predictor of pCR after nCT, but, in contrast with hormone receptor-negative BC, it is also associated with a poorer prognosis for recurrence and a trend towards worse overall survival in luminal B tumors. Research Sponsor: Instituto Salud Carlos III (Spain) (PI21/380); SEOM (Spanish Society of Medical Oncology).

Multivariate Cox model for RFI in luminal B breast cancer.

	Beta	Hazard ratio (HR)	95%CI HR	p
Tumor size (mm)	0.023468	1.0237	1.011-1.037	<0.001
Positive nodes (number)	0.101474	1.1068	1.045-1.172	<0.001
PgR positive	-1.112061	0.3289	0.144-0.751	0.008

Outcomes in premenopausal patients with HR+/HER2- breast cancer and lymph node micro-metastasis based on the 21-gene recurrence score. *First Author: Nadeem Bilani, Icahn School of Medicine at Mount Sinai Morningside-West, New York, NY*

Background: Postmenopausal patients with hormone receptor positive, HER2-negative (HR+/HER2-) early breast cancer (EBC) and 21-gene OncotypeDX (ODX) recurrence scores (RS) <26 do not benefit from chemoendocrine therapy (CET) compared to endocrine monotherapy (E). The TAILORx and RxPONDER trials demonstrated this was consistent in node-negative and node-positive disease, respectively. In premenopausal patients, however, guidelines for those with low RS diverge between disease involving 0 (pN0) vs. 1-3 (pN1a-c) lymph nodes. Additionally, treatment decisions are less clear for patients with micro-metastasis (pN1mi), who comprised only about 10% of patients in RxPONDER. This study used the *National Cancer Database* (NCDB) to assess treatment patterns and survival outcomes in premenopausal patients with EBC and lymph node micro-metastasis. **Methods:** A cohort of patients aged <50, diagnosed between 2004-2019 with HR+/HER2- EBC and who underwent ODX testing, was recruited from the NCDB. (A) Firstly, we described demographic and clinical characteristics of a sub-cohort with micro-metastasis using univariate statistics. (B) We confirmed the prognostic value of ODX in this sub-cohort with multivariate Cox regression analysis of overall survival (OS). (C) We explored patterns of practice amongst the total cohort with ODX <26 with chi-squared testing for differences in CET use by nodal status. (D) To elucidate the predictive value of this assay, we performed Kaplan-Meier models comparing OS for those with RS <26 receiving E vs. CET, controlling granularly for nodal status: (i) pN1a-c, (ii) pN1mi, and (iii) pN0. **Results:** Of $n=72,068$ patients aged <50 with HR+/HER2- EBC and ODX data, 6.1% ($n=4,402$) had micro-metastasis. (A) The median age of this subgroup was 45 (IQR 41-47) years. Most tumors were grade II ($n=2,472$, 57.7%) with ductal histology ($n=3,500$, 80.3%). 73.4% of pN1mi cases had RS <26, while 26.6% had RS ≥26. (B) Multivariate Cox regression – adjusting for comorbidity, race and chemotherapy use – confirmed significance in this pN1mi cohort of RS ≥26 prognosticating poorer OS compared to RS 0-15 (HR 4.42, 95% CI 2.35-8.31, $p<0.001$). (C) 29.0% ($n=1,033$) of patients with pN1mi and ODX <26 underwent CET, greater than 15.2% ($n=6,568$) with pN0 and less than 47.3% ($n=2,884$) with pN1a-c staging ($p<0.001$). (D) A benefit in OS ($p=0.017$) was observed in cases with RS <26 and pN1a-c using CET (5-year OS: 99%) vs. E (5-year OS: 97.5%), but not in pN1mi ($p=0.49$) or pN0 ($p=0.57$) disease. **Conclusions:** The management of premenopausal patients with HR+/HER2- EBC, isolated micro-metastasis, and ODX <26 is unclear. Our large registry study found the addition of chemotherapy to endocrine therapy was associated with improved survival in cases with ODX <26 involving 1-3 lymph nodes, but not in node-negative or micro-metastatic disease. Prospective trials are needed to confirm these findings. Research Sponsor: None.

Phase II randomized window of opportunity trial evaluating cytotoxic and immunomodulatory effects of intratumoral INT230-6 in early stage breast cancer: The INVINCIBLE trial. *First Author: Melanie Spears, Ontario Institute for Cancer Research, Toronto, ON, Canada*

Background: Most breast cancers are considered immunologically cold and are therefore minimally responsive to immunotherapies. Local cytotoxic therapies can induce cell death, expose tumor antigens, provide adjuvants for anti-tumor immune priming, and potentially increase responsiveness to immunotherapies. We conducted a randomized, double blind, Phase 2 presurgical Window-Of-Opportunity trial for intratumoral (IT) INT230-6 (comprising VINblastine (VIN) Cisplatin (VIN)) evaluating clinical and Biological Effects in patients with early-stage operable Breast Cancer (the INVINCIBLE trial NCT04781725). The trial evaluated the immune response within the tumor and microenvironment *in vivo* after IT INT230-6 injections. **Methods:** Women with newly diagnosed and awaiting surgery for early-stage intermediate or high-grade ER+ T1-T2 invasive breast cancers were recruited to the trial. Participating patients were allocated (2:1) to IT injections of INT230-6 vs saline placebo, prior to resection. RNA profiling of the pre-(baseline biopsy) and post-treatment (surgical resection) tumours using the Ion AmpliSeq Transcriptome Human Gene Expression (Thermo Fisher Scientific) and DNA sequencing using a large (500 gene) comprehensive genomic profiling panel (OCAPus,) was performed. **Results:** Significant tumor necrosis was observed in the majority of subjects injected with INT230-6. In the 60 pre-treatment biopsies profiled with OCAPus, the genes most frequently mutated included PIK3CA (38%), TP53 (23%), CDH1 (22%) and TBX3 (17%). Frequent copy number changes were identified in CCND1 (23%), FGFR1 (18%), and CDH1 (17%). Gene expression analysis showed significant differential gene expression between the baseline biopsy and surgical specimens in patients treated with the drug. Pathway analysis identified genes associated with TCR signaling, macrophage markers, IL-18 signaling and B cell receptor signaling were significantly up-regulated in the post treatment samples. **Conclusions:** This is the first study evaluating the potential biologic effects of intratumoral cytotoxicity with INT230-6 and its role as a potential immune priming therapy in traditional immune quiescent ER+ breast cancers. Treatment outcomes in patients with discordant recurrence score and RSclin risk predictions. *First Author: Augustin Vannier, University of Chicago, Chicago, IL*

Background: Guidelines recommend the use of genomic assays to aid decision making regarding the use of adjuvant chemotherapy (CT) for hormone receptor-positive, HER2-negative (HR+/HER2-) early breast cancer (EBC). Recently, the RSclin tool, which integrates the 21-gene recurrence score (RS) and clinicopathologic features, was developed to better estimate CT benefit. Here, we studied patients with RSclin/RS discordance to determine if patients (pts) should be treated according to RS or RSclin. **Methods:** This was a retrospective cohort study of pts from the National Cancer Database who were diagnosed with HR+/HER2- node negative EBC from 2010-2020 who underwent RS testing and received adjuvant endocrine therapy with or without CT. Pts were classified as low RS (≤ 26) or high RS (≥ 26) and low ($< 3\%$) versus high ($\geq 3\%$) predicted CT benefit per RSclin. The primary outcome was overall survival (OS) benefit associated with CT administration for pts with discordant RS/RSclin, measured as hazard ratio [HR] for receipt of CT. Hazard ratios were adjusted for age and comorbidity index, and inverse probability of treatment weighting was performed for age, comorbidity index, race, ethnicity, and insurance status. **Results:** 262,748 pts with EBC were included, with a median follow-up of 58 months. Median age was 60 years; 82% were White, 7% Black, 5% Hispanic, and 4% Asian/Pacific Islander. Median tumor size was 1.5 cm, and median RS was 15. The 31,955 cases with concordant high RS/RSclin had an OS benefit with CT (HR: 0.71, 95% CI: 0.67 - 0.75, $p < 0.001$), while the 206,631 cases with concordant low RS/RSclin did not have a survival benefit (HR: 1.00, 95% CI: 0.95 - 1.04, $p = 0.85$, Table). High RS with low RSclin was seen in 435 cases - all with grade 1 tumors, with RS no greater than 28, and tumor size under 1.3cm. No significant CT benefit was seen in this small subset of pts (HR 1.57, 95% CI 0.75 - 3.26, $p = 0.23$). In 23,727 pts with low RS but high RSclin, a CT benefit was seen (HR 0.73, 95% CI 0.67 - 0.78, $p < 0.001$). These pts had high-intermediate RS (median 23, interquartile range 20 - 24) with no other higher risk features. Similar results were seen in older (age > 50) and younger (age ≤ 50) subgroups - although no pts ≤ 50 were in the low RS/high RSclin group. **Conclusions:** RSclin may identify a small number of grade 1 tumors with high RS for which CT is not needed, and may help guide appropriate use of CT for EBC in the sizeable group with intermediate RS. Somatic mutations in tumor-adjacent normal breast tissue in young women with high risk family history. *First Author: Mariya Rozenblit, Yale School of Medicine, New Haven, CT*

Background: It's incompletely understood why some women without germline breast cancer predisposing mutations develop early onset breast cancer. Breast cancer in young women is often more aggressive, with high histologic grade, worse prognosis, and higher risk of recurrence. We hypothesize that these women have somatic mutations in the normal breast tissue that contribute to breast cancer tumorigenesis. **Methods:** Whole exome sequencing (WES) data was analyzed from normal tissue adjacent to breast tumor and compared to matched peripheral blood (n=28). All patients were <50yo, had high risk family history as per NCCN guidelines, and had negative Ambry Genetics panel testing. FFPE sections were reviewed by two pathologists to identify normal breast tissue furthest away from tumor. WES was performed on Illumina HS4000 using 100-base pair paired-end reads. Samples were mapped to the human reference genome (vGRCh38). PCR duplicates were marked (Picard), and indel regions were adjusted (GATK). High-quality germline variants (HaplotypeCaller), somatic mutations (Mutect), and indels (IndelGenotyper) were called. Low-quality variants were filtered out. The classification and number of mutations per gene per sample were extracted and analyzed. **Results:** Majority of patients were white (86%), median age 45, with invasive ductal carcinoma (86%), ER+/PR+/HER2- (100%). Median somatic variants per sample were 97 (range: 45-285), all single nucleotide variants, mostly missense mutations, C>T conversions were seen in 45% of mutations. This suggests cytidine deaminase (APOBEC) involvement. All samples had alterations in at least one of the top ten affected genes which include transcription factors in zinc finger family (listed below). Zinc finger proteins play a key role in tumorigenesis, cancer progression and metastasis in a variety of cancers. Upregulation of zinc finger proteins has been associated with worse prognosis in breast cancer. **Conclusions:** We describe novel somatic mutations in zinc finger proteins in normal breast tissue adjacent to tumor that may contribute to early onset breast cancer in patients with high risk family history. Impact of HER2 low expression in the Oncotype DX RS in patients with operable hormone receptor positive early stage breast cancer. First Author: Laura Sofia Munoz-Arcos, Weill Cornell Medicine, New York, NY

Background: Two thirds of breast carcinomas are human epidermal growth factor receptor 2 (HER2) low. To date, it is still unclear whether hormone receptor (HR) positive HER2 low tumors represent a distinct biological subtype. HER2 low status is not considered an independent predictive factor for benefit from adjuvant chemotherapy in HR positive early breast cancer. We aim to investigate the impact of HER2 low expression on the established predictive biomarker Oncotype DX RS in a cohort of patients with HR positive HER2 negative early breast cancer.

Methods: Retrospective study of patients with stage I-III HR positive HER2 negative breast cancer treated with upfront surgery between 2019-2022 at the Weill Cornell Breast Center and for whom Oncotype DX RS test was available. Patients were grouped to HER2-0 (immunohistochemistry (IHC) score of 0) or HER2 low (IHC score of 1+ or, 2+ with non-amplified *in situ* hybridization) expression. Clinicopathological characteristics and Oncotype DX RS were compared across the different categories of HER2 expression. **Results:** Of 509 patients included, 37% and 63% were grouped as HER2-0 and HER2 low, respectively. Median age at diagnosis was 61 years [IQR 50-69]. Sixty-eight percent of patients were postmenopausal. Stage I, II and III corresponded to 76%, 23% and 1% of patients, respectively. Seven percent of patients had nodal involvement. Ductal carcinoma was the most common histological type (75%) followed by lobular carcinoma (17%). Most tumors had low-intermediate histological grade (81%) with a median Ki-67 of 10% [IQR 5-15]. No significant difference was observed in clinicopathological characteristics between the HER2-0 and HER2 low groups. The overall median Oncotype DX RS was 16 [IQR 11-21]. The median Oncotype DX RS based on a HER2 expression of 0, 1+ and 2+ was 15, 17 and 17, respectively. There was no statistically significant difference between the Oncotype DX RS score and HER2 expression, when comparing HER2-0 to HER2 low ($p = 0.578$), HER2-0 to HER2-1+ ($p = 0.775$) and HER2-0 to HER2-2+ ($p = 0.157$). In the pre-menopausal and lobular carcinoma subgroups, the median Oncotype DX RS was 15 [IQR 9-21] and 17 [IQR 12-22], respectively; and there was no statistically significant difference between the Oncotype DX RS score and HER2 expression ($p > 0.05$). Post-surgery, 87%, 66% and 13% of patients received endocrine therapy, chemotherapy and radiation therapy, respectively. Median follow up time was 16 months [IQR 8-34]. Disease recurrence was documented in 9 (2%) patients. **Conclusions:** In this study, we found no differences in the Oncotype DX RS and the prognostic pathological features between the HER2-0 and HER2 low groups which is in line with previous retrospective studies. Survival analysis was limited by the median follow up. Further studies on the understanding of the biology of HER2-low and its clinical implications in early breast cancer are needed. Exploring HER2-low disease: Does it impact breast cancer survival? *First Author:* Assumpció López-Paradís, Medical Oncology Department, Catalan Institute of Oncology (ICO)-Badalona, B-ARGO (Badalona Applied Research Group in Oncology) and IGTP (Health Research Institute Germans Trias i Pujol), Universitat Autònoma de Barcelona, 08916, Badalona, Spain, Barcelona, Barcelona, Spain

Background: HER2-low has emerged as a potential new entity in breast cancer (BC). Data of this subset is still limited and prognostic results are controversial, suggesting HER2-low does not represent a distinct biological subtype. HER2-low account for up to 50% of BC, representing a potential therapeutic target with encouraging results in the metastatic setting. Hence, we pretend to analyze clinical characteristics of this subset to elucidate commented points. **Methods:** Confirmed HER2-negative BC patients (p) diagnosed between 2006-2017 were retrospectively reviewed in a single center study, in ICO-Badalona. HER2-positive and *in situ* carcinomas were excluded, and p were classified as HER2-low and HER2-O. The prevalence of HER2-low versus HER2-O among p, originally scored as HER2-negative, was measured. Demographics and clinicopathological characteristics were examined and compared via medical charts/ electronic health records. We aim to describe HER2-O/HER2-low populations, and explore its prognostic impact, using Kaplan-Meier and Cox regression models. **Results:** From 1451 infiltrating HER2-negative BC p, 87% were hormone receptor (HR)-positive vs 13% triple negative (TNBC). Overall, 43% were HER2-O and 57% HER2-low (61% IHC 1+ and 39% IHC 2+). Comparing HER2-O vs HER2-low, the latest showed significant higher proportion of ER-positive (80% vs 91.7%, $p = < 0.001$) and PR-positive (69.3% vs 79.1%, $p = < 0.001$) cases, but there were no differences between HER2-low 1+ vs 2+. HER2-O exhibited higher proportion of TNBC p (20% vs 8.3%, $p = 0.001$), grade III tumors (28.8% vs 23.5%, $p = 0.036$) and higher Ki67 median value (26.47% vs 23.88%, $p = 0.041$). No significant differences were observed in median age at diagnosis, menopausal status, clinical stage, clinical nodal status, histological subtype, time to recurrence, time to local recurrence and overall survival (OS). HER2-low presented longer time to distant recurrence (TDR) compared to HER2-O (67.8 vs 54.1 months, $p = 0.015$) and better BC-related OS (19.2 vs 16.3 years, $p = 0.033$). However, in the multivariate analysis, considering HER2, ER, PR, histological grade and nodal status, PR showed the strongest association with longer TDR (HR: 0.69; 95%CI 0.54-0.89, $p = 0.004$); and positive nodal status was the strongest factor related to worse BC-related OS (HR: 2.97; CI 2.10-4.21, $p = 0.000$). No statistical differences in TDR and BC-related OS were observed between HER2 1+ vs 2+ populations. **Conclusions:** HER2-low was significantly associated to HR-positive disease whereas TNBC, histological grade III and higher Ki67% were more represented in HER2-O group. Although HER2-O was related to worse TDR and BC-related OS, these findings could be explained by the presence of an enriched population in worse prognostic features, as suggested by multivariate analysis. New therapies for HER2-O disease are an unmet medical need. Research Sponsor: None.

Extracellular vesicle-derived non-coding RNAs to predict outcome in patients with triple-negative breast cancer (TNBC) with residual disease (RD).
First Author: Shane R Stecklein, University of Kansas Medical Center, Kansas City, KS

Background: TNBC patients with RD after neoadjuvant systemic therapy (NAST) have high risk of recurrence. Biomarkers to risk-stratify patients with RD could individualize adjuvant therapy and inform adjuvant therapy trials. We aim to investigate the impact of circulating extracellular vesicle (EV)-derived non-coding RNAs (exo-ncRNAs) on outcomes in TNBC patients with RD. **Methods:** The study population included 79 TNBC patients with RD post-NAST and available end-of-treatment plasma samples enrolled in an IRB-approved multisite prospective registry. EVs and their associated exo-ncRNAs were isolated by membrane affinity spin columns (Qiagen exoRNeasy). Exo-ncRNA was subjected to next-generation sequencing (Qiagen QIAseq miRNA library kit). $N=47$ served as a discovery cohort and $N=32$ served as validation cohort. With inclusion of transcripts expressed in $\geq 80\%$ of samples, there were 1,123 normalized reads/sample. Hazard ratios and C-statistics for event-free survival (EFS) were computed for each exo-ncRNA. We report exo-ncRNAs that were significantly associated with EFS in both the discovery and validation cohorts. **Results:** Patient and tumor characteristics were balanced in discovery and validation cohorts. Three exo-ncRNAs were associated with increased recurrence risk in both the discovery dataset (*miR-200a-3p*, HR=1.39, 95%CI 1.01-1.89, $P=0.04$, C-stat=0.55; *miR-203a-3p*, HR=1.77, 95%CI 1.15-2.73, $P=0.01$, C-stat=0.59; and *miR-7845-5p*, HR=1.53, 95%CI 1.15-2.05, $P=0.004$, C-stat=0.62) and the validation dataset (*miR-200a-3p*, HR=1.83, 95%CI 1.24-2.72, $P=0.003$, C-stat=0.76; *miR-203a-3p*, HR=1.78, 95%CI 1.10-2.87, $P=0.02$, C-stat=0.67; and *miR-7845-5p*, HR=2.06, 95%CI 1.06-4.01, $P=0.03$, C-stat=0.52). Using the miRNA Target Prediction Database (miRDB), we identified 1,088, 1,352, and 387 predicted targets for *miR-200a-3p*, *miR-203a-3p*, and *miR-7845-5p*, respectively. Amongst 2,827 prediction events there were 2,526 unique target mRNAs. 2,235 mRNAs were targets for one candidate miRNAs, 281 mRNAs were predicted targets for two candidate miRNAs, and 10 mRNAs were predicted as targets for all three candidate miRNAs. **Conclusions:** The expression of *miR-200a-3p*, *miR-203a-3p*, and *miR-7845-5p* in plasma-derived EVs in TNBC patients with RD after NAST is associated with increased risk of recurrence. We identified ten mRNAs that are predicted targets of all three of these miRNAs. If validated in additional cohorts these exo-ncRNAs could be used in a liquid-biopsy assay to identify high-risk patients with RD who could benefit from adjuvant treatment intensification. Assessment of the differential profile of breast intratumoral bacteria in treatment responders and nonresponders.
First Author: Amedra Basgaran, BioCortex Ltd, London, United Kingdom

Background: Despite improvements in breast cancer therapy, many patients do not respond to treatment: the response rate varies between 31 and 80% [Walks et al., 2019]. The tumor microenvironment contains a microbiome which is both cancer type-specific and different to surrounding normal tissue [Nejman et al., 2020]. It plays an important role in tumour microenvironment crosstalk with tumor cells and has been implicated in disease pathogenesis, being recognised in the latest hallmarks of cancer [Hanahan et Weinberg, 2011]. It has also successfully predicted treatment response [Chen et al., 2022; Hermida et al., 2022]. Here, we use conventional microbiome analysis alongside our proprietary mechanistically-powered technology platform to compare the intratumoral bacteria between responders and non-responders. We hypothesise that there are significant differences between those groups regarding composition and mechanistic function of the bacteria. **Methods:** The tumor microbiome can be deduced from existing sequencing data of tumor biopsy samples. Using 34 tumor DNA samples from 5 breast cancer studies, we compared the intratumoral bacterial profiles of responders to non-responders of various treatments. We performed microbiome analysis in R, including alpha diversity, compositional abundance profiles, and PERMANOVA (permutational analysis of variance). Additionally, BioCortex CarbonMirror version dated 2023-02-14 was used to infer mechanistic links between bacterial species and the up- and downregulation of genes implicated in the hallmarks of cancer. **Results:** The results show significant differences in diversity and compositional profile between responders and non-responders: Non-responders have significantly higher alpha diversity ($p<0.05$) and a higher proportion of Proteobacteria. PERMANOVA analysis revealed that while responders are more likely to have commensal bacteria, non-responder tumour microbiomes are more likely to harbor pathogenic species such as *Mycoplasmopsis fermentans*. Mechanistic analysis showed that for all responders the tumor microbiome is consistently promoting tumor suppressor genes and downregulating proto-oncogenes. In non-responders, however, the tumor microbiome is upregulating and downregulating both with unclear consistency. **Conclusions:** Our results show microbiome differences between responders and non-responders which were mechanistically implicated in tumor pathogenesis. Further analysis divided by the hallmarks of cancer is required to fully understand the non-responder microbiome links. The reported findings could make the tumor microbiome a useful biomarker aiding patient stratification for both prognosis and treatment choice. They also highlight a potentially meaningful mechanistic link between tumour microenvironment and treatment response that could be leveraged as a novel therapeutic avenue. Differential genomic and transcriptomic analysis of invasive lobular and ductal carcinomas.
First Author: Jason A Mouabbi, University of Texas MD Anderson Cancer Center, Houston, TX

Background: Invasive lobular carcinoma (ILC) is more aggressive than hormone receptor (HR)-positive invasive ductal carcinoma (IDC). However, in practice, ILC and IDC are often treated in a similar fashion with endocrine therapy and chemotherapy. Identifying novel biomarkers, genetic alterations, transcriptomic features, and tumor microenvironment (TME) variations could initiate the development of personalized treatment plans for patients with ILC. **Methods:** We collected ILC and luminal (non-basal/non-HER2) IDC samples from four datasets (TCGA, METABRIC, RATHER PMC4700448, and UQCCR PMC31263747) and performed differential expression and gene set enrichment analyses, revealing novel genomic, transcriptomic, and TME differences. Using methods from Bagaev et al., we quantified the activity of 29 functional gene expression signatures with single sample gene set enrichment analysis before clustering the samples into five TME subtypes; statistical significance was measured with the Mann-Whitney U test. Differential expression analysis of RNA-Seq data was completed using DESeq2. Further, we analyzed the frequency of specific biomarkers to identify potential therapeutic options. Mutations and biomarker enrichment were assessed using the chi-squared test. **Results:** We analyzed 1,735 samples (1,442 luminal IDCs and 293 ILCs). *CDH1* mutations were more prevalent in ILC samples (56%) compared to IDC samples (6%). Of the 44% of ILC samples with wild-type *CDH1*, 90% had low *CDH1* expression. Inference models showed differences in transcription factors expression between ILC and IDC. ILC had significantly higher expression of *TFAP2B*, *SOC2*, *NOSTRIN*, *THBS4*, *SCUBE2*, and *GDF9* and lower expression of *CDC44*, *PSMG1*, *LMOD1*, and *SLC7A5* (adj $p < 0.0001$ for all genes). Analysis of the TME showed that 44% of ILC samples were immune enriched with high *PDL1*, *CTLA4*, and *LAG3* expression. In comparison, approximately 30% of ILC samples contained enhanced vascularization and expressed high *VEGFA*, *PDGFRA*, and *PDGFRB*. Finally, compared to luminal IDC, ILC tend to have a statistically significant higher TROP2 expression, similar to that seen in basal subtype. **Conclusions:** ILC and IDC expressed distinct genomic alterations, gene expression, transcriptomic features, TMEs, and biomarkers. These differences can be used as a blueprint to tailor ILC phenotype-specific interventional clinical trials. Research Sponsor: None.

Characteristics associated with spatially resolved immune landscapes in triple-negative breast cancer in the FinXX trial and Mayo Clinic cohort.
First Author: Saranya Chumsri, Mayo Clinic, Jacksonville, FL

Background: Several studies have established the crucial role of preexisting immune response measured by tumor-infiltrating lymphocytes (TILs) in triple-negative breast cancer (TNBC). Emerging studies showed that not only the number of TILs but also the location of TILs is as critical. There are 3 distinct immune landscapes described based on the locations of TILs, namely immune enriched (IN), immune excluded (IE), and immune desert (ID), which are associated with outcomes in TNBC treated with immune-checkpoint inhibitors. Here we evaluated characteristics associated with each immune landscape. **Methods:** NanoString IO360, Digital Spatial Profiling (DSP), and CosMx, a spatial multi-omics single-cell imaging platform, were used. DSP was used to quantify 39 immune-related proteins in stromal and tumor-enriched segments from 44 TNBC samples from the FinXX trial (NCT00114816) and 276 samples from the Mayo Clinic (MC) TNBC cohort (Leon-Ferre BCRT 2018). CosMx was performed in 75 samples from the MC TNBC cohort. First, tumors with TIL quantified by H&E $\leq 30\%$ were classified as ID. The rest of the tumors were categorized according to the intratumoral CD8 protein expression by DSP, with IE having intratumoral CD8 in the lower median and IN having intratumoral CD8 in the upper median. Differential expression listed as log fold change (FC) was estimated from the linear mixed model with significance defined as two-sided $p < 0.05$. **Results:** Using DSP in the FinXX trial, intratumoral and stromal higher HLA-DR (FC 1.68, $p=0.001$), B2M (FC 0.8, $p=0.005$), CD4 (FC 0.74, $p=0.01$), and CD40 (FC 1.56, $p=0.001$) were associated with IN compared to ID. When comparing IE and IN, higher intratumoral CD11c (FC 0.97, $p=0.01$) and stromal CD4 (FC 0.89, $p=0.047$), CD20 (FC 0.85, $p=0.016$), CD40 (FC 0.95, $p=0.045$), and CD27 (FC 0.84, $p=0.024$) were associated with IN. Similar findings were observed in the MC cohort. Moreover, intratumoral NY-ESO-1 expression (FC 0.55, $p=0.03$) was associated with IN. Using GSEA with IO360 in the FinXX trial, PI3K-Akt signaling was associated with ID compared to IN ($p=0.01$). We further evaluated the differential gene expression in a spatially resolved manner using CosMx with single-cell sequencing in the MC cohort. Expressions of MHC class I and class II in tumor cells, including HLA-A, HLA-B, HLA-C, HLA-DRA, HLA-DRB1, HLA-DPA1, and HLA-E, were associated with IN compared to ID and IE. **Conclusions:** Using an in-depth analysis with spatially defined context, we identified characteristics associated with distinct immune landscapes in TNBC. Our study highlights the potential future implications of intratumoral MHC expression, CD40, and PI3K-AKT as biomarkers and therapeutic targets. Clinical trial information: NCT00114816. The somatic mutation profile of breast cancer in Uganda. *First Author: Manoj Menon, Fred Hutchinson Cancer Center, Seattle, WA*

Background: Breast cancer, the most common cancer in sub-Saharan Africa (SSA), is characterized by poor survival compared with resource-rich regions. A variety of factors are responsible for this disparity and include late stage at presentation, limited diagnostic and therapeutic options, and potentially biologically more aggressive disease. The application of next generation sequencing to cancer specimens in resource-rich regions has identified new molecular mechanisms. However, such molecular testing has generally not been applied to tumors from SSA where the aggressive nature and younger age of women with breast cancer argues for the potential for novel pathogenic mechanisms. Here, we describe the somatic mutation profile of breast cancer in Uganda. **Methods:** We enrolled 100 consecutive women with a new diagnosis of invasive breast cancer at the Uganda Cancer Institute (UCI) in Kampala - the primary cancer center of Uganda and neighboring countries. Histopathologic classification was performed at the UCI and reevaluated in a blinded fashion at the Fred Hutchinson Cancer Center (Seattle, WA). Demographic and clinical data were obtained. A biopsy specimen of the tumor tissue was obtained, snap frozen, processed using standard protocols to obtain DNA, and sequenced using the clinically-validated UW-OncoPlex assay, identifying all classes of variants and mutations. **Results:** We analyzed data from 100 women with a histologically-confirmed diagnosis of breast cancer between the ages of 35 and 65 - the vast majority of whom presented with either stage 3 or stage 4 (92%). All 100 tumor specimens were successfully sequenced, with 96 (96%) demonstrating somatic mutations. The most commonly altered gene was TP53, with mutations in 65% of patients, with identified variant classes including truncations (18), missense (19), and copy loss (33). *PIK3CA* mutations were identified in 36% of patients, while copy gain or amplification were identified in *MYC* (50%), *CCND1* (31%), *FGFR1* (26%), *EGFR* (9%), and *ERBB2* (24%). Nearly half of the women had either a mutation in *BRCA1* (24%) or *BRCA2* (24%); 6 (6%) of the tumors expressed mutations in both *BRCA1* and *BRCA2*. **Conclusions:** We identified a diverse landscape of somatic mutations - the prevalence of *BRCA1*, *BRCA2*, and *PIK3CA* mutations are considerably higher than in other documented populations. A better understanding of the mutational profile can provide biological insights, inform prognosis, and serve as a predictive biomarker. As mutations in *BRCA1/2* and *PIK3CA* can potentially be treated with targeted therapies (e.g. PARP inhibitor, PI3K inhibitor), such data can inform policymakers, allow for inclusion of these therapeutics in the formulary and in the WHO Model List of Essential Medicines, and reduce health disparities. Notably, all cases were successfully sequenced, with 96% of cases demonstrated somatic mutations, even without employing specific enrichment strategies commonly used in high-income countries. 10-year mastectomy trends among breast cancer phenotypes: A national cohort study. *First Author: Matthew Lewis Pierotti, Fox Chase Cancer Center, Philadelphia, PA*

Background: Breast cancer tumor phenotype has prognostic value with triple negative (TN) cancers having higher rates of distant metastases early. While tumor phenotypes are prognostic, published data demonstrates that the choice of local therapy does not affect this predisposition or affect survival. This study was performed to determine whether mastectomy is being performed more frequently for TN or HER2+ phenotypes, relative to hormone receptor positive (HR+) phenotypes despite the lack of benefit this should provide. **Methods:** Data from the National Cancer Database (NCDB) was analyzed from 2010 through 2019 to assess mastectomy trends and associations with patient and tumor characteristics. Women with invasive breast cancer were included. Women with Stage IV disease were excluded. Patients were categorized as mastectomy or breast conservation surgery. Patient and tumor characteristics were compared across groups using chi-square and Wilcoxon rank sum tests, and a multivariable logistic regression model was fit to assess the association between mastectomy and tumor phenotype controlling for patient and tumor characteristics. **Results:** 543,590 patients were evaluated. 173,380 (31.9%) patients underwent mastectomy, and 370,210 (68.1%) patients underwent breast conservation surgery. Mean age at diagnosis was 56. There were 425,174 HR+, 64,960 HER2+, and 53,456 TN tumors. The proportion of patients undergoing mastectomy peaked in 2013 at 36.14% before declining. Compared to HR+, HER2+ patients were more likely to undergo mastectomy, OR 1.39 $p < 0.0001$ (95% CI 1.35 - 1.43); however, there was no significant difference in mastectomy between HR+ patients and TN patients. Compared to whites, black patients were less likely to undergo mastectomy, OR 0.71 $p < 0.0001$ (95% CI 0.69 - 0.74), and individuals of Hispanic ethnicity less likely to undergo mastectomy, OR 0.92 $p < 0.0001$ (95% CI 0.89 - 0.95). Compared to private insurance, Medicare had a greater association with mastectomy, OR 1.2 $p < 0.0001$ (95% CI 1.18 - 1.23). There was no significant difference between other forms of insurance (Medicaid, other government insurance, no insurance) and private insurance. Education and income were not associated with different frequencies of mastectomy. Patients with higher comorbidity scores were more likely to undergo mastectomy. **Conclusions:** Mastectomy rates have been declining since 2013 at CoC centers. While TN breast cancer is not associated with increased mastectomy percent, mastectomy continues to be performed more frequently for HER2+ positive phenotype when adjusting for tumor and patient characteristics. These data suggest a need for education about HER2 positive phenotype due to a possible lack of understanding about the why such tumors pose a risk, and the role of local therapy in treating them. Phase II study on feasibility of sentinel lymph node biopsy for ycNO patients treated with primary chemotherapy in cT1-3N1M0 breast cancer (SHARE study). *First Author: Rikiya Nakamura, Department of Breast Surgery, Chiba Cancer Center, Chiba, Japan*

Background: Sentinel lymph node biopsy (SLNB)-guided axillary management is still debated for clinically node-positive breast cancer (BC) patients treated with neoadjuvant chemotherapy (NAC). Several phase II studies demonstrated high false-negative rates (FNR) in ycNO BC, but precise diagnostic imaging for nodal involvement may reduce FNR. To explore ideal imaging and lymphatic mapping, the Japanese Society for Sentinel Node Navigation Surgery conducted a prospective non-randomized phase 2 study (SHARE study, UMIN000030558). **Methods:** Clinical T1-3N1M0 BC was eligible under multimodal imaging of breast ultrasound, CT and/or MR mammography. Nodal metastasis was histologically confirmed. Standard regimen for NAC was performed by physician's choice. In case of ycNO BC, SLNB was planned and lymphatic mapping depended on each institutional practice. The primary endpoint is FNR of SLNB and secondary endpoints are the identification rate and outcome of ycNO BC patients at 2 years after surgery. Moreover, in cases of pNO(sn), pNO(i+)(sn) and pN1mi(sn), SLNB followed by lymph node sampling had been allowed instead of axillary lymph node dissection. Based on an estimated FNR of 5%, 224 patients were needed to give 80% power to reject the null hypothesis that the threshold of FNR is 15% with a one-sided type I error rate of 5%. **Results:** Between February 2018 and May 2021, 185 patients from 19 institutes were registered. After 27 ineligible cases of protocol deviation, non-ycNO or withdrawal of SLNB were excluded, 158 ycNO cases underwent SLNB and sentinel lymph nodes were detected in 153 cases. Among them, the median age was 52 years old. Clinical stage was IIA in 40 cases, IIB in 105 and IIIA in 8. Luminal subtype classified by ER, PR and HER2 expression was found in 60 cases, HER2 in 34, Luminal-HER2 in 35 and triple-negative in 24. Finally, 61 cases had positive nodes, which included 7 false-negative cases. FNR was 11.5% (90% confidence interval, 5.5% and 20.5%). The identification rate was 96.8% and the accuracy rate was 95.4%. Before NAC, multimodal imaging was performed in 148 cases (96.7%) and 1 nodal metastasis was detected in 62 cases (40.5%). When multimodal imaging, 1 nodal metastasis, multiple tracers, multiple sentinel lymph nodes were considered for subset analysis, the FNR was 12.1%, 9.1%, 11.1%, and 10.6%, respectively. If isolated tumor cells in lymph nodes had been defined as pathologically negative even after NAC, the FNR was 7.1%. **Conclusions:** Multimodal imaging could not improve FNR in ycNO BC. However, SLNB-guided axillary management should be considered when one positive-node is clinically converted to ycNO after NAC. We will report the outcome of ycNO BC cases next year. Clinical trial information: UMIN000030558. Research Sponsor: The Japanese Society for Sentinel Node Navigation Surgery.

Racial/ethnic and socioeconomic differences in breast cancer surgery performed and delayed surgical treatment: Mediating impact on mortality. *First Author: Ayrtton Bangolo, Palisades Medical Center, North Bergen, NJ*

Background: Breast cancer is the most common malignancy affecting women of all racial and ethnic backgrounds in the United States (US). Although Socioeconomic status (SES), race/ethnicity, and surgical type/delays are associated with breast cancer mortality outcomes, studies on these associations have been contrasting. This study examined the racial/ethnic and SES differences in surgical treatment types and delays. Also, we quantified the extent to which these differences explained the racial/ethnic disparities in breast cancer mortality. **Methods:** We studied 290,066 women 40+ years old diagnosed with breast cancer between 2010 and 2017 identified from the Surveillance, Epidemiology, and End Results database. We performed logistic regression models to examine the association of SES and race/ethnicity with surgical treatment type and delays. We performed mediation analysis models to quantify the extent to which mortality differences were mediated by treatment, sociodemographic, and clinicopathologic factors. The study subjects were de-identified, and there was no patient contact; thus, the study was exempted from an Institutional Review Board's (IRB) approval. A p-value less than 0.05 indicated significant associations for the descriptive statistics, logistic and Cox proportional hazard regressions, and mediation analysis. We used Stata 17 to perform the analyses. **Results:** Non-Hispanic (NH) Black [Odds ratio (OR) = 1.16, 95% CI: 1.13-1.19] and Hispanic women [OR = 1.27, 95% CI: 1.24-1.31] were significantly more likely to undergo mastectomy compared to NH White women. Similarly, NH Black and Hispanic women had higher odds of delayed surgical treatment than NH Whites. Patients in the highest SES quintile, compared to those in lowest the lowest, were less likely to experience breast cancer-specific mortality (BCSM). Variations in treatment, SES, and clinicopathological factors significantly explained 70% of the excess BCSM among NH Blacks compared to their NH White counterparts. **Conclusions:** In conclusion, health disparity continues to be a major societal concern in the US. It affects people of all ages, socioeconomic classes, and ethnic/racial backgrounds. The findings of this study showed that racial and ethnic minorities, the majority of whom have a lower socioeconomic position, are significantly disadvantaged regarding the evaluation, quality, cost, and duration of medical care. Future studies can assess the multifactorial effects of socio-demographic factors like SES, access to health care assessment, and educational background amidst other variables as a multidimensional predictor of treatment delay and overall survival of breast cancer and other health issues among minoritized populations. Disease outcomes by race in patients with high-risk triple negative breast cancer with residual disease after neoadjuvant chemotherapy: A post-hoc analysis of the EA1131 randomized clinical trial. *First Author: Olga Kantor, Brigham and Women's Hospital, Boston, MA*

Background: Black women with breast cancer have the highest breast cancer mortality (BCM) rates of any racial and ethnic group. The higher burden of triple negative breast cancer (TNBC) in Black women contributes to disparities in BCM, but the extent to which disparate outcomes exist in patients with similar tumor biology is uncertain. The objective of this study was to examine racial differences in disease outcomes and BCM between Black and White patients in a clinical trial population of high-risk TNBC with residual disease after neoadjuvant chemotherapy (NAC). **Methods:** From 2015-2021, the ECOG-ACRIN EA1131 clinical trial randomized 415 clinical stage II-III TNBC patients with residual disease after NAC to either adjuvant capecitabine or platinum. For this analysis, 366 patients with known self-reported Black or White race and follow-up data were included. The aim of this unplanned exploratory analysis was to examine locoregional recurrence (LRR), distant recurrence (DR), and BCM by race using Kaplan-Meier curves for unadjusted estimates and Cox modeling for adjusted analyses. **Results:** Racial distribution of the analysis population included 66 (18.0%) Black and 300 (82.0%) White patients. 239 (65.3%) patients presented with clinical stage II and 127 (34.7%) with stage III disease. All patients had residual pathological disease after NAC: 86 (23.5%) stage I, 176 (48.1%) stage II, and 102 (27.9%) stage III (n=2 unknown). Median age was 49 years in Black and 54 years in White patients, $p=0.003$. Disease presentation, response to chemotherapy, and treatment arm were similar by race. Median follow up was 20 months. 2-year estimated LRR occurred in 31.6% of Black and 18.6% of White patients although this was not statistically significant ($p=0.387$), and 2-year estimated DR and BCM were similar by race. Estimated 2-year outcomes are outlined. Models adjusted for race, age, stage, grade, treatment arm, and locoregional therapy did not identify race as an independent predictor of LRR, DR, or BCM. Higher pathologic stage was the only consistent independent predictor of recurrent disease or BCM (stage III with HR 6.14 for LRR; HR 5.16 for DR; HR 6.84 for BCM; all $p<0.001$). **Conclusions:** In this population of high-risk patients with residual TNBC after NAC with similar tumor biology treated on a clinical trial, there was a trend towards increased LRR in Black patients and similar DR and BCM between Black and White patients at 2 years of follow-up. This suggests that differences in BCM in other breast cancer populations may be at least partially driven by differences in tumor biology. Clinical trial information: NCT02445391. Research Sponsor: None.

Kaplan-meier estimates of 2-year LRR, DR, and BCM by race.

Estimated 2-year Outcome	Black	White	P-value
Isolated LRR	14.3%	4.3%	0.719
Any LRR	31.6%	18.6%	0.387
Any DR	42.2%	42.9%	0.873
BCM	23.8%	30.1%	0.274

A phase II randomized clinical trial to assess toxicity and quality of life of patients with breast cancer with hypofractionated versus conventional fractionation radiotherapy with regional nodal irradiation. *First Author: Gabriel Oliveira Bernardes Gil, Rede Mater Dei, Nova Lima, Brazil*

Background: The primary aim was comparing acute toxicity between conventional fractionated radiation therapy (CF-RT) and hypofractionated radiation therapy (HF-RT) for patients undergoing breast-conserving surgery or mastectomy with breast or chest wall and regional nodal irradiation (RNI). The secondary endpoints were acute and subacute toxicity, cosmesis, quality of life, and lymphedema features. **Methods:** Unblinded randomized trial with total of 86 patients treated with CF-RT ($n = 33$; 50 Gy/25 fractions $\pm$ sequential boost [10 Gy/5 fractions]) versus HF-RT ($n = 53$; 40 Gy/15 fractions $\pm$ concomitant boost [8 Gy/15 fractions]). Toxic effects and cosmesis evaluation used the Common Terminology Criteria for Adverse Events version 4.03 (CTCAE) and the Harvard/NSABP/RTOG scale. Patients-reported QoL was determined using European Organization for Research and Treatment of Cancer quality of life questionnaire (EORTC QLQ-C30) and the breast cancer-specific supplementary questionnaire (QLQ-BR23). Lymphedema determination compared volume differences between the affected and contralateral arms using the Casley-Smith volume formula. **Results:** Grade 2 and grade 3 skin rash dermatitis were lower with HF-RT than with CF-RT (28% vs. 52%, 0% vs. 6%; $p = 0.022$, respectively). HF-RT vs. CF-RT had lower rate of grade 2 hyperpigmentation (23% vs. 55%; $p = 0.005$). No differences in overall rates of any physician-assessed grade 2 or higher and grade 3 or higher acute toxicity between HF-RT vs. CF-RT were registered. There was no statistical difference between the CF-RT and the HF-RT regarding cosmesis, lymphedema rate (13% vs. 12% HF-RT vs. CF-RT; $p = 1.000$, respectively), and functional and symptom scales during irradiation and after six months of treatment. **Conclusions:** HF-RT showed lower rates of acute toxicity, with no changes in quality-of-life outcomes. Clinical trial information: NCT04015531. Research Sponsor: None.

Association of minimizing the false negative rate of axillary staging surgery in patients with cN1 breast cancer after neoadjuvant chemotherapy with surgical overtreatment. *First Author: Alison Laws, Dana-Farber Brigham Cancer Center, Boston, MA*

Background: Efforts to minimize the false negative rate (FNR) of axillary staging in cN1 breast cancer patients (pts) treated with neoadjuvant chemotherapy (NAC) have received much attention since the publication of ACOSOG Z1071. We first adopted sentinel node biopsy (SNB) with a requirement of retrieving ≥ 3 nodes, and later transitioned to targeted axillary dissection (TAD) with a requirement of retrieving the biopsy-proven clipped node (CN) and ≥ 3 nodes overall. Group consensus was to perform axillary lymph node dissection (ALND) if these technical requirements were not met. This study evaluates likelihood of surgical overtreatment with ALND due to technical failures of SNB or TAD in cN1 pts who converted to ypN0 status, and reports oncologic outcomes with each approach. **Methods:** Among 598 cN1 breast cancer pts treated with NAC from 2017-2022 in our prospective institutional database, we included 191 (31.9%) with attempted SNB or TAD and ypN0 status. We used descriptive statistics and chi-squared tests to compare technical complications of SNB vs. TAD resulting in requirement for ALND per group consensus despite ypN0 status. Kaplan Meier methods were used to determine oncologic outcomes in those treated with SNB or TAD alone. **Results:** Planned axillary surgery was SNB in 77 (40.3%) pts and TAD in 114 (59.7%). The CN was not visualized for seed localization in 14 pts (12.2% of planned TAD) and the seed was not found to be within the CN intra-operatively in 20 pts (20.0% of those with seed placed). Technical failures resulting in requirement of ALND per group consensus criteria occurred in 14 (18.2%) pts with planned SNB and 17 (14.9%) with planned TAD. Among planned TAD pts, the rate of not retrieving the CN did not change over time ($p=0.52$). Median follow-up in those treated with SNB alone ($n=79$) was 3.5 years with 1 (1.3%) axillary recurrence as well as 2 local and 2 distant recurrences and 1 non-breast cancer death. 3-yr recurrence-free survival was 90.4% (95%CI: 79.5-95.7%). Median follow-up in those with TAD alone ($n=92$) was 1.8 years with no recurrences or deaths. **Conclusions:** This study contributes to a growing body of literature supporting the oncologic safety of omitting ALND in cN1 ypN0 pts treated with NAC, irrespective of the axillary staging approach. Technical limitations in identifying ≥ 3 nodes or localizing and retrieving CNs resulted in overtreatment with ALND in a significant proportion ($\geq 15\%$) of ypN0 pts, without significant differences between SNB vs. TAD approaches. These data support consideration of re-evaluating NCCN guidelines recommending retrieval of ≥ 3 nodes and localization of the CN to minimize risk of overtreatment. Research Sponsor: None.

	Planned SNB (n=77)	Planned TAD (n=114)	p-value
Failed mapping	5 (6.5%)	3 (2.6%)	0.19
<3 nodes	9 (11.7%)	6 (5.3%)	0.11
CN not confirmed to be retrieved	—	8 (7.0%)	—
TOTAL	14 (18.2%)	17 (14.9%)	0.55

Invasive disease free survival and brain metastasis rates in patients treated with neoadjuvant chemotherapy with trastuzumab and pertuzumab. *First Author: Sonya Chew, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients (pts) with human epidermal growth factor receptor 2 (HER2) positive (+) early breast cancer (EBC) receiving neoadjuvant systemic therapy (NAST) have poorer outcomes if they have residual disease (RD) after surgery. HER2 negative (-) RD has been reported in 1/3 of pts after NAST. The KATHERINE trial suggests that pts with HER2- RD (8%) have better invasive disease-free survival (IDFS) with adjuvant (adj) trastuzumab emtansine (T-DM1) versus trastuzumab (H) alone. However, only 18% of the pts enrolled in the trial received NAST with trastuzumab and pertuzumab (HP). We aimed to analyze IDFS and brain metastasis (BM) rates in pts with HER2+ EBC in a modern population homogeneously treated with NAST. We also report the incidence of pts with HER2- RD and their outcomes. **Methods:** Clinicopathologic data for pts with HER2+ EBC who received NAST between 1 Jan 2019 and 31 Jan 2022 were reviewed. External assessment of HER2 status before NAST was allowed. HER2 status of the surgical specimens with RD were assessed internally at our center. IDFS was defined as the time from surgery until first occurrence of invasive cancer recurrence, distant recurrence, or death from any cause. **Results:** The total cohort was 594 pts. 456 (77%) and 138 (23%) received anthracycline-taxane and taxane based chemotherapy, respectively during NAST. 587 (99%) received HP and 7 (1%) received H alone. NAST was completed by 566 (95%) of pts. pCR (ypT0/isN0) was achieved in 325 (55%) and RD was seen in 269 (45%) pts. In 269 pts with RD, 46 (17%) did not have HER2 retesting and were excluded from the final analysis. In the remaining 223 pts, 143 (64%) were HER2+ and 80 (36%) were HER2-. In the 143 pts with HER2+ RD, adj TDM1, HP, H alone and no HER2 directed therapy were received by 120 (84%), 16 (11%), 1 (1%) and 6 (4%) of pts, respectively. In the 80 pts with HER2- RD, adj TDM1, HP, H alone and no HER2 directed therapy were received by 44 (55%), 27 (34%), 3 (4%) and 6 (7%) of pts, respectively. With a median follow up of 24 months, 7 pts developed BM at initial recurrence, 3/325 (0.9%) with pCR and 4/143 (2.8%) with HER2+ RD. None of the pts who developed BM had HER2- RD. IDFS events occurred in 22/594 (3%) pts. RD pts had a higher likelihood of having an IDFS event, 14/269 (5%) in RD and 8/325 (2%) in pCR ($p = 0.04$). In the evaluable 223 pts with RD there was no difference in IDFS between 10/143 (7%) pts with HER2+ RD or 4/80 (5%) with HER2- RD ($p = 0.10$). **Conclusions:** At a single center, in pts who predominantly received HP with chemotherapy as NAST, pts with RD had higher IDFS events than those with pCR. In those with RD, 36% lost HER2+ status; IDFS events appeared similar in those with HER2+ RD versus those with HER2- RD. The HER2 loss rate is higher than reported in KATHERINE possibly due to majority of pts receiving dual HP as NAST. The BM events seen in those with RD and pCR highlights the need for more effective therapy in NAST and adj setting to minimize BM risk. Research Sponsor: None.

Effect of tumor microenvironment on chemotherapy response of patients with triple-negative breast cancer receiving neoadjuvant chemotherapy. *First Author: Jae-Joon Kim, Pusan National University Yangsan Hospital, Yangsan-Si, South Korea*

Background: Triple-negative breast cancer (TNBC) is a breast cancer subtype that has poor prognosis and exhibits a unique tumor microenvironment, including the corresponding immunological environment. Analysis of the tumor microbiome has indicated a relationship between the tumor microenvironment and treatment response. Therefore, we attempted to reveal the role of the tumor microbiome in patients with TNBC that were receiving neoadjuvant chemotherapy. **Methods:** We collected TNBC patient RNA-seq samples from the Gene Expression Omnibus (GEO; n of pathological complete response [pCR] = 38, n of residual disease [RD] = 50) and extracted microbiome count data using Kraken2 and Bracken. Differential and relative abundance were estimated with linear discriminant analysis effect size (LEfSe). We calculated the immune cell fraction with CIBERSORTx and conducted survival analysis using the Cancer Genome Atlas patient data (n = 115). Correlations between the microbiome and immune cell compositions were analyzed and a prediction model was constructed to estimate drug response using random forest (RF) and support vector machine (SVM). **Results:** Among the drug response group, the beta diversity varied considerably; consequently, 20 genera and 24 species were observed to express a significant differential and relative abundance using LEfSe analysis. The drug response prediction model accuracy exhibited 76.47 and 88.24 percent in RF and SVM, respectively; specifically, *Pandoraea pulmonicola* and *Brucella melitensis* were found to be important features in determining drug response. In correlation analysis, *Geosporobacter ferrireducens*, *Streptococcus sanguinis*, and resting natural killer cells were the most correlated factors in the pCR group, whereas *Nitrosospora briensis*, *Plantactinospora* sp. BC1, and regulatory T cells (Tregs) were key features in the RD group. Further, M2 macrophages and *Brucella* showed significant differences in survival between the pCR and RD groups (p < 0.05). **Conclusions:** Our study demonstrated that the microbiome analysis of tumor tissue can predict chemotherapy response of patients with TNBC receiving neoadjuvant chemotherapy. Further, the immunological tumor microenvironment may be impacted by the tumor microbiome, thereby affecting the corresponding survival and treatment response. Use of machine learning to predict pathological complete response using multi-modal data from I-SPY2 clinical trials. *First Author: Fahad Shabbir Ahmed, Algorismus, LLC, Detroit, MI*

Background: The objective of the current analysis of the I-SPY 2 data from multiple breast cancer clinical trials for stages II and III cancers was to look at the possibility of developing a machine learning algorithm to predict pathological complete response using multimodal data. **Methods:** Imaging, clinical and biomarkers data form the I-SPY 2 trial was used in this analysis. Four different experiments were designed for to assess different data pre-processing and machine learning methods mainly deep neural networks (DNN) and random forest (RF) classifiers. Experiment 1 and 3 use DNNs while Experiment 2 and 4 used RFs; more over the first two experiments used data that was continuous in nature from the point of view of pre-performed imaging analysis while in later two experiments we had binarized all the variables using a median cutoff for high vs low values. The variables used were treatment recieved, HER2/neu receptor status, hormone receptor status, age, ethnicity, gynecological history, MRI feature data. All models were evaluated using robust testing methods that included sensitivity, specificity, positive predictive values (PPV), negative predictive values (NPV), accuracies (training and test sets), area-under the receiver-operator curve and F1-Score. **Results:** From a total of 985 patients with clinical data we used 384 that had multi-feature MRI data. Time series data for the initial scan (T0) and a scan 3 weeks later (T1). The final comparative analysis showed the best model among the 4 experiment the best performing algorithms for this analysis was random forests using median cutoffs with a best F1-score (0.43), specificity (86.4%), PPV (47.8%), accuracies (train sets, 100%; test sets, 75%), and AUROCs (0.78, 0.56-0.73). **Conclusions:** The use of machine learning to predict pathological complete response using multi-modal data shows good potential as a digital biomarker. However, these results need further validation before a clinical tool is available for the clinicians. Research Sponsor: None.

Neoadjuvant giredestrant + palbociclib (P) vs. anastrozole (A) + P in postmenopausal women with estrogen receptor-positive, HER2-negative, untreated early breast cancer (ER+, HER2- eBC): Patient (pt)-reported outcomes (PROs) in the randomized, open-label, international phase II coopERA BC study. *First Author: Yeon Hee Park, Samsung Medical Center, Seoul, South Korea*

Background: Endocrine therapies (ETs) are the therapeutic mainstay for ER+ BC but persistent adverse events (AEs; eg joint pain, especially with aromatase inhibitors) negatively impact quality of life, and resistance impacts efficacy. Giredestrant, a highly potent, nonsteroidal, oral selective ER antagonist and degrader (PO SERD), may help address these issues. coopERA BC (NCT04436744) evaluated giredestrant in eBC and met its primary endpoint, demonstrating a greater reduction of Ki67 with giredestrant vs. A after 2 weeks. Giredestrant was well tolerated as a single agent and with P. We report exploratory PRO analyses. **Methods:** Pts with cT1c-cT4a-c (≥ 1.5 cm within cT1c) ER+, HER2- untreated eBC and baseline Ki67 score $\geq 5\%$ were randomized 1:1 to 30 mg PO daily (QD) giredestrant or 1 mg PO QD A on days (D)1–14 of a window-of-opportunity phase. A 16-week neoadjuvant phase added 125 mg PO QD P on D1–21 of four 28-D cycles. Presence/frequency/severity/interference of relevant symptomatic AEs were assessed at Cycles 1–4 via NCI PRO-CTCAE library items; overall burden due to AEs, via FACT-G item GP5. **Results:** PRO completion rates were > 80% at all time points. PRO-CTCAE postbaseline frequency scores were comparable between arms and mostly 0/1 (never/rare; reported for: Diarrhea > 80% of pts; hot flash > 60%; joint pain > 65%; nausea > 90%; vomiting > 90%). No rash was reported by > 90% of pts; fatigue at 0/1 severity (none/mild) by > 75% and at 0/1 interference (none at all/a little bit) by 80%. Hot flash frequency scores of 2–4 (occasionally/frequently/almost constantly) were reported by 30% of pts in the giredestrant + P arm and 37% in the A + P arm; joint pain frequency scores of 2–4, by 25% and 35%. Worst postbaseline scores of 3–4 are shown in the table. FACT-G GP5 showed greater proportions of “improved/no change” responses in the giredestrant + P than the A + P arm at Cycles 2–4 (Cycle 2 75%; Cycle 3 71%; Cycle 4 68% vs. 62%; 66%; 53%), and smaller proportions of “worsened” responses (25%; 29%; 32% vs. 38%; 34%; 47%). **Conclusions:** This is the first analysis to our knowledge of PROs with a PO SERD in eBC; it showed that most pts reported minimal symptomatic AEs at frequency and severity levels that were generally numerically lower in the giredestrant + P than the A + P arm (particularly joint pain). Furthermore, there were numeric trends towards greater stability and improvement and less worsening of treatment burden in the giredestrant + P arm. Studies to further assess giredestrant’s clinical benefit are ongoing in the adjuvant setting. Clinical trial information: NCT04436744. Research Sponsor: F. Hoffmann-La Roche Ltd.

n/N pts (%)	Giredestrant + P	A + P
Frequency		
Diarrhea	0/108	3/103 (3)
Hot flash	18/106 (17)	12/101 (12)
Joint pain	8/108 (7)	17/103 (17)
Nausea	1/107 (1)	0/103
Vomiting	0/107	0/103
Fatigue severity	2/107 (2)	7/101 (7)

Taxane combined with lobaplatin or anthracycline for neoadjuvant treatment of triple-negative breast cancer: A single-center, randomized, controlled, phase-II clinical study. *First Author: Cheng Wang, Southwest Hospital, Army Medical University, Chongqing, China*

Background: Previously, we showed that addition of lobaplatin (L) to taxane combined with anthracycline could improve the pathologic complete response (pCR) rate and lengthen survival significantly if employed as neoadjuvant therapy in patients with triple-negative breast cancer (TNBC). We evaluated the efficacy and safety of neoadjuvant chemotherapy of taxane (T) combined with lobaplatin (L) or anthracycline (E) for patients with TNBC. **Methods:** Ninety-five patients with TNBC (stage I–III) who had not undergone any type of treatment were divided randomly into two groups: TL (docetaxel at 75 mg/m² and lobaplatin at 30 mg/m², D1, one cycle = 21 days, a total of six cycles) or TE (docetaxel at 75 mg/m² and epirubicin at 80 mg/m², D1, one cycle = 21 days, a total of 6 weeks or epirubicin at 80 mg/m² and cyclophosphamide at 600 mg/m², sequential docetaxel at 75 mg/m², D1, one cycle = 21 days, a total of eight cycles). Efficacy was evaluated every two cycles. The final surgical procedure was completed after fulfillment of neoadjuvant chemotherapy. The primary endpoint was the total pathologic complete response (tpCR) rate. The secondary endpoints were the objective response rate (ORR), safety, event-free survival (EFS), and overall survival (OS). The exploratory endpoint was biomarker analysis. **Results:** From June 2019 to November 2022, 97 patients were screened. Finally, 95 patients were enrolled. The median age of the study cohort was 49 years. Nine patients (9.5%) had stage-I disease, 61 patients (64.2%) had stage II, and 25 patients (26.3%) had stage III. Sixty-five patients (68.4%) had Ki67 $\geq 40\%$ and 30 patients (31.6%) had Ki67 < 40%. Seventy patients (73.7%) were cytokeratin (CK)5/6+ and 25 patients (26.3%) were CK5/6-. Of 95 patients, 47 were in the TL group and 48 in the TE group. The tpCR rate in the TL group was 46.8% (22/47), which was significantly higher than that in the TE group (22.9% (11/48); odds ratio (OR) = 2.960, 95% confidence interval (CI) = 1.223–7.164, P = 0.016). The ORR in the TL group was 95.7% (45/47), which was significantly higher than that in the TE group (75.0% (36/48); OR = 27.500, 95% CI = 1.576–35.683, P = 0.011). The prevalence of grade III/IV neutropenia in the TE group was 41.0% (9/22), which was significantly higher than that in the TL group (7.7% (2/26); OR = 8.308, 95% CI = 1.557–44.320, P = 0.013). There was no significant difference in the prevalence of other adverse reactions between the two groups. **Conclusions:** In the neoadjuvant treatment of TNBC, the TL regimen had a higher tpCR rate and ORR than those of the TE regimen, and was safer. Clinical trial information: ChiCTR1900023776. Research Sponsor: None.

Use of PLR and NLR to evaluate the efficacy and prognosis of neoadjuvant chemotherapy with lobaplatin in triple-negative breast cancer. *First Author: Cheng Wang, Southwest Hospital, Army Medical University, Chongqing, China*

Background: Previously, we showed that addition of lobaplatin (L) to taxane (T) combined with anthracycline (E) could improve the pathological complete response (pCR) rate of neoadjuvant therapy for triple-negative breast cancer (TNBC) and lengthen long-term survival significantly, but the therapeutic markers of this regimen are not known. We investigated if the platelet/lymphocyte ratio (PLR) and neutrophil/lymphocyte ratio (NLR) could be used to predict the efficacy of the TEL regimen. **Methods:** Eighty-three patients with TNBC (stage I–III) who received TEL (docetaxel (T) at 75 mg/m², epirubicin (E) at 80 mg/m², and lobaplatin (L) at 30 mg/m²) from January 2014 to August 2019 were recruited. They received four cycles before surgery and two cycles after surgery. Patients were divided into four groups according to the mean values of the PLR (145.71) and NLR (2.74): high PLR (PLR+), low PLR (PLR−), high NLR (NLR+), and low NLR (NLR−). Differences in the total pathological complete response (tpCR) rate, event-free survival (EFS), and overall survival (OS) were analyzed in different groups of patients using the TEL protocol. **Results:** The tpCR rate in the PLR+ group was 49.0% (25/51), which was significantly higher than that in the PLR− group (25.0% (8/32); odds ratio (OR) = 2.885, 95% confidence interval (CI) = 1.093–7.612, P = 0.032). The tpCR rate in the NLR+ group was 49.1% (26/53), which was significantly higher than that in the NLR− group (23.3% (7/30); OR = 3.164, 95% CI = 1.161–8.626, P = 0.024). The tpCR rate of the PLR+ group was 53.7% (22/41), which was significantly higher than that of the PLR+/NLR+ group (26.1% (11/42), with a high proportion of any index (OR = 3.263, 95% CI = 1.298–8.204, P = 0.012). The median duration of follow-up was 69 months. EFS and OS in the NLR+ group were significantly longer than those in the NLR− group (hazard ratio (HR) = 5.946, 95% CI = 1.526–23.169, P = 0.010 for EFS; HR = 7.803, 95% CI = 1.565–38.907, P = 0.012 for OS). Five-year EFS was 95.1% for the PLR+ group, 91.0% for the PLR+/NLR+ group, 76.0% for the PLR+/NLR− group, and 59.1% for the PLR−/NLR+ group. Compared with the PLR+/NLR+ group, patients in the PLR−/NLR− group had the longest EFS (P = 0.002). **Conclusions:** PLR and NLR could be used to predict the efficacy of neoadjuvant therapy with taxane, anthracycline, and lobaplatin regimen in TNBC, and the low-proportion group had a higher tpCR rate and a better long-term prognosis. Clinical trial information: ChiCTR-TRC-14005019. Research Sponsor: None.

Neoadjuvant therapy of HER2 directed conventional dendritic cell (DC1) intratumoral (IT) therapy plus weekly paclitaxel, trastuzumab, and pertuzumab in patients with HER-2 positive breast cancer: NATASHA trial. *First Author: Hyo S. Han, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Early stage HER2 positive breast cancer (BC) patients (pts) are commonly treated with neoadjuvant HER2-targeted therapy. Optimizing neoadjuvant therapy by improving efficacy while reducing toxicity is a critical unmet need. IT DC1 therapy combined with an IgG1 antibody mediating ADCC drives strong anti-HER-2 CD4 Th1 responses and complete tumor regression in preclinical models. We initiated a phase I/II neoadjuvant study to explore the efficacy and immune stimulation effects of an initial 6 weeks of immunotherapy phase (IP) using IT DC1 vaccine plus trastuzumab (H) and pertuzumab (P) (as source of IgG1) followed by 12 weeks of paclitaxel (T) and HP. **Methods:** Early stage HER2+ BC pts with tumor ≥ 1 cm were eligible. Treatment included IT DC1 weekly x6 followed by paclitaxel 80 mg/m² IV weekly x 12. Trastuzumab IV every (q) 3 weeks (8 mg/kg loading dose, then 6 mg/m²) and pertuzumab IV q 3 weeks (840 mg loading dose, then 420 mg) x 6 cycles starting from day 1. Two dose levels (DL) of IT DC1 (DL1 = 50 million and DL2 = 100 million cells) were evaluated including 6 pts in each DL. Once the optimal DL is determined based on toxicities, additional 22 patients will be enrolled in expansion phase 2 trial. The primary end point of the phase 1 is the safety, immune responses (measured by ELISPOT). MRI breast was performed at the baseline, post-immunotherapy and post-chemotherapy. Here we are reporting the safety and immune correlates in phase 1 study. **Results:** Twelve pts were enrolled between 10/2021 and 10/2022. Median age was 57 (range 34–74). Nine pts had hormone receptor positive disease with clinical stage I/II/III (5/5/2) and 4 pts had node positive disease. All pts completed IP and 10 patients completed THP chemotherapy as of 2/1/2023. Radiologic response per MRI breast on pre and post-IP showed 6 partial response, 3 complete response and 3 stable disease. Nine pts underwent surgery and 6 out of 9 pts had pCR (RCB 0). The most frequently observed toxicities were chills (50%), diarrhea (42%), nausea (42%), fatigue (42%), and headache (42%). ELISPOT demonstrated a significant decrease of HER2-specific T cell response following 6 weeks of DC1 IT injections in DL2 compared to DL1. **Conclusions:** The addition of IT DC1/HP to neoadjuvant chemotherapy was well tolerated with manageable toxicities. The 100 million DC1 led to a significant decrease in peripherally circulating anti-HER2 T cell response at week 6 following IP and improved radiologic tumor responses which correlates with a higher likelihood of pCR. Data from another IT DC1 trial suggests decreased circulating HER2 responsive T cells are due to increased trafficking of reactive T cells out of circulation into the tumor possibly leading to an enhanced anti-tumor effect. Updated results including correlative biomarkers will be presented at the meeting. Clinical trial information: NCT05325632. Research Sponsor: Moffitt Cancer Center Breast Research Funding.

Association between pCR, TILs, and Ki-67 at baseline and after 2 weeks in patients with triple-negative breast cancer (TNBC) treated with atezolizumab and chemotherapy +/- a preceding atezolizumab monotherapy window: A translational analysis of the neoMono trial. *First Author: Ramona Erber, Institute of Pathology, Universitätsklinikum Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, Comprehensive Cancer Center Erlangen-EMN (CCC ER-EMN), Erlangen, Germany*

Background: neoMono randomized patients (pts) with triple negative breast cancer (TNBC) to receive (Arm A) or not to receive (Arm B) 2-week Atezolizumab monotherapy prior to neoadjuvant 24-week Atezolizumab + chemotherapy. In prespecified interim analysis, no difference regarding pathological complete response (pCR) was observed among all pts. However, in regard to pCR rates, pts with PD-L1 positive TNBC seem to benefit from addition of the monotherapy window. Here we analyze the association between central TILs and Ki-67 at baseline (BL) / after 2 weeks (2w) and pCR. **Methods:** Ki-67 expression (% positive tumor cells) was analyzed using immunohistochemistry. Analysis of stromal TILs was performed according to the International TILs Working Group. Differences from BL at the 2w time point were denoted as Ki-67-diff and TIL-diff, respectively. Associations between pCR and BL/2w measurements were analyzed using logistic regression. Akaike information criterion (AIC) was used to evaluate goodness-of-fit between models. Since the a priori chosen biomarker thresholds (< 30% [Ki-67] and < 60% [TILs]) resulted in very low subgroup sizes, k-means clustering analysis was performed and association of the cluster labels with pCR was then investigated. **Results:** The analysis included 50 (Arm A) and 51 (Arm B) pts. The threshold of Ki-67 (< 30%) was reached in 98% (BL) and 92% (2w), that of TILs (< 60%) in 11% (BL) and 18% (2w), respectively. PD-L1 (BL) was < 1 in 26%. In separate logistic regression models (including BL and change), both BL-Ki-67 and BL-TILs were significantly though moderately associated with pCR. A combined model using both biomarkers yielded the best AIC. BL-Ki-67 and BL-TILs, as well as TIL-diff were highly significantly though again moderately associated with pCR. Cluster analysis I (using BL-Ki-67, Ki-67-diff, and PD-L1) yielded cluster 1 (medium BL-Ki-67 and subsequent increase) with a pCR rate of 50% compared to 77% in cluster 2 (high BL-Ki-67 and decreasing Ki-67). Similarly, cluster analysis II (using BL-TILs, TILs-diff and PD-L1) yielded cluster 3 (low BL-TILs/non-essential TILs change) with a low pCR rate of 55% compared to 84.4% and 85.7% for clusters 4 (low BL-TILs/substantial increase) and 5 (high BL-TILs/non-essential change), respectively. In a combined regression model of all clusters above, clusters 2 and 4 had the highest pCR probability. **Conclusions:** Our results demonstrate that while BL-Ki-67 and BL-TILs are highly informative of pCR probability, Ki-67-diff and even more so TIL-diff added further significant information. Analysis of the full neoMono dataset will allow us to investigate this association further and to potentially develop a predictive algorithm regarding pCR based on baseline and dynamic biomarkers. Poster Session

Artificial intelligence (AI) –based machine learning models (ML) for predicting pathological complete response (pCR) in patients with hormone receptor (HoR) –positive/HER2-negative early breast cancer (EBC) undergoing neoadjuvant chemotherapy (NCT): A retrospective cohort study. *First Author: Luca Mastrantonio, Medical Oncology, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli-IRCCS, Università Cattolica del Sacro Cuore, Roma, Italy*

Background: The rates of pCR after NCT in HoR positive/HER2 negative EBC are low. Thus, clinicians need validated, unbiased, and reliable tools to better predict pCR at individual patients' level. In this regard, AI can generate ML algorithms with these features, using clinical and pathological characteristics. **Methods:** Medical records were retrospectively retrieved for patients with EBC receiving NCT followed by surgery. Missing data were imputed using chained random forests. pCR was defined as absence of residual invasive cancer on pathological evaluation of the breast specimen and lymph nodes (ypT0/isN0). Differences between pCR and non-pCR patients were assessed using t test or chi-squared test. Eight ML models (c5.0, k-nearest neighbour, random forest [RF], neural network, support vector machine [linear/radial], boosted trees and boosted logistic regression) were trained and tuned. A stratified ten-fold cross-validation was used to prevent overfitting. Models performance was evaluated using the area under the receiver operating characteristics curve (AUC). Features importance was assessed. Disease-free survival (DFS) was evaluated using the Kaplan-Meier method and hazard ratios (HRs) using Cox regression. **Results:** 572 patients were included: 332 (58%) were pre-menopausal and median age was 49.0 (IQR 43–57); 330 (58%) were T2 and 273 (48%) were N1; 437 (76%) had a ductal adenocarcinoma and 308 (54%) were grade 3. Median estrogen and progesterone receptor (ER/PgR) expression was 90 (IQR 80–90) and 57.5 (IQR 5–90); median Ki67 was 35 (IQR 25–55) and 230 (40%) patients were HER2 zero. 565 (99%) patients received a combination of anthracyclines and taxanes; 434 (76%) received sequential and 137 (24%) concomitant CT. pCR was achieved in 87 patients (15%, 95% CI 12–18). Ten variables were included in the model: menopausal status, age, histology, grade, clinical T and N stage, ER/PgR status, Ki67 and HER2 status (zero/low). Among the evaluated models, the RF algorithm had the best performance: the AUC was 0.77 (95% CI 0.71–0.83) and sensitivity and specificity were 0.86 (95% CI 0.82–0.88) and 0.56 (95% CI 0.46–0.66). Variables with the highest importance were Ki67, ER/PgR status, age and nodal status. 511 patients were evaluable for survival: patients with pCR had a significant longer DFS compared to those who did not achieve pCR (HR 0.30; 95% CI 0.14–0.65, p = 0.002). Patients whose pCR was predicted by the model had longer DFS compared to those who pCR was not predicted (HR 0.56, 95% CI 0.21–0.87, p = 0.01). **Conclusions:** The RF-ML algorithm combining clinical and pathological characteristics has the potential to predict pCR in HoR positive/HER2 negative patients undergoing NCT, thus supporting clinicians to individualize treatment for EBC. Poster Session

Association between genomic alterations and response of triple-negative breast cancers (TNBC) to talimogene laherparepvec (TVEC) in combination with neoadjuvant chemotherapy (NACT). *First Author: Hatem Hussein Soliman, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: TVEC is an engineered oncolytic virus (OVs) approved for the treatment of melanoma. We published a phase 1/2 trial combining TVEC with NACT in early stage TNBC demonstrating increased pathologic complete response (pCR) compared to expected rates with NACT. RNAseq was performed on 37 pretreatment samples from enrolled patients to identify potential predictive genomic alterations. **Methods:** Transcriptomic RNA sequencing analysis was performed on macrodissected tumor tissue through the Moffitt Molecular Genomics core using Illumina Truseq RNA exome kits. Read adapters were detected using BBMerge (v37.88) and removed with cutadapt (v1.8.1). For gene expression analysis, processed raw reads were aligned to human genome HG19 using STAR (v2.5.3a). Gene expression was evaluated as read count at gene level with HTSeq (v0.6.1) and Gencode gene model v19. Gene expression data were normalized and differential expression between experimental groups were evaluated using DESeq2 (v1.38.2). Ensembl was used for SNP data search. **Results:** Tumor mutation burden was not significantly different between pCR and non-pCR samples (median 227 vs 222 mut/MB, $p = .11$). Top 5 upregulated non-immunoglobulin genes associated with pCR in baseline samples were MYBL1, DNAH8, NR2E1, FGFR2, and SLC12A1 ($FDR < 1\%$). A single nucleotide polymorphism (SNP) of the EIF2A gene (c.C290G, p.T97S) was the top variant associated with response present in 21/37 samples (non-pCR = 17/21 vs. pCR = 4/21, $FDR = < 1\%$). This exon 4 coding region SNP is present in 17% of Black, 35% of White, and 46% of Asian individuals but its biologic or clinical significance is unknown. Lower EIF2A pathway activation was associated with inferior response to therapy. Additional data will be presented at the meeting. **Conclusions:** Genomic alterations including a EIF2A SNP were correlated with response to OV plus NAC in TNBC. EIF2A is an important mediator of cellular responses to OV and may play a role in susceptibility to oncolysis. Additional investigation and validation of these variations in experimental models of OV susceptibility may provide predictive biomarkers for TNBC patients treated with OV plus NAC therapy. Clinical trial information: NCT02779855. Research Sponsor: Amgen.

Association of HER2/CEP17 ratio with pCR after HER2-directed neoadjuvant treatments in the phase III NeoALTTO trial. *First Author: Christian F. Singer, Klinische Abteilung für Allgemeine Gynäkologie und Gynäkologische Onkologie, Comprehensive Cancer Center - Universitätsklinik für Frauenheilkunde Medizinische Universität Wien / AKH, Wien, Vienna, Austria*

Background: HER2-directed therapies are approved for the treatment of patients with HER2-positive invasive breast cancer as defined by HER2 protein overexpression, or HER2 gene amplification based on HER2/chromosome enumeration probe (CEP17) ratio ≥ 2.2 . Above this accepted HER2 status determination, however, it is still unknown whether the efficacy of HER2-directed therapy in early breast cancer increases with increasing HER2/CEP17 ratios. Therefore, the purpose of the presented work is to evaluate whether quantitative assessment of the HER2/CEP17 ratio predicts pathological complete response (pCR) and event-free survival (EFS) of patients treated with neo-adjuvant HER2-based regimen in the prospective phase III NeoALTTO trial. **Methods:** 455 women with HER2-positive early breast cancer, who had received neo-adjuvant trastuzumab and/or lapatinib for 6 weeks and then together with 12 cycles of weekly paclitaxel were included in this analysis. The HER2/CEP17 ratio in the primary tumor samples was correlated with pCR and survival outcome. **Results:** The Median HER2/CEP17 ratio in NeoALTTO was 5.1 (range: 1.1 – 100.0), and ratios were not associated with age, hormone receptor status, or any of the other clinicopathological variables analyzed. The log HER2/CEP17 ratio significantly predicted for pCR in both uni-variate (OR: 1.83; 95% CI: 1.11 - 3.01, $p = 0.0176$) and multivariate analysis (OR: 1.79; 95% CI: 1.07 - 2.99, $p = 0.0257$). Higher HER2/CEP17 ratios were, however, not associated with improved EFS (adjusted HR = 0.79; $p = 0.3537$). A pCR prediction model which included HER2/CEP17 ratio, treatment arm, and hormone receptor status improved the predictive strength of treatment arm alone from a ROC AUC value of 0.60 to 0.69. **Conclusions:** In patients treated with HER2-based neoadjuvant therapy, quantitative analysis of the readily available pre-treatment HER2/CEP17 ratio by FISH is predictive of pCR but not EFS. Research Sponsor: The NeoALTTO trial received financial support from GlaxoSmithKline (until January 2015) and Novartis Pharma AG (as of January 2015).

Longitudinal MRI-based fusion novel model to predict pathological complete response in breast cancer treated with neoadjuvant chemotherapy: A multi-center, retrospective study. *First Author: Kun Wang, Department of Breast Cancer, Cancer Center, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China*

Background: Accurate identification of pCR to neoadjuvant chemotherapy (NAC) is important for determining appropriate surgery strategy and guiding the resection extent in breast cancer. However, a non-invasive tool to predict pCR accurately is lacking. Our study aims to develop ensemble learning models using longitudinal multiparametric MRI to predict pCR for each molecular subtype of breast cancer. **Methods:** In this study, all patients underwent pre-NAC and post-NAC MRI examinations, and we collected multiparametric MRI sequences. Post-operation pathologic results were used to determine the pathologic complete response (pCR). We extracted 14676 radiomics and 4096 deep learning features and calculated a set of additional delta-value features. Then in the primary cohort ($n = 409$), inter-class correlation coefficient test, U-test, Boruta and the least absolute shrinkage and selection operator (LASSO) regression were used to select the most optimal feature set for each subtype of breast cancer. Finally, 20, 15 and 13 features were selected to construct the models based on 5 specific algorithms with cross-validation method for predicting pCR in HR+/HER2-, HER2+ and TNBC subtypes. The ensemble learning strategy was used to integrate the single-modality models outputs and improve the prediction performance. The diagnostic performances of models were evaluated in the three external cohorts with larger sample size of patients ($n = 343, 170$ and 340 , respectively). **Results:** A total of 1262 patients with breast cancer from four centers were enrolled in this study, and pCR rates were 10.6% (52/491), 54.3% (323/595) and 37.5% (66/176) in HR+/HER2-, HER2+ and TNBC subtype. After model development, the Multi-Layer Perception (MLP) neural network yields the best diagnostic performances in all subtypes and feature sets. In the three subtypes, the stacking model integrating pre-, post- and delta- models yielded the highest AUCs of 0.959, 0.974 and 0.958 in the primary cohort, and AUCs of 0.882-0.908, 0.896-0.929 and 0.837-0.901 in the three external validation cohorts, respectively. In all subtypes, the stacking model had accuracies of 85.0%-88.9%, sensitivities of 80.0%-86.3%, and specificities of 87.4%-91.5% in the external validation cohorts. **Conclusions:** Our study established a novel tool to predict the responses of breast cancer to NAC and achieve excellent performance. The models could help to determine post-NAC surgery strategy for patients with breast cancer. Research Sponsor: National Science Foundation of China (82171898).

Circulating tumor DNA (ctDNA) monitoring in patients with breast cancer receiving neoadjuvant palbociclib and endocrine therapy: A secondary analysis of the NeoRHEA phase 2 study. *First Author: Alexandra Stanciu, Institut Jules Bordet, Bruxelles, Belgium*

Background: Personalized circulating tumor DNA (ctDNA) assays are being evaluated in early breast cancer (BC). We investigated the value of ctDNA monitoring in the NeoRHEA study. **Methods:** NeoRhea (NCT03065621) is a single arm phase 2 study in which patients with estrogen receptor (ER)+/HER2- early breast cancer were treated with neoadjuvant palbociclib + endocrine therapy (ET) for 4 months. Plasma samples were collected at four timepoints: pre-treatment (BL), after the first treatment cycle (C1D28), before surgery (Surgery) and one month post Surgery (End of Study). ctDNA detection was evaluated using the personalized RaDaR assay. Whole-exome sequencing (WES) was performed on BL tumor biopsies followed by a personalized assay development using tumor, plasma and normal DNA in order to track up to 48-patient specific somatic variants in plasma cell-free DNA (cfDNA) using next generation sequencing. Associations between ctDNA detection and BL clinical-pathological characteristics, cell cycle arrest (CCA) defined as Ki67 $\leq 2.7\%$ at surgery, residual cancer burden (RCB) rate and breast cancer free survival (BCFS) were investigated. **Results:** Of 100 patients enrolled, 78 patients and 302 plasma samples were successfully profiled by the RaDaR assay. The number of variants targeted by the assay ranged between 7-48 (median = 25). The median estimated variant allele fraction for ctDNA positive samples was 0.02% (range 0.0009%-0.91%). A total of 42/76 patients were ctDNA positive at BL, 4/76 at C1D28, 4/75 at Surgery and 0/75 at End of Study. Out of 78 patients, 68% were postmenopausal, 78 % had cT2 and 69% cN0 tumors, 20% had multifocal/multicentric tumors, 18% had histological grade 3 tumors, 76% had CCA (Ki67 not available in 20 patients) and 34% RCB 3 at surgery. ctDNA detection at BL was higher in histological grade 3 tumors ($p = 0.03$), lower in multifocal/multicentric tumors ($p = 0.01$), higher in RCB III tumors, ($p = 0.01$) but was not associated with CCA. With a median follow-up of 3.8 years (range 1-5 years), 4 patients developed distant and one patient locoregional recurrences. ctDNA detection after one month of treatment (logrank $p = 0.02$), but not at baseline ($p = 0.59$) nor at surgery ($p = 0.67$) was associated with worse BCFS. **Conclusions:** Detection of ctDNA in early-stage breast cancer is challenging. Our data suggests association of ctDNA detection with some pathological and clinical variables. Independent validation is needed. Clinical trial information: NCT03065621. Neoadjuvant tislelizumab plus nab-paclitaxel and carboplatin followed by adjuvant tislelizumab in patients with early triple-negative breast cancer. *First Author: Zefei Jiang, Department of Breast Oncology, The Fifth Medical Center of Chinese PLA General Hospital, Beijing, China*

Background: Triple-negative breast cancer (TNBC) is the subtype with the least favorable outcomes. However, TNBC is associated with higher immune cell abundance than other subtypes, making it a good candidate for immunotherapy. Neoadjuvant chemotherapy is the preferred treatment approach for early TNBC. Emerging evidence shows that additional immune checkpoint inhibitors (ICI) in neoadjuvant therapy significantly increases pathological complete response (pCR) and event-free survival in early TNBC. Treatment regimens of paclitaxel and carboplatin (TP) is class I recommendation for TNBC neoadjuvant therapy, the application of ICI with TP regimens is worth exploring. **Methods:** In this multicenter, open-label, phase II study, patients with untreated, histologically confirmed TNBC in stage II-III (per AJCC 8th edition) were enrolled. Patients received six cycles of neoadjuvant therapy with tislelizumab at 200 mg once every 3 weeks plus nab-paclitaxel (125 mg/m² on days 1 and 8) and carboplatin (at a dose based on an area under the concentration 2 on days 1 and 8) every 3 weeks. Patients who either completed or discontinued the neoadjuvant treatment would undergo definitive surgery. After surgery, the patients received adjuvant tislelizumab every 3 weeks for up to 12 cycles. The primary endpoint was the rate of pCR (ypT0/Tis ypN0). The secondary endpoints included 1-, 2-, 3-year event free survival rates and overall survival rates. Based on the Simon's Two-Stage design, if > 13 of 32 patients achieved pCR, the enrollment would proceed to full accrual of 62 patients as planned. If > 29 of 62 patients achieved pCR, we would deem the study to have met the primary endpoint. **Results:** From Mar 2021 to Jan 2022, 32 patients were enrolled; 18 of them achieved pCR, and therefore the study proceeded to complete the enrollment of 62 patients. At the data cut-off of Oct 13, 2022, 62 patients were enrolled, among which 50 patients received neoadjuvant treatment and underwent definitive surgery. The median age was 50 years. 36 (72.0%) patients had stage II breast cancer at diagnosis. 31 of the 50 patients achieved pCR (ypT0/Tis ypN0), and the pCR rate was 62.0% (95% CI, 47.2-75.4). Patients with immune cell PD-L1 expression ≥ 10% had numerically higher pCR rate (81.8% vs 53.6%) than those with PD-L1 expression < 10%. All 50 (100%) patients reported any grade of neoadjuvant treatment-related adverse events (TRAEs). Grade ≥ 3 TRAEs occurred in 27 (54%) patients. The rate of immune-related adverse events (irAEs) was 34% (17/50), with the common occurring (10%) irAE of hypothyroidism (n = 8, 16%). 2 (4.9%) patients experienced grade ≥ 3 irAEs. Severe adverse events were reported in 5 (10%) patients. **Conclusions:** The study has met its primary endpoint. Tislelizumab plus nab-paclitaxel and carboplatin achieved a higher pCR and was generally well tolerated in the neoadjuvant treatment of early TNBC. Clinical trial information: ChiCTR2100041675. Research Sponsor: This study was supported by BeiGene (Beijing) Co., Ltd.

NeolRX trial: Immunologic induction with peri-lymphatic cytokines to enhance pembrolizumab (pembro) response in stage II/III triple-negative breast cancer (TNBC). *First Author: David B. Page, Providence Cancer Institute, Portland, OR*

Background: The addition of pembro to neoadjuvant chemotherapy (NACT) improves pathological complete response (pCR) rate and recurrence-free survival in stage II/III TNBC, albeit with substantial chemotherapy-attributed toxicity. We hypothesize that locoregional cytokine therapy could be combined with pembro to optimize immune response and clinical outcome. In a phase Ib early-stage breast cancer trial, we previously demonstrated that peri-lymphatic cytokine injection (IRX-2 regimen, comprised of physiologic doses of IL-2, IFN γ , and other cytokines derived from activated donor lymphocytes, given with low-dose cyclophosphamide) is well tolerated and associated with increased intratumoral lymphocytes, T-cell activation, and PD-L1 expression. Here, we report preliminary outcomes of neolRX, a phase II trial evaluating induction IRX-2 + pembro preceding NACT + pembro. **Methods:** Subjects with stage II/III TNBC were randomized to receive induction pembrolizumab (all subjects: 200mg IV) +/- peri-areolar IRX-2 (IRX-2 arm: 1 ml SQ x2 daily for 10 days + cyclophosphamide 300 mg/m² IV x 1) preceding initiation of NACT + pembro. The primary endpoint was pCR rate following NACT + pembro (n = 15 subjects/arm planned); secondary endpoints were safety and tolerability. We explored post-induction/pre-NACT radiographic (ultrasound) and histologic outcomes (TILs, tumor regression) as a biomarker strategy to predict pCR. **Results:** The trial terminated after n = 12 subjects due to withdrawal of drug support for IRX-2. The IRX-2 arm achieved 83% pCR (n = 5/6, CI 36-100%) compared to 33% pCR with pembro alone (n = 2/6, CI 4-78%). The regimen was well-tolerated with minimal IRX-2-attributed toxicities (67% grade I skin bruise). Toxicities during NACT + pembro were similar to Keynote-522. 67% (n = 4/6) of IRX-2 subjects experienced week 3 radiographic regression, with evidence of brisk lymphocyte infiltration on week 3 biopsy, and with 100% pCR rate (n = 4/4) following NACT + pembro. n = 2/6 subjects receiving pembro+IRX-2 experienced pCR on week 3 biopsy, versus n = 0/3 evaluable in control arm. **Conclusions:** Induction IRX-2 + pembro is well tolerated and is associated with encouraging outcomes, supporting further study of peri-lymphatic induction cytokine therapy in stage II/III TNBC. Post-induction radiographic and histologic outcomes may identify patients with immune-responsive tumors, for whom NACT de-escalation may be a promising therapeutic approach to mitigate toxicity. Clinical trial information: NCT04373031. Research Sponsor: Merck Sharp & Dohme LLC, a subsidiary of Merck & Co., Inc.; Brooklyn Immunotherapeutics.

Neoadjuvant single-dose trilaciclib prior to combination chemotherapy in patients with early triple-negative breast cancer: Safety, efficacy, and immune correlate data from a phase 2 study. *First Author: Jeremy Meyer Force, Department of Medicine, Duke University, Durham, NC*

Background: Trilaciclib, an intravenous CDK4/6 inhibitor, induces transient G1 cell cycle arrest. In preclinical studies, trilaciclib demonstrated immune-modulating effects by enhancing T-cell activation, favorably altering the tumor microenvironment (TME), and improving long-term immune surveillance. Preliminary data from this phase 2, single-arm, open-label study of neoadjuvant trilaciclib in triple-negative breast cancer (TNBC; NCT05112536) showed that single-dose trilaciclib increased CD8+ T-cell/Treg ratios within the TME. Here, we combine immune analysis with clinical outcomes to identify correlates of treatment response. **Methods:** Patients (pts) with early-stage TNBC received single-dose trilaciclib followed by trilaciclib + dose-dense anthracycline/cyclophosphamide and taxane (AC/T). Per investigator discretion, pts received pembrolizumab (pembro) 400 mg Q6W from cycle 1 and/or carboplatin (carbo) AUC 1.5 QW from cycle 5. Tumor biopsies and blood samples were collected prior to treatment, 7 days post single-dose trilaciclib, and during surgery, with an additional blood sample at cycle 2. PD-L1 status was assessed per Ventana SP142 assay (positive immune cell score ≥ 1%). The primary objective is to evaluate the immune-based mechanism of action of single-dose trilaciclib. **Results:** As of January 3, 2023, 18/24 pts had completed treatment and/or had definitive surgery; 1 pt with neuroendocrine features discontinued due to disease progression. Median age was 57 years. At diagnosis, 79% of pts had stage II tumors (88% with ductal carcinoma; 38% with PD-L1+ tumors). 18 pts received pembro + carbo, 3 pts pembro only, and 3 pts carbo only. Common treatment-related adverse events (TRAEs) were fatigue (79%), nausea, (67%), alopecia (67%), and neutropenia events (63%); 42% of pts had grade 3/4 neutropenia events. 4 serious TRAEs occurred in 2 (8%) pts: pembro-related colitis and hypertransaminasemia, trilaciclib/paclitaxel-related urosepsis, and AC-related febrile neutropenia. Response data were available for 15 pts; pathological complete response (pCR) was observed in 7 (47%) pts, with pCR rates of 86% vs 13% for pts with PD-L1+ vs PD-L1- tumors, respectively. Immune analysis of the TME post trilaciclib monotherapy demonstrated several pCR-related features, such as increased stromal tumor-infiltrating lymphocytes and granzyme B+ cells. Correlative blood analysis revealed increased circulating baseline CD8+ T cells in pts achieving pCR. **Conclusions:** Safety and tolerability data are encouraging for trilaciclib in combination with AC/T ± pembrolizumab ± carboplatin in the neoadjuvant setting for early-stage TNBC. Preliminary efficacy data align with standard neoadjuvant chemotherapy regimens. Final pCR data from all pts and immune correlates from tumor and blood samples will be presented. Clinical trial information: NCT05112536. Research Sponsor: G1 Therapeutics, Inc.

Moderate physical exercise and immune system modulation in patients with breast cancer treated with neoadjuvant chemotherapy. *First Author: Ornella Garrone, Medical Oncology Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy*

Background: The link between physical activity (PA) and immune system is known. However, are not clearly understood which mechanisms are activated by PA. We investigated the effect of moderate PA (MPA), on a panel of circulating cytokines during neoadjuvant chemotherapy (CT) in patients (pts) with breast cancer. **Methods:** Pts received sequential epirubicin and cyclophosphamide for 4 cycles followed by weekly paclitaxel ± trastuzumab. MPA consisted of Nordic or fit walking, 3 workouts/week, 1 hour each, in the 9 weeks before Surgery (S). Blood samples were collected in pts underwent MPA (TR) and in a group of pts who declined MPA (UN) at baseline (T0), at day 1 of week 6 of paclitaxel (starting MPA) (T1) and before S (T2). At each time point the level of 22 cytokines (IL1b, IL2, IL4, IL5, IL6, IL7, IL8, IL10, IL12, IL13, IL15, IL17a, IL18, IL21, CCL2, CCL4, CXCL10, CCL22, IFN γ , TGF β , TNF α , VEGF) was measured using Simple Plex Ella. Sample size was calculated using effect size method considering a Cohen's d of 0.65 as observed for a candidate cytokine (IL-6) between two groups. Considering a desired statistical power of 0.8 and a probability level of 0.05 a minimum of 78 patients were required. The difference among the median value of cytokines was analysed using non parametric Mann Whitney U test. Comparisons between time points in the same group were analysed with Wilcoxon signed-rank test. **Results:** Accrual is completed. 61 pts were TR and 20 UN. Main patients' characteristics are listed. At T0 IL4, IL17, IL18 and VEGF level was significantly higher in UN respect to TR pts. At T1 IL4, IL17 and IL18 level remained significantly higher in UN pts. At T2, UN pts showed significantly higher value of IL4, IL6, IL7, IL8, IL17, IL18 VEGF and TGF β . IL21 was significantly higher in TR pts. Longitudinal analysis between T0 and T1 in TR and UN pts showed significantly lower level of CCL22 and significantly higher level of IL7, IL13 and CXCL10 in TR pts and significantly higher level of IL8 in UN pts. Longitudinal analysis between T1 and T2 showed significantly higher level of IL21, CXCL10, CCL22, TNF α and significantly lower level of IFN γ , IL6, IL8, CCL2, TGF β in TR pts and significantly lower level of CXCL10 in UN pts. **Conclusions:** TR and UN pts differed modestly at baseline including acceptance of MPA. The longitudinal analysis T0-T1 showed that CT induced more evident changes in TR than in UN pts. Longitudinal analysis T1-T2 demonstrated major changes in Th1 and Th2 cytokines only in TR pts. Overall, CT induced weak changes in UN and greater changes in TR pts strengthened by the addition of MPA. These observations suggest a more efficient immune system in TR pts and a possible additional benefit derived from MPA. Research Sponsor: GONO Foundation; ARCO Foundation.

Prospective evaluation of pathologic response with neoadjuvant chemo-immunotherapy in metaplastic breast cancer. *First Author: Nour Abuha-dra, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Metaplastic breast cancer (MpBC) is a rare aggressive histologic type of breast cancer that is often resistant to standard chemotherapy with pathologic complete response (pCR) rates ranging between 2-23%. PDL1 expression has been reported in up to 95% of primary MpBCs suggesting that response rates may be improved with addition of immune checkpoint blockade (ICB). Here we evaluate pCR rates (ypT0/is ypN0) in stage I-III MpBCs receiving neoadjuvant chemo-immunotherapy (NAT). **Methods:** The Memorial Sloan Kettering Cancer Center Rare Breast Cancer Program (CARE-4-RARE) is a new clinical and translational program dedicated to the study of rare breast cancers. Since the start of the program, 15 patients (pts) with early-stage MpBC have completed treatment with the neo-adjuvant KEYNOTE-522 regimen. Wilcoxon rank-sum and Fisher's exact tests were used to compare characteristics according to pCR status. All statistical tests used a significance level of 5%. **Results:** Median age at diagnosis was 50 (range, 43-60). All pts were female, 13% self-identified as Asians, 33% as Black and 53% as White. All tumors were poorly differentiated and of triple-negative phenotype, median tumor size was 3.2cm, 80% had stage II disease and 20% were clinically node positive. Metaplastic subtypes included 5 matrix-producing (33%), 3 spindle (20%), 4 squamous (27%), 3 mixed (20%). Of the 15 pts, 4 (27%) achieved a pCR, which suggest the possibility of a higher than expected pCR rate in MpBC with the addition of ICB to chemotherapy. We did not observe a significant difference in clinico-pathological features between pCR vs. non-pCR groups. We observed numerical differences in pCR between MpBC subtypes though the p-value was not significant due to limited sample size. Of these 4 pts, 2 had matrix-producing and 2 had mixed subtypes. Two pts with pCR only received Cb+P+Pem. Three pts (20%) experienced PD (squamous n = 2, spindle n = 1) necessitating discontinuation of NAT and expediting surgery. **Conclusions:** This is the first prospective study to evaluate neoadjuvant ICB in MpBC. These data suggest the possibility of a higher than expected pCR rate in MpBC with the addition of ICB to chemotherapy (27%). This work suggests that neoadjuvant ICB should be considered in MpBC with close monitoring. Notably, 50% of reported pCR in this cohort were in pts who only received Cb+P+Pem. In spite of improved pCR rates, 20% of pts progressed during NAT highlighting the need for better treatment strategies in this treatment-refractory subset of MpBC and close monitoring to allow resection before progression to inoperability. The dichotomy in responses to ICB (super-responsive vs. super-refractory) may suggest the presence of unique biomarkers for immune response in MpBC. By the 2023 ASCO Annual Meeting a total of 26 pts will have completed NAT; we will report updated outcomes along with correlative immune biomarkers (sTIL, PDL1, TMB). Research Sponsor: None.

Poster Session

Association of biophysics-based biomarker with tumor volumetric response in breast cancer treated with immunotherapy. *First Author: Daniel Cook, SimBioSys, Inc., Chicago, IL*

Background: The treatment landscape of triple negative breast cancer (TNBC) has rapidly changed in recent years, with immuno-oncology (IO) therapies, such as immune checkpoint inhibitors, leading to improvement in patient outcomes. However, the number of patients who benefit is less than 15%, and the therapy itself can prompt severe immune-related adverse events. Breast cancer tumor volume measurements derived from magnetic resonance imaging (MRI) have proven to be a strong predictor of outcome (survival) in patients who either achieve pathological complete response (pCR) or have residual cancer burden (RCB) (ACRIN6657/CALGB150007 I-SPY1). Using an integrative computational approach, we developed both the *TumorIO* biomarker and the *TumorIO Score* to predict response to IO therapy in breast cancer patients. Here, we assess the volumetric response in IO-treated patients and its relationship with the *TumorIO Score*. **Methods:** We assessed the relationship between breast tumor volumetric response to IO therapy and the *TumorIO Score*, a previously developed metric that relates probability of IO responsiveness to spatially-resolved tumor biology. We grouped patients into *TumorIO Score* high vs. low populations, and compared final volumes assessed by MRI and percent response to therapy between groups. **Results:** We analyzed the volumetric response of IO-treated patients from the I-SPY2 trial and from an independent cohort (total n = 67). Over 96% of the IO-treated patients in the I-SPY2 trial (n = 55) had a greater than 90% volumetric response, while in the independent cohort (n = 12) only 50% of patients had greater than 90% volumetric response. Across both cohorts, 95.8% of patients with a high *TumorIO Score* achieved > 90% reduction in tumor volume. Additionally, we identified three patients in our cohort that appeared not to respond to IO therapy, who were later classified as progressor, pseudo-progressor, and non-responder patients. The *TumorIO* biomarker was able to differentiate these three patients, as it associates a unique distinctive biological phenomenon with either response or lack of response. **Conclusions:** The *TumorIO Score* provides a novel technology to address several challenges in neoadjuvant IO therapy, namely: predicting which patients are likely to have pCR in response to IO therapy, as well as identifying patients likely to have a substantial volumetric response to IO. Additionally, this method may facilitate sub-categorizing patients likely to show radiological pseudo-progression prior to IO administration, although a larger cohort is needed to validate these findings. Poster Session

A prospective, phase II, neoadjuvant clinical study based on chemotherapy sensitivity in hormone receptor-positive, HER2-negative breast cancer: FINEST study. *First Author: Li Chen, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Neoadjuvant therapy for hormone receptor positive/HER2-negative breast cancer presents challenges in patient selection and treatment modalities. Chemotherapy and endocrine therapy are neoadjuvant options for this type of breast cancer. Neoadjuvant endocrine therapy (NET) has a similar response rate to chemotherapy. However, patient selection is a key factor. We designed this study to further optimize the selection of target population and treatment strategy. **Methods:** For breast cancer patients eligible for inclusion, patients were allocated to 2 cycles of chemotherapy using nab-paclitaxel with carboplatin. For patients with better efficacy ($\geq 40\%$ regression after 2 cycles), the original regimen was continued to complete 6 cycles (group A). For patients who had poor efficacy ($< 40\%$ regression after 2 cycles), patients were randomly assigned (1:3:1) to group B, C, D. Group B continued to use the same chemotherapy. Group C were received palidiciclib, letrozole and adebrelmab plus goserelin if patient was premenopausal. Group D were directly received surgery. Primary endpoints were pathologic complete response (pCR) rate and objective response rate (ORR). As the trial progresses, according to Bayesian model, the posterior distribution of pCR rates of group C would be updated. To explore the genomic feature, a genetic panel which includes 484 genes that are targets of approved and experimental therapies and frequently mutated genes in breast cancer was used. **Results:** From Nov 16, 2020 to Jun 10, 2022, 121 patients were enrolled. 76 patients with better efficacy were continued to complete 6 cycles (group A). And 45 patients were randomly assigned to groups C (27 patients), B (9 patients) and D (9 patients). The primary objective was not met. The total pCR rate was 4.1% (5/121) with all pCR patients are in group A. No significant differences were observed in pCR between group B, C and D. ORR was 81.8% in total cohort with 100% in group A, 20% in group B, 81.5% in group C and 0% in group D, respectively. Decreases in Ki-67 were similar across arms. According to the Bayesian model, there is no probability of success of phase 3 study. Therefore, the study was closed. Our analysis illustrated the most prevalent mutations were PIK3CA (41%), followed by TP53 (28%) and GATA3 (17%). We found that AKAP3, ASXL1, INSR, RET or TBX3 mutations were related to the limited treatment benefit of chemotherapy. Mutations in MAP3K1 were likely to be associated with the worse outcome in Group C. **Conclusions:** Neoadjuvant chemotherapy and neoadjuvant endocrine therapy are not mutually exclusive. The overall treatment strategy did not improve the efficacy, but there is still a possibility that some people can get an improvement from the strategy adjustment. Precision analysis may yield the characteristics of patients who would benefit from this shift in treatment strategy. Clinical trial information: NCT04215003. Whole-genome sequencing based assessment of HER2 focal amplification for precision oncology of breast cancers. *First Author: Ryul Kim, Genome Insight Inc., San Diego, CA*

Background: Focal oncogene amplification confers a growth advantage to tumor cells and drives cancer evolution. Herein, we aimed to explore focally amplified HER2 in breast carcinomas. **Methods:** We performed whole genome sequencing (WGS) and whole-transcriptome sequencing (WTS) in 787 breast cancer samples. HER2 focal amplification was defined as having a segment length less than 3Mbp and ≥ 4 higher copy number than the surrounding region. **Results:** Most of the patients were premenopausal women (n = 574, 72.9%) with a median age of 37 (range 21-76) years. We identified 57 (58.8%) and 27 (5.0%) samples with HER2 focal amplification in HER2-positive (n = 97) and even HER2-negative (n = 536) by immunohistochemistry (IHC) and in-situ hybridization (ISH) according to ASCO guideline for breast cancer, respectively. Regardless of HER2-positivity, HER2 focal amplification was significantly associated with higher HER2 RNA expression. Among 28 patients who received six cycles of docetaxel/carboplatin/trastuzumab/pertuzumab neoadjuvant therapy followed by curative surgery, 21 patients had HER2 focal amplification and 14 (66.7%) achieved pathologic complete remission (pCR). Intriguingly, all patients without HER2 focal amplification (n = 7) failed to achieve pCR. HER2 focal amplification showed enrichment of TP53 mutations (OR 0.245, q < 0.001), but was mutually exclusive with GATA3 mutations (OR 2.82, q = 0.055). The mutational spectrums suggested that the activity in APOBEC family of cytidine deaminases were responsible for the somatic single-nucleotide variants of breast cancer with HER2 focal amplification. Compared to samples without HER2 focal amplification, samples with HER2 focal amplification were less likely to have defective homologous recombination DNA repair pathway. HER focal amplifications were closely associated with various types of structural variations. Translocation partners of HER2 were widespread across the entire genome with notable exceptions on chromosome 2, and most of them were close to super-enhancers implying enhancer hijacking as one of mechanisms of HER2 overexpression. Breast cancers with or without HER2 focal amplification showed distinct RNA expression patterns. Notably, activity of genes involved in doxorubicin-resistance and AKT1 signaling were significantly associated with HER2 focal amplification. **Conclusions:** Our analysis demonstrates that WGS enables better classification of the HER2 amplification status in breast cancer than IHC with ISH, suggesting WGS as a sensitive tool for screening breast cancers for anti-HER2-targeted therapies. Social determinants of health and utilization of neoadjuvant chemotherapy in patients with triple negative breast cancer (TNBC) in the community oncology setting. *First Author: Michael A. Danso, US Oncology Network/Virginia Oncology Associates, Norfolk and Virginia Beach, VA*

Background: TNBC has a higher incidence in African American women compared to European American, often presents at a younger age or more advanced stage, and is associated with worse outcomes. The use of multi-agent neoadjuvant chemotherapy (NC) improves event-free survival and overall survival in patients with early-stage TNBC and is considered standard of care. Race and other social determinants of health (SDOH) have been shown to affect outcomes in patients with TNBC. Differences in use of NC associated with SDOH may be a contributing factor to inferior outcomes. The aim of this study is to determine if SDOH measures affect utilization of NC in patients with early-stage TNBC. **Methods:** This retrospective observational cross-sectional study examined patient profiles, treatment patterns and SDOH indicators among patients newly diagnosed with early-stage breast cancer in The US Oncology Network. Using iKnowMed EHR data, patients diagnosed with TNBC between 03/31/2017 and 09/30/2021 with stages II-IIIb disease or tumor size ≥ 2 cm (T2 or higher) were included. The initial TNBC diagnosis date was used as the index date for each patient and records were assessed from 6 months pre- to 6 months post-diagnosis for NC initiation, baseline characteristics, and social determinants, including Area Deprivation Index (ADI), a validated measure of socioeconomic status. **Results:** 3321 patients with TNBC were identified, with a mean age of 58 years; 59% were White, 15% Black, 3% Asian, and 23% other/unknown; and 2139 (64%) received NC. Patients who received NC relative to those who did not were younger (mean 55.9 vs 61.8; $p=0.001$), had higher BMIs (70% with BMI >25 vs ≤ 25 , $p=0.045$), and had commercial or Medicaid insurance (67.5% with commercial insurance or Medicaid vs. 52.5% with Medicare; $p=0.001$). Regional differences were observed, with proportionally fewer patients receiving neoadjuvant chemotherapy in the south US census regions and more in the west. There was no difference in NC use in Black vs White patients (66% vs 64%). No significant differences in receipt of NC were found for race, ethnicity, or ADI. **Conclusions:** In the community oncology setting, we did not observe inequities in the use of NC based on social determinants analyzed in this study, such as race, ethnicity, and ADI. Poorer outcomes observed in Black patients with TNBC may not be a result of underutilization of NC. Research Sponsor: None.

Use of PROMIS to capture patient reported outcomes over time for patients on I-SPY2. *First Author: Saya Jacob, University of California San Francisco, San Francisco, CA*

Background: Patient reported outcomes (PROs) capture direct feedback from patients in clinical trials. The NIH Patient-Reported Outcomes Measurement Information System (PROMIS) is an open source and validated PRO platform. Data on PROMIS score trajectories over time for breast cancer patients undergoing neoadjuvant chemotherapy (NAC) are limited. **Methods:** We administered paper surveys to patients enrolled on the I-SPY2 trial, a multicenter, randomized phase 2 trial comparing novel agents to standard NAC in high-risk breast cancer. PRO domains included PROMIS Physical Function, Anxiety, Depression, Applied Cognition and Fatigue. Surveys were administered at baseline (post-consent), C1D1, inter-regimen (~12 wks into NAC), pre-surgery and at 1, 6, 12, and 24 months post-surgery. Responses were scored using the HealthMeasures Scoring Service to generate a standardized T score, with a score of 50 representing the general US population mean. Higher Anxiety, Depression and Fatigue scores represent worse symptoms; higher Physical Function and Applied Cognition scores represent better symptoms. We calculated average scores by time-point and compared changes from baseline to various grouped time points using a paired t-test. **Results:** From 1/2012 to 7/2020, 1631 patients enrolled in I-SPY 2 with 959 completing the baseline survey. 62% had at least two "on-treatment" surveys, and 52% had at least one follow-up time-point. Average baseline PROMIS scores for Physical Function, Anxiety, Depression, Applied Cognition and Fatigue were 46.7, 55.1, 47.2, 53.3 and 46.0 respectively. Between baseline and the latest on-treatment time point we observed improvement in Anxiety (-5.2) and worsening in Physical Function, Applied Cognition and Fatigue (-5.4, -6.9 and +8.2 respectively). Between baseline and the latest post-surgery time point, we saw improved Anxiety (-5.9) and worsened Physical Function, Applied Cognition and Fatigue (-5.9, -3.6 and +4.3). Depression changed minimally. **Conclusions:** Using PROMIS, patients on I-SPY2 experienced worse Physical Function, Applied Cognition and Fatigue but improved Anxiety during and after treatment compared to baseline. While changes in Applied Cognition and Fatigue recovered partially after treatment, Physical Function scores did not, suggesting potential for longer term impact on quality of life. Clinical trial information: NCT01042379. Research Sponsor: U.S. National Institutes of Health; Quantum Leap Healthcare Collaborative.

The proliferation biomarker SPAG5 expression in HER2 low and HER2 overexpression early breast cancer (BC) predicting tumour response to neoadjuvant chemotherapy (NACT) with and without trastuzumab. *First Author: Tarek Mohamed Ahmed Abdel-Fatah, Nottingham Univ City Hosp NHS Trust, Nottingham, United Kingdom*

Background: HER2 low is defined by HER2 immunohistochemistry (IHC) score 1+ or 2+ with negative fluorescent in situ hybridization (FISH-). In metastatic BC the HER2 directing antibody drug conjugates (ADCs) had shown significant efficacy; however, its curative role in early BC has not defined yet. Here we aimed to study the clinical and molecular features of HER Low in 3850 cases of early BC and its response to NACT; Anthracycline/Taxane with/without Trastuzumab to optimize its clinical utility. **Methods:** Paired sections from pre and post NACT samples of 1250 early BCs (NACT cohort) were profiled for HER2 and SPAG5 using IHC and FISH. A novel triple coloured SPAG5 HER2 Ch17 probe was used as well HER2 Ch17 probe. ASCO guidelines were followed. Pre therapy samples of 400 BC were profiled for 450 customised genes using the Nano String nCounter platform. Moreover, 2600 cases of early BC who received adjuvant non-HER2 targeted therapies (ADJ cohort) were studied. The primary end point was pathological complete response (pCR). The Secondary endpoints were relapse free survival and biomarkers changes. **Results:** HER2 low was expressed in 31% (800/2600) of ADJ and 39% (490/1250) of NACT cohorts whereas HER2 overexpression (+) (HER2 IHC+3 or IHC+2/FISH+) was detected in 21% (540/2600) and 32% (401/1250) of ADJ and NACT cohorts; respectively. Compared to those with HER2 IHC 0 expression, HER2 low was associated with more aggressive features: ER-, PR-, Ki67+, SPAG5+, high grade, and p53 mutation and enriched in ERBB2 and its related genes EGFR, ERBB4, GRB7, SPAG5 and FGFR4; $p < 0.0001$. After NACT, HER2 low had the lowest pCR rate (16%; 57/348) compared to HER2 IHC+3 (54%; 120/223), HER2 IHC+2/FISH+ (23%; 14/60) and HER2 IHC 0 (25% (66/264); $p < 0.0001$. Compared to either HER2+ or HER2 IHC 0 cases; HER2 low had higher risk of 5 relapse [(HR (95% CI) = 2.04 (3.05-1.36); $p = 0.001$) and (HR (95% CI) = 1.45 (1.001-2.09); $p = 0.05$); respectively] after NACT. SPAG5 overexpression (+) determined the response for NACT. None of HER2 IHC +2 with negative SPAG5 (-) expression (0/170) either with FISH+ (0/112) or FISH- (0/58) achieved pCR whereas 47% (31/66) of those of HER IHC+2 with SPAG5+ achieved pCR after NACT ($p < 0.0001$). Similarly 73% (78/107) of HER2 IHC+3 with SPAG5+ achieved pCR after NACT+ Trastuzumab compared to 11% (10/95) of those with SPAG5-; $p < 0.0001$. Changes of HER2 expression after NACT was common (50%); 31% (106/348) of the resituate HER2 low tumours were HER2 IHC 0 and 7% were HER2+. Meanwhile 28% (17/60) of HER2 IHC+2/FISH+, 7% (15/223) of HER2 IHC+3 and 14% of HER2 IHC 0 changed into HER2 low. **Conclusions:** HER2 low is common in early BC and is associated with resistance to the anthracycline/Taxane NACT. Significant change of HER2 expression in the residual tumour is common after NACT. SPAG5 expression could help to optimize the use of NACT and ADCs in early BC. LESS: Single-arm study to de-escalate adjuvant endocrine therapy duration in post-menopausal women with HR+ HER2- early-stage breast cancer at very low risk of metastasis. *First Author: Elise Deluche, Centre Hospitalier Universitaire, Limoges, France*

Background: Adjuvant Endocrine Therapy (ET) is the cornerstone treatment of localized hormone-receptor positive (HR+) breast cancer, with demonstrated benefits on overall survival (30-40% relative decrease in mortality) but also on the risk of local and contralateral relapse (43-50% relative decrease). While the relative benefit of 5 years of ET is identical for small tumors as compared to larger ones, the absolute benefit is much lower, and the risk-benefit ratio becomes questionable given the frequent and impactful side effects of ET which are associated with non-adherence. If recent trials tested longer durations as compared to 5 years for high-risk cancers, older trials have tested shorter durations. Five years appeared at that time as the gold standard because of optimal benefit-risk ratios of tamoxifen among rather high-risk patients. However, shorter treatments of 2-3 years were already associated with substantial benefits and may be enough for very low risk patients. The purpose of this study is to demonstrate that adjuvant ET limited to 2 years of aromatase inhibitor (AI) in postmenopausal women at very low risk of recurrence as determined with a MammaPrint and Blueprint Ultra Low Risk Luminal test result can ensure very high survival without metastatic relapse and allows a reduction of side effects and a better quality of life. **Methods:** LESS (NCT05297617) is a prospective, national, multicenter, single-arm, interventional, non-threshold crossing phase II study evaluating a therapeutic de-escalation that limits adjuvant ET to 2 years of AI. Approximately 696 post-menopausal patients with an invasive unilateral, HR+, HER2-negative, without indication of adjuvant chemoT and genomically-assessed MammaPrint/Blueprint UltraLow risk Luminal A breast cancer tumors, will be enrolled. LESS will include two sub cohorts: the majority of patients with Grade 2, pT1c-2, pN0/N1mic tumors, and up to 80 patients ≥ 65 years with Grade 1, pT1, pN0 and Ki67 <10% tumors. The primary endpoint is distant metastasis free survival (DMFS) defined as the time from date of registration to date of first event of distant recurrence, death, or second primary non-breast invasive cancer. Secondary endpoints include the assessment of quality of life parameters and psychological aspects related to this de-escalation. The null hypothesis (H0) that, in the study population after 2 years of adjuvant AI, DMFS at 5 years is lower or equal to 94.5% will be tested against the alternative - that it is above 94.5%. For an expected DMFS of 96.7% under the alternative hypothesis, a total of 37 DMFS events are required in order to provide approximately 85% power at a one-sided significance level of 0.05 to reject H0 using a logrank test. The 1st patient was included in October 2022, initiating the 2-year inclusion period and 10 years FU per patient. Clinical trial information: NCT05297617. Research Sponsor: Agendia.

Phase III study to evaluate the efficacy and safety of GLSI-100 (GP2 + GM-CSF) in breast cancer patients with residual disease or high-risk PCR after both neoadjuvant and postoperative adjuvant anti-HER2 therapy: Flamingo-01. *First Author: Snehal Patel, Greenwich LifeSciences, Stafford, TX*

Background: GP2 is a biologic nine amino acid peptide of the HER2/neu protein delivered in combination with Granulocyte-Macrophage Colony Stimulating Factor (GM-CSF) that stimulates an immune response targeting HER2/neu expressing cancers, the combination known as GLSI-100. In a prospective, randomized, single-blinded, placebo-controlled, multicenter Phase IIb study, no recurrences were observed in the HER2+ population after 5 years of follow-up, if the patient was treated with GLSI-100, survived, and was followed for more than 6 months ($p = 0.0338$). Immunotherapy elicited a potent response measured by skin tests and immunological assays. Of the 146 patients that have been treated with GLSI-100 over 4 clinical trials, GLSI-100 was well-tolerated and no serious adverse events observed were considered related to the immunotherapy. **Methods:** This Phase III trial is a prospective, randomized, double-blinded, multi-center study. After 1 year of trastuzumab-based therapy, 6 intradermal injections of GLSI-100 or placebo will be administered over the first 6 months and 5 subsequent boosters will be administered over the next 2.5 years for a total of 11 injections over 3 years. The participant duration of the trial will be 3 years treatment plus 1 additional year follow-up for a total of 4 years following the first year of treatment with trastuzumab-based therapy. Patients will be stratified based on residual disease status at surgery, hormone receptor status and region. Approximately 498 patients will be enrolled. To detect a hazard ratio of 0.3 in invasive breast cancer free survival (IBCFs), 28 events will be required. An interim analysis for superiority and futility will be conducted when at least 14 events have occurred. This sample size provides 80% power if the annual rate of events in placebo patients is 2.4% or greater. Up to 100 non-HLA-A*02 subjects will be enrolled in an open-label arm. The patient population is defined by these key eligibility criteria: HER2/neu positive and HLA-A*02; residual disease or High risk pCR (Stage III at presentation) post neo-adjuvant therapy; exclude stage IV; completed at least 90% of planned trastuzumab-based therapy. Trial objectives were to determine if GP2 therapy increases IBCFs, to assess the safety profile of GP2 and to monitor immunologic responses to treatment and assess relationship to efficacy and safety. The study has been initiated at a number of sites in the US. The study is also expected to be opened in Spain, Germany, and France. Clinical trial information: NCT05232916. Research Sponsor: Greenwich LifeSciences.

lidERA Breast Cancer (BC): Phase III adjuvant study of giredestrant vs. physician's choice of endocrine therapy (PCET) in patients (pts) with estrogen receptor-positive, HER2-negative early BC (ER+, HER2- eBC). *First Author: Charles Geyer, NSABP Foundation and UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Despite best management with standard ETs, $\leq 20\%$ of pts with ER+, HER2- eBC develop resistance (due to *ESR1* mutations that can drive estrogen-independent transcription and proliferation) and have high recurrence rates. New treatments are needed to reduce recurrence risk and improve survival, tolerability, quality of life, and adherence. Giredestrant, a highly potent, nonsteroidal oral selective ER antagonist and degrader, achieves robust ER occupancy and is active against ER-sensitive or *ESR1*-mutated tumors. It is more potent *in vitro* and achieves higher ER occupancy *in vivo* than fulvestrant. Early-phase studies showed that 30 mg daily as a single agent has promising clinical and pharmacodynamic activity and is well tolerated for ER+, HER2- BC. **Methods:** lidERA BC (NCT04961996) is a Phase III, global, randomized, open-label, multicenter study evaluating adjuvant giredestrant vs. PCET in ER+, HER2- eBC. Pts are randomized 1:1 to oral 30 mg daily giredestrant or PCET (tamoxifen, anastrozole, letrozole, or exemestane; per prescribing information). Stratification factors: Risk (medium vs. high, based on anatomic [tumor size, nodal status] and biologic features [grade, Ki67, gene signatures if available]); geographic region (US/Canada/Western Europe vs. Asia-Pacific vs. rest of the world); prior chemotherapy (no vs. yes); menopausal status (pre-/peri- vs. postmenopausal). Pts will be treated for ≥ 5 years. Continuing PCET > 5 years is per investigator discretion and local standard of care. Eligibility: Female/male; medium/high-risk stage I-III ER+, HER2- eBC; prior curative surgery; completion of (neo)adjuvant chemotherapy (if given) and/or surgery < 12 months before enrollment; no prior ET (≤ 12 weeks of [neo]adjuvant ET allowed). For men and pre-/perimenopausal women, an LHRH agonist will be given per local prescribing information (mandatory for the giredestrant arm). Primary endpoint: Invasive disease-free survival (IDFS, excluding second non-primary BC). Secondary endpoints: Overall survival; IDFS (STEEP definition, including second non-primary BC); disease-free survival; distant recurrence-free survival; locoregional recurrence-free interval; safety; pharmacokinetics; pt-reported outcomes. This study also aims to improve health equity in research and expand clinical trial access. It will use/develop digital healthcare solutions, enabling better understanding of pts' needs and adherence to ET. The primary endpoint analysis will use a stratified log-rank test at an overall 0.05 significance level (two-sided). Interim and futility analyses are planned; an independent data monitoring committee will be in place. 2950/4100 pts have been recruited globally. Clinical trial information: NCT04961996. Research Sponsor: F. Hoffmann-La Roche Ltd.

Prospective single-arm study of endocrine therapies with ovarian function suppression in premenopausal patients with node-positive early breast cancer with low genomic risk (INTERSTELLAR trial, KBCSG-25). *First Author: Sung Gwe Ahn, Gangnam Severance Hospital, Yonsei University, Gangnam-Gu, NA, Korea, Republic of (South)*

Background: It is unclear whether the clinical benefit of cytotoxic adjuvant chemotherapy (CT) could be replaced by ovarian-function suppression (OFS) in premenopausal, estrogen receptor (ER)+HER2- breast cancer patients who have high clinical risk score and low genomic risk assessed by multigene assays. The TAILORx trial included a subgroup of premenopausal women with high clinical risk scores and midrange RS scores and found that CT, in addition to endocrine treatment (ET), offered clear benefits in terms of invasive disease-free survival (IDFS) and distant-recurrence-free survival (DRFS) compared to ET alone. However, a majority of the patients did not receive OFS, and the use of OFS as an alternative to chemotherapy in this population is still an area of ongoing research and debate. In addition, in premenopausal women of the RxPonder trial, which enrolled node-positive disease, it is noted that the addition of OFS to ET for at least 12 months improved IDFS numerically in the ET-alone arm, although this improvement did not reach statistical significance. We hypothesized that a favorable DRFS could be achieved by OFS plus ET without CT in premenopausal, pN1, ER+HER2- breast cancer with low genomic risk identified by an NGS-based multigene assay, the OncoFREE. **Methods:** The INTERSTELLAR trial is a prospective, multicenter, single-arm, non-inferiority clinical study. Premenopausal women aged ≤ 50 years with pT1-2 ER+HER2- breast cancer and 1-3 lymph node metastasis will be enrolled. They will be tested with OncoFREE, an NGS-based breast cancer prognosis multigene assay developed and available in South Korea, where a higher portion of the patients is premenopausal. Patients with low genomic risk (Decision Index ≤ 20) are administered OFS plus tamoxifen or an aromatase inhibitor for five years. We hypothesize that the 5-year DRFS of the single arm treated with OFS plus ET would be not inferior to 96.1%, which is observed in the chemo-ET arm from the premenopausal subgroup of the RxPonder trial. The one-sided test with a non-inferiority margin of 3% and statistical power of 80% at a significance level of 0.05 resulted in a sample size of 380 patients with low genomic risk. Considering a 70% designation to low genomic risk by OncoFREE and a 10% drop-out rate, 604 patients will be enrolled from 15 tertiary care hospitals in South Korea. The primary endpoint will be tested in the 380 patients with low genomic risk. The patients with high genomic risk will receive CT followed by ET and will be followed for survival analysis as a secondary end-point. The trial has not enrolled its first patient yet at the time of submission. Clinical trial information: NCT05333328. Research Sponsor: None.

ASCENT-05/OptimICE-RD (AFT-65): Phase 3, randomized, open-label study of adjuvant sacituzumab govitecan (SG) + pembrolizumab (pembro) vs pembro ± capecitabine (cape) in patients (pts) with triple-negative breast cancer (TNBC) and residual disease after neoadjuvant therapy (NAT) and surgery. First Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Boston, MA

Background: TNBC has an aggressive disease course with poor prognosis for pts with residual disease (RD) after NAT. In Ph 3 KEYNOTE-522, pts treated with poly-chemotherapy + the immune checkpoint inhibitor (ICI) pembro for ~1 year only had a 3-year event-free survival of 85% (Schmid P, et al. *NEJM*. 2022). SG is a Trop-2-directed antibody-drug conjugate approved for pretreated metastatic TNBC (mTNBC). In Ph 3 ASCENT, SG significantly improved both progression-free survival and overall survival (OS) compared with standard chemotherapy (CT) in pts with mTNBC who received ≥2 lines of therapy, with a manageable safety profile (Bardia A, et al. *NEJM*. 2021). Preclinical data suggest that SG also potentiates the activity of ICIs. The ASCENT-05 study will assess the value of adding SG to a pembro-based adjuvant therapy in pts with RD after NAT. **Methods:** ASCENT-05/OptimICE-RD (AFT-65, NCT05633654) is an open-label, global, multicenter, randomized, phase 3 study that evaluates efficacy and safety of SG + pembro versus pembro ± cape (per treating physician discretion) in pts with TNBC and RD in the post-NAT setting. Key eligibility criteria include pts ≥18 years with a history of cT1, cN1-2 or cT2-4, cN0-2 TNBC with RD in the breast or lymph node(s) after NAT and surgery. TNBC diagnosis per local assessment is based on estrogen receptor and progesterone receptor <10%, and HER2-negative per ASCO/CAP. Other inclusion criteria are receipt of ≥6 cycles of neoadjuvant anthracycline- and/or taxane-based CT ± PD-(L)1 inhibitor ± radiotherapy postoperatively as clinically indicated, and adequate organ function with ECOG performance status 0-1. Key exclusion criteria include metastatic disease, prior ipsilateral/contralateral invasive breast cancer, prior treatment directed to another stimulatory/co-inhibitory T-cell receptor, HER2-directed agents or TOPO-1 inhibitors, evidence of recurrent or distant metastatic disease after preoperative therapy and surgery, germline *BRCA* mutations, myocardial infarctions ≤6 months of enrollment or history of serious ventricular arrhythmia or LVEF <50%, and active serious infections requiring treatment. Pts will be randomized 1:1 to receive SG (10 mg/kg IV on d1 and d8, every 21d for 8 cycles) + pembro (200 mg IV on d1 every 21d for 8 cycles). Cape (1000 mg/m² twice daily, orally on d1-14, every 21d for 8 cycles) may be added to pembro in the control arm. The primary endpoint is invasive disease-free survival. Key secondary endpoints include OS, distant disease-free survival, incidence of treatment-emergent adverse events and clinical laboratory abnormalities, and time to worsening of quality of life based on FACT-B TOI scores. ASCENT-05 will enroll ~1500 pts and is currently open for recruitment. Clinical trial information: NCT05633654. Research Sponsor: Gilead Sciences, Inc.

FLEX, a real-world evidence full transcriptome study of 30,000 patients with early-stage breast cancer. First Author: Eric Allen Brown, Comprehensive Breast Care, Troy, MI

Background: Clinical trials have been an invaluable tool in providing improvements in the discovery, treatment, and quality of life for various diseases and disorders including breast cancer, which impacts millions of people each year. Historically, patient trial populations have not been racially diverse due to several factors such as bias, healthcare distrust, access, and eligibility criteria. However, current efforts are focused on improving diversity and inclusion to promote efficacy and health equity across all races/ethnicities. The ongoing, multi-center FLEX trial (NCT03053193), which pairs clinical data and full transcriptome expression data, seeks to enroll 30,000 patients to accelerate real world research. Due to the size of the database, it is also expected to capture patients typically underrepresented in clinical trials. **Methods:** FLEX is the first of its kind, prospective, observational trial that enrolls patients who are ≥18 years old with histologically proven stage I-III breast cancer with up to 3 positive lymph nodes. Patient eligibility for study enrollment include standard of care MammaPrint testing with or without Blueprint and consent to clinically annotated full transcriptome data collection. The study infrastructure facilitates the generation of hypotheses for targeted sub-studies. The FLEX network fosters collaboration with 114 sites, including one site in Greece and Israel, encouraging participating investigators to initiate sub-studies that can address research questions that are important for breast cancer management. All proposed sub-studies are vetted and approved by Research and Scientific Review Committees. Since launching in April 2017, 12,569 patients have been enrolled including those who have been historically underrepresented in trials (African American n=1025; Latin n=341; Asian n=156). Forty-two investigator initiated sub-studies have been approved and are in progress, with 40 abstracts accepted in national and international congresses. Five ongoing sub-studies within FLEX address differences in underlying biology and treatment response/management among African American, Latina, and Asian American patients with early-stage breast cancer. These studies provide a broader understanding of how differential gene expression patterns unique to racial/ethnic groups can impact treatment outcomes. With the large FLEX database, enrollment and sub-studies are extended to other racial/ethnic groups that are underrepresented in clinical trials, but not limited to specific groups. Overall, the FLEX study strives to use full transcriptome data to improve precision medicine in early-stage breast cancer. Clinical trial information: NCT03053193. Research Sponsor: Agendia Inc.

A phase II single-arm, open-label trial of T-DM1 (ado-trastuzumab emtansine) and neratinib for HER2-positive breast cancer with molecular residual disease (KAN-HER2 MRD). First Author: Mitchell Elliott, Division of Medical Oncology & Hematology, Department of Medicine, Princess Margaret Cancer Centre and University of Toronto, Toronto, ON, Canada

Background: HER2-positive breast cancer is a biologically and clinically aggressive subtype that has historically been associated with poor outcomes, but for which there are now multiple effective targeted therapies. Patients who have residual disease following standard neoadjuvant therapy have an elevated risk of metastatic recurrence. In addition, the detection of circulating tumor DNA (ctDNA) in the adjuvant period is strongly associated with relapse and can further stratify patients with residual disease. The ctDNA-based detection of molecular residual disease (MRD) is an emerging strategy to identify patients for treatment intensification, and may enable the development of novel curative treatment strategies for "recurrence interception". Preclinical and clinical evidence support the investigation of neratinib, an irreversible inhibitor of the HER2 tyrosine kinase, in combination with standard T-DM1 in the adjuvant setting for patients with HER2-positive breast cancer and evidence of MRD. **Methods:** KAN-HER2 MRD is a multicentre, investigator-initiated, open label, single arm phase II trial to evaluate the addition of neratinib to standard T-DM1 in patients with detected MRD. Participants with HER2-positive breast cancer and residual disease following neoadjuvant therapy are pre-screened (Part A) for MRD using a tumor-informed assay (NeoGenomics RaDaR). Those with ctDNA detected following 2-6 cycles of adjuvant T-DM1 will proceed to the interventional phase (Part B) where neratinib is added to standard T-DM1 at the previously-determined recommended phase 2 combination dose of 160 mg/day, in continuous cycles. The primary endpoint is the rate of ctDNA clearance at 12 weeks after treatment initiation (ctDNAw12); the study is designed with a 2-stage approach and has sufficient power to detect a clearance rate of 40%. Secondary endpoints include MRD rates and their clinical correlates, invasive disease free survival (IDFS), and safety. Bio-specimens including diagnostic biopsies, residual disease, and peripheral blood are being collected from all participants for additional correlative studies. Enrolment in Part A was initiated at the first trial site (Princess Margaret Cancer Centre) in December 2022. KAN-HER2 represents the first reported MRD-directed interception trial for HER2-positive breast cancer. Clinical trial information: NCT05388149. Research Sponsor: Ontario Institute for Cancer Research (OICR) Clinical Acceleration Team Award; Princess Margaret Cancer Foundation; Knight therapeutics, NeoGenomics.

MRD assay to evaluate recurrence and response via a tumor-informed assessment: MARIA-Breast observational trial. First Author: Edward D. Esplin, Invitae, San Francisco, CA

Background: The recognition that cancers release nucleic acids into the peripheral circulation of the patient has enabled a new paradigm for disease detection and surveillance. Detectable ctDNA in patients with solid tumors has been associated with disease prognosis pre-treatment, assessing response to therapy in the form of minimal residual disease (MRD), and monitoring for recurrence after curative intent treatment. Utilizing patient-specific genomic mutation profiling of an individual's cancer from a tissue sample, in conjunction with the patient's germline DNA, to create a personalized sequencing panel to then systematically analyze for a subset of these genetic mutations from ctDNA in blood is a strategy that has high sensitivity in detection of MRD. Studies have shown that pretreatment levels of ctDNA using this approach are a potential early indicator of disease recurrence after surgery, that ctDNA clearance may be an early predictor of favorable outcomes and have been shown to correlate with pathologic complete response (Forde et al. *N Engl J Med*. 2022, PMID: 35403841), and that this approach has high sensitivity in its ability to detect recurrence for patients in advance of the current standard of care (Abbosh et al. *Cancer Res* (2020) 80 (16_Supplement): CT023). **Methods:** This is a multi-site, prospective, observational trial in the United States of 200 patients with early stage breast cancer undergoing curative intent treatment, who have FFPE tissue available from resection sufficient for a patient-specific bespoke MRD assay who are willing to provide serial whole blood specimens for ctDNA analysis. Participants are asked to provide study specimens prior to initial treatment intervention, after curative intent surgical resection, during adjuvant therapy (as applicable) and pre-recurrence follow-up. ctDNA will be analyzed with an NGS-based, tumor-informed MRD assay that identifies somatic mutations from DNA obtained from the patient's tumor tissue, subtracts germline variants via NGS-based analysis of the patients germline DNA, and detects a selected set of between 18-50 tumor-specific ctDNA in their blood. All primary tumor specimens will undergo full exome sequencing using the Personalized Cancer Monitoring (PCM) assay. Impact of results of this CLIA-approved MRD assay on clinical decision making will be captured. The primary objective is to assess the ability of MRD to predict post-treatment recurrence. Further objectives are to correlate MRD status with pathologic complete response, determine the lead time to detection of recurrence compared to standard of care, and the association of MRD status with overall survival. Active enrollment started in March, 2022. Clinical trial information: NCT05219734. Research Sponsor: Invitae.

NRG-BR007: A phase III trial evaluating de-escalation of breast radiation (DEBRA) following breast-conserving surgery (BCS) of stage 1, HR+, HER2-, RS ≤18 breast cancer. *First Author: Julia R. White, University of Kansas Medical Center Comprehensive Cancer Center (KUMC CCC), Kansas City, KS*

Background: Approximately 50% of newly diagnosed invasive breast cancers are stage 1, with the majority being ER/PR-positive, HER2-negative. Genomic assays such as the Oncotype DX have identified patients (pts) with reduced risk of distant metastasis and without benefit from chemotherapy added to endocrine therapy, freeing them from excess toxicity. Genomic assays are also recognized as prognostic for in-breast recurrence (IBR) after BCS and could similarly allow de-escalation of adjuvant radiotherapy (RT). Reducing overtreatment is of interest to pts, providers, and payers. **Methods:** We hypothesize that BCS alone is non-inferior to BCS plus RT for in-breast recurrence and breast preservation in women intending endocrine therapy (ET) for stage 1 invasive breast cancer (ER &/or PR positive, HER2-negative with an Oncotype DX Recurrence Score [RS] of ≤18). Stratification is by age (<60; ≥60), tumor size (≤1 cm; >1-2cm), and RS (<11, 11-18). Pts are randomized post-BCS to Arm 1 with breast RT using standard methods (hypo- or conventional-fractionated whole breast RT with/without boost, or APBI) with ≥5 yrs of ET (tamoxifen or AI) or Arm 2 with ≥5 yrs of ET (tamoxifen or AI) alone. The specific regimen of ET in both arms is at the treating physician's discretion. Eligible pts are stage 1: pT1 (≤2 cm), pN0, age ≥50 to <70 yrs, s/p BCS with negative margins (no ink on tumor), s/p axillary nodal staging (SNB or ALND), ER &/or PR positive (ASCO/CAP), HER2-negative (ASCO/CAP), and Oncotype DX RS of ≤18 (diagnostic core biopsy or resected specimen). Primary endpoint is in-breast recurrence (invasive breast cancer or DCIS). Secondary endpoints are breast conservation rate, invasive in-breast recurrence, relapse-free interval, distant disease-free survival, overall survival, patient-reported breast pain, patient-reported worry about recurrence, and adherence to ET. We assume a clinically acceptable difference in IBR of 4% at 10 yrs to judge omission of RT as non-inferior (10-yr event-free survival for RT group is 95.6% vs 91.6% for the omission of RT group). BR007 is powered to detect non-inferiority with 80% power and a one-sided $\alpha=0.025$, assuming that there would be a ramp-up in accrual in the first two years (leveling off in Yrs 3-5); 1,670 pts (835 per arm) are required for randomization. Conservative loss to follow-up is 1% per yr. Some of the T1a pts screened may have Oncotype DX scores >18, making them ineligible for the study. In the accrual process, 1,714 pts will be required to register to ensure that our final randomized cohort is 1,670 pts. Current accrual (02-08-2023) is 370 screened and 323 randomized (~87% of predicted accrual). Clinical trial information: NCT04852887. Research Sponsor: U.S. National Institutes of Health.

SMALL: Open surgery versus minimally invasive vacuum-assisted excision for small screen-detected breast cancer—A UK phase III randomised multicentre trial. *First Author: Stuart McIntosh, Queen's University Belfast, Belfast, United Kingdom*

Background: Mammographic screening programmes reduce breast cancer mortality but detect many small tumours with favourable biology which may not progress. These are treated with surgery and adjuvant therapies, but associated morbidities mean there is a need to reduce overtreatment. Minimally invasive treatments such as vacuum-assisted excision (VAE) have been described but there is no prospective randomised evidence to support their routine use. SMALL (ISRCTN 12240119) is designed to establish the feasibility of using VAE to treat small tumours detected within the UK NHS Breast Screening Programme (BSP). **Methods:** Phase III multicentre randomised trial comparing surgery with VAE for screen-detected good prognosis cancers. Eligibility criteria are age ≥47 years, unifocal grade 1 tumours (maximum diameter 15mm), strongly ER/PR+ve and HER2-ve, with negative axillary staging. Patients are randomised 2:1 to VAE or surgery, with no axillary surgery in the VAE arm. Excision is assessed radiologically, and if incomplete, patients undergo surgery. Adjuvant radiotherapy and endocrine therapy are mandated in the VAE arm. Co-primary end-points are 1) Non-inferiority comparison of the requirement for a second procedure. 2) Single arm analysis of local recurrence (LR) at 5 years after VAE. Recruitment of 800 patients will permit demonstration of 10% non-inferiority of VAE for requirement of a second procedure, ensuring sufficient patients for single arm analysis of LR rates, where expected LR free survival is 99% at 5 years, with an undesirable survival probability after VAE of 97%. Secondary outcome measures include time to ipsilateral recurrence, overall survival, complications, quality of life and health economic analysis. A QuinteT Recruitment Intervention (QRI) is integrated throughout SMALL to optimise recruitment and informed consent. Recruitment challenges are identified by analysing recruiter/patient interviews, audio-recordings of trial discussions, and by review of screening, eligibility and recruitment data and study documentation. Solutions are developed collaboratively, including recruiter feedback and recruitment tips documents. Results: At 10th February 2023, 231 patients had been recruited from 32 centres, (~45% of eligible patients), with per site recruitment of 0.4-0.5 patients/month. Based on preliminary QRI findings, a recruitment tips document has been circulated (on discussing SMALL, providing balanced information on treatment options and explaining randomisation), with individual recruiter feedback underway and wider feedback planned shortly. Conclusion: SMALL has excellent recruitment to date, confirming feasibility and acceptability, and is expected to have a global impact on treatment of screen-detected breast cancer. Clinical trial information: ISRCTN12240119. Research Sponsor: National Institute for Health Research Health Technology Assessment Programme (UK).

Selective avoidance of sentinel lymph node biopsy after neoadjuvant chemotherapy in patients with HER-2 positive/triple negative breast cancer: Prospective, multi-center, single-arm study (ASLAN). *First Author: Jai Min Ryu, Division of Breast Surgery, Department of Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: According to advanced neoadjuvant chemotherapy (NACT), which dual HER2 blockade in HER2+ BC and adding carboplatin or immunotherapy in triple-negative breast cancer (TNBC) increased pathologic complete response (ypCR) rates up to 68% and 80%. Because ypCR patients showed better survival, the indications for NACT have expanded to early BC and the expected ypCR rate has increased. Therefore, it may be reasonable to consider omitting surgery in cases with excellent responses to NACT. Several recent retrospective studies and pilot prospective studies have reported axillary pathologic complete response (ApCR) is highly correlated with breast pathologic complete response (BpCR) in HER2+ or TNBC after NACT. The current report describes the design of omission of sentinel lymph node biopsy (SLNB) after NACT in HER2+ or TNBC patients with excellent response. Similarly, EUBREAST-01 (NCT04101851) study is ongoing omission of sentinel lymph node biopsy (SLNB) after NACT in HER2+/TNBC with radiologic complete remission and a BpCR. **Methods:** The ASLAN trial is a prospective, multicenter, single-arm, clinical study. Five tertiary care hospitals in South Korea are participating. Inclusion criteria: women aged 20-69; cT1-3N0-1M0; HER2+ or TNBC (defined by ER-negative (< 10% positive cells in IHC) and PgR-negative (< 10% positive cells in IHC)); expected complete remission at physical examination and radiological expected Tumor size ≤ 2cm or non-mass enhancement ≤ 4cm at breast MRI after standard NACT; planned breast conserving surgery (BCS) with whole-breast irradiation; ECOG performance status 0-1. Exclusion criteria: SLNB before NACT; previous axillary surgery; bilateral BC. Patients who are eligible proceed BCS. After BCS, patients who showed BpCR are enrolled with omission of SLNB. Patients with no BpCR proceed with routine axillary surgery. The assumption for acceptable 5-year RFS ≥84% is based on previous study findings. The calculated total case number for per-protocol analysis is N=178. Primary endpoint: 5-year recurrence free survival. Secondary endpoint: local recurrence free survival, breast cancer specific survival, overall survival, ipsilateral axillary recurrence interval, distant metastasis free survival, contralateral breast free survival, re-operation rate according to breast biopsy after NACT, adverse event, and quality of life. The first patient was enrolled on September 2021. Among 147 patients who screened, 106 patients have been enrolled in January 2022. We plan to complete the target accrual by December 2025. Clinical trial information: NCT04993625. Research Sponsor: NRF 2021R1A2C94010.

MELODY (Methods for Localization of Different Types of Breast Lesions): A prospective non-interventional multicenter cohort study to evaluate different imaging-guided methods for localization of malignant breast lesions (EUBREAST-4/iBRA-NET). *First Author: Maggie Banyas-Paluchowski, University Hospital Schleswig-Holstein Campus Lübeck, Lübeck, Germany*

Background: In the last decades, the proportion of breast cancer patients receiving breast-conserving surgery has increased, reaching 70-80% in developed countries. In case of non-palpable lesions, surgical excision requires some form of breast localization. While wire-guided localization has long been considered gold standard, it carries several limitations, including logistical difficulties, the potential for displacement and patient discomfort, and re-excision rates reaching 21%. Other techniques (radioactive seed or radio-occlude lesion localization, intraoperative ultrasound, magnetic, radiofrequency and radar localization) have been developed with the aim of overcoming these disadvantages. However, comparative data on the rates of successful lesion removal, negative margins and re-operations are limited. In the majority of studies, the patient's perspective with regard to discomfort and pain level has not been evaluated. The aim of MELODY is to evaluate different imaging-guided localization methods with regard to oncological safety, patient-reported outcomes, and surgeon and radiologist satisfaction. **Methods:** The EUBREAST and the iBRA-NET have initiated the MELODY study to assess breast localization techniques and devices from several perspectives (NCT05559411, <http://melody.eubreast.com>). MELODY is a prospective intergroup cohort study which enrolls female and male pts. requiring breast-conserving surgery and imaging-guided localization for invasive breast cancer or DCIS. Multiple or bilateral lesions and neoadjuvant chemotherapy are allowed. Primary outcomes are: 1) Intended target lesion and/or marker removal, independent of margin status on final histopathology, and 2) Negative resection margin rates at first surgery. Secondary outcomes are, among others: rates of second surgery and secondary mastectomy, Resection Ratio (defined as actual resection volume divided by the calculated optimum specimen volume), duration of surgery, marker dislocation rates, rates of marker placement or localization failure, comparison of patient-reported outcomes, rates of "lost markers" and diagnostician/radiologist's and surgeon's satisfaction as well as the health economic evaluation of the different techniques. Target accrual: 7,416 patients. Enrollment started in January 2023. The study will be conducted in 20 countries and is supported by the Oncoplastic Breast Consortium (OPBC), AWOgyn, AGO-B and SENATURK. Clinical trial information: NCT05559411. Research Sponsor: Endomag, Merit Medical, Sirius Pintuition and Hologic.

Omission of breast surgery for predicted pCR patients with MRI and vacuum-assisted biopsy in breast cancer after neoadjuvant chemotherapy: A multicenter, single-arm, non-inferiority trial (OPTIMIST trial). *First Author: Ji-Jung Jung, Department of Surgery, Seoul National University College of Medicine, Seoul, South Korea*

Background: Advances in chemotherapeutic and targeted agents have increased pathologic complete response (pCR) rates after neoadjuvant systemic therapy (NST). The role of surgery is essential to remove cancer when residual tumor is present, but it may be limited to pathologic confirmation in those with a pCR. As an alternative, pCR can be accurately evaluated with vacuum-assisted biopsy (VAB) in patients suggested to have a pCR on imaging. We aim to show a non-inferiority of omitting breast surgery in patients evaluated to have a pCR on image-guided VAB. **Methods:** The OPTIMIST trial is a prospective, multicenter, single-arm, non-inferiority clinical study. Sixteen tertiary care hospitals in South Korea are participating. Women diagnosed with invasive ductal carcinoma, a clip marker placed in the tumor, and who had completed NST with exceptional response are screened for eligibility. Inclusion criteria: women aged 19-75; cT1-2N0-2M0; triple-negative, HER2+, or low estrogen receptor (<10%); post-NST MRI size ≤ 1 cm and lesion-to-background signal enhancement ratio ≤ 1.6 . Exclusion criteria: malignant calcification > 2 cm; multifocal, bilateral, or inflammatory breast cancer; other malignancy within five years; BRCA1/2 mutation carrier. Under ultrasound or stereotactic guidance, VAB is performed targeting the clip marker to obtain a minimum of 6 cores using 7-10 G needles. When pCR is confirmed, breast surgery is omitted. cNO patients with post-NST MRI tumor size ≤ 0.5 cm and no suspicious lymph nodes, axillary lymph node surgery could also be omitted. Patients with residual tumor or atypical cells proceed with routine surgery. All patients are required to receive whole breast irradiation with tumor bed boost. According to previous studies, the 5-year disease-free survival (DFS) for patients with a pCR after NST was assumed to be 88%. The one-sided test with a non-inferiority margin of 4% and statistical power of 80% at a significance level of 0.05 resulted in a sample size of 384 patients to forego breast surgery. An expected 20% residual tumor on VAB and a 10% dropout resulted in a total of 533 subjects. Primary endpoint: 5-year DFS. Secondary endpoint: 5-year ipsilateral breast tumor recurrence-free survival, 5-year overall survival, 5-year invasive DFS, residual axillary lymph node rate, quality of life scores, symptoms (VAS), and medical cost. An interim analysis is planned at 50% enrollment with a median follow-up period of 1 year. The data safety monitoring board will determine the continuation of the study considering the 1-year DFS. The first patient was enrolled on September 22, 2022, and 12 patients have been enrolled as of February 14, 2023. We plan to complete the target accrual by December 2025. Clinical trial information: NCT05505357. Research Sponsor: National Cancer Center of Korea.

Phase 1 dose-escalation, dose-expansion trial of intratumoral HER2- and HER3-primed dendritic cells injections for the treatment of early-stage TNBC and HR low positive breast cancer: DecipHER trial. *First Author: Ricardo L Costa, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Patients with breast cancers (BCs) harboring low expression of hormone receptors (HRs) and human epidermal growth factor receptor-2 (HER2) have poor outcomes. Results from the KEYNOTE-522 trial showed that activation of the immune system using a PD1/PD-L1-targeted approach improves outcomes of patients with these high-risk tumors. Antigen-presenting cells (eg, dendritic cells [DCs]) are pivotal for robust cytotoxic responses due to broader activation of the adaptive immune system (ie, CD4⁺ and CD8⁺ Th1) against tumor-associated antigens (ie, HER2 or HER3) expressed by high-risk BCs. **Methods:** DecipHER is a dose-escalation, dose-expansion phase 1 trial designed to assess the safety and the preliminary efficacy of autologous, HER2- and HER3-primed DCs in combination with KEYNOTE 522 regimen in 30 patients. Patients with clinical stage cT1cN1/2 or cT2-4cN0-2, HR 20, HER2-negative BCs are eligible. Patients with inflammatory BC cancer and uncontrolled immune mediated diseases are excluded. After collection through apheresis, autologous DCs will be primed *ex vivo* against 6 HER2 and 8 HER3 immunogenic peptides. Participants will receive alternating ultrasound-guided intratumoral HER2 and HER3 DC injections administered twice a week for 8 doses in total starting 2 weeks prior to neoadjuvant therapy with KEYNOTE 522 regimen. The dose-escalation phase of the study has 3 planned cohorts (10-20, 30-50, 80-100 million DCs) and follows a 3+3 design (maximum n=18). The 12 additional patients enrolled will be treated at the maximum tolerated dose (MTD) in the dose-expansion cohort. The MTD will be defined as the highest dose level at which < 2 of 6 patients experience dose-limiting toxicities (grade ≥ 3 non-hematologic, ; grade ≥ 3 hematologic toxicity thought to be at least possibly related to DCs ; any grade 4 nausea, vomiting, or diarrhea [or grade 3 if duration > 3 days]) during the 5 weeks following treatment initiation with DCs. Secondary endpoints include the absolute risk of adverse events, clinical and pathological responses, and recurrence free survival. Tumor tissue, blood and stool samples will be collected for correlative analyses. The study is open at H. Lee Moffitt Cancer Center. Clinical trial information: NCT05504707. Research Sponsor: Shula's Foundation.

Tailored axillary surgery (TAS) in patients with clinically node-positive breast cancer in the upfront surgery setting: A prospective, single-arm, multicenter trial. *First Author: Kaori Terata, Department of Breast and Endocrine Surgery, Akita University Hospital, Akita, Japan*

Background: Axillary lymph node dissection (ALND), which can induce lymphedema, has been omitted in clinically node-negative(cNO) patients with positive sentinel lymph nodes (SLNs) if they meet the eligibility criteria of ACOSOG Z0011. Furthermore, the omission of ALND has been attempted through targeted axillary dissection (TAD) in patients whose cN+ status converts to ycNO after neoadjuvant chemotherapy. However, ALND remains the standard of care in patients with cN+ who undergo upfront surgery. The aims of this trial are to establish a surgical method of tailored axillary surgery (TAS), which combines TAD and SLN biopsy among patients with cN+ who undergo upfront surgery, and to determine the appropriate criteria for a Phase III TAS trial. **Methods:** We have planned a single-arm Phase II trial to confirm the feasibility and assess patient eligibility for TAS. A total of 300 patients will be enrolled from 33 study sites in Japan. The eligibility criteria are as follows: 1) histologically-proven invasive breast cancer, 2) upfront surgery is planned, 3) pathologically-diagnosed metastatic lymph node (cytology or core needle biopsy), 4) 1-3 LN metastases in level I by imaging, 5) cT1-3, and 6) females aged ≥ 18 and ≤ 74 years on the enrollment date. TAS involves removing marking lymph nodes by TAD (clip, wire, or tattoo) and SLNB, and ALND up to Level II are performed after TAS. These LNs are defined as non-TAS LNs. The primary endpoint is the non-TAS LNs positive rate. Clinicopathological factors (the number of suspected metastases by imaging, the number of metastases in LNs resected by TAS, tumor size, and invasive ductal/lobular carcinoma) are analyzed to predict the non-TAS LN metastasis rate (e.g., $< 10\%$). By using these clinicopathological factors, we determine the eligibility of TAS to omit ALND safely. The secondary endpoints are TAS LNs identification rate, labeled LNs identification rate, marked lymph node resection rate, arm edema incidence rate, and QOL (FACT-B, QuickDASH). After this feasibility study, we will conduct a phase III trial that omits ALND using TAS to investigate the regional recurrence rate. Research Sponsor: Okayama University.

DIRECT2: A randomized phase III trial with a fasting mimicking diet program to improve chemotherapy in patients with hormone receptor positive, HER2-negative breast cancer—A Dutch Breast Cancer Research Group study (BOOG). *First Author: Nadia de Gruil, Leiden University Medical Center, Leiden, Netherlands*

Background: Preclinical research has shown that fasting and/or a fasting mimicking diet (FMD) in addition to chemotherapy can enhance cancer treatment effectivity and reduce side-effects. The previous DIRECT1 phase 2 study (de Groot S, Nat. Commun. 2020) indicated that FMD could increase effectivity of neoadjuvant chemotherapy in patients with HER2-negative breast cancer. **Methods:** DIRECT2 is a multicenter, randomized, open label phase 3 study that investigates whether FMD compared to a regular diet during neoadjuvant chemotherapy can improve the pathological and/or radiological response rate in patients with hormone receptor positive (HR+), HER2-negative, stage II/III breast cancer. Secondary endpoints include quality of life, cognition, toxicity $\geq$ grade 3 and the immunomodulating effect of FMD. The FMD consists of a low-caloric diet of 600kcal/day starting 3 days prior to, and on the day of chemotherapy administration every 4 weeks, for a total of 5 FMD cycles during neoadjuvant chemotherapy (4 times dose dense Adriamycin plus cyclophosphamide followed by 12 times weekly paclitaxel). Patients will be supported and monitored by a centralized dietician during each FMD cycle. An additional MRI will be conducted after 4ddAC to evaluate efficacy mid-way through chemotherapy. Furthermore, an optional tumor biopsy will be done to determine the immunomodulatory effects of the FMD which will be determined using cutting-edge RNA sequencing and multispectral imaging techniques. Pathological response will be graded on the surgical specimen according to Miller & Payne 4/5, indicating a 90-100% tumor cell loss. Radiological response will be determined by MRI (RECIST1.1). In total 240 patients are needed to detect an increase from 20% to 37.5% in pathological response rate in the FMD arm allowing for 15% dropout, using a two-sided Z test with pooled variance and 5% significance level with a power of 80%. Randomization will be performed in Castor EDC with variable block sizes and stratified by clinical stage (stadium II versus III) and BMI (< 25 kg/m² versus ≥ 25 kg/m²). Inclusion criteria are HR+, HER2- breast cancer stage II-III, BMI > 18.5 kg/m², WHO status 0-2, without a history of malignancy in the past 5 years, invasive or ipsilateral non-invasive breast cancer. Patients will be excluded in case of pregnancy, lactation or metabolic disease that affects gluconeogenesis and adaptability to FMD. The trial is supported by grants from the Dutch Cancer Society and WCRF. The study is open since February 2023 for inclusion for 4 years and plans to recruit 240 patients in total in 20 participating hospitals in the Netherlands. Clinical trial information: NCT05503108. Research Sponsor: Dutch Cancer Society; World Cancer Research Fund (WCRF).

Metformin with neoadjuvant chemotherapy in localized triple negative and HER2neu-positive breast cancer: A prospective phase 2 open label randomized controlled trial (McBETH). *First Author: Mouna Bidaraguppe B M, New Delhi, India*

Background: Repurposing of drugs in cancer is an attractive strategy and metformin has long been an agent with promising yet unproven activity in breast cancer. Despite some recent studies showing inadequate efficacy in adjuvant setting, there is a lack of well powered studies in neo-adjuvant setting in localised breast cancer. Few past studies suggest that metformin may have anticancer effects in the subsets of Her2 neu positive as well as Triple negative breast cancer (TNBC). We initiated this study to investigate if metformin in combination with standard neo-adjuvant chemotherapy is effective in improving pathological complete response rates in these subsets among localised breast cancers. **Methods:** This is an investigator initiated randomised, open label, parallel-group superiority trial. All non diabetic localised chemo-naïve breast cancer patients aged ≥ 18 years planned for neo-adjuvant chemotherapy will be randomly allocated (stratified by HER 2 positive and TNBC) to receive standard neo-adjuvant chemotherapy with or without metformin (850mg twice daily) till the day of surgery. The patients will be followed up until the surgery. The primary objective of this study is to compare the pathological complete response rates (ypT0ypN0) in each arm. The secondary objectives are to compare pathological complete response rates in predefined subsets of HER2 positive and triple negative breast cancer, clinical response rates in each arm, patient reported outcomes in each arm (ESAS-r Scale), breast conservation surgery rates in each arm, incidence and severity of adverse events in both arms. Trial statistical design: Planned accrual is total 242 patients including 10% drop out rate. It is a superiority design with an absolute improvement of 11% in pathological complete response from a baseline of 33% in the standard arm. Conduct to date: study activation: May 2022. Enrolment: 116 subjects. Clinical trial information: REF/2022/05/054208. Research Sponsor: None.

A randomized phase 2 non-inferiority trial of (Z)-endoxifen and exemestane + goserelin as neoadjuvant treatment for premenopausal women with ER+/HER2- breast cancer (EVANGELINE). *First Author: Matthew P. Goetz, Mayo Clinic, Rochester, MN*

Background: Ovarian function suppression (OFS) when combined with tamoxifen or an aromatase inhibitor is the standard of care for premenopausal estrogen receptor positive (ER+) human epidermal growth factor receptor 2 negative (HER2-) breast cancer (BC) based on SOFT (Francis 2022) and TEXT (Pagani 2022) clinical trials and confirmed in a meta-analysis (EBCTCG 2022). However, estrogen deprivation in premenopausal women is associated with significant morbidity and up to 40% of premenopausal women with ER+/HER2- BC are intolerant of OFS. For these women, tamoxifen monotherapy is the only FDA approved option. Therefore, there is substantial room to improve endocrine therapy for premenopausal women with ER+/HER2- BC. (Z)-endoxifen is one of the most active anti-estrogen tamoxifen metabolites, with preclinical data demonstrating superiority to tamoxifen and letrozole in aromatase expressing xenograft models and evidence for antitumor activity in early phase clinical trials in patients with prior progression on endocrine therapy including tamoxifen. In addition to its ability to potentially block ER α , (Z)-endoxifen at clinically achievable concentrations inhibits protein kinase C beta 1 (PKC β 1), resulting in downstream AKT inhibition and apoptosis. It is hypothesized that (Z)-endoxifen, when delivered as monotherapy at doses that dually target both ER α and PKC β 1, will potentially inhibit BC proliferation while obviating the need for OFS in premenopausal women. If successful, this innovative approach could spare women with endocrine sensitive BC from the side effects of OFS. **Methods:** To further study (Z)-endoxifen in premenopausal women, a multicenter study in the United States, with possible expansion to other countries was designed (EVANGELINE; NCT05607004). This is a Phase 2, open-label, randomized, neoadjuvant study in premenopausal women with Stage IIA or IIB ER+/HER2- BC. Subjects are randomized 1:1 to either exemestane plus goserelin or (Z)-endoxifen. The primary objective is to determine whether the endocrine sensitive disease (ESD) rate (defined as Ki-67 $\leq 10\%$ after 4 weeks of neoadjuvant therapy) with (Z)-endoxifen is non-inferior to exemestane plus goserelin. Subjects will be enrolled with the intent of surgical treatment in the involved breast(s) after completing 6 months of neoadjuvant treatment. Safety, tolerability, response rates and surgical outcomes will be assessed. Disease progression will be monitored throughout study participation. Paired tumor biopsies and blood sampling will allow for a robust biomarker evaluation. Prior to initiating the Treatment Cohort (162 subjects), up to 12 subjects will be enrolled in a pharmacokinetic (PK) Run-in Cohort to identify the optimal dose for the Treatment Cohort. Enrolment in the PK Run-in cohort began in February 2023. Clinical trial information: NCT05607004. Research Sponsor: Atossa Therapeutics, Inc.; U.S. National Institutes of Health.

ORACLE-RIPA study: A phase II, randomized, open-label, parallel-group study comparing the immune modulation effect of neoadjuvant ribociclib, palbociclib, and abemaciclib in early ER+/HER2- breast cancer. *First Author: I-Chun Chen, National Taiwan University Hospital, Taipei, Taiwan*

Background: CDK4/6 inhibitors (CDK4/6i), ribociclib, palbociclib, and abemaciclib, provide similar progression-free survival (PFS) benefits when combined with endocrine therapy in ER+/HER2- metastatic breast cancer (MBC) patients. However, not all CDK4/6i have demonstrated overall-survival (OS) benefits in their respective phase III trials. Both, ribociclib and abemaciclib, have shown significant OS benefits in ER+/HER2- MBC patients, but palbociclib has not. Because of similar benefits of the 3 CDK4/6i on PFS, the OS benefit is likely not a result of differences in their synergistic efficacy of a CDK4/6i with endocrine therapy. CDK4 inhibition on cancer cells can also result in upregulation of MHC-I and MHC-II expression on cell surface and Rb-dependent interferon-gamma secretion. CDK6 inhibition might inhibit T cell and NK cell proliferation causing a negative effect on the tumor microenvironment. CDK6 inhibition can also reduce regulatory T cell numbers and increase cytokine production to enhance cytotoxic T cell function. Thus, we hypothesize that the differential impact of the 3 CDK4/6i on OS might be resulting from different immunomodulation effects. To investigate the functional alterations of the CDK4/6i on the BC microenvironment, the neoadjuvant treatment setting is best to compare the immune modulation effects of CDK4/6i from pre-treatment and post-treatment tumor tissues. **Methods:** This phase II multicenter, randomized, open-label, parallel-group study evaluates the immunomodulation effects of the 3 different CDK4/6i (ribociclib, palbociclib, or abemaciclib) combined with letrozole in neoadjuvant early ER+/HER2- breast cancer patients. A total of 20 patients will be enrolled into each treatment arm. The major inclusion criteria are female patients aged ≥ 20 years old, having a histologically and/or cytologically confirmed diagnosis of ER+ ($> 10\%$) and/or PR+, HER2 negative (IHC 0+/1+, or IHC 2+ plus FISH negative) breast cancer, stage II/III, and adequate organ function. The treatment will be 12 weeks of letrozole plus a CDK4/6i. Premenopausal patients will receive GnRH agonist. Breast tumor biopsy, blood and stool samples will be collected prospectively at the time prior to treatment initiation, at 2 weeks after treatment, and at surgery. A description summary will be utilized to compare the results between the 3 CDK4/6i. The trial results will address questions about differences or similarities of the 3 CDK4/6i within the same study. The study is currently enrolling at 3 medical centers in Taiwan. Clinical trial information: Pending formal number assignment. Research Sponsor: Novartis; National Taiwan University Hospital.

Neoadjuvant HER2-targeted therapy $\pm$ immunotherapy with pembrolizumab (neoHIP): An open label randomized phase II trial. *First Author: Heather L. McArthur, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Immune checkpoint inhibition (ICI) is synergistic with HER2-directed therapy in pre-clinical models. Clinically, pembrolizumab (K)-mediated ICI plus HER2-directed therapy with trastuzumab (H) was safe and demonstrated modest activity in H-resistant HER2-positive (HER2+) metastatic breast cancer. Because ICI may confer more robust activity when administered earlier in the course of disease, H and K administered in the curative-intent, treatment-naïve setting may allow for de-escalation of cytotoxics; confer life-long, tumor-specific immunity; and ultimately, improve cure rates. Moreover, the synergy of H and K with paclitaxel (T) may overcome the need for dual HER2-blockade with H plus pertuzumab (P). In this randomized, multicenter, phase II, open-label trial the efficacy and safety of neoadjuvant THP vs THP-K vs TH-K are explored. **Methods:** Patients (pts) ≥ 18 y with previously untreated, stage II-III, HER2+ breast cancer are being randomized and stratified by clinical nodal status (positive vs. negative) and hormone receptor status (positive vs. negative). In arm A, pts received T at 80mg/m² weekly for 12 weeks, H at 8mg/Kg (loading dose) and then 6mg/Kg every 3 weeks x 3 doses, P at 840 mg (loading dose) and then 420mg/Kg every 3 weeks x 3 doses (THP). In arm B, pts received THP plus K at 200mg every 3 weeks x 4 doses (THP-K). In arm C, pts received TH-K. After enrollment of 22 pts to arm C, a prespecified interim efficacy analysis was conducted, and enrollment to this arm was subsequently terminated. Enrollment to the other arms continues with 32/58 pts enrolled to arm A and 33/58 pts enrolled to arm B as of 2/14/2023. Definitive surgery is 3-6 weeks after the last dose. After surgery, pts are treated per the treating physician's discretion per local clinical standard. The primary end point is pathologic complete response (pCR) rate in the breast and axilla (ypT0/Tis ypN0). Secondary end points include pCR rate by ypT0ypN0 and ypT0/Tis, residual cancer burden index, event free survival, breast conserving surgery rate, safety and overall survival. Exploratory correlative studies will characterize potential immune biomarkers predictive of efficacy and/or toxicity. Clinical trial information: NCT03747120. Research Sponsor: Merck; BCRF.

A single-arm phase 2 study of peri-operative immune checkpoint inhibition and cryoablation in women with hormone receptor-negative, HER2-negative, early-stage/resectable breast cancer. *First Author: Heather L. McArthur, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Local tumor destruction with cryoablation (cryo) induces inflammation and releases antigens that can activate tumor-specific immune responses. Pre-clinically, cryo with immune checkpoint inhibition (ICI) augmented tumor-specific immune responses and prevented recurrence. Clinically, we established that peri-operative (peri-op) cryo with ICI [ipilimumab (ipi) +/- nivolumab (nivo)] was safe in patients (pts) with operable, early stage breast cancer (ESBC) and generated robust intra-tumoral and systemic immune responses. In this phase 2 study, we evaluate the disease specific impact of peri-op ICI in women with residual triple negative breast cancer (TNBC) after neoadjuvant chemotherapy (NAC), a subset at high risk of early relapse. **Methods:** Eligible women are ≥ 18 y, with ER $< 10\%$, PR $< 10\%$, HER2 negative (per ASCO/CAP definition), ≥ 1.0 cm, residual operable disease after taxane-based NAC. As of 2/14/21, 16/80 pts have been enrolled and treated with ipi/nivo/cryo followed by breast surgery and adjuvant nivo. Pts undergo percutaneous, image-guided cryo with concurrent research core biopsy 7-10 days prior to surgery and received ipi (1mg/kg IV) with nivo (240mg IV) 1 to 5 days prior to cryo. After surgery, pts received 3 additional doses of nivo at 240mg IV Q2 weeks. To reflect the US FDA approval of curative-intent pembrolizumab (pembro) in 2021, the protocol was recently amended to allow standard-of-care pembro as an alternative ICI option. Adjuvant capecitabine or olaparib is recommended for all patients per local standard-of-care. Patients will be stratified by NAC platinum administration, NAC anthracycline administration, and clinical nodal status (positive versus negative). The primary endpoint is 3-year Event Free Survival (EFS). Secondary endpoints include Invasive Disease-Free Survival (IDFS), Distant Disease-Free Survival (DDFS), overall survival (OS) and safety. Exploratory correlative studies will be performed on tumor and serum to characterize the immunologic impact of the intervention and to explore predictors of efficacy and toxicity. Clinical trial information: NCT03546686. Research Sponsor: Komen; ASCO; Bristol-Myers Squibb, BTG International Ltd.

Poster Session

A phase II study of concurrent WOKVAC vaccination with neoadjuvant chemotherapy and HER2-targeted monoclonal antibody therapy. *First Author: William R Gwin, University of Washington, Cancer Vaccine Institute, Seattle, WA*

Background: HER2+ breast cancer (BCa) is an aggressive breast cancer subtype. The treatment of Stage I-III HER2+ BCa with neoadjuvant chemotherapy and HER2 monoclonal antibodies (trastuzumab and pertuzumab) induces a pathologic complete response in 43-67% of patients. Residual HER2+ disease (i.e. residual cancer burden) after neoadjuvant therapy is associated with a significantly higher risk of recurrence. Evidence supports that HER2 immunity is progressively lost in HER2 oncogenesis and that restoration of HER2 specific CD4+ Th1 immunity is associated with a lower risk of recurrence. Trastuzumab can partially restore HER2 specific immunity, but only in a minority of patients. We have demonstrated that HER2 specific vaccination can augment HER2 specific immunity. While taxane chemotherapy can deplete immunosuppressive cells (MDSCs) 13 – 17 days after treatment creating an optimal time for vaccination. The WOKVAC vaccine is a plasmid vaccine encoding Th1 selective epitopes from HER2 and two other high-risk cancer antigens IGFBP-2 and IGF-1R. The Phase I trial of this vaccine reported that it is safe and all doses induced antigen specific Type I immune responses. We hypothesize that addition of WOKVAC to neoadjuvant chemo/HER2 targeted therapy will induce a significant increase in the number of patients with Th1 CD4+ and CD8+ T cells after neoadjuvant vaccine/chemo/HER2 therapy. **Methods:** Trial Design: Phase II single arm trial of WOKVAC vaccination with concurrent neoadjuvant taxane based chemotherapy, trastuzumab, and pertuzumab in patients with Stage I-III HER2+ (HR+/-) breast cancer. Enrolled patients will receive WOKVAC vaccine 150mcg on day 13 of cycles 1-3. WOKVAC vaccination may be given with either TCHP or THP. A maximum of 16 patients will be enrolled in this study. Objectives: The primary objective is to evaluate whether concurrent WOKVAC vaccine with chemotherapy and HER2 antibody therapy can significantly increase T-bet+ CD4+ and CD8+ TIL. Secondary objectives are to determine: (1) whether concurrent WOKVAC with neoadjuvant chemo/HER2 therapy is safe, (2) if the magnitude of vaccine induced antigen specific Th1 immunity after neoadjuvant therapy is associated with pathologic response. Statistical Methods: (1) In order to detect a 30% increase in the number of patients with Tbet+ CD4+ and CD8+ TIL in the enrolled patients with 80% power and a one-side alpha of 0.05, our enrollment goal for this study will be 16 patients. (2) Safety will be assessed per CTCAE v5.0. Benchmarks for safety needed to advance this trial concept to a Phase III study will be a grade 3 toxicity rate of $\leq 13\%$ and a grade 4 toxicity rate of $\leq 7\%$. (3) The induction of Th1 immunity will be compared against the presence or absence of a complete pathologic response to determine if there is a significant correlation using Pearson r correlation analysis. Targeted Accrual: The study will accrue up to 16 patients. Clinical trial information: NCT04329065. Research Sponsor: Department of Defense.

Oral Abstract Session

Second-line endocrine therapy (ET) with or without palbociclib (P) maintenance in patients (pts) with hormone receptor-positive (HR+/+)human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer (ABC): PALMIRA trial. *First Author: Antonio Llombart-Cussac, Hospital Arnau de Vilanova, Universidad Católica de Valencia, Medica Scientia Innovation Research (MEDSIR), Barcelona, Valencia, Spain*

Background: Cyclin-dependent kinases 4 and 6 inhibitors (CDK4/6i) in combination with ET has become a standard first-line treatment for pts with endocrine-sensitive, HR+/+/HER2- ABC. The optimal treatment after progression on a CDK4/6i remains unknown. This study aims to determine if P maintenance with an alternative ET improves the antitumor activity of second-line treatment in this patient population. **Methods:** A total of 198 pts with HR+/+/HER2- ABC who had disease progression to first-line P plus ET (aromatase inhibitor or fulvestrant) were included. Pts were eligible if they had clinical benefit to the first-line treatment defined as response or stable disease ≥ 24 weeks, or who had progressed on a P-based regimen in the adjuvant setting with disease progression after at least 12 months of treatment but no more than 12 months following P treatment completion. Pts were randomly assigned (2:1 ratio) to receive P plus second-line ET (letrozole or fulvestrant, based on prior ET) or second-line ET alone. Stratification factors were prior ET and the presence of visceral involvement. Primary endpoint was investigator-assessed progression-free survival (PFS) determined by RECIST v.1.1. Secondary endpoints included overall response rate (ORR), clinical benefit rate (CBR), overall survival, and safety. The 2-sided log-rank test ($\alpha = 0.05$) had an 80% power to detect a hazard ratio ≤ 0.59 in favor of P maintenance. **Results:** Between April 2019 and October 2022, 136 and 62 pts were randomized to receive P+ET and ET, respectively. Pts characteristics were well balanced. Median age was 59 years (range: 33-85), 61.1% were ECOG 0, 61.1% had visceral disease, and 89.9% received aromatase inhibitor + P as first-line treatment for metastatic disease. At median follow-up of 8.7 months and 155 PFS events, median investigator-assessed PFS was 4.2 months (95% CI 3.5–5.8) in the P+ET vs. 3.6 months (95% CI 2.7–4.2) in the ET arm (hazard ratio 0.8, 95% CI 0.6–1.1, $p=0.206$). This result was consistent across all stratification subgroups. 6-month PFS rate was 40.9% and 28.6% for P+ET and ET, respectively. Among 138 pts with measurable disease, no significant differences were observed in ORR (6.4% vs. 2.3%) or CBR (33.0% vs. 29.5%) for P+ET and ET, respectively. Grade 3-4 adverse events were higher in pts treated with P+ET (45.2% vs. 8.3%) and no new safety signals were identified. No treatment-related deaths were reported. **Conclusions:** For HR+/+/HER2- ABC pts, maintaining P with a second-line ET beyond progression on prior P-based therapy did not significantly improve PFS compared with second-line ET alone. Planned biomarker analysis may help identify which pts are more likely to benefit from this therapeutic approach. Clinical trial information: NCT03809988. Research Sponsor: Pfizer.

Oral Abstract Session

Dynamics and type of ESR1 mutations under aromatase inhibitor or fulvestrant combined with palbociclib after randomization in the PADA-1 trial. *First Author: Luc Cabel, Curie Institute, Saint-Cloud, France*

Background: In PADA-1, ER+ HER2- metastatic breast cancer patients who displayed a rising ESR1 mutation in blood (bESR1mut) during a first-line therapy with aromatase inhibitor (AI) and palbociclib were randomized between keeping the same treatment or switching to fulvestrant (FUL) and palbociclib (PAL) (Bidard, Lancet Oncol 2022). In this analysis, we investigated the kinetics of bESR1mut after randomization, under AI+PAL or FUL+PAL. **Methods:** Patients who had a rising bESR1mut detected and no synchronous disease progression underwent further serial ctDNA analyses at randomization and then every 2 months until disease progression. ctDNA analysis at randomization, i.e. before any change in endocrine therapy, was intended to study the impact of sampling fluctuations – since rising bESR1mut levels were often close to the limit of detection of the assay. bESR1mut detection was performed with droplet digital PCR (Jeannot, Oncogene 2020), while left over samples were subjected to next-generation sequencing, which allowed for bESR1mut typing and clonality assessment (Callens, Anal Chem 2022). **Results:** 172 patients were randomized in PADA-1 after having a rising bESR1mut and no synchronous disease progression. In these patients, bESR1mut had a median mutant allelic frequency of 0.8 % (range 0.1-25.8%) and a median copy number of 14 copies/ml of plasma (4-1033) on the “rising” sample, with no imbalance between randomization arms. Among them, N=75 (46.6%) had no bESR1mut detected at the repeat blood sample at randomization. Of note, these patients had a lower level of bESR1mut at “rising” compared to those who remained bESR1mut+ at randomization ($p=0.01$). After treatment start, patients who were switched to FUL+PAL experienced a higher rate of bESR1mut clearance at 2 months, compared to those remaining on AI (70.9% vs 32.8%, $p<0.001$). bESR1mut clearance at 2 months was associated with longer PFS (HR=0.36 95%CI=[0.25;0.52], $p<0.001$). The length of bESR1mut clearance was also longer in patients randomized to FUL (median: 7.3 mo 95%CI=[3.7;11.2] vs 1.9 mo 95%CI=[1.8;2.3]; $p<0.001$). At clinical disease progression, N=62 (83%) and N=49 (73%) patients tested positive for bESR1mut in the AI and FUL arms, respectively. Mutation typing in 95 patients with available material revealed that the Y537S mutation was the most prevalent (N=36, 37.9%), while N=25 (26.3%) and N=18 (69.2%) had polyclonal bESR1mut at time of rising bESR1mut and progression, respectively. The mutation type including Y537S- and the presence of polyclonal bESR1mut at time of rising bESR1mut did not influence patients' survival and hazard ratio between arms. **Conclusions:** bESR1mut ctDNA kinetics support the clinical benefit observed in the FUL+PAL arm over the AI+PAL arm. ESR1 mutation type and clonality did not impact the benefit of the treatment switch. Clinical trial information: NCT03079011. Research Sponsor: Pfizer; INCA PRT-K (Grant nb PRT-K19-110).

Oral Abstract Session

Final overall survival (OS) analysis from the phase 3 TROPICS-02 study of sacituzumab govitecan (SG) in patients (pts) with hormone receptor-positive/HER2-negative (HR+/HER2-) metastatic breast cancer (mBC). *First Author: Sara M. Tolaney, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Treatment of HR+/HER2- mBC includes sequential endocrine therapy (ET) combined with targeted agents followed by sequential single-agent chemotherapy (CT), which is associated with poor outcomes and quality of life. SG is a Trop-2-directed antibody-drug conjugate approved in multiple countries for pts with metastatic triple-negative breast cancer who received ≥ 1 prior systemic therapy and in the US for pts with pretreated HR+/HER2- mBC. In the phase 3 TROPICS-02 study, SG demonstrated a statistically significant OS benefit versus treatment of physician's choice (TPC) in pts with pretreated, ET-resistant HR+/HER2- mBC at the 2nd planned interim OS analysis with 390 events (median, 14.4 vs 11.2 mo; HR, 0.79 [95% CI, 0.65-0.96]; $P=0.02$; Rugo HS, et al. ESMO 2022. LBA76); this is considered the final analysis per the protocol. Here, we report the results of an exploratory analysis of OS from TROPICS-02 with a longer median follow-up (12.75 mo). **Methods:** Eligible pts with HR+/HER2- mBC who received prior taxane, ET, CDK4/6 inhibitor, and 2-4 prior lines of CT were randomly assigned 1:1 to receive SG (10 mg/kg IV d1 and 8, every 21 d) or TPC until disease progression or unacceptable toxicity. The primary endpoint was progression-free survival by blinded independent central review per RECIST v1.1. Key secondary endpoints included OS and safety. In an exploratory analysis, we evaluated OS by HER2 immunohistochemistry (IHC). **Results:** In total, 543 pts (median prior CT for mBC, 3; visceral metastases, 95%) were randomized to receive SG ($n=272$) or TPC ($n=271$). At data cutoff (Dec 1, 2022), 437 OS events had occurred (median follow-up, 12.75 mo), with 47 (8.7%) new deaths in the SG versus TPC groups (22 [8.1%] vs 25 [9.2%]) since the 2nd planned interim analysis. With this extended follow-up, SG continues to demonstrate improved OS versus TPC (median, 14.5 vs 11.2 mo; HR, 0.79 [95% CI, 0.65-0.95]; nominal $P=0.01$). The OS rates (95% CI) for SG versus TPC were 60.9% (54.8-66.4) and 47.1% (41.0-53.0) at 12 months, 39.2% (33.4-45.0) and 31.7% (26.2-37.4) at 18 months, and 25.6% (20.4-31.1) and 21.1% (16.3-26.3) at 24 months. Overall, 92% of pts were evaluable for HER2 status by IHC (HER2 IHC0, $n=217$; HER2-low, $n=283$). SG demonstrated improved OS versus TPC in the HER2 IHC0 (median, 13.6 vs 10.8 mo; HR, 0.86 [95% CI, 0.63-1.13]) and HER2-low (median, 15.4 vs 11.5 mo, HR, 0.74 [95% CI, 0.57-0.97]) groups. Updated safety will be reported at the time of presentation. **Conclusions:** The final OS analysis of the TROPICS-02 study confirms the clinically meaningful OS benefit of SG over single-agent CT in pts with pretreated, endocrine-resistant HR+/HER2-mBC. This improvement was independent of HER2-low status. This analysis reinforces SG as an effective and safe treatment for this pt population with limited treatment options. Clinical trial information: NCT03901339. Research Sponsor: Gilead Sciences, Inc.

Oral Abstract Session

A phase 2 study of HER3-DXd in patients (pts) with metastatic breast cancer (MBC). *First Author: Erika P. Hamilton, Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN*

Background: HER3-DXd is an antibody drug conjugate (ADC) comprised of a fully human anti-HER3 IgG1 monoclonal antibody (patritumab), attached to a topoisomerase 1 inhibitor via a tetrapeptide-based cleavable linker that has shown promising efficacy in pts with HER3-expressing MBC (Krop, 2022). This 3-part Phase 2 study examines efficacy of HER3-DXd across MBC subsets and defines the pt population likely to derive greater benefit (NCT04699630). **Methods:** Part A is reported here (Data cutoff 6Sep2022). Pts had HER2 negative MBC with measurable disease per RECIST v1.1, 0-2 prior chemo and prior endocrine therapy (ET) + CDK4/6 inhibitor for hormone receptor (HR)+ BC, or 1-3 prior chemo for triple negative BC (TNBC). Prior treatment (tx) with anti-HER3 agents and ADCs with exatecan derivatives were prohibited. Pts provided pre-tx tissue to evaluate the association of biomarker expression with progression free survival at 6 months (PFS_{6months}). Primary endpoints for Part A are objective response rate (ORR) and PFS_{6months}. Secondary endpoints are safety/tolerability, duration of response (DOR), and clinical benefit rate (CBR) (CR, PR or SD $\geq$ 180 days). **Results:** 60 pts were treated in Part A: median age 57.5 y, 98.3% female; median 5 prior lines of therapy (range 1-15). 32% had TNBC. 48% were HR+. 48% had liver and 32% had lung metastases. HER3 membrane expression was evaluated by overall % membrane positivity at 10X. 47/60 (78%) pts provided evaluable samples at baseline. Among evaluable pts, 64% (30/47) had HER3 expression $\geq$ 75%, 28% (13/47) had 25-74% expression and 8% (4/47) had <25% expression. The median tx duration was 5.2 mos and 21 pts remained on tx at data cut-off. All pts experienced a tx emergent adverse event and 93% of pts experienced a tx related AE (TRAE) with Gr $\geq$ 3 TRAE in 19 pts (32%). The most common ($\geq$ 25%) any grade TRAEs were nausea (50%), fatigue (45%), diarrhea (37%), vomiting (32%), alopecia and anemia (30% each). 7 pts (12%) experienced a serious AE (SAE), including 4 pts (7%) with a related SAE (interstitial lung disease, nausea/vomiting, pneumonitis, thrombocytopenia). 15% of pts experienced a dose reduction and 23% experienced a dose interruption due to an AE. 3 pts died while on tx, 2 unrelated to tx 1 cause unknown. ORR was 35% (95% CIs 23.1, 48.1) for all pts, and the CBR was 48% (95% CIs 35.2, 61.6). Pts with $\geq$ 75% HER3 expression had an ORR of 33% and CBR of 50%, pts with HER3 25-74% expression had an ORR of 46% and CBR of 54%. There were 4 pts with HER3 <25% expression, limiting efficacy assessment. The median DOR was 10.0 mos (95% CIs 5.5, NA). The PFS_{6months} was 60% for all pts, 50% for pts with HER3 $\geq$ 75%, and 70% for pts with HER3 25-74%. **Conclusions:** HER3-DXd had an acceptable safety profile, and the data further confirm the clinical activity in MBC in heavy pre-tx MBC across the broad range of HER3 expression levels. Parts B and Z are ongoing and data from this report support the potential entry of HER3-DXd into the therapeutic paradigm in MBC. Clinical trial information: NCT04699630. Oral Abstract Session

An age-specific pooled analysis of trastuzumab deruxtecan (T-DXd) in patients (pts) with HER2-positive (HER2+) metastatic breast cancer (mBC) from DESTINY-Breast01, -02, and -03. *First Author: Ian E. Krop, Yale Cancer Center, New Haven, CT*

Background: T-DXd is approved for use in pts with HER2+ unresectable or mBC after a prior anti-HER2-based regimen in the metastatic or (neo)adjuvant setting, based on the randomized phase 3 DESTINY-Breast03 study (Cortes et al. *N Engl J Med* 2022). Older pts with HER2+ mBC tend to have worse efficacy and safety outcomes, regardless of treatment (Evans et al. *Cancer Res* 2021). Outcomes of older pts treated with T-DXd have not been thoroughly examined. Here we report age-specific (<65 vs $\geq$ 65 years) efficacy and pooled safety analyses of T-DXd from DESTINY-Breast01, DESTINY-Breast02, and DESTINY-Breast03. **Methods:** DESTINY-Breast01 (data cutoff [DCO], March 26, 2021) and DESTINY-Breast02 (DCO, June 30, 2022) enrolled pts whose disease progressed on trastuzumab emtansine (T-DM1); DESTINY-Breast02 compared T-DXd to chemotherapy of physician's choice. DESTINY-Breast03 (DCO, July 25, 2022) included pts previously treated with trastuzumab and taxane; pts received either T-DXd or T-DM1. **Results:** At baseline, there were 44 (23.9%), 85 (20.9%), and 49 (18.8%) pts $\geq$ 65 years of age who received T-DXd in DESTINY-Breast01, DESTINY-Breast02, and DESTINY-Breast03, respectively. At DCO, median pooled treatment duration with T-DXd was 13.1 mo (range, 0.7-44.0) for pts <65 and 12.4 mo (range, 0.7-45.1) for pts $\geq$ 65. Key efficacy data are shown in the Table. Any-grade treatment-emergent adverse events (TEAEs), grade $\geq$ 3 TEAEs, and serious AEs were observed in 99.6%, 53.6%, and 24.3% of pts <65 and 100%, 65.5%, and 32.2% of pts $\geq$ 65, respectively. There were 125 (18.7%) and 45 (25.4%) TEAEs associated with T-DXd discontinuation in pts aged <65 and $\geq$ 65, respectively. Any-grade adjudicated drug-related interstitial lung disease/pneumonitis occurred in 11.8% of pts <65 and 17.5% of pts $\geq$ 65; grade 5 events occurred in 0.9% and 0.6% of pts <65 and $\geq$ 65, respectively. Additional efficacy and safety data will be presented. **Conclusions:** Results from this pooled analysis further demonstrate that T-DXd has a favorable benefit-risk profile in pts $\geq$ 65 years, with slightly increased toxicity, as expected. Clinical trial information: NCT03248492, NCT03523585, NCT03529110. Research Sponsor: Daiichi Sankyo Inc. and AstraZeneca.

Oral Abstract Session

Dynamic HER2-low status among patients with triple negative breast cancer (TNBC): The impact of repeat biopsies. *First Author: Yael Bar, Massachusetts General Hospital, Boston, MA*

Background: Trastuzumab deruxtecan (T-DXd) is FDA-approved for HER2-low, but not HER2-0 metastatic triple negative (TNBC) and hormone positive breast cancer. Therefore, identifying HER2-low status is of great clinical importance. Prior studies have shown HER2-low status in TNBC is dynamic, but the correlation between the number of successive biopsies (Bxs) conducted and the likelihood of a HER2-low result is unknown. **Methods:** Patients (pts) were identified from an institutional database including all pts with TNBC treated in a single large academic center between 2017-2022. Only pts with TNBC at diagnosis were included. Bxs without known HER2 status were excluded. Pathological, clinical, and demographic data were extracted. HER2-low was defined as HER2 IHC 1+, or 2+ with non-amplified ISH. The type of Bx was categorized as core Bx, surgical Bx, or metastatic Bx based on the timing and method of Bx acquisition. For the early-metastatic matched analysis, the core Bx was considered the early Bx, unless the core Bx was missing and then the surgical bx was used instead. For cases with several metastatic Bxs the first metastatic Bx was used. **Results:** 529 consecutive pts with TNBC at diagnosis were included. The proportion of pts with HER2-low result increased as the number of successive Bxs increased (60%, 74%, 83%, 87% and 100% when 1 (192 pts), 2 (235 pts), 3 (52 pts), 4 (38 pts), and 5-9 (12 pts) Bxs were conducted, respectively). In women without a prior HER2-low result, about one third converted to HER2-low with each successive additional biopsy (e.g. 322/529 at 1st biopsy, 44/131 on 2nd biopsy, 8/25 at 3rd biopsy, 3/8 at 4th biopsy). HER2 status distribution did not significantly vary between the different types of Bx (58%, 63%, and 54% of pts had a HER2-low result in their core, surgical or metastatic Bx, respectively; p=0.2). Among 246 women with matched core-surgical biopsies, one quarter changed their HER2 status (55% from low to 0, 44% from 0 to low, and 1% from low to 3+). Core-surgical HER2 status conversion rates did not differ between women who had neoadjuvant therapy with residual disease and women who had surgery as their primary intervention. Among women with both matched early-metastatic (70 pts) or two matched metastatic Bxs (39 pts), nearly half (44%) converted their HER2 status (68%, 26% and 6% or 35%, 59% and 6% were converted from low to 0, 0 to low and low to 3+ in the matched early-metastatic or the two matched metastatic Bxs, respectively). **Conclusions:** Our findings show that HER2 status is dynamic in pts with TNBC and support the idea that HER2-low is a spectrum, not a specific entity. We further report the novel finding that for pts with TNBC without a prior HER2-low result, repeat Bxs at progression can increase the chance of obtaining a HER2-low result and provide clinically impactful information. Whether the dynamic HER2 result represents underlying biology or analytic variation remains to be determined. Research Sponsor: None.

Oral Abstract Session

Randomized trial of fixed dose capecitabine compared to standard dose capecitabine in metastatic breast cancer: The X-7/7 trial. *First Author: Qamar J. Khan, University of Kansas Cancer Center, Westwood, KS*

Background: In metastatic breast cancer (MBC), oral capecitabine prescribed at the FDA approved dose of 1250 mg/m² twice daily, 14 days on followed by 7 days off, is associated with poor tolerance and high discontinuation rates. Mathematical models suggest a fixed dose, dose dense (7 days on, 7 days off) schedule may be optimal for capecitabine efficacy. We conducted a randomized trial to compare the efficacy and tolerability of fixed-dose capecitabine, 1500 mg twice daily, 7 days on, 7 days off (FD) to the FDA approved dose and schedule (SD). **Methods:** Females with MBC and any prior lines of endocrine therapy or chemotherapy were included. HER-2 positive patients were allowed with concurrent trastuzumab. Patients were stratified by line of chemotherapy (first or subsequent), measurable disease, and ER status, and randomized 1:1 to either FD or SD. The primary endpoint was 3-month progression free survival (PFS). Additional endpoints included PFS and overall survival (OS). Capecitabine related toxicities were solicited and graded at each visit. **Results:** Between October 2015 and April 2021, 153 patients were enrolled (N=80 FD, N=73 SD). 78% were hormone receptor positive/HER-2 negative, 11% each were HER-2 positive and triple negative. The 3-month PFS was 76% in the FD arm and 76% in the SD arm (HR=1.01; 95% CI, 0.52 to 1.94; p=0.99). Landmark analysis of PFS at 12, 24 and 36 months is reported. Non-proportional hazards were detected, so restricted mean survival time (RMST) was used to report estimates of effect. PFS (restricted mean) at 36 months was 13.9 months in the FD arm versus 14.6 months in the SD arm (hazard ratio for progression or death, 1.31; 95% CI, 0.56 to 1.15; p=0.24). OS (restricted mean) at 36 months was 21.2 months in the FD arm versus 19.6 months in the SD arm (hazard ratio for death, 0.80; 95% CI, 0.55 to 1.81; p=0.27). Toxicity related treatment discontinuation occurred in 21 patients (28.8%) in the SD arm compared to 6 patients (7.5%) in the FD arm (p<0.0006). Grade 2-4 toxicities (Table) occurred more frequently in patients receiving SD capecitabine (49.3%) as compared to FD capecitabine (25.0%) (p=0.0018). **Conclusions:** Fixed dose capecitabine (1500 mg twice daily) on a 7/7 schedule has less toxicity and similar survival when compared to standard BSA-based dosing on a 14/7 schedule in MBC. Clinical trial information: NCT02595320. Oral Abstract Session

CANKADO PRO-React eHealth support in patients with HR+ HER2- metastatic breast cancer receiving palbociclib and endocrine therapy and the affect on time to deterioration of quality of life: Primary outcome analysis of the multicenter randomized PreCycle trial. *First Author: Nadia Harbeck, Breast Center, Department of Obstetrics and Gynecology and CCC Munich, LMU University Hospital, Munich, Germany*

Background: The multicenter, randomized phase IV Intergroup PreCycle trial (NCT03220178) evaluated the impact of CANKADO-based ePRO assessment on quality of life (QoL) in HR+/HER2- locally advanced or metastatic breast cancer (MBC) patients (pts) treated with palbociclib (P) and an aromatase inhibitor or P+fulvestrant. CANKADO PRO-React, an EU-registered medical device, is an autonomous application reacting to changes in pt self-reported QoL. **Methods:** Between 2017 and 2021, 499 pts (median age 59y) from 71 centers were randomized (2:1, stratified by therapy line) between an active (A; CANKADO PRO-React) or an inactive arm (B; inform; limited CANKADO functionality). 412 pts (271 A; 141 B) were available for analysis of the primary endpoint, i.e. time to deterioration (TTD) of QoL (10-point drop on FACT-G), using an Aalen-Johansen estimator for cumulative incidence function of TTD DQoL with 95% pointwise confidence intervals (CI). Secondary endpoints included PFS, OS, and DQoL (QoL deterioration). **Results:** In all pts (ITT-ePRO), a significantly decreased risk (HR 0.6982) for the CANKADO active arm A with 95% CI [0.5059, 0.9635] regarding DQoL was observed (p=0.03). In 1stL pts (n=295), the decreased risk for arm A was 0.7162 (0.4839, 1.06; p=0.09), in 2ndL pts (n=117) 0.6614 (0.3744, 1.168; p=0.2). Absolute pt numbers declined in later visits; until about visit 30, FACT- G completion rates were 80% and higher; mean total scores were similar between arms; the change from baseline showed a linear decline and a nearly constant offset in favor of arm A, particularly in 1st L. No significant differences in clinical outcome were observed between arms: Median PFS (ITT population) was 21.4 (95% CI 19.4-23.7) (A) and 18.7 (15.1-23.5) months (B); median OS was not reached (A) and 42.6 months (B). **Conclusions:** PreCycle is the first multicenter randomized eHealth trial demonstrating a significant benefit of an interactive autonomous patient empowerment application on QoL in MBC pts receiving oral tumor therapy. Clinical trial information: NCT03220178. Research Sponsor: Pfizer.

Clinical Science Symposium

Association of tumor infiltrating lymphocyte quantity with survival in patients (pts) with metastatic breast cancer (MBC) receiving microtubule-targeting agents: Post hoc analysis CALGB 40502 (Alliance). *First Author: Daniel G. Stover, Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Stromal tumor infiltrating lymphocyte (sTIL) quantity is prognostic in primary breast cancer, yet MBC is characterized by lower sTILs. No study has definitively evaluated the association of sTIL quantity with survival outcome in the metastatic (met) setting without checkpoint blockade. CALGB (Alliance) 40502 was a randomized phase 3 trial of 799 MBC pts receiving first-line chemotherapy, comparing paclitaxel, nab-paclitaxel or ixabepilone with or without bevacizumab. We hypothesized that sTILs quantity is associated with outcome in MBC. **Methods:** 582 submitted hematoxylin and eosin slide images from 443 unique pts were evaluable for sTILs in accordance with International TILs Working Group methods. Analysis of sTILs was based on most recent available tissue, with 161/443 (36.3%) having recurrent/met tissue. Using prespecified thresholds of <5% (low) vs ≥5% (high) for sTIL distribution in the met setting, associations between sTILs low/high or as a continuous variable were evaluated with baseline characteristics and outcome. The primary objective was to evaluate the association of sTILs with progression-free survival (PFS) and overall survival (OS), with chemotherapy arm as a covariate. **Results:** High sTILs were more frequent among pts with hormone receptor (HR)-negative disease (64% HRneg vs 34% HRpos, p<0.001), with no significant association with treatment arm, age, menopausal status, race/ethnicity, or body mass index (BMI). Among all evaluable slides, mean sTILs were higher for primary tumors than met (mean 13.3% primary vs 8.4% met, p=3e-4). Among non-lymph node met sites, sTILs ranged from 1.3% (bone) to 9.5% (lung). Among 100 unique pts with paired primary and met slides, the primary had significantly greater mean sTILs (10.5% vs 7.7%, p=0.008). For the primary objective, Cox proportional hazard model of sTILs low vs high was significantly associated with worse PFS (HR 1.34; 95% CI 1.1-1.63, p=0.004) and OS (HR 1.32; 95% CI 1.07-1.63, p=0.009) when controlling for treatment arm. When controlling for both treatment arm and HR status, association of sTILs low vs high demonstrated similar trends but did not reach statistical significance for PFS (HR 1.2; 95% CI 0.97-1.47, p=0.09) or OS (HR 1.14; 95% CI 0.91-1.43, p=0.2). There was no significant interaction between sTILs and chemotherapy arm (all p-interaction >0.05). **Conclusions:** Immune activation measured by sTILs is significantly lower in met tumors than primary breast cancer and varies by met site. In this trial, sTILs were associated with progression-free and overall survival in chemotherapy-treated MBC, with a trend toward independent value adjusted for other prognostic features. Clinical trial information: NCT00785291. Research Sponsor: U.S. National Institutes of Health; Alliance Foundation Trials; BMS, Celgene.

Clinical Science Symposium

Characterization of the immune microenvironment in matched primary and metastatic breast cancer lesions from the AURORA study: BIG 14-01. *First Author: Florentine Hilbers, Department of Molecular Pathology, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Immunotherapy benefit in patients with metastatic breast cancer (MBC) is limited to patients with triple negative breast cancer and PD-L1 expression in the tumor sample. Multi-omics characterization of the anti-cancer immune response in MBC could provide novel insights into the mechanisms behind immune response failure. **Methods:** The AURORA program (NCT02102165) enrolled patients with MBC who received at most one line of treatment in the metastatic setting. RNA sequencing was performed on primary and metastatic lesions. Stromal tumor infiltrating lymphocytes (sTIL) were scored in line with the International Immuno-Oncology Biomarker Working Group for Breast Cancer recommendations. T cell and B cell receptor (TCR and BCR) analysis was performed with MiXCR. Deconvolution of bulk RNA sequencing data was performed using xCell. ImmuneScore-normalized Relative Abundance metastasis/primary Ratios (RAR) of immune cell types were calculated. All comparisons between primary and metastatic lesions were performed on matched samples. Wilcoxon signed-rank tests were used. **Results:** As expected, sTILs decreased from primary to metastatic lesion. However, 9% of metastatic lesions still had ≥20% sTILs. Matched RNA expression data was available for 204 patients. Relative abundance of macrophages (RAR 3.3, p<0.001) and Th1 cells (RAR 1.5, p<0.001) was increased in the metastases, while Treg cells (RAR 0.12, p<0.001), CD8+ T cells (RAR 0.32, p<0.001) and B cells (RAR 0.32, p<0.001) decreased the strongest. Metastases with ≥20% sTILs had higher Treg cells (p<0.001) and B cells (p<0.001) compared to metastases with low sTILs, which had more Th1 cells (p<0.001), mast cells (p<0.001) and NKT cells (p<0.001). De novo metastatic and synchronous primary samples had more BCR (p<0.001) and TCR (p<0.001) clones in common as compared to non-de novo metastatic cancers. **Conclusions:** sTIL percentage decreased from primary tumor to metastatic lesion. Metastatic lesions with many sTILs (≥20%) were enriched for immune response suppressing regulatory T cells. RNA expression levels from peripheral immune cells, a minimally invasive liquid biopsy source to predict response to therapy, survival and immune-related adverse events in patients with triple negative breast cancer enrolled in the GeparNuevo trial. *First Author: Hanna Huebner, Department of Gynaecology and Obstetrics, University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, Comprehensive Cancer Center Erlangen-EMN (CCC ER-EMN), Erlangen, Germany*

Background: The impact of immune checkpoint therapy on the tumor microenvironment including tumor-infiltrating immune cells is well described. However, little is known about the circulating immune repertoire and its association with treatment outcome. Hence, we set out to investigate the RNA phenotype of peripheral immune cells before and during treatment of patients enrolled in the GeparNuevo trial (Loibl S et al. Annals Oncol 2022). **Methods:** The GeparNuevo trial investigated the outcome after neoadjuvant nabP-EC-chemotherapy in combination with the anti-PD-L1 immune checkpoint inhibitor durvalumab versus placebo in patients with non-metastatic triple negative breast cancer. Blood was collected before therapy (baseline), after window, before epirubicin/cyclophosphamide and at end of treatment. RNA from circulating leucocytes of 117 patients was extracted and analyzed using a custom NanoString nCounter CodeSet. Expression of 290 immune-related genes was quantified. The association of RNA expression and signatures with outcome parameters like pathologic complete response (pCR), distant disease-free survival (DDFS), invasive disease-free survival (iDFS), overall survival (OS), and immune-related adverse events (irAEs) were investigated. **Results:** Immune cell type scores representing macrophages and neutrophils significantly increased during treatment, while B cell, T and Th1 cell scores decreased (p < 0.0001, respectively) regardless of treatment arm. Multivariate logistic respectively multivariate Cox regression analysis revealed a significant association of each baseline *DPP4* and *MYC* gene expression with pCR, DDFS, iDFS, and OS in patients. *CDK2*, *F5* and *HLA-DR* mRNA expressions were associated with the presence of irAEs. The signature score for *TNFR2* non-canonical *NF-κB* pathway, which is known for its protective capacity, was inversely associated with irAEs in the durvalumab arm (OR = 0.454, 95% CI 0.231-0.892, p = 0.0220). Multiple immune-related signatures at baseline were associated with tumor mutational burden. **Conclusions:** Our study indicates the importance of the peripheral immune phenotype for treatment response and survival. This association between RNA expression levels of circulating immune cells and outcome seems to be not only relevant for patients receiving immune checkpoint therapy, but also for those under standard chemotherapy alone. Clinical trial information: NCT02685059. Clinical Science Symposium

BRACELET-1 (PrE0113): Inducing an inflammatory phenotype in metastatic HR+/HER2- breast cancer with the oncolytic reovirus pelareorep in combination with paclitaxel and avelumab. *First Author: Amy Sanders Clark, University of Pennsylvania, Philadelphia, PA*

Background: In preclinical studies, the oncolytic reovirus pelareorep promoted an inflammatory tumor microenvironment (TME) by promoting greater infiltration of tumor infiltrating lymphocytes and upregulating PD-1/PD-L1 expression, potentially increasing the efficacy of immune checkpoint blockade. The addition of pelareorep to paclitaxel (PTX) was associated with improved survival (10.4 vs. 17.4 mos., HR = 0.65, $p = 0.1$) in a prior trial, with the greatest benefit in patients (pts) with hormone receptor-positive (HR+)/human epidermal growth factor receptor 2-negative (HER2-) disease ($N = 57$; 10.8 vs. 21.0 mos., HR 0.60, $p = 0.1$). **Methods:** This is a randomized phase 2 study in pts with HR+/HER2- metastatic breast cancer. Patients must have progressed on at least one hormone therapy with a CDK4/6 inhibitor. After a safety run-in for Cohort 3, patients were randomized 1:1:1 to PTX-alone (Cohort 1), PTX + pelareorep (Cohort 2), or PTX + pelareorep + avelumab (Cohort 3). The primary endpoint was overall response rate (ORR) at week 16 according to RECIST v1.1 without formal comparison across groups. Toxicity, progression-free survival (PFS) and overall survival were secondary endpoints. Blood samples were collected at cycle 1-day 1 (C1D1), C2D1 and C4D1, and T-cell receptor sequencing was performed. **Results:** Forty-eight pts were enrolled between June 2020 and June 2022. Median age was 55.5 yrs, range 37-74. Forty pts (83%) had visceral disease. Six pts (12%) previously received everolimus, and 3 alpelisib. Thirteen pts (27%) received prior taxanes in the neo/adjuvant setting. Three pts who withdrew consent prior to starting therapy and 2 pts who discontinued treatment after week 1 were considered non-responders and were censored for PFS. The most common pelareorep-associated toxicities were fever, chills, and flu-like infusion reactions, which were occasionally severe enough to require hospitalization in 5 (15%) pts despite acetaminophen prophylaxis. Nine pts (33%) discontinued pelareorep and 6 (35%) discontinued avelumab due to toxicity. Pelareorep increased T-cell repertoire turnover, with identification and expansion of new and pre-existing T-cell clones by C2D1. **Conclusions:** The addition of pelareorep to PTX is an active regimen with a high 6-month PFS rate worthy of further study. One third of patients discontinued either pelareorep or avelumab due to toxicity, highlighting the need for attentive supportive care. Survival data is maturing. Clinical trial information: NCT04215146. Research Sponsor: Oncolytics.

Poster Discussion Session

Efficacy of tucatinib+trastuzumab+capecitabine (TTC) after trastuzumab-deruxtecan (T-DXd) exposure in Her2-positive metastatic breast cancer: A French multicentre retrospective study. *First Author: Jean-Sebastien Frenel, Institut de Cancerologie de l'Ouest, Saint-Herblain, France*

Background: Recent guidelines have positioned T-DXd as a preferred treatment in the second line setting for HER2+ metastatic breast cancer (MBC). TTC is the preferred treatment in third line, however little is known on the efficacy of this combination after T-DXd exposure. **Methods:** We conducted a retrospective study in 12 French comprehensive cancer centers. All patients with HER2+ MBC treated with TTC after prior exposure to T-DXd were included. The primary end point was progression-free survival (PFS) in the whole population. Secondary end-points included overall survival (OS), PFS in subgroups and objective response rate. **Results:** Between 08/2020 and 12/2022, 101 patients were included. Median age was 56.4 y.o. (range 30.8 - 84.8). Median number of prior line of treatment for metastatic disease at TTC start was 4 (2 - 15). 82% and 95% of patients had received previous pertuzumab and T-DM1 respectively. The median duration of previous exposure to T-DXd was 8.9 months (1.4 - 31.4) and 82/101 (81%) patients had progressed under T-DXd while 19 had stopped T-DXd for toxicity or other reasons. TTC regimen was given as a 3rd line or 4th line for metastatic disease in 37/101 (37%) and beyond for the remaining patients. TTC was the immediate subsequent therapy to T-DXd for 86/101 pts (85%). With a median follow-up of 8.5 m (95%CI [7.7; 9.4]), 68/101pts (67%) have stopped TTC for progressive disease. Median PFS was 4.7 m (95%CI [3.8; 5.6]) and median OS not reached (95%CI [10.6; NA]) in the whole population. Patients treated with TTC as the immediate subsequent therapy to T-DXd, had a median PFS of 5.0 m (95%CI [4.0; 6.0]) and a median OS not reached (95%CI [11.9; NA]). Best response to TTC, evaluated by investigators in the 87/101 RECIST evaluable patients, was progressive disease, stable disease, partial response and complete response in 34%, 34%, 30% and 2% of patients respectively. At TTC initiation, 39 (39%) of patients had known brain metastases. Out of the 62 patients without known brain metastases at the initiation of TTC, 2 had brain metastases documented as a site of progression during TTC. **Conclusions:** In this large retrospective cohort, TTC shows significant efficacy for patients with HER2+ MBC previously exposed to T-DXd. Data and subgroup analyses will be updated for the meeting. Research Sponsor: None.

Poster Discussion Session

Pertuzumab retreatment in patients with HER2-positive locally advanced/metastatic breast cancer: Overall survival results of a phase III randomized trial (JBCRG-M05: PRECIOUS). *First Author: Yutaka Yamamoto, Kumamoto University Hospital, Kumamoto, Japan*

Background: We previously reported that pertuzumab (P) retreatment in combination with trastuzumab (T) + chemotherapy based on physician's choice (C) (PTC) significantly improved investigator-assessed progression-free survival (PFS) compared with T + C (TC) in patients with HER2-positive locally advanced/metastatic breast cancer (LA/MBC) previously treated with P-containing regimens in the phase III PRECIOUS study. Here we report updated OS at the median follow-up of 27.4 mo. **Methods:** Patients previously treated with P-containing regimens as 1st/2nd-line treatment for LA/MBC were randomly assigned 1:1 to two groups, PTC group and TC group, stratified by estrogen receptor (ER) status, previous treatment duration of P, number of previous chemotherapy regimens, and presence or absence of visceral metastasis. The primary endpoint was investigator-assessed PFS. The key secondary endpoints included OS, independent reviewer assessed PFS and safety. Superiority of PTC to TC will be tested using a log-rank test and a one-sided P-value of less than 0.05 will be considered an indicator of superiority. The distribution of OS will be estimated using the Kaplan-Meier method. In addition, the hazard ratio and one-sided 95% CI of the therapeutic effect between the groups will be calculated using the Cox proportional hazard model. **Results:** Of the 219pts enrolled, 217 (108 PTC, 109 TC) were included in the intent-to-treat analysis. At the data cutoff (Dec 31, 2021), OS and PFS events were 138 (63.6%) and 190 (87.6%), respectively. Updated median OS was significantly longer in the PTC group (median OS 36.2 vs. 26.5 mo.; HR = 0.73 [one side 95%CI upper limit, 0.97]; log-rank test $p = 0.0323$). In a prespecified subgroup analysis for OS including ER, visceral metastases, number of previous chemotherapy regimen was broadly constant without disease-free interval. Updated median investigator-assessed PFS (5.5 vs. 4.2 mo.; HR = 0.81 [one side 95%CI upper limit, 1.03]; stratified log-rank test $p = 0.019$) were also significantly better in the PTC group. Median PFS by independent review did not show the difference between two groups (4.4 vs. 4.4 mo.; HR = 1.03 [one side 95%CI upper limit, 1.36]; log-rank test $p = 0.561$). The serious adverse event rate did not differ between the groups (19.0% vs. 23.1%). There were no new safety signals in the two groups. **Conclusions:** Retreatment of P in combination with TC demonstrated significantly improved OS compared to TC. HER2 dual blockade with PT can contribute to improve survival in patients previously treated with P-containing regimens as 1st/2nd-line treatment for LA/MBC. Clinical trial information: NCT02514681. Research Sponsor: Chugai Pharmaceutical.

1016 Poster Discussion Session

The association of centromere amplification and response to trastuzumab in HER2+ metastatic breast cancer. *First Author: Charlotte Andrieu, National Institute for Cellular Biotechnology, School of Biotechnology, Dublin City University, Dublin, Ireland*

Background: Chromosomal instability and copy number aberration (CNA) burden can be associated with patients' survival in some cancers. Centromeres, chromosomal regions crucial for genomic stability, can be found altered by CNA in tumours but remain largely unexplored due to sequencing technologies. Using whole-genome sequencing (WGS) data from cases of long term, never relapsed HER2+ metastatic breast cancer (MBC) patients, also referred as exceptional responders (ExRs), we aim to better characterise the CNA profiles and underlying long-term survival of this "exceptional" cohort and investigate the centromeric and pericentromeric association with prognosis and treatment response. **Methods:** Two hundred and forty-three HER2+ MBC patients were enrolled in the HER2 Patients Project Database from St Vincent University Hospital, Dublin, Ireland. Eighty-five HER2+ MBC patients were identified as exceptional survivors (ExS) with an OS > 60 months (range 60-248 months), of which 28 never-relapsed and responded exceptionally (ExR) to trastuzumab. Patients with an OS < 60 months (N=158, range 0.2-59 months) were identified as non responders (NR). WGS was performed on 13 ExR tumours (primary or metastases) and matching control at a mean depth of 60X and 30X, respectively. Control-FREEC and CNVkit were used to characterise the CNA profiles and estimate the CNA burden. Samples from 10 NR patients were used for comparison with the ExR. **Results:** WGS analysis revealed that ExR samples are more impacted by gain rather than loss of copy overall, with a median fraction altered by gain of 0.24. No significant difference was observed between the ExR and NR in terms of CNA burden. However, a large fragment on chromosome 9 was amplified in 92% of ExR (12/13) which corresponded to the centromere (chr9q11) and a large heterochromatic block (chr9q12). A higher copy number status of this centromeric region was detected in the ExR, with a gain of at least 1 additional copy compared to the NR tumoral samples (P<0.001). The dichotomisation into high versus low copy number of the centromeric region of chromosome 9 was also observed in centromeres of chromosome 17 (P=0.009) and chromosome 19 (P<0.001). No case of polysomy was detected in our cohort and genes located near the centromeres, such as ERBB2 (amplified in both ExR and NR), were independent of the centromeres copy-number status. **Conclusions:** The identification of the genomic aberrations of these metastatic patients, treated with trastuzumab who never relapsed, increases our understanding of the mechanisms involved in MBC progression. Our results suggest that the centromere co-amplification of chr9q11-q12, chr17p11.1-q11.1 and chr19p11-q11 stratifies patients according to their OS. CNA status of the centromeric regions of chromosomes 9, 17 and 19 may therefore represent a novel prognostic predictor to trastuzumab response and new outcomes for patients. Research Sponsor: Cancer Clinical Research Trust (CCRT) Ireland.

First-line systemic treatment with palbociclib in women aged ≥70 years presenting with hormone receptor-positive advanced breast cancer: Results from the PALOMAGE program. *First Author: Elisabeth Carola, GHPSO, Senlis, France*

Background: Endocrine therapy (ET) combined with a CDK4/6 inhibitor is standard of care for hormone receptors-positive (HR+) advanced breast cancer (ABC). In France, 33% of BC are diagnosed in women aged 70 and older, contrasting with their constant underrepresentation in clinical trials. PALOMAGE, a prospective, observational, longitudinal real-life program, assessed the feasibility of ET combined with palbociclib (PAL), specifically in women aged ≥70 years with HR+ HER2- ABC. **Methods:** Depending on prior treatment for ABC and time of relapse, women were enrolled in two cohorts: ET-sensitive disease (no prior systemic treatment for ABC and no relapse within 1 year after adjuvant ET, cohort A) or ET-resistant disease (relapse on adjuvant ET or < 1 year after completion, or prior treatment for ABC, cohort B). Data collected at baseline and then every 3 months included: sociodemographic, clinical, biological, disease- and treatment-related, response, quality of life (QoL; EORTC QLQ-C30 and ELD14), geriatric (G8 and Geriatric-COre DatasEt (G-CODE)) and safety. Results of feasibility in cohort B (rate of PAL discontinuation at 6 months 28.8%) were reported at SABCS 2021. Here, we report results in cohort A, based on the rate of PAL discontinuation at 18 months for any reason as the primary endpoint. Secondary endpoints included time-to-treatment failure (TTF), progression-free survival (PFS), QoL, and safety. **Results:** For this analysis, 362 patients (from 130 sites) with sufficient data were considered: median age was 78 years (range: 70-94), ECOG was ≥2 in 19.2%, and visceral metastases was present in 39.8%. PAL starting dose was 125 mg, 100 mg, and 75 mg in 80.0%, 14.4%, and 5.6% of patients, respectively, and combined with an aromatase inhibitor in 93.6% or fulvestrant in 6.4%. Baseline scores showed G8 ≤14, ADL ≤5 and IADL ≤3 in 68.2%, 15.5% and 29.4% of patients, respectively. Among the 362 patients, 327 were evaluable for the primary endpoint. With a median follow-up of 20.7 months (95% CI: 18.8-22.0), the 18-month discontinuation rate for PAL was 41.9% (95% CI: 36.6%-47.2%), due to disease progression (20.8%), toxicity (7.7%), patient's choice (6.7%), death (4.6%), or other reason (2.1%). Median TTF and PFS were 22.7 months (95% CI: 19.1-26.0) and 28.1 months (95% CI: 25.6-not reached), respectively. Safety profile showed (360 patients evaluable) 54.4% all grade neutropenia (1.1% febrile neutropenia). Impact of geriatric status on effectiveness and safety will be presented, together with the evolution of QoL. **Conclusions:** In a large real-life population of older women with G8 impaired in two thirds and with ET-sensitive ABC, discontinuation rate of PAL at 18 months was 41.9%, with a median PFS of 28.1 months, consistent with PALOMA2 results. Optimized ET combined with PAL is feasible in unselected older women with HR+ ET-sensitive ABC. Research Sponsor: PFIZER.

1017 Poster Discussion Session

LEONARDA-1: Phase III randomized study of lerociclib plus fulvestrant in patients with HR+, HER2- locally advanced or metastatic breast cancer that has progressed on prior endocrine therapy. *First Author: Binghe Xu, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Lerociclib (GB491), a novel oral CDK4/6 inhibitor with continuously daily dosing, which has demonstrated anti-tumor response and a differentiated safety & tolerability profile in previous clinical trials. The LEONARDA-1 study assessed the efficacy of lerociclib and fulvestrant in endocrine-resistant advanced BC. **Methods:** This is a randomized, double-blind, placebo-controlled phase III study assessing lerociclib in combination with fulvestrant in pre/perimenopausal or postmenopausal, HR+, HER2- locally advanced or metastatic BC patients (pts) who had relapsed or progressed on prior endocrine therapy (ET). Eligible patients were allowed one prior line of chemotherapy for metastatic disease. Pre-/peri-menopausal pts also received goserelin. Pts were randomized 1:1 to receive lerociclib (150mg po bid, d1-28, q4w) or placebo (P) plus fulvestrant (F). The primary endpoint was investigator-assessed progression-free survival (PFS) based on RECIST v1.1. Secondary endpoints included PFS (assessed by BICR), overall survival (OS), response assessment, safety and tolerability, pharmacokinetic (PK) profile. **Results:** By December 2nd 2022 as data cut-off date, 275 pts were randomized, 137 to receive lerociclib + F and 138 to P + F. Median follow-up time was 7.36 months (range, 0.03-11.93+) for lerociclib + F vs 7.33 months (range, 0.03-11.27) for P + F. Baseline characteristics were well balanced (The median age was 54 years and 53.5 years, 41.6% and 44.9% were Pre-/peri-menopausal, 64.2% and 62.3% had visceral disease, 24.8% and 26.1% were primary resistant to prior ET, 28.5% and 29.0% received one line of chemotherapy for metastatic disease, respectively). At the time of cut-off date, 125 PFS events were observed with a median PFS of 11.07 months for lerociclib + F and 5.49 months for P + F (HR: 0.458; 95% CI: 0.317, 0.661, P<0.001 by log-rank test). In patients with measurable disease (n=240, 87.3%), the ORR was significantly higher in lerociclib + F 26.9% (2.5% complete response [CR]) vs 9.9% (0% CR) for P + F. Consistent benefit from lerociclib was seen in pre-/peri-menopausal and postmenopausal subjects. The most common adverse events (AEs) for lerociclib + F versus P + F were neutropenia (90.5% vs. 4.3%), leucopenia (86.9% vs. 6.5%), anemia (34.3% vs. 10.1%), thrombocytopenia (19.7% vs. 3.6%), and diarrhea (19.7% vs. 3.6%). Grade 3 or 4 neutropenia was reported in 46.7% pts on lerociclib + F (G3: 41.6%, G4: 5.1%) vs 0% pts on P + F. There was no case of ≥Grade3 diarrhea reported. The discontinuation rate due to AEs was 0.7% on lerociclib + F and 0% on P + F. Serious AEs were reported for 5.8% and 8.0%, respectively. **Conclusions:** Lerociclib at 150mg twice daily plus fulvestrant significantly improved PFS and ORR and demonstrated a favorable tolerable safety profile in pts with HR+ / HER2- endocrine-resistant advanced BC. Clinical trial information: NCT05054751. Research Sponsor: Genor Biopharmaceutical Ltd.

1019 Poster Discussion Session

Clinico-molecular characteristics associated with outcomes in breast cancer patients treated with CDK4/6 inhibitors: Results from the AURORA Molecular Screening Initiative. *First Author: Elisa Agostinetto, Institut Jules Bordet and Université Libre de Bruxelles (U.L.B.), Brussels, Belgium*

Background: CDK4/6 inhibitor (CDK4/6i) plus endocrine therapy (ET) is the recommended first line standard of care for patients with estrogen receptor positive (ER+), HER2-negative (HER2-) advanced breast cancer (ABC). However, not all patients derive the same benefit from this treatment. We aimed to identify factors associated with outcome in patients treated with CDK4/6i in a real-world setting. **Methods:** AURORA (NCT02102165) is an international program aimed at studying ABC by performing multi-omics profiling on paired primary tumors and metastases. Here we present exploratory results from AURORA patients treated with first line CDK4/6i + ET. DNA from primary and/or metastatic lesions and germline DNA was sequenced for 411 cancer-related genes. Endocrine resistance was defined according to the 5th ABC international consensus guidelines at the start of the first line. Local histology assessment of the primary tumor was used. Progression-free survival (PFS) was calculated from the start of CDK4/6i treatment until disease progression or death (whichever occurred first). **Results:** We analyzed 339 patients treated with CDK4/6i + ET in the first line. PFS differed significantly among the endocrine resistance subgroups (p<0.001). Both TP53 and acquired ESR1 mutations were associated with shorter PFS (hazard ratio [HR] 1.59 [95% CI 1.43-6.73], p=0.004 and 3.10 [95% CI 1.16-2.18], p=0.004 respectively). In a multi-variable analysis, acquired ESR1 mutations were significantly associated with worse PFS independently of endocrine resistance status (HR 2.42 [95% CI 1.01-5.79], p=0.048). Mutations in PIK3CA were not associated with outcome (HR 0.84 [95% CI 0.63-1.13], p=0.25). No PFS difference was observed between lobular and ductal tumors (HR 1.07 [95% CI 0.66-1.75], p=0.61). **Conclusions:** Endocrine resistance status and TP53 and acquired ESR1 mutations were associated with shorter PFS. Factors associated with poor outcome may be used to select patients to test alternative treatment strategies in clinical trials. Clinical trial information: NCT02102165. Research Sponsor: AURORA was funded by Breast Cancer Research Foundation (BCRF) as the main funder; Fondation Cancer (Luxembourg), Fondation contre le Cancer (Belgium), NIF Foundation, Barrie and Dena Webb, Candriam, Fondation Futur 21, Sogerim, Think Pink Belgium (SMART Fund), Cognizant Foundation, Eurofins Foundation, Fund Friends of BIG, managed by the King Baudouin Foundation; Pfizer grant for non-drug research; National Lottery (Belgium).

Subgroup	n (%)	PFS events	Median PFS months (95% CI)

Trastuzumab deruxtecan (T-DXd) vs treatment of physician's choice (TPC) in patients (pts) with HER2-low, hormone receptor-positive (HR+) unresectable and/or metastatic breast cancer (mBC): Exploratory biomarker analysis of DESTINY-Breast04. *First Author: Shanu Modi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: DESTINY-Breast04 (NCT03734029) showed improved progression-free survival (PFS) and overall survival for T-DXd vs TPC in pts with HER2-low (IHC 1+ or 2+/ISH-negative) mBC. We present exploratory biomarker analysis in pts with HER2-low, HR+ mBC. **Methods:** Biopsy specimens collected from 326 pts after prior treatment were analyzed using RNA-sequencing and intrinsic subtypes estimated by PAM50 gene expression. *ESR1* and *PIK3CA* mutations and known gene alterations associated with resistance to CDK4/6 inhibitors (CDK4/6i) were assessed in baseline (BL) circulating tumor DNA (ctDNA) samples from 414 pts by Guardant OMNI. Association with objective response rate (ORR) and PFS was evaluated. **Results:** Frequencies of BL intrinsic subtypes in the T-DXd and TPC arms were 41.3% and 46.6% for Luminal A, 48.0% and 37.9% for Luminal B, and 9.0% and 11.7% for HER2 enriched, respectively. According to ctDNA results in the T-DXd and TPC arms, respectively, *ESR1* mutations were observed in 51.3% and 54.0% of pts, *PIK3CA* mutations in 36.1% and 41.6% of pts, and at least one CDK4/6i resistance marker (pts with prior CDK4/6i) was detected in 71.5% and 70.2% of pts. Improved T-DXd efficacy was seen regardless of intrinsic subtype (Luminal A, Luminal B, HER2-enriched), *ESR1* mutation, *PIK3CA* mutation, or CDK4/6i resistance markers (Table). **Conclusions:** Greater clinical benefit was consistently observed with T-DXd vs TPC independent of intrinsic subtype, *ESR1* mutation, *PIK3CA* mutation, or known CDK4/6i resistance marker status. Clinical trial information: NCT03734029. Research Sponsor: This study was funded and designed by Daiichi Sankyo, Inc., and AstraZeneca.

Sequential use of antibody-drug conjugate after antibody-drug conjugate for patients with metastatic breast cancer: ADC after ADC (A3) study. *First Author: Rachel Occhiogrosso Abelman, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: Optimizing sequential use of Antibody Drug Conjugates (ADCs) is an area of unmet need and of rising clinical importance. With the recent approvals of sacituzumab govitecan (SG) for HR+/HER2- and triple negative metastatic breast cancer (MBC) as well as trastuzumab deruxtecan (T-DXd) for HER2-low MBC, many patients are now candidates for multiple ADCs. However, given potential cross-resistance based on antibody target vs payload (Coates et al, Cancer Discov. 2021), optimal sequencing remains uncertain. We evaluated the safety and efficacy of ADC after ADC for patients with HER2 negative MBC. **Methods:** We included all patients at an academic institution treated with more than one ADC for MBC. Each line of ADC beyond the first was evaluated for presence of the same "antibody target" or "payload" compared to prior ADC. Clinicopathological information was gathered by chart review. We defined "cross-resistance" as progressive disease (PD) at time of first restaging on second ADC. Progression-free survival (PFS) was evaluated as time from start of treatment to disease progression or death from any cause. All PFS estimation was done using the KM method. All pairwise comparisons across ADC were done using a Wilcoxon Rank Sum test to allow for divergences from normality in progression times. Significance was declared as a type I error less than 0.05. **Results:** A total of 193 patients with MBC were treated with ADCs between August 2014-February 2023. Among these, 32 patients were identified as having received more than one ADC (HR+/HER2- = 13, TNBC = 19, HER2 low = 22). Median age at time of second ADC was 57.1 years (range 31.3-88.6) and patients had received a median of 4 lines (range 2-12) of prior treatment before initiation of second ADC. The median PFS on the first ADC used (ADC1) was significantly longer at 7.55 months (95% CI 3.22-10.25) compared to a median of 2.53 months on the second ADC (ADC2) (95% CI 1.38-4.14) (p=0.006). PFS for ADC2 with antibody target change was 3.25 months (95% CI 1.38 months, n/a) compared to 2.30 months with no target change (95% CI 1.38 months, n/a) (p=0.16). At time of first imaging, cross-resistance was present in 17 cases (53.1%), absent in 12 (37.5%), and not evaluable in 3 cases. When the second ADC contained the same antibody target as the first, cross-resistance was present in 9/13 cases (69.2%), compared to 8/16 cases (50.0%) when the second ADC targeted a different tumor antigen. Similarly, differences were noted based on payload switch vs not. **Conclusions:** This study highlights a subset that had cross-resistance to ADC after ADC, while others had durable responses on latter lines of therapy, particularly if a different antibody target was utilized. Further research is needed to validate these findings and discern mechanisms of clinical resistance to guide optimal sequencing of ADC-based treatment options. HER2-low status discordance between primary and recurrent/metastatic breast cancer in a large-scale cohort. *First Author: Mingxi Lin, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Trastuzumab deruxtecan (T-DXd) was recently approved to treat unresectable/metastatic HER2-low breast cancer. However, patients whose primary tumor is HER2-0 but recurrent/metastatic lesion is HER2-low will lose therapeutic opportunities for T-DXd if a rebiopsy is not performed. In this study, with the largest sample size to date, we aimed to investigate the prevalence of HER2 status conversion. Moreover, it remains debated whether HER2-0 and HER2-low tumors have different prognoses, probably because previous studies did not assess HER2 status entirely based on recurrent/metastatic lesions. Our study aimed to fill this gap. **Methods:** We included 1299 patients with available HER2 status on both primary tumors and recurrent/metastatic lesions at Fudan University Shanghai Cancer Center and West China Hospital. **Results:** A total of 370 (28.5%) patients experienced HER2 status conversion throughout disease recurrence. 144 (31.7%) HER2-0 tumors converted to HER2-low. Inter-metastases heterogeneity of HER2 status was also observed. Compared to HER2-low tumors, HER2-0 tumors showed a higher TP53 mutation rate in the ER-positive subgroup, and a lower PIK3CA mutation rate in the ER-negative subgroup. Patients with tumors converting from HER2-0 to HER2-low had a longer overall survival (HR = 0.59, adjusted P = 0.033) than those with consistent HER2-0 status in the ER-negative subgroup. By combining four risk factors (ER status, Ki67 index, biopsy site, and disease-free interval), we established the first prediction tool to estimate the probability of HER2 status conversion from HER2-0 to HER2-low/positive. **Conclusions:** HER2 status was unstable during the disease course. Our prediction tool could help to screen out patients with a high probability of HER2 status conversion. Our results support that HER2-0 and HER2-low recurrent/metastatic tumors have different genomic features and prognoses. Research Sponsor: FUSCC.

Cyclin E cytoplasmic isoform to predict outcome and benefit to capecitabine treatment in patients with HR+/HER2- metastatic breast cancer from the GEICAM/2013-02 PEARL study. *First Author: Angel Guerrero, Instituto Valenciano de Oncología, GEICAM Spanish Breast Cancer Group, Valencia, Spain*

Background: Cytoplasmic cyclin E protein expression, serving as a surrogate for the low molecular weight cyclin E isoform (LMW-E), is a biomarker associated with aggressive breast cancer and predicts resistance to aromatase inhibitors in luminal breast cancer. We investigated the prognostic and predictive value of cytoplasmic and nuclear isoforms of cyclin E in HR+/HER2- metastatic breast cancer (MBC) patients receiving palbociclib CDK4/6 inhibitor and endocrine therapy (PALBO+ET) versus capecitabine (CAPE) in the GEICAM/2013-02 PEARL trial (NCT02028507). **Methods:** Expression of Cytoplasmic and Nuclear isoforms of cyclin E were assessed by immunohistochemistry (IHC). An H-score based on the proportion and intensity of stained cells was explored using median value to categorize in Low / High expression the Nuclear and Cytoplasmic scores (N and C, respectively). In addition, N and C were independently assigned according to staining intensity (1 = no staining, 2 = weak, 3 = intermediate and 4 = strong staining) and then, combined in 4 phenotypes (Ph): Ph1 (N-/C-); Ph2 (N+/C-); Ph3 (N+/C+); and Ph4 (N-/C+), where negative=1-2, and positive=3-4. Cox regression models' analysis were assessed to predict outcome and benefit to treatment, in terms of PFS and OS. Multivariate models were adjusted for confounders: age, site of disease, sites of metastasis, prior chemotherapy for MBC and treatment. Interaction analysis with treatment arm were performed. **Results:** Cyclin E protein was obtained from 344 tumors, with 73% being primary tumors and 27% metastatic. High expression of the Nuclear isoform was independently associated with significantly worse OS (median OS [mOS]=34.23 months [m] for low expression vs 25.72m for high expression; adjusted HR=1.48; p-value=0.016). Phenotype analysis supported this finding, with Ph3 (N+/C+) and Ph4 (N-/C+) demonstrating the worst (mOS=19.55m) and best (mOS=37.19m) outcomes, respectively (using Ph1 as reference, Ph3 HR=2.92; p-value=0.0013). The interaction between the treatment arm and Cytoplasmic cyclin E expression was significant (p=0.0052). Patients with high expression of the Cytoplasmic isoform had significantly better PFS with CAPE (mPFS=14.8m) than with PALBO + ET (mPFS=5.73m) (HR=1.9, p-value=0.0418). Ph4 (N-/C+) had also significantly better PFS for CAPE (mPFS=22.67m) than for PALBO + ET (mPFS=8.51m) (HR=2.94; p-value=0.036). **Conclusions:** This study confirms Cyclin E as a poor prognostic marker associated with worse overall survival in luminal MBC patients. Low molecular weight Cyclin E, detected as Cytoplasmic Cyclin E, identifies luminal MBC that benefit more from CAPE than from PALBO + ET. The low molecular weight Cyclin E isoform appears to be a promising predictive biomarker for the benefit of CAPE and resistance to PALBO + ET treatments in this population. Early prediction of endocrine responsiveness in ER+/HER2 negative MBC: Pilot study with 18F-fluoroestradiol (18F-FES) CT/PET. *First Author: Alessandra Grennari, Università del Piemonte Orientale - Dipartimento di Medicina Traslazionale - DIMET, Novara, Italy*

Background: Estrogen receptors (ER) are considered predictive biomarkers to identify ER+ MBC patients who would likely benefit from endocrine therapies (ET). However, 30 to 40% of ER+ MBC patients fail to achieve a durable response. 18F-FES PET/CT has been shown to represent a valuable and accurate diagnostic tool to determine ER status at the level of metastatic sites and can be proposed as a valid alternative to biopsy of metastatic lesions. In this trial, we evaluated 18F-FES PET/CT as a predictive tool for endocrine responsiveness in ER+ MBC. **Methods:** ET-FES is an international, multi-center, academic clinical trial, conducted within the JTC-2011 ERA-NET TRANSCAN programme. Patients with ER+/HER2- MBC and first evidence of relapse were eligible for the study. All patients underwent a baseline 18F-FES PET/CT in addition to conventional staging procedures. Tumors were classified as endocrine sensitive if overall Standardized Uptake Value (SUV) ≥ 2 ; SUVmax was measured in the 3 largest lesions to quantify ER expression and a cutoff value of 2 was used to dichotomize results (endocrine sensitive vs resistant). In the ET-FES trial, patients with SUV ≥ 2 received single agent ET until PD; patients with SUV < 2 were randomized to receive single agent ET or chemotherapy (CT). The predictive role of 18F-FES PET/CT results was assessed for PFS and OS by univariate and multivariate analyses. **Results:** Overall, 147 patients (142 for ITT analysis) were enrolled from 04/2015 to 12/2020; 113 presented with 18F-FES SUV ≥ 2 and received ET; 29 pts, with SUV < 2 were randomly assigned to ET or first line chemotherapy (CT), following local clinical practice. After a median follow up of 4.6 years, 51 deaths had occurred (54.2%). Median PFS was 18.0 months (95%CI 11.2- 22.9) in the overall population and in 18F-FES SUV ≥ 2 versus 12.4 months (95%CI 3.1 – NR) in patients with SUV < 2 treated with ET and 23.0 months (95%CI 7.7 – 30.0) if treated with CT. Median OS was not reached in the overall patient population and in patients with SUV ≥ 2 , treated with single agent ET. Median OS was 28.1 months (95%CI 14.2 – NR) in patients with SUV < 2 treated with ET versus 52.8 months (95%CI 16.1 – NR) if treated with CT. The Kaplan–Meier estimate of OS at 48 months was 64.4% (SE +/-5%) in all patients and 66% in 18F-FES SUV ≥ 2 ; at 60 months was 54.4% (SE +/-6%) and 57% (SE +/-5%), respectively. Among the 113 pts with SUV ≥ 2 treated with ET, the Kaplan–Meier estimate of OS at 60 months was 73.0% if treated with aromatase inhibitors versus 35% in case of fulvestrant or tamoxifen ($p < 0.0005$). **Conclusions:** ET-FES is the first prospective trial to assess the efficacy of ET alone in patients selected for endocrine responsiveness on the basis of whole body molecular ER imaging by 18F-FES PET/CT. These results suggest that the efficacy of ET may be maximized by using the appropriate assessment of endocrine responsiveness at the different metastatic sites. Clinical trial information: EUDRACT 2013-000-287-29. Research Sponsor: ERANET TRANSCAN JTC - AIRC (Italian Foundation for Cancer Research).

Poster Session

Clinical features, genomic landscapes, and survival outcomes of HER2-low breast cancer. *First Author: Jin Juan, Department of Breast and Urological Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Novel human epidermal growth factor receptor 2 (HER2)-directed antibody–drug conjugates prompt the identification of the HER2-low subtype. To investigate whether HER2-low breast cancer can be defined as a distinct biological subtype, our study conducted a comprehensive analysis on the clinical and molecular features among patients with different HER2 statuses. **Methods:** Clinical and genomic data of 579 metastatic breast cancer patients were reviewed from our next-generation sequencing (NGS) database. Genomic data of breast tumor samples was generated by targeted NGS using a cancer-related gene panel. The cohort included 220 HER2-zero, 194 HER2-low and 165 HER2-positive patients according to the HER2 status from the most recent pathological results. **Results:** First, the clinicopathological characteristics of HER2-low patients were associated with hormone receptor (HR) status. Less lymph node invasion and higher bone metastasis in HER2-low patients were probably because of the higher percentage of HR-positive tumors in HER2-low patients than HER2-zero and HER2-positive patients (63.19%, 42.02% and 28.00%, respectively, $p < 0.0001$). Second, HER2 status shifting from primary to recurrent breast cancer was common, with 38.1% and 48.4% of HER2-zero primary tumors converting to HER2-low tumors when they metastasized in the whole population and the HR-positive subgroup, respectively. Third, HER2-low patients had more brain and lung metastases and cases of de novo stage IV breast cancer than HER2-zero patients in the HR-positive subgroup. Fourth, germline *BRCA2* mutations were observed only in HER2-low patients (11/139, 7.91%) and HER2-low tumors had more somatic *PIK3CA* mutations than HER2-zero tumors in the HR-negative subgroup. Fifth, HER2-low patients had a longer median overall survival (mOS) and median disease-free survival (mDFS) than HER2-zero patients (mOS: 49.1 vs. 30.3 months, log rank $P = 0.0005$; mDFS: 28.17 vs. 20.27 months, log rank $P = 0.036$), but difference was not evident when paired by HR status. Finally, three molecular subtypes based on genomic alterations in HER2-low breast cancer were identified, and Cluster 2, which enriched in *TP53* mutations, was significantly associated with worse outcomes, which provided novel insights into heterogeneity in HER2-low breast cancer. **Conclusions:** The clinical and molecular significance of HER2-low status was influenced by HR expression, and HER2-low tumors had distinct features in subtype analyses based on HR status. Our elaboration of molecular subtypes in HER2-low tumors encourages clinicians to consider the heterogeneity in HER2-low breast cancer. Prostate-specific membrane antigen (PSMA) expression in patients with metastatic triple negative breast cancer: Initial results of the PRISMA study. *First Author: Guilherme Nader Marta, Academic Trials Promoting Team, Institut Jules Bordet and l'Université Libre de Bruxelles (U.L.B), Brussels, Belgium*

Background: Radioligand therapy (RLT) targeting prostate-specific membrane antigen (PSMA) prolongs survival of patients (pts) with prostate cancer. Preliminary immunohistochemistry (IHC)-based studies suggest that PSMA is highly expressed in triple negative breast cancer (TNBC). The PRISMA study aims to assess PSMA expression in pts with metastatic TNBC (mTNBC) via positron-emission tomography/computed tomography (PET/CT) to evaluate the feasibility of PSMA-targeted RLT for TNBC. **Methods:** PRISMA is a prospective, single-center study that enrolled pts with progressive mTNBC and measurable disease on ^{18}F -FDG PET/CT to undergo ^{68}Ga -PSMA-11 PET/CT. TNBC definition (ASCO/CAP) was based on the IHC of the primary breast cancer (BC) or metastasis. Target lesions (TL) were defined as metastatic lesions ≥ 1.5 cm with significant uptake in ^{18}F -FDG-PET/CT. The same TL regions were propagated to the ^{68}Ga -PSMA-PET/CT. ^{68}Ga -PSMA-11 maximum standard uptake value (SUV_{max}) was measured for each TL. PSMA patterns A and B were defined according to presence of a majority (pattern A) or a minority (pattern B) of positive TL on ^{68}Ga -PSMA (ie. uptake greater than that of normal liver parenchyma). Mann-Whitney U test was used to assess differences in median SUV_{max} (mSUV_{max}) between subgroups. **Results:** Ten pts with progressive mTNBC were enrolled. One pt was excluded due to lack of TL on ^{18}F -FDG-PET/CT. Median age was 48 years (range 36-68), median number of TL per patient was 8 (5-18). Five pts had a TNBC IHC since the initial BC diagnosis, while 4 had a switch to TNBC (4 with initial estrogen receptor [ER]-positive and 1 with HER2-positive BC). All evaluable pts had inter- and intra-organ heterogeneity in PSMA uptake in TL and 2 pts had some mismatch with FDG-positive and PSMA-negative TL. mSUV_{max} was 2.99 (range 1.7-6.3) in the overall population and was higher in pts with pattern A (5.1 vs 2.6 in patterns A and B, respectively, $p = 0.03$). mSUV_{max} was numerically higher in younger pts (5.0 vs 2.6 in pts < 50 y and ≥ 50 y, $p = 0.28$), PD-L1-positive (5.0 vs 2.7 in PD-L1-positive and -negative, $p = 0.14$), de novo metastatic disease (5.0 vs 2.9 in de novo and recurrent BC, $p = 0.38$) and those with ER-negative primary breast tumor (3.4 vs 3.0 in ER-negative and ER-positive primary BC, $p = 0.9$). **Conclusions:** A significant PSMA uptake was observed in a proportion of pts with mTNBC. Inclusion of additional pts and translational analyses will allow the identification of PSMA expression determinants. PSMA-targeted RLT may be considered as an innovative therapeutic strategy to be explored in selected pts with mTNBC. Research Sponsor: Association Jules Bordet.

Concordance between liquid and tissue biopsy in participants with newly diagnosed recurrent breast cancer. *First Author: Ana Elisa Lohmann, University of Western Ontario, London, ON, Canada*

Background: Tissue biopsy is recommended to confirm breast cancer (BC) recurrence. Liquid biopsy (including circulating tumour cells (CTCs) and circulating tumour DNA (ctDNA)) is a non-invasive approach for detecting cancer that may provide information to identify treatment choices and replace invasive biopsies. This ongoing study aims to assess the concordance between tissue and liquid biopsy testing in subjects presenting with suspicion of distant recurrence from BC. **Methods:** Patients with suspected metastatic BC were enrolled; tumour characteristics and treatment were recorded. Blood samples were collected within 30 days before tissue biopsy, or within 7-28 days after tissue biopsy and before any systemic or radiation treatment. Samples were shipped to EPIC Sciences and processed within 96 hours; after plasma isolation, nucleated cells were plated; slides and plasma were banked. CTCs were identified using Epic Sciences digital imaging and machine learning algorithms. Single-cell isolation for genomic ctDNA analysis was performed. Cell free DNA was analyzed using a validated NGS panel to detect ctDNA alterations. The presence of metastases was classified as suspicious, highly suspicious, definitely metastatic BC or other by the treating oncologist based on the patient's clinical presentation and biopsy pathology results. Epic Sciences classified samples into similar categories based on CTC and ctDNA assay results. These classifications were performed independently. Sensitivity of the Epic Sciences methodology to detect metastatic BC (as determined by the treating oncologist), and its false positive rate were calculated. **Results:** 100 patients were enrolled from June 2020 to October 2022; shipping delays precluded EPIC assays in six patients; 94 patients were analyzed. Of 83 cases deemed suspicious, highly suspicious, or definitely metastatic BC by the treating oncologist, 61 were also deemed so by Epic Sciences (sensitivity of 73.5%, 95% confidence interval, CI 63.1% - 81.9%). Of 66 cases assigned as suspicious, highly suspicious, or definitely metastatic BC by the Epic Sciences, 4 had new primary cancers (3 lung cancer, 1 hepatocarcinoma), for a false positive rate of 6.1% (95% CI 1.9% - 15.0%). One additional case was classified as un-specified adenocarcinoma (possibly breast) by the treating oncologist; resolution awaits further follow-up. **Conclusions:** Preliminary results show that 73.5% of distant BC recurrences were correctly identified by liquid biopsy. A small number of false positive results occurred in patients with other new primary cancers. Additional analyses with CTC characterization are ongoing. Poster Session

Effect of homologous recombination deficient (HRD) breast cancers on a distinct immune marker phenotype by comprehensive genomic and immune profiling (CGIP). *First Author: Heidi Chwan Ko, Labcorp Oncology, Durham, NC*

Background: Preclinical evidence suggests that breast cancer with features of genomic instability may upregulate the host antitumor immune response by producing neoantigens through DNA damage and increasing interferon production through the stimulator of interferon genes (STING) pathway. In this study, we evaluated the association between features of genomic instability and immune response in a real-world breast cancer population. **Methods:** We analyzed retrospective comprehensive genomic and immune profiling (CGIP) results from 529 breast tumors tested in the real-world clinical setting. We defined the HRD phenotype as tumor with any single nucleotide variants (SNV), indels, copy number variations (CNV) or fusions in the following genes: ARID1A, ATM, ATRX, BAP1, BARD1, BLM, BRCA1/2, BRIP1, CHEK1/2, FANCA, MRE11A, NBN, PALB2, RAD50 and RAD51. Otherwise, they were considered HR-proficient (HRP). PD-L1 expression (CPS positive ≥ 10) and TMB (high ≥ 10 Mut/Mb) were determined using IHC and DNA sequencing, respectively. mRNA expression signatures of tumor inflammation (TIGS, strong/moderate/weak), cell proliferation (CP, high/moderate/poor) and cancer testis antigen burden (CTAB, high/low) were determined by RNA-sequencing from a 395-gene panel. We used over-representation and proportion analysis using chi-squared test to determine association of HRD to immune correlates. **Results:** Among 529 cases, the median patient age was 63.2 years (25.5-93.5). The majority of patients were female (519, 98%), and the most common tumor histology was invasive ductal carcinoma (287, 54%). A total of 405 (77%) and 124 (23%) of patients had HRD and HRP phenotypes, respectively. A greater proportion of HRD tumors (16%) had higher TMB compared to HRP (5.6%, $p=0.003$). HRP tumors showed a relatively low CP index, whereas HRD tumors were associated with a moderate CP index score ($p=0.007$). HRD phenotype was associated with a significantly higher proportion of weakly inflamed tumors, as represented by lower TIGS scores ($p=0.007$). No significant difference in PD-L1 or CTAB was found between HRD and HRP phenotypes. **Conclusions:** Breast tumors with mutations in the HR genes demonstrated greater TMB and moderate cellular proliferation index of both tumor and immune cells, which suggest susceptibility to immune checkpoint inhibitors. Interestingly, this cohort lacked elevated markers of immune infiltration (TIGS), indicating a mechanism of potential tumor immune evasion. These results suggest that CGIP may allow for more informed treatment decisions in HRD breast cancers. Furthermore, assessment of HR status and immunotherapy susceptibility may support clinical trial selections for therapies targeting the complex interplay of genomic and immune components of breast cancer (e.g., a combination of PARP inhibitor and immunotherapy). Metastatic patterns and outcomes by HER2 and hormone receptor (HR) status in patients (pts) with metastatic breast cancer (mBC). *First Author: Qianyu Yuan, Flatiron Health, New York, NY*

Background: HER2-low status in mBC is predictive of benefit to trastuzumab deruxetan, but whether it is biologically distinct from HER2-neg disease is unclear. To better understand the prognostic significance of HER2-low status, we assessed patterns of metastases and real world overall survival (rWOS) by HER2 and HR status. **Methods:** Pts with mBC diagnosis from 1/1/2011 to 5/31/2022 were selected from the nationwide de-identified Flatiron Health electronic health record (EHR)-derived database. HER2 and HR status was derived from human abstraction (IHC 0-1+/2+/3+, FISH pos/neg, ER/PR) and machine learning-extraction (to classify IHC 0/1+). HER2 and HR tests prior and up to 60 days after metastatic diagnosis date (met Dx date) were included, results closest to met Dx date were used. Sites of metastasis (SOM) were grouped into mutually exclusive groups: brain, non-visceral (bone, skin, lymph node) and visceral (liver, lung, etc). Metastatic patterns stratified by HR/HER2 status were compared using chi-square tests. The association between HER2 status and rWOS, stratified by HR status, was evaluated using Cox models adjusted for age, race/ethnicity, practice, SOM, SES, and stage. rWOS stratified by HR/HER2 status and SOM were estimated via KM analysis. **Results:** Among 22,932 pts with mBC, HER2-low prevalence was 49%. HER2-low mBC was more likely to be HR+ than HER2-neg or HER2+ (84%, vs 70% and 65%; $p<0.01$). Pts with HER2-low and HER2-neg mBC had similar SOM overall, distinct from HER2+. For example, among HR+ pts, HER2-low and HER2-neg pts were less likely than HER2+ pts to have brain (4% and 4% vs 10%; $p<0.01$) or visceral metastases (51%, 50% vs 58%; $p<0.01$) but more likely to have non-visceral metastases (45% and 46% vs 32%; $p<0.01$). Compared to HER2-low pts, HER2-neg pts had similar rWOS if HR+ (hazard ratio 1.02, 95% CI 0.98-1.08) and slightly worse if HR-neg (hazard ratio 1.18, 95% CI 1.03-1.21). rWOS varied by HR/HER2 status and SOM. **Conclusions:** Our findings indicate that HER2-low mBC has biologic similarities to HER2-neg mBC. While slight differences were observed between HER2-neg and HER2-low pts in the HR-neg subgroup, overall rWOS differences were associated more strongly with HER2+ status, HR+ status, and metastatic pattern, indicating that HER2-low status may be more informative as a predictive rather than a prognostic biomarker. Research Sponsor: Flatiron Health.

Comparison of immune microenvironment between primary and metastatic breast tumors. *First Author: Heidi Chwan Ko, Labcorp Oncology, Durham, NC*

Background: Immune evasion is one of the mechanisms by which cancer cells gain the ability to metastasize from the primary tumor to distant sites. In triple-negative breast cancer (TNBC), metastatic tumors are shown to be more immunologically silent than primary tumors. As a result, there are varying degrees of responses to immunotherapy between early-stage and metastatic tumors. Positive clinical responses to immune checkpoint inhibitors (ICIs) are seen in patients with early-stage TNBC regardless of PD-L1 expression. In this study, we investigated the differences in the immune signatures of primary and metastatic breast cancer in a real-world patient population. **Methods:** We analyzed retrospective comprehensive genomic and immune profiling (CGIP) results from 529 breast tumors tested in the real-world clinical setting. Tumor specimens were classified as primary breast (PB), any lymph nodes (LN; regional and non-regional) or metastatic visceral (MV) sites. LN samples were chosen as positive controls due to expected elevated inflammatory signaling. PD-L1 (CPS positive ≥ 10) and TMB (high ≥ 10 Mut/Mb) were determined using IHC and DNA sequencing, respectively. mRNA expression signatures of tumor inflammation (TIGS, strong/moderate/weak) and expression of LAG3, TIGIT and TIM3 were determined by RNA-sequencing from a 395-gene panel. LAG3, TIGIT and TIM3 were selected due to emerging clinical trials in solid tumors. We used over-representation and proportion analysis using chi-squared test to determine the association of specimen sites to various genomic and immune correlates. **Results:** Among 529 cases, the median patient age was 63.2 years (25.5-93.5). The majority of patients were female (519, 98%), and the most common tumor histology was invasive ductal carcinoma (287, 54%). A total of 224 (42%), 72 (14%), and 232 (44%) of patients had specimens from PB, LN, MV, respectively, while 1 (0.19%) patient had an unknown source. Samples of PB harbored greater degree of immune infiltration, demonstrating higher TIGS score than MV ($p=0.014$). Primary lesions also demonstrated a greater proportion of PD-L1 positive than metastatic lesions (44% vs 21%, $p<0.001$) and higher expressions of immune checkpoints such as TIGIT ($p<0.001$), LAG3 ($p=0.037$) and TIM3 ($p<0.001$). **Conclusions:** We found that non-lymph node breast cancer metastases harbor a less active immune response than primary breast lesions, showing a lower degree of immune cell infiltration and decreased expression of immune checkpoint markers. These findings support the notion that the immune microenvironment of breast cancer metastases is immunosuppressive and may exhibit a tempered response to ICIs. Therefore, combination treatments of ICIs with chemotherapy, targeted therapies or cancer vaccines may be promising therapeutic approaches to enhance the immune responses and potentially overcome resistance to ICIs in metastatic breast cancer. Gene expression profiling of paired primary breast cancers and brain metastases to identify brain metastases-specific biological changes. *First Author: Gaia Griguolo, Department of Surgery, Oncology and Gastroenterology, University of Padua, and Division of Medical Oncology 2, Veneto Institute of Oncology IOV-IRCCS, Padova, Italy*

Background: Despite the clinical impact of breast cancer (BC) brain metastases (BM), their biological complexity still remains poorly understood. We here evaluate the genomic profile of paired primary and metastatic samples to characterize biological changes acquired by BC during metastatization to the brain. **Methods:** The expression of 758 BC-related genes was evaluated using the BC360 Panel (nCounter platform) in matched primary BC and their associated BM. Intrinsic molecular subtyping was determined using the PAM50 subtype predictor (Parker et al. JCO 2009). Hormone receptor (HR) and HER2 status were evaluated on the BCBM. A False Discovery Rate (FDR) corrected paired two-class SAM was used to identify changes in single genes expression between paired BC and BM samples. **Results:** Twenty-one matched primary BC and BM samples were analyzed. BC subtype evaluated on the BMs was distributed as follows: 24% (N=5) HR-/HER2-, 24% (N=5) HR+/HER2- and 52% (N=11) HER2+. A considerable shift in PAM50 subtype was observed between primary BC and paired BM. While subtype concordance was high for HER2-enriched (HER2-E) tumors (100%), all Luminal A (LumA) primary BCs switched to either HER2-E (75%) or Luminal B (LumB, 25%) on the BM sample, as did 45% of Basal-like BCs (Basal to HER2-E). A clinical switch from HER2- primary BC to HER2+ BM (defined by IHC and ISH) was observed in only one pair (5%). Consistently, HER2-E ($p<0.001$) and LumB ($p=0.001$) PAM50 signatures were significantly more expressed, while the LumA ($p<0.001$) and Normal-like ($p=0.001$) signatures were significantly less expressed in BMs as compared to paired primary BCs (FDR-corrected Wilcoxon paired signed rank test). No significant change was observed in the expression of the Basal-like signature ($p=0.562$). Among the 758 evaluated genes, 60 and 318 genes, respectively, were significantly up- and downregulated in BMs as compared to primary BC (FDR $<5\%$). Upregulated genes were enriched, among others, in genes involved in survival and migration (e.g. FGFR4), cell proliferation (e.g. CCNB1, CDK1) and HER2-amplicon (e.g. ERBB2, GRB7). Down-regulated genes were enriched in genes involved in immune response (e.g. CD8A, CCL5, PDCD1LG2, TNF), angiogenesis (e.g. PDGFRB) and response to hormonal stimuli (e.g. ESR1, BCL2). **Conclusions:** Gene-expression profiling of matched primary BCs and BMs shows recurrent gene expression modifications in metastatic samples which might have potential therapeutic implications (e.g. acquisition of HER2-E subtyping and increase in ERBB2 mRNA levels). Research Sponsor: University of Padova - STARS Grant; AIRC.

Primary Breast cancer	Brain Metastasis

UGT1A1 *28/*28 genotype and risk of toxicity and disease progression in breast cancer patients treated with sacituzumab govitecan-hziy. *First Author: Megan Wong, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: In metastatic and locally recurrent breast cancer the antibody drug conjugate, sacituzumab govitecan-hziy (SG), is approved as a second-line therapy in triple negative disease and a third-line therapy and beyond for ER+, endocrine resistant disease. UGT1A1 metabolizes the SN-38 payload of SG, and polymorphisms of the gene can lead to decreased enzyme activity and increased toxicity. We sought to determine if patients who were homozygous for the UGT1A1*28 allele (polymorphism (*28/*28)) experienced increased toxicity and a lower rate of disease progression when treated with SG. **Methods:** To evaluate the association of the *28/*28 genotype with the competing endpoints of Discontinuations for Disease Progression, Toxicity, and Futility, this pilot study undertook a single-center, retrospective chart review of breast cancer patients who received SG at City of Hope. Eligible subjects included breast cancer patients who received at least one dose of SG, had a known UGT1A1 status, and were followed for toxicity and disease progression. Data collection and analysis included reasons for discontinuing SG, onset of adverse effects, UGT1A1 status, age, gender, race and ethnicity, prior lines of therapy, and tumor receptor status. **Results:** Between July 2020 and September 2022, 67 women and 1 man underwent UGT1A1 testing prior to initiation of SG; the median age was 57.8 years, 75.0% had triple negative disease, and SG was given as a median third line of therapy. Seventeen (25%) patients were homozygous for *28 and 24 (35.3%) were heterozygous. Notably relating race and genotype, all 7 self-reported Black subjects were either carriers or homozygous for *28; there were no Black wildtype subjects. Most subjects were followed until Discontinuation for Disease Progression (55.9%), Toxicity (8.8%), or Futility (5.9%). Alternatively, 4.4% of subjects were lost to follow-up and 1 subject halted treatment due to cancer remission. The remaining 23.5% of subjects still took SG by the close of study in November 2022. On competing risk analysis comparing the wildtype group, *28/*28's association with increased Discontinuation for Toxicity, was confirmed with a Hazards Ratio of 5.52 (95% confidence interval [CI] 1.15-26.49, p = 0.03). In contrast, Discontinuation for Disease Progression was unassociated to *28/*28 status in comparison to the wildtype group with a Hazards Ratio of 0.80 (95% CI 0.39-1.65, p = 0.54). **Conclusions:** Despite the relatively small sample size, 25% of patients had the *28/*28 genotype. We confirmed that *28/*28 is associated with a higher risk for discontinuation of SG for toxicity without an association to disease progression based on mutation status. Early UGT1A1 testing as standard practice may identify patients at risk for excess toxicity, who may undergo early dose reductions to prevent discontinuation of this important advanced breast cancer treatment. Comprehensive characterization of androgen receptor expression in breast cancer. *First Author: Priya Jayachandran, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: The androgen receptor (AR) is a hormone-regulated transcription factor that plays an important role in breast cancer (BC) pathogenesis. While estrogen receptor inhibitors are well-studied in BC, the role of AR on prognosis and therapy is less well-known. Here we aim to characterize the clinicopathologic and molecular features of AR expression in BC. **Methods:** 27,169 BC samples were tested by NGS (592, NextSeq; WES, NovaSeq), WTS (NovaSeq) (Caris Life Sciences, Phoenix, AZ). Microsatellite-instability (MSI) was tested by IHC and NGS. Tumor mutational burden (TMB) totaled somatic mutations per tumor (high ≥ 10 mut/Mb). Tumors with AR-high(H) and AR-low(L) expression were classified by top and bottom quartile, respectively. Real world overall survival (OS) and treatment-associated survival was obtained from insurance claims and calculated from tissue collection or treatment start to last contact using Kaplan-Meier estimates. Statistical significance was determined by chi-square and Mann-Whitney U test with p-values adjusted for multiple comparisons (q<0.05). **Results:** Median AR expression was higher in lobular compared to ductal carcinoma (2.2-fold) and in HR+/HER2- compared to TNBC (13.9-fold). Compared to AR-L, AR-H BC had higher frequency of *PIK3CA* (50.6% vs 12.7%), *CDH1* (20% vs 2.2%), *ESR1* (12.8% vs 1.4%), *MAP3K1* (9.4% vs 1.4%), *GATA3* (11.2% vs 2.7%), *AKT1* (5.7% vs 1.4%), *NF1* (8.6% vs 3.6%), *ARID1A* (6.9 vs 3.6%), *SPEN* (2.8% vs 1.5%), and *PTEN* (7.9% vs 6.2%) mutations and TMB high (9.5% vs 7.7%), but lower frequency of dMMR/MSI-H (0.6% vs 1.7%) and PD-L1 (18.7% vs 45.3%) positivity (all p<0.05). AR-H tumors also showed enrichment of the *IL2-STAT5* pathway (NES: 1.33, FDR: 0.24). Further, AR-H BC had higher expression of immune checkpoint genes (*CD274*, *PDCD1LG2*, *LAG3*, *HAVCR2*, *FOXP3*, FC: 1.1-1.4, all p<0.05) and T cell inflamed scores (32.5% vs 26.2%, p<0.05). AR-H BC had increased immune cell infiltration of B cells (6% vs 4%), M2 Mφ (5% vs 2%), and NK cells (3% vs 2%), but decreased infiltration of M1 Mφ (2% vs 3%) (all p<0.05). AR-H BC had upregulation of M2 Mφ related genes (*ARG1*, *IL10*, *CCL17*, *CXCR1*, FC: 1.2-1.8, all p<0.05) and downregulation of M1 Mφ related genes (*CCL2*, *CCL5*, *CXCL9*, *CXCL10*, FC: 1-1.5, all p<0.05). AR-H BC was associated with improved OS compared to AR-L BC (mOS: 1843 vs 1096 days; HR 0.6, 95% CI 0.5-0.7, p<0.00001), and with doxorubicin (2294 vs 2054 days; HR 0.7, 95% CI 0.5-0.9, p<0.001), paclitaxel (2239 vs 1967 days; HR 0.7, 95% CI 0.5-0.9, p<0.001) and trastuzumab (inf vs 2351 days; HR 0.6, 95% CI 0.4-0.9, p<0.01) treatment. **Conclusions:** Our data suggest a strong association between AR expression and increased mutations in several cancer related genes, immune checkpoint markers, the *IL2-STAT5* pathway, differential immune cell infiltration, and improved overall survival. Negative estrogen receptor expression assessed by 18F-FES PET in metastatic breast cancer with ER-positive primary tumor. *First Author: Biyun Wang, Department of Breast Cancer and Urological Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: The 18F-fluoroestradiol positron emission tomography/computed tomography (18F-FES PET/CT) technique provides a convenient method to evaluate the overall estrogen receptor (ER) expression in metastatic breast cancer (MBC) patients. There are long debates on the characteristics and treatment strategy of patients with positive primary ER lesion but negative ER expression in metastatic disease. 18F-FES PET offers an opportunity to answer this question. **Methods:** This study enrolled MBC patients with ER-positive primary tumor who received 18F-FES PET/CT in our center. Descriptive statistics were used in clinicopathologic characteristics and compared with Chi square test or t test. Progression-free survival (PFS) was estimated by Kaplan-Meier method and compared by log-rank test. **Results:** 16.46% (52/314) patients with an ER-positive primary tumor had negative ER expression assessed by 18F-FES for MBC prior to receiving first-line systemic therapy. The rate of ER-negativity tested by 18F-FES was negatively co-related with levels of ER expression in early stage, with a positive to negative conversion in 2 of 3 (46.3%) ER-low (ie, ER 1%-9%) tumors, 7 of 10 (70.0%) ER-moderate (ie, ER 10%-49%) tumors, 16 of 114 (14.0%) ER-high (ie, ER 50%-95%) tumors, and 1 of 8 (12.5%) ER-very high (ie, ER > 95%) tumors (p < 0.001). Chemotherapy (83.33%, 40/48) was the most common treatment strategy afterward, among which capecitabine monotherapy (64.29%, 27/42) was a dominant alternative. PFS was significantly prolonged with capecitabine alone versus other chemotherapy (median PFS: 13.14 vs 6.21 months, p = 0.035). **Conclusions:** 18F-FES could identify negative conversion of ER in MBC which occurred frequently. Patients with lower ER expression in the primary lesion were more likely to have negative ER expression in the metastasis. In real-world clinical practice, chemotherapy was the primary choice by most physicians and capecitabine monotherapy had shown good efficacy. Research Sponsor: None.

Metastatic breast cancer (MBC) with ultra-high tumor mutational burden (UHTMB): A comprehensive genomic profiling (CGP) study. *First Author: Kristina Fanucci, Lifespan Health System, Providence, RI*

Background: Pts with MBC whose tumors feature high TMB (≥ 10 mutations/Mb) are eligible for on label immune checkpoint inhibitor (ICI) treatment. This study evaluated the genomic landscape of MBC with "Ultra high" TMB, defined at > 20 mutations/Mb. **Methods:** 2049 MBC underwent hybrid capture-based CGP to evaluate all classes of genomic alterations (GA), TMB, microsatellite instability (MSI) and trinucleotide mutational signatures. HER2 IHC results were available in a subset of pts. PD-L1 expression on immunocytes was determined by IHC (Ventana SP142). **Results:** 45/2049 (2.2%) of MBC were UHTMB. 45 (100%) pts had metastatic disease. 38 (84%) had documented Stage IV disease and 7 documented axillary LN metastases at the time of sequencing. Local breast tumor was used for CGP in 19 (42.2%) MBC and metastatic site biopsy was used in 26 (57.8%). When compared with 2004 non-UHTMB pts with UHTMB were older (mean 64.6 yrs vs 58.2 yrs p < .0001), more often had lobular histology (40.0% vs 14.5% p < .0001) and ER+ disease (86.6% vs 70.0%). Of the 35 UHTMB cases with HER2 IHC data available, 11 (31.4%) were HER2 IHC negative (0+), 21 (60.0%) were HER2-low status (9 1+ and 12 2+/ISH negative) and 3 (8.6%) were HER2 IHC positive (3+), 1/3 HER2 IHC2+ cases and 2/45 (4.4%) of all UHTMB cases were positive for HER2 copy number gain on CGP. UHTMB cases had more driver GA/tumor (mean 9.8 vs 5.7 p < .0001) and were less often TNBC (13.3% vs 27.0% p = .041) compared to non-UHTMB high cancers. Mutation signature analysis revealed APOBEC was predominant in UHTMB samples (82.5%); MMR signature was also observed in 10% of cases. MSI high status was significantly more frequent in UHTMB high cases (11.6% vs 0.4% p < .0001). GA more frequently identified in UHTMB cases included *CDH1* (45.5% vs 14.3% p < .0001), *PIK3CA* (81.8% vs 37.9% p < .0001), *CDKN2A* (11.4% vs 3.2% p = .017), *ARID1A* (25.0% vs 5.0% p < .0001) and *NF1* (20.5% vs 5.9% p = .0014). PD-L1 (*CD274*) gene amplification (2.3% vs 1.3%) or protein expression by the Ventana SP142 assay (57.14% vs 51.10%) were not significantly different among groups. **Conclusions:** UHTMB MBC is a rare, yet clinically important subset of clinically advanced breast cancer driven by APOBEC mutagenesis, with high incidence of ER+ lobular histology and frequent alterations in *CDH1* and *PIK3CA*. In addition to potential benefit from ICI based treatment, UHTMB MBC present with a high frequency of HER2-low status which may impact therapy decisions for this rare disease. Research Sponsor: Foundation Medicine.

	Cases with 10-20 Mut/Mb (120)	Cases with TMB < 20 Mut/Mb (2004)	Cases with TMB >20 Mut/Mb (45)	P Value (TMB < 20 vs >20)
Mean Age	60.3	58.2	64.6	0.000

Association of C-MYC, MYC target gene, and unfolded protein response (UPR) expression with clinical benefit from the oral aurora kinase A (AURKA) inhibitor, alisertib (A), in combination with paclitaxel (P) compared with P alone in patients (Pts) with HER2-negative metastatic breast cancer (MBC). First Author: Sara A. Byron, Integrated Cancer Genomics Division, Translational Genomics Research Institute, Phoenix, AZ

Background: AURKA is a key regulator of the mitotic spindle, G2/M transition and epithelial-mesenchymal transition. AURKA is amplified and/or overexpressed in breast cancer and is associated with therapy resistance and worse survival. A randomized phase II trial in hormone receptor (HR)-positive, HER2-negative and triple negative (TN) MBC pts showed that addition of A to weekly P significantly improved progression-free survival (PFS) compared with P alone (O'Shaughnessy J et al. *JAMA Network Open*, 2021). Pts' primary or metastatic disease tissues were analyzed for biomarkers associated with clinical benefit from A. **Methods:** Retrospective analysis of tumor whole exome and whole transcriptome sequencing of formalin-fixed paraffin embedded pre-treatment tissues from 96 pts (77 HR+, 19 TN) was performed. Clinical benefit from A+P or P was defined as having PFS of at least 6 mos and lack of benefit as PFS less than 6 mos. Enrichment for cancer gene mutations was assessed using Fisher's exact test. Transcriptome data were evaluated for differential expression with DeSeq2 and gene set enrichment analysis (GSEA) and compared to cancer hallmark gene sets. Molecular features were compared between A+P responders and non-responders, P responders and non-responders, and A+P and P responders. P-values <0.05 were considered significant. **Results:** *PIK3CA*, *TP53*, and *CDH1* were altered in 41%, 39%, and 13% of tumors, respectively, and these and other known cancer genes were not associated with A+P benefit. Alterations in *AKT1*, *PIK3CA*, *ERBB2*, *CDH1*, *TP53*, and *KMT2C/KMT2D*, as well as amplifications of *CCND1*, *MYB*, and *MDM2*, did not preclude benefit from A+P. RNA expression of AURKA, or its upstream regulator, FOXM1, was not significantly different based on treatment group or benefit from A+P or P. Increased C-MYC RNA expression (p=0.008), and enrichment for MYC targets and UPR by GSEA were enriched in pts with lack of benefit from P compared to those with benefit from P (p<0.05), but not in pts with lack of benefit from A+P. Wnt/Beta-catenin signaling was enriched in pts with lack of benefit from P compared to those with benefit from P (p=0.03), and with lack of benefit from A+P compared to those with benefit from A+P (p=0.086). Benefit from A+P was associated with enrichment for MYC targets and UPR compared with benefit from P (p=0.024), suggesting activity of A+P, but not P, with high MYC activation and UPR. **Conclusions:** A added to P improved PFS in HR+ HER2- and TN MBC pts compared with P alone. Pts whose breast cancers had increased C-MYC expression, high MYC activation and increased UPR on RNA expression derived greater clinical benefit from A+P than from P alone. Clinical trial information: NCT02187991. Research Sponsor: Takeda Pharmaceuticals.

Genomic characterization of the GATA3 mutational landscape in breast cancer. First Author: Jason A Mouabbi, University of Texas MD Anderson Cancer Center, Houston, TX

Background: GATA3 expression is broadly used as a biomarker for diagnosing cancer of breast origin and its expression is strongly associated with estrogen receptor (ER)-positive luminal phenotype. Although *GATA3* mutations are observed in 12-18% of breast cancers (BC), they are poorly characterized. Recently, the pharmacological inhibition of MDM2 has been shown to significantly impair tumor growth in *GATA3*-deficient models in vitro, in vivo, and patient-derived xenograft harboring *GATA3* somatic mutations. Therefore, given the potential targetability of *GATA3*-mutated BC cells, it is important to better understand and characterize the mutational landscape of *GATA3* to help guide future prospective clinical studies. **Methods:** We accessed a cohort of BC samples profiled genomically and transcriptomically from two open-source datasets: TCGA (n=961) and METABRIC (n=1866). We used the chi-squared test to analyze the frequency of *GATA3* mutations across PAM50 subtypes (Basal, HER2, Luminal A, Luminal B, Normal-like) and histological BC subtypes (invasive ductal carcinoma [IDC] and invasive lobular carcinoma [ILC]). Mutations affecting other genes in the *GATA3*-mutated samples and the *GATA3* wild-type (WT) samples were compared using the chi-squared test. We analyzed the mutational landscape of the *GATA3* gene and correlated different sites of mutations with *GATA3* expression, MDM2 amplification, other co-occurring mutations, and clinical behavior. *GATA3* expression levels were compared using the Mann-Whitney test. **Results:** Of the analyzed 2,827 BC samples, *GATA3* mutations were unevenly distributed in the five PAM50 subtypes, as Luminal A and B subtypes had the highest frequency (16% and 17%, respectively) and the basal subtype had no observed *GATA3* mutations (p<0.0001). Further analysis showed that *GATA3* mutations were more common in luminal IDC than ILC (17% vs 8.7%; p<0.0001). While mutations in *C9orf72*, *AKT1*, *TBX3* and *ARID1A* were more frequently co-occurring with *GATA3* mutations, mutations in *TP53*, *CDH1* and *PIK3CA* were mutually exclusive with *GATA3* mutations (adjusted p<0.0001 for all genes). Analysis of the *GATA3* mutational landscape identified two types of mutations in *GATA3*: a group of truncating mutations occurring at the end of the *GATA3* gene (after the 307 position including the splice site at 308) and a group occurring before the 307 position. The first group was associated with increased *GATA3* expression, MDM2 amplification, and was mutually exclusive with *TP53* mutations. The second group had little to no effect on *GATA3* expression and behaved similarly to *GATA3* WT. **Conclusions:** A subtype of *GATA3* mutations are mutually exclusive with *TP53* mutations and are associated with increased MDM2 amplification, making them an ideal target for clinical trials involving MDM2 inhibitors. Multi-factor dynamic analysis of ctDNA and CTC to aid the diagnostic prognosis of patients with metastatic breast cancer (MBC). First Author: Qiang Zhang, Northwestern University, Department of Medicine, Division of Hematology/Oncology, CTC Core Facility, Lurie Cancer Center, Chicago, IL

Background: The monitoring of circulating tumor DNA (ctDNA) and circulating tumor cell (CTC) in patients with MBC predicts treatment resistance and prognosis. We previously reported that *ESR1* alterations in ctDNA were associated with tumor tissue characteristics and CTCs which may help to elucidate disease prognosis in MBC (2019 ASCO#1036, 2022 ASCO#1057). Furthermore, ctDNA can be used to evaluate tumor heterogeneity in MBC (2020 ASCO#1028). Here, we report a multi-factor analysis in ctDNA and CTC which may help to elucidate disease prognosis in MBC. **Methods:** This study included 391 MBC patients who received systemic treatment before 2022 under an IRB-approved clinical trial at NU Lurie Cancer Center. Whole blood samples (7.5ml/each) were collected from all patients at three time points including before treatment, three months, and six months after treatment for CTC enumeration using the CELLTRACKS system (Menarini). The corresponding ctDNA was analyzed by Guardant360 NGS evaluating 74-gene mutations. The maximum follow-up period was 380 months from first diagnosis. Causal Inference with Ensemble Learning was used for statistical analyses. **Results:** Of the 391 patients ctDNA analysis, TP53 mutations were found in 160 patients (TP53^{Mut}, 40.92%), CDH1 mutations were found in 21 patients (CDH1^{Mut}, 5.37%), Myc mutations were found in 53 patients (Myc^{Mut}, 13.55%), and BRAF mutations were found in 35 patients (BRAF^{Mut}, 8.95%) inclusive of all timepoints. The corresponding ctDNA mutations were not detected in 231 patients for TP53 (TP53^{WT}, 59.08%), in 370 patients for CDH1 (CDH1^{WT}, 94.63%), in 338 patients for Myc (Myc^{WT}, 86.45%), or in 356 patients for BRAF (BRAF^{WT}, 91.05%). There was shorter median overall survival (mOS) in the ctDNA mutated groups compared to the non-mutated groups: 88 months TP53^{Mut} vs 184 months TP53^{WT}, HR 1.91, P = 0.0002; 133 months CDH1^{WT} vs 81 months CDH1^{Mut}, HR 2.03, P = 0.02; 76 months Myc^{Mut} vs 179 months Myc^{WT}, HR 3.24, P < 0.0001, and 77 months BRAF^{Mut} vs 146 months BRAF^{WT}, HR 2.45, P = 0.007. Furthermore, ≥5 CTCs were found in 32.42% patients. These patients had a shorter mOS compared to patients with no CTC detected at any time point (70.1 months vs 131 months; P < 0.001; HR 2.97). CTC-clusters were 50 times more likely to predict metastasis than single CTCs. We also found that greater than 5 CTC-clusters, clusters with 1-5, and no CTC-clusters were found in 12.55%, 11.25%, and 76.19% patients, respectively. Larger CTC-clusters had shorter mOS at 63 months, 121 months, and 163 months, respectively (P < 0.0001). **Conclusions:** In this study, we identified multiple liquid biopsy factors including ctDNA and CTC-clusters at various time points, and found that these are associated with prognosis. The synergy of multiple ctDNA mutations and CTC-clusters during treatment may expand the predictive role of liquid biopsy for the monitoring of disease progression in patients MBC. Poster Session

Preclinical and early clinical data of ZN-1041, a best-in-class BBB penetrable HER2 inhibitor to treat breast cancer with CNS metastases. First Author: Fei Ma, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China

Background: HER2+ breast cancer brain metastases (BCBM) is an aggressive malignancy with high prevalence and limited treatment options. ZN-1041 is a best-in-class HER2 inhibitor designed to be delivered across the blood-brain barrier (BBB) with high selectivity and broader safety margin to treat HER2+ BCBM. **Methods:** Brain penetration of ZN-1041 and other approved HER2 tyrosine kinase inhibitors (TKI) were evaluated. Anti-tumor activity of ZN-1041 alone or in combination were evaluated in xenograft models. ZN-A-1041-101 (NCT04487236) is an on-going phase 1, multicenter, open-label study. The study comprises first-in-human dose escalation of ZN-1041 monotherapy (phase 1a) in HER2+ solid tumor patients (pts) with or without BM, dose escalation (phase 1b) and expansion (phase 1c) of ZN-1041 in combination with capecitabine and trastuzumab in pts with HER2+ BCBM (including active BM). The primary objective was safety and tolerability. The secondary objective includes pharmacokinetics and anti-tumor response including ORR per RECIST 1.1 and intracranial ORR (iORR) per RANO-BM. **Results:** Unlike currently approved HER2 TKIs which are strong human efflux transporter P-gp and BCRP substrates, ZN-1041 is not a substrate of either and has high BBB permeability, therefore predicted to have good BBB penetration. ZN-1041 alone demonstrated dose-dependent and significant anti-tumor activity when compared to tucatinib in BM model. ZN-1041 could synergize with capecitabine and trastuzumab to demonstrate significantly improved intracranial efficacy in BM models, while maintaining good tolerability. In total, 21 HER2+ mBC pts were enrolled to complete phase 1a and 1b. No dose-limiting toxicities or treatment-related SAE were observed across all dose levels. PK exposure was increased with dose escalation and K_{puu,CSF} of ZN-1041 was 4.9. In ZN-1041 monotherapy, the overall ORR and iORR were 50% in TKI naïve, unequivocal HER2+ pts. The longest treatment duration was 15 months. As of data cutoff (Dec 02, 2022), totally 35 TKI naïve, HER2+ BCBM pts with median 2L treatments were enrolled for phase 1c and all pts were well tolerated to date. Adverse reactions of grade 3 or higher (≥5%) were hepatic function impairment (8.7%), headache (8.7%), hyperbilirubinemia (5.7%), ALT increased (5.7%), AST increased (5.7%), GGT increased (5.7%) and WBC decreased (5.7%). Among 19 BCBM pts with at least twice tumor assessment, the overall ORR was 78.9% (95% CI: 54.4–93.9) and iORR was 73.7% (95% CI: 48.8–90.9), DCR was 100%. In addition, 6 pts completed first tumor assessment and 5 achieved PR and 1 had SD per RECIST 1.1. **Conclusions:** Encouraging efficacy and tolerability was observed for ZN-1041 monotherapy or combined with capecitabine and trastuzumab in TKI naïve, HER2+ BCBM patients. A Phase 2 pivotal trial for HER2+ BCBM with ZN-1041, capecitabine and trastuzumab combination therapy is planned. Clinical trial information: NCT04487236. Research Sponsor: Suzhou Zanrong Pharma Limited.

Poster Session

Preclinical and early clinical data of ZN-1041 in combination with trastuzumab deruxtecan to treat breast cancer with or without CNS metastases.
First Author: Carey K. Anders, Duke Cancer Institute, Durham, NC

Background: While treatment options for advanced HER2+ breast cancer have improved, HER2+ breast cancer brain metastases (BCBM) remain a clinical challenge warranting the development of additional, brain permeable HER2-targeted therapies. ZN-1041 is a brain permeable, selective HER2-targeted oral tyrosine kinase inhibitor. Preclinical studies have demonstrated efficacy and safety of ZN-1041 warranting clinical development alone and in combination with approved monoclonal antibodies or antibody drug conjugates for patients (pts) with HER2+ BCBM. **Methods:** Anti-tumor activity of ZN-1041 alone or in combination with trastuzumab emtansine (TDM1), trastuzumab deruxtecan (TDXd), or trastuzumab (H) plus pertuzumab (P) was evaluated in BT474 BM orthotopic xenograft models. ZN-A-1041-101-US (NCT05593094) is an on-going phase 1, multicenter, open-label study. The study comprises dose escalation of ZN-1041 monotherapy (Phase 1a) in pts with HER2+ solid tumors with or without BM, dose escalation (Phase 1b) and expansion (phase 1c) of ZN-1041 in combination with TDM1 (Arm 1), TDXd (Arm 2), or HP as maintenance therapy (Arm 3) in pts with HER2+ mBC with or without BM. The primary objectives were safety, tolerability and recommended phase 2 dose. The secondary objective includes pharmacokinetics (PK) and preliminary efficacy per RECIST 1.1. **Results:** Preclinically, ZN-1041 alone or combined with TDM1, TDXd or HP demonstrated significant improvement in intracranial tumor growth inhibition compared to TDM1, TDXd, or HP alone. As of data cutoff, Phase 1a (n = 7 pts) and Arm 2 of Phase 1b (n = 3 pts) were completed. Among 10 pts enrolled, 8 pts had received prior HER2 TKI. In Phase 1a, ZN-1041 was well tolerated with no dose-limiting toxicities (DLTs) or drug discontinuation due to toxicity up to a dose of 800 mg BID. Adverse reactions were mainly grade 1. The most common treatment related adverse reactions (TRAEs≥15%) were grade 1 nausea (43%) and vomiting (29%), with no ≥ grade 2 diarrhea reported. PK exposure was increased with dose escalation. In Phase 1a, one pt with mBC (without BM) achieved a confirmed partial response (PR) at 400 mg BID dose for > 15 months; one with gastric cancer achieved stable disease at the first dose level of 50mg BID for nearly 1 year. In Phase 1b, pts who had previously progressed on TDXd and/or TKI were enrolled and received ZN-1041 at a dose of 800 mg BID in combination with TDXd. Combination therapy was well tolerated with no DLTs reported. One pt with BCBM who was previously on tucatinib and TDXd had a confirmed PR. **Conclusions:** Safety and tolerability was observed for ZN-1041 with maximum tolerated dose 800 mg BID as monotherapy and combined with TDXd in pts with advanced HER2+ malignancies. Encouraging efficacy was observed in treatment-refractory settings. Additional safety and efficacy data of ZN-1041 in combination with TDM1, TDXd or HP are warranted. Clinical trial information: NCT05593094. Research Sponsor: Suzhou Zanrong Pharma Limited.

Cardiac function of long-responders to dual anti-HER2 antibodies amongst patients with HER2 positive advanced breast cancer.
First Author: Kelvin K H Bao, Department of Clinical Oncology, Queen Elizabeth Hospital, Hong Kong, Hong Kong

Background: Dual anti-HER2 antibodies pertuzumab (P) and trastuzumab (T) in combination with taxane (D), followed by PT maintenance, is the standard first line treatment for HER2 positive advanced breast cancer (HER2+ ABC). Treatment associated cardiotoxicity necessitates regular cardiac function surveillance, which is a burden particularly for treatment long-responders. Data for cardiac safety of prolonged P+T exposure is scarce. We investigate the real-world impact on cardiac function in long-responders to treatment with dual anti-HER2 antibodies. **Methods:** We identified consecutive patients with HER2+ ABC who received the CLEOPATRA regimen (PT-D) between Jan 2014 and Dec 2020 from an institutional cancer registry. All patients had pre-treatment multiple-gated acquisition (MUGA) scan or echocardiogram, and subsequently at 3-monthly intervals until end of treatment to monitor left ventricular ejection fraction (LVEF). Patients on treatment for ≥36 months were considered long-responders. The Wilcoxon signed-rank test was used to assess any significant difference in LVEF at various landmark time-points in comparison to their pretreatment baseline. **Results:** 101 women with HER2+ ABC were eligible for analysis. Median age at treatment was 62 (IQR, 56.0-69.0). The median duration of treatment was 17.3 months (IQR, 9.0-31.3). 22.8% of patients were long-responders, who received a median of 67 cycles of treatment (IQR, 58-88). Compared to baseline, median LVEF was significantly decreased at 6m (median, 66% vs 69%, p=0.02), however there were no significant differences for any of the subsequent time-points up to 84 m. All of the larger LVEF drop (≥10% from baseline) occurred by the first 24 months, representing 4.7% of the overall measurements. Risk factors present for patients experienced treatment suspension (n=3) included previous exposures to anthracycline and left sided radiotherapy. **Conclusions:** In patients with HER2+ ABC who were long-responders to first-line PT-D, prolonged exposure to dual anti-HER2 antibodies was not associated with significant cardiotoxicity. It is safe to de-escalate the cardiac surveillance for this population. Research Sponsor: None.

Time-points (months)	Number of patients	Baseline LVEF (%) (median, IQR)	Subsequent LVEF (%) (median, IQR)	Wilcoxon signed-rank test
0	101	69 (64.0-72.5)	-	-
6	90	69 (64.8-72.3)	66 (63.0-72.0)	p=0.02
12	64	69 (63.5-72.0)	69 (63.0-73.0)	p=0.27
24	48	69 (65.0-72.8)	69 (63.0-73.0)	p=0.76
36	23	71 (63.5-74.5)	68 (63.0-72.0)	p=0.11
48	13	72 (63.5-74.5)	66 (64.0-72.0)	p=0.08
60	8	72 (63.0-74.0)	69 (63.5-71.5)	p=0.17

Anti-HER2 antibody inetetamab plus camrelizumab and utidelone for pre-treated HER2-positive metastatic breast cancer: Final results from the phase 2 ICU trial.
First Author: Huimin Lv, Department of Breast Disease, Henan Breast Cancer Center. The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, China

Background: We previously reported (Yan, ASCO 2022) promising efficacy and acceptable safety of anti-HER2 antibody inetetamab in combination with camrelizumab and utidelone regimen in preliminary 20 HER2-positive metastatic breast cancer (MBC) patients who progressed after at least two lines of HER2-directed therapies with trastuzumab and TKIs. Inetetamab is a novel anti-HER2 antibody. Camrelizumab is an anti-programmed death receptor 1 (PD-1) antibody. Utidelone, a genetically engineered epothilone analogue, has shown promising efficacy in heavily pretreated MBC. Here we report the final ICU study results. **Methods:** In the ICU study (NCT04681287), patients received intravenous camrelizumab (200 mg once every 3 weeks), inetetamab (initial dose of 8 mg/kg, then 6 mg/kg, once every 3 weeks), and utidelone (30 mg/m², days 1-5, every 3 weeks) until disease progression or intolerable toxicity. The primary endpoint was 3-month progression-free survival (PFS) rate according to the Response Evaluation Criteria in Solid Tumors, version 1.1. Secondary endpoints included objective response rate (ORR), PFS and safety. Simon's two-stage design was adopted for this study. All AEs were graded according to the grading criteria in the Common Terminology Criteria for the Evaluation of Adverse Events, 5th edition. **Results:** From Apr 23 2021 to Sept 1 2022, a total of 46 HER2-positive MBC patients were enrolled with median age of 52 (range 43-57). As of Jan 18, 2023, the median follow-up was 11.37 months. There were 12 patients (26.09%) with ER+/PR+, 7 patients (15.22%) with ER+/PR-, one patient (2.17%) with ER-/PR+, 26 patients (56.52%) with ER-/PR-. The median number of previous systemic therapies for advanced disease was three. Previous HER2-targeted therapies included trastuzumab (46 [100%]), TKIs (46 [100%], of which pyrotinib 39 [84.78%] and lapatinib 12 [26.09%]), pertuzumab (13 [28.26%]), and margetuximab (3 [6.52%]), T-DM1 or other HER2-ADC (7 [15.22%]). The 3-month PFS rate in 46 patients was 71.84%. The confirmed ORR was 28% (13/46), include one (2.17%) patient achieved complete response. The median PFS was 5.59 months. The most common treatment-related adverse events (TRAEs) were peripheral neuropathy (40 [86.96%]), capillary proliferation (27 [58.7%]), and alopecia (17 [36.96%]). Grade ≥3 TRAEs included rash (3 [6.52%]), peripheral neuropathy (1 [2.17%]) and AST increase (1 [2.17%]). Moreover, there were no grade 4 or above TRAEs. No related treatment discontinuation or deaths occurred. **Conclusions:** Final efficacy and safety results were consistent with previous ICU study preliminary analyses. The ICU study showed a favorable benefit-risk profile and is an important option for Chinese patients with HER2-positive MBC after at least two lines of HER2-directed therapies with trastuzumab and TKIs. Clinical trial information: NCT04681287. Research Sponsor: China Scientific Research Fund for HER2 Target from China Anti-Cancer Association (No.CORT-239-M14).

Zanidatamab (zani), a HER2-targeted bispecific antibody, in combination with docetaxel as first-line therapy (1L) for patients (pts) with advanced HER2-positive breast cancer (BC): Updated results from a phase 1b/2 study.
First Author: Xiaojia Wang, Department of Oncology, Zhejiang Cancer Hospital, Hangzhou, China

Background: Despite HER2-targeted agents improving outcomes in HER2-positive (+) BC, some pts develop resistance, relapse, or do not respond to current 1L therapies. Zani, also known as ZW25, is a novel HER2-targeted bispecific antibody that binds to two distinct extracellular domains of HER2. Preliminary results from this phase 1b/2 trial (NCT04276493) showed that zani plus docetaxel had a manageable safety profile and demonstrated promising antitumor activity in pts with advanced HER2+ BC; here we present the updated data following enrollment completion. **Methods:** Cohort 1 of this open-label study is evaluating zani in combination with docetaxel as a 1L therapy in adult females with advanced HER2+ BC who may have received prior neoadjuvant/adjunct therapy. Cohort 1a pts received zani 30 mg/kg intravenously (IV), Cohort 1b pts received zani 1800 mg IV, both with docetaxel 75 mg/m² IV every 3 weeks. The primary endpoints were safety and investigator (INV)-assessed objective response rate (ORR) per RECIST v1.1. Secondary endpoints included INV-assessed duration of response (DoR) and disease control rate (DCR). **Results:** As of Nov 22, 2022, 37 pts (median age 55.0 years [range: 33-80]) were assigned to Cohort 1a (n=10) or 1b (n=27). Median study follow-up was 15.5 months (range: 1.1-29.3); patients received a median of 13 treatment cycles (range 1-37) and 18 (48.6%) pts remained on treatment. Of the 33 efficacy evaluable (EE) pts, confirmed ORR was 90.9% (95% confidence interval [CI]: 75.7, 98.1). Efficacy data are summarized in Table. In total, 36 (97.3%) pts experienced ≥1 treatment-related adverse event (TRAE); 25 (67.6%) pts experienced ≥grade 3 TRAEs. The most common ≥grade 3 TRAEs were decreased neutrophil count, experienced by 18 (48.6%) pts, and decreased white blood cell count, experienced by 7 (18.9%) pts. Serious TRAEs occurred in 6 (16.2%) pts; no TRAEs led to death. **Conclusions:** Zani combined with docetaxel demonstrated promising antitumor activity as 1L therapy for advanced HER2+ BC, with a manageable safety profile. Clinical trial information: NCT04276493. Research Sponsor: BeiGene, Ltd.. This study was sponsored by BeiGene, Ltd. Medical writing support for the development of this abstract, under the direction of the authors, was provided by Emily Finn, MSc, of Ashfield MedComms, an Inizio company, and was funded by BeiGene, Ltd.

Summary of efficacy results (EE analysis set*)			
	Cohort 1a (n=8)	Cohort 1b (n=25)	Total (n=33)
Confirmed best overall response, n (%)

Updated results from a phase 2 study on dalpiciclib and pyrotinib, a dual-oral chemotherapy-free regimen in HER2-positive advanced breast cancer (DAP-HER-01). *First Author: Min Yan, Department of Breast Disease, Henan Breast Cancer Center. The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, China*

Background: Cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitors have shown synergistic effect with anti-HER2 therapy on hormone receptor (HR)-positive and HER2-positive breast cancer from preclinical models and several clinical studies, while data of this combination in HR-negative and HER2-positive diseases are limited so far. DAP-HER-01 (NCT04293276) was aimed at evaluate the efficacy and safety of the novel dual-oral, chemotherapy-free regimen of CDK4/6 inhibitor dalpiciclib and pan-HER tyrosine kinase inhibitor pyrotinib in HER2-positive advanced breast cancer (ABC) regardless of HR status, and reported to meet the primary endpoints previously (overall ORR 70%), in which HR-negative patients achieved a higher ORR (81.8%, vs 55.6% in HR-positive patients; Min Yan, et al. ESMO 2021, Poster 276P). Here we reported the updated results of this trial. **Methods:** DAP-HER-01 was a single-arm, phase 2 study conducted in HER2-positive ABC patients with no more than one prior systemic treatment at advanced setting. Enrolled patients received dalpiciclib and pyrotinib until progression, unaccepted toxicity, or no further benefit. The primary endpoint was ORR as per RECIST 1.1, and secondary endpoints included progression-free survival (PFS), overall survival and safety. **Results:** Between April 9, 2020, and May 19, 2021, 41 patients were enrolled and received study treatment, and 40 of them were assessable for efficacy. With a median follow-up of 19.2 months, the median progression-free survival (PFS) was 11.0 months (95% CI: 7.3-19.3). Considering HR status, the PFS in HR-negative patients was not matured (estimated median: 16.6 months; 95% CI: 7.3-NA), but still showed a tendency to be longer than that in HR-positive patients (median: 9.1 months; 95% CI: 5.4-11.0). Patients with brain metastases at baseline could also benefit from this treatment (median PFS: 11.0; 95% CI: 5.4-NA). Consistent with the safety data reported before, the most common grade 3 or 4 treatment-related adverse events were leukopenia (68.3%), neutropenia (65.9%) and diarrhea (19.5%). Most adverse events were tolerable, and no study-related death reported. **Conclusions:** Combined with previous reports, our findings suggest dalpiciclib combined with pyrotinib achieved promising efficacy and manageable toxicity in the treatment of HER2-positive ABC, including patients with HR-negative disease or brain metastases. This combination could be considered as a completely oral, chemo-free regimen for patients with HER2-positive ABC and is worthy of further study. Clinical trial information: NCT04293276. Real-world treatment patterns in patients with HER2+ unresectable or metastatic breast cancer: Interim results from HER2 REAL Asia cohort. *First Author: Soo-Chin Lee, National University Hospital, Singapore, Singapore*

Background: HER2 REAL (NCT04857619) is the first multi-country, retrospective study exploring the treatment practices and outcomes in patients (pts) with HER2+ locally advanced, unresectable (u)/metastatic (m) breast cancer (BC) from routine clinical care in the APAC and LATAM. **Methods:** Adult HER2+ u/mBC pts diagnosed since reimbursement or wider access of trastuzumab emtansine (T-DM1) or 01 Jan 2017, whichever was earlier with ≥ 12 months (mo) of follow-up data from index date (u/mBC diagnosis) and treated with ≥ 1 -line of therapy (LOT) were enrolled per medical chart review from 6 countries. Here we present interim descriptive analyses (cut-off 30 June 2022) on demographics, clinical characteristics, and treatment patterns. **Results:** Of the 763 enrolled pts, 370 with median (range) age of 55 (20–81) yrs from Hong Kong, Korea, Singapore, and Taiwan were eligible for interim analyses; 368 (99.5%) were female with 210 (57.1%) postmenopausal. A total of 210 (57.1%) pts with reported data had a median time of 2 (0–18) yrs from initial BC diagnosis to u/mBC relapse. At index date, majority had ductal carcinoma (227/254 [89.4%]), visceral (255/355 [71.8%]), and non-visceral (258/355 [72.3%]) metastases; 80/355 (22.5%) had CNS metastases. Family history of BC was reported by 45/370 (12.2%) pts completing the questionnaire; 209/370 (56.5%) had hormone receptor-positive BC. Treatments reported in the first to fifth line were quite variable. HER2-directed therapy was received by 323/367 (88.0%) in LOT1 (mainly trastuzumab [TRA] and pertuzumab [PTZ]-based) and 298/343 (86.9%) in LOT2 (mainly T-DM1). Median duration of LOT1 and LOT2 were 7.8 (0–130) and 5.0 (0–100) mo, respectively, that decreased to 2.3 (0–30) mo in LOT5. The prime reason for treatment discontinuation was disease progression (LOT1: 294 [80.1%]; LOT2: 273 [79.6%]; LOT3: 187 [68.5%]). Serious adverse effects from treatments were rare (LOT1: 7 [1.9%]; LOT2: 10 [2.9%]; LOT3: 5 [1.8%]). **Conclusions:** The interim analyses show heterogeneous treatment patterns in real-world among pts with HER2+ u/mBC progressing on HER2-directed therapies possibly due to access disparity in these 4 Asian countries. Clinical trial information: NCT04857619. Research Sponsor: AstraZeneca.

PLEASURABLE: Results and biomarkers analysis from the phase II study of dalpiciclib combined with pyrotinib and endocrine therapy (ET) in women with dual-receptor positive (ER+/HER2+) metastatic breast cancer (MBC). *First Author: Jian Zhang, Phase I Clinical Trial Center, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: In the front-line setting, our previous work demonstrated an impressive median progression-free survival (PFS) of 11.3 months with 66.7% response rate, and concluded a recommended phase 2 dose of pyrotinib 320mg/d, dalpiciclib (SHR6390, a novel CDK4/6i) 125mg/d, and letrozole 2.5mg/d for HR+/HER2+ MBC patients (pts) (Xichun Hu, FRONT ONCOL 2022). Results and biomarkers analysis from phase II dose expansion study are presented. **Methods:** ER+/HER2+ MBC Pts eligible for first- or second-line treatment were enrolled to receive dalpiciclib combined with pyrotinib and ET (letrozole or fulvestrant determined by physician's choice). The primary endpoint was objective response rate (ORR). For biomarkers analysis, ⁶⁸Ga-HER2 affibody, pre-treatment tissue-derived DNA and circulating tumor DNA (ctDNA) were assessed by PET/CT, and next-generation sequencing (NGS), respectively. **Results:** As of January 19, 2023, 48 pts were enrolled. 17 pts (35.4%) were treatment naïve, and 31 pts (64.6%) had received prior trastuzumab. The ORR was 68.1% (32/47) and disease control rate was 100% (47/47). In trastuzumab-naïve and trastuzumab-pretreated patients, ORR was 81.3% (13/16) and 61.3% (19/31), respectively. PFS and OS data were not mature by cut-off date. No new safety signals were observed. The most frequent treatment-related adverse events were neutropenia (95.8%; G3:60.4%, G4:6.3%), leukopenia (91.7%; G3:45.8%), diarrhea (87.5%; G3:2.1%), anemia (79.2%; G3:4.2%), oral mucositis (68.8%; G3:2.1%) and platelet count decreased (41.7%; G3:2.1%, G4:2.1%). The heterogeneity of ⁶⁸Ga-HER2 affibody uptake was observed among patients, both at baseline (N=16, median SUV_{max} 7.5, range, 2.3-34.9) and after 2 cycles of therapy (N=12, median SUV_{max} 4.0, range, 0-14.9). All patients with a decline in ⁶⁸Ga-HER2 affibody uptake (N=8) achieved partial response, while the uptake in non-responders was elevated (N=2). NGS was conducted to detect somatic and germline mutations in baseline tissue (n=10) and ctDNA (n=10) samples. Two patients with BRCA mutation (one had somatic BRCA1/2 mutation and another with germline BRCA2 mutation) had no tumor response. **Conclusions:** The chemotherapy-sparing regimens showed significant anti-tumor activity for ER+/HER2+ MBC pts in the front-line setting. The ⁶⁸Ga-HER2 affibody PET/CT may be a potential predictive biomarker of therapy response. Additional analysis including correlation of biomarkers with long-term outcomes is underway. Clinical trial information: NCT03772353. Research Sponsor: None.

Pyrotinib plus capecitabine for patients with HER2-positive metastatic breast cancer and brain metastases: 3-year follow-up results from the phase 2 PERMEATE trial. *First Author: Min Yan, Department of Breast Disease, Henan Breast Cancer Center. The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, China*

Background: HER2-positive metastatic breast cancer has a high risk of brain metastases, leading to poor survival. Our phase 2 PERMEATE trial (NCT03691051) has shown the promising efficacy of pyrotinib (an irreversible pan-HER receptor tyrosine kinase inhibitor) plus capecitabine in patients with HER2-positive metastatic breast cancer and brain metastases, with an intracranial objective response rate of 74.6% (44/59) and 42.1% (8/19) in patients with radiotherapy-naïve (cohort A) and radiotherapy-treated (cohort B) brain metastases, respectively. Here we updated 3-year follow-up results from this trial. **Methods:** Patients received 21-day cycles of pyrotinib (400 mg orally once daily) and capecitabine (1000 mg/m² orally twice daily on days 1-14) until disease progression or intolerable toxicity. Patients with progression isolated to the brain lesions would be withdrawn from the study, but could resume on the study treatment after local surgery or radiotherapy until the second progression at any site or death, at the discretion of the investigator. Intracranial and extracranial responses were assessed according to the Response Evaluation Criteria In Solid Tumors, version 1.1. Progression-free survival (PFS; time from the initiation of the study treatment to progression at any site or any-cause death), overall survival (OS), and second PFS (PFS2; time from progression isolated to the brain lesions to the second progression at any site) were reported. **Results:** By the data cutoff date on February 8, 2023, the median follow-up duration was 40.5 months (95% CI: 39.0-43.0). Cohort A showed a median PFS of 10.7 months (95% CI: 7.6-14.9) and a median OS of 35.9 months (95% CI: 25.1-not reached). The 1-year and 3-year OS rates were 84.6% (95% CI: 76.0-94.4) and 49.8% (95% CI: 38.0-64.6), respectively. Fifteen patients with progression isolated to the brain lesions in cohort A resumed on the study treatment after local treatment, with a median PFS2 of 10.4 months (95% CI: 6.5-19.7). Cohort B showed a median PFS of 5.6 months (95% CI: 5.4-11.9) and a median OS of 31.4 months (95% CI: 22.0-not reached). The 1-year and 3-year OS rates were 78.9% (95% CI: 64.0-99.6) and 29.1% (95% CI: 13.0-60.4), respectively. **Conclusions:** These findings suggest the long-term survival benefit provided by pyrotinib plus capecitabine in patients with HER2-positive metastatic breast cancer and brain metastases, especially in the radiotherapy-naïve cohort. Artificial intelligence–powered tumor-infiltrating lymphocytes analyzer to reveal distinct immune landscapes in breast cancer by molecular subtype and HER2 score. *First Author: Seunghwan Shin, Oncology, Lunit, Seoul, Korea, Republic of (South)*

Background: Tumor-infiltrating lymphocytes (TIL) reflect an ongoing anti-tumor immune response in the tumor microenvironment (TME) and have been studied as a predictive as well as prognostic biomarker in breast cancer (BC). The immune profile differs depending on BC molecular subtypes, with triple-negative BC (TNBC) and HER2-positive BC more frequently infiltrated by higher numbers of TIL than hormone receptor (HR)-positive tumors. In this study, we analyze TIL and immune phenotype by molecular subtype in BC and explore differences based on HER2 scores using an AI-powered TIL analyzer. **Methods:** A total of 1,973 cases of BC with molecular subtype, HER2 immunohistochemistry (IHC) or in situ hybridization (ISH) results, and TIL analysis from H&E slides from TCGA (n=1021), Samsung Medical Center (SMC, n=663), and KyungHee Medical Center (KHMC, n=289) were included in the analysis. The density of TIL were spatially analyzed from H&E WSI, and the immune phenotype (IP) was analyzed for each 1 mm²-sized patch. Tumor microenvironment (TME) was categorized into three types: inflamed (TIL distributed intratumorally), Immune-excluded (TIL excluded, out of cancer stroma), immune-desert (scant TIL in TME), and the score for each IP was calculated as the percentage of the total patches in WSI. **Results:** TNBC showed the highest TIL density in both cancer epithelium (214.5 ± 299.7/mm²) and stroma (1133.3 ± 1245.9/mm²), and a high percentage of inflamed IP (35.7%), IS (28.4 ± 28.1) than other subtypes (inflamed IP: 17.5%, IS 16.2±20.2, both p<0.001). HER2-positive BCs showed higher sTIL density (904.0 ± 901.7/mm²) compared to HR- positive BC (616.7 ± 794.1/mm²) but were associated with a higher percentage of immune-excluded IP (71.2%) and IES (57.6 ± 24.6). HR-positive BC had a high percentage of immune-desert IP (30.4%). In both HR-positive and negative BCs, higher IES was observed as the HER2 score increased. HER2-positive BC significantly showed a higher proportion of cancer stroma in the cancer region from WSI (Stromal ratio, 0.682 ± 0.149 vs. 0.578 ± 0.176, p<0.001). **Conclusions:** Different TIL densities and IP were seen in BC for each molecular subtype, pointing to a distinct immune landscape. HER2 score was associated with immune-excluded IP despite having higher TIL density, which should be considered for immunotherapy in BC. Research Sponsor: None.

Real-world patient characteristics and treatment patterns associated with tucatinib therapy in patients with HER2+ metastatic breast cancer. *First Author: Carey K. Anders, Duke University Cancer Institute, Durham, NC*

Background: Tucatinib (TUC) is an oral HER2-targeted therapy approved by the FDA in Apr 2020 for use in combination with trastuzumab and capecitabine (TRA+CAP) for patients with previously treated HER2+ metastatic breast cancer (MBC). In the randomized HER2CLIMB trial, median (95% CI) overall survival (mOS) and progression-free survival (PFS) for patients receiving TUC with TRA+CAP were 21.9 (18.3, 31.0) and 7.8 (7.5, 9.6) months, respectively. Median duration of therapy was 7.3 months. HER2CLIMB used a standard of care comparator arm and included patients with active and stable brain metastasis (BM). HER2CLIMB was conducted prior to approval of fam-trastuzumab deruxtecan (T-DXd) so did not assess the impact of TUC-based therapy following T-DXd. Objective: Describe patient characteristics, treatment patterns, and clinical outcomes for TUC-based treatment in the real-world setting. **Methods:** This retrospective study included patients in the Komodo Health dataset (aggregating data from patient administrative health claims in the United States) diagnosed with MBC between Jan 1, 2017 and Sep 3, 2022 and initiating TUC post- approval in Apr 2020. Patient characteristics were described in the baseline period (≤6 months from TUC initiation). Key outcomes were time to next treatment (TTNT; as a proxy for PFS), time to discontinuation (TTD), and persistence (proportion continuing treatment at each timepoint) in all TUC-treated patients, and in patients receiving TUC immediately following T-DXd. **Results:** Of 16,990 patients identified with HER2+ MBC, 528 received TUC-based treatment. Of these, 57 (11%), 164 (31%), 154 (29%), and 153 (29%) received TUC in first-line (1L), second-line (2L), third-line (3L), and fourth-line or later (4L+), respectively. Median follow-up from TUC initiation was 9 months. Overall, 400 patients (76%) had BM prior to initiating TUC (43 [75%], 138 [84%], 111 [72%], and 108 [71%] in 1L, 2L, 3L, and 4L+, respectively). Median (95% CI) TTNT was 10.7 (9.4, 13.1) months overall and 11.5 (9.6, 14.4) in patients receiving TUC in 2L or 3L. Median (95% CI) TTD was 8.5 (7.2, 9.3) months overall, and 9.1 (7.7, 9.9) in patients receiving TUC in 2L or 3L. TUC persistence in the overall cohort was 46% (91/200) at 12 months and 35% (40/115) at 18 months. Sixty-one patients (12%) received TUC immediately following T-DXd (median 4L; 12 in 2L/3L, 49 in 4L+); of whom 36 (59%) had BM prior to initiating TUC. TTNT and TTD for patients treated with TUC following T-DXd were 7.5 (5, 13.3) and 7.3 (3.2, 9.5) months, respectively. **Conclusions:** In the real-world setting, a higher proportion of patients receiving TUC had BM compared with the HER2CLIMB patient population. TUC-based treatment in the real world is used in multiple lines of therapy and is associated with a similar TTNT and TTD to PFS observed in HER2CLIMB, inclusive of a cohort of patients who received TUC following T-DXd therapy. Secondary primary malignancy risk by ER, PR, and HER-2 status in post-menopausal women with breast cancer: A population-based analysis. *First Author: Muhammad Hammad Khan, King Edward Medical University, Lahore, Pakistan*

Background: Breast cancer is the most commonly diagnosed cancer and second leading cause of death due to cancer in women in the United States. We aimed to determine site specific incidence of SPMs in post-menopausal women with primary BC using data from the US Surveillance, Epidemiology, and End Results (SEER-17) cancer registries. **Methods:** We retrospectively analyzed post-menopausal women aged 45 or older with a first primary breast cancer diagnosis between 2000 and 2019, excluding those aged 45 or younger or with non-breast cancers as their first malignancy. We defined SPMs as second malignancies occurring at least 6 months after the initial breast cancer diagnosis and calculated standardized incidence ratios (SIRs) and absolute excess risk (AER) using SEER*Stat. Statistical significance was determined using p-values <0.05 and a 95% CI assuming a Poisson distribution of SPM incidence. **Results:** Among 774,965 post-menopausal women ≥45 years old with primary breast cancer, 10.8% developed SPMs, with significantly increased risk compared to the general population (SIR=1.14, 95% CI=1.13-1.15, p<0.05), particularly for solid tumors (SIR=1.16, 95% CI=1.15-1.16, p<0.05) and certain malignancies including salivary gland (SIR=1.77), thyroid (SIR=1.56), endocrine system (SIR=1.56), and hematological malignancies such as ALL, ANLL, and AML (SIR>1.70). Women aged 45-59 and Black women had the highest risk for all malignancies. PR receptor-positive women had higher risk for thyroid SPMs, while PR-negative women had higher risk for SPMs in female genitalia, bones and joints, and hematological malignancies. HER-positive and triple-positive (HER ER PR) women had higher risk for thyroid and hematological SPMs, while triple-negative women had higher risk for ALL, ANLL, and AML. **Conclusions:** This study found that 11% of post-menopausal women with primary BC develop SPMs, with thyroid cancer being the most common. Black and older women (45-59 years) had a higher risk of developing SPMs. Research Sponsor: None.

HER2 persistence after treatment with T-DXd in breast and gastrointestinal cancers. *First Author: Joshua Z. Drago, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: T-DXd is a HER2-targeted antibody drug conjugate approved for treatment of advanced HER2-positive breast and gastroesophageal cancers and HER2-low breast cancers. The prevalence of HER2 loss after exposure to T-DXd is unknown and has implications for treatment strategies in refractory patients. **Methods:** We investigated clinically reported HER2 immunohistochemistry (IHC) scoring on post-treatment tissue biopsies from patients who received at least 2 cycles of T-DXd as of 2/2023. IHC was performed using mAB clone 4B5 (Ventana) and scored by ASCO/CAP guidelines on a scale of 0 to 3+. MSK-IMPACT next generation sequencing (NGS) was performed on paired pre- and post-treatment samples when available. Statistics are descriptive. **Results:** A total of 62 patients with breast, gastroesophageal, or colon cancer had available post-treatment biopsies. The majority (n = 51) had breast cancer, including 32 with HER2-positive and 19 with HER2-low disease. Median time on therapy was 30 weeks in HER2-positive and 21 weeks in HER2-low breast cancer. All 32 patients with HER2-positive breast cancer had detectable HER2 expression by IHC on post-treatment biopsies (median IHC score 2+; range 1+ to 3+). Of those with HER2-low breast cancer, 12 (63.1%) patients had detectable IHC after treatment. Of the 7 with IHC scores of zero, 3 also had scores of zero on the most proximal pre-treatment biopsies. Seven patients with gastroesophageal and 3 with colorectal cancer were included, with a median time on therapy of 12 and 9 weeks respectively, of which 1 (9%) exhibited HER2-loss after treatment. Among all patients with HER2-positive cancers, the rate of complete HER2-loss by IHC after exposure to T-DXd was 2.3%. Thirty-two patients had paired genomic analysis, including 25 breast and 7 gastrointestinal cancers. No change was observed in the fraction of genome altered (p = 0.0736, q = .327) or tumor mutational burden (p = 0.139, q = .487) with T-DXd exposure. Changes in *ERBB2* copy number did not show clear directionality, with 15 patients (46.7%) exhibiting *ERBB2* amplification pre-treatment and 12 (37.5%) post-treatment, the sum of 3 temporal gains and 6 losses of *ERBB2* amplification across the threshold of 1.8. **Conclusions:** HER2 remained detectable by IHC in the majority of patients treated with T-DXd in this cohort, especially those with HER2-positive cancers. These findings suggest that resistance to T-DXd may occur via target-independent factors, and that HER2 could still be exploited therapeutically in these populations. Further prospective studies using quantitative assays are needed to confirm these hypotheses. Research Sponsor: U.S. National Institutes of Health.

Tumor Type	N	Median Time on Tx (Wks)	Median HER2 IHC Post-Tx	IHC 0 Post-Tx
				N (%)
HER2-Positive Breast Cancer	32	30	2+ (1-3)	0 (0)
Her2-Low Breast Cancer	19	21	1+ (0-2)	7 (36)*
Gastroesophageal Cancer	7	12	3+ (0-3)	1 (14.2)
Colorectal Cancer	4	9	2+ (2-3)	0 (0)

Validation of a single-cell sequencing assay for the detection of circulating tumor cells in metastatic breast cancer. *First Author: David Bourdon, Epic Sciences, San Diego, CA*

Background: Blood Biopsy and the evaluation of Circulating Tumor Cells (CTC) has provided valuable clinical information for patients with metastatic breast cancer, specifically where a tissue biopsy is not feasible. A critical problem in the field is that most assays cannot distinguish true CTCs from other types of rare cells. By combining established protein biomarkers associated with circulating epithelial cells with single-cell whole-genome sequencing to assess copy number variations (CNVs, a signature for genomic instability - GI), we differentiate rare cells from true CTCs. Additionally, we can determine the presence or absence of regions that contain gene amplifications (e.g., ERBB2/HER2). Here we report the validation of a clinical blood biopsy CTC assay that can enumerate CTCs, determine if those CTCs have GI and if selected CTCs are expressing HER2 or ER antigens. **Methods:** Relevant cell line controls of epithelial origin and known expression levels of ER or HER2 were spiked into healthy donor whole blood at varying concentrations. The nucleated cells were deposited on microscope glass slides at high density. Immunofluorescence staining of slides was performed to identify the presence and localization of nuclei (via DAPI), pan-CK, HER2, ER, CD45 and CD31. Nucleated cells were classified as CTC candidates if they were pan-cytokeratin⁽⁺⁾ and CD45/CD31⁽⁻⁾, and were further characterized for expression of ER and HER2 protein. Defined CTC candidates were imaged and located by specific coordinates allowing single-CTC isolation for whole genome amplification. Single-cell sequencing data was then analyzed with the Epic CTC DNA copy number analysis pipeline to detect GI and amplification at the ERBB2 locus. **Results:** The limit of detection for CTCs was determined to be 1 CTC in 6 million white blood cells with a linear range of 1- 300 CTC per slide. The sensitivity and specificity for HER2 detection was determined to be 94% and 97%, respectively. ER assay sensitivity and specificity were 91% and 100%, respectively. Overall accuracy was 100% for HER2 and 94% for ER detection. Overall precision across all relevant variables produced %CVs <10% for HER2 and ER. A genome possessed GI if more than 12 large-scale transitions (LSTs) were detected. For detection of 2-fold amplification at the ERBB2 locus, gene amplification was detected with 85% sensitivity and 94% specificity. Tested healthy donor blood samples were absent of detected CTCs and lacked LST/GI or ERBB2 amplification in all (46) isolated WBCs. **Conclusions:** These results reflect the validation of a novel clinical assay combining CTC detection with single-cell GI and amplification of the ERBB2 locus. This assay better discriminates CTC detection with the addition of an assessment of GI. Additionally, along with protein expression measures of ER and HER2, it provides the ability to assess if HER2 expression is driven by ERBB2 amplification. Research Sponsor: Epic Sciences.

Poster Session

Impact of race and age on intrinsic subtype distribution and treatment decisions in metastatic breast cancer: Preliminary analysis of HARMONY (LCCC1829). *First Author: Joannie M. Ivory, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Gene expression profiling (GEP) is used to classify breast cancer (BC) into four intrinsic subtypes: Luminal A (LumA), Luminal B (LumB), HER2-Enriched, and Basal-like. Non-LumA subtypes are associated with poorer outcomes. Studies in early BC show that hormone receptor-positive (HR+)/HER2-negative (HER2-) tumors have a higher frequency of non-LumA subtypes in Black and younger (<50) women. Similarly, triple negative BC, which carries the poorest prognosis and is mostly Basal-like, are overrepresented in Black and younger women. These variations in intrinsic subtype contribute to outcomes disparities. The extent to which these racial and age differences in subtypes and mortality occur in metastatic breast cancer (MBC) is unknown. **Methods:** HARMONY (NCT03769415) is a prospective clinical trial in patients with newly diagnosed MBC. Bulk tumor GEP (PAM50 intrinsic subtyping) is performed on primary and metastatic tumors. A primary objective is to determine the extent and treatment implications of molecular discordance (defined *a priori* as treatment differences by intrinsic subtype compared to clinical subtype); other endpoints to be reported later include GEP comparisons between primary and metastatic samples. Here we examine differences in a) intrinsic subtype and b) treatment patterns in MBC by race and age. **Results:** At the time of analysis, the study had accrued 220 participants. Mean age was 58, 24% were Black women. Sixty-five percent had HR+/HER2- MBC, 14% HER2-positive, and 21% triple negative. Unlike in early BC, LumB exceeded LumA (LumA 27%, LumB 35%, HER2-Enriched 12%, Basal-like 25%). Similar to early BC, subtype varied by race and age with more non-LumA subtypes in young and Black women. Discordance between intrinsic and clinical subtype was seen in 24% of Black, 20% of White women, in 29% of younger and 18% of older women. Treatment patterns also differed by race and age, where a higher percentage of younger Black women received first-line chemotherapy compared to younger White women overall (45% vs. 10%, p=0.0025), and in HR+/HER2- disease (33% vs 8.7%, p=>0.05). No difference was seen in older women (24% vs 17%, p=0.44). Median progression free survival was worst in younger Black women compared to all other participants (5.4 vs 19.5 months, p=0.027), which may be driven by clinical subtype. **Conclusions:** Intrinsic subtype of tumors in a metastatic population has a different distribution by race and age than early BC, with more poor-prognosis non-LumA subtypes, and approximately 1 in 5 have discordance between clinical and molecular subtype, which may be therapeutically relevant. Clinical trial information: NCT03769415. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

First-in-human phase 1 dose escalation study of the KAT6 inhibitor PF-07248144 in patients with advanced solid tumors. *First Author: David Sommerhalder, NEXT Oncology, San Antonio, TX*

Background: KAT6A and KAT6B regulate gene transcription via acetylation of histone H3K23 and their dysregulation drives lineage-specific gene expression in cancer. We report dose escalation data from the first-in-human phase 1 (Part 1A and 1B; NCT04606446) study of the KAT6-selective inhibitor PF-07248144. **Methods:** Part 1A (monotherapy dose escalation) enrolled patients (pts) with advanced/metastatic ER+/HER2- breast cancer (mBC), CRPC, or NSCLC, resistant/intolerant to standard therapy. Part 1B (PF-07248144 + fulvestrant combination dose escalation) enrolled pts with advanced/metastatic ER+/HER2- mBC with disease progression after ≥1 line of CDK4/6 inhibitor and endocrine therapy (ET). PF-07248144 (1-15 mg in Part 1A) was administered orally once per day (QD) in 28-day cycles following Bayesian design with overdose control. Study objectives: primary - assess PF-07248144 safety and tolerability, including dose limiting toxicities (DLT); secondary - evaluate PF-07248144 pharmacokinetics (PK); and exploratory - evaluate pharmacodynamics (PD; peripheral blood mononuclear cells [PBMC] and tumor H3K23Ac inhibition) and antitumor activity (using RECIST 1.1 by investigator assessment). **Results:** At data cut off (30 Sep 2022), 29 pts were enrolled: 25 in Part 1A (12 mBC, 11 CRPC, 2 NSCLC) and 4 in Part 1B (mBC). Part 1A evaluated 5 dose levels (1-15 mg QD) and Part 1B evaluated 5 mg PF-07248144 QD + 500 mg fulvestrant. Median age across Part 1A and 1B was 67 yrs (range 48-90). A total of 83% (Part 1A) and 75% (Part 1B) of pts with mBC had received > 3 prior lines of systemic anticancer therapy. Three DLTs (Grade 3 [G3] neutropenia) were observed: 2 in Part 1A (8 mg and 2 mg QD) and 1 in Part 1B (5 mg QD). A maximum tolerated dose was not identified; 5 mg QD was identified as the recommended dose for expansion for both monotherapy and fulvestrant combination. Across Parts 1A and 1B, treatment-related AEs (TRAEs; any grade) in ≥20% pts were dysgeusia (72%), anemia (52%), neutropenia (48%), thrombocytopenia (31%), diarrhea (31%), white blood cells (WBC) decreased (28%), fatigue (24%), and aspartate aminotransferase increased (21%); the majority of TRAEs were G1-2. TRAEs ≥G3 seen in > 1 pt were neutropenia (6/29; 21%), anemia (5/29; 17%), and WBC decreased (2/29; 7%). PF-07248144 PK was linear between 1 and 15 mg. H3K23Ac inhibition (≥70%) in PBMCs was achieved at steady state at doses of ≥1 mg. Tumor H3K23Ac levels were reduced by > 50% in 4 paired tumor biopsies at exposures associated with preclinical anti-tumor activity. Confirmed and durable partial responses were observed in 1/8 (Part 1A) and 2/4 (Part 1B) response-evaluable pts with ER+/HER2- mBC who progressed on prior ET+CDK4/6 inhibitor treatment. **Conclusions:** PF-07248144 was well tolerated and associated with strong KAT6 inhibition in PBMCs and tumors and confirmed partial responses in pts with heavily treated ER+/HER2- mBC during dose escalation. Clinical trial information: NCT04606446. Research Sponsor: Pfizer.

Poster Session

Comparative overall survival of patients in trials of CDK4/6 inhibitors in combination with endocrine therapy in advanced breast cancer. *First Author: Coralea Kappel, University of Toronto, Toronto, ON, Canada*

Background: CDK4/6i and endocrine therapy (ET) are an international gold standard therapy in estrogen receptor (ER) positive and HER2-negative advanced breast cancer (aBC). Individual trials of abemaciclib, palbociclib and ribociclib show similar impact on progression-free survival yet differing statistical significance for OS. A robust comparative evaluation of the efficacy, safety, and tolerability of the three drugs is warranted. **Methods:** We searched PubMed, ASCO, ESMO and SABCS proceedings to identify phase 3 randomized clinical trials reporting OS of CDK4/6i in combination with ET in ER-positive aBC in first or second line. A network meta-analysis using WinBUGS was performed to evaluate comparative efficacy, based on the ET partner, in the absence of direct comparisons. Trial level data on common and serious adverse events (AE) were extracted for each drug. The odds ratio (OR) for each AE was calculated comparing each CDK4/6i to the respective endocrine therapy backbone (aromatase inhibitor (AI) or fulvestrant) alone. **Results:** Seven studies comprising 4087 patients met the inclusion criteria. Median follow up was 70.2 months. Four studies paired a CDK4/6i with an AI or tamoxifen, 3 studies were paired with fulvestrant. There were no statistically significant differences in OS between any of the CDK4/6i with any ET backbone. Compared to palbociclib, ribociclib and abemaciclib showed significantly lower grade 1-2 fatigue/asthenia (ribociclib OR 0.69 [95% CI 0.58, 0.83]; abemaciclib OR 0.6 [95% CI 0.49, 0.74]) and abemaciclib showed significantly lower grade 1-2 alopecia (abemaciclib 0.76 [95% CI 0.6, 0.97]). Compared to palbociclib, ribociclib and abemaciclib showed significantly higher GI toxicity (ribociclib any grade vomiting OR 1.71 [95% CI 1.36, 2.15]; abemaciclib any grade vomiting OR 2.1 [95% CI 1.61, 2.62], any grade diarrhea 13.2 [95% CI 10.31, 16.78]). Treatment discontinuation was highest with abemaciclib. **Conclusions:** In this network meta-analysis, there was no statistically significant difference in OS between CDK4/6i despite differences in individual trials. Real-world data analyses may help to identify if a there is a meaningful inter-drug difference in efficacy. Significant differences between CDK4/6i are observed for safety and tolerability outcomes. Research Sponsor: None.

Differences in OS between the CDK4/6i with any ET or AI backbone.

Lasofoxifene (LAS) plus abemaciclib (Abema) for treating *ESR1*-mutated ER+/HER2- metastatic breast cancer (mBC) after progression on prior therapies: ELAINE 2 study update. *First Author: Senthil Damodaran, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Endocrine therapy (ET), particularly aromatase inhibitors (AIs), for estrogen receptor (ER)-positive breast cancer can lead to acquired *ESR1* mutations (*mESR1*) driving endocrine resistance and tumor progression. Treatments for mBC with *mESR1* are limited, especially after progression on ET/cyclin-dependent kinase 4 and 6 inhibitor (CDK4/6i) combinations. In ELAINE 2, LAS, a next-generation ET (breast ER antagonist) plus Abema had a median progression-free survival (PFS) of ~13 mos, objective response rate (ORR) of 33%, and 24-wk clinical benefit rate (CBR) of 62% with a favorable safety profile in patients with resistant *mESR1* mBC (Damodaran S, et al. *J Clin Oncol*. 2022;40:16 suppl 1022). Here, we report ELAINE 2 data with longer patient follow up (Jan 31, 2023). **Methods:** In this open-label, phase 2, single-arm study, 29 women with *mESR1*, ER+/HER2- mBC that progressed on prior ET took oral LAS 5 mg/day and Abema 150 mg BID until disease progression/toxicity. The primary endpoint was safety/tolerability; secondary included PFS, CBR, and ORR. Data were summarized descriptively with no formal hypothesis testing. **Results:** Patients (median age 60 yrs) had received a median of 2 prior therapy lines for mBC; all but one had prior CDK4/6i exposure and 14 (48%) had prior chemotherapy for mBC. LAS/Abema was well tolerated with primarily grade 1/2 treatment-emergent adverse events (most commonly diarrhea, nausea, fatigue, and vomiting). One treatment withdrawal occurred due to grade 2 diarrhea. No deaths occurred. LAS dose was not reduced; Abema dose was reduced to 100 mg BID in 6 (21%) patients. Median PFS was 56.0 wks (~13 mos) and CBR 65.5% (95% CI, 47.3–80.1). Median overall survival was not estimable. In 18 patients with measurable lesions, ORR was 55.6% (95% CI, 33.7–75.4), with median time to response of 5.7 mos and median duration of response of 6.4 mos. Seventy-six percent, 56%, and 39% of patients were progression free at 6, 12, and 18 mos, respectively. Three (10%) patients had scan-identified venous thromboembolic events, with one symptomatic pulmonary embolism and one symptomatic deep vein thrombosis. In 26 patients with evaluable baseline and wk 4 ctDNA, *ESR1* mutant allele fraction decreased from baseline to wk 4 in 81% of patients and was not detected in 54%. **Conclusions:** With longer ELAINE 2 follow up, LAS/Abema continues to be well tolerated with clinically meaningful efficacy in women with *mESR1*, ER+/HER2- mBC that had progressed on ET and CDK4/6is. Decreases in *mESR1* ctDNA suggest effective target engagement of LAS. The PFS (median ~13 mos) and ORR (56%) with LAS/Abema are promising and a confirmatory phase 3 study (ELAINE 3) will begin in 2023. If ELAINE 2 results are confirmed, the combination of LAS and Abema would address a critical unmet need, providing a practice changing option for treating *mESR1* breast cancer. Clinical trial information: NCT04432454. Research Sponsor: Sermonix Pharmaceuticals.

Poster Session

Circulating tumor cells (CTCs) dynamics after CDK4/6i for hormone-receptor positive (HR+) metastatic breast cancer (MBC): A biomarker analysis of the PACE randomized phase II study. *First Author: Lorenzo Gerrata, CRO Aviano National Cancer Institute, IRCCS, Aviano, Italy*

Background: PACE is a multicenter randomized phase II trial investigating palbociclib (P) in combination with fulvestrant (F) after progression on any CDK4/6 inhibitor (CDK4/6i), with or without the PD-L1 inhibitor avelumab (A), in HR+/HER2- MBC. CTCs are rare cells in the blood stream whose detection is associated with worse outcome and treatment resistance. **Methods:** Eligible patients (pts) had HR+/HER2- MBC with prior progression after ≥ 6 months (mo) of AI and CDK4/6i for MBC, or during/within 12 mo in the adjuvant setting, with ≤ 1 prior chemotherapy for MBC. Pts were randomized 1:2:1 to F, F+P, or F+P+A. CTC detection and enumeration were performed utilizing CellSearch (Menarini Silicon Biosystems) at baseline (BL), at time of first tumor assessment (TTA1), and at progression. Results were dichotomized using the standard CTC threshold (≥ 5 CTCs/7.5 ml) into a novel prognostic classification: StageIV_{indolent} and StageIV_{aggressive} (Cristofanilli et al 2019). Concurrent ctDNA Sequencing was performed using Guardant360 (Guardant Health). **Results:** Of the 220 randomized pts, 203 (92%) had sample available for BL CTC enumeration, 155 had detectable CTCs (70.5%), and 99 (48.8%) were StageIV_{aggressive}. *De novo* disease at initial diagnosis was associated with StageIV_{aggressive} (47.5% vs 30.8% StageIV_{indolent}), and distribution of visceral versus non-visceral disease was similar across the two CTCs groups. StageIV_{aggressive} represented 38.3%, 54.8%, and 46.2% of the F, F+P and F+P+A treatment groups, respectively. BL CTCs were prognostic in the overall cohort; median PFS was 5.7mo vs 3.5mo for StageIV_{indolent} vs StageIV_{aggressive} (HR: 1.69, 90%CI 1.27-2.24, P<0.001). Median PFS for the F, F+P and F+P+A arms was 1.9mo, 4.6mo and 5.4mo in StageIV_{aggressive} compared to 8.2mo, 5.3mo and 8.3mo in StageIV_{indolent}. Among patients in the StageIV_{aggressive} subgroup, the F+P and F+P+A arms demonstrated improved outcomes compared to F alone. (F+P vs F HR 0.43, 90% CI 0.25-0.71, and F+P+A vs F HR 0.26, 90% CI 0.14-0.49). No benefit of F+P or F+P+A over F was observed in the StageIV_{indolent} subgroup (F+P vs F HR 1.45, 90% CI 0.87 - 2.40 and F+P+A vs F HR 1.06, 90% CI 0.61 - 1.84, each p(interaction)<0.01). Changes in StageIV CTC characterization (indolent vs aggressive) between BL and TTA1 among the subset of 175/203 pts with both timepoints available are reported. **Conclusions:** Baseline CTC enumeration is prognostic in patients receiving F with or without CDK4/6i. The StageIV_{aggressive} subgroup may derive preferential benefit with combinations of F+P or F+P+A over F alone. Findings should be confirmed in other studies. ctDNA analyses are ongoing. Clinical trial information: NCT03147287. Research Sponsor: Pfizer.

CTC at BL	CTC at TTA1	
	StageIV _{indolent}	StageIV _{aggressive}
StageIV _{indolent} (n=94)	72 (76.6%)	22 (23.4%)
StageIV _{aggressive} (n=81)	31(38.3%)	50 (61.7%)

Prognostic factors in hormone receptor positive oligometastatic breast cancer. *First Author: Lacaze Jean Louis, Institut Claudius Regaud (ICR), Institut Universitaire du Cancer de Toulouse-Oncopole (IUCT-O), Département d'Oncologie médicale, Toulouse, France*

Background: Some recommend curative treatment for oligometastatic breast cancer (OMBC). To date, no randomized clinical trial has demonstrated the benefits of such a strategy. We present the largest retrospective series of patients treated consecutively for ER and/or PR positive (HR+) OMBC in a single institution. The objective was to describe the clinical and biological characteristics and prognostic factors of HR+ OMBC. **Methods:** We retrospectively reviewed all patients treated consecutively from 2014 to 2018 at our institution for synchronous or metachronous metastatic breast cancer (MBC). HR+ OMBC was defined as MBC with up to five metastases at diagnosis, positive hormone receptor status, and no other inclusion criteria. Clinical and biological characteristics, treatment modalities - intent-to-cure vs palliative - and outcomes were recorded. Progression-free survival (PFS) and overall survival (OS) were calculated. Log rank test and Cox regression models were used for survival analyses including time-dependent variable. **Results:** Of 998 patients treated for MBC within our institution between 2014 and 2018, 11.3% (N=113/998) met inclusion criteria. 62.5% of them had SBR grade I/II HR+ OMBC and 80.5% had HR+/HER2- OMBC. 89.3% patients had only one organ involved. None had more than two; 89.3% patients had 1-3 metastases at diagnosis. Among these 113 patients, 63.7% had bone metastases, 54.9% had bone only metastases, 19.5% had visceral metastases, 17.7% had lymph node metastases, 7.1% had brain metastases, and 3.5% had other metastases. Forty-one patients (36.3%) were treated in a curative intent with systemic treatment plus ablative focal treatment of primary tumor – or local relapse – and all distant metastases. Median follow up was 67.2 months (95%CI=[63.1-75.4]). For the entire series, five-year PFS and OS were respectively 35.2% (95%CI=[25.6-44.6]) and 67.0% (95%CI=[56.7-75.3]) respectively. In univariable analysis, liver metastases was associated with worse OS (HR=3.13, 95%CI=[1.43-6.87], p=0.003). In multivariable analysis, HER2 positive status (HR=0.43, 95%CI=[0.21-0.90], p=0.024), bone only metastases (HR=0.46, 95%CI=[0.27-0.78], p=0.004), and intent-to-cure treatment (HR=0.53, 95%CI=[0.30-0.93], p=0.027) were significantly associated with longer PFS. In multivariate analysis, only intent-to-cure strategy was associated with better OS (HR=0.24, 95%CI=[0.09-0.60], p=0.002). **Conclusions:** This is the largest retrospective series of patients treated consecutively for HR+ OMBC to date. 71.5 % of OMBC and 11.3 % of all MBC are HR+ OMBC. Most had only one invaded organ and 1-3 metastases. Among our cohort, intent-to-cure treatment improve drastically HR+ OMBC PFS and OS. A multimodal intent-to-cure strategy should be routinely discussed for patients with HR+ metastatic breast cancer with one to five metastases at diagnosis. Research Sponsor: None.

ctDNA mutational profiles in luminal breast cancer with early vs late distant relapse: Geicam/2014-03. *First Author: Angel Guerrero, Fundación Instituto Valenciano de Oncología (FIVO), GEICAM Spanish Breast Cancer Group, Valencia, Spain*

Background: Patients with hormone receptor-positive early breast cancer (BC) can develop resistance to endocrine therapies (ET) and face a continuous risk of relapse, which can occur anywhere from a few months (m) to several decades after surgery. The causes of early vs late relapses are not well understood. Our research examines the presence of oncogenic drivers in circulating tumor DNA (ctDNA) at the time of relapse in patients with luminal BC who have either an early or late distant recurrence. **Methods:** We identified pts included in the GEICAM/2014-03 study (NCT02819882) with: 1) HR-positive BC, 2) metastatic relapse either <36m (early relapse, [early-R]) or >120m (late relapse, [late-R]) from diagnosis, and 3) ctDNA obtained before first line treatment for advanced disease. The AVEIO ctDNA assay was used for identifying genomic aberrations in 77 cancer-related genes. **Results:** Eighty-four pts, 36 in early-R and 48 in late-R groups, were selected. Median time to relapse was 24.97m in early-R vs 151.84m in late-R. Median time from last dose of adjuvant ET to relapse was 0.03m for early-R vs 74.06m for late-R. Median PFS to first line treatment was 7.62m in early-R and 35.15m in late-R. With a median follow-up of 32.08m, median OS after diagnosis of metastatic disease was 27.74m for early-R and not reached for late-R. ctDNA analysis detected at least 1 mutation (mut) in 71/84 (85%) pts (89% in early-R vs 81% in late-R). Early-R pts were enriched in mut in *TP53* (44% vs 19%), *ESR1* (11% vs 4%), *MAPK_ERK* pathway (14% vs 6%), and *ERBB2* copy number alterations (CNA) (25% vs 2%). *PI3K/AKT* pathway alterations had similar frequency in both recurrence groups (38% vs 42%) and they were not associated with OS. Seven *ESR1* mut were detected in 6 pts. In the early-R group there were 5 *ESR1* mut (71% of total *ESR1* mut), median mutant allele frequency (mMAF): 0.64%; while in the late-R, 2 *ESR1* mut (29%), mMAF: 0.4%. *ESR1* mut were associated with worse OS (median OS 48.48m vs 12.84m wild-type vs mutant; p=0.0025). There were 10 pts with *ERBB2* CNA at metastatic relapse: 9 (25%) in the early-R and 1 pts (2%) in the late-R. Seven pts (70%) had HER2-positive. Pts with ctDNA *ERBB2* CNA had worse OS (median OS 48.48m vs 20.52m wild-type vs mutant; p-adj=0.025). **Conclusions:** In luminal breast cancer (BC), early and late distant relapse differ at both the clinical and genomic levels. Early relapse is a highly aggressive form of the disease and is enriched in *TP53* mutations and actionable genetic alterations, such as mutations in the *ESR1* and CNA in *ERBB2*, as detected by ctDNA analysis at the time of metastatic relapse diagnosis. Clinical trial information: NCT02819882. Research Sponsor: AstraZeneca in alliance with Daiichi Sankyo Spain, Roche, Celgene, Pfizer and SEAGEN; AMACMEC Association.

Interim analyses (IA) of the giredestrant (G), G + abemaciclib (A), and G + ribociclib (R) arms in MORPHEUS Breast Cancer (BC): A phase I/II study of G treatment (tx) combinations in patients (pts) with estrogen receptor-positive, HER2-negative locally advanced/metastatic BC (ER+, HER2– LA/mBC). *First Author: Mafalda Oliveira, Vall d'Hebron University Hospital and Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Limitations of current approved endocrine therapies (ETs), a mainstay tx for ER+ BC, include incomplete ER signaling inhibition. Novel ETs, such as selective estrogen receptor antagonists and degraders (SERDs), may help overcome this. G, a potent, nonsteroidal, oral (PO) SERD, is well tolerated and has shown robust ER occupancy and encouraging antitumor activity as monotherapy and in combination with the cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) palbociclib (P). MORPHEUS BC (NCT04802759) is evaluating the safety and efficacy of G tx combinations in ER+, HER2– LA/mBC. We present results from the 16-week IA of G and G + CDK4/6i (A or R). **Methods:** Eligible pts had disease progression on 1–2 lines of ET (including a CDK4/6i) for LA/mBC. Pts were randomized 1:6 (planned n = 15 per arm) to receive G (30 mg PO QD; control arm), G + A (150 mg PO BID), or sequentially, G + R (600 mg PO QD) until disease progression/unacceptable toxicity. The study was not designed to make explicit power and type I error considerations for a hypothesis test. Primary endpoints were safety and objective response rate; other endpoints included progression-free survival, overall survival, clinical benefit rate, disease control rate (DCR), duration of response, and pharmacokinetics. Genetic alterations were defined using baseline circulating tumor DNA. **Results:** As of Feb 4, 2022, 15 pts were enrolled in the G + A arm; 73% received one prior line of tx in the LA/mBC setting; 27% received prior fulvestrant; 73% had liver metastases at baseline (BL). As of Sept 22, 2022, 11 and 16 (of whom 14 were evaluable) pts were enrolled in the G and G + R arms, respectively; 64%/86% received one prior line of tx in the LA/mBC setting; 73%/36% received prior fulvestrant; 73%/57% had liver metastases at BL. Three pts had a partial response (PR; G + A, n = 1; G + R, n = 2); 19 had stable disease (G, n = 5; G + A, n = 7; G + R, n = 7). DCRs were 36% (G), 40% (G + A), and 50% (G + R). Safety is shown. **Conclusions:** G combined with a CDK4/6i (A or R) was well tolerated, with no unexpected safety signals. Three PRs were seen in this heavily pretreated population of pts with disease progression post-CDK4/6i tx. This study provides the first data supporting the combinability of G with the CDK4/6is A and R, in addition to P as seen in prior studies. G can therefore be combined with all three approved CDK4/6is. Clinical trial information: NCT04802759. Research Sponsor: F. Hoffmann-La Roche Ltd.

Outcomes with first-line (1L) ribociclib (RIB) + endocrine therapy (ET) vs physician's choice combination chemotherapy (combo CT) by age in pre/perimenopausal patients (pts) with aggressive HR+/HER2– advanced breast cancer (ABC): A subgroup analysis of the RIGHT Choice trial. *First Author: Nagi S. El Saghir, American University of Beirut Medical Center, Beirut, Lebanon*

Background: The progression-free survival (PFS; primary endpoint) results from the Phase II RIGHT Choice trial demonstrated a statistically significant median PFS (mPFS) benefit of ~1 yr with RIB + ET over combo CT (mPFS, 24.0 vs 12.3 mo; hazard ratio [HR], 0.54; 95% CI, 0.36–0.79; *P* = .0007) in pts with aggressive HR+/HER2– ABC. Younger pts with aggressive ABC have a worse prognosis, which impacts treatment (tx) decisions. Hence, a subgroup analysis of key efficacy endpoints from RIGHT Choice by age (< 40 vs ≥ 40 y) was undertaken. **Methods:** Pre/perimenopausal pts (aged 18–59 y) with HR+/HER2– ABC and no prior systemic therapy for ABC were randomized 1:1 to either RIB with letrozole/anastrozole + goserelin or investigator's choice of combo CT (docetaxel + capecitabine, paclitaxel + gemcitabine, or capecitabine + vinorelbine). Pts in the trial had ABC not amenable to curative therapy and for which combo CT was clinically indicated by physician's judgment (ie, symptomatic visceral metastases, rapid progression of disease or impending visceral compromise, or markedly symptomatic non-visceral disease). **Results:** In total, 70 pts were aged < 40 y and 152 were aged ≥ 40 y. In the combo CT arm, pts aged < 40 y fared worse and had a shorter mPFS, shorter median time to tx failure (mTTF), and higher 3-month tx failure rate (TFR) than pts aged ≥ 40 y. Pts aged < 40 y showed a significant PFS benefit with RIB + ET vs combo CT (mPFS, not reached [NR] vs 10.2 mo; HR, 0.38). This PFS benefit with RIB + ET over combo CT was also observed in pts aged ≥ 40 y (21.2 vs 16.0 mo; HR, 0.71). Regardless of age, the mTTF was longer and the 3-month TFR was lower in the RIB + ET arm than the combo CT arm. The median time to response (mTTR), overall response rate (ORR), and clinical benefit rate (CBR) were similar between the two tx arms in both age groups. **Conclusions:** This analysis demonstrated a clinically meaningful PFS benefit and improved secondary outcomes with 1L RIB + ET over combo CT along with similar treatment responses in both tx arms in pts aged < 40 y as well as in those ≥ 40 y with aggressive HR+/HER2– ABC. This analysis supports RIB + ET as a preferred tx option in this pt population, including younger pts aged < 40 y. Clinical trial information: NCT03839823. Research Sponsor: Novartis Pharmaceuticals Corporation.

Endocrine therapy resistance (ETR) in hormone receptor-positive, HER2-negative metastatic breast cancer (HR+, HER2– mBC): Prevalence, biomarker characteristics, and outcomes. *First Author: Rinath Jeselsohn, Dana-Farber Cancer Institute, Boston, MA*

Background: ETR to prior adjuvant ET poses challenges to first-line treatment (1L tx) of HR+, HER2– mBC. Understanding patient (pt)/disease heterogeneity is crucial for developing new txs that target specific ETR mechanisms to improve pt outcomes. We investigate ETR, including prevalence, genomic profiles, and survival outcomes in pts with HR+, HER2– mBC treated in the 1L setting. **Methods:** This retrospective two-cohort study of pts initiating 1L systemic tx for mBC (diagnosed after Jan 1, 2015) used data from the Flatiron Health (FH) electronic health record-derived de-identified database (FH cohort), and FH-Foundation Medicine, Inc. (FMI) clinico-genomic database (CGDB cohort; solid biopsy FMI test required). The de-identified data originated from ~280 US cancer clinics (~800 sites of care). Pts with ETR to prior adjuvant ET were defined per ESMO guidelines (table footnote); primary ETR (1ETR) was divided into pts relapsing within 1 year (yr) or 1–2 yrs of adjuvant ET. Genomic profiles were assessed in the CGDB cohort. In both cohorts, real-world (rw) progression-free survival (PFS) and overall survival (OS) were estimated in pts who received 1L tx with fulvestrant (F) + CDK4/6i inhibitor (CDK4/6i). **Results:** In the FH cohort (N = 4052), 16.1% of pts had 1ETR (ET < 1 yr: 7.9%) and 33.9% had secondary ETR (2ETR). In the CGDB cohort (N = 696), *ESR1* mutations (*ESR1* m) were present in 10.8% of 158 pts with 1ETR (ET < 1 yr: 4.2%; 1–2 yrs: 16.1%) and 19.9% of 317 pts with 2ETR. In pts who received 1L F + CDK4/6i, shorter median (m) rwPFS (statistically significant) and OS (not significant) were seen in pts with 1ETR vs. 2ETR, but outcomes were not affected by the presence of *ESR1* m in pts with 2ETR. **Conclusions:** Overall, half of pts with 1L HR+, HER2– mBC have ETR to prior adjuvant ET. Pts with ETR have tumors with heterogeneous genomic profiles and varied survival outcomes. *ESR1* m are infrequent in pts with 1ETR and < 1 yr of adjuvant ET but are more common in 2ETR. In pts treated with 1L F + CDK4/6i, PFS and OS were worse with 1ETR than 2ETR. This study highlights the importance of further understanding the heterogeneity in molecular profiles and outcomes within ETR. Research Sponsor: F. Hoffmann-La Roche Ltd.

Efficacy and safety of tenalisib, a PI3K δ/γ and SIK3 inhibitor, in patients with locally advanced or metastatic breast cancer: Updated results from an on-going phase II study. *First Author: Tamta Makharadze, LTD High Technology Hospital Med Center, Batumi, Georgia*

Background: Several studies have shown that the upregulation of the PI3K-AKT-mTOR pathway interacts with the Estrogen Receptor pathway and confers endocrine resistance. Elevated Salt Inducible Kinase-3 (SIK3) expression, which often is overexpressed breast cancer, is shown to contribute to tumorigenesis. Tonalisib (RP6530), a highly selective, PI3Kδ/γ and SIK3 inhibitor, has shown promising efficacy in T-cell lymphoma with a distinct safety profile. Tonalisib's major metabolite, INO385 is a SIK3 inhibitor. Breast cancer cell line studies have demonstrated that tonalisib potentiated the activity of paclitaxel and doxorubicin. The aim of this phase II study was to investigate the efficacy and safety of single-agent tonalisib in patients (pts) with HR+ HER2- locally advanced or metastatic Breast cancer. **Methods:** This randomized, open-label study was designed to evaluate two doses (800 mg BID and 1200 mg BID) of Tonalisib in MBC pts (including TNBC) whose disease had progressed following at least one line of therapy. Tonalisib was administered orally daily for every 28 days cycles until the disease progression. The study would enroll forty pts (20 at each dosage level), with the primary outcome being the proportion of patients who did not have disease progression at the end of six months. Other outcomes were investigator-assessed ORR, PFS, DCR (DCR=CR+PR+SD) and Clinical Benefit Rate (CBR= CR+PR+SD≥24 weeks) as per RECIST v1.1 criteria. **Results:** The trial enrolled 40 pts. Pts had a median of 3 (range 1-7) prior therapies of which, 87% pts had prior endocrine therapy, which included 40% pts treated with an aromatase inhibitor and 30% of pts treated with fulvestrant as their last therapy respectively. Prior chemotherapy in any setting included taxane (60%), and anthracycline (47.5%). The median age was 63.8(31-71) years, 77.5% pts had visceral disease, and 95.0% had 2 or more metastatic lesions. As of 06-Feb-2023, of the 40 pts, 5 pts (12.5%) showed PR and 22 (55%) had SD. The CBR was 57.5% while the DCR was 67.5%. The median duration of response in PR pts and median duration of clinical benefit were 9.36 and 7.46 months respectively. The progression free survival (PFS) was 5.6 months (range: 0.93 to 15.26+ months). Drug related AEs were manageable. The most common AEs (≥10%) of any grade were transaminitis, GGT elevation, and rash. Grade 3/4 events were limited to GGT elevation (12.5%), and transaminitis (12.5%). Discontinuations due to related AEs were infrequent (<5%) and limited to two events (one event each of rash and GGT elevation). **Conclusions:** Based on the data from the ongoing study, tonalisib shows encouraging efficacy as a single agent in pts with relapsed/refractory HR+ HER2- difficult to treat MBC patients. Updated efficacy and tolerability data will be provided at the time of presentation. Clinical trial information: NCT05021900. Research Sponsor: Rhizen Pharmaceuticals AG.

Efficacy analysis of CDK4/6 inhibitors (CDKi) + endocrine therapy (ET) treatment in hormone receptor-positive/HER2-negative (HR+/HER2-) advanced breast cancer (aBC): Biomarker analysis including chemoendocrine score (CES) by CDKi type in SOLTI-1801_CDK-PREDICT study. *First Author: Pablo Tolosa Ortega, Medical Oncology Department, Hospital 12 de Octubre, Madrid, Spain*

Background: CDKi + ET improved progression-free survival (PFS) and ribociclib also overall survival (OS) in HR+/HER2- aBC first-line setting. Intrinsic subtypes (IS) are prognostic and predict benefit from CDKi + ET (Finn. SABCS 2017, Prat. JCO 2021, Tolosa. SABCS 2022). We previously reported a PAM50-based CES in HR+/HER2-negative early BC (Prat et al. CCR 2016). Here, we evaluated the association of CES with PFS following CDKi therapy in aBC. **Methods:** CDK-PREDICT prospectively evaluated 113 HR+/HER2- aBC patients (pts) treated in the first-line setting with CDKi + ET. RNA from FFPE metastatic tumors was analyzed at the nCounter (Nanostring Technologies) using a 72 custom gene panel including the PAM50 genes. CES was evaluated as a continuous variable, and categorically (CES-E[endocrine-sensitive], CES-I[intermediate] and CES-C[chemo-sensitive]) using the previously reported cut-offs. Multivariable analyses were used to test CES association with PFS. **Results:** The median follow-up for PFS was 18.5 m. PAM50 IS and CES distribution are shown. No statistically significant difference in mPFS by CDKi. CES (as a continuous variable or as group categories) was found significantly associated with mPFS. mPFS for CES-E pts was NR (95% CI: 26.0 - NR), 20.7m for CES-I (95% CI: 14.2 - 31.7m; HR= 1.98, p<0.05) and 11.7m for CES-C (CI 95%: 7.0 - 18.8; HR= 3.72, p<0.05). CES-C was associated with lower PFS compared to CES-I (aHR= 0.55, p=0.10) and CES-E (aHR= 0.29, p<0.05) independent of CDKi, ET, intrinsic subtype (Luminal versus not), endocrine sensitivity, onset metastatic and visceral disease. CES-C was significantly associated with higher expression of, MIA and lower expression of CCND1, CCNE1, FOXA1, MLPH and UBE2T compared with CES-E (p< 0.05). In CES-E pts mPFS for palbociclib was NR (IC95:22.9-NR) compare with 43.8 m for ribociclib (IC95: 12.0-NR); aHR=1.17 p=0.546), in CES-I pts mPFS for palbociclib was 18.9 m (IC95: 5.8-27.3) compare with 31.7 m for ribociclib (IC95: 12.2-NR); aHR=0.50 p=0.294), and in CES-C pts mPFS for palbociclib was 11.6 m (CI95: 2.7-15.7) compare with 10.0 m for ribociclib (CI95: 2.1-NR; aHR=0.48 p=0.102). Abemaciclib not reported due to low numbers (n=16). **Conclusions:** We confirmed independent prognostic value of CES in first-line setting, suggesting a not statistically significant benefit with ribociclib vs palbociclib in CES-I. Research Sponsor: This project has received a research grant from "Instituto de Salud Carlos III (ISCIII), Ministerio de Economía y Competitividad" (Spain) awarded within the National Research Program with reference PI 18/ O1408, co-funded with European Union ERDF funds.

Capivasertib (C) and fulvestrant (F) for patients (pts) with aromatase inhibitor (AI)-resistant HR+/HER2- advanced breast cancer (ABC): Characterization and management of common adverse events (AEs) from the phase 3 CAPItello-291 trial. *First Author: Hope S. Rugo, University of California San Francisco Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: In the CAPItello-291 trial in eligible pts with AI-resistant HR+/HER2- ABC, the addition of C (a potent, selective pan-AKT inhibitor) to F significantly improved PFS (primary endpoint) compared with placebo (P) in the overall (HR 0.60; 95% CI 0.51–0.71; p<0.001) and AKT pathway-altered population (HR 0.50; 95% CI 0.38–0.65; p<0.001). We report a detailed analysis of AEs. **Methods:** Pts were randomized 1:1 to receive F (500 mg IM on days 1 and 15 of cycle 1, and day 1 of each subsequent 28-day cycle) with either P or C (400 mg BID; 4 days on, 3 days off). Pts with HbA1c <8.0% and diabetes not requiring insulin were eligible. Incidence, management, and time to onset were summarized for common AEs (>10% any grade and >2.0% grade ≥3; CTCAE v5.0). **Results:** Overall, 708 pts were randomized to C+F (n=355) vs P+F (n=353); safety population C+F (n=355) vs P+F (n=350). Baseline risk factors potentially associated with hyperglycemia were a history of diabetes in 34 pts (10%) in the C+F arm vs 20 pts (6%) in the P+F arm (baseline median [range] HbA1c 5.4% [4.0–8.3] vs 5.4% [3.9–7.7]), median weight 65.0 kg (34–150) vs 66.5 kg (37–147) and 54% vs 53% of pts overweight/obese in the C+F vs P+F arms, respectively. Common AEs were diarrhea, rash, and hyperglycemia; maximum AE grade was mostly 1/2 and led to low rates of discontinuation. In the C+F arm, medications for the management of AEs were used in 151/257 pts (59%) with diarrhea (mostly loperamide; n=135), 109/135 pts (81%) with rash (mostly antihistamines; n=75/topical corticosteroids; n=64), and 28/60 pts (47%) with hyperglycemia (mostly metformin; n=18). **Conclusions:** Diarrhea, rash, and hyperglycemia, the most commonly reported AEs associated with AKT pathway inhibition, occur early in treatment with C+F, are generally low grade and manageable, and are associated with low rates of dose modifications/discontinuations. Clinical trial information: NCT04305496. Research Sponsor: AstraZeneca.

Clinical activity of camizestrant, a next-generation SERD, versus fulvestrant in patients with a detectable ESR1 mutation: Exploratory analysis of the SERENA-2 phase 2 trial. *First Author: Mafalda Oliveira, Medical Oncology Department and Breast Cancer Group, Vall d'Hebron University Hospital and Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Camizestrant, a next-generation oral selective estrogen receptor antagonist and degrader (ngSERD), was compared at two dose levels to fulvestrant 500 mg (F) in post-menopausal women with advanced ER+, HER2→ breast cancer with disease recurrence or progression after ≤1 endocrine therapy in the advanced setting in the Phase 2 randomized SERENA-2 study (NCT04214288). Camizestrant demonstrated statistically significant and clinically meaningful benefit vs F in progression-free survival (PFS) in the overall study population (Oliveira M et al. SABCS 2022 Annual Meeting. Abstract GS3-02.). **Methods:** Baseline circulating tumour DNA was collected at screening and/or Cycle 1 Day 1 and analysed by next-generation sequencing. A post hoc exploratory analysis compared investigator assessed PFS with camizestrant (data from 75 and 150 mg combined) vs F in patients with detectable baseline ESR1 (the gene that encodes ERα) hotspot mutations (ESR1m). Patients were divided into subgroups based on whether 1 or >1 ESR1m variants were detected, the specific ESR1m, and whether mutations were detected in BRCA1/2 or the MAPK pathway. The most prevalent mutations are presented. A Cox proportional hazards model was used to compare PFS. **Results:** 48/147 (32.7%) patients treated with camizestrant and 35/73 (47.9%) treated with F had a detectable ESR1m in at least 1 baseline sample. ESR1m were detected in 6/9 (67%) patients with a BRCA1/2 mutation and 5/26 (19%) with a MAPK pathway alteration; however, the numbers were too small to analyse efficacy in these subgroups. **Conclusions:** Camizestrant showed improved outcome vs F in patients with a detectable ESR1m at baseline and in the subgroups tested. The greatest median PFS improvement was seen in patients where a single ESR1m variant was detected, suggesting that early intervention upon detection of an ESR1m may provide the maximum patient benefit for camizestrant, a hypothesis that is being tested in the SERENA-6 clinical trial (NCT04964934). Clinical trial information: NCT04214288. Research Sponsor: Astra Zeneca.

Exploratory biomarker analysis of acclERA breast cancer (BC): Phase II study of giredestrant vs. physician's choice of endocrine therapy (PCET) for pre-viously treated, estrogen receptor-positive, HER2-negative advanced BC (ER+, HER2- aBC). *First Author: Ann Collier, Genentech, Inc., South San Francisco, CA*

Background: ET is the mainstay treatment of ER+ aBC. Giredestrant is a highly potent, nonsteroidal, oral selective ER antagonist and degrader (PO SERD) that achieves robust ER occupancy. acclERA BC (NCT04576455) is a Phase II, randomized, open-label study that evaluated giredestrant vs. PCET in the second- or third-line ER+, HER2- aBC setting. The study did not reach statistical significance for the primary endpoint of investigator-assessed progression-free survival, although giredestrant demonstrated a more pronounced effect in patients (pts) with *ESR1*-mutated (*ESR1m*) tumors. We present an exploratory biomarker analysis. **Methods:** Pts (N = 303) were post- or pre-/perimenopausal women, and men, with ER+, HER2- aBC who had received 1-2 prior lines of systemic therapy for aBC. Randomization was 1:1 to giredestrant (30 mg PO daily) or PCET (fulvestrant/aromatase inhibitor). Baseline plasma circulating tumor (ct)DNA (n = 232) was evaluated with the FoundationOne Liquid CDx (n = 229) or PredicineCARE (n = 3) assays; *ESR1* and other gene mutations in ctDNA were defined as variants with known or likely impact on protein function. Gene expression and PAM50 molecular subtype were assessed by RNAseq from tumor tissue (n = 184) which, based on collection date relative to aBC, was defined as representing early BC (eBC, n = 67), first line (1L, n = 64), or post-1L (n = 46). ER pathway activity was quantified by expression of a predefined set of 38 ER-induced or -repressed genes. **Results:** The majority of tumors were of the Luminal A (51%) and Luminal B (43%) PAM50 subtypes. Post-1L *ESR1m* tumors (n = 17) were significantly enriched for Luminal B (64%) compared with eBC (39%), 1L (44%), and post-1L tumors with no *ESR1m* detected (*ESR1nmd*; n = 29; 45%) (p < 0.001). Post-1L *ESR1nmd* tumors, but not *ESR1m* tumors, had significantly lower ER pathway activity compared with eBC or 1L tumors (p = 0.0001, 0.001). Within the post-1L subgroup, those with *ESR1m* had a distinct ctDNA mutational profile with more *GATA3* (n = 29) and fewer *CHEK2* mutations (n = 0) than *ESR1nmd* (n = 3 and n = 11, respectively). Tumor ER pathway activity and *ESR1* expression in tumor tissue, as well as pre-treatment ctDNA composite tumor fraction and *ESR1* variant allele frequency, were significantly correlated with best overall response to single-agent ET (partial response vs. progressive disease; p < 0.001, p = 0.022, p = 0.001, and 0.045, respectively). **Conclusions:** These data show that tumor response to single-agent ET is correlated with baseline ctDNA features and with tumor ER pathway activity. Interestingly, ER pathway activity was significantly lower in late-line tumors, except in *ESR1m* tumors. Overall, these results support the continued investigation of improved and personalized treatment options for pts with ER+, HER2- aBC. Clinical trial information: NCT04576455. Research Sponsor: F. Hoffmann-La Roche Ltd.

Indirect treatment comparison of first-line CDK4/6-inhibitors in post-menopausal patients with HR+/HER2- metastatic breast cancer. *First Author: Joseph J Zhao, Yong Loo Lin School of Medicine, National University of Singapore (NUS), Singapore, Singapore*

Background: In phase III studies, the CDK4/6-inhibitors palbociclib, ribociclib, and abemaciclib all have demonstrated similar clinical efficacy in hormone receptor-positive (HR+)-human epidermal growth factor receptor 2 negative (HER2-) metastatic breast cancer (MBC) with regards to the primary endpoint of progression-free survival (PFS). However, the lack of overall survival (OS) benefit in the PALOMA-2 study is inconsistent with the OS benefit seen with the other two CDK4/6-inhibitors. This study sought to elucidate indirect treatment survival outcomes between CDK4/6-inhibitors in this setting. **Methods:** Phase III randomized controlled trials comparing first-line aromatase inhibitor with or without a CDK4/6-inhibitor in post-menopausal patients with HR+/HER2- MBC. A graphical reconstructive algorithm was utilized to retrieve patient level time-to-event data from reported Kaplan-Meier OS and PFS curves. Survival analyses were conducted with Cox proportional hazards model with a shared-frailty term incorporated to account for inter-study differences. Two-stage indirect treatment comparison model was conducted as a sensitivity analysis. **Results:** Three randomized phase III trials – PALOMA-2, MONALEESA-2 and MONARCH-3 – comprising 1,827 patients were included. Indirect pairwise comparison of all CDK4/6-inhibitor showed no significant PFS differences across one-stage and two-stage models (all p > 0.05). Likewise, indirect treatment comparison between ribociclib vs palbociclib (one-stage: HR=0.903, 95%-CI: 0.746-1.094, p=0.297), abemaciclib vs palbociclib (one-stage: HR=0.843, 95%-CI: 0.690-1.030, p=0.094) and abemaciclib vs ribociclib (one-stage: HR=0.933, 95%-CI: 0.753-1.157, p=0.528) failed to demonstrate a significant OS difference. **Conclusions:** Findings from this indirect treatment comparison suggest no significant PFS or OS differences between CDK4/6-inhibitor agents when combined with an aromatase inhibitor in post-menopausal patients with HR+/HER2- MBC. Research Sponsor: None.

Indirect treatment comparison outcomes.

Oral elacestrant vs standard-of-care in estrogen receptor-positive, HER2-negative (ER+/HER2-) advanced or metastatic breast cancer (mBC) without detectable *ESR1* mutation (EMERALD): Subgroup analysis by prior duration of CDK4/6i plus endocrine therapy (ET). *First Author: Virginia G. Kaklamani, UT Health San Antonio, San Antonio, TX*

Background: The phase 3 EMERALD trial reported significantly prolonged progression-free survival (PFS) and a manageable safety profile with oral elacestrant (Ela) vs standard of care ET (SoC) in patients (pts) with ER+/HER2- mBC following progression on prior endocrine and CDK4/6i therapy. Duration of prior CDK4/6i was shown to be a potential predictor of efficacy in pts with *ESR1* mutations (*ESR1m*) receiving elacestrant. Median PFS (mPFS) for pts with *ESR1m* receiving <6 mos of prior CDK4/6i was 1.87 mos (Ela) vs 1.87 mos (SoC), compared with 4.14 mos (Ela) vs 1.87 mos (SoC) for pts receiving CDK4/6i ≥6 mos and 8.61 mos (Ela) vs 1.91 mos (SoC) for pts receiving ≥12 mos of prior CDK4/6i. Understanding the clinical activity of Elacestrant in *ESR1* non-detected (*ESR1nd*) ER+/HER2- mBC is still needed. Preclinical ER+ PDX models suggest that elacestrant is equally active in *ESR1* wild-type (*ESR1wt*) and *ESR1m*. In the PDX model ST3932 (*ESR1wt*), derived from a pt treated with palbociclib plus aromatase inhibitor (AI) that was resistant to palbociclib in vivo, elacestrant demonstrated statistically significant single-agent antitumor activity (Patel, 2019). **Methods:** Pts with ER+/HER2- advanced or mBC who previously had 1-2 lines of ET, mandatory CDK4/6i, and ≤1 chemotherapy were randomized, 1:1 to receive oral elacestrant or SoC (investigator's choice of AI or fulvestrant). An ad hoc subgroup analysis was performed on pts with *ESR1nd* by prior duration of CDK4/6i plus ET (<6 mos, ≥6 mos, ≥12 mos) in the advanced or metastatic setting. **Results:** Among the 478 pts enrolled, 250 (n=124, Ela; n=126, SoC) did not have a detectable *ESR1m*. Interestingly, in 41 pts with *ESR1nd* (n=20, Ela; n=21, SoC) that rapidly progressed on prior CDK4/6i plus ET (<6 mos), treatment with elacestrant was associated with prolonged mPFS vs SoC (5.32 mos vs 1.87 mos, respectively) (HR=0.518 [95% CI 0.216-1.165]), compared with a mPFS of 1.91 mos (Ela) vs 1.97 mos (SoC) for pts who were on CDK4/6i for ≥6 mos (HR=0.911 [95% CI 0.640-1.298]) and 2.33 mos (Ela) vs 2.04 mos (SoC) for pts who were on CDK4/6i for ≥12 mos (HR=0.886 [95% CI 0.586 - 1.337]). In these 41 pts, mean time to chemotherapy was 137.7 days for elacestrant vs 75.5 days for SoC. Safety results were consistent with previously reported data. Specific pt characteristic information will be provided in the presentation. **Conclusions:** In this post-hoc analysis, oral elacestrant delayed disease progression and time to subsequent chemotherapy in pts who did not have a detectable *ESR1m* and rapidly progressed within 6 months of CDK4/6i plus ET before study entry. Preclinical data support these findings. While caution needs to be exerted given small numbers, the results highlight the potential role of elacestrant in *ESR1wt* tumors, and more research is warranted. Clinical trial information: NCT03778931. Research Sponsor: Stemline Therapeutics, Inc.

Poster Session

A multicenter, single-arm, open-label trial of birociclib, a CDK4/6 inhibitor, as a single agent, in patients with refractory HR+/HER2- metastatic breast cancer. *First Author: Jiayu Wang, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, China*

Background: Birociclib is a new molecular entity and selective inhibitor of cyclin-dependent kinase (CDK) 4 and 6. This phase II study (NCT04539496) was to evaluate the single-agent efficacy and safety of Birociclib in patients with refractory HR+/HER2- metastatic breast cancer (MBC). **Methods:** This phase II study is a multicenter, single-arm, open-label trial in patients with HR+/HER2- MBC who had progressed after prior endocrine therapy and 1-2 prior chemotherapy regimens in the metastatic setting. Birociclib 480 mg was administered orally on a continuous schedule twice daily until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR). The secondary endpoints included disease control rate (DCR), clinical benefit rate (CBR), duration of response (DoR), progression-free survival (PFS), overall survival (OS) and safety. **Results:** 131 patients were enrolled from 29 hospitals in China between 10/2020 and 8/2021, with a median duration of follow-up of 17.74 months. Among them, 84.7% patients had visceral disease, and 61.1% patients had ≥3 metastatic sites. In the metastatic setting, patients had received a median of 3 (range, 1-6) prior systemic therapies including a median of 1 (1-2) chemotherapy regimen and 2 (1-5) endocrine therapy regimens. The investigator-assessed confirmed ORR was 22.9% (95% CI: 16.0-31.1); DCR was 66.4% (95% CI: 57.6-74.4); CBR was 39.7% (95% CI: 31.3-48.6), among which 1 (0.8%) patient was with confirmed complete response (CR) and 29 (22.1%) patients were with confirmed partial response (PR). Median DoR was 13.1 months (95% CI: 9.4-16.6). Median PFS was 7.4 months (95% CI: 5.5-9.2). The OS rates at 12 months and 21 months were 81.8% and 64.6%, respectively. Birociclib demonstrated similar activity in subgroups with visceral disease and liver disease, ORR were 20.7% (95% CI: 13.6-29.5) and 18.5% (95% CI: 9.9-30.0), DCR were 64.9% (95% CI: 55.2-73.7) and 66.6% (95% CI: 51.7-76.9), CBR were 39.6% (95% CI: 30.5-49.4) and 35.4% (95% CI: 23.9-48.2), DoR were 14.8 months (95% CI: 7.6-NA) and 11.2 months (95% CI: 5.5-NA), PFS were 8.2 months (95% CI: 5.5-9.3) and 7.3 months (95% CI: 5.388-9.101), respectively. The most common treatment-emergent adverse events (TEAE) were diarrhea [93.1% (all grades); 18.3% (≥grade 3)], neutropenia [87.0% (all grades); 43.5% (≥grade 3)], and leukocytopenia [86.3% (all grades); 32.8% (≥grade 3)]. Most of AEs were grade 1 or grade 2 and could be alleviated or cured by symptomatic treatment. **Conclusions:** In patients who have limited treatment options with refractory HR+/HER2- metastatic breast cancer, continuous dosing of single-agent Birociclib exhibited promising and sustaining clinical activity with acceptable safety profile, thus it provided an alternative orally administered therapy option. Clinical outcomes and correlation with longitudinal circulating tumor (ct) DNA dynamics of a phase I/II study of GSK525762 combined with fulvestrant in patients with hormone receptor-positive/HER2-negative (HR+/HER2-) advanced or metastatic breast cancer. *First Author: David W. Cescon, Princess Margaret Cancer Center, University Health Network and University of Toronto, Toronto, ON, Canada*

Background: Endocrine therapy is the main treatment option for hormone receptor-positive and human epidermal growth factor receptor 2-negative (HR+/HER2-) metastatic breast cancer (mBC). However, many patients experience disease progression due to resistance to endocrine therapy. Molibresib (GSK525762) is a small-molecule inhibitor of bromodomain and extra-terminal (BET) family proteins (BRD2, BRD3, BRD4, and BRDT). Pre-clinical data suggested that the combination of molibresib with endocrine therapy might overcome endocrine resistance. This study aimed to investigate the safety, tolerability, pharmacokinetics, pharmacodynamics, and efficacy (objective response rate [ORR]) of molibresib combined with fulvestrant in women with HR+/HER2- mBC. The association between early ctDNA dynamics and clinical outcomes was also assessed. **Methods:** In this phase I/II dose-escalation and expansion study, patients received oral molibresib 60 mg or 80 mg once daily in combination with intramuscular fulvestrant. Patients enrolled had relapsed/refractory, advanced/metastatic HR+/HER2- BC with disease progression on prior treatment with an aromatase inhibitor, with or without a cyclin-dependent kinase 4/6 (CDK4/6) inhibitor. Baseline and week 4 plasma samples were collected and tested using a 74-gene ctDNA panel. Molecular response (MR) was defined as at least 50% reduction of baseline ctDNA level calculated as the average allele frequency of detected single nucleotide variants or indels. **Results:** The study included 123 patients. The 3 most common molibresib-related adverse events (AEs) were nausea (52%), dysgeusia (49%), and fatigue (44%). At molibresib 60 mg, >90% patients experienced treatment-related AEs, with varying incidence of Grade ≥ 3 AEs (17%–71%) amongst subgroups. The ORR was 13% (95% confidence interval [CI], 8–20), not meeting the 25% threshold for proceeding to phase II. Among 82 patients with detected baseline circulating tumor DNA, a strong association was observed between baseline copy number amplification (CNA) presence and poor progression-free survival (PFS) with hazard ratio (HR) of 2.89 (95% CI, 1.73–4.83; $P < 0.0001$). MR was significantly correlated with better PFS (HR=0.38; 95% CI, 0.19–0.75; $P = 0.0037$), which was further improved when MR was refined as no baseline CNA (HR=0.22; 95% CI, 0.09–0.54; $P = 0.0003$). **Conclusions:** Molibresib in combination with fulvestrant did not demonstrate clinically meaningful activity in this study. Copy number adjusted ctDNA MR is a promising early marker for clinical benefit. Clinical trial information: NCT02964507. Research Sponsor: GlaxoSmithKline.

Poster Session

Impact of pathogenic germline BRCA1/2 and PALB2 mutations and tumor aneuploidy in patients with HR+/HER2- metastatic breast cancer treated with CDK4/6 inhibitors. *First Author: Jesús Fuentes Antrás, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, Canada*

Background: CDK4/6 inhibitors lack established predictors of efficacy in HR+/HER2- mBC. Pathogenic germline BRCA2 variants, somatic homologous recombination deficiency (HRD) and APOBEC signatures conferred worse survival in small series. Broader tumor DNA panels enable the detection of these and other parameters such as aneuploidy and tumor mutational burden. **Methods:** Clinical and molecular data from a single institution cohort of CDK4/6-treated HR+/HER2- mBC pts were analyzed. ECOG PS was 0–1. Clinical variables were collected retrospectively. Primary endpoints were progression-free survival (PFS) and overall survival (OS). Tumor-only sequencing was performed on clinical samples with 161-gene OCAV3, 523-gene TSO500 or 555-gene lab-developed NGS panels. HRD was assessed with the Signature Multivariate Analysis (SigMA) tool using a likelihood-based measure to estimate single base substitution signature 3. Aneuploidy scores were defined as the fraction of covered arms harboring arm-level somatic copy number alterations as determined by ASCETS v1.1. **Results:** 153 pts were available for analysis. Median age was 54 y (29–88). 74% were postmenopausal, 28% *de novo* metastatic and 67% had visceral disease. Palbociclib was used in 80%, ribociclib in 17% and abemaciclib in 3%, mostly as early lines (1L 65%, 2L 22%). Median follow up was 46 mo (7–84) and median time from sample collection to CDK4/6i was 0.6 y (–18.5–+2.6). 76% of samples have been sequenced. The median number of mutations (Mts) was 3 (1–32), most commonly in PIK3CA (37%), GATA3 (26%) and TP53 (20%). ESR1, KRAS and ARID1A, but not RB1 muts were numerically enriched in post-CDK4/6i mets (n=8). TP53 (HR 1.85 CI 1.02–3.33) and GATA3 (HR 0.48, CI 0.28–0.83) muts were associated with PFS. Germline (g) testing was available in 68 (44%) pts, with 21 pts carrying pathogenic variants including 11 BRCA2, 2 BRCA1 and 2 PALB2. Cox regression showed a strong negative impact of gBRCA1/2-PALB2 on PFS (HR 4.0 CI 2.0–7.9) and OS (HR 3.5 CI 1.6–7.7) adjusted for age, visceral disease and prior chemo. In 1L, mPFS/OS was 9.9/28.1 mo for gBRCA1/2-PALB2 carriers, 26.8/NR mo for non-carriers and 23.7/49.2 mo for untested (Cox HR PFS 5.1 CI 2.1–14.0; HR OS 4.0 CI 1.4–11.2). Pts with gATM/CHK2/BRIP1 had a 1L PFS/OS $\geq 15/45$ mo. Among 36 pts assessed for HRD, 22 were HRDlow and 14 HRDhigh with no significant survival association. 3/4 known gBRCA1/2 carriers were HRDhigh and 7/8 gWT HRDlow. In these pts, higher aneuploidy was associated with shorter PFS and OS (Cox HR PFS 2.0 CI 0.9–4.3, $p=0.07$; HR OS 2.6 CI 1.0–7.1; $p=0.05$). **Conclusions:** Pathogenic gBRCA1/2-PALB2 and higher aneuploidy were associated with shorter survival. Profiling of aneuploidy, HRD, TMB and APOBEC in all pts is ongoing including 55 baseline ctDNA samples and 361 samples from the GENIE BPC cohort. Results will account for FDR, left truncation and optimal cutoffs. ESR1 mutational landscape and impact of co-existing resistance variants on clinical outcomes in patients with metastatic breast cancer. *First Author: Arielle J Medford, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: Mutations in estrogen receptor 1 (ESR1) confer resistance to aromatase inhibitors but may retain sensitivity to selective estrogen receptor degraders (SERD). Recently, elacestrant, an oral SERD, was approved for patients with HR+/HER2- ESR1^{mut} metastatic breast cancer (MBC). In this study, we evaluated the genomic landscape of ESR1 alterations from a genomic database and also evaluated the impact of resistance-associated alterations on clinical outcomes. **Methods:** A large de-identified database of mutations detected in plasma cell-free DNA (cfDNA) from patients with HR+/HER2- MBC was assessed for ESR1 mutations and resistance-associated co-alterations. We used the Guardant 360 assay, a 70- to 74-gene targeted next generation sequencing panel and applied a breast cancer subtype classifier based on detected mutations (Bardia A, SABCS 2020). In addition, clinical outcomes were evaluated from a clinically annotated institutional dataset, linking genomic alterations with progression-free survival (PFS) and overall survival (OS) to single-agent SERD therapy for patients with MBC. **Results:** Among 11,456 patients with MBC and detectable cfDNA, 4,694 were classified as likely HR+/HER2-, of which 2,708 (58%) had ESR1 missense mutations, the majority of which occurred in the ligand binding domain (n = 2,690, 99%). Among the latter, alterations included 204 unique mutations, of which 55 were variants of uncertain significance (VUS). Multiple ESR1 mutations were detected in 979 (36%) patients. Among 567 patients classified as HR+/HER2- that underwent serial sampling, 136 (24%) had detectable ESR1 missense mutations that were previously undetectable. Within the ESR1^{mut} population, 1,990 (74%) had co-existing non-synonymous, non-VUS alterations at genes associated with SERD resistance: PIK3CA (n = 1,330; 49%), ARID1A (n = 314; 12%), PTEN (n = 201; 7%), ERBB2 (n = 180; 7%), AKT1 (n = 139; 5%), and NF1 (n = 103; 4%); top amplifications were FGFR1 (n = 522; 19%), EGFR (n = 277; 10%), and MYC (n = 177; 7%). Among a clinically annotated HR+/HER2- subgroup (n = 350), 51 patients received SERD monotherapy, either fulvestrant (n = 9) or oral SERD on clinical trial (n = 42); among 28 patients with cfDNA variants associated with SERD resistance, median PFS and OS were lower compared to the 23 patients without resistance mutations (PFS: 2.4 vs 11.3 mo; HR = 0.44; 95% CI, 0.23–0.81; $p = 0.008$; and OS: 21.1 vs 31.4 mo; HR 0.47; 95% CI, 0.22–0.98; $p = 0.045$). **Conclusions:** ESR1 mutations that qualify patients to receive approved SERD therapy are detectable by plasma-based genotyping and can associate with various genomic co-alterations, including variants that may impact clinical outcomes. Further research is needed to confirm the impact of co-alterations in additional datasets and evaluate the role of SERD-based combination therapy to further improve clinical outcomes of patients with MBC. Comparing the prognostic and predictive utility of serum thymidine kinase 1 and CA 15-3 in patients with hormone receptor positive metastatic breast cancer starting first-line endocrine therapy in SWOG S0226. *First Author: Erin Frances Cobain, University of Michigan, Ann Arbor, MI*

Background: Serum levels of thymidine kinase 1 activity (TKa), a fundamental enzyme in DNA synthesis and cellular proliferation, are prognostic of benefit from endocrine therapy (ET) in patients (pts) with hormone receptor positive (HR+) metastatic breast cancer (MBC) who participated in SWOG S0226, a prospective randomized trial comparing anastrozole vs. anastrozole and fulvestrant given in 4 week cycles. The assay for TKa (DiviTum TKa) was FDA approved in July 2022 for monitoring of postmenopausal HR+ MBC pts. The assay for circulating MUC1, CA 15-3, is routinely utilized in monitoring of pts with MBC. We compared the prognostic and predictive utilities of CA 15-3 and TKa in pts from S0226. **Methods:** TKa was measured in 1725 sera from 432 pts while CA 15-3 was measured in 1298 sera from 326 pts at baseline (BL), cycles 2, 3, 4 and 7. Prespecified cutoff levels of ≥ 250 DuA and ≥ 30 U/mL were considered high for TKa and CA 15-3 respectively. Progression-free survival (PFS) and overall survival (OS) were analyzed by Kaplan-Meier and Cox regression stratified by prior adjuvant tamoxifen use. To examine markers over time, a landmark Cox regression analysis was done starting at initiation of Cycle 4. BL and recent (Cycle 3 if available, otherwise Cycle 2) markers were assessed for simultaneous prediction of subsequent PFS and OS. **Results:** BL TKa was elevated in 190/432 (44%) and CA 15-3 was elevated in 254/326 (78%). Agreement between assays was 53%. Pts with high versus low BL TKa had significantly worse PFS (median 11.6 vs. 17.2 months, HR = 1.68, 95% confidence interval (CI) 1.37–2.06) and OS (median 34 vs. 58 months, HR = 2.16, 95% CI 1.73–2.70) whereas pts with high versus normal BL CA 15-3 had no significant difference in PFS (median 13.6 vs. 16.1 months, HR = 1.23, 95% CI 0.93–1.62) but worse OS (median 45 vs. 66 months, HR = 1.82, 95% CI 1.30–2.53). A multivariable Cox model with both markers shows only TKa as being prognostic for PFS (TKa HR = 1.61, 95% CI 1.28–2.03; CA 15-3 HR = 1.21, 95% CI 0.91–1.59), but both prognostic for OS (TKa HR = 2.09, 95% CI 1.61–2.71; CA 15-3 HR = 1.70, 95% CI 1.22–2.38). In the landmark multivariable analysis, positive TKa at BL was a strong predictor of PFS (HR = 1.65, 95% CI 1.28–2.14), but recent TKa was not (HR = 1.25, 95% CI 0.93–1.68). In contrast, positive CA15-3 at BL was not a predictor of PFS (HR = 0.73, 95% CI 0.46–1.17), but recent CA15-3 was (HR = 1.97, 95% CI 1.26–3.06). **Conclusions:** BL TKa is highly prognostic in pts with HR+ MBC initiating first-line systemic ET, with low BL TKa conferring superior prognosis. In contrast, CA 15-3 is only modestly prognostic at BL, but is prognostic after 3 cycles of treatment. These hypothesis-generating data suggest further study is needed to determine how these biomarkers should be employed in a complementary manner to monitor response to systemic therapy in HR+ MBC. Clinical trial information: NCT00075764. Research Sponsor: U.S. National Institutes of Health; AstraZeneca, Biovia.

Relation between circulating biomarkers at diagnosis of early luminal-like breast cancer and subsequent risk of distant metastases. *First Author: Yentl Lambrechts, Laboratory of Experimental Oncology (LEO), Department of Oncology, Leuven, Belgium*

Background: Predicting development of distant metastases after treatment of early luminal breast cancer (BC) remains a major challenge. Besides clinical-pathological features of the primary tumor, baseline circulating factors could also play a role as prognostic biomarkers. **Methods:** Patients with newly diagnosed early BC (grade 2/3, ER+, HER2-non- amplified) were selected from our institutional BC registry, with associated blood biobank collecting baseline plasma/serum samples at diagnosis. Circulating biomarkers potentially modulating the metastatic process (chemokines, micro-RNAs (miRNAs), Leukemia Inhibitory Factor (LIF), and osteopontin), and serum-induced functional myeloid interferon (IFN) and nuclear factor kappa-light-chain-enhancer of activated B cells (NFκB) signaling-responses, were measured at early BC diagnosis (before any treatment) in patients who subsequently developed distant metastasis within five years after diagnosis and therapy (META group) and in a 1:1 control group of patients, pairwise matched for age, tumor grade, stage, and histological subtype, who remained disease-free for at least seven years (NON-META group). All blood biomarkers were analyzed pair-wisely using the univariable Wilcoxon signed rank test (two-tailed). Multiple testing correction was done by applying a false discovery rate (FDR) of 0.05. In addition, a multivariable logistic regression analysis (MVA) was performed to find blood biomarkers signatures that can predict the development of metastases at first diagnosis of early BC. **Results:** 102 matched patient pairs were included. Univariable paired analysis showed significantly increased baseline expression of LIF ($p=0.012$) and six miRNAs (miR-143-3p: $p=0.015$; miR-197-3p: $p<0.001$; miR-223-3p: $p=0.006$; miR-223-5p: $p=0.045$; miR-338-3p: $p=0.045$; miR-365a-3p: $p=0.025$), and decreased serum-induced myeloid -IFN-responses ($p=0.023$) and ten miRNAs (let-7b-5p: $p=0.006$; miR-106a-5p: $p=0.045$; miR-106b-5p: $p=0.015$; miR-107: $p=0.014$; miR-144-3p: $p=0.015$; miR-15a-5p: $p=0.045$; miR-15b-3p: $p=0.032$; miR-185-5p: $p=0.045$; miR-18a-5p: $p=0.015$; miR-30b-5p: $p=0.045$) in the META group compared to the NON-META group. MVA yielded a seven-biomarker signature, which includes miR-197-3p ($p=0.008$), miR-139-5p ($p<0.001$), LIF ($p=0.007$), miR-106b-5p ($p=0.003$), serum-induced IFN/ISG response ($p=0.006$), miR-652-3p ($p=0.015$), and miR-133b ($p=0.025$) with a C-index of 0.79 (0.70-0.88) to predict distant metastases. After 5-fold internal cross-validation, C-index was 0.63 (0.52-0.74). **Conclusions:** Baseline circulating miRNAs, LIF, and serum-induced IFN-response levels at early luminal BC diagnosis are associated with subsequent distant metastases. Further external validation is required to confirm the prognostic value of these biomarkers. Research Sponsor: Kom op Tegen Kanker.

A phase I trial of palbociclib (palbo) and bosutinib (bos) with fulvestrant (fulv) in patients (pts) with hormone receptor-positive, HER2-negative (HR+/HER2-) metastatic breast cancer (MBC) refractory to an aromatase inhibitor (AI) and a CDK4/6 inhibitor (CDK4/6i). *First Author: Candace Bavette Mainor, Medstar Georgetown University Hospital-Lombardi Comprehensive Cancer Center, Washington, DC*

Background: Standard therapy for HR+/HER2- MBC includes a CDK 4/6i with endocrine therapy (ET). Eventual resistance results in progression of disease (PD). A potential mechanism of CDK4/6 resistance is through Src activation. Targeting Src and ET suppresses proliferation of ER+ hormone independent breast cancer cells. Therefore, adding bos, a Src inhibitor, to palbo + fulv may overcome this resistance and restore sensitivity to CDK4/6i. **Methods:** This is a single arm, 3+3 dose escalation phase I trial (NCT 03854903) of bos + palbo + fulv for pts with HR+/HER2- MBC who have PD after ≥ 1 AI, ≥ 1 CDK4/6i, and < 3 lines of chemo for MBC. Pts were enrolled in two cohorts, A and B, with two dose levels in cohort B. Fulv was given at standard dose. Cohort A: bos 300mg (D1-5/wk), palbo 75mg D1-21 q28 days, fulv; cohort B1: bos 300mg (D1-5/wk), palbo 100 mg D1-21 q28 days, fulv; cohort B2: bos 500mg (D1-5/wk), palbo 100 mg D1-21 q28 days, fulv. Primary objective was safety and tolerability, including MTD and recommended phase 2 dose (RP2D). Secondary objectives included ORR, and CBR 24 wks. Serum, plasma, and peripheral blood mononuclear cells were collected for Src activation, cell cycle profile arrays, and cytokine array screens. **Results:** 18 evaluable pts were enrolled between 4/2019 – 11/2022. To date, 16pts have completed and 2 pts remain on treatment. All pts had received prior palbo and 15/18 (83%) had received prior fulv. Median number of prior therapies in the metastatic setting was 3.2. The combination in cohort A and B1 was well tolerated. The combination in cohort B2 (bos 500mg D1-5/wk) was toxic which resulted in bos dose reduction in all pts in the B2 cohort. There were no DLTs. The RP2D was bos 300 mg D1-5/wk, palbo 100 mg D1-21 q28 days, and standard dose fulv. No pts came off treatment due to adverse events (AEs). Most common AEs were G1/2 (9 pts) and G3/4 (7 pts) neutropenia (no neutropenic fever); G1 nausea (8 pts); G1/2 (12pts) and G3 (1pt) diarrhea; G1/2 rash (4 pts), and no G5 events. Median PFS was 5.9 months with 95% CI (3, 10.1). CBR at 6 months was 50% (9/18) (95% CI (0.26, 0.74)). The ORR was 6% (0 CR, 1 PR cohort B2), but best response was SD in 11 pts. Correlative studies underway include assessment pre and post treatment of 1) Src levels and activity to confirm that bos is acting on target and 2) RNA sequencing of Src activation and cell cycle profiles and 3) cytokine array screens to test if Bos affects inflammatory markers. **Conclusions:** Bos + palbo + fulv was well tolerated at the RP2D. A robust CBR of 50% was seen despite all patients having prior PD on palbo and 83% on fulv. This is an effective combination for HR+/HER2- MBC which warrants further investigation and may represent a mechanism to overcome resistance to CDK4/6i and provide another oral treatment option. Clinical trial information: NCT03854903. Research Sponsor: Pfizer-Aspire award.

Alpelisib + endocrine therapy in patients with PIK3CA-mutated, hormone receptor-positive, human epidermal growth factor receptor 2-negative, advanced breast cancer: Analysis of all 3 cohorts of the BYLieve study. *First Author: Stephen Chia, University of British Columbia, Vancouver, BC, Canada*

Background: The phosphatidylinositol-4,5-bisphosphate 3-kinase catalytic subunit alpha (PIK3CA) gene is mutated in ~40% of patients (pts) with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer (ABC). Alpelisib (ALP), an α -selective PI3K inhibitor and de-grader, is indicated in combination with fulvestrant (FUL) for pts with HR+, HER2- ABC following progression on/after endocrine therapy (ET)-based treatments (tx). Primary analyses from the 3 cohorts of the Phase 2, open-label, noncomparative BYLieve study demonstrated the efficacy of ALP + ET in pts with HR+, HER2-, PIK3CA-mutated ABC who progressed on/after other tx, including immediately after a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i). Presented here are efficacy and safety data from the full 3 cohorts of the BYLieve study. **Methods:** Pts in all 3 cohorts completed ≥ 18 mo follow-up plus 1 mo safety follow-up. Efficacy assessments included DoR, BOR, PFS, PFS2, and OS. Safety/tolerability of ALP were also assessed. Median (m) PFS, PFS2, and OS were assessed by Kaplan-Meier methodology per local investigator assessment. **Results:** Cohort A (ALP + FUL) comprised 127 pts whose immediate prior tx was CDK4/6i + aromatase inhibitor (AI); Cohort B (ALP + letrozole) enrolled 126 pts whose immediate prior tx was CDK4/6i + FUL. In Cohort C (ALP + FUL), 126 pts had disease progression on/after AI and received CT or ET as immediate prior tx. Median follow-up for the 3 cohorts was 21.8, 25.3, and 18.5 mo, respectively. mPFS in Cohorts A, B, and C was 8.0 mo (95% CI, 5.6-8.6), 5.6 mo (3.7-7.1), and 5.6 mo (5.4-8.1), respectively; mPFS2 was 15.2 mo (95% CI, 11.4-21.7), 13.0 mo (10.2-13.9), and 13.5 mo (11.5-17.3), respectively. mOS in Cohorts A, B, and C was 27.3 mo (95% CI, 21.3-32.7), 29.0 mo (24.5-34.8), and 20.7 mo (16.9-28.1), respectively. Efficacy of ALP + ET in 2nd and 3rd lines will be presented. In Cohorts A, B, and C, respectively, 29 (22.8%), 19 (15.1%), and 23 (18.3%) pts discontinued tx due to adverse events (AEs). The most common any grade AEs in all 3 cohorts (A; B; C) were diarrhea ($n=82$, 64.6%; $n=86$, 68.3%; $n=68$, 54.0%), hyperglycemia ($n=76$, 59.8%; $n=82$, 65.1%; $n=85$, 67.5%), nausea ($n=59$, 46.5%; $n=69$, 54.8%; $n=51$, 40.5%), rash ($n=40$, 31.5%; $n=39$, 31.0%; $n=51$, 40.5%), and fatigue ($n=39$, 30.7%; $n=39$, 31.0%; $n=44$, 34.9%). Hyperglycemia was the most common grade ≥ 3 AE, observed in 37 (29.1%), 32 (25.4%), and 30 (23.6%) pts in Cohorts A, B, and C, respectively. **Conclusions:** After ≥ 18 mo follow-up, with mature data, ALP + ET demonstrated clinical activity in BYLieve Cohorts A, B, and C. Within the trial, ALP + ET showed median OS between 20.7 mo and 29.0 mo following prior CDK4/6i, chemotherapy, or ET. AEs associated with ALP were well defined and manageable, with no new safety signals observed in any cohort. Clinical trial information: NCT03056755. Phase 1/2 dose expansion study evaluating first-in-class eIF4A inhibitor zotatifin in patients with ER+ metastatic breast cancer. *First Author: Ezra Rosen, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Zotatifin (eFT226) is a first-in-class, potent and sequence selective inhibitor of RNA helicase eIF4A that promotes a stable mRNA:eIF4A: drug ternary complex at specific polypurine motifs within the 5'-UTR, preventing translation of select transcripts. In preclinical models zotatifin treatment simultaneously down-regulated translation of numerous oncogenes including CDK4, ER α , ERBB2, KRAS, and CCND1. **Methods:** Following a 3+3 dose escalation portion of the protocol (Part 1), Part 2 is a Simon's two-stage design of cohorts of up to 18 patients (pts) with ER+ metastatic breast cancer enrolled at the recommended phase 2 dose of zotatifin (0.07 mg/kg IV two weeks on/one week off) in combination with fulvestrant (ful) (ECBF: Expansion, Combination, Breast, Ful) or in combination with ful and abemaciclib (abema) (ECBF+A: Expansion, Combination, Breast, Ful + Abema). Key eligibility criteria included at least one line of therapy for advanced/metastatic disease, progression on hormone therapy, and in addition, the ECBF cohort required prior CDK 4/6 inhibitor (CDKI). Primary endpoint was objective response rate (ORR) per RECIST v1.1. Additional endpoints included safety, other efficacy analyses, and for Parts 1 and 2, characterization of pharmacodynamic (PD) markers and pharmacokinetics. **Results:** As of a data cut-off of Jan 31, 2023, 18 pts were enrolled in each cohort. Median prior metastatic lines of therapy were 3 and 7 in ECBF+A and ECBF, respectively. In 16 evaluable pts in ECBF+A cohort, there were two confirmed partial responses (PR), two additional PRs awaiting confirmatory scans, and 8 pts with best overall response (OR) of stable disease (SD). All pts with PR/unconfirmed PR received prior CDKI and ful, including one pt with disease progression on combination abema and ful as the last therapy prior to enrollment. In 18 evaluable pts in ECBF, there was one confirmed PR and six SD as best OR. There were no dose-limiting toxicities or grade (Gr) 5 adverse events (AEs) in either cohort. In ECBF+A the most common AEs (all Gr 1/2) were diarrhea (44%) and nausea (31%) and 21% of pts had Gr 3/4 AEs. The most common AEs in ECBF (all Gr 1/2) were nausea (39%) and constipation (27%), and 28% of pts had Gr 3/4 AEs. Blood-based PD markers and ctDNA in Part 1 showed dose-dependent evidence of target engagement and anti-tumor activity. **Conclusions:** In dose expansion cohorts of heavily pre-treated metastatic breast cancer pts, eIF4A inhibitor zotatifin showed evidence of anti-tumor activity in combination with fulvestrant and abemaciclib and had a favorable safety profile consisting of primarily grade 1/2 adverse events. Clinical trial information: NCT04092673. Research Sponsor: eFFECTOR Therapeutics, Inc.

Real-world (RW) outcomes of patients (pts) with advanced breast cancer (aBC) with and without resistance alterations (alts) detected in cell-free circulating tumor DNA (ctDNA) prior to CDK4/6 inhibitor (CDK4/6i) plus endocrine therapy (ET) treatment. *First Author: Seth Andrew Wander, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: CDK4/6i plus ET is standard of care first-line (1L) therapy for hormone receptor positive (HR+), HER2- aBC. While molecular analyses from trials and pts have identified several mechanisms of resistance to CDK4/6i plus ET, currently, no biomarkers (outside of hormone status) are used for therapy selection. We utilized RW data to assess impact of putative baseline CDK4/6i+ET resistance alts (CDK4/6i+ET-R) on clinical outcomes among pts with aBC treated with CDK4/6i. **Methods:** Pts with aBC were identified via the Guardant INFORM database; those with a ctDNA test within 90 days prior to CDK4/6i start were included in this analysis. Based on previous studies, oncogenic or likely oncogenic alterations (as characterized by OncoKB) in the following genes were considered CDK4/6i+ET-R alts: RB1, PTEN, AKT1, CCNE1, ERBB2, FGFR1, FGFR2, and KRAS. Pts with >1 CDK4/6i+ET-R alt were compared to pts without any CDK4/6i-R alts. Kaplan-Meier plots, log-rank tests (LR) and multivariate Cox proportional hazards models (HR) adjusted (adj) for age, sex, year of ctDNA test and line of therapy were used to assess differences in time to next treatment (TTNT) and overall survival (OS). **Results:** 1075 pts with aBC treated with CDK4/6i (27% receiving 1L treatment) met inclusion criteria, 293 of whom (27%) had >1 alt in a CDK4/6i+ET-R gene. Pts with CDK4/6i+ET-R alts had significantly shorter TTNT (8.7 mos vs 14.2 mos, LR p=0.001; adj HR 1.36, 95%CI 1.11-1.66, adj p=0.003) and OS (28.3 mos vs 60.9 mos, LR p<0.0001; adj HR 2.19, 95%CI 1.69-2.82, adj p<0.0001) compared to those without. This divergence was more pronounced for patients receiving 1L CDK4/6i (TTNT: 10.7 mos vs 24.6 mos, LR p=0.006, adj HR 1.84, 95%CI 1.18-2.87, adj p=0.007; OS: 23.8 mos vs 67.3 mos, LR p<0.0001, adj HR 3.27, 95%CI 1.89-5.62, adj p<0.0001). Individual gene contributions towards less favorable TTNT are shown. **Conclusions:** We demonstrate via RW data that patients with >1 pre-treatment ctDNA alt in a curated list of CDK4/6i+ET-R genes have significantly worse outcomes on CDK4/6i plus ET treatment, a difference more pronounced among patients receiving 1L therapy. This data is among the first successful efforts to validate a clinically useful multi-gene clinical biomarker that has the potential to predict CDK4/6i plus ET resistance. Further exploration of this signature's prognostic and predictive utility for CDK4/6i plus ET use is ongoing to better refine personalized treatment selection in HR+/HER2- aBC. Research Sponsor: None.

Gene	Total N	TTNT multivariate model adj HR (95%CI)	p-value
CCNE1	18	1.82 (0.98-3.38)	0.06
ERBB2	36	1.74 (1.09-2.76)	0.02
RB1	11	1.64 (0.72-3.73)	0.24
KRAS	59	1.63 (1.15-2.29)	0.006
AKT1	39	1.61 (1.01-2.56)	0.05

Discovery of CDK4/6 bifunctional degraders for ER+/HER2- breast cancer. *First Author: Hannah Majeski, San Diego, CA*

Background: CDK4/6 inhibitors (CDK4/6i) such as palbociclib and ribociclib are used to treat ER+/HER2- breast cancer, but patients can develop resistance via many mechanisms, several of which converge on the upregulation of CDK6. This has been shown to limit the effectiveness of CDK4/6i in ER+ breast cancer with up to 20% patients exhibiting innate resistance and up to 70% patients developing acquired resistance after 3 years on therapy (Scheidemann, 2021, doi:10.3390/ijms222212292). **Methods:** To address this limitation, we utilized our PRODEGY platform of Cereblon (CRBN) binders to synthesize CRBN mediated CDK4/6 bifunctional degraders to potentially inhibit tumor growth for treatment of naïve ER+/HER2- breast cancer and CDK4/6i resistant tumors. **Results:** Target degradation by immunoblot analysis of the triple negative breast cancer (TNBC) cell line, MDA-MB-231, treated with our CDK4/6 bifunctional degraders for 6 hours showed up to 85% degradation of CDK4 and CDK6 with DC₅₀s of 1-100nM. CDK4/6 phosphorylates the protein RB which releases the transcription factor E2F, inducing the expression of genes which promote cell cycle progression. Analysis of RB phosphorylation by in-cell western upon 24 hours of CDK4/6 degrader treatment showed phospho-RB IC₅₀s at <30nM. Cell cycle analysis by staining with propidium iodide after 24 hours of treatment with CDK4/6 degraders induced G0/G1 cell cycle arrest at concentrations as low as 10nM. We used a 2D colony formation assay (CFA) as a readout for inhibition of proliferation by cell cycle arrest. Our CDK4/6 degraders showed potent inhibition of cell proliferation with CFA IC₅₀s of <100nM in TNBC cell lines and <25nM in ER+ cell lines, including MCF7, T47D and ZR751 compared to CDK4/6i which ranged from 200nM to 500nM in MCF7 cells. We demonstrated that our CDK4/6 bifunctional degraders were significantly more potent in vitro than the CDK4/6i ribociclib and palbociclib, and the increased activity was due to CRBN mediated target degradation. Our CDK4/6 bifunctional degraders display excellent pharmacokinetic properties in mice with half-lives between 2-10 hours, oral bioavailability between 50-96%. MCF7 xenograft results with our proof-of-concept CDK4/6 degrader showed dose-dependent tumor growth inhibition and greater potency compared to the clinical CDK4/6i ribociclib. We saw tumor regression with our degrader at higher doses which we did not see at any dose of CDK4/6i. **Conclusions:** Our CDK4/6 bifunctional degraders display excellent single agent activity in vitro and in vivo particularly in comparison to clinically approved CDK4/6i, indicating that using a degrader approach to targeting this pathway may be more effective than current inhibitor therapies. Trop-2 mRNA expression and association with clinical outcomes with sacituzumab govitecan (SG) in patients with HR+/HER2- metastatic breast cancer (mBC): Biomarker results from the phase 3 TROPiCS-02 study. *First Author: Aditya Bardia, Medical Oncology, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: SG is a Trop-2-directed antibody-drug conjugate approved in multiple countries for patients with metastatic triple-negative breast cancer who received at least 1 prior systemic therapy and in the US for patients with pretreated HR+/HER2- mBC. In the TROPiCS-02 study, SG significantly improved progression-free survival (PFS; median, 5.5 vs 4.0 mo; HR, 0.66 [95% CI, 0.53-0.83]; P=0.0003) and overall survival (OS; median, 14.4 vs 11.2 mo; HR, 0.79 [95% CI, 0.53-0.83]; P=0.020) over treatment of physician's choice (TPC) in patients with pretreated, endocrine-resistant HR+/HER2- mBC. In TROPiCS-02 post hoc analyses, SG improved OS regardless of Trop-2 expression by immunohistochemistry (IHC; Rugo HS, et al. SABCS 2022), but association using more sensitive assays are lacking. Here, we examine efficacy outcomes for SG versus TPC by Trop-2 gene (*TACSTD2*) mRNA expression and the correlation of *TACSTD2* expression with other genes. **Methods:** Patients with HR+/HER2- mBC who received ≥1 prior taxane, endocrine therapy and a CDK4/6 inhibitor, and 2-4 prior chemotherapy regimens for mBC were randomized 1:1 to SG or TPC. The primary endpoint was PFS by central review per RECIST v1.1. RNA was isolated from archival tumor tissue samples using AllPrep DNA/RNA kits and libraries prepared with TruSeq RNA Exome Prep Kit. Sequencing was via NovaSeq (2x150bp). Gene expression quantitation was performed using Salmon. *TACSTD2* expression was defined as high or low via median cut. **Results:** In the mRNA analytical cohort (N=197), 49% had *TACSTD2* high expression (SG, n=51; TPC, n=46), and 51% had *TACSTD2* low expression (SG, n=47; TPC, n=53). Baseline characteristics were generally consistent between *TACSTD2* expression subsets and the intention-to-treat population. A positive concordance between *TACSTD2* expression and Trop-2 IHC (H-score) was observed (categorical concordance 71%; Cohen's kappa = 0.41). *TACSTD2* expression was similar across HER2 IHC0 and HER2-Low subgroups (log2 transcripts per million [TPM] of 3.36 [IQR, 2.76-4.22] and log2TPM of 3.44 [IQR, 2.59-4.22], respectively). SG showed a numerically higher median PFS (*TACSTD2* high, 7.3 vs 5.6 mo; *TACSTD2* low, 5.6 vs 2.8 mo) versus TPC regardless of *TACSTD2* expression. Similarly, for OS, outcomes favored SG over TPC regardless of *TACSTD2* expression. **Conclusions:** This mRNA-based biomarker analysis demonstrated that SG improves PFS and OS outcomes in patients with pretreated, endocrine-resistant HR+/HER2- mBC regardless of Trop-2 mRNA expression. There was no correlation between Trop-2 mRNA expression and HER2 status. Trop-2 mRNA expression was not predictive of benefit with SG. Additional studies are needed to determine whether Trop-2 mRNA expression has a prognostic role in mBC. Clinical trial information: NCT03901339. Research Sponsor: Gilead Sciences, Inc.

Targeting squalene epoxidase in breast-to-brain metastasis: A new therapeutic target for brain extravasation and colonization using animal models. *First Author: Pony Yu-Ling Lee, Pharmacology Discovery Services Taiwan, Ltd., partner lab of Eurofins, New Taipei City, Taiwan*

Background: Brain metastasis is the most common malignancy of the central nervous system which causes severe morbidity and mortality in multiple cancer types of patients and represents an unmet medical need. Several critical steps are required for a successful brain metastasis, including local invasion, intravasation, dissemination, extravasation, and colonization. Extensive research has been conducted to elucidate the mechanism of cancer metastasis with limited information toward how cancer cells extravasate and colonize. **Methods:** To understand the underlying molecular mechanisms and applications of molecular targets for brain metastasis therapy, murine models are employed for investigation of brain extravasation and colonization. To investigate the roles of SQLE in breast-to-brain metastasis *in vivo*, we silenced *SQLE* expression directly with lentiviral shRNA in the brain metastatic MDA-MB-231-BR cell line (231-BR/shSQLE) and used 231-BR cells expressing a scramble shRNA (231-BR/shScr) as the control. Brain metastases were induced by intracardiac, orthotopic, or direct intracranial injections of 231-BR/shSQLE or 231-BR/shScr cells into immune deficient mice. The essential roles of SQLE in the specific step(s) of breast-to-brain metastatic process were evaluated by *ex vivo* immunofluorescence analysis of brain slices from the animals. To verify SQLE as an oncogenic factor that can be selected as a potential therapeutic target in suppressing breast-to-brain metastasis, we evaluated the inhibitory effects of NB-598 (a SQLE inhibitor) in both the 231-BR orthotopic and intracardiac mouse models. **Results:** Recently, we identified a novel mechanism by which squalene epoxidase (SQLE), the second rate-limiting enzyme in the cholesterol biosynthesis, plays a critical role in the processes of breast cancer metastasized to the brain, especially in brain extravasation and colonization. Interestingly, the pharmacologic inhibition of SQLE has been widely used against fungal infections, and the next-generation SQLE inhibitors have been recently shown to exert an anticancer effect. Our data demonstrated that SQLE is essential for 231-BR cells to extravasate into the parenchyma as well as the formation of micro and macro-metastases in the brain. Interestingly, we found that astrocytes play a key role in supporting 231-BR-developed brain macro-metastasis. *In vitro* blood-brain barrier (BBB) models further demonstrated the critical roles of SQLE in promoting 231-BR cell invasion and penetration through BBB. Inhibition of SQLE by NB-598 demonstrated anti-tumor proliferation and anti-metastasis. **Conclusions:** Pharmacologic inhibition of SQLE by NB-598 suppressed 231-BR tumor growth at the mammary fat pad and distal metastases to organs, suggesting that targeting SQLE represents a therapeutic opportunity for breast cancer metastases. Influence of chromatin remodeling molecule ARID1A on metastatic heterogeneity in triple negative breast cancer: Binding of YAP. *First Author: Ye Wang, Department of Breast Cancer and Urological Medical Oncology, Fudan University Shanghai Cancer Center, Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China., Shanghai, Shanghai/China, China*

Background: Heterogeneity is the prominent character of TNBC and one predominant cause of treatment failure. As a key nuclear SWI/SNF protein complex subunit, ARID1A plays a critical role in tumor identity determining by manipulating gene expression. The present study aimed to investigate whether and how ARID1A determined the metastatic heterogeneity of triple-negative breast cancer. **Methods:** This study retrospectively collected and analysed clinical and pathological data from 258 patients diagnosed with triple-negative breast cancer at Fudan University Cancer Hospital from August 2015 to June 2016 to define the prognostic ability of ARID1A. CRISPR/Cas9 or plasmids-mediated ARID1A were used to determine the ARID1A function in regulating the metastatic character in TNBC. Cell morphology, tumor invasion, and metastasis were analyzed in terms of ARID1A status both in vitro and in vivo experiments. The molecular mechanism of ARID1A determining metastasis potential of TNBC was explored by RNA-Seq and nuclear positioning. **Results:** ARID1A low expression was found to have independent prognostic value for poor OS (43.9 vs 53.6 months, $P=0.0001$) and RFS (31.0 vs 45.5 months, $P=0.0029$) in TNBC patients. Both nuclear and cytoplasmic protein analysis and Immunofluorescent localization assay confirm that ARID1A recruits the Hippo pathway effector YAP into nucleus in human triple negative breast cancer cells. Next we designed the YAP truncator plasmid and confirmed by Co-Immunoprecipitation that ARID1A could competitively bind to the WW domain of YAP to form the ARID1A/YAP complex. Furthermore, down-regulation of ARID1A promoted migration and invasion both in human triple negative breast cancer cells and xenograft model through Hippo/YAP signaling axis. **Conclusions:** Our study provides new insights into the previously unrecognized role of ARID1A in TNBC metastasis, which might provide new therapeutic options for patients with TNBC. Olaparib (O) + ceralasertib (C) in patients (pts) with metastatic triple-negative breast cancer (mTNBC): Translational analysis of the VIOLETTE trial. *First Author: Natalia Lukashchuk, AstraZeneca, Cambridge, United Kingdom*

Background: O is a PARP inhibitor approved in a number of tumor types and for use in pts with germline (g) mutations in *BRCA* (*BRCAm*) HER2-negative metastatic breast cancer. C is an inhibitor of DDR kinase ATR. Analysis of VIOLETTE (NCT03330847) in pts with mTNBC showed no improvement in PFS with a combination of C and O vs. O, whether in the context of pathogenic *BRCAm*, non-*BRCA* HRR pathway mutations (*HRRm*), or homologous recombination repair (*HRR*) wildtype (*HRRwt*) tumors. We report an exploratory translational analysis of predictive genomic biomarkers of response to O $\pm$ C beyond *gBRCAm*. **Methods:** Pts received O (300 mg twice daily) $\pm$ C (160 mg daily; days 1–7; 28-day cycles) as a second- or third-line treatment option. Pts were prospectively stratified into molecular strata based on pathogenic/likely pathogenic alterations in *BRCA1/2* (*BRCAm*; $n=83$) or in ≥ 1 of 13 selected non-*BRCA* HRR genes (*HRRm*; $n=40$) or *HRRwt* ($n=103$) using FoundationOneCDx (F1CDx) sequencing assay of archival tumor sample. Advanced genomic analysis included genome-wide loss of heterozygosity (a marker of *HRR* deficiency [HRD]) with a 16% cut-off to define HRD+ ($\geq 16\%$) vs HRD- ($<16\%$), zygosity, and predicted g/somatic (s) status of *BRCA* and *HRR* alterations based on a validated computational FMI algorithm. Efficacy was evaluated by blinded independent central review of PFS, RECIST response, and best percentage change from baseline in target lesion size. **Results:** Out of evaluable pts for origin of *BRCAm* ($n=42$), 81% ($n=34$) were of germline, and 19% ($n=8$) were of somatic origin. Of pts evaluable for zygosity ($n=48$), most *BRCA* alterations were biallelic (90%; $n=43$), and of pts evaluable for HRD status ($n=47$), most were HRD+ (94%; $n=44$). Of *HRRwt* pts evaluable for HRD status ($n=79$), 57% were HRD+ ($n=45$). Responses by biomarker are shown. Responses in *BRCAm* pts were seen in all subgroups (zygosity, HRD, or g/s origin of mutation), including *sBRCAm* (ORR: $n=3/4$ on O; $n=2/4$ on O+C). Responses were also seen in patients with heterozygous *BRCA* alteration ($n=3/5$) by genomic result and in *BRCAm*/HRD- pts ($n=3/3$) across both arms. Pts with select *HRR* genes (*BARD1*, *RAD51C/D*, *ATM*, *CDK12*) also achieved responses on O or O+C. **Conclusions:** Responses to O were seen in pts with both *gBRCAm* and *sBRCAm*. Beyond *BRCAm*, the efficacy of O was observed in pts with alterations in select *HRR* genes, such as *BARD1* or *RAD51C/D*; further clinical investigation is required. Small sample size and HRD analysis performed on archival tumor samples should be considered limitations. Clinical trial information: NCT03330847. Research Sponsor: AstraZeneca.

The overall survival analysis of FUTURE-C-PLUS: Combination of famitinib with camrelizumab plus nab-paclitaxel as first-line treatment for advanced, immunomodulatory triple-negative breast cancer—An open-label, single-arm, phase 2 trial. *First Author: Li Chen, Cancer Center, Fudan University, Shanghai, China*

Background: Camrelizumab and nab-paclitaxel demonstrated promising anti-tumour activity in refractory metastatic immunomodulatory triple-negative breast cancer (TNBC) in FUTURE trial. Anti-angiogenic agents have been reported to facilitate immune infiltration. Famitinib is a tyrosine kinase inhibitor targeting VEGFR-2, PDGFR and c-kit. The FUTURE-C-PLUS trial (NCT04129996) which added famitinib to camrelizumab and nab-paclitaxel is a single-arm, phase 2 trial evaluating this novel triplet combinatorial strategy in patients with advanced immunomodulatory TNBC. Study design and the primary endpoint ORR has been reported previously (Zhi-ming Shao, et al. ASCO 2021, Abstract 1007). The final PFS data had been published in Clinical Cancer Research (Clin Cancer Res 2022;28:2807–17). Here, we reported the final overall survival of this trial. **Methods:** Briefly, this study enrolled women aged 18–70 years, with previously untreated, histologically confirmed, unresectable, locally advanced, recurrent or metastatic immunomodulatory TNBC. Immunomodulatory TNBC was defined as CD8 expression on at least 10% of cells using immunohistochemistry analysis. Eligible patients received the triple therapy. **Results:** Forty-eight patients were enrolled and treated between Oct 2019 and Oct 2020. The median follow-up was 33.1 months (range, 31.8–34.4). 39 (81.3%, 95% CI 70.2–92.3) patients had a confirmed objective response which has been reported in ASCO 2021. At this updating data cutoff (Feb 1, 2023), the median progression-free survival was 13.6 months (95% CI, 8.4–18.8). While overall survival was 29.4 months (95% CI, 23.3–35.5). The disease control rate was 95.8% (46/48). The most common treatment-related grade 3 or 4 adverse events were neutropenia (16 [33.3%]), anemia (5 [10.4%]), febrile neutropenia (5 [10.4%]), and thrombocytopenia (4 [8.3%]). No new safety concerns were detected. No treatment-related deaths were reported. **Conclusions:** These data, combined with those from our previous reports, provide further evidence for the triplet combination of famitinib, camrelizumab and nab-paclitaxel as an active therapy in advanced immunomodulatory TNBC. To our knowledge, this is the best overall survival reached in first-line treatment of advanced TNBC. A randomized controlled FUTURE-Super trial is ongoing to further validate these findings. Clinical trial information: NCT04129996. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co. Ltd. China.

ARID1A deficiency in triple-negative breast cancer induces adaptive immune resistance and sensitivity to immune checkpoint inhibitors. *First Author: Margaret Chen, Department of Breast Cancer and Urological Medical Oncology, Fudan University Shanghai Cancer Center, Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, 200032, PR China, Shanghai, China*

Background: Adaptive immune resistance (AIR) is pivotal to triple-negative breast cancer (TNBC) progression. Although immune checkpoint inhibitors (ICIs) shed new light on reversing AIR, the treatment effect and predictive markers of immunotherapy remain controversial. The present study focused on epigenetic regulation for TNBC AIR and explored whether this could be clinically targeted. **Methods:** Through screening an epigenetic gene set in TNBC patients from The Cancer Genome Atlas (TCGA), ARID1A was pinpointed as most significantly correlated with AIR. Humanized immune system (HIS) mice were adopted for TNBC transplantation, identifying CD8⁺ T cells as most significantly correlated with TNBC ARID1A. To probe the mechanism underlying TNBC ARID1A deficiency-induced CD8⁺ T cell malfunction and AIR, RNA-seq of both TNBC patients and TNBC cell lines were analyzed and the candidate mediator gene, PD-L1, was identified and verified through western blot, qPCR, IHC, dual luciferase reporter assay and cell co-culture. Chromatin immunoprecipitation and ATAC-seq further demonstrated direct binding of ARID1A to *NPM1* promoter to regulate PD-L1 expression. Finally, HIS mice were treated with ICI and the clinical trial CTR20191353 was retrospectively analyzed. **Results:** Among a series of epigenetic modulators, we first observed that ARID1A, a core subunit of the chromatin remodeling complex SWI/SNF, demonstrated highest correlation with AIR in TNBC patients. This was verified in HIS TNBC mice and a patient cohort from Fudan University Shanghai Cancer Center by higher malignancy observed in ARID1A-deficient TNBC. Both bulk and single-cell RNA-seq in TNBC patients uncovered an immunosuppressive microenvironment induced by TNBC ARID1A deficiency, and CD8⁺ T cells was identified as the immune cell type most significantly correlated with TNBC ARID1A. CD8⁺ T cell malfunction and AIR in ARID1A-deficient TNBC was induced by upregulated PD-L1, but ARID1A did not directly regulate PD-L1 expression. We found that ARID1A bound to the *NPM1* promoter and that ARID1A deficiency increased *NPM1* chromatin accessibility as well as gene expression, further activating PD-L1 transcription. In HIS mice, ICI demonstrated the potential to reverse TNBC ARID1A deficiency-induced AIR manifested by reducing tumor malignancy and activating antitumor immunity. In CTR20191353, a phase 1b clinical trial of pucotenlimab combined with chemotherapy for TNBC, patients with ARID1A deficiency demonstrated significantly better prognosis and the longest progression-free survival was found in ARID1A-low/PD-L1-high group. **Conclusions:** In AIR epigenetics, TNBC ARID1A deficiency induced AIR via the ARID1A/*NPM1*/PD-L1 axis, leading to poor outcome. While ARID1A deficiency provided survival advantage for TNBC cells, it simultaneously left the Achilles' heel which could be targeted with ICI. The case for acceleration of prospective multi- stakeholder led community-based research in young Black women with triple negative breast cancer (TNBC). *First Author: Jeanne Regnante, Tigerlily Foundation, Stone Ridge, VA*

Background: Black women face a three- fold increase in TNBC BRCA1 gene mutations. In TNBC, there is a higher rate of recurrence and metastasis to other organs. Lower access to timely care and more advance stage at diagnosis contribute to poorer outcomes. Black women have the lowest survival rate at each stage of TNBC diagnosis compared to other demographic groups. Research Question: Over the past 10 years, what real world community interventions have been published regarding risk for and diagnosis with TNBC in Black or African American women?

Methods: Using the following keywords: TNBC, diversity, health equity, young adults, Black, African American, authors conducted PUBMED and Google Scholar searches for years 2011 to 2022 to summarize publications on community-based interventions with Black or African American women at risk of or diagnosed with TNBC. **Results:** A validated publication assessment revealed 70 publications: 63 retrospective and 7 prospective studies. Prospective studies were categorized using the NASEM cancer continuum of care domains. The number of studies that addressed the domains included: risk=1, screening=1, diagnosis=3, treatment=2, survivorship=1 end of life=0, outcomes=1. No studies reported the following criteria: A co-creation approach with community-based participatory research principles; interventions led by patients and Black women who are at risk for TNBC; multi stakeholder interventions led by community leaders or patient organizations with long-standing trust of diverse populations; addressing and resolving social drivers of health inequities, mental health, palliative care services or implicit bias; or inclusion in clinical studies. **Conclusions:** It is critical to address the disproportionate impact of TNBC in partnership with Black women. To achieve equitable health outcomes, we advise public and private sector leaders to make more funding available to support community-engaged approaches in high prevalence geographic areas. 1) Provide CBPR training and opportunities for diverse investigators and patient- and community-based organizations. 2) Build capacity for social needs assessment and interventions. 3) Employ community-based implementation science focused on all care continuum domains including the gaps between domains. 4) Increase public awareness of health issues in Black women and address resistance, access and eligibility for participation in clinical research. 5) Offer RFPs to transform care through collaboration between researchers, providers, patient and community-based organizations, health departments, and payers; engaging clinical and lay navigators and community health workers; design solutions that address barriers; and development and implementation of policy with a focus on standardization, accountability, and enforceability. Phase Ib study of talimogene laherparepvec (T-VEC) in combination with chemotherapy (CT) or endocrine therapy (ET) in patients with metastatic, unresectable, or locoregionally recurrent HER2-negative breast cancer (BC). *First Author: Laura Ann Huppert, University of California, San Francisco, San Francisco, CA*

Background: Talimogene laherparepvec (TVEC) is a modified oncolytic herpes simplex 1 (HSV1) virus that may enhance tumor immune infiltration and is currently FDA-approved for the treatment of unresectable cutaneous, subcutaneous, and nodal melanoma. Anti-tumor responses have been seen both locally and systemically, and an abscopal systemic effect has been described in distant organ metastases. **Methods:** In this single arm, open label Phase Ib study, patients received intra-tumoral TVEC (first dose 10^6 PFU/mL followed by 10^8 PFU/mL q2-3 weeks; volume based on tumor size up to max 4mL) in combination with CT (gemcitabine/ carboplatin [GC], nab-paclitaxel [Nab-P], or paclitaxel [P]) or ET at the discretion of the treating physician. All patients had at least one 1 cm lesion that was injectable at the bedside. The primary endpoint was safety and tolerability. The secondary endpoint was response by RECIST 1.1. Blood and tissue-based immune correlates including injected and neighboring non-injected lesions were evaluated. **Results:** 19 pts were enrolled on this study (2/5/20 – 1/25/23) and evaluable for toxicity with 1 pt non-evaluable for efficacy due to early discontinuation. Median age was 52.1 years. Nine pts (47%) had HR+/HER2- BC and 10 pts (53%) had TNBC. Injected lesions included intact subcutaneous skin nodules (7), non-fungating breast or chest wall lesions (12), and fungating breast or chest wall lesions (9). Pts had a median of 3 prior lines of systemic therapy in the metastatic setting (range 0-9). 13 pts (74%) had visceral metastases. Pts received TVEC with the following treatment partners: GC (n=8, 42%), Nab-P (n=7, 37%), P (n=2, 11%), ET (n=2, 10%). Median treatment duration was 11.6 weeks (range 1.0-45.0 weeks). Grade 3-4 treatment-related adverse events included neutropenia (n=5, 26%), anemia (n=1, 5%), thrombocytopenia (n=1, 5%), and injection site skin ulceration (n=1, 5%). Three pts (16%) had Grade 1-2 injection site skin ulceration. Response per RECIST 1.1 was evaluated in 16 pts (2 pts had rapid progression prior to first response evaluation): PR (n=2, 13%), SD (n=5, 31%), and PD (n=9, 56%). Disease response at the site of TVEC injection was clinically evaluated in 18 pts, with response rates (RR) as follows: partial response (PR) (n=11, 61%), stable disease (SD) (n=4, 22%), and progressive disease (PD) (n=3, 17%). Mass cytometry (CyTOF) analysis demonstrated a decrease in HLA-DR expression circulating lymphocytes and in TIM3 expression across multiple cell types in responders vs. non-responders; updated correlative analyses will be presented. **Conclusions:** The addition of intra-tumoral TVEC to CT or ET is safe and tolerable in pts with advanced BC. This treatment induces changes in circulating immune responses. Clinical trial information: NCT03554044. Research Sponsor: Amgen.

Sociodemographic and clinicopathologic factors of triple negative breast cancer at an academic urban safety-net hospital. *First Author: Judy Jiaqi Wang, Boston Medical Center, Boston, MA*

Background: Racial disparities in breast cancer in the United States is a persistent and ongoing problem. Decades of research is derived from large population based data sets and little is published with granular detail of specific, actionable factors to target for interventions. From a large urban safety-net hospital, we evaluate sociodemographic and clinicopathologic factors on survival outcomes of triple negative breast cancer. **Methods:** We conducted a single-institution retrospective study of patients with invasive breast cancer, diagnosed and treated between January 2010 and December 2021 at an academic safety-net hospital where insurance systems allow for access and treatment for all patients. Demographic, tumor and treatment characteristics were obtained. Chi-square and ANOVA were used to examine associated factors among White, Black, and other races. Survival was analyzed using the Kaplan-Meier estimator and log-rank test. Significant risk factors were identified with Cox regression analysis. **Results:** 251 women with invasive triple negative breast cancer were diagnosed and treated during the study period. Median age was 58 years, 68.9% were non-white, and 64.9% were publicly insured or uninsured patients. Median time from diagnosis to treatment initiation was 29 days and follow up period was 1392 days. Having a non-English primary language and living in areas with lower socioeconomic indices are observed in non-White patients (P=0.003, 0.033) and predictive of a higher clinical stage at presentation (P=0.011, 0.021). Black patients were diagnosed at higher histologic grade (Black: 82.4%, White: 79.7%; P=0.003) and White patients were more likely to change facility during the treatment course (White: 32.4%, Black: 16.03%; P=0.005). No significant racial disparities were observed in time to treatment, recurrence rate, and overall survival. Among patients indicated for adjuvant therapies, including chemotherapy, immunotherapy, and radiation, rates of recommendation and completion of therapy did not vary by race. Five year survival did not significantly vary by race when adjusted for demographic and clinicopathologic factors. **Conclusions:** At an academic urban safety-net hospital where access to diagnostic and treatment resources are comparable across patient populations, no racial disparities were seen in treatment, recurrence, and survival outcomes. Further research on racial differences in breast cancer biology and health behaviors may improve understanding of triple negative disease or mitigate later stage diagnosis. Research Sponsor: None.

Early efficacy evaluation of ORIN1001, a first in class IRE1 alpha inhibitor, in advanced solid tumors. *First Author: Mothaffar F. Rimawi, Lester and Sue Smith Breast Center, Dan L. Duncan Comprehensive Cancer Center, Baylor College of Medicine, Houston, TX*

Background: ORIN1001 is a first-in-class small molecule targeting a novel enzyme with a unique mode of inhibition that selectively blocks the Inositol Requiring Enzyme 1 α (IRE1) RNase and blocks X-Box Binding Protein 1 (XBP1) activation in the endoplasmic reticulum. ORIN1001 is now undergoing Phase 1/2 clinical testing in advanced solid tumors. **Methods:** In a Phase 1 dose escalation trial (3+3 design), ORIN1001 was administered PO daily as a single agent in patients (pts) with advanced solid tumors and in combination with Abiraterone in pts with relapsed, refractory breast cancer. Safety, tolerability, pharmacokinetics, and preliminary efficacy of ORIN1001 was evaluated and a RP2D determined. **Results:** As of Jan, 2023, 30 patients with advanced cancer have received ORIN1001 as a single agent at doses up to 650 mg per day in 21-day continuous cycles and 13 patients with breast cancer have received ORIN1001 at doses up to 400 mg in combination with Abiraterone in 28-day continuous cycles. For single agent, DLTs consisting of thrombocytopenia were observed at 200 mg (2 pts) and 650 mg (2 pts) and, rash was observed at 200 mg (1 pt) and 500 mg (1 pt). For combination treatment, DLTs consisting of thrombocytopenia were observed at 300 mg (1 pt), fatigue/ rash at 400 mg (1 pt), febrile neutropenia/low WBC at 400/500 mg (1 pt at each dose). Common (> 15%) adverse events were predominantly nausea and/or vomiting (Grade 1-2 in severity). ORIN1001 exposure increased in a dose proportional manner with a mean $T_{1/2}$ at steady state of approximately 20 hours. For single agent, best response per RECIST 1.1 was partial response (PR) in 2 of 30 pts. These PRs included a stage IV colon cancer pt exceeding 44 months on treatment at 100 mg, and stage IV ER-/PR-/HER2+ breast cancer pt with 5 months on treatment at 500 mg. Stable disease (SD) was observed in a total of 16 of 30 pts with breast, colorectal, mesothelioma, liver, prostate, kidney or ovarian cancer. For combination therapy with Abiraterone, a PR was observed in one ER-/PR-/HER2- breast cancer pt at 300 mg ORIN1001 and SD was observed in 5 of 13 pts. SD included both triple negative and ER+/HER2- breast cancer pts at 300 or 400 mg with ongoing treatment exceeding 5 months. Of note, in a separate Phase 1 oncology basket trial in China, there were 2 PRs; 1 pt with stage IV NSCLC at 300 mg and 1 pt with metastatic castrate resistant prostate cancer at 100 mg exceeding 9 and 5 months of treatment with ORIN1001 in combination with Abiraterone, respectively. **Conclusions:** Phase 1 clinical evaluation of ORIN1001 has demonstrated tolerability and dose proportional PK. The proposed RP2D is estimated to be 500 mg and 300 mg ORIN1001 for single agent and in combination with Abiraterone, respectively. Early efficacy data with ORIN1001 demonstrate clinical responses (SD and PR) in multiple pts with heavily-pretreated advanced solid tumors as a single agent or in combination with Abiraterone in breast cancer patients. Clinical trial information: NCT03950570. Research Sponsor: Fosun Orinove.

Olaparib (O) in advanced triple negative breast cancer (aTNBC) patients (pts) with BRCA1/2 promoter methylation: GEICAM/2015-06 study (COMETA-Breast). *First Author: Juan De La Haba, Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC)–H. Universitario Reina Sofía, Universidad de Córdoba. GEICAM Spanish Breast Cancer Group, Cordoba, Spain*

Background: Epigenetic silencing by aberrant *BRCA1/2* promoters' methylation (*BRCA*-meth) can be responsible for a dysfunctional *BRCA* protein. *BRCA*-meth occurs in 15-57% of TNBC pts. *BRCA*-meth breast cancer (BC) display pathologic features and genetic profiles like germline *BRCA1/2*-mutated (*gBRCA1/2m*) carriers. O is a PARP inhibitor approved for treating *gBRCAm* HER2-negative advanced BC (aBC) pts. These are the results of a phase II study assessing the O efficacy in aTNBC pts with *BRCA1/2*-meth (NCT03205761). **Methods:** We included aTNBC pretreated pts (≥ 1 line) with centrally confirmed somatic *BRCA1/2*-meth (in most recent lesion(s) available) and no *gBRCA1/2m*. O 300mg b.i.d. was administered. *BRCA1/2* CpG island was considered methylated if value was $\geq 25\%$. Overall response rate (ORR) (complete response [CR] + partial response [PR]) according to RECIST 1.1) was the primary objective. Thirty-one evaluable pts were required based on an optimal 2-stage Simon's design (α error=0.05, 1- β error=80%), estimating an ORR increase of 24%, with a null hypothesis of 30%. Whole exome/transcriptome and 105-genes NGS assays (Tempus xE & xF) were performed on pretreatment tumor and sequential ctDNA of a long-term responder. **Results:** Eleven pts received ≥ 1 cycle of O (ITT population). Median age was 51 years (37-64), and 8 pts were postmenopausal. All MO pts at diagnosis had neo/adjuvant chemotherapy (CT). Median O exposure duration was 8 (1-88) weeks and relative dose-intensity was 97% (76-100), with any dose modifications in 6 pts. ORR was 9% (1 PR/11; 95% CI, 0.2-41). Clinical benefit rate (CR + PR + stable disease of any duration) was 36% (4/11; 95% CI, 11-69). Most pts (n=9) discontinued O due to BC progression. Median PFS was 2 months (95% CI, 1-4), and median OS was 9 months (95% CI, 1-14). One pt with confirmed PR was on O for >20 months. AEs were reported in 3 pts in line with O safety profile. No AE led to O discontinuation and no SAEs were reported. The statistical assumptions for the 1st Simon's model stage were not met ($\geq 4/12$ pts with CR or PR), so the recruitment did not proceed onto the 2nd stage. Preliminary NGS analysis on the long-term responder identified alterations on tumor (TP53, BCL11A, MYC) and on-treatment ctDNA (PMS2). **Conclusions:** In this proof-of-concept study, O did not show clinically nor statistically significant antitumor activity in pretreated aTNBC pts with *BRCA1/2*-meth. Clinical trial information: NCT03205761. Research Sponsor: None.

Phase II study of pembrolizumab plus mifepristone in patients with advanced HER2-negative breast cancer. *First Author: Nan Chen, University of Chicago, Chicago, IL*

Background: Metastatic breast cancer is incurable, and novel treatment (tx) strategies are needed. Single agent immune checkpoint inhibitor (ICI) tx has limited efficacy; combination approaches may yield better results. Multiple mechanisms of glucocorticoid-induced immunosuppression have been proposed, including the suppression of the cytotoxic Th1 cytokine response via glucocorticoid receptor (GR) activation. We hypothesize that pretreatment with a GR antagonist shifts the cytotoxic immune response toward Th1, thus enhancing response to ICIs. We present the safety and efficacy of the combination of pembrolizumab and mifepristone in advanced HER2-negative breast cancer. **Methods:** This (NCT03225547) was a phase II non-randomized study of pembrolizumab and mifepristone in patients (pts) with advanced HER2-negative breast cancer. Pts with prior ICI tx were excluded. Pts received mifepristone 300mg daily and pembrolizumab 200mg every 3 weeks; mifepristone was started 7 days prior to pembrolizumab. The primary endpoint was objective response rate (ORR). Secondary endpoints included progression-free survival (PFS), overall survival (OS), disease control rate (DCR), and safety and tolerability. **Results:** 18 patients were enrolled from March 2018 – November 2020; 10 patients with TNBC (cohort 1) and 8 patients with HR+ BC (cohort 2). Mean age was 53 yrs (range 33-74) and 33% of patients were self-reported Black. In cohort 1, 50% of patients were tx naive in this advanced setting, and 90% of patients had < 2 prior lines of tx. In cohort 2, 25% of patients had not received prior chemo in the metastatic setting. The overall ORR was 6%. One pt with TNBC had a complete response (CR). She received 36 cycles of tx; tx was discontinued due to mucositis and rash, and she remains in CR at >48 mos from start of tx. No patients in cohort 2 had a partial or complete response. The most common treatment-related adverse events were rash (61%), thyroid abnormality (17%), and pruritis (17%). 45% of patients experienced a grade 3 or 4 adverse event; all except one (hypokalemia) were due to rash. Rash was described as maculopapular dermatitis. The DCR at 18 weeks was 33.3% in the overall population; it was 44.4% in cohort 1 and 16.7% in cohort 2. Overall median PFS was 1.9 months [95% CI 1.8 – 3.6]. Overall median OS was 12.9 months [95% CI 5.8 – 23.0]. **Conclusions:** While this regimen demonstrated efficacy in a small subset of patients, including one pt with long-term CR, given the non-randomized design, we cannot determine if mifepristone enhanced the efficacy of ICI. In addition, a higher than anticipated rate of skin toxicity, possibly related to mifepristone enhancing the activity of ICI, was observed in the study, leading to early closure. While the benefit/risk analysis of this combination does not support further evaluation, additional investigation of alternative chemotherapy-free, immunomodulatory strategies is warranted. Clinical trial information: NCT03225547. Research Sponsor: Corcept Pharmaceuticals, Merck; U.S. National Institutes of Health.

The impact of social determinants of health (SDOH) on use of germline genetic testing for triple-negative breast cancer (TNBC) in the community oncology setting. *First Author: Robert Lawrence Reid, US Oncology Network/Virginia Cancer Specialists, Herndon, VA*

Background: TNBC presents at an earlier age of onset and at a more advanced stage, and is associated with a worse outcome in African American women. In a subset of patients, TNBC is associated with germline *BRCA1* and/or *BRCA2* mutations. Genetic testing improves breast cancer and other surveillance as well as treatment outcomes. Current NCCN Guidelines recommend germline testing for all patients with any stage TNBC. Previous versions recommended testing in patients aged 60 years or younger. This study aimed to identify factors associated with receiving genetic testing among patients with TNBC in the community oncology setting. **Methods:** This was a retrospective observational cross-sectional study examining patient profiles, demographics, SDOH indicators, and germline genetic testing data. Patients in The US Oncology Network diagnosed with any stage TNBC between 3/31/2017 and 9/30/2021 aged 60 years or younger were identified. Data from the iKnowMed EHR was used for patient identification, baseline characteristics, and social determinants, including area deprivation index (ADI), a validated measure of socioeconomic status (SES) based on address. Mean ADI percentile scores using national and state level benchmarks were calculated as well as stratifications above and below the 80th percentile (where higher scores > 80 are markers of low SES). Evidence of germline genetic testing (yes/no) was compiled from iKM, network genetic databases, and confirmatory chart audits. Only US Oncology Network sites participating in confirmatory audits were included in this analysis. **Results:** Among participating sites, 1318 patients with TNBC were identified with a mean age of 49 years; 58% were White, 22% Black, 3% Asian, and 16% other/unknown; and evidence for germline genetic testing was found for 981 (74.4%). Statistically significant differences in germline testing rates were found for age (48.4 years for tested, 50.7 years for not tested); race (67% for Black patients, 77% for White); US census region (68% in South, 70% in Midwest, 83% in Northeast, and 87% in West); practice size (mean number of physicians: 32.8 per practice for testing group, 29.2 for untested); and for nationally benchmarked ADI score (mean ADI of 42.3: tested and 47.1 for not tested). No significant difference was seen across the spectrum of ethnicity, with 82% testing among Hispanic or Latino patients compared with 74% for non-Hispanic or Latino, $p = 0.074$. No significant differences were observed for clinical variables. **Conclusions:** We report that 75% of patients with TNBC in our community oncology network received genetic testing. However, significantly lower testing rates were observed for patients who were Black, had lower SES, and resided in the South and Midwest geographic regions. Further research should be performed to understand reasons why testing was not done, to address barriers. Research Sponsor: None.

Efficacy of oral selective estrogen receptor degraders (SERDs) in the treatment of estrogen receptor positive (ER+), HER2-negative metastatic breast cancer (MBC): A stratified analysis of the ESR1 wild type (wt) and mutant (mt) subgroups. *First Author: Joseph J Zhao, Yong Loo Lin School of Medicine, National University of Singapore (NUS), Singapore, Singapore*

Background: Oral SERDs are a novel drug class developed to counteract endocrine resistance due to ESR1 mutations. Several SERDs have emerged from phase 2 and 3 trials, and the FDA has most recently limited approval for Elacestrant to patients with ESR1mt tumours despite PFS benefit in the overall population. Questions remain on whether patients with ESR1wt tumours stand to benefit from SERDs. We conducted an IPD meta-analysis of the trials EMERALD, SERENA2, ACELERA and AMEERA3 to compare survival outcomes of SERDs in the 2nd or 3rd line setting against endocrine therapy (ET), using KMSubtraction to unveil HRs of unreported ESR1wt subgroups from AMEERA3 and EMERALD. Meta-analysis results were stratified by ESR1 status. **Methods:** RCTs investigating the efficacy of novel SERDs versus ET for ER+, HER2- MBC, and which reported the Kaplan Meier (KM) plots of progression free survival (PFS) were selected after a systematic search of Embase and PubMed from inception until January 21, 2023. A graphical reconstructive algorithm was applied to estimate time-to-event outcomes from reported KM plots in all overall and reported subgroup cohorts, deriving IPD. A bipartite matching algorithm, KMSubtraction was used to subtract patients in the reported subgroup from the overall cohort, to derive survival data for unreported ESR1wt subgroups. An IPD meta-analysis was then performed, pooling data by ESR1 mutation. **Results:** A total of 1216 patients were included in this analysis. In the pooled analysis of the overall cohort, PFS benefit was observed with SERDs compared to treatment of physician's choice (TPC) (HR 0.787, 95%CI 0.683-0.908, $p < 0.001$). In the ESR1mt subgroup SERDs demonstrated improved PFS (HR 0.557, 95%CI 0.440-0.705, $p < 0.001$) compared with TPC. In the ESR1wt subgroup, SERDs demonstrated no significant PFS benefit (HR 0.948, 95%CI 0.790-1.137, $p = 0.565$) when compared to TPC. KMSubtraction was implemented on AMEERA3 to reveal survival data in ESR1wt subgroup. Amcenestrant revealed no significant PFS difference in the ESR1wt population (HR 1.197, 95% CI 0.857-1.670, $p = 0.291$) when compared to ET. Additionally, a separate analysis of EMERALD was performed using KMSubtraction to derive survival data of the ESR1wt subgroup comparing Elacestrant vs Fulvestrant. No significant PFS difference was observed between the 2 agents in the ESR1wt population (HR 0.832, 95% CI 0.587-1.178, $p = 0.299$). **Conclusions:** Our results suggest that PFS benefit in the overall population is mainly driven by the ESR1mt subgroup. These findings are in line with the recent FDA approval of Elacestrant for patients with ESR1mt tumours. Research Sponsor: None.

Subgroup	HR (CI)	P value
Overall	0.787 (0.683-0.908)	< 0.001
ESR1mt	0.557 (0.440-0.705)	< 0.001
ESR1wt	0.948 (0.790-1.137)	0.565

High dose alkylating chemotherapy for patients with oligometastatic breast cancer harboring homologous recombination deficiency: Results from the randomized phase 3 OLIGO study. *First Author: Annemiek Van Ommen-Nijhof, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Oligometastatic breast cancer (OMBC) is a clinical entity with favorable prognosis compared to MBC in general, but the optimal treatment for individual patients remains unclear. We compared high dose chemotherapy (HDCT) to conventional dose chemotherapy (CDCT) in patients receiving local ablative therapy (LAT) of all disease sites in HER2-negative OMBC that harbors homologous recombination deficiency (HRD). **Methods:** In this open-label phase 3 study, we randomly assigned patients with OMBC after 3 cycles of induction CDCT to either continue with CDCT (up to a maximum total of 8 cycles) or switch to HDCT. OMBC was defined as 1-3 distant metastatic lesions, with or without locoregional disease, all amenable to LAT. Main eligibility criteria included pathologic proof of a distant metastatic lesion, HRD (based on either germline *BRCA1/2* mutation and/or a BRCA-like profile in the tumor), and a favorable response to induction CDCT. The primary endpoint was event-free survival (EFS), defined as time since randomization to recurrence or death. Overall survival (OS), safety and quality of life (QoL) were key secondary endpoints. Following the advice of the independent data monitoring committee, analyses were performed before the prespecified number of events was reached. **Results:** Between November 2012 and May 2022, 36 patients were allocated to HDCT and 39 to CDCT. 52 (69%) tumors were triple negative and 23 (31%) were hormone receptor positive; 39 patients (52%) had a solitary metastasis and 43 (57%) had synchronous OMBC. After a median follow-up of 52 months (interquartile range 28-97), 42 EFS-events had occurred. Median EFS in the HDCT-group was 28 months (95% CI 21 – not reached (NR)) compared to 25 months (95% CI 14 – NR) in the CDCT-group (hazard ratio (HR) 0.78 (95% CI 0.42 – 1.42, $p = 0.411$). Median OS was 67 months (95% CI 37 – NR) in the HDCT-group versus 36 months (95% CI 26 – NR) in the CDCT-group (HR 0.74, 95% CI 0.37 – 1.48, $p = 0.398$). 5-year EFS was 40% and 30%, and 5-year OS was 51% and 49% in the HDCT- and CDCT-group, respectively. 34 (94%) patients in the HDCT-group experienced grade 3 or higher adverse events, compared to 25 (64%) patients in the CDCT-group; no grade 5 adverse events occurred. QoL was comparable between groups at 12 months. **Conclusions:** HDCT does not improve outcome compared to CDCT in patients with OMBC harboring HRD and can therefore not be recommended. Survival in this highly selected group of patients with OMBC, all receiving LAT, compares favorably to survival in the overall MBC population. The optimal systemic therapy for patients with OMBC requires further study. Clinical trial information: NCT01646034. Research Sponsor: Dutch Cancer Society.

Phase II study of trifluridine/tipiracil (FTD/TPI) in HER2-negative metastatic breast cancers with or without prior exposure to fluoropyrimidines. *First Author: Joline Si Jing Lim, Department of Haematology-Oncology, National University Cancer Institute, Singapore, Singapore*

Background: Fluoropyrimidines are commonly used in the treatment of patients (pts) with metastatic breast cancers (MBC). FTD/TPI is an oral drug combination of trifluridine with tipiracil, a thymidine phosphorylase inhibitor preventing rapid degradation of trifluridine, thus allowing for increased exposure to active agent, and has showed activity in pts with colorectal and gastric cancers despite prior exposure to fluoropyrimidines. We investigate the role of FTD/TPI in MBC pts with (Cohort A) or without (Cohort B) prior exposure to fluoropyrimidines in a single arm phase II study. **Methods:** Pts were treated with FTD/TPI, and enrolled first into a lead-in dose confirmation phase, followed by two parallel cohorts based on prior exposure to fluoropyrimidines. Primary objectives for each cohort included determination of progression-free survivals (PFS), and secondary objectives included determination of objective response rates (ORR), safety and tolerability. **Results:** A total of 74 pts were recruited (42 for Cohort A, 32 for Cohort B), of whom 4 belonged to lead-in phase. Dosing was confirmed at FTD/TPI 35mg/m² days 1-5 and 8-12 of 4-weekly cycles based on lead-in phase with no dose-limiting toxicities observed, and recruitment then proceeded in 2 parallel cohorts. All pts were evaluable for toxicity and survival analyses, and 72 were evaluable for ORR. Median age at enrollment was 62 years (range 32-85), with median of 4 (range 0-14) prior lines therapy in the metastatic setting, and 47% had de novo metastatic disease. Median PFS was 5.7 months (95% CI 3.8 to 8.3) and 9.4 months (95% CI 5.5 to 14.0) respectively in Cohorts A and B. Similar response rates were observed regardless of prior exposure to fluoropyrimidine, with ORR of 19.5% (95% CI 8.8 to 34.9) and 16.1% (95% CI 5.5 to 33.7) in Cohorts A and B, with 6-month clinical benefit rates of 56.1% (95% CI 39.7 to 71.5) and 61.3% (95% CI 42.2 to 78.2) respectively. Safety profile was consistent with known toxicities of FTD/TPI, with most common treatment-related adverse events of neutropenia, fatigue, nausea and anorexia. 64% of pts required dose modifications during study treatment, most commonly due to neutropenia, that could be overcome by dose reduction or prolongation from 4- to 5-weekly cycles. Only 1 pt required discontinuation due to toxicity from therapy. **Conclusions:** FTD/TPI showed promising anti-tumor activity with meaningful clinical benefit even among pts with prior exposure to fluoropyrimidines, and has a reasonable toxicity profile with appropriate dose modification. An oral chemotherapy option with good disease control provides an attractive treatment alternative to pts with MBC where quality of life is paramount, warranting further investigation in randomised studies. Clinical trial information: NCT04280536. Research Sponsor: National Medical Research Council, Singapore; Taiho pharmaceuticals.

Prognostic value of tumor-derived extracellular vesicles and circulating tumor cells in metastatic breast cancer (BC): A focus on inflammatory BC. *First Author: Eleonora Nicolò, Weill Cornell Medicine, New York, NY*

Background: Circulating tumor cells (CTCs) are an independent prognostic factor in metastatic breast cancer (MBC). The prognostic value of CTCs and the optimal cutoff for patients (pts) with inflammatory breast cancer (IBC), one of the most aggressive types of BC, has not been fully established. Recent evidence showed the complementary prognostic value of tumor-derived extracellular vesicles (tdEVs) to CTCs in MBC. The significance of tdEVs in IBC is unexplored. This study aimed to assess the prognostic value of CTCs and tdEVs in metastatic IBC. **Methods:** This study retrospectively analyzed 308 pts with MBC enrolled at Northwestern University (Chicago, IL) before starting a new line of therapy between 2016 and 2021 (NU16B06 trial). Blood samples were processed for CTCs using the CellSearch system. We applied the open source ACCEPT software to archived CellSearch images to enumerate CTCs and tdEVs. TdEVs cutoff levels were <20 (low), 20-79 (intermediate), and ≥80 (high), as previously reported. The association of CTCs and tdEVs with overall survival (OS) was tested in the overall population (OvP) and IBC pts. **Results:** Of the 308 pts, 69 were diagnosed with IBC. 51% of pts received first-line therapy. CTCs enumerated by ACCEPT were strongly correlated with manual count ($r=0.86$) and hence used for this analysis. Median CTC count was 1 [interquartile range (IQR) 0-7] in IBC pts and 3 (IQR 0-14) in non-IBC ($p=0.11$). A significantly lower median tdEVs count was observed in IBC (7; IQR 3-45) than in non-IBC (22; IQR 4-137) pts ($p=0.03$). In IBC, higher CTC and tdEV counts were seen in the triple negative subtype ($p=0.03$) and non-visceral involvement ($p=0.02$), respectively. In the OvP median OS (mOS) was worse among pts with ≥5 CTCs (HR 2.6; $p=0.001$) and with elevated tdEVs (HR 3.3; $p<0.001$). Only tdEVs were independently associated with poorer OS in multivariable analysis. In pts with <5 CTCs there was a stepwise decrement in OS with increased tdEVs count ($p<0.3$); in pts with ≥5 CTCs, elevated tdEVs levels were associated with significantly worse OS ($p=0.03$). IBC pts with ≥5 CTCs had shorter mOS (8 vs 47 months; HR 3.6; $p<0.001$); this association was weaker using ≥1 as CTC cutoff (HR 2.4; $p=0.01$). OS was adversely associated with increasing tdEVs levels (33 vs 23 vs 7 months for low, intermediate, and high subgroups, respectively; HR 3.7; $p=0.001$). Furthermore, elevated tdEVs were associated with shorter mOS in pts with ≥1 ($p=0.055$) and ≥5 CTCs ($p=0.6$). Among pts with <5 CTCs no significant difference emerged among tdEVs subgroups ($p=0.6$). **Conclusions:** This study confirmed the strong prognostic significance of CTCs and tdEVs in MBC, including IBC. Pts with IBC had fewer CTCs and tdEVs compared to non-IBC, probably due to the predominant lymphatic spread of IBC. tdEVs offer the possibility to better define prognosis of IBC pts. Further studies are needed to evaluate their complementarity to CTCs. Research Sponsor: None.

Preliminary results from a first-in-human study of ESG401, a trophoblast cell-surface antigen 2 (TROP2) antibody drug conjugate (ADC), in patients with locally advanced/metastatic solid tumors. *First Author: Fei Ma, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China*

Background: ESG401 is an innovative ADC composed of a humanized anti-TROP2 IgG1 monoclonal antibody conjugated to topoisomerase I inhibitor SN-38 via a proprietary stable-cleavable linker with DAR of 8. **Methods:** Patients (pts) aged ≥18 years with locally advanced/metastatic solid tumors refractory to/relapsed from standard treatment with measurable disease (RECIST v1.1) were eligible. ESG401 is administered intravenously by designated dose and regimen until unacceptable toxicity or progressive disease. The Bayesian Optimal Interval (BOIN) design was used to establish the MTD. **Results:** As of Feb 3, 2023, 35 pts with a median age of 53 were treated with ≥1 dose of ESG401 during escalation at doses of 2-20 mg/kg once Q3W (Regimen A), or 12-16 mg/kg D1,8,15 in a 4-week cycle (Regimen B). 80% of pts were ECOG ≤1, 63% of pts were 3L+; median 4 (2-10) prior lines, 94% of pts had visceral metas (11% brain, 63% liver, 60% lung) at baseline. Only one patient treated with 20 mg/kg experienced DLT. The MTD has not reached either regimen. The most common TRAEs were leukopenia (80%), neutropenia (69%), anemia (66%), fatigue (54%), nausea (51%), and vomiting (46%). The most common ≥ Grade 3 TRAEs were leukopenia (29%) and neutropenia (31%). There was no ≥ Grade 3 thrombocytopenia, diarrhea, skin rash, or oral mucositis. No Interstitial Lung Disease (ILD) was observed. Of 33 efficacy evaluable (EE) pts, 12 partial responses (PR) were observed and 4 pts had achieved SD ≥24 wks. The first dose level found PR (16 mg/kg Q3W) and afterward were taken as therapeutically relevant doses (TRD). The ORR and DCR were 36% (4/11) and 64% (7/11) in 11 TRD pts with TNBC, while 62% (8/13) and 77% (10/13) in 13 TRD pts with HR+/HER2-BC. Two pts with brain metas both got an obvious intracranial response (one pt whose intracranial lesion was significantly reduced to too small to measure). Until the cut-off date, 11 (31%) pts remained on treatment. Three pts were treated over 12 mons and the longest on-treatment duration was 12.9 mons. One pt had consistent PR up to 10.8 mons. **Conclusions:** The preliminary data demonstrated that ESG401 is safe and well-tolerated with promising signals of efficacy in heavily pretreated pts. These encouraging findings warrant further clinical evaluation. Clinical trial information: NCT04892342. Research Sponsor: Shanghai Escugen Biotechnology Co., Ltd.

Summary of tumor response per investigator.								
	Regimen A				Regimen B			
	8mg/kg (N=3)	12mg/kg (N=3)	16mg/kg (N=5 ^a)	20mg/kg (N=5)	12mg/kg (N=5)	14mg/kg (N=6)	16mg/kg (N=6)	Total (N=33)
PR ^b , n (%)	0	0	2 (40.0)	2 (40.0)	3 (60.0)	1 (16.7)	4 (66.7)	12 (36.4)
SD, n (%)	1 (33.3)	0	1 (20.0)	1 (20.0)	1 (20.0)	4 (66.7)	1 (16.7)	9 (27.3)
PD, n (%)	2 (66.7)	3 (100)	2 (40.0)	2 (40.0)	1 (20.0)	1 (16.7)	1 (16.7)	12 (36.4)

^a Includes pts who were assigned to 2mg/kg (N=1) and 4mg/kg Q3W (N=1) while eventually intra-pt escalated to 16mg/kg Q3W.
^b Per RECIST 1.1, but including single-point PRs, not confirmed responses.

Actionability of comprehensive genomic profiling compared to the tissue-based and plasma-based assay in patients with metastatic breast cancer: A real-world study. *First Author: Hiroshi Tada, Department of Breast and Endocrine Surgical Oncology, Graduate School of Medicine, Tohoku University, Sendai, Miyagi, Japan*

Background: Comprehensive genomic profiling (CGP) was officially approved in August 2021 in Japan under the national health insurance system with three CGP tests in June 2019: FoundationOne CDx (F1CDx), OncoGuide NCC Oncopanel (NCC), which are tissue-based assay (TBA), and FoundationOne Liquid CDx (F1LCDx, starting in August 2021) which is plasma-based panel (PBA). The Center for Cancer Genomics and Advanced Therapeutics (C-CAT) has collected genomic and clinical data of 2,617 Japanese breast cancer patients as of October 2022. Here we assess these PBA and TBA to detect pathogenic or driver alterations informative for matched therapy in patients with metastatic breast cancer (mBC). **Methods:** We queried consecutive mBC patient clinical-genomic data through the C-CAT Research-Use Portal from June 2019 to October 2022 were categorized based on PBA or TBA. We used ClinVar to identify if the called somatic alterations were pathogenic or likely pathogenic, and BoostDM (<https://www.intogen.org/boostdm/search>) to identify potential driver mutations of breast cancer. The proposed rate of matched therapy was determined. The incidence rates were compared using the Pearson χ^2 test. **Results:** Of 2,617 pts who underwent the CGP test, 2,259 (86%) received TBA (74% F1CDx and 12% NCC). The proportion of pts with ≥ 1 pathogenic variant with PBA and TBA was not significant (71.5% vs. 72.7%; $p=0.88$), but the proportion of pts with ≥ 1 driver mutation was significantly higher with PBA than TBA (75.4% vs. 69.8%; $p=0.03$). Regarding the proportion of pts who matched therapy or clinical trials presented among the pts for whom data were available, PBA was significantly lower than TBA (27.7% vs. 38.5%, $p < 0.001$). Although data on post-treatment is still being collected, the proportion of tested patients that received matched therapies recommended by molecular tumor boards of each institute was significantly lower for PBA (4.2% vs. 8.3%; $p=0.007$). **Conclusions:** This study is the first analysis of CGP for mBC in Japan using the C-CAT utilization program. Although significant alterations were well-detected in PBA, the proportion of pts who received matched-therapy post-testing was low for PBA. Possible causes include that PBA has fewer companion diagnoses than TBA in Japan and that PBA is more often used in later lines. Research Sponsor: None.

Association between baseline radiological tumor burden and outcomes in patients with metastatic breast cancer treated with an immune checkpoint inhibitor. *First Author: Lauren Claire Brown, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Lower baseline radiological tumor burden is associated with more favorable outcomes for patients with metastatic non-small cell lung cancer and melanoma treated with immunotherapy. However, minimal data is available for metastatic breast cancer patients. This is despite immunotherapy, in combination with chemotherapy, now being standard-of-care for a subset of metastatic breast cancer patients who have triple-negative disease and are PD-L1 positive. **Methods:** We reviewed data of 82 patients with metastatic breast cancer consecutively treated at our institution from August 2015 to October 2021, who received > 1 dose of an immune checkpoint inhibitor (anti-PD-1 or -PD-L1) within the context of a clinical trial. Baseline tumour burden was assessed by a single radiologist and calculated as sum of Response Evaluation Criteria in Solid Tumours 1.1 baseline target lesions (baseline tumour size [BTS]) or as sum of all measurable baseline lesions (total tumour burden [TTB]); the impact of both parameters on treatment outcomes was investigated. Treatment outcomes assessed were clinical benefit rate (complete response, partial response or stable disease for 6 months or more [CBR6]), disease free survival (DFS) and overall survival (OS). Multivariate analysis adjusted for ECOG status, line of treatment (first line vs second line or beyond), and whether immunotherapy was given in combination with chemotherapy or as monotherapy. **Results:** A total of 82 patients were included in the analysis. 43 patients (52%) received combination chemotherapy with immunotherapy, 39 patients (48%) received immune checkpoint inhibitor monotherapy. Median BTS and TTB were 36.5mm (range 0–204mm) and 43mm (range 0–1123mm) respectively. CBR6 was significantly associated with BTS ($p=0.004$) and TTB ($p=0.002$) quartiles, with clinical benefit time progressively increasing with decreasing tumor burden quartiles. Both increasing BTS ($p<0.001$) and TTB ($p<0.001$) across quartiles were significantly associated with shorter OS. There was a numerical, but not statistically significant, association between both parameters as quartiles (BTS, $p=0.25$; TTB, $p=0.07$) and PFS. In the bottom BTS quartile, 32% of patients were progression-free and 95% alive at 12 months, compared with 15% and 40% respectively in the top quartile. Similar results were seen when TTB was used as the baseline measurement: 32% progression-free and 95% alive at 12 months in the bottom quartile compared with 1% and 33% in the top quartile. Multivariate analysis confirmed that both BTS and TTB, considered as continuous variables, are independently associated with OS. **Conclusions:** Lower baseline radiological tumor burden is associated with better outcomes in patients with metastatic breast cancer treated with immune checkpoint inhibitors. Social determinants of health factors and palliative care services use among patients with metastatic breast cancer in Florida. *First Author: Fantine Giap, Department of Radiation Oncology, University of Florida College of Medicine, Gainesville, FL*

Background: ASCO recommends palliative care (PC) as an adjunct to the oncologic standard of care for patients with metastatic cancer. However, current evidence on PC utilization in patients with breast cancer and its relationship with area-level social determinants of health (SDoH) factors is limited. Therefore, we examined the associations between county-level factors and PC utilization among patients with metastatic breast cancer (mBC) in Florida. **Methods:** We extracted patient-level data ($n = 23,539$ patients diagnosed with mBC between 2012 and 2021) from the One-Florida+ Data Trust and linked it to county-level data (67 Florida counties) from the AHRQ-SDoH Database. PC utilization since cancer diagnosis was identified using ICD-9 code V66.7 or ICD-10 code Z51.5. We assessed differences in PC utilization with county-level SDoH factors (e.g., poverty rate, transportation resource, provider supply, racial segregation) using bivariate analysis. Multivariable Poisson regression, including significant factors from bivariate analysis, was used to compare the PC utilization for the SDoH factors. **Results:** Our study population's overall prevalence of PC utilization was 16.1%. PC utilization was higher for patients with mBC residing in counties with a higher proportion of residents living in poverty and with a greater supply of advanced practice providers (APP: NP, PA), general surgeons, and nursing homes. Patients with mBC in counties with higher proportions of residents who identified as immigrants, with limited English proficiency, without personal transportation, and having higher racial segregation had lower PC utilization. In adjusted analysis, the supply of APP (coefficient: 0.12) and nursing homes (coefficient: 0.09) was associated with increased PC utilization. Conversely, racial segregation (White vs. non-White) was associated with decreased PC utilization (coefficient: -0.07). **Conclusions:** PC utilization among patients with mBC was associated with several SDoH at the county level. Notably, low PC utilization was associated with racial residential segregation and fewer APPs and nursing homes. Further research is needed to identify mediators in these relationships to improve PC effectiveness for patients with mBC in Florida. Prognostic value of HER2-low status in breast cancer: A systematic review and meta-analysis. *First Author: Chiara Molinelli, Università degli Studi di Genova, Genoa, Italy*

Background: HER2-Low breast cancer (BC) has been recently identified as a new therapeutic target. However, it is unclear if HER2-Low status has an independent impact on prognosis, both in metastatic and early settings. **Methods:** A systematic literature research of PubMed, Cochrane and conference proceedings (ASCO meetings, SABCS and ESMO congress) up to December 8, 2022 was performed to identify studies comparing survival outcomes of patients affected by HER2-Low BC vs. HER2-zero BC. HER2-Low status was defined as immunohistochemistry score 1 + or 2+ without in situ hybridization amplification. Pooled hazard ratios (HRs) for survival endpoints in the metastatic [progression-free survival (PFS), overall survival (OS)] and in the early [disease free-survival (DFS) and OS] settings as well as their 95% confidence intervals (95%CI) were calculated using the random-effect model of Der Simonian and Laird. The above-mentioned endpoints were also assessed according to estrogen receptor (ER) status. **Results:** Among 1,916 identified records, 42 studies including 1,797,377 patients were eligible for this analysis. We show the pooled HRs in the overall population and specific subgroups. In the early setting, HER2-Low status was associated with significant improved DFS (HR 0.86, 95%CI 0.79-0.92, $p<0.001$) and OS (HR 0.84, 95%CI 0.77-0.92, $p<0.001$) when compared to HER2-zero status. Improved OS was observed in subgroup analysis for both ER-positive and ER-negative HER2-Low populations, while DFS improvement was observed only in the ER-positive subgroup. Similarly, in the metastatic setting, patients affected by HER2-Low BC showed better OS when compared to those with HER2-zero BC (HR 0.94, 95%CI 0.89-0.98, $p=0.008$). HER2-Low metastatic BC was associated with significant improvement in OS compared to HER2-zero BC also in ER-positive and ER-negative subgroups. No significant differences were found in terms of PFS. **Conclusions:** Compared with HER2-zero status, HER2-Low status appears to be associated with an increased OS both in the advanced and early settings, regardless of hormone-receptor expression. Research Sponsor: None.

Setting	Population	OS HR (95%CI)	p value	DFS HR (95%CI)	p value	PFS HR (95%CI)	p value
Early	Overall	0.84 (0.77-0.92)	<0.001	0.86 (0.79-0.92)	<0.001		
	ER-positive	0.85 (0.78-0.93)	0.001	0.86 (0.80-0.93)	<0.001		
	ER-negative	0.87 (0.84-0.89)	<0.001	0.90 (0.78-1.04)	0.155		
Metastatic	Overall	0.94 (0.89-0.98)	0.008			0.99 (0.96-1.03)	0.710
	ER-positive	0.92 (0.87-0.98)	0.013			1.13 (0.94-1.35)	0.192
	ER-negative	0.91 (0.87-0.95)	<0.001			0.92 (0.84-1.02)	0.103

Biomarker analysis of phase II pembrolizumab maintenance treatment after chemotherapy response in patients with HER2-negative inflammatory breast cancer and triple-negative breast cancer. *First Author: Toshiaki Iwase, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Accumulating toxicities make indefinite chemotherapy unfeasible for many patients with metastatic/recurrent HER2-negative inflammatory breast cancer (IBC) or triple-negative breast cancer (TNBC). We conducted a single-arm phase II trial of pembrolizumab monotherapy to determine the efficacy of maintenance immunotherapy in patients with metastatic HER2-negative aggressive breast cancer and to identify biomarkers correlated with disease control. **Methods:** The study enrolled patients who had a complete response, partial response, or stable disease after a minimum of 3 cycles of chemotherapy for metastatic TNBC/IBC regardless of PD-L1 expression between 2015 and 2022. Pembrolizumab was administered at 200 mg every 3 weeks until disease progression, intolerable toxicity, or 2 years of exposure to the drug. The primary endpoint was the 4-month disease control rate (DCR), and the secondary endpoint was progression-free survival (PFS). Correlative studies were performed to determine associations between clinical response, and immune profiling consisting of T-cell clonality, immunophenotyping, and dendritic cell (DC) function with blood collected at baseline and after 2 cycles of pembrolizumab treatment. **Results:** Of 43 treated patients, 11 had metastatic IBC and 32 had TNBC. The median number of prior lines of chemotherapy for metastatic disease was 1. During a median follow-up of 11.4 months, 33 patients had progressive disease and 25 were deceased. The 4-month DCR was 58.1% (95% CI: 43.4%-72.9%) and the median PFS was 4.8 months (95% CI: 3.0-7.1 months). The median PFS of the metastatic IBC group (2.2 months) and TNBC group (4.8 months) did not differ significantly ($p = .12$). Thirty-one patients discontinued treatment due to progressive disease rather than toxicity. Observed toxicities were consistent with the known profile of pembrolizumab. Correlative blood studies showed availability of PD-1 on CD8 T cells decreased on therapy. T-cell exhaustion markers 2B4, CTLA4, and TIM3 decreased in patients who had therapeutic benefit, while LAG3 increased in patients without benefit. During therapy, *ex vivo* cytokine synthesis (IL-6/IL-12/TNF α) by DCs was superior in patients who benefited from therapy and increased from pretreatment samples. High T-cell clonality at baseline predicted response to immunotherapy (10.4 vs 3.6 months, $p = .04$). Additionally, patients exhibiting the greatest clinical benefit also had a significant increase in T-cell clonality over the course of therapy (20% vs 5.9% mean increase, $p = .04$). **Conclusions:** Increased T-cell clonality and DC activity, along with reductions in T-cell exhaustion, were associated with prolonged disease control following pembrolizumab maintenance therapy, achieving acceptable disease control with manageable toxicity. Clinical trial information: NCT02411656. Research Sponsor: Merck.

Pilot study of a micro-organosphere drug screen platform to lead care in advanced breast cancer (MODEL-ABC). *First Author: David Graham, Xilis, Durham, NC*

Background: ASCO guidelines suggest using single agent chemotherapy for patients with advanced breast cancer (ABC). Single agent chemotherapy provides modest response rates in ABC, causing patients to be exposed to unnecessary toxicity without benefit. Thus, there is an unmet clinical need to develop a clinically applicable assay to guide treatment. We recently reported the use of Micro-Organospheres (MOS), which are gel droplets that encapsulate tumor cells creating miniature avatars of a patient's tumor and are amenable to high throughput dispensing and drug studies. In our current study, we evaluated the feasibility of generating and dosing MOS from ABC samples as a novel drug screen platform that led to the development and enrollment of a precision oncology trial, known as MODEL-ABC. **Methods:** We first performed a proof-of-concept study on 21 samples from patients with ABC and generated MOS. Drug screens were then performed on these MOS across 7 standard of care (SOC) chemotherapies commonly prescribed for ABC. These data resulted in a platform for the MODEL-ABC study that enrolled patients with ABC of any ER, PR, or HER2 subtype who were eligible for single agent chemotherapy to determine the feasibility of using MOS to predict response to therapy. In this study, biopsies from lesions ≥ 2 cm were obtained as part of SOC to generate MOS and perform drug screens. The patient subsequently received single agent chemotherapy per physicians' choice with either carboplatin, capecitabine, paclitaxel, eribulin, liposomal doxorubicin, gemcitabine, or vinorelbine. MOS were treated using the same chemotherapy as the patient along with 1-3 alternative single agent chemotherapies. **Results:** We generated MOS from 19/21 samples (90% success rate) across several breast cancer subtypes. Dose response curves of MOS were successfully generated across the 7 chemotherapies with a mean turnaround time of 21 ± 7 days validating the clinical applicability of MOS and leading to the MODEL-ABC trial. As of February 14, 2023, 4 of 15 patients have enrolled onto MODEL-ABC. All biopsies provided sufficient tissue for MOS generation, and drug screens were performed in 14-28 days across 2-4 chemotherapies. Two patients received capecitabine, one patient received eribulin, and one patient received paclitaxel. Full results of MODEL-ABC including correlation between MOS drug response and patient outcomes will be reported at the meeting. **Conclusions:** Our platform enables efficient establishment of MOS from ABC patient samples and allows for drug dosing studies to be performed in a clinically meaningful timeframe. Our preliminary data suggests it is feasible to obtain biopsies for MOS development and perform drug screens within 14 days. These findings provided the foundation for evaluating this technology as a potential ABC diagnostic tool and warrants further clinical development in ABC. Clinical trial information: NCT04655573. Research Sponsor: Xilis.

Association of pretreatment chest CT abnormalities with trastuzumab deruxtecan-associated pneumonitis. *First Author: Rachel Occhiogrosso Abelman, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: Trastuzumab deruxtecan (T-DXd) is an antibody-drug conjugate approved for HER2+ metastatic breast cancer (MBC) and HER2-low (IHC 1+ or 2+ with FISH-) MBC. Pneumonitis with T-DXd has been observed in 13.6% of patients (pts) on DESTINY-Breast 01 (including 2.2% fatal events) and 12.1% in pts on DESTINY-BREAST 04 (including 0.8% fatal events). There is an unmet need to determine if pts with baseline lung abnormalities are at increased risk for development of pneumonitis from T-DXd. **Methods:** This retrospective cohort study included all pts treated with T-DXd for MBC at an academic institution from 1/2020 to 2/2023 for more than 1 cycle (>21 days). Outcomes were evaluated from treatment initiation until 2/1/2023. Two board-certified radiologists blinded to outcomes reviewed staging chest CTs performed before initiating T-DXd and graded each scan on 16 parenchymal abnormalities, including presence of interstitial lung abnormalities (ILA). Pneumonitis was retrospectively adjudicated by an independent oncologist using chart review and graded according to CTCAE v5.0 and compared to the treating physician's assessment. The difference of proportions was analyzed with the Pearson Chi-Square test. Significance was declared at the 0.05 type I error threshold. **Results:** A total of 68 pts (median age 57.3 years) were included (30 = HER2+, 24 = HR+/HER2 low, 14 = TNBC/HER2 low). By independent assessment, 16 pts (23.5%) had grade 1 pneumonitis and 3 pts (4.4%) grade 2 pneumonitis. Median time from treatment initiation to pneumonitis was 83 days (range 35-266). By treating physician assessment, 5 pts (7.4%) developed grade 1 pneumonitis and 3 pts (4.4%) developed grade 2 pneumonitis. 16 of 68 pts (23.5%) had baseline ILA and 62 pts (91.2%) had at least one other parenchymal abnormality. As assessed by an independent oncologist, of pts with baseline ILA (N = 16), 12.5% developed T-DXd related pneumonitis, compared to 32.7% of pts without pre-existing ILA (N=52), $p=0.16$. There was no statistical difference in T-DXd related pneumonitis assessed by treating physician between pts with baseline ILA (2/16 patients, 12.5%) compared to pts without baseline ILA (7/52 pts, 13.5%), $p=0.68$. **Conclusions:** In this study, presence of baseline ILA was not associated with subsequent pneumonitis from T-DXd. Notably, the rate of independently assessed pneumonitis was higher than treatment-attributed pneumonitis as defined by the treating physician. Further research is needed to validate these findings and define predictors of treatment-associated pneumonitis. Research Sponsor: U.S. National Institutes of Health.

Rate of pretreatment abnormalities on CT chest in pts with MBC prior to treatment with T-DXd.	
Finding	Patients meeting criteria (Total N=68)
Interstitial lung abnormalities	16 (23.5%)
Radiation changes	48 (70.5%)
Bronchial wall thickening	55 (80.1%)
Emphysema	9 (13.2%)
Infectious or inflammatory ground-glass opacities	15 (22.1%)

Demographic and clinical characteristics of patients with metastatic breast cancer and leptomeningeal disease: A single center retrospective cohort study. *First Author: Laura Ann Huppert, University of California, San Francisco, San Francisco, CA*

Background: Patients (pts) with metastatic breast cancer (MBC) and leptomeningeal disease (LMD) have a poor prognosis with limited therapeutic options. It is critical to better understand the risk factors and natural history of this condition, including pts in a modern cohort. **Methods:** In this single center retrospective cohort study, we identified pts with radiographic and/or cytologic evidence of LMD who received care at the University of California San Francisco (UCSF) from 2000-2023. To identify pts, we used the UCSF Pathology Database, the UCSF Radiation Oncology Database, and EMERGE, a searchable copy of the medical record. We conducted chart review to identify demographic and clinical characteristics, treatment history, and overall survival (OS). **Results:** 106 pts with MBC and radiographic and/or cytologic evidence of LMD were identified. All but one pt was female (n=105; 99.1%); most pts were non-Hispanic (n=93, 87.7%) and white (n=74, 69.8%). Median age at the time of MBC diagnosis was 51.9 years; 25 pts (20%) had de novo metastatic disease. Most pts had invasive ductal carcinoma (n=71, 66.9%), with invasive lobular carcinoma making up 21.7% (n=23) of cases. Pts presented with the following BC subtypes: Hormone receptor (HR) positive, HER2 negative (n=50, 47.1%), HR+/HER2+ (n=19, 17.9%), HR-/HER2+ (n=9, 8.5%), and triple negative (TNBC; n=23, 21.7%). Most pts had brain metastasis (n=78, 73.6%) in addition to LMD. Median time from diagnosis of MBC to LMD was 17.6 months (0-101.2 months). Pts received a median of 3.0 lines of therapy prior to the diagnosis of LMD (range 0-11.0) and 1.0 lines after the diagnosis of LMD (range 0-4.0). Many pts received intrathecal (IT) therapy (n=42, 39.6%) and/or whole brain radiation therapy or spinal radiation (n=49, 46.2%). Median OS from the diagnosis of LMD to death was 3.3 months. There was no significant difference in median OS by subtype: HR+/HER2- 3.5 months, HER2+ 4.7 months, and TNBC 2.2 months ($p=0.45$). There was no significant difference in median OS by histology: ductal (3.3 months) vs. lobular (4.7 months) ($p=0.56$). Pts who received IT therapy survived longer than those not treated with IT therapy (4.7 vs. 2.5 months, $p=0.01$). There was no significant difference in median OS among pts diagnosed with LMD between 2000-2015 (2.9 months) vs. 2016-2023 (3.6 months) ($p=0.74$). **Conclusions:** This study represents one of the largest reported case series of pts with MBC and LMD, including a more modern cohort. There appeared to be an over-representation of pts with lobular cancer and those with de novo metastatic disease. Most pts had brain metastases in addition to LMD. Survival was short in all pts, particularly those who did not receive IT therapy. There was no significant difference in median OS in pts diagnosed with LMD from 2000-2015 vs. 2016-2023; this remains an area of unmet clinical need. Research Sponsor: None.

Distribution and outcomes of HER2-low and HER2-zero metastatic breast cancer in Black and younger women. *First Author: Paola Zagami, UNC Lineberger Comprehensive Cancer Center/University of Milan, Chapel Hill, NC*

Background: Black and younger patients with breast cancer (BC) have higher mortality. This racial disparity has been attributed to different BC biology, access to care, and treatment. With the advent of new antibody-drug conjugates (ADC) for metastatic BC (MBC), “HER2-negative” has been subdivided into HER2-low (IHC 1+ or 2+/ISH-negative) and HER2-0 (IHC 0). Little is known about these subcategories among Black and younger women with MBC. **Methods:** Clinical characteristics, treatment, and outcomes of patients diagnosed with HER2-negative MBC between 2011-2022 and with follow-up through a progression-free survival event on first-line therapy (PFS1) were retrieved from the UNC Metastatic Breast Cancer Database; hormone receptor (HR) and HER2 categories were by clinical criteria from the pathology report. Analyses were limited to HER2-negative BC and stratified/controlled by HR status. Fisher's exact tests were used to compare HER2 status across race and age. The Kaplan Meier method and log-rank tests, as well as Cox proportional hazards models estimated PFS1. **Results:** The cohort included 772 MBC patients (56% HER2-low and 44% HER2-0), 22% Black women and 30% < 50 years old at MBC diagnosis. There were no differences in proportion with HER2-low by race or age ($p > 0.5$). Patients with HER2-low had better observed median PFS1 compared to HER2-0, however, most of these differences were non-significant: overall (HR+ 12.2 vs 9.8m, $p = 0.11$, HR- 4.3 vs 3.3m, $p = 0.29$) and within race and age categories (see table). In Cox modeling, Black women had worse PFS1 ($p = 0.03$), that was no longer apparent after adjusting for HR status ($p = 0.1$), there was no difference by age. Patients with HER2-0 had worse PFS1 ($p = 0.0005$), which remained after adjusting for HR status ($p = 0.05$). In a multivariable model comparing HER2-0 to HER2-low, adjusting for race and HR status, PFS1 remained shorter in the HER2-0 group (hazard ratio: 0.84, CI 0.692 – 1.015, $p = 0.07$). Among those treated with uniform first-line therapy, better PFS1 was observed in HER2-low disease. This included 137 HR+ MBC treated with ET + CDK4/6i (mPFS1 14.3 v 10.3m, $p = 0.33$) and 170 HR- MBC treated with chemotherapy (mPFS1 4.0 v 3.1m, $p = 0.22$) with no variation by race or age. **Conclusions:** Within HER2-negative MBC, distribution of HER2-low and HER2-0 cancers does not differ by race and age. The clinical benefit of first-line therapy is strongly driven by HR status regardless of race and age, and is greater in HER2-low cancers although this cohort did not include HER2-directed ADCs. Research Sponsor: None.

Randomised open-label phase II study of induction standard of care fulvestrant and CDK4/6 inhibition with addition of ipatasertib in metastatic ER+/HER2- breast cancer patients without circulating tumour (ct) DNA suppression (FAIM). *First Author: Alicia Frances Clare Okines, The Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: The combination of fulvestrant and one of the three approved CDK4/6 inhibitors (i) is the standard of care for patients with ER+/HER2 metastatic breast cancer progressing on first-line endocrine therapy, or relapsing on or within a year of completing adjuvant endocrine therapy. AKT inhibition combined with fulvestrant has recently demonstrated clinically important activity in patients with advanced ER+/HER2- breast cancer progressing on first-line CDK4/6i plus an AI. Monitoring ctDNA dynamics has potential utility as an early response evaluation tool: Lack of suppression of ctDNA at day 15 in patients treated with palbociclib and fulvestrant in the PALOMA-3 trial was predictive for shorter PFS. We designed FAIM to establish whether the addition of the AKT inhibitor, ipatasertib, improves PFS in patients with poor ctDNA suppression during cycle 1 of fulvestrant and CDK4/6i. **Methods:** FAIM is a phase 2 multi-centre, randomised, open-label superiority trial in patients with ER+/HER2- advanced breast cancer, recruiting at centres in the UK. Patients will undergo ctDNA testing at days 1 and 15 of cycle 1 fulvestrant and CDK4/6i inhibitor. Eligible patients must be aged ≥18, have ER+ (≥1% or Allred score 3/8 or greater) and HER2- advanced breast cancer, measurable disease or assessable bone disease (RECIST 1.1), adequate organ function, fasting glucose ≤150mg/dL and HbA1c ≤7.5% and be eligible for NHS treatment with fulvestrant and CDK4/6i. Patients with diabetes requiring insulin, significant cardiac disease, a history of pneumonitis, or prior exposure to CDK4/6i are excluded. The FoundationOne Liquid CDx assay will be used for ctDNA analysis, a pan-cancer, tumour-agnostic liquid biopsy test that uses error-corrected next-generation sequencing. Patients with poor ctDNA suppression at day 15 will be eligible for the randomised (minimisation) study. Up to 483 patients starting fulvestrant and CDK4/6i will enroll for ctDNA screening to allow 174 patients to enter the randomised study. The primary endpoint of the study is to compare PFS in patients randomised to palbociclib/fulvestrant +/- ipatasertib. Secondary endpoints include safety, overall survival and overall response rate in all randomised patients and PFS in the sub-group of patients with alterations in the PIK3CA/AKT1/PTEN pathway. One hundred patients with ctDNA suppression at day 15, and up to 50 patients with no detectable ctDNA at day 1, will form additional control groups for exploratory outcome comparison to patients with poor ctDNA suppression. Enrolment began in December 2022 and is anticipated to continue for 2 years (NCT04920708). Clinical trial information: NCT04920708. Research Sponsor: Roche; Pfizer.

Imbalance in treatment discontinuation without progression between experimental and control arms among randomized trials in advanced breast cancer. *First Author: Faris Tamimi, Division of Medical Oncology & Hematology, Department of Medicine, Princess Margaret Cancer Centre and University of Toronto, Toronto, ON, Canada*

Background: In Randomized Controlled Trials (RCT), treatment discontinuation (TD) can result in censoring. Imbalanced frequency of TD between arms could impact interpretation of results. Here, we quantify TD between the experimental and control arms among RCT supporting registration of drugs for advanced breast cancer. **Methods:** We identified RCT supporting US Food and Drug Administration's approval of drugs for advanced breast cancer between 2013 and 2023. We extracted data for the number of participants with TD for reasons other than disease progression (PD), death, or completion of treatment. Odds ratio (OR) for TD comparing experimental to control arms were determined for each trial. To assess progression-free survival (PFS) translation into an overall survival (OS) benefit, we calculated hazard ratio (HR) for PFS/OS. Then we assessed whether there was quantitative association between the OR for TD and the ratio of HR for PFS/OS. Quantitative significance was defined according to the criteria of Burnand. **Results:** Analysis included 22 RCT comprising 13853 participants and supporting approval for 18 distinct drugs. TD was reported in 2212 (16.0%) participants. Among these participants, the leading causes of TD were withdrawal of consent (27.8%), site termination (20.7%), adverse events (17.2%), and loss of follow-up (10.9%). There was a statistically significant imbalance in the experimental arm in 4 RCT (18%) (Table), which was observed for everolimus, ribociclib (with fulvestrant), apalibisib, and neratinib. The OR for TD showed quantitative, but not statistically significant negative association with the ratio of the HR for PFS/OS (Beta -0.393; $p = 0.18$). **Conclusions:** TD without PD, death, or completion of treatment occurs in a substantial proportion of participants of several RCT supporting approval of drugs for advanced breast cancer. all the statistically significant imbalanced TD in the RCT were in experimental arms. Quantitative association between imbalanced TD and the ratio of HR for PFS/OS suggests imbalanced TD may impact ability to translate improvements in PFS to OS. Results of RCT with imbalance in TD should be interpreted cautiously. Research Sponsor: None.

Phase IIa study of αDC1 vaccines targeting HER2/HER3 combined with pembrolizumab in patients with asymptomatic brain metastasis from triple negative breast cancer or HER2+ breast cancer. *First Author: Shipra Gandhi, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Brain metastases develop in up to 50% patients (pts) with metastatic triple negative breast cancer (TNBC) and HER2+ BC, constituting an increasing source of morbidity and mortality. HER3, overexpressed in triple negative and HER2+ brain metastatic breast cancer (BMBC), is a resistance factor to HER2-targeted therapies and a driver of CNS metastasis. Disease progression is associated with loss of anti-HER2 and anti-HER3 immunity. Previously, we have demonstrated that glioma-specific peptide-loaded αDC1 which produce CXCL9, CXCL10, CXCL11, CCL5, the chemokines which attract CXCR3- and CCR5- expressing cytotoxic T-lymphocytes (CTLs) and T-helper 1 (Th1) cells, induce clinical responses and long-term disease stabilization in pts with aggressive recurrent primary brain tumors (Okada et al. JCO 2011. PMID: 21149657). We hypothesized that anti-HER2/3-loaded αDC1 in combination with PD1 blockade will result in strong Th1/CTL response against HER2/3 epitopes (Basu A et al. Cancer Immunol Res. 2022 PMID: 34785506), being effective against brain lesions and systemic disease. **Methods:** This is a phase II single-arm, non-randomized multicenter study (NCT04348747). Eligibility includes pts with triple negative and HER2+ BMBC ≥18 years, ECOG PS ≤1, normal marrow and organ function with asymptomatic untreated brain metastases ≥ 5 mm who will receive αDC1 q3 weeks x 3 along with pembrolizumab every 3 weeks. Thereafter, αDC1 booster doses (if available) would be administered every 3 months until disease progression, intolerable side effects or withdrawal from study, up to 24 months. Baseline and 9-week post-αDC1 peripheral biopsies (non-CNS) are required for six pts. 1 of the planned 21 pts have been enrolled and is undergoing treatment. Primary endpoint is CNS response rate (RR) by RANO-BM criteria. If no CNS response is observed after 12 pts, study will be terminated. If ≥ 1 response observed, then 9 more pts will be enrolled, for a total of 21 pts. If ≥ 3 CR are observed, the proposed therapy will be considered as promising for further evaluation. Secondary endpoints include non-CNS RR per RECIST v1.1, median CNS, non-CNS and overall progression-free survival, overall survival and safety. Exploratory endpoints include changes in intratumoral biomarkers (CTLs, PDL1, chemokines) in pre- and post-treatment peripheral tumor biopsies and immune changes in the blood. Clinical trial information: NCT04348747. Research Sponsor: Department of Defense.

Phase I study of adoptive T cell therapy following HER2-pulsed dendritic cell vaccine and pepinemab/trastuzumab in patients with metastatic HER2-positive breast cancer (MBC). *First Author: Hyo S. Han, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Despite major improvement of overall survival of HER2+ MBC with effective HER2 targeted therapies, many patients experience significant toxicities and develop progressive disease during treatment. Therefore, new and more effective therapeutic options are needed. This novel approach will evaluate whether the combination of three immunotherapies in addition to trastuzumab: dendritic cell (DC) vaccination, anti-SEMA4D blocking antibody (pepinemab) and CD4+ T cell adoptive transfer can lead to improved outcomes for patients with MBC refractory to HER2-targeted agents. BC have been considered as immunologically cold which is attributed to immune evasion and suppression of host effector immune cells homing into tumor bed. Progressive loss of Th1 immunity against HER2 oncovirion correlates with poor prognosis. HER2 peptide pulsed type I dendritic cells (HER2-DC1) re-stored anti-HER2 CD4+ Th1 immune response and improved pathologic complete response (pCR) in HER2+ BC. Antibodies to SEMA4D have been shown to modulate the TME by increasing effector cell infiltration and reducing immunosuppression. In preclinical studies, treatment with anti-SEMA4D and HER2-DC1 in mice bearing established HER2+ tumors improved DC homing, expansion of CD4+ T cells, and complete tumor regression, compared to treatment with anti-SEMA4D or HER2-DC1 alone. Further, subsequent expansion and adoptive transfer of CD4+ T cells induced synergistic anti-tumor activity by activating CD8+ T mediated cytotoxicity. Pepinemab was well-tolerated and showed signs of anti-tumor activity in in immunotherapy-resistant and PD-L1 negative/low non-small cell lung cancer patients when combined with checkpoint inhibitor (avelumab). **Methods:** This open label Phase I study is enrolling up to 28 patients with HER2+ MBC. Patients will be treated with 6 weekly injections of dendritic cell (DC1) vaccines in combination with trastuzumab and pepinemab. We hypothesize these therapies may elicit CD4+ HER2-specific T cell responses. HER2-specific T cells will be expanded ex vivo and subsequently infused to patients following lymphodepletion with cyclophosphamide. Trastuzumab and pepinemab will be given as maintenance in addition to booster DC1 vaccines. Patients (ECOG 0,1) must have had disease progression while on trastuzumab for the treatment of HER2+ MBC and received no more than 3 lines of chemotherapy in the setting of metastatic disease. Dose escalation will consist of 3-6 patients each with increasing amounts of transferred CD4+ T cells, followed by dose expansion of 10 patients at the MTD. The primary objective is safety and tolerability; secondary objectives will include evaluation of T cell immunity and immune subsets, efficacy, PK/PD/ADA of pepinemab, and biomarker assessments. Clinical trial information: NCT05378464. Research Sponsor: Moffitt Cancer Center Breast Cancer Funding; Bankhead and Coley Cancer Research Grant.

HER2CLIMB-05: Phase 3 study of tucatinib or placebo in combination with trastuzumab and pertuzumab as maintenance therapy for HER2+ metastatic breast cancer. *First Author: Erika P. Hamilton, Sarah Cannon Research Institute at Tennessee Oncology, Nashville, TN*

Background: The current first-line (1L) standard of care (SOC) for human epidermal growth factor receptor 2-positive (HER2+) metastatic breast cancer (MBC) is trastuzumab (T) plus pertuzumab (P) and a taxane. Despite advances in 1L SOC, most patients progress during maintenance therapy with T + P. Tucatinib is a tyrosine kinase inhibitor (TKI) approved in combination with T and capecitabine for adults with HER2+ MBC, with and without brain metastases (BM). In HER2CLIMB, the addition of tucatinib significantly prolonged progression-free survival (PFS) and overall survival (OS) in patients with HER2+ MBC and was well tolerated. Adding tucatinib also reduced the risk of disease progression or death in patients with untreated and/or active BM (Murthy et al. 2020, Curigliano et al. 2021). HER2CLIMB-05 investigates whether adding tucatinib to 1L SOC as maintenance therapy will extend PFS while maintaining quality of life (QOL). **Methods:** HER2CLIMB-05 (NCT05132582) is a phase 3, randomized, double-blind study evaluating tucatinib plus T + P as maintenance therapy for HER2+ MBC. Approximately 650 patients will be enrolled. Eligible patients will have advanced HER2+ disease, no progression on 4–8 cycles of prior 1L SOC, Eastern Cooperative Oncology Group Performance Status of 0 or 1, and no or asymptomatic BM. Exclusion criteria include prior treatment with anti-HER2 and/or anti-epidermal growth factor receptor TKI (prior SOC for early BC is permitted) or inability to undergo contrast magnetic resonance imaging of the brain. Patients will be randomized 1:1 to receive either tucatinib or placebo twice daily, with T + P once every 21 days. Patients with hormone receptor-positive disease may receive endocrine therapy. The primary endpoint is investigator-assessed PFS. Secondary endpoints include OS (key endpoint), PFS by Blinded Independent Central Review (BICR), time to deterioration of health-related QOL, central nervous system PFS, safety, and pharmacokinetic (PK) parameters. PFS and OS will be compared using a 2-sided stratified log-rank test between treatment groups. Time-to-event endpoints will be summarized using the Kaplan–Meier method. PK and safety data will be summarized using descriptive statistics. Enrollment is ongoing in the US, Canada, Brazil, APAC and EU countries with additional sites planned. Clinical trial information: NCT05132582. Research Sponsor: Seagen, Inc.

A phase 1, first-in-human, open label, escalation and expansion study of ORM-5029, a highly potent GSPT1 degrader targeting HER2, in patients with HER2-expressing advanced solid tumors. *First Author: Sara A. Hurvitz, Division of Hematology/Oncology, David Geffen School of Medicine at the University of California Los Angeles/Jonsson Comprehensive Cancer Center, Los Angeles, CA*

Background: Targeted protein degradation (TPD) molecules have expanded the therapeutic options through their catalytic mechanism of action (MOA) and ability to degrade “undruggable” proteins. To increase the efficacy versus tolerability window of protein degradation and improve drug delivery, ORM-5029 uses a Dual-Precision TPD (TPD²) approach combining the catalytic mechanism of TPDs with the precision of tumor-targeting therapeutic antibodies. ORM-5029 is a first-in-class human epidermal growth factor receptor 2 (HER2)-targeted antibody-drug conjugate (ADC) comprised of SMOI006, a highly potent GSPT1 degrader, conjugated to pertuzumab, a clinically validated antibody. HER2 is overexpressed in cancers such as breast, ovarian and gastric, and associated with early-onset aggressive disease. ORM-5029 is in development for treatment of HER2-expressing solid tumors. The MOA is mediated by targeted uptake of the ADC, release of the TPD payload, and cell death by GSPT1 degradation. ORM-5029 showed robust *in vitro* and *in vivo* efficacy in multiple HER2-expressing models with comparable activity to trastuzumab deruxtecan and strong activity in trastuzumab emtansine-refractory models. **Methods:** This phase 1 first-in-human study evaluates the safety, tolerability, and efficacy of ORM-5029 administered by intravenous infusion in patients (pts) with HER2-expressing advanced solid tumors (NCT05511844). The escalation, guided by the Bayesian Optimal Interval design, explores cohorts of ORM-5029 to identify the maximum tolerated dose (MTD) and/or expansion dose level (EDL). Each cohort will enroll ≥3 breast cancer pts with at least HER2 1+ (HER2 low) or greater by immunohistochemistry or positive by *in situ* hybridization. Expansion cohort A (HER2+ breast cancer) may enroll in parallel to escalation evaluating doses showing pharmacodynamic activity or efficacy. Up to 10 pts may be enrolled at each dose explored in cohort A. Enrollment into expansion cohort B (up to 21 pts) and cohort C (up to 22 pts) will begin once the EDL has been determined to further assess the safety, tolerability and efficacy of ORM-5029 using a Simon's optimal 2-stage design. Cohort B will enroll pts with HER2+ breast cancer refractory or intolerant to standard treatment after ≥2 HER2 therapies in the metastatic setting. Cohort C will enroll pts with advanced solid tumors that are refractory or intolerable to standard treatment or for which no standard treatment is available, including HER2+ gastric or gastroesophageal junction adenocarcinoma or tumors with HER2 expression, amplification or mutations (e.g., colorectal, bile duct, ovarian, bladder, non-small cell lung). Study enrollment began in October 2022 in the United States. Escalation cohort 1 was completed without DLT; enrollment in cohort 2 began as of December 2022. Clinical trial information: NCT05511844. Research Sponsor: Orum Therapeutics USA, Inc.

Poster Session

UCLA B-13: A phase 1b trial evaluating the safety of ribociclib, tucatinib, and trastuzumab in patients with metastatic, HER2+ breast cancer and a multicenter, randomized, open-label, phase 2 study of preoperative treatment with ribociclib, trastuzumab, tucatinib, with or without fulvestrant versus docetaxel, carboplatin, trastuzumab, and pertuzumab in HR+/HER-, HER2+ breast cancer. *First Author: Nicholas Patrick McAndrew, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA*

Background: Overexpression of the HER2 protein is an important prognostic and predictive biomarker in about 20% of breast cancers, and while trastuzumab-based regimens are still considered standard of care in the early and metastatic settings, these regimens require chemotherapy co-administration. Pre-clinical mouse models suggest that a tucatinib/CDK 4/6 inhibitor combination regimen may be equally effective as standard regimens. Thus, finding more effective/tolerable therapies for this disease remains an area of unmet need. This randomized, open label, phase II clinical trial will explore the safety and efficacy of two novel, chemotherapy free combination drug regimens, given neoadjuvantly, in patients with anatomic stage I-III, HER2+ breast cancer. **Methods:** Phase 1b dose escalation trial: To establish the safety profile of the combination of ribociclib and tucatinib, an initial dose-finding phase 1b trial will be performed in patients with metastatic HER2+ breast cancer before moving into the larger phase 2 trial. 3-6 patients will be assigned sequentially to groups of increasing doses of ribociclib (200mg-600 mg) with fixed doses of tucatinib (300mg) and trastuzumab (SOC dosing) for a total of four 28-day cycles. The recommended phase 2 dose will be established when 6 patients have been treated at the highest dose level cohort. As of January 2023, 1 participant has been enrolled in dose level 1. Phase 2 neoadjuvant trial: Following MTD determination and approval from regulatory boards and funding partners, a total of 100 patients will be enrolled in the phase 2 portion of the study. Enrollment will be stratified by hormone receptor status. Patients will be randomized 1:1 (25 in each group) to receive six cycles of one of the following regimens: ribociclib/trastuzumab/tucatinib +/- fulvestrant (28 day cycles) or docetaxel/carboplatin/trastuzumab/pertuzumab (SOC, 21 day cycles), preceded by one run-in cycle of trastuzumab/pertuzumab. To assess for changes in predictive molecular biomarkers, biopsies pre-and-post cycle 1 will be planned in all arms. Early imaging response assessments in the experimental arms will be planned after 2 cycles. Other endpoints include safety, changes in Ki67 expression, RCBi, biomarker analysis, and health-related quality of life. Clinical trial information: NCT05319873. Research Sponsor: Novartis, Seagen Inc.

EPIK-B6: A phase 2, open-label, 2-part, multicenter study of alpelisib in combination with fulvestrant for men and postmenopausal women with PIK3CA mutation HR-positive, HER2-negative, advanced breast cancer, which progressed on/after aromatase inhibitor treatment in Japan. First Author: Hiroji Iwata, Aichi Cancer Center Hospital, Aichi, Japan

Background: The *PIK3CA* oncogene mutation, seen in ~40% of patients with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer (aBC), is associated with endocrine treatment resistance and shorter survival. Alpelisib, an α -selective PI3K inhibitor and degrader, was established as standard therapy in combination with fulvestrant for patients with HR+, HER2-, *PIK3CA*-mutated aBC following progression on/after endocrine-based regimen based on the phase 3 SOLAR-1 study. However, alpelisib is not yet approved in Japan. In the SOLAR-1 study, a high percentage of Japanese patients experienced dose reductions/interruptions (78.5% vs 84.4%), and/or discontinuation (56.3% vs 25.0%) of alpelisib in early stages compared with overall population, due to adverse events such as rash and hyperglycemia. Thus, it is difficult to assess the consistency of the benefit of alpelisib + fulvestrant in Japanese patients as compared to overall population due to the short duration of alpelisib exposure and low-dose intensity. The EPIK-B6 study aims to determine the recommended dose (RD) of alpelisib in Japanese patients as well as assess the efficacy and safety of alpelisib + fulvestrant in Japanese men and postmenopausal women with HR+, HER2-, *PIK3CA*-mutated aBC, which progressed while on/after aromatase inhibitor treatment, prior/post CDK 4/6i use. **Methods:** The EPIK-B6 study is designed as a phase 2, open-labelled, 2-part, multicenter study. Part 1 is to determine RD of alpelisib to be used in part 2. Part 2 is designed to assess the efficacy and safety of alpelisib (RD starting on cycle 1 day 1 [C1D1]) + fulvestrant (500 mg on C1D1 and C1D15, and D1 of subsequent cycles) after completion of part 1, in participants with/without prior CDK 4/6i use. Adult Japanese men or postmenopausal women with confirmed HR+, HER2-, *PIK3CA*-mutated aBC and ≥ 1 measurable lesion as per RECIST 1.1 criteria are eligible. Patients previously treated with fulvestrant, any PI3K, mTOR or AKT inhibitors are excluded. Use of prophylactic antihistamine is highly recommended for prevention of rash. The primary endpoint for part 2 is overall response rate based on assessments per RECIST 1.1. Secondary endpoints include progression free survival, overall survival, clinical benefit rate, duration of response, time to response, time to deterioration of ECOG performance status, safety, tolerability, and pharmacokinetics. Part 1 has been completed, and recruitment for part 2 is ongoing until August 2023 approximately. As of December 2022, 9 and 8 patients are enrolled in part 1 and 2, respectively. The study will include approximately 50 participants. Primary Analysis is planned in 2024 after at least 6 months follow-up period. Clinical trial information: NCT04524000. Research Sponsor: Novartis.

evERA Breast Cancer (BC): Phase III study of giredestrant + everolimus vs exemestane + everolimus in patients (pts) with estrogen receptor-positive, HER2-negative locally advanced or metastatic BC (ER+, HER2- LA/mBC). First Author: Erica L. Mayer, Dana-Farber Cancer Institute, Boston, MA

Background: Endocrine therapy (ET) + a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) is the standard of care in pts with ER+, HER2- mBC in the first-line setting. Fulvestrant $\pm$ a CDK4/6i, and everolimus + exemestane are the current approved second-line regimens. However, therapeutic resistance to some ETs, such as aromatase inhibitors, can arise from *ESR1* mutations (m) driving estrogen-independent transcription and proliferation. Current post-CDK4/6i treatment options are suboptimal. New therapy options are therefore needed to reduce this risk and to improve outcomes, tolerability, quality of life, and adherence to treatment. Giredestrant is a highly potent, nonsteroidal oral selective ER antagonist and degrader (SERD) that achieves robust ER occupancy and is active regardless of *ESR1*-mut status. While Phase I SERD combination data in the post-CDK4/6i setting are encouraging, there are no randomized combination data. Combining giredestrant and everolimus may improve outcomes after CDK4/6is and in pts with *ESR1*m tumors. **Methods:** evERA BC (NCT05306340), a Phase III, global, randomized, open-label, multicenter study will evaluate the efficacy and safety of giredestrant + everolimus vs. exemestane + everolimus in pts with ER+, HER2- LA/mBC who had previous treatment with a CDK4/6i and ET in the LA/mBC or adjuvant setting. Pts will be randomized to either giredestrant (30 mg) + everolimus (10 mg) by mouth (PO) every day (QD), or exemestane (25 mg) + everolimus (10 mg) PO QD. Pts will receive treatment until disease progression or unacceptable toxicity. Pts will use a dexamethasone mouth rinse 4 times QD for 8 weeks concurrently with study treatment. Eligibility: Female/male pts ≥ 18 years with ER+, HER2- LA/mBC and disease progression ≥ 6 months (mo) after initiating ET + CDK4/6i in the LA/mBC setting (and ≥ 4 mo on most recent ET, if ET + CDK4/6i was not the most recent therapy received), or relapsed either while taking or within 12 mo of exposure to combination adjuvant ET (≥ 12 mo) + CDK4/6i (≥ 6 mo), and available blood sample for circulating tumor DNA central testing for *ESR1*m status. Men and pre-/perimenopausal women will receive a LHRH. Co-primary endpoints: Investigator-assessed progression-free survival (per RECIST v1.1) in the intent-to-treat and *ESR1*m populations. Secondary endpoints: Overall survival; objective response rate; duration of response; clinical benefit rate; pt-reported outcomes; safety; pharmacokinetics. Co-primary endpoint analyses will use a two-sided stratified log-rank test at an overall 0.05 significance level. An independent data monitoring committee will be in place for safety. Target enrollment is 320 pts, and this study is currently recruiting. Encore from SABCS 2022 (OT2-01-07). Clinical trial information: NCT05306340. Research Sponsor: F. Hoffmann-La Roche Ltd.

Poster Session

A phase 3 study of gedatolisib plus fulvestrant with and without palbociclib in patients with HR+/ HER2- advanced breast cancer previously treated with a CDK4/6 inhibitor plus a nonsteroidal aromatase inhibitor (VIKTORIA-1). First Author: Sara A. Hurvitz, David Geffen School of Medicine; University of California, Los Angeles; Jonsson Comprehensive Cancer Center, Santa Monica, CA

Background: Patients who receive frontline CDK4/6 inhibitor (CDK4/6i) therapy eventually experience disease progression. Resistance to CDK4/6i is likely a transient adaptive mechanism that may be reversed by inhibition of the PI3K/mTOR pathway. Thus, combination of CDK4/6i and PI3K/mTORi after disease progression on CDK4/6i could restore sensitivity to CDK4/6i and prevent activation of the PI3K/mTOR pathway. This hypothesis was evaluated in a Phase 1b study (Layman SABCS 2021) of gedatolisib (geda), a potent inhibitor of PI3K and mTOR. Subjects with HR+/HER2- ABC with prior CDK4/6i received geda (180 mg IV weekly for 3 weeks, then one week off) with palbociclib (palbo) and fulvestrant (FUL). Median PFS was 12.9 months with 63% overall response rate. Efficacy was observed regardless of *PIK3CA* mutation status (Wesolowski SABCS 2022). Geda was well tolerated, with few discontinuations due to treatment-related adverse events (4%). The most common AE was stomatitis; hyperglycemia of any grade occurred in 26% of patients. This preliminary data, dosing schedule, and study population characteristics form the basis for the Phase 3 trial, VIKTORIA-1 (NCT05501886). **Methods:** This Phase 3 multinational clinical trial will evaluate geda and FUL with or without palbo in patients with HR+/HER2- ABC previously treated with any CDK4/6i in combination with a non-steroidal aromatase inhibitor (AI) therapy. Those without tumor *PIK3CA* mutations will be assigned to Study 1 (n=351) and randomized to Arm A (geda, palbo, and FUL), Arm B (geda and FUL), or Arm C (FUL). Those with *PIK3CA* mutations will be assigned to Study 2 (n=350) and randomized to Arm D (geda, palbo, and FUL), Arm E (alpelisib and FUL), or Arm F (geda and FUL). Key eligibility criteria include adults with confirmed metastatic or locally advanced breast cancer, any menopausal status, radiologically evaluable disease, and prior CDK4/6i treatment in combination with a non-steroidal AI. Prior hormonal therapy, including SERDs, is allowed. Key exclusion criteria include prior treatment with a PI3K, Akt, or mTOR inhibitor, prior treatment with chemotherapy for advanced disease, more than two lines of prior endocrine therapy, bone only disease with no soft tissue components, active CNS metastases, and type 1 diabetes or uncontrolled type 2 diabetes. The primary endpoint is PFS assessed by blinded independent central review per RECIST v1.1. Secondary endpoints included overall survival, safety and tolerability, ORR, duration of response, time to response, CBR, quality of life, and pharmacokinetics. The trial is open for enrollment. Clinical trial information: NCT05501886. Research Sponsor: Celcuity, Inc.

AIPAC-003: A randomized, double-blind, placebo-controlled phase 3 trial testing eftilagimod alpha (soluble LAG-3) in patients with HER2-neg/low metastatic breast cancer receiving paclitaxel, following an open-label dose optimization. First Author: Nuhad K. Ibrahim, University of Texas MD Anderson Cancer Center, Houston, TX

Background: Eftilagimod alpha (efti), a soluble LAG-3 protein, acts as an MHC class II agonist that enhances immunity by mediating antigen presenting cell and CD8 T-cell activation. Data from a randomized, phase 2b trial of efti plus paclitaxel compared to placebo plus paclitaxel in patients (pts) with HR+ HER2- metastatic breast cancer (MBC) (AIPAC; NCT02614833) showed sustained pharmacodynamic activity that was linked to improved overall survival (OS) in the efti arm. AIPAC-003 is a randomized, double-blind, placebo-controlled phase 3 trial testing efti plus paclitaxel in HER2-neg/low MBC pts, including an initial open-label dose optimization lead-in (DOL) component to determine the optimal biological dose (OBD) of efti in this combination. **Methods:** Enrollment for the DOL will begin in March 2023 in max. 66 pts. Primary endpoints (EP) in the DOL include safety and tolerability of 90 mg vs 30 mg efti and defining the OBD of efti in combination with weekly paclitaxel. Determination of the OBD will be based on the totality of safety and tolerability data together with overall response rate (ORR) and pharmacodynamic marker (CD8+ T cells, absolute lymphocyte count) data. In the Phase 3 component approx. 771 pts are randomized to receive either paclitaxel + efti or paclitaxel + placebo in a double-blinded fashion. The primary EP for the proposed Phase 3 is OS. Key secondary EPs include progression free survival and ORR by RECIST 1.1, quality of life and safety. Pts will receive paclitaxel (80 mg/m² I.V. on D1, 8 and 15 in a 4-week cycle), followed by efti or placebo (DOL: 30 or 90 mg efti; Phase 3: OBD of efti or placebo) S.C. on D1 and 15 in a 4-week cycle for up to 12 months. Key inclusion criteria: Pts with either a) HR+ and HER2-neg/low and endocrine therapy-resistant MBC or b) TNBC not eligible for anti-PD-1-based therapy. Pts must have measurable disease, ECOG PS 0-1 and no prior chemo for metastatic disease. Research Sponsor: Immunet S.A.

Poster Session

TACTIVE-U: Phase 1b/2 umbrella study of ARV-471, a proteolysis targeting chimera (PROTAC) estrogen receptor (ER) degrader, combined with other anticancer treatments in ER+ advanced or metastatic breast cancer. *First Author: Rachel M. Layman, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ARV-471, an oral PROTAC ER degrader, was well tolerated and showed evidence of clinical activity in a phase 1/2 study in heavily pretreated patients with ER+/human epidermal growth factor receptor 2 (HER2)- advanced breast cancer. The CDK4/6 inhibitors abemaciclib and ribociclib are approved in combination with endocrine therapy as first- and second-line treatment for ER+/HER2- advanced or metastatic breast cancer; abemaciclib is also approved as monotherapy and in combination with other agents in additional breast cancer settings. ARV-471 combined with abemaciclib or ribociclib showed evidence of synergistic interactions in ER+ breast cancer cells and greater tumor growth inhibition in a xenograft breast cancer model compared with fulvestrant in combination with these agents. Here we describe the first sub-studies of the open-label, phase 1b/2 TACTIVE-U umbrella study, which evaluate the safety and clinical activity of ARV-471 plus abemaciclib (sub-study A; NCT05548127) and ribociclib (sub-study B; NCT05573555) in patients with ER+/HER2- advanced or metastatic breast cancer. Future combination sub-studies will be included in TACTIVE-U. **Methods:** Patients eligible for sub-studies A and B are aged ≥ 18 years, have histologically or cytologically confirmed ER+/HER2- advanced or metastatic breast cancer not amenable to surgical resection with ≥ 1 measurable lesion by RECIST 1.1, and have received ≤ 2 lines of prior therapy for advanced or metastatic disease and 1 line of any CDK4/6 inhibitor-based regimen in any setting. In sub-studies A and B, patients will receive ARV-471 orally once daily (QD) continuously in a dose escalation/de-escalation approach. In sub-study A, abemaciclib will be given orally twice daily continuously, and in sub-study B, ribociclib will be given orally QD for 21 days followed by 7 days off treatment. For both sub-studies, the primary endpoint of the phase 1b portion is dose-limiting toxicities to determine the recommended phase 2 dose of ARV-471 in combination with abemaciclib or ribociclib. Secondary endpoints of phase 1b are antitumor activity (overall response rate [ORR], clinical benefit rate [CBR], and duration of response [DOR]), progression free survival (PFS), safety (type, frequency, and severity of adverse events and laboratory abnormalities), and plasma concentrations of study drugs. Phase 2 further evaluates the antitumor activity of the combinations; the primary endpoint is ORR and secondary endpoints include antitumor activity (CBR and DOR), PFS, overall survival, safety, plasma concentration of study drugs, and changes in circulating tumor DNA. Clinical trial information: NCT05548127, NCT05573555. Research Sponsor: Arvinas Estrogen Receptor, Inc.

INAVO121: Phase III study of inavolisib (INAVO) + fulvestrant (FUL) vs. alpelisib (ALP) + FUL in patients (pts) with hormone receptor-positive, HER2-negative (HR+, HER2-) PIK3CA-mutated (mut) locally advanced or metastatic breast cancer (LA/mBC). *First Author: Dejan Juric, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: Standard-of-care (SoC) endocrine therapy (ET) for pts with HR+, HER2- LA/mBC was transformed by combinations with cyclin-dependent kinase 4/6 inhibitors (CDK4/6is); a CDK4/6i-based combination is approved in high-risk early BC. However, in most pts, mechanisms of resistance that emerge during or after treatment with a CDK4/6i and ET combination lead to relapse/disease progression. Dysregulating mutations in *PIK3CA*, occurring in ~40% of HR+, HER2- BCs, represent a common mechanism of resistance to CDK4/6is and ET combinations. ALP (a selective PI3K α inhibitor; PI3K α i) + FUL is approved for pts with HR+, HER2-, *PIK3CA*mut LA/mBC, but its widespread implementation in clinical practice has been challenging. As such, there is a significant need to develop PI3K α is with a better therapeutic index. INAVO is a highly potent and selective PI3K α i that also facilitates the degradation of mutated PI3K α isoform. INAVO has demonstrated manageable safety/tolerability, alone and in combination with SoC treatments in HR+, HER2-, *PIK3CA*mut LA/mBC. Moreover, an ongoing Phase I trial showed that INAVO + FUL elicited encouraging preliminary antitumor activity in heavily pretreated pts, including a CDK4/6i-based regimen. **Methods:** INAVO121 (NCT05646862) is a Phase III, randomized, open-label study evaluating INAVO + FUL vs. ALP + FUL in pts with HR+, HER2-, *PIK3CA*mut LA/mBC (confirmed by circulating-tumor DNA or tumor tissue), who progressed during or after a CDK4/6i-based regimen with adequate hematologic and organ function. Up to two prior lines of systemic therapy in LA/mBC, including one line of chemotherapy are allowed. Pts are randomized 1:1 to receive INAVO (9 mg oral daily; PO QD) + FUL (500 mg intramuscularly on Days [D] 1 and 15 of Cycle [C] 1, then D1 of subsequent cycles), or ALP (300 mg PO QD) + FUL. Randomization is stratified by visceral disease (yes vs. no) and prior CDK4/6i therapy (adjuvant vs. metastatic setting). Pts will receive treatment until disease progression or unacceptable toxicity. The primary endpoint is progression-free survival (PFS) by blinded independent central review (BICR). Secondary endpoints include overall survival, BICR-objective response rate, BICR-best overall response, BICR-duration of response, BICR-clinical benefit rate, safety, tolerability, pt-reported outcomes, and pharmacokinetics. The study is open for enrollment, targeting 400 pts at ~200 sites globally. A stratified log-rank test at an overall 0.05 significance level (two-sided) will be used for the primary endpoint analysis. Median PFS will be estimated using Kaplan–Meier methodology. An independent data monitoring committee will be in place for safety and efficacy. Clinical trial information: NCT05646862. Research Sponsor: F. Hoffmann–La Roche Ltd.

VERITAC-2: A global, randomized phase 3 study of ARV-471, a proteolysis targeting chimera (PROTAC) estrogen receptor (ER) degrader, vs fulvestrant in ER+/human epidermal growth factor receptor 2 (HER2)- advanced breast cancer. *First Author: Mario Campone, Institut de Cancérologie de l'Ouest Angers-Nantes, Angers, France*

Background: ARV-471 is an oral PROTAC ER degrader that binds to and degrades wild-type ER and clinically relevant mutants. ARV-471 directly recruits the ubiquitin-proteasome system to degrade ER, whereas selective ER degraders (SERDs) indirectly cause ER degradation. In a first-in-human phase 1/2 study, ARV-471 monotherapy was well tolerated and showed clinical activity in heavily pretreated patients with ER+/HER2- advanced breast cancer. The phase 3 monotherapy dose (200 mg once daily [QD]) was chosen due to comparable efficacy and favorable tolerability relative to 500 mg QD and robust ER degradation in paired tumor biopsies. The randomized phase 3 VERITAC-2 study (NCT05654623) will compare efficacy and safety of ARV-471 vs the SERD fulvestrant in patients with ER+/HER2- advanced breast cancer after prior combination cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitor therapy and endocrine therapy (ET). **Methods:** Eligible patients (aged ≥ 18 years) have a confirmed diagnosis of ER+/HER2- locoregional recurrent or metastatic breast cancer not amenable to surgical resection or radiation; 1 prior line of combination CDK4/6 inhibitor therapy and ET; ≤ 1 additional line of ET; most recent ET given for ≥ 6 months before disease progression; and radiological disease progression during or after the last line of therapy. Prior chemotherapy in the locally advanced or metastatic setting and prior fulvestrant are not permitted. Patients (N~560) are randomized 1:1 to receive 200 mg ARV-471 orally QD continuously or fulvestrant intramuscularly on days 1 and 15 in the first 28-day cycle and on day 1 in subsequent cycles; patients are stratified by *ESR1* mutation status and presence of visceral disease. The primary endpoint, progression-free survival, will be assessed by blinded independent central review in the intention-to-treat population and the *ESR1* mutation sub-population. Secondary outcome measures include overall survival, antitumor activity (objective response rate, duration of response, and clinical benefit rate), safety, and quality of life assessments. Clinical trial information: NCT05654623. Research Sponsor: Arvinas Estrogen Receptor, Inc.

CAPTOR-BC: Comprehensive analysis of spatial, temporal and molecular biomarkers predicting response and resistance to first-line treatment with ribociclib + ET in HR+, HER2- advanced breast cancer. *First Author: Peter A. Fasching, Erlangen University Hospital, Department of Gynecology and Obstetrics, Comprehensive Cancer Center Erlangen-EMN, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany*

Background: The combination of an oral CDK4/6 inhibitor with endocrine therapy (ET) has become the standard first-line therapy for women with advanced HR+/HER2- breast cancer. In this context, the broadest clinical trial data are available for ribociclib, a highly selective CDK4/6 inhibitor, with three phase III trials (MONALEESA-2, -3 and -7) consistently showing a significant overall survival benefit compared to ET monotherapy regardless of treatment line, menopausal status or combination partner. However, *de novo* or acquired resistance to CDK4/6 inhibitors does occur and biomarkers predicting treatment response or providing information on resistance mechanisms are only beginning to be understood. Comprehensive identification and validation of biomarkers before and during ribociclib therapy is needed to better understand mechanisms leading to disease progression, which will be the first step towards developing novel therapies and optimizing treatment sequences. **Methods:** CAPTOR-BC (NCT054552213) is a single-arm, open-label phase IV study evaluating the combination of ribociclib and ET according to SmPC in the first-line treatment of HR+ HER2- advanced breast cancer to identify and validate molecular and non-molecular biomarkers predictive of drug response and resistance. First patient first visit occurred in October 2022 and at least 1000 patients across more than 75 sites in Germany will be enrolled until October 2025. Progression-free survival (PFS) and overall survival (OS) at 12 months are the co-primary endpoints, quality of life (QoL) and toxicity are secondary endpoints. Exploratively, a comprehensive multi-omics biomarker discovery and validation program is integrated into the study. Besides tumor tissue, liquid biopsies profiling circulating tumor (ct)DNA, ctRNA, whole blood RNA, proteins from serum and plasma, and circulating immune cells will be evaluated before, during and after treatment or upon progression to determine correlations with PFS, OS, QoL and adverse events. Clinical trial information: NCT054552213. Research Sponsor: Institut fuer Frauengesundheit GmbH; Novartis.

Ribociclib (RIB) vs. palbociclib (PAL) in patients (pts) with hormone receptor-positive/HER2-negative/HER2-enriched (HR+/HER2-/HER2-E) advanced breast cancer (ABC): A head-to-head phase III study—HARMONIA SOLTI-2101/AFT-58. *First Author: Tomás Pascual, SOLTI Cancer Research Group, Barcelona, Spain. Medical Oncology Department, Hospital Clínic de Barcelona, Barcelona, Spain*

Background: RIB and PAL are CDK4/6 inhibitors with demonstrated efficacy in terms of progression-free survival (PFS) and similar tolerability in pts with HR+/HER2- ABC when combined with endocrine therapy (ET). Only RIB has demonstrated a consistent, statistically significant, and clinically meaningful overall survival (OS) benefit across the MONALEESA (ML) phase III trials, while PALOMA trials failed to achieve similar outcome. Given effective treatments (Tx) may change underlying tumor biology (TB), it is hypothesized that RIB changes TB, enabling a better response to subsequent therapy and thus improving OS. RNA-based intrinsic subtyping reflects differences in TB and has strong prognostic and predictive value in HR+/HER2- ABC. Non-Luminal subtypes, as HER2-E and basal-like (BL), are relatively endocrine-resistant and have poorer prognosis than luminal. Tumors can switch subtypes over time to a more aggressive and less endocrine-responsive biology, which may also be reversed by effective Tx. A retrospective analysis of pooled data from ML 2/3/7 trials showed that HER2-E tumors had surprising benefit from RIB, while BL tumors did not. Pre/clinical data and indirect comparisons suggest that RIB may outperform PAL in HER2-E. Thus, choosing pts with HER2-E tumors as a means of a well defined TB with relative endocrine resistance provides the right setup for HARMONIA study to explore likely differential re-sensitization to endocrine therapy with RIB vs. PAL and ultimately testing which CDK4/6i prepares best for continued response and OS benefit. In addition, HARMONIA explores the value of earlier Tx with chemotherapy (paclitaxel) + anti PD-1 (tislelizumab) in pts with BL tumors to leverage learnings from treating ET-insensitive triple-negative BC. **Methods:** This is an international, multicenter, randomized, open-label, phase III study, using prospective pre-selection based on TB in pts with HR+/HER2- ABC, with HER2-E tumors (main cohort) and with BL tumors (exploratory cohort). HER2-E cohort will randomized pts 1:1 to RIB+ET (letrozole or fulvestrant) or PAL+ET. As per recent protocol amendment, BL cohort pts will be treated with paclitaxel plus tislelizumab, an anti PD-1 monoclonal antibody, pts may be offered to try RIB + ET first, and will remain eligible for paclitaxel + tislelizumab upon progression. Primary endpoint (EP): PFS per RECIST v1.1. Secondary EP: OS, PFS2, clinical benefit rate, duration and time to response, quality of life, and exploratory EP, including subtype switching between primary and metastatic tumor, and after trial Tx. Interim and primary EP analysis will be performed after 224 and 310 PFS events are observed (~80% power using one-sided 5% α). HARMONIA will recruit in Spain (55 sites), Portugal (5), and US (35) within SOLTI & AFT network. Clinical trial information: NCT05207709. Research Sponsor: Novartis Pharma AG.

Poster Session

A phase 1b/2 dose escalation and expansion study of OP-1250 in combination with ribociclib or alpelisib in patients with advanced and/or metastatic estrogen receptor-positive (ER+)/HER2-negative (HER2-) breast cancer. *First Author: Virginia F. Borges, University of Colorado Cancer Center, Aurora, CO*

Background: Therapies targeting the estrogen receptor (ER) are standard of care in the management of ER+/HER2- metastatic breast cancer (MBC) and when administered concurrently with cyclin-dependent kinase (CDK) inhibitors are the most effective first-line therapy. CDK 4/6 inhibitors plus endocrine therapy improve progression-free survival and, for some agents, overall survival for patients with MBC. However, most patients will acquire resistance, highlighting an unmet need for more effective endocrine options in ER+ disease. OP-1250 is a small molecule oral complete estrogen receptor antagonist (CERAN) and selective estrogen receptor degrader (SERD) that binds the ligand binding domain of ER and completely blocks ER-driven transcriptional activity. OP-1250 potentially inactivates both wild-type and mutant forms of ER, the latter of which confers ligand independent activity as a mechanism of resistance to standard of care endocrine therapies. In preclinical studies, OP-1250 in combination with CDK4/6 inhibitors demonstrated synergistic activity in models of both wild-type ER and those with ESR1 (the gene that encodes ER) activating mutations, and in brain metastasis. OP-1250 is orally bioavailable with a favorable pharmacokinetic (PK) profile supportive of once-daily dosing, and a low probability of drug-drug interactions, making it an attractive agent for patients with ER+/HER2- MBC. **Methods:** The study (NCT05508906) is an open-label, multicenter, 2-part study of OP-1250 in combination with either the CDK4/6 inhibitor ribociclib or the PI3K inhibitor alpelisib for patients with MBC. Eligibility includes adults with evaluable (measurable or non-measurable) ER+/HER2- recurrent, locally advanced or MBC confirmed by histology/cytology, ≤ 2 prior hormonal regimens (prior CDK4/6 inhibitors allowed) and ≤ 1 prior line of chemotherapy. Patients in the alpelisib arm must have a PIK3CA mutation. A total of 30 patients will be enrolled in each arm. The dose escalation cohorts will evaluate the safety and PK of varied OP-1250 doses (30mg, 60mg, or 120mg) administered orally (PO) every day (QD) in combination with approved dosages of either ribociclib 600 mg PO QD or alpelisib 300 mg PO QD to identify the recommended phase 2 doses (RP2D). The dose expansion cohorts will assess additional safety and PK parameters and further explore the anti-tumor activity of OP-1250 in combination with ribociclib or alpelisib. Tolerability, safety and PK of OP-1250 in combination with ribociclib or alpelisib constitute the primary endpoints. Overall response rate, clinical benefit rate and duration of response are key secondary endpoints. Enrollment at approximately 20 sites in the United States and Australia is ongoing. Clinical trial information: NCT05508906. Research Sponsor: Olema Oncology; Novartis.

Harnessing olaparib, palbociclib, and endocrine therapy: A phase I/II trial of olaparib, palbociclib and fulvestrant in patients with BRCA mutation-associated, hormone receptor-positive, human epidermal growth factor receptor 2 (HER2)-negative metastatic breast cancer (HOPE). *First Author: Alexandra Torres, University of Pennsylvania-Abramson Cancer Center, Philadelphia, PA*

Background: Hormone receptor-positive (HR+) metastatic breast cancer (MBC) in patients (pts) with germline or somatic *BRCA1* or *BRCA2* (g/s*BRCA1/2*) mutations has dual drivers: hormone receptor signaling and homologous recombination deficiency. The PALOMA-3 trial showed superiority of fulvestrant (F) with palbociclib (P) compared to F alone. The OlympiAD trial showed the poly-ADP ribose polymerase inhibitor (PARPi) olaparib (O) to be superior to chemotherapy in *BRCA1/2*-associated MBC. However, treatment resistance inevitably develops; targeting dual therapeutic drivers concurrently may delay or circumvent resistance. O and P have overlapping hematologic toxicity and the safety of combined O, P and F is unknown. The tolerability of O + P is particularly relevant given the emergence of potentially less myelosuppressive PARPi. **Methods:** HOPE (NCT03685331) is a phase I/II trial to evaluate safety and efficacy of O, P and F in pts with g/s*BRCA1/2*-associated, HR+ MBC. Eligible pts have an ECOG performance status 0-1, measurable/evaluable breast cancer, any/no prior endocrine therapy, and 0-2 lines of chemotherapy prior to MBC diagnosis, or for MBC if no progression during therapy. Prior PARPi and CDK4/6i are permitted on phase I, and are permitted during phase II if there was no progression on them. Treatment (28-day cycles) consists of: O orally twice daily continuously; F 500mg intramuscularly on day 1 of each cycle plus load; and P orally once daily on days 1-21. Phase I begins with a 28-day safety run-in of O and F alone. O and P doses are based on dose level (DL): DL 0 (starting level), O 300mg, P 75mg; DL 1, O 300mg, P 100mg; DL 2, O 300mg, P 125mg; DL-1, O 250mg, P 75mg and DL-2, O 200mg, P 75mg. For phase II, O and P will be dosed at MTD. Pts have tissue collection at baseline and peripheral blood cfDNA analysis at baseline, at progression, and at all scan timepoints (every 3 cycles). Phase I primary endpoint is MTD. A 3+3 dose escalation design is used with a 30% rate of dose limiting toxicity (DLT) deemed acceptable, and 6 patients treated at a dose for it to be declared MTD. A minimum of 2 and a maximum of 18 patients will be enrolled on the phase I. Phase II primary endpoint is PFS using Kaplan-Meier methods and secondary efficacy endpoints are objective response rate and 24-week clinical benefit rate. Phase II will evaluate 54 subjects to provide 80% power to detect an increase in PFS from 7 months with O monotherapy to 10 months. Exploratory objectives include examination of baseline tissue for PARPi predictive biomarkers and measures of tumor immunogenicity as well as serial serum evaluation for reversion mutations. Enrollment is ongoing. Clinical trial information: NCT03685331. Research Sponsor: AstraZeneca, Pfizer; Susan G. Komen Career Catalyst Award.

The Amelia-1 study: A phase 1b/2 trial of evexomostat (SDX-7320) plus fulvestrant and alpelisib in patients with advanced breast cancer at risk for alpelisib-induced hyperglycemia. *First Author: Peter Cornelius, Syndevrx Inc., Cambridge, MA*

Background: Alpelisib, a selective PI3K p110 α inhibitor, was approved for breast cancer patients with PIK3CA mutations. An on-target toxicity of alpelisib is hyperglycemia and patients with baseline insulin resistance/elevated HbA1c are at greater risk of developing grade 3/4 hyperglycemia after receiving alpelisib. Restoring insulin sensitivity and reducing systemic insulin levels improved the efficacy of alpelisib in animal models of breast cancer. Evexomostat is a polymer-drug conjugate of a novel small molecule methionine aminopeptidase 2 (MetAP2) inhibitor. In normal mice, it reduced alpelisib-induced hyperglycemia/hyperinsulinemia and in an animal model of breast cancer synergized with alpelisib to regress tumor growth. In a Phase 1 trial, evexomostat improved insulin resistance in patients with elevated baseline insulin, reduced angiogenic factors in patients with elevated baseline levels, increased the insulin-sensitizing adipokine adiponectin and showed anti-metastatic effects in patients with advanced solid tumors. **Methods:** This is a phase 1b/2, open-label, single-arm pilot study (NCT05455619) in postmenopausal women with HR+, HER2- metastatic breast cancer with a PIK3CA mutation who progressed following treatment with endocrine therapy plus a CDK4/6 inhibitor and who are at risk for hyperglycemia (HbA1c between 5.5 and 6.4% inclusive). The primary goal is to determine the safety of evexomostat plus alpelisib and fulvestrant (the "triplet therapy"), including the severity and number of hyperglycemic events, as well as anti-tumor benefit. The starting dose of evexomostat in the triplet therapy is 36 mg/m² (n=6; one dose below the monotherapy MTD of 49 mg/m²). Once the MTD of evexomostat in the triplet therapy has been defined, up to 20 patients will be enrolled at that dose. An additional 20 patients may be enrolled to further characterize the safety and anti-tumor effect of the triplet therapy (up to 52 patients). This trial is open to accrual at multiple sites in the USA. Safety analysis includes the type, frequency, and severity of treatment-emergent adverse events (TEAEs) per NCI CTCAE, v5, and the number and proportion of patients with grade 3 or 4 hyperglycemia during the first 2 cycles of therapy, with an estimate of the exact upper one-sided 97.5% confidence bound. Efficacy analyses include objective response rate (ORR, consisting of complete response (CR) and partial response (PR)). The number of patients without disease progression six months from the start of the triplet therapy will be assessed. The CBR of CRs, PRs plus stable disease $\geq$ 24 weeks from C1D1 will be calculated. Overall survival data will be summarized as available. QoL will be analyzed according to functional scores and recommendations in the EORTC scoring manual. ECOG performance status and change from baseline will be summarized. Clinical trial information: NCT05455619. Research Sponsor: SynDevRx, Inc.

The ARETHA study: A phase 2 randomized control trial of eribulin with evexomostat (SDX-7320) or placebo for patients with metastatic triple-negative breast cancer (TNBC) and metabolic dysfunction. *First Author: Sherry Shen, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The prognosis for advanced/metastatic TNBC remains poor and novel therapeutic strategies are urgently needed. Insulin resistance and obesity contribute to TNBC progression and are independent predictors of worse survival. Methionine aminopeptidase 2 (MetAP2/p67) is overexpressed in many tumor types including breast. MetAP2 inhibitors exhibit broad anti-tumor activity and attenuate the effects of metabolic dysfunction on tumor growth. Evexomostat (SDX-7320) is a second-generation MetAP2 inhibitor that improved insulin sensitivity, reduced fat mass, and normalized adipokine levels in preclinical models of obesity and reduced tumor growth in TNBC preclinical models. In phase 1 trials, evexomostat monotherapy partially restored insulin sensitivity, reduced adipokines, and showed anti-metastatic effects in patients with advanced solid tumors. The goal of this phase 2 study is to test whether evexomostat prevents worsening of insulin resistance and augments tumor response in patients with metastatic TNBC and metabolic dysfunction in combination with eribulin chemotherapy, a standard of care treatment option after prior anthracycline and taxane exposure. **Methods:** This is a single-center phase 2 randomized control trial of evexomostat, a MetAP2 inhibitor, and eribulin chemotherapy. Key eligibility criteria include metastatic TNBC, measurable disease or $\geq$ 1 predominantly lytic bone lesion, baseline hemoglobin A1c $>$ 5.5% and/or BMI $\geq$ 30 kg/m², and $\leq$ 2 prior lines of therapy in the advanced/metastatic setting. Patients with uncontrolled or insulin-dependent type II diabetes, or who require combination anti-hyperglycemic therapy are excluded. During the safety run-in period, 15 patients will be assigned to receive evexomostat 49 mg/m² Q2 weeks and eribulin 1.4 mg/m² on days 1 & 8 of a 21-day cycle. Upon safety confirmation, an additional 40 patients will be randomized 2:1 to receive evexomostat or placebo with eribulin. The primary endpoint is metabolic efficacy assessed by change in Homeostatic Model Assessment for Insulin Resistance (HOMA-IR) score. Secondary endpoints include objective response rate, progression-free survival, safety and tolerability, patient-reported outcomes, and changes in metabolic markers and body composition. Historically, HOMA-IR scores double during chemotherapy, and this trial will test whether evexomostat attenuates the expected HOMA-IR rise. This trial will have $>$ 90% power to detect a difference between a 1.5-fold change in HOMA-IR in the control arm vs. no change in the evexomostat arm while controlling the Type I error at 5%. As of Feb 2022, 3 patients are enrolled; total accrual of 61 patients is planned with a goal of 55 evaluable patients. Clinical trial information: NCT05570253. Research Sponsor: SynDevRx, Inc.

Poster Session

A phase 2 randomized study of magrolimab combination therapy in adult patients with unresectable locally advanced or metastatic triple-negative breast cancer (mTNBC): ELEVATE-TNBC. *First Author: Natalie Rainey, Cairns and Hinterland Hospital and Health Service, Cairns, QLD, Australia*

Background: Improving outcomes in patients (pts) with TNBC remains a high unmet need. Immune checkpoint inhibitors (ICIs) + chemotherapy (chemo) is approved for newly diagnosed pts with PD-L1+ tumors. Further, single-agent sacituzumab govitecan (SG), a Trop-2-directed antibody-drug conjugate, is approved for pts with mTNBC who received $\geq$ 2 prior systemic therapies ($\geq$ 1 for metastatic disease). However, more options are needed for pts with PD-L1-negative mTNBC and for those with disease progression on chemo $\pm$ ICI. Magrolimab is a monoclonal antibody that blocks CD47, a "don't eat me" signal often overexpressed on TNBC cells. Magrolimab blockade of CD47 induces macrophage-mediated phagocytosis of tumor cells and has shown preclinical activity and promising clinical efficacy in hematologic malignancies. Certain chemos, including taxanes, enhance phagocytic signals on tumor cells, which may lead to synergistic antitumor activity with magrolimab. This study is evaluating the safety, tolerability, and efficacy of magrolimab + nab-paclitaxel/paclitaxel or + SG in mTNBC. **Methods:** This open-label study has 2 cohorts (C) with safety run-in and phase (ph) 2 portions. Eligible pts are $\geq$ 18 y with measurable disease per RECIST 1.1. C1 pts have PD-L1-negative untreated mTNBC. C2 pts have mTNBC and received 1 prior line of therapy in the advanced setting, a taxane in the neoadjuvant/adjuvant or metastatic setting, and, if PD-L1+, an ICI. Exclusion criteria include active central nervous system disease, RBC transfusion dependence, and prior treatment with CD47/SIRP α -targeting agents. C1 assesses nab-paclitaxel/paclitaxel + magrolimab (safety run-in) or $\pm$ magrolimab (ph 2; randomized 1:1). C2 assesses magrolimab + SG (safety run-in and ph 2). In C1 safety run-in, magrolimab is given intravenously (IV) as a 1-mg/kg priming dose on day (D) 1 of cycle 1 to mitigate on-target anemia, followed by 30 mg/kg (cycle 1: D8, 15, 22; cycle 2: D1, 8, 15, 22; cycle 3+: D1, 15) (28-d cycles). In C2 safety run-in, pts receive a 1-mg/kg priming dose on D1, followed by 30 mg/kg (cycle 1: D8, 15; cycle 2: D1, 8, 15) and 60 mg/kg (cycle 3+: D1) (21-d cycles). The recommended ph 2 dose (RP2D) is determined in the safety run-in, with de-escalation if prespecified dose-limiting toxicity (DLT) criteria are met. Once RP2D is determined, the ph 2 cohorts will follow their respective dose schedules. Nab-paclitaxel/paclitaxel and SG are given IV per standard of care. The primary endpoints are incidence of DLTs, adverse events, and abnormal lab results by CTCAE v5.0 (safety run-in); progression-free survival by RECIST 1.1 (ph 2 C1); and confirmed objective response rate by RECIST 1.1 (C2; pooled safety run-in and ph 2). Planned enrollment is $\approx$ 144 pts. Clinical trial information: NCT04958785. Research Sponsor: Gilead Sciences, Inc.

A randomized phase II clinical trial of talazoparib maintenance therapy in patients with triple-negative breast cancer who showed platinum-sensitivity on first- or second-line platinum-based chemotherapy: KCSG BR21-10. *First Author: Joohyuk Sohn, Division of Medical Oncology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, South Korea*

Background: A potent PARP inhibitor, talazoparib, demonstrated superior clinical activity compared to standard chemotherapy in germline BRCA1/2-mutant advanced breast cancer patients. However, the role of talazoparib treatment in BRCA1/2 wild-type triple-negative breast cancer (TNBC) patients remains undefined, although high incidence of homologous recombination deficiency (HRD) is one of the major characteristics of the TNBC. Previous studies indicated clinical responsiveness to platinum agents is a useful surrogate for HRD that may predict favorable PARP inhibitor response. Here, we present a phase II study to test talazoparib maintenance therapy in germline BRCA1/2 mutation unselected advanced TNBC patients after platinum-based chemotherapy. **Methods:** The KCSG BR21-10 study (NCT04755868) is a randomized double-blind placebo-controlled phase II clinical trial of talazoparib maintenance therapy in metastatic TNBC patients whose tumor showed platinum-sensitivity to first- or second-line platinum-based chemotherapy. The criteria for platinum-sensitivity were set as follows: remaining complete response (CR), partial response (PR), or stable disease (SD) after 6 to 9 tri-weekly doses or 18 to 27 weekly doses of platinum-based chemotherapy. The eligible TNBC patients are enrolled to the trial after completion of platinum-based therapy and 1:1 randomized to receive talazoparib (once daily 1.0 mg) or placebo maintenance therapy. The patient with any germline BRCA1/2 mutation status is eligible, and randomization stratification factors include line of platinum-based chemotherapy, response to platinum-based chemotherapy, and germline BRCA1/2 mutation status. The talazoparib/placebo maintenance treatment is initiated within 8 weeks after the last platinum chemotherapy. At the time of progression of disease, unblinding can be performed and patients in placebo arm may be eligible for crossover to talazoparib single treatment. The primary endpoint is progression-free survival (PFS) after randomization by RECIST 1.1, and the key secondary endpoints are overall survival, PFS2, objective response rate, adverse events by CTCAE 5.0 criteria, and quality of life. We also planned exploratory study to find predictive biomarker by tumor tissue and blood analysis. The median PFS from the randomization is expected to be 3 months in the placebo maintenance arm and we expect that talazoparib maintenance will improve PFS with hazard ratio of 0.65. It is predicted that a total of 206 patients (103 patients in each arm) are required with the α of 0.05 and power of 0.8 (1- β) by two-sided test, considering monthly 3% dropout rate. Currently, 23 of planned 206 patients have been enrolled. Clinical trial information: NCT04755868. Research Sponsor: Pfizer.

Phase I/II study of stereotactic radiosurgery with concurrent olaparib followed by adjuvant durvalumab and physician's choice systemic therapy in patients with breast cancer brain metastases. *First Author: Colette Shen, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Despite progress in the treatment of brain metastasis for HER2+ breast cancer, outcomes for patients with HER2-negative breast cancer brain metastases remain poor. Current standard of care consists of local therapies, including surgery and radiotherapy, followed by systemic therapy. Preclinical studies show inhibitors of poly(ADP-ribose) polymerase (PARP) are effective in combination with radiation therapy as a DNA damage response inhibitor. Triple-negative breast cancer (TNBC) has higher rates of homologous recombination deficiency compared to other breast cancer subtypes, and together with HER2-negative, BRCA-mutated breast cancer would be particularly sensitive to PARP inhibition. PARP inhibition has also demonstrated promising efficacy combined with immunotherapy in patients with germline BRCA-mutant and metastatic TNBC in clinical trials (MEDIOLA, TOPACIO). In addition, immunotherapy with stereotactic radiosurgery (SRS) is associated with favorable intracranial control and survival in patients with brain metastases. We hypothesize that this biologically-driven combination will enhance local control of SRS-treated brain metastases through synergy with PARP inhibition, while controlling micro-metastatic disease in the brain and extracranial sites via potentiation of the immune response. **Methods:** We are conducting a multi-institution, Phase I/II trial of SRS plus olaparib, followed by durvalumab (with physician's choice systemic therapy), for patients with TNBC (any BRCA status) or HER2-negative with BRCA-mutated (germline or somatic) breast cancer brain metastases [NCT04711824]. A total of 41 patients are planned for enrollment at 8 sites. The primary objectives are to evaluate safety and tolerability (Phase I) and determine intracranial disease control at 6 months (Phase II) of this treatment combination. Secondary objectives include determining clinical activity via intracranial and global progression-free survival, overall survival, and intracranial and extracranial response rate. Exploratory objectives will assess potential biomarkers of treatment response, including changes in circulating tumor cells and DNA in blood and cerebrospinal fluid, germline and tumor mutations in DNA repair pathway genes, and PD-L1 expression, as well as quality of life and patient-reported outcomes. A surgical sub-study (n=5) will evaluate olaparib concentration/distribution in resected brain metastases. As of January 2023, cohort 1 of phase I has been completed without dose-limiting toxicity. Clinical trial information: NCT04711824. Research Sponsor: AstraZeneca.

Poster Session

Phase II study of a PARP inhibitor in somatic *BRCA1/2* mutant metastatic breast cancer (MBC). *First Author: Neelima Vidula, Harvard Medical School, Massachusetts General Hospital, Boston, MA*

Background: While PARP inhibitors are approved for germline *BRCA1/2* mutant MBC, and are shown to improve both patient quality of life and progression-free survival (PFS), as a well-tolerated oral targeted therapy, their utility is limited as germline *BRCA1/2* mutations are present in 5-10% of breast cancer. We hypothesize that somatic *BRCA1/2* mutations may also respond to PARP inhibitors. We have demonstrated that somatic *BRCA1/2* mutations can be identified by cell-free DNA and tumor tissue genotyping assays in patients who are not known germline *BRCA1/2* carriers, and some of these are pathogenic. Using a circulating tumor cell culture model developed from a patient with a pathogenic somatic *BRCA1* mutation, we have shown that a PARP inhibitor can induce cell growth inhibition paralleling germline *BRCA1/2* mutant lines. In this trial, we are evaluating the efficacy of a PARP inhibitor in somatic *BRCA1/2* mutant MBC. Our work may help expand the number of patients with MBC who benefit from a PARP inhibitor. **Methods:** In this phase II investigator-initiated clinical trial, 30 patients with MBC harboring somatic *BRCA1/2* mutations identified via a CLIA certified cell-free DNA or tumor tissue genotyping assay are being enrolled at 7 academic centers. Mutations are evaluated for pathogenicity using validated genomic databases such as ClinVar by genetic counselors prior to enrollment. Patients may have metastatic triple-negative or hormone receptor positive (HR+)/HER2- breast cancer progressing on 1 prior therapy, and should not be known germline *BRCA1/2* carriers. Any number of prior therapies are allowed but patients must have adequate baseline performance status and organ function. Patients are treated with talazoparib 1 mg/day (a PARP inhibitor with high potency) until disease progression. Imaging (CT chest abdomen and pelvis as well as bone scan) occurs at baseline and every 3 months for disease assessment. The primary endpoint is progression-free survival (RECIST 1.1). This study has 81% power to demonstrate that talazoparib is associated with "success" (PFS > 12 weeks) in ≥53% patients (4% alpha). Key secondary endpoints include objective response rate and toxicity (NCI CTCAE v 5.0). Correlative studies include collecting cell-free DNA at baseline and monthly to identify the emergence of resistance mutations and impact of *BRCA1/2* reversion mutations and mutant allele fraction on response, and evaluating the Cancer Risk B (CR-B) assay, a novel method that identifies double-strand break repair mutations in circulating blood cells. The study (NCT03990896) is open at Massachusetts General Hospital, MD Anderson, Emory, University of California San Francisco, and Northwestern, and pending activation at Vanderbilt and Cornell, with 11 patients enrolled as of 2/2023. Clinical trial information: NCT03990896. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology; Pfizer ASPIRE Award.

Oral Abstract Session

AI blood signature in common blood tests for detection of gastric cancer in a cohort of 190,000 individuals. *First Author: Tsz Chun Bryan Wong, The Hong Kong University of Science and Technology, Hong Kong SAR, Hong Kong*

Background: Gastric cancer is the fourth leading cause of cancer death worldwide. Lack of symptoms in the early stage of disease leads to delayed presentation and low overall survival rate. Early detection is key, but there is not yet an established test for non-invasive gastric cancer screening. Routine blood test panels, including complete blood count, liver function, renal function and clotting profiles, could be potentially useful in reflecting bodily processes related to cancer. Current literature and territory-wide statistical data analyses from Hong Kong have shown these subtle changes and differences in measured levels of subcomponents between individuals with and without gastric cancer, that are not recognized clinically, form recognizable patterns distinct to gastric cancer. In this study, we hypothesized that gastric cancer signatures could be identified in routine blood data. Deep learning AI algorithms are used to identify the gastric cancer signature. Results from testing and validation of the identified routine blood signature using a Big Clinical Data cohort are reported. **Methods:** This is a territory-wide healthcare database study using data from Hong Kong Hospital Authority data collaboration laboratory. All patients prescribed with medications for dyspepsia and with all blood tests components (CBC, LFT, RFT, clotting function) available in the period between 2004-2015 inclusive were included. In the period, data from 2004 to 09 and 2011 to 14 were used as training cohort and the rest were used as testing cohort. A blood gastric cancer signature was generated using deep learning AI algorithms, and applied to predict gastric cancer in BigData population. **Results:** 193,117 patients were included in the captioned period, in whom 4,790 patients were diagnosed to have gastric cancer. 151,449 (3,815 pts with gastric cancer and 147,634 pts disease free) patients were included in training cohort. In the testing cohort in 2010 and 2015 (975 pts with gastric cancer and 40,693 pts disease-free), the tumor signature yielded a sensitivity of 0.79, specificity of 0.99, positive predictive value of 0.95 and a negative predictive value of 0.99. **Conclusions:** The hypothesis of the presence of a distinctive gastric cancer signature from parameters in routine blood test data is tested and validated in a large population cohort with dyspepsia. The signature has high accuracy and high sensitivity with low false positive and false negative rates. Multicenter prospective testing is being conducted in cohort indicated for OGD in Hong Kong. Research Sponsor: None.

Oral Abstract Session

Childhood leukemia survival in the US-Mexico border: Building sustainable leukemia care using health systems strengthening models. *First Author: Paula Aristizabal, University of California San Diego, San Diego, CA*

Background: Pediatric leukemia outcomes are poor in most low-and middle-income countries (LMIC) and exacerbated by healthcare systems ill-equipped to manage cancer. Effective leukemia management in LMIC involves curating epidemiologic data; providing healthcare workforce specialty training; developing evidence-based treatments and supportive care; safeguarding access to medications and equipment; providing patient and family psychosocial and financial support; partnering with non-governmental organizations, and ensuring treatment adherence. **Methods:** We describe the implementation of a collaborative program to achieve sustainable high-quality care for children with leukemia in a unique border health setting. In 2013, in a partnership between North-American and Mexican institutions, we used the health systems strengthening model developed by the World Health Organization (WHO) *Framework for Action* with domains in Services delivery, Workforce, Information systems, Access to essential medicines, Financing, and Leadership and Governance to implement a sustainable program aimed at improving acute lymphoblastic leukemia (ALL) outcomes at a public, referral hospital in the US-Mexico border region. We evaluated program sustainability indicators, and prospectively assessed clinical features, risk classification, and survival outcomes in children with ALL at Hospital General in Tijuana, Mexico from 2008-2012 (pre-implementation) and from 2013-2017 (post-implementation). **Results:** Our approach led to a fully-staffed leukemia service, sustainable training programs, evidence-based, data-driven projects to improve clinical outcomes, and funding for medications, supplies and personnel through local partnerships. Pre-implementation and post-implementation 5-year overall survival for children with standard-risk and high-risk ALL improved from 52% to 82% ($P = 0.023$) and from 46% to 76% ($P = 0.031$), respectively. All sustainability indicators significantly improved between 2013 and 2017. **Conclusions:** By using a health systems strengthening approach, we improved leukemia care and survival in a public Mexican hospital in the US-Mexico border region. The demonstrated increase in overall survival across a decade after the implementation of our program validates the use of the health systems strengthening models, as they are not only efficacious in improving clinical outcomes, but also serve as financially and organizationally means of building sustainable capacity. Our model serves as an example for future international partnerships aimed at sustainably improving cancer outcomes in LMIC. Future research should evaluate best practices in establishing global health collaborations with particular attention paid towards the individual circumstances that impact healthcare delivery locally in each unique community. Oral Abstract Session

Large-scale observational prospective cohort study of a multi-cancer early detection (MCED) test in symptomatic patients referred for cancer investigation. *First Author: Brian D Nicholson, University of Oxford, Oxford, United Kingdom*

Background: Delays in cancer diagnosis can lead to increased mortality, leading to specialized diagnostic pathways for symptomatic patients when cancer is suspected. Identification of circulating tumour DNA can stratify individuals into those more or less likely to have cancer and predict the cancer origin. This could both expedite cancer diagnosis and reduce harm and inefficient investigation in those who do not have cancer. We evaluated the performance of a next-generation sequencing MCED test (GRAIL, LLC) using cell-free DNA (cfDNA) isolated from whole blood in symptomatic patients referred to cancer diagnostic clinics by their primary care physician. **Methods:** Patients referred for urgent imaging, endoscopy or other diagnostic modalities to investigate symptoms suspicious for cancer were invited to take part. Participants with non-specific symptoms or being tested for lung, gynaecological, upper gastrointestinal (GI) or lower GI cancers gave a blood sample on the day they attended for urgent standard of care investigations. cfDNA was isolated from blood samples and stored until the MCED test was performed in batches, blinded to clinical outcome. The test's predictions (cancer signal detected yes/no; predicted signal origin) were compared with the diagnosis obtained by standard care to establish the positive and negative predictive value (PPV & NPV), sensitivity and specificity across the whole study population, by referral pathway, and by presenting symptom. In addition, sensitivity was analysed by cancer site and stage. **Results:** 6238 participants were recruited over 5 months from the 5 clinical pathways at 44 hospital sites in England and Wales. 5461 individuals had an MCED test result and diagnostic outcome and were evaluable. Mean age was 62.1 years (SD, 13.8), 3609 (66.1%) female, 2533 (46.4%) current or former smokers. 368 (6.7%) evaluable patients had a cancer diagnosed. The MCED test detected a cancer signal in 323 cases, 244 in whom cancer was diagnosed and 79 where it was not, yielding a PPV of 75.5% (95% CI 70.5-80.1%), NPV 97.6% (97.1-98.0%), sensitivity 66.3% (61.2-71.1%), and specificity 98.4% (98.1-98.8%). Sensitivity increased with increasing age and cancer stage, from 24.2% (16.0-34.1%) in Stage I to 95.3% (88.5-98.7%) in Stage IV. Sensitivity 80.4% (66.1-90.6%) and NPV 99.1% (98.2-99.6%) were highest for patients referred with symptoms qualifying for the upper GI pathway. **Conclusions:** This is the first large-scale prospective evaluation of an MCED test in a symptomatic population. These data provide the basis for a prospective, interventional study in patients presenting to primary care with non-specific signs and symptoms with low, but higher than background, probability of being due to cancer. Study data are also being used to enhance the negative predictive value of the current MCED classifier for a symptomatic population. Clinical trial information: ISRCTN10226380. Research Sponsor: GRAIL; UK NIHR.

Oral Abstract Session

Analysis of patient-physician portal secure message content and the associated cost savings in oncology practice. *First Author: Brandon Anderson, San Francisco Medical Center, Kaiser Permanente Northern California, San Francisco, CA*

Background: The consistent utilization of secure messaging ("SM") since the onset of the COVID-19 pandemic has provided cancer patients with unprecedented access to their medical providers, resulting in reduced out-of-pocket costs for patients at the expense of increased workload for oncologists. Herein we analyze oncology SM content and report estimated cost savings from reduced traditional clinic visits. **Methods:** This population-based retrospective cohort study examined the content of patient-initiated SM threads exchanged through the patient portal website or app over a one-year period (6/1/21 to 5/31/22) at 22 Kaiser Permanente Northern California Oncology practices. A trained physician researcher reviewed a random sample of 500 SM threads and categorized them by message content type, acuity, and appropriate level of service. Standard costs were applied using the average of 2021 and 2022 Center for Medicare Services physician fee schedule and US patient average specialty copayment. **Results:** During the study period, 49,230 patients initiated 398,835 unique SM threads to 238 oncology providers. The average number of replies to patients' initial messages was 2.6, with a mode of 1 (maximum 36). Of the SM threads reviewed, only 28.0% required oncologist expertise. Based on thread content, the remaining 72.0% may have been better managed by a nurse (35.4%), medical assistant (29.2%), primary care doctor (6.2%), or a different subspecialty provider (1.2%). Emergency care was required in 2.8% of the total threads reviewed. Significant medical care was provided to patients in 26.0% of the total SM threads which would traditionally require a billable visit (i.e., in-person, telephone, or video). We estimate that these clinical actions may represent 4,299,281.77 of savings in medical care (based on traditional 10-19-minute visits), and 4,562,672.40 in potentially avoided out-of-pocket co-pay costs for patients. **Conclusions:** Increased utilization of remote medical care and specifically SM has recently generated additional workload for oncologists that may have been more appropriately managed by alternative providers. The magnitude of unreimbursed medical care provided via SM and the use of SM by cancer patients for emergent medical situations creates an urgent need for new models to assist with practice management. An alternative architecture for triaging, managing, and billing SM that utilizes artificial intelligence, machine learning algorithms, or medical assistants, nurses, and other providers could help manage the burden experienced by oncologists. Oral Abstract Session

Prior authorizations for oral anticancer drugs and delayed prescription fills. *First Author: Michael Anne Kyle, Harvard Medical School (Boston, MA), Boston, MA*

Background: Oral anticancer drugs have proliferated in recent decades. These drugs are increasingly approved based on provisional data via the FDA's accelerated approval pathway and have high prices, motivating payers to closely monitor how they are used. We assessed use of prior authorization (PA) of oral cancer drugs for Medicare Part D beneficiaries and assessed the impact of PA on delays in prescription fills. **Methods:** Using Medicare Part D formulary and claims data from 2010-2019, we described trends in Part D plans' use of PA for oral oncology drugs, identified using the Oncology Care Model drug list (excluding hormonal therapies). We then examined changes in access to imatinib after the introduction of a new PA. We focused on imatinib because it is a highly effective first-in-class drug with a generic entrant in 2016. We compared Part D beneficiaries continuously enrolled in a plan with a policy change (new PA introduced) or a control plan (no change) in the 120 days before and after the policy change or equivalent date (control) and had at least three 30-day imatinib fills in the pre period. This restriction aimed to identify individuals filling regularly and plausibly expected to continue the drug. For each index fill in the post period, we calculated predicted fill (date of previous fill + days supply received). Our outcome variable was the difference (in days) between predicted and observed index fill date, censored at 120 days for post-period observations without an observed fill. We used an event study to model predicted vs. actual time to first fill following a policy change (new PA) relative to the controls (no change), adjusting for patient age, sex, low-income subsidy, average number of days between pre-period fills, year of fill, and plan type (standalone or Medicare Advantage). **Results:** The proportion of oral anticancer drugs requiring a PA increased from 52.8 to 96.3% from 2010 to 2019. For imatinib, PA increased from 65% to 89% from 2010-16, the year generic imatinib entered. PA for generic imatinib was 95% on market entry. In the imatinib event study sample, there were 1,354 index fills for patients. Unadjusted mean delay in index fill was 40 days for new PA and 15 days for controls; median difference was 4 and 3 days, respectively. Discontinuation was comparable: 9.3% (new PA) vs. 9.5% (control). The adjusted difference between predicted and actual fills for new PA was 20.3 days (95% CI 6.5-34.2, $p < 0.004$). **Conclusions:** Use of PA for oral oncology drugs has increased substantially over 10 years. In the setting of high prices and provisional outcomes data, PA may be appropriate. However, PA may delay fills, even for high-value drugs like imatinib. Oral anticancer drug adherence is an NCI priority; further study is warranted to identify opportunities to reduce administrative burden of PA and lessen barriers in access to effective medications. Oral Abstract Session

Observational prospective study of physical activity in patients with cancer to define an objective performance status (OPS). *First Author: Eva Ruiz-Hispán, University Hospital Fundacion Jimenez Diaz, Madrid, Spain*

Background: Clinical trials in patients with advanced cancer rely on a good selection of candidates based on their functional status. The Eastern Cooperative Oncology Group (ECOG) Performance Status is the most frequently used in adult patients and is based on the subjective impression of the clinician during the interview with the patient. The current use of wearable devices will allow clinicians to assess the functional status of candidates for a clinical trial in a more objective way. We aim to define an "Objective Performance Status" (OPS) by measuring the daily physical activity of patients with metastatic cancer and correlating it with the classical prognostic variables. **Methods:** We prospectively measured daily physical activity with a wearable device in 111 patients with metastatic cancer during the screening period for a phase 1 clinical trial to avoid treatment interference with the functional status. Daily steps/distance and sleeping hours were measured and correlated with overall survival (OS) to define the OPS. **Results:** Full data was available for 70 patients. Median survival was gradually shorter as physical activity decreases (HR 5.76 (95% CI 2.98-11.1) $P < 0.001$). The cut off selected to define the OPS was determined by univariate survival analysis and showed that patients who walk less than 1200 meters per day have 5 times the risk of mortality (poor OPS). Median OS was 3.2 months (95% CI 2.5-5.8) $P < 0.001$ for patients with poor OPS and 11.2 months for patients with good OPS (95% CI 7.2-31.3 $P < 0.001$). **Conclusions:** The objective assessment of performance status (OPS) using a wearable device to monitor the physical activity in patients with cancer is an independent prognostic factor for survival and is an objective predictor of mortality. Oral Abstract Session

SCORE: A multisite randomised controlled trial evaluating shared care for colorectal cancer survivors. *First Author: Michael Jefford, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*

Background: Few studies have considered shared follow up (FU) care (SC) between oncologists and primary care providers (PCPs). SCORE is the first large RCT of SC for survivors of colorectal cancer (CRC). Primary objective: compare SC vs UC on the EORTC QLQ-C30 Global Health Status/Quality of Life (GHQ-QoL) scale to 12 months (mo). Secondary objectives: compare SC vs UC on QoL; patient (pt) perceptions of care; costs and clinical care processes (CEA tests, recurrences). **Methods:** Pts had completed treatment for stage I-III CRC within 3 mo, had a PCP, and no prior cancer. After pt consent, PCPs could opt out. SC replaced 2 routine oncologist visits with PCP visits and included a survivorship care plan, concerns checklist and PCP management guidelines. PCPs were asked to request CEA tests at 3 and 9 mo visits. Assessments were at baseline (BL), 6 and 12 mo FU. Difference (diff) between groups on GHQ-QoL to 12 mo estimated from a mixed model for repeated measures (MMRM). Non-inferiority evaluated by comparing the lower limit of the two-sided 95% confidence interval (CI) for the estimated diff (SC-UC) against a non-inferiority margin (NIM) of -10 points. Per-protocol population (PPP) comprised all randomised pts with ≥ 1 post-BL questionnaire (6 +/- or 12mo) and, for SC, ≥ 1 of the PCP visits. **Results:** 150 pts were randomised to SC (N=74) or UC (N=76); 11 PCPs had declined. Median age 63 years, 39% women, 24% had radiation. Primary site: colon (59%), rectum (32%), overlapping (9%). 138/150 (92%) had BL and ≥ 1 post-BL GHQ-QoL score. 65/74 (88%) of SC pts attended 3- and/or 9-mo PCP visits. The mean (SD) GHQ-QoL scores at baseline / 6 mo / 12 mo were: 69 (18.7) / 69 (21.2) / 72 (20.2) for SC versus 68 (20.0) / 73 (15.1) / 73 (17.2) for UC. The MMRM mean estimate of GHQ-QoL across the 6 mo and 12 mo FU was 69 for SC and 73 for UC, mean diff -4.0 (95% CI: -9.0 to 0.9). The lower limit of the 95% CI did not cross the NIM. For the PPP (N=130/150), mean diff was -5.0 (95% CI: -10.1 to 0.2). No clear evidence of between group differences on other QoL, unmet needs or satisfaction scales (C30, CR29, SUNS, PSQ), accounting for multiplicity. At 12 mo, more patients in SC (40/62, 65%) vs UC (24/58, 41%) felt their PCP was sufficiently knowledgeable (AOPSS). At 12 mo, most popular preferences for FU were: SC for 40/63 (63%) in the SC group; similar preferences for SC 22/62 (35%) and 'Hospital-based care with the doctors that treated the cancer' 22/62 (35%) in UC. CEA completion was 89% at 3 mo and 83% at 9 mo in SC; 63% and 68% in UC. 5 recurrences in SC and 6 in UC arms. Pts in SC on average incurred A\$456 less in health costs vs UC pts. **Conclusions:** SCORE had high PCP participation and pt retention. Compared to UC, pts having SC had non-inferior QoL, and lower costs. Adherence to CEA testing was higher in SC. Pts exposed to SC prefer this model of FU. Oral Abstract Session

A cognitive behavioral digital therapeutic for anxiety and depression in patients with cancer: A decentralized randomized controlled trial. *First Author: Sean R. Zion, Blue Note Therapeutics, San Francisco, CA*

Background: Patients with cancer often experience clinically elevated levels of distress, including anxiety and depression. Psychological interventions, such as Cognitive Behavioral Stress Management (CBSM), have evidenced benefits on distress, quality of life, and long-term health outcomes, however, they are not widely available or easily accessible. Digitizing these interventions may be a means of democratizing access to cancer-focused and empirically-supported mental health care. **Methods:** This double-blind randomized controlled trial (RCT) compared the impact of a 10-module digitized CBSM app [attune] vs. a health education control app [cerena] on anxiety and depression symptoms in patients with cancer (n=449). Patients with non-metastatic (stage I-III) and hematological cancers who were receiving or recently (<6 months) completed systemic treatment and reported a PROMIS-A T-Score ≥60 were recruited to participate in this decentralized clinical trial through a nationwide online advertising campaign. The pre-specified primary outcome was change in anxiety symptoms (PROMIS-A) across conditions over time (week 0, 4, 8, and 12) in the intention-to-treat population analyzed using a linear mixed effects model with repeated measures. Secondary outcomes included change in depression symptoms (PROMIS-D) and global impression of change in anxiety and depression (PGI-C). **Results:** Patients in the study were 80.6% female, 76.5% white, and the mean (SD; range) age was 52.44 (11.46; 25-80) years. Compared to the control, attune participants showed significantly greater reductions in anxiety ($\beta = -0.03$; $p = 0.019$) and depression ($\beta = -0.02$; $p = 0.042$) symptoms over 12-weeks, and at end-of-study (week 12) there was a greater proportion of attune participants in the PROMIS-A ($\chi^2 = 7.13$; $p = 0.004$) and PROMIS-D ($\chi^2 = 3.53$; $p = 0.035$) mild-none symptom severity category. There were also significant group differences in PGI-C, with attune participants more likely to report 'much' or 'very much' improvement in their anxiety ($\chi^2 = 31.76$; $p < 0.001$) and depression symptoms ($\chi^2 = 19.70$; $p < 0.001$). **Conclusions:** Digital therapeutics have the potential to improve access to empirically supported psychological treatments for symptoms of anxiety and depression in patients with cancer. In this decentralized, double-blind RCT, we show that compared with a visually and functionally similar sham app, patients who used attune had significantly greater reductions in anxiety and depression symptoms over time. Moreover, at the end of the study, participants who used attune were significantly more likely to report their anxiety and depression symptoms were 'much' or 'very much' improved, indicating clinically meaningful change. Future work aims to explore implementation strategies to maximize benefit and accessibility of this cancer-specific digital therapeutic. Clinical trial information: NCT05227898. Research Sponsor: Blue Note Therapeutics.

Oral Abstract Session

Remote symptom-monitoring of patients with advanced lung cancer: A Danish national randomized controlled trial—The ProWide study. *First Author: Rasmus Blechingberg Friis, Department of Oncology, Regional Hospital West Jutland, Herning, Denmark*

Background: Symptom-monitoring of patients with lung cancer has previously been shown to improve clinical outcomes. We conducted a national randomized controlled trial to evaluate the effects of remote symptom-monitoring of patients with advanced lung cancer completing induction treatment in a Danish setting. **Methods:** Patients with stage III-IV lung cancer treated with palliative intention, ECOG performance status ≤ 2 , internet access and non-progressive disease after completed induction treatment were eligible. Patients were randomized 1:1 to remote symptom-monitoring (intervention arm) added to standard of care or standard of care alone (control arm). Maintenance therapy was allowed. Patients in the intervention arm weekly completed an electronic questionnaire from home covering 13 common symptoms related to lung cancer. A severity-threshold was applied to each question. When a threshold was exceeded, a notification was sent to a clinical nurse. The nurse was instructed to contact the patient and offer best supportive care. If disease progression was suspected, a computerized tomography (CT) scan was performed. Primary outcome was overall survival. Secondary endpoints included Health-related Quality of Life (HRQoL) measured by the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire EORTC QLQ-C30/LC13 and Hospital Anxiety and Depression Scale (HADS) scales. **Results:** Of 494 randomized patients, recruited from 8 departments, 239 were assigned to the intervention and 254 to standard of care (inclusion rate 75%). Weekly compliance to symptom-monitoring during the first year was 82% in the intention-to-monitor population. At a median follow-up of 2.6 years, no significant improvement in overall survival (OS) was found in the intervention arm compared to the control arm (hazard ratio (HR) 0.93, 95% confidence interval (CI); 0.75 to 1.16; $p = 0.54$). Sub-group analyses indicated improved OS for patients treated with carboplatin/vinorelbine (HR 0.65, CI 95%; 0.44-0.96, $p = 0.03$) and for patients treated in a department with prior implementation and use of patient-reported outcomes in clinical decision-making (HR 0.68, CI 95%; 0.46-1.01, $p = 0.054$). For prespecified scales in the HRQoL-analyses, no clinically meaningful effects were found. For physical functioning, mean overall change from baseline was 3.1 points (95% CI 0.1 to 6.2, $p = 0.043$), for pain, -3.9 points (95% CI; -8.4 to 0.7, $p = 0.096$) and for HADS-anxiety, -0.5 points (95% CI; -1.0 to 0.0, $p = 0.070$). **Conclusions:** Remote symptom-monitoring did not significantly improve clinical outcomes for patients with advanced lung cancer in a Danish population. The results indicated benefits for a sub-group of patients not receiving maintenance therapy and that prior organizational experiences may be a prerequisite for improving outcomes of symptom-monitoring. Clinical trial information: NCT03608410. Research Sponsor: Danish Cancer Society; Danish Research Center for Lung Cancer.

Poster Discussion Session

Association between state Medicaid policies and accrual of Black and Hispanic patients to cancer clinical trials. *First Author: Samuel U Takvorian, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: The U.S. Medicaid health insurance program may play a key role in mitigating racial and ethnic disparities in cancer clinical trial enrollment, given Medicaid's disproportionate representation of these populations and its coverage of the routine costs of trial participation in some states. We sought to evaluate the effect of Medicaid expansion under the Affordable Care Act (ACA) on changes in the accrual of racial and ethnic minority patients in cancer clinical trials, across all states and specifically those mandating Medicaid coverage of routine trial costs. **Methods:** The study used anonymous enrollment data from Medidata Rave, a large commercial clinical trial data collection platform. We conducted a retrospective difference-in-differences (DID) analysis to examine accrual demographics in states that expanded Medicaid eligibility under the ACA compared with non-expansion states, before and after expansion; and assessed effect modification based on state-mandated Medicaid coverage of routine trial costs. Participants included adults enrolled in interventional cancer clinical trials from 2012-2019, located in U.S. hospital referral regions with $>5\%$ Black or Hispanic population. The primary outcome was participant race/ethnicity, defined dichotomously as Black or Hispanic (vs non-Black, non-Hispanic). We used ordinary least squares regression to model participant race/ethnicity as a function of (1) an indicator for trial enrollment in an expansion state after policy implementation, (2) state fixed effects, and (3) year fixed effects, with standard errors clustered at the state level. To assess effect modification, we stratified the main model across states with and without coverage mandates of routine trial costs. **Results:** The study included 75,700 participants across 1,409 clinical trials and 351 sites. In expansion states, the proportion of participants who identified as Black and/or Hispanic increased from 13.4% before expansion to 13.8% after expansion (0.4 percentage-point [PP] change, 95% CI -0.8 to 1.7). In non-expansion states, this proportion decreased from 17.0% to 15.2% (-1.7 PP change, 95% CI -3.7 to 0.2). These trends yielded a non-significant DID estimate of 2.0 PP (95% CI -1.0 to 5.0). In stratified analyses, Medicaid expansion was associated with a 4.5 PP (95% CI 0.4 to 8.6) increase in the enrollment of Black and/or Hispanic participants in states with coverage mandates, but not in states without coverage mandates (1.1 PP, 95% CI -2.6 to 4.8). **Conclusions:** Medicaid expansion was associated with a significant increase in the proportion of Black and Hispanic oncology trial participants in states that mandated Medicaid coverage of the routine costs of trial participation, but not overall across all states. These findings suggest that Medicaid policies have the potential to advance equitable enrollment in cancer clinical trials. Research Sponsor: None.

Poster Discussion Session

Association of Medicaid expansion with treatment receipt, delays in treatment initiation, and survival among young adult women with breast cancer. *First Author: Xuesong Han, American Cancer Society, Atlanta, GA*

Background: Medicaid expansion under the Affordable Care Act has been shown to increase insurance coverage and early-stage cancer diagnoses for young adults (YAs), the age group with the highest uninsured rate. We examined whether Medicaid expansion was associated with increased receipt of timely, guideline-concordant treatment and survival among YA women newly diagnosed with breast cancer, the most common YA cancer diagnosis. **Methods:** Using the National Cancer Database, we identified 51,675 women aged 18-39 years who were diagnosed with breast cancer in 2011-2018. We applied the difference-in-differences (DD) method to estimate outcome changes pre vs. post Medicaid expansion, in expansion- vs. non-expansion states. Linear probability models estimated associations of Medicaid expansion with receipt of guideline-concordant treatment – including any endocrine therapy among women with ER-positive or PR-positive breast cancer, and any chemotherapy or targeted therapy among women with ER-negative and PR-negative breast cancer – and initiation of guideline-concordant treatment (surgery, chemotherapy, or targeted therapy for stage I-III diagnoses, and systemic therapy for stage IV diagnoses) <60 days after diagnosis. Flexible parametric survival models were used to estimate 2-year overall survival. DD models also adjusted for age, race/ethnicity, rurality, zip code-level income, comorbidity, and diagnosis year, with standard errors clustered at the state level. Analyses were stratified by stage at diagnosis (stage I-III vs. IV). **Results:** Of the subset of women with stage I-III ER-positive or PR-positive breast cancer, the percentage receiving endocrine therapy increased in expansion states (85.20% pre-expansion to 86.46% post-expansion), but decreased in non-expansion states (84.32% to 82.79%), resulting in a net increase of 2.42 percentage points (ppt; 95% CI = 0.56 to 4.28) associated with Medicaid expansion in the adjusted DD model. Among all women with stage I-III breast cancer, the percentage with treatment initiation <60 days after diagnosis decreased less in expansion states (84.10% pre-expansion to 82.36% post-expansion) than in non-expansion states (86.95% to 83.98%), resulting in a net reduction of 1.61 ppt (95% CI = 0.05 to 3.18) in treatment delays associated with Medicaid expansion. Notably, the 2-year overall survival increased in expansion states (96.84% pre-expansion to 96.99% post-expansion), but decreased in non-expansion states (97.24% to 96.30%), resulting in a net survival increase of 1.00 ppt (95% CI = 0.21 to 1.79) associated with Medicaid expansion. **Conclusions:** Among YA women with stage I-III breast cancer, Medicaid expansion was associated with increased receipt of guideline-concordant treatment, reduced delays in treatment initiation, and improved 2-year survival. Poster Discussion Session

State mandatory paid medical leave policies and survival among adults with cancer in the US. *First Author: Justin Michael Barnes, Department of Radiation Oncology, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: Cancer treatment is often costly and time intensive. Paid medical leave can help employed patients with cancer more effectively manage side effects and complete recommended cancer treatments without loss of income. Since 2012, several states have introduced mandatory paid medical leave policies. We examined whether mandatory paid medical leave policies were associated with better survival among working age adults with cancer. **Methods:** Adults ages 18 to 64 years diagnosed with cancer 2007-2019 were identified from the Surveillance, Epidemiology, and End Results registry program covering 12 states. The primary outcome was overall survival (OS). The exposure of interest was the presence of state mandatory paid medical leave policies. Difference-in-differences (DID) analyses with additive hazards regression models compared changes in OS from pre- to post- mandatory paid sick leave policy implementation in states with vs. without paid sick leave policies. Models adjusted for year-quarter fixed effects, state fixed effects, state Medicaid expansion status, age, race, sex, marital status, metropolitan residence status, county-level income, cancer site, cancer stage, and insurance status. Clustered standard errors by state were achieved via the cluster bootstrap. The plausibility of the common trends assumption was tested using event study analyses and was satisfied for all analyses. Primary analyses focused on data from 2007-2016, where information on month of diagnosis, county, and insurance coverage status were available (note these variables are not available for 2017-2019), though sensitivity analyses with data through 2019 without these additional variables were conducted. **Results:** A total of 1,491,208 adults with cancer were identified. In adjusted DID analyses, after policy implementation, 1-year OS improved from 85.0% to 86.4% in states with mandatory medical leave policies compared to 85.1% to 85.6% in states without such policies. This translates to a 0.85% improvement in 1-year OS (hazard DID: -0.0007, 95% CI = -0.0016 to -0.0001, $P = .027$). The largest improvement was found among the uninsured population (hazard DID: -0.0038, 95% CI = -0.0076 to -0.0011, $P = .013$). In sensitivity analyses with abbreviated data through 2019, results were similar (DID for 1-year OS: 1.3%; hazard DID: -0.0010, 95% CI = -0.0025, 0.0001, $P = .070$). **Conclusions:** State mandatory paid medical leave was associated with improved survival for working-age adults with newly diagnosed cancer, particularly for those who are uninsured. Policy changes that better support patients through cancer treatment may pay off with improved cancer outcomes. Research Sponsor: None.

Poster Discussion Session

Impact of the oncology care model (OCM) on Medicare payments, utilization, and care delivery: Update through year 5. *First Author: Gabriel A. Brooks, Dartmouth Cancer Center, Lebanon, NH*

Background: OCM was a voluntary episode-based alternative payment model designed to improve the value of care for fee-for-service Medicare beneficiaries receiving systemic therapy for cancer. Participating practices received monthly enhanced oncology services (MEOS) care coordination payments and could receive additional payments (or penalties) if they met quality and total episode spending goals during 6-month episodes. **Methods:** We used a difference-in-differences approach to evaluate OCM impacts on Medicare payments, utilization, and quality measures during 6-month episodes before (July '14-January '16) and after (July '16-June '21) OCM's start. Patient-episodes were attributed to OCM-participating practices ($n = 202$) or propensity-matched comparison practices ($n = 534$). Statistical significance was defined as $p \leq 0.10$ to avoid missing program impacts. **Results:** Total episode payments (TEP) for 6-month OCM episodes increased from 29,120 in the baseline period to 35,467 in the OCM period (+21.8%). In reference to comparison episodes, OCM led to a 499 relative reduction in TEP (90%CI -771, -227, -1.7% relative to baseline.) OCM had no significant impact on TEP for low-risk breast, prostate, and bladder cancers, and OCM led to a relative decrease of 755 (CI -1140, -371) for all other higher risk cancers. Reductions in TEP were largest for high-risk breast cancer, lymphoma, lung cancer and colorectal cancer. The overall OCM impact on TEP was attributable to relative reductions in both Part A payments (-152, [CI -257, -47]) and Part B payments (-276, [CI -459, -92]). There was no OCM impact on Part D payments. While OCM had no impact on Part B chemotherapy payments, OCM reduced Part B non-chemotherapy drug payments by 251 (CI -330, -173; -9.3%). Utilization analyses showed no impact of OCM on ED visits or hospitalizations, but OCM reduced the likelihood of ICU admission by 0.6 percentage points (PP; CI -1.0, -0.1, -5.4%). OCM had no impact on initial chemotherapy regimen selection, but OCM led to greater use of biosimilar cancer therapies and value sensitive changes in the use of antiemetics, bone supportive medications, and WBC growth factors (including greater use of biosimilar WBC growth factors; all $p < 0.10$). OCM reduced hospitalizations in the last 30 days of life by 0.8 PP (CI -1.6, -0.1; -1.5%) with no impact on use of chemotherapy or hospice at the end of life. Despite OCM-related TEP reductions, OCM resulted in net losses to Medicare after accounting for MEOS and performance-based payments. **Conclusions:** OCM led to reductions in TEP with similar or improved quality. Reductions in TEP were greatest for common, high-cost cancer types and were driven primarily by changes in use of supportive care medications. The Medicare Enhancing Oncology Model will build on the experience of OCM to further the goal of improving the quality and value of cancer care for Medicare beneficiaries. Patient- and clinician-directed implementation strategies to improve serious illness communication for high-risk patients with cancer: A cluster-randomized pragmatic trial. *First Author: Samuel U Takvorian, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: Early serious illness conversations (SICs) elicit patients' values, goals, and care preferences and have been shown to improve outcomes and reduce end-of-life healthcare utilization for patients with cancer. However, most patients with cancer die without a documented SIC. Given prior evidence that strategies informed by behavioral economics ("nudges") increase SIC rates, our objective was to test the independent and additive effects of clinician- and patient-directed nudges to increase SIC completion. **Methods:** We conducted a 2×2 factorial, cluster-randomized pragmatic trial (NCT04867850) to test the effects of nudges to clinicians, patients, or both, compared to usual care, on SIC completion. Usual care was an active control consisting of clinician-directed text messages sent before routine clinic sessions, identifying patients at high risk of 6-month mortality as predicted by a validated machine-learning prognostic algorithm. The clinician nudge additionally included weekly peer comparisons on clinician-level SIC completion rates. The patient nudge consisted of a patient-facing message sent electronically before an index clinic visit, asking a 3-question survey designed to prime patients for an SIC with their oncology team. Participants included medical/gynecologic oncologists and advanced practice providers (APPs) within a large academic health system and their high-risk patients. We independently randomized oncologist/APP clusters and patients to receive nudges vs. usual care. The primary outcome was a documented SIC in the electronic health record within 6 months of enrollment. Using a Cox proportional hazards model with cluster robust standard errors, we performed a time-to-event analysis and tested for heterogeneity of effect across prespecified subgroups. **Results:** From September 2021 to March 2022, the study accrued 4,450 patients (median age 67, 52.9% female, 17.3% Black, 2.7% Hispanic) seen by 166 clinicians across 4 hospitals and 6 community sites, randomized to clinician nudge ($n=1,179$), patient nudge ($n=997$), both ($n=1,270$), or active control ($n=1,004$). Overall patient-level rates of 6-month SIC completion were: 11.5% (clinician nudge), 11.5% (patient nudge), 14.1% (both), and 11.2% (active control). Compared to the active control, participants in the combination nudge arm were more likely to engage in SICs (hazard ratio [HR] 1.55, 95% confidence interval [CI] 1.00-2.40), whereas those in the clinician (HR 0.95, 95% CI 0.64-1.41) and patient (HR 0.99, 95% CI 0.73-1.33) nudge arms were not. There was no effect heterogeneity across age and race subgroups. **Conclusions:** Clinician- and patient-directed nudges may be synergistic in promoting serious illness communication at scale and equitably in routine cancer care. Effects on end-of-life care among decedents are forthcoming. Clinical trial information: NCT04867850. Research Sponsor: U.S. National Institutes of Health.

Engagement of Patients with Advanced Cancer (EPAC) randomized clinical trial: Long-term effects on survival and healthcare use. *First Author: Manali I. Patel, Stanford University, Stanford, CA*

Background: The Engagement of Patients with Advanced Cancer (EPAC) randomized Veterans with newly diagnosed stage 3 or 4 cancer or recurrent disease to usual care (control) or usual care with 6-month community health worker (CHW) support (intervention) to engage Veterans in end-of-life (EOL) goals and care preference discussions. At 6- and 15-months follow-up, the intervention tripled goals of care documentation (primary outcome), doubled hospice (secondary outcome), and reduced end-of-life (EOL) acute care use (secondary outcome). This post-hoc analysis after 10 years from study initiation evaluates effects on overall survival (OS) and EOL healthcare use. **Methods:** We abstracted dates of death, emergency department (ED), hospitalization, palliative care (PC), and hospice use within and outside Veterans Affairs (VA) using electronic health record and claims before data cut-off on February 1, 2023 for all EPAC participants. We compared OS using Kaplan Meier and log-rank, risk of death using Cox-proportional hazard models, ED, hospitalization, PC, and hospice use in the last 30 days of life using Logistic Regression, and incidence rate ratios of ED and hospitalizations using Poisson regression. **Results:** Among 213 participants, there were no imbalances in demographic or clinical characteristics. 165 (77.4%) were White, 211 (99%) males, 80 (37.6%) had lung cancer, and 118 (55.3%) had stage 4 disease. Median follow-up was 298 days (range 12-3438). Intervention group participants had greater OS (log rank $p=0.04$), 25% reduction in risk of death, lower acute care use, and greater PC and hospice use than control group participants. **Conclusions:** The CHW-led intervention significantly improved OS and maintained robust effects on EOL healthcare use. The intervention may have had unintended, unmeasured effects on other aspects of care, such as treatment and follow-up adherence, and/or hospice acceptance, which require investigation. Nonetheless, results support integration of community health workers into cancer care to improve clinical outcomes. Clinical trial information: NCT02966509. Research Sponsor: VA Office of Cultural Transformation; U.S. National Institutes of Health.

Identifying clinical trial candidates using AI predictions of treatment change: A pilot implementation study. *First Author: Kenneth L. Kehl, Dana-Farber Cancer Institute, Boston, MA*

Background: Precision oncology clinical trials often struggle to accrue due to the difficulty of identifying patients whose tumors meet complex tumor genomic matching criteria at propitious moments when they need new treatment. We conducted a pilot of deploying an artificial-intelligence (AI) model to find such patients and facilitate clinical trial matching workflows at a large academic cancer center. **Methods:** An AI model was trained to predict initiation of new palliative intent systemic therapy within 30 days of a given imaging report (CT, MRI, bone scan, or PET-CT), using the text of that report and prior reports for each patient. The model architecture and performance were previously published (Kehl et al, JCO-CCI 2021 5:622-630). From April to December 2022, the model was applied prospectively each time patients with solid tumors that had undergone next-generation sequencing underwent an imaging study. Model output was linked to the MatchMiner tool, which matches patients to clinical trials using tumor genomics (Klein et al, NPJ Precis Oncol 2022 6(1):69). The output consisted of lists of patients with tumor genomic matches to specific trials, sorted in order of the likelihood of changing treatment within 30 days. This information was provided to an oncology nurse navigator (ONN) charged with coordinating recruitment to early-phase targeted and immunotherapy trials. For 9 high priority trials, the ONN reviewed records for each patient flagged as likely to change treatment and contacted treating oncologists when patients appeared potentially eligible. The proportions of records leading to oncologist contact, and reasons for oncologist non-contact, were analyzed. **Results:** 2093 patients had tumors with genomic matches to the 9 trials of interest; 492 patients (24%) were deemed "likely" to change treatment by our AI model at least once during the pilot. The treating oncologist for 66 patients (3% of the total; 13% of 492 "likely" patients) was contacted after ONN review for potential eligibility. Reasons for not contacting treating oncologists included cases where they had already decided to continue current treatment (21%); the trial had no slots at the time (14%); or the patient was ineligible on nurse navigator review (12%); or had already been evaluated for the trial (7%), started new treatment (18%), or enrolled in hospice (5%). Of the 66 patients whose oncologists were contacted, 9 patients had a consult regarding early phase trials; 4 consented to participate; and all 4 received protocol treatment. **Conclusions:** Identifying potential precision clinical trial candidates by using AI to find patients likely to change treatment is feasible, but many other factors also impact potential trial enrollment. A prospective study is planned to evaluate the impact of sharing clinical trial information directly with treating oncologists when our model predicts a high probability of treatment change. Research Sponsor: U.S. National Institutes of Health; Doris Duke Charitable Foundation.

Poster Discussion Session

Developing machine learning algorithms incorporating patient reported outcome measures to predict acute care events among patients with cancer. *First Author: Thomas J Roberts, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Clinical trials have shown that collecting patient-reported outcome measures (PROMs) can improve outcomes among oncology patients. However, there remains uncertainty about how to best collect and use PROMs in routine clinical care. Since 2016 we have collected PROMs for patients receiving cancer treatment within a large health system containing academic and community sites. We sought to examine whether combining PROMs with electronic health record (EHR) data improves the performance of machine learning algorithms predicting patients' risk of 30-day acute care events. **Methods:** The sample included patients with solid tumors receiving curative- or palliative-intent systemic therapy between 9/1/20 and 7/31/22 who completed at least one PROMs survey. PROMs were collected via a 12-item questionnaire based on the Common Terminology Criteria for Adverse Events measurement system. Patients completed questionnaires via the EHR's patient portal or on tablets in waiting rooms. EHR data included 176 variables describing demographics, laboratory values, vital signs, diagnoses, medications, and prior healthcare encounters. A binomial outcome was calculated for each patient encounter to indicate whether the patient had an acute care event (ED visit or hospitalization) in the subsequent 30 days. Data were randomly assigned to training (70%) and test (30%) sets and were used to train and test four models: EHR + PROMs, EHR alone, PROMs alone, and 'PROMs plus,' which included PROMs and minimal EHR data such as age, sex, and site of cancer treatment, which served as an accessible proxy for cancer type. For each model, we compared multiple architectures and selected the best-performing model for comparison. **Results:** Between September 2020 and June 2022, 4,193 patients completed 20,359 PROM surveys during outpatient encounters. There were 2,118 30-day acute care events within the cohort. The area under the receiver operating curves (AUCs) were 0.84 (95% CI 0.81 to 0.86) for the EHR + PROMs model, 0.82 (95% CI 0.80 to 0.84) for the EHR alone model, 0.67 (95% CI 0.65 to 0.69) for the PROMs alone model, and 0.79 (95% CI 0.77 to 0.82) for the PROMs plus model. In the EHR alone and EHR + PROMs models, the most important variables were last albumin, white blood cell count and hemoglobin. In the PROMs plus model, the most important variables were age, treatment site, patient-reported pain, and patient-reported fatigue. **Conclusions:** Incorporating PROMs into machine learning models to predict risk of acute care events can improve model performance. Notably, the model combining PROMs with a small number of easily accessible EHR variables performed nearly as well as models including all EHR data. These models demonstrate the predictive value of PROMs in oncology patients and they lay the foundation for future interventions aiming to reduce acute care events among high-risk patients. Research Sponsor: U.S. National Institutes of Health.

Towards improvement of oncology care through digital technology: A snapshot of Resilience remote patient monitoring (RPM) system implementation across 19 hospitals in Europe. *First Author: Arlindo R. Ferreira, Resilience and Católica Medical School, Universidade Católica Portuguesa, Paris, France*

Background: In clinical trials, RPM based on patient reported outcomes (PROs) has been shown to reduce symptom burden, increase dose intensity, improve quality of life and overall survival, and is recommended by international guidelines in routine oncology practice during systemic treatment (Di Maio et al., Ann Oncol 2022). Resilience developed a digital RPM system for oncology (CE marked, class IIa medical device) which prompts patients weekly with a notification to complete a survey including common symptoms from the NCI's PRO-CTCAE questionnaire. Severe or worsening symptoms trigger an alert notification to the patient's cancer care team, as well as personalized self-management advice, empowerment and educational material to patients. In this study we report the real-world implementation of Resilience RPM system in France and Belgium. **Methods:** Aggregated system-level metrics were collected covering all participating hospitals between Nov 2021 - Dec 2022. Qualitative and quantitative assessments focused on patient and provider utilization of Resilience RPM system was done. The implementation included a continued interaction between Resilience and hospital personnel for training, coordination and technical support. **Results:** 19 hospitals deployed Resilience in France and Belgium, including two Organization of European Cancer Institutes (OECI)-designated cancer centers and community oncology hospitals. Three integrated RPM with their electronic medical record. Overall, 1262 pts were registered (age range, 20-94), 40% with breast, 20% gastrointestinal and 8% genitourinary cancers. In the last 6 months, the main RPM interface was the mobile app (70%). Patient adherence with weekly RPM surveys was 85%, with a median time from prompt receipt to survey completion of 5h20min. RPM retention for 3 months, regardless of disease status, was 80%. Irrespective of severity, the most commonly reported PROs were performance status decline (94%), pain (89%) and anorexia (82%). The most common severe alert notifications were for nausea (33%), pain (31%) and anorexia (23%). The median time to alert management by the care team was 12h (70% within 24h), with 70% of alerts managed by a nurse navigator follow-up call, 5% by a referral for internal/external appointments, 0.5% with an emergency room referral and 0.4% with a hospitalization referral. 87% (32/38) of providers were satisfied with integrating the solution into their organization and 80% (30/38) felt patients were better managed through use of Resilience RPM. **Conclusions:** Implementation of the Resilience RPM system was feasible across a diverse group of 19 cancer centers in France and Belgium, with high levels of patient and provider participation and engagement. Resilience RPM offers an evidence-based approach to improve the quality and patient-centeredness of cancer care. Research Sponsor: Resilience fundings.

AI-based radiomic biomarkers to predict PD-(L)1 immune checkpoint inhibitor response within PD-L1 high/low/negative expression categories in stage IV NSCLC. *First Author: George R. Simon, H. Lee Moffitt Cancer Center and Research Institute, Celebration, FL*

Background: Recent efforts exploring the utility of quantitative imaging (radiomic) biomarkers to predict response to immune checkpoint inhibitors (ICI) have shown promise to provide a more accurate and scalable method than biopsy-based PD-L1 IHC and tumor mutation burden. One of the challenges of evaluating ICI biomarkers on retrospective real-world data is the inherent association between a physician's treatment choice and PD-L1 expression status. This work investigates radiomics-based multi-modal biomarkers within patient cohorts receiving first-line therapy (ICI monotherapy, ICI plus chemotherapy, and chemotherapy), and in cohorts of all patients receiving ICI (all-lines) subdivided by PD-L1 expression. **Methods:** Using a large multi-institutional real-world dataset, we analyzed radiomic characteristics of 6,295 primary and metastatic lesions from 1,206 stage IV NSCLC patients treated with PD-(L)1 ICIs from nine institutions across the US and Europe. Patients with unavailable imaging follow-up or with EGFR/ALK oncogenic driver mutations were excluded from analysis, resulting in a total dataset of 791 subjects randomly assigned to training (N = 541) and validation sets (N = 250). Radiomic data was extracted from baseline CT scans capturing tumor heterogeneity, spicularity, and burden in the lung, lymph nodes, and liver. A multi-modal ensemble classifier combining demographic features, PD-L1 TPS, and radiomic data was developed to predict response to ICI therapy per RECIST 1.1 criteria. The model's performance was evaluated in terms of the area under the receiver operating characteristic curve (ROC-AUC) and compared to PD-L1 IHC using the two-tailed DeLong test. **Results:** In first-line cohorts, the model identified responders with an ROC-AUC of 0.83 (0.72-0.94, P = 0.005; N = 80, 81% PD-L1 >= 50%) in ICI monotherapy, 0.65 (0.47-0.83, P = 0.28; N = 78, 71% PD-L1 < 50%) in ICI plus chemotherapy, and 0.38 (0.002-0.76, P = 0.53; N = 37) in chemotherapy. In all-lines cohorts subdivided into PD-L1 high/low/negative expression categories, the model identified responders with an ROC-AUC of 0.72 (0.57-0.87, P = 0.005, N = 102), 0.74 (0.58-0.89, P = 0.003, N = 71), and 0.60 (0.46-0.74, P = 0.16, N = 77), respectively. **Conclusions:** Our study demonstrates that multi-modal models can predict ICI response with high performance. The stronger performance in patients receiving ICI therapy alone indicates the model's predictive, rather than prognostic, power. Furthermore, the model demonstrated good performance in identifying ICI responders within patient sub-cohorts defined by PD-L1 expression status. These insights may be used to inform clinical decision-making, such as escalation or de-escalation of concurrent chemotherapy in stage IV NSCLC patients. In our future work, we will investigate these questions in larger cohorts and prospective studies. Research Sponsor: Onc.AI.

Expanding veteran treatment access points through Close To Me (CTM) infusion service. *First Author: Jenna L Shields, VA National TeleOncology, VA National Oncology Program Office, Durham, NC*

Background: Diagnosing and treating more than 43,000 Veterans annually, the Veterans Affairs (VA) National Oncology Program (NOP) oversees the largest integrated providers of hematology/oncology services in the US. Within the VA, parenteral therapies are primarily offered at VA Medical Centers (VAMC) in urban areas, often inaccessible to rural patients. Travel distance, parking, time, and caregiver support can prevent patients from adhering to treatment regimens. To resolve these challenges, NOP launched the Close to Me (CTM) infusion service. The service seeks to reduce travel time for patients, improve VA care continuity, and increase access points to patient-centric care by administering treatments utilizing the network of VA Community Based Outpatient Clinics (CBOC). **Methods:** In the CTM CBOC infusion service select medications are compounded at the main VAMC, then transported via a registered nurse to the surrounding CBOCs for administration. Eligible patients must be established with a VA hematologist/oncologist and tolerated 1 cycle of treatment at the VAMC. Patients are assessed via telehealth prior to each treatment at the CBOC. Patient drive miles saved was calculated by subtracting the mileage between the patient's home address and the CBOC from the patient's home address and the VAMC, then multiplied by number of treatment visits at the CBOC. Medication cost avoidance was calculated by subtracting the VA purchase price from the 2023 published Centers for Medicare and Medicaid Services reimbursement rates, then multiplied by number of treatments received at the CBOC. The first CTM CBOC clinics were opened within the Minneapolis VA Health Care System in October 2021, followed by the VA Pittsburgh Healthcare System in June 2022. **Results:** From October 2021 through December 2022, 373 unique patients were treated within CTM CBOC clinics for a total of 532 patient visits. The CTM infusion service resulted in 43,249 patient drive miles saved and 813,352 in medication cost avoidance. No medical emergencies were reported during CTM CBOC treatments. One medication was discarded without use due to damage during shipping. One compounded product was not used due to change in patient status. One patient was non-adherent with treatment appointments on two occasions resulting in an overall 99.6% treatment adherence. **Conclusions:** The CTM infusion service optimizes current VA infrastructure to increase access points to hematology/oncology treatment, reduce travel burden for patients, increase treatment appointment adherence and reduce medication cost expenditures. To facilitate expansion of this successful service, NOP has provided funding and support to 11 additional VAMCs to implement one of the CTM solutions including CBOC, mobile infusion unit or home infusion. A comprehensive implementation toolkit was developed to encourage the independent adoption of this service at appropriate locations across VA. Research Sponsor: National Oncology Program, VA Specialty Care Services.

Improving cancer care in underserved regions through technology-enabled patient-reported outcomes. *First Author: Kingsley Ndoh, Hurone AI, Inc, Seattle, WA*

Background: The growing cancer burden in Africa is a major public health challenge. There were 8,944 new cases in Rwanda, with over 6,044 deaths reported in 2020. Unfortunately, there are only 13 oncologists in Rwanda for a population of 13 million people. The use of artificial intelligence (AI) tools and digital health in cancer treatment has the potential to mitigate the oncology workforce shortages, support clinical decision-making, and increase access to care. Hurone AI is a Seattle MedTech startup building culturally sensitive AI applications to address the oncologist-patient gaps and improve drug safety in underserved populations. Hurone's premier application, Gukiza, launched at the Rwanda Cancer Center in 2022 to conduct beta testing. Gukiza is a remote patient monitoring system that ensures patients can report side effects or symptoms from their phones and oncology care teams can get real-time treatment insights and provide timely and effective care. **Methods:** Hurone received ethical approval from the Rwanda National Ethical Committee to launch a pilot in September 2022. An initial 45 breast cancer patients aged 20 – 65 who were either newly diagnosed or on active treatment were recruited. Each patient periodically received prompts that asked them about side effects and to score the degree of severity. The questions were adapted from the NCI's adverse events repository. Gukiza analyzed each response and presented a visual analysis of each patient, enabling the cancer care team to send text-based interventions to the patient's phone. Potential emergencies are flagged and sent emergency numbers to call. Through Amazon's cloud analytic tools, Gukiza provides treatment insights to support oncologists' clinical decisions. **Results:** Results are summarized. **Conclusions:** Resource-appropriate digital technologies can be a useful tool in mitigating adverse events during cancer treatment and increasing access to timely care for patients. The data built in such systems can be a useful resource to individualize and improve cancer care and treatment outcomes. Research Sponsor: Amazon Web Services.

Smoking cessation support and knowledge among newly diagnosed individuals at community cancer centers (ECOG-ACRIN trial EAQ171CD). *First Author: Elyse R. Park, Massachusetts General Hospital, Boston, MA*

Background: ASCO recommends that all individuals diagnosed with cancer who smoke receive tobacco treatment support. Oncology clinicians can use the 5As (Ask, Advise, Assess, Assist (e.g., talk about quitting and recommend medication), and Arrange follow-up) to provide this support. Previous studies that have typically assessed clinician-reported delivery of 5As, so we assessed patient-reported receipt of 5As to 1) assess prevalence of 5As receipt and variations by tumor type (smoking vs non-smoking-related) and 2) associations between 5As receipt and patient knowledge about smoking risks and motivation to quit. **Methods:** We analyzed baseline data of 306 patients enrolled in a randomized trial coordinated by the ECOG-ACRIN NCI Community Oncology Research Program (NCORP) Research Base from 37 sub-affiliate Community and Minority/Underserved practices to ascertain whether 5A receipt differs for individuals with a smoking-related vs non-smoking-related tumor and whether patients' motivation and knowledge of the risks of continued smoking (0 to 10) differs by smoking-related tumor and 5As receipt. Eligibility criteria included a recent cancer diagnosis, English or Spanish-speaking, having smoked a cigarette in the past 30 days, and planning to receive treatment at a participating site. **Results:** 306 patients enrolled between 08/2019 and 12/2022 (70.9% female; 84.9% white non-Hispanic, 8.8% Black; 3% Hispanic; median age = 57 years); 51% had non-smoking-related tumors. Quit motivation was lower for non-smoking-related vs. smoking-related tumors (median= 7 (interquartile range (IQR): 5,9) vs median= 9 (IQR: 5,9) but knowledge of smoking risks (e.g., How much quitting improves chances of getting the full benefit of treatment) were similar (median = 10 (IQR: 8,10) vs 10 (IQR: 9,10)). Rates of Ask and Advise were high and similar for non-smoking-related and smoking-related tumors (Ask =94.7% vs 96.5% and Advise =89.3% vs 91.0%, respectively). However, rates of Assist were lower for non-smoking-related tumors vs. smoking-related tumors (e.g., talked about quitting =70.0% vs 79.2%; recommended cessation medication =63.3% vs. 72.2%) and Arrange follow-up =27.3% vs 37.5%. Quit motivation was lower for those who had not received the 5As (Ask median=7 (IQR 5,9) vs 9 (IQR 5,9); Assist talked about quitting median=7 (IQR: 5,9) vs 9 (IQR: 5,9) or Assist recommended cessation medication (median=6 (IQR: 5,9) vs 9 (IQR: 5,9)). **Conclusions:** Rates of assessing tobacco use and advising cessation at community cancer centers are high for addressing smoking but lower for actual assistance, particularly among patients with non-smoking-related tumors. This underscores the importance of clinicians discussing smoking, highlighting persistent smoking risks and the benefits of cessation, and providing actionable recommendations to reduce smoking risks for all patients. Clinical trial information: NCT03808818. Research Sponsor: U.S. National Institutes of Health.

Multidisciplinary prostate cancer consultation at home: Does the virtual visit platform adversely affect care for elderly patients or impact treatment recommendations? *First Author: Ryan P. Dorin, Hartford Healthcare, Hartford, CT*

Background: Amidst the COVID-19 pandemic, Hartford Healthcare (HHC) implemented a multidisciplinary virtual visit prostate cancer clinic (MDVV) to allow patients to receive cancer consultations at home. This clinic has shown significant logistical advantages for provision of coordinated cancer care. To evaluate concerns regarding usability of the telehealth platform for elderly patients, and the absence of in person physical exam at initial consult, we evaluated the MDVV in terms of patient satisfaction based on age, as well as for differences in treatment recommendations after patients were seen in-person at a pre-treatment follow up visit. **Methods:** Patients with newly diagnosed or progressive prostate cancer were offered a MDVV consultation. Those who assented had sequential virtual consultations with a urologic surgeon, a radiation oncologist, and a medical oncologist, followed by a group conference with all 3 specialists, and were guided through the visit by a nurse navigator. Patients then completed a 7 item satisfaction survey using a 5 point Likert scale evaluating their perception of the efficacy, efficiency, coordination, and overall value of the clinic. Responses were stratified by age group and compared. Chart review determined the impact of subsequent in person office visit on treatment recommendations, and the proportion of patients who underwent staging imaging according to NCCN guidelines. This was compared with a cohort of consecutive patients who completed traditional consults with two high volume prostate cancer surgeons immediately before the pandemic. **Results:** A total of 161 patients with newly diagnosed or progressive prostate cancer received a MDVV consultation from August 2020 – February 2023. Patient age ranged from 47-84 years (9% < 60 yrs, 52% 60-70 yrs, 34% 70-80 yrs, 5% >80 yrs). The median score for patient satisfaction on all 7 domains was 1 (strongly agree), and did not differ between age groups. There were no instances of a change in treatment recommendation after follow up in person office visit. While 100% of the MDVV cohort received multidisciplinary consultation before treatment, only 14/50 traditional cohort patients (28%) ultimately received the same (p<.001). 100% of MDVV patients underwent imaging according to NCCN guidelines, compared with 33/50 (66%) of traditional patients (p<.001). **Conclusions:** A virtual format for a multidisciplinary prostate cancer clinic is a logistically advantageous, effective means of offering in-home consultation to prostate cancer patients, leading to high patient satisfaction, regardless of age. The absence of in-person physical examination at initial consultation did not ultimately impact treatment recommendations. This format also improved access to multidisciplinary consultation and increased adherence to imaging guidelines. Research Sponsor: None.

The impact of the 4R Oncology model of team-based care delivery on timing and sequence of guideline recommended interdependent care in breast and lung cancers. *First Author: Raymond Liu, Department of Medical Oncology, Kaiser Permanente San Francisco Medical Center, San Francisco, CA*

Background: Team-based care improves quality, reduces fragmentation and lowers clinician burnout related to ad hoc care coordination. A key principle of teamwork is managing timing and sequence of interdependent care (Vogel JOP 2016). The 4R Oncology model featured by the NCI ASCO Teams project fosters effective teamwork by facilitating systematic timing / sequence of interdependent care (Trosman JOP 2016). 4R is Right Info / Care / Patient / Time. Using 4R, a large health system created a high-functioning care team and conducted optimizations of interdependent care in breast and lung cancers Oct 2020 - Dec 2021 (Liu JCOOP 2022). Optimizations focused on guideline-based care with suboptimal timing / sequencing in respective cancers. We present results of these optimizations. **Methods:** We compared data from electronic health record on timing and sequence of care between historical control cohorts of patients who received care pre-4R (breast n=270, lung n=173) to the post-optimization 4R cohorts (breast n=208, lung n=139). Patient and tumor characteristics between control and 4R cohorts in both breast and lung cancers were similar. **Results:** Timing and sequence of care for 5 of the 6 breast cancer metrics and all 6 lung cancer metrics was significantly improved between the control and 4R cohorts. Despite significant increase, the rate of timely care for some metrics remained low, such as referrals based on distress screening in breast cancer and palliative care in lung cancer. **Conclusions:** The 4R Oncology model is effective in applying teamwork principles and improving timing and sequence of guideline-based care. Opportunities for further improvement exist to expand the benefit of 4R to a higher number of patients. A learning system being established in our institution will inform iterative care optimizations. Research Sponsor: Genentech, Inc.

English- and Spanish-preferring patient perspectives on managing acute care needs at two disparate health systems. *First Author: Beverly Kyalwazi, University of Texas Southwestern, Dallas, TX*

Background: Although nearly every participating provider group in Medicare's Oncology Care Model sought to reduce emergency department (ED) use by their patients with cancer, few achieved this. Despite growing spread of specialized oncology urgent care clinics (OUCC) as an ED-alternative to treat commonly anticipated treatment-related symptoms, these clinics are underused. The University of Texas Southwestern (UTSW) and Dallas County Safety-net (Parkland Health) have run OUCCs since 2015. Parkland patients use the ED twice as often as UTSW patients in the first 6 months after cancer diagnosis. Utilizing semi-structured interviews, we investigated oncology patient perspectives on acute care needs and ED decision-making in both systems among English and Spanish-preferring patients. **Methods:** We interviewed 24 UTSW and 16 Parkland oncology patients (5 English-preferring, 11 Spanish-preferring). UTSW is an urban regional academic referral center serving nearly 8 million people with a cancer patient population that is 35% nonwhite and 7% Medicaid or uninsured. Parkland serves patients in Dallas County including a cancer patient population that is 77% nonwhite and 80% with Medicaid or county charity care (uninsured). Translated transcripts were analyzed using iterative thematic analysis and the constant comparative method. We evaluated decision-making, attitudes, beliefs, and barriers to access that influenced decisions to present to the ED across a diverse patient population. **Results:** Patients in both health systems endorsed that they did not receive adequate information about expected side effects from cancer treatment. UTSW patients described direct access (e.g., personal cell phone numbers) to their oncologist, whereas Parkland patients commonly relied on non-clinician family to triage symptoms. Parkland patients reported experiencing barriers to outpatient care (lack of insurance, language barriers, and limited access to outpatient care), and described an acculturation to visiting the ED for acute care needs. When patients called a clinician for triage advice, they were often referred to the ED. Overall, patients were largely unaware of OUCCs and a 24/7 telephone triage line, but were very interested in accessing the OUCC to avoid prolonged wait times and exposure to infectious pathogens in the ED. **Conclusions:** Among ED-visiting patients with cancer, we found notable disparities in rapid informal access to clinicians between oncology patients receiving care through UTSW compared to Parkland. Highlighting the available 24/7 phone line as part of patient counseling on treatment side-effects might mitigate this disparity in access, increase utilization of the OUCCs, and reduce low-acuity ED visits in both health systems. Patient perspectives provide valuable insights on how to better integrate care delivery innovations for this high-risk population. Implementation of a multi-cancer early detection (MCED) test using a centralized model within (w/i) a multi-state health system. *First Author: Gautum Agarwal, Mercy Hospital St. Louis, St. Louis, MO*

Background: Cancer is the second leading cause of death globally. Currently, USPSTF recommends screening for only 5 (breast, cervical, colorectal, lung [high-risk], prostate [individualized basis]) cancers, but ~70% of cancer-related deaths are from cancers without recommended screening. Galleri (GRAIL, LLC, Menlo Park, CA), an MCED test, that uses a cell-free DNA-based targeted methylation assay and machine learning classifiers to detect a shared cancer signal and predict the cancer signal origin is available for use as a complement to existing screening tests. We present a model of centralized MCED test implementation w/i a multi-state health system. **Methods:** From 11/2021-7/2022, clinical and operational leadership w/i the Mercy Health System (headquartered in St. Louis, MO), including 44 acute and specialty hospitals with over 4000 integrated providers and 44000 coworkers in 5 states (MO, KS, AR, OK, IL), created an MCED test implementation plan for their health system. **Results:** A model with centralized navigation was developed such that patients (pts) and providers contacted a singular team (MCED team) w/i the Mercy Precision Medicine Division using telemedicine to order an MCED test and navigate processes. In the 2 months prior to and after launch (7/12/2022), 12 medical education sessions were held for various groups w/i the health system, including the centralized MCED team, leaders of subspecialty departments, and all primary care providers, to inform on the MCED test implementation plan. In this model, access to MCED testing commences in 2 ways: (1) pts register through an online form or (2) providers w/i the health system submit a referral to the MCED team through the electronic medical record system. Pts are then contacted by a nurse practitioner on the MCED team for pretest counseling w/i 2 business days. If the pt is still interested after counseling, an MCED test is ordered. Pts go to 1 of 11 Mercy labs to have their blood drawn for MCED testing. "Cancer signal detected (CSD)" test results are given to a specialized navigator who helps schedule diagnostic testing and initial appointments with specialists and coordinates follow-up care and treatment (tx) w/i the health system. Early analytics show that from launch to 1/31/2023, there were 3777 total referrals (2931 pt, 846 provider) that led to 925 MCED test orders, of which 6 had a CSD result. Median time from a CSD test result to pt notification was 22.8 hours, to initial diagnostic evaluation was 3.1 days, and to a cancer diagnosis was 8.7 days. Median time from cancer diagnosis to initiation of tx or first postdiagnosis specialist visit was 33 days. **Conclusions:** This model allowed for efficient time to diagnosis and tx or triage of eligible-risk pts using an MCED test and is an example of how a healthcare system can incorporate and scale the implementation of the MCED test into clinical practice. Poster Session

Assessing mail-in cryopreservation for fertility preservation. *First Author: Andre R Belarmino, UCLA Health, Los Angeles, CA*

Background: Over 90% of oncologists agree that sperm banking should be offered to all men at risk of subfertility associated with cancer treatment, but fewer than 50% bring up the topic. Barriers cited include lack of time for the discussion, perceived high cost, and lack of convenient facilities. The advent of mail-in semen analysis (SA) testing and cryopreservation may improve access to this service via lower patient cost, decreased required oncologist logistical support, and home rather than local lab collection. That said, average sperm recovery rate after sample thaw is ~50% with immediate banking, and sperm recovery rate after delayed cryopreservation with a mail-in approach remains unknown. **Methods:** This is a prospective preliminary study assessing freeze-thaw total motile count at 3 time points of cryopreservation: upon receipt of sample, at 24 hours, and at 48 hours post collection. We collected 39 fresh semen samples from 13 healthy adult volunteers. Samples were diluted with 5mL of Fellow Health preservation solution and analyzed (World Health Organization guidelines V5). Samples were divided into 3 aliquots: Aliquot #1, T0 was immediately frozen with equal part cryoprotectant. Aliquot #2, T24 and aliquot #3, T48 were left at room temperature for 24 and 48 hrs respectively, analyzed, and then frozen. Aliquots were then thawed on a heat block at 37C for 10 minutes and analyzed. **Results:** Baseline SA values were: volume 3.3ml +/- 1.3, concentration 138.3 +/-57.4 x 10⁶, motility 49% +/-6%; Total Motile Count (TMC) 213 +/- 110 million. TMC was the primary endpoint as measured by baseline semen volume, concentration, and motility at 3 time points (T0, T24, T48). The average loss from freeze/thaw in TMC at T0 was 45%, at T24 was 55% relative to T24 pre-freeze, and at T48 was 59% relative to T48 pre-freeze (p = 0.013). On average, samples with starting TMC between 50-100 million had enough motile sperm for six intrauterine insemination (IUI) cycles when frozen and thawed at T0, two at T24, and two at T48. Samples with starting TMC between 100-200 million had enough motile sperm for 16 IUI cycles when frozen and thawed at T0, eight at T24, and four at T48. Samples with starting TMC > 200 million had enough motile sperm for 42 IUI cycles when frozen and thawed at T0, 21 at T24, and nine at T48. All samples had ample viable cells (> 50,000) at all three time points for in vitro fertilization (IVF). **Conclusions:** Mail-in cryopreservation using our improved methodology may increase access to this service for oncological patients while still facilitating reasonable assisted reproductive technology care relative to in-person cryopreservation. Differential responses to systemic therapy among patients who are financially fragile and receiving Medicaid: Results from ePRO and biometric monitoring study. *First Author: Scott David Ramsey, Fred Hutchinson Cancer Center, Seattle, WA*

Background: Cancer patients with Medicaid insurance have a 50% higher risk of unplanned ED admissions during systemic chemotherapy compared to commercially insured cancer patients. In a prospective study of an ePRO app and smartwatch to remotely monitor patients receiving anti-cancer therapy, we compared symptoms and biometric data among financially fragile (able vs. not to come up with \$2000 in 30 days for an unexpected expense) Medicaid enrollees and commercially insured patients with solid tumor malignancies. **Methods:** The study was conducted at 3 community oncology practices in WA state. (ML41539, ISRCTN25569053) The ePRO had 15 common treatment-related symptoms from the PRO-CTCAE survey. 30 patients initiating systemic treatment wore a Samsung Galaxy 3 watch and completed the ePRO daily on study provided smartphones for 2 weeks. EPRO app adherence (ratio of completed to expected entries) was 91%. Smartwatch adherence (ratio of days with any biosensor data to number of days expected) was 86%. Composite symptom scores were calculated from ePRO responses using a published mapping algorithm (Range 0-3). Repeat symptoms, number of unique symptoms scores >1, and average heart rate (HR) were compared. **Results:** Participants' average age was 60 (68% female; 75% no comorbidity, 45% metastatic, 10% Medicaid, 13% reported financial fragility). Treatments: chemotherapy only (56%); immunotherapy only (11%); combination therapy (33%). Financially fragile patients had significantly higher average HR, unique symptoms, and repeat symptoms (e.g., >1 day with symptoms). The average composite symptom score over 2 weeks was significantly higher for Medicaid enrollees, and trended higher for financially fragile patients. 16% of daily composite symptom scores recorded by Medicaid patients were 2 or greater, versus 7% for non-Medicaid patients (p<0.001). **Conclusions:** Medicaid-insured and financially fragile patients may have more adverse responses to systemic therapy compared to more advantaged patients. If supported in larger studies, the findings may have profound implications for research aimed at improving clinical management in financially disadvantaged cancer patients. Research Sponsor: Genentech/Roche.

Team-based versus technology-based supportive cancer care (SCC): Assessment of implementation across 24 different clinical settings. *First Author: Sacha Moufarrej, Division of Oncology, Stanford University School of Medicine, Stanford, CA*

Background: Advanced care planning and symptom management, otherwise known as Supportive Cancer Care (SCC), are fundamental services that patients should receive after a cancer diagnosis. We launched a 24-clinic site cluster randomized clinical trial in July 2022 comparing two SCC delivery approaches: a team-based intervention in which patients engage in advanced care planning and symptom assessments with a lay health worker versus a technology-based intervention in which patients receive internet-based SCC education. The preliminary aim of this study is to evaluate clinic characteristics that may impact implementation and effectiveness of these SCC delivery approaches. **Methods:** We invited study staff at all 24 sites, including community oncology clinics, Kaiser Permanente clinics, Veterans Affairs facilities, safety-net hospitals, and academic centers, to participate in a survey and semi-structured interview. We used Consolidated Framework for Implementation Research (CFIR) and Reach, Effectiveness, Adoption, and Implementation (RE-AIM) frameworks to assess organizational culture, readiness, facilitators, and barriers to SCC delivery. Surveys were analyzed using descriptive statistics; interviews were analyzed using thematic analysis. **Results:** Among 30 interview participants across 24 clinics, of which 23 completed surveys, 9 (30%) were clinic principal investigators, 11 (36.7%) were research staff, and 10 (33.3%) were implementation staff. Survey respondents implementing team-based SCC were more confident that their approach: 1) accounted for patient care preferences (93.3%) and 2) had strong evidence (86.7%) than respondents implementing technology-based SCC (62.5% and 25.0% respectively). More respondents implementing team-based SCC expressed confidence in organization leadership (100%) and adequate resources for SCC (86.7%) than respondents implementing technology-based SCC (75.0%). Among interview participants, team-based approaches for SCC delivery were considered more effective, as they could: 1) reduce time burden for clinicians 2) tailor delivery to patient preferences; and 3) increase patient support. Participants believed that team-based approaches would also be more difficult and costly to implement. Barriers to both SCC delivery approaches include: a) limited technology access for patients, b) competing organization priorities which limit staffing and funding for SCC, and c) information overload for patients and caregivers. **Conclusions:** Implementation of SCC delivery approaches is needed but requires organizational leadership and implementation resources. Team-based approaches are considered more effective, but barriers such as staffing and funding may inhibit the scalability. Implementation evaluations are crucial to understand real-world applicability and scalability of SCC delivery. Research Sponsor: Patient-Centered Outcomes Research Institute (PCORI).

Impact of geography on receipt of medical oncology consultation and neo-adjuvant chemotherapy for triple negative and HER2 positive breast cancer. *First Author: Elliott Kenneth Yee, University of Toronto, Toronto, ON, Canada*

Background: Consensus guidelines recommend consideration of neoadjuvant chemotherapy (NAC) for most patients with early-stage triple negative (TN) and HER2 positive (HER2+) breast cancer. Based on our previous work, most patients are not seen by a medical oncologist prior to surgery and do not receive NAC. Although potential barriers are not well understood, distance to cancer centres has been shown to mediate medical oncology referral and use of systemic therapy for other malignancies. We therefore aimed to characterize the impact of region of residence and cancer centre proximity on receipt of pre-treatment medical oncology consultation and NAC for patients with TN and HER2+ breast cancer. **Methods:** Using linked administrative healthcare datasets in Ontario, Canada, we performed a retrospective population-based geographic analysis of women diagnosed with stage I-III TN or HER2+ breast cancer from 2012-2019. Outcomes were pre-treatment medical oncology consultation and initiation of NAC. We created choropleth maps to assess the spatial distribution of outcomes across census divisions, displaying cancer centres and outcomes by colour gradient using geographic information system analysis. To assess the relationship between distance to the nearest cancer centre and outcomes, we performed a multivariable regression analysis adjusted for sociodemographic and clinical factors, including tumour extent and nodal status. **Results:** Within the cohort of 12,881 patients, there was no statistically significant relationship between incremental distance to the nearest cancer centre (≤ 5 vs. 5-10, 10-25, and ≥ 25 km) and rate of medical oncology consultation or receipt of NAC. Mapping analysis demonstrated high interregional outcome variability, ranging across census divisions from 12.2% to 64.3% for medical oncology consultation rate, and 9.3% to 64.3% for NAC rate. 77.7% of patients referred to medical oncology received NAC. **Conclusions:** Among patients with TN and HER2+ early breast cancer, rates of medical oncology consultation and NAC were not significantly impacted by distance to cancer centres but varied highly by region. This variability suggests that regional and/or provider practice patterns, rather than distance, may underlie discrepancies in referral for NAC. These findings can inform further studies and interventions aiming to improve equitable access to NAC for patients with TN and HER2+ breast cancer. Dose rounding bevacizumab and its biosimilars to reduce drug waste in the oncology care model in a community oncology network. *First Author: Puneeth Indurial, The U.S. Oncology Network, McKesson, The Woodlands, TX*

Background: The Oncology Care Model (OCM) was a 6-year long Medicare value-based care (VBC) program that rewarded practices for decreasing TCOC compared to a benchmark price, while maintaining high-quality cancer care. Drug waste from partially used single dose vials (SDV) of expensive anti-neoplastic agents is a leading contributor to avoidable Total Cost of Care (TCOC) expenditures for payers. Dose rounding (DR) of biological anti-neoplastic agents, using recommendations (https://www.nccn.org/docs/default-source/clinical/order-templates/hopa.pdf?sfvrsn=3af91118_6) from the Hematology Oncology Pharmacists Association (HOPA) and endorsed by the National Comprehensive Cancer Network (NCCN), is a standard approach to mitigate the impact of drug waste. Many of the practices in The US Oncology Network (The Network) adopted a DR program for biologic agents in 2018 as a strategy to reduce drug waste and TCOC. We studied the impact of a DR initiative targeting bevacizumab and its biosimilars (B+B) on TCOC and drug waste expenditures for The Network practices participating in the OCM. **Methods:** Claims data for 14 practices in The Network participating in the OCM were assessed. Drug administration data for B+B was used to evaluate drug waste, total dose, TCOC, DR and the financial impact of drug waste reduction on TCOC from 2017 to 2021. **Results:** In 2017, prior to implementing DR, an average of 5.3% (range 4.6% to 5.5%) of the total dose of B+B was wasted, with ~25% of B+B administrations having waste in excess of 10% of the total dose. Implementation of the initiative led to a reduction of waste on 30% of the total administrations of B+B across 14 OCM participant practices in The Network. As a result of DR, B+B drug waste decreased by 55% to an average of 2.5% (range -2.3% to 2.7%) of the total dose in 2021. Decreasing drug waste resulted in TCOC reduction of approximately \$100 per member episode per month (0.97% of TCOC) for episodes with B+B administrations in the OCM. The highest waste reduction was seen with B+B administered for treatment of gastrointestinal cancers (colon, rectal, anal, gastroesophageal, or pancreatic cancers) compared to other cancer types (lung, brain, ovarian, etc.), and for B+B administrations where drug waste was greater than 10% of the total dose (~50% reduction). **Conclusions:** Drug waste contributes avoidable expenditures to the TCOC. Implementing strategies such as DR can offset the impact of drug waste and offer meaningful TCOC savings for VBC programs such as the OCM. A similar DR approach may be adopted for other high-cost biologic agents where drug waste results from partial use of SDVs. Research Sponsor: None.

Implementation of a streamlined prior authorization process to improve cancer care delivery. *First Author: Aarti Sonia Bhardwaj, Division of Hematology and Medical Oncology, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Prior authorizations (PAs) for systemic cancer treatments are increasingly becoming a barrier to timely quality cancer care delivery. There is an extraordinary administrative burden placed on clinicians to complete peer to peers (P2P) and appeals when authorization specialists are unable to identify appropriate clinical data in the EHRs. This leads to delays in care, staff burnout and loss of revenue. At our tertiary academic cancer center, in partnership with our cancer registry and Epic teams, we propose shifting the clerical work required for intravenous chemotherapy PAs from clinicians to certified tumor registrars (CTRs) to improve documentation needed for authorization specialists and decrease PA associated clinician burnout. **Methods:** Clinicians first place the treatment plan order which goes to the CTR work queue. We leveraged the Epic staging smart form to consolidate and auto-populate a list of common data elements needed for PA (performance status, cancer biomarkers, stage, line of treatment, and goals of treatment). The CTRs then complete and validate all elements necessary for authorization specialists to obtain the PA. Our primary outcomes include: average monthly number of intravenous chemotherapy authorizations pending review (including P2P, appeals and authorizations requiring other clinical interventions from the primary team) during a pre (9/1/2021-9/30/22) and post-implementation (11/14/22-1/30/23) period. Analyses were conducted using descriptive statistics. **Results:** The average monthly number of authorizations pending review was 332 pre-implementation and 227 post-implementation, which is a 32% reduction. To account for temporal changes, when comparing December 2021 to January 2022 vs December 2022 and January 2023, the average number of referrals pending review was 276 vs 227 which is an 18% reduction. First line treatment regimens accounted for most regimens requiring review; 28% and 27% pre-implementation and post-implementation, respectively. Non-chemotherapeutics like lanreotide and feraheme had the highest pending review status pre and post-implementation respectively. Among chemo/immunotherapeutics, Nivolumab and Trastuzumab deruxtecan had the highest pending review status pre and post implementation, respectively. GI regimens had the highest number of regimens requiring review accounting for 17% vs 22% of all referrals pre and post implementation, respectively. **Conclusions:** By leveraging technology and increasing efficiencies of existing non-clinical staff workflows, we significantly decreased the number of ambulatory chemotherapy PAs that required further clinical review including P2P and appeals thereby improving efficient care delivery. Next steps include evaluation of sustained improvement, time to final authorization, revenue analysis and the impact on the well-being of clinicians. Best practices study to enhance the quality of multi-disciplinary teams in lung cancer care. *First Author: Marcos Gallego Llorente, Vintura, Baarn, Netherlands*

Background: Regular meetings at multi-disciplinary teams (MDTs) constitute a key moment in the care pathway in lung cancer, where physicians collectively discuss patient cases and decide on treatment plans. MDTs arguably increase the volume of patients treated, improve diagnosis, and positively impact on survival. However, the way MDTs are organized and function is variable across hospitals, countries and continents. Variations in MDT processes may lead to sub-optimal outcomes, such as inconsistencies on the numbers of patients treated with curative intent as well as variable 5-years survival rates for lung cancer. The importance of MDTs is ever increasing, as the therapeutical landscape is getting more complex every year, and treatments are evolving from a one-size-fits-all to a personalized approach. **Methods:** In this study, we gather the best practices in MDT processes, capabilities and governance in 24 leading hospitals throughout Europe and Canada. We map the MDT practices of each hospital into a coherent framework, and identify KPIs and best practices by conducting semi-structured interviews with health care professionals in each hospital and performing workshops with the entire MDT team. The primary research focuses on five key categories: access to the MDT, processes, technology (such as EMR, data sharing tools, and artificial intelligence), culture and capabilities. **Results:** We see a high variation in the way MDTs are organized, in time for discussion per patient, in the model of care and current MDT practices across the 24 hospitals in this project, along our five identified categories. We developed an MDT maturity model where we score individual elements within these five categories to identify the hospitals with the best MDT practices, and a total of 23 key success factors along the MDT process. The maturity model and the key success factors can be used as a self-assessment tool for MDT-teams for continuous quality improvement. **Conclusions:** MDTs have the potential to be a standard part of the patient care pathway, where excellence is consistently achieved when discussing patient cases. This work has identified the practices that are done best in leading hospitals and that have the potential to be progressively adopted. Furthermore, we see that the potential of decision support tools and other artificial intelligence is rarely leveraged by MDTs. Research Sponsor: AstraZeneca.

Real-world experience of an in-house dihydropyrimidine dehydrogenase (DPYD) genotype test to guide fluoropyrimidine (FP) dosing at a multisite cancer hospital. *First Author: Jai Narendra Patel, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: FPs, including 5-fluorouracil and capecitabine, are widely used to treat solid tumor malignancies like gastrointestinal (GI) cancers. One-third of patients (pts) develop severe toxicities which may lead to treatment delays or hospitalization. Toxicities can be partly due to genetic variations in *DPYD*. Herein, we describe the implementation of an in-house *DPYD* test and its impact on FP dosing at a multisite cancer hospital. **Methods:** This is an observational study of pts starting or continuing FP-based chemotherapy who received *DPYD* testing as part of routine care. Buccal swabs were collected in clinic and sent to an in-house lab for genotyping using a polymerase chain reaction-based Drug Metabolizing Enzyme assay that interrogates all 5 variants with moderate-to-strong evidence according to the Clinical Pharmacogenetics Implementation Consortium (CPIC) (c.1905+1G>A, c.2846A>T, c.1679T>G, c.1236G>A and c.557A>G). Phenotype translations and dosing were based on CPIC guidelines. Test results and dose recommendations were uploaded to the electronic medical record (EMR) and emailed to the care team. In April 2022, pre- and post-test EMR alerts were built to prompt test ordering and dose modifications. The primary objective was to evaluate the proportion of *DPYD* variant carriers in tested pts receiving FP. Secondly, we evaluated turnaround time and impact on FP dosing. **Results:** From March 2020-December 2022, 491 pts across 14 clinics received *DPYD* genotyping (54% male, 74% White, 20% Black, median age 53 years). GI cancers (~50% colorectal) represented 90% of the diagnoses. The median lab turnaround time was 3 (IQR 2-6) days. Pretreatment testing was ordered in 389 (79%) pts, of which 360 (93%) had results before cycle 1. Overall, 30 pts (6.1%) were heterozygous carriers (4.9% in pretreatment and 10.8% in reactive testing groups). Variants observed were c.1236G>A (n=13), c.2846A>T (n=8), c.1905+1G>A (*2A) (n=4), c.557A>G (n=4), and c.1679T>G (*13) (n=1). FP dose was modified in 27 (90%) pts (reduced in 25, avoided in 1, discontinued in 1). Of 19 carriers with pretreatment testing, 17 (90%) received an upfront dose reduction (mean reduction 42%; 3 had subsequent dose escalations); 1 avoided FP and 1 declined chemotherapy. Of 11 carriers with reactive testing, 9 had dose reductions (mean reduction 39%) and 2 discontinued FP due to toxicity. The mean FP dose intensity at cycle 1 was 56% in pretreatment carriers, 97% in reactive carriers, and 94% in wild type pts. **Conclusions:** *DPYD* genotype-guided FP dosing is feasible at a multisite cancer hospital. In-house rapid turnaround *DPYD* testing identified variant carriers and resulted in treatment/dose modifications for most carriers, potentially avoiding or mitigating severe toxicities and/or hospitalization, particularly with pretreatment testing. Toxicity evaluation is ongoing. Research Sponsor: Heineman Foundation of New York.

Outpatient practice utilization for CAR-T and T cell engager in patients with lymphoma and multiple myeloma. *First Author: Radhika Bansal, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: FDA-approved chimeric antigen receptor T-cell (CAR-T) and bispecific T cell engager (TCE) therapy are most commonly managed inpatient. Here we report our experience with hospital-based outpatient (HBO) management of patients (pts) receiving FDA-approved CAR-T or TCE and a predictive model for increased risk of early hospitalization (≤ 3 days post CAR-T). **Methods:** We reviewed the outcomes of pts who received FDA-approved CAR-T (axi-cel, brexu-cel, ide-cel, cilta-cel) or TCE (teclistamab) in the HBO unit between 3/2021 and 1/2023 at Mayo Clinic, Rochester. **Results:** HBO is closely integrated with inpatient practice and includes the same specialty trained clinical team. It is the first point of contact 24/7 for pts and triage evaluations. CAR-T and TCE are given on HBO followed by monitoring per REMS and as clinically needed until admission criteria is met. Remote patient monitoring (RPM) tools were used as part of outpatient monitoring. Out of 169 CAR-T pts, 87 (51%) were dosed with new indication/products (follicular lymphoma, mantle cell lymphoma, myeloma). Among those, 80 (92%) pts were dosed outpatient, among whom 21 (27%) were never hospitalized. CRS and ICANS incidences were comparable to that reported in registration studies. Median time to first admission from CAR-T infusion was 1 day (range, 0-9), with 31% (n=18/59) of admissions after day 3 post infusion. The most common cause of hospitalization was fever (n=40, 59%). Median length of hospital stay was 4 days (range, 1-49). Median time to tocilizumab (n=45, 80%), steroid (n=1, 2%), escalation of oxygen support (n=7, 12%), vasopressor (n=2, 3%), ventilator (n=1, 2%), hemodialysis (n=1, 2%) and ICU transfer (n=3, 5%) was 1 day (range, 0-31) after first admission. Use of bridging therapy, elevated CRP and LDH were predictive of early admission (ROC AUC 0.62). Four pts received teclistamab on HBO and enrolled in RPM. Data from more pts will be reported at ASCO. **Conclusions:** Our expanded study in CAR-T and TCE confirms that HBO is feasible and that CAR-T and TCE can be safely dosed outpatient. Approximately 31% of pts were admitted after 3 days from CAR-T infusion, and 27% of our pts were never admitted. Variables associated with aggressive disease can predict early hospitalization in pts receiving FDA-approved CAR-T. Extension of HBO practice to TCE is feasible. Research Sponsor: None.

Decreasing the burden of febrile neutropenia through dynamic remote patient monitoring: The DEFENDER program. *First Author: Joshua Pritchett, Mayo Clinic, Rochester, MN*

Background: Ambulatory management of select patients with febrile neutropenia (FN) may substantially decrease patients' burden of illness and improve their quality of life, and is recommended by American Society of Clinical Oncology (ASCO) guidelines. However, in the United States, inpatient management remains the universal standard. We hereby report the health care utilization associated with the DEFENDER remote patient monitoring (RPM) program, which leverages technology and virtual centralized nurse monitoring to facilitate ambulatory management of FN as an alternative to hospital-based care. **Methods:** Adult patients with cancer hospitalized with FN were assessed daily for eligibility to participate in the DEFENDER program. Eligibility criteria included MASCC score > 21 (per ASCO guidelines), and clinical judgment of the attending provider. Patients receiving cellular therapy (CAR-T, BMT) in the prior 100 days were excluded. Eligible patients agreeing to participate in the 30-day program were provided a kit containing cellular-enabled, pre-connected devices to facilitate monitoring, including twice-daily vital signs and electronic symptom questionnaires. Data were EHR-integrated in real-time and embedded decision trees facilitated alerts for adverse trends. RPM nurses responded to alerts and escalated care as indicated by pre-specified care pathways. Program assessment was performed at 20 weeks after full implementation. The primary outcome was the mean proportion of evaluable days spent inpatient (mPEDI) within 30 days of eligibility compared between those who participated in the program vs. those who declined. **Results:** 35 patients were offered participation in the DEFENDER program. Of these, 17 participated and 18 declined. Baseline characteristics are provided. Participating patients experienced mPEDI of 6.9% (Standard Error [SE], 3.7%), compared with 17.7% (SE, 3.6%) for patients who declined participation. Due to small sample size, this difference (10.8%) did not reach statistical significance (Wilcoxon Rank Sums p-value, 0.15). 30-day mortality did not differ between groups. Mean inpatient days were also lower for patients participating in the program. Additionally, when readmitted, patients participating in RPM experienced a trend toward shorter length of stay and lower rates of intensive care unit utilization. **Conclusions:** A trend towards decreased burden of inpatient care is evident among patients participating in the DEFENDER program. Further studies are warranted to assess comparative effectiveness of this model vs usual care. Research Sponsor: None.

Outcomes on the hematology malignancy hospitalist service: A model for inpatient care. *First Author: Alaina J. Kessler, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: The use of oncology hospitalists has been shown to improve quality outcomes among hospitalized patients, though there is limited data on the use of hospitalists to care for patients with hematologic malignancies. The Hematology Malignancy Hospitalist Service (HMHS) was created in efforts to decrease patient volume on the primary hematology malignancy services at an academic hospital. Patients with active oncologic issues requiring specialty oncology management were cared for by oncologists on the primary leukemia, lymphoma, and myeloma services while patients with acute medicine-related issues were cared for by medicine hospitalists on HMHS. **Methods:** Criteria were established based on level of acuity and reason for admission to HMHS, which was comprised of a hospitalist attending and nurse practitioner. New admissions to HMHS were evaluated by the primary hematology malignancy service team as consultants and remained involved in patient care as deemed appropriate. Oncology attendings continued to care for patients on the primary leukemia, lymphoma, and myeloma services. We conducted a retrospective analysis from 6/28/21 through 6/30/22 excluding 1/2/22 to 2/6/22 when HMHS was paused due to the COVID Omicron surge. We compared length of stay (LOS), discharge before noon (DBN), and 30-day readmission rates of patients admitted to the HMHS service and those admitted to the primary services to assess for differences in outcomes. **Results:** There were a total of 95 (12%) admissions to HMHS and 669 (88%) to the primary services; 35.6% patients were white, 21.7% Black, and 10.3% Asian and 26.3% patients identified as Hispanic. The average age was 61.6 years. The average LOS in days was 9 ± 9.09 , 16.03 ± 14.96 , 11.41 ± 14.88 , and 12.68 ± 11.40 ($p = 0.005$) for patients admitted to HMHS, leukemia, lymphoma and myeloma services, respectively. DBN on HMHS (6%) was similar to the leukemia service (6%) and improved compared to the lymphoma service (11%) and myeloma service (7%); $p = 0.66$. The 30-day readmission rate was also improved on HMHS (12%) compared to leukemia (21%), lymphoma (21%), and myeloma (18%); $p=0.25$. **Conclusions:** The development and implementation of a medicine hospitalist-driven hematology malignancy service significantly improved LOS without a negative impact on 30-day readmission rates when compared to a primary hematology malignancy service model. The addition of medicine hospitalists to the inpatient care of patients with hematologic malignancies demonstrates improvement in healthcare utilization. This is an important area for future evaluation to determine the most appropriate patients to admit to these services and assess other important outcomes. Research Sponsor: None.

Overcoming barriers and improving genetic testing completion rate for hereditary cancer in an underserved population at a large safety net hospital. *First Author: Autumn Vara, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Genetic testing is a routine practice in oncology care as outcomes of germline testing may impact surgical recommendations, open therapeutic options, as well as inform patients and family members of their cancer risks. Lyndon B. Johnson Hospital (LBJ) is a safety-net hospital that mainly serves low income and uninsured patients (pts), and LBJ oncology clinic is staffed by MD Anderson Medical Oncology faculty and fellows. Pre-test counseling with a certified genetic counselor was offered once a week by referral and transitioned to virtual template at the start of the COVID-19 pandemic. This transition in addition to barriers unique to the underserved population led to a decrease in test completion rates and introduced a backlog as patients were re-referred for completion of testing. We discuss our strategies in decreasing a 9-month backlog over the course of one year. **Methods:** Re-introduction of an on-site general oncology genetic counselor twice a week was implemented in addition to maintaining the virtual platform once a week. The on-site genetic counselor was embedded in the physician's clinic and rotated to ensure coverage for all clinic days. Manual chart review was conducted by on-site genetic counselor and patients were rescheduled to in-person template in conjunction with other same day appointments to improve no-show rate. Patients electing to proceed with germline testing signed appropriate written consent, patient assistance financial forms, and submitted samples prior to leaving clinic. **Results:** From January 2019 through December 2022, a total of 1716 patients including re-referrals were scheduled and 728 patients seen. When genetic counseling service was available as referral outside of oncology clinic, the completed visit rate was 48%, which decreased to 26% in 2020 after COVID-19 transition to virtual. The visit completion rate did improve to 36% in 2021 but the most improvement was seen with genetic counselor embedded in physician clinic with 69% in 2022. The number of genetic testing also increased with 79 ordered in 2021 to 211 ordered in 2022. Of those patients who met national criteria for germline testing and expressed verbal consent, 47% completed germline testing in 2021 which improved to 83% in 2022. **Conclusions:** In our experience, telehealth genetic services is not ideal in the underserved population as there are unique barriers. On-site embedded genetic counseling helps eliminate barriers by allowing patients to complete all steps necessary prior to leaving clinic, leading to successful test completion rates and improved quality of care. Research Sponsor: None.

	2019	2020	2021	2022
	In-Person (referral)	Virtual	Virtual	Virtual / In-Person (Embedded in Physician Clinic)
Completed Visits (%)	48%	26%	36%	34% / 69%
Absolute Number of Genetic Tests Ordered	NA	NA	79	211
Completed Genetic Tests by Eligible Pts (%)	NA	NA	47%	83%

Are we ready to mitigate time toxicity of cancer care? Oncologists' perceptions on digital interventions to fast-track cancer care. *First Author: Erin Mary Bange, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Patients spend substantial time receiving cancer care, and innovative strategies to decrease time toxicity are needed. We have shown that a text-based triage can identify patients tolerating checkpoint inhibitors (ICI) without toxicity who could safely fast-track directly to ICI infusion. However, oncologists' readiness to implement this strategy is unknown. **Methods:** This sequential mixed-methods study included oncologists treating solid-tumor patients with ICIs at Penn Medicine. In phase 1, participants completed a 26-item survey assessing readiness to implement a digital strategy, using the Acceptability, Appropriateness, and Feasibility of Intervention Measures (AIM, IAM, and FIM), as well as perspectives of time toxicity. Each measure consisted of 4 items on a 5-point Likert scale for which means (M) and standard errors (SE) were calculated. In phase 2, a focus group (FG) was led by Penn's Mixed Methods Research Lab to better understand the barriers and facilitators to implementing a digital strategy among oncologists. The FG transcript was reviewed and coded in NVivo with identification of emerging themes. **Results:** 32 faculty members were eligible, of whom 17 (53%) completed the survey and 14 (44%) participated in the FG. Respondents were 53% (n=9) female, 65% (n=11) White, and 53% (n=9) full-time clinicians (non-research faculty); 41% (n=7) reported > 10 years in practice. Quantitative analysis identified infusion (n=11, 65%), commuting (n=11, 65%), and waiting for the physician (n=8, 47%) as the top 3 sources of time toxicity among oncologists. Most agreed that novel interventions are needed to improve the patient-experience (M=4.9, SE=0.08) on a Likert scale of agreeability (1-5, 5=strongly agree). On this scale, our text-based digital strategy to allow patients to fast-track care was found to be acceptable (M=3.8, SE=0.1), appropriate (M=3.8, SE=0.1), and feasible (M=3.9, SE=0.1). Qualitative analysis revealed the following major themes: 1) barriers to implementing a text-based digital strategy including a) health system built for clinician convenience, b) concern with being viewed as "slackers" by administration, c) concerns about overlooking symptoms, d) difficulties identifying appropriate patients, and e) communication issues; and 2) facilitators to adopting this new strategy including a) openness to change, 2) utilizing strengths of care team, and 3) optimism of this digital tool. **Conclusions:** Oncologists recognize time toxicity is a common complication of cancer care. Digital interventions to triage patients who are not experiencing treatment toxicity—thereby reducing time toxicity—were deemed acceptable, appropriate, and feasible. To integrate this technology, further research is required to address key barriers to uptake in routine care. Antineoplastic and immunomodulating agent effects on immunization outcomes. *First Author: Jacob New, Department of Medicine, Scripps Clinic, La Jolla, CA*

Background: Oncologists face a challenge in advising patients on the infection risk associated with antineoplastic and immunomodulating medications, as the extent of risk posed by each medication is not well understood. The rapid administration of COVID-19 immunizations across the population provides an opportunity to assess the influence of immunosuppressing medications on infection outcomes post-vaccination. This study evaluated the effect of antineoplastic and immunomodulating medications as classified by the World Health Organization Anatomical Therapeutic Chemical Classification System (WHO ATC) on post-vaccination risk of COVID-19 infection and antibody response to multiple SARS-CoV-2 epitopes using serial serologic assessments. **Methods:** At a large, tertiary healthcare system in San Diego, we conducted an observational cohort study from December 11, 2020, to September 22, 2022, comparing vaccinated adult patients taking WHO ATC-classified immunosuppressing medications ("immunosuppressed" group) with matched control patients not prescribed these medications ("immunocompetent" group) for the outcome of PCR+ COVID-19 infection. A subset of immunosuppressed and immunocompetent individuals was consented to provide serial assessments of antibody response to multiple SARS-CoV-2 epitopes using the Genalyte serologic platform. **Results:** 12,709 vaccinated immunosuppressed patients and 197,151 immunocompetent controls were identified for matched analysis. Receiving an immunosuppressing medication conferred increased risk of COVID-19 infection post-immunization (HR: 1.5, 95% CI: 1.38 – 1.63, $p < 0.0001$). Among immunosuppressing medications, PD1/PD-L1 inhibiting monoclonal antibodies and calcineurin inhibitors were associated with increased risk of COVID-19 infection (HR: 2.33, 95% CI: 1.35 – 4.04, $p = 0.0038$; HR 2.72, 95% CI: 1.78 – 4.16, respectively). Receiving three and four COVID-19 immunizations reduced this risk, except in patients taking calcineurin inhibitors. Among 87 consented participants, 218 samples from multiple timepoints revealed a decreased antibody response to both spike S1 and S2 subunits following third and fourth immunization. Despite decreased seroconversion, this study found medications like CD20 inhibiting monoclonal antibodies and folic acid analogs did not increase the post-immunization risk of COVID-19. **Conclusions:** These results help elucidate the relationship between antineoplastic and immunomodulating medications and COVID-19 immunization outcomes. In our patients, seroconversion efficacy did not always correspond to post-immunization infection, consistent with COVID-19 disease risk being multifactorial. The findings of this study inform oncologists' shared decision-making process in advising patients of the risk of infection associated with immunomodulating medications and the potential impact on their vaccination response. Genomic therapy matching in rare and refractory cancers: Updated results from a retrospective cohort study in the Molecular Screening and Therapeutic (MoST) program. *First Author: Frank Po-Yen Lin, NHMRC Clinical Trials Centre, The University of Sydney, Sydney, NSW, Australia*

Background: Biomarker actionability and therapy matching are two central concepts in precision oncology. However, the best strategy to align therapy with genomic alterations remains unclear. Here we report the updated results from a cohort study conducted in an Australian precision oncology program (MoST, ACTRN12616000908437), examining a therapy matching strategy based on comprehensive genomic profiling (CGP) results. **Methods:** All patients (pts) with rare or advanced solid tumours undergoing CGP from 2016 to 2021 after exhausting standard treatments were included. The primary outcome was overall survival (OS) from the date of CGP result, estimated using the Kaplan-Meier method. Pts were grouped according to tiers of actionability determined by matching against the TOPOGRAPH knowledge base (<https://topograph.info>) and stratified into clinically active (Tier 1-3, therapies with evidence from prospective trials), investigational (Tier 3B and 4, therapies with evidence from another cancer type, preclinical, or retrospective studies), or unmatched tier groups. To assess between-group differences in OS, hazard ratios (HR) were estimated in a time-varying Cox regression model adjusting for time to initiation of subsequent therapy. **Results:** This updated analysis included 3,383 pts (79% rare and less common). The median follow-up was 22.6 months (mo). For 2,065 pts who did not receive treatment after CGP, the median OS (mOS) was 8.2 mo (95% CI 7.4 to 9.0). For 1,318 pts who received ≥ 1 line of therapy after CGP, the mOS was 14.1 mo (13.4 to 15.2). 1,270 pts (38%) carried a genomic alteration linked to clinically active therapies (Tier 1-3). Of these, 116 (3.4%) received matched treatment after CGP, experiencing longer survival compared with 410 (32.2%) that received only unmatched therapy (mOS 21.2 v 12.8 mo, HR 0.58, 0.45 to 0.76, $P < 0.001$). Whilst receiving a matched therapy in the investigational tier group ($n=133$, T3B/4) did not show significant differences in outcomes (mOS 14.5 v unmatched 12.8 mo, $n=536$, HR 0.88, 0.72 to 1.08, $p=0.24$), exploratory analyses identified differences in survival for a subset of 41 pts with Switch/Sucrose Non-Fermentable complex mutations receiving matched Tier 4 therapies (mOS 30.1 v 9.6 mo, HR 0.29, 0.17 to 0.51, $P < 0.0001$). Pts receiving repurposed drugs that matched solely on biomarkers in non-cognate cancer types (Tier 3B) showed no survival difference over unmatched therapy ($n=35$ v 469, mOS 13.6 v 12.5 mo, HR 0.96, 0.65 to 1.41, $p=0.83$). **Conclusions:** This study provides insight into how biomarker-linked therapies can be rationally prioritised in rare and advanced cancer populations. Addressing the barriers of access to Tier 1-3 therapies may broaden the utility of genomic biomarker testing. Off-label drug repurposing without direct supporting evidence should only be undertaken in a clinical trial setting. Distribution of alternate site infusion providers in the US. *First Author: Cindy Revol, Trilliant Health, Brentwood, TN*

Background: Spurred by the pandemic, chemotherapy treatments provided by alternate site infusion providers have been increasing. This diversification has the potential to increase access to care and improve patient satisfaction. However, it is currently unknown how equitably distributed these non-traditional infusion settings are, and whether these newer entrants are entering markets with need or markets with ample supply. In addition, many community oncologists are concerned about the ability to retain control over a patient's treatment and preserve the profits earned from drug infusions. Further, there are concerns regarding the lack of robust data on the safety of alternate site chemotherapy infusions. Industry analysts anticipate steady expansion in US markets for alternate site infusion with chemotherapy being a strong driver of growth. The objective of this study was to examine the distribution of alternate site infusion services across the US. **Methods:** Leveraging the Medicare home health infusion (MHHI) provider database from CMS, we calculated the rate of MHHI providers per 1000 Medicare beneficiaries in each US state. We reviewed company information to determine the geographic footprint of 3 alternate site infusion providers. **Results:** The median MHHI rate was 0.013 per 1000 beneficiaries (CO), the average rate was 0.031, with a minimum of 0 (ND, SD, WY) and a maximum of 0.202 (IL). ND, SD, WY, IN, KY, and OK have the lowest concentration of MHHI providers, whereas OR, KS, WA, NE, CA, and IL have the highest concentration. 3 alternate site infusion providers are Option Care, UnitedHealth's Optum Infusion Pharmacy, and Coram, CVS Specialty Infusion Services. Option Care has 162 in-person infusion centers located in 45 states. Option Care's presence is highest in CA (24), FL (9), WA (9), OH (8), VA (8), and TX (7). UnitedHealth's Optum Infusion Pharmacy has 30 in-person infusion suites located in 20 states, primarily concentrated in FL (6) and CA (4), but also provides home infusions in all 50 states. Like MHHI providers, neither of these alternate-site providers have locations in ND, SD, or WY. Coram announced a pilot with Cancer Treatment Centers of America in 2021 to provide home chemotherapy to patients in GA, but it is unclear if that pilot is ongoing; Coram provides home infusion therapy in 49 states. **Conclusions:** MHHI and alternate site infusion providers are in markets across the US. If alternate site chemotherapy infusion continues to grow, health system-owned and 3rd party entrant alternate site infusion providers are likely to prosper. Conversely, physician-owned practices could face competition and loss of important drug infusion revenue leading to increased consolidation among independent oncology providers. More research is needed to determine the impact on cost and patient outcomes of alternate site chemotherapy infusions – insights that will impact reimbursement and the rate at which these services continue to grow. Research Sponsor: Trilliant Health.

Surgical care and outcomes in older patients with cancer through implementation of a pre-surgical toolkit (OPTI-Surg): Interim results of a phase III cluster randomized trial (Alliance A231601CD). *First Author: George J. Chang, MD Anderson Cancer Center, Houston, TX*

Background: Frailty is common in older adults undergoing major cancer surgery. Mounting evidence indicates multimodal interventions to optimize patient functional status by addressing vulnerabilities associated with frailty before surgery result in decreased complications and enhanced functional recovery. This study tested the effectiveness of OPTI-Surg, a surgical prehabilitation toolkit for improving surgical care and outcomes in older patients undergoing major cancer surgery. Here, we report results from the planned futility interim analysis (IA). **Methods:** Thoracic (T), gastrointestinal (GI), and urologic (GU) oncological surgery practices affiliated with NCI's Community Oncology Research Program were randomized 1:1:1, stratified by practice type, to usual care (control), OPTI-Surg toolkit, or OPTI-Surg with an implementation coach. The toolkit was implemented at the practice level. It consisted of the 12-item Edmonton Frail Scale and guided recommendations for interventions directed at identified vulnerabilities. Eligible patients were adults ≥ 70 years old undergoing curative intent surgery for lung, gastrointestinal, or urologic cancers. Primary outcome was 8-week post-operative function (weekly caloric expenditure) derived from the validated Community Healthy Activities Model Program for Seniors (CHAMPS) questionnaire. A linear mixed model was used to compare usual care to the 2 OPTI-Surg arms combined, controlling for baseline function. **Results:** From July 2019 to October 2021, 225 patients, 50% of the total accrual goal, were enrolled from 29 practices, triggering the IA. Study was suspended to new patient accrual March to June 2020 due to the COVID-19 pandemic. There were no differences in demographics by arm (mean age 76.2 years; 46.4% women; 79.6% white; 20.4% lung resection, 69.8% major GI surgery, 9.8% total cystectomy). Of the 225 patients, 140 (47 Usual Care, 93 OPTI-Surg) were evaluable for the IA. There was no significant difference in post-operative function between OPTI-Surg and usual care (mean decrease of 0.59 kcal/week for OPTI-Surg patients and 0.19 kcal/week for usual care patients, $p = 0.762$, intraclass correlation = 0.033). Based on the futility analysis, the DSMB recommended closure of recruitment on September 16, 2022. **Conclusions:** Implementation of the OPTI-Surg toolkit did not significantly improve functional outcomes 8 weeks after surgery for patients aged 70 and older undergoing major cancer surgery compared to usual care. Future analysis of implementation and ethnographic data may identify reasons why significant differences between the intervention and usual care arms were not observed, potentially including disruptions due to the COVID-19 pandemic. Clinical trial information: NCT03857620. Research Sponsor: U.S. National Institutes of Health.

National lung cancer screening rates among women veterans within the Veterans' Health Administration. *First Author: Jennifer Bail, Birmingham VA Medical Center, Birmingham, AL*

Background: Lung cancer is the number one cause of cancer related death among women in the United States. United States Preventive Services Task Force (USPTF) lung cancer screening (LCS) guidelines recommend annual low dose computed tomography (LDCT) among high-risk populations. The data specifically on women veterans is sparse so we retrospectively examined LCS rates among women veterans within the VHA. **Methods:** Women veterans ages 50-80, current or former (quit within 15 years) smokers from 2013- 2021 were identified through the VA corporate data warehouse (CDW). Captured characteristics included: demographics, smoking history, and cancer screening history (lung, breast, cervical). Data was analyzed using R Studio software. **Results:** Women veterans with a history of smoking ($n=40,299$) tended to be aged ≥ 60 , white (66%), single (69%), unemployed (64%), urban dwelling (67%), and residing in Southeast U.S. (31%). Overall, cancer screening rates among women veterans was low (9% lung; 27% breast; 21% cervical). Of the women not screened for lung cancer (91%; $n=36,837$), 11% ($n=4,016$) had a personal history of cancer. While pack-year history was not documented for the vast majority (92%), 7% ($n=2,729$) reported a >30 pack-year smoking history (guideline at the time). Of these >30 pack-year smokers, 88% ($n=2,418$) were not screened for lung cancer. Other significant demographic predictors of increased LCS rates included Southeast Veterans Integrated Service Network (VISN region) and comorbidities such as bipolar disorder and diabetes likely due to increased exposure to healthcare. **Conclusions:** LCS rates, as well as breast and cervical, among women veterans within the VHA is low. The lack of documented pack-year history among women veterans with a history of smoking is concerning. Increased documentation of pack-year history may aid in identifying women for LCS. Efforts are ongoing nationally to implement an equitable centralized LCS program for all veterans and as part of that effort the Birmingham VA Health Care System has utilized their Lung precision Oncology program (LPOP) funding to pilot a structured lung cancer screening program within our Women's Health Clinic in 2022. Association between inpatient clinical nursing acuity and 30-day rehospitalization among hospitalized patients with advanced cancer. *First Author: Daniel E Lage, Massachusetts General Hospital, Boston, MA*

Background: Half of patients with advanced cancer experience multiple hospital readmissions, which are burdensome to patients and their family members. During hospitalization, nurses provide assistance with medication administration, activities of daily living (ADLs), and other care needs. However, it is not known how nursing support required during hospitalization may relate to hospital readmissions. Using data from a post-discharge supportive care trial, we analyzed the association between nursing acuity on day of discharge to home and 30-day rehospitalization among patients with advanced cancer. **Methods:** The data for this exploratory analysis came from a single-arm pilot trial (n=54) of a nurse practitioner-led supportive care telehealth intervention at Massachusetts General Hospital (MGH). We enrolled English-speaking adults with advanced breast, gastrointestinal, genitourinary, or thoracic cancers who had an unplanned hospitalization and were being discharged home without hospice. MGH uses the Harris Healthcare AcuityPlus workload and productivity system to measure patients' need for nursing care twice daily, in order to define nurse staffing levels. AcuityPlus groups patients into six levels of acuity (1=0-5 hours; 2=5-7 hours; 3=7-10 hours; 4=10-14 hours; 5=14-20 hours; 6=20+ hours). We conducted chart reviews to determine 30-day hospital readmission rates and analyzed the last AcuityPlus assessment before hospital discharge. We described rates of 30-day hospital readmissions by nursing acuity level. **Results:** From 01/07/21 to 05/28/21, we enrolled 54 patients (median age=65.0 years; 59.3% and 22.2% had advanced gastrointestinal or thoracic cancers, respectively). On day of discharge, no patients were classified as acuity level 1, while 25.9% of patients were classified as acuity level 2. 53.7% were in acuity level 3 and 20.4% were in acuity levels 4-6. Further, at discharge, 64.8% of patients received partial or extended assistance with ADLs, and 53.7% were assessed at least every 2 hours. At 30 days, 10 (18.5%) patients were readmitted to the hospital, all of whom were in acuity category 3 or higher on the day of discharge. No patients in acuity level 2 were readmitted. **Conclusions:** In this cohort of hospitalized patients with advanced cancer enrolled in a post-discharge supportive care study, overall need for nursing care, ADL support, and assessment was high, with over 70% of patients receiving at least 7 hours of nursing care on the day of discharge. While some nursing care received was influenced by inpatient nursing protocols, all readmitted patients had high nursing needs at discharge. These results support further study in larger cohorts of the relationship between inpatient nursing needs and likelihood of readmission in hospitalized patients with advanced cancer to improve support at home for recently hospitalized patients. Clinical trial information: NCT04640714. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Evolving adjuvant estrogen therapy prescribing among breast oncology workforce. *First Author: Kayla Polcari, University of Chicago, Chicago, IL*

Background: An oncologist shortage and rising number of breast cancer survivors has created a strained workforce. Care models that incorporate advanced practice providers (APPs) are recommended to meet this rising demand, particularly during survivorship. The objective of this study is to describe the evolving oncology workforce using anti-estrogen prescribing as a surrogate for breast cancer survivorship care. **Methods:** We used Medicare Part D Public Use Files to identify prescribers of anti-estrogen therapy from 2013 to 2020. We included medications primarily prescribed in the adjuvant setting for estrogen receptor positive breast cancer, including anastrozole, letrozole, exemestane, tamoxifen, raloxifene, fulvestrant, and toremifene. We assessed the volume of physician and APP prescribers and claims by provider type using descriptive statistics and logistic regression. Individual prescribers were included if they had more than 10 claims. **Results:** The overall number of anti-estrogen claims did not change significantly from 2013 to 2020, with an average of 3,224,361 annually. There was a significant increase in APP prescribers from 7,815 (8.6%) in 2013 to 12,961 (18.3%) in 2020. There was a reduction in physician prescribers by 24,815 (9.7%) over the same period with an overall net decrease of total prescribers of 19,669 (21.7%). The average annual claims per individual prescriber rose from 2013 to 2020 (Physicians: 2013: 37.5 to 2020: 45.2, $p < 0.001$; APP: 2013: 28.2 to 2020: 37.0, $p < 0.001$). The percentage of claims attributed to APP prescribers rose substantially from 6.6% in 2013 to 15.5% in 2020. This represents an increase from 220,000 prescriptions in 2013 to over 480,000 in 2020. **Conclusions:** Our results indicate an ongoing shift in the provider composition responsible for delivering breast cancer survivorship care. Over the time frame analyzed, there was no significant change in number of prescription claims annually, but an overall decrease in providers. Thus, the rise in APP prescribers is not driven by an increased prescribing volume, but rather seems to reflect an evolving surgical oncology workforce. This has significant implications for the future access to and delivery of timely high-quality cancer care. Research Sponsor: None.

Effect of an oncology care management program on unplanned hospital admissions in a commercially insured population. *First Author: Wendy L. French, Optum Health Solutions, Eden Prairie, MN*

Background: Despite advances in cancer outcomes, costs of cancer care continue to rise. Acute care utilization contributes significantly to these costs. The Cancer Support Program's (CSP) care management services focus on providing education on symptom management, palliative care and advance care planning, addressing psychosocial needs and closing gaps in care in members with cancer who are at high risk for unplanned hospital admissions (UHA). **Methods:** Beginning 1/1/22, commercially insured members with an active cancer diagnosis were clinically stratified as high or low risk for UHA. All high-risk members were invited to participate in the CSP program. Individuals who agreed to participate received individualized telephonic care management support. Medical claims from 1/1/22 through 9/30/22 were evaluated, and rates of UHA were compared between participants and non-participants within the identified high-risk population for an average period of 4 months after identification (the period equivalent to the average enrollment period of participants). **Results:** The study population included 3,113 members who stratified as high risk. Of those, 36% were enrolled in the program. Reasons for non-enrollment include inability to reach (72%), member refused (27%) and bad contact information (1%). There were no statistically significant differences between the two groups' demographic composition except for age (the enrolled group had slightly more in the 51-64 age group [63% vs. 59%; $p < 0.001$] and slightly fewer in the > 65 age group [9% vs. 15%; $p < 0.001$]). There were 358 UHA in the participating group and 737 UHA in the non-participating group. When normalized, there were 1,179 UHA per thousand members per year (PTMPY), 99% CI [1,171 UHA, 1,184 UHA] (bootstrap) in the participating group and 1,526 UHA PTMPY, 99% CI [1,523 UHA, 1,535 UHA] (bootstrap) in the non-participating group. **Conclusions:** Early results show lower UHA rates for members who participated in the care management program, suggesting the program is effective in reducing acute care utilization within the high-risk population. Limitations of this study include potential enrollment bias, changes in risk status from clinical or social factors, and the potential for human error or inconsistency in the risk stratification process. Further study is underway to validate these results. Research Sponsor: None.

An AI tool for chest X-ray interpretation and lung cancer pre-screening in developing countries. *First Author: Iván Romarico González Espinoza, Hospital Angeles Puebla, Puebla, Mexico*

Background: The current lung cancer screening strategy has not had a major impact on public health, facing many challenges during its implementation in developing countries. Although chest radiography (CXR) is not the study of choice for screening; it is one of the most accessible studies used at all levels of care, so implementing an AI tool capable of CXR interpretation as well as lung cancer risk assessment on a large scale could improve the selection of patients for lung cancer screening. The aim of our study was to develop and evaluate this tool. **Methods:** The dataset used for this tool development was obtained from the NIH "ChestX-ray14" public database. The set was divided into 3 subgroups for training, testing, and validation in a ratio of 80/10/10% respectively. We performed a structuration of metadata and an exploratory analysis as well as preprocessing of the images to standardize their size and resolution before the training. A model based on the adaptation of the momentum for learning was used as an optimizer of the CNN algorithm used. Additionally, a questionnaire based on the PLCO clinical criteria was included for the identification of patients at high risk of developing lung cancer. **Results:** Standard performance metrics were evaluated as shown. **Conclusions:** Our model is comparable to certified radiologists in accuracy at identifying patterns of a CXR. The use of clinical patient information improves the pre-selection of patients with a high risk of developing lung cancer. In developing countries, the implementation of this tool on a large scale will allow more patients to be screened and early diagnosed. Research Sponsor: None.

Deep learning-based approach to predict multiple genetic mutations in colorectal and lung cancer tissues using hematoxylin and eosin-stained whole-slide images. *First Author: Teppei Konishi, Biomy Inc., Tokyo, Japan*

Background: The presence of genetic mutations is a vital prognostic in many types of cancer. However, genomic testing is expensive and challenging to perform. In contrast, hematoxylin and eosin (H&E) staining is relatively inexpensive and straightforward. Thus, in this study, we propose a method of predicting the presence of genetic mutations using H&E-stained whole-slide images (WSIs). **Methods:** We divided each H&E-stained WSI into small pieces or "patches." We used a deep learning model to classify each patch based on the presence of tumor-containing regions. We then extracted image features from each tumor-containing patch using a deep learning-based feature extractor. We created image features for the entire WSI by concatenating the features of the patches. We then trained genetic mutation classification models using the WSI features as the input and the presence or absence of genetic mutations as the output. Finally, we evaluated the performance of these models using the area under the receiver operating characteristic curve (AUC). **Results:** First, we evaluated our methods using The Cancer Genome Atlas (TCGA) colorectal cancer dataset. We used H&E-stained WSIs and data associated with Microsatellite Instability (MSI) and BRAF gene mutations, which are directly relevant to therapeutic strategies, obtained from an independent clinical cohort of 566 patients with TCGA colon and rectum adenocarcinoma. We divided the data into training, validation, and test splits, comprising 367, 90, and 109 patients, respectively. We used the training and validation splits for model training and selection, and the test split for model evaluation. The AUC values of the classification models and associated 95% confidence intervals (CIs) were 0.721 (CI = 0.572–0.870) for MSI and 0.712 (CI = 0.547–0.877) for BRAF gene mutations. We also applied our approach to MUC16, KRAS, and ALK mutations using the TCGA lung cancer dataset. We divided 909 TCGA lung adenocarcinoma and lung squamous cell carcinoma patients into training, validation, and test splits, comprising 582, 146, and 181 patients, respectively. In contrast with those of the colorectal dataset, WSI image features were generated using all patches. The AUC values on the test splits were 0.897 (CI = 0.85–0.95) for MUC16, 0.845 (CI = 0.75–0.94) for KRAS, and 0.756 (CI = 0.57–0.94) for ALK mutations. **Conclusions:** We proposed an approach to predict the presence of genetic mutations using only H&E-stained WSIs and evaluated its performance using colorectal and lung cancer datasets. Our model has the potential to predict the presence of certain genetic mutations with superior performance. These predictions can be used to improve the accuracy of prognostic prediction using WSIs alone. Research Sponsor: Biomy Inc.

Gene expression-based machine learning approach to predict immunotherapy response and survival in patients with advanced cancer. *First Author: Zheng Zhang, Department of Urology, Peking University First Hospital; The Institution of Urology, Peking University; Beijing Key Laboratory of Urogenital Diseases (Male) Molecular Diagnosis and Treatment Center; National Urological Cancer Center, Beijing, China*

Background: Immune checkpoint blockades (ICBs) have drastically improved the clinical outcomes of cancer patients, while only ~30% of them get significant benefits from immunotherapy. TMB, PD-L1, TNB, GEP (Cristescu et al. 2018) and other conventional biomarkers can explain only ~60% of the ICB response, suggesting that novel factors are yet to be discovered. **Methods:** Gene expression profiles and clinical information of 672 patients were collected from IMvigor210 (n=348, bladder cancer), Pender et al. (n=98, 20 tumor types), Kim et al. (n=45, gastric cancer) and CheckMate (n=181, kidney cancer) cohorts, in which all patients were treated with ICBs. In each sample, gene expression intensities normalized by RPKM were ranked in descender order (range of 1-20000) and scaled into the 0-1 range lastly. To identify immune signatures that correlated with both response and survival, 1000+ immune genes were downloaded from InnatDB database, and their expression values were compared between the two groups of IMvigor210 data which were divided according to response (CR+PR vs. SD+PD, Wilcoxon test) or overall survival (≥mOS vs. <mOS, Cox survival analysis). Bayesian-regularization neural networks (BRNN) model was used to develop the risk model to predict ICB response and prognosis. 75% of IMvigor210 data were randomly selected as the training set, and the remaining 25% as the test set. The performance of predictor was independently validated in Pender et al., Kim et al., and CheckMate cohorts subsequently. ROC curves were used to evaluate the predictive accuracy to response. Survival plots were created using the Kaplan-Meier estimator, and data were analyzed by log-rank test. **Results:** 40 DEGs (including top20 DEGs positively correlated with ORR/OS and top20 DEGs negatively correlated with ORR/OS) were identified as immune signatures, in which each gene signature could significantly distinguish ICB response and survival. Our model outperformed TMB or GEP in the prediction of response in IMvigor210 (Model = 0.986 vs. TMB = 0.728 vs. GEP = 0.551), Pender et al. (Model = 0.757 vs. TMB = 0.593 vs. GEP = 0.621), Kim et al. (Model = 0.881 vs. GEP = 0.828), and CheckMate (Model = 0.927 vs. TMB = 0.543) cohorts when AUC was used as performance metric. Meanwhile, our model showed promising results for differentiating longer survivors from shorter survivors with p value < 0.0001, 0.064, 0.021, and 0.0006 in IMvigor210, Pender et al., Kim et al., and CheckMate cohorts respectively. **Conclusions:** We proposed a deep learning model to predict ICB response and survival, in which feature selection based on immune gene expression order, allowing all kinds of platforms and expression data types. Our model showed a robust prediction not only in bladder cancer, but also in other pan-cancer types. Research Sponsor: ChosenMed Technology (Zhejiang) Co., Ltd.

Prediction of cancer treatment response from histopathology images through imputed transcriptomics. *First Author: Danh-Tai Hoang, The Biological Data Science Institute, College of Science, The Australian National University, Canberra, Australia*

Background: In recent years, the use of tumour molecular profiling within the clinic has allowed for more accurate cancer diagnostics, as well as the delivery of precision oncology. Rapid advances in digital histopathology have allowed the extraction of clinically relevant information embedded in tumor slides by applying machine learning methods, capitalizing on recent advancements in image analysis via deep learning. However, as in many supervised learning approaches, predicting response to therapy using whole slide images (WSI) of tissue stained with hematoxylin and eosin (H&E) requires large datasets comprising matched imaging and response data, severely restricting the applicability of this approach. **Methods:** To overcome this critical challenge, we introduce here for the first time a generic methodology for generating WSI-based predictors of patients' response for a broad range of cancer types and therapies, which does not require matched WSI and response data for training. The approach, termed ENLIGHT-DeepPT, consists of: (1) DeepPT, a new deep-learning framework that predicts exome-wide tumor mRNA expression from slides, and (2) ENLIGHT, a recently published response prediction algorithm, applied here to predict response based on the DeepPT predicted expression values, instead of measured values. **Results:** First, we study the ability to predict tumor expression, showing that DeepPT successfully predicts transcriptomics in all 16 TCGA cohorts tested and generalizes well to two independent datasets. Second, aligned with our key aim, we analyze six independent clinical trial datasets of patients with different cancer types that were treated with various targeted and immune therapies, on which DeepPT was never trained. We show that ENLIGHT, without any adaptation, can successfully predict the true responders from the expression values imputed by DeepPT, using only H&E images: ENLIGHT-DeepPT successfully predicts true responders in these cohorts with an overall odds ratio of 2.19, increasing the baseline response rate by 38.8% on average among predicted responders. **Conclusions:** ENLIGHT-DeepPT is the first approach to successfully predict response to multiple targeted and immune cancer therapies directly from H&E slides, without requiring any drug-specific training data. ENLIGHT-DeepPT can provide rapid treatment recommendations without requiring tumor sequencing, bringing precision oncology to low-income countries and other situations where NGS is prohibitive. Utilizing predictive modeling to identify patients at high risk of death from immune checkpoint inhibitor therapy-related pneumonitis. *First Author: Antonious Ziad Hazim, Mayo Clinic, Rochester, MN*

Background: Immune checkpoint inhibitor therapy-related (ICI) pneumonitis poses a significant challenge in patients with cancer. There is a need for predictive modeling to identify those at high risk of developing serious adverse events of ICI pneumonitis. **Methods:** A newly created database of cancer patients diagnosed with ICI pneumonitis seen at Mayo Clinic from 2014-2022 was utilized for exploratory data analysis. Modeling was used to determine if three clinical outcomes could be predicted, namely risk of death from: pneumonitis prior to starting immunotherapy, pneumonitis at time of diagnosis of ICI pneumonitis, and any cause at time of ICI pneumonitis diagnosis. The data consisted of 170 patients with annotation for 71 clinical features. Data was divided into features available at time of cancer diagnosis and at time of ICI pneumonitis diagnosis. Exploratory modeling was performed using the gradient boosting technique Xgboost (Chen, 2015) and conducted using k-fold balanced cross validation best practices as well as a train/test/validate schema with 70%/20%/10% data proportions, respectively. Model reverse engineering was done with Shapley statistics (Lundberg, 2017) to determine which features had the largest contribution per model. Once identified, only those highly weighted features were used for logistic regression analysis providing more reproducible predictions by decreasing model variance. **Results:** Risk of death from pneumonitis prior to starting immunotherapy was modeled with an area under the curve of the receiver operator characteristic (AUC-ROC) of 0.79 with the most contributory features including lymphocyte count, oxygen dependence, PFT values, and PD-L1 expression. Logistic regression produced an AUC-ROC of 0.87 (95% CI 0.72-1.0, $p < 0.0013$). Risk of death from pneumonitis at the time of ICI pneumonitis diagnosis was modeled with an AUC-ROC of 0.85 and the most contributory features were similar to the list described in the previous endpoint. Logistic regression produced an AUC-ROC of 0.89 (95% CI 0.81-0.96, $p < 0.0001$). Risk of death from any cause at the time of ICI pneumonitis diagnosis until follow up concluded by 12/2022 produced a model with an AUC-ROC of 0.75 with the most contributory features including supplemental oxygen, PFT values, basic laboratory values, and PD-L1 expression, among others. Logistic regression produced an AUC-ROC of 0.85 (95% CI 0.76-0.93, $p < 0.0001$). **Conclusions:** We demonstrate that commonly available clinical data can be used to identify patients at high risk of death from ICI pneumonitis. This study identified clinical features that were predictive in each scenario from which further concerted effort could produce a new clinical model to provide clinician decision support when considering immunotherapy. Further studies should be done to further elucidate feature interdependence and generalizability. Research Sponsor: None.

Can synthetic data accurately mimic oncology clinical trials? *First Author: Samer El Kababji, CHEO Research Institute, Ottawa, ON, Canada*

Background: There is strong interest by researchers, the pharmaceutical industry, medical journal editors, funders of research, and regulators in sharing clinical trial data. Reusing data extracts the most utility possible from patient contributions. The majority of patients do want to share their data for secondary research purposes. However, data access for secondary analysis remains a challenge. A key reason why individual-level data is not made directly available to data users by authors and data custodians is concern over breaches of patient privacy. Synthetic data generation (SDG) is an effective way to address privacy concerns that can enable the broader sharing of clinical trial datasets. However, a key question is whether the reproducibility of the generated data is adequate to draw reliable conclusions. **Methods:** We synthesized datasets from five pragmatic breast cancer clinical trials performed by the REaCT group (<https://react.ohri.ca/>). A sequential synthesis method, a type of machine learning was performed. The published analysis of each trial was repeated on each synthetic dataset to evaluate reproducibility. We evaluated reproducibility on three criteria: (a) decision agreement: the direction and statistical significance of the primary endpoint effect estimates are the same as the real data, (b) estimate agreement: the parameter estimates from the synthetic data are within the 95% confidence interval of the real data, and (c) the confidence interval overlap between real and synthetic parameters is above 50%. In addition, we evaluated privacy using a membership disclosure metric. This evaluates the ability of an adversary to determine that a target individual was in the original dataset using the synthetic data, computed as an F1 classification accuracy score. **Results:** Our results show that decision and estimate agreements held true across all five trials, and the confidence interval overlap was high. The risks of membership disclosure are all below the established 0.2 threshold. **Conclusions:** In this study, we were able to successfully generate synthetic datasets that accurately replicated original data from 5 oncology trials and yielded the same results as in the original published studies, with a very low risk of membership disclosure. With proper modeling techniques, synthetic datasets can play a key role in data democratization and the reuse of oncology clinical trials. Research Sponsor: CHEO Research Institute.

Trial Name	NCT	Decision Agreement	Estimate Agreement	CI Overlap	Membership Disclosure*
REACT-G G2	NCT02428114 & NCT02816164	Y	Y	94%	0.06
REACT-HER2+	NCT02632435	Y	Y	70%	-0.11
REACT-ILIIAD	NCT02861859	Y	Y	97%	0.02
REACT-ZOL	NCT03664687	N/A**	81%***	73%***	0.02
REACT-BTL	NCT02721433	Y	Y	79%	0.18

* A commonly used F1 threshold for acceptable membership disclosure is less than 0.2 and can be negative. ** Not applicable because the published analysis was descriptive only. *** This is the average across all descriptive values.

Clinically oriented prediction of patient response to targeted and immunotherapies from the tumor transcriptome. *First Author: Ranit Aharonov, Pangea Biomed, Tel Aviv, Israel*

Background: Precision oncology is gradually advancing into mainstream clinical practice, demonstrating significant survival benefits. However, eligibility and response rates remain limited in many cases, calling for better predictive biomarkers. **Methods:** We present ENLIGHT, a transcriptomics-based computational approach that identifies clinically relevant genetic interactions and uses them to predict a patient's response to a variety of therapies in multiple cancer types, importantly, without training on previous treatment response data. Consequently, in addition to its ability to predict patients' response to approved and well-studied therapies, ENLIGHT can predict the response to new treatments in early development, even before clinical data has accumulated. Accordingly, we study ENLIGHT in two translationally relevant scenarios: Personalized Oncology (PO), aimed at prioritizing approved treatments to a given patient, and Clinical Trial Design (CTD), selecting the subset of most likely responders in a patient cohort. **Results:** Evaluating ENLIGHT's performance on 21 blinded clinical trial datasets spanning 11 indications and 15 different drugs in the PO setting, we show that it can effectively predict a patient's treatment response across multiple therapies and cancer types, with an overall odds ratio of 2.59 ($p=3.41e-8$), and a 36% increase in response rate over the baseline ($p=3.30e-13$). Its prediction accuracy is better than other state-of-the-art transcriptomics-based signatures. Unlike most signatures that are prognostic or provide insights for only very few, specific treatments, ENLIGHT provides matching scores to a broad range of treatments. Quite strikingly, its performance is comparable to that of supervised predictors developed for specific indications and drugs. In combination with the IFN- γ signature, ENLIGHT achieves an odds ratio larger than 4 in predicting response to immune checkpoint therapy. In the CTD scenario, our results show that by excluding non-responders ENLIGHT can enhance clinical trial success for immunotherapies and other monoclonal antibodies, achieving > 90% of the response rate attainable under an optimal exclusion strategy. **Conclusions:** ENLIGHT is a powerful transcriptomics-based precision oncology pipeline developed by Pangea Biomed that broadly predicts response to both extant and novel targeted and immune therapies, going beyond context-specific biomarkers. Research Sponsor: Pangea Biomed; U.S. National Institutes of Health.

Relevance and accuracy of ChatGPT-generated NGS reports with treatment recommendations for oncogene-driven NSCLC. *First Author: Zac Hamilton, University of Illinois Chicago, Chicago, IL*

Background: Next-generation sequencing (NGS) is a routine clinical practice in advanced NSCLC. NGS reports are information-dense and clinical interpretation remains a challenge. ChatGPT is a large language model (LLM) AI chatbot that can generate text in response to user-generated prompts. We sought to assess the clinical relevance and accuracy of ChatGPT-generated NGS reports with first-line (1L) treatment recommendations for NSCLC patients with targetable driver oncogenes. **Methods:** Eight driver oncogenes with FDA-approved targeted treatment for 1L stage IV NSCLC were identified in the latest NCCN Clinical Practice Guidelines available to the AI model (version 5, September 2021). The prompt, "Create a next-generation sequencing report with a list of first-line treatment options for a patient with stage IV non-small cell lung cancer with an [oncogenic driver]." was run in a separate "new chat" 10 times for each driver oncogene ($n=80$). Each ChatGPT output was recorded and scored. The Relevance Score (RS) awarded 1 point for every NCCN preferred option and 0.5 points for each "other recommended" treatment listed in the AI-generated output, divided by the maximum possible score for the driver oncogene. Spurious recommendations were awarded 0 points. The Accuracy Score (AS) represents reported treatment options listed in NCCN over the total number of treatments in a report. Percentage of reports listing an NCCN-preferred 1L therapy, a clinical trial as an option, and character and word count were also captured. **Results:** The average length of the AI-generated NGS reports was 117 words (range: 44 – 232). The median number of treatments recommended was 5 (range: 3 – 8). An oncogenic driver-specific preferred 1L treatment was included in 55 reports (68.8%), and a recommendation to explore clinical trials was listed in 43 reports (53.8%). The RS for the total sample was 0.59 (95% CI: 0.52 – 0.65), and the AS was 46.0% (95% CI: 40.2% – 51.8%). **Conclusions:** ChatGPT can rapidly generate concise NGS reports with treatment options for NSCLC with driver oncogenes. Recommendation relevance was moderate, and accuracy was limited with high variability across oncogenes. Overall, ChatGPT recommendations were promising given the complexity of the task with no prompting or training provided to the AI. As LLM AI platforms mature, they may generate more relevant and accurate NGS reports, offering a potentially valuable tool for NGS report annotation for clinicians, and increased accessibility for patients. Research Sponsor: RHN is a recipient of the Robert A. Winn Diversity in Clinical Trials Career Development Award, funded by Bristol Myers Squibb Foundation.

Identification of genes encoding targets associated with adverse events in multiple myeloma. *First Author: Xuan Xu, Kansas State University–Olathe, Olathe, KS*

Background: Despite novel therapeutic options, understanding the toxicity profile of anti multiple myeloma (MM) drug regimens (AMDR) is vital. Data suggests adverse event (AE) profile is orchestrated by certain associated genes. The purpose of this study is to explore the interplay of genes, regimens, AEs and provide genetic evidence for a linkage between regimens and the presence of AEs. **Methods:** We examined a group of AMDRs retrieved from the FDA Adverse Event Reporting System. Drug-associated genes were obtained from the Drug Gene Interaction Database, DGIdb. Then, genes were imported to the Online Mendelian Inheritance in Man (OMIM) to search for the existing clinical synopses (features) in the peer reviewed biomedical material, or phenotypes when no data was available. Clinical synopses were then linked to MedDRA. Gene gene interaction was also determined through the Search Tool for the Retrieval of Interacting Genes/Proteins (STRING). We then constructed a detailed large MM pharmacogenetic network to illustrate the linkage among drugs, genes and MM via various expert integrated resources. AMDR responses were then assessed at the DNA and protein levels by modularizing genetic causation into different scenarios i) a direct drug effect on gene expression; ii) the secondary or tertiary effect of drug(s) on subsequent drug metabolism or disposition altering gene expression pathways; iii) modulation of another biological network that disturbs drug effect on gene expression resulting in exacerbating AE occurrence. **Results:** We found multiple genes including *CTLA4*, *NFKB1*, *PSMB8*, *CCND1* and *HLAA* were complicit/associated with different AEs including cardiac or hepatobiliary disorders or other serious events. Our results suggested the expression of *CTLA4* was influenced by multiple AMDRs from combinations of bortezomib (V), lenalidomide (R), melphalan (M), or dexamethasone (D). When AMDRs involve these agents, the occurrence of pericardial disorders due to the treatment exhibited high confidence. We also found carfilzomib (K) combinations (Kd or KRd) were associated with *PSMB8* which was likely to be the genetic factor concomitant with heart failures, cardiac arrhythmias, or hepatobiliary toxicities. Furthermore, our findings suggested *NFKB1*, thalidomide associated gene interacting with *PSMB8*, may present the same toxicity events in hepatobiliary disorders. **Conclusions:** Understanding the genomic basis of specific drug-AE combinations could reveal molecular mechanisms underlying drug-gene-AE associations and recognize the causality of AEs. When considering alternative agents in MM, our study offers insights for predicting treatment responses such as *PSMB8* which could potentially cause an off target effect of K on cardiomyocyte 20S beyond MM cells. Our plan is to integrate this novel computational biology approach with translational medicine to further investigate our observation. Research Sponsor: None.

Lost in translation? Information exchange during breast cancer care and implications for technology design. *First Author: Megan Salwei, Vanderbilt University Medical Center, Nashville, TN*

Background: Almost 4 million women in the US have had breast cancer, with 300,000 women diagnosed each year. Treatment decision-making following breast cancer diagnosis can be challenging as there are often several clinically appropriate treatment options, each with differing impacts on patient short- and long-term quality of life. Further, patients must manage this information during a time of high emotional burden, which can hinder decision-making. Not surprisingly, studies have found that less than 50% of patients believe their treatment plan aligns with their preferences. Numerous decision aids have been developed to support patient decision-making. However, sustained use of decision aids is limited due to poor integration in clinical workflow. We need to better understand the complex workflows and needs of decision aid users - patients and breast cancer clinicians. In this study, we investigate the information exchange between patients and clinicians when making breast cancer treatment decisions and identify design requirements for patient-centered decision support tools. **Methods:** This study is part of a larger research project to design a COMputerized PATient-centered Collaborative Technology (COMPACT) to support personalized breast cancer decision-making. We observed clinicians at one academic medical center's breast center from February-August 2022. Participating clinicians were followed throughout their clinical shift. Using a tablet computer and smart pencil, we recorded all aspects of clinician workflow. Written notes were transcribed and uploaded into Dedoose. Two human factors researchers inductively coded each observation in a consensus-based process. **Results:** We observed 79 hours of clinical care and 119 patient encounters across 20 observations of various clinical roles. Overall, we found that patients with breast cancer must manage an enormous amount of highly complex information that includes technical medical terms, mathematical concepts (e.g., risk), and uncertainty. We identified over 20 distinct decisions that patients face during their cancer journey, which were interdependent and evolved over time. We identified numerous patient-specific factors that influenced treatment decision-making, such as the patient's work and family circumstances. For instance, one patient was organizing a conference and needed to plan her surgery around this event. Patients were frequently asked to remember and relay information across members of the care team, indicating inadequate system support of information transfer within the large cancer team. Based on these findings, we identified design requirements for interventions to support care coordination and patient-centered decision-making. **Conclusions:** These findings can inform the design of interventions to support breast cancer decision-making and improve patient-centered cancer care. An intelligent machine learning model for real-time early detection of undesirable cancer events: AIM2REDUCE. *First Author: Robert C. Grant, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Cancer and its treatment cause undesirable cancer events (UCEs). Automated warning systems could reduce the frequency and severity of UCEs by alerting the healthcare team and allocating preventative interventions. Most previous studies predicted single UCEs at the initiation of treatment. In AIM2REDUCE, we developed and evaluated a general-purpose system for predicting UCEs during outpatient systemic anti-cancer therapy. **Methods:** Each time a patient receives treatment, AIM2REDUCE applies machine learning to the preceding data in the electronic medical record (EMR) to predict future UCEs. We identified patients treated for aerodigestive cancers from the EMR at Princess Margaret Cancer Centre, who were randomly split into development, validation, and test cohorts. Features included cancer diagnosis, treatment sessions with doses, laboratory tests, and patient-reported symptoms. UCEs are listed in the Table. We trained LASSO regression and random forests models in the training cohort and tuned hyperparameters in the validation cohort using Bayesian optimization. We evaluated performance across discrimination, calibration, and net benefit in the test cohort. **Results:** The cohort included 5,760 patients who received 175,565 treatment sessions, with 13,612,746 unique data points across 102 features. Of these patients, 2,352 (40.8%) were female, the median age was 64.0 years (interquartile range 14.0), the most common diagnoses were lung cancer (2,071, 36.0%) and pancreatic cancer (926, 16.1%), and the most common treatment regimens were weekly gemcitabine (433, 7.5%) and maintenance pemetrexed (417, 7.2%). The Table shows the performance of AIM2REDUCE. **Conclusions:** We demonstrate that longitudinal machine learning systems trained using EMR data can accurately predict a wide range of UCEs. Based on these results, automated warning systems should be implemented and evaluated in real-time clinical practice. Research Sponsor: Princess Margaret Cancer Centre.

UCE prevalence and AIM2REDUCE prediction performance in the test cohort.

Association of smoking history extracted from electronic health records (EHR) using machine-learning methods and tumor characteristics in patients with lung cancer. *First Author: Semanti Mukherjee, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Though smoking is a major risk factor for lung cancer, it has been a challenge to collect patients' smoking history information accurately from the EH due to data inconsistency and incompleteness. To address these challenges, we utilized a weak supervision methodology to automatically annotate smoking status of patients with lung cancer and correlated it with tumor characteristics. **Methods:** We analyzed 6,355 patients with lung cancer who underwent tumor profiling with MSK-IMPACT. In total, 14,555 unstructured clinical notes were extracted from EHR at the Memorial Sloan Kettering Cancer Center. The weak supervision methodology used a generative model for intermediate labels that were subsequently tuned by machine-learning classifier to generate the final labels. Clinical notes from a randomly sampled set of 564 patients were manually curated and used for performance assessment. The rest of the patients were split into training and validation datasets used for model training and hyperparameter tuning. Pack years were also extracted from clinical notes using Natural Language Processing. We next conducted multivariate analyses for primary and metastatic tumor samples separately to correlate smoking metrics with tumor characteristics including tumor mutation burden (TMB) and chromosomal instability, as inferred by the fraction of genome altered (FGA) after controlling for age at sequencing, gender, histological subtypes, ancestry, coverage and tumor purity. **Results:** The weak supervision classifier had almost perfect performance for 2-label classification model (ever smokers and never smokers) with macro F1-score: 97.7%, balanced accuracy: 97.1%, 97.1%, precision:98.4%, 98.4% and recall: 99.5%,94.6% respectively. For 3-label classification model (never smoker, former smoker, and current smoker), the macro F1-score was 79.8%; balanced accuracy: 97.1%, 86.7%, 71.2%, precision: 93.9%, 90.1%, 61.7%, recall: 96.1%, 93.3%, 46.0% respectively. Analyzing genomic data, we observed that smoking status (smoker vs. never smoker) and pack-years were associated with TMB in both primary and metastatic tumor samples ($p<2e-16$). FGA was marginally associated with smokers compared to never smokers in primary tumor samples ($p=0.06$). Among smokers diagnosed with lung adenocarcinoma, significantly high FGA in primary tumor samples was observed in males compared to females after adjusting for pack-years and other variables ($p=3.3e-3$). **Conclusions:** We demonstrated high performance of our approach for automated curation of smoking history from EHR. The genomic results confirmed distinct mutational patterns associated with smoking behavior in patients with lung cancer. We are currently exploring multimodal approaches by including chest CT images and "time of quitting" to improve performance of the 3-class model. Early assessment of sotorasib for treatment of patients with advanced non-small cell lung cancer using real-world data in the United States. *First Author: Dvir Aran, Faculty of Biology, Technion-Israel Institute of Technology, Haifa, Israel*

Background: Sotorasib is the first small molecule for targeting tumors with KRAS G12C mutations. Despite promising early results which led to expedited approval, recent interim results from the phase III clinical trial suggest similar efficacy to standard-of-care chemotherapy docetaxel. Here we perform the first evaluation of sotorasib for the treatment of non-small cell lung cancer (NSCLC) in real-world setting. **Methods:** Elevance Health claims data was used. Lung cancer (LC) patients with sotorasib claims between June 2021-August 2022 were identified (assumed to be NSCLC). LC patients treated with docetaxel as second-line+ were used as control group. Potential confounding factors, including social determinant index (SDI), age, gender, Charlson Comorbidity Index (CCI), and metastases profile were addressed using inverse probability treatment weighting (IPTW). Outcomes were hospitalizations and real-world overall survival (rWOS), which was estimated using weighted Kaplan-Meier estimator. For comparison with the clinical trial population-level adjustments were performed. **Results:** Cohorts included 105 sotorasib-treated and 448 docetaxel-treated patients. Sotorasib-treated were primarily female, of older age and had more comorbidities. Post-treatment all-cause hospitalization rates were similar during the first 3 months (36% in both). Most common hospitalization diagnosis was gastrointestinal (GI) related which was uncommon in the control group (29% vs. 8%, $p < .001$). No evidence for liver toxicity was identified. For a subset of patients it was possible to perform survival analysis. Adjusted survival curves of RWD and the clinical trial (CodeBreak-100) were indistinguishable following population-level adjustment ($p = 0.92$). Adjusted RWD sotorasib and the control cohorts revealed non-significant difference in rWOS up to 6-months of follow-up (62% sotorasib vs. 55% docetaxel; $p = 0.1$). **Conclusions:** We present the first analysis of sotorasib in US real-world settings. This early analysis suggests that sotorasib does not provide survival benefit at 6-months follow-up. Sotorasib is associated with increased GI-related severe adverse events. RWD can be used to provide early information in expedited FDA approved treatments. Research Sponsor: None.

Accuracy of a clinical decision support system in identifying patients at risk of cancer in primary care. *First Author: Bea Bakshi, C the Signs, Cambridge, MA*

Background: 85% of patients diagnosed with cancer are symptomatic at presentation. Yet a delay in diagnosis (e.g. missing a presentation) can result in late stage detection and poorer outcomes. Clinical decision support systems (CDSS) have been used in other fields to calculate risk and support standardization of care. However, little has been reported about successful implementation of CDSS with determining cancer risk. C the Signs is a CDSS which uses artificial intelligence, mapped with the latest evidence and guidance, to assist healthcare professionals in identifying patients at risk of cancer and determining the most appropriate pathway for diagnosis. The aim of this study is to assess the accuracy of C the Signs in a real-world setting. **Methods:** A retrospective observational study was conducted in the National Health Service in England utilizing all patients risk assessed for cancer through the Electronic Healthcare Record (EHR) integrated C the Signs platform between 1st January 2021 and 31st August 2022. A total of 118,677 patients were risk assessed. All patients were followed up for 6 months post risk assessment to determine outcome. A sub-analysis was performed on the patients who were flagged at risk of cancer through C the Signs and subsequently diagnosed with cancer to establish the CDSS's cancer origin accuracy (the ability for the system to accurately predict which cancer the patient is at risk of). **Results:** 7,295 patients were diagnosed with cancer within 6 months of a C the Signs risk assessment. 7,056 patients were successfully identified at risk of cancer by the CDSS with a sensitivity of 96.7%. There were 103,168 false positives with a specificity of 7.37%. Of the 8,453 patients who were identified as not at risk of cancer using the CDSS, 239 had a confirmed cancer diagnosis within 6 months of risk assessment (with a negative predictive value 97.2%). The cancer origin accuracy of C the Signs was 85.6% across all cancers. **Conclusions:** A cancer CDSS like C the Signs can be used to accurately identify patients at risk of cancer. More research is needed to understand the specificity and false positive rate, and the impact of identifying these patients with non-cancer disease. Research Sponsor: None.

Natural language processing identification of documented mental health symptoms associated with risk of mental health disorders in patients with cancer. *First Author: Isabel D. Friesner, University of California, San Francisco, San Francisco, CA*

Background: Delayed diagnosis and care of mental health disorders (MHD) is a significant challenge in the care for patients with cancer. The objective of this study was to use natural language processing (NLP) to identify words related to mental health documented in clinical notes surrounding the time of cancer diagnosis and assess their predictive ability of future, new MHD. **Methods:** This single institution cohort study consisted of patients diagnosed with cancer between January 2012 and November 2022. Cancer and MHD were identified based on ICD-10 codes obtained from deidentified electronic health record data. MHD included psychotic disorders (F20-29), mood disorders (F30-39), and anxiety disorders (F40-48). The clinical Text Analysis Knowledge Extraction System was applied to deidentified clinical notes, and symptoms mapped to SNOMED concepts relevant to mental health were identified. These mental health symptoms were aggregated in the 15 days preceding and 15 days following a first cancer diagnosis and analyzed across MHD status. Patient characteristics including sex, age, race, cancer, and insurance were also analyzed. **Results:** This cohort consisted of 64,010 patients with cancer who had no documented MHD prior to cancer diagnosis, with a majority being 40-64 years old (45.8%) or 65+ (43.7%) and identifying as male (53.0%) or white (60.2%). Most patients had prostate (12.5%), hematologic (10.8%), or breast (10.3%) cancer and private insurance (46.2%). 9,825 (15.3%) patients developed a newly documented MHD, with a median time of 139 days (IQR: 40-466) from cancer diagnosis. The top five most common mental health documented symptoms for all patients were normal mood (23.3%), mental state finding (17.9%), worried (10.2%), feeling content (9.9%), and cognitive function finding (6.6%). Those who had a future MHD had higher documented rates across all mental health symptoms. Multivariate cox proportional hazards model identified 18-39 years old, female, white, and Medicaid or Medicare insurance as independent factors associated with an increased risk of a future, new MHD. Prostate cancer was associated with lower risk of a future MHD. Panic (OR 2.1 [95% CI 1.8-2.4]), feeling nervous (1.9 [1.5-2.4]), feeling guilt (1.9 [1.4-2.5]), mild anxiety (1.8 [1.4-2.4]), and feeling frustrated (1.4 [1.2-1.6]) were identified as the symptoms most strongly associated with an increased risk of a future MHD. **Conclusions:** NLP extracted mental health symptoms documented in clinical notes correlated with an increased risk of documented MHD. Computational approaches may be tools for improving the timely diagnosis of MHD and referral to specialty services. Further work is needed to investigate potential disparities in documentation and management of care for patients with cancer who develop MHD, including delays between documentation and eventual diagnosis. ALAN as an omic tool to build gene signatures and to stratify patients. *First Author: Hannah E. Bergom, University of Minnesota, Minneapolis, MN*

Background: Understanding aberrant gene behavior is critical towards devising clinical therapeutics or gene based diagnostic panels. Clustering and AI/ML have clinical utility, but they do not contextualize changes in gene behavior that result from differences in cell type, microenvironment, or prior treatments. Here, we developed the Algorithm for Linking Activity Networks (ALAN), an informatics algorithm that allows rapid functional comparisons of all detectable genes between clinically annotated patient cohorts. ALAN outputs quantify gene behavior without any additional inputs and can be applied on all forms of clinical omic data. We tested the utility of ALAN to identify the molecular features of resistance and novel precision therapeutics. **Methods:** We applied the ALAN algorithm in prostate tissue using whole-transcriptome sequencing (WTS) data from SU2C/PCF (n = 209, metastatic prostate cancer), TCGA (n = 493, primary prostate cancer), and GTEx (n = 245, benign prostate tissue). We conducted informatics analysis of whole-exome sequencing (WES) data from SU2C/PCF (n = 444 mPC), Fred Hutch (n = 130 mPC), and MCTP (n = 61 mPC) to identify mPC patients with amplifications in *RSPO2*. We scored an ALAN gene signature in a patient with single-cell RNA sequencing pre and post AR inhibition (n = 112, 83). We examined ChIP-seq data to evaluate binding of AR and Co-factors at the CD276 transcription regulatory sequences. **Results:** In mPCs, ALAN unbiasedly identified genes that prior studies have implicated as resistance mechanisms towards enzalutamide. In this process, ALAN nominated *RSPO2*, a secreted protein, as a potential resistant gene that has never been targeted in mPC. In recent studies, we found *RSPO2* amplifications in 19.7-28.5% of mPC. We utilized ALAN outputs to build a novel gene signature that was exclusively enriched (p-value < 0.0001) in the transcriptome collected from single cells of a post-resistant mPC sample. We also utilized ALAN to stratify the optimal mPC patients in receiving precision therapies against B7-H3 (CD276). B7-H3 is an immune regulatory molecule in the B7 superfamily that includes PD-L1 and CTLA-4 and has not been targeted in mPC. B7-H3 was unlike other B7 family members and exhibited robust association with AR co-factors and AR signaling. We confirmed ALAN findings as multiple B7-H3 transcriptional enhancers and promoters were bound by AR and AR-cofactors. **Conclusions:** ALAN is an algorithm that can be readily deployed on existing clinical omic data to build gene signatures, identify resistant genes, and risk stratify patients. ALAN nominated a novel therapeutic target, *RSPO2*, which is recurrently amplified in mPC patients. ALAN predicted that mPCs with high baseline levels of AR activity would be optimal candidates for B7-H3 precision therapeutics. Altogether, ALAN outputs should be considered for making clinical decisions that would benefit by comprehensive comparisons of all detectable genes. Deep learning to estimate RECIST in patients with cancer treated in real-world settings. *First Author: Irbaz Bin Riaz, Dana-Farber Cancer Institute, Boston, MA*

Background: Creating large oncology clinical-genomic datasets is laborious and time-consuming. Deep learning approaches that extract RECIST outcomes at scale from observational electronic health records (EHR) data could tremendously facilitate precision oncology research. **Methods:** This retrospective study included patients with solid tumors treated on therapeutic clinical trials from 2004-2022 at Dana-Farber Cancer Institute with radiology reports in EHR and RECIST labels available from the tumor imaging metrics core. Each RECIST label was generated using corresponding radiology reports at a given time point. Patients were sampled into training, validation, and held-out test sets. A deep learning model (RECIST model) was trained to predict two outcomes: overall response and progressive disease at each time point, using reports from that time point and prior time points for each patient. This trained RECIST deep learning model was deployed on real-world radiology reports, and results were compared with true labels abstracted by trained human curators using the PRISMM framework. **Results:** This study included 5153 patients with a total of 99,318 radiological reports who had RECIST annotations (median age at protocol enrollment [IQR] 60 years [52-57]; females 61% [3133]; and white 90% [4653]). The most common cancer types included breast (n=1006; 20%) lung (n=573; 11%), and ovarian cancer (n=539; 10%). The training subset included 4121 (79.9%) patients, the validation subset 518 (10.1%), and the held-out test set 514 (9.9%) patients. In the test set, the results showed an AUC of 0.86, and 0.87 with the best F1 scores of 0.72 and 0.63 for predicting overall response, and progressive disease, respectively. The real-world data set included 4482 patients. RECIST model evaluation on real-world radiology reports showed good performance for ascertaining PRISMM annotations of progression from those reports (AUC 0.83, best F1 0.68), but poor performance for ascertaining PRISMM annotations of response (AUC 0.63, best F1 0.28). Evaluation metrics are outlined in the Table. **Conclusions:** This study demonstrated the feasibility of using deep learning approaches to predict RECIST outcomes from radiology reports for patients with solid cancer tumors. The results show that the deep learning model accurately predicted RECIST labels on a held-out test set and real-world radiology reports for the outcome of progressive disease. These findings could accelerate precision oncology research providing a scalable way of ascertaining cancer outcomes from observational EHR data. Research Sponsor: None.

Classification	Evaluation Metric	Validation subset	Held-out test set	Real world set

Trial eligibility criteria (EC) and diversity among patients with advanced non small cell lung cancer (advNSCLC). *First Author: Maneet Kaur, Flatiron Health, New York, NY*

Background: FDA guidance encourages using real world data in developing diversity plans for clinical trials. Diversity plans may incorporate more inclusive (or expanded) EC, which may increase enrollment of minoritized populations. Whether broadened EC affect the diversity of eligible participants is unknown. **Methods:** Using the nationwide Flatiron Health electronic health record-derived deidentified database, we included patients with advNSCLC from 1/17-11/30/22 with a line of therapy (LOT) (N=61596). EC were defined by FDA, NCI/CTEP, and ASCO/FoCR standards, and included ECOG, ALT, AST, ALP, bilirubin, eGFR, CrCl, HGB, ANC & PLT -90 to +7 days from first LOT. Claims-linkage identified brain mets (BM), congestive heart failure (CHF), hepatitis C (HCV) & B (HBV), HIV and myocardial infarction (MI) within 6 months of first LOT. Logistic regression estimated odds ratios (OR) for exclusion by criterion associated with gender, age, race/ethnicity and area-level socioeconomic status (SES). Adjusting for clinical characteristics, Cox regression estimated hazard ratios (HR) for real world overall survival (rWOS). **Results:** Female patients (vs male patients) had greater odds of exclusion by CrCl (OR 2.9), eGFR (OR 1.27) & BM (OR 1.30). Compared to non-Latinx (NL) white patients, NL Black patients had greater odds of exclusion by ECOG (OR 1.17), CrCl (OR 1.33), eGFR (OR 1.61), HGB (OR 2.2), ANC (OR 1.71), HIV (OR 5.31), CHF (OR 1.31), HBV (OR 2.29) and HCV (OR 2.73); NL Asian patients by ALT (OR 1.64), ALP (OR 1.71), CrCl (OR 1.63), BM (OR 1.45) and HBV (OR 26.2); and Latinx patients by ALP (OR 1.56), HIV (OR 2.23) and HCV (OR 1.47). Compared to younger patients (18-49), older patients (75-84) had greater odds of exclusion by ECOG (OR 2.12), bilirubin (OR 1.53), CrCl (OR 41.9), eGFR (OR 9.54), CHF (OR 4.9) and MI (OR 4.7). Patients with the lowest (vs highest) quintile of SES had greater odds of exclusion by ECOG (OR 1.29) and HGB (OR 1.52). Among patients with complete data on all non-claims criteria (N=22117), the impact of expanding EC on diversity is shown, except SES which was similar. Compared to standard EC, the group with expanded EC had lower rWOS (adj HR 1.32; 95% CI 1.28-1.37). **Conclusions:** Expanding EC has the potential to increase the proportion and absolute number of Black, older, and female patients in advNSCLC trials. The resulting more diverse eligible population may have different clinical outcomes compared to a cohort defined by more restrictive EC. Future work will explore generalizability of findings to other clinical contexts. Research Sponsor: This study was sponsored by Flatiron Health, Inc., which is an independent subsidiary of the Roche Group.

Impact of COVID-19 pandemic mitigation strategies on industry and NCI cancer treatment trials. *First Author: Joseph M. Unger, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The onset of the COVID-19 pandemic resulted in major disruptions in enrollment and conduct of cancer clinical trials. In response, regulators allowed modifications to traditional trial processes to enable clinical research and care to continue. The American Society of Clinical Oncology and Friends of Cancer Research established a task force to evaluate how sponsors perceived the impact of these mitigation strategies on data quality and overall trial conduct. **Methods:** The study used a survey and live interviews of industry and National Cancer Institute (NCI) cooperative group sponsors of cancer treatment trials. Sponsors with trials active in the United States from January 2015-May 2022 were eligible. We assessed perceived impacts of the pandemic on protocol deviations, types of mitigation strategies, trial closures, dropouts, adverse events (AEs), and data integrity. Descriptive statistics were used for survey data summaries. Key findings from semi-structured interviews were described by theme. **Results:** Of forty-one eligible sponsors, 20 (49%; 15/36 industry and 5/5 cooperative group) completed the survey; eleven (55%; 7/15 industry and 4/5 cooperative group) were interviewed. Sixty percent of sponsors reported large portfolios (>10 trials) of phase II and/or phase III trials. The most widely adopted mitigation strategies were remote distribution of oral anticancer therapies (70%), remote consenting (65%), and remote symptom monitoring for AEs (65%). The proportion of sponsors reporting a “substantial” increase in protocol deviations compared to the pre-pandemic period dropped from 42% in the initial wave (March-April 2020) to 16% thereafter. Sponsors primarily reported “no change” in trial drop-out rates (77%), the number of trials closed due to low accrual (90%), or rates of AEs (81%) at any point during the pandemic. Overall, most (83%) respondents reported the pandemic had “minimal” (14) or “no” impact (1) on data integrity. In interviews, many sponsors reported persistent time delays in data entry related to labor shortages at sites. **Conclusions:** This study represents the first systematic evaluation of clinical trial sponsors about the impact of the COVID-19 pandemic on the conduct of cancer clinical trials. Remote clinical trial conduct mitigation strategies were broadly adopted. Despite an observed increase in protocol deviations, most sponsors reported the pandemic had minimal or no impact on data integrity. The COVID-19 pandemic impacted how cancer clinical trials were performed and has likely accelerated a trend towards greater flexibility in trial conduct that was already emerging, with potential benefits of reduced burden and improved access for patients and sites. Future work is planned to further quantify the impact of the pandemic and trial mitigation strategies on the quality of trial data both overall and for historically under-represented patient groups. Toxicity reporting consistency and subjective minimizing language use in colorectal cancer (CRC) and pancreatic cancer (PaC) clinical trials: A systematic review of phase III randomized controlled trials (RCTs) presented at ASCO between 2012-2022. *First Author: James Yu, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Objective and complete toxicity reporting in clinical trials is critical for patient-centered shared decision-making. Conference abstracts inform initial impressions of practice-changing treatments. **Methods:** We performed a systematic review of all abstracts of CRC and PaC phase 3 RCTs presented at ASCO annual meetings between 2012–2022; long-term follow-up, supportive care, and solely non-pharmacological studies were excluded. Objective minimization of adverse event (AE) reporting was defined as absent and/or incomplete reporting of cumulative grade 3-5 CTCAE (common terminology criteria for AE). We also assessed the use of subjective minimizing language (Chin-Yee et al ASH 2022), defined as use of “acceptable,” “tolerable,” “manageable”, “favorable” (primary minimization terms), or “feasible”, “safe”, “patients did well”, “limited” (secondary minimization terms), terms that falsely imply patients deemed the therapy as such. Presence/absence of PRO or QOL data was also assessed. **Results:** 63 RCTs met entry criteria (42 CRC, 21 PaC), detailed in Table. Most trials studied chemotherapy +/- other drugs (52; 83%). 17% of all abstracts did not provide any information on AE. Quantitative data on AEs were reported by 38 (60%) of abstracts. However, serious AE reporting was frequently absent (Table), with some trials reporting only specific toxicities (e.g. cytopenias) instead of cumulative CTCAE. Only 7 (11%) of abstracts noted the occurrence or absence of fatal AE. Any subjective-minimizing language was used in 15 (24%) abstracts. Notably, none of the abstracts using subjective-minimizing language provided information on fatal AE rates, nor reported on the patient perspective via QOL or PRO. Average grade ≥ 3 AE in the experimental arm were similar in abstracts with vs without minimizing language (44% vs 45%). **Conclusions:** Our systematic review of ph 3 RCTs in GI oncology presented at ASCO annual meetings reveals that subjective minimizing language is often used to describe serious toxicities, and without formally assessing the patient voice. Serious AE reporting is frequently absent or incomplete. Research Sponsor: None.

No. of abstracts	63 (Total)	42 (CRC)	21 (PaC)
No. of Pts, Mean (Range)	621 (40 - 6088)	719 (108-6088)	425 (40-1062)
Absent AE Reporting, No. (%)	11 (17%)	7 (17%)	4 (19%)
Absent Fatal AE reporting	56 (89%)	37 (88%)	19 (90%)
Absent Grade ≥ 3 CTCAE reporting	48 (76%)	30 (71%)	18 (86%)
Use of any subjective minimizing language	15 (24%)	8 (19%)	7 (33%)
Primary terms use	13 (21%)	8 (19%)	5 (24%)
Secondary term use	4 (6%)	2 (5%)	2 (10%)

Technology-enabled clinical trials: Intentional capture of source data (IDC) in the electronic-health record (EHR) and direct transfer to trial database (electronic data capture (EDC)) in a phase II multicenter trial. *First Author: Trevor Joseph Royce, Flatiron Health, New York, NY*

Background: Traditional data collection for clinical trials can be cumbersome and inefficient. FDA guidance now promotes capturing clinical trial source data in electronic form and transmitting it to the EDC, recognizing that this should reduce double data entry and improve data quality and timeliness. Electronic data originators can include the EHR, which can be used during routine clinical care and for gathering data during a clinical investigation. We evaluated a pilot of structured EHR data transfer to EDC in a clinical trial setting. **Methods:** IDC capability in the EHR was developed and applied to a subset of patients for an open label prospective Phase II study. EHR variables, that include free text, standard dictionaries (eg CTCAEv5, CDISC, First Databank), and derived responses, were mapped to the electronic case report form (eCRF). Bulk transmission of IDC clinical data (adverse events, AEs; concomitant medications, CMs; past medical history, PMH) from the EHR to EDC was executed at a designated time point during study conduct. We assessed the quantity (records) and quality (queries) of data captured and transferred, and timeliness of entry. Data to be used for the production analysis of the trial was collected via eCRF in an EDC system in parallel per usual standards. **Results:** Data for 102 patients across 8 sites of care by 99 different users was captured in the EHR via IDC from 3/1/2021 to 9/9/2022 and transferred from EHR to EDC in bulk on 9/9/22. 3,958 data records were transferred (852 AEs; 1,581 CMs; 1,525 PMHs). Of the AEs, 99% had an associated grade. Of the CMs and PMHs, none were copy-forwarded (all were entered *de novo*). Regarding queries in the EDC for transcription error validation among matching records, EHR data produced 205 opened edit check queries from 12 edit checks across all domains (149 AEs, 0 CMs, and 56 PMHs). Regarding timeliness, 95% of matched records were entered in IDC prior to entry in the production EDC. **Conclusions:** For an open label Phase II study, clinical trial source data was captured electronically through IDC using the EHR as the data originator, and directly bulk-transmitted to EDC. This may enable the elimination of transcription of source data entry into eCRF and result in more timely access to the data in the EDC. Additional investigation into how IDC with EHR-to-EDC compares in quality to traditional EDC is warranted. Planned follow up research includes interviewing site users to evaluate their experiences with IDC data entry. Research Sponsor: Genentech; Flatiron Health.

The inclusion of health-related quality of life and other patient-reported outcomes in landmark trials for Food and Drug Administration oncology drug approvals: An analysis of cancer drug approvals between 2006 and 2022. *First Author: Ademola Samuel Ojo, Howard University Hospital, Washington, DC*

Background: How patients feel and function are essential elements of the clinical benefit of interventions which is often not captured by traditional measures of clinical benefit such as progression-free survival and overall survival. Health-related quality of life, functional status, symptom burden, and other patient-reported outcomes (PROs) assess the impact of interventions from the patient's point of view. The aim of this study is to assess the inclusion of PROs in landmark trials leading to FDA oncology drug approvals. **Methods:** This is a retrospective cross-sectional study of pivotal trials leading to FDA oncology approvals between January 2006 and December 2022 based on the FDA oncology approval notifications. The trial protocols of all pivotal trials were evaluated for inclusion of health-related quality of life or other PROs as an outcome measure. The approved therapies were classified into first-line, adjuvant/maintenance, and second or later line of treatment. Chi-square tests were used to assess the relationship between the line of treatment and the inclusion of PROs in the trial protocol. **Results:** There were 420 oncology approvals during the study period with the highest number of approvals in a single year in 2020 (56) and the least in 2007 (7). Lung cancer has the highest number of approvals (61, 14.5%) followed by lymphoma (50, 12%), leukemia (49, 11.7%), genitourinary malignancies (48, 11.4%), breast cancer (36, 8.6%), gastrointestinal malignancies (32, 7.6%), plasma cell disorders (30, 7.1%) melanoma (20, 4.8%), gynecological malignancies (20, 4.8%), hepatobiliary malignancies (14, 3.3%) and head/neck cancers (14, 3.3%). The approved therapies were first line (146, 34.8%), second or higher line (226, 53.8%), and adjuvant/maintenance therapies (48, 11.4%). PROs were included in 40.7% of the pivotal trials. There is a rising trend in the inclusion of PROs from 5.5% of pivotal trials in 2006 to 31% in 2022. Trials on first-line therapies are more likely to include PROs compared to second or higher-line therapies (44.5% vs 36.7%; $p = 0.13$). **Conclusions:** Although there is a rising trend in the inclusion of health-related quality of life and other PROs in pivotal trials for FDA oncology drug approvals, most pivotal trials did not include PROs as outcome measures. Research Sponsor: None.

Endpoints reported in phase 3 randomized clinical trials at ASCO 2022. *First Author: Laure-Anne Marie Nicole Teuwen, Department of oncology, Antwerp University Hospital, Edegem, Belgium*

Background: The goal of phase 3 randomized clinical trials (RCTs) is to show clinically meaningful benefit for patients. An analysis of phase 3 RCTs presented at the ASCO 2022 Annual Meeting (ASCO22) was undertaken to assess which endpoints were evaluated. **Methods:** A systematic analysis was undertaken of ASCO22 abstracts from phase 3 RCTs reporting primary, secondary, interim, updated, and subgroup analyses, as well as trials reporting methodology of currently enrolling studies. Trials that reported posthoc, exploratory, biomarker, and retrospective analyses of RCTs were excluded. Information from ASCO22 materials and clinical trial registration websites was recorded by two independent researchers. **Results:** In total, 166 RCTs were identified: 93 trials with 50,781 enrolled patients and 73 trials expected to enroll 52,098 patients. More trials reported on patients with locally advanced/metastatic cancer (64.5%) compared to localized cancer (35.5%). Funding source was pharmaceutical or biotechnology company in 62%. Within locally advanced/metastatic trials, overall survival (OS) was a primary endpoint in 40%, while progression-free survival (PFS) was a primary or co-primary endpoint in 45% and 13% respectively. Other primary endpoints included (invasive) disease-free survival ((i)DFS), event free survival (EFS), overall response rate and pathological complete response. In trials that did not include OS as a primary endpoint, OS was a secondary endpoint in 88% ($n = 56/64$). Within the localized group, trials were subdivided into adjuvant, neo-adjuvant, definitive and other categories. Within the adjuvant trials ($n = 27$), the most common primary endpoint was (i)DFS (37%), followed by OS (15%). Other primary endpoints included recurrence-free survival, invasive breast cancer free survival, metastasis-free survival, EFS, and PFS. Across all trials, quality of life (QOL) was never reported as a primary endpoint, however it was as a secondary or other outcome in 53% for locally advanced/metastatic trials and 42% for localized trials. When comparing the endpoints reported in the ASCO22 abstract and meeting materials with those listed on the trial registration website, discordance was noted in 14%. **Conclusions:** Phase 3 RCTs presented at ASCO22 represented participation from over 100,000 patients, however, fewer than half in locally advanced/metastatic cancer and fewer than one quarter in localized disease utilized OS as a primary endpoint. QOL was listed as an endpoint in roughly one half of all trials. Endpoints reported did not match registration data in a significant minority. Debate over which endpoints should be used for cancer RCTs should be informed by this data. Research Sponsor: None.

Utilizing Drug Combo to improve the design of phase 1 trials for anticancer drugs. *First Author: Lei Wang, Department of Biomedical Informatics, The Ohio State University, Columbus, OH*

Background: Accurate prior knowledge of a single drug or drug combination on toxicity, pharmacokinetics (PK), maximum tolerated dose (MTD), and dose-limiting toxicity (DLT) can help oncologists and statisticians design an efficient phase 1 clinical trial. However, most of the relevant knowledge is shattered in various databases. More importantly, MTD and DLT are missing in any databases. This study constructed a comprehensive knowledge base with expert-curated MTD and DLT knowledge from published anticancer drug combination phase 1 clinical trial results. We also demonstrated the utility of the knowledgebase to design a more efficient phase 1 trial. **Methods:** Toxicity, pharmacology, and PK knowledge were integrated from publicly available data sources, including DrugBank, SIDER, and drug labels. An interdisciplinary team manually curated the MTD and DLT knowledge. Relevant papers were discovered by PubMed keyword search (drug name + MTD or RP2D). Details regarding patient eligibility, treatment information (dose, formula, and schedule), trial design method, dose levels, DLT definition, MTD or Recommended phase 2 dose, and DLT incident were curated in the structured data format and stored in a database. Rxnorm and MedDRA were used for normalizing drug names and DLT. **Results:** Currently, 2358 papers on cancer drugs phase 1 trial have been curated. Additionally, pharmacological and PK knowledge of 197 cancer drugs, ADE information from 1094 drug labels, and more than 500,000 pieces of DDI evidence were integrated into the knowledge base. This knowledge base (drugcombo.info) could help researchers design an efficient phase 1 trial. For example, based on knowledge from Drug Combo, the combination of nivolumab and axitinib did not have potential PK DDI and severe overlapping toxicity. The reviewing physician considered a phase 1b study to start at a curated 5 mg maximum dose of axitinib with dose reduction to 3 and 2 mg and maintenance of a 3-mg/kg dose of nivolumab based on guidelines. With such additional preliminary knowledge, the reviewing statistician felt the adaptive statistical methods could be applied to redesign this phase I combination trial and minimize patient exposure to sub-therapeutic dose levels. **Conclusions:** To our knowledge, Drug Combo is the first knowledge that integrated curated MTD and DLT knowledge. It would promote applying curated knowledge to better design phase I trials to treat cancer. Research Sponsor: U.S. National Institutes of Health.

Streamlining regulatory review in a multicenter platform trial: Opportunity to enhance patient centered care and drive innovation and efficiency. *First Author: Alexis Colley, University of California, San Francisco, San Francisco, CA*

Background: In addition to being required by the Federal Policy for the Protection of Human Subjects for United States-based institutions that receive federal funding and are engaged in cooperative research projects, the use of a central Institutional Review Board (cIRB) has multiple benefits. Yet more advanced trial designs have unique needs and challenges that may hinder adoption of an efficient cIRB. Platform trials, which require both a master protocol and successive individual protocol amendments for each new agent, are prone to high regulatory burden that can slow trial recruitment, representing a significant workload for study personnel. Specific challenges for platform trials include high burden of new amendments and IRB review schedules staggered across sites, making it challenging to have all sites operating under the same amendment concurrently. **Methods:** Administrative assessments were collected over the course of the I-SPY2 trial. The primary outcome of interest was time from amendment submission to approval (calculated as the number of days from submission to the local IRB by the site investigators to approval by the local IRB). Quantitative data in terms of hours spent on regulatory tasks pre- and post-cIRB implementation was estimated. Site investigators were asked in December 2022 to complete a brief questionnaire to investigate perceptions on changes to workload and level of comfort using a cIRB. **Results:** Amendments were activated when 50% of high accruing sites had IRB approval. The number of sites with approval for an amendment to go live was < 25% prior to cIRB adoption, and 83% after. Following transition to the cIRB in February 2021, the mean time from amendment submission to approval decreased from 54.4 to 20.7 days by Jan 2023. Changes to the informed consent were possible once the cIRB was adopted, including: standardizing site-specific IRB language in a section of the consent, so it need not be adjusted with every new agent amendment; standardizing site-specific workflows; shortening consent and making it more patient friendly. The average time that CRCs spent on regulatory work at each site decreased by an average of 160 minutes, but was variable, revealing continued use of local IRB, other committees at some sites. A total of 14 respondents completed the survey; most respondents indicated that keeping up with the amendment approval process was easier post-cIRB and 94% were comfortable relying on a cIRB. The short time for cIRB approval revealed the inefficiency of other processes, including coverage analysis and building of drug order sets. **Conclusions:** Active engagement of cIRB leadership and IRB working group has enabled regulatory review that now takes less than 30 days. The cIRB is now the standard for the I-SPY family of trials. Other services can also be shared and will continue to drive efficiency and reduce the regulatory burden for sites. Use of gender-neutral language in clinical trial protocols in select cancers. *First Author: Garima Gupta, University of Kentucky, Lexington, KY*

Background: Around 21% of Generation Z Americans self-identify as lesbian, gay, bisexual, transgender (LGBT), nearly double the proportion of millennials. Despite Affordable Care Act Section 1557 in 2020, transgender individuals continue to have poor access to quality cancer care, including clinical trials. The National Institutes of Health (NIH) recognizes that using gender-neutral language in healthcare is one of many ways to improve sexual and gender minorities (SGM) related health disparities. This study examines use of gender-neutral language in clinical trial protocols in select cancers. **Methods:** Data was collected from clinicaltrials.gov, a commonly used resource for patients and providers. Phase III clinical trials with all recruitment statuses in the US from 2017 to 2022 were included. Cancer types were limited to those with highest risk of using gender-biased language: breast, ovarian, endometrial, fallopian tube, cervical, prostate, testicular, and penile. For each trial, frequency of use of following terms was recorded by searching under study details section: male, female, she, her, he, his, him, man/men, woman/women, breastfeeding/nursing/lactating/pregnant mother or female or woman. Mean frequency was compared between 2017-19 and 2020-22 using Wilcoxon signed-rank test. Funder type, eligible sex, gender-based eligibility and gender eligibility description were also collected. Data were compared between 2017-19 (pre-1557) and 2020-22 (post-1557) using Fisher exact test. **Results:** 243 studies were included in the analysis; 130 were pre- and 113 were post-1557. 103/130 (80%) studies between 2017-19 and 78/113 (70%) between 2020-22 included at least one gender-biased term or "male/female" outside of eligible sex description ($p = 0.05$), depicting a trend towards improvement; stronger improvement was noted in non-NIH funded studies versus NIH-funded studies. Mean frequency of gender-biased terms was higher in 2017-19 compared to 2020-22 (2.25 vs 1.88, $p = 0.02$). 27/130 studies (21%) between 2017-19 and 21/113 (19%) of studies between 2020-22 required gender-based eligibility ($p = 0.40$). Amongst these, 100% of studies between 2017-19 and 95% of studies between 2020-22 either provided no description or used this clause incorrectly, commenting on sex assigned at birth and not gender identity. This indicates lack of awareness regarding difference between sex assigned at birth and gender identity. While it is evident to investigators during registration on clinicaltrials.gov that eligible sex refers to biological sex, it is not to anyone reviewing the trial for enrollment, resulting in implicit bias. **Conclusions:** Our study highlights the dire need to address SGM-related health disparities and brings attention towards paucity of gender-neutral language in clinical trial protocols. This step is critical in providing more inclusive care and capturing the rising population of LGBT individuals. Research Sponsor: None.

Survival-inferred fragility index of FDA-approved cancer drugs using surrogate endpoints. *First Author: Jonathan Ofer, Davidoff Cancer Center, Rabin Medical Center–Beilinson Hospital, Petah Tikvah, Israel*

Background: The survival-inferred fragility index (SIFI) quantifies the robustness of positive trials by estimating the number of changes in a survival analysis that would render the results insignificant. Here, we use a variation of SIFI (SIFI-median) in which the median patient is reassigned between study groups until significance is lost. Our goal was to study the robustness of oncology randomized controlled trials (RCTs) leading to drug approval by the FDA based on surrogate time-to-event endpoints. **Methods:** In this cross-sectional study, we identified phase II-III RCTs between 2010 and 2020. We reconstructed individual patient data from published Kaplan-Meier plots of surrogate time-to-event endpoints and calculated the SIFI-median, i.e., the minimum number of median survivor reassignments from the intervention group to the control group that would cause the loss of statistical significance. **Results:** A total of 101 studies comprising 60697 patients met the inclusion criteria. The most common surrogate endpoint was PFS 86 (85.1%), followed by DFS 7 (6.9%). The SIFI-median was 23 (interquartile range [IQR], 12 to 37) and the SIFI-median as a proportion of sample size was 5.3% (IQR, 2.7% to 8.1%). Forty-five studies (44.5%) had SIFI-median less than 5% of the total sample size which was often less than the number of censored patients during early follow-up. The SIFI-median was less than 1% of the total sample size in 10 studies (9.9%). **Conclusions:** Low fragility indices indicates that the statistical conclusions of clinical studies could be reversed with a small number of variations. The lack of statistical robustness in multiple FDA-approved drugs suggests higher uncertainty in their clinical benefit. Research Sponsor: None.

Trends in U.S and global patient enrollment from 2014 to 2022 in lung cancer clinical trials supporting marketing applications: An FDA analysis. *First Author: Oladimeji Akinboro, Office of Oncologic Diseases, Office of New Drugs, Center for Drug Evaluation and Research, U.S. Food and Drug Administration, Silver Spring, MD*

Background: Oncology drug development is an increasingly global endeavor, however it is unclear how enrollment in registration clinical trials for lung cancer have been impacted. Clinical trial data must be reflective of the intended population in order to be considered applicable to U.S patients and medical practice, and for FDA review. **Methods:** Registration clinical trials supporting lung cancer indications submitted to FDA from 2014 to 2022 were included. Patient enrollment per country was extracted for each trial, and countries were grouped into 9 global regions. The proportion of patients enrolled in the U.S and global regions were calculated for each trial. For the purpose of this analysis, MRCTs were defined as trials that enrolled at least 5% of patients from each of ≥ 3 global regions with no region accounting for $\geq 70\%$ of patient enrollment. Trial-level patient enrollment was aggregated into 3 triennia: 2014-2016, 2017-2019, and 2020-2022. **Results:** A total of 66 pivotal trials supporting 59 applications submitted to FDA were evaluated during the study period. Of these, 91% ($n=60$) were for non-small cell lung cancer while 9% ($n=6$) were for small cell lung cancer; 59% ($n=39$) were randomized controlled trials (RCTs) while 41% ($n=27$) were single-arm trials; 53% ($n=35$) were for biologics while 47% ($n=31$) were for non-biologics; and 86% ($n=30$) of the biologics-based regimens were anti-programmed death (ligand)-1 antibody-containing regimens. The proportion of trials with no U.S patient enrollment increased from 4.8% in 2014-2016 to 19.0% in 2020-2022 while those with $\geq 10\%$ U.S patient enrollment declined from 71.4% in 2014-2016 to 52.3% in 2020-2022. There was a decline in the proportion of trials conducted as MRCTs since 2014 from 85.7% in 2014-2016 to 66.7% in 2020-2022. **Conclusions:** This exploratory analysis suggests that there may be declining U.S patient enrollment in lung cancer pivotal trials, and the proportion of these trials conducted as MRCTs may also be declining. These patterns of decline appear to be driven by the countries selected for patient enrollment in RCTs rather than in single-arm trials. Pivotal trials that do not enroll U.S patients and are not conducted as true MRCTs may have limited applicability to U.S patients. Research Sponsor: None.

Quantifying the growth of clinical actionability in precision oncology using OncoKB. *First Author: Sarah P. Suehnholz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: OncoKB (www.oncokb.org), Memorial Sloan Kettering's (MSK) precision oncology knowledge base, contains curated information about the oncogenic effect and therapeutic implications of somatic alterations in cancer and is the first cancer variant database to be partially recognized by the US-FDA. Individual mutations and structural alterations in OncoKB are assigned a level of evidence based on whether the alteration is a predictive biomarker of response or resistance to a genomically matched standard care or investigational drug in a specific cancer subtype. As of February 2023, OncoKB includes annotations for >6200 alterations in >700 cancer-associated genes, including 50 level 1 or 2 standard care genes (specified in the FDA drug label or professional guidelines) as well as 9 level 3A and 12 level 4 genes (predictive of drug response based on well-powered clinical studies or compelling biological evidence, respectively). OncoKB data is used internally to annotate >15,000 MSK patient sequencing reports annually, and its content is integrated into the cBioPortal for Cancer Genomics. **Methods:** To quantitate the expansion of the clinical actionability landscape in precision oncology, we annotated the clinical sequencing results of 47,271 solid tumor samples from the AACR Project GENIE cohort (GENIE 11.0 - public) using two versions of OncoKB, the first from March 2017 and the second from November 2022. **Results:** From 2017 to 2022, we observed a 22.7% increase in the fraction of samples with a standard care biomarker (levels 1 and 2), and a 21.4% decrease in the fraction of samples with a driver alteration that was not clinically actionable. The tumor agnostic approvals of the anti-PD1 antibody pembrolizumab in microsatellite instability high (MSI-H) and tumor mutational burden high (TMB-H) solid tumors resulted in a 11.1% increase of samples with a level 1 biomarker. In sum, of the 38,722 samples across 66 cancer types with limited to no actionability in 2017 (levels 3B, 4 or no level), 21.7% became clinically actionable (levels 1, 2 or 3A) by November 2022. This is an upper bound estimate as it includes samples that may have been eligible for an FDA-approved precision oncology therapy based on cancer subtype alone. **Conclusions:** Our analysis highlights the significant expansion of precision oncology-based therapeutic options for patients with cancer over the past 5 years, as well as the ongoing unmet need for novel precision oncology approaches designed to address oncogenic but not currently actionable drug targets. Research Sponsor: None.

Clinical actionability of solid tumor samples from AACR project GENIE cohort.

Highest OncoKB Level of Evidence	OncoKB version March 2017	OncoKB version Nov. 2022
Level 1 (including MSI-H)	7.7%	21.0%
Level 1 (only TMB-H)	0%	9.2%
Level 2	1.2%	1.4%
Level 3A	9.2%	4.3%
Level 3B	20.0%	13.6%
Level 4	8.6%	20.6%
Driver without actionability	44.2%	22.8%
No Driver or no alteration	9.1%	7.1%

Clinical pathways innovation: A lesson on the value of clinician based feedback and collaboration with Flatiron Health. *First Author: Christopher Davella, Department of Hematology/Oncology, University of Pennsylvania, Philadelphia, PA*

Background: Clinical pathways have emerged as a strategy to provide value-based care by reducing treatment variation across oncology practice. Despite evidence for cost reduction and improved patient outcomes, adoption of clinical pathways has met resistance in the oncology community given concerns regarding the impact on workflow, and cost. Flatiron Assist, an EMR based pathways tool, is a promising solution to minimizing workflow friction by providing a novel, streamlined user interface. **Methods:** The Abramson Cancer Center at the University of Pennsylvania and Flatiron Health conducted a pilot study from August 2021-December 2022 to test the use of Flatiron Assist within its thoracic oncology practices. The goal of the pilot was to increase utilization as well as usability of the pathways tool over time through clinician and developer iterative collaboration. Penn's clinical pathways were incorporated into the tool and integrated into the EMR. An education program trained clinicians on the tool's functionality. Based on clinician feedback, the Penn team identified two areas of improvement for the tool: speed and organization of the tool keys and prompts. Changes made over time included: 1) increasing the speed of the tool 2) restructuring the organization of keys and prompts, and 3) creation of a "hot button" for three common clinical scenarios in order to increase efficiency. Speed of the application (session length in seconds), utilization of the hot button (number of sessions/overall sessions) and overall physician adoption (treatment ordering with Flatiron Assist/total thoracic orders) were calculated during the pilot. **Results:** Provider utilization of the pathways tool increased over time with a baseline adoption rate of 29% in August 2021 and a peak of 74% in April 2022. Median session length decreased over time from 106.4 seconds (August 2021) to 39.9 seconds (December 2022). Peak performance for session length was 38.2 seconds (November 2022). Usage of the hot button introduced in August 2022 has increased over time from 27.6% of sessions to 41.8% in November 2022. Thoracic providers ordered, on average, 1.7 new treatment plans per week, resulting in less than 1.5 extra minutes of work per week with optimal use of the pathways tool. **Conclusions:** Collaboration between Penn and Flatiron Health effectively reduced specific areas of friction associated with the use of Flatiron Assist. Changes made to the speed, button organization and functionality of the tool contributed to increased clinician utilization over time. Future development of EMR based pathway tools should incorporate clinician engagement and feedback. Research Sponsor: None.

Completion rates and trends of the patient-reported outcomes version of the Common Terminology Criteria for Adverse Events (PRO-CTCAE) across 14 oncology clinical trials. *First Author: Jessica A Emerson, Clario, Philadelphia, PA*

Background: With growing emphasis on patient-centered regulatory decision making, there is a greater need to incorporate the patient's voice in oncology clinical trials. Regulatory guidelines outline core patient-reported outcomes (PROs) to include which can inform risk/benefit evaluation. Self-reported symptomatic adverse events (AE) form part of these core PROs, with the new 2023 draft FDA guidance acknowledging the benefits of including them to enhance the assessment of tolerability in early phase dose optimization trials. Given the clinical symptoms and disease burden in oncology, patient burden needs to be thoughtfully considered when incorporating PROs into trials. We assessed trends and feasibility of electronic data collection for symptomatic AEs by analyzing completion compliance and time to complete the Patient-Reported Outcomes version of the Common Terminology Criteria for Adverse Events (PRO-CTCAE) across 14 oncology trials. **Methods:** All PRO-CTCAE were collected electronically on Clario Tablets. Operational data for completion status (completed or missed) and duration of time to complete the PRO-CTCAE in seconds was extracted. Completion rates over time were examined overall and for every 3-month interval (quarters Q1 to Q9+). The median was selected for analyses of time to complete to account for skewness. **Results:** The sample included 14 studies across Phase I-III trials across a range of cancers including multiple myeloma, mesothelioma and cancers of the lung, prostate, head/neck, gastric, breast, and ovary. Study durations were 24 weeks and up. The PRO-CTCAE form was completed 13,122 times and missed in 1,182 instances, giving an overall completion rate of 91.7%. On average, 25 questions (range 5-47) covered an average of 13 symptoms (range: 4-25). Completion rate was not associated with the number of questions asked or time since enrollment. The overall median time to complete the PRO-CTCAE was 82s (study-specific median range: 24s to 276s). Examining time to completion as a function of the number of questions revealed a significant positive association, such that each additional question added 5.2 seconds to the time it took to complete the assessment. **Conclusions:** Completion compliance was high for PRO-CTCAE and remained high regardless of study length and the number of questions included in the PRO-CTCAE form. This suggests that electronic PRO-CTCAE is a feasible solution for collecting self-reported symptomatic AEs. Although time to complete the form increased with the number of questions, results suggest that including a higher number of PRO-CTCAE questions does not negatively impact compliance rate. Our data showing high completion rates may also reflect the benefits of electronic PROs in reducing patient burden and enhancing data quality, as acknowledged by regulatory agencies. Association of remote, longitudinal patient-reported outcomes (PROs) and step counts with hospitalization or death among patients with advanced cancer undergoing chemotherapy: Secondary analysis of the PROStep randomized trial. *First Author: Ravi Bharat Parikh, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: Patients with advanced cancer undergoing chemotherapy experience significant symptoms and declines in functional status, which are often associated with poor outcomes. Remote monitoring of PROs (symptoms) and step counts (functional status), may proactively identify patients at risk of hospitalization or death. Our objectives were to evaluate the association of 1) longitudinal PROs with step counts, and 2) PROs and step counts with hospitalization or death. **Methods:** The PROStep randomized trial (NCT04616768) enrolled 108 patients with advanced gastrointestinal (GI) or lung cancers undergoing cytotoxic chemotherapy at a large academic cancer center. Patients were randomized to weekly text-based monitoring of 8 PROs (each measured on a 0-4 scale) + continuous step count monitoring via Fitbit, vs usual care. This pre-planned secondary analysis included 57 of 75 patients randomized to the intervention who had PRO and step data. We analyzed associations between PROs and mean daily step count, and associations of PROs and step counts with the composite outcome of hospitalization or death, using bootstrapped generalized linear models to account for longitudinal data. **Results:** Among 57 evaluable patients, mean age was 57 years, 24 (42%) were female, 49 (86%) were White, 43 (75%) had advanced GI cancer, and 14 (25%) had advanced lung cancer. A 1-point weekly increase (on a 32-point scale) in aggregate PRO score was associated with 247 fewer mean daily steps (95% CI -277, -213, $p < 0.001$). PROs most strongly associated with step count decline were patient-reported activity level (daily step change -892), nausea (-677), and constipation (-524). 25 patients (44%) were hospitalized ($n = 21$) or died ($n = 8$). A 1-point weekly increase in aggregate PRO score was associated with 20% greater odds of hospitalization or death (adjusted odds ratio [aOR] 1.2, 95% CI 1.1, 1.4, $p = 0.008$). PROs most strongly associated with hospitalization/death were pain (aOR 3.2), decreased activity (aOR 3.2), dyspnea (aOR 2.6) and sadness (aOR 2.1). A decrease in 1000 steps was associated with 16% greater odds of hospitalization or death (aOR 1.2, 95% CI 1.0, 1.3, $p = 0.03$). Compared to baseline, mean daily step count decreased 6.7%, 8.5%, 16.2% in the 3, 2, and 1 weeks prior to hospitalization/death. Mean aggregate PRO score increased by 11.0%, 25.3%, 36.4% in the 3, 2, and 1 weeks prior to hospitalization/death. **Conclusions:** In this secondary analysis of a randomized trial, increased PRO-based symptom burden was associated with lower daily step count. Higher symptom burden and decreased step count were independently associated with and predictably worsened close to hospitalization or death. Future interventions should leverage longitudinal PRO and step data to identify risk for poor outcomes. Clinical trial information: NCT04616768. Research Sponsor: U.S. National Institutes of Health.

The Tempus TIME trial portal and clinical trial enrollment. *First Author: Amol Rao, Memorial Care, Fountain Valley, CA*

Background: The TIME Trial Program is a research network that screens > 1 million patients daily via EMR integrations and NGS testing through an automated trial matching platform and human review. There are enormous complexities following patients longitudinally as their clinical status changes while accurately matching them with hundreds of studies. The TIME Trials Portal, which stores both clinical trial documents and patient status updates, allows for real-time communication between the TIME team and Clinical Sites. **Methods:** After both an automated and nursing review, eligible trial patients are uploaded into the TIME Trials Portal. This database tracks the patient's name, date of birth, biomarkers, clinical status, trial matches, free text comments, and upcoming physician, radiology, and laboratory appointments. To protect Personal Health Information, each Clinical Site can only view their own patients. Patient status is classified as Needs Review, Monitoring, Enrolled, Inactive. Each update is time-stamped and tracked. Enrolled patients have the trial name, consent date, and other pertinent information documented. **Results:** The data from 2020 to 2022 includes 71 TIME Sites. Over this period, 6,816 patients were added to the TIME Trials Portal for an average of 219 per month. Of these, 1,891 patients were no longer eligible due to worsening performance status, trial closure, death, and other causes. The TIME team provided 8,643 patient updates compared to 7,442 Clinical Site updates. Clinical Sites spent 1,231.7 hours using the TIME Therapies Portal resulting in 623 total consents. Data from 2022 alone, demonstrated that 30 (42.3%) Clinical Sites with EMR integrations were responsible for 4,491 (76.3% of the total) patient updates translating into 288 (82.1%) of all consents. Also in 2022, of the 27 (38%) Clinical Sites that updated their patient's status > 50 times consented 291 (82.9% of the total) patients. **Conclusions:** By 2022, the TIME Trials Portal was averaging approximately 400 new patients monthly resulting in a 13.1X increase in patients added from the program's inception. Clinical Sites updated the patient status over 7,400 times spending over 1,200 hours using the TIME Trials Portal. The highest-performing Clinical Sites, which enrolled approximately 80% of the total patients, included those with EMR integrations and/or > 50 patient updates yearly. The TIME Trials Portal enabled patient tracking and communication to facilitate clinical trial enrollment. Research Sponsor: Tempus Laboratories.

Differences in perceptions and use of remote patient monitoring technology in rural cancer programs. *First Author: David Penberthy, Penn State Health, Hershey, PA*

Background: While the benefits and acceptability of remote patient monitoring (RPM) during cancer care are well documented, barriers to implementation and use of these digital technologies remain. Feasibility may be particularly restricted in rural settings. The Association of Community Cancer Centers (ACCC) surveyed U.S. cancer programs, patients with cancer and caregivers in various geographic settings to illuminate the current practice landscape and perceptions regarding the use of digital technologies to monitor patients for adverse events and collect patient reported outcomes (PROs). **Methods:** ACCC convened an expert advisory committee and patient advocacy partners to guide development of two surveys, one for cancer program staff and the other for patients/caregivers. Surveys were distributed between December 2022 and January 2023 and included 25 closed and open-ended questions. Exploratory analysis was performed and responses were compared between rural, suburban, and urban settings for both groups, with comparisons made by two tailed Fisher's exact test. **Results:** There were 128 cancer program staff and 162 patient/caregiver responses. Of staff respondents (52% physicians, 20% other clinicians, 21% administrators/managers), 58% work in urban, 30% suburban, and 13% rural settings. Of the patient/caregiver respondents (56% patients, 44% caregivers), 28% live in urban, 51% suburban, and 21% rural areas. 56% of rural, 24% of urban, and 26% of suburban respondents indicated that their cancer programs have not implemented and are not considering implementing RPM. Of rural program staff, 44% indicated they have no experience/familiarity with RPM, compared to 7% for urban and 13% for suburban staff ($p < .001$, $p = .03$, respectively). Fewer rural programs, as compared to urban, use secure text messaging (6% vs. 42%; $p = .008$) or automated phone surveys (6% vs. 34%; $p = .03$). More rural patients/caregivers compared to their urban/suburban counterparts indicated concerns about privacy (47% vs 27%; $p = .02$), concerns about the need to pay (44% vs. 19%; $p = .004$), and lack of strong cell service (5% vs 21%; $p = .007$) as barriers to RPM technology use. **Conclusions:** RPM is gaining momentum in academic and community cancer program settings; however, significant gaps exist in RPM experience and implementation for rural cancer programs. In addition to well-documented disparities in access to internet and cellular service for rural patients, perceptions about privacy and cost pose additional barriers. Secure text messaging and automated surveys are often used as example solutions to bridge digital literacy and access gaps, yet cancer programs in rural areas are less likely to use these technologies. Tailored patient/provider education, funding/reimbursement strategies, and advocacy for policies expanding technology infrastructure may be needed for cancer programs to equitably provide RPM technologies. Global adoption of remote technologies to enable patient-centric oncology clinical trials: Analysis by the Bloomberg New Economy International Cancer Coalition. *First Author: Robert Michael Daly, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Fewer than 5% of patients with cancer enroll in a clinical trial, partly due to the significant financial and logistical burden on patients, especially among underserved populations. The COVID-19 pandemic marked a significant shift in the adoption of remote technologies and decentralized trial operations by major pharmaceutical companies. We sought to determine the current global state of adoption of these technologies, understand factors that are driving or preventing adoption of them, and highlight aspirations and direction for industry to enable more patient-centric trials. **Methods:** The multi-stakeholder Bloomberg New Economy International Cancer Coalition composed of patient advocacy, industry, government regulators, and academic medical centers developed a survey directed to global biopharmaceutical companies of the Coalition with a focus on registrational clinical trials. The survey was organized into three main sections: 1) Impact of different remote monitoring and data collection technologies on patient-centricity; 2) Adoption of these technologies in oncology and all therapeutic areas; 3) Barriers/facilitators to adoption. **Results:** Administered from October 1 to December 31, 2022, a total of 8 companies completed the survey (response rate: 100%), representing 33% of oncology market by revenues in 2021. Across nearly all remote monitoring and data collection technologies, adoption in oncology trials lags that of all trials. In the current state, eDiary/eCOA is the most utilized technology with 56% and 51% adoption for all trials and oncology trials, respectively, whereas visits in local physician networks is the least adopted at 12% and 7%, respectively. Looking forward, the difference between the current and aspired adoption rate in 5 years for oncology is large, with respondents expecting a 40% or greater absolute adoption increase in 8 out of the 11 technologies (Table). Furthermore, respondents identified digitally enabled recruitment, local or mobile imaging capabilities, and local physician networks as those technologies that would be most impactful for improving patient-centricity in the long term. **Conclusions:** This survey is the first by a coalition of global stakeholders to determine the current state and future aspirations for the use of remote technologies in oncology clinical trials. These efforts may galvanize momentum towards greater adoption of enabling technologies supporting a new paradigm of trials that are more accessible, less burdensome, and more inclusive. Research Sponsor: None.

Remote technologies	Current State	5-Yr Aspiration
eDiary/eCOA	51%	81%
Digitally-enabled enrollment	26%	70%
Patient engagement dashboard	25%	79%
Digitally-enabled recruitment	20%	70%
Remote monitoring	13%	55%
Telemedicine visits	11%	58%
Mobile/local labs	11%	47%
Mobile/local imaging	9%	49%
Local physician networks	7%	51%

Longitudinal changes in patient reported outcome measures in patients with cancer six months prior to death: A case-control study. *First Author: Samantha Tam, Henry Ford Health, Detroit, MI*

Background: Provider assessments consistently fall short in determining when cancer patients enter into the terminal phase of their disease. Despite prior desires to spend their last days outside an institution, patients often seek emergency room care and most report never having a palliative consultation at the time of their terminal admission. Patient reported outcome measures (PROMs) are derived directly from the patient and may provide insight into the experience near the end of life to facilitate earlier involvement of supportive oncology. This study aims to compare PROMs in the 6 months prior to death to those not dying among patients with cancer. **Methods:** This study uses a routine PROMs program implemented since September 2020 for all patients with a cancer diagnosis at a tertiary care hospital. This study focused on PROMs using 3 domains of the Patient Reported Outcomes Measurement Information System (PROMIS): physical function, pain interference, and fatigue; PROMs frequency mirrored patients' oncologic visits. Using a retrospective case-control study, patients who had died within 6 months of a PROMs response (cases) were compared to controls who were alive at the time of the case's death. Cases were matched 1:2 to controls by age at PROMs completion, gender, cancer disease site, and stage. Generalized estimating equation (GEE) models adjusted for age at PROMs completion, gender, cancer disease site, stage, and correlations between individual patient encounters were used to compare mean PROMs scores between cases and controls in each domain. **Results:** In total, 274 cases were compared to 270 unique controls. Univariate comparisons between cases and controls demonstrated significant differences only in Charlson Comorbidity Index (CCI), with cases demonstrating worse CCI (3.3 ± 2.5) compared to controls (2.3 ± 2.2 ; $p < 0.001$). Time from diagnosis to PROMs completion was not different between groups (4.08 versus 4.10 years, $p = 0.798$). Over the 6 months prior to death, 10.5%/15.0%/32.0% cases had severe pain/fatigue/physical function scores compared to 3.3%/3.7%/8.7% in controls ($p < 0.001$). GEE models demonstrated that cases had a higher mean fatigue score of 5.34 points (95% CI = 3.81 to 6.88), higher mean pain interference score of 4.92 points (95% CI = 3.42 to 6.43), and lower mean physical function score of 7.39 points (95% CI = -8.84 to -5.93) indicating more severe symptom scores for cases in all three domains. **Conclusions:** On average, patients experiencing death within 6 months of PROMs completion demonstrated worse physical functioning, pain interference, and fatigue scores compared to their age, gender, cancer disease site, and stage matched controls. The differences in PROMs scores represent a first step to improving understanding of PROMs during the terminal stage of disease and may guide indicators for earlier need of supportive oncology support. Research Sponsor: Henry Ford Foundation.

Acceptability and effectiveness of digital prehabilitation and personalised support for patients with cancer in the UK National Health Service. *First Author: Venetia Wynter-Blyth, Onkohealth, London, United Kingdom*

Background: Prehabilitation is associated with increased tolerance to oncology treatments, reduced post-operative complications and hospitalisations. Most prehabilitation programmes are delivered in hospitals or community centres. However, large-scale implementation is limited by problems of access, workforce demands, travel costs and sustainability. Digital technology presents an opportunity to address concerns and broaden access. The aim of this study was to explore the feasibility, acceptability and effectiveness of a digital prehabilitation service. **Methods:** Since January 2022 a digital coaching model of physical, nutritional and psychological optimisation was implemented across a sample of NHS hospitals, provided by Onkohealth Ltd. Patients were onboarded onto the 12-week programme through a native app or, for those without access to smart technology, a web-based pathway. Baseline health metrics were collected through a combination of validated survey tools and wearable technology. Patients were matched to a personal health coach for ongoing guidance and support. The intervention combined digital behaviour change techniques with remote monitoring and real-time targeted support from their coach when the need is triggered. Self-reported physical activity (PA) was recorded and calculated as METS min week⁻¹. Psychological wellbeing outcomes and e-PROMs included self-efficacy, quality of life [EQ5D5L Health Utility (EQ-HU)] and a visual analogue scale (EQ-VAS)] before and after completion of the 12-week programme. **Results:** 303 patients were referred to the service. 228 (75.2%) accepted and started the programme. 167 (74%) followed an app-based programme. 24 patients (12.2%) discontinued. 103 patients, on different oncological pathways, completed the 12-week programme. 30 completed a median of 4 weeks pre-operatively. 12 started post-operatively. 61 received chemotherapy (neoadjuvant: 17; adjuvant: 23 and palliative: 21). A complete pre-post data set was available for 47 patients. There were significant improvements for all study metrics: PA mean difference 323 METS min week⁻¹ (95% CI 45 to 600), $p = 0.024$; distress mean difference -1.2 (95% CI -2.3 to -0.1), $p = 0.025$; anxiety mean difference -1.5 (95% CI -2.7 to -0.3), $p = 0.018$; depression mean difference -1.3 (95% CI -2.5 to -0.1), $p = 0.04$; EQ-HU median 0.71 (IQR 0.57-0.84) to median 0.77 (IQR 0.65-0.84), $p = 0.041$; EQ-VAS mean difference 15.4 (95% CI 5.7 to 25.0), $p = 0.003$; self efficacy mean difference 3.2 (95% CI 0.6 to 5.7), $p = 0.015$. **Conclusions:** This is the first study on the implementation and effectiveness of a digital model of prehabilitation and coaching for cancer patients. Patients respond positively in nearly all dimensions of physical and psychological health despite being on oncological treatments, with a significant improvement in self-efficacy, EQ-HU and EQ-VAS. Research Sponsor: None.

Patient-reported usefulness of an intervention to promote job retention among women undergoing (neo)adjuvant breast cancer chemotherapy. *First Author: Victoria Susana Blinder, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Women who undergo (neo)adjuvant breast cancer chemotx are at risk of job loss, especially if they lack work accommodations. We developed TEAMWork (Talking to Employers And Medical staff about Work), an English/Spanish mobile application (app) to help women identify work accommodations relevant to their needs, negotiate with their employers to receive these accommodations, and communicate with the clinic team to manage symptoms. TEAMWork will be compared to a booklet as a job-retention tool in an ongoing randomized clinical trial (RCT). Here we present acceptability data based on RCT participants' perceptions of the app's usefulness. **Methods:** Eligible participants were women aged 18-64, who spoke English/Spanish, were able to use and had access to a smartphone/tablet, were undergoing or planned to undergo (neo)adjuvant chemotx for stage I-III breast cancer, and were working full or part time for pay. Women who had stopped working due to the diagnosis were eligible. Those who had stopped working for reasons unrelated to breast cancer (e.g., prior illness disability) were ineligible. Online surveys were self-administered or administered interview-style (per participant preference) at baseline and midway through the planned chemotx. In the second survey, participants were asked if they had used TEAMWork at all since enrollment; those who said they had used it were asked about the app's usefulness. **Results:** 58 participants received the app; 56 received the booklet. 64% were white, 18% were Black, and 12% were Asian; 7% were Hispanic. 4% were Spanish-speaking. 79% had at least a college education. When surveyed half-way through their chemotx regimen, 62% of those randomized to the app said they had used the app; only 25% of those randomized to the booklet said they had used the booklet ($p < 0.0001$). Among those who reported having used the app ($n=36$), 86% said they were very (44%) or somewhat (42%) satisfied with TEAMWork, and 94% said they thought TEAMWork would be very (61%) or somewhat (33%) helpful to other patients. Additional details about the perceived usefulness of the app are shown. **Conclusions:** Compared to participants randomized to the booklet, more than twice as many who received the app reported that they had used their assigned intervention. Among those who used it, the app was well-received and was deemed especially helpful for communicating with medical providers. Recruitment to the RCT is ongoing, and job retention results will be presented when data are mature. Efforts are under way to increase the diversity of the study sample based on ethnicity, language, and education. Clinical trial information: NCT03572374. Research Sponsor: U.S. National Institutes of Health.

Comparison of publications between cancer sites in high impact factor journals. *First Author: Nikita Sinha, UNC Chapel Hill, Chapel Hill, NC*

Background: Prior studies have shown disparities in federal funding allocation by cancer site after accounting for mortality, incidence, and person-years of life lost. Whether disparities exist in publications in high impact factor journals is unknown. The aim of this study is to analyze research publications in high impact factor journals by cancer site relative to their burden from 2000 to 2018. **Methods:** Abstracts from the top 55 impact factor journals from 2000 to 2018 were extracted from PubMed. We developed an algorithm to search the title of the abstract to determine whether the abstract was about cancer and identify the cancer type. The algorithm was validated against the gold standard of human review in 1143 abstracts and yielded a sensitivity and a specificity of >95%. An article proportion for each cancer site was calculated (abstracts for a cancer site / total cancer abstracts). Article proportion was compared to cancer site-specific incidence, mortality and lethality from NCI's SEER database using scatter plots and non-parametric Wilcoxon signed rank test. **Results:** We identified 128,377 articles; 31,045 (24%) were about cancer. Cancers with the most publications in high impact factor journals were breast (22%), lung (11%), and colorectal (10%) cancer. Breast, lung and colorectal cancer were also well represented in high impact factor journals compared to their incidence, mortality, and lethality. Gynecologic (ovarian, cervical, and endometrial), pancreatic, hepatobiliary, and prostate cancers were poorly represented in all 3 metrics. Breast, lung, and colorectal cancer ranked in the top half of Article to Lethality scores, while the gynecologic, pancreatic, and hepatobiliary cancers were in the bottom half ($p < 0.05$ for all comparisons). Comparison of rankings by lethality versus by funding indicates relative underfunding of the gynecologic, pancreatic, hepatobiliary, and prostate cancers. **Conclusions:** Research publications in high impact factor journals by cancer site are not proportionate to individual societal cancer burden. Significant disparities exist between breast, lung, and colorectal cancer when compared to gynecologic, pancreatic, hepatobiliary, and prostate cancers relative to their disease burden. Underfunding of these cancer sites likely contributes to this publication gap. Research Sponsor: U.S. National Institutes of Health.

Rank	Cancer Type	Article to Lethality	p-value (to uterus)	p-value (to cervix)	p-value (to ovary)	p-value (to pancreas)	p-value (to liver)

Association of state policies regulating short-term limited-duration insurance plans and cancer stage at diagnosis. *First Author: Justin Michael Barnes, Department of Radiation Oncology, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: In 2018, federal regulations expanded access to short-term limited duration insurance (STLD) plans. STLD plans generally limit coverage of medical services and have no cost-sharing caps, which can delay a cancer diagnosis. Furthermore, uptake of STLD plans can destabilize individual insurance markets, leading to increased prices and subsequent barriers to care for comprehensive insurance plan enrollees. Several states introduced legislation prohibiting and/or limiting STLD plans, but it is unclear whether STLD plans or policies restricting their proliferation have affected cancer stage at diagnosis. **Methods:** Individuals ages 18-64 years with staged first primary malignancies diagnosed 2016-2019 were identified from the Surveillance, Epidemiology, and End Results (SEER) database. Difference-in-differences (DID) analyses evaluated changes in early-stage (stages 0 [breast and bladder only] through II) diagnoses from pre- (2016-2017) to post- STLD expansion (2019; 2018 was excluded as washout/phase-in period) between states with policies prohibiting and/or limiting STLD plans vs. states with no policies regulating STLD plans. In some states limiting but not prohibiting STLD plans, insurers stopped selling STLD plans; we conducted additional analyses by state STLD plan availability in 2019. Linear probability models utilized cluster-robust standard errors (clustered at state level) and adjusted for fixed state and year effects, sociodemographic covariates, and cancer site. Sensitivity analyses excluded states that expanded and/or substantially changed Medicaid eligibility during the study period. The plausibility of the parallel trends assumption was tested in adjusted models restricted to the pre-policy period (2016-2017) and was satisfied for all analyses. **Results:** 398,190 individuals were included. In adjusted DID analyses, early-stage diagnoses increased 0.95 percentage points (95% CI = 0.53 to 1.38, $p<.001$) in states that prohibited vs. did not regulate STLD plans, but there was no relative change in early-stage diagnoses in states with other policies limiting STLD plans ($p=.25$). Relative to states where STLD plans remained available, there was a nonsignificant increase in early-stage diagnoses in states where legislation stopped the sale of STLD plans, with greater evidence for an increase after excluding states with Medicaid eligibility changes (1.03, 95% CI = 0.71 to 1.35, $p<.001$). There were no differential changes in early-stage diagnoses by state group in falsification tests limited to individuals >65 years-old, who were Medicare-eligible. **Conclusions:** State legislation prohibiting and/or leading to the cessation of STLD plans was associated with an increased rate of early-stage cancer diagnoses. Alternatively, the proliferation of STLD plans was associated with a differential decreased rate of early-stage cancers. Research Sponsor: None.

"It was so many hoops to jump through": Patient-reported administrative burden from disability, Family and Medical Leave Act (FMLA), and insurance appeals. *First Author: Fumiko Chino, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: A breast cancer (BC) diagnosis places physical, emotional, and financial stress on patients. The full spectrum of administrative burdens that patients carry, while simultaneously dealing with cancer treatment, is unexplored. **Methods:** From 6-7/2022, Breastcancer.org community members consented to an anonymous online survey in English or Spanish. The survey assessed patient-reported disability claims [short-term (ST) or long-term (LT)], FMLA application, and appeals of insurance claim denials. Multivariable analysis (MVA) modeled associations with 1) disability application and 2) helpfulness of FMLA. Eligibility included: US resident, age ≥ 18 , and BC diagnosis within 10 years. **Results:** Of 2,420 members screened, 1,710 met eligibility, and 1,437 completed the survey (84% participation rate). Nearly all (94%) identified as women; 60% identified as White, 27% Hispanic, 8% Black, or 4% Other race. Median age was 46 years (range: 19-85), and median time since diagnosis was 2 years (range: 0-10). 75% were on active treatment; 11% had metastatic disease. About one-third of respondents (32%) applied for ST disability, and 26% for LT disability (10% applied for both). A lower proportion of White patients applied for disability (ST: 17% White, 25% Black, 33% Hispanic; LT: 9%, 15%, 35%, both $p<0.001$). Patients with metastatic disease applied for LT disability more often (23% vs 16% non-metastatic, $p=0.01$). Although most were approved (74% ST, 63% LT); about one-quarter (23% ST, 29% LT) found disability very/extremely difficult to apply for, with no variation by race, ethnicity, or disease status (all $p>.05$). On MVA, Hispanic patients (OR=5.39, 95%CI 3.96-7.34) and those with metastatic disease (OR=1.52, 95%CI 1.01-2.30) had increased odds of filing for disability. Of respondents who filed for FMLA (27%), 25% found it a very/extremely difficult application. Of 289 FMLA recipients, one-half found it very/extremely helpful. On MVA, longer time since diagnosis was associated with perceived helpfulness (OR=1.16, 95%CI 1.03-1.30). One-third of respondents filed an appeal of an insurance denial: this was more common among those with metastatic disease (41% vs 32% non-metastatic, $p=0.02$) and less common in White patients (26% White, 39% Black, 45% Hispanic; $p<0.001$). Of respondents who appealed, most (57%) filed between 2-5 times; patients with metastatic disease were more likely to have to file >5 times (18% vs 7%, $p=0.005$). **Conclusions:** Patient administrative burden impacted one-third of BC patients, with larger burdens on historically marginalized or minoritized groups (e.g., Black and Hispanic patients; those with metastatic disease). State and national legislative priorities should work to standardize and streamline application processes so patients can have the financial stability to focus on cancer treatment and recovery goals. Clinical practice guideline descriptions of oncologic drugs granted FDA accelerated approval: A cross-sectional study. *First Author: Maryam Mooghali, Yale School of Medicine, New Haven, CT*

Background: The Food and Drug Administration's (FDA's) accelerated approval (AA) pathway allows drugs to be approved using surrogate endpoints, while requiring that sponsors complete postmarketing requirement (PMR) studies verifying clinical benefit. Subsequently, FDA determines whether AA can be converted to standard approval or be withdrawn. It is unclear whether clinical practice guidelines reflect PMR results or FDA regulatory decisions. As most drugs granted AA are cancer therapies, we investigated whether and how National Comprehensive Cancer Network (NCCN) guidelines reflect underlying evidence supporting AAs and subsequent FDA decisions. **Methods:** In this cross-sectional study, we used Drugs@FDA to identify drug indications granted AA by FDA for oncologic indications from 2016-2018, PMR status and results, and whether AA was converted to regular approval or withdrawn. We excluded pediatric and tumor-agnostic indications. PMR studies were classified as positive if the results from primary efficacy endpoint were statistically significant ($P<0.05$) favoring the drug. For each AA indication, we searched relevant NCCN guidelines for their recommendations and examined if AA status, PMR results, and updated FDA decisions were reflected. **Results:** Among 36 oncology drug indications granted AA from 2016 to 2018, 29 (81%) NCCN guidelines did not mention that the drug was approved via AA pathway or had not yet verified clinical benefit. For all 36 (100%) indications, NCCN guidelines did not state that approval was based on surrogate endpoints. As of December 31, 2022, among 16 drug indications that were converted to standard approval, 13 (81%) guidelines reflected FDA's updated decisions. Among 8 indications withdrawn after AA, 5 (63%) guidelines reflected the withdrawn status. Of 6 drug indications with negative PMR study results that were withdrawn, 2 (33%) were still recommended in NCCN guidelines thereafter. **Conclusions:** NCCN guidelines do not consistently reflect FDA regulatory status or PMR study results, highlighting the need for more up-to-date and accurate information to guide clinical practice. Research Sponsor: Arnold Ventures.

NCCN Guidelines' recommendations for cancer drugs granted FDA AA, N (%) ^a						
PMR results	Total drug indications converted to standard approval	Guidelines reflecting conversion to standard approval	Guidelines reflecting all PMR results for those converted to standard approval	Total drug indications withdrawn [†]	Guidelines reflecting withdrawal	Guidelines reflecting PMR results for those withdrawn
All positive	13	10 (77%)	11 (85%)	0	0 (0%)	0 (0%)
Mixed positive and negative	2	2 (100%)	1 (50%)	1	0 (0%)	0 (0%)
All negative / negative and pending	1	1 (100%)	0 (0%)	6	4 (67%)	3 (50%)

^a12 drug indications have not yet been converted or withdrawn, 2 (17%) of which had negative PMR results. 11 drug indication withdrawal was based on a terminated PMR; withdrawal was reflected in guidelines.

Trends in new and persistent opioid use in older adults with cancer. *First Author: Laura Van Metre Baum, Yale School of Medicine, Department of Medicine, New Haven, CT*

Background: While ongoing efforts to decrease opioid use have dramatically altered the prescribing landscape, the impact on patients with cancer is not well understood. We examined trends in new and persistent opioid use in opioid-naïve older patients with and without cancer in the United States. **Methods:** This retrospective cohort study used SEER-Medicare linked data for patients with solid tumors malignancies diagnosed from 2012 through 2017, and a random sample of patients without cancer. We included patients who did not receive opioids for 3 months prior to the diagnosis or randomly assigned index date. We identified new opioid use (claim in 0-90 days after diagnosis/index date), early persistent opioid use (claims in days 0-90 and 91-180), and long-term persistent opioid use (claims in days 0-90 and 91-180 and months 13-15). Further analysis focused on 4 clinical strata: non-cancer, metastatic cancer, cancer treated with surgery alone, and cancer treated with surgery plus chemotherapy and/or radiotherapy ("surgery+"). We calculated relative changes in the predicted probability of opioid use from 2012 to 2017 based on a logit model adjusted for patient demographics. **Results:** We identified 238,470 eligible patients with cancer (mean age 76.3 years). Among patients with cancer, 46.4% had new opioid use; use was higher among those receiving surgery+ (70.6%), those treated with surgery alone (58.8%) and those with metastatic cancer (50.0%), compared to patients without cancer (6.9%). From 2012 to 2017, the predicted probability of new opioid use declined in all groups, with lower relative decline in the cancer subgroups (6.8% surgery+; 9.5% surgery alone; 10.2% metastatic cancer) compared to the non-cancer comparator (24.7%). For instance, in patients with metastatic cancer, predicted probability of new use decreased from 52.4 to 47.1% (10.2%) vs. 8.0 to 6.0% (24.7%) in patients without cancer. Relative decline in predicted probability of long-term persistent opioid use was lower in the surgical cancer strata (44.2% surgery+; 46.1% surgery alone) vs. the non-cancer comparator (54.0%). **Conclusions:** While opioid use remains common in patients with cancer, new and persistent opioid use declined over time in all patients, though with steeper relative declines in non-cancer compared to cancer populations. Our study suggests important but tempered effects of the changing opioid climate on patients with cancer. Research Sponsor: Food and Drug Administration (FDA) of the U.S. Department of Health and Human Services (HHS).

Opioid use by clinical stratum (2012–2017).

Cost-effectiveness of trastuzumab deruxtecan in HER2 low metastatic breast cancer. *First Author: James Dickerson, Stanford Hospital & Clinics, Stanford, CA*

Background: In recent years, metastatic breast cancer treatment has been revolutionized by new therapies that improve overall survival in phase three randomized clinical trials. These drugs are often more expensive than traditional cytotoxics. In 2022, the Destiny-Breast04 trial results showed that trastuzumab deruxtecan (T-DXd) improved survival in HER2 low metastatic breast cancer patients; FDA approval shortly thereafter greatly expanded the potential market capitalization of T-DXd. While the trial demonstrated T-DXd's clinical efficacy, its cost-effectiveness remains unknown.

Methods: We developed a decision-analytic state transition Markov model to simulate a hypothetical cohort of HER2 low metastatic breast cancer patients to assess the cost-effectiveness of T-DXd compared to a physician's choice chemotherapy from a US healthcare payer perspective over a lifetime horizon. Each month, simulated patients could remain progression-free, progress, have a non-interstitial lung disease (ILD) treatment-related adverse event leading to drug discontinuation (TRAE), have ILD leading to drug discontinuation, progress after either a TRAE or ILD, or die. Patients with either a TRAE or ILD were presumed to be progression free directly after discontinuation of the offending agent, and hence eligible for a different therapy. We calibrated the model to outcome data from the Destiny-Breast04 trial, supplemented with data from other relevant metastatic breast cancer clinical trials. Health-related quality-of-life weights were derived from studies of metastatic breast cancer patients. Drug prices (2020 USD) were extracted from the Federal Supply Schedule. Outcomes included discounted (3% annual) quality-adjusted life years (QALYs), life years, lifetime costs, and incremental cost-effectiveness ratios (ICER). We varied T-DXd price and efficacy in a two-way sensitivity analysis to assess our findings' robustness.

Results: Modeled life expectancies with T-DXd and chemotherapy were 26.5 and 21.5 months, respectively (T-DXd: 1.19 QALYs; chemotherapy: 0.93 QALYs). Discounted lifetime costs were 315,000 for T-DXd and 203,000 for chemotherapy; T-DXd cost 431,000 per QALY gained, surpassing a cost effectiveness threshold of 150,000 per QALY gained. The two-way sensitivity analysis showed that, across a range of plausible efficacies, T-DXd would need a price reduction of approximately 50% to be cost-effective at the \$150,000 threshold. **Conclusions:** While providing clinical benefits, our model-based analysis finds that at current prices, T-DXd for HER2 low metastatic breast cancer is not cost-effective at traditional thresholds. Substantial price reduction for T-DXd to a level much closer to prices of comparator cytotoxics could greatly increase the value for money T-DXd provides patients. Race and ethnicity reporting by US federal standards in high-impact phase 2/3 oncology clinical trial publications. *First Author: Kekoa A. Tappara, Stanford Cancer Institute, Palo Alto, CA*

Background: There are 5 races defined by the US Office of Management & Budget (OMB): White, Black, Asian, American Indian and Alaska Native (AIAN), and Native Hawaiian and other Pacific Islander (NHOPI) with Hispanic ethnicity. Despite the existing 1997 race standards, race reporting in oncology clinical trials is still dismal. Here we aim to 1) quantify cancer trial publications reporting race/ethnicity, 2) determine representation in published trials, and 3) identify geographic patterns of reporting race/ethnicity by 1st author. **Methods:** PubMed/Embase were queried for phase 2/3 clinical trials of the 6 most common cancers, published in 4 high-impact journals between 2012-2022, each reviewed by 2 independent reviewers. Trials were excluded for non-US 1st author and those including multiple cancers. Representation quotients (RQ) for each race were calculated by dividing the percent of clinical trial patients by the proportion of year-matched, site-specific incident cancers in the US (Cancer in North America data). RQ of 1 represents equal clinical trial representation compared to US cancer incidence. Trial characteristics were recorded. Descriptive statistics were calculated. RQ statistics were calculated using Kruskal-Wallis tests with Bonferroni Corrections (P_{BC}) for multiple testing. **Results:** Of 1,149 publications assessed, 342 were included (224 JCO, 84 NEJM, 18 Lancet, and 16 JAMA) with 258,123 patients, 60% phase 3, and 45% US Northeast 1st author. By cancer site, 31% breast, 24% lung, 18% prostate, 18% kidney/bladder, 5% colorectal, and 4% endometrial publications were included. Race was reported in 245 publications (72%) varying by journal: 81% JAMA, 78% Lancet, 72% JCO, and 67% NEJM. Specific race/ethnicity were reported in 239 publications (70%) for White, 201 (59%) for Black, 185 (54%) for Asian, 62 (18%) for Hispanic, 48 (14%) for AIAN, and 29 (9%) for NHOPI patients. Among publications reporting race, RQ varied after adjusting for multiple testing ($P_{BC} < .001$) with median (IQR) RQ of 1.0 (0.9-1.1) for White, 0.6 (0.1-2.7) for Asian, 0.4 (0.1-0.7) for Black, 0.0 (0.0-0.0) for AIAN, and 0.00 (0.0-0.0) for NHOPI patients. Stratified by cancer, RQ significantly differed by race for all cancers ($P_{BC} < .001$), except colorectal ($P_{BC} = .004$) and endometrial cancer ($P_{BC} > .99$). NHOPI was the only race with median RQ of 0.00 for all cancers. AIAN and NHOPI race reporting by 1st author was observed most in CA, while Hispanic was observed most in TX. **Conclusions:** While 72% of phase 2/3 cancer clinical trials published in high-impact journals report race, 91% do not report NHOPI race. Indigenous patients have the lowest reporting in cancer clinical trials. Our findings support a call to action to mandate consistent race/ethnicity reporting for publication. US clinical trialists and publishers should comply with mandated US OMB federal reporting guidelines in oncology publications. Data transparency and demographic representation in approval packages of FDA-approved oncology drugs from 2012-2021. *First Author: Jingyi Liu, Brigham and Women's Hospital, Boston, MA*

Background: Over the past decade, the U.S. Food and Drug Administration (FDA) has leveraged regulations and guidance documents to accelerate improvements in demographic reporting and encourage adequate representation of minorities in clinical trials. This cross-sectional study aims to assess the impact of these interventions by characterizing demographic data reporting and representation by sex, age, and racial and ethnic identity in pivotal trials supporting novel cancer therapeutics approved by the FDA from 2012 through 2021. **Methods:** Study demographic data were abstracted from FDA drug approval packages and US cancer population demographic data was abstracted from US Cancer Statistics. The percentages of trials reporting sex, age, racial and ethnic identity of participants in drug approval packages were calculated and participation to prevalence ratios (PPRs) were calculated by dividing the percentage of participants in each demographic by the percentage of the US cancer population in each group. PPRs were constructed for each pivotal trial by cancer type. Adequate representation was defined as PPR 0.8-1.2 and the proportion of trials which were adequately representative of each demographic was calculated and trended over time. **Results:** From 2012 through 2021, the FDA approved 118 cancer therapeutics, based on 131 pivotal trials. For drugs approved 2012-2016, the majority of associated pivotal trials reported participation based on sex (100% of trials), age (100%) and White (98%), Black (75%) or Asian (84%) racial identity, but not American Indian or Alaskan Native racial identity (18%) or Hispanic ethnic identity (41%). For drugs approved 2017-2021, there were no significant improvements in demographic data reporting, although there was a trend towards increased reporting on Hispanic ethnic identity from 2012-2016 (41%) to 2017-2021 (65%) ($p = 0.06$). For drugs approved 2012-2016, most pivotal trials adequately represented female participants (78% of trials) and participants identifying as White (87%), but few pivotal trials adequately represented older adults (7%), participants identifying as Black (11%), American Indian or Alaskan Native (0%), Asian (18%) or Hispanic (5%). Representation in pivotal trials did not significantly improve for any demographic for drugs approved 2017-2021 ($p > 0.05$). **Conclusions:** This study found that the last decade's efforts to improve demographic data transparency and representation in clinical trials have not yet borne fruit for novel cancer therapeutics. More consequential FDA regulations may be necessary. Beyond the FDA, demographic data transparency and adequate minority representation in oncology clinical trials is an all-stakeholder responsibility. A more just clinical trial infrastructure requires greater collaboration between the FDA, sponsors, enrollers, contract research organizations and cooperative groups. Research Sponsor: None.

Association of participation in Medicare's Oncology Care Model with spending, utilization, and quality outcomes among commercially insured and Medicare Advantage members: A national difference-in-differences analysis. *First Author: Samyukta Mullangi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Medicare's Oncology Care Model (OCM) was a voluntary, episode-based model between 2016 and 2021 that provided participating practices with additional payments to fund care enhancements such as extended clinical hours and urgent care. While it resulted in net losses for traditional Medicare beneficiaries, the OCM may have had "spillover" improvements on spending, utilization, and quality for commercially insured (CM) and Medicare Advantage (MA) members who were not targeted by the program. **Methods:** This retrospective analysis used claims from Elevance Health, a large national payer, to identify commercially insured and Medicare Advantage members diagnosed with breast, colorectal, lung, prostate, and pancreatic cancer initiating systemic therapy between 2014 to 2021. We identified 85 OCM practices and 581 matched non-OCM practices based on episode, practice, demographic, and market factors. The exposure variable was participation in the OCM model. All outcomes were defined in 6-month episodes; the primary outcome was overall inflation-adjusted spending; secondary outcomes included hospitalization and emergency room visits, and end-of-life acute care utilization. We utilized adjusted difference-in-differences linear probability models, with state-level fixed effects to control for market price variability, to estimate the association between OCM participation and all outcomes. **Results:** We studied 45,296 episodes of care in OCM practices and 122,231 episodes in non-OCM practices among CM and MA members during the post-implementation period. OCM participation was associated with a \$5,275 (SE \$749.40) reduction in total allowed spending ($p < 0.001$), driven by reductions in outpatient and systemic therapy spending. OCM was associated with improvements in end-of-life utilization and ED visits but none in hospitalizations and timely chemotherapy initiation. **Conclusions:** Participation in the OCM was associated with modest spillover spending benefit onto CM and MA members, but minimal utilization and quality benefits. Resultant practice innovations may have benefited non-targeted patients. Evaluations limited to targeted patients may have underestimated the full impact of the OCM. Research Sponsor: None.

Is Medicare Advantage associated with more favorable health care access, acute care utilization, and affordability among beneficiaries with cancer?
First Author: Vishal R. Patel, Dell Medical School, The University of Texas at Austin, Austin, TX

Background: The Medicare Advantage (MA) program provides care to nearly half of Medicare beneficiaries, including a rapidly growing population of cancer survivors. Although MA was designed to optimize healthcare access, outcomes, and affordability, it is unknown whether these effects have been achieved in cancer survivors. **Methods:** We performed a cross-sectional study of Medicare beneficiaries ≥65 years with a self-reported history of cancer in the 2019 National Health Interview Survey. We used multivariable logistic regression to evaluate the association between Medicare program type (MA vs traditional Medicare, TM) and measures of healthcare access, acute care utilization, and affordability. **Results:** We identified 4,451 beneficiaries with a history of cancer, corresponding to 26.6 million weighted cancer survivors in 2019. Of beneficiaries, 35.8% were enrolled in MA while 64.2% were enrolled in TM. The age, sex, racial and ethnic composition, household income, primary site of cancer, and comorbidity burden of MA and TM beneficiaries were similar. In adjusted analysis, there were no differences in health care access or acute care utilization between TM and MA beneficiaries. However, survivors enrolled in MA were more likely to worry about (34.3% vs 29.4%; aOR, 1.3 [95% CI, 1.1-1.5]) or have problems paying (13.6% vs 11.1%; aOR, 1.4 [95% CI, 1.1-1.8]) medical bills. **Conclusions:** MA beneficiaries with a previous cancer diagnosis more often struggle paying medical bills despite similar healthcare access and preventive care as TM. Despite generous benefits and attractive incentives for care coordination and health management, privately run MA plans may not be more cost-effective than TM for cancer survivors. Our study informs ongoing congressional deliberations to re-evaluate the role of MA in promoting equity among beneficiaries. Research Sponsor: None.

Dosage optimization in drug development: An FDA Project Optimus analysis of postmarketing requirements issued to repair the cracks.
First Author: Brian Heiss, Center for Drug Evaluation and Research, U.S. Food and Drug Administration, Silver Spring, MD

Background: Dosage optimization (DO) is a critical aspect of oncology drug development. Because of this, the US FDA, through Project Optimus, has focused on reforming the DO and dosage selection paradigm for oncology products. When approving products, FDA may determine that although the recommended dosage possesses a favorable benefit:risk (BR) profile, there are significant safety concerns that require evaluation of alternative dosages to potentially improve the BR profile. Such postmarketing requirements (PMRs)—issued as a condition of approval—are examined here to better understand the characteristics and potential limitations of DO studies in the postmarketing setting. **Methods:** Between Jan. 1, 2010 to Dec. 31, 2022, oncology new molecular entities (NMEs) and original applications for biologics, hereafter referred to as new drugs, approved by CDER with at least one PMR issued for DO were identified in the FDA electronic records database. The designs and results of the associated trials or analyses for these PMRs, along with the status of the PMRs, were collected and evaluated. **Results:** There were 24 PMRs issued for 21 new drugs (15% of 138 total approved new drugs). The most common drug classes were: tyrosine kinase inhibitors (TKIs) (10), antibody drug conjugates (ADCs) (3), or GTPase Inhibitors (2). The following trials or analyses were planned to address these PMRs: randomized dose-comparison trials (18), non-randomized dose-finding trials (2), food effect trials (2), exposure-response analysis (1), and pending (1). The planned sample sizes for the 18 dose-comparison trials were 3 with <100 patients, 4 with 100 to 199 patients, 7 with 200 to 500 patients, and 4 with >500 patients. The dose-comparison trials used the following (co)primary endpoints: response rate (12), safety (7), OS (3), and PFS (2). Fourteen PMRs were either fulfilled (11) or released (3). Of the 11 fulfilled PMRs, 8 led to dosage changes for 5 new drugs (cabazitaxel, carfilzomib, ponatinib, ceritinib, and pexidartinib), and 3 did not lead to dosage changes. Ten PMRs are ongoing. The median time from issuance to fulfillment or release (not including ongoing PMRs) was 6 years (range: 0.7 to 8.3). **Conclusions:** A high proportion (15%) of new drugs required a PMR, which generally involved conducting a randomized trial with a substantial patient enrollment to evaluate an alternative dosage(s). This process was slow with a median of 6 years to fulfill a PMR. DO in the premarket setting has the potential to rapidly maximize BR, avoiding both patient exposure to unnecessary toxicity and large, resource-intensive, multi-year postmarketing trials. Project Optimus is working with stakeholders to advance a DO paradigm that occurs early and throughout premarket development to ensure an optimized recommended dosage at the time of approval. Association of accelerated approval (AA) status with National Comprehensive Cancer Network (NCCN) guideline recommendation for cancer drug indications: A cross-sectional study.
First Author: Edward Robert Scheffer Cliff, Program on Regulation, Therapeutics and Law, Boston, MA

Background: Many oncology drugs are approved via FDA's accelerated approval pathway based on trials showing changes to surrogate measures only 'reasonably likely' to predict clinical benefit. Despite this preliminary evidence, accelerated approval drugs are incorporated into clinical practice and included in guidelines. We assessed NCCN evidence and preference ratings for drugs with accelerated vs traditional approval. **Methods:** Accelerated approval oncology drugs were identified using an FDA list as of June 30 2022. Drug labelling revealed other oncology indications of these drugs. Accelerated approvals were stratified if they had been converted to traditional approval after confirmatory studies or withdrawn. Indications with no NCCN guidelines or tumor-agnostic approvals were excluded. Relevant NCCN guidelines were reviewed as of Oct 19 2022. Each indication was assessed for ratings of level of evidence and treatment preference. Levels of evidence included category 1 (consensus, high-level evidence), 2A (consensus, lower-level evidence), 2B (lower-level evidence without consensus), or 3 (major disagreement). Treatment preference rankings included preferred, alternative preferred, other recommended, or useful in certain circumstances. **Results:** Among 315 indications for 100 drugs, 156 (50%) had traditional approval and 159 (50%) had current or previous accelerated approval. Among accelerated approval indications, 78 (49%) had been converted to traditional approval and 21 (13%) withdrawn. Among all indications, 105 (33%) were rated as category 1 evidence, 185 (59%) as 2A, 6 (2%) as 2B, and 2 (0.6%) as 3. The treatment preference for 153 (49%) was preferred, for 55 (17%) was recommended, for 5 (2%) was alternative preferred, and for 38 (12%) was useful in certain circumstances. Compared to traditional approval, accelerated approval indications less often had category 1 evidence (3% v 47%), and were less often listed as preferred (40% v 58%). Converted accelerated approval indications had mid-range ratings for evidence (38% category 1) and treatment preference (47% preferred). 11 withdrawn accelerated approval indications remained in NCCN guidelines. **Conclusions:** In most cases, NCCN guidelines identified accelerated approval indications as having lower evidence than traditionally approved cancer drugs. Many traditional approvals and conversions from accelerated approvals had only category 2A evidence, suggesting better evidence is needed for traditional approval of oncology drugs. But in about half of accelerated approval indications withdrawn by the drug's manufacturer, NCCN continued recommending the drug. Professional organizations like NCCN should ensure their guidelines reflect that accelerated approval drugs are being marketed based on preliminary evidence. Research Sponsor: Arnold Ventures.

System-wide approach on biosimilars adoption in oncology: Strategic plan on switching and cost savings.
First Author: Suwicha Limvorasak, Cedars-Sinai Medical Center, Los Angeles, CA

Background: Biosimilars provide competitive, lower-cost alternatives to biologic drugs in cancer treatment. As more agents become available in the US, institutions have to implement a strategy for successful adoption that is feasible, safe and provide price competition among biosimilar manufacturers. **Methods:** We aimed to standardize biosimilar utilization across the Cedars-Sinai Health System (CSHS) by integrating institutionally developed clinical pathways and insurance prior-authorization into the existing electronic health record (EHR). The initial study was limited to bevacizumab, rituximab and trastuzumab. To align with CSHS guideline recommendations, biosimilar indications for use were reviewed by each disease related group (DRG). Biosimilar brands for each drug were selected through a formulary process vetted by the Pharmacy & Therapeutics Committee. Physicians were permitted to opt-out of switching via an option provided within the electronic order set. To test feasibility of this approach, patients were divided into two groups as 1) main medical center (Cedars Sinai Medical Center) and 2) Cedars-Sinai Cancer affiliated sites. Feasibility was defined as a compliance rate of 80% or greater at the main medical center and 75% or greater at the affiliated sites. This study was powered to detect a minimum difference at 5.7% and 8.9%, respectively. **Results:** Between January 2021 to September 2022, a total of 1,139 cancer patients who initiated treatment with bevacizumab, rituximab or trastuzumab were identified through the EHR, of whom 650 were eligible (age 18-96; 61% female, 39% male). Using our approach, the compliance rate was 86% at the main site (p<0.001, 95%CI: 82.5-89.1) and 88% (p<0.001, 95%CI: 82.1-91.7) at the affiliated sites, resulting in a 56% improvement from baseline (86% vs. 55%, p<0.001). Among 14% of patients who did not switch to institutional-preferred biosimilar brands, the most common reasons for this were payer mandated use of an alternate brand (5%), off-label indication (4%), enrolled in patient assistance program (3%) and physician preference (2%). Five patients (<1%) did not switch to biosimilars due to history of infusion reactions. Insurance type (HMO, PPO, Medicare, others) was not associated with non-compliance (p=0.876). Cost savings were projected to be over \$4 million over a duration of two years. **Conclusions:** Enterprise-wide switching to one specific biosimilar brand is feasible and facilitated through leveraging of the EHR. This approach optimized existing organizational infrastructure to standardize biosimilar utilization and promote substantial cost savings. Research Sponsor: NCCN/Pfizer Biosimilar Project Funding.

	Main medical center (n=450)	Affiliated sites (n=200)
Switching to preferred biosimilar brand(s)		
Bevacizumab	78%	76%
Rituximab	92%	91%
Trastuzumab	92%	98%
Total	86%	88%
Not switching to preferred biosimilar brand(s)		
Use other biosimilar brand(s)	5%	1%
Use reference brand(s)	9%	11%

Correlation between Oncotype DX, Predict, and Nottingham Prognostic Index on HR+, HER2- early breast cancer treatment: The current value of molecular testing. *First Author: Leticia Campoverde, University of Miami Hospital/Jackson Memorial Hospital, Miami, FL*

Background: The Oncotype DX Breast Recurrence Score (ODX) assay is a 21-gene assay validated in hormone receptor-positive, HER2 negative invasive breast cancer (BC) to predict chemotherapy benefit and risk of distant recurrence at 10 years regardless of node status and is also a strong predictor of mortality. ODX can minimize the misuse of chemotherapy, financial burden, and improve clinical outcomes. ODX is not widely used in Ecuador due to socio-economic and healthcare access disparities; instead, many physicians stratify patients' risk according to clinicopathological and immunohistochemical features. We aim to compare the differences between ODX and two of the most common stratification clinical tools: Predict Score (PS) and Nottingham prognostic index (NPI). **Methods:** Retrospective analysis of women with early BC who underwent ODX testing in Ecuador from May 2020 to January 2023. Inclusion criteria: early BC (T1-T3 / N0-N1a); estrogen receptor (ER) positive; HER2 negative by immunohistochemistry; and available data of tumor size, grade, lymph node status, and Ki67 proliferation index. Exclusion criteria: patients with recurrent BC, incomplete pathology, or immunohistochemistry data. PS and NPI were calculated using online tools. The correlation between PS, NPI, and ODX scores was analyzed using Spearman's correlation coefficient in SPSS. **Results:** 77 patients underwent ODX testing, of which 58 patients (mean age 55 years old) met the inclusion criteria. Invasive breast carcinoma not otherwise specified was the most common type (48 patients (82%). Risk scores generated by PS correlated strongly with NPI for all patients ($r=0.47$; $p \leq 0.001$). A strong correlation was also found between ODX and NPI (0.79 , $p<0.027$). Risk scores were then stratified by patient risk category. For low-risk patients, 68% of correspondence between ODX and PS was found, and 98% between ODX and NPI. Intermediate-risk patients showed a correspondence between ODX and PS of 5% and 9% for ODX and NPI. High-risk patients showed a correspondence of 50% between ODX and PS and 17% between ODX and NPI. **Conclusions:** ODX risk recurrence for low-risk patients is highly correlated with PS and NPI. For intermediate and high-risk patients determined by PS and NPI, ODX testing provided valuable and prognostic information and should be considered to guide adjuvant treatment. Research Sponsor: None.

Risk stratification according to ODX, PS and NPI.

ODX	PS	NPI
Low risk (0-15 pts. and < 50 y/o, or 0-25 pts. and > 50 y/o) 45 (78%)	Low risk (<3 pts.) 34 (59%)	Excellent prognosis (<2.4 pts.) 15 (26%)
Low-intermediate risk (16-20 pts. and < 50 y/o) 5 (9%)		Good prognosis (2.4 -3.4 pts.) 31 (53%)
Intermediate risk (21-25 pts. and < 50 y/o) 1 (3%)	Intermediate risk (3-5 pts.) 20 (34%)	Moderate prognosis (3.41-5.4 pts.) 11 (19%)
High risk (> 26 pts.) 6 (10%)	High risk (>5 pts.) 3 (5%)	Poor prognosis (> 5.4 pts.) 1 (3%)

Use and value of self-management (SM) recommendations in a real-world evidence study evaluating digital patient monitoring (DPM) of patients (pts) receiving cancer care. *First Author: Manuela Eicher, University of Lausanne, Lausanne, Switzerland*

Background: SM includes pts' abilities and activities to manage symptoms, treatment (tx), and any problems inherent to a chronic condition. Tailored SM support is recommended in cancer care. DPM enables pts to systematically self-report disease- or tx-related symptoms, communicate directly with healthcare professionals (HCPs), and access support materials. This observational study evaluated the real-world use of the Symptom Navi Program (SNP; Bern, Switzerland) SM materials on the Kaiku Health DPM platform (Helsinki, Finland) in collaboration with F. Hoffmann-La Roche Ltd (Roche; Basel, Switzerland). **Methods:** Adults diagnosed with locally advanced or metastatic non-small/small cell lung cancer, or any stage HER2-positive breast cancer being treated with locally approved and reimbursed drugs with an expected tx duration of >3 months, had access to a DPM solution that provided disease- and tx-tailored modules, including SNP SM recommendations for selected mild or moderate symptoms. The co-primary endpoints were DPM adoption and adherence. Here we report secondary endpoints; the perceived clinical impact, DPM module and service experience (assessed via Customer Effort Score [CES] and Customer Satisfaction Score [CSS]), and use of DPM features such as SM recommendations, via a DPM tool questionnaire. **Results:** Of the 89 enrolled pts, 66 had completed the DPM tool questionnaire at Week 6 of DPM use (data cutoff: June 9, 2022). Among the educational content, the symptom feedback library was accessed most. Pts spent up to a median of 12 minutes on Roche educational or SNP SM materials. The majority of pts (45/66 (68%)) considered the symptom questionnaires to cover all/most of the symptoms they experienced; 18/66 (27%) experienced only fair/partial symptom coverage; 49% (25/51) of pts whose symptoms were not covered contacted their HCP team. 34 pts (52%) took action based on the symptom questionnaire feedback; the most common action was SM recommendations applied according to symptom level (21/66 (32%)), followed by sending a message via the platform to the care team (8/66 (12%)). Half of pts found the SNP SM recommendations helpful/very helpful and 22 pts agreed that the SNP SM recommendations almost always/sometimes supported them in delaying contacting an HCP at an emergency room. At Week 6, the CES was 80%, CSS was 71%, and 48% (32/66) of pts felt that this service improved their care. **Conclusions:** Pt feedback showed that SNP SM recommendations were the most used action in response to the symptom questionnaire feedback and were perceived by most to be helpful/very helpful. These results support the use of SM recommendations in pts with cancer to help them self-manage tx-related symptoms experienced; future studies are needed to further explore their impact and usefulness, and to form recommendations for routine use in clinical practice. Research Sponsor: F. Hoffmann-La Roche Ltd.

Telemedicine-supervised cancer therapy for patients with an aggressive lymphoma and metastatic lung cancer in the U.S. Veterans Affairs National TeleOncology Service. *First Author: Chenyu Lin, Durham VA Medical Center and Duke University, Durham, NC*

Background: Telemedicine is increasingly used in cancer care but has mostly been applied to surveillance and oral therapy rather than parenteral treatments. In the U.S. Veterans Affairs National TeleOncology service (NTO), patients receive intravenous cancer treatments locally under remote supervision from a disease-specialized oncologist. We analyzed care delivered by the NTO for patients with an aggressive lymphoma (AL) and metastatic lung cancer (mLC). **Methods:** The demographics of veterans with AL and mLC enrolled in NTO between 2020-2023 were compared to patients receiving in-person care at the VA. From these NTO cohorts, two subsets of patients receiving 1st line therapy for diffuse large B cell lymphoma (DLBCL) and stage IV non-small cell lung cancer (NSCLC) were extracted and compared to control arms of in-person care matched 1:4 by stage, age, PDL1 (NSCLC), and cytogenetics (DLBCL). Fisher's exact test was used for categorical variables, t test for continuous variables, log rank for survival, and negative binomial for count outcomes. **Results:** 140 patients with AL or mLC (40 DLBCL, 13 Hodgkin, 2 Burkitt, 61 NSCLC, 24 SCLC) were enrolled in NTO, spanning 12 U.S. states. Compared to in-person care ($n = 7,561$), NTO had more rural (56% vs. 34%, $p < 0.001$) and white patients (89% vs. 77%, $p = 0.002$). With a median follow-up of 256 days (IQR, 154 - 415), NTO mLC and AL patients had a median of 15 and 17 telemedicine visits, respectively. 13 of 55 AL (24%) and 56 of 85 mLC (66%) patients received systemic therapy of any line, while 38 (69%) of AL were on surveillance. 7 mLC and 2 AL patients were referred externally for care. 11 patients with DLBCL and 30 patients with stage IV NSCLC started 1st line therapy while in NTO, which were compared to matched controls. NTO and matched control had similar mean time from referral to first appointment and from diagnosis to first treatment. There were no significant differences in progression-free survival between NTO and matched controls for NSCLC (HR 1.1, 95% CI 0.7-1.8) or DLBCL (HR 0.5, 95% CI 0.1-2.3). COVID infections in the first 12 months and number of ED visits in the first 3 months of treatment were not statistically different from controls. **Conclusions:** The NTO service demonstrates the feasibility of infusional chemioimmunotherapy administration under the direction of a remote tele-oncologist. This model has the potential to improve access to specialized oncology care for rural populations and provides a framework for decentralized clinical trials. Research Sponsor: U.S. National Institutes of Health.

Patients starting 1st line therapy.

SpotCheck: A skin cancer diagnostic clinical trial comparing dermoscopy-enhanced telemedicine to in-person evaluation. *First Author: Jenne P. Ingrassia, NYU Langone Health, New York City, NY*

Background: Low socioeconomic status and long distances to a diagnosing provider are factors associated with poor melanoma outcomes, including advanced stage at presentation. Telemedicine offers improved access to diagnostic services for patients in medically underserved communities. Dermoscopy is an established skin imaging method with greater diagnostic accuracy for skin cancers compared to naked eye examination alone. We evaluated the safety and efficacy of a dermoscopy-enhanced, store-and-forward telemedicine-based skin cancer diagnostic platform in a prospective clinical trial. **Methods:** Participants were recruited primarily through advertisements in local newspapers. Subjects with self-identified skin lesions concerning for malignancy could have up to three lesions evaluated. Clinical and dermoscopic images of each lesion were captured, and were stored-and-forwarded to a team of three dermatologists (TeleTeam) working remotely, and independently. Participants were also evaluated face-to-face by a dermatologist (F2F). Participants were offered biopsies by the F2F (if needed) at the time of the visit, or at a follow up visit if the biopsy was only recommended by one or more members of the TeleTeam. The TeleTeam was blinded to the F2F recommendations. **Results:** We enrolled 146 subjects with 375 lesions of concern for skin cancer between September 2020 and December 2022. Baseline characteristics: 94 (64%) female; median age 65 years (range: 25-90 years); 92 (63%) non-Hispanic White; 22 (15%) Black; 11 (7%) Hispanic White; 8 (6%) Asian; 13 (9%) other or preferred not to say. Nineteen participants (13%) had a prior skin cancer including 2 with melanoma (one also with basal cell carcinoma (BCC)), and 17 with keratinocyte cancers (BCC and/or squamous cell carcinoma (SCC)). Overall, 363/375 (97%) skin lesions were clinically or histopathologically benign; 14/146 (10%) patients had a malignant or atypical skin growth. These included 12 skin cancers: 1 stage IA melanoma (0.5mm in thickness); 1 in-situ melanoma; 8 BCC; 2 in-situ SCC; and 2 moderately or severely atypical nevi. F2F recommended biopsy for both melanomas, 7 BCC and 1 SCC. TeleTeam recommended biopsy for both melanomas, 7 BCC, 2 SCC, and both moderately or severely atypical nevi. F2F identified 10/14 malignant or atypical skin growths; the TeleTeam identified 13/14. The benign:malignant ratio of the F2F and TeleTeam recommended biopsies were 2.7:1 and 5.8:1, respectively. The TeleTeam benign:malignant ratio decreased to 4.5:1 after the first 35 subjects were evaluated. **Conclusions:** Dermoscopy-enhanced telemedicine evaluation appears to be a safe and effective method to triage skin lesions for in-person medical evaluation and biopsy to diagnose skin cancer. Deployment of this diagnostic modality may help reduce melanoma health disparities arising in communities lacking dermatologists. Clinical trial information: NCT04411810. Research Sponsor: Melanoma Research Alliance; Sergei S. Zlinkoff Foundation for Medical Education; Ronald O. Perleman Department of Dermatology Orbusch Brand Pilot Program for Diseases of the Skin.

A study to assess the diagnostic performance of a digital remote monitoring tool for patients with cancer: The POSITEA-VA study. *First Author: Charles Georges Parnot, Cureety, Dinan, France*

Background: Remote monitoring of cancer patients is known to improve survival by allowing early reporting and management of adverse events (AEs). Moreover, there is growing interest in connected, digital tools to monitor AEs by collecting patient-reported outcomes (PROs). However, countless PRO data can be overwhelming for daily clinical practice. To be simple and efficient, PRO tools should provide clear and actionable information to practitioners. In this study, we sought to validate an algorithm, Cureety TechCare, that proposes a simple clinical classification derived from AEs reported by patients. The primary objective was to assess the diagnostic performance of the algorithm using real-life data collected by the Cureety digital platform. **Methods:** Cancer patients using the Cureety Tech Care medical device were prompted to complete, at least once a week on their phone or computer, a PRO questionnaire personalized to their treatment and disease. An algorithm then computed, from the reported AEs, a simple "clinical classification" indicative of the patient's health state, with just four possible levels: red, orange, yellow, green (from most to less at-risk). These classifications allow the medical team to efficiently prioritize patients most at risk, by considering the patient either "flagged" as needing additional phone or in-person follow-up (red or orange), or "not flagged" (yellow or green). For this observational study, 400 questionnaires were randomly selected from patients that used the Cureety platform between October 1st, 2019, and September 30th, 2022. The questionnaire data were then independently assessed by 2 oncologists who were blinded to the Cureety TechCare classification. These expert classifications provided the references to calculate the sensitivity (ratio of true positive in the "flagged" group) and specificity (ratio of true negative in the "not flagged" group) of the algorithm. **Results:** Out of the 400 patients, 60 were in the "flagged" group based on the expert evaluations (with 47 true positives from the algorithm) and 340 in the "not flagged" group (with 321 true negatives). The sensitivity of Cureety TechCare was 78.3% (95% CI: 67.9%-88.8%), and its specificity was 94.4% (95% CI: 92.0%-96.9%). In addition, the algorithm correctly marked as "flagged" 95.8% (23/24) of the most at-risk patients, identified as "red" by the experts. **Conclusions:** The study demonstrated satisfactory accuracy of Cureety TechCare against a clinician-driven assessment. Its use to complement standard of care is thus clinically relevant, and it can be trusted as a useful supplementary indicator of the patient's health state. The simplicity of the output makes it particularly useful as a tool to prioritize care, with a clear four-level, color-coded clinical classification to represent the combined AEs reported by the patient. Clinical trial information: NCT05653609. Research Sponsor: None.

Impact of state policies on telehealth use among the privately insured with newly diagnosed cancer. *First Author: Ya-Chen Tina Shih, MD Anderson Cancer Center, Houston, TX*

Background: The COVID-19 public health emergency (PHE), declared on January 31, 2020, relaxed many telemedicine restrictions. Yet there remains wide variation across states on the coverage and reimbursement of telemedicine services and rules to permit practicing across state lines. Research has shown expanded access to telemedicine is beneficial to cancer patients, making it important to understand the relationship between state policies and the use of telemedicine. **Methods:** We identified privately insured non-elderly patients newly diagnosed with any of five common cancers (female breast, prostate, lung, colorectal, and lymphoma) between March 2019 and March 2021 from Optum Clinformatics Data Mart. We characterized state telehealth policies by parity status (coverage & payment parity, coverage parity only, and none) and rules for cross-state practice (allowed with vs. without limitations). We applied interrupted time series analysis to examine the trend of telemedicine use before and after the declaration of COVID-19 PHE and conducted multivariable logistic regression to examine the association between state policies and telemedicine use while controlling for other confounders. **Results:** Of the 10,813 privately insured non-elderly patients, the adjusted rate of telemedicine use was 23.6%. The average age was 53.2 (SD = 9.24). Race/ethnicity distribution was 71.20% non-Hispanic White, 10.07% non-Hispanic Black, 8.56% Hispanics, 3.77% Asians, and 6.39% others. Lymphoma, female breast, colorectal, lung, and prostate cancer accounted for 10.55%, 46.55%, 13.27%, 7.56%, and 22.07% of patients. A sharp increase was observed early on (from 32.4% in March 2020 to 42.5% in April 2020), followed by a steady decline, down to < 15% by March 2021. Compared to patients residing in states with coverage and payment parity, those in states with only coverage parity and no parity were significantly less likely to use telemedicine (OR = 0.79, 95% CI: [0.71 – 0.88]; OR = 0.77, [0.68 – 0.87]). Patients residing in states with more restrictions/regulations on cross-state practice were significantly less likely to use telemedicine (OR = 0.84, [0.76 – 0.93]) than those in states that were less restrictive. Other factors predicting lower likelihood of telemedicine use included older age (OR = 0.69 [0.62-0.77] for age 50-64 vs. 20-49), non-Hispanic Black (OR = 0.84 [0.72 – 0.98] vs. non-Hispanic White), colorectal cancer (OR = 0.82 [0.70 – 0.96] vs. female breast), and more recent diagnosis. **Conclusions:** With the approaching end of COVID-19 PHE, states are deciding whether to permanently relax certain telemedicine policies or return to existing more restrictive policies. Our study suggests patients residing in states that move toward less generous parity and more restrictive cross-state practice rules may be less likely to benefit from telemedicine. Trends and disparities in oncology telehealth after the initial pandemic era. *First Author: Michael Jisoo Lee, San Francisco Medical Center, Kaiser Permanente Northern California, San Francisco, CA*

Background: While the COVID pandemic elevated the usage of telehealth to unprecedented levels, it remains unclear whether telehealth use is sustained after the initial pandemic era, and whether there remain demographic differences in telehealth utilization. In this study, we compared telehealth trends amongst different demographic populations in a large integrated healthcare system. **Methods:** Utilization of various visit types (office, video, telephone) was investigated in this population-based retrospective cohort study at 22 Kaiser Permanente Northern California Hematology and Oncology clinics from 10/1/2020 to 6/1/2022. We explored trends associated with the COVID 19 pandemic and after the initial pandemic era as well as demographic differences, using Chi-square for categorical and the Mann-Whitney U Test for non-parametric comparisons. **Results:** During the study period, there were 341,089 hematology/oncology visits with MD/DO providers, including 83,756 (24.5%) office, 125,162 (36.7%) video, and 132,171 (38.7%) telephone. Total monthly visits remained stable, with a monthly average of 1,765 (10.9%) for new visits and 14,476 (89.1%) for return visits. Monthly telehealth visits (telephone + video) peaked in January, 2021 (85.6% of total visits) and subsequently declined by June, 2022 (68.7% of total visits). Telephone visits increased from 46.1% of telehealth visits to 58.9% over the study period. Amongst telehealth visits, video visits remained popular for new appointments (56.9%) while telephone visits were more common for return appointments (60.7%). After the initial pandemic era, telehealth utilization continued to differ amongst different demographic populations. Video visits remained a significantly higher fraction of all visits ($p < 0.01$) in: (1) less than 45 year-old (60.0%) compared to older than 80 year-old (33.2%); (2) primary English speakers (50.7%) compared to those who require an interpreter (41.5%); (3) patients with commercial insurance (58.2%) compared to those with Medicaid (47.0%) or Medicare (45.2%); (4) non-Hispanic Whites (51.4%) and Asians (52.2%) compared to Hispanic Whites (45.0%) and Blacks (43.6%); (5) patients with the lowest neighborhood deprivation index (NDI) quartile (living in the least deprived neighborhood) (54.0%) vs the highest quartile (46.1%). **Conclusions:** After the initial pandemic era, telehealth utilization declined slightly over time but remained a common method of providing oncology care. Video visits continued to be widely utilized for initial visits whereas there was a shift to telephone visits for follow up appointments over time. Disparities in telehealth, especially in video visits, continued to be seen in various demographic populations by age, English proficiency, insurance plan, race/ethnicity and neighborhood deprivation index. Continued high utilization of telehealth should inform policy and practices in the post-pandemic era. Research Sponsor: Kaiser Permanente.

Korean Precision Medicine Networking Group study of molecular profiling guided therapy based on genomic alterations in advanced solid tumors (KOSMOS) II (KCSG AL 22-09). *First Author: Sun Young Kim, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Next-generation sequencing (NGS) has been introduced to many Korean institutions as molecular diagnostics for cancers since 2017, when it was reimbursed by the National Health Insurance Service. However, molecularly-guided treatment (MGT) options based on NGS results have been limited due to the strict regulation for prescribing outside of the approved indication, lack of clinical trial availability, and limited access to molecular tumor boards (MTB) in most institutions. Given our previous KOSMOS study results, which showed MGT was available for 54% (124/198) of patients based on local NGS (ESMO Open 2022;7(6, Suppl 1); 100653), KOSMOS-II study was designed to demonstrate MGT would be feasible and effective via a nation-wide precision medicine platform. **Methods:** This national, prospective, pragmatic, multi-cohort study comprised of a framework to screen pts with metastatic solid tumors for actionable genetic alterations (GA) based on local NGS testing and to recommend MGT by a remote and centralized MTB held weekly or biweekly. MGT can be one of the following options: Tier 1, the therapeutic use of investigational drugs targeting GAs including ALK, EGFR, ERBB2, BRAF, FH, ROS1, RET, or high tumor mutational burden; Tier 2, drugs that are allowed for treatment outside of the approved indications by the National Health Insurance; Tier3, clinical trials matched for GA recommended by MTB. To estimate the proportion of patients receiving MGT to be $50 \pm 3.25\%$ with 95% confidence interval, we will enroll 1,000 pts, considering 5% drop-out rate. The clinical benefit rate of MGT beyond 16 ± 2 weeks is the second co-primary endpoint, which is expected to be 30% with type I error of 5% and 90% power. Pts must have progressed ≥ 1 or more lines of therapies; have undergone NGS testing; are able to provide the Variant Call Format (vcf) file of the NGS results. MTB determines clinical actionability of GA and recommends MGT if possible, according to Tier 1,2, or 3. The vcf files and matched clinical information will be deposited to the repository of National Center Center Korea and will be curated in a de-identified clinico-genomic database. As of Feb 2023, 139 of planned 1,000 have been enrolled. Clinical trial information: NCT05525858. Research Sponsor: Ministry of Health and Welfare, South Korea; Roche Korea.

Open label single arm study to assess the implementation of home based daratumumab administration in patients being treated for multiple myeloma. *First Author: Adam F Binder, Sidney Kimmel Cancer Center at Thomas Jefferson University, Philadelphia, PA*

Background: Multiple myeloma (MM) is an incurable hematologic malignancy that has a high burden of care for patients and their caregivers. Over the last two decades, the treatment landscape for MM has changed dramatically. However, treatment burden with frequent visits to offices and the hospital is high. We need innovative care delivery models to alleviate these burdens. Chemotherapy at home remains uncommon in the US, though models for its use exist globally. In these models, home-based chemotherapy is safe, preferred by patients, and can be administered at lower cost. Herein, we propose a home-based subcutaneous daratumumab and hyaluronidase-fihj (dara) program for patients with MM. We hypothesize that this program will be feasible, reduce patient treatment and financial burden, and improve quality of life.

Methods: We designed an open label single arm study to assess the implementation of home administration of dara. The primary objective is to evaluate (n=20) treatment satisfaction of patients, using the Cancer Therapy Satisfaction Questionnaire (CTSQ), when they receive care at home as compared to the standard of care (SOC). Secondary outcomes include evaluating adherence to home delivery, quality of life (EORTC QLQ-30), financial burden (COST survey), safety of home administration, and barriers to home administration. At the end of the study, we will conduct semi-structured interviews to assess patient experience with home administration of chemotherapy. Patients will be eligible for study participation if they have a diagnosis of multiple myeloma, are in the monthly phase of dara treatment and are treated with either monotherapy or in combination with oral agents. All participants who are interested and eligible will be on study for 8 cycles of dara (2 cycles of dara in the infusion center (IC) followed by 4 cycles at home and then 2 cycles in the IC). During the home administration phase, 1-3 days prior, patients will go to a local lab or have at home labs. On day of at home dara, the drug will be mixed and packaged by our pharmacy, and then delivered at room temperature to the patient's home by our home infusion courier. The patient will take pre-medications 1-3 hours prior to nurse arrival. The nurse arrives, confirm pre-medications were taken. Pre-treatment vitals and post treatment vitals will be obtained. Drug will be administered as per label instructions. At the beginning of each cycle, patient reported outcome surveys and quality of life surveys will be collected. During the home administration phase, details on barriers to maintaining adherence (i.e. issues with storage, delivery, disposal of medication) will be collected. The study opened for enrollment on November 8th, 2022. As of February 1st 2023, 9 patients have consented and 5 patients are on-treatment. Clinical trial information: NCT05511428. Research Sponsor: Janssen.

Progress report of a cross-organ and biomarker-based platform study: BELIEVE trial NCCH1901. *First Author: Yayoi Ando, National Cancer Center Hospital, Chuo-Ku, Japan*

Background: Cancer Genomic Medicine (CGM) has been developing and more patients have received the comprehensive genomic profiling (GCP) test under national healthcare system in Japan. However, the number of patients who could receive the genomically matched therapy based on the results of CGP tests was limited. To improve the drug accessibility, we initiated a cross-organ, biomarker-based clinical trial (NCCH1901, the BELIEVE trial). It was a platform trial and could be considered as the Japanese counterpart to the National Cancer Institute's Molecular Analysis for Therapy Choice (NCI-MATCH) study in the United States. **Methods:** It was a multi-institutional joint research nationwide led by NCCH with a master's protocol. Several drug cohorts were pre-established, allowing patients to participate in molecularly targeted treatments recommended as a result of CGP test. All drugs were provided for free from the pharmaceutical companies. The objective of this trial was to administer off-label drugs for the respective genomic abnormalities and collect efficacy and safety data for patients of the drugs. The primary endpoint was the response rate based on the best overall response for up to 16 weeks. This trial has been conducted under both of the Japanese Clinical Trial Act and the patient-proposed healthcare services which enable patients to receive unapproved, off-label drugs partially covered by National Health Insurance. The protocol and the informed consent forms were approved by the National Cancer Center Hospital (NCCH) certified review board and the Ministry of Health, Labour and Welfare (MHLW). The trial was registered in the Japan Registry of Clinical Trials (jRCTs031190104). As of January 31, 2023, we have 20 drug cohorts and the planned number of enrollments for each cohort was 50 with the target lesions and 30 without the target lesions. There were more than 500 patients so far. The most common cancer was brain tumours, followed by carcinoma of endocrine organs and the colorectal cancer. *BRAF* mutation and *ERBB2* amplification were the frequent genomic abnormalities registered in this trial. Five drug cohorts have already finished recruiting and 2 drug cohorts assessed their efficacies. We are still continuing to discuss several pharmaceutical companies to increase the drugs cohorts in this platform. This trial is now recruiting the patients and is contributing significantly to increase the treatment opportunity for the cancer patients. Clinical trial information: jRCTs031190104. Research Sponsor: the Japan Agency for Medical Research and Development; ONO PHARMACEUTICAL CO., LTD and Otsuka Pharmaceutical Co., Ltd.

Screening for high frequency malignant disease (SHIELD). *First Author: HA NGUYEN, Guardant Health, Inc. (Redwood City, CA), Redwood City, CA*

Background: Insufficient adherence to guideline recommended cancer screening undermines the effectiveness of current modalities to improve cancer related outcomes, resulting in an unmet clinical need. Implementation of a convenient blood-based cancer screening option, utilizing a test with high sensitivity and specificity, has the potential to address this unmet need. We aim to evaluate the performance of a blood-based multi-cancer screening test in a population of screen eligible individuals across multiple cancer types, encompassing a diverse representation of racial and ethnic groups. **Methods:** SHIELD (Screening for High Frequency Malignant Disease; NCT#05117840) is a prospective, observational, multi-center basket study in the United States and Europe designed to recruit individuals undergoing screening across multiple cancer types. The study's primary objective is to evaluate the performance of a blood-based multi-cancer screening test (GuardantLUNAR-2, Guardant Health, US) to detect cancer in screen-relevant individuals compared to the reference standard cancer screening modality. Each study cohort represents a unique cancer type(s). Eligible individuals consent to whole blood collection within 90 days of the standard of care screening for the respective cancer type. Clinical diagnoses, e.g., cancer, are made per standard of care. Primary outcomes: sensitivity, specificity, negative and positive predictive value of the blood-based multi-cancer screening test. Secondary outcomes: number of screen-detected cancers, early and late-stage screen-detected cancers per 1000 screened individuals. One- and two-year clinical outcomes are collected by implementing HIPAA compliant, patient-level linkage of trial data with real-world data sources (Medidata, USA) to which patients consent subsequent to main study consent. Cohort A: Lung cancer screening. Eligibility is aligned with USPSTF screening recommendations; age 50-80 years with > 20 pack-year smoking history who are current smokers or quit within the past 15 years, without any history of cancer or preinvasive lung lesions, and without recent surgery or trauma. This cohort will enroll 9,000 subjects over 24 months at up to 120 global sites. This cohort was initiated in January 2022. As of January 2023, 94 study sites have been activated with 4,977 individuals consented and 4,866 individuals enrolled (defined as study blood sample collected). To date, 4679/4977 (94%) individuals consented to the linkage process. Cohort A is on track to meet enrollment targets by the end of 2023 and on track for final primary outcome data collection by December 2024. Clinical trial information: NCT05117840. Research Sponsor: Guardant Health.

Infrastructure for rare cancer in the Netherlands: Towards a comprehensive platform for early detection and diagnosis of rare cancers (FORCE). *First Author: Carolina R.C. Pieterman, The Netherlands Cancer Institute Amsterdam/UMC Utrecht ENETS Centre of Excellence, Department of Endocrine Oncology, Utrecht, Netherlands*

Background: One in five patients with cancer has a rare type of tumor. For these patients, randomized controlled trials are often infeasible and, compared to patients with a more common tumor, their prognosis is poor due to late or incorrect diagnosis and fewer available treatment options. Moreover, most patients with rare cancer do not benefit yet from recent developments in ultrasensitive profiling of circulating cell-free DNA (USccfDNA). In some more common cancers, USccfDNA has improved early primary detection, detection of minimal residual disease (MRD), and early recurrence. The information needed to apply USccfDNA in most rare cancers is lacking, which delays innovation of personalized treatments and deprives these patients of a chance for a better outcome. FORCE aims to improve treatment outcomes for patients with rare cancers by systematically collecting their clinical data, tumor tissue and peripheral blood components. **Methods:** Retrospectively and prospectively collected data are used to build a data warehouse that provides comprehensive insight into the long-term biology of a rare cancer. The data warehouse is visualized as a train. The locomotive represents the infrastructure, which uses web-based tools for FAIR, comprehensive, multidisciplinary, data collection, workflow support and storage. The built-in "Call-me-in" module enables anyone who has been diagnosed with a rare tumor to collaborate and contribute their data to FORCE under strict privacy regulations. Each train carriage represents the data concerning a coherent set of rare tumor types, reflecting the ten domains defined by European Reference Network (ERN) Rare Adult Solid Cancers (EURACAN). Neuroendocrine neoplasms (NEN, EURACAN domain 4) is the first carriage joined to the FORCE infrastructure and serves as a use-case for the FORCE infrastructure. Currently, the first patients are being included in the prospective multicenter clinical biobank that makes optimal use of existing (data) infrastructure. A legal joint data registry agreement has been developed to enable a shared clinical biobank with a federated structure, and facilitate sharing of data and samples among participating institutes. FORCE-NEN has also developed a governance structure for the carriage and its relation to the central FORCE infrastructure. Both documents will serve as an adaptable template for other carriages. FORCE is now available for further international collaboration. We established a unique infrastructure in the Netherlands that combines the collection of clinical data, tumor and peripheral blood components of patients with a rare tumor, starting with NEN. The FORCE infrastructure will enable studies to optimize early primary detection, detection of minimal residual disease (MRD), and early recurrence by USccfDNA assays and facilitate future clinical trials. Research Sponsor: Koninkrijk Wilhelmina Fonds (KWF, the Dutch cancer foundation).

The PLATON Network: An interactive platform for precision oncology. *First Author: Salah-Eddin Al-Batran, Institut für Klinische Krebsforschung IKF GmbH am Krankenhaus Nordwest, Frankfurt Am Main, Germany*

Background: To increase the access of patients to precision oncology and personalized medicine, we need not only to undertake molecular profiling but rather we need to interlink patients, physicians and researchers using modern technological opportunities, increasing the likelihood of providing new therapies to patients with suitable targets. The PLATON Network (NCT05489250, IKF-T008) addresses these important issues. **Methods:** The PLATON Network (PLATON) is an interactive structure aiming at improving personalized medicine for all tumor entities (starting with upper GI tumors). The goal of the PLATON Network is to provide a platform for connecting medical practitioners, researchers and patients to personalized cancer treatments. The platform combines comprehensive molecular profiling, data on active clinical trials, remote data access with networking solutions, implemented substudies and associated educational and discussion forums. The main elements of PLATON are: a Platform-study design, an interactive Cloud-based WebApp, Networking, a Molecular Pathology Case Discussion Board, an educational forum, and a BioDataBank. The network will be composed of a global network of cancer centers and cancer specialists who can submit genomic data of their patients to PLATON. The WebApp allows members and associated scientists to view each other's current patients' clinical and molecular data and get into contact with the treating physicians or identify patients for ongoing biomarker-driven clinical trials using advanced algorithms. The PLATON Network also offers molecular testing via Foundation CDx and CDx Liquid for standardized NGS testing and functions as an umbrella for substudies within the platform design. PLATON enrolls patients during first line treatment and collects information on routine clinical data (baseline data, medical history, histopathology reports, treatment decisions, etc.). During follow up, all anti tumor therapy lines, tumor response and survival data are recorded. Importantly, quality of life data is captured monthly under therapy (with EORTC QLQ-30, -BIL21, -HCC18, -PAN26, -STO22 and EQ-5D-5L) and at further follow up (with EQ-5D-5L). So far, 110 cancer centers have joined the PLATON network. Over 200 patients with upper GI tumors received comprehensive molecular profiling and 162 cases were reviewed and discussed in the Molecular Pathology Case Discussion Board. Five sub-projects/-studies have been initiated under the umbrella of PLATON. The educational forum is in the planning stage. PLATON is conducted by the Institute of Clinical Cancer Research (IKF) in Frankfurt with the supervision of an independent scientific steering committee. Research Sponsor: Institute of Clinical Cancer Research at Krankenhaus Nordwest, Frankfurt am Main, Germany.

Mixed-methods clinical trial to evaluate the feasibility of the CURATE.AI optimised digital cognitive rehabilitation therapeutic (COR-Tx) in patients post brain radiotherapy. *First Author: Marlena N. Raczowska, The N.1 Institute for Health, National University of Singapore, Singapore, Singapore*

Background: Cognitive decline may be exacerbated, in brain tumour patients, by prior radiotherapy (RT). Traditional interventions to mitigate this typically involve fixed dose or intensity pharmacological and/or cognitive rehabilitation therapies that often elicit sub-optimal or no response, due to the dynamically evolving patient state and low adherence. Personalised digital therapeutics (DTx) may be more effective for this population. Further, gamification has previously shown to induce positive health behavioural change and improve intervention adherence. To this end, we have developed the CURATE.AI COR-Tx platform, a gamified DTx, that combines a previously validated, small-data artificial intelligence-derived dose optimisation technology with digital multitasking cognitive training. This novel DTx dynamically personalises treatment by using the patient's own longitudinal performance data to generate an evolving digital avatar that guides training intensity throughout the intervention. Herein, we aim to evaluate feasibility, user experience and usability of the DTx platform in brain tumour patients post-RT. **Methods:** This is a prospective, mixed-methods, interventional, single-arm, decentralised feasibility clinical trial. The primary objective is to evaluate feasibility of the CURATE.AI COR-Tx platform as both a digital intervention (DI) and digital diagnostic (DD) for cognitive function in 15 patients with brain tumour post-RT. The personalised and home-based DI involves completing three 12-min sessions per week for 10 weeks, starting 1 month post-RT. Cognitive function will be assessed via a combined non-digital cognitive evaluation and a DD session at five time points: prior to RT, pre- & post-DI and 16- and 32-weeks post-DI. Feasibility outcomes relating to acceptability, demand, implementation, practicality and limited efficacy testing and additional secondary and exploratory outcomes relating to usability and user experience will be collected by the clinical team and through semi-structured patient interviews and a study team focus group discussion at study completion. We will adopt a mixed-methods approach for data analysis. Feasibility of the CURATE.AI COR-Tx platform will be evaluated through thematic analysis for qualitative outcomes (acceptability and practicality), and descriptive and correlational analysis for quantitative outcomes (demand and implementation). We will adopt the CONSORT traffic light system to decide on future expansion into a large-scale randomised control trial. This trial began in April 2021 and has enrolled 14 of planned 15 patients at the time of submission. Clinical trial information: NCT04848935. Research Sponsor: Singapore Cancer Society; National Research Foundation Singapore.

Electronic collection of cancer patient-reported outcomes using a novel digital oncology platform: A multi-site randomized controlled trial. *First Author: Chris Fidyk, Vinehealth Digital Limited, London, United Kingdom*

Background: Cancer is the leading contributor of disease burden worldwide, and incidence rates are estimated to rise 47% by 2040. With increasing numbers of people living with cancer, alongside healthcare workforce shortages, current models for cancer monitoring and surveillance are unsustainable. Within the UK's National Health Service (NHS), this is exacerbated by a rising backlog following the COVID-19 pandemic. Furthermore, a 2020 Macmillan Cancer Support survey showed that current patient information and support is scattered, inaccessible, and poorly personalized. There is an urgent need for effective personalized tools to support cancer patient self-management and data collection to enable healthcare professional (HCP) monitoring and remote follow-up. **Methods:** A multi-site randomized controlled trial is underway within the NHS to evaluate the implementation of a novel digital oncology platform (Vinehealth) for personalized support. Vinehealth consists of a mobile patient application, integrated wearables data, and a clinician dashboard. The study aims to recruit 180 patients across 8 NHS Trusts diagnosed with (i) colorectal, breast, or lung cancer undergoing adjuvant systemic treatment (chemotherapy +/- targeted therapies) post surgery, or (ii) asymptomatic breast cancer undergoing neoadjuvant treatment. A power calculation was conducted relating to the primary objective demonstrating the efficacy in improvement of QoL in the interventional arm, providing 80% power and at a significance level of 0.05. Enrolled patients will be randomized (1:1) between standard of care (SoC) and interventional arms (SoC plus Vinehealth platform). The main objective is to assess if implementation of Vinehealth improves patients' quality of life (QoL) compared to SoC based on EQ-5D-5L, EORTC QLQ-C30, and FACT-G (PWB) questionnaires. Secondary objectives include assessing patient compliance with electronic patient-reported outcome (ePRO) data collection and patient self-management of symptoms. The study will further evaluate whether Vinehealth improves the process of care (assessed through medication adherence) and reduces emergency healthcare utilization (including ED/GP visits/admissions and acute oncology hotline use). Questionnaires are completed by all patients at baseline, 6, 12, 18 and 24 weeks. Qualitative interviews will be conducted with a subset of interventional arm patients and HCPs from each NHS Trust to understand engagement with the Vinehealth platform. To our knowledge, this is the first multi-site RCT within the NHS to evaluate the impact of a digital oncology platform on cancer patients' QoL, ePRO compliance, process of care, and healthcare utilization. The trial is expected to end by September 2023 with results being reported in January 2024. Clinical trial information: ISRCTN44293246. Research Sponsor: Innovate UK.

Liquid biopsy-informed precision oncology study to evaluate utility of plasma genomic profiling for therapy selection. *First Author: Jessica Tao, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: Liquid biopsies have enabled a transformation in the management of patients with cancer as they have the potential to detect, characterize, and monitor tumor burden. However, the increasing complexity involved in the integration of genomic data into clinical practice has presented challenges with the practical implementation of liquid biopsies in clinical cancer care. To address these challenges, multidisciplinary teams comprised of experts within oncology, genetics, pathology, and informatics have created Molecular Tumor Boards (MTBs), which can improve clinical outcomes for cancer patients by efficiently utilizing the technologies created by the rapidly expanding precision oncology industry. Nevertheless, there remains a gap in the optimal implementation and interpretation of these diagnostic findings to maximize patient outcomes and access to standard of care therapies and clinical trials. **Methods:** We instigated a prospective observational liquid biopsy-informed precision oncology study, in which patients with metastatic solid tumors will be matched with genotype-driven therapies via serial liquid biopsies (NCT05585684). Liquid biopsy-derived genotypes will be generated through a clinical NGS assay (PGDX Plasma Focus) and will be annotated by an automated ensemble approach for variant actionability assessment, developed by the Johns Hopkins MTB, followed by a treatment recommendation. Key eligibility criteria include patients ≥ 18 years old, with ECOG performance status of 0-1 and with metastatic disease that have relapsed or progressed after standard of care first-line therapies or patients for which first-line standard of care therapeutic options are not expected to yield a clinical response. The primary objectives of the trial focus on feasibility of the approach and evaluating the fraction of patients with actionable mutations, for which the MTB recommendation is enacted upon. Unique to this study, a recommendation to not pursue genotype-targeted therapy is equally considered for personalized clinical decision making. Secondary objectives are to investigate whether enacting upon MTB recommendations improves progression-free and overall survival and perform a comparative analysis with tumor-based NGS. Exploratory objectives are to determine if serial molecular profiling after initiation of systemic treatment is sufficient to determine therapeutic response, compare with RECIST radiographic response and determine whether changes in liquid biopsy dynamics correlate with progression-free and overall survival. This study will enroll 150 patients with solid tumors, including lung, esophageal, breast, and head and neck cancer and mesothelioma to evaluate the clinical utility of liquid biopsy genomic profiling. Patient accrual for this study initiated in February 2023. Clinical trial information: NCT05585684. Research Sponsor: Personal Genome Diagnostics/Labcorp.

An interventional study of the impact of digital patient monitoring (DPM) on health outcomes, healthcare resource utilization, and feasibility of a combination with at-home treatment (tx) for delivery of systemic anticancer tx in clinical practice. *First Author: Sanna Iivanainen, Oulu University Hospital, Oulu, Finland*

Background: Disease- and tx-related symptoms negatively affect quality of life and may become life-threatening. There is a need for improved understanding, prevention, reduction and mitigation of symptoms, and tools to facilitate remote tracking of pt-reported outcomes (PROs) and support self-management of symptoms. As anticancer txs are increasingly given outside of the clinical settings, DPM tools are becoming more important to support remote symptom management. DPM can improve clinical care and pt outcomes; however, broad adoption requires proven usability and demonstration of real-world clinical utility/impact. ORIGAMA (NCT05694013) is an interventional, open-label, multi-country platform study investigating the clinical utility of DPM tools with specific txs. ORIGAMA will assess atezolizumab (atezo)-specific Roche DPM Modules (F. Hoffmann-La Roche Ltd, Basel, Switzerland; hosted on Kaiku Health DPM platform [Helsinki, Finland]) in two cohorts, to study the impact of DPM on clinical outcomes and healthcare resource utilization, and its feasibility to support at-home tx administration. **Methods:** Adult pts with ECOG PS of 0–2, an email address, and access to an internet-capable device and internet connection are eligible. In Cohort A, systemic tx-naïve pts with metastatic non-small cell lung cancer (NSCLC), extensive-stage SCLC, or Child–Pugh A unresectable hepatocellular carcinoma, with a life expectancy of ≥ 12 weeks (wks) will be randomized 1:1 to a locally approved anticancer regimen of intravenous atezo and local standard-of-care (SoC) support with/without access to the Roche DPM Module. Pts will receive tx until progressive disease or per local SoC. Cohort B will assess the Roche DPM Module in pts receiving 3 cycles of subcutaneous atezo in a hospital setting, followed by 13 cycles of at-home administration by a healthcare professional. Eligible pts have programmed-death ligand 1-positive (expression on $\geq 1\%$ of tumor cells), NSCLC (Stages IIB, IIIA, IIIB [T3–N2]), have completed adjuvant chemotherapy 4–12 wks prior to randomization, and must have a complete resection. Future cohorts may be added to investigate digital health solutions in other tx settings. The primary endpoints are the mean difference in change of the pt-reported Total Symptom Interference Score at Wk 12 from baseline (Cohort A), and flexible care adoption rate at Cycle 6 (Cohort B). The primary analysis for Cohort A will occur when all randomized pts have been followed for ≥ 12 wks and for Cohort B when all pts have completed 16 cycles of tx. Other endpoints include safety and PROs. An exploratory analysis of overall survival will be performed. ~400 pts in Cohort A and 40 pts in Cohort B will be enrolled. Recruitment has started; the first pt to be enrolled in February 2023. Clinical trial information: NCT05694013. Research Sponsor: F. Hoffmann-La Roche Ltd.

Evaluating the diagnostic performance of ^{18}F -fluciclovine for detection of recurrent brain metastases after radiation therapy: Results from a prospective phase 2 trial. *First Author: Rupesh Kotecha, Miami Cancer Institute, Miami, FL*

Background: Differentiating radiation necrosis from tumor progression remains one of the most commonly encountered and clinically challenging scenarios after radiation therapy (RT) for brain metastases (BM). PURSUE (NCT04410367) evaluated the diagnostic performance of ^{18}F -fluciclovine, an amino acid PET radiopharmaceutical, based on various lesion metrics, to establish image interpretation criteria (IIC) for suspected recurrent BM after RT. **Methods:** Patients with solid tumor BM were enrolled across 7 US sites if they had a previously irradiated 'reference' lesion equivocal on MRI for recurrence and were planned for craniotomy. ^{18}F -Fluciclovine PET (185 MBq) took place <42 days post-MRI and 1-21 days pre-craniotomy. The primary endpoint was the diagnostic performance (sensitivity, specificity, positive-, and negative-predictive value [PPV/NPV]) of different thresholds of lesion ^{18}F -fluciclovine uptake on qualitative, visual reads vs central histopathological analysis. Lesion ^{18}F -fluciclovine uptake was assessed qualitatively by 3 independent blinded readers who visually rated the uptake as 'mild' (up to blood pool), 'moderate' (above blood pool to parotid), or 'marked' (above parotid). Secondary endpoints included the diagnostic performance based on different thresholds of quantitative (e.g., lesion SUV) and dynamic measures of uptake. A committee, including 2 expert imaging physicians independent to PURSUE, reviewed all data in round-table meetings to establish the IIC, which were subsequently used to assess diagnostic performance. **Results:** All 23 reference lesions in 23 subjects underwent histopathological analysis, with 10 (43%) confirmed as recurrent tumor. The highest performing qualitative measure was 'marked', rendering a sensitivity of 92-100%, with variable specificity of 40-80% across readers. SUV_{max} was a reader-independent, high-performing quantitative metric on ROC analysis (AUC 0.87, SUV_{max} threshold 4.8 conferring a sensitivity of 80% and specificity of 85%). Dynamic measures did not provide added diagnostic value. After analyzing these metrics, the committee established IIC as: Lesions with ^{18}F -fluciclovine uptake of a SUV_{max} equal to or greater than 4.8, or visually greater than the parotid gland, should be considered suspicious for recurrence. Otherwise, recurrence should be considered unlikely. Application of the IIC resulted in a sensitivity of 80%, specificity of 77-85%, PPV of 73-80%, and NPV of 83-85% across the readers. **Conclusions:** This is the first prospective multicenter trial to evaluate PET characteristics of suspected recurrent BM after RT, verified by histopathology. Qualitative and quantitative IIC show ^{18}F -fluciclovine to be a high-performing diagnostic tool. These IIC will help evaluate the diagnostic performance of ^{18}F -fluciclovine PET in future trials. Clinical trial information: NCT04410367. Research Sponsor: Blue Earth Diagnostics.

Oral Abstract Session

Phase II study of short course hypofractionated proton beam therapy incorporating ^{18}F -DOPA-PET/MRI for elderly patients with newly diagnosed glioblastoma. *First Author: Sujay A. Vora, Mayo Clinic Arizona, Scottsdale, AZ*

Background: Elderly patients with glioblastoma have a poor prognosis with phase III trials reporting median overall survival (OS) and global time to deterioration of 6-9 and 1.2 months respectively. ^{18}F -DOPA (3,4-dihydroxy-6-[^{18}F]-fluoro-L-phenylalanine) positron emission tomography (PET) is sensitive and specific for identifying regions of high density and biologically aggressive glioblastoma. Proton beam therapy (PBT) can spare more healthy tissue that may improve quality of life for this patient population. With improved targeting of disease along with dosimetric advantages of PBT, this phase II trial tested whether hypofractionated PBT can offer both improved survival and quality of life. **Methods:** Patients with newly diagnosed glioblastoma aged ≥ 65 years without contraindications to ^{18}F -DOPA were eligible. Target volumes were defined by PET (tumor/normal brain $\text{SUV} \geq 2.0$) and MRI areas of contrast enhancement including surgical cavity. Patients received dose escalated hypofractionated PBT of 35-40 GyE to PET/MRI over 5-10 treatments with 10 mm margin. Patients received concurrent/adjuvant temozolomide. With an alpha of 0.1, 18 of 39 patients would be required to be alive at 12 months for the study to be considered a success. Kaplan-Meier/Cox regression analysis was performed for progression free survival (PFS) and OS. Toxicities were evaluated with CTCAE v4.0. Patients completed EORTC BN20, QLQ-C30, and MMSE questionnaires. Time to deterioration, defined as a 10-point decrease in the score of the function domain or 10-point increase in score of symptom domain, was evaluated. **Results:** Between 5/2019-6/2021, 43 patients were enrolled, with 4 patients withdrawing due to progression/insurance denial prior to beginning protocol therapy. The median age was 70.2 yrs. and median follow-up was 12.5 months. MGMT methylation was present in 13 (33%). Tumors were multifocal in 10 (26%) and unifocal in 29 (74%). The primary endpoint was met with median PFS/OS was 6.5/12.9 months for all patients and for MGMT methylated patients 11.9/29.8 months respectively. Grade 3 baseline adjusted treatment related adverse events included 1 (3%) confusion, 2 (5%) fatigue, and 1 (3%) seizure. There were no grade 4/5 events. Multivariate analysis revealed MGMT unmethylated, ECOG 2 and biopsy only patients had worse survival. PET volume was more predictive than MRI volume for OS with PET volume > 26 cc having a hazard ratio of 3.7. The median time to global deterioration per QLC-C30 was 6.3 months. **Conclusions:** This phase II trial incorporating ^{18}F -DOPA PET-guided dose escalated hypofractionated proton beam treatment for elderly patients with glioblastoma met its primary endpoint for improved OS and patient reported quality of life compared to historical controls. Further investigation is warranted. Clinical trial information: NCT03778294. Research Sponsor: Marley/Matheson.

PD1 inhibition and G1TR agonism in combination with fractionated stereotactic radiotherapy for the treatment of recurrent glioblastoma: A phase 2, multi-arm study. *First Author: Stephen Joseph Bagley, University of Pennsylvania, Philadelphia, PA*

Background: Despite preclinical evidence that fractionated stereotactic radiotherapy (FSRT) is immunostimulatory, there remains a paucity of data regarding immune effects of FSRT in patients treated with immune checkpoint blockade (ICB). To evaluate the immune impact of FSRT in glioblastoma (GBM), which is refractory to single-agent ICB, and to evaluate the efficacy of the addition of FSRT to ICB for this disease, we conducted a phase 2 trial of the combination of retifanlimab (anti-PD1), INCAGN01876 (G1TR agonist), and FSRT (8 Gy x 3 fractions) in patients with recurrent GBM (rGBM). **Methods:** This single-center trial enrolled patients with no prior bevacizumab and dexamethasone dose $\leq$ 2mg/day. The study included a single-arm, primary efficacy cohort (Cohort A) treated with retifanlimab, INCAGN01876, and FSRT, and a two-arm neoadjuvant window-of-opportunity cohort (Cohort B) for patients needing tumor resection. In Cohort B, patients on Arm B1 received single doses of retifanlimab/INCAGN01876 plus FSRT prior to surgical resection, and patients on Arm B2 received single doses of retifanlimab/INCAGN01876 without FSRT prior to surgical resection. We used flow cytometry on tumor tissue and peripheral blood mononuclear cells and plasma proteomics to explore the immune consequences of neoadjuvant ICB, with vs. without neoadjuvant FSRT. Primary endpoint: ORR in Cohort A (null hypothesis, ORR 5%; alternative hypothesis, ORR 25%; $n = 16$ for 80% power, $\alpha = 0.05$). Secondary endpoints: progression-free survival (PFS) and overall survival (OS), separately in Cohorts A, B1, B2. Data cut-off: January 18, 2023. **Results:** 32 evaluable patients: Cohort A, $n = 16$; Cohort B, $n = 16$ (Arm B1, $n = 8$; Arm B2, $n = 8$). Median follow-up time: 20 months. Most common grade 3/4 treatment-related adverse events: cerebral edema (34%), fatigue (16%). Efficacy in Cohort A: no objective responses, best response of stable disease in 9/16 patients (56%), median PFS 3.9 months (95% CI 2.1–6.2 months), median OS 9.4 months (95% CI 8.2–10.6 months). Median PFS and OS were significantly longer in Cohort B1 (neoadjuvant immunotherapy + FSRT) vs. Cohort B2 (neoadjuvant immunotherapy, no FSRT): PFS 11.7 vs. 2.0 months ($p = 0.0002$), OS 20.1 vs. 9.4 months ($p = 0.001$). Inflammatory cytokine responses were stronger and more sustained in Cohort B1 vs. Cohort B2, with concomitant increases in proliferative T cell responses. **Conclusions:** The combination of retifanlimab, INCAGN01876, and FSRT did not demonstrate efficacy in patients with rGBM when administered without surgical resection. However, among patients receiving neoadjuvant immunotherapy prior to surgical resection, the addition of neoadjuvant FSRT was associated with a significant survival advantage as well as increased inflammatory and cellular immune responses. Neoadjuvant FSRT + ICB warrants further evaluation in rGBM. Clinical trial information: NCT04225039. Research Sponsor: Incyte; Conquer Cancer Foundation of the American Society of Clinical Oncology.

Oral Abstract Session

Phase II trial of pembrolizumab in patients with brain metastases.

First Author: Priscilla Kaliopi Brastianos, Massachusetts General Hospital and Harvard Medical School, Boston, MA

Background: Brain metastases are an increasing challenge in oncology due to increasing incidence and limited treatments. Recent studies suggest that brain metastases harbor a tumor microenvironment characterized by immunosuppressive phenotypes, which contribute to treatment resistance. Therefore, a logical therapeutic strategy for brain metastases is to evaluate immune-based strategies that augment T cell cytotoxicity. **Methods:** This study was designed as an open-label, single-stage, single-arm phase 2 clinical trial evaluating the intracranial efficacy of pembrolizumab, a PD-1 inhibitor, in patients with brain metastases of diverse histologies. The target accrual was 58 patients to achieve at least 52 evaluable patients (i.e., received at least one dose of pembrolizumab). The primary endpoint was intracranial benefit, defined as a best response of complete response, partial response, or stable disease by RANO criteria during treatment. The study design compared a null intracranial benefit rate of 10% against an alternative of 24%. If at least 8 patients among the total of 52 had intracranial benefit, the primary efficacy endpoint would be met and pembrolizumab would be considered worthy of further study in this patient population. This design has a type-I error of 10% and power of 89% (target type-II error of 15%). **Results:** In the 57 evaluable patients, median age was 53 (range 28–80) and 81% were female. Tumor histologies included breast ($n = 35$), non-small cell lung cancer ($n = 7$), melanoma ($n = 2$), small-cell lung cancer ($n = 2$), sarcoma ($n = 2$), ovarian ($n = 1$), pituitary carcinoma ($n = 1$), pituitary neuroendocrine tumor ($n = 1$), esophageal adenocarcinoma ($n = 1$), prostate ($n = 1$), renal cell carcinoma ($n = 1$), neuroendocrine carcinoma ($n = 1$), unknown primary ($n = 1$) and sinonasal adenocystic carcinoma ($n = 1$). For the patients with breast cancer, 16 patients had HER-2 positive disease, 17 patients had hormone receptor-positive disease, and 11 patients had the triple-negative subtype. The study met its primary endpoint and achieved an intracranial benefit rate of 42.1% (90% confidence interval [CI]: 31–54%). In addition, seven patients, who had either breast cancer, melanoma or sarcoma, had durable intracranial anti-tumor activity (> 2 years). The extracranial benefit rate in patients with evaluable extracranial disease based on RECIST 1.1 criteria was 45% (18/40; 90% CI: 31–59%). Median overall survival was 8.0 months (90% CI: 5.5–8.7 months). Grade 4 toxicities at least possibly related to treatment were observed in 2 patients: cerebral edema ($n = 2$). Thirteen patients discontinued treatment for adverse events. **Conclusions:** Our study of pembrolizumab met overall primary endpoint for intracranial benefit in patients with brain metastases. These results suggest that PD-1 blockade may serve as the backbone of therapeutic strategies for a select group of patients with brain metastases and warrants further evaluation. Clinical trial information: NCT02886585. Research Sponsor: Merck Sharp & Dohme; Massachusetts General Hospital.

Oral Abstract Session

Anti-telomerase vaccine in patients with newly diagnosed, unmethylated MGMT glioblastoma: A phase II study. *First Author: Antoine F Carpentier, Hôpital Saint-Louis, Paris, France*

Background: TERT, a subunit of the telomerase complex, is largely expressed in almost all cancers. Among those cancers, glioblastomas (GBM) harbor the highest incidence of activating mutations within the TERT promoter (over 85% of patients). This high incidence underlies the potential role of TERT in oncogenesis, and points out TERT as a highly relevant tumor target in GBM. UCPvax is a therapeutic vaccine composed of two CD4 helper peptides derived from TERT, combined with the montanide adjuvant. We conducted a phase IIa trial to test the immunogenicity, safety and efficacy of UCPvax in patients with newly diagnosed GBM. **Methods:** Key inclusion criteria were: histologically confirmed, non-mutated IDH1 glioblastoma, unmethylated MGMT promoter status, previous treatment with concomitant radiotherapy and temozolomide (TMZ), Karnofsky Performance status (KPS) $\geq 70\%$, steroids < 10 mg/day equivalent prednisone, and lymphocytes count $\geq 0.8 \times 10^9/L$. One month after completion of radiation/TMZ, patients started UCPvax vaccinations on days 1, 8, 15, 29, 36 and 43, then every two months until tumor progression, without additional cure of TMZ. Peripheral blood mononuclear cells were collected before treatment, at 1 and 2 months after treatment and, at each vaccination boost. The primary endpoint was an anti-TERT specific CD4 T-cell response measured *ex vivo* in peripheral blood using IFN-gamma ELISPOT at 2 months. Secondary endpoints included safety, overall survival (OS) and progression-free survival (PFS). **Results:** Thirty-one adult patients (median age 60-yr old, median KPS 90%) were included in this study. All patients received at least one vaccination, and vaccinations were given for 4.5 months on average (min 2–max 14). At baseline, only one patient had a pre-existing anti-TERT CD4 T-cell response (3%). After immunizations, *de novo* induction and/or amplification of an anti-TERT response were found in 29/30 pts (97%). An epitope spread response against other tumor-associated antigens was detected in 12/25 pts (48%). No severe (grade 3–4) toxicity was attributable to the vaccination. All patients developed local skin reactions ($\leq$ grade 2), 16 patients complained of transient asthenia ($\leq$ grade 2), and 13 patients experienced local pain ($\leq$ grade 2). In the intent-to-treat population ($n=31$), the PFS was 8.9 months (95% CI: 7.6–10.6) and the median OS was 17.9 months (95% CI: 16–23). Two years after diagnosis, 26% of the patients were still alive. OS was significantly improved in the patients developing an epitope spread response vs the others (19.3 vs 15.8 months, respectively, $p=0.03$). **Conclusions:** UCPvax is highly immunogenic and provides an interesting OS rate in this population of poor prognosis, unmethylated MGMT GBM patients. These data support further clinical studies of UCPvax in GBM patients. Clinical trial information: NCT04280848. Research Sponsor: PHRC.

2007

Oral Abstract Session

INB-200 phase I study of gene modified autologous gamma-delta ($\gamma\delta$) T cells in patients with newly diagnosed glioblastoma multiforme (GBM) receiving maintenance temozolomide (TMZ). *First Author: Mina Lobbous, University of Alabama at Birmingham, Birmingham, AL*

Background: MHC unrestricted $\gamma\delta$ T cells target NKG2D ligands upregulated on tumor cells. IN8bio's DeltEx chemotherapy resistant cell therapy (CRCT), is a novel $\gamma\delta$ T cell genetically engineered to express MGMT to convey temozolomide (TMZ) resistance and allow combination therapy. NCT04165941, a Phase 1 trial assessing the safety of single and multiple infusions of autologous CRCT cells presents updated safety and efficacy data. **Methods:** Adult newly diagnosed GBM patients with adequate organ function and KPS $\geq 70\%$ are enrolled. Cells engineered from apheresis were infused through a Rickham catheter placed during surgery. Cohorts (C) 1, 2 and 3 each receive 1, 3 and 6 doses of cells respectively on day (D) 1 of each 28-day maintenance cycle. Patients receive 1×10^7 $\gamma\delta$ T cells intratumorally with 150 mg/m² of TMZ intravenously on D1 of maintenance with the standard Stupp maintenance regimen on D2-5. Primary endpoint is safety; secondary endpoints include progression free and overall survival. Immunologic and genomic correlative analyses are being conducted. Dose limiting toxicities (DLTs) are defined as treatment related $\geq$ grade 3 cardiopulmonary or hepatic toxicity, grade 4 toxicity exceeding 72 hours or neurologic deterioration that exceeds 2 weeks. **Results:** 15 patients (53% male; median age 69 (range: 21–76); 80% IDH-WT, 66.7% MGMT unmethylated) were enrolled with 8 dosed ($N=3$ in C1, 4 in C2, 1 in C3). No patients experienced DLTs, cytokine release syndrome (CRS), or neurotoxicity (ICANS). The most common adverse events (AEs) were Grade 1/2 events including fever, fatigue, nausea, headache, platelet count decreased, incision site pain attributable to TMZ, radiotherapy or disease. One subject had Grade 3 treatment related AEs of UTI, dehydration, and thrombocytopenia. Three evaluable C1 patients have PFS of 8.3, 11.9, 7.4 months and OS of 15.6, 17.7 and 9.6 months respectively. In C2, four patients have been dosed, with no DLTs in 3 evaluable patients; 2 remain progression free at 18.9 and 14.8 months, while a third died without relapse due to pulmonary embolus at 8.7 months. One C3 patient has completed 5 of 6 planned doses without DLT. Patient recruitment continues with anticipated completion in 2023. **Conclusions:** Data demonstrates that single, repeat doses of CRCT gamma delta T cells have manageable toxicity with continued encouraging trend in PFS and warrants further assessment. Clinical trial information: NCT04165941. Research Sponsor: IN8bio, Inc.

Oral Abstract Session

Belzutifan treatment for von Hippel-Lindau (VHL) disease-associated central nervous system (CNS) hemangioblastomas (HBs) in the phase 2 LITESPARK-004 study. *First Author: Othon Iliopoulos, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA*

Background: Patients (pts) with VHL disease are at risk for developing multiorgan tumors and cysts, including CNS HBs. The first-in-class hypoxia-inducible factor 2 α (HIF-2 α) inhibitor belzutifan showed clinically meaningful antitumor activity in VHL disease-associated renal cell carcinoma (RCC) and other neoplasms in the ongoing, single-arm, phase 2 LITESPARK-004 study (NCT03401788). We present updated results for the subgroup of pts with CNS HBs. **Methods:** Adults with a VHL disease diagnosis based on germline VHL alteration, ≥ 1 measurable RCC tumor, no RCC tumor > 3 cm or other VHL tumor requiring immediate surgical intervention, no evidence of metastatic disease, no prior systemic anticancer treatment, and an ECOG PS score of 0 or 1 received belzutifan 120 mg orally once daily. End points evaluated in pts with CNS HBs included objective response rate (ORR), duration of response (DOR), time to response (TTR), and progression-free survival (PFS) per RECIST v1.1 by an independent review committee; linear growth rate (LGR); and safety. CNS HBs were assessed using 2 methodologies: 1) with measurable (≥ 1 cm) and/or nonmeasurable disease at baseline and with associated cysts, if present; and 2) with measurable disease at baseline, excluding associated cysts, if present, from the lesion measurement. **Results:** Of 61 enrolled pts, 50 (82%) had ≥ 1 CNS HB evaluable at baseline, and 22 (59%) pts had undergone ≥ 1 CNS-related surgery within 4 years prior to starting belzutifan treatment. As of the April 1, 2022 data cutoff date, median study follow-up for pts with CNS HBs was 38.0 mo (range, 36.1–46.1). ORR was 44% (n = 22; 95% CI, 30–59; 4 CRs, 18 PRs), and DCR was 90% (n = 45; 95% CI, 78–97). Median TTR was 5.4 mo (range, 2.3–33.1), and median DOR was not reached (NR; range, 3.7+ to 38.7+ mo). Median PFS was NR (95% CI, 38 mo to NR). After initiating belzutifan, median LGR for all evaluable pts was -1.6 mm/year (range, -7.0 to 3.1). Of all pts, 25/50 (50%) had ≥ 1 measurable CNS HBs, excluding any associated cysts. For these pts, ORR was 76% (95% CI, 55–91; 1 CR, 18 PRs), and DCR was 96% (n = 24; 95% CI, 80–100). Median TTR was 3.1 mo (range, 2.5–27.8), and median DOR was NR (range, 3.7+ to 38.7+ mo). Median PFS was NR (95% CI, 36 mo to NR). After initiating belzutifan, median LGR was -1.1 mm/year (range, -3.9 to -0.1). Of all pts, 1/50 (2%) underwent a CNS-related surgery after starting belzutifan. Two (3%) pts discontinued treatment due to treatment-related adverse events. **Conclusions:** With more than 3 years of treatment with belzutifan, consistent and durable antitumor activity was observed in pts with CNS HBs, which is consistent with findings in other VHL disease-associated neoplasms. Using different methodologies of assessing tumors, our data demonstrated that belzutifan induced the shrinkage of VHL disease-related CNS HBs with or without the presence of associated cysts. Clinical trial information: NCT03401788. Prognostic evaluation of surgical re-resection for recurrent glioblastoma using the novel RANO classification for extent of resection: A report of the RANO resect group. *First Author: Philipp Karschnia, Department of Neurosurgery, Ludwig-Maximilians-University, Munich, Germany*

Background: The clinical effects of re-resection for recurrent glioblastoma remain controversial, and the role of post-operative tumor volume is unclear since leaving certain tumor volumes deliberately behind cannot be ethically justified. A surgical classification system was previously proposed for stratification based upon residual contrast-enhancing (CE) tumor: RANO class 1 was defined as 'supramaximal CE resection' (including non-CE tumor removal), class 2 as 'maximal CE resection', class 3 as 'submaximal CE resection', and class 4 as 'biopsy'. We aimed to (I) explore the prognostic role of extent of re-resection using this classification and (II) define clinical factors which consolidate the effects of re-resection. **Methods:** The RANO resect group retrospectively compiled a global, eight-center cohort of patients with first recurrence from a previously resected glioblastoma. The combined associations of re-resection and clinical factors with outcome were analyzed. Kaplan-Meier survival analysis and log-rank test were applied to calculate survival, and Cox's proportional hazard regression models to adjust for multiple variables (significance level: $p \leq 0.05$). A propensity score-matched analysis was constructed to mimic a randomized clinical trial comparing the different RANO classes. **Results:** We encountered 681 patients with first recurrence of IDH-wildtype glioblastoma, including 310 patients who underwent re-resection at first recurrence. The use of re-resection was associated with prolonged survival also when stratifying for molecular and clinical confounders on multivariate analysis including pre-operative tumor volume, MGMT promotor status, and non-surgical therapies (HR: 0.65, CI: 0.5–0.8; $p = 0.001$); and ≤ 1 cm³ residual CE tumor translated into improved survival compared to non-surgical management. Accordingly, 'maximal resection' (class 2) had superior survival compared to 'submaximal resection' (class 3) (median OS after recurrence: 12 vs. 9 months; $p = 0.003$). Adjuvant chemotherapy further augmented the beneficial effects of lower residual CE tumor. Conversely, 'supramaximal resection' of non-CE tumor (class 1) was not associated with prolonged survival but frequently accompanied by post-operative deficits, hampering further treatment. The prognostic role of residual CE tumor was confirmed in propensity score analyses. **Conclusions:** Extent of resection for recurrent glioblastoma as quantified by residual CE tumor is highly prognostic and the RANO resect classification may serve to stratify patients accordingly. Chemotherapy may favorably contribute to the prognostic associations of re-resection. When pursuing resection of non-CE tumor, intraoperative mapping strategies to minimize the risk of post-operative deficits are recommended. Research Sponsor: None.

Clinical Science Symposium

Clinical and analytical validation of a targeted gene expression biomarker predicting meningioma outcomes and radiotherapy responses. *First Author: William Cheng Chen, UCSF Department of Radiation Oncology, San Francisco, CA*

Background: Surgery is the mainstay of treatment for meningioma, the most common primary intracranial tumor, but improvements in meningioma risk stratification are needed and current indications for postoperative radiotherapy are controversial. Here we report multicenter clinical and analytical validation of a gene expression biomarker using 1856 retrospective and prospective meningiomas from 12 institutions across 3 continents. Our results reveal the gene expression biomarker provides additional information for meningioma outcomes compared to other classification systems, including prediction of radiotherapy responses. **Methods:** Gene expression profiling and regularized Cox regression was performed on a discovery cohort of 173 meningiomas to generate a 34-gene expression biomarker and continuous risk score for local recurrence. The model and thresholds for low, intermediate, and high-risk scores were locked and applied to 3 validation cohorts: a multicenter retrospective clinical validation cohort (N = 6 centers, N = 866 meningiomas, median follow-up 5.2 years), a prospective investigator-blinded clinical validation cohort from RTOG 0539 (N = 103 meningiomas, median follow-up 8.4 years), and an analytical validation set for test/re-test and FFPE/frozen analyses, as well as comparison across different platforms for gene expression quantification (N = 8 centers, N = 1219 meningiomas). Gene expression biomarker performance was compared to 9 contemporary molecular classification systems. Favorable versus unfavorable meningiomas were defined as gene expression low risk with any resection, or gene expression intermediate risk with gross-total resection (favorable), versus gene expression intermediate risk with subtotal resection, or gene expression high risk with any resection (unfavorable). **Results:** The biomarker outperformed WHO grade (5-year local freedom from recurrence [LFFR] delta-AUC 0.11, 95% CI 0.07–0.17, $p < 0.001$) and all other classification systems for LFFR and OS on multivariate analysis, achieving a negative predictive value for recurrence at 5-years of 91.9%. The biomarker was predictive for LFFR after postoperative radiotherapy, with a hazard ratio of 0.33 for unfavorable primary WHO grade 2 meningiomas (95% CI 0.14–0.76, $P = 0.009$), and 0.54 for unfavorable propensity-matched meningiomas across all WHO grades (95% CI 0.37–0.78, $p = 0.0001$). The biomarker reclassified 39.8% of prospectively collected meningiomas from RTOG 0539, including downstaging 30.5% of patients who received postoperative radiotherapy, and was independently prognostic for overall survival on multivariate analysis. **Conclusions:** A targeted gene expression biomarker improves discrimination of meningioma outcomes compared to recent classification systems and predicts postoperative radiotherapy responses. Clinical Science Symposium

A genomic score to predict local control among patients with brain metastases managed with radiation. *First Author: Nayan Lamba, Brigham and Women's Hospital, Boston, MA*

Background: Clinical predictors of local recurrence following radiation among patients with brain metastases (BrM) provide limited explanatory power. As a result, radiation doses and fractionation schemes are prescribed with a "one-size-fits-all" approach. We sought to develop a DNA-based signature of radiation-based efficacy among patients with BrM, utilizing readily testable genes, to identify subpopulations at greater vs. lesser risk of recurrence. **Methods:** We retrospectively identified 570 patients with 1,487 distinct BrM managed with whole-brain (WBRT) or stereotactic radiation therapy (SRS/SRT) at a tertiary cancer center (2013–2020) for whom next-generation sequencing panel data (OncoPanel, 239 genes) were available on at least one tumor specimen. Local recurrence was assessed in a manner consistent with Response Assessment in Neuro-Oncology – Brain Metastases guidelines (i.e., radiographic enlargement of $>20\%$ in maximal cross-sectional diameter). Enlarging lesions managed with salvage treatment prior to $>20\%$ enlargement were considered to have recurred on the date of salvage therapy. Fine/Gray's competing risks regression was utilized to compare local recurrence on a per-metastasis level among patients with vs. without somatic alterations of likely biological significance across 84 OncoPanel genes with a mutational frequency $>0.5\%$. Genes with a q-value <0.10 were utilized to develop a numeric "Brain-Radiation Prediction Score" ("Brain-RPS") to quantify local recurrence risk. **Results:** Genomic alterations of potential biological relevance in 11 (ATM, MYCL, PALB2, FAS, PRDM1, PAX5, CDKN1B, EZH2, NBN, DIS3, MDM4) and two genes (FBXW7 and AURKA) were associated with a decreased or increased risk of local recurrence, respectively (q-value <0.10). Weighted scores corresponding to the strength of association with local failure for each gene were summed to calculate a patient-level RPS. On multivariable Fine/Gray's competing risks regression, RPS [1.66 (1.44–1.92, $p < 0.001$)], metastasis-associated edema [1.89 (1.38–2.59), $p < 0.001$] and receipt of WBRT without SRS/SRT or neurosurgical resection [2.73 (1.78–4.20), $p < 0.001$] were independent predictors of local failure. **Conclusions:** We developed a genomic score that can be calculated from an extracranial or intracranial site to quantify local recurrence risk following brain-directed radiation. Prior attempts to develop a biomarker-based radiation response signature have not been BrM-specific and have primarily relied on RNA-based measures of radiosensitivity, limiting their utility in clinical practice. To our knowledge, this represents the first study to systematically correlate DNA-based alterations with radiation-based outcomes among patients with BrM. If validated, Brain-RPS has potential to facilitate clinical trials aimed at genomic personalization of radiation treatment among patients with BrM. Clinical Science Symposium

External validation and nomogram for risk factors of CNS metastasis in patients with clinically localized melanoma. *First Author: Merve Hasanov, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Surveillance for CNS mets is not routinely performed in CLM due to lack of evidence-based guidelines. We previously reported factors associated with CNS mets in CLM in a single institution study (MD Anderson Cancer Center; MDA). However, external validation of predictors is needed to develop evidence-based surveillance strategies. **Methods:** Demographics, primary tumor characteristics, and clinical events were collected for pts diagnosed with AJCC 8th edition Stage I-II melanoma in 1998-2014 in two institutions: MDA and Melanoma Institute Australia (MIA). Cumulative incidence of CNS mets was determined by competing risks method, including death; pts without CNS mets and alive at last follow-up (FU) were censored. The external validation of the MDA prognostic model was determined by calibration and discrimination using data from MIA. A ratio of observed and predicted outcomes (O/P ratio) was used to summarize calibration. An O/P ratio of 1 indicates perfect calibration, < 1 too high, and > 1 too low. The prediction model's discriminative ability was obtained by area under operating characteristic curve (AUC), ranging from 0.5 (none) to 1.0 (perfect) discrimination. Nomograms for predicting Cumulative Incidence of CNS mets were produced. **Results:** MDA and MIA cohorts included 4,332 and 9,610 pts, respectively. Pts and clinical characteristics were similar in the cohorts. Median FU time was longer for MDA than MIA (88.9 vs. 26.3 months). The 2-, 5-, 10-year (yr), and final cumulative incidence of CNS mets were 1.5%, 4.9%, 7.8%, and 11.0% for MDA and 1.4%, 4.7%, 7.9%, and 10.8% for MIA pts, respectively. The initial MDA predictive model considered for validation included gender, primary tumor site, melanoma subtype, Breslow thickness (BT), ulceration, mitotic rate (MR), lymphovascular invasion and perineural invasion. External validation of the predictive model was performed at 2, 5, and 10 yrs. The original model's validation properties were not ideal with the predicted estimates overestimating the observed values; thus the model was refined. The final reduced model evaluated included primary tumor site, melanoma subtype, BT, and MR. For calibration, O/P ratio (95% CI) for this model was 0.96 (0.75, 1.17) at 2 yrs, 0.97 (0.84, 1.11) at 5 yrs, and 1.03 (0.91, 1.15) at 10 years. The AUCs (95% CI) for 2, 5, and 10 yrs were 0.75 (0.70, 0.81), 0.71 (0.68, 0.75), and 0.69 (0.65, 0.72), respectively. The reduced model had similar AUCs with, but better calibration results than the original model. Nomograms of pts with high- and low-risk of CNS mets will be presented. A risk calculator will be available. **Conclusions:** A validated nomogram including primary tumor site, melanoma subtype, BT, MR can predict risk of CNS mets in CLM. This nomogram/risk calculator will help stratify CLM pts for CNS mets risk and facilitate development of personalized CNS surveillance strategies. Poster Discussion Session

A radiomic-based predictive model of lung adenocarcinoma brain metastases and molecular subtypes. *First Author: Xiancheng Wu, Department of Medicine, Division of Internal Medicine, University of Pittsburgh, Pittsburgh, PA*

Background: Non-small cell lung cancer (NSCLC) comprises the largest portion of brain metastases (BM) from solid cancer with 40% of patients developing BM during the course of their disease. There are currently no reliable prediction tools for identifying patients at risk for BM, especially in the early-stage setting where MRI screening is not performed. Furthermore, in the later stage setting, brain MRI are only performed annually. Therefore, there is a critical need to identify high-risk patients for BM that could benefit from MRI surveillance. **Methods:** We identified 162 lung adenocarcinoma (LUAD) patients with (N = 66) or without (N = 96) BM that had treatment-naïve CT scans with a segmentable lesion. The tumor, surrounding ground glass opacity and necrosis were segmented via 3D slicer to create a volume of interest for radiomic texture analysis and 400 features were extracted. The Least Absolute Shrinkage and Selection Operator (LASSO) logistic regression feature selection method was used to select the most relevant features and models were built using the machine learning method XGBoost classifier. Training and testing sets with random splitting was used for cross validation. We report the accuracy, sensitivity, specificity, and area under the curve (AUC) for each model. **Results:** Among the extracted features that LASSO deemed as most discriminative for development of BM, we identified the most relevant features using XGBoost that predicted BM with 79% accuracy, 83% sensitivity, 72% specificity, and 79% AUC ($p = 0.01$) in the overall population. The addition of ground glass opacity and necrosis to the model did not significantly improve performance. Furthermore, the model distinguished those with metachronous vs synchronous BM with 84% accuracy, 83% sensitivity, 86% specificity, and 83% AUC ($p = 0.04$). Our model held up across molecular subtypes (*EGFR* and *KRAS* mutant). Importantly, the model was predictive in early-stage patients with 92% accuracy, 96% sensitivity, 83% specificity, and 95% AUC ($p = 0.0005$). Moreover, our model predicted for high vs. low overall survival, and was BM-specific as it was not predictive of other sites of metastases. We further developed a model from the CT features that correctly classified *KRAS* mutant vs. *KRAS* wild type LUAD with 77% accuracy, 73% sensitivity, 80% specificity, and 80% AUC ($p = 0.002$). **Conclusions:** Utilizing a radiomics approach, we were able to predict BM from primary lung CT features including in stage I and II disease, predict synchronous vs metachronous BM, and distinguish distinct molecular LUAD subtypes. We are currently validating our BM prediction model in a large independent cohort and developing models to classify targetable LUAD-BM molecular alterations utilizing brain MRI scans. These studies will identify patients that require MRI surveillance in the early-stage setting and more intensive surveillance in the late-stage setting for BM. Poster Discussion Session

Pretreatment clinical parameters associated with intracranial progression burden following an initial stereotactic radiosurgery course in a multi-institutional brain metastases cohort. *First Author: Christina C Huang, Department of Radiation Oncology, Duke University Medical Center, Durham, NC*

Background: While brain metastasis (BM) velocity is a valuable prognostic metric at time of intracranial progression (ICP), pre-SRS risk factors for post-SRS high-burden intracranial progression (ICP) remain poorly characterized. We hypothesized that pre-SRS clinical parameters are associated with subsequent high-burden (ICP), defined as either ≥ 5 (ICP5) or new/progressive ≥ 11 BMs (ICP11). **Methods:** All patients completing an initial SRS course for BMs at two institutions from 1/2015-12/2020 were retrospectively identified. Patients with prior whole brain radiation therapy (WBRT) and/or BM resection were eligible. Demographic and clinical parameters were collected. ICP was defined as any radiographic concern for distant and/or in-field progression per multidisciplinary consensus. Overall survival (OS) and freedom from ICP were estimated via the Kaplan Meier method. Cox models assessed association between parameters and freedom from ICP5 and ICP11. **Results:** We identified 1383 patients completed SRS, with a median follow up of 8.7 months. Patients were 54.8% female, 45.6% with KPS ≥ 90 , and a median of 63.4 years old. Primary tumor types included non-small cell lung (48.7%), breast (14.7%), and melanoma (8.5%). 46.9% had oligometastatic disease (≤ 5 metastatic foci: including BMs) at SRS, and 53.4% underwent SRS for > 1 BM. 10.3% of patients had undergone prior WBRT and 26.1% surgical resection. 555 patients (40.1%) experienced ICP following SRS, of whom 72.6% had 1-4, 11.5% had 5-10, and 15.9% had ≥ 11 new/progressive BMs. Among patients with ICP, 6-month freedom from ICP was 35.5% (95% CI: 31.1-40.5%) for those with 1-4 BMs at time of ICP, 29.7% (95% CI: 20.4-43.3%) for 5-10 BMs, and 20.5% (95% CI: 13.5-30.1%) for ≥ 11 BMs ($p = 0.016$). Respective 12-month OS rates were 56.8% (95% CI: 52.1-61.9%), 46.0% (95% CI: 35.1-60.1%), and 38.7% (95% CI: 29.4-50.9%; $p < 0.001$). Neurologic symptoms at time of ICP were observed in 21.1% of patients with 1-4 BMs, 28.1% with 5-10 BMs, and 50.0% with new/progressive ≥ 11 BMs ($p < 0.001$). On multivariable analysis, superior freedom from high-burden ICP was associated with the following pre-SRS parameters: oligometastatic burden (ICP5: HR 0.68, 95% CI: 0.47-0.99; ICP11: 0.59, 95% CI: 0.36-0.97), no prior immunotherapy (ICP11: HR 0.57, 95% CI: 0.34-0.57), and a single BM at time of initial SRS (1 vs 2 BM, ICP 5: HR 0.51, 95% CI: 0.31-0.82; ICP11: HR 0.45, 95% CI: 0.24-0.84), while primary tumor type was not associated with ICP5 or ICP11. **Conclusions:** Pre-SRS parameters including polymetastatic burden, prior receipt of immunotherapy, and > 1 BM were associated with post-SRS high-burden ICP. High burden ICP developed earlier following SRS completion and was associated with higher rates of neurologic decline and inferior OS. Research Sponsor: None.

Longitudinal single-cell (sc) immune profiling of cerebrospinal fluid (CSF) from melanoma patients (pts) with leptomeningeal disease (LMD) treated with intrathecal (IT) and intravenous (IV) nivolumab (N). *First Author: Golnaz Morad, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: LMD is associated with an extremely poor prognosis in melanoma pts, who currently have very limited treatment options. Our group previously reported initial safety and efficacy results from the dose escalation portion of a first in human phase I/IB trial using IT and IV N (NCT03025256) in melanoma LMD pts. Here we present longitudinal sc profiling of immune cells in CSF from a subset of pts in this trial to better understand the immune composition of this unique microenvironment and features associated with treatment and outcomes. **Methods:** 39 CSF samples were collected longitudinally from 5 long survivors (LS; IT N number of doses received 10-92) and 5 rapid progressors (RP; IT N doses 2-9) and profiled by sc RNA sequencing. Raw FASTQ reads were aligned to the GRCh38 human reference genome using Cell Ranger v6.0.0 to generate the count matrix. All samples were aggregated by Seurat v4.3.0 and data integration was performed using Harmony v0.1.0. Cells were filtered by following criteria: (1) $> 20\%$ mitochondrial content, or (2) $\text{express} < 100$ or $> 2,500$ -5,000 genes, according to sample specific distribution. Empty droplets and doublets were identified by EmptyDrops function from the R package DropletUtils v1.18.0 and DoubletFinder v2.0.3, respectively. We applied normalization, FindVariableFeatures ($n = 2,000$), scaling, PCA, UMAP and FindClusters to summarize the integrated samples and determine cell clusters. Cell types were annotated based on (1) canonical marker genes using FindAllMarkers, (2) published gene expression signatures, and (3) reference-based tool using Symphony v0.1.0 on published data: GSE164378 and GSE158803. Statistical analysis was conducted using the Wilcoxon rank-sum test. **Results:** A total of 10 patients were included in this pilot analysis. Five pts were LS (2 males; IT dose 5 mg, 1 pt; 10 mg, 2 pts; 20 mg, 2 pts; 2 BRAF mutant; 5 negative CSF cytology at baseline) and 5 pts were RP (3 males; IT dose 5 mg, 1 pt; 20 mg, 2 pts; 50 mg, 2 pts; 4 BRAF mutant; 4 positive CSF cytology at baseline). At baseline [prior to cycle (C)1 of IT N], LS pts had a higher percentage of NK cells (relative to total immune cells; $P = 0.036$) and mucosal-associated invariant T cells (relative to total T cells; $P = 0.021$) than RP pts. Prior to C2, LS had a significantly higher percentage of T cells (relative to all cells; $P = 0.036$). The abundance of immune cells and tumor cells were not different between the two groups at C3, at which point pts have received two doses of IT N and one dose of IV N. **Conclusions:** Exploratory sc analysis of longitudinal CSF samples of LMD pts suggest that baseline immune features may predict outcomes with IT N. Analysis of additional pts is ongoing to provide further insights. Research Sponsor: Dr. Miriam and Sheldon G. Adelson Medical Research Foundation; U.S. National Institutes of Health; Bristol-Myers Squibb.

Long-term survival with IDH wildtype glioblastoma: First results from the ETERNITY Brain Tumor Funders' Collaborative Consortium (EORTC 1419). First Author: Michael Weller, Department of Neurology, University Hospital and University of Zurich, Zürich, Switzerland

Background: Median survival with glioblastoma remains in the range of 12 months on population levels. Only few patients survive for more than 5 years. Patient and disease features associated with long-term survival remain poorly defined. **Methods:** European Organization for Research and Treatment of Cancer (EORTC) 1419 (ETERNITY) is a registry study supported by the Brain Tumor Funders Collaborative in the US and by the EORTC Brain Tumor Group. Patients with glioblastoma surviving at least 5 years from diagnosis were identified at 24 sites in Europe, US, and Australia. In patients with isocitrate dehydrogenase (IDH) wildtype tumors, prognostic factors were analyzed using the Kaplan-Meier method and the Cox proportional hazards model. A population-based reference cohort was obtained from the Cantonal cancer registry Zurich. **Results:** At the cut-off of July 2020, 280 patients with histologically centrally confirmed glioblastoma (189 IDH wildtype, 80 IDH mutant, 11 not otherwise specified) had been registered. In the IDH wildtype population, median age was 56 years (range 24-78 years), 96 patients (50.8%) were female, 139 patients (74.3%) had tumors with O⁶-methylguanine DNA methyltransferase (MGMT) promoter methylation. Median overall survival was 9.9 years (95% CI 7.9–11.9). Patients without recurrence experienced longer median survival (not reached) than patients with one or more recurrences (8.92 years) ($p < 0.001$) and had a high rate of MGMT promoter unmethylated tumors. **Conclusions:** Freedom from progression is a powerful predictor of overall survival in long-term survivors with glioblastoma. Never relapsing patients often have MGMT promoter-unmethylated glioblastoma and may represent a distinct subtype of glioblastoma. Clinical trial information: NCT03770468. BORTEM-17: A phase IB/II single arm, multicentre study investigating the efficacy of sequential bortezomib and temozolomide in recurrent GBM with unmethylated MGMT promoter—The results of an interim analysis. First Author: Dorota Gopen, Haukeland University Hospital, Department of Oncology, Bergen, Norway

Background: Glioblastoma (GBM) is the most frequent, lethal primary brain tumor in adults. Patients harboring tumors with functional O⁶ methylguanine DNA methyltransferase (MGMT) DNA enzyme gain limited benefit from temozolomide therapy. As shown in preclinical studies, bortezomib depletes the MGMT enzyme, restoring the tumor's susceptibility to temozolomide, if administered in a precise schedule when the MGMT enzyme is depleted. We hypothesized that recurrent GBM patients with unmethylated MGMT promoter may obtain clinical benefit from sequential BTZ and TMZ treatment. **Methods:** BORTEM-17 is a multicenter, open label, single arm, non-randomized phase IB/II trial to investigate potential survival benefit for recurrent glioblastoma patients administered bortezomib 48hrs prior to temozolomide. Sample size is calculated to 63 patients, of whom 10 included in phase IB. The doses of bortezomib is 1.3mg/m² intravenously days 1, 4, and 7 during 4-week cycle, and temozolomide 200mg/m² days 5-7. The control group is a retrospective cohort of 467 patients treated at 2 referral hospitals in Norway from January 2015 to December 2017. For the survival analysis, the patients included in BORTEM-17 (n=44) were compared with MGMT unmethylated control, age matched patients (n=116). The pre-defined interim analysis was performed after inclusion of 15 patients and as more than 2 of 15 patients had clinical benefit, the study was continued. **Results:** Until January 2023, 44 patients with median age 55 years (range 25-69), 30 males and 14 females were treated. Median KPS was 90 (70-100) and median NANO score 1 (0-7). The interim analysis was performed after inclusion of 15 patients in the phase IB and II and clinical benefit was observed in 5 patients. Two of them had tumor volume reduction and three experienced stable disease. The study proceeded to the next step. No treatment related deaths were observed. The most common adverse effects included hematological toxicity, gastrointestinal symptoms, muscle weakness, lower back pain and fatigue. Patients that progressed during the BORTEM-17 trial and were fit for further therapy received treatment at their physician's discretion. The preliminary data analysis after 44 of planned 63 patients were treated indicate prolonged median survival for BORTEM-17 patients 19.0 months vs 12.2 months of control MGMT unmethylated age matched patients. Median survival after recruitment is 5.5 months (1.0-23.8). **Conclusions:** The sequential BTZ+TMZ therapy is safe, feasible and effective as indicated by preliminary data when 70% of planned MGMT unmethylated patients have been included. Preliminary data indicate that the combination of BTZ and TMZ may offer an additional line of treatment with limited toxicity to the group of patients with particularly dismal prognosis. Clinical trial information: NCT03643549. Research Sponsor: Norwegian Cancer Society and KLINBEFORSK Norway.

RANO 2.0: Proposal for an update to the Response Assessment in Neuro-Oncology (RANO) criteria for high- and low-grade gliomas in adults. First Author: Patrick Y. Wen, Dana-Farber Cancer Institute, Boston, MA

Background: Response Assessment in Neuro-Oncology (RANO) criteria for high-grade and low-grade glioma (HGG and LGG) were developed to improve reliability of response assessment in glioma trials. Several limitations of the original RANO criteria have been reported. **Methods:** To address limitations of the original RANO criteria, a large cohort of patients with newly diagnosed and recurrent glioblastoma were evaluated comparing RANO-HGG with modified RANO (mRANO) and immunotherapy RANO (iRANO) criteria to inform the following proposed updates (RANO 2.0). **Results:** Based on the 2021 WHO classification of glioma, we recommend a single common set of criteria for all gliomas regardless of WHO grade and IDH mutational status. These criteria will be used for all trials regardless of the treatment modalities being evaluated. In newly diagnosed glioblastoma, the post-radiotherapy MRI, usually obtained approximately 4 weeks after completion of radiotherapy, rather than the post-surgical MRI as proposed in original RANO criteria, will be used as the baseline for comparison of subsequent scans. Since the incidence of pseudoprogression is high in the first 3 months following radiotherapy, confirmation of progression during this period with a repeat MRI (in 4-8 weeks) will be required for determining radiographic progression of disease (PD) if the patient is clinically stable. However, confirmation scans are not mandatory after this period nor for recurrent tumors since these scans do not appear to improve reliability in determining progression. For agents with a high likelihood of producing pseudoprogression such as viral therapies and some other immunotherapies, mandatory confirmation of progression with a repeat MRI is an option. The primary measurement will remain the 2-dimensional maximum cross-sectional area of tumor as the simplest method, but where resources are available, volumetric measurements are an option. For IDH wild-type tumors with contrast enhancement, non-enhancing tumor will no longer be evaluated with the possible exception of patients receiving antiangiogenic therapies. However, in tumors with a significant non-enhancing component, both the contrast enhancing and non-enhancing components will be evaluated as target lesions. **Conclusions:** We hope that these and other proposed changes by the RANO working group will improve response assessment in glioma clinical trials and help the development of more effective therapy for patients. EO2401 (E) peptide immunotherapy + nivolumab (N) +/- bevacizumab (B) in recurrent glioblastoma (GB): EOGBM1-18/ROSALIE. First Author: Wolfgang Wick, Universitätsklinikum Heidelberg and German Cancer Research Center, Heidelberg, Germany

Background: EO2401 was designed to activate/expand existing memory T cells recognizing specific protein sequences from gut bacteria, which cross-react with tumor associated antigens (TAAs). E contains 3 CD8 HLA-A2 epitopes with mimicry to GB-TAAs (IL13Rα2, BIRC5, and FOXM1) and the CD4 epitope UCP2. **Methods:** Patients (pt) at 1st progression GB received E (300 µg/peptide, q2w x4 then q4w) with N (3 mg/kg q2w) in cohorts: 1a E x2 → EN; 2a/1, 2a/2 and 2b EN from start; 2c EN x2 → surgery → EN; 3/1 and 3/2 EN + B (10mg/kg q2w) (Table). **Results:** Among 100 treated pt EN +/- B was well tolerated, with E associated events limited to local skin reactions (45% of pt; 96% Grades 1/2, and 4% Grade 3) and N/B-tox consistent with historical data. EN induced immune response against all 3 mimics in 94% of 35 tested pt (all pt responded against at least 2 mimics), detectable as early as 2 weeks after first EN, and with durations beyond 10 months. Cross-reactivity against human peptides found in 89%. **Conclusions:** EN +/- B was well tolerated and generated fast and durable immune responses. EN survival like current standards. Delayed N was not advantageous for outcome. sLDB increased trt duration of EN, and improved efficacy. Continuous B plus EN further improved efficacy. Neo-/adjuvant EN was clinically feasible. Updated data, including C3/2 to confirm C3/1, to be presented. Clinical trial information: NCT04116658. Research Sponsor: Enterome.

Immune profiling in patients with glioblastoma treated with VT1021 in a phase I/II expansion study. *First Author: Jian Jennifer Chen, Vigeo Therapeutics, Inc., Cambridge, MA*

Background: The cyclic peptide VT1021 is a first-in-class therapeutic agent that has been shown to inhibit tumor growth via stimulation of thrombospondin-1 (TSP-1) and reprogramming the immune tumor microenvironment (TME) in preclinical models. Subsequently, VT1021 has been tested in a phase I/II clinical study in solid tumors (NCT03364400) and has advanced to a phase II/III clinical study in glioblastoma (NCT03970447). VT1021 has demonstrated promising single-agent clinical activity against recurrent glioblastoma (rGBM) in a phase I/II expansion study. Among 22 evaluable subjects with rGBM, 3 had complete response (CR), 1 had partial response (PR), and 6 had stable disease (SD) with an average study duration of over 120 days. One subject has been on VT1021 treatment for > 900 days with no measurable lesion left. The overall disease control rate (DCR) was 45%. Here, we sought to examine the peripheral immune cell profile(s) in response to VT1021 and explore the association between these profiles and clinical responses in rGBM subjects. **Methods:** In the phase I/II expansion study, 22 evaluable rGBM subjects received VT1021 at a dose of 11.8 mg/kg (twice per week intravenously) until disease progression. Peripheral blood samples were collected from all evaluable subjects; immune cell profiles were analyzed by flow cytometry. **Results:** The immune profiles following VT1021 treatment on day 1 did not vary significantly among rGBM subjects, regardless of response. Intriguingly, after long-term VT1021 treatment (day 53), our analysis of the immune profiles revealed beneficial and sustained changes in three cytotoxic T Cell (CTL) parameters and PD-L1⁺ MDSCs that correlated with response. Specifically, CR/PR subjects showed a 20% increase in total CTLs (Pre 33.79% vs. 6hr 40.42%), a 66% increase in proliferating CTLs (Pre 1.37% vs. 6hr 2.28%) and a 63% increase in CTL/Treg ratio (Pre 7.85 vs. 6hr 12.81) on day 53 of VT1021 treatment. In contrast, SD and PD subjects exhibited no change or decrease in these three CTL parameters, respectively. We also observed that CR/PR subjects experienced a sustained decrease in PD-L1⁺ MDSCs after VT1021 treatment (day 1 Pre 95.96% vs. day 53 Pre 92.66% and day 53 6hr 88.06%). Conversely, the sustained decrease of PD-L1⁺ MDSCs after VT1021 treatment was not observed in SD and PD subjects. **Conclusions:** Here we report that the durable responses of peripheral immune cells to VT1021 may be associated with better clinical outcomes in rGBM subjects. These findings are consistent with the MOA of TSP-1 to reprogram the TME by stimulating immune and inflammatory cell functions. While the interpretation of our data is limited by the lack of a control arm and the small sample size, the results provide a signal and warrant continued analysis of these parameters in the ongoing phase II/III trial. Research Sponsor: Vigeo therapeutics.

Ombipepimut dosing emulsion (ODE) + bevacizumab (bev) vs bev alone in patients (pts) with recurrent or progressive glioblastoma (rGBM).

First Author: Samuel Aaron Goldlust, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ

Background: ODE is an investigational cancer vaccine derived from Wilms tumor 1. WIZARD was a randomized, adaptive, phase 3 study to test ODE + bev vs bev in rGBM pts (NCT03149003). Patients were stratified prior to randomization based upon KPS [60 or 70] vs [80 to 100] and extent of resection at initial diagnosis. Patients with low KPS (e.g., 60) are generally underrepresented in clinical trials. **Methods:** Pts ≥18 years with GBM at first recurrence were enrolled. Overall survival (OS) was the primary endpoint; the key secondary endpoint was the 12-month OS rate. The primary and the key secondary endpoints were tested using 1-sided test with an overall significance level 2.5%. The Lan-DeMets error spending function based upon O'Brien-Fleming stopping boundaries was used to adjust the significance level for the interim and final analyses. **Results:** From April 2018 to Aug 2021, 217 pts were randomized 1:1; 109 to ODE + bev and 108 to bev. OS was analyzed after 185 events with a median follow-up of 31.8 months (mo). Pts at baseline had a median age of 60 years, 45.2% reported corticosteroid use, 29% had KPS 60 or 70, 7.8% had tumors that harbored IDH1 or 2 mutations, and the median tumor volume was 10,532 mm³. Baseline characteristics between treatment arms were balanced in the ITT and KPS subgroups. Pts with KPS 60 or 70 had more corticosteroid use, worse NANO scores, and larger tumor burden than those with KPS 80-100. The study did not meet its primary endpoint of OS by ITT (ODE + bev: 10.2 mo vs bev: 9.4 mo, 1-sided p-value: 0.2159). Pts with KPS 60 or 70 had longer OS when treated with ODE + bev (8.2 vs 6.3 mo, 45% death risk reduction, 1-side p value: 0.0119). Grade 1 or 2 injection site reaction was the most common TEAE in the ODE + bev arm. No clinically significant difference in safety was noted between KPS subgroups. **Conclusions:** The data in pts with KPS 60 or 70 suggested benefit with ODE + bev that was consistent across different endpoints and that warrants further validation. Clinical trial information: NCT03149003. Research Sponsor: Sumitomo Pharma Oncology.

Final analysis of 2-THE-TOP: A phase 2 study of TTFIELDS (Optune) plus pembrolizumab plus maintenance temozolomide (TMZ) in patients with newly diagnosed glioblastoma. *First Author: David D. Tran, Department of Neurological Surgery, Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA*

Background: TTFIELDS induce anti-tumor immunity via simultaneous activation of type-1 interferon (T1IFN) pathways of the STING and AIM2 inflammasomes and immunogenic cell death. Thus, TTFIELDS-treated GBM cells may provide a complete in situ vaccination platform and synergize with immune checkpoint inhibitors to prolong survival in GBM patients. **Methods:** We enrolled 26 newly diagnosed GBM patients in a pilot phase 2 study combining TTFIELDS, pembrolizumab and maintenance temozolomide (TMZ). To distinguish immune effects of TTFIELDS from those of pembrolizumab, TTFIELDS was started at cycle 1 of TMZ while pembrolizumab (200 mg IV every 3 weeks) at cycle 2 of TMZ. Primary endpoints were progression-free survival (PFS) versus case-matched controls treated with TTFIELDS plus TMZ only in the EF-14 study. Secondary endpoints included overall survival (OS), toxicity, and signature and mechanism of response by multiomics analyses of PBMCs and tumors. **Results:** The median age was 60.5 years. Fourteen (54%) had biopsy only or partial resection. Nineteen (73%) had unmethylated MGMT and 3 (11.5%) had an IDH mutation. Median PFS was 12.0 months versus 5.8 months in a case-matched control cohort of 26 patients (HR = 0.466; 95% CI: 0.234-0.936; Log Rank $P = 0.007$). Twelve-month PFS was 50.0% versus 28.2% in controls; $P = 0.058$. Median OS was 24.8 months versus 14.7 months in controls (HR = 0.388; 95% CI: 0.194-0.775; $P = 0.039$). Two-year OS was 52.4% versus 12.0% in controls; $P = 0.004$. Six of 15 (40%) patients with measurable disease achieved partial to complete response. In a Cox regression analysis adjusting for key prognostic factors, P -value reached 0.0317 for PFS and 0.0074 for OS. The most common serious adverse events were thromboses, seizures, and metabolic disturbances in 4 (15%), 3 (11.5%), and 2 (7.7%) patients, respectively. Molecular analyses prior to the addition of pembrolizumab confirmed robust T cell activation by TTFIELDS via the T1IFN trajectory, as evidenced by a high correlation between TCRab clonal expansion and T1IFN responsive plasmacytoid dendritic cells (Spearman coefficient = -0.8; $P = 0.014$) and defined a T cell-based gene signature of TTFIELDS effects. Subsequently, the ability of the top expanded TCRab clones to adapt to the everchanging tumor microenvironment through successful clonal switching by 2 months after the addition of pembrolizumab strongly predicted response to the triple combination in a Cox HR fit model for OS with a concordance rate of 0.876, Log Rank $P = 0.031$. **Conclusions:** The triple combination was well tolerated and demonstrated promising efficacy in newly diagnosed GBM. Multiomics analyses confirmed the robust in situ immunizing property of TTFIELDS with synergy with pembrolizumab and identified potential signatures of response to TTFIELDS and the triple combination. Correlative analysis will be updated. Clinical trial information: NCT03405792. Research Sponsor: Novocure.

Short-length DNA fragments in plasma to predict clinical outcome in unresected glioblastoma patients. *First Author: Maxime Fontanilles, INSERM UMR 1245 Brain And Cancer Genomics, Rouen, France*

Background: Early prediction of therapeutic response is an important issue in glioblastoma patients. Cell-free DNA (cfDNA) concentration in plasma shown potential prognostic value. cfDNA release is influenced by non-tumor parameters. Short-length cfDNA (sDNA) may better reflect tumor evolution. The aim was to investigate plasmatic sDNA as prognostic marker in unresected glioblastoma patients. **Methods:** An ancillary study of a prospective trial was conducted (GLIOPLAK trial). Patients had newly diagnosed and histomolecular confirmed glioblastoma *IDH* wild-type (WHO 2021 classification). Patients with resected tumor were excluded. All patients underwent radiotherapy/temozolomide (RT/TMZ) schedule after biopsy. Plasmas were collected at three times during first-line treatment: before (pre-), after (post-) RT and at the time of disease progression/relapse. Cell-free DNA (cfDNA) was extracted from plasma using the QIAamp circulating nucleic acid kit (Qiagen). Short-length DNA (sDNA) fragments (equal or lower than 250 bp length) concentration was calculated based on AUC after automated electrophoresis using 4200 TapeStation System. Primary objective was to investigate the impact on survival of sDNA during RT/TMZ phase. Secondary objectives were to explore the association between tumor volume, corticosteroid exposition and sDNA. **Results:** Thirty-eight patients were included: median age was 63 [interquartile range 55-66], 84.2% (n=32) had Karnofsky index higher than 80% at baseline and median overall survival (OS) was 13.3 months [CI 95% 11.5; 15.5]. sDNA was detected in 69.4% at the pre-RT time (mean 722.3 pg/ml $\pm$ sd 1257.7) and in 83.3% at the post-RT-time (686.1 pg/ml $\pm$ 1217.1). One third of the patients experienced a sDNA decrease between pre- and post-RT time. Presence of sDNA at the pre-RT time was associated with improved OS: median of 11.7 months [9.8-19.6] in the sDNA(+) group (n=25) versus 8.8 months [5.5-NA] in the sDNA(-) group (n=11), HR 0.309 [0.133-0.716], log rank p=0.004. Decrease of sDNA concentration was also associated with better outcome compared to stability or increase of sDNA between pre- and post-RT: respectively median OS 14.1 vs 10.1 months, 0.424 [0.197-0.909], p=0.02. Corticosteroid exposition and dose were not correlated to sDNA concentration at pre-RT or sDNA variation (respectively correlation coefficient 0.081 and 0.047). At pre-RT, presence of sDNA was independent of tumor volume: mean 265.0 cm³ $\pm$ 84.7 in sDNA(+) group vs 237.7 cm³ $\pm$ 115.7 in sDNA(-) group, p=0.492. Total circulating cfDNA concentration did not influence OS in our cohort. **Conclusions:** sDNA during the RT/TMZ phase is an independent prognostic marker in unresected glioblastoma patients. The role of sDNA as a biomarker for adaptive treatment after RT as well as non-invasive molecular characterization tool can be explored in dedicated trial. Clinical trial information: NCT02617745. ctDNA detection in patients with brain metastases arising from solid tumors. *First Author: Laura Alder, Duke University Medical Center, Durham, NC*

Background: While circulating tumor DNA (ctDNA) is a routine tool for therapeutics in metastatic solid tumors, data in those with stable and active brain metastases (BrMs) is limited. We assessed genomic alterations in ctDNA from patients (pts) with solid tumor BrMs in three groups: isolated BrMs/stable extracranial disease (iCNS), concurrent brain and extracranial progression (cCNS), and extracranial progression with no active BrMs at ctDNA draw (eCNS). We also compared ctDNA alterations between pts with and without BrMs. **Methods:** Pts with BrMs and a Guardant 360 profile (n=253) from the Duke Molecular Registry of Tumors between 01/2014 – 12/2020 were identified. Intracranial and extracranial disease status were determined via investigator assessment (RECIST and RANO-BM criteria) within 30 days of ctDNA test. Mutant allele fraction (MAF) was defined as the % of mutant alleles divided by total alleles at a given loci. Differences in mean ranks of the MAF % maximum were compared using the Kruskal-Wallis test and pairwise comparisons with the Dwass, Steel, Critchlow-Fligner multiple comparisons post-hoc procedure. We compared differences in MAF >1% using the chi-square test. **Results:** Among the 253 pts with BrMs: 29 (12%) had iCNS, 160 (63%) cCNS, and 64 (25%) eCNS. The two most common tumor types were breast (BC, 12.0%) and non-small cell lung cancer (NSCLC, 76.4%). Median MAF was lower in the iCNS group (1.6%) vs cCNS (4.8%) p=0.002, but eCNS did not differ (2.6%). In pts with BC BrMs, *ESR1* mutations were most frequent in the iCNS group (67%), followed cCNS (54%) then eCNS (18%) (p = 0.09) as were *PIK3CA* mutations, iCNS(50%), cCNS (46%), and eCNS (27%), p = 0.55. In pts with NSCLC BrMs, *EGFR* mutations were most frequent in the iCNS followed by cCNS then eCNS (67%, 40% and 37%, p = 0.08). *KRAS* mutations were more frequent in cCNS followed by eCNS and iCNS (30%, 17% and 6% p = 0.031). Patients with no BrMs (n=449) included 24% breast and 76% NSCLC. In the ctDNA, *ESR1* and *BRCA2* mutations were more frequent in pts with BC BrMs than those without (60% vs 25%, p<0.001) and (17% vs 5%, p=0.022), respectively. Mutations in *EGFR* were more frequent in pts with BrMs vs without (36% vs 17%, p<0.001). Sequencing from both BrMs tissue and ctDNA were available for 8 pts (4cCNS and 4 iCNS). 7 of these (87.5%) had identical mutations in tumor and ctDNA. **Conclusions:** This study illustrates the feasibility of detecting actionable mutations from ctDNA among pts with BrMs, with and without extracranial disease. A higher frequency of actionable mutations in several targetable genes was observed in ctDNA when comparing pts with and without BrMs, thus providing therapeutic opportunities. Additional studies comparing ctDNA and alterations in BrMs tissue are needed to determine if ctDNA can be considered a surrogate to support treatment decisions. Research Sponsor: None.

Association of CDK4 amplification with duration of response to bevacizumab in glioblastoma. *First Author: John L. Villano, University of Kentucky, Lexington, KY*

Background: Bevacizumab remains the standard second line therapy in glioblastoma (GBM) with reported improved progression free survival, but not overall survival. We investigated a large clinico-genomic database of GBM patients treated with bevacizumab for molecular alterations associated with treatment outcome. **Methods:** Molecular profiles of GBM were tested by next-generation sequencing (NGS) of DNA (592 genes, NextSeq or whole-exome sequencing, Novaseq) and RNA (whole transcriptome sequencing, NovaSeq) at Caris Life Sciences (Phoenix, AZ). Gene amplification was determined by NGS with a threshold of ≥ 6 copies. Real-world survival information was obtained from insurance claims data. Time-on-treatment (TOT) of bevacizumab was calculated from start to finish of treatment while post-bevacizumab overall survival (bevOS) from start of bevacizumab to last day of contact. Short-term (ST) and long-term (LT) responders were defined as those with TOT ≤ 6 months and ≥ 1 year, respectively. Kaplan-Meier estimates were calculated and significance was determined as p values of < 0.05 . For molecular comparisons, Fisher's exact tests and Mann-Whitney U were used when appropriate. **Results:** Among the total of 383 ST and 107 LT patients identified, no significant difference in gender or age were seen. The LT cohort had significantly longer bevOS compared to the ST cohort (HR 0.27, [95% CI: 0.28-0.35], p < 0.0001). Interestingly, CDK4 amplification was seen in 23% (18/78) of LT patients but only 7% (21/300, p = 0.0002) of ST. When investigating the total cohort of 498 GBM treated with bevacizumab, CDK4 amplified patients demonstrated significantly improved TOT compared to non-amplified (HR: 0.639, [0.48-0.85, p = 0.002]). Conversely, the ST cohort had significantly more *EGFR* amplifications than the LT cohort (43%, 130/300 vs. 19%, 15/79, p < 0.0001). In the total bevacizumab-treated cohort, *EGFR*-amplified GBM had significantly worse TOT on bevacizumab than non-*EGFR* amplified GBM (HR 1.387, [1.15-1.67], p < 0.001). No associations were seen in other alterations explored including *PIK3CA* mutation (HR = 0.81 [0.587-1.113], p = 0.2), *EGFR* mutation (HR: 1.209, [0.977-1.495], p = 0.1) or *RAF1* (HR: 0.647, [0.318-1.317], p = 0.2). **Conclusions:** Using a large clinical genomic database with GBM subjected to comprehensive molecular profiling, we demonstrated that amplification of CDK4 and *EGFR* were associated with long-term and short-term responses to bevacizumab, respectively. This warrants further investigation in independent cohorts controlled for age and other prognostic factors. If confirmed, a genetic basis for treatment optimization may provide meaningful clinical outcomes. Research Sponsor: University of Kentucky; CARIS.

Poster Session

Evaluating the diagnostic performance of leptomeningeal diagnosis with CNSide compared to standard cytology. *First Author: Haley Appel, Miami Cancer Institute, Baptist Health South Florida, Miami, FL*

Background: Prior reports cited detection rates of leptomeningeal metastases (LM) using CNSide vs standard CSF cytology of 78% vs 55% in NSCLC and 84% vs 52% in various solid tumor cohorts. The objective of this study was to compare the real-world performance of the CNSide assay in diagnosing LM versus CSF cytology from lumbar puncture (LP) and established EANO-ESMD LM diagnostic criteria (EANO). **Methods:** We retrospectively analyzed all neuro-oncology patients from January, 2020 to December, 2022 with suspected LM who underwent LP with CSF cytology and CNSide. The CNSide assay included tumor cells (CSF-TCs) and cell-free DNA (cfDNA). LM diagnostic probability was defined by EANO criteria. Descriptive statistics and confusion matrix were calculated. **Results:** 87 patients (66 [76%] women) met eligibility criteria for inclusion with median age of 63 (23-87) years; 35 (40%) had uncontrolled systemic disease. The most common primary histologies were breast (45%) and lung (41%); 33% of primary lung cancers harbored molecular alterations, while primary breast cancers expressed hormone receptors in 69% and *HER2* alterations in 10%. Across all primary histologies, 53 (61%) cases harbored molecular alterations, of which 27 (31%) had molecular alterations also detected by CNSide. For 7 (8%) cases with negative cytology and CNSide, CNSide detected alterations by cfDNA assays. LM was diagnosed by CSF cytology in 23 (27%) cases, consistent with confirmed LM by EANO. 36 (41%) cases had confirmed LM by CSF cytology or CNSide; all cytology positive and equivocal cases were detected by CNSide. Patients with negative CSF cytology were further defined as probable (19, 23%), possible (35, 42%), or (7, 8%) lack of evidence by EANO. Modifying EANO criteria to include both standard CSF cytology and CNSide led to 36 (41%) confirmed LM cases, an increase of 13 cases in addition to the 23 cytology positive cases (+56.5%). Compared to CNSide, standard CSF cytology had a sensitivity of 70%, but an expected 100% specificity. Compared to the established higher specificity of CNSide, EANO had 100% sensitivity, but only 18% specificity for diagnosing LM, assuming all EANO possible, probable, or confirmed cases were positive, while specificity improved to 74% with slight decrease sensitivity to 94% if only probable or confirmed cases were considered positive. **Conclusions:** In the largest, retrospective, single institution, real-world study, implementation of CNSide showed increased sensitivity relative to standard cytology and increased specificity relative to EANO criteria, and provided clinically relevant, cell-based molecular and cell-free DNA analyses. CNSide increased the diagnostic yield by 56.5%. Research Sponsor: None.

Leptomeningeal carcinomatosis and brain metastases in gastroesophageal carcinoma: A real-world analysis of outcomes, clinical and pathologic characteristics. *First Author: Thais Baccili Cury Megid, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Brain metastasis (BM) and Leptomeningeal Carcinomatosis (LC) are uncommon complications in gastroesophageal carcinoma (GEC) patients (pts). These patients have a poor prognosis and are challenging to study. We described the clinicopathologic features and outcomes in the largest real-world cohort of CNS metastasis in GEC pts. **Methods:** We conducted a single-center retrospective study of GEC pts treated at the Princess Margaret Cancer Centre from 2007 to 2021 who developed BM. Clinicopathologic characteristics and treatment modalities were reviewed. Survival was calculated from the date of BM or LC diagnosis until date of death/last follow-up using the Kaplan-Meier method. A multivariable Cox proportional hazards regression model was used to examine the association of baseline covariates and survival. **Results:** Of 3283 consecutive pts with GEC, 101 (3.08%) were diagnosed with BM and 20 with LC (0.61%). Most pts with BM were male (75.3%), non-Asian (93%), with a primary gastroesophageal junction tumor (47%) and adenocarcinoma histology (86%). Among pts with known HER2 status (N=48), 60% were HER2 positive (defined as IHC 3+ or IHC 2+/FISH+). All patients with LC had adenocarcinoma histology; most were signet-ring subtype (85%), poorly differentiated (80%) histology and only 15% (2/13) were HER2 positive. Median survival was 0.8; 3.8; and 7.7 months (mo) in BM pts treated with palliative care only, radiation only and surgery followed by radiation, respectively ($p < 0.001$). In LC, median survival was 0.7 mo in pts who had palliative care only (7/20) and 2.7 mo for those (13/20) who had whole brain radiation therapy (WBRT) ($p = .008$). Multivariate analysis showed a higher probability of death in patients with number of BM ≥ 4 ($p = 0.02$) and predicted superior survival in patients who received radiation and surgery followed by radiation ($p = 0.02$). **Conclusions:** This is the most comprehensive summary of clinicopathologic characteristics and survival in patients with GEC and BM and LC disease to date. Biomarker analysis reveals an enriched frequency of HER2 expression in BM, while this is uncommon in pts with LC. BM pts who were treated with surgery followed by radiation had a significantly improved OS. WBRT benefited patients with LC over palliative care alone. These findings add to our understanding for the management of this understudied population with poor survival. Research Sponsor: None.

BM pts	Median Survival (months) (95%CI)
Palliative Care	0.76 (0.20, 4.26)
Radiation (WBRT/SRS)	3.8 (2.16, 5.85)
Surgery followed by Radiation	7.71 (5.76, 16.45)
	$p \text{ value} < 0.001$
LC pts	
Palliative Care	0.7 (0, 1.58)
WBRT	2.7 (1.35, 6.0)
	$p < 0.008$

INTRAMET: Results of a prospective, single-arm, open-label phase II trial of intraoperative radiotherapy after resection of brain metastases. *First Author: Stefanie Brehmer, Department of Neurosurgery, University Medical Center Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany*

Background: Brain metastases (BM) occur in about 10-20% of all cancer patients during the course of their disease. The current standard of care for lesions that cause mass effects is neurosurgical resection followed by adjuvant radiotherapy of the resection cavity. We here report efficacy data of the INTRAMET trial (NCT03226483), which tested intraoperative radiation therapy (IORT) using a high-dose, single fraction to the tumor bed. **Methods:** Patients ≥ 18 years and Karnofsky (KPS) ≥ 50 with suspected BM were included. A frozen-section confirmed metastasis and technically applicable IORT were mandatory. Exclusion criteria were surgical or MRI contraindications, meningeal infiltration, or IORT Dmax doses exceeding 8 Gy at risk structures. IORT was performed after tumor resection in the operating room with a mobile low energy X-ray device emitting a spherical radiation field with a sharp dose gradient. A dose of 30Gy was prescribed to the surface of the resection cavity. The primary endpoint was cumulative local control rate (LCR). Secondary endpoints were incidence of other (distant) BM (RCR), overall survival (OS), time to the next systemic treatment and adverse event rates (AE). **Results:** In total, 35 of the originally 50 planned patients were recruited. After a pre-specified interim analysis, the study was prematurely halted due to good safety and outcomes profiles. 54.3% were men, the mean age was 64 (45-85) years. The mean follow-up was 25.7 (0.8-64.5) month. At the time of this report, 51.4% of patients were alive. 68.6% primary histologies corresponded to lung primaries. The LCR was 94.3% (95% CI 82.9-98.8%) and RCR was 57.1% (95% CI 40.7-72.4%). 8.6% patients or lesions developed out of field leptomeningeal progression. The mean OS was 37.4 months (95% CI 28.9-46.9). For those patients undergoing salvage whole brain RT (WBRT), the median initiation time was 147 (20-601) days with a significant survival benefit for those not requiring WBRT ($p = 0.027$). No significant survival differences were identified according to primary histology ($p = 0.618$), immunotherapy ($p = 0.928$), seizures at baseline ($p = 0.169$), KPS ($p = 0.056$) or radionecrosis appearance ($p = 0.214$). Mean time to next systemic treatment was 45.0 (95% CI 35.1-54.8) days. No G4-5 AE related to IORT occurred. The overall radionecrosis (RN) rate was 20% ($n = 5$ G1, $n = 1$ G2, $n = 1$ G3). No risk factors could be associated to RN. Post-surgical seizures were present in 28.6% patients, with eloquent localizations as the only predictive factor ($p = 0.008$). **Conclusions:** IORT for resected BM yields excellent local control rates and has a toxicity profile similar to those reported in post-operative SRS trials. By easing a prompt initiation of subsequent systemic treatments, IORT might shorten the overall treatment courses of many cancer patients. Clinical trial information: NCT03226483. Research Sponsor: None.

A radiomics model developed from pre-metastatic brain magnetic resonance imaging to predict brain metastasis in non-small-cell lung cancer: Evidence to the seed-and-soil theory. *First Author: Xiao Chu, Department of Radiation Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Steven Paget's "seed and soil" theory suggests that both the primary tumor and the target host organ play important roles in successful metastasis development. In this proof-of-concept study, we proposed that inter-individual differences exist in the brain's congeniality for developing brain metastasis (BM), and validated the theory via developing a non-invasive radiomics BM prediction model. **Methods:** 256 non-small cell lung cancer (NSCLC) patients with no BM at baseline brain magnetic resonance imaging (MRI) were selected, 128 patients developed BM within three years after diagnosis and 128 remained BM-free. For radiomics analysis, both the BM and non-BM groups were randomly distributed into training and testing datasets at a 70%-30% ratio. Baseline brain MRI (representing the soil) and chest computed tomography (CT, representing the seed) radiomics features were extracted to develop the BM prediction models. We first developed radiomics models using the training dataset and subsequently validated the models in the testing dataset. A radiomics BM score (RadBM score) was generated and BM-free survival were compared between RadBM score-high and RadBM score-low groups. **Results:** The radiomics model developed from baseline brain MRI features alone can predict BM development in NSCLC patients. Furthermore, a fusion model integrating brain MRI features with primary tumor CT features (seed-and-soil model) provided synergetic effect and was more efficient in predicting BM (areas under the receiver operating characteristic curve 0.84 [95% confidence interval: 0.80-0.89] and 0.80 [95% confidence interval: 0.71-0.88] in the training and testing datasets, respectively). BM-free survival was significantly shorter in the RadBM score-high group versus the RadBM score-low group (Log-rank $P < 0.001$). Cumulative BM rate at 3-year were 75.8% and 24.2% for RadBM score-high and RadBM score-low group, respectively. **Conclusions:** The results demonstrated that intrinsic features of a non-metastatic organ exert a significant impact on metastasis development, which is first-in-class in metastasis prediction studies and provided novel evidence for the "seed-and-soil" theory of tumor metastasis. Radiomics BM prediction model utilizing both pre-metastatic brain and primary tumor features might provide a useful tool for identifying NSCLC patients more prone to develop BM and providing individualized management for these patients. Risk of brain metastases in metastatic non-small cell lung cancer without baseline brain metastasis: Pooled analysis of individualized patient data from three randomized clinical trials involving first-line atezolizumab treatment. *First Author: Yue Zhou, Fudan University Shanghai Cancer Center, Shanghai, Shanghai, China*

Background: Data on the efficacy of immune checkpoint inhibitors on delaying or preventing the occurrence of brain metastases (BMs) in metastatic NSCLC without initial BMs is limited. We explored the benefit of first-line atezolizumab versus chemotherapy in the occurrence of BMs in patients without baseline BMs. **Methods:** Individual patient data from IMpower1301, IMpower131, and IMpower150 were pooled. All patients in the intention to treat population were analyzed. Primary endpoints included BM free survival (BMFS) and the cumulative incidence of BM. Patients without baseline BMs were categorized into two groups: patients who received treatment including atezolizumab (atezolizumab group) and patients who received comparator chemotherapies (chemotherapy group). **Results:** In 2543 patients without baseline BMs, 87 (3.4%) developed BM, including 58 (3.4%) and 29 (3.4%) in the atezolizumab group and the chemotherapy group, respectively. The median BMFS was 8.31 months (95% CI 7.79-8.67). The cumulative incidence of BM at 6 months, 12 months, and 24 months was 1.9%, 3.1%, and 3.8%, respectively. Compared to the chemotherapy group, BMFS was significantly improved in the atezolizumab group (8.6 months versus 7.3 months, $p < 0.001$). After taking the competing risk events into account, no significant difference of the cumulative incidence of BM was observed between the two groups ($p = 0.671$), suggesting that the significantly better BMFS in the atezolizumab group analyzed by Kaplan-Meier method should be due to the lower incidence of extracranial progression or death. Baseline bone metastasis and non-squamous NSCLC were identified as two risk factors for BM. **Conclusions:** In patients with NSCLC without baseline BMs, first-line atezolizumab improved BMFS but not the cumulative incidence of BM compared to chemotherapy, indicating that atezolizumab could not reduce the intrinsic risk of intracranial tumor spreading. Research Sponsor: None.

Cumulative incidence (%) of BM for patients without baseline BMs.

	All	Atezolizumab group	Chemotherapy group
6 months	1.84	1.92	1.69
12 months	3.12	3.22	2.94
24 months	3.78	3.79	3.76

BM, brain metastasis.

The prognostic role of ventricular size and its dynamics in patients with leptomeningeal metastases from solid tumors. *First Author: Emilie Le Rhun, University Hospital Zurich, Zurich, Switzerland*

Background: Hydrocephalus is a common radiological sign in patients with leptomeningeal metastasis (LM) from solid tumors and can be assessed using the Evans index (EI) with high interrater agreement. Normal ranges of EI values have been defined as 0.27 ± 0.05 for females and 0.28 ± 0.06 for males aged 65-69 for the diagnostic work-up of dementia. **Methods:** We retrospectively assembled a cohort of 113 adult patients with a diagnosis of LM from solid extra-central nervous system tumors and explored the association of ventricular size assessed by the EI at diagnosis, of its modification between diagnosis and evaluation at first follow-up (> 21 days after diagnosis), and at first progression, with outcome. **Results:** Median age was 58.2 years (interquartile range (IQR) 46.1-65.7), 41 patients (36%) were male, the most frequent cancers were lung cancer ($n = 39$, 35%), breast cancer ($n = 36$, 32%) and melanoma ($n = 23$, 20%). The median EI at baseline was 0.28 (IQR 0.26-0.31) and the EI value was 0.27 or more in 67 patients (59%) and 0.30 or more in 37 patients (33%). Among patients with MRI follow-up, the EI was increased in 19 of 47 patients (40%), including 9 of 47 patients (30%) and 10 of 47 patients (59%), respectively, without and with LM progression at first follow-up. At LM progression, an increase of EI was noted in 18 of 34 patients (53%). The median LM-specific progression-free (LM-PFS) survival was 1.8 months (IQR 0.8-3.7). The baseline EI was not significantly associated with LM-PFS (numerical values: $p = 0.299$). Median LM-PFS was 2.7 months (IQR 1.2-5.0) with an EI of 0.26 or less versus 1.3 months (IQR 0.6-3.1) with an EI of 0.27 or more ($p = 0.296$). It was 2.5 months (IQR 0.9-6) with an EI of 0.29 or less versus 1.1 months (IQR 0.5-2.4) with an EI of 0.30 or more ($p = 0.147$). An increase of 0.01 or more of the baseline EI first evaluation was associated with inferior LM-PFS ($p = 0.007$). The median overall survival was 2.9 months (IQR 1-7.2). The baseline EI was not associated with survival ($p = 0.067$), however, patients with a baseline EI of 0.26 or less had a longer survival than those with an EI of 0.27 or more (5.3 months, IQR 2.4-10.8, versus 1.3 months, IQR 0.6-4.1) ($p = 0.006$). Median survival was 3.7 months (IQR 1.4-8.3) with an EI of 0.29 or less versus 1.8 months (IQR 0.8-4.1) with an EI of 0.30 or more ($p = 0.109$). Among patients with follow-up scans available, median overall survival was 9.7 months (IQR 5.6-21.4) for patients with stable or decreased EI at first follow-up as opposed to 6.4 months (IQR 3.2-10.5) for those with an increase in the EI ($p = 0.292$). **Conclusions:** The EI at baseline is prognostic in LM on univariate analysis. An increase of EI during the follow-up is associated with inferior LM-PFS. Expanding the sample size and evaluation of confounding factors such as prior or concurrent treatment will help to better define the role of EI assessments in LM. Research Sponsor: None.

HER2-low breast cancer brain metastases: Incidence and treatment implications. *First Author: Rania Chehade, University of Toronto, Sunnybrook Hospital, Toronto, ON, Canada*

Background: Brain metastases (BrM) are a major cause of morbidity and mortality among women with breast cancer (BC). Central nervous system (CNS)-penetrating systemic therapies for patients with HER2-negative BrM are lacking; this is particularly problematic for patients with triple negative disease (TNBC) who have a high likelihood of developing BrM. Given CNS activity of trastuzumab deruxtecan, efficacy for patients with HER2-low BrM is of interest. **Methods:** A retrospective study of two cohorts of patients who underwent surgery for BC BrM at Sunnybrook Health Sciences Centre between 1999-2013 and 2008-2018 were identified. Estrogen receptor, progesterone receptor, and human epidermal growth factor receptor-2 (HER2) status were assessed based on 2018 ASCO/CAP guidelines. HER2-zero was defined as immunohistochemistry (IHC) 0; HER2-low was defined as IHC 1+ or IHC 2+ with fluorescence in situ hybridization (FISH) negative status. HER2-positive was defined as IHC 3+ or IHC 2+ with positive FISH. Clinicopathological features were recorded. We also assessed the prognostic association between extent of HER2 expression and i) brain-specific progression free survival (bsPFS), as well as ii) overall survival (OS). **Results:** Out of 137 patients with resected BrM, tissue for HER2 assessment was available in 74.5% ($n=102$) of cases. In this cohort, the median age at BrM diagnosis was 53.5 (range, 32-85). 18.6% ($n=19$) had leptomeningeal disease and 68.6% ($n=70$) had extracranial disease. 53% ($n=54$) of the BrM were HER2-positive; 29.4% ($n=30$) were HER2-low and 17.6% ($n=18$) had HER2-zero status. Among BrM that were triple negative based on ASCO/CAP guidelines, 14 out of 22 cases (63.6%) were re-classified as being HER2-low. 15/25 (60%) BrM that were hormone receptor positive/HER2 negative (HR+/HER2-) based on ASCO/CAP guidelines were re-classified as being HER2-low. In total, 51 patients had matched primary breast and BrM tissue available; results of HER2 status when categorized as HER2-zero, HER2-low and HER2-positive were concordant in 82.3% ($n = 42/51$) of cases (Cohen's kappa 0.58, $p=0.0719$). In 7 cases, the primary breast tissue was HER2-zero whereas the BrM was either HER2-low ($n=5$) or HER2-positive ($n=2$). In only one case (2%), expression of HER2 was lower in the BrM (HER2-low) compared to the primary BC (HER2-positive). Median time from primary BC to the development of BrM was 35 months (IQR, 14-69) in the overall cohort; patients with HER2-zero BrM had a numerically longer time to development of BrM (45.8 months), compared to those with HER2-low (35 months) and HER2-positive (35 months) BrM ($p=0.948$). There was no significant association between HER2-zero, HER2-low and HER2-positive status in BrM and either bsPFS or OS. **Conclusions:** Among patients with surgically resected BrM, a high proportion of those with metastatic TNBC and HR+/HER2-negative disease have "HER2-low" BrM with potential to benefit from HER2-targeted therapy. Poster Session

A systematic review and meta-analysis of intrathecal versus alternate routes of delivery for HER2-targeted therapies in patients with HER2+ breast cancer leptomeningeal metastases. *First Author: Anna-Maria Lazaratos, Université de Montréal, Montreal, QC, Canada*

Background: Patients with HER2+ breast cancer (BC) frequently develop leptomeningeal metastases (LM). While HER2-targeted therapies have demonstrated efficacy in the neoadjuvant, adjuvant, and metastatic settings, including for parenchymal brain metastases, their efficacy for patients with LM has not been studied in a randomized controlled trial. However, several single-armed prospective studies, case series and case reports have studied oral, intravenous (IV), or intrathecally (IT) administered HER2-targeted therapy regimens for patients with HER2+ BCLM. **Methods:** We conducted a systematic review and meta-analysis of individual patient data to evaluate the efficacy of HER2-targeted therapies in HER2+ BCLM in accordance with PRISMA guidelines. Targeted therapies evaluated were trastuzumab (IT or IV), pertuzumab, lapatinib, neratinib, tucatinib, trastuzumab-emtansine (T-DM1) and trastuzumab-deruxtecan (TDXd). The primary endpoint was overall survival (OS), with progression-free survival (PFS) as a secondary endpoint. To assess differences between groups, shared frailty Cox regression models were used to estimate the hazard ratio (HR), 95% confidence interval (CI) and p-value. **Results:** 7780 abstracts were screened, identifying 44 publications with 200 patients, corresponding to 257 lines of HER2-targeted therapy for BC LM which met inclusion criteria. In univariable (OS: HR=0.9, 95% CI: 0.64-1.4, $P=0.76$; PFS: HR=0.8, 95% CI: 0.57-1.2, $P=0.35$) and multivariable (OS: HR=1.4, 95% CI: 0.68-3.1, $P=0.4$; PFS: HR=0.8, 95% CI: 0.41-1.7, $P=0.6$) analyses, we observed no significant difference between IT, oral or IV administration of HER2-targeted therapy. Meanwhile, ECOG performance status remained independently associated with prolonged OS (HR=2.2, 95% CI: 1.5-3.2, $P<0.001$) and PFS (HR=2.2, 95% CI: 1.5-3.2, $P<0.001$ and HR=1.9, 95% CI: 1.4-2.8, $P<0.001$) in the final multivariable model. ECOG status was not associated with route of trastuzumab delivery ($P>0.40$). Anti-HER2 monoclonal antibody-based regimens did not demonstrate superiority over HER2 tyrosine kinase inhibitors (OS: $P=0.647$; PFS: $P=0.983$). In a cohort of 7 patients, TDXd demonstrated improved OS compared to other HER2-targeted therapies and compared to T-DM1 ($P<0.05$). **Conclusions:** The results of this meta-analysis suggest that IT administration of HER2-targeted therapy for patients with HER2+ BCLM confers no additional benefit over oral and/or IV treatment regimens. We also present the first evidence supporting the efficacy of TDXd compared to alternative strategies for this patient population. Although the number of patients receiving TDXd in this cohort is small, this novel agent offers promise for this patient population and requires further investigation in prospective studies. Poster Session

Assessment of electronic health record (EHR)-based machine learning (ML) in predicting risk of brain metastasis among patients with early-stage non-small-cell lung cancer (eNSCLC). *First Author: Hossein Honarvar, ConcertAI, Cambridge, MA*

Background: Among patients (pts) with eNSCLC, development of brain metastasis (BM) is a poor prognostic sign, but routine surveillance for BM is not recommended post-therapy. EHR-based ML algorithms may identify pts who would benefit from active brain MRI surveillance and/or treatment intensification in the early-stage setting. **Methods:** ConcertAI Patient360 database, consisting of structured and curated EHR records from pts receiving care in ~900 US oncology clinics, was used to identify pts diagnosed with stage IB-IIIA NSCLC without prior evidence of BM between Jan 2010 – December 2021. Presence of BM was identified from human curation of patient documents. Gradient boosting (GB), random forest (RF), and logistic regression (LR) algorithms with 3-fold cross-validation were trained and compared to predict risk of BM at two landmarks: 18 and 24 months (mos) from initial diagnosis (index). Pts who did not develop BM and either died or were lost to follow-up prior to landmark times were removed. Feature importance was defined using Shapley Additive Explanation (SHAP)-derived marginal odds ratios (OR). Due to low prevalence of BM, AUPRC was used as performance metric. Pts in the 1st and 4th quartiles of predicted probabilities from GB model were flagged as low-risk vs. high-risk. **Results:** Among 7473 pts in 18 mos model, median age was 68.4 years (IQR 13.2), 50.5% were female, and 10.9% were black. Demographics were similar for 6863 pts in 24 mos model. 6.4% and 8.3% developed BM at 18 and 24 mos. Ability of GB, RF, and LR models to predict BM was similar with validation AUPRC of 0.109 at 18 mos and 0.137 at 24 mos. In the GB model, BM prevalence in high-risk vs. low-risk group was 10.3% vs. 3.1% at 18 mos and 13.4% vs. 4.4% at 24 mos. In both landmark models, NO stage and surgery within 90 days after index diagnosis were protective against BM, while presence of EGFR targetable mutations, adenocarcinoma (AD) histology, higher platelets (PLT), and history of pneumonia were risk factors. A glucose-by-histology interaction was found: For pts with normal blood glucose (GLU), risk of BM was independent of histology, for pts with high GLU, AD conferred greater risk of BM. **Conclusions:** An EHR-based ML model identified risk factors for developing BM among pts with eNSCLC and may identify pts who would benefit from active brain MRI surveillance and treatment intensification. Research Sponsor: ConcertAI.

Large-scale clinico-genomic models of solid tumor CNS metastasis.

First Author: Justin Jee, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Central nervous system (CNS) metastasis is a major cause of cancer death and morbidity, but the clinico-genomic covariates of CNS metastasis have been studied in small cohorts. We sought to i) determine whether models predicting patient time to CNS metastasis (ttCNS) trained on a large, automatically annotated clinico-genomic dataset could stratify ttCNS risk in an external, manually curated cohort and ii) use these data to study the genomic risk factors for metastasis at scale.

Methods: We leveraged the AACR Project GENIE Biopharma Collaborative (BPC), a structured curation of electronic health records at four cancer centers using the PRISMM method, to train natural language processing (NLP) algorithms to annotate metastatic sites from radiology reports. We applied these algorithms to all reports for MSK patients with tumor sequencing with our FDA-authorized targeted sequencing platform. We used the resulting clinico-genomic data to train random survival forests (RSF) to predict radiographically confirmed ttCNS from time of sample acquisition for patients with non-small cell lung (NSCLC, N = 7,263), breast (BRC, N = 5,195; HR+ N = 4,050, HER2+ N = 879, triple-negative (TNBC) N = 866), and colorectal cancer (CRC, N = 4,320) using stage, gene-level pathogenic alterations, pre-existing metastatic sites, histopathology, prior and current treatment, and patient demographics as variables, excluding those reaching the endpoint prior to sample acquisition. We also predicted time to bone, liver, and adrenal metastases. RSFs were validated in the manually curated, non-MSK BPC cohort. **Results:** RSFs had predictive power for ttCNS in validation datasets (NSCLC c-index: 0.66, BRC: 0.71 (HR+ only: 0.71, HER2+ only: 0.69, TNBC: 0.62), CRC: 0.67, all $p < 0.001$). Pre-existing metastatic involvement, and genomic, histopathologic and clinical features had non-overlapping information for predicting ttCNS. We explored genomic covariates of ttCNS and other sites using Cox proportional hazards models adjusted for disease stage. Within individual cancer types, the hazard ratios of gene-level changes leading to the four considered sites of metastasis were correlated (Pearson R = 0.71-0.98); in all cancer types the highest correlations were between ttCNS and ttAdrenal metastases. Across cancer types, genomic alterations leading to metastatic sites were less correlated (R = -0.22-0.48). For example, CDKN2A/B and MYC alterations shortened ttCNS in NSCLC and HR+ BRC but not in HR- BRC. PTEN was associated with shortened ttCNS in TNBC and NSCLC but not CRC and other breast subtypes. **Conclusions:** Automatically annotated cohorts provide a means of studying drivers of metastasis at scale. Pre-existing non-CNS sites are associated with shorter ttCNS. Genomic alterations predisposing to CNS metastases frequently predispose to other organ metastases, although in general the genomics of organotropism are highly cancer-specific. Multi-cancer brain metastasis risk score development and validation using 220,246 whole transcriptomes and machine learning. *First Author: Jim Abraham, Caris Life Sciences, Phoenix, AZ*

Background: Brain metastases occur in multiple cancer types with higher prevalence in lung, breast, melanoma, and GI cancers. The prognoses of patients who develop brain metastases are very poor and identification of brain metastasis risk could be useful for prognostication, monitoring, and therapy selection. **Methods:** Data from the whole transcriptome of 220,246 tumor profiles were analyzed and multiple machine learning models were trained on various molecular subtypes. The dataset was split 50% for training and the other 50% for testing. UMAP was employed for dimensionality reduction and the patterns learned across the entirety of the training dataset irrespective of brain metastasis were leveraged on the testing data set. Patients with brain metastasis were identified using the presence of ICD-10 code C79.31 (Secondary malignant neoplasm of the brain). As the absence of C79.31 could be due to the event not happening yet, patients without brain metastasis were stratified into groups based on 3, 4 or greater than 5 years without a C79.31 ICD-10 code. The brain metastasis risk score was defined by empirical evaluation of the positive predictive value in 7 groups of risk probabilities. The validation set contained 1,217 patients with brain metastasis and 4,631 without an observed brain metastasis within 3 years. **Results:** In the validation set, the prevalence of brain metastases within the risk scores across all cancer types ranged from 4% with the lowest risk score to 94% in the highest with 71% of cases receiving the lowest 2 risk scores, 15% the 2 intermediate risk scores, and 14% the 3 highest risk scores. For breast, lung and colon cancers, the prevalence of brain metastasis ranged from 4-10% in patients with the lowest risk scores to 92-100% in patients with the highest however the distribution of cases with each risk score was markedly different across cancer type. Breast cancer had 62% of cases receiving the lowest 2 risk scores versus 27% in lung, and 92% in colon. Breast cancer had 18% of cases receiving the 3 highest risk scores while lung had 42% and colon only 2% of cases with those 3 highest scores. **Conclusions:** Whole transcriptome data can be leveraged by a machine learning platform that employs dimensionality reduction techniques along with transfer learning to predict the risk of brain metastasis. This tool can be used to augment the clinical picture of cancer patients an unmet clinical opportunity to inform prognosis, monitoring, and therapeutic selection. Research Sponsor: None.

Surgically targeted radiation therapy (STaRT) for recurrent glioblastoma: Initial outcomes from a prospective multicenter registry. *First Author: Ahmad Ozair, Miami Cancer Institute, Baptist Health South Florida, Miami, FL*

Background: Surgically targeted radiation therapy (STaRT), using a novel bioresorbable collagen brachytherapy device containing 4 Cesium-131 sources, is FDA-cleared for use as adjuvant radiation therapy (RT) post-resection in both newly diagnosed and recurrent intracranial neoplasms. Intraoperative initiation of brachytherapy potentially minimizes post-resection tumor regrowth with a favorable dosimetric profile compared to external beam radiation. This work sought to determine early patterns of care and the safety of this approach in recurrent GBM. **Methods:** This prospective multi-institutional observational study (NCT04427384) included recurrent GBM patients who underwent maximum safe resection (MSR) and permanent implantation of the device(s) (GammaTile, GT Medical Technologies, Tempe, AZ, US). Descriptive and comparative analyses regarding patient characteristics and early clinical outcomes were performed. Toxicities were categorized using the CTCAE v5.0 adverse event (AE) criteria. **Results:** During 10/2020-01/2023, 14 participating sites enrolled 45 patients with recurrent GBM for STaRT; 2 patients had two sites treated for a total of 47 implants. 67% of patients were treated at the first recurrence, 24% at the second, and 13% at the third, respectively. The median age was 61 (range 28-75), 36% were female, and 23% were > 65 years. 85% of patients received prior same-site RT with the median time from last RT to implantation of 14.6 months (range 3.5-57). The median maximum preoperative size was 4.2 cm (range 1.6-7.0) and the median volume was 20.8 cm³ (range 0.8-130). 68% of resections were gross-total, 17% near-total, and 15% sub-total; the median time needed for device implantation was 5 minutes (range 1.0-13). Median follow-up was 5.2 months (range 0.6-23.2). Median Karnofsky performance status (KPS) at screening, at initial postoperative assessment, and 3 months were all 80 (range 40-100). 7 attributed AEs occurred in 13% (6/45) of patients, all grade 3 AEs: 2 CSF leaks, 2 seizures, 1 cerebral edema, 1 pseudomeningocele, and 1 left hemiparesis. All except one were coded as related to both radiation and surgery; the patient with pseudomeningocele experienced a seizure at 47 days that was considered related to radiation alone. **Conclusions:** Early data from this prospective registry demonstrate the feasibility and safety of STaRT in recurrent GBM. Data on 6-month progression-free survival will be presented at the conference. A prospective randomized trial of adjuvant systemic therapy (AST) +MSR+STaRT versus MSR+AST is planned for initiation in 2023. Research Sponsor: GT Medical Technologies.

Cerebrospinal fluid immunological cytokines to predict intracranial tumor response to immunotherapy in non-small cell lung cancer patients with brain metastases: GASTO 1060. *First Author: Likun Chen, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Immunotherapy has been the standard first-line therapy in patients with advanced non-small cell lung cancer (NSCLC), and shown a certain efficacy for patients with brain metastases. However, the appropriate predictive biomarkers for intracranial tumor response to immunotherapy are unclear. We conducted this prospective study to explore the immunological cytokines in cerebrospinal fluid (CSF) to predict intracranial tumor response to immunotherapy in NSCLC patients with brain metastases. **Methods:** We prospectively enrolled treatment-naïve, EGFR/ALK wild-type NSCLC patients with brain metastases in this study. Patients received chemotherapy plus camrelizumab (a humanized anti-PD-1 monoclonal antibody) as first-line treatment, and paired plasma and cerebrospinal fluid (CSF) samples were collected at baseline and first treatment evaluation (8-week). All samples were detected for 92 Immunology cytokines using the Olink panels, and were explored for predictive biomarkers to immunotherapy. The Mann-Whitney U test was performed to compare the immunological cytokine expression between intracranial response and non-response groups. And logistic LASSO regression model was used to variate selection and develop a CSF immuno-cytokine model to predict intracranial tumor response. **Results:** Between April 2020 and May 2022, a total of 28 patients were enrolled this study. At baseline, most immunological cytokines were significantly lower in paired CSF than in plasma, whereas a subset including CD83, PTN, TNFRSF21, TWEAK, ICOSLG, DCN, IL-18 and MCP-1 were increasing expressed in CSF samples. For patients with objective intracranial tumor response compared to patients with non-response, the baseline CSF levels of LAMP3 were significantly higher, whereas the CXCL10, IL-12, CXCL11, IL-18, TIE2, HGF and PDCD1 levels were significantly lower. And patients with lower HGF, IL-18 or PDCD1 levels had significantly longer intracranial progression-free survival to immunotherapy. The above CSF immunological cytokines were significantly decreased at first treatment evaluation in patients with intracranial tumor response. Our logistic CSF immuno-cytokine model selected TIE2, IL-18, LAMP3, PDCD1 and IL-12 that were significantly associated with intracranial tumor response, and yielded a mean AUC of 0.91, compared to PD-L1 expression (mean AUC of 0.72). **Conclusions:** Immunological cytokines in CSF could predict intracranial tumor response to immunotherapy in NSCLC patients with brain metastases, and findings require validation in a larger prospective cohort. Analysis of tumor progression among patients with glioma after COVID-19 infection. *First Author: Tim Gregory, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: As of January 2023, there have been 6.7 million worldwide deaths attributed to SARS-CoV-2 COVID-19, which has impacted outcomes and medical care for all patients. Relatively little is known about the direct effects mediated by the virus on CNS tumor biology, despite the fact that viral neurotropism is well described, various coronavirus receptors have been observed in glioblastoma (GBM) tissues, and differential monocytic infiltration has been proposed to dysregulate the immune microenvironment. We detected a trend of rapid progression following COVID-19 infection among several patients with primary brain tumor patients and sought to systematically evaluate the pace of progression among infected patients in our institution. **Methods:** A single-institutional database of COVID-19 patients and an electronic medical record (EMR) search tool were used to identify a total cohort of 67 patients with glioma for retrospective analysis. This included 38 GBMs, 18 IDH-mutant gliomas, 5 ependymomas, 2 pilocytic astrocytomas, 1 diffuse midline glioma, 1 diffuse hemispheric glioma, and 1 ganglioglioma patients, each of whom had a documented COVID-19 infection between June 2020-December 2022. Hyperprogression was defined as tumor increase $\geq 40\%$ compared to previous scan using RECIST size criteria. **Results:** Thirty-nine (58%) patients experienced tumor progression following COVID-19 infection at a median of 34 days (range=1-734 days) after testing positive for COVID-19. Twenty-two (56%) had received COVID-19 vaccine before their infection and 5 (13%) had asymptomatic infections. Twenty-two patients had measurably increased tumor area by a median of 63% (range=10-2,900%), 18 of which constituted hyperprogression; 16 patients developed multifocal disease, 8 developed new nodular enhancement, 3 developed leptomeningeal disease (LMD), and 2 experienced increased infiltrative disease alone. Ten patients' presentation with new glioma was preceded by COVID-19 infection by a median of 31 days. GBM patients represented the majority of progression events, among whom 59% progressed within 60 days of documented infection (median 25 days). This subgroup of GBM with rapid progression within 60 days had a mOS from infection of 5.2 months; 89% had TERT promoter mutations and 42% had MGMT promoter methylation. **Conclusions:** Glioma patients appear to have disease progression at an accelerated pace in the first two months after COVID-19 infection. This suggests that glioma patients should continue observing strict precautions to prevent infection and should be clinically monitored vigilantly after infection, with consideration for short interval imaging during treatment. These preliminary data warrant further investigation exploring changes of immune cell infiltration in the tumor microenvironment and the possible correlation between tumor progression and COVID-19. An exploratory clinical trial on intra-lumbar injection of B7H3-specific allogeneic universal CAR-T cells in patients with recurrent high-grade gliomas. *First Author: Xiaoyun Shang, T-MAXIMUM Pharmaceutical (Suzhou) Co., Ltd., Suzhou, China*

Background: No standard-of-care treatment was established for recurrent high-grade gliomas (rHGGs) yet. Intrathecal infusion of autologous chimeric antigen receptor-T (CAR-T) cells has displayed potent anti-tumor activity in one patient (Brown et al. N Engl J Med 2016). We evaluated the safety, efficacy, pharmacokinetic (PK) and pharmacodynamic (PD) characteristics of B7H3-specific allogeneic universal CAR-T (B7H3 UCAR-T) cells in patients with rHGGs. **Methods:** Eligible patients who had received standard treatment for newly-diagnosed high-grade gliomas but failed were treated with 2.5×10^7 B7H3 UCAR-T cells via intra-lumbar injection every month. Eligibility criteria included histologic and/or cytologic rHGGs, B7H3-positive antigen expression rate of $>50\%$ in tumor tissue and Karnofsky performance status (KPS) ≥ 40 . The primary endpoint was treatment-related adverse events (TAEs); secondary endpoints include overall survival (OS) and objective response rate (ORR); exploratory endpoints were PK and PD characteristics of B7H3 UCAR-T cells. **Results:** In the 7 patients enrolled, 4 (57.1%) were female, 5 (71.4%) glioblastoma (WHO Grade IV) and 2 (28.6%) diffuse midline glioma (WHO Grade IV), and the mean age was 40.4 years. The most common reported TAEs were increased cerebrospinal fluid (CSF) IL-6 (7/7, 100%), headache (7/7, 100%), increased blood IL-6 (6/7, 86%) and fever (6/7, 86%). No adverse events of grade 3 or greater related to B7H3 UCAR-T cells were reported. All the adverse events recovered or relieved after treatment. No typical or severe systemic cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS) or graft versus host disease (GvHD) were observed during the study period. Based on Immunotherapy Response Assessment in Neuro-Oncology (iRANO), 3 of 7 patients had response to therapy (42.9%; 95% CI: 15.8 to 75.0) and 7 of 7 patients were stable disease (100%; 95% CI: 64.6 to 100). As of cutoff date (January 30, 2023), two patients died. The median OS was not reached (95% CI: 12.9 to could not be estimated). The median follow-up for OS was 15.6 months (95% CI: 14.7 to 16.1). OS rate at 12 months was 85.7% (95% CI: 48.7 to 97.4). The CAR DNA copy numbers increased 1 day after each administration and persist at least 1 month in cerebrospinal fluid. IL-6 concentrations in CSF and peripheral blood increased after each administration while the change and concentration values in peripheral blood were much lower than those in CSF. **Conclusions:** In patients with rHGGs, B7H3 UCAR-T cells was not associated with any toxic effects of grade 3 or higher. B7H3 UCAR-T cells resulted in a significantly longer overall survival and a higher objective response rate than history data. B7H3 UCAR-T cells persist well in patients. Clinical trial information: ChiCTR2100047968. Research Sponsor: T-MAXIMUM Pharmaceuticals (Suzhou) Co., Ltd.

Safety, efficacy, and biomarker analysis of response to engineered tumor-infiltrating lymphocytes secreting anti-PD-1 antibody in recurrent glioblastoma: An open-label, two-arms, phase 1 study. *First Author: Yu Yao, Department of Neurosurgery, Huashan Hospital, Shanghai Medical College, Fudan University, Shanghai, China*

Background: Adoptive cell therapy using tumor-infiltrating lymphocytes (TILs) is effective against solid tumors with convincing evidence. But T-cells infused were exhausted when they encountered PD-1-mediated immunosuppression in the microenvironment. Here, we generated a modified autologous TILs secreting antibody targeting PD-1 (PD1-TIL), and conducted a first-in-human, two arms, phase 1 study (NCT03347097) in recurrent glioblastoma who had a poor prognosis with estimated 6-9 months of median overall survival (OS). **Methods:** Patients were included to be treated with PD1-TIL or TIL cell products intravenously every one month following surgery. The primary endpoint was safety and feasibility. The secondary endpoints were disease control rate (DCR), OS, immunologic responses and biomarker analysis. The clinical response to cell therapy was assessed by MRI according to iRANO criteria. Here, patients with clinical benefit (CR, PR, and SD) were defined as responder. **Results:** A total of 21 consecutive patients (median age 45 years, range 20-64) received infusions of cell products (7 patients for PD1-TIL with 1 excluded, 14 patients for TIL with 2 excluded). 52% (11/21) and 29% (6/21) of 21 patients had methylated MGMT promoter and IDH1/2 mutant respectively. No significant differences in baseline characteristics between groups were found. Both of PD1-TIL and TIL infusions were well tolerated with no unexpected high-grade adverse events. Of 7 evaluable patients in PD1-TIL group, 1 had PR for more than 26 months, 2 had SD lasting for 7.7 months and 24 months, and 4 had PD after infusion. The DCR, 1-year and 2-years survival rates in PD1-TIL group were 43% (3/7), 86% (6/7) and 29% (2/7) respectively. In TIL group, 3 patients had SD and the others had PD. The DCR, 1-year and 2-years survival rates in TIL group were half of that in PD1-TIL group. Survival analysis showed that patients treated by PD1-TIL had extended OS than those received TIL (16.1 vs. 11.2 months, $P = 0.047$). Among 21 patients, clinical responders had significantly improved OS (30.9 vs. 10.7 months, $P = 0.001$) than non-responders. We also found a high capacity for engraftment and persistence of infused TILs in peripheral blood which could be detectable at 6 months after treatment. Existence of neoantigen-reactive T cell clonotypes in cell products may be important for responding because missing of missense mutations predicted to generate a neoantigen after cell therapy was a remarkable signature in responders. Responsive tumors were also associated with tumor microenvironment profiles. **Conclusions:** This first-in-human study establish the preliminary feasibility, safety and encouraging efficacy of PD1-antibody-secreting TILs, and may constitute a new treatment strategy by T-cell genetic engineering in glioblastoma. Clinical trial information: NCT03347097. Research Sponsor: National Key R&D Program of China; National Natural Science Foundation of China.

Lisavanbulin in patients with recurrent glioblastoma: Phase 2a results and a consolidated analysis of response-predictive biomarkers. *First Author: Juanita Suzanne Lopez, The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: Lisavanbulin (BAL101553, prodrug of BAL27862) destabilizes microtubules and promotes tumor cell death by modulating the spindle assembly checkpoint. BAL27862 is a lipophilic small molecule shown in rodents to penetrate the brain, with antitumor activity in orthotopic glioblastoma (GBM) models. In the Phase 1 part of this study¹ (NCT02490800), 2 of 5 patients with recurrent IDH-mutated G4 astrocytoma treated at active dose levels (15-30 mg/day) showed long-lasting objective responses and strong end-binding protein 1 (EB1) expression in GBM tissue by IHC. EB1 is a regulator protein on microtubules. **Methods:** The objective of the Phase 2 study was to investigate prospectively the response-predictive value of EB1, and to identify RNA-based response signatures in patients with recurrent GBM. A Simon's two-stage design was used with an objective response rate (ORR) $\geq 2/9$ required in Stage 1 to enable a final ORR $\geq 6/19$. A prescreening program identified patients with EB1-positive archival GBM tissue. All patients received 25 mg oral lisavanbulin once daily. RNA-seq was performed on archival GBM tissues. **Results:** GBM tissue samples from 64 of 629 patients (10.2%) obtained from 13 sites in four countries were EB1-positive, and 18 of these patients received lisavanbulin. Of 9 patients with measurable disease evaluable for response in Stage 1, one patient had a partial response, and another had a 44% target lesion area reduction. Despite sustained activity in these patients, formal stage transition criteria were not met, and the study was closed. IHC testing for EB1 did not show sufficient enrichment for response, but it is thought that IDH status may play a role. In addition, RNA-seq analyses identified a five-gene signature that is distinct from expression patterns observed with EB1-IHC positivity, and predicts current responses irrespective of IDH status. This signature is characterized by homeobox gene downregulation, which may be implicated in the control of microtubule dynamics. **Conclusions:** This Phase 2a study supports previous study results that lisavanbulin is associated with durable responses and clinical benefit in a subset of patients with GBM. RNA-seq analyses of GBM samples suggest further evaluation of the lisavanbulin predictive response signature. ¹Lopez et al, JCO 2019; 37,15 suppl, 2025. Clinical trial information: NCT02490800. A single-arm, phase 2 clinical trial of abemaciclib in adult patients with recurrent grade 3 oligodendroglioma. *First Author: Stephen Joseph Bagley, Hospital of the University of Pennsylvania, Philadelphia, PA*

Background: Oligodendroglioma is a malignant glial neoplasm arising primarily in young adults. Although radiotherapy (RT) and chemotherapy result in durable disease control, tumor recurrence is inevitable and life-limiting. The cyclin D1-CDK4 axis is frequently dysregulated in recurrent oligodendroglioma. Abemaciclib is a selective CDK4/6 inhibitor that has been shown to achieve pharmacologically-relevant concentrations in brain tumor tissue. **Methods:** We conducted a single-center, single-arm, phase 2 trial evaluating the efficacy of abemaciclib in patients with recurrent oligodendroglioma, IDH-mutant and 1p/19q-codeleted, WHO Grade 3, following prior RT and ≥ 1 line of alkylating chemotherapy. Patients received abemaciclib 200mg twice daily. Primary endpoint was progression-free survival status at 6 months (PFS-6). Ten patients were needed for 80% power to detect the difference between the null (PFS-6 = 50%) and alternative (PFS-6 = 85%) hypotheses; one-sided $\alpha = 0.05$. Modified RANO criteria were used for patients with enhancing tumors and RANO low-grade glioma criteria for patients with nonenhancing tumors. **Results:** Between November 2019 - August 2022, 10 patients were enrolled (Baseline Characteristics). Most common treatment-related adverse event (trAE) was grade 1-2 diarrhea, occurring in all 10 patients. Grade 3-4 trAEs included grade 4 thrombocytopenia (n=2), grade 3 neutropenia (n=1), grade 3 fatigue (n=2), and grade 3 ALT increase (n=1). In patients with enhancing tumor (n=9), best response was partial response in 2 patients (ORR=22.2%; DOR 13.1 and 7.7 months, respectively), stable disease (SD) in 3 patients (33.3%; duration of SD 17.0, 6.7, and 2.5 months, respectively), progressive disease in 3 patients (33.3%), and not evaluable in 1 patient (11.1%). In the patient with nonenhancing tumor, best response was SD (duration 10.2 months). Median PFS was 7.7 months (95% CI, 1.7 – 13.1 months); median overall survival was not reached (median follow-up 17 months). The study's primary endpoint was not met; 5/10 patients (50%) were alive and progression-free at 6 months, below the minimum required (8/10) to consider abemaciclib worthy of further investigation. **Conclusions:** Despite objective responses and durable disease control in a small subset of patients, the efficacy of abemaciclib in recurrent grade 3 oligodendroglioma was not adequate to warrant further clinical evaluation of abemaciclib monotherapy in unselected patients. Correlative studies are ongoing to identify which patients with oligodendroglioma may benefit from abemaciclib. Clinical trial information: NCT03969706. Research Sponsor: Eli Lilly.

Final results of phase 2 trial of personal dendritic cell (DC) vaccines loaded with autologous tumor antigens (ATA) in newly diagnosed glioblastoma (GBM). *First Author: Daniela Annenelie Bota, University of California Irvine, Irvine, CA*

Background: Standard GBM therapy is associated with early progression and poor overall survival (OS). DC-ATA AV-GBM-1, a personal vaccine consisting of autologous DC pulsed with ATA, was investigated in a multicenter trial in patients with newly diagnosed GBM. **Methods:** Key eligibility criteria for surgical collection of tumor were clinical suspicion of new primary GBM & age 18-70 years. ATA lysate was prepared from irradiated tumor cells that were self-renewing in serum-free media. Autologous monocytes (MC) were collected by leukapheresis. Prior to initiating concurrent radiation therapy (RT) and temozolomide (TMZ), patients were enrolled with intent-to-treat (ITT) with DC-ATA after RT/TMZ. Eligibility included confirmation of primary GBM, availability of ATA & MC, KPS > 70 and plans for RT/TMZ. DC-ATA was manufactured during RT/TMZ. MC were differentiated into DC by culturing with IL-4 & GM-CSF, then DC were incubated with ATA. DC-ATA was suspended in 500 mg GM-CSF just prior to s.c. injections at weeks 1, 2, 3, 8, 12, 16, 20, & 24 (8 doses). Patients were not excluded based on apparent disease progression or PFS. Standard adjuvant TMZ regimens were started after the 3 weekly injections. Primary endpoint was $> 75\%$ OS 14.6 months from ITT enrollment. Secondary endpoints included median OS & progression-free survival (PFS). **Results:** Cell line and MC collection were successful for 97% of patients. Median age of the 60 ITT enrollees was 59 years. 3 patients withdrew before starting DC-ATA; 57 received 392 injections; 68% received all 8. Most common AE attributed to DC-ATA were local injection site reactions (16%) & flu-like symptoms (10%), but 33% experienced seizures. After 3 years of follow up, OS at 14.6 mos is 52.7% (95% CI 39.8, 65.8), median OS 16.0 mos (95% CI 12.9, 21.7) & median PFS 10.4 mos (95% CI 8.6, 11.6). OS rates at 1, 2, & 3 years are 70.1%, 32.4%, & 23.2%. Longer OS was associated with 8 DC-ATA doses ($p < 0.0001$), on < 2 mg/day dexamethasone (dex) at start of DC-ATA ($p = 0.005$), > 6 cycles of adjuvant TMZ ($p = 0.0054$), & KPS 90 or 100 ($p = 0.010$) at enrollment. Independent variables per multivariate Cox regression analysis were 8 DC-ATA doses, dex dose, IDH mutated, TMZ > 6 cycles, & MGMT promoter methylated. Concurrent TMZ regimens included TMZ alone (n = 28), TMZ + anti-VEGF (n = 14), & TMZ + tumor treating fields (TTF) (n = 10); 8 received no concurrent TMZ. OS was longer in patients treated with concurrent TMZ alone compared to no TMZ ($p = 0.0003$), TMZ + anti-VEGF ($p = 0.045$) or TMZ + TTF ($p = 0.045$). The only common features among 7 patients progression-free at 3 years are 8 DC-ATA injections, age < 60 , & < 2 mg dex. **Conclusions:** DC-ATA was reliably produced and injections well-tolerated in combination with various TMZ-based regimens, but the primary OS objective was not achieved. PFS was encouraging, but did not translate into improved OS, perhaps because DC-ATA was limited to 8 injections. Clinical trial information: NCT03400917. Research Sponsor: AIWITA Biomedical, Inc.

Phase I/IIa study of concomitant radiotherapy with olaparib and temozolomide in unresectable high grade glioma patients: OLA-TMZ-RTE-01.

First Author: Dinu Stefan, Centre François Baclesse, Radiation Oncology Department, Caen, France

Background: Although the Stupp protocol (radiotherapy + temozolomide (TMZ)) remains the mainstay of glioblastoma (GBM) first line treatment after extended surgery, the prognosis is still poor. PARP inhibitors, such as olaparib, may improve GBM outcomes by enhancing cytotoxic effects of ionizing radiation and TMZ. The non-dividing nature of normal brain cells allows a dedicated tumor radiosensitization. We implemented a phase I/IIa trial to assess safety and efficacy of olaparib combined with TMZ concomitant with intensity modulated radiotherapy (IMRT) as a first line treatment in unresectable GBM patients (pts). We herein present results of the phase I step. **Methods:** Based on the Stupp protocol, 2 treatment periods were considered. The radiotherapy period (RT) occurs after surgery: pts received IMRT (60 Gy/30 fractions/6 wks), oral TMZ (75 mg/m²) during IMRT, and olaparib orally given at the same dose until 4 wks after the end of IMRT. For the maintenance period (MT) from 4 wks after IMRT, pts received TMZ (150 mg/m², days D) 1-5 every 28 days, for 6 cycles) plus olaparib at the MT dose level up to disease progression or unacceptable toxicity. The phase I included 2 sequential dose escalations (DE1, DE2) of olaparib to split both periods for DLT (Dose Limiting Toxicities) assessment. Olaparib dose levels (DL) were: 50 mg Q12H D1-3 (DL1), 100 mg Q12H D1-3 (DL2) or D1-5 (DL3), 200 mg Q12H D1-3 (DL4) or D1-5 (DL5) or 200 mg Q12H continuously (DL6). Pts in DE1 received olaparib only during RT to determine the MTD1 (Maximum-Tolerated Dose), by assessing DLT on this period. Next, after olaparib administered at MTD1 during RT, pts in DE2 received olaparib during MT to determine MTD2 ($\leq$ MTD1) during the MT period, assessing DLT from the first 2 cycles. DE1 and DE2 were performed by a TITE-CRM (Time-To-Event Continual Reassessment Method). **Results:** From 2017 to 2021, 30 pts were enrolled: 20 (67%) men, median age 59 yrs [range 25-70]. 16 and 11 pts were assessable for determining MTD1 and MTD2, respectively. In DE1, 2 pts received olaparib at DL1, 6 at DL2, 6 at DL3, 1 at DL4 and 1 at DL5. 4 pts observed DLT (3 at DL3, 1 at DL5): thrombocytopenia G3-4 (n=4) + neutropenia G4 (n=2). MTD1 was defined as DL2 with estimated probability of DLT of 22.1% [95%CI 8-40.5]. In DE2, 2 pts were treated at DL1, 9 at DL2. 1 pt observed DLT at DL2: thrombocytopenia G4. MTD2 was defined as DL2 with estimated probability of DLT of 13.3% [0.2-0.35]. No interruption of IMRT for toxicity was observed. Excepted DLT, permanent olaparib discontinuation for toxicity was observed in 1 pt during RT and 2 pts during MT. Toxicity induced temporary TMZ interruption in 4 pts, none with permanent discontinuation. No toxic death was observed. **Conclusions:** Olaparib 100 mg Q12H D1-3 in concomitant with the Stupp protocol has an acceptable safety profile in unresectable GBM pts: it warrants efficacy determination, in the ongoing phase IIa step. Clinical trial information: NCT03212742. Research Sponsor: French Cancer Institute and French Health Ministry (ref: PHRC-K15-135, INCa-DGOS_9780); Astra-Zeneca for Olaparib supply.

Potential predictive biomarker for response to radiotherapy and CXCL12 inhibition in glioblastoma in the phase I/II GLORIA trial. *First Author: Frank Anton Giordano, Department of Radiation Oncology, University Medical Center Mannheim, University of Heidelberg, Mannheim, Germany*

Background: Standard of care (SOC) treatment achieves poor clinical outcomes in patients with glioblastoma (GBM), particularly in the absence of MGMT promoter hypermethylation. Preclinical models suggest that GBM recurrence is facilitated by CXCL12-mediated recruitment of bone marrow-derived cells capable of vasculogenesis after radiotherapy (RT). We have recently reported favorable safety and feasibility data of the phase I/II GLORIA trial, which combines RT and the CXCL12-neutralizing L-RNA aptamer olaptesed pegol (NOX-A12) in patients with newly diagnosed, incompletely resected or unresected GBM lacking MGMT promoter hypermethylation (NCT04121455). Here we report on clinical outcomes and their correlation with potential biomarkers. **Methods:** 10 patients with newly diagnosed incompletely resected (n=8) or biopsied (n=2) GBM with ECOG=2, age ≥ 18 and without MGMT promoter hypermethylation were enrolled. All patients received standard RT (60 Gy in 30 fractions or 40.05 Gy in 15 fractions) and escalating dose levels of continuous (24/7) i.v. infusions of NOX-A12 for 26 weeks. While the previously reported primary endpoint was safety, secondary efficacy endpoints included progression-free survival (PFS) and overall survival (OS). Biomarker assessment was performed with a six-plex immunofluorescence staining (CODEX) of neuropathologically confirmed tumor areas of pretreatment tissues for CXCL12, CD31 (endothelial cells), GFAP (glioma cells), CD68 (macrophages, microglia), α SMA (pericytes), Ki-67 (proliferating cells) and a nuclear marker. An independent patient cohort treated with SOC (n=15) matched by clinical and histopathological features was used for comparisons of efficacy and biomarker assessment. **Results:** Median PFS of the GLORIA cohort was 5.7 (range 1.9–8.5) months and the median OS was 12.7 (4.7–18.4) months. Biomarker analyses revealed that a higher frequency of CXCL12 expressing endothelial and glioma cells (EG12 score) significantly correlated with PFS ($r=0.87$; $p=0.005$) in patients treated with RT and NOX-A12, but not with SOC ($r=0.10$; $p=0.724$). GLORIA patients with a high EG12 score (median classifier) had a significantly longer PFS than those with lower scores (3.0 vs. 6.0 months; $p=0.031$) and a trend towards prolonged OS (11.1 vs. 15.8 months; $p=0.075$). These correlations were not seen in the reference cohort treated with SOC (PFS: 6.0 vs. 4.6 months; $p=0.502$; OS: 10.0 vs. 9.6 months; $p=0.243$). **Conclusions:** We show superior clinical efficacy of RT and NOX-A12 in patients with high frequency of CXCL12 expressing endothelial and glioma cells, suggesting the use of the EG12 score as a novel predictive biomarker for CXCL12-directed therapies in GBM. Clinical trial information: NCT04121455. Research Sponsor: TME Pharma AG.

Post-marketing surveillance safety analysis of patients with CNS malignancies treated with tumor treating fields (TTFields) therapy between 2011–2022. *First Author: Maciej M. Mrugala, Department of Neurology and Hematology-Oncology, Mayo Clinic Cancer Center, Phoenix, AZ*

Background: Glioblastoma (GBM) has a poor prognosis. Standard treatments are associated with systemic toxicity, further increasing the disease burden in this patient population. Tumor Treating Fields (TTFields) are electric fields that disrupt cancer cell processes which affect cancer cell viability, and are generated by a portable, wearable device which is locoregional and noninvasive. TTFields therapy was approved by the FDA for the treatment of newly diagnosed (nd) and recurrent (r) GBM based on the phase 3 EF-14 (TTFields therapy 200 kHz + temozolomide) and EF-11 (TTFields 200 kHz) studies, respectively. TTFields therapy is also approved for pleural mesothelioma. We report an updated global, post-marketing surveillance (PMS) safety analysis of patients with CNS malignancies treated with TTFields therapy over an 11-year timeframe. This analysis represents the largest dataset of TTFields therapy use to date. **Methods:** Unsolicited safety data were collected from routine post-marketing activities for patients (N = 25,898) in North America, Europe, Middle East and Africa and Japan, from October 2011 to March 2022. AEs were stratified by diagnosis, age, and sex and categorized using MedDRA version 25.1. **Results:** Diagnoses were ndGBM (68%), rGBM (26%), anaplastic astrocytoma/oligodendroglioma (4%) and other (2%). Baseline demographics were reflective of real-world practice: median (range) age was 59 (3–103) years; two-thirds of patients were male. Most (69%) patients were 18–65 years; 0.4% were < 18 years, and 30% were > 65 years. All-cause and TTFields-related AEs occurred in 18,798 (73%) and 14,599 (56%), patients, respectively. The most common device-related AE was skin reaction (43% patients overall). There were no major differences in occurrence of this AE between pediatric, adult, and elderly groups (39%, 42%, and 45%, respectively), or between males and females (41% and 46%, respectively). The incidence of device-related skin reactions was higher in ndGBM than rGBM (46% vs 34%, respectively), in line with previous reports. Only 405 (2%) of patients overall reported an AE of treatment-related ‘quality-of-life decreased’. In line with the phase 3 studies, there were no treatment-related systemic AEs. **Conclusions:** In this updated global PMS safety analysis, TTFields therapy demonstrated a tolerable safety profile in patients with CNS malignancies, with no new safety findings. In line with previous real-world and clinical data, most AEs were localized, non-serious skin events, which were consistent between age groups. Such events can typically be managed easily using prophylaxis and topical therapies, together with optimization of caregiver techniques. Importantly, no TTFields therapy-related systemic AEs were detected. Research Sponsor: Novocure Ltd.

A phase 0 pharmacokinetic trigger trial of infigratinib in patients with recurrent high-grade glioma. *First Author: Nader Sanai, Ivy Brain Tumor Center, Phoenix, AZ*

Background: This Phase 0 trial evaluates tumor pharmacokinetic (PK) and pharmacodynamic (PD) responses of fibroblast growth factor receptor (FGFR) inhibitor, infigratinib, in participants with recurrent high-grade glioma carrying FGFR1 K656E or FGFR3 K650E mutation or FGFR3-TACC3 translocation. Patients with high unbound drug concentrations in the gadolinium-nonenhancing tumor region were graduated to a therapeutic regimen of infigratinib. **Methods:** Recurrent high-grade glioma patients received 7 days of infigratinib (125 mg QD) prior to planned resection at 7–9 hours following the last dose. Tumor tissue (enhancing and nonenhancing regions), cerebrospinal fluid (CSF), and plasma were collected. Total and unbound infigratinib concentrations were measured using validated LC-MS/MS methods. A PK ‘trigger’ determined eligibility for the therapeutic expansion phase and was defined as unbound [infigratinib] > 5-fold biochemical IC50 (i.e., 5 nM) in non-enhancing tumor. PD response was assessed by quantification of percentage of positive pERK, MIB-1, and Cleaved Caspase 3 cells in the surgical tissue compared to baseline archival/biopsy tissue. Patients with tumors exceeding the PK threshold for unbound drug concentration were eligible for expansion phase therapeutic dosing of infigratinib. **Results:** Seven patients were enrolled into the Phase 0 study with 3 patients who met the PK threshold continued to the expansion phase. In non-enhancing tumor region, the mean unbound concentration of infigratinib was 3.5 nM (n=7). The mean non-enhancing tumor-to-plasma coefficient for unbound drug (Kp,uu) was calculated to be 1.4. The suppression of pERK levels and MIB-1 levels was observed in 17% (1/6) and 67% (4/6) of the patients, respectively. At a median follow-up of 16.3 months [range: 2.8–18.7 months], the median progression-free survival (PFS) was 2.8 months (n=3). One patient remains on treatment. No grade 3+ toxicities were observed, and no adverse events resulted in discontinuation of therapy. **Conclusions:** Despite relatively high unbound tumor-to-plasma (Kp,uu) value, infigratinib achieves sub-optimal unbound drug concentration in the non-enhancing brain tumor tissue. Pharmacodynamic response with archival tissue as comparator did not reveal inhibition of pERK. Clinical trial information: NCT04424966. Safety and efficacy of tumor treating fields (TTFields) prior and concomitant to radiotherapy in patients with newly diagnosed glioblastoma: Results from PriCoTTF. *First Author: Seid Kebir, Department of Neurology and Center for Translational Neuro- and Behavioral Sciences (C-TNBS), Division of Clinical Neurooncology, University Medicine Essen, University Duisburg-Essen, Essen, Germany*

Background: Tumor Treating Fields (TTFields) therapy is a locoregional, antimitotic cancer modality that utilizes electric fields delivered non-invasively to the tumor region using arrays. Preclinical findings have demonstrated that TTFields have an enhanced inhibitory effect on glioblastoma (GBM) cell proliferation when used concomitantly with radiotherapy (RT). These results provided the rationale for the phase 1/2 PriCoTTF study that investigated the safety and efficacy of TTFields therapy initiated prior and concomitant to radio-chemotherapy in adult patients with newly diagnosed (nd)GBM. **Methods:** TTFields therapy was initiated following surgery and continued concomitant with radio-chemotherapy and adjuvant chemotherapy for a total of approximately 9 months. TTFields rechallenge was permitted upon GBM recurrence. RT was conducted with arrays placed on the patients’ scalp. The primary endpoint was safety and tolerability gauged by a series of pre-selected treatment-limiting toxicities (TLTs). **Results:** The baseline characteristics of 33 patients enrolled to date were typical for GBM, except for a small proportion of patients with gross total resection (22.5%). The frequency of adverse events (AEs) grade ≥ 3 was comparable to other studies in GBM. Of note, grade ≥ 3 skin AEs only occurred in 2 patients (6%) and no patients developed a TLT. The median duration of TTFields therapy was 8.4 months. Median overall survival (OS) was not reached (48% of events had occurred), which precluded conclusions regarding efficacy. However, notably, multivariable Cox regression found that OS was independently associated with the number of days patients achieved > 23 h TTFields therapy (HR 0.96, 95% CI 0.93–0.99, P = 0.008). **Conclusions:** The PriCoTTF study met its primary endpoint by finding that TTFields therapy concomitant with RT was well tolerated in patients with ndGBM. This included that high-grade skin toxicities were rare. Longer follow up is needed to estimate the efficacy of TTFields therapy in this setting, and will need to consider the relatively low overall duration of TTFields therapy and proportion of patients who received GTR. H3.3-K27M neontigen vaccine elicits anti-tumor T cell immunity against diffuse intrinsic pontine glioma: The phase I ENACTING trial. *First Author: Yang Zhang, Beijing Tiantan Hospital, Capital Medical University, Beijing, China*

Background: Diffuse intrinsic pontine glioma (DIPG) harboring H3.3-K27M mutation is a malignant pediatric brain tumor with a >90% mortality rate within two-year of diagnosis. Current therapeutic options for DIPG are limited. Aiming to improve therapeutic outcomes, we herein report the preliminary findings of a phase I trial studying a neontigen peptide vaccine targeting H3.3-K27M. **Methods:** ENACTING is an open-label, single center, two-armed phase 1 trial to assess the safety and T cell immunity of a neontigen peptide vaccine against H3.3-K27M. Patients aged ≥ 5 years old with newly diagnosed DIPG were consented and screened. HLA-A*02+ / H3.3-K27M+ patients were enrolled to a two-arm study: Arm A consists of subjects receiving open debulking surgery, and Arm B consists of subjects without surgery eligibilities who received stereotactic biopsy. All patients subsequently received conformal radiotherapy and neontigen vaccine treatment designed to elicit both CD4+ and CD8+ T cell immune response. Vaccine was administered intramuscularly in combination with polyinosinic-polycytidylic acid-poly-L-lysine carboxymethylcellulose (Poly-ICLC). The primary objective is to evaluate the safety (AEs graded by CTCAE v4.03) and survival outcomes. Secondary objectives include maximum tolerated dose (MTD) and immunological responses. **Results:** As of Jan 2023, 11 patients have been treated, with 7 in Arm A and 4 in Arm B. No grade 3–4 treatment-related adverse events have been observed, with fever (81.9%) and injection site pain (54.5%) being the most common AEs. Among 10 efficacy-assessable patients, median progression-free survival (mPFS) and median overall survival (mOS) were 11.4 months (95% CI: 5.8–14.7) and 15.4 months (95% CI: 7.53–not reached), respectively. One-year OS rate was 66.7% (95% CI: 42–100%). One patient was assessed as complete response (CR). T cell responses against neontigen were detected and H3.3-K27M mutation-specific CD4+ and CD8+ TCR clones were validated. **Conclusions:** The H3.3-K27M neontigen vaccine was well tolerated. Initial results from this ongoing study suggest that, compared with other current therapies against DIPG, H3.3-K27M peptide vaccination may provide superior patient survival outcomes. Clinical trial information: NCT04749641. Research Sponsor: Guangdong TCRcure Biopharma Technology Co., Ltd, Guangzhou, China.

Phase 1 study of pritimumab in brain cancer. *First Author: Jose Arganda Carrillo, Pacific Neuroscience Institute and Saint John's Cancer Institute at Providence Saint John's Health Center, Santa Monica, CA*

Background: Pritumumab, a fully human IgG1 (kappa) monoclonal antibody (mAb), was originally isolated from a patient with cervical carcinoma. This classical example of a natural human anti-cancer antibody recognizes an altered form of the cytoskeletal protein vimentin, referred to as ectodomain vimentin (EDV). EDV is an ideal target for immunotherapy as it is expressed on the surface of tumor cells and is significantly overexpressed in glioblastomas (GBM). A multi-center phase 1 study was performed to assess the safety and pharmacokinetics of Pritumumab (NCT04396717). **Methods:** Eligible patients included age ≥ 18 years, histologically confirmed diagnosis of a central nervous system cancer, and have failed prior standard therapy. Exclusion criteria included insufficient time from prior therapy characterized as less than 28 days from cytotoxic therapy, less than 14 days from non-cytotoxic investigational agent, and less than 7 days for non-cytotoxic or immunotherapy agent. Dose Escalation Schema: Five cohort arms with up to 6 patients at each dose level included Cohort 1 (1.6 mg/kg), Cohort 2 (4.8 mg/kg), Cohort 3 (8.0 mg/kg), Cohort 4 (12.0 mg/kg), and Cohort 5 (16.2 mg/kg) on weekly 3+3 dosing schedule. Dose escalation was based on the dose-limiting toxicities (DLT) encountered through Day 28 of treatment. Pharmacokinetics: Blood and CSF samples were collected for pharmacokinetic (PK) analysis both pre- and post-dose. **Results:** 24 patients provided informed consent and 9 were excluded for not meeting eligibility. 15 patients received the investigational agent and were evaluable for safety and efficacy analyses. 12/15 patients had a diagnosis of glioblastoma and one patient each had anaplastic astrocytoma, oligodendroglioma, and non-small lung cancer with brain metastases. 13 patients discontinued treatment due to disease progression, one due to PI discretion for an unrelated CNS infection, and one withdrew for personal reasons. One partial response showed nearly a 98.0% and 40.8% reduction in 2 tumor lesions for 17 months on study. There were no dose-limiting toxicities to this natural human IgG mAb. The most common adverse events at least possibly attributed to Pritumumab were fatigue (53.3%) and constipation (33.3%). Other rare side effects, possibly related to Pritumumab, occurred at 6.7% were nausea, joint tenderness, dehydration, hypomagnesemia, neuropathy, pruritus, scalp dryness, dry skin (face), and depression. There were no Grade 3, 4, or 5 adverse events attributed to pritimumab. Preliminary pharmacokinetic (PK) data shows volume of distribution as 38.36 mL/kg and clearance of Pritumumab as 0.1305 mL/h/kg. The half-life of Pritumumab was found to be 12.5 days. **Conclusions:** Single agent Pritumumab is safe up to a dose of 16.2 mg/kg every 7 days in brain tumor patients. A phase 2 study is being planned as single agent and in combination with checkpoint inhibitors in both recurrent gliomas and upfront with chemoradiation in newly diagnosed gliomas. Clinical trial information: NCT04396717. Research Sponsor: Nascent Biotech, Inc.

New ESMO scale for clinical actionability of molecular targets (ESCAT) for gliomas based on a multicentric real world data cohort using next-generation sequencing (NGS). *First Author: Oriol Mirallas, Vall d'Hebron University Hospital and Institute of Oncology (VHIO), Barcelona, Spain*

Background: The ESMO ESCAT scale rank molecular alterations (MA) based on the published evidence supporting their clinical use. Building on our proposal for the first ESCAT classification for primary brain tumors (pBT) [Mirallas *et al.* ESMO 2022], we aim to describe the clinical actionability of NGS in a multicentric glioma cohort and gather clinical factors that enrich patients with MA to justify performing NGS. **Methods:** A multicentric retrospective study included pts with molecular profiling using NGS methods (Foundation Medicine, local NGS, Caris, OncoPrint, and fusion panels). Clinical actionability was classified using the ESCAT scale; Tier 1 (ready for clinical implementation), Tier 2 (alteration-drug match with antitumor activity), Tier 3 (supported in other tumor types), and Tier 4 (preclinical evidence). Clinical factors considered for enrichment were diagnosis of glioblastoma (GBM), sex, and age ≤ 40 years, differences between groups were determined using Chi-squared test. The overall survival (OS) was calculated through Kaplan-Meier method and cox hazard ratio were fitted. **Results:** A total of 361 pts with NGS performed between Feb 2018 and Dec 2022 at 4 hospitals in Spain. Median age was 51.5 (range, 3.3-83.8), 77% had ECOG ≥ 1 , 39.2% were women, 23.4% were 40 or younger, 20.8% had IDH1mut, and 73.5% had a diagnosis of GBM. The distribution of MA according to ESCAT was: 10 pts ESCAT 1 (5 BRAFV600E mut, 5 NTRK 1-3 fusions); 75 pts ESCAT 2 (67 IDH1 mut, 6 FGFR-TACC rearrangement, 4 FGFR 1-3 mut, 3 IDH2 mut); 105 pts ESCAT 3 (98 PIK3CA/PTEN mut, 12 PTEN loss, 11 H3K27M mut, 6 BRAF fusion, 2 MET mut, 1 FGFR3 amplification); 93 pts ESCAT 4 (119 TERT mut, 77 EGFR gain, 67 CDKN2A loss, 58 CDKN2B loss, 48 EGFRvIII rearrangement, 46 ATRX mut, 40 EGFR mut, 8 ATM mut). Prevalence of Tier 1-2 MA was 23.6%. In relation to enrichment factors: 12% > 40 y pts had ESCAT1-2 vs 61% in ≤ 40 y ($p < 0.001$), pts with GBM had a 11% prevalence vs 61% non-GBM ($p < 0.001$), and non-gender differences were seen. The median OS for Tier 1-2 was 135 months (95% CI 166-99) vs Tier 3-4 of 24 months (95% CI 21.5-29.6). Significantly worse OS was observed for Tier 3-4 gliomas (HR: 4.11; 2.84-5.95, $p < 0.001$), and remained significant after adjusting for histology and hospital center ($p < 0.01$). **Conclusions:** The prevalence of ESCAT Tier 1-2 alterations is high in gliomas suggesting that molecular profiling should be offered, at least, in tertiary centers where these techniques are available. Potential enrichment factors to offer NGS were age and non-GBM pBT, but not gender. Research Sponsor: VHIO.

Zotiraciclib (TG02) for newly diagnosed glioblastoma in the elderly or for recurrent glioblastoma: The EORTC 1608 STEAM trial. *First Author: Emilie Le Rhun, University Hospital Zurich, Zurich, Switzerland*

Background: Zotiraciclib (TG02) is an oral multi-cyclin dependent kinase (CDK) inhibitor, including CDK-9, that inhibits tumor growth down-stream via depletion of survival proteins such as MCL-1 and MYC. MCL-1 and MYC are frequently overexpressed in glioblastoma. **Methods:** The EORTC 1608 (NCT03224104) (STEAM) phase 1b trial had a three parallel group (A,B,C) open-label, non-randomized, multicenter design. Groups A and B explored the maximum tolerated dose (MTD) of zotiraciclib in elderly patients (more than 65 years) with IDH1^{R132H}-non-mutant newly diagnosed glioblastoma or anaplastic astrocytoma, in combination with hypofractionated radiotherapy alone (group A) or temozolomide alone (group B), based on O⁶-methylguanine DNA methyltransferase promoter methylation status determined centrally. Group C explored single agent activity of zotiraciclib in IDH1^{R132H}-non-mutant glioblastoma or anaplastic astrocytoma at first relapse after temozolomide chemoradiotherapy with a primary endpoint of progression-free survival at 6 months. Secondary objectives included efficacy, quality of life, and safety. **Results:** The MTD was 150 mg in combination with radiotherapy alone (group A, n=12) or temozolomide alone (group B, n=9) in elderly patients. Two dose-limiting toxicities were observed at 150 mg, one in group A (grade 3 seizure) and one in group B (multiple grade 1 events). Main toxicities included neutropenia, gastro-intestinal disorders, and hepatotoxicity. Progression-free survival at 6 months in group C (n=50) was 6.7%. **Conclusions:** Zotiraciclib exhibits overlapping toxicity with alkylating agents and low clinical activity as a single agent. Larger randomized trials may be required to explore activity in combination with radiotherapy or temozolomide. Clinical trial information: NCT03224104. Research Sponsor: Cothra.

Distinct molecular features and potential therapeutic strategies for spinal cord gliomas. *First Author: Frances Elaine Chow, Department of Neurological Surgery, Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA*

Background: Spinal cord gliomas (SCG) are rare primary CNS tumors with varied prognosis. Standard treatment remains poorly defined, as no clear survival advantage exists with extensive resection, radiation, or chemotherapy. Mounting evidence suggests that tumors from different regions of the CNS harbor unique molecular signatures. In a retrospective study, we comprehensively characterized molecular alterations to identify potential therapeutic strategies in the largest cohort of SCG reported to date. **Methods:** We performed centralized pathology review and analyzed SCG with next-generation sequencing of DNA (592 gene NextSeq or WES, Novaseq), RNA (WTS, NovaSeq) and pyrosequencing (MGMT promoter methylation, MGMTme). We estimated tumor microenvironment cell infiltration by quantiseq & Epithelial-Mesenchymal Transition (EMT) by RNAseq. We used X2/Fisher's-exact/Mann-Whitney U tests for comparison & determined significance ($p < 0.05$), adjusting for multiple comparison by the Benjamini-Hochberg method ($q < 0.05$). **Results:** We analyzed 39 surgically accessible SCG (19 high grade, 17 low grade, 3 NOS); ependymomas were excluded. The most common alterations were mutations in H3F3A (31%), TP53 (25%), ATRX (21%), NF1 (18%) & BRAF fusion (19%). H3F3A mutations occurred exclusively in high grade SCG (63%, $q < 0.05$) while BRAF fusions occurred exclusively in low grade SCG (60%, $p < 0.05$). TP53 mutations were more prevalent in high grade SCG (50% vs. 8%, $p < 0.05$). Compared to intracranial gliomas ($n = 6732$), SCG harbor significantly more frequent H3F3A (31% vs. 1.6%), KRAS mutations (10% vs. 0.7%) & BRAF fusions (19% vs. 0.7%) but less frequent TERT (4.3% vs. 66%) & PTEN (0 vs. 27%) mutations or EGFR amplification (0 vs. 28%) (all $q < 0.05$). SCG rarely harbor the canonical intracranial alterations IDH1 (2.6% vs. 17%), EGFRvIII (0 vs. 17%) or MGMTme (19% vs. 47%) ($p < 0.05$). SCG have greater penetration of immune infiltrates of DCs (median cell fraction/MCF: 13% vs. 9%), T regs (positive percent: 47% vs. 26%) & B cells (MCF: 9% vs. 7%), with less penetration of monocytes (MCF: 0 vs. 2%) ($q < 0.05$). EMT score associates with high grade glioma in intracranial disease ($q < 0.05$) but does not recapitulate in SCG ($p > 0.05$). **Conclusions:** Clinical management of SCG is currently drawn from experience with intracranial gliomas. Our results identify unique molecular features of SCG suggesting an underlying biology distinct from intracranial gliomas. In SCG, H3F3A mutations are exclusive to high grade while BRAF fusions are exclusive to low grade; SCG rarely harbor canonical intracranial alterations such as IDH1, EGFR or MGMTme; and SCG have greater penetration of DCs with less penetration of monocytes. We provide a biological explanation for limited effectiveness of current therapies in SCG with potential implications for chemotherapy, targeted and immunotherapy. Our work underscores the need for investigations dedicated uniquely to SCG. Research Sponsor: U.S. National Institutes of Health.

Prospective phase I study of checkpoint blockade for the treatment of patients with newly diagnosed high-grade glioma prior to radiochemotherapy: Results of nivolumab plus ipilimumab treatment arm. *First Author: Santosh Kesari, Saint John's Cancer Institute at Providence Saint John's Health Center, Santa Monica, CA*

Background: The limited success of checkpoint inhibitors (CPI) targeting the programmed death-1 (PD-1) axis in the adjuvant setting for glioblastoma has prompted a deeper understanding of the brain tumor and immune microenvironment and evaluating how the sequence of immunotherapy administration impacts antitumor response. We initiated a feasibility study (NCT03425292) of postoperative nivolumab (anti-PD-1) monotherapy and combination therapy in adults with newly diagnosed high-grade gliomas (HGG) prior to radiotherapy. **Methods:** Within six weeks from surgical resection of newly diagnosed HGG, patients in study Arm 3 received nivolumab 300 mg every 2 weeks and ipilimumab 1 mg/kg every 6 weeks until disease progression or unacceptable toxicity. The primary endpoint was the rate of dose-limiting toxicities (DLT). Secondary objectives included adverse events, antitumor activity and pharmacodynamic effects of study treatment. Next-generation sequencing (NGS) was performed on archival tumor specimens before treatment and at the time of subsequent surgery. **Results:** Fifteen patients were treated with nivolumab plus ipilimumab. 27% (4/15) of patients were receiving dexamethasone at treatment initiation. MGMT promoter was methylated in 5 tumors, unmethylated in 9, and equivocal in one. The most common treatment-related adverse events (AEs) were rash, pruritus, fatigue, nausea, and anorexia. Grade 3 AEs were lipase increased (n = 2), anorexia (n = 1), pruritus (n = 1), and rash (n = 3), and Grade 4 cerebral edema occurred in 1 patient. Median progression-free survival (mPFS) was 1.3 months and median overall survival (mOS) was 19.3 months. Paired tumor specimens obtained before and after treatment were analyzed in six patients and revealed molecular changes in response to treatment as well as differences between patients with shrinking tumors versus progressing tumors. **Conclusions:** We show that nivolumab plus ipilimumab can be safely administered prior to radiation. To our knowledge, this is the first study in which checkpoint blockade therapy was administered for newly diagnosed glioblastoma prior to standard radiotherapy. Despite the short mPFS, mOS was suggestive of a potential long-term benefit from early CPI exposure, and three patients deferred chemoradiation greater than seven months. Analysis of other study arms is ongoing. Clinical trial information: NCT03425292. Research Sponsor: PHASE ONE – The Road to Curing Cancer; Glen Turner, Jamie Siminoff.

Real-world experience with tumor treating fields (TTFields) in newly diagnosed glioblastoma: A survival meta-analysis with systematic review. *First Author: Matthew T. Ballo, Department of Radiation Oncology, West Cancer Center, Germantown, TN*

Background: Tumor Treating Fields (TTFields) are electric fields that exert forces on cancer cells, disrupting processes critical for cancer cell viability and tumor progression. TTFields therapy became an FDA-approved treatment option for patients with newly diagnosed glioblastoma (GBM) in 2015 on the basis of the randomized controlled EF-14 study (NCT00916409). Subsequent approvals worldwide and increased adoption of TTFields has led to the question of whether or not a consistent survival benefit has been observed in the real-world setting, and whether device usage has played a role. **Methods:** A literature search was conducted using PubMed, Embase, and the Cochrane Library to identify clinical studies evaluating overall survival in adult patients with GBM treated with TTFields therapy. Comparative studies and single-cohort studies reporting on survival outcomes were included in the analysis. Inter-study heterogeneity was assessed using the Cochran Q test and quantified using the Higgins I² statistic. Survival curves were pooled using a distribution-free random-effects method. **Results:** Our review identified 8 studies evaluating the clinical efficacy of TTFields therapy in newly diagnosed GBM, with patients spanning diverse geographic regions. Of these 8, 6 studies (reporting on a total of 1378 patients) compared the addition of TTFields therapy to standard of care (SOC) vs SOC alone, and were included in a pooled analysis for overall survival. Meta-analysis of comparative studies indicated a significant improvement in overall survival for patients treated with TTFields therapy vs those not receiving treatment (hazard ratio [HR]: 0.62; 95% CI, 0.52–0.73; $P < 0.001$). Inter-study heterogeneity was examined, and a sensitivity analysis indicated the pooled effect was robust and not dependent on any individual study. Among post-approval studies, the pooled median overall survival was 22.2 months (95% CI, 17.3–42.6) for TTFields-treated patients and 17.3 months (95% CI, 13.6–22.0) for the non-TTFields group. Rates of gross total resection were generally higher in the real-world setting, irrespective of TTFields use. Furthermore, among studies reporting data on TTFields device usage, an average device usage rate of 75% or higher was found to consistently associate with prolonged survival when compared to an average usage rate below 75% (pooled HR: 0.63; 95% CI, 0.48–0.83; $P = 0.001$). **Conclusions:** Meta-analysis of comparative studies suggests a significant survival benefit with TTFields therapy added to standard radiochemotherapy for patients with newly diagnosed GBM, and that a 75% usage rate may be meaningful in the real-world setting. Lisavanbulin (BAL101553), a novel, oral microtubule destabilizer plus radiation in patients with newly diagnosed, MGMT promoter unmethylated glioblastoma: A phase 1 Adult Brain Tumor Consortium study (ABTC1601). *First Author: Matthias Holdhoff, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: Lisavanbulin (BAL101553, prodrug of BAL27862) is a novel, oral microtubule destabilizer that leads to cell death mediated by modulating the spindle assembly checkpoint. It has promising antitumoral activity in orthotopic glioblastoma (GBM) models in combination with radiation (RT) ± temozolomide (TMZ), including in MGMT promoter unmethylated (uMGMT) tumors. Lisavanbulin is a lipophilic and small molecule (MW 387), and data in rodents showed its ability to cross the blood-brain barrier (brain-plasma ratio 1:1). **Methods:** This multicenter phase 1 study was to determine the MTD of oral Lisavanbulin in combination with standard RT (60 Gy in 30 fractions) in patients with newly diagnosed uMGMT GBM. Dose escalation followed a modified 3+3 design. The safety evaluation period ended 4 weeks after completion of radiation, which was also the end of study. Patients were allowed to continue treatment with standard adjuvant TMZ as per treating physician's recommendation. **Results:** Twenty-six patients with uMGMT GBM (median age 64y, 42.3% male, 61.5% with gross total resection, median KPS 80) were enrolled. Two GBM harbored an IDH1 mutation. Patients were treated at 5 different dose levels of Lisavanbulin administered once daily for 6 weeks concomitantly with RT: Lisavanbulin 4 mg (5 pts), 6 mg (5 pts), 8 mg (7 pts), 12 mg (5 pts), and 15 mg (4 pts). The initial starting dose was 8 mg. Due to Grade 4 aseptic meningoencephalitis in the first patient, the study was held and the dose decreased to 4 mg. Dose escalation resumed and continued to 15 mg with 1 DLT of Grade 2 confusion and memory impairment observed at 12 mg. A planned dose expansion was not conducted due to discontinuation of funding. Grade 3 AEs were hypertension (2), seizure (2), cognitive disturbance (1), cerebral edema (1), hyponatremia (1), and lymphopenia (1); no additional grade 4 AE was observed other than the 1 case of aseptic meningoencephalitis. Median OS was 12.8 months (95%CI: 9.1–18.3 months). At data cut-off, 8 subjects (30.8%) were still alive. 38.5% subjects had no information on disease progression and were censored during the estimation of PFS. The median PFS was 7.7 months (95%CI: 3.0–9.5 months). **Conclusions:** The maximum studied safe dose for Lisavanbulin in combination with RT in newly diagnosed uMGMT GBM was determined at 15 mg daily during radiation. Overall, the safety of this combination was acceptable. Next steps in developing Lisavanbulin in newly diagnosed GBM include safety studies in combination with TMZ and of TMZ+RT in MGMT promoter methylated GBM prior to formally studying efficacy in a prospective randomized trial. Clinical trial information: NCT03250299. Research Sponsor: U.S. National Institutes of Health.

Safety and feasibility of JAK inhibitor ruxolitinib in newly-diagnosed high-grade gliomas (CRUX): Final toxicity report. *First Author: Manmeet Singh Ahluwalia, Miami Cancer Institute, Baptist Health South Florida, Miami, FL*

Background: Dysregulation of the JAK/STAT pathway in newly-diagnosed high-grade gliomas (nHGG) is linked to enhanced survival and proliferation of tumor cells. Ruxolitinib, a small molecule inhibitor of JAK1, JAK2, and JAK3, limits glioma growth in preclinical models. This concept was explored in a phase I trial (NCT03514069), whose final report on toxicity is presented here. **Methods:** This non-randomized prospective study included 60 WHO Grade 3-4 nHGG patients who received standard of care (SOC) therapy along with ruxolitinib in a 3+3 dose-escalation design; level 1 of 10 mg BID, level 2 of 15 mg BID, level 3 of 20 mg BID, level -1 of 5 mg BID. The primary study objective was the determination of the maximum tolerated dose (MTD) of ruxolitinib in combination with chemoradiation. The secondary objective was the determination of safety, overall survival (OS), and progression-free survival (PFS). The exploratory aims were to investigate relationships between clinical outcomes and genomic signatures. **Results:** 60 patients were enrolled, with a median age of 60.5 years (range 22–78). 23 (38%) patients were female and 37 (62%) were male. 29 (48%) were MGMT unmethylated and received ruxolitinib with radiation of 60 Gy over 6 weeks. 31 (52%) patients were MGMT methylated and received ruxolitinib with 75 mg/m² of temozolomide (TMZ) with radiation of 60 Gy over 6 weeks. The 1-year OS rate was 77% for all GBM patients; 62% for arm 1 (unmethylated MGMT) and 93% for arm 2 (methylated MGMT). Median OS for arm 1 was 18.1 months (10.1, NA) and was not reached for arm 2. MTD for both cohorts was 20 mg BID. No dose-limiting toxicities were observed. Toxicities attributable to study medications included four grade 4 AEs including seizure, respiratory distress, somnolence, and thromboembolic event along with 14 grade 3 adverse events (AEs), including respiratory distress, seizure, gait disturbance, weakness, thrombocytopenia, cognitive disturbance, urinary retention, and meningitis. **Conclusions:** Ruxolitinib therapy is safe and feasible in combination with TMZ and radiation. Efficacy of ruxolitinib plus SOC appears promising compared to historical benchmarks for both MGMT methylated and MGMT unmethylated cohorts. A randomized phase 2 trial is planned. Clinical trial information: NCT03514069. Research Sponsor: Cleveland Clinic.

Phase I and pharmacodynamic study of arsenic trioxide plus radiotherapy for newly diagnosed glioblastoma. *First Author: Samuel Ryu, Stony Brook University School of Medicine, Stony Brook, NY*

Background: Arsenic Trioxide (ATO) demonstrated prolonged survival in a transplanted rodent glioblastoma (GBM) model. Given the lack of effective therapies before temozolomide was available, the NCI funded NABTT Brain Tumor Consortium initiated a Phase I study of ATO with radiation in patients with newly diagnosed glioblastoma. Dose escalations using two different schedules of ATO were studied. **Methods:** Patients with newly diagnosed GBM (MGMT and IDH mutation status unknown) were assigned to receive ATO once or twice weekly during the 6-week course of radiation. The starting ATO dose was 0.25 mg/kg. This was escalated by 0.05 mg/kg until an MTD was reached. Patients did not receive ATO or other adjuvant therapy once the radiation was completed. As ATO affected tumor vasculature and blood flow in experimental imaging studies, perfusion MRIs were obtained before ATO administration and one and six weeks later. Survival was a secondary endpoint. **Results:** Thirty-one patients were enrolled: median age 54.9 years, 68% male, 77% patients KPS >90, 77% had tumor resection. The MTD was determined to be 0.4mg/kg on the weekly schedule and 0.3mg/kg on the biweekly schedule. ATO was well tolerated with 81% of patients completing the 6 weeks combined treatment. Major dose limiting toxicities were increased aspartate and alanine aminotransferases and one case of hyperkalemia. For all patients the median overall survival (mOS) was 17.7 months and the median progression-free survival (mPFS) was 5.4 months. However, there was a significant survival difference between the two ATO dose schedules across all doses with a mOS of 22.8 months in the biweekly schedule, vs 12.1 months in the weekly schedule ($P = 0.039$). There was a similar difference in mPFS (10.2 months vs 3.2 months, respectively, $P = 0.004$). Similarly, there were significant differences in perfusion imaging between the two ATO dose schedules with relative cerebral blood flow showing a significant decrease after one week of ATO treatment on the biweekly schedule ($p = 0.007$). **Conclusions:** The MTDs of ATO in patients with GBM administered once or twice weekly for six weeks with standard radiation were determined. This regimen was well tolerated. Survival in patients on the biweekly schedule was much better (22.8 months) than expected in patients not receiving temozolomide. In addition, patients on biweekly ATO also had significant changes on MRI perfusion studies suggesting a pharmacodynamic effect of this agent. These findings should be explored further in patients with newly diagnosed MGMT unmethylated GBM where temozolomide has very limited activity. Clinical trial information: NCT00045565. Research Sponsor: U.S. National Institutes of Health.

Depth of radiographic response (DpR) and time to tumor regrowth (TTG) to predict overall survival following anti-VEGF therapy in recurrent glioblastoma. *First Author: Benjamin M. Ellingson, University of California Los Angeles, Los Angeles, CA*

Background: Anti-angiogenic therapies, anti-VEGF agents, cause high radiographic response rates due to reduction in vascular permeability. However, we theorized the degree of tumor shrinkage combined with the duration of response might be a more meaningful measure of tumor control and may better reflect real patient benefit. In the current study, we investigate the association between model-derived parameters describing enhancing tumor volumetric dynamics and overall survival (OS) in recurrent glioblastoma treated with anti-VEGF therapy from multiple clinical trials. **Methods:** N=134 patients treated with bevacizumab +/- irinotecan (BRAIN Trial; NCT00345163) and N=121 patients treated with cabozantinib (XL184-201; NCT00704288) were used to identify potential imaging biomarkers, and N=63 patients in the bevacizumab control arm in a phase III trial (GLOBE Trial; NCT02511405) were used as a validation dataset. Enhancing tumor volumes were estimated using T1 subtraction maps, and a biexponential model was used to model tumor response (d) and regrowth (g) rates, as well as time to tumor regrowth (TTG), the inflection point where the tumor stops shrinking and starts to regrow, and the depth of response (DpR) after initiation of anti-VEGF therapy for each patient. Log-rank, univariate, and multivariable Cox regression were used to quantify the relationship of these parameters and OS. **Results:** Optimized thresholds based on maximum hazard ratio occurred at $d=0.11$ months⁻¹ ($P=5 \times 10^{-9}$ training; $P=0.0082$ validation); $g=0.07$ months⁻¹ ($P=5 \times 10^{-20}$ training; $P<0.0001$ validation); TTG of 3.8 months ($P=6 \times 10^{-17}$ training; $P<0.0001$ validation); and DpR of 11.3% ($P=0.0026$ training; $P=0.0177$ validation). Univariate and multivariable Cox regression using these thresholds and controlling for age and baseline tumor volume confirmed that d , g , TTG, and DpR were all significant and independent predictors of OS in both phase II training and phase III validation datasets ($P<0.01$). Additionally, patients exhibiting combinations of a high DpR and/or long TTG showed differential median OS, while patients with favorable diffusion MR phenotypes exhibited a longer OS and significantly longer TTG. **Conclusions:** Volumetric response and regrowth rates, TTG, and DpR using a biexponential model are significant and independent predictors of OS in recurrent glioblastoma treated with anti-VEGF therapy. Clinical trial information: NCT00345163; NCT00704288; NCT02511405. Research Sponsor: U.S. National Institutes of Health.

Efficacy of function-enhanced, re-activatable, dual-specific CAR T cells pre-loaded with oncolytic virus for immunotherapy of high-grade glioma. *First Author: Mason Webb, Mayo Clinic, Rochester, MN*

Background: While cancer therapeutics have made tremendous progress within the past several decades, this benefit has not been seen in many primary cancers of the brain. Particularly confounding have been high-grade gliomas (HGG), which retain a dismal prognosis. Currently, novel therapies are being explored to rise to this unmet, critical need. One such therapy are CAR T cells, immune cells which have been engineered to target malignancy-specific antigens. Unfortunately, the efficacy of CAR T cell therapies against solid tumors is significantly limited, in large part due to impaired expansion/persistence in the immune suppressive tumor microenvironment (TME). Here we show that *in vivo* reactivation of CAR T cells through their native T Cell Receptor (TCR) by an oncolytic virus (OV) has therapeutic benefit in HGG. **Methods:** An EGFRvIII third-generation MSGV1 retroviral CAR construct containing the CD28, 4-1BB, and CD3z moieties, in tandem with the scFv derived from the human monoclonal antibody 139 and the marker Thy1.1 (38) was used to generate our CAR T cells. C57Bl/6 mice were used for *in vivo* experiments and both B16- and CT2A-EGFRvIII murine glioma cell lines were injected in the brain to model HGG. OVs and CAR T cells were given systemically by tail vein. OVs used include reovirus, vesicular stomatitis virus, and adenovirus. **Results:** By using OV in combination with EGFRvIII CAR T cells, we were able to generate a CD8 CAR population with TCR specificity for both the EGFRvIII and OV epitopes. These dual-specific (DS) CAR T expressed a memory phenotype and persisted for much longer than conventional CAR T cells. Further, we showed that these DS CAR T cells are more cytotoxic and can respond more rapidly than their conventional counterparts. We created a novel delivery mechanism for this combination OV + CAR T therapy using virus-loaded CAR T cells to bypass initial antiviral clearance from the immune system. Treatment with these OV-loaded CAR T cells lead to significant benefit in mice with HGG tumors which could be further enhanced by a systemic boost with OV, which rapidly re-activated DS CAR T cells against tumor and resulted in long-term cures of greater than 80% of treated animals. **Conclusions:** These promising results show that DS CAR T cells can overcome the critical therapeutic challenge of CAR T as a treatment for solid tumors. Given these promising results, we will go on to develop a clinical trial in which CAR T cells will be pre-loaded with OV and administered intravenously to patients with HGG, followed by systemic boosting with virus to re-activate DS CAR T cells against their tumor. Ultrasensitive detection and monitoring of central nervous system tumors from plasma using personalized whole-genome ctDNA profiling. *First Author: Ivy Tran, NYU Langone Health, New York, NY*

Background: Patients with the central nervous system (CNS) tumors are largely followed up by imaging. Current plasma-based liquid biopsy techniques have limited utility in neuro-oncology due to a low circulating cell-free tumor DNA (ctDNA) burden, blood-brain barrier, and low number of mutations in coding regions. Whole genome sequencing (WGS)-derived patient specific mutational signature from a matched tumor-normal WGS can provide a personalized, highly sensitive and specific approach to detect mutations in ctDNA and provide blood-based monitoring in brain tumor patients. Furthermore, it can be performed on lower amount of peripheral blood since WGS requires less sequencing depth compared to targeted ctDNA panels. **Methods:** We have profiled a cohort of 28 extra- and intra-axial adult and pediatric brain tumors including adult and pediatric low- and high-grade glioma (9), meningiomas (11), medulloblastomas (5), ependymomas (2), neurocytoma (1). Tumor DNA was extracted from archival pathology tissue, normal DNA from unsorted white blood cells, and ctDNA from 1-2 mL of post-surgery plasma. WGS was performed with 40x coverage for Tumor-Normal DNA and 20x for ctDNA. Using WGS of matched Tumor-Normal and plasma samples, we derived a personalized mutational pattern using SNVs, indels, and copy numbers for quantification and ultrasensitive detection of ctDNA in plasma samples. An AI-based error suppression model was implemented to filter out the noise in the cell-free DNA (cfDNA) while the personalized mutational signature was used to detect the ctDNA in the cfDNA and to amplify the somatic signal to determine the Tumor Fraction at the time of diagnosis, during the therapy or surveillance period. The ctDNA Tumor Fraction (TF) was compared to the clinical status and MRI-based imaging. **Results:** All subtypes of brain tumors contained enough mutations to derive personalized mutational signatures. Most mutations were distributed in the noncoding DNA. TF correlated with clinical status and with the disease course on imaging at given time points reaching a 10^{-4} minimal residual disease detection sensitivity. We were able to detect ctDNA across all WHO grades ranging from WHO 1 meningioma to WHO 4 glioblastoma and medulloblastoma. Furthermore, we were able to detect tumor-specific copy number aberrations such as MYCN amplification in plasma samples and mutational signatures. **Conclusions:** Here we demonstrate that patient-specific WGS tumor signature in ctDNA from plasma can be used for sensitive monitoring of adults and children with primary low- and high-grade CNS tumors. Immune checkpoint inhibitor (ICI) therapy in glioblastoma: Institutional experience at the Massachusetts General Hospital (MGH). *First Author: John Yohan Rhee, Massachusetts General Hospital, Boston, MA*

Background: Immune checkpoint inhibitors (ICI) have resulted in promising outcomes in systemic cancer but response in glioblastoma (GBM) has not met early expectations based on early clinical trial results. Conflicting data exists regarding the incidence of pseudoprogression after ICI in brain tumors. Here, we present our institutional experience of the radiographic response following ICI therapy in GBM both at initial diagnosis and recurrence. **Methods:** We retrospectively identified IDH-wildtype GBM (per 2021 WHO criteria) patients treated either at time of initial diagnosis or at recurrence with nivolumab, pembrolizumab, or durvalumab between 2015 and 2022 at MGH. Overall radiographic and clinical responses after initiation of ICI were assessed in both groups. **Results:** 56 pts (18 female, 38 male) were identified (average age 58.6). Eight (14.3%) patients had ICI-related non-hematological toxicities, including granulomatous folliculitis, arthritis and myositis, headache, acneiform rash, transaminitis, and gastritis). Four (7.1%) of the eight patients had to discontinue treatment due to ICI-related severe toxicity (hepatitis and/or gastritis) and were not included in the final response assessment. Of the remaining 52 patients, none had evidence of pseudoprogression related to ICI. We did not identify any complete response (CR) or partial response (PR) secondary to ICI monotherapy. In the 13 patients treated at initial diagnosis, the following radiographic responses were seen: CR=0, PR=0, stable disease (SD)=5 (38.5%), and progressive disease (PD)=8 (61.5%). In the 39 patients treated at disease recurrence, the responses were: CR=0, PR=4 (10.3%), SD=10 (33.3%), PD= 22 (56.4%). Noteworthy, all patients with PR were concurrently treated with bevacizumab. **Conclusions:** 0/52 patients showed radiographic response after ICI monotherapy. While treatment was overall tolerated, ICI therapy was discontinued due to toxicity in 7% of patients. Pseudoprogression attributable to ICI was not seen in any of the patients treated. Phase I study of BTK inhibitor ibrutinib with temozolomide and radiation in newly-diagnosed glioblastoma (EQUILIBRIUM): Final trial report. *First Author: Manmeet Singh Ahluwalia, Miami Cancer Institute, Baptist Health South Florida, Miami, FL*

Background: Novel therapeutic strategies are urgently needed in newly-diagnosed glioblastoma (GBM). Ibrutinib, an oral small molecule inhibitor of BTK, is currently being investigated for several B-cell malignancies and solid tumors. Preclinical evidence suggests ibrutinib in inhibiting cancer stem cell in glioblastoma. We sought to investigate the safety and tolerability of ibrutinib in nGBM. **Methods:** A non-randomized, prospective phase I trial was conducted in nGBM patients with Karnofsky performance status $\geq 70\%$ and normal organ function, who received standard of care chemoradiation plus ibrutinib in a 3+3 dose-escalation design (level 1: 420 mg daily, level 2: 560 mg daily, level -1: 280 mg daily). Primary study objective was to determine maximum tolerated dose (MTD) of ibrutinib in combination with radiotherapy (RT) of 60 Gy over 6 weeks with/without 75 mg/m² of temozolomide (TMZ). Secondary objective was to determine safety, overall survival (OS), and progression-free survival. **Results:** 26 patients were enrolled, with 12 (46%) females. Median age was 61.5 years (range 76-22). 15 (58%) patients were MGMT methylated and 11 (42%) were unmethylated. Dose-limiting toxicities (DLTs) were observed at all dose levels of ibrutinib plus RT (ibru+RT) cohort. MTD of ibrutinib was noted to be 420 mg daily with RT+TMZ. All MGMT methylated and 2 unmethylated patients received ibrutinib+RT+TMZ. Remaining 9 unmethylated received ibru+RT. In ibru+RT+TMZ, median cycles of TMZ were 4 (range 0-6) and of ibrutinib were 3 (range 0-26). EGFR amplification status was available for 22 patients, of which 8 (36%) were amplified. Survival outcomes are described, stratified using log-rank test. **Conclusions:** 420 mg of ibrutinib daily is safe and feasible in combination with TMZ and radiation in nGBM. Outcomes of ibrutinib appears promising compared to historical survival data in the MGMT methylated cohorts. Further trials are planned. Clinical trial information: NCT03535350. Research Sponsor: None.

Group	N	Median OS, [months (95%CI)]	1-year OS, [% (95%CI)]	2-year OS [% (95%CI)]	3-year OS, [% (95%CI)]
Overall	26	21.9 (18.8-NA)	80 (66-97)	42 (26-70)	0.19 (7-50)
MGMT Methylated	15	26.0 (22.0-NA)	100 (100-100)	56 (34-95)	35 (15-82)
MGMT Unmethylated	11	14.0 (8.54-NA)	51 (28-94)	2 (6-70)	NA
Received ibrutinib+RT+TMZ	17	26.0 (21.8-NA)	100 (100-100)	52 (31-90)	33 (14-77)

Vulnerability to immune therapy in BRAF- and MYB-altered pediatric gliomas. *First Author: Michael DeCuyper, Ann and Robert H Lurie Children's Hospital, Chicago, IL*

Background: The frequency and expression of predictive immune biomarkers in pediatric gliomas is relatively unknown. Here, we sought to define predictive signatures of immunotherapy responders by examining immune checkpoint expression, immune cell population signatures, and gene amplifications in a variety of pediatric gliomas. **Methods:** We profiled a cohort of pediatric, adolescent, and young adult glioma samples submitted to Caris Life Sciences (Phoenix, AZ) for analysis (N = 207). The cohort was further stratified by driver mutations: IDH mutant (N = 103), H3-3A mutant (N = 36), MYB-altered (N = 4), BRAF-altered (N = 39), and IDH wild type (IDH WT) (N = 25). De-identified next generation DNA sequencing (592-gene or whole exome) and RNA (whole transcriptome) sequencing were used to determine tumor-infiltrating immune cell signatures and immune checkpoint protein expression. Transcriptomic signatures predictive of response to immunotherapy (T cell inflamed score) and replication stress response defect (RSRD) score were calculated on transcripts per million (TPM) values. Immune cell fractions were estimated using RNA deconvolution (quanTIseq). **Results:** BRAF-altered tumors showed the highest IFN gamma signature (a clinically relevant inflammatory biomarker), a high pro-inflammatory M1 macrophage signature, and very high CD4+/CD8+ T cell signatures compared to other tumor groups. IDH mutant, but not WT gliomas, were relatively deficient in T cell infiltration but revealed an increase in dendritic cell signatures. IDH WT gliomas showed more T cell enrichment but higher immune suppressive checkpoint expression. H3-3A mutant tumors showed relatively low immune cell infiltration and immune checkpoint expression. Pro-inflammatory M1 macrophages were lower in the high-grade glioma microenvironment compared to low-grade. Immune suppressive M2 macrophages were elevated in the IDH WT microenvironment relative to other gliomas. There was no apparent difference in the frequency of PD-1+ T cells and tumor-expressed PD-L1 among the various molecularly defined pediatric glioma groups. **Conclusions:** In general, BRAF- and MYB-altered gliomas displayed high immune activation relative to other tumors. IDH WT tumors have an immune suppressive microenvironment with relatively high immune checkpoint expression. Based on predictive markers, BRAF- and MYB-driven gliomas show signatures suggesting the possibility of a greater response to immunotherapies than IDH WT/mutant gliomas or H3-3A gliomas. Interrogating drug action and immune response in organotypic glioma microenvironment. *First Author: Jiyong Liang, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The glioma tumor microenvironment is characteristic of a high level of heterogeneity and a profoundly immune suppressive phenotype as driven by the presence of glioma stem cells and abundant innate immune cells of the myeloid lineages, rendering glioblastomas (GBM) recalcitrant to conventional treatments and immunotherapies. To address the full complexity of the brain tumor with its diverse components, we have developed an organotypic slice culture system to overcome several limitations of the other preclinical models and allow interrogation of drug action and immunomodulatory agents in human GBM *ex vivo*. **Methods:** We performed extensive characterization of the organotypic glioma slice system and optimization of the *ex vivo* tissue culture conditions, and determined the longitudinal dynamics of slice cell viability, relative tumor versus immune cellularity, and responses to a selection of therapeutic agents and cytokines by multiplexed flow cytometry and single cell transcriptome (scRNA seq) profiling. **Results:** Single cell transcriptomic analysis showed that both tumor and immune cell heterogeneity were preserved *ex vivo* for the two-week observation time, which exhibited tumor-type specific gene expression profiles suggesting cooperative interactions among cell populations. Consistent with the findings in fresh tumor specimens and an immune suppressive microenvironment, we found a scarcity of T lymphocytes in IDH mutant gliomas, whereas abundant T cells were found in recurrent GBM slices that persisted *ex vivo*. Additional analyses revealed that T cell infiltration in GBM was associated with the mesenchymal-like molecular phenotype, which exhibited remarkable intratumor heterogeneity highlighting the presence of stem-like cells and a unique cell population expressing aberrant cancer genes and antigen presenting molecules. We further found that T cells in organotypic GBM slices acquired a potent effector phenotype in response to cytokine-induced reprogramming of microglia and tumor-associated macrophages. In addition, scRNA seq also revealed a population of cancer-associated fibroblast-like cells that are present in all tumors sequenced, which may function to mediate the interactions between immune and tumor cells as our data suggested. **Conclusions:** We demonstrated that the organotypic slice culture system we developed is compatible with genomic, pharmacological, and immunotherapeutic manipulations and provided data showing that organotypic slice culture preserves glioma microenvironment *ex vivo* allowing acquisition of crucial information of response of heterogeneous patient tumor tissue to the agent tested. This method represents a unique mechanism by which therapy development can be facilitated in an *ex vivo* setting. Research Sponsor: MD Anderson MoonShot Program.

A phase 0/2 trigger trial of niraparib in patients with newly diagnosed glioblastoma. *First Author: Shweta Mehta, Ivy Brain Tumor Center, Phoenix, AZ*

Background: Poly (ADP-ribose) polymerase (PARP) mediates DNA damage response; niraparib is an investigational PARP1/2-selective inhibitor. This Phase 0 study evaluates newly-diagnosed glioblastoma (GBM) tumor pharmacokinetics (PK) and pharmacodynamics (PD), graduating patients with O6-methylguanine methyltransferase (MGMT) unmethylated tumors into a therapeutic regimen of niraparib plus fractionated radiotherapy when high unbound drug concentrations are present in gadolinium-enhancing tumor. **Methods:** Patients with presumed newly-diagnosed GBM were enrolled in a phase 0 study receiving 4 days of niraparib (300/200 mg QD) prior to planned resection 3-5 or 8-12 hours following the last dose. Tumor tissue (enhancing and non-enhancing regions), cerebrospinal fluid (CSF), and plasma were collected. Total and unbound niraparib concentrations were measured using validated LC-MS/MS methods. PARP inhibition was assessed by quantification of PAR induction after 10 Gy ex vivo irradiation in surgical tissue compared to non-irradiated control tissue. A PK 'trigger' determined eligibility for the therapeutic expansion phase and was defined as unbound [niraparib] > 5-fold biochemical IC50 (i.e., 19 nM) in non-enhancing tumor. Patients with MGMT unmethylated tumors exceeding this PK threshold were eligible for expansion phase dosing of niraparib plus radiotherapy followed by a maintenance phase of niraparib. **Results:** All patients (n=35) enrolled in the phase 0 portion of the study met the PK threshold. In non-enhancing tumor regions, the mean unbound concentration of niraparib was 253.2 nM in 32 evaluable GBM patients. The suppression of PAR levels after ex vivo radiation was observed in 75% of the patients (18/24). Eleven out of 18 patients with unmethylated tumors enrolled in phase 2. Five of the 6 initial patients enrolled in phase 2 experienced thrombocytopenia related to niraparib, and 3/5 cases were deemed serious and life-threatening. Consequently, starting dose in both phases was lowered to 200 mg, and no serious AEs were observed thereafter. At a median follow-up of 8.1 months [range: 6.0-12.9 months], PFS6 was 64% (n=11) with 4 patients remaining on treatment and 5 patients ongoing survival follow-up. **Conclusions:** Niraparib achieves pharmacologically-relevant concentrations in non-enhancing, newly-diagnosed GBM tissue in excess of any other studied PARP inhibitor. Clinical trial information: NCT05076513. Research Sponsor: The Ben and Catherine Ivy Foundation; Barrow Neurological Foundation.

Intra-operative desorption-electrospray ionization mass-spectrometry for real-time diagnosis, margin assessment, and maximization of brain cancer resection. *First Author: Diogo Garcia, Mayo Clinic Florida, Jacksonville, FL*

Background: Despite advances in our understanding of brain cancer, the ability to discern between infiltrated and non-infiltrated tissue with current adjuncts, remains elusive. Isocitrate dehydrogenase (IDH) mutation is unique to IDH-mut glioma cells and can be used as a surrogate for tumor infiltration. Further, emerging evidence has shown unique signatures in brain cancer lipidomic profiling, with lipid metabolism playing a key role in brain cancer biology. Here, we aimed to evaluate the impact of desorption electrospray ionization-mass spectrometry (DESI-MS) as a near real-time method to determine infiltration status and the use of DESI-MS to perform intra-operative histological diagnosis. **Methods:** This is a prospective multi-institution cohort study using intra-operative DESI-MS on freshly obtained tumor samples to evaluate 2-hydroxyglutarate (2HG), with post-hoc validation by review by a board-certified neuropathologist. For tumor cell estimation and tissue diagnosis, high-throughput DESI-MS was used for rapid analysis of high-density arrays using lipidomic profiling. Analysis of the data was performed using a pre-written algorithm employing a combination of Python- and MATLAB-based custom software allowing results in less than a second per sample. **Results:** A total of 496 tumor biopsies from 72 patients have been analyzed. Earlier iterations focused on absolute quantitation of 2HG in 247 biopsies from 49 patients to determine IDH genotype yielding sensitivity, specificity, and accuracy values of 89, 100, and 94% for core biopsies (71). Improvement in accuracy was obtained with relative measurement of 2HG in comparison to glutamate allowing for detection of IDH-mut infiltration at the margin, resulting in 93% sensitivity, 100% specificity, and 98% accuracy with turnover times averaging 3 minutes in 183 biopsies from 23 patients. Margin assessment beyond the limits of neuro-navigation and surgeon assessment showed tumor infiltration in 88% of margin biopsies from IDH mutant tumors (30 of 34 biopsies) with 100% accuracy. Intra-operative tissue diagnosis was pursued in 66 unique tumor samples using DESI-MS lipidomic profiling, including samples of normal brain parenchyma, gliomas, meningiomas and pituitary adenomas, split into two microarray sets (36 and 40 samples). Using estimated principal components as input features, high accuracy (> 90%; ROC AUCs $\geq$ 0.89) was obtained for supervised tissue classification using simple machine learning algorithms. **Conclusions:** We present a novel system for intra-operative evaluation of tumor infiltration at the margin in gliomas and for intra-operative tissue diagnosis of brain cancer. Our method identified tumor infiltration beyond the surgical margins and serves as a foundation for future uses employing DESI-MS to allow for molecularly guided surgery in IDH-mut gliomas. Investigation of leptomeningeal disease in high grade glioma and characterization of molecular alterations. *First Author: Madison L. Shoaf, Emory University, Atlanta, GA*

Background: Leptomeningeal disease (LMD) is a challenging complication of high grade glioma (HGG) and questions remain regarding risk factors, molecular associations, and optimal treatment. Here we report updated results on a larger cohort from our previously reported multicenter study (Shoaf 2022, Neuro-Oncology). **Methods:** Patients with molecularly-profiled HGG (Caris Life Sciences; Phoenix, AZ) with LMD at 3 institutions were included. NextGen Sequencing of DNA (592 gene or whole exome) and RNA (whole transcriptome) were tested. Medical records were reviewed for clinicopathologic characteristics and outcome. Kaplan-Meier estimates of survival were performed using Cox's proportional hazard model. Mann-Whitney U or Chi-square tests were applied for molecular comparison as appropriate and adjusted for multiple comparisons. **Results:** Seventy-two patients (female: 20, male: 52; median age: 54.5y) were identified, comprising 65 grade 4 tumors (glioblastoma [GBM]: 62; gliosarcoma: 2; H3K27M diffuse midline glioma: 1), 5 grade 3 tumors (astrocytoma: 4; pleomorphic xanthoastrocytoma: 1), and 1 astrocytoma NOS. LMD diagnosed at glioma diagnosis (n=23) vs. recurrence (n=44) was associated with longer post-LMD survival [pLMD-OS: 16.9m vs. 5.5m, p<0.0001] but similar overall survival [mOS: 16.9m vs. 20.9m; p=0.36]. Pathology-diagnosed LMD (n=15) vs. MRI-diagnosed LMD (n=54) was associated with longer post-LMD survival [pLMD-OS: 15.2m vs. 6.2m, p=0.0002] but similar overall survival [mOS: 16.9m vs. 20.9m; p=0.72]. Post-LMD survival [pLMD-OS: 8.7m vs. 6.8m, p=0.33] and overall survival [mOS: 21.1m vs. 20.9m, p=0.20] were similar for supratentorial (n=45) vs. infratentorial/spinal (n=10) locations, and post-LMD survival did not significantly differ for symptomatic (n=40) vs. asymptomatic (n=22) patients [pLMD-OS: 6.6m vs. 10.5m, p=0.13]. pTERT mutation (73%), MGMT methylation (38%), EGFR amplification (31%), and PTEN mutation (28%) were the most prevalent molecular alterations in this group. Comparison of grade 4 LMD tumors with an independent GBM cohort (n=5431) suggested a male predominance (73.4% vs. 58.5%, p=0.016) and a trend towards more frequent mutations in RB1 (25% vs. 9.2%, p=0.002) and MDM4 (12.7% vs. 4.3%, p=0.01) and amplification of WIF1 (6.1% vs. 0.3%, p=0.006), CHIC2 (17.0% vs. 5.2%, p=0.002), and LGR5 (5.9% vs. 0.4%, p=0.012). The expression of immune checkpoint-related genes was similar, although a trend towards immunologically "colder" tumors in the LMD cohort was observed. However, these effects were not significant after correcting for multiple comparisons. **Conclusions:** LMD is more common in male patients and may be associated with various genomic alterations and tumor microenvironment differences. Overall survival does not differ from patients without LMD, but these differences may provide clues to the pathogenesis and treatment resistance of GBM. Research Sponsor: None.

Intraoperative glioma characterization using time-resolved fluorescence spectroscopy. *First Author: Simon Menaker, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Extent of surgical resection significantly improves progression-free and overall survival in glioma patients. Due to the infiltrative nature of gliomas, tumor margin detection is often difficult, and current intraoperative visualization methods are limited. Time-resolved fluorescence spectroscopy (TRFS) has the potential of differentiating glioma from normal brain tissue, thereby maximizing extent and safety of resection. **Methods:** Twenty-seven preoperative patients diagnosed with glioma met inclusion criteria for an IRB-approved study aimed to assess the accuracy of TRFS relative to tissue histopathology for differentiating glioma from normal cortex (NC), normal white matter (NWM), and white matter with edema (WME). A multi-channel TRFS system was developed for in vivo brain tissue and tumor characterization during glioma surgery. A custom-designed fiber optic probe was used to deliver ultrafast laser pulses to tissue regions of interest and collect fluorescence signals, with simultaneous registration to intraoperative neuronavigation. The fluorescence light was collected using a photomultiplier tube and digitized across six wavelength bands. Biopsies were taken at each measurement site for evaluation by a blinded neuropathologist to determine the accuracy of TRFS, which was calculated using parameters derived from the recorded fluorescence pulse and used to characterize tissue signatures. **Results:** During surgical resection of 27 patients, 162TRFS measurements were collected in vivo followed by biopsy of the same tissue. Samples from brain tumors (39 low grade gliomas (LGG, WHO grade I to III), 35 high grade gliomas (HGG, WHO grade IV)) were compared with 47 samples of normal brain tissue (NC and NWM). The time-resolved system was able to differentiate LGG from normal tissue with 97% sensitivity and 93% specificity (93% PPV and 98% NPV). When all tumor grades were tested, the sensitivity dropped to 91% (96% PPV and 86% NPV), which we believe reflects the heterogeneity of HGG. HGG alone showed a sensitivity of 83% and specificity of 93% (91% PPV and 88% NPV). Normal cortex had the fastest decays across all wavelength bands among different tissue types, WME had longer decays compared to other tissue types at all wavelengths, and HGG had a variable but predictably different fluorescence decay pattern. **Conclusions:** TRFS is an intraoperative tool that can distinguish glioma from normal brain tissue and has the potential to maximize safe surgical resection. Research Sponsor: Cedars-Sinai Medical Center.

Detection of methylation-based prognostic signatures in liquid biopsy specimens from patients with meningiomas. *First Author: Grayson Herrgott, Henry Ford Health, Detroit, MI*

Background: Detection of distinct epigenetic biomarkers in circulating cell-free DNA (cfDNA) of liquid biopsy (LB) specimens (e.g. blood) fosters opportunity for prognostication of central nervous system (CNS) tumors and has not been thoroughly explored in patients with meningiomas. **Methods:** We profiled the cfDNA methylome (EPIC array) in serum from patients with meningiomas (MNG; n = 93) and harnessed internal and external meningioma tissue methylome data with reported follow up (n = 77). To predict recurrence risk (RR), we consolidated a tissue cohort with at least 5 years of follow up and divided them into confirmed recurrence (CR; either reported progressive disease in post-surgical imaging, or additional resections following initial surgery) and confirmed no-recurrence (CNR: no confirmed disease progression w/in at least 5-years of follow-up). Then through application of an iterative process consisting of multiple tissue- and serum-based supervised analyses, we identified risk-specific methylation markers with potential for serum application. which, when inputted into a random forest algorithm allowed for segregation of both tumor tissue and liquid biopsy specimens according to recurrence risk. We estimated immune cell composition using MethylCIBERSORT, where a reference methylome atlas of chosen immune cell types was utilized to deconvolute the MNG samples. **Results:** The resulting recurrence risk classifier demonstrated an appreciable predictive power in classifying samples as high or low recurrence risk across the tumor tissue cohort (ACC: 87.7%, CUI+: 86.4%). When compared to another classifier of rivaling purpose, our model demonstrated statistically significant agreement across primary meningioma samples ($\kappa = 0.269$, $p = 0.01$), and more accurately predicted samples to recur across expanded time windows (time to recurrence > 5 yrs). Across resulting liquid biopsy classifications, recurrence risk subgroups were analogous with reported risk factors, including WHO grade, extent of resection, and tumor location. Recurrence risk subgroups also demonstrated differential estimated immune cell contributions, with low-risk samples exhibiting a "hot" profile, or enrichment of B-Cells, CD56- and CD4 T-Cells, and natural killer cells. Notably, the estimated neutrophil to lymphocyte ratio, previously purported to be relevant to tumor prognosis, was appreciably higher for those meningioma samples with the highest recurrence risk. **Conclusions:** DNA methylation markers identified in the serum are suitable for the development of machine learning-based models which present high predictive power to prognosticate patients with meningioma and estimate a differential immune profile across recurrence risk groups. After validation in an external cohort, this noninvasive approach may improve the presurgical therapeutic management of patients with meningiomas. Research Sponsor: Hermelin Brain Tumor Center.

3D volume growth rate evaluation in the EORTC-BTG-1320 clinical trial for recurrent WHO grade 2 and 3 meningiomas. *First Author: Emeline Tabouret, Aix-Marseille Univ, APHM, CNRS, INP, Inst Neurophysiopathol, CHU Timone, Service de Neurooncologie, Marseille, France*

Background: We previously reported that tumor 3D volume growth rate (3DVGR) classification could help in the assessment of drug activity in patients with meningioma (Graillon *et al.* 2021). This classification segregates meningioma response into three main classes and a total of five subclasses (class 1 = volume decrease $\geq 25\%$; 2A = tumor stabilization; 2B = 3DVGR severe slowdown; 3A and 3B = respective low and quick progression) based on the 3DVGR before and under treatment. The EORTC-BTG-1320 clinical trial was a randomized phase II trial evaluating the use of trabectedin for recurrent WHO 2 or 3 meningioma (Preusser *et al.* 2022). Objective: To evaluate the discriminative value of 3DVGR classification for response and clinical benefit prediction in the EORTC-BTG-1320 clinical trial. **Methods:** All patients with at least one available additional MRI before inclusion were included. 3D volume was evaluated on all consecutive MRI until progression. 3DVGR classification was applied on them as previously described. Clinical benefit was defined as neurological and/or functional status improvement and/or steroid decrease or discontinuation. **Results:** 17 patients were included in this post-hoc analysis with a median age of 58 years (range, 38-73). Treatments were trabectedin, bevacizumab, hydroxyurea or palliative care in 9, 3, 2 and 3 patients respectively. At first evaluation, 3DVGR classes were 1, 2A, 2B, 3A, 3B and not evaluable in 8%, 15%, 8%, 23%, 38% and 8%, respectively. Best 3DVGR classification was 1, 2A, 3A, 3B and not evaluable in 15%, 31%, 15%, 31% and 8%, respectively. 3DVGR did not differ by methylation subgroups and NF2 or CDKN2A alterations. All patients with progression-free survival longer than 6 months presented with best 3DVGR class 1 or 2. In contrast, all patients with PFS shorter than 6 months presented with best 3DVGR class 3 or not evaluable due to early progression. Median overall survival was 34.7 months for the entire cohort. 3DVGR classes 1 and 2 (combined) had a median overall survival of 34.7 months *versus* 7.2 months for class 3. Best objective response according to modified Macdonald response criteria were stable disease, progression or undetermined in 8, 6 and 3 patients respectively. Regarding the 8 stable patients, they were segregated into classes 1, 2, 3 or undetermined by the 3DVGR classification in 2, 4, 1 and 1 patients, respectively. Finally, all class 1 patients, 75% of class 2 patients and only 17% of class 3 patients presented with clinical benefit (neurological and/or functional status improvement and/or steroid decrease or discontinuation), respectively. **Conclusions:** Tumor 3DVGR classification may be helpful to discriminate early signal of treatment activity in an independent randomized phase II clinical trial. Clinical trial information: NCT02234050. Research Sponsor: PharmaMar, S.A.

FOXC1 expression in meningiomas. *First Author: Michelle Wedemeyer, Nationwide Children's Hospital, Columbus, OH*

Background: Meningiomas account for nearly 1/3 of brain tumors and are characterized by a low mutational burden and dysregulation of DNA methylation. The promoter of FOXC1 is hypomethylated relative to dura in meningiomas of all grades and knockdown of FOXC1 in murine models causes craniofacial hypoplasia and absent frontal dura, suggesting a role as a meningeal identity gene. Here we perform a multi-omic analysis of FOXC1 expression in a large cohort of meningiomas. **Methods:** A total of 555 meningiomas (148 grade I, 255 grade II and 87 grade III) were analyzed with next-generation DNA sequencing (592 gene NextSeq panel; n=150 or Agilent WES whole exome sequencing, n=405) and whole mRNA (WTS, NovaSeq, 555) at Caris Life Sciences (Phoenix, AZ). Top quartile transcripts per million (TPM) for FOXC1 expression were considered high (FOXC1-H) and bottom quartile low (FOXC1-L). Immune cell infiltration was estimated using RNA deconvolution by QuantiSeq to calculate median cell fractions (MCF) or positive percentages (PP). Data were analyzed using X2/Fisher's-exact/Mann-Whitney U tests. A p-value < 0.05 after BH correction was considered significant. **Results:** Median FOXC1 expression was 33 TPM. Expression of FOXC1 transcript was higher in lower grade tumors (I: 34, II: 29, III: 27, $q < 0.05$). NF2 mutations were significantly more common in FOXC1-L than FOXC1-H tumors (45% vs. 68%, $q < 0.05$). Although a higher percentage of FOXC1-H meningiomas harbored TERT promoter mutations (2% vs. 9%, $p < 0.05$) and a higher percentage of FOXC1-L meningiomas harbored a TRAF7 mutation (19% vs. 5.5%, $p < 0.05$), these differences were not significant after correction for multiple comparisons. Programmed cell death ligand1 (PD-L1/CD274, 2.27 vs. 492) and MHC-I (HLA-A: 58 vs. 109, HLA-B: 59 vs. 74, and HLA-C: 61 vs. 101) transcripts were more highly expressed in FOXC1-H than FOXC1-L tumors. FOXC1-L tumors exhibited significantly more B cells (MCF: 5% vs. 4%), M1 Macrophages (MCF: 2% vs. 1%), CD8+ T cells (PP: 27% vs. 7%), and a higher interferon gamma transcript signature than FOXC1-H. Infiltrates of NK cells (MCF: 3.5% vs. 4.3%) and dendritic cells (MCF: 6% vs. 8%) were higher in FOXC1-H (all $q < 0.05$). **Conclusions:** The craniofacial patterning transcription factor FOXC1 was found to be widely expressed in a large cohort of meningiomas and its expression is inversely correlated with WHO tumor grade. Multi-omic analysis reveals a significant relationship between FOXC1 transcript levels and key markers of the immune environment including PD-L1 transcript expression. These data suggest that FOXC1 is a marker of meningiomas in addition to its role as a meningeal identity marker during development. Functional studies are warranted to determine whether FOXC1 is necessary for meningioma growth, whether FOXC1 plays a direct immunomodulatory role in meningiomas, and whether the lower FOXC1 expression levels in high grade tumors represent a more embryonic phenotype. The ketogenic diet plus standard of care for adults with recently diagnosed glioblastoma: Results from a phase 1 trial. *First Author: Lj Amaral, Cedars-Sinai, Los Angeles, CA*

Background: Facing limited treatment options, brain tumor patients are often highly motivated to use complementary therapies, including diet, to help themselves. There is now an abundance of preclinical evidence suggesting possible benefit with a ketogenic diet (KD) for brain tumor patients, but clinical evidence is still limited. Thus, we conducted a single-arm, phase 1 safety and feasibility trial of a KD among patients with recently diagnosed glioblastoma (GBM) during standard-of-care (SOC) treatment. **Methods:** Adults with GBM within 3 months of diagnosis followed a supervised 16-week diet intervention of a standard 3:1 KD (Fat(g):Carbohydrate+Protein(g)) plus SOC chemoradiation. Primary outcome was safety, evaluated by weekly assessments of weight and body mass index (BMI). Secondary outcomes included feasibility (pre-specified as > 50% of patients maintaining blood ketone levels > 0.3 mM over 50% of study days), progression-free survival (PFS), overall survival (OS), health-related quality-of-life (QOL), and cognitive function. Twice daily blood glucose and ketone levels, weight/BMI, physical activity, and sleep were assessed by remote monitoring. **Results:** Seventeen patients were evaluable: 53% women, median age 55, median Karnofsky Performance Status 85. All participants met the primary safety objective with no instances of excessive weight loss or related serious adverse events. Adherence to KD was high: all 17 patients maintained nutritional ketosis (≥ 0.3 mM/dL) > 50% of study days, where 14 patients maintained nutritional ketosis > 85% of study days. Median time to ketosis from diet initiation was 3 days. Diet-related AEs were mild and manageable; no patients came off study due to inability to tolerate KD. Median progression-free survival (PFS) and overall survival (OS) were 12.5 months and 28.6 months from KD initiation respectively. QOL, symptom control, and cognitive function remained stable or improved, although these did not reach statistical significance. **Conclusions:** This phase 1 trial demonstrates that KD is safe and feasible for GBM patients receiving SOC, may improve outcomes, and provides a foundation for future randomized trials to assess efficacy. Clinical trial information: NCT03451799. Research Sponsor: Cedars Sinai.

Osmotic blood-brain barrier disruption with mannitol followed by methotrexate, rituximab, and carboplatin in treating patients with newly diagnosed primary central nervous system lymphoma. *First Author: Prakash Ambady, Providence Brain and Spine Institute, Portland, OR*

Background: Osmotic blood-brain barrier disruption (BBBD) uses intra-arterial (IA) mannitol to open the neuro-vascular unit to enhance delivery of therapeutic agents to the brain. We report the results of a multi-institutional, single arm, phase 2 study evaluating the efficacy and safety of BBBD-enhanced chemotherapy in combination with immunotherapy in patients with newly diagnosed primary central nervous system lymphoma (PCNSL). PCNSL is a rare non-Hodgkin's lymphoma that is limited to the brain, cerebrospinal fluid, spinal cord and/or the vitreoretinal compartment. **Methods:** Non-immunocompromised subjects with newly diagnosed PCNSL received rituximab IV over 5 hours on day 1. On days 2 and 3, under general anesthesia in the angiography suite, subjects received IA mannitol immediately followed by IA methotrexate over 10 minutes, and then IA carboplatin over 10 minutes. Subjects received sodium thiosulfate IV for hearing protection at 4 and 8 hours after each carboplatin dose. Treatment was repeated every month for up to 12 courses in the absence of disease progression or unacceptable toxicity. Per institutional recommendations, further accrual was terminated during the COVID-19 pandemic. Contrast MRI was used for response assessment based on IPCG criteria. **Results:** Twenty subjects (10 F, 10 M, Median KPS = 80; range 40-100) received a median of 8 cycles at 3 US institutions. Sixteen radiographic complete responses (80%) and 1 partial response were documented, 3 subjects were not evaluable (2 withdrew consent and 1 unrelated death). Median PFS was 55.2 months (95% CI :10.3 – not reached) and Median Overall survival was 82.8 months (95% CI :19.8-145.8). Fourteen patients (82% of evaluable patients) had grade 3 or 4 adverse events (AE). Grade 4 AEs (n = 14 in n = 7 patients) included neurologic toxicities (ischemia, cervical cord inflammation, neuropathy) and blood/bone marrow toxicities (lymphopenia, neutropenia, granulocytopenia). There were no treatment-related deaths. **Conclusions:** We demonstrate the feasibility of performing BBBD in a multi-institutional setting with excellent PFS and OS in patients without whole brain radiation or autologous transplant. Our CR rates, PFS and OS are comparable to other IV high-dose MTX regimens, with acceptable toxicity profile and no documented treatment-related deaths. Clinical trial information: NCT00293475. MTHFR polymorphisms and neurotoxicity and overall survival after methotrexate-based therapy in primary CNS lymphoma. *First Author: Philipp Karschnia, Department of Neurosurgery, Ludwig-Maximilians-University, Munich, Germany*

Background: The folate-antagonist methotrexate (HD-MTX) is an integral to induction chemotherapy for primary CNS lymphoma (PCNSL); however, it can be associated with toxicities, including injury to cerebral white matter known as leukoencephalopathy. Methylene tetrahydrofolate Reductase (MTHFR) is involved in intracellular folate metabolism, and MTHFR polymorphisms may affect CNS-specific side effects of HD-MTX. Here, we evaluated the possible association of MTHFR polymorphisms and HD-MTX related CNS toxicity. **Methods:** We retrospectively searched our institutional database at the Massachusetts General Hospital for newly diagnosed PCNSL patients treated with HD-MTX (without use of radiotherapy or intrathecal chemotherapy). MTHFR polymorphisms were correlated with evolution of leukoencephalopathy over a time period of five years and patient outcomes. ROC curves were generated to estimate the diagnostic ability of specific MTHFR genotypes. Survival was calculated using Kaplan-Meier survival analysis and log-rank test. The significance level was set at $p \leq 0.05$. **Results:** Among 68 PCNSL patients, MTHFR polymorphisms were found in 60 individuals (88.2%; 677C>T: 29 patients, 1298A>C: 18 patients, combined 677C>T & 1298A>C: 13 patients). Neither MTX clearance nor disease response to HD-MTX was affected by specific genotypes, and complete response was achieved in 72.1% of patients by induction with HD-MTX-based therapy. However, the 1298A>C genotype was associated with increased frequency and severity of leukoencephalopathy over time ($\chi^2 = 7.43$). Such genotype predicted treatment-induced leukoencephalopathy with a sensitivity of 71.0% and a specificity of 62.2% (ROC: $p = 0.019$). While progression-free survival did not differ in genotype-based subgroups, overall survival was significantly lower when the 1298A>C genotype was present. **Conclusions:** The MTHFR 1298A>C genotype may serve to identify PCNSL patients at elevated risk for HD-MTX-induced leukoencephalopathy. This was associated with reduced overall survival, potentially due to decreased functional status in patients less suitable for aggressive subsequent therapies. Research Sponsor: None.

Belzutifan treatment of Von Hippel-Lindau (VHL) related central nervous system (CNS) hemangioblastomas (HBs): A single institution experience. *First Author: Othon Iliopoulos, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA*

Background: Patients with inactivating germline mutations in the VHL gene develop CNS (brain and/or spine) HBs and/or renal cancers, pheochromocytomas and pancreatic neuroendocrine tumors. The oral HIF2a inhibitor belzutifan has been approved by FDA for the treatment of VHL-related HBs. We present here data on a cohort of VHL patients with CNS HBs treated with belzutifan in a single institution. **Methods:** Adult VHL patients, with radiologically documented CNS (brain and/or spine) HBs that displayed documented growth within the last 6 months prior to therapy, were treated with an initial dose of 120 mg belzutifan orally per day. Target lesions included HBs > 0.4cm long in one maximal cross-sectional diameter. Lesions were imaged by MRI at 1.5, 3, 6 months after initiation of treatment and at 6-month intervals thereafter. Solid enhancing lesions, associated cysts and peritumoral edema were recorded and quantified. Tumor sizes were evaluated by RECIST 1.1 criteria and volumetric analysis. All patients were evaluated and treated in the Hemangioblastoma Center and the VHL Clinic of the Massachusetts General Hospital Cancer Center. **Results:** At the time of analysis, 9 females and ten 10 male VHL patients (n=19) have been treated. Median age at treatment initiation was 36 yo (range 19-59). Median follow up is 12 months (range 1-19.5 months). Two patients were not yet evaluable for response. Of 17 evaluable patients, 8 had a PR (ORR 47%; 95% CI, 34-60), 8 had SD and 1 patient had progression (PD, 5.8%). Two patients had dose reduction to 80 mg/d because of anemia. No patient had grade 3 or greater toxicity and no patient experienced a CNS related toxicity during treatment. Volumetric analysis of solid and cystic components of the lesions, VHL germline mutations and other correlates of response to belzutifan will be presented. **Conclusions:** Real world data collected at a single institution confirm the high response rate of both solid and cystic components of CNS HBs to the FDA approved HIF2a inhibitor, belzutifan. Belzutifan was well tolerated. Further prospective controlled studies addressing the optimal dose, schedule and duration of treatment of HBs with belzutifan are required. Research Sponsor: None.

The clinical relevance of margins in frameless stereotactic radiosurgery for intact brain metastases: A randomized trial of 0 vs 2 mm margins. *First Author: Aditya Juloori, Department of Radiation and Cellular Oncology, University of Chicago, Chicago, IL*

Background: Stereotactic radiosurgery (SRS) is a commonly utilized treatment strategy for brain metastases which offers a relatively low rate of morbidity and high rate of local control. SRS delivers an ablative dose of radiation in a single session to a limited target volume while minimizing dose to surrounding normal tissue. Image-guided linear accelerator (LINAC)-based frameless SRS has enabled effective, safe delivery of high dose radiation without the discomfort and logistical complications associated with use of a rigid frame. Localization errors during frameless SRS vary depending on the specific LINAC configuration and immobilization technique. The clinical relevance of potential inaccuracies in localization with frameless SRS remains controversial. When employing frameless systems, many centers will account for set-up uncertainties by adding a circumferential margin of 1-3 mm around the GTV to create a planning target volume (PTV). This PTV expansion ensures adequate tumor coverage if target motion occurs, but exposes more normal brain tissue to radiation and may increase the risk of adverse events, chiefly radionecrosis. There is limited literature available to guide radiation oncologists on the appropriate choice of margin size, if any, for frameless SRS. There are no randomized data evaluating the safety and efficacy of omitting the margin entirely. Given the paucity of data examining margin extent and the potentially significant consequences for treatment efficacy and morbidity, we propose a phase II randomized prospective clinical trial evaluating 0 vs 2 mm marginal GTV to PTV expansions for treating patients with intact brain metastases with frameless SRS. **Methods:** Eligible patients will have brain metastases from solid tumors with ECOG performance status of 0-2 and life expectancy of >3 months. Patients must have 1 - 5 newly diagnosed well-circumscribed, measurable intraparenchymal brain metastases with maximum tumor diameter ≤ 3.0 cm. At least one lesion must be ≥ 0.5 cm in maximum diameter to be considered measurable. SRS will be delivered in a single fraction to either 20 Gy or 18 Gy dependent on tumor size. Importantly, PTV margin randomization is blinded and occurs after delineation of tumor volume by radiation oncologist to not bias contouring based on knowledge of margin randomization. This is two-armed multi-center phase II randomized controlled trial. The trial is powered to demonstrate non-inferiority of the experimental arm with regard to the primary endpoint of local PFS at 6 months and the superiority of the experimental arm with regard to the secondary endpoint of radionecrosis or pseudoprogression. We expect the total study duration, from the start of screening for the first participant until the end of follow-up for the last one, to be approximately six years. We plan to accrue 166 patients to this trial at all sites. Clinical trial information: NCT02747303. Research Sponsor: None.

A phase 0/1a study of BI 907828 concentrations in brain tissue and a nonrandomized, open-label, dose escalation study of BI 907828 in combination with radiotherapy in patients with newly diagnosed glioblastoma (GBM). *First Author: Jann Nagina Sarkaria, Mayo Clinic, Rochester, MN*

Background: Murine double minute 2 (MDM2) directly regulates the stability of the tumor suppressor p53, and dysregulation of this pathway can critically disrupt cellular response to genomic stress and lead to cell death. BI 907828 is a highly potent inhibitor of the MDM2-p53 interface that triggers accumulation of p53 and subsequent apoptosis in multiple GBM patient-derived xenografts (PDXs) with wild-type p53. Moreover, the combination of BI 907828 and radiotherapy provides significant survival extension in multiple orthotopic GBM PDXs. **Methods:** An integrated Phase 0/1 trial design is being used to evaluate the potential for BI 907828 to achieve a therapeutic concentration in brain tumor tissue and to test the safety of the combination with radiation. The co-primary endpoints for the Phase 0 study are i) measured total concentration of BI 907828 and ii) calculated unbound concentration of BI 907828 in contrast and non-contrast enhancing regions of tumor. Key inclusion criteria for the Phase 0 study are patients at least 18 years of age, ECOG performance status of 0 or 1, histologic or radiologic new diagnosis of GBM, and planned surgical resection. The first approximately 6 patients enrolled in the Phase 0 will be treated at the starting dose of 30 mg, and the future patients enrolled will be dosed at higher levels (45 mg or 60 mg) provided there are no safety concerns. If dose-limiting toxicities (DLTs) are encountered, then a Bayesian Logistic Regression Model (BLRM) with overdose control will be used to guide the dose level decisions for the additional patients. Multiple, image-registered tumor samples and intra-operative plasma samples will be analyzed for BI 907828 by LC-MS/MS. Intra-tumoral variation in BI 907828 will be correlated with pharmacodynamic effects of MDM2 inhibition (elevation of p53, p21, MDM2, GDF15, PUMA). Those patients completing the Phase 0 study and who meet additional eligibility criteria can enroll on the Phase 1a portion of the study. The pathologic inclusion criteria are TP53 wild-type, IDH1/2 wild-type, MGMT unmethylated GBM. Co-primary endpoints for the Phase 1a trial are i) occurrence of DLTs during and within 21 days after completion of radiation therapy, and ii) occurrence of adverse events throughout the treatment period. Tolerability of inter-patient dose-escalation of BI 907828 (30, 45, 60 mg) combined with radiation therapy (60 Gy in 30 fractions) will be evaluated with dose-escalation guided by a two-parameter BLRM with overdose control. Patients will remain on BI 907828 monotherapy following completion of radiotherapy until progression. To date, two patients have enrolled on the Phase 0 study, and one patient went on to enroll on the Phase 1a portion of the study. Clinical trial information: NCT05376800. Research Sponsor: Boehringer Ingelheim.

Phase 3 TRIDENT study (EF-32): Tumor treating fields (TTFields; 200 kHz) concomitant with chemoradiation, and maintenance TTFields therapy/temozolomide in newly diagnosed glioblastoma. *First Author: Wenying Shi, Department of Radiation Oncology, Thomas Jefferson University, Philadelphia, PA*

Background: Tumor Treating Fields (TTFields) therapy, a noninvasive and locoregional antimitotic cancer treatment modality, is approved for newly diagnosed (nd), recurrent glioblastoma (r) GBM and mesothelioma. In patients with ndGBM, progression-free survival (PFS) and overall survival (OS) were significantly improved with TTFields therapy/temozolomide (TMZ) vs TMZ alone in the pivotal EF-14 study, leading to FDA approval in ndGBM. To avoid potential impedance of radiotherapy (RT), TTFields therapy was administered following RT/TMZ; however, preclinical studies have demonstrated that TTFields therapy enhances the therapeutic effect of RT. **Methods:** TRIDENT (EF-32; NCT04471844), a phase 3, global, randomized study, will evaluate TTFields therapy concomitant with RT/TMZ in patients ≥ 18 years of age (≥ 22 years in the US) with histologically-confirmed ndGBM, ≥ 3 months life expectancy, and ≥ 70 Karnofsky performance status. Patients will be stratified on the basis of MGMT promoter methylation status and extent of resections. Approximately 950 patients will be assigned 1:1 to continuous TTFields therapy (200 KHz, ≥ 18 h/day) concomitant with RT/TMZ (experimental arm) or RT/TMZ alone (control arm). Patients in the experimental arm will receive TTFields therapy continuously from the first day of chemoradiation. Patients in the control group will begin TTFields at the same time as maintenance TMZ, approximately one month after completion of chemoradiation. TTFields therapy will continue in both treatment groups until second disease progression (PFS2) or 24 months (if clinically able). The primary endpoint is median OS, and secondary endpoints include PFS, 1- and 2-year survival rates, objective response rate, PFS2, 6- and 12-month PFS rates, safety, and quality of life (EORTC QoL questionnaires). The ability of TTFields therapy to extend OS in a dose-dependent manner is an exploratory endpoint. The sample size is powered for a hazard ratio of < 0.8 with a 5% type I error. The hypothesis that first-line TTFields therapy/RT/TMZ can significantly improve OS vs RT/TMZ will be tested using a stratified log-rank test. The study is expected to enroll patients at 150 sites, with enrollment currently open in 9 countries. Clinical trial information: NCT04471844. Research Sponsor: Novocure.

A first-in-human pharmacodynamic evaluation of dual polyamine depletion for patients with high-grade gliomas. *First Author: Cecile Riviere-Cazaux, Mayo Clinic, Rochester, MN*

Background: No drug has improved survival for patients with high-grade gliomas (HGGs) since temozolomide in 2005. Relatively little is known about the live response of *in situ* gliomas to therapeutic intervention. Phase 0 studies that leverage access to the live human glioma *in situ*, including via microdialysis to sample the live glioma microenvironment, provide an attractive and feasible solution to this problem. We performed intraoperative microdialysis to evaluate the extracellular metabolome of divergent regions in 15 HGG resections. Our data revealed a conserved metabolic signature of HGGs and a novel glioma-associated metabolite, guanidinoacetate (GAA). Pathways enriched in this tumor signature included methionine and polyamine metabolism. Although GAA is typically converted to creatine, we hypothesize that the high flux of ornithine through ornithine decarboxylase (ODC) results in excess GAA accumulation. As such, in a Phase 0 trial, we will evaluate *in situ* glioma responses to polyamine depletion via ODC inhibition (Difluoromethylornithine, DFMO), with or without blockade of polyamine uptake (AMXT 1501), to identify candidate extracellular biomarkers of target engagement and cytotoxicity. **Methods:** Patients will be recruited who are undergoing a clinically indicated subtotal resection for a known or suspected high-grade glioma (NCT05717153). At the end of the surgery, two microdialysis catheters will be implanted for post-operative microdialysis, one in residual tumor and one in brain adjacent to tumor for an internal control. Beginning on post-operative day (POD) 1, patients will be randomized to one of the following three groups, including administration of vehicle, DFMO (500 mg, PO, BID) and AMXT 1501 (600 mg, PO, BID): 1) DFMO + AMXT 1501 (POD1-5); 2) Vehicle (POD1-POD2), followed by DFMO + AMXT 1501 (POD3-POD5); 3) DFMO alone (POD1-POD2), followed by DFMO + AMXT 1501 (POD3-POD5). Throughout this time, extracellular metabolite levels of polyamines, guanidinoacetate, and glutamate will be quantified from microdialysate collected every two hours from intraoperatively implanted 100 kDa microdialysis catheters. The primary outcome of this study is to determine how polyamine depletion impacts extracellular intratumoral guanidinoacetate abundance. The secondary outcomes of this study are to (1) determine the impact of polyamine depletion on polyamine abundance and the global extracellular metabolome within live human gliomas, *in situ*, and (2) assess the feasibility of longitudinal microdialysis for pharmacodynamic analysis within live human gliomas *in situ* in the post-operative setting. Clinical trial information: NCT05717153. Research Sponsor: U.S. National Institutes of Health.

Low-intensity focused ultrasound with systemic microbubble oscillators for blood-brain barrier disruption for liquid biopsy in glioblastoma (LIBERATE). *First Author: Manmeet Singh Ahluwalia, Miami Cancer Institute, Baptist Health South Florida, Miami, FL*

Background: Liquid biopsy in glioblastoma (GBM) is hindered by a lack of requisite circulating-free DNA (cfDNA) levels in blood due to the blood-brain barrier (BBB). This results in challenges to the identification of blood-based biomarkers and the development of novel biomarker-driven systemic therapies. Real-time image-guided low intensity focused ultrasound (LIFU) combined with IV microbubble oscillators (DEFINITY), non-invasively causes BBB disruption (BBBD). This clinical trial aims to evaluate the utility of LIFU for increasing cfDNA in blood for liquid biopsy in GBM. **Methods:** LIBERATE is a prospective, multi-center, self-controlled, ongoing, pivotal trial evaluating safety and technical efficacy of LIFU for BBBD to increase cfDNA in blood for GBM. Patients aged > 18 -80 years with suspected GBM planned for tumor biopsy or resection at eleven centers in North America are being included. Patients with multifocal tumors or tumors arising from deep midline, thalamus, cerebellum, or brainstem are excluded. Patients are administered IV oscillating microbubbles for enhancing sonication, after which MR-guided BBBD using a 220 kHz LIFU device is performed with real-time acoustic feedback for effective cavitation. Before and after procedure, phlebotomies and MRI brain are performed to evaluate outcomes. The primary study endpoint is defined, per subject, as the ratio between their cfDNA level in blood 1-hour post-LIFU compared to cfDNA level in blood pre-procedure. The primary study hypothesis is that BBBD with LIFU leads to ≥ 2 -fold increase in cfDNA in blood. The secondary hypothesis is that there exists $\geq 75\%$ agreement between biomarker pattern in cfDNA sample from 1-hour post-LIFU sample and biomarker pattern in tumor tissue obtained later. The trial has been powered to evaluate both primary and secondary hypotheses. Based on an assumed true agreement rate of 91% and a one-sided alpha of 0.025, an exact test for binomial proportions provides a sample of $N=50$ with 84% power for the secondary hypothesis. Exploratory endpoints include (1) sensitivity of detection of known somatic mutations in cfDNA from blood samples collected before and after LIFU, (2) estimation of cfDNA levels post-LIFU in samples collected at 30 minutes, 1 hour, 2 hour, and 3 hour to determine time of greatest yield, (3) correlation of MRI parameters related to grading of BBBD and biomarkers positive in cfDNA from post-LIFU blood samples. Patient enrollment commenced in 2022 and 7 patients have been recruited by 02/13/2023. Clinical trial information: NCT05383872. Research Sponsor: Insightec.

Efficacy and safety study of neoadjuvant efineptakin alfa (NT-17) and pembrolizumab in recurrent glioblastoma. *First Author: Mason Webb, Mayo Clinic, Rochester, MN*

Background: Glioblastoma (GBM) is the most common and aggressive form of brain tumor in adults. Despite maximal surgical resection, irradiation, and chemotherapy, median overall survival (OS) remains at only 30 weeks for recurrent GBM (rGBM) patients, emphasizing the need for novel treatments. GBM tumors are immunologically 'cold,' in that they have an immune-suppressive microenvironment with a low number of tumor-infiltrating lymphocytes (TIL). Interleukin 7 (IL-7) plays a key role in T cell development and survival. The physiological level of IL-7 increases to stimulate T cell expansion in lymphopenic condition. Previous studies have shown that lymphopenic GBM patients have shorter survival. However, their IL-7 levels are unexpectedly low. Efineptakin alfa (NT-17), a long-acting IL-7, has been shown to increase effector CD8 T cells and reduce suppressor T-regulatory cells in murine GBM models, with subsequently improved OS. Further, we recently completed a Phase I study which showed that NT-17 is safe, well-tolerated, and increased absolute lymphocyte counts (ALC) in newly diagnosed GBM patients. Phase II dosing was determined through this Phase I study reaching maximum tolerated dose. Thus, we hypothesized that NT-17 may reverse GBM-associated immune suppression and potentiate the effect of an immune checkpoint inhibitor, leading to an increase in TILs and improved survival. Our preliminary data suggests that combining NT-17 with pembrolizumab, an anti-PD-1 antibody, improves survival in murine glioma models. The purpose of this study is to evaluate the safety and efficacy of combining NT-17 and pembrolizumab in rGBM patients. **Methods:** This is an open-label single arm one-stage Phase II study of NT-17 and pembrolizumab as neoadjuvant and adjuvant therapy with surgery for adult patients with rGBM. We plan to enroll 30 evaluable patients, including a 6-patient safety run-in. Key eligibility criteria include candidates willing to undergo clinically indicated resection or biopsy, age ≥ 18 years, Karnofsky performance status ≥ 70 , and dexamethasone dose > 2 mg/day ≤ 2 days prior to registration. The primary endpoint is a 9-month OS rate. Secondary endpoints include progression-free survival, objective response rate, changes in ALC, and adverse events profile. The correlative endpoints include studies to assess the anti-glioma immune response, changes in T cell subsets, T cell effector function, cytokine analysis, and immunohistochemical analysis of GBM tissue. Longitudinal cerebrospinal fluid proteomics is optional. This study opened on 1/20/2023. Two of the planned 30 patients had been enrolled by submission on 2/14/2023. Clinical trial information: NCT05465954. Research Sponsor: Supported in part by a research grant from Investigator-Initiated Studies Program of Merck Sharp & Dohme LLC.; The Ivy Foundation; Mayo Clinic Comprehensive Cancer Center; Humor to Fight the Tumor.

Phase II trial of combination pembrolizumab, olaparib, and temozolomide for patients with recurrent glioma. *First Author: Lauren Schaff, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Diffuse gliomas are primary brain tumors characterized by substantial morbidity and mortality. Standard treatment includes maximal safe surgical resection followed by combination radiation and chemotherapy. Despite aggressive treatment, diffuse gliomas inevitably recur. Alkylating agents, and in particular temozolomide, play an important role in the treatment of gliomas, resulting in single-strand DNA breakages which require PARP activity for detection and repair. Gliomas with mutations in *isocitrate dehydrogenase (IDH) 1 or 2* have an accumulation of 2-hydroxyglutarate (2HG) which results in a *BRCA*-like state of homologous recombination deficiency (HRD). When PARP is inhibited in the setting of HRD, single-strand DNA damage progresses to double-strand breaks resulting in synthetic lethality. PARP inhibition has also been shown to increase mutational burden and neoantigen expression ("immune-priming") and increases tumor-infiltrating lymphocytes and expression of PD-L1. Here, we present an ongoing clinical trial combining the checkpoint inhibitor pembrolizumab, the PARP inhibitor olaparib, and temozolomide for treatment of recurrent gliomas with HRD. **Methods:** This is an open-label, non-randomized phase II trial of combination pembrolizumab, olaparib, and temozolomide for patients with recurrent glioma. The main study cohort (A) will consist of 52 patients with recurrent enhancing grade 2 or 3 IDH-mutant gliomas. An exploratory cohort (B) will consist of 5 patients with recurrent IDH-wildtype gliomas and mutations associated HRD. Study intervention is administered in 21-day cycles and includes pembrolizumab (200mg IV q3 weeks day 1), olaparib (200mg bid orally days 8-14) and temozolomide (50mg/m² orally days 8-14). The primary outcome is overall response rate (ORR) in cohort A. Secondary objectives include safety and toxicity of triplet therapy, overall and progression-free survival, and best radiographic response. Exploratory objectives will describe outcomes in the IDH-wildtype cohort and associate response to tumor markers obtained through archival tissue and cell free DNA of cerebrospinal fluid. The trial includes a 6-patient safety lead-in to assess tolerability of triplet therapy. Cohort A patients must have grade 2 or 3 IDH-mutant glioma without known CDKN2A/B loss. Patients in Cohort B must have IDH-wildtype glioma with an alternate deleterious mutation involved in homologous recombination. Additional inclusion criteria include age ≥ 18 , ECOG 0-1, and glioma recurrent after prior therapy with measurable disease by RANO. Patients must be on a stable dose of corticosteroids not to exceed 2mg/day. There are no restrictions regarding number of recurrences or prior therapies if an appropriate washout has been completed. To date, seven of 57 patients have enrolled. The safety-lead in was completed without dose-limiting toxicities. Clinical trial information: NCT05188508. Research Sponsor: MSKCC; Merck.

Phase 1b multicenter study to evaluate CHM 1101 in patients with recurrent or progressive glioblastoma. *First Author: Jason Blair Litten, Chimeric Therapeutics, Carlton, Australia*

Background: Glioblastoma multiforme (GBM) is the most common and most aggressive primary brain tumor. More than 300,000 new cases are diagnosed globally with over 250,000 deaths each year (Sung H, et al. *CA Cancer J Clin.* 2021). Patients with recurrent GBM have a poor prognosis, with limited treatment options and a median survival of less than 1 year (Gallego. *Curr Oncol.* 2015). While prior attempts to treat GBM with chimeric antigen receptor (CAR) T-cells have been limited by tumor heterogeneity, chlorotoxin (CLTX)-directed CAR T-cells in mice demonstrated broad anti-tumor activity and prolonged survival with no off-tumor toxicity or antigen escape (Wang, et al. *Sci Transl Med*, 2020). CLTX, a 36-amino acid peptide identified in scorpion venom, selectively binds to malignant glioma cells through matrix metalloproteinase-2 (MMP2) and clinical administration of CLTX-based biologics has been well tolerated in patients (Mamelak, et al. *J Clin Oncol*, 2005, Patil, et al. *Neurosurgery*, 2019). CHM 1101 is the first CAR T to utilize CLTX as its tumor targeting domain for autologous CAR T-cell therapy. A single-center first-in-human phase 1 study of CHM 1101 in patients with recurrent GBM is ongoing. **Methods:** Clinical Trial NCT05627323 is a phase 1b, multi-center study of CHM 1101 in adult subjects with MMP2+ recurrent or progressive GBM after standard therapy. After leukapheresis and tumor resection, pts will receive CHM 1101 at Dose Level 1 (240×10^6 CAR T cells) or Dose Level 2 (440×10^6 CAR T-cells), divided across 3 once-weekly intracranial (intracavitary and intraventricular) administrations; after disease assessment at 28 days, additional doses of CHM 1101 can be administered on a weekly schedule. Eligible subjects have a prior histologically confirmed diagnosis of a grade 4 GBM, a grade 2 or 3 malignant glioma with radiographic progression consistent with a grade 4 GBM (IDH wild type), grade 4 diffuse astrocytoma (IDH mutant), or a unifocal relapse of GBM. MMP2+ tumor expression is confirmed by IHC ($\geq 20\%$ moderate/high MMP2 score [2+ or 3+]). The primary endpoint is safety; key secondary endpoints include feasibility, progression-free survival, overall survival, response rate (RANO criteria), and cellular kinetics. Recruitment is ongoing. Clinical trial information: NCT05627323. Research Sponsor: Chimeric Therapeutics.

Oral Abstract Session

Initial results from the phase 2A trial of visugromab (CTL-002) + nivolumab in advanced/metastatic anti-PD1-L1 relapsed/refractory solid tumors (The GDFATHER-TRIAL). *First Author: Ignacio Melero Bermejo, Laboratory of Immunology, Clínica Universitaria de Navarra, Pamplona, Spain*

Background: Increasing evidence has emerged that Growth and Differentiation Factor 15 (GDF-15) plays a critical role in tumoral immunosuppression. Apart from blocking immune-cell entry into the tumor microenvironment, GDF-15 also has a major impact on the formation of the immune synapse. Many tumors overexpress GDF-15 and have hijacked this mechanism to block immunotherapy success. Here we report initial results of the phase 2a part of the GDF-15 neutralizing antibody visugromab (CTL-002) in combination with nivolumab. **Methods:** At cut-off date (06-Feb-2023), a total of 79 pts with advanced/metastatic solid tumors have been enrolled and were treated with visugromab 10 mg/kg Q2W in combination with nivolumab 240 mg Q2W in the phase 2a expansion part of the CTL-002-001 phase 1/2 trial (NCT04725474). The primary endpoint of the phase 2a expansion is the Objective Response Rate (ORR) according to RECIST v1.1. Tumor assessments were performed every 8 weeks and patients had to be relapsed/refractory to a minimum of 12 weeks continuous prior anti-PD1/-PD-L1-containing therapy, with relapse or progression after initial response to have occurred on continued anti-PD1/PD-L1 therapy. Phase 2a contained several indication-specific expansion cohorts (e.g. NSCLC, Bladder Cancer, HCC, Melanoma), following a Simon 2-stage design, and two cohorts were already expanded to stage 2 in light of initial responses observed. An additional expansion cohort is a pan-tumor basket cohort with sequential tumor biopsies for biomarker analyses. A key component of this multi-arm trial is an extensive translational research program to identify response-predictive tumor and immunologic marker and pattern. **Results:** Across several expansion cohorts, durable tumor regressions were observed, including several partial responses (PR) and one complete response (CR) in heavily pretreated patients with a median of 3 prior lines of systemic therapy for advanced/metastatic cancer, including at least one prior line of anti-PD1/-PD-L1 therapy and being relapsed/refractory to it. In NSCLC, so far 13 pts underwent at least one tumor assessment. Of these, two experienced a PR (one confirmed), three additional tumor shrinkage > 5% (TS) and one longer-term SD (LT-SD) were seen. In bladder cancer, 7 patients underwent at least one tumor assessment with 1 confirmed CR, 1 TS and 1 LT-SD. The treatment was overall well tolerated. **Conclusions:** These initial phase 2a results demonstrate promising clinical activity for the combination of visugromab and nivolumab in heavily pretreated anti-PD1/-PD-L1 refractory/relapsed solid tumor patients across various indications, including induction of confirmed partial and complete responses. Extensive biomarker evaluations are ongoing to further evaluate potential response-predictive markers identified during phase 1 development. Clinical trial information: NCT04725474. Research Sponsor: Catalm GmbH.

Oral Abstract Session

Tumor mutational burden (TMB) measurement from an FDA-approved assay and real-world overall survival (rWOS) on single-agent immune checkpoint inhibitors (ICI) in over 8,000 patients across 24 cancer types. *First Author: David R. Gandara, Division of Hematology/Oncology, Department of Medicine, UC Davis Comprehensive Cancer Center, Sacramento, CA*

Background: There is controversy around the applicability of TMB across cancer types and reliability between assays from different manufacturers. The KEYNOTE 158 trial supported FDA approval of the Foundation Medicine test (FoundationOne CDx) at TMB ≥ 10 mut/Mb as a solid tumor companion diagnostic (CDx) for single-agent pembrolizumab in 2nd+ line. Using a large real-world dataset with validated rWOS endpoint data, we evaluated the clinical validity of the TMB measurement by the FDA approved test in over 8,000 patients across 24 cancer types who received single agent ICI. **Methods:** Following a prespecified analysis plan, this study used the nationwide (US-based) de-identified Flatiron Health-Foundation Medicine clinico-genomic database (FH-FMI CGDB), with data originating from approximately 280 US cancer clinics (~800 sites of care). The overall cohort included patients from 24 cancer types of interest with adv/metastatic disease treated with single-agent anti-PD(L)1 therapy in the FH network between 1/1/2011 - 9/30/2022. This study used the TMB algorithm from the FDA-approved test supporting solid tumor CDx and composite mortality variable validated against the national death index. Relative hazards of death by TMB interval were assessed using Cox PH models adjusted for ECOG PS, prior treatment, sex, age, opioid rx pre-therapy, genetic ancestry, and socioeconomic assessment. Multi-solid tumor cohort Cox models were additionally adjusted for MSI status, with baseline hazards stratified by cancer type. **Results:** 8,440 patients from 24 cancer types met inclusion criteria for the overall cohort. Adjusting for aforementioned factors, the hazards of death (HR, (95% CI)) across the entire cohort, relative to TMB < 5, was 0.95 (0.89 - 1.02) for TMB 5-10, 0.79 (0.73 - 0.85) for TMB 10-20, and 0.52 (0.47 - 0.58) for TMB 20+. Adjusted Cox models comparing TMB ≥ 10 vs. TMB < 10 were pre-specified for cancer types with at least 15 death events in each group: breast 0.51 (0.35 - 0.76), colorectal 0.37 (0.27 - 0.49), cancers of unknown primary 0.52 (0.30 - 0.90), endometrial 0.38 (0.26 - 0.55), gastric 0.46 (0.34 - 0.62), head & neck 0.49 (0.33 - 0.73), melanoma 0.55 (0.43 - 0.71), non-small cell lung 0.76 (0.71 - 0.83), small cell lung 0.69 (0.44 - 1.09), and urothelial 0.63 (0.53 - 0.75). Additional individual tumor types, stratification by MSI status, and time to next treatment associations to be presented at conference. **Conclusions:** Across a heterogeneous cohort, and within individual cancer types with sufficient power, elevated TMB using the TMB measurement based on the FDA-approved test associated with more favorable rWOS on ICI than for similar patients with lower TMB levels. Completed and ongoing randomized controlled trials are encouraged to report out subgroup analyses comparing ICI vs. comparator arm by TMB level. Research Sponsor: Foundation Medicine; Flatiron Health.

Oral Abstract Session

Initial results from a first-in-human, phase I study of immunomodulatory aryl hydrocarbon receptor (AhR) inhibitor BAY2416964 in patients with advanced solid tumors. *First Author: Ecaterina Elena Dumbrava, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: AhR activation is involved in tumor growth, immunomodulation, and resistance to immune checkpoint inhibitors. BAY2416964 is a novel, potent, oral AhR inhibitor (AhRi) that antagonizes AhR ligand-induced immunosuppressive effects, resulting in enhanced proinflammatory activity of antigen-presenting cells and T cells and reduced activity of immunosuppressive myeloid cells. **Methods:** A first-in-human, Phase I clinical trial of AhRi BAY2416964 (NCT04069026) is evaluating its safety, pharmacokinetics, pharmacodynamics, recommended Phase II dose, and anti-tumor activity per RECIST v1.1 and iRECIST. BAY2416964 was administered orally in patients with advanced solid tumors in a dose-escalation cohort using a modified toxicity probability interval (mTPI) design. The initial expansion cohorts enrolled patients with non-small-cell lung cancer (NSCLC) and head and neck squamous cell carcinoma (HNSCC). **Results:** As of November 4, 2022, 72 patients had been treated with BAY2416964: 39 patients in dose escalation and 33 patients in the initial dose expansion treated with 500 mg twice daily (25 NSCLC, 8 HNSCC). The most common tumor types enrolled in dose escalation were colorectal cancer ($n=12$), breast cancer ($n=6$), and pancreatic cancer ($n=4$). Median age was 61 years (range 35-80). 51/72 (70.8%) patients had received ≥ 3 lines of therapy (including 16 [22.2%] who had received ≥ 6 lines) and 47/72 (65.3%) had received immune checkpoint inhibitors. Drug-related treatment-emergent adverse events (TEAEs) of all grades reported in $\geq 10\%$ of patients were nausea (13.9%; 1.4% grade 3) and fatigue (11.1%; 1.4% grade 3). Most drug-related TEAEs were grade 1 or 2; 9 (12.5%) patients experienced drug-related grade 3 TEAEs and no patients experienced drug-related grade ≥ 4 TEAEs. No dose-limiting toxicities were observed. Two patients in dose expansion discontinued treatment due to drug-related TEAEs. Plasma exposure to BAY2416964 increased according to dose and food intake. Analysis of biomarkers demonstrated evidence of target engagement and an increase in immune activation at the doses tested. Of 67 patients evaluable for response by RECIST, 22 (32.8%) had stable disease per RECIST v1.1, including 1 with thymoma in dose escalation achieving an iRECIST partial response. **Conclusions:** BAY2416964 was well tolerated across all dose levels and regimens tested. Initial evaluation of biomarkers shows BAY2416964 inhibits AhR and modulates immune functions. Encouraging preliminary anti-tumor activity was observed in heavily pretreated patients. The disease-specific dose-expansion part of this study is ongoing. The observed manageable safety profile also supports combination therapies. Clinical trial information: NCT04069026. Research Sponsor: Funding by Bayer AG, medical writing support provided by Complete HealthVizion.

Oral Abstract Session

Evaluation of change in RECIST tumor size and survival in patients with rare cancers treated with checkpoint inhibitor therapy (SWOG S1609). *First Author: Megan Othus, Fred Hutchinson Cancer Center, Seattle, WA*

Background: RECIST has been used for over twenty years to evaluate changes in tumor burden. At each scan, the sum of maximum diameters of "target" lesions are measured. Changes in the sum are categorized into an "objective status" at each scan, including complete and partial response and stable and progressive disease. Prior research among patients treated with chemotherapy did not find a threshold effect corresponding to the RECIST categories; instead a linear association was observed. Herein we use a unique clinical trial resource, a basket trial of patients with rare cancer treated with combination anti-CTLA-4 and anti-PD-1 therapy, to evaluate the association between quantitative change in RECIST tumor burden and survival among patients treated with checkpoint inhibitor therapy. **Methods:** The study population was 796 patients enrolled on the S1609 DART (Dual Anti-CTLA-4 & Anti-PD-1 blockade in Rare Tumors) trial, a basket immunotherapy trial evaluating ipilimumab plus nivolumab across solid rare tumor subtypes. The analysis population was 720 patients; patients not eligible ($n=50$; mostly due to non-rare diagnosis), THOSE who did not receive protocol therapy ($n=22$), OR WHOSE DISEASE WAS NOT evaluated by RECIST ($n=4$; gestational trophoblastic disease evaluated by -hCG) were excluded. All patients had RECIST-measurable disease at study entry. Associations between overall and progression-free survival (OS and PFS) and change in tumor burden between baseline and the first scan were evaluated using log-rank tests and Cox regression models stratified by basket. Landmark analyses (at day 65) controlled for lead-time bias. Linear regression models and R^2 were estimated for median and 2-year estimates across tumor change intervals. **Results:** The median age of the cohort was 61, 52% were the distribution of percent change in tumor burden at the first scan. The linear correlation between median and 6-month PFS and change in tumor burden had $R^2=0.92$ and 0.74 ; median and 1-year OS had $R^2=0.79$ and 0.79 . Martingale residuals for both PFS and OS showed linear trends up to tumor increase of +50% with no thresholds at definitions of partial response or stable disease. **Conclusions:** This is the first evaluation of the association between numeric changes in RECIST tumor burden among patients receiving checkpoint therapy. Our results suggest that similar to results among patients who received chemotherapy there is a linear correlation with PFS and OS. As a consequence, the thresholds for RECIST categories do not correspond to thresholds in patient outcomes. Research Sponsor: U.S. National Institutes of Health; Bristol-Myers Squibb.

Oral Abstract Session

Interim update of the ATRC-101 phase 1b trial in advanced solid tumors.

First Author: Bartosz Chmielowski, University of California Los Angeles, Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: ATRC-101 monoclonal antibody targets tumor-specific ribonucleoprotein complex (RNP) and elicits anti-tumor immunity, innate and adaptive, in preclinical models. **Methods:** Phase 1b is evaluating ATRC-101 as monotherapy, every 3 (3M) or 2 (2M) weeks (wk), and ATRC-101 in combination with pembrolizumab (3P) in participants (pts) with advanced solid tumors. ATRC-101 target expression is determined by CAP-CLIA IHC assay. For pts described herein, pre-treatment (tx) tumor biopsies were assessed for target expression by IHC retrospectively or prospectively. Enrollment in 3M and 3P is currently open to pts who are target positive (RNP+ve) by IHC with an H-score ≥ 50 . Objectives are safety (primary), PK, immunogenicity, recommended dose for expansion, activity by RECIST1.1 and biomarker analyses in pre-tx and on-tx tumors. **Results:** As of Nov 18th, 2022, 67 pts received ≥ 1 dose of ATRC-101 (median prior tx 5, range 1-12). Tumor types were colorectal (CRC, 28), ovarian (10), breast (9), melanoma (8), non-small cell lung (NSCLC, 6), head and neck squamous cell (3), urothelial (1), esophageal (1) and small bowel (1). Tx emergent adverse events (TEAEs) Grade ≥ 3 occurred in 22 (33%) pts and were related to ATRC-101 in 2 (3%). No tx discontinuations or dose reductions related to ATRC-101. RECIST1.1 best overall responses in efficacy evaluable 61 pts included 1 complete response (CR) in RNP+ve melanoma (3P, 10mg/kg), and 1 partial response (PR) in RNP+ve NSCLC (3M, 30mg/kg). Further, disease stabilized (SD) in 24 pts (39%) and 35 pts had disease progression (PD, 57%) with evidence of association between anti-tumor activity and target expression. Of 24 SD, 22 were in monotherapy cohorts and included 9 CRC pts with highly refractory disease. **Conclusions:** ATRC-101 alone and in combination with pembrolizumab continues to be well tolerated with evidence of anti-tumor activity. Interim data support ongoing enrollment of pts with RNP+ve pre-tx tumors. Updated and new data including durability of disease control will be presented. Clinical trial information: NCT04244552. Research Sponsor: Atreca.

Oral Abstract Session

Phase I study of the bifunctional anti-PD-L1/TGF- β RII agent SHR-1701 combined with SHR2554, an EZH2 inhibitor, in patients with previously treated advanced lymphoma and solid tumors. First Author: Kaichao Feng, Department of Bio-therapeutic, The First Medical Center, Chinese PLA General Hospital, Beijing, China

Background: Despite the remarkable successes of cancer immunotherapies, the majority of patients (pts) experience only partial response and most pts will progress. Enhancer of zeste homolog 2 (EZH2) as an epigenetic target for cancer therapy has been shown to enhanced antigen presentation and synergize with immunotherapy in preclinical studies. This study investigates the safety and efficacy of SHR-1701 (anti-PD-L1/TGF- β RII) plus SHR2554 (EZH2i) in pts with pretreated advanced lymphoma and solid tumors. **Methods:** This open-label, single-arm, phase 1 study enrolled pts with pretreated advanced lymphoma and solid tumors. Escalating doses of SHR2554 (300–350mg bid) plus fixed-dose SHR-1701 (30mg/kg q3w) were evaluated in the dose-escalation phase. SHR2554 at the recommended phase 2 dose (RP2D) plus SHR-1701 were administered in the dose-expansion phase. The primary end point was determination of the RP2D of SHR2554 plus SHR-1701. Secondary end points included safety and preliminary activity. **Results:** By January 6, 2023, 33 patients were enrolled (dose-escalation: n=7; dose-expansion, n=26). No dose-limiting toxicities were observed, and RP2D was established as SHR2554 350mg bid plus SHR-1701 30mg/kg q3w. Treatment-related adverse events (TRAEs) occurred in 13 of 32 patients (40.6%), mainly including platelet count decreased (21.9%), anemia (15.6%) and vomiting (15.6%). The most common Grade ≥ 3 TRAEs were anemia (3.1%) and fever (3.1%). In the efficacy-evaluable population (n = 26), objective response rate (ORR) was 57.7%, including 2 complete response (CR) achieved by patients with Metastatic Renal Cell Carcinoma and classical Hodgkin lymphoma (cHL). 16 patients with relapsed/refractory classical Hodgkin lymphoma (cHL) after a median of 10 prior lines of therapy have been enrolled. 16 (100%) cHL pts had received prior anti-PD1/PD-L1 antibody therapy, and 15 (93.8%) prior epigenetic therapies, such as decitabine or chidamide. Out of 14 cHL-evaluable patients, ORR was 100% and the CR rate was 7.1%. **Conclusions:** SHR-1701 combined with SHR2554 showed acceptable safety profile and encouraging antitumor activity in immunotherapy-pretreated cHL, establishing the foundation for further exploration. Clinical trial information: NCT04407741. Research Sponsor: None.

Oral Abstract Session

Phase 1/2 Study of DF1001, a novel tri-specific, NK cell engager therapy targeting HER2, in patients with advanced solid tumors: Phase 1 DF1001 monotherapy dose-escalation results. First Author: Howard Safran, Brown University School of Medicine-Rhode Island Hospital, Providence, RI

Background: DF1001 is a first in class, Tri-specific, NK cell Engager Therapy (TriNKET), that uses HER2 as an anchor to modulate innate and adaptive immunity. DF1001 redirects both NK and CD8 T cells to reprogram the tumor microenvironment, turning cold tumors hot. DF1001-001 (NCT04143711) is an ongoing phase I/II, first in human study investigating the safety, tolerability, clinical and biologic activity of DF1001. The safety, pharmacokinetic (PK), pharmacodynamic (PD) and efficacy data from the phase 1 monotherapy escalation and safety/PK/PD expansion is presented in this report. **Methods:** The Phase 1 dose escalation of DF1001-001 evaluated doses ranging from 0.000052-15mg/kg in patients with advanced and/or refractory solid tumors. Safety/PK/PD expansions, mandating paired biopsies, enrolled at doses 0.52-15mg/kg for biomarker assessment in patients with at least HER2 1+ expressing tumors. The primary objective of the Phase 1 study was to evaluate the safety of DF1001. The secondary objective was to assess efficacy. **Results:** As of 8 Dec 2022, 36 patients were treated in the dose escalation and 68 patients were treated in the safety/PK/PD expansion. 63% of the patients were female with a median age of 61 years. Most common tumor types included breast (38%), urothelial carcinoma (10%), esophageal (8%), non-small cell lung (7%) and colorectal (7%) cancer. Treatment Related Adverse Events (TRAE) were reported in 79% of patients. TRAEs were mostly low grade (86% were Grade 1-2) and rarely led to treatment discontinuation. No Grade 4 or 5 TRAEs were reported. The most common TRAEs were infusion related reactions (26%), asthenia (15%) and fatigue (12%). No dose limiting toxicities were detected, and the MTD has not been reached. Best overall response (BoR) of Partial Response (PR) by RECIST 1.1 was observed in 5 patients, with duration of up to 13 months, and 22 patients experienced stable disease (SD), for a Clinical Benefit Rate (CBR) of 39.7%. Responders included patients with refractory lung and breast cancer, whose tumors expressed HER2 1+ to 3+ by IHC. Biomarker analysis in responders demonstrated increases in inflammatory cytokines and chemokines by gene expression profiling, and consonant increases in NK and CD8 cells in the tumor microenvironment, consistent with TriNKET mechanism of action (MOA). **Conclusions:** In this dose escalation study, DF1001 is shown to be a safe and well-tolerated novel NK cell engager therapy targeting HER2. DF1001 monotherapy demonstrates promising anti-tumor activity in treatment refractory patients with a spectrum of HER2 expression as well as MOA consistent pharmacodynamic changes in the tumor. This promising data set supports further exploration of DF1001 alone, and in combination with other compounds, as a potential novel therapeutic option for patients with solid tumors. Clinical trial information: NCT04143711. Research Sponsor: Dragonfly Therapeutics, Inc.

Clinical Science Symposium

Clinical and immune phenotypes associated with immune checkpoint inhibitor-induced autoimmune diabetes. First Author: Karina Nicole Ruiz-Esteves, Massachusetts General Hospital, Boston, MA

Background: ICI-induced autoimmune diabetes (ICI-DM) is an immune-related adverse event (IrAE) that affects approximately 1% of patients who receive ICI. Most reports of ICI-DM suggest that it resembles fulminant type 1 diabetes, with low or absent endogenous insulin production at presentation. However, milder cases have recently been reported, suggesting a more heterogeneous disease. In this study, we identified distinct clinical phenotypes of ICI-DM that may improve individualized approaches to management. **Methods:** We performed a retrospective chart review of 16,582 patients treated with either anti-PD1, anti-PDL1, anti-CTLA4, or combination between 2010 and 2022 in a multi-centered academic hospital system. We identified patients with ICI-DM as those with a new diagnosis of type 1 diabetes or drug-induced diabetes and a prescription for medium- or long-acting insulin following ICI therapy; cases were confirmed by chart review by two board-certified endocrinologists. To phenotype ICI-DM based on endogenous insulin production, we reviewed all patients with ICI-DM who had a C-peptide level in our system, which allowed us to identify and subdivide 57 cases of ICI-DM. These patients were further characterized at both initial presentation and up to 30 months of follow-up. **Results:** We identified six distinct groups of ICI-DM based on the presence (A+) or absence (A-) of diabetes-specific autoantibodies, further divided by level of endogenous insulin production, preserved (B+), low (B+/-) or undetectable (B-). In our cohort, A+B- patients showed to have the lowest time to diagnosis (median 45 days) and high rates of both DKA and hospitalization (67%) at presentation. At the other end of the spectrum, A-B+ patients had a longer time to diagnosis (median 176 days) and no evidence of DKA or hospitalization at presentation. Surprisingly, all groups had similar insulin requirements without significant dosage variations at 30-month follow up. Elevated lipase levels varied widely across groups with the highest rate (66.7%) reported in the A+B- cohort. The prevalence of thyroiditis in our cohort was highest in the A-B- group but did not seem to follow any specific distribution. **Conclusions:** Our study examined the largest data set to date of deep clinical phenotyping of patients with ICI-DM. We define at least three distinct subsets of ICI-DM, with A+B- patients being most similar to the initially described cases of fulminant type 1 diabetes. Patients with negative antibodies seem to have a milder form of the disease. Our findings also suggest significant heterogeneity and distinct underlying mechanisms amongst cases of ICI-DM. Further studies will be needed to elucidate whether these findings could extrapolate to other individual IrAEs, which may also encompass distinct phenotypes with distinct mechanisms. Clinical Science Symposium

First-line treatment of fecal microbiota transplantation for immune-mediated colitis. *First Author: Yinghong Wang, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The management of moderate to severe immune-mediated colitis (IMC) includes immunosuppression with steroids and/or biologic agents. Long-term immunosuppression increases the risk for infections and steroid side-effects. Fecal microbiota transplantation (FMT) is increasingly used for the treatment of refractory IMC but has not been studied in the front-line setting. Here we aim to test the hypothesis that front-line FMT can alleviate IMC symptoms while reducing unnecessary exposure to steroids and their complications. **Methods:** We will report interim data from a prospective clinical trial exploring the efficacy and safety of FMT as a first-line treatment for IMC. To be included, patients had to 1) have symptoms of immune-mediated diarrhea or colitis grade ≥ 2 within 45 days of FMT and 2) not have received any immunosuppressive treatment for IMC or any other indication around the time of FMT. **Results:** Seven patients have been enrolled in the trial thus far. Patients received front-line FMT within a median of 35 days (IQR: 18-57 days) from IMC onset. Five (71.4%) patients had symptom improvement within a median of 1 day (IQR: 1-5 days) after FMT. The only FMT-related adverse events reported were transient fever and self-resolving abdominal cramping in three patients (42.8%) within the first week of FMT. All patients stopped immunotherapy due to IMC. Six (85.7%) were able to resume cancer treatment after FMT with 4 patients (57.1%) resuming immunotherapy. Four patients (57.1%) had colitis remission by the end of the study period, with one additional patient showing signs of symptom improvement but passing away before IMC outcome could be assessed. **Conclusions:** This study is the first to evaluate the safety and efficacy of front-line FMT for the treatment of IMC. While more patients are needed before final conclusions can be drawn, our initial results suggest that FMT can be an effective first-line treatment for IMC that can be delivered in a timely manner and quickly provide symptom relief in a majority of patients while avoiding the use of steroids and allowing the safe resumption of immunotherapy. Therefore, first-line FMT may be a safe and effective steroid sparing alternative to the current standard of care treatment for IMC. Clinical trial information: NCT04038619. Research Sponsor: Adopt a scientist, The University of Texas MD Anderson Cancer Center Internal Funding.

Characteristic	No. (%) (n=7)
Median days from initial IMC to FMT (IQR)	35 (18-57)
Symptom improvement after FMT	5 (71.4%)
Median days from FMT to symptom improvement (IQR)	1 (1-5)
FMT-related complications within 30 days	3 (42.8%)
Colitis remission at the last follow up, n=6	4 (83.3%)

Rapid Abstract Session

Baseline autoantibody profiling in patients with NSCLC with pre-existing autoimmune diseases or who had received prior anti-PD-1 therapy before enrolling in the TAIL study. *First Author: Delys Rodriguez-Abreu, Complejo Hospitalario Universitario Insular-Materno Infantil, Las Palmas De Gran Canaria, Spain*

Background: Patients (pts) with pre-existing autoimmune diseases (AID) and prior immune checkpoint inhibitor (ICI) experience were historically excluded from studies with ICIs. Moreover, about 50% pts with pre-existing autoimmunity have a flare up when given ICI therapies (1). In this post-hoc exploratory analysis, we characterized the baseline autoantibody (AAb) profiles and evaluated its correlation with efficacy and safety outcomes in NSCLC pts with either pre-existing AID or who had prior ICI therapy and received atezolizumab in the TAIL study (2). **Methods:** Plasma samples were obtained from 57 NSCLC pts prior to receiving atezolizumab (TAIL study, NCT03285763). AAb testing was performed using tailored immuno-oncology bead-based antigen arrays comprising 1,340 tumor, AID and immune pathway antigens (3, 4). The cohort includes 39 pts with prior ICI therapy or prior AID (experimental group) and 18 pts without prior ICI therapy or AID (control group). Differences in IgG AABs were compared between the experimental and control group in pts with or w/o irAE and overall survival (OS) longer or shorter than 11.1 months (median OS in overall population in TAIL). Furthermore, the AAb profiles of a subgroup of pts with therapeutic benefit (OS ≥ 11.1 months) and no or low grade irAEs (standard toxicity grade ≤ 2) were analyzed. Statistical analysis included 2-way permutation-based ANOVA (factors: outcome, study group) and Significance Analysis of Microarrays (SAM). **Results:** While pre-treatment AABs were detected in the overall cohort, significant differences in AAB were observed between the experimental and control group at baseline, which were associated with OS and irAEs. In experimental group pts, pre-existing AABs to AQP4 and NCOA1 predicted the development of irAEs. Differences were also observed in AABs predicting longer OS. AABs to CENPT were specifically identified in pts in the experimental group with longer OS, whereas AABs to SOX5 were elevated in pts of the control group with longer OS. In the subgroup of pts with therapeutic benefit and no or low risk of irAE, AABs to IL6, CENPT and the cancer testis antigens NY-ESO-2 and MAGEB2 were elevated in the experimental group. **Conclusions:** This AAB analysis provides important preliminary data in helping to understand the drivers of clinical outcomes with ICIs in pts with pre-existing AID and prior ICI therapy. The findings seem biologically plausible as some of the identified antigens refer to the breach of tolerance to classical AAB targets e.g. CENPT, AQP4 and to an immune response to classic tumor antigens e.g. NY-ESO-2 and MAGEB2. Further validation of the AAB profiling approach is warranted to shed insights on potential therapeutically actionable antigens and generate data orthogonal to efforts to identify biomarkers that are predictive of efficacy and safety outcomes with ICI therapies. Clinical Science Symposium

Identifying molecular targets for rational immunosuppressive strategies in patients with immune checkpoint therapy-induced myocarditis and myositis. *First Author: Bilal Ahmed Siddiqui, MD Anderson Cancer Center, Houston, TX*

Background: Immune checkpoint therapies (ICTs) can induce durable anti-tumor responses but also life-threatening immune-related adverse events (irAEs). Myocarditis, myositis, and myasthenia gravis (MG) are rare, often concurrent irAEs with mortality up to 40%. Steroids are the standard first-line treatment and have significant adverse events with prolonged use. We and others have identified serum autoantibodies in these irAEs, suggestive of B cell contribution to pathogenesis. Furthermore, although prior studies have shown T cells and myeloid cells in inflamed muscle tissue, their specific subtype and role in disease pathogenesis have yet to be defined. This understanding may contribute to the development of more effective immunosuppressive strategies. Hypothesis: In addition to T cells, plasma B and myeloid cells contribute to the pathogenesis of ICT-induced myocarditis, myositis, and MG. **Methods:** We enrolled patients with suspected ICT-induced myocarditis, myositis, and MG on an IRB-approved laboratory protocol. Diagnosis required: 1) symptoms requiring hospitalization; 2) elevated serum markers (creatinine kinase $\geq 5\times$ normal, troponin >99 th percentile or detection of autoantibodies for MG); and 3) positive biopsy, electromyography, or cardiac MRI. Patients underwent standard diagnostic testing (including endomyocardial and/or skeletal muscle biopsy) and treatment as clinically indicated. **Results:** 23 patients were enrolled (n=13, confirmed irAE; n=10, negative control). Most patients received combination ICT (10/13, 77%). Anti-striated muscle and/or acetylcholine receptor binding antibodies were detected in 7/13 patients (54%), including 3 without MG (known to have both T and B cell etiologies). Single cell RNA sequencing of patient tissue (confirmed irAEs: cardiac n=10, skeletal n=9; control: cardiac n=4, skeletal n=5) identified specific populations of myeloid and CD8⁺ T cells conserved between inflamed cardiac and skeletal muscle. **Conclusions:** Specific populations of T cells, myeloid cells, and plasma B cells are potential targets for rational immunosuppressive strategies in ICT-induced myocarditis and myositis and will be tested in murine models to inform future clinical trial design. Research Sponsor: Parker Institute for Cancer Immunotherapy.

Rapid Abstract Session

Targeting CD47 in lymphoid malignancies with CAR T cells. *First Author: Alexander Paul Boardman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Despite major therapeutic advances of chimeric antigen receptor (CAR) T cells directed against CD19 in relapsed and refractory non-Hodgkin lymphoma (NHL), two thirds of patients experience relapse within the first two years. Nearly one third of these relapses are associated with CD19 antigen-loss escape thus leveraging alternate CAR targets may improve outcomes. CD47, an anti-phagocytic "don't eat me" receptor known to be overexpressed in NHL, is an ideal CAR target as it is potentially indispensable for tumor progression. **Methods:** CD47-CAR binding domains were engineered either as a camelid single variable heavy chain nanobody (CD47-VHH-CAR) or as the CD47 binding domain of cognate receptor SIRP α (SIRP α -CAR), each combined with a CD28 costimulatory domain and a CD3 ζ activation domain with two mutated ITAMs (1XX). In vitro co-culture assays were performed with lymphoid mouse tumor cell lines BM185 and A20. For in vivo experiments, syngeneic BALB/c mice were sublethally irradiated for lymphodepletion then injected intravenously with 1×10^5 luciferase⁺ BM185 cells. Two days later, mice were injected with 2×10^6 CAR T cells, and bioluminescence imaging was performed to monitor tumor progression. For bio-localization experiments, CAR T cells were co-transduced with a separate vector encoding luciferase. **Results:** CD47-CAR T cell expansion in vitro was hindered due to fratricide, which can be rescued by CD47 CRISPR knockout. Both CD47-VHH-CAR and SIRP α -CAR T cells exhibited potent and specific in vitro lysis of BM185 and A20 cells. CD47-VHH-CAR T cells showed transient anti-leukemia activity, however, survival was not significantly prolonged. T cell bio-localization analysis revealed that, compared to CD19-CAR T cells, CD47-VHH-CAR T cells exhibited prolonged retention in the thorax with minimal bone marrow trafficking, suggesting CD47 antigen-specific pulmonary sequestration, and inferior expansion. SIRP α -CAR T cells engineered to secrete pro-inflammatory cytokine IL-18 significantly improved CAR T cell expansion, resulting in bone marrow trafficking and clearance of BM185 tumor. However, recipients of IL-18-secreting SIRP α -CAR T cells experienced lethal CAR T cell-related toxicity. To improve the safety of CD47-CAR T cells, we engineered an NFAT-responsive vector expressing the CD47-CAR modified with E. coli-derived dihydrofolate reductase drug destabilization domain to limit CD47-CAR expression to T cells exposed to the stabilizing antibiotic trimethoprim and receiving a licensing NFAT signal from a CD19-CAR. **Conclusions:** In vivo activity of CD47-targeting CAR T cells is limited by thoracic retention and limited expansion, which can be partially overcome by overexpression of IL-18, though enhanced toxicity precludes survival prolongation. Our findings suggest that strategies to spatiotemporally restrict CAR expression or activation will be necessary to achieve safe and efficacious CD47-CAR T cell activity. Rapid Abstract Session

Association of common inherited *NOD2* mutations with exceptional response to immune checkpoint inhibitors. *First Author: Megan Babette Barnett, Garvan Institute of Medical Research, Darlinghurst, NSW, Australia*

Background: Melanomas and lung cancers usually display a large burden of somatically mutated proteins, yet only a subset of individuals can be induced to mount a therapeutic immune response against tumours. Inherited mutations in immune regulatory genes may be one factor predisposing to a heightened immune response with addition of an immune stimulus. **Methods:** Germline whole genome sequencing (WGS) was performed in a patient with exceptional response (ExR) to targeted radiotherapy for metastatic melanoma (complete abscopal response). A target variant gene was identified, and interrogated within a prospectively recruited cohort of patients with ExR or non-response to anti-PD1 for non-small cell lung cancer (NSCLC). Results were experimentally tested in mice and validated in an independent mixed cancer clinical cohort. **Results:** Compound heterozygous variants in *NOD2* were found within the patient with abscopal response (expected genotype frequency 1.3 in 10,000), whose cancer regression occurred concurrently with a flare of pre-existing Crohn's colitis (a *NOD2*-associated condition). Patients treated with anti-PD1 for NSCLC were prospectively recruited (n=144). Individuals with ExR to PD1 were selected, defined by progression-free survival (PFS) ≥ 2 years and ≥ 1 CTCAE grade 2 or higher immune-related adverse event (n=40). Median follow-up was 41 months (median PFS not reached). Patients with best response of progressive disease were selected for comparison (n=18, median PFS 2.76m, 95% CI, 2.1-3.81). WGS from blood was analysed for all human *NOD2* variants known to impair *NOD2* signalling. Of ExR patients, 25% carried 1 or more functional *NOD2* variants, totalling 11 of 80 alleles (13.8%); more than twice the expected allele frequency (6.58%, p=0.0199). Within non-responders, 1 patient carried a variant *NOD2* allele (1 of 36 alleles, 2.78%). The association between *NOD2* loss-of-function and heightened immune response to anti-PD1 was experimentally tested in *Nod2*-null C57BL/6J (*Nod2*^{ts}) mice. *Nod2*^{ts} mice transplanted with a syngeneic cell line and treated with anti-PD1 showed greater tumour response compared with *Nod2*^{wild-type} littermates (60-day OS 41.67% vs 0%, p<0.01). Flow cytometry of tumours showed greater proportion of (CD44^{hi} CD62L^{low}) CD8⁺ and CD4⁺ effector memory differentiated cells within *Nod2*^{ts} versus *Nod2*^{wild-type} animals (p<0.05). Results were validated within an independent clinical cohort (n=105). Overall response rate to PD1 in patients with mutant vs wild-type *NOD2* was 50% versus 15% (p=0.03). **Conclusions:** These results provide four complementary lines of evidence that common inherited defects in the immune regulatory gene *NOD2* promote exceptional immune response following acute triggers to control cancer. *NOD2* may be a biomarker for treatment stratification or a therapeutic target to enhance anti-PD1 response. Rapid Abstract Session

Association of ctDNA tumor fraction with survival in advanced non-small cell lung cancer (NSCLC) treated with maintenance durvalumab in the UNICANCER SAFIRO2-Lung/IFCT1301 trial. *First Author: Filippo Gustavo Dall'Olio, Cancer Medicine Department, Institut Gustave Roussy, Villejuif, France*

Background: ctDNA shed is a promising biomarker for cancer immunotherapy, with patients (pts) having higher concentration of plasma ctDNA being reported to have poorer outcome. Its role in the maintenance setting with immune checkpoint inhibitors remains unexplored. In SAFIRO2-Lung, advanced NSCLC pts were enrolled to receive a platinum-based chemotherapy. After 4 cycles, if stable or in response, pts with no targetable alterations were oriented to the immunotherapy sub-study and randomized between maintenance durvalumab or Standard of Care (SoC) (PMID 35802649). Durvalumab prolonged survival only in the PD-L1 $\geq 1\%$ subgroup. Here we explored Tumor Fraction (TF) as determined by Low-Pass Whole Genome Sequencing as a biomarker for immunotherapy irrespective of PD-L1. **Methods:** SAFIRO2-Lung (NCT02117167) is a multicentric, randomized phase 2 clinical trial. Plasma samples were obtained at randomization, just before maintenance treatment initiation. DNA was extracted using the Maxwell RSC ccfDNA Plasma Kit (Promega, AS1840). Sequencing libraries were prepared using the Low Input SureSelectXT protocol (Agilent, G9916A). Pooled libraries were sequenced on a NovaSeq 6000 platform (Illumina) as 2 × 150 bp paired-end reads (NovaSeq 6000 SP Reagent Kit v1.5). Genomic copy number aberrations and TF were investigated using the ichorCNA (V0.2.0) tool. TF $\geq 2\%$ was considered positive. For the survival analyses, a landmark approach was performed, by considering the randomization date as the landmark time. Progression Free Survival (PFS) was the primary endpoint, defined as the time from randomization until the date of objective radiological disease progression, clinical progression or death. The secondary endpoint was Overall Survival (OS). **Results:** 50 out of 121 plasma samples from pts randomized to durvalumab were analyzed for the feasibility part. 34 pts (68%) were < 65 years, 33 (66%) were male. PD-L1 expression was available for 18 pts and 39% of them had PD-L1 $\geq 1\%$. Median TF was 1.1%, 8 pts (16%) had a TF $\geq 2\%$, ranging from 2.2% to 23.3%. TF at randomization was marginally correlated with the presence of liver metastases (p 0.063) and with the sum of target lesions (p 0.081). No significant correlation was observed with PD-L1 positivity. Pts with TF $\geq 2\%$ had lower median PFS 1.7months (m) (95% CI 1.2 – 4.2) vs 5.8m (95% CI 2.9 – 7.5) for those with TF < 2%, p 0.0003. Similarly, median OS was lower for pts with TF > 2% 10.4m (95% CI 4.2 – 18.7) vs 25.9m (95% CI 18.2 – NR) for those with TF < 2%, p 0.0002. Data will be presented on the whole cohort, including control group receiving SoC, to discriminate between a prognostic or a predictive value of TF. **Conclusions:** TF was positive in 16% of pts randomized to durvalumab in the SAFIRO2-Lung trial. This population seems to have a limited benefit from maintenance durvalumab after induction chemotherapy. Clinical trial information: NCT02117167. Research Sponsor: Unicancer.

Rapid Abstract Session

Intestinal microbiome characterization in immune checkpoint inhibition (ICI) resistant disease. *First Author: Pavlina Spiliopoulou, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: The gut microbiome modifies response to ICI treatment. Despite durable response rates seen with ICI, most pts do not benefit from treatment (primary resistance) or have only a period of disease control (acquired resistance). The Immune Resistance Interrogation Study (IRIS, NCT03702309) is a prospective pan-cancer study that aims at characterizing ICI-resistant disease through multiomic and gut microbial composition profiling. Herein we compare the gut microbial diversity of pts with PR vs AR to PD-1/PD-L1 based treatment as part of the wider IRIS framework. **Methods:** Patients who progressed after anti-PD1/PD-L1-based ICI were classified into 2 groups. Acquired resistance (AR): complete response (CR), partial response (PR) or stable disease (SD) for ≥ 6 months (m) with subsequent (PD) or PD after ≥ 3 m from last dose of adjuvant ICI; or primary resistance (PR): PD at first imaging, SD but progressed ≤ 6 m or progression ≤ 3 m from last dose of adjuvant ICI. Stool samples were collected at time of PD and underwent DNA extraction and metagenomic sequencing. Species-level Shannon diversity indices were calculated and compared using unpaired Wilcoxon test. Principal component analysis (PCA) of Bray-Curtis dissimilarity indices was performed to assess differences in taxonomic composition. **Results:** Stool samples from 62 pts (PR n=38; AR n=24) were evaluated. Tumor types were melanoma n=37 (60%), head and neck n=17/62 (27%), gastrointestinal n=3/62 (5%), gynaecological n=2/62 (3%) and other n=3/61 (5%). Most pts n=59/62 (95%) were treated with palliative intent, and n= 3/62 (5%) with adjuvant therapy. Anti-PD-1/PD-L1 monotherapy was received by 32/62 (52%) pts and n=30/62 (48%) received combination anti-PD-1/PD-L1 with either anti-CTLA-4 inhibition, experimental immunotherapy, chemotherapy, or targeted treatment. The median Shannon diversity index was similar between pts with PR (median: 3.5; range: 2.5 - 4.3) vs AR (median: 3.4; range: 0.9 – 3.9; p = 0.7). There were no differences in composition by group by PCA of Bray-Curtis dissimilarity indices. Abundance testing did not reveal any differentially abundant species between pts with AR vs PR while controlling for antibiotic use within 1m of sampling and type of treatment. No taxa were significantly different between AR and PR; top taxa per group are shown. **Conclusions:** Primary analysis showed no significant differences in gut microbial composition between primary vs acquired resistance to ICI. Comparative analysis between ICI-resistance samples and ICI-naïve samples from historical patient cohorts is underway. These results will be collated with other analyses from IRIS to create a multi-modal characterisation of ICI resistance. Clinical trial information: NCT03702309. Research Sponsor: Princess Margaret Foundation funding.

ICI-resistance	Differentially abundant taxa	Fold change
Primary	Clostridium disporicum	3.6 log fold change, q-val: 0.36
Acquired	Bacteroides fragilis	3.8 log fold-change, q-val: 0.12

Poster Discussion Session

Phase 1 results with anti-CD19 allogeneic CAR T ALLO-501/501A in relapsed/refractory large B-cell lymphoma (r/r LBCL). *First Author: Frederick L. Locke, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Approximately 50% to 60% of pts with r/r LBCL will either not achieve a complete response (CR) or will relapse with current treatments and require additional therapy. Autologous anti-CD19 chimeric antigen receptor T (CAR T) therapies have revolutionized the care of patients whose disease progresses following standard therapies, but patient-specific manufacturing processes and long wait times to treatment present challenges for their broad clinical use. Allogeneic (healthy-donor-derived), off-the-shelf, anti-CD19 (CAR T) treatment promises broader and more rapid access to one-dose treatment with curative intent. Initial phase 1 data for the anti-CD19 AlloCAR T cell product ALLO-501 (NCT03939026) and successor, ALLO-501A (NCT04416984), demonstrated a manageable safety profile with no dose-limiting toxicities (DLTs), and efficacy comparable to autologous CAR T therapy in pts with r/r LBCL who were autologous CAR T-naïve. This update provides additional follow up and a focus on participants who received the conditioning regimen and cells made with an optimized manufacturing process currently under study in the first potentially pivotal trial for an allogeneic CAR T product. **Methods:** In these two multicenter, single-arm, open-label, phase 1 trials, a cohort of autologous CAR T-naïve pts with r/r LBCL underwent 3-day lymphodepletion (LD) with FCA90, fludarabine (F, 30 mg/m²/day), cyclophosphamide (C, 300 mg/m²/day), and ALLO-647 (A [anti-CD 52 mAb] 30 mg/day; total dose: 90 mg) followed by a single dose of ALLO-501 or ALLO-501A produced by the Allo manufacturing process. **Results:** As of Jan 26, 2023, 12 pts received the FCA90 LD regimen and CAR T therapy with 100% receiving product per specifications with a median time from enrollment to LD of 3 days. Median follow-up time (actual) was 7.1 months (range: 1.4, 36.0). No DLTs, severe (Gr3+) cytokine-release syndrome (CRS), immune effector cell-associated neurotoxicity syndrome (ICANS), or graft-versus-host disease (GVHD) events occurred. An overall response rate and a CR rate of 66.7% and 58.3%, respectively, were observed. Median DOR was 23.1 months. Among 8 pts with the opportunity to be followed for 6 months, 5 (62.5%) had achieved CR and 4 (50.0%) sustained CR through 6 months. Analyses of vector copy number pharmacokinetics at Days 28 and 56 documented substantial and sustained expansion of CAR T cells. **Conclusions:** A one-time dose of allogeneic CAR T therapy following LD with FCA90 provided durable responses with a manageable safety profile in patients with r/r LBCL comparable to those treated with autologous CAR T cells. This treatment enables rapid access to off-the-shelf treatment with a median time from trial enrollment to treatment of 3 days. These findings support broader evaluation of ALLO-501A in the ongoing, first potentially pivotal phase 2 trial (ALPHA2) of off-the-shelf allogeneic CAR T cells. Clinical trial information: NCT03939026. Research Sponsor: Allogene Therapeutics.

Poster Discussion Session

CLDN6 CAR-T cell therapy of relapsed/refractory solid tumors ± a CLDN6-encoding mRNA vaccine: Dose escalation data from the BNT211-01 phase 1 trial using an automated product. *First Author: Andreas Mackensen, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany*

Background: We are developing a chimeric antigen receptor (CAR)-T cell therapy targeting claudin 6 (CLDN6), an oncofetal antigen that is undetectable in healthy somatic tissue and highly expressed in various solid cancers. Autologous CLDN6 CAR-T cells are being tested alone and in combination with CLDN6-encoding CAR-T cell Amplifying RNA Vaccine (CARVac), a nanoparticulate RNA vaccine designed to stimulate and expand CLDN6 CAR-T cells. **Methods:** The ongoing first-in-human trial BNT211-01 evaluates the safety and feasibility of CLDN6 CAR-T cell transfer ± CARVac in lymphodepleted patients with relapsed/refractory solid tumors. Patients are pre-screened for CLDN6 expression with a cut-off of 50% positivity of intermediate or strong intensity by immunohistochemistry staining. Key endpoints are safety, tolerability, and anti-tumor activity. Pharmacokinetics of adoptively transferred CAR-T cells in peripheral blood is monitored by quantitative PCR. Dose escalation proceeds according to a classical 3+3 design, testing CLDN6 CAR-T cells at each dose level as both as monotherapy and in combination with CARVac. We previously reported results from 22 patients from 4 dose escalation cohorts with a manual CAR-T production process ± CARVac (ESMO-IO LBA38) which followed the same methodology. We observed durable responses along with a manageable safety profile, in line with commercial CAR-T products used to treat B-cell malignancies. No on-target/off-tumor toxicity and only a single case of (grade 1) neurotoxicity was observed. Given the encouraging efficacy, we have implemented an automated process to scale-up manufacturing. Accordingly, we are repeating the dose escalation with an automated CAR-T cell product, and with a modified CARVac regimen. As of 1st February 2023, 7 patients with epithelial ovarian carcinoma (EOC), 4 with testicular germ cell tumors (GCT), and a further 5 patients with tumors of various indications have been infused with CAR-T cells up to DL2. We intend to submit efficacy, safety and CAR T-cell pharmacokinetics data from 5 cohorts treated with 1x10⁶, 1x10⁷ or 1x10⁸ CLDN6 CAR-T cells ± CARVac with a data cut-off of March 14th, 2023 from ≥17 treated patients as a late-breaking abstract. Clinical trial information: NCT04503278. Research Sponsor: BioNTech SE.

Poster Discussion Session

A phase 1/2a study of T3011, an oncolytic HSV expressing IL-12 and PD-1 antibody, administered via intratumoral (IT) injection as monotherapy in advanced solid tumors. *First Author: Dongmei Ji, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: T3011, a replication-competent, genetically modified, next-generation oncolytic herpes simplex viruses (oHSV), deletes one copy of ICP34.5 and retains ICP47, thus maximizing replication activity and virulence attenuation of the virus. Moreover, T3011 was inserted with biologically active IL-12 and anti-PD-1 antibody genes. Therefore, while lysing tumor cells, T3011 can significantly improve the tumor microenvironment and elicit the body's specific anti-tumor immunity. **Methods:** An open-label, dose escalation and expansion study of T3011 administered via IT injection as a single agent in patients (pts) with advanced solid tumors. Pts who progressed on or were intolerable to the standard of care were eligible and received T3011 IT therapy Q2W in several dose cohorts (2.5x10⁵ ~ 1x10⁸ PFU/mL). The primary endpoints were safety and tolerability. Key secondary endpoints were PK/PD profile, efficacy endpoints including ORR, DCR, DOR, PFS by investigator per RECIST1.1 and OS. **Results:** As of 18 Jan. 2023, 90 Pts received T3011 monotherapy. Median follow-up time is 5.7(0.5-22.5) months. No DLT events were reported. Treatment-related adverse events (TRAEs) were observed in 66.7% pts (≥G3 TRAEs and treatment discontinuation both in 2.2% [2/90]), and treatment-related SAEs occurred in 2.2% (2/90) pts. The most frequently reported TRAEs (≥5%) were pyrexia (21.1%, 19/90), influenza like illness (8.9%, 8/90), TSH increased (6.7%, 6/90), proteinuria (6.7%, 6/90), facial edema, white blood cell count decreased, AST increased and anemia (5.6%, 5/90, each). MTD was not reached, RP2D was determined as 1x10⁸ PFU/mL. Over 80% of pts had viral DNA undetected in their blood, urine and saliva after injection. Moreover, almost all injection site and occlusive dressing samples that tested positive for viral DNA were confirmed to be free of viral activity. The confirmed ORR was 11% (6/55), DCR was 49% (27/55) in 55 pts (HNSCC, sarcoma, melanoma, breast cancer, etc.) treated under RP2D evaluable for tumor response. The median PFS was 2.8 mos (95%CI: 1.84, 4.60) in all 76 Pts received T3011(RP2D). 19 head and neck squamous-cell carcinoma (HNSCC) pts progressed on platinum-based chemotherapy and anti-PD-1/PD-L1 therapy treated with T3011(RP2D), median PFS was 3.9 mos (95%CI: 0.89, NA; 1 pt failed from chemotherapy only for PFS analysis set). 12 HNSCC pts had at least one tumor evaluation post-dose, the confirmed ORR and DCR was 25% (3/12) and 50% (6/12) respectively. **Conclusions:** The safety profile and clinical compliance of T3011 IT therapy are excellent. T3011 injected locally will not spread to blood, urine and saliva, regional shedding doesn't raise the possibility of transmission to the local and systemic environment. The encouraging anti-tumor activity of T3011 monotherapy in advanced HNSCC pts supports further evaluation in phase II studies. Clinical trial information: NCT05602792. Research Sponsor: ImmVira Co. LTD.

Poster Discussion Session

A phase I/II trial investigating safety and efficacy of autologous TAC01-HER2 in relapsed or refractory solid tumors. *First Author: Benjamin L. Schlechter, DFCI/BWH cancer center, Boston, MA*

Background: Despite recent therapeutic developments for patients with advanced, metastatic, unresectable HER2+ solid cancers, significant unmet medical needs still exist, especially in tumors other than breast and gastric. The T cell antigen coupler (TAC) technology is a novel approach to modifying T cells, allowing them to recognize and treat HER2+ solid tumors. The TAC receptor redirects T cells to tumor cells, and upon tumor cell recognition, co-opts the natural T cell receptor (TCR) to yield safer anti-tumor responses versus chimeric antigen receptor (CAR) T cells. In preclinical studies, TAC T cells led to complete tumor clearance in mouse models of human cancer, without any TAC-related toxicities. **Methods:** In the ongoing clinical trial (NCT04727151), TAC01-HER2 treatment of HER2+ solid tumors is hypothesized to result in safe and effective anti-tumor responses. Subjects undergo leukapheresis, bridging therapy (if needed) while their TAC01-HER2 are engineered, lymphodepletion chemotherapy (LDC), and finally TAC01-HER2 infusion. In phase I dose escalation, the primary objective is to evaluate the safety of TAC01-HER2 at increasing doses of 0.3, 0.8, 3, and 8 x 10⁵ cells/kg in HER2+ solid tumors (1+, 2+ or 3+ as identified by immunohistochemistry) in adult subjects who have progressed after ≥2 lines of systemic therapy. Dose limiting toxicities (DLTs) are assessed up to 28 days from cell infusion. In Phase II, dose expansion groups will further evaluate the safety, efficacy, and pharmacokinetics of the optimal TAC01-HER2 dose in HER2+ breast and other solid tumor types. **Results:** As of 10 Feb 2023, 18 patients have been treated in Cohorts 1-4 with breast, colorectal, gall bladder, gastroesophageal junction, gastric, esophageal, lung, and ovarian cancers. One DLT event of grade 3 pneumonitis has been reported in one subject in Cohort 4 (8 x 10⁵ cells/kg). No neurotoxicity has been reported. Most subjects treated at Cohorts 3 and 4 experienced Grade ≤2 CRS which resolved with standard therapy. Twelve subjects have reported a total of 21 serious adverse events, 17 unrelated to TAC01-HER2 except for one Grade 3 pneumonitis, one Grade 1 and two Grade 2 CRS. Most adverse events were related to LDC or the underlying malignancy. At Cohort 2 (0.8 x 10⁵ cells/kg), a partial response was observed in a subject with refractory metastatic gastric adenocarcinoma (3+ HER2) at 1st scan, with a 35% reduction in measurable disease and clinical benefit was maintained for 4 months. A 55% disease control rate was observed at Cohorts 2-4 at 1st scan. **Conclusions:** Dose escalation of TAC01-HER2 is ongoing, with seven subjects treated and three more scheduled in Cohort 4. These results in a heavily pre-treated cancer population show manageable safety and promising clinical activity with a novel T cell therapy that may have broad clinical applicability in HER+ cancers. Clinical trial information: NCT04727151. Research Sponsor: Triumvira.

Poster Discussion Session

Safety and early biologic effects of phase 1 PERIO-01 trial of pressure-enabled drug delivery (PEDD) of TLR9 agonist SD-101 and immune checkpoint inhibition (ICI) in uveal melanoma metastatic to the liver (MUM). *First Author: Kamaneh Montazeri, Massachusetts General Hospital, Boston, MA*

Background: Delivery barriers due to intratumoral pressure and immunosuppression related to myeloid-derived suppressor cells (MDSC) in liver tumors have created challenges for immunotherapy. TLR9 agonists seem to improve response to ICI. PERIO-01 is a first-in-man trial of PEDD of SD-101 using hepatic arterial infusion (HAI) with ICI in MUM. **Methods:** PERIO-01 is an open-label phase 1 trial of SD-101 given by HAI in MUM (NCT04935229). The study consists of dose-escalation cohorts of SD-101 alone (Cohort A), with nivolumab (Cohort B), or nivolumab + ipilimumab (Cohort C). SD-101 is delivered over 2 cycles, with 3 weekly doses per cycle. Blood, liver metastasis (LM) and normal liver biopsies are collected for correlative studies. **Results:** At data cutoff, 33 patients were enrolled, 30 of whom received at least one dose of SD-101, 13 in Cohort A (2, 4, and 8 mg), 15 patients in Cohort B (2 mg and 4 mg) and 2 patients in Cohort C (2 mg). The median age was 63 years of equal gender. Only 3 patients were treatment-naïve and 2 were HLA-A*02:01+ who received prior tebentafusp. Nine subjects had 4-7 LM and 4 had > 10. The median index LM size was 4.7 cm. Only one patient experienced a grade ≥3 adverse event (AE) related to SD-101, which was increased liver enzymes. All AEs related to cytokine release syndrome have been low-grade with the most common being fever (9), chills (5), and dizziness (4). Treatment resulted in high liver drug levels (median at 2 mg = 1540 ng/g and 8 mg = 2325 ng/g, p = 0.035), with only transient exposure in the periphery (< 4 hours) and a maximum peak serum level of 554 mg/ml 30 minutes post-infusion. Increases in serum IL-18 and IFNγ were noted, with highest levels at 8 mg. Expansion of natural killer cells were detected in 9 of 10 patients from flow cytometry data peripherally. Monocytic MDSC levels were decreased in 5 of 5 patients on immunofluorescence, and NanoString analysis revealed decreases in ARG-1 and IDO-1 gene levels up to 100 days from initial treatment. Broad immunostimulatory gene expression changes were noted in tumor and normal liver following SD-101, including increases in IFNB1 and IL-9. Using the available samples from 13 patients, 7 of 10 had decrease in ctDNA, with complete clearance in 3, along with circulating tumor cell decreases in 6 of 13. In cohort B at 2 mg, 5 of 6 with available response data have stable disease with a median duration of disease control of 12 weeks (range = 7.5-24) at data cutoff. **Conclusions:** HAI of SD-101 has been well tolerated and associated with encouraging immunologic activity. Evidence of biologic effects at the lower doses of SD-101 with nivolumab is encouraging and enrollment with escalation continues in Cohorts B and C. Clinical trial information: NCT04935229. The immune microenvironment in hormone positive, HER2 negative breast cancer: A focus on tumour infiltrating lymphocytes, spatial phenotypes and tertiary lymphoid structures. *First Author: Mairi Lucas, St Vincents University Hospital, Dublin, Ireland*

Background: Hormone positive, HER 2 negative breast cancer (ER+/HER2-) has traditionally been considered an immune cold tumour subtype. Research to date indicates that TILs in ER+/HER2- breast cancer may be a negative prognostic marker. However, there is a paucity of data in this area regarding immune subpopulations and spatial phenotypes. Tertiary lymphoid structures (TLS) have been associated with improved prognosis and response to immunotherapy in other solid organ malignancies. We aim to explore the immune microenvironment in early stage ER+/HER2- breast cancer with a focus on tumour infiltrating lymphocytes, spatial phenotypes and tertiary lymphoid structures (TLS). **Methods:** Full face sections of archival tissue samples from patients with early stage ER+/HER2- breast cancer were stained with CD45 antibody (DAKA clone M0701) via the automated Leica Bond III system. Open source digital pathology analysis software, Qupath, was utilised to identify positive cells and calculate the percentage of positive CD45 staining cells (CD45%) within the tumour area. Spatial analysis was done to divide tumour area into three spatial phenotypes; Immune cold -lacking immune infiltrate; Immune excluded- immune cells restricted to the tumour periphery and immune hot - immune cells infiltrating the tumour core. A tissue micro array (TMA) was created and stained manually with a multiplex chromogenic immunohistochemistry panel for CD20/CD3/DCLamp to identify immune subpopulations associated with tertiary lymphoid structures. **Results:** A total of 409 patient samples were included in the analysis. 89% (n=367) of samples had a CD45% of 0-10%. CD45% stratification by 21-gene-recurrence score(RS) into Low, Intermediate and High showed a statistically higher CD45% in those with a High RS compared to Low RS (p value= 0.0015). We identified a trend towards worse disease free survival (DFS) in the CD45%high group which did not reach statistical significance. The immune hot spatial phenotype was associated with a worse DFS (p value = 0.034) with no statistically significant difference in DFS between immune cold and immune excluded phenotypes. The majority of samples had minimal immune infiltrate. Staining with a TLS panel revealed that samples with a significant infiltrate could broadly be divided into T cell only infiltrate or those with the presence of TLS, the significance of this is unclear. **Conclusions:** The majority of ER+/HER2- breast cancer samples had low numbers of TILs, however there is clear heterogeneity within this subgroup. Spatial elements and immune cell subpopulations may further guide the value of TILs in prognosis in this breast cancer subtype. Research Sponsor: Royal College of Surgeons Ireland.

Poster Discussion Session

A phase 1 study of AGEN2373, a novel CD137 agonist antibody designed to avoid hepatotoxicity, in patients with advanced solid tumors. *First Author: Minal A. Barve, Mary Crowley Cancer Research Center, Dallas, TX*

Background: We present results from the completely enrolled monotherapy arm of the first-in-human dose escalation study of AGEN2373, a novel CD137 agonist antibody engineered to maximize efficacy by circumventing the dose-limiting hepatotoxicity reported for prior CD137 agonists (NCT04121676). AGEN2373 binds to a unique epitope of CD137 on effector T and NK cells in the tumor and tumor-draining lymph nodes, promoting co-engagement of activating Fcγ receptors. CD137 (4-1BB) is a tumor necrosis factor receptor superfamily protein and co-stimulatory receptor that promotes anti-tumor activity of adaptive and innate immune cells, making it an attractive target for immunotherapy. **Methods:** 46 patients (pts) received AGEN2373 IV every 2 weeks (Q2W), Q3W, or Q4W at doses between 0.03 and 10 mg/kg in a 3+3 design. Key endpoints included safety, tolerability, PK, preliminary efficacy, and PD markers. Imaging was Q8W. **Results:** Pts were enrolled between Oct 2019 and May 2022 with a median follow-up of 7.2 months. The median age was 64 (range 33-82). The most common tumor types were colorectal cancer, 13 pts (28%) and sarcoma, 8 (17%). Median prior therapies were 4 (range 1-14) including 48% with prior immunotherapy. There were no dose-limiting toxicities (DLTs) and no treatment-related hepatitis. 37% of pts had treatment-related AEs (TRAEs). TRAEs >10% were limited to fatigue (17%) and nausea (15%). There were no G3, 4 or 5 TRAEs. Pharmacokinetic parameters including half-life, clearance, and volume of distribution were consistent with a human IgG1 Fc backbone. Induction of soluble CD137 was dose dependent with 2 mg/kg as the lowest saturating dose and minimum predicted efficacious dose. In 19 pts treated at 2 mg/kg or higher who had at least one post-baseline scan, the overall response rate (ORR) was 11% (n=2); 37% had SD (n=7) resulting in a disease control rate (DCR) (CR, PR or SD) of 47%. Notable responses include: a pt with vulvar SCC who had progressed rapidly on pembrolizumab and had a confirmed partial response (cPR) while remaining on AGEN2373 x 2 mg/kg q2w for ~40 wks, and a pt with ampullary carcinoma with 4 prior regimens had a cPR on AGEN2373 x 6 mg/kg q3w with complete resolution of the pancreatic lesion. A pt with CRPC had a 38% tumor reduction in liver target lesions (confirmed) on AGEN2373 x 10mg/kg q3w but was non-evaluable due to palliative radiation to bone metastases. **Conclusions:** AGEN2373 showed objective responses as monotherapy in heavily pretreated pts with solid tumors and was well-tolerated with no evidence of hepatotoxicity. This distinguishes AGEN2373 from previous CD137-targeted agents that reported dose-limiting hepatotoxicity. Combination therapy with botensilimab, a novel Fc-enhanced CTLA-4 antagonist, is being studied in pts with PD(L)-1 pretreated melanoma. Clinical trial information: NCT04121676. Research Sponsor: Agenus; Gilead.

Poster Discussion Session

A phase 1a dose-escalation study of PY159, a monoclonal antibody targeting TREM1 (triggering receptor expressed on myeloid cells 1). *First Author: Ira Seth Winer, Barbara Ann Karmanos Cancer Institute, Detroit, MI*

Background: This study aimed to characterize the safety of PY159 (an agonist antibody to TREM1 that reprograms immunosuppressive intratumoral myeloid cells) as a single agent and in combination with pembrolizumab in subjects with advanced refractory solid tumors, including subjects refractory to immune checkpoint inhibitors. **Methods:** Two strata were evaluated, PY159 as a single agent and in combination with pembrolizumab, using an accelerated 3+3 dose escalation study design. Dosing was intravenous once every 3 weeks. Disease assessment by RECIST 1.1 was performed every 6 weeks. The single-agent stratum included 7 dose levels of PY159 (range, 0.01–10 mg/kg). The combination stratum included 4 dose levels of PY159 (range, 0.3–10 mg/kg). Pharmacokinetics were evaluated at specified time points. Archival tumor tissue was analyzed for TREM1 expression by immunohistochemistry. Based on preclinical immunohistochemistry data, HR+ HER2- and triple-negative breast cancer, gastric cancer, pancreatic cancer, head and neck cancer, non-small cell lung cancer, and gynecologic cancers were studied. **Results:** Thirty-seven subjects (median age 65 years; range 29–86 years; 22 female and 15 male) with an ECOG PS <2 were enrolled and all but 5 were RECIST-evaluable (3 withdrew consent, 1 sustained a TEAE, and 1 had a DLT, an asymptomatic grade-3 transaminitis). Twenty subjects received single-agent PY159 and 17 received PY159 in combination with pembrolizumab. Four subjects experienced a grade-3 TRAE, 14 a low-grade immune-related reaction, 18 an SAE (related in 2), and 14 an immune-related adverse event (arthralgias). There were no SUSARs. Five subjects sustained high-grade TRAE resulting in discontinuation. TREM1 levels in the tumors ranged from 0 to 15%. Pharmacokinetic parameters were linear beyond the 0.3 mg/kg dose, dose proportional with a half-life of 8–9 days, and unaffected by pembrolizumab. Radiographic response included 2 partial responses (1 each in an ovarian and pancreatic cancer subject) and stable disease in 9 subjects, ranging from 12 to 96+ weeks. Two subjects continue receiving PY159. **Conclusions:** PY159 was well tolerated, with an acceptable safety profile, as a single agent and in combination with pembrolizumab. A dose for expansion was derived and enrollment of subjects with 7 prespecified cancers is ongoing. Clinical trial information: NCT04682431. Research Sponsor: Pionyr Immunotherapeutics.

Poster Discussion Session

First-in-human, phase 1a dose finding of LVGN6051 CD137/4-1BB agonistic antibody with or without pembrolizumab in patients with advanced solid tumors. *First Author: Adil Daud, University of California-San Francisco, San Francisco, CA*

Background: LVGN6051 is a conditional 4-1BB agonistic monoclonal antibody with Fcγ-receptor IIB selective binding in the tumor microenvironment for optimal activity. Preclinical studies showed potent antitumor activity by LVGN6051 alone and in combination with anti-PD-1 antibody. **Methods:** We conducted this first in human (FIH) multicenter phase 1 dose escalation study in the US. Eligible pts with advanced solid tumor malignancies received escalating doses of LVGN6051 alone or in combination with pembrolizumab 200 mg IV Q3W until unacceptable toxicity, progressive disease, or withdrawal of consent. **Results:** As of Jan 23, 2023, 55 pts were enrolled and received LVGN6051 alone with the dose range of 0.003–7 mg/kg (n=18), or combination therapy of LVGN6051 2 mg/kg + pembrolizumab (n=22) or LVGN6051 4 mg/kg + pembrolizumab (n=15). The median age was 58 years (range 20-83) and number of prior therapies was 5; 46 pts (84%) had ECOG PS 1 and 21 pts (38%) had received prior immune checkpoint inhibitors (ICI). In pts who received LVGN6051 alone, the MTD was not reached up to 7 mg/kg and the RP2D was selected as 4 mg/kg IV Q3W for tolerance. The RP2D for combination therapy was established as LVGN6051 4 mg/kg and pembrolizumab 200 mg IV Q3W. Pts received a median of 2.8 months and a mean of 4.0 months (range 0.5 – 19.2) of study treatment. 33 pts (60%) experienced any grade treatment-related adverse events (TRAEs) with noteworthy (> 5%) AST increased (27%), ALT increased (26%), thrombocytopenia (16%), infusion related reaction (IRR) (9%), fatigue (7%), lipase increased (6%), nausea (6%) and chills (6%), 14 pts (25%), 14 pts (25%), 14 pts (25%) and 13 combination therapy, showed ≥ grade 3 TRAEs: AST increased (11%), ALT increased (9%), thrombocytopenia (7%), fatigue (4%), IRR (2%), lipase increased (2%) and nausea (2%). 6 drug-related serious adverse events and 1 DLT (grade 4 thrombocytopenia), all in combination therapy, were reported. In 42 evaluable pts, the disease control rate (DCR) was 50%. Combination therapy showed that target lesions were reduced by 57%, 42% and 48% in melanoma (n=2) and pancreatic cancer (n=1), respectively. Among 11 melanoma pts (10 had progressed on anti-CTLA4 and anti-PD-1 therapy), 2 PR and 5 SD were observed per RECIST 1.1, including one being treated for 19+ months (26+ cycles). Pts with HNSqCC (n=1) and CRPC (n=1) also showed remarkable tumor shrinkage. Paired tumor biopsies for single cell RNAseq biomarker exploration confirmed activation of effector T cells following LVGN6051 treatment. **Conclusions:** We established the RP2Ds of LVGN6051 alone and in combination with pembrolizumab in this FIH phase 1a study. These regimens were well tolerated. Preliminary efficacy data showed encouraging anti-tumor activity in heavily pretreated pts who had progressed on ICI. Phase 1b dose expansion for the combination therapy is ongoing in pts with melanoma, GI malignancies and NSCLC. Clinical trial information: NCT04130542. Research Sponsor: Lyngen Biopharma Holdings Limited.

Poster Discussion Session

A phase 1/2 study of the TORC1/2 inhibitor onataseritib combined with toripalimab in patients with advanced solid tumors. *First Author: Pei Shu, Clinical Trial Center, National Medical Products Administration Key Laboratory for Clinical Research and Evaluation of Innovative Drugs, West China Hospital, Sichuan University, Chengdu, China*

Background: Pre-clinical studies suggest synergistic activity of the combination of inhibitors of mTOR with a PD-1 antibody in solid tumors. Here we report updated results of a phase 1/2 open-label, dose escalation and expansion trial of the oral TORC1/2 inhibitor, onataseritib (ATG-008) in combination with toripalimab (tori), a PD-1 monoclonal antibody, in patients (pts) with advanced solid tumors. **Methods:** This study consists of dose escalation and dose expansion. The primary objective in the dose escalation phase was to evaluate safety and tolerability of onataseritib combined with tori, followed by a dose expansion phase to assess antitumor efficacy and verify the safety and tolerability profile of the combination therapy. Primary endpoints included maximum tolerated dose (MTD), recommended phase II dose (RP2D) and efficacy of the combination. Other endpoints included pharmacokinetics and exploratory biomarkers of drug activity. Prior PI3K/AKT/mTOR inhibitor therapy was excluded, regardless of PD-L1 expression. Onataseritib was administered orally once a day (QD) at three dose levels (15, 20 and 30mg) in combination with tori at the approved dose of 240 mg, once every 21 days (Q3W). **Results:** As of Oct 21, 2022 cut-off, 46 advanced solid tumor pts were enrolled with 10 pts in the dose escalation phase and 36 pts in the dose expansion phase. Median age was 53 years. Baseline ECOG scores were 0 (13 pts) and 1 (33 pts) with a median of 2 prior lines of therapy (0-7); 27 pts had stage IV disease. Twenty-one cervical cancer (CC) pts were enrolled in total with the similar baseline characteristics. No dose-limiting toxicity was reported in dose escalation phase. The study did not reach MTD. Forty-five pts (97.8%) had ≥ 1 TEAEs; 32 (69.6%) pts had grade ≥ 3 TEAEs. The most common grade ≥ 3 TEAEs included lymphocyte count decreased (23.9%), rash (19.6%) and hyperglycemia (10.9%). The RP2D for onataseritib was determined to be 15 mg in combination with the recommended dose of tori. Among the 46 treated pts, ORR was 26.1% (12/46, all confirmed), and DCR was 73.9%. In 21 pts with CC, ORR was 52.4%, including 1 CR and 10 PR, and DCR was 90.5%. One CC pt with negative PD-L1 expression achieved CR and remains on treatment after 883 days. The ORR was 75% (6/8) and 41.7% (5/12) for CC pts with PD-L1 positive and negative expressions, respectively. One CC pt with prior anti-PD-1 therapy also reached PR. Another PR was achieved in nasopharyngeal carcinoma (NPC) for over 2 years. Median PFS in all treated pts and CC cohort was 4.3 months(m) and 7.2 m, respectively. Pharmacokinetic profiles of ATG-008 in combination with PD-1 antibody were similar to ATG-008 monotherapy, across Asia Pacific and U.S. patient populations. **Conclusions:** Onataseritib in combination with tori is tolerable with encouraging response rate and disease stabilisation in pts with advanced solid tumors, especially in CC pts. Expansion enrolment for CC and NPC is ongoing. Clinical trial information: NCT04337463. Research Sponsor: Antengene Corporation.

Poster Discussion Session

AMPLIFY-201, a first-in-human safety and efficacy trial of adjuvant ELI-002 2P immunotherapy for patients with high-relapse risk with KRAS G12D- or G12R-mutated pancreatic and colorectal cancer. *First Author: Eileen Mary O'Reilly, Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY*

Background: RAS mutations occur in 25% of solid tumors with G12D being the most frequent variant. ELI-002 2P is a vaccine comprised of lymph-node targeted Amphiphile (Amph)-modified G12D and G12R mutant KRAS peptides with an Amph-modified CpG oligonucleotide adjuvant designed to expand polyfunctional mutant KRAS-specific T cells. Preclinical amphiphile data (relative to non-amphiphile controls) showed increased immunogenicity, tumor clearance and survival in mouse models. **Methods:** This first-in-human multicenter phase I trial assessed safety, immunogenicity and antitumor activity using a novel adjuvant trial design in patients (pts) with minimal residual disease (MRD) following standard of care treatment. Eligibility: elevated circulating tumor DNA (ctDNA) and/or serum tumor biomarker elevation (CA19-9/CEA), and KRAS/NRAS mutation. In a 3+3 dose escalation, n=22 received a subcutaneous course of 6 prime and 4 booster injections of fixed dose Amph-peptides (1.4 mg), admixed with escalating Amph-CpG-7909 (Table). Dose escalation based on observed safety in first 28 days. Safety, antitumor activity including biomarker reduction/clearance and relapse free survival using Immune Response Evaluation Criteria in Solid Tumors (IRECIST) were assessed. Immunogenicity assessed by direct ex vivo Fluorespot and intracellular cytokine staining of peripheral blood mononuclear cells (T-cell responders = ≥ 2 -fold increase over baseline) and by tumor CD3 immunohistochemistry in subset who underwent a biopsy. **Results:** No dose-limiting toxicities, treatment related SAEs or cytokine release syndrome were observed, and no maximum tolerated dose was identified. Safety: all grade 1, fatigue (19%), headache (19%), and injection site reaction (9.5%). Biomarker reduction was observed in 15/19 (79%) and in 5/5 at highest doses; clearance of MRD was observed in 4/19 (21% - n=2 pancreas, n=2 colorectal). Polyfunctional mKRAS-specific T cell responses observed in 80% of pts (n=12/15), with both CD8+ and CD4+ T cell responses for most, and CD3+ T cells observed on biopsies. The recommended phase 2 dose (RP2D) is 10.0 mg Amph-CpG-7909. **Conclusions:** ELI-002 2P, evaluated in a novel MRD+ trial, was safe with ctDNA and serum tumor biomarker reduction and clearance and notable immune responses. The RP2D is the start dose for a phase 1/randomized phase 2 study evaluating a new seven peptide formulation for G12 D, R, V, S, A, C, and G13D mutated solid tumors (NCT05726864). Clinical trial information: NCT04853017. Research Sponsor: Elicio Therapeutics.

Poster Discussion Session

A phase 1 dose-escalation study of RiMO-301 with palliative radiation in advanced tumors. *First Author: Matthew Koshy, University of Chicago, Chicago, IL*

Background: Nanoscale metal-organic frameworks (MOFs) are a new class of organic-inorganic hybrid nanomaterials constructed from metal centers and organic ligands. Preclinical studies have shown that nanoscale MOFs can enhance the antitumor effects of ionizing radiation via a unique radiotherapy-radiodynamic therapy mode of action, and MOFs plus radiation can enhance the immunotherapeutic effects of immune checkpoint inhibitors. RiMO-301 is a hafnium-based MOF which enhances radiotherapy and checkpoint blockade immunotherapy without showing systemic toxicity in preclinical models. RiMO-301 is the first MOF to enter clinical trials on human patients. **Methods:** This is a multicenter, open-label, first-in-human dose-escalation phase I trial of RiMO-301 [NCT03444714]. The primary objective is to determine the maximum tolerated dose (MTD) of locally injected RiMO-301 with or without the PD-1 inhibitor pembrolizumab in patients treated with concurrent palliative doses of radiation (20 Gy in 5 fractions or 30 Gy in 10 fractions) using a 3+3 design. The MTD is defined as the dose associated with dose-limiting toxicity (DLT) in less than 33% of patients. The secondary objective is to evaluate antitumor response (objective response rate, ORR) using RECIST and iRECIST criteria. **Results:** A total of 25 patients were enrolled and treated with escalating doses of RiMO-301 (relative to tumor volumes). No protocol defined DLT was reported. The observed possibly treatment related adverse events included mild dermatitis radiation, mild dysgeusia, diarrhea, mild hypotension (30 days post treatment) and mild dizziness (30 days post treatment). One patient each experienced a Grade 2 alanine aminotransferase increase 45 days post treatment, a Grade 2 dry mouth, and a Grade 3 pain at the injection site. Nineteen patients were evaluable, with 13 and 6 patients, respectively, for RiMO-301 without and with pembrolizumab treatments. By iRECIST criteria, RiMO-301 without pembrolizumab demonstrated 38.5% (5/13) ORR (1 complete response and 4 partial responses) with 2 additional patients experiencing 20-30% tumor size reduction. RiMO-301 with pembrolizumab exhibited 66.7% (4/6) ORR with the 2 remaining patients showing 15-20% tumor size reduction. Preliminary pharmacokinetic analysis indicated that the hafnium concentrations in the systemic circulation were either below or barely above the level of detection. **Conclusions:** RiMO-301 with or without pembrolizumab was well tolerated and demonstrated promising signs of efficacy in patients with advanced tumors when treated with concurrent palliative radiotherapy. The results support the use of RiMO-301 as a potential radio-enhancer and will prompt further phase 2 studies in the development of RiMO-301 for patients undergoing radiotherapy. Clinical trial information: NCT03444714. Research Sponsor: Coordination Pharmaceuticals Inc.

Poster Session

Phase 1 first-in-human study of PF-07257876, a novel CD47/PD-L1 bispecific checkpoint inhibitor, in patients with PD-1/PD-L1-refractory and -naïve advanced solid tumors. *First Author: Benedito A. Carneiro, Legorreta Cancer Center, Brown University, Providence, RI*

Background: Tumor expression of the antiphagocytic protein CD47 (integrin associated protein) may lead to immunotherapy resistance (IO-R). PF-07257876 is a novel, IgG1, Fc-active, bispecific antibody targeting CD47 and PD-L1 designed to reverse IO-R, decrease anemia risk, and eliminate a priming dose. We report a Phase 1 dose escalation study (NCT04881045) in patients (pts) with advanced solid tumors, both IO-refractory and IO-naïve. **Methods:** The study enrolled pts ≥ 18 yrs with advanced non-small-cell lung carcinoma (NSCLC) and squamous cell carcinoma of the head and neck (SCCHN) with PD-L1 expression $>1\%$ post anti-PD-1/PD-L1 therapy. Pts with other PD-L1+ tumors known to express CD47 were included (prior IO not required). Pts received PF-07257876 at escalating dose levels in 28-day cycles. Primary objectives were safety (dose-limiting toxicity [DLT] rate), tolerability, and determination of Recommended Phase 2 Dose (RP2D). Secondary and exploratory objectives included pharmacokinetics (PK), blood receptor occupancy (RO), CD47 levels by immunohistochemistry (IHC), tissue biopsy findings, and objective response rate (ORR) per RECIST v.1.1. **Results:** As of 200CT2022, 18 pts were enrolled (NSCLC: n = 6; SCCHN: n = 4; other: n = 8). Median (range) age 68 (46–79) yrs. PF-07257876 was given at ascending doses, 150–2400 mg by subcutaneous (SC) injection or SC infusion every 2 weeks. 16 (89%) pts had treatment-related adverse events (TRAEs): Grades 1/2: n = 12 (67%); Grade 3: n = 1 (6%); Grade 4: n = 3 (17%); no Grade 5. Most common TRAEs: injection site reaction/erythema (n = 13, 72%), thrombocytopenia (n = 6, 33%), anemia (n = 5, 28%), and nausea (n = 4, 22%). DLTs occurred in 2 of 3 pts at the highest tested dose (Grade 4 neutropenia and thrombocytopenia, n = 1; Grade 4 thrombocytopenia, n = 1; both pts recovered). One pt with IO-R SCCHN had a confirmed partial response (duration of response 16 wks). ORR was 5.6% (1/18). Drug exposure increase after 1st dose was not dose proportional. Blood RO was $> 95\%$ for PD-L1 and $> 70\%$ for CD47 with drug exposure. All pts' baseline CD47 IHC levels were moderate to high. Pharmacodynamics cytokine profiling showed notable dose-response increases of IFN γ , TNF α , CXCL9/10, CCL3/4, without IL-6 increase. **Conclusions:** PF-07257876 was well tolerated with manageable toxicity. Incidence and grade of anemia or thrombocytopenia were manageable. Target engagement of CD47 and PD-L1 in peripheral blood was high. Innate and adaptive cytokine modulation was observed. Antitumor activity was modest. Expansion is ongoing at 1800 mg. Clinical trial information: NCT04881045. Research Sponsor: Pfizer.

A phase Ib trial of the VEGF fusion protein HB002.1T plus chemotherapy in patients with advanced solid tumors. *First Author: Junli Xue, Department of Medical Oncology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China*

Background: HB002.1T is a recombinant human vascular endothelial growth factor receptor (VEGF)-IgG Fc fusion protein, which functions as a decoy receptor to bind VEGF-A, VEGF-B and placental growth factor (PlGF). In phase Ia, HB002.1T monotherapy showed encouraging anti-tumor activity in gallbladder cancer. **Methods:** This study aimed to evaluate efficacy and safety of HB002.1T plus chemotherapy (mainly based on platinum, paclitaxel, gemcitabine, etc.) in advanced solid tumors. The tumor assessment was evaluated by investigator according to RECIST v1.1. The study included part 1 and part 2, part 1 study was dose escalation (12mg/kg, 16mg/kg Q3W) and dose expansion conducted in patients (pts) with advanced solid tumors, part 2 study was dose expansion (16mg/kg Q3W) in specified tumors (cohort 1: ovarian and cervical, cohort 2: pancreatic, gallbladder and bile duct cancer). **Results:** As of Dec 20, 2022, 68 (42F/26M) advanced solid tumor pts were enrolled in the study with 32 pts in part 1 and 36 pts in part 2. 33.3% pts failed at least 3 lines of therapy before enrollment. 63 (92.6%) pts had stage IV disease. Median age was 58. It is to be noted that 12 efficacy assessment evaluable pts with ovarian cancer (1 with 12mg/kg in part 1, 11 with 16mg/kg in part 2) were all stage IV, which included 3 complete response (CR), 6 partial responses (PR) and 3 stable disease (SD). Median progression free survival (PFS) was 7.3 months and 6-month PFS rate was 58.3%. The ORR and DCR were 75%, 100% respectively. The most common treatment related adverse events (TRAEs) included neutropenia (9/12, 75.0%) and leukocytopenia (8/12, 66.7%). 8 (8/12, 66.7%) pts had grade ≥ 3 TRAEs, which neutropenia (4/12, 33.3%) and leukocytopenia (3/12, 25.0%) were commonly observed. Part 1: In 28 pts whose tumor assessment were available, including 1 gastric cancer patient achieved CR, 11 pts achieved PR (2 gastric, 2 ovarian, 2 cervical, 1 maxillary, 1 lung, 1 parotid, 1 nasopharynx, 1 pancreatic) and 15 achieved SD. Part 2: 32 pts were available for tumor assessment, including 4 achieved CR (3 ovarian, 1 cervical), 10 achieved PR (4 ovarian, 2 cervical, 3 biliary, 1 pancreatic), and 16 achieved SD. Overall, in Part 1 and 2, TRAEs occurred in 64 (64/68, 94.1%) pts. The most common TRAEs were leukocytopenia (28/68, 41.2%), neutropenia (26/68, 38.2%) and proteinuria (25/68, 36.8%). 34 (34/68, 50.0%) pts had grade ≥ 3 TRAEs, which neutropenia (15/68, 22.1%) and leukocytopenia (11/68, 16.2%) were commonly observed. TRAE leading to discontinuation occurred in 3 pts. No death was reported related with HB002.1T. **Conclusions:** The Pts were well tolerated to 12mg/kg and 16mg/kg HB002.1T dose combined with chemotherapy, and HB002.1T showed acceptable safety profile. As well as, promising anti-tumor activity was observed in various tumors, especially in advanced ovarian cancer. More data is being accumulated, and confirmatory clinical trials are being prepared. Clinical trial information: NCT04802980. Research Sponsor: Shanghai Huaota Biopharma Co., Ltd.

Poster Session

A phase 1 dose-escalation study to investigate the safety, efficacy, pharmacokinetics, and pharmacodynamic activity of cln-619 (Anti-MICA/B antibody) alone and in combination with pembrolizumab in patients with advanced solid tumors. *First Author: Judy S. Wang, Sarah Cannon Research Institute at Florida Cancer Specialists, Sarasota, FL*

Background: MICA and MICB are stress-induced ligands upregulated on the majority of human tumors. Engagement of MICA/B by the activating receptor NKG2D on NK cells and several subsets of T cells results in immune-mediated target cell lysis. However, proteases in the tumor microenvironment cleave cell surface MICA/B, enabling immune evasion. CLN-619 is a humanized MICA/B-specific IgG1 monoclonal antibody designed to prevent the proteolytic release of MICA/B, restoring immune-mediated tumor cell lysis. CLN-619 is expected to have broad anti-tumor activity. **Methods:** This phase 1, multicenter, open-label, first-in-human dose-escalation study (NCT05117476) enrolls patients (pts) with advanced solid tumors who progressed on available therapies, were intolerant to treatment, or refused noncurative standard treatment. CLN-619 alone (dose levels (DL) of 0.1, 0.3, 1, 3, 6, 10mg/kg) were administered intravenously every three weeks. Corticosteroid pre-medication for infusion related reaction (IRR) prophylaxis were required starting at the 3 mg/kg DL. A parallel dose-escalation is exploring CLN-619 (DL 1.0 mg/kg and higher) in combination with pembrolizumab. Response (RECIST 1.1) is assessed every 9 weeks. Data from the monotherapy dose escalation are described. **Results:** As of Dec 2, 2022, 23 pts (median age, 63 y, range 47-83) were enrolled, 48% were male and 61% had ECOG PS 1. Major tumor types included colon (4), cervical (3), lung (3) and prostate (3). All pts received prior systemic therapy (median 3, range 1-7); 12 patients had prior checkpoint inhibitor. The median number of CLN-619 cycles received was 2 (range, 0-8). Treatment-emergent adverse events (TEAEs) in $\geq 20\%$ of pts were abdominal pain (26%), nausea (22%), pyrexia (22%), and infusion related reaction (IRR) (22%). IRRs occurred at dose levels of 0.3 mg/kg and higher. All IRR occurred in Cycle 1 and resolved within 3 hours of onset. One case of Gr3 laryngeal edema occurred at the 10 mg/kg DL in the absence of required steroid premedication and led to dose discontinuation. No fatal TEAEs were reported. A nearly dose-proportional increase in CLN-619 exposure was observed between the 0.1 mg/kg and 10 mg/kg dose levels. CLN-619 half-life ranged from 87.6 to 307 hours for DL ranging from 0.1 mg/kg to 6 mg/kg. There was one confirmed complete response in a patient with recurrent salivary gland tumor who progressed following a complete response on a PD-1 blocking agent. Another patient with cervical cancer maintained SD for 9 cycles before progressing. **Conclusions:** CLN-619 therapy was well tolerated at doses ranging from 0.1 to 10 mg/kg and demonstrated monotherapy clinical activity, including objective response in a patient progressing after PD-1. Updated data from the dose-escalation portion of the trial will be presented. Clinical trial information: NCT05117476. Research Sponsor: Cullinan Oncology, Inc.

Poster Session

A phase 1, first-in-human, open-label, dose escalation and dose expansion study of TST005 in patients with locally advanced or metastatic solid tumors. *First Author: Anthony W. Tolcher, NEXT Oncology, San Antonio, TX*

Background: TST005 is a novel bi-functional fusion protein combining a high affinity PD-L1 mAb and a differentiated TGF- β trap with improved stability. In pre-clinical study, TST005 showed no antibody-dependent dependent cytotoxicity (ADCC) or complement dependent cytotoxicity (CDC) activity. **Methods:** This is a Phase 1, dose escalation study with classic 3+3 design to evaluate the safety, tolerability, PK and pharmacodynamic and preliminary anti-tumor activity of TST005 and determine the maximum tolerated dose and/or the Recommended Phase 2 Dose (RP2D). Eligible solid tumor patients who have failed prior standard therapy(ies) and have received no more than one prior immune checkpoint inhibitor (ICI) treatment will be enrolled to receive TST005 intravenous (IV) infusion every 3 weeks until disease progression assessed by the Investigator per RECIST v1.1 and/or immune RECIST, or unacceptable toxicity. **Results:** The study is ongoing at 4 clinical centers in US and China. As of 31 Jan 2023, 18 eligible subjects have been enrolled into different TST005 dose levels: 2 at dose of 1mg/kg, 4 at 3 mg/kg, 4 at 10 mg/kg, 3 at 20 mg/kg, and 5 at the last dose level of 30 mg/kg. The enrollment is still ongoing. No DLT was observed so far. The most common treatment-emergent adverse events (TEAEs) ($> 10\%$) included: fatigue (38.9%), rash (22.2%), anemia (16.7%), myalgia (16.7%), and arthralgia, dehydration diarrhea, dry skin, hematuria, hypokalemia, pruritus, lymphocyte count decreased were 11.1%. 7 patients (38.9%) experienced $\geq$ Grade 3 (G3) TEAEs according to CTCAE V5.0, 1 of whom were considered as related to TST005: it was an infusion related reaction (G3), and caused discontinuation of treatment. Two subjects experienced IRRs (G2 and G3 respectively), both at the dose of 3mg/kg cohort. One subject of 30mg/kg dose cohort presented a squamous cell carcinoma of skin, which is known as a classic side effect of TGF- β directed therapies. The subject was discontinued from study and to receive resection. No treatment-related deaths occurred. TST005 demonstrated a nonlinear PK profile between 1 to 20 mg/kg with calculated $t_{1/2}$ of 4-9 days. ADA was observed in most ADA evaluable subjects, PK at doses ≥ 10 mg/kg were not impacted by ADA. At 20mg/kg, the receptor occupancy increased to $> 90\%$ immediately after infusion and remain at this level up to CD21. Start from 1mg/kg, serum TGF- β 1 was depleted immediately after dosing, sustained to next dose of TST005. 11 subjects had at least one post treatment tumor assessment per RECIST 1.1. 7 subjects (63.6%) had best overall response of SD. No PR or CR had been observed. **Conclusions:** TST005 monotherapy demonstrated a good safety and tolerability, nonlinear PK characteristics and significant target engagement in patients with advanced solid tumors. Continue investigation of TST005 as monotherapy or in combination with other therapies are warranted. Clinical trial information: NCT04958434. Research Sponsor: Suzhou Transcenta Therapeutics Co., Ltd.

Leveraging innate immunity with AFM24, a novel CD16A and epidermal growth factor receptor (EGFR) bispecific innate cell engager: Interim results for the non-small cell lung cancer (NSCLC) cohort. *First Author: Anthony B. El-Khoueiry, University of Southern California, Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Patients with EGFR mutant NSCLC who progress on or after small molecule EGFR inhibitors have only limited treatment options. AFM24 is a tetravalent, bispecific innate cell engager that binds EGFR on solid tumor cells and CD16A on NK cells to redirect and enhance antitumor antibody-dependent cellular cytotoxicity, thus acting independently of the EGFR downstream signaling pathway and EGFR expression levels. The Phase 1 dose escalation phase of the presented study (NCT04259450) established the recommended Phase 2 dose of AFM24 monotherapy at 480 mg based on tolerability, receptor occupancy, and pharmacokinetics (PK). Correlative science data revealed an activation and enrichment of immune cells in the tumor microenvironment. **Methods:** The Phase 2a expansion phase is evaluating 480 mg AFM24 in patients with EGFR mutant NSCLC, relapsed or refractory to ≥ 1 prior lines of therapy; EGFR-positivity is defined as positive staining for EGFR in $\geq 1\%$ of tumor cells per local immunohistochemistry assay. The study follows Simon's two-stage design. The primary endpoint is overall response rate per local RECIST v1.1; secondary endpoints include safety, PK, and immunogenicity. Efficacy per iRECIST is an exploratory endpoint. AFM24 is administered intravenously once weekly in a 28-day cycle. Tumor assessments are performed at initial screening, cycles 2, 4, 6, 8, and every 3 cycles thereafter. **Results:** As of December 2022, 14 patients (median [range] age 55 [37-82]; 12 male; 11 Asian, 3 White) were enrolled; the median number of prior therapies was 2.5 (1-12). Median treatment duration with AFM24 was 6.7 weeks (1.0-26.1). Best objective response in 10 evaluable patients was confirmed partial response in 1 patient (change from baseline -45%); 4 patients exhibited stable disease, 1 was confirmed. Tumor shrinkage occurred in 2 patients with stable disease (-6%, -18%). The tumor control rate was 50%. Treatment-related adverse events (TRAEs) were reported in 13 patients; infusion related reactions (IRRs, 12), dermatitis acniform, neutrophil count decreased, decreased appetite, and myalgia (2 each) were most common. Grade ≥ 3 TRAEs occurred in 4 patients and included decreased neutrophil count (2), lymphopenia, and IRR (1 each). Grade 5 pneumonitis was observed in 1 patient with disease progression and multiple comorbidities; relation to AFM24 could not be ruled out. As of January 2023, enrollment is ongoing; results of the interim analysis will be presented. **Conclusions:** AFM24 demonstrated clinical activity and acceptable safety in heavily pretreated patients with EGFR mutant NSCLC. The novel mechanism of action of AFM24 could add to the therapeutic options for patients with EGFR expressing tumors and is under clinical evaluation as a single agent and in combination with atezolizumab or autologous NK cells. Clinical trial information: NCT04259450. Research Sponsor: Affimed GmbH.

Clinical development of the bispecific PSMAxCD3 antibody CC-1. *First Author: Christopher Hackenbruch, University Hospital Tübingen, German Cancer Consortium (DKTK), Department of Internal Medicine, Clinical Collaboration Unit Translational Immunology, Tübingen, Germany*

Background: While being highly efficient in hematological malignancies, bispecific antibodies (bsAbs), alike CAR T cells, are yet not successful in solid tumors. Moreover, all available T cell-mobilizing strategies cause side effects that endanger patients and, in case of bsAbs, limit applicable doses and thus efficacy. We report on the clinical development of CC-1, a PSMAxCD3 bsAb, in an IgG-based format that induces fully target cell-restricted T cell activity (Zekri et al, EMBO Mol Med, 2020). Targeting PSMA, which is expressed on malignant cells and on the neovasculature, improves accessibility of the tumor site for immune effector cells as critical prerequisite for success in solid tumors. Notably, CC-1 binds a unique PSMA epitope which is expressed on malignant cells both of prostate carcinoma (PC) and 50% of patients with squamous cell carcinoma (SCC) of the lung. **Methods:** A FIH trial evaluating CC-1 with pre-emptive Tocilizumab included patients with metastatic castration resistant prostate carcinoma (mCRPC) (NCT04104607) and consisted of two parts. Dose escalation (n=10-66) using a novel intra-individual dose escalation design to rapidly reach the target dose of 826µg to determine safety, tolerability and maximum tolerated dose (MTD) (Labrenz et al, Pharm Stat, 2022). The dose expansion cohort exposed patients to CC-1 at MTD and explored efficacy to define RP2D (n=14). Our second phase I trial enrolls patients with SCC of the lung (NCT04496674) to receive CC-1 in combination with checkpoint inhibition. Based on the meanwhile available very favorable safety and preliminary efficacy data, a third phase I trial was initiated where CC-1 is evaluated as first line treatment in patients with hormone sensitive biochemical recurrence (BCR) of PC (NCT05646550), where tumor burden is low and accordingly lower side effects and long-lasting efficacy are expected. **Results:** Recruitment in the dose escalation part of the trial in mCRPC has been completed and the target dose was reached and MTD defined without DLT upon treatment of the 9th and 14th patient, respectively. 24 patients completed treatment, with the most frequently observed toxicity being cytokine release syndrome (CRS, max. 2°) (88%). Besides grade 1 to 2 hypertension (46%) and xerostomia (8%), no further CC-1 related toxicities were observed. A rapid and profound decline of elevated PSA levels was observed in all but one patient, with up to 60% reduction compared to baseline. So far 5 patients received multiple treatment cycles at MTD-level. One patient with SCC of the lung has been treated and CC-1 was escalated up to 153µg without occurrence of CRS. In the phase I trial in BCR of PC, the first three patients were enrolled in February 2023. **Conclusions:** CC-1 is a promising compound with a favourable toxicity profile and promising clinical activity. Details on study designs and updated data from the 3 clinical trials will be presented at the meeting. Clinical trial information: NCT04104607, NCT04496674, NCT05646550. Phase Ib/Ia safety and efficacy of PM8002, a bispecific antibody targeting PD-L1 and VEGF-A, as a monotherapy in patients with advanced solid tumors. *First Author: Ye Guo, Shanghai East Hospital, School of Medicine, Tongji University, Shanghai, China*

Background: PM8002 is a bispecific antibody targeting both PD-L1 and VEGF-A. We had completed dose escalation from 1mg/kg to 45mg/kg and had not found DLT/MTD. In a Phase Ib dose expansion and Phase Ia studies we are evaluating the safety and preliminary anti-tumor activity of PM8002 as a monotherapy. Here, we provide an update of PM8002 Phase Ib/Ia results. **Methods:** During Phase Ib dose-expansion and Phase Ia studies, the majority of patients received PM8002 at 20mg/kg Q2W or 30mg/kg Q3W as a monotherapy (recommended phase II doses). The primary endpoint was ORR with secondary endpoints/objectives including safety. **Results:** As of Feb 3, 2023, 263 patients of advanced solid tumor with prior 0 to 4 line systematic treatment had been enrolled (1mg/kg Q2W [n=1], 10mg/kg Q2W [n=1], 20mg/kg Q2W [n=190], 20mg/kg Q3W [n=4], 30mg/kg Q2W [n=4], 30mg/kg Q3W [n=52], and 45mg/kg Q3W [n=11]). The median duration of exposure was 10.6 weeks (range, 0.1—51.0). Of the 263 enrolled patients, 211 had completed their first evaluation for efficacy. The overall ORR, regardless of tumor type, was 15.2% (32/211) with 32 PRs (20 confirmed PRs), and the DCR was 75.4% (159/211) per RECIST 1.1. Twenty-five patients with cervical cancer had an ORR of 28% (7/25). Twenty-six patients with renal cell carcinoma had an ORR of 26.9% (7/26). Twenty-six patients with platinum-resistant ovarian cancer had an ORR of 15.4% (4/26), and 27 patients with NSCLC (with EGFR mutations) had an ORR of 18.5% (5/27). Any-grade TRAEs occurred in 68.8% patients (181/263), with 18.3% Grade ≥3 (48/263). The most common TRAEs were proteinuria (17.5%), hypertriglyceridemia (11.4%), Aspartate aminotransferase (9.9%), Alanine aminotransferase increased (9.5%), Hypoalbuminemia (8.7%), and increased gamma-glutamyl transferase levels (6.8%). Thirty-six patients (13.7%) discontinued PM8002 due to TRAEs. No death-related cases occurred, and most patients remain on treatment. **Conclusions:** PM8002 showed encouraging antitumor activity and good safety in patients with advanced solid tumors. Phase Ib/Ia of PM8002 as a monotherapy and Phase II combination trials of PM8002 with chemotherapy are ongoing for multiple indications. Clinical trial information: ChiCTR2000040552. Research Sponsor: Biotheus Inc.

Poster Session

Preliminary results of a phase I dose escalation study of IMM2510, a PD-L1 and VEGF bispecific fusion protein, in patients with advanced tumors. *First Author: Xiangdong Cheng, Zhejiang Cancer Hospital, Hangzhou, China*

Background: It is well established that anti-PD-1/PD-L1 and anti-VEGF therapies have excellent synergic effects. Previous clinical trials showed that immunotherapy using anti-PD-1/PD-L1 combined with various VEGF/VEGFR targeting agents achieved better efficacy for advanced tumors. IMM2510 is a novel bispecific fusion protein targeting PD-L1 and VEGFs with good efficacy and safety profile verified by our preclinical study. Here we report the preliminary data of an ongoing phase I dose escalation clinical trial of IMM2510 in human. **Methods:** A phase I, multicenter, open labelled, dose escalation study, was designed to evaluate the safety, efficacy, pharmacokinetics (PK) and pharmacodynamics (PD) of IMM2510. Patients (pts) with advanced solid tumors who had undergone more than two prior lines of PD-1/PD-L1 or antiangiogenic inhibitor therapies were excluded. IMM2510 was administered intravenously Q2W by using accelerated titration (0.007 mg/kg, 0.03 mg/kg) followed by 3+3 dose escalation design (0.1 mg/kg, 0.3 mg/kg, 1.0 mg/kg, 3.0 mg/kg, 6.0 mg/kg, and 10.0 mg/kg) to evaluate the safety and to determine recommended phase II dose (RP2D). Anti-tumor activity was evaluated based on RECIST v1.1. **Results:** As of Dec 15, 2022, 22 pts had received IMM2510 at 8 dose levels (0.007 mg/kg-10.0 mg/kg), the median age was 55.5 yrs, the median prior line of therapy was 3, ranging 1-12. No DLT was observed. The most common TRAEs (≥ 20%) were infusion related reaction (IRR) (63.6%), diarrhea (22.7%), anemia (22.7%). 4 pts experienced G3 TRAEs, including IRR (4.5%), diarrhea (4.5%), pain in extremity (4.5%), C-reactive protein increased (4.5%), prolactin increased (4.5%) and lymphocyte count decreased (4.5%). No G4/G5 TRAE occurred. MTD had not been reached. Based on 17 evaluable pts, 1 confirmed PR was observed after 24-week of treatment at 3.0 mg/kg in an ongoing patient with lung squamous cell carcinoma who was IO resistant to prior therapies. Additionally, SDs were seen in 4 patients (1 ovarian serous carcinoma at 0.1 mg/kg, 1 cervical squamous cell carcinoma at 3.0 mg/kg, 1 malignant pleural mesothelioma at 6.0 mg/kg, and 1 breast invasive ductal carcinoma at 10.0 mg/kg). After the cut-off date, another NSCLC patient at 10.0 mg/kg achieved PR after 9-week of treatment and was ongoing on the study. Preliminary PK analysis demonstrated that T_{1/2} of IMM2510 was around 6 days at the high dose levels. PD data showed that at doses of 3.0 mg/kg or greater, the circulating VEGF-A was completely blocked after first administration till the end of treatment. **Conclusions:** These data indicated that IMM2510 is well tolerated at the dose levels evaluated, and preliminary anti-tumor efficacy in solid tumors is encouraging. The phase I/II is ongoing. Clinical trial information: chict20211203. Research Sponsor: ImmuneOnco Biopharmaceuticals (Shanghai) Inc.

Preliminary results of a phase 1/2, first-in-human, open-label, dose escalation study of ZL-1211 (anti-Claudin 18.2 mAb) in patients with unresectable or metastatic solid tumors. *First Author: Sunil Sharma, Honor Health, Scottsdale, AZ*

Background: ZL-1211 is a humanized immunoglobulin G1 monoclonal antibody targeting Claudin18.2. Site mutations (S239D and I332E) were introduced in the Fc portion of ZL-1211 to enhance antibody dependent cellular cytotoxicity. Herein, we present the preliminary results from the ongoing dose escalation part of the study. **Methods:** This is a first-in-human, phase 1/2, multicenter, dose escalation/cohort expansion study of ZL-1211 administered intravenously to adult patients with Claudin 18.2-positive advanced solid tumors. A Bayesian optimal interval design with 3+3 run-in was adopted to assess 5 dose levels of ZL-1211 monotherapy (1 to 40 mg/kg biweekly) for phase 1 dose escalation, followed by phase 2 cohort expansion. The primary objectives were to determine the maximum tolerated dose and/or the recommended phase 2 dose, assess the safety/tolerability, and evaluate the preliminary antitumor activities of ZL-1211. Tumor assessments were performed every 8 weeks per RECIST v1.1. Blood samples were collected for pharmacokinetic (PK) analyses. **Results:** As of Dec 12, 2022, 19 patients (11 pancreatic cancer, 6 gastric cancer, 1 esophageal cancer, and 1 bile duct cancer) had been enrolled in the dose escalation phase to receive ZL-1211 at 1 mg/kg (n = 3), 5 mg/kg (n = 7), 10 mg/kg (n = 4), and 20 mg/kg (n = 5). The median age was 60 years and the majority of the patients (78.9%) received ≥ 2 lines of prior systemic therapy. No dose limiting toxicities (DLT) had been observed as of the cut-off date. The most common treatment-related adverse events (TRAEs) were gastrointestinal disorders, including nausea (11/19, 57.9%), vomiting (6/19, 31.6%), and abdominal pain (3/19, 15.8%). Other common TRAEs (≥ 15%) were hypoalbuminaemia (3/19, 15.8%) and infusion-related reactions (3/19, 15.8%). Grade 3 TRAEs occurred in 3 patients, 1 with nausea and vomiting, 1 with platelet count decreased, and 1 with anaemia, leukopenia, platelet count decreased, and weight decreased. No Grade ≥ 4 TRAEs were reported. Two patients experienced serious TRAEs: 1 reporting 2 cases each of grade 3 vomiting and nausea and 1 reporting a grade 3 platelet count decreased and a grade 2 abdominal pain, all of which had recovered. TRAEs led to treatment interruption in 5 patients (26.3%) and treatment withdrawal in 1 patient (5.3%). No TRAEs leading to death were reported. Six of 9 tumor-evaluable patients achieved stable disease as the best overall response. Three patients had tumor regression: 17.1% in a pancreatic cancer patient of the 5 mg/kg cohort; 14.5% in a pancreatic cancer patient and 24.9% in a gastric cancer patient in the 10 mg/kg cohort. Preliminary PK analyses revealed linear PK of ZL-1211 over the dose range tested. **Conclusions:** ZL-1211 displayed an acceptable safety/tolerability profile to date and demonstrated preliminary antitumor effects. Clinical trial information: NCT05065710. Research Sponsor: Zai Biopharmaceutical (Suzhou) Co., Ltd.

A phase 1/2 study of a first-in-human immune-stimulating antibody conjugate (ISAC) BDC-1001 in patients with advanced HER2-expressing solid tumors. *First Author: Bob T. Li, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: BDC-1001 is a HER2-targeted immune-stimulating antibody conjugate (ISAC), designed to trigger local activation of the innate immune system and generate a durable tumor-targeted adaptive immune response. BDC-1001 incorporates a trastuzumab biosimilar (EG12014) conjugated to a proprietary TLR7/8 agonist using a non-cleavable linker and a cell membrane-impermeable payload. An international phase 1/2 study was initiated to evaluate the safety of BDC-1001 ± nivolumab (nivo) and to identify the recommended phase 2 dose (RP2D) considering PK/PD analyses and preliminary efficacy. **Methods:** Dose-escalation (3+3, +backfills) enrolled patients (pts) with HER2-positive (amplified, or IHC 3+) or HER2 low (IHC 2+ and not amplified) solid tumors who had progressed after standard therapies. BDC-1001 was given IV q3w, q2w, or q1w as monotherapy (mono; n=91) and q2w or q1w with nivo 240 mg q2w (combo; n=27). **Results:** As of Nov 23, 2022, 118 pts with 16 different tumor types, were enrolled with BDC-1001 doses ranging from 0.15 to 20 mg/kg. Mean age was 61 yrs with a median of 4 and 5 prior lines of therapy (range, 1-11; 1-14; prior anti-HER2 therapy (HER2Tx) [66%/70%], immunotherapy (IO) [23%/22%]) for mono and combo, respectively. Median follow-up time was 5.0-6.1 months. Treatment was well tolerated with only 1 DLT (Gr3 supraventricular tachycardia) at 8 mg/kg q1w combo cohort. Low-grade IRRs were the most common related TEAEs (mono, 26.5%; combo, 25.9%). A related SAE (Gr4, bronchopulmonary hemorrhage) was seen in 1 pt (mono, 1.1%). Antitumor activity was observed at a range of doses and malignancies. There were 4 confirmed (RECIST 1.1) durable PRs (all in MSS tumors with low/intermediate TMB, prior Tx: 1 HER2Tx, 1 IO) including 1 pt with colon cancer (CRC) in the 5 mg/kg q3w mono cohort, and 3 in the 20 mg/kg q2w cohorts (mono 1/7; combo 2/7; ovarian, biliary, and rectal cancers). After the data cut, an additional PR (unconfirmed) was reported at week 6 in a pt with CRC receiving 12m/kg 1wq combo. Ten additional pts had SD lasting ≥6 months (8 mono; 2 combo; prior Tx: 6 HER2Tx, 1 IO; e.g., ovarian, endometrial, colorectal, gastric). Durable SDs were most frequent in the q2w cohorts. BDC-1001 exposure (e.g., C_{min}) correlated with activity among pts in q2w cohorts. Increases in myeloid and T cell infiltration markers in post-Tx tumor biopsies align with mechanism of action (MoA). No anti-drug antibodies were detected. **Conclusions:** BDC-1001 mono and combo were well-tolerated. Targeted serum exposure levels were achieved, and encouraging clinical activity was noted in heavily pretreated pts with various HER2 positive tumors, especially in the 20 mg/kg q2w cohorts. Immune biomarker changes from plasma and tumor were consistent with MoA of this ISAC. These data support further development of BDC-1001 with phase 2 expansion in HER2-expressing solid tumors at the RP2D. Clinical trial information: NCT04278144. Selective recognition of over-expressed self-antigens in solid tumors using calibrated CAR-T therapy. *First Author: Farzad Haerizadeh, Bio4t2, San Diego, CA*

Background: CAR-T has shown promise in patients with a subset of solid tumors. Future development depends on identifying CAR-T that differentiate between normal and malignant cells. The PrismCore platform develops CAR-T targeting self-antigens using three principles: 1) identification of targets uniformly expressed on solid tumors, 2) over-expression on the surface of invasive cancers compared to healthy cells, and 3) elevated levels linked to tumor aggressiveness. PrismCore produces CAR-T for treating multiple solid tumor types by calibrating T-cell activity against self-antigens only when present at elevated densities. **Methods:** PrismCore generates CAR-T by combining computational biology with empirical observations to target over-expressed self-antigens. Proto-libraries of CARs are created using synthetic single-domain antibodies and structural/signaling components. Bio-screening is performed using combinatorial libraries generated through computational simulation. Lead CAR-T are identified through iterative *in vitro* and *in vivo* testing and evaluated for safety in non-human primates (NHP). **Results:** PrismCore platform has identified engineered T cells against several self-antigens, with the first CAR-T, termed B4t2-001, advanced to clinical testing against the target BT-001. Libraries (1E10 to 1E11) of camelid antibodies were designed, synthesized, and assessed. Selected antibody variants subsets were combinatorially assembled into CAR-Ts and rigorously screened against gradient of BT-001. Six candidates were advanced to further testing in mice to evaluate anti-tumor effect and sustained *in vivo* biological activity. B4t2-001 was evaluated in NHP that express basal levels of BT-001. No toxicity observed despite measurable circulating CAR-T and *in vitro* activity to NHP BT-001 when at high density. The turnaround from target selection to B4t2-001 for clinical evaluation was six months. **Conclusions:** We report pre-clinical data for B4t2-001 that safely and effectively targets BT-001 when overexpressed on tumors. This is a novel target for T-cell therapy and is at elevated levels on multiple different types of solid tumors. BT-001 participates in pathobiology, tumor invasion as well as metastasis, and level of expression inversely correlates with overall survival. B4t2-001 demonstrated target density-dependent response, potency, durability of effect and safety in preclinical models and is undergoing phase I clinical evaluation (NCT05621486) in patients with different types of solid tumors. Research Sponsor: Bridgeway Group.

Peri Cruiser CAR-T: An innovative platform to reduce on-target off-tumor toxicity of CAR-T therapy. *First Author: shuangshuang zhang, Suzhou Immunofoco Biotechnology Co., Ltd, Shanghai, shanghai, China*

Background: On-target off-tumor toxicity is a significant concern in Chimeric Antigen Receptor (CAR)-T therapies, especially for solid tumors, leading to adverse effects on normal tissues and impacting on treatment efficacy. To address this challenge, a modified form of CAR-T cells named Peri Cruiser CAR-T has been developed by using miRNA technology to knock down three adhesion genes that mediate T cell trans-endothelial migration to normal tissues, aiming to block the extravasation of CAR-T cells so that the on-target off-tumor toxicity could be prevented without compromising anti-tumor efficacy. In this study, we provided a proof of concept by using the epithelial cell adhesion molecule (EpCAM) as a targeting tumor-associated antigen (TAA). **Methods:** An miRNA cassette was incorporated into the vectors of anti-human or mouse EpCAM CARs. The knockdown efficiency, endothelial adhesion efficiency, effector functions and memory phenotypes *in vitro* were evaluated. To determine the toxicity *in vivo*, the anti-mouse EpCAM CAR-T cells were administered to non-tumor bearing NSG mice, and the body weight and T cell infiltration in normal tissues was evaluated. Anti-tumor efficacy was also evaluated in NSG mice with subcutaneous and metastatic tumor models by anti-human EpCAM CAR-T cells. **Results:** Our Peri Cruiser CAR-T platform was capable to effectively downregulate the target genes by 10 folds. The knockdown is stable after extended culture and antigen engagement *in vitro*. This knockdown of targeted genes significantly decreased T cell adhesion to endothelial cells and corresponding ligands, but did not affect T cell activation or effector functions such as cytotoxicity and IFN gamma release. Surprisingly, lowering the levels of these adhesion molecules improved the memory phenotypes of CAR-T cells as indicated by increased portion of CCR7+CD45RO+ cells. *In vivo* studies showed that conventional EpCAM CAR-T-injected mice experienced severe weight loss and all had to be sacrificed before day 8, the IHC staining of CD3 revealing massive infiltration of T cells in lung, liver, and kidney. However, the incorporation of the miRNA cassette prevented T cell infiltration in normal tissues, reversed the toxicity, and ensured the survival of all mice. The anti-tumor efficacy of these T cells was evaluated *in vivo* and found to decrease metastasis as effectively as the conventional CAR-T cells in a metastasis model of HCT116-Luc, although there was a slightly but not significantly decreased efficacy in a subcutaneous model of HCT116. **Conclusions:** The Peri Cruiser CAR-T platform can significantly improve the safety of CAR-T cells without compromising their efficacy to eliminate tumor cells in primary site and metastasis. This technology opens another avenue to safely target a variety of other TAA by CAR-T even when there is the potential of on-target off-tumor toxicity in normal tissues for those antigens. Poster Session

A phase 1/2 study of the safety, tolerability, and preliminary efficacy of the anti-GITR monoclonal antibody, INCAGN01876, combined with immunotherapies (IO) in patients (Pts) with advanced cancers. *First Author: Martin Gutierrez, Hackensack University Medical Center, Hackensack, NJ*

Background: INCAGN01876 is a GITR agonist designed to induce antitumor immunity by promoting effector T cells while inhibiting Tregs. Recent clinical studies suggest that combining IO with immune agonists such as INCAGN01876 may extend clinical benefit in pts with cancer. **Methods:** This global open-label nonrandomized phase 1/2 study assessed the safety, tolerability, recommended phase 2 dose (RP2D), and efficacy of INCAGN01876 + nivolumab (NIVO) and/or ipilimumab (IPI) (NCT03126110). Eligible pts (≥18 y) had locally advanced/metastatic cancer. Phase 1 (dose escalation) consisted of 4 treatment groups: A, INCAGN01876 1, 3, 5, 10 mg/kg Q2W + NIVO 240 mg Q2W; B, INCAGN01876 1, 3, 5, 10 mg/kg for 2 doses then NIVO 240 mg Q2W; C, INCAGN01876 1, 3, 5 mg/kg Q2W + IPI 1 mg/kg Q6W; D, INCAGN01876 1 mg/kg Q2W + NIVO 3 mg/kg Q2W + IPI 1 mg/kg Q6W. INCAGN01876 RP2D was assessed via a 3+3+3 design. Phase 2 (dose expansion) evaluated INCAGN01876 RP2D in combination IO in select tumors; data will be presented elsewhere. **Results:** As of Nov 9, 2021, 51 pts (A, n=17; B, n=13; C, n=15; D, n=6) were enrolled (most common tumors: breast, gastric, and ovarian [each n=8]; prior PD-(L)1 therapy, n=12). One pt in D had DLTs (nonserious grade [gr] 3 pruritus and rash); MTD was not reached; INCAGN01876 300 mg Q2W was selected as RP2D. All pts in A, B, D, and 93.3% in C had TEAEs. Twenty-six pts had gr ≥3 TEAEs (A, n=10; B, n=5; C, n=7; D, n=4), most commonly, pneumothorax (A [5 mg/kg], n=2) and anemia (B [1, 5 mg/kg], n=2; C [1, 3, 5 mg/kg], n=3). INCAGN01876-related TEAEs occurred in 8, 6, 10, and 5 pts in A, B, C, and D, respectively. Most common immune-related AEs in A: pruritus (gr 1/2, n=2); in B: rash (gr 1, n=2), simultaneous rash and pruritus (gr 1, n=4); in C: pruritus (gr 1/2, n=2), rash (gr 1, n=2), simultaneous rash and pruritus (gr 1, n=2); in D: simultaneous pruritus and rash (gr 3, n=1); 3 pts (A [1 mg/kg], n=1; C [3 mg/kg], n=1; D, n=1) had infusion-related reactions. One pt in A (10 mg/kg Q2W) discontinued treatment due to a pneumonia TEAE. Best unconfirmed overall responses (per RECIST v1.1) were 1 complete response (CR; duration of response [DOR], 1065 days) in renal cancer and 1 partial response (PR; DOR, 573 days) in breast cancer in A; 1 CR (DOR, 876 days) in cervical cancer in B; 1 PR (DOR, 169 days) in ovarian cancer and 1 PR (DOR, 281 days) in lung cancer in C; none in D. The disease control rate was 35.3% in A, 23.1% in B, 33.3% in C, and 0% in D. **Conclusions:** INCAGN01876 plus NIVO and/or IPI was generally well tolerated in pts with advanced tumors; most common toxicities were mild to moderate pruritus and rash. No novel safety signals were seen. INCAGN01876 300 mg Q2W was selected as RP2D based on safety and preliminary PK/PD data and used for expansion in combination with NIVO or IPI. Clinical trial information: NCT03126110. Research Sponsor: Incyte Corporation.

Effect of a novel expansion process on tumor-infiltrating lymphocyte (TIL) polyfunctionality, cytotoxicity, and expansion, while preserving cells in a less differentiated and more stem-like phenotype. *First Author: Andrew Yuhas, Iovance Biotherapeutics, Inc., San Carlos, CA*

Background: Adoptive cell therapy using autologous TIL has shown durable responses in patients with metastatic melanoma and some epithelial tumors (Chesney *JITC* 2022; Schoenfeld *SITC* 2021; O'Malley *SITC* 2021). Data suggest that maintaining a higher proportion of less differentiated and more stem-like TIL can associate with persistence and response in patients with metastatic melanoma (Krishna *Science* 2020; Rosenberg *Clin Cancer Res* 2011). Here, we describe a novel TIL expansion process that increases TIL expansion and preserves cells in a less-differentiated and more stem-like phenotype with enhanced functional output. **Methods:** Tumors of various histologies, including lung, breast, and renal cancer, were fragmented and expanded using either a standard process or a newly developed process that uses a different combination of cytokines during the pre-rapid expansion protocol (pre-REP) stage and another combination of cytokines and a pathway inhibitor during the REP stage to control T-cell activation and differentiation. The expansion potential, viability, and phenotypic and functional attributes of the final TIL products were evaluated by a variety of assays. **Results:** When compared with standard TIL expansion, the novel process increased yield and viability while preserving TIL in a less differentiated and more functional state, as evidenced by increased expression of the memory-associated markers CD27, CD28, CD62L, and IL-7R, with reduced expression of the activation markers CD38, CD39, and CD69, and lower levels of the inhibitory markers LAG3, TIM3, TIGIT, and TOX. Importantly, the novel process led to a pronounced increase in the tumor-homing marker CXCR3 as well as TIL polyfunctionality as evidenced by increased co-expression of IFN γ , TNF α , and IL-2 while showing an enrichment in genes associated with stem-like cells and a reduction in exhaustion-associated genes. Pseudotime trajectory analysis also demonstrated that the new expansion process maintained TIL in a less differentiated and more stem-like state. Together, these phenotypic and functional characteristics translated into increased cytotoxicity even after repeated stimulation. **Conclusions:** Our novel TIL expansion process improves multiple metrics that correlate with both TIL persistence and response, including enhanced polyfunctionality, reduced inhibitory receptor expression and a less differentiated and more stem-like phenotype, while increasing yield. These effects may translate into a more vigorous and less differentiated TIL infusion product with improved cytotoxicity and persistence. A pilot study of lymphodepletion intensity for PBMC-derived, neoantigen-specific CD8+ T cells (Neo-Ts) therapy in patients with advanced solid tumors. *First Author: Dandan Li, Biotherapy Center, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Adoptive T cell therapy (ACT) using neoantigen-specific CD8+ T cells (Neo-Ts) derived from patient PBMC was recently developed aiming to target individual patient's unique tumor mutations and increase treatment efficacy. But the optimal lymphodepletion intensity for Neo-T therapy has yet to be determined. **Methods:** In this phase I clinical trial (NCT02959905), we generated Neo-Ts from patients with locally advanced or metastatic melanoma or colon cancers that were refractory to standard therapies, and evaluated the effects of lymphodepletion at various dosages (high: 2x500 mg/m² cyclophosphamide and 2x25 mg/m² fludarabine; low: 1x500 mg/m² cyclophosphamide and 2x25 mg/m² fludarabine; and no lymphodepletion) during Neo-T therapy. The primary end point was safety and the secondary end point was objective response rate (ORR). **Results:** We showed that Neo-T therapy was safe with lymphodepletion at dosages from no lymphodepletion to high intensity. The median PFS was 7.1 months (95% CI: 3.7-9.8), and median overall survival (OS) was 16.8 months (95% CI: 11.9-31.7). The ORR was 33.3% (3/9) among all groups. Three patients achieved PR, two of them were in the group without lymphodepletion. One of the PR patients refractory to prior anti-PD-1 therapy also responded to Neo-T therapy. Neoantigen specific TCRs were examined in two responding patients and showed expansion and persistence after treatment. **Conclusions:** Neo-T therapy with low intensity lymphodepletion or no lymphodepletion could be a safe and promising regimen for advanced solid tumors. Clinical trial information: NCT02959905. Research Sponsor: None.

AFNT-211: An FAS-41BB-enhanced TCR-T cell therapy with stem-like properties targeting KRAS G12V-expressing solid tumors. *First Author: Michele Hoffmann, Affini-T Therapeutics, Watertown, MA*

Background: KRAS is the most common oncogenic driver mutation in solid tumors, promoting the initiation and progression of many incurable cancers, including colorectal, pancreatic and lung cancer. While small molecule inhibitors to KRAS^{G12C} mutations have been approved, there are no targeted therapies available for patients with highly prevalent KRAS^{G12V} mutations. TCR-T cell therapies have demonstrated remarkable responses in clinical trials, but their durability has been limited by the immunosuppressive tumor microenvironment (TME). AFNT-211 is an autologous T cell therapy engineered to express an HLA-A*11:01 KRAS^{G12V}-specific TCR, further enhanced with CD8 α / β coreceptor and a FAS-41BB switch receptor to drive T cell persistence and durable clinical responses. CD8 α / β coreceptor enables a coordinated CD4+/CD8+ T cell response and FAS-41BB converts the FAS ligand (FASL) TME death signal into a costimulatory signal through 41BB activation. **Methods:** AFNT-211 was assessed for efficacy *in vitro* against a panel of KRAS^{G12V}-expressing tumor cell lines and *in vivo* using human xenograft mouse models. *In vitro* safety studies were performed to assess potential cross-reactivity, alloreactivity, and cytokine-independent growth. The clinical manufacturing process consists of autologous CD4+/CD8+ T cells transduced with lentivirus and expanded using culture conditions that drive robust expansion while preserving stem-like properties. Phenotypic and functional analyses of AFNT-211 were performed using flow cytometry and cell-based assays. **Results:** Coculture of AFNT-211 with a panel of KRAS^{G12V}-expressing tumor cell lines led to significant effector cytokine secretion, T cell proliferation, and tumor cell killing. The CD8 α / β coreceptor enabled CD4+ T cell recognition of KRAS^{G12V} and greater overall cytotoxicity. The FAS-41BB switch receptor dramatically augmented the magnitude and durability of the anti-tumor response against FASL-expressing tumor cells. XScan mutagenesis and potential off-target peptide testing revealed no significant cross-reactivities. No alloreactivity was observed against a panel of lymphoblastoid cell lines presenting the most frequent HLA types in the US population. Potent anti-tumor response was observed *in vivo* in a mouse xenograft model. Affini-T's Thrive manufacturing platform used for the production of AFNT-211 consistently delivers >30-40e⁹ TCR-engineered T cells with a high frequency of naive and central memory T cells expressing negligible markers of exhaustion. **Conclusions:** The AFNT-211 manufacturing process generates a large number of TCR-T cells with desirable stem-like properties optimized for clinical dosing. Preclinical data demonstrated a potent and safe profile for AFNT-211 that supports clinical development in HLA-A*11:01 patients with advanced/metastatic solid tumors harboring a KRAS G12V mutation. Research Sponsor: Affini-T therapeutics.

A phase 1 dose escalation trial of ex-vivo expanded allogeneic cord blood-derived natural killer cell immunotherapy for pediatric solid tumor malignancies. *First Author: Sajad Khazal, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Despite aggressive multimodality therapy, survival outcomes of most patients with recurrent/refractory solid tumors remain dismal. Pre-clinical data have shown that natural killer (NK) cells play a significant role in controlling cancer progression, metastasis, and survival. In this phase I dose escalation trial, we evaluated the safety and phase 2 recommended dose of cord blood derived NK cells in children and young adults with recurrent/refractory pediatric solid tumors. **Methods:** Eligible patients were 1-40 years old. Cord blood donors were 4, 5, or 6/6 HLA matched. Ex-vivo, antigen presenting cell-mediated expansion of human cord blood derived NK cells was performed over 14 days. All patients received lymphodepleting regimen with cyclophosphamide (500 mg/m²/day) and etoposide (100 mg/m²/day) for 5 days (days -7 to -3) followed by 2 days rest and a single infusion of NK cells on Day 0. The study evaluated two dose levels using a standard 3+3 phase I trial design with an expansion cohort at the maximum tolerated dose. **Results:** Twelve patients (median age 16 years) received NK cells infusions. Tumor types included osteosarcoma (n = 7), Ewing sarcoma (n = 4), and synovial sarcoma (n = 1). Three patients received NK cells at dose level 1 (5 X 10⁷/Kg), and nine patients at dose level 2 (1 X 10⁸/Kg), which was determined to be the recommended Phase 2 dose. No dose-limiting toxicities were observed. Most adverse events were grade 1 and 2 (fatigue, dizziness, nausea and vomiting). Most frequently observed grade 3 and 4 adverse events were leukopenia, neutropenia, lymphopenia, and thrombocytopenia. No cytokine release syndrome or neurotoxicity was observed. Allogeneic NK cells were detected in recipients' peripheral blood as high as 100% of all NK cell populations and as late as 9 days post infusion. Of the 9 patients evaluable for tumor response, 3 patients (with osteosarcoma) had stable disease and 6 had progressive disease. **Conclusions:** Allogeneic ex-vivo expanded NK cells immunotherapy demonstrated favorable safety profile in patients with advanced pediatric solid tumors. Strategies to improve efficacy are warranted including using adjuvant therapy to increase persistence, more stringent selection strategies and gene editing approaches to increase alloreactivity against recipient tumor cells. Clinical trial information: NCT03420963. Research Sponsor: The University of Texas MD Anderson Cancer Center.

Safety and efficacy of Sleeping Beauty TCR-T cells targeting shared *KRAS* and *TP53* mutations expressed by solid tumors in first-in-human phase 1 study. *First Author: Maria Pia Morelli, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Solid tumors present driver mutations in *KRAS*, *TP53*, and *EGFR* genes on their surface in the context of human leukocyte antigen (HLA) molecules to T-cell receptors (TCRs) expressed by T cells. Non-viral genetic engineering of patient T cells with the Sleeping Beauty transposon/transposase system can generate driver mutation-reactive TCR-T cells. **Methods:** This is a first-in-human phase 1/2 study of autologous Sleeping Beauty TCR-T cell therapy for patients with non-small cell lung (NSCLC), colorectal, endometrial, pancreatic, ovarian and bile duct cancer whose tumors contain at least one of the targeted driver mutations in *KRAS*, *TP53*, and *EGFR*. The primary objective of the phase 1 portion is to define the incidence of dose-limiting toxicities (DLTs) and the maximum tolerated dose or recommended phase 2 dose to be explored in disease specific cohorts during phase 2. Dose levels of 0.1×10^{10} (DL1), 1.7×10^{10} (DL2) or 7.15×10^{10} (DL3) TCR-T cells are being explored. Any of the six tumor types or 12 TCRs within the library can be used for the Phase 1 portion of the trial. **Results:** As of February 14, 2023, three patients have been treated with Sleeping Beauty TCR-T cells on this study. The first was a 34 year old female with stage IV mucinous adenocarcinoma NSCLC refractory to chemotherapy and immunotherapy who received DL1 (0.9×10^{10} TCR-T cells) targeting *KRAS*^{G12D} and HLA-A*11:01, second was a 54 year old female with stage IVA chemotherapy resistant colorectal cancer who received DL2 (6.4×10^{10} TCR-T cells) targeting p53^{R175H} and HLA-A*02:01 and the third was a 60 year old male with stage IV pancreatic cancer refractory to chemotherapy who received DL2 (5.8×10^{10} TCR-T cells) targeting *KRAS*^{G12V} and HLA-A*11:01. Overall, a manageable safety profile with no unexpected adverse events, DLTs or immune effector cell-associated neurotoxicity syndrome (ICANS) was observed. Patients 1, 2 and 3 had cytokine release syndrome grades 2, 3 and 1, respectively, that were self-limiting or resolved with standard management and anti-IL-6 antibody in the case of Patient 2. Best overall responses were partial response for Patient 1 with six month progression-free survival, stable disease for Patient 2 and progressive disease for Patient 3. Persistence of TCR-T cells was observed in all patients at last follow-up and out to 6 months in the case of Patient 1. Acceleration to DL3 is under consideration based on a continued manageable safety profile. **Conclusions:** This is the first-in-human experience administering Sleeping Beauty TCR-T cells. Signs of efficacy, safety and persistence of TCR-T cells was observed. Thus, this treatment has promise for patients with solid tumors expressing shared mutations in driver genes. The trial is actively enrolling new patients and treating at one of the two highest dose levels. Clinical trial information: NCT05194735. Research Sponsor: Alauos Therapeutics.

Phase I results of human endogenous retrovirus type-E (HERV-E) TCR transduced T-cells in patients (pts) with metastatic clear cell renal cell carcinoma (mccRCC). *First Author: Rosa Nadal, Laboratory of Transplantation Immunotherapy, Cellular and Molecular Therapeutics Branch, NHLBI, NIH, Bethesda, MD*

Background: The CT-RCC HERV-E is expressed in the majority of ccRCC tumors with no expression in normal tissues. T-cells transduced to express a HERV-E TCR are cytotoxic to ccRCC and mediate tumor regression of human ccRCC in a murine model. We developed a method to manufacture HERV-E TCR transduced T-cells (HERV-E TCR) for clinical development. **Methods:** We conducted a phase I dose-escalation trial (DL1: 1×10^6 , DL2: 5×10^6 , DL3: 1×10^7 & DL4: 5×10^7 cells/kg) to evaluate the safety of adoptively infused HERV-E TCR in mcrRCC pts. HERV-E TCR contain T-cells engineered to express an HLA-A*11 restricted HERV-E TCR and a truncated CD34 cassette for *in vivo* monitoring. Eligible HLA-A*11 pts had mcrRCC, ECOG 0-1 & prior antiangiogenic & checkpoint inhibitors therapy unless contraindicated/unavailable. Cyclophosphamide & fludarabine were given followed by HERV-E TCR infusion & IL-2 administration. **Results:** 14 HLA-A*11+ pts (median age 56) were treated including 3 pts in each DLs 1-3 & 5 pts in DL4. 86% had ≥ 3 prior treatment lines (range 1-7); 36% had high-dose IL2, 57% ipilimumab-Nivolumab & 50% ≥ 3 lines of anti-VEGFR therapy. Bone, liver & brain metastases were present in 71%, 43%, and 14% of pts. All HERV-E TCR products met sterility, purity, and potency criteria for release and infusion (Table). No HERV-E TCR dose-limiting toxicities or treatment-related deaths occurred. Pts received a mean: 12 IL-2 doses (IQR 11-14). 57% pts had G3-4 febrile neutropenia & 7% G3-4 capillary leak syndrome. 1 pt experienced G2 skin rash possibly related to HERV-E TCR. Best response included 7% pts with partial response & 29% with stable disease ≥ 8 weeks. The mPFS: 62 days (IQR 31,90). At DL4, TCR transgene expression was detectable in PBMCs at a mean 6.3% (range (r) 0.02-25), 12.3% (r 0.01-61.2), 3.45% (r 0.00-13.7) & 2.89% (r 0.00-11.5) on days 4, 7, 14, & 21. HERV-E TCR were detected in the malignant pleural effusion of 1 pt. **Conclusions:** This is the first trial evaluating TCR-engineered T-cells targeting a human endogenous retrovirus in ccRCC. The manufacturing method utilized produced large numbers of highly purified CD8+ HERV-E reactive T-cells that were not associated with any dose limiting toxicities when given at doses up to 5×10^7 cells/kg. For pts in DL4, HERV-E TCR were observed to proliferate *in vivo*, traffic to a metastatic site, and induce tumor regression in one mcrRCC pts. Clinical trial information: NCT03354390. Research Sponsor: U.S. National Institutes of Health.

Effect of the killing style of individual CAR T cells on the clinicopathological behavior of therapeutic products in the clinic. *First Author: Ahmed Z Gad, Center for Cell and Gene Therapy, Texas Children's Hospital, Houston Methodist Hospital, Baylor College of Medicine, Houston, TX*

Background: CAR T cell products that signal through CD28 and 41BB are highly effective against B lineage leukemia, despite exhibiting distinct efficacy and toxicity profiles in patients. Specifically, CD28 has been linked to higher upfront lytic activity and toxicity, while 41BB induces longer CAR T cell persistence and more durable progression free survival. We reasoned that the killing style of individual CAR T cells can explain the clinicopathological behavior of CAR T cell products in the clinic. **Methods:** We studied the cellular kinetics of CD28 and 41BB signaling CD19 CAR T cell products approved in the clinic, their single cell killing behavior in high throughput, the molecular composition of the lipid rafts inside the CAR immune synapse (CARIS) they form with their target cells, and their CARIS mechanical properties, then corroborated these findings in one kinetic model to explain their distinct clinicopathological behavior in the clinic. **Results:** We discovered that tumor encounter polarizes CD28 CAR T cell products to a predominance of more differentiated CD8 effectors that rely on short-lived highly lethal synapses with tumor cells. CD28 CAR T cell mediated synapses are characterized by fast mechanical buildup and resolution and brisk shuttling of CAR and other associated molecules into the CARIS and rapid polarization of the killing machinery in a manner that supports a mastery of serial killing mediated by perforin and granzymes. In contrast, 41BB responds to tumor stimulation by a T_H2 -polarizing cytokine milieu that robustly expands a balanced CD4/CD8 population of effectors preserving a central memory phenotype. 41BB CAR T cells engage in lengthier synapses characterized by slower accumulation of CAR molecules in a mechanically tonic CARIS and rather collaborative yet lengthy Fas ligand-mediated killing process. **Conclusions:** We show here that CAR T cell signaling domains mediate distinct killing dynamics that can explain their behavior in patients. By understanding and potentially modulating these dynamics, the CAR T cell functionality and toxicity can be rationally optimized. Initial results from a first in human dose escalation trial of a novel immune stimulating oncolytic adenovirus, AdAPT-001^{TGF- β Trap}. *First Author: Anthony Paul Conley, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: As a class, oncolytic adenoviruses (OAV), modified agents of the common cold, specifically target and lyse tumor cells, and by expression of cytotoxic transgenes activate an immune response. AdAPT-001 is an OAV, which carries a transforming growth factor beta (TGF- β) trap that neutralizes the immunosuppressive and profibrotic cytokine, TGF- β . Preclinically, AdAPT-001^{TGF- β Trap} eradicates non-T-cell infiltrated tumors. The aim of this Phase 1 study was to assess the safety and tolerability and, secondarily, the efficacy of AdAPT-001^{TGF- β Trap} after single intra-tumoral injection (IT) (Phase 1a) and multidose IT injection (Phase 1b) in patients with advanced refractory solid tumors. **Methods:** This was an open label, single-arm, multicenter dose escalation design trial. AdAPT-001^{TGF- β Trap} was administered by intratumoral injection. 9 patients were in a single-dose group, where doses of 2.5×10^{11} , 5.0×10^{11} , 1.0×10^{12} viral particles (VPs), were tested, and 19 patients with a median age of 70, 5 median prior regimens, and a median ECOG score of 1 received AdAPT-001 every 2 weeks at 1.0×10^{12} VPs until progression. **Results:** AdAPT-001^{TGF- β Trap} was well tolerated with local inflammation, fever, and fatigue as the main side effects. No dose limiting toxicities, no grade 4 toxicities, or treatment-related serious adverse events (SAEs) were seen. Tumor types were sarcoma (n = 8), melanoma (n = 2), head & neck (n = 5), gastric (n = 1), rectal (n = 1), breast (n = 1), fallopian (n = 1). Biological activity (virus replication, local reactions, and tumor shrinkage) was observed. The duration of local reactions and virus replication suggested that dosing every 2 weeks was appropriate. The overall responses to treatment were as follows: 5 patients had durable stable disease for 6 months or more, 1 patient had a partial response, and 2 patients demonstrated pseudoprogression with inflammation of uninjected as well as the injected tumor, 5 patients had stable disease for approximately 2 months and 15 patients had progressive disease. 2 abscopal responses have been seen to date. The data also suggest a dose-response relationship, with higher and more frequent doses associated with better outcomes. Peripheral lymphocyte subset analysis and serum cytokine analysis are ongoing. **Conclusions:** AdAPT-001^{TGF- β Trap} is well tolerated and no dose limiting toxicities were observed with the single or multidosing protocol described. Evidence of an antitumor effect was seen. The recommended Phase 2 dose was 1.0×10^{12} VPs administered by intratumoral injection once every 2 weeks. Combination of AdAPT-001^{TGF- β Trap} with a checkpoint inhibitor is planned. Clinical trial information: NCT04673942. Research Sponsor: EpicentRx.

Harnessing the power of tumor-infiltrating lymphocytes: A first-in-human study of GT201 as monotherapy in advanced solid tumors. *First Author: Yarong Liu, Grit Biotechnology, Shanghai, China*

Background: Genetically engineered TIL has shown features such as prolonged memory that can improve therapeutic efficacy in tumor mouse models. GT201 is an engineered TIL that expresses a membrane-bound IL-15 (mIL-15), and preclinical studies have demonstrated enhanced antitumor reactivity. A phase 1 study was initiated to evaluate the preliminary safety of GT201 and to identify Optimal Biological Dose (OBD) suitable for monotherapy expansion. **Methods:** The dose-escalation study (using TITE-BOIN design) intended to enroll patients (pts) with advanced treatment-refractory solid tumors. Once the OBD is identified, a monotherapy expansion phase will be opened for patients with various solid tumors. Enrolled patients were pre-conditioned with a nonmyeloablative (NMA) lymphodepletion regimen and treated by autologous infusion of the GMP-grade G201 cell product, followed with supportive low dose IL-2 administration. **Results:** As of January 17, 2023, the dose-escalation study enrolled 4 pts, all of whom were female with a median age of 52.6 years. The median number of infused TIL cells was 5.3E+09. All pts experienced TRAEs, with the majority being grade 1 or 2. The most common grade 3/4 TRAEs were lymphopenia (100%), leukopenia (25%) and neutropenia (25%), which were related to the NMA regimen. No dose-limiting toxicities (DLTs) or TIL-related grade ≥3 TRAEs were observed. Median time on study was 17 wks (6–30 wks). One pt with highly treatment-refractory cervical cancer experienced a confirmed partial response (PR) after 16 wks that was durable for 30 wks (RECIST 1.1). Two pts (cervical cancer and melanoma) experienced disease stabilization, while another malignant melanoma pt experienced progressive disease. Despite varying doses of TILs (5.0E+09 to 1.40E+10) and IL-2 (up to 3.0E+05 IU/kg), all patients receiving GT201 therapy showed robust T cell expansion post-infusion, with higher doses of IL-2 leading to more rapid TIL expansion. GT201 TILs could be detected in patients after one month post-infusion, indicating promising activation and long-term persistence of the infused TILs. Based on safety, tolerability, PKs, and preliminary efficacy, a TIL dose of 1.0E+10 and an IL-2 dose of 3.0E+05IU/kg was selected as the OBD for the study. **Conclusions:** The results of the first-in-human study of GT201, a mIL-15 expressed on TILs, demonstrate promising preliminary findings as a monotherapy in pts with advanced cancers. The administration of GT201 was associated with robust T cell expansion, as well as prolonged persistence of infused TILs. Results of mIL-15 expressed TIL demonstrates that GT201 has good tolerability with encouraging preliminary antitumor activity as a monotherapy. Further investigations, including correlative biomarker analyses and updated safety and clinical outcome data, will be presented at the meeting. Clinical trial information: NCT05430360. Research Sponsor: Grit Biotechnology.

Preclinical evaluation of targeting PRAME with TCR mimic CAR T cells in AML. *First Author: Danielle Kirkey, Fred Hutchinson Cancer Center, Seattle, WA*

Background: Chimeric antigen receptor (CAR) T cell therapy has revolutionized cancer treatment, but has had limited success against AML in part due to overlap of cell surface antigens expressed in AML and normal hematopoietic cells. To identify AML-restricted targets, we interrogated the transcriptome from over 3000 AML patients and found PRAME (Preferentially Expressed Antigen in Melanoma), an intracellular protein, to be a highly expressed AML-restricted target. Using a novel approach to target intracellular antigens, we developed a PRAME CAR T cell using a TCR mimic (mTCR) antibody, which recognizes the PRAME peptide/HLA-A2 complex on the tumor cell surface. To conduct final IND-enabling studies, we generated an *in vivo* patient derived xenograft (PDX) model to treat with PRAME^{mTCR}CAR T cells. Here we demonstrate the *in vivo* activity of PRAME^{mTCR}CAR T cells against a PDX AML model. **Methods:** We used the VL and VH sequences from the PRAME TCR mimic antibody (Pr20) to construct the single chain fragment variable domain into the 41-BB/CD3ζ CAR vector. The PDX model was derived from a PRAME⁺/HLA-A2⁺ pediatric patient with AML. PDX cells were transduced with *fluciferase* for noninvasive bioluminescent IVIS imaging to monitor leukemic progression. PDX leukemia-bearing mice were treated with unmodified T-cells or PRAME^{mTCR}CAR T cells at 5x10⁵ cells (1:1 CD4:CD8) per mouse 1 week after leukemia injection. Leukemia burden was measured by IVIS imaging and peripheral blood analysis. **Results:** Treatment with PRAME^{mTCR}CAR T cells led to eradication of leukemia with all mice alive >100 days post-treatment, while control mice (unmodified T cells) had disease progression at Day 50 (p=0.001). Average leukemia burden in the control cohort was 3.5% at week 6 and 41.75% at week 11, while no leukemia was detected following CAR T cell treatment. In addition, the control arm had a marked expansion of leukemia with a 7.75 and 429.6 fold increase in radiance by IVIS at 6 and 11 weeks post-treatment. No significant increase in radiance was seen in the PRAME^{mTCR}CAR T cell treated group. Human T cells (CD45+/CD3+) were detectable in the peripheral blood at Day 7 and 14 post-treatment in both the unmodified and CAR T cell treated groups. **Conclusions:** We demonstrate the therapeutic potential of targeting PRAME with mTCR CAR T cells in AML. We show potent efficacy with eradication of leukemia in PDX-bearing mice following treatment with PRAME^{mTCR}CAR T cells resulting in prolonged survival. These results provide a novel approach to target PRAME with CAR T cells and provide compelling data to evaluate PRAME^{mTCR}CAR T cells for use in clinical trials against AML. Research Sponsor: Project StElla.

		Treatment	
		Unmodified T cell (N=5)	PRAME ^{mTCR} CAR T cell (N=5)

MT-6402, an engineered toxin body (ETB) targeting PD-L1: Interim efficacy and safety data. *First Author: Minal A. Barve, Mary Crowley Cancer Research Center, Dallas, TX*

Background: MT-6402, an engineered toxin body (ETB) , has been designed to be effective in patients (pts) previously treated with checkpoint inhibitors (CPIs) by utilizing 3 unique mechanisms of action (MOA): (i) remodeling of the tumor micro-environment by elimination of PD-L1⁺ immunosuppressive cells like myeloid-derived suppressor cells (MDSCs), (ii) direct cell kill of PD-L1⁺ expressing tumor cells, (iii) delivery of HLA-A*02 restricted cytomegalovirus (CMV) peptide pp65 to PD-L1 expressing cells to direct a CMV specific CD8 T-cell response against the tumor. **Methods:** Dose escalation continues with MT-6402 (QW in 4-week cycles) in pts with relapsed/refractory PD-L1⁺ solid tumors. After clearing doses of 16, 24, 32, 42 and 63 µg/kg, 83 µg/kg is being evaluated. Safety, tolerability, efficacy, pharmacokinetics, and pharmacodynamic data are reported. **Results:** MT-6402 at 63 µg/kg in 1 pt with metastatic nasopharyngeal carcinoma (NPC) who progressed after radiation, chemotherapy, and CPI (PD-L1 CPS=2%, not HLA-A*02) resulted in a PR (63% reduction in target lesion) after 2 cycles. This pt had an increase in CD8/CD4 and immune activation cytokines (IL-2, TNFα, IFNγ) consistent with elimination of MDSCs. A pt with NSCLC (osseous disease only) that had progressed after CPI showed resolution of 3/4 osseous metastases and decreased radiotracer uptake by the remaining bone metastasis. This patient had high PD-L1 tumor expression and HLA-A*02/CMV*. Complete CMV-specific T-cell extravasation was noted by C1D8 consistent with haplotype-specific CMV antigen delivery for presentation on the tumor surface by MHC class I. All cohorts had reductions in peripheral PD-L1⁺ MDSCs, monocytes and dendritic cells after MT-6402 without effect on PD-L1⁺ cells with the most depletion at the highest doses. Most pts displayed CD8⁺ T-cell expansion and elevations of serum IL-2 and TNFα, consistent with PD-L1-mediated immunotolerance. MT-6402 was well tolerated with 2 dose limiting toxicities reported: Grade (G)2 maculopapular rash at 24 µg/kg, G3 IRR at 63µg/kg. No G ≥ 4 AEs occurred. Infusion-Related Reactions in 3 pts (G1, G2, and G3) and Cytokine Release Syndrome (G1 [2 pts] at both 32 and 42µg/kg and G2 [1 pt] at 16µg/kg) occurred. **Conclusions:** MT-6402 utilizes three PD-L1-targeted and unique MOAs: direct cell-kill, reduced immunosuppression, and increased immunorecognition. As of Feb 2023, 5 dose cohorts have completed. MT-6402 was well tolerated without CLS or payload-derived toxicity as is observed with traditional immunotoxins and ADCs, respectively. A PR in 1 pt with CPI-refractory NPC (CPS 2%, CMV) and regression of osseous metastases in a pt with NSCLC (TPS 80%, HLA-A*02/CMV*) following disease progression on CPI occurred. These results show MT-6402 monotherapy activity though unique MOAs and provide rationale for MT-6402 dose expansion. Clinical trial information: NCT04795713. Product characteristics and clinical trial design for T-Plex: Multiplexed, enhanced T cell receptor engineered T cell therapy for solid tumors. *First Author: Shrikanta Chattopadhyay, TScan Therapeutics, Waltham, MA*

Background: Checkpoint immunotherapies have revolutionized the treatment of solid tumors yet durably benefit a minority of patients because they rely on endogenous anti-tumor T cells. In patients lacking functional anti-tumor T cells, a solution is engineering their T cells with exogenous T cell receptors (TCRs) to efficiently target and kill tumor cells. Initial clinical trials with TCR engineered T cell therapies (TCR-Ts) only produced partial, short-lasting responses because they targeted single tumor antigens. Solid tumors are notoriously heterogeneous not only with highly variable antigen expression levels but also with recently identified HLA gene losses occurring in up to 40% of solid tumors, enabling tumor cells to evade T cell attack. **Methods:** To overcome this heterogeneity, TScan has developed T-Plex, a multiplexed therapy comprising 2-3 different TCR-Ts, chosen from a collection of TCR-Ts called the ImmunoBank, to target different tumor antigens presented on different HLA types with confirmed tumor expression. **Results:** To deepen clinical responses, TCR-T cells are engineered to express the CD8α/β co-receptors that, in preclinical experiments, enable CD4+ helper T cells to become >100-fold more cytotoxic and secrete cytokines at >100-fold lower target antigen levels. Finally, to enable T cell persistence despite immunosuppressive TGF-β in the tumor microenvironment, engineered TCR-T cells express the dominant negative TGF-β receptor allowing ~10-fold improved proliferation and ~2-fold improved cytokine production in the presence of TGF-β. The inclusion of these additional genes is enabled by a transposon manufacturing system with no cargo limit. Patient selection for the Phase 1 study uses a separate screening protocol to identify patients any time during standard clinical care so they can rapidly enroll into the treatment protocol upon progression. Screening comprises germline HLA testing, then archival tumor testing for antigen expression and HLA loss. Treatment includes standard lymphodepletion followed by 2 doses of T-Plex infused 28 days apart. T-Plex initially starts with 2 TCR-Ts targeting different MAGE-A1 antigens presented either on HLA-A*02:01 or HLA-C*07:02. Dose escalation starts with testing the single TCR-Ts individually in dose levels 1 and 2. The two TCR-Ts will then be combined and escalated in dose levels 3 and 4. Additional TCR-Ts added to the ImmunoBank will go through dose levels 1 and 2 as single therapies before becoming available for multiplexed dose levels 3 and 4. Primary endpoints include safety and feasibility, secondary endpoints are response rates and duration of response and exploratory endpoints measure T cell persistence. **Conclusions:** Four additional TCR-Ts are on track to be added to the ImmunoBank in 2023 which makes 50-80% of patients with common solid tumors eligible for multiplexed TCR-T therapy. Preclinical testing of FOLR1-CAR T cells against osteosarcoma (OS). *First Author: Michelle Choe, Fred Hutchinson Cancer Center, Seattle, WA*

Background: Survival rates for OS are poor. Prior literature suggests folate receptor- α (FOLR1) overexpression in OS, making it a target for CAR T development. **Methods:** OS transcriptome data from TCGA, PCGP and NCI PIVOT programs were interrogated for FOLR1 gene expression. A 2nd generation FOLR1-CAR T cell was created by fusing the ScFv from farletuzumab (anti-FOLR1 monoclonal antibody) with a 4-1BB costimulatory and CD3 ζ cytotoxicity domain. Non-transduced (NT) T cells served as controls. *In vitro* functional analysis was performed against U2OS cell line using flow cytometry (FC) and Incucyte. U2OS xenograft in NSG mice was generated via intra-femoral inoculation for local tumor and via tail vein (TV) tumor injection for pulmonary disease. Tumor engraftment was confirmed by *in vivo* imaging system (IVIS). Disease progression was monitored by IVIS and CT imaging. 5 million T cells were administered via TV. Circulating human T cells (HTC) collected from retro-orbital peripheral blood (PB) were detected via FC. **Results:** FOLR1 transcript was expressed in >75% of OS in TCGA, PCGP and PIVOT. *In vitro* evaluation of FOLR1-CAR T demonstrated robust antitumor activity (E:T ratio 1:1) with cytotoxicity of 76.5% and 95.5% at 6 and 24 hrs. Disease progression was observed in NT T cell treated mice, with an average fold increase in IVIS radiance of 35.1 in local (n=2) and 142.8 in pulmonary disease (n=3) over 11 weeks (wks) versus complete resolution of local (n=2) and pulmonary disease (n=3) in FOLR1-CAR T treated mice (see table). NT T treated mice with local disease demonstrated significant bone destruction; no local tumors were found in FOLR1-CAR T treated mice. HTC (CD45+/CD3+) expansion was detected in PB one wk post-treatment (PT); in mice with metastasis 0.190% and 0.136% of live circulating cells were human T cells in FOLR1-CAR T and NT T treated mice, respectively. Improved overall survival was observed in FOLR1-CAR T treated mice (>100 vs 87.5 days). **Conclusions:** FOLR1-CAR T cells appear to have *in vivo* activity against U2OS cell line and support further testing of safety and feasibility in an early phase clinical trial for relapsed/refractory OS. Research Sponsor: Sam Day Foundation.

A subset of neutrophils as a predictive biomarker for immunotherapy response in patients with non-small-cell lung cancer and melanoma. *First Author: Yuval Shaked, Technion, Haifa, Israel*

Background: Despite the remarkable success of immunotherapy, only ~20-40% of cancer patients display an extended durable response. Pre-existing biomarkers for immunotherapy outcome are significantly limited in their predictive power, e.g., PDL-1 expression by tumor cells (AUC ~ 0.6-0.75). This requires additional efforts to search for new approaches to discover new biomarkers in immune-oncology. While mice are the most widely used and cost-effective model to study human disease, translating preclinical biomarkers into clinical practice faces significant obstacles – in part due to the lack of diverse or appropriate models. In this study we have taken a holistic approach to search for new biomarkers for immunotherapy outcomes, with the aim to improve translatability of the findings and their validity in cancer patients. **Methods:** Several pre-clinical models were used, each capturing one possible mechanistic aspect of immunotherapy response, such as tumor- and host-dependency, in order to reflect the variability seen in human cancers. These models have been analyzed for myeloid cell composition within tumors and peripheral blood using high throughput techniques such as single-cell RNA sequencing and mass cytometry, followed by rigorous bioinformatic tools. Peripheral blood mononuclear cells (PBMCs) were obtained from non-small cell lung cancer (NSCLC, n = 34) and melanoma (n = 38) patients prior to immune-checkpoint inhibitor backbone therapy as monotherapy or in combination with chemotherapy. These results were validated on additional human bulk mRNA datasets (n = 417). **Results:** Using the preclinical models, we identified interferon-stimulated, Ly6E^{hi} neutrophils as a pre-treatment, blood-borne biomarker for anti-PD1 response. These results were validated in PBMCs of advanced metastatic NSCLC and malignant melanoma patients predominately treated with immune checkpoint inhibitor-based therapy, with a high degree of accuracy (AUC ~ 0.9). These results were also validated in independent cohorts of immunotherapy-treated patients with other cancer types obtained from bulk mRNA datasets including renal cell carcinoma (n = 109), urothelial carcinoma (n = 228) and additional melanoma patients (n = 80). Functional studies revealed that Ly6E^{hi} neutrophils sensitize otherwise resistant tumors to anti-PD1 therapy, in part by directly activating cytotoxic T cells and contributing to tumor cell killing, while operate upstream of T cells in the immunotherapy response. **Conclusions:** Our study demonstrates a pragmatic approach to search for new, clinically relevant and functionally active cellular biomarkers for immunotherapy outcomes in humans. This study paves the way for a conceptual framework to advance the field of immuno-oncology by utilizing this approach for successful clinical trials. Research Sponsor: European Research Council.

A novel platform to enrich for tumor-specific T cells in non-small-cell lung cancer. *First Author: Stephanie J Hachey, ImmunoTarget Therapeutics, Inc., Irvine, CA*

Background: To induce robust cellular immunity against non-small cell lung cancer (NSCLC), the leading cause of cancer-related death in the US, we have developed an innovative cell-based therapeutic platform technology to generate polyclonal, neoantigen-reactive T cells *in vitro*. **Methods:** Surgically resected NSCLC tissue and peripheral matched blood were collected from 17 patients under an IRB-approved protocol. From 3 of the patient-derived NSCLC specimens, methods were tested to enhance immunogenicity and stimulate neoantigen-specific immune responses. We then use a novel, human vascularized microtumor (VMT) platform to assess the sensitivity of tumor cells to T-cell mediated attack at the individual patient level. **Results:** The therapeutic platform induced a significant increase in T cell proliferation, interferon-gamma secretion, and blast phenotype of lymphocyte populations compared to T cells primed by standard methods. Interestingly, for one patient, immunosuppression of the T cell response with concomitant increase in CD96, an immune checkpoint receptor implicated in lung cancer progression, was observed in the tumor. Importantly, using sequencing data from one patient, an analytical and machine learning pipeline detected putative neoantigens using our therapeutic platform technology and not with standard methods. **Conclusions:** The therapeutic platform can be used to directly generate cell-based immunotherapies and to facilitate neoantigen discovery and development of targeted cancer immunotherapies. Our goal is to advance novel approaches to effectively mobilize anti-tumor immunity and overcome treatment resistance in NSCLC. Research Sponsor: U.S. National Institutes of Health.

The exploratory case-control study on prediction of immune checkpoint inhibitor-induced thyroiditis by human leukocyte antigen types. *First Author: Yutaka Natori, Fukushima Medical University, Fukushima-Shi, Japan*

Background: Given the function of human leukocyte antigen (HLA) in immunity, variation of the HLA type could affect the development of immune-related adverse events (irAEs) that is induced by immune checkpoint inhibitors (ICIs). In this study, we examined whether HLA types of cancer patients could be a marker for the development of irAE thyroiditis. **Methods:** In the present case-control study, we randomly selected 20 cancer patients who received ICIs and developed thyroiditis (irAE thyroiditis group) and 51 who did not develop thyroiditis (No irAE thyroiditis group). The 51 patients were subdivided into 31 who did not develop any irAEs (No irAEs group) and 20 who developed irAEs other than thyroiditis (irAEs other than thyroiditis group). HLA types were classified at the amino acid sequence level (Field 2 resolution). Frequency of the HLA types of each group was compared. **Results:** There was no significant difference in HLA type prevalence, comparing the irAE thyroiditis group and the No irAE thyroiditis group. When comparing the irAE thyroiditis group with the No irAEs group, the irAE thyroiditis group had significantly higher HLA-X, HLA-Y, and HLA-Z (Tentative names are used here, and actual HLA types will be announced at the time of publication). This result suggested that irAEs other than thyroiditis in the control group could be noise. HLA-X had a specificity of 96.8% for the development of irAE thyroiditis. HLA-Y had a sensitivity of 80.0%. Patients carrying both HLA-X and HLA-Y had the highest specificity of 100.0%. There was a significant difference in frequency of HLA-Y between irAEs other than the thyroiditis group and the No irAEs group. HLA-Y may be a universal marker for any irAEs. On the other hand, HLA-X is a specific marker for thyroid irAE. The median time of onset of irAE thyroiditis in all patients was 72 days after ICI administration. Patients with both HLA-X and HLA-Y tended to have an earlier onset with a median onset time of 53 days. **Conclusions:** We found an association between specific HLA types and the development of irAE thyroiditis. The present study indicates that HLA types could be a predictive marker for the development of irAE thyroiditis. Research Sponsor: Japan Society for the Promotion of Science.

C-reactive protein as a response biomarker to immune checkpoint blockade: A meta-analysis. *First Author: Alexander B Karol, Department of Medicine, Icahn School of Medicine at Mount Sinai, Mount Sinai Hospital, New York, NY*

Background: Tumor-promoting inflammation is a hallmark of cancer pathogenesis and is associated with poor outcomes and treatment resistance. C-reactive protein (CRP) is a routinely measured acute phase reactant whose synthesis is stimulated by cytokines and may thereby represent a surrogate for tumor promoting inflammation. Pre-treatment CRP has been associated with resistance to immune checkpoint blockade (ICB) in several studies. However, whether post-treatment changes in CRP correlate with ICB outcomes has not been systematically examined. **Methods:** We performed a systematic review to identify cohort studies or clinical trials in solid tumor patients receiving ICB therapy with CRP response comparator pairs (high/low) available. We included studies that had hazard ratio (HR) of overall survival (OS), progression-free survival (PFS), or odds ratio (OR) of objective response rate (ORR) available. We performed a meta-analysis using a random-effect model to evaluate if post-treatment changes in CRP are associated with ORR, PFS, or OS. Subgroup analysis for primary cancer type was performed. Heterogeneity was assessed using the I-squared statistic. **Results:** We screened 691 eligible studies; 19 met inclusion criteria and 2,101 patients were included. Patients experiencing post-ICB declines in CRP had improved ORR HR=4.67 [95% CI] [2.81-7.78] ($p<0.0001$, $I^2=42\%$), PFS HR=2.47 [1.98-3.09] ($p<0.0001$, $I^2=18\%$), and OS HR=2.28 [1.68-3.08] ($p<0.0001$, $I^2=56\%$). Heterogeneity among subgroups was low in ORR ($I^2=14.6\%$) and PFS analysis ($I^2=0\%$), and moderate in OS analysis ($I^2=64.2\%$). **Conclusions:** In patients receiving ICB therapy, post-treatment declines in CRP were associated with improved ORR, PFS, and OS across multiple histologies. These findings support the integration of on-treatment CRP decline as a clinically relevant response biomarker for novel therapies directed at modulating tumor-promoting inflammation. A meta-regression analysis will help determine optimal post-treatment CRP cutpoints. Pooled OR of ORR [95%CI] and HR [95%CI] of PFS and OS with subgroup analysis results and heterogeneity assessment. Research Sponsor: None.

Clinical outcomes of immune checkpoint inhibitor treatment in patients with classic cold tumors identified to have a high tumor mutational burden via ctDNA. *First Author: Reagan Barnett, Guardant Health, Inc., Redwood City, CA*

Background: Some cancers, including breast, ovarian, pancreatic, and prostate cancers, are traditionally considered “cold” tumors, less likely to trigger an immune response and/or respond to immune checkpoint inhibitors (ICIs). However, some patients with these cancer types may benefit from ICIs. Here we investigate if a high blood tumor mutational burden (bTMB-H) may predict benefit to ICIs in such tumor types. **Methods:** We retrospectively queried the Guardant Health database for patients with advanced breast ($n=8531$), ovarian ($n=1106$), upper GI/pancreatic ($n=5110$), and prostate ($n=7153$) cancer who had ctDNA next-generation sequencing (Guardant360, Redwood City, CA) as part of routine clinical care from 2020-2022. Mutation profiles were evaluated for patients with bTMB-H (based on previously reported 80th percentiles for each tumor type, breast ≥ 15.31 mut/Mb, ovarian ≥ 14.98 mut/Mb, pancreatic ≥ 11.36 mut/Mb, prostate ≥ 13.4 mut/Mb) vs those with bTMB below this threshold (bTMB-L). A subset of cases were analyzed in a multi-institutional clinical cohort with a bTMB of ≥ 10 mut/Mb ($n=35$). **Results:** bTMB-H was observed in 9.5% of patients with breast cancer, 5.1% ovarian, 2.0% pancreatic, and 4.4% prostate. Genes more often mutated in patients with pTMB-H vs pTMB-L in each cancer type included *TP53* and *PIK3CA* in breast cancer; *TP53* and *CHEK2* in ovarian; *ATM* and *CHEK2* in pancreatic; *TP53* and *AR* in prostate (all p values <0.01). Patients in the clinical cohort ($n=35$) had a median age of 74 (range: 40-85) 29/35 White / 4/35 Black, 27 prostate, 1 breast, 3 upper GI. Patients underwent first ctDNA analysis after a median of 3 (range 0-11) lines of therapy. The median bTMB detected was 16.59 mut/Mb (range: 10.02-152.85); six patients (6/35) were MSI-H. Twenty-three patients received ICI after a median of 6 (range: 0-8) lines of therapy, either alone (9, 39%) or in combination with hormonal therapy (5, 22%), chemotherapy (3, 13%) or targeted therapy (6, 26%). The median time to progression on ICI was 5.0 (95% CI, 3.6-6.4) months and median duration of response was 19.8 months (12.1-20.2). The ORR for evaluable patients was 13% and 74% of patients had progressed on therapy at time of data cut-off. **Conclusions:** “Cold” tumors represent a meaningful portion of patients with advanced cancer in which ICIs are not typically leveraged, and ctDNA was a feasible tool for identifying patients with bTMB-H who achieved durable responses from ICI-based therapy. The efficacy in this clinical cohort of traditionally “cold” tumors approaches other pan-cancer cohorts that include more traditionally immunoresponsive tumor types; further research is warranted to explore predictive value of bTMB, including potential tumor-specific thresholds, for optimizing patient selection for ICIs. Blood-based assessment of patients with mismatch repair-deficient tumors enrolled in NCI-MATCH Arm Z1D (nivolumab). *First Author: Chris Alan Karlovich, Molecular Characterization Laboratory, Frederick National Laboratory for Cancer Research, Frederick, MD*

Background: NCI-MATCH was the largest precision medicine initiative conducted to date. Arm Z1D was a study of nivolumab in patients (pts) whose tumors were mismatch repair deficient (MMRd) by immunohistochemistry (IHC). Plasma was available for analysis of circulating tumor DNA (ctDNA), a component of cell-free DNA (cfDNA), in 39 of 47 pts enrolled to treatment. Large ctDNA gene panels that interrogate microsatellite instability (MSI), tumor mutational burden (TMB) and other complex biomarkers may provide an important complement to tumor-based assessments. **Methods:** 10–30 ng of cfDNA extracted from Streck tubes was tested with a modified version of the 523-gene TruSight[®] Oncology 500 ctDNA RUO assay (Illumina, San Diego, CA). Blood MSI (bMSI) status was calculated by interrogating ~2400 microsatellite sites and applying an experimentally validated cut-off. Blood TMB (bTMB) was calculated as total number of nonsynonymous and synonymous SNVs and Indels identified per Mb. Tumor sequencing was performed with the 143-gene OncoPrint Comprehensive Assay v2. Overlap of tumor and plasma gene panels was evaluated for concordance. MMRd was evaluated by MLH1 and MSH2 IHC expression. MSI PCR testing was performed on 7 microsatellite sites. Clinical response was assessed by RECIST v1.1 criteria. **Results:** ORR was 31% (12/39) for 39 MMRd patients with plasma samples. Among these, 34 pts (87%) were classified as MSI-high (MSI-H) by ctDNA at baseline. The 5 MSS cases included 1 CR, 2 PRs and 2 unevaluable for response. The median bTMB was 56.4 mut/Mb (range: 1.65 – 435 mut/Mb). All pts had at least one oncogenic/likely oncogenic alteration identified in plasma. Of 136 of these mutations identified in tumor, 107 (78.6%) were detected in plasma. The most frequently mutated genes in plasma included *TP53* ($n=26$ pts), *RNF43* ($n=16$ pts, all G659Vfs*41) and *PIK3CA* ($n=16$ pts). *MLH1* ($n=5$) and *MSH2* ($n=5$) mutations were also identified. *RNF43* G659Vfs*41, which was not interrogated by the targeted tumor panel, is known to be strongly associated with MSI-H status. In this heavily pre-treated cohort (median prior therapies = 3), variants in genes commonly associated with clonal hematopoiesis of indeterminate potential were identified in all pts. Changes in cfDNA tumor fraction tracked with clinical response in 4 of 4 pts where on-treatment blood was collected for TSO 500 assessment. **Conclusions:** 78.6% of oncogenic/likely oncogenic alterations found in tumor were also identified in plasma. 87% of MMRd pts by tumor IHC were defined as MSI-H by baseline ctDNA, and median bTMB was 56.4 mut/Mb. These data suggest blood-based MSI and TMB should be further explored as biomarkers for the non-invasive identification of patients who may be candidates for immune checkpoint blockade, particularly when tissue is limiting. Time-dependent efficacy of immune checkpoint inhibitors in the treatment of metastatic cancers: A meta-analysis. *First Author: Thierry Landre, Hôpitaux-Universitaires-Paris-Seine-St-Denis, AP-HP, Paris, France*

Background: Immune checkpoint inhibitors (ICIs) have been established as the standard of care for numerous advanced malignancies. Emerging evidence suggests that the time-of-day of administering these immunotherapies may impact patient outcomes. We sought to determine the consistency in the impact of ICI time-of-day infusion on survival of patients with metastatic cancer. **Methods:** We performed a meta-analysis of published studies that have reported on ICI time-of-day infusion and efficacy in patients with advanced solid tumors. Overall survival (OS) and progression free survival (PFS) were compared between patients who had received ICIs before and after the daily time cut-off of each study. Hazard ratios (HRs) with their 95% confidence interval (CI) were collected from the studies and pooled. **Results:** This meta-analysis identified 7 studies of 1019 patients (PS 0, 43%; PS 1, 39%; males, 65%; females, 35%) who had stage IV non-small cell lung cancer (NSCLC), urothelial cancer, renal cell carcinoma, or melanoma, and were treated with mostly anti-PD-1 (nivolumab or pembrolizumab), anti-PD-L1 (atezolizumab), and anti-CTLA-4 (ipilimumab) agents. The time cut-offs selected to stratify patterns of ICI infusion were 16:00 or 16:30 in 5 studies (based on differences in adaptive immune response reported in previous vaccination studies) and 13:00 (based on median time of ICI infusions) in 2 studies. The pooled analysis of OS results showed a statistically significant benefit in favor of patients receiving infusions in the morning or in the early part of the day with a HR: 0.49, [95% CI: 0.36-0.69] ($p<0.0001$). A similar benefit was observed for PFS with a HR: 0.56, [0.44-0.72] ($p<0.00001$). **Conclusions:** Patients with advanced cancers may benefit from earlier time-of-day ICI infusions. Our findings are consistent with established circadian mechanisms that control immune cell functions and trafficking over a 24-h period. Prospective randomized trials are warranted to establish ICI timing recommendations for optimizing treatment efficacy in patients with different cancer types and at minimal cost. Pan-cancer analysis of natural killer (NK) cell infiltration in human malignancies: Molecular features and clinical implications. *First Author: Nick Zorko, University of Minnesota, Minneapolis, MN*

Background: NK cells are part of the innate immune system that are not antigen-specific, but can be redirected to targets of interest using multiple strategies. Advantages of NK cells over T cells include the use of allogeneic off-the-shelf products and lower risk of cytokine release syndrome. Numerous NK-specific immunotherapies are under development for the treatment of cancer, although none are yet FDA-approved. Here, we conducted a pan-cancer analysis of NK cell abundance in >90,000 tumor samples across 45 cancer types using the Caris Precision Oncology Alliance (POA) database. Features of prostate cancer (PCa, n=3365) and renal cell carcinoma (RCC, n=1106) were explored in depth. **Methods:** DNA (targeted/whole-exome) and RNA (whole-transcriptome) sequencing was performed for patient tumors (N=90,916) submitted to Caris Life Sciences (Phoenix, AZ). NK cell fractions were inferred from RNA-seq data using quantTiseq (Finotello, 2019). Real-world overall survival (OS) was determined from insurance claims, and Kaplan-Meier estimates were calculated. Statistical significance was determined using χ^2 and Mann-Whitney U tests with corrections for multiple hypothesis testing where appropriate. **Results:** Median NK cell fractions ranged from 7-9% (medulloblastoma and gliomas) to 2% (thyroid and thymic cancers), with intermediate levels observed for PCa (4.6%) and RCC (3.1%). High (> median) NK cell fractions were associated with improved OS (hazard ratios, 0.28–0.84, $p<0.05$) for 28 of 45 cancer types, while 16 of 45 including low-grade glioma, GIST, and thyroid had HR <1.0 (0.264–0.997) with 95% CI crossing 1.0. Improved OS was notable in PCa (HR 0.46, 95% CI 0.38–0.56, $p<0.0001$) and RCC (HR 0.52; 95% CI 0.39–0.70, $p<0.0001$). Unexpectedly, tumors with higher NK infiltrates were less frequently PD-L1+ (SP142) by IHC in PCa (2.8% vs 5.4%, $p=0.08$) and RCC (12.4% vs 30.8%, $p<0.0001$) (i.e. an inverse relationship), despite a lack of correlation of NK infiltration with dMMR/MSI status or tumor mutation burden (TMB) in both cancers. Conversely, increased NK infiltration was associated with a 1.4- to 2.1-fold increased mRNA expression of immunomodulatory receptors *LAG3* and *TIGIT* in both PCa ($p<0.0001$) and RCC ($p<0.0001$), but a 1.4-fold decrease in *B7-H3* in RCC ($p<0.0001$). **Conclusions:** High NK cell infiltration is associated with improved OS in numerous cancer types, including many with inadequate therapeutic options. Our findings suggest broad deployment of NK engagers and CAR-NK products in a range of malignancies. The positive correlation between NK cells and *LAG3/TIGIT* suggest that combination approaches may be warranted. The inverse relationship between NK infiltrates and PD-L1, and lack of association with standard immune therapy markers (MSI status, TMB), indicates the potential use of NK cell approaches in situations where other immunotherapies are ineffective. The prognostic ability of immune scoring system Immunoscore in patients with localized colon cancer: A systematic review and meta-analysis. *First Author: John Lois Padayao, St. Luke's Medical Center, Quezon City, Philippines*

Background: Assessment of tumor recurrence risk as well as prognosis in resectable colon cancer are still mainly based on the histopathological criteria of tumor invasion reflected in the TNM classification. Robust data in colorectal tumor research show the value of tumor microenvironment and tumor-infiltrating lymphocytes (TILs) as novel parameters to predict recurrence and survival. The utility of the derived tumor Immunoscore via digital pathology is now being promoted to refine the prognosis of early colon cancer patients together with the TNM staging to guide treatment decisions, but is not yet a recommendation in international consensus guidelines. This study assessed the prognostic value of this diagnostic tool in predicting clinical outcomes. **Methods:** A systematic literature search using PubMed, Embase, and Cochrane CENTRAL Library was conducted to identify observational or randomized controlled studies from January 2008 and December 2022 according to pre-specified inclusion and exclusion criteria which examined the relationship between Immunoscore and long-term prognosis (overall survival and disease free survival) in patients with localized colon cancer. Hazard ratios with 95% confidence interval for overall survival (OS) and disease-free survival (DFS) were extracted. Pooled estimates of the prognostic ability of Immunoscore were obtained using bivariate random effects model. Statistical heterogeneity between studies was evaluated with I^2 statistics and explored through sensitivity analysis. **Results:** A total of 5,718 patients from 11 studies were included in the meta-analysis. Moderate heterogeneity between studies for both DFS ($I^2=27\%$) and OS ($I^2=33\%$) was seen. The pooled analysis indicated that compared to those with high Immunoscore, colon cancer patients with low Immunoscore were associated with shorter disease-free survival (HR 1.75, 95% CI 1.53–2.49) and overall survival (HR 1.87 95% CI 1.45–2.13). In the subgroup analyses, this association was consistent across geographic regions and maximum time of follow up. **Conclusions:** A low Immunoscore was significantly associated with poorer clinical outcomes in terms of disease-free survival and overall survival. The use of Immunoscore provides valuable estimate of the risk of recurrence in patients with early colon cancer and has the potential to greatly affect treatment decisions in conjunction with the existing risk assessment system. Leflotolimod (TLR agonist) and ipilimumab in patients with advanced solid tumors: A phase I trial. *First Author: Mirella Nardo, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The TLR-9 agonist lefotolimod (MGN1703) significantly increases the Th1 response in pre-clinical models and has demonstrated antitumor activity in early phase clinical trials. This trial assessed the safety and preliminary efficacy of the rational combination of lefotolimod with ipilimumab in patients (pts) with advanced solid tumors. **Methods:** This was a single-center, open-label, investigator-initiated, dose-finding, and expansion Phase I trial (ClinicalTrials.gov no. NCT02668777). Key inclusion criteria were histologically confirmed advanced solid tumor, ECOG performance status ≤ 2 ; age ≥ 18 years. Patients (pts) were enrolled at escalating doses of lefotolimod (15–120 mg/kg), subcutaneously (SC) administered weekly and a fixed dose of ipilimumab 3 mg/kg in a 3-week cycle. For the expansion cohort, lefotolimod was administered intratumorally (IT) at 15 mg weekly. The primary endpoint was safety and tolerability according to CTCAE v4.0, dose-limiting toxicity (DLT) and maximum tolerated dose (MTD)/recommended Phase II dose (RP2D) for the lefotolimod in this combination. The secondary endpoint was efficacy, evaluated according to Immune-Related Response Criteria (irRC). Exploratory endpoints included changes in the intratumoral T-cell microenvironment in pre- and post-treatment tumor biopsies and the correlation of immune biomarkers with response. **Results:** From March 2017 to February 2020, 28 pts were enrolled. Median age was 56 years (range: 19–92). Median prior lines of therapy was 4 (range: 0–12). Pts 1–4 received lefotolimod 15 mg SC, pts 5–8 received lefotolimod 30 mg SC, pts 9–12 received lefotolimod 60 mg SC, pts 13–19 received lefotolimod 120 mg SC, and pts 20–28 received lefotolimod 15 mg IT. Eleven pts had at least one treatment-related AE (TRAE). The most common TRAE was skin rash (n=4, 14.2%), followed by fatigue (n=3, 10.7%) and pruritis (n=2, 7.1%). There were no grade 4 or 5 AEs, none of the pts required dose reduction, and there was no discontinuation of treatment due to AEs. DLT and MTD were not reached and the RP2D was established as lefotolimod SC 120 mg weekly with ipilimumab 3mg/Kg every 3 weeks. Of the 28 pts, 8 pts had stable disease as best response. 7 pts could not be evaluated by irRC due to clinical progression before restaging, non-measurable lesions and withdrawal of consent. Paired biopsy samples were analyzed by flow cytometry. Pro-inflammatory immune conditioning of the tumor microenvironment by the combination of the TLR9 agonist MGN1703 in combination with ipilimumab showed increases in intra-tumoral CD8 T cell frequency, memory CD8 phenotype (CD45RO+) and proliferation (Ki67+). **Conclusions:** The combination of high subcutaneous doses or intra-tumoral administration of lefotolimod in combination with ipilimumab is safe and well tolerated in patients with advanced cancers, with preliminary antitumor activity observed. Clinical trial information: NCT02668777. Research Sponsor: U.S. National Institutes of Health; MD Anderson Cancer Center Support Grant (NIH/NCI P30 CA016672).

Modi-1, anti-citrullinated neopeptide vaccine, alone and combined with checkpoint inhibitors in patients with head and neck, breast, renal, and ovarian cancers: ModiFy phase I/II basket clinical trial—Report after completion of monotherapy dose-finding. *First Author: Christian H.H Otten-smeier, The Clatterbridge Cancer Centre NHS Foundation Trust, Liverpool, United Kingdom*

Background: Stressful conditions in the tumor microenvironment induce autophagy, resulting in high levels of calcium in autophagosomes, in turn activating peptidyl-larginine deiminase enzymes; these convert arginine residues within polypeptides to citrulline and alter proteolytic cleavage. MHC-II presents these citrullinated peptides to CD4⁺ T cells. Modi-1 comprising three citrullinated, adjuvanted peptides targeting vimentin and enolase to inducing and expanding CD4⁺ T cells. At the tumor site the CD4⁺ T cells release proinflammatory cytokines including INF γ , further upregulating MHC class II. This enables presentation of endogenous citrullinated peptides on the tumor cells in a positive feed-forward loop. **Methods:** ModiFy is an open-label, multicohort, multicenter, adaptive Phase I/II basket trial for patients with unresectable Head and Neck Squamous Cell Carcinoma (SCCHN), Triple Negative Breast Cancer (TNBC), Renal Cell Carcinoma and High Grade Serous Ovarian Carcinoma (HGSOC). Patients are treated with Modi-1 alone or - if eligible for standard of care checkpoint inhibitor (CPI) monotherapy - Modi-1 + SoC CPI. The Modi-1 only expansion cohorts will recruit 16 patients per tumor type, Modi-1+CPI will recruit 21 patients per tumor type. Study objectives are safety, the breadth and strength of the cellular immune response, ORR, duration of response, PFS, and OS. **Results:** As of February 2023, the monotherapy dose-finding has completed. 3 patients received Modi-1v (vimentin only) 80 μ g/peptide and 3 patients received Modi-1 at 400 μ g/peptide (vimentin + enolase peptides) as part of the monotherapy dose escalation. No DLTs were observed, triggering enrolment into the monotherapy expansion cohorts. 20 evaluable pts have received Modi-1v (3 pts Modi-1v 80 μ g/peptide, 17 Modi-1 400 μ g/peptide): 16 had HGSOC, 2 TNBC, 2 SCCHN with 53 doses received; 2 patients have been treated beyond 24 weeks. All patients had skin reactions consistent with a delayed-type hypersensitivity reaction at injection sites. Vaccinations have been well tolerated with 71 adverse reactions in 15 patients reported. All were Grade 1 or 2 except for four Grade 3 reactions in 3 patients (anemia, fatigue, and injection site reactions). There have been no SAEs. Elevation in anti-CCP antibodies has not been seen. In 13 response-evaluable patients, best overall response by RECIST v1.1 included 1 PR (SCCHN), 6 SD and 6 PD. The study is currently enrolling into the combination with checkpoint inhibition dose escalation cohorts and the monotherapy expansion cohorts. **Conclusions:** Modi-1 is well tolerated, and the early monotherapy efficacy data are encouraging. Safety and early efficacy data are supportive of further development of combination with CPI. Clinical trial information: NCT05329532. Research Sponsor: Scancell Ltd.

Investigation of synthetic lethality gene pairs in the DNA damage response pathway in response to immunotherapy in pan-cancer. *First Author: Hongyan Huang, Department of Oncology, Beijing Shijitan Hospital, Capital Medical University, Beijing, China*

Background: The concept of synthetic lethality (SL) refers to the phenomenon where the simultaneous loss of function of two genes leads to cell death, while the loss of function of either gene alone has no effect. PARP inhibitors target poly ADP ribose polymerase (PARP) enzymes, which are involved in DNA repair, are the successful cases of utilizing synthetic lethality-based therapy to treat cancers with DNA damage response (DDR) deficiency. The prognosis for cancer patients already has a combination of synthetic lethal mutations especially in DDR pathway can vary and it is not yet fully understood how these mutations may impact the response to immunotherapy. **Methods:** SL gene combinations in the DDR pathway were screened out from SynLethDB database (<http://histone.sce.ntu.edu.sg/SynLethDB/>). The immunotherapy cohort (Samstein 2019, n=1661) and non-immunotherapy cohort (Zehir 2017, n=10336) with solid tumor were used to Kaplan-Meier analyze the correlation between SL gene combinations and prognosis. TMB scores were compared between DDR co-mutation group and non DDR co-mutation group. For investigating the associations between immune infiltrates and genetic features, TIMER 2.0 database (<http://timer.cistrome.org/>) was conducted to estimation of immune infiltration levels on DDR mutation genes in pan-cancer. **Results:** 430 pairs of DDR mutation combinations were used to subgroup stratification, the DDR co-mutation group was associated with worse prognosis in non-immunotherapy cohort (HR=1.305, p<0.0001) but better in immunotherapy cohort (HR=0.741, p<0.0061). Interestingly, the TMB score in the DDR co-mutation group was significantly higher than non DDR co-mutation group (mean 50.03 vs 8.868, p<0.0001) in immunotherapy cohort. The high-frequency mutation combinations (>10%) were ATM-POLE (14.40%), ATM-ATR (13.60%), ATR-BRCA2 (13.60%), ATM-BRCA2 (12.00%) and BRCA2-RECQL4 (10.40%), respectively. Comparing common immune component with statistically significant under different DDR mutant genes, the ATM-POLE co-mutation tumor tended to have more CD4+ T cell infiltration while the ATM-ATR co-mutation tumor appeared to have more myeloid dendritic cell infiltration. **Conclusions:** The combinations of DDR SL mutation tumor might result to worse prognosis whereas these patients might benefit from immunotherapy. Our results will help to shed light on the complex interplay for the combinations of SL mutation in DDR pathway between cancer cells and the immune system and provide new insights into the development of effective cancer treatments. A phase 1 first-in-human study of interferon beta (IFN β) and membrane-stable CD40L expressing oncolytic virus (MEM-288) in solid tumors including non-small-cell lung cancer (NSCLC). *First Author: Andreas Nicholas Saltos, Moffitt Cancer Center, Tampa, FL*

Background: MEM-288 is a conditionally-replicative oncolytic adenovirus expressing human IFN β and a recombinant membrane-stable form of CD40L (MEM40L). Pre-clinical studies show MEM-288 induces robust dendritic cell-mediated systemic T cell responses capable of inhibiting abscopal tumor growth as monotherapy and synergizes with immune checkpoint inhibitors (ICI). **Methods:** MEM-288 is being evaluated in this Phase 1 open-label trial (NCT05076760) in pts with select solid tumors including NSCLC (a) refractory to standard therapy and (b) with a tumor lesion deemed feasible for biopsy and MEM-288 intratumoral (i.t.) injection. The primary objective is to determine using a BOIN design a recommended phase II dose of MEM-288 across 3 dose levels (DL1-3) spanning 1e10 to 1e11 viral particles by i.t. injection once every 3 weeks. Secondary objectives include efficacy assessment, including response rate of injected and non-injected tumors assessed separately. Tumor biopsies obtained immediately prior to the 1st and 2nd injections are used to explore biomarkers and anti-tumor immune responses. **Results:** As of February 2023, 12 pts (11 NSCLC and 1 pancreatic cancer; n = 3 DL1, n = 5 DL2, n = 4 DL3) have enrolled. The median number of MEM-288 i.t. injections was 2 (1-3), median age was 63 (39-76), and median prior lines of therapy was 3 (1-5). Radiology-guided injections were administered in superficial/palpable tumors and visceral lesions. No dose limiting toxicities occurred. Treatment-related adverse events observed in > 1 pt include grade 1 injection site reaction (42%) and chills (17%). Of 10 response-evaluable pts, 4 (40%) pts had shrinkage of injected tumor (range -26 to -54%); 3 (30%) PR and 1 (10%) SD. Multiple pts also had stabilization or shrinkage of distal non-injected lesions. Best overall response was 3 (30%) stable disease and 7 (70%) progressive disease. After a single MEM-288 injection, biopsies show decreased tumor cell percentage concomitant with substantial increases in overall CD8⁺ T cells, increased T clonotype diversity in both tumor and peripheral blood, and increased TCF1⁺ stem-like CD8⁺ T cells that are strongly associated with response to ICIs. Plasma cytokine analysis showed increases in IFN γ and of IFN-inducible cytokines and chemokines, supportive of stimulation of systemic response after MEM-288. Of note, a pt with strong stimulation of tumor and systemic T cell immunity after MEM-288 had subsequent CR (ongoing > 7 months) to docetaxel + ramucirumab following prior treatment failure with platinum doublet + ICI received before MEM-288. **Conclusions:** Preliminary safety, antitumor and immune response data are encouraging. Updated results and immune data from this study will be presented. An expansion arm is planned with combination MEM-288 and anti-PD1 antibody in pts with advanced NSCLC refractory to ICI. Clinical trial information: NCT05076760. Research Sponsor: Memgen.

VirMAP for cancer: Characterization of the intratumoral virome in virally associated cancers and a resource for investigators. *First Author: Yongwoo David Seo, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: A major barrier to understanding the role of viruses in cancer progression has been the lack of sensitivity of current tools to assemble viral genomes in an untargeted way. Here, we utilize our novel VirMAP algorithm to identify eukaryotic and prokaryotic viruses associated with cancers, using RNA sequencing data from The Cancer Genome Atlas (TCGA). **Methods:** VirMAP was run on 16 TCGA RNASeq datasets of primary tumor tissues, with a focus on cancers with known viral associations (including cervical, head and neck, liver, stomach, esophagus and ovarian). Previously published survival data were used for exploratory analysis. Overall survival (OS) was assessed using the Kaplan-Meier method, and p-values were calculated using log-rank test. Multivariate analysis (MVA) was done using Cox proportional hazards model to control for age, sex, stage, and histology. **Results:** Viral sequence recovery (among 537 billion sequencing reads from 6185 patients) was at least equal to previously published algorithms such as Kraken, but with higher taxonomic resolution; overall recovery was 0.0041% from 16 tumor types. Cancers with high viral loads such as cervical cancer demonstrated high recovery rates (0.012% of all reads mapped to viral taxa, followed by 0.004% for liver, 0.0018% head and neck, 0.0016% stomach, 0.0009% esophageal, and 0.0002% ovarian). There was a wide range of viral signature richness, with cervical cancer showing the highest viral read count predominated by 18 different HPV serotypes; in contrast, stomach cancer had lower abundance but contained over 300 unique viral species. Exploratory analysis revealed novel correlations between viral signatures and OS. In cervical cancer, presence of HPV45 predicted worse survival (median OS 837 days vs 4086, p=0.0043); MVA demonstrated hazard ratio (HR) of 5.7 [2.6-11.4, p<0.0001]. In stomach cancer, patients often had more than one viral taxon present (mean 3.7, range 0-18); presence of seven or more unique taxa predicted worse OS (median OS 403 days vs 1153, p=0.0001). MVA showed HR of 1.1 for every additional taxon (p=0.0004). Across all 16 tumor types, the detection of phage virus was associated with worse OS (1073 days vs. 2094 days for non-phage virus and 2131 days for no virus, p<0.0001). **Conclusions:** VirMAP performs deep characterization of the tumor-associated virome in both high and low abundance settings, with generation of partial genome reconstructions and strain level taxonomic classification including phages. Further work is ongoing to optimize viral read normalization based on genome length, as well as subset analysis with disease-specific modifiers such as histology, race, and exposures. Utilizing publicly available platforms such as TCGA, clinical and correlative published data can be leveraged to better understand the nuanced pleiotropic effects of the tumor virome on cancer progression. Uliedlimab and toripalimab combination therapy in treatment naïve advanced NSCLC: Phase 1b/2 clinical trial results using CD73 as a potential predictive biomarker. *First Author: Qing Zhou, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou 510080, China, Guangzhou, China*

Background: CD73 is a rate-limiting enzyme in adenosine pathway promoting immune suppression in tumor microenvironment. The role of CD73 as a novel target in cancer immune therapy is further supported by correlation between its high expression in tumors and poor prognosis in cancer pts. Here we evaluate safety and efficacy of uliedlimab, a differentiated CD73 antibody, in combination with toripalimab, a PD-1 antibody, in treatment naïve NSCLC pts. In particular, we investigate the correlation between clinical response and tumor CD73 expression to assess its value as a potential predictive biomarker, following a previous study where a correlation was indicated (Robert F, et al. ASCO 2021). **Methods:** Pts with treatment naïve advanced NSCLC (EGFR/ALK wild type) were enrolled in a dose-expansion cohort and received uliedlimab (20mg/kg or 30mg/kg Q3W) in combination with toripalimab 240mg Q3W. Safety, the primary endpoint, and clinical efficacy including ORR, determined by iRECIST, were evaluated. Baseline CD73 and PD-L1 expression in tumor specimens were measured by IHC. The cut-off value for CD73^{High} expression was assessed by ROC analysis for correlation with ORR. **Results:** As of 12/2/22, 66 pts were enrolled (median age 62.5 years, ECOG PS 0 40.6%, male 84.8% and never smokers 22.7%) and received at least one dose. Treatment-related adverse events (TRAEs) occurred in 86.4% of pts (Gr $\geq$ 3, 15.2%) with no grade 5 TRAE. One patient was discontinued due to TRAE (1.5%). Efficacy was analyzed in 48 pts who were enrolled at least 90 days prior to data cut-off, allowing for two assessments. Baseline PD-L1 and CD73 expression was available in 45 pts. 40% of tumor or immune cells with $\geq$ 1+ staining intensity by IHC was determined as a preliminary cut-off for CD73^{High} (the area under ROC curve =0.72, p=0.02). While ORR and DCR were 31.3% (15/48) and 79.2% (38/48) respectively in all pts, ORR appeared higher in CD73^{High} pts (50%, 9/18) and much lower in CD73^{Low} pts (14.8%, 4/27). Highest ORR was found in a cohort with CD73^{High} and PD-L1 TPS $\geq$ 1% (57.1%, 8/14). **Conclusions:** Uliedlimab and toripalimab combination therapy was well-tolerated in treatment naïve advanced NSCLC pts. Clinical response of the therapy seems to correlate with high tumor CD73 expression, indicating a potential value of CD73 as a predictive biomarker. The study warrants a biomarker-guided randomized clinical trial that is currently in preparation. Clinical trial information: NCT04322006. Research Sponsor: I-Mab Biopharma.

Enhancing STING activation by cyclic dinucleotide-manganese particles for systemic cancer immunotherapy. *First Author: Xingwu Zhou, University of Michigan, Ann Arbor, MI*

Background: Activating the innate immune pathway of stimulator of interferon genes (STING) can elicit potent anti-tumor immunity via the production of type-I interferons (IFN-I). However, cyclic-dinucleotide (CDN) STING agonists have undesirable pharmacological properties. Most CDNs in clinical development are administered intratumorally, thus precluding their applications in treating metastasis, hematologic malignancies, and hard-to-reach solid tumors. Here, we report the development of a new nanoparticle system for the systemic delivery of CDN STING agonists with potent efficacy, favorable pharmaceutical properties, and acceptable safety profiles. **Methods:** Nutritional metal ions play crucial roles in modulating immune pathways, which could potentially be used for enhancing STING activation. We screened different metal ions and found that manganese ion (Mn^{2+}) achieved strong synergy with CDN STING agonists for inducing IFN-I production. We further developed a new nanoparticle system for co-delivery of Mn^{2+} and CDN for systemic cancer immunotherapy. **Results:** Mn^{2+} induced up to 77-fold enhancement in CDN-mediated STING activation. Mixing CDNs with Mn^{2+} resulted in the self-assembly of nanocrystals, and the lipid layer coating led to uniform nanoparticles. The resulting STING-activating CDN-Mn nanoparticle (SNP) given intravenously elicited IFN-I responses, attenuated the suppressive functions of myeloid cells, remodeled the immunosuppressive tumor microenvironment, and expanded CD8⁺ T cells for sustained tumor control. Intravenous SNP therapy resulted in robust anti-tumor efficacy in multiple murine tumor models, including a genetically engineered mouse model of MMTV-PyMT triple-negative breast cancer. We have also demonstrated the robust anti-tumor efficacy of SNP against VX2 head and neck squamous cell carcinomas (HNSCC) in New Zealand white rabbits. Mechanistically, the efficacy of intravenous SNP therapy was dependent on the host STING expression but independent of the tumor STING expression. In addition, the anti-tumor efficacy of SNP was decreased in mice lacking *Irfar1* or *Irfng1* expression in the B16F10 melanoma model, showing the crucial effects of IFN-I and IFN-II responses. Lastly, SNP was effectively uptaken by human PBMCs and elicited IFN-I responses when injected into fresh human tumor biopsies derived from HNSCC patients. **Conclusions:** SNP empowers highly effective systemic cancer immunotherapy via nanotechnology. It also underscores the potential of utilizing metal ions for immune-mediated disease treatment. Research Sponsor: U.S. National Institutes of Health.

Phase 1 clinical trial results for NG-350A, a novel transgene-armed and tumor-selective vector: Differential effects of intravenous (IV) versus intra-tumoral (IT) dosing on immune pharmacodynamics (PD). *First Author: Minesh Patel, Akamis Bio, Abingdon, United Kingdom*

Background: Tumor-selective therapeutic viral vectors are often limited to IT delivery. NG-350A, a blood stable adenoviral vector, selectively replicates in tumors and expresses an agonist anti-CD40 payload. We assessed the impact of IV vs IT delivery during the phase 1 FORTITUDE study (NCT03852511). **Methods:** NG-350A was dose-escalated in separate IT or IV cohorts of patients (pts) with metastatic/advanced epithelial tumors. Pts received either 1 (Day[D1]) or 4 IT injections (D1, 8, 15, 22) of up to 1×10^{12} viral particles (vp) or 3 IV infusions completed in <9 days (doses of 1×10^{11} to 6×10^{12} vp). Serum samples were taken immediately after dosing (pharmacokinetics [PK]) and during follow-up (PD). Baseline and on-treatment (D15+) tumor biopsies were taken. **Results:** In total, 25 pts received NG-350A monotherapy, 9 by IT and 16 by IV dosing. Both IV and IT dosing elicited similar anti-drug (virus) antibody responses and limited viral shedding. Peak vp Cmax was variable with IT dosing but dose-related with IV dosing. Vector DNA was detected by qPCR in tumor biopsies after higher IV dose levels (including up to ~7 weeks post dosing) and IT injection. Dose-dependent, sustained and specific increases in inflammatory cytokines related to the expected effects and timing of the anti-CD40 transgene production (IL-12, IL-17A, IL-2, IFN- γ) were detected in serum of pts treated at higher IV doses. By contrast, limited evidence of such PD effects was seen with IT dosing. Transgene was not detectable in core needle biopsies; however, a novel serum biomarker assay detected transgene mRNA at D8 or D15 in five pts who received higher IV dose levels. Importantly, both IV and IT dosed NG-350A was well-tolerated, with no treatment-related SAEs occurring in >1 pt and no DLTs at the highest dose levels tested. No evidence of anti-CD40 transgene-related toxicity was seen with IV or IT dosing, with few hepatic AEs and no Grade ≥ 3 CRS. Follow-up for imaging was limited; however, stable disease was observed in 3/6 pts at IV Dose Level 3. **Conclusions:** This analysis provides the first clear evidence that an IV-dosed tumor-selective viral vector can drive expression of immuno-stimulatory payloads with functional PD consequences in advanced cancers. The improved PK and PD profile of IV vs IT dosed NG-350A also highlights the benefits of systemic delivery for such vectors. Dose-escalation of NG-350A + pembrolizumab to identify a dose for efficacy assessments continues in the FORTIFY study (NCT05165433). Clinical trial information: NCT03852511. Research Sponsor: Akamis Bio.

Key PK and PD outcomes by route of administration.

	IT D1 (n=6)	IT D1 2 (n=3)	IV D1 (n=6)	IV D1 2 (n=4)	IV D1 3 (n=6)
Peak PK Cmax (mean vp/mL)	2.3×10^6	1.2×10^7	8.0×10^6	1.0×10^8	2.3×10^8
Viral DNA detected in tumor biopsy (n)	3/6	3/3	0/6	1/1	5/6
Sustained cytokine response observed (n)	0/6	1/3	0/6	3/4*	2/6

*One pt had no follow-up beyond D1.

T cell engager (TCE) score in patients treated with bispecific CD3 TCE in phase I clinical trials. *First Author: Noé Herbel, Gustave Roussy, Drug Development Department (DITEP), Villejuif, France*

Background: Immune prognostic scores, such as the Gustave Roussy Immune (GRIM) score have been investigated in patients (pts) treated with immune checkpoint blockers. We aimed to determine whether we could improve the selection of pts that could benefit from new immunotherapies such as bispecific CD3 T cell engagers (TCE) antibodies in pts treated in phase I clinical trials (CT), by building a new prognostic score. **Methods:** All patients treated with bispecific CD3 TCE in phase I CT from July 2018 to February 2023 at the Drug Development Department at Gustave Roussy were enrolled in the study. Univariate and multivariate analyses (UVA and MVA) were conducted on demographic, clinical and biological data to assess their prognostic value on progression free survival (PFS). MVA results were used to build a new prognostic score (TCE score). This score was then validated on overall survival (OS). The predictive ability (on PFS and OS) of the TCE score was assessed using Harrell's C index. It was compared with the GRIM and Royal Marsden Hospital (RMH) scores predictive ability on PFS and OS. **Results:** A total of 67 patients (47 men, 20 women) with metastatic solid cancer or advanced hematological cancer were included. Median age was 62 years old. The most represented tumor types were prostate cancer (33%), lymphoma (25%) and small cell lung carcinoma (24%). UVA on PFS showed that elevated C-reactive protein (CRP) (HR: 2.36; 95%CI: 1.35-4.16; $p = 2.10^{-3}$) and lactate dehydrogenase (LDH) (HR: 3.00; 95%CI: 1.63-5.53; $p = 2.10^{-4}$) were associated with a worst PFS. In MVA, LDH (HR: 2.49; 95%CI: 1.30-4.74, $p = 1.10^{-4}$) and CRP levels (HR: 1.92; 95%CI: 1.1-3.46; $p = 1.10^{-4}$) were independent negative prognostic factors for PFS. The TCE score was based on MVA results (CRP > 10g/L: +1; LDH > 250U/L: +1). It showed that pts with a high score (1-2) had a shorter PFS (median PFS: 2.8 months) and OS (median OS: 9.9 months) than low score (0) pts (median PFS: 5.8 months; median OS: not reached). TCE score's Harrell's C index for PFS was 0.63 and 0.64 for OS. For GRIM and RMH scores, Harrell's C index for PFS were respectively 0.60 and 0.55. For OS it was respectively 0.58 and 0.53. **Conclusions:** To select patients for Bispecific CD3 TCE phase I CT, we built a new prognostic score, based on LDH and CRP levels, that can be used as prognostic of PFS and OS. TCE score is more reliable than GRIM and RMH scores to prognose PFS and OS. Research Sponsor: None.

A phase 1 study of the OX40 agonist, BGB-A445, with or without tislelizumab, an anti-PD-1 monoclonal antibody, in patients with advanced solid tumors. *First Author: Jayesh Desai, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*

Background: OX40 is an immune costimulatory receptor, expressed on activated CD4⁺ and CD8⁺ T cells, which promotes T cell proliferation and survival in the tumor microenvironment. BGB-A445 is a novel monoclonal antibody (mAb) OX40 agonist that does not compete with endogenous OX40 ligand binding. BGB-A445 has demonstrated antitumor activity as a single agent and in combination with an anti-PD-1 mAb in preclinical studies. Here, we report data from the ongoing dose-escalation part of a multicenter, phase 1 dose escalation/expansion study (NCT04215978) of BGB-A445 alone or in combination with tislelizumab (TIS) in patients (pts) with advanced solid tumors. **Methods:** Eligible pts were enrolled into seven sequential dose escalation cohorts of BGB-A445 IV as monotherapy (Part A) or five increasing dose levels of BGB-A445 IV in combination with TIS 200 mg IV (Part B) on day 1 of 21-day cycles. Dose escalation was guided by a Bayesian (mTPI-2) approach. This study assessed safety, tolerability, pharmacokinetics (PK) profile, and preliminary antitumor activity (RECIST v1.1). **Results:** As of August 31, 2022, 59 pts were enrolled in Part A and 32 pts in Part B. Median (range) age was 59 years (28-80) and 61 years (37-75) in Parts A and B, respectively; 26 (44%) and 13 (41%) pts were male, respectively. $\geq$ Grade 3 treatment-emergent AEs (TEAEs) were reported in 24 (41%) and 17 (53%) pts in Parts A and B, respectively; the most commonly reported (≥ 3 reported) $\geq$ grade 3 TEAEs were gastrointestinal disorders (diarrhea, nausea, and abdominal pain). Serious TEAEs were reported in 23 (39%) pts in Part A and 16 (50%) in Part B. Treatment-related AEs leading to treatment discontinuation were reported in 1 (2%) pt in Part A and 0 (0%) pts in Part B. In Part A, all grade immune-mediated AEs (imAEs) were reported in 11 (19%) pts; no pts reported $\geq$ grade 3 imAEs. In Part B, all grade imAEs were reported in 14 (44%) pts; $\geq$ grade 3 imAEs were reported in 1 (3%) pt (one event each of rash maculopapular and diarrhea). There were no dose-limiting toxicities or concerning patterns of safety/tolerability observed. BGB-A445 PK (maximum concentration [C_{max}] and area under the curve from day 0 to 21 [AUC_{0-21}]) were linear and dose proportional in all tested dose ranges. In the efficacy-evaluable population of Parts A ($n=50$) and B ($n=30$), respectively, partial response was observed in 2 (4%) pts (unconfirmed) and 7 (23%) pts (confirmed); stable disease in 18 (36%) and 13 (43%) pts (confirmed), and progressive disease in 26 (52%) and 8 (27%) pts. **Conclusions:** In the dose escalation part of this study, BGB-A445 alone or in combination with TIS was generally well tolerated across all doses in pts with advanced solid tumors, and demonstrated preliminary antitumor activity as both a single and combination agent. The dose expansion part of the study is ongoing in pts with non-small cell lung cancer and head and neck squamous cell carcinoma. Clinical trial information: NCT04215978. Research Sponsor: BeiGene, Ltd.; The authors wish to thank all BGB-A317-A445-101 study investigators, research staff, and patients. This study was sponsored by BeiGene, Ltd. IMPORT-201 (IMP-MEL): A phase 1 first-in-human dose finding/randomized phase 2 study of a novel iNKT agonist IMM60 and pembrolizumab for advanced melanoma and metastatic non-small cell lung cancer (NSCLC). *First Author: Nicholas Coupe, Oxford University Hospital, Oxford, United Kingdom*

Background: Invariant natural killer T-cells (iNKTs) share features of NK-like cells and T-cells, playing a role in both innate and adaptive immune responses. The importance of this relatively rare lymphocyte subset has generated interest due to its dual ability to have a direct cytotoxic effect on CD1d expressing tumors as well as to induce long-lasting antitumor CD8 T cell responses mediated by cross-priming and licensing of dendritic cells. While many current clinical approaches involve the use of allogeneic iNKT cells, here we describe initial clinical studies with IMM60, a synthetically derived agonist of iNKT cells formulated in a liposome (PORT-2). In preclinical studies, IMM60 treatment results in maturation of DCs and B cells and a potent stimulation of iNKT cell-derived IFN- γ . In murine efficacy studies, IMM60 demonstrated monotherapy activity in multiple PD-1 resistant models (e.g., B16-F10), as well as upregulation of PD-L1 expression on cancer cells and re-sensitization to PD-1 inhibition. **Methods:** The IMPORT-201 trial is a multicenter, international expansion of an open-label first-in-human phase I/II investigator initiated study (IMP-MEL). Ph 1 is currently enrolling patients with NSCLC or melanoma. IMM60-containing liposomes are administered IV Q3W at 3 escalating dose levels for 6 doses as monotherapy or with pembrolizumab 200mg Q3W. The Ph I portion of the study seeks to establish the recommended Ph 2 dose of IMM60 alone and in combination with pembrolizumab. The Ph 2 evaluates IMM60 monotherapy, PD-1 monotherapy, and the combination. **Results:** Eight patients with melanoma (n=4) or NSCLC (n=4) have been enrolled in the IMM60 monotherapy dose cohorts. These patients were heavily pretreated, having a median of 3.5 prior therapies (range 2-7). One patient with NSCLC has been enrolled to the IMM60 + pembrolizumab combination cohort. IMM60 was well tolerated with no treatment-related SAEs or G3-5 AEs, and no MTD was determined. The most common related AE is G1-2 fatigue, reported in 2 patients. In the monotherapy cohort, a preliminary review of individual target lesions showed 2 lesions that completely resolved, 1 lesion with 69% decrease in size, 10 lesions that were stable, and 6 lesions with >20% increase in size. Serum biomarker analysis demonstrated evidence of iNKT and NK activation, as well as increases in dendritic and CD86+ B cells. Pharmacokinetics demonstrate dose proportionality with a terminal half-life of ~8 hours. **Conclusions:** IMM60 is well tolerated as monotherapy and in combination with pembrolizumab at the doses tested. These data show that a single agent iNKT agonist can be safely administered in a heavily pre-treated population and initiate immune activation. The combination with pembrolizumab is ongoing, and updated results of the Ph 1 portion of the study will be reported. Clinical trial information: NCT05709821. Research Sponsor: Portage Biotech/iOx Therapeutics.

Efficacy and safety of IBI110 in combination with sintilimab and lenvatinib in first-line of advanced hepatocellular carcinoma: Preliminary results from a phase Ib study. *First Author: Ming Liu, Key laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital & Institute, Beijing, China*

Background: Sintilimab plus bevacizumab has been approved as first-line treatment in patients (pts) with advanced hepatocellular carcinoma (HCC). Dual inhibition of PD-1 and lymphocyte-activation gene 3 (LAG-3) may improve anti-tumor effect synergistically. IBI110 plus sintilimab has shown preliminary antitumor activity in advance solid tumors. This phase Ib cohort study evaluated the efficacy, tolerability, and safety of IBI110 in combination with sintilimab and lenvatinib as first-line treatment in pts with advanced HCC. **Methods:** This phase Ib study enrolled pts with histologically or cytologically diagnosed or clinically confirmed unresectable or metastatic hepatocellular carcinoma, no previous systemic treatment. Patients received IBI110 200mg IV Q3W and sintilimab 200mg IV Q3W, in combination with lenvatinib (weight <60kg: 8mg, weight $\geq$ 60 kg: 12mg) orally administered once daily, until disease progression, unacceptable toxicity or death. The primary objective was to evaluate the safety, tolerability, and efficacy of the combination therapy per RECIST v1.1. **Results:** As the data cutoff date on January 9th 2023, 28 pts were enrolled (median age: 59 years; ECOG PS=0: 6 pts; stage C per Barcelona Clinic Liver Cancer [BCLC]: 13 pts). All 28 pts were included for safety analysis. Treatment-related adverse events (TRAEs) of any grade occurred in 27 pts (96.4%) and the most frequent TRAEs included hypertension (50%), hypothyroidism (42.9%), neutrophil count decreased (39.3%). Grade $\geq$ 3 TRAEs occurred in 16 pts (57.1%) and grade $\geq$ 3 irAEs occurred in 4 (14.3%) pts. Two (7.1%, 2/28) pts experienced TRAE leading to drug discontinuation. One pt experienced investigator-assessed treatment related death. As of data cutoff, for 27 pts with at least one efficacy evaluation, the objective response rate (ORR) was 29.6% (95% CI, 13.8-50.2). The disease control rate (DCR) was 85.2% (95% CI, 66.3-95.8), and 11 pts were still in treatment. With a median follow up of 12.2 months (95%CI, 11.0-12.6), the median progression-free survival (PFS) was 9.9 months (95%CI, 5.7-NC) and the 9-month PFS rate was 54.5% (95%CI, 33.8-71.2). The median overall survival (OS) was not reached. **Conclusions:** In this phase Ib study, IBI110 in combination with sintilimab and lenvatinib as first line therapy demonstrated robust response and survival benefit with manageable safety profile in patients with advanced hepatocellular carcinoma. This combination therapy need to be further explored in this population. Clinical trial information: NCT04085185. Research Sponsor: Inovvent Biologics, Inc., China.

Efficacy and safety of IBI110 in combination with sintilimab in first-line advanced HER2-negative gastric cancer or gastroesophageal junction cancer: Updated results from a phase Ib study. *First Author: Chenyu Mao, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China*

Background: Sintilimab plus oxaliplatin and capecitabine (XELOX) has become the standard of care in patients (pts) with untreated advanced, recurrent, or metastatic gastric or gastroesophageal junction adenocarcinoma (G/G/EJ AC) in China. Dual inhibition of PD-1 and lymphocyte-activation gene 3 (LAG-3) may further improve anti-tumor effect. The preliminary safety and efficacy data of IBI110 plus sintilimab and XELOX in pts with first-line G/G/EJ AC were previously presented (Chenyu Mao et al. ASCO 2022). Here, we presented updated safety and efficacy results of this study. **Methods:** This phase Ib study enrolled patients with previously untreated, unresectable, locally advanced or recurrent/metastatic HER2-negative G/G/EJ AC. Pts received IBI110 200mg IV Q3W and sintilimab 200mg IV Q3W plus XELOX (oxaliplatin 130 mg/m² Q3W and capecitabine 1000mg mg/m²/time twice daily [BID]) until disease progression, unacceptable toxicity or death. The primary objectives were to evaluate the safety, tolerability, and efficacy of the combination therapy per RECIST v1.1. **Results:** As of data cutoff January 9th 2023, 17 pts were assessed as evaluable (median age: 61 years; ECOG PS=1: 14 pts; all gastric cancer). All pts (17/17, 100%) experienced treatment-related adverse events (TRAEs) of any grade, and the most commonly TRAEs were neutrophil count decreased (64.7%), white blood cell count decreased (52.9%), platelet count decreased (52.9%). Grade $\geq$ 3 TRAEs occurred in 11 pts (64.7%), the most frequent grade $\geq$ 3 TRAEs were consistent with TRAEs of any grade. Investigator-assessed immune-mediated adverse events (irAEs) occurred in 10 pts (58.8%). Grade $\geq$ 3 irAEs occurred in 3 pts (17.6%), all led to discontinuation. No treatment-related death occurred. As data cutoff, among 17 efficacy-evaluable pts, the unconfirmed and confirmed objective response rate (ORR) were 88.2% (95% CI, 63.6-98.5) and 64.7% (95% CI, 38.3-85.8), respectively. The disease control rate (DCR) was 94.1% (95% CI, 71.3-99.9). With a median follow up of 13.1 months (95% CI, 7.1-NC), the median duration of response (DoR) and progression-free survival (PFS) were 11.6 months (95% CI, 2.5-14.4) and 12.9 months (95% CI, 3.8-15.8), respectively. The median overall survival (OS) was not reached, and the 12-months OS rate was 70.6% (95% CI, 43.1-86.6). **Conclusions:** IBI110 in combination with sintilimab and XELOX demonstrated manageable safety and encouraging efficacy results in patients with first-line gastric adenocarcinoma. This is the first positive trial to show clinical benefits of a LAG3 plus PD-1 inhibitor combined with chemotherapy for this population. Clinical trial information: NCT04085185. Research Sponsor: Inovvent Biologics, Inc.

Dynamic change of immune phenotype assessed by artificial intelligence (AI)-powered analysis of tumor-infiltrating lymphocytes (TILs) during neoadjuvant durvalumab with or without tremelimumab (D+/-T) in head and neck squamous cell carcinoma (HNSCC). *First Author: Hyunwook Kim, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: The results of a phase II trial evaluating preoperative durvalumab with or without tremelimumab (D+/-T) in resectable HNSCC (NCT03737968) suggest that the neoadjuvant immunotherapy is associated with pathologic tumor regression with manageable safety profiles. Here, we applied AI-powered spatial TIL analyzer, Lunit SCOPE IO, to tumor specimens of the patients included in the trial to assess the impact of spatial TIL density and inflamed immune phenotype (IIP) on immunotherapy responses. **Methods:** H&E-stained whole-slide images (WSIs) of pre- and post-treatment tumor specimens from HNSCC pts enrolled in the aforementioned D+/-T trial were collected. Patients with locally advanced but operable HNSCC were randomly assigned in 1:1 to receive a single dose of D (1,500mg) or D+T (1,500mg+75mg) followed by surgery, at Severance Hospital in Seoul, Korea. Lunit SCOPE IO was used to segment tumor epithelium and stroma to identify and quantify intratumoral TIL (iTIL) and stromal TIL. IIP was defined as the proportion of high iTIL area more than 33.3% of analyzable area. Clinical data and the combined positive scores (CPS) of PD-L1 were also collected. **Results:** A total of 39 paired tumor samples of pre- and post-treatment WSI (23 from D+T and 16 from D) were included. Overall, tumor regression grade 2 (TRG2, $\geq$ 50% of tumor regression) was achieved in 15.4% (6/39) pts, and downstaging after treatment was achieved in 35.9% (14/39) pts. By pre-treatment WSIs, 38.5% (15/39) samples were classified as IIP, and subgroups of D+T and D had 34.8% (8/23) and 43.8% (7/16), respectively. In the D+T arm, the proportions of TRG2 were 25% (2/8) in IIP versus 13.3% (2/15) in non-IIP, whereas D arm had 28.6% (2/7) TRG2 in IIP, but no TRG2 in non-IIP (0/9), respectively. Comparing the WSI of pre- and post-D+/-T samples, the proportion of IIP was significantly increased to 66.7% from 38.5 ($p=0.015$). The increase in IIP proportion was prominent in the D+T arm (34.8% to 69.6%, $p=0.043$), but not in the D arm (43.8% to 62.5%, $p=0.37$). Similarly, PD-L1 CPS increased after therapy, especially in the D+T group (mean CPS 6.0 to 20.7, $p=0.009$). Interestingly, pts who remained non-IIP in both pre- and post-treatment (25.6%, 10/39) had significantly poor prognosis compared to the others, as the 12-month disease-free survival (DFS) rate was 50.0% vs 93.1% (median DFS 13.4m vs not reached, hazard ratio [HR] 4.26, 95% confidence interval [CI] 1.32-13.8, $p=0.009$). This prognostic impact was prominent in the D+T arm (HR 6.75, 95% CI 1.49-30.6, $p=0.004$). **Conclusions:** Neoadjuvant durvalumab +/- tremelimumab promotes dynamic change toward inflamed immune phenotype, resulting in favorable clinical outcomes. Resistance mechanism of stand-still-non-inflamed patients even on D+/-T should be further investigated. Clinical trial information: NCT03737968. Multiplexed trackable intratumor microdosing of the investigational STING agonist TAK-676 alone and in combination in the native tumor microenvironment of patients with head and neck cancer: A phase 0 trial. *First Author: Karthik Rajasekaran, The University of Pennsylvania, Philadelphia, PA*

Background: TAK-676 is a novel synthetic STING agonist developed to induce an inflammatory state through release of interferon (IFN), production of proinflammatory chemokines and cytokines, and activation of innate and adaptive immune cells in the tumor microenvironment (TME). To gain early mechanistic insights on the effects of TAK-676 in the native TME alone and in combination with standard-of-care chemotherapies, we completed a Phase 0 intratumoral microdosing trial in head and neck squamous cell carcinoma patients using the Comparative In Vivo Oncology (CIVO) platform. CIVO enables direct evaluation of biomarker response in trackable, distinct regions of drug exposure upon resection. These studies were designed to identify rational combinations that could be evaluated in future clinical trials with therapeutic intent. **Methods:** This IRB-approved study was conducted at four centers within the United States. Fifteen subjects provided Informed Consent and enrolled in the trial. Microdoses ($\leq 1/100^{\text{th}}$ systemic dose) of TAK-676, carboplatin, 5-FU, paclitaxel, and combinations thereof, were simultaneously injected via CIVO to eligible patients presenting with a surface-accessible primary or metastatic lesion ≥ 2 cm and planned surgical resection of the target lesion at 24 (n=8) or 72–96 (n=7) hours. Injection sites were identified via co-injection of fluorescent tracking markers (CIVO GLO). Multiplexed ISH, IHC, and spatial molecular profiling via GeoMx and CosMx were used to resolve molecular responses at each injection site. Patients were monitored for adverse events (AEs) for 28 days following injection. **Results:** TAK-676 exposure was associated with increased IFN signaling in all samples analyzed at the 24-hour cohort. This was accompanied by increased expression of pro-inflammatory cytokines and chemokines, “M1-like” macrophages, NK cells, and CD8+ T cells. Spatial profiling with GeoMx and CosMx revealed an IFN signature and elevated pro-inflammatory markers across multiple cell types throughout the TME. In addition, exposure to TAK-676 plus chemotherapy resulted in localized enhancement of apoptosis vs. chemotherapy alone across multiple tumors. The responses observed at 24 hours were transient and not detected in the 72–96-hour cohort. No AEs related to injection procedure or contents were reported. **Conclusions:** Intratumor microdosing via CIVO of TAK-676 alone and in combination with chemotherapy was shown to promote an early pro-inflammatory response, providing evidence of an on-target mechanism of action. The absence of effect at the late timepoints could be due to pharmacokinetics of drug exposure or compensatory signaling within the TME. In this Phase 0 clinical trial we safely demonstrated precise, mechanistic effects of TAK-676 on the native TME of intact human tumors. Clinical trial information: NCT04541108. SpliceIO: A robust platform for the discovery and validation of splicing-derived neoantigens. *First Author: Gayatri Arun, Envisagenics Inc., Long Island, NY*

Background: Splicing dysregulation is a major hallmark of cancer, affecting tumor progression, metastasis, and therapy resistance. Aberrant alternative splicing plays a critical role in generating tumor-specific neoantigens targetable through an arsenal of immunotherapeutic modalities. Such neoantigens cannot be discovered using conventional DNA-based tools; they require specialized software for alternative splicing analysis using RNA-seq data. **Methods:** Envisagenics has developed SpliceIO, a proprietary software platform for splicing-derived neoantigen discovery. SpliceIO uses RNA-seq data to uncover extracellular neoantigens encoded by transmembrane proteins or presented to immune cells through the MHC complex. This predictive ensemble maximizes the value of RNA-seq data to predict fundamental aspects of neoantigen activity, such as their protein localization, MHC binding affinity, epitope accessibility and cancer pathway relevance. Here, we summarize the discovery and validation of novel splicing-derived neoantigens identified using SpliceIO in acute myeloid leukemia and colorectal cancer. **Results:** We analyzed $>10,000$ RNA-seq samples from the four tumor types and controls derived from 32 normal tissues. To maximize the prevalence of neoantigen target candidates in patient subpopulations, RNA-seq samples were pre-stratified using SpliceSlice, a proprietary software for spliceosomal profiling. As a result, patients sharing common spliceosome alterations were grouped into 11 coherent subsets that are distinct from normal tissue. Using this approach, we have discovered several promising candidates that we prioritized for experimental validations. SpliceIO target candidates were validated experimentally in cancer cell lines and primary tumor tissues to confirm RNA expression, translation, and membrane localization. Additionally, we performed proteomics to evaluate the presence of neopeptides generated from the unique splicing events. Using this approach, we have discovered and validated several tumor specific splicing derived neoantigens that are also recurrent in $>15\%$ of the population. **Conclusions:** Together, our results strongly support the role of aberrant splicing as a major source of tumor-specific neoantigens. Our combined computational and experimental approach promotes novel target discovery, enabling the development of novel immunotherapeutics for cancer treatment. The initial report of phase I trial of VG2025, a non-attenuated HSV-1 oncolytic virus expressing IL-12 and IL-15/RA payloads, in patients with advanced solid tumors. *First Author: Siqing Fu, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: VG2025 is a non-attenuated HSV-1 Oncolytic virus (OV). The wildtype neurovirulence is controlled by the Transcription and Translation Dual Regulation (TTDR) of ICP27 and ICP34.5 proteins. IL-12, IL-15, IL-15Ra payloads are controlled by tumor promoter CxCR4. The native promoter of ICP27 was replaced with a promoter for Carcinoembryonic Antigen (CEA). Here we report a first-in-human, open label, study to evaluate the safety, pharmacokinetics (PK), and biologic effects of VG2025 in patients (pts) with advanced solid tumors progressed after standard of care from China and United States. The study is actively recruiting. NCT05266612. **Methods:** Dose escalation follows a 3+3 design at 4 dose levels as intratumoral, and image guided injections into deep lesions on days 1 and 15 of each 28 days treatment cycle. PK and viral shedding (DNA), samples from biopsies, blood, urine, and swabs from injection site and other anatomical locations were analyzed by PCR. Changes of cytokines and lymphocyte subsets in blood were also observed as pharmacodynamic parameters. **Results:** As of 10 Jan 2023, 10 pts received doses of 1.0×10^8 and 2.0×10^8 PFU. 5 males and 5 females with the median age of 58 years were enrolled. 20% were PD(L1) refractory, 20% had 2 Prior lines of therapy and 60% ≥ 3 . The Median CEA level was 7.4. Tumor types were: 2 Duodenal Adeno Ca., 1 Pancreatic, 1 Ovarian, 1 Leiomyosarcoma, 1 Salivary Duct Ca., 1 Hepatocellular Ca (HCC), 1 Intrahepatic Cholangiocarcinoma (ICC), 1 Colorectal Ca (CRC) and 1 Colon Ca. No Dose Limiting Toxicities were observed. Any grade treatment-related AEs (TRAEs) was 70%, the most common TRAEs was fever 60%. Grade ≥ 3 TRAEs were 50% [3 pts had grade 4 Lymphocyte decreased (all recovered)], 1 had grade 3 COVID-19 and 1 had grade 3 nausea and vomiting. 4 pt had SAEs (2 cases of COVID-19, 1 Ascites and 1 Nausea and Vomiting). No TRAEs leading to dose reduction and treatment discontinuation. No pts had positive viral shedding. 4 pts were efficacy evaluable; ORR 25% (1 pt with ICC had confirmed PR with -45%) and DCR 100% based on RECIST v1.1. The PR pt had meaningful reductions in CEA levels. Tumor shrinkage was also observed in non-injected lesions demonstrating an abscopal effect. Nanostring analysis of paired biopsies from the PR pt demonstrate upregulation of genes for integrin signaling pathway, activation of CD8+ T cells and T cell-based immunity, upregulation of antigen-presenting MHC (HLA-DQA1 and HLA-DRB1) and chemokine receptor (CMKLR1) genes. Cellular immunity was activated by upregulation of Th1 cells, macrophage-associated genes and downregulation of Treg-associated genes. The results are consistent with the mechanism of action of VG2025. Analysis is ongoing with other subjects. **Conclusions:** Monotherapy activity was observed with an acceptable safety profile in heavily pretreated pts with advanced solid tumors. Clinical trial information: NCT05266612. Research Sponsor: Virogin Biotech Canada Ltd.; Virogin (Shanghai) Biotech Co. Ltd.

Patient perspectives on BCMA-targeted therapies for multiple myeloma: A survey conducted in a patient advocacy group. *First Author: Jennifer M. Ahlstrom, HealthTree Foundation, Lehi, UT*

Background: The emergence of B-cell maturation antigen (BCMA) targeted therapies in multiple myeloma (MM) has led to improvements in clinical outcomes in patients with heavily pretreated disease. Little is known about patients' knowledge, decision-making process, and openness to these novel therapies that include chimeric antigen receptor (CAR) T-cell therapy and bispecific antibodies. This study aims to understand patient perspectives on these BCMA-targeted therapies. **Methods:** This is a cross-sectional survey completed by patients with MM enrolled in HealthTree Cure Hub, an online portal for patients with plasma cell dyscrasias to help navigate their disease. An 18-question survey was developed by the research team, then reviewed and adjusted by HealthTree's Patient Advocacy Panel and a physician panel. Responses were analyzed descriptively and reported in aggregate. **Results:** From 10/28/2022 to 1/12/2023, 325 patients with MM participated in the survey (mean age: 66 ± 8 years; 54% female; 90% White; years since diagnosis: 6.6 ± 4.7 ; lines of therapy: 3.0 ± 2.6). In general, 26% of patients were open to trying a new therapy right away and 43% were open but would like more information on safety and efficacy. BCMA-targeted therapies were well known with 92% of patients having heard about them. Among respondents for each question, 65% were likely or very likely to try a CAR T-cell therapy if offered and 74% were likely or very likely to try a bispecific therapy; while 17% and 13%, respectively, needed more information to decide. The most requested domains of information were efficacy, side effects (SEs), eligibility, and administration process for both CAR T-Cell and bispecific therapies. "How soon can I receive it" was ranked higher for bispecific therapy while "where can I receive it" was ranked higher for CAR T-cell therapy, relatively. The top attributes of therapy profiles were prolonged life, improved quality of life, longer progression-free survival, and tolerable SEs. To receive an effective therapy, the top acceptable trade-offs included frequent monitoring of SEs and initiating a new drug in a hospital setting, while patients were least willing to compromise on caregiver burden. Additionally, the most acceptable SEs were those that were asymptomatic but would need routine monitoring to prevent serious complications, and those that were cosmetic but non-life-threatening. **Conclusions:** This study found a high level of openness in patients with MM to try BCMA-targeted therapies if offered. Information on efficacy, safety, availability, and eligibility may assist patients on their decision-making. Patients were willing to accept certain trade-offs for a treatment that could be clinically beneficial. Incorporating patients' goals, values, and preferences alongside clinical factors and other considerations may further optimize treatment decisions and improve patient outcomes. Use of proteomimetic polymers for delivery of tumor antigens and adjuvants through formation of stable electrostatic complexes with small molecule STING agonists. *First Author: Max Mu Wang, Medical Scientist Training Program, Northwestern University, Chicago, IL*

Background: Utilizing tumor antigens for the development of patient-specific cancer vaccines has been a promising therapeutic strategy. However, significant challenges remain in delivering subunit vaccine components to elicit anti-tumor immune responses. To overcome these, we developed rationally designed cancer vaccines using a new nanoplatform called the Protein-Like Polymer (PLP) with unique characteristics that allow for sustained delivery of tumor antigens in conjunction with immunomodulatory compounds. **Methods:** PLPs containing antigens were synthesized via ring-opening metathesis polymerization (ROMP) and characterized using HPLC, LC-MS, NMR, and GPC. A library of compounds were generated with different sidechain linkage chemistries (amide, ester, or disulfide linkage), DPs, and inclusion of PEG side chains. In vitro assays using gp100-specific T Cells were conducted with fluorescently labeled and non-labeled polymers. In vivo experiments were done using B16 murine melanoma transplanted tumor models. Ability of PLPs to co-deliver immunomodulatory compounds was tested using a small molecule STING agonist 2'3' cGAMP. **Results:** Conjugating antigens to the polymer backbone using a cleavable disulfide linkage, designed to be reduced intracellularly, resulted in the best subcellular localization and immune activation (higher levels of immune cell proliferation, cytokine production, and expression of activation markers). Incorporating a diluent amount of PEG side chains increased resistance to enzymatic degradation while improving bioactivity and cell uptake. In vivo studies using PLPs conjugated with melanoma-associated antigen gp100 showed the reductions in tumor size with increased immune cell proliferation and activation in a B16 melanoma model. Additionally, increasing the degree of polymerization, and therefore the density of antigen side chains per unit polymer, improved vaccine efficacy and resistance to proteolysis. Mice treated with STING agonists electrostatically coupled to PLPs showed significantly smaller tumors vs no-treatment at day 14 (0.038g vs 0.76g; $p < 0.0001$) and allowed for subcutaneous administration of the small molecule, which normally must be injected intratumorally. **Conclusions:** Our work demonstrates the potential of PLPs to overcome inherent difficulties associated with developing cancer vaccines. The modularity of the platform allows for complex nano-architectures including systems capable of delivering challenging compounds, ie small molecule STING agonists, subcutaneously through electrostatic coupling. This technology has the potential to revolutionize cancer vaccinology. Research Sponsor: U.S. National Institutes of Health.

Relationship between tumor microenvironment (TME)-based histomic TGF β signature (TGFbs), stromal fibroblast recruitment, and exclusion of immune cells as immunotherapy resistance mechanisms. *First Author: Gahee Park, Lunit Inc., Seoul, South Korea*

Background: TGF- β activates fibroblasts within the TME and may be associated with poor response to immunotherapy. However, objective and reliable assessment of the TGFbs by gene expression profiling (GEP) is challenging. Using H&E whole-slide images (WSI) from The Cancer Genome Atlas (TCGA), we developed an artificial intelligence (AI) model to predict a normalized TGFbs, applying it to real-world datasets (RWDs) of advanced solid tumor patients treated with immunotherapy. **Methods:** The TGFbs was defined using the mean GEP values of the 'Hallmark TGF- β signaling' gene set. H&E WSIs of 23 carcinoma types from TCGA (n=6,945) were used to discover the association of the TGFbs with various cell types, including fibroblasts and tumor-infiltrating lymphocytes (TILs) detected by an AI model, Lunit SCOPE IO (AI-1). Another custom AI model (AI-2) to predict TGFbs was developed by integrating self-supervised and supervised features and other semantic content extracted by AI-1 with multilayered perceptron classifiers. TGFbs prediction scores from the AI-2 were applied to 5 different RWDs containing 1,792 immunotherapy-treated patients (> 16 primary tumor types). The immune-excluded phenotype (IEP) was defined by high stromal TIL and low intratumoral TIL density. **Results:** In the TCGA dataset, TGFbs and fibroblast density detected by AI-1 were closely correlated ($R=0.19$, $p<0.001$) compared to other cell types, with both highest in pancreatic adenocarcinoma (PAC)(median [interquartile range, IQR] 0.73 [0.66-0.80], 1306 [985-1588]/mm², respectively) and CMS4 colorectal cancer (0.61 [0.54-0.67], 868 [582-1128]/mm²) compared to other cancers (0.57 [0.47-0.66], 577 [295-890]/mm²). The AI-2 predicted TGFbs with area-under-the-curve of 0.781 on cross-validation within the TCGA dataset. The TGFbs of immunotherapy-treated RWDs were inferred from their corresponding H&E WSI, with scores comparable to those from the TCGA (0.42 [0.16-0.60] vs 0.58 [0.48-0.67]), with PAC having the highest TGFbs (0.65 [0.45-0.77]) in the RWD as well. Interestingly, TGFbs inferred scores and fibroblast density were significantly correlated ($R=0.7$, $p<0.001$) in the RWD and also significantly correlated with the IEP (0.52 [0.30-0.66]) compared to other immune phenotypes (0.42 [0.16-0.60], $p<0.001$). In the RWD, patients with inferred TGFbs in the upper 75% quartile had a poor clinical response to immunotherapy (objective response rate: 15.1% vs 20.7%, median progression-free survival 3.0 m vs 4.0 m, hazard ratio 1.21, 95% confidence interval 1.07-1.36, $p=0.002$). **Conclusions:** TGFbs is closely correlated with fibroblast density within the TME and may confer resistance to immunotherapy. Unique morphologic features of the TGFbs can be captured by AI, enabling scalable application to various datasets for clinical and translational research. Research Sponsor: None.

Phase I study of MP0317, a FAP-dependent DARPIn, for tumor-localized CD40 activation in patients with advanced solid tumors. *First Author: Carlos A. Gomez-Roca, Institut Claudius Regaud, IUCT-Oncopole, Toulouse, France*

Background: CD40 is a master switch for both innate and adaptive immune systems. The clinical development of CD40 agonists has been hampered by dose-limiting toxicity (DLT) due to systemic CD40 activation and peripheral target-mediated drug disposition (TMDD). MP0317 is a CD40-agonistic DARPIn (designed ankyrin repeat protein), developed to reduce systemic toxicity. MP0317 is exclusively active in the presence of fibroblast activating protein (FAP) expressed by cancer associated fibroblasts in the tumor microenvironment. This allows reaching serum levels that overcome the TMDD and have the potential to deliver sustained and tumor-localized CD40 activation. Ongoing clinical testing aims at establishing its safety/tolerability profile, PK/PD characteristics, and a recommended dose for combination therapy. **Methods:** NCT05098405 is a Phase 1, multicenter, open label, dose escalation study followed by a safety expansion part in adult patients with advanced solid tumors. The dose escalation scheme uses an adaptive Bayesian logistic regression model with overdose control. Peripheral blood biomarkers are analyzed by immunoassays and flow cytometry, and baseline and on-treatment tumor biopsies are characterized by RNA sequencing and immunofluorescence. Eligible patients are enrolled into 9 sequentially escalating dose cohorts of MP0317 (0.03-10 mg/kg), administered IV 3-weekly (Q3W) or 1-weekly (Q1W) until disease progression or unacceptable toxicity. **Results:** At submission, 23 patients across 6 cohorts completed the study, with no DLT observed. Patient enrolling in higher dose cohorts is ongoing. The most frequent AE was grade 2 infusion related reaction in 5 patients. The 23 patients received ≥ 2 (range 2-8) doses (range 0.03 – 3 mg/kg) of MP0317 across five Q3W and one Q1W cohorts and completed the 28-day DLT period. PK data confirmed all patients were exposed to MP0317 with broadly dose-dependent C_{max} and no sign of accumulation. PD data was derived from patients dosed with 0.03 – 3 mg/kg. Soluble biomarkers (sFAP and sCD40) showed target engagement in periphery with signs of FAP saturation at ≥ 0.5 mg/kg. Colocalization of MP0317 with FAP and CD40 in the tumor was confirmed in 4 out of 8 evaluable paired tumor biopsies. Whole transcriptome and gene set enrichment analyses showed an upregulation of genes related to B-cell trafficking (CXCL3, CXCR5, CCR6, CCL20) upon treatment. Transient increase of IFN γ -induced chemokines (CXCL9, CXCL10) was observed, whereas the pro-inflammatory cytokines (TNF α , IL-2, IL-6, IL-8) were not upregulated. **Conclusions:** Clinical data and the lack of pro-inflammatory circulating cytokines confirm MP0317 is safe and well-tolerated, while analysis of paired pre- and on-treatment tumor biopsies suggests early evidence of tumor-localized CD40 activation. The current data enables further evaluation in a combination setting. Clinical trial information: NCT05098405. Research Sponsor: Molecular Partners AG.

Clinical outcomes in phase 1 clinical trials (Ph1-CT) when treating patients (pts) with novel immunotherapy (IT) agents at early lines for advanced disease. *First Author: Juan José Soto, Medical Oncology Department-Phase 1 Functional Unit | Catalan Institute of Oncology (ICO), Hospitalet De Llobregat, Barcelona, Spain*

Background: Cancer pts can be offered IT drugs within Ph1-CT before having exhausted standard of care (SoC) therapies. However, whether this strategy may improve pts' outcomes remains unclear. We assess the benefits of receiving novel IT compounds within Ph1-CT at early lines for advanced disease. **Methods:** We retrospectively reviewed a correlative series of pts with advanced solid tumors treated with IT within Ph1-CT at the Phase 1 Unit of Catalan Institute of Oncology (ICO), Barcelona, Spain, from January 2018 to July 2022. Primary aim was to assess clinical outcomes measured by median progression-free survival (mPFS) and median overall survival (mOS) according to number of prior lines (PL) for recurrent/metastatic disease, prior IT, availability of alternative SoC in our country, IT biomarker-selected population and grade 3-4 toxicity (G3-4 Tox) by multivariate analysis (MVA). Overall response rate (ORR) was evaluated by RECIST 1.1. Clinical benefit rate (CBR) was defined as complete/partial response + stable disease for ≥ 6 months (m). PFS/QOS were calculated by Kaplan-Meier method. Log-rank test was used for comparisons. MVA was performed by Cox regression. **Results:** A total of 228 pts were assessed: IT monotherapy = 49 (21.5%), IT combinations = 179 (78.5%) (IT+IT = 111 [48.7%], IT+targeted therapy = 24 [10.5%], IT+others = 44 [19.3%]). Forty-nine (21.5%) pts were included according to IT biomarkers (PDL1, TIM3 expression, MSI-H, others). Median age was 62 y (24-83), 62.7% were men. All pts had ECOG ≤ 1 . The 4 most frequent cancer types were HNSCC (19.7%), NSCLC (15.4%), glioblastoma (10.5%) and urothelial (10.1%). Number of PL: 0 = 33 (14.5%) pts, 1 = 92 (40.3%) pts, $\geq 2 = 103$ (45.2%) pts. Sixty-three (27.6%) pts had received prior IT and 159 (69.7%) had alternative available SoC. Overall G3-4 Tox rate was 21.5% (20.6% in pts IT-treated). ORR and CBR were higher in pts IT-naïve than in pts IT-treated (21.2% vs 12.7% [$p=.18$] and 35.7% vs 25.4% [$p=.26$], respectively). With a median follow-up of 19m, overall mPFS and mOS were 3.5m (2.7-3.9) and 9.8m (8.5-11.5), respectively. In the MVA, lesser number of PL, SoC availability and biomarker selection positively impacted on mOS. After Ph1-CT treatment, 111 (48.7%) pts received further treatment: 19.3% within clinical trial, 29.4% with SoC. **Conclusions:** In our cohort of pts treated within IT Ph1-CT, those with less PL of treatment, with available alternative SoC and/or selected by biomarker achieved higher PFS and OS. These results suggest that treating pts with novel IT agents at early lines might positively impact on survival. Research Sponsor: None.

Variables	PFS(m)	OS(m)
PL		
≤ 1 / ≥ 2	4.3 / 2.4 p .0002	13.3 / 8.7 p .001
≤ 2 / ≥ 2	3.6 / 1.7 p .001	10.5 / 7.8 p .001
Prior IT (yes/no)	2.3 / 3.5 p .007	9.3 / 8.5 p .66
SoC available (yes/no)	3.8 / 2.1 p .0003	10.8 / 8.7 p .03
Biomarker selection (yes/no)	5.3 / 2.7 p .07	12 / 8 p .03

Patient-derived skin MicroOrganoSpheres and clinical response to immunotherapy. *First Author: Rikhia Chakraborty, Xilis, Durham, NC*

Background: Immunotherapies, including immune checkpoint inhibitors (ICI), have revolutionized the treatment of many cancers, producing significant improvements in survival in patients with many different cancers. However, the intended anti-tumor effects also result in a unique form of autoimmunity, known as immune-related adverse events (irAEs), which have emerged as a limiting factor for many immunotherapies. Cutaneous irAEs (cirAEs), the most frequently occurring ICI-related toxicities, have been associated with improved efficacy and survival but, in their severe forms, require systemic steroids and have in cases led to premature ICI discontinuation and fatality. There is a need for both robust biomarkers and adequate models that effectively predict which patients who develop irAEs may have improved outcomes. **Methods:** Using a microfluidic droplet technology that generates "mini" patient-derived organoids called MicroOrganoSpheres (MOS), we successfully generated skin MOS from skin biopsy samples in both healthy skin and tumor-involved skin that sustain the original patient skin immune microenvironment over three weeks. Using this model, we assessed skin cell toxicity and cytokine release in response to ICI and targeted therapies. **Results:** Clinical responses were largely consistent with the skin and tumor MOS assay readouts, indicating that MOS recapitulates the potential association between skin irAEs and efficacy. Matched pairs of patient melanoma and skin MOS showed good concordance with patient outcome indicating that MOS recapitulates the potential association between skin irAEs and efficacy. Enrichment of genes associated with atopic dermatitis, vitiligo, and psoriatic dermatitis were observed in MOS generated from skin of an ICI-sensitive patient compared to the MOS generated from skin of an ICI-resistant patient. These results indicated that the skin MOS platform can potentially predict the dermatological toxicity of ICI. As the MOS assay can be completed within 12 days after biopsy acquisition, this novel technology may enable personalized medicine approaches by prediction of cirAEs and efficacy for individual patients. **Conclusions:** This is the first study to date demonstrating the application of a patient-derived immune competent skin model deployable for assessing ICI efficacy and toxicity response. Matched tumor skin MOS from the same patients recapitulated the clinically observed association between ICI efficacy and toxicity and may provide key indicators for prospective irAE-predicting clinical trials. Safety and efficacy of HB0025, an anti-PD-1/VEGF bispecific antibody fusion protein, in patients with advanced solid tumors: Preliminary results from an FIH trial. *First Author: Yiqun Du, Phase I Clinical Trial Center, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: HB0025 is a recombinant humanized anti-PD-L1 monoclonal antibody-VEGFR1 fusion Protein. Nonclinical data both in vitro and vivo have shown high-affinity binding to both targets as well as the inhibition of tumor growth in animal models. Here, we present preliminary safety and efficacy data from a dose escalation phase I study of HB0025. **Methods:** Eligible patients (pts) were ≥ 18 years old (ECOG PS 0–1) who had advanced solid tumors (NSCLC, gynecological tumors, digestive system tumors, etc.) and failed standard treatment. This phase 1 dose escalation includes accelerated titration (0.01, 0.03, 0.1 and 0.3 mg/kg) and conventional 3+3 dose escalation (1.0, 3.0, 6.0, 10, 12, 20, and 30.0 mg/kg). HB0025 is administered intravenously every 14 days (Q2W). Objectives include evaluation of safety, pharmacokinetics (PK), pharmacodynamics (PD), immunogenicity, and antitumor activity. Adverse events (AEs) were reported with CTCAE v5.0 and DLTs were evaluated within a 28-day window. **Results:** As of Aug 30th 2022, 30 pts including 8 male and 22 female from Caucasian and Mongoloid have received HB0025 at doses of 0.01 mg/kg (n=1), 0.03 mg/kg (n=2), 0.1 mg/kg (n=1), 0.3 mg/kg (n=1), 1.0 mg/kg (n=3), 3.0 mg/kg (n=7), 6.0 mg/kg (n=7), 10.0 mg/kg (n=5), and 12.0 mg/kg (n=3) Q2W. Overall, the median age was 55 years and the median lines of previous treatment was four. Of the 22 evaluable pts dosed at ≥ 3 mg/kg Q2W, the ORR was 9.1% (2/22) and the disease control rate (DCR) was 50% [11/22]. Among the 2 responders, a CR (colorectal ca) pt whose prior therapy was no immune checkpoint inhibitor (ICI) or bevacizumab have continued more than 36 weeks; and a PR (NSCLC) pt with duration more than 18 weeks whose tumor was 60.2% regression and prior ICI failure. Till the date of submission, the therapy was continuing for the CR and PR pts. Treatment-related adverse events (TRAEs) occurred in 83.3% of pts. The grade 3 TRAEs occurred in 20% [6/30] and treatment-related SAEs occurred in 13.3% [4/30]. One DLT occurred in the 12.0 mg/kg cohort. No death occurred related to HB0025. TRAEs leading to treatment discontinuation occurred in 13.3% of pts [4/30]. The most frequent TRAEs were hypertriglyceridemia (23.3%), hypercholesterolemia (23.3%), anemia (16.7%), alanine aminotransferase increase (16.7%), and proteinuria (13.3%). **Conclusions:** HB0025 shows manageable safety and promising anti-tumor activity in pts with various solid tumors. To better characterize the risk-benefit profile, HB0025 is currently enrolled at 20.0 mg/kg Q2W and is being explored at doses 10 mg/kg in expansion cohorts. The future data, including PK, PD and ADA will be presented. Clinical trial information: NCT04678908. Research Sponsor: Huaota Biopharma, Inc.

Efficacy and predictors of response of nivolumab in treatment-refractory MSI solid tumors: Results of a tumor-agnostic DRUP cohort. *First Author: Birgit Geurts, Department of Molecular Oncology & Immunology, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Microsatellite unstable (MSI) tumors represent 4% of all cancer diagnoses and are known to be sensitive to immune checkpoint inhibitors (ICI). Despite the progress made, a significant proportion of patients with MSI tumors does not respond, highlighting the urgent need to identify additional predictive biomarkers. In this study, we evaluated the efficacy of the PD-1 inhibitor nivolumab across pre-treated solid MSI tumors and performed extensive biomarker analysis to better characterize ICI-effectiveness in this setting. **Methods:** Adult patients with MSI tumors who exhausted all standard of care treatment options were eligible for inclusion and were enrolled in the Drug Rediscovery Protocol (DRUP), a clinical trial that treats cancer patients with approved targeted- and immunotherapies outside their registered indication, based on their tumor molecular profile (NCT0295234). Patients were treated with nivolumab (four cycles of 240 mg every 2 weeks, followed by 480 mg every 4 weeks) until disease progression or unmanageable toxicity. Primary endpoint was clinical benefit (CB, objective response (OR) or stable disease ≥ 16 weeks). Whole genome sequencing and RNA sequencing were performed on pre-treatment biopsies to reveal potential predictors of response or resistance to anti-PD1. **Results:** 130 evaluable patients were enrolled with in total 16 different tumor types. CB was observed in 62% (95% CI 46 – 54) ($N = 80$) with an OR in 45% (95% CI 53 – 70) ($N = 58$). After a median follow-up of 14.5 months (95% CI 13 – 19), median progression free survival was 18 months (95% CI 9 – not reached) and median overall survival was not reached. HLA class I status and mutational burden were not significantly associated with CB. However, in depth biomarker analyses identified that mutational burden was predictive of CB in HLA-wildtype patients (52%) but not in HLA class I mutants (48%). Strikingly, in contrast to the paradigm that neoantigen-specific adaptive immunity is primarily involved in clearing MSI tumors, transcriptomics indicated that, compared to non-CB, CB was characterized by significantly higher expression of key modulators in innate immunity, including non-classical HLA transcripts ($P = 4.2 \times 10^{-3}$), NKGD2 ligands MICA/MICB ($P = 6.4 \times 10^{-3}$), killer immunoglobulin-like receptors ($P = 0.047$) and butyrophilins ($P = 0.024$). **Conclusions:** Nivolumab proved highly effective in pre-treated, advanced solid MSI tumors. Genomic analysis revealed that neoantigen burden only determined ICI-effectiveness in patients with wildtype HLA class I. Furthermore, transcriptomics revealed a central role of innate immunity in ICI-effectiveness in MSI tumors, which aligns with the fact that these tumors frequently lose HLA class I antigen presentation. Together, these results inform novel biomarker strategies to further refine precision medicine in this patient population. Clinical trial information: NCT0295234. Immunotherapy for localized dMMR/MSI tumors: First interim analysis of the IMHOTE trial. *First Author: Christelle De La Fouchardiere, Medical Oncology Department, Centre Leon Berard, Lyon I University, Lyon, France*

Background: Immune checkpoint inhibitors (ICI) have demonstrated their efficacy in advanced dMMR/MSI (deficient mismatch repair/microsatellite instability) tumors and increasing data are also accumulating in localized resectable stages with about 60% of pathological complete response rate. The goal of the IMHOTE trial is to assess the safety and efficacy of peri-operative pembrolizumab in localized dMMR/MSI tumors independently of their anatomical origin. **Methods:** IMHOTE is a prospective, multicenter, phase II study aimed to include 120 patients (pts) with localized resectable dMMR/MSI tumors, eligible for curative surgery. Pembrolizumab 400 mg flat dose is administered as a perioperative treatment with 1 or 2 doses every 6 weeks before surgery and thereafter every 6 weeks for one year. Primary objective is to evaluate the pathological complete response (pCR) rate defined as ypT0N0 stage. Secondary objectives are to assess major pathological response, centralized pathological review, safety, clinical response rate, recurrence-free survival and overall survival. Here, we present the interim analysis of safety and pathologic response data for the first 70 treated pts. **Results:** Median age was 67.5 years (26-89), 54.3% were males, and 42.0% were ECOG-PS 0. Surgery was performed in 54/70 pts including 27/35 colorectal (CRC), 16/21 oesogastric (OGC), 4/5 endometrial (EC) and 7/9 other (6 small intestine, 1 bile duct) (OC) cancers. 16 pts (22.9%) were not operated, mainly due to patient's decision following complete clinical response (n=7). Only one patient was not submitted to surgery because of disease progression. Focusing on the 54 operated pts, 31 and 23 pts received 1 and 2 neoadjuvant pembrolizumab doses respectively. The pCR rate was 38.9% (40.7%, 25.0%, 0.0% and 85.7% in CRC, OGC, EC and OC respectively). Grade 3-4 immune-related adverse events were observed in 4 (5.7%) patients including transaminases increase (n=1), arthritis (n=1), acute kidney injury (n=1) and pneumonitis (n=1). **Conclusions:** In this IMHOTE interim analysis, we observed a limited complete pathologic response rate to short-course neoadjuvant pembrolizumab. If we add patients in clinical complete response who chose not to be operated to those with pCR, our results compare with those previously reported. But we can also hypothesize that preoperative treatment duration should be prolonged to obtain more pCR. Overall, tolerance of pembrolizumab was acceptable without new safety signal. Centralized pathological review, major pathological response evaluation and clinical response rate analysis are ongoing. IMHOTE trial has been registered (first post: March 12th, 2021). Clinical trial information: NCT04795661. Research Sponsor: French Ministry of Health.

Poster Session

Partial tumor irradiation plus pembrolizumab in treating large advanced solid tumor metastases. *First Author: Mark Charles Korpics, University of Chicago, Chicago, IL*

Background: We previously demonstrated the safety of stereotactic body radiotherapy followed by pembrolizumab (SBRT+P) in patients with advanced solid tumors. This phase 1 clinical trial was expanded to study the safety of partial tumor irradiation (partial-Rx). We assessed irradiated local failure (LF) and clinical outcomes with correlations to biomarkers including CD8-T-cell radiomics score (RS) and circulating cytokines. **Methods:** Patients received SBRT to 2-4 metastases and pembrolizumab ≤ 7 days after SBRT. Tumors < 65 cc received the full radiation dose (complete-Rx), whereas tumors > 65 cc received partial-Rx. Landmark analysis was used to assess the relationship between tumor response and overall survival (OS). Multivariable analysis was performed for RS and circulating cytokines. **Results:** In the combined (expansion plus original) cohort, 97 patients (219 metastases) were analyzed and received SBRT+P. Forty-six (47%) patients received > 1 partial-Rx treatment. There were 7 (7.2%) dose-limiting toxicities (DLTs). 1-year LF was 7.6% overall, and 13.3% and 5.4% for partial-Rx and complete-Rx tumors, respectively (hazard ratio 2.32, 95% confidence interval: 0.90-5.97, $p = 0.08$). The overall, unirradiated, and irradiated objective response rate was 22%, 12%, and 34%, respectively. Irradiated tumor response to SBRT+P was associated with prolonged OS; 1-year OS was 71% (responders), 42% (mixed-responders), and 0% (non-responders) ($p < 0.01$). High-RS was significantly associated with improved LF, progression-free survival (PFS), and OS. Elevated circulating IL-8 was independently associated with inferior PFS and OS. **Conclusions:** SBRT+P is safe in patients with large, advanced solid tumors. Additional studies are warranted to assess non-inferiority of complete versus partial irradiation of tumors in the setting of immunotherapy. Clinical trial information: NCT02608385. Research Sponsor: Merck Investigator Studies Program.

Differences in real-world pembrolizumab dosing patterns (every 3 weeks versus every 6 weeks) across a large cancer center network. *First Author: Divya Natesan, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Pembrolizumab (pembro) is an intravenous immune checkpoint inhibitor used for anti-cancer treatment, with equivalent monotherapy dosing options of 200 mg every 3 weeks (Q3W) or 400 mg every 6 weeks (Q6W). Pembro Q6W dosing was approved for use in April 2020 after the Q3W dose had already been established. As pembro dosing patterns in real-world practice are not well-described, we evaluated this in a large cancer center network consisting of a central site (CS) and 36 community network sites (NS). **Methods:** We retrospectively reviewed the charts of all patients who received pembro monotherapy for cancer treatment between 4/2020 – 4/2022 at UPMC Hillman Cancer Center sites across the state of Pennsylvania, as well as sites in New York and Ohio. We performed statistical comparisons using the Fisher's exact test and Wilcoxon rank-sum test. **Results:** We identified 1,640 patients who received pembro monotherapy, including 377 patients at the CS and 1,263 patients in the NS, with characteristics displayed. Pembro Q6W dosing was significantly more common at the CS than in the NS (42% vs. 15%, $p < 0.0001$). When analyzed by tumor type, pembro Q6W dosing was significantly more common at the CS than in the NS for head & neck (53% vs. 11%, $p < 0.0001$), thoracic (49% vs. 15%, $p < 0.0001$), skin (60% vs. 19%, $p < 0.0001$), and genitourinary (30% vs. 16%, $p = 0.015$) cancers, but not for other tumor types. Within the NS, 30% (11/36) of sites only utilized pembro Q3W dosing and never administered Q6W dosing to patients. Of note, some patients who received pembro Q6W dosing received pembro Q3W dosing initially, either as part of a pembro-containing multidrug regimen or as monotherapy. Excluding patients initially treated with a multidrug regimen to reduce confounding factors, we found that of the patients who received pembro Q6W dosing, 47% (65/137) at the CS and 28% (48/169) in the NS were initially treated with pembro Q3W monotherapy before transitioning to Q6W monotherapy ($p = 0.0008$). **Conclusions:** In our large cancer center network, pembro Q6W dosing was significantly more common at the CS than in the NS. Switching from pembro Q3W to Q6W dosing was also significantly more common at the CS. Further work is needed to clarify the patient, provider, and institutional factors influencing differences in pembro dosing patterns in real-world practice, as well as the impact of dosing patterns on care delivery outcomes such as cost and accessibility. Research Sponsor: None.

Genomic alterations associated with response to immune checkpoint inhibitors in rare cancers: A biomarker exploration study from the Australian Molecular Screening and Therapeutics (MoST) Program. *First Author: Maya Kansara, Garvan Institute of Medical Research, Sydney, NSW, Australia*

Background: Despite immune checkpoint inhibitors (ICI) demonstrating efficacy in over 15 cancer types, evidence in most rare cancers remains scarce, reflecting the challenges of conducting prospective trials. This Australia-wide study reports real-world (RW) objective responses to ICIs targeting the programmed death-(ligand)1 (PD-1/PD-L1) pathway in a large precision oncology program, and associations between response and genomic alterations in rare cancers. **Methods:** This study was conducted within the framework of the MoST Program (ACTRN12616000908437), where adult patients (pts) with advanced solid tumors were screened using comprehensive genomic profiling (CGP). Only pts who received ICI after CGP were included in this analysis. The best overall response (BOR) to ICI was reported by the treating oncologist during the follow-up period. Best response was categorized as complete (CR), partial (PR), stable (SD), or progressive (PD). Two categories were defined: responders were individuals reported to have experienced CR or PR, while non-progressors were those with CR, PR, or SD. The association between tumor mutational burden (TMB) and response categories was assessed by area under the receiver operator characteristic curve (AUC). Odds ratios (OR) of specific genomic alterations associated with each category were also estimated. **Results:** Between Dec 2016 and Aug 2022, 4343 pts were screened; 3471 (80%) rare cancer pts, of whom 556 went on to 90 different ICI trials after undergoing CGP. In 273 pts treated with ICI where BOR was reported by the treating oncologist, the median survival was 17.3 months (95% CI 15.0 to 20.4). 13 pts (4.8%) had CR reported, including 8 pts with unapproved indications: 3 sarcomas, and 1 each, small cell carcinoma of unknown primary, adenoid cystic carcinoma, pituitary adenoma, thymoma, and pancreatic adenocarcinoma. 45 (16.5%) and 112 (41.0%) had PR and SD reported, respectively. High TMB, defined as ≥ 10 non-synonymous tumor mutations/megabase, was identified in 39 (14.3%) pts. TMB was associated with response (AUC 0.715, 0.630 to 0.800) and non-PD (AUC 0.600, 0.528 to 0.671) to ICI. Further exploratory analyses identified that alterations in *EP300* ($n = 7$, OR, 9.8, 1.9 to 52), *PTCH1* ($n = 6$, OR, 15.5, 1.7 to 141), *MSH6* and *KMT2D* ($n = 6$ each, OR, 7.7, 1.4 to 43), and *NFI* ($n = 10$, OR, 3.89, 1.1 to 13.9) were associated with CR/PR. Genomic *ARID1A* alterations ($n = 18$) were associated with non-PD (OR 5.16, 1.2 to 22.9), as were alterations in the SWI/SNF complex ($n = 20$, OR 3.64, 95% CI 1.0 to 12.8). **Conclusions:** Notwithstanding their limitations, these real-world data suggest that rare cancer patients may also benefit from ICI. Further prospective investigations into pan-cancer genomic biomarkers of response are warranted. Clinical trial information: ACTRN12616000908437. Research Sponsor: Government grants.

Immune checkpoint inhibitor in high-risk oral potentially malignant disorders (IMPEDE study): An interim analysis on safety. *First Author: Andrea Alberti, Medical Oncology Unit, Department of Medical & Surgical Specialties, Radiological Sciences & Public Health, University of Brescia, ASST Spedali Civili, Brescia, Italy*

Background: Oral Potentially Malignant Disorders (OPMD) represent the most common oral precancerous condition, with a variable risk of malignant transformation. The most effective biomarker in predicting malignant transformation risk is loss of heterozygosity (LOH). Patients (pts) carrying OPMD with LOH at 3p14 and/or 9p21 plus LOH at another locus have an expected 3-year risk of developing oral cancer of 35%. This chromosomal profile is found in about 30% of OPMD. IMPEDE is a phase II, open-label, single-arm trial designed to evaluate the efficacy of PD-L1 inhibitor avelumab in reverting cancer transformation risk in OPMD with LOH. In this analysis, we report the first safety results, while data about treatment activity need longer follow up. **Methods:** During the screening period, pts undergo OPMD biopsy. If pathological diagnosis of dysplasia is confirmed, LOH valuation is performed and in case of positivity of this biomarker, subjects receive a short course of immunotherapy with avelumab 800 mg every 2 weeks for 4 total administrations. Follow-up after last avelumab dose is performed monthly and adverse event data are collected at every visit. Six months after treatment start, surgery and LOH re-assessment are performed. **Results:** Between November 2020 and December 2022, 49 pts were screened in 8 Italian centers. Of these, 16 pts (33%) had a LOH and 12 received the treatment (3 males, median age 65.5 years, range 49-81). Nine out of 12 treated patients had a previous oral cancer. After a median follow up of 14 months, 39 adverse events (AE) of any grade were reported, of these 18 were considered as immune related AEs (irAE). The most frequent AEs was grade 1 (G1) oral pain (4/12 pts), managed with local painkillers. Only three G2 irAEs were reported, namely amylase/lipase increase, psoriasis and fever. No grade 3-4 AEs were described, and no patient had to stop immunotherapy because of toxicities. Local excision after immunotherapy was not delayed by any treatment toxicities. **Conclusions:** This is the first trial with immunotherapy in an enriched population of OPMD selected according to LOH. First results support the feasibility of this approach, showing that immunotherapy with avelumab is safe and does not compromise subsequent local surgery. Clinical trial information: NCT04504552. Research Sponsor: Italian association for cancer research (AIRC).

Phase II basket trial evaluating the efficacy of pembrolizumab (PE) combined with vorinostat (VO) in patients (pts) with recurrent and/or metastatic squamous cell carcinoma (SCC). *First Author: Christophe Le Tourneau, Curie Institute, Paris, France*

Background: Epigenetic modulation plays a major role in escaping tumor immunosurveillance and confers resistance to immune checkpoint inhibitors. Preclinical evidence suggests that modulating the epigenome might improve the efficacy of immunotherapy. **Patients and Methods:** PEVOsq is an open-label, non-randomized, multi-center, basket phase II trial, evaluating the efficacy of pembrolizumab in combination with vorinostat in patients with recurrent and/or metastatic squamous cell carcinoma of the cervix, head and neck, anus, vulva/vagina, penis, and lung. Patients had to be PD1/PD-L1 antagonist-naïve. There was no selection based on PD-L1 expression nor on HPV status, and no restriction in terms of prior lines of treatments. Pembrolizumab dose was 200 mg Q3W IV, and vorinostat 400 mg QD PO. Sample size was determined for each cohort using an A'Hern design. Primary endpoint was objective response rate (ORR) according to RECISTv1.1. Secondary endpoints included safety, progression-free survival (PFS), overall survival (OS), and duration of response (DOR). **Results:** Among 112 included patients, 111 were evaluable for safety and 107 for efficacy. The lung cohort was closed prematurely because of lack of enrollment. Median age was 61 years old [range: 18-85] and the median number of prior lines of therapies was 1 [range: 0-4]. ORR, PFS, G3/4 treatment related adverse events (TRAE), and OS are reported. 28 patients (26%) had an objective response and median DOR was 9.7 months [95%CI: 3.1-15.2]. Results per PD-L1 status will be presented at the meeting. Pembrolizumab and vorinostat were stopped for toxicity in 9% and 39% of patients, respectively. 60% of patients had a dose-reduced of vorinostat for toxicity. Pembrolizumab safety was as expected. Main vorinostat toxicities included hematological toxicity, gastrointestinal disorders, and asthenia and creatinine increase. **Conclusions:** Pembrolizumab combined with vorinostat showed encouraging antitumor activity in squamous cell carcinoma with unselected PD1/PD-L1 status, especially in cervical and anal cancer, although vorinostat dose had to be reduced because of toxicity in a substantial proportion of patients. Clinical trial information: NCT04357873. Research Sponsor: Fondation ARC; MSD; ERAPERMED; Agence National pour la recherche.

Efficacy and safety summary per cohorts.

Cohort	Primary endpoint ORR N (%)	Secondary endpoints		
		PFS (month) Median [95%CI]	OS (month) Median [95%CI]	G3/4 TRAEs N (%)
Cervix	9/23 (39)	4.2 [2.3-8.2]	10.3 [5.7-NR]	11/25 (44)

Retrospective analysis on association of ABO blood type and immune checkpoint inhibitor response. *First Author: Akshay Batra, University of Vermont, Burlington, VT*

Background: The presence or lack of a collection of antigenic cell surface markers on red blood cells makes up the ABO blood groups that contribute to various immunogenic neoantigens. Variations in the T-cell diversity and HLA haplotype with different blood types might affect a patient's response to Immune checkpoint inhibitors (ICIs). However, the association between the ABO blood type and ICIs is not well studied. **Methods:** We did a retrospective observational study to investigate the influence of ABO blood groups on patients receiving ICIs at the University of Vermont Cancer Centre. We examined the medical records of people who received ICIs as first-line therapy between January 2017 and June 2022 and collected demographic data, including age, sex, ethnicity, cancer stage, type and metastasis. We looked at overall survival and the occurrence of immune-related adverse events (irAEs) in different blood type subgroups and calculated relative risks. **Results:** A total of 288 cases were identified, out of which 169 had documented blood type, including 75 with A, 19 with B, 72 with O and 3 with AB blood type. The mean age was 63.71 years (Standard deviation (SD): 11.52), 58.6% were males, and ethnicity was 94.7% White, 1.2% Asian and 0.6% Hispanic. Lung cancer was most commonly identified at 41%, and 60% of total cancers were stage 4. The median ECOG status was 1 and the Charlson comorbidity index was 6. 36% of cases developed irAEs, whereas mortality was 39% during the study period. The relative risk of irAEs with blood type A and B compared to O was 0.89 and 0.83, respectively but wasn't statistically significant. The relative risk of irAEs of AB compared to O blood type was statistically significant at 2.63 (CI: 1.95-3.54). The relative risk of death in A and B blood types compared to O wasn't statistically significant. No patients in the AB blood group died. **Conclusions:** Clinically significant association wasn't found between different blood types and irAEs or mortality except for the increased risk of irAEs with AB compared to O. With the rapidly growing use of ICIs, prospective trials are needed to better understand the true risk of developing irAEs in patients with AB blood type. Research Sponsor: None.

Descriptive characteristics	RR (A to O)	RR (B to O)	RR (AB to O)
Adverse Events	0.89 (CI: 0.57-1.37)	0.83 (CI: 0.40-1.72)	2.63 (CI: 1.95-3.54)
Death	0.90 (CI: 0.61-1.32)	0.72 (CI: 0.35-1.48)	NA

Phase 1B study of avelumab and whole brain radiotherapy (WBRT) in patients with leptomeningeal disease (LMD) from epithelial carcinomas: Final results and molecular analyses with single cell RNA sequencing. *First Author: Yolanda Pina, Moffitt Cancer Center, Tampa, FL*

Background: Leptomeningeal disease (LMD) from epithelial cancer has a dismal prognosis with median overall survival (OS) of 3-4 months (mo) using PD-1 axis blocking therapy. Preclinical studies showed that this combination promotes antigen presentation within the CSF compartment, increases BBB permeability and increases ingress of activated T cells into the meninges/CSF space. In an open-label phase 1B trial, we tested the safety and efficacy of Avelumab in combination with WBRT in patients with LMD (NCT0371768). **Methods:** Patients received concurrent Avelumab 800 mg IV q2 weeks for up to 5 cycles (until PD or unacceptable toxicity) with WBRT 3000 cGy in 10 daily fractions. Primary endpoints were safety/DLTs and 3-month OS. Secondary endpoints included CSF T-cell transcriptome trajectory i.e., single cell RNA sequencing (scRNAseq). Patients with prior PD-1/PD-L1/CTLA-4/CD137 targeting therapy within 6 mo were excluded. **Results:** 15 patients were enrolled with disease sites that included breast (8), lung (4), nasopharyngeal (1), ovary (1), and pancreas (1). Patients were 87% female, median age 59 range 32-82. One patient did not complete WBRT. Two of 15 patients had grade 3/4 immune-related AEs (i.e., hypoadrenalism, hypothyroidism, lymphopenia); 5 patients had treatment-related <grade 3 AEs, including hypoadrenalism, anemia, diarrhea, hypothyroidism, lymphopenia, thrombocytopenia, leukopenia). There were no grade 5 toxicities. Median follow up was 3.7 mo (range, 0.9-36.8 mo; 95% CI 1.3-14.7 mo). The median follow-up time for survival analyses of the study was 19.8 mo. Ten out of 15 patients (66.7%) were alive at 3 mo. Median OS was 10.5 (95% CI 1.2 - 19.8 mo). 1-year OS was 44% (95% CI: 19-68%). Median PFS was 4.3 mo (95% CI, 0.9-15.2 mo), Fig. 3B. Two patients remain alive and clinically well. scRNAseq analyses are underway; signatures correlated with outcomes in short versus long term survivors. **Conclusions:** The combination of Avelumab and WBRT is safe, well tolerated, and demonstrates encouraging activity in patients with LMD with an OS that is longer than other published series. Multiple platform interrogation of CSF will be used to explore mechanisms of LMD response and resistance. Functional studies of scRNAseq and short versus long term survivors should be further explored. Clinical trial information: NCT03719768. Research Sponsor: Pfizer.

A phase 1/2 study of retifanlimab (INCMGA00012, Anti-PD-1), INCAGN02385 (Anti-LAG-3), and INCAGN02390 (Anti-TIM-3) combination therapy in patients (Pts) with advanced solid tumors. *First Author: Omid Hamid, The Angeles Clinic & Research Institute, A Cedars-Sinai Affiliate, Los Angeles, CA*

Background: In cancer treatment (tx), loss of T-cell function is associated with progressive expression of checkpoint (CP) molecules, and resistance or relapse following PD-(L)1 inhibitor therapy is a high unmet need. LAG-3 and TIM-3 are key CP pathways implicated in resistance to PD-1 inhibitors and have shown synergistic effects upon triple inhibition with PD-1 in a murine model. This open-label, nonrandomized phase 1/2 study (NCT04370704) aims to determine optimal doses and preliminary safety and efficacy for the monoclonal antibody combinations of INCAGN02385, INCAGN02390, and retifanlimab. Here we report initial safety and efficacy results. **Methods:** Study consists of 4 parts in phase 1 and 2 expansion cohorts in phase 2. In phase 1, parts 1 and 2 determined safety of INCAGN02385 350 mg Q2W + INCAGN02390 400 mg Q2W and INCAGN02385 350 mg Q2W + INCAGN02390 400 mg Q2W + retifanlimab 500 mg Q4W, respectively; parts 3 and 4 will test additional dosing schedules. Pts enrolled had previously treated (including PD-(L)1) locally advanced unresectable or metastatic solid tumors, with no prior LAG-3- or TIM-3-directed therapy. **Results:** As of June 28, 2021, 21 pts were enrolled in parts 1 (n=10) and 2 (n=11); 62% of pts were <65 years and 38% were male. Pts had median 3 (range 1-9) prior lines of therapy, including prior anti-PD-(L)1 (part 1, 8 pts; part 2, 11 pts); pt tumor types are listed. Nineteen pts discontinued tx, 1 due to toxicity. Nine pts in part 1 and 10 pts in part 2 had tx-emergent adverse events (TEAEs), most commonly anemia and diarrhea (each 30%) in part 1 and anemia (36%) in part 2 (all tx-unrelated). Serious tx-related TEAEs occurred in 1 pt in part 1 (grade [G]3 vasculitis) and 1 pt in part 2 (G3 myocarditis and pericardial effusion). Most common G $\geq$ 3 TEAE was G3 anemia (part 1, 2 pts; part 2, 3 pts); 1 pt in part 1 had a G5 TEAE of sepsis unrelated to tx, with COVID-19 infection. In part 2, 1 pt had an infusion-related reaction, and 1 pt had immune-related TEAEs of pericardial effusion and myocarditis (both G3 and tx-related), which resolved after steroid therapy and tx discontinuation. Best overall response in part 1 was stable disease, and in part 2 was a confirmed and durable partial response in 1 pt with CP therapy-refractory melanoma. **Conclusions:** Doublet anti-LAG-3 + anti-TIM-3 and triplet anti-LAG-3 + anti-TIM-3 + retifanlimab regimens in the study were generally well tolerated in heavily pretreated pts, with a safety profile consistent with that of CP monotherapy and no novel toxicities. Optimal doses of both combinations are to be further evaluated in the ongoing study in first-line tx of melanoma. Clinical trial information: NCT04370704. Research Sponsor: Incyte Corporation.

A phase 1B dose escalation study of ETC-159 in combination with pembrolizumab in advanced or metastatic solid tumours. *First Author: David Shao Peng Tan, National University Cancer Institute, Singapore and Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore*

Background: ETC-159 is a small molecule porcupine inhibitor, in a prior Phase 1 study was safe as a monotherapy at 16 mg or at 24 mg with the addition of preventive denosumab for bone protection. In this Ph1B open-label trial the safety, MTD, PK and pharmacodynamics (PD) of ETC-159 in combination with pembrolizumab were determined (NCT02521844). **Methods:** Eligible patients had adequate organ function, advanced or metastatic solid malignancies and had failed standard treatments. Patients' refractory/resistant to prior PD-1 treatment were allowed and all patients had to have serum β -CTX levels below 600 pg/mL (or <1000 pg/mL and preventive denosumab). Dose escalation followed a 3+3 design with a DLT period of 42 days. ETC-159 was dosed orally QOD in 21-day cycles (8-24 mg); pembrolizumab was dosed IV at 200 mg Q3W. Day 1 and trough PK were determined for ETC-159 and pembrolizumab. Responses were assessed every 6 weeks (RECIST 1.1). **Results:** 20 patients were enrolled, 6 in the 8 mg cohort and 14 in the 16 mg cohort (50% M and 50% F, mean age of 51.4 y). All patients have been discontinued: 16 due to disease progression; 1 due to AEs, 2 developed contra-indication to denosumab & pembrolizumab, 1 withdrawal of consent. PK parameters of ETC-159 in the first cycle were consistent with prior single agent data. TEAEs were reported in all subjects in the study with most events being grade 1/2, with dysgeusia (65%), β -CTX increase (30%), fatigue (25%), constipation (20%), and nausea (20%) being the most common. DLTs were G3 colitis and G3 immune-related enteritis (16 mg, 2 patients), and pneumonitis and erythema with fever (8 mg, 1 patient). Other drug related SAEs were G2 thyroiditis, hematuria, and thrombocytopenia. No fractures or other drug related skeletal SAEs. Of the 15 evaluable patients, 6 (40%) demonstrated clinical benefit (1 PR, 5 SDs) in combination with pembrolizumab (2 ovarian, 1 lung, 1 pancreatic, 1 urachal, 1 MSS CRC patient with RSP0 fusion), at the first assessment, in a predominantly MSS population (65% MSS, 25% unknown, 10% MSI). Pharmacodynamics, (hair follicle *Axin2* reduction), was detected at both dose levels and was $\geq$ 80% from baseline on D15. **Conclusions:** ETC-159 + pembrolizumab was well tolerated; 8 mg of ETC-159 in combination with pembrolizumab was determined to be the MTD/ RD. Preliminary data suggest Wnt signaling inhibition in combination with checkpoint inhibition may provide clinical benefit in MSS patients. Clinical trial information: NCT02521844. IMM01 plus tislelizumab in patients with advanced solid tumors and lymphoma: An open-label, multicenter, phase 1b/2 dose escalation and expansion study (IMM01-04). *First Author: Zhengbo Song, Zhejiang Cancer Hospital, Hangzhou, China*

Background: IMM01, a recombinant SIRP α -Fc fusion protein, can activate macrophages to enhance anti-tumor activity by blocking CD47-SIRP α interaction. Based on preclinical results, IMM01 showed unique property of weak human erythrocyte conjugation. IMM01 plus tislelizumab has the potential to augment both innate and adaptive anti-tumor immune responses. **Methods:** This study included the phase 1b dose escalation part and the phase 2 dose expansion part. The dose escalation part was conducted with a standard 3+3 design to evaluate the safety, MTD/RP2D and anti-tumor activity in patients with advanced solid tumors. IMM01 (1.0, 1.5, 2.0 mg/kg) was administered once a week and tislelizumab (200mg) was administered once every 3 weeks. The results of the dose escalation part were reported here. **Results:** As of 26 Dec 2022, 14 pts were enrolled in the dose escalation part, including 5 NSCLC, 2 SCLC, 2 ESCC, 2 CRC, 1 HCC, 1 melanoma and 1 cervical carcinoma. Median age was 61 years (range 49-70). Median of prior therapies was 4 (range 1-10), and 13 pts (92.9%) received previous anti PD-1/L1 treatment. Treatment-related adverse events (TRAEs) occurred in 14 pts (100.0%) to date. Most TRAEs were grade 1-2. The most common TRAEs ($\geq$ 10%) of all grades were anaemia (85.7%), platelet count decreased (28.6%), asthenia (28.6%), white blood cell count decreased (21.4%), lymphocyte count decreased (21.4%), IRR (21.4%), proteinuria (21.4%), gamma-glutamyltransferase increased (14.3%), white blood cell count increased (14.3%), blood creatine phosphokinase MB increased (14.3%), neutrophil count decreased (14.3%), neutrophil count increased (14.3%), hyponatraemia (14.3%) and hyponatraemia (14.3%). The Grade 3-4 TRAEs were lymphocyte count decreased (21.4%), white blood cell count decreased (14.3%), platelet count decreased (14.3%), blood creatine phosphokinase MB increased (7.1%), blood pressure increased (7.1%) and anaemia (7.1%). No DLT occurred. No TRAE leading to treatment discontinuation was reported. 2 pts (14.3%) had treatment related SAE (2 platelet count decreased), they recovered without platelet transfusion and no bleeding occurred. In 14 pts, 1 pt had confirmed PR and 3 pts had SD. One heavily pre-treated NSCLC pt in the 2.0 mg/kg dose cohort had confirmed PR at Week 12, who was resistant to anti PD-1. One NSCLC pt in 1.5 mg/kg dose cohort and 2 pts (1 SCLC, 1 CRC) in 2.0 mg/kg dose cohort had SD. The treatments of these four pts are ongoing. **Conclusions:** Up to 2mg/kg IMM01 plus tislelizumab is well tolerated. The RP2D of IMM01 was determined as 2mg/kg, this was the highest IMM01 dose evaluated in human as a single agent. IMM01 plus tislelizumab showed preliminarily anti-tumor activity in patients with advanced solid tumors. The dose expansion part in advanced solid tumors and lymphoma is ongoing. Clinical trial information: chict20220791. Research Sponsor: ImmuneOnco Biopharmaceuticals (Shanghai) Inc.

Deciphering primary and acquired immunotherapy resistance with whole genome and transcriptome analysis (WGTA). *First Author: Sofia Genta, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: Most cancer patients (pts) do not respond to antiPD1/PDL1 immune checkpoint inhibitors (ICI) or experience only a temporary benefit. Comprehensive molecular profiling with WGTA could broaden our understanding of the mechanisms contributing to primary (Pr) and acquired resistance (Ar) to ICI and identify novel predictive biomarkers. **Methods:** The Princess Margaret investigator-initiated Immune Resistance Interrogation Study (NCT04243720) aims to comprehensively characterize ICI-resistant cancers (Genta et al. ASCO 2021). Fresh tumor biopsies and blood samples were obtained from solid tumor pts at the time of PD on ICI-based treatment. DNA/RNA was extracted from tumor tissue and paired buffy coat and sequenced using an Illumina NovaSeq6000 system (2x150 paired reads for WG and 2X100 paired reads for WT). Copy number alterations (CNA), structural variants (SVs), mutation signatures and genes expression were assessed. Wald test in univariable and multi-variable logistic regression model was used for comparison. **Results:** As of January 2023, 73 pts (45 Pr/28 Ar) were enrolled. WGTA was completed in 22 pts (14 Pr/8 Ar). Key pt characteristics included: median age 60.5 years (range 26-79); male 68%/female 32%; melanoma 50%, squamous cell cancer of the head and neck 36%, and other tumor types 14%. Forty-one percent of the pts were treated with PD-1/PD-L1 inhibitor monotherapy and 59% with PD-1/PD-L1 inhibitor combinations. There were no significant differences in median tumor mutation burden (TMB, coding; 2.8, range 0.6-30.5 for Pr vs 4.4, range 1.6-12.8 for Ar), median percent genome altered by CNA (43% Pr vs 65% Ar) or median number of SVs (144, range 9-775, for Pr vs 76, range 25-924, for Ar pts). After performing RNA sequencing we observed a significantly higher expression of the epithelial mesenchymal transition (EMT) hallmark gene-set from msigDB and of 3 previously reported ICI-resistance gene expression signatures in Pr vs Ar ($p \leq 0.05$) in univariable analysis. The signatures included genes involved in the regulation of EMT, cellular de-differentiation and a cancer associated fibroblast (CAF) signature (IPRES signature, Hugo et al. Cell 2016; melanocytic plasticity signature [MPS], Pérez-Guijarro et al. Nat Med 2020; LRRC15 CAF signature, Dominguez et al. Cancer Discov. 2020). After adjusting for cancer type, the MPS signature was significantly associated with Pr vs Ar resistance in multivariable analysis ($p = 0.048$). **Conclusions:** No significant differences between Ar and Pr were observed in genomic features including TMB, CNAs and number of SVs. Cancers primary resistant to ICI were characterized by a higher expression of EMT, cell de-differentiation and CAF related genes, detected with transcriptome analysis. Our findings might indicate these features as possible driver of early ICI progression. Analysis of additional samples is ongoing. PD-1 inhibitors combined with radiotherapy and GM-CSF, sequentially followed by IL-2 (PRaG 2.0) regimen in advanced refractory solid tumors: A prospective, multicenter, single-arm clinical trial. *First Author: Pengfei Xing, The Second Affiliated Hospital of Soochow University, Suzhou, China*

Background: Low frequency of durable responses in patients treated with immune checkpoint inhibitors demands taking complementary strategies in order to boost immune responses against cancer. Our previous PRaG trial also demonstrated that PD-1 inhibitors in combination with radiotherapy and granulocyte macrophage-colony stimulating factor (GM-CSF) could improve clinical response in patients with advanced refractory solid tumors (ChiCTR1900026175). In an effort to further enhance efficacy, we conducted the PRaG 2.0 trial (ClinicalTrials.gov: NCT04892498) and optimized the PRaG regimen by incorporating interleukin-2 (IL-2). **Methods:** The PRaG 2.0 regimen was administered to patients with advanced refractory solid tumors who lacked or were unable to tolerate standard-of-care treatments. A treatment cycle consisted of radiotherapy (5 or 8Gy×2-3f) delivered for one metastatic lesion, PD-1 inhibitor dosing within one week after completion of radiotherapy, GM-CSF 200µg subcutaneous (SC) injection once daily for 7 days, and then sequentially followed by IL-2 2million IU SC once daily for 7 days. PRaG 2.0 regimen was repeated every 21 days for at least 2 cycles until no appropriate lesions for irradiation or reached the tolerance dose of normal tissues. Patients who could not continue radiotherapy and had not yet developed progression disease (PD) allowed PD-1 inhibitors to be continued as maintenance therapy until PD or unacceptable toxicity but no more than one year. The primary endpoint was Progression-Free Survival (PFS). **Results:** As of 31st October 2022, 51 patients were enrolled in the study, and 42 completed at least one tumor assessment. The median Progression-Free Survival (PFS) was 5.8 months, and the median overall survival (OS) was 13.5 months. The objective response rate (ORR) was 21.4%, and the disease control rate (DCR) was 61.9% according to RECIST version 1.1. Lower plasma levels of Interleukin (IL)-6 and IL-17 at baseline were found to be associated with improved PFS. Treatment-related adverse events (TRAE) experienced in 34 of 42 (78.6%) patients, with 4 patients (9.5%) experiencing Grade ≥ 3 TRAEs. TRAEs leading to discontinuation of all study treatments occurred in three patients (7.1%). **Conclusions:** The PRaG 2.0 trial demonstrates that PD-1 inhibitors in combination with radiotherapy, GM-CSF, and IL-2 could be a potential treatment regimen for patients with advanced refractory solid tumors, with an acceptable benefit/risk profile. Clinical trial information: NCT04892498. Research Sponsor: None.

The impact of renin-angiotensin-aldosterone system inhibitors on immune checkpoint inhibitor-associated adverse cardiovascular events. *First Author: Cho Hung Chiang, National Taiwan University Hospital, Taipei, Taiwan*

Background: Immune checkpoint inhibitors (ICIs) are associated with adverse cardiovascular events that impair patient outcomes. Previous observational studies showed that renin-angiotensin-aldosterone system inhibitors (RAASi) may mitigate the cardiotoxicity associated with chemotherapeutic agents. However, the effects of RAASi on ICI-associated adverse cardiovascular events are unknown. **Methods:** We conducted a 1:1 propensity score-matched cohort study involving ICI-treated patients at two tertiary referral centers in Taiwan. The propensity score matching model includes age, sex, hypertension, diabetes mellitus, chronic kidney disease, Eastern Cooperative Oncology Group (ECOG) Performance Scale, cancer stage, and cancer type. The primary outcome was major adverse cardiovascular events (MACE), defined as a composite of myocardial infarction (MI), ischemic stroke, peripheral arterial occlusive disease (PAOD), pulmonary embolism (PE), deep venous thrombosis (DVT), heart failure, pericardial disease, myocarditis, and cardiac arrhythmias. The secondary outcomes were arterial thrombotic events (MI, ischemic stroke, PAOD) and venous thrombotic events (PE and DVT). **Results:** We identified 684 patients eligible for inclusion, from which 164 patients who received RAASi were matched to patients who did not receive RAASi. Over a median follow-up of 9.1 months, the incidence rate of MACE for RAASi and non-RAASi recipients was 6.5 and 13.9 per 100 patient-years, respectively, resulting in an incidence rate ratio of 0.47 [95% CI: 0.21–1.00] (p = 0.038). In a multivariate Cox proportional hazard model adjusting for cancer therapy, RAASi recipients had an approximately 60% reduction in the risk for MACE (HR, 0.37 [95% CI: 0.16–0.86], p = 0.021). In the secondary analysis, RAASi were associated with a reduction in venous thrombotic events (HR, 0.11 [95% CI: 0.02–0.63], p = 0.013), but not for arterial thrombotic events (HR, 0.47 [95% CI: 0.06–3.38], p = 0.45). **Conclusions:** In patients receiving ICI therapy, the use of RAASi is associated with a decreased cardiovascular risk, particularly for venous thrombotic events. Research Sponsor: None.

Outcomes	RAASi No. of cases	Non-RAASi No. of cases	Univariate hazard ratio (95% CI)	P-value	Multivariate hazard ratio ^a (95% CI)	P-value
Major adverse cardiovascular events	13 (8%)	18 (11%)	0.52 (0.25-1.07)	0.074	0.37 (0.16-0.86)	0.021
Arterial thrombotic events	3 (2%)	3 (2%)	0.60 (0.12-3.04)	0.54	0.47 (0.06-3.38)	0.45
Venous thrombotic events	3 (2%)	6 (4%)	0.34 (0.08-1.37)	0.130	0.11 (0.02-0.63)	0.013

Durvalumab + tremelimumab in biologically selected advanced/metastatic solid tumors. *First Author: Christelle De La Fouchardiere, Medical Oncology Department, Centre Leon Berard, Lyon I University, Lyon, France*

Background: Tremelimumab (T) in combination with Durvalumab (D) is approved by the FDA for the treatment of unresectable hepatocellular carcinoma and metastatic non-small cell lung cancer. We prospectively examined its clinical activity in a cohort of biologically-selected advanced/metastatic solid tumors from the MOST Plus clinical trial (NCT NCT02029001). **Methods:** Adult patients (pts) previously treated by at least one prior line but immunotherapy-naïve were eligible if their tumor harbored TMB-H (>10mut/Mb) and/or MSI/dMMR (by PCR and IHC tests), and/or PD1/PD-L1/CTLA4 amplification and/or POLD1 or POLE mutation. T was administered for up to 4 cycles (75mg, IV, Q4W) and D (1500mg, IV, Q4W) until disease progression, unacceptable toxicity or patient/investigator decision. Tumor response was assessed as per RECIST 1.1 and adverse events reported according to NCI-CTCAE v4.03. **Results:** 70 patients were enrolled (24 male, median age: 65 years [33-88], MSI n=56, TMB-H n=10, PDL1 and PDL2 ampl. n=1, POLE mut. n=1, MSH6 mut. n=1, MSH2 mut. n=1). The median number of prior lines of systemic therapy was 1 (range: 0-4). Main tumor types were colorectal (44%), endometrial (19%), and stomach (7%) carcinomas. As of October 2022, overall response (ORR) rate was 52.8% (21.4% CR, 31.4% PR). With a median follow-up of 37 months, median PFS and OS were 8.4 months [95% CI: 4.4- 22.1] and 37.2 months [95% CI: 10.4-NE], respectively. Median duration response of response was not reached. Overall, 24.3% of patients experienced at least one serious treatment-related (TR) adverse event. Two TR-deaths were reported (haemophagocytic lymphohistiocytosis and nephritis). ORR, median PFS and OS are reported. **Conclusions:** T+D is a highly efficient combination in biologically selected tumors leading to a high complete response rate. Enrolment is still ongoing, to further evaluate the utility of a maintenance treatment, i.e the optimal treatment duration. Clinical trial information: NCT02029001. Research Sponsor: Fondation ARC.

Updated results and biomarker analyses from the phase 2 trial (BBCAPX study) of sintilimab plus bevacizumab and CapeOx as first-line treatment in patients with RAS-mutant, microsatellite stable, unresectable metastatic colorectal cancer. *First Author: Ying Yuan, Department of Medical Oncology, Key Laboratory of Cancer Prevention and Intervention, Ministry of Education, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: RAS-mutant and microsatellite stable (MSS) metastatic colorectal cancer (mCRC) patients have an immunosuppressive microenvironment and show a low response rate to immunotherapy. Sintilimab plus bevacizumab and CapeOX (BBCAPX) has proved its efficacy and safety in above unresectable mCRC patients (Xuefeng Fang et al. ASCO 2022). Here, we report updated efficacy, safety, progression-free survival (PFS) and biomarker analyses from this single arm, open-label, phase 2 trial (NCT05171660). **Methods:** RAS-mutant and MSS mCRC patients received sintilimab (200 mg, day 1) plus bevacizumab (7.5mg/kg, day 1) and oxaliplatin (135 mg/m², day 1) and capecitabine (1g/m², bid, day 1-14) of each 21-day cycle. Clinical response was assessed every 2 cycles via RECIST 1.1 criteria. Whole exome sequencing (WES) and 289 NanoString panel RNA sequencing was performed for tumor mutational burden, genomic alteration, immune microenvironment and other biomarker analysis. **Results:** 25 patients with unresectable metastases were enrolled after the assessment of CRC multidisciplinary team. 2 (8.0%) patients showed complete response (CR), 19 (76.0%) patients had a partial response (PR) and 4 (16.0%) had stable disease. Objective response rate (ORR) reached 84.0% and disease control rate was 100.0%. The median PFS was 18.2 months for the full analysis set. The most common treatment-related adverse events (TRAEs) in all grades were anemia (21/25, 84.0%), neutropenia (20/25, 80.0%) and hand-foot syndrome (14/25, 56.0%). The most frequent grade 3 or 4 TRAEs were neutropenia (3/25, 12.0%) and alanine transaminase increased (2/25, 8.0%). No grade 5 adverse events occurred. In biomarker exploration, after treatment, as compared with the baseline, the results of WES suggested 5 patients appeared TTN/OBSCN “double-hit” and copy number variants burden was significantly decreased in tumor tissues. Nanostring panel RNA sequencing analysis found that there was a better tumor immune microenvironment cell infiltration in CR/PR patients compared with non-CR/PR patients tumors as well as PFS-long group (< 12.5 months) compared with PFS-short group (≥ 12.5 months). **Conclusions:** Combination treatment of sintilimab plus bevacizumab and CapeOX as first-line treatment demonstrated a high ORR (84.0%) and a manageable safety profile in RAS-mutant, MSS unresectable mCRC. Exploratory biomarker assessment analysis showed some patients changed into “immune-hot” subtype after the treatment. We are launching a phase 3, randomized, open-label, multicentric clinical trial (NCT04194359) to further evaluate the effect, safety and prognostic biomarkers of this combination in RAS mutant, MSS mCRC patients when compared with that of bevacizumab and CapeOX. Clinical trial information: NCT05171660. Research Sponsor: Inovvent Biologics, Inc.

Poster Session

Prospective cardiovascular surveillance of immune checkpoint inhibitor-based combination therapy in patients with early-stage, triple-negative breast cancer. *First Author: Vishnu Venkatesh, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Both pembrolizumab and anthracyclines (AC) can cause adverse cardiovascular events; combination therapy is approved for high-risk, early-stage, triple-negative breast cancer (TNBC) and may further increase real-world cardiovascular risk. Cardiac surveillance with serial troponin measurements has been advocated in this population, though evidence supporting this approach is lacking. **Methods:** High-sensitivity troponin I (hs-TnI) was prospectively measured at baseline and with each treatment cycle in cancer patients receiving immune checkpoint inhibitors (ICI) at a single center as part of an institutional surveillance protocol for ICI-related adverse events from 2020-2022. Acute cardiac injury was defined as ≥ 1 abnormal hs-TnI value ($>17\text{ng/dL}$ in women and $>35\text{ng/dL}$ in men) with normal baseline hs-TnI, or at least 20% increase in hs-TnI from abnormal baseline. The incidence of acute cardiac injury and all-cause mortality were compared between patients receiving ICI in combination with AC versus ICI without AC. **Results:** Among 215 patients treated with ICI with baseline and ≥ 1 follow-up hs-TnI value, 28 patients (13%) received ICI with AC, all of whom were women with early-stage TNBC receiving pembrolizumab and AC-containing chemotherapy. 187 patients (87%) received ICI without AC for other oncological indications. Patients receiving ICI with AC were younger and more likely to be female than patients receiving ICI without AC ($p<0.001$) with lower rates of smoking, hypertension, and diabetes ($p<0.04$). Acute cardiac injury was observed in 33 patients, 21% of those receiving ICI with AC ($N=6$) and 14% of those receiving ICI without AC ($N=27$; $p=0.34$). Among these 33 patients, 2 patients were treated for ICI-associated myocarditis (1 receiving ICI with AC, 1 receiving ICI without AC); 67% of those receiving ICI with AC ($N=4$) were continued on ICI while only 30% of those receiving ICI without AC ($N=8$) were continued on ICI ($p=0.16$). The rate of all-cause mortality was significantly lower in patients receiving ICI with AC (0%) as compared to patients receiving ICI without AC (40%, $p<0.001$). **Conclusions:** Among women with early stage TNBC receiving pembrolizumab with AC, the rate of acute cardiac injury by surveillance troponin measurements was numerically but not statistically higher than for patients receiving ICI without AC for other oncological indications, though the rate of all-cause mortality was significantly lower. These findings suggest that surveillance troponin monitoring may have less clinical utility among women with early-stage TNBC receiving ICI-based combination therapy as compared to other patient populations receiving ICI. Further study is needed to understand the mechanistic and prognostic significance of acute cardiac injury in patients with TNBC receiving ICI-based combination chemotherapy. Research Sponsor: None.

A novel method that leverages existing data to conduct comparative analyses of competing assets: Sugemalimab and agents targeting the PD-L1/PD-1 axis as an example. *First Author: Antonio Tito Fojo, Columbia University Medical Center, New York, NY*

Background: Non-small-cell lung cancer (NSCLC) remains the leading cause of cancer-related mortality worldwide. Numerous immune checkpoint inhibitors (ICIs) targeting the programmed cell death protein-1/programmed death ligand-1 (PD-1/PD-L1) axis have garnered regulatory approvals. A novel method of comparative analysis that discerns differences/similarities amongst such agents could reduce redundancy and hopefully enhance true competition. **Methods:** We've described an approach for assessing efficacy that assumes changes in tumor quantity result from two simultaneous processes – exponential decay of the treatment-sensitive fraction of tumor at rate d , and exponential growth of the resistant fraction at rate g . Using this method, the USFDA analyzed data from 9934 patients with NSCLC enrolled in registration trials treated with chemotherapy, targeted therapies, and immunotherapies concluding g is inversely associated with survival across treatment types and encouraging prospective studies to evaluate whether g derived from early tumor measurements might serve as an earlier clinical trial endpoint (Gong ASCO 2020). Using data provided by EQRx and CStone we analyzed the GEMSTONE-302 trial comparing chemotherapy +/- the PD-L1 inhibitor sugemalimab in first line NSCLC. **Results:** 88% of the data could be analyzed. Regression without growth was seen in 10-12% of both arms with indistinguishable d values. Evidence of tumor growth was estimable as a g value in 68-71% with statistically slower g values and longer tumor doubling times (TDT) seen with sugemalimab + chemotherapy [0.0012/day (0.0005-0.0022); TDT 578d] than placebo + chemotherapy [0.0025/day (0.0013-0.0035); TDT 277d] $p<0.0001$. A comparative analysis with FDA data from 1521 patients who received Combo ICI in front line, finds comparable/slightly slower g values for sugemalimab + chemotherapy using all or a fraction of the data. **Conclusions:** We used a method of analysis that estimates rates of tumor growth (g) to analyze the efficacy of the PD-L1 antagonist, sugemalimab, in NSCLC. Because time is included in our equations the intervals of assessment are rendered inconsequential, making this method of analysis ideal for virtual comparisons. We confirmed the value of sugemalimab in the first-line setting by demonstrating its data track very closely with data aggregated from randomized trials reported by the USFDA in patients treated with Combo ICI in front line. Because g values can be estimated with fewer data it can be leveraged for early decisions. Research Sponsor: None.

Median g by line/type of therapy.

The controversial abscopal effect: A single-center experience about the combination of stereotactic radiotherapy with pembrolizumab in patients with metastatic dMMR/MSI-H colorectal cancer. *First Author: Annaliese Gandini, IRCCS Ospedale Policlinico San Martino, Genoa, Italy, Italy*

Background: Colorectal cancer (CRC) patients with mismatch repair system deficiency (dMMR/MSI-H) have shown impressive responses to immune checkpoint inhibitors in any lines of treatment. However, almost 30% of these patients are primary refractory and another 30% develop secondary resistance. Thus, many treatment combinations are being pursued to overcome resistance. One of the proposed strategies is the addition of radiotherapy to immunotherapy based on the potential abscopal effect and its consequent on-target and off-target activity. **Methods:** Between November 2019 and April 2021, we conducted a prospective interventional single-institution study to assess the feasibility, disease control and safety of the combination of pembrolizumab with stereotactic ablative radiotherapy (SABR) in a cohort of 14 consecutive dMMR CRC patients. SABR was administered in combination within the second or third cycle of Pembrolizumab 200 mg infused every 21 days. SABR was delivered on one or more targetable metastases with the ablative dose of 15 Gy in the first fraction followed by a second fraction of 5 Gy. **Results:** Fourteen patients were enrolled and 11 received radiotherapy in combination with Pembrolizumab as per protocol. Three patients who started Pembrolizumab never received radiotherapy due to deterioration of their general conditions, leading to death within two months. Two out of these three patients were $BRAF^{V600E}$ mutated. Five patients (35.7%) received Pembrolizumab as first line, 6 (43%) as second line and 3 (21%) as third or later lines. Six out of 14 patients (42.9%) harboured $BRAF^{V600E}$ mutation, 2 out of 14 (14.3%) RAS mutation and the others were RAS/BRAF wild type. Objective response was observed in 4 out of 14 patients (29%) and disease control was achieved in 7/14 patients (50%). Among these, six patients (42%) achieved a disease control lasting more than 15 months. This regimen caused substantial toxicity, mainly linked to SABR. Any grade TRAEs occurred in 50% of patients, with one patient with G1 event, three patients with G2 events, and two patients with G3 events (pneumonia, bowel perforation); no treatment-related deaths were observed. **Conclusions:** These data do not show hint of added efficacy of Pembrolizumab by SART in unresectable dMMR/MSI-H mCRC. Research Sponsor: IRCCS Ospedale Policlinico San Martino.

DURTRERAD: A phase II open-label study evaluating feasibility and efficacy of durvalumab (D) and durvalumab plus tremelimumab (DT) in combination with radiotherapy (RT) in non-resectable locally advanced HPV-negative head and neck squamous cell carcinoma (LA-HNSCC). *First Author: Ulrich Keilholz, Charité-Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Charité Comprehensive Cancer Center, Berlin, Germany*

Background: Concurrent platinum-based chemo-RT is the standard treatment for LA-HNSCC, despite of limited efficacy in poor-risk patients and long-term toxicity. Targeting PD-L1 with D has activity in recurrent/metastatic (RM)-HNSCC, and the combination with the CTLA4 targeting agent T was considered to augment the immunotherapy efficacy of a chemotherapy-free regimen. Thus DURTRERAD was designed as a randomized two-arm phase II study to investigate, whether D or DT combined with RT was feasible in the patient population and a 1-year progression free survival rate of 50% was reached. **Methods:** The phase II study planned to enroll 60 patients in each treatment arm. Key selection criteria were patients with advanced HPV negative unresectable HNSCC planned for definitive radiotherapy. Treatments: First dose of immunotherapy 14 days prior to start of RT (70Gy over 7 weeks). D (1500mg q 3 weeks x 13) or DT (D: 1500mg q 3 weeks x 13 + T: 4 x 75 mg in weeks 5,9,13,17). Planned treatment duration was 51 weeks in both arms. Treatment was considered feasible in case of $<10\%$ treatment discontinuations. An interim analysis for feasibility was planned after treatment of 6 patients per arm and a utility analysis was performed after treatment of 18 patients, resulting in premature closure of the trial. **Results:** Patient accrual in 4 centers in Germany from 9/2018 - 9/2020. The interim feasibility analysis of DT revealed that 5/6 patients stopped treatment due to 1 grade 5 and 1 grade 4 immune related AE and 3 non-immune related AEs, respectively. Thus, the DT arm was prematurely terminated, and only the D monotherapy arm continued. Utility analysis of D monotherapy: One of 12 patients stopped treatment due to immune related toxicity, and 7 patients experienced disease progression on treatment or died within the first year. The median PFS was 39 weeks, the 1 year PFS rate was 42%. **Conclusions:** Even though D was previously proven as an active agent in RM-HNSCC, and there DT was not associated with increased toxicity, DT in combination with RT was not feasible in our poor prognostic, vulnerable patient cohort of HPV negative LA-HNSCC. D monotherapy in combination with RT was well tolerated, but revealed a low level of efficacy, when administered in the trial schedule, starting 2 weeks prior to RT. Similar to results in lung cancer, start of immunotherapy after completion of radiotherapy may be of interest. Clinical trial information: NCT03624231. MyTACTIC: Efficacy and safety of atezolizumab (atezo) + chemotherapy (chemo) in patients (pts) with advanced unresectable/metastatic solid tumors with high tumor mutational burden (TMB-H) or high microsatellite instability (MSI-H)/deficient mismatch repair (dMMR). First Author: David R. Spigel, Department of Thoracic Medical Oncology, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN

Background: MyTACTIC (NCT04632992) is a phase II, non-randomized, multi-arm basket study evaluating targeted therapies as single agents or combinations in pts with advanced solid tumors with specific biomarkers. We present the efficacy and safety of arm E from MyTACTIC: atezo + chemo in pts whose tumors have TMB-H and/or MSI-H/dMMR. **Methods:** Enrolled pts were ≥ 18 years old, with histologically/cytologically confirmed advanced unresectable/metastatic solid tumors with TMB-H (TMB ≥ 10 mut/Mb) and/or MSI-H/dMMR and ECOG PS ≤ 2 ; those with symptomatic/actively progressing CNS metastases were excluded. Pts received intravenous atezo 1200 mg every 21 days and physician's choice chemo (docetaxel; paclitaxel; capecitabine) until progressive disease (PD), toxicity or death. Primary endpoint: investigator-assessed confirmed objective response rate (cORR). Secondary endpoints included disease control rate (DCR; confirmed complete response [CR] + partial response [PR] + stable disease [SD] or non-CR/non-PD for ≥ 70 days), duration of response (DOR), progression-free survival (PFS) and safety. **Results:** At data cutoff (May 16, 2022), 25 pts with 10 tumor types had received atezo + chemo. Median age was 69 years (range 37–83), 88% of pts had ECOG PS ≤ 1 and 20 pts with metastatic disease had a median of 1 prior line of therapy (range 1–4). Twenty-three pts had TMB-H (2 missing), 7 had MSI-H and 7 had dMMR (12 missing); 7 pts had TMB-H and MSI-H/dMMR. cORR was 28.0% (7/25; 95% CI 12.1–49.4), including 1 CR (colon cancer) and 6 PRs. Responses were observed in 6/10 tumor types studied. cORR was 12.5% in pts with TMB-H alone (2/16) and 71.4% (5/7) in pts with TMB-H and MSI-H/dMMR. DCR was 32.0% (8/25; 95% CI 14.9–53.5). Median DOR and median PFS were 7.4 months (95% CI 7.4–not estimable) and 3.9 months (95% CI 2.2–8.4), respectively. The safety profile of atezo + chemo was consistent with previous reports for this combination. The most common treatment-related adverse events (TRAEs) were diarrhea (60%) and fatigue (32%). Grade 3/4 TRAEs occurred in 32% of pts and there were no serious or grade 5 TRAEs. **Conclusions:** In this small cohort, treatment with atezo + chemo demonstrated clinical activity in pts with advanced solid tumors with TMB-H and/or MSI-H/dMMR. Responses were observed in different tumor types and were numerically higher in pts whose tumors had both biomarkers vs those with TMB-H alone. Further analyses with a larger cohort and longer follow-up will be required to confirm these results. Clinical trial information: NCT04632992. Pan-cancer analysis of IDO1 transcriptome expression and its impact on outcome in patients treated with immune checkpoint inhibitors. First Author: Yu Fujiwara, Department of Medicine, Icahn School of Medicine at Mount Sinai, Mount Sinai Beth Israel, New York, NY

Background: The immunosuppressive tumor microenvironment (TME) is a major component of resistance to immune checkpoint inhibitors (ICIs). Tryptophan catabolism is recognized as a metabolic pathway leading to immunosuppression and indoleamine 2,3-dioxygenase 1 (IDO1), an enzyme catabolizing tryptophan to kynurenine, has been investigated as a potential target. Analyzing the association of IDO1 and immune molecules in the TME could better elucidate the role of IDO1 as an immunotherapeutic strategy. Thus, we performed pan-cancer transcriptome analysis of IDO1 according to cancer types and immune molecules in the TME and evaluated survival outcomes in patients treated with ICIs based on IDO1 expression levels. **Methods:** Comprehensive transcriptome analysis of IDO1 and selected immune molecules in 514 patients with advanced solid tumors at the Moores Cancer Center at the University of California San Diego was performed. The rate of "High" (75–100 percentile), "Intermediate" (25–74), and "Low" (0–24) IDO1 RNA expression in each cancer type was calculated (rank compared to 735 controls). Univariate and multivariate analyses of the odds ratio (OR) for high IDO1 expression based on factors such as immune checkpoints, cancer types, microsatellite instability (MSI), and tumor mutational burden (TMB) were conducted. Additionally, progression-free survival (PFS) and overall survival (OS) from the time of ICI therapy based on IDO1 expression was compared by the Kaplan-Meier method. Multivariate analysis of survival outcomes was performed using the Cox proportional hazards model. **Results:** Overall, 91 of 514 patients (17.7%) were classified into "High", 228 (44.4%) into "Intermediate", and 195 (37.9%) into "Low" IDO1 RNA expression. High IDO1 expression was seen in uterine (54.2%), ovarian (37.2%), and lung cancer (25.0%). In multivariate analysis, high STAT1 and CD40 expression, ovarian cancer, and uterine cancer were correlated with high IDO1 expression. In patients treated with ICIs (N = 217), "High" IDO1 expression (N = 49) was associated with better PFS (HR = 0.57, 95%CI: 0.40–0.83, p = 0.003) and OS (HR = 0.52, 95%CI: 0.47–0.83, p = 0.006) than "Intermediate/Low" IDO1 expression (N = 168). Multivariate analysis incorporating age, sex, IDO1, PD-1, PD-L1, PD-L2, CTLA-4, LAG3, cancer types, TMB, and MSI revealed that IDO1 (HR = 0.28, 95%CI: 0.11–0.69, p = 0.006) and PD-1 (HR = 0.24, 95%CI: 0.09–0.65, p = 0.005) are independent predictive factors for longer OS. **Conclusions:** IDO1 RNA levels are high in $>25\%$ of uterine, ovarian, and lung cancers but differ from patient to patient between and within tumor types. High IDO1 levels correspond with longer PFS and OS from start of ICI therapy. These results suggest the importance of patient selection through pan-cancer molecular analysis and the potential role of IDO1 as a predictive marker for ICI therapy. High transferrin receptor expression marks tumors with increased immune-effector infiltration and expression of targetable checkpoint molecules: Results of a multi-cancer analysis in solid tumors. First Author: Asaad Trabolsi, Jackson Memorial Hospital/ University of Miami, Miami, FL

Background: The cell-surface transferrin receptor, TFR1, encoded by *TFRC*, imports iron-bound transferrin into cells to drive tumor proliferation. We have found worse prognosis with high *TFRC* expression across multiple tumor types. The mechanism by which *TFRC* drives tumor cell-intrinsic oncogenesis is multifactorial, but its interaction with the tumor microenvironment (TME) has not been studied. Here, we assessed TME infiltration by immune effector populations and immune checkpoint expression. **Methods:** Tissue samples underwent comprehensive molecular profiling at Caris Life Sciences: Next-gen sequencing of DNA (592 Gene Panel, NextSeq, or whole exome sequencing, NovaSeq), RNA-seq (NovaSeq, whole transcriptome sequencing, WTS) and immunohistochemistry. RNA deconvolution analysis by the Microenvironment Cell Populations (MCP)-counter method quantified immune populations to assess T cells, B cells, natural killer cells (NK) and myeloid dendritic cells (MDC). Analyses compared quartiles of *TFRC* mRNA expression between Q4 (*TFRC*-H) high and Q1 (*TFRC*-L) low expressors. **Results:** Among 27,607 patients with non-small cell lung cancer (NSCLC), 5,332 with prostate cancer (PC), and 14,287 with colorectal cancer (CRC), *TFRC*-H tumors were associated with high tumor mutational burden (TMB-high, ≥ 10 mutations/MB), and *TP53* mutation (q<0.05). Multiple immune checkpoint genes showed significantly higher expression in *TFRC*-H relative to *TFRC*-L in all tumor types, including *CD274* (PDL1), *LAG3*, *PDCD1LG2* (PDL2), and *CTLA4* (Table; All values are statistically significant: q<0.05). Moreover, TME assessment by MCP-counter showed significantly increased infiltration by total T cells, CD8+ cells, B cells, NK cells, and MDCs in *TFRC*-H (Table). Finally, among patients who received Check-point inhibitors (CPI), *TFRC*-L had improved survival (HR=0.807 (95% CI 0.76 – 0.85) p<0.00001) in NSCLC but no difference was found in CRC or PC. **Conclusions:** Our study is the first to reveal the TME characteristics associated with *TFRC* expression in a variety of solid tumor types. We found *TFRC*-H tumors have increased infiltration by immune effector populations but also express significantly higher levels of immune checkpoint molecules, highlighting immune exhaustion. Altered iron metabolism has been shown to promote tumorigenesis and here we identify a new role for *TFRC* in remodeling the TME. TFR1-targeting therapeutic agents are in clinical development and warrant further investigation in combination with CPIs. Research Sponsor: None.

Distributional range of tumor mutational burden (TMB) across multiple cancer types emphasizing the importance of different cutoff values in different tumor types for clinical interpretation: A consensus statement from the SEQUOIA consortium. First Author: Wojciech Swat, Cancer Genomics and Molecular Pathology, Bioreference Laboratory, Elmwood Park, NJ

Background: The measurement of tumor mutational burden (TMB) is critical to select patients who are expected to respond to immune checkpoint inhibitors or immunotherapy (IO). The majority of the clinical guidelines on the interpretation & utility of TMB values are based on studies performed on lung cancer, setting a cutoff of 10. Laboratories that are using comprehensive genomic profiling (CGP) for tumor testing are reporting TMB values &/or interpretations (high/low) beyond lung cancer. Multiple studies have shown that the TMB signature is not universal, but rather tumor &/or even patient-specific. However, the pan-cancer trial for IO (KEYNOTE-158) failed to consider setting different cutoffs per tumor type. Currently, no major guidelines or consensus statements address the issue of reporting TMB as a biomarker beyond lung cancer. In the current study, the membership of the SEQUOIA (Sequencing & Oncology Informatics Academic Team) Consortium investigates the landscape of TMB values across multiple cancer types. **Methods:** We investigated TMB values in 11,670 patient samples (M = 6225; F = 5445) across 13 different tumor types & histological subtypes, including cancers with lung, colorectal, gastrointestinal, brain, prostate, pancreatic, biliary, endometrioid, ovarian, skin, hematological (CLL myeloma) & lymphoid origin. All samples were processed by a CGP panel of 523 genes. Multiple specimen types were included in the study consisting of tissue, blood, marrow, & lymph node. **Results:** The range of TMB values varied significantly across different cancer types & histological subtypes. The colorectal, melanoma & endometrial cancers have a wider range of TMB values (2–400 mutations/MB) relative to prostate, breast, myeloma, & serous cancers (0–30 mutations/MB). Along with the range, the mean, & median TMB values are also significantly varied across these tumor types. We also identified that a subset of patients exhibits high TMB (>30 mutations/MB) values across almost all types of cancer. **Conclusions:** TMB values & their association with response to immune checkpoint inhibitors are not very well studied in all cancer types, although a TMB cut-off of 10 mutations/MB was defined as TMB-high for FDA-approved IO in patients with unresectable or metastatic solid tumors. The range, mean, median, cut-offs & clinical interpretations of TMB-high & low for IO based therapies for different tumor types has not been well established. Our data confirm the wide range, mean, & median across different tumor types, & thus laboratories & oncologists need to be cautious in the clinical interpretation of TMB values for patient management. Future studies should assess responsiveness to IO in specific tumor types based on TMB value to determine tumor-specific TMB cutoff values. Research Sponsor: None.

Quantitative 3D assessment of the lung cancer microenvironment using multi-resolution open-top light-sheet microscopy. *First Author: Caleb R Stoltzfus, Alpenglow Biosciences, Inc., Seattle, WA*

Background: Non-small cell lung cancer (NSCLC) tissue is a valuable resource for diagnosis, treatment planning, and drug development. Current 2D histopathological techniques introduce under-sampling error (i.e., a single 5 μm section represents 0.5% of a 1 mm thick biopsy), interobserver variability, and failure to capture the biology contained within the entire tissue sample. We have developed a suite of technologies to stain, chemically clarify, image, visualize, and analyze entire, intact lung tissue samples. Herein, we present analysis methods for comprehensive 3D assessment of intact NSCLC tissue. **Methods:** Human NSCLC tissue, stored frozen in optimal cutting temperature (OCT) compound, was fixed in 4% paraformaldehyde, stained with nuclear (TOPRO-3) and general protein (Eosin) fluorescent dyes, and optically cleared using a modified iDISCO protocol with ethyl cinnamate as the refractive index matching solution. Twenty tissue samples measuring 1-5 mm^3 in volume were imaged at 2 $\mu\text{m}/\text{pixel}$ resolution with a hybrid open-top light-sheet microscope. Smaller regions of interest (ROIs) with interesting pathologic features were re-imaged at higher resolution, 0.17 $\mu\text{m}/\text{pixel}$. Visualization and analysis was performed using Aivia software, custom spatial analysis software and python scripts. **Results:** All NSCLC tissue samples were successfully imaged in 3D at both low and high resolution. Computational approaches, such as machine learning, were used to segment and classify tumor cells and lymphocytes within the high resolution ROIs. In one example we quantified a 0.0045 mm^3 ROI containing 1×10^9 voxels. We segmented 1,474 unique objects, and classified 683 (46%) of the objects as lymphocytes and 309 (20%) of the cells as tumor cells. We found that on average the lymphocytes were within 12 μm of the nearest tumor cell. Additionally the tissue was broken into separate lymphocyte dense (58% of volume) and tumor dense regions (42% of volume). Further analysis is in progress to quantify more features, such as tertiary lymphoid structures, stromal cells, and fibrosis over the full 20 sample dataset. **Conclusions:** We successfully implemented 3D machine learning analysis pipelines using images from intact NSCLC tissue samples measuring up to 5 mm^3 . The imaging was performed using our custom hybrid open-top light-sheet microscope. This novel method enables us to identify and quantify key histological features such as tumor cells and lymphocytes within the tumor microenvironment. In addition, machine learning driven algorithms clustered cells into distinct tissue regions in 3D which enables a more precise assessment of disease state and heterogeneity. Further investigation is ongoing to link these results to patient outcomes. Research Sponsor: Alpenglow Biosciences.

Genomic landscapes to characterize mismatch-repair deficiency (dMMR)/microsatellite instability-high (MSI-H) gastrointestinal (GI) cancers stratified by tumor mutation burden (TMB). *First Author: Jingyuan Wang, Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA*

Background: TMB is a predictive biomarker for immune checkpoint inhibitor treatment in dMMR/MSI-H cancers. We aimed to characterize specific molecular features of a large cohort of dMMR/MSI-H GI tumors with a range of TMB levels. **Methods:** A total of 2272 GI tumors tested as dMMR/MSI-H were analyzed using Next-generation sequencing (NGS) and immunohistochemistry (IHC) (Caris Life Sciences, Phoenix, AZ). MMR/MSI status was evaluated by a combination of IHC, Fragment Analysis and NGS. TMB-H were defined using differing TMB cutoffs (10, 20, 50 mutations/Mb). Molecular features were compared in four groups (TMB < 10 vs 10-20 vs 20-50 vs ≥ 50 mutations/Mb) using Fisher-Exact or Chi-square and adjusted for multiple comparison by Benjamini-Hochberg. The impact of TMB on tumor immune environment was analyzed using a TCGA cohort. Significance was determined by adjusted (adj) $P < 0.05$. **Results:** Tumors with TMB over 10, 20, 50 mutations/Mb were observed in 95.38%, 86.05% and 14.47% respectively in the dMMR/MSI-H GI cohort. Compared to other groups, dMMR/MSI-H GI tumors with TMB over 50 mutations/Mb exhibited the highest mutations rates in *RNF43*, *MSH6*, *KMT2D*, *BRCA2* and *ASXL1* (Top 5, all $P_{\text{adj}} < 0.0001$). Among the four MMR genes, only *MLH1* mutation had no association with higher TMB. The rates of *CNNE1* amplification (i.e. the Cycle E1 gene) and HER2 overexpression were the highest in tumors with TMB below 10 mutations/Mb (all $P_{\text{adj}} < 0.05$). The association between PD-L1 positivity and TMB levels was only observed in gastroesophageal cancers ($P = 0.03$). The lymphocyte infiltration signature score, IFN γ response and M1 macrophage infiltration were significantly lower, while fraction of genome alterations was significantly increased in dMMR/MSI-H tumors with TMB below 10 mutations/Mb, compared to other subgroups (all $P < 0.05$). Neoantigens were significantly enriched in those with TMB over 50 mutations/Mb, compared to other subgroups ($P < 0.0001$). **Conclusions:** This is the largest study to investigate the distinct molecular landscape of dMMR/MSI-H GI cancers with different degrees (magnitude) of TMB. These data may inform our understanding of the efficacy of ICB in dMMR/MSI-H GI tumors. Research Sponsor: None.

Incorporating long non-coding RNA (lncRNA) into genome-wide biomarker screening for prognostic gene signatures of immunotherapy outcomes. *First Author: Xuefeng Wang, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Emerging data have shown that long non-coding RNA (lncRNAs) have the potential to become biomarkers in cancers with potential roles in regulating cell proliferation, apoptosis, migration, invasion and maintenance of stemness during cancer development. In this research, we aimed for a genome-wide biomarker screening approach incorporating lncRNA in order to identify key molecules and pathways involved in ICI response and resistance. **Methods:** We utilized clinical and transcriptomic data collected under the Total Cancer Care Protocol (NCT03977402) and Avatar project within the Oncology Research Information Exchange Network (ORIEN). We analyzed RNA-seq data from a total of 875 ICI treated pts. A novel resampling-based technique with elastic net regression was utilized for genome-wide biomarker screening, in which Cox regression was used for survival outcomes and logistic regression for a 2-year-based dichotomized outcome. All search was done through 200 resampling steps, each consisting of randomly selecting 80% of pts and 80% of all gene signatures. Moreover, we searched the genes that are most complementary to the established immune cell scores (i.e., Ecotyper and xCell) by incorporating these scores into the regression adjustment. Finally, we applied the same approach to identify prognostic long non-coding RNA (lncRNA) signatures. All analyses were carried out on all ICI pts, as well as on subgroups stratified by cancer type. **Results:** Of 875 pts treated with ICI, 125 had melanoma, 143 had kidney cancer, 126 had non-small lung cancer, and 110 had head and neck cancer. The genome-wide selection method successfully identified a panel of top prognostic genes and pathways for all cancer types included. In melanoma, the top five prognostic genes were *ZDHHC2*, *CBX4*, *MET*, *NTN4*, and *HLA-DQA1*, with 80%, 78%, 77.5%, 77.5%, 76.5% resampling-based selection probability respectively; the top five lncRNAs were *AC073655.3*, *AC116348.3*, *PITPNA-AS1*, *AC011447.3*, and *AL021978.1*. When adjusting for the immune scores in the selection model, the top five prognostic protein-coding genes in melanoma were *TENM3*, *POLR2J3*, *SCCPDH*, *MET* and *SLAH1*, and the top five lncRNAs were *AC007620.2*, *PITPNA-AS1*, *HCG11*, *SLC25A5-AS1*, and *LINC02258*, respectively. **Conclusions:** Our analysis has successfully identified gene panels of mRNA and lncRNA molecules with potential roles related to ICI mechanisms of action. Ongoing analyses are further investigating the potential mechanisms and pathways linking these molecules and will be presented at the meeting. Research Sponsor: Oncology Research Information Exchange Network (ORIEN) Foundation; Community Foundation Tampa Bay.

STK11 alterations as predictive biomarkers of resistance to immune checkpoint inhibitors in multiple cancers with mismatch repair gene alterations. *First Author: Michael Iglesia, Siteman Cancer Center, Washington University School of Medicine, St. Louis, MO*

Background: *STK11* is an important tumor suppressor gene that encodes for a serine-threonine kinase involved in a variety of metabolic functions. *STK11* alterations are associated with an inert or cold tumor microenvironment in KRAS-mutant lung adenocarcinoma, and are a major driver of primary resistance to immune checkpoint inhibitors (ICIs). Here, we explored *STK11* alterations as predictive biomarkers of resistance to ICIs in multiple solid tumors with mismatch repair (MMR) gene alterations. **Methods:** The cBioCancer Genomics Portal (cBioportal, <http://www.cbioportal.org>) was used to obtain genomic data. The association between *STK11* alterations and median overall survival (mOS) was explored in an ICI-treatment cohort comprising a total of 1572 evaluable patients. This cohort includes patients with cancers of the lung, colon, unknown primary, head and neck, gastroesophageal, bladder, skin (melanoma), brain, breast and kidney that had received at least one dose of ICI. These were then cross-referenced with patients who had MSK-IMPACT testing done in the context of routine clinical care. Kaplan-Meier survival curves were generated and compared using log-rank testing. **Results:** In the ICI-treated patients cohort (N = 1572), 96 patients (6.1%) had *STK11* alterations. Patients with *STK11* alterations had higher median tumor mutation burden (TMB) than patients without *STK11* alterations (8.81 mut/Mb vs. 5.87 mut/Mb, $p < 0.0001$). Yet, they had worse mOS (7 m, 95% CI: 6-13 m vs. 20 m, 95% CI: 18-22 m, $p < 0.001$). MMR alterations (not including gene promoter methylation) were identified in 103 (6.6%) and co-occurrence of *STK11* with MMR alterations was identified in 9 (0.6%) patients. Compared to patients without MMR or *STK11* alterations (N = 1382), the mOS was better in patients with MMR alterations without *STK11* alterations (N = 94) (59 m vs. 19 m, $p = 0.0004$) and trending for worse in patients with MMR and *STK11* alterations (N = 9) (5 m vs. 19 m, $p = 0.117$). The mOS was better in patients with MMR alterations without *STK11* alterations compared to patients with MMR and *STK11* alterations (59 m vs 5 m, $p = 0.016$). Controlling for KRAS mutation status, a multivariable Cox regression model shows that besides MMR and *STK11* alteration status ($p = 0.0008$), BRAF mutant status ($p = 0.0001$, HR 0.598; 95% CI, 0.459-0.779) was another biomarker associated with significantly better OS. Lung cancer diagnosis was associated with worse OS ($p = 0.0016$, HR 1.340; 95% CI, 1.117-1.607). **Conclusions:** In a large cohort of ICI-treated patients with multiple cancers, *STK11* alterations were associated with worse mOS despite having higher TMB. MMR alterations were only predictive of response to ICIs in patients without *STK11* alterations. Our findings suggest that *STK11* alterations in patients with MMR alterations could potentially identify patients who are less likely to respond to ICIs but more data are needed. Research Sponsor: None.

Poster Session

The differential response to immune checkpoint inhibitors (ICIs) according to mismatch repair alterations in gastrointestinal (GI) non-colorectal cancers (non-CRCs) and the impact of dual vs. monotherapy ICIs on survival in GI (CRC and non-CRC) cancers. *First Author: Moh'd M. Khushman, Washington University in St. Louis, Siteman Cancer Center, St. Louis, MO*

Background: In patients with mismatch repair deficient (dMMR) colorectal cancers (CRCs), we previously reported that loss of expression of MSH2 and MSH6 (MutS co-loss) was associated with better response to ICIs and longer median overall survival (mOS) compared to loss of expression of MLH1 and PMS2 (MutL co-loss). Here, we expanded our analysis and included gastrointestinal (GI) non-CRCs and explored the impact of dual vs. monotherapy ICIs on mOS in GI (CRC and non-CRC) cancers. **Methods:** Specimens were profiled by next-generation sequencing (592, NextSeq; WES, WTS NovaSeq) (Caris Life Sciences, Phoenix, AZ). MMR/microsatellite instability (MSI) status was determined by immunohistochemistry (IHC) of MMR protein. Real world OS was extracted from insurance claims and calculated using Kaplan-Meier estimates for molecularly defined cohorts from first treatment with ICIs (Nivolumab, Nivo; Ipilimumab, ipi; or Pembrolizumab, pembro) to last contact. Statistical significance was determined using chi-square and Mann-Whitney U test with p-values adjusted for multiple comparisons ($q < 0.05$). **Results:** The GI non-CRC cohort (N=19,767) included cancers of the esophagus, stomach, gastroesophageal junction, pancreas, bile duct and small bowel with 97 (0.49%) patients having MutS co-loss, and 494 (4.03%) patients having MutL co-loss. MutS co-loss was associated with increased *KRAS* (45.4% vs 25.2%, $q < 0.01$), *CDKN2A* (29.2% vs 9.0%), *GNAS* (27.8% vs 7.8%) and *SMAD4* (17.5% vs 5.9%) mutations compared to MutL co-loss. Independent of treatment, MutS co-loss (N=74) had improved mOS compared to MutL co-loss (N=332) (40.4 m vs. 26.2 m, HR = 0.66; (95% CI: 0.46-0.95), $P=0.024$). In patients treated with ICIs, the mOS in MutS co-loss (N=21) was better compared to MutL co-loss (N=76) (not reached (NR) vs. 25.4 m, HR = 0.23 (95% CI: 0.07-0.75), $p=0.008$). At 3 years, more than 80% of the patients with MutS co-loss were alive. Of particular importance, when looking at all GI (CRC and non-CRC) patients, the mOS of MutL co-loss treated with ipi/nivo (N=18) trended for better mOS compared to MutL co-loss treated with pembro (N=215) (NR vs. 28.2m (HR=0.39; (95% CI: 0.14-1.07), $p=0.057$), while the mOS of MutS co-loss treated with ipi/nivo (N=6) was not different compared to MutS co-loss treated with pembro (N=44) (NR vs. NR, HR=0.75 (95% CI: 0.094-5.92), $p=0.78$). **Conclusions:** In ICI-treated GI non-CRCs, the mOS was longer in MutS co-loss compared to MutL co-loss. In ICI-treated GI (CRC and non-CRC) patients with MutL co-loss, there was a trend for better survival with ipi/nivo compared to pembro. Our data suggest that the MutS vs. MutL status may guide the choice of ICIs regimen (Dual vs. Monotherapy) but more data are needed. Research Sponsor: None.

Spatial distribution of B cells and lymphocyte clusters for the treatment of non-small cell lung cancer. *First Author: Corinne Ramos, ImaBiotech, Loos, France*

Background: The presence of tertiary lymphoid structure (TLS) in tumor tissues has been reported to be a factor associated with a good prognosis in several types of cancers including non-small cell lung cancer (NSCLC). However, the relationship between TLS spatial organization and the treatment response remains unknown in NSCLC who received anti-PD-1 antibody. The purpose of this study was to evaluate the effect of the various stages of the spatial organization of the TLS from locally concentrated aggregates of immune cells, through clearly defined B cell follicles to mature follicles in NSCLC and its relationship with the tumor microenvironment on anti-PD1 treatment response. **Methods:** Frozen sections from retrospectively collected surgically resected NSCLC tumors treated with adjuvant pembrolizumab therapy were used. The TLS in tumor tissues was detected by high-plex imaging mass cytometry staining and the difference in TLS spatial organization was compared to the features of the tumor microenvironment and the objective response rate of the patients. **Results:** TLS identified and characterized according to their spatial organization within or adjacent to the tumor showed that the presence of tumor-associated TLS (TA-TLS) correlated with favorable response to anti-PD-1 therapy. The abundance and the spatial distribution of B cells allowed for a better definition of the correlation between B cell subsets with clinical outcomes showing that the heterogeneity in these TA-TLS influences the predictivity significance to anti-PD-1 therapy. **Conclusions:** Identifying the phenotypic heterogeneity of intratumor B cells and their functional connection to CD8 T cell helps optimally guide the anti-PD-1 treatment strategy. This spatial mechanistic insight also provides an exciting opportunity for translation of B cell-based immunotherapies into clinics complementary to existing T cells centric strategies. Artificial intelligence (AI)-powered spatial analysis of macrophages in tumor microenvironment and its association with interferon-gamma (IFNG) signature and immune phenotype (IP) in pan-cancer dataset. *First Author: Chiyeon Oum, Lunit Inc., Seoul, South Korea*

Background: Macrophages are known to play a crucial role in cancer progression, but few studies have reported macrophage spatial distribution and its association with genomic signatures and tumor-infiltrating lymphocytes (TIL). Here, we applied an AI-powered Whole Slide Image (WSI) analyzer in The Cancer Genome Atlas (TCGA) pan-cancer dataset to show correlation between specific localization of macrophage and anti-tumor activity, which is reflected by IFNG signature and IP based on spatial TIL density. **Methods:** For spatial macrophage analysis in TCGA pan-cancer dataset, we used Lunit SCOPE IO, an AI-powered H&E WSI analyzer, which identifies and quantifies various classes of cells such as tumor cell, macrophage, and TIL within cancer or stroma area. IPs were defined as follows: inflamed IP (IIP) as high intratumoral TIL (iTIL) and stromal TIL (sTIL); immune-excluded IP (IEP) as low iTIL and high sTIL; immune-desert IP (IDP) as low TIL overall. The immune cell profiling and quantification of the IFNG signature score were analyzed by using CIBERSORT and RSEM. **Results:** In TCGA dataset (N = 7,402), median macrophage density in total TME area (tMP) was 19.9 /mm² (interquartile range [IQR] 9.0-44.9), and it was highly enriched in lung adenocarcinoma (median 65.1, IQR 34.3-110.0), lung squamous cell carcinoma (61, 32.4-101.3), and head and neck squamous cell carcinoma (39.4, 19.6-77.3). Based on IP classification, tMP was highly enriched in IIP (37.8, 18.7-73.8) compared to IEP (25.5, 13.8-48.6) and IDP (8.9, 4.4-17.1). Interestingly, spatial analysis showed that intratumoral macrophage density (iMP) in IIP was highly enriched compared to the others (mean fold change 2.57) and the difference of stromal macrophage density (sMP) among IPs was relatively smaller (mean fold change x1.85). Classified into four groups based on median values of iMP and sMP, high-iMP/high-sMP group had the highest proportion of IIP (47.3% vs 18.7%, $p < 0.001$), whereas low-iMP/high-sMP group had the highest one of IEP (54.9% vs 32.3%, $p < 0.001$) compared to the others, respectively. Moreover, the high-iMP/high-sMP group had the highest level of IFNG signature score among 4 groups (x2.13 times higher, $p < 0.001$). Notably, both iMP and sMP were significantly correlated with CD68 expression (rho 0.292 and 0.287) but CSF1R expression was more strongly correlated with iMP (rho 0.259) compared to sMP (rho 0.078). **Conclusions:** IIP, IFNG signature, and CSF1R expression are more strongly correlated with intratumoral macrophage density versus stromal macrophage density, suggesting a relationship between macrophage location and function in the TME warranting further investigation. Role of HLA class-I antigen peptide loading complex components in immune evasion and treatment sensitivity in human lung cancer. *First Author: Adrien Costantini, Yale University, New Haven, CT*

Background: Determinants of sensitivity and resistance to immune checkpoint inhibitors (ICIs) are poorly understood. An intact HLA class-I antigen presentation machinery (APM) is necessary for tumor-antigen recognition by effector T-cells and disruptions to the APM can cause ICI resistance. The peptide loading complex (PLC) is a multi-chaperone complex located in the endoplasmic reticulum in which tapasin (Tap), calreticulin (CalR) and ERp57 play major roles. The PLC allows for optimal peptide selection and loading onto HLA class-I heavy chain and is critical for adequate cell surface presentation of peptide-HLA complexes. We studied the frequency and clinical significance of cancer-cell selective PLC protein defects in human NSCLC. **Methods:** Multiplex quantitative immunofluorescence (mQIF) was performed to simultaneously and spatially measure cytochrome (CK), Tap, CalR, ERp57 and CD8 protein levels in 1,031 primary NSCLCs from 5 independent cohorts represented in tissue microarrays. The protein levels were measured in CK-positive cancer-cells and in CK-negative stromal cells. The presence of lower marker levels in malignant cells relative to stromal cells within the same sample was considered as cancer-cell selective downregulation. Cohorts #1-3 included baseline samples from patients treated without ICIs and Cohort #4 included samples from patients treated with ICIs. Cohort #5 contained lung adenocarcinomas clinically tested for EGFR and KRAS mutations. The association between the levels of Tap, CalR and ERp57, their association with clinicopathologic variables, CD8+ T-cell levels and outcomes were studied. **Results:** mQIF analysis identified cancer-cell selective downregulation of Tap, CalR and/or ERp57 in 73%, 81%, 68% and 75% of cases from Cohorts #1-4, respectively. The most common PLC alterations were cancer-cell downregulation of Tap alone in Cohorts #1 (32%), #3 (34%) and #4 (36%); and Tap-CalR in Cohort #2 (29%). Tap and ERp57 levels were significantly higher in stage IV than in earlier stage tumors. The PLC marker levels and the frequency of cancer-cell selective downregulation were comparable across EGFR and KRAS mutated samples. NSCLCs with cancer-cell Tap downregulation had lower CD8+ T-cell infiltration and shorter OS across all cohorts that reached statistical significance in Cohort #4 (median OS 12.08 vs 21.00, HR=1.72, 95% CI 1.02-2.89, $p=0.034$). The cancer-cell selective downregulation of CalR was associated with shorter OS in cohorts #1 and #3. **Conclusions:** HLA class-I PLC components show variable levels in treatment naive NSCLCs. Downregulation of Tap in cancer-cells, alone or in combination with other PLC members occurs in up to 60% of cases and is associated with reduced CD8+ TILs and shorter OS preferentially in patients treated with ICIs. Cancer-cell Tap downregulation could mediate primary ICI resistance and has biomarker potential. Research Sponsor: U.S. National Institutes of Health; ERS, Fulbright, Fondation ARC; Merck.

Pan-cancer associations of B7-H3 (CD276) transcriptional expression across human malignancies. *First Author: Justin Hwang, University of Minnesota, Minneapolis, MN*

Background: B7-H3 (CD276) is a transmembrane glycoprotein of the B7 superfamily that includes PD-L1 and CTLA-4. B7-H3 targeted therapeutics have demonstrated promising results in both solid tumors and hematologic cancers. To understand the applicability of B7-H3 targeted therapies, we characterized the landscape of clinical outcomes, genomic, transcriptomic, and immunological features associated with B7-H3 mRNA expression in > 93,000 samples across > 45 cancer types from a large real-world clinico-genomics database. **Methods:** DNA (592-gene/whole exome) and RNA (whole transcriptome) sequencing was performed for samples submitted to Caris Life Sciences (Phoenix, AZ). Differential expression of individual genes was analyzed, with pathway enrichment assessed by Gene Set Enrichment Analyses (GSEA). RNA deconvolution was used to estimate immune cell infiltration of tumor microenvironments using quanTseq (Finotello, 2019). Real-world overall survival (OS) was determined from insurance claims data and Kaplan-Meier estimates were calculated. Statistical significance was determined using χ^2 and Mann-Whitney U tests with Benjamini-Hochberg corrections for multiple hypothesis testing where appropriate. **Results:** B7-H3 mRNA displayed robust expression in many prevalent cancer types, including prostate, pancreatic, breast, colorectal, ovarian, and lung cancers (n = 3407, 4624, 8639, 12,862, 8004, and 13,502, respectively). High B7-H3 expression predicted worse OS in ovarian cancer (1.38 HR, 95% CI 1.23-1.53, p < 0.001) and lung adenocarcinoma (1.45 HR, 95% CI 1.34-1.57, p < 0.001), and better OS in prostate (0.84 HR, 95% CI 0.71-0.99, p < 0.05). Notably, high B7-H3 was detected in tumors with known driver mutations (e.g. *EGFR*, *ESR1*, *KRAS*, *SPOP*) or undruggable therapeutic targets (*TP53*, *APC*). When examining Hallmark gene signatures, we found that B7-H3-high samples demonstrated consistent enrichment for pathways involved in epithelial to mesenchymal transition (EMT), WNT, TGF- β , and Notch signaling (FDR < 0.05) across cancer types. Additionally, high B7-H3 expression was correlated with greater proportions of pro-inflammatory M1 macrophages but lower proportions of effector CD8+ T cells and NK cells across multiple cancer types. **Conclusions:** We demonstrate B7-H3 to be a promising pan-tumor target, with most solid tumors showing robust expression which is often associated with worse OS. In several major cancers, high B7-H3 expression was associated with mutational and transcriptomic repertoires not easily targeted by current precision therapies. We find B7-H3-high tumors to have increased potential for myeloid-driven immune induction, making them potentially more amenable to immunomodulatory therapies, in particular, those targeting B7-H3. Further work is warranted to elucidate different mechanistic interactions of B7-H3 with specific oncogenic pathways in each cancer type. Novel STK11 differentiation phenotype classifier STK11-DPC: Immunosuppressive tumor microenvironment (TME) and response to immune checkpoint blockade (ICB) in STK11-deficient NSCLC. *First Author: Jacob Kaufman, The James Cancer Hospital and Solove Research Institute, Columbus, OH*

Background: Loss of STK11 occurs in 20-25% of NSCLC and confers poor prognosis and resistance to ICB. STK11 loss affects lineage plasticity in murine models and differentiation phenotypes in patients. However, interactions between differentiation state, TME, and clinical outcomes are not well characterized. **Methods:** This is a retrospective and descriptive study across eight transcriptomic datasets of 2118 non-squamous NSCLC with 314 STK11 mutations, including 628 patients randomized to docetaxel or atezolizumab in the OAK and POPLAR clinical trials. STK11-DPC applies a validated gene signature to assess functional STK11 loss, then uses a rule-based classifier to define three differentiation lineages: "Neuroendocrine," "TTF1-Low," and "TTF1-Positive." TME is assessed by xCell immune deconvolution, and patient outcomes assessed by Cox proportional hazards regression models. **Results:** STK11-DPC significantly outperforms STK11 mutations in predicting decreased MHC-1, MHC-2, interferon-stimulated genes, and immune infiltration (P < 1e-8 for each). Each of the three differentiation groups has low immune infiltration compared to STK11 WT tumors, but we observe distinctive TME phenotypes corresponding to the Neuroendocrine and TTF1-Low groups. Neuroendocrine tumors have low expression of pro-inflammatory genes in the TNF/NF κ B and JAK/STAT signaling pathways (P < 1e-10), while TTF1-Low tumors show hallmarks of increased inflammation, with higher PMN-MDSC, CD8 and NK signatures, but relative exclusion of dendritic cells (P < 1e-6 for each). These differences persist after controlling for KRAS, KEAP1, and TP53 mutations. Conversely, STK11-deficient tumors in WT-like or TTF1-Positive groups have TME more similar to STK11-WT tumors and show increased immune infiltration. STK11-DPC was prognostic when applied to OAK and POPLAR, with worse OS in Neuroendocrine (HR 1.6, P = 0.006) and TTF1-Low (HR 2.4, P = 5.8e-10) groups. Survival in both arms was equally poor in these groups. In contrast, STK11-deficient tumors with WT-Like or TTF1-Positive phenotypes had better OS with atezolizumab compared to docetaxel (HR 0.5, P = 0.03). **Conclusions:** STK11-DPC is highly predictive of immune exclusion and NSCLC patient outcomes. It identifies STK11-deficient subsets with increased immune infiltration and improved ICB response, and two putatively immune-resistant subgroups with markedly different TME phenotypes: Neuroendocrine tumors have an anti-inflammatory phenotype, while TTF1-Low tumors exhibit chronic inflammation. Performance of STK11-DPC as a predictive biomarker warrants further validation in additional patient cohorts, while the apparent TME differences suggest distinct and non-overlapping mechanisms of ICB resistance and may guide development of precision treatment strategies. Clinical and biological activity of FLX475, an oral CCR4 antagonist, in advanced cancer. *First Author: Dirk G. Brockstedt, RAPT Therapeutics, Inc., South San Francisco, CA*

Background: FLX475 is a potent and selective CCR4 antagonist, designed to block the recruitment of immunosuppressive regulatory T cells (T_{reg}) into tumors without affecting healthy tissues. Blocking migration of T_{reg} into the tumor microenvironment (TME) has the potential to restore antitumor immunity and synergize with a variety of conventional and immunotherapy-based approaches to overcome immune resistance and broaden clinical efficacy. In a recent interim clinical update from the ongoing FLX475-02 Phase 1/2 trial, evidence of monotherapy and combination activity were reported. FLX475 monotherapy induced complete responses in two of the six evaluable subjects enrolled with EBV+ NK/T cell lymphoma. In checkpoint inhibitor naive non-small-cell lung cancer (NSCLC), 4/13 subjects (31%) had confirmed partial responses (PRs) following treatment with the combination of FLX475 and pembrolizumab. In this analysis we present biomarker data from patients with broad range of tumor types treated with FLX475 monotherapy. We provide evidence to substantiate the mechanism of action and support the combination of FLX475 with pembrolizumab. **Methods:** Flow cytometry was used to measure relative proportions of T_{reg} in the periphery. CD8 and FOXP3 positive cells in tumor biopsies were quantified by immunohistochemistry (IHC). Gene set enrichment analysis and immune deconvolution methods were used to interrogate RNAseq data derived from tumor biopsies. **Results:** FLX475 monotherapy results in a small but significant increase in proportion of circulating CD25+CD127-/low CD4+ T_{reg} by day 8 of treatment. IHC analysis revealed a trend towards increased CD8:FOXP3 ratio in the TME of patient biopsies. Transcriptomic profiles from tumor biopsies of FLX475 monotherapy treated patients exhibited significant changes in immune pathways likely to benefit the antitumor response. Using global gene expression analyses we identified that FLX475 monotherapy altered the transcriptome of tumors to resemble those from patients with favorable clinical outcome to anti-PD(L)-1 treatment. Consistent with the proposed mechanism of action, immune deconvolution identified that FLX475-treated patients experienced a decrease in T_{reg} cell populations. **Conclusions:** FLX475 monotherapy results in beneficial changes in the TME consistent with our proposed mechanism of action. FLX475 monotherapy is modifying the tumor microenvironment toward a phenotype associated with response to anti-PD-1/anti-PD-L1. Clinical trial information: NCT03674567. Tracking plasticity along with proliferation and immune evasion using FOXC1, MKI67 and PDL1 for prediction of therapeutic response and risk for hyperprogressive disease with PD1/PDL1 inhibitors in advanced/metastatic cancers: Pan-tumor validation in clinical trial and real-world cohorts. *First Author: Partha S Ray, Onconostic Technologies, Evanston, IL*

Background: Accurate prediction of therapeutic response (TR) to treatment with immune checkpoint blockade (ICB) as well as any resultant durable clinical benefit in terms of improved progression-free survival (PFS) and overall survival (OS) is not consistently achieved with existing biomarkers like PDL1 or tumor mutational burden (TMB). We hypothesized that a multi-marker predictive biomarker strategy that tracks plasticity using FOXC1 expression, in parallel to tumor proliferation and immune evasion, using expression of MKI67 and PDL1, respectively, may demonstrate superior TR prediction, and also enable accurate prediction of risk for hyperprogressive disease (HPD). **Methods:** Pre-treatment tumor RNA-Seq data obtained from training/validation clinical trial cohorts and real-world patients diagnosed with advanced/metastatic non-small cell lung cancer (NSCLC, n=82/28) and melanoma (n=154/121) were analyzed for FOXC1, MKI67 and PDL1 expression, and correlated with overall response rate (ORR), PFS, OS and HPD, the latter defined as time-to-treatment-failure $\leq$ 2 months post-treatment initiation. Optimized biomarker cutoff values based on model area-under-curve were leave-one-out cross validated and cancer-type specific (CTS) prediction algorithms derived. The unmodified strategy was then validated in the independent, CTS validation datasets. **Results:** ORR prediction accuracy was confirmed in validation datasets with high accuracy: NSCLC AUC=0.96, OR=9.63 (0.98-94.54, 95%CI) p=0.03 and melanoma AUC=0.91, OR=3.85 (1.73-8.58, 95%CI), p=0.0005. Predicted Responders consistently displayed superior PFS and OS compared to predicted Non-Responders: NSCLC PFS HR=0.51 (0.32-0.82, 95%CI) p=0.007, OS HR=0.44 (0.27-0.73, 95%CI) p=0.003; melanoma PFS HR=0.45 (0.30-0.68, 95%CI) p=0.002, OS HR=0.43 (0.26-0.71, 95%CI) p=0.002. Patients at risk for HPD were identified with high accuracy: NSCLC AUC=0.96, OR=9.67 (2.95-31.73) p<0.0001; melanoma AUC=0.98, OR=44.36 (11.73-167.74, 95%CI) p<0.0001. **Conclusions:** Tracking multiple dimensions of cancer biology including plasticity (using FOXC1), as opposed to tracking immune evasion alone, proved to be a superior and accurate pan-cancer, tissue-agnostic predictor of TR to ICB therapy in advanced/metastatic tumors in terms of ORR, PFS, OS as well as HPD risk prediction. This approach merits further testing in prospective clinical trials. Research Sponsor: None.

Phase I evaluation of PRGN-2009 alone and in combination with bintrafusp alfa in patients (pts) with recurrent/metastatic (R/M) HPV-associated cancers (HPV-C). *First Author: Charalampos S. Floudas, Center for Immunology, CCR, NCI, NIH, Bethesda, MD*

Background: Combinatorial treatments may improve efficacy in checkpoint blockade resistant (CBR) R/M HPV-C. PRGN-2009 is a gorilla adenovirus immunotherapy vaccine containing 35 non-HLA-restricted epitopes of HPV-16 and 18. We conducted a first-in-human Phase I study of PRGN-2009 alone and combined with bintrafusp alfa (BA), a bifunctional TGF- β “trap”/anti-PD-L1 fusion protein in adult pts with pretreated R/M HPV-C. We report safety and efficacy results. **Methods:** Pts received PRGN-2009 1×10^{11} or 5×10^{11} particle units (PU) SC Q2W for 3 times, then Q4W (dose escalation part, DEP) or the recommended phase 2 dose (RP2D) of PRGN-2009 plus BA 1200 mg IV Q2W (combination part, CP) until progressive disease, unacceptable toxicity or patient withdrawal. Primary endpoints were safety and RP2D; secondary endpoints included overall response rate (RECIST 1.1). Exploratory endpoints included the induction of HPV-16/18 specific T-cell responses in peripheral blood mononuclear cells collected pre- and post-PRGN-2009 treatment. **Results:** Between August 11, 2020, and May 5, 2022, 17 pts were enrolled. Median follow-up at data cutoff was 7.4 months and 18.6 months for the DEP and CP, respectively. In the DEP, 6 pts received PRGN-2009, for a median duration of 3.0 months (range 1.8-17.9). Five pts had ≥ 3 prior lines of anticancer therapy. There were no dose limiting toxicities. Adverse events (AE) related to treatment (TRA) were Grade 1-2 flu-like syndrome, injection site reactions, fatigue, rash. 5×10^{11} PU was selected as RP2D. Stable disease was noted in 4 pts, longest duration being 14.9 months. In the CP, 11 high-risk HPV positive pts received PRGN-2009 with BA for a median duration of 10.0 months (range 0.5-23.0). Four pts (36.3%) had received ≥ 3 prior treatment lines; 10 pts (90.9%) were CBR. Grade 3 TRAEs occurred in 1 pt (9.1%); duodenal hemorrhage [DH] attributable to BA; 2 pts (18.1%) had grade 4 TRAEs (DH, pharyngeal mucositis [n=1 each], attributable to BA). Both pts with DH were concurrently receiving NSAIDs. No treatment-related deaths occurred; one pt with DH died after refusing core standard medical management. Of 10 pts evaluable for response one CBR pt had a complete response (duration 15.3 months); partial responses were seen in two pts (one CBR). Overall response rate was 30.0% (95% CI 6.7-65.3%). Two pts were treated beyond progression without delayed response. Median overall survival was 7.4 months (95% CI, 2.9-26.8 months) for DEP and 12.5 months (95% CI, 9.6-inestimable) for CP. Post vaccination 14/16 (88%) pts developed T-cell responses to HPV-16 and/or HPV-18, with 6/6 in DEP and 8/10 in CP. **Conclusions:** PRGN-2009 is safe, well-tolerated, and induces HPV-specific T-cell immune responses. Further, PRGN-2009 combined with BA demonstrated clinical activity in pts with pretreated HPV-associated cancers, naive or resistant to checkpoint blockade. Clinical trial information: NCT04432597. Effect of personalized immunization with GNOS-PV02 of patients with hepatocellular carcinoma on TCR clonal expansion, tumor infiltration, and vaccine-specific reactivity. *First Author: Renzo Perales, Geneos Therapeutics, Plymouth Meeting, PA*

Background: Tumor-specific neoantigens can be identified from cancer biopsies and used to develop personalized therapeutic cancer vaccines (PTCV) to prime neoantigen-specific T cell responses. Here, we characterized the antitumor neoantigen-specific reactivity of tumor-infiltrating, high-frequency TCR clones in a patient treated with personalized therapeutic DNA cancer vaccine GNOS-PV02 in the ongoing GT-30 advanced hepatocellular carcinoma single-arm open-label multi-center phase Ib/IIa trial (NCT04251117). **Methods:** Paired blood and tumor biopsy samples from patient #8 enrolled in the GT-30 study were collected before and after treatment with GNOS-PV02 (1mg) + plasmid-encoded IL-12 (0.3mg) + Pembrolizumab (200mg). GNOS-PV02 and IL-12 were administered at Q3W for the first 4 doses, then, at Q9W. Pembrolizumab was administered Q3W. Neoantigen positivity was evaluated by IFN- γ -ELISpot. TCR β sequencing was performed on all 4 samples and single-cell TCR and transcriptome sequencing was performed from T cells isolated from the post-treatment blood sample. After vaccination, three newly identified TCRs in blood and tumor were inserted into a pMXs-IRES-GFP retroviral plasmid vector and used to generate engineered TCR T cells. Engineered T cells were tested against the neoantigens included in PTCV by flow cytometry. **Results:** The treatment resulted in a partial response with a decrease in tumor size of 44% by RECIST 1.1. Five vaccine-encoded responding neoantigens were identified. Differential abundance frame network analysis revealed that 27 of 42 (64.28%) significantly expanded peripheral TCR clones were also found enriched in the tumors post-treatment. Importantly, we observed an increase in cumulative frequency (from 0.4 to 7.7%), and absolute numbers (from 3 to 14) of significantly expanded vaccine-specific TCR clones in the tumor. Increased TCR clonality confirmed a focused tumor repertoire response. Single-cell sequencing data analysis revealed that the 6 most expanded clones in blood were activated CD8+CD69+ T cells (81.82%). Three full TCR sequences from T cell clones newly present in the tumor post-vaccination were selected, synthesized and cloned. TCR-engineered patient-specific T cells showed a dose-dependent CD8+ and CD4+ T cell activation (CD69+) upon stimulation with a pool of epitopes covering all the neoantigens in the patient's PTCV. **Conclusions:** PTCV treatment resulted in neoantigen-specific T cell responses, clonal expansion in the periphery and primary lesion, and tumor infiltration of T cells with an activated phenotype. TCR-engineered high-frequency T cells found in the tumor are reactive to PTCV-encoded neoantigens post-treatment. These results may account for the observed objective decrease in the primary tumor size. Research Sponsor: Geneos Therapeutics.

Immunogenicity and clinical activity of tipapkinogen sovavivec (TG4001), an HPV-16 cancer vaccine: A randomized phase 2 study in advanced anogenital cancers. *First Author: Christophe Le Tourneau, Institut Curie, Paris, France*

Background: Human papillomavirus 16 (HPV-16) infection is associated with several cancer types with limited treatment options in the locally R/M settings. Furthermore, immune checkpoint inhibitors have limited activity against advanced HPV-cancers. TG4001 is a viral vector vaccine targeting HPV E6 and E7 antigens. We have previously shown in a single-arm, dose finding phase 1 study that TG4001 combined with PD-L1 blockade using avelumab was safe and associated with a response rate of 22%. Herein we report preliminary data on immunogenicity and clinical activity of TG4001 in a randomized phase 2 study comparing TG4001 plus avelumab versus avelumab alone. **Methods:** Eligibility criteria: R/M HPV16+ anogenital cancer including cervical, vulvar, vaginal, penile, and anal cancers; immunotherapy naive and with no more than one prior line of chemotherapy. HPV-16 positivity was required and centrally determined using a PCR based assay. Patients were randomly assigned 1:1 to receive either TG4001 plus avelumab (Vaccine arm) or avelumab alone. Randomization was stratified by tumor type (cervical, anal, genital). TG4001 was administered s.c at 5×10^7 pfu, Q1w for 5 weeks, then Q2w until month 6 followed by Q12w until progressive disease and avelumab i.v at 800 mg Q2w until progressive disease. PBMCs were collected at baseline, day 43 and day 85 to assess T-cell responses against E6 and E7 antigens using ex-vivo IFN γ ELISPOT and immunophenotyping of circulating T cells. Vaccine immune response (IR) was defined as onset of a new T-cell response against either antigen or amplification of a pre-existing response under treatment. Tumor response was assessed using RECIST 1.1. **Results:** 59 pts had been randomized by the time of data cut-off. IR was assessed in 24 pts in the vaccine arm and 16 pts in the avelumab arm. T cells against E6 or E7 antigens at baseline were rare with only 4 pts having a low intensity ELISPOT readout against either target prior to initiation of treatment. 11/24 pts in the vaccine arm had an IR, while none of the patients in the avelumab arm had an IR. Occurrence of IR was detected at day 43 and tended to gain in intensity at D85. In the vaccine arm, IR was associated with tumor response with 3 clinical responders among 11 pts with positive IR versus 1 response observed among the 13 patients without IR. Conversely, only 2 progressive disease pts among 11 positive IR compared favorably to the 6/13 vaccine arm pts with no IR. Remarkably, a complete clinical response was observed in a vaccine treated pt exhibiting the strongest E6 and E7 IR. **Conclusions:** TG4001 can induce a de novo immune response against HPV-16 antigens E6 and E7 in advanced HPV-16 cancers. The data suggest that these IRs are associated with anti-tumor response and that TG4001 vaccination in combination with ICI has the potential to drive clinical benefit in R/M anogenital cancers. Clinical trial information: NCT03260023. Phase 1 dose escalation study of DSP107, a first-in-class CD47 and 4-1BB targeting fusion protein, in combination with atezolizumab in patients with advanced solid tumors. *First Author: Anwaar Saeed, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: DSP107 is a bi-functional fusion protein composed of sequences from the extracellular domain of SIRP α and 4-1BB ligand (4-1BBL). The SIRP α arm targets CD47 overexpressed on tumor cells, blocking the “don’t eat me” checkpoint and anchoring trimeric 4-1BBL to the tumor, which interacts with 4-1BB expressed on activated immune cells. This results in proliferation and conditional activation of effector cytotoxic T-cells in the tumor microenvironment. Thereby, DSP107 triggers both innate and adaptive immune responses. Phase 1 monotherapy dose escalation data demonstrated an excellent safety profile with no binding to red blood cells and no dose limiting toxicities (DLTs), hematological or hepato-toxicities. Here we describe data from the completed DSP107 plus atezolizumab combination dose escalation portion of study NCT04440735. **Methods:** Adult patients with advanced solid tumors were treated with weekly intravenous DSP107 infusions (1, 3 or 10 mg/kg; N = 6-7 patients/dose cohort) and atezolizumab (1200 mg) Q3W during 3-week treatment cycles. The primary objective was to determine the safety and tolerability of DSP107 in combination with atezolizumab. Restaging imaging was performed every two months and evaluated by RECIST v1.1 criteria. **Results:** In 19 patients, DSP107 with atezolizumab was well tolerated with no DLTs. Grade 1-2 treatment related adverse events (AEs) were observed in 68% of patients (13/19). The most frequent AEs included diarrhea (21%), fatigue (21%), infusion related reaction (IRR; 16%), nausea, decreased appetite, arthralgia, myalgia and Grade 1 anemia (11% each). IRRs were managed during subsequent infusions by reducing the infusion rate and administering IV fluids. Stable disease (SD) as best response was observed in 8/19 (42%) patients with treatment duration currently up to 10.5 months. At the highest dose of DSP107 (10 mg/kg), 3/7 patients had SD (1 microsatellite stable-colorectal cancer (MSS-CRC) patient with KRAS mutation had 16% target lesion shrinkage and no progression for 7 months). An additional 2 patients with advanced MSS-CRC (with BRAF and KRAS mutations, respectively) demonstrated deep and durable responses (-73 and -76% reduction in target lesions) including disappearance of pulmonary and hepatic target lesions in one patient. These patients currently continue to receive treatment after > 8 and > 6 months, respectively. **Conclusions:** DSP107 is a novel, CD47 and 4-1BB targeting fusion protein with a differentiated safety, binding and pharmacodynamic profile compared to other CD47 and 4-1BB targeting agents. These Phase 1 data suggest that the combination of DSP107 with PD(L)1 blockade may have anti-tumor activity in cold tumors such as MSS-CRC. Clinical trial information: NCT04440735. Using machine learning to characterize lung cancer microenvironment and the development of a model to predict the presence of similar microenvironment in other cancers. *First Author: Ahmad Charifa, Genomic Testing Cooperative, Irvine, CA*

Background: Poor response to immune checkpoint inhibitors (ICI) in colorectal cancer (CRC) is believed to be due to lack of immune suppressive tumor microenvironment (TME). In contrast, lung cancer TME is believed to be significantly more immunologically active and responsible for the relative success of ICI in lung cancer. We evaluated the TME in lung cancer and CRC using 43 immune biomarkers quantified using RNA sequencing and developed a model to classify TME into immunologically active (similar to lung cancer) vs inactive (similar to colorectal). These 43 immune biomarkers included B- and T-cell markers, cytokines and chemokines. **Methods:** RNA was extracted from FFPE samples from 707 patients with lung cancer, 227 patients with CRC, 131 patients with breast cancer, 111 patients with ovarian cancer, and 72 patients with pancreatic cancer. The expression levels of the 42 immunological markers were quantified using next generation sequencing (NGS) as a part of larger targeted RNA sequencing panel of 1408 genes. Using a machine learning algorithm, we first selected the relative genes that distinguish between two classes using two criteria: performance of each gene with K-fold cross-validation (K=12) and second based on stability measure using statistical significance tests. The selected genes were then used to predict one class from the other using random forest classifier. Samples were divided into a training set (67%) and testing set (33%). **Results:** A Bayesian-based algorithm selected the expression of 20 genes that were significantly relevant in differentiating between immunologically active and inactive TME. Using these 20 genes in Random Forest model, we can distinguish between lung and CRC with AUC of 0.997 (95% CI: 0.992-1.00) in the training set and AUC of 0.923 (95% CI: 0.880-0.966) in the testing set. Testing 131 breast cancer samples showed 23 (18%) with TME that can be classified as immunologically active. Of 111 ovarian samples 13 (12%) showed immunologically active TME and of 72 pancreatic samples, 17 (24%) showed microenvironment classified as active. The 20 genes that were adequate to distinguish between TME active vs inactive are: CD74, FCGBP, IL1R1, CD44, CD274, FCGR2B, IL21R, IL1RAP, IL7R, CD79A, CCL2, CYFIP2, CD19, IL2RA, CD8A, CD79B, ID1, CD22, FZD10, and IL1B, listed in order of their importance. **Conclusions:** This data shows that lung cancer TME is significantly different from that of CRC. Only 20 immune biomarkers adequate to distinguish between the two TME. The relevant biomarkers included CD274 (PD-L1) as well as one marker for T-cells (CD8A) but three markers for B-cells (CD19, CD22 and CD79B). This suggests that B-cells play a significant role in immunologically active TME and should be explored further as biomarkers for predicting response to ICI therapy. A phase I study of nelmastobart (hSTC810), an anti-BTN1A1 antibody, in patients with advanced solid tumors. *First Author: Soohyeon Lee, Korea University Anam Hospital, Seoul, South Korea*

Background: Butyrophilin 1A1 (BTN1A1) is a novel immune checkpoint that is primarily expressed by tumor cells in a manner that is mutually exclusive with PD-(L)1. BTN1A1 can potentially be targeted to extend new immunotherapeutic treatment options to patients (pts) whose tumors are unresponsive to anti-PD-(L)1 therapy. This phase I study describes the safety and clinical activity of Nelmastobart (hSTC810), a humanized monoclonal antibody targeting BTN1A1, in pts with advanced solid tumors. **Methods:** Nelmastobart was administered intravenously every 2 weeks across 6 dose levels from 0.3 mg/kg to 15 mg/kg. The primary objectives were to determine the safety profile and maximum tolerated dose (MTD) and/or recommended phase 2 dose (RP2D). Using a 3+3 design, dose-escalation cohorts were evaluated for dose-limiting toxicities (DLT) during the first 2 cycles. Backfill cohorts were allowed once a dose was deemed safe. Response was assessed using RECIST 1.1 every 4 cycles (8 weeks). Pts were treated until disease progression or unacceptable toxicity. **Results:** As of January 30, 2023, enrollment in the dose-escalation cohorts is complete. A total of 39 pts with colon (n=14), lung (NSCLC n=3; SCLC n=2), urothelial (n=3), breast, cholangiocarcinoma, melanoma, ovarian, pancreatic (n=2) each, adrenocortical, anal, esophageal, H&N, PEComa, skin, and thymic (n=1) cancers each were treated in the dose-escalation and backfill cohorts. Median duration of therapy for all pts was 8 weeks (maximum 29 weeks). Most common treatment related adverse events (TRAEs) reported were grade 1-2 fatigue (6%), headache (5.9%), and nausea (4.4%); furthermore, there were no TRAEs $\geq$ 3. No pts was discontinued or required dose reduction due to TRAEs. There were no DLTs across all dose levels and the MTD was not reached. In evaluable pts, one confirmed partial response was observed in MSI-H colon cancer (3 mg/kg) and 13 pts (colon, H&N, lung, melanoma, ovarian, thymic carcinoma) had a best response of stable disease (SD) across multiple dose levels. Median duration of PR/SD pts on study was 17.5 weeks. Interim pharmacokinetics (PK) analysis demonstrated consistent exposure with linear PK. Pharmacodynamic analysis measuring cytokines and cell-based markers is pending and will be presented. Based on the safety, efficacy, and PK, we recommend 15 mg/kg Q2W as the RP2D. **Conclusions:** Nelmastobart is well-tolerated without DLTs up to the final dose of 15 mg/kg. Current data show evidence of anti-tumor activity and durable SD. Clinical development planning for a phase Ib/II clinical trial is underway to further characterize the therapeutic dose and efficacy in select solid tumors. Clinical trial information: NCT05231746. Multisystem immune-related adverse events from dual agent immunotherapy use. *First Author: Yuchen Li, Department of Oncology, Juravinski Cancer Centre, Hamilton, Ontario, Hamilton, ON, Canada*

Background: Immune-related adverse events (irAEs) are commonly seen in cancer patients who undergo immunotherapy treatment. Increasingly, there has been recognition that multiple different irAEs can occur during or/and after a single course of immunotherapy treatment, known as multisystem irAEs, though much remains unknown. The primary objective of this study was to assess for rate of multisystem irAEs in patients who received dual agent ipilimumab and nivolumab for cancer treatment. **Methods:** A retrospective cohort review was completed that included all cancer patients seen at Juravinski Cancer Centre who received at least one dose of ipilimumab and nivolumab from January 1, 2018 to May 31, 2022. Patient characteristics, cancer types, and number and types of irAEs were recorded. Multivariate logistic regressions were also completed comparing those who developed multisystem irAEs, single irAE, and no irAE. **Results:** A total of 123 patients were included in this study. Median age was 59 years old, with 69% male. 72 out of 123 patients (59%) had melanoma, 50/123 (41%) had renal cell carcinoma (RCC), and 1/123 (1%) had breast cancer. At least one irAE was seen in 72% of patients who were treated with ipilimumab and nivolumab, and most irAEs occurred during the combination phase (89% of first irAE, 59% of second irAE, 75% of third irAE, and 50% of fourth irAE). Multisystem irAEs were seen in 40% of the overall cohort. The most common irAE type was dermatitis (22%), followed by colitis (19%), hepatitis (17%), and thyroiditis (15%). 30 out of 89 patients (34%) who experienced irAE(s) required hospital admission for inpatient treatment of irAE(s). Patients who experienced multisystem irAEs had significantly higher rates of response to immunotherapy irAE ($p < 0.001$) and improved overall survival (OS) than those who experienced single or no irAE. **Conclusions:** From our single-centre cohort study, there appeared to be a higher than previously quoted number of patients who experienced irAEs after receiving ipilimumab and nivolumab, with majority of them developing multisystem irAEs. Many patients experienced debilitating associated symptoms and hospital admission relating to irAEs. It is important for both the counselling and consent of patients, and for patient education, to discuss the possibility of multiple irAEs prior to dual immunotherapy initiation. Cardiotoxicity surveillance among patients with cancer treated with immunotherapy. *First Author: Juliana Goes Martins Fagundes, Oncoclinicas Paraiba (Centro Paraibano de Oncologia), Joao Pessoa, Brazil*

Background: With the advancements of immunotherapy procedures and, more specifically, immunological checkpoint inhibitors (ICIs), the scenario of cancer treatment, whether in its early or advanced stages, have changed. With the expansion of ICIs usage, cardiovascular toxicities have been reported, but more robust data are needed to guide the follow-up of patients and toxicity prevention. **Methods:** This research is a single-centered, prospective observational cohort study that evaluated patients treated with ICIs regardless of indication, with or without chemotherapy combination. Patients underwent echocardiography evaluation with global longitudinal strain (GLS) and myocardial work, electrocardiogram, and collection of biomarkers before the start of treatment, in the second month after treatment started, and every 3 months, subsequently. Evaluations stopped once treatment completed one year, or the medication was discontinued either due to toxicity or disease progression. Cardiotoxicity (CT) was defined by $\geq 10\%$ reduction in left ventricular ejection fraction (LVEF) by less than 50%, troponin elevation by ≥ 0.30 ng/ml, or reduction in relative GLS by $\geq 15\%$. Frequencies were compared using Fisher's comparative test, as appropriate, and Mann-Whitney test for numerical variables. Statistical significance will be considered as $p < 0.05$ for two-tailed tests. **Results:** Out of the 98 patients scheduled for treatment, 39 patients underwent at least 2 evaluations and had their exams analyzed. There was a 26% incidence of overall CT, with half of these patients by LVEF reduction criteria and, considering only patients with lung cancer, there was an incidence of 35% with CT. Dividing the total sample into CT and non-CT groups, a higher number of men, smokers and patients with lung cancer was observed, as well as a lower LVEF baseline (67% vs 62.50, $p = 0.014$) in the CT group. Concomitant chemotherapy or higher baseline coronary calcium scores did not appear to increase the risk of CT among patients, but the use of beta-blockers was restricted to patients who did not develop an event. There was a reduction in myocardial work parameters in the 2nd month assessment: global index (GWI) 1833 vs 2334, $p = 0.006$, constructive work (GCW) 2299 vs 2683, $p = 0.040$, and work efficiency (GWE) 83 vs 95, $p = 0.025$ and tendency towards increased myocardial work loss (GWW) 286 vs 116, $p = 0.064$, in the comparison between groups. Those who met CT criteria had a longer overall survival, as did those who developed other immune-mediated adverse events and metformin users. **Conclusions:** This was the first study that carried out cardiotoxicity surveillance in patients undergoing immunotherapy, with a surprising finding of events in a small but high-risk sample. The development of immune-mediated toxicities seems to be related with therapeutic response. Also, the use of metformin seems to contribute to this response, as already demonstrated in preclinical studies. Research Sponsor: None.

Comparing the impact of steroid sparing immunosuppression vs. steroid monotherapy for immune-related adverse events in non-small cell lung cancer and melanoma. *First Author: Sharjeel Syed, University of Chicago Medical Center, Department of Medicine, Chicago, IL*

Background: The effect of steroid-sparing immunosuppressive agents (SSiAs) for immune-related adverse events (irAEs) on immune checkpoint inhibitor (ICI) antitumor activity is not well-known. We compared tumor outcomes of patients who received corticosteroid monotherapy versus those who received an addition of SSiA for irAE treatment. **Methods:** We conducted a retrospective case-control study of patients age ≥ 18 years with melanoma or non-small cell lung cancer (NSCLC) who were treated with ≥ 1 ICI at a quaternary care center between 1/1/2016-11/1/2021. Patients must have received systemic corticosteroids or an SSiA for irAE treatment at least 1 week prior to death. Patients were divided into two cohorts: only corticosteroids (CS cohort) or steroids+SSiA (SSiA cohort). We used propensity score nearest-neighbor matching to match on tumor type, stage, and prior lines of therapy. Primary outcomes were progression-free survival (PFS) and overall survival (OS). Secondary outcomes included time from start of irAE treatment to irAE resolution. Hazard ratios (HR) for PFS and OS were calculated using the Cox proportional hazard regression method with time to steroid and SSiA as a time-varying covariate. **Results:** After matching, 48 patients were included, 24 in each cohort. Median age was 65. 41.7% of patients had NSCLC and 58.3% melanoma, 79.2% had stage 4 disease. 62.5% received ICIs as first line therapy, 33.3% as second-line, and 4.2% as third-line or higher. There was no significant demographic difference between the cohorts. Colitis was the most common irAE (39.6%). After adjusting for age, tumor type, tumor stage, and weeks from ICI start to steroid start, patients in the SSiA cohort had a shorter OS (HR 2.31, $p = 0.037$). We did not find a statistically significant difference for PFS (unadjusted HR 0.52, $p = 0.20$; adjusted HR 0.62, $p = 0.34$). Time from irAE treatment to resolution was longer in the SSiA cohort (8.1 weeks) compared to the CS cohort (4.9 weeks), but this did not reach statistical significance ($p = 0.07$). **Conclusions:** We found an association between decreased OS and use of SSiAs for irAE treatment compared to CS monotherapy, but no significant difference in PFS between the two cohorts. Large, prospective, randomized controlled trials are needed to separate the effects of SSiAs from high-dose CS in order to guide optimal treatment of irAEs. Research Sponsor: University of Chicago Institute of Translational Medicine Clinical and Translational Science Award K12/KL2 Grant 5K12TR002387-05; COVID-19 Funds to Retain Clinical Scientists by the SECURED (Supporting Early Career University Researchers to Excel through Disruptions) Steering Committee.

A phase II randomized trial of talimogene laherparepvec (T-VEC) oncolytic immunotherapy with or without radiotherapy for patients with cutaneous metastases from solid tumors. *First Author: Christopher A. Barker, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Talimogene laherparepvec (T-VEC) is an oncolytic immunotherapy made from a modified herpes virus expressing granulocyte-macrophage colony-stimulating factor and is FDA approved for the treatment of advanced melanoma. Laboratory studies suggest radiotherapy (RT) may interact with oncolytic immunotherapy to facilitate an immune-mediated anticancer response. We hypothesized that the combination of T-VEC+RT would produce tumor responses in distant (non-irradiated and non-injected) metastases. **Methods:** A prospective phase II, randomized, Simon two-stage clinical trial of T-VEC with or without RT was conducted with the primary objective of determining if the response rate of the largest non-injected and non-irradiated metastasis was $\geq 27\%$. Eligible patients had ≥ 1 cutaneous metastasis from a solid tumor amenable to T-VEC and RT and 1 measurable metastasis that would not be treated with T-VEC or RT. Using type I and II error probabilities of 10% and 20%, it was calculated that 9 patients would be enrolled in each arm, and if at least 1 of 9 patients subjects exhibited a response, then 6 additional patients would be enrolled in the second stage. Tumor and overall response was assessed using modified World Health Organization (mWHO) and immune related response criteria (irRC). Treatment-emergent and treatment-related adverse events (TEAEs and TRAEs) were characterized using CTCAE v4.0. **Results:** 19 patients were enrolled and randomized to receive T-VEC alone (n=9) or T-VEC+RT (n=10). One patient in each arm demonstrated a complete response in the largest non-irradiated and non-injected metastasis but progressed in new metastases. The composite response rate in target tumors not injected or irradiated was 13% and 0% in the T-VEC alone and T-VEC+RT arms, respectively. The composite response rate in target tumors treated with T-VEC alone or T-VEC+RT was 7% and 22%, respectively. Because no patient exhibited an overall mWHO or irRC defined response and due to slow accrual, the trial was closed after the first stage of enrollment despite meeting the prespecified response rate to continue enrollment in the second stage. Grade 3-4 TEAEs and TRAEs occurred in 9 and 2 patients, with similar frequencies between study arms. The most common AE was fever and occurred in 47% of patients. Peripheral blood-based immunologic analyses will be presented. **Conclusions:** The response rate in the largest non-injected or non-irradiated metastasis following T-VEC with or without RT given to a cutaneous metastasis from solid tumor could be $\geq 27\%$ but was not determined in this trial due to premature closure, in part due to slow accrual rate and no observed mWHO defined overall responses. Cutaneous metastases responded more often after TVEC+RT than T-VEC alone, but the response in non-injected and non-irradiated tumors was more frequent after T-VEC alone. Clinical trial information: NCT02819843. Research Sponsor: Amgen.

A phase I/IIa study to assess the safety, tolerability, PK, and PD of T3011, a genetically modified oncolytic virus (OVs) administered intravenously (IV) in patients with advanced solid tumors. *First Author: Ziming Li, Lung Cancer Center, Shanghai Chest Hospital, Shanghai JiaoTong University, Shanghai, China*

Background: T3011 is a genetically modified, next-generation oncolytic HSV-1 with 2 exogenous genes encoding the active heterodimer human IL-12 and the Fab fragment of an anti-human PD-1 antibody. T3011 intratumoral injection (IT) was reported to be well tolerated in patients (pts). IV therapy of OVs is rare and provides an attractive option to many pts with advanced cancers that are not candidates for IT therapy. **Methods:** It is a phase I/IIa multi-center, open label, single ascending dose (SAD)/multiple ascending dose (MAD) study to evaluate T3011 IV therapy. The primary objective is to evaluate the safety and tolerability. Dose cohort and regimen are shown in Table. PK and PD profiles are tested in samples of blood, saliva, urine, and tumor tissue. **Results:** As of 16 Dec 2022, 15 pts with stage IV disease were enrolled, 9 pts had received at least 3 lines of prior therapy. The median follow-up time is 1.58 months. Treatment-emergent adverse event (TEAE) occurred in 15 (100%) pts and treatment-related adverse event (TRAЕ) occurred in 10 (66.7%) pts. G3 TEAE in 3 (20%) pts (hypertriglyceridemia, dyspnea, lymphopenia) and G3 TRAЕ in 1 (6.7%) pt (lymphopenia), no ≥ G4 AE reported. Dyspnea, the only reported SAE (1, 6.7%), is drug-unrelated. TRAЕs were lymphopenia (5, 33.3%), anemia (1, 6.7%), diarrhea (1, 6.7%), malaise (1, 6.7%), urticaria (1, 6.7%), rash (1, 6.7%), constipation (1, 6.7%), flu like symptoms (1, 6.7%), headache (1, 6.7%) and abnormal laboratory test results (incidence were all 6.7%), most of them are mild and manageable. No AEs led to drug withdrawal. No DLT occurred; MTD was not reached. 11/15 pts achieved stable disease (SD) by RECIST v1.1. DCR was 73.3%. 1 pt with colorectal cancer who experienced irinotecan-based chemotherapy, anti-VEGF and radiotherapy in Cohort 1 had a long-term SD for over 4 months. In SAD part, T3011 DNA in blood at 2 hours post-dose was detected in 0% (0/3), 0% (0/4), 66.7% (2/3) and 100% (2/2) pts in Cohort 1, 2, 3 and 4 respectively. The DNA copies in pts of Cohort 4 are significantly higher than those of Cohort 3 (Mean viral DNA copies/ul 49.6 vs. 5.7). In cohort 2 of MAD part, T3011 DNA in blood at 2 hours post-dose was detected in 0% (0/3), 66.7% (2/3) and 100% (3/3) pts at C1D1, C1D4 and C1D8 respectively. T3011 DNA was not detected in saliva or urine samples. Pre-existing HSV-1 IgG was shown to hardly affect T3011 activity. **Conclusions:** T3011 IV is safe and well tolerated, and unlikely to spread to close contacts. Preliminary efficacy is encouraging. T3011 DNA in blood is in a dose-dependent manner with additive effect from repeated doses supporting continued recruitment of pts to higher dose cohorts. Clinical trial information: NCT05598268. The study of immune-related adverse events in a community-based centre. *First Author: Sandhya Cautha, Bronxcare Health System, Bronx, NY*

Background: The effectiveness of immunotherapy is often hindered by the development of immune-related adverse events (irAE). Racial minorities were under-represented in the key clinical trials that led to the approval of different immune checkpoint inhibitors (ICI). In this study, we explore the side effect profile of immune checkpoint inhibitors in our patient population that comprises almost entirely of minorities, mostly African Americans (AA) and Hispanics. We hypothesize that due to race-based differences in immune milieu of the body and disease susceptibility, the timing and severity of immunotherapy-related irAE would be different in AA and Hispanics compared to Caucasians. This can translate into a difference in clinical outcomes as well. There have been some suggestions of a positive association of the development of irAE with cancer survival, although the data is limited and heterogeneous. The purpose of our study is to study the frequency and severity of irAEs in racial minority groups, compare them with previous clinical trials population, and add valuable real-world data in this underrepresented group of patients. **Methods:** A retrospective chart review was performed on adult patients with solid malignancies treated with any ICI between January 1, 2015 and April 30, 2022. Patients were classified according to age (greater/equal to 65y or younger), sex, race (self-identified), primary cancer, and type of immunotherapy received. Outcome data using type and severity of irAE, time to development of irAE, and any association with clinical outcomes was collected and analyzed using descriptive statistics as well as univariate analysis. **Results:** A total of 78 patients were included in the final analysis. The mean age was 68 years; 51% were males; 42.3% were Hispanics, 37% were AA, 19.7% were others, and 1% were Whites. Most common malignancy was lung cancer (65.5%). Most common ICI agent used was Pembrolizumab (n = 52) and 2 patients were treated with combination therapy using Ipilimumab and Nivolumab. 41 (52.5%) patients had irAE of any grade while 9 (11.5%) patients experienced grade 3 side effects. None of the patients experienced grade 4 side effects. Most common irAE of any grade was hypothyroidism (n = 14) while most common grade 3 side effect was colitis (n = 6). 31 patients were less than 65y of age. There was no significant difference in irAE in patients less than 65 years of age vs ≥ 65 years (51.6% vs 53.1%) or grade 3 irAE (9.6% vs 12.7%). **Conclusions:** In our study population consisting mostly of AA and Hispanics, the rate of irAE of any grade as well as grade 3 or 4 irAE with ICI therapy was comparable to what was seen in clinical trials involving these drugs. This data and its potential effects on survival outcomes need to be analyzed in prospective studies involving a larger number of patients. Research Sponsor: None.

The incidence of thyroid-related adverse events in solid tumors receiving immune checkpoint blockade with curative intent: A meta-analysis. *First Author: Susu Zhou, Department of Medicine, Icahn School of Medicine at Mount Sinai, Mount Sinai Beth Israel., New York, NY*

Background: Adjuvant/neoadjuvant treatments with immune checkpoint blockade (ICB) improve survival outcomes in patients with several types of cancer. However, immune-related adverse events (irAEs) which frequently involve the thyroid gland may lead to delays in curative treatments such as surgery and radiotherapy. Thus, it is essential to report the incidence of thyroid-related adverse events (AEs) associated with the addition of ICB to conventional therapy with curative intent through a meta-analysis of randomized controls trials (RCTs). **Methods:** We performed a systematic search of PubMed, Embase, Web of Science, and Cochrane library for RCTs evaluating ICB-containing treatment of solid tumors with curative intent. We calculated the odds ratio (OR) of all-grade and grade 3-5 thyroid-related AEs including thyroiditis, hyperthyroidism, and hypothyroidism. We performed a meta-analysis using the random-effect model to compare the incidence of thyroid-related AEs in patients who received therapy with and without the addition of ICB. Subgroup analysis based on the type of ICB (anti-PD-1, anti-PD-L1, and anti-CTLA-4) was conducted. **Results:** 24 RCTs comprising 12,199 patients were analyzed. The addition of ICB was associated with higher incidence of all-grade thyroiditis (OR=3.53, 95%CI:1.88-6.64, p<0.0001), hyperthyroidism (OR=7.18, 95%CI:4.30-12.01, p<0.00001), and hypothyroidism (OR=5.39, 95%CI:3.68-7.90, p<0.00001). In subgroup analysis, PD-1 and PD-L1 inhibitors were particularly associated with higher incidence of hyperthyroidism and hypothyroidism. The incidence of grade 3-5 thyroid-related AEs in patients who received therapy with the addition of ICB was 0.13% (thyroiditis, N=4/3135), 0.20% (hyperthyroidism, N=12/5877), and 0.19% (hypothyroidism, N=12/6369). **Conclusions:** The addition of ICB to conventional therapy with curative intent was associated with an increased risk of all-grade thyroid-related AEs, but the incidence of grade 3-5 AEs was low. These results suggest ICB may be added safely as an adjunct to curative treatments such as surgery and radiotherapy. Clinicians should monitor patients' thyroid function and maintain vigilance for symptoms and signs of thyroid disease. OR (95% CI) and number of studies (N) for thyroid-related AEs with subgroup analysis. Research Sponsor: None.

Association between physical activity, immune-related adverse events, and mortality in patients undergoing immune checkpoint inhibition. *First Author: Rik Jasper Verheijden, University Medical Center Utrecht, Utrecht, Netherlands*

Background: Immune checkpoint inhibitors (ICIs) have improved prospects for some, but not all patients with cancer and frequently induce severe immune-related adverse events (irAEs). While physical activity (PA) has been associated with prolonged survival and diminished toxicity of chemotherapy, its association with ICI efficacy and toxicity is currently unknown. Hence, here we study the association between PA in patients undergoing ICI, and survival and severe irAE occurrence. **Methods:** Patients with advanced cancer receiving anti-PD-L1 based immunotherapy at our academic center were enrolled in the UNICIT cohort. All participants who completed the PA questionnaire (SQUASH) at ICI initiation between 10-2019 and 01-2022 were included in this study. PA was quantified by calculating Metabolic Equivalent Task (MET) hours per week and moderate to vigorous sport and leisure time activity. Association of PA with overall survival (OS) was assessed using Cox proportional hazard regression. Association of PA with occurrence of a severe irAE (grade 3 or higher) within one year was assessed using logistic regression in patients with at least one year follow-up. All analyses were adjusted for sex, age, tumor type, treatment intent and ICI type. **Results:** In total, 251 patients were included, with a median follow-up of 20 months and a median age of 64 years. The majority (153 patients) had melanoma. Median OS was not reached. Compared to low levels of total PA, intermediate and high levels of total MET-hours were associated with prolonged survival (adjusted hazard ratios: 0.56 (95%CI 0.31-1.02) and 0.47 (95%CI 0.26-0.86), respectively; table). Thirty eight out of 209 patients with at least one year of follow-up developed severe irAEs within the first year. Compared to patients with low total PA levels, patients with intermediate or high levels of total PA have a lower odds of developing severe irAEs (adjusted odds ratios: 0.35 (95%CI 0.12-0.90) and 0.19 (95%CI 0.06-0.56), respectively). Similar trends of prolonged OS and reduced odds of severe irAE occurrence were observed in patients who performed more moderate to vigorous sport and leisure time activity. **Conclusions:** Higher physical activity levels at start of ICI treatment are associated with prolonged survival and lower risk of severe irAEs. Future research needs to elucidate whether inactive patients benefit from increasing PA levels after diagnosis. Research Sponsor: None.

Development of a novel immune-related toxicity grading system for predicting outcomes in patients with solid tumours treated with immune checkpoint inhibitors (ICI). *First Author: Matthaios Kapiris, King's College London, London, United Kingdom*

Background: Adoption of ICI in clinical practice has led to improved outcomes in many tumour types. Their use is associated with immune related adverse events (irAEs), with unpredictable onset targeting multiple organs and for which conventional CTCAE toxicity grading has significant limitations. In addition, the correlation of irAEs to efficacy of ICI is becoming increasingly recognised. Here we present a novel toxicity assessment tool and describe its relationship with cancer outcomes. **Methods:** Data were collected from the Pathobiology of Adverse Immune Reactions (PAIR) prospective cohort study at Guy's Hospital from February 2018 until end of May 2022. Solid tumour patients with advanced disease naïve to ICI who received at least 1 dose were included. Minimum 6 months of follow-up was required. irAEs were captured based on the OST score which evaluates the number of affected Organs (O), number of Severe CTCAE (G3) toxicities (S) and sum of all grade Toxicities (T). OST was calculated at death or end of follow-up. Patients were divided in high and low toxicity groups, defined by the median value for each parameter. Descriptive statistics and crude and multivariate survival Cox Proportional Hazards regression analyses were performed accounting for age, tumour type and treatment. **Results:** A total of 123 patients were included. Median age was 68 years (range 23-87 yrs); 67 (54%) were male; 104 (85%) were White Caucasian. Most common tumour types were melanoma (33%), non-small cell lung (24%) and renal cell carcinoma (22%). Forty-six patients (37%) received Ipilimumab-Nivolumab, 37 (30%) Pembrolizumab and 24 (20%) Nivolumab. Twenty-two (18%) had autoimmune disease at baseline. Hypothyroidism (6%) and psoriasis (2%) were most common. Median number of affected organs was 2 (range 0-7), 32 (26%) had ≥ 1 G3 toxicity and the median T score was 3 (range 0-15). Survival data were available for 120 patients. After median follow-up of 39 months, 66 deaths (53.7%) occurred. Median OS was 16.9 months (95% CI: 9.9-24.1). High toxicity groups presented reduced risk of death compared to low-toxicity groups when evaluated for individual OST parameters [HR for Organ tox group (95% CI): 0.359 (0.198-0.649), HR for Severity group (95% CI): 0.402 (0.200-0.808), HR for Toxicity score group (95% CI): 0.353 (0.190-0.657)]. Of the three parameters, the number of Organs (O) was most strongly associated with reduced risk of death when analysed as a continuous variable [HR (95% CI): 0.683 (0.577-0.808)]. **Conclusions:** We have developed a novel immune toxicity grading system which can potentially predict survival outcomes for patients treated with ICI. Further prospective evaluation and correlation to translational secondary endpoints with immunological phenotyping is ongoing. External validation is warranted to support further use of OST in routine clinical practice. Sex differences in burden of adverse events in patients receiving immunotherapy. *First Author: Rosalba Miceli, Unit of Biostatistics for Clinical Research, Department of Epidemiology and Data Science, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy*

Background: The association between sex and the occurrence of immune-related adverse events (irAEs) in cancer patients who receive immune checkpoint inhibitors (ICIs) is an area of growing interest. Despite the collection of irAEs data in registration studies, the impact of sex differentiation is rarely published, and comparative analyses using meta-analytic approaches of retrospective data has produced contrasting results. G-DEFINER is a multicentre project evaluating the irAEs inequalities between female (F) and male (M) cancer patients treated with ICIs. The project explored the sex and gender differences spanning from clinical to personal and lifestyle traits (including diet and quality of life). Gene-expression profiling for immune assessment, SNPs, cytokines (blood samples) and microbiota analyses (faecal samples) are also being performed to identify the features associated with irAEs development. **Methods:** irAE burden (B) was estimated as the sum of the average and worst grade of irAEs occurring at each time. The cumulative sum of time-specific Bs was used as irAE burden index (BI). Median BI (mBI) was modelled using quantile regression models. A univariable analysis (UA), 1st G ≥ 2 irAE crude incidence curves (CCI) were estimated in a competing risks setting (competing event: deaths without irAE), and event-free survival (EFS) curves were estimated with the Kaplan-Meier method and compared with the log-rank test. Multivariable analysis (MA) of CCI and EFS was performed using Fine&Gray and Cox models, respectively. **Results:** At closing date (31st January 2023) the study has enrolled 256 patients. Our subgroup analysis includes 204 patients (86 F, 118 M) with median follow-up of 13 months; IQR: 6.1-20 months). Patients' age, previous oncologic treatments, cancer type (lung, melanoma, head&neck, colorectal MSI high, urogenital), PS ECOG, ICI type, concomitant chemotherapy (about 20%), and disease setting were well balanced in the two sex groups. F temporarily interrupted ICI administration more frequently than M (44 vs 29%, $p=0.034$) mainly due to irAEs (27 vs 11%); 83% F vs 71% M ($p=0.069$) contributed with 204 vs 240 any grade irAEs (significant differences: 36 vs 21% endocrine, $p=0.016$; 20% vs 9% hepatic, $p=0.040$). F more frequently developed G1 (64 vs 53%), G2 (49 vs 40%), G3 (24 vs 17%), G4 (6% vs 2%) irAEs. mBI was significantly higher in F both at UA ($p=0.024$) and MA ($p=0.048$). First G ≥ 2 irAE6- (12) month estimates in F vs M were 55% vs 45% (65% vs 53%) ($p=0.073$ UA and 0.140 MA). EFS between group difference was not significant both at UA ($p=0.206$) and MA ($p=0.729$). **Conclusions:** F experience a higher irAE burden and require close monitoring in order to avoid ICI interruption. The results also underline the need of using a measure of irAE cumulative load to gain insights into between groups differences. Clinical trial information: NCT04435964. Effect of fecal transplantation on patients' reported outcome after immune checkpoint inhibitor colitis. *First Author: Yinghong Wang, MD Anderson Cancer Center, Houston, TX*

Background: The use of fecal microbiota transplantation (FMT) has traditionally been reserved for the treatment of recurrent *Clostridioides difficile* infections (CDI). As the gut microbiome has been increasingly acknowledged to play a role in a variety of bodily processes, FMT has seen its application extended to other gastrointestinal disorders. Immune-mediated colitis (IMC) is a similar entity to inflammatory bowel disease and arises as a side effect of immune checkpoint inhibitor therapy to stimulate the immune response. Treatment of IMC is mostly limited to immunosuppressants e.g. corticosteroids, infliximab, and vedolizumab. Cases refractory to such medications pose a significant challenge. FMT has been shown to be a successful treatment in refractory IMC in small case series, further large studies are needed to determine its efficacy. **Methods:** We measured the efficacy of FMT for refractory IMC among 47 patients via chart review and clinical assessment and patients' reported outcome (PRO) via established MD Anderson Symptom Inventory (MDASI). Among them, 9 patients had concurrent CDI as well at the time of diagnosis. **Results:** Forty-seven patients were included in our study. Most patients had a peak diarrhea grade ≥ 3 (93.6%) and colitis grade ≥ 2 (91.5%). Ulcerous (23, 49.0%) and non-ulcerous (12, 25.5%) inflammation were the predominant endoscopic findings. 45 (95.7%) patients received corticosteroids, and 43 patients (91.5%) received add-on infliximab or vedolizumab. IMC symptom response was 85.1% after FMT with median time to response of 4.5 days. The transient complications rate is 34.0% at 7 days and 17.0% at 30 days. Response rate among the 38 patients without concurrent CDI was 86.8%. Forty-one (87.2%) patients demonstrated clinical remission by the end of the study period. On the PRO analysis, we observed a favorable trend of significant patient-reported symptom reduction on diarrhea during 12 weeks after FMT, along with improved daily physical functioning on working. **Conclusions:** FMT may serve as a potential treatment option in IMC refractory to standard treatment to avoid long-term steroid dependency and immunosuppression. It is effective to maintain IMC remission with a low complication rate. The role of the gut microbiome in cancer and the implications for FMT remain uncertain and need further elucidation. Clinical trial information: NCT03819296. Research Sponsor: Moonshot, Gateway, Sabin Fellowship, HESI.

FMT outcome on colitis.

Symptom improvement after FMT, all patients – no (%)	40 (85.1%)

Timing of immunotherapy-induced pneumonitis in patients with primary lung malignancy. *First Author: Megan Winter, Albert Einstein Medical Center, Philadelphia, PA*

Background: Pneumonitis is a widely recognized side effect of immunotherapy with increased incidence in non-small cell lung cancers as compared to other solid organ malignancies. A review of the literature demonstrates an incidence of 5% in patients receiving PD-1/PD-L1 inhibitors. While biopsy provides definitive diagnosis of immunotherapy-induced pneumonitis, clinical symptoms and radiologic features are most utilized with treatment guided by the grade of toxicity. The ability to predict the timing, which patients, and to what extent pneumonitis will present has been a significant challenge. Our study aims to look at the timing of onset of immunotherapy-induced pneumonitis in patients treated with checkpoint inhibitors for primary lung cancer to elicit patterns which may assist in diagnosis and appropriate treatment. **Methods:** This is a single-institution, retrospective study reviewing patients with primary lung cancer who received checkpoint inhibitors between January 2018 and January 2023. The focus was on the date of initiation of therapy and the date of onset of pneumonitis. Immunotherapy-induced pneumonitis was defined as development of abnormal imaging findings with or without respiratory symptoms following initiation of immunotherapy and graded by the Common Terminology Criteria for Adverse Events (CTCAE). Additional patient demographics were collected to assess secondary patterns. **Results:** A total of 117 patients met the specified search criteria. Of these, 10 patients (8.5%) met the criteria for immunotherapy-induced pneumonitis. The average time between receiving the first dose of immunotherapy and the development of immunotherapy-induced pneumonitis was 66.5 days (range of 1 to 163 days). The average number of cycles received before diagnosis was 3.7, with most cases occurring after less than 5 cycles provided (7 out of 10). The grade of pneumonitis ranged from 1 to 5. All patients had non-small cell lung cancer, with the most prevalent histology being squamous cell carcinoma, ranging from stage III to stage IV. Durvalumab was the most prevalent immunotherapy (6 of the 10). **Conclusions:** The timing of immunotherapy-induced pneumonitis, while variable, occurred after receiving less than 5 cycles in majority of our cases, with most occurring after just 1 cycle. Interestingly, durvalumab was the most common immunotherapy in these cases. While our study is limited by the number of patients, the incidence of pneumonitis in our study was close to that of the national average and may, also, be reflective of the timing of immunotherapy-induced pneumonitis. Additional studies with larger numbers of patients are needed. Research Sponsor: None.

Risk of immune-related adverse events (irAE) with immune checkpoint inhibitors (ICI) in patients (pts) with family history (FH) of autoimmune disease (AID). *First Author: Piyush Grover, Melanoma Institute Australia, The University of Sydney, Sydney, Australia*

Background: Pts with personal history (PH) of AID are at increased risk of irAE following ICI. Risk of irAE in pts with FH of AID is unknown. **Methods:** In this retrospective cohort study, consecutive pts were recruited from 2 Australian melanoma cancer centers. Pts who received anti-PD-1 (PD1) based ICI with FH of AID were eligible. Pts with PH of AID were excluded. Toxicity data (CTCAE v5.0) was obtained and stratified by FH of AID (first/second/third degree relative). Descriptive statistics and Fisher's Exact test were used for analysis. **Results:** 396 melanoma cases were screened, of which 44 (11.1%) were eligible for inclusion. Baseline characteristics are summarized. 57 irAE occurred in 44 pts. The most common irAE were dermatological (n=11; 19.3%), colitis (n=8; 14.0%), endocrinopathies (n=8; 14.0%), hepatitis (n=7; 12.3%) and arthritis (n=7; 12.3%). Among 57 irAE, frequency of Grade 1,2,3 and 4 irAE was 16 (28.1%), 26 (45.6%), 12 (21.0%) and 3 (5.3%) respectively. Corticosteroids were used for 31 (54.4%) irAE. Hospital admission for management of irAE occurred in 11 pts (25.0%). ICI was discontinued in 20 pts (45.5%) due to irAE. In pts with irAE, FH of that irAE/AID was present in 6 pts (13.6%) (n=2 x arthritis, n= 2 x psoriasis, n= 1 x Crohn's disease, n= 1 x Grave's disease), and 4 of these patients had a first-degree relative with an AID. 3/6 pts had ICI ceased due to an irAE (peak toxicity Grade was 3) and 4/6 pts had RECIST response. There was no association in development of irAE between patients with FH of AID in a first-degree relative and those with FH of AID in second or third degree relative (p=0.17). Rate of irAE in pts with FH of AID was not statistically higher to that reported in registration trials of similar regimens (p=0.40). **Conclusions:** FH of AID is common in melanoma pts and was not associated with higher rate or morbidity of irAE. FH AID should be routinely collected, and larger scale studies need to be performed. Research Sponsor: None.

Immune related adverse events (irAEs) in patients with solid tumors and advanced chronic kidney disease (CKD) receiving checkpoint inhibitors (CPIs). *First Author: Dalia Kaakour, University of California Irvine Department of Medicine, Orange, CA*

Background: Randomized controlled trials evaluating CPIs in the management of solid tumors have typically excluded patients with advanced CKD and end-stage renal disease (ESRD). Limited available data evaluating the safety of CPI use in this patient population demonstrated a similar incidence of irAEs in patients with advanced CKD compared to those with normal or mildly impaired renal function, with majority of irAEs being grade 1 or 2. CPIs are not modified by dialysis due to their molecular size and, as such, do not require renal dosing. **Methods:** We performed a retrospective analysis of patients over 18 years of age with solid tumors and advanced CKD, who received CPIs at the University of California Irvine from 1/2015 to 6/2021. Advanced CKD was defined as glomerular filtration rate (GFR) less than 60 ml/min. Patients must have received at least one dose of a PD-1/PD-L1 or CTLA-4 inhibitor as a single-agent or in combination with another therapy. Patients were stratified by severity of CKD, including CKD3 (GFR of 30-59 ml/min), CKD4 (GFR of 15-29 ml/min), and CKD 5/ESRD (GFR less than 15 ml/min). **Results:** A total of 32 patients were included, 24 (75.00%) with CKD3, 6 (18.25%) with CKD4, and 2 (6.25%) with CKD5/ESRD. 10 (31.25%) patients were female and 22 (68.75%) were male. Median age was 73.5 years [range: 26 to 98]. 22 (68.75%) received CPI monotherapy and 10 (31.25%) received a combination of CPI with another agent. After initiation of CPI therapy, 16 (50.00%) patients experienced an irAE, with a total of 23 unique irAEs due to some patients experiencing multiple irAEs. In patients with irAEs, 13 (81.25%) received CPI monotherapy and 3 (18.75%) received CPI combined with another agent. In patients with CKD3, CKD4, and CKD5/ESRD, 14 (87.50%), 2 (12.60%), and 0 (0.00%) experienced irAEs, respectively. Types of irAEs observed are listed, with the most common being colitis in 6 (26.1%) patients, endocrinopathies in 4 (17.39%) patients, and dermatologic in 4 (17.39%) patients. 18 (78.26%) of unique irAEs were grade 1 or 2, while 5 (21.74%) were grade 3 or higher. 10 (43.48%) of irAEs were managed with steroids as per physician discretion, 8 (80.00%) with CKD3 and 2 (20.00%) with CKD4. **Conclusions:** The safety of CPIs in patients with solid tumors and advanced CKD has not been rigorously evaluated. Recognizing the small sample size and retrospective nature of this dataset, the incidence and type of irAEs in patients with advanced CKD appears similar to that of patients with normal renal function or mild renal impairment. More prospective data in this population is needed, particularly in patients with CKD5/ESRD. Types of irAEs in patients with advanced CKD. Research Sponsor: None.

Edema and serositis as an adverse event in patients with cancer receiving immune checkpoint blockade: Systematic review to evaluate this immune-related adverse event and associated treatment strategies. *First Author: Evelyn Elias, Mount Sinai Beth Israel, New York, NY*

Background: Immune checkpoint blockade (ICB) is a standard therapeutic option for certain patients with solid tumors, often leading to durable responses. Immune-related adverse events (irAEs) can impact treatment duration and patients' quality of life. The mechanism of irAEs is proposed to be an inflammatory response triggered by blocking immune checkpoints, and nonspecific symptoms like edema and fluid accumulation can occur. We performed a systematic review to summarize reported studies evaluating edema and serositis to explore edema and serositis as an irAE and management strategies. **Methods:** We performed a database search in Medline, Embase, and Web of Science for studies reporting the incidence and outcome of immune-related generalized edema (irGE) including peripheral edema, capillary leak syndrome, serositis, pleural/peritoneal/pericardial effusion, and anasarca as an irAE among patients with solid tumors treated with ICB. Two independent reviewers analyzed the eligibility of each article. Those that did not report outcomes related to irGE were excluded. The number of patients, cancer type, name and type of ICB, type of irGE, treatment of irGE, and treatment outcome for irGE were extracted from each article to summarize the characteristics of irGE. **Results:** 662 articles were identified, and 80 studies were included (65 case reports/series, 8 cohort studies, 3 phase 1/2 clinical trials) that described clinical characteristics and treatment outcomes for AEs from 196 patients, and 259 irGE incidences reported. The median age was 62 (Interquartile range: 55-68). 35.9% of cases were female (n=28/78). Commonly reported irGEs were pericardial effusion (n=115, 44.4%), pleural effusion (n=58, 22.4%), peripheral edema (n=40, 15.4%), and ascites (n=19, 7.3%). PD-1 blockade was utilized in 75.8% of cases, followed by PD-L1 blockade (14.9%) and dual ICB (CTLA4 and PD-1 blockade, 4.6%). Common cancers where irGE occurred were: lung cancer (63.9%), malignant melanoma (17.0%), and urothelial carcinoma (3.1%). We classified irGEs into primary irGE (n=84, 42.9%), secondary to other irAEs (n=41, 20.9%), secondary to pseudoprogression (n=14, 7.1%), and cancer progression (n=13, 6.6%). Glucocorticoid was used to manage irGEs in 91 patients (46.4%); 48 cases (24.5%) required the prednisone-equivalent dose of > 1 mg/kg/day. ICB discontinuation was confirmed in 96 cases (49.0%) among which 53 (27.0%) permanently stopped ICB use due to irGEs. **Conclusions:** irGE is an important irAE among patients with solid tumors receiving ICB. Most cases required glucocorticoid therapy along with discontinuation of ICB, which could result in poorer quality of life and potentially impact outcomes. The pathophysiology, incidence and clinical outcomes of irGE need to be accurately described in further studies. Research Sponsor: None.

Real-world data: Clinical characteristics and outcomes of patients with advanced hepatocellular carcinoma treated with atezolizumab plus bevacizumab in Veteran Health Administration. *First Author: Munaf Alkadimi, University of Texas Health Science Center at San Antonio, San Anonio, TX*

Background: Advanced Hepatocellular carcinoma (HCC) is an aggressive tumor, and most patients have a poor prognosis. Recent clinical trials have demonstrated improved survival with molecularly targeted treatment and immunotherapy. Atezolizumab plus Bevacizumab (A+B) is the recommended first-line treatment for advanced HCC based on the phase 3 IMbrave 150 trial. However, in a real-life setting, many patients do not meet the inclusion criteria of this landmark trial. This study proposes a retrospective review of outcomes of advanced HCC patients receiving A + B in Veterans Health Administration (VHA). **Methods:** Patients with advanced HCC receiving 1st line systemic therapy with A+ B at the VHA between Dec 1, 2019, to Mar 1, 2022, were selected from the electronic medical records (EMR) using ICD-9 and ICD-10 codes. Abstractors reviewed EMR and followed from their index date of A+B initiation until death or their last VHA visit, with the study period ending on Jan 31, 2023. The Chi-Squared test was used to compare rates, and the Mann-Whitney test was used to compare medians. **Results:** A total of 332 patients met the study criteria. The median age was 67 yrs., 99% were males, 63% non-Hispanic White, 26% were Black, 66 % had ECOG $\geq$ 1, 84% had CPS class A, 16% had CPS class B and C, 62% had grade 2 ALBI score, 56% had viral hepatitis-caused HCC, 80 % had cirrhosis, and 67% had prior local therapies. The outcomes are shown. **Conclusions:** In our real world, despite having similar PFS as the phase 3 IMbrave 150 trial, our OS at 12 months was lower (52% vs. 67%), given that we had more elderly patients with moderate liver dysfunction and 40% were non-white. This study provides actual outcomes in clinical practice where patients do not match the study population of the pivotal trial. Research Sponsor: None.

End points for VA HCC patients given AB as 1st line.	
Characteristic of Interest	All Patients
N ($\geq$ 6 mo from initiation to abstraction)	332

Frequency of delayed immune-related adverse events (irAEs) in hospitalized patients treated with immune checkpoint inhibitors (ICIs). *First Author: Sienna Durbin, Massachusetts General Hospital, Boston, MA*

Background: Across cancer types and indications, the use of ICIs is increasing. Guidelines indicate that most irAEs occur in the months immediately following receipt of ICI. Little is known about the frequency of delayed irAEs following ICI administration. **Methods:** Patients who received ICIs and were hospitalized following ICI initiation between January 2011 and October 2022 were identified using pharmacy and hospital admission databases. Patient demographics, and oncologic and irAE history were extracted from the medical record. All admissions were reviewed by two physicians to evaluate for irAEs, which were defined as suspected or confirmed using published disease-specific criteria. We examined the number of irAEs hospitalizations at < 6 months, 6-12 months, 1-2 years, 2-5 years, and >5 years from the first dose of the most recent line of ICI to date of admission. **Results:** Among the 930 patients hospitalized with irAEs, average age was 66.0 years (range 18.3 - 96.2) and 61.2% were male. Most common tumor types were melanoma (42.0%), lung (24.1%), and gastrointestinal (12.7%). Median time from start of last line of ICI to hospitalization was 98 days (IQR 37-244.3). One hundred sixty-six patients (19.4%) had been treated with >1 prior line of ICI and 102 (11.0%) were diagnosed with multiple irAEs during the same admission. Of all patients admitted, 147 (15.7%) presented 6 months - 1 year after start of ICI line, 79 (8.4%) presented after 1-2 years, 35 (3.7%) presented after 2-5 years, and 2 (0.2%) presented after >5 years. Rates of irAEs by time from start of ICI line are demonstrated. **Conclusions:** Although irAEs occur in a time-dependent fashion, delayed, serious irAEs in hospitalized patients are common (28% at 6+ months), with a subset presenting two years or more after start of ICI. Providers must remain vigilant for potential irAEs regardless of elapsed time from ICI, especially as patients live longer and ICIs become widely used in different settings. Future work is needed to define potential triggers of and patients at risk for delayed irAEs. Research Sponsor: None.

Pan tumor outcomes to immune checkpoint inhibitors in patients of Native American origin in the United States: The multicenter POINT-US study. *First Author: Minh Duc Phan, Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: Despite receiving identical standard-of-care therapies, epidemiological data indicate that Native American (NA) patients (pts) with cancer have worse outcomes vs. White pts. ICIs have revolutionized the treatment of certain tumors, however pts from certain racial and ethnic groups, including NA pts, are underrepresented in ICI trials. **Methods:** This is an ongoing multi-center retrospective study across four U.S. academic cancer centers that serve a high volume of NA pts. We included pts with self-reported race as NA in electronic medical records. We evaluated clinical outcomes and immune-related adverse events (irAEs) of 71 NA pts age ≥ 18 years with various solid tumors treated with ICI-based therapies between 2015 to 2021. irAEs were defined based on the Common Terminology Criteria for Adverse Events (version 5.0) or RECIST 1.1, as available, was used to determine objective response rate (ORR). Kaplan Meier log-rank method was used to generate median progression free survival (mPFS) and median overall survival (mOS). **Results:** Median age (range) at ICI initiation was 62 (24-81) years; 43 (60%) were males, with 26 (37%) females, 2 pts with missing gender data. 55 (77%) of pts had ECOG performance status 0. The distribution of top six tumor types included (number of pts [%]): non-small cell lung cancer (NSCLC) 22 (31%), renal cell carcinoma (RCC) 16 (23%), melanoma 7 (10%), small cell lung cancer (SCLC) 4 (6%), hepatocellular carcinoma 4 (6%); colorectal adenocarcinoma, head and neck squamous cell carcinoma, cervical squamous cell carcinoma each had 3 pts (4%). Most pts (51 [72%]) received single agent ICI, 12 (17%) had dual ICI, 4 (6%) had chemotherapy+ ICI, and remaining had either ICI + tyrosine kinase inhibitor or ICI + study drug (4 [6%]). 55% of pts with NSCLC underwent tumor next-generation sequencing (NGS) while <30% of patients with renal cell carcinoma or melanoma had tumor NGS performed. Among 71 pts, 17 (24%) had any grade (G) irAE, 4 (6%) were reported to be ≥ 3 . The median time to irAE onset was 18 weeks and 3 (4%) pts discontinued ICI due to irAEs. The mPFS, mOS and ORR for the most frequent tumors (N ≥ 5) are shown. **Conclusions:** Although limited by sample size, our emerging data provides new insights into ICI efficacy and irAEs in NA pts that have been unknown to date. To our knowledge, this is the first and only attempt to date evaluating ICI outcomes in NA pts. Updated clinical data and tumor genomics will be presented at the meeting. Research Sponsor: FDA.

Tumor	Number of pts	Median PFS (months) [95% confidence interval]	Median OS (months)	Objective response rate (partial or complete response) (%)
			[95% confidence interval]	
NSCLC	22	7 [0-14.2]	19 [1.2-36.8]	33

Safety and efficacy of immune checkpoint inhibitors (ICIs) in patients (pts) with cardiac metastases (mets) from solid tumors. *First Author: Amin Nassar, Yale Cancer Center, New Haven, CT*

Background: Given underlying differences in the tumor microenvironment across metastatic sites, ICIs demonstrate variable efficacy depending on sites of met involvement. Data on the safety and outcomes of pts on ICIs with cardiac mets are limited. **Methods:** In an international multi-center retrospective study, pts with solid tumors and baseline mets to the heart who had received ≥ 1 cycle of ICIs were included. Immune-related adverse events (irAEs) were graded per CTCAE v5.0. Objective response rates (ORR) were evaluated by RECIST1.1 when available. Median overall survival (mOS) and median progression-free survival (mPFS) were calculated from time of ICI initiation using the Kaplan-Meier method. **Results:** 110 pts across 20 institutions were identified with a median follow-up of 36 (95% CI 26-51) months. Melanoma (38%, n=42) and non-small cell lung cancer (NSCLC, 24%, n=26) were the most common cancers. Median age at ICI initiation was 65 (IQR: 59-75) years and 29% (n=26) received combination ICI therapy with anti-PD1 and anti-CTLA4. Overall, 62% (n=68) received ICIs as 1st line. The mets were mostly located in the atria (37%, n=41) and ventricles (35%, n=39). At ICI initiation, 21% (n=23) had a cardiac thrombus. Of 78 pts with available echocardiographic data at time of ICI initiation, the mean ejection fraction was 61 $\pm$ 7.1%. Cardiology referrals and cardiac MRIs since time of cancer diagnosis were completed on 53% (n=58) and 47% (n=52) of pts, respectively. Overall, 36.4% (n=40) of pts had cardiac complications from the mets, including arrhythmias (13%, n=14), arterial/venous emboli (3.6%, n=4), and cardiac tamponade (2.7%, n=3). For NSCLC, ORR, mPFS (95% CI), and mOS (95% CI) were 23%, 4.4 months (3.0-7.5), and 9.9 months (5.9-14.7), respectively. For melanoma, ORR, mPFS, and mOS were 35.7%, 9.1 months (5.2-20), and 29 months (14-58), respectively. Cardiac met ORRs for NSCLC and melanoma were 27% and 43%, respectively. 74% (N=71/96) of pts with evaluable response data had concordant response in the burden of overall disease and cardiac disease. irAEs are shown. **Conclusions:** Although cardiac mets are frequently associated with cardiac complications, ICIs demonstrate meaningful efficacy with no overtly concerning safety signals. Close to three-quarter of pts have concordant response in the overall disease and cardiac disease burden. Multi-disciplinary approach involving cardiologists and oncologists need to be implemented to appropriately manage pts with cardiac mets. Research Sponsor: None.

irAE leading to discontinuation	26 (29%)

Incidence and characterization of neurological adverse events among a retrospective cohort of patients receiving immune checkpoint inhibitors. *First Author: John Hunting, Wake Forest Baptist Medical Center, Winston-Salem, NC*

Background: The rising usage of immune checkpoint inhibitors (ICIs) has increased the incidence of rare adverse events in routine practice. Neurological adverse events (nAEs) are a heterogeneous group of outcomes that are infrequent and typically diagnosed by exclusion. They more often involve the peripheral (e.g., neuropathy, myasthenia gravis) than the central nervous system (e.g., encephalitis, hypophysitis). Evidence remains extremely limited with no large cohorts and incidence reported through small case series. This study aimed to analyze data from all clinically significant nAEs to characterize their risk factors, incidence, severity, and management. **Methods:** We created a retrospective registry of all patients who received at least one dose of an ICI for any indication between 2/1/2011 and 4/7/2022 at a comprehensive cancer center and its outreach clinics. Study personnel reviewed clinical documentation from all patients to collect data on treatment-emergent adverse events; attribution and severity were estimated using National Cancer Institute guidelines and the Common Terminology Criteria for Adverse Events. The investigators created a secure, cloud-based registry (REDCap), validated it with data quality rules, and resolved all discrepancies; clinical research specialists at Vasta Global captured most of the data. Categorical variables were compared using Fisher's exact test. Statistical significance defined as p < 0.05. The study had institutional IRB approval. **Results:** In the total cohort of 3,137 patients, there were 47 nAEs (1.49%). The majority of these nAEs were peripheral (31, 0.99%; grade 3/4 in 14 patients, 0.45%) as opposed to central (16, 0.50%; grade 3/4 in 8, 0.25%). Pre-existing neurological comorbidities were present in five patients who had central nAEs (stroke = 3, dementia = 2) and in one patient with a peripheral nAE (stroke = 1). All high-grade (3-4) central nAEs occurred among renal (4, 50%), melanoma (3, 38%), or lung (1, 12.5%) primaries which was statistically significant when compared to other grade 3/4 adverse events (p < 0.0001) or no adverse events (p < 0.0001). Median days from first ICI to nAE was 55 [IQR [22-175] and average treatment with prednisone equivalent was 2.5 mg/kg, std 4.6. **Conclusions:** The incidence of nAEs (1-2%) appeared higher than prior estimates in this retrospective patient registry which included patients who did not have neurology consultation or specific billing codes. All high-grade nAEs occurred in a tumor type known to favor metastases to the brain. With similar patterns among low grade events, an underlying mechanism of molecular mimicry seems more likely. Both time to presentation and treatment remained highly heterogeneous. Further research is needed on treatment-emergent nAEs to determine if they are potentiated by neurologic comorbidities or subclinical brain metastases. Research Sponsor: None.

A comprehensive pan-cancer analysis of PD-L1 expression using clone E1L3N in Chinese patients with cancer. *First Author: Huangbin Lu, Department of Research and Development, Amoy Diagnostics Co., Ltd., Xiamen, China*

Background: Immune checkpoint inhibitors (ICIs) benefit patients with multiple cancer types, and the expression of programmed death ligand 1 (PD-L1) protein assessed by immunohistochemistry (IHC) has been correlated with response and survival benefit from anti-PD-1/PD-L1 ICI therapies in several cancer types. IHC assay with E1L3N clone is currently approved by the NMPA for PD-L1 detection in non-small cell lung cancer (NSCLC), but its performance in other cancer types needs to be further validated. Thus, we performed this study to examine the prevalence of PD-L1 expression in a wide variety of tumor types in Chinese pan-cancer patients using the E1L3N antibody clone. **Methods:** From 2019 to 2022, a total of 13,647 patient across multiple tumor types were analyzed. Tumor tissue samples were subjected to IHC. PD-L1 expression was tested using the E1L3N PD-L1 IHC assay (Amoy Diagnostics, Xiamen, China), and scored with the tumor proportion score (TPS) and combined positive score (CPS). PD-L1 expression status was identified as positive and negative according to TPS or CPS. For NSCLC: negative (TPS < 1%), low expression (TPS 1-49%), and high expression (TPS ≥ 50%). For gastric/gastroesophageal junction carcinoma (GC/GJC): negative (CPS < 1), low expression (CPS 1-5), and high expression (CPS ≥ 5). For other cancer: negative (CPS < 1), low expression (CPS 1-10), and high expression (CPS ≥ 10). **Results:** In total, 14 cancer types were enrolled in the present study, including 68.2% NSCLC, 6.9% colorectal carcinoma (CRC), and 3.8% GC/GJC, and the remaining 21.1% include esophageal cancer (EC), breast cancer, cervical cancer (CC), biliary tract cancer (BTC), pancreatic cancer (PC), ovarian cancer, renal cancer, small cell lung cancer, urothelial carcinoma (UC), bladder cancer, head and neck squamous cell carcinoma (HNSCC), etc. PD-L1 positivity by TPS was observed in 52.5% NSCLC patients, similar to the frequency of PD-L1 expression in Chinese NSCLC patients detected using 22C3 clone. 76.0% and 36.7% of GC/GJC patients with PD-L1-positive tumors at a CPS cutoff of ≥ 1 and ≥ 5, respectively. PD-L1 positive expression frequency was higher than that in western GC/GJC patients detected using 22C3 and 28-8 clone (as reported from previous research: PD-L1 positivity with CPS ≥ 1 was 45.5% using the 22C3 assay and 49.1% using the 28-8 assay). 73.6% and 17.5% of CRC patients with PD-L1-positive tumors at a CPS cutoff of ≥ 1 and ≥ 10, respectively. In addition, 8 tumors (EC, CC, breast cancer, PC, BTC, UC, HNSCC, and bladder cancer) had the prevalence of PD-L1 CPS ≥ 1 greater than 50%. **Conclusions:** E1L3N can be used as a reliable alternative antibody clone to evaluate PD-L1 expression status not only in NSCLC patients but also in other cancer types. Factors associated with severe immune checkpoint inhibitor-induced pneumonitis. *First Author: Hamzah Abu-Sbeih, The Ohio State University, Columbus, OH*

Background: Immune checkpoint inhibitor (ICI) induced pneumonitis (ICIp) can be severe and even fatal, but risk factors for severe ICIp remain poorly characterized. In this abstract, we characterize ICIp and assess factors associated with severe disease. **Methods:** This is a retrospective study of consecutive patients who received ICI therapy and developed ICIp at the Ohio State University (2013-2020). Patients with ICIp were identified from a pharmacy database using ICD-10 codes followed by chart review to confirm diagnosis. ICIp was graded based on the CTCAE v5.0 criteria. Laboratory values were collected at the onset of ICIp. A thoracic radiologist reviewed chest imaging for pattern and severity. Survival probabilities were estimated with Kaplan-Meier curve and compared with log rank test. **Results:** Of 2963 patients who received ICI, we identified 119 patients (4%) with ICIp: 75 (63%) were males; 79 (66%) received PD-1 inhibitor monotherapy; and 71 (60%) had lung cancer. ICIp was severe (grade 1-2) in 69 patients (58%) and mild (grade 3-5) in 50 (42%). 74 patients (62%) were hospitalized. 63 patients (53%) needed oxygen supplementation. ICI therapy was held in all patients except one. ICI was rechallenged in 26 patients; 6 of them (23%) had recurrence of ICIp symptoms. All but 2 patients received steroids for the treatment of ICIp. 10 patients received non-steroidal medications (7 IVIG, 2 infliximab, 1 rituximab, 1 abatacept, 1 cyclophosphamide). Steroids were tapered in 6 patients of those who received non-steroidal medications. 3 of the patients who received IVIG had improvement of symptoms. Factors associated with severe ICIp. 21 patients (18%) died while hospitalized for ICIp are shown. Patients with severe ICIp had shorter overall survival than those with mild ICIp (P < 0.001). **Conclusions:** ICIp is a serious adverse event that limits ICI treatment and can lead to hospitalization and death. Factors associated with severe ICIp in our study include lower lymphocyte and eosinophil counts, lower albumin levels, finding of consolidation or bronchiectasis on imaging, and lower predicted FVC and TLC. Prospective studies are merited to validate our findings and to investigate the appropriate treatment of ICIp. Research Sponsor: None.

Fecal microbiota transplantation for refractory immune-checkpoint-inhibitor colitis. *First Author: Arielle Elkrief, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Immune-related colitis (irColitis) is associated with significant morbidity and mortality among patients treated with immune checkpoint inhibition (ICI). The gut microbiota has been implicated in the pathophysiology of irColitis. We hypothesized that abnormal fecal microbiome features would be present at the time of irColitis onset, and that restoring the microbiome to a healthy state would mitigate disease severity. **Methods:** We present fecal microbiota profiles from N = 18 patients with irColitis and describe our clinical experience of N = 5 patients treated with healthy donor fecal microbial transplantation (FMT). Recipients of ICI between May 2019 and June 2021 at Memorial Sloan Kettering Cancer Center whose stool samples were investigated for diarrhea were included in our dataset (N = 100). N = 18 patients with a diagnosis of irColitis were identified. Patients that had other causes of diarrhea were classified as part of the “no-colitis” comparator group (N = 32). All patients with infectious causes of diarrhea (*C. difficile*, other GI pathogen) were excluded from the analysis. Stool samples were profiled by whole metagenomic shotgun sequencing. FMT products from individual healthy donors were procured from the OpenBiome fecal bank and delivered via colonoscopy. **Results:** There was no difference in alpha diversity between the irColitis and no-colitis groups. Patients in the irColitis group had significantly higher relative abundance of *Proteobacteria* at the time of symptom onset compared to the no-colitis group (p = 0.04). *Escherichia spp.* and *Klebsiella spp.* were associated with irColitis, also described in multivariate analyses. Five patients with irColitis refractory to steroids and biologics received healthy-donor FMT, with initial clinical improvement in irColitis symptoms observed in four of five (80%) patients. Two out of five subsequently exhibited recurrence of irColitis symptoms following a course of antibiotics for pneumonia and urinary tract infection, respectively. Both received a second “salvage” FMT that was, again, followed by clinical improvement of irColitis. In these two cases, fecal profiles demonstrated dysbiotic shifts in the gut microbiome post-antibiotics characterized by *Proteobacteria* expansion, which was salvaged post salvage FMT, mirroring clinical resolution of irColitis symptoms. **Conclusions:** We observed that *Proteobacteria* expansion is characteristic of irColitis at time of symptom onset. FMT was followed by clinical improvements in several cases of refractory irColitis. Strategies to restore or prevent microbiome injury—with a particular focus on salvage FMT after antibiotic injury—in the context of immunotherapy toxicities could be further explored in prospective clinical trials. Immune-related adrenal insufficiency: A single center retrospective analysis. *First Author: Natalya Polshina, Moscow Clinical Scientific Center Named after Loginov A.F., Moscow, Russian Federation*

Background: Immune checkpoint inhibitors (ICI) became widely used for treatment of various malignancies. They may cause different immune-related adverse events (irAEs), including adrenal insufficiency (irAI). irAI was reported to be comparatively uncommon but potentially life threatening. We conducted a retrospective single center study to identify and describe the incidence and characteristics of AI associated with ICI. **Methods:** We reviewed the medical records of patients treated at an oncological department at Loginov Moscow Clinical Scientific Center between Sep'2019 and Jan'2023 with immunotherapy under direct cortisol monitoring every 6-8 weeks. The main criteria for AI was low serum cortisol in the absence of glucocorticoid intake. **Results:** A total 101 patients (pts) treated by ICI or ICI in combination with chemotherapy or targeted therapy for various malignancies were included in our retrospective analysis. 16 patients (15.8%) were diagnosed with AI: 7 pts with renal cell carcinoma (RCC), 6 pts with melanoma (2 in adjuvant setting), 1 with non-small-cell lung cancer (NSCLC), 1 with small-cell lung cancer (SCLC), 1 with MSI-high colorectal cancer (CRC). Median age was 65 (range 46-79), the majority (10 pts, 62.5%) were male. The median time of irAI onset from ICI start was 5 months (range 2-15). Assessment of serum cortisol was performed every 6-8 weeks routinely and off-schedule in patients who had new onset AI-like symptoms. The most frequent symptoms were unspecific and included fatigue and weakness (100%), loss of appetite/anorexia (69%), hypotension (50%), weight loss (44%), insomnia (38%), chills (31%), nausea/vomiting (31%), muscle pain or cramps (31% and 25% respectively), dizziness (25%), dry mouth (25%), headache (13%), fever (6%). Remarkably, laboratory detected serum cortisol decline preceded any AI symptoms in 7 patients (43.7%). Other 7 patients (43.7%) had concurrent secondary hypothyroidism which suggested panhypopituitarism. Hydrocortisone replacement led to rapid symptoms recovery in 15/16 patients. Additional treatment with fludrocortisone was required for only one patient who had primary/mixed AI due to bilateral metastases of RCC in adrenal glands. All patients resumed immunotherapy after symptoms resolved. Only 1 patient needed treatment modification (ipilimumab cessation). By 12th February 2023 median follow-up from irAI onset is 7 months (range 0.5-37), 12 patients are alive, they all remain on permanent hydrocortisone replacement therapy. **Conclusions:** Routine cortisol assessment during immunotherapy allowed us to detect irAI in 15.8% of patents that is higher than usually reported. Detection of irAI before clinical presentation let us prevent severe consequences including life threatening. We consider that routine cortisol assessment during immunotherapy should be implemented in clinical practice. Research Sponsor: None.

Impact of obesity on the risk of immune-related adverse events (irAEs) among patients receiving immune-checkpoint inhibitors (ICI) treatment: A retrospective cohort study. *First Author: Mohamed I. Elsaid, The Ohio State University College of Medicine, Columbus, OH*

Background: Recent studies suggest that obesity is linked to improved progression-free and overall survivals in patients treated with Immune-Checkpoint Inhibitors (ICI). Studies have also shown that irAEs occurrence following ICI infusion is associated with improved survival. Current evidence on the relationship between obesity and the risk of irAEs has been inconclusive. We aimed to assess the impact of obesity on the risk of irAEs after ICI infusion using data from a large retrospective cohort. **Methods:** The study included newly diagnosed stage I-VI cancer patients treated with ICIs between 2012 and 2021 at the Ohio State University Comprehensive Cancer Center. Patients' body mass index (BMI) data at or before ICI infusion were classified into normal <25.0 Kg/M², 25 to <30 Kg/M² overweight and obese ≥ 30 Kg/M². An incident irAE was defined as any gastrointestinal, pulmonary, dermatological, endocrine or hepatobiliary irAEs following ICI infusion. Cox proportional hazard models were fitted to test the associations between obesity and 1) any irAEs and 2) organ-specific irAEs. We evaluated the dose-response association between BMI and irAEs using a three-knot restricted cubic spline in the adjusted Cox proportional models. **Results:** A total of 4,761 patients were included in the study with a median age of 62 years, 59.2% males and 89% White non-Hispanics. An estimated 34.7%, 31.5% and 33.8% of patients had normal, overweight, and obese BMIs. The median time to incident irAEs was 4.3 months. An estimated 2,791 (58.6%) experienced an irAE, with 28.8% having gastrointestinal, 17.7% pulmonary, 23.7% dermatological, 21.8% endocrine, and 4.4% hepatobiliary irAEs. BMI was a significant predictor of increased risk of irAEs, adjusted hazard ratio (aHR) 1.08 (95% CI: 0.98 to 1.19) overweight vs. normal BMI and aHR 1.17 (95% CI: 1.06 to 1.28) obese vs. normal BMI. In the organ-specific irAEs models, obese vs. normal BMI patients had higher risks of gastrointestinal aHR 1.23 (95% CI: 1.07 to 1.41), dermatological aHR 1.25 (95% CI: 1.07 to 1.28), and hepatobiliary aHR 1.61 (95% CI: 1.11 to 2.36) irAEs. A dose-response was observed in the relationship between BMI and the risk of irAEs whereby patients with BMIs lower than 22 Kg/M² (median normal BMI range 18.5-24.9 Kg/M²) had lower risks of irAEs [BMI 18.5 Kg/M² vs. 22 Kg/M², aHR 0.93 (95% CI, 0.88 to 0.97)] and those with BMIs higher than 22 Kg/M² had higher risks of irAEs [BMI 30 Kg/M² vs. 22 Kg/M², aHR 1.19 (95% CI, 1.09 to 1.29)] and [BMI 40 Kg/M² vs. 22 Kg/M², aHR 1.22 (95% CI, 1.11 to 1.34)]. **Conclusions:** Among patients treated with ICIs, higher BMI was significantly associated with an increased risk of irAEs. Patients with obesity should be monitored for symptom management following ICIs infusion. Our findings help to explain the previously reported benefits of increased BMI and higher irAEs rates on improved survival. Research Sponsor: None.

Poster Session

Incidence, risk factors, and outcomes of immune-related adverse events (irAEs) in a prospective, pan-tumor population. *First Author: Aanika Balaji, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: irAEs associated with immune checkpoint inhibitors (ICIs) can result in morbidity and mortality. The incidence, spectrum, and risk factors for irAEs are usually reported from retrospective studies and clinical trials, which typically exclude patients (pts) with pre-existing autoimmune disease (AD). The prevalence and risk factors for irAEs in a diverse, pan-tumor, real-world setting is not well understood. **Methods:** From 06/2021 to 2/2023, we prospectively enrolled pts receiving ICIs (alone or in combination as standard-of-care) at a tertiary care center in this iMCore network study. Univariate and multivariate logistic regressions and survival curves were used to interrogate risk factors for irAE development and the relationship between irAEs, graded using CTCAE v5.0, and clinical response by RECIST 1.1. **Results:** 132 pts with prior ICI therapy were prospectively followed. Median age was 65 years (IQR 56-72), 35% were female, 69% were white, and 24% were black. Most common tumor histologies were: hepatocellular, renal cell, bladder, non-small cell lung, and head and neck carcinoma. 23% (n=30/132) received dual ICI (nivolumab+ipilimumab). In the whole cohort, 36.4% (n=48/132) of pts developed any-grade irAE and 10.6% (n=14/132) developed a severe irAE (grades 3-5). There were 2 fatal irAEs (n=1 hepatitis, n=1 myocarditis) representing 1.5% of the total cohort. The median time to first irAE was 1.8 months (mos; IQR 1.2-3.1) for anti-PDL1 monotherapy, 1.2 mos (IQR 0.7-2.2) for dual ICI, 4.4 mos (0.2-8.7) for PDL1+chemotherapy, and 2.1 mos (1.3-3.1) for PDL1+other. A subgroup of pts (10.6%; n=14/132) had pre-existing AD and 50% (n=7/14) had ever received immunosuppression for their AD. Among pts with AD, the incidence of irAEs was 57% (n=8/14) vs 33.9% (n=40/118) among those without AD. Antitumor response for pts with AD was 27.3% vs 25.8% those without AD. Receipt of dual ICI therapy was associated with increased risk of any-grade irAE (OR 2.87 p=0.02) and severe irAE (OR 40.9 p=0.004). Pts with any grade irAEs were significantly more likely to experience a partial/complete response vs pts without irAEs (OR 4.14 p=0.02) and this relationship was preserved after adjustment for single vs dual ICI. Pts who did not develop irAEs had an overall response rate (ORR) of 18.2%, mPFS of 3.5 mos (IQR 1.6-7.3), and mOS 7.3 mos (IQR 3.8-9.9) vs pts who developed any grade irAE who had an ORR of 37.8%, mPFS of 5.9 mos (IQR 3.3-8.8), and mOS 8.6 mos (IQR 4.9-11.4). **Conclusions:** In this pan-tumor, prospective cohort study of pts receiving ICI therapy in a real world setting, we identified that pts with pre-existing AD and those on dual ICI had increased risk of irAE development. This signals the need for closer monitoring, early recognition, and management of irAEs in these pts. In addition, pts who developed irAEs were more likely to experience partial or complete response in a diverse tumor cohort. Research Sponsor: Genentech.

Discontinuation of immunotherapy over 2 years for patients with non-small cell lung cancer (NSCLC): A search for predictors. *First Author: Priscilla Cascetta, Institut Gustave Roussy, Villejuif, Paris, France*

Background: In advanced NSCLC, treatment completion at 24 months emerged in trials evaluating immune checkpoint inhibitors (ICI). Nevertheless, in clinical practice the question of the optimal treatment duration is under debate. **Methods:** We performed a retrospective study on advanced NSCLC treated with ICI (alone or with chemotherapy) at Gustave Roussy before 2021. Among patients still receiving ICI at 12 months, we analyzed the reasons for ICI discontinuation at 18 and 24 months. **Results:** Of the 682 patients treated with ICI (first-line for n=230, 33.7%), 159 (23.3%) received ICI for ≥ 12 months and 122 (17.9%) for ≥ 18 months. Between 18-24 months, 20 (57.1%) patients interrupted ICI for progressive disease (PD), 8 (22.8%) for toxicity and 7 (20.0%) after discussion with the patient. Out of the 88 (12.9%) patients who completed 2-years of ICI (median duration of treatment: 31.46 months, first-line for n=51), 22 (25.0%) patients discontinued ICI for PD and 40 (45.5%) without PD: 14 (15.9%) for toxicities, patient request or unknown causes and 26 (29.5%) for clinical decision before (n=16, 61.5%) or after (n=10, 38.5%) 30 months of treatment. Discontinuation according to phase III clinical trial design was supported by complete response (CR) by PET imaging +/- tissue biopsy of metabolically active lesions +/- ctDNA in 17 (65.4%) cases just before therapy discontinuation. After a median follow-up of 45.6 months since treatment discontinuation for these 26 patients, only two experienced PD at 4 and 6 months from ICI interruption, in both cases with no proof of CR at ICI discontinuation (p=0.111). The remaining 26 (29.5%) patients who continued ICI after 2 years, are on treatment based either on absence of CR at PET-CT +/- tissue biopsy of metabolically active lesions (n=20, 76.9%) or after discussion with the patients (n=6, 23.1%). After a median follow-up of 40.17 months from the 24-months landmark, the median progression-free survival was unchanged in both continuation and discontinuation groups. **Conclusions:** The patients who completed 2-years of ICI treatment usually continue to experience long-term response after discontinuation. Considering that a subgroup of patients could still benefit from maintained ICI administration, PET imaging was considered to guide ICI cessation or continuation. Prospective studies specifically designed to investigate biomarkers of maintained responses or residual disease (imaging, ctDNA, multi-omics including microbiome) are required to establish the indication for ICI continuation or stop for each patient. Phase 1 study of LB1410, a bivalent TIM-3/PD-1 bispecific antibody, in patients with advanced solid tumors or lymphoma. *First Author: Jiajian Liu, Shanghai, China*

Background: Cancer immunotherapies targeting PD-1 or PD-L1 have been proven effective in causing durable antitumor immune responses with less toxicity in many types of tumors. However, the response rate of anti-PD-1/PD-L1 treatments is far from satisfactory and most patients show primary or acquired resistance to the treatments. Tim-3, one of the next generation of immune checkpoint targets, co-expressed on exhausted T cells with PD-1. It is also expressed by innate immune populations, including NK and DC. Dual blocking PD-1 and Tim-3 not only on T cells but also on DC, NK cells may achieve better clinical benefit. LB1410 is a recombinant humanized anti-PD-1/TIM-3 bispecific antibody (BsAb) developed by L&L Biopharma Co., Ltd. for the patients who are resistant to or refractory from PD-1/PD-L1 treatments. It blocked the immune checkpoint PD-1 and TIM-3-mediated immunosuppressive signal pathways simultaneously, showed better T/DC cell activity and in vivo anti-tumor efficacy compared to Tim-3 and PD-1 antibody combination in preclinical studies. **Methods:** This is a FIH, multicenter, non-randomized, open label, phase 1 study of LB1410 in Participants With Advanced Solid Tumor or Lymphoma (Keyplus-001). The planned sample size is approximately 100 patients in two parts: part 1 dose escalation will evaluate safety, tolerability, pharmacokinetics (PK), pharmacodynamics, and determine the maximum tolerated dose (MTD) and/or the recommended phase 2 dose (RP2D), and Part 2 dose expansion will further characterize the safety profile and preliminary tumor response in several cohorts including NSCLC, CRC, EC etc. Enrollment criteria include adults with life expectancy of > 3 months, ECOG performance status 0-1, histologically or cytologically confirmed advanced and/or metastatic solid tumor malignancies or lymphoma for which standard treatment fails, or no standard treatment is available, or standard treatment is not applicable at this stage. Exclusion criteria include pregnancy, lactation, or breastfeeding, ongoing or recent evidence of significant autoimmune disease that required treatment with systemic immunosuppressive treatments. The primary endpoints are incidence of dose limiting toxicities and adverse events, MTD, and recommended phase 2 dose. Secondary objectives will evaluate PK parameters, preliminary antitumor activity, and immunogenicity of LB1410. Besides, the pharmacodynamics (PD) biomarkers related to LB1410 treatment, clinical activity will be explored. This clinical trial is in progress; cohorts 1 to 5 in dose escalation part have been completed. Clinical trial information: NCT05357651. Research Sponsor: L&L Biopharma Co., LTD., Shanghai, China.

A phase 1 first-in-human clinical trial of HMBD-002, an IgG4 monoclonal antibody targeting VISTA, in advanced solid tumors. *First Author: Jordi Rodon Ahnert, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: V-domain Ig Suppressor of T-cell Activation (VISTA), is an immune checkpoint regulator found on tumor, myeloid, and other immune cells. Its presence has been shown to enhance tumor growth, create an immunosuppressive microenvironment, and may potentially contribute to developing resistance to anti-CTLA-4 and anti-PD-1/PD-L1 therapies. Therefore, VISTA represents a promising therapeutic target. HMBD-002, a non-depleting, high-affinity IgG4 monoclonal antibody against VISTA, has demonstrated significant inhibition of tumor growth in preclinical studies, both as a monotherapy and in combination with pembrolizumab. HMBD-002 acts by increasing T-cell activity and reprogramming the suppressive tumor microenvironment to a proinflammatory antitumor phenotype. Cancer types including triple-negative breast cancer (TNBC) and non-small cell lung cancer (NSCLC), which exhibit high expression levels of VISTA in the TME, provide a rational basis for exploring these indications in clinical studies. **Methods:** This phase 1/2, open-label, multi-center trial is being conducted in two parts to evaluate the safety, pharmacokinetics, and antitumor activity of HMBD-002, an IgG4 monoclonal antibody targeting VISTA, as a monotherapy and in combination with pembrolizumab. The dose-escalation stage (Part 1) will follow a standard 3 + 3 study design with weekly dosing and adaptive dose-escalation increments to determine the recommended phase 2 dose (RP2D) for subsequent disease-directed studies. Monotherapy escalation cohorts 1-4 have been completed without dose-limiting toxicities (DLTs). The dose-expansion stage (Part 2) will evaluate the antitumor activity of HMBD-002 alone and combined with pembrolizumab in patients with TNBC and NSCLC, as well as a wide range of VISTA-expressing malignancies. Exploratory analyses will be conducted to assess treatment-induced immunological changes both systemically and within the tumor microenvironment. Longitudinal blood samples will be evaluated using single-cell mass cytometry (CYTOF) and multiplex cytokine analysis. Pre and on-treatment tumor tissue samples will be assessed for VISTA & PD-L1 expression using IHC. Additionally, tumor tissues will be evaluated using multiplex immunofluorescence, and gene-expression profiling. Biomarker correlations with clinical outcomes may lead to the identification of predictive markers of response to HMBD-002. Clinical trial information: NCT05082610. Research Sponsor: Hummingbird Bioscience Inc., Houston, TX, USA & Singapore; Cancer Prevention and Research Institute of Texas (CPRIT) Grant DP190027.

A phase 1, first-in-human (FIH) study of autologous macrophages engineered to express an anti-HER2 chimeric antigen receptor (CAR) in participants (pts) with HER2-overexpressing solid tumors. *First Author: Yara Abdou, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Macrophages are abundant in the solid tumor microenvironment (stME) and can promote tumor growth (M2) or enhance anti-tumor immunity (M1). CAR expression can redirect macrophage function to selectively target and phagocytose antigen overexpressing cancer cells. CAR-M can reprogram the stME and present neoantigens to T cells, leading to epitope spreading and anti-tumor immunity. CT-0508 is comprised of autologous monocyte-derived proinflammatory macrophages expressing an anti-HER2 CAR. Pre-clinical studies showed that CT-0508 induced targeted cancer cell phagocytosis while sparing normal cells, decreased tumor burden, prolonged survival, and was safe. Notably, anti-HER2 CAR-M treatment led to activation of the stME, with infiltration of CD8+ and CD4+ T cells, NK cells, dendritic cells, and increased activated CD8+ tumor infiltrating lymphocytes. In a pre-clinical anti-PD1 resistant solid tumor model, mice that received anti-HER2 CAR-M and anti-PD1 demonstrated improved tumor control, overall survival, and TME activation compared to single treatment alone, indicating synergy and capacity for CAR-M to sensitize solid tumors to checkpoint blockade. **Methods:** This Phase 1, First in Human study evaluates the safety, tolerability, cell manufacturing feasibility, trafficking, TME activation, and preliminary evidence of efficacy of investigational product CT-0508 in 18 participants (pts) with locally advanced (unresectable) /metastatic solid tumors overexpressing HER2. Pts previously treated with anti-HER2 therapies are eligible. Filgrastim mobilized autologous CD14+ monocytes are collected by apheresis, followed by manufacturing and cryopreservation. Group 1 pts (n = 9; enrollment complete) received fractionated doses of CT-0508 over Days 1, 3, and 5. Group 2 pts (n = 9) receive CT-0508 as a single infusion on D1. Additional cohorts include: CT-0508 co-administered with pembrolizumab and CT-0508 monotherapy administered intraperitoneally in pts with peritoneal predominant disease. Correlative assessments include pre- and post-treatment biopsies and blood samples for safety (immunogenicity), trafficking (PCR, RNA scope), CT-0508 persistence in blood and tumor, target antigen engagement, TME modulation (single cell RNA sequencing), immune response (TCR sequencing) and others. Clinical trial information: NCT04660929. Research Sponsor: Carisma Therapeutics.

A phase 1 trial of umbilical cord blood-derived tumor-reactive PD-L1+ natural killer cells engineered to express soluble IL-15 (TRACK-NK) in patients with non-small-cell lung cancer (NSCLC) refractory to PD-1/PD-L1 inhibitors. *First Author: Miguel Angel Villalona-Calero, Department of Medical Oncology and Therapeutics Research, City of Hope National Medical Center, Duarte, CA*

Background: The mechanism by which patients with PD-L1 – tumors can respond favorably to anti-PD-L1 monoclonal antibody therapy has been shown to involve the PD-L1+ NK cell in the tumor microenvironment (TME). PD-L1 is induced on the cell surface when NK cells recognize tumors, leading to enhanced NK-cell function without exhaustion. The PD-L1 + NK cell is capable of trafficking to the lung TME, recognizing and killing tumor cells as well as inducing activation of endogenous T cells via potent cytokine secretion, all without the expression of a chimeric antigen receptor (CAR). TRACK-NK cells are PD-L1+ NK cells derived from cord blood (CB) and engineered to express soluble IL-15 (sIL-15). The TRACK-NK cells express high levels of tumor reactive receptors that recognize "tumor stress" including DNAM-1, NKP30 and NKG2D. TRACK-NK cells induced significant reduction in tumor volume in mice injected with human A549 NSCLC cells compared to mock-transduced NK cells, or NK cells expressing sIL-15 (sIL-15-NK) but without *ex vivo* activation. Survival was also prolonged in the H460 NSCLC model compared to vehicle alone. We hypothesized that TRACK-NK cells can be safely administered, and will provide meaningful clinical benefit in patients with NSCLC. **Methods:** NCT05334329 is a first-in-human, phase 1 dose finding study of allogeneic, off-the shelf frozen and thawed TRACK-NK cells in patients with NSCLC progressing on treatment with PD-1/PD-L1 inhibitors. TRACK-NK cells (CB NK cells engineered with retroviral transduction to express sIL-15 and *ex vivo* expanded and activated to express PD-L1) are administered in four weekly intravenous infusions per cycle following lymphocyte depletion (Fludarabine/Cyclophosphamide x 3 days) in the outpatient setting. Patients not experiencing disease progression (per RECIST v1.1) following cycle 1 may receive a second cycle. Primary endpoints include: 1. Toxicity/adverse events as per NCI-CTCA version 5.0, and ASTCT Consensus Grading for Cytokine Release Syndrome (CRS) and Neurotoxicity; and 2. Magnitude/duration of TRACK-NK cell persistence in peripheral blood via droplet digital PCR. We are employing a Utility Based-Bayesian Optimal Interval design to direct optimal dose determination. Dose limiting toxicity is defined as any ≥ grade 3 non-hematologic toxicity; any grade 3 CRS that does not resolve to ≤ grade 1 within 7 days; any ≥ grade 4 CRS; any ≥ grade 2 neurotoxicity that does not resolve to grade 1 within 72 hours; any ≥ grade 3 autoimmune, hypersensitivity, and acute graft-versus-host reactions. Correlatives also include cytokines levels, quantity and activation of CD4 and CD8 cells in peripheral blood, and NK and T cell trafficking and TME changes in paired tumor biopsies using quantitative immunofluorescence and gene expression analysis. Clinical trial information: NCT05334329. Research Sponsor: U.S. National Institutes of Health; Cytoimmune.

Phase I study of NEROFE and doxorubicin in KRAS-mutated ST2-positive solid tumors. *First Author: Benjamin Adam Weinberg, Ruesch Center for the Cure of Gastrointestinal Cancers, Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC*

Background: KRAS-mutated tumors are notoriously difficult to treat clinically with targeted therapies. Recent advances targeting KRAS G12C with sotorasib and adagrasib are encouraging but limited to a small subset of patients. NEROFE is a 14 amino acid peptide which inhibits suppression of tumorigenicity 2 (ST2; member of the interleukin 1 [IL-1] receptor family and IL-33 receptor), a novel immune checkpoint present on tumor cells and tumor-associated macrophages. ST2 blockade with NEROFE has been shown to transform an immunosuppressive tumor microenvironment into an immune-stimulatory microenvironment. NEROFE also has been shown to induce microRNA miR-217 which downregulates KRAS and MAPK1/2 gene expression in preclinical models. When combined with low-dose doxorubicin, NEROFE has a synergistic effect on inducing apoptosis in KRAS-mutated, ST2-positive cell lines and xenograft models. **Methods:** This is a phase I trial of NEROFE given at 48 mg/m² (dose level [DL] -1), 96 mg/m² (DL1), 192 mg/m² (DL2), or 288 mg/m² (DL3) IV weekly with doxorubicin 8 mg/m² IV weekly. A standard 3+3 dose escalation/de-escalation is used. The primary objective is to determine the recommended phase II dose. Patients are eligible if they have an advanced solid tumor with a KRAS mutation and ST2-positivity (via immunohistochemistry [IHC], centrally confirmed with pre-screening allowed). Patients must have measurable disease amenable to serial biopsy. Patients must have had progression or intolerance to all standard therapies or must decline available standard therapy. Pharmacokinetic profiles will be analyzed from serial blood draws pre- and 1, 2, 4, 6, and 24 hours post-infusion on cycle 1 day 1 and cycle 2 day 1. Pre- and on-treatment tumor biopsies are mandatory. Correlative studies include IHC for ST2 expression, immune cell infiltration and blood-based analyses of KRAS mRNA, miR-217, and cytokines. Enrollment to DL1 began in Q1 2023 (NCT05661201). Clinical trial information: NCT05661201. Research Sponsor: Immune System Key Ltd; Ruesch Center for the Cure of Gastrointestinal Cancers.

GNC-038, a tetra-specific antibody, in patients with R/R non-Hodgkin lymphoma or acute lymphoblastic leukemia: A phase 1 study design and rationale. *First Author: Jianxiang Wang, Institute of Hematology, Chinese Academy of Medical Sciences, Tianjin, China*

Background: Bispecific T cell engagers can mediate single antigen-specific cell cytotoxicity, but cannot preempt clonal relapse, or modify the immunosuppressive cancer cell surface. The first-in-class octavalent, CD19xCD3x4-1BBxPD-L1 tetra-specific antibody, GNC-038, functions as a CD19-specific T cell engager by mediating direct antitumor activity, but further, GNC-038 overcomes inhibition of T cells by PD-L1 based on its 4 binding sites. The antitumor activity of GNC-038 is mediated by activating CD3 and 4-1BB signaling on T cells and targeting high expression of CD19 or PD-L1 on tumor cells. Preclinical studies showed GNC-038 has robust antitumor activity. Considering its favorable tolerance and pharmacokinetics in cynomolgus monkeys, we developed a phase I study to investigate GNC-038 for the treatment of relapsed/refractory non-Hodgkin lymphoma (NHL) and relapsed/refractory acute lymphoblastic leukemia (ALL). **Methods:** Patients diagnosed with relapsed/refractory non-Hodgkin lymphoma or acute lymphoblastic leukemia are currently being enrolled in this phase I study to evaluate the safety, tolerability and pharmacokinetics of GNC-038. This study will be conducted in two phases, dose-escalation (Ia) and dose-expansion (Ib). During the dose escalation phase, R/R-NHL patients will receive GNC-038 (0.016-6 µg/kg/d) as continuous intravenous (cIV) infusion for 8 weeks. Further escalation will be conducted with step-up dosing: cIV infusion of 3.6 µg/kg/d GNC-038 will be administered during week 1 followed by higher doses on subsequent weeks (9, 13.5, 20.25 or 30 µg/kg/d). R/R-ALL patients will receive GNC-038 by cIV infusion for 8 weeks (0.016-16 µg/kg/d). During the dose-expansion phase, one or more dosages will be chosen for further investigation in specific indications. The primary endpoints are dose limiting toxicity (DLT), maximum tolerated dose (MTD), treatment emergent adverse events (TEAE) and recommended phase 2 dose (RP2D). Secondary endpoints are adverse events (AEs), pharmacokinetics, objective response rate (ORR), duration of response (DOR), progression free survival (PFS) and overall survival (OS). Exploratory endpoints are biomarker assessment, anti-drug antibody (ADA) and pharmacodynamics. The dose expansion phase (Ib) has been initiated. Clinical trial information: NCT04606433. Research Sponsor: Sichuan Baili Pharmaceutical Co., Ltd.

A phase I/II dose escalation and expansion trial to evaluate safety and preliminary efficacy of BNT141 in patients with claudin-18.2-positive solid tumors. *First Author: Kyriakos P. Papadopoulos, START San Antonio, San Antonio, TX*

Background: Claudin-18.2 (CLDN18.2), whose expression is normally restricted to short-loop gastric epithelial cells, is ectopically expressed in tumors with unmet needs such as gastric, gastroesophageal junction (GEJ), pancreatic, ovarian, and biliary tract tumors. CLDN18.2 has thus emerged as a promising target for therapeutic antibody development. BNT141 is a novel RNA-based therapeutic that comprises two pseudouridine-modified mRNAs encapsulated in lipid nanoparticles. Upon intravenous injection, BNT141 is preferentially taken up by the liver where RNAs are translated and released into the circulation as fully assembled anti-CLDN18.2 antibodies. The resulting antibody is sequence identical to IMAB362, a CLDN18.2-targeted antibody that provided clinical benefit as an add-on to chemotherapy in the Phase III SPOTLIGHT trial (Shitara *et al. J Clin Oncol.* 2023). RNA-encoded antibodies can be developed more rapidly compared with recombinant antibodies and have the potential for favorable PK/PD properties and improved tolerability. **Methods:** This is a Phase I/II, open-label, multisite, dose escalation and expansion trial to examine safety, efficacy, and PK/PD of BNT141 in patients with CLDN18.2+ tumors (NCT04683939). The trial comprises 3 parts: dose escalation with BNT141 as monotherapy, dose escalation with BNT141 in combination with nab-paclitaxel and gemcitabine, and dose expansion. For monotherapy dose escalation, patients with CLDN18.2+ gastric, GEJ, pancreatic, mucinous ovarian, and biliary tract cancers who have exhausted or are ineligible for the current standard of care are eligible. CLDN18.2 positivity is defined as intermediate/strong staining intensity in ≥50% of tumor cells evaluated using a validated immunohistochemistry assay. Doses of BNT141 are escalated in up to 8 planned dose levels (DLs) until the maximum tolerated dose (MTD) is reached. For combination dose escalation, patients with advanced CLDN18.2+ pancreatic adenocarcinoma or cholangiocarcinoma who are eligible for treatment with nab-paclitaxel/gemcitabine will be included. Combination therapy will start at the first safe DL where the target antibody concentration is reached during monotherapy. Combination dose escalation will continue in parallel with the monotherapy part and will define the recommended Phase II dose (RP2D). For both parts, up to 10 additional patients may be enrolled at the MTD level to collect further safety and PK/PD data. For dose expansion, 2 cohorts of patients with CLDN18.2+ pancreatic adenocarcinoma or cholangiocarcinoma will receive combination therapy (nab-paclitaxel/gemcitabine) together with BNT141 at the defined RP2D. The study was initiated in January 2022 and recruitment is ongoing in the USA and Canada. Sites in Spain, Portugal, Germany, Denmark, Netherlands and the UK will be opened in 2023. Clinical trial information: NCT04683939. Research Sponsor: BioNTech SE.

Poster Session

A phase I/II dose escalation trial with expansion cohorts to evaluate safety and preliminary efficacy of BNT142 in patients with prospectively confirmed claudin 6-positive solid tumors. *First Author: Timothy A. Yap, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Claudin 6 (CLDN6), an oncofetal antigen that is expressed on the cell surface of several solid cancers, including testicular (95% of cases) and ovarian cancers (55% of cases), is a suitable target for cancer immunotherapy (Reinhard *et al. Science.* 2020; Haanen *et al. AACR* 2022). BNT142 comprises lipid nanoparticle-encapsulated RNAs that encode for a T-cell-engaging bispecific antibody against CLDN6 and the T cell receptor-associated molecule CD3. The resulting tribody is produced from two RNA molecules coding for CLDN6-recognizing single-chain variable fragments connected by a CD3-binding fragment antigen-binding region. After intravenous administration, BNT142 is directed to the liver where both RNAs are translated, assembled, and secreted as antibodies into the circulation. While classical recombinant protein antibody formats are affected by issues with stability and a lengthy manufacturing process, novel RNA-encoded antibodies can be developed quickly and will potentially provide more favorable exposure profiles. A previous preclinical study examining the therapeutic effect of RNA-encoded bispecific CLDN6xCD3 antibodies showed tumor regression in xenograft animal models with CLDN6+ tumors (Stadler *et al. Nat Med.* 2017). **Methods:** This is a first-in-human, Phase I/II, open-label, multicenter, dose escalation trial with expansion cohorts to evaluate the safety, efficacy, PK and PD of BNT142 in patients with CLDN6+ advanced solid tumors (NCT05262530). Patients with advanced/metastatic CLDN6+ testicular, ovarian, endometrial, and non-squamous non-small-cell lung cancer (NSCLC) are eligible for inclusion and are prospectively selected for trial entry using a CLDN6 immunohistochemistry assay in a central laboratory. Patients must have exhausted standard therapies available likely to confer a clinical benefit or not be a candidate for such available therapies. The trial design consists of a dose escalation and dose expansion part. In the dose escalation part, the treatment dose will be escalated in up to 8 dose levels (DLs) until the maximum administered and tolerated dose has been reached. Once a DL has been declared safe, the DL cohort may be backfilled to determine safety, PK/PD, and anti-tumor activity. Patients with rare or not otherwise specified CLDN6+ tumors not included in the eligible tumor types can be included in the dose escalation part. The recommended Phase II dose (RP2D) will be determined by data collected at all DLs. In the dose expansion part, CLDN6+ patients with testicular cancer, ovarian cancer, and non-squamous NSCLC who have received at least 1 systemic therapy will be treated at the RP2D. The trial was initiated in March 2022 and recruitment is ongoing at global locations in Europe and the USA. Additional sites will be opened in Europe, USA, and Asia in 2023. Clinical trial information: NCT05262530. Research Sponsor: BioNTech SE.

Trial START-001: A phase 1/2 study of STAR0602, a first-in-class, selective T cell receptor (TCR)-targeting, bifunctional antibody-fusion molecule, as monotherapy in patients with antigen-rich tumors post checkpoint inhibitor (CPI) treatment. *First Author: Ryan J. Sullivan, Massachusetts General Hospital, Boston, MA*

Background: Many patients do not respond to CPI-based therapies and most responders eventually develop resistance. Thus, the development of more effective therapies for CPI treatment resistance is a significant unmet medical need. STAR0602, a first-in-class, TCR β chain-targeting bifunctional antibody fused to a costimulatory molecule, binds the germline Vβ6/Vβ10 TCRs of human alpha/beta (αβ) T cells, and promotes the selective activation and expansion of CD8⁺ and CD4⁺ Vβ6/Vβ10 effector memory T cells by simultaneously engaging direct TCR activation with IL-2 receptor binding and activation in *cis*. Preclinical studies with STAR0602 and its murine surrogate showed potent single-agent anti-tumor activity in multiple CPI-refractory human organoid and murine syngeneic tumor models, and acceptable tolerability and limited cytokine release in monkeys and mice. Durable anti-tumor responses, with long-term protection from tumor re-challenge, was associated with *de novo* expansion and tumor infiltration of targeted Vβ T cell subsets with a novel effector memory gene signature and striking increase in TCR repertoire diversity. These data provide strong scientific rationale to investigate the safety and efficacy of STAR0602 in patients with CPI-resistant cancers. **Methods:** Using a 3+3 trial design, Phase 1 of START-001 is a dose escalation through eight provisional dose levels of STAR0602, administered via an intravenous infusion once every two weeks, to determine a recommended Phase 2 dose (RP2D), based on safety and tolerability, pharmacokinetics, pharmacodynamics, and preliminary anti-tumor activity. Subjects must have one of the following, histologically confirmed solid tumors that are unresectable, locally advanced or metastatic and for which standard curative therapies do not exist or are no longer effective: 1) high mutational burden solid tumors (TMB-H); 2) MSI-H/mismatch repair-deficient (dMMR) cancers; 3) Virally associated tumors including Merkel cell carcinoma, cervical, oropharyngeal, anal, penile, vaginal, and vulvar cancers. After an RP2D is selected, Phase 2 (dose expansion at this RP2D) will begin to further investigate the safety and preliminary anti-tumor activity of STAR0602 in 10 provisional cohorts of patients who have the following solid tumors: TMB-H, CPI experienced; TMB-H, no prior CPI experience; MSI-H/dMMR; virally associated tumors; K-RAS wild-type and MSI-L/MMR proficient colorectal cancer (CRC); K-Ras mutant CRC; metastatic triple-negative breast cancer; relapsed and refractory epithelial ovarian cancer; metastatic castration-resistant prostate cancer; primary stage IV or recurrent non-small cell lung cancer. Phase 1 enrollment has begun since January 2023. Clinical trial information: NCT05592626. Research Sponsor: Marengo Therapeutics, INC.

Poster Session

A first-in-human study of XTX301, a masked, tumor-activated interleukin-12 (IL-12), in patients with advanced solid tumors. *First Author: John George Knecht, Clear Lake Oncology, Webster, TX*

Background: Interleukin-12 (IL-12) is a proinflammatory cytokine that has shown promise as an immunotherapy for cancer. Although it has demonstrated potent antitumor activity in mouse models of cancer, development of IL-12 in the clinical setting has been limited by severe toxicities with systemic administration. XTX301 is a half-life extended, masked and tumor-activated IL-12. XTX301 is designed to be pharmacologically inactive in non-tumor tissue when circulating systemically, and unmasked by matrix metalloproteases (MMPs) preferentially active in the tumor microenvironment (TME). The masking domain is engineered to be removed via cleavage at a protease cleavage site in the XTX301 linker by MMPs. XTX301 is designed to produce a localized anti-tumor immune response while limiting exposure of the active form of XTX301 in non-tumor tissue, and thereby improving the therapeutic index of IL-12. Using a murine analog of XTX301 (mXTX301), tumor growth inhibition was demonstrated *in vivo* in murine models with a single dose of mXTX301. In mouse tumors, mXTX301 stimulated the infiltration of cytotoxic CD8+ T cells and induced pro-inflammatory gene expression signatures. Preclinical data have demonstrated tumor-selective activity of mXTX301 in mice with limited and reversible peripheral toxicities of XTX301 in non-human primates [Malkova et al., AACR 2023]; these data are supportive of further clinical development. **Methods:** XTX301-01 trial (NCT05684965) is a first-in human, multicenter, Phase 1, open label study to establish the safety and tolerability of monotherapy XTX301, and to determine a recommended phase 2 dose (RP2D). Additional objectives include assessment of pharmacokinetics (PK), pharmacodynamics (PD), immunogenicity and anti-tumor activity of XTX301. The study will enroll patients with solid tumors, including lymphoma, that have locally advanced or metastatic disease and have failed standard therapy, standard therapy does not confer survival benefit, or standard therapy is not available. Patients in part 1A will receive XTX301 monotherapy every 3 weeks via intravenous infusion in an outpatient setting, using a 3+3 dose escalation design. The starting dose for XTX301 is 5 ug/kg. Part 1B will further examine multiple doses of XTX301 as monotherapy in patients with select advanced solid tumors to further characterize PK, PD and dose response relationships. Part 1B will require mandatory fresh tumor biopsies before and after initiation of study drug administration to fully characterize the PD profile and PK of XTX301 in the tumor. Enrollment to the study is planned to begin in the first quarter of 2023. Clinical trial information: NCT05684965. Research Sponsor: Xilio Development, Inc.

Poster Session

A phase II study of durvalumab re-treatment +/- prednisone in patients who discontinued prior checkpoint therapy due to immune related toxicity (CCTG IND.238A). *First Author: Peter Michael Ellis, Juravinski Cancer Inst, Hamilton, ON, Canada*

Background: Up to 18% of patients permanently discontinue immune checkpoint blockade (ICB) therapy following G3/G4 immune-related adverse events (irAEs) even if reversible / easily managed with replacement therapy or steroids. Safety concerns exist with ICB re-treatment. Given the potential benefit of ICB and evidence that patients with irAEs may exhibit greater efficacy, there is interest in ICB rechallenge following successful management of G3/G4 irAEs in patients who have had benefit, and trials to prospectively investigate ways to prevent irAE recurrence are needed. Durvalumab is a human monoclonal antibody of IgG1κ subclass that binds to PD-L1. Canadian Cancer Trials Group (CCTG) IND.238A is a phase 2, open label, multi-centre study of durvalumab +/- prednisone rechallenge in patients who were benefitting from prior ICB but discontinued due to irAEs. **Methods:** Eligible patients have received prior anti-PD-(L)1 ICB alone or in combination with anti-CTLA-4 ICB, with or without chemotherapy/targeted therapy, and experienced either: 1) G3 or selected G4 irAEs (i.e. endocrinopathies manageable with replacement therapy; hematologic toxicity) that required drug discontinuation; 2) prolonged G2 irAEs where therapy was discontinued due to poor tolerability. Prior irAE must have resolved to ≤G1, patients must have completed steroid therapy and have documented RECIST 1.1 CR, PR, or prolonged SD (≥8 weeks) to initial ICB. Patients with prior (neo)adjuvant/consolidation ICB are eligible provided there has been ≥6-month treatment free interval before enrollment. Based on prior irAE, patients are allocated into either: 1) the High Risk cohort, receiving durvalumab (1500mg IV Q4W in all cohorts) + prednisone 0.5mg/kg/day for C1-2, or; 2) the Standard Risk cohort, where they are randomized to receive either durvalumab + prednisone 10mg/day for C1-2 (Cohort 2A) or durvalumab alone (Cohort 2B). Three to 6 patients are enrolled into each cohort initially, then each cohort expands up to a total of 60 evaluable patients (20 per cohort). Safety review takes place following enrollment of the 1st, 3rd, 6th and 10th patient in each cohort. Safety review occurs 4 weeks after the 1st patient treated on each cohort and subsequently once the last patient has been followed for at least 4 weeks. The primary endpoint is the incidence of treatment-related AEs (CTCAE v5.0), estimated as percentages of patients with each AE (90% exact CI will be calculated). Secondary objectives are ORR (RECIST 1.1 and iRECIST) and efficacy of corticosteroids in preventing recurrent or new ≥G2 irAEs (90% exact CI will be calculated). Exploratory endpoints include PFS / iPFS by Kaplan-Meier method, exploration of blood- and stool-based irAE biomarkers and PD-L1 expression. As of January 30, 2023, 12 of planned 60 patients have been enrolled. Clinical trial information: NCT03847649. Research Sponsor: AstraZeneca Canada Inc.; Canadian Cancer Society.

High-dose vitamin C to enhance neoadjuvant immune checkpoint therapy in mismatch repair proficient colon cancer: The ALFEO pilot study. *First Author: Andrea Sartore-Bianchi, Department of Oncology and Hemato-Oncology, Università degli Studi di Milano, Milan, Italy & Department of Hematology, Oncology, and Molecular Medicine, Grande Ospedale Metropolitano Niguarda, Milan, Italy*

Background: Most colon cancer (CC) patients can be treated with upfront curative surgery; however, relapse often occurs and the disease becomes deadly. Neoadjuvant chemotherapy does not jeopardize timing or quality of surgery and enhances relapse-free outcomes in proficient mismatch-repair (pMMR) CC (Morton et al, J Clin Oncol 2023). In the same setting, the use of immune checkpoint inhibitors (ICIs) with a single dose of ipilimumab (Ipi) and two doses of nivolumab (Nivo) proved to be feasible without delaying surgery and resulting in 23% major pathological responses (mPR) (Chalabi et al, ASCO 2022). We have previously shown that high dose vitamin C (HDVitC) triggers tumor infiltration and activation of CD8+ T cells in mouse tumors, enhancing efficacy of ICIs in pMMR CC preclinical models (Magri et al, Sci Transl Med 2020). **Methods:** ALFEO is an open-label pilot trial of neoadjuvant CC treatment to test whether HDVitC can enhance the efficacy of ICIs in this setting. Main inclusion criteria are pMMR CC stage cT4N0/TxN1-2/[cM1 liver-limited disease with favorable oncological criteria candidate for upfront surgery on both T and M after multidisciplinary team evaluation]. Patients will receive Nivo i.v. 3 mg/kg D1 and D15, Ipi i.v. 1 mg/kg D 1 and VitC 70 g/ m² D1-3 and 15-17. Tumor assessment will be performed at D21-28, followed by surgery within D28. Primary objective is activity of Nivo/Ipi + HDVitC; secondary objective is safety; exploratory objectives are correlation between efficacy and pharmacodynamic including tumor microenvironment changes. Primary endpoint is mPR rate. Considering the proof-of-principle nature of the trial, a design with a boundary for early stopping (both futility/utility and toxicity) and a fixed maximum sample size of 24 patients has been chosen. mPR for the Ipi/Nivo has been set at 23% (H₀), while H₁ at 75%. A Bayesian hypothesis test-based design (Zhou et al, Pharm Stat 2021) will be used for decision-making. Su. Clinical trial information: ECTR2022-502101-15-00. Research Sponsor: PNRR-MAD-2022-12376593; Fondazione Oncologia Niguarda.

Phase 1/2 study of mRNA-4359 administered alone and in combination with immune checkpoint blockade in adult participants with advanced solid tumors. *First Author: John D. Powderly, Carolina BioOncology Institute, Huntersville, NC*

Background: mRNA-4359 is a lipid nanoparticle encapsulated mRNA-based cancer vaccine encoding for concatemeric program death-ligand 1 (PD-L1) and indoleamine 2,3-dioxygenase 1 (IDO1) antigens given as an intramuscular injection. These proteins are found across a wide range of cancer types. PD-L1 is a cell surface receptor expressed on both tumor and regulatory immune cells and functions as a checkpoint to inhibit T cell function, while IDO1 is an L-tryptophan metabolizing enzyme involved in T cell suppression and immune tolerance. Both are thought to impart an inhibitory tumor microenvironment which allows tumor cells to escape immune monitoring and clearance. T cells that can target PD-L1 and IDO1 are known to pre-exist in cancer patients and a recent study leveraging a peptide-based vaccine approach demonstrated they can be induced to elicit clinically meaningful and durable tumor responses in patients with metastatic melanoma when combined with PD-1 inhibition. mRNA-4359 encodes immunogenic peptides proposed to generate anti-PD-L1/IDO1-specific T-cells to kill immunosuppressive regulatory cells as well as cancer cells which express those antigens and thus tip the balance towards an inflammatory and/or immune permissive tumor microenvironment. Additionally, combination with checkpoint inhibition may further amplify this anti-tumor immunostimulatory effect, resulting in superior clinical outcomes. **Methods:** The primary objective of this first in human, open label Phase 1/2 study is to assess safety and tolerability, with secondary objectives to measure T cell profile changes and initial anti-tumor activity. Arm 1a entails dose escalation of mRNA-4359 monotherapy with dose levels guided by a modified continual reassessment method in participants with locally advanced/metastatic cancers, including cutaneous melanoma, non-small cell lung cancer (NSCLC), non-muscle invasive bladder cancer, head/neck squamous cell carcinoma, microsatellite stable colorectal cancer, basal cell carcinoma or triple negative breast cancer. Arm 1b will be dose confirmatory and will run concurrently with a pharmacodynamic arm; both will assess mRNA-4359 in combination with pembrolizumab in patients with primary/secondary checkpoint inhibitor refractory locally advanced/metastatic melanoma or NSCLC. The totality of available data from these arms will be used to support determination of a recommended phase 2 dose. Arm 2 includes two single arm expansion cohorts evaluating mRNA-4359 in combination with pembrolizumab therapy in patients who have not received any prior therapy for their cancer in this setting of locally advanced/metastatic melanoma (Cohort 1) or locally advanced/metastatic NSCLC with PD-L1 TPS of $\geq 1\%$ (Cohort 2). Study enrollment into Arm 1a has commenced in the United States and Australia with plans to open sites in Europe later in 2023. Clinical trial information: NCT05533697. Research Sponsor: Moderna Therapeutics, Inc.

A phase I trial of diphencyprone for cutaneous neurofibromas in adult patients with neurofibromatosis type 1. *First Author: Dina Poplasky, Department of Dermatology, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Neurofibromatosis type 1 (NF1) is an autosomal dominant genetic tumor predisposition syndrome affecting about 1 in 2500 people. Affected patients develop a variety of skin findings including café-au-lait macules, axillary freckling, and cutaneous neurofibromas (cNFs). These patients also have an increased risk of malignant tumors including gliomas and soft tissue sarcomas. However, the cNFs, of which a patient can have thousands, are often cited as the most burdensome sign. Despite their benign nature, these tumors can be physically bothersome and cause significant emotional distress. To date, there are no effective pharmacotherapies for these tumors. This is a single-center, phase I, open label trial to evaluate the safety, tolerability, and efficacy of diphencyprone (DPCP), a topical hapten that induces a delayed-type hypersensitivity skin reaction, for the treatment of cNFs in adults with NF1. **Methods:** This trial is enrolling NF1 patients aged 18 and older with at least four cNFs greater than 4mm. Subjects taking systemic immunosuppressants, those with underlying immunodeficiency or uncontrolled intercurrent illnesses, and those who are pregnant or nursing are excluded from the study. DPCP 0.04% ointment is administered topically once weekly to up to 20 cNFs in a localized area for 10 weeks. The primary endpoint is to determine the safety and tolerability of DPCP ointment in the treatment of cNFs. Adverse events are graded according to the Common Terminology Criteria for Adverse Events (CTCAE) version 5.0. To assess subjective tolerability, subjects score their symptoms, including pain, stinging, burning, and pruritus from 0 (none) to 3 (severe). Efficacy and tumor regression are assessed using the Response Evaluation Criteria in Solid Tumors guidelines in conjunction with photographs and manual tri-axial tumor measurements. Additionally, qualitative assessments are made by the study team using 3D whole-body photography. One treated tumor is tracked throughout the study with optical coherence tomography (OCT) imaging. Skin biopsies of a cNF and surrounding tissue are collected at baseline, on Day 17 after treatment initiation, and four weeks post-treatment for exploratory endpoints. Quantitative RT-PCR and single-cell RNA sequencing studies will assess gene expression changes in immune and tumor cell-related genes pre- and post-treatment with DPCP. Immunohistochemistry and proteomic profiling will be performed to characterize changes in the tumor microenvironment. Genetic testing for the NF1 germline mutation will be correlated with treatment response. Enrollment is ongoing with a target of 20 participants. Since September 2022, the study has enrolled 12 patients and five have completed the study. Clinical trial information: NCT05438290. Research Sponsor: The Friedman Brain Institute, Icahn School of Medicine at Mount Sinai.

Phase 2 trial of epidermal growth factor (EGF) vaccine CIMAvax in combination with pembrolizumab in first line and maintenance setting in advanced non-small cell lung cancer patients. *First Author: Prantesh Jain, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: CIMAvax-EGF is a novel growth-factor depleting immunotherapy consisting of human recombinant EGF conjugated to recombinant P64k derived from *Neisseria meningitidis*, that elicits an anti-EGF antibody response, resulting in reduction of circulating EGF levels. A randomized phase 3 study of CIMAvax-EGF administered as switch maintenance therapy after first-line platinum-based chemotherapy in patients with advanced NSCLC demonstrated overall survival (OS) advantage in comparison to best supportive care alone, particularly in patients with high baseline serum EGF levels. A phase 1 trial combining CIMAvax-EGF with nivolumab, an anti-PD1 immune checkpoint inhibitor, showed that the combination is safe and appears to induce higher rate of good anti-EGF antibody response within the first 8 weeks of therapy compared to historical comparison group receiving CIMAvax-EGF alone. CIMAvax-EGF is currently being investigated in combination with pembrolizumab in a multi-arm phase II trial as 1L therapy in combination with pembrolizumab for patients with EGFR/ALK wildtype NSCLC and PD-L1 $> 50\%$ (Cohort C) and as maintenance therapy after completing 1L chemoimmunotherapy for patients with PD-L1 $< 50\%$ (Cohorts D and E). Accrual to this trial is ongoing (NCT02955290). **Methods:** This is an open-label, non-randomized, multi-site, phase 2 basket trial. CIMAvax-EGF (2.4 mg IM every 2 weeks x 4 doses, then every 4 weeks thereafter) is being tested as first-line therapy in combination with pembrolizumab (200 mg IV every 4 weeks) in patients with advanced NSCLC with PD-L1 $\geq 50\%$ (Cohort C), using a Simon two stage design (n up to 41). A safety lead-in consisting of the first 6 NSCLC patients was completed. There were no G3 or higher adverse events attributed to the combination within the first 4 weeks of protocol treatment. Patients with advanced squamous NSCLC (Cohort D, n=50) and non-squamous NSCLC (without EGFR/ALK/ROS-1/KRAS mutations; Cohort E, n=45) with PD-L1 expression $< 50\%$ and no evidence of progression of disease by RECIST 1.1 criteria after at least 4 cycles of induction platinum-based doublet with pembrolizumab, prior to initiation of standard of care maintenance therapy will be enrolled to receive protocol treatment with pembrolizumab in combination with CIMAvax-EGF as maintenance therapy. The primary endpoint is to evaluate objective response rate (Cohort C), and 12-month PFS in Cohorts D and E. Secondary endpoints include 12-month overall survival in all cohorts. Exploratory objectives include characterizing tissue-based immune and EGFR signaling profile as well as serum EGF levels, anti-EGF antibody levels and other blood-based biomarkers in relation to clinical outcomes. Clinical trial information: NCT02955290. Research Sponsor: Roswell Park Cancer Institute.

A prospective observational study investigating the impact of immune checkpoint inhibitors for cancer on fertility in males and females of child-bearing age (immuno-fertility). *First Author: Rachel J Keogh, Beaumont RCSI Cancer Centre, Dublin 9, Ireland*

Background: Anti-PD-1/PD-L1/CTLA4 agents have revolutionized the treatment landscape of many cancer types, resulting in durable responses. With recent approvals in the adjuvant setting, the long-term consequences of immune checkpoint inhibitors (ICIs) such as the impact on fertility are of increasing clinical relevance. The impact of ICI therapy on fertility is poorly understood. Based on published data, we hypothesize that patient fertility may be affected by ICIs via several mechanisms, including: endocrine dysfunction, direct impact on gametogenesis, or autoantibody formation. **Methods:** We designed a prospective, multi-center translational study that aims to identify the effects of ICIs on fertility. We aim to recruit 88 patients over 3-4 years. Participants of child-bearing age as defined by study protocol who are due to start ICIs for any solid tumour malignancy, will be eligible. The primary endpoint of the study is a change in anti-Müllerian hormone level and antral follicle count in females, and a change in sperm concentration, motility, morphology in males measured before and serially during ICI therapy (up to 24 months). Secondary endpoints include analysis of FSH, LH, testosterone levels, the proportion of patients with a persistent change in any one reproductive parameter as assessed at follow-up visits, frequency of oligo/amenorrhoea in females and immunologic changes in seminal fluid in males. **Conclusions:** ICIs have led to a significant improvement in the long-term survival in selected patients with cancer. This study will elucidate the effects of ICIs on both male and female fertility over time, and provide useful information to guide patients and their care teams regarding long-term effects of ICIs on fertility. Recruitment is ongoing. Research Sponsor: Irish Cancer Society.

Abatacept for immune checkpoint inhibitor associated myocarditis (ATRIUM): Phase 3, investigator-initiated, randomized, placebo-controlled study to evaluate the efficacy and safety of abatacept compared to placebo in hospitalized patients with immune checkpoint inhibitor associated myocarditis. *First Author: Kerry Lynn Reynolds, Division of Oncology, Department of Medicine, Massachusetts General Hospital, Boston, MA*

Background: Patients with myocarditis secondary to treatment with an immune checkpoint inhibitor (ICI) represent a poor prognosis population with a critical unmet clinical need. Data have shown that the rate of major adverse cardiac events (MACE) with ICI myocarditis despite administration of corticosteroids ranges from 25-50%. Abatacept is a selective co-stimulation modulator that inhibits T cell activation by binding to CD80 and CD86, thereby blocking its interaction with CD28. In preclinical animal models of ICI myocarditis, the administration of abatacept led to a reduction in cardiac immune activation and an increase in survival. **Methods:** The abatacept for immune checkpoint inhibitor associated myocarditis (ATRIUM) trial is designed as a phase 3, investigator-initiated, randomized, placebo-controlled study to evaluate the efficacy and safety of abatacept compared to placebo in hospitalized participants with ICI associated myocarditis. Hospitalized participants diagnosed with ICI-related myocarditis, as defined by the International Cardio-Oncology Society, ≥ 18 , with serum evidence of ongoing myocardial injury (troponin ≥ 5 times the upper limit normal), and treated, or with intent to treat, with 1000 mg of solumedrol/day are eligible. In the randomized protocol, participants receive either abatacept (10 mg/kg) or placebo given IV followed by study drug infusion/placebo again at 24 hours and on day 14. Of note, there is an optional 4th dose on day 28. The primary aim is to test whether abatacept, as compared to placebo, is associated with a reduction in MACE among participants hospitalized with myocarditis secondary to an ICI. The primary outcome, MACE, is a composite of first occurrence of cardiovascular death, non-fatal sudden cardiac arrest, cardiogenic shock, significant ventricular arrhythmias, significant bradyarrhythmias, or incident heart failure. Each component of the primary composite end point will be evaluated individually as a secondary endpoint, as are troponin levels, rates of deep venous thrombosis and pulmonary embolism, and incidence rates of treatment-related adverse events. Exploratory outcomes focus on cancer outcomes, healthcare utilization, quality of life, and correlative studies. Recently, the trial has been amended to allow eligible participants who have achieved an ATRIUM primary end-point prior to randomization to be eligible for inclusion in the RESCUE arm of the protocol where they will be given open-label Abatacept on day 1, 2, 14, with optional dose at 28. The study is open at 20 sites across the US with a plan for a total of 50 locations across US and Canada. This study is recruiting at time of submission. Target enrollment is 390 patients. Clinical trial information: NCT05335928. Research Sponsor: Bristol Myers Squibb.

BL-B01D1, a first-in-class EGFRxHER3 bispecific antibody-drug conjugate (ADC), in patients with locally advanced or metastatic solid tumor: Results from a first-in-human phase 1 study. *First Author: Li Zhang, Department of Medical Oncology, State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, Guangdong, China*

Background: BL-B01D1 is a first-in-class novel ADC consisting of an EGFRxHER3 bispecific antibody linked to a novel TOP-1 inhibitor payload via a cleavable linker. We now present safety/efficacy results from a FIH phase I study of BL-B01D1. **Methods:** This study included patients (pts) with locally advanced or metastatic solid tumors. For dose escalation (D-ESC, i3+3), BL-B01D1 was administered intravenously at doses of 0.27, 1.5, 3.0 mg/kg QW, 2.5, 3.0, 3.5 mg/kg D1D8 Q3W or 4.5, 5.0, 6.0 mg/kg D1 Q3W. A subset of pts were enrolled into dose-expansion (D-EXP) at Q3W regimens. **Results:** As of Dec 31, 2022, 150 pts were enrolled and received at least one dose (D-ESC, n=25; D-EXP, n=125). DLTs were neutropenia, febrile neutropenia and thrombocytopenia at 3.0 mg/kg QW and 3.5 mg/kg D1D8 Q3W. The MTDs were determined to be 3.0 mg/kg D1D8 Q3W and 6.0 mg/kg D1 Q3W. D-EXP was carried out at 2.5, 3.0 mg/kg D1D8 Q3W and 4.5, 5.0, 6.0 mg/kg D1 Q3W. 144 pts were enrolled across all Q3W dose levels (D-ESC and D-EXP), including 89 NSCLC, 7 SCLC, 27 nasopharyngeal cancer (NPC), 19 HNSCC and 2 others. Most common TRAEs (>10%, all grade / ≥ G3) were leukopenia (60%/30%), neutropenia (51%/34%), anemia (45%/15%), thrombocytopenia (44%/19%), alopecia (30%/0%), nausea (29%/<1%), vomiting (28%/0%), asthenia (21%/<1%), decreased appetite (22%/<1%), asthenia (21%/<1%), hypophagia (16%/0%), diarrhoea (15%/2%), mouth ulceration (15%/<1%), rash (13%/0%). No ILD was observed. 122 pts were evaluable for efficacy (at least 1 tumor assessment). PK and other details will be updated in the meeting. **Conclusions:** BL-B01D1 demonstrated encouraging efficacy in heavily pretreated metastatic/locally advanced solid tumors, especially in pts with EGFRm NSCLC. The safety profile showed adequate safety and tolerability. Clinical trial information: NCT05194982. Research Sponsor: Sichuan Baili Pharmaceutical Co., Ltd.

First-in-human study of ABBV-011, a seizure-related homolog protein 6 (SEZ6)-targeting antibody-drug conjugate, in patients with small cell lung cancer. *First Author: Daniel Morgensztern, Washington University School of Medicine, St. Louis, MO*

Background: Small cell lung cancer (SCLC) has a dismal prognosis and new therapies are urgently needed. SEZ6 is a transmembrane protein expressed in SCLC tumors that may be used as a therapeutic target. ABBV-011 is an antibody-drug conjugate (ADC) targeting SEZ6 with a calicheamicin payload, which has shown antitumor activity in preclinical models of SCLC. Preliminary results from the monotherapy dose-escalation and -expansion cohorts of the first-in-human ABBV-011 study are presented. **Methods:** Phase 1, open-label, multicenter study (NCT03639194) of ABBV-011 alone or in combination with budigalimab, a programmed cell death 1 inhibitor. Primary objectives were to assess the safety and tolerability and to determine the maximum tolerated dose (MTD) and/or recommended phase 2 dose of ABBV-011. Adults (≥18 years) with relapsed/refractory SCLC (1–3 lines of prior therapy) were enrolled. Dose escalation was guided by Bayesian continual reassessment method. ABBV-011 was administered intravenously at doses from 0.3 to 2.0 mg/kg once every 3 weeks. Dose expansion was conducted in SEZ6-selected patients. **Results:** At data cutoff on August 22, 2022, 99 patients were treated with ABBV-011 monotherapy. Median age was 63 years (range, 41–79), 50% of patients were male, and 68% had received ≥2 prior therapies. ABBV-011 ADC pharmacokinetics were approximately dose-proportional with an elimination half-life of 4.6 days across the dose range of 0.3–2.0 mg/kg. In dose escalation (n=26), 1 patient had a dose-limiting toxicity of grade (G) 3 fatigue at 2.0 mg/kg. We report safety and efficacy results for 40 patients in the dose-expansion 1.0-mg/kg ABBV-011 cohort. Median duration of treatment was 12 weeks (range, 1.9–63.3). Treatment-emergent adverse events (TEAEs) occurred in 39 (98%) patients, the most frequent being fatigue (48%), nausea (45%), anorexia (38%), thrombocytopenia (38%), and vomiting (35%). G3 TEAEs occurred in 18 (45%) patients, the most frequent being fatigue, thrombocytopenia, and neutropenia (10% each); 1 G4 TEAE of dyspnea was reported. Seven patients died due to malignant neoplasm/disease progression (n=6) or respiratory distress (n=1); none were related to ABBV-011. Hepatotoxicity was observed, including G≥2 TEAEs of hyperbilirubinemia (18%), increased gamma-glutamyltransferase (8%), ascites (5%), veno-occlusive liver disease (3%), and portal hypertension (3%). Confirmed objective response rate was 25% (10 partial responses [PR]), with median duration of response of 4.2 months (95% CI: 2.6, 6.7). Clinical benefit rate (CBR) was 65% (10 PR and 16 stable disease) and CBR lasting >12 weeks was 43%. The median progression-free survival was 3.5 months. **Conclusions:** The MTD was not reached and ABBV-011 was well tolerated at 1.0 mg/kg with promising antitumor activity observed. Further evaluation of ABBV-011 is ongoing. Clinical trial information: NCT03639194. Research Sponsor: AbbVie.

Detection of peritoneal metastases during cytoreductive surgery using pegsitacianine, a pH sensitive imaging agent: Final results from a phase 2 study. *First Author: Patrick Wagner, Allegheny Health Network Cancer Institute, Pittsburgh, PA*

Background: For patients with peritoneal metastatic disease, extent of cytoreductive surgery (CRS) is a major prognostic factor for long-term survival, regardless of primary tumor type. Pegsitacianine is a systemically delivered pH-sensitive polymeric micellar fluorescent nanoprobe developed to intraoperatively identify residual disease and augment the completeness of CRS following standard of care radiographic imaging, visualization, palpation, and intended resection. **Methods:** NCT04950166 was a Phase 2, non-randomized, open-label, multi-center U.S. study. Patients eligible for CRS were administered a single intravenous dose of pegsitacianine at 1 mg/kg within 24–72 hours prior to surgery. After completion of intended CRS, the peritoneal cavity was systematically re-examined under near-infrared (NIR) illumination to evaluate for fluorescent tissue. Post-standard of care fluorescent tissue detected by pegsitacianine guidance was excised and sent for evaluation for presence of residual tumor by histopathology. Clinically significant events (CSE) were defined as detection of histologically confirmed residual disease excised under pegsitacianine guidance following standard CRS, resulting in additional excision or a change in the assessment of completeness of CRS. Treatment-related and treatment-emergent adverse events were coded by CTCAE (v5.01). **Results:** A total of 40 patients were enrolled and evaluable for CSE. Evaluable patients were defined as patients who completed pegsitacianine dosing, underwent CRS with post-SOC evaluation of the peritoneal cavity, and had evidence of disease upon histopathological evaluation of surgical specimens. These 40 patients represented 6 different primary tumor types (appendiceal, colorectal, endometrial, mesothelioma, ovarian, pancreatic). At the patient level, CSEs were detected in 20 of 40 (50%) patients. Patient-level false positive rate – wherein all pegsitacianine-guided fluorescent tissue specimens resected post-CRS were determined to be negative for cancer by histopathology – occurred in 12.5% of patients. Pegsitacianine was well tolerated with no SAEs. Treatment-related, non-anaphylactic infusion reactions occurred in 26% of patients and were transient, with a median duration of 9 minutes. **Conclusions:** Pegsitacianine received Breakthrough Therapy Designation from the U.S. Food and Drug Administration as a result of data collected in this trial. Pegsitacianine is well-tolerated and facilitates the recognition of occult residual disease following CRS. The high rate of residual disease detection suggests pegsitacianine has the potential to augment surgeon performance during CRS, leading to improved completeness of cytoreduction and patient outcomes. Methylated DNA biomarkers and incident cancer in the American Cancer Society (ACS) Cancer Prevention Study-3 (CPS-3) cohort. *First Author: Alpa Patel, American Cancer Society, Kennesaw, GA*

Background: Multi-cancer early detection (MCED) tests are being developed to complement current single-cancer screening, and are based on next-generation sequencing of cell-free DNA in blood plasma with subsequent analysis of genomic features by machine-learning algorithms. To evaluate the detectability of cancer signals in individuals without known cancer at the time of blood draw, we assessed pre-diagnostic signals using a previously validated locked, methylation-based assay in plasma samples from the ACS CPS-3 cohort. **Methods:** CPS-3 is a prospective cohort study of cancer incidence and mortality. Participants (N=294,000) donated a blood sample (36 mL) at enrollment (2006-2013) and are followed for cancer outcomes via routine linkages with population-based cancer and death registries. Selected participants diagnosed with cancer within 3 years (Y) of blood donation and an equivalent number of matched non-cancer participants were chosen for processing. Despite differences in sample collection (tube, protocol) and long storage time in freezer, standard requirements for MCED sample quality were applied. Primary outcome: demonstrate that cancer signal was detectable via the MCED test up to 3Y prior to conventional diagnosis. Secondary outcomes: assess detectability based on time from blood draw and other clinical factors. Sampling weights were considered in the statistical analyses. **Results:** Of 268,726 CPS-3 participants, 2,850 were selected and assayed by cohort sampling, and 2,754 were included in the primary analysis set. CPS-3 cohort demographics and cancer incidence patterns compared to Surveillance, Epidemiology, and End Results suggested that this cohort is younger and healthier than the U.S. population. The test negative rate was 100% among non-cancers. The test positive rate (TPR) stratified by time between blood draw and clinical diagnosis was 2.3% (3Y), 6.0% (2Y), 15.2% (1Y). For eventually fatal cancers, TPR was 5.1% (3Y), 21.6% (2Y), 55.1% (1Y) vs 1.8%, 4.1%, 10.2% for non-fatal cancers. By stage, within 1Y, TPR was 73.7% for Distant at 4-6 months (M) and 94.1% at 1-3M vs 26.7% for Regional at 4-6M and 71.0% at 1-3M. The overall accuracy of predicting cancer signal origin was 95% (1Y). Many cancers were detected 3Y prior to clinical diagnosis: for example, a case of colon/rectum cancer at Regional stage was detected at 991 days. **Conclusions:** The ACS CPS-3 cohort includes persons at lower-than-average risk of cancer but offered a bio-specimen repository with sufficient plasma samples to assess the preclinical detectability of cancer signals by retrospective evaluation. Rapid changes in detectability over time underscore the short preclinical time scales for aggressive cancers to develop, and therefore to be detected. These insights into cancer biology reinforce the importance of pre-diagnostic samples in the study of cancer signals for early detection.
